TextBuilder Type: TextBuilder An instance of the TextBuilder data type.

NewCapacity

Type: Integer

The maximum number of characters that can be contained in the memory allocated by the current instance. Its value can range from Length to MaxCapacity.

Return Value

OldCapacity Type: Integer The maximum number of characters that can be contained in the memory allocated by the current instance.

TextBuilder.Clear Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Removes all characters from the current TextBuilder instance.

Syntax

```
TextBuilder.Clear()
```

Parameters

TextBuilder Type: TextBuilder An instance of the TextBuilder data type.

See Also

TextBuilder.EnsureCapacity Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Ensures that the capacity of this TextBuilder instance is at least the specified value.

Syntax

```
[Ok := ]  TextBuilder.EnsureCapacity(NewCapacity: Integer)
```

Parameters

TextBuilder Type: TextBuilder An instance of the TextBuilder data type.

NewCapacity
Type: Integer
The minimum capacity to ensure.

Return Value

Ok Type: Boolean **true** if the capacity of the TextBuilder is at least the specified value, otherwise **false**. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

TextBuilder.Insert Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Inserts a string into this TextBuilder instance at the specified character position.

Syntax

```
[Ok := ]  TextBuilder.Insert(Position: Integer, Text: Text)
```

Parameters

TextBuilder Type: TextBuilder An instance of the TextBuilder data type.

Position
Type: Integer
The position in this TextBuilder instance where insertion begins.

Text
Type: Text
The string to insert.

Return Value

Ok Type: Boolean **true** if the insertion of the specified succeeded, otherwise **false**. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

TextBuilder.Length Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Gets or sets the length of this TextBuilder instance.

Syntax

```
[OldLength := ]  TextBuilder.Length([NewLength: Integer])
```

NOTE

This method can be invoked using property access syntax.

Parameters

TextBuilder Type: TextBuilder An instance of the TextBuilder data type.

NewLength

Type: Integer

The new length of this TextBuilder instance.

Return Value

OldLength Type: Integer The length of this TextBuilder instance.

See Also

TextBuilder.MaxCapacity Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Gets the maximum capacity of this TextBuilder instance.

Syntax

```
MaxCapacity :=   TextBuilder.MaxCapacity()
```

NOTE

This method can be invoked using property access syntax.

Parameters

TextBuilder Type: TextBuilder An instance of the TextBuilder data type.

Return Value

MaxCapacity Type: Integer The maximum capacity of this TextBuilder instance.

TextBuilder.Remove Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Removes the specified range of characters from this TextBuilder instance.

Syntax

```
[Ok := ]  TextBuilder.Remove(StartIndex: Integer, Count: Integer)
```

Parameters

TextBuilder Type: TextBuilder An instance of the TextBuilder data type.

StartIndex
Type: Integer
The one-based position in this TextBuilder instance where removal begins.

Count
Type: Integer
The number of characters to remove.

Return Value

Ok Type: Boolean **true** if the specified range of characters was successfully removed, otherwise **false**. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

TextBuilder.Replace Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Replaces all occurrences of a specified string in this TextBuilder instance with another specified string.

Syntax

```
[Ok := ]  TextBuilder.Replace(OldText: Text, NewText: Text)
```

Parameters

TextBuilder Type: TextBuilder An instance of the TextBuilder data type.

OldText
Type: Text
The string to replace.

NewText
Type: Text
The string that replaces OldText.

Return Value

Ok Type: Boolean **true** if all occurrences of a specified string were successfully replaced, otherwise **false**. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

TextBuilder.Replace Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Replaces, within a substring of this instance, all occurrences of a specified string in this TextBuilder instance with another specified string.

Syntax

```
[Ok := ]  TextBuilder.Replace(OldText: Text, NewText: Text, StartIndex: Integer, Count: Integer)
```

Parameters

TextBuilder Type: TextBuilder An instance of the TextBuilder data type.

OldText
Type: Text
The string to replace.

NewText
Type: Text
The string that replaces OldText.

StartIndex
Type: Integer
The position in this TextBuilder instance where the substring begins.

Count
Type: Integer
The length of the substring.

Return Value

Ok Type: Boolean **true** if all occurrences of a specified string were successfully replaced, otherwise **false**. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

TextBuilder.ToText Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Converts the value of this TextBuilder instance to a Text.

Syntax

```
Result :=   TextBuilder.ToText()
```

Parameters

TextBuilder Type: TextBuilder An instance of the TextBuilder data type.

Return Value

Result Type: Text The result text.

TextBuilder.ToText Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Converts the value of a substring of this TextBuilder instance to a Text.

Syntax

```
Result :=   TextBuilder.ToText(StartIndex: Integer, Count: Integer)
```

Parameters

TextBuilder Type: TextBuilder An instance of the TextBuilder data type.

StartIndex
Type: Integer
The starting position of the substring in this TextBuilder instance.

Count
Type: Integer
The number of characters in the substring.

Return Value

Result Type: Text The result text substring.

Time Data Type

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Denotes a time ranging from 00:00:00.000 to 23:59:59.999. An undefined or blank time is specified by 0T.

The displayed text format of the time is determined by your Regional and Language Options in Windows.

The following are examples of valid assignments of times to a Time variable *MyTime*. Time must be set by specifying hours, minutes, and seconds.

```
MyTime := 0T;
MyTime := 115900T;
Message(Format(MyTime));
MyTime := 115934T;
Message(Format(MyTime));
MyTime := 115934.444T;
Message(Format(MyTime));
MyTime := 235900T;
Message(Format(MyTime));
MyTime := 030000T;
Message(Format(MyTime));
```

The following shows what the message windows display accordingly on a computer with the regional format set to English (United States) for the syntax examples above.

11:59:00 AM

11:59:34 AM

11:59:34.444 AM

11:59:00 PM

3:00:00 AM

SQL Server

Microsoft SQL Server stores information about both date and time in columns of the DATETime type. Dynamics 365 uses only the time part and inserts a constant value for the date: 01-01-1754.

The Dynamics 365 undefined time is represented by the same value as an undefined date. The undefined date is represented by the earliest valid DateTime in SQL Server, which is 01-01-1753 00:00:00:000.

Variant Data Type

2/17/2021 • 3 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Represents an AL variable object. The AL variant data type can contain many AL data types.

The following methods are available on instances of the Variant data type.

METHOD NAME	DESCRIPTION
IsAction()	Indicates whether an AL variant contains an Action variable.
IsAutomation()	Indicates whether an AL variant contains an Automation variable.
IsBigInteger()	Indicates whether an AL variant contains a BigInteger variable.
IsBinary()	Indicates whether an AL variant contains a Binary variable.
IsBoolean()	Indicates whether an AL variant contains a Boolean variable.
IsByte()	Indicates whether an AL variant contains a Byte data type variable.
IsChar()	Indicates whether an AL variant contains a Char variable.
IsClientType()	Indicates whether an AL variant contains a ClientType variable.
IsCode()	Indicates whether an AL variant contains a Code variable.
IsCodeunit()	Indicates whether an AL variant contains a Codeunit variable.
IsDataClassificationType()	Indicates whether a AL variant contains a DataClassification variable.
IsDate()	Indicates whether an AL variant contains a Date variable.
IsDateFormula()	Indicates whether an AL variant contains a DateFormula variable.
IsDateTime()	Indicates whether an AL variant contains a DateTime variable.
IsDecimal()	Indicates whether an AL variant contains a Decimal variable.
IsDefaultLayout()	Indicates whether an AL variant contains a DefaultLayout variable.
IsDotNet()	Indicates whether an AL variant contains a DotNet variable.
IsDuration()	Indicates whether an AL variant contains a Duration variable.
IsExecutionMode()	Indicates whether an AL variant contains an ExecutionMode variable.

METHOD NAME	DESCRIPTION
IsFieldRef()	Indicates whether an AL variant contains a FieldRef variable.
IsFile()	Indicates whether an AL variant contains a File variable.
IsFilterPageBuilder()	Indicates whether an AL variant contains a FilterPageBuilder variable.
IsGuid()	Indicates whether an AL variant contains a Guid variable.
IsInStream()	Indicates whether an AL variant contains an InStream variable.
IsInteger()	Indicates whether an AL variant contains an Integer variable.
IsJsonArray()	Indicates whether an AL variant contains a JsonArray variable.
IsJsonObject()	Indicates whether an AL variant contains a JsonObject variable.
IsJsonToken()	Indicates whether an AL variant contains a JsonToken variable.
IsJsonValue()	Indicates whether an AL variant contains a JsonValue variable.
IsNotification()	Indicates whether an AL variant contains a Notification variable.
IsObjectType()	Indicates whether an AL variant contains an ObjectType variable.
IsOption()	Indicates whether an AL variant contains an Option variable.
IsOutStream()	Indicates whether an AL variant contains an OutStream variable.
IsRecord()	Indicates whether an AL variant contains a Record variable.
IsRecordId()	Indicates whether an AL variant contains a RecordId variable.
IsRecordRef()	Indicates whether an AL variant contains a RecordRef variable.
IsReportFormat()	Indicates whether an AL variant contains a ReportFormat variable.
IsSecurityFiltering()	Indicates whether an AL variant contains a SecurityFiltering variable.
IsTableConnectionType()	Indicates whether an AL variant contains a TableConnectionType variable.
IsTestPermissions()	Indicates whether an AL variant contains a TestPermissions variable.
IsText()	Indicates whether an AL variant contains a Text variable.

METHOD NAME	DESCRIPTION
IsTextBuilder()	Indicates whether an AL variant contains a TextBuilder variable.
IsTextConstant()	Indicates whether an AL variant contains a Text constant.
IsTextEncoding()	Indicates whether an AL variant contains a TextEncoding variable.
IsTime()	Indicates whether an AL variant contains a Time variable.
IsTransactionType()	Indicates whether an AL variant contains a TransactionType variable.
IsWideChar()	Indicates whether an AL variant contains a WideChar variable.
IsXmlAttribute()	Indicates whether an AL variant contains an XmlAttribute variable.
IsXmlAttributeCollection()	Indicates whether an AL variant contains an XmlAttributeCollection variable.
IsXmlCData()	Indicates whether an AL variant contains an XmlCData variable.
IsXmlComment()	Indicates whether an AL variant contains an XmlComment variable.
IsXmlDeclaration()	Indicates whether an AL variant contains an XmlDeclaration variable.
IsXmlDocument()	Indicates whether an AL variant contains an XmlDocument variable.
IsXmlDocumentType()	Indicates whether an AL variant contains an XmlDocumentType variable.
IsXmlElement()	Indicates whether an AL variant contains an XmlElement variable.
IsXmlNamespaceManager()	Indicates whether an AL variant contains an XmlNamespaceManager variable.
IsXmlNameTable()	Indicates whether an AL variant contains an XmlNameTable variable.
IsXmlNode()	Indicates whether an AL variant contains an XmlNode variable.
IsXmlNodeList()	Indicates whether an AL variant contains an XmlNodeList variable.
IsXmlProcessingInstruction()	Indicates whether an AL variant contains an XmlProcessingInstruction variable.
IsXmlReadOptions()	Indicates whether an AL variant contains an XmlReadOptions variable.
IsXmlText()	Indicates whether an AL variant contains an XmlText variable.

METHOD NAME	DESCRIPTION
IsXmlWriteOptions()	Indicates whether an AL variant contains an XmlWriteOptions variable.

Variant.IsAction Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Indicates whether an AL variant contains an Action variable.

Syntax

```
Ok :=   Variant.IsAction()
```

> **NOTE**
> This method can be invoked using property access syntax.

Parameters

Variant Type: Variant An instance of the Variant data type.

Return Value

Ok Type: Boolean **true** if the AL variant contains an Action variable, otherwise **false**.

Example

The following example determines whether an AL variant contains an Action variable. The MyAction variable is assigned to the variant variable that is named MyVariant. The **IsAction** method determines whether the variant contains an Action variable and stores the return value in the varResult variable. In this case, the variant contains an Action variable so **Yes** is returned and displayed in a message box. The IsCode Method (Variant) determines whether the variant contains a code variable. The return value is **No** because the variant does not contain a code.

```
var
    MyAction: Action;
    MyVariant: Variant;
    varResult: Boolean;
    Text000: Label 'Does the variant contain an Action variable? %1.';
    Text001: Label 'Does the variant- contain a code variable? %1.';
begin
    MyVariant := MyAction;
    varResult := MyVariant.IsAction;
    Message(Text000,varResult);
    varResult := MyVariant.IsCode;
    Message(Text001, varResult);
end;
```

Variant.IsAutomation Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Indicates whether an AL variant contains an Automation variable.

Syntax

```
Ok :=   Variant.IsAutomation()
```

> **NOTE**
> This method can be invoked using property access syntax.

Parameters

Variant Type: Variant An instance of the Variant data type.

Return Value

Ok Type: Boolean **true** if the AL variant contains an Automation variable, otherwise **false**.

Example

The following example determines whether an AL variant contains an Automation variable. The MyAutomation variable is assigned to the variant variable that is named MyVariant. The **IsAutomation** method determines whether the variant contains an Automation variable and stores the return value in the varResult variable. In this case, the variant contains an Automation variable so **Yes** is returned and displayed in a message box. The IsCode Method (Variant) determines whether the variant contains a code variable. The return value is **No** because the variant does not contain a code.

```
var
    MyAutomation: Automation "AFormAut 1.0 Type Library";
    MyVariant: Variant;
    varResult: Boolean;
    Text000: Label 'Does the variant contain an Automation variable? %1.';
    Text001: Label 'Does the variant- contain a code variable? %1.';
begin
    MyVariant := MyAutomation;
    varResult := MyVariant.IsAutomation;
    Message(Text000,varResult);
    varResult := MyVariant.IsCode;
    Message(Text001, varResult);
end;
```

Variant Data Type

Variant.IsBigInteger Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Indicates whether an AL variant contains a BigInteger variable.

Syntax

```
Ok :=   Variant.IsBigInteger()
```

NOTE

This method can be invoked using property access syntax.

Parameters

Variant Type: Variant An instance of the Variant data type.

Return Value

Ok Type: Boolean **true** if the AL variant contains a BigInteger variable, otherwise **false**.

Variant.IsBinary Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Indicates whether an AL variant contains a Binary variable.

Syntax

```
Ok :=   Variant.IsBinary()
```

NOTE

This method can be invoked using property access syntax.

Parameters

Variant Type: Variant An instance of the Variant data type.

Return Value

Ok Type: Boolean **true** if the AL variant contains a Binary variable, otherwise **false**.

See Also

Variant Data Type

Developing Extensions

Variant.IsBoolean Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Indicates whether an AL variant contains a Boolean variable.

Syntax

```
Ok :=   Variant.IsBoolean()
```

> **NOTE**
> This method can be invoked using property access syntax.

Parameters

Variant Type: Variant An instance of the Variant data type.

Return Value

Ok Type: Boolean **true** if the AL variant contains a Boolean variable, otherwise **false**.

Example

The following example determines whether an AL variant contains a Boolean variable. The code initializes the MyBoolean variable with a Boolean value. The MyBoolean variable is assigned to the variant variable that is named MyVariant. The **IsBoolean** method determines whether the variant contains a Boolean variable and stores the return value in the varResult variable. In this case, the variant contains a Boolean variable so **true** is returned and displayed in a message box. The Boolean value is obtained from the **Critical** field in the **Item** table. The IsCode Method (Variant) determines whether the variant contains a code variable. The return value is **false** because the variant does not contain a code.

```
var
    ItemRec: Record Item;
    MyBoolean: Boolean;
    MyVariant: Variant;
    varResult: Boolean;
    Text000: Label 'Does the variant >%1< contain a Boolean variable? %2.';
    Text001: Label 'Does the variant >%1< contain a code variable? %2.';
begin
    MyBoolean := ItemRec.Critical;
    MyVariant := MyBoolean;
    varResult := MyVariant.IsBoolean;
    Message(Text000,MyVariant,varResult);
    varResult := MyVariant.IsCode;
    Message(Text001,MyVariant,varResult);
end;
```

Variant.IsByte Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Indicates whether an AL variant contains a Byte data type variable.

Syntax

```
Ok :=   Variant.IsByte()
```

> **NOTE**
> This method can be invoked using property access syntax.

Parameters

Variant Type: Variant An instance of the Variant data type.

Return Value

Ok Type: Boolean **true** if the AL variant contains a Byte variable, otherwise **false**.

Example

The following example determines whether an AL variant contains a Byte data type variable. The code initializes the MyByte data type variable with the constant text string **A**. The MyByte variable is assigned to the variant variable that is named MyVariant. The **IsByte** method determines whether the variant contains a Byte variable and stores the return value in the varResult variable. In this case, the variant contains a Byte variable so **true** is returned and displayed in a message box.

```
var
    MyByte: Byte;
    MyVariant: Variant;
    varResult: Boolean;
    Text000: Label 'Does the variant contain a byte variable? %1.';
begin
    MyByte := 'A';
    MyVariant := MyByte;
    varResult := MyVariant.IsByte;
    Message(Text000,varResult);
end;
```

Variant.IsChar Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Indicates whether an AL variant contains a Char variable.

Syntax

```
Ok :=   Variant.IsChar()
```

NOTE

This method can be invoked using property access syntax.

Parameters

Variant Type: Variant An instance of the Variant data type.

Return Value

Ok Type: Boolean **true** if the AL variant contains a Char variable, otherwise **false**.

Variant.IsClientType Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Indicates whether an AL variant contains a ClientType variable.

Syntax

```
Ok :=   Variant.IsClientType()
```

> **NOTE**
> This method can be invoked using property access syntax.

Parameters

Variant Type: Variant An instance of the Variant data type.

Return Value

Ok Type: Boolean **true** if the AL variant contains a ClientType variable, otherwise **false**.

Developing Extensions

Variant.IsCode Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Indicates whether an AL variant contains a Code variable.

Syntax

```
Ok :=   Variant.IsCode()
```

> **NOTE**
> This method can be invoked using property access syntax.

Parameters

Variant Type: Variant An instance of the Variant data type.

Return Value

Ok Type: Boolean **true** if the AL variant contains a Code variable, otherwise **false**.

Example

The following example determines whether an AL variant contains a code variable. The code initializes the MyCode variable with a string value. The MyCode variable is assigned to the variant variable that is named MyVariant. The **IsCode** method determines whether the variant contains a code variable and stores the return value in the varResult variable. In this case, the variant contains a code variable so **true** is returned and displayed in a message box. The IsText Method (Variant) determines whether the variant contains a text variable. The return value is **false** because the variant does not contain a text.

```
var
    MyCode: Code[100];
    MyVariant: Variant;
    varResult: Boolean;
    Text000: Label 'Does the variant >%1< contain a code variable? %2.';
    Text001: Label 'Does the variant >%1< contain a text variable? %2.';
begin
    MyCode := 'A1297';
    MyVariant :=  MyCode;
    varResult := MyVariant.IsCode;
    Message(Text000,MyVariant,varResult);
    varResult := MyVariant.IsText;
    Message(Text001,MyVariant,varResult);
end;
```

Variant.IsDate Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Indicates whether an AL variant contains a Date variable.

Syntax

```
Ok :=   Variant.IsDate()
```

> **NOTE**
> This method can be invoked using property access syntax.

Parameters

Variant Type: Variant An instance of the Variant data type.

Return Value

Ok Type: Boolean **true** if the AL variant contains a Date variable, otherwise **false**.

Example

The following example determines whether an AL variant contains a Date variable. The code initializes the MyDate variable with a Date value. The MyDate variable is assigned to the variant variable that is named MyVariant. The **IsDate** method determines whether the variant contains a Date variable and stores the return value in the varResult variable. In this case, the variant contains a Date variable so **true** is returned and displayed in a message box. The IsCode Method (Variant) determines whether the variant contains a Code variable. The return value is **false** because the variant does not contain a code.

```
var
    MyDate: Date;
    MyVariant: Variant;
    varResult: Boolean;
    Text000: Label 'Does the variant >%1< contain a date variable? %2.';
    Text001: Label 'Does the variant >%1< contain a code variable? %2.';
begin
    MyDate := Today;
    MyVariant :=  MyDate;
    varResult := MyVariant.IsDate;
    Message(Text000,MyVariant,varResult);
    varResult := MyVariant.IsCode;
    Message(Text001,MyVariant,varResult);
end;
```

Variant.IsExecutionMode Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Indicates whether an AL variant contains an ExecutionMode variable.

Syntax

```
Ok :=   Variant.IsExecutionMode()
```

> **NOTE**
> This method can be invoked using property access syntax.

Parameters

Variant Type: Variant An instance of the Variant data type.

Return Value

Ok Type: Boolean **true** if the AL variant contains an ExecutionMode variable, otherwise **false**.

Developing Extensions

Variant.IsFieldRef Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Indicates whether an AL variant contains a FieldRef variable.

Syntax

```
Ok :=   Variant.IsFieldRef()
```

NOTE

This method can be invoked using property access syntax.

Parameters

Variant Type: Variant An instance of the Variant data type.

Return Value

Ok Type: Boolean **true** if the AL variant contains a FieldRef variable, otherwise **false**.

See Also

Variant Data Type
Getting Started with AL
Developing Extensions

Variant.IsFile Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Indicates whether an AL variant contains a File variable.

Syntax

```
Ok :=   Variant.IsFile()
```

NOTE

This method can be invoked using property access syntax.

Parameters

Variant Type: Variant An instance of the Variant data type.

Return Value

Ok Type: Boolean **true** if the AL variant contains a File variable, otherwise **false**.

See Also

Variant Data Type
Getting Started with AL
Developing Extensions

Variant.IsFilterPageBuilder Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Indicates whether an AL variant contains a FilterPageBuilder variable.

Syntax

```
Ok :=   Variant.IsFilterPageBuilder()
```

NOTE

This method can be invoked using property access syntax.

Parameters

Variant Type: Variant An instance of the Variant data type.

Return Value

Ok Type: Boolean **true** if the AL variant contains a FilterPageBuilder variable, otherwise **false**.

Example

The following example uses the IsFilterPageBuilder method on a filter page object that includes a filter control for the **Date** system table.

```
var
    varDateItem: Text;
    varFilterPageBuilder: FilterPageBuilder;
    myVariant: Variant;
begin
    varDateItem := 'Date record';
    varFilterPageBuilder.AddTable(varDateItem + ‘ 1’,DATABASE::Date);
    myVariant := varFilterPageBuilder;
    if not myVariant.IsFilterPageBuilder then
      ERROR(‘This variant should contain a FilterPageBuilder variable’);
end;
```

Variant.IsGuid Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Indicates whether an AL variant contains a Guid variable.

Syntax

```
Ok :=   Variant.IsGuid()
```

NOTE

This method can be invoked using property access syntax.

Parameters

Variant Type: Variant An instance of the Variant data type.

Return Value

Ok Type: Boolean **true** if the AL variant contains a Guid variable, otherwise **false**.

Variant.IsInStream Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Indicates whether an AL variant contains an InStream variable.

Syntax

```
Ok :=   Variant.IsInStream()
```

NOTE

This method can be invoked using property access syntax.

Parameters

Variant Type: Variant An instance of the Variant data type.

Return Value

Ok Type: Boolean **true** if the AL variant contains an InStream variable, otherwise **false**.

Variant.IsInteger Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Indicates whether an AL variant contains an Integer variable.

Syntax

```
Ok :=   Variant.IsInteger()
```

NOTE

This method can be invoked using property access syntax.

Parameters

Variant Type: Variant An instance of the Variant data type.

Return Value

Ok Type: Boolean **true** if the AL variant contains an Integer variable, otherwise **false**.

Variant.IsJsonArray Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Indicates whether an AL variant contains a JsonArray variable.

Syntax

```
Ok :=   Variant.IsJsonArray()
```

> **NOTE**
> This method can be invoked using property access syntax.

Parameters

Variant Type: Variant An instance of the Variant data type.

Return Value

Ok Type: Boolean **true** if the AL variant contains a JsonArray variable, otherwise **false**.

Variant.IsJsonObject Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Indicates whether an AL variant contains a JsonObject variable.

Syntax

```
Ok :=   Variant.IsJsonObject()
```

NOTE

This method can be invoked using property access syntax.

Parameters

Variant Type: Variant An instance of the Variant data type.

Return Value

Ok Type: Boolean **true** if the AL variant contains a JsonObject variable, otherwise **false**.

Variant.IsJsonToken Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Indicates whether an AL variant contains a JsonToken variable.

Syntax

```
Ok :=   Variant.IsJsonToken()
```

NOTE

This method can be invoked using property access syntax.

Parameters

Variant Type: Variant An instance of the Variant data type.

Return Value

Ok Type: Boolean **true** if the AL variant contains a JsonToken variable, otherwise **false**.

Variant.IsJsonValue Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Indicates whether an AL variant contains a JsonValue variable.

Syntax

```
Ok :=   Variant.IsJsonValue()
```

NOTE

This method can be invoked using property access syntax.

Parameters

Variant Type: Variant An instance of the Variant data type.

Return Value

Ok Type: Boolean **true** if the AL variant contains a JsonValue variable, otherwise **false**.

Variant.IsNotification Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Indicates whether an AL variant contains a Notification variable.

Syntax

```
Ok :=   Variant.IsNotification()
```

> **NOTE**
> This method can be invoked using property access syntax.

Parameters

Variant Type: Variant An instance of the Variant data type.

Return Value

Ok Type: Boolean **true** if the AL variant contains a Notification variable, otherwise **false**.

Variant.IsObjectType Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Indicates whether an AL variant contains an ObjectType variable.

Syntax

```
Ok :=   Variant.IsObjectType()
```

> **NOTE**
> This method can be invoked using property access syntax.

Parameters

Variant Type: Variant An instance of the Variant data type.

Return Value

Ok Type: Boolean **true** if the AL variant contains a ObjectType variable, otherwise **false**.

See Also

Variant Data Type

Variant.IsOption Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Indicates whether an AL variant contains an Option variable.

Syntax

```
Ok :=   Variant.IsOption()
```

NOTE

This method can be invoked using property access syntax.

Parameters

Variant Type: Variant An instance of the Variant data type.

Return Value

Ok Type: Boolean **true** if the AL variant contains an Option variable, otherwise **false**.

See Also

Variant Data Type
Getting Started with AL
Developing Extensions

Variant.IsOutStream Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Indicates whether an AL variant contains an OutStream variable.

Syntax

```
Ok :=   Variant.IsOutStream()
```

NOTE

This method can be invoked using property access syntax.

Parameters

Variant Type: Variant An instance of the Variant data type.

Return Value

Ok Type: Boolean **true** if the AL variant contains an OutStream variable, otherwise **false**.

See Also

Getting Started with AL
Developing Extensions

Variant.IsRecord Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Indicates whether an AL variant contains a Record variable.

Syntax

```
Ok :=   Variant.IsRecord()
```

> **NOTE**
> This method can be invoked using property access syntax.

Parameters

Variant Type: Variant An instance of the Variant data type.

Return Value

Ok Type: Boolean **true** if the AL variant contains a Record variable, otherwise **false**.

Example

The following example determines whether an AL variant contains a record variable. The Get method gets customer number 10000 from the **Customer** table. The record is stored in the MyRecord variable. The MyRecord variable is assigned to the variant variable that is named MyVariant. The **ISRecord** method determines whether the variant contains a Record variable and stores the return value in the varResult variable. In this case, the variant contains a Record variable so **true** is returned and displayed in a message box. The IsCode Method (Variant)determines whether the variant contains a code variable. The return value is **false** because the variant does not contain a code.

```
var
    MyRecord: Record Customer;
    MyVariant: Variant;
    varResult: Boolean;
    Text000: Label 'Does the variant >%1< contain a record variable? %2.';
    Text001: Label 'Does the variant >%1< contain a code variable? %2.';
begin
    MyRecord.Get('10000');
    MyVariant := MyRecord;
    varResult := MyVariant.IsRecord;
    Message(Text000,MyVariant,varResult);
    varResult := MyVariant.IsCode;
    Message(Text001,MyVariant,varResult);
end;
```

Variant.IsRecordId Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Indicates whether an AL variant contains a RecordId variable.

Syntax

```
Ok :=   Variant.IsRecordId()
```

NOTE

This method can be invoked using property access syntax.

Parameters

Variant Type: Variant An instance of the Variant data type.

Return Value

Ok Type: Boolean **true** if the AL variant contains a RecordId variable, otherwise **false**.

Variant.IsText Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Indicates whether an AL variant contains a Text variable.

Syntax

```
Ok :=   Variant.IsText()
```

> **NOTE**
> This method can be invoked using property access syntax.

Parameters

Variant Type: Variant An instance of the Variant data type.

Return Value

Ok Type: Boolean **true** if the AL variant contains a Text variable, otherwise **false**.

Example

The following example determines whether an AL variant contains a text variable. The code initializes the MyText variable with a text value. The MyText variable is assigned to the variant variable that is named MyVariant. The **IsText** method determines whether the variant contains a text variable and stores the return value in the varResult variable. In this case, the variant contains a text variable so **Yes** is returned and displayed in a message box. The **IsCode** method determines whether the variant contains a code variable. The return value is **No** because the variant does not contain a code.

```
var
    MyText: Text[50];
    MyVariant: Variant;
    varResult: Boolean;
    Text000: Label 'Does the variant >%1< contain a text variable? %2.';
    Text001: Label 'Does the variant >%1< contain a code variable? %2.';
begin
    MyText := 'This is some text';
    MyVariant :=  MyText;
    varResult := MyVariant.IsText;
    Message(Text000,MyVariant,varResult);
    varResult := MyVariant.IsCode;
    Message(Text001,MyVariant,varResult);
end;
```

Variant.IsTextConstant Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Indicates whether an AL variant contains a Text constant.

Syntax

```
Ok :=   Variant.IsTextConstant()
```

> **NOTE**
> This method can be invoked using property access syntax.

Parameters

Variant Type: Variant An instance of the Variant data type.

Return Value

Ok Type: Boolean **true** if the AL variant contains a Text constant, otherwise **false**.

Example

The following example determines whether an AL variant contains a text constant. The code assigns the Text000 text constant to the variant variable that is named MyVariant. The **IsTextCONSTANT** method determines whether the variant contains a text constant and stores the return value in the varResult variable. In this case, the variant contains a text constant so **Yes** is returned and displayed in a message box.

```
var
    MyVariant: Variant;
    varResult: Boolean;
    Text000: Label 'This is some text.";
    Text001: Label 'DOes the variant contain a text constant? %1.';
begin
    MyVariant := Text000;
    varResult := MyVariant.IsTextConstant;
    Message(Text001,MyVariant,varResult);
    Message(Text001,varResult);
end;
```

Variant.IsTime Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Indicates whether an AL variant contains a Time variable.

Syntax

```
Ok :=   Variant.IsTime()
```

> **NOTE**
> This method can be invoked using property access syntax.

Parameters

Variant Type: Variant An instance of the Variant data type.

Return Value

Ok Type: Boolean **true** if the AL variant contains a Time variable, otherwise **false**.

Example

The following example determines whether an AL variant contains a time variable. The code initializes the MyTime variable with a Time value. The MyTime variable is assigned to the variant variable that is named MyVariant. The **IsTime** method determines whether the variant contains a Time variable and stores the return value in the varResult variable. In this case, the variant contains a Time variable so **Yes** is returned and displayed in a message box. The IsCode Method (Variant) determines whether the variant contains a Code variable. The return value is **No** because the variant does not contain a code.

```
var
    MyTime: Time;
    MyVariant: Variant;
    varResult: Boolean;
    Text000: Label 'Does the variant >%1\< contain a time variable? %2.';
    Text001: Label 'Does the variant >%1\< contain a code variable? %2.';
begin
    MyTime := Time;
    MyVariant := MyTime;
    varResult := MyVariant.IsTime;
    Message(Text000,MyVariant,varResult);
    varResult := MyVariant.IsCode;
    Message(Text001,MyVariant,varResult);
end;
```

Indicates whether an AL variant contains an XmlText variable.

Syntax

```
Ok :=   Variant.IsXmlText()
```

NOTE

This method can be invoked using property access syntax.

Parameters

Variant Type: Variant An instance of the Variant data type.

Return Value

Ok Type: Boolean **true** if the AL variant contains an XmlText variable, otherwise **false**.

Variant.IsXmlWriteOptions Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Indicates whether an AL variant contains an XmlWriteOptions variable.

Syntax

```
Ok :=   Variant.IsXmlWriteOptions()
```

> **NOTE**
> This method can be invoked using property access syntax.

Parameters

Variant Type: Variant An instance of the Variant data type.

Return Value

Ok Type: Boolean **true** if the AL variant contains an XmlWriteOptions variable, otherwise **false**.

Version Data Type

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Represents a version matching the format: Major.Minor.Build.Revision .

The following methods are available on the Version data type.

METHOD NAME	DESCRIPTION
Create(String)	Creates a version object from the provided string. The string should be in the format W.X.Y.Z, where W, X, Y and Z represent positive integers and where Y and Z are optional. If the input string is not in the expected format, an exception is thrown.
Create(Integer, Integer [, Integer] [, Integer])	Creates a version object from the major, minor, build and revision numbers provided.

The following methods are available on instances of the Version data type.

METHOD NAME	DESCRIPTION
Build()	Gets the build number of the version.
Major()	Gets the major number of the version.
Minor()	Gets the minor number of the version.
Revision()	Gets the revision number from the version.

Version.Create Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Creates a version object from the provided string. The string should be in the format W.X.Y.Z, where W, X, Y and Z represent positive integers and where Y and Z are optional. If the input string is not in the expected format, an exception is thrown.

Syntax

```
Value :=   Version.Create(Version: String)
```

Parameters

Version
Type: String
The string to convert into a version object.

Return Value

Value Type: Version The version created from the provided string.

Version.Create Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Creates a version object from the major, minor, build and revision numbers provided.

Syntax

```
Value :=   Version.Create(Major: Integer, Minor: Integer [, Build: Integer] [, Revision: Integer])
```

Parameters

Major

Type: Integer

The major version number.

Minor

Type: Integer

The minor version number.

Build

Type: Integer

The build version number.

Revision

Type: Integer

The revision version number.

Return Value

Value Type: Version The version created from the provided major, minor, build and revision numbers.

See Also

Version.Build Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Gets the build number of the version.

Syntax

```
BuildVersion :=   Version.Build()
```

NOTE

This method can be invoked using property access syntax.

Parameters

Version Type: Version An instance of the Version data type.

Return Value

BuildVersion Type: Integer The build version number of the version.

See Also

Version Data Type

Developing Extensions

Version.Major Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Gets the major number of the version.

Syntax

```
MajorVersion :=   Version.Major()
```

NOTE

This method can be invoked using property access syntax.

Parameters

Version Type: Version An instance of the Version data type.

Return Value

MajorVersion Type: Integer The major version number of the version.

See Also

Version Data Type

Version.Minor Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Gets the minor number of the version.

Syntax

```
MinorVersion :=   Version.Minor()
```

NOTE

This method can be invoked using property access syntax.

Parameters

Version Type: Version An instance of the Version data type.

Return Value

MinorVersion Type: Integer The minor version number of the version.

See Also

Version Data Type

Version.Revision Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Gets the revision number from the version.

Syntax

```
RevisionVersion :=   Version.Revision()
```

NOTE

This method can be invoked using property access syntax.

Parameters

Version Type: Version An instance of the Version data type.

Return Value

RevisionVersion Type: Integer The revision version number of the version.

WebServiceActionContext Data Type

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 2.0.*

Represents an AL WebServiceActionContext.

The following methods are available on instances of the WebServiceActionContext data type.

METHOD NAME	DESCRIPTION
AddEntityKey(Integer, Any)	Add a new <fieldId, value> pair to the collection of entity keys.
GetObjectId()	Gets the object ID.
GetObjectType()	Gets the object type.
GetResultCode()	Gets the web service action result status code.
SetObjectId(Integer)	Sets the object ID.
SetObjectType(ObjectType)	Sets the object type.
SetResultCode(WebServiceActionResultCode)	Sets the web service action result status code.

WebServiceActionContext.AddEntityKey Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 2.0.*

Add a new <fieldId, value> pair to the collection of entity keys.

Syntax

```
[Ok := ]  WebServiceActionContext.AddEntityKey(FieldId: Integer, FieldValue: Any)
```

Parameters

WebServiceActionContext Type: WebServiceActionContext An instance of the WebServiceActionContext data type.

FieldId
Type: Integer
The field ID of the entity key.

FieldValue
Type: Any
The value for the field in the entity key.

Return Value

Ok Type: Boolean **true** if adding the entity key succeeded, otherwise **false**. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

Example

```
actionContext.AddEntityKey(Rec.FieldNO(Id), ToSalesHeader.Id);
```

For a complete code example, see Creating and Interacting with an OData V4 Bound Action.

WebServiceActionContext.GetObjectId Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 2.0.*

Gets the object ID.

Syntax

```
ObjectId :=   WebServiceActionContext.GetObjectId()
```

Parameters

WebServiceActionContext Type: WebServiceActionContext An instance of the WebServiceActionContext data type.

Return Value

ObjectId Type: Integer The object ID.

WebServiceActionContext.GetObjectType Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 2.0.*

Gets the object type.

Syntax

```
ObjectType :=   WebServiceActionContext.GetObjectType()
```

Parameters

WebServiceActionContext Type: WebServiceActionContext An instance of the WebServiceActionContext data type.

Return Value

ObjectType Type: ObjectType The object type.

See Also

WebServiceActionContext.GetResultCode Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 2.0.*

Gets the web service action result status code.

Syntax

```
ResultCode :=   WebServiceActionContext.GetResultCode()
```

Parameters

WebServiceActionContext Type: WebServiceActionContext An instance of the WebServiceActionContext data type.

Return Value

ResultCode Type: WebServiceActionResultCode The web service action result status code.

WebServiceActionContext.SetObjectId Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 2.0.*

Sets the object ID.

Syntax

```
WebServiceActionContext.SetObjectId(ObjectId: Integer)
```

Parameters

WebServiceActionContext Type: WebServiceActionContext An instance of the WebServiceActionContext data type.

ObjectId
Type: Integer
The new object ID.

Example

```
actionContext.SetObjectId(Page::SalesInvoiceCopy);
```

For a complete code example, see Creating and Interacting with an OData V4 Bound Action.

See Also

WebServiceActionContext.SetObjectType Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 2.0.*

Sets the object type.

Syntax

```
WebServiceActionContext.SetObjectType(ObjectType: ObjectType)
```

Parameters

WebServiceActionContext Type: WebServiceActionContext An instance of the WebServiceActionContext data type.

ObjectType
Type: ObjectType
The new object type.

Example

```
actionContext.SetObjectType(ObjectType::Page);
```

For a complete code example, see Creating and Interacting with an OData V4 Bound Action.

See Also

WebServiceActionContext.SetResultCode Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 2.0.*

Sets the web service action result status code.

Syntax

```
WebServiceActionContext.SetResultCode(ResultCode: WebServiceActionResultCode)
```

Parameters

WebServiceActionContext Type: WebServiceActionContext An instance of the WebServiceActionContext data type.

ResultCode
Type: WebServiceActionResultCode
The new web service action result status code.

Example

```
...
// Set the result code to inform the caller that an item was created.
actionContext.SetResultCode(WebServiceActionResultCode::Created);
...
```

For a complete code example, see Creating and Interacting with an OData V4 Bound Action.

XmlAttribute Data Type

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Represents an XML attribute.

The following methods are available on the XmlAttribute data type.

METHOD NAME	DESCRIPTION
Create(String, String)	Creates an XmlAttribute node.
Create(String, String, String)	Creates an XmlAttribute node.
CreateNamespaceDeclaration(String, String)	Creates an attribute that represents a namespace declaration.

The following methods are available on instances of the XmlAttribute data type.

METHOD NAME	DESCRIPTION
AddAfterSelf(Any,...)	Adds the specified content immediately after this node.
AddBeforeSelf(Any,...)	Adds the specified content immediately before this node.
AsXmlNode()	Converts the node to an XmlNode.
GetDocument(var XmlDocument)	Gets the XmlDocument for this node.
GetParent(var XmlElement)	Gets the parent XmlElement of this node.
IsNamespaceDeclaration()	Determines if this attribute is a namespace declaration.
LocalName()	Gets the local name of the attribute.
Name()	The qualified name of the attribute.
NamespacePrefix()	Gets the prefix of the attribute (if any).
NamespaceUri()	Gets the namespace URI of the attribute.
Remove()	Removes this node from its parent element.
ReplaceWith(Any,...)	Replaces this node with the specified content.
SelectNodes(String, var XmlNodeList)	Selects a list of nodes matching the XPath expression.

METHOD NAME	DESCRIPTION
SelectNodes(String, XmlNamespaceManager, var XmlNodeList)	Selects a list of nodes matching the XPath expression.
SelectSingleNode(String, var XmlNode)	Selects the first XmlNode that matches the XPath expression.
SelectSingleNode(String, XmlNamespaceManager, var XmlNode)	Selects the first XmlNode that matches the XPath expression.
Value([String])	Gets or sets the value of the attribute.
WriteTo(OutStream)	Serializes and saves the current node to the given variable.
WriteTo(XmlWriteOptions, OutStream)	Serializes and saves the current node to the given variable.
WriteTo(var Text)	Serializes and saves the current node to the given variable.
WriteTo(XmlWriteOptions, var Text)	Serializes and saves the current node to the given variable.

XmlAttribute.Create Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Creates an XmlAttribute node.

Syntax

```
XmlAttribute :=   XmlAttribute.Create(Name: String, Value: String)
```

Parameters

Name

Type: String

The qualified name of the attribute. If the name is of the form {{namespace}}localName, it will be qualified with the given namespace.

Value

Type: String

The value of the attribute.

Return Value

XmlAttribute Type: XmlAttribute The created XmlAttribute node.

See Also

XmlAttribute Data Type

XmlAttribute.Create Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Creates an XmlAttribute node.

Syntax

```
XmlAttribute :=   XmlAttribute.Create(LocalName: String, NamespaceUri: String, Value: String)
```

Parameters

LocalName

Type: String

The local name of the attribute.

NamespaceUri

Type: String

The namespace URI of the attribute.

Value

Type: String

The value of the attribute.

Return Value

XmlAttribute Type: XmlAttribute The created XmlAttribute node.

See Also

XmlAttribute Data Type

XmlAttribute.CreateNamespaceDeclaration Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Creates an attribute that represents a namespace declaration.

Syntax

```
XmlAttribute :=   XmlAttribute.CreateNamespaceDeclaration(Prefix: String, NamespaceUri: String)
```

Parameters

Prefix

Type: String

The prefix of the attribute (if any).

NamespaceUri

Type: String

The URI of the attribute. If the prefix is xmlns, then this parameter must be http://www.w3.org/2000/xmlns/; otherwise an exception is thrown.

Return Value

XmlAttribute Type: XmlAttribute The created XmlAttribute node.

See Also

XmlAttribute Data Type

Developing Extensions

XmlAttribute.AddAfterSelf Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Adds the specified content immediately after this node.

Syntax

```
[Ok := ]  XmlAttribute.AddAfterSelf(Content: Any,...)
```

Parameters

XmlAttribute Type: XmlAttribute An instance of the XmlAttribute data type.

Content
Type: Any
The content to add after this node.

Return Value

Ok Type: Boolean **true** if the operation was successful; otherwise **false**. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

See Also

XmlAttribute Data Type
Getting Started with AL
Developing Extensions

XmlAttribute.AddBeforeSelf Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Adds the specified content immediately before this node.

Syntax

```
[Ok := ]  XmlAttribute.AddBeforeSelf(Content: Any,...)
```

Parameters

XmlAttribute Type: XmlAttribute An instance of the XmlAttribute data type.

Content
Type: Any
The content to add before this node.

Return Value

Ok Type: Boolean **true** if the operation was successful; otherwise **false**. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

See Also

XmlAttribute Data Type
Getting Started with AL
Developing Extensions

XmlAttribute.AsXmlNode Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Converts the node to an XmlNode.

Syntax

```
XmlNode :=   XmlAttribute.AsXmlNode()
```

Parameters

XmlAttribute Type: XmlAttribute An instance of the XmlAttribute data type.

Return Value

XmlNode Type: XmlNode An XmlNode value that references the current XmlAttribute.

See Also

XmlAttribute Data Type
Getting Started with AL
Developing Extensions

XmlAttribute.GetDocument Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Gets the XmlDocument for this node.

Syntax

```
[Ok := ]  XmlAttribute.GetDocument(var Document: XmlDocument)
```

Parameters

XmlAttribute Type: XmlAttribute An instance of the XmlAttribute data type.

Document
Type: XmlDocument
The owning XmlDocument of this node.

Return Value

Ok Type: Boolean **true** if the operation was successful; otherwise **false**. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

See Also

XmlAttribute Data Type
Getting Started with AL
Developing Extensions

XmlAttribute.GetParent Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Gets the parent XmlElement of this node.

Syntax

```
[Ok := ]  XmlAttribute.GetParent(var Parent: XmlElement)
```

Parameters

XmlAttribute Type: XmlAttribute An instance of the XmlAttribute data type.

Parent
Type: XmlElement
The parent XmlElement of this node.

Return Value

Ok Type: Boolean **true** if the operation was successful; otherwise **false**. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

See Also

XmlAttribute Data Type

Developing Extensions

XmlAttribute.IsNamespaceDeclaration Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Determines if this attribute is a namespace declaration.

Syntax

```
IsNamespaceDeclaration :=   XmlAttribute.IsNamespaceDeclaration()
```

NOTE

This method can be invoked using property access syntax.

Parameters

XmlAttribute Type: XmlAttribute An instance of the XmlAttribute data type.

Return Value

IsNamespaceDeclaration Type: Boolean **true** if the attribute represents a namespace declaration, otherwise **false**.

See Also

XmlAttribute Data Type

Developing Extensions

XmlAttribute.LocalName Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Gets the local name of the attribute.

Syntax

```
LocalName :=   XmlAttribute.LocalName()
```

NOTE

This method can be invoked using property access syntax.

Parameters

XmlAttribute Type: XmlAttribute An instance of the XmlAttribute data type.

Return Value

LocalName Type: String The local name of the attribute.

See Also

XmlAttribute Data Type
Getting Started with AL
Developing Extensions

XmlAttribute.Name Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

The qualified name of the attribute.

Syntax

```
Name :=   XmlAttribute.Name()
```

NOTE

This method can be invoked using property access syntax.

Parameters

XmlAttribute Type: XmlAttribute An instance of the XmlAttribute data type.

Return Value

Name Type: String The qualified name of the node.

See Also

XmlAttribute Data Type
Getting Started with AL
Developing Extensions

XmlAttribute.NamespacePrefix Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Gets the prefix of the attribute (if any).

Syntax

```
NamespacePrefix :=   XmlAttribute.NamespacePrefix()
```

NOTE

This method can be invoked using property access syntax.

Parameters

XmlAttribute Type: XmlAttribute An instance of the XmlAttribute data type.

Return Value

NamespacePrefix Type: String The prefix of the attribute (if any).

See Also

XmlAttribute Data Type
Getting Started with AL
Developing Extensions

XmlAttribute.NamespaceUri Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Gets the namespace URI of the attribute.

Syntax

```
NamespaceUri :=   XmlAttribute.NamespaceUri()
```

NOTE

This method can be invoked using property access syntax.

Parameters

XmlAttribute Type: XmlAttribute An instance of the XmlAttribute data type.

Return Value

NamespaceUri Type: String The namespace URI of the attribute.

See Also

XmlAttribute Data Type

Developing Extensions

XmlAttribute.Remove Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Removes this node from its parent element.

Syntax

```
[Ok := ]  XmlAttribute.Remove()
```

Parameters

XmlAttribute Type: XmlAttribute An instance of the XmlAttribute data type.

Return Value

Ok Type: Boolean **true** if the operation was successful; otherwise **false**. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

See Also

XmlAttribute Data Type
Getting Started with AL
Developing Extensions

XmlAttribute.ReplaceWith Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Replaces this node with the specified content.

Syntax

```
[Ok := ]  XmlAttribute.ReplaceWith(Node: Any,...)
```

Parameters

XmlAttribute Type: XmlAttribute An instance of the XmlAttribute data type.

Node
Type: Any
The content with which to replace the current node.

Return Value

Ok Type: Boolean **true** if the operation was successful; otherwise **false**. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

See Also

XmlAttribute Data Type

Developing Extensions

XmlAttribute.SelectNodes Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Selects a list of nodes matching the XPath expression.

Syntax

```
[Ok := ]  XmlAttribute.SelectNodes(XPath: String, var NodeList: XmlNodeList)
```

Parameters

XmlAttribute Type: XmlAttribute An instance of the XmlAttribute data type.

XPath
Type: String
The XPath expression.
NodeList
Type: XmlNodeList
An XmlNodeList containing a collection of nodes matching the XPath expression.

Return Value

Ok Type: Boolean **true** if the operation was successful; otherwise **false**. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

See Also

XmlAttribute Data Type

Developing Extensions

XmlAttribute.SelectNodes Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Selects a list of nodes matching the XPath expression.

Syntax

```
[Ok := ]  XmlAttribute.SelectNodes(XPath: String, NamespaceManager: XmlNamespaceManager, var NodeList:
XmlNodeList)
```

Parameters

XmlAttribute Type: XmlAttribute An instance of the XmlAttribute data type.

XPath
Type: String
The XPath expression.

NamespaceManager
Type: XmlNamespaceManager
An XmlNamespaceManager to use for resolving namespaces for prefixes in the XPath expression.

NodeList
Type: XmlNodeList
An XmlNodeList containing a collection of nodes matching the XPath expression.

Return Value

Ok Type: Boolean **true** if the operation was successful; otherwise **false**. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

See Also

XmlAttribute Data Type

XmlAttribute.SelectSingleNode Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Selects the first XmlNode that matches the XPath expression.

Syntax

```
[Ok := ]  XmlAttribute.SelectSingleNode(XPath: String, var Node: XmlNode)
```

Parameters

XmlAttribute Type: XmlAttribute An instance of the XmlAttribute data type.

XPath
Type: String
The XPath expression.

Node
Type: XmlNode
The first XmlNode that matches the XPath query.

Return Value

Ok Type: Boolean **true** if the operation was successful; otherwise **false**. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

Developing Extensions

XmlAttribute.SelectSingleNode Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Selects the first XmlNode that matches the XPath expression.

Syntax

```
[Ok := ]  XmlAttribute.SelectSingleNode(XPath: String, NamespaceManager: XmlNamespaceManager, var Node:
XmlNode)
```

Parameters

XmlAttribute Type: XmlAttribute An instance of the XmlAttribute data type.

XPath
Type: String
The XPath expression.

NamespaceManager
Type: XmlNamespaceManager
An XmlNamespaceManager to use for resolving namespaces for prefixes in the XPath expression.

Node
Type: XmlNode
The first XmlNode that matches the XPath query.

Return Value

Ok Type: Boolean **true** if the operation was successful; otherwise **false**. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

XmlAttribute.Value Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Gets or sets the value of the attribute.

Syntax

```
[Value := ]  XmlAttribute.Value([NewValue: String])
```

NOTE

This method can be invoked using property access syntax.

Parameters

XmlAttribute Type: XmlAttribute An instance of the XmlAttribute data type.

NewValue

Type: String

The new value of the attribute.

Return Value

Value Type: String The value of the attribute.

XmlAttribute.WriteTo Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Serializes and saves the current node to the given variable.

Syntax

```
[Ok := ]  XmlAttribute.WriteTo(OutStream: OutStream)
```

Parameters

XmlAttribute Type: XmlAttribute An instance of the XmlAttribute data type.

OutStream
Type: OutStream
The OutStream to which you want to save the serialized representation of the node.

Return Value

Ok Type: Boolean **true** if the operation was successful; otherwise **false**. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

XmlAttribute.WriteTo Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Serializes and saves the current node to the given variable.

Syntax

```
[Ok := ]  XmlAttribute.WriteTo(WriteOptions: XmlWriteOptions, OutStream: OutStream)
```

Parameters

XmlAttribute Type: XmlAttribute An instance of the XmlAttribute data type.

WriteOptions
Type: XmlWriteOptions
Specifies options for customizing how the node is serialized.

OutStream
Type: OutStream
The OutStream to which you want to save the serialized representation of the node.

Return Value

Ok Type: Boolean **true** if the operation was successful; otherwise **false**. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

XmlAttributeCollection Data Type

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Represents a collection of XML attributes.

The following methods are available on instances of the XmlAttributeCollection data type.

METHOD NAME	DESCRIPTION
Count()	Gets the number of attributes in the XmlAttributeCollection.
Get(Integer, var XmlAttribute)	Gets the specified attribute.
Get(String, var XmlAttribute)	Gets the specified attribute.
Get(String, String, var XmlAttribute)	Gets the specified attribute.
Remove(XmlAttribute)	Removes the specified attribute from the collection.
Remove(String)	Removes the specified attribute from the collection.
Remove(String, String)	Removes the specified attribute from the collection.
RemoveAll()	Removes all attributes from the collection.
Set(String, String)	Sets the value of the specified attribute or creates it if is not part of the collection.
Set(String, String, String)	Sets the value of the specified attribute or creates it if is not part of the collection.

XmlAttributeCollection.Count Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Gets the number of attributes in the XmlAttributeCollection.

Syntax

```
Count :=   XmlAttributeCollection.Count()
```

NOTE

This method can be invoked using property access syntax.

Parameters

XmlAttributeCollection Type: XmlAttributeCollection An instance of the XmlAttributeCollection data type.

Return Value

Count Type: Integer The number of attributes in the XmlAttributeCollection.

XmlAttributeCollection.Get Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Gets the specified attribute.

Syntax

```
[Ok := ]  XmlAttributeCollection.Get(Index: Integer, var Result: XmlAttribute)
```

Parameters

XmlAttributeCollection Type: XmlAttributeCollection An instance of the XmlAttributeCollection data type.

Index
Type: Integer
The index of the attribute to retrieve.

Result
Type: XmlAttribute
Variable containing the requested XmlAttribute if the operation is successful.

Return Value

Ok Type: Boolean **true** if the operation was successful; otherwise **false**. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

XmlAttributeCollection.Get Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Gets the specified attribute.

Syntax

```
[Ok := ]  XmlAttributeCollection.Get(Name: String, var Result: XmlAttribute)
```

Parameters

XmlAttributeCollection Type: XmlAttributeCollection An instance of the XmlAttributeCollection data type.

Name
Type: String
The qualified name of the attribute to retrieve.

Result
Type: XmlAttribute
Variable containing the requested XmlAttribute if the operation is successful.

Return Value

Ok Type: Boolean **true** if the operation was successful; otherwise **false**. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

XmlAttributeCollection.Get Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Gets the specified attribute.

Syntax

```
[Ok := ]  XmlAttributeCollection.Get(LocalName: String, NamespaceUri: String, var Result: XmlAttribute)
```

Parameters

XmlAttributeCollection Type: XmlAttributeCollection An instance of the XmlAttributeCollection data type.

LocalName
Type: String
The local name of the attribute to retrieve.

NamespaceUri
Type: String
The namespace URI of the attribute to retrieve.

Result
Type: XmlAttribute
Variable containing the requested XmlAttribute if the operation is successful.

Return Value

Ok Type: Boolean **true** if the operation was successful; otherwise **false**. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

XmlAttributeCollection.Remove Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Removes the specified attribute from the collection.

Syntax

```
XmlAttributeCollection.Remove(Attribute: XmlAttribute)
```

Parameters

XmlAttributeCollection Type: XmlAttributeCollection An instance of the XmlAttributeCollection data type.

Attribute
Type: XmlAttribute
The attribute to remove.

XmlAttributeCollection.Remove Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Removes the specified attribute from the collection.

Syntax

```
XmlAttributeCollection.Remove(Name: String)
```

Parameters

XmlAttributeCollection Type: XmlAttributeCollection An instance of the XmlAttributeCollection data type.

Name

Type: String

The qualified name of the attribute to remove.

See Also

XmlAttributeCollection.Remove Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Removes the specified attribute from the collection.

Syntax

```
XmlAttributeCollection.Remove(LocalName: String, NamespaceUri: String)
```

Parameters

XmlAttributeCollection Type: XmlAttributeCollection An instance of the XmlAttributeCollection data type.

LocalName

Type: String

The local name of the attribute to remove.

NamespaceUri

Type: String

The namespace URI of the attribute to remove.

XmlAttributeCollection.RemoveAll Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Removes all attributes from the collection.

Syntax

```
XmlAttributeCollection.RemoveAll()
```

Parameters

XmlAttributeCollection Type: XmlAttributeCollection An instance of the XmlAttributeCollection data type.

See Also

XmlAttributeCollection Data Type

XmlAttributeCollection.Set Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Sets the value of the specified attribute or creates it if is not part of the collection.

Syntax

```
XmlAttributeCollection.Set(Name: String, Value: String)
```

Parameters

XmlAttributeCollection Type: XmlAttributeCollection An instance of the XmlAttributeCollection data type.

Name

Type: String

The fully qualified name of the attribute to set.

Value

Type: String

The value to set for the attribute.

See Also

XmlAttributeCollection Data Type

XmlAttributeCollection.Set Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Sets the value of the specified attribute or creates it if is not part of the collection.

Syntax

```
XmlAttributeCollection.Set(LocalName: String, NamespaceUri: String, Value: String)
```

Parameters

XmlAttributeCollection Type: XmlAttributeCollection An instance of the XmlAttributeCollection data type.

LocalName
Type: String
The local name of the attribute to set.

NamespaceUri
Type: String
The namespace URI of the attribute to set.

Value
Type: String
The value to set for the attribute.

XmlCData Data Type

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Represents a CData section.

The following methods are available on the XmlCData data type.

METHOD NAME	DESCRIPTION
Create(String)	Creates an XmlCData node.

The following methods are available on instances of the XmlCData data type.

METHOD NAME	DESCRIPTION
AddAfterSelf(Any,...)	Adds the specified content immediately after this node.
AddBeforeSelf(Any,...)	Adds the specified content immediately before this node.
AsXmlNode()	Converts the node to an XmlNode.
GetDocument(var XmlDocument)	Gets the XmlDocument for this node.
GetParent(var XmlElement)	Gets the parent XmlElement of this node.
Remove()	Removes this node from its parent element.
ReplaceWith(Any,...)	Replaces this node with the specified content.
SelectNodes(String, var XmlNodeList)	Selects a list of nodes matching the XPath expression.
SelectNodes(String, XmlNamespaceManager, var XmlNodeList)	Selects a list of nodes matching the XPath expression.
SelectSingleNode(String, var XmlNode)	Selects the first XmlNode that matches the XPath expression.
SelectSingleNode(String, XmlNamespaceManager, var XmlNode)	Selects the first XmlNode that matches the XPath expression.
Value([String])	Gets or sets the value of this node.
WriteTo(OutStream)	Serializes and saves the current node to the given variable.
WriteTo(XmlWriteOptions, OutStream)	Serializes and saves the current node to the given variable.
WriteTo(var Text)	Serializes and saves the current node to the given variable.

METHOD NAME	DESCRIPTION
WriteTo(XmlWriteOptions, var Text)	Serializes and saves the current node to the given variable.

XmlCData.Create Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Creates an XmlCData node.

Syntax

```
CDataNode :=   XmlCData.Create(Value: String)
```

Parameters

Value

Type: String

A string that contains the value of the new XmlCData node.

Return Value

CDataNode Type: XmlCData The created XmlCData node.

XmlCData.AddAfterSelf Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Adds the specified content immediately after this node.

Syntax

```
[Ok := ]  XmlCData.AddAfterSelf(Content: Any,...)
```

Parameters

XmlCData Type: XmlCData An instance of the XmlCData data type.

Content
Type: Any
The content to add after this node.

Return Value

Ok Type: Boolean **true** if the operation was successful; otherwise **false**. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

See Also

XmlCData.AddBeforeSelf Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Adds the specified content immediately before this node.

Syntax

```
[Ok := ]  XmlCData.AddBeforeSelf(Content: Any,...)
```

Parameters

XmlCData Type: XmlCData An instance of the XmlCData data type.

Content
Type: Any
The content to add before this node.

Return Value

Ok Type: Boolean **true** if the operation was successful; otherwise **false**. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

XmlCData.AsXmlNode Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Converts the node to an XmlNode.

Syntax

```
XmlNode :=   XmlCData.AsXmlNode()
```

Parameters

XmlCData Type: XmlCData An instance of the XmlCData data type.

Return Value

XmlNode Type: XmlNode An XmlNode value that references the current XmlCData.

See Also

XmlCData.GetDocument Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Gets the XmlDocument for this node.

Syntax

```
[Ok := ]  XmlCData.GetDocument(var Document: XmlDocument)
```

Parameters

XmlCData Type: XmlCData An instance of the XmlCData data type.

Document
Type: XmlDocument
The owning XmlDocument of this node.

Return Value

Ok Type: Boolean **true** if the operation was successful; otherwise **false**. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

See Also

XmlCData.GetParent Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Gets the parent XmlElement of this node.

Syntax

```
[Ok := ]  XmlCData.GetParent(var Parent: XmlElement)
```

Parameters

XmlCData Type: XmlCData An instance of the XmlCData data type.

Parent
Type: XmlElement
The parent XmlElement of this node.

Return Value

Ok Type: Boolean **true** if the operation was successful; otherwise **false**. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

See Also

XmlCData.Remove Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Removes this node from its parent element.

Syntax

```
[Ok := ]  XmlCData.Remove()
```

Parameters

XmlCData Type: XmlCData An instance of the XmlCData data type.

Return Value

Ok Type: Boolean **true** if the operation was successful; otherwise **false**. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

XmlCData.ReplaceWith Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Replaces this node with the specified content.

Syntax

```
[Ok := ]  XmlCData.ReplaceWith(Node: Any,...)
```

Parameters

XmlCData Type: XmlCData An instance of the XmlCData data type.

Node
Type: Any
The content with which to replace the current node.

Return Value

Ok Type: Boolean **true** if the operation was successful; otherwise **false**. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

XmlCData.SelectNodes Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Selects a list of nodes matching the XPath expression.

Syntax

```
[Ok := ]  XmlCData.SelectNodes(XPath: String, var NodeList: XmlNodeList)
```

Parameters

XmlCData Type: XmlCData An instance of the XmlCData data type.

XPath
Type: String
The XPath expression.

NodeList
Type: XmlNodeList
An XmlNodeList containing a collection of nodes matching the XPath expression.

Return Value

Ok Type: Boolean **true** if the operation was successful; otherwise **false**. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

See Also

XmlCData.SelectNodes Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Selects a list of nodes matching the XPath expression.

Syntax

```
[Ok := ]  XmlCData.SelectNodes(XPath: String, NamespaceManager: XmlNamespaceManager, var NodeList:
XmlNodeList)
```

Parameters

XmlCData Type: XmlCData An instance of the XmlCData data type.

XPath
Type: String
The XPath expression.

NamespaceManager
Type: XmlNamespaceManager
An XmlNamespaceManager to use for resolving namespaces for prefixes in the XPath expression.

NodeList
Type: XmlNodeList
An XmlNodeList containing a collection of nodes matching the XPath expression.

Return Value

Ok Type: Boolean **true** if the operation was successful; otherwise **false**. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

XmlCData.SelectSingleNode Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Selects the first XmlNode that matches the XPath expression.

Syntax

```
[Ok := ]  XmlCData.SelectSingleNode(XPath: String, var Node: XmlNode)
```

Parameters

XmlCData Type: XmlCData An instance of the XmlCData data type.

XPath
Type: String
The XPath expression.

Node
Type: XmlNode
The first XmlNode that matches the XPath query.

Return Value

Ok Type: Boolean **true** if the operation was successful; otherwise **false**. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

XmlCData.Value Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Gets or sets the value of this node.

Syntax

```
[Value := ]  XmlCData.Value([NewValue: String])
```

NOTE

This method can be invoked using property access syntax.

Parameters

XmlCData Type: XmlCData An instance of the XmlCData data type.

NewValue

Type: String

The new value of this node.

Return Value

Value Type: String The value of this node.

XmlCData.WriteTo Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Serializes and saves the current node to the given variable.

Syntax

```
[Ok := ]  XmlCData.WriteTo(OutStream: OutStream)
```

Parameters

XmlCData Type: XmlCData An instance of the XmlCData data type.

OutStream
Type: OutStream
The OutStream to which you want to save the serialized representation of the node.

Return Value

Ok Type: Boolean **true** if the operation was successful; otherwise **false**. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Serializes and saves the current node to the given variable.

Syntax

```
[Ok := ]  XmlCData.WriteTo(WriteOptions: XmlWriteOptions, OutStream: OutStream)
```

Parameters

XmlCData Type: XmlCData An instance of the XmlCData data type.

WriteOptions
Type: XmlWriteOptions
Specifies options for customizing how the node is serialized.

OutStream
Type: OutStream
The OutStream to which you want to save the serialized representation of the node.

Return Value

Ok Type: Boolean **true** if the operation was successful; otherwise **false**. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

Version: *Available from runtime version 1.0.*

Selects the first XmlNode that matches the XPath expression.

Syntax

```
[Ok := ]  XmlComment.SelectSingleNode(XPath: String, var Node: XmlNode)
```

Parameters

XmlComment Type: XmlComment An instance of the XmlComment data type.

XPath
Type: String
The XPath expression.

Node
Type: XmlNode
The first XmlNode that matches the XPath query.

Return Value

Ok Type: Boolean **true** if the operation was successful; otherwise **false**. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

XmlComment.SelectSingleNode Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Selects the first XmlNode that matches the XPath expression.

Syntax

```
[Ok := ]  XmlComment.SelectSingleNode(XPath: String, NamespaceManager: XmlNamespaceManager, var Node:
XmlNode)
```

Parameters

XmlComment Type: XmlComment An instance of the XmlComment data type.

XPath
Type: String
The XPath expression.

NamespaceManager
Type: XmlNamespaceManager
An XmlNamespaceManager to use for resolving namespaces for prefixes in the XPath expression.

Node
Type: XmlNode
The first XmlNode that matches the XPath query.

Return Value

Ok Type: Boolean **true** if the operation was successful; otherwise **false**. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

XmlComment.Value Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Gets or sets the string value of this comment.

Syntax

```
[Value := ]  XmlComment.Value([NewValue: String])
```

> **NOTE**
> This method can be invoked using property access syntax.

Parameters

XmlComment Type: XmlComment An instance of the XmlComment data type.

NewValue
Type: String
The new value of this comment.

Return Value

Value Type: String The new value of this comment.

XmlComment.WriteTo Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Serializes and saves the current node to the given variable.

Syntax

```
[Ok := ]  XmlComment.WriteTo(OutStream: OutStream)
```

Parameters

XmlComment Type: XmlComment An instance of the XmlComment data type.

OutStream
Type: OutStream
The OutStream to which you want to save the serialized representation of the node.

Return Value

Ok Type: Boolean **true** if the operation was successful; otherwise **false**. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

Syntax

```
[Ok := ]  XmlComment.WriteTo(WriteOptions: XmlWriteOptions, OutStream: OutStream)
```

Parameters

XmlComment Type: XmlComment An instance of the XmlComment data type.

WriteOptions
Type: XmlWriteOptions
Specifies options for customizing how the node is serialized.

OutStream
Type: OutStream
The OutStream to which you want to save the serialized representation of the node.

Return Value

Ok Type: Boolean **true** if the operation was successful; otherwise **false**. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

XmlDeclaration Data Type

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Represents an XML declaration.

The following methods are available on the XmlDeclaration data type.

METHOD NAME	DESCRIPTION
Create(String, String, String)	Creates an XmlDeclaration node.

The following methods are available on instances of the XmlDeclaration data type.

METHOD NAME	DESCRIPTION
AddAfterSelf(Any,...)	Adds the specified content immediately after this node.
AddBeforeSelf(Any,...)	Adds the specified content immediately before this node.
AsXmlNode()	Converts the node to an XmlNode.
Encoding([String])	Gets or sets the encoding of the XML document.
GetDocument(var XmlDocument)	Gets the XmlDocument for this node.
GetParent(var XmlElement)	Gets the parent XmlElement of this node.
Remove()	Removes this node from its parent element.
ReplaceWith(Any,...)	Replaces this node with the specified content.
SelectNodes(String, var XmlNodeList)	Selects a list of nodes matching the XPath expression.
SelectNodes(String, XmlNamespaceManager, var XmlNodeList)	Selects a list of nodes matching the XPath expression.
SelectSingleNode(String, var XmlNode)	Selects the first XmlNode that matches the XPath expression.
SelectSingleNode(String, XmlNamespaceManager, var XmlNode)	Selects the first XmlNode that matches the XPath expression.
Standalone([String])	Gets or sets the standalone property for this document.
Version([String])	Gets or sets the version property for this document.
WriteTo(OutStream)	Serializes and saves the current node to the given variable.

METHOD NAME	DESCRIPTION
WriteTo(XmlWriteOptions, OutStream)	Serializes and saves the current node to the given variable.
WriteTo(var Text)	Serializes and saves the current node to the given variable.
WriteTo(XmlWriteOptions, var Text)	Serializes and saves the current node to the given variable.

XmlDeclaration.Create Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Creates an XmlDeclaration node.

Syntax

```
XmlDeclaration :=   XmlDeclaration.Create(Version: String, Encoding: String, Standalone: String)
```

Parameters

Version

Type: String

The version of the XML, usually "1.0".

Encoding

Type: String

The encoding for the XML document.

Standalone

Type: String

A string containing "yes" or "no" that specifies whether the XML is standalone or requires external entities to be resolved.

Return Value

XmlDeclaration Type: XmlDeclaration The created XmlDeclaration node.

XmlDeclaration.AddAfterSelf Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Adds the specified content immediately after this node.

Syntax

```
[Ok := ]  XmlDeclaration.AddAfterSelf(Content: Any,...)
```

Parameters

XmlDeclaration Type: XmlDeclaration An instance of the XmlDeclaration data type.

Content
Type: Any
The content to add after this node.

Return Value

Ok Type: Boolean **true** if the operation was successful; otherwise **false**. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

XmlDeclaration.AddBeforeSelf Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Adds the specified content immediately before this node.

Syntax

```
[Ok := ]  XmlDeclaration.AddBeforeSelf(Content: Any,...)
```

Parameters

XmlDeclaration Type: XmlDeclaration An instance of the XmlDeclaration data type.

Content
Type: Any
The content to add before this node.

Return Value

Ok Type: Boolean **true** if the operation was successful; otherwise **false**. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

XmlDeclaration.AsXmlNode Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Converts the node to an XmlNode.

Syntax

```
XmlNode :=   XmlDeclaration.AsXmlNode()
```

Parameters

XmlDeclaration Type: XmlDeclaration An instance of the XmlDeclaration data type.

Return Value

XmlNode Type: XmlNode An XmlNode value that references the current XmlDeclaration.

See Also

XmlDeclaration Data Type
Getting Started with AL

XmlDeclaration.Encoding Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Gets or sets the encoding of the XML document.

Syntax

```
[Value := ]  XmlDeclaration.Encoding([NewValue: String])
```

NOTE

This method can be invoked using property access syntax.

Parameters

XmlDeclaration Type: XmlDeclaration An instance of the XmlDeclaration data type.

NewValue

Type: String

The new value for the encoding of the XML document.

Return Value

Value Type: String The encoding of the XML document.

See Also

XmlDeclaration.GetDocument Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Gets the XmlDocument for this node.

Syntax

```
[Ok := ]  XmlDeclaration.GetDocument(var Document: XmlDocument)
```

Parameters

XmlDeclaration Type: XmlDeclaration An instance of the XmlDeclaration data type.

Document
Type: XmlDocument
The owning XmlDocument of this node.

Return Value

Ok Type: Boolean **true** if the operation was successful; otherwise **false**. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

See Also

XmlDeclaration Data Type

XmlDeclaration.GetParent Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Gets the parent XmlElement of this node.

Syntax

```
[Ok := ]  XmlDeclaration.GetParent(var Parent: XmlElement)
```

Parameters

XmlDeclaration Type: XmlDeclaration An instance of the XmlDeclaration data type.

Parent
Type: XmlElement
The parent XmlElement of this node.

Return Value

Ok Type: Boolean **true** if the operation was successful; otherwise **false**. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

See Also

XmlDeclaration Data Type

XmlDeclaration.Remove Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Removes this node from its parent element.

Syntax

```
[Ok := ]  XmlDeclaration.Remove()
```

Parameters

XmlDeclaration Type: XmlDeclaration An instance of the XmlDeclaration data type.

Return Value

Ok Type: Boolean **true** if the operation was successful; otherwise **false**. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

See Also

XmlDeclaration Data Type
Getting Started with AL

XmlDeclaration.ReplaceWith Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Replaces this node with the specified content.

Syntax

```
[Ok := ]  XmlDeclaration.ReplaceWith(Node: Any,...)
```

Parameters

XmlDeclaration Type: XmlDeclaration An instance of the XmlDeclaration data type.

Node
Type: Any
The content with which to replace the current node.

Return Value

Ok Type: Boolean **true** if the operation was successful; otherwise **false**. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

See Also

XmlDeclaration.SelectNodes Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Selects a list of nodes matching the XPath expression.

Syntax

```
[Ok := ]  XmlDeclaration.SelectNodes(XPath: String, var NodeList: XmlNodeList)
```

Parameters

XmlDeclaration Type: XmlDeclaration An instance of the XmlDeclaration data type.

XPath
Type: String
The XPath expression.

NodeList
Type: XmlNodeList
An XmlNodeList containing a collection of nodes matching the XPath expression.

Return Value

Ok Type: Boolean **true** if the operation was successful; otherwise **false**. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

See Also

XmlDeclaration.SelectNodes Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Selects a list of nodes matching the XPath expression.

Syntax

```
[Ok := ]  XmlDeclaration.SelectNodes(XPath: String, NamespaceManager: XmlNamespaceManager, var NodeList:
XmlNodeList)
```

Parameters

XmlDeclaration Type: XmlDeclaration An instance of the XmlDeclaration data type.

XPath
Type: String
The XPath expression.

NamespaceManager
Type: XmlNamespaceManager
An XmlNamespaceManager to use for resolving namespaces for prefixes in the XPath expression.

NodeList
Type: XmlNodeList
An XmlNodeList containing a collection of nodes matching the XPath expression.

Return Value

Ok Type: Boolean **true** if the operation was successful; otherwise **false**. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

XmlDeclaration.SelectSingleNode Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Selects the first XmlNode that matches the XPath expression.

Syntax

```
[Ok := ]  XmlDeclaration.SelectSingleNode(XPath: String, var Node: XmlNode)
```

Parameters

XmlDeclaration Type: XmlDeclaration An instance of the XmlDeclaration data type.

XPath
Type: String
The XPath expression.

Node
Type: XmlNode
The first XmlNode that matches the XPath query.

Return Value

Ok Type: Boolean **true** if the operation was successful; otherwise **false**. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

XmlDeclaration.Standalone Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Gets or sets the standalone property for this document.

Syntax

```
[Value := ]  XmlDeclaration.Standalone([NewValue: String])
```

NOTE

This method can be invoked using property access syntax.

Parameters

XmlDeclaration Type: XmlDeclaration An instance of the XmlDeclaration data type.

NewValue

Type: String

A string containing the standalone property for this document.

Return Value

Value Type: String The standalone property for this document.

XmlDocument Data Type

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Represents an XML document.

The following methods are available on the XmlDocument data type.

METHOD NAME	DESCRIPTION
Create()	Creates an XmlDocument.
Create(Any,...)	Creates an XmlDocument.
ReadFrom(String, var XmlDocument)	Reads and parses the XML document from the given data source.
ReadFrom(String, XmlReadOptions, var XmlDocument)	Reads and parses the XML document from the given data source.
ReadFrom(InStream, var XmlDocument)	Reads and parses the XML document from the given data source.
ReadFrom(InStream, XmlReadOptions, var XmlDocument)	Reads and parses the XML document from the given data source.

The following methods are available on instances of the XmlDocument data type.

METHOD NAME	DESCRIPTION
Add(Any,...)	Adds the specified content as a child of this document.
AddAfterSelf(Any,...)	Adds the specified content immediately after this node.
AddBeforeSelf(Any,...)	Adds the specified content immediately before this node.
AddFirst(Any,...)	Adds the specified content at the start of the child list of this document.
AsXmlNode()	Converts the node to an XmlNode.
GetChildElements()	Gets a list containing the child elements for this document, in document order.
GetChildElements(String)	Gets a list containing the child elements for this document, in document order.
GetChildElements(String, String)	Gets a list containing the child elements for this document, in document order.
GetChildNodes()	Gets a list containing the child elements for this document, in document order.

METHOD NAME	DESCRIPTION
GetDeclaration(var XmlDeclaration)	Gets the XML declaration for this document.
GetDescendantElements()	Gets a list containing the descendant elements for this document, in document order.
GetDescendantElements(String)	Gets a list containing the descendant elements for this document, in document order.
GetDescendantElements(String, String)	Gets a list containing the descendant elements for this document, in document order.
GetDescendantNodes()	Gets a list containing the descendant nodes for this document, in document order.
GetDocument(var XmlDocument)	Gets the XmlDocument for this node.
GetDocumentType(var XmlDocumentType)	Gets the Document Type Definition (DTD) for this document.
GetParent(var XmlElement)	Gets the parent XmlElement of this node.
GetRoot(var XmlElement)	Gets the root element of the XML tree for this document.
NameTable()	Gets the XmlNameTable associated with this document.
Remove()	Removes this node from its parent element.
RemoveNodes()	Removes the child nodes from this document.
ReplaceNodes(Any,...)	Replaces the children nodes of this document with the specified content.
ReplaceWith(Any,...)	Replaces this node with the specified content.
SelectNodes(String, var XmlNodeList)	Selects a list of nodes matching the XPath expression.
SelectNodes(String, XmlNamespaceManager, var XmlNodeList)	Selects a list of nodes matching the XPath expression.
SelectSingleNode(String, var XmlNode)	Selects the first XmlNode that matches the XPath expression.
SelectSingleNode(String, XmlNamespaceManager, var XmlNode)	Selects the first XmlNode that matches the XPath expression.
SetDeclaration(XmlDeclaration)	Sets the XML declaration for this document.
WriteTo(OutStream)	Serializes and saves the current node to the given variable.
WriteTo(XmlWriteOptions, OutStream)	Serializes and saves the current node to the given variable.
WriteTo(var Text)	Serializes and saves the current node to the given variable.
WriteTo(XmlWriteOptions, var Text)	Serializes and saves the current node to the given variable.

XmlDocument.ReadFrom Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Reads and parses the XML document from the given data source.

Syntax

```
[Ok := ]  XmlDocument.ReadFrom(Text: String, var Result: XmlDocument)
```

Parameters

Text

Type: String

A string containing an XML document.

Result

Type: XmlDocument

The XmlDocument parsed from the given data source.

Return Value

Ok Type: Boolean **true** if the operation was successful; otherwise **false**. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Reads and parses the XML document from the given data source.

Syntax

```
[Ok := ]  XmlDocument.ReadFrom(Text: String, ReadOptions: XmlReadOptions, var Result: XmlDocument)
```

Parameters

Text

Type: String

A string containing an XML document.

ReadOptions

Type: XmlReadOptions

Specifies options for customizing how the document is parsed.

Result

Type: XmlDocument

The XmlDocument parsed from the given data source.

Return Value

Ok Type: Boolean **true** if the operation was successful; otherwise **false**. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

XmlDocument.AddFirst Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Adds the specified content at the start of the child list of this document.

Syntax

```
[Ok := ]  XmlDocument.AddFirst(Content: Any,...)
```

Parameters

XmlDocument Type: XmlDocument An instance of the XmlDocument data type.

Content
Type: Any
The content to be added as a child of this document.

Return Value

Ok Type: Boolean **true** if the operation was successful; otherwise **false**. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

XmlDocument.AsXmlNode Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Converts the node to an XmlNode.

Syntax

```
XmlNode :=   XmlDocument.AsXmlNode()
```

Parameters

XmlDocument Type: XmlDocument An instance of the XmlDocument data type.

Return Value

XmlNode Type: XmlNode An XmlNode value that references the current XmlDocument.

See Also

XmlDocument.GetChildElements Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Gets a list containing the child elements for this document, in document order.

Syntax

```
ChildElements :=   XmlDocument.GetChildElements()
```

Parameters

XmlDocument Type: XmlDocument An instance of the XmlDocument data type.

Return Value

ChildElements Type: XmlNodeList A list containing the child elements for this document, in document order.

See Also

XmlDocument.GetChildElements Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Gets a list containing the child elements for this document, in document order.

Syntax

```
ChildElements :=   XmlDocument.GetChildElements(Name: String)
```

Parameters

XmlDocument Type: XmlDocument An instance of the XmlDocument data type.

Name
Type: String
The fully qualified name of the elements to retrieve.

Return Value

ChildElements Type: XmlNodeList A list containing the child elements for this document, in document order.

See Also

XmlDocument.GetChildElements Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Gets a list containing the child elements for this document, in document order.

Syntax

```
ChildElements :=   XmlDocument.GetChildElements(LocalName: String, NamespaceUri: String)
```

Parameters

XmlDocument Type: XmlDocument An instance of the XmlDocument data type.

LocalName
Type: String
The local name of the elements to retrieve.

NamespaceUri
Type: String
The namespace URI of the elements to retrieve.

Return Value

ChildElements Type: XmlNodeList A list containing the child elements for this document, in document order.

XmlDocument.GetDeclaration Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Gets the XML declaration for this document.

Syntax

```
[Ok := ]  XmlDocument.GetDeclaration(var Result: XmlDeclaration)
```

Parameters

XmlDocument Type: XmlDocument An instance of the XmlDocument data type.

Result
Type: XmlDeclaration
The XML declaration for this document.

Return Value

Ok Type: Boolean **true** if the operation was successful; otherwise **false**. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

XmlDocument.GetDescendantElements Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Gets a list containing the descendant elements for this document, in document order.

Syntax

```
DescendantElements :=   XmlDocument.GetDescendantElements()
```

Parameters

XmlDocument Type: XmlDocument An instance of the XmlDocument data type.

Return Value

DescendantElements Type: XmlNodeList A list containing the descendant elements for this document, in document order.

XmlDocument.GetDocument Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Gets the XmlDocument for this node.

Syntax

```
[Ok := ]  XmlDocument.GetDocument(var Document: XmlDocument)
```

Parameters

XmlDocument Type: XmlDocument An instance of the XmlDocument data type.

Document
Type: XmlDocument
The owning XmlDocument of this node.

Return Value

Ok Type: Boolean **true** if the operation was successful; otherwise **false**. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

XmlDocument.GetDocumentType Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Gets the Document Type Definition (DTD) for this document.

Syntax

```
[Ok := ]  XmlDocument.GetDocumentType(var DocumentType: XmlDocumentType)
```

Parameters

XmlDocument Type: XmlDocument An instance of the XmlDocument data type.

DocumentType
Type: XmlDocumentType
The Document Type Definition (DTD) for this document.

Return Value

Ok Type: Boolean **true** if the operation was successful; otherwise **false**. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

XmlDocument.GetParent Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Gets the parent XmlElement of this node.

Syntax

```
[Ok := ]  XmlDocument.GetParent(var Parent: XmlElement)
```

Parameters

XmlDocument Type: XmlDocument An instance of the XmlDocument data type.

Parent
Type: XmlElement
The parent XmlElement of this node.

Return Value

Ok Type: Boolean **true** if the operation was successful; otherwise **false**. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

See Also

XmlDocument.GetRoot Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Gets the root element of the XML tree for this document.

Syntax

```
[Ok := ]  XmlDocument.GetRoot(var Result: XmlElement)
```

Parameters

XmlDocument Type: XmlDocument An instance of the XmlDocument data type.

Result
Type: XmlElement
The root element of the XML tree for this document.

Return Value

Ok Type: Boolean **true** if the operation was successful; otherwise **false**. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

XmlDocument.NameTable Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Gets the XmlNameTable associated with this document.

Syntax

```
NameTable :=   XmlDocument.NameTable()
```

NOTE

This method can be invoked using property access syntax.

Parameters

XmlDocument Type: XmlDocument An instance of the XmlDocument data type.

Return Value

NameTable Type: XmlNameTable The XmlNameTable associated with this document.

See Also

XmlDocument.Remove Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Removes this node from its parent element.

Syntax

```
[Ok := ]  XmlDocument.Remove()
```

Parameters

XmlDocument Type: XmlDocument An instance of the XmlDocument data type.

Return Value

Ok Type: Boolean **true** if the operation was successful; otherwise **false**. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

See Also

XmlDocument.ReplaceNodes Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Replaces the children nodes of this document with the specified content.

Syntax

```
[Ok := ]  XmlDocument.ReplaceNodes(Content: Any,...)
```

Parameters

XmlDocument Type: XmlDocument An instance of the XmlDocument data type.

Content
Type: Any
The content that replaces the children nodes.

Return Value

Ok Type: Boolean **true** if the operation was successful; otherwise **false**. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

See Also

XmlDocument Data Type

XmlDocument.ReplaceWith Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Replaces this node with the specified content.

Syntax

```
[Ok := ]  XmlDocument.ReplaceWith(Node: Any,...)
```

Parameters

XmlDocument Type: XmlDocument An instance of the XmlDocument data type.

Node
Type: Any
The content with which to replace the current node.

Return Value

Ok Type: Boolean **true** if the operation was successful; otherwise **false**. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

XmlDocument.SelectNodes Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Selects a list of nodes matching the XPath expression.

Syntax

```
[Ok := ]  XmlDocument.SelectNodes(XPath: String, var NodeList: XmlNodeList)
```

Parameters

XmlDocument Type: XmlDocument An instance of the XmlDocument data type.

XPath
Type: String
The XPath expression.

NodeList
Type: XmlNodeList
An XmlNodeList containing a collection of nodes matching the XPath expression.

Return Value

Ok Type: Boolean **true** if the operation was successful; otherwise **false**. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

See Also

XmlDocument Data Type

XmlDocument.SelectNodes Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Selects a list of nodes matching the XPath expression.

Syntax

```
[Ok := ]  XmlDocument.SelectNodes(XPath: String, NamespaceManager: XmlNamespaceManager, var NodeList:
XmlNodeList)
```

Parameters

XmlDocument Type: XmlDocument An instance of the XmlDocument data type.

XPath
Type: String
The XPath expression.

NamespaceManager
Type: XmlNamespaceManager
An XmlNamespaceManager to use for resolving namespaces for prefixes in the XPath expression.

NodeList
Type: XmlNodeList
An XmlNodeList containing a collection of nodes matching the XPath expression.

Return Value

Ok Type: Boolean **true** if the operation was successful; otherwise **false**. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

See Also

XmlDocument Data Type

XmlDocument.SelectSingleNode Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Selects the first XmlNode that matches the XPath expression.

Syntax

```
[Ok := ]  XmlDocument.SelectSingleNode(XPath: String, var Node: XmlNode)
```

Parameters

XmlDocument Type: XmlDocument An instance of the XmlDocument data type.

XPath
Type: String
The XPath expression.

Node
Type: XmlNode
The first XmlNode that matches the XPath query.

Return Value

Ok Type: Boolean **true** if the operation was successful; otherwise **false**. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

See Also

XmlDocument Data Type

XmlDocument.SelectSingleNode Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Selects the first XmlNode that matches the XPath expression.

Syntax

```
[Ok := ]  XmlDocument.SelectSingleNode(XPath: String, NamespaceManager: XmlNamespaceManager, var Node:
XmlNode)
```

Parameters

XmlDocument Type: XmlDocument An instance of the XmlDocument data type.

XPath
Type: String
The XPath expression.

NamespaceManager
Type: XmlNamespaceManager
An XmlNamespaceManager to use for resolving namespaces for prefixes in the XPath expression.

Node
Type: XmlNode
The first XmlNode that matches the XPath query.

Return Value

Ok Type: Boolean **true** if the operation was successful; otherwise **false**. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

XmlDocument.SetDeclaration Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Sets the XML declaration for this document.

Syntax

```
[Ok := ]  XmlDocument.SetDeclaration(Declaration: XmlDeclaration)
```

Parameters

XmlDocument Type: XmlDocument An instance of the XmlDocument data type.

Declaration
Type: XmlDeclaration
The new value of the XML declaration of this document.

Return Value

Ok Type: Boolean **true** if the operation was successful; otherwise **false**. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

See Also

XmlDocument.WriteTo Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Serializes and saves the current node to the given variable.

Syntax

```
[Ok := ]  XmlDocument.WriteTo(OutStream: OutStream)
```

Parameters

XmlDocument Type: XmlDocument An instance of the XmlDocument data type.

OutStream
Type: OutStream
The OutStream to which you want to save the serialized representation of the node.

Return Value

Ok Type: Boolean **true** if the operation was successful; otherwise **false**. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

Example

The following example illustrates how to create a Stream from a Blob and write to a Stream from an XML document.

```
pageextension 50100 CustomerListExt extends "Customer List"
{
    trigger OnOpenPage();
    var
        xmlDoc: XmlDocument;
        xmlDec: XmlDeclaration;
        xmlElem: XmlElement;
        xmlElem2: XmlElement;
        TempBlob: Record TempBlob Temporary;
        outStr: OutStream;
        inStr: InStream;
        TempFile: File;
        fileName: Text;
    begin
        xmlDoc := xmlDocument.Create();
        xmlDec := xmlDeclaration.Create('1.0', 'UTF-8', '');
        xmlDoc.SetDeclaration(xmlDec);

        xmlElem := xmlElement.Create('root');
        xmlElem.SetAttribute('release', '2.1');

        xmlElem2 := XmlElement.Create('FirstName');
        xmlElem2.Add(xmlText.Create('Max'));

        xmlElem.Add(xmlElem2);
        xmlDoc.Add(xmlElem);

        // Create an outStream from the Blob, notice the encoding.
        TempBlob.CreateOutStream(outStr, TextEncoding::UTF8);

        // Write the contents of the doc to the stream
        xmlDoc.WriteTo(outStr);

         // From the same Blob, that now contains the XML document, create an inStr
        TempBlob.CreateInStream(inStr, TextEncoding::UTF8);

        // Save the data of the InStream as a file.
        File.DownloadFromStream(inStr, 'Export', '', '', fileName);
    end;
}
```

XmlDocument.WriteTo Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Serializes and saves the current node to the given variable.

Syntax

```
[Ok := ]  XmlDocument.WriteTo(WriteOptions: XmlWriteOptions, OutStream: OutStream)
```

Parameters

XmlDocument Type: XmlDocument An instance of the XmlDocument data type.

WriteOptions
Type: XmlWriteOptions
Specifies options for customizing how the node is serialized.

OutStream
Type: OutStream
The OutStream to which you want to save the serialized representation of the node.

Return Value

Ok Type: Boolean **true** if the operation was successful; otherwise **false**. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

XmlDocumentType Data Type

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Represents an XML document type.

The following methods are available on the XmlDocumentType data type.

METHOD NAME	DESCRIPTION
Create(String)	Creates an XmlDocumentType node.
Create(String, String)	Creates an XmlDocumentType node.
Create(String, String, String)	Creates an XmlDocumentType node.
Create(String, String, String, String)	Creates an XmlDocumentType node.

The following methods are available on instances of the XmlDocumentType data type.

METHOD NAME	DESCRIPTION
AddAfterSelf(Any,...)	Adds the specified content immediately after this node.
AddBeforeSelf(Any,...)	Adds the specified content immediately before this node.
AsXmlNode()	Converts the node to an XmlNode.
GetDocument(var XmlDocument)	Gets the XmlDocument for this node.
GetInternalSubset(var Text)	Gets the internal subset for this Document Type Definition (DTD).
GetName(var Text)	Gets the name for this Document Type Definition (DTD).
GetParent(var XmlElement)	Gets the parent XmlElement of this node.
GetPublicId(var Text)	Gets the public identifier for this Document Type Definition (DTD).
GetSystemId(var Text)	Gets the system identifier for this Document Type Definition (DTD).
Remove()	Removes this node from its parent element.
ReplaceWith(Any,...)	Replaces this node with the specified content.
SelectNodes(String, var XmlNodeList)	Selects a list of nodes matching the XPath expression.

METHOD NAME	DESCRIPTION
SelectNodes(String, XmlNamespaceManager, var XmlNodeList)	Selects a list of nodes matching the XPath expression.
SelectSingleNode(String, var XmlNode)	Selects the first XmlNode that matches the XPath expression.
SelectSingleNode(String, XmlNamespaceManager, var XmlNode)	Selects the first XmlNode that matches the XPath expression.
SetInternalSubset(String)	Sets the internal subset for this Document Type Definition (DTD).
SetName(String)	Sets the name for this Document Type Definition (DTD).
SetPublicId(String)	Sets the public identifier for this Document Type Definition (DTD).
SetSystemId(String)	Sets the system identifier for this Document Type Definition (DTD).
WriteTo(OutStream)	Serializes and saves the current node to the given variable.
WriteTo(XmlWriteOptions, OutStream)	Serializes and saves the current node to the given variable.
WriteTo(var Text)	Serializes and saves the current node to the given variable.
WriteTo(XmlWriteOptions, var Text)	Serializes and saves the current node to the given variable.

XmlDocumentType.Create Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Creates an XmlDocumentType node.

Syntax

```
XmlDocumentType :=   XmlDocumentType.Create(Name: String)
```

Parameters

Name

Type: String

A string that contains the qualified name of the DTD, which is the same as the qualified name of the root element of the XML document.

Return Value

XmlDocumentType Type: XmlDocumentType The created XmlDocumentType node.

XmlDocumentType.Create Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Creates an XmlDocumentType node.

Syntax

```
XmlDocumentType :=   XmlDocumentType.Create(Name: String, PublicId: String)
```

Parameters

Name

Type: String

A string that contains the qualified name of the DTD, which is the same as the qualified name of the root element of the XML document.

PublicId

Type: String

A string that contains the public identifier of an external public DTD.

Return Value

XmlDocumentType Type: XmlDocumentType The created XmlDocumentType node.

XmlDocumentType.Create Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Creates an XmlDocumentType node.

Syntax

```
XmlDocumentType :=   XmlDocumentType.Create(Name: String, PublicId: String, SystemId: String)
```

Parameters

Name

Type: String

A string that contains the qualified name of the DTD, which is the same as the qualified name of the root element of the XML document.

PublicId

Type: String

A string that contains the public identifier of an external public DTD.

SystemId

Type: String

A string that contains the system identifier of an external private DTD.

Return Value

XmlDocumentType Type: XmlDocumentType The created XmlDocumentType node.

XmlDocumentType.Create Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Creates an XmlDocumentType node.

Syntax

```
XmlDocumentType :=   XmlDocumentType.Create(Name: String, PublicId: String, SystemId: String,
InternalSubSet: String)
```

Parameters

Name

Type: String

A string that contains the qualified name of the DTD, which is the same as the qualified name of the root element of the XML document.

PublicId

Type: String

A string that contains the public identifier of an external public DTD.

SystemId

Type: String

A string that contains the system identifier of an external private DTD.

InternalSubSet

Type: String

A string that contains the internal subset for an internal DTD.

Return Value

XmlDocumentType Type: XmlDocumentType The created XmlDocumentType node.

XmlDocumentType.AddAfterSelf Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Adds the specified content immediately after this node.

Syntax

```
[Ok := ]  XmlDocumentType.AddAfterSelf(Content: Any,...)
```

Parameters

XmlDocumentType Type: XmlDocumentType An instance of the XmlDocumentType data type.

Content
Type: Any
The content to add after this node.

Return Value

Ok Type: Boolean **true** if the operation was successful; otherwise **false**. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

XmlDocumentType.AddBeforeSelf Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Adds the specified content immediately before this node.

Syntax

```
[Ok := ]  XmlDocumentType.AddBeforeSelf(Content: Any,...)
```

Parameters

XmlDocumentType Type: XmlDocumentType An instance of the XmlDocumentType data type.

Content
Type: Any
The content to add before this node.

Return Value

Ok Type: Boolean **true** if the operation was successful; otherwise **false**. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Gets the internal subset for this Document Type Definition (DTD).

Syntax

```
[Ok := ]  XmlDocumentType.GetInternalSubset(var Result: Text)
```

Parameters

XmlDocumentType Type: XmlDocumentType An instance of the XmlDocumentType data type.

Result
Type: Text
A string that contains the internal subset for this Document Type Definition (DTD).

Return Value

Ok Type: Boolean **true** if the operation was successful; otherwise **false**. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

XmlDocumentType.GetName Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Gets the name for this Document Type Definition (DTD).

Syntax

```
[Ok := ]  XmlDocumentType.GetName(var Result: Text)
```

Parameters

XmlDocumentType Type: XmlDocumentType An instance of the XmlDocumentType data type.

Result
Type: Text
A string that contains the name for this Document Type Definition (DTD).

Return Value

Ok Type: Boolean **true** if the operation was successful; otherwise **false**. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

XmlDocumentType.GetParent Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Gets the parent XmlElement of this node.

Syntax

```
[Ok := ]  XmlDocumentType.GetParent(var Parent: XmlElement)
```

Parameters

XmlDocumentType Type: XmlDocumentType An instance of the XmlDocumentType data type.

Parent
Type: XmlElement
The parent XmlElement of this node.

Return Value

Ok Type: Boolean **true** if the operation was successful; otherwise **false**. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

XmlDocumentType.GetPublicId Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Gets the public identifier for this Document Type Definition (DTD).

Syntax

```
[Ok := ]  XmlDocumentType.GetPublicId(var Result: Text)
```

Parameters

XmlDocumentType Type: XmlDocumentType An instance of the XmlDocumentType data type.

Result
Type: Text
A string that contains the public identifier for this Document Type Definition (DTD).

Return Value

Ok Type: Boolean **true** if the operation was successful; otherwise **false**. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

XmlDocumentType.GetSystemId Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Gets the system identifier for this Document Type Definition (DTD).

Syntax

```
[Ok := ]  XmlDocumentType.GetSystemId(var Result: Text)
```

Parameters

XmlDocumentType Type: XmlDocumentType An instance of the XmlDocumentType data type.

Result
Type: Text
A string that contains the system identifier for this Document Type Definition (DTD).

Return Value

Ok Type: Boolean **true** if the operation was successful; otherwise **false**. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

XmlDocumentType.Remove Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Removes this node from its parent element.

Syntax

```
[Ok := ]  XmlDocumentType.Remove()
```

Parameters

XmlDocumentType Type: XmlDocumentType An instance of the XmlDocumentType data type.

Return Value

Ok Type: Boolean **true** if the operation was successful; otherwise **false**. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

See Also

XmlDocumentType Data Type

XmlDocumentType.ReplaceWith Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Replaces this node with the specified content.

Syntax

```
[Ok := ]  XmlDocumentType.ReplaceWith(Node: Any,...)
```

Parameters

XmlDocumentType Type: XmlDocumentType An instance of the XmlDocumentType data type.

Node
Type: Any
The content with which to replace the current node.

Return Value

Ok Type: Boolean **true** if the operation was successful; otherwise **false**. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

XmlDocumentType.SelectNodes Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Selects a list of nodes matching the XPath expression.

Syntax

```
[Ok := ]  XmlDocumentType.SelectNodes(XPath: String, var NodeList: XmlNodeList)
```

Parameters

XmlDocumentType Type: XmlDocumentType An instance of the XmlDocumentType data type.

XPath
Type: String
The XPath expression.

NodeList
Type: XmlNodeList
An XmlNodeList containing a collection of nodes matching the XPath expression.

Return Value

Ok Type: Boolean **true** if the operation was successful; otherwise **false**. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

XmlDocumentType.SelectNodes Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Selects a list of nodes matching the XPath expression.

Syntax

```
[Ok := ]  XmlDocumentType.SelectNodes(XPath: String, NamespaceManager: XmlNamespaceManager, var NodeList:
XmlNodeList)
```

Parameters

XmlDocumentType Type: XmlDocumentType An instance of the XmlDocumentType data type.

XPath
Type: String
The XPath expression.

NamespaceManager
Type: XmlNamespaceManager
An XmlNamespaceManager to use for resolving namespaces for prefixes in the XPath expression.

NodeList
Type: XmlNodeList
An XmlNodeList containing a collection of nodes matching the XPath expression.

Return Value

Ok Type: Boolean **true** if the operation was successful; otherwise **false**. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

XmlDocumentType.SelectSingleNode Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Selects the first XmlNode that matches the XPath expression.

Syntax

```
[Ok := ]  XmlDocumentType.SelectSingleNode(XPath: String, var Node: XmlNode)
```

Parameters

XmlDocumentType Type: XmlDocumentType An instance of the XmlDocumentType data type.

XPath
Type: String
The XPath expression.
Node
Type: XmlNode
The first XmlNode that matches the XPath query.

Return Value

Ok Type: Boolean **true** if the operation was successful; otherwise **false**. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

XmlDocumentType.SelectSingleNode Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Selects the first XmlNode that matches the XPath expression.

Syntax

```
[Ok := ]  XmlDocumentType.SelectSingleNode(XPath: String, NamespaceManager: XmlNamespaceManager, var Node: XmlNode)
```

Parameters

XmlDocumentType Type: XmlDocumentType An instance of the XmlDocumentType data type.

XPath
Type: String
The XPath expression.

NamespaceManager
Type: XmlNamespaceManager
An XmlNamespaceManager to use for resolving namespaces for prefixes in the XPath expression.

Node
Type: XmlNode
The first XmlNode that matches the XPath query.

Return Value

Ok Type: Boolean **true** if the operation was successful; otherwise **false**. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

XmlDocumentType.SetInternalSubset Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Sets the internal subset for this Document Type Definition (DTD).

Syntax

```
[Ok := ]  XmlDocumentType.SetInternalSubset(Value: String)
```

Parameters

XmlDocumentType Type: XmlDocumentType An instance of the XmlDocumentType data type.

Value
Type: String
A string that contains the new internal subset for this Document Type Definition (DTD).

Return Value

Ok Type: Boolean **true** if the operation was successful; otherwise **false**. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

XmlDocumentType.SetName Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Sets the name for this Document Type Definition (DTD).

Syntax

```
[Ok := ]  XmlDocumentType.SetName(Value: String)
```

Parameters

XmlDocumentType Type: XmlDocumentType An instance of the XmlDocumentType data type.

Value
Type: String
A string that contains the new name for this Document Type Definition (DTD).

Return Value

Ok Type: Boolean **true** if the operation was successful; otherwise **false**. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

XmlDocumentType.WriteTo Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Serializes and saves the current node to the given variable.

Syntax

```
[Ok := ]  XmlDocumentType.WriteTo(OutStream: OutStream)
```

Parameters

XmlDocumentType Type: XmlDocumentType An instance of the XmlDocumentType data type.

OutStream
Type: OutStream
The OutStream to which you want to save the serialized representation of the node.

Return Value

Ok Type: Boolean **true** if the operation was successful; otherwise **false**. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

XmlDocumentType.WriteTo Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Serializes and saves the current node to the given variable.

Syntax

```
[Ok := ]  XmlDocumentType.WriteTo(WriteOptions: XmlWriteOptions, OutStream: OutStream)
```

Parameters

XmlDocumentType Type: XmlDocumentType An instance of the XmlDocumentType data type.

WriteOptions
Type: XmlWriteOptions
Specifies options for customizing how the node is serialized.

OutStream
Type: OutStream
The OutStream to which you want to save the serialized representation of the node.

Return Value

Ok Type: Boolean **true** if the operation was successful; otherwise **false**. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

XmlElement Data Type

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Represents an XML element.

The following methods are available on the XmlElement data type.

METHOD NAME	DESCRIPTION
Create(String)	Creates an XmlElement node.
Create(String, String)	Creates an XmlElement node.
Create(String, String, Any,...)	Creates an XmlElement node.
Create(String, Any,...)	Creates an XmlElement node.

The following methods are available on instances of the XmlElement data type.

METHOD NAME	DESCRIPTION
Add(Any,...)	Adds the specified content as a child of this element.
AddAfterSelf(Any,...)	Adds the specified content immediately after this node.
AddBeforeSelf(Any,...)	Adds the specified content immediately before this node.
AddFirst(Any,...)	Adds the specified content at the start of the child list of this element.
AsXmlNode()	Converts the node to an XmlNode.
Attributes()	Gets a collection of the attributes of this element.
GetChildElements()	Gets a list containing the child elements for this element, in document order.
GetChildElements(String)	Gets a list containing the child elements for this element, in document order.
GetChildElements(String, String)	Gets a list containing the child elements for this element, in document order.
GetChildNodes()	Gets a list containing the child elements for this element, in document order.
GetDescendantElements()	Gets a list containing the descendant elements for this element, in document order.
GetDescendantElements(String)	Gets a list containing the descendant elements for this element, in document order.

METHOD NAME	DESCRIPTION
GetDescendantElements(String, String)	Gets a list containing the descendant elements for this element, in document order.
GetDescendantNodes()	Gets a list containing the descendant nodes for this element, in document order.
GetDocument(var XmlDocument)	Gets the XmlDocument for this node.
GetNamespaceOfPrefix(String, var Text)	Gets the namespace associated with a particular prefix for this element.
GetParent(var XmlElement)	Gets the parent XmlElement of this node.
GetPrefixOfNamespace(String, var Text)	Gets the prefix associated with a namespace URI for this element.
HasAttributes()	Gets a boolean value indicating whether this element has at least one attribute.
HasElements()	Gets a value indicating whether this element has at least one child element.
InnerText()	Gets the concatenated values of the node and all its child nodes.
InnerXml()	Gets the markup representing only the child nodes of this node.
IsEmpty()	Gets a value indicating whether this element contains no content.
LocalName()	Gets the local name of this element.
Name()	Gets the fully qualified name of this element.
NamespaceUri()	Gets the namespace URI of this element.
Remove()	Removes this node from its parent element.
RemoveAllAttributes()	Removes the attributes of this element.
RemoveAttribute(String)	Removes the specified attribute from this element.
RemoveAttribute(String, String)	Removes the specified attribute from this element.
RemoveAttribute(XmlAttribute)	Removes the specified attribute from this element.
RemoveNodes()	Removes the child nodes from this element.
ReplaceNodes(Any,...)	Replaces the children nodes of this element with the specified content.
ReplaceWith(Any,...)	Replaces this node with the specified content.
SelectNodes(String, var XmlNodeList)	Selects a list of nodes matching the XPath expression.

METHOD NAME	DESCRIPTION
SelectNodes(String, XmlNamespaceManager, var XmlNodeList)	Selects a list of nodes matching the XPath expression.
SelectSingleNode(String, var XmlNode)	Selects the first XmlNode that matches the XPath expression.
SelectSingleNode(String, XmlNamespaceManager, var XmlNode)	Selects the first XmlNode that matches the XPath expression.
SetAttribute(String, String)	Sets the value of the specified attribute or create it if is not part of the element's attribute collection.
SetAttribute(String, String, String)	Sets the value of the specified attribute or create it if is not part of the element's attribute collection.
WriteTo(OutStream)	Serializes and saves the current node to the given variable.
WriteTo(XmlWriteOptions, OutStream)	Serializes and saves the current node to the given variable.
WriteTo(var Text)	Serializes and saves the current node to the given variable.
WriteTo(XmlWriteOptions, var Text)	Serializes and saves the current node to the given variable.

XmlElement.Create Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Creates an XmlElement node.

Syntax

```
XmlElement :=   XmlElement.Create(Name: String)
```

Parameters

Name

Type: String

The fully qualified name of the element to create.

Return Value

XmlElement Type: XmlElement The created XmlElement node.

XmlElement.Create Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Creates an XmlElement node.

Syntax

```
XmlElement :=   XmlElement.Create(LocalName: String, NamespaceUri: String)
```

Parameters

LocalName

Type: String

The local name of the element to create.

NamespaceUri

Type: String

The namespace URI of the element to create.

Return Value

XmlElement Type: XmlElement The created XmlElement node.

XmlElement.Create Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Creates an XmlElement node.

Syntax

```
XmlElement :=   XmlElement.Create(LocalName: String, NamespaceUri: String, Content: Any,...)
```

Parameters

LocalName

Type: String

The local name of the element to create.

NamespaceUri

Type: String

The namespace URI of the element to create.

Content

Type: Any

The content to add to the element to create.

Return Value

XmlElement Type: XmlElement The created XmlElement node.

XmlElement.Add Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Adds the specified content as a child of this element.

Syntax

```
[Ok := ]  XmlElement.Add(Content: Any,...)
```

Parameters

XmlElement Type: XmlElement An instance of the XmlElement data type.

Content
Type: Any
The content to be added as a child of this element.

Return Value

Ok Type: Boolean **true** if the operation was successful; otherwise **false**. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

See Also

Getting Started with AL
Developing Extensions

XmlElement.AddAfterSelf Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Adds the specified content immediately after this node.

Syntax

```
[Ok := ]  XmlElement.AddAfterSelf(Content: Any,...)
```

Parameters

XmlElement Type: XmlElement An instance of the XmlElement data type.

Content
Type: Any
The content to add after this node.

Return Value

Ok Type: Boolean **true** if the operation was successful; otherwise **false**. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

XmlElement.AddBeforeSelf Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Adds the specified content immediately before this node.

Syntax

```
[Ok := ]  XmlElement.AddBeforeSelf(Content: Any,...)
```

Parameters

XmlElement Type: XmlElement An instance of the XmlElement data type.

Content
Type: Any
The content to add before this node.

Return Value

Ok Type: Boolean **true** if the operation was successful; otherwise **false**. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

XmlElement.AddFirst Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Adds the specified content at the start of the child list of this element.

Syntax

```
[Ok := ]  XmlElement.AddFirst(Content: Any,...)
```

Parameters

XmlElement Type: XmlElement An instance of the XmlElement data type.

Content
Type: Any
The content to be added as a child of this element.

Return Value

Ok Type: Boolean **true** if the operation was successful; otherwise **false**. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

See Also

XmlElement Data Type

XmlElement.AsXmlNode Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Converts the node to an XmlNode.

Syntax

```
XmlNode :=   XmlElement.AsXmlNode()
```

Parameters

XmlElement Type: XmlElement An instance of the XmlElement data type.

Return Value

XmlNode Type: XmlNode An XmlNode value that references the current XmlElement.

See Also

XmlElement Data Type
Getting Started with AL
Developing Extensions

XmlElement.Attributes Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Gets a collection of the attributes of this element.

Syntax

```
Attributes :=   XmlElement.Attributes()
```

Parameters

XmlElement Type: XmlElement An instance of the XmlElement data type.

Return Value

Attributes Type: XmlAttributeCollection The attributes of this element.

See Also

XmlElement Data Type

XmlElement.GetChildElements Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Gets a list containing the child elements for this element, in document order.

Syntax

```
ChildElements :=   XmlElement.GetChildElements()
```

Parameters

XmlElement Type: XmlElement An instance of the XmlElement data type.

Return Value

ChildElements Type: XmlNodeList A list containing the child elements for this element, in document order.

See Also

XmlElement Data Type

XmlElement.GetChildElements Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Gets a list containing the child elements for this element, in document order.

Syntax

```
ChildElements :=   XmlElement.GetChildElements(Name: String)
```

Parameters

XmlElement Type: XmlElement An instance of the XmlElement data type.

Name
Type: String
The fully qualified name of the elements to retrieve.

Return Value

ChildElements Type: XmlNodeList A list containing the child elements for this element, in document order.

XmlElement.GetChildElements Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Gets a list containing the child elements for this element, in document order.

Syntax

```
ChildElements :=   XmlElement.GetChildElements(LocalName: String, NamespaceUri: String)
```

Parameters

XmlElement Type: XmlElement An instance of the XmlElement data type.

LocalName
Type: String
The local name of the elements to retrieve.

NamespaceUri
Type: String
The namespace URI of the elements to retrieve.

Return Value

ChildElements Type: XmlNodeList A list containing the child elements for this element, in document order.

XmlElement.GetNamespaceOfPrefix Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Gets the namespace associated with a particular prefix for this element.

Syntax

```
[Ok := ]  XmlElement.GetNamespaceOfPrefix(Prefix: String, var Result: Text)
```

Parameters

XmlElement Type: XmlElement An instance of the XmlElement data type.

Prefix
Type: String
A string that contains the namespace prefix to look up.

Result
Type: Text
The namespace URI associated with the given prefix for this element.

Return Value

Ok Type: Boolean **true** if the operation was successful; otherwise **false**. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

See Also

XmlElement Data Type

Developing Extensions

XmlElement.GetParent Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Gets the parent XmlElement of this node.

Syntax

```
[Ok := ]  XmlElement.GetParent(var Parent: XmlElement)
```

Parameters

XmlElement Type: XmlElement An instance of the XmlElement data type.

Parent
Type: XmlElement
The parent XmlElement of this node.

Return Value

Ok Type: Boolean **true** if the operation was successful; otherwise **false**. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

See Also

XmlElement.GetPrefixOfNamespace Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Gets the prefix associated with a namespace URI for this element.

Syntax

```
[Ok := ]  XmlElement.GetPrefixOfNamespace(Namespace: String, var Result: Text)
```

Parameters

XmlElement Type: XmlElement An instance of the XmlElement data type.

Namespace
Type: String
A namespace URI to look up.

Result
Type: Text
A string that contains the namespace prefix.

Return Value

Ok Type: Boolean **true** if the operation was successful; otherwise **false**. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

See Also

Developing Extensions

XmlElement.HasAttributes Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Gets a boolean value indicating whether this element has at least one attribute.

Syntax

```
Value :=   XmlElement.HasAttributes()
```

NOTE

This method can be invoked using property access syntax.

Parameters

XmlElement Type: XmlElement An instance of the XmlElement data type.

Return Value

Value Type: Boolean **true** if the current node has at least one attribute, otherwise **false**.

See Also

XmlElement Data Type
Getting Started with AL
Developing Extensions

XmlElement.HasElements Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Gets a value indicating whether this element has at least one child element.

Syntax

```
Value :=   XmlElement.HasElements()
```

NOTE

This method can be invoked using property access syntax.

Parameters

XmlElement Type: XmlElement An instance of the XmlElement data type.

Return Value

Value Type: Boolean **true** if this element has at least one child element, otherwise **false**.

See Also

XmlElement Data Type

Developing Extensions

XmlElement.InnerText Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Gets the concatenated values of the node and all its child nodes.

Syntax

```
Value :=   XmlElement.InnerText()
```

NOTE

This method can be invoked using property access syntax.

Parameters

XmlElement Type: XmlElement An instance of the XmlElement data type.

Return Value

Value Type: String The concatenated values of the node and all its child nodes.

See Also

XmlElement Data Type

Developing Extensions

XmlElement.InnerXml Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Gets the markup representing only the child nodes of this node.

Syntax

```
Value :=   XmlElement.InnerXml()
```

NOTE

This method can be invoked using property access syntax.

Parameters

XmlElement Type: XmlElement An instance of the XmlElement data type.

Return Value

Value Type: String The markup representing only the child nodes of this node.

See Also

Developing Extensions

XmlElement.IsEmpty Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Gets a value indicating whether this element contains no content.

Syntax

```
Value :=   XmlElement.IsEmpty()
```

NOTE

This method can be invoked using property access syntax.

Parameters

XmlElement Type: XmlElement An instance of the XmlElement data type.

Return Value

Value Type: Boolean **true** if this element does not have content, otherwise **false**.

See Also

XmlElement Data Type

XmlElement.LocalName Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Gets the local name of this element.

Syntax

```
Value :=   XmlElement.LocalName()
```

NOTE

This method can be invoked using property access syntax.

Parameters

XmlElement Type: XmlElement An instance of the XmlElement data type.

Return Value

Value Type: String The local name of this element.

See Also

XmlElement Data Type
Getting Started with AL

XmlElement.Name Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Gets the fully qualified name of this element.

Syntax

```
Value :=   XmlElement.Name()
```

NOTE

This method can be invoked using property access syntax.

Parameters

XmlElement Type: XmlElement An instance of the XmlElement data type.

Return Value

Value Type: String The fully qualified name of this element.

See Also

XmlElement Data Type
Getting Started with AL

XmlElement.NamespaceUri Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Gets the namespace URI of this element.

Syntax

```
Value :=   XmlElement.NamespaceUri()
```

NOTE

This method can be invoked using property access syntax.

Parameters

XmlElement Type: XmlElement An instance of the XmlElement data type.

Return Value

Value Type: String The namespace URI of this element.

See Also

XmlElement.Remove Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Removes this node from its parent element.

Syntax

```
[Ok := ]  XmlElement.Remove()
```

Parameters

XmlElement Type: XmlElement An instance of the XmlElement data type.

Return Value

Ok Type: Boolean **true** if the operation was successful; otherwise **false**. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

See Also

XmlElement.RemoveAllAttributes Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Removes the attributes of this element.

Syntax

```
XmlElement.RemoveAllAttributes()
```

Parameters

XmlElement Type: XmlElement An instance of the XmlElement data type.

See Also

XmlElement Data Type
Getting Started with AL
Developing Extensions

XmlElement.RemoveAttribute Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Removes the specified attribute from this element.

Syntax

```
XmlElement.RemoveAttribute(Name: String)
```

Parameters

XmlElement Type: XmlElement An instance of the XmlElement data type.

Name

Type: String

The fully qualified name of the attribute to remove.

See Also

XmlElement Data Type
Getting Started with AL
Developing Extensions

XmlElement.RemoveAttribute Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Removes the specified attribute from this element.

Syntax

```
XmlElement.RemoveAttribute(LocalName: String, NamespaceUri: String)
```

Parameters

XmlElement Type: XmlElement An instance of the XmlElement data type.

LocalName
Type: String
The local name of the attribute to remove.

NamespaceUri
Type: String
The namespace URI of the attribute to remove.

See Also

XmlElement Data Type
Getting Started with AL
Developing Extensions

XmlElement.RemoveAttribute Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Removes the specified attribute from this element.

Syntax

```
XmlElement.RemoveAttribute(Attribute: XmlAttribute)
```

Parameters

XmlElement Type: XmlElement An instance of the XmlElement data type.

Attribute
Type: XmlAttribute
The XmlAttribute to remove.

See Also

XmlElement Data Type
Getting Started with AL
Developing Extensions

XmlElement.RemoveNodes Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Removes the child nodes from this element.

Syntax

```
XmlElement.RemoveNodes()
```

Parameters

XmlElement Type: XmlElement An instance of the XmlElement data type.

See Also

XmlElement Data Type
Getting Started with AL
Developing Extensions

XmlElement.ReplaceNodes Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Replaces the children nodes of this element with the specified content.

Syntax

```
[Ok := ]  XmlElement.ReplaceNodes(Content: Any,...)
```

Parameters

XmlElement Type: XmlElement An instance of the XmlElement data type.

Content
Type: Any
The content that replaces the children nodes.

Return Value

Ok Type: Boolean **true** if the operation was successful; otherwise **false**. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

See Also

XmlElement Data Type
Getting Started with AL
Developing Extensions

XmlElement.ReplaceWith Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Replaces this node with the specified content.

Syntax

```
[Ok := ]  XmlElement.ReplaceWith(Node: Any,...)
```

Parameters

XmlElement Type: XmlElement An instance of the XmlElement data type.

Node
Type: Any
The content with which to replace the current node.

Return Value

Ok Type: Boolean **true** if the operation was successful; otherwise **false**. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

See Also

XmlElement Data Type

Developing Extensions

XmlElement.SelectNodes Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Selects a list of nodes matching the XPath expression.

Syntax

```
[Ok := ]  XmlElement.SelectNodes(XPath: String, var NodeList: XmlNodeList)
```

Parameters

XmlElement Type: XmlElement An instance of the XmlElement data type.

XPath
Type: String
The XPath expression.

NodeList
Type: XmlNodeList
An XmlNodeList containing a collection of nodes matching the XPath expression.

Return Value

Ok Type: Boolean **true** if the operation was successful; otherwise **false**. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

See Also

XmlElement Data Type
Getting Started with AL
Developing Extensions

XmlElement.SelectNodes Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Selects a list of nodes matching the XPath expression.

Syntax

```
[Ok := ]  XmlElement.SelectNodes(XPath: String, NamespaceManager: XmlNamespaceManager, var NodeList:
XmlNodeList)
```

Parameters

XmlElement Type: XmlElement An instance of the XmlElement data type.

XPath
Type: String
The XPath expression.

NamespaceManager
Type: XmlNamespaceManager
An XmlNamespaceManager to use for resolving namespaces for prefixes in the XPath expression.

NodeList
Type: XmlNodeList
An XmlNodeList containing a collection of nodes matching the XPath expression.

Return Value

Ok Type: Boolean **true** if the operation was successful; otherwise **false**. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

See Also

XmlElement Data Type

Developing Extensions

XmlElement.SelectSingleNode Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Selects the first XmlNode that matches the XPath expression.

Syntax

```
[Ok := ]  XmlElement.SelectSingleNode(XPath: String, var Node: XmlNode)
```

Parameters

XmlElement Type: XmlElement An instance of the XmlElement data type.

XPath
Type: String
The XPath expression.

Node
Type: XmlNode
The first XmlNode that matches the XPath query.

Return Value

Ok Type: Boolean **true** if the operation was successful; otherwise **false**. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

See Also

XmlElement.SelectSingleNode Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Selects the first XmlNode that matches the XPath expression.

Syntax

```
[Ok := ]  XmlElement.SelectSingleNode(XPath: String, NamespaceManager: XmlNamespaceManager, var Node:
XmlNode)
```

Parameters

XmlElement Type: XmlElement An instance of the XmlElement data type.

XPath
Type: String
The XPath expression.

NamespaceManager
Type: XmlNamespaceManager
An XmlNamespaceManager to use for resolving namespaces for prefixes in the XPath expression.

Node
Type: XmlNode
The first XmlNode that matches the XPath query.

Return Value

Ok Type: Boolean **true** if the operation was successful; otherwise **false**. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

XmlElement.SetAttribute Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Sets the value of the specified attribute or create it if is not part of the element's attribute collection.

Syntax

```
XmlElement.SetAttribute(Name: String, Value: String)
```

Parameters

XmlElement Type: XmlElement An instance of the XmlElement data type.

Name

Type: String

The fully qualified name of the attribute to set.

Value

Type: String

The value to set for the attribute.

See Also

XmlElement Data Type

XmlElement.SetAttribute Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Sets the value of the specified attribute or create it if is not part of the element's attribute collection.

Syntax

```
XmlElement.SetAttribute(LocalName: String, NamespaceUri: String, Value: String)
```

Parameters

XmlElement Type: XmlElement An instance of the XmlElement data type.

LocalName
Type: String
The local name of the attribute to set.

NamespaceUri
Type: String
The namespace URI of the attribute to set.

Value
Type: String
The value to set for the attribute.

XmlElement.WriteTo Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Serializes and saves the current node to the given variable.

Syntax

```
[Ok := ]  XmlElement.WriteTo(OutStream: OutStream)
```

Parameters

XmlElement Type: XmlElement An instance of the XmlElement data type.

OutStream
Type: OutStream
The OutStream to which you want to save the serialized representation of the node.

Return Value

Ok Type: Boolean **true** if the operation was successful; otherwise **false**. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

XmlElement.WriteTo Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Serializes and saves the current node to the given variable.

Syntax

```
[Ok := ]  XmlElement.WriteTo(WriteOptions: XmlWriteOptions, OutStream: OutStream)
```

Parameters

XmlElement Type: XmlElement An instance of the XmlElement data type.

WriteOptions
Type: XmlWriteOptions
Specifies options for customizing how the node is serialized.

OutStream
Type: OutStream
The OutStream to which you want to save the serialized representation of the node.

Return Value

Ok Type: Boolean **true** if the operation was successful; otherwise **false**. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

See Also

XmlNamespaceManager Data Type

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Represents a namespace manager that can be used to resolve, add and remove namespaces to a collection. It also provides scope management for these namespaces.

The following methods are available on instances of the XmlNamespaceManager data type.

METHOD NAME	DESCRIPTION
AddNamespace(String, String)	Adds the given namespace to the collection.
HasNamespace(String)	Gets a value indicating whether the supplied prefix has a namespace defined for the current scope.
LookupNamespace(String, var Text)	Gets the namespace URI for the specified prefix.
LookupPrefix(String, var Text)	Finds the prefix declared for the given namespace URI.
NameTable([XmlNameTable])	Gets or sets the XmlNameTable associated with this object.
PopScope()	Pops a namespace scope off the stack.
PushScope()	Pushes a namespace scope onto the stack.
RemoveNamespace(String, String)	Removes the given namespace for the given prefix.

XmlNamespaceManager.AddNamespace Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Adds the given namespace to the collection.

Syntax

```
XmlNamespaceManager.AddNamespace(Prefix: String, Uri: String)
```

Parameters

XmlNamespaceManager Type: XmlNamespaceManager An instance of the XmlNamespaceManager data type.

Prefix

Type: String

The prefix to associate with the namespace being added. Use an empty string to add a default namespace.

Uri

Type: String

The namespace to add.

Developing Extensions

XmlNamespaceManager.HasNamespace Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Gets a value indicating whether the supplied prefix has a namespace defined for the current scope.

Syntax

```
HasNamespace :=   XmlNamespaceManager.HasNamespace(Prefix: String)
```

Parameters

XmlNamespaceManager Type: XmlNamespaceManager An instance of the XmlNamespaceManager data type.

Prefix
Type: String
The prefix of the namespace you want to find.

Return Value

HasNamespace Type: Boolean **true** if the supplied prefix has a namespace defined for the current scope, otherwise **false**.

See Also

XmlNamespaceManager Data Type
Getting Started with AL
Developing Extensions

XmlNamespaceManager.LookupNamespace Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Gets the namespace URI for the specified prefix.

Syntax

```
[Ok := ]  XmlNamespaceManager.LookupNamespace(Prefix: String, var Result: Text)
```

Parameters

XmlNamespaceManager Type: XmlNamespaceManager An instance of the XmlNamespaceManager data type.

Prefix
Type: String
The prefix whose namespace URI you want to resolve. To match the default namespace, pass an empty string.

Result
Type: Text
The namespace URI for prefix.

Return Value

Ok Type: Boolean **true** if the operation was successful; otherwise **false**. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

See Also

XmlNamespaceManager Data Type
Getting Started with AL
Developing Extensions

XmlNamespaceManager.LookupPrefix Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Finds the prefix declared for the given namespace URI.

Syntax

```
[Ok := ]  XmlNamespaceManager.LookupPrefix(Uri: String, var Result: Text)
```

Parameters

XmlNamespaceManager Type: XmlNamespaceManager An instance of the XmlNamespaceManager data type.

Uri

Type: String

The namespace to resolve for the prefix.

Result

Type: Text

The matching prefix. If there is no mapped prefix, the method returns an empty string.

Return Value

Ok Type: Boolean **true** if the operation was successful; otherwise **false**. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

XmlNamespaceManager.NameTable Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Gets or sets the XmlNameTable associated with this object.

Syntax

```
[Value := ]  XmlNamespaceManager.NameTable([NewValue: XmlNameTable])
```

NOTE

This method can be invoked using property access syntax.

Parameters

XmlNamespaceManager Type: XmlNamespaceManager An instance of the XmlNamespaceManager data type.

NewValue

Type: XmlNameTable

The new XmlNameTable to associate with this object. Setting the NameTable will reset the state of the XmlNamespaceManager.

Return Value

Value Type: XmlNameTable The XmlNameTable associated with this object.

XmlNamespaceManager.RemoveNamespace Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Removes the given namespace for the given prefix.

Syntax

```
XmlNamespaceManager.RemoveNamespace(Prefix: String, Uri: String)
```

Parameters

XmlNamespaceManager Type: XmlNamespaceManager An instance of the XmlNamespaceManager data type.

Prefix

Type: String

The prefix for the namespace.

Uri

Type: String

The namespace to remove for the given prefix. The namespace removed is from the current namespace scope. Namespaces outside the current scope are ignored.

Developing Extensions

XmlNameTable.Add Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Atomizes the specified string and adds it to the XmlNameTable.

Syntax

```
[AddedKey := ]  XmlNameTable.Add(Key: String)
```

Parameters

XmlNameTable Type: XmlNameTable An instance of the XmlNameTable data type.

Key
Type: String
The string to add.

Return Value

AddedKey Type: String The new atomized string or the existing one if it already exists

See Also

XmlNameTable Data Type
Getting Started with AL
Developing Extensions

XmlNameTable.Get Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Gets the atomized string with the specified value.

Syntax

```
[Ok := ]  XmlNameTable.Get(Key: String, var Result: Text)
```

Parameters

XmlNameTable Type: XmlNameTable An instance of the XmlNameTable data type.

Key
Type: String
The string to find.

Result
Type: Text
The atomized string object if the string has been atomized.

Return Value

Ok Type: Boolean **true** if the key exists, otherwise **false**. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

XmlNode Data Type

2/17/2021 • 2 minutes to read • Edit Online

> **Version**: *Available from runtime version 1.0.*

Represents a XML node which can either be for instance an XML attribute, an XML element or a XML document.

The following methods are available on instances of the XmlNode data type.

METHOD NAME	DESCRIPTION
AddAfterSelf(Any,...)	Adds the specified content immediately after this node.
AddBeforeSelf(Any,...)	Adds the specified content immediately before this node.
AsXmlAttribute()	Converts the node to an XmlAttribute node. The operation will fail if the node is not an XmlAttribute.
AsXmlCData()	Converts the node to an XmlCData node. The operation will fail if the node is not an XmlCData.
AsXmlComment()	Converts the node to an XmlComment node. The operation will fail if the node is not an XmlComment.
AsXmlDeclaration()	Converts the node to an XmlDeclaration node. The operation will fail if the node is not an XmlDeclaration.
AsXmlDocument()	Converts the node to an XmlDocument node. The operation will fail if the node is not an XmlDocument.
AsXmlDocumentType()	Converts the node to an XmlDocumentType node. The operation will fail if the node is not an XmlDocumentType.
AsXmlElement()	Converts the node to an XmlElement node. The operation will fail if the node is not an XmlElement.
AsXmlProcessingInstruction()	Converts the node to an XmlProcessingInstruction node. The operation will fail if the node is not an XmlProcessingInstruction.
AsXmlText()	Converts the node to an XmlText node. The operation will fail if the node is not an XmlText.
GetDocument(var XmlDocument)	Gets the XmlDocument for this node.
GetParent(var XmlElement)	Gets the parent XmlElement of this node.
IsXmlAttribute()	Gets a value indicating whether this node is an XmlAttribute.
IsXmlCData()	Gets a value indicating whether this node is an XmlCData.
IsXmlComment()	Gets a value indicating whether this node is an XmlComment.

METHOD NAME	DESCRIPTION
IsXmlDeclaration()	Gets a value indicating whether this node is an XmlDeclaration.
IsXmlDocument()	Gets a value indicating whether this node is an XmlDocument.
IsXmlDocumentType()	Gets a value indicating whether this node is an XmlDocumentType.
IsXmlElement()	Gets a value indicating whether this node is an XmlElement.
IsXmlProcessingInstruction()	Gets a value indicating whether this node is an XmlProcessingInstruction.
IsXmlText()	Gets a value indicating whether this node is an XmlText.
Remove()	Removes this node from its parent element.
ReplaceWith(Any,...)	Replaces this node with the specified content.
SelectNodes(String, var XmlNodeList)	Selects a list of nodes matching the XPath expression.
SelectNodes(String, XmlNamespaceManager, var XmlNodeList)	Selects a list of nodes matching the XPath expression.
SelectSingleNode(String, var XmlNode)	Selects the first XmlNode that matches the XPath expression.
SelectSingleNode(String, XmlNamespaceManager, var XmlNode)	Selects the first XmlNode that matches the XPath expression.
WriteTo(OutStream)	Serializes and saves the current node to the given variable.
WriteTo(XmlWriteOptions, OutStream)	Serializes and saves the current node to the given variable.
WriteTo(var Text)	Serializes and saves the current node to the given variable.
WriteTo(XmlWriteOptions, var Text)	Serializes and saves the current node to the given variable.

XmlNode.AddAfterSelf Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Adds the specified content immediately after this node.

Syntax

```
[Ok := ]  XmlNode.AddAfterSelf(Content: Any,...)
```

Parameters

XmlNode Type: XmlNode An instance of the XmlNode data type.

Content
Type: Any
The content to add after this node.

Return Value

Ok Type: Boolean **true** if the operation was successful; otherwise **false**. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

See Also

XmlNode.AddBeforeSelf Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Adds the specified content immediately before this node.

Syntax

```
[Ok := ]  XmlNode.AddBeforeSelf(Content: Any,...)
```

Parameters

XmlNode Type: XmlNode An instance of the XmlNode data type.

Content
Type: Any
The content to add before this node.

Return Value

Ok Type: Boolean **true** if the operation was successful; otherwise **false**. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

XmlNode.AsXmlAttribute Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Converts the node to an XmlAttribute node. The operation will fail if the node is not an XmlAttribute.

Syntax

```
XmlAttribute :=   XmlNode.AsXmlAttribute()
```

Parameters

XmlNode Type: XmlNode An instance of the XmlNode data type.

Return Value

XmlAttribute Type: XmlAttribute An XmlAttribute value that references the current XmlNode.

See Also

XmlNode Data Type
Getting Started with AL
Developing Extensions

XmlNode.AsXmlCData Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Converts the node to an XmlCData node. The operation will fail if the node is not an XmlCData.

Syntax

```
XmlCData :=   XmlNode.AsXmlCData()
```

Parameters

XmlNode Type: XmlNode An instance of the XmlNode data type.

Return Value

XmlCData Type: XmlCData An XmlCData value that references the current XmlNode.

See Also

XmlNode Data Type
Getting Started with AL

XmlNode.AsXmlComment Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Converts the node to an XmlComment node. The operation will fail if the node is not an XmlComment.

Syntax

```
XmlComment :=   XmlNode.AsXmlComment()
```

Parameters

XmlNode Type: XmlNode An instance of the XmlNode data type.

Return Value

XmlComment Type: XmlComment An XmlComment value that references the current XmlNode.

See Also

XmlNode Data Type
Getting Started with AL
Developing Extensions

XmlNode.AsXmlDeclaration Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Converts the node to an XmlDeclaration node. The operation will fail if the node is not an XmlDeclaration.

Syntax

```
XmlDeclaration :=   XmlNode.AsXmlDeclaration()
```

Parameters

XmlNode Type: XmlNode An instance of the XmlNode data type.

Return Value

XmlDeclaration Type: XmlDeclaration An XmlDeclaration value that references the current XmlNode.

See Also

XmlNode Data Type

XmlNode.AsXmlDocument Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Converts the node to an XmlDocument node. The operation will fail if the node is not an XmlDocument.

Syntax

```
XmlDocument :=   XmlNode.AsXmlDocument()
```

Parameters

XmlNode Type: XmlNode An instance of the XmlNode data type.

Return Value

XmlDocument Type: XmlDocument An XmlDocument value that references the current XmlNode.

See Also

XmlNode Data Type

XmlNode.AsXmlDocumentType Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Converts the node to an XmlDocumentType node. The operation will fail if the node is not an XmlDocumentType.

Syntax

```
XmlDocumentType :=   XmlNode.AsXmlDocumentType()
```

Parameters

XmlNode Type: XmlNode An instance of the XmlNode data type.

Return Value

XmlDocumentType Type: XmlDocumentType An XmlDocumentType value that references the current XmlNode.

See Also

XmlNode.AsXmlElement Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Converts the node to an XmlElement node. The operation will fail if the node is not an XmlElement.

Syntax

```
XmlElement :=   XmlNode.AsXmlElement()
```

Parameters

XmlNode Type: XmlNode An instance of the XmlNode data type.

Return Value

XmlElement Type: XmlElement An XmlElement value that references the current XmlNode.

See Also

XmlNode Data Type

XmlNode.AsXmlProcessingInstruction Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Converts the node to an XmlProcessingInstruction node. The operation will fail if the node is not an XmlProcessingInstruction.

Syntax

```
XmlProcessingInstruction :=   XmlNode.AsXmlProcessingInstruction()
```

Parameters

XmlNode Type: XmlNode An instance of the XmlNode data type.

Return Value

XmlProcessingInstruction Type: XmlProcessingInstruction An XmlProcessingInstruction value that references the current XmlNode.

See Also

XmlNode Data Type

XmlNode.AsXmlText Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Converts the node to an XmlText node. The operation will fail if the node is not an XmlText.

Syntax

```
XmlText :=   XmlNode.AsXmlText()
```

Parameters

XmlNode Type: XmlNode An instance of the XmlNode data type.

Return Value

XmlText Type: XmlText An XmlText value that references the current XmlNode.

XmlNode.GetDocument Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Gets the XmlDocument for this node.

Syntax

```
[Ok := ]  XmlNode.GetDocument(var Document: XmlDocument)
```

Parameters

XmlNode Type: XmlNode An instance of the XmlNode data type.

Document
Type: XmlDocument
The owning XmlDocument of this node.

Return Value

Ok Type: Boolean **true** if the operation was successful; otherwise **false**. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

See Also

XmlNode Data Type

XmlNode.GetParent Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Gets the parent XmlElement of this node.

Syntax

```
[Ok := ]  XmlNode.GetParent(var Parent: XmlElement)
```

Parameters

XmlNode Type: XmlNode An instance of the XmlNode data type.

Parent
Type: XmlElement
The parent XmlElement of this node.

Return Value

Ok Type: Boolean **true** if the operation was successful; otherwise **false**. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

XmlNode.IsXmlAttribute Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Gets a value indicating whether this node is an XmlAttribute.

Syntax

```
Value :=   XmlNode.IsXmlAttribute()
```

NOTE

This method can be invoked using property access syntax.

Parameters

XmlNode Type: XmlNode An instance of the XmlNode data type.

Return Value

Value Type: Boolean **true** if this node is an XmlAttribute node, otherwise **false**.

XmlNode.IsXmlCData Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Gets a value indicating whether this node is an XmlCData.

Syntax

```
Value :=   XmlNode.IsXmlCData()
```

NOTE

This method can be invoked using property access syntax.

Parameters

XmlNode Type: XmlNode An instance of the XmlNode data type.

Return Value

Value Type: Boolean **true** if this node is an XmlCData node, otherwise **false**.

XmlNode.IsXmlComment Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Gets a value indicating whether this node is an XmlComment.

Syntax

```
Value :=   XmlNode.IsXmlComment()
```

NOTE

This method can be invoked using property access syntax.

Parameters

XmlNode Type: XmlNode An instance of the XmlNode data type.

Return Value

Value Type: Boolean **true** if this node is an XmlComment node, otherwise **false**.

XmlNode.Remove Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Removes this node from its parent element.

Syntax

```
[Ok := ]  XmlNode.Remove()
```

Parameters

XmlNode Type: XmlNode An instance of the XmlNode data type.

Return Value

Ok Type: Boolean **true** if the operation was successful; otherwise **false**. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

See Also

Developing Extensions

XmlNode.ReplaceWith Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Replaces this node with the specified content.

Syntax

```
[Ok := ]  XmlNode.ReplaceWith(Node: Any,...)
```

Parameters

XmlNode Type: XmlNode An instance of the XmlNode data type.

Node
Type: Any
The content with which to replace the current node.

Return Value

Ok Type: Boolean **true** if the operation was successful; otherwise **false**. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

XmlNode.SelectNodes Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Selects a list of nodes matching the XPath expression.

Syntax

```
[Ok := ]  XmlNode.SelectNodes(XPath: String, var NodeList: XmlNodeList)
```

Parameters

XmlNode Type: XmlNode An instance of the XmlNode data type.

XPath
Type: String
The XPath expression.
NodeList
Type: XmlNodeList
An XmlNodeList containing a collection of nodes matching the XPath expression.

Return Value

Ok Type: Boolean **true** if the operation was successful; otherwise **false**. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

See Also

XmlNode Data Type

XmlNode.SelectNodes Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Selects a list of nodes matching the XPath expression.

Syntax

```
[Ok := ]  XmlNode.SelectNodes(XPath: String, NamespaceManager: XmlNamespaceManager, var NodeList:
XmlNodeList)
```

Parameters

XmlNode Type: XmlNode An instance of the XmlNode data type.

XPath
Type: String
The XPath expression.

NamespaceManager
Type: XmlNamespaceManager
An XmlNamespaceManager to use for resolving namespaces for prefixes in the XPath expression.

NodeList
Type: XmlNodeList
An XmlNodeList containing a collection of nodes matching the XPath expression.

Return Value

Ok Type: Boolean **true** if the operation was successful; otherwise **false**. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

See Also

XmlNode Data Type

Developing Extensions

XmlNode.SelectSingleNode Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Selects the first XmlNode that matches the XPath expression.

Syntax

```
[Ok := ]  XmlNode.SelectSingleNode(XPath: String, var Node: XmlNode)
```

Parameters

XmlNode Type: XmlNode An instance of the XmlNode data type.

XPath
Type: String
The XPath expression.

Node
Type: XmlNode
The first XmlNode that matches the XPath query.

Return Value

Ok Type: Boolean **true** if the operation was successful; otherwise **false**. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

XmlNode.WriteTo Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Serializes and saves the current node to the given variable.

Syntax

```
[Ok := ]  XmlNode.WriteTo(OutStream: OutStream)
```

Parameters

XmlNode Type: XmlNode An instance of the XmlNode data type.

OutStream
Type: OutStream
The OutStream to which you want to save the serialized representation of the node.

Return Value

Ok Type: Boolean **true** if the operation was successful; otherwise **false**. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

See Also

XmlNode.WriteTo Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Serializes and saves the current node to the given variable.

Syntax

```
[Ok := ]  XmlNode.WriteTo(WriteOptions: XmlWriteOptions, OutStream: OutStream)
```

Parameters

XmlNode Type: XmlNode An instance of the XmlNode data type.

WriteOptions
Type: XmlWriteOptions
Specifies options for customizing how the node is serialized.

OutStream
Type: OutStream
The OutStream to which you want to save the serialized representation of the node.

Return Value

Ok Type: Boolean **true** if the operation was successful; otherwise **false**. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

XmlNodeList Data Type

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Represents a collection of XML nodes.

The following methods are available on instances of the XmlNodeList data type.

METHOD NAME	DESCRIPTION
Count()	Gets the number of nodes in the XmlNodeList.
Get(Integer, var XmlNode)	Gets a node at the given index.

See Also

Getting Started with AL
Developing Extensions

XmlNodeList.Count Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Gets the number of nodes in the XmlNodeList.

Syntax

```
Count :=   XmlNodeList.Count()
```

NOTE

This method can be invoked using property access syntax.

Parameters

XmlNodeList Type: XmlNodeList An instance of the XmlNodeList data type.

Return Value

Count Type: Integer The number of nodes in the XmlNodeList.

See Also

Getting Started with AL
Developing Extensions

XmlNodeList.Get Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Gets a node at the given index.

Syntax

```
[Ok := ]  XmlNodeList.Get(Index: Integer, var Node: XmlNode)
```

Parameters

XmlNodeList Type: XmlNodeList An instance of the XmlNodeList data type.

Index
Type: Integer
The one-based index into the list of nodes.

Node
Type: XmlNode
The XmlNode with the specified index in the list.

Return Value

Ok Type: Boolean **true** if a node is found at the given index, otherwise **false**. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

Xmlport Data Type

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

XmlPorts are used to export or import data between an external source and a Microsoft Dynamics Business Central database.

The following methods are available on the Xmlport data type.

METHOD NAME	DESCRIPTION
Export(Integer, var OutStream [, var Record])	Creates an XML data stream (XML document) and sends it to a chosen destination.
Import(Integer, var InStream [, var Record])	Reads and parses an incoming XML data stream (XML document).
Run(Integer [, Boolean] [, Boolean] [, var Record])	Loads and executes the XmlPort that you specify.

The following methods are available on instances of the Xmlport data type.

METHOD NAME	DESCRIPTION
Break()	Exits from a loop or a trigger in a data item trigger of a report or XmlPort.
BreakUnbound()	Exits from a loop on records in an XmlPort trigger.
CurrentPath()	Returns the CurrentPath for a given node, used when exporting an XmlPort.
Export()	Creates an XML data stream (XML document) and sends it to a chosen destination.
FieldDelimiter([String])	Gets and sets the FiledDelimiter used when running, importing or exporting the XmlPort.
FieldSeparator([String])	Gets and sets the FieldSeparator used when running, importing or exporting the XmlPort.
Filename([String])	Gets the current value of the FileName Property of an XmlPort and sets this property to a new value.
Import()	Reads and parses an incoming XML data stream (XML document).
ImportFile([Boolean])	Gets or sets the ImportFile property.
Quit()	Aborts the processing of a report or XmlPort.

METHOD NAME	DESCRIPTION
RecordSeparator([String])	Gets and sets the RecordSeparator used when running, importing or exporting the XmlPort.
Run()	Loads and executes the XmlPort that you specify.
SetDestination(var OutStream)	Sets the destination OutStream of the XmlPort.
SetSource(var InStream)	Sets the source InStream of the XmlPort.
SetTableView(var Record)	Applies the table view on the current record as the table view for the page, report, or XmlPort.
Skip()	Skips the current iteration of the current report or XmlPort.
TableSeparator([String])	Gets and sets the TableSeparator used when running, importing or exporting the XmlPort.
TextEncoding([TextEncoding])	Gets and sets the TextEncoding used when running, importing or exporting the XmlPort.

XMLport Overview

Xmlport.Export Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Creates an XML data stream (XML document) and sends it to a chosen destination.

Syntax

```
[Ok := ]  Xmlport.Export(Number: Integer, var OutStream: OutStream [, var Record: Record])
```

Parameters

Number

Type: Integer

The ID of the XmlPort that you want to run.

OutStream

Type: OutStream

Where the XmlPort object will write the XML data stream.

Record

Type: Record

The record to use in the XmlPort. Any filters attached to the record will be used. This parameter is optional. If this parameter is omitted, all records in the table are exported.

Return Value

Ok Type: Boolean **true** if the operation was successful; otherwise **false**. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

See Also

Xmlport Data Type
Getting Started with AL
Developing Extensions

Xmlport.Import Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Reads and parses an incoming XML data stream (XML document).

Syntax

```
[Ok := ]  Xmlport.Import(Number: Integer, var InStream: InStream [, var Record: Record])
```

Parameters

Number

Type: Integer

The ID of the XmlPort that you want to run. If the XmlPort that you specify does not exist, a run-time error occurs.

InStream

Type: InStream

The source from which the import XmlPort object will read the XML data stream.

Record

Type: Record

The record to use in the XmlPort. Any filters that are attached to the record will be used. This parameter is optional. If this parameter is omitted, all records in the table are imported. For example, you can use this parameter to change the values of properties such as FieldSeparator or TextEncoding, depending on each record that is imported.

Return Value

Ok Type: Boolean **true** if the operation was successful; otherwise **false**. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

See Also

Xmlport Data Type

Developing Extensions

Xmlport.Run Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Loads and executes the XmlPort that you specify.

Syntax

```
Xmlport.Run(Number: Integer [, RequestWindow: Boolean] [, Import: Boolean] [, var Record: Record])
```

Parameters

Number

Type: Integer

Specifies the XmlPort to run.

RequestWindow

Type: Boolean

Specify true to show request page; specify false to run the report and skip the request page. This parameter overrides the setting of the UseRequestPage Property of the XMLPort. If you do not provide a value for the RequestWindow parameter, then the setting of the UseRequestPage property is used. > Web client does not support request pages with XmlPorts. If the XMLPort will appear in the web client, you should set the value to false; otherwise, you will get an error at runtime.

Import

Type: Boolean

Specifies whether the XMLPort imports or exports data. Specify true to run the XmlPort and import data; specify false to export data.This parameter is most relevant when the XmlPort does not use a request page and the Direction Property of the XmlPort is set to Both. In this instance, you use the parameter to specify the direction of the data. If the XmlPort uses a request page, then a direction option appears on the request page that enables the user can choose to import or export data. The Import parameter specifies the default value in the direction on option on the request page. If the Direction property is set to Import or Export, then you must set this parameter to match the direction that is set by the Direction property; otherwise, you will get an error at runtime. The default is true.

Record

Type: Record

The record to use in the XmlPort. The system will use any filters that are attached to the specified record.

Xmlport.Break Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Exits from a loop or a trigger in a data item trigger of a report or XmlPort.

Syntax

```
Xmlport.Break()
```

Parameters

Xmlport Type: Xmlport An instance of the Xmlport data type.

See Also

Xmlport Data Type
Getting Started with AL
Developing Extensions

Xmlport.BreakUnbound Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Exits from a loop on records in an XmlPort trigger.

Syntax

```
Xmlport.BreakUnbound()
```

Parameters

Xmlport Type: Xmlport An instance of the Xmlport data type.

See Also

Xmlport Data Type
Getting Started with AL
Developing Extensions

Xmlport.CurrentPath Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Returns the CurrentPath for a given node, used when exporting an XmlPort.

Syntax

```
Path :=   Xmlport.CurrentPath()
```

Parameters

Xmlport Type: Xmlport An instance of the Xmlport data type.

Return Value

Path Type: String The current path for a given node.

Xmlport.Export Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Creates an XML data stream (XML document) and sends it to a chosen destination.

Syntax

```
[Ok := ]  Xmlport.Export()
```

Parameters

Xmlport Type: Xmlport An instance of the Xmlport data type.

Return Value

Ok Type: Boolean **true** if the serialization of the XML document was successful, otherwise **false**. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

Xmlport.FieldDelimiter Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Gets and sets the FiledDelimiter used when running, importing or exporting the XmlPort.

Syntax

```
[Delimiter := ]  Xmlport.FieldDelimiter([Delimiter: String])
```

NOTE

This method can be invoked using property access syntax.

Parameters

Xmlport Type: Xmlport An instance of the Xmlport data type.

Delimiter

Type: String

The new value of the FieldDelimiter.

Return Value

Delimiter Type: String The FieldDelimiter used when running, importing or exporting the XmlPort.

Xmlport.FieldSeparator Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Gets and sets the FieldSeparator used when running, importing or exporting the XmlPort.

Syntax

```
[Separator := ]  Xmlport.FieldSeparator([Separator: String])
```

> **NOTE**
> This method can be invoked using property access syntax.

Parameters

Xmlport Type: Xmlport An instance of the Xmlport data type.

Separator
Type: String
The new value of the FieldSeparator.

Return Value

Separator Type: String The FieldSeparator used when running, importing or exporting the XmlPort.

See Also

FieldSeparator Property
Xmlport Data Type

Developing Extensions

Xmlport.Filename Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Gets the current value of the FileName Property of an XmlPort and sets this property to a new value.

Syntax

```
[FileName := ]  Xmlport.Filename([FileName: String])
```

NOTE

This method can be invoked using property access syntax.

Parameters

Xmlport Type: Xmlport An instance of the Xmlport data type.

FileName

Type: String

The new file name.

Return Value

FileName Type: String The current value of the FileName Property of an XmlPort.

See Also

Xmlport Data Type
FileName Property

Developing Extensions

Xmlport.Import Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Reads and parses an incoming XML data stream (XML document).

Syntax

```
[Ok := ]  Xmlport.Import()
```

Parameters

Xmlport Type: Xmlport An instance of the Xmlport data type.

Return Value

Ok Type: Boolean **true** if the import of the XML document was successful, otherwise **false**. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

See Also

Xmlport Data Type
Getting Started with AL
Developing Extensions

Xmlport.ImportFile Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Gets or sets the ImportFile property.

Syntax

```
[ImportFile := ]  Xmlport.ImportFile([ImportFile: Boolean])
```

> **NOTE**
> This method can be invoked using property access syntax.

Parameters

Xmlport Type: Xmlport An instance of the Xmlport data type.

ImportFile
Type: Boolean
The new value of the ImportFile property. If the XmlPort is designed for export only and the new value of this property is **true**, an XmlPortExportDirectionException is thrown. If the XmlPort is designed for import only and the new value of this property **false**, an XmlPortImportDirectionException is thrown.

Return Value

ImportFile Type: Boolean The current value of the ImportFile property.

Xmlport.Quit Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Aborts the processing of a report or XmlPort.

Syntax

```
Xmlport.Quit()
```

Parameters

Xmlport Type: Xmlport An instance of the Xmlport data type.

See Also

Xmlport.RecordSeparator Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Gets and sets the RecordSeparator used when running, importing or exporting the XmlPort.

Syntax

```
[Separator := ]  Xmlport.RecordSeparator([Separator: String])
```

> **NOTE**
> This method can be invoked using property access syntax.

Parameters

Xmlport Type: Xmlport An instance of the Xmlport data type.

Separator
Type: String
The new value of the RecordSeparator.

Return Value

Separator Type: String The RecordSeparator used when running, importing or exporting the XmlPort.

See Also

Xmlport Data Type
RecordSeparator Property

Xmlport.Run Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Loads and executes the XmlPort that you specify.

Syntax

```
Xmlport.Run()
```

Parameters

Xmlport Type: Xmlport An instance of the Xmlport data type.

See Also

Xmlport Data Type

Developing Extensions

Xmlport.SetDestination Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Sets the destination OutStream of the XmlPort.

Syntax

```
Xmlport.SetDestination(var OutStream: OutStream)
```

NOTE

This method can be invoked using property access syntax.

Parameters

Xmlport Type: Xmlport An instance of the Xmlport data type.

OutStream

Type: OutStream

The new destination OutStream of the XmlPort.

Xmlport.SetSource Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Sets the source InStream of the XmlPort.

Syntax

```
Xmlport.SetSource(var InStream: InStream)
```

NOTE

This method can be invoked using property access syntax.

Parameters

Xmlport Type: Xmlport An instance of the Xmlport data type.

InStream

Type: InStream

The new source InStream of the XmlPort.

Xmlport.SetTableView Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Applies the table view on the current record as the table view for the page, report, or XmlPort.

Syntax

```
Xmlport.SetTableView(var Record: Record)
```

Parameters

Xmlport Type: Xmlport An instance of the Xmlport data type.

Record

Type: Record

The record that has a table view that you want to apply to the page or data item.

Xmlport.TableSeparator Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Gets and sets the TableSeparator used when running, importing or exporting the XmlPort.

Syntax

```
[Separator := ]  Xmlport.TableSeparator([Separator: String])
```

NOTE

This method can be invoked using property access syntax.

Parameters

Xmlport Type: Xmlport An instance of the Xmlport data type.

Separator

Type: String

The new value of the TableSeparator.

Return Value

Separator Type: String The TableSeparator used when running, importing or exporting the XmlPort.

Xmlport.TextEncoding Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Gets and sets the TextEncoding used when running, importing or exporting the XmlPort.

Syntax

```
[Encoding := ]  Xmlport.TextEncoding([Encoding: TextEncoding])
```

NOTE

This method can be invoked using property access syntax.

Parameters

Xmlport Type: Xmlport An instance of the Xmlport data type.

Encoding

Type: TextEncoding

The new value of the TextEncoding.

Return Value

Encoding Type: TextEncoding The TextEncoding used when running, importing or exporting the XmlPort.

XmlProcessingInstruction Data Type

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Represents a processing instruction, which XML defines to keep processor-specific information in the text of the document.

The following methods are available on the XmlProcessingInstruction data type.

METHOD NAME	DESCRIPTION
Create(String, String)	Creates an XmlProcessingInstruction node.

The following methods are available on instances of the XmlProcessingInstruction data type.

METHOD NAME	DESCRIPTION
AddAfterSelf(Any,...)	Adds the specified content immediately after this node.
AddBeforeSelf(Any,...)	Adds the specified content immediately before this node.
AsXmlNode()	Converts the node to an XmlNode.
GetData(var Text)	Gets the content of the processing instruction, excluding the target.
GetDocument(var XmlDocument)	Gets the XmlDocument for this node.
GetParent(var XmlElement)	Gets the parent XmlElement of this node.
GetTarget(var Text)	Gets the target of the processing instruction.
Remove()	Removes this node from its parent element.
ReplaceWith(Any,...)	Replaces this node with the specified content.
SelectNodes(String, var XmlNodeList)	Selects a list of nodes matching the XPath expression.
SelectNodes(String, XmlNamespaceManager, var XmlNodeList)	Selects a list of nodes matching the XPath expression.
SelectSingleNode(String, var XmlNode)	Selects the first XmlNode that matches the XPath expression.
SelectSingleNode(String, XmlNamespaceManager, var XmlNode)	Selects the first XmlNode that matches the XPath expression.
SetData(String)	Sets the content of the processing instruction, excluding the target.

METHOD NAME	DESCRIPTION
SetTarget(String)	Sets the target of the processing instruction.
WriteTo(OutStream)	Serializes and saves the current node to the given variable.
WriteTo(XmlWriteOptions, OutStream)	Serializes and saves the current node to the given variable.
WriteTo(var Text)	Serializes and saves the current node to the given variable.
WriteTo(XmlWriteOptions, var Text)	Serializes and saves the current node to the given variable.

XmlProcessingInstruction.Create Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Creates an XmlProcessingInstruction node.

Syntax

```
XmlProcessingInstruction :=   XmlProcessingInstruction.Create(Target: String, Data: String)
```

Parameters

Target

Type: String

The target of the processing instruction.

Data

Type: String

The content of the processing instruction, excluding the target.

Return Value

XmlProcessingInstruction Type: XmlProcessingInstruction The created XmlProcessingInstruction node.

See Also

XmlProcessingInstruction Data Type
Getting Started with AL
Developing Extensions

XmlProcessingInstruction.AddAfterSelf Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Adds the specified content immediately after this node.

Syntax

```
[Ok := ]  XmlProcessingInstruction.AddAfterSelf(Content: Any,...)
```

Parameters

XmlProcessingInstruction Type: XmlProcessingInstruction An instance of the XmlProcessingInstruction data type.

Content
Type: Any
The content to add after this node.

Return Value

Ok Type: Boolean **true** if the operation was successful; otherwise **false**. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

See Also

XmlProcessingInstruction Data Type
Getting Started with AL

XmlProcessingInstruction.AddBeforeSelf Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Adds the specified content immediately before this node.

Syntax

```
[Ok := ]  XmlProcessingInstruction.AddBeforeSelf(Content: Any,...)
```

Parameters

XmlProcessingInstruction Type: XmlProcessingInstruction An instance of the XmlProcessingInstruction data type.

Content
Type: Any
The content to add before this node.

Return Value

Ok Type: Boolean **true** if the operation was successful; otherwise **false**. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

XmlProcessingInstruction.AsXmlNode Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Converts the node to an XmlNode.

Syntax

```
XmlNode :=   XmlProcessingInstruction.AsXmlNode()
```

Parameters

XmlProcessingInstruction Type: XmlProcessingInstruction An instance of the XmlProcessingInstruction data type.

Return Value

XmlNode Type: XmlNode An XmlNode value that references the current XmlProcessingInstruction.

See Also

XmlProcessingInstruction.GetData Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Gets the content of the processing instruction, excluding the target.

Syntax

```
[Ok := ]  XmlProcessingInstruction.GetData(var Result: Text)
```

Parameters

XmlProcessingInstruction Type: XmlProcessingInstruction An instance of the XmlProcessingInstruction data type.

Result
Type: Text
The content of the processing instruction, excluding the target.

Return Value

Ok Type: Boolean **true** if the operation was successful; otherwise **false**. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

See Also

XmlProcessingInstruction.GetDocument Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Gets the XmlDocument for this node.

Syntax

```
[Ok := ]  XmlProcessingInstruction.GetDocument(var Document: XmlDocument)
```

Parameters

XmlProcessingInstruction Type: XmlProcessingInstruction An instance of the XmlProcessingInstruction data type.

Document
Type: XmlDocument
The owning XmlDocument of this node.

Return Value

Ok Type: Boolean **true** if the operation was successful; otherwise **false**. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

See Also

XmlProcessingInstruction.GetParent Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Gets the parent XmlElement of this node.

Syntax

```
[Ok := ]  XmlProcessingInstruction.GetParent(var Parent: XmlElement)
```

Parameters

XmlProcessingInstruction Type: XmlProcessingInstruction An instance of the XmlProcessingInstruction data type.

Parent
Type: XmlElement
The parent XmlElement of this node.

Return Value

Ok Type: Boolean **true** if the operation was successful; otherwise **false**. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

See Also

XmlProcessingInstruction Data Type

XmlProcessingInstruction.GetTarget Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Gets the target of the processing instruction.

Syntax

```
[Ok := ]  XmlProcessingInstruction.GetTarget(var Result: Text)
```

Parameters

XmlProcessingInstruction Type: XmlProcessingInstruction An instance of the XmlProcessingInstruction data type.

Result
Type: Text
The target of the processing instruction.

Return Value

Ok Type: Boolean **true** if the operation was successful; otherwise **false**. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

See Also

XmlProcessingInstruction Data Type

XmlProcessingInstruction.Remove Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Removes this node from its parent element.

Syntax

```
[Ok := ]  XmlProcessingInstruction.Remove()
```

Parameters

XmlProcessingInstruction Type: XmlProcessingInstruction An instance of the XmlProcessingInstruction data type.

Return Value

Ok Type: Boolean **true** if the operation was successful; otherwise **false**. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

Developing Extensions

XmlProcessingInstruction.ReplaceWith Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Replaces this node with the specified content.

Syntax

```
[Ok := ]  XmlProcessingInstruction.ReplaceWith(Node: Any,...)
```

Parameters

XmlProcessingInstruction Type: XmlProcessingInstruction An instance of the XmlProcessingInstruction data type.

Node
Type: Any
The content with which to replace the current node.

Return Value

Ok Type: Boolean **true** if the operation was successful; otherwise **false**. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

See Also

XmlProcessingInstruction.SelectNodes Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Selects a list of nodes matching the XPath expression.

Syntax

```
[Ok := ]  XmlProcessingInstruction.SelectNodes(XPath: String, var NodeList: XmlNodeList)
```

Parameters

XmlProcessingInstruction Type: XmlProcessingInstruction An instance of the XmlProcessingInstruction data type.

XPath
Type: String
The XPath expression.

NodeList
Type: XmlNodeList
An XmlNodeList containing a collection of nodes matching the XPath expression.

Return Value

Ok Type: Boolean **true** if the operation was successful; otherwise **false**. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

See Also

XmlProcessingInstruction Data Type

XmlProcessingInstruction.SelectNodes Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Selects a list of nodes matching the XPath expression.

Syntax

```
[Ok := ]  XmlProcessingInstruction.SelectNodes(XPath: String, NamespaceManager: XmlNamespaceManager, var
NodeList: XmlNodeList)
```

Parameters

XmlProcessingInstruction Type: XmlProcessingInstruction An instance of the XmlProcessingInstruction data type.

XPath
Type: String
The XPath expression.

NamespaceManager
Type: XmlNamespaceManager
An XmlNamespaceManager to use for resolving namespaces for prefixes in the XPath expression.

NodeList
Type: XmlNodeList
An XmlNodeList containing a collection of nodes matching the XPath expression.

Return Value

Ok Type: Boolean **true** if the operation was successful; otherwise **false**. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

XmlProcessingInstruction.SelectSingleNode Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Selects the first XmlNode that matches the XPath expression.

Syntax

```
[Ok := ]  XmlProcessingInstruction.SelectSingleNode(XPath: String, var Node: XmlNode)
```

Parameters

XmlProcessingInstruction Type: XmlProcessingInstruction An instance of the XmlProcessingInstruction data type.

XPath
Type: String
The XPath expression.

Node
Type: XmlNode
The first XmlNode that matches the XPath query.

Return Value

Ok Type: Boolean **true** if the operation was successful; otherwise **false**. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

XmlProcessingInstruction.SelectSingleNode Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Selects the first XmlNode that matches the XPath expression.

Syntax

```
[Ok := ]  XmlProcessingInstruction.SelectSingleNode(XPath: String, NamespaceManager: XmlNamespaceManager,
var Node: XmlNode)
```

Parameters

XmlProcessingInstruction Type: XmlProcessingInstruction An instance of the XmlProcessingInstruction data type.

XPath
Type: String
The XPath expression.

NamespaceManager
Type: XmlNamespaceManager
An XmlNamespaceManager to use for resolving namespaces for prefixes in the XPath expression.

Node
Type: XmlNode
The first XmlNode that matches the XPath query.

Return Value

Ok Type: Boolean **true** if the operation was successful; otherwise **false**. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

XmlProcessingInstruction.SetData Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Sets the content of the processing instruction, excluding the target.

Syntax

```
[Ok := ]  XmlProcessingInstruction.SetData(Value: String)
```

Parameters

XmlProcessingInstruction Type: XmlProcessingInstruction An instance of the XmlProcessingInstruction data type.

Value
Type: String
The new content of the processing instruction, excluding the target.

Return Value

Ok Type: Boolean **true** if the operation was successful; otherwise **false**. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

XmlProcessingInstruction.SetTarget Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Sets the target of the processing instruction.

Syntax

```
[Ok := ]  XmlProcessingInstruction.SetTarget(Value: String)
```

Parameters

XmlProcessingInstruction Type: XmlProcessingInstruction An instance of the XmlProcessingInstruction data type.

Value
Type: String
The new target of the processing instruction.

Return Value

Ok Type: Boolean **true** if the operation was successful; otherwise **false**. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

XmlProcessingInstruction.WriteTo Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Serializes and saves the current node to the given variable.

Syntax

```
[Ok := ]  XmlProcessingInstruction.WriteTo(OutStream: OutStream)
```

Parameters

XmlProcessingInstruction Type: XmlProcessingInstruction An instance of the XmlProcessingInstruction data type.

OutStream
Type: OutStream
The OutStream to which you want to save the serialized representation of the node.

Return Value

Ok Type: Boolean **true** if the operation was successful; otherwise **false**. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

XmlProcessingInstruction.WriteTo Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Serializes and saves the current node to the given variable.

Syntax

```
[Ok := ]  XmlProcessingInstruction.WriteTo(WriteOptions: XmlWriteOptions, OutStream: OutStream)
```

Parameters

XmlProcessingInstruction Type: XmlProcessingInstruction An instance of the XmlProcessingInstruction data type.

WriteOptions
Type: XmlWriteOptions
Specifies options for customizing how the node is serialized.

OutStream
Type: OutStream
The OutStream to which you want to save the serialized representation of the node.

Return Value

Ok Type: Boolean **true** if the operation was successful; otherwise **false**. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

XmlReadOptions Data Type

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Represents the options configuring how XML is loaded from a data source.

The following methods are available on instances of the XmlReadOptions data type.

METHOD NAME	DESCRIPTION
PreserveWhitespace([Boolean])	Gets or sets a value that indicates whether insignificant white space should be preserved during parsing.

See Also

Getting Started with AL
Developing Extensions

XmlReadOptions.PreserveWhitespace Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Gets or sets a value that indicates whether insignificant white space should be preserved during parsing.

Syntax

```
[Value := ]  XmlReadOptions.PreserveWhitespace([NewValue: Boolean])
```

NOTE

This method can be invoked using property access syntax.

Parameters

XmlReadOptions Type: XmlReadOptions An instance of the XmlReadOptions data type.

NewValue

Type: Boolean

The new value of the flag.

Return Value

Value Type: Boolean **true** if insignificant white spaces are preserved during parsing, otherwise **false**.

XmlText Data Type

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Represents the text content of an element or attribute.

The following methods are available on the XmlText data type.

METHOD NAME	DESCRIPTION
Create(String)	Creates an XmlText node.

The following methods are available on instances of the XmlText data type.

METHOD NAME	DESCRIPTION
AddAfterSelf(Any,...)	Adds the specified content immediately after this node.
AddBeforeSelf(Any,...)	Adds the specified content immediately before this node.
AsXmlNode()	Converts the node to an XmlNode.
GetDocument(var XmlDocument)	Gets the XmlDocument for this node.
GetParent(var XmlElement)	Gets the parent XmlElement of this node.
Remove()	Removes this node from its parent element.
ReplaceWith(Any,...)	Replaces this node with the specified content.
SelectNodes(String, var XmlNodeList)	Selects a list of nodes matching the XPath expression.
SelectNodes(String, XmlNamespaceManager, var XmlNodeList)	Selects a list of nodes matching the XPath expression.
SelectSingleNode(String, var XmlNode)	Selects the first XmlNode that matches the XPath expression.
SelectSingleNode(String, XmlNamespaceManager, var XmlNode)	Selects the first XmlNode that matches the XPath expression.
Value([String])	Gets or sets the value of this node.
WriteTo(OutStream)	Serializes and saves the current node to the given variable.
WriteTo(XmlWriteOptions, OutStream)	Serializes and saves the current node to the given variable.
WriteTo(var Text)	Serializes and saves the current node to the given variable.

METHOD NAME	DESCRIPTION
WriteTo(XmlWriteOptions, var Text)	Serializes and saves the current node to the given variable.

XmlText.Create Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Creates an XmlText node.

Syntax

```
Value :=   XmlText.Create(Content: String)
```

Parameters

Content

Type: String

A string that contains the value of the new XmlText node.

Return Value

Value Type: XmlText The created XmlText node.

See Also

XmlText Data Type
Getting Started with AL
Developing Extensions

XmlText.AddAfterSelf Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Adds the specified content immediately after this node.

Syntax

```
[Ok := ]  XmlText.AddAfterSelf(Content: Any,...)
```

Parameters

XmlText Type: XmlText An instance of the XmlText data type.

Content
Type: Any
The content to add after this node.

Return Value

Ok Type: Boolean **true** if the operation was successful; otherwise **false**. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

XmlText.AddBeforeSelf Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Adds the specified content immediately before this node.

Syntax

```
[Ok := ]  XmlText.AddBeforeSelf(Content: Any,...)
```

Parameters

XmlText Type: XmlText An instance of the XmlText data type.

Content
Type: Any
The content to add before this node.

Return Value

Ok Type: Boolean **true** if the operation was successful; otherwise **false**. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

XmlText.AsXmlNode Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Converts the node to an XmlNode.

Syntax

```
XmlNode :=   XmlText.AsXmlNode()
```

Parameters

XmlText Type: XmlText An instance of the XmlText data type.

Return Value

XmlNode Type: XmlNode An XmlNode value that references the current XmlText.

See Also

XmlText Data Type

Developing Extensions

XmlText.GetDocument Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Gets the XmlDocument for this node.

Syntax

```
[Ok := ]  XmlText.GetDocument(var Document: XmlDocument)
```

Parameters

XmlText Type: XmlText An instance of the XmlText data type.

Document
Type: XmlDocument
The owning XmlDocument of this node.

Return Value

Ok Type: Boolean **true** if the operation was successful; otherwise **false**. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

See Also

XmlText Data Type

XmlText.GetParent Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Gets the parent XmlElement of this node.

Syntax

```
[Ok := ]  XmlText.GetParent(var Parent: XmlElement)
```

Parameters

XmlText Type: XmlText An instance of the XmlText data type.

Parent
Type: XmlElement
The parent XmlElement of this node.

Return Value

Ok Type: Boolean **true** if the operation was successful; otherwise **false**. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

See Also

XmlText.Remove Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Removes this node from its parent element.

Syntax

```
[Ok := ]  XmlText.Remove()
```

Parameters

XmlText Type: XmlText An instance of the XmlText data type.

Return Value

Ok Type: Boolean **true** if the operation was successful; otherwise **false**. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

See Also

XmlText Data Type

XmlText.ReplaceWith Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Replaces this node with the specified content.

Syntax

```
[Ok := ]  XmlText.ReplaceWith(Node: Any,...)
```

Parameters

XmlText Type: XmlText An instance of the XmlText data type.

Node
Type: Any
The content with which to replace the current node.

Return Value

Ok Type: Boolean **true** if the operation was successful; otherwise **false**. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

See Also

XmlText.SelectNodes Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Selects a list of nodes matching the XPath expression.

Syntax

```
[Ok := ]  XmlText.SelectNodes(XPath: String, var NodeList: XmlNodeList)
```

Parameters

XmlText Type: XmlText An instance of the XmlText data type.

XPath
Type: String
The XPath expression.

NodeList
Type: XmlNodeList
An XmlNodeList containing a collection of nodes matching the XPath expression.

Return Value

Ok Type: Boolean **true** if the operation was successful; otherwise **false**. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

See Also

XmlText Data Type

XmlText.SelectNodes Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Selects a list of nodes matching the XPath expression.

Syntax

```
[Ok := ]  XmlText.SelectNodes(XPath: String, NamespaceManager: XmlNamespaceManager, var NodeList:
XmlNodeList)
```

Parameters

XmlText Type: XmlText An instance of the XmlText data type.

XPath
Type: String
The XPath expression.

NamespaceManager
Type: XmlNamespaceManager
An XmlNamespaceManager to use for resolving namespaces for prefixes in the XPath expression.

NodeList
Type: XmlNodeList
An XmlNodeList containing a collection of nodes matching the XPath expression.

Return Value

Ok Type: Boolean **true** if the operation was successful; otherwise **false**. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

See Also

Developing Extensions

XmlText.SelectSingleNode Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Selects the first XmlNode that matches the XPath expression.

Syntax

```
[Ok := ]  XmlText.SelectSingleNode(XPath: String, var Node: XmlNode)
```

Parameters

XmlText Type: XmlText An instance of the XmlText data type.

XPath
Type: String
The XPath expression.

Node
Type: XmlNode
The first XmlNode that matches the XPath query.

Return Value

Ok Type: Boolean **true** if the operation was successful; otherwise **false**. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

XmlText.SelectSingleNode Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Selects the first XmlNode that matches the XPath expression.

Syntax

```
[Ok := ]  XmlText.SelectSingleNode(XPath: String, NamespaceManager: XmlNamespaceManager, var Node: XmlNode)
```

Parameters

XmlText Type: XmlText An instance of the XmlText data type.

XPath
Type: String
The XPath expression.

NamespaceManager
Type: XmlNamespaceManager
An XmlNamespaceManager to use for resolving namespaces for prefixes in the XPath expression.

Node
Type: XmlNode
The first XmlNode that matches the XPath query.

Return Value

Ok Type: Boolean **true** if the operation was successful; otherwise **false**. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

XmlText.Value Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Gets or sets the value of this node.

Syntax

```
[Value := ]  XmlText.Value([NewValue: String])
```

NOTE

This method can be invoked using property access syntax.

Parameters

XmlText Type: XmlText An instance of the XmlText data type.

NewValue

Type: String

The new value of this node.

Return Value

Value Type: String The value of this node.

XmlText.WriteTo Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Serializes and saves the current node to the given variable.

Syntax

```
[Ok := ]  XmlText.WriteTo(OutStream: OutStream)
```

Parameters

XmlText Type: XmlText An instance of the XmlText data type.

OutStream
Type: OutStream
The OutStream to which you want to save the serialized representation of the node.

Return Value

Ok Type: Boolean **true** if the operation was successful; otherwise **false**. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

XmlText.WriteTo Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Serializes and saves the current node to the given variable.

Syntax

```
[Ok := ]  XmlText.WriteTo(WriteOptions: XmlWriteOptions, OutStream: OutStream)
```

Parameters

XmlText Type: XmlText An instance of the XmlText data type.

WriteOptions
Type: XmlWriteOptions
Specifies options for customizing how the node is serialized.

OutStream
Type: OutStream
The OutStream to which you want to save the serialized representation of the node.

Return Value

Ok Type: Boolean **true** if the operation was successful; otherwise **false**. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

XmlWriteOptions Data Type

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Represents the options configuring how XML is saved.

The following methods are available on instances of the XmlWriteOptions data type.

METHOD NAME	DESCRIPTION
PreserveWhitespace([Boolean])	Gets or sets a value that indicates whether insignificant white space should be preserved during serialization.

See Also

XmlWriteOptions.PreserveWhitespace Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Gets or sets a value that indicates whether insignificant white space should be preserved during serialization.

Syntax

```
[Value := ]  XmlWriteOptions.PreserveWhitespace([NewValue: Boolean])
```

> **NOTE**
> This method can be invoked using property access syntax.

Parameters

XmlWriteOptions Type: XmlWriteOptions An instance of the XmlWriteOptions data type.

NewValue
Type: Boolean
The new value of the flag.

Return Value

Value Type: Boolean **true** if insignificant white spaces should be preserved during serialization, otherwise **false**.

Properties Overview

2/17/2021 • 2 minutes to read • Edit Online

This section describes the properties that are available to developers in Dynamics 365 Business Central. Properties can be set explicitly in AL code using syntax such as:

```
Promoted = true;
PromotedCategory = Process;
ApplicationArea = All;
```

In the sections below, properties are sorted according to the object(s) they apply to.

- Table and Table Extension Properties
- Page and Page Extension Properties
- Codeunit Properties
- Query Properties
- Report Properties
- XMLPort Properties
- Control Add-In Properties
- Enum Properties
- View Properties
- Profile Properties
- Integrating with Dynamics 365 for Sales

Table, Table Fields, and Table Extension Properties

2/17/2021 • 4 minutes to read • Edit Online

The following topic lists properties that apply to the table object and table fields and, in some cases, to the table extension object as specified below.

PROPERTY NAME	AVAILABLE FOR TABLE EXTENSION OBJECT	APPLIES TO
Access Property		• Table • Table fields
AccessByPermission Property		• BLOB field • BigInteger field • Boolean field • Code field • Date field • DateFormula field • DateTime field • Decimal field • Duration field • GUID field • Integer field • OemCode field • OemText field • Option field • RecordID field • TableFilter field • Text field • Time field
AutoFormatExpression Property		• BigInteger field • Boolean field • Code field • Date field • DateFormula field • DateTime field • Decimal field • Duration field • GUID field • Integer field • OemCode field • OemText field • Option field • RecordID field • Text field • Time field

PROPERTY NAME	AVAILABLE FOR TABLE EXTENSION OBJECT	APPLIES TO
AutoFormatType Property		• BigInteger field • Boolean field • Code field • Date field • DateFormula field • DateTime field • Decimal field • Duration field • GUID field • Integer field • OemCode field • OemText field • Option field • RecordID field • Text field • Time field
AutoIncrement Property		• BigInteger field
BlankNumbers Property		• BigInteger field • Boolean field • Date field • DateTime field • Decimal field • Duration field • Integer field • Option field • Time field
BlankZero Property		• BigInteger field • Boolean field • Decimal field • Duration field • Integer field • Option

PROPERTY NAME	AVAILABLE FOR TABLE EXTENSION OBJECT	APPLIES TO
CalcFormula Property		• BigInteger field • Boolean field • Code field • Date field • DateTime field • Decimal field • Duration field • GUID field • Integer field • Media field • MediaSet field • Option field • RecordID field • Text field • Time field
Caption Property	X	• Table object • BLOB Field • BigInteger field • Boolean field • Code field • Date field • DateFormula field • DateTime field • Decimal field • Duration field • GUID field • Integer field • OemCode field • OemText field • Option field • RecordID field • TableFilter field • Text field • Time field
CaptionClass Property	X	• BigInteger field • Boolean field • Code field • Date field • DateFormula field • DateTime field • Decimal field • Duration field • GUID field • Integer field • OemCode field • OemText field • Option field • RecordID field • Text field • Time field

PROPERTY NAME	AVAILABLE FOR TABLE EXTENSION OBJECT	APPLIES TO
CaptionML Property	X	• Table object • BLOB Field • BigInteger field • Boolean field • Code field • Date field • DateFormula field • DateTime field • Decimal field • Duration field • GUID field • Integer field • OemCode field • OemText field • Option field • RecordID field • TableFilter field • Text field • Time field
CharAllowed Property		• Code field • OemCode field • OemText field • Text field
ClosingDates Property	X	• Date field
Compressed Property		• BLOB field
Data Type		• Table fields
DataClassification		• Table object
DataCaptionFields Property	X	• Table object
DataPerCompany Property		• Table object
DateFormula Property		• Code • OemCode field • OemText field • Text field

PROPERTY NAME	AVAILABLE FOR TABLE EXTENSION OBJECT	APPLIES TO
Description Property	X	• Table object • BLOB field • BigInteger field • Boolean field • Code field • Date field • DateFormula field • DateTime field • Decimal field • Duration field • GUID field • Integer field • OemCode field • OemText field • Option field • RecordID field • TableFilter field • Text field • Time field
DrillDownPageID Property		• Table object
Editable Property		• BigInteger field • Boolean field • Code field • Date field • DateFormula field • DateTime field • Decimal field • Duration field • GUID field • Integer field • OemCode field • OemText field • Option field • RecordID field • Text field • Time field

PROPERTY NAME	AVAILABLE FOR TABLE EXTENSION OBJECT	APPLIES TO
Enabled Property		• BLOB field • BigInteger field • Boolean field • Code field • Date field • DateFormula field • DateTime field • Decimal field • Duration field • GUID field • Integer field • OemCode field • OemText field • Option field • RecordID field • TableFilter field • Text field • Time field
ExtendedDataType Property		• BigInteger field • Boolean field • Code field • Date field • DateFormula field • DateTime field • Decimal field • Duration field • GUID field • Integer field • OemCode field • OemText field • Option field • RecordID field • Text field • Time field
Extensible Property		• Table object
ExternalName Property		• Table object
ExternalSchema Property		• Table object

PROPERTY NAME	AVAILABLE FOR TABLE EXTENSION OBJECT	APPLIES TO
FieldClass Property		• BigInteger field • Boolean field • Code field • Date field • DateFormula field • DateTime field • Decimal field • Duration field • GUID field • Integer field • OemCode field • OemText field • Option field • RecordID field • Text field • Time field
InitValue Property		• BigInteger field • Boolean field • Code field • Date field • DateFormula field • Decimal field • Duration field • GUID field • Integer field • OemCode field • OemText field • Option field • RecordID field • Text field • Time field
LinkedInTransaction Property		• Table object
LinkedObject Property		• Table object
LookupPageID Property		• Table object
MaxValue Property		• BigInteger field • Boolean field • Date field • DateTime field • Decimal field • Duration field • Integer field • Option field • Time field

PROPERTY NAME	AVAILABLE FOR TABLE EXTENSION OBJECT	APPLIES TO
MinValue Property		• BigInteger field • Boolean field • Date field • DateTime field • Decimal field • Duration field • Integer field • Option field • Time field
NotBlank Property		• BigInteger field • Boolean field • Code field • Date field • DateFormula field • DateTime field • Decimal field • Duration field • GUID field • Integer field • OemCode field • OemText field • Option field • RecordID field • Text field • Time field
Numeric Property		• Code field • OemCode field • OemText field • Text field
ObsoleteReason		• Table object • Table keys • Text field
ObsoleteState		• Table object • Table keys • Text field
OptionCaption Property	X	• Option field
OptionMembers Property		• Option field
PasteIsValid Property		• Table object

PROPERTY NAME	AVAILABLE FOR TABLE EXTENSION OBJECT	APPLIES TO
Permissions Property		• Table object
ReplicateData Property		• Table object
Scope (Table) Property		• Table object
SignDisplacement Property		• BigInteger field • Boolean field • Date field • DateTime field • Decimal field • Duration field • Integer field • Option field • Time field
SQLDataType Property		• Code field • OemCode field
SqlTimeStamp Property		• BigInteger
SubType Property (BLOB)		• BLOB field
TableRelation Property		• BigInteger field • Boolean field • Code field • Date field • DateFormula field • DateTime field • Decimal field • Duration field • GUID field • Integer field • OemCode field • OemText field • Option field • RecordID field • Text field • Time field
TableType Property		• Table object

PROPERTY NAME	AVAILABLE FOR TABLE EXTENSION OBJECT	APPLIES TO
ValidateTableRelation Property		• BigInteger field • Boolean field • Code field • Date field • DateFormula field • DateTime field • Decimal field • Duration field • GUID field • Integer field • OemCode field • OemText field • Option field • RecordID field • Text field • Time field
ValuesAllowed Property		• BigInteger field • Boolean field • Code field • Date field • DateFormula field • DateTime field • Decimal field • Duration field • GUID field • Integer field • OemCode field • OemText field • Option field • RecordID field • Text field • Time field
Width Property	X	• BigInteger field • Code field • Decimal field • Duration field • Integer field • OemCode field • OemText field • Text field

Page, Page Fields, and Page Extension Properties

2/17/2021 • 3 minutes to read • Edit Online

This topic lists properties that apply to the page object, page fields, and page extension object.

Page object properties

The following properties all apply to the page object, only some of these properties can be set for a page extension object as specified below. This list is sorted alphabetically by property name. For page properties sorted by method on a page, see Page Properties.

PROPERTY NAME	AVAILABLE FOR PAGE EXTENSION OBJECT	APPLIES TO
Access Property		• Codeunit • Query • Table • Table Field • Enum Type • Interface
AccessByPermission Property		• Page object • Field control • Part control • Action
AdditionalSearchTerms Property		• Page object
AdditionalSearchTermsML Property		• Page object
ApplicationArea Property	X (see next column)	• Page object (cannot be specified for a page extension object) • Field control • Part control • Action
AssistEdit Property		• Field control
AutoFormatExpression Property		• Field control
AutoFormatType Property		• Field control
AutoSplitKey Property		• Page object

PROPERTY NAME	AVAILABLE FOR PAGE EXTENSION OBJECT	APPLIES TO
BlankNumbers Property		• Field control
BlankZero Property		• Field control
CaptionML Property	X	• Page object • Container control • Group control • Field control • Part control • ActionGroup • Action • Separator
CaptionClass Property	X	• Field control
CharAllowed Property		• Field control
ClosingDates Property	X	• Field control
ColumnSpan Property		• Field control
ContextSensitiveHelpPage Property	X	• Page object
ContainerType Property	X	• Container control
DataCaptionExpression Property	X	• Page object
DateFormula Property		• Field control
DecimalPlaces Property		• Field control
DelayedInsert Property		• Page object
DeleteAllowed Property		• Page object

PROPERTY NAME	AVAILABLE FOR PAGE EXTENSION OBJECT	APPLIES TO
Description Property	X	• Page object • Container control • Group control • Field control • Part control • ActionGroup • Action
DrillDown Property		• Field control
DrillDownPageId Property		• Field control
Editable Property		• Page object • Group control • Field control • Part control
Ellipsis Property		• Action
Enabled Property	X	• Group control • Field control • Part control • ActionGroup • Action
EntityCaption Property		• Page object
EntityCaptionML Property		• Page object
EntityName Property		• Page object • Part control
EntitySetCaption Property		• Page object
EntitySetCaptionML Property		• Page object
EntitySetName Property		• Page object • Part control
ExtendedDataType Property		• Field control
Extensible Property		• Page object

PROPERTY NAME	AVAILABLE FOR PAGE EXTENSION OBJECT	APPLIES TO
FreezeColumn Property	X	• Group control
GridLayout Property		• Group control
Gesture Property		• Action
HideValue Property	X	• Field control
IndentationControls Property		• Group control
InFooterBar Property	X	• Action
InsertAllowed Property		• Page object
InstructionalTextML Property	X	• Page object • Group control
Image Property		• Field control • ActionGroup • Action
Importance Property	X	• Field control
LinksAllowed Property		• Page object
LookupPageId Property		• Field control
Lookup Property		• Field control
ModifyAllowed Property		• Page object
MultipleNewLines Property		• Page object
Multiplicity Property		• Page part
MinValue Property		• Field control
MaxValue Property		• Field control

PROPERTY NAME	AVAILABLE FOR PAGE EXTENSION OBJECT	APPLIES TO
MultiLine Property		• Field control
NavigationPageId Property		• Field control
NotBlank Property		• Field control
Numeric Property		• Field control
ObsoleteState Property		• Page object • Action • Action area • Action group • Action separator • Area • Chart part • Field control • Group • Label • Part • System part
ObsoleteReason Property		• Page object • Action • Action area • Action group • Action separator • Area • Chart part • Field control • Group • Label • Part • System part
ODataEDMType Property	X	• Page object • Field control
ODataKeyFields Property		• Page object
OptionCaptionML Property		• Field control
PageType Property		• Page object
Permissions Property		• Page object

PROPERTY NAME	AVAILABLE FOR PAGE EXTENSION OBJECT	APPLIES TO
PopulateAllFields Property		• Page object
Promoted Property	X	• Action
PromotedActionCategories Property	X	• Page object
PromotedActionCategoriesML Property	X	• Page object
PromotedCategory Property	X	• Action
PromotedIsBig Property	X	• Action
PromotedOnly Property	X	• Action
Provider Property		• Part control
QuickEntry Property	X	• Field control
RefreshOnActivate Property		• Page object
RowSpan property		• Field control
RunObject Property		• Action
RunPageLink Property		• Action
RunPageMode Property		• Action
RunPageOnRec Property		• Action
RunPageView Property		• Action
SaveValues Property		• Page object
Scope Property		• Action
ShortcutKey Property		• Action

PROPERTY NAME	AVAILABLE FOR PAGE EXTENSION OBJECT	APPLIES TO
ShowAsTree Property		• Group control
ShowCaption Property	X	• Group control • Field control
ShowFilter Property		• Page object • Part control
ShowMandatory Property		• Field control
SignDisplacement Property		• Field control
SourceTable Property		• Page object
SourceTableTemporary Property		• Page object
SourceTableView Property		• Page object
Style Property	X	• Field control
StyleExpr Property	X	• Field control
SubPageView Property		• Part control
SubPageLink Property		• Part control
TableRelation Property		• Field control
ToolTipML Property	X	• Field control • Part control • ActionGroup • Action
UpdatePropagation Property		• Part control
UsageCategory Property		• Page object
ValuesAllowed Property		• Field control

PROPERTY NAME	AVAILABLE FOR PAGE EXTENSION OBJECT	APPLIES TO
Visible Property	X	• Group control • Field control • Part control • ActionGroup • Action • View
Width Property	X	• Field control

Integrating Microsoft Dataverse for Extension Development

2/17/2021 • 2 minutes to read • Edit Online

NOTE

Effective November 2020:

- Common Data Service has been renamed to Microsoft Dataverse. Learn more
- Some terminology in Microsoft Dataverse has been updated. For example, *entity* is now *table* and *field* is now *column*. Learn more

Develop extensions and streamline the workflow by synchronizing Microsoft Dataverse data with Dynamics 365 Business Central.

For developing extensions to integrate with sales data, you simply enable the tables used in Microsoft Dataverse. The extension development process includes the following set of properties in Dynamics 365 Business Central to enable field mapping. You can enable the field mapping by using the following properties. The tables are extensible, so that you can update Microsoft Dataverse with data as well.

Associated table and field properties

The following properties are used for integrating with Microsoft Dataverse:

PROPERTIES	APPLIES TO	DESCRIPTION
TableType Property	Tables	Specifies the table type. This enables the table to integrate with the external database. For example, `CDS`.
ExternalName Property	Tables, Fields	Specifies the name of the original table in the external database when used as a table property. Specifies the field name of the corresponding field specified in the external table when used as a field property.
ExternalAccess Property	Fields	Specifies the access to the underlying Microsoft Dataverse table when Microsoft Dataverse tables are generated using the **AL Table Proxy Generator** tool, see AL Proxy Table Generator
ExternalType Property	Fields	Specifies the data type of the corresponding column in the Microsoft Dataverse table.

PROPERTIES	APPLIES TO	DESCRIPTION
OptionMembers Property	Fields	Sets the option values for a field, text box, or variable.
OptionOrdinalValues Property	Fields	Specifies the list of option values. You can set this property, if the **ExternalType** is set to **Picklist**.

Enabling the table

Typically in Microsoft Dataverse, tables handle the internal processes. In order to access to the underlying Microsoft Dataverse table, you use the `TableType` property and select the value called **CDS**. This enables the table as an integration table for integrating Dynamics 365 Business Central with Microsoft Dataverse. The table is mainly based on a table in Microsoft Dataverse, such as the Accounts table.

Snippet support

Typing the shortcut `ttable` will create the basic layout for a table object when using the AL Language extension in Visual Studio Code.

Example

In the following example, the `SalesIntegration` table uses the `TableType` and `ExternalName` properties to link the underlying **Microsoft Dataverse** table for mapping the columns from the `Sales` table with the specified fields.

```
table 50100 SalesIntegration
{
    TableType = CDS;
    ExternalName = 'Sales';

    fields
    {
        field(1; ActualSales; Integer)
        {
            ExternalName = 'ActualSale';
            ExternalAccess = Full;
            ExternalType = 'String';
        }

        field(2; SalesCategories; Option)
        {
            ExternalName='SalesCategory';
            ExternalAccess = Read;
            ExternalType = 'Picklist';
            OptionMembers = Manufacturing, Marketing, Support;
            OptionOrdinalValues = -1, 1, 2;
        }
    }
}
```

Properties

Table and Field Triggers

2/17/2021 • 2 minutes to read • Edit Online

Dynamics 365 Business Central recognizes certain actions that happen to a table when you use it, for example, when you insert or modify data. In response, you specify to execute AL code defined in a trigger. Triggers are predefined methods that are executed when certain actions happen. The bodies of these methods are initially empty and must be defined by the developer. Defining AL code in triggers allows you to change the default behavior of Dynamics 365 Business Central.

The triggers in a table can be divided into two categories:

- Table triggers
- Field triggers

Tables have the following triggers.

TABLE TRIGGER	RUNS WHEN
OnInsert Trigger	A new record is inserted into the table.
OnBeforeInsert Trigger	A new record is inserted into the table.
OnAfterInsert Trigger	A new record is inserted into the table.
OnModify Trigger	A record in the table is modified.
OnBeforeModify Trigger	A record in the table is modified.
OnAfterModify Trigger	A record in the table is modified.
OnDelete Trigger	A record in the table is deleted.
OnBeforeDelete Trigger	A record in the table is deleted.
OnAfterDelete Trigger	A record in the table is deleted.
OnRename Trigger	A record is modified in a primary key field.
OnBeforeRename Trigger	A record is modified in a primary key field.
OnAfterRename Trigger	A record is modified in a primary key field.

Fields have the following triggers.

FIELD TRIGGER	RUNS WHEN
OnValidate (Fields) Trigger	Data is entered in a field or when the VALIDATE (Record) is executed.
OnLookup (Fields) Trigger	Lookup is activated.

FIELD TRIGGER	RUNS WHEN
OnBeforeValidate (Fields) Trigger	Before data is entered in a field.
OnAfterValidate (Fields) Trigger	After data is entered in a field.

Page and Action Triggers

2/17/2021 • 2 minutes to read • Edit Online

Page triggers allow you to use AL code to control the behavior of the system as a result of an event on the page, such as a page opening or a field changing its value. You typically use page triggers for advanced validation and logic.

Page triggers can be divided into three categories:

- General page triggers that apply to the entire page
- Field page triggers that apply to a field control on a page
- Action triggers that apply to an action on a page.

> **IMPORTANT**
> If you define two methods that have the same name, one defined in a page and the other in a table that is referenced by the page, you cannot invoke the method defined in the page directly. By default, a call to the method invokes the method that is defined in the table. This behavior occurs when the method is called from a source expression or a trigger.

General Triggers

The following table lists triggers that apply to the entire page.

PAGE TRIGGER NAME	RUNS
OnInit Trigger	When the page is loaded, but before the controls are available.
OnOpenPage Trigger	When the page is initialized and the controls are available.
OnClosePage Trigger	When the page about to close and after OnQueryClosePage Trigger trigger.
OnFindRecord Trigger	When the page is opened and a record is retrieved from a table.
OnNextRecord Trigger	When the page changes from displaying one record to another record in a table. For example, on a Customer card page, this happens when a user selects **Next** (Ctrl+Page Down) or **Previous** (Ctrl+Page Up).
OnAfterGetCurrRecord Trigger	After the current record is retrieved from the table.
OnAfterGetRecord Trigger	When a record has been retrieved but not yet displayed.
OnNewRecord Trigger	When a new record has been initialized but not yet displayed.
OnInsertRecord Trigger	When a new record is about to be inserted in the table.

PAGE TRIGGER NAME	RUNS
OnModifyRecord Trigger	When a record is about to be modified in the table.
OnDeleteRecord Trigger	When a record is about to be deleted from the table.
OnQueryClosePage Trigger	When the page is about to close, but before the OnClosePage Trigger.

Field Triggers

The following table describes the triggers that are available on field controls.

CONTROL TRIGGER	RUNS
OnValidate (Page fields) Trigger	When the user changes the value in a field and then selects away from the field so that the field loses focus.
OnLookup (Page fields) Trigger	When the user requests a lookup by clicking a field's lookup button or pressing F4.
OnDrillDown Trigger	When the user requests a drill-down by choosing the field's drill-down button or pressing Shift+F8.
OnAssistEdit Trigger	When the user requests assist-edit by choosing an AssistEdit button or by pressing Shift+F4.

Action Triggers

The following table lists triggers that apply to actions on a page.

TRIGGERS	RUNS
OnAction Trigger	When an action is initiated on a page.

Page Background Triggers

The following table lists triggers that apply to page background tasks. For more information, see Page Background Tasks.

TRIGGERS	RUNS
OnPageBackgroundTaskCompleted	Runs after a page background task has successfully completed.
OnPageBackgroundTaskError	Runs when an error occurs in a page background task.

Triggers

Codeunit Triggers

2/17/2021 • 2 minutes to read • Edit Online

The following triggers apply to codeunits.

CODEUNIT TRIGGER NAME	RUNS
OnRun Trigger	When the codeunit is executed.
OnBeforeTestRun Trigger	Before a test method of a test codeunit is run.
OnAfterTestRun Trigger	After a test method of a test codeunit is run.
OnCheckPreconditionsPerCompany Trigger	Before an extension upgrade of an upgrade codeunit is run.
OnCheckPreconditionsPerDatabase Trigger	Before an extension upgrade of an upgrade codeunit is run.
OnUpgradePerCompany Trigger	When an extension upgrade of an upgrade codeunit is run.
OnUpgradePerDatabase Trigger	When an extension upgrade of an upgrade codeunit is run.
OnValidateUpgradePerCompany Trigger	After an extension upgrade of an upgrade codeunit is run.
OnValidateUpgradePerDatabase Trigger	After an extension upgrade of an upgrade codeunit is run.
OnInstallAppPerCompany Trigger	When an extension installation or reinstallation in an install codeunit is run.
OnInstallAppPerDatabase Trigger	When an extension installation or reinstallation in an install codeunit is run.

Triggers

Report and Data Item Triggers

2/17/2021 • 2 minutes to read • Edit Online

In reports, triggers are typically used to perform calculations and verification. Triggers let you control how data is selected and retrieved in a more complex and effective way than you can achieve by using properties.

Report Triggers

The following table lists triggers that apply to the report itself.

TRIGGER	RUNS
OnInitReport Trigger	When the report is loaded.
OnPreReport Trigger	Before the report is run, but after the **RequestPage** has been run.
OnPostReport Trigger	After the report has run, but not if the report was stopped manually or by the QUIT Method (Report, XMLport).

Data Item Triggers

The following table lists triggers that apply to each data item on the report.

TRIGGER	RUNS
OnPreDataItem Trigger	Before the data item is processed, but after the associated variable has been initialized.
OnAfterGetRecord (Data Items) Trigger	When a record has been retrieved from the table.
OnPostDataItem Trigger	When the data item has been iterated for the last time.

Report Triggers
Triggers

XMLport Triggers

2/17/2021 • 2 minutes to read • Edit Online

The following triggers apply to XMLports.

XMLport triggers

XMLPORT TRIGGER	RUNS
OnAfterAssignField Trigger	Runs after a field has been assigned a value and before it is validated and imported. This trigger is only used to import data.
OnAfterAssignVariable Trigger	Runs after the value defined in the XML document is assigned to the text variable. This trigger is only used to import data.
OnAfterGetField Trigger	Runs after a field is passed to the XML document. This trigger is only used to export data.
OnAfterGetRecord (XMLports) Trigger	Runs after a record is retrieved from a table and before it is exported to the XML document. This trigger is only used to export data.
OnAfterInitRecord Trigger	Runs after a record is loaded. This trigger is only used to import data.
OnAfterInsertRecord Trigger	Runs after a record has been inserted into a database table. This trigger is only used to import data.
OnAfterModifyRecord Trigger	Runs after a record has been modified. The trigger is used to import data.
OnBeforeInsertRecord Trigger	Runs after a record has been loaded and before it is inserted into a database table. This trigger is only used to import data.
OnBeforeModifyRecord Trigger	Runs before a record is modified. This trigger is used to import data.
OnBeforePassField Trigger	Runs before a field is passed to the XML document. This trigger is only used to export data.

XMLPORT TRIGGER	RUNS
OnBeforePassVariable Trigger	Runs after the source expression has been formatted into a text variable and before the text variable is passed to the XML document. This trigger is only used to export data.
OnInitXMLport Trigger	Executes when the XMLport is loaded and before any table views and filters are set.
OnPreXMLport Trigger	Runs after the table views and filters are set and before the XMLport is run.
OnPostXMLport Trigger	Runs after the XMLport is run.
OnPreXMLItem Trigger	Runs after the table is initialized and before you start exporting data to an XML object. This trigger only applies to XMLport elements that have a source type of Table. This trigger is only used to export data.

Query Triggers

2/17/2021 • 2 minutes to read • Edit Online

This topic describes the AL triggers that are available for queries. Triggers are typically used to perform calculations and verification. Triggers let you control how data is selected and retrieved in a more complex and effective way than you can achieve by using properties.

Query object triggers

The following table lists the triggers that apply to the query object.

TRIGGER	RUNS
OnBeforeOpen	Before the query object is run and the dataset is generated. For example, you can use the **OnBeforeOpen** trigger to apply filters using the **SETFILTER** method.

Security and Protection in Business Central

2/17/2021 • 2 minutes to read • Edit Online

An enterprise business solution must have a built-in security system that helps protect your database and the information that it contains from unauthorized access. It must also allow you to specify what authorized users are allowed to do in the database, such as what data they can read and modify. The following sections help you understand and improve the security of Business Central.

Application Security

Security Tips for Business Users

Online Security

On-Premises Security

IMPORTANT

Starting March, 2020, Business Central only supports Transport Layer Security (TLS) version 1.2 or later. This applies to Business Central 2019 release wave 2 online and on-premises (version 15.x). Upgrade to Business Central 2019 release wave 2 or later to remove support for earlier versions of TLS. If your solution or an add-on uses TLS 1.0 or 1.1, you must update that configuration or add-on to TLS 1.2 or later as soon as possible. For more information, see Blog post: Update to TLS 1.2 or later in Dynamics 365 Business Central in 2019 release wave 2.

Security Tips for Business Users

2/17/2021 • 2 minutes to read • Edit Online

This article describes how you can work with end-users and configure their devices to improve the security.

> [IMPORTANT] Use this article together with industry standard security practices for securing users and their access to company data. This article describes additional considerations for how you can work with end-users and configure their devices to improve security.

Kiosks and shared devices

Customers using kiosks, where multiple users sign into Business Central with their own identity from that terminal, should apply additional security practices for an appropriate level of isolation between users.

- Before ending a session at the kiosk, business users should remember to sign out of Business Central, then close all browser windows. Closing the Business Central browser tab or closing the browser without signing out may not fully complete the signout process.
- Each user should use private or guest browsing modes so that any data cached by Business Central is discarded when the browser is closed. Private or guest browsing may degrade some Business Central features and performance optimizations that are only available when the browser provides access to its storage mechanisms.

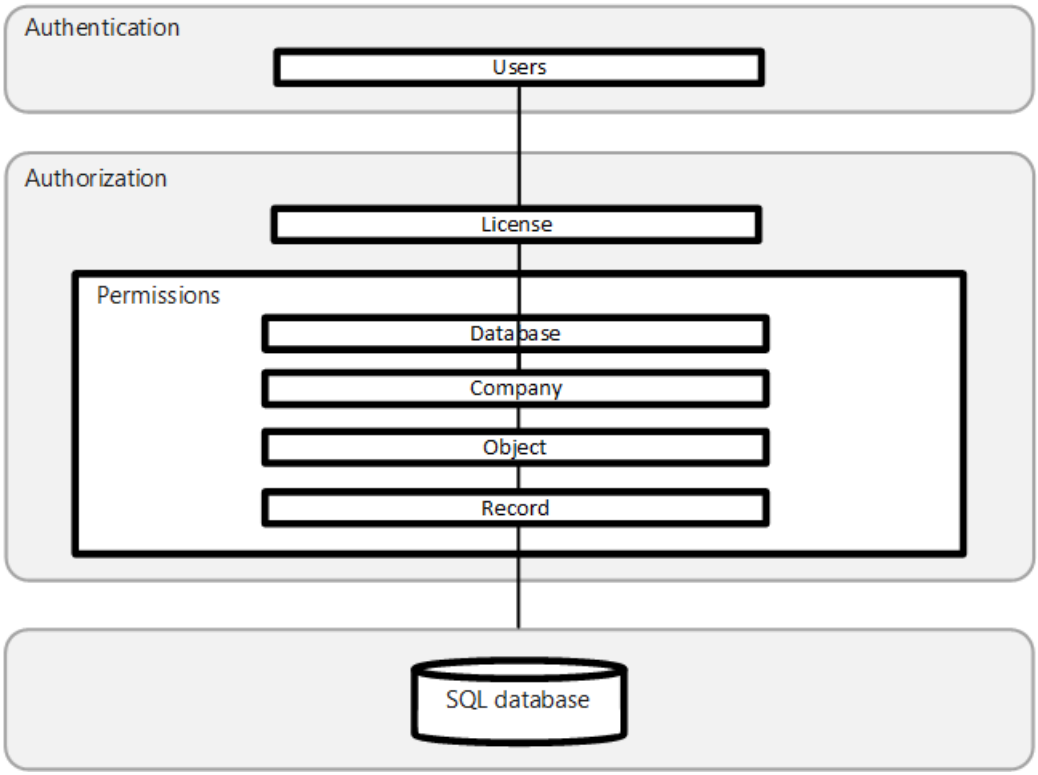
Application Security in Business Central

2/17/2021 • 2 minutes to read • Edit Online

This section helps you understand and improve the security of your Business Central application regardless of where it is hosted. In the articles listed below, you will find guidance and recommended practices related to authentication, authorization, and auditing, as well as data encryption and secure development practices that can be applied to any Business Central environment.

Business Central uses a layered approach to application security, as outlined in the following diagram.



Authentication

Before users can sign-in to the Business Central application, they must be authenticated as valid user in the system. Business Central On-Premises supports several authentication methods, such as Windows and Azure Active Directory. Business Central Online uses strictly Azure Active Directory (Azure AD). For more information, see the following articles:

Managing Users and Permissions

Authentication and Credential Types

Multi-factor Authentication

The authentication method configured for Business Central Server is also used to access web services. For more information, see Web Services Authentication.

Authorization

Once authenticated, authorization determines which areas a user can access, such as the pages and reports that they can open, and the permissions that they have on associated data. For more information, see the following articles:

User Permissions in the Application

Analyzing Permission Changes Trace Telemetry

Data Security

Removing Elements from the User Interface According to Permissions

Analyzing Authorization Telemetry

Using OAuth to Authorize Business Central Web Services

Auditing

Business Central includes several auditing features that help you track information about who is signing-in, what their permissions are, what data have they changed, and more. For more information, see the following articles:

Authorization Assessment

Data Auditing

Security Auditing

Data Classification

Data Encryption

You can encrypt data on the Business Central server by generating new or importing existing encryption keys that you enable on the Business Central server instance that connects to the database. For more information, see Encrypting Data in Dynamics 365 Business Central.

Security Development Lifecycle

Microsoft's Security Development Lifecycle (SDL) is a software development process that helps developers build more secure software and address security compliance requirements while reducing development cost. For more information, see Security Development Lifecycle.

Business Central Online Security

2/17/2021 • 2 minutes to read • Edit Online

This section helps you understand and improve the security of your Dynamics 365 Business Central tenant. In the links below you will find information, guidance and recommended practices related to authentication, data encryption and safely integrating with other services. You will also find information on Business Central's certifications and regulatory compliance.

Authentication

Business Central Online uses Azure Active Directory (Azure AD) as the authentication method, which is automatically set up and managed for you.

Data isolation and encryption

Data belonging to a single tenant is stored in an isolated database and is never mixed with data from other tenants. This ensures complete isolation of data in day-to-day use as well as in backup-restore scenarios. Furthermore, Business Central Online uses encryption to help protect tenant data:

- Data is encrypted at-rest by using Transparent Data Encryption (TDE) and backup encryption.
- Data backups are always encrypted.
- All network traffic inside the service is encrypted by using industry standard encryption protocols.

Service integration

We recommend that you use encrypted network protocols to connect to the PowerBI server and Business Central web services. For more information, see the following articles:

Connect to Business Central with Power BI

Using Security Certificates with Business Central On-Premises

Business Central On-Premises Security

2/17/2021 • 2 minutes to read • Edit Online

This section helps you understand and improve the security of Business Central hosted on-premises. In the links below you will find information, hardening guidance and recommended best practices addressing client, database, server and network security.

Authentication

Before users can sign-in to the Business Central application, they must be authenticated as valid user in the system. Business Central supports several authentication methods. You configure the authentication method on the server-tiers of Business Central.

For more information, see Authentication and Credential Types.

Server Security

Business Central Server handles communication between clients and databases, controlling authentication, event logging, scheduled tasks, reporting and more. The following articles explain how to improve the security of Business Central Server instances.

Hardening Business Central Server Security

Locking Down Server Communication settings

Client Security

The following articles explain how to improve the security of connections from the clients to the Business Central Server.

Configuring SSL to Secure the Client Connections

Using Security Certificates with Business Central On-Premises

Database Security

The articles in this section explain how to improve database security in Business Central.

The following articles discuss configurations that you can perform on the Business Central Server:

Configuring the Database

Encrypt Traffic

The following are general articles about SQL Server security that can also help secure the database:

Upgrade to TLS 1.2

IMPORTANT

Starting March, 2020, Business Central only supports Transport Layer Security (TLS) version 1.2 or later. This applies to Business Central 2019 release wave 2 online and on-premises (version 15.x). Upgrade to Business Central 2019 release wave 2 or later to remove support for earlier versions of TLS. If your solution or an add-on uses TLS 1.0 or 1.1, you must update that configuration or add-on to TLS 1.2 or later as soon as possible. For more information, see Blog post: Update to TLS 1.2 or later in Dynamics 365 Business Central in 2019 release wave 2.

Service Overview for Business Central Online

2/17/2021 • 5 minutes to read • Edit Online

Dynamics 365 Business Central is a complete enterprise resource planning (ERP) software solution for mid-sized organizations that is fast to implement, easy to configure, and simple to use, both on-premises and online. Sign up for a trial before you decide to move to the cloud, and read this article to learn about the systems that make Business Central online run as a service that you can bet your business on.

Lifecycle policy

Business Central online is governed by Microsoft's Modern Lifecycle Policy, which means continuous service updates and a major update every six months. For more information, see Dynamics 365 Business Central Service Compliance and Dynamics 365 release schedule and early access.

Get an overview of new and upcoming changes in the Dynamics 365 release plans.

Global availability

Business Central online is available in a number of markets, and new countries go live on a quarterly basis. For more information, see Countries and Translations Supported.

Built upon a foundation of trust, security, and compliance

On the Service Trust site, review the available independent audit reports for Microsoft's Cloud services. Find information about compliance with data protection standards and regulatory requirements, such as International Organization for Standardization (ISO), Service Organization Controls (SOC), National Institute of Standards and Technology (NIST), Federal Risk and Authorization Management Program (FedRAMP), and the General Data Protection Regulation (GDPR).

For example, you can find audit reports and certifications for ISO27001, ISO27018, ISO27017, ISO 27701, or the SOC 2 Type II reports at https://servicetrust.microsoft.com/.

Databases and backups

Business Central online runs on Azure and uses Azure SQL Database as the database that stores your data. A tenant's data is stored at rest in the Azure region that is closest to their geographical location. Administrators can always find the exact Azure region that hosts their environments in the Business Central administration center. For an overview of Azure geographies and regions, see the Azure global infrastructure site.

Databases are protected by automatic backups that are kept for 30 days. Administrators of a Business Central tenant can't directly access or manage these backups because they're managed automatically by Microsoft. But admins can restore their environments to a specific point in time in the past using the Business Central admin center. For more information, see Restoring an environment and Automated backups - Azure SQL Database.

Your data is safe with us. Should anything go wrong, different resources within Microsoft take action. If an Azure region is temporarily unavailable, for example, the customers' data is preserved using automatic geo-redundant backups, so your data becomes available again once the Azure region is back online. All these steps are triggered automatically. Read a general description of how Azure maintains their service level agreements at High availability for Azure SQL Database and SQL Managed Instance. In extreme cases, such as if the region would be expected to be offline longer, we would start the process of restoring the data from the various Business Central environments geo-redundant backups into another region within the same geography. Although such cases happen rarely, recovering data into another Azure region is a standard, well-described

internal procedure, which we practice regularly as a part of our audits and internal drills.

Similarly, we apply automated tasks for performance tuning, high availability, disaster recovery, and backups. For more information about these types of task, see the Azure SQL docs.

Service level agreements (SLA)

Business Central online is governed under the Modern Lifecycle Policy. The service level agreement terms are described in the document that you can download from the **Service Level Agreements for Microsoft Online Services** section on the Licensing terms page.

Furthermore, administrators can monitor a tenant's health and specify upgrade windows in the Business Central Administration Center.

Databases are protected by automatic backups that are kept for 30 days. Administrators of a Business Central tenant can't directly access or manage these backups because they're managed automatically by Microsoft. But admins can restore their environments to a specific point in time in the past using the Business Central admin center. For more information, see Restoring an environment and Automated backups - Azure SQL Database.

For more information about Azure SQL, see High availability for Azure SQL Database and SQL Managed Instance.

Service updates

Business Central online is a service that consists of a Microsoft-maintained platform and business functionality. Microsoft partners can provide more business functionality, such as to address specific industry or localization needs. Both business functionality and service components are monitored continuously and updated as appropriate. Generally, new capabilities are made available as part of major updates. Critical fixes are rolled out as soon as possible after they passed tests and have been verified in Microsoft's protected staging environment. For more information, see Major Updates of Business Central Online. You can always refer to the release plan for an overview of new and upcoming functionality, and you can keep an eye out for the minor updates at aka.ms/bclastminorupdate.

For each environment, administrators can set a maintenance window for when Microsoft is allowed to update that environment. For more information, see Managing Updates in the Business Central Admin Center. Microsoft then schedules updates of the business functionality to be applied during these maintenance windows.

An exception to this type of schedule is the continuous updates to the underlying service. The service components apply to multiple environments, such as all tenants in a region. So Microsoft schedules those updates to a time when traffic is lower in each region, typically during the evening or night. Typically, these service updates are transparent to any users, as the service is designed to manage traffic in a way that any users still working in Business Central are not affected by these service updates.

> **TIP**
> All updates that Microsoft applies to Business Central online are also shipped with the subsequent cumulative update for Business Central. For an example, see Update 17.1 for Microsoft Dynamics 365 Business Central online 2020 release wave 2.

Performance Overview

2/17/2021 • 2 minutes to read • Edit Online

The following sections help you understand and improve the performance of Business Central. The content is centered around the different ways a functional consultant, a developer, or an administrator can make changes with a performance impact.

- Visit Performance Tips for Business Users to learn more about tips on how you can work with end-users to improve the performance.
- Visit How Application Configurations Affect Performance to learn about how in-product configurations affect performance.
- Visit Performance Articles for Developers to learn about how to code for performance in AL, and how to identify performance issues using the Performance Toolkit extension. The extension is available for free on AppSource.
- Visit Performance in Business Central Online to learn more about performance in the Business Central service.
- Visit Performance of Business Central On-Premises Installations to learn more about the various ways the different components in Business Central can be configured to achieve better performance for an on-premises installation.
- Visit How to Work with a Performance Problem to learn more on how to tackle a performance problem.

The video series *Performance Considerations when Building an App* is also a good starting point to learn more about performance of Business Central:

- Performance Considerations when Building an App, Part I

  https://www.youtube.com/embed/MooYL05V11Y

  This first part of performance considerations videos focuses on basic principles. It makes you aware of why it is essential to consider performance in every line of code you write, and it introduces the performance implications of the general architectural document and posting design patterns of Business Central.

- Performance Considerations when Building an App, Part II

  https://www.youtube.com/embed/VN7V4GyULtY

  Learn about best practices on implementing the existing data retrieval methods, learn how to greatly improve performance by minimizing server roundtrips, and get introduced to important dos and don'ts when coding for performance.

How Application Configurations Affect Performance

2/17/2021 • 4 minutes to read • Edit Online

The sections in this article are tips and tricks on how to set up Business Central for performance and also describe how in-product configurations affect the performance of Business Central.

Uninstall extensions that you don't use

Any extensions that you install can affect the overall system performance. So if you've installed an app from AppSource, but later discover it's not needed, then uninstall it. The same advice applies to the extension that comes preinstalled in an environment. For example, uninstall all migration extensions after you've migrated data, or if you don't intend to migrate data.

Run things in the background

It's often desirable to offload work from the user session to happen in the background. Examples are:

- Schedule long running reports to run in background
- Schedule jobs (for example posting) to run in background
- Enable background posting in areas where your business is using reservations and item tracking using serial and lot numbers
- Adjust item costs as a periodic background job. Don't adjust automatically.

> **TIP**
> don't run job queues too frequently.

Avoid locking

When the Business Central database needs to have exclusive access to a table or a data row, it will issue a lock. If another session needs to access a locked resource, it needs to wait until the session holding the lock is finished with its work. There are a few places in the Business Central application where you can reduce the risk of locking.

Use number series that allow gaps

Number series in Business Central are shared resources that sometimes cause locking issues. Not all records that you create in Business Central are financial transactions that must use sequential numbering. Customer cards, sales quotes, and warehouse activities are examples of records that are assigned a number from a number series. They aren't subject to financial auditing and can be deleted. For all such number series, consider using number series that allow gaps to avoid locking issues. For more information, see Gaps in Number Series.

Be cautious with the Rename/Copy company operations

The **Rename company** and **Copy company** operations aren't intended to run while business transactions are being applied to Business Central. First, the operations are likely to induce locks on the tables that data is copied from. These locks will block users from transacting in the company. Second, the operations use resources on the database, which can in turn cause resource starvation for users working in other companies.

If you must do a **Rename/Copy company** operation, it's highly recommended to do it outside working hours. Turn off scheduled jobs to avoid locking issues.

The **Copy Company** operation also has a number of long term effects including the following:

- Increased database size
- Upgrade operations take longer
- Larger .bacpac files when requesting backups from the Business Central administration center

  This also means that export/import operations involving .bacpac files take longer

> **NOTE**
> For Business Central online, the **Rename company** operation is no longer supported. Instead, you can change a company's display name.

Periodic activities that maintain performance

Block inactive customers, vendors, or items to improve filtering and searching on document data entry

- Block Customers
- Block Vendors
- Block Items from Sales or Purchasing

Performance effect of enabling integration on a table

There's a performance overhead involved in enabling integration on an entity such as **Customer** or **Contact**. Only enable integration if you intend to integrate with Dynamics 365 Sales. Enable it only on the required entities.

For more information, see Synchronizing Data in Business Central and Dynamics 365 Sales.

Functionality with known performance impact

These areas of the application are known to cause a performance impact and require extra testing with realistic data setup before they're rolled out.

- Security filtering mode
- Inventory Posting
- Dimensions
- Dynamic Order tracking
- Automatic reservation
- Item tracking and Lot/SN Expiration dates
- Change log

Manage the database access intent on reports, API pages, and queries

Business Central supports the **Read Scale-Out** feature in Azure SQL Database and SQL Server to load-balance analytical workloads. **Read Scale-Out** is built in to Business Central online, but it can also be enabled for on-premises.

Read Scale-Out applies to queries, reports, or API pages. With these objects, instead of sharing the primary, they can be set up to run against a read-only replica. This setup essentially isolates them from the main read-write workload. This way, they won't affect the performance of business processes.

A drawback of reading from a replica is that it introduces a slight delay compared to reading from the primary database. **Read Scale-Out** is controlled by the DataAccessControl property on objects. This property determines whether to use a replica if one is available. If this delay isn't acceptable for an object, you can overwrite the default database access intent from the UI. For more information, see Managing Database Access Intent

Don't do these things

Finally, make sure that you don't repeat these performance mistakes that we have seen cause massive performance issues for customers:

- Don't adjust cost item entries with a high frequency.
- Don't set up a change log for everything. For more information, see Auditing Changes in Business Central.
- Don't run job queues too frequently.
- Don't adjust item costs automatically if you have many item entries. Run in the background instead.
- Don't postpone setting up global dimensions, because it can be a heavy operation when you have much data. Set up correct global dimensions to avoid changing them later on.
- Don't run the **Copy company** operation during business hours.

Performance Tips for Business Users

2/17/2021 • 4 minutes to read • Edit Online

This section describes how you can work with end-users to improve the performance that each individual experiences with Business Central.

Choosing a desktop browser

Business Central supports multiple browsers. Each browser offers a variety of features and capabilities. The browser plays a significant role in the responsiveness and fluidity of the user interface.

- Where possible, avoid older browsers such as Internet Explorer and Edge Legacy. Modern browsers generally offer better performance. See the list of supported and recommended browsers for Business Central online and Business Central on-premises.

  > **IMPORTANT**
  > Business Central will end support for Internet Explorer and Edge Legacy in April 2021. Consider switching to a modern browser, such as the new Microsoft Edge, before support ends.

- Always keep your browser updated to the latest version, which may include the latest performance enhancements.
- Some Business Central performance features and optimizations, such as page caching, are only available for modern browsers.

Browsers and page caching

The overall structure of a page (but not business data) is cached on the client device when a page is accessed the first time. The next time that same page is accessed, the layout of the page will be immediately displayed, while the latest data is fetched from the Business Central service. To take full advantage of page caching, Business Central requires a modern browser with access to the browser's storage mechanisms.

BROWSER	PAGE CACHING AVAILABILITY
Microsoft Edge	Available
Chrome	Available
Safari	Partly available. In some cases, users won't benefit from page caching across sessions.
FireFox	Partly available. In some cases, users won't benefit from page caching across sessions.
Edge Legacy	Unavailable
Internet Explorer	Unavailable

IMPORTANT

Browsers that run in private or guest mode typically discard browser storage when the browser window is closed. This discards cached data and users won't be able to take advantage of page caching the next time they sign into Business Central. Users relying on private or guest browsing to work across multiple identities and organizations are advised to use browser profiles instead.

Any browser policies or settings that restrict access to local storage or the browser's IndexedDB may prevent Business Central from applying performance optimizations.

Choosing a network connection

If a choice of networks is available, consider connecting to a secure network that has lower latency. In general, the user interface performs better when latency is low.

Keep powered up

Newer browsers and operating systems are generally better at handling resources such as memory, network, and storage. Some devices will automatically limit resources available to the browser when running on battery power. Consider keeping laptops and similar devices plugged in to a power source for best performance.

Making pages load faster

Business Central has numerous mechanisms that make the user interface more responsive and help pages load faster. For example:

- List pages load records in small batches while the user scrolls through the list, allowing it to scale to very large tables.
- The overall structure of a page (but not business data) is cached on the client device after a page is accessed the first time.
- The time taken to load any page is also affected by the number of controls shown on the page. Users can improve performance on complex pages using these methods:
  - By *collapsing* secondary content that may be needed only occasionally. For example, when the FactBox pane on a page is collapsed, Business Central saves time from attempting to process and display all the related facts.
  - By *hiding* secondary content entirely from the page. For example, hiding Role Center parts or columns that are not used by the user, department, or organization will also improve the time needed to load the page. Learn more about Personalizing Your Workspace.

Agility of navigating and entering data

Raw speed is not the only factor that determines whether users have a pleasant and performant experience. Business Central provides numerous features that increase efficiency when exploring, navigating and entering data:

- Keyboard Shortcuts
- Focusing on lists
- Quick Entry
- Finding Pages and information with Tell Me
- Finding Pages and Reports with the Role Explorer
- Optimize your workspace for data entry
- Entering or editing using Microsoft Excel

Attaching pictures and other files

High quality images or large documents can take time to process or download from Business Central. Consider the following that may improve performance when working with files:

- Reduce the size or quality of any images or photos that you upload. Some addon apps for Business Central that capture images from your device may also include settings for image quality.
- To avoid having to download files repeatedly simply to preview them, consider storing files on external storage that allows previewing of pictures and documents, such as SharePoint Online. You can then create a link from a record in Business Central to that file. Generally reducing the number of images and documents stored in Business Central also lightens the load of routine database maintenance tasks.
  Learn how to Manage Attachments, Links, and Notes on Cards and Documents.

Searching and filtering records

Search in lists searches all columns in a table. To avoid resource starvation on broad data searches, a search might be subject to a timeout in which case the user will see a *"Searching for rows is taking too long. Try to search or filter using different criteria."* message.

Users experiencing slow search in lists should consider using a column filter instead. Learn about Searching and Filtering.

Performance Articles For Developers

2/17/2021 • 16 minutes to read • Edit Online

In this article, you can read about ways to tune performance when developing for Business Central.

- Writing efficient pages
- Writing efficient Web Services
- Writing efficient reports
- AL performance patterns
- Efficient Data access
- Testing and validating performance
- Tuning the Development Environment

Writing efficient pages

There are many patterns that a developer can use to get a page to load faster. Consider the following patterns:

- Avoid unnecessary recalculation
- Do less
- Offloading the UI thread

Pattern - Avoid unnecessary recalculation

To avoid unnecessary recalculation of expensive results, consider caching the data and refresh the cache regularly. Let's say you want to show the top five open sales orders or a VIP customers list on the role center. The content of such a list probably doesn't change significantly every hour. There's no need to calculate that from raw data every time the page is loaded. Instead, create a table that can contain the calculated data and refresh every hour/day using a background job.

Another example of unexpected recalculation is when using query objects. In contrast to using the record API, query results aren't cached in the primary key cache in the Business Central server. Any use of a query object will always go to the database. So, sometimes it's faster to not use a query object.

Pattern - Do less

One way to speed up things is to reduce the work that the system must do. For example, to reduce slowness of role centers, consider how many page parts are needed for the user. Another benefit of a simple page with few UI elements can also be ease of use and navigation.

Remove calculated fields from lists if they aren't needed, especially on larger tables. Also, if indexing is inadequate, calculated fields can significantly slow down a list page.

Consider creating dedicated lookup pages instead of the normal pages when adding a lookup (the one that looks like a dropdown) from a field. Default list pages will run all triggers and FactBoxes even if they aren't shown in the lookup. For example, Business Central 2019 release wave 1 added dedicated lookup pages for Customer, Vendor, and Item to the Base Application.

Pattern - Offloading the UI thread

To get to a responsive UI fast, consider using Page Background Tasks for calculated values, for example, the values shown in cues.

For more information about Page Background Tasks, see Page Background Tasks.

Writing efficient Web Services

Business Central supports for Web services to make it easier to integrate with external systems. As a developer, you need to think about performance of web services both seen from the Business Central server (the endpoint) and as seen from the consumer (the client).

Endpoint performance

Anti-patterns (don't do this)

Avoid using standard UI pages to expose as web service endpoints. Many things, like FactBoxes, aren't exposed in OData, but will use resources to compute.

Things that have historically caused performance issues on pages that are exposed as endpoints are:

- Heavy logic in `OnAfterGetCurrRecord`
- Many SIFT fields
- FactBoxes

Avoid exposing calculated fields, because calculated fields are expensive. Try to move them to a separate page or to refactor the code so the value is stored on the physical table (if applicable). Complex types are also a performance hit because they take a lot of time to calculate.

Don't use temp tables as a source if you have many records. Temp tables that are based on APIs are a performance hit. The server has to fetch and insert every record, and there's no caching on data in temp tables. Paging becomes difficult to do in a performant manner. A rule of thumb is if you have more than 100 records, don't use temp tables.

Don't insert child records belonging to same parent in parallel. This condition causes locks on parent and Integration Record tables because parallel calls try to update the same parent record. The solution is to wait for the first call to finish or use $batch, which will make sure calls get executed one after another.

Performance patterns (do this)

- Instead of exposing UI pages as web service endpoints, use the built-in API pages because they've been optimized for this scenario. Select thehighest API version available. Don't use the beta version of the API pages. To read more about API pages, see API Page Type.
- The choice of protocol for the endpoint can have a significant impact on performance. Favor OData version 4 for the fastest performance. It's possible to expose procedures in a codeunit as an OData end point using unbound actions. To read more about OData unbound actions, see Creating and Interacting with an OData V4 Unbound Action.
- For OData, limit the set ($filter or $top) if you're using an expensive $expand statement. If you've moved calculated fields to a separate page, then it's good practice to limit the set to get better performance.
- If you want OData endpoints that work as data readers (like for consumption in Power BI), consider using API queries and set DataAccessIntent = ReadOnly. For more information, see API Query Type and DataAccessIntent Property.
- Use OData transaction $batch requests where relevant. They can reduce the number of requests the client needs to do when errors occur. For more information, see Tips for working with the APIs - OData transactional $batch requests.

Web service client performance

The online version of Business Central server has set up throttling limits on web service endpoints to ensure that excessive traffic can't cause stability and performance issues.

Make sure that your client respects the two HTTP status codes *429 (Too Many Requests)* and *504 (Gateway Timeout)*.

- Handling status code 429 requires the client to adopt a retry logic while providing a cool off period. You can apply different strategies, like:
  - Regular interval retry
  - Incremental intervals retry
  - Exponential back-off
  - Randomization
- Handling status code 504 - Gateway Timeout requires the client to refactor the long running request to execute within time limit by splitting the request into multiple requests. Then, deal with potential 429 codes by applying a back off strategy.

Read more about web service limits, see Working with API limits in Dynamics 365 Business Central.

The same advice applies for outgoing web service calls using the AL module HttpClient. Make sure your AL code can handle slow response times, throttling, and failures in external services that you integrate with.

Writing efficient reports

Reports generally fall into two categories. They can be specific to a single instance of an entity, like an invoice. Or, they can be of a more analytical nature that joins data from multiple instances of multiple entities. Typically, performance issues in reports lie in the latter category. The following articles contain advice about implementing faster reports:

- To use queries to implement fast reports, see Queries in Business Central.
- Compared to Word layouts, RDL layouts can result in slower performance with document reports, especially for actions related to the user interface (like sending emails). For more information, see Creating an RDL Layout Report.

Read more about how to tune RDLC reports here:

- RDLC Performance Optimization Tips

Efficient extracts to data warehouses

When establishing a data warehouse, you typically need to do two types of data extraction:

1. A historical load (all data from a given point-in-time)
2. Delta loads (what's changed since the historical load)

The fastest way to get a historical load from Business Central online is to get a database export as a BACPAC file (using the Business Central admin center) and restore it in Azure SQL Database or on a SQL Server. For on-premises installations, you can just take a backup of the tenant database.

The fastest (and the less disruptive) way to get delta loads from Business Central online is to set up API queries configured with read-scaleout and use the data audit field **LastModifiedOn** (introduced in version 17.0) on filters.

AL performance patterns

Knowledge about different AL performance patterns can greatly improve the performance of the code you write. In this section, we'll describe the following patterns and their impact on performance.

- Use built-in data structures
- Run async (and parallelize)
- Use set-based methods instead of looping

- Other AL performance tips and tricks

Pattern - Use built-in data structures

AL comes with built-in data structures that have been optimized for performance and server resource consumption. Make sure that you're familiar with them to make your AL code as efficient as possible.

When concatenating strings, make sure to use the `TextBuilder` data type and not repeated use of the `+=` operator on a `Text` variable. For more information, see TextBuilder Data Type.

If you need a key-value data structure that is optimized for fast lookups, use a `Dictionary` data type. For more information, see Dictionary Data Type.

Use a `List` data type if you need an unbound "array" (where you would previously create a temporary table object). For more information, see List Data Type.

Use the `Media` or `Mediaset` data types instead of the `Blob` data type. The `Media` and `MediaSet` data types have a couple advantages over the `Blob` data type when working with images. First of all, a thumbnail version of the image is generated when you save the data. You can use the thumbnail when loading a page and then load the larger image asynchronously using a page background task. Second, data for `Media` and `MediaSet` data types is cached on the client. Data for the `Blob` data type is never cached on the server. It's always fetched from the database.

Pattern - Run async (and parallelize)

It's often desirable to offload AL execution from the UI thread to a background session.

Here are some examples of this pattern:

- Don't let the user wait for batches
- Split large tasks into smaller tasks and run them in parallel

There are many different ways to spin up a new task:

- Job Queue
- TaskScheduler.CreateTask
- StartSession
- Page Background Task

They come with different characteristics as described in this table:

METHOD TO START A NEW TASK	PROPERTIES
Page Background Task	Can (will) be canceled Read-only Call back to parent session Lightweight
StartSession	Created immediately Runs on same server Not as controlled as a Page Background Task
Task	Queued up Any server in a cluster can start it Survives server restarts No logging

METHOD TO START A NEW TASK	PROPERTIES
Job queue	Scheduled Recurrence Any server in a cluster can start it Survives server restarts Logging of results

Pattern - Use set-based methods instead of looping

The AL methods such as `FindSet`, `CalcFields`, `CalcSums`, and `SetAutoCalcFields` are examples of set-based operations that are much faster than looping over a result set and do the calculation for each row.

- CalcFields, CalcSums, and Count
- FindSet Method

One common use of the `CalcSums` method is to efficiently calculate totals.

Try to minimize work done in the `OnAfterGetRecord` trigger code. Common performance coding patterns in this trigger are:

- Avoiding `CalcFields` calls. Defer them until the end.
- Avoiding repeated calculations. Move them outside the loop, if possible.
- Avoid changing filters. This pattern requires the server to throw away the result set.

Consider using a query object if you want to use a set-based coding paradigm. These pros and cons for using query objects:

PROS FOR USING A QUERY OBJECT	CONS FOR USING A QUERY OBJECT
- Will bypass the AL record API where server reads all fields. - With a covering index, you can get fast read performance for tables with many fields. - Can join multiple tables.	- Query object result sets aren't cached in the servers primary key (data) cache. - No writes are allowed. - You can't add a page on a query object.

Read more about query objects here:

- Using Queries Instead of Record Variables
- Query object
- Query overview
- TopNumberOfRows Property
- Query Objects and Performance

Pattern - Use partial records when looping over data or when table extension fields aren't needed

When writing AL code for which the fields needed on a record are known, you can use the partial records capability to only load out these fields initially. The remaining fields are still accessible, but they'll be loaded as needed.

Partial records improve performance in two major ways. First, they limit the fields that need to be loaded from the database. Loading more fields leads to more data being read, sent over the connection, and created on the record. Second, partial records limit the number of table extensions that need to be joined.

The performance gains compound when looping over many records, because both effects scale with the number of rows loaded.

For more information, see Using Partial Records.

Other AL performance tips and tricks

If you need a fast, non-blocking number sequence that can be used from AL, refer to the number sequence object type. Use a number sequence object if you:

- Don'twant to use a number series.
- Can accept holes in thenumberrange.

For more information, see NumberSequence Data Type.

Table extension impact on performance

Table extensions are eager-joined in the data stack when accessing the base table. It's currently not possible to define indexes that span base and extension fields. So avoid splitting your code into too many table extensions. Also, be careful about extending central tables, such as General Ledger entry, because it can severely hurt performance.

An alternative when doing data modeling for extending a table with new fields is to use a related table and define a FlowField on the base table.

Here are the pros and cons of the two data models:

DATA MODEL FOR EXTENDING A TABLE	PROPERTIES
Table extension	Fields can be added to lists and are searchable. Always loaded with the base table. Expensive at runtime but easy to use. Use only for critical fields.
Related tables	Need to set up table relations. Dedicated page for editing. Requires flow field to be shown in lists. Doesn't affect performance of base table. Excellent for FactBoxes.

Limit your event subscriptions

The following are best practices for getting performant events:

- There's no significant cost of having a publisher defined.
- Static automatic has a cost over manually binding (there's an overhead of creating and disposing objects).
- Codeunit size of the subscriber matters. Try to have smaller codeunits.
- Use single instance codeunits for subscribers, if possible.

Table events change the behavior of SQL optimizations on the Business Central Server in the following ways:

- The Business Central Server will issue SQL update/delete statements row in a for loop rather than one SQL statement.
- They impact `ModifyAll` and `DeleteAll` methods that normally do bulk SQL operations to be forced to do single row operations.

Efficient data access

Many performance issues are related to how data is defined, accessed, and modified. It's important to know how concepts in AL metadata and the AL language translate to their counterparts in SQL.

Tables and keys

Many performance issues can be traced back to missing indexes (also called keys in Business Central), but index design is often not a key skill for AL developers. For best performance, even with large amounts of data, it's imperative to design appropriate indexes according to the way your code will access data.

These articles on indexing are worth knowing as an AL developer:

- Table Keys and Performance in Business Central
- Key Property
- About SQL Server indexes

Indexes have a cost to update, so it's recommended to not use them too frequently.

SumIndexField Technology (SIFT)

SumIndexField Technology (SIFT) lets you quickly calculate the sums of numeric data type columns in tables, even in tables with thousands of records. The data type includes Decimal, Integer, BigInteger, and Duration. SIFT optimizes the performance of FlowFields and query results in a Business Central application.

Ensure appropriate SIFT indices for allFlowFields of type sum or count.

Read more about SIFT here:

- SumIndexField Technology (SIFT)
- SIFT and Performance
- Tuning and Tracing
- SIFT and SQL Server

The following article can help you find missing SIFT indexes on FlowFields:

Troubleshooting: Long Running SQL Queries Involving FlowFields by Disabling SmartSQL.

How AL relates to SQL

The AL programming language, to some degree, hides how data is read and written to the database. To effectively code for performance, you need to know how AL statements translate to the equivalent SQL statements.

The following articles cover how AL relates to SQL:

- AL Database Methods and Performance on SQL Server
- Data Access
- Data read/write performance
- Bulk Inserts

How to get insights into how AL translates to SQL

If you want to track how Business Central Server translates AL statements to SQL statements, use either database statistics in the AL debugger or telemetry on long running queries.

Read more here:

- About database statistics in the AL debugger
- Telemetry on Long Running SQL Queries

Using Read-Scale Out

Business Central supports the **Read Scale-Out** feature in Azure SQL Database and SQL Server. **Read Scale-Out** is used to load-balance analytical workloads in the database that only read data. **Read Scale-Out** is built in as part of Business Central online, but it can also be enabled for on-premises.

Read Scale-Out applies to queries, reports, or API pages. With these objects, instead of sharing the primary, they can be set up to run against a read-only replica. This setup essentially isolates them from the main read-write workload so that they won't affect the performance of business processes.

As a developer, you control **Read Scale-Out** on report, API page, and query objects by using the DataAccessControl property. For more information, see Using Read Scale-Out for Better Performance.

Testing and validating performance

It's imperative to test and validate a Business Central project before deploying it to production. In this section, you find resources on how to analyze and troubleshoot performance issues and guidance on how to validate performance of a system.

Performance Unit Testing

You can use the `SessionInformation` data type in unit tests that track the number of SQL statements or rows read. Use it before and after the code to be tested. Then, have assert statements that check for normal behavior.

For more information, see SessionInformation Data Type.

Performance Scenario and Regression Testing

Use the Performance Toolkit to simulate the amount of resources that customers use in realistic scenarios to compare performance between builds of their solutions.

The Performance Toolkit helps answer questions such as, "Does my solution for Business Central support X number of users doing this, that, and the other thing at the same time?"

For more information, see The Performance Toolkit Extension.

Performance Throughput Analysis

The Performance Toolkit doesn't answer questions such as, "How many orders can Business Central process per hour?" For this kind of analysis, test the time to execute key scenarios using the Performance Toolkit, and then use the guidance on Operational Limits for Business Central Online. For advanced analysis, consider using a queueing model such as a M/M/1 queue to answer whether the system can process the workload you intend.

Performance telemetry

The following performance telemetry is available in Azure Application Insights (if that has been configured for the environment):

- Database locks
- Long Running AL operations
- Long Running SQL Queries
- Page views
- Reports
- Sessions started
- Web Service Requests

Read more in this section: How to use telemetry to analyze performance

Troubleshooting

The following articles can be of help in troubleshooting performance issues:

- Find missing SIFT indexes for FlowFields by Disabling SmartSQL
- Use Page Inspection to find extensions participating on a page
- Viewing Table Sizes

Tuning the Development Environment

The following articles explain what you can do as a developer to tune your development environment for better performance:

- Optimizing Visual Studio Code for AL Development
- Code Analysis on large projects

Performance in Business Central Online

2/17/2021 • 2 minutes to read • Edit Online

These sections describe how settings in Business Central online impact the performance experience of users.

Performance on sandbox environments

The Business Central service offers the ability to test code in a sandbox environment before to deploying to a production environment.

Users often can't get the same performance and reliability in Business Central online as they get in their production environments. This discrepancy is caused by a couple factors.

Firstly, it's the nature of the operations that our users do in the sandbox environments. Some typical examples of this are:

- Frequent publishing and installation of per-tenant extensions (PTEs), which aren't yet of production quality
- Creating multiple companies for different users to try their scenarios
- Initializing test environments with data via RapidStart

Secondly, it is because the sandbox services configuration. Sandbox configurations tend to be more dense and have different thresholds than production. Read more about sandboxes in Managing Environments.

Telemetry

For monitoring and analyzing performance issues in the Business Central service, we recommend connecting Azure AppInsights to the environments that you want to get signals from. For more information, see Sending telemetry to Microsoft Azure Application Insights.

Here are some ways where telemetry can help troubleshoot performance issues:

AREA	TELEMETRY	WHY
Page Background Task	Authorization signal	Each page background task will open a new session. Any expensive action in the OnCompanyOpen trigger will slow down opening new sessions.
Sign-in	Authorization signal	Any expensive action in the OnCompanyOpen trigger will slow down opening new sessions.
Something was slow during this period of time	Company lifecycle signal	Check whether a copy-company operation was running while the performance issue occurred.
Something was slow during this period of time	Database locks signal	Maybe the performance issue was because of locking in the database.
Suddenly the XYZ page is slow	Extension lifecycle signal	Maybe an extension was installed that interferes with the page in question.

AREA	TELEMETRY	WHY
Some pages or reports are slow to load	Long running SQL queries	Investigate whether the data operations on the page or report are taking a long time to complete.
A report is slow	Report signal	Check whether the report is reading more data than you expected.
System UI feels slow	Web service requests signal	Calling your environment too aggressively with web service requests can affect performance of the system.

This page shows an overview of all currently available signals: Monitoring and Analyzing Telemetry.

Operational Limits

Large-scale cloud services use shared resources to achieve the best possible use of resources – like IO, CPU, and memory. To ensure that tenants run smoothly, limits are applied to various operations. These limits control things like: how long an operation can run before being canceled, or how many operations can run at the same time. Some of the operations include:

- Web service requests
- Report and query generation
- Client connections
- Background task execution

Without limits, one tenant could use many more resources than other tenants. Other tenants running on the same resources might experience slower performance. Although you can't change these limits, it's useful to be aware of them. For more information about the limits, see Operational Limits for Business Central Online.

Performance of Business Central On-Premises Installations

2/17/2021 • 6 minutes to read • Edit Online

In this section, we highlight a number of resources that might be useful when doing performance investigations and tuning of on-premises installations. On-premises, in this context, means deployment to any environment that isn't the Business Central service. Running Business Central on Azure resources is also considered on-premises.

Content is ordered into the following groups:

- Tuning the technology stack
- Scaling Business Central
- Measure and monitor performance

Performance tuning the technology stack

A Business Central installation typically consists of the following components, which can be tuned to improve performance:

- Client
- Web Server
- Server (service-tier)
- Database

Client

There are three things of importance when dealing with client performance:

- Hardware of the computer running the client
- Choice of browser
- Network bandwidth and latency between the client and the data center running Business Central

These subjects are described in Performance Tips for Business Users.

Web Server

You can improve web server performance by configuring Kernel-mode authentication:

- Configuring Kernel Mode Authentication on the Business Central Web Server

Business Central Server (service-tier)

You can adjust the following Business Central Server settings related to database performance.

SERVER SETTING	DESCRIPTION	READ MORE
BufferedInsertEnabled	Disabling bulk inserts can be helpful when you're troubleshooting failures that occur when inserting records.	Disabling Bulk Inserts
DisableQueryHintForceOrder	Check if this setting is set to **true**.	Configuring Query Hints for Optimizing SQL Server Performance with Business Central

SERVER SETTING	DESCRIPTION	READ MORE
DisableQueryHintLoopJoin	Check if this setting is set to **true**.	Configuring Query Hints for Optimizing SQL Server Performance with Business Central
DisableSmartSql	If the performance of loading a page that contains FlowFields in Business Central is bad, you might want to try isolating and testing FlowField queries separately.	Troubleshooting: Long Running SQL Queries Involving FlowFields by Disabling SmartSQL
EnableCloudReplicationMaintenance	Specifies whether to keep the cloud replication status in the database up to date. When enabled, synchronize operations on tenants and extensions will update records in the **Intelligent Cloud Status** table, and set change tracking on tables that are configured to replicate data. Enabling this setting isn't required for migrating most on-premises solutions to the cloud, and you'll improve synchronization and upgrade performance by disabling it.	Configuring Business Central Server - EnableCloudReplicationMaintenance
EnableProfileCacheSynchronization	Specifies whether profile cache synchronization across multiple server instances is enabled. However, enabling this setting may lower the tenant performance.	Configuring Business Central Server - EnableProfileCacheSynchronization
SqlBulkImportBatchSize	Specifies how many SQL memory chunks that a data import must be distributed across. Lowering the value increases the number of network transfers and decreases performance. But it also lowers the amount of memory that the server instance consumes.	Database Settings

SERVER SETTING	DESCRIPTION	READ MORE
SessionEventTableRetainInterval NonInteractiveSessionsLogRetainInterval SessionEventTablePurgeLookupPeriod	The system table **2000000111 Session Event** stores information about sessions between Business Central Server instances and clients. Entries are recorded for various events, like when a user signs in or out of the client, or when a web service request starts or stops. It's a good idea to limit the number of entries in this table because performance can be adversely affected as the table size grows. Under normal conditions, you shouldn't experience any problems. But there might be situations or periods, typically dealing with web service calls, during which a high number of session events occur. These three settings enable you to control the table size by specifying how long to keep entries in the table before they are automatically deleted.	Configuring Business Central Server - Session Event Table

Web service limits

You can adjust server instance settings related to web service calls to implement resource governance (and avoid resource starvation on the server instances) here:

- SOAP Services Settings
- OData Services Settings

Task Scheduler

You can adjust server instance settings related to the task scheduler to implement resource governance (and avoid resource starvation on the server instances) here:

- Maximum Concurrent Running Tasks

Database (SQL Server or Azure SQL database)

First of all, make sure that you avoid common pitfalls in your SQL Server setup:

- Installation Considerations for Microsoft SQL Server and Business Central
- Setting SQL Compatibility Level to Optimize Database Performance

Tune data access

These articles describe how you can use SQL Server table partitioning and data compression to get faster data retrieval:

- Using SQL Server table partitioning
- Using SQL Server data compression

SQL Server vs. Azure SQL database

Read more about the difference between SQL Server and Azure SQL database performance:

- Differences between Azure SQL database and SQL Server

Using Read-Scale Out

If you run the Business Central database in a High Availability architecture, you can use the built-in **Read Scale-Out** feature in Azure SQL Database or SQL Server to load-balance read-only workloads. **Read Scale-Out** uses

read-only replicas instead of sharing the primary database. This way, read-only workloads (reports, queries, and API pages) will be isolated from the main read-write workload (codeunits). They won't affect the performance of business processes.

For more information, see Using Read Scale-Out for Better Performance.

Troubleshooting database performance issues

These articles can be useful when troubleshooting database performance issues:

- Troubleshooting: Long Running SQL Queries Involving FlowFields by Disabling SmartSQL
- Configuring Query Hints for Optimizing SQL Server Performance with Business Central
- Troubleshooting: Using Query Store to Monitor Query Performance in Business Central

Performance of BACPAC generation

The sqlpackage is the command-line tool used to generate BACPAC/DACPAC files. The February 2019 update of sqlpackage solved a significant schema-compare performance issue that occurred when generating scripts. Make sure you use **version 18.1 or later** if you experience issues in BACPAC generation performance.

You can also limit the amount of SQL schema to restore from a BACPAC. On tables used only with temporary record variables and pages, set the TableType property to **Temporary**.

Performance impact on setting up CDC on SQL Server

There's a performance impact if you set up CDC on the database. SQL Server will be slower (depending on the retention period used). You'll also need storage for the extra data.

Performance impact of enabling Transparent Data Encryption (TDE)

Enabling Transparent Data Encryption (TDE) has a slight performance degradation on SQL Server because it needs CPU resources for the encryption/decryption of data.

Scaling Business Central

On compute (Business Central Server and Web servers), it's possible to scale horizontally by separating Business Central Server instances and Web servers on different nodes. For more information, see Configuring Business Central Server.

It's also common on larger installations to separate traffic based on client type (direct UI and OData traffic to different Business Central Server instances); possibly cohosting Business Central Server instances and Web servers on the same nodes.

The Business Central Server has a built-in thread dispatcher for AL execution. If you have more cores available, then the dispatcher allows for more parallel execution. But keep in mind that AL execution is single-threaded until the Business Central 2019 release wave 2 (when we introduced async processing). For long running operations, such as heavy reports, using faster CPUs will give better performance.

On the database side, make sure SQL Server has enough resources for sessions (both CPU and memory) and try to optimize the setup of SQL Server to Business Central. For more information, see Installation Considerations for Microsoft SQL Server and Business Central.

Measure and Monitor performance

The following resources describe ways that you measure and monitor performance in your Business Central on-premises installation:

- Monitoring Business Central Server Events
- Tools for Monitoring Performance Counters and Events
- Troubleshooting: Using the Event Viewer to Monitor Long Running SQL Queries in Business Central
- Troubleshooting: Using Query Store to Monitor Query Performance in Business Central

How to Work with a Performance Problem

How to work with a performance problem

2/17/2021 • 2 minutes to read • Edit Online

What do you do if users complain that "it is slow"? In this section, we describe a troubleshooting process that can help to guide you to find the root cause of the problem.

Before getting started on solving a performance tuning problem, it often helps to define and quantify "slow" and also negotiate acceptable values for execution time of "slow" operations with users. This is sometimes called "establishing a baseline."

To define baselines for performance, and to test whether new code or extensions introduce a performance regression, you can use the Performance Toolkit extension. The extension makes it easier to simulate and compare user experiences to your baseline. The following are examples of when the extension can help:

- When you want to ensure that new code does not introduce a regression.
- In a sandbox environment when, for example, the number of users running the same process increases significantly.
- When you want to roll out a new process, or install a new extension.

To solve a performance problem, a common pattern is to do iterations of the following:

1. Measure system performance and collecting performance data
2. Locate a bottleneck
3. Eliminate the bottleneck

and continue until the "slow" operations are comparable to the established baseline.

Business Central Web Services

2/17/2021 • 5 minutes to read • Edit Online

Business Central supports two types of web services: SOAP and OData. Web services are a lightweight, industry-standard way to make application functionality available to a variety of external systems and users. Developers can create and publish functionality as web services, where they expose pages, codeunits, or queries, and even enhance a page web service by using an extension codeunit. When Business Central objects are published as web services, they are immediately available on the network.

Business Central web services are stateless and do not preserve the values of global variables or single-instance codeunits between calls.

Comparing SOAP and OData Web Services

Developers planning to create Microsoft Dynamics NAV web services may need to decide which type of web service is better suited to their needs. The following table shows the types of web service applications that you can create for the web service protocols.

OBJECT	SOAP WEB SERVICES	ODATA WEB SERVICES
Pages	Yes: Create, Read, Update, and Delete operations (CRUD)	Yes: Create, Read, Update, and Delete operations (CRUD)
Codeunits	Yes	Yes (through OData unbound actions)
Queries	No	Yes: Read-only

Business Central supports OData web services in addition to the SOAP web services that have been available since Microsoft Dynamics NAV 2009.

SOAP Web Services

SOAP web services allow full flexibility for building operation-centric services. They provide industry standard interoperability. Windows Communication Framework (WCF) has supported SOAP services since its initial release in .NET Framework 3.0, and later releases of the .NET Framework have added additional support and default bindings to make it easier to build SOAP services using WCF.

The most common type of messaging pattern in SOAP is the Remote Procedure Call (RPC), where one network node (the client) sends a request message to another node (the server), and the server sends a response message to the client.

OData Web Services

The OData standard is well suited for web service applications that require a uniform, flexible, general purpose interface for exposing create retrieve update delete (CRUD) operations on a tabular data model to clients. OData is less suited for applications that are primarily RPC-oriented or in which data operations are constrained to certain prescribed patterns. OData supports Representational State Transfer (REST)-based data services, which enable resources, identified using Uniform Resource Identifiers (URIs), and defined in an abstract data model (EDM), to be published and edited by web clients within corporate networks and across the Internet using simple Hypertext Transfer Protocol (HTTP) messages. OData services are lightweight, with functionality often referenced directly in the URI.

Whereas SOAP web services expose a WSDL document, OData web services expose an EDMX document

containing metadata for all published web services.

OData is supported in PowerPivot, a data-analysis add-in to Microsoft Excel that provides enhanced Business Intelligence capabilities. PowerPivot supports sharing and collaboration on user-generated business intelligence solutions in a Microsoft SharePoint Server environment. For more information about PowerPivot, see https://www.powerpivot.com/.

The extensions to the Atom Publishing Protocol defined in the AtomPub extensions to the OData protocol documentation (which you can download here) describe how REST-based data services can enable resources, identified using URIs and defined in an abstract data model (EDM), to be published and edited by web clients within corporate networks and across the Internet using simple HTTP messages.

In addition to the AtomPub format, the OData implementation in Business Central also supports the JSON format, a somewhat less verbose format that may perform better in low-bandwidth environments.

Page Web Services

When you expose a page as an OData web service, you can query that data to return a service metadata (EDMX) document, an AtomPub document, or a JavaScript Object Notation (JSON) document. You can also write back to the database if the exposed page is writable. For more information, see OData Web Services.

When you expose a page as a SOAP web service, you expose a default set of operations that you can use to manage common operations such as Create, Read, Update, and Delete. Page-based web services offer built-in optimistic concurrency management. Each operation call in a page-based web service is managed as a single transaction.

For SOAP services, you can also use extension codeunits to extend the default set of operations that are available on a page. Adding an extension codeunit to a page is useful if you want to perform operations other than the standard Create, Read, Update, and Delete operations. The benefit of adding an extension codeunit to a page is that you can make the web service complete by adding operations that are logical to that service. Those operations can use the same object identification principle as the basic page operations.

Codeunit Web Services

For SOAP services only, codeunit web services provide you with the most control and flexibility. When a codeunit is exposed as a web service, all functions defined in the codeunit are exposed as operations.

Query Web Services

When you expose a Business Central query as an OData web service, you can query that data to return a service metadata (EDMX) document or an AtomPub document. For more information about how to create and use Business Central queries, see Query Object.

Web Services and Regional Settings

Data is formatted according to the value of the **Services Language** setting for the relevant Business Central Server instance. The default value is **en-us**. This means that Business Central Server interprets all incoming data as the specified culture, such as dates and amounts.

If you know that the **Services Language** setting is always en-us, for example, your code can be based on that assumption. In a multilanguage environment, you will see more predictable transformations of data if data that is transmitted through web services is in a consistent culture.

Similarly, you can use the **ServicesOptionFormat** setting to specify how Business Central Server must understand option values. If you set the **ServicesOptionFormat** setting to *OptionString*, Business Central Server understand option values as the *name* of the option value, which is always en-us. If you set the setting to *OptionCaption*, web service data will be interpreted in the language specified by the **Services Language** setting.

Web Services in Multitenant Deployments

If your Business Central solution is used in a multitenant deployment architecture, you must make sure that any code that generates or consumes a web service specifies the relevant tenant. Web services are set up in the application, but typically you want to consume company-specific and tenant-specific data.

If you use the GETURL method, the generated URL will automatically apply to the user's tenant ID. For more information, see GETURL Method.

The URL for accessing a web service in a multitenant deployment must specify the tenant ID in one of two ways: As a query parameter, or as a host name. If you use host names for tenants, the host name must be specified as an alternative ID.

For example, the following URL consumes the **Customer** ODATA web service for a specific tenant:

```
https://localhost:7048/BC130/OData/Company('CRONUS-International-Ltd.')/Customer?Tenant=Tenant1
```

For more information, see Multitenant Deployment Architecture.

Terms of Use

2/17/2021 • 2 minutes to read • Edit Online

By accessing or using any API or Web service exposed in Business Central, you are agreeing to the Microsoft APIs Terms of Use.

For more information, see Microsoft APIs Terms of Use.

Publishing a Web Service

2/17/2021 • 3 minutes to read • Edit Online

You can set up a web service in the Business Central Web client or Dynamics NAV Client connected to Business Central. You must then publish the web service so that it is available to service requests over the network. Users can discover web services by pointing a browser at the computer that is running Business Central Server and requesting a list of available services. When you publish a web service, it is immediately available over the network for authenticated users. All authorized users can access metadata for Business Central web services, but only users who have sufficient Business Central permissions can access actual data.

Creating and Publishing a Web Service

The following steps explain how to create and publish a web service.

1. Open the client.
2. Choose the icon, enter **Web Services**, and then choose the related link.
3. In the **Web Services** page, choose **New**.
4. In the **Object Type** column, select **Codeunit**, **Page**, or **Query**.

   > **NOTE**
   > **Codeunit** and **Page** are valid types for SOAP web services. **Page** and **Query** are valid types for OData web services.

5. In the **Object ID** column, select the object ID of the object that you want to expose. For example, to expose the customer card as a web service, enter **21**.

   If the database contains multiple companies, you can choose an object ID that is specific to one of the companies.

6. In the **Service Name** field, assign a name to the web service. For example, if you expose the customer card as a web service, enter **Customers**.

   - **Codeunit** and **Page** are valid types for SOAP web services. **Page** and **Query** are valid types for OData web services.
   - If the database contains multiple companies, you can choose an object ID that is specific to one of the companies.
   - The service name is visible to consumers of your web service and is the basis for identifying and distinguishing web services, so you should make the name meaningful.
   - If you are setting up integration with Microsoft Outlook using codeunit 5313, then you must use **DynamicsNAVsynchOutlook** as the service name.

7. Select the check box in the **Published** column.

   When you publish the web service, in the **OData URL** and **SOAP URL** fields, you can see the URLs that are generated for the web service. You can test the web service immediately by choosing the links in the **OData URL** and **SOAP URL** fields. Optionally, you can copy the value of the field and save it for later use.

After you publish a web service, it is available on the Business Central Server computer that you were connected

to when you published. The web service is available across all Business Central Server instances running on the server computer.

You can verify the availability of that web service by using a browser, or you can choose the link in the **OData URL** and **SOAP URL** fields in the **Web Services** window. The following procedure illustrates how you can verify the availability of the web service for later use.

Verify the availability of a web service

1. In your browser, enter the relevant URL. The following table illustrates the types of URLs that you can enter. For SOAP web services, use the following format for your URI.

WEB SERVICE TYPE	SYNTAX	EXAMPLE
SOAP	https://*Server.SOAPWebServicePort*/*ServerInstance*/WS/*CompanyName*/services/	https://localhost:7047/BC160/WS/CRONUS International Ltd./services/
OData	https://*Server.ODataWebServicePort*/*ServerInstance*/OData/Company('*CompanyName*')	https://localhost:7048/BC160/OData/Company('CRONUS International Ltd.')

   The company name is case-sensitive.

   > **TIP**
   > If you're using the Business Central API, you can see a description of the endpoints at Endpoints for the APIs for Dynamics 365 Business Central On-Premises and Online.

2. Review the information that is displayed in the browser. Verify that you can see the name of the web service that you have created.

When you access a web service, and you want to write data back to Business Central , you must specify the company name. You can specify the company as part of the URI as shown in the examples, or you can specify the company as part of the query parameters. For example, the following URIs point to the same OData web service and are both valid URIs.

```
https://localhost:7048/<serverinstance>/OData/Company('CRONUS International Ltd.')/Customer
```

```
https://localhost:7048/<serverinstance>/OData/Customer?company='CRONUS International Ltd.'
```

Unpublishing a web service

To unpublish a webs service, clear the **Published** check box. This will make the web service inaccessible.

> **IMPORTANT**
> When you unpublish a web service that is marked for **All Tenants**, other web services that use the same object will be automatically unpublished, even though the **Published** check box is still selected for these web services.

Handling UI Interaction When Working with Web Services

2/17/2021 • 2 minutes to read • Edit Online

Whether you are publishing or consuming web services, exceptions and dialog boxes that may be displayed while code runs must be handled correctly. Exceptions must be handled to prevent the system from ending the web service client execution. You can handle exceptions in the following ways:

- Writing conditional code inside Business Central.
- Writing the code in the web service client application.

The most robust solution is to use both methods.

Publishing Web Services

When publishing a web service, you must make sure that the code that you are publishing does not assume the ability to interact with a user through the UI. You can use the GUIALLOWED Method to suppress the UI. For example, you can use this method to determine whether a codeunit is being called from the client or from a web service client. You must make sure to suppress errors when a codeunit is called from a web service client.

When implementing a conditional code check in Business Central, you should implement the check only around code that could cause an error. You should not encapsulate the whole business logic.

> **NOTE**
> The server returns the following exception when trying to invoke a dialog UI through a web service: **Microsoft.Dynamics.Nav.Types.Exceptions.NavNCLCallbackNotAllowedException: Callback functions are not allowed.**

AL Keywords That Can Cause Faults or Exceptions

Variables of the Dialog Data Type or any of the methods listed as dialog methods can cause callback not allowed exceptions when they are called from a web service application. The Message Method (Dialog) is the only method in this category that does not cause an exception.

Other keywords that you should not use are:

- PAGE.RUN
- PAGE.RUNMODAL
- ACTIVATE
- REPORT.RUN
- REPORT.RUNMODAL
- HYPERLINK
- FILE.UPLOAD
- FILE.DOWNLOAD

You should also avoid operations on client-side Automation and .NET Framework interoperability objects.

Consuming Web Services

You must handle exceptions in client code that calls a Business Central web service. Appropriate exception capturing code should be included around any call to a Business Central web service.

Publish a Web Service

Managing Time Zones with Web Services

2/17/2021 • 2 minutes to read • Edit Online

Business Central Server provides a **Services Default Time Zone** setting for defining the time zone in which web service calls run. This setting affects both SOAP and OData web services, in addition to NAS Services.

Time Zone Configuration

You can configure the Services Default Time Zone using the Server Administration Tool, Business Central Windows PowerShell Cmdlets, or by directly editing CustomSettings.config, the configuration file for the relevant Business Central Server instance. The following table describes the possible values for the **Services Default Time Zone** setting.

VALUE	DESCRIPTION
UTC	Specifies that all business logic for services on the server instance runs in Coordinated Universal Time (UTC). This is the default value. This is how web services business logic was handled in Microsoft Dynamics NAV 2009 SP1 and Microsoft Dynamics NAV 2009.
Server Time Zone	Specifies that services use the time zone of the computer that is running Business Central Server.
ID of any Windows time zone	Specifies that services use a Windows time zone as defined in the system registry under HKEY_LOCAL_MACHINE\SOFTWARE\Microsoft\Windows NT\CurrentVersion\Time Zones. For example, Romance Standard Time is a valid Windows time zone value.

When a web service writes data back to Business Central , dates and times are based on the setting of the Services Default Time Zone setting. However, the web service consumer can override the setting and specify a different time zone.

> **NOTE**
> Business Central Server stores dates and times as UTC. When a web service receives data from Business Central Server, the time zone is UTC even if the Services Default Time Zone setting is set to a different time zone.

For example, if the Services Default Time Zone setting is set to **UTC+3**, the following table describes two scenarios where a web service consumer modifies Business Central data and sends this back to Business Central Server.

WEB SERVICE CHANGES THE DATETIME FIELD TO	BUSINESS CENTRAL SERVER INTERPRETS THE DATETIME VALUE AS	BUSINESS CENTRAL SERVER SAVES THE DATETIME VALUE AS
01/01/2014 17:00 UTC+1	01/01/2014 17:00 UTC+1	01/01/2014 16:00 UTC
01/01/2014 17:00	01/01/2014 17:00 UTC+3	01/01/2014 14:00 UTC

Preserving Data When Working with a Statically Generated Proxy

2/17/2021 • 2 minutes to read • Edit Online

You can lose data if you develop a web service client that interacts with a statically generated proxy. Similarly, a client web service cannot detect if a field has been added to or removed from a page since a proxy was last generated. This topic describes an approach for avoiding this pitfall.

Avoiding Data Loss by Building the Proxy with Your Client Application

To avoid data loss due to a statically generated proxy, automatically generate your proxy whenever you build your client.

Assume you have published page 21, Customer Card, as a SOAP web service with **Customer** as the **Service Name** value. Add a service reference to this web service from a C# console application and insert the following code in the `Main` method:

```
static void Main(string[] args)
{
  CustomerService.Customer_Service svc
      = new CustomerService.Customer_Service();
  svc.UseDefaultCredentials = true;
  Customer c = svc.Read("01121212");
  Console.WriteLine(c.Name);
  Console.ReadKey();
}
```

When you run the application, you will see the following output (assuming the CRONUS International Ltd. demonstration database):

```
Spotsmeyer's Furnishings
```

Then go back to page 21 and set the **Name** property for the control that is bound to the **Name** field to **CustomerName**, and save the page.

Finally, switch back to the console application without updating the web reference and run the code. Instead of getting an error message that indicates that the web request does not match the web service description, you do not get an error message, and `Console.WriteLine` shows an empty line.

Web Services Overview

Web Services Authentication

2/17/2021 • 4 minutes to read • Edit Online

When users send a request for a web service, they're authenticated according to the credential type that is configured for Business Central Server. To access a web service, users must provide valid credentials for the credential type being used. If Business Central is configured for Windows credential type, then users are automatically authenticated against the Windows account that their computer is running under. In this case, they aren't prompted for their credentials. For other credential types, users are prompted to enter a user name and password.

> **IMPORTANT**
> With Business Central online, the use of access keys (Basic Auth) for web service authentication is deprecated. We recommend that you use OAuth2 instead. For more information, see Using OAuth to Authorize Business Central Web Services.

About NavUserPassword and AccessControlService credential types

If your solution uses NavUserPassword or AccessControlService as the credential type, users can access data through SOAP and OData web services by specifying a password or access key. You set up the user accounts in the Business Central client, based on how they'll access Business Central data. For example, if you set up a user account that will allow an external application to read Business Central data through a web service, you can generate a web service access key and specify that key for the relevant user accounts. Then, you add the access key to the configuration of the application that consumes the web service. In contrast, when users access Business Central data through a web service in Microsoft Excel, for example, they specify a password instead of a web service access key.

Business Central also supports OAuth authentication on OData and SOAP endpoints. OAuth is an open standard for authorization that provides client applications with secure delegated access to server resources. OAuth enables you to extend single sign-on with Microsoft 365 to Business Central web services. For more information, see Using OAuth to Authorize Business Central Web Services (OData and SOAP).

> **IMPORTANT**
> If the Business Central Server is configured to use NavUserPassword or AccessControlService authentication, then the username, password, and access key can be exposed if the SOAP or OData data traffic is intercepted and the connection string is decoded. To avoid this condition, configure SOAP and OData web services to use Secure Socket Layer (SSL).

Unicode characters in user name or password

When Business Central data is consumed by a web service, users can't be authenticated if their user name or password contains Unicode characters. This condition is a limitation in the basic authentication mechanism that is defined in the HTTP/1.1 specification.

The same limitation applies to exposing Business Central data in external products such as a browser or a Microsoft .NET Framework assembly.

How to use an Access Key for SOAP and OData Web Service

Authentication

If your solution is configured for NavUserPassword or AccessControlService authentication, then you can configure Business Central user accounts to include an access key that can be used instead of a password to authenticate SOAP and OData web service requests. A web service access key is a random 44 character string that is associated with the user account. Because it can only be used for SOAP and OData web services, it doesn't require the same level of protection as a password.

Generate a Web Service Access Key

Follow these instructions to generate a web service access key for a user. You perform these steps from the user setup in Business Central client.

1. Choose the icon, enter **Users**, choose the related link, and then open the user account that you want to edit.
2. In the **Web Service Access** section, select the **Web Service Access Key** field.
3. In the **Set the Web Service Access Key** window, if you do not want the key to expire, select the **Key Never Expires** check box. If you want the key to expire, set the **Key Expiration Date** field to the date.
4. Choose the **OK** button.

   The access key is automatically generated. If you're signed in as the user that you modified, the key appears in the **Web Service Access Key** field. Otherwise, the key is masked so only asterisks (*) are shown.

Implement the Web Service Access Key

Typically, you would create a user account strictly for web services, and then use the account's credentials, which include the user name and access key, in a web service application. For example, if you develop your own web service application, then you can design your application to programmatically pass the credentials to the web service. Some applications let you provide the connection credentials through a user interface. The steps for implementing the web service access key are done in Business Central client.

1. Create a user specifically for web services.

   For more information, see Manage Users and Permissions.
2. Sign in as the new user, and generate a web service access key in the user account.
3. Use the access key in the web service application.

Authentication and Credential Types

Using Security Certificates with Business Central On-Premises

2/17/2021 • 7 minutes to read • Edit Online

> **NOTE**
> Dynamics NAV Client connected to Business Central is **DISCONTINUED AFTER:** Business Central Spring 2019.

You use certificates to help secure connections over a wide area network (WAN), such as connections from the Business Central Web Server, Dynamics NAV Client connected to Business Central, and web services to the Business Central Server. Implementing security certificates on your deployment environment requires modifications to various components, like the Business Central Server, Business Central Web Server, and clients.

About Security Certificates

A certificate is a file that Business Central Server uses to prove its identity and establish a trusted connection with the client that is trying to connect. Business Central can support the following configurations:

- *Chain trust*, which specifies that each certificate must belong to a hierarchy of certificates that ends in a root authority at the top of the chain.
- *Peer trust*, which specifies that both self-issued certificates and certificates in a trusted chain are accepted.

The implementation in this section describes the chain trust configuration, which is the more secure option.

> **NOTE**
> An instance of Business Central Server that has been configured for secure WAN communication always prompts users for authentication when they start the client, even when the client computer is in the same domain as Business Central Server.

Certificates for Production

In a production environment, you should obtain a certificate from a certification authority or trusted provider. Some large organizations may have their own certification authorities, and other organizations can request a certificate from a third-party organization.

Obtaining Certificates

You implement chain trust by obtaining X.509 service certificates from a trusted provider. These certificates and their root certification authority (CA) certificates must be installed in the certificates store on the computer that is running Business Central Server. The CA certificate must also be installed in the certificate store on computers that are running the Business Central Web Server and Dynamics NAV Client connected to Business Central so that clients can validate the server.

Most enterprises and hosting providers have their own infrastructure for issuing and managing certificates. You can also use these certificate infrastructures. The only requirement is that the service certificates must be set up for key exchange and therefore must contain both private and public keys. Additionally, the service certificates that are installed on Business Central Server instances must have the Service Authentication and Client Authentication certificate purposes enabled.

IMPORTANT

Microsoft recommends against using wildcard SSL certificates in Business Central installations. Wildcard certificates pose security risks because if one server or sub-domain is compromised, all sub-domains may be compromised. Wildcard certificates also introduce a new style of impersonation attack. In this attack, the victim is lured to a fraudulent resource in the certified domain through phishing. Conventional certificates detect this attack, because the user's browser checks that the private key is hosted on a server whose name matches the one displayed in the browser's address window.

Run the Certificates Snap-in for Microsoft Management Console

Some of the following procedures use the Certificates snap-in for Microsoft Management Console (MMC). If you do not already have this snap-in installed, you can add it to the MMC. For information see Add the Certificates Snap-in to an MMC.

Install and Configure the Certificates

You install the security certificates on the computers running Business Central Server, Business Central Web Server, and Dynamics NAV Client connected to Business Central. The root CA certificate and the service certificate are used in the configuration, but client certificates are not.

Install Certificates on components

1. Follow the installation instructions that are available from your certificate provider to install the root CA and service certificates on the following computers:

   - Install the root CA on the computer that is running Business Central Server and all computers that are running Business Central Web Server instances and Dynamics NAV Client connected to Business Central.
   - Install the service certificate on the computer that is running Business Central Server only.

2. Make sure that the **Server Authentication** and **Client Authentication** certificate purposes are enabled for the service certificate.

   A certificate can be enabled for several different purposes. The **Server Authentication** and **Client Authentication** purposes must be enabled. You can enable or disable other purposes to suit your requirements.

   You enable certificate purposes by using the Certificates Snap-in for MMC. For more information, see Modify the Properties of a Certificate.

Grant access to the Business Central Server service account

After you have installed the root CA and the service certificate on the computer running Business Central Server, you must grant access to the service account that is associated with the server so that the service account can access the service certificate's private key.

1. In the left pane of MMC, expand the **Certificates (Local Computer)** node, expand the **Personal** node, and then select the **Certificates** subfolder.
2. In the right pane, right-click the certificate, select **All Tasks**, and then choose **Manage Private Keys**.
3. In the **Permissions** dialog box for the certificate, choose **Add**.
4. In the **Select Users, Computers, Service Accounts, or Groups** dialog box, enter the name of the dedicated domain user account that is associated with Business Central Server, and then choose the **OK** button.
5. In the **Full Control** field, select **Allow**, and then choose the **OK** button.

6. In the right pane, select the certificate.
7. In the **Certificate** dialog box, choose the **Details** tab, and then select the **Thumbprint** field.
8. Copy the value of **Thumbprint** field.

   For example, copy the hexadecimal characters to text editor, such as Notepad. Delete all spaces from the thumbprint string. If the thumbprint is `c0 d0 f2 70 95 b0 3d 43 17 e2 19 84 10 24 32 8c ef 24 87 79`, then change it to `c0d0f27095b03d4317e219841024328cef248779`.

   > **TIP**
   > It is important that the thumbprint does not contain any invisible extra characters; otherwise you will experience problems when using it later. To avoid this, see Certificate thumbprint displayed in MMC certificate snap-in has extra invisible unicode character.

Configure the Business Central Server instance

The Business Central Server instance configuration includes several settings for certificates and enabling remote logins. You can modify a server instance by using Business Central Server Administration tool or Business Central Administration Shell. For details about how to modify a server instance, see Configuring Business Central Server.

1. Run the Business Central Server Administration tool.
2. Under **General**, change the following settings for the Business Central Server instance.

SETTING	NEW VALUE	DESCRIPTION
Credential Type	`NavUserPassword`, `Username`, or `AccessControlService`	The default value is `Windows`. When you change it to `NavUserPassword`, `Username`, or `AccessControlService`, client users who connect to the server are prompted for user name and password credentials.
Certificate Thumbprint	Value of the **Thumbprint** field in the previous procedure.	Remove any leading or trailing spaces in the thumbprint.

3. If you want to use secure web services, then under **SOAP Services** and **OData Services**, select the **Enable SSL** check box.
4. Save and the new values for the server instance.
5. Restart the Business Central Server instance.

   If there is a problem, see Windows Event Viewer.

Configure the Business Central Web Server and Dynamics NAV Client connected to Business Central

The chain trust configuration allows client users to log on to one or more instances of Business Central Server as long as their login credentials have been associated with user accounts in Business Central. The client validates that the server certificate is signed with the root CA.

After you have installed the root CA on the computer running the Business Central Web Server or Dynamics

NAV Client connected to Business Central, you must modify the client configuration file.

Modify the Business Central Web client configuration file

1. On the computer that is installed the Business Central Web Server, open the navsetting.json configuration file in a text editor, such as Notepad.

2. Change the following settings:

KEY	NEW VALUE	DESCRIPTION
ClientServicesCredentialType	`NavUserPassword`, `Username`, or `AccessControlService`	The default value is `Windows`. When you change it to `NavUserPassword`, `Username`, or `AccessControlService`, client users who connect to the server are prompted for user name and password credentials.
DnsIdentity	The subject name of the service certificate	The default value is <identity>. Replace this with the subject name or common name (CN) of the certificate that is used on the computer that is running Business Central Server.

3. Save the navsettings.json configuration file.

Modify the Dynamics NAV Client connected to Business Central configuration file

1. Open the ClientUserSettings.config configuration file.

   The location of this file is *Users\<username>\AppData\RoamingLocal\Microsoft\Dynamics 365 Business Central*.

   By default, this file is hidden. Therefore, you may have to change your folder options in Windows Explorer to view hidden files.

   > **NOTE**
   > If you want to change default Dynamics NAV Client connected to Business Central settings for all future users, edit the default ClientUserSettings.config file — that is, the one in C:\Program Files (x86)\Microsoft Dynamics 365 Business Central\160. Be sure that you run your text editor with Administrator privileges when you do so.

2. Modify the following settings.

KEY	NEW VALUE	DESCRIPTION
ClientServicesCredentialType	`NavUserPassword`, `Username`, or `AccessControlService`	The default value is `Windows`. When you change it to `NavUserPassword`, `Username`, or `AccessControlService`, client users are prompted for user name and password credentials.

KEY	NEW VALUE	DESCRIPTION
DnsIdentity	The subject name of the service certificate.	The default value is <identity>. Replace this with the subject name or common name (CN) of the certificate that is used on the computer that is running Business Central Server.

3. Save and close the ClientUserSettings.config file.

When starting the Dynamics NAV Client connected to Business Central, users are prompted for a valid user name and password.

Web Services Best Practices

2/17/2021 • 2 minutes to read • Edit Online

This article provides recommendations that you can implement to make your web services applications easier to understand and maintain.

RECOMMENDATION	EXAMPLE
Use the HTTPS protocol to send data between Business Central and the web service consumer. The examples in this section use the HTTP protocol to illustrate the setup, but we recommend that your solution uses transport-level security.	In the application that consumes the Business Central web service, require that URIs are accessed by using HTTPS. For example, a more secure URI for the OData web services on your local computer is `https://localhost:7048/BC130/OData/`.
Use singular forms of names. This provides meaningful singular entity names in the generated proxy classes.	When publishing page 21, Customer Card, use **Customer** as the service name instead of **Customers** or **CustomerCard**.
Avoid using spaces and other characters because they are transformed to underscores or other characters that may not be displayed as you want and could lead to ambiguity.	When publishing page 42, Sales Order, remove the space and use **SalesOrder** as the service name.
Use Pascal casing when you combine words. Pascal casing capitalizes the first character of each word, including acronyms and initialisms that are more than two letters long.	Use **SalesOrder** or **ContactPerson** as the service name.

SOAP Web Services

2/17/2021 • 2 minutes to read • Edit Online

SOAP web services enable full flexibility for building operation-centric services. They provide industry-standard interoperability and channel and host pluggability.

You can use SOAP to interact with page or codeunit web services in Business Central .

SOAP Web Service URIs

2/17/2021 • 2 minutes to read • Edit Online

Web service users can discover published web services by pointing a browser or a tool such as the Web Services Discovery Tool at the computer running Business Central Server and getting a list of available services. For SOAP web services, you typically enter a URI in a browser to view a list of available Business Central web services or to view a schema for a particular web service.

URIs for SOAP Web Services

To display all published SOAP web services that are exposed by a Business Central Server instance, use a URI of the following type:

```
https://<Server>:<Port>/<ServerInstance>/WS/<CompanyName>/services
```

The following example displays all published SOAP web services that are exposed for the CRONUS International Ltd. demonstration database.

```
https://localhost:7047/BC130/WS/CRONUS%20International%20Ltd/services
```

To view the schema for a particular service, use a URI of the following type:

```
https://<Server>:<Port>/<ServerInstance>/WS/<CompanyName>/Page/<servicename>
```

The following example displays the schema for the Customer service for the CRONUS International Ltd. demonstration database.

```
https://localhost:7047/BC130/WS/CRONUS%20International%20Ltd/Page/Customer
```

You can also use a URI for a codeunit web service, as shown in the following example:

```
https://localhost:7047/BC130/WS/CRONUS%20International%20Ltd/Codeunit/Letters
```

Basic Page Operations

2/17/2021 • 2 minutes to read • Edit Online

When you publish a page as a SOAP web service, it has a set of default operations that are exposed to consumers of the web service.

These operations match the actions a user can perform by interacting with a page using the RoleTailored client. The same page- and table-based business logic is executed.

The following table lists the operations and provides links to reference pages.

Pages that are backed by virtual tables are not editable through web services. When such pages are published as SOAP web services, the only operations that are available are **Read**, **ReadMultiple**, and **IsUpdated**.

The term *entity* that is used in the operation signatures describes the data type that is used. The actual entity is defined by the page that is exposed because it contains all controls that are defined on the page. The controls are normally bound to the page's source table. The entity also contains a key that is a special string that uniquely identifies the source table record with a timestamp. This key is used as an argument in many page operations.

All basic page operations are atomic, which means that either all relevant records are affected or no records are affected, even if there was a faulty condition in only one record.

OPERATION	DESCRIPTION AND SIGNATURE
Create Operation	Creates a single record. `void Create(ref Entity entity)`
CreateMultiple Operation	Creates a set of records. `void CreateMultiple(ref Entity[] entity)`
Delete Operation	Deletes a single record. `bool Delete(string key)`
Delete_*part* Operation	Deletes a subpage of the current page. `bool Delete_<part>(string key)`
GetRecIdFromKey	Converts a key, which is always part of the page result, to a record ID. `string GetRecIdFromKey(string key)`
IsUpdated Operation	Checks if an object has been updated since the key was obtained. `bool IsUpdated(string key)`
Read Operation	Reads a single record. `Entity Read(string no)`

OPERATION	DESCRIPTION AND SIGNATURE
ReadByRecId Operation	Reads the record that is identified by RecId. You can use GetRecIdFromKey to obtain a record ID. If the record is not found, then the operation returns null. `Entity ReadByRecId(string formattedRecId)`
ReadMultiple Operation	Reads a filtered set of records, paged. `Entity [] ReadMultiple(Entity_Filter[] filterArray, string bookmarkKey, int setSize)`
Update Operation	Updates a single record. `void Update(ref Entity entity)`
UpdateMultiple Operation	Updates a set of records. `void UpdateMultiple(ref Entity[] entity)`

SOAP Web Services

Create Operation

2/17/2021 • 2 minutes to read • Edit Online

Creates a single record. The supplied record object is overwritten with the version that is created by the page.

Method Signature

```
void Create(ref Entity entity)
```

Parameters

PARAMETER	DESCRIPTION
entity	Type: Entity A variable of a specific object type that represents the page.

Results

RESULT NAME	DESCRIPTION
entity	Type: Entity A variable of a specific object type that represents the page. Contains the latest values that are present on the page after the record has been inserted into the table.

Faults

SOAP FAULT MESSAGE	DESCRIPTION
The [*record name*] already exists. Identification fields and values: [*field*]=[*value*]	Indicates that the record insertion would violate key constraints.

Other faults are possible if they are generated by the AL code.

Usage Example

```
Customer cust = new Customer();
cust.Name = "Customer Name";
service.Create(ref cust);
```

See Also

Basic Page Operations

CreateMultiple Operation

2/17/2021 • 2 minutes to read • Edit Online

Creates a set of records. The supplied record object is overwritten with the version that is created by the page.

Method Signature

```
void CreateMultiple(ref Entity[] entity)
```

Parameters

PARAMETER	DESCRIPTION
entity[]	Type: An array of Entities An array of a specific object type that represents the page.

Results

RESULT NAME	DESCRIPTION
entity[]	Type: An array of Entities An array of a specific object type that represents the page. Contains the latest values that are present on the page after the records have been inserted into the table.

Faults

SOAP FAULT MESSAGE	DESCRIPTION
The [*record name*] already exists. Identification fields and values: [*field*]=[*value*]	Indicates that the insertion of at least one of the records would violate key constraints.

Other faults are possible if they are generated by the AL code.

The CreateMultiple operation is executed as a single transaction unless the AL code explicitly commits the transaction. Either all or none of the records are inserted unless the application code does not explicitly call COMMIT.

Usage Example

```
Customer[] custArray = new Customer[3];
for (int i = 0; i < custArray.Length; i++)
{
  custArray[i] = new Customer();
  custArray[i].Name = "Customer Name " + i.ToString();
}
service.CreateMultiple(ref custArray);
```

See Also

Basic Page Operations

Delete Operation

2/17/2021 • 2 minutes to read • Edit Online

Deletes a single record.

Executing the Delete operation in a web service first executes the OnDeleteRecord Trigger on the designated page. If application code in the OnDeleteRecord trigger for the page returns **true**, then the OnDelete Trigger for the corresponding table is executed. If no fault occurs, then the record is deleted from the database.

If the application code in the trigger returns **false**, then the OnDelete trigger is not executed. This does not necessarily mean that the record has not been deleted because it may have been deleted explicitly by the application code for the page's OnDeleteRecord trigger.

The return value from the Delete operation is the return value from the page's OnDeleteRecord trigger.

If Delete returns **true**, then the record has been deleted. If Delete has thrown a fault, then the record has not been deleted. But when Delete returns **false**, then this indicates that there was application logic involved, and the record may or may not have been deleted.

Method Signature

```
bool Delete(string key)
```

Parameters

PARAMETER	DESCRIPTION
key	Type: String The bookmark of the record, including both primary key and concurrency information.

Results

RESULT NAME	DESCRIPTION
Delete_Result	Type: Boolean The value that is returned by the OnDeleteRecord page trigger.

Faults

SOAP FAULT MESSAGE	DESCRIPTION
Other user has modified [*record name*].	Indicates that another user or process has modified the record after it has been retrieved for this delete operation.
[*record name*] [*field*] [*value*] does not exist.	Indicates that the record has been deleted by another user or process after it has been retrieved for this delete operation.

SOAP FAULT MESSAGE	DESCRIPTION

Other faults are possible if they are generated by the AL code.

Usage Example

```
      using System;
using System.Collections.Generic;
using System.Text;

namespace ConsoleApplication
{
    // Imports newly generated web service proxy.
    using WebService;

    class Program
    {
        static void Main(string[] args)
        {
            // Creates instance of service and sets credentials.
            Customer_Service service = new Customer_Service();
            service.UseDefaultCredentials = true;
            Customer cust = new Customer();
            cust.Name = "Customer Name";
            service.Create(ref cust);
            cust = service.Read(cust.No);
            service.Delete(cust.Key);
        }
    }
}
```

See Also

Basic Page Operations

Delete_<part> Operation

2/17/2021 • 2 minutes to read • Edit Online

Deletes records on a subpage of the current page.

This operation is exposed only by pages that have subpages, which are pages that have parts of type Page. For example, the Sales Order page has a part with the name SalesLines, which has PartType equal to Page and PagePartID equal to "Sales Order Subform." The name of the operation that is exposed by the Sales Order page is Delete_SalesLines.

When you call this operation, you delete a record of the subpage. When you call Read on a page that has a subpage, you get the records of the top-level page and the corresponding records of the subpage. To modify them or add to them, you must modify the whole top-level record.

Executing the Delete_<part> operation in a web service first executes the OnDeleteRecord Trigger on the designated record of the subpage. If application code in the OnDeleteRecord trigger for the record of the subpage returns **true**, then the OnDelete Trigger for the corresponding table is executed. If no fault occurs, then the record of the subpage is deleted from the database.

If the application code in the trigger returns **false**, then the OnDelete trigger is not executed. This does not necessarily mean that the record of the subpage has not been deleted because it may have been deleted explicitly by the application code for the page's OnDeleteRecord trigger.

The return value from the Delete_<part> operation is the return value from the page's OnDeleteRecord trigger.

If Delete returns **true**, then the record of the subpage has been deleted. If Delete has thrown a fault, then the record of the subpage has not been deleted. When Delete returns **false**, there was application logic involved, and the record of the subpage may or may not have been deleted.

Method Signature

```
bool Delete_<part>(string key)
```

Parameters

PARAMETER	DESCRIPTION
key	Type: String The bookmark of the record of the subpage, including both primary key and concurrency information.

Results

RESULT NAME	DESCRIPTION
Delete_Result	Type: Boolean The value that is returned by the OnDeleteRecord page trigger.

Faults

SOAP FAULT MESSAGE	DESCRIPTION
Other user has modified [*record name*].	Indicates that another user or process has modified the record of the subpage after it has been retrieved for this delete operation.
[*record name*] [*field*] [*value*] does not exist.	Indicates that the record of the subpage has been deleted by another user or process after it has been retrieved for this delete operation.

Other faults are possible if they are generated by the AL code.

Usage Example

This example presents a console application that is created in Visual Studio after registering and publishing the Sales Order page. After you publish the page as a web service, you must also add a web reference to it. This task is also described in the walkthrough.

```
using Delete_SalesLinesSample.DynamicsNAVService;

namespace Delete_SalesLinesSample
{
    class Program
    {
        static void Main(string[] args)
        {
            DynamicsNAVService.SalesOrder_Binding so = new SalesOrder_Binding();
            so.UseDefaultCredentials = true;

            SalesOrder salesOrder = so.Read("2001");
            Sales_Order_Line[] salesLines = salesOrder.SalesLines;

            if (salesLines.Length > 0)
            {
                string key = salesLines[0].Key;
                so.Delete_SalesLines(key);
            }
        }
    }
}
```

See Also

Basic Page Operations

GetRecIdFromKey

2/17/2021 • 2 minutes to read • Edit Online

Converts a key to a record ID. The key is always part of the page result.

Method Signature

```
string GetRecIdFromKey(string key)
```

Parameters

PARAMETER	DESCRIPTION
key	Type: String The bookmark of the record that includes both primary key and concurrency information.

Results

RESULT NAME	DESCRIPTION
String	Type: String The record ID that was obtained from the key.

Faults

SOAP FAULT MESSAGE	DESCRIPTION
[*record name*] [*field*] [*value*] does not exist.	Indicates that the record has been deleted by another user or process after it has been retrieved for this operation.

Usage Example

```
Customer_Service service = new Customer_Service();
Customer cust = new Customer();
service.UseDefaultCredentials = true;
string id = service.GetRecIdFromKey(cust.No);
cust = service.ReadByRecId(id.ToUpper());
```

See Also

Basic Page Operations

IsUpdated Operation

2/17/2021 • 2 minutes to read • Edit Online

Checks if an object has been updated since the key was obtained. This operation returns **true** if the object has been updated by any user; otherwise, **false**. Concurrency management prevents a record being changed if it has been subsequently updated. This check proactively prevents that failure.

Method Signature

```
bool IsUpdated(string key)
```

Parameters

PARAMETER	DESCRIPTION
key	Type: String The bookmark of the record, including both primary key and concurrency information.

Results

RESULT NAME	DESCRIPTION
IsUpdated_Result	Type: Boolean Returns **true** if and only if another user has modified the record.

Faults

SOAP FAULT MESSAGE	DESCRIPTION
[*record name*] [*field*] [*value*] does not exist.	Indicates that the record has been deleted by another user or process after it has been retrieved for this operation.

Usage Example

```
using System;
using System.Collections.Generic;
using System.Text;

namespace ConsoleApplication
{
    // Imports newly generated web service proxy.
    using WebService;

    class Program
    {
       static void Main(string[] args)
           {
              // Creates instance of service and sets credentials.
              Customer_Service service = new Customer_Service();
              service.UseDefaultCredentials = true;

              Customer cust = new Customer();
              cust.Name = "Customer Name";
              service.Create(ref cust);
              cust = service.Read(cust.No);
              if (!service.IsUpdated(cust.Key))
           {
              // Add code here to modify record.
           }
        }
    }
}
```

See Also

Basic Page Operations

Read Operation

2/17/2021 • 2 minutes to read • Edit Online

Reads a single record.

> **NOTE**
> The signature of an operation changes if the page contains one or more unbound fields in the root content area. If there are unbound fields, then the names from the `SourceExpr` property for the unbound fields are added as the first parameters to the operation. They are added according to the tab order of the page. For an example, see the Item Journal.

Method Signature

```
Entity Read(string no)
```

Parameters

PARAMETER	DESCRIPTION
no	Type: String The primary key of the requested record. This argument is a filter on the primary key and returns the first record that matches the filter. When special characters, such as an apostrophe, equal sign, or ampersand, are part of the key, you must enclose the argument with quotation marks. For example, when you write C# code, you should use standard quotation marks for strings and also use additional single quotation marks around a value, such as `"'A&B'"`.

Results

RESULT NAME	DESCRIPTION
entity	Type: Entity A variable of a specific object type that represents the page. Contains the latest values that are present on the page. If the record with the given primary key does not exist, then no value is returned. In the .NET Framework, a null reference is returned.

Faults

This operation does not return a fault when a matching record is not present. Instead, it returns no value. In C#, you should test whether the result is a null reference. Otherwise, you may get a NullReferenceException

exception.

Faults are possible if they are generated by the AL code.

Usage Example

```
Customer customer = new Customer();
customer.Name = "Customer Name";
service.Create(ref customer);
customer = service.Read(customer.No);
```

See Also

Basic Page Operations

ReadByRecId Operation

2/17/2021 • 2 minutes to read • Edit Online

Reads the record that is identified by the record ID.

Method Signature

```
Entity ReadByRecId(string formattedRecId)
```

Parameters

PARAMETER	DESCRIPTION
formattedRecId	Type: String The RecId that is used to read the record.

Results

RESULT NAME	DESCRIPTION
entity	Type: Entity A variable of a specific object type that represents the page. Contains the latest values that are present on the page. If the record is not found, then the operation returns **null**.

Faults

This operation does not return a fault when a matching record is not present. Instead, it returns **null**. In C#, you should test whether the result is a null reference. Otherwise, you may get a NullReferenceException exception.Faults are possible if they are generated by the AL code.

Usage Example

```
public void ReadById(String id)
{
  Customer_Service service = new Customer_Service();
  Customer cust = new Customer();
  service.UseDefaultCredentials = true;
  cust = service.ReadByRecId(id.ToUpper());
}
```

See Also

Basic Page Operations

ReadMultiple Operation

2/17/2021 • 2 minutes to read • Edit Online

Reads a filtered set of records. This operation returns an array of entities. The ReadMultiple operation allows the consumer of a web service to specify the number of records to be returned at one time. This can reduce load on the server.

> **NOTE**
> Records on a page that were inserted after the page was retrieved are not read. Records on a page may be incorrectly included in the retrieved dataset if they were deleted after the page was retrieved.

Method Signature

```
Entity [] ReadMultiple(Entity_Filter[] filterArray, string bookmarkKey, int setSize)
```

Parameters

PARAMETER	DESCRIPTION
filterArray	Type: Entity_Filter[] An array of record filters.
bookmarkKey	Type: String The last record bookmark of the page that was previously read. To return the first page of results, set *bookmarkKey* to NULL.
setSize	Type: Integer The size of the set to be returned. To return the complete set of results, set *setSize* to zero. To reverse the order of the results, set *setSize* to negative.

Results

RESULT NAME	DESCRIPTION

RESULT NAME	DESCRIPTION
entity[]	Type: An array of Entities An array of a specific object type that represents the page. Contains the latest values that are present on the page. The server will return at most *setSize* records. If all records have been already returned, then subsequent calls will return no records (a 0-element array in C#). You should keep calling the ReadMultiple method until no records are returned.
entity.Key	Type: String The key of the last record read. In C#, you can access it with `Entity[Entity.Length-1].Key`. Pass this as *bookmarkKey* for the next ReadMultiple call.

Faults

This operation does not throw faults when no matching records are present. Instead, it returns an empty record list.

Faults are possible if they are generated by the AL code.

Remarks

Retrieving Last Page

To retrieve the last record of a page, set *setSize* to -1. Using negative numbers in *setSize* sorts the records in descending order.

Entity_Filter

You use the *Entity_Filter* parameter with the ReadMultiple operation. It describes a filter that can be applied on a specific field in a record. The *Entity_Filter* parameter contains two members: Field and Criteria.

- Field contains the name of the field that the filter is applied to. This name comes from the Entity_Fields enum.
- Criteria is of type string and can contain any valid Business Central style filter that is specified in a standard Business Central filter format.

Usage Examples

The following example returns the first 100 customer names that start with an S.

```
List<Customer_Filter> filterArray = new List<Customer_Filter>();
Customer_Filter nameFilter = new Customer_Filter();
nameFilter.Field = Customer_Fields.Name;
nameFilter.Criteria = "S*";
filterArray.Add(nameFilter);
Customer[] custList = service.ReadMultiple(filterArray.ToArray(), null, 100);
```

This example uses the *bookmarkKey* argument to read customer records in batches of 10:

```
Customer_Service service = new Customer_Service();
service.UseDefaultCredentials = true;

const int fetchSize = 10;
string bookmarkKey = null;
List<Customer> customerList = new List<Customer>();

// Reads customer data in pages of 10.
Customer[] results = service.ReadMultiple(new Customer_Filter[] { }, bookmarkKey, fetchSize);
while (results.Length > 0)
{
    bookmarkKey = results.Last().Key;
    customerList.AddRange(results);
    results = service.ReadMultiple(new Customer_Filter[] { }, bookmarkKey, fetchSize);
}

// Prints the collected data.
foreach (Customer customer in customerList)
{
    Console.WriteLine(customer.Name);
}
```

Basic Page Operations

Update Operation

2/17/2021 • 2 minutes to read • Edit Online

Updates a single record. The updated record is passed as a reference and is updated with the latest version.

Method Signature

```
void Update(ref Entity entity)
```

Parameters

PARAMETER	DESCRIPTION
entity	Type: Entity A variable of a specific object type that represents the page.

Results

RESULT NAME	DESCRIPTION
entity	Type: Entity A variable of a specific object type that represents the page. Contains the latest values that are present on the page after the record has been updated by the business logic or another concurrent process.

Faults

SOAP FAULT MESSAGE	DESCRIPTION
Other user has modified [*record name*].	Indicates that another user or process has modified the record after it has been retrieved for this update operation.
[*record name*] [*field*] [*value*] does not exist.	Indicates that the record has been deleted by another user or process after it has been retrieved for this update operation.
The [*record name*] already exists. Identification fields and values: [*field*]=[*value*]	Indicates that the renaming of the record would violate key constraints.

Other faults are possible if they are generated by the AL code.

Usage Example

```
Customer cust = new Customer();
cust.Name = "Customer Name ";
service.Create(ref cust);
cust.Name = cust.Name + "Updated";
service.Update(ref cust);
```

See Also

Basic Page Operations

UpdateMultiple Operation

2/17/2021 • 2 minutes to read • Edit Online

Updates a set of records. The updated array of records is passed as a reference and is updated with the latest version.

> **NOTE**
> The UpdateMultiple operation attempts to update one field at a time. This can cause errors if the updated value in one field prevents another field's value from being valid. You can resolve this by deleting and inserting lines instead of updating fields.

Method Signature

```
void UpdateMultiple(ref Entity[] entity)
```

Parameters

PARAMETER	DESCRIPTION
entity[]	Type: An array of Entities. An array of a specific object type that represents the page.

Results

RESULT NAME	DESCRIPTION
entity[]	Type: An array of Entities An array of a specific object type that represents the page. Contains the latest values that are present on the page after the records have been updated by the business logic or another concurrent process.

Faults

SOAP FAULT MESSAGE	DESCRIPTION
Other user has modified [*record name*].	Indicates that another user or process has modified the record after it has been retrieved for this update operation.
[*record name*] [*field*] [*value*] does not exist.	Indicates that the record has been deleted by another user or process after it has been retrieved for this update operation.
The [*record name*] already exists. Identification fields and values: [*field*]=[*value*]	Indicates that the renaming of the record would violate key constraints.

Other faults are possible if they are generated by the AL code.

The UpdateMultiple operation is executed as a single transaction unless the AL code explicitly commits the transaction. Either all or none of the records are updated provided that the application code does not explicitly call COMMIT.

Usage Example

The following example adds the string "Updated" to the name of the first 100 customer names that start with S.

```
List<Customer_Filter> filterArray = new List<Customer_Filter>();
Customer_Filter nameFilter = new Customer_Filter();
nameFilter.Field = Customer_Fields.Name;
nameFilter.Criteria = "S*";
filterArray.Add(nameFilter);
Customer[] custList = service.ReadMultiple(filterArray.ToArray(), null, 100);
for (int i = 0; i < custList.Length; i++)
{
  custList [i].Name = custList [i].Name + " Updated";
}
service.Update(ref custList)
```

Using SystemService to Find Companies

2/17/2021 • 2 minutes to read • Edit Online

You can use the SystemService service in a SOAP web service application to retrieve a list of companies available in a specific database. A company name is typically part of the URI when you access a Business Central web service, and the system service lets you retrieve names of available companies. If you do not specify a company name in a URI, then the default company is used.

In this procedure, you use the SystemService service to retrieve and print a list of companies in Visual Studio.

Use the SystemService service to find companies

1. In Visual Studio, on the **File** menu, point to **New**, and then choose **Project**.
2. Expand the **Visual C#** node, select **Windows**, and then select **Console Application**.

   Caution

   Do not double-click or otherwise dismiss the **New Project** dialog box.
3. Enter **FindingCcompanies** as the **Name** for the application, and then choose **OK**.
4. In Solution Explorer, right-click the **References** node in the project, and then choose **Add Service Reference**.
5. In the **Add Service Reference** dialog box, choose the **Advanced** button, choose the **Add Web Reference** button, type or paste the URL that you used when checking the WSDL, such as `https://localhost:7047/BC130/WS/Services`, and then choose the green arrow to visit the URL.
6. When the **SystemService** service is displayed, choose **View Service**, wait for the service to be displayed, and then choose **Add Reference**. Rename the Web reference name from **localhost** to **NavSOAPService**.
7. On the **Program.cs** tab, replace the stub code with the following.

```
using System;
using System.Collections.Generic;
using System.Linq;
using System.Text;

namespace FindingCompanies
{
    using System;
    using BCSOAPService;

    public class Program
    {
        static void Main(string[] args)
        {
            // Creates instance of service and set credentials.
            var systemService = new SystemService
            {
                UseDefaultCredentials = true
            };

            // Loads all companies into an array.
            var companies = systemService.Companies();

            // Runs through and print all companies.
            // Also prints company name in encoded form.
            foreach (string company in companies)
            {
                Console.WriteLine(company);
                Console.WriteLine((Uri.EscapeDataString(company)));
            }
            Console.ReadLine();
        }
    }
}
```

8. Save (press Ctrl+F6) and compile (press F6) the **FindingCompanies** application.
9. Press F5 to run the application in debug mode.

   A list of all companies in the current database is presented in a command session.

SOAP Web Services

Using Properties Indicate the Presence of a Value in a Field

2/17/2021 • 2 minutes to read • Edit Online

When you set a field to a value in the code for a web service client and then send the value back to the web service, such as when you use the Create Operation or the Update Operation, the field value is not actually updated to anything other than its default value. This issue can occur if you are using proxies that are generated by Visual Studio or the tools in the .NET Framework SDK. This topic describes the issue and shows how to avoid the problem.

Using Properties to Indicate the Presence of Values

The problem occurs because of the way proxies are auto-generated and the way the .NET Framework handles values in XML documents that are exchanged between the web service and the client. The issue is not specific to Business Central.

For example, the following code shows the schema for the two fields on this Customer Card web service:

```
<xsd:element minOccurs="0" maxOccurs="1" name="Credit_Limit_LCY" type="xsd:decimal" />
<xsd:element minOccurs="0" maxOccurs="1" name="Salesperson_Code" type="xsd:string" />
```

Both fields are optional, which means that they do not have to be present in the XML document. One field is declared as a Decimal data type in Business Central. The other field is a string because it is declared as a Text data type in Business Central.

If both values are present, then the XML document should contain the following elements:

```
<Credit_Limit_LCY>1000</Credit_Limit_LCY>
<Salesperson_Code>JR</Salesperson_Code>
```

But if there is no information about the credit limit, then the document should contain the following element:

```
<Salesperson_Code>JR</Salesperson_Code>
```

If the credit limit is zero, then the document should contain the following line:

```
<Credit_Limit_LCY>0</Credit_Limit_LCY>
```

For the decimal type and all .NET Framework value types, you can handle this state in the proxy objects by using a **Boolean *Specified** property:

```
if (salesOrder.Credit_Limit_LCYSpecified)
    there is a value present in salesOrder.Credit_Limit_LCY
else
    there is no useful value in salesOrder.Credit_Limit_LCY
```

If you assign a non-default value in the value type, then you should confirm this by setting the accompanying **Boolean *Specified** property to `true`:

```
salesOrder.Credit_Limit_LCY = 1000;
salesOrder.Credit_Limit_LCYSpecified = true;
```

To specify that there is no meaningful value in the `salesOrder.Credit_Limit_LCY` value type, set the accompanying **Boolean *Specified** property to `false`:

```
salesOrder.Credit_Limit_LCYSpecified = false;
```

The value in the `salesOrder.Credit_Limit_LCY` value type will now be disregarded.

.NET Framework reference types, such as the String class, are handled differently because .NET Framework declarations that are based on those types can be null, which means that they can have an explicit expression of no value present:

```
if (salesOrder.Salesperson_Code != null)
    there is a value present in salesOrder.Salesperson_Code
else
    there is no value in salesOrder.Salesperson_Code
```

If you assign a value, then you implicitly also define it as present:

```
salesOrder.Salesperson_Code = "JR";
```

To specify that there is no useful value in `salesOrder.Salesperson_Code`, you should set it to null:

```
salesOrder.Salesperson_Code = null;
```

Example

```
SalesOrder salesOrder = new SalesOrder();
salesOrder.Order_Date = DateTime.Today;
salesOrder.Order_DateSpecified = true;
salesOrder.Currency_Code = "SEK";

salesOrderService.Create(ref salesOrder);
```

OData Web Services

2/17/2021 • 2 minutes to read • Edit Online

The Open Data Protocol (OData) is a web protocol that is designed for querying tabular data and provides you with an alternative to SOAP-based web services. OData builds on web technologies such as HTTP, the Atom Publishing Protocol (AtomPub), and JavaScript Object Notation (JSON) to provide access to information from different applications, services, and stores. OData uses URIs for resource identification and commits to an HTTP-based, uniform interface for interacting with resources. This commitment to core Web principles allows for OData to enable a new level of data integration and interoperability across a broad range of clients, servers, services, and tools.

You can use OData web services to show Business Central data, and you can update data in a Business Central database using OData web services.

OData can be found in other Microsoft products and technologies, including the following:

- Microsoft Excel implements OData for its PowerPivot add-in.
- Microsoft SharePoint can expose its list-oriented data with OData.
- Microsoft Azure Table Services are based on OData.

The topics in this section describe the key concepts and techniques for accessing Business Central data from OData applications that are supported by Business Central .

Write to the database through an OData web service that exposes a writable page.	Using OData Web Services to Modify Data

Enabling and Configuring OData on the Business Central Server

The Business Central Server instance has several configurations settings that enable and control OData services. For more information, see OData Services Settings.

Known Limitations

Filters

You can specify filters in OData web services in general that are not supported in Business Central , such as using an OR operator to filter on two different fields. In those cases, you will see the following error:

```
An error occurred while processing this request.
 The 'OR' operator is not supported on distinct fields on an OData filter.
```

Lambda operators

Lambda operators are not supported by Business Central OData APIs. If lambda operators are used, the filter expression will be ignored.

UI pages

If you use Web services that are based on UI pages, you must expect the same behavior from the Web service as from the UI page. If you want to have full control and separation of concern it is recommended to use the Business Central APIs instead.

Deep patching

Business Central supports deep insert, but not deep patching. Multiple requests will need to be issued when patching nested entities.

SOAP Web Services

Using OData V3 to Return-Obtain an AtomPub Document

2/17/2021 • 3 minutes to read • Edit Online

When you register an OData web service, you expose an OData V3 service endpoint that can be accessed from a uniform resource identifier (URI) by using a web browser or any other HTTP client. OData V3 clients can use Atom Publishing Protocol (AtomPub) documents to interact with Business Central data. AtomPub is a simple HTTP-based protocol for creating and updating web resources. It is related to the Atom Syndication Format, which is XML for web feeds. In these procedures, you obtain different kinds of AtomPub documents or feeds from a Business Central OData web service. AtomPub documents and feeds are XML.

> **NOTE**
> This article applies only to OData V3. You can't use the article with OData V4 endpoints.

Obtain an AtomPub Document or Feed

Depending on how you construct your URI, you can return an AtomPub document or an AtomPub feed. A feed is a request for data that can change over time. For example, this can be news content or other kinds of information. In the case of Business Central, the information is database content.

1. Register and publish a page web service by using the Business Central Web client. See Publishing a Web Service.

   The AtomPub documents that are shown in this article are based on the page 21, the **Customer Card** page, with **Customer** as the service name. The concepts and steps are the same for any Business Central Web client page that you register and publish as a web service.

   > **NOTE**
   > You can also register and publish a Business Central query as a web service.

2. Start Windows Internet Explorer. In the **Address** field, enter a URI in this format:

   ```
   https://<Server>:<WebServicePort>/<ServerInstance>/OData
   ```

   If Business Central Server is running on the local computer with the default Business Central Server instance and OData port, then the address is:

   ```
   https://localhost:7048/<server instance>/OData
   ```

   The browser should now show the web service that you have published in the format of an AtomPub document:

3. If you have multiple companies, then you can modify your URI to return a feed that enumerates all available companies:

```
https://localhost:7048/<server instance>/OData/Company
```

> **IMPORTANT**
>
> You must modify your Internet Explorer settings to display the actual XML for a feed instead of the feed content that has changed. Choose **Internet Options**, choose **Content**, choose **Feeds and Web Slices**, and then clear the **Turn on feed reading view** check box. Restart Internet Explorer to enable the new setting.

Obtain a Keyed Service Entry

With a keyed service entry, you specify content from a particular row in a Business Central table. The AtomPub document will contain information that is specific to that row. This procedure assumes that you have registered and published a page web service in the previous procedure.

1. Start Windows Internet Explorer. In the **Address** field, enter a URI in the following format to get the entry for the CRONUS International Ltd. company:

```
https://localhost:7048/<server instance>/OData/Company('CRONUS-International-Ltd.')
```

2. To get the data feed for the Customer table in the CRONUS International Ltd. company database, enter a URI in the following format:

```
https://localhost:7048/<server instance>/OData/Company('CRONUS-International-Ltd.')/Customer
```

3. To additionally constrain data to a specific keyed customer in the Customer table, enter a URI in the following format, using the customer no. for the record you want. The example uses customer no. 01121212:

```
https://localhost:7048/<server instance>/OData/Company('CRONUS-International-
Ltd.')/Customer('01121212')
```

Obtain a Filtered Data Feed

With a filtered data feed, you use special syntax in the URI to define a query on the available data. For details on the specific filters available for Business Central OData web service applications and the syntax for using them, see Using Filter Expressions in OData URIs.

1. Start Windows Internet Explorer. In the **Address** field, enter a URI in the following format to get the entry for the CRONUS International Ltd. company:

```
https://localhost:7048/<server instance>/OData/Company('CRONUS-International-Ltd.')/Customer?
$filter=City-eq-'Birmingham'
```

OData Web Services

Use OData to Return and Obtain a Service Metadata Document

2/17/2021 • 2 minutes to read • Edit Online

The Entity Data Model (**EDM**) is a specification for defining the data that is used by applications that are built on the Entity Framework. **EDMX** is an XML-based file format that is the packaging format for the service metadata of a data service. When you interact with an OData service that is published from Business Central, you can request EDM-based proxies and then use tools such as LINQ to create data access logic. LINQ is a programming model that developers can use to query data from a variety of data sources, including OData. For more information, see LINQ (Language-Integrated Query)

The Business Central implementation of EDM follows the .NET 4.0 WCF Data Service Framework implementation.

The following guidelines have been implemented for EDM.

- Business Central field names are mapped to EDMX property names by replacing spaces with underscores.
- Primary key fields in tables are automatically defined as properties in the service metadata document even if they are not exposed on a page as controls.

Obtain a service metadata (EDMX) document

1. You can obtain service metadata documents for either page or query web services. This example uses a page web service. Register and publish a page web service by using the Business Central Web client. See Publishing a Web Service..
2. Start Windows Internet Explorer. In the **Address** field, enter a URI in this format:

   ```
   https://<Server>:<WebServicePort>/<ServerInstance>/OData/$metadata
   ```

   If Business Central Server is running on the local computer and is using the default Business Central Server instance and OData port, then the address is:

   ```
   https://localhost:7048/<server instance>/OData/$metadata
   ```

   The browser should now show the complete metadata for the page web service that you have published. The beginning of this document looks like this:

OData Web Services

Using OData to Return or Obtain a JSON Document

2/17/2021 • 2 minutes to read • Edit Online

You can publish a page as a web service and consume it using JavaScript Object Notation (JSON).

Obtain a document based on JSON

1. You can build applications that consume and display Business Central data using JSON. This example assumes that you have registered and published a page web service in Business Central.
2. Start Windows Internet Explorer. In the **Address** field, enter a URI in this format:

   ```
   https://<Server>:<WebServicePort>/<ServerInstance>/OData/<web service>?$format=json
   ```

   If Business Central Server is running on the local computer and is using the default Business Central Server instance and OData port, and you have published a web service that is based on page 21 that is called **Customer**, then the address is:

   ```
   https://localhost:7048/BC130/OData/Customer?$format=json
   ```

   This generates a text file that contains metadata and data from the web service. You can open the file from the browser, or you can save it to disk.

   > **NOTE**
   > The value of the format attribute must be lowercase: `?$format=json`.

   If you want to consume the web service as JSON-P, you can add the `?$callback=<callback function name>` parameter.

   You can use a similar URI to return the web service as an AtomPub document, in which case the attribute is `?$format=atom`. For more information, see Using OData to Return-Obtain an AtomPub Document.

Using OData Web Services to Modify Data

Using Filter Expressions in OData URIs

2/17/2021 • 3 minutes to read • Edit Online

You can use filter expressions in OData URIs to limit the results that are returned in an AtomPub document. This topic identifies the filter expressions that you can use, describes the equivalent field or table filter that you can use in AL, and presents examples to show the syntax for using filter expressions in OData web service URIs and applications.

Filter Expressions

To add a filter to an OData URI, add `$filter=` to the end of the name of the published web service. For example, the following URI filters the **City** field in the **Customer** page to return all customers who are located in Miami:

```
https://localhost:7048/BC130/OData/Company('CRONUS International Ltd.')/Customer?$filter=City eq 'Miami'
```

The following table shows the filters that are supported in Business Central OData web services and the equivalent AL filter expressions. All examples are based either on page 21, Customer (published as **Customer**), or on page 20, General Ledger Entry (published as **GLEntry**).

> **NOTE**
> Filters that do not have equivalent AL expressions might take longer to process compared to filters that do have equivalent AL expressions. The reason is that filters that do not have equivalent AL expressions are processed on the Business Central Server tier, while filters that do have equivalent AL expressions are processed on the Business Central database tier.

DEFINITION	EXAMPLE AND EXPLANATION	EQUIVALENT AL EXPRESSION
Select a range of values	`$filter=Entry_No gt 610 and Entry_No lt 615` Query on GLEntry service. Returns entry numbers 611 through 614.	..
And	`$filter=Country_Region_Code eq 'ES' and Payment_Terms_Code eq '14 DAYS'` Query on Customer service. Returns customers in Spain where Payment_Terms_Code=**14 DAYS**.	&

DEFINITION	EXAMPLE AND EXPLANATION	EQUIVALENT AL EXPRESSION
Or	`$filter= Country_Region_Code eq 'ES' or Country_Region_Code eq 'US'` Query on Customer service. Returns customers in Spain and the United States. **Alert:** You can use OR operators to apply different filters on the same field. However, you cannot use OR operators to apply filters on two different fields.	|
Less than	`$filter=Entry_No lt 610` Query on GLEntry service. Returns entry numbers that are less than 610.	<
Greater than	`$filter= Entry_No gt 610` Query on GLEntry service. Returns entry numbers 611 and higher.	>
Greater than or equal to	`$filter=Entry_No ge 610` Query on GLEntry service. Returns entry numbers 610 and higher.	>=
Less than or equal to	`$filter=Entry_No le 610` Query on GLEntry service. Returns entry numbers up to and including 610.	<=
Different from (not equal)	`$filter=VAT_Bus_Posting_Group ne 'EXPORT'` Query on Customer service. Returns all customers with VAT_Bus_Posting_Group not equal to EXPORT.	<>
endswith	`$filter=endswith(VAT_Bus_Posting_Group,'RT')` Query on Customer service. Returns all customers with VAT_Bus_Posting_Group values that end in RT.	
startswith	`$filter=startswith(Name, 'S')` Query on Customer service. Returns all customers names beginning with “S”.	

DEFINITION	EXAMPLE AND EXPLANATION	EQUIVALENT AL EXPRESSION
substringof	`$filter=substringof(Name, 'urn')` Query on Customer service. Returns customer records for customers with names containing the string "urn".	
indexof	`$filter=indexof(Location_Code, 'BLUE') eq 0` Query on Customer service. Returns customer records for customers having a location code beginning with the string BLUE.	
replace	`$filter=replace(City, 'Miami', 'Tampa') eq 'CODERED'`	
substring	`$filter=substring(Location_Code, 5) eq 'RED'` Query on Customer service. Returns true for customers with the string RED in their location code starting as position 5.	
tolower	`$filter=tolower(Location_Code) eq 'code red'`	
toupper	`$filter=toupper(FText) eq '2ND ROW'`	
trim	`$filter=trim(FCode) eq 'CODE RED'`	
concat	`$filter=concat(concat(FText, ', '), FCode) eq '2nd row, CODE RED'`	
round	`$filter=round(FDecimal) eq 1`	
floor	`$filter=floor(FDecimal) eq 0`	
ceiling	`$filter=ceiling(FDecimal) eq 1`	

Referencing Different Data Types in Filter Expressions

You must use the appropriate notation for different data types with filter expressions.

- String values must be delimited by single quotation marks.
- Numeric values require no delimiters.

For more information about data types and other information about conventions and standards for OData URIs, see Atom Publishing Protocol: URI Conventions. Conventions for data types are addressed in section 2.2.2, "Abstract Type System."

OData Web Services

Microsoft OData Docs - Query options overview

Using FlowFilters in OData URIs

2/17/2021 • 2 minutes to read • Edit Online

You can set FlowFilters on the data that your OData web service extracts from the Business Central database.

FlowFilters are a special kind of filter that you use to set ranges on calculations that are shown in FlowFields. For more information, see FlowFilter Overview. FlowFilters for a page are included in the metadata for that page when it is published as a web service. You can then use FlowFilters as filters in a URI that specifies a query against page data. However, only those FlowFilters that are required to calculate the FlowFields that are exposed on the page as controls are included.

Use FlowFilters to Query Data on the Item Card Page

In this procedure, you create and publish a web service from the **Item Card** page in Business Central and then query the data in that web service by using a FlowFilter.

1. Register and publish a page web service by using the Business Central Web client. See Publishing a Web Service.

   Register and publish page 30, Item Card, and name the service **ItemCard**.

2. Start Windows Internet Explorer, and then in the **Address** field, enter a URI in this format:

   ```
   https://<Server>:<WebServicePort>/<ServerInstance>/OData/$metadata
   ```

   If Business Central Server is running on the local computer and uses the default Business Central Server instance and the default OData port, then the address is:

   ```
   https://localhost:7048/BC130/OData/$metadata
   ```

3. Examine the metadata that is returned by this URI. At the end of the list is a set of parameters that end in the word `Filter`. This is the list of FlowFilters for the page:

   ```
   <Property Type="Edm.String" Name="Location_Filter" Nullable="true"/>
   <Property Type="Edm.String" Name="Drop_Shipment_Filter" Nullable="true"/>
   <Property Type="Edm.String" Name="Variant_Filter" Nullable="true"/>
   <Property Type="Edm.String" Name="Lot_No_Filter" Nullable="true"/>
   <Property Type="Edm.String" Name="Serial_No_Filter" Nullable="true"/>
   <Property Type="Edm.String" Name="Date_Filter" Nullable="true"/>
   ```

   NOTE

   The set of FlowFilters that is listed in the page metadata may not match the set of FlowFilters on the equivalent page in the Business Central Web client. This is because the Business Central Web client shows all FlowFilter fields that are defined on the table on which the page is based. The metadata only shows the FlowFilters that are used to calculate the FlowField controls that are exposed on the page.

4. Create a URI that returns information for a single item card. For example:

```
https://localhost:7048/BC130/OData/Company('CRONUS-International-Ltd.')/ItemCard('1906-S')
```

This is the "ATHENS Mobile Pedestal" item. The value for the *Qty_on_Sales_Order* parameter is 33:

```
<d:Qty_on_Sales_Order m:type="Edm.Decimal">33</d:Qty_on_Sales_Order>
```

5. Apply a FlowFilter to that item and specify **GREEN** as the value for the **Location_Filter**:

```
https://localhost:7048/BC130/OData/Company('CRONUS-International-Ltd.')/ItemCard('1906-S')?
$filter=Location_Filter eq 'GREEN'
```

The item is returned as before, the value of the FlowField that has changed. The value for the *Qty_on_Sales_Order* parameter is now 27:

```
<d:Qty_on_Sales_Order m:type="Edm.Decimal">27</d:Qty_on_Sales_Order>
```

This indicates that there are 27 ATHENS Mobile Pedestals on sales orders designated for the GREEN location.

OData Web Services

Server-Driven Paging in OData Web Services

2/17/2021 • 2 minutes to read • Edit Online

Server-driven paging ensures that the quantity of data that is returned by an OData URI does not overwhelm Business Central Server or client program that you use to capture data, while optimizing performance.

> **NOTE**
> The term *page* in this topic refers only to a page that contains OData results and is not related to Business Central page objects.

Configuring Server-Driven Paging

You configure server-driven paging with the **Max Page Size** setting in the configuration for the Business Central Server instance that you are using for OData services. To modify the setting, you can use Server Administration Tool or [Business Central Windows PowerShell Cmdlets](/powershell/business-central/overview). For more information about **Max Page Size** and other Business Central Server parameters, see Configuring Business Central Server.

The **Max Page Size** setting specifies the maximum number of entities returned per page of OData results. The default value is 1000. You can consider a page to be a chunk of data. A large data feed is divided into chunks of data. Each chunk contains no more entities than the value of **Max Page Size**. An increase in the value of **Max Page Size** creates fewer chunks (or pages) per request, which in turn, decreases the processing time. However, an increase in the **Max Page Size** will increase the memory consumption on the Business Central Server or client. If the value is too large, it can overload the memory on Business Central Server. For performance reasons, you should try to set the value of the **Max Page Size** as large as possible without overloading Business Central Server. If the computer that is running Business Central Server is returning out of memory exceptions, then you should reduce the value of **Max Page Size** until the errors stop.

When using OData with queries that are set with a top number of rows by either the TopNumberOfRows Property and TopNumberOfRows Method, you should set the **Max Page Size** value greater than the value of the **TopNumberOfRows** property and **TopNumberOfRows** method. For more information, see Using OData with Queries That are Set with a Top Number of Rows.

> **NOTE**
> In the CustomSettings.config file for Business Central Server, the **Max Page Size** setting is called **ODataServicesMaxPageSize**.

OData Web Services

Using Containments and Associations

2/17/2021 • 3 minutes to read • Edit Online

Containments and associations are relationships between pages in Business Central. OData web services support navigation between pages using containments and associations.

- **Containments**: Some pages in Business Central contain subpages. When you publish such a page, the subpages are automatically available in the web service as containments.
- **Associations**: When a field on a page has a **TableRelation** property, the specified table has a **LookupPageId** property that points to a different page. When you publish a page containing such a field as a web service, you must also publish the page that is pointed to by **LookupPageId** property. You can then link from the first page to the second page in a single URI.

Identifying Containments and Associations in Metadata

OData metadata shows containments and associations with the **NavigationProperty** tag. For example, if you published page 42, Sales Order, and page 22, Customer List, and then obtained the service metadata document for the server instance, you would see this tag in the metadata:

```
<NavigationProperty Name="SalesOrderSalesLines" ToRole="SalesOrderSalesLines" FromRole="SalesOrder"
Relationship="NAV.SalesOrder_SalesOrderSalesLines"/>
```

This tag is followed by metadata that's specific to the **SalesOrderSalesLines** subpage. This page metadata indicates that this **NavigationProperty** tag is a containment:

```
<EntityType Name="SalesOrderSalesLines">
<Key>
     <PropertyRef Name="Document_No"/>
     <PropertyRef Name="Document_Type"/>
     <PropertyRef Name="Line_No"/>
</Key>
     <Property Name="Document_Type" Nullable="false" Type="Edm.String"/>
     <Property Name="Document_No" Nullable="false" Type="Edm.String"/>
     .......many additional properties........
     <Property Name="ShortcutDimCode_x005B_7_x005D_" Nullable="true" Type="Edm.String"/>
     <Property Name="ShortcutDimCode_x005B_8_x005D_" Nullable="true" Type="Edm.String"/>
</EntityType>
```

Elsewhere in the metadata, you would see additional **NavigationProperty** lines and a series of **Association** tags. Two of these tags have a **Multiplicity** parameter with a value of **0..1**:

```
<Association Name="SalesOrder_Sell_to_Customer_No_Link">
     <End Type="NAV.SalesOrder" Multiplicity="*" Role="SalesOrder"/>
     <End Type="NAV.CustomerList" Multiplicity="0..1" Role="Sell_to_Customer_No_Link"/>
</Association>
<Association Name="SalesOrder_Bill_to_Customer_No_Link">
     <End Type="NAV.SalesOrder" Multiplicity="*" Role="SalesOrder"/>
     <End Type="NAV.CustomerList" Multiplicity="0..1" Role="Bill_to_Customer_No_Link"/>
</Association>
```

These tags describe two associations from the Sales Order page to the Customer List page:

- The Sell-to Customer No. field.
- The Bill-to Customer No. field.

Using Containments

When you publish a page that has a subpage, you can identify that subpage in the AtomPub document that is returned for the published page. For example, when you publish page 42, Sales Order, you can access a single record on the page using a URI such as the following:

```
https://localhost:7048/<server instance>/OData/Company('CRONUS-International-
Ltd.')/SalesOrder(Document_Type='Order',No='101005')/
```

The following line in the returned AtomPub document for the record provides link information for a containment:

```
<link rel="https://schemas.microsoft.com/ado/2007/08/dataservices/related/SalesOrderSalesLines"
            type="application/atom+xml;type=feed" title="SalesOrderSalesLines"
            href="SalesOrder(Document_Type='Order',No='101005')/SalesOrderSalesLines" />
```

Notice the `type=feed` in the line above. To access the subpage data feed, use a URI that incorporates the link that was identified in the previous document:

```
https://localhost:7048/<server instance>/OData/Company('CRONUS-International-
Ltd.')/SalesOrder(Document_Type='Order',No='101005')/SalesOrderSalesLines
```

Using Associations

Associations are possible when two published pages are linked. Here is an example:

- Page 42, Sales Order, has its **SourceTable** property set to table 36, Sales Header. The source expression for the **Sell_to_Customer_No** control on page 42 is field 2, Sell-to Customer No., in table 36.
- Field 2, Sell-to Customer No., in table 36 has a **TableRelation** property set to table 18, Customer, field No.
- Table 18, Customer, has a **LookupPageId** property set to page 22, Customer List.

Thus if both page 42, Sales Order, and page 22, Customer List, are published as web services, then an OData URI can link from the **Sell_to_Customer_No** control on page 42 to the related entity on page 22.

Because of this association, you can create OData URIs to access data on the Customer List page as you work with data on the Sales Order page.

If you publish pages 42 and 22 as web services, then you can return an AtomPub document for the Sales Order page. The following URI returns data for a single record on the page, which is order number 101005:

```
https://localhost:7048/<server instance>/OData/Company('CRONUS-International-
Ltd.')/SalesOrder(Document_Type='Order',No='101005')/
```

A set of three tags near the top of the returned document show one containment (**SalesOrderSalesLines**) and two associations (**Sell_to_Customer_No** and **Bill_to_Customer_No**) on the page. Notice the `type=entry` in the following lines:

```
<link rel="https://schemas.microsoft.com/ado/2007/08/dataservices/related/SalesOrderSalesLines"
             type="application/atom+xml;type=feed" title="SalesOrderSalesLines"
             href="SalesOrder(Document_Type='Order',No='101005')/SalesOrderSalesLines" />
<link rel="https://schemas.microsoft.com/ado/2007/08/dataservices/related/Sell_to_Customer_No_Link"
             type="application/atom+xml;type=entry" title="Sell_to_Customer_No_Link"
             href="SalesOrder(Document_Type='Order',No='101005')/Sell_to_Customer_No_Link" />
<link rel="https://schemas.microsoft.com/ado/2007/08/dataservices/related/Bill_to_Customer_No_Link"
              type="application/atom+xml;type=entry" title="Bill_to_Customer_No_Link"
              href="SalesOrder(Document_Type='Order',No='101005')/Bill_to_Customer_No_Link" />
```

This information provides the necessary information to create a URI to access a record on the Customer List page by using an association:

```
https://localhost:7048/<server instance>/OData/Company('CRONUS-International-Ltd.')
             /SalesOrder(Document_Type='Order',No='101005')/Sell_to_Customer_No_Link
```

The following URI returns the same information with direct access to the Customer List page:

```
https://localhost:7048/<server instance>/OData/CustomerList('30000')
```

OData Web Services

Using OData with Queries That are Set with a Top Number of Rows

2/17/2021 • 2 minutes to read • Edit Online

Business Central queries include the TopNumberOfRows Property and TOPNUMBEROFROWS Method that can be used to specify the maximum number of rows to include in the resulting dataset. The OData configuration includes the **Max Page Size** setting that specifies the maximum number of entities returned per page of OData results. The default value is 1000.

To ensure that the OData results include the correct number of entities when you are using a query that is set with a top number of rows, you should set the **Max Page Size** value greater than the value that is set by the **TopNumberOfRows** property and **TopNumberOfRows** method. Otherwise, the **TopNumberOfRows** property and **TopNumberOfRows** method are ignored and the query dataset will be returned in the OData results.

> **NOTE**
>
> Typically, the **TopNumberOfRows** property or **TopNumberOfRows** method are used to return a relatively small number of entities, such as the top five, ten, or 100 entities. Therefore, in most cases, the value of the **TopNumberOfRows** property and **TopNumberOfRows** method will be less than the **Max Page Size**, so that you will not have to change the **Max Page Size** setting.

For information about how to change the **Max Page Size** setting, see Configuring Business Central Server and Server-Driven Paging in OData Web Services.

Basic Page Operations

Using OData Web Services to Modify Data

2/17/2021 • 2 minutes to read • Edit Online

You can write to the Business Central database using an OData web service that exposes a writable page. For example, you can expose a page as an OData web service and implement it in a portal that is based on Microsoft SharePoint Online. Users of the portal can then modify the data.

Modifying Data Using OData Web Services

If an editable page is exposed as a web service, the data in the underlying table can be accessed and modified by an OData call. Business Central supports the following OData operations for modifying data.

ODATA CALL	DATA IMPACT	TRIGGERS RUN ON PAGE AND TABLE IN BUSINESS CENTRAL
`POST`	Creates a new entity.	`OnNewRecord` and `OnInsert`
`PATCH`	Modifies the specified existing entity.	`OnModify`
`DELETE`	Deletes the specified existing entity.	`OnDelete`

All calls fail if the user does not have the relevant permissions, and if the relevant property on the page, **InsertAllowed**, **ModifyAllowed**, or **DeleteAllowed**, is set to **No**.

You can use an OData web service in applications where you want users to be able to modify Business Central data the Business Central Web client. For example, you can show fields from the **Customer** table on a mobile device or in a browser so that a user can create, update, or delete customers in the Business Central database.

PATCH operations requires the 'If-Match' header to be set, either with a retrieved ETag or with '*'.

Company-Specific and Tenant-Specific OData Calls

In your implementation of the web service, you can specify which company in the database that a user can write to in the URIs that expose the web services. Similarly, you can specify the specific tenant that the change applies to if the database handles more than one tenant.

If you do not specify a company, Business Central will identify a default company. The default company is found in the following order of sequence:

1. The ServicesDefaultCompany setting in the Tenants.config file.
2. The ServicesDefaultCompany setting in the CustomSettings.config file for Business Central Server.
3. The company in the current tenant when there is only one company.

   If the OData request is for modifying metadata, Business Central will return the first company in the tenant database because metadata applies to all companies in the database.

If no default company can be found based on the criteria, an error message appears.

Creating and Interacting with an OData V4 Bound Action

2/17/2021 • 2 minutes to read • Edit Online

This topic provides an overview of how to expose a procedure as an OData V4 web service action and how to verify that the service is working as expected.

Declaring the OData bound action

The following example shows you how you can declare an OData bound action on a page exposed as a web service. For that, you need to add a procedure to the `SalesInvoiceCopy` page, expose the procedure using the `[ServiceEnabled]` attribute, and use the `WebServiceActionContext` and `WebServiceActionResultCode` AL types to set the result of the function.

> **NOTE**
> Bound actions cannot be added by extending an existing page that has been exposed as a web service.

```
page 50110 SalesInvoiceCopy
{
    ODataKeyFields = "Id";
    SourceTable = "Sales Header";

    layout
    {
        area(Content)
        {
            group(GroupName)
            {
                field(Id; Id)
                {
                    ApplicationArea = All;
                }

                field("No."; "No.")
                {
                    ApplicationArea = All;
                }

                field("Sell-to Customer No."; "Sell-to Customer No.")
                {
                    ApplicationArea = All;
                }
            }
        }
    }

    trigger OnOpenPage()
    begin
        SetRange("Document Type", "Document Type"::Invoice);
    end;

    [ServiceEnabled]
    procedure Copy(var actionContext: WebServiceActionContext)
    var
        FromSalesHeader: Record "Sales Header";
        ToSalesHeader: Record "Sales Header";
        SalesSetup: Record "Sales & Receivables Setup";
        CopyDocMgt: Codeunit "Copy Document Mgt.";
        DocType: Option Quote,"Blanket Order",Order,Invoice,"Return Order","Credit Memo","Posted
Shipment","Posted Invoice","Posted Return Receipt","Posted Credit Memo";
    begin
        SalesSetup.Get;
        CopyDocMgt.SetProperties(true, false, false, false, false, SalesSetup."Exact Cost Reversing
Mandatory", false);

        FromSalesHeader.Get("Document Type", "No.");
        ToSalesHeader."Document Type" := FromSalesHeader."Document Type";
        ToSalesHeader.Insert(true);

        CopyDocMgt.CopySalesDoc(DocType::Invoice, FromSalesHeader."No.", ToSalesHeader);

        actionContext.SetObjectType(ObjectType::Page);
        actionContext.SetObjectId(Page::SalesInvoiceCopy);
        actionContext.AddEntityKey(Rec.FIELDNO(Id), ToSalesHeader.Id);

        // Set the result code to inform the caller that an item was created.
        actionContext.SetResultCode(WebServiceActionResultCode::Created);
    end;
}
```

Registering and publishing the page as a web service

1. Open the Business Central Web Client.
2. In the **Search** box, enter **Web Services**, and choose the related link.
3. In the **Web Services** page, on the **Home** tab, choose **New**.
4. In the **Object Type** column, select **Page**. In the **Object ID** column, enter 43, and in the **Service Name** column, enter `SalesInvoiceCopy`.
5. Select the check box in the **Published** column.
6. When you publish the web service, in the **OData URL** and **SOAP URL** fields, you can see the URLs that are generated for the web service.

Verifying the web service availability

HTTP request

```
POST /ODataV4/Company({companyName})/SalesInvoiceCopy({id})/NAV.Copy
```

Request headers

HEADER	VALUE
Authorization	Bearer {token}. Required.

Example

```
{baseurl}/ODataV4/Company('CRONUS%20USA%2C%20Inc.')/SalesInvoiceCopy('S-ORD101001')/NAV.Copy
```

Walkthrough: Creating and Interacting With an OData V4 Bound Action

2/17/2021 • 4 minutes to read • Edit Online

This walkthrough illustrates how you can publish a Business Central function as an OData V4 web service action.

About This Walkthrough

This walkthrough provides an overview of how to expose a function as a web service action and how to verify that the service is working as expected. The walkthrough illustrates the following tasks:

- Publishing a Business Central function as a web service.
- Verifying web service availability from a browser.

Prerequisites

To complete this walkthrough, you will need:

- Microsoft Dynamics NAV 2017 CTP 10 with a developer license.
- CRONUS International Ltd. demonstration database.
- The **Postman** app for testing the web service URI.

Publishing a Function as a Web Service

You publish a function as a Web service action by using the Dynamics NAV Development Environment to create the function and the Business Central Windows client or the Business Central Web client for publishing the objects the function is for. The tutorial provides an example that will return a location header. A location header would be used to later issue a get request for the resulting object. Refer to the **Return a Value** section for an example that will return a value specified in your function.

To create the function

Create a Copy action on the Sales Invoice page.

1. Open the Dynamics NAV Development Environment and then connect to the CRONUS International Ltd. company.

   Object Designer opens automatically in the development environment.

2. Open page 43, **Sales Invoice**.
3. Create a new function on the page named `Copy`.
4. Open the properties for the function and set the properties to the following values.

PROPERTY	VALUE
Local	No
FunctionVisibility	External
ServiceEnabled	Yes

5. Open **Locals** for the function and set the parameters to the following values.

PARAMETER	VALUE
VAR	Yes
Name	ActionContext
DataType	DotNet
SubType	Microsoft.Dynamics.Nav.Runtime.WebServiceActionContext.'Microsoft.Dynamics.Nav.Ncl, Culture=neutral, PublicKeyToken=31bf3856ad364e35'

6. Select the **Variables** tab and add the following variables.

NAME	DATATYPE	SUBTYPE
ToSalesHeader	Record	36
FromSalesHeader	Record	36
SalesSetup	Record	311
ODataActionManagement	Codeunit	6711
CopyDocMgt	Codeunit	6620
DocType	Option	OptionString = Quote,Blanket Order,Order,Invoice,Return Order,Credit Memo,Posted Shipment,Posted Invoice,Posted Return Receipt,Posted Credit Memo

7. Add the code that copies the sales document, for example.

```
SalesSetup.GET;
CopyDocMgt.SetProperties(
TRUE,FALSE,FALSE,FALSE,FALSE,SalesSetup."Exact Cost Reversing Mandatory",FALSE);

FromSalesHeader.GET(Rec."Document Type",Rec."No.");
ToSalesHeader."Document Type" := FromSalesHeader."Document Type";
ToSalesHeader.INSERT(TRUE);
CopyDocMgt.CopySalesDoc(DocType::Invoice,FromSalesHeader."No.",ToSalesHeader);

// Add the necessary keys of the newly created entity using that entity's backing table to identify
the field no. and it's value.
ODataActionManagement.AddKey(Rec.FIELDNO(Id),ToSalesHeader.Id);

// Depending on what the result was of the action
// - Created: SetCreatedPageResponse(ActionContext, PAGE::"Sales Invoice");
// - Updated: SetUpdatedPageResponse(ActionContext,PAGE::"Sales Invoice");
// - Deleted: SetDeleteResponse(ActionContext);
ODataActionManagement.SetCreatedPageResponse(ActionContext,PAGE::"Sales Invoice");
```

8. Save and compile the **SalesInvoice** page.

To register and publish a page as a Web service

1. Open Business Central and connect to the CRONUS International Ltd. company.
2. In the **Search** box, enter **Web services**, and then choose the related link.
3. In the **Web Services** page, on the **Home** tab, choose **New**.
4. In the **Object Type** column, select **Page**. In the **Object ID** column, enter `43`, and in the **Service Name** column, enter `SalesInvoice`.
5. Select the check box in the **Published** column.
6. Choose the **OK** button.

Verifying the Web Service Availability

After publishing a web service, verify that the port that web service applications will use to connect to your web service is open. The default port for OData V4 web services is 7047. You can configure this value by using the Server Administration Tool.

To verify availability of a Microsoft Dynamics NAV Web service action

1. Start **Postman** or another tool that can execute a POST command against the web service URI.
2. In the **Address** field, enter a URI in this format:
   ```
   https://<Server>:
   <WebServicePort>/<ServerInstance>/api/beta/companies(<companyid>)/salesInvoices(<invoiceid>)/Microsoft.NAV.Copy)
   ```
   .
   - `<Server>` is the name of the computer that is running Business Central Server.
   - `<WebServicePort>` is the port that OData V4 is running on. The default port is 7047.
   - `<ServiceInstance>` is the name of the Business Central Server instance for your solution. The default name is DynamicsNAV90.

   Example if the default Business Central Server is running on your local computer.
   ```
   https://localhost:7047/BC130/api/beta/companies(b9248a6e-966d-478c-a25d-
   d91d28610397)/salesInvoices(8cc52602-3aa4-4256-b2c7-fdfef5248cbf)/Microsoft.NAV.Copy)
   ```
3. Postman should now show the web service function that you have published, and perform the action of copying an invoice.

Return a value

1. Open the Dynamics NAV Development Environment and connect to the application database.
2. Open page 43, **Sales Invoice**.
3. Create a new function called **Example**.
4. Open **Properties** for the function and set the properties to the following values.

PROPERTY	VALUE
Local	No
FunctionVisibility	External
ServiceEnabled	Yes

5. Open **Locals** for the function parameters to the following values.
6.

PARAMETER	VALUE	TEST
inParam	Text	test

7. Select the **Return Value** tab and then add the following values.
8.

NAME	RETURNTYPE
outParam	Text

9. Then add the following code for the **Example** function:

```
outParam := inParam + ' Completed';
```

10. You can now issue a post request:
```
https://localhost:7047/Navision_NAV/ODataV4/Company('CRONUS International
Ltd.')/SalesInvoice('Invoice', '1004')/NAV.Example
```
with a JSON body of:
```
{ "inParam": "Hello World" }
```

11. The returned value will be returned in the body of the message.

```
{
    "@odata.context":
"https://farpedro.northamerica.corp.microsoft.com:7047/Navision_NAV/ODataV4/$metadata#Edm.String",
    "value": "Hello World Completed"
}
```

You have now published a Business Central function as an OData V4 web service action and verified that the service works as expected. To read more about web services, see the **See Also** section below.

Creating and Interacting with an OData V4 Unbound Action

2/17/2021 • 2 minutes to read • Edit Online

Unbound actions represent reusable operations that you can perform using an OData request. Use unbound actions when there is no particular entity that the action needs to be bound to.

Declaring, registering, and publishing the OData unbound action

To declare an OData unbound action define a codeunit with a procedure with the desired business logic.

The following example illustrates a simple codeunit with three procedures that can be exposed as a web service and called as OData unbound actions.

```
codeunit 50100 "MiscOperations"
{
    procedure Ping(input: Integer): Integer
    begin
        exit(-input);
    end;

    procedure Delay(delayMilliseconds: Integer)
    begin
        Sleep(delayMilliseconds);
    end;

    procedure GetLengthOfStringWithConfirmation(inputJson: Text): Integer
    var
        c: JsonToken;
        input: JsonObject;
    begin
        input.ReadFrom(inputJson);
        if input.Get('confirm', c) and c.AsValue().AsBoolean() = true and input.Get('str', c) then
            exit(StrLen(c.AsValue().AsText()))
        else
            exit(-1);
    end;
}
```

Registering and publishing the codeunit as a web service

Registering and publishing the codeunit is identical to how you work with other web services. For more information, see Publish a Web Service.

Verifying web service availability

HTTP Request

To call specific procedure on a codeunit use the base OData URL for the codeunit and procedure name separated by an underscore.

```
POST /ODataV4/{serviceName}_{procedureName}?company={companyName|companyId} HTTP/1.1
{requestBody}
```

Request Headers

HEADER	VALUE
Authorization	Bearer {token}. Required.

Example Request

```
POST {baseUrl}/ODataV4/MiscOperations_GetLengthOfStringWithConfirmation?company=CRONUS%20USA%20Inc. HTTP/1.1
{
    "inputJson": "{\"str\":\"Hello world!\",\"confirm\":true}"
}
```

Example Response

```
HTTP/1.1 200 OK
{
  "@odata.context": "{baseUrl}/ODataV4/$metadata#Edm.Int32",
  "value": 12
}
```

Getting Started Developing Connect Apps for Dynamics 365 Business Central

2/17/2021 • 7 minutes to read • Edit Online

A Connect app establishes a point-to-point connection between Dynamics 365 Business Central and a 3rd party solution or service and is typically created using standard REST API to interchange data. Any coding language capable of calling REST APIs can be used to develop your Connect app. In the following section you can read about how you get started exploring the available APIs for Dynamics 365 Business Central.

To explore and develop against APIs in Dynamics 365 Business Central, you must first sign up for a trial tenant and then you have to connect and authenticate. To do that, follow the steps below.

1. Sign up for Dynamics 365 Business Central.
   When you have your tenant, you can sign into the UI to play with the product, as well as explore the APIs
2. There are two different ways to connect to and authenticate against the APIs.
   - Use Azure Active Directory (AAD) based authentication against the common API endpoint: `https://api.businesscentral.dynamics.com/v2.0/<environment name>/api/v2.0`
   - Use basic authentication with username and password (a so-called web service access key) against the common API endpoint that includes the user domain, for example `https://api.businesscentral.dynamics.com/v2.0/production/cronus.com/api/v2.0`.

     IMPORTANT

     When going into production, you should use Azure Active Directory (AAD)/OAuth v2 authentication and the common endpoint `https://api.businesscentral.dynamics.com/v2.0/production/api/v2.0`. For exploring and initial development, you can use basic authentication.

For constructing the URL to the environment, the path needs to contain the environment name. To get all environments for the tenant call `GET https://api.businesscentral.dynamics.com/environments/v2.0/`. That will return the name for all environments in the tenant. OAuth required for this endpoint. See Exploring the APIs with Postman and AAD authentication below.

In the following sections you can read more about setting up the two types of authentication and using both authentication methods in Postman.

APIs can also be explored through the OpenAPI specification for Business Central.

Setting up basic authentication

If you prefer to set up an environment with basic authentication just to explore the APIs, you can skip setting up the AAD based authentication for now and proceed with the steps below. If you, however, want to go into production, you must use AAD/Oauth v2 authentication, see the section Setting up Azure Active Directory (AAD) based authentication.

1. To set up basic authentication, log into your tenant, and in the **Search** field, enter **Users** and then select the relevant link.
2. Select the user to add access for, and on the **User Card** page, in the **Web Service Access Key** field, generate a key.
3. Copy the generated key and use it as the password for the username.

Now that we have the username and password, we can connect and authenticate. You can do this from code, or API explorers such as Postman or Fiddler. In the Exploring the APIs with Postman and basic authentication section we will use Postman.

Setting up Azure Active Directory (AAD) based authentication

Sign in to the Azure Portal to register Dynamics 365 Business Central as an app and thereby provide access to Dynamics 365 Business Central for users in the directory.

1. Follow the instructions in the Integrating applications with Azure Active Directory article. The next steps elaborate on some of the specific settings you must enable.
2. On the **API permissions** page for your app, click the **Add a permission** button.
3. Make sure the **Microsoft APIs** tab is selected. In the *Commonly used Microsoft APIs* section, click on the **Dynamics 365 Business Central** and select **Delegated permissions**.
4. Ensure that the right permission is checked: **user_impersonation**. Use the search box if necessary.
5. Click the **Add permissions** button.

> **NOTE**
> If **Dynamics 365** does not show up in search, it's because the tenant does not have any knowledge of Dynamics 365. To make it visible, an easy way is to register for a free trial for Dynamics 365 Business Central with a user from the directory.

6. From the **Certificates & secrets** page, in the **Client secrets** section, choose **New client secret**:
   - Type a key description (of instance app secret),
   - Select a key duration of either In 1 year, In 2 years, or Never Expires.
   - When you press the Add button, the key value will be displayed, copy, and save the value in a safe location.

> **NOTE**
> You'll need this key later to configure the project in Visual Studio. This key value will not be displayed again, nor retrievable by any other means, so record it as soon as it is visible from the Azure portal.

You have now set up the AAD based authentication. Next, you can go exploring the APIs, see the Exploring the APIs with Postman and AAD authentication section below.

Exploring the APIs with Postman and basic authentication

In this `Hello World` example, we are going over the basic steps required to retrieve the list of customers in our trial tenant. This example is based on running with basic authentication.

1. First, in Postman, set up a `GET` call to the base API URL.
   - When you call the base API URL, you will get a list of all the available APIs. You can append `$metadata` to the URL to also get information about the fields in the APIs. The list of supported APIs and fields information can also be found in the API documentation.
   - Since we are using basic authentication, we need to include the users domain in the URL, for example, call

```
GET https://api.businesscentral.dynamics.com/v2.0/<your tenant domain>/<environment
name>/api/v2.0
```

.

> **NOTE**
>
> The parameter `<your tenant domain>` is your default Azure Active Directory GUID.

2. On the **Authorization** tab in Postman select **Basic Auth** in the **Type** and provide the Username and **Web Service Access Key** from above as password.

3. Choose **Send** in Postman to execute the call, and inspect the returned body, which should include a list of the APIs.

Exploring the APIs with Postman and AAD authentication

In this `Hello World` example, we are going over the basic steps required to retrieve the list of customers in our trial tenant. This example is based on running with AAD authentication.

1. First, in Postman, set up a `GET` call to the base API URL.
   - When you call the base API URL, you will get a list of all the available APIs. You can append `$metadata` to the URL to also get information about the fields in the APIs. The list of supported APIs and fields information can also be found in the API documentation, for example, call
     `GET https://api.businesscentral.dynamics.com/v2.0/environment name/api/v2.0`
2. On the **Authorization** tab in Postman select **OAuth 2.0** in the **Type** and then choose **Get New Access Token**.
3. In the **GET NEW ACCESS TOKEN** window, enter the following information as specified below:
   - In the **Token name** field, choose a descriptive name.
   - In the **Grant type** field, choose **Authorization Code**.
   - In the **Callback URL** field, specify the URL specified as the sign-on URL/Reply URL in the Azure Portal.
   - In the **Auth URL** field, specify a URL such as
     ```
     https://login.windows.net/<your tenant domain>/oauth2/authorize?
     resource=https://api.businesscentral.dynamics.com
     ```
     .
   - In the **Access Token URL** field, specify a URL such as
     ```
     https://login.windows.net/<your tenant domain>/oauth2/token?
     resource=https://api.businesscentral.dynamics.com
     ```
     .
   - In the **Client ID** field, enter the Application ID from the registered app in Azure Portal.
   - In the **Client Secret** field, enter the key generated under **Keys** that you copied in step 6 in the Setting up Azure Active Directory (AAD) based authentication.
   - In the **Client Authentication** field, choose the **Send client credentials in body** option.
4. Choose the **Request token** button. The first time you log in, you will get prompted for consent.
5. Scroll down and choose **Use token** button.
   An Authorization request header is now added containing the Bearer token.
6. Choose **Send** in Postman to execute the call, and inspect the returned body, which should include a list of the APIs.

NOTE

For OAuth for testing purposes, a multi-tenant AAD app has been created. Admin consent is needed before the ADD app can be used. Information is as follows:

- Grant Type: Implict
- Callback URL: https://localhost
- Auth URL: https://login.microsoftonline.com/common/oauth2/authorize?resource=https://api.businesscentral.dynamics.com
- Client ID: 060af3ac-70c3-4c14-92bb-8a88230f3f38

Calling the API

Each resource is uniquely identified through an ID, see the following example of calling `GET <endpoint>/companies`:

```
{
    "@odata.context": "<endpoint>/$metadata#companies",
    "value": [
        {
            "id": "bb6d48b6-c7b2-4a38-9a93-ad5506407f12",
            "systemVersion": "18453",
            "name": "CRONUS USA, Inc.",
            "displayName": "CRONUS USA, Inc.",
            "businessProfileId": ""
        }
    ]
}
```

The resource ID must be provided in the URL when trying to read or modify a resource or any of its children. The ID is provided in parenthesis () after the API endpoint. For example, to GET the "CRONUS USA, Inc." company details, you must call `<endpoint>/companies(bb6d48b6-c7b2-4a38-9a93-ad5506407f12)/`.

All resources, such as customers, invoices etc., live in the context of a parent company, of which there can be more than one in the Dynamics 365 Business Central tenant. Therefore, it is a requirement to provide the company ID in the URL for all resource API calls. To GET all customers in the "CRONUS USA, Inc." company, we must call a GET on the URL `<endpoint>/companies(bb6d48b6-c7b2-4a38-9a93-ad5506407f12)/customers`.

Tips for Working with APIs

Tips for working with the APIs

2/17/2021 • 3 minutes to read • Edit Online

GET

- Call (GET) the endpoint to list all the API
- Call (GET) the endpoint with `$metadata` to list all metadata for the API
- Calling a resource API (GET) will return a list of all instances of the resource type
- Each resource is uniquely identified through an ID, see the following example:

```
{
    "@odata.context": "<endpoint>/$metadata#companies",
    "value": [
        {
            "id": "bb6d48b6-c7b2-4a38-9a93-ad5506407f12",
            "systemVersion": "18453",
            "name": "CRONUS USA, Inc.",
            "displayName": "CRONUS USA, Inc.",
            "businessProfileId": ""
        }
    ]
}
```

- The resource ID must be provided in the URL when trying to read or modify a resource or any of its children. The ID is provided in () after the API endpoint. For example, to GET the "CRONUS USA, Inc." company details, you must call `<endpoint>/companies(bb6d48b6-c7b2-4a38-9a93-ad5506407f12)/`
- All resources live in the context of a parent company, which means that the company ID must be provided in the URL for all resource API calls. For example, to GET all customers in the "CRONUS USA, Inc." company, you must call `<endpoint>/companies(bb6d48b6-c7b2-4a38-9a93-ad5506407f12)/customers`

Accept-Language

By specifying `Accept-Language` in the request header, you can set a specific language for your web service response. It's strongly recommended to use this setting, if your app is dependent on a web service response to be in a specific language. If `Accept-Language` is set, it will override default settings. This setting also controls the regional formatting settings, affecting behavior such as how date and time will be formatted.

One of the most common examples is showing error messages to the users in their language. To see which possible error messages to display, see Error Codes. Another common example is displaying reports in a specific language, see the example below for how to specify `Accept-Language`. The following example sets the language to always be `en-US`.

Example

```
GET
businesscentralPrefix/companies({id})/salesInvoices({salesInvoiceId})/pdfDocument({salesInvoiceId})/content
```

Request headers

HEADER	VALUE

HEADER	VALUE
Authorization	Bearer {token}. Required.
Accept-Language	en-US

Request body

Do not supply a request body for this method.

Reponse

If successful, this method returns a `200 OK` response code and a report PDF file in the response body.

OData transactional $batch requests

> **APPLIES TO:** Business Central 2020 release wave 2 (version 17.1) and later

It's possible to specify that all inner requests in a certain OData $batch request are processed in a transactional way. If one of the inner requests fails after another request (or requests) has committed changes, all changes within a batch will be reverted as if the batch request never happened. Transactional $batch requests are useful in scenarios where a single business operation spans multiple requests, because they prevent adverse effects if parts of the operation fail. Also, they can improve performance by reducing the number of requests the client needs to do when errors occur.

To enable transactional batch behavior, include the `Isolation: snapshot` header with the $batch request.

Example

```
POST businesscentralPrefix/api/v2.0/$batch HTTP/1.1
```

Request headers

HEADER	VALUE
Authorization	Bearer {token}. Required.
Content-Type	application/json. Required for JSON Batch content.
Accept	application/json
Isolation	snapshot

Request body

The following request body contains three inner requests. The first two requests should execute successfully. The last request includes content that triggers a validation failure, so the request fails.

```
{
	"requests": [
		{
			"method": "PATCH",
			"url": "items(7ce0af2e-0963-460f-9b1f-0014aea3e117)",
			"headers": {
				"Company": "CRONUS International Ltd.",
				"Content-Type": "application/json",
				"If-Match": "*"
			},
			"body": {
				"displayName": "Touring Bicycle v2"
			}
		},
		{
			"method": "PATCH",
			"url": "items(7ce0af2e-0963-460f-9b1f-0014aea3e117)/picture(7ce0af2e-0963-460f-9b1f-
0014aea3e117)/contentValue",
			"headers": {
				"Company": "CRONUS International Ltd.",
				"Content-Type": "application/json",
				"If-Match": "*"
			},
			"body": {
				"value": "Picture Blob"
			}
		},
		{
			"method": "PATCH",
			"url": "items(7ce0af2e-0963-460f-9b1f-0014aea3e117)",
			"headers": {
				"Company": "CRONUS International Ltd.",
				"Content-Type": "application/json",
				"If-Match": "*"
			},
			"body": {
				"type": "Invalid Type"
			}
		}
	]
}
```

Response

The following response includes successful responses for the first two inner requests, and an error for the last inner request. Because the `Isolation: snapshot` header was present in the batch request, none of the changes made by either of the successful inner requests are applied after completion of the batch request.

```
{
	"responses": [
		{
			"id": null,
			"status": 200,
			"headers": {
				"content-type": "application/json; odata.metadata=minimal",
				"odata-version": "4.0"
			},
			"body": {
				"displayName": "Touring Bicycle v2",
				// ...
			}
		},
		{
			"id": null,
			"status": 204,
			"headers": {}
		},
		{
			"id": null,
			"status": 400,
			"headers": {
				"content-type": "application/json; odata.metadata=minimal",
				"odata-version": "4.0"
			},
			"body": {
				"error": {
					"code": "Unknown",
					"message": "'Invalid Type' is not an option. The existing options are:
Inventory,Service,Non-Inventory  CorrelationId:  x."
				}
			}
		}
	]
}
```

Performance Articles For Developers

Developing a Custom API

2/17/2021 • 7 minutes to read • Edit Online

This walkthrough describes how to develop a custom API page by using an AL extension and accessing it to retrieve responses and make updates through the API.

About this walkthrough

At a high-level, this process involves the following tasks:

1. Develop an AL extension with a new API page.
2. Add necessary fields, properties, and subpages to the API page.
3. Access the API page and get the response.

> **TIP**
> The code in this sample has also been published to the BCTech repo. For more information, see Introduction to Custom API.

Prerequisites

This walkthrough requires the following:

- Business Central, including the following:
  - The CRONUS International Ltd. demonstration data.
  - Visual Studio Code with the AL Language extension installed. For more information, see Getting Started with AL and AL Language Extension Configuration. The AL Language extension for Visual Studio is free, and you can download it from Marketplace.

Creating source tables for the API

To expose data in an API page, the first thing needed is a source table. For the purpose of this walkthrough we will create a table object that describes the schema for a car brand.

1. Create a new table. For more information, see Tables Overview.
2. Name the table **Car Brand**, and specify **50100** as the table ID.
3. Add any necessary fields for a car brand as shown below:

```
table 50100 "Car Brand"
{
    DataClassification = CustomerContent;
    Caption = 'Car Brand';

    fields
    {
        field(1; Name; Text[100])
        {
            Caption = 'Name';
        }
        field(2; Description; Text[100])
        {
            Caption = 'Description';
        }
        field(3; "Country"; Text[100])
        {
            Caption = 'Brand Id';
        }
    }

    keys
    {
        key(PK; Name)
        {
            Clustered = true;
        }
    }
}
```

4. Now, create a new table for **Car Model**, and specify **50101** as the table ID.
5. Add any necessary fields for a car model as shown in the example below. Make sure to have a field for **Brand Id** and that **TableRelation** is set to **"Car Brand".SystemId**.

```
table 50101 "Car Model"
{
    DataClassification = CustomerContent;
    Caption = 'Car Model';

    fields
    {
        field(1; Name; Text[100])
        {
            Caption = 'Name';
        }
        field(2; Description; Text[100])
        {
            Caption = 'Description';
        }
        field(3; "Brand Id"; Guid)
        {
            TableRelation = "Car Brand".SystemId;
            Caption = 'Brand Id';
        }
        field(4; Power; Integer)
        {
            Caption = 'Power (cc)';
        }
        field(5; "Fuel Type"; Enum "Fuel Type")
        {
            Caption = 'Fuel Type';
        }
    }

    keys
    {
        key(PK; Name, "Brand Id")
        {
            Clustered = true;
        }
    }
}

enum 50100 "Fuel Type"
{
    Extensible = true;
    value(0; Petrol)
    {
        Caption = 'Petrol';
    }
    value(1; Diesel)
    {
        Caption = 'Diesel';
    }
    value(2; Electric)
    {
        Caption = 'Electric';
    }
}
```

TIP

As it can be seen in field number 5 **"Fuel Type"**, make sure to use Enums instead of Options. When they are used in API pages, Options are generated as type strings in the metadata: `<Property Name="fuelType" Type="Edm.String"/>`. Whereas Enums have their own types and all available Enum members are generated in the metadata: `<Property Name="fuelType" Type="Microsoft.NAV.fuelType"/>`.

```
< EnumType Name="fuelType" Type="Microsoft.NAV.fuelType">
            <Member Name="Petrol" Value="0"/>
            <Member Name="Diesel" Value="1"/>
            <Member Name="Electric" Value="2"/>
   </EnumType>
```

Creating API pages

In the following, we will create two API pages for both **Car Brand** and **Car Model** tables. API pages are specific pages with the `PageType` property set to `API`. For more information, see API Page Type.

To create API pages to display Car Brand and Car Model

1. Create a new API page.
2. Name the page **API Car Model**, and specify **50101** as the page ID.
3. Specify the **Car Model** table as the source table.
4. Specify `APIVersion`, `APIPublisher`, `APIGroup`, `EntityName`, and `EntitySetName` for your API page. These properties will affect your custom endpoint:
   `https://api.businesscentral.dynamics.com/v1.0/<user domain name>/api/<API publisher>/<API group>/<API version>/companies(<company id>)/carModel`
   . For more information, see Business Central API endpoints and Calling the API.
5. Specify `EntityCaption` and `EntitySetCaption`. These two properties are generated in the entityDefinitions
   `https://api.businesscentral.dynamics.com/v1.0/<user domain name>/api/<API publisher>/<API group>/<API version>/entityDefinitions`
   which are localized and translatable.
6. Make sure to set the `ODataKeyFields` property to `SystemId`. A SystemId field is a GUID data type field that specifies a unique, immutable (read-only) identifier for records in the table. For more information, see Table Object.

```
page 50101 "API Car Model"
{
    PageType = API;

    APIVersion = 'v1.0';
    APIPublisher = 'bctech';
    APIGroup = 'demo';

    EntityCaption = 'CarModel';
    EntitySetCaption = 'CarModels';
    EntityName = 'carModel';
    EntitySetName = 'carModels';

    ODataKeyFields = SystemId;
    SourceTable = "Car Model";

    Extensible = false;
    DelayedInsert = true;

    layout
    {
        area(content)
        {
            repeater(Group)
            {
                field(id; Rec.SystemId)
                {
                    Caption = 'Id';
                    Editable = false;
                }
                field(name; Rec.Name)
                {
                    Caption = 'Name';
                }
                field(description; Rec.Description)
                {
                    Caption = 'Description';
                }
                field(brandId; Rec."Brand Id")
                {
                    Caption = 'Brand Id';
                }
                field(power; Rec.Power)
                {
                    Caption = 'Power';
                }
                field(fuelType; Rec."Fuel Type")
                {
                    Caption = 'Fuel Type';
                }
            }
        }
    }
}
```

7. Now, repeat the steps 1-6 for **API Car Brand** page.
8. You can define a **API Car Model** part in **API Car Brand** page. Make sure to use the SystemId field when defining the SubPageLink. This will generate **ReferentialConstraints** property in the metadata as below:

```
<NavigationProperty Name="carModels" Type="Collection(Microsoft.NAV.carModel)" Partner="carBrand"
ContainsTarget="true">
<ReferentialConstraint Property="id" ReferencedProperty="brandId"/>
</NavigationProperty>
```

And the **API Car Brand** page:

```
page 50100 "API Car Brand"
{
    PageType = API;

    APIVersion = 'v1.0';
    APIPublisher = 'bctech';
    APIGroup = 'demo';

    EntityCaption = 'CarBrand';
    EntitySetCaption = 'CarBrands';
    EntityName = 'carBrand';
    EntitySetName = 'carBrands';

    ODataKeyFields = SystemId;
    SourceTable = "Car Brand";

    Extensible = false;
    DelayedInsert = true;

    layout
    {
        area(content)
        {
            repeater(Group)
            {
                field(id; Rec.SystemId)
                {
                    Caption = 'Id';
                    Editable = false;
                }

                field(name; Rec.Name)
                {
                    Caption = 'Name';
                }
                field(description; Rec.Description)
                {
                    Caption = 'Description';
                }
                field(country; Rec.Country)
                {
                    Caption = 'Country';
                }
                part(carModels; "API Car Model")
                {
                    Caption = 'Car Models';
                    EntityName = 'carModel';
                    EntitySetName = 'carModels';
                    SubPageLink = "Brand Id" = Field(SystemId);
                }
            }
        }
    }
}
```

TIP

Parts are defined as 1-N relationship by default. You can, however, define it to be as 1-0, 1-1 relationship. In order to achieve that add the **CaptionML = ENU = 'Multiplicity=ZeroOrOne';** property in your part as shown below:

```
part(carModels; "API Car Model")
   {
       CaptionML = ENU = 'Multiplicity=ZeroOrOne';
       EntityName = 'carModel';
       EntitySetName = 'carModels';
       SubPageLink = "Brand Id" = Field(SystemId);
   }
```

This will change the **NavigationalProperty** in the metadata from a Collection to an object as shown below:

```
<NavigationProperty Name="carModel" Type="Microsoft.NAV.carModel" ContainsTarget="true">
           <ReferentialConstraint Property="id" ReferencedProperty="brandId"/>
       </NavigationProperty>
```

Using carBrand and carModel APIs

Both API pages support create, read, update, and delete operations. If you want to disallow create, update, and delete operations, you can use the **InsertAllowed**, **ModifyAllowed**, and **DeleteAllowed** properties respectively.

Now, we will create a car brand:

```
POST https://api.businesscentral.dynamics.com/v2.0/<environmentName>/api/bctech/demo/v1.0/companies(<company
id>)/carBrands

{
    "name": "CARBRAND1",
    "description": "Car Brand 1",
    "country": "Italy"
}
```

We can make a `GET` request to retrieve the car brands:

```
GET https://api.businesscentral.dynamics.com/v2.0/<environmentName>/api/bctech/demo/v1.0/companies(<company
id>)/carBrands
```

Which will result in following response:

```
{

"@odata.context":"https://api.businesscentral.dynamics.com/v2.0/<environmentName>/api/bctech/demo/v1.0/$meta
data#companies(<company id>)/carBrands",
   "value":[
      {
         "@odata.etag":"W/\"JzQ0O2c4UTNaRHErODdzODZnVlJxN2tNTkt3SHBwajNBaHNSdStNeEFONGUwVkE9MTswMDsn\"",
         "id":"24cafc3a-b1fe-ea11-9306-000d3a482952",
         "name":"CARBRAND1",
         "description":"Car Brand 1",
         "country":"Italy"
      }
   ]
}
```

We can now create a car model that belongs to the car brand that we just created. Since the navigational property is defined in the API page as a part, we can create a car model in one of the following different ways:

Example 1

```
POST https://api.businesscentral.dynamics.com/v2.0/<environmentName>/api/bctech/demo/v1.0/companies(<company
id>))/carBrands(24cafc3a-b1fe-ea11-9306-000d3a482952)/carModels
{
    "name": "MODEL1",
    "description": "Model 1",
    "power": 1700,
    "fuelType": "Petrol"
}
```

Example 2

```
POST https://api.businesscentral.dynamics.com/v2.0/<environmentName>/api/bctech/demo/v1.0/companies(<company
id>))//carModels
{
    "name": "MODEL1",
    "brandId": "24cafc3a-b1fe-ea11-9306-000d3a482952",
    "description": "Model 1",
    "power": 1700,
    "fuelType": "Petrol"
}
```

Example 3

And the navigational property also allows us to do a deep insert; deep insert is the creation of an entity instance and related entity instances, in a single `POST` request. So you can combine car brand and car model creation in a single request as illustrated below:

```
POST https://api.businesscentral.dynamics.com/v2.0/<environmentName>/api/bctech/demo/v1.0/companies(<company
id>))//carBrands
{
    "name": "CARBRAND2",
    "description": "Car Brand 2",
    "country": "Germany",
    "carModels": [{
        "name": "MODELA",
        "description": "Model A",
        "power": 0,
        "fuelType": "Electric"
       },
       {
        "name": "MODELB",
        "description": "Model B",
        "power": 0,
        "fuelType": "Electric"
       }]
}
```

> **NOTE**
>
> The sample code is published to the BCTech repo. For more information, see Introduction to Custom API.

General tips for custom APIs

1. Use SystemId as the OData primary key.

2. Make sure that all the table fields in TableRelations/SubPageLinks are available in the API pages and make sure to define the relationship multiplicity (1-0/1-1 or 1-N).
    - Doing so enables the platform to generate ReferentialConstraints, that OData consumers can use to understand the relations between entities
    - The platform will also create bi-directional relationship if possible, allowing consumers to access to the parent by just adding "/parentEntity" in the URI
3. Use Enumerations.
4. Make sure to localize your custom API pages:
    - Use `EntityCaption` and `EntitySetCaption` properties
    - Use captions for Enums
    - All these localizations can be retrieved through
      ```
      https://api.businesscentral.dynamics.com/v2.0/<environmentName>/api/<API publisher>/<API group>/<API version>/entityDefinitions
      ```

Customizing an Integration with Microsoft Dataverse

2/17/2021 • 17 minutes to read • Edit Online

NOTE

Effective November 2020:

- Common Data Service has been renamed to Microsoft Dataverse. Learn more
- Some terminology in Microsoft Dataverse has been updated. For example, *entity* is now *table* and *field* is now *column*. Learn more

This walkthrough describes how to customize an integration between Business Central and Microsoft Dataverse. The walkthrough will guide you through setting up an integration between an employee in Business Central and a worker in Microsoft Dataverse.

TIP

Sample code that shows how to integrate an employee in Business Central and a worker in Microsoft Dataverse is available in the BCTech repository.

About this walkthrough

This walkthrough describes how to integrate new and existing extensions with Microsoft Dataverse. At a high-level, those process involve the following tasks:

1. Develop an AL extension to integrate tables in Microsoft Dataverse and Business Central. For more information, see Developing Extensions in AL.
2. Create an integration table object in Business Central for mapping a Microsoft Dataverse table to a Business Central record type.
3. Use a Microsoft Dataverse integration table as the data source for a page in Business Central that displays data from Microsoft Dataverse table rows.
4. Extend a page in Business Central for coupling and synchronizing table rows in Microsoft Dataverse with table records in Business Central.
5. Use events to create an integration table and a field mapping between a table in Business Central and an integration table for Microsoft Dataverse.
6. Develop another AL extension to extend an existing integration between tables in Microsoft Dataverse and Business Central.
7. Create a table extension for an existing integration table object.
8. Use events to add custom integration field mappings for existing integration table mappings.

NOTE

The customization in this walkthrough is done entirely in Business Central online, and does not describe how to modify your Microsoft Dataverse solution, for example, by adding or modifying tables and forms.

Prerequisites

This walkthrough requires the following:

- Microsoft Dataverse, including the following:
  - Worker table.

    > **NOTE**
    > To get the worker table you must install the Talent Core HR solution. For more information, see Microsoft Dataverse tables.

  - The URL of your Microsoft Dataverse environment.
  - The user name and password of a user account that has full permissions to add and modify tables.
- Business Central, including the following:
  - The CRONUS International Ltd. demonstration data.
  - Integration with Microsoft Dataverse is enabled, including the default synchronization setup and a working connection between Business Central and Microsoft Dataverse.
  - Visual Studio Code with the AL Language extension installed. For more information, see Getting Started with AL and AL Language Extension Configuration. The AL Language extension for Visual Studio is free, and you can download it from Marketplace.

    > **NOTE**
    > Make sure that your integration user has permission to access the Worker table in Microsoft Dataverse.

Create an integration table in Business Central for the Microsoft Dataverse table

To integrate data from a Microsoft Dataverse table into Business Central, you must create a table object in Business Central that is based on the Microsoft Dataverse table, and then import the new table into the Business Central database. For this walkthrough we will create a table object that describes the schema for the **Worker** table in Microsoft Dataverse in the Business Central database.

> **NOTE**
> The table can contain some or all of the fields from the Microsoft Dataverse table. However, if you want to set up bi-directional synchronization you must include all fields in the table.

To create the integration table for the worker table in Business Central

1. Create a new AL extension. For more information, see Developing Extensions in AL.
2. Export the **AL Table Proxy Generator** tool called **altpgen.exe** from the Visual Studio Code AL extension. This executable tool allows you to create integration tables. When you have installed the AL Language extension, go to the equivalent of this folder: `C:\Users\<myname>\.vscode\extensions\microsoft.al-4.0.209721\bin` and find the `altpgen.exe` file. For more information, see AL Table Proxy Generator.
3. In PowerShell, run the tool with the following arguments:

```
-project:<Your AL project folder>
-packagecachepath:<Your AL project cache folder>
-serviceuri:<Microsoft Dataverse server URL>
-entities:cds_worker
-baseid:50000
```

This starts the process for creating the table. When completed, the output path contains the `.al` file that contains the description of the **CDS Worker** integration table with ID 50000. This table is set to the table type **CDS**.

Create a page for displaying Microsoft Dataverse data

For scenarios where we want to view Microsoft Dataverse data for a specific table, we can create a page object that uses the integration table for the Microsoft Dataverse table as its data source. For example, we might want to have a list page that displays the current records in a Microsoft Dataverse table, such as all workers. In this walkthrough we will create a list page that uses the generated integration table **CDS Worker** with ID 50000 as its data source.

To create a list page to display Microsoft Dataverse workers

1. Create a new page. For more information, see Pages Overview.
2. Name the page **CDS Worker List**, and specify **50001** as the page ID.
3. Specify the **CDS Worker** integration table as the source table as shown below:

```
page 50001 "CDS Worker List"
{
    PageType = List;
    SourceTable = "CDS Worker";
    Editable = false;
    ApplicationArea = All;
    UsageCategory = Lists;
    ...

    layout
    {
        // add fields to display on the page
    }

    actions
    {
        area(processing)
        {
            action(CreateFromCDS)
            {
                ApplicationArea = All;
                Caption = 'Create in Business Central';
                Promoted = true;
                PromotedCategory = Process;
                ToolTip = 'Generate the table from the coupled Microsoft Dataverse worker.';

                trigger OnAction()
                var
                    CDSWorker: Record "CDS Worker";
                    CRMIntegrationManagement: Codeunit "CRM Integration Management";
                begin
                    CurrPage.SetSelectionFilter(CDSWorker);
                    CRMIntegrationManagement.CreateNewRecordsFromCRM(CDSWorker);
                end;
            }
        }
    }

    var
        CurrentlyCoupledCDSWorker: Record "CDS Worker";

    trigger OnInit()
    begin
        Codeunit.Run(Codeunit::"CRM Integration Management");
    end;

    procedure SetCurrentlyCoupledCDSWorker(CDSWorker: Record "CDS Worker")
    begin
        CurrentlyCoupledCDSWorker := CDSWorker;
    end;
}
```

4. Add the fields from the integration table to display on the page in the `layout` section.

Enable coupling and synchronization between Worker in Microsoft Dataverse and in Business Central

To connect a Business Central table record with a Microsoft Dataverse table row, you create a coupling. A coupling consists of the primary ID, which is typically a GUID, from a Microsoft Dataverse row and the integration ID, also often a GUID, from Business Central.

1. Create a new codeunit.
2. In codeunit **CRM Setup Defaults** (ID 5334), subscribe to the **OnGetCDSTableNo** event, as follows:

```
[EventSubscriber(ObjectType::Codeunit, Codeunit::"CRM Setup Defaults", 'OnGetCDSTableNo', '', false, false)]
local procedure HandleOnGetCDSTableNo(BCTableNo: Integer; var CDSTableNo: Integer; var handled: Boolean)
begin
    if BCTableNo = DATABASE::Employee then begin
        CDSTableNo := DATABASE::"CDS Worker";
        handled := true;
    end;
end;
```

You can now use the table to create a page for coupling Business Central records with Microsoft Dataverse rows.

3. In codeunit **Lookup CRM Tables** (ID 5332), subscribe to the **OnLookupCRMTables** event, as follows:

```
[EventSubscriber(ObjectType::Codeunit, Codeunit::"Lookup CRM Tables", 'OnLookupCRMTables', '', true, true)]
local procedure HandleOnLookupCRMTables(CRMTableID: Integer; NAVTableId: Integer; SavedCRMId: Guid; var
CRMId: Guid; IntTableFilter: Text; var Handled: Boolean)
begin
    if CRMTableID = Database::"CDS Worker" then
        Handled := LookupCDSWorker(SavedCRMId, CRMId, IntTableFilter);
end;

local procedure LookupCDSWorker(SavedCRMId: Guid; var CRMId: Guid; IntTableFilter: Text): Boolean
var
    CDSWorker: Record "CDS Worker";
    OriginalCDSWorker: Record "CDS Worker";
    CDSWorkerList: Page "CDS Worker List";
begin
    if not IsNullGuid(CRMId) then begin
        if CDSWorker.Get(CRMId) then
            CDSWorkerList.SetRecord(CDSWorker);
        if not IsNullGuid(SavedCRMId) then
            if OriginalCDSWorker.Get(SavedCRMId) then
                CDSWorkerList.SetCurrentlyCoupledCDSWorker(OriginalCDSWorker);
    end;

    CDSWorker.SetView(IntTableFilter);
    CDSWorkerList.SetTableView(CDSWorker);
    CDSWorkerList.LookupMode(true);
    if CDSWorkerList.RunModal = ACTION::LookupOK then begin
        CDSWorkerList.GetRecord(CDSWorker);
        CRMId := CDSWorker.WorkerId;
        exit(true);
    end;
    exit(false);
end;
```

To create actions on the employee page for managing coupling and synchronization

To enable users to create couplings between records in the two systems, we will extend the **Employee Card** page with actions for creating and deleting couplings, and for synchronizing. The following code example adds those actions to **Employee Card**.

```
pageextension 50101 "Employee Synch Extension" extends "Employee Card"
{
    actions
    {
        addlast(navigation)
        {
            group(ActionGroupCDS)
            {
                Caption = 'CDS';
                Visible = CDSIntegrationEnabled;

                action(CDSSynchronizeNow)
```

```
                {
                    Caption = 'Synchronize';
                    ApplicationArea = All;
                    Visible = true;
                    Image = Refresh;
                    Enabled = CDSIsCoupledToRecord;
                    ToolTip = 'Send or get updated data to or from Microsoft Dataverse.';

                    trigger OnAction()
                    var
                        CRMIntegrationManagement: Codeunit "CRM Integration Management";
                    begin
                        CRMIntegrationManagement.UpdateOneNow(RecordId);
                    end;
                }
                action(ShowLog)
                {
                    Caption = 'Synchronization Log';
                    ApplicationArea = All;
                    Visible = true;
                    Image = Log;
                    ToolTip = 'View integration synchronization jobs for the customer table.';

                    trigger OnAction()
                    var
                        CRMIntegrationManagement: Codeunit "CRM Integration Management";
                    begin
                        CRMIntegrationManagement.ShowLog(RecordId);
                    end;
                }
                group(Coupling)
                {
                    Caption = 'Coupling';
                    Image = LinkAccount;
                    ToolTip = 'Create, change, or delete a coupling between the Business Central record and
a Microsoft Dataverse row.';

                    action(ManageCDSCoupling)
                    {
                        Caption = 'Set Up Coupling';
                        ApplicationArea = All;
                        Visible = true;
                        Image = LinkAccount;
                        ToolTip = 'Create or modify the coupling to a Microsoft Dataverse Worker.';

                        trigger OnAction()
                        var
                            CRMIntegrationManagement: Codeunit "CRM Integration Management";
                        begin
                            CRMIntegrationManagement.DefineCoupling(RecordId);
                        end;
                    }
                    action(DeleteCDSCoupling)
                    {
                        Caption = 'Delete Coupling';
                        ApplicationArea = All;
                        Visible = true;
                        Image = UnLinkAccount;
                        Enabled = CDSIsCoupledToRecord;
                        ToolTip = 'Delete the coupling to a Microsoft Dataverse Worker.';

                        trigger OnAction()
                        var
                            CRMCouplingManagement: Codeunit "CRM Coupling Management";
                        begin
                            CRMCouplingManagement.RemoveCoupling(RecordId);
                        end;
                    }
                }
```

```
            }
        }
    }

    trigger OnOpenPage()
    begin
        CDSIntegrationEnabled := CRMIntegrationManagement.IsCDSIntegrationEnabled();
    end;

    trigger OnAfterGetCurrRecord()
    begin
        if CDSIntegrationEnabled then
            CDSIsCoupledToRecord := CRMCouplingManagement.IsRecordCoupledToCRM(RecordId);
    end;

    var
        CRMIntegrationManagement: Codeunit "CRM Integration Management";
        CRMCouplingManagement: Codeunit "CRM Coupling Management";
        CDSIntegrationEnabled: Boolean;
        CDSIsCoupledToRecord: Boolean;

}
```

Customizing Uncoupling

Tables might require custom code to remove couplings, for example, to change tables before or after uncoupling. To enable custom uncoupling, specify the uncoupling codeunit when you create an integration table mapping. To do this, adjust the function **InsertIntegrationTableMapping** in your codeunit, as follows:

```
local procedure InsertIntegrationTableMapping(var IntegrationTableMapping: Record "Integration Table
Mapping"; MappingName: Code[20]; TableNo: Integer; IntegrationTableNo: Integer; IntegrationTableUIDFieldNo:
Integer; IntegrationTableModifiedFieldNo: Integer; TableConfigTemplateCode: Code[10];
IntegrationTableConfigTemplateCode: Code[10]; SynchOnlyCoupledRecords: Boolean)
begin
    IntegrationTableMapping.CreateRecord(MappingName, TableNo, IntegrationTableNo,
IntegrationTableUIDFieldNo, IntegrationTableModifiedFieldNo, TableConfigTemplateCode,
IntegrationTableConfigTemplateCode, SynchOnlyCoupledRecords,
IntegrationTableMapping.Direction::Bidirectional, 'CDS', Codeunit::"CRM Integration Table Synch.",
Codeunit::"CDS Int. Table Uncouple");
end;
```

During the custom uncoupling process, codeunit Int. Rec. Uncouple Invoke (ID 5357) raises and publishes events. You can add code that subscribes to these events so that you can add custom logic at different stages of the uncoupling process. The following table describes the events that are published by codeunit Int. Rec. Uncouple Invoke.

- **OnBeforeUncoupleRecord** - Occurs before remove coupling, and can be used to change data before uncoupling. For an example, see codeunit CDS Int. Table. Subscriber, which includes the event subscriber function HandleOnBeforeUncoupleRecord. The event resets the company ID on the uncoupled tables in Microsoft Dataverse.
- **OnAfterUncoupleRecord** - Occurs after coupling is removed, and can be used to change data after uncoupling. For an example, see codeunit CDS Int. Table. Subscriber, which includes the event subscriber function HandleOnAfterUncoupleRecord. The event removes couplings to the contacts linked to the uncoupled customers and vendors.

For more information about how to subscribe to events, see Subscribing to Events.

Be aware that custom uncoupling is running in background as it could modify Microsoft Dataverse tables and it might take significant time.

TIP

To reset Company ID on uncoupling custom tables just like the base Microsoft Dataverse tables, users can subscribe to the OnHasCompanyIdField event in codeunit CDS Integration Mgt. (ID 7200), as follows:

```
[EventSubscriber(ObjectType::Codeunit, Codeunit::"CDS Integration Mgt.", 'OnHasCompanyIdField', '',
false, false)]
local procedure HandleOnHasCompanyIdField(TableId: Integer; var HasField: Boolean)
begin
  if TableId = Database::"CDS Worker" then
    HasField := true;
end;
```

Create default integration table mappings and field mappings

For synchronization to work, mappings must exist to associate the table ID and fields of the integration table (in this case, **CDS Worker**) with the table in Business Central (in this case table **Employee**). There are two types of mapping:

- **Integration table mapping** - Integration table mapping links the Business Central table to the integration table for the Microsoft Dataverse table.
- **Integration field mapping** - Field mapping links a field in a table row in Microsoft Dataverse with a field in a record in Business Central. This determines which field in Business Central corresponds to which field in Microsoft Dataverse. Typically, there are multiple field mappings for a table.

In this scenario, we will create integration table and field mappings so that we can synchronize data for a worker in Microsoft Dataverse with an employee in Business Central.

To create an integration table mapping

We can create the integration table mapping by subscribing to the **OnAfterResetConfiguration** event in codeunit **CDS Setup Defaults** (ID 7204).

1. Create a codeunit.
2. Add a local procedure called **InsertIntegrationTableMapping**, as follows:

```
local procedure InsertIntegrationTableMapping(var IntegrationTableMapping: Record "Integration Table
Mapping"; MappingName: Code[20]; TableNo: Integer; IntegrationTableNo: Integer;
IntegrationTableUIDFieldNo: Integer; IntegrationTableModifiedFieldNo: Integer;
TableConfigTemplateCode: Code[10]; IntegrationTableConfigTemplateCode: Code[10];
SynchOnlyCoupledRecords: Boolean)
begin
    IntegrationTableMapping.CreateRecord(MappingName, TableNo, IntegrationTableNo,
IntegrationTableUIDFieldNo, IntegrationTableModifiedFieldNo, TableConfigTemplateCode,
IntegrationTableConfigTemplateCode, SynchOnlyCoupledRecords,
IntegrationTableMapping.Direction::Bidirectional, 'CDS');
end;
```

3. In codeunit **CDS Setup Defaults**, subscribe to the **OnAfterResetConfiguration** event, as follows:

```
[EventSubscriber(ObjectType::Codeunit, Codeunit::"CDS Setup Defaults", 'OnAfterResetConfiguration',
'', true, true)]
local procedure HandleOnAfterResetConfiguration(CDSConnectionSetup: Record "CDS Connection Setup")
var
    IntegrationTableMapping: Record "Integration Table Mapping";
    IntegrationFieldMapping: Record "Integration Field Mapping";
    CDSWorker: Record "CDS Worker";
    Employee: Record Employee;
begin
    InsertIntegrationTableMapping(
        IntegrationTableMapping, 'EMPLOYEE-WORKER',
        DATABASE::Employee, DATABASE::"CDS Worker",
        CDSWorker.FieldNo(cdm_workerId), CDSWorker.FieldNo(ModifiedOn),
        '', '', true);

    ...
end;
```

For each integration table mapping entry, there must be integration field mapping entries to map the fields of the records in the table and the integration table. The next step is to add integration field mappings for each field in the **Employee** table in Business Central that we want to map to the **Worker** table in Microsoft Dataverse.

To create integration fields mappings

To create an integration field mapping, follow these steps:

1. Add a local procedure called **InsertIntegrationFieldMapping** to the codeunit that you created in step 1 of the previous process, as follows:

```
procedure InsertIntegrationFieldMapping(IntegrationTableMappingName: Code[20]; TableFieldNo: Integer;
IntegrationTableFieldNo: Integer; SynchDirection: Option; ConstValue: Text; ValidateField: Boolean;
ValidateIntegrationTableField: Boolean)
var
    IntegrationFieldMapping: Record "Integration Field Mapping";
begin
    IntegrationFieldMapping.CreateRecord(IntegrationTableMappingName, TableFieldNo,
IntegrationTableFieldNo, SynchDirection,
        ConstValue, ValidateField, ValidateIntegrationTableField);
end;
```

2. In the event subscriber that we created for our integration table mapping (in step 3 in the previous process), after we insert the integration table mapping we will add field mappings, as follows:

```
InsertIntegrationFieldMapping('EMPLOYEE-WORKER', Employee.FieldNo("First Name"),
CDSWorker.FieldNo(cdm_FirstName), IntegrationFieldMapping.Direction::Bidirectional, '', true, false);
```

3. Now repeat these steps for each field that we want to map.

> **TIP**
> If a field in one of the tables does not have a corresponding field in the other table, we can use a constant value.

4. After publishing the extension, we can update the default mappings to include our new integration table mapping by opening the **CDS Connection Setup** page in Business Central and choosing **Use Default Synchronization Setup**.

Users can now manually synchronize employee records in Business Central with Worker table rows in Microsoft

Dataverse from the Business Central client.

> **TIP**
> To learn how to schedule the synchronization by using a job queue entry, examine the code on the **RecreateJobQueueEntry** function in codeunit **CRM Integration Management** (ID 5330) and see how it is called by the integration code for other Microsoft Dataverse tables in the codeunit. For more information, see Scheduling a Synchronization.

Enable customers to reset selected integration table mappings to the default settings

Customers might make changes to the integration table mappings that they later regret. To enable them to reset selected custom integration table mappings to the default, rather than all custom table mappings, follow these steps:

- In the same codeunit created for this section, add an event subscriber to **OnBeforeHandleCustomIntegrationTableMapping** and point to the default behavior, as follows:

```
[EventSubscriber(ObjectType::Codeunit, Codeunit::"CRM Integration Management",
'OnBeforeHandleCustomIntegrationTableMapping', '', false, false)]
local procedure HandleCustomIntegrationTableMappingReset(var IsHandled: Boolean;
IntegrationTableMappingName: Code[20])
var
    IntegrationTableMapping: Record "Integration Table Mapping";
begin
    case IntegrationTableMappingName of
        'EMPLOYEE-WORKER':
            begin
                InsertIntegrationTableMapping(
                    IntegrationTableMapping, 'EMPLOYEE-WORKER',
                    DATABASE::Employee, DATABASE::"CDS Worker", C
                    DSWorker.FieldNo(cdm_workerId), CDSWorker.FieldNo(ModifiedOn),
                    '', '', true);
                InsertIntegrationFieldMapping('EMPLOYEE-WORKER',
                    Employee.FieldNo("First Name"), CDSWorker.FieldNo(cdm_FirstName),
                    IntegrationFieldMapping.Direction::Bidirectional, '', true, false);
                ...
                IsHandled := true;
            end;
            ...
    end;
end;
```

> **IMPORTANT**
> You must set the the IsHandled property to `true` to avoid triggering the default implementation. Otherwise, all custom table mappings will be reset to default, regardless of the user's selection.

Customizing Synchronization

When synchronizing data, some tables may require custom code to successfully synchronize data. Other tables might require the initialization of fields, the validation of relationships, or the transformation of data.

You can either use the standard transformation rules on page **Integration Field Mapping List** (ID 5361) or you can transform data programmatically. For more information, see Transformation Rules.

During the synchronization process, certain events are published and raised by codeunit **Integration Table Synch.** (ID 5335). We can add code that subscribes to these events so that we can add custom logic at different stages of the synchronization process. The following table describes the events that are published by codeunit

Integration Table Synch..

EVENT	DESCRIPTION
OnFindUnCoupledDestinationRecord	Occurs when the process tries to synchronize an uncoupled record (new record). Use this event to implement custom resolution algorithms for automatic mapping between records. For example, use this event to automatically map records by fields. For an example, see codeunit **CRM Int. Table. Subscriber**, which includes the event subscriber function **CRMTransactionCurrencyFindUncoupledDestinationRecord**. The event resolves Business Central currency codes with ISO currency codes in Microsoft Dataverse.
OnBeforeApplyRecordTemplate	Occurs before applying configuration templates to new records, and can be used to implement algorithms for determining which configuration template to use.
OnAfterApplyRecordTemplate	Occurs after configuration templates are applied to new records, and can be used to change data after configuration templates have been applied.
OnBeforeTransferRecordFields	Occurs before transferring data in modified fields (which are defined in the **Integration Field Mapping** table) from the source table to the destination table. It can be used to validate the source or destination before the data is moved.
OnAfterTransferRecordFields	Occurs after transferring modified field data (which are defined in the Integration Field Mapping table) from the source table to the destination table. It can be used to transfer additional data, validate lookups, and so on. Setting the **AdditionalFieldsWereModified** parameter will cause a destination record modification even though no fields were modified.
OnBeforeInsertRecord	Occurs before inserting a new destination record, and can be used to initialize fields, such as primary keys.
OnAfterInsertRecord	Occurs after a new destination record is inserted, and can be used to perform post-insert operations such as updating related data.
OnBeforeModifyRecord	Occurs before modifying an existing destination record, and can be used to validate or change data before modification.
OnAfterModifyRecord	Occurs after an existing destination record is modified, and can be used to perform post-modify operations such as updating related data.
OnTransferFieldData	Occurs before an existing destination field value is transferred to a source field, and can be used to perform specific transformations of data when the data types of the source and the destination field are different but can be mapped.

For more information about how to subscribe to events, see Subscribing to Events.

TIP

In order to have Company ID mapping for custom tables just like the base Microsoft Dataverse tables , users can subscribe to the **OnBeforeInsertRecord** event in codeunit **Integration Rec. Synch. Invoke** (ID 5345), as follows:

```
  [EventSubscriber(ObjectType::Codeunit, Codeunit::"Integration Rec. Synch. Invoke",
'OnBeforeInsertRecord', '', false, false)]
  local procedure HandleOnBeforeInsertRecord(SourceRecordRef: RecordRef; DestinationRecordRef:
RecordRef)
  var
      CDSIntegrationMgt: Codeunit "CDS Integration Mgt.";
  begin
  if DestinationRecordRef.Number() = Database::"CDS Worker" then
      CDSIntegrationMgt.SetCompanyId(DestinationRecordRef);
  end;
```

For more information on base Microsoft Dataverse tables, see Data Ownership Models.

Create a table extension for an integration table in Business Central

Let us explore another scenario. If we added an **Industry** field to the **Contact** table in Microsoft Dataverse, and now want to include the field in our integration with Microsoft Dataverse.

TIP

Sample code that customizes an integration between a contact in Business Central and a contact in Microsoft Dataverse by adding a new field is available in the BCTech repository.

To create the integration table extension for table "CRM Contact" (ID 5342)

1. Create a new AL extension.
2. Locate the **AL Table Proxy Generator** tool. See the previous section.
3. In PowerShell, run the tool with the following arguments:

   ```
   -project:<Your AL project folder>
   -packagecachepath:<Your AL project cache folder>
   -serviceuri:<CDS server URL>
   -entities:contact
   -baseid:60000
   ```

   The process for creating the table starts. The AL Table Proxy Generator tool finds that an integration table for the **Contact** table already exists, so it creates a table extension with only new fields; in this case **Industry**. When the process is completed, the output path contains the `WorkerExt.al` file.

Extend the contact table and page with the Industry field

To synchronize the **Industry** field we need to add the field in Business Central. The following code example extends table **Contact** and page **Contact Card** with new the field. For example:

```
tableextension 60001 ContactExtension extends Contact
{
    fields
    {
        field(70116; "Industry"; Text[100])
        {
        }
    }
}

pageextension 60001 ContactCardExtension extends "Contact Card"
{
    layout
    {
        addlast(General)
        {
            field("Industry"; "Industry")
            {
                ApplicationArea = All;
                Caption = 'Industry';
            }
        }
    }
}
```

Add new integration field mapping for Industry

Now that we have the field in both Business Central and Microsoft Dataverse, we can add a new integration field mapping for it. To do that we will subscribe to the **OnAfterResetContactContactMapping** event in codeunit **CDS Setup Defaults** (ID 7204), as follows:

```
[EventSubscriber(ObjectType::Codeunit, Codeunit::"CDS Setup Defaults", 'OnAfterResetContactContactMapping',
'', true, true)]
local procedure HandleOnAfterResetContactContactMapping(IntegrationTableMappingName: Code[20])
var
    CDSContact: Record "CRM Contact";
    Contact: Record Contact;
    IntegrationFieldMapping: Record "Integration Field Mapping";
begin
    InsertIntegrationFieldMapping(
        IntegrationTableMappingName,
        Contact.FieldNo("Industry"),
        CDSContact.FieldNo(cr07b_Industry),
        IntegrationFieldMapping.Direction::Bidirectional,
        '', true, false);
end;
```

After we publish the extension we can update the mappings by running the **CDS Connection Setup** page and choosing **Use Default Synchronization Setup**.

AL Table Proxy Generator

2/17/2021 • 2 minutes to read • Edit Online

NOTE

Effective November 2020:

- Common Data Service has been renamed to Microsoft Dataverse. Learn more
- Some terminology in Microsoft Dataverse has been updated. For example, *entity* is now *table* and *field* is now *column*. Learn more

The **AL Table Proxy Generator** tool can be used to generate one or more tables for integration with Microsoft Dataverse. When one or more tables are present in Microsoft Dataverse, but not in Dynamics 365 Business Central, the tool can be run to generate integration or proxy tables for the specified table or tables.

An integration or proxy table is a table that represents a table in Microsoft Dataverse. The integration table includes fields that correspond to columns in the Microsoft Dataverse table. The integration table acts as a link or connector between the Business Central table and the Microsoft Dataverse table.

The **AL Table Proxy Generator** tool is available with the **AL Language** extension. Look for the **altpgen.exe** tool in the equivalent folder of `c:\users\<username>\.vscode\extensions\<al extension version>\bin`.

Generating proxy tables

1. Start Windows PowerShell as an administrator.
2. From the command prompt, write `.\altpgen.exe` followed by the parameters as described below.

```
-Project
-PackageCachePath
-ServiceURI
-Entities
-BaseId
-[TableType]
```

3. The table or tables are generated in the folder of the specified AL project.

Parameters

PARAMETER	DESCRIPTION
Project	The AL project folder to create the table(s) in.
PackageCachePath	The AL project cache folder for symbols. **Note:** It is important that the latest symbols have been downloaded because these are used for comparison when the tool runs.
ServiceURI	The server URL for Microsoft Dataverse. For example, `https://tenant.crm.dynamics.com`.

PARAMETER	DESCRIPTION
Entities	The table(s) to create in AL. If multiple, this must be specified as a comma-separated list. **Note:** It is important that all related tables are specified too. Related tables are, for example, used for lookups and if the related tables are not found, a lookup will no longer be working. For more information, see the section Specifying tables.
BaseId	The assigned starting ID for the generated new table(s) in AL.
TableType	The table type for the table(s) in AL. The options are `CDS` and `CRM`. **Note:** If unspecified, the system looks both for `CDS` and `CRM` tables .

Specifying tables

The `Entitites` parameter specifies the logical names of the table(s) to create in AL. To know which ones to specify you need to check the *main* table relationships in Microsoft Dataverse. For more information, see Table relationships overview. You specify all tables that you want created, including the related tables, in the `Entities` parameter separated by commas.

Related tables

An example could be, that you want to generate an AL proxy table for the **CDS Worker Address** (cdm_workeraddress).

If you run the altpgen tool and only specify `cdm_workeraddress`, the tool will not generate the `Worker` lookup field, because no related table `Worker` is specified.

If you, in the `Entities` parameter specify `cdm_workeraddress, cdm_worker`, the `Worker` lookup field will be generated. Furthermore, if your *symbols contain* the `cdm_worker` table definition, the `Worker` table will not be created as it's already in your symbols. If your *symbols do not contain* the `cdm_worker` table, the `Worker` table will be created together with the `Worker Address` table.

Creating a new integration table

The following example starts the process for creating a new integration table in the specified AL project. When complete, the output path contains the **Worker.al** file that contains the description of the **50000 CDS Worker** integration table. This table is set to the table type **CDS**.

```
.\altpgen -project:"C:\myprojectpath" -packagecachepath:"C:\mypackagepath" -
serviceuri:"https://tenant.crm.dynamics.com" -entities:cdm_worker,cdm_workeraddress -baseid:50000 -
tabletype:CDS
```

Custom Integration with Microsoft Dataverse

Microsoft Power Platform Integration with Business Central

2/17/2021 • 2 minutes to read • Edit Online

PREVIEW: This feature is in preview in Business Central 2020 release wave 2

> **NOTE**
>
> Effective November 2020:
>
> - Common Data Service has been renamed to Microsoft Dataverse. Learn more
> - Some terminology in Microsoft Dataverse has been updated. For example, *entity* is now *table* and *field* is now *column*. Learn more

> **NOTE**
>
> The **Business Central Virtual Entity (Preview)** app available on AppSource is being updated to reflect new terminology with an upcoming release. This also applies to that terminology used in Business Central.

> **IMPORTANT**
>
> This functionality requires version 17 for Business Central, while service update 189 is required for Microsoft Dataverse. The release information for Microsoft Dataverse is published on the latest version availability page.

Business Central Virtual table, which is published on AppSource, is a virtual data source in Microsoft Dataverse, and enables create, read, update, delete (CRUD) operations from Microsoft Dataverse and Microsoft Power Platform. By definition, the data for virtual tables does not reside in Microsoft Dataverse. Instead, it continues to reside in Business Central. To enable operations on Business Central tables in Microsoft Dataverse, tables must be made available as virtual tables in Microsoft Dataverse.

Prerequisite reading

To work with Business Central virtual tables, you must understand how Microsoft Dataverse and virtual tables work. Therefore, the following documentation is a prerequisite:

- What is Microsoft Dataverse?
- Table overview
- Table relationships overview
- Create and edit virtual tables that contain data from an external data source
- Overview of creating apps in Power Apps

Virtual tables for Business Central

Open Data Protocol (OData) APIs exposed through API Pages in Business Central can be consumed in Microsoft Dataverse and virtual tables can be generated. Virtual tables in Microsoft Dataverse acts as regular tables and therefore also in Power Platform. Makers can now build experiences in customer engagement apps with data directly from Business Central with full CRUD capability and without copying to Microsoft Dataverse, and

leverage all the logic already residing in Business Central.

Using Custom APIs as basis for virtual tables

Since the virtual tables depend on APIs exposed on Business Central, custom APIs can also used for generating virtual tables. For more information, see Developing a Custom API.

Known limitations

There are known limitations with Business Central virtual tables including:

- Flows are not triggered for virtual tables. Currently, Business Central has no way to signal Microsoft Dataverse about data change events.
- Virtual tables cannot be used in Charts. Microsoft Dataverses does not support virtual tables being using in Charts.
- Relations between native and virtual tables. This is currently a limitation of the **Preview** version of Business Central virtual tables solution.
- Virtual tables cannot be customized on Microsoft Dataverse, for example, adding new columns. All modifications to virtual tables must happen in the API exposed on Business Central. But custom APIs can be developed and consumed as virtual tables.
- Attachment and Images/Pictures are not supported for virtual tables.
- BLOB to multiline support is not supported in the preview.
- Advanced search has some limitations. Each query designed translates to an OData query against Business Central.
  - The following predicates are not supported: **Does Not Equal**, **Does Not Contain**, **Does Not Begin With**, **Does Not End With**, **Does Not Contain Data**, and **Contains Data**.
  - Combining **And** and **Or** groups across columns.
  - Filtering on related tables.
- PowerApp Portals are not supported in current preview.

Table Modeling

2/17/2021 • 11 minutes to read • Edit Online

PREVIEW: This feature is in preview in Business Central 2020 release wave 2

> **NOTE**
>
> Effective November 2020:
>
> - Common Data Service has been renamed to Microsoft Dataverse. Learn more
> - Some terminology in Microsoft Dataverse has been updated. For example, *entity* is now *table* and *field* is now *column*. Learn more

> **NOTE**
>
> The **Business Central Virtual Entity (Preview)** app available on AppSource is being updated to reflect new terminology with an upcoming release. This also applies to that terminology used in Business Central.

> **IMPORTANT**
>
> This functionality requires version 17 for Business Central, while service update 189 is required for Microsoft Dataverse. The release information for Microsoft Dataverse is published on the latest version availability page.

Building an app requires capabilities to perform relational modeling between tables that are being used in the app. In the context of virtual tables, there will be scenarios where virtual tables and native tables in Microsoft Dataverse must work together to enable the desired user experience. This topic explains concepts of relational modeling that can be implemented using virtual tables for Business Central.

Generating virtual tables

By default, virtual tables for Business Central do not exist in Microsoft Dataverse. A user must query the catalog table to view the tables that are available in the linked instance of Business Central. From the catalog, the user can select one or more tables, and then request that Microsoft Dataverse generates the virtual tables. This procedure is explained in later sections.

Table fields

When a virtual table is generated for a Business Central table, the system tries to create each field in the Business Central table in the corresponding virtual table in Microsoft Dataverse. In an ideal case, the total number of fields will be the same in both tables, unless there is a mismatch in supported data types between Business Central and Microsoft Dataverse. For data types that are supported, the column properties in Microsoft Dataverse are set based on the properties in Business Central.

The rest of this section describes supported and unsupported data types. For more information about columns in Microsoft Dataverse, see Columns overview.

DATA TYPE IN BUSINESS CENTRAL	MODELED DATA TYPE IN MICROSOFT DATAVERSE
Real	Decimal For information about the possible mismatch, see the next table.
Long	Decimal, where the precision equals 0 (zero)
Int	Integer
String (non-memo), String (memo)	String – single line of text, String – multiple lines of text
UtcDateTime	DateTime (DateTimeFormat.DateAndTime, DateTimeBehavior.TimeZoneIndependent) An empty date (January 1, 1900) in Business Central is surfaced as a null value in Microsoft Dataverse.
Date	DateTime - (DateTimeFormat.DateOnly, DateTimeBehavior.TimeZoneIndependent) An empty date (January 1, 1900) in Business Central is surfaced as an empty value in Microsoft Dataverse.
Enum	Picklist Business Central enumerations (enums) are generated as global OptionSets in Microsoft Dataverse. Matching between the systems is done by using the **External Name** property of values. Enum integer values in Microsoft Dataverse are not guaranteed to be stable between the systems. Therefore, you should not rely on them, especially in the case of extensible enums in Business Central, because these enums do not have a stable ID either. OptionSet metadata is updated when an table that uses the OptionSet is updated.

Fields of the *real* and *long* data types in Business Central are modeled as the *decimal* data type in Microsoft Dataverse. Because of the mismatch in precision and scale between the two data types, the following behavior must be considered.

USE CASE	RESULTING BEHAVIOR
Microsoft Dataverse has higher precision.	This use case should never occur unless the metadata is out of sync.
Business Central has higher precision.	During a read operation, the value is rounded to the closest precision value in Microsoft Dataverse. If the value is edited in Microsoft Dataverse, it is rounded to the closest precision value in Business Central. During a write operation, the value that is specified in Microsoft Dataverse is written, because Business Central supports higher precision.
Microsoft Dataverse has higher scale.	Not applicable.

USE CASE	RESULTING BEHAVIOR
Business Central has higher scale.	Microsoft Dataverse shows the Business Central value, even if it exceeds 100 billion. However, there will be a loss of precision. For example, 987,654,100,000,000,000 is shown in Microsoft Dataverse as "987,654,099,999,999,900". If the value of this column is edited in Microsoft Dataverse, Microsoft Dataverse validation throws an error that the value exceeds the maximum value before that value is sent to Business Central.

The following data types in Business Central are not supported in Microsoft Dataverse. Fields of these data types in Business Central tables will not be made available in the corresponding virtual tables in Microsoft Dataverse. If fields of these data types are used as parameters in Open Data Protocol (OData) actions, those actions will not be available for use in the corresponding virtual tables. For more information about OData actions, see the OData actions section later in this topic.

Table key - primary key

In Business Central, tables use the SystemId (GUID) as the primary key, which uniquely identifies a record in a Business Central. In Microsoft Dataverse, the SystemId exposed by the table is used as the primary key.

Primary column/field

In Microsoft Dataverse, each table must have a primary column. This column must be a single column of the string type. The primary column is used in Microsoft Dataverse in the following scenarios:

- The default views that are created for an table include the primary column.
- The quick view form for an table includes the primary column.
- A lookup to another table is added to a page and shows the data from the primary column.

The primary field for a virtual table for Business Central is designed to use **displayname** field on table if present. If this field is not present the first string field is chosen as the primary field.

Relations

> **IMPORTANT**
> A write transaction that spans a virtual table and a native table is not supported. Using this form of transaction is not recommended, as there is no way to ensure consistency.

Relations in Business Central tables are modeled as one-to-many (1:n) or many-to-one (n:1) relations. These relations are modeled as relationships in the virtual table in Microsoft Dataverse. Note that many-to-many (n:n) relations are not supported in Business Central.

For example, in Business Central, if table A has a foreign key to table B, this relation will be modeled as an n:1 relationship in virtual table table A in Microsoft Dataverse. The schema name of this relationship in Microsoft Dataverse uses the naming convention **dyn365bc_<source table name>_<target_table name>**. This naming convention has a maximum string length of 120 characters. Any relation where the schema name will produce a name that exceeds 120 characters will not be generated in the virtual table in Microsoft Dataverse. It is required that the foreign key is a SystemId (GUID). If the foreign key is of a different type then the relation will not be generated.

The external name of this relationship uses the naming convention **<relation name>**. The external name is used to determine the relation in Business Central when the query that is sent to Business Central is built.

When a relationship is generated for a virtual table in Microsoft Dataverse, a new column of the lookup type is also added to the source table. In the preceding example, when the relationship is created, a new lookup column that uses the naming convention **dyn365bc_<target_table>_id** is added to source table table A. Because there can be several relations in an table in Business Central, the same number of lookup fields (one per related table) will be created in the source virtual table. When this lookup field is added to a page or a view, it will show the primary field value from the related table.

A relationship in the virtual table in Microsoft Dataverse will be generated only if the related table in the relation already exists as a virtual table in Microsoft Dataverse. In the preceding example, if table B does not exist as a virtual table in Microsoft Dataverse, the relation to table B will not be created in table A when table A is generated as a virtual table. This relation will be added to table A only when table B is generated as a virtual table. Therefore, when a virtual table is generated for Business Central, validations are done to ensure that only relationships that can be complete and functional are generated in the virtual table that is being generated.

In summary, a relationship to another Business Central virtual table might not exist in the virtual table for either of the following reasons:

- The Business Central table that is participating in the relationship does not exist as a virtual table.
- The foreign key is not SystemId (GUID).
- The length of the name of the relationship exceeds 120 characters.

> **NOTE**
> If an error is encountered when any part of a Business Central virtual table is generated in Microsoft Dataverse, the virtual table will not be created at all. If relationships do not exist for either of the preceding reasons, the situation is not considered an error.

Native table–to–native table relationships

Native table–to–native table relationships are the standard Microsoft Dataverse functionality, where relationships are resolved by using the GUID of the related table. (This GUID is the table key.) The GUID identifies the unique table record in the related table.

Virtual table–to–virtual table relationships

The relationships between two Business Central virtual tables are driven by the relation metadata in the Business Central tables. As was explained earlier, these relations are generated as relationships in Microsoft Dataverse when the virtual table is generated. As in the behavior for native tables in Microsoft Dataverse, these relationships use the GUID to identify the unique record of the table in Business Central. Semantically, the GUID on the Business Central virtual table behaves like the GUID on the native Microsoft Dataverse table. For information about the implementation of the GUID in Business Central virtual tables, see the table key/primary key section earlier in this topic.

In the preceding example, the GUID of the related table is the table key of table B and will be used to build queries to identify a record in Business Central. The relation that table A has to table B will be used.

Therefore, in effect, the table name is the only information that is used in a relation that comes from Business Central. The table name gives access to the primary field in the related table, so that it can be shown in the lookup. It also gives access to the GUID of the related table, so that it can be used in other queries, as was explained earlier. The actual field that the relation is built on in the Business Central table is not used at all.

Virtual table–to–native table relationship

The relationship between Business Central virtual table and native table is not supported in the preview version of Business Central virtual table solution.

Enums

Enums in Business Central are modeled as OptionSets in Microsoft Dataverse. When a virtual table for Business Central is generated, the required enums are generated as OptionSets. If an OptionSet already exists, it is used instead.

Company

If Business Central has multiple companies, the default company must be selected. This can be done either on a Business Central virtual table configuration page or on a User table page.

Furthermore, every virtual table for a Business Central table have a relationship to the cdm_company table in Microsoft Dataverse. The cdm_company table is a native table in Microsoft Dataverse and is part of the Dynamics365Company solution. As always, when a relationship is created, a lookup column is also created in the virtual table for the related table (cdm_company in this case). This lookup column is named **Company**, and it must be used to provide an optimal user experience where users can select a value in a list or go to the details of the related record. A column that is named **Company Code** is also added in the virtual table. This column must be used in programming. A Virtual Table can only interact with one Company at a time. Connection to other Companies can be made in either the connection setup page or overridden on the individual user.

OData actions

OData actions in the Business Central tables are made available as custom actions in Microsoft Dataverse. For more information about custom actions and what they enable in Microsoft Dataverse, see Custom actions.

OData actions generated for Business Central have only one parameter which is the table. There is no output parameter.

Labels and localization

Labels that are defined on metadata, such as table names and field names in Business Central, are retrieved when virtual tables are generated in Microsoft Dataverse. The labels are retrieved using an API on Business Central called **tableDefinitions**. This API is available on every API route, and will serve translations and other table metadata, not suited for OData `$metadata`. But with both the tableDefinition and `$metadata` Microsoft Dataverse has all it needs to generate localized virtual tables.

Any runtime labels are returned in the language of the current user context. In other words, they are returned in the language that is specified on that user's UserInfo record in Business Central. This behavior also applies to error messages.

Error handling

Business Central create, read, update, and delete (CRUD) business logic on tables and backing tables is run when it is called through the virtual table in Microsoft Dataverse. If any exception is thrown on the Business Central side, the last message in the error log is returned to Microsoft Dataverse and is thrown as an InvalidPluginExecutionException exception that contains the message from Business Central. Because the Business Central code runs in the context of the user, the language of the error message is based on the language that is specified on the UserInfo record in Business Central. If any messages that are written to the info log in Business Central do not result in an exception, they are not shown in Microsoft Dataverse.

Calculated/unmapped fields

Calculated and unmapped fields in Business Central tables are also available in the corresponding virtual tables in Microsoft Dataverse.

Application Lifecycle Management for Solutions that use Virtual Tables

2/17/2021 • 5 minutes to read • Edit Online

PREVIEW: This feature is in preview in Business Central 2020 release wave 2

NOTE

Effective November 2020:

- Common Data Service has been renamed to Microsoft Dataverse. Learn more
- Some terminology in Microsoft Dataverse has been updated. For example, *entity* is now *table* and *field* is now *column*. Learn more

NOTE

The **Business Central Virtual Entity (Preview)** app available on AppSource is being updated to reflect new terminology with an upcoming release. This also applies to that terminology used in Business Central.

IMPORTANT

This functionality requires version17 for Business Central, while service update 189 is required for Microsoft Dataverse. The release information for Microsoft Dataverse is published on the latest version availability page.

The application lifecycle for an end-to-end solution using Business Central virtual tables will encompass both Business Central as well as Microsoft Dataverse.

Solution management

Virtual tables for Business Central do not exist in Microsoft Dataverse until they are created. Virtual tables must be created inside a solution. The **MicrosoftBusinessCentralERPVE** solution is used for this purpose. This solution will contain all the virtual tables that are created from an instance of Business Central.

MicrosoftBusinessCentralERPVE is a managed solution. By definition, a managed solution cannot be modified after it has been generated. However, **MicrosoftBusinessCentralERPVE** is a managed solution that grants privileges to update the components (that is, virtual tables) that are inside it. Therefore, new virtual tables can be added to the solution as they are created, and existing virtual tables can be updated as required. Nevertheless, the privileges to modify the managed solution are available only to the platform itself. Users cannot make changes directly to the solution.

Because **MicrosoftBusinessCentralERPVE** is a managed solution, solutions from customers, partners, and independent software vendors (ISVs) can take a dependency on it. This capability allows for consistent application lifecycle management (ALM) for solutions that use and depend on the virtual tables for Business Central.

When a solution that depends on **MicrosoftBusinessCentralERPVE** is exported, placeholders for the virtual tables that are used in the solution are added in the exported solution. When that solution is imported into another Microsoft Dataverse environment, the import process also generates the dependent Business Central virtual tables in the **MicrosoftBusinessCentralERPVE** solution for the Business Central instance that is

connected to the Microsoft Dataverse environment. Therefore, **MicrosoftBusinessCentralERPVE** must already exist before a solution that depends on it is imported. Otherwise, an error message is shown. Additionally, if a dependent table is not available in the Business Central instance, the virtual table for that table will not be generated. Virtual tables are generated only for tables that are available.

The following list describes other solutions that Business Central virtual tables require to work, and that must be available in the Microsoft Dataverse environment:

- **MicrosoftBusinessCentralERPVE** - Solution that contains the generated virtual tables.
- **MicrosoftBusinessCentralERPCatalog** – This solution provides a catalog of the available tables in a Business Central instance. It also provides the connection that is used to set up a configuration. For more information, see the later sections of this topic.
- **MicrosoftBusinessCentralVESupport** – This solution provides the virtual table provider for Business Central. The provider can communicate with Business Central and Microsoft Dataverse. For more information, see the next section.
- **Dynamics365Company** – This solution adds the Company table, which is referenced by all Business Central tables that have a **PrimaryCompanyContext** metadata value.

All these solutions must be present in an environment. Otherwise, virtual tables will not work with Business Central apps. These solutions are packaged together to allow for easier portability across environments.

Managing tables from multiple environments

The **MicrosoftBusinessCentralVESupport** solution consists of the **msdyn_ businesscentralvirtualtable** table. This table represents the virtual table data source for Business Central that captures connection setup information. Each record in this table represents a connection to a Business Central instance.

A catalog is used to list all the tables in a Business Central instance that are available for virtualization in Microsoft Dataverse (in other words, all the tables in Business Central that are enabled for Open Data Protocol [OData]). The catalog is part of the default **MicrosoftBusinessCentralERPCatalog** solution and is applicable to a Business Central instance.

Note that each Microsoft Dataverse environment must point to only one Business Central instance at any time, and each Business Central environment must point to only one Microsoft Dataverse environment. Therefore, there should be only one record in the **msdyn_businesscentralvirtualtable** table.

The **mserp_businesscentralvirtualtable** table that represents the catalog can be queried to list the tables in a Business Central instance. Because this table is a virtual table, the catalog is never persisted in Microsoft Dataverse.

Notice that the name of the catalog table has the "mserp_" prefix. This prefix identifies the tables in the catalog as Business Central tables. The same prefix is also added to the system names of the virtual tables that are generated for Business Central in the **MicrosoftBusinessCentralERPVE** solution. Therefore, the maker can distinguish Business Central virtual tables from other tables. The prefix is set in the managed solution and cannot be changed.

Managing tables from multiple ISV solutions

One or more ISV solutions will take a dependency on the **MicrosoftBusinessCentralERPCatalog** solution to use virtual tables for Business Central. Because custom tables in Business Central use the same catalog as out-of-box tables in Business Central, the virtual tables for custom Business Central tables will also be generated in the **MicrosoftBusinessCentralERPVE** solution.

The established guidelines and ALM for table development in Business Central ensure that there are no conflicting table names across ISV solutions. Therefore, no conflicts of this type can occur when virtual tables are generated in Microsoft Dataverse for custom Business Central tables from multiple ISV solutions. All virtual

tables for Business Central tables, including custom tables, will have the "mserp_" prefix that was mentioned earlier.

Managing a Business Central instance in a Microsoft Dataverse environment for virtual tables

One Business Central instance must be linked to a Microsoft Dataverse environment for virtual tables. The connection setup information that is required is captured in a virtual table data source for Business Central. This data source is included in the **MicrosoftBusinessCentralERPCatalog** solution.

> The **Business Central Virtual Entity (Preview)** app available on AppSource is being updated to reflect new terminology with an upcoming release. This also applies to that terminology used in Business Central.

> **IMPORTANT**
>
> This functionality requires version 17 of Business Central and service update 189 for Microsoft Dataverse. The release information for Microsoft Dataverse is published on the latest version availability page.

This topic provides step-by-step instructions on how to set up and configure virtual tables for Business Central in Microsoft Dataverse.

Getting the solution

First get the Business Central Virtual Entity solution from AppSource.

The following solutions are installed in Microsoft Dataverse once the Business Central virtual tables is installed from AppSource.

- **Dynamics365Company** - This adds the **cdm_company** table, which is referenced by all Business Central virtual tables. All communication to Business Central requires the company ID in the request.
- **MicrosoftBusinessCentralVESupport** - This provides the core support for the Business Central virtual table feature.
- **MicrosoftBusinessCentralERPCatalog** - This provides a list of available Business Central.
- **MicrosoftBusinessCentralVEAnchor** - This serves as a container, holding information needed for AppSource.
- **MicrosoftBusinessCentralERPVE** - Virtual tables generated for Business Central will be contained in this solution. tables are added at runtime once they are made visible.

Authentication and authorization

After the solutions are installed in the Microsoft Dataverse environment, connection can be set up to a Business Central environment. *Both environments have to be in the same tenant.*

The next step in the process is to provide Microsoft Dataverse with the Business Central environment and company to connect to. The following steps walk through this part of the process.

0. In Business Central, go to the page 'AAD Applications' and toggle the app 'Dynamics 365 Business Central for Virtual tables' to **Enabled**. This will allow Microsoft Dataverse to communicate with Business Central.

1. In Microsoft Dataverse, go to the table **Business Central Virtual Data Source Configuration**.
2. Select and edit the data source named "Business Central".
3. On the Business Central Virtual Data Source Configuration, set the environment name. Unless changed, Business Central tenants will have an default environment called 'production'.
4. Save changes before setting **Default Company**. Else, company cannot be set in the next step.
5. Set the **Default Company** value.
6. Save the changes.

Making virtual tables visible

Due to the large number of OData enabled tables available in Business Central, by default, the tables are not available as virtual tables in Microsoft Dataverse. The following steps allow for enabling tables to be virtual, as needed.

1. In Microsoft Dataverse, go to **Data -> tables** and search for *Available Business Central table*. Make sure to search for All and not just Default.
2. Choose **Data** in the horizontal menu to view the available data.
3. Locate and edit the table that you want to enable.
4. Set **Visible** to **Checked** and save. This will generate the virtual table, so that it will appear in all of the appropriate menus, and in advanced find dialog box.

Refreshing virtual table metadata

The virtual table metadata can be force-refreshed when it is expected for the table metadata in Business Central to have changed. This can be done by setting **Refresh** to **Checked** and saving. This will sync the latest table definition from Business Central to Microsoft Dataverse and update the virtual table.

Referencing virtual tables

The virtual tables are all generated in the **MicrosoftBusinessCentralERPVE** solution. That means the items in the solution change as you make tables visible/hidden, but it is still a managed solution that you can take dependency on. The standard ALM flow would be to just take a standard reference to a virtual table from this solution with the **Add existing** option in the ISV solution. It will then show as a missing dependency of the solution and be checked at solution import time. During import if a specified virtual table does not yet exist, it would automatically be made visible without needing additional work.

To consume virtual tables:

1. Create a separate solution as usual in Microsoft Dataverse, which will contain the consuming logic.
2. Select **tables > Add Existing**. Select the virtual table that you want to reference from the list.
3. When prompted to select assets to add, select any forms, views, or other elements that you want to customize, then select **Finish**.

From the development tooling, existing elements such as forms can be modified for the virtual table. Additionally, new forms, views, and other elements can also be added.

When the solution is exported, it will contain hard dependencies on the virtual table generated in the **MicrosoftBusinessCentralVE** solution.

> **IMPORTANT**
>
> This functionality requires version 17 of Business Central, while service update 189 is required for Microsoft Dataverse. The release information for Microsoft Dataverse is published on the latest version availability page.

This topic is a collection of frequently asked questions about Business Central virtual tables.

What version of Business Central do I need?

Version 17.0 of Business Central is needed. Version 17 contains v2.0 of the standard APIs and improvements to the OData stack that enable APIs to be exposed and consumed as virtual tables.

Can a solution from an independent software vendor (ISV) take a dependency on virtual tables? What does the application lifecycle management (ALM) look like?

Yes. The virtual tables are all generated in the **MicrosoftBusinessCentralERPVE** solution, which is API-managed. In other words, the items in the solution change as you make tables visible or hidden, but the solution is still a managed solution that you can take dependency on. The standard ALM flow just takes a standard reference to a virtual table from this solution with the **Add existing** option in the ISV solution. Missing dependency of the solution will be checked when the solution is imported and during import, if a specified virtual table does not yet exist, the virtual table is automatically made visible.

Which tables from Business Central do users see in the catalog in Microsoft Dataverse?

Generally, users see all tables exposed as API pages with the exception of Microsoft legacy API pages: beta and v1.0.

Do all Microsoft Power Platform users have to be users in Business Central?

Any user of Microsoft Power Platform who tries to access Business Central data through a virtual table must also exist as a user in Business Central. Therefore, technically, not *all* users have to be users in Business Central. Only those users who access Business Central data through virtual tables must be users in Business Central.

Where do I find the catalog table?

In the **Advanced find** window, the table is named **Available Business Central tables**.

Can I change the prefix for the virtual tables?

No. All Business Central virtual tables should be generated in the **MicrosoftBusinessCentralERPVE** solution, and they all have the "dyn365bc_" prefix. This prefix will not be changed.

How can I show, in the same grid, data from multiple virtual tables that are joined to a physical table record in Microsoft Dataverse?

This approach is not currently possible in Microsoft Dataverse.

If I want a default value to be entered in a column during pre-create, will an initValue on the data table then work?

Yes. Here is the order of calls:

1. Microsoft Dataverse sends a create or update message.
2. All the existing logic on the Business Central table and backing tables is invoked. This logic includes default value entry that might change values.
3. Microsoft Dataverse sends another Retrieve (single) message to get the latest copy of the data, including any columns that default values were entered for.

Developing Pages and Tables for Microsoft Teams Integration

2/17/2021 • 3 minutes to read • Edit Online

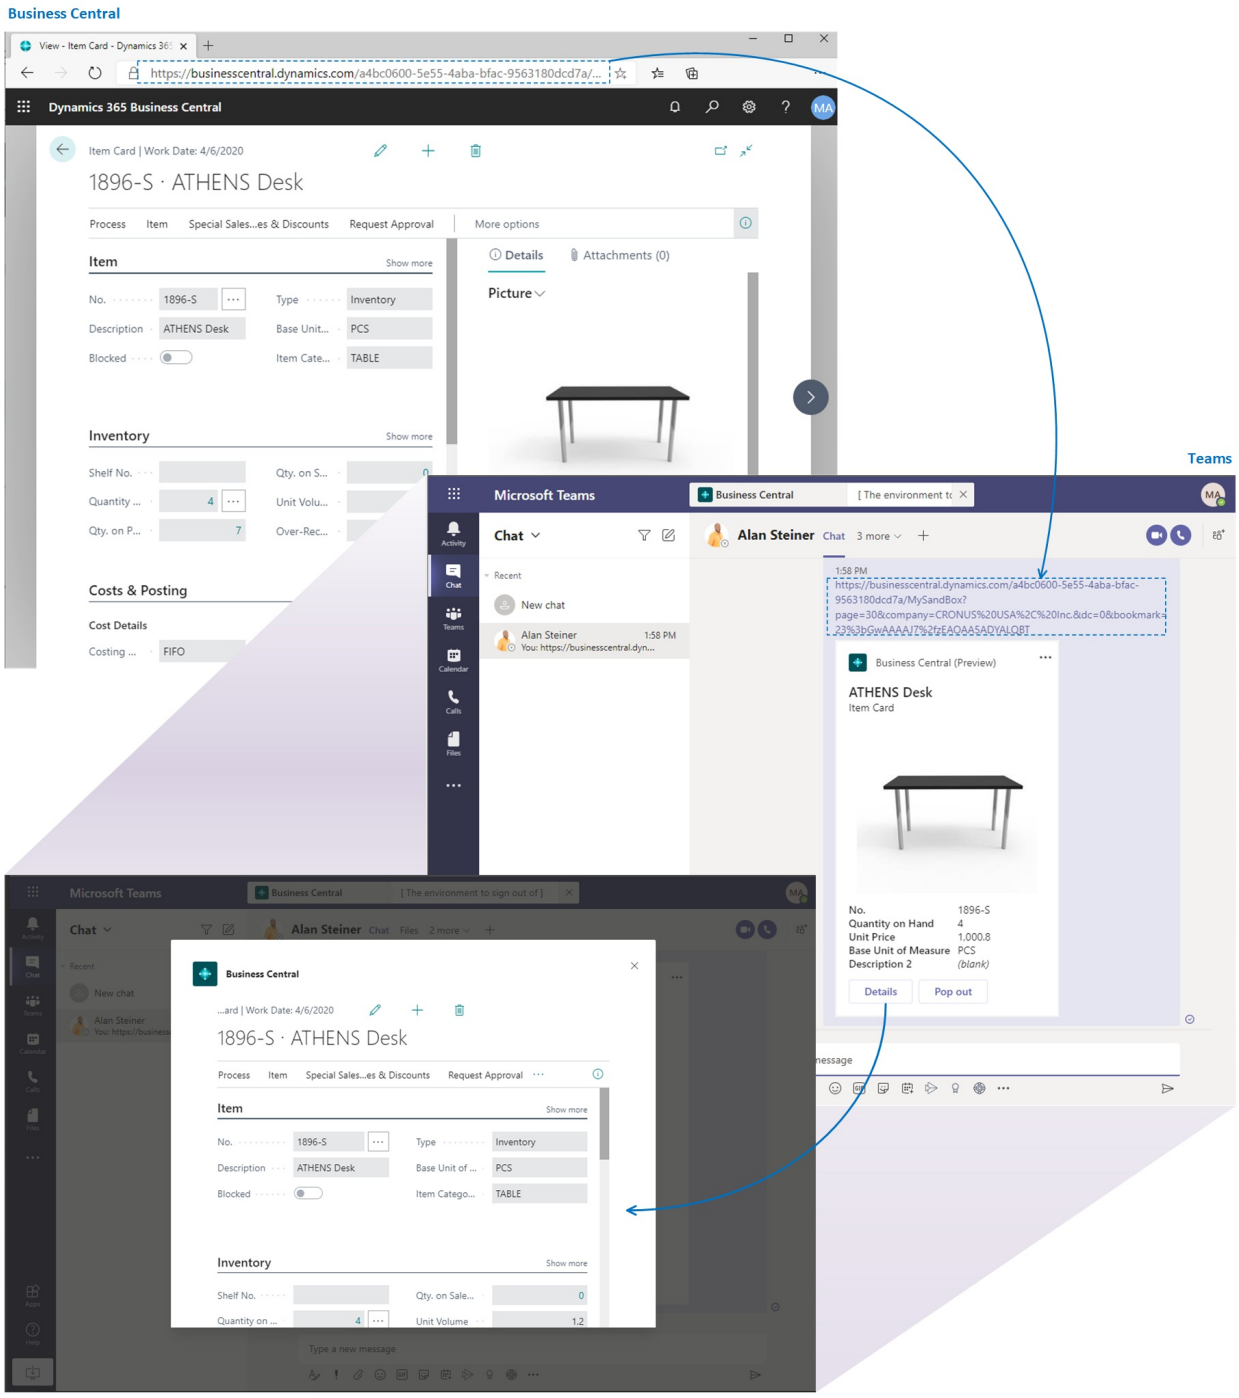
APPLIES TO: Business Central online

Microsoft Teams is a Microsoft 365 product that lets you connect with others, collaborate seamlessly and simplify work. Business Central offers an app that connects Teams to your business data in Business Central so users can quickly share details across team members and respond faster to inquiries. In this article, you'll learn how you can develop pages and tables so that data appears in Teams as you want.

Introduction to the Business Central app for Teams

In short, the app lets users:

- Copy a link to any Business Central record and paste it into Teams conversation to share with your coworkers. In Teams, the link will expand that into a compact card that displays a defined set of fields about the record.
- From the card in teams, users can select a button to view more details about the record. The card opens into window inside Teams that includes FactBoxes and other embedded content, such as charts. With the proper permissions, anyone in the conversation can edit fields, start workflows, and take action from the window - without having to switch from Teams.



Managing, Installing, and Using the Business Central App for Teams

For more details about installing and using the Business Central app in Teams from an admin and user perspective, see Business Central and Microsoft Teams Integration.

Development overview

Users can choose which links to records are pasted into Teams. The pasted links are then displayed as cards. As a developer, you can choose which fields are shown on the card, and the look and behavior of the card details.

About cards

The Business Central app for Teams is designed to work with entity pages that represent a single record. More specifically, it's designed for Card, Document, or ListPlus pages. Teams is ready to work with links to these page types and the underlying data in the source tables. In most cases, displaying a card in Teams requires no additional development effort. But if a card doesn't display the fields and data you want, you have a couple options in AL code for making changes:

- Use a field group control on the source table

  This method primarily involves using the `Brick` field group on the page's source table.

- Use Teams-specific events

  There are currently two events that you can code against to change the fields that display in the card at runtime. We recommend that you use these events as an additive measure.

In most cases, we recommend you set the `Brick` field group instead of using events to define card content. Using the `Brick` field group ensures a consistent experience across the Business Central Web client, mobile devices, and Teams. If a table doesn't include a `Brick` field group, you should add one, then use the events to change the fields as needed.

For more information about these two development options, see Extending Teams Cards.

About card details

Users can select the **Details** button on a Teams card to drill into the details of the card. This button opens the Business Central Web client in a window that's embedded inside Teams. The window displays the target page object. The page includes any extensions to the page and its source table, role customizations, and user personalization. The experience is nearly identical to that of displaying the same record in the Business Central Web client, except with some minor client differences.

You can modify or extend the layout and behavior of the page, like you would any page. The changes you make will affect the page in all Business Central clients, not just in Teams. You can't implement functionality that is available only in Teams but not other Business Central clients. For more information about implementing pages, see Pages Overview.

Preparing your environment for development and testing

Developing for Teams integration is similar to other development activities in Business Central. It requires Visual Studio Code, installed with the AL language extension, and knowledge of the AL language. However, because the Business Central app for Teams only supports Business Central online, you must deploy your extensions to an online sandbox to test the implementation. For more information about sandboxes, see Sandbox Environments for Dynamics 365 Business Central Development.

Extending Teams Cards

2/17/2021 • 10 minutes to read • Edit Online

APPLIES TO: Business Central online

In this article, you'll learn how to customize the fields that display on a Teams card. You customize the fields by using a field groups control on the source table or using events. You can also combine these two methods to achieve the results that you want.

Extend Teams cards by using field groups

This section explains how to customize the fields that display on Teams card by setting metadata in Business Central page and table objects.

Understanding the card layout in Teams

The main metadata elements for displaying fields in Teams are the `Brick` field group, together with the page and field captions. However, with the lack of a `Brick` field group on a table, the `Dropdown` field group and primary keys will play a role in determining the fields that display. This section describes how the app selects and arranges fields on the card in Teams. Use this information to help define your `Brick` field group.

What fields are displayed

Although it's recommended, a `Brick` field group isn't required to display a card in Teams. Lacking a `Brick` field group, the app will fall back to use either `DropDown` field group or the primary key fields of on the source table, according to the following flow:

1. If a `Brick` field group exists, the app uses the fields specified by the `Brick` field group.
2. If a `Brick` field group doesn't exist, the app uses fields that are defined in `Dropdown` field group.
3. If `Dropdown` field group doesn't exist, then the primary key fields and fields called Name or Description in the table are used.

How fields are arranged

The app will arrange fields on cards in Teams based on one of two templates, depending on whether a media field is included in the `Brick` field group. Except media data type fields, the order of fields on the card is determined by the field order in the `Brick` field group. You can't reposition fields, add new controls like actionable buttons, or change the overall style of a card.

The two templates and how they order fields are explained in the following table.

WITH MEDIA	WITHOUT MEDIA
	The card is laid out from top to bottom as follows: 1. The second field defined in `Brick` field group appears first in a large font. 2. The page's caption property value 3. The media thumbnail 4. The remaining brick fields in the order they're defined. Guidelines: • For the second field, it's a good idea to use a field that best identifies the record, like a name or description field. • Don't place a media field as the second field in the `Brick` field group. It doesn't matter where you place the field otherwise - it will appear after the page caption. • If there's more than one media field in the `Brick` field group, only the first one listed is used. • BLOB data type fields aren't supported.	The card is laid out from top to bottom as follows: 1. The page's caption property value 2. The second field defined in `Brick` field group. 3. The remaining brick fields in the order they're defined. Guidelines: • BLOB data type fields aren't supported.

Using the Brick field group

By default, the fields that display on a card in Teams are based on the `Brick` field group that's defined on a page's source table. The `Brick` field group is the same element that determines which fields display with records in list pages viewed as tiles in the client. So you'll have to keep it in mind when designing for Teams.

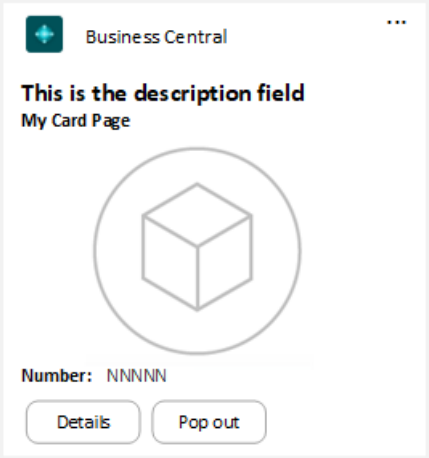
Use the `Brick` field group to identify a subset of table fields that best summarize a record. Typically, you include fields that allow users to quickly identify the record and give insight about the record at a glance. The following code is snippet of `Brick` field group on a table:

```
fieldgroups
{
    fieldgroup(Brick; field[, field][, field])
    {
    }
}
```

The order that you specify fields is important. For an explanation, see Understanding the card layout in Teams in this article.

Example

This code example adds a simple table and card page. The `Brick` field group specifies which fields of the table will display in a Teams card, as illustrated by the following figure:



```
Table 50100 MyTable
{

    fields
    {
        field(1; Number; Integer)
        {
        }
        field(2; Description; Text[50])
        {
        }
        field(3; Inventory; Integer)
        {
        }
        field(4; Image; Media)
        {
        }
    }

    keys
    {
        key(PK; Number)
        {
        }
    }

    fieldgroups
    {
        fieldgroup(Brick; Number, Description, Image)
        {
        }
    }
}

page 50100 MyPage
{
    PageType = Card;
    ApplicationArea = All;
    UsageCategory = Administration;
    SourceTable = MyTable;
    Caption = 'My Card Page';

    layout
    {
        area(Content)
        {
            group(GroupName)
            {
                field(Number; Number)
                {
                    ApplicationArea = All;
                }
                field(Description; Description)
                {
                    ApplicationArea = All;
                }
                field(Inventory; Inventory)
                {
                    ApplicationArea = All;
                }
            }
        }
    }
}
```

For more information about how to specify the `Brick` field group. see Displaying Data as Tiles.

Extensibility limitations on the Brick field group

The following list provides information to keep in mind when designing table and table extension objects in your extensions:

- You can add a `Brick` field group to a new table object.
- You can add a `Brick` field group to a table extension object as long as the base table it extends doesn't already have one.
- In a table extension object, you can't add to or overwrite a `Brick` field group that's already specified for a base table.

Extending Teams cards by using events

Business Central offers the following events for customizing the fields and data that appear in a Teams card:

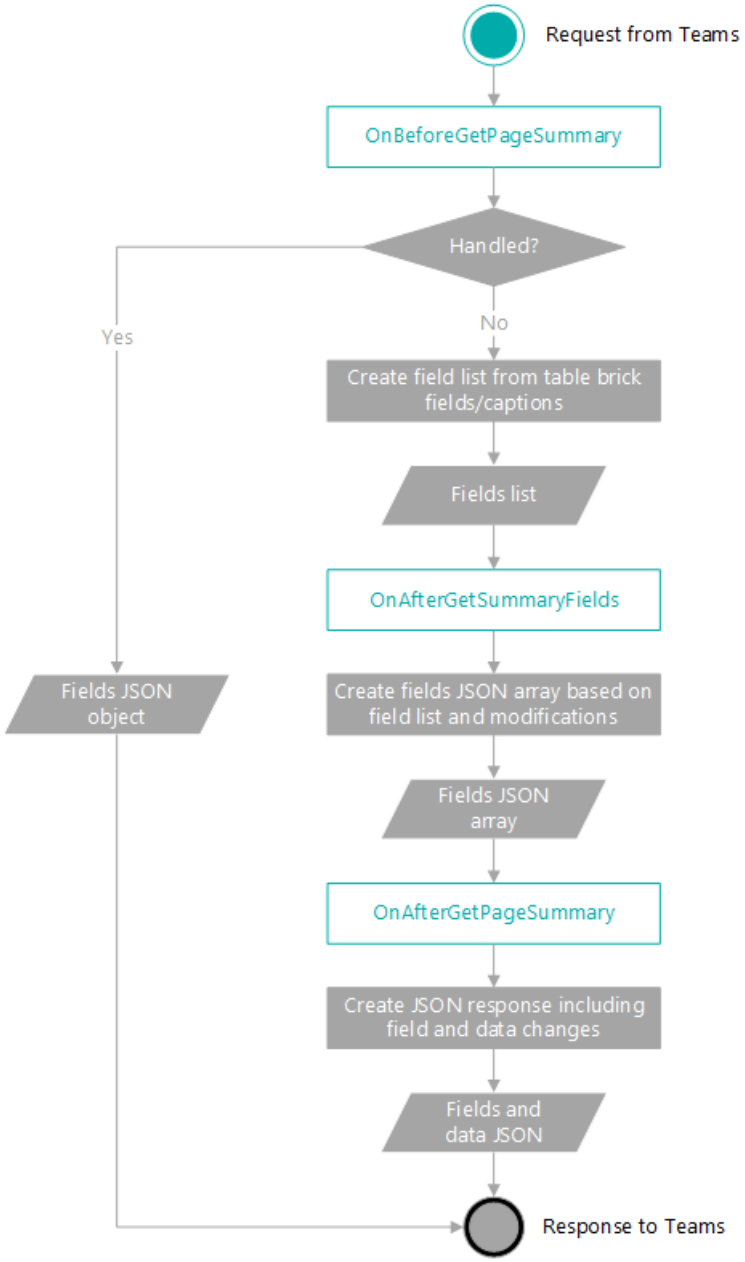
EVENT	DESCRIPTION
OnBeforeGetPageSummary	Use this event to override **all data** for a Card. By handling the event, you can specify a custom set of key-value pairs that will be displayed. The platform won't attempt to select any list of fields or their corresponding values if you subscribe to this event.
OnAfterGetSummaryFields	Use this event to specify a custom set of fields from the same table as the record. Using this method you can add more fields than are those fields specified by the `Brick` field group on the source table. For example, you could add fields that are added to the source table by a table extension.
OnAfterGetPageSummary	Use this event to modify fields and their values that are already selected for the card by the platform. For example, you could change the captions or value of a field.

The events are part of the Page Summary Provider module of the Microsoft System Application.

> **NOTE**
> In most cases, we recommend you set the `Brick` field group instead of using events to define card content. This ensures a consistent experience across the Business Central Web client, mobile devices, and Teams.

Event flow

The following figure illustrates the sequence of the events and operations involved in building the card in Teams. The flow has been simplified for illustration purposes.



OnBeforeGetPageSummary event

The OnBeforeGetPageSummary event gives you the most control over the fields and data that appears in the card. With this event, you specify a complete set of fields as key-value pairs using JSON Array. Only these fields will appear on the card, even if the source table has a `Brick` field group or other extensions include code that modifies the card.

Syntax

The OnBeforeGetPageSummary event subscription has the following syntax:

```
[EventSubscriber(ObjectType::Codeunit, Codeunit::"Page Summary Provider", 'OnBeforeGetPageSummary', '',
false, false)]
local procedure OnBeforeGetPageSummary(PageId: Integer; RecId: RecordId; var FieldsJsonArray: JsonArray; var
Handled: Boolean);
```

Parameters

PARAMETER	DESCRIPTION
`PageId`	The ID of the page for which to retrieve page summary.

PARAMETER	DESCRIPTION
`RecId`	The underlying record ID of the source table for the page being retrieved, based on the bookmark.
`FieldsJsonArray`	A JSON array that includes the fields and values to display on the card, if the event is handled.
`Handled`	Specifies whether the event has been handled and no further execution should occur.

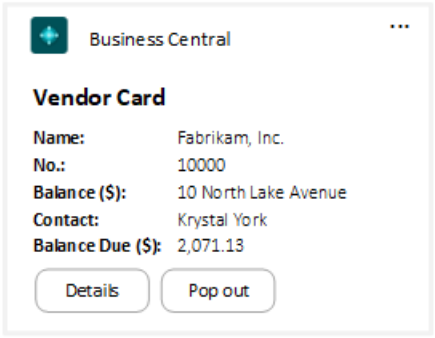
Behavior and recommended use

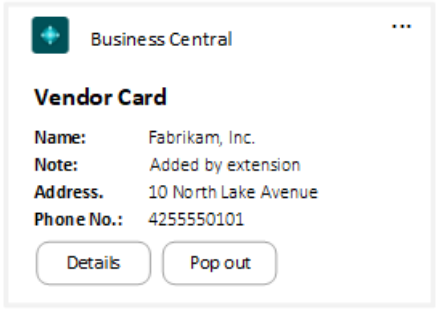
This event is raised before platform tries to get summary fields for the card from the table, for example, from the `Brick` field group. So when you subscribe to this event, the fields in the `Brick` field group aren't used. Subscribing to this event prohibits other extensions from adding, modifying, or removing summary fields on the card by the other event.

For these reasons, use this event only if you don't want to use any fields of the source table in the card.

Example

The following code example uses the OnBeforeGetPageSummary event to change the fields on a Teams card, as shown in the following table:

BEFORE	AFTER
	




```
[EventSubscriber(ObjectType::Codeunit, Codeunit::"Page Summary Provider", 'OnBeforeGetPageSummary', '',
false, false)]
local procedure OnBeforeGetPageSummary(PageId: Integer; RecId: RecordId; FieldsJsonArray: JsonArray; var
Handled: Boolean)
var
    Vendor: Record Vendor;
begin
    if PageId <> Page::"Vendor Card" then
        exit;

    if not Vendor.Get(RecId) then
        exit;

    AddField(FieldsJsonArray, 'Name', Vendor.Name, 'Text');
    AddField(FieldsJsonArray, 'Note', 'Added by extension', 'Text');
    AddField(FieldsJsonArray, 'Address', Vendor.Address, 'Text');
    AddField(FieldsJsonArray, 'Phone No.', Vendor."Phone No.", 'Text');

    Handled := true;
end;

local procedure AddField(var FieldsJsonArray: JsonArray; Caption: Text; FieldValue: Text; FieldType: Text)
var
    FieldsJsonObject: JsonObject;
begin
    FieldsJsonObject.Add('caption', Caption);
    FieldsJsonObject.Add('fieldValue', FieldValue);
    FieldsJsonObject.Add('fieldType', FieldType);
    FieldsJsonArray.Add(FieldsJsonObject);
end;
```

OnAfterGetSummaryFields event

The OnAfterGetSummaryFields event lets you add or remove from the set of fields selected by the platform. For example, if the platform automatically selects fields based on its `Brick` field group, use this event to add fields from the same table, which aren't part of the `Brick` field group.

Syntax

```
[EventSubscriber(ObjectType::Codeunit, Codeunit::"Page Summary Provider", 'OnAfterGetSummaryFields', '',
false, false)]
local procedure OnAfterGetSummaryFields(PageId: Integer; RecId: RecordId; var FieldList: List of [Integer]);
```

Parameters

PARAMETER	DESCRIPTION
`PageId`	The ID of the page object in Business Central that the card is generated for.
`RecId`	The underlying record ID in the source table for the page being retrieved, based on the bookmark.
`FieldList`	The list of fields that will be returned.

Behavior and recommended use

This event is raised after the platform gets the summary fields from the table.

The event the ideal for specifying a custom set of fields from the same table. It enables the platform to fetch the corresponding values for the current record. If you extended a table with fields, use this event to add the fields to the card.

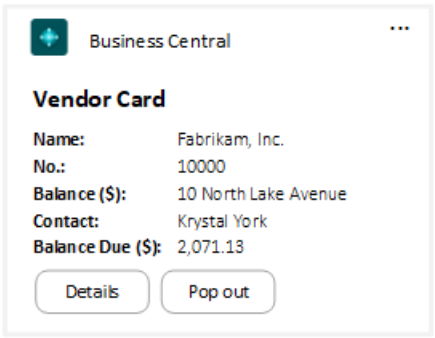
Here are some considerations, when using this event:

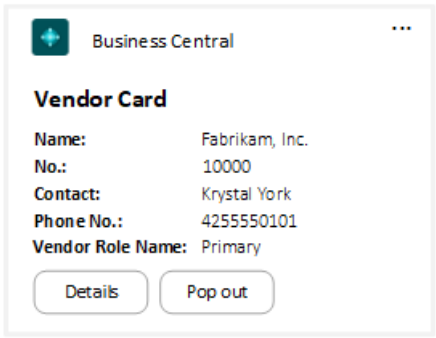
- Use the FieldList to add or remove individual fields you want to show on the card in Teams.
- Fields on the card in Teams are shown in the order specified the `FieldList`.
- Don't remove all fields from the list, because you'll be removing fields that are added by other partner extensions.

Example

The following code example uses the OnAfterGetSummaryFields event to change the fields on a Teams card, as shown in the following table:

BEFORE	AFTER
	





```
[EventSubscriber(ObjectType::Codeunit, Codeunit::"Page Summary Provider", 'OnAfterGetSummaryFields', '',
false, false)]
local procedure OnAfterGetSummaryFields(PageId: Integer; RecId: RecordId; var FieldList: List of [Integer])
var
    Vendor: Record Vendor;
begin
    if PageId <> Page::"Vendor Card" then
        exit;

    // Remove Balance Due  details
    FieldList.Remove(Vendor.FieldNo("Balance Due (LCY)"));
    FieldList.Remove(Vendor.FieldNo("Balance (LCY)"));

    // Add contact number
    FieldList.Add(Vendor.FieldNo("Phone No."));

    // Add new field "Vendor Role Name" from extension
    FieldList.Add(Vendor.FieldNo("Vendor Role Name"));
end;
```

In the code, the **Vendor Role Name** field is defined in a table extension object that extends the **Vendor** table.

OnAfterGetPageSummary event

This event allows you to modify, add, or remove fields included in the card through the direct access to the FieldsJsonArray.

Syntax

```
[EventSubscriber(ObjectType::Codeunit, Codeunit::"Page Summary Provider", 'OnAfterGetPageSummary', '',
false, false)]
local procedure OnAfterGetPageSummary(PageId: Integer; RecId: RecordId; var FieldsJsonArray: JsonArray);
```

Parameters

PARAMETER	DESCRIPTION
`PageId`	The ID of the page for which to retrieve page summary.
`RecId`	The underlying record ID of the source table for the page being retrieved, based on the bookmark.
`FieldsJsonArray`	A Json array that lists the fields to include in the card, overriding the current fields and values set for the card.

Behavior and recommended use

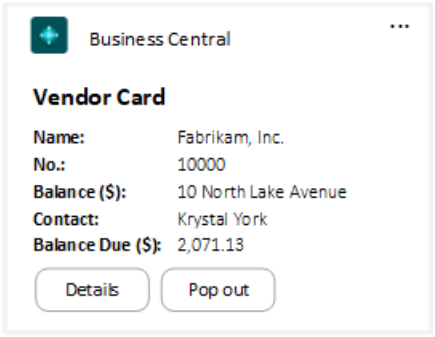
This event is ideal for modifying the list of fields and their values that are selected by the platform.

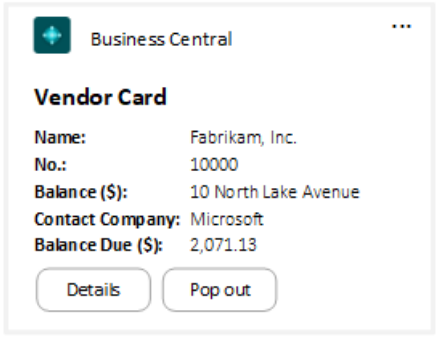
Use the event to change the value of existing fields or to add fields that don't already exist on the record.

Example

The following code example uses the OnAfterGetPageSummary event to change the fields on a Teams card, as shown in the following table:

BEFORE	AFTER
	





```
[EventSubscriber(ObjectType::Codeunit, Codeunit::"Page Summary Provider", 'OnAfterGetPageSummary', '',
false, false)]
local procedure OnAfterGetPageSummary(PageId: Integer; RecId: RecordId; var FieldsJsonArray: JsonArray)
var
    FieldJsonToken: JsonToken;
    CaptionToken: JsonToken;
    fieldNo: Integer;
begin
    if PageId <> Page::"Vendor Card" then
        exit;

    // Change value of field caption
    for fieldNo := 0 to FieldsJsonArray.Count() - 1 do begin
        FieldsJsonArray.Get(fieldNo, FieldJsonToken);
        FieldJsonToken.AsObject().Get('caption', CaptionToken);
        if CaptionToken.AsValue().AsText() = 'Contact' then begin
            // FieldJsonToken.AsObject().Replace('caption', 'Contact Company');
            // FieldJsonToken.AsObject().Replace('fieldValue', 'Microsoft');
            FieldJsonToken.AsObject().Replace('caption', 'Note');
            FieldJsonToken.AsObject().Replace('fieldValue', 'Added by extension');
            FieldsJsonArray.Set(fieldNo, FieldJsonToken);
            exit;
        end;
    end;
end;
```

In the code, the **Vendor Role Name** field is defined in a table extension object that extends the **Vendor** table.

FAQ for Microsoft Teams Integration with Business Central

2/17/2021 • 2 minutes to read • Edit Online

APPLIES TO: Business Central online

What's the technology behind the card in Teams?

The ability to translate a URL into a card is known as link *unfurling* and is one of many extensibility points offered by Teams. When the Business Central link is pasted into message box of a Teams conversation, Teams does the following operations:

1. Matches the domain of the URL to Business Central, which is associated with the Business Central app for Teams.
2. Connects to a micro-service that forms part of the Business Central Online services
3. Returns an adaptive card.

Adaptive cards are platform-agnostic way to display compact blocks of information. To learn more, see Link unfurling and Cards in the Teams documentation.

What's the technology behind the card details?

Within the portfolio of extensibility points, Teams offers *task modules*. A task module is a mechanism to display a task-focused window within Teams. Applying the strengths of Business Central's modern client stack, Teams displays an adaptation of the Business Central Web client in this window.

To learn more, see Task Modules in the Teams documentation.

What licenses are required for these features to work?

This table gives you an overview of the licenses needed for these features in a Teams conversation.

WHAT	TEAMS LICENSE	BUSINESS CENTRAL LICENSE
Send a card	✅	✅
View a card	✅	
View card details	✅	✅

What permissions in Business Central are required for these features to work?

A user who pastes a link into a conversation must have at least read permission to the page and data that is targeted by the link. Otherwise, the link won't expand into card. This requirement is identical to what is required in Business Central.

Once a card has been submitted in a conversation, any user in that conversation can view that card without having permission to Business Central. However, to view the card details, users have to have at least read

permission to the target page and data. To make changes to data, they'll need modify permissions.

Does the Business Central app for Teams allow me to create tabs in Teams for displaying Business Central?

No. This scenario isn't supported. The Business Central platform doesn't provide any extensibility or standard features to display a page inside a Teams tab.

Does the Business Central app for Teams allow me to connect to Teams APIs?

The Business Central platform doesn't provide any specific ways to call Team APIs from AL code, such as programmatically creating a new team with channels and users. To extend Business Central using Teams APIs, known as "connectors", see Teams extensibility documentation at https://developer.microsoft.com/en-us/microsoft-teams.

Deprecated Tables

2/17/2021 • 2 minutes to read • Edit Online

INTRODUCED IN: Business Central 2020 release wave 1

In the latest version of Business Central, a number of tables have been deprecated. The following tables have been marked with an `ObsoleteState:Removed`. Code that uses the deprecated table or tables, must be rewritten to use the new table or tables. The deprecated tables are mapped as follows:

DEPRECATED TABLE NAME	NEW TABLE NAME
NAV App	Published Application
NAV App Object Metadata	Application Object Metadata
NAV App Resource	Application Resource
NAV App Dependencies	Application Dependency
NAV App Tenant App	Installed Application

Technical Upgrade

Deprecated Features in W1

2/17/2021 • 7 minutes to read • Edit Online

This article describes the features that have been moved, removed, or replaced in the W1 version of Business Central. This information will change with future releases, and might not include each deprecated feature.

Deprecated features won't be available in future versions of Business Central, which can happen for different kinds of reasons. For example, a feature may no longer be relevant, or something better may have become available. If you use a feature that is listed, either the feature itself or an extension of it, you should look for or develop an alternative.

The next sections give a brief description of the deprecated features, state what happened to the feature, and explain why. The following table gives a few examples of what we mean by "moved, removed, or replaced."

STATE	EXAMPLES
Moved	The capability has been moved from local functionality to W1 because it was no longer specific to one or more country versions. The capability was combined with other related functionality to eliminate redundancy.
Removed	The capability will be removed from Business Central in a coming release.
Replaced	Something better has become available, and will be used instead.

Changes in 2022 release wave 1

Web Service Access Keys (Basic Auth) for Business Central Online (SaaS)

The following feature will be **Removed** with Business Central 2022 release wave 1.

MOVED, REMOVED, OR REPLACED?	WHY?
Removed (for SaaS only)	The capability to access web services in Business Central using Web Service Access Key (Basic Auth) is deprecated for SaaS. OAuth2 will be the authentication option for SaaS. OAuth samples are published in the BCTech repo. For on-premises, Web Service Access Key (Basic Auth) will remain an option for the time being. This change has no impact on how Business Central connects to external services.

Changes in 2021 release wave 2

Standard APIs, Beta version

The following feature will be **Removed** with Business Central 2021 release wave 2.

MOVED, REMOVED, OR REPLACED?	WHY?

MOVED, REMOVED, OR REPLACED?	WHY?
Removed	Beta version of the standard APIs will be removed by 2021 release wave 2. At this point, Beta APIs will not be available in new releases of Business Central. There are many improvements to v1.0 and v2.0 of the standard APIs. Improvements include more APIs, better performance and improved OData capabilities. It's recommended that integrations move to v2.0 of the standard APIs.

Automation APIs, Beta version

The following feature will be **Removed** with Business Central 2021 release wave 2.

MOVED, REMOVED, OR REPLACED?	WHY?
Removed	Beta version of the Automation APIs will be removed by 2021 release wave 2. At this point, Automation Beta APIs will not be available in new releases of Business Central. It's recommended that integrations move to v2.0 of the Automation APIs.

Changes in 2021 release wave 1

Expose UI pages as SOAP endpoints (Warning)

In Business Central 2021 release wave 1, a warning will be shown if you expose UI pages as SOAP endpoints. The capability of exposing UI pages as SOAP endpoints will be removed in a later release.

MOVED, REMOVED, OR REPLACED?	WHY?
Replaced	SOAP has been superseded by OData V4. SOAP endpoints will be deprecated as of Business Central 2021 release wave 1, but the feature won't be removed in this release. It's recommended that integrations are migrated to OData V4 as soon as possible.

OData V3

The following feature will be **Removed** with Business Central 2021 release wave 1.

MOVED, REMOVED, OR REPLACED?	WHY?
Removed	OData V3 has been superseded by OData v4. OData V3 is deprecated, and will be removed as of Business Central 2021 release wave 1. It's recommended that integrations are migrated to OData v4 as soon as possible.

Deprecated Features in 2020 release wave 1

The following feature was marked as obsolete:pending in 2020 release wave 1.

Best Price Calculations

When you have recorded special prices and line discounts for sales and purchases, Business Central ensures that your profit on item trade is always optimal by automatically calculating the best price on sales and purchase documents and on job and item journal lines.

MOVED, REMOVED, OR REPLACED?	WHY?
Replaced	The functionality is replaced with new calculations that you can extend to include additional sources or calculation methods. The current capabilities will be available, and can be used in parallel with the new, until 2021 release wave 1. For more information, see Extending Best Price Calculations.

Deprecated Features in 2019 release wave 2

The following sections describe the features that were deprecated in 2019 release wave 2.

The Bank Data Conversion Service

You can use the bank data conversion service from AMC to convert bank data from an XML file that you export from Business Central into a format that your bank can accept.

MOVED, REMOVED, OR REPLACED?	WHY?
Moved	The functionality has been moved to an extension. It now ships as the AMC Banking 365 Fundamentals extension, which can convert bank data to formats that are used by more than 600 banks worldwide. For more information, see Using the AMC Banking 365 Fundamentals extension.

The Windows Client

You can use Business Central in the Windows client that is installed on your computer.

MOVED, REMOVED, OR REPLACED?	WHY?
Removed	Business Central continues to evolve the modern client experiences where users work with Business Central in the browser, Windows 10 desktop app, or mobile apps on Android and iOS. The legacy Dynamics NAV Windows client is no longer available for deployment. Instead, users can switch to the modern experience in the browser, the Android/iOS mobile apps, or the Windows 10 desktop app (available through the respective stores).

Reports 204-207

You can generate external-facing documents, such as sales invoices and order confirmations, that you send to customers as PDF files.

The reports in the 204-207 range are replaced by the following updated reports in the 1304 to 1307 range:

- 204, Sales-Quote -> 1304, Standard Sales-Quote
- 205, Order-Confirmation -> 1305, Standard Sales-Order Conf.
- 206, Sales-Invoice -> 1306, Standard Sales-Invoice
- 207, Credit-Memo -> 1307, Standard Sales-Credit Memo

> **NOTE**
>
> The **No. of Copies** field is removed from the new reports because of performance reasons and because selection of the quantity to print works differently on modern printers. To print a report more than once, users can list the same report multiple times on the **Report Selection** page for the document type in question.

MOVED, REMOVED, OR REPLACED?	WHY?
Replaced	The reports in the 204-207 range are replaced by the reports in the 1304 to 1307 range. To avoid duplicated features, the reports in the 204-207 range will be removed.

User Personalizations and Profile Configurations

You can personalize pages and configure profiles by adding or removing fields, and Business Central will save your changes.

MOVED, REMOVED, OR REPLACED?	WHY?
Replaced	The shift to AL caused the legacy personalization and profile configuration features to become outdated, so we have introduced new tooling. In this release, existing personalizations and configurations are discarded, and you must use the new tools to recreate them. Your new changes will be kept in future releases.

Excel COM Add-In

You can export data to an Excel workbook.

MOVED, REMOVED, OR REPLACED?	WHY?
Removed	The Excel COM add-in was installed along with the Windows client. Now that the Windows Client is no longer available, neither is the add-in. To export data to Excel, use the **Edit in Excel** action.

Printing Programmatically

You can print documents such as invoices automatically, without prompting the user or without the user choosing to do so.

MOVED, REMOVED, OR REPLACED?	WHY?
Removed	This feature was tied to the Windows Client, which is no longer available.

Objects that have been marked as obsolete

Part of deprecating features is marking the objects that comprise them as "obsolete." Before we deprecate an object, we tag it as "obsolete:pending" to alert our partners of it's deprecation. The object will have the tag for one year before we remove it from Business Central.

Breaking Changes

When we move, remove, or replace an object, breaking changes can result in other apps or extensions that use the object. To help our partners identify and resolve breaking changes, we have created a Breaking Changes document that lists known issues and suggestions for what to do about them.

Features that are available only in the online version

Some features are available only under very specific circumstances, or not at all intended for use in on-premises versions of Business Central. For a list and descriptions of those features, see Features not implemented in on-

premises deployments.

Deprecated Fields, and Fields Marked as Obsolete

2/17/2021 • 42 minutes to read • Edit Online

In the latest version of Business Central, a number of fields have been deprecated in the current release or marked to be obsolete in a later release.

Definitions

Deprecated fields fall into one of the following groups:

1. Fields moved to an extension by Microsoft

   Partner impact: Remember to install the extension when you upgrade an existing solution from an earlier version of Business Central.

   Specifically for the extensions that are required for connecting on-premises solutions with Business Central online for intelligent insights, you must install the **Intelligent Cloud Base Extension** extension first, and then the product-specific extension or extensions.

2. Fields marked as **Obsolete:Pending**

   Partner impact: None in the current release, this is just a heads-up that a change is coming.

3. Fields no longer in use in Microsoft code

   Partner impact: Refactor your code as soon as possible.

Fields marked as ObsoleteState:Pending in Business Central

A number of fields are marked as ObsoleteState:Pending. There is no impact on code in this release.

Austria

The following fields are marked as ObsoleteState:Pending in the AT version.

TABLE ID	TABLE NAME	FIELD ID	FIELD NAME	COMMENTS
98	General Ledger Setup	11011	Sales VAT Advance Notif. Nos.	Will be removed in a later release.

For more information about the impact, see The new Item Categories feature replaced the Product Group feature in Dynamics NAV 2017 on the Dynamics NAV team blog. For more information about item categories, see How to: Categorize Items in the Dynamics 365 Business Central documentation.

Fields moved to an extension by Microsoft in Business Central

A number of fields have been moved from the base application to an extension.

Czech Republic

The functionality for Different types of disposal and maintenance in the Czech version has been moved to the Different types of disposal and maintenance (CZ) extension. For more information, see Different types of disposal and maintenance (CZ) Extension in the Dynamics 365 Business Central documentation.

Important Information and Considerations for Before Upgrading to Dynamics 365 Business Central

Deprecated Features in the Austrian Version of Dynamics 365 Business Central

2/17/2021 • 3 minutes to read • Edit Online

This topic lists and describes the local functionality for Austria that has been removed from Business Central, made available from a new page or report, or replaced by a new feature.

Batch Print Sales and Purchase Documents When Posting

When you batch post sales or purchase documents, you can select to also print the related reports.

MOVED, REMOVED, OR REPLACED?	WHY?
Moved	The Batch Print when Posting feature is no longer specific to Austria, so we have made it generally available in the standard product.

Copy Existing Items to Create New Items

When you add a new item, to save time, you can use the **Copy Item** function to copy an existing item to use as a template for a new item.

MOVED, REMOVED, OR REPLACED?	WHY?
Moved	The Copy Item feature is no longer specific to Austria, so we have made it generally available in the standard product.

Physical Inventory Order

You can take inventory of your items by using the **Physical Inventory Order** and **Physical Inventory Recording** pages. The physical inventory order contains data for planning, realizing, and analyzing physical inventory. The physical inventory recording contains the items and quantities to be counted and forms the basis of the print-out to be used in the warehouse.

MOVED, REMOVED, OR REPLACED?	WHY?
Moved	The Physical Inventory Order feature is no longer specific to Austria, so we have made it generally available in the standard product.

Blanket Order Archiving and Document Line Tracking

You can archive and delete blanket sales and purchase orders. You can view documents that are related to sales order lines and purchase order lines, including from archived order lines. Related documents that you can track include quotes, shipments, receipts, and blanket orders. This helps you to identify documents used to process orders.

MOVED, REMOVED, OR REPLACED?	WHY?
Moved	Blanket Order Archiving and Document Line Tracking features are no longer specific to Austria, so we have made them generally available in the standard product.

Austria Local Functionality

Deprecated Features in the Belgian Version of Microsoft Dynamics 365 Business Central

2/17/2021 • 2 minutes to read • Edit Online

This topic lists and describes the local functionality for Belgium that has been removed from Dynamics 365 Business Central, made available from a new page or report, or replaced by a new feature.

Isabel integration

You can integrate with Isabel to make it easy to upload and download bank files.

MOVED, REMOVED, OR REPLACED?	WHY?
Removed	This feature uses an automation that is not supported by the Dynamics 365 Business Central compiler and blocks the C/AL to AL conversion. In an earlier release we made this functionality unavailable, and now we have removed it. Microsoft partners can provide their solutions for customers who need to integrate with Isabel.

Belgium Local Functionality

Deprecated Features in the Canadian Version of Dynamics 365 Business Central

2/17/2021 • 2 minutes to read • Edit Online

This topic lists and describes the local functionality for Canada that has been removed from Business Central, made available from a new page or report, or replaced by a new feature.

Customer Statement Report

Shows a list of financial transactions for a selected customer statements for a given period of time. For example, use the report as part of your payment collection process.

MOVED, REMOVED, OR REPLACED?	WHY?	WHEN?
Replaced	The Standard Statement report (report 1316) provides the same capabilities as the Customer Statement report (report 10072), plus the ability to customize layouts in Word, and it is available for all countries.	2019 release wave 2

Aged Accounts Payable Report

Shows a list of aged remaining balances for each vendor for a given period of time.

MOVED, REMOVED, OR REPLACED?	WHY?	WHEN?
Replaced	The Aged Accounts Payable report (report 322) provides the same capabilities as the (local) Aged Accounts Payable (report 10085) and it is available for all countries.	2019 release wave 2

Aged Accounts Receivable Report

Shows a list of aged remaining balances for each customer for a given period of time.

MOVED, REMOVED, OR REPLACED?	WHY?	WHEN?
Replaced	The Aged Accounts Receivable report (report 120) provides the same capabilities as the (local) Aged Accounts Receivable (report 10040) and it is available for all countries.	2019 release wave 2

Canadian Local Functionality in Business Central

Deprecated Features in the Czech Version of Dynamics 365 Business Central

2/17/2021 • 39 minutes to read • Edit Online

This topic lists and describes the local functionality for Czech that has been removed from Business Central, made available from a new page or report, or replaced by a new feature.

Statutory Company Information

With this feature, users can:

- define company officials and designate them as General Manager, Accounting Managers, and Finance Managers for usage in internal and external documents.
- define document footers in different languages. Such footers can be used in different reports and documents.
- additional company registration numbers and other registration information can be stored in Company Information, for customers and vendors, and used in documents.

MOVED, REMOVED, OR REPLACED?	WHY?	WHEN?
Moved	The Statutory Company Information is no longer specific to Czech, so we have made it generally available in the standard product.	2020 release wave 2

Different types of disposal and maintenance

In the Czech accounting, it is necessary to post different types of disposal and different types of maintenance of Fixed Assets to specific G/L Accounts. A standard way offers only one method of disposal and maintenance posting.

A new setup was added for this feature – **FA Extended Posting Group** table. This table allows to set up for each **FA Posting group** different G/L accounts for:

- posting disposal in combination with **Reason Code** used in disposal transaction.
- posting maintenance in combination with **Maintenance Code** used in maintenance transaction.

MOVED, REMOVED, OR REPLACED?	WHY?	WHEN?
Moved	The functionality for Different types of disposal and maintenance in the Czech version will be moved to the Fixed Asset Localization for Czech extension.	2021 release wave 1

Posting Description

This feature enables users to customize the way Dynamics NAV is storing Posting Descriptions during posting to General Ledger Entries.

MOVED, REMOVED, OR REPLACED?	WHY?	WHEN?
Removed	This feature is deprecated and no longer needed and as not mandatory it will be deleted.	CU for 01.2021 release 2020 wave 2

General Entry Description

This feature transfers Sales and Purchase document line descriptions to G/L Entry description (instead of document header defined Posting Description). This functionality can be set separately for each account type in the document line.

MOVED, REMOVED, OR REPLACED?	WHY?	WHEN?
Moved	The General Entry Description is no longer specific to Czech, so we have made it generally available in the standard product. In standard product is available only for G/L Accounts.	2019 release wave 2

General Journal Reconciliation

This functionality has been extended. Net Change in Jnl. and Balance after Posting are not designated for G/L Accounts marked as Reconciliation Account only, but for all G/L Accounts used in the general journal, and also for other account types - Bank Account, Customer, Vendor, Fixed Asset and IC Partner. The functionality works with amounts in general journal lines and does not calculate VAT amounts for VAT Accounts.

MOVED, REMOVED, OR REPLACED?	WHY?	WHEN?
Removed	This feature is deprecated and no longer needed and as not mandatory it will be deleted.	CU for 01.2021 release 2020 wave 2

Industry Classification

This feature adds **Industry Code** classification field to Customer/Vendor tables and Sales/Purchase documents.

MOVED, REMOVED, OR REPLACED?	WHY?	WHEN?
Removed	Lack of use. The business need that this functionality was introduced to cover is no longer relevant. Functionality will be deleted.	CU for 01.2021 release 2020 wave 2

VAT Rounding Improvements

Necessary standard functionality modification to round the VAT amount according to the Czech Republic law requirements. The VAT Rounding is subject of VAT Law 235/2004 (§37). The rounding procedure uses rounding precision in order to calculate the result. Further additions include an ability to select special rounding precisions (special rounding is identified by a new field **Round VAT Coeff.** on the **General Ledger Setup** form) during VAT calculation for the following entities in G/L posting, Sales and Purchase.

MOVED, REMOVED, OR REPLACED?	WHY?	WHEN?
Removed	This feature is no longer mandatory by law from 2019 and will be deleted.	CU for 01.2021 release 2020 wave 2

Postponing VAT on Sales Credit Memo

Special function for the Sales Credit memo documents can be used. It is important to know (by §42 part 3b) of VAT Law 235/2004) the delivery date of the Sales Credit memo document. User can fill in the delivery date in the Posted Sales Credit Memo as the new VAT Date.
Sales VAT Postponed Account field has been added in the **VAT Posting Setup**. The **Postponed VAT** field was filled in the **VAT Entry**.

MOVED, REMOVED, OR REPLACED?	WHY?	WHEN?
Removed	This feature is no longer mandatory by law from 2019 and will be deleted.	CU for 01.2021 release 2020 wave 2

Non-deductible VAT

This functionality is important due to §76 of VAT Law 235/2004 – the shortened claim to deduction. The functionality includes:

- extension of **VAT Posting Setup** – allow Non-deductible VAT.
- special Non-deductible VAT Setup – user can set up Non Deductible VAT % and applicability.
- user can see **VAT % (Non-deductible)**, **VAT Base (Non-deductible)**, **VAT Amount (Deductible)** in the **VAT Entry**.
- extension of VAT Statement functionality.

MOVED, REMOVED, OR REPLACED?	WHY?	WHEN?
Removed	This feature will be not supported in extension-based Czech online tenants and will be deleted.	CU for 01.2021 release 2020 wave 2

VAT Registration in Other Countries

This functionality extends the possibility to work with VAT and allows the user to:

- set up the company as the VAT payer in the another EU country.
- set up exchange rates for **Fulfillment Country**.
- set up **Registration Country** for Customers and Vendors.
- set up **Registration Country Routes** for changing **VAT Bus. Posting Group**.
- define the **VAT Country** and the **VAT Fulfillment Country** on Documents.
- work with VAT Statement and VAT Settlement for fulfillments in another **VAT Fulfillment Country**.

MOVED, REMOVED, OR REPLACED?	WHY?	WHEN?
Removed	This feature will be not supported in extension-based Czech online tenants and will be deleted.	CU for 01.2021 release 2020 wave 2

VAT Identifier

This feature extends **VAT Identifier** within **VAT Posting Setup**. Adds source table for **VAT Identifier** and allow specify additional legal texts for printing in VAT recapitulation on tax documents. The **VAT Identifier** field is the part of the **VAT Entry**.

MOVED, REMOVED, OR REPLACED?	WHY?	WHEN?
Replaced	This feature was replaced by standard functionality of VAT Clauses and is no longer used and it will be deleted.	CU for 01.2021 release 2020 wave 2

Reverse Charge Statement

The amendment of VAT Law 235/2004 (§ 92a – 92e) introduced the VAT reverse charge calculation also for specific domestic fulfillments. A Reverse Charge Statement has to be submitted to the Tax Office electronically.

This feature allows user to:

- select combinations in **VAT Posting Setup** to include into the **Reverse Charge Statement**.
- set the Tariff Number Statement Code and Unit of Measures for **Reverse Charge Statement**.
- input all information on Sales and Purchase documents needed for electronic file submission.
- print **Reverse Charge Statement** and export statement data into the file for electronic submission.

MOVED, REMOVED, OR REPLACED?	WHY?	WHEN?
Removed	This feature is no longer mandatory by law and will be deleted.	CU for 01.2021 release 2020 wave 2

Fixed Assets Classification - SKP codes

SKP code is a code from the Standard Production Classification register. The Standard Production Classification was established by the Czech Statistical Office. This code is used for Fixed Asset classification and categorizing to the tax depreciation group. New **SKP Code** table and **SKP Code field** on Fixed Asset were added.

MOVED, REMOVED, OR REPLACED?	WHY?	WHEN?
Removed	This feature is no longer mandatory by law and will be deleted.	CU for 01.2021 release 2020 wave 2

Fixed Assets - Depreciation FA Appreciation From

This feature allows you calculate depreciation for additional FA appreciation on fully depreciated fixed asset.

MOVED, REMOVED, OR REPLACED?	WHY?	WHEN?
Removed	This feature will be not supported in extension based Czech SaaS environment and will be deleted.	CU for 01.2021 release 2020 wave 2

Fixed Assets – item consumption for maintenance

Fixed Asset Maintenance functionality was improved by extending the functionality in Item Journal. New fields

FA No. and **Maintenance Code** added to **Item Journal Line** table. These fields are used if purpose of item consumption is Fixed Asset Maintenance.

When the Item Negative Adjustment is posted in Item Journal, the **Maintenance Ledger Entry** will be created and posted automatically, based on **Automatic Maintenance Posting** field in **Inventory Setup**. For manually posting and/or item costs adjusting to maintenance, the report **Adj. Maintenance-Item Entries** was created.

MOVED, REMOVED, OR REPLACED?	WHY?	WHEN
Removed	This feature is deprecated and no longer needed and as not mandatory it will be deleted.	CU for 01.2021 2019 release wave 2

Multiple Interest Rates

When you create finance charge terms and reminder terms, for delayed payment penalty, you can specify multiple interest rates so that the penalty fee is calculated from different interest rates in different periods.

MOVED, REMOVED, OR REPLACED?	WHY?	WHEN
Moved	The Multiple Interest Rates feature is no longer specific to Czech, so we have made it generally available in the standard product.	2020 release wave 2

Deletion of Posted Documents feature

The majority of legislation's requires companies to keep their electronic record indefinitely or for a specific period of time. In order to avoid situation of accidental deletion of Sales and Purchase documents, Business Central prevents users to do this.

MOVED, REMOVED, OR REPLACED?	WHY?	WHEN?
Replaced	This Deletion of Posted Documents feature is no longer specific to Czech, so we have made it generally available in the standard product.	2019 release wave 2

Tax corrective documents for VAT

According to the VAT law amendment (Act No 235/2004 Coll.; amended with Act No 47/2011 Coll.), companies must correct the VAT base and amount when they are changed due to different reason (financial discount, payment discount and other corrections).

The printout of the correction document is named **Tax Correction Document**.

In the moment of paying the invoice with a defined payment discount, a Sales (or Service) Credit-Memo will be created. The document will reflect payment discount amount and calculated VAT Amount. The document can be printed in an ordinary way. The printout of the created Credit-Memo is a **Tax Corrective Document**. A Tax Corrective Document for payment discounts will be created if a payment discount is calculated based on an amount including VAT (it means the **Adjust for Payment Disc.** field is active in the **General Ledger Setup** form) and for those combinations which are active in the **Adjust for Payment Discount** fields in the **VAT Posting Setup**. In other cases payment discount will be calculated in an ordinary way.

MOVED, REMOVED, OR REPLACED?	WHY?	WHEN?
Removed	This feature will be not supported in extension based Czech SaaS environment and will be deleted.	CU for 01.2021 release 2020 wave 2

Vendor Templates

New feature for creating templates for different group of vendors has been added - **Vendor Templates**. This feature copies similar functionality for customers – **Customer templates**. The Vendor Template feature makes creating vendors from contacts easy and decreases amount of mistakes. When the user creates a new Vendor, **Apply Template** function can be used. Some fields will be automatically filled in thanks to that.

MOVED, REMOVED, OR REPLACED?	WHY?	WHEN
Removed	This feature is deprecated and no longer needed and as not mandatory it will be deleted.	CU for 01.2021 2019 release wave 2

Item Charges Enhancements

This feature allows the user to set and check the usage of item charges in Sales and Purchase. You can set the following options:

- assign item charge for the usage only in Sales or only in Purchase.
- disable assigning to different source lines – Receipt Lines, Transfer Receipt Lines, Return Shipment Lines, Sales Shipment Lines, Return Receipt Lines.
- check if item charge is assigned at Receive/Shipment posting.

MOVED, REMOVED, OR REPLACED?	WHY?	WHEN
Removed	Lack of use. The business need that this functionality was introduced to cover is no longer relevant. Functionality will be deleted.	CU for 01.2021 2019 release wave 2

No. Series Enhancements

The majority of companies in the Czech Republic request the following improvements to be implemented in No. Series setup.

No. Series Mask

New field **Mask** for No. Series structure mask added to the **No. Series** table where the user defines a position structure of the number generated in this No. Series. This feature makes creating new No. Series lines for new fiscal year easy and decreases the amount of mistakes.

This **Mask** creates a new No. Series line using the new **No. Series Mask Generator** function.

No. Series Links

New **No. Series Link** table added. The table contains setup of No. Series links for various system functions.

MOVED, REMOVED, OR REPLACED?	WHY?	WHEN
Removed	Lack of use. The business need that this functionality was introduced to cover is no longer relevant. Functionality will be deleted.	CU for 01.2021 2019 release wave 2

Certificate Management

For Electronic Registration of Sales (EET) functionality was introduced Certificate Management functionality to allow storing and assignment of certificates in EET.

MOVED, REMOVED, OR REPLACED?	WHY?	WHEN?
Moved	The Certificate Management feature is no longer specific to Czech, so we have made it generally available in the standard product.	2019 release wave 2

Packaging Tax Calculation

Companies selling or consuming goods on local market are liable of declaring package tax to the authorities. To do this Dynamics NAV enables users to:

- set package materials.
- collect data about sales and consumption of items with packages.
- calculate and report package tax for above mentioned transactions and items.

MOVED, REMOVED, OR REPLACED?	WHY?	WHEN
Removed	Lack of use. The business need that this functionality was introduced to cover is no longer relevant. Functionality will be deleted.	CU for 01.2021 2019 release wave 2

Small regulatory features and best practices

Following small regulatory features and local practices of Czech companies will be removed.

Dimension for VAT Entry

New field **Dimension Set ID** added to **VAT Ledger Entry** table.

Disable Cards Deleting

This feature enhance standard functionality to completely disallows the user to delete records in master data with entries (such as G/L accounts, Customers, Vendors, Items). This is driven by **Delete Card with Entries** field in **General Ledger Setup**.

Field for Full Description

In earlier versions, the character limit for **Description** and **Name** fields was 50. Therefore was a new field **Full Description** in all master data tables introduced to fulfill legal requirements for master data naming.

You can now enter up to 100 characters in all **Description** and **Name** fields across Business Central and it covers now the business need that this functionality was introduced.

Posted Warehouse Documents cannot be deleted

The majority of legislation's requires companies to keep their electronic record indefinitely or for a specific period of time. In order to avoid situation of accidental deletion of Warehouse documents, Business Central prevents users to do this.

Indivisible Unit of Measure

New field **Indivisible Unit** in **Unit of Measure** and **Item Unit of Measure** tables is added to avoid entering a decimal numbers in **Quantity** field in documents when Item should be posted in specific unit of measure.

Customer Template extension

New fields added to **Customer Template** to enhance data set populated in new customer card created from contact.

Quote Validity field on the Sales/Purchase Quote

New **Quote Validity** date field added to Sales/Purchase Quote documents to identify quote expiration.

This feature is replaced by Quote Validity feature introduced in standard product in 2019 release wave 1.

Original User ID on Sales/Purchase documents

New **Original User ID** field added to Sales/Purchase documents to identify creator of the document.

Check Balance in General Ledger Journal

Additional feature for disabling balance check by **Correction** field in General Ledger Journal posting.

MOVED, REMOVED, OR REPLACED?	WHY?	WHEN
Removed	Lack of use. The business need that this functionality was introduced to cover is no longer relevant. Functionality will be deleted.	CU for 01.2021 2019 release wave 2

Objects and Fields that are deleted in Dynamics 365 Business Central

The following list shows additional fields that are deleted as a result of the features that have been removed.

TABLENO	TABLENAME	NO.	FIELDNAME	OBSOLETESTATE	OBSOLETEREASON
18	Customer	11793	Default Ship-to Address Code	Removed	Replaced by **Ship-to Code**

Czech Local Functionality

Deprecated Features in the Dutch Version of Dynamics 365 Business Central

2/17/2021 • 2 minutes to read • Edit Online

This topic lists and describes the local functionality for the Netherlands that has been removed from Business Central, made available from a new page or report, made available to one or more additional countries, or replaced by a new feature.

Checking Totals for Purchase Invoices and Purchase Credit Memos

If the total amount on a purchase document does not match the total amount from the purchase lines, you can find out why by letting Business Central calculate the total amount, total base amount, total VAT amount, and total amount including VAT for the purchase lines. The totals display in fields at the bottom of the **Purchase Invoice** or **Purchase Credit Memo** pages.

By default, Business Central does not show these totals. To display them, on the **Purchases & Payables Setup** page, choose the **Show Totals on Purch. Inv./CM.** check box.

> **NOTE**
> To use this feature, your purchase invoices or purchase credit memos must have at least one purchase line, and a quantity. Additionally, when you turn on this feature Business Central recalculates totals on all purchase invoices and credit memos. Depending on the number of documents, this can take some time.

MOVED, REMOVED, OR REPLACED?	WHY?
Moved	The feature to check totals for purchase invoices and credit memos is no longer specific to the Netherlands, so we have made it generally available in the standard product.

Standard Sales and Purchase Codes

If you often need to create sales and purchase lines with similar information, you can set up standard codes representing sales and purchase lines that you can then insert on recurring sales and purchase documents, for example, for recurring replenishment orders.

MOVED, REMOVED, OR REPLACED?	WHY?
Removed	The feature has been removed from the Dutch version because it is generally available in the standard product.

Fields marked as ObsoleteState:Pending

The following fields are marked as ObsoleteState:Pending in the NL version.

TABLE ID	TABLE NAME	FIELD ID	FIELD NAME	COMMENTS

TABLE ID	TABLE NAME	FIELD ID	FIELD NAME	COMMENTS
312	Purchases & Payables Setup	11312	Show Totals on Purch. Inv./CM.	Will be removed in a later release.

Deprecated Features in the Finnish Version of Dynamics 365 Business Central

2/17/2021 • 2 minutes to read • Edit Online

This topic lists and describes the local functionality for Finland that has been removed from Business Central, made available from a new page or report, or replaced by a new feature.

Multiple Interest Rates

When you create finance charge terms and reminder terms, for delayed payment penalty, you can specify multiple interest rates so that the penalty fee is calculated from different interest rates in different periods.

MOVED, REMOVED, OR REPLACED?	WHY?
Moved	The Multiple Interest Rates feature is no longer specific to Finland, so we have made it generally available in the standard product.

Fields marked as ObsoleteState:Pending

Currently, no fields are marked as ObsoleteState:Pending in the FI version.

Finland Local Functionality

Deprecated Features in the German Version of Dynamics 365 Business Central

2/17/2021 • 3 minutes to read • Edit Online

This topic lists and describes the local functionality for Germany that has been removed from Business Central, made available from a new page or report, or replaced by a new feature.

Batch Print Sales and Purchase Documents When Posting

When you batch post sales or purchase documents, you can select to also print the related reports.

MOVED, REMOVED, OR REPLACED?	WHY?
Moved	The Batch Print when Posting feature is no longer specific to Germany, so we have made it generally available in the standard product.

Copy Existing Items to Create New Items

When you add a new item, to save time, you can use the **Copy Item** function to copy an existing item to use as a template for a new item.

MOVED, REMOVED, OR REPLACED?	WHY?
Moved	The Copy Item feature is no longer specific to Germany, so we have made it generally available in the standard product.

Physical Inventory Order

You can take inventory of your items by using the **Physical Inventory Order** and **Physical Inventory Recording** pages. The physical inventory order contains data for planning, realizing, and analyzing physical inventory. The physical inventory recording contains the items and quantities to be counted and forms the basis of the print-out to be used in the warehouse.

MOVED, REMOVED, OR REPLACED?	WHY?
Moved	The Physical Inventory Order feature is no longer specific to Germany, so we have made it generally available in the standard product.

Blanket Order Archiving and Document Line Tracking

You can archive and delete blanket sales and purchase orders. You can view documents that are related to sales order lines and purchase order lines, including from archived order lines. Related documents that you can track include quotes, shipments, receipts, and blanket orders. This helps you to identify documents used to process orders.

MOVED, REMOVED, OR REPLACED?	WHY?
Moved	Blanket Order Archiving and Document Line Tracking features are no longer specific to Germany, so we have made them generally available in the standard product.

Deprecated Features in the Icelandic Version of Dynamics 365 Business Central

2/17/2021 • 2 minutes to read • Edit Online

This topic lists and describes the local functionality for Iceland that has been removed from Business Central, made available from a new page or report, or replaced by a new feature.

Icelandic Tax Regulations of Conditional Discounts

The local tax regulation of conditional discounts feature enables you to issue a credit memo if a conditional discount is given to a customer. The payment for a conditional discount must be made within a specified period.

MOVED, REMOVED, OR REPLACED?	WHY?
Moved	This feature is no longer specific to Iceland, so we have made it generally available in the standard product. There is a field for number series for credit invoices on the **Sales and Receivables Setup** form, and a field on the **Customer Ledger Entry** table to link the appropriate entries to a credit invoice.

Fields marked as ObsoleteState:Pending

The following fields are marked as ObsoleteState:Pending in the IS version.

TABLE ID	FIELD ID	COMMENTS
21	10900	Will be removed in a later release.

Deprecated Features in the Italian Version of Dynamics 365 Business Central

2/17/2021 • 2 minutes to read • Edit Online

This topic lists and describes the local functionality for Italy that has been removed from Business Central, made available from a new page or report, or replaced by a new feature.

Report Trade with Customers and Vendors in Blocked Countries/Regions

You must submit a periodic report of transactions with customers and vendors in certain countries/regions that the Italian government has identified in a block list.

MOVED, REMOVED, OR REPLACED?	WHY?
Removed	The functionality for blocked countries/regions has been removed from the Italian version.

Multiple Interest Rates

When you create finance charge terms and reminder terms, for delayed payment penalty, you can specify multiple interest rates so that the penalty fee is calculated from different interest rates in different periods.

MOVED, REMOVED, OR REPLACED?	WHY?
Moved	The Multiple Interest Rates feature is no longer specific to Italy, so we have made it generally available in the standard product.

Switzerland Local Functionality

Deprecated Features in the UK Version of Dynamics 365 Business Central

2/17/2021 • 4 minutes to read • Edit Online

This topic lists and describes the local functionality for the United Kingdom that has been removed from Business Central, made available from a new page or report, or replaced by a new feature.

Accounting periods and system calendar

If your fiscal year is different than the calendar, you can measure your fiscal period in other units of time, such as months or quarters. To do this, you set up system calendars and accounting periods.

MOVED, REMOVED, OR REPLACED?	WHY?
Removed	Lack of use. Additionally, there are standard features for accounting periods that provide most of the same functionality as the UK accounting periods.

Create and export a Bankers' Automated Clearing Service file

You can use Bankers' Automated Clearing Service (BACS) to process financial transactions electronically. To do so, you must export vendor payments to a BACS file using the Export BACS option.

MOVED, REMOVED, OR REPLACED?	WHY?
Removed	This banking format standard is no longer used. This functionality is now covered by extensions such as the Envestnet Yodlee Bank Feeds, AMC Banking, and various other formats.

Non-invoiced stock reports

For month-end reconciliation and auditing, you can use the **Stock Received Not Invoiced** report to view stock that is received but not yet invoiced, and the **Stock Shipped Not Invoiced** report to see stock that has been shipped but not yet invoiced.

MOVED, REMOVED, OR REPLACED?	WHY?
Moved	The functionality for the Shipped, Non-Invoiced Sales Orders and the Received, Not Invoiced Purchase Order reports are no longer specific to the UK, so we have made them generally available as views for sales orders and purchase orders. The views are available in the Navigation Pane as Shipped Not Invoiced and Shipped Not Received options under Sales Orders and Purchase Orders, respectively.

Print Unposted Sales and Unposted Purchase reports

The Unposted Sales and Unposted Purchase reports let you print a list of sales and purchase documents that are not yet posted.

MOVED, REMOVED, OR REPLACED?	WHY?
Moved	The Unposted Sales and Unposted Purchase reports are now available from the Navigation Pane as views under Sales Orders and Purchase Orders.

Other VAT reports

You can use the following reports for VAT reporting:

- **Day Book VAT Entry** - Displays the daily total for VAT entries for a specific period.
- **Day Book Cust. Ledger Entry** - Displays the daily total for customer ledger entries for a specific period.
- **Day Book Vendor Ledger Entry** - Displays the daily total for vendor ledger entries for a specific period.

MOVED, REMOVED, OR REPLACED?	WHY?
Moved	These VAT-related reports are no longer specific to the UK, so we have made them generally available in the standard product.

Specify the Supply Type on documents

You can specify supply types such as sales, loan, exchange, hire, lease, rental, sales on commission, on tax invoices. To do this, you must update the codes and names of the supply types in the **Types of Supply** window.

MOVED, REMOVED, OR REPLACED?	WHY?
Removed	Lack of use. The business need that this functionality was introduced to cover is no longer relevant.

Multiple interest rates

When you create finance charge terms and reminder terms, for delayed payment penalty, you can specify multiple interest rates so that the penalty fee is calculated from different interest rates in different periods.

MOVED, REMOVED, OR REPLACED?	WHY?
Moved	The Multiple Interest Rates feature is no longer specific to the UK, so we have made it generally available in the standard product.

Direct Sales Details and Direct Purchase Details reports

You can view headers with order numbers and descriptions from sales and purchase documents, and filter or select data for these reports based on the general ledger account number, document number, and posting date.

MOVED, REMOVED, OR REPLACED?	WHY?
Removed	Lack of use.

Objects and Fields that are deleted in Dynamics 365 Business Central

Table 10505 has been deleted. The following list shows additional fields that are deleted as a result of the features that have been removed.

TABLE ID	FIELD ID	COMMENTS
23	10550	Deleted.
81	10550	Deleted.
81	10551	Deleted.
81	10552	Deleted.
81	10553	Deleted.
271	10550	Deleted.
312	10550	Deleted.
312	10551	Deleted.
334	10505	Deleted.
363	10550	Deleted.
7118	10505	Deleted.
7152	10550	Deleted.

Fields marked as ObsoleteState:Pending

The following fields are marked as ObsoleteState:Pending in the UK version.

TABLE ID	FIELD ID	COMMENTS
18	10500	Will be removed in a later release.
23	10500	Will be removed in a later release.
36	10501	Will be removed in a later release.
38	10501	Will be removed in a later release.
112	10501	Will be removed in a later release.
114	10501	Will be removed in a later release.
122	10501	Will be removed in a later release.
124	10501	Will be removed in a later release.
5107	10501	Will be removed in a later release.
5109	10501	Will be removed in a later release.

The following tables are marked as ObsoleteState:Pending in the UK version.

TABLE ID	TABLE NAME	FIELD ID	FIELD NAME	COMMENTS
10533	MTD-Liability	All	All	Will be removed in a later release.
10534	MTD-Payment	All	All	Will be removed in a later release.
10535	MTD-Return Details	All	All	Will be removed in a later release.

United Kingdom Local Functionality

Deprecated Features in the United States Version of Dynamics 365 Business Central

2/17/2021 • 2 minutes to read • Edit Online

This topic lists and describes the local functionality for the United States that has been removed from Business Central, made available from a new page or report, or replaced by a new feature.

Customer Statement Report

Shows a list of financial transactions for a selected customer statements for a given period of time. For example, use the report as part of your payment collection process.

MOVED, REMOVED, OR REPLACED?	WHY?	WHEN?
Replaced	The Standard Statement report (report 1316) provides the same capabilities as the Customer Statement report (report 10072), plus the ability to customize layouts in Word, and it is available for all countries.	2019 release wave 2

Aged Accounts Payable Report

Shows a list of aged remaining balances for each vendor for a given period of time.

MOVED, REMOVED, OR REPLACED?	WHY?	WHEN?
Replaced	The Aged Accounts Payable report (report 322) provides the same capabilities as the (local) Aged Accounts Payable (report 10085) and it is available for all countries.	2019 release wave 2

Aged Accounts Receivable Report

Shows a list of aged remaining balances for each customer for a given period of time.

MOVED, REMOVED, OR REPLACED?	WHY?	WHEN?
Replaced	The Aged Accounts Receivable report (report 120) provides the same capabilities as the (local) Aged Accounts Receivable (report 10040) and it is available for all countries.	2019 release wave 2

Fields marked as ObsoleteState:Pending

The following fields are marked as ObsoleteState:Pending in the US version.

TABLE ID	TABLE NAME	FIELD ID	FIELD NAME	COMMENTS
98	General Ledger Setup	10004	SAT Certificate Thumbprint	Will be removed in a later release.
10000	PAC Web Service	22	Certificate Thumbprint	Will be removed in a later release.

Deployment of Dynamics 365 Business Central

2/17/2021 • 2 minutes to read • Edit Online

The topics in the Deployment section are intended to help a partner prepare a Business Central solution for a customer online or on-premises.

Take prospects and customers online

You can give prospects a quick introduction to Business Central by asking them to get a free trial, and by showing them the apps in AppSource, for example. You can also create and give powerful demos that will attract prospects in your market space. With Business Central online, data is stored in the Microsoft cloud, removing the need to install SQL Server locally, for example. So for you as a reseller, deployments of Business Central online are taken care of for you so that you can focus on your prospects and customers.

Get set up for selling Business Central online

If your organization has a background as resellers of Dynamics NAV or other on-premises products, you have to get set up in the Microsoft Partner Center. For more information, see Get Started as a Reseller of Business Central Online.

For more information about reseller readiness for Business Central, see Build Your Business on Dynamics 365 Business Central.

Give powerful demos

You can create a trial environment based on the Business Central content pack in cdx.transform.microsoft.com.

For more information, see Preparing Demonstration Environments of Dynamics 365 Business Central.

Managing Business Central online

For more information about administering online tenants, see Administration of Business Central Online.

When to choose on-premises deployment

There can be many reasons to prefer to deploy Business Central on-premises rather than using online deployments.

Key Features of Setup for On-Premises Deployments

With Business Central Setup, you can:

- Install different components on different computers.
- Choose from a selection of predefined installation options, or create your own custom list of components and options to install.
- Preconfigure components before installation.
- Create, save, or load setup configuration files that capture your selection of components and configuration information.

You use setup to install software and to create custom deployments that you can distribute to different users across a company.

Installation Notes

- Before installing Business Central components on a computer, you must remove (uninstall) any previous

versions.

- All components must be from the same version and build of Business Central for the software to run correctly.
- If you have either SQL Server 2000 or Microsoft SQL Server Desktop Engine (MSDE) installed on a computer where you want to install Business Central, then you must remove it before you begin installing. The presence of either of these database products causes a setup error.

Managing Business Central on-premises

For more information about administering on-premises deployments, see Administration of Business Central On-Premises.

Configuring the Help Experience

Part of your configuration is to specify where to look up the Help for the solution. For on-premises deployments, you can choose to install the legacy Help Server, for example. For more information, see Configuring the Help Experience.

Features not implemented in on-premises deployments of Dynamics 365 Business Central

2/17/2021 • 3 minutes to read • Edit Online

This topic lists features that are available in Business Central but not in on-premises deployments. The topic is divided into two sections:

- The first section lists features that are available under very specific circumstances in on-premises deployments.
- The second section lists features that are not intended for use with on-premises deployments. There are no plans to implement these features.

Features that require specific circumstances

The following features are not available in all on-premises deployments because they require specific circumstances.

FEATURE	DESCRIPTION
Read/write data with Excel add-in	The Excel add-in that enables update of data requires Azure Active Directory as the authentication mechanism.
Excel financial reports	The Excel add-in that is used with the predefined Excel-based financial reports requires Azure Active Directory as the authentication mechanism.
Coversheets for contact management	The integration with Word to create the coversheets requires Azure Active Directory as the authentication mechanism.
Built-in Power BI reports and charts	The integration with Power BI requires Azure Active Directory as the authentication mechanism.
Built-in Power Automate Management	You can use the built-in workflows in on-premises deployments of Business Central, provided that you connect to Power Automate using Azure Active Directory as the authentication mechanism. This can be done using the Azure Active Directory Assisted Setup guide in Business Central. Microsoft Azure and Microsoft Power Automate require Azure Active Directory authentication; however, your Business Central on-premises deployment does not have to use Azure Active Directory as the general authentication mechanism.
Built-in web services	A number pages and queries are exposed as web services. However, the default endpoint must be manually updated before the web services can be consumed.
Outlook add-in	The Outlook add-in requires Dynamics NAV User/Password or Azure Active Directory as the authentication mechanism.

FEATURE	DESCRIPTION
Standard REST API	Business Central contains new standard REST APIs. However, on-premises deployments cannot be reached through Microsoft Graph or the common endpoint, `https://api.businesscentral.dynamics.com/v1.0/api/beta`. Instead, you must connect directly to the on-premises deployment, just as when you connect to web services.
Sales and Inventory Forecast	This functionality requires an Azure Machine Learning subscription.
Image Analyzer	This functionality requires an Computer Vision service.
Cortana Intelligence in Cash Flow Forecast	This functionality requires an Azure Machine Learning subscription.

Features not intended for use in on-premises deployments

The following features are not intended for use in on-premises deployments. There are no plans to implement these features in on-premises deployments.

FEATURE	DESCRIPTION
Default Power BI reports	Automatic deployment and configuration of Power BI reports is not supported in on-premises deployments of Business Central.
Bulk Invoicing from Microsoft Bookings	Integration with the Bookings app that is available in certain Microsoft 365 subscriptions is not supported.
Create workflow from Power Automate	Power Automate does not integrate with on-premises workflow functionality. You cannot create new workflows based on existing Power Automate templates in on-premises deployments of Business Central.
Sandbox environments	The sandbox environment that you can use to develop extensions against for the new developer experience cannot connect to an on-premises deployment. For more information, see Get started with the Container Sandbox Development Environment.
In-product search	In online deployments of Business Central, Tell Me, the in-product search, also searches in content on the docs.microsoft.com site. For on-premises deployments, this is not supported.
Late Payment Prediction	The Late Payment Prediction functionality is not supported in on-premises deployments of Business Central.
Use the company hub to manage work across multiple companies.	Integration with the company hub is not supported in on-premises deployments of Business Central.
Inviting the external accountant	Integration with the now deprecated Dynamics 365 — Accountant Hub and the existing company hub is not supported in on-premises deployments of Business Central.

System Requirements for Dynamics 365 Business Central 2020 Release Wave 2

2/17/2021 • 8 minutes to read • Edit Online

The following sections list the minimum hardware and software requirements to install and run Business Central on-premises (version 17). **Minimum** means that later versions (such as SP1, SP2, or R2 versions) of a required software product are also supported.

> **NOTE**
> Business Central Setup installs some software if it's not already present in the target computer. For more information, see the "Additional Information" section for each component.

CLIENT COMPONENTS

Web Client

The following table shows the minimum system requirements for the Business Central Web client on-premises.

SPECIFICATION	REQUIREMENT
Supported browsers	Recommended browsers: • New Microsoft Edge, latest version • Google Chrome for Windows, latest version • Mozilla Firefox for Windows, latest version • Safari for macOS, latest version Other supported browsers: • Internet Explorer 11, latest version • Microsoft Edge Legacy, latest version Cookies and JavaScript must be enabled in the browser.

Business Central Mobile App

The following table shows the minimum system requirements for the Business Central Mobile App.

For the latest information, see the app in the Windows Store, App Store, or Google Play.

SPECIFICATION	REQUIREMENT
Supported operating systems	• Windows 10 S, Home, Pro, Enterprise, or Education (32-bit and 64-bit editions). • Android 6.0 or higher (tablet and phone). • iOS 10.0 or higher (iPad and iPhone).

SPECIFICATION	REQUIREMENT
Additional hardware	• 1-GB RAM for Android and Windows.
Additional information	• Device diagonal screen size 7" for tablets. • Screen resolution 960 × 510 for tablets. • Device diagonal screen size 4" for phones. • Screen resolution 854 x 480 for phones.

Microsoft Office Applications

Business Central on-premises offers various features that require Office apps to be available on client devices. The following table shows the minimum system requirements for the features.

SPECIFICATION	REQUIREMENT
Excel	• Sending data to Excel requires Microsoft Office 2019, Excel for web, or Excel mobile app for iOS or Android™. • Editing in Excel using the Excel Add-In requires Microsoft Office 2019 or Excel for web.
Word	• Microsoft Office 2019, Word for web, or Word mobile app for iOS or Android™.
Outlook	Please see Business Inbox in Microsoft Outlook.
Additional software	• A third-party telephony or VoIP app such as Skype or Microsoft Teams is required for placing calls from Business Central.

AL Development

The following table shows the minimum system requirements for customizing or extending Business Central using the AL language in Visual Studio Code.

SPECIFICATION	REQUIREMENT
Supported operating systems	• Windows Server 2019 • Windows Server, version 1809 or later • Windows 10 For information about the supported versions and their lifecycles, see Windows lifecycle fact sheet.
Required software	• Visual Studio Code • AL language extension

SPECIFICATION	REQUIREMENT
Hardware resources	• Hard disk space: 500 MB. • CPU: four cores minimum • Memory: 16 GB for development only. 16 GB for developing and locally deploying small extensions (<1000 objects>). 32-64 GB for developing and locally deploying large extensions (>1000 objects).
Reports	• For creating and editing RDL report layouts: ◦ Report Builder for SQL Server 2016, or ◦ Visual Studio 2017 with Microsoft Rdlc Report Designer for Visual Studio installed. • For creating and editing Word report layouts: ◦ Word 2016 or later

For more information, see Getting Started with AL.

SERVER COMPONENTS

Business Central Server

The following table shows the minimum system requirements for Business Central Server.

SPECIFICATION	REQUIREMENT
Supported operating systems	• Windows 10 Pro, Enterprise, or Education (64-bit edition) • Windows Server 2019 (Datacenter, Standard) • Windows Server, version 1809 or later (Datacenter, Standard) • Windows Server 2016 (Datacenter, Standard) For information about the supported versions and their lifecycles, see Windows lifecycle fact sheet.
Hardware resources	• Hard disk space: 500 MB. • Memory: 2 GB.
Dynamics 365 Sales integration	• Windows Identity Framework. For a list of supported Dynamics 365 Sales versions, see Microsoft Dynamics 365 for Sales Integration Requirements.
Additional software	• Microsoft .NET Framework 4.8 • Windows PowerShell 4.0.

SPECIFICATION	REQUIREMENT

Additional information	• Business Central Setup installs the following software if it's not already present on the target computer:
	  ◦ Microsoft .NET Framework 4.8
	  ◦ Windows Identity Framework.

Business Central Web Server Components

SPECIFICATION	REQUIREMENT
Supported operating systems	• Windows 10 Pro, Enterprise, or Education (64-bit edition) • Windows Server 2019 (Datacenter, Standard) • Windows Server, version 1809 or later (Datacenter, Standard) • Windows Server 2016 (Datacenter, Standard) For information about the supported versions and their lifecycles, see Windows lifecycle fact sheet.
Web server	• Internet Information Services 10
Additional software	• Microsoft .NET Framework 4.8 • Windows PowerShell 4.0.

Additional information	• Business Central Setup installs the following software if it's not already present on the target computer.
	  ◦ Microsoft .NET Core 1.0 Windows Server Hosting. This software is installed by Business Central Setup if not already present.
	  ◦ Microsoft .NET Framework 4.8
	  ◦ Internet Information Services 10 is installed with the required features enabled.
	• For more information about configuring IIS, see Configuring IIS

Business Central Database Components for SQL Server

The following table shows the minimum system requirements for Business Central database components for SQL Server.

SPECIFICATION	REQUIREMENT
Supported operating systems	• Windows 10 Pro, Enterprise, or Education (64-bit edition) • Windows Server 2019 (Datacenter, Standard) • Windows Server, version 1809 or later (Datacenter, Standard) • Windows Server 2016 (Datacenter, Standard) For information about the supported versions and their lifecycles, see Windows lifecycle fact sheet.

SPECIFICATION	REQUIREMENT
Hardware resources	For more information, see Hardware and Software Requirements for Installing SQL Server. From this page, you can also access requirements for other versions of SQL Server.
SQL Server	• Microsoft SQL Server 2019 Express, Standard, or Enterprise. • Microsoft SQL Server 2017 Express, Standard, or Enterprise. • Microsoft SQL Server 2016 Express, Standard, or Enterprise (Service Pack 2 or later). • Azure SQL Database Managed Instance, Elastic Pool, or Single Database.
Service Packs and Cumulative Updates	Unless explicitly stated, all released Service Packs and Cumulative Updates of the above Microsoft SQL Server versions are supported. it's recommended to always be on the latest released Service Pack and Cumulative Update.
Additional information	Business Central Setup installs the following software if it's not already present on the target computer: • SQL Server 2016 Express (64-bit edition). If the operating system on the target computer doesn't support SQL Server 2016 Express, Setup displays a pre-requisite warning. In this case, you should exit Setup. Then, update the operating system on the computer to one that does support SQL Server 2016 Express and run Setup again.

Business Central Help Server Requirements

The following table shows the minimum system requirements for the Business Central Help Server.

SPECIFICATION	REQUIREMENT
Supported operating systems	• Windows 10 Pro, Enterprise, or Education (64-bit editions) • Windows Server 2019 (Datacenter, Standard) • Windows Server, version 1809 or later (Datacenter, Standard) • Windows Server 2016 (Datacenter, Standard) For information about the supported versions and their lifecycles, see Windows lifecycle fact sheet.
Hardware resource	• Hard disk space: 500 MB. • Memory: 2 GB.
Web server	• Internet Information Services 10.
Additional software	• Microsoft .NET Framework 4.8

SPECIFICATION	REQUIREMENT

Additional information	• Business Central Setup installs the following software if it's not already present on the target computer.
	  ◦ Microsoft .NET Framework 4.8
	  ◦ Internet Information Services 10.
	• Windows Search must be enabled on the computer that you install the Business Central Help Server on.

ADDITIONAL COMPONENTS AND FEATURES

Automated Data Capture System

The following table shows the minimum system requirements for Automated Data Capture System (ADCS) for Business Central.

SPECIFICATION	REQUIREMENT
Additional software	• MSXML version 6.0. • Telnet or Microsoft Windows HyperTerminal. • VT100 Plug-in for each computer on which you install ADCS. • Microsoft Loopback Adapter.
Additional information	• VT100 Plug-in acts as a virtual Telnet server. • Starting with Business Central 2020 release wave 1, the VT100 Plug-in for ADCS is no longer included on installation media. You can use VT100 Plug-in from previous releases. However, remember to test that it works properly. • HyperTerminal is no longer included with Windows.

Business Inbox in Microsoft Outlook

The following table shows the minimum system requirements for using Business Central as your business inbox in Outlook.

SPECIFICATION	REQUIREMENT
Supported Outlook Applications	• Outlook 2019 or later • Outlook on the web • Outlook Web App for iPad • Outlook Web App for iPhone • Outlook Web App for Android™.
Supported Exchange Servers	• Exchange Online • Exchange Server 2019 In deployments that use Exchange Server, the Exchange PowerShell endpoint must be accessible by Business Central Server.

SPECIFICATION	REQUIREMENT
Supported Authentication	• The Business Central Server must be configured to run with NavUserPassword, ACS, or AAD Credentials Type. Also, the Business Central Web client must be configured for Secure Sockets Layer (SSL).
Supported Browsers	• When using Outlook on the web, your computer must be running a supported browser listed in the Business Central Web client Requirements.
Supported Operating Systems	• When using Outlook Web App for iPad, iPhone, or Android™, your mobile device must use a supported operating system that's listed in the Business Central Mobile App section.

Microsoft Outlook Legacy Add-In

The following table shows the minimum system requirements for the Business Central legacy Add-In for Outlook for synchronization with Outlook.

SPECIFICATION	REQUIREMENT
Supported Outlook Applications	• Outlook 2019.
Supported Exchange Servers	• Exchange Server 2019 • Exchange Online.

Microsoft Dynamics 365 for Sales Integration

The following table shows the product version requirements for integrating Business Central with Dynamics 365 Sales, and the versions in which users can view the availability of items in Business Central from Dynamics 365 Sales.

SALES/DYNAMICS NAV/BUSINESS CENTRAL	2016/UPDATE 1/ONLINE	SALES ENTERPRISE (V8.X)	SALES ENTERPRISE AND SALES PROFESSIONAL (V9.X)
Dynamics NAV 2016	Supported ***	Supported ***	Supported ***
Dynamics NAV 2017	Supported *	Supported *	Supported *
Dynamics NAV 2018	Supported *	Supported *	Supported *
Business Central (online)	Not supported	Supported *	Supported *
Business Central (on-premises)	Supported *	Supported *	Supported *

Legend:

- "*" item availability capability is supported.
- "**" integration solution can be installed from the Dynamics NAV 2016 DVD, but viewing item availability isn't supported.
- "***" viewing item availability isn't supported

> **NOTE**
> AD, IFD and Claims authentication types are supported for the 2016 on-premises version of Dynamics 365 Sales. OAuth and Office 365 authentication are supported for the 2016 Update 1 and online versions of Dynamics 365 Sales. For more information about authentication types, see Connection strings in XRM tooling to connect to Dynamics 365.

Business Central as an App for SharePoint

The following table shows the minimum system requirements for Business Central as an App for SharePoint.

SPECIFICATION	REQUIREMENT
Supported SharePoint servers	• SharePoint Server 2016 • SharePoint Online.

Deployment

System Requirements for Dynamics 365 Business Central 2020 Release Wave 1

2/17/2021 • 9 minutes to read • Edit Online

The following sections list the minimum hardware and software requirements to use or connect to Business Central online, and to install and run Business Central on-premises (version 16). **Minimum** means that later versions (such as SP1, SP2, or R2 versions) of a required software product are also supported.

> **NOTE**
> Business Central Setup installs some software if it's not already present in the target computer. For more information, see the "Additional Information" section for each component.

Client Components

Web Client Requirements

The following table shows the minimum system requirements for the Business Central Web client on-premises.

SPECIFICATION	REQUIREMENT
Supported browsers	Recommended browsers: • New Microsoft Edge for Windows • Google Chrome for Windows (81.0 or later) • Mozilla Firefox for Windows (75.0 or later) • Safari for macOS (75.0 or later) Other supported browsers: • Internet Explorer 11 • Microsoft Edge Legacy Cookies and JavaScript must be enabled in the browser.
Business inbox in Outlook	• Microsoft 365, Microsoft Office 2019, or Microsoft Office 2016.
Sending data to Excel	• Microsoft 365, Microsoft Office 2019, or Microsoft Office 2016.
Editing in Excel using the Excel Add-in	• Excel 2019, Excel 2016, or Excel Online. For more information, see Exporting Your Business Data to Excel.
SharePoint Online links	• Microsoft Office 2019, Microsoft Office 2016, or Microsoft 365.

SPECIFICATION	REQUIREMENT
Printing reports to Excel or Word	• Microsoft Office 2019, Microsoft Office 2016, or Microsoft 365.
Additional information	If you experience problems using the Business Central Web client, you can try to turn off browser tools, such as translator tools that may run in the background.

Business Central Tablet Client and Phone Client (in a Browser) Requirements

The following table shows the minimum system requirements for the Business Central tablet client and Business Central phone client running in a desktop browser when used for development and testing purposes.

SPECIFICATION	REQUIREMENT
Server component	Identical to the Business Central Web client.
Supported browsers	Identical to the Business Central Web client.

Business Central Mobile App Requirements

The following table shows the minimum system requirements for the Business Central Mobile App.

For the latest information, see the app in the Windows Store, App Store, or Google Play.

SPECIFICATION	REQUIREMENT
Supported operating systems	• Windows 10 S, Home, Pro, Enterprise, or Education (32-bit and 64-bit editions). • Android 6.0 or higher (tablet and phone). • iOS 10.0 or higher (iPad and iPhone).
Additional hardware	• 1-GB RAM for Android and Windows.
Additional software	• A third-party telephony or VoIP app such as Skype is required for placing calls from Business Central. • A third-party email program such as Outlook is required for sending emails from Business Central. • Microsoft Office 2019, Office 2016, or Microsoft 365 is required for sending data to Microsoft Excel or to Microsoft Word.
Additional information	• Device diagonal screen size 7" for tablets. • Screen resolution 960 × 510 for tablets. • Device diagonal screen size 4" for phones. • Screen resolution 854 x 480 for phones.

AL Development Requirements

The following table shows the minimum system requirements for customizing or extending Business Central using the AL language in Visual Studio Code.

SPECIFICATION	REQUIREMENT
Supported operating systems	• Windows Server 2019 • Windows Server, version 1809 or later • Window Server 2016. • Windows 10 - supported versions.
Required software	• Visual Studio Code • AL language extension
Hardware resources	• Hard disk space: 500 MB. • CPU: four cores minimum • Memory: 16 GB for development only. 16 GB for developing and locally deploying small extensions (<1000 objects>). 32-64 GB for developing and locally deploying large extensions (>1000 objects).
Reports	• For creating and editing RDL report layouts: ◦ Report Builder for SQL Server 2016, or ◦ Visual Studio 2017 with Microsoft Rdlc Report Designer for Visual Studio installed. • For creating and editing Word report layouts: ◦ Word 2016 or later

For more information, see Getting Started with AL.

Server Components

Business Central Server Requirements

The following table shows the minimum system requirements for Business Central Server.

SPECIFICATION	REQUIREMENT
Supported operating systems	• Windows 10 Pro, Enterprise, or Education (64-bit edition). • Windows Server 2019 (Datacenter, Standard) • Windows Server, version 1809 or later (Datacenter, Standard) • Windows Server 2016 Standard, Essentials, or Datacenter. .
Hardware resources	• Hard disk space: 500 MB. • Memory: 2 GB.
Dynamics 365 Sales integration	• Windows Identity Framework. For a list of supported Dynamics 365 Sales versions, see Microsoft Dynamics 365 for Sales Integration Requirements.

SPECIFICATION	REQUIREMENT
Additional software	• Microsoft .NET Framework 4.8 • Windows PowerShell 4.0.

Additional information	• Business Central Setup installs the following software if it's not already present on the target computer:
	  ◦ Microsoft .NET Framework 4.8
	  ◦ Windows Identity Framework.

Business Central Web Server Components Requirements

SPECIFICATION	REQUIREMENT
Supported operating systems	• Windows 10 Pro, Enterprise, or Education (64-bit edition). • Windows Server 2019 (Datacenter, Standard) • Windows Server, version 1809 or later (Datacenter, Standard) • Windows Server 2016 Standard, Essentials, or Datacenter. .
Web server	• Internet Information Server 10, Internet Information Server 8.5, or Internet Information Server 8.0.
Additional software	• Microsoft .NET Framework 4.8 • Windows PowerShell 4.0.

Additional information	• Business Central Setup installs the following software if it's not already present on the target computer.
	  ◦ Microsoft .NET Core 1.0 Windows Server Hosting. This software is installed by Business Central Setup if not already present.
	  ◦ Microsoft .NET Framework 4.8
	  ◦ Internet Information Server 10, Internet Information Server 8.5, or Internet Information Server 8.0. The version depends on the operating system. Internet Information Server is installed with the required features enabled.
	• For more information about configuring IIS, see Configuring IIS

Business Central Database Components for SQL Server Requirements

The following table shows the minimum system requirements for Business Central database components for SQL Server.

SPECIFICATION	REQUIREMENT

SPECIFICATION	REQUIREMENT
Supported operating systems	• Windows 10 Pro, Enterprise, or Education (64-bit edition). • Windows Server 2019 (Datacenter, Standard) • Windows Server, version 1809 or later (Datacenter, Standard) • Windows Server 2016 Standard, Essentials, or Datacenter.
Hardware resources	For more information, see Hardware and Software Requirements for Installing SQL Server. From this page, you can also access requirements for other versions of SQL Server.
SQL Server	• Microsoft SQL Server 2019 Express, Standard, or Enterprise. • Microsoft SQL Server 2017 Express, Standard, or Enterprise. • Microsoft SQL Server 2016 Express, Standard, or Enterprise (Service Pack 1 or later). • Azure SQL Database Managed Instance, Elastic Pool, or Single Database.
Service Packs and Cumulative Updates	Unless explicitly stated, all released Service Packs and Cumulative Updates of the above Microsoft SQL Server versions are supported. it's recommended to always be on the latest released Service Pack and Cumulative Update.
Additional information	Business Central Setup installs the following software if it's not already present on the target computer: • SQL Server 2016 Express (64-bit edition). If the operating system on the target computer doesn't support SQL Server 2016 Express, Setup displays a pre-requisite warning. In this case, you should exit Setup. Then, update the operating system on the computer to one that does support SQL Server 2016 Express and run Setup again.

Business Central Help Server Requirements

The following table shows the minimum system requirements for the Business Central Help Server.

SPECIFICATION	REQUIREMENT
Supported operating systems	• Windows 10 Pro, Enterprise, or Education (64-bit editions). • Windows Server 2019 (Datacenter, Standard) • Windows Server, version 1809 or later (Datacenter, Standard) • Windows Server 2016 Standard, Essentials, or Datacenter.
Hardware resource	• Hard disk space: 500 MB. • Memory: 2 GB.

SPECIFICATION	REQUIREMENT
Web server	• Internet Information Server 10, Internet Information Server 8.5, or Internet Information Server 8.0.
Additional software	• Microsoft .NET Framework 4.8

Additional information	• Business Central Setup installs the following software if it's not already present on the target computer.
	  ◦ Microsoft .NET Framework 4.8
	  ◦ Internet Information Server 10, Internet Information Server 8.5, or Internet Information Server 8.0. The version depends on the operating system. it's installed with the required features enabled.
	• Windows Search must be enabled on the computer that you install the Business Central Help Server on.

Additional Components and Features

Automated Data Capture System Requirements

The following table shows the minimum system requirements for Automated Data Capture System (ADCS) for Business Central.

SPECIFICATION	REQUIREMENT
Additional software	• MSXML version 6.0. • Telnet or Microsoft Windows HyperTerminal. • VT100 Plug-in for each computer on which you install ADCS. • Microsoft Loopback Adapter.
Additional information	• HyperTerminal is no longer included with Windows. For more information, see What happened to HyperTerminal? in the Windows Help. • VT100 Plug-in acts as a virtual Telnet server.

> **NOTE**
> Starting with Business Central 2020 release wave 1, the VT100 Plug-in for ADCS is no longer included on installation media. You can use VT100 Plug-in from previous releases. However, remember to test that it works properly.

Business Inbox in Microsoft Outlook Requirements

The following table shows the minimum system requirements for using Business Central as your business inbox in Outlook.

SPECIFICATION	REQUIREMENT

SPECIFICATION	REQUIREMENT
Supported Outlook Applications	• Outlook 2016 or later • Outlook Web App • Outlook Web App for iPad • Outlook Web App for iPhone • Outlook Web App for Android.
Supported Exchange Servers	• Exchange Online • Exchange Server 2019 • Exchange Server 2016 In deployments that use Exchange Server, the Exchange PowerShell endpoint must be accessible by Business Central Server.
Supported Authentication	• The Business Central Server must be configured to run with NavUserPassword, ACS, or AAD Credentials Type. Also, the Business Central Web client must be configured for Secure Sockets Layer (SSL).
Supported Browsers	• When using the Outlook Web App (Microsoft Outlook Web App), your computer must be running a supported browser listed in the Business Central Web client Requirements.
Supported Operating Systems	• When using Outlook Web App for iPad, iPad, or Android, your mobile device must use a supported Operating System listed in Business Central Mobile App Requirements.

Microsoft Outlook Add-In Requirements

The following table shows the minimum system requirements for the Business Central Add-In for Outlook for synchronization with Outlook.

SPECIFICATION	REQUIREMENT
Supported Outlook Applications	• Outlook 2019 • Outlook 2016
Supported Exchange Servers	• Exchange Server 2019 • Exchange Server 2016 • Exchange Online.

Microsoft Dynamics 365 for Sales Integration Requirements

The following table shows the product version requirements for integrating Business Central with Dynamics 365 Sales, and the versions in which users can view the availability of items in Business Central from Dynamics 365 Sales.

SALES/DYNAMICS NAV/BUSINESS CENTRAL	2015/UPDATE 1/ONLINE	2016/UPDATE 1/ONLINE	SALES ENTERPRISE (V8.X)	SALES ENTERPRISE AND SALES PROFESSIONAL (V9.X)
Dynamics NAV 2016	Supported ***	Supported ***	Supported ***	Supported ***
Dynamics NAV 2017	Supported **	Supported *	Supported *	Supported *
Dynamics NAV 2018	Supported **	Supported *	Supported *	Supported *
Business Central (online)	Not supported	Not supported	Supported *	Supported *
Business Central (on-premises)	Supported **	Supported *	Supported *	Supported *

Legend:

- "*" item availability capability is supported.
- "**" integration solution can be installed from the Dynamics NAV 2016 DVD, but viewing item availability isn't supported.
- "***" viewing item availability isn't supported

> **NOTE**
> AD, IFD and Claims authentication types are supported for the 2015 and 2016 on-premises versions of Dynamics 365 Sales. OAuth and Microsoft 365 authentication are supported for the 2015, 2015 Update 1, and 2016 Update 1 online versions of Dynamics 365 Sales. For more information about authentication types, see Connection strings in XRM tooling to connect to Dynamics 365.

Business Central as an App for SharePoint Requirements

The following table shows the minimum system requirements for Business Central as an App for SharePoint.

SPECIFICATION	REQUIREMENT
Supported operating systems	• Windows Server 2019 Standard, Essentials, or Datacenter. • Windows Server 2016 Standard, Essentials, or Datacenter.
Additional software	• SharePoint 2013 Service Pack 1. • SharePoint Online.

System Requirements for Dynamics 365 Business Central 2019 Release Wave 2

2/17/2021 • 9 minutes to read • Edit Online

The following sections list the minimum hardware and software requirements to use or connect to Business Central online, and to install and run Business Central on-premises (version 15). **Minimum** means that later versions (such as SP1, SP2, or R2 versions) of a required software product are also supported.

> **NOTE**
> Business Central Setup installs some software if it's not already present in the target computer. For more information, see the "Additional Information" section for each component.

Client Components

Web Client Requirements

The following table shows the minimum system requirements for the Business Central Web client on-premises.

SPECIFICATION	REQUIREMENT
Supported browsers	Recommended browsers: • New Microsoft Edge for Windows • Google Chrome for Windows (77.0 or later) • Mozilla Firefox for Windows (69.0 or later) • Safari for macOS (12.0 or later) Other supported browsers: • Internet Explorer 11 • Microsoft Edge Legacy Cookies and JavaScript must be enabled in the browser.
Business inbox in Outlook	• Microsoft 365, Microsoft Office 2019, or Microsoft Office 2016.
Sending data to Excel	• Microsoft 365, Microsoft Office 2019, or Microsoft Office 2016.
Editing in Excel using the Excel Add-in	• Excel 2019, Excel 2016, or Excel Online. For more information, see Exporting Your Business Data to Excel.
SharePoint Online links	• Microsoft Office 2019, Microsoft Office 2016, or Microsoft 365.

SPECIFICATION	REQUIREMENT
Printing reports to Excel or Word	• Microsoft Office 2019, Microsoft Office 2016, or Microsoft 365.
Additional information	If you experience problems using the Business Central Web client, you can try to turn off browser tools, such as translator tools that may run in the background.

Business Central Tablet Client and Phone Client (in a Browser) Requirements

The following table shows the minimum system requirements for the Business Central tablet client and Business Central phone client running in a browser when used for development and testing purposes.

SPECIFICATION	REQUIREMENT
Server component	Identical to the Business CentralWeb client.
Supported browsers	The following desktop browsers are supported: • Microsoft Edge • Internet Explorer 11 (build 11.0.9600.17239) for Windows 10. • Google Chrome 72.0 for Windows. • Mozilla Firefox 65.0 for Windows. • Safari 10.0 for macOS. Cookies and JavaScript must be enabled in the browser.

Business Central Mobile App Requirements

The following table shows the minimum system requirements for the Business Central Mobile App.

For the latest information, see the app in the Windows Store, App Store, or Google Play.

SPECIFICATION	REQUIREMENT
Supported operating systems	• Windows 10 S, Home, Pro, Enterprise, or Education (32-bit and 64-bit editions). • Android 6.0 or higher (tablet and phone). • iOS 10.0 or higher (iPad and iPhone).
Additional hardware	• 1-GB RAM for Android and Windows.
Additional software	• A third-party telephony or VoIP app such as Skype is required for placing calls from Business Central. • A third-party email program such as Outlook is required for sending emails from Business Central. • Microsoft Office 2019, Office 2016, or Microsoft 365 is required for sending data to Microsoft Excel or to Microsoft Word.

SPECIFICATION	REQUIREMENT
Additional information	• Device diagonal screen size 7" for tablets. • Screen resolution 960 × 510 for tablets. • Device diagonal screen size 4" for phones. • Screen resolution 854 x 480 for phones.

AL Development Requirements

The following table shows the minimum system requirements for customizing or extending Business Central using the AL language in Visual Studio Code.

SPECIFICATION	REQUIREMENT
Supported operating systems	• Windows Server 2019 • Windows Server, version 1809 or later • Window Server 2016. • Windows 10 - supported versions.
Required software	• Visual Studio Code • AL language extension
Hardware resources	• Hard disk space: 500 MB. • CPU: Four cores minimum. • Memory: 16 GB for development only. 16 GB for developing and locally deploying small extensions (<1000 objects>). 32-64 GB for developing and locally deploying large extensions (>1000 objects).
Reports	• For creating and editing RDL report layouts: ◦ Report Builder for SQL Server 2016, or ◦ Visual Studio 2017 with Microsoft Rdlc Report Designer for Visual Studio installed. • For creating and editing Word report layouts: ◦ Word 2016 or later.

For more information, see Getting Started with AL.

Server Components

Business Central Server Requirements

The following table shows the minimum system requirements for Business Central Server.

SPECIFICATION	REQUIREMENT

SPECIFICATION	REQUIREMENT
Supported operating systems	• Windows 10 Pro, Enterprise, or Education (64-bit edition). • Windows Server 2019 (Datacenter, Standard) • Windows Server, version 1809 or later (Datacenter, Standard) • Windows Server 2016 Standard, Essentials, or Datacenter.
Hardware resources	• Hard disk space: 2 GB. • Memory: 2 GB for only running the application. 16 GB for publishing the application to the server.
Dynamics 365 Sales integration	• Windows Identity Framework. For a list of supported Dynamics 365 Sales versions, see Microsoft Dynamics 365 for Sales Integration Requirements.
Additional software	• Microsoft .NET Framework 4.7.2. or 4.8 • Windows PowerShell 4.0.
Additional information	• Business Central Setup installs the following software if it's not already present on the target computer: ◦ Microsoft .NET Framework 4.7.2. ◦ Windows Identity Framework.

Business Central Web Server Components Requirements

SPECIFICATION	REQUIREMENT
Supported operating systems	• Windows 10 Pro, Enterprise, or Education (64-bit edition). • Windows Server 2019 (Datacenter, Standard) • Windows Server, version 1809 or later (Datacenter, Standard) • Windows Server 2016 Standard, Essentials, or Datacenter.
Web server	• Internet Information Server 10, Internet Information Server 8.5, or Internet Information Server 8.0.
Additional software	• Microsoft .NET Framework 4.7.2 or 4.8. • Windows PowerShell 4.0.

SPECIFICATION	REQUIREMENT

Additional information	• Business Central Setup installs the following software if it's not already present on the target computer.
	  ◦ Microsoft .NET Core 1.0 Windows Server Hosting. This version is installed by Business Central Setup if not already present.
	  ◦ Microsoft .NET Framework 4.7.2.
	  ◦ Internet Information Server 10, Internet Information Server 8.5, or Internet Information Server 8.0, depending in the operating system, with the required features enabled.
	• For more information about configuring IIS, see Configuring IIS.

Business Central Database Components for SQL Server Requirements

The following table shows the minimum system requirements for Business Central database components for SQL Server.

SPECIFICATION	REQUIREMENT
Supported operating systems	• Windows 10 Pro, Enterprise, or Education (64-bit edition). • Windows Server 2019 (Datacenter, Standard) • Windows Server, version 1809 or later (Datacenter, Standard) • Windows Server 2016 Standard, Essentials, or Datacenter.
Hardware resources	For more information, see Hardware and Software Requirements for Installing SQL Server. From this page, you can also access requirements for other versions of SQL Server.
SQL Server	• Microsoft SQL Server 2019 Express, Standard, or Enterprise. • Microsoft SQL Server 2017 Express, Standard, or Enterprise. • Microsoft SQL Server 2016 Express, Standard, or Enterprise. • Azure SQL Database Managed Instance, Elastic Pool, or Single Database.
Service Packs and Cumulative Updates	Unless explicitly stated, all released Service Packs and Cumulative Updates of the above Microsoft SQL Server versions are supported. It's recommended to always be on the latest released Service Pack and Cumulative Update.

SPECIFICATION	REQUIREMENT
Additional information	Business Central Setup installs the following software if it's not already present on the target computer: • SQL Server 2016 Express (64-bit edition). If the operating system on the target computer does not support SQL Server 2016 Express, Setup displays a pre-requisite warning. In this case, you should exit Setup and then update the operating system on the computer to one that does support SQL Server 2016 Express. Then run Setup again.

Business Central Help Server Requirements

The following table shows the minimum system requirements for the Business Central Help Server.

SPECIFICATION	REQUIREMENT
Supported operating systems	• Windows 10 Pro, Enterprise, or Education (64-bit editions). • Windows Server 2019 (Datacenter, Standard) • Windows Server, version 1809 or later (Datacenter, Standard) • Windows Server 2016 Standard, Essentials, or Datacenter.
Hardware resource	• Hard disk space: 500 MB. • Memory: 2 GB.
Web server	• Internet Information Server 10, Internet Information Server 8.5, or Internet Information Server 8.0.
Additional software	• Microsoft .NET Framework 4.7.2 or 4.8.
Additional information	• Business Central Setup installs the following software if it's not already present on the target computer. ◦ Microsoft .NET Framework 4.7.2. ◦ Internet Information Server 10, Internet Information Server 8.5, or Internet Information Server 8.0. depending on the operating system, with the required features enabled. • Windows Search must be enabled on the computer that you install the Business Central Help Server on.

Additional Components and Features

Automated Data Capture System Requirements

The following table shows the minimum system requirements for Automated Data Capture System (ADCS) for Business Central.

SPECIFICATION	REQUIREMENT
Additional software	• MSXML version 6.0. • Telnet or Microsoft Windows HyperTerminal. • VT100 Plug-in for each computer on which you install ADCS. • Microsoft Loopback Adapter.
Additional information	• HyperTerminal is no longer included with Windows. For more information, see What happened to HyperTerminal? in the Windows Help. • VT100 Plug-in acts as a virtual Telnet server.

Business Inbox in Microsoft Outlook Requirements

The following table shows the minimum system requirements for using Business Central as your business inbox in Outlook.

SPECIFICATION	REQUIREMENT
Supported Outlook Applications	• Outlook 2016 or later • Outlook Web App (OWA) • OWA for iPad • OWA for iPhone • OWA for Android.
Supported Exchange Servers	• Exchange Online • Exchange Server 2019 • Exchange Server 2016 In deployments that use Exchange Server, the Exchange PowerShell endpoint must be accessible by Business Central Server.
Supported Authentication	• The Business Central Server must be configured to run with NavUserPassword, ACS, or AAD Credentials Type. Also, the Business Central Web client must be configured for Secure Sockets Layer (SSL).
Supported Browsers	• When using the Outlook Web App (OWA), your computer must be running a supported browser listed in the Business Central Web client Requirements.
Supported Operating Systems	• When using OWA for iPad, OWA for iPad, or OWA for Android, your mobile device must use a supported Operating System listed in Business Central Mobile App Requirements.

Microsoft Outlook Add-In Requirements

The following table shows the minimum system requirements for the Business Central Add-In for Outlook for synchronization with Outlook.

SPECIFICATION	REQUIREMENT
Supported Outlook Applications	• Outlook 2019 • Outlook 2016
Supported Exchange Servers	• Exchange Server 2019 • Exchange Server 2016 • Exchange Online.

Microsoft Dynamics 365 for Sales Integration Requirements

The following table shows the product version requirements for integrating Business Central with Dynamics 365 Sales, and the versions in which users can view the availability of items in Business Central from Dynamics 365 Sales.

SALES/DYNAMICS NAV/BUSINESS CENTRAL	2015/UPDATE 1/ONLINE	2016/UPDATE 1/ONLINE	SALES ENTERPRISE (V8.X)	SALES ENTERPRISE AND SALES PROFESSIONAL (V9.X)
Dynamics NAV 2016	Supported ***	Supported ***	Supported ***	Supported ***
Dynamics NAV 2017	Supported **	Supported *	Supported *	Supported *
Dynamics NAV 2018	Supported **Supported *	Supported *	Supported *	
Business Central (online)	Not supported	Not supported	Supported *	Supported *
Business Central (on-premises)	Supported **Supported *	Supported *	Supported *	

Legend:

- "*" item availability capability is supported.
- "**" integration solution can be installed from the Dynamics NAV 2016 DVD, but viewing item availability is not supported.
- "***" viewing item availability is not supported

> **NOTE**
>
> AD, IFD and Claims authentication types are supported for the 2015 and 2016 on-premises versions of Dynamics 365 Sales. OAuth and Microsoft 365 authentication are supported for the 2015, 2015 Update 1, and 2016 Update 1 online versions of Dynamics 365 Sales. For more information on authentication types, see Connection strings in XRM tooling to connect to Dynamics 365.

Business Central as an App for SharePoint Requirements

The following table shows the minimum system requirements for Business Central as an App for SharePoint.

SPECIFICATION	REQUIREMENT

SPECIFICATION	REQUIREMENT
Supported operating systems	• Windows Server 2019 Standard, Essentials, or Datacenter. • Windows Server 2016 Standard, Essentials, or Datacenter.
Additional software	• SharePoint 2013 Service Pack 1. • SharePoint Online.

System Requirements for Dynamics 365 Business Central April '19

2/17/2021 • 11 minutes to read • Edit Online

The following sections list the minimum hardware and software requirements to use or connect to Business Central online, and to install and run Business Central on-premises (version 14). **Minimum** means that later versions (such as SP1, SP2, or R2 versions) of a required software product are also supported.

> **NOTE**
> Business Central Setup installs some software if it isn't already present in the target computer. For more information, see the "Additional Information" section for each component.

Client Components

Browser Requirements

The following table shows the minimum system requirements for using Business Central in a browser.

SPECIFICATION	REQUIREMENT
Supported browsers	Recommended browsers: • New Microsoft Edge for Windows • Google Chrome for Windows (77.0 or later) • Mozilla Firefox for Windows (69.0 or later) • Safari for macOS (12.0 or later) Other supported browsers: • Internet Explorer 11 • Microsoft Edge Legacy Cookies and JavaScript must be enabled in the browser.
Business inbox in Outlook	• Microsoft 365, Microsoft Office 2019, or Microsoft Office 2016.
Sending data to Excel	• Microsoft 365, Microsoft Office 2019, or Microsoft Office 2016.
Editing in Excel using the Excel Add-in	• Excel 2019, Excel 2016, or Excel Online. For more information, see Exporting Your Business Data to Excel.
SharePoint Online links	• Microsoft Office 2019, Microsoft Office 2016, or Microsoft 365.

SPECIFICATION	REQUIREMENT
Printing reports to Excel or Word	• Microsoft Office 2019, Microsoft Office 2016, or Microsoft 365.
Additional information	If you experience problems using the Business Central Web client, you can try to turn off browser tools, such as translator tools that may run in the background.

Business Central Mobile App Requirements

The following table shows the minimum system requirements for the Business Central Mobile App.

For the latest information, see the app in the Windows Store, App Store, or Google Play.

SPECIFICATION	REQUIREMENT
Supported operating systems	• Windows 10 S, Home, Pro, Enterprise, or Education (32-bit and 64-bit editions). • Android 6.0 or higher (tablet and phone). • iOS 10.0 or higher (iPad and iPhone).
Additional hardware	• 1-GB RAM for Android and Windows.
Additional software	• A third-party telephony or VoIP app such as Skype is required for placing calls from Business Central. • A third-party email program such as Outlook is required for sending emails from Business Central. • Microsoft Office 2019, Office 2016, or Microsoft 365 is required for sending data to Microsoft Excel or to Microsoft Word.
Additional information	• Device diagonal screen size 7" for tablets. • Screen resolution 960 × 510 for tablets. • Device diagonal screen size 4" for phones. • Screen resolution 854 x 480 for phones.

AL Development Requirements

The following table shows the minimum system requirements for customizing or extending Business Central using the AL language in Visual Studio Code.

SPECIFICATION	REQUIREMENT
Supported operating systems	• Windows Server 2019 • Windows Server, version 1809 or later • Window Server 2016. • Windows 10 - supported versions.

SPECIFICATION	REQUIREMENT
Required software	• Visual Studio Code • AL language extension
Hardware resources	• Hard disk space: 500 MB. • CPU: Four cores minimum • Memory: 16 GB for development only. 32 GB for developing and deploying locally. 64 GB for developing large apps.

For more information, see Getting Started with AL.

Dynamics NAV Client connected to Business Central Requirements

The following table shows the minimum system requirements for using the Dynamics NAV Client connected to Business Central.

SPECIFICATION	REQUIREMENT
Supported operating systems	• Windows 10 Pro, Enterprise, or Education (32-bit and 64-bit editions). **Important:** Windows 10 S isn't supported. • Windows Server 2019 (Datacenter, Standard) • Windows Server, version 1809 or later (Datacenter, Standard) • Windows Server 2016 Standard, Essentials, or Datacenter.
Hardware resources	• Hard disk space: 200 MB. • Memory: 1 GB.

Reports	• For editing RDLC report layouts:
	  ◦ Report Builder for SQL Server 2016, or
	  ◦ Visual Studio 2017 with Microsoft Rdlc Report Designer for Visual Studio installed.
	• For editing Word layouts:
	  ◦ Microsoft Word 2016 or later

Outlook client integration and mail merge	• Microsoft 365, Microsoft Office 2019, or Microsoft Office 2016.
Import and export with Microsoft Excel and Office XML, and SharePoint links	• Microsoft 365, Microsoft Office 2019, or Microsoft Office 2016.
Editing in Excel using the Excel Add-in	• Excel 2019 or Excel 2016. For more information, see Exporting Your Business Data to Excel. For Business Central on-premises, see Setting up the Excel Add-In for Editing Data since the same steps apply to Business Central on-premises.

SPECIFICATION	REQUIREMENT
Email logging	• Active Directory and Microsoft Exchange Server 2019 or Exchange Server 2016. • Microsoft Exchange Online, or Exchange Online as part of a Microsoft 365 subscription.
Additional software	• Microsoft .NET Framework 4.7.2 or 4.8
Additional information	• Business Central Setup installs the following software if it isn't already present in the target computer: ◦ Microsoft .NET Framework 4.7.2. • The Dynamics NAV Client is available in a 32-bit version and 64-bit version. On a 32-bit Windows operating system, the 32-bit version is run. On a 64-bit Windows operating system, the 64-bit version is run by default; however, you can also run the 32-bit version if it's required. • Business Central Setup can only install the Excel Add-in if Excel is present on the target computer. • Outlook synchronization isn't supported on 64-bit versions of Office.

Dynamics NAV Development Environment Requirements

The following table shows the minimum system requirements for the Dynamics NAV Development Environment.

SPECIFICATION	REQUIREMENT
Supported operating systems	• Windows 10 Pro, Enterprise, or Education (32-bit and 64-bit editions). • Windows Server 2019 (Datacenter, Standard) • Windows Server, version 1809 or later (Datacenter, Standard) • Windows Server 2016 Standard, Essentials, or Datacenter.
Hardware resources	• Hard disk space: 200 MB. • Memory: 1 GB.

Reports	• For creating and editing RDL report layouts:
	  ◦ Report Builder for SQL Server 2016, or
	  ◦ Visual Studio 2017 with Microsoft Rdlc Report Designer for Visual Studio installed.
	• For creating and editing Word report layouts:
	  ◦ Word 2016 or later

Additional software	• Microsoft .NET Framework 4.7.2 or 4.8

SPECIFICATION	REQUIREMENT

Additional information	• Business Central Setup installs the following software if it isn't already present in the target computer:
	  ◦ Microsoft .NET Framework 4.7.2.
	  ◦ SQL Server Native Client 11.0.
	  ◦ Report Builder for SQL Server 2016. This version isn't installed if a version of SQL Server Report Builder or Microsoft Visual Studio is already present on the target computer
	• If the development environment and Business Central Server are on the same computer, then only a 64-bit operating system is supported.

Server Components (on-premises)

Business Central Server Requirements

The following table shows the minimum system requirements for Business Central Server.

SPECIFICATION	REQUIREMENT
Supported operating systems	• Windows 10 Pro, Enterprise, or Education (64-bit edition). • Windows Server 2019 • Windows Server, version 1809 or later • Windows Server 2016 Standard, Essentials, or Datacenter. .
Hardware resources	• Hard disk space: 500 MB. • Memory: 2 GB.
Dynamics 365 Sales integration	• Windows Identity Framework. For a list of supported Dynamics 365 Sales versions, see Microsoft Dynamics 365 for Sales Integration Requirements.
Additional software	• Microsoft .NET Framework 4.7.2 or 4.8 • Windows PowerShell 4.0.

Additional information	• Business Central Setup installs the following software if it isn't already present on the target computer:
	  ◦ Microsoft .NET Framework 4.7.2.
	  ◦ Windows Identity Framework.

Business Central Web Server Components Requirements

SPECIFICATION	REQUIREMENT

SPECIFICATION	REQUIREMENT
Supported operating systems	• Windows 10 Pro, Enterprise, or Education (64-bit edition). • Windows Server 2019 (Datacenter, Standard) • Windows Server, version 1809 or later (Datacenter, Standard) • Windows Server 2016 Standard, Essentials, or Datacenter. .
Web server	• Internet Information Server 10, Internet Information Server 8.5, or Internet Information Server 8.0.
Additional software	• Microsoft .NET Framework 4.7.2 or 4.8. • Windows PowerShell 4.0.

Additional information	• Business Central Setup installs the following software if it isn't already present on the target computer.
	  ◦ Microsoft .NET Core 1.0 Windows Server Hosting. This version is installed by Business Central Setup if not already present.
	  ◦ Microsoft .NET Framework 4.7.2.
	  ◦ Internet Information Server 10, Internet Information Server 8.5, or Internet Information Server 8.0, depending in the operating system, with the required features enabled.
	• For more information about configuring IIS, see Configuring IIS

Business Central Database Components for SQL Server Requirements

The following table shows the minimum system requirements for Business Central database components for SQL Server.

SPECIFICATION	REQUIREMENT
Supported operating systems	• Windows 10 Pro, Enterprise, or Education (64-bit edition). • Windows Server 2019 (Datacenter, Standard) • Windows Server, version 1809 or later (Datacenter, Standard) • Windows Server 2016 Standard, Essentials, or Datacenter.
Hardware resources	For more information, see Hardware and Software Requirements for Installing SQL Server. From this page, you can also access requirements for other versions of SQL Server.

SPECIFICATION	REQUIREMENT
SQL Server	• Microsoft SQL Server 2019 Express, Standard, or Enterprise. • Microsoft SQL Server 2017 Express, Standard, or Enterprise. • Microsoft SQL Server 2016 Express, Standard, or Enterprise. • Azure SQL Database Managed Instance, Elastic Pool, or Single Database.
Service Packs and Cumulative Updates	Unless explicitly stated, all released Service Packs and Cumulative Updates of the above Microsoft SQL Server versions are supported. It is recommended to always be on the latest released Service Pack and Cumulative Update.
Additional information	Business Central Setup installs the following software if it isn't already present on the target computer: • SQL Server 2016 Express (64-bit edition). If the operating system on the target computer does not support SQL Server 2016 Express, Setup displays a pre-requisite warning. In this case, you should exit Setup and then update the operating system on the computer to one that does support SQL Server 2016 Express. Then run Setup again.

Business Central Help Server Requirements

The following table shows the minimum system requirements for the Business Central Help Server.

SPECIFICATION	REQUIREMENT
Supported operating systems	• Windows 10 Pro, Enterprise, or Education (64-bit editions). • Windows Server 2019 (Datacenter, Standard) • Windows Server, version 1809 or later (Datacenter, Standard) • Windows Server 2016 Standard, Essentials, or Datacenter.
Hardware resource	• Hard disk space: 500 MB. • Memory: 2 GB.
Web server	• Internet Information Server 10, Internet Information Server 8.5, or Internet Information Server 8.0.
Additional software	• Microsoft .NET Framework 4.7.2 or 4.8.

SPECIFICATION	REQUIREMENT

Additional information	• Business Central Setup installs the following software if it isn't already present on the target computer.
	  ◦ Microsoft .NET Framework 4.7.2.
	  ◦ Internet Information Server 10, Internet Information Server 8.5, or Internet Information Server 8.0. depending on the operating system, with the required features enabled.
	• Windows Search must be enabled on the computer that you install the Business Central Help Server on.

Additional Components and Features

Automated Data Capture System Requirements

The following table shows the minimum system requirements for Automated Data Capture System (ADCS) for Business Central.

SPECIFICATION	REQUIREMENT
Additional software	• MSXML version 6.0. • Telnet or Microsoft Windows HyperTerminal. • VT100 Plug-in for each computer on which you install ADCS. • Microsoft Loopback Adapter.
Additional information	• HyperTerminal is no longer included with Windows. • VT100 Plug-in acts as a virtual Telnet server.

Requirements for using Business Central on-premises as your Business Inbox in Microsoft Outlook

The following table shows the minimum system requirements for using Business Central on-premises as your business inbox in Outlook.

SPECIFICATION	REQUIREMENT
Supported Outlook Applications	• Outlook 2016 or later • Outlook Web App (OWA) • OWA for iPad • OWA for iPhone • OWA for Android.
Supported Exchange Servers	• Exchange Online • Exchange Server 2019 • Exchange Server 2016 In deployments that use Exchange Server, the Exchange PowerShell endpoint must be accessible by Business Central Server.

SPECIFICATION	REQUIREMENT
Supported Authentication	• The Business Central Server must be configured to run with NavUserPassword, ACS, or A<ure AD as the authentication type. Also, the Business Central Web client must be configured for Secure Sockets Layer (SSL).
Supported Browsers	• When using the Outlook Web App (OWA), your computer must be running a supported browser listed in the Business Central Web client Requirements.
Supported Operating Systems	• When using OWA for iPad, OWA for iPad, or OWA for Android, your mobile device must use a supported Operating System listed in Business Central Mobile App Requirements.

Microsoft Outlook Add-In Requirements

The following table shows the minimum system requirements for the Business Central Add-In for Outlook for synchronization with Outlook.

SPECIFICATION	REQUIREMENT
Supported Outlook Applications	• Outlook 2019 • Outlook 2016
Supported Exchange Servers	• Exchange Server 2019 • Exchange Server 2016 • Exchange Online.

Microsoft Dynamics 365 for Sales Integration Requirements

The following table shows the product version requirements for integrating Business Central with Dynamics 365 Sales, and the versions in which users can view the availability of items in Business Central from Dynamics 365 Sales.

SPECIFICATION	REQUIREMENT
Microsoft Dynamics CRM versions	• Microsoft Dynamics CRM 2015 or Microsoft Dynamics CRM 2016 Note: AD, IFD, and Claims authentication types are supported for above editions. • Microsoft Dynamics CRM Online 2015, Microsoft Dynamics CRM Online 2015 Update 1, or Microsoft Dynamics CRM Online 2016 Update 1 or Microsoft Dynamics 365 Note: OAuth and Microsoft 365 authentication types are supported for these editions. For more information on authentication types, see Connection strings in XRM tooling to connect to Dynamics 365.

SPECIFICATION	REQUIREMENT
Business Central Integration Solution (.zip)	For Dynamics CRM 2015, Dynamics CRM Online 2015, and Dynamics CRM Online 2015 Update 1: • Use the DynamicsNAVIntegrationSolution.zip file that is found on the Dynamics NAV 2016 installation media (DVD) to install the solution. • Item Availability isn't supported on Dynamics CRM 2015, versions Update 1 and Online. For more information, see Preparing Dynamics 365 for Sales for Integration.

SALES/DYNAMICS NAV/BUSINESS CENTRAL	2015/UPDATE 1/ONLINE	2016/UPDATE 1/ONLINE	SALES ENTERPRISE (V8.X)	SALES ENTERPRISE AND SALES PROFESSIONAL (V9.X)
Dynamics NAV 2016	Supported ***	Supported ***	Supported ***	Supported ***
Dynamics NAV 2017	Supported **	Supported *	Supported *	Supported *
Dynamics NAV 2018	Supported **	Supported *	Supported *	Supported *
Business Central (online)	Not supported **	Not supported **	Supported *	Supported *
Business Central (on-premises)	Supported **	Supported *	Supported *	Supported *

Legend:

- "*" item availability capability is supported.
- "**" integration solution can be installed from the Dynamics NAV 2016 DVD, but viewing item availability isn't supported.
- "***" viewing item availability isn't supported

> **NOTE**
> AD, IFD and Claims authentication types are supported for the 2015 and 2016 on-premises versions of Dynamics 365 Sales. OAuth and Microsoft 365 authentication are supported for the 2015, 2015 Update 1, and 2016 Update 1 online versions of Dynamics 365 Sales. For more information on authentication types, see Use connection strings in XRM tooling to connect to Dynamics 365 for Customer Engagement apps (on-premises).

Software Lifecycle Policy and Dynamics 365 Business Central On-Premises Updates

2/17/2021 • 2 minutes to read • Edit Online

This article outlines the lifecycle and support policies for Dynamics 365 Business Central on-premises updates.

Fixed Lifecycle Policy

Dynamics 365 Business Central (on-premises) October'18 and April '19 Update software is covered by the Fixed Lifecycle Policy.

Licensed customers must stay current with updates to the Dynamics 365 Business Central on-premises software in accordance with the following servicing and system requirements. This policy requires the customer to maintain an Enhancement Plan and deploy updates as noted later in this article.

RELEASE	VERSION	BUILD NUMBER	AVAILABILITY	MAINSTREAM SUPPORT ENDS
Dynamics 365 Business Central (on-premises)	October'18 Update (version 13.x)	24630	November 1, 2018	**
Dynamics 365 Business Central (on-premises)	April '19 Update (version 14.x)	29537	April 1, 2019	October 10, 2023

** In order to obtain mainstream support after April 14, 2020, customers must update to the April 2019 release or a later update for the April 2019 version

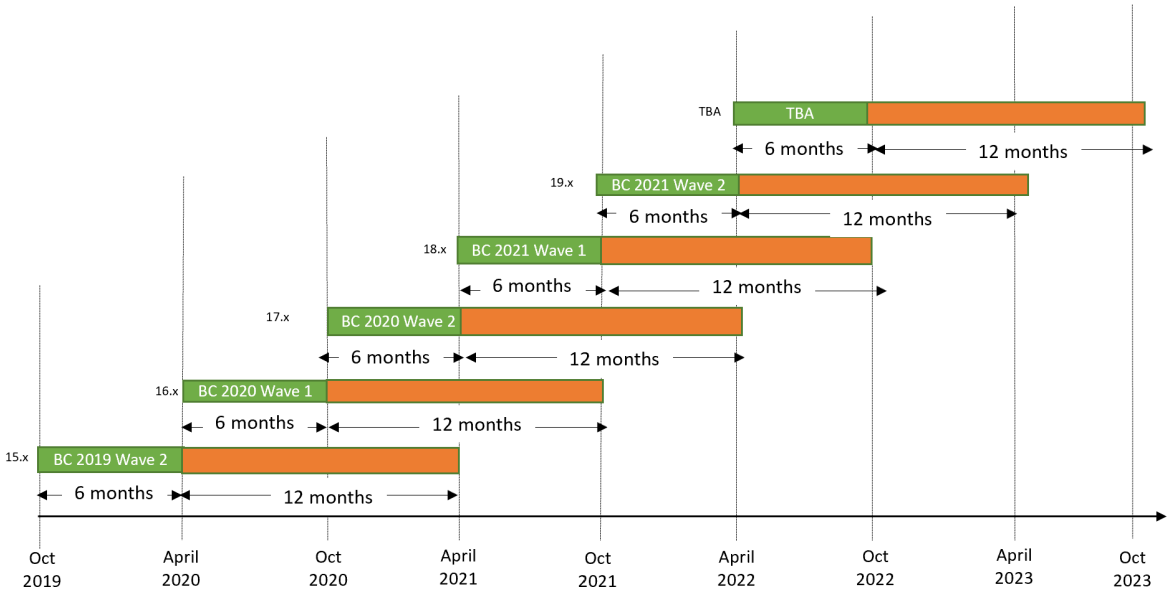
Modern Lifecycle Policy

Dynamics 365 Business Central (on-premises) 2019 release wave 2 and newer updates are covered by the Modern Lifecycle Policy.

The customer is in full control of its on-premises deployments and must follow this policy. The customer is in control of installing updates in its on-premises environments. Microsoft will support the Dynamics 365 Business Central (on-premises) software as indicated on the Microsoft Lifecycle Policy for Business Central on-premises page, but only if the customer keeps the deployed software current according to this policy. By keeping current, you're getting all the latest feature and bug fixes.

The following image illustrates the update schedule for Dynamics 365 Business Central.

Modern Lifecycle Policy



Modern Lifecycle Policy Legend

← 6 months →	6 months incidates features/bugs/regulatory fixes released for this cycle
← 12 months →	12 months incidates bugs/regulatory fixes released for this cycle

FAQ About the Windows Client and Business Central

2/17/2021 • 5 minutes to read • Edit Online

The first releases of Business Central on premises included an installed client derived from Dynamics NAV. Starting with 2019 release wave 2, this legacy component, referred to as "the Windows client", will no longer be available for Business Central. Find answers for some of the most common questions here.

I have heard "modern clients only". What is this about?

Businesses and users want to be reassured that only the newest, most advanced, and up-to-date tools are being used to access their data. With Business Central 2019 release wave 2, released October 2019, users switch to the **modern experience** in the browser ("the web client"), the Android or iOS mobile apps, or the Windows 10 desktop app, which are available through the respective stores.

Connecting the Windows client to Business Central is not supported in Business Central 2019 release wave 2 and onwards.

Why is Microsoft discontinuing the Windows client?

Our customers must feel comfortable that the tools they use are fit for new hardware, operating systems, and changing environments. We have accelerated our investment in speed and productivity features for the modern clients, thereby achieving a major milestone in its transformation into a world-class desktop experience for both new and expert users.

While the Windows client was inherently bound to the Windows operating system, the modern clients allow us to reach more customers and more users within an organization, no matter their platform or device of choice. The latest technologies allow us to innovate at a rapid pace and respond to accelerating compliance requirements, the changing technology landscape, and requests from the community. In addition, the lower installation footprint on client devices makes it easier for IT departments and hosters to maintain and support their user base.

When is the Windows client discontinued in Business Central?

From **October 2019**, with Business Central 2019 release wave 2.

It was first announced in 2018 at various conferences and then with a detailed timeline earlier in 2019. For more information, see Business Central April 2019 Update and the road ahead.

Will the Windows client still be supported in older releases of Business Central and Dynamics NAV?

Yes. You can safely continue to use the Windows client on premises and receive support as long as you follow the lifecycle policy for your on-premises installations of Business Central. For more information, see Lifecycle FAQ - Dynamics.

The Windows client **remains supported** for the Business Central April 2019 release and all earlier releases of Business Central on premises and Dynamics NAV, in accordance with the support lifecycle process.

Does this impact me if I use Business Central online?

No. This change only impacts on-premises installations because the Windows client was only available on premises.

Does this impact me if I use Business Central on premises?

Yes. When you **choose to upgrade** to Business Central 2019 release wave 2 or later, you must switch to access Business Central using one of the modern clients. The most popular choice on desktop computers is the web-browser client where your browser is pointing to an on-premises web server using a URL, such as this example (not active): `https://myserver.mydomain.com/BC170`

What if I really want to have an installable component or at least an icon on my desktop?

You can always add a browser shortcut on your desktop or pin the web page with Business Central to your Windows task bar. Alternatively, the Business Central Windows 10 desktop app, which is available from Microsoft Store, is a great way to access Business Central both online and on-premises. To get the app, go to Microsoft Dynamics 365 Business Central in the store.

How does this impact mobile?

There is **no impact** on mobile apps for Business Central as they are already part of the modern-client family. For more information about the mobile apps, seeGetting Business Central on Your Mobile Device.

Can I still work with Business Central data in Excel?

Yes. There are multiple ways to work with Business Central and Excel, including the following:

- The Open in Excel feature that downloads any list as an Excel file for your processing or reporting
- The Edit in Excel feature that allows you to edit almost any list-based data in Excel and publish it back to Business Central

For more information, see Viewing and Editing in Excel From Business Central. For instructions on how to configure it for on-premises, see Setting up the Excel Add-In for Editing Business Central Data.

Note that the legacy, COM-based Excel plugin that used to be included on the installation media is no longer supported.

Can I still use the same Outlook add-in?

Yes. This change does not impact the Outlook add-in. In fact, the modern Outlook add-in is based on the same familiar web experience. For more information, see Using Business Central as your Business Inbox in Outlook.

What happened to C/SIDE, the legacy development environment?

In line with the retirement of the Windows client, Business Central 2019 release wave 2 marks a milestone as the first release without the legacy development environment (also known as C/SIDE). The modern developer experience, which is based on Visual Studio Code and the new AL language, supports developing large apps, such as the base application from Microsoft.

Therefore, C/SIDE is discontinued for Business Central going forward. Partners enjoy tremendous productivity and performance gains after moving to the newest tools. For more information, see Development in AL.

Which features are available in the modern clients and where can I find the roadmap?

Business Central is a highly adaptable modern business management solution. It is rich in features and options and is continuously being enhanced. The roadmap is best represented by the release plans, which are updated every six months. For more information, see Overview of Dynamics 365 Business Central 2019 release wave 2.

Dynamics 365 Business Central On-Premises October'18 Updates

2/17/2021 • 4 minutes to read • Edit Online

This article lists cumulative updates released for the October'18 release of Microsoft Dynamics 365 Business Central on-premises. A cumulative update is a cumulative set of files that includes hotfixes and regulatory features for Business Central. If you have customers using Business Central October'18 on-premises, we recommend applying the latest cumulative update. For customers using Business Central online, check the Business Central Admin center to see whether the tenants have been updated.

Each cumulative update is intended mainly for solutions that are experiencing the problems described in the Support articles linked to below. However, you're advised to always keep your solution updated with the latest cumulative update. Support professionals in Customer Support Services are ready to help you if:

- You're in doubt about whether a cumulative update addresses your specific problem
- You want to confirm whether any special compatibility, installation, or download issues are associated with a particular cumulative update.

For more information, see https://support.microsoft.com/contactus/.

The latest cumulative update listed includes new hotfixes and regulatory, plus hotfixes and regulatory features released in previous cumulative updates.

We recommend that you install the latest cumulative update.

Available updates for Business Central October 2018

The following table lists the cumulative updates that have been released for the October'18 release of Business Central (version 13). The cumulative updates include hotfixes that apply to all countries and hotfixes that apply to specific local versions. Check the relevant Support article for a description.

Dynamics 365 Business Central On-Premises Spring 2019 Updates

2/17/2021 • 4 minutes to read • Edit Online

This article lists updates released for the Spring '19 release of Business Central on-premises. A cumulative update is a cumulative set of files that includes hotfixes and regulatory features for Business Central. We recommend applying the latest cumulative update. For customers using Business Central online, check the Business Central Admin center to see whether the tenants have been updated.

Each cumulative update is intended mainly for solutions that are experiencing the problems described in the linked Support. However, you're advised to always keep your solution updated with the latest cumulative update. Support professionals in Customer Support Services are ready to help you if:

- You're in doubt about whether a cumulative update addresses your specific problem
- You want to confirm whether any special compatibility, installation, or download issues are associated with a particular cumulative update.

For more information, see https://support.microsoft.com/contactus/.

The latest cumulative update listed includes new hotfixes and regulatory, plus hotfixes and regulatory features released in previous cumulative updates.

We recommend that you install the latest cumulative update.

Available updates for Business Central April 2019

The following table lists the cumulative updates released for the Spring 2019 release of Business Central (version 14). The cumulative updates include hotfixes that apply to all countries and hotfixes that apply to specific local versions. Check the relevant Support article for a description.

KNOWLEDGE BASE ID	TITLE	RELEASE DATE	BUILD NO.	LOCAL VERSIONS INCLUDED
5000693	Cumulative Update 21	February 2021	Application 14.22.46358 Platform Build 14.0.46351	AT, administrative unit, BE, CH, CZ, DE, DK, ES, FI, FR, IS, IT, NA, NL, NO, NZ, RU, SE, UK

Dynamics 365 Business Central On-Premises 2019 Release Wave 2 Updates

2/17/2021 • 3 minutes to read • Edit Online

This article lists updates released for the Microsoft Dynamics 365 Business Central 2019 release wave 2 for on-premises. An update is a set of files that includes all hotfixes and regulatory features that have been released for Business Central. If you have customers using Business Central 2019 release wave 2 on-premises, we recommend you apply this update so that your customers are using the latest version of Business Central. If you have customers using Business Central online, check the Business Central Admin center to see if the tenants have been updated.

Each update is intended mainly for solutions that are experiencing the problems described in the Support articles linked to below. However, you're advised to always keep your solution updated with the latest update. If you're in doubt about whether this update addresses your specific problem, or you want to confirm whether any special compatibility, installation, or download issues are associated with a particular update, then contact Customer Support Services. They are ready to help you. For more information, see https://support.microsoft.com/contactus/.

The latest update listed in this article includes hotfixes and regulatory features released for Business Central. The latest update also includes hotfixes and regulatory features released in previous updates.

You should always install the latest update.

Available updates for Business Central 2019 Release Wave 2

The following table lists the updates that have been released for 2019 release wave 2 of Business Central (version 15). The updates include hotfixes that apply to all countries and hotfixes that apply to specific local versions. Check the relevant Support article for a description.

KNOWLEDGE BASE ID	TITLE	RELEASE DATE	BUILD NO.	LOCAL VERSIONS INCLUDED
5000694	Update 15.15	February 2021	Application Build 15.15.46359 Platform Build 15.0.46345	AT, AU, BE, CH, CZ, DE, DK, ES, FI, FR, IS, IT, NA, NL, NO, NZ, RU, SE, UK
4595150	Update 15.14	January 2021	Application Build 15.14.46107 Platform Build 15.0.46099	AT, AU, BE, CH, CZ, DE, DK, ES, FI, FR, IS, IT, NA, NL, NO, NZ, RU, SE, UK
4583552	Update 15.13	December 2020	Application Build 15.13.45740 Platform Build 15.0.45731	AT, AU, BE, CH, CZ, DE, DK, ES, FI, FR, IS, IT, NA, NL, NO, NZ, RU, SE, UK
4583512	Update 15.12	November 2020	Application Build 15.12.45390 Platform Build 15.0.45381	AT, AU, BE, CH, CZ, DE, DK, ES, FI, FR, IS, IT, NA, NL, NO, NZ, RU, SE, UK

KNOWLEDGE BASE ID	TITLE	RELEASE DATE	BUILD NO.	LOCAL VERSIONS INCLUDED
4583500	Update 15.11	October 2020	Application Build 15.11.44966 Platform Build 15.0.44957	AT, AU, BE, CH, CZ, DE, DK, ES, FI, FR, IS, IT, NA, NL, NO, NZ, RU, SE, UK
4576663	Update 15.10	September 2020	Application Build 15.10.44664 Platform Build 15.10.44655	AT, AU, BE, CH, CZ, DE, DK, ES, FI, FR, IS, IT, NA, NL, NO, NZ, RU, SE, UK
4563414	Update 15.9	August 2020	Application Build 15.9.44343 Platform Build 15.0.44325	AT, AU, BE, CH, CZ, DE, DK, ES, FI, FR, IS, IT, NA, NL, NO, NZ, RU, SE, UK
4563406	Update 15.8	July 2020	Application Build 15.8.43801 Platform Build 15.0.43794	AT, AU, BE, CH, CZ, DE, DK, ES, FI, FR, IS, IT, NA, NL, NO, NZ, RU, SE, UK
4564071	Update 15.7	June 2020	Application Build 15.7.43293 Platform Build 15.0.43283	AT, AU, BE, CH, CZ, DE, DK, ES, FI, FR, IS, IT, NA, NL, NO, NZ, RU, SE, UK
4549685	Update 15.6	May 2020	Application Build 15.6.42646 Platform Build 15.0.42629	AT, AU, BE, CH, CZ, DE, DK, ES, FI, FR, IS, IT, NA, NL, NO, NZ, RU, SE, UK
4549678	Update 15.5	April 2020	Application Build 15.5.41926 Platform Build 15.0.41893	AT, AU, BE, CH, CZ, DE, DK, ES, FI, FR, IS, IT, NA, NL, NO, NZ, RU, SE, UK
4538888	Update 15.4	March 2020	Application Build 15.4.41213 Platform Build 15.0.41193	AT, AU, BE, CH, CZ, DE, DK, ES, FI, FR, IS, IT, NA, NL, NO, NZ, RU, SE, UK
4539530	Update 15.3	February 2020	Application Build 15.3.40822 Platform Build 15.0.40791	AT, AU, BE, CH, CZ, DE, DK, ES, FI, FR, IS, IT, NA, NL, NO, NZ, RU, SE, UK
4533389	Update 15.2	December 2019	Application Build 15.2.39040 Platform Build 15.0.38951	AT, AU, BE, CH, CZ, DE, DK, ES, FI, FR, IS, IT, NA, NL, NO, NZ, RU, SE, UK
4528699	Update 15.1	November 2019	Application Build 15.1.38071 Platform Build 15.0.37898	AT, AU, BE, CH, CZ, DE, DK, ES, FI, FR, IS, IT, NA, NL, NO, NZ, RU, SE, UK

Dynamics 365 Business Central On-Premises 2020 Release Wave 1 Updates

2/17/2021 • 3 minutes to read • Edit Online

This article lists updates released for the Microsoft Dynamics 365 Business Central 2020 release wave 1 for on-premises. An update is a set of files that includes all hotfixes and regulatory features that have been released for Business Central. If you have customers using Business Central 2020 release wave 1 on-premises, we recommend you apply this update so that your customers are using the latest version of Business Central. If you have customers using Business Central online, check the Business Central Admin center to see if the tenants have been updated.

Each update is intended mainly for solutions that are experiencing the problems described in the Support articles linked to below. However, you're advised to always keep your solution updated with the latest update. If you're in doubt about whether this update addresses your specific problem, or you want to confirm whether any special compatibility, installation, or download issues are associated with a particular update, then contact Customer Support Services. They are ready to help you. For more information, see https://support.microsoft.com/contactus/.

The latest update listed in this article includes hotfixes and regulatory features released for Business Central. The latest update also includes hotfixes and regulatory features released in previous updates.

You should always install the latest update.

Available updates for Business Central 2020 Release Wave 1

The following table lists the updates that have been released for 2020 release wave 1 of Business Central (version 16). The updates include hotfixes that apply to all countries and hotfixes that apply to specific local versions. Check the relevant Support article for a description.

KNOWLEDGE BASE ID	TITLE	RELEASE DATE	BUILD NO.	LOCAL VERSIONS INCLUDED
5000695	Update 16.10	February 2021	Application Build 16.10.21502 Platform Build 16.0.21469	AT, AU, BE, CH, CZ, DE, DK, ES, FI, FR, IS, IT, NA, NL, NO, NZ, RU, SE, UK
4595151	Update 16.9	January 2021	Application Build 16.9.20537 Platform Build 16.0.20513	AT, AU, BE, CH, CZ, DE, DK, ES, FI, FR, IS, IT, NA, NL, NO, NZ, RU, SE, UK
4583553	Update 16.8	December 2020	Application Build 16.8.19389 Platform Build 16.0.19389	AT, AU, BE, CH, CZ, DE, DK, ES, FI, FR, IS, IT, NA, NL, NO, NZ, RU, SE, UK
4583513	Update 16.7	November 2020	Application Build 16.7.18411 Platform Build 16.0.18359	AT, AU, BE, CH, CZ, DE, DK, ES, FI, FR, IS, IT, NA, NL, NO, NZ, RU, SE, UK

KNOWLEDGE BASE ID	TITLE	RELEASE DATE	BUILD NO.	LOCAL VERSIONS INCLUDED
4583501	Update 16.6	October 2020	Application Build 16.6.17046 Platform Build 16.0.17024	AT, AU, BE, CH, CZ, DE, DK, ES, FI, FR, IS, IT, NA, NL, NO, NZ, RU, SE, UK
4563415	Update 16.5	September 2020	Application Build 16.5.15953 Platform Build 16.5.15941	AT, AU, BE, CH, CZ, DE, DK, ES, FI, FR, IS, IT, NA, NL, NO, NZ, RU, SE, UK
4563415	Update 16.4	August 2020	Application Build 16.4.15445 Platform Build 16.0.15420	AT, AU, BE, CH, CZ, DE, DK, ES, FI, FR, IS, IT, NA, NL, NO, NZ, RU, SE, UK
4563407	Update 16.3	July 2020	Application Build 16.3.14238 Platform Build 16.0.14195	AT, AU, BE, CH, CZ, DE, DK, ES, FI, FR, IS, IT, NA, NL, NO, NZ, RU, SE, UK
4549686	Update 16.2	June 2020	Application Build 16.2.13779 Platform Build 16.0.13772	AT, AU, BE, CH, CZ, DE, DK, ES, FI, FR, IS, IT, NA, NL, NO, NZ, RU, SE, UK
4549686	Update 16.1	May 2020	Application Build 16.1.12805 Platform Build 16.0.12758	AT, AU, BE, CH, CZ, DE, DK, ES, FI, FR, IS, IT, NA, NL, NO, NZ, RU, SE, UK

Dynamics 365 Business Central On-Premises 2020 Release Wave 2 Updates

2/17/2021 • 2 minutes to read • Edit Online

This article lists updates released for the Microsoft Dynamics 365 Business Central 2020 release wave 2 for on-premises. An update is a set of files that includes all hotfixes and regulatory features that have been released for Business Central. If you have customers using Business Central 2020 release wave 2 on-premises, we recommend you apply this update so that your customers are using the latest version of Business Central. If you have customers using Business Central online, check the Business Central Admin center to see if the tenants have been updated.

Each update is intended mainly for solutions that are experiencing the problems described in the Support articles linked to below. However, you're advised to always keep your solution updated with the latest update. If you're in doubt about whether this update addresses your specific problem, or you want to confirm whether any special compatibility, installation, or download issues are associated with a particular update, then contact Customer Support Services. They are ready to help you. For more information, see https://support.microsoft.com/contactus/.

The latest update listed in this article includes hotfixes and regulatory features released for Business Central. The latest update also includes hotfixes and regulatory features released in previous updates.

You should always install the latest update.

Available updates for Business Central 2020 Release Wave 2

The following table lists the updates that have been released for 2020 release wave 2 of Business Central (version 17). The updates include hotfixes that apply to all countries and hotfixes that apply to specific local versions. Check the relevant Support article for a description.

KNOWLEDGE BASE ID	TITLE	RELEASE DATE	BUILD NO.	LOCAL VERSIONS INCLUDED
5000696	Update 17.4	February 2021	Application Build 17.4.21531 Platform Build 17.0.21516	AT, AU, BE, CH, CZ, DE, DK, ES, FI, FR, IS, IT, NA, NL, NO, NZ, RU, SE, UK
4595152	Update 17.3	January 2021	Application Build 17.3.20605 Platform Build 17.0.20517	AT, AU, BE, CH, CZ, DE, DK, ES, FI, FR, IS, IT, NA, NL, NO, NZ, RU, SE, UK
4583554	Update 17.2	December 2020	Application Build 17.2.19367.19396 Platform Build 17.0.19353.19391	AT, AU, BE, CH, CZ, DE, DK, ES, FI, FR, IS, IT, NA, NL, NO, NZ, RU, SE, UK
4583515	Update 17.1	November 2020	Application Build 17.1.18256.18792 Platform Build 17.0.18204.18738	AT, AU, BE, CH, CZ, DE, DK, ES, FI, FR, IS, IT, NA, NL, NO, NZ, RU, SE, UK

Running a Container-Based Development Environment

2/17/2021 • 3 minutes to read • Edit Online

Dynamics 365 Business Central is available as artifacts for running on Docker on a Windows system with Docker installed.

> **TIP**
> Use the `Get-BCArtifactUrl` from the BCContainerHelper PowerShell module to get the artifact URL for the version of Dynamics 365 Business Central that you want.

Install and configure Docker

Install Docker and configure it for Windows Containers.

1. Please choose the version of Docker that is appropriate for the host operating system.
   - For Windows 10, use Docker Community Edition. For more information, see Install instructions.
   - For Windows Server, use Docker Enterprise Edition. For more information, see Install instructions.
2. For Windows 10, switch Docker to use Windows containers. By default Docker Community Edition uses Linux containers.

   To switch to Windows containers, in the Taskbar, right-click the Docker icon  , and then select **Switch to Windows Containers**. For more information, see Switch between Windows and Linux containers.

> **NOTE**
> You can run Business Central on Docker using Docker commands, or you can use the BCContainerHelper PowerShell module. The BCContainerHelper module removes a lot of the complexity of running Docker.

Using Docker commands

Open a Command Prompt as Administrator. In the command prompt, identify your version of Windows (example 10.0.19041.329). Run this command to pull the latest version of the generic image used to to run Business Central on Docker:

```
docker pull mcr.microsoft.com/businesscentral:10.0.19041.329
```

Use this command to run a sandbox container with the US localization of version 16.3.14085.14363 on Docker:

```
docker run -e accept_eula=Y -m 4G -e
artifacturl=https://bcartifacts.azureedge.net/sandbox/16.3.14085.14363/us
mcr.microsoft.com/businesscentral:10.0.19041.329
```

> **IMPORTANT**
> You must specify the correct Windows Version in the generic image name. If your version of Windows doesn't have a corresponding generic Docker image, you might need to use Hyper-V isolation.

After starting the `docker run` command above, you will see log entries similar to the following:

```
Initializing...
Starting Container
Hostname is b8c6941bb168
...
Container IP Address: 172.21.4.208
Container Hostname  : b8c6941bb168
Container Dns Name  : b8c6941bb168
Web Client          : https://b8c6941bb168/BC/
Admin Username      : admin
Admin Password      : Zupa5925
Dev. Server         : https://b8c6941bb168
Dev. ServerInstance : BC

Files:
http://b8c6941bb168:8080/ALLanguage.vsix
http://b8c6941bb168:8080/certificate.cer

Initialization took 66 seconds
Ready for connections!
```

At this point, you can open your browser and type in the Web client URL from the log. You will be prompted to log in with the Admin Username/Password that is shown.

> **NOTE**
> The container image uses a so called self-signed certificate for HTTPS communication. Because of that, your browser might warn you that the page you are requesting is unsafe. In those specific circumstances, and only for test and development environments, it is safe to ignore this warning. If you want to resolve this warning, you can install the certificate on your PC. For more information, see the link under **Files** in the log entries.

Using the BCContainerHelper PowerShell module

To support the use of containers, optional PowerShell scripts are available, which support setup of development environments. Use the `BCContainerHelper` to work with containers. On a Windows 10, Windows Server 2016 or Windows server 2019 machine, start Powershell as an Administrator and type:

```
install-module BCContainerHelper -force
```

To see which functions are available in the BCContainerHelper module use the following command:

```
Write-BCContainerHelperWelcomeText
```

To get quickly get started, run the following command from the BCContainerHelper module:

```
$artifactUrl = Get-BcArtifactUrl -type sandbox -country us -select Latest
New-BCContainer -accept_eula -containerName mysandbox -artifactUrl $artifactUrl
```

The `BCContainerHelper` will create a folder on the C:\ drive called *bcartifacts.cache* for caching artifacts. It will also create a folder under C:\ProgramData called BCContainerHelper and will place all working files underneath that folder. The C:\ProgramData\BCContainerHelper folder will be shared to the container for transfer of files etc. If you do not specify a username and a password, it will ask for your password and use the current Windows username. If you specify your windows password, the container setup will use Windows Authentication integrated with the host. The `BCContainerHelper` will also create shortcuts on the desktop for the Dynamics 365 Business Central Web client, a container prompt, and a container PowerShell prompt.

The `BCContainerHelper` module also allows you to add the `-includeCSide` switch (For Business Central versions 14 or earlier) in order to add the Dynamics 365 Business Central Windows client and C/SIDE to the desktop and export all objects to a folder underneath C:\ProgramData\BCContainerHelper\Extensions for the object handling functions from the module to work.

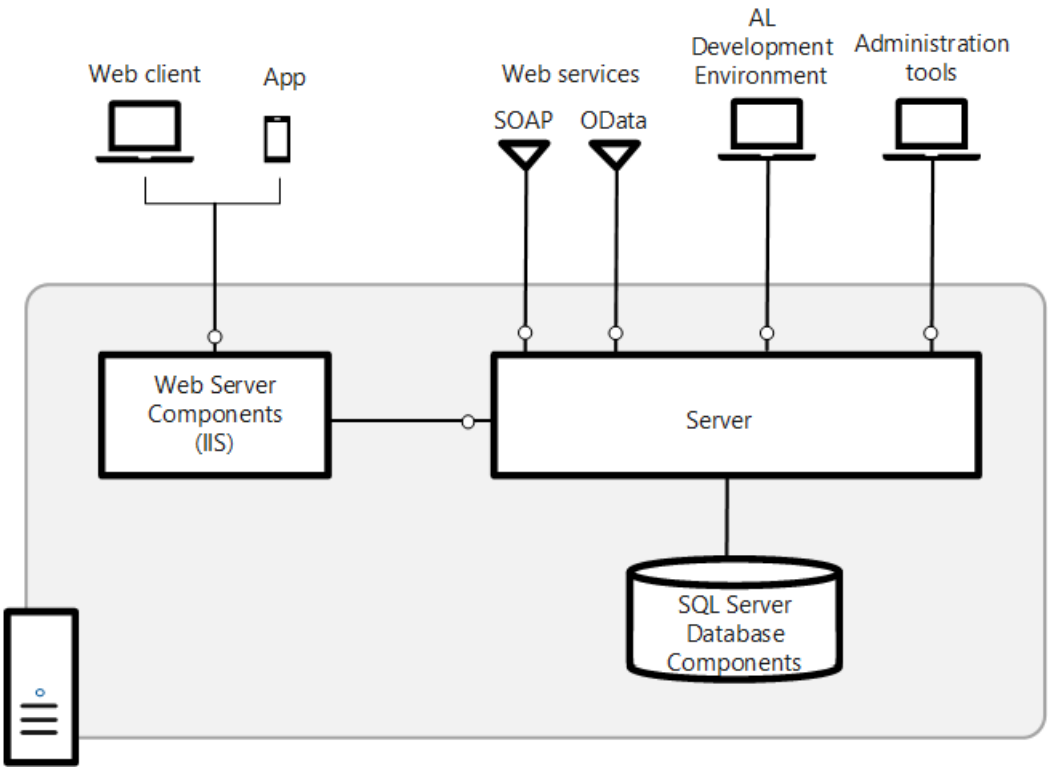
Business Central Component and System Topology

2/17/2021 • 3 minutes to read • Edit Online

The Business Central deployment includes three core components for serving the application to users. It also includes various tools and components for managing, developing, extending, and testing the application.

Multi-Tier System Topology

To understand the components is useful to first look at the base topology of a Business Central deployment, as illustrated in the following diagram:



Components

Main components

Every deployment must include the core components: Web server, Server, and SQL Database.

COMPONENT	DESCRIPTION	MORE INFORMATION
SQL Database	An SQL Server or Azure SQL Database database that contains application object definitions and business data. In a multitenant deployment, the application and business data can be separated into different databases: the application database and the tenant, which is the database that contains the business data. In this case, there can be one or more tenants for a single application database.	Creating Databases Deploy a Business Central Database to Azure SQL Database

COMPONENT	DESCRIPTION	MORE INFORMATION
Server	Business Central Server is a .NET-based Microsoft service application that uses Windows Communication Framework to handle communication between clients and databases. It controls authentication, event logging, scheduled tasks, reporting, and more.	Configuring Business Central Server
Web Server	An Internet Information Server (IIS) web site, provisioned with the Business Central Web Server components, that enables access from the Business Central Web client and mobile apps.	Business Central Web Server
Business Central App	A desktop, phone, and tablet app for Business Central.	Windows Store App Store Google Play
Web services	SOAP and OData Web Services for exposing application functionality to external systems and users. Developers can create and publish functionality as web services. They expose pages, codeunits, or queries, and even enhance a page web service by using an extension codeunit.	Web Services

Development and administration components

COMPONENT	DESCRIPTION	MORE INFORMATION
AL development environment	An AL language extension for Visual Studio Code for developing applications and extensions.	Getting Started with C/SIDE and AL for On-Premises.
Business Central Server Administration tool	A Microsoft Management Console (MMC) for creating and configuring Business Central Server instances.	Business Central Server Administration Tool
Business Central Administration Shell	Windows PowerShell modules for managing the deployment, including tasks such adding and configuring Business Central Server and Web server instances, databases, and users, and administering extension packages.	Windows PowerShell Cmdlets for Business Central

Additional components

COMPONENT	DESCRIPTION	MORE INFORMATION
Demo Database	A database that contains application objects and sample business data for demonstration purposes.	

COMPONENT	DESCRIPTION	MORE INFORMATION
Dynamics NAV Development Environment	The C/SIDE client that was available in Dynamics NAV for developing applications using C/AL. In Business Central, this component is only required for doing upgrades but you can still use it to develop applications.	**DISCONTINUED AFTER:** Business Central Spring 2019 Development in C/AL in the Dynamics NAV Developer and IT Pro Help.
Dynamics NAV Development Shell	Windows PowerShell modules for merging and modifying application object files and creating extension packages. Installed with the Dynamics NAV Development Environment.	**DISCONTINUED AFTER:** Business Central Spring 2019 Windows PowerShell Cmdlets for Business Central
Dynamics NAV Client connected to Business Central	Windows Desktop application for accessing Business Central.	**DISCONTINUED AFTER:** Business Central Spring 2019
Microsoft Outlook Integration	A Business Central Server component for integrating with Microsoft Outlook.	**DISCONTINUED AFTER:** Business Central Spring 2019
Microsoft Outlook Add-in	A component to synchronize data, such as to-dos, contacts, and tasks, between Business Central and Outlook. The Outlook Add-In uses Business Central web services.	Setting Up the Office Add-ins for Outlook Integration
Microsoft Excel Add-in	A component that enables users to export data from Business Central to Excel.	**DISCONTINUED AFTER:** Business Central Spring 2019
Excel Add-in	A component that enables users to export data from Business Central to Excel.	Setting up the Excel Add-In
Page Testability	A Business Central Server component for testing pages.	
Automated Data Capture System	A system that tracks the movement of items in a warehouse.	Use Automated Data Capture Systems (ADCS **DISCONTINUED AFTER:** Business Central 2019 Release Wave 1. The VT100 Plug-in is no longer included on the product installation media.
ClickOnce Installer Tools	Tools for implementing ClickOnce installation for the Dynamics NAV Client connected to Business Central.	**DISCONTINUED AFTER:** Business Central Spring 2019 Deploying Microsoft Dynamics NAV Windows client Using ClickOnce in the Dynamics NAV Developer and IT Pro Help.

COMPONENT	DESCRIPTION	MORE INFORMATION
NAS Service	A server component that executes business logic without a user interface or user interaction. NAS services in Business Central Server support applications such as Microsoft Outlook Integration and the Job Queue.	Instead of using NAS services, we recommend that you use the Task Scheduler (see Task Scheduler. If you decide to use NAS, and want to read more about its configuration, see Configuring NAS Services in the Dev and IT Pro Help for Microsoft Dynamics NAV 2018.

Multitenant Deployment Architecture

Planning Your Dynamics 365 Business Central Deployment

2/17/2021 • 2 minutes to read • Edit Online

This article outlines some of the things you should consider and decide on before you install Business Central.

Most of the topics discussed in this article can be changed at any time after the initial installation.

Network Topology

A Business Central deployment consists of various components that support the production, development, and testing. These components can be installed on various computers. The deployment process varies depending on the topology that you implement.

For more information, see Deployment Topologies.

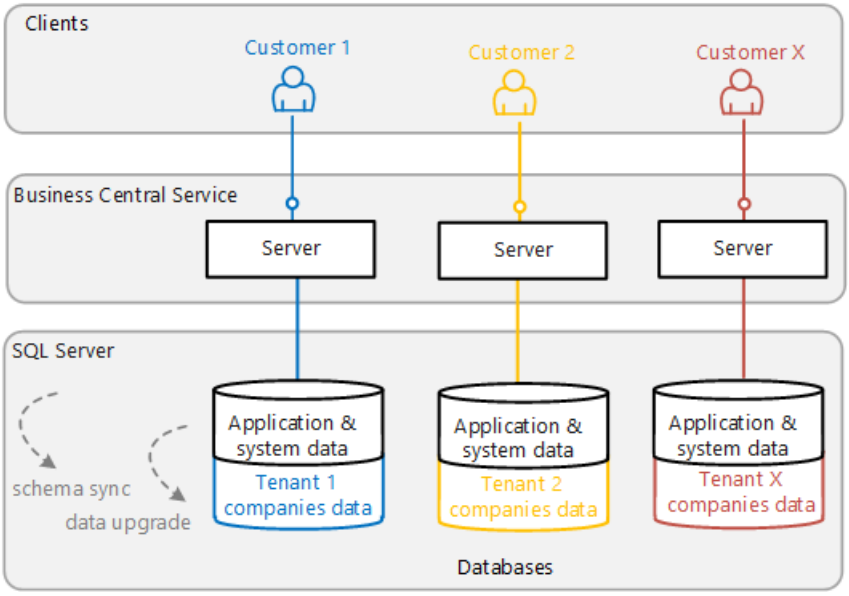
Single-tenancy and Multitenancy

A Business Central solution consists of an application (the code) and business data (the customer's data). This information is stored in a database and accessed through a Business Central Server instance. There are two different two deployment architectures to choose from: single-tenant and multitenant.

> **NOTE**
> For this discussion, a *customer* refers to a business or a group of legal entities whose data can be stored in one database, isolated from other customers. In Business Central, a customer can consist of one or more companies.

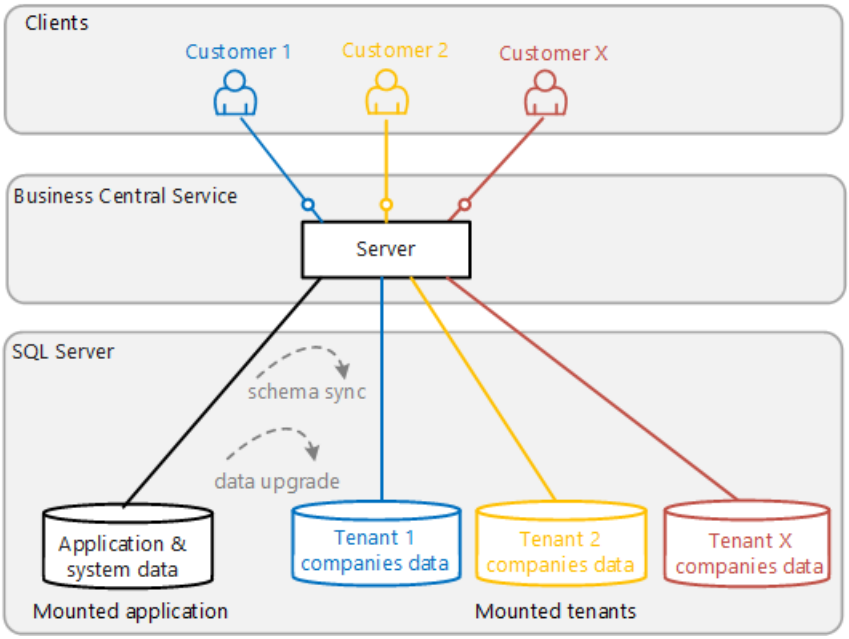
Single-tenant architecture

Business Central is installed as a single-tenant deployment by default. In a single-tenant deployment, the application and the business data are stored in the same database. Each customer solution has its own Business Central Server and database.



Multinenant architecture

In a multitenant deployment, the application and business data are stored in separate databases. There's a single Business Central Server and application database for multiple customers. But each individual customer has their own database for storing business data, which is referred to as a *tenant*.



Multitenancy centralizes the maintenance of the application, and at the same, time isolates each tenant. This architecture makes upgrading easier compared with a single-tenant deployment. For more information, see Multitenant Deployment Architecture.

User Authentication

Business Central supports several credential mechanisms for authorizing users trying to access data. By default, Windows authentication is used.

For more information, see Authentication and Credential Types.

Business Central Server Service Account

The central component of a Business Central deployment is the Business Central Server, which handles all communication between the client and the databases. The Business Central Server requires a log on account, referred to as the service account. By default, the Network Service Account is used. The Network Service Account is acceptable in a test environment, but we recommend that you use a domain account in your production environment.

For more information, see Provisioning the Business Central Server Service Account.

Enhancing Connection Security

Business Central offers features that help secure connections over a wide area network (WAN), such as connections from the Business Central Web Server, Dynamics NAV Client connected to Business Central, and web services to the Business Central Server. The implementation of these security features requires that you obtain a certificate from a certification authority or trusted provider.

For more information, see:

Using Security Certificates with Business Central On-Premises

Configuring SSL to Secure the Business Central Web Client Connection

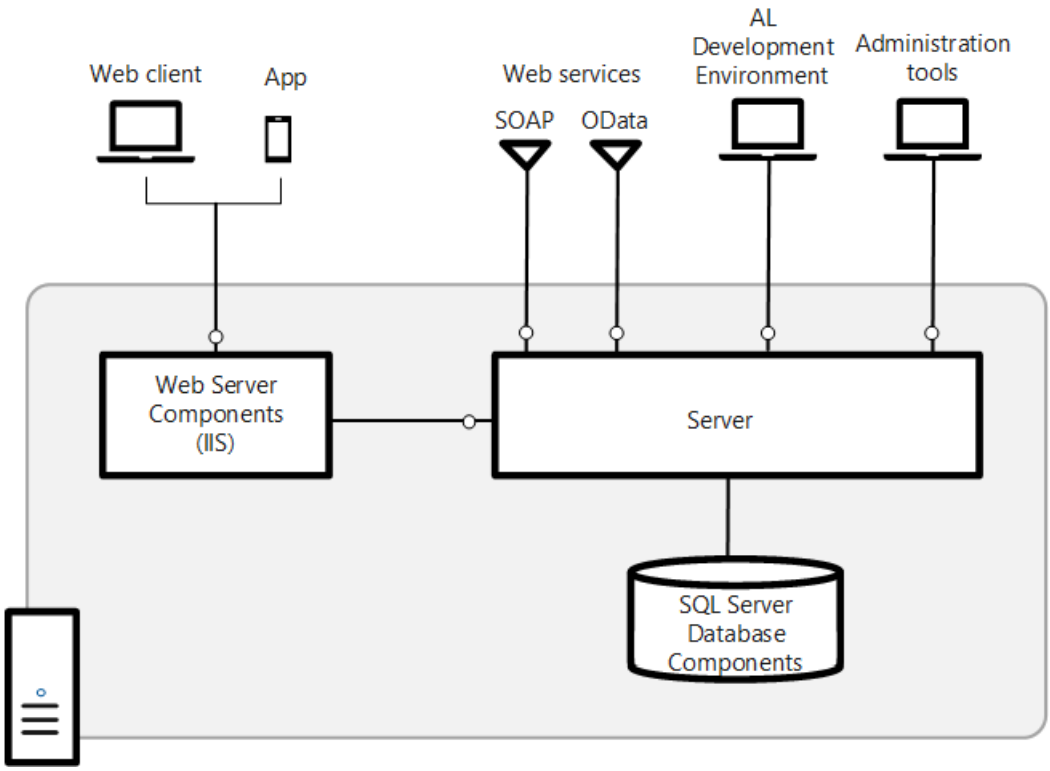
Deployment Topologies

2/17/2021 • 2 minutes to read • Edit Online

A Business Central deployment consists of various components that support the production, development, and testing. These components can be installed on various computers, in different combinations. The deployment process varies depending on the topology that you implement. This article provides an overview of the supported topologies.



Deployment Scenarios

The following table lists some of the most typical deployment topologies for the Business Central, with links to detailed instructions. However, components can be installed on one, two, or three machines in any combination. So your scenario might vary.

TOPOLOGY	DESCRIPTION	MORE INFORMATION
Demonstration	Installs an end-to-end environment, complete with the base application and demonstration data for a single company, on a single computer. The installation enables access to Business Central from the Web client and App, and development. The deployment requires minimal hardware resources, preparation, and configuration.	Deploying a Demonstration Environment

TOPOLOGY	DESCRIPTION	MORE INFORMATION
Single-computer	Installs the Business Central Web Server components, Business Central Server, and the SQL Server database components on the same computer.	Deploying in a Single Computer Environment
Two-computer	Installs the Business Central Web Server components on one computer and the Business Central Server and the SQL Server database components on another computer.	Deploying in a Two Computer Environment
Three-computer	Installs the Business Central Web Server components, Business Central Server, and the SQL Server database components on separate computers.	Deploying in a Three Computer Environment

Install Business Central Using Setup
Business Central Web Server Overview

Deploying a Business Central Demonstration Environment

2/17/2021 • 2 minutes to read • Edit Online

This deployment scenario installs the major Business Central components on a single computer, complete with a base application and database with demonstration data. After the installation, you will have an end-to-end environment, where you can access Business Central data from the Web client. The installation requires minimal hardware resources, preparation, and configuration.

Installed Components and Configuration

Components

This scenario installs the following components:

- Business Central Web Server components
- Internet Information Services

  If IIS is already installed, then the setup will enable any required features that are not currently enabled.
- Business Central Server
- SQL Server Database Components, including CRONUS International Ltd. demonstration database and demo license.

  For information about what you can do with this license, see Demonstration License for Business Central On-Premises.
- Business Central Server Administration tool
- Al Development Environment

Configuration

This scenario uses the default setting of Business Central Setup, which includes the following:

- Business Central Web Server components
  - Port: 8080 (inbound rule automatically added to Windows Firewall)
  - Protocol: HTTP
- Windows authentication for authenticating users.
- Business Central Server configuration:
  - Service instance: BC160
  - Client service port: 7046
  - SOAP web services port: 7047
  - OData web services port: 7048
- Business Central database components configuration:
  - Service instance: BCDEMO

    - Database: Demo Database BC (15-0)
- NETWORK SERVICE account is used as the service account for Business Central Server and database.

Prepare for the Business Central Web client installation

1. Get access to the Business Central installation media. For example, this could be a DVD or network drive that contains the Business Central installation files.
2. Make sure that the computer meets the hardware and software requirements.

   For more information, see System Requirements.

Run Business Central Setup

1. From the Business Central installation media, run the setup.exe file to start the Business Central Setup.
2. Follow the setup until you get to the **Dynamics 365 Business Central** page, then choose **Advanced installation option** > **Install Demo**.

   The installation starts. This can take several minutes.

Open the Business Central Web client

- To open the Business Central Web client from the computer where you installed Business Central, on the **Start** menu, choose **All Programs**, and then choose **Business Central Web Client**.
- To open the Business Central Web client from other devices on the network, open an Internet browser, and type the following URL in the address box:

  ```
  https://ComputerName:8080/BC150
  ```

  Substitute **ComputerName** with the name of the computer where you installed Business Central. If you are working on the computer where you installed Business Central, then you can use **localhost**.

  For example:

  ```
  https://localhost:8080/BC150
  ```

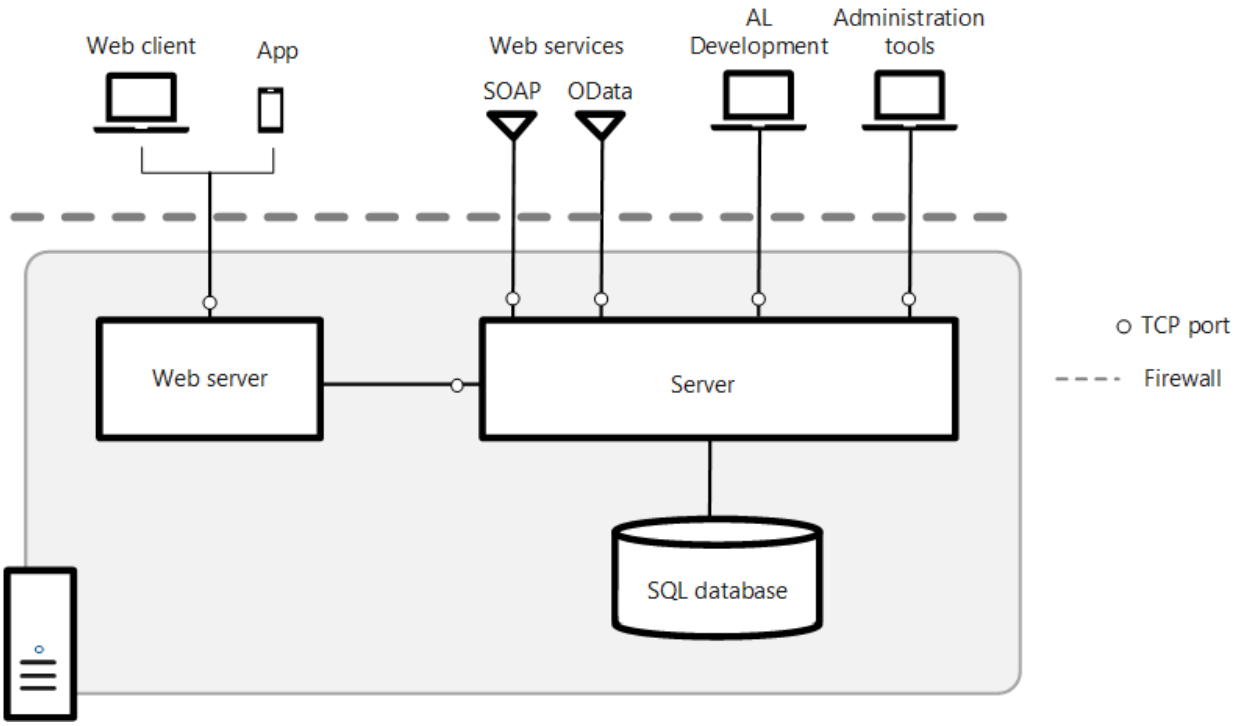
Deploying Business Central in a Single-Computer Topology

2/17/2021 • 3 minutes to read • Edit Online

In this scenario, you install the Business Central Web Server components, Business Central Server, and the SQL Server database components on the same computer.



Pre-Installation Tasks

The following table includes tasks to perform before you install.

TASK	DESCRIPTION	FOR MORE INFORMATION, SEE
Make sure that system requirements are met.	Verify that the computer has the required hardware and software installed.	System Requirements
Install Internet Information Services.	When you install the Business Central Web Server components, Business Central Setup creates a website for the Business Central Web client on IIS. If IIS is already installed, then make sure that the required features are enabled. **Note:** This step is optional because instead of installing and configuring IIS manually, you can use Business Central Setup to install IIS and enable the required features by setting the **Install IIS Prerequisites** option to **Yes**.	Configure Internet Information Services

TASK	DESCRIPTION	FOR MORE INFORMATION, SEE
Determine the TCP ports for the Business Central Web client, client services, and SOAP/OData web services (optional) and allow communication on the port through Windows Firewall.	Business Central Setup creates a website on IIS. During Setup, you will have to choose the port to use for the site. The default port is port 8080. The default client services port is 7046. If you will enable SOAP and OData web services, you will also need to specify a port for each. The default ports are 7047 and 7048. If you choose to do so, Business Central Setup will automatically create an inbound rule in Windows Firewall that allows communication on the ports. Otherwise, you will have to do this manually.	Create an Inbound Port Rule in the Windows documentation.
Set up the service account for Business Central Server and the SQL Server database.	Optional. When you install Business Central Server, you can specify a user account that will be used to log on to the Business Central Server instance and Business Central database. The default service account is Network Service. If you want to use Network Service, then no action is required for this task.	Provisioning a Service Account
Obtain and install an SSL certificate.	Optional. If you want to configure SSL on the connection to Business Central Web client, then complete the following procedures: - Obtain an SSL certificate. - Import the certificate into the local computer store of the computer on which you will install the Business Central Web Server components. - Obtain the certificate's thumbprint. **Note:** You can also configure SSL after you have installed the Business Central Web client. For more information, see Post-installation Tasks.	Configure SSL to Secure the Web Client Connection

Installation Tasks

The following table includes tasks for installing the Business Central components.

TASK	DESCRIPTION	FOR MORE INFORMATION, SEE

TASK	DESCRIPTION	FOR MORE INFORMATION, SEE
Install Business Central Web Server components, Business Central Server, and SQL Server database components.	Run the Business Central Setup setup.exe file, choose the **Advanced installation options** > **Choose an installation option** > **Custom**, and then choose the **Server**, **SQL Server Database Components**, **Server**, and **Web Server Components** options.	Install Business Central Using Setup

Post-installation Tasks

The following table includes tasks that configure the Business Central Web Server components after installation. These tasks are optional depending on your organizational and network requirements.

TASK	DESCRIPTION	FOR MORE INFORMATION, SEE
Change the user authentication method.	The Business Central supports the following authentication methods: Windows, UserName, NavUserPassword, and AccessControlService. By default, Windows authentication is used.	Authentication and User Credential Type
Secure the connection to the Business Central Web client with SSL.	You can help secure Business Central data that is transmitted over the Internet by enabling Secure Sockets Layer (SSL) on the connection to the Business Central Web client.	Configure SSL to Secure the Web Client Connection
Change the configuration of the Business Central Web Server.	There are several parameters in the navsettings.json configuration file for the Business Central Web Server that you can modify to change the behavior of the Business Central Web client. Some of the more common parameters include the Business Central Server instance, company, language, time zone, regional settings, session time out, and online Help URL.	Configuring Business Central Web Server
Set up multiple Business Central Web client applications.	You can set up multiple web server instances for the Business Central Web client on the existing website. The web server instances will use the same address (URL) except with an alias that specifies the specific application.	Creating and Managing Business Central Web Server Instances Using PowerShell
Configure web browsers on devices.	The Business Central Web client supports several different web browsers. To access the Business Central Web client, the web browser must be enabled on a device with cookies and JavaScript.	Web Client Requirements

Installing Business Central Using Setup

2/17/2021 • 6 minutes to read • Edit Online

You use Business Central Setup to install the different components that comprise a Business Central production, demonstration, or development environment. For a list of components, see Components and Topology.

About Setup

Setup is available on the installation media (DVD) in the setup.exe file. When you run the setup.exe file, a wizard leads you through installation process. You can install individual components or select predefined options that install a logical collection of components.

Configuration settings

During Setup, you're presented with various configuration settings. Some settings require that you set them. Other settings have a default value. The default value in many cases is sufficient for the initial installation. After you run Setup, you can change the configuration settings by using other tools such as the Business Central Server Administration tool and Business Central Administration Shell.

Prerequisite Installations by Setup

There are some components that require other software to run. For example, the database requires SQL Server and the Web client requires IIS. Setup will install several of these prerequisites, like installing SQL Server Express and enabling IIS. You can see which prerequisites Setup installs in the System Requirements.

Downloading Business Central for installation

Business Central is available for downloading from Microsoft Support. For each major release, minor updates are published on a regular basis. The downloaded files contain the installation media, which includes the setup.exe file.

> **IMPORTANT**
> We recommend that you install the latest update for the release you want to install. However, if you are installing a version for upgrade, make sure that you choose a target version that is compatible with the version that you will be upgrading. For more information, see Dynamics 365 Business Central Upgrade Compatibility Matrix.

Download the files

1. Go to the update page for the release that you want to install:
   - Business Central 2018
   - Business Central Spring 2019
   - Business Central 2019 Release Wave 2
   - Business Central 2020 Release Wave 1
2. In the **Cumulative Updates** table, select the link in the **Knowledge Base ID** column for the update you want.
3. In the **Resolution** section, select the link under **How to obtain the Microsoft Dynamics 365 Business Central files**.
4. Follow the instructions.

Before you run Setup

1. Plan your deployment and identify the components that you want to install.
2. Verify that the target computer meets the hardware and software requirements for the components that you want to install. For more information, see System Requirements.
3. Make sure that you're an administrator on the computer where you run Setup.
4. Determine the HTTP ports that you'll use for components.

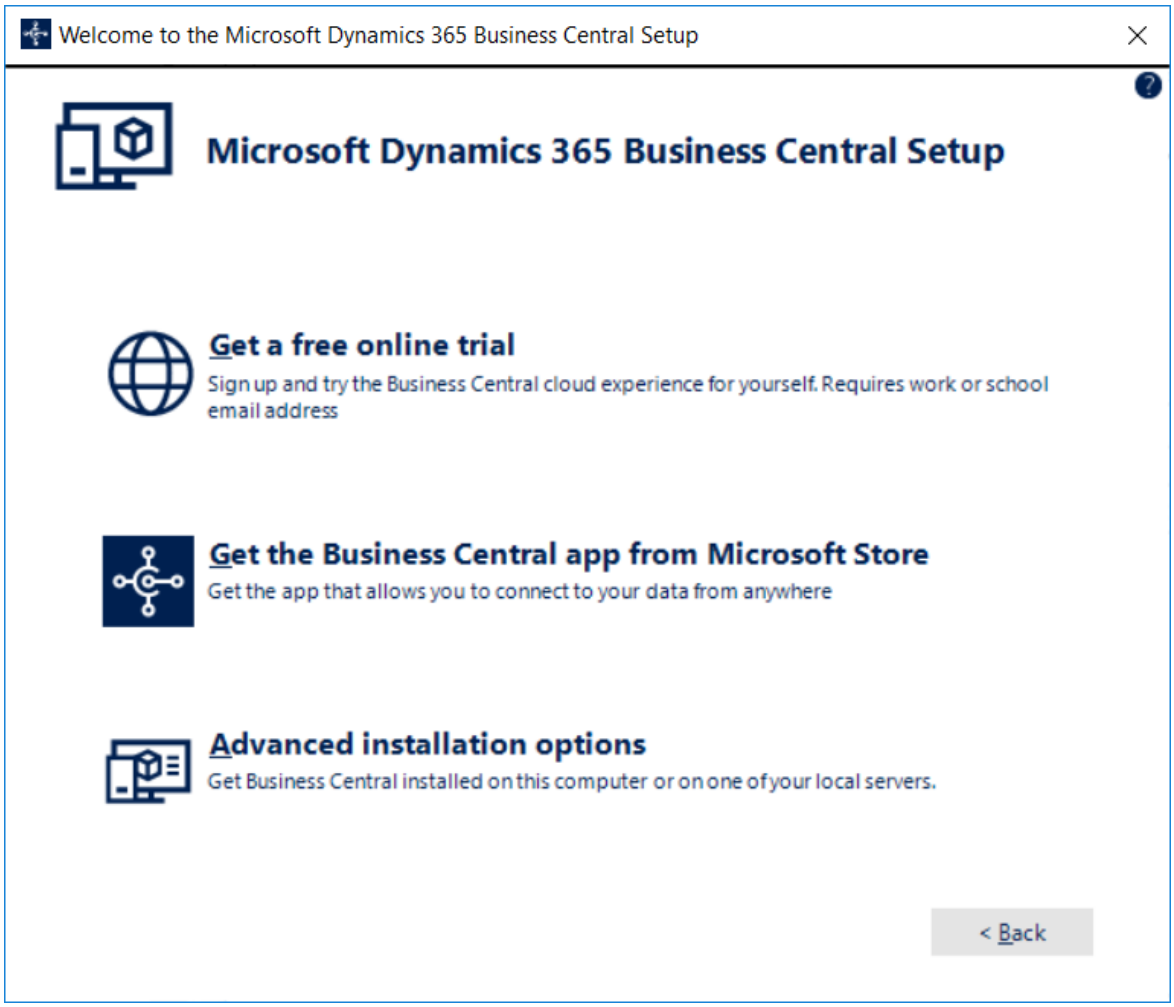
   During setup, you'll have to specify the following HTTP ports:

PORT	DESCRIPTION	DEFAULT
Management services	The listening TCP port for the Business Central Server Administration tool.	7045
Client services	The listening HTTP port for client services.	7046
SOAP services	The listening HTTP port for SOAP web services.	7047
OData service	The listening HTTP port for OData web services.	7048
Developer services	The listening HTTP port for Microsoft Dynamics NAV Developer web services	7049

   Select a port number that isn't being used by another service. Or, if you use a port that's used by another service, stop the other service before you run setup. For example, if you have an older version of Dynamics NAV Server or Business Central Server installed, then configure the new server instance to use other ports than the old server instance, or stop the old server instance before you install the new one.

Run Setup

1. In the installation media (DVD) folder, double-click the setup.exe.
2. Follow Setup until you get to the **Dynamics 365 Business Central** page.



- Choose **Get a free online trial to sign up** if you interested in hearing about and trying the cloud experience.
- Choose **Get the Business Central app from the Microsoft Store** to download a companion app that mimics that Web client but has the same look-and-feel as the mobile apps. For more information, see Installing the Microsoft Dynamics 365 Business Central App.
- Choose **Advance installation options** to install a demonstration environment or individual components. Then, follow the on-screen instructions to complete the installation.

Cancel Setup

Setup doesn't provide a **Cancel** button on all pages. But, you can cancel the installation from any page by choosing the **Close** button. All Business Central components are removed from the computer. The only software that Setup can't remove are:

- Database files, such as the Demo database.
- Prerequisites for Business Central components that Setup can install, such as the .NET Framework.

Run Setup from a command prompt

You can run Business Central Setup from a command prompt. Before installation, run it from the installation media. After the initial installation, you can run it from the location where it's automatically stored on your computer. The default location is:

```
C:\Program Files (x86)\Common Files\Microsoft Dynamics 365 Business Central\<Version number>\Setup
```

You can use the following options with Setup.exe.

SETUP OPTION	DESCRIPTION
/config <Setup config file>	Specifies path and file name information for a Setup configuration file to load. This option is the only required option.
/help	Displays Help about Setup.exe options.
/log <log path>	Specifies path and file name information for a Setup log file to be created by Setup. The file must not exist before you run Setup.
/quiet	Specifies that Setup doesn't display anything on the screen. All configuration information is taken from the specified configuration file.
/repair	Repairs the current installation of Business Central.
/uninstall	Removes the current installation Business Central.

Save, Edit, and Load a Setup Configuration File

During Setup, you can save the configuration settings to a file before you finish. Then later, you can load the configuration file. Using a configuration file makes it faster to replicate the same configuration for another deployment.

Save to a Setup configuration file

1. Choose **Save** on the **Specify parameters** page in Setup. This page is available when you run Setup unless you select **Install Demo**, which skips all other Setup pages.
2. Type a file name for the configuration file. An .xml extension is added automatically.
3. Choose **Save**.

   You now return to the **Specify parameters** page, where you can continue with installing software. You can also close Setup if you only have to create a Setup configuration file.

Edit a Setup configuration file

You edit the file using an XML editor or text editor. Setup configuration files contain two types of settings.

SETTING TYPE	PURPOSE
Component	For each component, there are three separate values, all displayed on a single line: - **ShowOptionNode** Specifies whether the component should be displayed in Setup. For silent installs, this parameter isn't relevant. - **State** There are two possible values: **Local**, indicates that the component is included in the install. **Absent** indicates that the component isn't included. - **Id** Identifies the component You can change value for **State** or **ShowOptionNode**, but not for **Id**. Also, you can't add or remove a component.

SETTING TYPE	PURPOSE
Parameter	These settings contain configuration information for components. As with Components, you can modify a parameter's **Value**, but not its **Id**.

Load a Setup configuration file

The option to load a Setup configuration file is on the **Choose an installation option** page in Setup.

> **NOTE**
>
> If you are using a Setup configuration file that was created from an earlier version of Business Central or Dynamics NAV, be aware that there might be some elements that are no longer supported because the feature has been deprecated. For example, the elements that have the following IDs are no longer supported as og 2019 release wave 2: "RoleTailoredClient", "ExcelAddin, "ClassicClient", "ClickOnceInstallerTools", "STOutlookIntegration", "PublicWinBaseUrl", and "ACSUri".

1. On the **Choose an installation option** page, choose **Load Configuration**.

   This option is located under **Custom Components**.

   > **IMPORTANT**
   >
   > A Setup configuration file contains information about which components to install and which settings to apply to each component. Therefore, you should not customize the list of components or configure components in Setup before you load a Setup configuration file because loading the configuration overwrites all prior customization and configuration.

2. In the **Open** dialog box, select or browse to the Setup configuration file that you want to open. Then, double-click the file.

   Setup now shows the **Customize the installation** page. It's modified according to the component selection in the configuration file.

3. Modify the list of components to install or choose **Next** to continue to the **Specify parameters** page.

4. Configure these settings or choose **Apply** to accept these values and continue.

Provisioning the Business Central Server Service Account

2/17/2021 • 9 minutes to read • Edit Online

The Business Central Server account is used by Business Central clients to log on to the Business Central Server instance. The Business Central Server then uses the service account to log on to the Business Central database. When you install Business Central Server, you identify an Active Directory account to provide credentials for the server. By default, Setup runs Business Central Server under the Network Service account, a predefined local account used by the service control manager. This account has minimum privileges on the local computer and acts as the computer on the network.

Domain user account versus Network Service account

We recommend that you create a domain user account for running Business Central Server. The Network Service account is considered less secure because it is a shared account that can be used by other unrelated network services. Any users who have rights to this account have rights to all services that are running on this account. If you create a domain user account to run Business Central Server, you can use the same account to run SQL Server, whether or not SQL Server is on the same computer.

There is no specific action required for provisioning the Network Service account. The only recommendation is to verify that the account has the necessary database privileges in SQL Server as described in the Giving the service account database privileges in SQL Server section.

Provisioning a domain user account

If you are running the Business Central Server under a domain user account, you must:

- Enable the account to log in as a service
- Enable the account to register an SPN on itself
- Add the account to the SMSvcHost.exe.config file
- Give the account necessary database privileges in SQL Server

Prerequisite

Delete the **Dynamics 365 Business Central** folder in the **ProgramData** folder of your system drive, for example, `C:\ProgramData\Microsoft\Microsoft Dynamics 365 Business Central`.

The **ProgramData** is folder is typically hidden, so you might have to change the folder options for your system drive to show hidden files, folders, and drives.

Enabling the account to log in as a service

Depending on various factors, the account may already have this ability to log in as a service. For example, if you have already installed SQL Server and configured it to run under the same account, SQL Server will have modified the account to log in as a service.

When this permission is lacking, Business Central Server instances may not be able to start.

For instructions for enabling an account to log in as a service, see Manage User Accounts in Windows Server.

Enabling the account to register an SPN on itself

To enable secure mutual authentication between clients and Business Central Server, you must configure the Business Central Server account to self-register Service Principal Names (SPNs). Mutual authentication is recommended in a production environment but may not be necessary in a testing or staging environment. This is done by modifying the account in Active Directory.

For more information, see Service Principal Names in the Active Directory documentation.

Add the account to the SMSvcHost.exe.config file

Business Central uses Net.TCP Port Sharing Service, which is managed by SMSvcHost.exe. The SMSvcHost.exe.config contains information about the identities (or accounts) that can use the service. These accounts are specified as security identifiers (SIDs) in the section of the SMSvcHost.exe.config file. By default, permission is implicitly granted to system accounts, such as NetworkService. For other accounts, you must explicitly add the SID for the account to the SMSvcHost.exe.config file as follows:

1. Get the SID of the user account.

   The SID is an alphanumeric character string, such as S-1-5-20 or S-1-5-32-544. There are different ways to get the SID, such using Windows Management Instrumentation Control Command-line (WMIC) or the computer's registry.

   - To use WMIC, open a command prompt, and run the following command:

     ```
     wmic useraccount get name,sid
     ```

     This will display a list of user accounts and their SIDs.

   - To use the registry, run regedit, and then go to the *HKEY_LOCAL_MACHINE\SOFTWARE\Microsoft\Windows NT\CurrentVersion\ProfileList* folder. This folder list the SIDs for each user account. To find the SID that corresponds to the user account that you want, look at the *ProfileImagePath* key data.

2. Using a text editor, open the SMSvcHost.exe.config file.

   You will find the SMSvcHost.exe.config file in the installation folder for the latest :NET Framework version on the Business Central Server computer; for example, `C:\Windows\Microsoft.NET\Framework64\v4.0.30319`.

3. Add the SID to the element as follows, and then save the file:

   ```
   <system.serviceModel.activation>
       <net.tcp listenBacklog="10" maxPendingConnections="100" maxPendingAccepts="2"
   receiveTimeout="00:00:10" teredoEnabled="false">
           <allowAccounts>
               <!-- Your Business Central Server account -->
               <add securityIdentifier="N-N-N-N"/>
           </allowAccounts>
       </net.tcp>
   ```

For more information about SMSvcHost.exe and the SMSvcHost.exe.config file, see Configuring the Net.TCP Port Sharing Service.

There is not action required for provisioning the Network Service account. The only recommendation is to verify that the account has the necessary database privileges in SQL Server as described in the next section.

Giving the service account database privileges in SQL Server

The Business Central Server service account must have specific roles and permissions in SQL Server to access a Business Central database. The roles and permissions are applied on the server-level and database-level, as

outlined in the following table and explained in detail in the sections that follow:

LEVEL	ROLES AND PERMISSIONS
Server-level	Login: **dbcreator** role On master database: **Select** permission on the database **Select** permission on the dbo.ndosrvproperty table
Database-level	**db_datareader**, **db_datawriter**, and **db_ddladmin** roles **View change tracking** permission on the database schema

When you install the Business Central database by using Business Central Setup or the New-NAVDatabase cmdlet, you can specify the Business Central Server account. In these cases, the server account that you specify will be given privileges in SQL Server. However, we recommend that you use the guidelines in this section to ensure that the service account has the minimum required privileges.

To verify server-level and database-level privileges on SQL Server after you create your Business Central database, use SQL Server Management Studio and, if necessary, modify privileges. If you do not already have it, you can download and install SQL Server Management Studio from here.

Assign privileges on the server-level

On the server-level, the service account must be set up with a login that has the following roles and permissions:

- **dbcreator** server role

  This privilege is only required for database creation. Consider removing it from the service account once the system has been set up. Or run the setup operations of the Business Central database with a service account that has this extended privilege.

- On the master database, the service account must have the following permissions:
  - **Select** permission on the database
  - **Select** permission on the **dbo.ndosrvproperty** table of the database

To assign privileges on the server-level, complete the following tasks in SQL Server Management Studio:

1. Start SQL Server Management Studio and connect to the instance where the Business Central database is installed.
2. Create a login for the Business Central Server account:
   a. Navigate the tree view: **Security**, **Logins**.
   b. Right-click **Logins** and select **New Login**.
   c. Choose **Search** and use the **Select User or Group** dialog box to identify the Business Central Server account.
   d. Choose **OK** to exit the New Login dialog box.
3. Grant the login the server-level role **dbcreator**:
   a. Navigate the tree view: **Security**, **Logins**.
   b. Right-click the Business Central Server account, and then choose **Properties**.
   c. Click on **Server Roles**.
   d. Check the **dbcreator** box.

e. Choose **OK**.

4. Add the login as a user on the master database:

   a. Navigate the tree view: **Databases**, **System Databases**, **master**, **Security**, **Users**.
   b. Right-click **Users** and choose **New User**.
   c. Choose the ellipse button at the far right of the second line in the **Database User – New** dialog box.
   d. In the **Select Login** dialog box, enter or browse for the login you created for the Business Central Server account.
   e. Enter a name in the **User name** field (the first line in the **Database User - New** dialog box).
   f. Choose **OK** to exit the **Database User - New** dialog box.

5. Grant **Select** permission to Business Central Server login on the master database.

   a. In the tree view, right-click **master** and choose **Properties**. Then do the following in the **Database Properties – master** dialog box.
   b. Under **Select a Page**, choose **Permissions**.
   c. Under **Name**, choose the login you created for the Business Central Server account name.
   d. Under **Permissions for <username>**, on the **Explicit** tab, scroll down to down to the **Select** line, and select the check box in the **Grant** column.
   e. Choose **OK** to exit the **Database Properties – master** dialog box.

6. Grant **Select** permission to Business Central Server login on the dbo.ndosrvproperty table.

   a. Navigate the tree view: **Databases**, **System Databases**, **master**, **Tables**, **System Tables**.
   b. Right-click the **dbo.ndosrvproperty** table and choose **Properties**.
   c. Under **Select a Page**, choose **Permissions**.
   d. Choose **Search** and use the **Select User or Group** dialog box to identify the login for the Business Central Server account.
   e. Under **Permissions for <username>**, on the **Explicit** tab, scroll down to down to the **Select** line, and select the check box in the **Grant** column.
   f. Choose **OK** to exit the **Table Properties – dbo.ndosrvproperty** dialog box.

Assign privileges on the Business Central database-level

On the Business Central database, the service account must have the following roles and permissions:

- **db_datareader**, **db_datawriter**, and **db_ddladmin** database roles
- **View change tracking** permission on the database schema (dbo)

You can set permissions directly on the database user that you set up for service account. However, we recommend that you create a role that includes the permissions, and then assign the user to the role.

To set up these permissions, complete the following steps:

1. Add the login as a user on the database and assign database roles

   a. Navigate the tree view: **Databases**, **<your Business Central database>**, **Security**, **Users**.
   b. Right-click **Users** and choose **New User**.
   c. In the **Database User – New** dialog box, choose the ellipse button at the far right of the second line.
   d. Choose the login you created for the Business Central Server account name, and then choose **OK**.

2. Create a database role for the runtime permissions on the database:

   a. In the tree view, under the database, navigate to **Security**, **Roles**.

   b. Right-click **Database Roles** and choose **New Database Role**.

   c. Choose the **General** page, and then:

a. Enter a role name, such as **BCServer_runtime**.
b. Under **Schemas owned by the role**, select **db_datareader**, **db_datawriter**, and **db_ddladmin**.
c. Under **Members of this role**, choose **Add**, then browse for and select the server account user.

d. Choose the **Securables** page, and then:

a. Choose **Search**.
b. Choose **All objects of the types...**, and then **OK**.
c. Select **Schemas**, and then **OK**.
d. Under **Securables**, select the **dbo** schema.
e. Under **Permissions for dbo**, select **Grant** for the **View change tracking** permission.
f. Choose **OK** to finish.

Sample SQL queries

Instead of manually completing the previous steps, you can use the following SQL queries, which you can execute separately or combine and run as one.

Server-level query

```
USE [master]
GO

CREATE LOGIN [domain\accountname] FROM WINDOWS
CREATE USER [domain\accountname] FOR LOGIN [domain\accountname]
GRANT SELECT ON [master].[dbo].[$ndo$srvproperty] TO [domain\accountname]
ALTER SERVER ROLE [dbcreator] ADD MEMBER [domain\accountname]
GO
```

Database-level query

```
USE [Business Central Database]
GO

CREATE ROLE bc_server_runtime
ALTER ROLE db_datareader ADD MEMBER bc_server_runtime
ALTER ROLE db_datawriter ADD MEMBER bc_server_runtime
ALTER ROLE db_ddladmin ADD MEMBER bc_server_runtime
GRANT VIEW CHANGE TRACKING on schema::[dbo] TO  bc_server_runtime
GRANT VIEW DATABASE STATE TO bc_server_runtime
GRANT ALTER ON DATABASE::[Business Central Database] TO bc_server_runtime
GO

CREATE USER [domain\accountname] FOR LOGIN [domain\accountname]
GO

ALTER ROLE bc_server_runtime ADD MEMBER [domain\accountname]
GO
```

Configuring Business Central Server

Using Security Certificates with Business Central On-Premises

2/17/2021 • 7 minutes to read • Edit Online

> **NOTE**
> Dynamics NAV Client connected to Business Central is **DISCONTINUED AFTER:** Business Central Spring 2019.

You use certificates to help secure connections over a wide area network (WAN), such as connections from the Business Central Web Server, Dynamics NAV Client connected to Business Central, and web services to the Business Central Server. Implementing security certificates on your deployment environment requires modifications to various components, like the Business Central Server, Business Central Web Server, and clients.

About Security Certificates

A certificate is a file that Business Central Server uses to prove its identity and establish a trusted connection with the client that is trying to connect. Business Central can support the following configurations:

- *Chain trust*, which specifies that each certificate must belong to a hierarchy of certificates that ends in a root authority at the top of the chain.
- *Peer trust*, which specifies that both self-issued certificates and certificates in a trusted chain are accepted.

The implementation in this section describes the chain trust configuration, which is the more secure option.

> **NOTE**
> An instance of Business Central Server that has been configured for secure WAN communication always prompts users for authentication when they start the client, even when the client computer is in the same domain as Business Central Server.

Certificates for Production

In a production environment, you should obtain a certificate from a certification authority or trusted provider. Some large organizations may have their own certification authorities, and other organizations can request a certificate from a third-party organization.

Obtaining Certificates

You implement chain trust by obtaining X.509 service certificates from a trusted provider. These certificates and their root certification authority (CA) certificates must be installed in the certificates store on the computer that is running Business Central Server. The CA certificate must also be installed in the certificate store on computers that are running the Business Central Web Server and Dynamics NAV Client connected to Business Central so that clients can validate the server.

Most enterprises and hosting providers have their own infrastructure for issuing and managing certificates. You can also use these certificate infrastructures. The only requirement is that the service certificates must be set up for key exchange and therefore must contain both private and public keys. Additionally, the service certificates that are installed on Business Central Server instances must have the Service Authentication and Client Authentication certificate purposes enabled.

IMPORTANT

Microsoft recommends against using wildcard SSL certificates in Business Central installations. Wildcard certificates pose security risks because if one server or sub-domain is compromised, all sub-domains may be compromised. Wildcard certificates also introduce a new style of impersonation attack. In this attack, the victim is lured to a fraudulent resource in the certified domain through phishing. Conventional certificates detect this attack, because the user's browser checks that the private key is hosted on a server whose name matches the one displayed in the browser's address window.

Run the Certificates Snap-in for Microsoft Management Console

Some of the following procedures use the Certificates snap-in for Microsoft Management Console (MMC). If you do not already have this snap-in installed, you can add it to the MMC. For information see Add the Certificates Snap-in to an MMC.

Install and Configure the Certificates

You install the security certificates on the computers running Business Central Server, Business Central Web Server, and Dynamics NAV Client connected to Business Central. The root CA certificate and the service certificate are used in the configuration, but client certificates are not.

Install Certificates on components

1. Follow the installation instructions that are available from your certificate provider to install the root CA and service certificates on the following computers:

   - Install the root CA on the computer that is running Business Central Server and all computers that are running Business Central Web Server instances and Dynamics NAV Client connected to Business Central.
   - Install the service certificate on the computer that is running Business Central Server only.

2. Make sure that the **Server Authentication** and **Client Authentication** certificate purposes are enabled for the service certificate.

   A certificate can be enabled for several different purposes. The **Server Authentication** and **Client Authentication** purposes must be enabled. You can enable or disable other purposes to suit your requirements.

   You enable certificate purposes by using the Certificates Snap-in for MMC. For more information, see Modify the Properties of a Certificate.

Grant access to the Business Central Server service account

After you have installed the root CA and the service certificate on the computer running Business Central Server, you must grant access to the service account that is associated with the server so that the service account can access the service certificate's private key.

1. In the left pane of MMC, expand the **Certificates (Local Computer)** node, expand the **Personal** node, and then select the **Certificates** subfolder.
2. In the right pane, right-click the certificate, select **All Tasks**, and then choose **Manage Private Keys**.
3. In the **Permissions** dialog box for the certificate, choose **Add**.
4. In the **Select Users, Computers, Service Accounts, or Groups** dialog box, enter the name of the dedicated domain user account that is associated with Business Central Server, and then choose the **OK** button.
5. In the **Full Control** field, select **Allow**, and then choose the **OK** button.

6. In the right pane, select the certificate.
7. In the **Certificate** dialog box, choose the **Details** tab, and then select the **Thumbprint** field.
8. Copy the value of **Thumbprint** field.

   For example, copy the hexadecimal characters to text editor, such as Notepad. Delete all spaces from the thumbprint string. If the thumbprint is `c0 d0 f2 70 95 b0 3d 43 17 e2 19 84 10 24 32 8c ef 24 87 79`, then change it to `c0d0f27095b03d4317e219841024328cef248779`.

> **TIP**
> It is important that the thumbprint does not contain any invisible extra characters; otherwise you will experience problems when using it later. To avoid this, see Certificate thumbprint displayed in MMC certificate snap-in has extra invisible unicode character.

Configure the Business Central Server instance

The Business Central Server instance configuration includes several settings for certificates and enabling remote logins. You can modify a server instance by using Business Central Server Administration tool or Business Central Administration Shell. For details about how to modify a server instance, see Configuring Business Central Server.

1. Run the Business Central Server Administration tool.
2. Under **General**, change the following settings for the Business Central Server instance.

SETTING	NEW VALUE	DESCRIPTION
Credential Type	`NavUserPassword`, `Username`, or `AccessControlService`	The default value is `Windows`. When you change it to `NavUserPassword`, `Username`, or `AccessControlService`, client users who connect to the server are prompted for user name and password credentials.
Certificate Thumbprint	Value of the **Thumbprint** field in the previous procedure.	Remove any leading or trailing spaces in the thumbprint.

3. If you want to use secure web services, then under **SOAP Services** and **OData Services**, select the **Enable SSL** check box.
4. Save and the new values for the server instance.
5. Restart the Business Central Server instance.

   If there is a problem, see Windows Event Viewer.

Configure the Business Central Web Server and Dynamics NAV Client connected to Business Central

The chain trust configuration allows client users to log on to one or more instances of Business Central Server as long as their login credentials have been associated with user accounts in Business Central. The client validates that the server certificate is signed with the root CA.

After you have installed the root CA on the computer running the Business Central Web Server or Dynamics

NAV Client connected to Business Central, you must modify the client configuration file.

Modify the Business Central Web client configuration file

1. On the computer that is installed the Business Central Web Server, open the navsetting.json configuration file in a text editor, such as Notepad.

2. Change the following settings:

KEY	NEW VALUE	DESCRIPTION
ClientServicesCredentialType	`NavUserPassword`, `Username`, or `AccessControlService`	The default value is `Windows`. When you change it to `NavUserPassword`, `Username`, or `AccessControlService`, client users who connect to the server are prompted for user name and password credentials.
DnsIdentity	The subject name of the service certificate	The default value is <identity>. Replace this with the subject name or common name (CN) of the certificate that is used on the computer that is running Business Central Server.

3. Save the navsettings.json configuration file.

Modify the Dynamics NAV Client connected to Business Central configuration file

1. Open the ClientUserSettings.config configuration file.

   The location of this file is *Users\<username>\AppData\RoamingLocal\Microsoft\Dynamics 365 Business Central*.

   By default, this file is hidden. Therefore, you may have to change your folder options in Windows Explorer to view hidden files.

   > **NOTE**
   > If you want to change default Dynamics NAV Client connected to Business Central settings for all future users, edit the default ClientUserSettings.config file — that is, the one in C:\Program Files (x86)\Microsoft Dynamics 365 Business Central\160. Be sure that you run your text editor with Administrator privileges when you do so.

2. Modify the following settings.

KEY	NEW VALUE	DESCRIPTION
ClientServicesCredentialType	`NavUserPassword`, `Username`, or `AccessControlService`	The default value is `Windows`. When you change it to `NavUserPassword`, `Username`, or `AccessControlService`, client users are prompted for user name and password credentials.

KEY	NEW VALUE	DESCRIPTION
DnsIdentity	The subject name of the service certificate.	The default value is <identity>. Replace this with the subject name or common name (CN) of the certificate that is used on the computer that is running Business Central Server.

3. Save and close the ClientUserSettings.config file.

When starting the Dynamics NAV Client connected to Business Central, users are prompted for a valid user name and password.

Business Central Web Server Overview

2/17/2021 • 4 minutes to read • Edit Online

Giving users access to data from the Business Central Web client, companion app, and Outlook add-in requires a Internet Information Services (IIS) website as part of your deployment. The website, which we refer to as Business Central Web Server instance, hosts the files that provide content and services to client users over the Internet. This article highlights several factors to consider to help you set up Business Central Web Server instances that suit your deployment requirements.

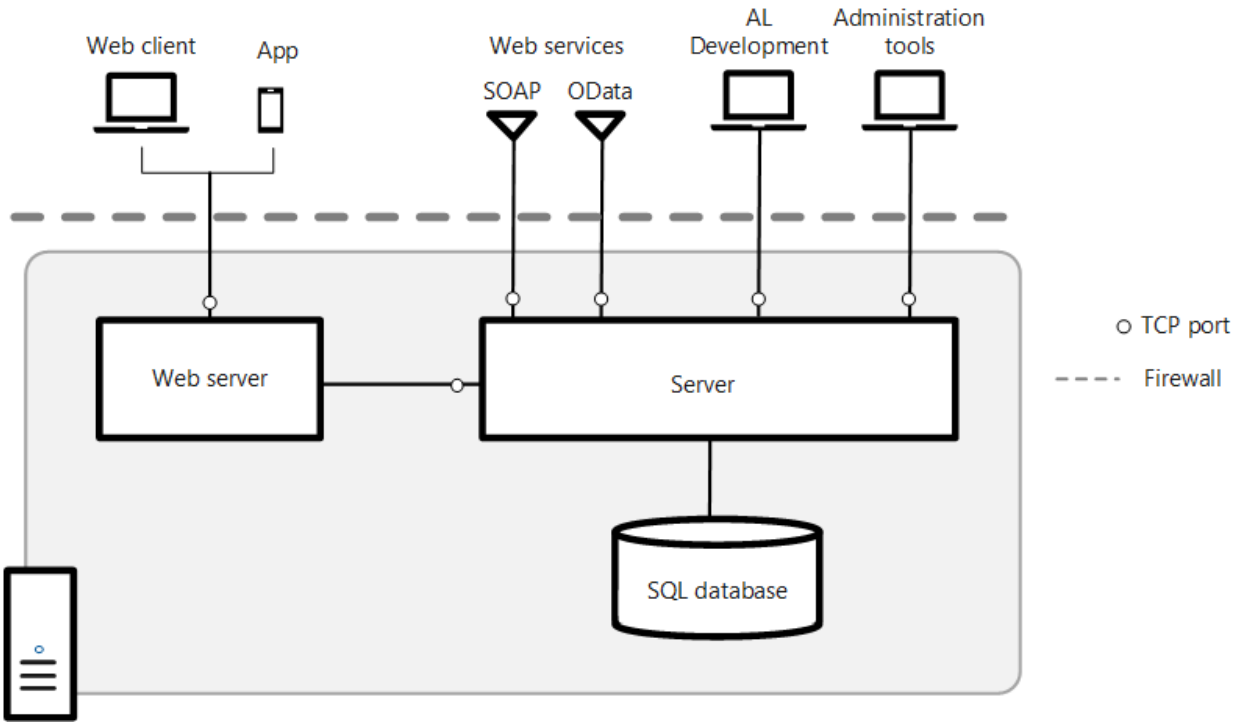
If you just want to get started installing the Business Central Web Server components, see Install Business Central Using Setup.

ASP .NET Core on IIS

Business Central Web Server instances run on ASP.NET Core on IIS, which in part dictates the directory structure of the instances. For more information about ASP .NET Core, see Introduction to ASP.NET Core.

Network Topology

The following illustration shows the component infrastructure that supports Business Central Web Server instances on your network.



Each Business Central Web Server instance must connect to a Business Central Server, which in turn connects to the database that contains the application and business data. Multiple Business Central Web Server instances can connect to the same Business Central Server. You can deploy these components on one computer or on separate computers. For example, you can install the Business Central Web Server instance on one computer and the Business Central Server and SQL Server database on another computer. The topology that you choose depends on the network resources and the infrastructure of the Business Central components. The installation and configuration process is different for each scenario.

For information about the common deployment scenarios, see Deployment Topologies.

Creating a Business Central Web Server instance

There are two ways to create a Business Central Web Server instance. You can use the Business Central Setup Setup or the Business Central Web Server PowerShell cmdlets.

Using Business Central Setup Setup

Setup is the quickest way to get a web server instance up and running, and is typically how you install the first Business Central Web Server instance in your deployment.

- Setup installs the Business Central Web Server components, which does the following:
  - Installs and configure IIS with the required prerequisites, including Microsoft .NET Core - Windows Server Hosting
  - Installs a web server instance on IIS.
  - Installs components and files in a **WebPublish** folder that enables you to add additional web server instances without having to use the Business Central installation media (DVD).
- You can only use Setup to install a single Business Central Web Server instance.
- Setup does not let you choose the site deployment type for the web server instance. By default, it creates a SubSite instance. For more information, see Site Deployment Types.
  For information about how to install the Business Central Web Server components, see Install Business Central Using Setup.

Using Business Central Web Server PowerShell cmdlets

There are several PowerShell cmdlets that enable you to create, configure, and remove Business Central Web Server instances from a command line interface. To create a web server instance, you use the New-NAVWebServerInstance cmdlet, which has the following advantages over Setup:

- You can create multiple web server instances.
- You have more flexibility regarding the site deployment type of the Business Central Web Server instances on IIS. For example, you can create a root-level website instance or a subsite application instance under a container website.

> **IMPORTANT**
> Using New-NAVWebServerInstance cmdlet requires that Microsoft .NET Core Windows Server Hosting is installed and IIS is installed and configured with the prerequisites. So unless you have previously installed the Business Central Web Server components by using Setup, you will have to install and configure the prerequisites manually. For more information about the prerequisites, see Configure Internet Information Services.

For information about how to create a Business Central Web Server instance by using the New-NAVWebServerInstance cmdlet, see Creating and Managing Business Central Web Server Instances Using PowerShell.

Deployment Phases

Typically, you will deploy the Business Central Web client in phases, which can influence the network topology and security settings that you deploy. For example, in the development phase, you develop, test, and fine-tune the application. In this phase, you might consider deploying the Business Central Web client in a single-computer scenario. When you move to the production phase, you deploy the Business Central Web client in the full network infrastructure.

Security

User Authentication

Business Central supports four methods for authenticating users who try to access the Business Central Web client: Windows, UserName, NavUserPassword, and AccessControlService. Windows authentication is configured by default. For more information, see Users and Credential Types and Authentication and User Credential Type.

Service Account for Business Central Server and Business Central Database Access

When you install Business Central Server and Business Central database components, you must identify an Active Directory account to provide credentials for the servers. By default, Setup runs Business Central Server and the Business Central database under the Network Service account, a predefined local account that is used by the service control manager.

> **TIP**
> We recommend that you create and use a domain user account for running Business Central Server and accessing the Business Central database. The Network Service account is considered less secure because it is a shared account that can be used by other unrelated network services.

For more information, see Provisioning a Service Account.

Securing the Connection to Microsoft Dynamics NAV Web Client With SSL

You can help secure Business Central data that is transmitted over the Internet by enabling Secure Sockets Layer (SSL) on the connection to the Business Central Web client. You can configure SSL when you install the Business Central Web Server components or after the installation.

For more information, see Configure SSL to Secure the Web Client Connection.

Configuring Business Central Web Server Instances

2/17/2021 • 11 minutes to read • Edit Online

Accessing Business Central from the Business Central Web client or App requires a Business Central Web Server instance on IIS. You create a Business Central Web Server instance for the Business Central Web Server by using the Business Central Setup to install the Business Central Web Server or by running the New-NAVWebServerInstance cmdlet. When you set up a web server instance, you are configuring the connection from the Business Central Web Server to the Business Central Server instance. The connection settings, along with several other configuration settings, are saved in a configuration file for the web server instance.

About the configuration file

The configuration file for the web server instances is a .json file type called **navsettings.json**. The navsettings.json file is a Java Script Object Notification file type that is similar to files that use the XML file format.

After installation, you can change the configuration by modifying the navsettings.json. There are two ways to modify this file: directly or using PowerShell.

Where to find the navsettings.json file

The navsettings.json file is stored in the physical path of the web server instance, which is by default is *%systemroot%\inetpub\wwwroot\[WebServerInstanceName]*.

[WebServerInstanceName] corresponds to the name (alias) of the web server instance in IIS, for example, *c:\inetpub\wwwroot\BC160*.

Modify the navsettings.json file directly

1. Open the navsettings.json in any text or code editor, such as Notepad or Visual Studio Code.

   Each setting is defined by a key-value pair.

   - In the navsettings.json file, a setting has the format:

     ```
     "keyname": "keyvalue",
     ```

   The `keyname` is the name of the configuration setting and the `keyvalue` is the value.

   For example, the configuration setting that specifies the Windows credential type for authenticating users is:

   ```
   "ClientServicesCredentialType":  "Windows",
   ```

   Include values in double quotes.

2. Find the configuration settings that you want to change, and then change the values.

   See the Settings section for a description of each setting.

3. When you are done making changes, save the file.

4. Restart the Business Central Web Server instance for the changes to take effect.

For example, in IIS Manager, in the **Connections** pane, select website node for Business Central Web Server, and then in the **Actions** pane, choose **Restart**. Or, from your desktop, run `iisreset`.

Modify the navsettings.json file by using the Set-NAVWebServerInstanceConfiguration cmdlet

The PowerShell script module **NAVWebClientManagement.psm1** includes the Set-NAVWebServerInstanceConfiguration cmdlet that enables you to configure a web server instance.

1. Depending on your installation, run the Dynamics NAV Development Shell or Windows PowerShell as an administrator.

   For more information, see Get started with the Business Central Web Server cmdlets.

2. For each setting that you want to change, at the command prompt, run the following command:

   ```
   Set-NAVWebServerInstanceConfiguration -Server [MyComputer] -ServerInstance [ServerInstanceName] -
   WebServerInstance [MyBCWebServerInstance] -KeyName [Setting] -KeyValue [Value]
   ```

   Replace:

   - `[MyComputer]` with the name of the computer that is running the Business Central Server
   - `[ServerInstanceName]` with the name of the server instance, such as **BC160**.
   - `[MyBCWebServerInstance]` with the name of the web server instance for the Business Central Web Server.
   - `[KeyName]` with the name of the setting. Refer to the next section in this article.
   - `[KeyValue]` with the new value of the setting.

Settings in the navsettings.json

The navsettings.json has the following structure, where settings are included under one of two root elements: `NAVWebSettings` and `ApplicationIdSettings`:

```
{
  "NAVWebSettings": {
     "//ServerInstance":  "Name of the Business Central Server instance to connect to (for client) or listen
on (for server).",
     "ServerInstance":  "BC150",
      [...more keys]
 },
  "ApplicationIdSettings": {
      "BlogLink": "https://myBCBlog.com",
      [...more keys]
  }
}
```

`//` indicates a comment that provides help for the setting, and has no effect on the Web Server instance.

The following table describes the settings that are available in the navsettings.json for each root element. If you do not see a setting in the file, this is because some settings are not automatically included as a key in the file. For these settings, you can add the key manually. If you do not add the key, the default value of the setting is used.

> **IMPORTANT**
> If modifying the file directly, place values in double quotes `""`.

`NAVWebSettings` element settings

SETTING/KEYNAME	DESCRIPTION
AllowedFrameAncestors	Specifies the host name of any web sites in which the Business Central Web client or parts of are embedded. By default, the Business Central Web Server will not allow a website to display it inside an iframe unless the website is hosted on the same web server. This value of this setting is a comma-separated list of host names (URIs). Wildcard names are accepted. For example: `https:mysite.sharepoint.com, https:*.myportal.com`
AllowNtlm	Specifies whether NT LAN Manager (NTLM) fallback is permitted for authentication. To require Kerberos authentication, set this value to `false`. Values: `true`, `false` Default value: `true`
AuthenticateServer	Specifies whether to authenticate the server by enabling service identity checks on protocol between the Web server and the Business Central Server instance. Values: `true`, `false` Default value: `true`
ClientServicesCredentialType	Specifies the authorization mechanism that is used to authenticate users who try to connect to the Business Central Web Server. For more information, see Authentication and User Credential Type. The credential type must match the credential type configured for the Business Central Server instance that the Business Central Web Server connects to. For information about how to set up the credential type on Business Central Server, see Configuring Business Central Server. Values: Windows, UserName, NavUserPassword, AccessControlService Default value: Windows

SETTING/KEYNAME	DESCRIPTION
ClientServicesChunkSize	Sets the maximum size, in kilobytes, of a data chunk that is transmitted between Business Central Web Server and Business Central Server. Data that is transmitted between Business Central Web Server and Business Central Server is broken down into smaller units called chunks, and then reassembled when it reaches its destination. Values: From 4 to 80. Default value: 28
ClientServicesCompressionThreshold	Sets the threshold in memory consumption at which Business Central Web Server starts compressing data sets. This limits amount of consumed memory. The value is in kilobytes. Default value: 64
ClientServicesPort	Specifies the TCP port for the Business Central Server. This is part of the Business Central Server's URL. Values: 1-65535 Default value: 7046
ClientServicesProtectionLevel	Specifies the security services used to protect the data stream between the Business Central Web Server and Business Central Server. This value must match the value that is specified in the Business Central Server configuration file. For more information, see Configuring Business Central Server. Values: EncryptAndSign, Sign, None Default value: EncryptAndSign
DefaultRelativeHelpPath	Specifies the default Help article to open if no other context-sensitive link is specified. Default value: none
Designer	Specifies whether the in-client designer is enabled in the Business Central Web client. Set to `true` to enable designer. For more information, see Using Designer.

SETTING/KEYNAME	DESCRIPTION
DnsIdentity	Specifies the subject name or common name of the service certificate for Business Central Server. This parameter is only relevant when the ClientServicesCredentialType is set to UserName, NavUserPassword, or AccessControlService, which requires that security certificates are used on the Business Central Web Server and Business Central Server to protect communication. **Note:** You can find the subject name by opening the certificate in the Certificates snap-in for Microsoft Management Console (MMC) on the computer that is running Business Central Web Server or Business Central Server. For more information, see Authentication and User Credential Type. Value: The subject name of the certificate. Default value: none
GlobalEndPoints	Specifies the comma-separated list of global endpoints that are allowed to call this website. The values must include http scheme and fully qualified domain name (FDQN), such as `https://businesscentral.microsoft.com`. "GlobalEndPoints": "null,ms://businesscentral,ms://dynamicsnav" Default value: none
HelpServer	Specifies the name of the Business Central Help Server if the deployment uses Help Server. If the deployment uses an online library, remove this setting. Default value: none
HelpServerPort	Specifies the TCP port on the specified Business Central Help Server if the deployment uses Help Server. If the deployment uses an online library, remove this setting. Default value: none
LoadScriptsFromCdn	Specifies whether to load scripts from Content Distribution Networks (CDNs). This only applies to scripts that are available from a CDN, like jQuery. If set to `false`, scripts will be loaded from the Web server, which is useful in, for example, an intranet scenario where there is no internet access. Default value: `true` **DISCONTINUED AFTER:** Business Central Spring 2019
ManagementServicesPort	The listening TCP port for the Business Central management endpoint. Valid range: 1-65535 Default value: 7045

SETTING/KEYNAME	DESCRIPTION
OfficeSuiteShellServiceClientTimeout	Defines the time Business Central will wait for the Office Suite Shell Service to respond. **Important:** This setting has been deprecated in Business Central, and it has no effect on the Web Server instance. Default value: 10
PersonalizationEnabled	Specifies whether personalization is enabled in the Business Central Web client. Set to `true` to enable personalization. For more information, see Managing Personalization.
ProductName	Specifies the full name of the application.
ProductNameShort	Specifies the short name of the application.
ProductNameMarketing	Specifies the marketing name of the application.
RequireSsl	Specifies whether SSL (https) is required. If the value is set to `true`, all cookies will be marked with a `\u0027secure\u0027` attribute. If SSl is enabled on the Web server, you should set this to `true`. Values: `true`, `false` Default value: `false`
Server	Specifies the name of the computer that is running the Business Central Server. Default value: localhost
ServerInstance	Specifies the name of the Business Central Server instance that the Business Central Web Server connects to. Default value: BC160
ServicePrincipalNameRequired	If this parameter is set to `true`, then the Business Central Web Server can only connect to a Business Central Server instance that has been associated with a service principal name (SPN). If this parameter is set to `false`, then the Business Central Web Server attempts to connect to the configured Business Central Server service, regardless of whether that service is associated with an SPN. For more information about SPNs, see Configure Delegation. Default: `false`

SETTING/KEYNAME	DESCRIPTION
SessionTimeout	Specifies the maximum time that a connection between the Business Central Web Server and the Business Central Server can remain idle before the session is stopped. In the Business Central Web Server, this setting determines how long an open Business Central page or report can remain inactive before it closes. For example, when the SessionTimeout is set to 20 minutes, if a user does not take any action on a page within 20 minutes, then the page closes and it is replaced with the following message: **The page has expired and the content cannot be displayed.** The time span has the format [dd.]hh:mm:ss[.ff]: - dd is the number of days - hh is the number of hours - mm is the number of minutes - ss is the number of seconds - ff is fractions of a second Default value: 00:20:00
ShowPageSearch	Specifies whether to show the  **Tell me what you want to do** icon in the Business Central header. This feature lets users find Business Central objects, such as pages, reports, and actions. If you do not want to show the **Tell me what you want to do** icon, then set the parameter to `false`. Default value: `true`

SETTING/KEYNAME	DESCRIPTION
UnknownSpnHint	Specifies whether to use a server principal name when establishing the connection between the Business Central Web Server server and Business Central Server. This setting is used to authenticate the Business Central Server, and it prevents the Business Central Web Server server from restarting when it connects to Business Central Server for the first time. You set values that are based on the value of the ServicePrincipalNameRequired key. Value: The value has the following format. (net.tcp://BCServer:Port/ServerInstance/Service)=NoSpn|SPN - BCServer is the name of the computer that is running the Business Central Server. - Port is the port number on which the Business Central Server is running. - ServerInstance is the name of the Business Central Server instance. - NoSpn|SPN specifies whether to use an SPN. If the ServicePrincipalNameRequired key is set to `false`, then set this value to NoSpn. If the ServicePrincipalNameRequired key is set to `true`, then set this value to Spn. Default value: (net.tcp://localhost:7046/BC160/Service)=NoSpn If you set this key to the incorrect value, then during startup, the Business Central Web Server will automatically determine a correct value. This will cause the Business Central Web Server to restart. **Note:** For most installations, you do not have to change this value. Unlike the Dynamics NAV Client connected to Business Central, this setting is not updated automatically. If you want to change the default value, then you must change it manually.
UseAdditionalSearchTerms	Specifies whether **Tell me** uses the additional search terms that are defined on pages and reports. The additional search terms are specified by the AdditionalSearchTerms and AdditionalSearchTermsML properties. If you set this to `false`, the additional search terms are ignored. Default value: true

`ApplicationIdSettings` element settings

SETTING/KEYNAME	DESCRIPTION
BaseHelpUrl	Specifies the link to the online Help library that the deployment uses, such as *https://mysite.com/{0}/mylibrary/*. Default value: none For more information, see Configuring the Help Experience.

SETTING/KEYNAME	DESCRIPTION
BlogLink	Specifies the target of the **blog** link on the **Help & Support** page. Use this link to give users access to your end-user blog. Value: a valid URL Default value: https://go.microsoft.com/fwlink/?linkid=2076643|
ComingSoonLink	Specifies the target of **coming soon** link on the **Help & Support** page. Use this link to give users access to information about your roadmap or any upcoming features and fixes. Value: A valid URL. Default value: https://go.microsoft.com/fwlink/?linkid=2047422
CommunityLink	Specifies the URL to a community or resource for sharing information. Value: a valid URL Default value: https://go.microsoft.com/fwlink/?LinkId=287089|
ContactSalesLink	Specifies the target of the contact sales link on the **Help & Support** page. Use this link to give users access to your sales-focused web page where users can engage with your sales process. **Note:** This setting and link are not used for Business Central on-premises.
SigninHelpLink	Specifies the URL to open if the user selects help on the sign-in page box. Value: a valid URL Default value: none

Configuring Internet Information Services for Business Central

2/17/2021 • 2 minutes to read • Edit Online

This topic describes the configuration of Internet Information Service (IIS) that is required for running Business Central. When you install the Business Central Web Server components, you can use the Business Central Setup to install and configure the IIS features, so you do not have to do this manually.

Required IIS Features

IIS must have the following features enabled:

- HTTP Activation
- NET Extensibility 4.5, .NET Extensibility 4.6, or .NET Extensibility 4.6 (depending on Windows version)
- ASP.NET 4.5, ASP.NET 4.6, or ASP.NET 4.7 (depending on Windows version)
- ISAPI Extensions
- ISAPI Filters
- Request Filtering
- Windows Authentication
- Default Document
- Directory Browsing
- HTTP Errors
- Static Content

Configure Headers in Application Request Routing (ARR) Rules

If you are hosting the Business Central Web Server components on an IIS server farm that is using Application Request Routing (ARR), you must configure headers. Business Central Web Server runs on ASP .NET Core, which requires both an `X-Forwarded-For` header and `X-Forwarded-Proto` header in ARR routing rules. However, by default, ARR only adds the `X-Forwarded-For` header; not the `X-Forwarded-Proto` header. So will have to configure the `X-Forwarded-Proto` header manually.

On the server farm in IIS, add or edit a routing rule to include a server variable for `X-Forwarded-Proto`. For example, using IIS Manager, select **Routing Rules** > **URL Rewrite** > **Edit** > **Server Variables**, and then add a server variable that has the following settings:

NAME	VALUE	REPLACE
`HTTP_X_FORWARED_PROTO`	`http` or `https`	`true`

Business Central Web Server Overview

Configuring SSL to Secure the Business Central Web Client Connection

2/17/2021 • 3 minutes to read • Edit Online

We recommend that you secure Business Central data that is transmitted over the Internet by enabling Secure Sockets Layer (SSL) on the connection to Business Central Web client.

SSL is a web protocol that encrypts data that is transmitted over a network to make the data and the network more secure and reliable. A website that is enabled with SSL uses Hypertext Transfer Protocol Secure (HTTPS) instead of Hypertext Transfer Protocol (HTTP) as a communication protocol. Enabling SSL on a website requires that an SSL certificate is installed on the web server. An SSL certificate is a small file that the web server uses to prove its identity and establish a trusted connection with the browser that is trying to access Business Central Web client. When a browser connects to the Business Central Web client, the web server replies by sending its certificate to the browser. This certificate contains the web server's public encryption key and the name of the authority that granted the certificate. The browser verifies the certificate using the authority's public key.

To configure SSL, you must follow the steps in this article.

> **NOTE**
> You can configure SSL when you install the Business Central Web Server components using Business Central Setup .

Obtaining and Installing an SSL Certificate

In a production environment, you should obtain an SSL certificate from a certification authority. Some large organizations may have their own certification authorities, and other organizations can request a certificate from a third-party organization. In a test environment or development environment, you can create your own self-signed certificate.

Adding an HTTPS Binding That Uses the Certificate on the Dynamics 365 Business Central Website

After you get the certificate, you add a binding to the https protocol on the website. When you add the binding, you associate it with the certificate.

Add an https binding with the certificate to the website

1. Open Internet Information Services (IIS) Manager.
2. In the **Connections** pane, expand the **Sites** node, and then choose the Business Central Web client site to which you want to add the binding.

   By default, the site has the name **Dynamics 365 Business Central Web Client**.
3. In the **Actions** pane, choose **Bindings**.
4. In the **Site Bindings** dialog box, choose **Add**.
5. In the **Add Site Binding** dialog box, set the **Type** field to **https**.

   You can use the default port 443 or change it to another port. If you change it to another port, you will have to provide the port number in the URL when you try to open the client.

6. Set the **SSL certificate** field to the certificate that you obtained or created for the site.
7. Choose the **OK** button, and then choose the **Close** button.

Redirecting HTTP to HTTPS (Optional)

To ensure that users always access the site that is secured with SSL, you can automatically redirect HTTP requests to HTTPS. This means that users do not have to explicitly include https in the URL in the browser. For example, the nonsecure URL of the Business Central Web client could be `https://MyWebclient:8080/BC150` and the secure URL could be `https://MyWebclient:443/BC150`. If a user types `https://MyWebclient:8080/BC150`, the browser automatically redirects to `https://MyWebclient:443/BC150`.

There are different ways to redirect HTTP requests to HTTPS. The following procedure describes how to redirect HTTP requests to HTTPS by installing the Microsoft Application Request Routing for IIS 8 and modifying the configuration file for the Business Central Web Server instance.

Redirect HTTP to HTTPS

1. Download and install Microsoft Application Request Routing for IIS. For example, you can download from Microsoft Application Request Routing.
2. On the computer that is running Business Central Web Server components, open the web.config file for the Business Central Web Server instance. Use a text editor, such as Notepad.

   The web.config file is located in the physical path of the web application on IIS. By default, the path is %systemroot%\inetpub\wwwroot\[VirtualDirectoryName]. For example, the folder for the default application is %systemroot%\inetpub\wwwroot\BC160.
3. In the `<system.webServer>` element, add the following elements.

```
<rewrite>
  <rules>
    <rule name="Redirect to HTTPS">
      <match url="(.*)" />
      <conditions>
        <add input="{HTTPS}" pattern="off" ignoreCase="true" />
      </conditions>
      <action type="Redirect" url="https://{SERVER_NAME}/{R:1}" redirectType="SeeOther" />
    </rule>
  </rules>
</rewrite>
```

4. Save the navsettings.json file.

Business Central Web Server Overview

Setting Up Multiple Business Central Web Server Instances Using PowerShell

2/17/2021 • 5 minutes to read • Edit Online

Although you can use the Business Central Setup to install the Business Central Web Server components and create a single web server instance in IIS for client connection, there may be scenarios when you want to set up multiple instances. For example, you could set up a separate Business Central Web Server instance for the different companies of a business. For this scenario, you can use the Business Central Web Server PowerShell cmdlets, which are outlined in the following table.

CMDLET	DESCRIPTION
New-NAVWebServerInstance	Creates a new Business Central Web Server instance and binds this instance to a Business Central Server instance.
Set-NAVWebServerInstanceConfiguration	Specifies configuration values for a named Business Central Web Server instance.
Get-NAVWebServerInstance	Gets the information about the Business Central Web Server instances that are registered on a computer.
Remove-NAVWebServerInstance	Removes an existing Business Central Web Server instance.

Get started with the Business Central Web Server cmdlets

The Business Central Web Server cmdlets are contained in the PowerShell script module **NAVWebClientManagement.psm1**, which is available on the Business Central installation media (DVD).

The module is installed with the Business Central Server or the Business Central Web Server components.

There are different ways to launch this module and start using the cmdlets:

- If you are working on the computer where the Business Central Server was installed, run the Business Central Administration Shell as an administrator.

  For more information, see Business Central PowerShell Cmdlets.

- If you installed the Business Central Web Server components, just start Windows PowerShell as an administrator.

- Otherwise, start Windows PowerShell as an administrator, and use the Import-Module cmdlet to import the **NAVWebClientManagement.psm1** file:

  ```
  Import-Module -Name [filepath]
  ```

  For example:

  ```
  Import-Module -Name "C:\Program Files\Microsoft Dynamics 365 Business
  Central\130\Service\NAVWebClientManagement.psm1"
  ```

For more information, see the Windows PowerShell docs.

Creating Business Central Web Server instances

Get Access to the WebPublish folder

To create a new web server instance, you need access to the **WebPublish** folder that contains the content files for the Business Central Web Server components.

- This folder is available on the Business Central installation media (DVD) and has the path "DVD\WebClient\Microsoft Dynamics NAV\13x\Web Client\WebPublish".
- If you installed the Business Central Web Server components, this folder has the path "C:\Program Files\Microsoft Dynamics 365 Business Central\160\Web Client\WebPublish".

You can use either of these locations or you can copy the folder to more convenient location on your computer or network.

Decide on the site deployment type for the instance

When you create a new Business Central Web Server instance, you can choose to create either a RootSite or SubSite type. Each instance type has a different hierarchical structure in IIS, which influences its configuration and the URLs for the accessing from the Business Central Web client.

RootSite

A *RootSite* instance is a root-level web site that is complete with content files for serving the Business Central Web client. It is configured with its own set of bindings for accessing the site, such as protocol (http or https) and communication port. The structure in IIS looks like this:

```
- Sites
  - BusunessCentralWebSite (web site)
    + nn-NN (language versions)
    + www (content)
    navsettings.json
    ...
```

The Business Central Web client URL for the RootSite instance has the format:

`https://[WebserverComputerName]:[port]`

For example: `https://localhost:8080`.

SubSite

A *SubSite* instance is a web application that is under a container web site. The container web site is configured with a set of bindings, but the site itself has no content files. The content files are contained in the application (SubSite). The SubSite inherits the bindings from the container web site. This is the deployment type that is created when you install Business Central Web Server components in the Setup wizard. Using the New-NAVWebServerInstance cmdlet, you can add multiple SubSite instances in the container web site. The structure in IIS for two instances looks like this in IIS:

```
- Sites
  - BusunessCentralWebSite (web site)
    - BusinessCentralWebInstance1 (application)
      + nn-NN (language versions)
      + www
      navsettings.json
      ...
    - BusinessCentralWebInstance2 (application)
      + nn-NN (language versions)
      + www
      navsettings.json
      ...
```

The Business Central Web client URL of a SubSite instance is generally longer than a RootSite because it also contains the application's alias (or virtual path) for the instance, which you define. The URL for a SubSite instance has the format:

`https://[WebserverComputerName]:[port]/[WebServerInstance]`

For example: `https://localhost:8080/BusinessCentralWebInstance1` and `https://localhost:8080/BusinessCentralWebInstance2`.

Run the New-NAVWebServerInstance cmdlet

At the command prompt, run the New-NAVWebServerInstance cmdlet. The following are simple examples for creating a RootSite and SubSite deployment type.

RootSite example:

```
New-NAVWebServerInstance -WebServerInstance MyBCWebsite -Server MyBCServer -ServerInstance
MyBCServerInstance -SiteDeploymentType RootSite -WebSitePort 8081 -PublishFolder "C:\Web Client\WebPublish"
```

SubSite example:

```
New-NAVWebServerInstance -WebServerInstance MyWebApp -Server MyBCServer -ServerInstance MyBCServerInstance -
SiteDeploymentType Subsite -ContainerSiteName MySiteContainer -WebSitePort 8081 -PublishFolder
"C:\WebClient\WebPublish"
```

- Susbtitute *MyBCWebsite* with the name that you want to give the web application in IIS for the web server instance. If you are creating a SubSite deployment type, this name will become part of the URL for opening the Business Central Web client application, for example, https://MyWebServer:8081/MyWebApp.
- Susbtitute *MyBCServer* to the name of the computer that is running the Business Central Server to which you want to connect.
- Susbtitute *MyBCServerInstance* with the name of the Business Central Server instance to use.
- Substitute *MySiteContainer* with name of the container web site under which you want to add the instance. If you specify a name that does not exist, then a new container web site will be created, which contains the new web server instance.
- Susbtitute *8081* with the port number that you want to bind the instance to. If you do not specify a port number, then port 80 is used.
- Substitute *C:\WebClient\WebPublish* with the path to your WebPublish folder. By default, the cmdlet looks in the'C:\Program Files\Microsoft Dynamics 365 Business Central\160\Web Client' folder. So if you are working on a computer where the Business Central Web Server components are installed, you do not

have to set this parameter.

> **NOTE**
>
> This command only sets the required parameters of the NAVWebServerInstance cmdlet. The cmdlet has several other parameters that can use to configure the web server instance. For more information about the syntax and parameters, see New-NAVWebServerInstance.

Modifying a Business Central Web Server instance

After you create the web server instance, if you want to change its configuration, you can use the Set-NAVWebServerInstanceConfiguration cmdlet. Or, you can modify the configuration file (navsettings.json) of the instance directly. For more information, see Configuring Web Server Instances.

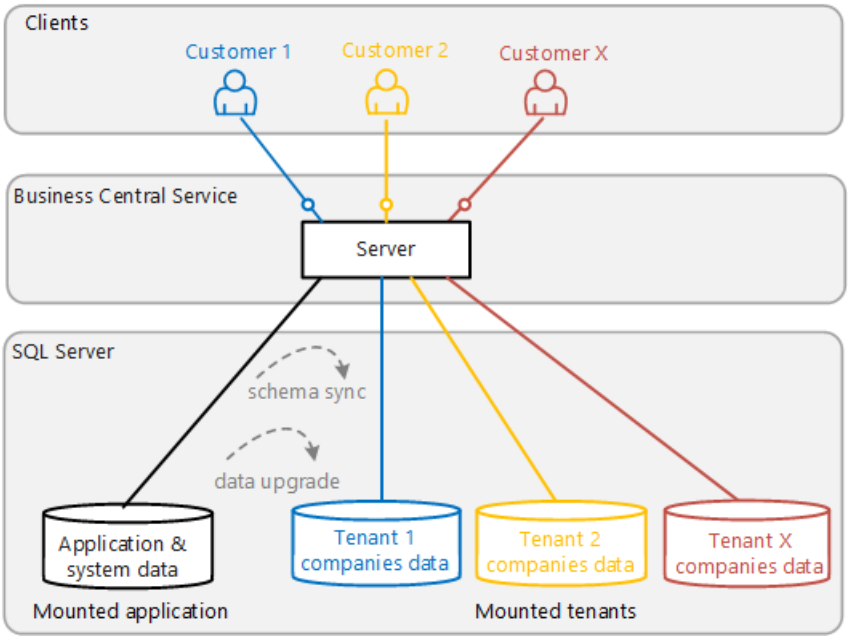
Multitenant Deployment Architecture in Business Central

2/17/2021 • 6 minutes to read • Edit Online

Business Central supports deployments where several different companies access a centrally maintained Business Central application. By using this *multitenancy* support, you can add new customers to your solution easily, and you can roll out updates quickly with limited downtime for your customers.



NOTE

You don't have to turn your Business Central solution into a multitenant deployment. You can install and run Business Central as a classic one-server-one-database deployment.

In a multitenant deployment, information about the Business Central application is stored in a separate application database. Your customers' data is stored in separate business databases, each of which is a *tenant* in your deployment. By separating application from data, you can deploy the same solution to many customers with centralized maintenance of the application and isolation of each tenant. The application database contains the tables that define an application, such as the **Object** table and other system tables.

For example, if your current solution contains 10 companies in the Business Central database, you can choose to create separate Business Central databases to store each company's business data. The knowledge about the shared application is then stored in a dedicated application database. Business Central includes Windows PowerShell cmdlets that create an application database, and other cmdlets that enable you to create and administer tenant-specific databases.

You can choose to upgrade to Business Central and not change your deployment so that you still have a single database that has one or more companies in it. You can also choose to extract the application tables to an application database but still have one business data database that has one or more companies in it. In both scenarios you have not migrated to multitenancy, but in the second scenario you have prepared your solution so that you can move to multitenancy at a later point.

Tenants, Companies, and Databases

A tenant is an entity that uses your solution and stores data in a business database. This is often either a business or a group of legal entities whose data can be stored in one database. In practical terms, a tenant is a database that stores business data for one or more Business Central companies. Each tenant is connected to a Business Central Server instance, but the Business Central Server instance can support multiple tenants.

When you deploy and maintain a Business Central solution, you must activate the relationship between the Business Central Server instance by mounting the tenant to the Business Central Server instance. You can do this by using the Business Central Server Administration tool or by running the **Mount-NAVTenant** and **Sync-NAVTenant** cmdlets from the Business Central Administration Shell. Similarly, to disconnect a tenant, you can use the Business Central Server Administration tool or run the **Dismount-NAVTenant** cmdlet. For more information, see How to: Mount or Dismount a Tenant on a Microsoft Dynamics Server Instance.

When tenants are mounted, the tenant configurations are stored in the **dbo.ndotenants** table of the application database that is connected to the Business Central Server instance. If you connect additional Business Central Server instances to the same application database, the added server instances will automatically inherit the tenant configurations from the application database. This means that existing tenants will be automatically mounted to the new server instance. In addition, if you must mount or dismount a tenant, you only have to perform the operation on one of the Business Central Server instances. The other server instances will automatically detect and update to the changes.

When you refer to a tenant, you refer to it by the tenant ID. The first tenant that is mounted against a Business Central Server instance has the tenant ID **default**. However, you can choose to set up host names for the tenants in your deployment. For example, if you want a tenant to access Business Central through a URL, you can set up a tenant-specific subdomain. The users in that tenant will then access Business Central through a URL such as *https://mytenant.myservice.com*. The tenant host name, *mytenant.myservice.com*, must be specified as an alternative ID in the tenant configuration. You can specify alternative IDs for a tenant by using the **Mount-NAVTenant** Windows PowerShell cmdlet.

Companies

A tenant database can contain one or more Business Central companies. It's not the number of companies in a database that determines whether you are running a multitenant environment. The deciding factor is whether you have created an application database, and if you have more than one tenant database connected to the application database.

Databases

When information about the application is stored in a separate application database, you maintain the application centrally without affecting the various tenants that use the application. Each tenant database contains the business data for one or more specific companies and doesn't contain all of the application metadata.

For example, if you want to modify a report, and your solution is used by 25 customers, you modify the report in the application database. When each customer then accesses the report, they see the modified report.

Deployment Scenarios Supported in Business Central

The following table compares deployment scenarios.

INCLUDES APPLICATION DATABASE	NO. OF BUSINESS DATABASES PER APPLICATION DATABASE	NO. OF COMPANIES IN BUSINESS DATABASE	MULTITENANT DEPLOYMENT
No	1	1	No
Yes	1	1	No

INCLUDES APPLICATION DATABASE	NO. OF BUSINESS DATABASES PER APPLICATION DATABASE	NO. OF COMPANIES IN BUSINESS DATABASE	MULTITENANT DEPLOYMENT
Yes	1	2	No
Yes	2	1	Yes
Yes	2	2	Yes

In the table, the number of companies and business databases are shown as either 1 or 2. But most of the time there are either 1 or more than 2.

The table describes different deployments of a Business Central solution. For example, a deployment with one database and a single company versus a deployment with two or more business databases for each application database. Of those two scenarios, only the second is a multitenant deployment because it connects multiple tenant databases (the business databases) with a single application database. The table also illustrates that you can have multiple companies in a business database. Finally, you can have an application database and a single business database that contains multiple companies. This is a single-tenant deployment.

The Application in Multitenant Deployments

In a Business Central application that is used in a multitenant deployment, some areas require you to set up web services. Since web services are created in the application database, you must create at least one tenant that has write access to the application database. This setting is determined by the *Allow application database writes* parameter when you mount a tenant against a Business Central Server instance. For more information, see How to: Mount or Dismount a Tenant on a Microsoft Dynamics Server Instance.

For example, you can create a dedicated administration tenant that you mount against the Business Central Server instance when you create web services for an application.

If you have an existing Business Central application that you want to use in a multitenant deployment, there are a number of changes that you have to make. This includes setting up the permission sets in a way that supports all tenants that use that application.

URLs and Tenants

In multitenant deployments, URLs must specify the tenant that the URL applies to. If you have C/AL code that constructs URLs, you must update the code to include the tenant. Alternatively, update your code with the GETURL Function to get the URLs calculated for you. The same applies to hyperlinks in report objects, for example.

The URL can specify the tenant ID or the tenant host name if you specify host names as alternative IDs for tenants. For example, the following URL consumes the **Customer** ODATA web service for a specific tenant:

```
https://localhost:7048/BC/OData/Company('CRONUS-International-Ltd.')/Customer?Tenant=Tenant1
```

If the *mytenant.myservice.com* host name has been specified as an alternative ID for the tenant Tenant1, then the following URL returns the same ODATA web service:

```
https://mytenant.myservice.com:7048/BC/OData/Company('CRONUS-International-Ltd.')/Customer
```

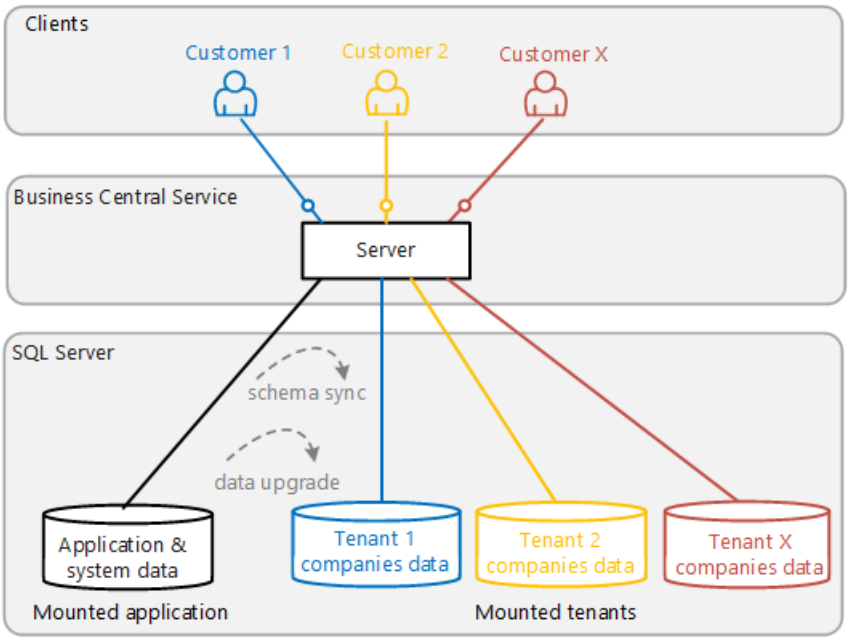
Microsoft Dynamics 365 Windows PowerShell Cmdlets

How to: Mount or Dismount a Tenant on a Microsoft Dynamics Server Instance

Multitenant Deployment Setup Guide

2/17/2021 • 2 minutes to read • Edit Online

This article provides an introduction to the most common tasks you'll do to set up and maintain a Business Central Server multitenant deployment.



Create an application database

The application database includes tables that store information about the application and system, required by all tenants. There are two ways to create an application database:

- Start from scratch and use the New-NAVApplicationDatabase cmdlet.

  This cmdlet is available in the Business Central Administration Shell. It creates a database in SQL Server that's initialized with the required tables and data. For more information, see Create an Application Database.

- Export the application objects from an existing database to a new database.

  If you already have a database that includes the application, you can use the Export-NAVApplication cmdlet to export only the application objects to a new database. For more information, see Exporting the Application Tables to a Dedicated Application Database.

Configure the Business Central Server for multitenancy

To set up the Business Central Server instance for multitenancy, make the following changes to the server instance configuration:

1. Enable the **Multitenant** setting.
2. Set the server instance to connect to the application database by changing these settings: **DatabaseServer**, **DatabaseServer**, and **DatabaseServer**.

For more information, see Configuring Business Central Server and Connecting a Business Central Server Instance to a Database.

TIP

Instead of doing the two previous steps, you could use the Mount-NAVApplication cmdlet. Running this cmdlet will enable the **Multitenant** and set up the data base connection.

Publish the symbols and extensions

Before mounting tenants, publish the system symbols and extensions that make up your application. Publish the system application and base application extensions as a minimum. Then, as needed, publish any Microsoft and third-party extensions tenants may use.

For more information, see Publishing and Installing an Extension.

Create, mount, and synchronize tenants

The tenant database includes tables for storing customer data that's accessible from the application. The tenant database is often referred to as just the *tenant*. The basics tasks for getting a new tenant up and running, and keeping it up to date, are as follows:

1. Create an empty database with the wanted collation in SQL Server.
2. Mount the database as a tenant of the Business Central Server instance.

   This operation connects the tenant database to the Business Central Server so it can process data requests from the application. See Mount or Dismount a Tenant.
3. Synchronize the tenant database with the application.

   The application database stores information that defines the basic structure or schema required for all tenant databases. This operation updates the tenant database schema with the definitions in application database. See Synchronizing the Tenant.
4. Synchronize and install extensions.

   The last step is to install all the extensions that you want to use on the tenant. Many extensions define table objects and table extension objects for storing data. So, before you can install an extension, you have to synchronize it with the tenant to update the tenant database's schema. See Publishing and Installing an Extension.

TIP

For more detailed steps, see Create a Tenant Database.

Multitenant Deployment Overview Architecture
Multitenant Deployment Architecture

Migrating to Multitenancy

2/17/2021 • 2 minutes to read • Edit Online

You can choose to migrate your Business Central solution to a multitenant deployment architecture where you maintain a single application that is used by two or more companies that store their data in separate databases.

This can make maintenance of your solution easier if you support multiple customers with the same application functionality.

Tenants and Companies

When you upgrade your application and the data to Business Central, you have a database that has the same number of companies as you had before the upgrade. This database is considered a *tenant*. This does not mean that you have to turn your solution into a multitenant deployment. But it means that you can if you want to.

For example, your Business Central deployment in the earlier version consisted of a database that has 20 companies. In other words, you support 20 companies that all share the same application functionality. In this example, the companies are separate companies that have nothing to do with each other except that they are supported by you in one database. In Business Central, you can choose to extract the application-wide tables into a separate database and keep the data for all 20 companies in the original database. This becomes a single-tenant business data database. Then, you can choose to split the business data database into one for each company so that you run a truly multitenant environment. The application is stored separately in the application database, and you maintain application functionality centrally. When you modify the application, you make the changes available to one tenant at a time. As a result, if something goes wrong, all other tenants are not affected.

Compare this to earlier versions of Business Central where a database could contain several companies. These companies could be related or not, but they would all use the same application and write to the same database. Also, when you modified the application, it would affect all companies immediately. So if something went wrong, all companies would be affected.

> **NOTE**
> The email logging functionality in Business Central requires the Business Central Server service account to have access to the Exchange server. But in a multitenant deployment, this is not always possible.

In multitenant deployments of Business Central, permission sets are stored centrally in the application database, so only the administrator of the central application can add, remove, or modify permission sets. Instead, the tenants can use user groups to manage permissions.

Migration Process

If you decide to move to a multitenant architecture, you must complete the following steps:

1. Move the tables that describe the application to a separate database. For more information, see Separating Application Data from Business Data.

   After this step, you have two databases: an application database and a business data database.

2. Split the business data database into one for each company. For more information, see Creating Tenants from Companies.

   After this step, you have an application database and a business data database for each company in the

original database. The company-specific business data databases are tenants, and your solution is multitenant.

If you want to move back to storing application tables and business data in a single database, you can use the Business Central Windows PowerShell cmdlets to merge the databases. For more information, see Merging an Application Database with a Tenant Database.

Separating Application Data from Business Data

2/17/2021 • 8 minutes to read • Edit Online

Business Central separates tables that describe the application from the tables that contain business data. Depending on your deployment scenario, you can choose to store all Business Central tables in one database, or you can export the application tables to a dedicated database. In multitenant deployments, the application must be stored in a dedicated database.

Application Database versus Business Data Databases

The application database contains tables that describe your application. This includes a description of the objects that your application consists of, and other data that is common to all tenants. The data that users enter in your application is stored in the business data database because this data is specific to their company. Optionally, you can create multiple business data databases, such as if you want to support your customers as tenants.

When you have exported the application tables to a separate database, you can no longer access the business database from the Dynamics NAV Development Environment. This is because the metadata for the tables in the business database is stored in the application database and modified in that database.

For example, if you want to modify a report, you modify the report object in the application database. Then, when you deploy the updated application to your production environment, when a user accesses the report, they see the modified report.

Business Central includes Windows PowerShell cmdlets that help you export application tables to a dedicated database, and other cmdlets to help you maintain a multitenant deployment. For more information, see Business Central Windows PowerShell Cmdlets.

Distribution of the System Tables in Each Database

The application tables are system tables that define the application. Other system tables remain in the business data database. For example, the following table lists some of the system tables that are moved to the application database when you run the Export-NAVApplication cmdlet and other tables that remain in the business data database. This is a partial list to give an idea of how tables are distributed:

APPLICATION DATABASE	BUSINESS DATA DATABASE
Add-in	Access Control
Application Dependency	Active Session
Application Object Metadata	API Webhook Notification
Application Resource	API Webhook Notification Aggr
Chart	API Webhook Subscription
Configuration Package File	Company
Debugger Breakpoint	Device
Debugger Watch	Data Sensitivity

APPLICATION DATABASE	BUSINESS DATA DATABASE
Entitlement	Document Service
Entitlement Set	Intelligent Cloud
Installed Application	Intelligent Cloud Status
Media	Isolated Storage
Media Resources	Object Options
Media Set	Object Metadata Snapshot
Membership Entitlement	Object Translation
Object	Integration Page
Object Metadata	Object Metadata Snapshot
Object Tracking	Object Translation
OData Edm Type	Object Access Intent Override

Exporting the Application Tables to a Dedicated Application Database

To export the application tables from an existing database to another database, Business Central provides a Windows PowerShell cmdlet as part of the Business Central Administration Shell.

The following procedure illustrates how you can separate the application tables in an existing database into two databases: an application database and a business data database. You can automate this process and combine it with the use of other cmdlets. For more information, see the samples in the Windows PowerShell scripts in the **...\WindowsPowerShellScripts\Multitenancy** folder on the Business Central product media.

Export the application tables to a dedicated database

1. Stop all Business Central Server services that access the database that you are modifying. This includes the Business Central Server instance.
2. Back up your databases.
3. Run the Business Central Administration Shell as an administrator.

   > **IMPORTANT**
   > You must run the program as administrator. Also, you must ensure that scripting is enabled on the computer.

   For more information, see Business Central Windows PowerShell Cmdlets.
4. Uninstall the extensions.

   To uninstall an extension, you use the Uninstall-NAVApp cmdlet.

   ```
   Uninstall-NAVApp -ServerInstance <server instance name> -Tenant default -Name <extensions name> -
   Version <extension version>
   ```

   Replace `<extension name>` and `<extension version>` with the exact name and version the installed extension. Set `<tenant ID>` to `default` or omit the `-Tenant` parameter.

   For example, together with the Get-NAVApp cmdlet, you can uninstall all extensions with a single command:

   ```
   Get-NAVAppInfo -ServerInstance <server instance name> -Tenant default | % { Uninstall-NAVApp -
   ServerInstance <server instance name> -Tenant default -Name $_.Name -Version $_.Version -Force}
   ```
5. To export the application tables, type the following command:

   ```
   Export-NAVApplication –DatabaseServer <server name> -DatabaseInstance <instance name> –DatabaseName
   <name of original database> –DestinationDatabaseName <name of new application database> -
   ServiceAccount <the account used by server instance if not NT AUTHORITY\NETWORK SERVICE>
   ```

   For example, to run the cmdlet against the CRONUS International Ltd. demonstration database, type the following command:

```
Export-NAVApplication –DatabaseServer 'MyServer' –DatabaseInstance 'BCDemo' –DatabaseName 'Demo
Database BC' –DestinationDatabaseName 'Business Central App'
```

In the example, the database server name is **MyServer** , and the SQL Server instance is **BCDemo**. The name of the new application database can be anything. You can specify a name that reflects your application.

The application database is created on the same SQL Server instance as the original database. In the example, if you connect to the **BCDemo** instance using SQL Server Management Studio you will see two databases: the original database, **Demo Database BC**, and the new application database, **Business Central**.

At this stage, the original database still contains the application tables, and you can still access it using the Dynamics NAV Development Environment. Next, you must remove the application tables from the original database to make it a tenant database.

> **TIP**
> Optionally, you can combine the Export-NAVApplication and Remove-NAVApplication cmdlets. For an example of how you can combine the two cmdlets, see the **Example** section.

6. To remove the application tables from the original database, run the Remove-NAVApplication cmdlet as follows:

```
Remove-NAVApplication –DatabaseServer <server name> -DatabaseInstance <instance name> –DatabaseName
<name of the original database>
```

For example, to run the cmdlet against the CRONUS International Ltd. demonstration database where you have exported the application tables, type the following command:

```
Remove-NAVApplication –DatabaseServer 'MyServer' –DatabaseInstance 'BCDEMO' –DatabaseName 'Demo
Database BC'
```

You will be asked to confirm that you want to remove the tables.

> **WARNING**
> Running the **Remove-NAVApplication** cmdlet is not reversible. When you have removed the application tables from the database, you cannot import them again. Make sure that you have a full backup available.

At the end of the process, you have two databases. In the example earlier in this topic, the databases are as follows.

DATABASE NAME	DATABASE TYPE	DESCRIPTION
Demo Database BC	Business data database	Contains the data from the original database.
Business Central App	Application database	Contains the tables that define the application.

7. Clear the `DatabaseName` setting in the Business Central Server instance configuration file by using the Set-

NAVServerConfiguration cmdlet:

```
Set-NAVServerConfiguration –ServerInstance <server instance name> –element appSettings –KeyName
'DatabaseName' –KeyValue ''
```

8. Start the Business Central Server instance by using the Start-NAVServerInstance cmdlet:

```
Start-NAVServerInstance –ServerInstance <server instance name>
```

9. Mount the application database on the Business Central Server instance by using the Mount-NAVApplication cmdlet:

```
Mount-NAVApplication –ServerInstance <server instance name> –DatabaseServer <server name\instance
name> –DatabaseName <application database name>
```

10. Mount the business data database (tenant) on the server instance by using the Mount-NAVTenant cmdlet:

```
Mount-NAVTenant –ServerInstance <server instance name> -Id <tenant name> –DatabaseServer <server
name\instance name> -DatabaseName <business data database> -OverwriteTenantIdInDatabase
```

11. Reinstall extensions.

    In this step, you reinstall the same extensions that were installed on the tenant before. To install an extension, you use the Install-NAVApp cmdlet.

    a. It can be helpful to get a list of the published extensions and their version. To get a list of all published extensions, use the Get-NAVAppInfo cmdlet:

    ```
    Get-NAVAppInfo -ServerInstance <server instance> | Repair-NAVApp
    ```

    b. If your solution uses the System Application, install this first.

    ```
    Install-NAVApp -ServerInstance <server instance> -Name "System Application" -Version
    <extension version>
    ```

    Replace `<extension version>` with the exact version of the published System Application.

    c. Install the Base Application.

    ```
    Install-NAVApp -ServerInstance <server instance> -Name "Base Application" -Version <extension
    version>
    ```

    Replace `<extension version>` with the exact version of the published Base Application.

    d. Install the Application extension. This extension is required to install Microsoft extensions.

    ```
    Install-NAVApp -ServerInstance <server instance> -Name "Application" -Version <extension
    version>
    ```

    Replace `<extension version>` with the exact version of the published Application extension.

    e. Install other extensions, including Microsoft and third-party extensions.

```
Install-NAVApp -ServerInstance <server instance name> -Name <extension name> -Version
<extension version>
```

For more information, see Business Central Windows PowerShell Cmdlets.

Example

The following code example illustrates how you can manually write commands in the Business Central administration shell. The commands create an application database based on an existing Business Central database.

The sample commands are assumed to run in the Business Central administration shell based on the CRONUS International Ltd. demonstration database on a local computer.

```
Stop-NAVServerInstance –ServerInstance 'businesscentral_server_instance'
Export-NAVApplication –DatabaseServer 'MyServer' –DatabaseInstance 'BCDEMO' –DatabaseName 'Demo Database BC'
–DestinationDatabaseName 'Business Central App'| Remove-NAVApplication –DatabaseName 'Demo Database BC' -
Force
Set-NAVServerConfiguration –ServerInstance 'businesscentral_server_instance' –element appSettings –KeyName
'DatabaseName' –KeyValue ''
Start-NAVServerInstance –ServerInstance 'businesscentral_server_instance'
Mount-NAVApplication –ServerInstance 'businesscentral_server_instance' –DatabaseServer 'MyServer\BCDEMO' –
DatabaseName 'Business Central App'
Mount-NAVTenant –ServerInstance 'businesscentral_server_instance' -Id tenant1 –DatabaseServer
'MyServer\BCDEMO' -DatabaseName 'Demo Database BC' -OverwriteTenantIdInDatabase
```

In the example, the commands stop the Business Central Server service, creates the application database, clears the default database name in the server configuration, and then restarts the service. Then, the application database and the tenant database are mounted, and the configuration is saved in the Tenants.config file on the server. As a result, you have an application database and a single-tenant deployment. When you try to open the Dynamics NAV Client connected to Business Central, an error displays because you have not specified a tenant. So in the **Select Server** window, in the **Server Address** field, add the tenant ID to the address. In this example, the address is **localhost:7046/BC160/tenant1**.

TIP

For an example of how you can automate the process of transferring user accounts from the original database to the new application database, see the HowTo-ExportNAVApplicationDatabase.ps1 sample script. This and other sample scripts are in the **...\Windows PowerShell\Multitenancy** folder on the Business Central product media. The ExportNAVApplicationDatabase.ps1 sample script can be run in the context of the NAVUpgradeSamples.psm1 script module file. When you call a script such as this, it will export the application tables to a new application database and copy all accounts and SQL Server user roles to the application database. To only transfer the account that the Business Central Server instance uses, use the *–ServiceAccount* parameter for the **Export-NAVApplication** cmdlet. In the examples in this topic, this parameter has not been specified. As a result, the default account, NT AUTHORITY\NETWORK SERVICE, is set up with the required user roles.

Installation Considerations for Microsoft SQL Server and Business Central

2/17/2021 • 7 minutes to read • Edit Online

This article describes the requirements for installing and configuring Microsoft SQL Server to work with Business Central.

Dynamics NAV can run on Microsoft SQL Server and Microsoft Azure SQL Database. For a list of supported editions of SQL Server, see SQL Server Requirements.

Using Microsoft SQL Server

Storage

Use different disks or disk partitions for the following:

- Windows operating system.
- Data files for the system databases.
- Log files for system and user databases.
- Data and log files for the TempDB database.

For optimal read/write performance, make sure that disks that are used for SQL Server data files are formatted using 64 KB block size.

Virus scanning

To help you decide which kind of antivirus software to use on the computers that are running Microsoft SQL Server in your environment, see How to choose antivirus software to run on computers that are running SQL Server.

Memory

For optimal read performance, maximize the available memory on the server according to the version and edition of SQL Server used. Refer to the SQL Server documentation for maximum values.

SQL Server components

If you are installing Microsoft SQL Server for use with Business Central, then install the following components:

- Database Engine Services
- Client Tools Connectivity
- Management Tools - Complete

Setup options for Microsoft SQL Server

When you are running Microsoft SQL Server Setup, you must provide additional information. Your responses can affect how you use SQL Server with Dynamics NAV.

TempDB database configuration

For servers with less than 8 cores, create as many data files for the TempDB database as the number of cores. For servers with more than 8 cores, start with 8 data files, and increment with 4 files at a time, if needed.

Make sure that all data files for the TempDB database are of the same size.

Consider putting data and log files for TempDB on a local SSD drive if you are using SAN storage.

Data file and log file configuration

Auto-growth of the database and/or transaction log files in production can degrade performance as all transaction must queue up and wait for SQL Server to grow the file before it can begin to process transactions again. This can create bottlenecks. We strongly recommend growing data and log files during off-peak periods and by 10% to 25% of the current size. We do not recommend disabling "Auto-Grow", as in an emergency it is still better to have SQL Server to auto-grow files than to run out of disk space and bring the database down.

Max degree of parallelism (MAXDOP)

The SQL queries generated by Dynamics NAV is of OLTP type (many, small transactions). It is therefore recommended to run Dynamics NAV with `MAXDOP` set to the value 1.

On SQL Server 2014, `MAXDOP` can only be set on the instance level, changing an advanced server configuration option. On SQL Server 2016, `MAXDOP` can be set on the database level, changing a database scoped configuration.

Both advanced server configuration options and database scoped configurations can be set by using SQL Server Management Studio, see the SQL Server documentation for details.

> **NOTE**
> If you are running SQL Server Enterprise Edition, index maintenance can be done in parallel. If you run maintenance jobs to do this work in off-peak hours, you might want to set `MAXDOP` back to 0 while running these jobs. On SQL Server 2016, it is possible to set MAXDOP directly in the Rebuild Index Task wizard.

Instance configuration

If you plan on installing the Business Central Demo database, and you want Business Central Setup to use an already installed version of SQL Server (and not to install SQL Server Express), you must create a SQL Server instance named **BCDEMO** in SQL Server before you run Setup. Otherwise, Setup will install SQL Server Express automatically, even if there is a valid version of SQL Server already on the computer. If you do not plan to install the Demo database, or if you have no objection to using SQL Server Express, you are free to use the **default instance** and **Instance ID** on the **Instance Configuration** page, or to specify any instance name.

Database engine service

Each SQL Server instance is run by its own windows service. The following two things are important to configure for these services

Startup options

Enable trace flags 1117 and 1118 as startup options for SQL Server 2014. For SQL Server 2016, these trace flags are enabled by default.

Startup options can be set by using SQL Server Configuration Manager, see the SQL Server documentation for details.

Service account

We recommend that you use dedicated domain user accounts for the Windows services running your Business Central Server instances and your SQL Server instances, instead of a Local System account or the Network Service account.

The Business Central Server account must have privileges on the SQL Server instances and on the Dynamics NAV database(s). See Provisioning the Server Service Account for details.

For installations on SQL Server 2014, consider adding the service account for the SQL Server engine to the **Perform Volume Maintenance Tasks** security policy. For SQL Server 2016, it is possible to do this from the installer.

Database configurations

After Dynamics NAV has been installed, it is important to check a few settings on the Dynamics NAV database(s).

This is especially important for databases, which have been upgraded from previous versions of SQL Server.

Statistics

The databases used by Business Central should have set the options AUTO_CREATE_STATISTICS and AUTO_UPDATE_STATISTICS to the value ON (this is the default behavior and should not be changed)

SQL Server (2014 and earlier) uses a threshold based on the percent of rows changed before triggering an update of the statistics for a table regardless of the number of rows in the table. It is possible to change this behaviour by setting trace flag 2371 as a startup option for the instance. See Knowledge Base article ID 2754171, https://support.microsoft.com/en-gb/help/2754171/controlling-autostat-auto-update-statistics-behavior-in-sql-server for more information about when to set this trace flag.

SQL Server (starting with 2016 and under the compatibility level 130) uses a threshold that adjusts according to the number of rows in the table. With this change, statistics on large tables will be updated more often.

Even with "Auto Update Statistics" enabled, we still strongly recommend running a periodic SQL Agent job to update statistics. This is because "Auto Update Statistics" will only be triggered according to the rules described above. On large tables with tens of millions of records (such as Value Entry, Item Ledger Entry and G/L Entry), a small percentage of data in a given statistic such as [Entry No.] can change and have a material effect on the overall data distribution in that statistic. This can cause inefficient query plans, resulting in degraded query performance until any threshold is reached. We recommend using the T-SQL procedure "sp_updatestats" to update statistics, as it will only update statistics where data has been changed. We recommend creating a SQL Agent Job that runs daily or weekly (depending on transaction volume) during off-peak hours to update all statistics where data has changed.

Index fragmentation

Another important administration task that helps to reduce data size and improve performance is to reduce fragmentation for tables and non-clustered indexes. This article in the SQL Server documentation is a good starting point to learn more: Resolve index fragmentation by reorganizing or rebuilding indexes.

Other database options

We recommend to set the database option PAGE_VERIFY to the value CHECKSUM for all databases (including TEMPDB) as this is the most robust method of detecting physical database corruption. This is the default setting for new installations.

Backup

Remember to setup backup of both system and user databases. Remember also to test restore procedures regularly.

Using Microsoft Azure SQL Database

You can deploy a Business Central database to Azure SQL Database. Azure SQL Database is a cloud service that provides data storage as a part of the Azure Services Platform.

To optimize performance, we recommend that the Business Central Server instance that connects to the database is also deployed on a virtual machine in Azure. Additionally, the virtual machine and SQL Database must be in the same Azure region.

For development and maintenance work on Business Central applications, if the Dynamics NAV Development Environment is installed on the same virtual machine in Azure as the Business Central Server, then you can connect to the Azure SQL database from the development environment.

For more information, see Deploying a Business Central Database to Azure SQL Database.

Data Encryption between Business Central Server and SQL Server

When SQL Server and Business Central Server are running on different computers, you can make this data

channel more secure by encrypting the connection with IPSec. (Other encryption options are not supported.) For information on how to do this, see Encrypting Connections to SQL Server, which is part of SQL Server 2008 Books Online in MSDN library.

Configuring the Business Central Database

2/17/2021 • 7 minutes to read • Edit Online

For a Business Central Server instance to connect to and access a database in SQL Server, the server instance must be authenticated by the database. As in SQL Server, Business Central supports two authentication modes for database communication: Windows Authentication and SQL Server Authentication. When you set up Business Central, you must ensure that database authentication is configured correctly on both the server instance and database, otherwise the server instance will not be able to connect to the database. By default, Windows Authentication is configured on the server instance and database. With Windows Authentication the Business Central Setup does the work for you.

This article describes how to configure SQL Server Authentication. You perform the configuration in two places: on the databases in SQL Server and on the Business Central Server instance. The procedure is different when the Business Central Server instance is configured as a multitenant server instance than when it is not a multitenant server instance.

Set Up an Encryption Key

When using SQL Server authentication, Business Central requires an encryption key to encrypt the credentials (user name and password) that the Business Central Server instance uses to connect to the Business Central database in SQL Server. The encryption key must be installed on the computer where the Business Central Server is installed and also in the database in SQL Server. In a multitenant deployment, the encryption key must be installed in the application database.

To set up an encryption key, you can use one of the following methods:

- You can create and import your own encryption key by using Business Central Administration Shell cmdlets, as described in the following procedure.
- If you are configuring SQL Server authentication on a Business Central Server instance for the first time, you can use the Business Central Server Administration tool which can automatically create and install a system encryption key. If you decide to use this method, no action is required.

Create and import encryption key

1. In the Business Central Administration Shell, run the New-NAVEncryptionkey cmdlet.

   This creates a file that contains an encryption key. If you already have an encryption key file, you can skip this step.

2. Run the Import-NAVEncryptionkey cmdlet to install the encryption key on the Business Central Server instance and database.

On the computer running the Business Central Server instance, the encryption key file has the name BC160.key and is stored in the `%systemroot%\ProgramData\Microsoft\Microsoft Dynamics NAV\[version]\Server\Keys`. In the database, the encryption key is registered in the dbo.ndopublicencryptionkey table. In a multitenant deployment, the encryption key is registered in the application database.

Configure SQL Authentication on the Database

This section describes how to configure a Business Central database to use SQL Server Authentication with a Business Central Server instance. You can complete the steps in this procedure by using SQL Server Management Studio or Transact-SQL.

> **IMPORTANT**
> In a deployment where the Business Central Server instance is configured as a multitenant server instance, you must complete the following procedure on the application database and tenant database.

Configure SQL Server Authentication on the database in SQL Server

1. Configure the SQL Server instance (Database Engine) that hosts the Business Central database to use SQL Server Authentication.

   To use SQL Server authentication, you configure the database instance to mixed authentication mode (SQL Server and Windows Authentication). For more information, see Change Server Authentication Mode.

2. In the SQL Server instance, create a login that uses SQL Server authentication.

   For more information, see Create a Login.

3. Map the login to a user in the Business Central database, and give the user the relevant privileges in the Business Central database.

   For more information, see Create a Database User in the SQL Server docs and the Giving the service account database privileges in SQL Server in the current article.

Configure SQL Server Authentication on the Business Central Instance (Non-Multitenant)

You configure the Business Central Server instance with the login credentials (user name and password) of the user account in the Business Central database in SQL Server that you want to use for authentication. You can do this using the Business Central Server Administration tool or Business Central Administration Shell.

Configure SQL Authentication on a server instance using Business Central Server Administration tool

1. Open the Business Central Server Administration tool.
2. In the console tree, which is the left pane, expand the node for the computer that contains the Business Central Server instance, and then select the Business Central Server instance.
3. In the **Actions** pane, choose **Database Credentials**.
4. On the **Database Credentials** page, choose the **Edit** button.
5. Set the **Database Authentication Type** to **SQL Authentication**.
6. In the **Database User Name** field, type the login name for the database user that you want to use to access the Business Central database in SQL Server.
7. In the **Password** field, type the login password for the database user that you want to use to access the Business Central database in SQL Server.
8. Choose the **Save** button, and then on the **Enable Encryption on SQL Server Connections** dialog box, choose the **OK** button.

   Encryption keys are used to help secure the login credentials over the connection between the Business Central Server instance and the Business Central database in SQL Server.

9. On the **Information** dialog box about encryption, choose the **OK** button.

   This dialog box is to inform you to enable encryption on SQL Server connections, which is disabled by default.

10. If you want to enable encryption on SQL Server connections, in the **Action** pane, choose **Configuration**, and then choose the **Edit** button. In the **Database** tab, select **Enable Encryption on SQL Connections**, choose the **Save** button, and then the **OK** button.

11. Restart the server instance.

Configure SQL Authentication on a server instance using Business Central Administration Shell

- If you are modifying an existing Business Central Server instance, run the Set-NAVServerConfiguration cmdlet.

  Use the *DatabaseCredentials* parameter to provide the login credentials of the database user that you want to use to access the application database.

- If you are creating a new Business Central Server instance, run the New-NAVServerInstance cmdlet.

  Use the *DatabaseCredentials* parameter to provide the login credentials of the database user that you want to use to access the application database.

Configure SQL Server Authentication on Business Central Instance in a Multitenant Deployment

This section describes how to configure a Business Central database to use SQL Server Authentication with a Business Central Server instance. You can complete the steps in this procedure by using SQL Server Management Studio or Transact-SQL.

To configure a SQL Server Authentication on a Business Central Server instance, you set up the server instance with the login credentials (user name and password) for the user accounts for the application and tenant databases in SQL Server. You can do this using the Business Central Server Administration tool or Business Central Administration Shell.

Configure SQL Authentication using Business Central Server Administration tool

1. Open the Business Central Server Administration tool.
2. In the console tree, which is the left pane, expand the node for the computer that contains the Business Central Server instance, and then select the Business Central Server instance.
3. Configure SQL Server Authentication with the application database as follows:
   a. In the **Actions** pane, choose **Database Credentials**.
   b. On the **Database Credentials** page, choose the **Edit** button.
   c. Set the **Database Authentication Mode** to **SQL Server Authentication**.
   d. In the **Database User Name** field, type the login name for the database user that you want to use to access the Business Central application database in SQL Server.
   e. In the **Password** field, type the login password for the database user that you want to use to access the Business Central database in SQL Server.
   f. Choose the **Save** button, and then on the **Enable Encryption on SQL Server Connections** dialog box, choose the **OK** button.

      Encryption keys are used to help secure the login credentials over the connection between the Business Central Server instance and the Business Central database in SQL Server.

   g. On the **Information** dialog box about encryption, choose the **OK** button.

      This dialog box is to inform you to enable encryption on SQL Server connections, which is

disabled by default.

h. If you want to enable encryption on SQL Server connections, in the **Action** pane, choose **Configuration**, and then choose the **Edit** button. In the **Database** tab, select **Enable Encryption on SQL Connections**, choose the **Save** button, and then the **OK** button.

4. To configure SQL Server Authentication with the tenant database, mount the tenant to the Business Central Server instance and specify the login credentials (user name and password) for the database user that you want to use to access the Business Central tenant database in SQL Server.

   If the tenant is already mounted to the Business Central Server instance, you must dismount the tenant, and mount it again.

   For more information see Mount or Dismount a Tenant.

5. Restart the server instance.

Configure SQL Authentication using Business Central Administration Shell

1. Configure SQL Server Authentication with the application database as follows:

   - If you are modifying an existing Business Central Server instance, run the Set-NAVServerConfiguration cmdlet.

     Use the *DatabaseCredentials* parameter to provide the login credentials of the database user that you want to use to access the application database.

   - If you are creating a new Business Central Server instance, run the New-NAVServerInstance cmdlet.

     Use the *DatabaseCredentials* parameter to provide the login credentials of the database user that you want to use to access the application database.

2. To configure SQL Authentication with the tenant database, run the Mount-NAVTenant cmdlet.

   Use the *DatabaseCredentials* parameter to provide the login credentials of the database user that you want to use to access the tenant database.

Creating Databases in Business Central

2/17/2021 • 5 minutes to read • Edit Online

APPLIES TO: Business Central 2019 release wave 2 and later

This article describes how to create new databases in Business Central for storing application and business data.

Overview

Application and tenant databases

There are two types of databases: application and tenant.

- The application database stores data that defines the application and its business logic. This data includes descriptions of the objects and the code of your application. Essentially, it includes data that are common to all tenants. It's the application database to which you publish your extensions, including the base application, system application, and other extensions.
- The tenant database is often referred as just the tenant. The tenant database stores the actual business data for specific companies, for example, data that users enter and modify by using the application. It's the tenant database on which you install extensions that are published to the application database.

In a single-tenant deployment architecture, the application data and business (tenant) data are stored in the same database. That is, there's only one database. If you want to set up single-tenant deployment, you only have to create an application database.

If you have a multitenant deployment architecture, you create an application database and one or more tenant databases.

Supported collations

Business Central supports Windows collations only. For a list of Windows collations, see Windows Collations in the SQL Server documentation.

Create an application database

To create an application database, for either a single-tenant or multitenant deployment, you use the New-NAVApplicationDatabase cmdlet. This cmdlet is available in the Business Central Administration Shell. You use the New-NAVApplicationDatabase cmdlet to create either new database or initialize an existing empty database to make it an Business Central application database.

- If you create a new database, the cmdlet will add a database in SQL Server. The database includes the tables and data required for a Business Central application database. The cmdlet creates a master data file (MDF) and log data file (LDF). Using the cmdlet, you can set the database name, the collation, and where to store the data files. Other database options are set for you.
- If you use the cmdlet with an existing database, the cmdlet modifies the existing database to include Business Central application tables and data. You configure a database beforehand, setting options that aren't done by the cmdlet, such as options for the data files (MDF/NDF/LDF) and their filegroups, table partitioning, and more.

To create an application database, complete the following steps:

1. Run the Business Central Administration Shell as an administrator.

Make sure that the Window user that you run as has the appropriate privileges on the SQL Server as described in Assign privileges on the Business Central database-level.

2. Run the New-NAVApplicationDatabase cmdlet to create a new database or initialize an existing database.

```
New-NAVApplicationDatabase [-DatabaseServer <database server name>\<database server instance>] -
DatabaseName <String> [-DatabaseLocation <String>] [[-Collation] <String>] [-
ApplicationDatabaseCredentials <PSCredential>]
```

To create a new application database, set `-DatabaseName` to the name you want to give the database, and the `-Collation` to the wanted collation. If you omit the `-Collation`, then Latin1_General_100_CS_AS is used by default. Optionally, set the `-DatabaseLocation` to the directory path where you want to store the data files; otherwise the database files will be stored in the default SQL Server location.

To use an existing empty database, set the `-DatabaseName` to the name of the existing database. You can't use the `-Collation` parameter to change the current collation of the database.

The following example creates a new database called MyBCApplicationDB. The database is given the collation Latin1_General_100_CS_AS on the SQL Server instance BCDEMO. The database files are stored in the default data directory for the SQL Server instance (for example, C:\Program Files\Microsoft SQL Server\MSSQL13.BCDEMO\MSSQL\DATA).

```
New-NAVApplicationDatabase -DatabaseServer .\BCDEMO -DatabaseName "MyBCApplicationDB"
```

When the database has been successfully created, text similar to the following displays:

```
DatabaseServer      : .\BCDEMO
DatabaseName        : MyBCApplicationDB
DatabaseCredentials :
DatabaseLocation    :
Collation           : Latin1_General_100_CS_AS
```

3. Connect Business Central Server instance to the new database.

For example:

```
Set-NAVServerConfiguration BC160 -KeyName DatabaseName -KeyValue "MyBCApplicationDB"
```

4. Run the Set-NAVApplication cmdlet to set the application version on the database.

To set the application version, use the `-ApplicationVersion` parameter. The value must have the format `major.minor.[build[.revision]]`, such as '15.1', '15.1.0', or 15.1.0.0'. For example:

```
Set-NAVApplication BC160 -ApplicationVersion 15.1.0.0 -Force
```

This step is required to synchronize your tenant and extensions later. This step sets a value to the `applicationversion` column in the **ndodbproperty** table of the application database.

5. Give the Business Central Server service account privileges to the database.

For more information, see Provisioning the Business Central Server Service Account.

If you have a multitenant deployment, go to the next section about creating a tenant database.

6. If you have a single-tenant deployment, you can now synchronize the tenant. For a multitenant

deployment, go to the next section.

Run the Sync-NAVTenant cmdlet to synchronize the tenant. For example:

```
Sync-NAVTenant -ServerInstance BC160
```

This step will create the tenant-related tables in the database.

Create a tenant database

Complete the followings step to create a new tenant database in a multitenant deployment.

1. In SQL Server, create a new database.

   > **IMPORTANT**
   > Set the collation to the same as the application database.

2. Give the Business Central Server service account privileges to the database, like you did with the application database.

   For more information, see Provisioning the Business Central Server Service Account.

3. Mount the database as a tenant to the application.

   To mount the tenant, use the Mount-NAVTenant cmdlet. For example:

   ```
   Mount-NAVTenant -ServerInstance BC160 -DatabaseName "BCTenantDB" -DatabaseServer .\BCDEMO -Tenant
   BCTenant1 -AllowAppDatabaseWrite
   ```

   > **NOTE**
   > For now, we recommend that you use the `-AllowAppDatabaseWrite` parameter. Later, you can dismount and mount the tenant again without the parameter if needed.

4. Synchronize the tenant.

   Use the Sync-NAVTenant cmdlet. For example:

   ```
   Sync-NAVTenant -ServerInstance BC160 -Tenant BCTenant1 -Mode Sync
   ```

   This step will create the tenant-related tables in the database.

Next steps

Complete the following steps to get the application up and running on your tenants.

1. Publish the system symbols and extensions that make up your application. For example, publish the system application, base application, Microsoft extensions, and third-party extensions.

   See Publishing and Installing an Extension

2. Synchronize and install extensions on the tenant.

   See Publishing and Installing an Extension

3. Add a company to the database.

   To add a company, run the New-NAVCompany cmdlet.

4. Export and import existing permissions sets.

   A new database won't include any permission sets except for the SUPER permission set. Also, there will only be one user, typically for your account. You can either create permissions sets from scratch or export the sets from an existing database. As a minimum, it's a good idea to export the BASIC permissions set. The BASIC permission set grants the minimum permissions required for any user to access the application.

   For more information, see Export Permission Sets and Special Permission Sets.

Running a Business Central Database on Azure SQL Database

2/17/2021 • 7 minutes to read • Edit Online

This article describes how you can deploy a Business Central database to Microsoft Azure SQL Database.

> **TIP**
> For multi-tenancy mode installations, the procedures outlined here must be performed both for the application database as well as for the tenant databases.

Prerequisites

Make sure that you have the following prerequisites for completing this procedure:

- A Microsoft Azure subscription and access to the Azure portal.
- A Business Central database installed on a SQL Server Database Engine instance.

Create and configure an Azure SQL Database Server

In the Azure portal, create an SQL Database Server for hosting the Business Central database. For more information about how to create and configure an SQL Database server, see Create your first Azure SQL Database.

Here are some important notes when creating the Azure SQL Database:

1. Specify a login name and password for the server. You'll use this information in the next steps when you deploy the Business Central database to Azure SQL and set up the Business Central Server to authenticate with the database.
2. Configure the server to allow for access by Windows Azure Services.
3. Make a note of the SQL Database server name because you'll need it later.

   The name has a format similar to: `mysqldatabaseserver.database.windows.net`.
4. Configure the server firewall to allow for access by the IP address of the computer that you're using to deploy the Business Central database.

   For information, see How to: Configure Firewall Settings (Azure SQL Database).

Prepare the Business Central Database(s)

Make sure the database meets these requirements:

1. Upload a valid Business Central license file to the database.

   For more information, see Uploading a License File for a Specific Database.
2. Delete all users of the database that use Windows authentication.

   Make sure to delete `NT AUTHORITY\NETWORK SERVICE` and `NT AUTHORITY\SYSTEM`. Only users with SQL

authentication are allowed in Azure SQL Database.

3. Delete any deadlock monitors for the Business Central database.

   SQL Server Management Studio, you can run a query similar to the following query:

   ```
   use [Demo Database BC (14-0)]

   DROP VIEW [dbo].[deadlock_report_event_file_view]
   ```

   For more information about the deadlock monitor, see Monitoring SQL Database Deadlocks.

Deploying using BACPAC files

For smaller databases (typically up to 50 GB), you can deploy them using a BACPAC file. This method requires the database to be off-line (the Business Central Server instance cannot be connected to the database).

For multi-tenancy mode installations, complete the steps for both the application database and the tenant databases.

Export Business Central Database to a BACPAC File

When you deploy your application online, you must provide a compressed .zip file that contains the database as data-tier application file, known as BACPAC (.bacpac) file. This article describes how you to create the BACPAC files and zip. You can do this using SQL Server Management Studio or the SqlPackage.exe command-line tool.

1. In SQL Server Management Studio, connect to the server instance that hosts the database.
2. In **Object Explorer**, right-click either the database, choose **Task**, and then choose **Export Data-tier Application**.
3. Follow the steps in the **Export Data-tier Application** wizard to export the database to a BACPAC file on your computer or network.

   You can use any name for the BACPAC file. For more information about exporting databases to BACPAC format, see Export a Data-tier Application.

Import the BACPAC to Azure SQL

In this task, you'll import the BACPAC files to the Azure SQL Database server instance.

1. In SQL Server Management Studio, connect to Azure SQL Database server instance that you created.
   a. Select **File** > **Connect Object Explorer**.
   b. In the **Server Name**, enter the server name assigned to your Azure SQL Database server.

      For example, *mysqldatabaseserver.database.windows.net*. You can get this information from the **Overview** page in the Azure portal.

   c. Set **Authentication** to **SQL Server Authentication**.
   d. Enter the login name and password that you set up in the first task when creating the Azure SQL Database server.
   e. Select **Connect**.
2. Import the BACPAC file that you created for the Business Central Database.

   This step creates a new database on the Azure SQL Database server instance. The database is based on the BACPAC file. It uses the same schema and includes all the data of the original database.

a. In **Object Explorer**, right-click the **Databases** folder for the Azure SQL database, and select **Import Data-tier Application**.

b. Follow the wizard. On the **Import Settings** page, browse for the BACPAC that you create, and choose **Next**.

   During this step, you'll specify a name for the database. You can give it any valid name you like.

c. Review the **Database Settings** page. Make changes if needed, and then choose the **Next** > **Finish**.

Now, you're ready to configure the Business Central Server instance.

Deploying/migrating existing databases

For larger databases (typically bigger than 50 GB), deployments with BACPAC file aren't recommended. Instead, we recommend using the migration tools and options described in the Azure Database Migration Guide.

Configure the Business Central Server instance

The next task is to configure the Business Central Server instance to connect to the databases in Azure SQL Database. You can configure the server instance using the Business Central Server Administration tool or the Set-NAVServerConfiuration cmdlet of Business Central Administration Shell.

1. Set up SQL Server authentication that uses the login account for the application database in Azure SQL Database.

   For more information, see Configuring SQL Server Authentication.

2. Configure the database connection settings to point to the application database:

SETTING (KEY)	VALUE
Database Instance (DatabaseInstance)	Empty
Database Name (DatabaseName)	The name of the database in Azure SQL Database.
Database Server (DatabaseServer)	The name of the Azure SQL database server, for example, *mysqldatabaseserver.database.windows.net*.

   For more information, see Configuring Business Central Server.

3. Restart the Business Central Server instance.

   The Business Central database is now deployed and configured on Azure.

   - If you have a single-tenant server instance, your deployment is ready to use.
   - If you have a multitenant server instance, go to the next step.

4. Mount the tenant database (multitenant-only).

   The final step in a multi-tenant deployment is to mount Azure SQL Database that holds the business data as a tenant on the Business Central Server instance. Mount the tenant using the Business Central Server Administration tool or Mount-NAVTenant cmdlet of Business Central Administration Shell.

   When mounting the tenant, provide the following information:

SETTING (KEY)	VALUE
Database Name (DatabaseName)	The name of the tenant database in Azure SQL Database.
Database Server (DatabaseServer)	The name of the Azure SQL database server, for example, *mysqldatabaseserver.database.windows.net*.
Login name and password (DatabaseCredentials)	The credentials of the login account used of Azure SQL Database server instance.

For more information, see Mount or Dismount a Tenant on a Microsoft Dynamics Server Instance.

Additional information

Changing database login account database

If you want to use a different login account for the database, do the following steps:

1. Create a new login that uses SQL Server authentication.

   For more information, see Create a Login.

2. Map the login to a user in the Business Central database, and add the user to the **db_owner** role of the Business Central database.

   For more information, see Create a Database User.

Colocation of the Business Central Server instance and the database

To minimize network latency between the Business Central Server instance and a database running on Azure SQL and optimize performance, we recommend that the Business Central Server instance that connects to the database is deployed onto a virtual machine in Azure. Additionally, the virtual machine and the database must be in the same Azure region.

Differences between Azure SQL database and SQL Server

When comparing the performance of Azure SQL database and a SQL Server deployed to a virtual machine, a few things are important to take into account:

- Azure SQL database is a high-availability database with a number of secondary replicas where writes must be confirmed for commits to be done. Secondary replicas will affect the performance of write operations (any inserts, updates, or deletes). For high throughput systems, running the database on SQL Server might be a better option. In this case, high-availability can be achieved using delayed durability or async commits. This condition will affect the data volume that you're ready to sacrifice if a database crash occurs.
- Azure SQL database is a scalable and intelligent service that includes features such as high-availability, backups, automatic index tuning, security vulnerability assessment, and advanced threat detection. When choosing a pricing tier for running your production database, make sure that you compare Azure SQL database to a similar setup for SQL Server on a virtual machine (including the cost of administration and maintenance).
- The performance of an Azure SQL database is correlated to the price you pay for usage, and new pricing models evolve over time. Use the scalability options within the service to change the database performance tier for your installation as your workload changes over time.

Reducing Data Stored in Business Central Databases

2/17/2021 • 2 minutes to read • Edit Online

The article provides an overview of the different ways to reduce the amount of data stored in a Business Central database. Reducing the size of your database serves the following purposes:

- Prevents reaching the size limit when using Business Central online.
- Improves runtime performance.
- Improves database management processes, like backing up and restoring databases.

These measures are typically done by an application administrator or developer.

Delete unused companies

If you have companies that are no longer needed, such as test companies or the Demo company, delete these companies.

Delete documents

Over time, the database will accumulate historical data for documents, like invoiced purchase orders. If these documents are no longer needed, delete them.

For more information, see Manage Storage by Deleting Documents or Compressing Data.

Use retention policies

Retention policies allow you to specify how frequently you want Business Central to automatically delete outdated data in tables that contain log entries and archived records.

For more information, see Define Retention Policies.

Migrate BLOB data types to Media or MediaSet

Data in Media or Media set data types aren't counted in the database limit. As an extension developer, consider migrating data from blobs to the Media or MediaSet datatypes for your own extensions.

For more information, see Working With Media on Records.

Compress tables

Business Central supports data compression of tables. Compressing table data saves space and helps improve performance of I/O-intensive workloads.

> **NOTE**
> With Business Central online, page-level data compression is automatically enabled on tables in a tenant. It's applied to Microsoft extensions and third-party extensions, unless the **CompressionType** property on a table is explicitly set to `None`.

There are two ways to enable or change data compression in Business Central:

- On a table-level, use the CompressionType property on table objects.
- On a database-level (on-premises only), use the Start-NAVDatabaseCompression cmdlet. This cmdlet is only available with Business Central 2020 release wave 1 and later.

For more information about data compression, see Data Access - Using SQL Server data compression.

Introducing the Dynamics 365 Business Central Mobile App

2/17/2021 • 3 minutes to read • Edit Online

The app displaying the Business Central tablet client and Business Central phone client is targeted at users in small and medium sized businesses that want to access data from a tablet or a phone. The main advantages of this offering are portability and flexibility, which allows end users to perform tasks when they are away from their desk. Having a Dynamics 365 Business Central solution that runs on a smaller device also brings it in the hands of many more users and your app is easy to distribute.

> **IMPORTANT**
>
> The Business Central tablet client and Business Central phone client do not replace the Business Central Web client. Instead, they offer a touch interface for a limited set of application scenarios compared to the Business Central Web client.

The Business Central Web client supports more complex business processes and heavier data entry than it is possible on the Business Central tablet client and Business Central phone client. Business Central is also designed for intensive use, and the user can have multiple windows open at the same time, but this is neither possible in Business Central phone client or Business Central tablet client. For more information, see Differences and Limitations When Developing Pages for the Business Central Mobile App.

The design for the Business Central tablet client is optimized for the touch experience and reduced use of the on-screen keyboard. On the other hand, the design for the Business Central phone client is about touch optimization, given its smaller screen size. The Business Central phone client layout is designed to support one-hand and both hands use, which allows the important data and buttons to be available within thumbs reach.

> **NOTE**
>
> In this documentation, you will see mentions of Business Central tablet client, Business Central phone client, and *Dynamics 365 Business Central Mobile App*. Business Central tablet client and Business Central phone client describe the interface tailored to the category of mobile device, which is one of the tools available for developers for designing mobile solutions, whereas *Dynamics 365 Business Central Mobile App* is the common name for the app across all devices; the end result made with these tools.

Considering the user scenarios

When you design your solution for the Business Central tablet client and the Business Central phone client, you must make sure that scenarios are simple enough to be meaningful and usable. The tablet and phone designs are meant for lighter tasks and are useful, for example, for traveling salespeople or service technicians who need a portable, online, easy-to-use app that provides an overview, for example, of daily tasks and items in stock.

Depending on the scenarios that your tablet and phone solution will support, it will either make sense to create a new Role Center for tablet and phone only, or share the same Role Center across all of the client types. In some cases, it can make sense to have a user sign in with two different profiles, one for a desktop client and one for mobile devices. In other cases, duplicating pages and designing specific duplicates to be device-oriented is the best solution.

If you have existing page objects that you want to make available on Business Central tablet client or Business Central phone client, we strongly recommend that you plan time to evaluate carefully which actions, sections,

and fields will be needed for the user scenarios you want to enable. Fields and actions that are not needed should not be visible to users of your app. The UI must be simplified significantly to work well on a small device. For more information, see Designing for Different Screen Sizes on Tablet and Phone.

Supported credential types

Business Central tablet client and Business Central phone client support the same credential types as Business Central Web client. For more information, see Authentication and Credential Types.

Preparing For and Installing the Microsoft Dynamics 365 Business Central App

2/17/2021 • 2 minutes to read • Edit Online

This article describes how to prepare for and install the Business Central App when you have on-premises solution. If you have a Business Central Online, there is no preparation (see Getting Business Central on Your Mobile Device).

The Business Central App is available for download for devices that use following operating systems (OS):

OS	DESCRIPTION	DOWNLOAD
iOS	Mobile app for iPad and iPhone	App Store
Android	Mobile app for Android phones	Google Play
Windows 10 or Xbox One	A companion desktop app that mimics that Business Central Web client but has the same look-and-feel as mobile apps.	Windows Store

Like the Business Central Web client, the Business Central App relies on a Business Central web server instance that connects to Business Central Server and database. The Business Central App uses the same application code as the Web client, except it renders the application in a different format.

Preparing the environment

To install a working Business Central App, the following requirements must be met:

- You must have a working Business Central on-premises solution that includes a web server instance, server, and database (application and business data).
- The Business Central Web Server instance must be configured for:
  - https (SSL)
  - For the iOS app, the navsettings.json file must include the `"GlobalEndPoints"` parameter with the following endpoints as a minimum: null, ms://businesscentral, and ms://dynamicsnav. For example:

    ```
    "GlobalEndPoints": "null,ms://businesscentral,ms://dynamicsnav"
    ```

    You can set other endpoints, but these endpoints must be included for the app to work.
- You are set up as a user in Business Central.

  If you installed Business Central, then by default, your Windows account has been added as a user.
- The computer on which you install the app must meet the requirements outlined on the download page for the app.

Install the Business Central App

1. Go to the download page from links provided in the preceding table, and select **Get**.

   You can also install the desktop app by running setup.exe from the Dynamics 365 Business Central installation media (DVD). Follow Setup until you come to the **Dynamics 365 Business Central** page, select **Get the Business Central app from the Microsoft Store**, and then **Get**.

2. On the **Welcome** page, select **Connect to a local or hosted service**.

3. In the **Service name** box, enter the URL for your Business Central Web Server instance.

   This is the same URL that you use for opening the Business Central Web client, and has the format: `https://<hostname>:<port>/<web server instance>`, for example, `https://mycomputer:443/BC150`.

   Select the arrow to continue.

4. When prompted, provide a valid user name and password for accessing Business Central.

   For example, if your deployment is using Windows authentication, this would be your Windows user name and password.

   Select the arrow to continue.

   When completed, the Business Central App will open.

Using HTTPS and Certificates in Business Central Mobile App

2/17/2021 • 2 minutes to read • Edit Online

Business Central Mobile App only works using an HTTPS protocol. This means that you must configure a valid certificate on the server. If a trusted, valid, and signed certificate is configured on the Business Central Server, the end user does not have to do anything. However, if a self-signed certificate is configured on the Business Central Server, the end user must install a certificate on their device. The steps for implementing certificates will vary depending on the platform the user is using.

For more information, see Using Security Certificates with Business Central On-Premises.

> **IMPORTANT**
> It is recommended to *only* use self-signed certificates for testing purposes and never in a production environment.

Business Central Server Administration tool

2/17/2021 • 4 minutes to read • Edit Online

The Business Central Server Administration tool is a Microsoft Management Console (MMC) snap-in for creating and managing Business Central Server instances.

> **TIP**
> You can also administrate your Business Central deployment using Windows PowerShell cmdlets. For more information, see Microsoft Dynamics 365 Windows PowerShell Cmdlets.

Install the Business Central Server Administration tool

To install Business Central Server Administration tool, use the Business Central Setup and choose either **Server Option** or **Administration Tool** under the custom options page. For more information, see Installing Business Central Using Setup.

Run the Business Central Server Administration tool

You typically run the Business Central Server Administration tool by choosing **Business Central Administration** from the Start menu. Or, you can open the MMC first and then add the Business Central snap-in. In this case, choose **Run** from the Start menu and then specify the Microsoft Management Console:

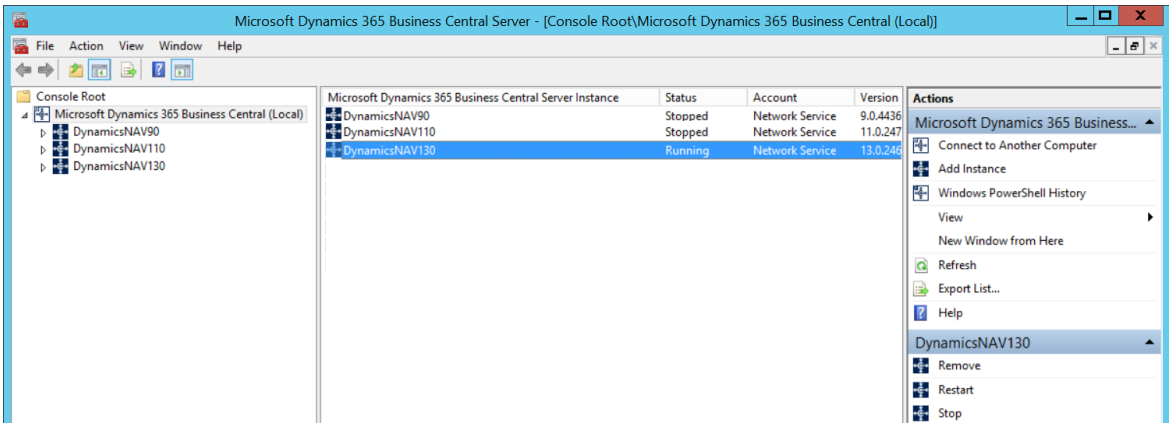
```
mmc
```

> **IMPORTANT**
> Only members of the Administrator group on the computer are able to use the Business Central Server Administration tool.
>
> The Business Central Server Administration tool is not supported for multi-user environments.

Navigating the Business Central Server Administration tool

Business Central Server Administration tool is divided into panes:

- The left pane shows a tree view that lists all Business Central Server computers that you are administering from this computer and all Business Central Server instances on those computers.



- The **center pane** shows information about the item that you have selected in the left pane. When the selected item is a computer running Business Central Server, the center pane shows a list of Business Central Server instances on that computer and the status of each instance (running or stopped), and the name of the account the instance is running under.

  When the item selected in the left pane is a Business Central Server instance, the center pane shows the settings for that instance. For information about a specific setting, see Configuring Business Central Server Instances.

- If the Business Central Server is configured for multitenancy, then you can expand the Business Central Server instance items in the left pane to display a **Tenants** item. Select the **Tenants** item to display all the tenants that are mounted on a Business Central Server instance in the center pane. For more information, see Multitenant Deployment Architecture

- The **right pane** displays available actions for the object that is selected in the left pane. These options differ depending on whether a Business Central Server computer or a Business Central Server instance is selected.

- The **Windows PowerShell History** pane lists the Windows PowerShell commands that the equivalent of the tasks you perform in the Business Central Server Administration tool. You can access the Windows PowerShell History pane from the **Actions** menu and from the right pane. To run a command that is shown in the **Windows PowerShell History** pane, you can copy the command and paste it into the Dynamics NAV Administration Shell, for example.

Connect to remote computers and multiple server instances

You can use the Business Central Server Administration tool to connect to other computers on your network where Business Central Server instances are installed, and then manage those instances.

1. Configure the remote computers to receive Windows PowerShell remote commands by running the Enable-PSRemoting cmdlet on each computer.

2. Next, you can start the Business Central Server Administration tool.

3. If you want to connect to a single remote computer, you can start the Business Central Server Administration tool from the Start menu of your computer.

4. If you want to connect to multiple remote computers, you must start the Business Central Server Administration tool from the **Run** program that you can access in the Start menu,

   a. Enter the command `mmc`.
   b. In the Management Console, on the **File** menu, choose **Add/Remove Snap-in** to open the **Add or remove Snap-ins** dialog box.
   c. In the **Available snap-ins** list, double-click **Microsoft Dynamics 365 Business Central**.

d. In the **Connect to another computer** dialog box, type the name of a Business Central Server computer in the **Server Name** box, and then choose **OK**.
e. Double-click *Microsoft Dynamics 365 Business Central** again, and then enter the name of a different Business Central Server computer in the **Server Name** box. Choose **OK**.

You can also accept the default value, which is **(Local)**, if this is one of the Business Central Server computers that you will be administering.

f. Continue selecting Business Central Server computers as needed. When you are finished selecting computers, choose **OK** to close the **Add or remove Snap-ins** dialog box.

Now you see multiple Business Central Server computers listed in the tree view pane of the Business Central Server Administration tool.

> **TIP**
> When you close MMC, you are prompted to save your settings to a Microsoft Management Console (.msc) file. If you save your settings, then you can use this file to open MMC with your Business Central Server computers already listed

Authentication and Credential Types for Dynamics 365 Business Central

2/17/2021 • 4 minutes to read • Edit Online

In Business Central online, users are added through the Microsoft 365 admin center. Once users are created in Microsoft 365, they can be imported into the **Users** window in Business Central. For more information, see Managing Users and Permissions in the business functionality content.

Configuring Authentication for On-Premises Deployments

An on-premises deployment of Business Central supports several credential authorization mechanisms for users. When you create a user, you provide different information depending on the credential type that you are using in the current Business Central Server instance.

> **IMPORTANT**
>
> All users of a Business Central Server instance must be using the same credential type. In on-premises deployments, you can specify which credential type is used for a particular Business Central Server instance in the Business Central Server Administration tool.

Credential Types

Business Central on-premises supports the following credential types.

CREDENTIAL TYPES	DESCRIPTION
Windows	With this credential type, users are authenticated using their Windows credentials. You can only specify Windows as the credential type if the corresponding user exists in Windows (Active Directory, local workgroup, or the local computer's users). Because they are authenticated through Windows, Windows users are not prompted for credentials when they access Business Central.
UserName	With this setting, the user is prompted for username/password credentials when they access Business Central. These credentials are then validated against Windows authentication by Business Central Server. There must already be a corresponding user in Windows. Security certificates are required to protect the passing of credentials across a wide-area network. Typically, this setting should be used when the Business Central Server computer is part of an authenticating Active Directory domain, but the computer where the Dynamics NAV Client connected to Business Central is installed is not part of the domain.

CREDENTIAL TYPES	DESCRIPTION
NavUserPassword	With this setting, authentication is managed by Business Central Server but is not based on Windows users or Active Directory. The user is prompted for username/password credentials when they start the client. The credentials are then validated by an external mechanism. Security certificates are required to protect the passing of credentials. This mode is intended for hosted environments, for example, where Business Central is implemented in Azure.
AccessControlService	With this setting, Business Central relies on Azure Active Directory (Azure AD) for user authentication services. Azure AD is a cloud service that provides identity and access capabilities, such as for applications on Azure, in Microsoft Microsoft 365, and for applications that install on-premises. If the Business Central Server instance is configured to use AccessControlService authentication, you can specify an Azure AD account for each user in the **Office 365 Authentication** field so that they can access both the Business Central and their Microsoft 365 site. Also, if you use Business Central in an app for SharePoint, users have single sign-on between the SharePoint site and Business Central. For more information, see Authenticating Users with Azure Active Directory or Authenticating Users with Active Directory Federation Services. Security certificates are required to protect the passing of credentials across a wide-area network.
None	For internal use on system sessions and typically should not be used. If you choose **None**, then the Business Central Server instance cannot start.
ExchangeIdentity and TaskScheduler	For internal use only. Do not use.

IMPORTANT

If Business Central Server is configured to use NavUserPassword or AccessControlService authentication, then the username, password, and access key can be exposed if the SOAP or OData data traffic is intercepted and the connection string is decoded. To avoid this condition, configure SOAP and OData web services to use Secure Socket Layer (SSL). For more information, see How to: Implement Security Certificates in a Production Environment in the ITPro content for Microsoft Dynamics NAV 2018.

Configuring the Credential Type for Client and Server

For on-premises deployment, you must make sure that clients and Business Central Server are configured to use the same credential type.

When you change the credential type for a Business Central Server instance and the relevant client configurations, the changes take effect when you restart the Business Central Server instance and users connect to the instance again.

Server Configuration

To edit the configuration for the Business Central Server instance, you can use either the Business Central Server Administration tool or the Business Central Administration Shell. In the Business Central Server Administration tool, you configure the credential type in the **Credential Type** field on the **General** tab. Alternatively, you can edit the CustomSettings.config file. For more information, see Configuring Business Central Server.

Client Configuration

In the relevant configuration file, find the **ClientServicesCredentialType** parameter and change the value to one of the options listed earlier.

For the Business Central Web client users, you must modify the *navsettings.json* for the Business Central Web Server. The navsettings.json file is a Java Script Object Notification file type that is similar to files that use the XML file format. The file is stored in the physical path of the web server instance, which is by default is *c:\inetpub\wwwroot\BC160*. For more information, see Settings in the navsettings.json.

For each Dynamics NAV Client connected to Business Central user, you must modify the ClientUserSettings.config file. The default location for this file is **C:\Users\<username>\AppData\Roaming\Microsoft\Microsoft Dynamics NAV\130**, where *<username>* is the name of the user. For more information, see Configuring the Microsoft Dynamics NAV Windows Client in the ITPro content for Microsoft Dynamics NAV 2018.

Security Certificates

With UserName, NavUserPassword, and AccessControlService credential types require that you install and configure security certificates on components. For more information, see Using Security Certificates with Business Central On-Premises

Configuring Business Central Server

Configuring Business Central Server

2/17/2021 • 65 minutes to read • Edit Online

When you run Business Central Setup and install Business Central Server, you provide information that is then used as the configuration for the default Business Central Server instance. This information is stored in a configuration file for the server instance called CustomSetting.config. The default location of the CustomSettings.config file is *C:\Program Files\Microsoft Dynamics 365 Business Central\160\Service*.

After you install Business Central Server, you can change any of the settings, including other settings that weren't available to you in Setup.

> **NOTE**
> Each Business Central Server instance has its own CustomSettings.config file.

Configuring Business Central Server in Setup

You configure the default instance of Business Central Server by running Business Central Setup and selecting one of the following options:

- Demo Option
- Server Option
- Developer Option
- Customize > Server

After you specify an installation option or customize your component list, the **Specify parameters** pane is displayed in Setup. The list of parameters that you see depends on which components you've selected for configuration. Setup provides a short description for each parameter.

Configuring Business Central Server After Installation

After you install Business Central Server, you can change the configuration settings in the CustomSettings.config file of a Business Central Server instance in the following ways:

- Using the Business Central Server Administration tool.

  For more information, see Settings in the Business Central Server Administration Tool and Business Central Server Administration Tool.

- Using the Set-NAVServerConfiguration cmdlet that is available in the Business Central Administration Shell.

  For more information, see Using Administration Shell Cmdlets to Modify Settings.

- By directly editing CustomSettings.config using a text editor.

  We recommend that you don't directly edit the configuration file. If you make any errors in typing, the server instance might not start.

Restarting Business Central Server after modifications

If you use the Business Central Server Administration tool or modify the CustomSettings.config file directly, you must restart the Business Central Server instance before any changes can take effect.

The Set-NAVServerConfiguration cmdlet doesn't always require restarting the server instance. It depends on the configuration setting that you change. There are several settings that are *dynamically updatable*. *Dynamically updatable* means that a server instance restart isn't necessarily required after modification. For more information, see Modifying dynamically updatable settings.

These settings are indicated by the text **Dynamically Updatable: Yes** in the tables that follow,

Business Central Server Instance Settings

This section describes all the configuration settings for a Business Central Server instance. The settings are grouped according to the tabs under which they appear in the Business Central Server Administration tool.

- The **Setting** column displays the name of the setting as it appears in the Business Central Server Administration tool.
- The **Key Name** column displays the name of the setting as it appears in the CustomSettings.config file. It's

also the name for the setting when you run the Set-NAVServerConfiguration cmdlet.

General Settings

The following table describes fields on the **General** tab in the Business Central Server Administration tool.

SETTING	KEY NAME	DESCRIPTION
AL Function Logging Threshold - Application Insights	ALLongRunningFunctionTracingThresholdForApplicationInsights	Specifies the amount of time (in milliseconds) that an AL function can run before a warning event is recorded in the partner's Application Insights resource trace log. If you don't want a threshold, set the value to -1. To collect this telemetry data, the **Application Insights Instrumentation Key** setting must be configured. For information about analyzing this telemetry, see Analyzing Long Running AL Methods Telemetry. Default: -1 Dynamically Updatable: Yes **APPLIES TO:** Business Central 2020 release wave 2 (version 17.1) and later.
Application Insights Instrumentation Key	ApplicationInsightsInstrumentationKey	Specifies the instrumentation key of the Microsoft Azure Application Insights resource to use for gathering and analyzing telemetry data emitted by the server instance. When this setting is configured, the server instance will send telemetry data to Application Insights for analysis and presentation. This setting only applies to a server instance that is configured as a single-tenant instance (**Multitenant** setting is disabled). For a multitenant server instance, this setting is ignored. You set the Application Insights instrumentation key on a per-tenant basis, when you mount tenants. For more information, see Enable Sending Telemetry to Application Insights. Default: empty Dynamically Updatable: No

SETTING	KEY NAME	DESCRIPTION
Build Restriction	ClientBuildRestriction	Specifies what happens when a Business Central client tries to connect to the Business Central Server instance when the client is running a different build version of Business Central than the server instance. Values: **AlwaysConnect** **WarnClient** Before connecting the client to the server instance, a message appears that informs the user that the build versions for the client and server instance are different. The user can choose to continue or cancel the connection. **DoNotAllow** A message appears that informs the user that the client and server instance build versions are different. The client doesn't connect to the server instance. **Note:** With the Business Central Web client and Business Central tablet client, this setting compares the build version of the Business Central Web Server on IIS with the Business Central Server instance. It controls the connection between Business Central Web Server and the server instance. Default: WarnClient Dynamically Updatable: No
Certificate Thumbprint	ServicesCertificateThumbprint	If you use security certificates to protect communications between Business Central Server and client services or web services over an open or wide-area network, you must provide the certificate thumbprint to Business Central Server by updating this setting. For more information, see Using Security Certificates. Default: Dynamically Updatable: No

SETTING	KEY NAME	DESCRIPTION
Compile and Load Business Application	CompileBusinessApplicationAtStartup	Specifies whether the server instance compiles business application assemblies and loads them to cache memory when it starts. The assemblies are then retrieved from memory when requested by a Business Central client. This setting reduces the time it takes to load application objects the first time the client requests them after the server instance has started. However, it will also slightly increase the memory usage by the server instance. When the server instance starts for the first time, it compiles the business application assemblies and loads them to the cache memory of the computer. The assemblies, along with metadata such object timestamp information, are also stored to a temporary folder on the computer's file system. When the server instance is restarted, it compares the assemblies stored in memory with corresponding objects in the connected database. An assembly will be reused if the following conditions are met: - The connected database is the same as before, based on the *databasemagic* field in the property table. - The object time stamp that is recorded on the compiled assembly matches the object timestamp in metadata of the connected database. If the conditions aren't met for an assembly or an assembly for an object in the database isn't found in the memory, then a new assembly is built and stored for reuse to cache memory and the file system of the server instance compute for reuse. If you disable this setting, individual assemblies will be compiled on-demand as application objects are requested by the Business Central client. The compiled assemblies won't be reused on later server instance restarts. Notes: • This setting doesn't apply to query objects. • Assembly compilation happens asynchronously. • On average, all application objects will be loaded within the first few minutes that the server instance operates. Default: Enabled Dynamically Updatable: No

SETTING	KEY NAME	DESCRIPTION
Credential Type	ClientServicesCredentialType	Specifies the authentication mechanism for Business Central users of the Business Central Server instance. The options are **Windows**, **Username**, **NavUserPassword**, **AccessControlService**, and **None**. For more information, see Authentication and User Credential Types. If you choose **AccessControlService**, you must specify a federation metadata location for use with Azure AD. If you choose **NavUserPassword** and specify a token signing key, you can use both NavUserPassword and AccessControlService. Notes: • **None** is for internal use on system sessions and typically shouldn't be used. If you choose **None**, then the Business Central Server instance can't start. • **ExchangeIdentity** and **TaskScheduler** are for internal use only, and shouldn't be used. Default: Windows Dynamically Updatable: No
Data Cache Size	DataCacheSize	The contextual size of the data cache. The value must be in the range 1-20. Default: 9 Dynamically Updatable: Yes
Default Client	DefaultClient	Specifies the client type that is used to generate URLs when the client type is set to Default. The options are **Conversational**, **Windows**, **Web**, **SOAP**, and **OData**. Default: Conversational Dynamically Updatable: No

SETTING	KEY NAME	DESCRIPTION
Default Language	DefaultLanguage	Specifies which of the installed Business Central languages on the server instance will be used as the default language in the clients. Set the value to a valid language culture name, such en-US or da-DK. In the web and tablet clients, this setting determines the language used if the browser's language setting doesn't match any installed language or a language in the **Supported Languages** setting. In the Business Central Windows client, this value is used if the language setting of the computer doesn't have a match. If there are application-specific configuration settings, this setting will be overridden by the default language setting that is specified in application-specific configuration file. For more information, see Set-NAVServerAppConfiguration cmdlet. Default: en-US Dynamically Updatable: No
Diagnostic Trace Level	TraceLevel	Specifies the lowest severity level of custom telemetry events to be emitted and recorded in the event log for the Business Central Server instance. The events include system telemetry trace events and custom telemetry events. Telemetry events have IDs from 700-706. The setting has the following values, which correspond to the event severity levels (listed from highest to lowest level): **Critical**, **Error**, **Warning**, **Normal** (this value corresponds to the **Information** level), **Verbose**, and **Off**. You use this setting to filter out lower-level events from the log. For example, if you set this setting to **Error**, only **Error** and **Critical** events will be logged. Set to **Off** if you don't want to record telemetry events. When set to **Off**, events aren't emitted. **Note:** Telemetry trace events are recorded in the Business Central Server channel logs, which you can see in Event Viewer, under **Applications and Services Logs** > **Microsoft** > **DynamicsNAV** > **Common** > **Admin**. Default: Normal Dynamically Updatable: Yes

SETTING	KEY NAME	DESCRIPTION
Diagnostic Trace Level for External Proxies	ExternalTraceLevel	Specifies the lowest severity level of telemetry events from external proxies that you want the Business Central Server instance to emit if an error related to the external system occurs on the server instance. This setting pertains to systems and components that Business Central integrates with, like Dynamics 365 Sales (CRM/Xrm). The server instance listens for event traces from the external proxy. If an error occurs on the server instance, it will emit the last 10 telemetry trace events from the external proxy. The trace events can then be recorded in the Windows event log or picked up by other event trace collection tools. The setting has the following values, which correspond to the event severity levels (listed from highest to lowest level): **Critical**, **Error**, **Warning**, **Information**, **Verbose**, and **Off**. Events that have a lower severity level than the set value won't be emitted. For example, if you set this setting to **Error**, only **Error** and **Critical** events will be emitted. Set to **Off** if you don't want to emit any of these events. Default: Error Dynamically Updatable: Yes
Disable Token-Signing Certificate Validation	DisableTokenSigningCertificateValidation	Specifies whether to enable or disable the validation of the token-signing certificate used by Active Directory Federation Services (AD FS). If the check box is cleared (or the value set to `false`), the validation is enabled. If the check box is selected (or the value is set to `true`), then validation is disabled. Disable token signing certificate validation when configuring Azure Active Directory authentication with single sign-on. Default: Checkbox cleared; set to `false`. Dynamically Updatable: No
Enable AL Function Timing	ALFunctionTimingEnabled	Specifies whether AL function timing is enabled. When enabled, data about AL extension performance will be collected and can be viewed in Application Insights and page inspection. For more information, see Analyzing Long Running AL Methods Telemetry and Inspecting and Troubleshooting Pages. Default: Enables Dynamically Updatable: Yes **APPLIES TO:** Business Central 2020 release wave 2 (version 17.1) and later.
Enable Certificate Validation	ServicesCertificateValidationEnabled	Specifies whether validation is done on the security certificate. Default: Enabled Dynamically Updatable: No

SETTING	KEY NAME	DESCRIPTION
Enable Debugging	EnableDebugging	Specifies whether the Business Central Server instance starts with debugging enabled. If this option is enabled, the following occurs: When the client first connects, all C# files for the application are generated. C# files persist between Business Central Server restarts. Application objects are compiled with debug information. Default: Not enabled Dynamically Updatable: No
Enable Event Logging to Windows Application Log	EnableApplicationChannelLog	Specifies whether to record admin and operational type events in the **Windows Application** log. This setting will record errors, warnings, and information messages that occur on server instance. The events are stored on the computer that is running Business Central Server. Because Business Central Server instance events are always logged to the **Application and Services Logs**, you can disable logging Business Central Server instance events in the Windows Application log and not lose any data. For more information, see Monitoring Business Central Server Events Using Event Viewer and Disable Logging Events to the Windows Application Log. **Important:** If you 're using System Center Operations Manager to monitor Business Central Server instances, don't disable logging to the Windows Application log. If you do, monitoring won't work. Default: Enabled Dynamically Updatable: No
Enable File Access by AL Functions	EnableALServerFileAccess	Specifies whether AL functions of the file data type can access files on the Business Central Server computer. Default: Enabled Dynamically Updatable: No
Enable Full AL Function Tracing	EnableFullALFunctionTracing	Specifies whether full AL function tracing is enabled on Event Tracing for Windows (ETW) sessions. When this setting is enabled, all AL function calls and statements are traced. When this setting is disabled, only root AL function calls are traced. Statements and functions that are called from a function aren't traced. For more information, see Monitoring Business Central Server Events . Default: Not enabled Dynamically Updatable: Yes

SETTING	KEY NAME	DESCRIPTION
Enable Incremental Company Deletion	UseIncrementalCompanyDelete	Specifies whether to delete companies incrementally. If enabled, when you delete a company, the company record is deleted from the database immediately. But the company data that is stored in the SQL tables will be deleted later by a system task in task scheduler. You can override this setting when using the Remove-NAVCompany cmdlet by setting the -ForceImmediateDataDeletion parameter. Default: Not enabled Dynamically Updatable: Yes
Enable Partial Records	EnablePartialRecords	Specifies whether records can be partially loaded with only some fields. Other fields are loaded as needed, or in other words, just-in-time loaded. For more information, see Using Partial Records. Default: Enabled Dynamically Updatable: No
AllowSessionWhileSyncAndDataUpgrade	AllowSessionWhileSyncAndDataUpgrade	Specifies whether new client sessions can be created while the tenant's state is **OperationalWithSyncPending**. The **OperationalWithSyncPending** state occurs when changes have been made to application tables, but the changes haven't been synchronized with the tenant. In this state, unless you enable client sessions, clients trying to connect with will get an error message similar to: **The tenant 'tenantID' is not accessible**. Default: Not enabled Dynamically Updatable: Yes
Lockout Sign-In Attempts Count	LockoutPolicyFailedAuthenticationCount	Specifies the number of failed sign-in attempts on a user account (within the time window set by the **Lockout Failed Sign-In Attempts Window** setting) at which the user account is disabled. Default: 0 Dynamically Updatable: No
Lockout Failed Sign-In Attempts Window	LockoutPolicyFailedAuthenticationWindow	Specifies time window, in seconds, during which consecutive failed authentication attempts are counted. This setting works in conjunction with the **Account Lockout Max. Sign-In Attempts** setting. When the number of failed sign-in attempts by a user hits the value of the **Account Lockout Max. Sign-In Attempts** setting within this time window, the user account is disabled. Default: 0 Dynamically Updatable: No

SETTING	KEY NAME	DESCRIPTION
Max Concurrent Calls	MaxConcurrentCalls	The maximum number of concurrent client calls that can be active on this server instance. Range: 1 - 2,147,483,647 You can also use **MaxValue** as a value to indicate no limit. Default: 40 Dynamically Updatable: No
Max Data Rows Allowed to Send to Excel	MaxRowsToExportToExcel	Specifies the maximum number of rows that can be included in an Excel document that is generated from a list type page in the client. If you don't want to have a limit on rows, set the value to **MaxValue**. **Note:** This setting only pertains to list type pages in the client. For other pages types, like cards, the limit on rows is configured in the client. Default: MaxValue Dynamically Updatable: Yes
Maximum Stream Read Size	MaxStreamReadSize	Specifies the maximum number of bytes that can be read from a stream (InStream object) in a single AL read operation, such a READ or InStream.READTEXT function call. This setting pertains to UTF-8 and UTF-16 text encoding; not MS-DOS encoding. Default: 1000000 Dynamically Updatable: Yes
Multitenant	Multitenant	Specifies if the Business Central Server instance can be used in a multitenant environment. Tenant databases can only be mounted on the Business Central Server instance if this setting is selected. For more information, see Multitenant Deployment Architecture. Default: Not enabled Dynamically Updatable: No
Network Protocol	NetworkProtocol	Specifies the network protocol for accessing the database. Valid values: Default, Named, Sockets, MultiProtocol Default: Default Dynamically Updatable: No
Services Default Company	ServicesDefaultCompany	Specifies the Business Central company that the client services, OData web services, and NAS services use as the default company. If your Business Central database contains only one company, leave the setting blank. Default: Dynamically Updatable: No

SETTING	KEY NAME	DESCRIPTION
Services Default Time Zone	ServicesDefaultTimeZone	Specifies the time zone in which web service and NAS services calls are run. Values: **UTC** All business logic for web services and NAS services on the server instance runs in Coordinated Universal Time (UTC). **Server Time Zone** Services use the time zone of the computer that is running Business Central Server. **ID of any time zone recognized by the current version of Windows** Specifies any Windows time zone as defined in the system registry under HKEY_LOCAL_MACHINE\SOFTWARE\Microsoft\Windows NT\CurrentVersion\Time Zones. For example, Romance Standard Time. Default: UTC Dynamically Updatable: No
Services Language	ServicesLanguage	Specifies the global language version to use for text strings with SOAP and OData web services. The value must be valid culture name for a language that is available for the Microsoft Dynamics NAV solution, such as en-US and da-DK. Default: en-US Dynamically Updatable: No
Services Option Text Source	ServicesOptionFormat	Specifies the source of the text strings to use for the option values of an option data type field. Values: **OptionString** Uses the text strings that are specified by the OptionString Property of a field. **OptionCaption** Uses the text strings that are specified by the OptionCaption Property of a field. Default: OptionCaption Dynamically Updatable: No

SETTING	KEY NAME	DESCRIPTION
Session Event Table Retain Interval	SessionEventTableRetainInterval	Specifies the amount of time that sessions are stored in the **Session Event** table (ID 2000000111) before they are deleted. Sessions that exceed the time limit are first deleted the next time a purge is run on the **Session Event** table, as determined, in part, by the **SessionEventTablePurgeLookupPeriod** setting. The default is once a day. Time interval format: [dd.]hh:mm:ss[.ff] Where: dd: days hh: hours mm: minutes ss: seconds ff: hundredths of a second Default: 90.00:00:00 (90 days) Dynamically Updatable: No
Non-Interactive Sessions Log Retain Interval	NonInteractiveSessionsLogRetainInterval	Specifies the amount of time that background and web service sessions are stored in the **Session Event** table (ID 2000000111) before they are deleted. Sessions that exceed the time limit are first deleted the next time a purge is run on the **Session Event** table, as determined, in part, by the **SessionEventTablePurgeLookupPeriod** setting. The default is once a day. Time interval format: [dd.]hh:mm:ss[.ff] Where: dd: days hh: hours mm: minutes ss: seconds ff: hundredths of a second Default: 5.00:00:00 (5 days) Dynamically Updatable: No
not available	SessionEventTablePurgeLookupPeriod	Specifies how much time must lapse after the **Session Event** table is purged before it can be purged again. Purging is triggered when a new session of any type is created and the time that has lapsed since last purge exceeds the **SessionEventTablePurgeLookupPeriod** value. When the **Session Event** table is purged, all sessions older than the retain interval (as set by the **Session Event Table Retain Interval** or **Non-Interactive Sessions Log Retain Interval** settings) are deleted from the table. Time interval format: [dd.]hh:mm:ss[.ff] Where: dd: days hh: hours mm: minutes ss: seconds ff: hundredths of a second Default: 1.00:00:00 (1 day) Dynamically Updatable: No

SETTING	KEY NAME	DESCRIPTION
Supported Languages	SupportedLanguages	Specifies which of the installed Business Central languages on the server instance will be available for use in the clients. If you don't specify a language, then all installed languages will be available. In the client, users can switch among the supported languages. The setting's value is a semicolon-separated list that contains the language culture names for each language. For example, if you want client users to be able to choose among da-DK, en-US, and en-CA, set the value to da-DK;en-US;en-CA. If you specify any languages in this setting, then you must include the language that you specified in the Default Language setting. If there are application-specific configuration settings, this setting will be overridden by the supported language setting that is specified in application-specific configuration file. For more information, see Set-NAVServerAppConfiguration cmdlet. Default: Dynamically Updatable: No
Token Signing Validation Mode	TokenSigningCertificateValidationMode	Specifies which certificate validation mode to use for token signing validation. This setting is applicable only if the **Enable Certificate Validation** setting is selected. **IssuerNameValidation** validates tokens by verifying the issuer name (tenant) only. **PeerOrChainValidation** validates tokens by verifying that the certificate is either in the Trusted People store or is part of a chain trust to a certification authority in the Trusted Root store. Default: IssuerNameValidation Dynamically Updatable: No
UI Elements Removal	UIElementRemovalOption	Specifies whether UI elements are hidden when the related object isn't accessible according to the license or according to user permissions or both. For more information, see Hiding UI Elements. Default: LicenseFileandUserPermissions Dynamically Updatable: No
Use NTLM Authentication	ServicesUseNTLMAuthentication	Specifies whether NTLM authentication is enabled for web services. To require Kerberos authentication, disable this option. Default: Not enabled Dynamically Updatable: No
not available	XmlMetadataCacheSize	For internal use only. Default: 500

Database Settings

The following table describes fields on the **Database** tab in the Business Central Server Administration tool.

NOTE

If the Business Central Server instance is configured as a multitenant server instance, then except for the **Database Name**, **Database Instance**, and **Database Server** settings, the settings apply to both the application database and the tenant database.

SETTING	KEY NAME	DESCRIPTION
Database Instance	DatabaseInstance	The name of the SQL Server database instance to connect to. If the value is a null string (""), Business Central Server instance connects to the default database instance of SQL Server. If the Business Central Server instance is configured as a multitenant server instance, then this setting specifies the SQL Server database instance that hosts the application database. Default: NAVDEMO Dynamically Updatable: No
Database Name	DatabaseName	The name of the Business Central database in SQL Server. If the Business Central Server instance is configured as multi-tenant server instance, then this setting specifies the application database. Default: "Demo Database BC (14-0)" Dynamically Updatable: No
Database Server	DatabaseServer	A valid network name for the computer that is running SQL Server. If the Business Central Server instance is configured as multi-tenant server instance, then this setting specifies the computer that hosts the application database. Default: The computer that you selected in Business Central Setup. Dynamically Updatable: No
Disable SmartSQL	DisableSmartSql	Specifies whether the SmartSQL performance optimization feature is disabled. - If the check box is selected, SmartSQL is disabled. - If the check box is cleared, SmartSQL is enabled. When SmartSQL is enabled, Business Central Server converts FIND calls and FlowField calculations into a single SQL statement. This can improve performance when running pages that contain FlowFields. However, it can be helpful to disable SmartSQL when troubleshooting database queries because statements are separated into more discrete statements. For more information, see Troubleshooting: Long Running SQL Queries Involving FlowFields by Disabling SmartSQL. Default: SmartSQL performance optimization is enabled (check box is cleared) Dynamically Updatable: Yes

SETTING	KEY NAME	DESCRIPTION
Disable SQL Query Hint FORCE ORDER	DisableQueryHintForceOrder	Specifies whether the FORCE ORDER Query Hint is used in queries. FORCE ORDER instructs the query optimizer to preserve the join order that is indicated by the query syntax. If you clear the check box (`false`), the FORCE ORDER is used in queries. For more information, see Configuring Query Hints for Optimizing SQL Server Performance. Default: FORCE ORDER is disabled (check box is selected) Dynamically Updatable: Yes
Disable SQL Query Hint LOOP JOIN	DisablQueryHintLoopJoin	Specifies whether the LOOP JOIN Query Hint is used in queries. LOOP JOIN instructs the query optimizer to use LOOP JOIN for all join operations in the whole query. If you clear the check box (`false`), the LOOP JOIN hint is used in queries. For more information, see Configuring Query Hints for Optimizing SQL Server Performance. Default: LOOP JOIN is disabled (check box is selected) Dynamically Updatable: Yes
Disable SQL Query OPTIMIZE FOR UNKNOWN	DisableQueryHintOptimizeForUnknown	Specifies whether the OPTIMIZE FOR UNKNOWN Query Hint is used in queries. OPTIMIZE FOR UNKNOWN instructs the query optimizer to use statistical data instead of the initial values for all local variables when the query is compiled and optimized, including parameters created with forced parameterization. If you clear the check box (`false`), the OPTIMIZE FOR UNKNOWN hint is used in queries. For more information, see Configuring Query Hints for Optimizing SQL Server Performance. Default: OPTIMIZE FOR UNKNOWN is enabled (check box is cleared) Dynamically Updatable: Yes
Enable Buffered Insert	BufferedInsertEnabled	Specifies whether to buffer rows that are being inserted into a SQL Server database table. When this parameter is enabled, up to 5 rows will be buffered in the table queue before they are inserted into the table. To optimize performance in a production environment, you should enable this parameter. In a test environment, you can disable this parameter to help debug failures that occur when you insert rows in an SQL database table. For more information, see Bulk Inserts. Default: Enabled Dynamically Updatable: No

SETTING	KEY NAME	DESCRIPTION
Enable Encryption on SQL Server Connections	EnableSqlConnectionEncryption	Specifies whether the SQL connect string should request encryption when connecting to SQL Server services. Default: Not enabled Dynamically Updatable: No
Enable SQL Read-Only Replica Support	EnableSqlReadOnlyReplicaSupport	Specifies whether the server instance is allowed to connect to an SQL Server secondary read-only replica of an Always On availability group. Using read-only replicas helps balance workloads and improve performance. To take advantage of this setting, the database must be set up with read-scale out support. For more information, see Using Read Scale-Out for Better Performance Default: Not enabled Dynamically Updatable: No
Enable Trust of SQL Server Certificate	TrustSQLServerCertificate	Specifies whether Business Central Server should trust the SQL Server certificate. Default: Not enabled Dynamically Updatable: No
Search Timeout	SearchTimeout	Specifies the time (in seconds) that a search operation on lists in the client will continue until it's stopped. When the limit is reached, the following message displays in the client: **Searching for rows is taking too long. Try to search or filter using different criteria.** Time format: hh:mm:ss Default: 00:00:10 Dynamically Updatable: Yes
SQL Bulk Import Batch Size	SqlBulkImportBatchSize	Specifies how many SQL memory chunks that a data import must be distributed across. Lowering the value increases the number of network transfers and decreases performance, but also lowers the amount of memory that the server instance consumes. If the database is on SQL Server 2016 or later, a low value can lead to large data files. If you don't want to use batching, specify 0. Default: 448 Dynamically Updatable: No
SQL Command Timeout	SqlCommandTimeout	Specifies the contextual time-out for a SQL command. Default: 0:30:00 Dynamically Updatable: No
SQL Connection Idle Timeout	SqlConnectionIdleTimeout	Specifies the time that a SQL connection can remain idle before being closed. The value has the format hh:mm:ss. Default: 00:05:00 Dynamically Updatable: Yes

SETTING	KEY NAME	DESCRIPTION
SQL Connection Timeout	SqlConnectionTimeout	Specifies the time to wait while trying to connect to the database before stopping the attempt and generating an error. This setting also applies to begin, rollback, and commit of transactions. The value has the format hh:mm:ss. Default: 00:01:30 Dynamically Updatable: Yes
SQL Management Command Timeout[1]	SqlManagementCommandTimeout	Specifies the timeout for SQL commands related to management operations, for example schema synchronization and company management operations. This setting enables you to set a different timeout for management operations than for normal, day-to-day, runtime operations like a Record.FINDSET, which are controlled by the **SQLCommand Timeout** setting. When a negative value is specified for this setting, the **SQL Command Timeout** will be used. The value has the format hh:mm:ss. Default: -1 Dynamically Updatable: Yes
Enable SQL Parameters by Ordinal	SqlParametersByOrdinal	Specifies whether parameters in SQL statements are referenced by their ordinal number. Enabling this setting improves performance when using buffered inserts. Default: Enabled Dynamically Updatable: No
SQL Query Logging Threshold	SqlLongRunningThreshold	Specifies the amount of time (in milliseconds) that an SQL query can run before a warning event is recorded in the application log for the server instance. If this threshold is exceeded, the following event is logged: Action completed successfully, but it took longer than the given threshold. Default: 1000 Dynamically Updatable: Yes

Client Services Settings

The following table describes fields on the **Client Services** tab in the Business Central Server Administration tool.

SETTING	KEY NAME	DESCRIPTION

SETTING	KEY NAME	DESCRIPTION
Allowed File Types	ClientServicesAllowedFileTypes	Specifies the file types that can be stored by the server when requested by the client. The value is a semicolon-separated list of the file name extensions. The server won't store other file types. Example values: • Blank or empty string (`""`): The setting is disabled. File types will be limited based on **Prohibited File Types** setting instead. • Asterisk (`*`): Specifies that all file types are allowed. • List of file type extensions separated by semi-colons, for example `txt;xml;pdf` : Specifies that only .txt, .xml, and .pdf file types can be stored. Trailing semicolons are ignored. Default: blank Dynamically Updatable: Yes
Chunk Size	ClientServicesChunkSize	The default size for a chunk of data that is transferred between Business Central Server and the Dynamics NAV Client connected to Business Central or Business Central Web Server, in kilobytes. The range of values is from 4 to 80. Default: 28 Dynamically Updatable: No
Compression Threshold	ClientServicesCompressionThreshold	The threshold in memory consumption at which Business Central Server starts compressing datasets, in kilobytes. Default: 64 Dynamically Updatable: No
Enable Client Services	ClientServicesEnabled	Specifies whether client services are enabled for this server instance. Default: Enabled Dynamically Updatable: No

SETTING	KEY NAME	DESCRIPTION
Exchange Auth. Metadata Location	ExchangeAuthenticationMetadataLocation	Specifies the URLs for the Microsoft Exchange authentication metadata document of the services or authorities that are trusted to sign Exchange identity tokens. This setting is used for setting up the Office Add-Ins for Outlook. For more information about the Office Add-ins, see Setting Up the Office Add-Ins for Outlook Integration The value is URL that is used to confirm the identity of the signing authority when using Exchange Authentication. The URL is compared to the Exchange authentication metadata document URL in the Exchange identity token. The scheme and host part of the two URLs must match to pass authentication. Paths in the URLs require only a partial match. With a multitenant server instance, the **Exchange Auth. Metadata Location** setting (if any) on the tenant will overrule the value of this setting. Value: - One or more valid URLs. A URL must include the scheme, such as https:// or https://, and the host name. - Separate multiple URLs with a comma. - Wildcards (*) in URLs are supported. Default: https://outlook.office365.com/ Dynamically Updatable: No
Idle Client Timeout	ClientServicesIdleClientTimeout	The interval of time that a Business Central Server client session can remain inactive before the session is dropped. Time interval format: [dd.]hh:mm:ss[.ff] Where: dd: days hh: hours mm: minutes ss: seconds ff: hundredths of a second Set **Idle Client Timeout** to equal or lower than the **Keep Alive Interval**, to enable **Idle Client Timeout**. You can also use **MaxValue** as a value to indicate no time-out. Default: MaxValue Dynamically Updatable: Yes
Keep Alive Interval	ClientServicesKeepAliveInterval	Specifies the time interval between keep-alive messages that are sent from the Dynamics NAV Client connected to Business Central to the server instance. This setting is used to keep inactive sessions alive until the time that is specified by the **Idle Client Timeout** setting expires. You should use a time interval that is less than the **Idle Client Timeout** setting, to hold the session constantly alive. For more information, see Understanding Session Timeouts. Time interval format: [dd.]hh:mm:ss[.ff] Default: 120 Dynamically Updatable: No

SETTING	KEY NAME	DESCRIPTION
Max Concurrent Connections	ClientServicesMaxConcurrentConnections	Specifies the maximum number of concurrent client connections that the current Business Central Server instance accepts. You can use **MaxValue** as a value to indicate no limit. Default: 500 Dynamically Updatable: No
Max Items in Object Graph	ClientServicesMaxItemsInObjectGraph	The maximum number of objects to serialize or deserialize. Default: 512 Dynamically Updatable: No
Max Number of Orphaned Connections	ClientServicesMaxNumberOfOrphanedConnections	Specifies the maximum number of orphaned connections to be kept alive at the same time for the time that is specified by **ReconnectPeriod**. A connection is orphaned when the client is involuntarily disconnected from Business Central Server. You can also use **MaxValue** as a value to indicate no limit. Default: 20 Dynamically Updatable: No
Max Upload Size	ClientServicesMaxUploadSize	The maximum size of files that can be uploaded to or downloaded from Business Central Server, in megabytes. Use this setting to avoid out-of-memory errors. Default: 150 Dynamically Updatable: No
Operation Timeout	ClientServicesOperationTimeout	The maximum time that Business Central Server can take to return a call from the client. Time span format: [dd.]hh:mm:ss[.ff] Where: dd: days hh: hours mm: minutes ss: seconds ff: hundredths of a second You can also use **MaxValue** as a value to indicate no time-out. Default: MaxValue Dynamically Updatable: No
Port	ClientServicesPort	The listening HTTP port for client services. Valid range: 1 - 65535 Default: 7046 Dynamically Updatable: No

SETTING	KEY NAME	DESCRIPTION
Prohibited File Types	ClientServicesProhibitedFileTypes	Specifies the file types that can't be stored by the server when requested by the client. The value is a semicolon-separated list of the file name extensions. This setting is ignored if the **Allowed File Types** setting has a value. Example values: • Asterisk (`*`): All file types are prohibited. • Blank or empty string (`""`): The default value is used. • Whitespace string (`" "`): All file types are allowed. • List of file types separated by a semicolon, for example `txt;xml;pdf` : Prohibits the file types txt, xml and pdf. Trailing semi-colons will be ignored. Default: ade;adp;app;asp;bas;bat;chm;cmd;com;cpl; csh;exe;fxp;gadget;hlp;hta;inf;ins;isp;its;js;jse; ksh;lnk;mad;maf;mag;mam;maq;mar;mas;mat;mau; mav;maw;mda;mdb;mde;mdt;mdw;mdz;msc;msi; msp;mst;ops;pcd;pif;prf;prg;pst;reg;scf;scr; sct;shb;shs;url;vb;vbe;vbs;vsmacros;vss;vst;vsw;ws;wsc;wsf;wsh Dynamically Updatable: Yes
Protection Level	ClientServicesProtectionLevel	Specifies the security services for protecting the data stream between clients and Business Central Server. All Dynamics NAV Client connected to Business Central clients connecting to the Business Central Server instance must have the same ProtectionLevel value in their ClientUserSettings.config files. For more information, see Configuring the Windows Client in the Dev and IT Pro Help for Microsoft Dynamics NAV 2018. For background information about transport security, see Understanding Protection Level (links to MSDN Library). Values: EncryptAndSign, Sign, None Default: EncryptAndSign Dynamically Updatable: No
Reconnect Period	ClientServicesReconnectPeriod	The time during which a client can reconnect to a running instance of Business Central Server. Time span format: [dd.]hh:mm:ss[.ff] Where: dd: days hh: hours mm: minutes ss: seconds ff: hundredths of a second You can also use **MaxValue** as a value to indicate no time limit. Default: 00:10:00 Dynamically Updatable: No

SETTING	KEY NAME	DESCRIPTION
Token Signing Key	ClientServicesTokenSigningKey	Specifies the signing information that you obtain from the Microsoft Azure portal. The parameter value is a 256-bit symmetric token signing key for use with Azure Access Control service (ACS). This parameter is relevant only when **Credential Type**, on the **General** tab, is set to **AccessControlService**. Default: EncryptAndSign Dynamically Updatable: No
Use the Simplified Filters	UseSimplifiedFilters	Specifies how the search on list pages behaves for plain text search filters. Pain text search filters don't use search symbols like @ or *. If you enable this setting, the search uses a case sensitive and accent sensitive search to find fields that start with the provided filter text. For example, the search on **man** returns all records that include a field that starts with *man* (lowercase m), and the search on **Man** returns all records that include a field that starts with *Man* (uppercase M). Notice that you can get the same results by entering **man*** and **Man*** respectively. If the setting is disabled (which is default), the search on **man** and **Man** return the same results, which are all records that include fields that contain the text *man*, regardless of the case. For more information about the search, see Sorting, Searching, and Filtering Lists. Default: Not enabled Dynamically Updatable: No
Web Client Base URL	PublicWebBaseUrl	Specifies the root of the URLs that are used to open hyperlinks to pages and reports in the Business Central Web client. For example, you can change the value if you want to change the externally facing endpoint. The base URL must have the following syntax: `http[s]://[hostname]:[port]/[webserverinstance]` This field maps to the `PublicWebBaseUrl` setting in the CustomSettings.config file for the Business Central Server instance. Default: The URL of the Web client Dynamically Updatable: No

SETTING	KEY NAME	DESCRIPTION
Windows Client Base URL	PublicWinBaseUrl	Specifies the root of the URLs that are used to open hyperlinks to pages and reports in the Dynamics NAV Client connected to Business Central. For example, you can change the value if you want to change the externally facing endpoint. The base URL must have the following syntax: `DynamicsNAV://[hostname]:[port]/[instance]/` This field maps to the `PublicWinBaseUrl` setting in the CustomSettings.config file for the Business Central Server instance. Default: The URL of the Windows client Dynamically Updatable: No

SOAP Services Settings

The following table describes fields on the **SOAP Services** tab in the Business Central Server Administration tool.

SETTING	KEY NAME	DESCRIPTION
Enable SOAP Services	SOAPServicesEnabled	Specifies whether SOAP web services are enabled for this server instance. Default: Not enabled Dynamically Updatable: No
Enable SSL	SOAPServicesSSLEnabled	Specifies whether SSL (https) is enabled for the SOAP web service port. For more information, see Using Security Certificates with Business Central On-Premises. Default: Not enabled Dynamically Updatable: No
Max Connections	SOAPMaxConnections	Specifies the maximum number of simultaneous SOAP requests on the server instance (for all tenants). When the limit is exceeded, an error occurs. If you don'tt want a limit, set the value **0**. Default: 0 Dynamically Updatable: Yes
Max Connections Per Tenant	SOAPMaxConnectionsPerTenant	Specifies the maximum number of simultaneous SOAP requests per tenant. When the limit is exceeded, an error occurs. If you do not want a limit, set the value **0**. Default: 0 Dynamically Updatable: Yes
Max Concurrent Requests[1]	SOAPMaxConcurrentRequests	Specifies the maximum number of SOAP requests per tenant that the server instance can process at the same time. If you don't want a limit, set the value `0`. Default: 5 Dynamically Updatable: Yes

SETTING	KEY NAME	DESCRIPTION
Max Queued Requests[1]	SOAPRequestQueueSize	Specifies the maximum number of pending SOAP connections per tenant waiting to be processed. When the limit is exceeded, a 429 (Too Many Requests) error occurs. If you don't want a limit, set the value `0`. Default: 95 Dynamically Updatable: Yes
Max Message Size	SOAPServicesMaxMsgSize	Specifies the maximum permitted size of a SOAP web services request, in kilobytes. When a request exceeds this limit, a 413: Request Entity Too Large error occurs. **Important:** This setting also pertains to OData web services. Default: 65536 Dynamically Updatable: No
Port	SOAPServicesPort	The listening HTTP port for SOAP web services. Valid range: 1 - 65535 Default: 7047 Dynamically Updatable: No
SOAP Base URL	PublicSOAPBaseUrl	Specifies the root of the URLs that are used to access SOAP web services. For example, you can change the value if you want to change the externally facing endpoint. The base URL must have the following syntax: http[s]://*hostname.port*/*instance*/WS/ This field maps to the `PublicSOAPBaseUrl` setting in the CustomSettings.config file for the Business Central Server instance. Default: The SOAP URL for the server instance Dynamically Updatable: No
Timeout	SOAPServicesOperationTimeout	Specifies the maximum amount of time that the server can allocate to a single SOAP request. When the limit is exceeded, a timeout error occurs. Time span format: hh:mm:ss If you do not want a timeout, set the value to **MaxValue**. Default: 00:10:00 Dynamically Updatable: Yes

OData Services Settings

The following table describes fields on the **OData Services** tab in the Business Central Server Administration tool.

SETTING	KEY NAME	DESCRIPTION
Enable Add-in Annotations	ODataEnableExcelAddInAnnotations	Specifies whether Excel add-in annotations should be provided in OData metadata. Default: Enabled Dynamically Updatable: No

SETTING	KEY NAME	DESCRIPTION
Enable API Services	ApiServicesEnabled	Specifies whether API web services are enabled for this server instance. Default: Not enabled Dynamically Updatable: No
Enable OData Services	ODataServicesEnabled	Specifies whether OData web services are enabled for this Business Central Server instance. Default: Enabled Dynamically Updatable: No
Enable SSL	ODataServicesSSLEnabled	Specifies whether SSL (https) is enabled for the OData web service port. For more information, see Using Security Certificates with Business Central On-Premises. Default: Not enabled Dynamically Updatable: No
Enable V3 Endpoint	ODataServicesV3EndpointEnabled	Specifies whether the ODataV3 service endpoint will be enabled. Default: Enabled Dynamically Updatable: No
Enable V4 Endpoint	ODataServicesV4EndpointEnabled	Specifies whether the ODataV4 service endpoint will be enabled. Default: Enabled Dynamically Updatable: No
Max Connections	ODataMaxConnections	Specifies the maximum number of simultaneous OData requests on the server instance (for all tenants). When the limit is exceeded, a 429 (Too Many Requests) error occurs. If you don't want a limit, set the value `0`. OData requests consume server instance resources, which can affect the performance of the clients if the number of requests gets too large. This setting enables you to control the resources allocated for OData requests. Default: 0 Dynamically Updatable: Yes
Max Connections Per Tenant	ODataMaxConnectionsPerTenant	Specifies the maximum number of simultaneous OData requests per tenant. When the limit is exceeded, a 429 (Too Many Requests) error occurs. If you don't want a limit, set the value 0. If the server isn't configured for multitenancy or only has a single tenant, then this setting does the same as the **Max Connections** (ODataMaxConnections) setting. OData requests consume server instance resources and can affect the performance of the clients if the number of requests gets too large. This setting enables you to control the resources allocated for OData requests. Default: 0 Dynamically Updatable: Yes

SETTING	KEY NAME	DESCRIPTION
Max Page Size	ODataServicesMaxPageSize	Specifies the maximum number of entities returned per page of OData results. For more information, see Server-Driven Paging in OData Web Services. Default: 20000 Dynamically Updatable: No
OData Base URL	PublicODataBaseUrl	Specifies the root of the URLs that are used to access OData web services. For example, you can change the value if you want to change the externally facing endpoint. The base URL must have the following syntax: http[s]://*hostname*:*port*/*instance*/OData/ This field maps to the `PublicODataBaseUrl` setting in the CustomSettings.config file for the Business Central Server instance. Default: The OData URL for the server instance Dynamically Updatable: No
Port	ODataServicesPort	The listening HTTP port for Business Central OData web services. Valid range: 1 - 65535 Default: 7048 Dynamically Updatable: No
V3 Max Concurrent Requests[1]	ODataV4MaxConcurrentRequests	Specifies the maximum number of OData V3 requests per tenant that the server instance can process at the same time. Requests that exceed the limit will wait in the queue until a time slot becomes available. If you don't want a limit, set the value `0`. Default: 5 Dynamically Updatable: Yes
V3 Max Queued Requests[1]	ODataV4MaxRequestQueueSize	Specifies the maximum number of pending OData V3 requests per tenant waiting to be processed. When the limit is exceeded, a 429 (Too Many Requests) error occurs. If you don't want a limit, set the value `0`. Default: 95 Dynamically Updatable: Yes
V4 Max Concurrent Requests[1]	ODataV4MaxConcurrentRequests	Specifies the maximum number of OData V4 requests per tenant that the server instance can actively process at the same time. Requests that exceed the limit will wait in the queue until a time slot becomes available. If you don't want a limit, set the value `0`. Default: 5 Dynamically Updatable: Yes

SETTING	KEY NAME	DESCRIPTION
V4 Max Queued Requests[1]	ODataV4MaxRequestQueueSize	Specifies the maximum number of pending OData V4 requests per tenant waiting to be processed. When the limit is exceeded, a 429 (Too Many Requests) error occurs. If you don't want a limit, set the value `0`. Default: 95 Dynamically Updatable: Yes
Timeout	ODataServicesOperationTimeout	Specifies the maximum amount of time that the server instance can allocate to a single OData request. When the limit is exceeded, a 408 (Request Timeout) error occurs. If you don't want a limit, set the value to `MaxValue`. Time format: hh:mm:ss Default: 00:08:00 Dynamically Updatable: Yes

IMPORTANT

The maximum permitted size of an OData web services request is specified by the **Max Message Size** option on the **SOAP Services** tab.

NAS Services Settings

The following table describes fields on the **NAS Services** tab in the Business Central Server Administration tool.

NOTE

Instead of using NAS services, we recommend that you use the Task Scheduler (see Task Scheduler. If you decide to use NAS, and want to read more about its configuration, see Configuring NAS Services in the Dev and IT Pro Help for Microsoft Dynamics NAV 2018.

SETTING	KEY NAME	DESCRIPTION
Enable Debugging	NASServicesEnableDebugging	Specifies if the Business Central Debugger must attach to the NAS Services session. When this is enabled, the NAS Services session waits 60 seconds before the first AL statement is run. Default: Not enabled Dynamically Updatable: No
Run NAS Services with Admin Rights	NASServicesRunWithAdminRights	Specifies whether NAS services run operations with administrator rights instead of the rights granted to the Business Central Server service account. If you select this setting, NAS services will have full permissions in Business Central, similar to the permissions that are granted by the SUPER permission set. The Business Central Server service account isn't required to be set up as a user in Business Central. If you clear this setting, the Business Central Server service account must be added as a user in Business Central and assigned the permissions that are required to perform the operations. Default: Not enabled Dynamically Updatable: No

SETTING	KEY NAME	DESCRIPTION
Startup Argument	NASServicesStartupArgument	Specifies a string argument that will be used when NAS services start. The argument typically specifies an application type, sometimes with additional configuration information. Example value: `"OSYNCH"` Default: Dynamically Updatable: No
Startup Codeunit	NASServicesStartupCodeunit	Specifies the codeunit that contains the method that will be called by the **NASStartupMethod** setting. Example values: **0** When **NASStartupCodeunit** is set to 0, NAS Services don't start. This value is the default value. **55** When NAS services start, they run the trigger specified by the NAS Startup Method in codeunit 55. **Note:** When the codeunit specified by **NASStartupCodeunit** is a single instance codeunit, the NAS service session will remain alive even after you run all code in the specified **NASStartupMethod**. Default: Dynamically Updatable: No
Startup Method	NASServicesStartupMethod	Specifies the method that will be called in the **NASStartupCodeunit**. Example values: **""** If no start method is specified (null string), the OnRun trigger is called. **StartNAS** NAS services run the StartNAS method in the NAS Startup Codeunit. Default: Dynamically Updatable: No

Management Services Settings

The following table describes fields on the **Management Services** tab in the Business Central Server Administration tool.

SETTING	KEY NAME	DESCRIPTION
Enable Management Services	ManagementServicesEnabled	Specifies whether Business Central Server Administration tool is enabled for this server instance. Default: Enabled Dynamically Updatable: No
Port	ManagementServicesPort	The listening TCP port for the Business Central Server Administration tool. Valid range: 1 - 65535 Default: 7045 Dynamically Updatable: No

Azure Key Vault Client Identity Tab Settings

The following table describes fields on the **Azure Key Vault Client Identity** tab in the Business Central Server Administration tool.

These settings are used when you want to use Azure Key Vaults to store extension secrets and data encryption keys. For more information, see Setting up App Key Vaults and Data Encryption.

SETTING	KEY NAME	DESCRIPTION
Client Certificate Store Location	AzureKeyVaultClientCertificateStoreLocation	Specifies the location of the certificate store where the key vault reader certificate is stored. **LocalMachine** specifies that the certificate is stored in a certificate store for the computer that the Business Central Server is running on. **CurrentUser** specifies that the certificate is stored in a certificate store for your account on the computer that the Business Central Server is running on. Default: LocalMachine Dynamically Updatable: No
Client Certificate Store Name	AzureKeyVaultClientCertificateStoreName	Specifies the certificate store where the key vault reader certificate is stored. Default: My Dynamically Updatable: No
Client Certificate Thumbprint	AzureKeyVaultClientCertificateThumbprint	Specifies the thumbprint of the certificate used by the key vault reader application in Azure. Default: My Dynamically Updatable: No
Client ID	AzureKeyVaultClientId	Specifies the application (client) ID of the key vault reader application in Azure. The value is a GUID. Default: 00000000-0000-0000-0000-000000000000 Dynamically Updatable: No

Azure Key Vault Extension Secrets Tab Settings

The following table describes fields on the **Azure Key Vault Extension Secrets** tab in the Business Central Server Administration tool.

SETTING	KEY NAME	DESCRIPTION
Enable Publisher Validation	AzureKeyVaultAppSecretsPublisherValidationEnabled	Specifies whether extensions can only use key vaults that belong to their publishers. • **true** turns on validation. Extensions can only use key vaults that belong to their publishers. This setting blocks attempts in AL to read secrets from another publisher's key vault. • **false** turns off validation. **Important** For security reasons, we recommend that you don't turn this setting off, unless you trust all etxtensions that might get installed on the tenant. An extension publisher's identity is specified when the extension is published. However, the validation is done at runtime. This setting doesn't affect extensions that don't use app key vault secrets. For more information, see App Key Vaults - Security Considerations. Default: true Dynamically Updatable: No

Azure Active Directory (Azure AD) Settings

The following table describes fields on the **Azure Active Directory (Azure AD)** tab in the Business Central Server Administration tool.

The settings in this tab configure the Business Central Server instance to use Azure AD authentication. The settings are only relevant when the server instance is configured Access Control Service, that is, when the **Credential Type** is set to **AccessControlService**. For more information about authenticating using Azure AD, see Authenticating Users with Azure Active Directory.

SETTING	KEY NAME	DESCRIPTION
Application Client Certificate Thumbprint	AzureActiveDirectoryClientCertificateThumbprint	Specifies the thumbprint of the x509 certificate that is used with the Azure AD application client for authentication. A public certificate file (.cer) must be installed on the application client and associated with an Azure AD service principal. A private certificate file (.pfx) must be installed on the computer on which the Business Central Server instance is installed. The server instance service account must have access to the private key of that certificate. Default: Dynamically Updatable: No
Application Client ID	AzureActiveDirectoryClientId	Specifies the ID of the application tenant. The ID is used when accessing data in Azure AD. The authentication token for communicating with Azure AD should be retrieved by specifying the **Application Client Certificate Thumbprint**, with a fallback to use the **Application Client Secret**. Default: 00000000-0000-0000-0000-000000000000 Dynamically Updatable: No

SETTING	KEY NAME	DESCRIPTION
Application Client Secret	AzureActiveDirectoryClientSecret	Specifies the secret to use with **Application Client ID** for Azure AD authentication. Default: Dynamically Updatable: No
Azure AD App ID URI	AppIdUri	Specifies the App ID URI that is registered for Business Central in the Microsoft Azure Active Directory (Azure AD). You use this setting to configure Business Central web services for OAuth authentication, specifically when the *Credential Type* setting is **AccessControlService**. it's used to validate the security tokens that the server instance receives in SOAP and OData calls. The App ID URI is a logical identifier and doesn't have to represent a valid location, although it's common practice to use the physical URL of the Business Central web service. The App ID URI is typically the same as the value of *wtrealm* parameter of the **ACSUri** setting that is included in the ClientUserSettings.config file for the Dynamics NAV Client connected to Business Central. An example of an App ID URI is *https://localhost:7047/*. For more information about how to use the Azure Active Directory App ID URI with OAuth authentication, see Using OAuth to Authenticate Web Services (Odata and SOAP). Default: Dynamically Updatable: No
Enable Membership Entitlement	EnableMembershipEntitlement	Configures the server instance to use membership entitlement for controlling access the Business Central. This setting is typically only used for software as a service (SaaS) solutions. Default: Dynamically Updatable: No
Excel add-in AAD client app ID	ExcelAddInAzureActiveDirectoryClientId	This setting is used to set up the Excel Add-in that enables users to use Excel to modify and update Business Central data. The setting specifies the client ID of the Azure AD tenant that is used for the Excel add-in. The Excel add-in requires a separate Azure AD tenant. For more information, see Configuring the Excel Add-In. Default: Dynamically Updatable: No

SETTING	KEY NAME	DESCRIPTION
Extended Security Token Lifetime	ExtendedSecurityTokenLifetime	Specifies the number of hours that are added to the lifetime of Azure AD security tokens, which are used to authenticate client users. When the lifetime expires, the client is disconnected from the server instance. An event with a message such as "The SAML2 token is invalid because its validity period ended." is recorded in the event log for the server instance. In general, the lifetime of security tokens is 1 hour. Valid range: 0 to 24 hours Default: 0 Dynamically Updatable: No
Valid Audiences	ValidAudiences	Specifies the allowed audiences for Azure AD authentication. This setting is used to authenticate other Azure AD applications that will communicate with the server instance. The value is a semicolon-separated list of audiences. You specify an audience by using the App URI ID or App ID that is assigned to the application in Azure AD. Default: Dynamically Updatable: No
WS-Federation Login Endpoint	WSFederationLoginEndpoint	Specifies the URL for the federation sign-on page that Business Central redirects to when configured for single sign-on. You must specify a URL in the following format: `https://login.microsoftonline.com/[AADTENANTID]/wsfed?wa=wsignin1.0%26wtrealm=...%26wreply=....` The placeholder [AADTENANTID] represents the GUID of your Azure AD tenant. If the server instance has to support multiple Azure AD tenants, then the **Azure AD Tenant ID** parameter that is specified when mounting a tenant replaces the placeholder. Default: Dynamically Updatable: No

SETTING	KEY NAME	DESCRIPTION
WS-Federation Metadata Location	ClientServicesFederationMetadataLocation	Specifies the URL for the federation metadata document that describes the configuration information for your Azure AD tenant. The federation metadata document is used to validate the security tokens that the Business Central Web client and Business Central tablet client receive, and to establish a trust relationship with between Business Central and an application that you've added to Azure AD. You must specify a URL in the following format: `https://login.microsoftonline.com/[AADTENANTID]/Federat 06/FederationMetadata.xml` The placeholder [AADTENANTID] represents the GUID of your Azure AD tenant. If the server instance has to support multiple Azure AD tenants, then the Azure AD Tenant ID parameter that is specified when mounting a tenant replaces the placeholder. This parameter is relevant only when **Credential Type**, on the **General** tab, is set to **AccessControlService**. For more information, see Authenticating Users with Azure Active Directory. Default: Dynamically Updatable: No

Data Encryption Settings

The following table describes fields on the **Data Encryption** tab in the Business Central Server Administration tool.

For more information about data encyrption, see Data Encryption.

SETTING	KEY NAME	DESCRIPTION
Encryption Key Provider	EncryptionProvider	Specifies where the encryption key used to encrypt data in the database is stored, either **LocalKeyFile** or **AzureKeyVault** values. If you use **AzureKeyVault**, see the **Azure Key Vault Encryption Provider** tab settings. Default: LocalKeyFile Dynamically Updatable: No
Key URI	AzureKeyVaultKeyUri	Specifies the URI of the key in the Key Vault encryption provider setup. Default: Dynamically Updatable: No

Task Scheduler Settings

The following table describes fields on the **Task Scheduler** tab in the Business Central Server Administration tool.

The task scheduler processes jobs and other processes on a scheduled basis. For more information about task scheduler, see Task Scheduler.

SETTING	KEY NAME	DESCRIPTION

SETTING	KEY NAME	DESCRIPTION
Enable Task Scheduler	EnableTaskScheduler	Specifies whether the server instance starts with the task scheduler enabled. If this option is enabled, the server instance will process scheduled tasks. Default: Enabled Dynamically Updatable: No
Maximum Concurrent Running Tasks	TaskSchedulerMaximumConcurrentRunningTasks	Specifies the maximum number of tasks that can run simultaneously on the server instance. The value that you specify will depend on the hardware (CPUs) of the deployment environment and what you want to prioritize: client performance or scheduled tasks (such as job queue entries). The setting is particularly relevant when the server instance is used for both scheduled tasks and client services. If there are many jobs running at the same time, you might experience that the response time for clients gets slower. In which case, you could decrease the value. However, if the value is too low, it might take longer than desired for scheduled tasks to process. When you've a dedicated server instance for scheduled tasks, this setting is less important with respect to client performance. Default: 10 Dynamically Updatable: Yes
System Task Start Time	TaskSchedulerSystemTaskStartTime	Specifies the time of day after which system tasks can start. The time is based on the time zone of the computer that is running the server instance. The value has the format hh:mm:ss. Default: 00:00:00 Dynamically Updatable: Yes
System Task End Time	TaskSchedulerSystemTaskEndTime	Specifies the time of day after which system tasks can't start. The time is based on the time zone of the computer that is running the server instance. The value has the format hh:mm:ss. Default: 23:59:59 Dynamically Updatable: Yes
not available	XmlMetadataCacheSize	For internal use only. Default: 500

Asynchronous Processing Settings

APPLIES TO: Business Central 2019 release wave 2 and later

The following table describes fields on the **Asynchronous Processing** tab in the Business Central Server Administration tool.

SETTING	KEY NAME	DESCRIPTION

SETTING	KEY NAME	DESCRIPTION
Child Sessions Max Concurrency	ChildSessionsMaxConcurrency	Specifies the maximum number of child sessions that can run concurrently per parent session of a page background task. When the value is exceeded, additional child sessions will be queued and run when a slot becomes available as other child sessions are finished. Default: 5 Dynamically Updatable: Yes **INTRODUCED IN:** Version 15.2
Child Sessions Max Queue Length	ChildSessionsMaxQueueLength	Specifies the maximum number of child sessions that can be queued per parent session of a page background task. If the value is exceeded, an error occurs. Default: 100 Dynamically Updatable: Yes **INTRODUCED IN:** Version 15.2
Page Background Task Default Timeout	PageBackgroundTaskDefaultTimeout	Specifies the default amount of time that page background tasks can run before being canceled. Page background tasks can be also given a timeout value when enqueued at runtime. The **Page Background Task Default Timeout** setting is used when no timeout is provided when the page background task is enqueued. The value has the format hh:mm:ss. Default: 00:02:00 Dynamically Updatable: Yes
Page Background Task Max Timeout	PageBackgroundTaskMaxTimeout	Specifies the maximum amount of time that page background tasks can run before being canceled. Page background tasks can be also given a timeout value when enqueued at runtime. If a page background task is enqueued with a timeout greater than the **Page Background Task Max Timeout** setting, the **Page Background Task Max Timeout** setting is used instead. The value has the format hh:mm:ss. Default: 00:10:00 Dynamically Updatable: Yes

For more information about page background tasks, see Page Background Tasks.

Reports Settings

The following table describes fields on the **Reports** tab in the Business Central Server Administration tool.

SETTING	KEY NAME	DESCRIPTION

SETTING	KEY NAME	DESCRIPTION
Default Max Documents[1]	ReportDefaultMaxDocuments	Specifies the number of documents that can be merged when using WordMergeDataItem property on reports. If exceeded, the report will be canceled by the server. Developers can override this setting by using the MaximumDocumentCount property of a report. Client users can do the same when running a report from the report request page. If you don't want a limit, set the value to **MaxValue**. Default: 200 Dynamically Updatable: Yes
Default Max Rendering Timeout [1]	ReportDefaultTimeout	Specifies the maximum execution time that it can take to generate a report. If exceeded, the report will be canceled by the server. Developers can override this setting by using the ExecutionTimeout property of a report. Client users can do the same when running a report from the report request page. If you don't want a limit, set the value to **MaxValue**. For more information about how reports are canceled, see Report Generation and Cancellation Flow. Timeout format: [dd.]hh:mm:ss[.ff] Default: 06:00:00 Dynamically Updatable: Yes
Default Max Rows [1]	ReporDefaultMaxRows	Specifies the maximum number of rows that can be processed in a report by default. If exceeded, the report will be canceled by the server. Developers can override this setting by using the MaximumDataSetSize property of a report. Client users can do the same when running a report from the report request page. If you don't want a limit, set the value to **MaxValue**. For more information about how reports are canceled, see Report Generation and Cancellation Flow. Default: 500000 Dynamically Updatable: Yes

SETTING	KEY NAME	DESCRIPTION
Enable Application Domain Isolation	ReportAppDomainIsolation	Specifies whether application domain isolation is used for rendering custom RDLC layouts. This setting pertains to on-premise installations only. Enabling application domain isolation provides a more secure and reliable environment for processing custom RDLC layouts. However, it can considerably increase the time it takes to render reports. Disabling application domain isolation can improve the rendering time but might have a negative impact on security and reliability. Default: Enabled Dynamically Updatable: No
Enable Save as Excel on Request Pages of RDLC-layout Reports	EnableSaveToExcelForRdlcReports	Specifies whether users can open or save a report as an Excel document if the report uses an RDLC layout. If you clear this check box, the **Excel** option is removed from the **Print** menu on the request page. Default: Enabled Dynamically Updatable: No
Enable Save as Word on Request Pages of RDLC-layout Reports	EnableSaveToWordForRdlcReports	Specifies whether users can open or save a report as a Microsoft Word document if the report uses an RDLC layout. If you clear this check box, the **Word** option is removed from the **Print** menu on the request page. Default: Enabled Dynamically Updatable: No
Enable Save from Report Preview	EnableSaveFromReportPreview	Specifies whether users can save a report as a PDF, Microsoft Word, or Microsoft Excel document from the report preview window. If you clear this check box, the **Save As** icon is removed from the report preview window. Default: Enabled Dynamically Updatable: No
Enforce Cloud Print Support	ReportCloudPrintingEnforced	Specifies whether cloud printing is supported for reports. This setting must be enabled to send print jobs to any printer that is set up by an extension that subscribes to the OnAfterDocumentPrintReady event. If you disable this setting, the OnAfterDocumentPrintReady event is never raised, and print jobs are directed to the default printing on the server. Default: Enabled Dynamically Updatable: No

SETTING	KEY NAME	DESCRIPTION
Max Documents (hard limit)[1]	ReportMaxDocuments	Specifies the maximum number of documents that can be merged when using WordMergeDataItem property on reports using a Word layout. If exceeded, the report will be canceled by the server. To turn off this limit set the value to **MaxValue**. Timeout format: [dd.]hh:mm:ss[.ff] Default: 500 Dynamically Updatable: Yes
Max Rendering Timeout (hard limit)	ReportTimeout	Specifies the maximum execution time that it can take to generate a report. If exceeded, the report will be canceled by the server. If you don't want a limit, set the value to **MaxValue**. For more information about how reports are canceled, see Report Generation and Cancellation Flow. Timeout format: [dd.]hh:mm:ss[.ff] Default: 12:00:00 Dynamically Updatable: Yes
Max Rows (hard limit)	ReportMaxRows	Specifies the maximum number of rows that can be processed in a report. If exceeded, the report will be canceled by the server. You can also use MaxValue to indicate no limit. If you don't want a limit, set the value to **MaxValue**. For more information about how reports are canceled, see Report Generation and Cancellation Flow. Default: 1000000 Dynamically Updatable: Yes
Report PDF Font Embedding	ReportPDFFontEmbedding	Specifies whether fonts are embedded in PDF files that are generated for reports when the report uses an RDLC report layout at runtime. This setting applies when reports are run and saved as PDF files on the client (from the report request page or print preview window) or on the server instance (by the SAVEAS function or SAVEASPDF function in AL code). **Note:** This setting doesn't apply when a report uses a Word report layout at runtime. You embed fonts in a PDF of a report to make sure that the PDF will use the same fonts as the original file, no matter where the PDF is opened and which fonts are installed on the computer. However, embedding fonts can significantly increase the size of the PDF files. Disabling font embedding decreases the size of the report PDF files. **Note:** This setting is a global setting for font embedding in report PDF files. You can override this setting on a report basis by the specifying the PDFFontEmbedding property. Default: Enabled Dynamically Updatable: No

SETTING	KEY NAME	DESCRIPTION
not available	CalculateBestPaperSizeForReportPrinting	Determines the paper size to use when printing reports from the client. If set to `true`, the system calculates which of the available paper sizes on the printer is best suited for printing, and then uses that paper size. If set to `false`, the printer's default paper size is used. Default: true

[1] **APPLIES TO:** Business Central 2020 release wave 2 and later

Query Settings

The following table describes fields on the **Query** tab in the Business Central Server Administration tool.

SETTING	KEY NAME	DESCRIPTION
Max Execution Timeout	QueryTimeout	Specifies the maximum execution time that it can take to generate a query. If exceeded, the query will be canceled by the server. If you don't want a limit, set the value to **MaxValue**. Timeout format: [dd.]hh:mm:ss[.ff] Default: MaxValue Dynamically Updatable: Yes
Max Rows	QueryMaxRows	Specifies the maximum number of rows that can be processed in a query. If exceeded, the query will be canceled by the server. You can also use MaxValue to indicate no limit. If you don't want a limit, set the value to **MaxValue**. Default: MaxValue Dynamically Updatable: Yes

Extensions Settings

The following table describes fields on the **Extensions** tab in the Business Central Server Administration tool.

SETTING	KEY NAME	DESCRIPTION
Enable Profile Cache Synchronization	EnableProfileCacheSynchronization	Specifies whether profile cache synchronization across multiple server instances is enabled. This setting is relevant when there's more than one server instance connected to the same database or tenant. When not enabled, changes done to profile configurations on one server instance won't show on other server instances until the first server instance is restarted. When enabled, profile configuration changes will be automatically synchronized and propagated across all server instances. However, enabling this setting will lower the tenant performance. For more information about profiles and configurations, see Designing Profiles. Default: Not enabled (false) Dynamically Updatable: No

SETTING	KEY NAME	DESCRIPTION
Overwrite Existing Translations	OverwriteExistingTranslations	Specifies whether to overwrite existing text translations in the base application with text translations included in extensions. Default: Enabled Dynamically Updatable: No
Required Extensions	RequiredExtensions	Specifies a list of required extensions that can't be uninstalled by using the **Extension Management** page in the client. The extensions can still be uninstalled by using the Uninstall-NAVApp cmdlet of the Business Central Administration Shell. You specify an extension by its AppID (which is a GUID). When you've more than one extension, separate each AppID with a semicolon. The AppID for the BaseApp extension is 437dbf0e-84ff-417a-965d-ed2bb9650972 and System Application extension is 63ca2fa4-4f03-4f2b-a480-172fef340d3f. Default: Blank or "" (empty string) Dynamically Updatable: Yes **APPLIES TO:** Business Central 2019 release wave 2 (version 17.0) and later
Solution Version Extension	SolutionVersionExtension	Specifies the ID of the extension whose version number will show as the Application Version on the client's Help and Support page. Typically, you'd use the extension considered to be your solution's base application. If your solution uses the Microsoft Base Application, set the value to `437dbf0e-84ff-417a-965d-ed2bb9650972`. Default: 00000000-0000-0000-0000-000000000000 Dynamically Updatable: Yes

Development Settings

The following table describes fields on the **Development** tab in the Business Central Server Administration tool.

SETTING	KEY NAME	DESCRIPTION

SETTING	KEY NAME	DESCRIPTION
Allowed Extension Target Level	ExtensionAllowedTargetLevel	Specifies the allowed target level when publishing extensions. The options are **Internal**, **Extension**, **Solution**, **Personalization**, **Cloud**, and **OnPrem**. **Note:** The **Internal**, **Extension**, **Solution**, and **Personalization** options have been deprecated and replaced with **Cloud** and **OnPrem**. - If you specify the **OnPrem** option, the allowed compilation target is set to everything on-premises. The **OnPrem** setting allows using all restricted APIs. The `target` setting in the `app.json` file must also be set to **OnPrem**. For more information, see JSON Files. - If you specify the **Cloud** option, the allowed extension target level is set to SaaS. - By adding the setting `"target":"Cloud"` in the manifest enables you to submit the extension to AppSource. **Note:** It's recommended to use either **OnPrem** or **Cloud** options to set Allowed Extension Target Level. Default: Internal Dynamically Updatable: No
Debugger – Long Running SQL Statements Threshold	LongRunningSqlStatementsInDebuggerThreshold	Specifies the amount of time (in milliseconds) that an SQL query can run before it's logged in debugger telemetry. Default: Enabled Dynamically Updatable: Yes
Debugger - Number of SQL Statements to Show	AmountOfSqlStatementsInDebugger	Specifies the number of SQL statements used in the debugger. The higher number you choose, the more data will be sent to the debugger. Default: Enabled Dynamically Updatable: Yes
Debugger - Show Long Running SQL Statements	EnableLongRunningSqlStatementsInDebugger	Specifies whether long running SQL statements will be shown in the debugger. Default: Enabled Dynamically Updatable: Yes
Debugger - Show SQL Statements	EnableSqlInformationDebugger	Specifies whether the debugger should collect the last used SQL statements and show them in the debugger. Default: Enabled Dynamically Updatable: Yes
Debugging Allowed	DebuggingAllowed	Specifies whether AL debugging is allowed for the Business Central Server instance. Default: Enabled Dynamically Updatable: No

SETTING	KEY NAME	DESCRIPTION
Enable Debugging	EnableDebugging	Specifies whether the Business Central Server instance starts with debugging enabled. If this option is enabled, the following occurs: When the client first connects, all C# files for the application are generated. C# files persist between Business Central Server restarts. Application objects are compiled with debug information. Default: Not enabled Dynamically Updatable: No
Enable Developer Service Endpoint	DeveloperServicesEnabled	Specifies whether the Developer service endpoint is enabled. This setting must be enabled to publish extensions and download symbols. - If the check box is selected, the extension can be published to the allowed extension target level. - If the check box isn't selected, the extension can't be published. - This setting can also be controlled from the .xml file. Default: Not enabled (check box is cleared) Dynamically Updatable: No
Enable Loading Application Symbol References at Server Startup	EnableSymbolLoadingAtServerStartup	Specifies whether application symbol references should be loaded at server startup. This setting must be enabled to allow any symbol generation. If the setting isn't enabled, the **generatesymbolreference** setting doesn't have any effect. For more information, see Running C/SIDE and AL Side-by-Side. Default: Not enabled (check box is cleared) Dynamically Updatable: No
Enable Multithreaded Compilation of Published Extensions Service Endpoint	EnableMultithreadedCompilation	Specifies whether to use multiple threads for compiling AL extensions that are published to the server instance. Using multiple threads can make compilation faster, but might impact the responsiveness of other sessions that are running on the server instance. Default: Enabled Dynamically Updatable: No **APPLIES TO:** Business Central 2019 release wave 2 (version 17.0) and later.

SETTING	KEY NAME	DESCRIPTION
Enable SSL	DeveloperServicesSSLEnabled	Specifies whether SSL (HTTPS) is enabled for the developer web service port. SSL (Secure Sockets Layer) secures the connection for the web services. - If the check box is selected, then SSL is enabled. - If the check box isn't selected, the developer web service port can't establish a secure connection. Default: Not enabled (check box is cleared) Dynamically Updatable: No
Enable Test Automation	TestAutomationEnabled	Specifies whether test automation is enabled. For more information about test automation, see Testing the Application Overview. Default: Enabled Dynamically Updatable: No
HttpClient AL Function Maximum Timeout	NavHttpClientMaxTimeout	Specifies the maximum allowed timeout value that can be set for the HttpClient Timeout AL method. The value has the format HH:MM:SS. Default: 00:05:00 Dynamically Updatable: Yes
HttpClient AL Function Response Size	NavHttpClientMaxResponseContentSize	Specifies the maximum size in megabytes of a response buffer used by the HttpClient AL function. The maximum allowed extension size can be adjusted based on the HttpClient AL Function Maximum Timeout setting. Default: 15 Dynamically Updatable: Yes
Port	DeveloperServicesPort	The listening HTTP port for Microsoft Dynamics NAV Developer web services. Valid range: 1 - 65535 Default: 7049 Dynamically Updatable: No

Compatibility Settings

The following table describes settings that you can adjust for compatibility with other systems. In most cases, we don't recommend that you change these settings from their default values.

SETTING	KEY NAME	DESCRIPTION

SETTING	KEY NAME	DESCRIPTION
Enable Client Callbacks in Write Transactions	AllowSessionCallSuspendWhenWriteTransactionStarted	Specifies whether callbacks from the server to clients are allowed during write transactions. Client callbacks, for example, are used when displaying a dialog that requires user input. The setting applies to production and test environments. However, one of the main reasons for testing, to catch cases where a transaction is kept open during the suspension of AL execution. Default: Enabled (check box is selected) Dynamically Updatable: No
Enable Cloud Replication Maintenance	EnableCloudReplicationMaintenance	Specifies whether to keep the cloud replication status in the database up to date. When enabled, synchronize operations on tenants and extensions will update records in the **Intelligent Cloud Status** table, and set change tracking on tables that are configured to replicate data. Enabling this setting isn't required for migrating most on-premises solutions to the cloud, and you'll improve synchronization and upgrade performance by disabling it. Default: Disabled (check box is cleared) Dynamically Updatable: Yes **APPLIES TO:** Business Central 2020 release wave 2 (version 17.4) and later.
Security Protocol	SecurityProtocol	Specifies the default security protocol level for the server instance. This setting also controls the HttpClient. Values: **Ssl3**, **Tls**, **Tls11**, **Tls12**, **SystemDefault**. For more information about these values, see SecurityProtocolType Enum. Default: **Tls12** Dynamically Updatable: No
Unsupported Language IDs[1]	UnsupportedLanguageIds	Specifies which installed Business Central languages aren't available for use in the clients. Use this setting to prevent including languages that have the same name but different culture identifiers (LCIDs). A culture identifier is a standard international numeric abbreviation. For example, the LCID for *Spanish - Spain (Traditional)* is 1034, and *English - United States* is 1033. The setting's value is a semicolon-separated list that contains the LCIDs for each language. Default: **1034** Dynamically Updatable: No
Use Client Timestamp For Report Execution Timestamp	ReplaceReportExecutionTimeWithClientTime	Specifies whether to replace the report execution timestamp with the client timestamp instead of the server instance timestamp. Default: Enabled (check box is selected) Dynamically Updatable: No

SETTING	KEY NAME	DESCRIPTION
Use FIND('-') to Populate Pages Instead of FIND('=><')	UseFindMinusWhenPopulatingPage	Specifies whether pages are initially populated by using FIND('-') instead of FIND('=><'). This setting is relevant to pages that display lists in descending order. Enabling this setting ensures that the first record, instead of the last record, is in focus when the page opens. Pages that use the OnFindRecord trigger will ignore this setting and always use FIND('=><'). Default: Enabled (check box is selected) Dynamically Updatable: No

[1] Introduced in Business Central 2020 release wave 1, update 16.4.

> **IMPORTANT**
> Starting March, 2020, Business Central only supports Transport Layer Security (TLS) version 1.2 or later. This applies to Business Central 2019 release wave 2 online and on-premises (version 15.x). Upgrade to Business Central 2019 release wave 2 or later to remove support for earlier versions of TLS. If your solution or an add-on uses TLS 1.0 or 1.1, you must update that configuration or add-on to TLS 1.2 or later as soon as possible. For more information, see Blog post: Update to TLS 1.2 or later in Dynamics 365 Business Central in 2019 release wave 2.

Upgrade Settings

APPLIES TO: Business Central 2019 release wave 2 and later

The following table describes fields on the **Upgrade** tab in the Business Central Server Administration tool.

SETTING	KEY NAME	DESCRIPTION
Integration Records Table (ID)	IntegrationRecordsTableId	Specifies the ID of the application table that is used to store integration record IDs. This setting only applies when you upgrade from Business Central Spring 2019 (version 14) to Business Central 2019 release wave 2 (version 15). It ensures that current integration record IDs that are used in the application can be used as-is after upgrade. When a database is upgraded, a **SystemId** column will be added to the **Integration Records** table, and each record in the table will be assigned a **SystemId** value. The base application looks to this column to identify integration records. If you specify the **Integration Records Table (ID)** setting, the data upgrade process will set the **SystemId** to the same value as integration record ID; otherwise, the value is randomly assigned by the system. If you aren't upgrading to the Business Central 2019 release wave 2 base application, you can either skip this upgrade step by setting the value to 0. This is the case, when you've a fully customized application or you're only doing a technical upgrade. Or, if you 're using a different integration record table than **5151 Integration Record**, set the value to ID of your custom integration record table. The custom integration record table must include the following columns as a minimum (with exact naming): Integration ID, Record ID, Table ID. Default: 5151 Dynamically Updatable: Yes

SETTING	KEY NAME	DESCRIPTION
not available	DestinationAppsForMigration	Specifies the extensions that Microsoft and 3rd-party extensions have a dependency on. The dependencies typically include the base application, system application, and test application. Only use this setting when upgrading from Business Central Spring 2019. The setting is used during the data upgrade process. If configured, when an extension is published, the server instance will automatically modify the manifest of the extension to include the required dependencies. Default: Dynamically Updatable: No

Using Business Central Administration Shell to Modify Server Instance Settings

The Business Central Administration Shell includes several `Set-` cmdlets that enable you to create and modify Business Central Server instances.

The main cmdlet for configuring a server instance is the Set-NAVServerConfiguration cmdlet. You can use this cmdlet to change any of the configuration settings that are listed in the previous sections. To change a configuration setting, you set `-KeyName` parameter to the **Key Name** that corresponds to the setting, and set the `-KeyValue` parameter to the new value. For example, you can change the value for `DatabaseServer` to `DatabaseServer.Domain.Com` for the server instance named `MyInstance` by executing this cmdlet:

```
Set-NAVServerConfiguration -ServerInstance "MyInstance" -KeyName "DatabaseServer" -KeyValue
"DatabaseServer.Domain.Com"
```

Modifying dynamically updatable settings

For dynamically updatable settings, use the `-ApplyTo` parameter to specify how to apply the change. The change can be written directly to the configuration file (CustomSettings.config) and applied to the current server instance state. The option you choose will determine whether a server instance restart is required for the change to take effect. The parameter has three options, as described in the following table:

OPTION	DESCRIPTION
ConfigFile	Saves the change to the configuration file of the server instance. The change won't take effect until the server instance is restarted.
Memory	Applies the change only to the server instance's current state. The changes take effect immediately, without having to restart the server instance. The change is stored in memory. The next time the server instance is restarted, it reverts to the setting in the configuration file.
All	Applies the change to the server instance's current setting state (in memory) and to the configuration file. The changes take effect immediately, without having to restart the server instance.

For example, the following command sets the value for the `MaxStreamReadSize` key to `42424242`, without having to restart the server instance.

```
Set-NAVServerConfiguration -ServerInstanceMyInstance -KeyName MaxStreamReadSize -KeyValue 42424242 -ApplyTo
Memory
```

For more information about running the Business Central Administration Shell, see Microsoft Dynamics NAV Windows PowerShell Cmdlets.

Configuring Business Central Web Server Instances

2/17/2021 • 11 minutes to read • Edit Online

Accessing Business Central from the Business Central Web client or App requires a Business Central Web Server instance on IIS. You create a Business Central Web Server instance for the Business Central Web Server by using the Business Central Setup to install the Business Central Web Server or by running the New-NAVWebServerInstance cmdlet. When you set up a web server instance, you are configuring the connection from the Business Central Web Server to the Business Central Server instance. The connection settings, along with several other configuration settings, are saved in a configuration file for the web server instance.

About the configuration file

The configuration file for the web server instances is a .json file type called **navsettings.json**. The navsettings.json file is a Java Script Object Notification file type that is similar to files that use the XML file format.

After installation, you can change the configuration by modifying the navsettings.json. There are two ways to modify this file: directly or using PowerShell.

Where to find the navsettings.json file

The navsettings.json file is stored in the physical path of the web server instance, which is by default is *%systemroot%\inetpub\wwwroot\[WebServerInstanceName]*.

[WebServerInstanceName] corresponds to the name (alias) of the web server instance in IIS, for example, *c:\inetpub\wwwroot\BC160*.

Modify the navsettings.json file directly

1. Open the navsettings.json in any text or code editor, such as Notepad or Visual Studio Code.

   Each setting is defined by a key-value pair.

   - In the navsettings.json file, a setting has the format:

     ```
     "keyname": "keyvalue",
     ```

   The `keyname` is the name of the configuration setting and the `keyvalue` is the value.

   For example, the configuration setting that specifies the Windows credential type for authenticating users is:

   ```
   "ClientServicesCredentialType":  "Windows",
   ```

   Include values in double quotes.

2. Find the configuration settings that you want to change, and then change the values.

   See the Settings section for a description of each setting.

3. When you are done making changes, save the file.

4. Restart the Business Central Web Server instance for the changes to take effect.

For example, in IIS Manager, in the **Connections** pane, select website node for Business Central Web Server, and then in the **Actions** pane, choose **Restart**. Or, from your desktop, run `iisreset`.

Modify the navsettings.json file by using the Set-NAVWebServerInstanceConfiguration cmdlet

The PowerShell script module **NAVWebClientManagement.psm1** includes the Set-NAVWebServerInstanceConfiguration cmdlet that enables you to configure a web server instance.

1. Depending on your installation, run the Dynamics NAV Development Shell or Windows PowerShell as an administrator.

   For more information, see Get started with the Business Central Web Server cmdlets.

2. For each setting that you want to change, at the command prompt, run the following command:

   ```
   Set-NAVWebServerInstanceConfiguration -Server [MyComputer] -ServerInstance [ServerInstanceName] -
   WebServerInstance [MyBCWebServerInstance] -KeyName [Setting] -KeyValue [Value]
   ```

   Replace:

   - `[MyComputer]` with the name of the computer that is running the Business Central Server
   - `[ServerInstanceName]` with the name of the server instance, such as **BC160**.
   - `[MyBCWebServerInstance]` with the name of the web server instance for the Business Central Web Server.
   - `[KeyName]` with the name of the setting. Refer to the next section in this article.
   - `[KeyValue]` with the new value of the setting.

Settings in the navsettings.json

The navsettings.json has the following structure, where settings are included under one of two root elements: `NAVWebSettings` and `ApplicationIdSettings`:

```
{
  "NAVWebSettings": {
     "//ServerInstance":  "Name of the Business Central Server instance to connect to (for client) or listen
on (for server).",
     "ServerInstance":  "BC150",
      [...more keys]
 },
  "ApplicationIdSettings": {
      "BlogLink": "https://myBCBlog.com",
      [...more keys]
  }
}
```

`//` indicates a comment that provides help for the setting, and has no effect on the Web Server instance.

The following table describes the settings that are available in the navsettings.json for each root element. If you do not see a setting in the file, this is because some settings are not automatically included as a key in the file. For these settings, you can add the key manually. If you do not add the key, the default value of the setting is used.

> **IMPORTANT**
> If modifying the file directly, place values in double quotes `""`.

`NAVWebSettings` element settings

SETTING/KEYNAME	DESCRIPTION
AllowedFrameAncestors	Specifies the host name of any web sites in which the Business Central Web client or parts of are embedded. By default, the Business Central Web Server will not allow a website to display it inside an iframe unless the website is hosted on the same web server. This value of this setting is a comma-separated list of host names (URIs). Wildcard names are accepted. For example: `https:mysite.sharepoint.com, https:*.myportal.com`
AllowNtlm	Specifies whether NT LAN Manager (NTLM) fallback is permitted for authentication. To require Kerberos authentication, set this value to `false`. Values: `true`, `false` Default value: `true`
AuthenticateServer	Specifies whether to authenticate the server by enabling service identity checks on protocol between the Web server and the Business Central Server instance. Values: `true`, `false` Default value: `true`
ClientServicesCredentialType	Specifies the authorization mechanism that is used to authenticate users who try to connect to the Business Central Web Server. For more information, see Authentication and User Credential Type. The credential type must match the credential type configured for the Business Central Server instance that the Business Central Web Server connects to. For information about how to set up the credential type on Business Central Server, see Configuring Business Central Server. Values: Windows, UserName, NavUserPassword, AccessControlService Default value: Windows

SETTING/KEYNAME	DESCRIPTION
ClientServicesChunkSize	Sets the maximum size, in kilobytes, of a data chunk that is transmitted between Business Central Web Server and Business Central Server. Data that is transmitted between Business Central Web Server and Business Central Server is broken down into smaller units called chunks, and then reassembled when it reaches its destination. Values: From 4 to 80. Default value: 28
ClientServicesCompressionThreshold	Sets the threshold in memory consumption at which Business Central Web Server starts compressing data sets. This limits amount of consumed memory. The value is in kilobytes. Default value: 64
ClientServicesPort	Specifies the TCP port for the Business Central Server. This is part of the Business Central Server's URL. Values: 1-65535 Default value: 7046
ClientServicesProtectionLevel	Specifies the security services used to protect the data stream between the Business Central Web Server and Business Central Server. This value must match the value that is specified in the Business Central Server configuration file. For more information, see Configuring Business Central Server. Values: EncryptAndSign, Sign, None Default value: EncryptAndSign
DefaultRelativeHelpPath	Specifies the default Help article to open if no other context-sensitive link is specified. Default value: none
Designer	Specifies whether the in-client designer is enabled in the Business Central Web client. Set to `true` to enable designer. For more information, see Using Designer.

SETTING/KEYNAME	DESCRIPTION
DnsIdentity	Specifies the subject name or common name of the service certificate for Business Central Server. This parameter is only relevant when the ClientServicesCredentialType is set to UserName, NavUserPassword, or AccessControlService, which requires that security certificates are used on the Business Central Web Server and Business Central Server to protect communication. **Note:** You can find the subject name by opening the certificate in the Certificates snap-in for Microsoft Management Console (MMC) on the computer that is running Business Central Web Server or Business Central Server. For more information, see Authentication and User Credential Type. Value: The subject name of the certificate. Default value: none
GlobalEndPoints	Specifies the comma-separated list of global endpoints that are allowed to call this website. The values must include http scheme and fully qualified domain name (FDQN), such as `https://businesscentral.microsoft.com`. "GlobalEndPoints": "null,ms://businesscentral,ms://dynamicsnav" Default value: none
HelpServer	Specifies the name of the Business Central Help Server if the deployment uses Help Server. If the deployment uses an online library, remove this setting. Default value: none
HelpServerPort	Specifies the TCP port on the specified Business Central Help Server if the deployment uses Help Server. If the deployment uses an online library, remove this setting. Default value: none
LoadScriptsFromCdn	Specifies whether to load scripts from Content Distribution Networks (CDNs). This only applies to scripts that are available from a CDN, like jQuery. If set to `false`, scripts will be loaded from the Web server, which is useful in, for example, an intranet scenario where there is no internet access. Default value: `true` **DISCONTINUED AFTER:** Business Central Spring 2019
ManagementServicesPort	The listening TCP port for the Business Central management endpoint. Valid range: 1-65535 Default value: 7045

SETTING/KEYNAME	DESCRIPTION
OfficeSuiteShellServiceClientTimeout	Defines the time Business Central will wait for the Office Suite Shell Service to respond. **Important:** This setting has been deprecated in Business Central, and it has no effect on the Web Server instance. Default value: 10
PersonalizationEnabled	Specifies whether personalization is enabled in the Business Central Web client. Set to `true` to enable personalization. For more information, see Managing Personalization.
ProductName	Specifies the full name of the application.
ProductNameShort	Specifies the short name of the application.
ProductNameMarketing	Specifies the marketing name of the application.
RequireSsl	Specifies whether SSL (https) is required. If the value is set to `true`, all cookies will be marked with a `\u0027secure\u0027` attribute. If SSl is enabled on the Web server, you should set this to `true`. Values: `true`, `false` Default value: `false`
Server	Specifies the name of the computer that is running the Business Central Server. Default value: localhost
ServerInstance	Specifies the name of the Business Central Server instance that the Business Central Web Server connects to. Default value: BC160
ServicePrincipalNameRequired	If this parameter is set to `true`, then the Business Central Web Server can only connect to a Business Central Server instance that has been associated with a service principal name (SPN). If this parameter is set to `false`, then the Business Central Web Server attempts to connect to the configured Business Central Server service, regardless of whether that service is associated with an SPN. For more information about SPNs, see Configure Delegation. Default: `false`

SETTING/KEYNAME	DESCRIPTION
SessionTimeout	Specifies the maximum time that a connection between the Business Central Web Server and the Business Central Server can remain idle before the session is stopped. In the Business Central Web Server, this setting determines how long an open Business Central page or report can remain inactive before it closes. For example, when the SessionTimeout is set to 20 minutes, if a user does not take any action on a page within 20 minutes, then the page closes and it is replaced with the following message: **The page has expired and the content cannot be displayed.** The time span has the format [dd.]hh:mm:ss[.ff]: - dd is the number of days - hh is the number of hours - mm is the number of minutes - ss is the number of seconds - ff is fractions of a second Default value: 00:20:00
ShowPageSearch	Specifies whether to show the  **Tell me what you want to do** icon in the Business Central header. This feature lets users find Business Central objects, such as pages, reports, and actions. If you do not want to show the **Tell me what you want to do** icon, then set the parameter to `false`. Default value: `true`

SETTING/KEYNAME	DESCRIPTION
UnknownSpnHint	Specifies whether to use a server principal name when establishing the connection between the Business Central Web Server server and Business Central Server. This setting is used to authenticate the Business Central Server, and it prevents the Business Central Web Server server from restarting when it connects to Business Central Server for the first time. You set values that are based on the value of the ServicePrincipalNameRequired key. Value: The value has the following format. (net.tcp://BCServer:Port/ServerInstance/Service)=NoSpn|SPN - BCServer is the name of the computer that is running the Business Central Server. - Port is the port number on which the Business Central Server is running. - ServerInstance is the name of the Business Central Server instance. - NoSpn|SPN specifies whether to use an SPN. If the ServicePrincipalNameRequired key is set to `false`, then set this value to NoSpn. If the ServicePrincipalNameRequired key is set to `true`, then set this value to Spn. Default value: (net.tcp://localhost:7046/BC160/Service)=NoSpn If you set this key to the incorrect value, then during startup, the Business Central Web Server will automatically determine a correct value. This will cause the Business Central Web Server to restart. **Note:** For most installations, you do not have to change this value. Unlike the Dynamics NAV Client connected to Business Central, this setting is not updated automatically. If you want to change the default value, then you must change it manually.
UseAdditionalSearchTerms	Specifies whether **Tell me** uses the additional search terms that are defined on pages and reports. The additional search terms are specified by the AdditionalSearchTerms and AdditionalSearchTermsML properties. If you set this to `false`, the additional search terms are ignored. Default value: true

`ApplicationIdSettings` element settings

SETTING/KEYNAME	DESCRIPTION
BaseHelpUrl	Specifies the link to the online Help library that the deployment uses, such as *https://mysite.com/{0}/mylibrary/*. Default value: none For more information, see Configuring the Help Experience.

SETTING/KEYNAME	DESCRIPTION
BlogLink	Specifies the target of the **blog** link on the **Help & Support** page. Use this link to give users access to your end-user blog. Value: a valid URL Default value: https://go.microsoft.com/fwlink/?linkid=2076643|
ComingSoonLink	Specifies the target of **coming soon** link on the **Help & Support** page. Use this link to give users access to information about your roadmap or any upcoming features and fixes. Value: A valid URL. Default value: https://go.microsoft.com/fwlink/?linkid=2047422
CommunityLink	Specifies the URL to a community or resource for sharing information. Value: a valid URL Default value: https://go.microsoft.com/fwlink/?LinkId=287089|
ContactSalesLink	Specifies the target of the contact sales link on the **Help & Support** page. Use this link to give users access to your sales-focused web page where users can engage with your sales process. **Note:** This setting and link are not used for Business Central on-premises.
SigninHelpLink	Specifies the URL to open if the user selects help on the sign-in page box. Value: a valid URL Default value: none

Setting Up Multiple Business Central Web Server Instances Using PowerShell

2/17/2021 • 5 minutes to read • Edit Online

Although you can use the Business Central Setup to install the Business Central Web Server components and create a single web server instance in IIS for client connection, there may be scenarios when you want to set up multiple instances. For example, you could set up a separate Business Central Web Server instance for the different companies of a business. For this scenario, you can use the Business Central Web Server PowerShell cmdlets, which are outlined in the following table.

CMDLET	DESCRIPTION
New-NAVWebServerInstance	Creates a new Business Central Web Server instance and binds this instance to a Business Central Server instance.
Set-NAVWebServerInstanceConfiguration	Specifies configuration values for a named Business Central Web Server instance.
Get-NAVWebServerInstance	Gets the information about the Business Central Web Server instances that are registered on a computer.
Remove-NAVWebServerInstance	Removes an existing Business Central Web Server instance.

Get started with the Business Central Web Server cmdlets

The Business Central Web Server cmdlets are contained in the PowerShell script module **NAVWebClientManagement.psm1**, which is available on the Business Central installation media (DVD).

The module is installed with the Business Central Server or the Business Central Web Server components.

There are different ways to launch this module and start using the cmdlets:

- If you are working on the computer where the Business Central Server was installed, run the Business Central Administration Shell as an administrator.

  For more information, see Business Central PowerShell Cmdlets.

- If you installed the Business Central Web Server components, just start Windows PowerShell as an administrator.

- Otherwise, start Windows PowerShell as an administrator, and use the Import-Module cmdlet to import the **NAVWebClientManagement.psm1** file:

  ```
  Import-Module -Name [filepath]
  ```

  For example:

  ```
  Import-Module -Name "C:\Program Files\Microsoft Dynamics 365 Business
  Central\130\Service\NAVWebClientManagement.psm1"
  ```

For more information, see the Windows PowerShell docs.

Creating Business Central Web Server instances

Get Access to the WebPublish folder

To create a new web server instance, you need access to the **WebPublish** folder that contains the content files for the Business Central Web Server components.

- This folder is available on the Business Central installation media (DVD) and has the path "DVD\WebClient\Microsoft Dynamics NAV\13x\Web Client\WebPublish".
- If you installed the Business Central Web Server components, this folder has the path "C:\Program Files\Microsoft Dynamics 365 Business Central\160\Web Client\WebPublish".

You can use either of these locations or you can copy the folder to more convenient location on your computer or network.

Decide on the site deployment type for the instance

When you create a new Business Central Web Server instance, you can choose to create either a RootSite or SubSite type. Each instance type has a different hierarchical structure in IIS, which influences its configuration and the URLs for the accessing from the Business Central Web client.

RootSite

A *RootSite* instance is a root-level web site that is complete with content files for serving the Business Central Web client. It is configured with its own set of bindings for accessing the site, such as protocol (http or https) and communication port. The structure in IIS looks like this:

```
- Sites
  - BusunessCentralWebSite (web site)
    + nn-NN (language versions)
    + www (content)
    navsettings.json
    ...
```

The Business Central Web client URL for the RootSite instance has the format:

`https://[WebserverComputerName]:[port]`

For example: `https://localhost:8080`.

SubSite

A *SubSite* instance is a web application that is under a container web site. The container web site is configured with a set of bindings, but the site itself has no content files. The content files are contained in the application (SubSite). The SubSite inherits the bindings from the container web site. This is the deployment type that is created when you install Business Central Web Server components in the Setup wizard. Using the New-NAVWebServerInstance cmdlet, you can add multiple SubSite instances in the container web site. The structure in IIS for two instances looks like this in IIS:

```
- Sites
  - BusunessCentralWebSite (web site)
    - BusinessCentralWebInstance1 (application)
      + nn-NN (language versions)
      + www
      navsettings.json
      ...
    - BusinessCentralWebInstance2 (application)
      + nn-NN (language versions)
      + www
      navsettings.json
      ...
```

The Business Central Web client URL of a SubSite instance is generally longer than a RootSite because it also contains the application's alias (or virtual path) for the instance, which you define. The URL for a SubSite instance has the format:

`https://[WebserverComputerName]:[port]/[WebServerInstance]`

For example: `https://localhost:8080/BusinessCentralWebInstance1` and `https://localhost:8080/BusinessCentralWebInstance2`.

Run the New-NAVWebServerInstance cmdlet

At the command prompt, run the New-NAVWebServerInstance cmdlet. The following are simple examples for creating a RootSite and SubSite deployment type.

RootSite example:

```
New-NAVWebServerInstance -WebServerInstance MyBCWebsite -Server MyBCServer -ServerInstance
MyBCServerInstance -SiteDeploymentType RootSite -WebSitePort 8081 -PublishFolder "C:\Web Client\WebPublish"
```

SubSite example:

```
New-NAVWebServerInstance -WebServerInstance MyWebApp -Server MyBCServer -ServerInstance MyBCServerInstance -
SiteDeploymentType Subsite -ContainerSiteName MySiteContainer -WebSitePort 8081 -PublishFolder
"C:\WebClient\WebPublish"
```

- Susbtitute *MyBCWebsite* with the name that you want to give the web application in IIS for the web server instance. If you are creating a SubSite deployment type, this name will become part of the URL for opening the Business Central Web client application, for example, https://MyWebServer:8081/MyWebApp.
- Susbtitute *MyBCServer* to the name of the computer that is running the Business Central Server to which you want to connect.
- Susbtitute *MyBCServerInstance* with the name of the Business Central Server instance to use.
- Substitute *MySiteContainer* with name of the container web site under which you want to add the instance. If you specify a name that does not exist, then a new container web site will be created, which contains the new web server instance.
- Susbtitute *8081* with the port number that you want to bind the instance to. If you do not specify a port number, then port 80 is used.
- Substitute *C:\WebClient\WebPublish* with the path to your WebPublish folder. By default, the cmdlet looks in the'C:\Program Files\Microsoft Dynamics 365 Business Central\160\Web Client' folder. So if you are working on a computer where the Business Central Web Server components are installed, you do not

have to set this parameter.

> **NOTE**
>
> This command only sets the required parameters of the NAVWebServerInstance cmdlet. The cmdlet has several other parameters that can use to configure the web server instance. For more information about the syntax and parameters, see New-NAVWebServerInstance.

Modifying a Business Central Web Server instance

After you create the web server instance, if you want to change its configuration, you can use the Set-NAVWebServerInstanceConfiguration cmdlet. Or, you can modify the configuration file (navsettings.json) of the instance directly. For more information, see Configuring Web Server Instances.

Configuring Web Server Instances

Configuring the Business Central Database

2/17/2021 • 7 minutes to read • Edit Online

For a Business Central Server instance to connect to and access a database in SQL Server, the server instance must be authenticated by the database. As in SQL Server, Business Central supports two authentication modes for database communication: Windows Authentication and SQL Server Authentication. When you set up Business Central, you must ensure that database authentication is configured correctly on both the server instance and database, otherwise the server instance will not be able to connect to the database. By default, Windows Authentication is configured on the server instance and database. With Windows Authentication the Business Central Setup does the work for you.

This article describes how to configure SQL Server Authentication. You perform the configuration in two places: on the databases in SQL Server and on the Business Central Server instance. The procedure is different when the Business Central Server instance is configured as a multitenant server instance than when it is not a multitenant server instance.

Set Up an Encryption Key

When using SQL Server authentication, Business Central requires an encryption key to encrypt the credentials (user name and password) that the Business Central Server instance uses to connect to the Business Central database in SQL Server. The encryption key must be installed on the computer where the Business Central Server is installed and also in the database in SQL Server. In a multitenant deployment, the encryption key must be installed in the application database.

To set up an encryption key, you can use one of the following methods:

- You can create and import your own encryption key by using Business Central Administration Shell cmdlets, as described in the following procedure.
- If you are configuring SQL Server authentication on a Business Central Server instance for the first time, you can use the Business Central Server Administration tool which can automatically create and install a system encryption key. If you decide to use this method, no action is required.

Create and import encryption key

1. In the Business Central Administration Shell, run the New-NAVEncryptionkey cmdlet.

   This creates a file that contains an encryption key. If you already have an encryption key file, you can skip this step.

2. Run the Import-NAVEncryptionkey cmdlet to install the encryption key on the Business Central Server instance and database.

On the computer running the Business Central Server instance, the encryption key file has the name BC160.key and is stored in the `%systemroot%\ProgramData\Microsoft\Microsoft Dynamics NAV\[version]\Server\Keys`. In the database, the encryption key is registered in the dbo.ndopublicencryptionkey table. In a multitenant deployment, the encryption key is registered in the application database.

Configure SQL Authentication on the Database

This section describes how to configure a Business Central database to use SQL Server Authentication with a Business Central Server instance. You can complete the steps in this procedure by using SQL Server Management Studio or Transact-SQL.

> **IMPORTANT**
> In a deployment where the Business Central Server instance is configured as a multitenant server instance, you must complete the following procedure on the application database and tenant database.

Configure SQL Server Authentication on the database in SQL Server

1. Configure the SQL Server instance (Database Engine) that hosts the Business Central database to use SQL Server Authentication.

   To use SQL Server authentication, you configure the database instance to mixed authentication mode (SQL Server and Windows Authentication). For more information, see Change Server Authentication Mode.

2. In the SQL Server instance, create a login that uses SQL Server authentication.

   For more information, see Create a Login.

3. Map the login to a user in the Business Central database, and give the user the relevant privileges in the Business Central database.

   For more information, see Create a Database User in the SQL Server docs and the Giving the service account database privileges in SQL Server in the current article.

Configure SQL Server Authentication on the Business Central Instance (Non-Multitenant)

You configure the Business Central Server instance with the login credentials (user name and password) of the user account in the Business Central database in SQL Server that you want to use for authentication. You can do this using the Business Central Server Administration tool or Business Central Administration Shell.

Configure SQL Authentication on a server instance using Business Central Server Administration tool

1. Open the Business Central Server Administration tool.
2. In the console tree, which is the left pane, expand the node for the computer that contains the Business Central Server instance, and then select the Business Central Server instance.
3. In the **Actions** pane, choose **Database Credentials**.
4. On the **Database Credentials** page, choose the **Edit** button.
5. Set the **Database Authentication Type** to **SQL Authentication**.
6. In the **Database User Name** field, type the login name for the database user that you want to use to access the Business Central database in SQL Server.
7. In the **Password** field, type the login password for the database user that you want to use to access the Business Central database in SQL Server.
8. Choose the **Save** button, and then on the **Enable Encryption on SQL Server Connections** dialog box, choose the **OK** button.

   Encryption keys are used to help secure the login credentials over the connection between the Business Central Server instance and the Business Central database in SQL Server.

9. On the **Information** dialog box about encryption, choose the **OK** button.

   This dialog box is to inform you to enable encryption on SQL Server connections, which is disabled by default.

10. If you want to enable encryption on SQL Server connections, in the **Action** pane, choose **Configuration**, and then choose the **Edit** button. In the **Database** tab, select **Enable Encryption on SQL Connections**, choose the **Save** button, and then the **OK** button.

11. Restart the server instance.

Configure SQL Authentication on a server instance using Business Central Administration Shell

- If you are modifying an existing Business Central Server instance, run the Set-NAVServerConfiguration cmdlet.

  Use the *DatabaseCredentials* parameter to provide the login credentials of the database user that you want to use to access the application database.

- If you are creating a new Business Central Server instance, run the New-NAVServerInstance cmdlet.

  Use the *DatabaseCredentials* parameter to provide the login credentials of the database user that you want to use to access the application database.

Configure SQL Server Authentication on Business Central Instance in a Multitenant Deployment

This section describes how to configure a Business Central database to use SQL Server Authentication with a Business Central Server instance. You can complete the steps in this procedure by using SQL Server Management Studio or Transact-SQL.

To configure a SQL Server Authentication on a Business Central Server instance, you set up the server instance with the login credentials (user name and password) for the user accounts for the application and tenant databases in SQL Server. You can do this using the Business Central Server Administration tool or Business Central Administration Shell.

Configure SQL Authentication using Business Central Server Administration tool

1. Open the Business Central Server Administration tool.

2. In the console tree, which is the left pane, expand the node for the computer that contains the Business Central Server instance, and then select the Business Central Server instance.

3. Configure SQL Server Authentication with the application database as follows:

   a. In the **Actions** pane, choose **Database Credentials**.

   b. On the **Database Credentials** page, choose the **Edit** button.

   c. Set the **Database Authentication Mode** to **SQL Server Authentication**.

   d. In the **Database User Name** field, type the login name for the database user that you want to use to access the Business Central application database in SQL Server.

   e. In the **Password** field, type the login password for the database user that you want to use to access the Business Central database in SQL Server.

   f. Choose the **Save** button, and then on the **Enable Encryption on SQL Server Connections** dialog box, choose the **OK** button.

      Encryption keys are used to help secure the login credentials over the connection between the Business Central Server instance and the Business Central database in SQL Server.

   g. On the **Information** dialog box about encryption, choose the **OK** button.

      This dialog box is to inform you to enable encryption on SQL Server connections, which is

disabled by default.

h. If you want to enable encryption on SQL Server connections, in the **Action** pane, choose **Configuration**, and then choose the **Edit** button. In the **Database** tab, select **Enable Encryption on SQL Connections**, choose the **Save** button, and then the **OK** button.

4. To configure SQL Server Authentication with the tenant database, mount the tenant to the Business Central Server instance and specify the login credentials (user name and password) for the database user that you want to use to access the Business Central tenant database in SQL Server.

   If the tenant is already mounted to the Business Central Server instance, you must dismount the tenant, and mount it again.

   For more information see Mount or Dismount a Tenant.

5. Restart the server instance.

Configure SQL Authentication using Business Central Administration Shell

1. Configure SQL Server Authentication with the application database as follows:

   - If you are modifying an existing Business Central Server instance, run the Set-NAVServerConfiguration cmdlet.

     Use the *DatabaseCredentials* parameter to provide the login credentials of the database user that you want to use to access the application database.

   - If you are creating a new Business Central Server instance, run the New-NAVServerInstance cmdlet.

     Use the *DatabaseCredentials* parameter to provide the login credentials of the database user that you want to use to access the application database.

2. To configure SQL Authentication with the tenant database, run the Mount-NAVTenant cmdlet.

   Use the *DatabaseCredentials* parameter to provide the login credentials of the database user that you want to use to access the tenant database.

Installing Business Central Using Setup

Encrypting Data in Dynamics 365 Business Central

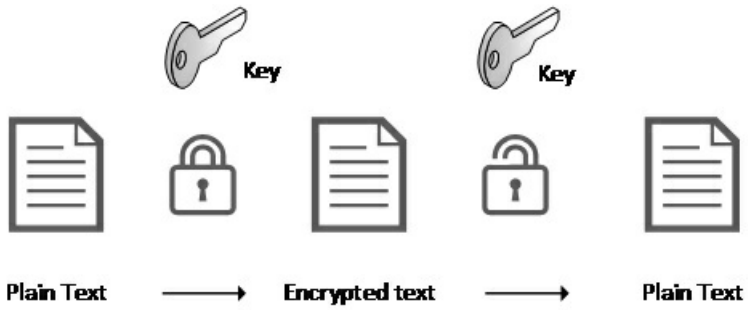
2/17/2021 • 2 minutes to read • Edit Online

This article gives an overview of data encryption and how to use it to add security Dynamics 365 Business Central.

> **NOTE**
> This applies only to on-premises versions of Business Central. For online versions, encryption is always enabled and you cannot turn it off.

Cryptography overview

The methods that support cryptography provide services that enable developers manage encrypting and decrypting data. Each tenant supports a single encryption key which is used for encrypting and decrypting data stored in the database. Additional methods are provided to assist building robust solutions when working with encryption and for managing the encryption keys.



Encryption keys are stored in a secure location, and retrieved at runtime when needed. Additional functionality is provided to export and import keys, which is important when moving solutions from one location to another.

Encryption key management

The process of encrypting and decrypting data requires a key. An encryption key is typically a random string of bits generated specifically to scramble and unscramble data. Encryption keys are created by using algorithms designed to make sure that each key is unique and unpredictable. The keys that are used by Dynamics 365 Business Central are generated by the .NET Framework Data Protection API.

Each tenant supports having a single encryption key. To use the encryption methods, a key must be created. There are two ways of doing this; either by importing a key or by creating a key. The **CREATEENCRYPTIONKEY** method will create an encryption key in a system that does not have a key present. Alternatively, if a key exists, you can use the **IMPORTENCRYPTIONKEY** method to introduce a key to a keyless system.

> **WARNING**
> **CREATEENCRYPTIONKEY** will fail if the key already exists, you must then call **DELETEENCRYPTIONKEY** to clear the state. **IMPORTENCRYPTIONKEY** will throw a warning if a key already exists, regardless of if the key is present on the system or not.

Best practices

These are some best practices we recommend that you follow:

- Make sure to always backup your key and store it securely. Use the **EXPORTENCRYPTIONKEY** method and keep the output file in a secure location.
- Use the Dynamics 365 permission system to restrict access to encryption key logic.
- Be aware of the difference between the **ENCRYPTIONKEYEXISTS** and **ENCRYPTIONENABLED** methods.

ENCRYPTIONKEYEXISTS versus ENCRYPTIONENABLED

The encryption key is stored in a file in a directory that the Dynamics 365 Business Central service has access to. When a key is created or imported, data is recorded in the tenant table registering that encryption has now been enabled. Any subsequent calls to **ENCRYPTIONENABLED** will return true after the tenant table has been updated with this information. However, if the encryption file is deleted, then **ENCRYPTIONENABLED** will continue to return true. Use the **ENCRYPTIONKEYEXISTS** method to perform a file system check to see whether the key is present.

Data Encryption

Setting up the Excel Add-In for Editing Business Central Data

2/17/2021 • 9 minutes to read • Edit Online

You can set up the Business Central deployment to support an Excel add-in that enables users in the Business Central client to work with data from list pages in Excel. Users can get fresh data from Business Central into Excel and push updated data from Excel to Business Central.

Without this add-in, users can open a list page in Excel from the **Open in Excel** action on the page. But the **Open in Excel** action doesn't allow them to push changed data back to Business Central. When this add-in is set up, the **Open in Excel** action is replaced by the **Edit in Excel** action. The add-in is based on the Microsoft Dynamics Office Add-In.

> **NOTE**
> The Excel add-in is not available in the mobile apps.

This article provides guidance for how to configure Business Central so that users can edit data in Excel.

> **NOTE**
> This article does not apply to the older Excel add-in that was available for installation with the Dynamics NAV Client connected to Business Central client by using the Business Central Setup in versions older than 2019 release wave 2.

Deploy the Excel add-in for Business Central online

For Business Central online, the administrator can deploy the add-in for all users. But users can also install the add-in themselves, provided they have permission to configure their Office experience.

> **TIP**
> In some organizations, administrators cannot deploy add-ins centrally. For more information, see Determine if Centralized Deployment of add-ins works for your organization.

To deploy the Excel add-in for all users

1. As the administrator, sign in to the Microsoft commercial website and find the add-in at https://appsource.microsoft.com/product/office/WA104379629.
2. Choose the **Get it now** button.

   You'll be redirected to the Microsoft 365 admin center.
3. In the left panel, go to **Settings**, and then choose **Add-ins**.
4. In the **Configure add-in** pane, specify which users to grant access to the add-in.
5. Save your changes.

When users now choose the **Edit in Excel** action, the add-in will launch as a pane in Excel. Each user will be automatically logged in and connected to their Business Central, but if a user cannot connect automatically, you

can unblock them by asking them to follow the steps in the To configure the connection section.

To add the Excel add-in locally

1. Open Excel, and then open any Excel workbook.
2. On the **Insert** menu, choose **Office Add-ins**, and then choose **Admin managed** or **Store** as appropriate.
3. Search for *Dynamics Office Add-In*, and then install the add-in.

When the add-in is installed, it shows up as a panel in Excel. Next, you must configure the connection.

To configure the connection

1. In the Dynamics 365 Excel add-in, choose **Add server information**, and then in the **Server URL** field, enter `https://exceladdinprovider.smb.dynamics.com`.
2. Choose the OK button, and then confirm that the app reloads.
3. When prompted, sign in with your Azure Active Directory account.
4. Optionally, choose the environment and company that you want to connect to.

The add-in is now connected to your Business Central, and you can edit data and publish the changes to Business Central.

> **TIP**
> If the workbook is not automatically saved to the user's OneDrive, then recommend them to save all workbooks that they export from Business Central. When they open the workbook again, the connection is still available, so they do not have to configure the connection again.

> **NOTE**
> In certain deployments, the administrator must configure network access to unblock the Excel add-in. For more information, see Preparing Your Network for the Excel Add-In.

Troubleshooting

Sometimes, users run into problems with the Excel add-in. In this section, we provide tips for how to unblock users in certain circumstances.

ISSUE	SOLUTION OR WORKAROUND	COMMENTS
The add-in doesn't start	Check if the add-in is deployed centrally, or if the user is blocked from installing it locally.	The admin can configure Office so that users cannot acquire add-ins. In those cases, the admin must deploy the add-in centrally. For more information, see Deploy add-ins in the admin center.
Data does not load into Excel	Test the connection by opening another list in Excel from Business Central. Alternatively, open the workbook in Excel in a browser.	If the user has specified a company name that contains special characters, the add-in might not be able to connect.
Data can't publish back to Business Central.	Test the connection by opening the workbook in Excel in a browser.	Sometimes an extension can block the publishing job. If the page is extended or customized, remove the extensions, and then try again.

ISSUE	SOLUTION OR WORKAROUND	COMMENTS
The dates are wrong	Excel might show times and dates in a different format than Business Central. This does not make them wrong, and the data in Business Central will not get messed up.	

Deploy the Excel add-in for Business Central on-premises

Your on-premises deployment must meet the following prerequisites:

- Azure Active Directory (Azure AD) used to authenticate users.

  The Business Central Server instance, clients, and users must be configured for Azure Active Directory (Azure AD) authentication.

  For more information, see Authenticating Users with Azure Active Directory.

- OData enabled and uses Secure Sockets Layer (SSL) for authentication.

  For more information, see Using Security Certificates with Business Central On-Premises.

- Business Central Web Server installed and configured to use SSL (https).

  For more information, see Install Business Central and Configure SSL to Secure the Connection to Web Client.

- If your deployment is multitenant, Business Central Web client must accept host names for tenants.

  For more information, see Configure the Web Server to Accept Host Names for Tenants.

- Business Central client computers have a supported version of Excel.

  For more information, see System Requirements.

Expose the Business Central application Web API in Azure AD

APPLIES TO: Business Central On-Premises

When Business Central is configured for Azure AD authentication, the Business Central application is registered as an application in an Azure AD. Before the Excel add-in can be configured, you must configure the Business Central application in Azure AD to expose its Web API.

For information about how to expose the Web API, see Quickstart: Configure an application to expose web APIs.

Register and configure an Azure AD application for the Excel Add-in in Microsoft Azure

APPLIES TO: Business Central On-Premises

When Azure AD authentication was set up for your Business Central deployment, an Azure AD tenant was created in Microsoft Azure, and an application for Business Central was registered in the tenant. The Excel add-in requires that you add (register) a separate Azure AD application in the Azure AD tenant.

1. Register an Azure AD application for the Excel add-in.

   You add the Azure AD application by using the Azure portal. For guidelines, see Register your application with your Azure Active Directory tenant.

   When you add an application to an Azure AD tenant, you must specify the following information:

SETTING	DESCRIPTION
Name	The name of your application as it will display to your users, such as *Excel Add-in for Business Central*.
Supported account types	Specifies which accounts that you would like your application to support. For purposes of this article, select **Accounts in this organizational directory only**.
Redirect URI	Specifies the type of application that you're registering and the redirect URI (or reply URL) for your application. Select the type to **Web**, and in the redirect URL box, enter URL for signing in to the Business Central Web client, for example `https://localhost:443/BC170/SignIn`. The URI has the format `https://<domain or computer name>/<webserver-instance>/SignIn`, such as `https://cronusinternationltd.onmicrosoft.com/BC170/SignIn` or `https://MyBcWebServer/BC170/Signin`. **Important** The portion of the reply URL after the domain name (in this case `BC170/SignIn`) is case-sensitive, so make sure that the web server instance name matches the case of the web server instance name as it is defined on IIS for your Business Central Web Server installation.

When completed, the **Overview** displays in the portal for the new Excel Add-in application.

2. Grant the Excel add-in application permission to access the Business Central application Web API.

   Give the Azure AD application for the Excel add-in delegated permission to access the Business Central application Web API in Azure AD (which you exposed earlier in this article). This permission allows users of the Excel add-in to access the OData web services to read and write data.

   a. From the application's **Overview**, select **API Permissions**.
   b. Select the **Add a permission**
   c. On the **APIs my organization uses**, select the Business Central application.
   d. Select **Delegated permission**.
   e. Select the permission from the list, and then select **Add Permission**.

   For information, see Quickstart: Configure a client application to access web APIs.

3. Configure OAuth2 authentication in the Excel add-in.

   The Excel add-in requires OAuth2 implicit grant flow to be enabled on the Excel Add-in application. You configure OAuth2 in the manifest file for the Excel Add-in application. From the application's **Overview**, select **Manifest**, and then set `"oauth2AllowIdTokenImplicitFlow"` and `"oauth2AllowImplicitFlow"` to `true`:

   ```
   "oauth2AllowIdTokenImplicitFlow": true,
   "oauth2AllowImplicitFlow": true,
   ```

4. In the manifest, add the following URL entry to the `"replyUrlsWithType":`:

```
{
    "url": "https://az689774.vo.msecnd.net/dynamicsofficeapp/v1.3.0.0/*",
    "type": "Web"
}
```

Remember to add a comma before or after this entry, depending on where you add it in the list.

5. Copy the **Application (Client) ID** that is assigned to Excel add-in application.

   You can get this value from the **Overview** page for the application. You'll need it to configure the Business Central Server instance.

This completes the work you have to do in the Azure portal. The final configuration is to add the Excel add-in to the Business Central Server instances.

Configure the Business Central Server Instances

APPLIES TO: Business Central On-Premises

You add the Excel add-in to the Business Central Server instances in your deployment. You can use either the Business Central Server Administration tool or Set-NAVServerConfiguration cmdlet in the Business Central Administration Shell.

1. In the Business Central Server Administration tool, in the **Azure Active Directory** section, set the **Excel add-in AAD client ID** field to the application (client) ID for the Excel add-in application that you copied from the Azure portal.

   If you use the Set-NAVServerConfiguration cmdlet, set the `ExcelAddInAzureActiveDirectoryClientId` key.

2. In the **Client Services** section, set the **Web Client Base URL** field to the base URL of the Business Central Web client.

   This value is the root portion of all URLs that are used to access pages in the web client. The value must have the format `https://[hostname:port]/[instance]`, such as `https://MyBCWebServer/BC` or `https://cronusinternationltd.onmicrosoft.com/BC170`.

   If using the **Set-NAVServerConfiguration** cmdlet, set the `PublicWebBaseUrl` key.

3. In the **OData Services** section, set the **OData Base URL** field to the public URL for accessing OData services.

   The URL must have the following format `https://<hostname>:<port>/<instance>/ODataV4/`, such as `https://localhost:7048/BC170/ODataV4/`.

   With the **Set-NAVServerConfiguration** cmdlet, set the `PublicODataBaseUrl` key.

Prepare devices and network for the Excel Add-In

Network services such as proxies or firewalls must allow routing between each client device on which the Add-In is installed and a number of service endpoints. For a list of endpoints, see Preparing your network for the Excel Add-In.

Use the Excel Add-In

Your users can now use the Excel add-in. When a list page shows the **Edit in Excel** action, then users can open lists, such as the **Customers** page, in Excel and work with the data there. They use the add-in to update data in Business Central and get fresh data from the database. For more information, see Viewing and Editing in Excel From Business Central.

Configuring Business Central Server
Authenticating Users with Azure Active Directory

Setting up App Key Vaults for Business Central On-premises

2/17/2021 • 7 minutes to read • Edit Online

APPLIES TO: Business Central 2020 release wave 2 and later

Business Central extensions can be developed to get secrets from Azure Keys Vaults. This article describes the tasks required to set up Azure Keys Vaults for storing extension secrets and configure them in your Business Central deployment.

For more information about developing extensions with key vaults, see Using Key Vault Secrets in Business Central Extensions.

Prerequisites

To complete the tasks in this article, you need:

- An Azure subscription with an Active Directory tenant.

  You sign up for an Azure subscription at https://azure.microsoft.com. For information about getting an Azure AD tenant, see How to get an Azure Active Directory tenant.

- A security certificate

  Later, you'll have to register and configure an application in Azure AD for reading key vaults. This step requires a certificate. The certificate is used to prove the application's identity when requesting upon request. For a production environment, obtain a certificate from a certification authority or trusted provider.

  In a test environment, if you don't have a certificate, then you can create your own self-signed certificate. For example, on the Business Central server computer, start Windows PowerShell as an administrator. Then at the prompt, run the following commands:

  ```
  $cert = New-SelfSignedCertificate -Subject "BusinessCentralKeyVaultReader" -Provider "Microsoft
  Strong Cryptographic Provider"
  $cert.Thumbprint
  Export-Certificate -Cert $cert -FilePath c:\certs\BusinessCentralKeyVaultReader.cer
  ```

  These commands add a certificate called BusinessCentralKeyVaultReader to the computer's **LocalMachine** > **Personal (My)** certificate store.

Create the Azure Key Vault with secrets

Now, you create one or more key vaults in Azure, and add the secrets that you want to make available to your extensions. An extension can be set up with one or two key vaults.

There are different ways to create an Azure key vault. For example, you can use the Azure portal, Azure CLI, and more.

- The easiest way is to use the Azure portal. For instructions, see Quickstart: Set and retrieve a secret from Azure Key Vault using the Azure portal.

  After you create the key vault, add the secrets.

- For using other methods, see Azure Key Vault Developer's Guide.

Register a key vault reader application in Azure AD

Next, register an application on your Azure AD tenant for reading secrets from the key vaults. When Azure AD authentication was set up, an Azure AD tenant was created in Azure. Reading key vaults requires a separate application registration with the Azure AD tenant. You can use an existing application.

The steps in this task are done from the Azure portal.

1. Sign in to Azure portal at portal.azure.com and set the portal to your Azure Active Directory tenant.
2. Register an Azure AD application for the reading key vault.

   You add the new application by using the Azure portal. For guidelines, see Register your application with your Azure Active Directory tenant.

   When you add an application to an Azure AD tenant, you must specify the following information:

SETTING	DESCRIPTION
Name	The name of your application as it will display to your users, such as *Business Central Key Vault Reader*.
Supported account types	Specifies which accounts that you would like your application to support. For purposes of this article, select **Accounts in this organizational directory only**.

   When completed, the **Overview** displays in the portal for the new application.

   Copy the **Application (client) ID**. You'll use this information later.
3. Upload the security certificate to the registered application.

   In this step, you upload the certificate file that you obtained as part of the prerequisites.

   Go to the key vault reader application overview page. Select **Certificates & secrets** > **Upload certificate**. Follow the instructions to locate and upload the certificate.

Grant the key vault reader application permission to key vaults

In this task, you grant the key vault reader application permission to read secrets from your key vaults.

The steps in this task are done from the Azure portal.

1. Open the key vault in the portal.
2. Select **Access policies**, then **Add Access Policy**.
3. Set **Secret Permissions** to **Get**.
4. Choose **Select principal**, and on the right, search for either **Application (client) ID** or display name for the key vault reader application.
5. Select **Add**.
6. Select **Save**.

At this point, the work in Azure is finished.

Configure the Business Central Server to use the Apps Key Vault feature

Next, you configure the Business Central Server instance to use the key vault reader application and its certificate, which you registered in Azure AD, for authenticating to the key vaults.

If you're running a container-based environment, you have two options for configuring the server instance. You can either do it manually or use the Set-BcContainerKeyVaultAadAppAndCertificate script. Using the Set-BcContainerKeyVaultAadAppAndCertificate script is simpler and recommended.

Configure a container-based Business Central Server instance

If you are running a container-based environment, use the Set-BcContainerKeyVaultAadAppAndCertificate.ps1 script that is available in the NAV Container Helper GitHub repository at https://github.com/microsoft/navcontainerhelper/blob/master/ContainerHandling/Set-BcContainerKeyVaultAadAppAndCertificate.ps1.

Manually configure a Business Central Server instance

To complete this task, you'll need the user name of the service account that runs the Business Central Server.

1. If not already done, import your key vault certificate and its private keys to the local certificate store for the Business Central server computer.

   You can import the certificate either using the MMC snap-in or Import-PfxCertificate cmdlet from a Windows PowerShell prompt.

   For example, the following PowerShell command installs a certificate to the local machine's personal store:

   ```
   Import-PfxCertificate -FilePath "C:\certificates\BusinessCentralKeyVaultReader.pfx" -Password
   (ConvertTo-SecureString -String "pfxpassword" -AsPlainText -Force) -CertStoreLocation
   Cert:\LocalMachine\My\
   ```

2. Give the service account used by the Business Central Server instance permission to access the certificates private key.

   To do this using the MMC:

   a. Open the MMC snap-in for certificates. See How to: View Certificates with the MMC Snap-in.

   b. Expand the **Certificates (Local Computer)** node, expand the **Personal** node, and then select the **Certificates** subfolder.

   c. In the right pane, right-click the certificate, select **All Tasks**, and then choose **Manage Private Keys**.

   d. In the **Security** dialog box, choose **Add**.

   e. In the **Select Users, Computers, Service Accounts, or Groups** dialog box, enter the name of the dedicated domain user account that is associated with Business Central Server, for example, NETWORK SERVICE. Then, choose the **OK** button.

   f. In the **Full Control** field, select **Allow**, and then choose the **OK** button.

3. Make a note of the certificate thumbprint because you'll need it in the next step. See How to: Retrieve the Thumbprint of a Certificate.

4. Configure the Business Central Server instance.

   Now, you'll configure App Key Vault settings on the server instance. The following table describes the settings that you must configure:

SETTING (KEY NAME)	VALUE
Client Certificate Store Location (AzureKeyVaultClientCertificateStoreLocation)	Set to the certificate store location where key vault certificate was stored. Example: LocalMachine
Client Certificate Store Name (AzureKeyVaultClientCertificateStoreName)	Set to the certificate store name where key vault certificate was stored. Example: MY
Client Certificate Thumbprint (AzureKeyVaultClientCertificateThumbprint)	Set to the thumbprint for the key vault certificate. Example: 649419e4fbb87340f5a0f995e605b74c5f6d943e
Client ID (AzureKeyVaultClientId)	Set to the **Application (client) ID** of the key vault reader application registered in your Azure AD tenant. Example: ed4129d9-b913-4514-83db-82e305163bec
Enable Publisher Validation (AzureKeyVaultAppSecretsPublisherValidationEnabled)	Specifies whether extensions can only use key vaults that belong to their publishers. Enabling this setting (`true`) blocks attempts in AL to read secrets from another publisher's key vault. When extensions that use key vault secrets are published, you must provide your Azure AD tenant ID, which is done by using the Publish-NAVApp cmdlet with the `-PublisherAzureActiveDirectoryTenantId` parameter. **Important** We recommend that you only set it to `false` if you trust all extensions that will be installed. For more information, see App Key Vaults - Security considerations. Example: true

You can configure the instance using the Business Central Server Administration tool or Set-NAVServerConfiguration cmdlet.

To use the Set-NAVServerConfiguration cmdlet, start the Business Central Administration Shell as an administrator, and run the following commands one at a time. Replace brackets with your own values.

```
Set-NAVServerConfiguration -ServerInstance <serverInstance> -KeyName
AzureKeyVaultClientCertificateStoreLocation -KeyValue <certificate store location>
Set-NAVServerConfiguration -ServerInstance <serverInstance> -KeyName
AzureKeyVaultClientCertificateStoreName -KeyValue <certifcate store>
Set-NAVServerConfiguration -ServerInstance <serverInstance> -KeyName
AzureKeyVaultClientCertificateThumbprint -KeyValue <certificate thumbprint>
Set-NAVServerConfiguration -ServerInstance <serverInstance> -KeyName AzureKeyVaultClientId -KeyValue
<application ID of key vault reader app in Azure>
Set-NAVServerConfiguration -ServerInstance <serverInstance> -KeyName
AzureKeyVaultAppSecretsPublisherValidationEnabled -KeyValue <true|false>
Restart-NAVServerInstance -ServerInstance <serverInstance>
```

At this point, you can run your extensions that use key vault secrets to read secrets from key vault.

TIP

If your on-premises solution uses the ImportStreamWithUrlAccess method, you must have set up an Azure blob storage account and stored the account name and account keys in the current subscription's Azure KeyVault using the identifiers TEMPORARYDOCUMENTSTORAGEACCOUNT and TEMPORARYDOCUMENTSTORAGEKEY. That way, your users can use the integration with Outlook.

Business Central Performance Counters

2/17/2021 • 7 minutes to read • Edit Online

The following table describes the performance counters that are available in Business Central for monitoring Business Central Server instances.

Client session counters

These counters pertain to sessions from the clients, NAS, and web services, to the server instance.

COUNTER	DESCRIPTION
# Active child sessions	Number of active child sessions on the Business Central Server instance. An active child session is a connection to the server instance from a Business Central client, such as the Dynamics NAV Client connected to Business Central or Business Central Web client, NAS, or Web services. A child session is created by a background task that is run asynchronously on a page. For more information, see Page Background Tasks.
# Active sessions	Number of active sessions on the Business Central Server instance. An active session is a connection to the Business Central Server instance from a Business Central client, such as the Dynamics NAV Client connected to Business Central or Business Central Web client, and Web services (OData and SOAP).
Server operations/sec	Number of operations that have started on the Business Central Server per second. An operation is a call to the Business Central Server instance from a Business Central client to run Business Central objects. Note: OData and SOAP requests are not included.
Average server operation time (ms)	Average duration of server operations in milliseconds.

SQL Server connection counters

These counters pertain to the connection from the server instance to the SQL Server instance and databases.

COUNTER	DESCRIPTION
# Mounted tenants	Number of tenants that are mounted on the Business Central Server instance. This counter is relevant with a multitenant server instance, where tenants are often mounted and dismounted.

COUNTER	DESCRIPTION
# Open connections	The current number of open connections from the Business Central Server instance to Business Central databases on SQL Servers. The value is always equal to the sum of the **# Open tenant connections** counter and the **# Open application connections** counter. -We recommend that you use these counters instead.
# Open application connections	Current number of open application connections from the Business Central Server instance to the Business Central application database on SQL Servers. Because all connections are to only one application database, you will see failures when the total number of connections for all server instances exceeds the maximum number of connections allowed to the database.
# Open tenant connections	Current number of open tenant connections from the Business Central Server instance to Business Central tenant databases on SQL Servers. If there are multiple tenant databases, you cannot see the distribution of opened connections per database (or database pool). With Azure SQL Database, connections are denied if the throttling limit is reached. The limit depends on the database configuration. Be aware that in clusters, other server instances will also have connections to the same database, so the total load on a database requires that you look at multiple server instances.
% Query repositioning rate	Percentage of queries that are re-executed when fetching the query result.
Hard throttled connections	Number of connections that were hard-throttled.
Soft throttled connections	Number of connections that were soft-throttled.
Transient errors	Number of transient errors.
Heartbeat time (ms)	The time that it takes to complete a single write to a system table. Conceptually, this counter measures the time it takes to call the application database server to update the 'last active' field the **dbo.Service Instance** table for the Business Central Server instance. Every 30 seconds, the instance writes a record to indicate that the instance is "alive." You can use this counter to indicate if there is network latency between the Business Central Server and the database.

COUNTER	DESCRIPTION
# Preferred connection total requests	Count of the total number of requests to the preferred connection cache. The preferred connection cache contains requests from the SQL connection pool that was last used by a Business Central user.
% Preferred connection cache hit rate	Percentage of hits in the preferred connection cache, compared to the total number of requests.

Data and caching counters

These counters pertain to the data caching on the server instance.

COUNTER	DESCRIPTION
# Calculated fields cache total requests	Count of the total number of requests to the calculated fields cache. The calculated fields cache contains the results of CALCFIELDS method (Record) calls.
% Calculated fields cache hit rate	Percentage of hits in the calculated fields cache, compared to the total requests to the calculated fields cache.
# Command cache total requests	Count of the total number of requests to the command cache. The command cache contains the results of all SQL commands.
% Command cache hit rate	Percentage of hits in the command cache, compared to the total requests to the command cache.
# Primary key cache total requests	Count of the total number of requests to the primary key cache. The primary key cache contains the results of requests to get a record by using its primary key.
% Primary key cache hit rate	Percentage of hits in the primary key cache, compared to the total requests to the primary key cache.
# Result set cache total requests	Count of the total number of requests to the result set cache. The result set cache contains result sets that are returned from SQL Server.
% Result set cache hit rate	Percentage of hits in the result set cache, compared to the total requests to the result set cache. The value also depends on the usage pattern and which parts of the application are is used. For example, the SELECTLATESTVERSION method will clear the cache, which results in a lower hit rate. In general, reading frequently updated values will lower the hit rate because the cache synchronization across Business Central Server instances will remove stale values, which causes re-reads.
# Rows in all temporary tables	Count of number of rows in all temporary tables.

Scheduled task counters

These pertain to tasks that are run by Task Scheduler.

COUNTER	DESCRIPTION
# Available tasks	Remaining number of tasks that can potentially run simultaneously before the maximum number of tasks is reached. The value of this counter is the value the **Maximum # of tasks** counter minus the value of the **# Running tasks** counter.
# of task errors/sec	Number of errors per second that are caused by running tasks. The task are causing errors in AL or exceptions on the server instance. If the value is greater than zero for an extended period of time, this typically indicates a failing task that keeps getting rescheduled.
# Running tasks	Number of tasks that are currently running on the server instance. The value is limited to the value of the **Maximum # of tasks** counter.
Average task execution time	The average time (in ticks) that tasks have taken to complete. Task execution time is counted regardless of whether the task completed successfully or raised an error. There is no general rule for what the normal operations level is. To analyze this counter, look for large spikes to identify long-running tasks. **Note:** A tick is the smallest unit that the your system uses for time measurements, and it is typically determined by the operating system. For example, in Windows, a single tick represents one hundred nanoseconds, which means that there are 10,000 ticks in a millisecond. Tick durations can differ bewteen systems, so be aware of this fact when comparing absolute values across systems.
Maximum # of tasks	The maximum number of tasks that can run simultaneously. This value is defined by the **Maximum Concurrent Running Tasks** (TaskSchedulerMaxConcurrentRunningTasks) setting in the server instance configuration. Therefore, this value is constant until the server instance setting is changed and the instance is restarted.
Total # Pending tasks	The total number of tasks in the shared task list that are waiting to be picked up by server instances connected to this application database. The tasks counted are those that are ready and have been scheduled to run now or earlier and that are not currently running.
Total # Running tasks	Total number of tasks in the shared task list that are currently running by any server instance connected to this application database.
Time (ms) since the list of running tasks last had capacity for new tasks	The time (ms) since the list of running tasks last had capacity for new tasks.

For more information about task scheduler, see Task Scheduler.

Monitoring Business Central Server Events

2/17/2021 • 2 minutes to read • Edit Online

You can monitor events on Business Central Server to diagnose conditions and troubleshoot problems that affect operation and performance.

Event Logging Overview

Business Central uses Event Tracing for Windows (ETW), which is a subsystem of Windows operating systems. ETW provides a tracing mechanism for events that are raised by an application or service. ETW enables you to use industry standard tools such as Windows Performance Monitor, PerfView, Event Viewer, and Windows PowerShell to dynamically collect data on trace events that occur on the Business Central Server.

Events that occur on Business Central Server instances are recorded in Windows Event logs on the Business Central Server computer. Dynamics 365 Business Central uses channels on all events. Event channels provide a way to collect and view events from a specific provider, which in this case is Business Central Server, and group the events according to predefined types, such as admin, operational, and debug. For example, in Event Viewer, Business Central Server instance events are collected in the Admin, Operational, and Debug channel logs for Business Central in the Applications and Services Logs.

For more general information about ETW and event channels, see Event Tracing for Windows and Event Logs and Channels in Windows Event Log.

Monitoring Business Central Server Event Traces

Event tracing provides detailed information about what is occurring on the Business Central Server and application when users work with Business Central. This can help you identify and analyze problems or conditions that affect performance. Event tracing enables you to dynamically monitor Business Central Server without having to restart the server or Business Central clients. By using industry-standard tools for event tracing, you can start and stop event tracing sessions, and then view the trace event data from a stored log file.

You can use event tracing to track the following operations on Business Central Server instances:

- Running Business Central reports, queries, and XMLports.
- Execution of SQL statements by Business Central Server.
- Execution of AL functions.
- Telemetry.
- Windows event log events.

Event Trace Monitoring Tools

There are various industry-standard tools that you can use to collect event trace data. The procedures in this section use Windows Performance Monitor, PerfView, Event Viewer, and Windows PowerShell to illustrate how you can collect and view event trace data. For details about how to use these tools and others, refer to the documentation available with the tool. For an overview of some of the tools, see Tools for Monitoring Performance Counters and Events.

Business Central Server Trace Events

2/17/2021 • 8 minutes to read • Edit Online

This article provides an overview of the trace events that are generated by Business Central server instance.

Overview

- There are two event trace providers that publish different trace events to the event log: **Microsoft-DynamicsNAV-Server** and **Microsoft-DynamicsNAV-Common**. The **Microsoft-DynamicsNAV-Common** provider is strictly for telemetry trace events. All other events use **Microsoft-DynamicsNAV-Server**. You typically need to specify the event trace provider in the monitoring tool that you are using.
- There are several types of trace events for each event trace provider, including: Windows event viewer, SQL traces, service calls, AL function calls, and telemetry. Trace event types are identified by a keyword with a corresponding decimal and hexadecimal value. The keywords and values enable you to collect data on specific trace events. Some tools support the hexadecimal values only and other tools support both hexadecimal and decimal.
- For some trace events, there is separate event for when an operation starts and when it stops. This enables you to determine the duration of the operation. Some monitoring tools, such as PerfView, will automatically return the duration in the stop event.
- Some monitoring tools might interpret and display the collected event trace differently than others. For more information, see Event Trace Data.

Windows Event Viewer Trace Events

Windows Event Viewer trace events track errors, warnings, and information messages that provide information about the condition or state of Business Central Server instances. These events can be viewed in the **DynamicsNAV** channel logs and **Application** log of Event Viewer on the computer that is running Business Central Server. For more information, see Monitoring Business Central Server Events Using Event Viewer.

EVENT TRACE PROVIDER	KEYWORD	DECIMAL VALUE	HEXADECIMAL VALUE
Microsoft-DynamicsNAV-Server	EventViewer	1	0x1

For a list and description of EventViewer trace events, see Business Central Server Admin and Operational Events.

SQL Trace Events

SQL trace events track a specific set of SQL statements that are executed from the Business Central Server instance against the Business Central database on SQL Server.

EVENT TRACE PROVIDER	KEYWORD	DECIMAL VALUE	HEXADECIMAL VALUE
Microsoft-DynamicsNAV-Server	SQLTracing	2	0x2

The event data that is collected includes: session ID, tenant ID, the Business Central user, and the SQL statement.

For more information, see Event Trace Data.

The following table lists the SQL trace events.

ID	EVENT (TASK/OPCODE)	WHAT IS TRACED
1	ExecuteScalar/Start	SQL statements that query a database table and return a single field from a row in the query result.
2	ExecuteScalar/Stop	SQL statements that query a database table and return a single field from a row in the query result.
3	ExecuteNonQuery/Start	SQL statements that return a number of rows from a database table
4	ExecuteNonQuery/Stop	SQL statements that return a number of rows from a database table
5	ExecuteReader/Start	SQL statements that return a set of rows from a database table.
6	ExecuteReader/Stop	SQL statements that return a set of rows from a database table.
7	ReadNextResult/Start	SQL statements that return the next result from a database query.
8	ReadNextResult/Stop	SQL statements that return the next result from a database query.
9	ReadNextRow/Start	SQL statements that return the next row in database table.
10	ReadNextRow/Stop	SQL statements that return the next row in database table.
11	BeginTransaction/Start	SQL statements that start a database transaction.
12	BeginTransaction/Stop	SQL statements that start a database transaction.
13	Prepare/Start	SQL statements that create a prepared version of the command on an instance of SQL Server.
14	Prepare/Stop	SQL statements that create a prepared version of the command on an instance of SQL Server.
15	OpenConnection/Start	SQL statements that open connection to the database from the connection pool.

ID	EVENT (TASK/OPCODE)	WHAT IS TRACED
16	OpenConnection/Stop	SQL statements that open connection to the database from the connection pool.
17	Commit/Start	SQL statements that commit a database transaction.
18	Commit/Stop	SQL statements that commit a database transaction.
19	Rollback/Start	SQL statements that cancel the changes in a pending database transaction.
20	Rollback/Stop	SQL statements that cancel the changes in a pending database transaction.

Service Call Trace Events

Service call trace events track when Business Central clients run the Business Central objects: Queries, Reports, and XMLports.

EVENT TRACE PROVIDER	KEYWORD	DECIMAL VALUE	HEXADECIMAL VALUE
Microsoft-DynamicsNAV-Server	ServiceCall	4	0x4

The event data that is collected includes: session ID, tenant ID, Business Central user, and the Business Central object ID. For more information, see Event Trace Data.

The following table lists the service call trace events.

ID	EVENT (TASK/OPCODE)	WHAT IS TRACED
300	RunQuery/Start	Business Central Query objects that are opened and closed.
301	RunQuery/Stop	Business Central Query objects that are opened and closed.
302	RunReport/Start	Business Central Report objects that are opened and closed.
303	RunReport/Stop	Business Central Report objects that are opened and closed.
310	RunXmlPort/Start	Business Central XMLport objects that are opened and closed.
311	RunXmlPort/Stop	Business Central XMLport objects that are opened and closed.

ID	EVENT (TASK/OPCODE)	WHAT IS TRACED
500	OpenSession	Dynamics NAV Client connected to Business Centrals and Business Central Web clients establish a connection to the Business Central Server instance.
501	CloseSession	Dynamics NAV Client connected to Business Centrals and Business Central Web clients establish a connection to the Business Central Server instance.

AL Methods Trace Events

AL function tracing events track the execution of AL functions and statements on the Business Central Server instance.

EVENT TRACE PROVIDER	KEYWORD	DECIMAL VALUE	HEXADECIMAL VALUE
Microsoft-DynamicsNAV-Server	ALTracing	8	0x8

The event data that is collected includes: session ID, tenant ID, Business Central user, AL function, AL statements, and line number. For more information, see Event Trace Data.

> **IMPORTANT**
>
> If the Business Central Server instance is not configured for full AL function tracing, then only root-level AL function will be traced. Statements and AL functions that are called from functions will not be traced. By default, the Business Central Server instance is not configured for full AL function tracing. For information about how to specify full AL function tracing, see Configuring Business Central Server.

The following table lists the AL function tracing events.

ID	EVENT (TASK/OPCODE)	WHAT IS TRACED				
400	ExecuteALFunction/Start	AL functions that are called.		401	ExecuteALFunction/Stop	AL functions that are called.
402	ExecuteALFunctionFailed	Errors that occur when executing AL functions. The errors can be caused by exceptions or ERROR Function (Dialog) calls.				

ID	EVENT (TASK/OPCODE)	WHAT IS TRACED				
403	ExecuteALFunction	AL statements that are executed. **Important:** This trace event is only traced when the Business Central Server is configured to full AL function tracing.				

Telemetry Trace Events

Telemetry trace events can provide data about operations in the application and how it is being used in production. These events include both system telemetry trace events and user-defined, custom telemetry trace events.

EVENT TRACE PROVIDER	KEYWORD	DECIMAL VALUE	HEXADECIMAL VALUE
Microsoft-DynamicsNAV-Common	TelemetryTracing	32	0x20

Custom telemetry trace events are emitted from the application. These are events that are sent by SENDTRACETAG method calls from inside the application. For more information about custom telemetry trace events, see Instrumenting an Application for Telemetry.

Some of the important event data that is collected for both system and custom telemetry trace events includes: tag, category, message, dataclassification. For more information about this data, see Event Trace Data.

Telemetry events can have one of the following event IDs, based on the data classification and verbosity (or seveity level):

DATA CLASSIFICATION	VERBOSITY	ID
All except CustomerContent and EndUserIdentifiableInformation	Critical	700
	Error	701
	Informational	702
	Informational	703
	Verbose	704
	Warning	705

DATA CLASSIFICATION	VERBOSITY	ID
	Informational	706
CustomerContent or EndUserIdentifiableInformation	Critical	707
	Error	708
	Informational	709
	Informational	710
	Verbose	711
	Warning	712

NOTE

Event IDs 703, 706, and 710 are used only for system telemetry trace events. All other IDs are used for both system and custom events.

Event Trace Data

The following table lists the arguments that make up the data collected for trace events. When viewing event trace data, the way that the arguments are interpreted and displayed can vary depending on the tool that you use.

ARGUMENT	DESCRIPTION	TRACE EVENT TYPE				
category	Specifies the category of the telemetry trace event.	Telemetry (TelemetryData)				
connectionType	Specifies the RoleTailored client that has established the connection to the Business Central server instance. Values include Dynamics NAV Client connected to Business Central and Business Central Web client.	Service calls (ServiceCall)				

ARGUMENT	DESCRIPTION	TRACE EVENT TYPE				
dataclassification	Specifies the RoleTailored client that has established the connection to the Business Central server instance. Values include Dynamics NAV Client connected to Business Central and Business Central Web client.	Service calls (ServiceCall)				
failureMessage	Includes the error message that is returned when a AL function fails.	AL function trace events (ALTracing)				
functionName	Specifies the AL function that was executed.	AL function trace events (ALTracing)				
lineNumber	Specifies the line number of the statement in the AL code of the Business Central object that was executed.	AL function trace events				
message	Specifies the error, warning, or information message text that was issued for a trace event	Windows event log trace events (EventViewer) Telemetry (TelemetryData)				
objectId	Specifies the ID of the Business Central object that was executed in the session.	Service calls trace events (ServiceCall) AL function trace events (ALTracing)				

ARGUMENT	DESCRIPTION	TRACE EVENT TYPE				
objectType	Specifies the Business Central object type that executed by a AL function or statement. Values include the following: CodeUnit, Page, Query, Report, Table, and XMLport.	AL function trace events (ALTracing)				
sessionId	Specifies the ID that is assigned to the session that is used by the operation. Each operation establishes a session with the Business Central Server instance from a connection in the Business Central Server's connection pool.	All				
sqlStatement	Specifies the SQL statement that was executed on the session.	SQL trace events (SQLTracing)				
statement	Specifies the AL statement that was executed on the session.	AL function trace events		tag	Specifies the ID of the telemetry trace event. For system telemetry trace events, this ID is autogenerated. For custom telemetry trace events, it is user-defined.	Telemetry (TelemetryData)

ARGUMENT	DESCRIPTION	TRACE EVENT TYPE				
tenantId	Specifies the ID of the tenant database that is mounted on the Business Central Server instance. If the Business Central Server instance is not configured for multitenancy, then the value is empty. For more information about multinenancy, see Multitenant Deployment Architecture.	All				
userName	Specifies the Business Central user account that is logged on to the session.	All

Business Central Server Admin and Operational Events (EventViewer) List

2/17/2021 • 11 minutes to read • Edit Online

Events have the source `BusinessCentralServer$[ServerInstance]`. Each event has a unique ID and is assigned to a task category. The source, IDs, and task categories enable you to filter the events that display in Event Viewer. For a description of the task categories, see Task Categories.

The following table lists the events that are generated by the Business Central Server.

EVENT ID	LEVEL	TASK CATEGORY	CHANNEL	MESSAGE/REMARKS					
112	Error	12	Operational	Message: Fatal Sql error. The connection can no longer be used. Remarks: An error occurred on the connection from the Business Central Server instance to the SQL database and the connection could not been established. This					

EVENT ID	LEVEL	TASK CATEGORY	CHANNEL	MESSAGE/REMARKS						
				error could be caused by one of the following reasons: - The Business Central Server has been stopped. - The SQL server connection settings are incorrect - A network failure has occurred. - A hardware failure has occurred on the server or on your computer. To resolve this issue, try to restart the Business Central Server or see Troubleshooting: A fatal						

EVENT ID	LEVEL	TASK CATEGORY	CHANNEL	MESSAGE/REMARKS

EVENT ID	LEVEL	TASK CATEGORY	CHANNEL	MESSAGE/REMARKS
				Central Server.

Task Categories

Task categories logically classify events according to the operations that they perform. In Event Viewer, you can sort, include, or exclude events in the Windows Application log based on the task categories. A task category is defined by a decimal number. The following table lists the task categories that are associated with Business Central Server events.

TASK CATEGORY	DESCRIPTION
8	Service connects to the Business Central Server instance.
11	Service disconnects from the Business Central Server instance.
12	Information, warning, or error message from the Business Central Server instance.
13	Exception thrown by Business Central Server.

Monitoring Business Central Server Events Using Event Viewer

2/17/2021 • 5 minutes to read • Edit Online

Events that occur on the Business Central Server instances can be recorded in event logs on the computer that is running Business Central Server. You can view the events by using Event Viewer.

About Business Central Server Events in Event Viewer

Events that occur on Business Central Server instances are recorded in the event channels specific to Business Central and also in the general Windows Application log. Event channels provide a way to collect and view events from a specific event trace provider. This differs from the Windows Application log which contains system-wide events from multiple publishers (applications and components).

Business Central channel logs

In the Event Viewer console tree, open **Applications and Services Logs** > **Microsoft** > **DynamicsNAV**.

Server folder

The **Server** folder contains events from the event trace provider called **Microsoft-DynamicsNAV-Server**. The events are recorded in the following logs:

LOG	DESCRIPTION
Admin	Includes events that target end users and IT administrators. These events typically indicate a problem that requires action to resolve the problem. An example of an admin event is a tenant database failing to mount on the Business Central Server instance. For a list and description of these events, see Business Central Server Admin and Operational Events.
Operational	Includes events that provide information about an operation that occurred on Business Central Server instances. These events are typically ordinary operating events that do not require any action but can be used to analyze and diagnose a problem. An example of an operational event is the shutting down of the Business Central Server instance. For a list and description of these events, see Business Central Server Admin and Operational Events.
Debug	Includes the trace event types: SQL (SQLTracing), service calls (ServiceCalls), and AL function calls (ALTracing). For more information about the different trace events and others ways to monitor them, see Business Central Server Trace Events and Monitoring Business Central Server Events . **Note:** In Event Viewer, this log is hidden and disabled by default. For information about how to show and enable this log, see Enable Business Central Debug Logs in Event Viewer.

Common folder

The **Common** folder contains telemetry events from the event trace provider called **Microsoft-DynamicsNAV-Common**. This folder contains strictly telemetry events, which have IDs 700-707. The telemetry events are recorded in the following logs:

LOG	DESCRIPTION
Admin	Includes custom telemetry trace events that are emitted from the application. These are events that are sent by SENDTRACETAG method calls from inside the application. For more information, see Instrumenting an Application for Telemetry. **Note** The Business Central Server instance includes a configuration setting called **Diagnostic Trace Level** (`TraceLevel` in the customsettings.config file) that enables you to specify the lowest severity level of telemetry events to be recorded in the event log, or even turn off telemetry event logging altogether. If you do not see the expected events, then verify the Business Central Server instance configuration with an administrator. For information, see Configuring Business Central Server.
Operational	Not applicable.
Debug	Includes system telemetry trace events that occur. **Note:** In Event Viewer, this log is hidden and disabled by default. For information about how to show and enable this log, see Enable Business Central Debug Logs in Event Viewer.

Application log

The Application log includes admin and operational type events (errors, warnings, and information messages) that occur on the Business Central Server instance.

To view the **Application** log, in the console tree, choose **Windows Logs**, **Applications**.

The events in this log are the same events that are recorded in the **Admin** and **Operation** logs in the **DynamicsNAV** > **Server** channel. Therefore, you can consider the **Application** log to be a secondary log for these events. Unless you are using System Center Operations Manager to monitor Business Central Server events, you can disable logging Business Central Server events to the Windows Application log and rely on **Applications and Services Logs** instead. For more information, see Disable Logging Events to the Windows Application Log.

> **NOTE**
> Trace events are not included in this log.

Filtering Dynamics Server Events in Event Viewer

By default, the Business Central Server logs contain events of all levels (error, warning, and information) for all Business Central Server instances. You can use the filtering functionality that is available in Event Viewer to display only Business Central Server instance events that meet specific criteria. For example, if you have several

Business Central Server instances, you can filter logs to show only events from a specific Business Central Server instance. For more information, see the following example.

Example

Your Business Central Server is running several instances that are configured with multiple tenants. In Event Viewer, you want to view only errors that occurred in the last 24 hours on the tenant *MyTenant1* of the Business Central Server instance *MyNavServerInstance1*.

To filter the event log

1. For example, in the console tree of Event Viewer, choose **Applications and Services Logs** > **Microsoft** > **DynamicsNAV** > **Server**.
2. Select the **Admin** log.
3. In the **Action** pane, choose **Filter Current Log**.

   The **Filter Current Log** window opens.
4. On the **Filter** tab, set the **Logged** drop-down list to **Last 24 hours**.
5. In the **Error Level** section, select the **Error** check box.
6. Choose the **XML** tab.

   XML similar to the following is displayed:

   ```
   <QueryList>
     <Query Id="0" Path="Microsoft-DynamicsNAV-Server/Admin">
       <Select Path="Microsoft-DynamicsNAV-Server/Admin">
         *[System[(Level=2) and TimeCreated[timediff(@SystemTime) <= 604800000]]]
     </Query>
   </QueryList>
   ```

   `Microsoft-DynamicsNAV-Server` indicates that Business Central Server is the provider of the events in the log.
7. Select the **Edit** query manually check box, and then choose the **Yes** button.
8. In the `<Select Path="Microsoft-DynamicsNAV-Server/Admin">` element, after `*[System[(Level=2) and TimeCreated[timediff(@SystemTime) <= 86400000]]]`, add the following lines:

   ```
   and
   *[EventData[Data[@Name='tenantId'] and Data  = 'MyTenant1']]
   and
   *[EventData[Data[@Name='serverInstanceName'] and Data='MyNavServerInstance1']]
   ```

   The complete XML should look similar to the following XML:

```
<QueryList>
  <Query Id="0" Path="Microsoft-DynamicsNAV-Server/Admin">
    <Select Path="Microsoft-DynamicsNAV-Server/Admin">
      *[System[(Level=2) and TimeCreated[timediff(@SystemTime) <= 604800000]]]
      and
      *[EventData[Data[@Name='tenantId'] and Data  = 'MyTenant1']]
      and
      *[EventData[Data[@Name='serverInstanceName'] and Data='MyNavServerInstance1']]
    </Select>
  </Query>
</QueryList>
```

9. Choose the **OK** button.

The **Admin** log displays only errors that occurred in the last 24 hours on tenant *Tenant1* and Business Central Server instance *MyNavServerInstance1*. The applied filter can be removed. Alternatively, you can save it as a custom view. For more information about filtering in Event Viewer, see Filter Displayed Events and Advanced XML filtering in the Windows Event Viewer.

How to: Use Performance Monitor to Collect Event Trace Data

2/17/2021 • 3 minutes to read • Edit Online

This topic describes how to use Windows Performance Monitor to collect event trace data for Business Central Server. To collect trace event data, you create a Data Collector Set, and then start the Data Collector Set.

Create a Data Collector Set for collecting Business Central trace event data

1. Start Windows Performance Monitor.
   - Choose **Start**, in the **Search** box, type **perfmon**, and then choose the related link.
2. In the navigation tree, expand **Data Collector Sets**, right-click **User-defined**, choose **New**, and then choose **Data Collector Set**.
3. On the **Create new Data Collector Set Wizard** page, enter a name for the new data collector set, select **Create manually (Advanced)**, and then choose the **Next** button.
4. On the **What type of data do you want to include** page, select the **Event trace data** check box, and then choose the **Next** button.
5. On the **Which event trace providers would you like to enable** page, choose the **Add** button to add a provider.
6. In the **Event Trace Providers** list, select **Microsoft-DynamicsNAV-Server**, and then choose the **OK** button.
7. If you want to collect data for all trace events, choose the **Next** button. If you want to collect data on specific trace events, do the following:
   a. In the **Properties** list, select **Keywords (Any)**, and then choose the **Edit** button.
   b. On the **Property** page, in the **Manual** box, type the keyword decimal value for the trace event. For a list of keyword values for trace events, see Business Central Server Trace Events.

      For example, if you want to collect data on service call trace events, then type **4**. If you want to collect data on more than one trace event, add the keyword values for each trace event and then use the sum in the **Manual** box. For example, if you want to collect data on service calls (keyword decimal value = 4) and AL functions (keyword decimal value = 8), then use the value **12**.

      > **NOTE**
      > Performance Monitor will automatically convert the value to hexadecimal, such as 0x4 or 0xC. You can also enter the keyword hexadecimal values directly.

   c. Choose the **OK** button, and then **Next** button.
8. On the **Where would you like the data to be stored** page, set the **Root directory** box to the folder where you want to save the event trace log file that is generated when you run the Data Collector Set.
9. Choose the **Finish** button to complete the wizard

The new Data Collector Set appears under **User Defined** in the navigation pane.

Complete the next procedure to increase trace buffer settings to make sure that events are not dropped when collecting trace event data.

Change the Data Collector Set trace buffers

1. In the navigation pane, select the new Data Collector Set.
2. In the main pane, right-click the **DataCollector01** item, and then choose **Properties**.
3. In the **Properties** dialog box, choose the **Trace Buffers** tab.
4. Set the following properties.

PROPERTY	RECOMMENDED MINIMUM VALUES
Buffer size	128
Minimum buffers	50
Maximum buffers	50

   You might have to adjust these properties based on the monitoring sessions and expected number of events that will be collected. If a large number of events are collected, then the trace buffer size and count might have to be increased.

5. Choose the **OK** button to save and close the **Properties** dialog box.

To start and stop a Data Collector Set

- To start to collect data, right-click the Data Collector Set, and then choose **Start**.
- To stop collecting data, right-click the Data Collector Set, and then choose **Stop**.

For information about how to schedule a time to start and stop collecting data, see Schedule Data Collection in Windows Performance Monitor.

The collected event trace data is stored in an event trace log (.etl) file in the location that you specified. You can view the data in the log file by using various industry-standard tools, such as PerfView. For information about how to use PerfView to view the event trace data, see Use PerfView to View Event Trace Data.

How to: Use PerfView to Collect Event Trace Data

2/17/2021 • 2 minutes to read • Edit Online

This topic describes how to use PerfView to collect event trace data for Business Central Server. When you collect event trace data, the data is stored in an event trace log (.etl) file in a location that you choose.

To install PerfView

- Go to https://go.microsoft.com/fwlink/?LinkID=313428, and then follow the instructions to download and install PerfView.

To collect event trace data

1. Open PerfView.exe.
2. On the **Collect** menu, choose **Collect**.

   The **Collecting data over a user specified interval** dialog box appears.
3. Set the **Data file** field to the path and name of the log file in which to store the trace event data. The file name must have the .etl file name extension.
4. Choose **Advanced options**.

   The upper part of the **Advanced options** area includes check boxes and fields that specify the providers from which to collect event trace data.
5. In the **Additional providers** field, type **Microsoft-DynamicsNAV-Server**.
   - If you want to filter on a specific trace event, include a colon after **Microsoft-DynamicsNAV-Server**, followed by the hexadecimal keyword value for the trace event. For example, to collect trace events data on service call trace events only, then type **Microsoft-DynamicsNAV-Server:0x4**.
   - If you want to collect data on more than one trace event, add the keyword values for each trace event and then use the sum in the field. For example, if you want to collect data on service calls (keyword value = 0x4) and AL function traces (keyword value = 0x8), then type **Microsoft-DynamicsNAV-Server:0xC** in the field. In hexadecimal, the sum of 0x4 and 0x8 is 0xC.
6. Clear the check boxes above the **Additional providers** field for any providers that you do not want to collect data for.
7. To start recording data, choose the **Start Collection** button.
8. To stop recording data, choose the **Stop Collection** button.

The collected event trace data is stored in an event trace log (.etl) file in the location that you specified. You can view the data in the log file by using various industry-standard tools, such as PerfView. For information about how to use PerfView to view the event trace data, see Use PerfView to View Event Trace Data.

To view event trace data from an event trace log file

1. Open PerfView.exe.
2. In PerfView, use the left pane to locate the .etl file that you want to view.

   The left pane displays the current directory and the files that PerfView is set up to browse. To change a

directory, choose a subdirectory from the list or type the directory (for example, c:\PerfLogs) in the text box at the top of the pane.

3. Double-click the .etl file that you want to view.

   Several items appear in the left pane under the .etl file that you selected.

4. To view the event traces, double-click **Events**.

   The **Events** window opens to display the contents of the .etl file. Trace events are listed in the left pane.

5. To view details about a trace event, double-click the trace event.

How to: Use LogMan to Collect Event Trace Data

2/17/2021 • 2 minutes to read • Edit Online

This article describes how to use logman to collect event trace data for Business Central Server. Logman (logman.exe) comes with the Windows Operating System. You can use it to create and manage event trace session and performance logs from the command prompt.

This article provides a brief introduction to using logman to collect trace event data for Business Central Server and telemetry events. For more detailed information about logman, see Logman.

Collect event trace data

You can collect Business Central Server trace event data from two different trace event providers: **Microsoft-DynamicsNAV-Server** and **Microsoft-DynamicsNAV-Common**. **Microsoft-DynamicsNAV-Server** is used for trace events like SQL traces, AL function traces, and session calls. **Microsoft-DynamicsNAV-Common** is used for telemetry events.

Data that is collected with logman is stored in an event trace log (.etl) file.

The following steps give you an example of how to use logman.

1. Open the command prompt, and change to the directory that contains the `logman.exe` file.

   This is typically `C:\Windows\System32`

2. At the command prompt, run one of the following commands to create a trace data collector.

   For telemetry trace events:

   ```
   logman create trace MyTelemetryTraceData -p Microsoft-DynamicsNAV-Common -o
   c:\perflogs\MyTelemetryTraceData.etl
   ```

   For server trace events:

   ```
   logman create trace MyServerTraceData -p Microsoft-DynamicsNAV-Server -o
   c:\perflogs\MyServerTraceData.etl
   ```

   These commands will create event log files named `MyTelemetryTraceData.etl` and `MyServerTraceData.etl` in the `c:\perflogs` folder of your computer.

3. To start the trace session, run one of the following commands.

   For telemetry trace events:

   ```
   logman start MyTelemetryTraceData
   ```

   For server trace events:

   ```
   logman start MyServerTraceData
   ```

4. To stop the trace session, run one of the following commands.

For telemetry trace events:

```
logman stop MyTelemetryTraceData
```

For server trace events:

```
logman stop MyServerTraceData
```

The data is now stored in an .etl file.

View trace event data

There are various industry tools available for viewing data in .etl files.

For example, from the command line, you can use the tracerpt command to create dump files, summary, and report files. The following code creates files for the MyTelemetryTraceData_000001.etl file:

```
tracerpt c:\perflogs\MyTelemetryTraceData_000001.etl -o c:\perflogs\MyTelemetry-dmp.xml -of XML -summary
c:\perflogs\MyTelemetry-summary.txt -report c:\perflogs\MyTelemetry-rpt.xml
```

You can also use PerView. For more information, see Use PerfView to View Event Trace Data.

Monitoring Business Central Server Events with PowerShell

2/17/2021 • 3 minutes to read • Edit Online

Events that occur on the Business Central Server instances are recorded in event logs on the computer that is running Business Central Server. You can view the events by using Windows PowerShell as described in this article.

PowerShell Get-WinEvent Cmdlet

You can use the Get-WinEvent cmdlet of Windows PowerShell to view Business Central Server instance events and trace events in the event logs and event tracing log files on the Business Central Server computer. The Get-WinEvent cmdlet retrieves the same events that can be viewed in Event Viewer under **Applications and Services Logs** > **Microsoft** > **DynamicsNAV** (see Monitoring Business Central Server Events Using Event Viewer).

The Get-WinEvent cmdlet includes several parameters that enable you to filter the events that you view and specify how the events are displayed. Windows PowerShell enables you can create scripts that perform complex operations for extracting and displaying specific event data. For more information about the Get-WinEvent cmdlet, see Get-WinEvent.

For more information about installing and getting started with Windows PowerShell, see Getting Started with Windows PowerShell.

To use the Get-WinEvent Cmdlet to view events

1. If you want to view events in a **Debug** log, ensure that the log is enabled. The **Admin** and **Operational** logs are enabled by default.

   For information, see To enable the Business Central Server Debug Log from Windows PowerShell.

2. On the computer that is running Business Central Server, start Window PowerShell.

   For more information, see Starting Windows PowerShell.

3. At the command prompt, enter the `Get-WinEvent` command. The following table provides some simple example commands.

TO VIEW	COMMAND
Events in the all **DynamicsNAV** > **Server** logs	`Get-WinEvent -ProviderName Microsoft-DynamicsNAV-Server`
Events in the all **DynamicsNAV** > **Common** logs	`Get-WinEvent -ProviderName Microsoft-DynamicsNav-Common`
Events in the **DynamicsNAV** > **Server** > **Admin** log	`Get-WinEvent -LogName Microsoft-DynamicsNAV-Server/Admin`
Events in the **DynamicsNAV** > **Common** > **Admin** log	`Get-WinEvent -LogName Microsoft-DynamicsNav-Common/Admin`

TO VIEW	COMMAND
Events in the Business Central Server Operational log	`Get-WinEvent -LogName Microsoft-DynamicsNAV-Server/Operational`
Trace events in the Business Central Server Debug log	`Get-WinEvent -LogName Microsoft-DynamicsNAV-Server/Debug -Oldest`

To enable the Debug Logs from Windows PowerShell

There are two debug logs for Business Central: **Microsoft-DynamicsNAV-Server/Debug** and **Microsoft-DynamicsNav-Common/Debug**.

1. On the computer that is running Business Central Server, start Window PowerShell as an administrator.
2. At the command prompt, run the following commands:

```
wevtutil.exe set-log "Microsoft-DynamicsNAV-Server/<Debug>" /q:true /e:true
```

```
wevtutil.exe set-log "Microsoft-DynamicsNav-Common/<Debug>" /q:true /e:true
```

TIP

You can also enable the Debug log from Event Viewer. For more information, see Enable Analytic and Debug Logs.

Filtering Business Central Server Events

You can filter the events that you view in a Business Central Server log by setting the *FilterXpath* parameter of the Get-WinEvent cmdlet. The following examples illustrate how you can use the *FilterXpath* parameter to filter the Business Central Server events.

Example 1

The following example uses the Get-WinEvent cmdlet to view errors in the Business Central Server Admin log for the tenant *MyTenant1* on the server instance *MyNavServerInstance1*.

```
Get-WinEvent -LogName 'Microsoft-DynamicsNAV-Server/Admin' -FilterXPath "*[System[(Level=2)]] and *
[EventData[Data[@Name='tenantId'] and (Data = 'MyTenant1')]] and *
[EventData[Data[@Name='serverInstanceName'] and Data='MyNavServerInstance1']]" | Format-List -Property
Message-
```

Example 2

The following is an example of a Windows PowerShell script that you can create and run to view trace events in the Business Central Server Debug log. The script returns the start and stop AL function trace events that take more than four seconds to execute on the tenant *MyTenant1* of the server instance *MyNavServerInstance1*.

```
$maxAllowedSeconds = 4

$xPath = "*[System[(EventID = 400 or EventID = 401)]] and " +
         "*[EventData[Data[@Name='tenantId'] and (Data  = 'MyTenant1')]] and " +
         "*[EventData[Data[@Name='serverInstanceName'] and Data='MyNavServerInstance1']]"

$events = Get-WinEvent -LogName 'Microsoft-DynamicsNAV-Server/Debug' -FilterXPath $xPath -Oldest -MaxEvents
10000

Write-Host "List of AL functions that took more than $maxAllowedSeconds  seconds to execute :" -
ForegroundColor DarkYellow

for($i = 0; $i -lt  $events.Length; $i+=2)
{
   $seconds = ($events[$i + 1].TimeCreated - $events[$i].TimeCreated).Seconds

   if ($seconds -ge $maxAllowedSeconds )
   {
     Write-Host $events[$i].Message `r`n -ForegroundColor Magenta
   }
}
```

You can create the script by using, for example, Notepad or Windows PowerShell Integrated Scripting Environment (ISE). You save the script as .ps1 file type, and then run it from the Windows PowerShell.

Turn Off or Limit Telemetry Trace Events

2/17/2021 • 2 minutes to read • Edit Online

The application and platform can emit many telemetry trace events, which can be collected using various event trace tools. For example, telemetry trace events are recorded in the Business Central Server channel logs, which you can see in Event Viewer, under **Applications and Services Logs** > **Microsoft** > **DynamicsNAV** > **Common** > **Admin**.

The number of events can place a large demand on the logging resources on the computer running the Business Central Server instance. To help alleviate this demand, the Business Central Server instance includes a configuration setting called **Diagnostic Trace Level** (`TraceLevel` in the customsettings.config file) that enables you to specify the lowest severity level of customer telemetry trace events that are emitted from the application, or even turn off telemetry events altogether. Custom telemetry trace events have IDs from 700-712.

To configure the **Diagnostic Trace Level** setting, you can use the Business Central Server Administration tool, modify the Business Central Server instance configuration file (CustomSettings.config) directly, or use the Set-NAVServerConfiguration cmdlet of the Business Central Administration Shell.

> **TIP**
> Custom telemetry events are generated by calls to the SENDTRACETAG method in code. For more information, see Instrumenting an Application for Telemetry.

Use the Business Central Server Administration tool

1. To start the Business Central Server Administration tool, select **Start**, and in the **Search programs and files** box, type **Microsoft Dynamics365 Business Central Administration**, and then choose the related link.
2. In the left pane, under **Console root**, select the Business Central Server instance.
3. In the center pane, select the **Edit** button.
4. Under **General**, set the **Diagnostic Trace Level**:

   You use this setting to filter out lower-level events from being emitted. For example, if you set this setting to **Error**, only **Error** and **Critical** events will be emitted.

   Set to **Off** if you do not want to emit telemetry trace events.
5. Select the **Save** button, and then select the **OK** button.

   You must restart the Business Central Server instance for the changes to take effect.
6. To restart, the Business Central Server instance, in the left pane, select the Business Central computer.

   Unless you are administering a remote computer, this is Business Central (local).
7. In the center pane, right-click an instance, and then select **Restart**.

Modify the CustomSettings.config file

1. Open the CustomSettings.config file for the Business Central Server instance in a text editor, such as Notepad.

By default, the file is located in the C:\Program Files\Microsoft Dynamics 365 Business Central\160\Service folder or C:\Program Files\Microsoft Dynamics 365 Business Central\160\Service\Instances\<instancename> folder (for multitenant installations).

2. Set the **TraceLevel** setting to **Critical**, **Error**, **Warning**, **Normal** (this corresponds to the **Information** level), **Verbose**, or **Off**.
3. Save the file, and then restart the Business Central Server instance.

Use the Business Central Administration Shell

1. Start the Business Central Administration Shell.
2. At the command prompt, run the following command:

```
Set-NAVServerConfiguration -ServerInstance MyServerInstance -KeyName TraceLevel -KeyValue level -
ApplyTo All
```

Substitute `MyServerInstance` with the name of the Business Central Server instance and `level` with either `Critical`, `Error`, `Warning`, `Normal`, `Verbose`, or `Off`.

For more information about how to use the Business Central Administration Shell, see Business Central PowerShell Cmdlets and Set-NAVServerConfiguration Cmdlet.

Monitoring and Analyzing Long Running SQL Queries

2/17/2021 • 2 minutes to read • Edit Online

Microsoft Dynamics NAV 2017 was the first version that allows long running SQL queries to be logged to the Windows Event Log. The queries are logged when the application communicates with the database and the call to the database takes too long. Starting in Business Central 2019 release wave 2, long running queries can also be emitted as telemetry to Microsoft Azure Application Insights. Using Application Insights requires that you first enable it on your tenant.

Defining the long running SQL queries threshold

The time logged when a SQL query runs is the time spent on the called database as seen from the server. There are multiple reasons that can cause a delay. For example, a delay happens when the database waits for a lock to release. Or it runs an operation that's missing indexes.

The threshold of when a SQL query is considered to be long running is controlled by the Business Central Server configuration setting **SqlLongRunningThreshold**. The default value is 1000 milliseconds (ms). By default, the threshold is set to 1000 milliseconds. In this case, if a SQL query runs longer 1000 ms, a message is recorded in the event log and emitted as telemetry. The message indicates that the action took longer than expected or longer than the given threshold. For more information about setting the **SqlLongRunningThreshold** by using Business Central Server Administration tool, see Configuring Business Central Server.

You can also change the setting by Set-NAVServerConfiguration cmdlet in Business Central Administration Shell. The cmdlet includes the `-ApplyTo Memory` parameter that enables you to change the setting without doing a server restart. For example, to change the threshold dynamically to 2000 ms, run the Business Central Administration Shell as Administrator and then type the following PowerShell cmdlet:

```
Set-NAVServerConfiguration -ServerInstance <ServerInstanceName> -KeyName SqlLongRunningThreshold -KeyValue
2000 -ApplyTo Memory
```

Monitor and analyze data

To use the Windows Event Log, see Troubleshooting: Using the Event Viewer to Monitor Long Running SQL Queries.

To set up and use Application Insights, see Enabling Application Insights for Tenant Telemetry.

Setting SQL Compatibility Level to Optimize Database Performance

2/17/2021 • 2 minutes to read • Edit Online

If your Business Central database is running on Azure SQL Database or SQL Server 2016 or later, set the database's compatibility level to match the database server. This will equip the database with the latest optimization features of Azure SQL Database or SQL Server. This is particularly relevant for demonstration databases that are installed by using the Business Central Setup because the default compatibility level matches SQL Server 2014.

To change the compatibility level

You change the compatibility level of the database by using SQL Server Management Studio. There are two ways to do this:

- Open the database properties, select the **Options** page, and then set the **Compatibility Level**:.

  For more information, see View or Change the Compatibility Level of a Database.

- Run the following query:

  ```
  ALTER DATABASE <database name> SET COMPATIBILITY_LEVEL = { 140 | 130 }
  ```

  where:

  - `<database name>` is the name of the database to be modified.
  - `140` sets the database to be compatible with SQL Server 2017
  - `130` sets the database to be compatible with SQL Server 2016 and Azure SQL Database

  For more information, see ALTER DATABASE (Transact-SQL) Compatibility Level.

> **NOTE**
> The compatibility level for Azure SQL Database is subject to change. Refer to Azure SQL Database documentation for latest compatibility level.

Data Access

2/17/2021 • 9 minutes to read • Edit Online

Data that is needed in the client goes through the following path from the Business Central Server to the SQL Server database:

1. If the data is cached in the Business Central Server data cache, it is returned.
2. If the data is not cached in the Business Central Server data cache, it is fetched from SQL Server over the network as follows:
   a. If the data resides in SQL Servers data cache, it is returned.
   b. If the data does not reside in SQL Servers data cache, it is fetched from storage and returned.

Business Central Server data caching

In Business Central, the data cache is shared by all users who are connected to the same Business Central Server instance. This means that after one user has read a record, a second user who reads the same record gets it from the cache.

The following AL functions utilize the cache system:

- GET
- GETBYSYSTEMID
- FIND
- FINDFIRST
- FINDLAST
- FINDSET
- COUNT
- ISEMPTY
- CALCFIELDS

There are two types of caches, global and private:

- Global cache is for all users connected to a Business Central Server instance.
- Private cache is per user, per company, in a transactional scope. Data in a private cache for a given table and company is flushed when a transaction ends.

The cache that is used is determined by the lock state of a table. If a table is not locked, then the global cache is queried for data; otherwise, the private cache is queried.

Results from query objects are not cached.

For a call to any of the **FIND** functions, 1024 rows are cached. You can set the size of the cache by using the **Data Cache Size** setting in the Business Central Server configuration file. The default size is 9, which approximates a cache size of 500 MB. If you increase this number by one, then the cache size doubles.

You can bypass the cache by using the SELECTLATESTVERSION method (Database).

Business Central synchronizes caching between Business Central Server instances that are connected to the same database. By default, the synchronization occurs every 30 seconds.

You can set the cache synchronization interval by using the *CacheSynchronizationPeriod* parameter in the CustomSettings.config file. This parameter is not included in the CustomSetting.config file by default, so you

must add it manually using the following format:

```
<add key="CacheSynchronizationPeriod" value="hh:mm:ss" />
```

For example, to set the interval to 50 seconds, set the `value` to `"00:00:50"`. For more information about the CustomSettings.config file, see Configuring Business Central Server.

Business Central Server connections to SQL Server

Starting from Microsoft Dynamics NAV 2013, the Business Central Server uses ADO.NET to connect to the SQL Server database. Installations of Microsoft Dynamics NAV 2009 and earlier uses ODBC to connect to the SQL Server database.

The ADO.NET interface is a managed data access layer that supports SQL Server connection pooling, which can dramatically decrease memory consumption by Business Central Server. SQL Server connection pooling also simplifies deployment of the Business Central three-tier architecture for deployments where the three tiers are installed on separate computers. Specifically, administrators are no longer required to manually create SPNs or to set up delegation when the client, Business Central Server, and SQL Server are on separate computers.

There is no longer a one-to-one correlation between the number of client connections and the number of SQL Server connections. In earlier versions of Business Central, each SQL Server connection could consume up to 40 MB of memory. Additionally, memory allocation is now in managed memory, which is generally more efficient than unmanaged memory.

Records are retrieved using Multiple Active Result Sets (MARS). methods such as NEXT, FIND('-'), FIND('+'), FIND('>'), and FIND('<') are generally faster with MARS than the server cursors that earlier versions of Business Central used.

Data read/write performance

AL functions COUNT and AVERAGE formulas can use SIFT indexes. For more information, see CALCSUMS method (Record) and CALCFIELDS method (Record). MIN and MAX formulas use SQL Server MIN and MAX functions exclusively.

RecordIds and SQL Variant columns in a table do not prevent the use of BULK inserts. For more information, see Bulk Inserts.

In most cases, filtering on FlowFields issues a single SQL statement. In earlier versions of Business Central, filtering on FlowFields issued an SQL statement for each filtered FlowField and for each record in the table in order to calculate the filtered FlowFields. The exceptions in Business Central in which filtering on FlowFields does not issue a single SQL statement are as follows:

- You use the ValueIsFilter option on a field and the field has a value.
- A second predicate is specified on a source field and the field that is used for the second predicate has a value. For example, when you specify the CalcFormula Property for a FlowField, you can specify table filters in the **Calculation Formula** window. If you specify two or more filters on the same source field, then filtering does not issue a single SQL statement.

In most cases, calling the FIND or NEXT functions after you have set the view to include only marked records issues a single SQL statement. In earlier versions of Business Central, calling FIND or NEXT functions that have marked records issued an SQL statement for each mark. There are some exceptions if many records are marked. For more information, see MARKEDONLY method (Record).

Using SQL Server table partitioning

As of Microsoft Dynamics NAV 2018, the use of SQL Server table and index partitioning is a supported configuration. The data of partitioned tables and indexes is divided into units that can be spread across more than one filegroup in a SQL Server database. All partitions of a single index or table must reside in the same database. The table or index is treated as a single logical entity when queries or updates are performed on the data. Prior to SQL Server 2016 SP1, partitioned tables and indexes were not available in every edition of SQL Server. Partitioning large tables or indexes can have the following manageability and performance benefits:

- You can perform maintenance operations on one or more partitions more quickly. The operations are more efficient because they target only these data subsets, instead of the whole table. For example, you can choose to rebuild one or more partitions of an index.
- You might be able to improve query performance, based on the types of queries you frequently run and on your hardware configuration. When SQL Server performs data sorting for I/O operations, it sorts the data first by partition. SQL Server accesses one drive at a time, and this might reduce performance. To improve data sorting performance, stripe the data files of your partitions across more than one disk by setting up a RAID (redundant array of independent disks). In this way, although SQL Server still sorts data by partition, it can access all the drives of each partition at the same time.
- You can use partitioning to distribute parts of tables to different IO sub systems. For example, you could archive data for old transactions on slow and inexpensive disks and keep current data on solid-state drives (SSD). You can improve performance by enabling lock escalation at the partition level instead of a whole table. This can reduce lock contention on the table.

For more general information about partitioned tables and indexes in SQL Server, see Partitioned Tables and Indexes.

How Business Central supports partitioning

If you have altered tables in a Business Central database to make them partitioned tables, the synchronization engine, which is responsible for mapping the logical metamodel to physical tables, will respect this configuration during upgrades. After a schema upgrade, even if tables have been dropped and recreated, the partitioning strategy applied to the original tables will be added to the upgraded tables. You can create a partitioned table or index in SQL Server by using SQL Server Management Studio or Transact-SQL.

> **NOTE**
> For partitioning to work, the partition column must be part of the clustering key on the table.

Table Partioning Example

This example uses Transact-SQL to change table **G_L Entry** to be partitioned on the **Posting Date** field, with data partitioned on the year, and where all partitions are aligned to the PRIMARY file group.

1. In SQL query editor, create a partition function that creates partitions that divide on year (this can be used for partitioning multiple tables):

```
CREATE PARTITION FUNCTION [DataHistoryPartitionmethod] (datetime)
AS RANGE LEFT FOR VALUES (
'20151231 23:59:59.997',
'20161231 23:59:59.997',
'20171231 23:59:59.997',
'20181231 23:59:59.997'  )
GO
```

2. Create a partition scheme that maps partitions to file groups. In this example, all partitions are mapped to the PRIMARY file group (this can be used for partitioning multiple tables):

```
CREATE PARTITION SCHEME DataHistoryPartitionScheme
AS PARTITION DataHistoryPartitionmethod ALL TO ([PRIMARY])
GO
```

3. In the Dynamics NAV Development Environment, add the **Posting Date** field to the primary key.

   For more information, see Table Keys.

4. In the Transact-SQL Editor, partition table **G_L Entry** by using the previously defined partition scheme:

```
ALTER TABLE [dbo].[G_L Entry]
DROP CONSTRAINT [G_L Entry$0]
GO

ALTER TABLE [dbo].[G_L Entry]
ADD CONSTRAINT [G_L Entry$0] PRIMARY KEY CLUSTERED
(
[$companyId], [Entry No_], [Posting Date]
)
ON DataHistoryPartitionScheme( [Posting Date] )
GO
```

TIP

SQL Server Management Studio includes the **Create Partition Wizard** to help you create partitioning functions, partitioning schemes, as well as changing a table to be partitioned. For more information, see Create Partitioned Tables and Indexes.

Using SQL Server data compression

As of Business Central April 2019, it is possible to configure data compression directly in table metadata by using the CompressionType property in AL or CSIDE. Previously, compression could only be configured in SQL Server. You use data compression to help reduce the size of selected tables in the database. In addition to saving space, data compression can help improve performance of I/O-intensive workloads because the data is stored in fewer pages and queries will read fewer pages from disk. This is especially useful if your storage system is based on disks and not SSD.

However, extra CPU resources are required on the database server to compress and decompress the data while data is exchanged with the Business Central Server.

With the **CompressionType** property, you can configure row or page type compression or configure the table not to use compression. With these compression settings, Business Central table synchronization process will make changes to the SQL Server table, overwriting the current compression type, if any. You can choose to control data compression directly on SQL Server by setting the **CompressionType** property to **Unspecified**, in which case table synchronization process will not control the data compression.

To evaluate whether a table is a good candidate to compress, you can use the stored procedure `sp_estimate_data_compression_savings` in SQL Server. For more information, see sp_estimate_data_compression_savings (Transact-SQL).

Because SQL Server supports data compression on the partition level, you can combine SQL Server data compression with table partitioning (see the previous section) to achieve flexible data archiving on historical parts of a large table, without having the CPU overhead on the active part of the table.

> **NOTE**
>
> Prior to SQL Server 2016 SP1, compression was not available in every edition of SQL Server.

For more general information about table compression in SQL Server, see Data Compression. For guidance on strategy, capacity planning, and best practices for data compression, see Data Compression: Strategy, Capacity Planning and Best Practices.

GetBySystemId(Guid)

Table Keys and Performance in Business Central

2/17/2021 • 2 minutes to read • Edit Online

When you write AL code that searches through a subset of the records in a table, you must consider what keys are defined for the table and write code that optimizes for the keys. For example, the entries for a specific customer are usually a small subset of a table containing entries for all the customers.

Defining Keys to Improve Performance

The time that it takes to complete a loop through a subset of records depends on the size of the subset. If a subset cannot be located and read efficiently, then performance deteriorates.

To maximize performance, you must define the keys in the table that support the code that you run. You must then specify these keys correctly in your code.

For example, to retrieve the entries for a specific customer, you apply a filter to the Customer No. field in the Cust. Ledger Entry table. To run the code efficiently on Microsoft SQL Server, you must define a key in the table that has Customer No. as the first field.

The table could have the following keys:

- Entry No.
- Customer No.,Posting Date

The following is an example of code that finds a subset of records.

```
SETRANGE("Customer No.",'1000');
IF FIND('-') THEN
REPEAT
UNTIL NEXT = 0;
```

SQL Server automatically chooses which index to use in order to retrieve data in the most efficient way. SQL Server calculates the cost of retrieving data using different indexes and then chooses the path that has the smallest cost. For Business Central, that calculation is based only on the statistical distribution of values in a column.

For example, if a table contains 1000 rows and a column in the table contains either the value 0 or the value 1, then that column is said to have a low selectivity. If instead a column contained the values ranging from 1 to 500 then the column is said to have a high selectivity. In the following code example, SQL Server chooses an index that contains the HighSelectivityColumn and then sorts the rows by the LowSelectivityColumn.

```
SETCURRENTKEY("LowSelectivityColumn");
SETFILTER("LowSelectivityColumn",'1');
SETFILTER("HighSelectivityColumn",'777');
FIND('-')
```

Data Access
Bulk Inserts

Bulk Inserts

2/17/2021 • 2 minutes to read • Edit Online

By default, Business Central automatically buffers inserts in order to send them to Microsoft SQL Server at one time.

By using bulk inserts, the number of server calls is reduced, thereby improving performance.

Bulk inserts also improve scalability by delaying the actual insert until the last possible moment in the transaction. This reduces the amount of time that tables are locked; especially tables that contain SIFT indexes.

Application developers who want to write high performance code that utilizes this feature should understand the following bulk insert constraints.

Bulk Insert Constraints

If you want to write code that uses the bulk insert functionality, you must be aware of the following constraints.

Records are sent to SQL Server when the following occurs:

- You call `COMMIT` to commit the transaction.
- You call `MODIFY` or `DELETE` on the table.
- You call any `FIND` or `CALC` methods on the table.

Records are not buffered if any of the following conditions are met:

- The application is using the return value from an `INSERT` call; for example, "`IF (GLEntry.INSERT) THEN`".
- The table that you are going to insert the records into contains any of the following:
  - BLOB fields
  - Fields with the **AutoIncrement** property set to **True**

The following code example cannot use buffered inserts because it contains a `FIND` call on the **GL/Entry** table within the loop.

```
IF (JnlLine.FIND('-')) THEN BEGIN
  GLEntry.LOCKTABLE;
  REPEAT
    IF (GLEntry.FINDLAST) THEN
      GLEntry.NEXT := GLEntry."Entry No." + 1
    ELSE
      GLEntry.NEXT := 1;
    // The FIND call will flush the buffered records.
    GLEntry."Entry No." := GLEntry.NEXT ;
    GLEntry.INSERT;
  UNTIL (JnlLine.FIND('>') = 0)
END;
COMMIT;
```

If you rewrite the code, as shown in the following example, you can use buffered inserts.

```
IF (JnlLine.FIND('-')) THEN BEGIN
  GLEntry.LOCKTABLE;
  IF (GLEntry.FINDLAST) THEN
    GLEntry.Next := GLEntry."Entry No." + 1
  ELSE
    GLEntry.Next := 1;
  REPEAT
    GLEntry."Entry No.":= GLEntry.Next;
    GLEntry.Next := GLEntry."Entry No." + 1;
    GLEntry.INSERT;
  UNTIL (JnlLine.FIND('>') = 0)
END;
COMMIT;
// The inserts are performed here.
```

Disabling Bulk Inserts

Disabling bulk inserts can be helpful when you are troubleshooting failures that occur when inserting records. To disable bulk inserts, you set the *BufferedInsertEnabled* parameter in the CustomSettings.config file of the Business Central Server to **FALSE**. For more information, see Configuring Business Central Server.

AL Database Methods and Performance on SQL Server

2/17/2021 • 5 minutes to read • Edit Online

This topic describes the relationship between basic database methods in AL and SQL statements.

Get, Find, and Next

The AL language offers several methods to retrieve record data. In Dynamics 365 Business Central, records are retrieved using multiple active result sets (MARS). Generally, retrieving records with MARS is faster than with server-side cursors. Additionally, each function is optimized for a specific purpose. To achieve optimal performance you must use the method that is best suited for a given purpose.

- **Record.Get** is optimized for getting a single record based on primary key values.
- **Record.Find** is optimized for getting a single record based on the primary keys in the record and any filter or range that has been set.
- **Record.Find('-')** and **Record.Find('+')** are optimized for reading primarily from a single table when the application might not read all records. Find('-') is implemented by issuing a self-tuning TOP X call, where X can change over time, based on statistics of the number of rows read.

  The following are examples of scenarios in which you should use the Find('-') function to achieve optimal performance:

  - Before you post a general journal batch, you must check all journal lines for validity and verify that all lines balance. After the first line when an error is found, you do not have to retrieve the rest of the rows.
  - if you want to fulfill multiple outstanding orders from a recent purchase but you do not know how many orders are covered by the purchase.
- **Record.FindSet(ForUpdate, UpdateKey)** is optimized for reading the complete set of records in the specified filter and range. The *UpdateKey* parameter does not influence the efficiency of this method in Dynamics 365 Business Central, such as it did in Microsoft Dynamics NAV 2009.

  FindSet is not implemented by issuing a TOP X call.
- **Record.FindFirst** and **Record.FindLast** are optimized for finding the single first or last record in the specified filter and range.
- **Record.Next** can be called at any time. However, if **Record.Next** is not called as part of retrieving a continuous result set, then Business Central calls a separate SQL statement in order to Find the Next record.

Dynamic result sets

Any result set that is returned from a call to the Find methods discussed in the previous section is dynamic. That means that the result set is guaranteed to contain any changes that you make further ahead in the result set. However, this feature comes at a cost. if any modifications are made to a table which is being traversed, then Business Central might have to issue an extra SQL statement to guarantee that the result set is dynamic.

The following code shows how records are most efficiently retrieved. **FindSet** is the most efficient method to use because this example reads all records.

```
if FindSet then
  repeat
    // Insert statements to repeat.
  until Next = 0;
```

CalcFields, CalcSums, and Count

Each call to **CalcFields**, **CalcField**, **CalcSums**, or **CalcSums** methods that calculates a sum requires a separate SQL statement unless the client has calculated the same sum or another sum that uses the same SumIndexFields or filters in a recent operation, and therefore, the result is cached.

Each **CalcFields** or **CalcSums** request should be confined to use only one SifT index. The SifT index can only be used if:

- All requested sum-fields are contained in the same SifT index.
- The filtered fields are part of the key fields specified in the SifT index containing all the sum fields.

if neither of these requirements is fulfilled, then the sum will be calculated directly from the base table.

In Dynamics 365 Business Central, SifT indexes can be used to count records in a filter provided that a SifT index exists that contains all filtered fields in the key fields that are defined for the SifT index.

SetAutoCalcFields

It is a common task to retrieve data and request calculation of associated FlowFields. The following example traverses customer records, calculates the balance, and marks the customer as blocked if the customer exceeds the maximum credit limit. **Note:** the Customer record and associated fields are *imaginary* in the following examples.

```
if Customer.FindSet() then repeat
  Customer.CalcFields(Customer.Balance)
  if (Customer.Balance > MaxCreditLimit) then begin
    Customer.Blocked := true;
    Customer.Modify();
  end
  else if (Customer.Balance > LargeCredit) then begin
    Customer.Caution := true;
    Customer.Modify();
  end;
until Customer.Next = 0;
```

In Dynamics 365 Business Central, you can do this much faster. First, we set a filter on the customer. This could also be done in Business Central 2009, but behind the scenes the same code as mentioned earlier would be executed. In Dynamics 365 Business Central, setting a filter on a record is translated into a single SQL statement.

```
Customer.SetFilter(Customer.Balance,'>%1', LargeCredit);
if Customer.FindSet() then repeat
  Customer.CalcFields(Customer.Balance)
  if (Customer.Balance > MaxCreditLimit) then begin
    Customer.Blocked := true;
    Customer.Modify();
  end
  else if (Customer.Balance > LargeCredit) then begin
    Customer.Caution := true;
    Customer.Modify();
  end;
until Customer.Next = 0;
```

In the previous example, an extra call to CalcFields still must be issued for the code to be able to check the value of Customer.Balance. In Dynamics 365 Business Central, you can optimize this further by using the new **SetAutoCalcFields** method.

```
Customer.SetFilter(Customer.Balance,'>%1', LargeCredit);
Customer.SetAutoCalcFields(Customer.Balance)
if Customer.FindSet() then repeat
  if (Customer.Balance > MaxCreditLimit) then begin
    Customer.Blocked := true;
    Customer.Modify();
  end
  else if (Customer.Balance > LargeCredit) then begin
    Customer.Caution := true;
    Customer.Modify();
  end;
until Customer.Next = 0;
```

Insert, Modify, Delete, and LockTable

Each call to **Insert**, **Modify**, or **Delete** methods requires a separate SQL statement. if the table that you Modify contains SumIndexes, then the operations will be much slower. As a test, select a table that contains SumIndexes and execute one hundred **Insert**, **Modify**, or **Delete** operations to measure how long it takes to maintain the table and all its SumIndexes.

The **LockTable** method does not require any separate SQL statements. It only causes any subsequent reading from the table to lock the table or parts of it.

ModifyAll and DeleteAll

Using **ModifyAll** and **DeleteAll** can improve performance by limiting the amount of SQL calls needed. However, be aware that **ModifyAll** and **DeleteAll** will revert to individual calls if any of the following conditions exist:

- There is trigger code on the table.
- There are event subscribers to the following events: OnBeforeModify, OnAfterModify, OnGlobalModify, OnBeforeDelete, OnAfterDelete, OnGlobalDelete, and OnDatabaseModify.
- Security filtering is active.
- The table contains `Media` or `MediaSet` data type fields.
- There are fields that are added through companion tables.

Table Keys and Performance

Query Objects and Performance

2/17/2021 • 3 minutes to read • Edit Online

A *query* is an object in Dynamics 365 Business Central that you use to specify a set of data that you want to read from the Business Central database. You can query the database to retrieve one or more fields from a single table or multiple tables. You can specify how to join the tables in the query. You can specify totaling methods on fields, such as sums and averages. This topic describes how to design queries and table keys in the most efficient way.

FlowFields in Queries

A sub-query is automatically added to the SQL statement to retrieve each FlowField in a query. This allows Business Central to retrieve all the data in one request.

> **IMPORTANT**
>
> You cannot use a FlowField on a virtual table in a query because this cannot be converted automatically into a SQL statement.

Covering Indexes

When you use a query to select a subset of fields in a table, you should consider taking advantage of the covering index strategy. A *covering index* is the index that contains all output fields required by the operation performed on that index. A covering index data access strategy can greatly improve performance because the database must retrieve only data from the index instead of finding data by using the index and then retrieving the data in the clustered index. A covering index data access strategy can be used when the following conditions are true:

- All columns in a given data item are part of a single Business Central key.
- All columns that are used in the DataItem table filters are part of the same Business Central key.
- If two DataItems are linked, then the field on the parent DataItem that links the two DataItems (the **Reference Field** on the **DataItemLink** property), must be part of the same Business Central key as the columns in the child DataItem.

The SQL Server optimizer automatically chooses a covering index strategy whenever possible.

For more information about SQL Server covering indexes, see SQL Server Optimization.

For more information about SQL Server clustered and non-clustered indexes, see Types of Indexes.

Covering SIFT Indexes

Similar to how indexes can be used to retrieve data for a query, SIFT indexes can be used to retrieve data for a query that contains totals. SIFT totals are maintained after each insert, modify, or delete call, and so some or all of the totals are already calculated. A SIFT index can be used when the following conditions are true:

- The query contains at least one aggregated column with **Method Type** set to **Totals** and with **Method** set to either **Sum**, **Count**, or **Average**.
- If a DataItem contains an aggregated column, then all columns under that DataItem must be aggregated

columns, must use either the **Sum**, **Count**, or **Average** method, and must be part of a SumIndexField defined on a single Business Central key.

- In a query in which you have aggregations but not on all DataItems, then for the DataItems without aggregations, the columns are part of a SumIndexField.
- All non-aggregated columns under the DataItem that have aggregation are part of the key fields defined for the same SIFT index.
- All columns that are used in the DataItem table filters are part of the same Business Central key.
- If two DataItems are linked, then the field on the parent DataItem that links the two DataItems (the **Reference Field** in the **DataItemLink** property) must be part of the same Business Central key as the columns in the child DataItem.

Business Central Server automatically use a SIFT index for query objects whenever possible.

Differences Between Query and Record Result Sets

Business Central does not do any caching for query result sets. When you run a query, Business Central always gets the data directly from SQL Server.

Query result sets are not guaranteed to be dynamic, whereas record result sets are always dynamic. This means that if you insert or modify data in result set row that you have not yet looped through, then it is not guaranteed that the query result set includes those changes.

Enabling and Disabling Selected Query Hints

SQL Server query optimizer will try to select the best execution plan for SELECT, INSERT, UPDATE, and DELETE statements. Most of the time, query optimizer makes the right choice. Query hints are strategies that can be enforced by the SQL Server query processor to override any execution plan that the query optimizer might select for a query. The Business Central Server instance includes configuration settings that let you enable or disable the use of the selected query hints on the database.

For more information, see Configuring Query Hints for Optimizing SQL Server Performance with Business Central.

Optimizing SQL Server Performance with Business Central

Using Read Scale-Out for Better Performance

2/17/2021 • 3 minutes to read • Edit Online

INTRODUCED IN: Business Central 2020 release wave 1

The way Business Central Server interacts with the database can broadly be categorized in two patterns:

- Business processes that read and write data, such as codeunits that run from UI pages or web services.
- Analytical workloads that only read data, such as queries, reports, or API pages.

Where business process transactions typically are frequent and small, transactions from analytical workloads typically read many data and run for a long time. Mixing these two types of transactions in the same database often lead to performance problems. The analytical transactions can cause locking issues, which in turn impose waiting time for business processes. This condition also may disrupt the data cache in the database. Data will essentially be moved from the cache that speeds up business process transactions

If you run the Business Central database in a High Availability architecture, you can use the built-in **Read Scale-Out** feature in Azure SQL Database or SQL Server to load-balance read-only workloads. **Read-Scale-Out** uses the capacity of a read-only replica instead of sharing the read-write replica (also known as the primary database). This way, read-only workloads like reports, queries, and API pages, are isolated from the main read-write workload codeunits. So they won't affect the performance of business processes. As an added bonus, read-only workloads will run on a dedicated database and their performance will likely be better.

Getting started using read scale-out

To start using read scale-out, do these three steps:

1. Enable read scale-out on the Business Central database.
2. As a developer, define the default database access intent (read-only or read-write) on selected reports or query objects.
3. If needed, overwrite the default database access intent on reports, pages of the type API, and queries at runtime.

Enable read scale-out on the Business Central database

In the Business Central Online service, read scale-out is readily available and automatically enabled on the databases.

For on-premises installations, see Configuring your Business Central database for read scale-out to learn how to enable read scale-out on the databases.

Define the default database access intent in AL code

When you develop solutions for Business Central in AL, you can set the default intended database access intent (read-only or read-write) on reports and query objects that you create. For more information, see DataAccessIntent property.

Overwrite the database access intent on reports, API pages, and queries

Read scale-out may introduce a slight delay when reading data from a database's secondary replica. The delay is caused by the way High Availability databases replicate data changes from the primary database to secondary replicas. If a delay isn't acceptable for an object, you can overwrite the default database access intent.

For more information, see Managing Database Access Intent.

FAQ about read scale-out

Which objects are supported?

Reports, API pages, and query objects.

What happens if there's a failover to the replica being used for reading?

The Business Central Server specifies database access intent as a parameter in the connection string to the database. The Business Central Server doesn't know about primary/secondary replicas. So if there's a fail-over, the Business Central Server will be redirected by the database.

Why is there a delay in when a data change is available on the secondary replicas?

When data is committed to the primary database, the transaction log entries are log-shipped to the transaction log for the secondary replicas. Then, an asynchronous transaction log "redo" operation makes the data available in the secondary databases.

What about Sandboxes?

Sandbox environments can't be enabled with read scale-out. Objects that use the **DataAccessIntent** property will compile and run. But they'll just access the primary database.

Performance Overview

Configuring a Business Central Database for Read Scale-Out

2/17/2021 • 2 minutes to read • Edit Online

INTRODUCED IN: Business Central 2020 release wave 1

In the Business Central Online service, read scale-out is readily available and automatically enabled on the databases.

For Business Central on-premises, you must do the following steps:

1. Check whether your database supports read scale-out.
2. Enable read scale-out on the database.

   If the Business Central database runs on Azure SQL Database, determine whether the performance tier of the database supports read scale-out. You can then enable it if it's supported. For more information, see Use read-only replicas to load-balance read-only query workloads in the Azure SQL Database documentation.

   If the Business Central database runs on SQL Server, determine whether your installation supports read scale-out and how to enable the feature. For more information, see Configure read-only routing for an Always On availability group in the SQL Server documentation.
3. Enable SQL read-only replica support on the Business Central Server instance.

   Business Central Server includes the **Enable SQL Read-Only Replica Support** (EnableSqlReadOnlyReplicaSupport) setting. This setting isn't enabled by default. For more information, see Configuring Business Central Server.

Troubleshooting: Using Query Store to Monitor Query Performance in Business Central

2/17/2021 • 2 minutes to read • Edit Online

What is SQL Server Query Store?

The SQL Server Query Store feature provides you with insight on database query plan choice and performance. It simplifies database performance troubleshooting by helping you quickly find performance differences caused by query plan changes. Query Store automatically captures a history of queries, plans, and runtime statistics, and retains these for your review.

Where is SQL Server Query Store available?

SQL Server Query Store is available in SQL Server (starting with SQL Server 2016) and in Azure SQL Database.

What are the common scenarios for using the Query Store feature?

Query Store keeps a history of compilation and runtime metrics throughout query execution. With this information, you can get some answers on questions about your workload, such as:

- What was the last *n* queries executed on the database?
- What were the number of executions for each query?
- Which queries had the longest average execution time within last hour?
- Which queries had the biggest average physical IO reads in last 24 hours, with corresponding average row count and execution count?

Do you want to read more?

Please visit the SQL Server documentation for more information on setup, configuration and usage of Query Store:

Monitoring Performance By Using the Query Store

Troubleshooting: Using the Event Viewer to Monitor Long Running SQL Queries in Business Central

2/17/2021 • 2 minutes to read • Edit Online

This article shows how you can monitor long running SQL queries in Event Viewer. You use the information determine SQL queries that are good candidates for optimization.

Resolution

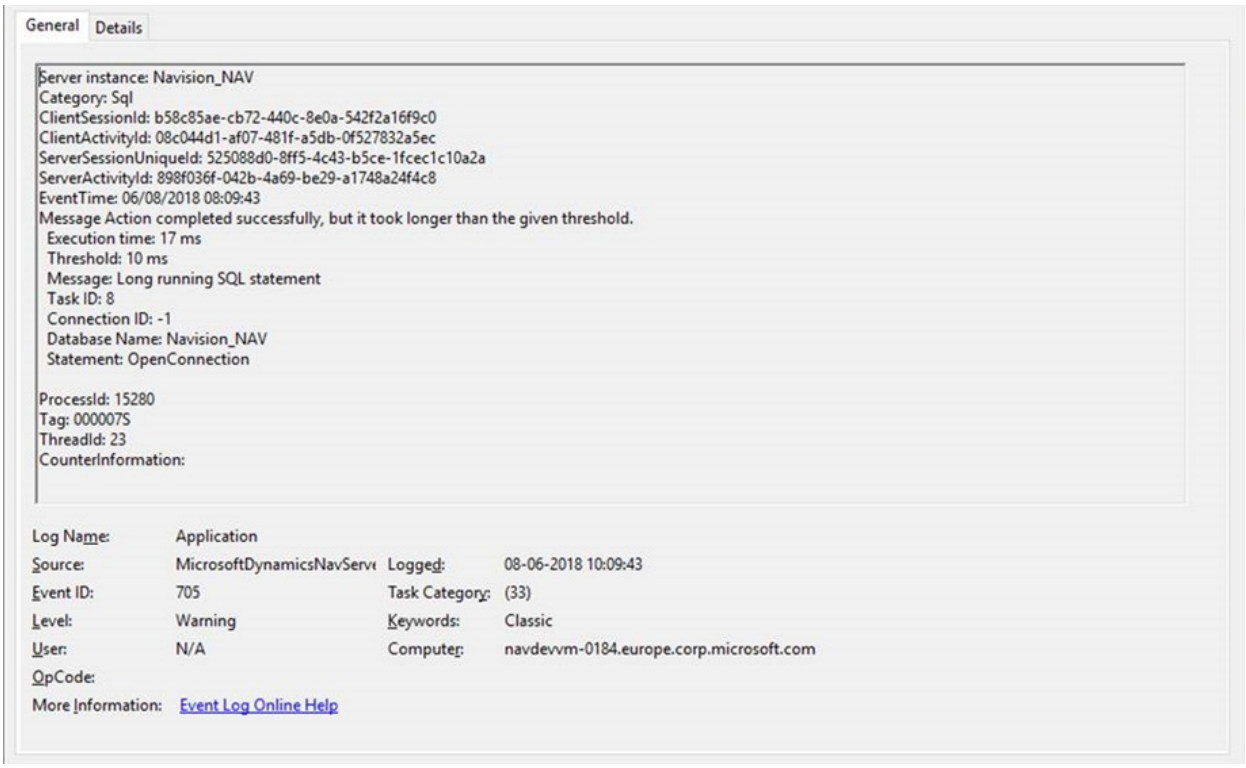
Identifying long running SQL queries can be a good starting point when doing a performance analysis. Open the Event Viewer and go to the Windows Logs Application.

> **NOTE**
>
> The SQL queries which exceed the set threshold will be displayed in the Application window of the Event Viewer as *Warning*.

If the value of the SqlLongRunningThreshold key was set to the default value of 1000 milliseconds, you'll see the message: "*Action completed successfully, but it took longer than the given threshold.*" for actions that took longer.

To meet performance expectations in production, you can set the threshold to a different value. You can set the threshold without restarting the server instance. For more information on how to set the threshold, see Monitoring Long Running SQL Queries using the Event Log.

If the value of the SqlLongRunningThreshold key was set to the default value of 1000 milliseconds, you'll see the message: "*Action completed successfully, but it took longer than the given threshold.*" for actions that took longer. To meet your performance expectations in production, you can set the threshold to a different value without doing a server restart. For more information, see Monitoring Long Running SQL Queries using the Event Log.



Using the AL call stack

Long running queries that involve the explicit execution of AL code will include an AL call stack in the event log. Long running queries that aren't the result of explicit AL code won't include an AL call stack. For example:

- GetPage calls that load data into the UI.
- Calls to triggers that don't include any code. These calls won't include an AL call stack, because there no AL code is run.

Looking at the AL call stack can help you identify what caused the delay. For queries that include an AL call stack, the generated SQL statement is listed in the `AL CallStack` column. The following code example shows which AL method generated a slow running query.

```
Server instance: BC
Category: Sql
ClientSessionId: 00000000-0000-0000-0000-000000000000
ClientActivityId: 828c9342-891a-4631-8eb3-a1da7304fdc9

Monitoring and Analyzing Telemetry

2/17/2021 • 4 minutes to read • Edit Online

APPLIES TO: Business Central 2019 release wave 2 and later

Business Central emits telemetry data for various activities and operations on tenants and extensions. Whether running Business Central Online or On-premises, you can set up your tenants to send telemetry to Application Insights. Application Insights is a service hosted within Azure that gathers telemetry data for analysis and presentation. For more information, see What is Application Insights?. Monitoring telemetry gives you a look at the activities and general health of your tenants. It helps you diagnose problems and analyze operations that affect performance.

Tenant-level and extension-level telemetry

Application Insights can be enabled on two different levels: tenant and extension. When enabled on the tenant, either for a Business Central online tenant or on-premises Business Central Server instance, telemetry is emitted to a single Application Insights resource for gathering data on tenant-wide operations.

With Business Central 2020 release wave 2 and later, Application Insights can also be enabled on a per-extension basis. An Application Insights key is set in the extension's manifest (app.json file). At runtime, certain events related to the extension are emitted to the Application Insights resource. This feature targets publishers of per-tenant extensions to give them insight into issues in their extension before partners and customers report them.

Available telemetry

In Application Insights, telemetry from Business Central is logged as traces. Currently, Business Central offers telemetry on the following operations:

AREA	DESCRIPTION	ONLINE	ON-PREMISES	EXTENSION SUPPORT	MORE INFORMATION
App key vault secrets	Provides information about the retrieval of secrets from Azure Key Vaults by extensions.	✓ [1]	✓ [1]	✓	See...
Authorization	Provides information about user sign-in attempts. Information includes success or failure indication, reason for failure, user type, and more.	✓			See...

[1]This signal is only emitted to the Application Insights resource that's specified in the extension.

[2]Introduced in Business Central 2020 release wave 1, version 16.3. For extension telemetry, this signal was introduced in 2020 release wave 2, version 17.1.

Enabling Application Insights

Sending telemetry data to Application Insights requires you have an Application Insights resource in Azure. Once you have the Application Insights resource, you can start to configure your tenants and extensions to send telemetry data to your Application Insights resource. The configuration is different for Online and On-premises:

- For Business Central Online, Application Insights is enabled by using the Administration Center. For more information, see Enable Sending Telemetry to Application Insights.
- For Business Central On-premises, see Enable Sending Telemetry to Application Insights.
- For extensions, see Sending Extension Telemetry to Azure Application Insights.

Viewing telemetry data in Application Insights

Telemetry from Business Central is stored in Azure Monitor Logs in the *traces* table. You can view collected data by writing log queries. Log queries are written in the Kusto query language (KQL). For more information, see Logs in Azure Monitor and Overview of log queries in Azure Monitor.

As a simple example, do the following steps:

1. In the Azure portal, open your Application Insights resource.
2. In the **Monitoring** menu, select **Logs**.
3. On the **New Query** tab, type the following to get the last 100 traces:

```
traces
| take 100
| sort by timestamp desc
```

About Custom Dimensions

Each trace includes a `customDimensions` column. The `customDimensions` column, in turn, includes a set dimensions that contain metrics specific to the trace. Each of these custom dimensions has a limit of 8000 characters. If a dimension's value exceeds 8000 characters, additional dimensions will be added to the trace for containing the excess characters. There can be up to two additional parameters, each with a maximum 8000 characters. The additional dimensions will have the names that `<custom_dimension_name>_1` and `<custom_dimension_name>_2`, where `<custom_dimension_name>` is the name of the original dimension. For example, if the custom dimension is `extensionCompilationDependencyList`, then the additional dimensions would be `extensionCompilationDependencyList_1` and `extensionCompilationDependencyList_2`.

> **NOTE**
>
> The 8000 character limit is governed by the Application Insights API.

Application Insights sample code

On the Business Central BCTech repository on GitHub, samples of KQL code are available to make it easy to get started using Application Insights.

For more information, see Business Central BCTech repository on GitHub.

Enabling Application Insights for Tenant Telemetry On-Premises

2/17/2021 • 2 minutes to read • Edit Online

APPLIES TO: Business Central 2019 release wave 2 and later

This article describes how to set up tenants to send telemetry data to Azure Application Insights for on-premises environments.

> **IMPORTANT**
> Currently, emitting data to Azure Application Insights resources in Germany regions, like **(Europe) Germany West Central** or **(Europe) Germany North** , doesn't work. Until this issue is fixed, the mitigation is to create an Azure Application Insights resource in a region outside of Germany. Then, when the issue has been fixed, move the resource to the preferred region.

Get started

1. Create an Application Insights resource.

   See Create an Application Insights resource.

2. Get the instrumentation key of the Application Insights resource, which you can get from the Azure Portal.

Enable on tenants

Once you have the resource and its key, you can enable your tenants to send telemetry to your Application Insights resource.

The way you enable Application Insights depends on whether the Business Central Server instance is configured as a single-tenant or multitenant instance:

- For a single-tenant server instance, you set the **Application Insights Instrumentation Key** setting of the server instance. For more information, see Configuring Business Central Server.
- For a multitenant server instance, you enable this feature on a per-tenant basis when you mount tenants on the Business Central Server instance. The Mount-NAVTenant cmdlet includes the `-ApplicationInsightsKey` parameter that you set to the instrumentation key, for example:

  ```
  Mount-NAVTenant -ServerInstance BC150 -Tenant tenant1 -DatabaseName "Demo Database BC (15-0)" -
  DatabaseServer localhost -DatabaseInstance BCDEMO -ApplicationInsightsKey 11111111-2222-3333-4444-
  555555555555
  ```

Enable in Docker

If you are running Business Central in Docker using the latest BcContainerHelper, you can specify the Application Insights Key when creating the container and this will be used in server instance settings if the container is single-tenant or for the default tenant if the container is multi-tenant.

```
New-BcContainer `
    -accept_eula `
    -updateHosts `
    -artifactUrl (Get-BCArtifactUrl -country us) `
    -applicationInsightsKey "11111111-2222-3333-4444-555555555555"
```

You can specify the same or another key when creating additional tenants:

```
New-BcContainerTenant -tenantId "additional" -applicationInsightsKey "55555555-4444-3333-2222-111111111111"
```

Monitoring and Analyzing With Telemetry

Analyzing App Key Vault Secret Trace Telemetry

2/17/2021 • 6 minutes to read • Edit Online

APPLIES TO: Business Central 2020 release wave 2 and later

App key vault telemetry gathers information about the acquisition of secrets in Azure Key Vaults by extensions at runtime. For an overview of app key vaults and secrets, see Using App Key Vaults with Business Central Extensions.

The app key vault secret process has two operations: *initialization* and *retrieval*. The telemetry data provides information about the success or failure for each of these operations. There are various conditions that cause a failure. The failure messages provide insight into the cause of the failure, helping you identify, troubleshoot, and resolve issues.

Initialization

Initialization is the first stage. It verifies the configuration of the app key vault provider in the extension and on the service. This stage is initiated by the `TryInitializeFromCurrentApp` method call in the extension code. Some conditions that cause failures in this stage include:

- The extension doesn't specify a key vault in it's app.json file.
- The Azure Key Vault Client Identity settings are incorrect. For example, it could be that the application (client) ID that you specified for the key vault reader application in Azure is wrong.
- The Business Central Server lacks permission to the private key of the Azure Key Vault client certificate.

Retrieval

Retrieval is the second stage, and occurs after a successful initialization. In this stage, the service tries to get a secret from a specified key vault. This stage is initiated by the `GetSecret` method call in the extension code. Some conditions that cause failures include:

- The secret name requested by the extension is doesn't exist or isn't valid.
- The key vault doesn't exist.
- The application ID doesn't have permission to read from the key vault.

For more information about using key vault secrets with extensions, see App Key Vaults with Business Central Extensions.

App Key Vault secret initialization succeeded

Occurs when an extension secret was successfully initialized.

General dimensions

DIMENSION	DESCRIPTION OR VALUE
message	**App Key Vault initialization succeeded: '{keyVaultUri}'.**
severityLevel	**1**

Custom dimensions

DIMENSION	DESCRIPTION OR VALUE
alObjectId	Specifies the ID of the AL object that was run by request.
alObjectName	Specifies the name of the AL object that was run by request.
alObjectType	Specifies the type of AL object that was run by request.
alStackTrace	The stack trace in AL.
clientType	Specifies the type of client that executed the request, such as **Background** or **Web**. For a list of the client types, see ClientType Option Type.
component	**Dynamics 365 Business Central Server**.
componentVersion	Specifies the version number of the component that emits telemetry (see the component dimension.)
deprecatedKeys	A comma-separated list of all the keys that have been deprecated. The keys in this list are still supported but will eventually be removed in the next major release. We recommend that update any queries that use these keys to use the new key name.
eventId	**RT0014**
extensionId	Specifies the AppID of the extension that requested the secret.
extensionName	Specifies the name of the extension that requested the secret.
extensionPublisher	Specifies the publisher of the extension that requested the secret.
extensionVersion	Specifies the version of the extension that requested the secret.
keyVaultUrls	Specifies the DNS name of the Azure key vault that was used in the request. The keyVaultUris are specified in the app.json file of the extension.
telemetrySchemaVersion	Specifies the version of the Business Central telemetry schema.

App Key Vault initialization failed

Occurs when a key vault failed to be initialized.

General dimensions

DIMENSION	DESCRIPTION OR VALUE
message	**App Key Vault initialization failed.**

DIMENSION	DESCRIPTION OR VALUE
severityLevel	3

Custom dimensions

DIMENSION	DESCRIPTION OR VALUE
alObjectId	Specifies the ID of the AL object that was run by request.
alObjectName	Specifies the name of the AL object that was run by request.
alObjectType	Specifies the type of AL object that was run by request.
alStackTrace	The stack trace in AL.
clientType	Specifies the type of client that executed request, such as **Background** or **Web**. For a list of the client types, see ClientType Option Type.
component	**Dynamics 365 Business Central Server**.
componentVersion	Specifies the version number of the component that emits telemetry (see the component dimension.)
deprecatedKeys	A comma-separated list of all the keys that have been deprecated. The keys in this list are still supported but will eventually be removed in the next major release. We recommend that update any queries that use these keys to use the new key name.
eventId	**RT0015**
extensionId	Specifies the AppID of the extension that requested the secret.
extensionName	Specifies the name of the extension that requested the secret.
extensionPublisher	Specifies the publisher of the extension that requested the secret.
extensionVersion	Specifies the version of the extension that requested the secret.
failureReason	Specifies the error that occurred.
telemetrySchemaVersion	Specifies the version of the Business Central telemetry schema.

App Key Vault secret retrieval succeeded

Occurs when a secret used by an extension is successfully retrieved from an Azure Key Vault.

General dimensions

DIMENSION	DESCRIPTION OR VALUE
message	**App Key Vault secret retrieval succeeded from key vault '{keyVaultUri}'.**
severityLevel	1

Custom dimensions

DIMENSION	DESCRIPTION OR VALUE
alObjectId	Specifies the ID of the AL object that was run by request.
alObjectName	Specifies the name of the AL object that was run by request.
alObjectType	Specifies the type of AL object that was run by request.
alStackTrace	The stack trace in AL.
clientType	Specifies the type of client that executed the SQL Statement, such as **Background** or **Web**. For a list of the client types, see ClientType Option Type.
component	**Dynamics 365 Business Central Server**.
componentVersion	Specifies the version number of the component that emits telemetry (see the component dimension.)
deprecatedKeys	A comma-separated list of all the keys that have been deprecated. The keys in this list are still supported but will eventually be removed in the next major release. We recommend that update any queries that use these keys to use the new key name.
eventId	**RT0016**
extensionId	Specifies the AppID of the extension that requested the secret.
extensionName	Specifies the name of the extension that requested the secret.
extensionPublisher	Specifies the publisher of the extension that requested the secret.
extensionVersion	Specifies the version of the extension that requested the secret.
keyVaultUrl	Specifies the DNS name of the Azure key vault that was used in the request. The keyVaultUris are specified in the app.json file of the extension.
telemetrySchemaVersion	Specifies the version of the Business Central telemetry schema.

App Key Vault secret retrieval failed

Occurs when an extension failed to retrieve a secret from a specified Azure key vault.

General dimensions

DIMENSION	DESCRIPTION OR VALUE
message	**App Key Vault secret retrieval failed from key vault '{keyVaultUri}'.**
severityLevel	3

Custom dimensions

DIMENSION	DESCRIPTION OR VALUE
alObjectId	Specifies the ID of the AL object that was run by request.
alObjectName	Specifies the name of the AL object that was run by request.
alObjectType	Specifies the type of AL object that was run by request.
alStackTrace	The stack trace in AL.
clientType	Specifies the type of client that executed the SQL Statement, such as **Background** or **Web**. For a list of the client types, see ClientType Option Type.
component	**Dynamics 365 Business Central Server**.
componentVersion	Specifies the version number of the component that emits telemetry (see the component dimension.)
deprecatedKeys	A comma-separated list of all the keys that have been deprecated. The keys in this list are still supported but will eventually be removed in the next major release. We recommend that update any queries that use these keys to use the new key name.
eventId	**RT0017**
extensionId	Specifies the AppID of the extension that requested the secret.
extensionName	Specifies the name of the extension that requested the secret.
extensionPublisher	Specifies the publisher of the extension that requested the secret.
extensionVersion	Specifies the version of the extension that requested the secret.

DIMENSION	DESCRIPTION OR VALUE
keyVaultUrl	Specifies the DNS name of the Azure key vault that was used in the request. The keyVaultUris are specified in the app.json file of the extension.
telemetrySchemaVersion	Specifies the version of the Business Central telemetry schema.

Analyzing Company Lifecycle Trace Telemetry

2/17/2021 • 11 minutes to read • Edit Online

INTRODUCED IN: Business Central 2020 release wave 1, version 16.1

Company lifecycle telemetry gathers data about the success or failure of the following company-related operations:

- creating a company
- copying a company
- deleting a company

Failed operations result in a trace log entry that includes a reason for the failure.

Company created

Occurs when the company has been successfully created.

General dimensions

DIMENSION	DESCRIPTION OR VALUE
message	**Company created: {companyName}** `{companyName}` indicates the name of the new company.
severityLevel	**1**

Custom dimensions

DIMENSION	DESCRIPTION OR VALUE
aadTenantId	Specifies that Azure Active Directory (Azure AD) tenant ID used for Azure AD authentication. For on-premises, if you aren't using Azure AD authentication, this value is **common**.
clientType	Specifies the type of client that executed the SQL Statement, such as **Background** or **Web**. For a list of the client types, see ClientType Option Type.
companyName	Specifies the display name of the Business Central company.
component	**Dynamics 365 Business Central Server**
componentVersion	Specifies the version number of the component that emits telemetry (see the component dimension.)
deprecatedKeys	Specifies a comma-separated list of all the keys that have been deprecated. The keys in this list are still supported but will eventually be removed in the next major release. We recommend that update any queries that use these keys to use the new key name.

DIMENSION	DESCRIPTION OR VALUE
environmentName	Specifies the name of the tenant environment. See Managing Environments.
environmentType	Specifies the environment type for the tenant, such as **Production**, **Sandbox**, **Trial**. See Environment Types
eventId	**LC0001**
result	**Success**
serverExecutionTime	Specifies the amount of time it took the server to create the company. The time has the format hh:mm:ss.sssssss.
sqlExecutes	Specifies the number of SQL statements that were executed.
sqlRowsRead	Specifies the number of table rows that were read by the SQL statements.
telemetrySchemaVersion	Specifies the version of the Business Central telemetry schema.
totalTime	Specifies the amount of time it took to create the company. The time has the format hh:mm:ss.ssssss.

Company creation canceled

Occurs when creating a company was canceled.

General dimensions

DIMENSION	DESCRIPTION OR VALUE
message	**Company creation canceled: {companyName}** `{companyName}` indicates the name of the company being created.
severityLevel	2

Custom dimensions

DIMENSION	DESCRIPTION OR VALUE
aadTenantId	Specifies that Azure Active Directory (Azure AD) tenant ID used for Azure AD authentication. For on-premises, if you aren't using Azure AD authentication, this value is **common**.
clientType	Specifies the type of client that executed the SQL Statement, such as **Background** or **Web**. For a list of the client types, see ClientType Option Type.
companyName	Specifies the display name of the Business Central company.

DIMENSION	DESCRIPTION OR VALUE
component	**Dynamics 365 Business Central Server**.
componentVersion	Specifies the version number of the component that emits telemetry (see the component dimension.)
deprecatedKeys	Specifies a comma-separated list of all the keys that have been deprecated. The keys in this list are still supported but will eventually be removed in the next major release. We recommend that update any queries that use these keys to use the new key name.
environmentType	Specifies the environment type for the tenant, such as **Production**, **Sandbox**, **Trial**. See Environment Types
eventId	**LC0002**
failureReason	**Operation was canceled**
result	**Failure**
serverExecutionTime	Specifies the amount of time it took the server create the company before being canceled. The time has the format hh:mm:ss.sssssss.
sqlExecutes	Specifies the number of SQL statements that were executed by the operation.
sqlRowsRead	Specifies the number of table rows that were read by the SQL statements.
telemetrySchemaVersion	Specifies the version of the Business Central telemetry schema.
totalTime	Specifies the amount of time used to create the company before being canceled. The time has the format hh:mm:ss.sssssss.

Company creation failed

Occurs when a company failed to be created.

General dimensions

DIMENSION	DESCRIPTION OR VALUE
message	**Company creation failed: {companyName}** `{companyName}` indicates the name of the company being created.
severityLevel	1

Custom dimensions

DIMENSION	DESCRIPTION OR VALUE
aadTenantId	Specifies that Azure Active Directory (Azure AD) tenant ID used for Azure AD authentication. For on-premises, if you aren't using Azure AD authentication, this value is **common**.
clientType	Specifies the type of client that executed the SQL Statement, such as **Background** or **Web**. For a list of the client types, see ClientType Option Type.
companyName	Specifies the display name of the Business Central company.
component	**Dynamics 365 Business Central Server**.
componentVersion	Specifies the version number of the component that emits telemetry (see the component dimension.)
deprecatedKeys	Specifies a comma-separated list of all the keys that have been deprecated. The keys in this list are still supported but will eventually be removed in the next major release. We recommend that update any queries that use these keys to use the new key name.
environmentType	Specifies the environment type for the tenant, such as **Production**, **Sandbox**, **Trial**. See Environment Types
eventId	**LC0003**
failureReason	Specifies the exception that indicates the cause of the failure.
result	**Failure**
serverExecutionTime	Specifies the amount of time it took the server create the company before it failed. The time has the format hh:mm:ss.sssssss.
sqlExecutes	Specifies the number of SQL statements that were executed by the operation.
sqlRowsRead	Specifies the number of table rows that were read by the SQL statements.
telemetrySchemaVersion	Specifies the version of the Business Central telemetry schema.
totalTime	Specifies the amount of time used to create the company before it failed. The time has the format hh:mm:ss.sssssss.

Company copied

Occurs when a company has been copied from another company successfully.

General dimensions

DIMENSION	DESCRIPTION OR VALUE
message	**Company copied: {companyNameSource} to {companyNameDestination}** • `{companyNameSource}` is name of the company that was copied. • `{companyNameDestination}` is the name of new company that was created.
severityLevel	2

Custom dimensions

DIMENSION	DESCRIPTION OR VALUE
aadTenantId	Specifies that Azure Active Directory (Azure AD) tenant ID used for Azure AD authentication. For on-premises, if you aren't using Azure AD authentication, this value is **common**.
clientType	Specifies the type of client that executed the SQL Statement, such as **Background** or **Web**. For a list of the client types, see ClientType Option Type.
companyNameDestination	Specifies the name of the new company.
companyNameSource	Specifies the name of the Business Central company.
component	**Dynamics 365 Business Central Server**.
componentVersion	Specifies the version number of the component that emits telemetry (see the component dimension.)
deprecatedKeys	Specifies a comma-separated list of all the keys that have been deprecated. The keys in this list are still supported but will eventually be removed in the next major release. We recommend that update any queries that use these keys to use the new key name.
environmentType	Specifies the environment type for the tenant, such as **Production**, **Sandbox**, **Trial**. See Environment Types
eventId	**LT0004**
result	**Success**
serverExecutionTime	Specifies the amount of time it took the server to copy the company. The time has the format hh:mm:ss.sssssss.
sqlExecutes	Specifies the number of SQL statements that were executed by the operation.
sqlRowsRead	Specifies the number of table rows that were read by the SQL statements.

DIMENSION	DESCRIPTION OR VALUE
telemetrySchemaVersion	Specifies the version of the Business Central telemetry schema.
totalTime	Specifies the amount of time it took to copy the company. The time has the format hh:mm:ss.sssssss.

Company copy canceled

Occurs when a copying a company was canceled.

General dimensions

DIMENSION	DESCRIPTION OR VALUE
message	**Company copied canceled: {source company name} to {destination company name}** • `{companyNameSource}` is name of the company that was being copied. • `{companyNameDestination}` is the name of new company that was being created.
severityLevel	2

Custom dimensions

DIMENSION	DESCRIPTION OR VALUE
aadTenantId	Specifies that Azure Active Directory (Azure AD) tenant ID used for Azure AD authentication. For on-premises, if you aren't using Azure AD authentication, this value is **common**.
clientType	Specifies the type of client that executed operation, such as **Background** or **Web**. For a list of the client types, see ClientType Option Type.
companyName	Specifies the display name of the Business Central company.
component	**Dynamics 365 Business Central Server**.
componentVersion	Specifies the version number of the component that emits telemetry (see the component dimension.)
environmentType	Specifies the environment type for the tenant, such as **Production**, **Sandbox**, **Trial**. See Environment Types
eventId	**LC0005**
failureReason	**Operation was canceled**.
result	**Failure**

DIMENSION	DESCRIPTION OR VALUE
serverExecutionTime	Specifies the amount of time it took the server to copy the company. The time has the format hh:mm:ss.sssssss.
sqlExecutes	Specifies the number of SQL statements that were executed.
sqlRowsRead	Specifies the number of table rows that were read by the SQL statements.
telemetrySchemaVersion	Specifies the version of the Business Central telemetry schema.
totalTime	Specifies the amount of time used to do the operation. The time has the format hh:mm:ss.sssssss.

Company copy failed

Occurs when a company failed to be copied from another company.

General dimensions

DIMENSION	DESCRIPTION OR VALUE
message	**Company copy failed: {companyNameSource} to {companyNameDestination}** • `{companyNameSource}` is name of the company that was being copied. • `{companyNameDestination}` is the name of new company that was being created.
severityLevel	3

Custom dimensions

DIMENSION	DESCRIPTION OR VALUE
aadTenantId	Specifies that Azure Active Directory (Azure AD) tenant ID used for Azure AD authentication. For on-premises, if you aren't using Azure AD authentication, this value is **common**.
clientType	Specifies the type of client that executed the SQL Statement, such as **Background** or **Web**. For a list of the client types, see ClientType Option Type.
companyName	Specifies the display name of the Business Central company.
component	**Dynamics 365 Business Central Server**.
componentVersion	Specifies the version number of the component that emits telemetry (see the component dimension.)
environmentType	Specifies the environment type for the tenant, such as **Production**, **Sandbox**, **Trial**. See Environment Types

DIMENSION	DESCRIPTION OR VALUE
eventId	**LC0006**
failureReason	Specifies the exception that indicates the cause of the failure.
result	**Failure**
serverExecutionTime	Specifies the amount of time on the server. The time has the format hh:mm:ss.ssssss.
sqlExecutes	Specifies the number of SQL statements that were executed.
sqlRowsRead	Specifies the number of table rows that by the SQL statements.
telemetrySchemaVersion	Specifies the version of the Business Central telemetry schema.
totalTime	Specifies the amount of time used to create the company before it failed. The time has the format hh:mm:ss.ssssss.

Company deleted

Occurs when a company has been deleted successfully.

General dimensions

DIMENSION	DESCRIPTION OR VALUE
message	**Company deleted: {companyName}** `{companyName}` indicates the name of the company that was deleted.
severityLevel	1

Custom dimensions

DIMENSION	DESCRIPTION OR VALUE
aadTenantId	Specifies that Azure Active Directory (Azure AD) tenant ID used for Azure AD authentication. For on-premises, if you aren't using Azure AD authentication, this value is **common**.
clientType	Specifies the type of client that executed the SQL Statement, such as **Background** or **Web**. For a list of the client types, see ClientType Option Type.
companyName	Specifies the display name of the Business Central company.
component	**Dynamics 365 Business Central Server**.
componentVersion	Specifies the version number of the component that emits telemetry (see the component dimension.)

DIMENSION	DESCRIPTION OR VALUE
environmentType	Specifies the environment type for the tenant, such as **Production**, **Sandbox**, **Trial**. See Environment Types
eventId	**LC0007**
result	**Success**
serverExecutionTime	Specifies the amount of time it took on server. The time has the format hh:mm:ss.sssssss.
sqlExecutes	Specifies the number of SQL statements that the operation executed.
sqlRowsRead	Specifies the number of table rows that were read by the SQL statements.
telemetrySchemaVersion	Specifies the version of the Business Central telemetry schema.
totalTime	Specifies the amount of time it took to delete the company. The time has the format hh:mm:ss.sssssss.

Company deletion canceled

Occurs when deleting a company failed was canceled.

General dimensions

DIMENSION	DESCRIPTION OR VALUE
message	**Company deletion canceled: {companyName}** `{companyName}` indicates the name of the company that was being deleted.
severityLevel	2

Custom dimensions

DIMENSION	DESCRIPTION OR VALUE
aadTenantId	Specifies that Azure Active Directory (Azure AD) tenant ID used for Azure AD authentication. For on-premises, if you aren't using Azure AD authentication, this value is **common**.
clientType	Specifies the type of client that executed the SQL Statement, such as **Background** or **Web**. For a list of the client types, see ClientType Option Type.
companyName	Specifies the display name of the Business Central company.
component	**Dynamics 365 Business Central Server**.

DIMENSION	DESCRIPTION OR VALUE
componentVersion	Specifies the version number of the component that emits telemetry (see the component dimension.)
environmentType	Specifies the environment type for the tenant, such as **Production**, **Sandbox**, **Trial**. See Environment Types
eventId	**LC0008**
failureReason	**Operation was canceled**
result	**Failure**
serverExecutionTime	Specifies the amount of time it took on server. The time has the format hh:mm:ss.sssssss.
sqlExecutes	Specifies the number of SQL statements that executed by the operation.
sqlRowsRead	Specifies the number of table rows that were read by the SQL statements.
telemetrySchemaVersion	Specifies the version of the Business Central telemetry schema.
totalTime	Specifies the amount of time used to delete the company before being canceled. The time has the format hh:mm:ss.sssssss.

Company deletion failed

Occurs when a company failed to be deleted.

General dimensions

DIMENSION	DESCRIPTION OR VALUE
message	**Company deletion failed: {companyName}** `{companyName}` indicates the name of the company that was being deleted.
severityLevel	3

Custom dimensions

DIMENSION	DESCRIPTION OR VALUE
aadTenantId	Specifies that Azure Active Directory (Azure AD) tenant ID used for Azure AD authentication. For on-premises, if you aren't using Azure AD authentication, this value is **common**.

DIMENSION	DESCRIPTION OR VALUE
clientType	Specifies the type of client that executed the SQL Statement, such as **Background** or **Web**. For a list of the client types, see ClientType Option Type.
companyName	Specifies the display name of the Business Central company.
component	**Dynamics 365 Business Central Server**.
componentVersion	Specifies the version number of the component that emits telemetry (see the component dimension.)
environmentType	Specifies the environment type for the tenant, such as **Production**, **Sandbox**, **Trial**. See Environment Types
eventId	**LC0009**
failureReason	Specifies the exception that caused the failure.
result	**Failed**
serverExecutionTime	Specifies the amount of time it took on server. The time has the format hh:mm:ss.sssssss.
sqlExecutes	Specifies the number of SQL statements that executed by the operation.
sqlRowsRead	Specifies the number of table rows that were read by the SQL statements.
telemetrySchemaVersion	Specifies the version of the Business Central telemetry schema.
totalTime	Specifies the amount of time used to delete the company before it failed. The time has the format hh:mm:ss.sssssss.

Analyzing Configuration Package Lifecycle Trace Telemetry

2/17/2021 • 4 minutes to read • Edit Online

APPLIES TO: Business Central 2020 release wave 2, version 17.2, and later

Configuration package telemetry gathers data about the following operations on configuration packages:

- Export
- Import
- Apply
- Delete

For information about working with configuration packages, see Prepare a Configuration Package in the Business Central Application Help.

Configuration package export started

Occurs when an export operation on a configuration package is started.

General dimensions

DIMENSION	DESCRIPTION OR VALUE
message	**Configuration package export started: {alPackageCode}**
severityLevel	**1**

Custom dimensions

DIMENSION	DESCRIPTION OR VALUE
eventId	**AL0000E3F**
alExecutionId	Specifies the ID of the export operation.
alObjectId	**8614**, which is the ID of the base application codeunit that handles the export of configuration packages.
alObjectName	**Config. XML Exchange**, which is the name of the base application codeunit that handles the export of configuration packages.
alObjectType	**CodeUnit**
alPackageCode	Specifies the ID of the configuration package being exported.

Common custom dimensions

The following table explains additional custom dimensions that are common to all configuration package traces.

DIMENSION	DESCRIPTION OR VALUE
aadTenantId	Specifies that Azure Active Directory (Azure AD) tenant ID used for Azure AD authentication. For on-premises, if you aren't using Azure AD authentication, this value is **common**.
alCategory	**RapidStart**
alDataClassification	**SystemMetadata**
component	**Dynamics 365 Business Central Server**.
componentVersion	Specifies the version number of the component that emits telemetry (see the component dimension.)
environmentType	Specifies the environment type for the tenant, such as **Production**, **Sandbox**, **Trial**. See Environment Types.
telemetrySchemaVersion	Specifies the version of the Business Central telemetry schema.

Configuration package exported successfully

Occurs when an export operation on a configuration package completes successfully.

General dimensions

DIMENSION	DESCRIPTION OR VALUE
message	**Configuration package exported successfully: {alPackageCode}**
severityLevel	**1**

Custom dimensions

DIMENSION	DESCRIPTION OR VALUE
eventId	**AL0000E3G**
alExecutionId	Specifies the ID of the export operation.
alExecutionTimeInMs	Specifies the number of milliseconds it took to complete the export operation.
alObjectId	**8614**, which is the ID of the base application codeunit that handles the export of configuration packages.
alObjectName	**Config. XML Exchange**, which is the name of the base application codeunit that handles the export of configuration packages.
alObjectType	**CodeUnit**

DIMENSION	DESCRIPTION OR VALUE
alPackageCode	Specifies the ID of the configuration package that was exported.
See common custom dimensions	

Configuration package import started

Occurs when an import operation on a configuration package is started.

General dimensions

DIMENSION	DESCRIPTION OR VALUE
message	**Configuration package import started: {alPackageCode}**
severityLevel	**1**

Custom dimensions

DIMENSION	DESCRIPTION OR VALUE
eventId	**AL0000E3H**
alExecutionId	Specifies the ID of the import operation.
alObjectId	**8614**, which is the ID of the base application codeunit that handles the import of configuration packages.
alObjectName	**Config. XML Exchange**, which is the name of the base application codeunit that handles the import of configuration packages.
alObjectType	**CodeUnit**
alPackageCode	Specifies the ID of the configuration package being imported.
See common custom dimensions	

Configuration package imported successfully

Occurs when an import operation on a configuration package completes successfully.

General dimensions

DIMENSION	DESCRIPTION OR VALUE
message	**Configuration package imported successfully: {alPackageCode}**
severityLevel	**1**

Custom dimensions

DIMENSION	DESCRIPTION OR VALUE
eventId	**AL0000E3I**
alExecutionTimeInMs	Specifies the number of milliseconds it took to complete the import operation.
alExecutionId	Specifies the ID of the import operation.
alPackageCode	Specifies the ID of the configuration package that was imported.
alObjectId	**8614**, which is the ID of the base application codeunit that handles the import of configuration packages.
alObjectName	**Config. XML Exchange**, which is the name of the base application codeunit that handles the import of configuration packages.
alObjectType	**CodeUnit**
See common custom dimensions	

Configuration package apply started

Occurs when an apply operation on a configuration package is started.

General dimensions

DIMENSION	DESCRIPTION OR VALUE
message	**Configuration package apply started: {alPackageCode}**
severityLevel	**1**

Custom dimensions

DIMENSION	DESCRIPTION OR VALUE
eventId	**AL0000E3N**
alExecutionId	Specifies the ID of the apply operation.
alObjectId	**8611**, which is the ID of the base application codeunit that handles applying configuration packages.
alObjectName	**Config. Package Management**, which is the name of the base application codeunit that handles applying configuration packages.
alObjectType	**CodeUnit**

DIMENSION	DESCRIPTION OR VALUE
alPackageCode	Specifies the ID of the configuration package being applied.
See common custom dimensions	

Configuration package applied successfully

Occurs when an apply operation on a configuration package completes successfully.

General dimensions

DIMENSION	DESCRIPTION OR VALUE
message	**Configuration package applied successfully: {alPackageCode}**
severityLevel	1

Custom dimensions

DIMENSION	DESCRIPTION OR VALUE
eventId	**AL0000E3O**
alExecutionId	Specifies the ID of the apply operation.
alExecutionTimeInMs	Specifies the number of milliseconds it took to complete the apply operation.
alErrorCount	Specifies the number of errors that occurred when applying the configuration package.
alFieldCount	Specifies the number of fields that were included in the migration table of the applied configuration package.
alObjectId	**8611**, which is the ID of the base application codeunit that applies configuration packages.
alObjectName	**Config. Package Management**, which is the name of the base application codeunit that applies configuration packages.
alObjectType	**CodeUnit**
alPackageCode	Specifies the ID of the configuration package that was applied.
alRecordCount	Specifies the number of records that were included in the applied configuration package.
See common custom dimensions	

Configuration package deleted successfully

Occurs when a configuration package is deleted successfully.

General dimensions

DIMENSION	DESCRIPTION OR VALUE
message	**Configuration package deleted successfully: {alPackageCode}**
severityLevel	1

Custom dimensions

DIMENSION	DESCRIPTION OR VALUE
eventId	**AL0000E3P**
alObjectId	**8611**, which is the ID of the base application codeunit that deletes configuration packages.
alObjectName	**Config. Package Management**, which is the name of the base application codeunit that handles deleting configuration packages.
alObjectType	**CodeUnit**
alPackageCode	Specifies the ID of the configuration package that was deleted.
See common custom dimensions

Analyzing Database Lock Timeout Trace Telemetry

2/17/2021 • 5 minutes to read • Edit Online

INTRODUCED IN: Business Central 2020 release wave 1, version 16.0

Database lock timeout telemetry gathers information about database locks that have timed out. The telemetry data allows you to troubleshoot what caused these locks.

In the client, when a lock has timed out, the user is presented with a message, similar to the following message:

The operation could not complete because a record in the [table name] table was locked by another user. Please retry the activity.

Two types of trace events are emitted to Application Insights:

- The first is a **Database lock timed out** event. This event includes general information about the lock request. This event includes information like the AL object and code that is impacted by the lock, the extension involved, and more.
- The **Database lock timed out** event then triggers one or more **Database lock snapshot** events. **Database lock snapshot** events provide details about SQL sessions that hold database locks at the time of lock timeout, including the session that caused the lock timeout. These events include specific details about the SQL lock request on the database, like the type, status, mode, and the table.

> **TIP**
> When analyzing database lock timeout telemetry, it's useful to look at combined data from the **Database lock timed out** event and **Database lock snapshot** events. You can combine data from different events by using *joins* in your Kusto queries. For an example, see LockTimeouts.kql in the **Microsoft/BCTech** repository on GitHub. For more general information about using joins, see Joins in Azure Monitor log queries in the Microsoft Azure documentation.

Database lock timed out

Occurs when a database lock has timed out.

General dimensions

DIMENSION	DESCRIPTION OR VALUE
message	**Database lock timed out**
severityLevel	3

Custom dimensions

DIMENSION	DESCRIPTION OR VALUE
aadTenantId	Specifies that Azure Active Directory (Azure AD) tenant ID used for Azure AD authentication. For on-premises, if you aren't using Azure AD authentication, this value is **common**.

DIMENSION	DESCRIPTION OR VALUE
alExecutingMethodScope	Specifies the AL action that is running the transaction that caused the lock.
alObjectId	Specifies the ID of the running AL object that requested the lock.
alObjectName	Specifies the name of the running AL object that requested the lock. not shown
alObjectType	Specifies the type of the running AL object that requested the lock, such as a page or report.
alStackTrace	The stack trace in AL.
clientType	Specifies the type of client that executed the SQL Statement, such as **Background** or **Web**. For a list of the client types, see ClientType Option Type.
companyName	Specifies the display name of the Business Central company.
component	**Dynamics 365 Business Central Server**
componentVersion	Specifies the version number of the component that emits telemetry (see the component dimension.)
deprecatedKeys	Specifies a comma-separated list of all the keys that have been deprecated. The keys in this list are still supported but will eventually be removed in the next major release. We recommend that update any queries that use these keys to use the new key name.
eventId	**RT0012**
environmentName	Specifies the name of the tenant environment. See Managing Environments.
environmentType	Specifies the environment type for the tenant, such as **Production**, **Sandbox**, **Trial**. See Environment Types
extensionId	Specifies the AppID of the extension that was involved in the lock.
extensionName	Specifies the name of the extension that was involved in the lock.
extensionVersion	Specifies the version of that was involved in the lock.
sessionId	Specifies the ID of the session that requested the lock.
snapshotId	Specifies the ID of the database snapshot. This ID is used to identify associated **Database lock snapshot** trace events.

DIMENSION	DESCRIPTION OR VALUE
sqlServerSessionId	Specifies the ID of the SQL server session that requested the lock.
telemetrySchemaVersion	Specifies the version of the Business Central telemetry schema.

Database lock snapshot

Occurs when a database lock has timed out. Each **Database lock snapshot** trace event is associated with a specific **Database lock timed out** trace event.

General dimensions

DIMENSION	DESCRIPTION OR VALUE
message	**Database lock snapshot: {snapshotId}** The value of the `{snapshotId}` maps to the `snapshotId` dimension of the **Database lock timed out** trace event that triggered this event.
severityLevel	3

Custom dimensions

DIMENSION	DESCRIPTION OR VALUE
aadTenantId	Specifies that Azure Active Directory (Azure AD) tenant ID used for Azure AD authentication. For on-premises, if you aren't using Azure AD authentication, this value is **common**.
alExecutingMethodScope	Specifies the AL action that is running the transaction that caused the lock.
alObjectId	Specifies the ID of the running AL object that requested the lock.
alObjectName	Specifies the name of the running AL object that requested the lock.
alObjectType	Specifies the type of the running AL object that requested the lock, such as a page or report.
alStackTrace	The stack trace in AL.
component	**Dynamics 365 Business Central Server**
componentVersion	Specifies the version number of the component that emits telemetry (see the component dimension.)

DIMENSION	DESCRIPTION OR VALUE
deprecatedKeys	Specifies a comma-separated list of all the keys that have been deprecated. The keys in this list are still supported but will eventually be removed in the next major release. We recommend that update any queries that use these keys to use the new key name.
eventId	**RT0013**
environmentName	Specifies the name of the tenant environment. See Managing Environments.
environmentType	Specifies the environment type for the tenant, such as **Production**, **Sandbox**, **Trial**. See Environment Types
extensionId	Specifies the AppID of the extension that was involved in the lock.
extensionName	Specifies the name of the extension that was involved in the lock.
extensionVersion	Specifies the version of that was involved in the lock.
sessionId	Specifies the ID of the session that requested the lock.
snapshotId	Specifies the ID of the database snapshot. All messages in the snapshot share this ID.
sqlLockRequestMode	Specifies the lock mode that determines how concurrent transactions can access the resource. For more information, see Lock Modes.
sqlLockRequestStatus	Specifies the current status of the lock, which can be one of the following values: • `CNVRT` - means that the lock is transitioning from another mode, but the conversion is blocked by another process that holds a lock with a conflicting mode. • `GRANT` - means that the lock is active. • `WAIT` - means that the lock is blocked by another process that holds a lock with a conflicting mode.
sqlLockResourceType	Specifies the database resource affected by the lock. For example, `DATABASE`, `FILE`, `OBJECT`, `PAGE`, `KEY`, and more.
sqlServerSessionId	Specifies the ID of the SQL server session that requested the lock.
sqlTableName	Specifies the name of table on which the lock was held.
telemetrySchemaVersion	Specifies the version of the Business Central telemetry schema.

Analyzing Email Trace Telemetry

2/17/2021 • 2 minutes to read • Edit Online

APPLIES TO: Business Central 2020 release wave 2, update 17.2, and later

Email telemetry gathers data about the following operations:

- An email was sent successfully
- An attempt to send an email failed

Before you can collect this data, you'll have to set up email. For more information, see Set Up Email in the Business Central application help.

Email sent successfully

Occurs when an email was successfully sent from the client.

General dimensions

DIMENSION	DESCRIPTION OR VALUE
message	**Email sent successfully**
severityLevel	**1**

Custom dimensions

DIMENSION	DESCRIPTION OR VALUE
aadTenantId	Specifies that Azure Active Directory (Azure AD) tenant ID used for Azure AD authentication. For on-premises, if you aren't using Azure AD authentication, this value is **common**.
alCategory	**Email**
alConnector	Specifies the email-provider connector used to send the email. Possible values include: • Current User • Microsoft 365 • SMTP • Other custom connectors installed by extensions. The connector is specified on the email accounts that are set up in Business Central. For more information, see Adding Email Accounts.
alDataClassification	**SystemMetadata**
alEmailMessageID	Specifies the GUID assigned to email, like C7A56676-9F3F-4044-90F0-D7F3196AC366.
alObjectId	**8888**, which is the ID of the system application codeunit that sends emails.

DIMENSION	DESCRIPTION OR VALUE
alObjectName	**Email Dispatcher**, which is the name of the system application codeunit that sends the emails.
alObjectType	**CodeUnit**
component	**Dynamics 365 Business Central Server**.
componentVersion	Specifies the version number of the component that emits telemetry (see the component dimension.)
environmentName	Specifies the name of the tenant environment. See Managing Environments. This dimension isn't included for Business Central on-premises environments.
environmentType	Specifies the environment type for the tenant, such as **Production**, **Sandbox**, **Trial**. See Environment Types
eventId	**AL0000CTV**
telemetrySchemaVersion	Specifies the version of the Business Central telemetry schema.

Failed to send email

Occurs when an email failed to be sent from the client.

General dimensions

DIMENSION	DESCRIPTION OR VALUE
message	**Failed to send email.**
severityLevel	1

Custom dimensions

DIMENSION	DESCRIPTION OR VALUE
aadTenantId	Specifies that Azure Active Directory (Azure AD) tenant ID used for Azure AD authentication. For on-premises, if you aren't using Azure AD authentication, this value is **common**.
alCategory	**Email**
alConnector	Specifies the email-provider connector used to send the email. Possible values include: • Current User • Microsoft 365 • SMTP • Other custom connectors installed by extensions. The connector is specified on the email accounts that are set up in Business Central. For more information, see Adding Email Accounts.

DIMENSION	DESCRIPTION OR VALUE
alDataClassification	**SystemMetadata**
alEmailMessageID	Specifies the GUID assigned to email, like C7A56676-9F3F-4044-90F0-D7F3196AC366.
alObjectId	**8888**, which is the ID of the system application codeunit that sends emails.
alObjectName	**Email Dispatcher**, which is the name of the system application codeunit that sends the emails.
alObjectType	**CodeUnit**
component	**Dynamics 365 Business Central Server**.
componentVersion	Specifies the version number of the component that emits telemetry (see the component dimension.)
environmentName	Specifies the name of the tenant environment. See Managing Environments. This dimension isn't included for Business Central on-premises environments.
environmentType	Specifies the environment type for the tenant, such as **Production**, **Sandbox**, **Trial**. See Environment Types
eventId	**AL0000CTP**
telemetrySchemaVersion	Specifies the version of the Business Central telemetry schema.

TIP

You can also view failed emails in the **Email Outbox** page in the Business Central client.

Analyzing Extension Lifecycle Trace Telemetry

2/17/2021 • 30 minutes to read • Edit Online

INTRODUCED IN: Business Central 2020 release wave 1, version 16.3. For extension telemetry, this signal was introduced in 2020 release wave 2, version 17.1

Extension lifecycle telemetry gathers data about the success or failure of the following extension-related operations:

- Compiling an extension
- Synchronizing an extension
- Publishing an extension
- Installing an extension
- Updating an extension
- Uninstalling an extension
- Unpublishing an extension

Failed operations result in a trace log entry that includes a reason for the failure.

Data is gathered when the operations are done using:

- Extension Management page in the client.
- Manage Apps page in the Business Central administration center.
- Extension management PowerShell cmdlets from the Business Central Administration Shell.

Behavior overview

- Compiling, publishing, and unpublishing extensions

  Data for these operations is only recorded for extensions that are published in the tenant scope.

  - For on-premises, it includes extensions that are published by running the Publish-NAVApp cmdlet with the `-Scope Tenant` parameter.
  - For online, it includes per-tenant extensions uploaded from the **Extension Management** page in the client. It doesn't include Microsoft extensions or AppSource extensions.

- Synchronizing extensions

  - For on-premises, data for this operation is recorded when an extension is synchronized by using the Sync-NAVApp cmdlet.
  - For online, data is recorded when an extension is installed from the **Extension Management** page in the client. Or, when upgraded from the Manage Apps page in the Business Central administration center.

- Installing and uninstalling extensions

  - For on-premises, data for these operations is recorded when an extension is installed or uninstalled by using the Install-NAVApp cmdlet or Uninstall-NAVApp cmdlet. Or, when an extension is installed or uninstalled from the **Extension Management** page in the client.
  - For on-premises, data for these operations is recorded when an extension is installed or uninstalled from the **Extension Management** page in the client.

- Updating an extension
  - For on-premises, data for this operation is recorded when an extension is upgraded by using the Start-NAVAppDataUpgrade cmdlet.
  - For online, data is recorded when an extension is updated from the Manage Apps page in the Business Central administration center.
- For some operations, you might experience that certain custom dimensions aren't available.

  The reason is that custom dimensions are added to the signal gradually, as the information is retrieved. If the operation fails before the custom dimension is retrieved, it isn't included in the result.

  For example, if you try to uninstall an extension using the Ininstall-NAVApp cmdlet, and the specified extension name is wrong, the operation fails. In this case, the `extensionid` and `extensionVersion` will be excluded from the results.

ENVIRONMENT/SERVER-SIDE OPERATIONS

Extension compiled successfully

Occurs when an extension compiles successfully on the service. An extension compiles when it's published or when it's repaired by using the Repair-NAVApp cmdlet.

General dimensions

DIMENSION	DESCRIPTION OR VALUE
message	**Extension compiled successfully: {extensionName} version {extensionVersion} by {extensionPublisher} ({extensionId})**
severityLevel	**1**

Custom dimensions

DIMENSION	DESCRIPTION OR VALUE
aadTenantId	Specifies that Azure Active Directory (Azure AD) tenant ID used for Azure AD authentication. For on-premises, if you aren't using Azure AD authentication, this value is **common**.
component	**Dynamics 365 Business Central Server**.
componentVersion	Specifies the version number of the component that emits telemetry (see the component dimension.)
deprecatedKeys	Specifies a comma-separated list of all the keys that have been deprecated. The keys in this list are still supported but will eventually be removed in the next major release. We recommend that update any queries that use these keys to use the new key name.
environmentType	Specifies the environment type for the tenant, such as **Production**, **Sandbox**, **Trial**. See Environment Types
eventId	**LC0020**

DIMENSION	DESCRIPTION OR VALUE
extensionCompilationDependencyList	Specifies details about the extensions on which the compiled extension has dependencies. **Note:** If the value exceeds 8000 characters, one or two additional dimensions will be included in the trace to cover the complete dependency list. For more information, see About Custom Dimensions.
extensionCompilationResult	**Compilation succeeded without errors or warnings.**
extensionName	Specifies the name of the extension that was compiled.
extensionId	Specifies the AppID of the extension that was compiled.
extensionPublishedAs	Specifies whether the compiled extension was published as one of the following options: • **Dev** - published from the AL development environment. • **Global** - published to the global scope. • **Tenant** - published to the tenant scope.
extensionPublisher	Specifies the extension's publisher.
extensionScope	Specifies whether the extension was published to one of the following scopes: • **Global** - the extension can be installed on all tenants connected the service instance. • **Tenant** - the extension can only be installed on the tenant to which it was published. .
extensionVersion	Specifies the version of the compiled extension.
result	**Success**
serverExecutionTime	Specifies the amount of time it took the server to complete the request. The time has the format hh:mm:ss.sssssss.
totalTime	Specifies the amount of time it took to process the request. The time has the format hh:mm:ss.sssssss.
telemetrySchemaVersion	Specifies the version of the Business Central telemetry schema.

Extension failed to compile

Occurs when an extension failed to compile on the service. An extension compiles when it's published or when it's repaired by using the Repair-NAVApp cmdlet.

General dimensions

DIMENSION	DESCRIPTION OR VALUE
message	**Extension failed to compile: {extensionName} version {extensionVersion} by {extensionPublisher} ({extensionId})**
severityLevel	3

Custom dimensions

DIMENSION	DESCRIPTION OR VALUE
aadTenantId	Specifies that Azure Active Directory (Azure AD) tenant ID used for Azure AD authentication. For on-premises, if you aren't using Azure AD authentication, this value is **common**.
component	**Dynamics 365 Business Central Server**.
componentVersion	Specifies the version number of the component that emits telemetry (see the component dimension.)
deprecatedKeys	Specifies a comma-separated list of all the keys that have been deprecated. The keys in this list are still supported but will eventually be removed in the next major release. We recommend that update any queries that use these keys to use the new key name.
environmentType	Specifies the environment type for the tenant, such as **Production**, **Sandbox**, **Trial**. See Environment Types
eventId	**LC0021**
extensionCompilationDependencyList	Specifies details about the extensions on which the compiled extension has dependencies. **Note:** If the value exceeds 8000 characters, one or two additional dimensions will be included in the trace to cover the complete dependency list. For more information, see About Custom Dimensions.
extensionCompilationResult	Specifies details about the error that occurred during compilation.
extensionName	Specifies the name of the extension that failed to compile.
extensionId	Specifies the AppID of the extension that failed to compile.
extensionPublishedAs	Specifies whether the extension was published as one of the following options: • **Dev** - published from the AL development environment. • **Global** - published to the global scope. • **Tenant** - published to the tenant scope.
extensionPublisher	Specifies the extension's publisher.

DIMENSION	DESCRIPTION OR VALUE
extensionScope	Specifies whether the extension was published to one of the following scopes: • **Global** - the extension can be installed on all tenants connected the service instance. • **Tenant** - the extension can only be installed on the tenant to which it was published. .
extensionVersion	Specifies the version of the compiled extension.
failureReason	Specifies the error that occurred when compiling the extension.
result	**Failure**
serverExecutionTime	Specifies the amount of time it took the server to complete the request. The time has the format hh:mm:ss.sssssss.
totalTime	Specifies the amount of time it took to process the request. The time has the format hh:mm:ss.sssssss.
telemetrySchemaVersion	Specifies the version of the Business Central telemetry schema.

Extension published successfully

Occurs when an extension published successfully on the service.

General dimensions

DIMENSION	DESCRIPTION OR VALUE
message	**Extension published successfully: {extensionName} version {extensionVersion} by {extensionPublisher} ({extensionId})**
severityLevel	1

Custom dimensions

DIMENSION	DESCRIPTION OR VALUE
aadTenantId	Specifies that Azure Active Directory (Azure AD) tenant ID used for Azure AD authentication. For on-premises, if you aren't using Azure AD authentication, this value is **common**.
component	**Dynamics 365 Business Central Server**.
componentVersion	Specifies the version number of the component that emits telemetry (see the component dimension.)

DIMENSION	DESCRIPTION OR VALUE
deprecatedKeys	Specifies a comma-separated list of all the keys that have been deprecated. The keys in this list are still supported but will eventually be removed in the next major release. We recommend that update any queries that use these keys to use the new key name.
environmentType	Specifies the environment type for the tenant, such as **Production**, **Sandbox**, **Trial**. See Environment Types
eventId	**LC0014**
extensionId	Specifies the AppID of the extension that was published.
extensionIsRad	Specifies whether the extension that was RAD published. **True** indicates the extension was RAD published. **False** indicates normal publishing. RAD (Rapid Application Development) publishing is done from the AL development environment. RAD publishing is a partial publishing operation that only publishes objects application objects that have changed during development. For more information, see Working with Rapid Application Development.
extensionName	Specifies the name of the extension that published.
extensionId	Specifies the AppID of the extension that published.
extensionPublishedAs	Specifies whether the extension was published as one of the following options: • **Dev** - published from the AL development environment. • **Global** - published to the global scope. • **Tenant** - published to the tenant scope.
extensionPublisher	Specifies the extension's publisher.
extensionScope	Specifies whether the extension was published to one of the following scopes: • **Global** - the extension can be installed on all tenants connected the service instance. • **Tenant** - the extension can only be installed on the tenant to which it was published. .
extensionVersion	Specifies the version of the published extension.
result	**Success**
serverExecutionTime	Specifies the amount of time it took the server to complete the request. The time has the format hh:mm:ss.sssssss.
sqlExecutes	Specifies the number of SQL statements that the request executed.

DIMENSION	DESCRIPTION OR VALUE
sqlRowsRead	Specifies the number of table rows that were read by the SQL statements.
telemetrySchemaVersion	Specifies the version of the Business Central telemetry schema.
totalTime	Specifies the amount of time it took to process the request. The time has the format hh:mm:ss.sssssss.

Extension failed to publish

Occurs when an extension failed publish on the service.

General dimensions

DIMENSION	DESCRIPTION OR VALUE
message	**Extension failed to publish: {extensionName} version {extensionVersion} by {extensionPublisher} ({extensionId})**
severityLevel	**3**

Custom dimensions

DIMENSION	DESCRIPTION OR VALUE
aadTenantId	Specifies that Azure Active Directory (Azure AD) tenant ID used for Azure AD authentication. For on-premises, if you aren't using Azure AD authentication, this value is **common**.
component	**Dynamics 365 Business Central Server**.
componentVersion	Specifies the version number of the component that emits telemetry (see the component dimension.)
deprecatedKeys	Specifies a comma-separated list of all the keys that have been deprecated. The keys in this list are still supported but will eventually be removed in the next major release. We recommend that update any queries that use these keys to use the new key name.
environmentType	Specifies the environment type for the tenant, such as **Production**, **Sandbox**, **Trial**. See Environment Types
eventId	**LC0015**
extensionId	Specifies the AppID of the extension that was published.

DIMENSION	DESCRIPTION OR VALUE
extensionIsRad	Specifies whether the extension that was RAD published. **True** indicates the extension was RAD published. **False** indicates normal publishing. RAD (Rapid Application Development) publishing is done from the AL development environment. RAD publishing only is a partial publishing operation that only publishes objects application objects that have changed during development. For more information, see Working with Rapid Application Development.
extensionName	Specifies the name of the extension that published.
extensionId	Specifies the AppID of the extension that published.
extensionPublishedAs	Specifies whether the extension was published as one of the following options: • **Dev** - published from the AL development environment. • **Global** - published to the global scope. • **Tenant** - published to the tenant scope.
extensionPublisher	Specifies the extension's publisher.
extensionScope	Specifies whether the extension was published to one of the following scopes: • **Global** - the extension can be installed on all tenants connected the service instance. • **Tenant** - the extension can only be installed on the tenant to which it was published. .
extensionVersion	Specifies the version of the published extension.
failureReason	Specifies the error that occurred when publishing.
result	**Failure**
serverExecutionTime	Specifies the amount of time it took the server to complete the request. The time has the format hh:mm:ss.sssssss.
sqlExecutes	Specifies the number of SQL statements that the request executed.
sqlRowsRead	Specifies the number of table rows that were read by the SQL statements.
telemetrySchemaVersion	Specifies the version of the Business Central telemetry schema.
totalTime	Specifies the amount of time it took to process the request. The time has the format hh:mm:ss.sssssss.

Extension unpublished successfully

Occurs when an extension was unpublished successfully on the service.

General dimensions

DIMENSION	DESCRIPTION OR VALUE
message	**Extension unpublished successfully: {extensionName} version {extensionVersion} by {extensionPublisher} ({extensionId})**
severityLevel	1

Custom dimensions

DIMENSION	DESCRIPTION OR VALUE
aadTenantId	Specifies that Azure Active Directory (Azure AD) tenant ID used for Azure AD authentication. For on-premises, if you aren't using Azure AD authentication, this value is **common**.
component	**Dynamics 365 Business Central Server**.
componentVersion	Specifies the version number of the component that emits telemetry (see the component dimension.)
deprecatedKeys	Specifies a comma-separated list of all the keys that have been deprecated. The keys in this list are still supported but will eventually be removed in the next major release. We recommend that update any queries that use these keys to use the new key name.
environmentType	Specifies the environment type for the tenant, such as **Production**, **Sandbox**, **Trial**. See Environment Types
eventId	**LC0018**
extensionId	Specifies the AppID of the extension that was unpublished.
extensionName	Specifies the name of the extension that was unpublished.
extensionId	Specifies the AppID of the extension that was unpublished.
extensionPublishedAs	Specifies whether the extension was published as one of the following options: • **Dev** - published from the AL development environment. • **Global** - published to the global scope. • **Tenant** - published to the tenant scope.
extensionPublisher	Specifies the extension's publisher.

DIMENSION	DESCRIPTION OR VALUE
extensionScope	Specifies whether the extension was published to one of the following scopes: • **Global** - the extension can be installed on all tenants connected the service instance. • **Tenant** - the extension can only be installed on the tenant to which it was published. .
extensionVersion	Specifies the version of the unpublished extension.
result	**Success**
serverExecutionTime	Specifies the amount of time it took the server to complete the request. The time has the format hh:mm:ss.sssssss.
sqlExecutes	Specifies the number of SQL statements that the request executed.
sqlRowsRead	Specifies the number of table rows that were read by the SQL statements.
telemetrySchemaVersion	Specifies the version of the Business Central telemetry schema.
totalTime	Specifies the amount of time it took to process the request. The time has the format hh:mm:ss.sssssss.

Extension failed to un-publish

Occurs when an extension fails to unpublish on the service.

General dimensions

DIMENSION	DESCRIPTION OR VALUE
message	**Extension failed to un-publish: {extensionName} version {extensionVersion} by {extensionPublisher} ({extensionId})**
severityLevel	**3**

Custom dimensions

DIMENSION	DESCRIPTION OR VALUE
aadTenantId	Specifies that Azure Active Directory (Azure AD) tenant ID used for Azure AD authentication. For on-premises, if you aren't using Azure AD authentication, this value is **common**.
component	**Dynamics 365 Business Central Server**.
componentVersion	Specifies the version number of the component that emits telemetry (see the component dimension.)

DIMENSION	DESCRIPTION OR VALUE
deprecatedKeys	Specifies a comma-separated list of all the keys that have been deprecated. The keys in this list are still supported but will eventually be removed in the next major release. We recommend that update any queries that use these keys to use the new key name.
environmentType	Specifies the environment type for the tenant, such as **Production**, **Sandbox**, **Trial**. See Environment Types
eventId	**LC0019**
extensionId	Specifies the AppID of the extension that failed to unpublish.
extensionName	Specifies the name of the extension that failed to unpublish.
extensionPublishedAs	Specifies whether the extension was published as one of the following options: • **Dev** - published from the AL development environment. • **Global** - published to the global scope. • **Tenant** - published to the tenant scope.
extensionPublisher	Specifies the extension's publisher.
extensionScope	Specifies whether the extension was published to one of the following scopes: • **Global** - the extension can be installed on all tenants connected the service instance. • **Tenant** - the extension can only be installed on the tenant to which it was published. .
extensionVersion	Specifies the version of the unpublished extension.
failureReason	Specifies the error that occurred when unpublishing.
result	**Failure**
serverExecutionTime	Specifies the amount of time it took the server to complete the request. The time has the format hh:mm:ss.sssssss.
sqlExecutes	Specifies the number of SQL statements that the request executed.
sqlRowsRead	Specifies the number of table rows that were read by the SQL statements.
telemetrySchemaVersion	Specifies the version of the Business Central telemetry schema.
totalTime	Specifies the amount of time it took to process the request. The time has the format hh:mm:ss.sssssss.

TENANT OPERATIONS

Extension synchronized successfully

Occurs when an extension synchronizes successfully on the tenant.

General dimensions

DIMENSION	DESCRIPTION OR VALUE
message	**Extension synchronized successfully: {extensionName} version {extensionVersion} by {extensionPublisher} ({extensionId})**
severityLevel	1

Custom dimensions

DIMENSION	DESCRIPTION OR VALUE
aadTenantId	Specifies that Azure Active Directory (Azure AD) tenant ID used for Azure AD authentication. For on-premises, if you aren't using Azure AD authentication, this value is **common**.
component	**Dynamics 365 Business Central Server**.
componentVersion	Specifies the version number of the component that emits telemetry (see the component dimension.)
deprecatedKeys	Specifies a comma-separated list of all the keys that have been deprecated. The keys in this list are still supported but will eventually be removed in the next major release. We recommend that update any queries that use these keys to use the new key name.
environmentName	Specifies the name of the tenant environment. See Managing Environments.
environmentType	Specifies the environment type for the tenant, such as **Production**, **Sandbox**, **Trial**. See Environment Types
eventId	**LC0012**
extensionId	Specifies the AppID of the extension that was synchronized.
extensionName	Specifies the name of the extension that was synchronized.
extensionPublishedAs	Specifies whether the extension was published as one of the following options: • **Dev** - published from the AL development environment. • **Global** - published to the global scope. • **Tenant** - published to the tenant scope.
extensionPublisher	Specifies the extension's publisher.

DIMENSION	DESCRIPTION OR VALUE
extensionScope	Specifies whether the extension was published to one of the following scopes: • **Global** - the extension can be installed on all tenants connected the service instance. • **Tenant** - the extension can only be installed on the tenant to which it was published. .
extensionSynchronizationMode	Specifies whether the extension was synchronized in one of the following modes: • **Add** - The database schema defined by the objects in the extension are added to the database schema of the tenant database. This mode is typically used mode after you publish an extension for the first time. • **Clean** - The database schema defined by all versions of the extension will be removed from the database and all data is lost. This mode is typically used when an extension will no longer be used and all versions unpublished. • **Development** - This mode is acts similar to Add, except it is intended for use during development. It lets you to sync the same version of an extension that is already published. However, to run this mode, only one version the App can be currently published. • **ForceSync** - This mode like **Add** except it supports destructive schema changes (like removing fields, renaming them, changing their datatypes, and more). It is typically used during development, and is the mode used when an extension is published and installed from the AL development environment. For more information about the modes, see Sync-NAVApp cmdlet -Mode.
extensionVersion	Specifies the version of the extension was synchronized.
result	**Success**
serverExecutionTime	Specifies the amount of time it took the server to complete the request. The time has the format hh:mm:ss.sssssss.
sqlExecutes	Specifies the number of SQL statements that the request executed.
sqlRowsRead	Specifies the number of table rows that were read by the SQL statements.
telemetrySchemaVersion	Specifies the version of the Business Central telemetry schema.
totalTime	Specifies the amount of time it took to process the request. The time has the format hh:mm:ss.ssssss.

Extension synchronized failed

Occurs when an extension fails to synchronize on the tenant.

General dimensions

DIMENSION	DESCRIPTION OR VALUE
message	**Extension failed to synchronize: {extensionName} version {extensionVersion} by {extensionPublisher} ({extensionId})**
severityLevel	1

Custom dimensions

DIMENSION	DESCRIPTION OR VALUE
aadTenantId	Specifies that Azure Active Directory (Azure AD) tenant ID used for Azure AD authentication. For on-premises, if you aren't using Azure AD authentication, this value is **common**.
component	**Dynamics 365 Business Central Server**.
componentVersion	Specifies the version number of the component that emits telemetry (see the component dimension.)
deprecatedKeys	Specifies a comma-separated list of all the keys that have been deprecated. The keys in this list are still supported but will eventually be removed in the next major release. We recommend that update any queries that use these keys to use the new key name.
environmentName	Specifies the name of the tenant environment. See Managing Environments.
environmentType	Specifies the environment type for the tenant, such as **Production**, **Sandbox**, **Trial**. See Environment Types
eventId	**LC0013**
extensionId	Specifies the AppID of the extension that failed to synchronize.
extensionName	Specifies the name of the extension that failed to synchronize.
extensionPublishedAs	Specifies whether the extension was published as one of the following options: • **Dev** - published from the AL development environment. • **Global** - published to the global scope. • **Tenant** - published to the tenant scope.
extensionPublisher	Specifies the extension's publisher.

DIMENSION	DESCRIPTION OR VALUE
extensionScope	Specifies whether the extension was published to one of the following scopes: • **Global** - the extension can be installed on all tenants connected the service instance. • **Tenant** - the extension can only be installed on the tenant to which it was published. .
extensionSynchronizationMode	Specifies whether the extension was synchronized in one of the following modes: • **Add** - The database schema defined by the objects in the extension are added to the database schema of the tenant database. This mode is typically used mode after you publish an extension for the first time. • **Clean** - The database schema defined by all versions of the extension will be removed from the database and all data is lost. This mode is typically used when an extension will no longer be used and all versions unpublished. • **Development** - This mode is acts similar to Add, except it is intended for use during development. It lets you to sync the same version of an extension that is already published. However, to run this mode, only one version the App can be currently published. • **ForceSync** - This mode like **Add** except it supports destructive schema changes (like removing fields, renaming them, changing their datatypes, and more). It is typically used during development, and is the mode used when an extension is published and installed from the AL development environment. For more information about the modes, see Sync-NAVApp cmdlet -Mode.
extensionVersion	Specifies the version of the extension was synchronized.
failureReason	Specifies the error that occurred when synchronizing the extension.
result	**Failure**
serverExecutionTime	Specifies the amount of time it took the server to complete the request. The time has the format hh:mm:ss.sssssss.
sqlExecutes	Specifies the number of SQL statements that the request executed.
sqlRowsRead	Specifies the number of table rows that were read by the SQL statements.
telemetrySchemaVersion	Specifies the version of the Business Central telemetry schema.
totalTime	Specifies the amount of time it took to process the request. The time has the format hh:mm:ss.sssssss.

Extension installed successfully

Occurs when an extension installs successfully on a tenant.

General dimensions

DIMENSION	DESCRIPTION OR VALUE
message	**Extension installed successfully: {extensionName} version {extensionVersion} by {extensionPublisher} ({extensionId})**
severityLevel	1

Custom dimensions

DIMENSION	DESCRIPTION OR VALUE
aadTenantId	Specifies that Azure Active Directory (Azure AD) tenant ID used for Azure AD authentication. For on-premises, if you aren't using Azure AD authentication, this value is **common**.
component	**Dynamics 365 Business Central Server**.
componentVersion	Specifies the version number of the component that emits telemetry (see the component dimension.)
deprecatedKeys	Specifies a comma-separated list of all the keys that have been deprecated. The keys in this list are still supported but will eventually be removed in the next major release. We recommend that update any queries that use these keys to use the new key name.
environmentName	Specifies the name of the tenant environment. See Managing Environments.
environmentType	Specifies the environment type for the tenant, such as **Production**, **Sandbox**, **Trial**. See Environment Types
eventId	**LC0010**
extensionId	Specifies the AppID of the extension that was installed.
extensionName	Specifies the name of the extension that failed to synchronize.
extensionPublishedAs	Specifies whether the extension was published as one of the following options: • **Dev** - published from the AL development environment. • **Global** - published to the global scope. • **Tenant** - published to the tenant scope.
extensionPublisher	Specifies the extension's publisher.

DIMENSION	DESCRIPTION OR VALUE
extensionScope	Specifies whether the extension was published to one of the following scopes: • **Global** - the extension can be installed on all tenants connected the service instance. • **Tenant** - the extension can only be installed on the tenant to which it was published. .
extensionVersion	Specifies the version of the extension was installed.
result	**Success**
serverExecutionTime	Specifies the amount of time it took the server to complete the request. The time has the format hh:mm:ss.sssssss.
sqlExecutes	Specifies the number of SQL statements that the request executed.
sqlRowsRead	Specifies the number of table rows that were read by the SQL statements.
telemetrySchemaVersion	Specifies the version of the Business Central telemetry schema.
totalTime	Specifies the amount of time it took to process the request. The time has the format hh:mm:ss.sssssss.

Extension failed to install

Occurs when an extension failed to install on a tenant.

General dimensions

DIMENSION	DESCRIPTION OR VALUE
message	**Extension failed to install: {extensionName} version {extensionVersion} by {extensionPublisher} ({extensionId})**
severityLevel	**3**

Custom dimensions

DIMENSION	DESCRIPTION OR VALUE
aadTenantId	Specifies that Azure Active Directory (Azure AD) tenant ID used for Azure AD authentication. For on-premises, if you aren't using Azure AD authentication, this value is **common**.
component	**Dynamics 365 Business Central Server**.
componentVersion	Specifies the version number of the component that emits telemetry (see the component dimension.)

DIMENSION	DESCRIPTION OR VALUE
deprecatedKeys	Specifies a comma-separated list of all the keys that have been deprecated. The keys in this list are still supported but will eventually be removed in the next major release. We recommend that update any queries that use these keys to use the new key name.
environmentName	Specifies the name of the tenant environment. See Managing Environments.
environmentType	Specifies the environment type for the tenant, such as **Production**, **Sandbox**, **Trial**. See Environment Types
eventId	**LC0011**
extensionId	Specifies the AppID of the extension that failed to uninstall.
extensionName	Specifies the name of the extension that failed to uninstall.
extensionPublishedAs	Specifies whether the extension was published as one of the following options: • **Dev** - published from the AL development environment. • **Global** - published to the global scope. • **Tenant** - published to the tenant scope.
extensionPublisher	Specifies the extension's publisher.
extensionScope	Specifies whether the extension was published to one of the following scopes: • **Global** - the extension can be installed on all tenants connected the service instance. • **Tenant** - the extension can only be installed on the tenant to which it was published. .
extensionVersion	Specifies the version of the extension was installed.
failureReason	Specifies the error that occurred when the extension was installed.
result	**Failed**
serverExecutionTime	Specifies the amount of time it took the server to complete the request. The time has the format hh:mm:ss.sssssss.
sqlExecutes	Specifies the number of SQL statements that the request executed.
sqlRowsRead	Specifies the number of table rows that were read by the SQL statements.
telemetrySchemaVersion	Specifies the version of the Business Central telemetry schema.

DIMENSION	DESCRIPTION OR VALUE
totalTime	Specifies the amount of time it took to process the request. The time has the format hh:mm:ss.sssssss.

Extension un-installed successfully

Occurs when an extension is successfully uninstalled from a tenant.

General dimensions

DIMENSION	DESCRIPTION OR VALUE
message	**Extension un-installed successfully: {extensionName} version {extensionVersion} by {extensionPublisher} ({extensionId})**
severityLevel	1

Custom dimensions

DIMENSION	DESCRIPTION OR VALUE
aadTenantId	Specifies that Azure Active Directory (Azure AD) tenant ID used for Azure AD authentication. For on-premises, if you aren't using Azure AD authentication, this value is **common**.
component	**Dynamics 365 Business Central Server**.
componentVersion	Specifies the version number of the component that emits telemetry (see the component dimension.)
deprecatedKeys	Specifies a comma-separated list of all the keys that have been deprecated. The keys in this list are still supported but will eventually be removed in the next major release. We recommend that update any queries that use these keys to use the new key name.
doNotSaveData	Specifies whether the uninstall operation was run with option not to save the data in database table fields that are added by the extension. When using the Uninstall-NAVApp cmdlet, this condition is set with the -DoNotSaveData switch parameter.
environmentName	Specifies the name of the tenant environment. See Managing Environments.
environmentType	Specifies the environment type for the tenant, such as **Production**, **Sandbox**, **Trial**. See Environment Types
eventId	**LC0016**
extensionId	Specifies the AppID of the extension that was uninstalled.
extensionName	Specifies the name of the extension that was uninstalled.

DIMENSION	DESCRIPTION OR VALUE
extensionPublishedAs	Specifies whether the extension was published as one of the following options: • **Dev** - published from the AL development environment. • **Global** - published to the global scope. • **Tenant** - published to the tenant scope.
extensionPublisher	Specifies the extension's publisher.
extensionScope	Specifies whether the extension was published to one of the following scopes: • **Global** - the extension can be installed on all tenants connected the service instance. • **Tenant** - the extension can only be installed on the tenant to which it was published. .
extensionVersion	Specifies the version of the extension was uninstalled.
result	**Success**
serverExecutionTime	Specifies the amount of time it took the server to complete the request. The time has the format hh:mm:ss.sssssss.
sqlExecutes	Specifies the number of SQL statements that the request executed.
sqlRowsRead	Specifies the number of table rows that were read by the SQL statements.
telemetrySchemaVersion	Specifies the version of the Business Central telemetry schema.
totalTime	Specifies the amount of time it took to process the request. The time has the format hh:mm:ss.sssssss.

Extension failed to un-install

Occurs when an extension failed to uninstall on a tenant.

General dimensions

DIMENSION	DESCRIPTION OR VALUE
message	**Extension failed to un-install: {extensionName} version {extensionVersion} by {extensionPublisher} ({extensionId})**
severityLevel	3

Custom dimensions

DIMENSION	DESCRIPTION OR VALUE
aadTenantId	Specifies that Azure Active Directory (Azure AD) tenant ID used for Azure AD authentication. For on-premises, if you aren't using Azure AD authentication, this value is **common**.
component	**Dynamics 365 Business Central Server**.
componentVersion	Specifies the version number of the component that emits telemetry (see the component dimension.)
deprecatedKeys	Specifies a comma-separated list of all the keys that have been deprecated. The keys in this list are still supported but will eventually be removed in the next major release. We recommend that update any queries that use these keys to use the new key name.
doNotSaveData	Specifies whether the uninstall operation was run with option not to save the data in database table fields that are added by the extension. When using the Uninstall-NAVApp cmdlet, this condition is set with the -DoNotSaveData switch parameter.
environmentName	Specifies the name of the tenant environment. See Managing Environments.
environmentType	Specifies the environment type for the tenant, such as **Production**, **Sandbox**, **Trial**. See Environment Types
eventId	**LC0017**
extensionId	Specifies the AppID of the extension that failed to uninstall.
extensionName	Specifies the name of the extension that failed to uninstall.
extensionPublishedAs	Specifies whether the extension was published as one of the following options: • **Dev** - published from the AL development environment. • **Global** - published to the global scope. • **Tenant** - published to the tenant scope.
extensionPublisher	Specifies the extension's publisher.
extensionScope	Specifies whether the extension was published to one of the following scopes: • **Global** - the extension can be installed on all tenants connected the service instance. • **Tenant** - the extension can only be installed on the tenant to which it was published. .
extensionVersion	Specifies the version of the extension that failed to uninstall.

DIMENSION	DESCRIPTION OR VALUE
failureReason	Specifies the error that occurred when the extension was uninstalled.
result	**Failure**
serverExecutionTime	Specifies the amount of time it took the server to complete the request. The time has the format hh:mm:ss.sssssss.
sqlExecutes	Specifies the number of SQL statements that the request executed.
sqlRowsRead	Specifies the number of table rows that were read by the SQL statements.
telemetrySchemaVersion	Specifies the version of the Business Central telemetry schema.
totalTime	Specifies the amount of time it took to process the request. The time has the format hh:mm:ss.ssssss.

Extension updated successfully

Occurs when an extension updates successfully on the service.

> **NOTE**
> Data is also recorded for any upgrade code that was run. For more information, see Analyzing Extension Update Trace Telemetry.

General dimensions

DIMENSION	DESCRIPTION OR VALUE
message	**Extension updated successfully: {extensionName} version {extensionVersion} by {extensionPublisher}**
severityLevel	**1**

Custom dimensions

DIMENSION	DESCRIPTION OR VALUE
aadTenantId	Specifies that Azure Active Directory (Azure AD) tenant ID used for Azure AD authentication. For on-premises, if you aren't using Azure AD authentication, this value is **common**.
component	**Dynamics 365 Business Central Server**.
componentVersion	Specifies the version number of the component that emits telemetry (see the component dimension.)

DIMENSION	DESCRIPTION OR VALUE
deprecatedKeys	Specifies a comma-separated list of all the keys that have been deprecated. The keys in this list are still supported but will eventually be removed in the next major release. We
environmentName	Specifies the name of the tenant environment. See Managing Environments.
environmentType	Specifies the environment type for the tenant, such as **Production**, **Sandbox**, **Trial**. See Environment Types
eventId	**LC0022**
extensionCulture	Specifies the language version for which the extension that was upgraded. The value is a language culture name, such as **en-US** or **da-DK**. If a language wasn't specified when the extension was installed, then en-US is used by default.
extensionId	Specifies the AppID of the extension that failed to uninstall.
extensionName	Specifies the name of the extension that was being upgraded.
extensionPublisher	Specifies the extension's publisher.
extensionVersion	Specifies the new version of the extension being upgraded.
extensionVersionFrom	Specifies the old version of the extension being upgraded.
result	**Success**
serverExecutionTime	Specifies the amount of time it took the server to complete the request. The time has the format hh:mm:ss.sssssss.
sqlExecutes	Specifies the number of SQL statements that the request executed.
sqlRowsRead	Specifies the number of table rows that were read by the SQL statements.
telemetrySchemaVersion	Specifies the version of the Business Central telemetry schema.
totalTime	Specifies the amount of time it took to process the request. The time has the format hh:mm:ss.sssssss.

Extension failed to update

Occurs when an extension failed to update on the service.

> **NOTE**
> Data is also recorded for any upgrade code that was run. For more information, see Analyzing Extension Update Trace Telemetry.

General dimensions

DIMENSION	DESCRIPTION OR VALUE
message	**Extension failed to update: {extensionName} version {extensionVersion} by {extensionPublisher} ({extensionId})**
severityLevel	3

Custom dimensions

DIMENSION	DESCRIPTION OR VALUE
aadTenantId	Specifies that Azure Active Directory (Azure AD) tenant ID used for Azure AD authentication. For on-premises, if you aren't using Azure AD authentication, this value is **common**.
component	**Dynamics 365 Business Central Server**.
componentVersion	Specifies the version number of the component that emits telemetry (see the component dimension.)
deprecatedKeys	Specifies a comma-separated list of all the keys that have been deprecated. The keys in this list are still supported but will eventually be removed in the next major release. We recommend that update any queries that use these keys to use the new key name.
environmentName	Specifies the name of the tenant environment. See Managing Environments.
environmentType	Specifies the environment type for the tenant, such as **Production**, **Sandbox**, **Trial**. See Environment Types
eventId	**LC0023**
extensionCulture	Specifies the language version for which the extension that was upgraded. The value is a language culture name, such as **en-US** or **da-DK**. If a language wasn't specified when the extension was installed, then en-US is used by default.
extensionId	Specifies the AppID of the extension that failed to uninstall.
extensionName	Specifies the name of the extension that was being upgraded.
extensionPublisher	Specifies the extension's publisher.
extensionVersion	Specifies the new version of the extension being upgraded.

DIMENSION	DESCRIPTION OR VALUE
extensionVersionFrom	Specifies the old version of the extension being upgraded.
failureReason	Specifies the error that occurred during upgrade.
result	**Failure**
serverExecutionTime	Specifies the amount of time it took the server to complete the request. The time has the format hh:mm:ss.sssssss.
sqlExecutes	Specifies the number of SQL statements that the request executed.
sqlRowsRead	Specifies the number of table rows that were read by the SQL statements.
telemetrySchemaVersion	Specifies the version of the Business Central telemetry schema.
totalTime	Specifies the amount of time it took to process the request. The time has the format hh:mm:ss.sssssss.

Analyzing Extension Update Trace Telemetry

2/17/2021 • 2 minutes to read • Edit Online

INTRODUCED IN: Business Central 2020 release wave 1, version 16.2

Extension upgrade telemetry gathers information about failures that occur during extension upgrades. Specifically, it provides information about exceptions that are thrown by code run by upgrade codeunits. The trace events include the following information:

- The codeunit that threw the exception.
- AL stack trace.
- Exception message.

This data can help you identify, troubleshoot, and resolve issues with per-tenant and AppSource extensions that are blocking data upgrade.

Extension Update Failed: exception raised in extension

Occurs when an extension upgrade fails because of an exception in an upgrade codeunit.

General dimensions

DIMENSION	DESCRIPTION OR VALUE
message	**Extension Update Failed: exception raised in extension {extensionName} by {extensionPublisher} (updating to version {extensionTargetedVersion})**
severityLevel	**3**

Custom dimensions

DIMENSION	DESCRIPTION OR VALUE
aadTenantId	Specifies that Azure Active Directory (Azure AD) tenant ID used for Azure AD authentication. For on-premises, if you aren't using Azure AD authentication, this value is **common**.
alObjectId	Specifies the ID of the AL object that was run by request.
alStackTrace	The stack trace in AL.
companyName	The display name of the Business Central company that was used at time of execution.
component	**Dynamics 365 Business Central Server**.
componentVersion	Specifies the version number of the component that emits telemetry (see the component dimension.)

DIMENSION	DESCRIPTION OR VALUE
deprecatedKeys	A comma-separated list of all the keys that have been deprecated. The keys in this list are still supported but will eventually be removed in the next major release. We recommend that update any queries that use these keys to use the new key name.
environmentName	Specifies the name of the tenant environment. See Managing Environments.
environmentType	Specifies the environment type for the tenant, such as **Production**, **Sandbox**, **Trial**. See Environment Types
eventId	**RT0010**
extensionName	Specifies the name of the extension that was being upgraded.
extensionId	Specifies the AppID of the extension that was being upgraded.
extensionTargetedVersion	Specifies the new version of the extension being upgraded.
extensionVersion	Specifies the old version of the extension being upgraded.
failureReason	Specifies the exception that was thrown by the upgrade code. Some exception messages can contain customer data. As a precaution, Business Central only emits information that's classified as SystemMetadata. Exception messages that contain other data classifications, like customer data, are not shown. Instead, the following message is shown: "Message not shown because the NavBaseException(string, Exception, bool) constructor was used."
failureType	**DataUpdate**
telemetrySchemaVersion	Specifies the version of the Business Central telemetry schema.

Analyzing Field Monitoring Telemetry

2/17/2021 • 3 minutes to read • Edit Online

APPLIES TO: Business Central 2020 release wave 2 (update 17.1) and later

Keeping sensitive data secure and private is a core concern for most businesses. To add a layer of security, you can monitor important fields when someone changes a value. For example, you might want to know if someone changes your company's IBAN number.

To gather this data, you'll have to start field monitoring and specify the fields that you want to monitor. For more information, see Auditing Changes in Business Central - Monitoring Sensitive Fields in the Application help.

Telemetry is then logged for the following operations:

- When field monitoring is stopped or started
- When a field is added or removed for monitoring
- When a field value is changed

Sensitive field monitor status changed

Occurs when the field monitor feature is started or stopped in the company.

General dimensions

DIMENSION	DESCRIPTION OR VALUE
message	**Sensitive field monitor status has changed to {almonitorStatus}**
severityLevel	1

Custom dimensions

DIMENSION	DESCRIPTION OR VALUE
aadTenantId	Specifies that Azure Active Directory (Azure AD) tenant ID used for Azure AD authentication. For on-premises, if you aren't using Azure AD authentication, this value is **common**.
alDataClassification	**SystemMetadata**
almonitorStatus	**Yes** - the field monitor feature was started. **No** the field monitor feature was stopped.
alObjectId	**1392**
alObjectName	**Monitor Sensitive Field**
alObjectType	**CodeUnit**
component	**Dynamics 365 Business Central Server**

DIMENSION	DESCRIPTION OR VALUE
componentVersion	Specifies the version number of the component that emits telemetry (see the component dimension.)
deprecatedKeys	Specifies a comma-separated list of all the keys that have been deprecated. The keys in this list are still supported but will eventually be removed in the next major release. We recommend that update any queries that use these keys to use the new key name.
environmentName	Specifies the name of the tenant environment. See Managing Environments. This dimension isn't included for Business Central on-premises environments.
environmentType	Specifies the environment type for the tenant, such as **Production**, **Sandbox**, **Trial**. See Environment Types. This dimension isn't included for Business Central on-premises environments.
eventId	**AL0000DD3**
extensionName	Specifies the name of the base application.
extensionId	Specifies the ID of the base extension.
extensionPublisher	Specifies the publisher of the extension.
extensionVersion	Specifies the version of the base application.
telemetrySchemaVersion	Specifies the version of the Business Central telemetry schema.

Sensitive field value has changed

Occurs the value of a monitored field has changed in the company.

General dimensions

DIMENSION	DESCRIPTION OR VALUE
message	**Sensitive field value has changed: {alfieldCaption} in table {altableCaption}**
severityLevel	**1**

Custom dimensions

DIMENSION	DESCRIPTION OR VALUE
aadTenantId	Specifies that Azure Active Directory (Azure AD) tenant ID used for Azure AD authentication. For on-premises, if you aren't using Azure AD authentication, this value is **common**.

DIMENSION	DESCRIPTION OR VALUE
alDataClassification	**SystemMetadata**
alfieldCaption	Specifies the name of the field that was changed.
altableCaption	Specifies the name of the table that the changed field is included.
alObjectId	**1392**
alObjectName	**Monitor Sensitive Field**
alObjectType	**CodeUnit**
component	**Dynamics 365 Business Central Server**
componentVersion	Specifies the version number of the component that emits telemetry (see the component dimension.)
deprecatedKeys	Specifies a comma-separated list of all the keys that have been deprecated. The keys in this list are still supported but will eventually be removed in the next major release. We recommend that update any queries that use these keys to use the new key name.
environmentName	Specifies the name of the tenant environment. See Managing Environments. This dimension isn't included for Business Central on-premises environments.
environmentType	Specifies the environment type for the tenant, such as **Production**, **Sandbox**, **Trial**. See Environment Types. This dimension isn't included for Business Central on-premises.
eventId	**AL0000CTE**
extensionName	Specifies the name of the base application.
extensionId	Specifies the ID of the base extension.
extensionPublisher	Specifies the publisher of the extension.
extensionVersion	Specifies the version of the base application.
telemetrySchemaVersion	Specifies the version of the Business Central telemetry schema.

NOTE

Changes to fields in the following tables are always logged:

- Fields in the **Field Monitoring Setup** table. Many of the fields are included on the **Field Monitoring Setup** page.
- Fields in the **Change Log Setup (Field)** table. Many of the fields are included on the **Field Monitoring Worksheet** page.
- The **Contact Email** field in the **User** table.

Analyzing Long Running AL Methods Telemetry

2/17/2021 • 3 minutes to read • Edit Online

APPLIES TO: Business Central 2020 release wave 2 and later, version 17.1

The Business Central Server server will emit telemetry about the execution time of long running AL methods, including the time spent in the database. The signal also includes a breakdown of how much time each event subscriber added to the total time. As a partner, this data gives you insight into bad performing code and enables you to troubleshoot performance issues caused by extensions.

> **NOTE**
> To collect this telemetry for Business Central on-premises, the **AL Function Timing** and **AL Function Logging Threshold - Application Insights** settings must be configured on the Business Central Server instance. For more information, see Configuring Business Central Server. With Business Central online, this telemetry is enabled with a specific threshold on a case-by-case basis by the service.

General dimensions

The following table explains the general dimensions included in the trace. The table lists the dimensions that are specific to Business Central.

DIMENSION	DESCRIPTION OR VALUE
message	**Operation exceeded time threshold (AL method)**
severityLevel	2

CustomDimensions

This table describes the different dimensions of a **Operation exceeded time threshold (AL method)** operation.

COLUMN (KEY)	DESCRIPTION OR VALUE
aadTenantId	Specifies that Azure Active Directory (Azure AD) tenant ID when using Azure AD authentication. For on-premises, if you aren't using Azure AD authentication, this value is **common**.
alMethod	The name of the long running AL method.
alObjectId	The type of the AL object that executed the AL method.
alObjectName	The name of the AL object that executed the AL method.
alObjectType	The type of the AL object that executed the AL method.
alStackTrace	The stack trace in AL.

COLUMN (KEY)	DESCRIPTION OR VALUE
clientType	Specifies the type of client that executed the AL method, such as Background or Web. For a list of the client types, see ClientType Option Type.
companyName	The display name of the Business Central company that was used at time of execution.
component	**Dynamics 365 Business Central Server**
componentVersion	Specifies the version number of the component that emits telemetry (see the component dimension.)
deprecatedKeys	A comma-separated list of all the keys that have been deprecated. The keys in this list are still supported but will eventually be removed in the next major release. We recommend that update any queries that use these keys to use the new key name.
environmentType	Specifies the environment type of the Business Central solution, such as Production or Sandbox.
environmentName	Specifies the environment name of the Business Central solution, such as Production or Sandbox.
eventId	**RT0018**
executionTime	Specifies the total time that it took to execute the AL method. The value has the format hh:mm:ss.sssssss.
extensionInfo	Specifies information about individual extensions that contributed to the execution time spent in the call stack up until the point at which the long-running threshold was exceeded and the trace was emitted. The following information is included for each extension: • `id` - the ID of the extension. • `extensionName` - the name of the extension. • `extensionVersion` - the version of the extension. • `extensionPublisher` - the publisher of the extension. • `subscriberExecutionCount` - the number of event subscribers executed in this extension. • `executionTime` - the total execution time for this extension in the call stack. The value has the format hh:mm:ss.sssssss.
extensionName	Specifies the name of the extension that was currently executing when the long-running threshold was exceeded and the trace was emitted.
extensionPublisher	Specifies the publisher of the extension that was currently executing when the long-running threshold was exceeded and the trace was emitted.

COLUMN (KEY)	DESCRIPTION OR VALUE
extensionVersion	Specifies the version of the extension that was currently executing when the long-running threshold was exceeded and the trace was emitted.
extensionId	Specifies the ID of the extension that was currently executing when the long-running threshold was exceeded and the trace was emitted.
longRunningThreshold	Specifies the time that defines a long-running AL method, after which the trace is emitted. The value has the format hh:mm:ss.sssssss.
telemetrySchemaVersion	Specifies the version of the Business Central telemetry schema.

Analyzing Long Running Operation (SQL Query) Telemetry

2/17/2021 • 4 minutes to read • Edit Online

A SQL query that takes longer than 1000 milliseconds to execute will be sent to your Application Insights resource.

To get a quick overview, you can go the Application Insights Overview dashboard.

> **NOTE**
> With Business Central On-premises, you can change the threshold that defines long running queries. For more information, see Defining Long Running SQL Queries Threshold.

There are multiple reasons that affect the time it takes SQL queries to run. For example, the database could be waiting for a lock to be released. Or, the database is executing an operation that does badly because of missing indexes. Sometimes you can look at the SQL statement that was generated by the code to see what caused the delay. This information is found in the **CustomDimension** data, specifically the **AL Stack Trace** column.

Dimensions in Application Insights

This table explains the columns included in long running query events emitted to Application Insights. Bold text indicates that the value of the columns is a constant. Some columns are standard for Application Insights. These columns are indicated by *Application Insights*.

COLUMN	DESCRIPTION OR VALUE
timestamp	Specifies the date and time that the long running query event occurred, such as 2019-08-20T07:23:07.9996696Z
message	Version 16.1 and later: **Operation exceeded time threshold (SQL query)** Before version 16.1: **Action took longer than expected**
severityLevel	**2** (This level indicates a warning. Long running queries are always recorded as warnings)
itemType	**trace**
customDimensions	(see table that follows)
operation_Name	**Long Running Operation (SQL Query)** **Note:** The use of the `operation_Name` column was deprecated in version 16.1. In future versions, data won't be stored in this column. So in version 16.1 and later, use the custom dimension column `eventID` column custom in Kusto queries instead of `operation_Name`.
operation_Id	Specifies the GUID assigned to the client operation. An operation is created whenever the user does something in the client, such as selecting an action.
operation_ParentId	Currently this column is the same as the operation_Id. This behavior might change in a future release.
session_Id	Specifies the GUID of the client session. When a client makes a connection to the Business Central Server instance, a session is created and assigned an ID.
client_Type	*Application Insights*
client_IP	*Application Insights*
client_City	*Application Insights*
client_StateOrProvince	*Application Insights*
client_CountryOrRegion	*Application Insights*
cloud_RoleName	Specifies the display name of Business Central tenant. For on-premises, this value is the same as the cloud_RoleInstance.
cloud_RoleInstance	Specifies the name of Business Central tenant.

COLUMN	DESCRIPTION OR VALUE
appId	*Application Insights*
appName	*Application Insights*
iKey	*Application Insights*
sdkVersion	*Application Insights*

CustomDimensions

This table describes the different dimensions of a **Long Running Operation (SQL Query)** operation.

COLUMN (KEY)	DESCRIPTION OR VALUE
extensionVersion	Specifies the version of the extension.
telemetrySchemaVersion	Specifies the version of the Business Central telemetry schema.
componentVersion	Specifies the version number of the component that emits telemetry (see the component dimension.)
environmentType	Specifies the environment type of the Business Central solution, such as Production or Sandbox.
environmentName	Specifies the environment name of the Business Central solution, such as Production or Sandbox.
extensionName	Specifies the name of the extension.
alObjectType	The type of the AL object that executed the SQL statement
alObjectName	The name of the AL object that executed the SQL statement
alStackTrace	The stack trace in AL.
companyName	The display name of the Business Central company that was used at time of execution.
extensionId	Specifies the AppID of the extension.
eventId	**RT0005** This dimension was introduced in Business Central 2020 release wave 1, version 16.1.
aadTenantId	Specifies that Azure Active Directory (Azure AD) tenant ID when using Azure AD authentication. For on-premises, if you aren't using Azure AD authentication, this value is **common**.
clientType	Specifies the type of client that executed the SQL Statement, such as Background or Web. For a list of the client types, see ClientType Option Type.
alObjectId	The type of the AL object that executed the SQL statement.
component	Specifies the Business Central Server instance name and the platform version.
executionTime	Specifies the time that it took to execute the SQL statement**. The value has the format hh:mm:ss.sssssss.
longRunningThreshold	Specifies the amount of time that an SQL query can run before a warning event is recorded. The value has the format hh:mm:ss.sssssss. This threshold is controlled by the Business Central Server configuration setting called SqlLongRunningThreshold.
sqlStatement	Specifies the SQL statement that was executed for the long running query. The value is limited to 8192 characters. If the value exceeds 8192 characters, it will be truncated in manner that still provides the most pertinent information.
deprecatedKeys	A comma-separated list of all the keys that have been deprecated. The keys in this list are still supported but will eventually be removed in the next major release. We recommend that update any queries that use these keys to use the new key name.

** From telemetrySchemaVersion **0.6** and onwards, this value also includes the CompanyOpen operation.

Example

The following code snippet shows an example of the CustomDimensions.

```

Analyzing Report Generation Telemetry

2/17/2021 • 10 minutes to read • Edit Online

INTRODUCED IN: Business Central 2020 release wave 1

Report generation telemetry gathers data about reports that are run on the service. It provides information about whether the report dataset generation succeeded, failed, or was canceled. For each report, it tells you how long it ran, how many SQL statements it executed, and how many rows it consumed.

You use this data to gather statistics to help identify slow-running reports.

Success report generation

Occurs when a report dataset generates without any errors.

General dimensions

The following table explains the general dimensions of this trace.

DIMENSION	DESCRIPTION OR VALUE
operation_Name	**Success report generation** **Note:** The use of the `operation_Name` column was deprecated in version 16.1. In future versions, data won't be stored in this column. So in version 16.1 and later, use the custom dimension column `eventID` column custom in Kusto queries instead of `operation_Name`.
message	Version 16.1 and later: **Report rendered: {report ID} - {report name}** Before version 16.1: **The report {report ID} '{report name}' rendered successfully**
severityLevel	1

Custom dimensions

DIMENSION	DESCRIPTION OR VALUE
aadTenantId	Specifies that Azure Active Directory (Azure AD) tenant ID used for Azure AD authentication. For on-premises, if you aren't using Azure AD authentication, this value is **common**.
alObjectId	Specifies the ID of the report object that was run.
alObjectName	Specifies the name of the report object that was run.
alObjectType	**Report**.
alStackTrace	The stack trace in AL.

DIMENSION	DESCRIPTION OR VALUE
clientType	Specifies the type of client that executed the SQL Statement, such as **Background** or **Web**. For a list of the client types, see ClientType Option Type.
companyName	Specifies the display name of the Business Central company for which the report was run.
component	**Dynamics 365 Business Central Server**.
componentVersion	Specifies the version number of the component that emits telemetry (see the component dimension.)
deprecatedKeys	Specifies a comma-separated list of all the keys that have been deprecated. The keys in this list are still supported but will eventually be removed in the next major release. We recommend that update any queries that use these keys to use the new key name.
environmentName	Specifies the name of the tenant environment. See Managing Environments.
environmentType	Specifies the environment type for the tenant, such as **Production**, **Sandbox**, **Trial**. See Environment Types
eventId	**RT0006** This dimension was introduced in Business Central 2020 release wave 1, version 16.1.
extensionId	Specifies the appID of the extension that the report object belongs to.
extensionName	Specifies the name of the extension that the report object belongs to.
extensionVersion	Specifies the version of the extension that the report object belongs to.
numberOfRows	Specifies the number of rows/records generated for the report dataset.
reportingEngine	Specifies the reporting engine used to generate the report, such as **ProcessingOnly**, **Rdlc**, or **Word**. This dimension was added in version 17.3
result	**Success**
serverExecutionTime	Specifies the amount of time it took the service to complete the request[1]. The time has the format hh:mm:ss.sssssss.
sqlExecutes	Specifies the number of SQL statements that the report executed[1].

DIMENSION	DESCRIPTION OR VALUE
sqlRowsRead	Specifies the number of table rows that were read by the SQL statements[1].
telemetrySchemaVersion	Specifies the version of the Business Central telemetry schema.
totalTime	Specifies the amount of time it took for the system to generate the dataset and render the report[1]. The time has the format hh:mm:ss.sssssss.

[1]From telemetrySchemaVersion **0.6** and onwards, this value also includes the CompanyOpen operation.

Failed report generation

This operation occurs when the report dataset couldn't be generated because of an error.

General dimensions

The following table explains the general dimensions of the **Failed report generation** operation.

DIMENSION	DESCRIPTION OR VALUE
message	Version 16.1 and later: **Report rendering failed: {report ID} - {report name}** Before version 16.1: **The report {report ID} '{report name}' couldn't be rendered**
operation_Name	**Failed report generation** **Note:** The use of the `operation_Name` column was deprecated in version 16.1. In future versions, data won't be stored in this column. So in version 16.1 and later, use the custom dimension column `eventID` column custom in Kusto queries instead of `operation_Name`.
severityLevel	3

Custom dimensions

DIMENSION	DESCRIPTION OR VALUE
aadTenantId	Specifies that Azure Active Directory (Azure AD) tenant ID used for Azure AD authentication. For on-premises, if you aren't using Azure AD authentication, this value is **common**.
alObjectId	Specifies the ID of the report object that was run.
alObjectName	Specifies the name of the report object that was run.
alObjectType	**Report**.
alStackTrace	The stack trace in AL.

DIMENSION	DESCRIPTION OR VALUE
cancelReason[2]	Specifies why the report was canceled.
clientType	Specifies the type of client that executed the SQL Statement, such as **Background** or **Web**. For a list of the client types, see ClientType Option Type.
companyName	Specifies the display name of the Business Central company for which the report was run.
component	**Dynamics 365 Business Central Server**.
componentVersion	Specifies the version number of the component that emits telemetry (see the component dimension.)
deprecatedKeys	Specifies a comma-separated list of all the keys that have been deprecated. The keys in this list are still supported but will eventually be removed in the next major release. We recommend that update any queries that use these keys to use the new key name.
environmentName	Specifies the name of the tenant environment. See Managing Environments.
environmentType	Specifies the environment type for the tenant, such as **Production**, **Sandbox**, **Trial**. See Environment Types
eventId	**RT0006** This dimension was introduced in Business Central 2020 release wave 1, version 16.1.
extensionId	Specifies the appID of the extension that the report object belongs to.
extensionName	Specifies the name of the extension that the report object belongs to.
extensionVersion	Specifies the version of the extension that the report object belongs to.
numberOfRows	Specifies the number of rows/records generated for the report dataset.
result	Specifies the title of the exception that was thrown, such as **NavNCLDialogException**.
serverExecutionTime	Specifies the amount of time used by service on the request. The time has the format hh:mm:ss.ssssss.
sqlExecutes	Specifies the number of SQL statements that the report executed.
sqlRowsRead	Specifies the number of table rows that were read by the SQL statements.

DIMENSION	DESCRIPTION OR VALUE
telemetrySchemaVersion	Specifies the version of the Business Central telemetry schema.
totalTime	Specifies the amount of time used to generate the dataset and render the report before it failed. The time has the format hh:mm:ss.sssssss.

[2] Available in Business Central 2020 release wave 2 and later only.

Analyzing report generation failures

When a report fails to generate, the `result` column in the CustomDimensions will include the title of the exception that was thrown by the service or the AL code.

Cancellation report generation

This operation occurs when the report dataset generation was canceled. There are various conditions that can cancel a report. The **Cancellation report generation** operation emits different trace messages for each condition.

General dimensions

The following table explains the general dimensions of the **Cancellation report generation** operation.

DIMENSION	DESCRIPTION OR VALUE
operation_Name	**Cancellation report generation** **Note:** The use of the `operation_Name` column was deprecated in version 16.1. In future versions, data won't be stored in this column. So in version 16.1 and later, use the custom dimension column `eventID` column custom in Kusto queries instead of `operation_Name`.
message	Specifies the reason why the report was canceled. See Analyzing cancellation messages section for details.
severityLevel	2

Custom dimensions

DIMENSION	DESCRIPTION OR VALUE
aadTenantId	Specifies that Azure Active Directory (Azure AD) tenant ID used for Azure AD authentication. For on-premises, if you aren't using Azure AD authentication, this value is **common**.
alObjectId	Specifies the ID of the report object that was run.
alObjectName	Specifies the name of the report object that was run.
alObjectType	**Report**.
alStackTrace	The stack trace in AL.

DIMENSION	DESCRIPTION OR VALUE
clientType	Specifies the type of client that executed the SQL Statement, such as **Background** or **Web**. For a list of the client types, see ClientType Option Type.
companyName	Specifies the display name of the Business Central company for which the report was run.
component	**Dynamics 365 Business Central Server**.
componentVersion	Specifies the version number of the component that emits telemetry (see the component dimension.)
deprecatedKeys	Specifies a comma-separated list of all the keys that have been deprecated. The keys in this list are still supported but will eventually be removed in the next major release. We recommend that update any queries that use these keys to use the new key name.
environmentName	Specifies the name of the tenant environment. See Managing Environments.
environmentType	Specifies the environment type for the tenant, such as **Production**, **Sandbox**, **Trial**. See Environment Types
eventId	**RT0007** This dimension was introduced in Business Central 2020 release wave 1, version 16.1.
extensionId	Specifies the appID of the extension that the report object belongs to.
extensionName	Specifies the name of the extension that the report object belongs to.
extensionVersion	Specifies the version of the extension that the report object belongs to.
telemetrySchemaVersion	Specifies the version of the Business Central telemetry schema.

Analyzing report cancellations

The cancellation messages indicate events that caused the report to be canceled. The telemetry can help identify slow-running reports - reports that take longer than expected to run and generate a large number of rows.

> **NOTE**
>
> The service evaluates cancellation events in a specific order, and the evaluation is done every five seconds. For more information, see Report Generation and Cancellation Flow.

Cancellation event received. Requesting cancellation of the action.

This message occurs when the session canceled a report as it was being generated.

Received a cancellation request from the user. Requesting cancellation of the action.

This message occurs when a user canceled a report in the client as it was being generated.

The action took longer to complete ({0}) than the specified threshold ({1}). Requesting cancellation of the action.

The service is configured to cancel reports if they take longer to generate than a set amount of time. With Business Central online, you can't change the threshold. With Business Central on-premises, you change the threshold by setting the **Max Execution Timeout** parameter on the Business Central Server instance. There's no timeout for on-premises by default. For more information, see Configuring Business Central Server.

The rendering of the word report has been cancelled because it took longer than the specified threshold ({0})"

This message occurs when a report that based on a Word layout takes longer to generate than the specified threshold. The event is only relevant for Business Central online. There's no timeout for on-premises.

The number of processed rows exceeded ({0} rows) the maximum number of rows ({1} rows). Requesting cancellation of the action.

The service is configured to cancel reports if they generate more than a set number of rows. With Business Central online, you can't change this threshold. With Business Central on-premises, you change the threshold by setting the **Max Rows** parameter on the Business Central Server instance. There's no limit on rows for on-premises by default. For more information, see Configuring Business Central Server.

Report cancelled but a commit occurred

This operation occurs when the report dataset generation was canceled but a COMMIT operation occurred before the cancellation. This pattern isn't recommended. Reconsider the report design.

General dimensions

The following table explains the general dimensions of the **Report cancelled but a commit occurred** operation.

DIMENSION	DESCRIPTION OR VALUE
message	The report <ID> '<Name>' is being canceled, but a COMMIT() has been performed. This can lead to data inconsistency if the report is not idempotent
severityLevel	2

Custom dimensions

DIMENSION	DESCRIPTION OR VALUE
aadTenantId	Specifies that Azure Active Directory (Azure AD) tenant ID used for Azure AD authentication. For on-premises, if you aren't using Azure AD authentication, this value is **common**.
alObjectId	Specifies the ID of the report object that was run.
alObjectName	Specifies the name of the report object that was run.
alObjectType	**Report**.
alStackTrace	The stack trace in AL.
cancelReason	The reason why the report was cancelled
clientType	Specifies the type of client that executed the SQL Statement, such as **Background** or **Web**. For a list of the client types, see ClientType Option Type.

DIMENSION	DESCRIPTION OR VALUE
companyName	Specifies the display name of the Business Central company for which the report was run.
component	**Dynamics 365 Business Central Server**.
componentVersion	Specifies the version number of the component that emits telemetry (see the component dimension.)
deprecatedKeys	Specifies a comma-separated list of all the keys that have been deprecated. The keys in this list are still supported but will eventually be removed in the next major release. We recommend that update any queries that use these keys to use the new key name.
environmentName	Specifies the name of the tenant environment. See Managing Environments.
environmentType	Specifies the environment type for the tenant, such as **Production**, **Sandbox**, **Trial**. See Environment Types
eventId	**RT0011** This dimension was introduced in Business Central 2020 release wave 1, version 16.1.
extensionId	Specifies the appID of the extension that the report object belongs to.
extensionName	Specifies the name of the extension that the report object belongs to.
extensionPublisher	Specifies the name of the extension publisher that the report object belongs to.
extensionVersion	Specifies the version of the extension that the report object belongs to.
telemetrySchemaVersion	Specifies the version of the Business Central telemetry schema.

Analyzing Incoming Web Services Request Telemetry

2/17/2021 • 5 minutes to read • Edit Online

INTRODUCED IN: Business Central 2020 release wave 1

Web services telemetry gathers data about SOAP, OData, and API requests through the service. It provides information like the request's endpoint, time to complete, the SQL statements run, and more.

As a developer, you use the data to learn about conditions that you can change to improve performance. The following table provides some examples:

CONDITION	ANALYSIS
A web service request results in a long running SQL query	Adjust or fine-tune code.
Web service requests to a specific endpoint read more rows than requests to the other endpoints	Consider adding filtering to limit the rows that are read.
Fewer API type requests compared with other types	With SOAP and OData requests, computation resources are used on UI elements that aren't relevant. Instead of exposing normal pages as web service endpoints, use the built-in API pages. API pages are optimized for this scenario.
High number of requests to endpoints that include Power BI	This condition may indicate excessive Power BI integration.

For more performance guidelines, see Writing efficient Web Services.

> **NOTE**
> Business Central online and on-premises are configured with various limits on web service requests. For example, there is a request timeout and a maximum connections limit. For online, you can't change these limits, but it is helpful to know what the limits are. See Current API Limits. For on-premises, you change the limits on the Business Central Server instance. See Configuring Business Central Server. Web service calls that exceed the timeout limit result in a **408 - Request Timeout**. These calls are recorded in Application Insights with a totalTime that is equal to the timeout threshold.

General dimensions

The following table explains the general dimensions included in an incoming **Web Services Call** trace. The table lists the dimensions that are specific to Business Central.

DIMENSION	DESCRIPTION OR VALUE
operation_Name	**Web Services Call** **Note:** The use of the `operation_Name` column was deprecated in version 16.1. In future versions, data won't be stored in this column. So in version 16.1 and later, use the custom dimension column `eventID` column custom in Kusto queries instead of `operation_Name`.

DIMENSION	DESCRIPTION OR VALUE
message	Version 16.1 and later (depending on the type): • **Web service called (API): {endpoint}** • **Web service called (ODataV4): {endpoint}** • **Web service called (ODataV3): {endpoint}** • **Web service called (SOAP): {endpoint}** Before version 16.1: • **Received a web service request of type API** • **Received a web service request of type ODataV4** • **Received a web service request of type ODataV3** • **Received a web service request of type SOAP**
severityLevel	**1**

Custom dimensions

The following table explains the custom dimensions included in a **Web Services Call** trace.

DIMENSION	DESCRIPTION OR VALUE
aadTenantId	Specifies that Azure Active Directory (Azure AD) tenant ID used for Azure AD authentication. For on-premises, if you aren't using Azure AD authentication, this value is **common**.
alObjectId	Specifies the ID of the AL object that was run by request.[1]
alObjectName	Specifies the name of the AL object that was run by the request.[1]
alObjectType	Specifies the type of the AL object that was run by the request.[1]
category	Specifies the service type. Values include: **API**, **ODataV4**, **ODataV3**, and **SOAP**.
component	**Dynamics 365 Business Central Server**
componentVersion	Specifies the version number of the component that emits telemetry (see the component dimension.)
deprecatedKeys	A comma-separated list of all the keys that have been deprecated. The keys in this list are still supported but will eventually be removed in the next major release. We recommend that update any queries that use these keys to use the new key name.
endpoint	Specifies the endpoint for the request.
environmentName	Specifies the name of the tenant environment. See Managing Environments.
environmentType	Specifies the environment type for the tenant, such as **Production**, **Sandbox**, **Trial**. See Environment Types
eventId	**RT0008** This dimension was introduced in Business Central 2020 release wave 1, version 16.1.
httpHeaders	Introduced in version 16.3. Specifies the http headers set in the request.

DIMENSION	DESCRIPTION OR VALUE
httpMethod	Introduced in version 16.3. Specifies the HTTP method used in the request. Values include: POST, GET, PUT, PATCH, orDELETE.
httpStatusCode	Introduced in version 16.3. Specifies the http status code returned when a request has completed. This dimension further indicates whether request succeeded or not, and why. Use it to verify whether there was an issue with a request even though the request was logged as successful. The dimension displays one of the following values: • **200** OK. The request succeeded. • **401** Access denied. The user who made the request doesn't have proper permissions. For more information, see Web Services Authentication and Assign Permissions to Users and Groups. • **404** Not found. The given endpoint was not valid. For more information, see Publishing a Web Service • **408** Request timed out. The request took longer to complete than the threshold configured for the service. For information about this threshold in Business Central online, see OData request limits. For on-premises, the timeout is determined by the ODataServicesOperationTimeout setting of the Business Central Server. For more information, see Configuring Business Central Server • **429** Too Many Requests. The request exceeded the maximum simultaneous requests allowed on the service. For information about this threshold in Business Central online, see OData request limits. For on-premises, the timeout is determined by the ODataMaxConnections setting of the Business Central Server. For more information, see Configuring Business Central Server This dimension was introduced in Business Central 2020 release wave 1, version 16.3. This dimension is not populated for SOAP endpoints.
serverExecutionTime	Specifies the amount of time it took the server to complete the request**. The time has the format hh:mm:ss.sssssss.
sqlExecutes	Specifies the number of SQL statements that the request executed.[1] [2]
sqlRowsRead	Specifies the number of table rows that were read by the SQL statements.[1] [2]
totalTime	Specifies the amount of time it took to process the request.[2] The time has the format hh:mm:ss.sssssss.
telemetrySchemaVersion	Specifies the version of the Business Central telemetry schema.

[1]This dimension isn't relevant for $metadata calls, like `https://localhost:7048/BC/ODataV4/$metadata`, so it won't be in the trace.

[2]From telemetrySchemaVersion **0.6** and onwards, this value also includes the CompanyOpen operation.

Example trace

The following code snippet is a CustomDimensions example:

{"telemetrySchemaVersion":"0.6","componentVersion":"16.0.11329.0","environmentType":"Production","deprecatedKeys":"Company name, AL

Analyzing Outgoing Web Service Request Telemetry

2/17/2021 • 3 minutes to read • Edit Online

APPLIES TO: Business Central 2020 release wave 2 and later

Outgoing web service request telemetry gathers data about outgoing web service requests sent using the AL HTTPClient module. As a partner, the data gives you insight into the execution time and failures that happen in external services that your environment and extensions depend on. Use the data to monitor environments for performance issues caused by external services, and be more proactive in preventing issues from occurring.

General dimensions

The following table explains the general dimensions included in an outgoing **Web Services Call (Outgoing)** trace. The table lists the dimensions that are specific to Business Central.

DIMENSION	DESCRIPTION OR VALUE
message	**Web Service Called (Outgoing): {endpoint}**
severityLevel	**1**

Custom dimensions

The following table explains the custom dimensions included in a **Web Services Call** trace.

DIMENSION	DESCRIPTION OR VALUE
aadTenantId	Specifies that Azure Active Directory (Azure AD) tenant ID used for Azure AD authentication. For on-premises, if you aren't using Azure AD authentication, this value is **common**.
alAuthenticationMethod	Specifies the user authentication used by the Business Central service . Values include: Windows, UserName, NavUserPassword, AccessControlService. For more information about the authentication types, see Authentication and Credential Types.
alHttpTimeout	Specifies the timeout defined for the request. The timeout is the time to wait before a request gets canceled. The value has the format hh:mm:ss. The timeout is defined either by the NavHttpClientMaxTimeout setting on the Business Central Server instance or by a TimeOut method call in extension code. The TimeOut method call takes precedence.
alObjectId	Specifies the ID of the AL object that made the request.
alObjectName	Specifies the name of the AL object that made the request.
alObjectType	Specifies the type of the AL object that made the request.
companyName	Specifies the display name of the Business Central company from which the request was made.
component	**Dynamics 365 Business Central Server**
componentVersion	Specifies the version number of the component that emits telemetry (see the component dimension.)
deprecatedKeys	A comma-separated list of all the keys that have been deprecated. The keys in this list are still supported but will eventually be removed in the next major release. We recommend that update any queries that use these keys to use the new key name.
endpoint	Specifies the endpoint for the request. The endpoint is cleaned to include only the base URI.
environmentName	Specifies the name of the tenant environment. See Managing Environments.
environmentType	Specifies the environment type for the tenant, such as **Production**, **Sandbox**, **Trial**. See Environment Types
eventId	**RT0019**
extensionId	Specifies the appID of the extension that made the request.
extensionName	Specifies the name of the extension that made the request.
extensionVersion	Specifies the version of the extension that made the request.

DIMENSION	DESCRIPTION OR VALUE
httpHeaders	Introduced in version 17.2. Specifies the http headers set in the request.
httpMethod	Specifies the HTTP method used in the outgoing request. Values include: POST, GET, PUT, PATCH, orDELETE.
httpReturnCode	**Deprecated in version 17.2. Use the dimension httpStatusCode instead.** Specifies the http status code returned when a request has completed. This dimension further indicates whether request succeeded or not, and why. Use it to verify whether there was an issue with a request even though the request was logged as successful. The dimension displays one of the following values: • **200** OK. The request succeeded. • **404** Not found. The given endpoint wasn't valid.
httpStatusCode	Specifies the http status code returned when a request has completed. This dimension further indicates whether request succeeded or not, and why. Use it to verify whether there was an issue with a request even though the request was logged as successful. The dimension displays one of the following values: • **200** OK. The request succeeded. • **404** Not found. The given endpoint wasn't valid.
serverExecutionTime	Specifies the amount of time it took the server to complete the request, including the time to open the company. The time has the format hh:mm:ss.sssssss.
totalTime	Specifies the amount of time it took to process the request, including the time to open the company. The time has the format hh:mm:ss.sssssss.
telemetrySchemaVersion	Specifies the version of the Business Central telemetry schema.

Example trace

The following code snippet is a CustomDimensions example:

Analyzing Web Service Access Key Telemetry

2/17/2021 • 3 minutes to read • Edit Online

APPLIES TO: Business Central 2020 release wave 2, version 17.3, and later

The Business Central emits telemetry data about the success or failure of authenticating web service access keys on web service requests.

In a future release, web service access key feature will be deprecated. As a partner or customer, this data lets you monitor the use of web service access keys on your environments in preparation for this change.

For information about web service access keys, see How to use an Access Key for SOAP and OData Web Service Authentication.

Authentication with web service key succeeded

Occurs when a web service access key was authenticated successfully.

General dimensions

The following table explains the general dimensions included in the trace. The table lists the dimensions that are specific to Business Central.

DIMENSION	DESCRIPTION OR VALUE
message	**Authentication with Web Service Key succeeded: {endpoint}**
severityLevel	**1**

Custom dimensions

The following table explains the custom dimensions included in the trace.

DIMENSION	DESCRIPTION OR VALUE
aadTenantId	Specifies that Azure Active Directory (Azure AD) tenant ID used for Azure AD authentication. For on-premises, if you aren't using Azure AD authentication, this value is **common**.
alObjectId	Specifies the ID of the AL object that was run by request.
authenticationStatus	**Succeeded**
authenticationType	Specifies whether the service uses NavUserPassword or AccessControl (Azure AD) authentication.
category	Specifies the service type. Values include: **Api**, **ODataV4**, **ODataV3**, and **SOAP**.
component	**Dynamics 365 Business Central Server**
componentVersion	Specifies the version number of the component that emits telemetry (see the component dimension.)

DIMENSION	DESCRIPTION OR VALUE
deprecatedKeys	A comma-separated list of all the keys that have been deprecated. The keys in this list are still supported but will eventually be removed in the next major release. We recommend that update any queries that use these keys to use the new key name.
endpoint	Specifies the endpoint for the request. Private and sensitive information is omitted from the endpoint.
environmentType	Specifies the environment type for the tenant, such as **Production**, **Sandbox**, **Trial**. See Environment Types
eventId	**RT0020** This dimension was introduced in Business Central 2020 release wave 1, version 16.1.
telemetrySchemaVersion	Specifies the version of the Business Central telemetry schema.

Authentication with web service key failed

Occurs when a web service access key failed to authenticate.

General dimensions

The following table explains the general dimensions included in the trace. The table lists the dimensions that are specific to Business Central.

DIMENSION	DESCRIPTION OR VALUE
message	**Authentication with Web Service Key failed: {endpoint}**
severityLevel	**3**

Custom dimensions

The following table explains the custom dimensions included in the trace.

DIMENSION	DESCRIPTION OR VALUE
aadTenantId	Specifies that Azure Active Directory (Azure AD) tenant ID used for Azure AD authentication. For on-premises, if you aren't using Azure AD authentication, this value is **common**.
alObjectId	Specifies the ID of the AL object that was run by request.
authenticationStatus	**Failed**
authenticationType	Specifies whether the service uses NavUserPassword or AccessControl (Azure AD) authentication.
category	Specifies the service type. Values include: **Api**, **ODataV4**, **ODataV3**, and **SOAP**.
component	**Dynamics 365 Business Central Server**

DIMENSION	DESCRIPTION OR VALUE
componentVersion	Specifies the version number of the component that emits telemetry (see the component dimension.)
deprecatedKeys	A comma-separated list of all the keys that have been deprecated. The keys in this list are still supported but will eventually be removed in the next major release. We recommend that update any queries that use these keys to use the new key name.
endpoint	Specifies the endpoint for the request. Private and sensitive information is omitted from the endpoint.
environmentType	Specifies the environment type for the tenant, such as **Production**, **Sandbox**, **Trial**. See Environment Types
eventId	RT0021
failureReason	Specifies the exception that was thrown by the server. Some exception messages can contain customer data. As a precaution, Business Central only emits information that's classified as SystemMetadata. Exception messages that contain other data classifications, like customer data, are not shown. Instead, the following message is shown: "Message not shown because the NavBaseException(string, Exception, bool) constructor was used."
telemetrySchemaVersion	Specifies the version of the Business Central telemetry schema.

Example trace

The following code snippet is a CustomDimensions example:

Session Timeout Settings and Configuration

2/17/2021 • 4 minutes to read • Edit Online

When you start a client, such as connecting to Business Central in a browser, a connection is established with the Business Central Server instance and a corresponding session is added on Business Central Server.

Business Central Server includes several timeout settings that determine when a session closes as a result of inactivity over the client connection, lost client connection, or closing of the client. To help you configure the timeout settings, this document provides an overview of how the session timeouts work and answers some basic questions about session behavior.

Session timeout settings overview

This section provides an overview of the settings that are available in Business Central to control when a Business Central Server session for a Business Central client connection times out and closes. Some of the settings are set on Business Central Server and others are set for the Business Central Web client. For more details about using these settings, see the other sections in this topic.

Business Central Server timeout settings

The following table describes the session timeout settings that are used by Business Central Server.

SETTING	DESCRIPTION	REMARKS
ClientServicesReconnectPeriod	The amount of time during which a client can reconnect to an existing session on Business Central Server before a session closes.	For more information, see Configuring How Long a Session Remains Open after the Client Connection is Lost.
ClientServicesIdleClientTimeout	The interval of time that a Business Central client connection can remain inactive before the session is closed.	For more information, see Configuring How Long a Session Remains Open When the Client Connection is Inactive.

These settings are available in the CustomSettings.config file of Business Central Server. For more information about this file, see Configuring Business Central Server.

Business Central Web client timeout settings

The following table describes the session timeout settings that are used by the Business Central Web client.

SETTING	DESCRIPTION	REMARKS
SessionTimeout	Specifies the amount of time that session remains open when there is no activity over the connection from the Business Central Web client to Business Central Server.	For more information, see Configuring Business Central Server.

This setting is available in the navsettings.json configuration file of the Business Central Web Server. For more information about this file, see Configuring Web Server.

Configuring How Long a Session Remains Open When the Client

Connection is Inactive

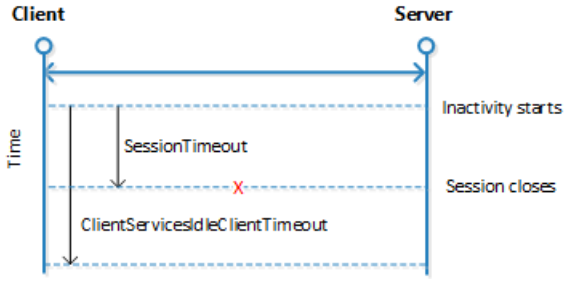
Inactivity on a connection is when the Business Central client is not sending messages to Business Central Server.

Configuring the inactive session timeout for the Business Central Web client

There are two settings that control when a Web client session closes because of inactivity on a connection:

- *ClientServicesIdleClientTimeout* setting on Business Central Server.
- *SessionTimeout* setting on the Business Central Web Server.

The session closes according to the setting that has the shortest time period. By default, the *ClientServicesIdleClientTimeout* setting is set to **MaxValue**, which means no time limit, and the *SessionTimout* setting is 00:20:00 (20 minutes). This means that when client connection is inactive, a session will close after 20 minutes. The following figure illustrates the timeout behavior:

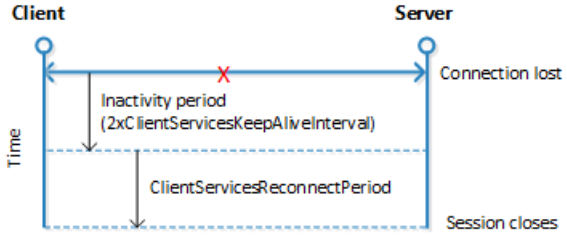


Configuring How Long a Session Remains Open after the Client Connection is Lost

Occasionally, a Business Central client can lose the network connection to Business Central Server. You can use *ClientServicesReconnectPeriod* setting on Business Central Server to control how long a session remains open after the connection is lost to allow time for the client to reconnect to the session.

The time a session remains open actually depends two settings: *ClientServicesKeepAliveInterval* and *ClientServicesReconnectPeriod*. The *ClientServicesKeepAliveInterval* setting is used to specify an initial inactivity period. The initial inactivity period is equal to two times the *ClientServicesKeepAliveInterval* setting value. After this initial inactivity period, the session remains open for the time period that is specified *ClientServicesReconnectPeriod* setting. By default, the *ClientServicesKeepAliveInterval* setting is 120 seconds (2 minutes) and the *ClientServicesReconnectPeriod* setting is 10 minutes. This means that Business Central Server waits approximately 14 minutes for the client to reconnect before closing the session.

The following figure illustrates the reconnect session timeout behavior.



The process that occurs when a client does not reconnect to the session is explained as follows:

1. The connection is lost and the initial inactivity period starts (default is 4 minutes).
2. After the initial inactivity period, the service channel enters a faulted state.

   When the service channel is in the faulted state, Business Central Server considers the session with the

client as orphaned and waits for it to reconnect.

3. If the client does not reconnect within the time period that is specified by the *ClientServicesReconnectPeriod* setting (default is 10 minutes), then Business Central Server closes the session.

4. The session is then removed from the **Active Session** table in the Business Central.

FAQ

This section answers some typical questions about session timeout.

What happens to the session if the client loses the connection to Business Central Server?

By default, it will take approximately 14 minutes for the Business Central Server to close the current session. The time it takes to close the session is in part determined by the *ClientServicesReconnectPeriod* setting on Business Central Server plus an initial 10 minute inactivity period. For more information, see Configuring How Long a Session Remains Open after the Client Connection is Lost.

What happens if the session is still active when Business Central Server tries to close it?

1. The server stops any executing threads when the next statement is to be executed and the current call stack is aborted so any uncommitted transactions will be rolled back.

2. The server cancels any callbacks to the client (similar to waiting for the response to a Confirm dialog).

3. The session is closed, and then removed from the Active Session table.

Preparing Dynamics 365 Sales for Integration

2/17/2021 • 2 minutes to read • Edit Online

This article describes how to set up and configure Dynamics 365 Sales for integrating with Business Central. Complete the following tasks:

1. Create a user for connecting to and synchronizing data from Business Central.
2. Install the Business Central integration solution for Dynamics 365 Sales.

   This task is optional. You only need to complete this task if you want the functionality that is provided by the Business Central integration solution.

> **IMPORTANT**
> To perform the tasks in this topic, you must have the System Administrator security role or equivalent privileges in Dynamics 365 Sales.

Create a Dynamics 365 for Sales User for Connecting to Business Central

As a minimum, this user must be a non-interactive user account that has the required privileges to write, read, modify, and delete data in the entities that will be integrated with Business Central.

You will use this user account to set up the connection to Dynamics 365 Sales from Business Central.

> **IMPORTANT**
> You should not use this account to sign in to Dynamics 365 Sales to modify entities records that are integrated with Business Central because the changes will be ignored by integration synchronization jobs in Business Central.

Create the connection user

- For more information about how to create users in Dynamics 365 Sales, see https://go.microsoft.com/fwlink/?LinkID=616518.

Install the Business Central Integration Solution

Business Central includes a solution that enables users to access coupled records in Business Central, such as customers and items, from records in Dynamics 365 Sales, such as accounts and products. The solution adds a link on the Dynamics 365 Sales record pages that opens the coupled Business Central record. The solution is also used to display information from Business Central in a part on certain entity records in Dynamics 365 Sales, such as accounts. Installing this solution is optional.

1. From Business Central installation media (DVD), copy either the DynamicsNAVIntegrationSolution_v8.zip or DynamicsNAVIntegrationSolution_v9.zip file to your computer.

   These files are located in the **CrmCustomization** folder. This file is the solution package.

   Use the zip version that matches the Dynamics 365 Sales SDK version. Use DynamicsNAVIntegrationSolution_v8.zip for legacy services running CRM or Dynamics 365 Sales version 8.x and earlier. Use DynamicsNAVIntegrationSolution_v9.zip for Dynamics 365 Sales versions 9.0 and

later.

2. In Dynamics 365 Sales, import the DynamicsNAVIntegrationSolution.zip as a solution.

   This step adds the **Business Central Connection** entity and **Business Central Account Statistics** entity in the system and additional items such as Business Central integration security roles.

   For more information about how to manage solutions in Dynamics 365 Sales, https://go.microsoft.com/fwlink/?LinkID=616519.

3. (Optional) Set up the **Business Central Connection** entity to display in the **Settings** area of Dynamics 365 Sales.

   This setup enables Dynamics 365 Sales users who are assigned the **Business Central Admin** role to modify the entity in Dynamics 365 Sales. For more information about how to modify entities in Dynamics 365 Sales, see https://go.microsoft.com/fwlink/?LinkID=616521.

4. Assign the **Business Central Integration Administrator** role to the Business Central connection user.

5. Assign the **Business Central Integration User** role to all users who require the use of the features provided by the Business Central integration solution.

If you install the Business Central integration solution after you have set up the connection to Dynamics 365 Sales from in Business Central, you must modify the connection setup to point to the URL of the Business Central Web client.

Connecting On-Premises Versions

Registering Business Central On-Premises in Azure AD for Integrating with Other Services

2/17/2021 • 5 minutes to read • Edit Online

APPLIES TO Business Central on-premises. Business Central online is automatically configured for integration with other online services.

This article describes how to set up Business Central on-premises to use services that are based on Microsoft Azure. There are several services that you can integrate with Business Central on-premises, like Cortana Intelligence and Power BI. Before using the services, you have to register Business Central on-premises in Azure Active directory and give it access to the services. For example, the Sales and Inventory Forecast extension requires that you specify an API key and API URI. Other services require similar information.

NOTE

In Business Central version earlier than 16.4, the **Set up Azure Active Directory** wizard has an **Auto register** action. Previously, you could use this action to automatically register Business Central in Azure AD. The auto-register functionality has since been removed. Now, you must register the application manually, regardless of your version. The wizard in earlier versions still includes the **Auto register** link. But the link now opens this article, which guides you through the manual registration.

Prerequisites

- An Azure Active Directory (AD) tenant.

  You'll need a tenant on Azure AD that has at least one user. For more information, see Quickstart: Set up a tenant.

  If the Business Central deployment is using Azure AD authentication, then you already have a tenant with users. See Authenticating Business Central Users with Azure Active Directory.

  If your deployment uses NavUserPassword authentication, you'll need the credentials (sign in email and password) of a user account later in this article.

- An Azure portal account

  You'll need an account for accessing the Azure portal. In most cases, this account is the same as your Business Central account. You'll use this account to access Azure Active AD tenant via the Azure portal.

Register an application in Azure Active Directory

The first task is to use Azure portal to register an application for Business Central on your Azure AD tenant. As part of the registration, you'll also give the relevant services access to the application. The purpose of registration is to ensure Business Central on-premises and the services know each other's Azure Active Directory (Azure AD) details.

TIP

The following steps describe how to register a new application. However, if you're using AZure AD authentication, you already have a registered application for Business Central. So instead of registering a new application, you can use the existing application. But if you do, make sure you modify it based on the information in the steps that follow.

1. Sign in to the Azure portal and register an application for Business Central on-premises in Azure Active Directory tenant.

   a. Follow the general guidelines at Register your application with your Azure Active Directory tenant.

      When you add an application to an Azure AD tenant, you must specify the following information:

SETTING	DESCRIPTION
Name	Specify a name for your Business Central on-premises solution, such as *Business Central on-premises* or *Azure Services for Business Central on-premises*.
Supported account types	Select **Accounts in any organizational directory (Any Azure AD directory - Multitenant)**
Redirect URI	Set the first box to **Web** to specify a web application. Enter the URL for your Business Central on-premises browser client, followed by *OAuthLanding.htm*. For example, *https://MyServer:443/BC160/OAuthLanding.htm*. This file is used to manage the exchange of data between Business Central on-premises and other services through Azure AD.

      When completed, an **Overview** displays in the portal for the new application.

   b. Copy the **Application (Client) ID** that was assigned the application and also redirect URL that you specified. You'll use this information later.

2. Create a client secret for the registered application.

   a. Follow the general guidelines at Add credentials to your web application.

   b. Before you leave the **Certificates & secrets** page, copy the secret's value to a temporary location. The value isn't accessible once you leave the page. You'll use this key later in your client application code.

3. Grant the registered application delegated permission to access the required service APIs, like Power BI.

   Follow the general guidelines at Add permissions to access web APIs for each service.

   Use the following table to help you set the minimum permissions:

API / PERMISSION NAME	TYPE	DESCRIPTION
Microsoft Graph / User.Read	Delegated	Sign in and read user profile
Power BI Service / Report.Read.All	Delegated	View all reports

Set up the registered application in Business Central

After you register the application, the next task is to configure the Business Central tenant to use the application. You'll need the information about the application that you created in the previous task: redirect URL, application (client) ID, and client secret.

1. In the top-right corner, choose the  icon, enter **Assisted Setup**, and then choose the related link.
2. Select **Set up Azure Active Directory**, then **Next**.

   The **Connect With Azure** page opens.
3. In the **Redirect URL** field, make sure the URL matches the redirect URL that's assigned the registered Business Central application in Azure AD.
4. In the **Application ID** field, specify the application (client) ID of the Business Central application in Azure AD that you copied in the previous task.
5. In the **Key** field, specify the value of the client secret used by the Business Central application in Azure AD.
6. Choose **Next**.

   If you're using NavUserPassword authentication, you're prompted to sign in to the Azure AD tenant. In this case, enter the sign in email and password of a valid account.

Unless you see an error message, you're now done. The Business Central on-premises solution is registered and ready to connect to services such as Cortana Intelligence, or embedding Power BI in Business Central.

Fixing problems

This section provides solutions to problems that might occur.

Sorry, but we're having trouble signing you in

When you try to connect, you get a message similar to the following:

AADSTS50011: The reply URL specified in the request does not match the reply URLs configured for the application: '1111111-aaaa-2222-bbbb-333333333333'

To fix this issue, verify that the **Reply URL** in the Setup Azure AD page is correct. It must match the Reply URL set on the registered app in Azure AD.

Upgrading to Dynamics 365 Business Central

2/17/2021 • 2 minutes to read • Edit Online

This section provides an overview of how to upgrade to Business Central. The upgrade process depends on different factors, including on your decision to deploy Business Central on-premises or move your solution online.

> **TIP**
>
> Before you decide how to upgrade your solution, make sure that you read the upgrade considerations at Important Information and Considerations for Before Upgrading to Dynamics 365 Business Central.

Depending on your decision to upgrade to either Business Central online or on-premises, different scenarios are supported. Read the upgrade considerations, and then revise the supported scenarios in the respective sections. If you cannot find guidance for your migration scenario, you can check at the Ideas site if someone else has already suggested support for the same migration path. For more information, see https://aka.ms/businesscentralideas.

Depending on which version you are upgrading from, you may have to convert or migrate the existing Help for your solution. For more information, see Migrate Legacy Help to the Business Central Format and User Assistance Model.

Supported Upgrade Paths to Dynamics 365 Business Central Releases

2/17/2021 • 2 minutes to read • Edit Online

Business Central is available in several release versions. You can upgrade an existing Dynamics NAV or Business Central solution to any of these releases. Depending on your solution's current version, it might not be possible to upgrade directly to a particular release. You might have to upgrade indirectly through an intermediate release, before upgrading to the target release.

The following sections provide the supported upgrade paths to the different Business Central releases.

> **NOTE**
> Minor updates are regularly made available for the major releases. Make sure you upgrade to an update of the release version that is compatible with your source source version. Otherwise, you might encounter problems upgrading the application. For more information, see Dynamics 365 Business Central Upgrade Compatibility Matrix.

Upgrade to Business Central October 2018 (v13)

SOURCE VERSION	UPGRADE PATH
• Microsoft Dynamics NAV 2015 • Microsoft Dynamics NAV 2016 • Microsoft Dynamics NAV 2017 • Microsoft Dynamics NAV 2018	Direct

Upgrade to Business Central Spring 2019 (v14)

Migrating On-Premises Data to Business Central Online

Upgrading to Dynamics 365 Business Central On-Premises Spring 2019 (v.14)

2/17/2021 • 2 minutes to read • Edit Online

The upgrade process depends on different factors, such as the version of Dynamics NAV that you are upgrading from, and the degree to which your solution differs from the standard version of Dynamics NAV. The mains tasks range from converting the database to upgrading application code and data.

Use the following table to determine the procedures that you must complete for your upgrade scenario:

SCENARIO	TASKS
Full upgrade from one of the following versions: • Microsoft Dynamics NAV 2015 • Microsoft Dynamics NAV 2016 • Microsoft Dynamics NAV 2017 • Microsoft Dynamics NAV 2018 • Business Central October 2018	From these versions, you can upgrade directly to the latest version of Business Central by following these tasks: 1. Upgrade the Application Code 2. Upgrade the Data
Full upgrade from one of the following versions: • Microsoft Dynamics NAV 2013 • Microsoft Dynamics NAV 2013 R2	1. Upgrade to Microsoft Dynamics NAV 2018. For more information, see Upgrading to Microsoft Dynamics NAV 2018. 2. Upgrade to Business Central. a. Upgrade the Application Code b. Upgrade the Data: Single-Tenant Deployment or Upgrade the Data: Multitenant Deployment

SCENARIO	TASKS
Full upgrade from one of the following versions: • Microsoft Dynamics NAV 2009 SP1 • Microsoft Dynamics NAV 2009 R2 • Microsoft Dynamics NAV 5.0 • Microsoft Dynamics NAV 4.0	There are two different upgrade paths to Business Central, depending on the version you are upgrading from. For Microsoft Dynamics NAV 5.0 and Microsoft Dynamics NAV 4.0, you must go through Microsoft Dynamics NAV 2013. For Microsoft Dynamics NAV 2009 SP1 and Microsoft Dynamics NAV 2009 R2, you can choose to go through Microsoft Dynamics NAV 2013 or Microsoft Dynamics NAV 2015 **Through Microsoft Dynamics NAV 2013** 1. Upgrade to Microsoft Dynamics NAV 2013. For more information, see Upgrading to Microsoft Dynamics NAV 2013 in Previous Versions Documentation. 2. Upgrade to Microsoft Dynamics NAV 2018. For more information, see Upgrading to Microsoft Dynamics NAV 2018. 3. Upgrade to Business Central. a. Upgrade the Application Code b. Upgrade the Data: Single-Tenant Deployment or Upgrade the Data: Multitenant Deployment **Through Microsoft Dynamics NAV 2015** 1. Upgrade to Microsoft Dynamics NAV 2015. For more information, see Dynamics NAV Team Blog. 2. Upgrade to Business Central. a. Upgrade the Application Code b. Upgrade the Data: Single-Tenant Deployment or Upgrade the Data: Multitenant Deployment After the upgrade, links between interaction records and logged email messages is lost. To resolve this issue, the administrator has to log all mails again to restore the links. For more information, see Logging Interaction Links are Lost When You Upgrade from Microsoft Dynamics NAV 2009 R2.
Platform-only upgrade of Dynamics NAV or Business Central to a new platform version, such as with a cummulative update	• Technical Upgrade You can also use this procedure to convert a database to Business Central technical requirements, and then upgrade the application and data later.

Before you begin the upgrade process, see Important Information and Considerations for Before Upgrading for tips about things to consider when you prepare to upgrade to Business Central.

Important Information and Considerations for Before Upgrading to Dynamics 365 Business Central Spring 2019 and Later Versions

2/17/2021 • 5 minutes to read • Edit Online

Depending on which version you are upgrading from, and the degree to which your solution differs from the standard version of Business Central, you may want to prepare your solution for the upgrade. This topic provides important information and tips for things to consider when you prepare to upgrade to Business Central.

Migrate from Dynamics NAV to Business Central online

You can upgrade to Business Central online from supported versions of Dynamics NAV on-premises, provided that your application customization is handled by extensions. Any data from tables with code customizations cannot be carried forward from Dynamics NAV.

> **NOTE**
> Upgrade your solution to Business Central Spring 2019 (version 14) or later, and then migrate to Business Central online.

The process consists of two parts:

- Upgrade from Dynamics NAV to Business Central using the tools described in Upgrading to Business Central on-premises (version 14). For more information, see Supported Upgrade Paths to Dynamics 365 Business Central Releases.
- Convert non-standard functionality and customizations to apps and per-tenant extensions. For more information, see Deploying a Tenant Customization.
- Run the cloud migration tool as described in Running the Cloud Migration Tool, and then switch to use Business Central online going forward.

Upgrading from Dynamics NAV

This section lists specific changes between Dynamics NAV and Business Central.

Codeunit 1 has been deprecated and replaced

Dynamics NAV included codeunit **1 ApplicationManagement**. In Business Central, this codeunit has been retired, and new 'system' codeunits have been introduced in the 2 billion range.

For information, see Transitioning from Codeunit 1 to System Codeunits.

V1 Extensions have been discontinued

With Business Central, extensions V1 are no longer supported for on-premise installations. As a result, any custom extensions V1 must be converted to extensions V2 in the old environment before upgrading to Business Central.

For information about how to convert to extensions V2, see Converting Extensions V1 to Extensions V2.

MenuSuite not used for page and report search

With Business Central, the MenuSuite is no longer used to control whether a page or report can be found in the

search feature of the Web client. This is now determined by specific properties on the page and report objects. As part of the application code upgrade process, you change these properties on existing pages and reports used by the MenuSuite to ensure that they are still searchable from the Web client. For more information, see Making Pages and Reports Searchable After an Upgrade.

Dynamics 365 Sales integration

Because of changes in Dynamics 365 Sales and the integration since pervious releases, if your application is integrating with Dynamics 365 Sales, then you must perform a full upgrade instead of just a technical upgrade.

New and changed application features

There a several new and changed application features available in Business Central April 2019 for users, administrators, and developers. For an overview of these features, see Overview of Dynamics 365 Business Central April '19 release.

To take advantage of these all these features, you will have to perform an application code upgrade, not just a technical (platform) upgrade.

Changes to profiles in the CRONUS International Ltd. demonstration database and promoted actions

With the Business Central April 2019 release, profiles that are part of the CRONUS International Ltd. demonstration database, such as the **Sales Order Processor** profile, customize fewer pages compared to earlier releases. For customers that rely on these profiles, their users might experience slight differences in the layout of actions in the action bar on pages. Additionally, the layout of promoted actions on over 380 core application pages has been fine-tuned.

To ensure that users are not disrupted by these changes, we recommend that administrators and partners who are upgrading a customer to Business Central April 2019, review the layout of promoted actions when combined with their own code and profile customization.

Names of variables

Business Central introduces new methods and statements. If your solution includes variables where the name is now used by a standard AL method or statement such as REGISTERTABLECONNECTION or FOREACH, you must change the variables before you upgrade to Business Central. Alternatively, you can enclose the variable names in quotation marks. If you do not, and you import an object that has this code in text format, you cannot compile the object.

Deprecated or redesigned functionality

If you are upgrading a solution that depends on functionality that is deprecated or changed in the default version of Business Central, you must verify that the upgrade codeunits migrate data correctly. See the See Also section for links to descriptions of deprecated functionality.

Deprecated fields and fields marked as obsolete

Sometimes Microsoft will refactor code so that fields are no longer used, or the functionality is moved from the base application to an extension, for example. Typically, the upgrade toolkit will manage the upgrade impact, but for transparency, you can find a list of fields that are deprecated in the current release or marked to be obsolete in a later release. For more information, see Deprecated Fields, and Fields Marked as Obsolete.

Upgrade codeunits

When you introduce changes to the database schema, Business Central will check if these changes are

destructive or not. If the database check indicates that the change may lead to data deletion, such as if you are dropping a table column so that the contents of that column will be deleted, this is considered a destructive change. You will be prompted to handle the situation using upgrade codeunits.

Company names

If a company name includes a special character, an error may display during the upgrade. In this context, special characters include the following:
[~ @ # $ % & * ( ) . ! % - + / = ?]

If you are going to upgrade a database where one or more company name includes a special character, we recommend that you rename the company before you start the upgrade process. After the upgrade is successfully finished, you can rename the company again.

System tables with non-English names

In older versions of Dynamics NAV, you could translate the columns in system tables to a language other than English. Starting with version 3.0, we advised heavily against this, and versions later than Microsoft Dynamics NAV 2013 R2 require that all columns in all system tables are in English. As a result, if you try to open a database with non-English system tables in Microsoft Dynamics NAV 2013 R2 or later, an error displays, saying that one or more columns do not exist.

Make sure that all objects where compiled in a development environment with the right .ETX and .STX files. You can verify that you are running in the correct environment with English (US) as the base language by opening the **ndo$dbproperty** table in SQL Server Management Studio. In the **Identifiers** column, the word `Object` must be written exactly as shown here.

Transitioning from Codeunit 1 to System Codeunits

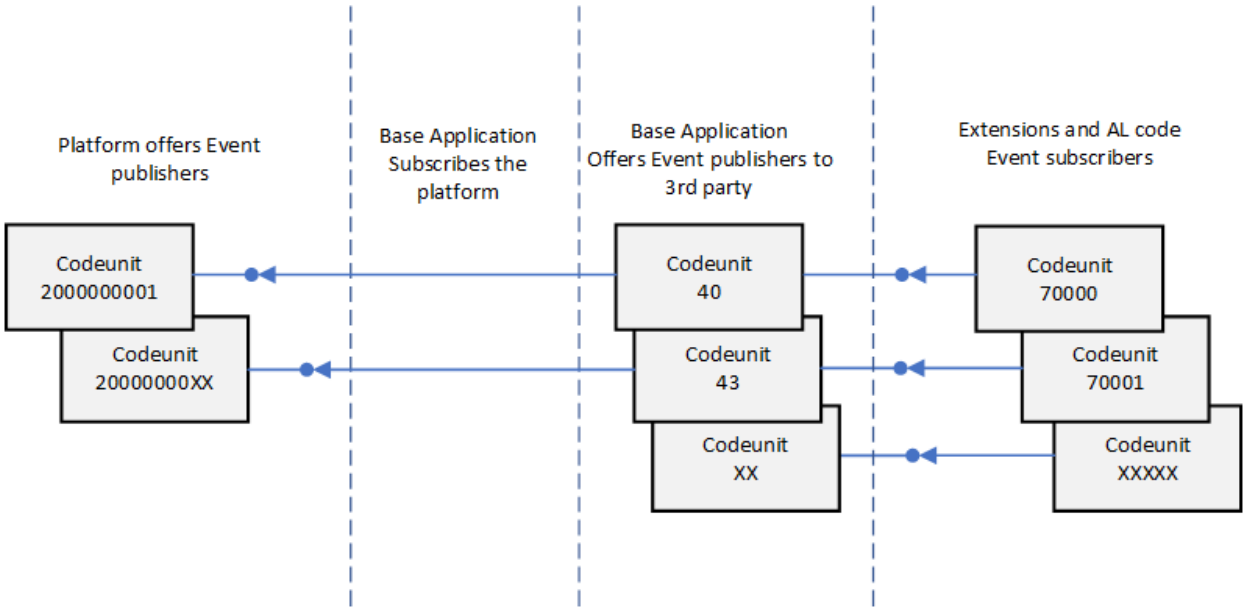
2/17/2021 • 3 minutes to read • Edit Online

With Business Central, codeunit 1 **Application Management** has been removed and replaced with new System codeunits. No functionality has been removed by this change. All system method triggers, event publishers, and their code have been moved to other codeunits.

However, this change will affect the upgrade process from Dynamics NAV and how you develop from now on.

Overview

The foundation of this change is events - publishers and subscribers. System codeunits don't contain code. They only contain event publishers. Instead of running codeunit 1 and calling respective functions, Business Central Server runs system codeunits. The system codeunits will in turn raise published events. There are various management codeunits that subscribe to these events. Like codeunit 1, these subscriber codeunits contain method triggers and integration event publishers. They can call application functionality and raise events. The following figure illustrates the process:



About system codeunits

- They have IDs in the 2 billion range.
- You can't modify them.
- Currently, we don't recommend that code subscribes to the events in the new system codeunits 2000000001..2000000010 directly. Although not blocked, it might be in a future release. Instead, you should subscribe to one of the integration events.

Mapping Codeunit 1 method triggers to events

The following table lists the mappings between the codeunit 1 triggers and the new method triggers/publishers in the management codeunits.

CODEUNIT 1 TRIGGER	NEW CODEUNIT ID	NEW CODEUNIT NAME	NEW METHOD
CompanyClose	40	LogInManagement	CompanyClose

CODEUNIT 1 TRIGGER	NEW CODEUNIT ID	NEW CODEUNIT NAME	NEW METHOD
CompanyOpen	40	LogInManagement	CompanyOpen

What does this mean for upgrade?

Full upgrade - application code and data

Move custom logic from the old codeunit 1 to the management codeunits and methods. Change custom code that call into codeunit 1 to call or subscribe to the new methods. You can do this step as part of the application code upgrade.

Technical upgrade

After you convert the old database to the Business Central platform, import and compile the replacement codeunit 1 object. You get the replacement object from Codeunit 1 Replacement.

Converting a Database to Business Central Spring 2019 - Technical Upgrade

2/17/2021 • 13 minutes to read • Edit Online

See print-friendly quick reference

This article describes how to convert a database from one of the following versions to the latest Business Central platform:

- Microsoft Dynamics NAV 2015
- Microsoft Dynamics NAV 2016
- Microsoft Dynamics NAV 2017
- Microsoft Dynamics NAV 2018

This article can also be used to update your current Business Central database to the latest cumulative update (CU) platform.

Overview

About technical upgrade and database conversion

Converting a database, which is often referred to as a *technical upgrade*, changes the database so that it works on the latest Business Central platform. The conversion updates the system tables of the old database to the new schema (data structure), and upgrades of all reports to support Report Viewer 2015. It provides you with the latest platform features and performance enhancements.

The process is slightly different when you have multitenant deployment compared to a single-tenant deployment. The steps that follow indicate the differences where applicable.

> **IMPORTANT**
>
> Before you begin, read the article Important Information and Considerations for Before Upgrading. This article contains information about limitations in a technical upgrade, such as using V1 extensions or Dynamics 365 Sales integration.
>
> If you are upgrading a single-tenant database to Business Central Cumulative Update 02, 03, 04, or 05, read Tenant synchronization issue with technical upgrade to Business Central Cumulative Updates 02–05 on the Business Central for Partners blog before starting the upgrade.

Tools

To complete the steps in the article, you will use the following tools:

- Dynamics NAV Development Environment (the version that matches your old database and the new version)
- Dynamics NAV Server Administration tool and/or Business Central Server Administration tool
- SQL Server Management Studio

Task 1: (Dynamics NAV upgrade only) Preparation

1. Transition from the use of codeunit 1

With Business Central, codeunit 1 Application Management is no longer used and has been replaced. For more information, see Transitioning from Codeunit 1. To prepare for this change when doing a technical upgrade, do the following:

a. If you have any custom code in codeunit 1, export the existing codeunit 1 as a .fob or .txt file.
b. Go to Codeunit 1 Replacement, and make a .txt file that includes the replacement code for codeunit 1. You will use this file later.

2. Convert V1 extensions to V2 extensions

   Business Central does not support V1 extensions. If you are updating a Dynamics NAV database that includes custom V1 extensions, and you want to continue to use them, you have to convert them to V2 extensions. For more information, see Converting Extensions V1 to Extensions V2.

   V1 extensions that are produced by Microsoft (first-party extensions, publisher=Microsoft) are now available as V2 extensions on the Business Central installation media (DVD), so you do not have to convert these. If you want to keep the functionality provided and data collected by these V1 extensions, you will have to publish the V2 versions as part of the technical upgrade later in Task 4.

   You will have to uninstall all V1 extension to successfully completes the technical upgrade.

Task 2: Preparing the Old Database

Before you convert the old database to Business Central, complete the following steps.

1. Make a copy of the old database or create full database backup.

   For more information, see Create a Full Database Backup (SQL Server).

2. For single-tenant mode, uninstall all extensions. For multitenant mode, uninstall all V1 extensions.

   You can do this from **Extension Management** page in the Dynamics NAV client or by using the Uninstall-NAVApp cmdlet of the Dynamics NAV Administration Shell.

   To get a list of the extensions that are installed, run this command:

   ```
   Get-NAVAppInfo -ServerInstance <ServerInstanceName> -Tenant <TenantID>
   ```

   For a single-tenant mode, set the `-Tenant` parameter to `default`. V1 extensions are indicated by `ExtensionType: CSIDE`.

   For each extension, run this command to uninstall it:

   ```
   Uninstall-NAVApp -ServerInstance <ServerInstanceName> -Name <Name> -Version <N.N.N.N>
   ```

   Alternately, to remove them all at once, you can run this command:

   ```
   Get-NAVAppInfo -ServerInstance <ServerInstanceName> -Tenant default | % { Uninstall-NAVApp -
   ServerInstance <ServerInstanceName> -Name $_.Name -Version $_.Version }
   ```

3. Unpublish extensions versions that you do not want to use in the upgraded database. This is optional and typically done for V1 extensions because they are no longer supported.

   For example:

   ```
   Unpublish-NAVApp -ServerInstance dynamicsnav110 -Name System -Version 11.0.12925.0
   ```

4. Open the Dynamics NAV Development Environment that matches the Dynamics NAV or Business Central version of the old database, and then connect to the old application database.

   For more information, see Open Databases.

5. In Object Designer, verify that all objects are compiled and no objects are locked.

   For more information about compiling objects, see Compiling Objects.

   If one or more objects are locked, the conversion process cannot update the database version number. As a result, the conversion does not complete. For more information, see Locking and Unlocking Objects.

6. On the **Tools** menu, choose **Build Server Application Objects**, and then choose the **Yes** button.

7. If any errors occur, they are shown in the **Error List** window. Make sure that you address all compilation errors before you continue.

8. Run the schema synchronization with validation to synchronize the database schema changes.

   For more information, see Synchronizing the Tenant Database and Application Database.

9. Upload the Business Central Partner license to the database.

   For more information, see Uploading a License File for a Specific Database.

   > **IMPORTANT**
   > The license that you upload must be a developer license. During the conversion, the development environment will convert the report objects that are stored in the old database to the RDL format.

10. (Multitenant only) Dismount tenants.

    Use the Dynamics NAV Server Administration tool or Dismount-NAVTenant cmdlet of the Dynamics NAV Administration Shell to dismount all tenants from the Dynamics NAV Server instance.

    ```
    Dismount-NAVTenant -ServerInstance <serverinstance> -Tenant <tenantID>
    ```

11. Stop the Dynamics NAV Server instance, and close the development environment.

    You can use the Dynamics NAV Server Administration tool or Set-NAVServerInstance cmdlet of the Dynamics NAV Administration Shell.

    To use the Set-NAVServerInstance cmdlet, run the following command:

    ```
    Set-NAVServerInstance –ServerInstance <ServerInstanceName> -Stop
    ```

12. Clear all records from the **dbo.Server Instance** and **dbo.Debugger Breakpoint** tables in the old application database in SQL Server.

    Using SQL Server Management Studio, open and clear the **dbo.Server Instance** and **dbo.Debugger Breakpoint** tables of the old database. For example, you can run the following SQL query:

    ```
    DELETE FROM [<My NAV Database Name>].[dbo].[Server Instance]
    DELETE FROM [<My NAV Database Name>].[dbo].[Debugger Breakpoint]
    ```

13. Close all to connections to the database.

This includes but is not limited to Dynamics NAV client tools and SQL Server Management Studio.

Task 3: Run Technical Upgrade on the Old Database

Next, you will convert the old database so that it can be used with Business Central.

> **TIP**
> If you want to write a script that helps you convert databases, you can use the Invoke-NAVDatabaseConversion function in the Dynamics NAV Development Shell.

> **IMPORTANT**
> Before you run the technical upgrade, delete any corrupt databases that are on the same SQL Server instance as the database that you intend to upgrade. Otherwise, when you run the database conversion, you will get the error "The Symbol Reference field on the Object Metadata table does not exist in the SQL Server table or view.".

1. If the database is on Azure SQL Database, add your user account to the **dbmanager** database role on the master database.

   This membership is only required for converting the database, and can be removed afterwards.

2. Install Business Central.

   Run the Business Central Setup, and install the following components as a minimum:

   - Server
   - SQL Server Database Components
   - Administration Tool
   - Dynamics NAV Development Environment

   > **IMPORTANT**
   > For a multitenant installation, configure the Business Central Server instance to be a multitenant instance.

3. Run the newly installed Dynamics NAV Development Environment as an administrator.

   - If the Dynamics NAV Development Environment is already connected to the old application database, a dialog box about converting the database appears. Go to the next step.
   - Otherwise, connect to the old application database that you prepared in the previous task, and then go to the next step.

   For more information, see Open Databases.

   > **IMPORTANT**
   > If you do not run the development environment as an administrator, you will get an error and the conversion will be stopped.

4. In the dialog box that appears, read the instructions about converting the database carefully because this action cannot be reversed. When you are ready, choose the **OK** button, and then choose the **OK** button to confirm that you want to convert the database.

   Dynamics NAV Development Environment will now convert the database. This includes an upgrade of

system tables and reports.

5. When you are notified that the conversion was successful, choose the **OK** button.
6. If the database references any assemblies (such as client control add-ins) that are not included on the Business Central installation media (DVD), then add the assemblies to the Add-ins folder on Business Central Server.

   For Business Central Server, the default path is the C:\Program Files\Microsoft Dynamics 365 Business Central\160\Service\Add-ins folder.
7. Connect a Business Central Server instance to the converted database.

   Use the Business Central Server Administration tool or the Set-NAVServerConfiguration cmdlet to connect a Business Central Server instance to the converted database.

   > **IMPORTANT**
   > The service account that is used by the Business Central Server instance must be a member of the **db_owner** role in the Dynamics NAV database on SQL Server or Azure SQL Database.

   For more information, see Connect a Server Instance to a Database and Giving the account necessary database privileges in SQL Server.
8. Go to the development environment, and set it to use the Business Central Server instance that connects to the database.

   For more information, see Change the Server Instance.
9. If upgrading from Dynamics NAV, import the codeunit 1 replacement text file you created earlier.
10. Compile all objects without table schema synchronizing (**Synchronize Schema** set to **Later**); you will do this later.

    For more information, see Compiling Objects.
11. Fix compilation errors.

    If any errors occur, they are shown in the **Error List** window. For help on resolving the errors, see the following:

    - Resolving Compilation Errors

    You can find all objects which did not compile in the **Object Designer** window, by setting a field filter on the **Compiled** field.
12. Recompile V2 extensions that you uninstalled previously.

    Use the Repair-NAVApp cmdlet of the Business Central Administration Shell to compile the published extensions to make sure they are work with the new platform.

    For example, you can run the following command to recompile all extensions:

    ```
    Get-NAVAppInfo -ServerInstance <ServerInstanceName> | Repair-NAVApp
    ```
13. (Multitenant only) Mount the tenant.

    Use the Mount-NAVTenant cmdlet.

```
Mount-NAVTenant -ServerInstance <serverinstance> -Tenant <tenantID> -DatabaseName
<tenantdatabasename>
```

`-AllowAppDatabaseWrite` is optional but is required for some post-upgrade tasks, like upgrading the control add-ins. When you are done upgrading, you can dismount and mount the tenant without this parameter as needed.

14. Run the schema synchronization with validation to complete the database conversion.

    For more information, see Synchronizing the Tenant Database and Application Database.

Task 4: Post-upgrade

1. Upgrade Javascript-based control add-ins to new versions.

   The Business Central Server installation includes new versions of Microsoft-provided Javascript-based control add-ins, such as the Business Chart control add-in. If you application is using any of these add-ins, you must upgrade them to the new versions as follow:

   a. Open the Business Central client.

   b. Search for and open the **Control Add-ins** page.

   c. Choose **Actions** > **Control Add-in Resource** > **Import**.

   d. Locate and select the .zip file for the control add-in and choose **Open**.

      The .zip files are located in the **Add-ins** folder of the Business Central Server installation. There is a sub-folder for each add-in. For example, the path to the Business Chart control add-in is

      ```
      C:\Program Files\Microsoft Dynamics 365 Business Central\140\Service\Add-
      ins\BusinessChart\Microsoft.Dynamics.Nav.Client.BusinessChart.zip
      ```

      .

   e. After you have imported all the new control add-in versions, restart Web Server instance.

2. (Single tenant only) Install the V2 extensions that you uninstalled previously.

   Use the Install-NAVApp cmdlet to compile the published extensions to make sure they are work with the new platform.

   For each V2 extension, run the following command to install it:

   ```
   Install-NAVApp -ServerInstance <ServerInstanceName> -Name <Name> -Version <N.N.N.N>
   ```

3. (Dynamics NAV 2017 or 2018 upgrade only) If the old database used first-party V1 extensions (publisher Microsoft), then you should publish and install the corresponding V2 extensions that are found on the installation media (DVD). For example, **Sales and Inventory Forecast** and **PayPal Payment Standards** were available as V1 extensions. Now, they are available as V2 extensions.

   a. Publish the system.app and test.app symbol files.

      If you installed the **AL Development Environment**, you can find the symbol files where you installed the environment, which by default is C:\Program Files (x86)\Microsoft Dynamics 365 Business Central\160. Otherwise, you can find the files in the **ModernDev** folder on the installation media.

      To publish the symbols, open the Business Central Administration Shell as an administrator, and run the following command for each of the symbol files:

```
Publish-NAVApp -ServerInstance <ServerInstanceName> -Path <SymbolFilePath> -PackageType
SymbolsOnly
```

b. Generate the application symbol references by using the finsql.exe file.

   Open a command prompt as an administrator, change to the directory where the `finsql.exe` file has been installed as part of Dynamics NAV Development Environment, and then run the following command:

```
finsql.exe Command=generatesymbolreference,  ServerName=<DatabaseServerName>\
<DatabaseInstance>, Database="<MyDatabaseName>"
```

   Replace values for the `Database` and `ServerName` settings to suit.

   If the application database contains test objects (ID 130000-139999), then make sure to exclude these objects when generating symbols. You can do this by using the `-Filter` parameter and running the command twice:

```
finsql.exe command=generatesymbolreference, ServerName=<DatabaseServerName>\
<DatabaseInstance>, Database="<MyDatabaseName>, filter="Object ID=1..129999"
```

```
finsql.exe command=generatesymbolreference, ServerName=<DatabaseServerName>\
<DatabaseInstance>, Database="<MyDatabaseName>, filter="Object ID=140000..1999999999"
```

   NOTE

   This command does not generate a file. It populates the **Object Metadata** table in the database.

   When you run the command, the console returns to an empty command prompt, and does not display or provide any indication about the status of the run. However, the finsql.exe may still be running in the background. It can take several minutes for the run to complete, and the symbols will not be generated until such time. You can see whether the finsql.exe is still running by using Task Manager and looking on the **Details** tab for **finsql.exe**.

   When the process ends, a file named **navcommandresult.txt** is saved to the Dynamics NAV Client connected to Business Central installation folder. If the command succeeded, the file will contain text like `[0] [06/12/17 14:36:17] The command completed successfully in '177' seconds.` If the command failed, another file named **naverrorlog.txt** will be generated. This file contains details about the error(s) that occurred.

   For more information about generation symbols, see Running C/SIDE and AL Side-by-Side.

c. Configure the **Enable loading application symbol references at server startup** (EnableSymbolLoadingAtServerStartup) setting on the Business Central Server instance, and restart the instance.

   For more information, see Configuring Business Central Server.

d. Publish the new V2 extension by running the Publish-NAVApp cmdlet for each extension:

```
Publish-NAVApp -ServerInstance <ServerInstanceName> -Path <ExtensionFileName>
```

e. Synchronize the schema with the database by running the Sync-NAVApp cmdlet for each extension:

```
Sync-NAVApp -ServerInstance <ServerInstanceName> -Name <Name> -Version <N.N.N.N>
```

f. For each V2 extension, run the following command to install it:

```
Install-NAVApp -ServerInstance <ServerInstanceName> -Name <Name> -Version <N.N.N.N>
```

4. (Dynamics NAV upgrade only) Transition the custom code in the old codeunit 1 to use the new system event implementation.

   For more information, see Transitioning from Codeunit 1.

5. (Microsoft Dynamics NAV 2016 upgrade only) Modify C/AL code to ensure that the **My Settings** page works properly in the Business Central Web client.

   For more information, see Resolving My Settings Page Implementation After a Database Conversion.

6. (Dynamics NAV upgrade only) Configure pages and reports included in the MenuSuite to be searchable in the Web client.

   The MenuSuite is no longer used to control whether a page or report can be found in the search feature of the Web client. This is now determined by specific properties on the page and report objects. For more information, see Making Pages and Reports Searchable in Web client After an Upgrade.

7. Build the object search index to make objects able to be searched from **Tell Me** in the client. If you completed step 6, you can skip this step.

   In the **Tools** menu of the Dynamics NAV Development Environment, select **Build Object Search Index**.

8. Upload the customer license to the converted database.

   For more information, see Uploading a License File for a Specific Database.

   You have now completed the conversion of the database to be accessed from Business Central. To test the converted database, you can connect it to the Business Central Server instance that is used by Dynamics NAV clients, and then open a client.

Database and Windows collations

Starting from SQL Server 2008, SQL Server collations are fully aligned with the collations in Windows Server. If you upgrade to Business Central from Microsoft Dynamics NAV 2009, the step to convert the database includes upgrading the database from using SQL collations to using Windows collation. This collation change provides users with the most up-to-date and linguistically accurate cultural sorting conventions. For more information, see Collation and Unicode Support.

Business Central Technical Upgrade Quick Reference

2/17/2021 • 2 minutes to read • Edit Online

This article provides an overview of the technical upgrade process for Business Central. For more detailed steps, see Technical Upgrade.

Prerequisites

STEP	MORE INFO	DONE
Convert custom V1 extensions to V2 extensions.	See...	
Transitioning from codeunit 1.	See...	

Prepare the old application database

STEP	MORE INFO	DONE
Backup the database(s).	See...	
(Single-tenant mode only) Uninstall all extensions. (Multitenant mode) Unintsall all V1 extensions.	See...	
(Optional) Unpublish unwanted extension versions .	See...	
Ensure all objects are compiled, unlocked, and tables are synchronized.	See...	
Upload a Business Central partner license.	See...	
(Multitenant mode only) Dismount the tenant	See...	
Stop the Dynamics NAV or old Business Central Server Instance		
Clear the **dbo.Server Instance** and **dbo.Debugger Breakpoint** tables in SQL Server.	See...	
Close all connections to the database.		

Run the technical upgrade

STEP	MORE INFO	DONE
Install Business Central.	See...	
Open the Dynamics NAV Development Environment as an administrator.		
Connect to and convert the application database.	See...	
Add custom control add-ins to the server instance.	See...	
Connect a Business Central Server instance to the converted application database.	See...	
Connect development environment to the server instance.	See...	
Import codeunit 1 replacement.	See...	
Compile all objects. **Important:** Choose to synchronize schema **later**.	See...	
Fix compilation errors.	See...	
Repair published V2 extensions.	See...	
(Multitenant mode only) Mount the tenant database.	See...	
Synchronize the tenant/database.	See...	

Post-upgrade tasks

STEP	MORE INFO	DONE
Upgrade Javascript-based control add-ins to new versions available on Business Central Server.	See...	
(Single-tenant mode only) Install the V2 extensions that were previously uninstalled.	See...	
If the old database used first-party V1 extensions, publish and install the V2 extensions that replace them. **Important** As part of this step, make sure to publish the system and test symbols and generate application symbols.	See...	

STEP	MORE INFO	DONE
Transition custom code from old codeunit 1 to management codeunits. (Dynamics NAV 2018 and earlier)	See...	
Configure pages and reports included in the MenuSuite to be searchable in the Web client (Dynamics NAV 2018 and earlier)	See...	
Build object search index.		
Upload the customer license.	See...	

Upgrading the Application Code in Dynamics 365 Business Central

2/17/2021 • 18 minutes to read • Edit Online

Typically, customers want all the customizations that have been implemented in their existing databases to be migrated to their new Business Central databases. Depending on the version of Business Central that a database is being upgraded from, the amount of code changes between the two versions can vary. To upgrade the application code, you must merge code from different versions of the application. This merge process is known as a *code upgrade* or *application upgrade*. You must upgrade the application before you upgrade the data.

> **IMPORTANT**
>
> Before you begin, read the article Important Information and Considerations for Before Upgrading. This article contains information about limitations and things that might require you to perform extra tasks before you upgrade, such as the use of extensions V1 and the deprecation of codeunit 1.

Application Upgrade Overview

During an upgrade, you have to first identify which changes you have to make, and then you'll have to upgrade the application objects and the application code, and finally, you might have to upgrade data so that it fits the new database schema.

For the application portion of the upgrade, you must analyze and process code changes by comparing and merging three separate versions of the database:

VERSION	DESCRIPTION
Original version	This is the baseline version of the solution that you want to upgrade, such as the original release of Business Central October 2018 or Microsoft Dynamics NAV 2018.
Modified version	This is the version that you want to upgrade, such as a customer's Business Central October 2018 or Microsoft Dynamics NAV 2018 database with customizations and add-on solutions.
Target version	This is the target of the merge process that you want to upgrade your application to, such as the standard version of the Business Central database.

When you merge the application objects from these three versions, you can import the result into a new Business Central database that then contains the upgraded application. At the end of the process, you export the merged Business Central objects from this database to a .fob file that you will use during the data upgrade.

Single-tenant and multitenant deployments

The process for upgrading the application code is basically the same for a single-tenant and multitenant deployment. However, there are some inherent differences because with a single-tenant deployment, the application and business data is included in the same database, while with a multitenant deployment application code is in a separate database than the business data (tenants). Here is the general process for each deployment type. In the tasks that follow this section, tasks are marked as *Single-tenant only* or *Multitenant only* where

applicable.

Single-tenant

1. Upgrade the application code.
2. Create a new database on the new platform.
3. Import the upgraded application to the new database.
4. Export the application to a .fob file.
5. Upgrade the data. Here you will import the .fob file.

Multitenant

1. Upgrade the application code.
2. Create a new database on the new platform.
3. Import the upgraded application to the new database.
4. Upgrade the data by mounting the tenant on the application database.

With a multitenant deployment, you will perform the steps in this article on the application database, that is, the database that contains the application object definitions.

Different ways of upgrading application code

You can use any tool or set of tools to help you compare and merge code. Dynamics NAV and Business Central include Windows PowerShell cmdlets and sample scripts that can help you upgrade your application. The cmdlets are available through the Microsoft Dynamics NAV Development Shell and Dynamics NAV Development Shell, or by importing the Microsoft.Dynamics.NAV.Model.Tools.psd1 module into the Windows PowerShell Integrated Scripting Environment (ISE). You can find the sample scripts on the product installation media, in the *WindowsPowerShellScripts\ApplicationMergeUtilities* folder. We recommend that you use these cmdlets and sample scripts because they can make it faster to merge most changes. For example, you can combine several steps in a command that uses a cmdlet such as the Merge-NAVApplicationObject. The sections in this article describe how you can use the Merge-NAVApplicationObject cmdlet and other Windows PowerShell cmdlets. For more information, see Comparing and Merging Application Object Source Files.

Task 1: Install the Prerequisites and Tools

To complete the tasks in this article, you will use various tools and components of the old Dynamics NAV version and Business Central. Ensure that you have the following installed:

Dynamics NAV to Business Central upgrade

PRODUCT	TOOL/COMPONENT
Old Dynamics NAV version	• Dynamics NAV Development Environment • Dynamics NAV Development Shell
Business Central	• Business Central Server • Dynamics NAV Development Shell(**DISCONTINUED AFTER:** Business Central Spring 2019) • Business Central Administration Shell • Dynamics NAV Development Environment (**DISCONTINUED AFTER:** Business Central Spring 2019)

Business Central to Business Central upgrade

PRODUCT	TOOL/COMPONENT
Old Business Central version	• Dynamics NAV Development Environment • Dynamics NAV Development Shell
New Business Central version	• Business Central Server • Dynamics NAV Development Shell(**DISCONTINUED AFTER:** Business Central Spring 2019) • Business Central Administration Shell • Dynamics NAV Development Environment(**DISCONTINUED AFTER:** Business Central Spring 2019)

Task 2: Prepare the Application Object Text Files

You must prepare text files that contain the application objects for the different application versions previously described (original, modified, and target). The text files provide the input for the application merge process.

There are three ways to export application objects to text files:

- Use the Dynamics NAV Development Environment version that matches the application database version.

  For more information see To export objects by using the development environment UI.

- Use the finsql.exe that matches the application database version to run the ExportObjects command.

  For more information, see To export objects by running finsql.exe with the ExportObjects command .

- Use the Microsoft Dynamics NAV Development Shell or Dynamics NAV Development Shell version that matches the application database version.

  This is the way that is described in the tasks of this article. Note that the Microsoft Dynamics NAV Development Shell is not available for Microsoft Dynamics NAV 2013 and Microsoft Dynamics NAV 2013 R2. For these versions, you must use development environment or finsql.exe.

Create the application text files

> **NOTE**
> Be sure to upload a valid developer license to the database before doing the following steps.

1. Create four folders on the computer, and name them as follows:

   - ORIGINAL

     This folder will be used to store the application object text file(s) from the baseline version, such as the original release of Business Central October 2018, Microsoft Dynamics NAV 2018, or Microsoft Dynamics NAV 2017.

   - MODIFIED

     This folder will be used to store the application object text file(s) from the modified version, such as the customer's database.

   - TARGET

     This folder will be used to store the application object text file(s) from the latest Business Central version.

- **RESULT**

  This folder will be used to store the application object text file(s) that are the result of the application merge. It will also contain zero or more .CONFLICT files that describe conflicting code.

2. Export all application objects except system tables from the original version of the old application database, such as the original Microsoft Dynamics NAV 2018 database.

   Do not export system tables, which have the IDs in the 2000000000 range. Name the file **OldBaseVersion.txt**, and then save the file in the **ORIGINAL** folder that you created earlier.

   For example, start the Microsoft Dynamics NAV Development Shell version that matches the database version, and run the **Export-NAVApplicationObject** function as follows:

   ```
   Export-NAVApplicationObject –DatabaseServer MyServer –DatabaseName "Demo Database NAV (11-0)" –Path
   C:\Upgrade\ORIGINAL\OldBaseVersion.txt -Filter 'Id=1..1999999999'
   ```

3. Export all application objects, except system tables, from the old modified application database, such as the customer's customized Microsoft Dynamics NAV 2018 database.

   Name the file **OldCustomVersion.txt**, and then save the file in the **MODIFIED** folder that you created earlier.

   For example (using the Microsoft Dynamics NAV Development Shell version that matches the database version), if the customer's database is called *MyCustomerNAV2016Database*, you can run the following command:

   ```
   Export-NAVApplicationObject –DatabaseServer MyServer –DatabaseName "MyCustomerNAV2018Database" –Path
   C:\Upgrade\MODIFIED\OldCUSTOMVersion.txt -Filter 'Id=1..1999999999'
   ```

   > **TIP**
   > In some cases, existing customizations might be irrelevant after the upgrade because they correspond to new functionality in Business Central.

4. Export all application objects, except system tables, from the new base version, such as the original Business Central database.

   Name the file **NewBaseVersion.txt**, and then save the file in the **TARGET** folder that you created earlier.

   For example, using the Dynamics NAV Development Shell for Business Central, run the following command:

   ```
   Export-NAVApplicationObject –DatabaseServer MyServer –DatabaseName "Demo Database BC (14-0)" –Path
   C:\Upgrade\Target\NewBaseVersion.txt -Filter 'Id=1..1999999999'
   ```

Optionally, you can use the Split-NAVApplicationObjectFile cmdlet to split each text file into separate text files for each application object. This can make it easier to keep track of the process. The end result at this stage is three folders with one or more text files that contain the three sets of application objects that you want to merge.

Task 3: Merge Versions

You now merge the three sets of application objects to create the application for the new database. This section illustrates how to do this by using the Merge-NAVApplicationObject cmdlet.

The product installation media contains sample scripts that provide examples of how you can use the Merge-NAVApplicationObject cmdlet to merge application objects. For more information, see Merge Application Changes.

> **NOTE**
> In certain scenarios, you can choose to use the Compare-NAVApplicationObject cmdlet to identify the changes between the existing customized application and the new application. You can then choose to use the Update-NAVApplicationObject cmdlet to apply all or some of the changes to the new version. For more information, see Compare and Update Application Object Source Files. However, we recommend that you use the Merge-NAVApplicationObject cmdlet in most cases.

Merge the application object versions into text files

1. Run the new Dynamics NAV Development Shell as an administrator.
2. At the command prompt, change to the directory that contains the four folders that contain the application text files, and then run the following command:

   ```
   Merge-NAVApplicationObject -OriginalPath ORIGINAL -TargetPath TARGET -ModifiedPath MODIFIED -
   ResultPath RESULT
   ```

   For example:

   ```
   Merge-NAVApplicationObject -OriginalPath C:\Upgrade\ORIGINAL -TargetPath C:\Upgrade\TARGET -
   ModifiedPath C:\Upgrade\MODIFIED -ResultPath C:\Upgrade\RESULT
   ```

Depending on the number of objects that you are merging and the number of differences found, this can take a few seconds, a few minutes, or longer. When the cmdlet completes, the result of the merge is shown, including a description of any application objects with conflicting code. The **RESULT** folder will contain a text file (.TXT) for each merged application object and possibly one or more .CONFLICT files that describe the code conflicts that occurred during the merge.

At this point, you can either go to Task 4 to analyze and eventually resolve the conflicts, or you can go directly to Task 5 to import the merged objects as-is from the **RESULT** folder to the new Business Central database.

Task 4: Handling Conflicts

Depending on the application that you are upgrading, you can choose to analyze and fix the conflicting code before you import the merged objects into the Dynamics NAV Development Environment for Business Central. The conflicts are shown in the merged text files but are also identified in .CONFLICT files in the subfolders of the **RESULT** folder. The subfolders **ConflictOriginal**, **ConflictModified**, and **ConflictTarget** folders then contain copies of the source files from the versions that have conflicting code.

You can analyze the conflicts in any tool, make the relevant changes, and then run the merge operation again. For more information, see Handling Merge Conflicts. Alternatively, you can go directly to task 5 to import the merged files into the Dynamics NAV Development Environment, and resolve the conflicts there.

Task 5: Import and Compile Merged Objects in an Empty Database

After you have completed the merge, you import the new merged application objects as text files into a new (empty) Business Central database, and then compile all objects. You must resolve any compilation errors before you can continue. The text files include successfully merged code, and code that is partially merged. You can import the partially merged objects into the Business Central development environment and resolve the

conflicts there.

1. Create a new Business Central database for the new upgraded application. The database should be empty, except for the system tables.

   For example, give the database the name *My Upgraded App*. For more information, see Creating and Altering Databases.

   > **IMPORTANT**
   > You must set the collation of the new database to match the collation of the old application database. To see the collation of the old database, open it in the old Dynamics NAV Development Environment version, then choose **File** > **Database** > **Alter** > **Collation**.

2. Make sure the database includes a valid Business Central license.

   For more information, see Uploading a License File for a Specific Database

3. Import the new merged application object text files (.TXT) from the **Result** folder into the new database.

   There are three ways to import the files:

   - Use the Dynamics NAV Development Environment for Business Central.

     For more information see To import objects by using the development environment UI.

   - Use the finsql.exe to run the ImportObjects command.

     For more information, see To import objects by running finsql.exe with the ImportObjects command .

   - Use the Dynamics NAV Development Shell (or Microsoft.Dynamics.NAV.Model.Tools.psd1 module).

     The shell includes the **Join-NAVApplicationObjectFile** cmdlet and **Import-NAVApplicationObject** function. The **Join-NAVApplicationObjectFile** cmdlet combines multiple application object text files into one text file. The **Import-NAVApplicationObject** function runs the ImportObjects command to import an object file.

     This means that you can run a command similar to following to create a single text file from the merge application text files in the **Result** folder:

     ```
     Join-NAVApplicationObjectFile –Source C:\Upgrade\RESULT\*.txt -Destination C:\Upgrade\all-merged.txt
     ```

     Then, you can run this command to import the text file:

     ```
     Import-NAVApplicationObject –DatabaseServer MyServer –DatabaseName "My Upgraded App" –Path C:\Upgrade\all-merged.txt
     ```

4. Connect the new Business Central Server instance to the database.

   You can do this with the Business Central Server Administration tool or the Set-NAVServerConfiguration cmdlet in the Dynamics NAV Administration Shell. In addition, you must add the service account that is used by the Business Central Server instance as a member of the **db_owner** role in the Business Central database on SQL Server.

   For more information about how to do this using the Business Central Server Administration tool, see How to: Connect a Microsoft Dynamics NAV Server Instance to a Database and Giving the account

necessary database privileges in SQL Server.

5. Compile all the newly imported objects. Choose to synchronize **later**.

   You can use the Dynamics NAV Development Environment or finsql.exe. For more information, see Compiling Objects.

   If you use the Dynamics NAV Development Environment, you will first have to set it to use the Business Central Server instance that connects to the database. For more information, see Change the Server Instance Used in C/SIDE.

   When you compile the objects, an error is thrown for each code conflict, and you can use the tools that are available in the development environment to resolve the conflicts.

Task 6: Check/change the application family and version

The application and tenant databases are tagged with `Family` and `Version`. To perform the data upgrade, the `Family` on the application must match that tenant's `Family`. The `Version` of the application must be greater than or equal to the tenant's `Version`. The easiest way to ensure that `Family` and `Version` of the upgraded application are compatible for data upgrade is to set `Family` to the same value as the old application, and set the `Version` to a higher value than the old application.

To get the `Family` and `Version`, use the Get-NAVApplication cmdlet, for example:

```
Get-NAVApplication -ServerInstance BC
```

To set the `Family` and `Version`, use the Set-NAVApplication cmdlet. For example, to set the family, run the following command:

```
Set-NAVApplication -ServerInstance <ServerInstanceName> -ApplicationFamily <Family>
```

To increase the version by 1, run the following command:

```
Set-NAVApplication -ServerInstance <ServerInstanceName> -IncrementApplicationVersion
```

Or, to specify change to another version, run the following command:

```
Set-NAVApplication -ServerInstance <ServerInstanceName> -ApplicationVersion <N.N.N.N> -Force
```

Task 7: (Dynamics NAV upgrade only) Configure pages and reports to be searchable

The MenuSuite is no longer used to control whether a page or report can be found in the search feature of the Web client. This is now determined by specific properties on the page and report objects. This task is not required at this point, and can be done after the data upgrade as well.

For more information, see Making Pages and Reports Searchable After an Upgrade.

Task 8: Build object search index

Build the object search index to make objects able to be searched from **Tell Me** in the client. If you completed step 7, you can skip this step.

In the **Tools** menu of the Dynamics NAV Development Environment, select **Build Object Search Index**.

For more information, see Making Pages and Reports Searchable After an Upgrade.

Task 9. (Dynamics NAV upgrade only) Transition the custom code from old codeunit 1 to use the new implementation

Because codeunit 1 has been deprecated in Business Central, you must move any custom logic that was included in the old codeunit 1 into the management codeunits and methods described in the article Transitioning from Codeunit 1.

You now have a new database with a fully upgraded application. For a multitenant deployment, you can start the data upgrade. For this, you will use the new server instance that connects to the upgraded application database. See Upgrading the Data.

Task 10: (Single-tenant mode only) Export all objects

With a single-tenant deployment, export all objects of the new database to a .fob type file, such as **objects.fob** file. You will use this .fob file as part of the data upgrade process. The export must include customized objects, upgraded reports, and all other Business Central objects.

As with exporting objects in Task 1, you can use either the development environment, finsql.exe, or Dynamics NAV Development Shell.

With the Dynamics NAV Development Shell, you can run a command that is similar to the following:

```
Export-NAVApplicationObject c:\Upgrade\objects.fob -DatabaseName "My Upgraded App" -DatabaseServer
[server_name]\[database_instance]
```

This completes the upgrade of the application code for single-tenant deployment. Next, you must upgrade the data in the database. See Upgrading the Data.

Task 11: (Multitenant mode only) Import the upgrade toolkit objects

The upgrade toolkit includes upgrade codeunits for handling the data upgrade.

For W1 versions, you can find the default upgrade toolkit objects in the **UpgradeToolKit\Data Conversion Tools** folder on the Business Central installation media (DVD). Choose the FOB that matches the Dynamics NAV version from which you are upgrading:

FROM	TO BUSINESS CENTRAL APRIL 2019	TO BUSINESS CENTRAL OCTOBER 2018
Microsoft Dynamics NAV 2015	Upgrade80014x.FOB	Upgrade800130.FOB
Microsoft Dynamics NAV 2016	Upgrade90014x.FOB	Upgrade900130.FOB
Microsoft Dynamics NAV 2017	Upgrade100014x.FOB	Upgrade1000130.FOB
Microsoft Dynamics NAV 2018	Upgrade110014x.FOB	Upgrade1100130.FOB
Business Central Fall 2018	Upgrade13x14x.FOB	Not applicable

For local versions, you will find the upgrade toolkit objects in the **UpgradeToolKit\Local Objects** folder. The files follow the same naming convention except they include the 2-letter local version, such as **Upgrade110014x.DK.fob** for Denmark or **Upgrade110014x.DE.fob** for Germany.

For information about importing objects, see Importing Objects.

Task 12: (Multitenant mode only) Publish extensions

1. Unpublish the existing system, test, and application symbols by using the Unpublish-NAVAPP cmdlet:

```
Unpublish-NAVApp -ServerInstance <ServerInstanceName> -Name <name> -Version <n.n.n.n>
```

2. Publish the system and test symbols.

   Symbols are a prerequisite for extensions. If you installed the **AL Development Environment**, you can find the symbol files where your installed the environment, which by default is C:\Program Files (x86)\Microsoft Dynamics 365 Business Central\160. Otherwise, you can find the files in the **ModernDev** folder on the installation media.

   To publish the symbols, open the Business Central Administration Shell as an administrator, and run the following command for each of the symbol files:

```
Publish-NAVApp -ServerInstance <ServerInstanceName> -Path <SymbolFilePath> -PackageType SymbolsOnly
```

3. Generate the application symbol references by using the finsql.exe file as follows:

   a. Make sure that **Enable loading application symbol references at server startup** (EnableSymbolLoadingAtServerStartup) is set on the Business Central Server instance.

      For more information, see Configuring Dynamics NAV Server.

   b. Open a command prompt as an administrator, change to the directory where the `finsql.exe` file has been installed as part of Dynamics NAV Development Environment, and then run the following command:

```
finsql.exe Command=generatesymbolreference, Database="<MyDatabaseName>", ServerName=
<DatabaseServerName>\<DatabaseInstance>
```

      Replace values for the `Database` and `ServerName` settings to suit.

      If the application database contains test objects (ID 130000-139999), then make sure to exclude these objects when generating symbols. You can do this by using the `-Filter` parameter and running the command twice:

```
finsql.exe command=generatesymbolreference, ServerName=<DatabaseServerName>\
<DatabaseInstance>, Database=<MyDatabaseName>, filter="Object ID=1..129999"
```

```
finsql.exe command=generatesymbolreference, ServerName=<DatabaseServerName>\
<DatabaseInstance>, Database=<MyDatabaseName>, filter="Object ID=140000..1999999999"
```

      > **NOTE**
      > This command does not generate a file. It populates the **Object Metadata** table in the database.

   c. When you run the command, the console returns to an empty command prompt, and does not display or provide any indication about the status of the run. However, the finsql.exe may still be

running in the background. It can take several minutes for the run to complete, and the symbols will not be generated until such time. You can see whether the finsql.exe is still running by using Task Manager and looking on the **Details** tab for **finsql.exe**.

When the process ends, a file named **navcommandresult.txt** is saved to the Dynamics NAV Client connected to Business Central installation folder. If the command succeeded, the file will contain text like `[0] [06/12/17 14:36:17] The command completed successfully in '177' seconds.` If the command failed, another file named **naverrorlog.txt** will be generated. This file contains details about the error(s) that occurred.

For more information about generation symbols, see Running C/SIDE and AL Side-by-Side.

4. Publish new versions of the Microsoft extensions.

   The Business Central installation media (DVD) includes several new versions of Microsoft extensions (that is, extensions that have **Microsoft** as the publisher). If your old deployment uses these extensions, you have to upgrade the old versions to the new versions.

   IMPORTANT

   For Denmark (DK) and German (DE) versions. Some of the local functionality has been moved from the base application to extensions.

   If you are upgrading from a Denmark (DK) version of Dynamics NAV 2017 or earlier, you must publish and install the following extensions to get the local functionality:

NAME	EXTENSION PACKAGE
OIOUBL	OIOUBL.app
Payroll Data Import Definitions (DK)	ImportDKPayroll.app
Payment and Reconciliation Formats (DK)	FIK.app
Tax File Formats (DK)	VATReportsDK.app

   If you are upgrading from a German (DE) version of Dynamics NAV or Business Central October 2018 (Cumulative Update 2 or earlier), you must publish and install the following extensions to get the local functionality:

NAME	EXTENSION PACKAGE
ELSTER VAT Localization for Germany	Elster.app

   The new versions are found in the `\Extensions` folder of the installation media.

   To publish the new extension version, run the Publish-NAVApp cmdlet:

   ```
   Publish-NAVApp -ServerInstance <ServerInstanceName> -Path <ExtensionFileName>
   ```

Upgrading the Data to Business Central: Single-Tenant Deployment

2/17/2021 • 20 minutes to read • Edit Online

See print-friendly quick reference

This article describes the tasks required for upgrading the data of a Dynamics NAV or Business Central database to a Business Central major version or cumulative update.

This article pertains to a single-tenant deployment. For upgrade instructions for a multitenant deployment, see Upgrading the Data: Multitenant Deployment.

About Data Upgrade

You use data conversion tools provided with Business Central to convert the old data with the old version's table and field structure, so that it functions together with the new version's table and field structure. Mainly, only table objects and table data are modified during the data upgrade process. Other objects, such as pages, reports, codeunits, and XMLports are upgraded as part of the application code upgrade process.

The data upgrade process described in this article leads you through the database conversion (technical upgrade) and then the upgrade of the actual data, which is achieved by using the upgrade toolkit/upgrade codeunits.

Prerequisites

Before you start the upgrade tasks, make sure you meet the following prerequisites:

1. Your computer uses the same codepage as the data that will be upgraded.

   If you use conflicting codepages, some characters will not display in captions, and you might not be able to access the upgraded database. This is because Dynamics NAV must remove incorrect metadata characters to complete the data upgrade. In this case, after upgrade, you must open the database in the development environment on a computer with the relevant codepage and compile all objects. This adds the missing characters again.

   Optionally, you can export the captions before the upgrade. For more information, see How to: Add Translated Strings for Conflicting Text Encoding Formats.

2. (Upgrading from Dynamics NAV only) Custom V1 extensions used in the old deployment have been converted to V2 extensions.

   For more information, see Converting Extensions V1 to Extensions V2.

3. You have upgraded the application code, and have the FOB files that contain the upgraded application code.

   For more information about upgrading the application code, see Upgrading the Application Code.

4. You have the upgrade toolkit FOB files for the version that you are upgrading from.

   The upgrade toolkit includes upgrade codeunits for handling the data upgrade. The upgrade toolkit can be in the same FOB file as the application code or in a separate FOB file.

   For W1 versions, you can find the default upgrade toolkit objects in the **UpgradeToolKit\Data**

Conversion Tools folder on the Business Central installation media (DVD). Choose the FOB that matches the Dynamics NAV version from which you are upgrading:

FROM	TO BUSINESS CENTRAL APRIL 2019	TO BUSINESS CENTRAL OCTOBER 2018
Microsoft Dynamics NAV 2015	Upgrade80014x.FOB	Upgrade800130.FOB
Microsoft Dynamics NAV 2016	Upgrade90014x.FOB	Upgrade900130.FOB
Microsoft Dynamics NAV 2017	Upgrade100014x.FOB	Upgrade1000130.FOB
Microsoft Dynamics NAV 2018	Upgrade110014x.FOB	Upgrade1100130.FOB
Business Central Fall 2018	Upgrade13x14x.FOB	Not applicable

For local versions, you will find the upgrade toolkit objects in the **UpgradeToolKit\Local Objects** folder. The files follow the same naming convention except they include the 2-letter local version, such as **Upgrade110014x.DK.fob** for Denmark or **Upgrade110014x.DE.fob** for Germany.

5. You have exported the customized permission sets (except SUPER) and permissions from the old database that you want to reuse in the upgraded database.

   - When upgrading from Dynamics NAV

     To export permission sets and permissions, you run running XMLPort 9171 and 9172.

     It is important that you exclude the SUPER permission set when running XMLPort 9171. You can do this by adding the filter `Role ID is <>SUPER`.

     For more information, see Exporting and Importing Permission Sets and Permissions.

   - When upgrading from an earlier version of Business Central

     In the client, search for and open the **Permission Sets** page, select the user-defined permission sets that you want to keep, and then choose **Export Permission Sets**. This action runs XMLPort **9173 Export Permission Sets**.

6. If the old deployment uses data encryption, you have exported the encryption key file that it used for the data encryption.

   For more information, see How to: Export and Import Encryption Keys.

7. (Optional) Make a copy of the configuration file (web.config or navsettings.json) for all Business Central Web Server instances in the old deployment.

8. Business Central has been installed.

   As a minimum, you must install the following components:

   - Server
   - SQL Server Components
   - Business Central Web Server components
   - Dynamics NAV Development Environment(**DISCONTINUED AFTER:** Business Central Spring 2019).
   - AL Development Environment
   - (optionally) Business Central Server Administration tool

   For more information, see Installing Business Central Using Setup.

> **NOTE**
> If the old Dynamics NAV application uses Payment Services for Microsoft Dynamics ERP, be aware that this was discontinued in Microsoft Dynamics NAV 2017. This means that most of the objects that are associated with this feature will be deleted during the upgrade. Some objects you will have to manually delete.

Task 1: Create full SQL backup of old database

Create a full backup of the old database in the SQL Server. Alternatively, you can make a copy of the old database and perform the upgrade tasks on the copy.

For more information, see Create a Full Database Backup (SQL Server).

Task 2 Uninstall all extensions in old database

Open the Dynamics NAV Administration Shell or Business Central Administration Shell that matches to old database, and run these commands:

1. To get a list of the extensions that are installed, run this command:

   ```
   Get-NAVAppInfo -ServerInstance <ServerInstanceName> -Tenant default
   ```

   Replace `<ServerInstanceName>` with the name of the Dynamics NAV Server instance that the database connects to.

2. For each extension, run this command to uninstall it:

   ```
   Uninstall-NAVApp -ServerInstance <ServerInstanceName> -Name <Name> -Version <N.N.N.N>
   ```

   Replace `<ServerInstanceName>` with the name of the Dynamics NAV Server instance that the database connects to.

   Replace `<Name>` and `<N.N.N.N>` with the name and version of the Extension V1 as it appeared in the previous step.

   Alternately, to remove them all at once, you can run this command:

   ```
   Get-NAVAppInfo -ServerInstance <ServerInstanceName> -Tenant default | % { Uninstall-NAVApp -
   ServerInstance <ServerInstanceName> -Name $_.Name -Version $_.Version }
   ```

Task 3: Upload Business Central partner license to old database

By using the Dynamics NAV Development Environment that matches the old database, upload the Business Central license to the database.

For more information, see Uploading a License File for a Specific Database.

Task 4: Delete all objects except tables in old database

In the development environment version that matches the database, open the old database, open Object Designer, select all objects except tables, and then choose **Delete**.

You can also use the DeleteObjects command of the finsql.exe.

Task 5: Clear server instance and debugger breakpoint records in old database

Clear all records from the **dbo.Server Instance** and **dbo.Debugger Breakpoint** tables in the database in SQL Server.

1. Make sure that you stop the old server instance, and close any tools that connect to the database, such as the Dynamics NAV Administration Tool and development environment.
2. Using SQL Server Management Studio, open and clear the **dbo.Server Instance** and **dbo.Debugger Breakpoint** tables of the old database. For example, you can run the following SQL query:

```
DELETE FROM [<My NAV Database Name>].[dbo].[Server Instance]
DELETE FROM [<My NAV Database Name>].[dbo].[Debugger Breakpoint]
```

Task 6: Convert old database to Business Central

If the database is on Azure SQL Database, you must first add your user account to the **dbmanager** database role on master database. This membership is only required for converting the database, and can be removed afterwards.

To convert the old database to the Business Central format, run the new Dynamics NAV Development Environment for Business Central, open the old database, and follow the conversion instructions.

If you do not run the development environment as an administrator, you will get an error and the conversion will be stopped.

For more information about how to open a database, see Open a Database.

> **IMPORTANT**
> Do not run schema synchronization at this time. Choose to run it **later**.

Task 7: Import upgraded application objects to converted database

Using Dynamics NAV Development Environment for Business Central, import the application objects that you want in the database. This includes the application objects FOB file (from the application code upgrade) and the upgrade toolkit objects FOB file.

1. Import the application objects FOB file first, and then import the upgrade toolkit FOB file.

   For more information, see Importing Objects.

2. **IMPORTANT** When prompted about table synchronization, set the **Synchronize Schema** option to **Later**.

3. When you import the FOB file, if you experience metadata conflicts, the **Import Worksheet** windows appears.

   Review the Worksheet page. For more information, see Import Worksheet.

   Choose **Replace All**, and then **OK** to continue.

Task 8: Connect a Business Central Server instance to converted database

You use the Business Central Server Administration tool or Set-NAVServerConfiguration cmdlet in the Business Central Administration Shell to connect a Business Central Server instance to the converted database.

The service account that is used by the Business Central Server instance must be a member of the **db_owner** role in the Business Central database on SQL Server or Azure SQL Database.

For more information, see Connecting a Server Instance to a Database and Giving the account necessary database privileges in SQL Server.

> **IMPORTANT**
> When upgrading a large database, you should increase the **SQL Command Timeout** setting for the Business Central Server instance, to avoid timeouts during schema synchronization. The default setting is 30 minutes.

Task 9: Compile all objects in converted database

1. In the Dynamics NAV Development Environment, set it to use the server instance that connects to the database.

   For more information, see Changing the Server Instance.

2. Use the Dynamics NAV Development Environment or finsql.exe to compile all objects. This includes the imported application objects, data tables, and system tables.

   > **IMPORTANT**
   > Choose to run schema synchronization later. For example, in Object Designer, choose **Tools**, choose **Compile**, set the **Synchronize Schema** option to **Later**, and then choose **OK**. For more information, see Compiling Objects.

3. (Upgrade from Microsoft Dynamics NAV 2016 and earlier only) If you get errors on the following table objects, use the Object Designer to delete the objects because they are no longer used.

   - Table 470 Job Queue (replaced by the Task Scheduler)
   - Table 824 DO Payment Connection Details
   - Table 825 DO Payment Connection Setup
   - Table 827 DO Payment Credit Card
   - Table 828 DO Payment Credit Card Number
   - Table 829 DO Payment Trans. Log Entry
   - Table 1510 Notification Template

   > **IMPORTANT**
   > When you delete a table object, in the **Delete** confirmation dialog box that appears, set the **Synchronize Schema** option to **Force**.
   >
   > In this step, it's very important that you do not use the **Sync. Schema For All Tables** option from the **Tools** menu.

4. (Upgrade from Microsoft Dynamics NAV 2016 and earlier only) If the old database includes test runner codeunits, you will get errors on these codeunits that the OnBeforeTestRun and OnAfterTestRun trigger signatures are not valid. To fix these issues, you change the signature of the OnBeforeTestRun and OnAfterTestRun triggers to include the *TestPermission* parameter.

   For more information, see Resolving OnBeforeTestRun and OnAfterTestRun Trigger Errors When

Converting a Database.

The triggers for codeunit **130400 CAL Test Runner** and **130402 CAL Command Line Test Runner** will be updated for you during the data upgrade.

Task 10: (Upgrade from Dynamics NAV 2018 or Business Central Fall 2018 only) Increase the application version of converted database

You must increase the application version that is assigned to the database.

Use the Set-NAVApplication cmdlet of the Business Central Administration Shell to increase the application version number of the database from its current version.

To see the current version, use the following command:

```
Get-NAVApplication -ServerInstance <ServerInstanceName>
```

To increase the version by 1, run the following command:

```
Set-NAVApplication -ServerInstance <ServerInstanceName> -IncrementApplicationVersion
```

Or, to specify change to another version, run the following command:

```
Set-NAVApplication -ServerInstance <ServerInstanceName> -ApplicationVersion <N.N.N.N> -Force
```

For example, if the old version was `11.0.24279.0`, then you could change the version to `14.0.24279.0`.

Task 11: Run the schema synchronization on converted database

Synchronize the database schema with validation.

For example, run the Sync-NAVTenant cmdlet from the Business Central Administration Shell.

```
Sync-NAVTenant -ServerInstance <ServerInstanceName>
```

When completed, the tenant (database) should have the status **OperationalDataUpgradePending**. To verify this, run the following cmdlet:

```
Get-NAVTenant -ServerInstance <ServerInstanceName> -tenant default
```

For more information, see Synchronizing the Tenant Database and Application Database.

Task 12: Run data upgrade on converted database

A data upgrade runs the upgrade toolkit objects, such as upgrade codeunits and upgrade tables, to migrate business data from the old table structure to the new table structure. You can start the data upgrade from the Dynamics NAV Development Environment or Business Central Administration Shell.

1. Open the Business Central Administration Shell as an administrator, and then run Start-NavDataUpgrade cmdlet as follows:

```
Start-NavDataUpgrade -ServerInstance <ServerInstanceName> -FunctionExecutionMode Serial -
ContinueOnError
```

Replace `<ServerInstanceName>` with the name of the Business Central Server instance that is connected to the database.

> **NOTE**
> In the last phase of data upgrade, all companies will be initialized by running codeunit 2 Company Initialization. This is done automatically. If you want to skip company initialization, then use the `Start-NavDataUpgrade` with the `-SkipCompanyIntitialization` parameter.

To view the progress of the data upgrade, you can run Get-NavDataUpgrade cmdlet with the `-Progress` switch.

The data upgrade process runs `CheckPreconditions` and `Upgrade` functions in the upgrade codeunits. If any of the preconditions are not met or an upgrade function fails, you must correct the error and resume the data upgrade process. If CheckPreconditions and Upgrade functions are executed successfully, codeunit 2 is automatically run to initialize all companies in the database unless you set the `-SkipCompanyIntitialization` parameter.

2. Check for and resolve upgrade errors.

   Run the following command to get a list of any errors that have occurred:

   ```
   Get-NAVDataUpgrade -ServerInstance <ServerInstanceName> -ErrorOnly
   ```

   Resolve the errors before going to the next task.

Task 13: Upgrade Javascript-based control add-ins to new versions

The Business Central Server installation includes new versions of Microsoft-provided Javascript-based control add-ins, such as the Business Chart control add-in. If you application is using any of these add-ins, you must upgrade them to the new versions as follow:

1. Open the Business Central client.

   If the application uses the Business Chart control add-in, you will get an error about **High Charts**. Upgrading the Business Chart control add-in will clear this error.

2. Search for and open the **Control Add-ins** page.

   The page lists all the registered control add-ins.

3. Choose **Actions** > **Control Add-in Resource** > **Import**.

4. Locate and select the .zip file for the control add-in and choose **Open**.

   The .zip files are located in the **Add-ins** folder of the Business Central Server installation. There is a sub-folder for each add-in. For example, the path to the Business Chart control add-in is

   ```
   C:\Program Files\Microsoft Dynamics 365 Business Central\140\Service\Add-
   ins\BusinessChart\Microsoft.Dynamics.Nav.Client.BusinessChart.zip
   ```

   .

5. After you have imported all the new control add-in versions, restart Web Server instance.

Task 14: Publish and generate symbols for extensions

Complete this task if you are upgrading one of the following:

- Microsoft Dynamics NAV 2018 deployment that uses V2 extensions.
- Denmark (DK) version of Microsoft Dynamics NAV 2017 or earlier
- German (DE) version of Dynamics NAV or Business Central October 2018 (Cumulative Update 2 or earlier)

In this task, you will publish and generate symbols that are required for using V2 extensions. Symbols are the application programming interface between AL code and C/AL code. Symbols enable the ability to reference C/AL objects from AL objects. Symbols are provided as an extension package, and are published to the server instance, but not installed on tenants. There are three types of symbols: system, application, and test. System symbols contained references to the platform system objects. The application symbols contained references to the business application objects. The test symbols contained references to the test libraries used by Microsoft extensions.

1. To get list of the extensions currently published symbols, run the following command from the Business Central Administration Shell:

   ```
   Get-NAVAppinfo -ServerInstance <ServerInstanceName> -SymbolsOnly
   ```

2. Unpublish the existing system, test, and application symbols by using the Unpublish-NAVAPP cmdlet:

   ```
   Unpublish-NAVApp -ServerInstance <ServerInstanceName> -Name <name> -Version <n.n.n.n>
   ```

3. Publish the system.app and test.app symbol files.

   If you installed the **AL Development Environment**, you can find the symbol files where your installed the environment, which by default is C:\Program Files (x86)\Microsoft Dynamics 365 Business Central\160. Otherwise, you can find the files in the **ModernDev** folder on the installation media.

   To publish the symbols, open the Business Central Administration Shell as an administrator, and run the following command for each of the symbol files:

   ```
   Publish-NAVApp -ServerInstance <ServerInstanceName> -Path <SymbolFilePath> -PackageType SymbolsOnly
   ```

4. Generate the application symbol references by using the finsql.exe file as follows:

   a. Make sure that **Enable loading application symbol references at server startup** (EnableSymbolLoadingAtServerStartup) is set on the Business Central Server instance.

      For more information, see Configuring Business Central Server.

   b. Open a command prompt as an administrator, change to the directory where the `finsql.exe` file has been installed as part of Dynamics NAV Development Environment, and then run the following command:

      ```
      finsql.exe Command=generatesymbolreference, Database="<MyDatabaseName>", ServerName=
      <DatabaseServerName>\<DatabaseInstance>
      ```

      Replace values for the `Database` and `ServerName` settings to suit.

      If the application database contains test objects (ID 130000-139999), then make sure to exclude these objects when generating symbols. You can do this by using the `-Filter` parameter and

running the command twice:

```
finsql.exe command=generatesymbolreference, ServerName=<DatabaseServerName>\
<DatabaseInstance>, Database="<MyDatabaseName>", filter="Object ID=1..129999"
```

```
finsql.exe command=generatesymbolreference, ServerName=<DatabaseServerName>\
<DatabaseInstance>, Database="<MyDatabaseName>", filter="Object ID=140000..1999999999"
```

> **NOTE**
> This command does not generate a file. It populates the **Object Metadata** table in the database.

c. When you run the command, the console returns to an empty command prompt, and does not display or provide any indication about the status of the run. However, the finsql.exe may still be running in the background. It can take several minutes for the run to complete, and the symbols will not be generated until such time. You can see whether the finsql.exe is still running by using Task Manager and looking on the **Details** tab for **finsql.exe**.

When the process ends, a file named **navcommandresult.txt** is saved to the Dynamics NAV Client connected to Business Central installation folder. If the command succeeded, the file will contain text like `[0] [06/12/17 14:36:17] The command completed successfully in '177' seconds.` If the command failed, another file named **naverrorlog.txt** will be generated. This file contains details about the error(s) that occurred.

For more information about generation symbols, see Running C/SIDE and AL Side-by-Side.

d. Restart the Business Central Server instance.

Task 15: Upgrade or repair V2 extensions

Complete this task if you are upgrading from a Microsoft Dynamics NAV 2018 deployment that uses V2 extensions. In this step, you will upgrade the V2 extensions that you previously uninstalled. The upgrade process will reinstall these extensions.

The Business Central installation media (DVD) includes several new versions of Microsoft extensions (that is, extensions that have **Microsoft** as the publisher). If your old deployment uses these extensions, you have to upgrade the current versions to the new versions.

1. To get list of the extensions currently published on the application, run the following command from the Business Central Administration Shell:

```
Get-NAVAppinfo -ServerInstance <ServerInstanceName>
```

2. Upgrade the Microsoft extensions that were published in the old deployment to new versions.

The new extension versions are found in the `\Extensions` folder of the installation media (DVD). Follow these steps for each extension by using the Business Central Administration Shell:

a. Publish the new extension version by running the Publish-NAVApp cmdlet:

```
Publish-NAVApp -ServerInstance <ServerInstanceName> -Path <ExtensionFileName>
```

b. Synchronize the schema with the database by running the Sync-NAVApp cmdlet:

```
Sync-NAVApp -ServerInstance <ServerInstanceName> -Name <Name> -Version <N.N.N.N>
```

c. Upgrade the data of the extensions.

To run the data upgrade, run the Start-NAVAppDataUpgrade cmdlet:

```
Start-NAVAppDataUpgrade -ServerInstance <ServerInstanceName> -Name <Name> -Version <N.N.N.N>
```

Apart from upgrading the data, this command will install the new extension version.

For more information about publishing extensions, see Publish and Install an Extension.

3. Repair, synchronize, and install other currently published extension versions that you still want to use, but have not been upgraded to new versions.

For each extension, complete the following steps from the Business Central Administration Shell:

a. Compile the extension to make it work with the new platform by running the Repair-NAVApp cmdlet.

```
Repair-NAVApp -ServerInstance <ServerInstanceName> -Name <Extension Name> -Version <N.N.N.N>
```

b. Synchronize the schema with the database by running the Sync-NAVApp cmdlet:

```
Sync-NAVApp -ServerInstance <ServerInstanceName> -Name <Name> -Version <N.N.N.N>
```

c. Install the extension by running the Install-NAVApp cmdlet:

```
Install-NAVApp -ServerInstance <ServerInstanceName> -Name <Name> -Version <N.N.N.N>
```

4. (Optional) Unpublish unused extension versions by running the Unpublish-NAVApp:

```
Unpublish-NAVApp -ServerInstance <ServerInstanceName> -Name <Name> -Version <N.N.N.N>
```

Task 16: Publish and install local functionality extensions

Complete this task if you are upgrading one of the following:

- Denmark (DK) version of Microsoft Dynamics NAV 2017 or earlier
- German (DE) version of Dynamics NAV or Business Central October 2018 (Cumulative Update 2 or earlier)

With these language versions, some of the local functionality has been moved from the base application to extensions. These extensions will have to be published and installed to maintain the functionality. The extensions are avilable on the installation media (DVD).

If you are upgrading from a Denmark (DK) version, you must publish and install the following extensions to get the local functionality:

NAME	EXTENSION PACKAGE
OIOUBL	OIOUBL.app

NAME	EXTENSION PACKAGE
Payroll Data Import Definitions (DK)	ImportDKPayroll.app
Payment and Reconciliation Formats (DK)	FIK.app
Tax File Formats (DK)	VATReportsDK.app

If you are upgrading from a German (DE) version you must publish and install the following extensions to get the local functionality:

NAME	EXTENSION PACKAGE
ELSTER VAT Localization for Germany	Elster.app

Follow these steps for each extension by using the Business Central Administration Shell:

1. Publish the new extension version by running the Publish-NAVApp cmdlet:

   ```
   Publish-NAVApp -ServerInstance <ServerInstanceName> -Path <ExtensionFileName>
   ```

   The new extension versions are found in the `\Extensions` folder of the installation media (DVD).

2. Synchronize the schema with the database by running the Sync-NAVApp cmdlet:

   ```
   Sync-NAVApp -ServerInstance <ServerInstanceName> -Name <Name> -Version <N.N.N.N>
   ```

3. Install the newly published local functionality extensions by running the Install-NAVApp cmdlet:

   ```
   Install-NAVApp -ServerInstance <ServerInstanceName> -Name <Name> -Version <N.N.N.N>
   ```

Task 17: Import permission sets and permissions

Import the permission sets and permissions XML files that you exported from the old database as follows:

- Upgrade from Dynamics NAV:

  1. Open table **2000000004 Permission Sets** in the client, and delete all permission sets except SUPER.

     > **NOTE**
     > You are only required to delete those permission sets that are also included in the permission sets XML file that you will import. Because if you try to import a permission set with the same name as one already in the database, you will get an error.

  2. Run XMLport **9171** and XMLport **9172** to import the permission sets and permission XML files.

     For more information, see How to: Export and Import Permission Sets and Permissions.

- Upgrade from an earlier Business Central version:

  1. In the client, search for and open the **Permission Sets** page.

2. Delete all user-defined permissions.
3. Choose **Import Permission Sets**, then select the permissions set file that you exported previously.

   This action runs the XMLPort **9174 Import Tenant Permissions**.

Task 18: (Optional) Import data encryption key

If you want to use data encryption as before, you must import the data encryption key file that was exported previously.

For more information, see Exporting and Importing Encryption Keys.

Task 19: Set the language of customer database

In the Dynamics NAV Development Environment, choose **Tools**, choose **Language**, and then select the language of the original customer database.

Task 20: (Optional) Update Web Server instance configuration file

If you have installed the Business Central Web Server, populate the navsettings.json file for the Business Central Web Server instance with the settings of the old web.config file or navsettings.json.

- If the old deployment used a web.config file, then you have to manually change the settings in the navsetting.json file that is used on the new Business Central Web Server instance.
- If you upgraded from Business Central October 2018, you can replace the navsettings.json file on the new Business Central Web Server instance with the old file. However, as of Business Central April 2019, the following settings are now configured under a root element called `ApplicationIdSettings` instead of the root element `NAVWebSettings`.
  - `AndroidPrivacy`
  - `AndroidSoftwareLicenseTerms`
  - `AndroidThirdPartyNotice`
  - `BaseHelpUrl`
  - `BaseSettingsSectionName`
  - `CommunityLink`
  - `FeedbackLink`
  - `IosPrivacy`
  - `IosSoftwareLicenseTerms`
  - `IosThirdPartyNotice`
  - `KeyboardShortcutsLink`
  - `PrivacyLink`
  - `LegalLink`
  - `SignInHelpLink`

  If the old navsettings.json file uses any of these settings, then you will have to move them from the `NAVWebSettings` element to the `ApplicationIdSettings` element.

For more information about the navsettings.json file, see Configuring Business Central Web Server Instances.

(Optional) Task 21: Delete upgrade objects

At this point, you have upgraded the database to Business Central. Now, you can delete the upgrade codeunits and upgrade table objects that you imported in task 9. This task is recommended but not required.

When you delete tables, on the **Delete** dialog box, set the **Synchronize Schema** option to **Force**.

Upgrading the Data to Business Central: Multitenant Deployment

2/17/2021 • 8 minutes to read • Edit Online

See print-friendly quick reference

This article describes the tasks required for upgrading data to the latest Business Central in a multitenant deployment.

About Data Upgrade

In this scenario, you already have an upgraded application that is mounted on a Business Central Server. You will then mount the old tenants on the server instance and perform the data upgrade.

You use data conversion tools provided with Business Central to convert the old data with the old version's table and field structure, so that it functions together with the new version's table and field structure. Mainly, only table objects and table data are modified during the data upgrade process. Other objects, such as pages, reports, codeunits, and XMLports are upgraded as part of the application code upgrade process.

The data upgrade process described in this article leads you through the database conversion (technical upgrade) and then the upgrade of the actual data, which is achieved by using the upgrade toolkit/upgrade codeunits.

> **IMPORTANT**
> Before you begin, read the article Important Information and Considerations for Before Upgrading. This article contains information about limitations and things that might require you to perform extra tasks before you upgrade, such as the use of extensions V1 and the deprecation of codeunit 1.

Prerequisites

Before you start the upgrade tasks, make sure you have the following prerequisites:

1. Your computer uses the same codepage as the data that will be upgraded.

   If you use conflicting codepages, some characters will not display in captions, and you might not be able to access the upgraded database. This is because Business Central must remove incorrect metadata characters to complete the data upgrade. In this case, after upgrade, you must open the database in the development environment on a computer with the relevant codepage and compile all objects. This adds the missing characters again.

2. (Upgrading from Dynamics NAV only) Custom V1 extensions used in Dynamics NAV have been converted to V2 extensions.

   For more information, see Converting Extensions V1 to Extensions V2.

3. Business Central has been installed with the upgraded application and upgrade toolkit.

   As a minimum, you must install the following components:

   - Business Central Server instance connected to the application database.
   - Dynamics NAV Development Environment for Business Central

- AL Development Environment

  This installs the required system and test symbols for V2 extensions.

- Business Central Server Administration tool (optional)
- Business Central Web Server components (not required for upgrade).

For more information about upgrading the application code, see Upgrading the Application Code.

4. Permission sets (except SUPER) and permissions have been exported from the old tenant database.

   - When upgrading from Dynamics NAV

     To export permission sets and permissions, you run running XMLPort 9171 and 9172.

     It is important that you exclude the SUPER permission set when running XMLPort 9171. You can do this by adding the filter `Role ID is <>SUPER`.

     For more information, see Exporting and Importing Permission Sets and Permissions.

   - When upgrading from an earlier version of Business Central

     In the client, search for and open the **Permission Sets** page, select the user-defined permission sets that you want to keep, and then choose **Export Permission Sets**.

5. If the old application uses data encryption, you have the encryption key file that it used for the data encryption.

   For more information, see Export and Import Encryption Keys.

> **NOTE**
> If the old Dynamics NAV application uses Payment Services for Microsoft Dynamics ERP, be aware that this was discontinued in Microsoft Dynamics NAV 2017. This means that most of the objects that are associated with this feature will be deleted during the upgrade. Some objects you will have to manually delete.

Prepare the tenant database for data upgrade

You perform these tasks on each tenant that you want to upgrade.

1. Backup the tenant database.

   Create a full backup of the old database in the SQL Server. Alternatively, you can make a copy of the old database and perform the upgrade tasks on the copy.

   For more information, see Create a Full Database Backup (SQL Server).

2. (Dynamics NAV upgrade only) Uninstall all V1 extensions.

   Make sure that all V1 extensions are uninstalled. Open the Dynamics NAV Administration Shell that matches to old database, and run these commands:

   a. To get a list of the V1 extensions that are installed, run this command:

   ```
   Get-NAVAppInfo -ServerInstance <OldServerInstanceName> -Tenant <TenantID>
   ```

   V1 extensions are indicated by `CSIDE` in the `Extension Type` column. 2. For each extension, run the Uninstall-NAVApp cmdlet to uninstall it:

```
Uninstall-NAVApp -ServerInstance <OldServerInstanceName> -Name <Name> -Version <N.N.N.N>
```

3. Dismount the tenant.

   Before you upgrade the tenant, you must dismount it from the old server instance. To dismount the tenant, run the Dismount-NAVTenant cmdlet:

   ```
   Dismount-NAVTenant -ServerInstance <OldServerInstanceName> -Tenant <TenantID>
   ```

Run the data upgrade on the tenant

You perform these tasks on each tenant that you want to upgrade.

1. Mount the tenant.

   Mount the tenant on the new Business Central Server instance that connects to the newly application database. To mount the tenant, use the Mount-NAVTenant cmdlet:

   ```
   Mount-NAVTenant -ServerInstance <ServerInstanceName> -DatabaseName <Database name> -DatabaseServer
   <server\instance> -Tenant <TenantID> -AllowAppDatabaseWrite
   ```

   IMPORTANT

   You must use the same tenant ID for the tenant that was used in the old deployment; otherwise you will get an error when mounting or syncing the tenant. If you want to use a different ID for the tenant, you can either use the `-AlternateId` parameter now or after upgrading, dismount the tenant, then mount it again using the new ID and the `OverwriteTenantIdInDatabase` parameter.

   NOTE

   For upgrade, we recommend that you use the `-AllowAppDatabaseWrite` parameter. After upgrade, you can dismount and mount the tenant again without the parameter if needed.

2. Synchronize the tenant.

   Synchronize the tenant database schema with validation by running the Sync-NAVTenant cmdlet from the Business Central Administration Shell.

   ```
   Sync-NAVTenant -ServerInstance <ServerInstanceName> -Tenant <TenantID>
   ```

   When completed, the tenant should have the status **OperationalDataUpgradePending** or, if there are published extensions with newer versions than on the tenant, **OperationalSyncPending**. To verify this, run the following cmdlet:

   ```
   Get-NAVTenant -ServerInstance <ServerInstanceName> -tenant default -ForceRefresh
   ```

3. If there are published extensions with newer versions than on the tenant, synchronize all published extensions with the tenant database.

   Synchronize the schema with the database by running the Sync-NAVApp cmdlet for each extension version:

```
Sync-NAVApp -ServerInstance <ServerInstanceName> -Name <Name> -Version <N.N.N.N> -Tenant <TenantID>
```

Or, to synchronize all published extensions using one command:

```
Get-NAVAppInfo -ServerInstance <ServerInstanceName> -Tenant <TenantID> | % { Sync-NAVApp -
ServerInstance <ServerInstanceName> -Name $_.Name -Version $_.Version }
```

When completed, the tenant should have the status **OperationalDataUpgradePending**.

4. Run the data upgrade.

   A data upgrade runs the upgrade toolkit objects, such as upgrade codeunits and upgrade tables, to migrate business data from the old table structure to the new table structure. It will also upgrade the published extensions.

   a. Open the Business Central Administration Shell as an administrator, and then run Start-NavDataUpgrade cmdlet as follows:

```
Start-NavDataUpgrade -ServerInstance ServerInstanceName> -FunctionExecutionMode Serial -
ContinueOnError
```

   Replace `<ServerInstanceName>` with the name of the Business Central Server instance that is connected to the database.

   > **NOTE**
   > In the last phase of data upgrade, all companies will be initialized by running codeunit 2 Company Initialization. This is done automatically. If you want to skip company initialization, then use the `Start-NavDataUpgrade` with the `-SkipCompanyIntitialization` parameter.

   To view the progress of the data upgrade, you can run Get-NavDataUpgrade cmdlet with the `-Progress` switch.

   The data upgrade process runs `CheckPreconditions` and `Upgrade` functions in the upgrade codeunits. If any of the preconditions are not met or an upgrade function fails, you must correct the error and resume the data upgrade process. If CheckPreconditions and Upgrade functions are executed successfully, codeunit 2 is automatically run to initialize all companies in the database unless you set the `-SkipCompanyIntitialization` parameter.

   b. Check for and resolve upgrade errors.

      Run the following command to get a list of any errors that have occurred:

```
Get-NAVDataUpgrade ServerInstanceName> -ErrorOnly
```

      Resolve the errors before going to the next step.

5. Install extensions on the tenant.

   Install the desired extensions on the tenant by running the Install-NAVApp cmdlet:

```
Install-NAVApp -ServerInstance <ServerInstanceName> -Name <Name> -Version <N.N.N.N>
```

Post-upgrade tasks

1. Import permission sets and permissions

   Import the permission sets and permissions XML files that you exported from the old database as follows:

   - For upgrade from Dynamics NAV:

     a. Open table **2000000004 Permission Sets** in the client, and delete all permission sets except SUPER.

     > **NOTE**
     > You are only required to delete those permission sets that also included in the permission sets XML file that you will import. Because if you try to import a permission set with the same name as on already in the database, you will get an error.

     b. Run XMLport **9171** and XMLport **9172** to import the permission sets and permission XML files.

     For more information, see How to: Export and Import Permission Sets and Permissions.

   - For upgrade from an earlier Business Central version:

     a. In the client, search for and open the **Permission Sets** page.
     b. Delete all user-defined permissions.
     c. Choose **Import Permission Sets**, then select the permissions set file that you exported previously.

2. Import encryption keys.

   For more information, see Exporting and Importing Encryption Keys.

3. (Optional) Update Web Server instance configuration file

   If you have installed the Business Central Web Server, populate the navsettings.json file for the Business Central Web Server instance with the settings of the old web.config file or navsettings.json.

   - If the old deployment used a web.config file, then you have to manually change the settings in the navsetting.json file that is used on the new Business Central Web Server instance.
   - If you upgraded from Business Central October 2018, you can replace the navsettings.json file on the new Business Central Web Server instance with the old file. However, as of Business Central April 2019, the following settings are now configured under a root element called `ApplicationIdSettings` instead of the root element `NAVWebSettings`.
     - `AndroidPrivacy`
     - `AndroidSoftwareLicenseTerms`
     - `AndroidThirdPartyNotice`
     - `BaseHelpUrl`
     - `BaseSettingsSectionName`
     - `CommunityLink`
     - `FeedbackLink`
     - `IosPrivacy`
     - `IosSoftwareLicenseTerms`

- `IosThirdPartyNotice`
- `KeyboardShortcutsLink`
- `PrivacyLink`
- `LegalLink`
- `SignInHelpLink`

If the old navsettings.json file uses any of these settings, then you will have to move them from the `NAVWebSettings` element to the `ApplicationIdSettings` element.

For more information about the navsettings.json file, see Configuring Business Central Web Server Instances.

4. Upload the customer license.

   For more information, see Uploading the License File

Business Central Multitenant Full Upgrade Quick Reference

2/17/2021 • 2 minutes to read • Edit Online

This article provides an overview of the full upgrade process for Business Central in a multitenant deployment. For more detailed steps, see Upgrading the Data: Multitenant Mode.

Prerequisite tasks

STEP	MORE INFO	DONE
In the old deployment, convert custom V1 extensions to V2 extensions.	See...	
Export permissions and permission sets from the old deployment. **Important:** Make sure computer uses the same codepage as the data.	See...	
Export encryption keys from the old deployment.	See...	
Prepare for transitioning from codeunit 1.	See...	
Install Business Central components.	See...	

Upgrade the application and prepare it for data upgrade

STEP	MORE INFO	DONE
Upgrade the application code.	See...	
Mount the upgraded application on the Business Central Server instance.	See...	
Import upgrade toolkit (.fob)	See...	
Publish system and test symbols from the installation media, and generate application symbols.	See...	
Publish the new Microsoft extension versions from the installation media.	See...	
Upload a Business Central partner license.	See...	

Prepare the tenant database for data upgrade

STEP	MORE INFO	DONE
Backup the tenant database.	See...	
Uninstall all V1 extensions.	See...	
Dismount the tenant from the old server instance.	See...	

Run the data upgrade on the tenant

STEP	MORE INFO	DONE
Mount the tenant on the Business Central Server instance. **Important:** Use the `-AllowAppDatabaseWrite` parameter.	See...	
Synchronize the tenant.	See...	
Synchronize all extensions.	See..	
Run the data upgrade. **Important:** If there are V2 extensions, you must use the `-FunctionExecutionMode Serial` parameter.	See...	
Install the new V2 extensions that were not installed in the old tenant.	See...	

Post-upgrade tasks

STEP	MORE INFO	DONE
Import permissions and permission sets.	See...	
Import encryption keys	See...	
Upload the customer license.	See...	

Installing a Business Central Spring 2019 Cumulative Update

2/17/2021 • 7 minutes to read • Edit Online

This article describes how to install a cumulative update for Business Central on-premises. A cumulative update is a set of files that include hotfixes and regulatory features released for Business Central.

Download the cumulative update package

The first thing to do is to download the Cumulative Update package that matches your Business Central deployment.

1. Go to the relevant list of available updates for your on-premises version of Business Central. Then, choose the Cumulative Update you want.

   For a list of supported versions of Business Central on-premises, see the See Also section.

2. From the cumulative update page, under the **Resolution** section, select the link for downloading the update and follow the instructions.

3. On the computer where you downloaded cumulative update, extract files from all .zip files.

The cumulative update includes files that are separated into the following folders:

- APPLICATION folder

  Used for updating your application with the new or modified application objects that form the cumulative update.

- DVD

  Contains the full Business Central product, including the Business Central installation program (setup.exe) and tools for upgrading to the platform.

When this step is done, you can continue to update your Business Central deployment to the new platform and application.

Update the platform

The following components are part of the Business Central platform:

- Business Central Web Server
- Business Central Server
- SQL Server components
- Dynamics NAV Client connected to Business Central

To upgrade to the latest platform, the database must be converted by using the Dynamics NAV Development Environment.

1. (Single-tenant deployment only) Uninstall all extensions.

   If the Business Central Server is configured as a single-tenant instance, you must uninstall all extensions from tenant. For example, using the Uninstall-NAVApp cmdlet from the Business Central Administration Shell, you can run the following command:

```
Get-NAVAppInfo -ServerInstance <ServerInstanceName> -Tenant default | % { Uninstall-NAVApp -
ServerInstance <ServerInstanceName> -Name $_.Name -Version $_.Version }
```

2. Install Business Central components of the cumulative update.

   There are two ways to install components. You can use the setup.exe file from the installation media or manually patch files to the existing installation:

   - Using setup.exe

     a. Uninstall the current version of Business Central.

        You can uninstall it by running setup.exe found in the DVD folder of the download or from Control Panel.

     b. From the DVD folder, run setup.exe to install Business Central.

        As a minimum, install the following components: Server, Web Server Components, SQL Server Components, and the Dynamics NAV Development Environment. For more information, see Installing Business Central Using Setup.

   - Manually patch the components

     With this way, you copy component files from installation media (DVD) to the current installation folders as described in the following table:

COMPONENT	COPY FROM DVD	TO CURRENT INSTALLATION FOLDER
Server	DVD\ServiceTier\program files\Microsoft Dynamics NAV\140	C:\Program Files\Microsoft Business Central<140>\Service
WebClient	DVD\WebClient\Microsoft Dynamics NAV\140\Web Client	C:\Program Files\Microsoft Dynamics 365 Business Central<140>\Web Client
Windows Client and Development Environment	DVD\RoleTailoredClient\program files\Microsoft Dynamics NAV\140\RoleTailored Client	C:\Program Files (x86)\Microsoft Dynamics 365 Business Central<140>\RoleTailored Client
Microsoft Office Outlook Integration	• DVD\Outlook\program files\Microsoft Dynamics NAV\140\OutlookAddin • Microsoft.Dynamics.NAV.OLSync.NAVSyncAddIn.dll	• C:\Program Files(x64)\Microsoft Office\Office <version> • C:\Program Files (x64)\Microsoft Office\Office\xx-XX

TIP

Before you install, save a copy of the configuration files for the Business Central Server (CustomSettings.config), the Business Central Web Server (navsettings.json), and Dynamics NAV Client connected to Business Central (ClientUserSettings.config). You can then refer to settings the copies to configure the components again.

3. Start the new development environment as an administrator

4. Open the application database.

   For more information, see Open a Database.

5. If prompted, follow instructions to convert it to the new platform.

6. (Multitenant deployment only) Mount an old tenant to the Business Central Server instance.

   you'll have to do this step and the next for each tenant. For more information, see Mount or Dismount a Tenant.

7. Synchronize the database (tenant).

   For more information about syncing, see Synchronizing the Tenant Database and Application Database.

Update the application

The APPLICATION folder includes the following files:

- AccumulatedChangeLog...txt
- Changelog...txt
- CUObjects...fob
- Objects..Objects...txt

Using Dynamics NAV Development Environment for Business Central, complete one of the following tasks.

> **NOTE**
> If a license update is required for a regulatory feature, customers can download an updated license from CustomerSource (see How to Download a Microsoft Dynamics 365 Business Central License from CustomerSource), and partners can download their customers' updated license from VOICE (see How to Download a Microsoft Dynamics 365 Business Central Customer License from VOICE).

Update an unmodified application to the Business Central cumulative update objects

1. Open the database in the development environment.
2. Import the CUObjects...fob into the application database.

   For more information, see Importing Objects.

3. Replace the existing objects in the database with the cumulative update objects.

Update a modified application to the Business Central cumulative update objects

1. Import the CUObjects...fob into the application database.

   For more information, see Importing Objects.

2. When prompted, open the **Import Worksheet**, and review the information.

   a. Replace objects in the database that have NOT been modified.

   b. If a table in the cumulative update has a new field and the same table in your database has been modified, use the **Merge: Existing<-New** or **Merge: New<-Existing** option in the **Import Worksheet** to import the new fields.

   c. For other objects that have been modified, use the CUObjects...txt file to compare and merge the cumulative update objects with the objects in your database.

      For more information about the worksheet, see Import Worksheet.

> **NOTE**
> If you don't want to use the Worksheet, you can use the Changelog...txt file to manually apply the changes to the objects in your database.

Updating from Business Central October 2018 DE Cumulative Update 2 or earlier

Starting with Cumulative Update 03, the ELSTER local functionality is contained in an extension instead of the base application. If you want the latest updates to the ELSTER functionality, you must publish and install the ELSTER extension. Publishing the extension is described later. To prepare for this step, delete the following objects from the application database: page 11016, page 11017, page 11019, and report 11016. These objects will be replaced by the ELSTER extension.

Make sure you synchronize the tenant after you delete the objects.

Set the application version of database to the application version of the cumulative update

Increase the application version of the application database in order to do a data upgrade. We recommend that you change to the application version to that of the cumulative update. You can get this version from the cumulative update release page. For more information, see Version numbers in Business Central.

To set the application version, use the Set-NAVApplication cmdlet of the Business Central Administration Shell to set the application version as follows:

```
Set-NAVApplication -ServerInstance <ServerInstanceName> -ApplicationVersion
Major.CU.ApplicationBuild.Revision -Force
```

Synchronize and upgrade tenants

1. (Multitenant deployment only) Mount the tenant.

   For more information, see Mount or Dismount a Tenant .

2. Synchronize the tenant.

3. Run a data upgrade.

   Run Start-NavDataUpgrade cmdlet of the Business Central Administration Shell:

   ```
   Start-NavDataUpgrade -ServerInstance <ServerInstanceName> -Tenant <TenantID>
   ```

   Replace `<TenantID>` with the tenant ID of the database. If you don't have a multitenant server instance, use `default` or omit this parameter.

Publish and install/upgrade extensions

Complete this task if you're updating:

- A Business Central October 2018 DE version earlier than Cumulative Update 3 and you want the latest updates to the Elster functionality. Use this procedure to install the following extension:

NAME	EXTENSION PACKAGE
ELSTER VAT Localization for Germany	Elster.app

- A Business Central application that uses extensions.

  The Business Central installation media (DVD) includes several new versions of Microsoft extensions (that

is, extensions that have **Microsoft** as the publisher). If your old deployment uses these extensions, you have to upgrade the current versions to the new versions.

Also, repair other extensions used in the old deployment that you still want to use so the extensions work on the new platform.

The general steps for this task are listed below. For detailed steps, see Publishing, Upgrading, and Installing Extensions During Upgrade .

1. Publish new system, test, and application symbols.

   Unpublish the old versions first.

2. Publish the new extension versions from the DVD.

   The extensions include new versions of Microsoft extensions that you already have used on your application, and the ELSTER app for the DE version. The new extension versions are found in the `\Extensions` folder of the installation media (DVD).

3. Synchronize the tenant database with the schema changes of the extensions.

4. Upgrade the data associated with the Microsoft extensions. This step isn't required the first time you publish the ELSTER extension.

5. Install the newly published extensions on tenants.

6. Repair, synchronize, and install any custom extensions (third-party) that are currently published. Do this step for old extensions that you still want to use.

   This step ensures that the extensions work on the new platform and application versions.

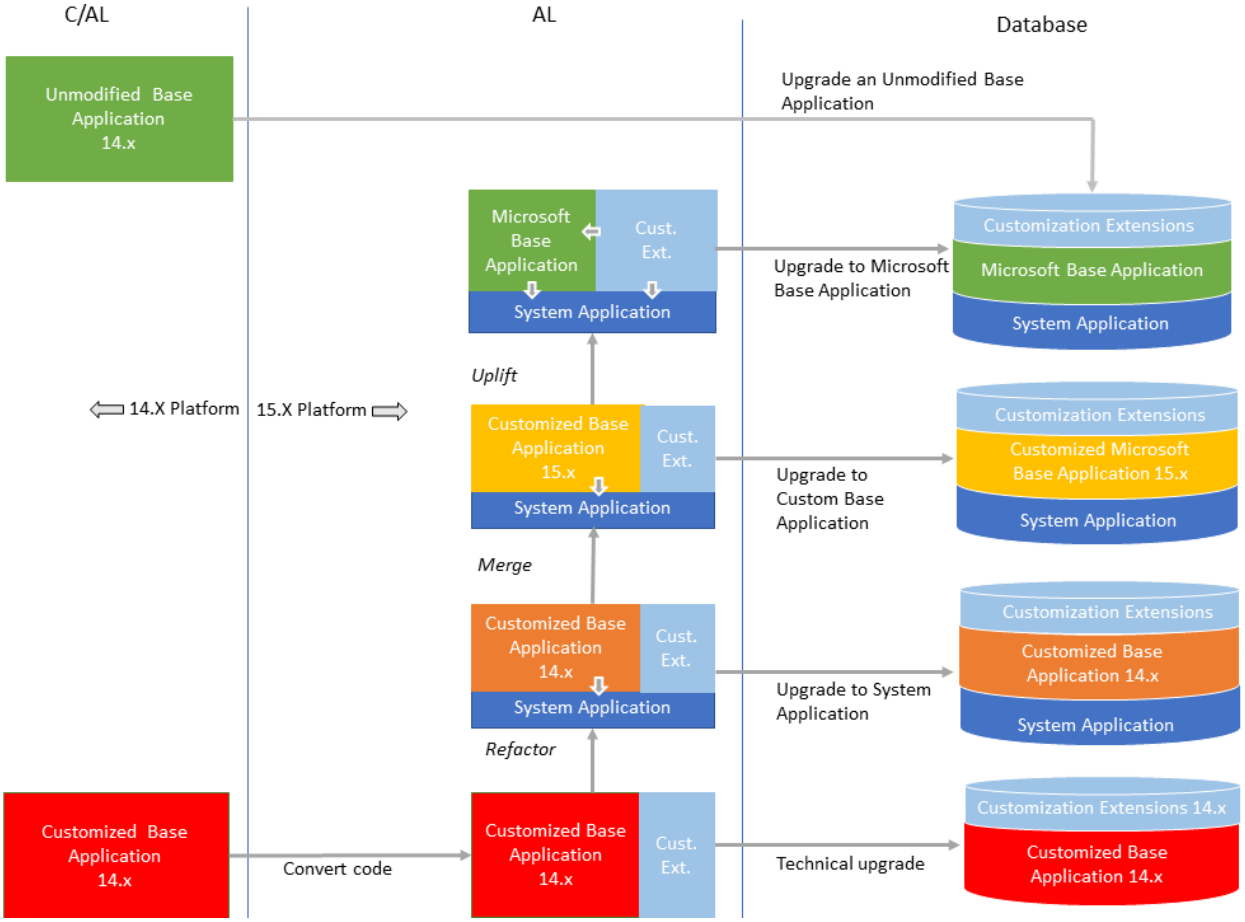
Upgrading to Dynamics 365 Business Central 2019 Release Wave 2

2/17/2021 • 3 minutes to read • Edit Online

Business Central 2019 release wave 2 (version 15) marks the release where C/AL has been completely replaced by AL. The 2019 release wave 2 is the first version that does not include the classic development environment (also known as C/SIDE). From an application perspective, this means that Business Central 2019 Wave 2 is completely extension-based. The Business Central base application is now delivered as an AL extension instead of C/AL. Additionally, application functionality that is not related to the business logic has been moved into separate modules that are combined into an extension known as the System Application. This change will influence how you perform the upgrade compared to earlier releases.

Upgrade paths

When upgrading your Business Central Spring 2019 (version 14) solution to version 15, the goal is to move towards a full uptake of the Business Central base and system applications, as they are, and migrating code customizations to add-on extensions. There are different upgrade paths that you follow to get to this state, as illustrated in the following figure.



As mentioned, the recommended upgrade path for a customized solution is to uptake the version 15 Microsoft Base Application and System Application, and move all code customizations to extensions. However, we realize that the complexity of some solutions will make this path very difficult. If this path is not currently realistic for your solution, then we recommend as a minimum to upgrade to a version 15 customized base application.

IMPORTANT

Be aware that for each path, once the database has been synchronized and data upgraded, it becomes more difficult to bring your solution to the next path. This will require significant manual work until tooling is available in a future release.

For details about each path, see the following articles:

- Upgrade of an Unmodified Application
- Technical Upgrade of Customized Application

The following articles are currently being formalized and will be available as soon as possible

- Upgrade to the System Application
- Upgrade to a Customized Version 15 Base Application
- Upgrade to the Microsoft Base Application

NOTE

Upgrading to Dynamics 365 Business Central 2019 Release Wave 2 requires that you first upgrade to Dynamics 365 Business Central Spring 2019 (version 14).

New and changed application features

There a several new and changed platform application features available in Business Central April 2019 release wave2 for users, administrators, and developers. For an overview of these features, see Overview of Dynamics 365 Business Central 2019 release wave 2.

To take advantage of these all these features, you will have to perform an application code upgrade, not just a technical (platform) upgrade.

Components

Base Application

The base application contains the objects (such as table, pages, codeunits, and reports) that define the business logic and functionality of the solution. In version 14 and earlier, the base application also contained system objects that were not specifically related to the business logic. In version 15, the standard business objects are now included in the Microsoft Base Application extension, and the system objects have been moved to the System Application extension.

System Application

In version 15.0, application functionality that is not related to the business logic has been moved into separate modules that are combined into an extension known as the System Application. For an introduction to the System Application, see For more information, see Overview of the System Application.

Symbols

Symbols are the application programming interface between AL code and C/AL code. Symbols enable the ability to reference C/AL objects from AL objects. Symbols are provided as an extension package, and are published to the server instance similar to application extensions, but not installed on tenants.

In version 14.0, with the base application being C/AL, there are three types of symbols: system, application, and test. System symbols contained references to the platform system objects. The application symbols contained references to the business application objects. The test symbols contained references to the test libraries used by Microsoft extensions.

In version 15, with the move to AL, the only symbols required are the system symbols, which are still provided on the version 15.0 installation media (DVD).

Customization extensions

Customization extensions are AL extensions that add functionality to the base application or system application. These extensions can be Microsoft (1st party) or 3rd party extensions. 3rd party extensions are extensions that your organization provides or extensions that are provided by others, such as from ISVs or from App Source.

Dynamics 365 Business Central Upgrade Compatibility Matrix

Dynamics 365 Business Central Upgrade Compatibility Matrix

2/17/2021 • 2 minutes to read • Edit Online

You can upgrade Business Central Spring 2019 (version 14) directly to 2019 release wave 2 (version 15) or to 2020 release wave 1 (version 16). And, of course, you can upgrade 2019 release wave 2 directly to 2020 release wave 1 (version 16). For an overview of the supported paths, see Supported Upgrade Paths.

However, minor updates are regularly made available for each major release, like 14.1 or 15.2. When upgrading, it's important to target an update version that's compatible with your current version.

Before choosing the target version

Before you choose the target version for your upgrade, read the Some Known Issues article. This article will describe issues in Business Central versions that affect upgrade.

Version 14 compatibility

The following table lists the Business Central 14 versions and the minimum 15, 16, and 17 version that's compatible for upgrade.

VERSION 14	VERSION 15	VERSION 16	VERSION 17
14.0 (GA and cumulative update 01)	15.0	16.0	17.0
14.3 (cumulative update 02)	15.0	16.0	17.0
14.4 (cumulative update 03)	15.0	16.0	17.0
14.5 (cumulative update 04)	15.0	16.0	17.0
14.6 (cumulative update 05)	15.1	16.0	17.0
14.7 (cumulative update 06)	15.2	16.0	17.0
14.8 (cumulative update 07)	15.3	16.0	17.0
14.9 (cumulative update 08)	15.3	16.0	17.0
14.10 (cumulative update 09)	15.4	16.0	17.0
14.11 (cumulative update 10)	15.5	16.0	17.0
14.12 (cumulative update 11)	15.6	16.1	17.0

VERSION 14	VERSION 15	VERSION 16	VERSION 17
14.13 (cumulative update 12)	15.7	16.2	17.0
14.14 (cumulative update 13)	15.8	16.3	17.0
14.15 (cumulative update 14)	15.9	16.4	17.0
14.16 (cumulative update 15)	15.10	16.5	17.0
14.17 (cumulative update 16)	15.11	16.6	17.0
14.18 (cumulative update 17)	15.12	16.7	17.1
14.19 (cumulative update 18)	15.13	16.8	17.2
14.20 (cumulative update 19)	15.14	16.9	17.3
14.21 (cumulative update 20)	15.15	16.10	17.4
14.22 (cumulative update 21)[1]	15.16	16.11	17.5

For example, you can upgrade version 14.0 to any 15 or 16 version. You can only upgrade version 14.11 to version 15.5 (or later) or version 16.0 (or later).

To see the available updates for Business Central 2019 Release Wave 2, see Released Updates for Microsoft Dynamics 365 Business Central 2019 Release Wave 2 on-premises.

[1]The compatible upgrade versions for this version aren't available yet. If you are currently operating on this version, you'll have to wait until the next round of updates before you upgrade.

Version 15 compatibility

The following table lists the Business Central 15 versions and the minimum 16 and 17 version that's compatible for upgrade.

VERSION 15	VERSION 16	VERSION 17
15.0 to 15.4	16.0	17.0
15.5	16.1	17.0
15.6	16.2	17.0
15.7	16.3	17.0

VERSION 15	VERSION 16	VERSION 17
15.8	16.4	17.0
15.9	16.5	17.0
15.10	16.6	17.0
15.11	16.7	17.1
15.12	16.8	17.2
15.13	16.9	17.3
15.14	16.10	17.4
15.15[1]	16.11	17.5

To see the available updates for Business Central 2020 Release Wave 1, see Released Updates for Microsoft Dynamics 365 Business Central 2020 Release Wave 1 on-premises.

Version 16 compatibility

The following table lists the Business Central 16 versions and the minimum 17 version that's compatible for upgrade.

VERSION 16	VERSION 17
16.0 to 16.5	17.0
16.6	17.1
16.7	17.2
16.8	17.3
16.9	17.4
16.10[1]	17.5

To see the available updates for Business Central 2020 Release Wave 2, see Released Updates for Microsoft Dynamics 365 Business Central 2020 Release Wave 2 on-premises.

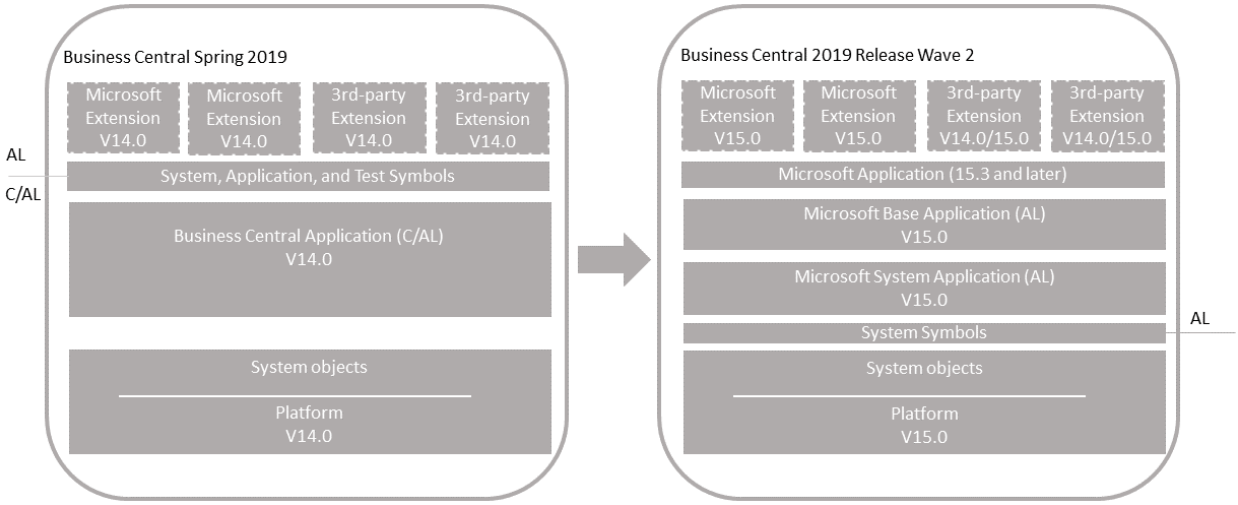
Upgrading to Business Central

Upgrading an Unmodified Application to Dynamics 365 Business Central 2019 Release Wave 2

2/17/2021 • 13 minutes to read • Edit Online

Use this scenario if you have a Business Central Spring 2019 (referred to as version 14) application that doesn't include any code customization. Your solution might include Microsoft (first party) extensions and customization extensions (3rd-party). With this upgrade, you'll replace the C/AL base application with the new Business Central 2019 release wave 2 base application extension. The result will be a fully upgraded Business Central 2019 release wave 2 (referred to as version 15) application and platform.



Single-tenant and multitenant deployments

The process for upgrading the similar for a single-tenant and multitenant deployment. However, there are some inherent differences. With a single-tenant deployment, the application code and business data are in the same database. In a multitenant deployment, application code is in a separate database (the application database) than the business data (tenant). In the procedures that follow, for a single-tenant deployment, consider references to the *application database* and *tenant database* as the same database. Steps are marked as *Single-tenant only* or *Multitenant only* where applicable.

Prerequisite

1. Upgrade to Business Central Spring 2019 (version 14).

   There are several updates for version 14.

   - If you're upgrading from Business Central Fall 2018 (version 13) or Dynamics NAV, we recommend you upgrade to the latest update for version 14 that has a compatible update for version 15.
   - If your solution is already on version 14, then you don't have to upgrade to the latest version 15 update. For more information, see Dynamics 365 Business Central Upgrade Compatibility Matrix.

   To download the latest update, go to Released Cumulative Updates for Microsoft Dynamics 365 Business Central Spring 2019 Update on-premises.

   For information about how to do the upgrade, see Upgrading to Dynamics 365 Business Central On-Premises.

2. Disable data encryption.

   If the current server instance uses data encryption, disable it. You can enable it again after upgrading.

For more information, see Managing Encryption and Encryption Keys.

Instead of disabling encryption, you can export the current encryption key, which you'll then import after upgrade. However, we recommend disabling encryption before upgrading.

Task 1: Install Business Central (version 15)

1. Download the latest available update for Business Central 2019 version 15 that is compatible with your version 14.

   To download the latest update, go to Released Updates for Microsoft Dynamics 365 Business Central 2019 Release Wave 2 on-premises.

   The guidelines in this article assume that you're running the latest available update.

2. Before you install version 15, it can be useful to create desktop shortcuts to the version 14.0 tools, such as the Business Central Server Administration tool, Business Central Administration Shell, and Dynamics NAV Development Shell because the Start menu items for these tools will be replaced with the version 15 tools.

3. Install Business Central version 15 components.

   If you don't uninstall version 14, then you must either specify different port numbers for components (like the Business Central Server instance and web services) during installation, or you must stop the version 14.0 Business Central Server instance before you run the installation. Otherwise, you'll get an error that the Business Central Server failed to install.

   For more information, see Installing Business Central Using Setup.

Task 2: Prepare the version 14 databases for upgrade

1. Make backup of the databases.

2. Start Business Central Administration Shell for version 14 as an administrator.

3. Uninstall all extensions from the old tenants.

   In this step, you uninstall the Base Application, System Application (if used), and any other extensions that are currently installed on the database.

   a. Get a list of installed extensions.

      This step is optional, but it can be useful to the names and versions of the extensions.

      To get a list of installed extensions, use the Get-NAVAppInfo cmdlet.

      ```
      Get-NAVAppInfo -ServerInstance <server instance name> -Tenant <tenant ID>
      ```

      For a single-tenant deployment, set the `<tenant ID>` to default.

   b. Uninstall the extensions.

      To uninstall an extension, you use the Uninstall-NAVApp cmdlet.

      ```
      Uninstall-NAVApp -ServerInstance <server instance name> -Name <extensions name> -Tenant
      <tenant ID> -Version <extension version> -Force
      ```

      Replace `<extension name>` and `<extension version>` with the exact name and version the

published System Application.

For example, together with the Get-NAVApp cmdlet, you can uninstall all extensions with a single command:

```
Get-NAVAppInfo -ServerInstance <server instance name> -Tenant <tenant ID>| % { Uninstall-
NAVApp -ServerInstance <server instance name> -Tenant <tenant ID> -Name $_.Name -Version
$_.Version -Force}
```

4. Unpublish all extensions from the application server instance.

   To unpublish an extension, use the Unpublish-NAVApp cmdlet:

   ```
   Unpublish-NAVApp -ServerInstance <server instance name> -Name <extension name> -Version <extension
   version>
   ```

   Together with the Get-NAVAppInfo cmdlet, you can unpublish all extensions by using a single command:

   ```
   Get-NAVAppInfo -ServerInstance <BC14 server instance> | % { Unpublish-NAVApp -ServerInstance <BC14
   server instance> -Name $_.Name -Version $_.Version }
   ```

5. Unpublish all system, test, and application symbols.

   To unpublish symbols, use the Unpublish-NAVAPP cmdlet with the `-SymbolsOnly` switch.

   ```
   Get-NAVAppInfo -ServerInstance <BC14 server instance> -SymbolsOnly | % { Unpublish-NAVApp -
   ServerInstance <BC14 server instance> -Name $_.Name -Version $_.Version }
   ```

   What are symbols?

6. (Multitenant only) Dismount the tenants from the application server instance.

   To dismount a tenant, use the Dismount-NAVTenant cmdlet:

   ```
   Dismount-NAVTenant -ServerInstance <server instance name> -Tenant <tenant ID>
   ```

7. Stop the server instance.

   ```
   Stop-NAVServerInstance -ServerInstance <server instance name>
   ```

Task 3: Convert the version 14 database to the version 15 platform

This task runs a technical upgrade on the application database to convert it from the version 14 platform to the version 15 platform. The conversion updates the system tables of the database to the new schema (data structure). It provides the latest platform features and performance enhancements.

1. Start Business Central Administration Shell for version 15 as an administrator.
2. Run the Invoke-NAVApplicationDatabaseConversion cmdlet to start the conversion:

   ```
   Invoke-NAVApplicationDatabaseConversion -DatabaseServer <database server name>\<database server
   instance> -DatabaseName "<database name>"
   ```

When completed, a message like the following displays in the console:

```
DatabaseServer      : .\BCDEMO
DatabaseName        : Demo Database BC (14-0)
DatabaseCredentials :
DatabaseLocation    :
Collation           :
```

Task 4: Connect and configure the version 15 server for app migration

When you installed version 15 in **Task 1**, a version 15 Business Central Server instance was created. In this task, you change server configuration settings that are required to complete the upgrade. Some of the changes are only required for version 14 to version 15.0 upgrade and can be reverted after you complete the upgrade.

1. Set the server instance to connect to the application database.

   ```
   Set-NAVServerConfiguration -ServerInstance <server instance name> -KeyName DatabaseName -KeyValue "
   <database name>"
   ```

   In a single tenant deployment, this command will mount the tenant automatically. For more information, see Connecting a Server Instance to a Database.

2. Configure the server instance for migrate extensions to the use the new base application and system application extensions.

   ```
   Set-NAVServerConfiguration -ServerInstance <server instance name> -KeyName
   "DestinationAppsForMigration" -KeyValue '[{"appId":"63ca2fa4-4f03-4f2b-a480-172fef340d3f",
   "name":"System Application", "publisher": "Microsoft"},{"appId":"437dbf0e-84ff-417a-965d-
   ed2bb9650972", "name":"Base Application", "publisher": "Microsoft"}]'
   ```

   This setting serves the following purposes:

   - When you run the data upgrade on a tenant, the server will run the data upgrade for the base and system application extensions. The base and system applications will be automatically installed on the tenant also.
   - Lets you republish extensions that haven't been built on version 15. The extensions typically include the third-party extensions that were used in your version 14. When you publish the extensions, the extension manifests are automatically modified with a dependency on the base and system applications.

3. Disable task Scheduler on the server instance for purposes of upgrade.

   ```
   Set-NavServerConfiguration -ServerInstance <server instance name> -KeyName "EnableTaskScheduler" -
   KeyValue false
   ```

   Be sure to re-enable task scheduler after upgrade if needed.

4. Restart the server instance.

   ```
   Restart-NAVServerInstance -ServerInstance <server instance name>
   ```

Task 5: Increase the application version

This task is optional, but it's recommended. You can choose to skip it for now and do it later. In this task, you'll

increase the application_version that's stored in ndodbproperty table of the application database. The application version isn't changed automatically. The application version serves two purposes:

- Enables running the Start-NAVDataUpgrade cmdlet later in Task 8 of this article. The application version is compared with the tenant's version. If the application version is greater, a data upgrade can be run. If you skip this task, you'll have to use the `-SkipAppVersionCheck` switch with Start-NAVDataUpgrade cmdlet in Task 8.
- The application version is shown in the client on the **Help and Support** page. This task ensures that page displays the latest application version.

The version has the format `major.minor.build.revision`, such as, '14.3.14824.1'. As a minimum, you increase the revision by 1. However, we recommend setting the value to application build number for the version 15 update. You can get this number from the Released Updates for Microsoft Dynamics 365 Business Central 2019 Release Wave 2 on-premises page.

To change the application version, run the Set-NAVApplication cmldet:

```
Set-NAVApplication -ServerInstance <server instance name> -ApplicationVersion <new application version> -
Force
```

For example:

```
Set-NAVApplication -ServerInstance BC150 -ApplicationVersion 15.1.38071.0 -Force
```

Later, when you synchronize and upgrade the tenant(s), the new application version will be updated in the tenant database (ndotenantproperty table).

Task 6: Publish the symbols and extensions

In this task, you'll publish the platform symbols and extensions. As minimum, you publish the new base application and system application extensions from the installation media (DVD). You also publish new versions of any Microsoft extensions and third-party extensions that were used on your old deployment.

Publishing an extension adds the extension to the application database that is mounted on the server instance. Once published, it's available for installing on tenants. This task updates internal tables, compiles the components of the extension behind-the-scenes, and builds the necessary metadata objects that are used at runtime.

The steps in this task continue to use the Business Central Administration Shell for version 15 that you started in the previous task.

1. Publish version 15 system symbols extension.

   The symbols extension contains the required platform symbols that the base application depends on. The symbols extension package is called **System.app**. You find it where the **AL Development Environment** is installed. The default path is C:\Program Files (x86)\Microsoft Dynamics 365 Business Central\150\AL Development Environment.

   ```
   Publish-NAVApp -ServerInstance  <server instance name> -Path "<path to system.app>" -PackageType
   SymbolsOnly
   ```

   What are symbols?

2. Publish the **System Application** extension (Microsoft_System Application.app).

   You find the (Microsoft_System Application.app in the **Applications\System Application\Source**

folder of installation media (DVD).

```
Publish-NAVApp -ServerInstance <server instance name> -Path "<path to Microsoft_System
Application.app>"
```

What is the System Application?

3. Publish the Business Central base application extension (Microsoft_Base Application.app).

   The **Base Application** extension contains the application business objects. You find the (Microsoft_Base Application.app in the **Applications\BaseApp\Source** folder of installation media (DVD).

   ```
   Publish-NAVApp -ServerInstance <server instance name> -Path "<path to Microsoft_Base
   Application.app>"
   ```

4. Publish the Microsoft_Application extension (update to 15.3 and later only)

   The Microsoft_Application extension is a new extension introduced in 15.3. For more information about this extension, see The Microsoft_Application.app File.

   a. Get the Microsoft_Application extension package and source code.

      With update 15.4 or later, the extension package and source code are on the installation media. Complete this step only if you're installing update 15.3. The Microsoft_Application extension isn't on the 15.3 installation media.

      With update 15.3, you must download extension package and source code from the Microsoft Download Center. To download, go to https://download.microsoft.com/download/9/9/1/991764bc-5f99-4be7-957a-f132ac0633ef/Application.zip.

   b. Publish the Microsoft_Application.app package.

      ```
      Publish-NAVApp -ServerInstance <server instance name> -Path "<folder
      path>\Microsoft_Application.app"
      ```

5. Publish the new versions of Microsoft extensions.

   In this step, you publish new versions of Microsoft extensions that were used on your version 14 deployment. You find the extensions in the **Applications** folder of the installation media (DVD).

   ```
   Publish-NAVApp -ServerInstance <server instance name> -Path "<path to Microsoft extension>"
   ```

   For example:

   ```
   Publish-NAVApp -ServerInstance BC150 -Path
   "C:\W1DVD\Applications\SalesAndInventoryForecast\Source\SalesAndInventoryForecast.app"
   ```

6. Publish 3rd-party extensions.

   Publish 3rd-party extensions that were used on your version 14 solution. If you have new versions of these extensions, built on the Business Central version 15, then publish the new versions. Otherwise, republish the same versions that were previously published in the old deployment.

```
Publish-NAVApp -ServerInstance BC150 -Path "<path to extension>"
```

Task 7: Restart the server instance

Restart the Business Central Server to free up resources for completing the upgrade.

```
Restart-NAVServerInstance -ServerInstance <server instance name>
```

This step is important, otherwise you might experience issues when you run the data upgrade.

Task 8: Synchronize the tenant

In this task, you'll synchronize the tenant's database schema with any schema changes in the application database and extensions.

If you have a multitenant deployment, do these steps for each tenant.

1. (Multitenant only) Mount the tenant to the version 15 server instance.

   To mount the tenant, use the Mount-NAVTenant cmdlet:

   ```
   Mount-NAVTenant -ServerInstance <server instance name> -DatabaseName <database name> -DatabaseServer
   <database server>\<database instance> -Tenant <tenant ID> -AllowAppDatabaseWrite
   ```

   IMPORTANT

   You must use the same tenant ID for the tenant that was used in the old deployment; otherwise you'll get an error when mounting or syncing the tenant. If you want to use a different ID for the tenant, you can either use the `-AlternateId` parameter now or after upgrading, dismount the tenant, then mount it again using the new ID and the `OverwriteTenantIdInDatabase` parameter.

   NOTE

   For upgrade, we recommend that you use the `-AllowAppDatabaseWrite` parameter. After upgrade, you can dismount and mount the tenant again without the parameter if needed.

   At this stage, the tenant state is OperationalWithSyncPending.

2. Synchronize the tenant with the application database.

   Use the Sync-NAVTenant cmdlet:

   ```
   Sync-NAVTenant -ServerInstance <server instance name> -Mode Sync -Tenant <tenant ID>
   ```

   With a single-tenant deployment, you can omit the `-Tenant` parameter and value.

3. Synchronize the tenant with the **System Application** extension.

   Use the Sync-NAVApp cmdlet:

```
Sync-NAVApp -ServerInstance <server instance name> -Tenant <tenant ID> -Name "System Application" -
Version <extension version>
```

Replace `<extension version>` with the exact version of the published System Application. To get the version, you can use the Get-NAVAppInfo cmdlet.

4. Synchronize the tenant with the Business Central Base Application extension.

   ```
   Sync-NAVApp -ServerInstance <server instance name> -Tenant <tenant ID> -Name "Base Application" -
   Version <extension version>
   ```

   Replace `<extension version>` with the exact version of the published Base Application.

5. Synchronize the tenant with the Application extension.

   ```
   Sync-NAVApp -ServerInstance <server instance name> -Tenant <tenant ID> -Name "Application"
   ```

6. Synchronize the tenant with Microsoft and 3rd-party extensions.

   For each extension, run the Sync-NAVApp cmdlet:

   ```
   Sync-NAVApp -ServerInstance BC150 -Tenant default -Name "<extension name>" -Version <extension
   version>
   ```

> **TIP**
> When you synchronize an extension, the extension takes ownership of any tables that it includes. In SQL Server, you'll notice that the table names will be suffixed with the extension ID. For example, Base Application tables will have `437dbf0e-84ff-417a-965d-ed2bb9650972` in the name. In addition, the systemId column is added to application tables that are not already part of an extension.

Task 9: Upgrade the data

In this task, you run a data upgrade on tables to handle data changes made by platform and extensions.

If you have a multitenant deployment, do these steps for each tenant.

1. Upgrade the data to the platform, system application, and base application.

   a. To run the data upgrade, use the Start-NavDataUpgrade cmdlet:

      ```
      Start-NAVDataUpgrade -ServerInstance <server instance name> -Tenant <tenant ID> -
      FunctionExecutionMode Serial [-SkipAppVersionCheck]
      ```

      You only need to use the -SkipAppVersionCheck if you didn't increase the application version in Task 5.

   b. To view the progress of the data upgrade, you can run Get-NavDataUpgrade cmdlet with the `-Progress` switch.

   This step will automatically install the base application and system application on the tenant.

2. Upgrade the new versions of Microsoft extensions and third-party extensions.

Complete this task to upgrade any Microsoft extensions used in the old deployment to new versions on the installation media. The new versions are in the **Application** folder of the DVD. There's a folder for each extension. The extension package (.app file) is in the **Source** folder.

To upgrade an extension, run Start-NAVAppDataUpgrade cmdlet:

```
Start-NAVAppDataUpgrade -ServerInstance <server instance name> -Name "<extension name>" -Version
<extension version>
```

This step will also automatically install the new extension version on the tenant.

3. (Multitenant only) Repeat steps 1 through 3 for each tenant.

Task 10: Install 3rd-party extensions

Complete this task to install third-party extensions for which a new version wasn't published. For each extension, run the Install-NAVApp cmdlet:

```
Install-NAVApp -ServerInstance <server instance name> -Name <extension name> -Version <extension version>
```

At this point, the upgrade is complete, and you can open the client.

Post-upgrade tasks

1. Enable task scheduler on the server instance.
2. (Multitenant only) For tenants other than the tenant that you use for administration purposes, if you mounted the tenants using the `-AllowAppDatabaseWrite` parameter, dismount the tenants, then mount them again without using the `-AllowAppDatabaseWrite` parameter.
3. If you want to use data encryption as before, enable it.

   For more information, see Managing Encryption and Encryption Keys.

   Optionally, if you exported the encryption key instead of disabling encryption earlier, import the encryption key file to enable encryption.

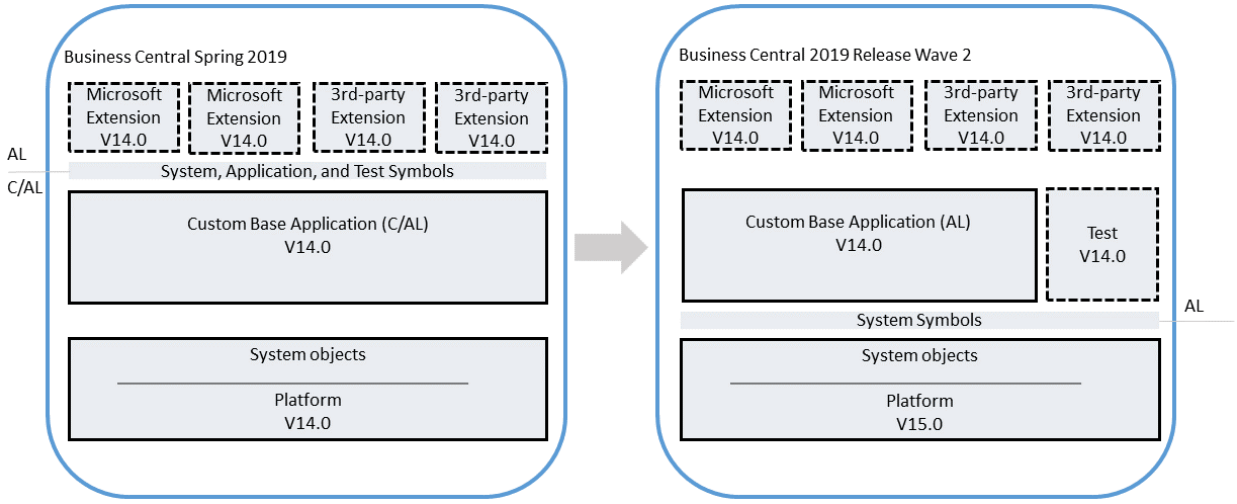
Upgrading to Business Central

Technical Upgrade to Dynamics 365 Business Central 2019 Wave 2

2/17/2021 • 10 minutes to read • Edit Online

Use this process when you have a code customized Business Central application (version 14) that you want to upgrade to the Business Central 2019 release wave 2 platform (version 15). This process won't upgrade the application to the latest version. You'll convert the entire application from C/AL to an AL base application extension.



Single-tenant and multitenant deployments

The process for upgrading is similar for a single-tenant and multitenant deployment. However, there are some inherent differences. With a single-tenant deployment, the application and business data are included in the same database. While with a multitenant deployment, application code is in a separate database (the application database) than the business data (tenant). In the procedures that follow, for a single-tenant deployment, consider references to the *application database* and *tenant database* as the same database. Steps are marked as *Single-tenant only* or *Multitenant only* where applicable.

Prerequisites

1. Upgrade to Business Central Spring 2019 (version 14).

   There are several updates for version 14. When upgrading from Business Central Fall 2018 (version 13) or Dynamics NAV, upgrade to the latest version 14 update that has a compatible version 15 update. For more information, see Dynamics 365 Business Central Upgrade Compatibility Matrix.

   If your solution is already on version 14, then you don't have to upgrade to the latest version 15 update.

   To download the latest update, go to Released Cumulative Updates for Microsoft Dynamics 365 Business Central Spring 2019 Update on-premises.

   For information, see Upgrading to Dynamics 365 Business Central On-Premises.

2. Disable data encryption.

   If the current server instance uses data encryption, disable it. You can enable it again after upgrading.

   For more information, see Managing Encryption and Encryption Keys.

Instead of disabling encryption, you can export the current encryption key, which you'll then import after upgrade. However, we recommend disabling encryption before upgrading.

Task 1: Install Dynamics 365 Business Central 2019 release wave 2 (version 15.0)

1. Before you install version 15, it can be useful to create desktop shortcuts to the version 14.0 tools, such as the Business Central Server Administration tool, Business Central Administration Shell, and Dynamics NAV Development Shell because the Start menu items for these tools will be replaced with the version 15.0 tools.

2. Install all components of Business Central 2019 release wave 2 (version 15).

   If you didn't uninstall version 14.0, then you must either specify different port numbers for components during installation or stop the version 14.0 Business Central Server instance before you run the installation. Otherwise, you'll get an error that the Business Central Server failed to install.

   For more information, see Installing Business Central Using Setup.

3. Copy the version 14 **CodeViewer** add-in to the version 15.0 server installation.

   a. Find the **CodeViewer** folder in the **Add-ins** folder of the version 14 RoleTailored client installation. By default, the folder path is C:\Program Files (x86)\Microsoft Dynamics 365 Business Central\140\RoleTailored Client\Add-ins.

   b. Copy the folder to the **Add-ins** folder of the version 15 server installation. By default, the folder path is C:\Program Files\Microsoft Dynamics 365 Business Central\150\Service\Add-ins. Replace the existing folder and files, if any.

   CodeViewer is no longer used in version 15. But it's required because of references that exist in the converted application. If you omit this step, you might get compilation errors later.

Task 2: Convert your application from C/AL to AL

Convert your solution from C/AL code to AL code. For more information, see Code Conversion from C/AL to AL.

Task 3: Prepare the application database for technical upgrade

1. Make backup of the database.

2. Make sure that you have the extension packages for all published extensions.

   You'll need these packages later to publish and install the extensions again.

3. Uninstall all extensions from the old tenants.

   Run the Business Central Administration Shell for version 14.0 as an administrator. To uninstall an extension, you use the Uninstall-NAVApp cmdlet. For example, together with the Get-NAVAppInfo cmdlet, you can uninstall all extensions with a single command:

   ```
   Get-NAVAppInfo -ServerInstance <BC14 server instance> -Tenant <tenant ID> | % { Uninstall-NAVApp -
   ServerInstance <BC14 server instance> -Name $_.Name -Version $_.Version -Tenant <tenant ID>}
   ```

   If you have a single tenant deployment, you can omit the `-Tenant` parameter and value.

4. Unpublish all extensions from the application server instance.

   To unpublish extensions, use the Unpublish-NAVAPP cmdlet. Together with the Get-NAVAppInfo cmdlet,

you can uninstall all extensions from the tenant using a single command:

```
Get-NAVAppInfo -ServerInstance <BC14 server instance> | % { Unpublish-NAVApp -ServerInstance <BC14
server instance> -Name $_.Name -Version $_.Version }
```

5. Unpublish all system, test, and application symbols.

   To unpublish symbols, use the Unpublish-NAVAPP cmdlet. You can unpublish all symbols by using the Get-NAVAppInfo cmdlet with the `-SymbolsOnly` switch as follows:

   ```
   Get-NAVAppInfo -ServerInstance <BC14 server instance> -SymbolsOnly | % { Unpublish-NAVApp -
   ServerInstance <BC14 server instance> -Name $_.Name -Version $_.Version }
   ```

   What are symbols?

6. (Multitenant only) Dismount the tenants from the application server instance.

   To dismount a tenant, use the Dismount-NAVTenant cmdlet:

   ```
   Dismount-NAVTenant -ServerInstance <BC14 server instance> -Tenant <tenant ID>
   ```

7. Stop the server instance.

   ```
   Stop-NAVServerInstance -ServerInstance <BC14 server instance>
   ```

Task 4: Convert the version 14.0 application database to the version 15.0 platform

This task runs a technical upgrade on the application database. A technical upgrade converts the database from the version 14.0 platform to the version 15.0 platform. This conversion updates the system tables of the database to the new schema (data structure). It also provides the latest platform features and performance enhancements.

1. Start Business Central Administration Shell for version 15.0 as an administrator.
2. Run the Invoke-NAVApplicationDatabaseConversion cmdlet to start the conversion:

   ```
   Invoke-NAVApplicationDatabaseConversion -DatabaseServer <database server>\<database instance> -
   DatabaseName "<BC14 database name>"
   ```

   When completed, a message like the following displays in the console:

   ```
   DatabaseServer      : .\BCDEMO
   DatabaseName        : Demo Database BC (14-0)
   DatabaseCredentials :
   DatabaseLocation    :
   Collation           :
   ```

Task 5: Connect and configure the version 15 server instance

When you installed version 15 in **Task 1**, a version 15 Business Central Server instance was created. In this task, you change server configuration settings that are required to complete the upgrade. Some of the changes are

only required for version 14 to version 15.0 upgrade and can be reverted after you complete the upgrade.

1. Set the server instance to connect to the application database.

   ```
   Set-NAVServerConfiguration -ServerInstance <BC15 server instance> -KeyName DatabaseName -KeyValue "
   <BC14 database name>"
   ```

   In a single tenant deployment, this command mounts the tenant automatically. For more information, see Connecting a Server Instance to a Database.

2. Disable task scheduler on the server instance for purposes of upgrade.

   ```
   Set-NavServerConfiguration -ServerInstance <BC15 server instance> -KeyName "EnableTaskScheduler" -
   KeyValue false
   ```

   Be sure to re-enable task scheduler after upgrade if needed.

3. Restart the server instance.

   ```
   Restart-NAVServerInstance -ServerInstance <BC15 server instance>
   ```

Task 6: Publish system symbols, base application, and test library extensions

In this task, you'll publish extensions to the version 15.0 server instance. Publishing adds the extension to the application database that is mounted on the server instance. The extension is then available for installing on tenants later. It updates internal tables, compiles the components of the extension behind-the-scenes, and builds the necessary metadata objects that are used at runtime.

The steps in this task continue to use the Business Central Administration Shell for version 15.0 that you started in the previous task.

1. Publish the system symbols extension for version 15.

   The symbols extension contains the required platform symbols that the base application depends on. The symbols extension package is called **System.app**. You find it where the **AL Development Environment** is installed. The default installation path is C:\Program Files (x86)\Microsoft Dynamics 365 Business Central\150\AL Development Environment.

   ```
   Publish-NAVApp -ServerInstance <BC15 server instance> -Path "<path to the System.app file>" -
   PackageType SymbolsOnly
   ```

2. Publish the custom base application extension that you created in **Task 2**.

   ```
   Publish-NAVApp -ServerInstance <BC15 server instance> -Path "<path to the base application extension
   package file>"
   ```

3. Publish the test library extension if you created one in **Task 2**.

   ```
   Publish-NAVApp -ServerInstance <BC15 server instance> -Path "<path to the test library extension
   package file>"
   ```

Task 7: Synchronize tenant and synchronize/install base application and test library extensions

This task updates the tenant database schema with schema changes in system objects and application objects. You'll synchronize the tenant to the custom base application and test library extension (if any). When you synchronize the tenant, extensions take ownership of the tables in the SQL Database.

If you have a multitenant deployment, run these steps for each tenant (replacing `<tenant ID>` with the appropriate tenant ID).

1. (Multitenant only) Mount the tenant to the version 15 server instance.

   To mount the tenant, use the Mount-NAVTenant cmdlet:

   ```
   Mount-NAVTenant -ServerInstance <BC15 server instance> -DatabaseName "<BC14 database name>" -
   DatabaseServer <database server>\<database instance> -Tenant <tenant ID> -AllowAppDatabaseWrite
   ```

   IMPORTANT

   You must use the same tenant ID for the tenant that was used in the old deployment; otherwise you will get an error when mounting or syncing the tenant. If you want to use a different ID for the tenant, you can either use the `-AlternateId` parameter now or after upgrading, dismount the tenant, then mount it again using the new ID and the `OverwriteTenantIdInDatabase` parameter.

   NOTE

   For upgrade, we recommend that you use the `-AllowAppDatabaseWrite` parameter. After upgrade, you can dismount and mount the tenant again without the parameter if needed.

2. Synchronize the tenant to the system objects.

   Use the Sync-NAVTenant cmdlet:

   ```
   Sync-NAVTenant -ServerInstance <BC15 server instance> -Tenant <tenant ID> -Mode Sync
   ```

   With a single-tenant deployment, you can omit the `-Tenant` parameter and value.

   At this stage, the tenant state is **Operational**.

3. Synchronize the tenant to the base application extension (Base Application).

   Use the Sync-NAVApp cmdlet:

   ```
   Sync-NAVApp -ServerInstance <BC15 server instance> -Name "Base Application" -Version <extension
   version> -tenant <tenant ID>
   ```

   With this step, the base app takes ownership of the database tables. When completed, in SQL Server, the table names will be suffixed with the base app extension ID.

4. Install custom base application extension on the tenant.

   To install the extension, you use the Install-NAVApp cmdlet.

```
Install-NAVApp -ServerInstance <BC15 server instance> -Name "Base Application" -Version <extension
version>
```

At this point, the base application is upgraded to the version 15 platform and is operational. You can open the application in the client.

5. Synchronize and install the test library extension.

   This step is like what you did for the custom base application in steps 3 and 4.

Task 8: Configure the version 15 server instance for migrating extensions

In this task, you configure the version 15 server so that the Microsoft and third-party extensions that were installed in the version 14 deployment can be reinstalled. You'll configure the `DestinationAppsForMigration` parameter of the server instance with information about the custom base application and test library. Specifically, you need the appId, name, and publisher assigned to these extensions. With the `DestinationAppsForMigration` parameter set, when you publish the Microsoft and third-party extensions, the server instance will automatically modify the manifest of the extensions to include the dependency on the base application and test library extension, allowing them to be published.

1. Get the appId, name, and publisher of the custom base application and test library.

   ```
   Get-NAVAppInfo -ServerInstance <BC15 server instance>
   ```

2. Set the `DestinationAppsForMigration` parameter for the server instance configuration to include the information about the custom base application and test library (if used). For example:

   ```
   Set-NAVServerConfiguration -ServerInstance <BC15 server instance> -KeyName
   "DestinationAppsForMigration" -KeyValue '[{"appId":"437dbf0e-84ff-417a-965d-ed2bb9650972",
   "name":"Base Application", "publisher": "Microsoft"},{"appId":"<test library extension app ID>",
   "name":"<test library extension name>", "publisher": "<test library publisher>"}]'
   ```

3. Restart the server instance.

Task 9: Publish, synchronize, and install extensions on the tenants

Now, you can install the Microsoft and 3rd-party extensions that were installed on the tenant before the upgrade.

1. Publish the old extension versions.

   ```
   Publish-NAVApp -ServerInstance <BC15 server instance> -Path "<path to extension package file>"
   ```

   You only need to do this step once.

2. Synchronize the extension.

   ```
   Sync-NAVApp -ServerInstance <BC15 server instance> -Name "<extension name>" -Version <extension
   version> -tenant <tenant ID>
   ```

3. Install the extension:

```
Install-NAVApp -ServerInstance <BC15 server instance> -Name "<extension name>" -Version <extension version> -tenant <tenant ID>
```

4. Repeat steps 2 and 3 for each extension and on each tenant.

Now, your application is fully upgraded to the version 15 platform.

Task 10: Post-upgrade

1. Upgrade Javascript-based control add-ins to new versions.

   The Business Central Server installation includes new versions of the following Microsoft-provided Javascript-based control add-ins that must be upgraded.

   - Microsoft.Dynamics.Nav.Client.BusinessChart
   - Microsoft.Dynamics.Nav.Client.FlowIntegration
   - Microsoft.Dynamics.Nav.Client.OAuthIntegration
   - Microsoft.Dynamics.Nav.Client.PageReady
   - Microsoft.Dynamics.Nav.Client.PowerBIManagement
   - Microsoft.Dynamics.Nav.Client.RoleCenterSelector
   - Microsoft.Dynamics.Nav.Client.SocialListening
   - Microsoft.Dynamics.Nav.Client.SatisficationSurvey
   - Microsoft.Dynamics.Nav.Client.TimelineVisualization
   - Microsoft.Dynamics.Nav.Client.VideoPlayer
   - Microsoft.Dynamics.Nav.Client.WebPageViewer
   - Microsoft.Dynamics.Nav.Client.WelcomeWizard

   To upgrade the control add-ons, do the following steps:

   a. Open the Business Central client.

   b. Search for and open the **Control Add-ins** page.

   c. Choose **Actions** > **Control Add-in Resource** > **Import**.

   d. Locate and select the .zip file for the control add-in and choose **Open**.

      The .zip files are located in the **Add-ins** folder of the Business Central Server installation. There's a subfolder for each add-in. For example, the path to the Business Chart control add-in is

      ```
      C:\Program Files\Microsoft Dynamics 365 Business Central\150\Service\Add-ins\BusinessChart\Microsoft.Dynamics.Nav.Client.BusinessChart.zip
      ```

      .

   e. After you've imported all the new control add-in versions, restart Business Central Server instance.

2. Enable task scheduler on the server instance.

3. (Multitenant only) For tenants other than the tenant that you use for administration purposes, if you mounted the tenants using the `-AllowAppDatabaseWrite` parameter, dismount the tenants, then mount them again without using the `-AllowAppDatabaseWrite` parameter.

4. If you want to use data encryption as before, enable it.

   For more information, see Managing Encryption and Encryption Keys.

   Optionally, if you exported the encryption key instead of disabling encryption earlier, import the encryption key file to enable encryption.

Installing a Business Central 2019 Release Wave 2 Update

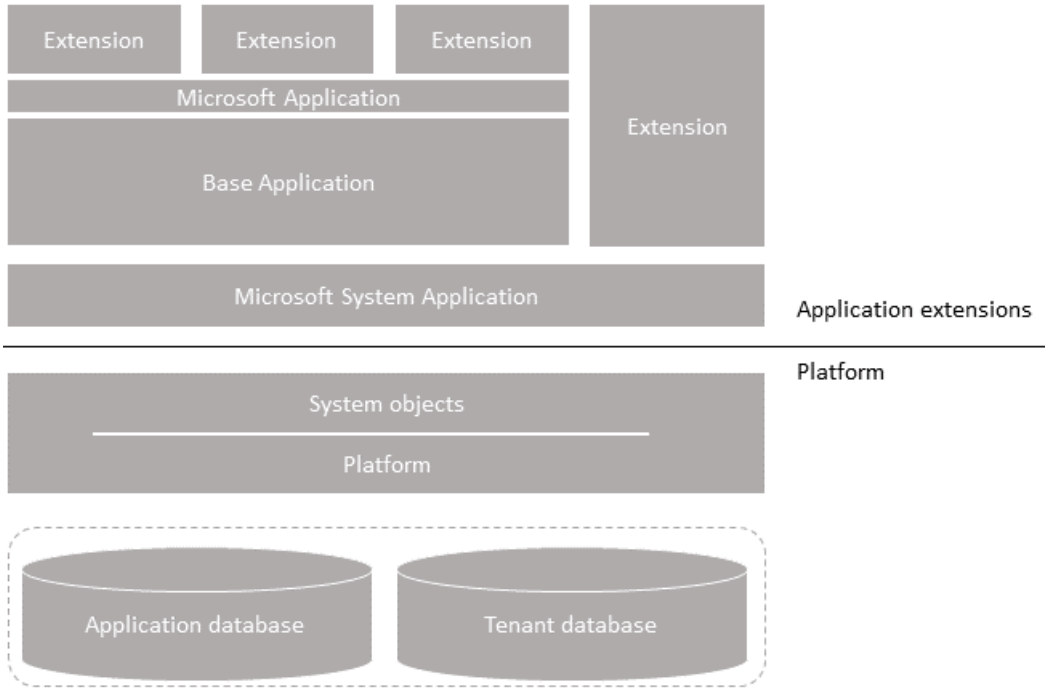
2/17/2021 • 17 minutes to read • Edit Online

This article describes how to install an update for Business Central on-premises. An update is a set of files that includes all hotfixes and regulatory features that have been released for Business Central.

You can choose to update only the platform or both the platform and application code. The installation guidelines are separated into PLATFORM tasks and APPLICATION tasks.

Overview

The following figure provides a high-level representation of a Business Central solution and the components that are involved in the installation of an update.



The databases store the application metadata and business data. If you have a single-tenant deployment, this data is stored in a single database. A multitenant deployment stores the application metadata in the application database and the business data in one or more tenant databases.

Application stack

The application includes AL extensions that define the objects and code that makes up the business logic. For example, objects include tables, report, pages, codeunits, and more. Each extension is compiled and delivered as an .app file, which is published to the Business Central Server instance.

- Base application

  As a minimum, the solution always includes the Base Application. The Base Application contains the objects (such as table, pages, codeunits, and reports) that define the business logic and functionality of the solution. The Base Application can be either the Microsoft Base Application or a customized Base Application. The Microsoft Base Application is the standard application that is on the installation media (DVD). A customized Base Application is an application that includes customized code.

The Microsoft System Application extension includes functionality that isn't directly related the business logic. For more information, see Overview of the System Application. When using the Microsoft Base Application, your solution uses the System Application. With a custom Base Application, your solution may or may not use the System Application. If it doesn't, you can skip any steps in this article related to the System Application.

- Extensions

  Extensions add functionality and features to the Base Application or System Application. Extensions can be either Microsoft extensions or third-party extensions. Microsoft extensions are available on the DVD. Third-party extensions are extensions developed by your organization or by another organization, like an ISV.

Single-tenant and multitenant deployments

The process for upgrading is similar for a single-tenant and multitenant deployment. However, there are some inherent differences. With a single-tenant deployment, the application and business data are included in the same database. While with a multitenant deployment, application code is in a separate database (the application database) than the business data (tenant). In the procedures that follow, for a single-tenant deployment, consider references to the *application database* and *tenant database* as the same database. Steps are marked as *Single-tenant only* or *Multitenant only* where applicable.

Platform versus application update

A platform update doesn't change the application. It involves converting your databases to the new platform and recompiling the existing extensions to ensure that they're compatible with the new platform.

An application update involves:

- Publishing new versions of extensions that include the latest application modifications
- Synchronizing the databases with any schema change introduced by the new extensions
- Updating affected data.

The installation media (DVD) includes new versions of Microsoft's Base Application, System Application, and extensions. The DVD also includes the AL source code for the Microsoft Base Application. This code useful if you have a custom base application. You can use the code to compare and merge updates into your application. You'll only have to recompile third-party extensions that you don't have a new version to publish.

PREPARATION

Download update package

The first thing to do is to download the update package that matches your Business Central solution.

1. Go to the list of available updates for your on-premises version of Business Central. Then, choose the update that you want.
2. From the update page, under the **Resolution** section, select the link for downloading the update, and follow the instructions.
3. On the computer where you downloaded the update .zip file, extract the all the files to a selected location.

   When extracted, the update includes the DVD folder. This folder contains the full Business Central product. For example, the folder includes the Business Central installation program (setup.exe), tools for upgrading to the platform, and the Microsoft extensions.

When this step is completed, you can continue to update your Business Central solution to the new platform and application.

Prepare existing databases

1. Back up your databases.
2. Run the Business Central Administration Shell as an administrator.
3. (Single-tenant only) Uninstall all extensions from the all tenants.

   In this step, you uninstall the Base Application, System Application (if used), and any other extensions that are currently installed on the database.

   a. Get a list of installed extensions.

      This step is optional, but it can be useful to the names and versions of the extensions.

      To get a list of installed extensions, use the Get-NAVAppInfo cmdlet.

      ```
      Get-NAVAppInfo -ServerInstance <server instance name>
      ```

   b. Uninstall the extensions.

      To uninstall an extension, you use the Uninstall-NAVApp cmdlet.

      ```
      Uninstall-NAVApp -ServerInstance <server instance name> -Tenant <tenant ID> -Name <extensions
      name> -Version <extension version> -Force
      ```

      Replace `<extension name>` and `<extension version>` with the exact name and version the installed extension. For single-tenant deployment, set `<tenant ID>` to `default` or omit the `-Tenant` parameter.

      For example, together with the Get-NAVApp cmdlet, you can uninstall all extensions with a single command:

      ```
      Get-NAVAppInfo -ServerInstance <server instance name> -Tenant <tenant ID> | % { Uninstall-
      NAVApp -ServerInstance <server instance name> -Tenant <tenant ID> -Name $_.Name -Version
      $_.Version -Force}
      ```

4. Unpublish the existing system symbols.

   To unpublish the system symbols, use the Unpublish-NAVApp cmdlet as follows:

   ```
   Unpublish-NAVApp -ServerInstance <server instance> -Name System -version <version>
   ```

   What are symbols?.

5. (Multitenant only) Dismount the tenants from the application database.

   To dismount a tenant, use the Dismount-NAVTenant cmdlet:

   ```
   Dismount-NAVTenant -ServerInstance <server instance> -Tenant <tenant ID>
   ```

Install Business Central components

From the installation media (DVD), run setup.exe to uninstall the current Business Central components and install the Business Central components included in the update.

1. Stop the Business Central Server instance.

   ```
   Stop-NAVServerInstance -ServerInstance <server instance>
   ```

2. Run setup.exe to uninstall your current version of Business Central.

3. Run setup.exe again to install components of the update.

   a. Follow setup pages until you get to the **Microsoft Dynamics 365 Business Central Setup** page.

   b. Select **Advanced installation options** > **Choose an installation option** > **Custom**.

   c. On the **Design customization the installation** page, select the following components as a minimum:

      - AL Development Environment (optional but recommended)
      - Server
      - Web Server Components.

   d. Select **Next**.

   e. On the **Specify parameters** page, set the fields as needed.

      > **IMPORTANT**
      > Clear the **SQL Database** field so that it is blank. At this time, do not set this to the database that you want to update; otherwise, the installation of the Business Central Server will fail. You will connect the database to the Business Central Server later after it is converted to the new platform.

   f. Select **Apply** to complete the installation.

For more information, see Installing Business Central Using Setup.

PLATFORM UPDATE

Follow the next few tasks to convert your database to the new platform of the update. A multitenant deployment includes the application and tenant databases. The conversion updates the system tables of the database to the new schema (data structure) and provides the latest platform features and performance enhancements.

Also, to ensure that the existing published extensions work on the new platform, you'll recompile the extensions.

Convert existing database to new platform

1. Run the Business Central Administration Shell as an administrator.

2. Run the Invoke-NAVApplicationDatabaseConversion cmdlet to start the database conversion to the new platform.

   In a multitenant deployment, run this cmdlet against the application database.

   ```
   Invoke-NAVApplicationDatabaseConversion -DatabaseServer <database server name>\<database server
   instance> -DatabaseName "<database name>" [-Force]
   ```

   For example, in a single tenant deployment:

```
Invoke-NAVApplicationDatabaseConversion -DatabaseServer .\BCDEMO -DatabaseName "Demo Database BC (15-
0)"
```

In a multitenant deployment, run this cmdlet against the application database and use the `-Force` parameter. For example:

```
Invoke-NAVApplicationDatabaseConversion -DatabaseServer .\BCDEMO -DatabaseName "BC15 Application" -
Force
```

When completed, a message like the following displays in the console:

```
DatabaseServer      : .\BCDEMO
DatabaseName        : Demo Database BC (15-0)
DatabaseCredentials :
DatabaseLocation    :
Collation           :
```

NOTE

Depending on the update that you're installing, you might get a message similar to the following:

```
Invoke-NAVApplicationDatabaseConversion : A technical upgrade of database <database name> on
server '.\<database instance>' cannot be run, because the database's application version 'NNNNNN'
is greater than or equal to the platform version 'NNNNNN'
```

This is not an error, and you can continue installing the update. This message is recorded as a warning in the event log as well. This message indicates that the application database is already compatible with the new platform, which happens when the update does not make any schema changes to the system tables.

Connect server instance to database

1. (Multitenant only) Enable the server instance as a multitenant instance:

   ```
   Set-NAVServerConfiguration -ServerInstance <server instance> -KeyName Multitenant -KeyValue true
   ```

2. Connect the server instance to connect to the database.

   ```
   Set-NAVServerConfiguration -ServerInstance <server instance> -KeyName DatabaseName -KeyValue "
   <database name>"
   ```

   In a multitenant deployment, the database is the application database. For more information, see Connecting a Server Instance to a Database.

3. Restart the server instance.

   ```
   Restart-NAVServerInstance -ServerInstance <server instance>
   ```

Publish the new system symbols

Use the Publish-NAVApp cmdlet to publish the new symbols extension package. This package is called **System.app**. If you've installed the **AL Development Environment**, you find the file in the installation folder. By default, the folder path is C:\Program Files (x86)\Microsoft Dynamics 365 Business Central\150\AL

Development Environment. Or, it's also on the installation media (DVD) in the ModernDev\program files\Microsoft Dynamics NAV\150\AL Development Environment folder.

```
Publish-NAVApp -ServerInstance <server instance> -Path "<path to the System.app file>" -PackageType SymbolsOnly
```

Recompile published extensions

Compile all published extensions against the new platform.

> **NOTE**
> If you plan on updating the application you can skip this step for extensions for which you have new versions built on the new platform. For example, this includes Microsoft extensions that are on the DVD.

1. To compile an extension, use the Repair-NAVApp cmdlet, For example:

   ```
   Repair-NAVApp -ServerInstance <server instance> -Name <extension name> -Version <extension name>
   ```

   To compile all published extensions at once, you can use this command:

   ```
   Get-NAVAppInfo -ServerInstance <server instance> | Repair-NAVApp
   ```

2. Restart the server instance.

   ```
   Restart-NAVServerInstance -ServerInstance <server instance>
   ```

Synchronize tenant

1. (Multitenant only) Mount the tenant to the new Business Central Server instance.

   You'll have to do this step and the next for each tenant. For more information, see Mount or Dismount a Tenant.

2. Synchronize the tenant.

   Use the Sync-NAVTenant cmdlet:

   ```
   Sync-NAVTenant -ServerInstance <server instance> -Tenant <tenant ID> -Mode Sync
   ```

   For a single-tenant deployment, you can either set the `<tenant ID>` to `default` or omit the `-Tenant <tenant ID>` parameter. For more information about syncing, see Synchronizing the Tenant Database and Application Database.

Upgrade control add-ins

The Business Central Server installation includes new versions of the Microsoft-provided Javascript-based control add-ins, like Microsoft.Dynamics.Nav.Client.BusinessChart, Microsoft.Dynamics.Nav.Client.VideoPlayer, and more. If your solution uses any of these control add-ins, upgrade them to the latest version.

To upgrade the control add-ins, do the following steps:

1. Open the Business Central client.
2. Search for and open the **Control Add-ins** page.
3. Choose **Actions** > **Control Add-in Resource** > **Import**.
4. Locate and select the .zip file for the control add-in and choose **Open**.

   The .zip files are located in the **Add-ins** folder of the Business Central Server installation. There's a subfolder for each add-in. For example, the path to the Business Chart control add-in is

   ```
   C:\Program Files\Microsoft Dynamics 365 Business Central\150\Service\Add-ins\BusinessChart\Microsoft.Dynamics.Nav.Client.BusinessChart.zip
   ```

   .
5. After you've imported all the new control add-in versions, restart Business Central Server instance.

> **NOTE**
> At this point, if you want to update the application, you can skip the next step and proceed APPLICATION.

(Single-tenant only) Reinstall extensions

In this task, you reinstall the same extensions that were installed on the tenant before. If you're planning on updating the application, then you only do this step on third-party extensions.

To install an extension, you use the Install-NAVApp cmdlet.

1. If your solution uses the System Application, install this first.

   ```
   Install-NAVApp -ServerInstance <server instance> -Name "System Application" -Version <extension version>
   ```

   Replace `<extension version>` with the exact version of the published System Application.
2. Install the Base Application.

   ```
   Install-NAVApp -ServerInstance <server instance> -Name "Base Application" -Version <extension version>
   ```

   Replace `<extension version>` with the exact version of the published Base Application.
3. Install the Application extension as needed.

   ```
   Install-NAVApp -ServerInstance <server instance> -Name "Application" -Version <extension version>
   ```

   Replace `<extension version>` with the exact version of the published Application extension.
4. Install other extensions, including Microsoft and third-party extensions.

   ```
   Install-NAVApp -ServerInstance <server instance name> -Name <extension name> -Version <extension version>
   ```

At this point, your solution has been updated to the latest platform.

APPLICATION UPDATE

Follow the next tasks to update the application code to the new features and hotfixes. The tasks include publishing new versions of the System Application, Base Application, and add-on extensions.

You publish the System Application extension only if it was used in old solution. Add-on extensions include Microsoft and third- party extensions that were used in the old solution.

> **NOTE**
> If a license update is required for a regulatory feature, customers can download an updated license from CustomerSource (see How to Download a Microsoft Dynamics 365 Business Central License from CustomerSource), and partners can download their customers' updated license from VOICE (see How to Download a Microsoft Dynamics 365 Business Central Customer License from VOICE).

Upgrade System Application

Follow these steps if your existing solution uses the Microsoft System Application. Otherwise, you can skip this procedure.

1. Publish the **System Application** extension (Microsoft_System Application.app).

   You find the (Microsoft_System Application.app in the **Applications\System Application\Source** folder of installation media (DVD).

   ```
   Publish-NAVApp -ServerInstance <server instance name> -Path "<path to Microsoft_System
   Application.app>"
   ```

2. Synchronize the tenant(s) with the **System Application** extension (Microsoft_System Application):

   Use the Sync-NAVApp cmdlet:

   ```
   Sync-NAVApp -ServerInstance <server instance name> -Tenant <tenant ID> -Name "System Application" -
   Version <extension version>
   ```

   Replace `<extension version>` with the exact version of the published System Application.

   > **TIP**
   > To get a list of all published extensions, along with their names and versions, use the Get-NAVAppInfo cmdlet.

3. Run the data upgrade on the System Application.

   To run the data upgrade, use the Start-NavAppDataUpgrade cmdlet:

   ```
   Start-NAVAppDataUpgrade -ServerInstance <server instance name> -Tenant <tenant ID> -Name "System
   Application" -Version <extension version>
   ```

   Upgrading data updates the data in the tables of the tenant database to the schema changes made to tables of the System Application.

Upgrade Base Application

Microsoft Base Application

Follow these steps if your existing solution uses the Microsoft Base Application.

1. Publish the Business Central Base Application extension (Microsoft_Base Application.app).

   The **Base Application** extension contains the application business objects. You find the Microsoft_Base Application.app in the **Applications\BaseApp\Source** folder of installation media (DVD).

   ```
   Publish-NAVApp -ServerInstance <server instance name> -Path "<path to Microsoft_Base
   Application.app>"
   ```

2. Synchronize the tenant with the Business Central Base Application extension (Microsoft_BaseApp):

   ```
   Sync-NAVApp -ServerInstance <server instance name> -Tenant <tenant ID> -Name "Base Application" -
   Version <extension version>
   ```

   Replace `<extension version>` with the exact version of the published Base Application.

   With this step, the base app takes ownership of the database tables. When completed, in SQL Server, the table names will be suffixed with the base app extension ID. This process can take several minutes.

3. Run the data upgrade on the Base Application.

   To run the data upgrade, use the Start-NavAppDataUpgrade cmdlet:

   ```
   Start-NAVAppDataUpgrade -ServerInstance <server instance name> -Tenant <tenant ID> -Name "Base
   Application" -Version <extension version>
   ```

   Upgrading data updates the data in the tables of the tenant database to the schema changes made to tables of the Base Application.

Upgrade custom Base Application

With a custom Base Application, you may want the new application features and hotfixes in the Microsoft Base Application. If so, you'll have to merge the modifications made in the Microsoft Base Application into your custom Base Application. Then, create a new version of your custom Base Application.

The source code for the new Microsoft Base Application version is in the **Base Application.Source.zip** file. This file is on the installation media (DVD), in the **Applications\BaseApp\Source** folder. You can compare this source code with the source code of the previous Microsoft Base Application and your custom application source. Then merge the code into a new custom application version.

After you've created the new version of your custom application, you publish it to the application server instance. Then, you synchronize and run the data upgrade on the tenants.

Upgrade Microsoft extensions

If your old solution used Microsoft extensions, then you upgrade these extensions to the new versions that are available on the Business Central installation media (DVD). The new versions are in the **Applications** folder, which contains a subfolder for each extension. The extension package (.app file) that you need for publishing the extension is in the **Source** folder, for example, **Applications\SalesAndInventoryForecast\Source\SalesAndInventoryForecast.app**.

The general steps for this task are listed below. For detailed steps, see Publishing, Upgrading, and Installing Extensions During Upgrade.

Publish and install Microsoft_Application extension (update to 15.3 and later only)

The Microsoft_Application extension is a new extension introduced in 15.3. For more information about this extension, see The Microsoft_Application.app File.

1. Get the Microsoft_Application extension package and source code.

   With update 15.4 or later, the extension package and source code are on the installation media. Complete this step only if you're installing update 15.3. The Microsoft_Application extension isn't on the 15.3 installation media.

   With update 15.3, you must download extension package and source code from the Microsoft Download Center. To download, go to https://download.microsoft.com/download/9/9/1/991764bc-5f99-4be7-957a-f132ac0633ef/Application.zip.

2. If your base application has an ID other the Microsoft ID (437dbf0e-84ff-417a-965d-ed2bb9650972), you have to modify the Microsoft_Application extension. Skip this step if you're using the Microsoft Base Application or a custom base application that has the Microsoft ID.

   The Microsoft_Application extension must include a dependency reference to your custom base application instead of Microsoft's. To make this change, use the extension's source code that you downloaded. For example:

   a. Extract the source code from the Application.source.zip file.

   b. Create a Visual Studio Code project that includes the extracted files. You can give the project any valid name.

   c. In the extension's app.json file, change the base application dependency to match your base application.

      > **IMPORTANT**
      > Do not change the name of the extension. It must have the name **Application**; otherwise you won't be able to publish the other Microsoft extensions.

   d. Build the extension package.

3. Publish the Microsoft_Application.app package.

```
Publish-NAVApp -ServerInstance <server instance name> -Path "<folder path>\Microsoft_Application.app"
```

4. Synchronize the tenant database with the schema changes of the Microsoft_Application extension.

```
Sync-NavApp -ServerInstance <server instance name> -Tenant <tenant ID> -Name <extension name> -Tenant
<tenant ID>
```

5. Install the Microsoft_Application extension on your tenants.

```
Install-NAVApp -ServerInstance <server instance name> -Tenant <tenant ID> -Name Application
```

Publish and install Microsoft extensions

Complete these steps for each Microsoft extension that you want to upgrade.

1. Publish the new extension versions from the installation media (DVD).

```
Publish-NAVApp -ServerInstance <server instance name> -Path <path to extension package file>
```

2. Synchronize the tenant database with the schema changes of the extensions.

```
Sync-NavApp -ServerInstance <server instance name> -Tenant <tenant ID> -Name <extension name> -
Version <extension version>
```

3. Upgrade the data associated with the Microsoft extensions. This step will automatically install the new version on the tenant

```
Start-NAVAppDataUpgrade -ServerInstance <server instance name> -Tenant <tenant ID> -Name <extension
name> -Version <extension version>
```

Upgrade Third-Party extensions

If the old solution used third-party extensions, and you still want to use them, they must be compiled to work on the new platform. Then, you reinstall the extensions on tenants.

As an alternative, if you have the source for these extensions, you can build and compile a new version of the extension in the AL development environment. Then, you upgrade to the new version as described in the previous task.

Post Upgrade - Change application version

(Optional) This task isn't required for installing the update. However, it might be useful for support purposes and answering a common question about the application version.

On the **Help and Support** page in the client, you'll see an application version, such as 15.1.2345.6. For an explanation of the number, see Version numbers in Business Central. This version number isn't updated automatically when you install an update. If you want the application version to reflect the version of the update or your own version, you change it manually as described here.

We recommend setting the value to application build number for the version 15 update. You get the number from the Released Updates for Microsoft Dynamics 365 Business Central 2019 Release Wave 2 on-premises.

1. Run the Set-NAVApplication cmldet:

```
Set-NAVApplication -ServerInstance <server instance name> -ApplicationVersion <new application
version> -Force
```

   For example:

```
Set-NAVApplication -ServerInstance BC150 -ApplicationVersion 15.3.38071.0 -Force
```

2. Run the Sync-NAVTenant cmdlet to synchronize the tenant with the application database.

```
Sync-NAVTenant -ServerInstance <server instance name> -Mode Sync -Tenant <tenant ID>
```

   With a single-tenant deployment, you can omit the `-Tenant` parameter and value.

3. Run the Start-NavDataUpgrade cmdlet to change the version number:

```
Start-NAVDataUpgrade -ServerInstance <server instance name> -Tenant <tenant ID>
```

Upgrading to Dynamics 365 Business Central 2020 Release Wave 1

2/17/2021 • 2 minutes to read • Edit Online

Business Central 2020 release wave 1 (version 16) is the second major release that is fully AL-based. Business Central 2019 release wave 2 (version 15) marked the release in which C/AL was replaced by AL. The classic development environment, known as C/SIDE, has been deprecated. From an application perspective, Business Central is now extension-based only. The Business Central base application is delivered as an AL extension. Also, application functionality that isn't related to the business logic has been moved into separate modules. These modules are combined into an extension known as the System Application. This change will influence how you do the upgrade compared to earlier releases.

Upgrade path

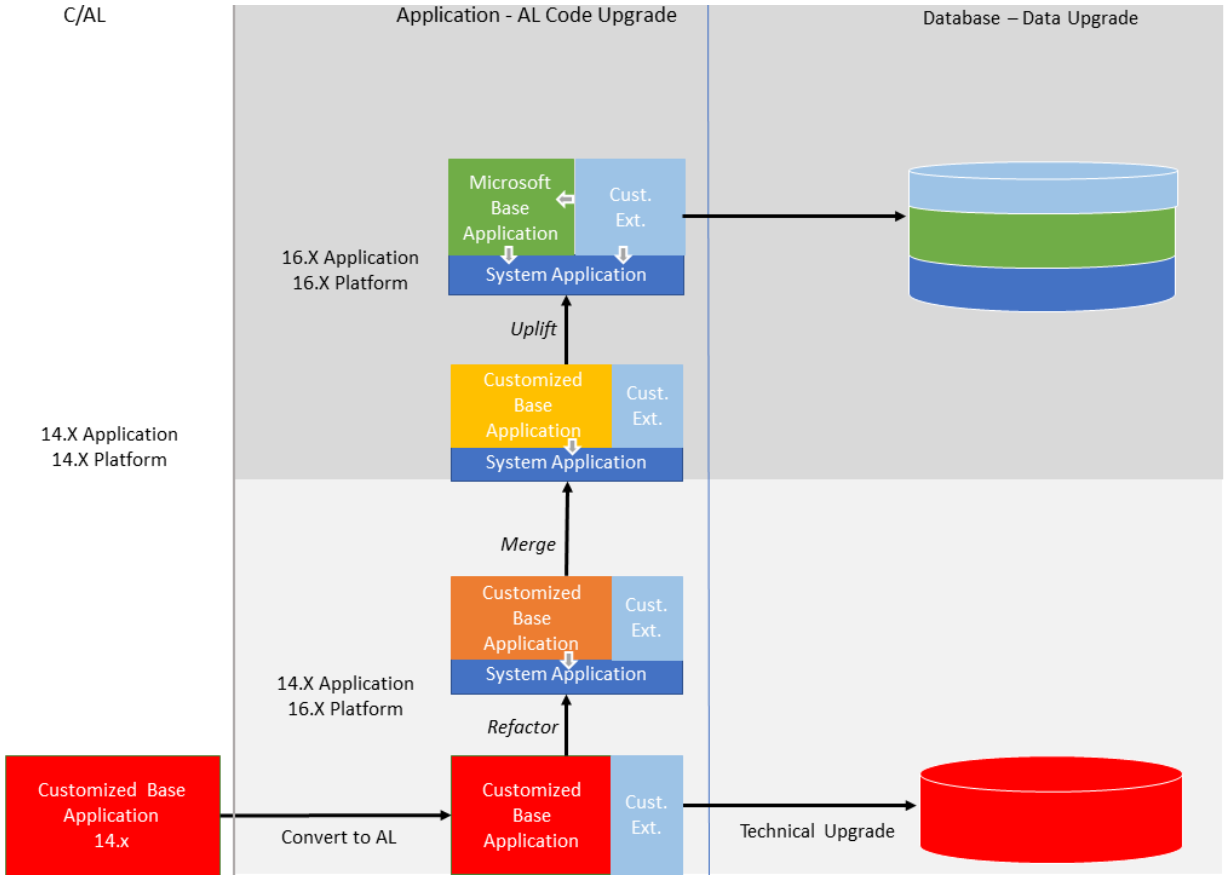
Depending on your current version, a direct upgrade to version 16 isn't always possible. You may have to first upgrade to an intermediate version. The following table describes the upgrade paths for supported versions:

SOURCE VERSION	PATH	COMMENT
• Microsoft Dynamics NAV 2015 (version 8) • Microsoft Dynamics NAV 2016 (version 9) • Microsoft Dynamics NAV 2017 (version 10) • Microsoft Dynamics NAV 2018 (version 11) • Business Central October 2018 (version 13)	1. Business Central Spring 2019 (version 14) 2. Business Central 2020 Release Wave 2 (version 16)	This path requires you convert your application from C/AL to AL.
• Business Central Spring 2019 (version 14) • Business Central 2019 Release Wave 2 (version 15)	Direct to version 16	

Your current version doesn't have to be the latest update for the version. However, for intermediate versions, use to the latest available update.

Upgrade overview

When upgrading your Business Central Spring 2019 (version 14) solution to version 16, the goal is to move towards a full uptake of the Business Central base and system applications, as they are, and migrating code customizations to addon extensions. There are different upgrade levels that you follow to get to this state, as illustrated in the following figure. We recommend that you refactor to the system application as a minimum.



Technical Upgrade

Although it's recommend to refactor to the system application as a minimum, you can do a technical upgrade only. A technical upgrade changes the database so that it works on the latest Business Central platform. The conversion updates the system tables of the old database to the new schema (data structure). It provides you with the latest platform features and performance enhancements.

When upgrading from version 14, part of the technical upgrade process includes converting your customized base application from C/AL to AL.

New and changed features

There are several new and changed platform and application features available in Business Central 2020 release wave 1. These changes affect users, administrators, and developers. For an overview of these features, see Overview of Dynamics 365 Business Central 2020 release wave 1.

To take advantage of these features, you'll have to do an application code upgrade, not just a technical (platform) upgrade.

Deprecated features

Before you upgrade, review the following articles to get an overview of features deprecated in this release:

- Deprecated Tables
- Deprecated Features in W1

  From this article, use the links in the table of content to view deprecated features specific to local versions

Migrating from on-premises to online

For information about migrating an on-premises solution to online, see Migrate to Business Central Online from Business Central On-premises.

Dynamics 365 Business Central Upgrade Compatibility Matrix

Dynamics 365 Business Central Upgrade Compatibility Matrix

2/17/2021 • 2 minutes to read • Edit Online

You can upgrade Business Central Spring 2019 (version 14) directly to 2019 release wave 2 (version 15) or to 2020 release wave 1 (version 16). And, of course, you can upgrade 2019 release wave 2 directly to 2020 release wave 1 (version 16). For an overview of the supported paths, see Supported Upgrade Paths.

However, minor updates are regularly made available for each major release, like 14.1 or 15.2. When upgrading, it's important to target an update version that's compatible with your current version.

Before choosing the target version

Before you choose the target version for your upgrade, read the Some Known Issues article. This article will describe issues in Business Central versions that affect upgrade.

Version 14 compatibility

The following table lists the Business Central 14 versions and the minimum 15, 16, and 17 version that's compatible for upgrade.

VERSION 14	VERSION 15	VERSION 16	VERSION 17
14.0 (GA and cumulative update 01)	15.0	16.0	17.0
14.3 (cumulative update 02)	15.0	16.0	17.0
14.4 (cumulative update 03)	15.0	16.0	17.0
14.5 (cumulative update 04)	15.0	16.0	17.0
14.6 (cumulative update 05)	15.1	16.0	17.0
14.7 (cumulative update 06)	15.2	16.0	17.0
14.8 (cumulative update 07)	15.3	16.0	17.0
14.9 (cumulative update 08)	15.3	16.0	17.0
14.10 (cumulative update 09)	15.4	16.0	17.0
14.11 (cumulative update 10)	15.5	16.0	17.0
14.12 (cumulative update 11)	15.6	16.1	17.0

VERSION 14	VERSION 15	VERSION 16	VERSION 17
14.13 (cumulative update 12)	15.7	16.2	17.0
14.14 (cumulative update 13)	15.8	16.3	17.0
14.15 (cumulative update 14)	15.9	16.4	17.0
14.16 (cumulative update 15)	15.10	16.5	17.0
14.17 (cumulative update 16)	15.11	16.6	17.0
14.18 (cumulative update 17)	15.12	16.7	17.1
14.19 (cumulative update 18)	15.13	16.8	17.2
14.20 (cumulative update 19)	15.14	16.9	17.3
14.21 (cumulative update 20)	15.15	16.10	17.4
14.22 (cumulative update 21)[1]	15.16	16.11	17.5

For example, you can upgrade version 14.0 to any 15 or 16 version. You can only upgrade version 14.11 to version 15.5 (or later) or version 16.0 (or later).

To see the available updates for Business Central 2019 Release Wave 2, see Released Updates for Microsoft Dynamics 365 Business Central 2019 Release Wave 2 on-premises.

[1]The compatible upgrade versions for this version aren't available yet. If you are currently operating on this version, you'll have to wait until the next round of updates before you upgrade.

Version 15 compatibility

The following table lists the Business Central 15 versions and the minimum 16 and 17 version that's compatible for upgrade.

VERSION 15	VERSION 16	VERSION 17
15.0 to 15.4	16.0	17.0
15.5	16.1	17.0
15.6	16.2	17.0
15.7	16.3	17.0

VERSION 15	VERSION 16	VERSION 17
15.8	16.4	17.0
15.9	16.5	17.0
15.10	16.6	17.0
15.11	16.7	17.1
15.12	16.8	17.2
15.13	16.9	17.3
15.14	16.10	17.4
15.15[1]	16.11	17.5

To see the available updates for Business Central 2020 Release Wave 1, see Released Updates for Microsoft Dynamics 365 Business Central 2020 Release Wave 1 on-premises.

Version 16 compatibility

The following table lists the Business Central 16 versions and the minimum 17 version that's compatible for upgrade.

VERSION 16	VERSION 17
16.0 to 16.5	17.0
16.6	17.1
16.7	17.2
16.8	17.3
16.9	17.4
16.10[1]	17.5

To see the available updates for Business Central 2020 Release Wave 2, see Released Updates for Microsoft Dynamics 365 Business Central 2020 Release Wave 2 on-premises.

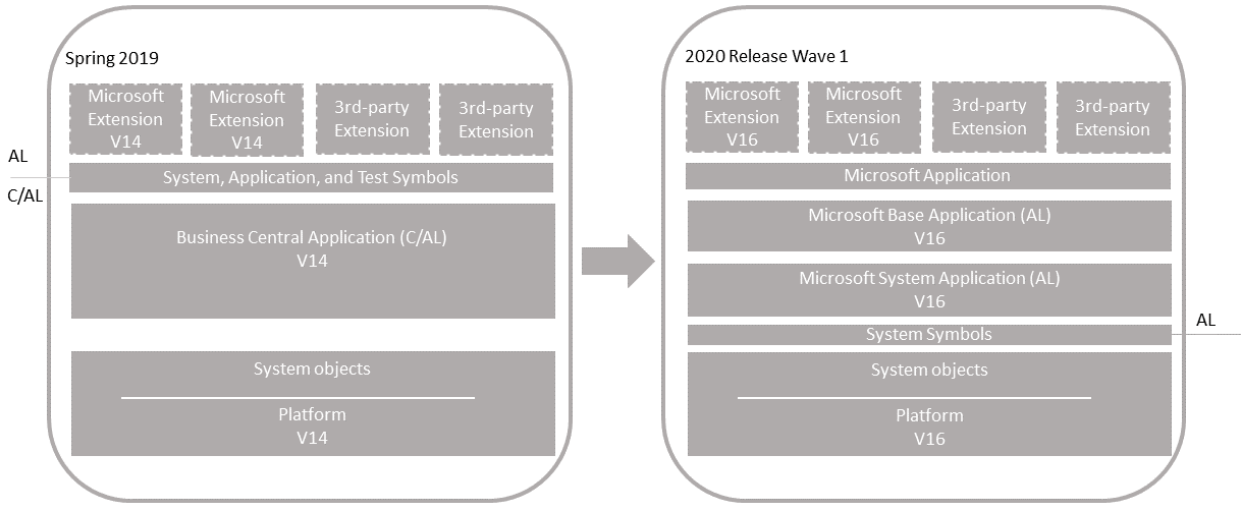
Upgrading to Business Central

Upgrading Unmodified C/AL Application to Version 16

2/17/2021 • 15 minutes to read • Edit Online

Use this scenario if you have a Business Central Spring 2019 (version 14) application or earlier that doesn't include any code customization. Your solution might include Microsoft (first party) extensions and customization extensions (3rd-party). With this upgrade, you'll replace the C/AL base application with the new system and base application extensions. The result will be a fully upgraded Business Central 2020 release wave 1 (version 16) application and platform.



Single-tenant and multitenant deployments

The process for upgrading the similar for a single-tenant and multitenant deployment. However, there are some inherent differences. With a single-tenant deployment, the application code and business data are in the same database. In a multitenant deployment, application code is in a separate database (the application database) than the business data (tenant). In the procedures that follow, for a single-tenant deployment, consider references to the *application database* and *tenant database* as the same database. Steps are marked as *Single-tenant only* or *Multitenant only* where applicable.

Prerequisite

1. Upgrade to Business Central Spring 2019 (version 14).

   - If your solution is already on version 14, then no action on this step is required.
   - If you're upgrading from Business Central Fall 2018 (version 13) or Dynamics NAV, we recommend you upgrade to the latest update for version 14 that has a compatible update for version 16. For more information, see Dynamics 365 Business Central Upgrade Compatibility Matrix.

   To download the latest update, go to Released Cumulative Updates for Microsoft Dynamics 365 Business Central Spring 2019 Update on-premises.

   For information about how to do the upgrade, see Upgrading to Dynamics 365 Business Central On-Premises.

2. Disable data encryption.

   If the current server instance uses data encryption, disable it. You can enable it again after upgrading.

   For more information, see Managing Encryption and Encryption Keys.

Instead of disabling encryption, you can export the current encryption key, which you'll then import after upgrade. However, we recommend disabling encryption before upgrading.

Task 1: Install version 16

1. Download the latest available update for version 16 that is compatible with your version 14.

   To download the latest update, go to Released Updates for Microsoft Dynamics 365 Business Central 2019 Release Wave 2 on-premises.

   The guidelines in this article assume that you're running the latest available update.

2. Before you install version 16, it can be useful to create desktop shortcuts to the version 14.0 tools, such as the Business Central Server Administration tool, Business Central Administration Shell, and Dynamics NAV Development Shell because the Start menu items for these tools will be replaced with the version 16 tools.

3. Install Business Central version 16 components.

   You'll have to keep version 14 installed to complete some steps in the upgrade process. When you install version 16, you must either specify different port numbers for components (like the Business Central Server instance and web services) or stop the version 14.0 Business Central Server instance before you run the installation. Otherwise, you'll get an error that the Business Central Server failed to install.

   For more information, see Installing Business Central Using Setup.

Task 2: Prepare version 14 databases

1. Make backup of the databases.

2. Start Business Central Administration Shell for version 14 as an administrator.

3. Uninstall all extensions from the old tenants.

   In this step, you uninstall any extensions that are currently installed on the database.

   a. Get a list of installed extensions.

      This step is optional, but it can be useful to the names and versions of the extensions.

      To get a list of installed extensions, use the Get-NAVAppInfo cmdlet.

      ```
      Get-NAVAppInfo -ServerInstance <server instance name> -Tenant <tenant ID>
      ```

      For a single-tenant deployment, set the `<tenant ID>` to default.

   b. Uninstall the extensions.

      To uninstall an extension, you use the Uninstall-NAVApp cmdlet.

      ```
      Uninstall-NAVApp -ServerInstance <server instance name> -Name <extensions name> -Tenant
      <tenant ID> -Version <extension version> -Force
      ```

      Replace `<extension name>` and `<extension version>` with the exact name and version the published System Application.

      For example, together with the Get-NAVApp cmdlet, you can uninstall all extensions with a single command:

```
Get-NAVAppInfo -ServerInstance <server instance name> -Tenant <tenant ID>| % { Uninstall-
NAVApp -ServerInstance <server instance name> -Tenant <tenant ID> -Name $_.Name -Version
$_.Version -Force}
```

4. Unpublish all extensions from the application server instance.

   To unpublish an extension, use the Unpublish-NAVApp cmdlet:

   ```
   Unpublish-NAVApp -ServerInstance <server instance name> -Name <extension name> -Version <extension
   version>
   ```

   Together with the Get-NAVAppInfo cmdlet, you can unpublish all extensions by using a single command:

   ```
   Get-NAVAppInfo -ServerInstance <BC14 server instance> | % { Unpublish-NAVApp -ServerInstance <BC14
   server instance> -Name $_.Name -Version $_.Version }
   ```

5. Unpublish all system, test, and application symbols.

   To unpublish symbols, use the Unpublish-NAVAPP cmdlet with the `-SymbolsOnly` switch.

   ```
   Get-NAVAppInfo -ServerInstance <BC14 server instance> -SymbolsOnly | % { Unpublish-NAVApp -
   ServerInstance <BC14 server instance> -Name $_.Name -Version $_.Version }
   ```

   What are symbols?

6. (Multitenant only) Dismount the tenants from the application server instance.

   To dismount a tenant, use the Dismount-NAVTenant cmdlet:

   ```
   Dismount-NAVTenant -ServerInstance <server instance name> -Tenant <tenant ID>
   ```

7. Stop the server instance.

   ```
   Stop-NAVServerInstance -ServerInstance <server instance name>
   ```

Task 3: Convert the version 14 database

This task runs a technical upgrade on the application database to convert it from the version 14 platform to the version 16 platform. The conversion updates the system tables of the database to the new schema (data structure). It provides the latest platform features and performance enhancements.

1. Start Business Central Administration Shell for version 16 as an administrator.
2. Run the Invoke-NAVApplicationDatabaseConversion cmdlet to start the conversion:

   ```
   Invoke-NAVApplicationDatabaseConversion -DatabaseServer <database server name>\<database server
   instance> -DatabaseName "<database name>"
   ```

   When completed, a message like the following displays in the console:

```
DatabaseServer      : .\BCDEMO
DatabaseName        : Demo Database BC (14-0)
DatabaseCredentials :
DatabaseLocation    :
Collation           :
```

Task 4: Configure version 16 server for DestinationAppsForMigration

When you installed version 16 in **Task 1**, a version 16 Business Central Server instance was created. In this task, you change server configuration settings that are required to complete the upgrade. Some of the changes are only required for version 14 to version 16.0 upgrade and can be reverted after you complete the upgrade.

1. Set the server instance to connect to the application database.

   ```
   Set-NAVServerConfiguration -ServerInstance <server instance name> -KeyName DatabaseName -KeyValue "
   <database name>"
   ```

   In a single tenant deployment, this command will mount the tenant automatically. For more information, see Connecting a Server Instance to a Database.

2. Configure the server instance for migrate extensions to the use the new base application and system application extensions.

   ```
   Set-NAVServerConfiguration -ServerInstance <server instance name> -KeyName
   "DestinationAppsForMigration" -KeyValue '[{"appId":"63ca2fa4-4f03-4f2b-a480-172fef340d3f",
   "name":"System Application", "publisher": "Microsoft"},{"appId":"437dbf0e-84ff-417a-965d-
   ed2bb9650972", "name":"Base Application", "publisher": "Microsoft"}]'
   ```

   This setting serves the following purposes:

   - When you run the data upgrade on a tenant, the server will run the data upgrade for the base and system application extensions. The base and system applications will be automatically installed on the tenant also.
   - Lets you republish extensions that haven't been built on version 16. The extensions typically include the third-party extensions that were used in your version 14. When you publish the extensions, the extension manifests are automatically modified with a dependency on the base and system applications.

   For more information about this setting, see DestinationAppsForMigration.

3. Disable task Scheduler on the server instance for purposes of upgrade.

   ```
   Set-NavServerConfiguration -ServerInstance <server instance name> -KeyName "EnableTaskScheduler" -
   KeyValue false
   ```

   Be sure to re-enable task scheduler after upgrade if needed.

4. Restart the server instance.

   ```
   Restart-NAVServerInstance -ServerInstance <server instance name>
   ```

Task 5: Increase application version

This task is optional, but it's recommended. You can choose to skip it for now and do it later. In this task, you'll

increase the application_version that's stored in ndodbproperty table of the application database. The application version isn't changed automatically. The application version serves two purposes:

- Enables running the Start-NAVDataUpgrade cmdlet later in Task 8 of this article. The application version is compared with the tenant's version. If the application version is greater, a data upgrade can be run. If you skip this task, you'll have to use the `-SkipAppVersionCheck` switch with Start-NAVDataUpgrade cmdlet in Task 9.
- The application version is shown in the client on the **Help and Support** page. This task ensures that page displays the latest application version.

The version has the format `major.minor.build.revision`, such as, '14.3.14824.1'. As a minimum, you increase the revision by 1. However, we recommend setting the value to application build number for the version 16 update. You can get this number from the Released Updates for Microsoft Dynamics 365 Business Central 2019 Release Wave 2 on-premises page.

To change the application version, run the Set-NAVApplication cmldet:

```
Set-NAVApplication -ServerInstance <server instance name> -ApplicationVersion <new application version> -
Force
```

For example:

```
Set-NAVApplication -ServerInstance BC160 -ApplicationVersion 16.0.38071.0 -Force
```

Later, when you synchronize and upgrade the tenant(s), the new application version will be updated in the tenant database (ndotenantproperty table).

Task 6: Import version 16 license

1. Use the Import-NAVServerLicense to upload the version 16 license to the database.

   ```
   Import-NAVServerLicense -ServerInstance <server instance name> -LicenseFile <path and file name>
   ```

2. Restart the server instance.

   ```
   Restart-NAVServerInstance -ServerInstance <server instance name>
   ```

Task 7: Publish symbols and extensions

In this task, you'll publish the platform symbols and extensions. As minimum, you publish the new base application and system application extensions from the installation media (DVD). You also publish new versions of any Microsoft extensions and third-party extensions that were used on your old deployment.

Publishing an extension adds the extension to the application database that is mounted on the server instance. Once published, it's available for installing on tenants. This task updates internal tables, compiles the components of the extension behind-the-scenes, and builds the necessary metadata objects that are used at runtime.

The steps in this task continue to use the Business Central Administration Shell for version 14 that you started in the previous task.

1. Publish version 16 system symbols extension.

   The symbols extension contains the required platform symbols that the base application depends on. The

symbols extension package is called **System.app**. You find it where the **AL Development Environment** is installed. The default path is C:\Program Files (x86)\Microsoft Dynamics 365 Business Central\160\AL Development Environment.

```
Publish-NAVApp -ServerInstance  <server instance name> -Path "<path to system.app>" -PackageType
SymbolsOnly
```

What are symbols?

2. Publish the **System Application** extension (Microsoft_System Application.app).

   You find the (Microsoft_System Application.app in the **Applications\System Application\Source** folder of installation media (DVD).

   ```
   Publish-NAVApp -ServerInstance <server instance name> -Path "<path to Microsoft_System
   Application.app>"
   ```

   What is the System Application?

3. Publish the Business Central base application extension (Microsoft_Base Application.app).

   The **Base Application** extension contains the application business objects. You find the (Microsoft_Base Application.app in the **Applications\BaseApp\Source** folder of installation media (DVD).

   ```
   Publish-NAVApp -ServerInstance <server instance name> -Path "<path to Microsoft_Base
   Application.app>"
   ```

4. Publish the Microsoft_Application extension

   The Microsoft_Application extension is a new extension introduced in 15.3. For more information about this extension, see The Microsoft_Application.app File.

   ```
   Publish-NAVApp -ServerInstance <server instance name> -Path "<folder path>\Microsoft_Application.app"
   ```

5. Publish the new versions of Microsoft extensions.

   In this step, you publish new versions of Microsoft extensions that were used on your version 14 deployment. You find the extensions in the **Applications** folder of the installation media (DVD).

   ```
   Publish-NAVApp -ServerInstance <server instance name> -Path "<path to Microsoft extension>"
   ```

   For example:

   ```
   Publish-NAVApp -ServerInstance BC160 -Path
   "C:\W1DVD\Applications\SalesAndInventoryForecast\Source\SalesAndInventoryForecast.app"
   ```

6. Publish 3rd-party extensions.

   Publish 3rd-party extensions that were used on your version 14 solution. If you have new versions of these extensions, built on the Business Central version 16, then publish the new versions. Otherwise, republish the same versions that were previously published in the old deployment.

   ```
   Publish-NAVApp -ServerInstance BC150 -Path "<path to extension>"
   ```

Task 8: Restart server instance

Restart the Business Central Server to free up resources for completing the upgrade.

```
Restart-NAVServerInstance -ServerInstance <server instance name>
```

This step is important, otherwise you might experience issues when you run the data upgrade.

Task 9: Synchronize tenant

In this task, you'll synchronize the tenant's database schema with any schema changes in the application database and extensions.

If you have a multitenant deployment, do these steps for each tenant.

1. (Multitenant only) Mount the tenant to the version 16 server instance.

   To mount the tenant, use the Mount-NAVTenant cmdlet:

   ```
   Mount-NAVTenant -ServerInstance <server instance name> -DatabaseName <database name> -DatabaseServer
   <database server>\<database instance> -Tenant <tenant ID> -AllowAppDatabaseWrite
   ```

   > **IMPORTANT**
   > You must use the same tenant ID for the tenant that was used in the old deployment; otherwise you'll get an error when mounting or syncing the tenant. If you want to use a different ID for the tenant, you can either use the `-AlternateId` parameter now or after upgrading, dismount the tenant, then mount it again using the new ID and the `OverwriteTenantIdInDatabase` parameter.

   > **NOTE**
   > For upgrade, we recommend that you use the `-AllowAppDatabaseWrite` parameter. After upgrade, you can dismount and mount the tenant again without the parameter if needed.

   At this stage, the tenant state is OperationalWithSyncPending.

2. Synchronize the tenant with the application database.

   Use the Sync-NAVTenant cmdlet:

   ```
   Sync-NAVTenant -ServerInstance <server instance name> -Mode Sync -Tenant <tenant ID>
   ```

   With a single-tenant deployment, you can omit the `-Tenant` parameter and value.

3. Synchronize the tenant with the **System Application** extension.

   Use the Sync-NAVApp cmdlet:

   ```
   Sync-NAVApp -ServerInstance <server instance name> -Tenant <tenant ID> -Name "System Application" -
   Version <extension version>
   ```

   Replace `<extension version>` with the exact version of the published System Application. To get the version, you can use the Get-NAVAppInfo cmdlet.

4. Synchronize the tenant with the Business Central Base Application extension.

   ```
   Sync-NAVApp -ServerInstance <server instance name> -Tenant <tenant ID> -Name "Base Application" -
   Version <extension version>
   ```

   Replace `<extension version>` with the exact version of the published Base Application.

5. Synchronize the tenant with the Application extension.

   ```
   Sync-NAVApp -ServerInstance <server instance name> -Tenant <tenant ID> -Name "Application"
   ```

6. Synchronize the tenant with Microsoft and 3rd-party extensions.

   For each extension, run the Sync-NAVApp cmdlet:

   ```
   Sync-NAVApp -ServerInstance BC160 -Tenant default -Name "<extension name>" -Version <extension
   version>
   ```

TIP

When you synchronize an extension, the extension takes ownership of any tables that it includes. In SQL Server, you'll notice that the table names will be suffixed with the extension ID. For example, Base Application tables will have `437dbf0e-84ff-417a-965d-ed2bb9650972` in the name. In addition, the systemId column is added to application tables that are not already part of an extension.

Task 10: Upgrade data

In this task, you run a data upgrade on tables to handle data changes made by platform and extensions.

If you have a multitenant deployment, do these steps for each tenant.

1. Upgrade the data to the platform, system application, and base application.

   a. To run the data upgrade, use the Start-NavDataUpgrade cmdlet:

      ```
      Start-NAVDataUpgrade -ServerInstance <server instance name> -Tenant <tenant ID> -
      FunctionExecutionMode Serial [-SkipAppVersionCheck]
      ```

      You only need to use the -SkipAppVersionCheck if you didn't increase the application version in Task 5.

   b. To view the progress of the data upgrade, you can run Get-NavDataUpgrade cmdlet with the `-Progress` switch.

   This step will automatically install the base application and system application on the tenant.

2. Upgrade the new versions of Microsoft extensions and third-party extensions.

   Complete this task to upgrade any Microsoft extension and third-party extension. Microsoft extensions used in the old deployment to new versions on the installation media. The new versions are in the **Application** folder of the DVD. There's a folder for each extension. The extension package (.app file) is in the **Source** folder.

   a. Install **Application** extension.

You'll have to install the **Application** extension first, otherwise you can't upgrade Microsoft extensions.

```
Install-NAVApp -ServerInstance <server instance name> -Tenant <tenant ID> -Name "Application"
```

b. For each extension, run Start-NAVAppDataUpgrade cmdlet:

```
Start-NAVAppDataUpgrade -ServerInstance <server instance name> -Name "<extension name>" -
Version <extension version>
```

This step will also automatically install the new extension version on the tenant.

3. (Multitenant only) Repeat steps 1 through 3 for each tenant.

Task 11: Install 3rd-party extensions

Complete this task to install third-party extensions for which a new version wasn't published. For each extension, run the Install-NAVApp cmdlet:

```
Install-NAVApp -ServerInstance <server instance name> -Name <extension name> -Version <extension version>
```

Task 12: Upgrade control add-ins

The Business Central Server installation includes new versions of the Microsoft-provided Javascript-based control add-ins, like Microsoft.Dynamics.Nav.Client.BusinessChart, Microsoft.Dynamics.Nav.Client.VideoPlayer, and more. If your solution uses any of these control add-ins, upgrade them to the latest version.

To upgrade the control add-ins from the client, do the following steps:

1. Open the Business Central client.
2. Search for and open the **Control Add-ins** page.
3. Choose **Actions** > **Control Add-in Resource** > **Import**.
4. Locate and select the .zip file for the control add-in and choose **Open**.

   The .zip files are located in the **Add-ins** folder of the Business Central Server installation. There's a subfolder for each add-in. For example, the path to the Business Chart control add-in is `C:\Program Files\Microsoft Dynamics 365 Business Central\160\Service\Add-ins\BusinessChart\Microsoft.Dynamics.Nav.Client.BusinessChart.zip`.

5. After you've imported all the new control add-in versions, restart Business Central Server instance.

Alternatively, you can use the Set-NAVAddin cmdlet of the Business Central Administration Shell. For example, the following commands update the control add-ins installed by default. Modify the commands to suit:

```
$InstanceName = 'BC160'
$ServicesAddinsFolder = 'C:\Program Files\Microsoft Dynamics 365 Business Central\160\Service\Add-ins'
Set-NAVAddIn -ServerInstance $InstanceName -AddinName 'Microsoft.Dynamics.Nav.Client.BusinessChart' -
PublicKeyToken 31bf3856ad364e35 -ResourceFile ($AppName = Join-Path $ServicesAddinsFolder
'BusinessChart\Microsoft.Dynamics.Nav.Client.BusinessChart.zip')
Set-NAVAddIn -ServerInstance $InstanceName -AddinName 'Microsoft.Dynamics.Nav.Client.FlowIntegration' -
PublicKeyToken 31bf3856ad364e35 -ResourceFile ($AppName = Join-Path $ServicesAddinsFolder
'FlowIntegration\Microsoft.Dynamics.Nav.Client.FlowIntegration.zip')
Set-NAVAddIn -ServerInstance $InstanceName -AddinName 'Microsoft.Dynamics.Nav.Client.OAuthIntegration' -
PublicKeyToken 31bf3856ad364e35 -ResourceFile ($AppName = Join-Path $ServicesAddinsFolder
'OAuthIntegration\Microsoft.Dynamics.Nav.Client.OAuthIntegration.zip')
Set-NAVAddIn -ServerInstance $InstanceName -AddinName 'Microsoft.Dynamics.Nav.Client.PageReady' -
PublicKeyToken 31bf3856ad364e35 -ResourceFile ($AppName = Join-Path $ServicesAddinsFolder
'PageReady\Microsoft.Dynamics.Nav.Client.PageReady.zip')
Set-NAVAddIn -ServerInstance $InstanceName -AddinName 'Microsoft.Dynamics.Nav.Client.PowerBIManagement' -
PublicKeyToken 31bf3856ad364e35 -ResourceFile ($AppName = Join-Path $ServicesAddinsFolder
'PowerBIManagement\Microsoft.Dynamics.Nav.Client.PowerBIManagement.zip')
Set-NAVAddIn -ServerInstance $InstanceName -AddinName 'Microsoft.Dynamics.Nav.Client.RoleCenterSelector' -
PublicKeyToken 31bf3856ad364e35 -ResourceFile ($AppName = Join-Path $ServicesAddinsFolder
'RoleCenterSelector\Microsoft.Dynamics.Nav.Client.RoleCenterSelector.zip')
Set-NAVAddIn -ServerInstance $InstanceName -AddinName 'Microsoft.Dynamics.Nav.Client.SatisfactionSurvey' -
PublicKeyToken 31bf3856ad364e35 -ResourceFile ($AppName = Join-Path $ServicesAddinsFolder
'SatisfactionSurvey\Microsoft.Dynamics.Nav.Client.SatisfactionSurvey.zip')
Set-NAVAddIn -ServerInstance $InstanceName -AddinName 'Microsoft.Dynamics.Nav.Client.SocialListening' -
PublicKeyToken 31bf3856ad364e35 -ResourceFile ($AppName = Join-Path $ServicesAddinsFolder
'SocialListening\Microsoft.Dynamics.Nav.Client.SocialListening.zip')
Set-NAVAddIn -ServerInstance $InstanceName -AddinName 'Microsoft.Dynamics.Nav.Client.VideoPlayer' -
PublicKeyToken 31bf3856ad364e35 -ResourceFile ($AppName = Join-Path $ServicesAddinsFolder
'VideoPlayer\Microsoft.Dynamics.Nav.Client.VideoPlayer.zip')
Set-NAVAddIn -ServerInstance $InstanceName -AddinName 'Microsoft.Dynamics.Nav.Client.WebPageViewer' -
PublicKeyToken 31bf3856ad364e35 -ResourceFile ($AppName = Join-Path $ServicesAddinsFolder
'WebPageViewer\Microsoft.Dynamics.Nav.Client.WebPageViewer.zip')
Set-NAVAddIn -ServerInstance $InstanceName -AddinName 'Microsoft.Dynamics.Nav.Client.WelcomeWizard' -
PublicKeyToken 31bf3856ad364e35 -ResourceFile ($AppName = Join-Path $ServicesAddinsFolder
'WelcomeWizard\Microsoft.Dynamics.Nav.Client.WelcomeWizard.zip')
```

At this point, the upgrade is complete, and you can open the client.

Post-upgrade tasks

1. Enable task scheduler on the server instance.
2. (Multitenant only) For tenants other than the tenant that you use for administration purposes, if you mounted the tenants using the `-AllowAppDatabaseWrite` parameter, dismount the tenants, then mount them again without using the `-AllowAppDatabaseWrite` parameter.
3. If you want to use data encryption as before, enable it.

   For more information, see Managing Encryption and Encryption Keys.

   Optionally, if you exported the encryption key instead of disabling encryption earlier, import the encryption key file to enable encryption.
4. Grant users permission to the *Open in Excel* and *Edit in Excel* actions.

   Version 16 introduces a system permission that protects these two actions. The permission is granted by the system object **6110 Allow Action Export To Excel**. Because of this change, users who had permission to these actions before upgrading, will lose permission. To grant permission again, do one of the following steps:

   - Assign the **EXCEL EXPORT ACTION** permission set to appropriate users.
   - Add the system object **6110 Allow Action Export To Excel** permission directly to appropriate

permission sets.

For more information about working with permission sets and permissions, see Export and Import Permission Sets.

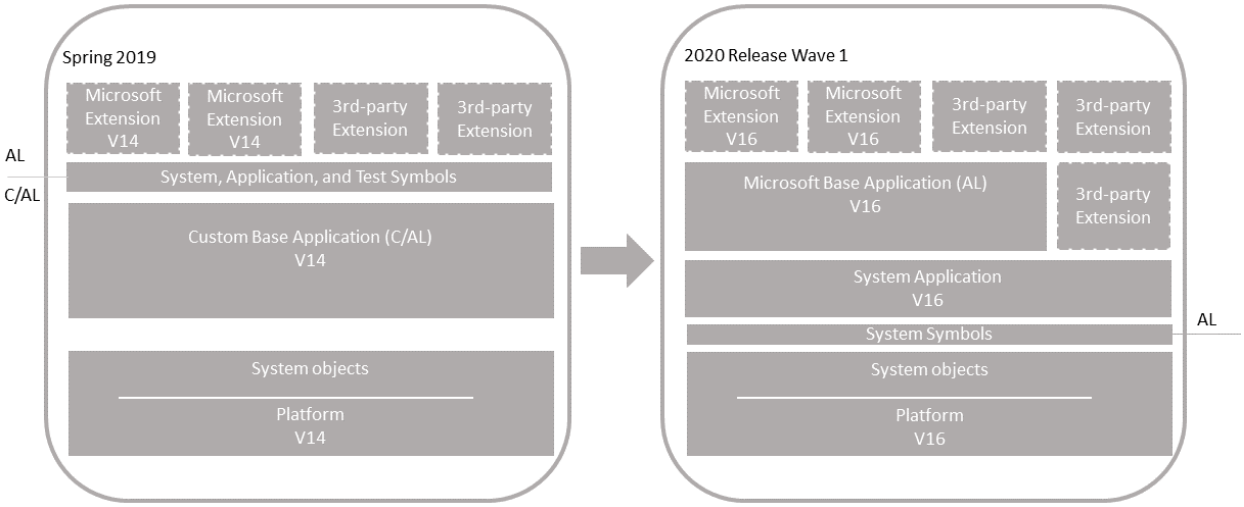
Upgrading Customized C/AL Application to Microsoft Base Application Version 16

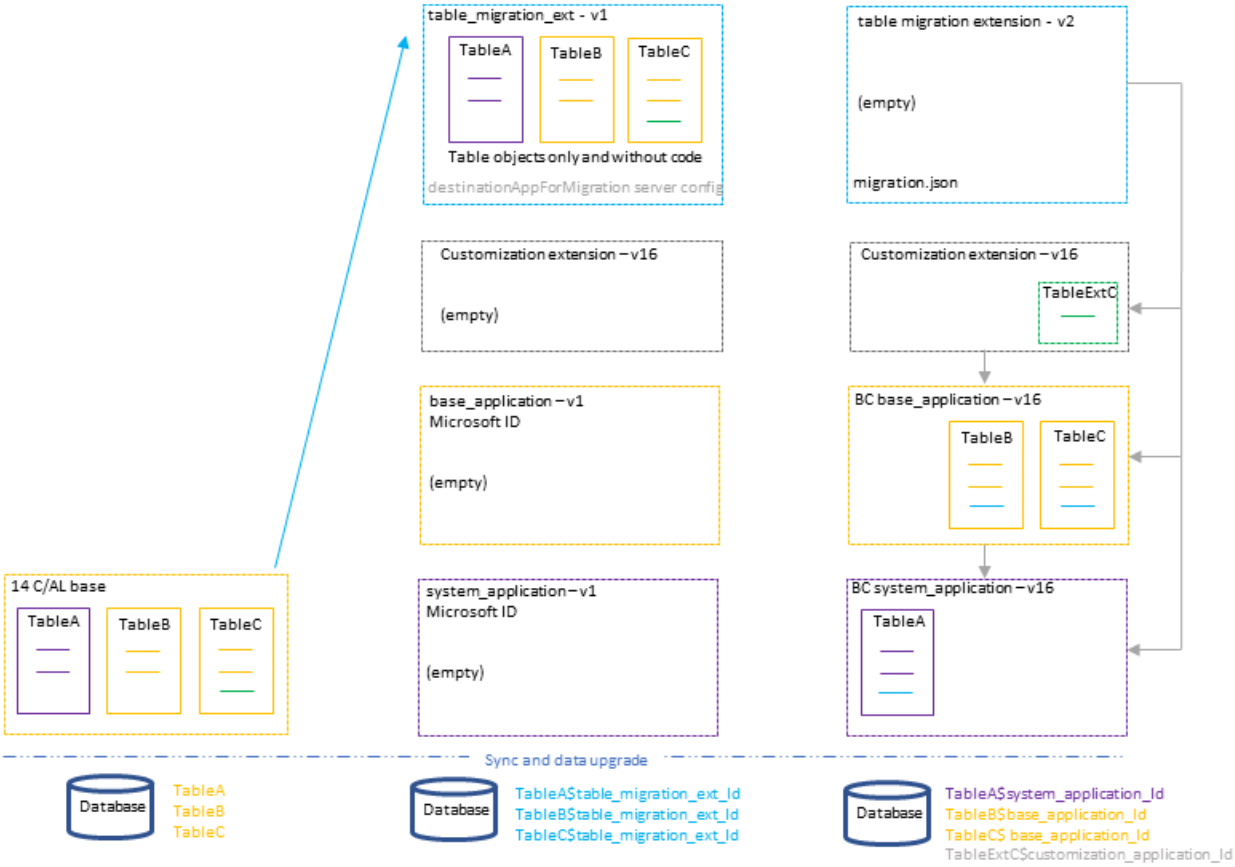
2/17/2021 • 20 minutes to read • Edit Online

This article describes how to upgrade a customized version 14 application to a version 16 solution that uses the Microsoft Base Application.



Overview

The upgrade is divided into two sections: Application Upgrade and Data Upgrade. The Application Upgrade section deals with upgrading the application code. For the application upgrade, you'll have to create several extensions. Some of these extensions are only used for upgrade purposes. The Data Upgrade section deals with upgrading the data on tenants - publishing, syncing, and installing extensions. For this scenario, the data upgrade consists of two phases for migrating data from the current tables to extension-based tables. The following figure illustrates the upgrade process.



The process uses two special features for migrating tables and data to extensions:

- destinationappsformigration server setting

  The *destinationappsformigration* setting is a configuration setting on the Business Central Server. In short, it's used to transfer ownership of the existing tables to the table migration extension. For more information, see DestinationAppsForMigration.

- migration.json file

  The *migration.json* file is used to migrate tables and fields from one extension to another. In this case, migration is from the table migration extension to system and base application tables. For more information about the migration.json, see The Migration.json File.

Single-tenant and multitenant deployments

The process for upgrading is similar for a single-tenant and multitenant deployment. However, there are some inherent differences. With a single-tenant deployment, the application and business data are included in the same database. While with a multitenant deployment, application code is in a separate database (the application database) than the business data (tenant). In the procedures that follow, for a single-tenant deployment, consider references to the *application database* and *tenant database* as the same database. Steps are marked as *Single-tenant only* or *Multitenant only* where applicable.

Prerequisites

- Get the required version of the txt2al conversion tool.

  During the upgrade, you'll use the txt2al conversion tool to convert existing tables to the AL syntax. You'll need to use a version of txt2al conversion tool that supports the `--tableDataOnly` parameter. This parameter was first introduced in version 14.12 (cumulative update 11, platform 14.0.41862). So if you're upgrading from version 14.11 (cumulative update 10) or earlier, you'll have to download the txt2al conversion tool from a later version 14 update. See Released Cumulative Updates for Microsoft Dynamics 365 Business Central Spring 2019 Update on-premises.

Install version 16

1. Download the latest available update for Business Central 2020 release wave 1, version **16.5** or later, that is compatible with your version 14.

   For more information, see Dynamics 365 Business Central Upgrade Compatibility Matrix.

   > **IMPORTANT**
   > You must use version 16.5 or later, otherwise you'll run problems during upgrade because of missing enum objects later in this procedure. For more information, see Some Known Issues.

2. Before you install version 16, it can be useful to create desktop shortcuts to the version 14.0 tools, such as the Business Central Server Administration tool, Business Central Administration Shell, and Dynamics NAV Development Shell because the Start menu items for these tools will be replaced with the version 16 tools.

3. Install Business Central version 16 components.

   You'll have to keep version 14 installed to complete some steps in the upgrade process. When you install version 16, you must either specify different port numbers for components (like the Business Central Server instance and web services) or stop the version 14.0 Business Central Server instance before you run the installation. Otherwise, you'll get an error that the Business Central Server failed to install.

   For more information, see Installing Business Central Using Setup.

APPLICATION UPGRADE

This section describes how to upgrade the application code. This work involves creating various extensions.

Task 1: Move code customizations to extensions

The first step, and the largest step, is to create extensions for the customizations compared to the Microsoft base application.

Task 2: Create table migration extension

In this step, you create an extension that consists only of the non-system table objects from your custom base application. The table objects will only include the properties and field definitions. They won't include AL code on triggers or methods. This extension is an interim extension used only during the upgrade.

You'll create two versions of this extension. The first version contains the table objects. The second version, is an empty extension that contains a migrate.json file.

Create the first version

1. Create a folder where you'll store exported txt files for tables (for example, C:\export2al\bc14tablesonly).

2. Start the Dynamics NAV Development Shell for version 14.

3. Run Export-NAVApplicationObject cmdlet to export only tables from the database.

```
Export-NAVApplicationObject -DatabaseServer .\BCDEMO -DatabaseName "Demo Database BC (14-0)" -
ExportToNewSyntax -Path "C:\export2al\bc14tablesonly\exportedbc14-tables.txt" -Filter
'Type=Table;Id=1..1999999999'
```

4. Use the txt2al conversion tool to convert the exported tables to the AL syntax. Use the `--tableDataOnly`

parameter to include table and field definitions only.

```
txt2al --source=C:\export2al\bc14tablesonly --target=C:\export2al\bc14tablesonly\al --tableDataOnly
```

For more information about this tool, see The Txt2Al Conversion Tool.

> **NOTE**
> If the `--tableDataOnly` parameter isn't available, you'll need a later version ot the txt2al conversion tool. See Prerequisites for more information.

5. Make sure you've installed the latest AL Extension for Visual Studio Code from the version 16 DVD.

   For more information, see Getting Started with AL.

6. In Visual Studio Code, create an AL project for table migration extension using the **AL: Go!** command.

   Set the target platform to **5.0 Business Central 2020 release wave 1**.

   For more information, see Getting Started with AL.

7. Configure the project's app.json file:

   - Set the `"name"`, `"publisher"`, and `"version"`. You can use any valid values.
   - Delete the `"application"` parameter.
   - Clear the `"dependencies"`.
   - Set the `"idRanges"` to cover the table object IDs or clear all values.
   - Add the `"target"` parameter and set it to `"Onprem"`.

   Make a note of the `"id"` setting value, which is the ID assigned to the table migration extension. You'll use this ID later in the process. **Don't** use the ID in the following example. It's for illustration purposes only.

```
{
  "id": "11111111-aaaa-2222-bbbb-333333333333",
  "name": "bc14tablesonly",
  "publisher": "My publisher",
  "version": "1.0.0.0",
  "brief": "",
  "description": "",
  "privacyStatement": "",
  "EULA": "",
  "help": "",
  "url": "",
  "logo": "",
  "dependencies": [],
  "screenshots": [],
  "platform": "16.0.0.0",
  "idRanges": [  ],
  "contextSensitiveHelpUrl": "https://bc14tablesonly.com/help/",
  "showMyCode": true,
  "runtime": "5.0",
  "target": "OnPrem"
}
```

8. Create an `.alpackages` folder in the root folder of the project and then copy the system (platform) symbols extension (System.app file) to the folder.

The System.app file is located where you installed the AL Development Environment. By default, the folder path is C:\Program Files (x86)\Microsoft Dynamics 365 Business Central\160\AL Development Environment. This package contains the symbols for all the system tables and codeunits.

9. Add the AL files that you converted tables to the project.

   The folder used in this article is C:\export2al\bc14tablesonly\al.

   > **IMPORTANT**
   > If you're upgrading a **CH** or **NA** local version (14.18 or later), you'll have to rename the primary keys in some tables. For more information, see Known Issues.

10. Build the extension package for the first version.

    To build the extension package, press Ctrl+Shift+B. This step creates an .app file for your extension. The file name has the format <publisher>_<name>_<version>.app.

Create the second version

1. In Visual Studio Code, create a new file called migration.json file and add it to the project's root folder.
2. In the migration.json, include rules for the Microsoft base application, system application, and your customization extensions.

```
{
    "apprules": [
        {
            "id": "63ca2fa4-4f03-4f2b-a480-172fef340d3f"
        },
        {
            "id": "437dbf0e-84ff-417a-965d-ed2bb9650972"
        },
        {
            "id": "<NNNNNNNN-NNNN-NNNN-NNNN-NNNNNNNNNNNN>"
        },
        {
            "id": "<NNNNNNNN-NNNN-NNNN-NNNN-NNNNNNNNNNNN>"
        }
    ]
}
```

   In the example code:

   - `63ca2fa4-4f03-4f2b-a480-172fef340d3f` identifies the system application extension
   - `437dbf0e-84ff-417a-965d-ed2bb9650972` identifies the base application extension
   - The two other IDs are examples that identify other new customization extensions you might have. Replace or remove these entries as needed.

   For more information about the migration.json, see The Migration.json File.

3. Delete the AL objects.
4. Increase the `version` in the app.json file.
5. Build the extension package for the second version.

   To build the extension package, press Ctrl+Shift+B.

Task 3: Create empty extensions System, Base, and customization

extensions

Create two empty extensions: one for the Microsoft base application and another for the System Application. Also, create an empty extension for each new customization extension. The only file in the extension project that is required is an app.json.

You can create the empty extension like any other extension by adding an AL project in Visual Studio Code:

1. In Visual Studio Code, select **View** > **Command Palette** > **AL: Go!** and follow instructions.
2. Delete the HelloWorld.al sample file from the project.
3. Modify the app.json file.

   The important settings in the app.json file `"id"`, `"name"`, `"version"`, `"publisher"`, and `"dependencies"`.

   - The `id` and `name` must match the value used by Microsoft's extensions.
   - Set the `version` to any version lower than 16.0.0.0.
   - You'll also have to include the `"publisher"`. You can use your own publisher name or `"Microsoft"`.
   - Remove all other settings. It's important that there are no `"dependencies"` set.

   The app.json files for the **System Application** and **Base Application** extensions, should look similar to following examples:

   System Application

   ```
   "id": "63ca2fa4-4f03-4f2b-a480-172fef340d3f",
   "name": "System Application",
   "publisher": "Microsoft",
   "version": "14.0.0.0",
   ```

   Base Application

   ```
   "id": "437dbf0e-84ff-417a-965d-ed2bb9650972",
   "name": "Base Application",
   "publisher": "Microsoft",
   "version": "14.0.0.0",
   ```

4. Build and compile the extension package. To build the extension package, press Ctrl+Shift+B.

> **TIP**
> This step is only required if you need to trigger a data upgrade on these extensions, which you'll do by running Start-NavAppDataUpgrade on these extensions in Task 15. For the scenario in this article, at a minimum this step is required for the System and Base Applications. You can skip this step for any customization extensions that do not not include upgrade code.

DATA UPGRADE

Task 4: Prepare databases

1. Make backup of the databases.
2. Disable data encryption.

   If the current server instance uses data encryption, disable it. You can enable it again after upgrading.

For more information, see Managing Encryption and Encryption Keys.

Instead of disabling encryption, you can export the current encryption key, which you'll then import after upgrade. However, we recommend disabling encryption before upgrading.

3. Start Business Central Administration Shell for version 14 as an administrator.
4. (Single-tenant only) Uninstall all extensions from the tenants.

   To uninstall an extension, you use the Uninstall-NAVApp cmdlet. For example, you can uninstall all extensions with a single command:

   ```
   Get-NAVAppInfo -ServerInstance <server instance name> -Tenant <tenant ID>| % { Uninstall-NAVApp -
   ServerInstance <server instance name> -Tenant <tenant ID> -Name $_.Name -Version $_.Version -Force}
   ```

5. (Single-tenant only) Unpublish all extensions from the application server instance.

   To unpublish an extension, use the Unpublish-NAVApp cmdlet. For example, you can unpublish all extensions by using a single command:

   ```
   Get-NAVAppInfo -ServerInstance <BC14 server instance> | % { Unpublish-NAVApp -ServerInstance <BC14
   server instance> -Name $_.Name -Version $_.Version }
   ```

6. Unpublish all system, test, and application symbols.

   To unpublish symbols, use the Unpublish-NAVAPP cmdlet with the `-SymbolsOnly` switch.

   ```
   Get-NAVAppInfo -ServerInstance <BC14 server instance> -SymbolsOnly | % { Unpublish-NAVApp -
   ServerInstance <BC14 server instance> -Name $_.Name -Version $_.Version }
   ```

   What are symbols?

7. (Multitenant only) Dismount the tenants from the application server instance.

   To dismount a tenant, use the Dismount-NAVTenant cmdlet:

   ```
   Dismount-NAVTenant -ServerInstance <server instance name> -Tenant <tenant ID>
   ```

8. Stop the server instance.

   ```
   Stop-NAVServerInstance -ServerInstance <server instance name>
   ```

Task 5: Convert version 14 database

This task runs a technical upgrade on the application database. The task converts the database from the version 14 platform to the version 16 platform. The conversion updates the system tables of the database to the new schema (data structure). It provides the latest platform features and performance enhancements.

1. Start Business Central Administration Shell for version 16 as an administrator.
2. Run the Invoke-NAVApplicationDatabaseConversion cmdlet to start the conversion:

   ```
   Invoke-NAVApplicationDatabaseConversion -DatabaseServer <database server name>\<database server
   instance> -DatabaseName "<database name>"
   ```

When completed, a message like the following displays in the console:

```
DatabaseServer      : .\BCDEMO
DatabaseName        : Demo Database BC (14-0)
DatabaseCredentials :
DatabaseLocation    :
Collation           :
```

Task 6: Configure version 16 server for DestinationAppsForMigration

In this step, you configure the version 16 server instance. In particular, you configure it to migrate the table migration extension that you created earlier. The migration is controlled by the `DestinationAppsForMigration` setting for the server instance. For more information about the `DestinationAppsForMigration` setting, see DestinationAppsForMigration.

1. Set the server instance to connect to the application database.

   ```
   Set-NAVServerConfiguration -ServerInstance <server instance name> -KeyName DatabaseName -KeyValue "
   <database name>"
   ```

   In a single tenant deployment, this command will mount the tenant automatically. For more information, see Connecting a Server Instance to a Database.

2. Configure the `DestinationAppsForMigration` setting of the server instance to table migration extension.

   You'll need the ID, name, and publisher for the table migration extension that you created in **Task 2**.

   ```
   Set-NAVServerConfiguration -ServerInstance <server instance name> -KeyName
   "DestinationAppsForMigration" -KeyValue '[{"appId":"<table migration extension ID>", "name":"<table
   migration extension>", "publisher": "<publisher>"}]'
   ```

   > **NOTE**
   > You can add multiple extensions to this setting.

3. Disable task scheduler on the server instance for purposes of upgrade.

   ```
   Set-NavServerConfiguration -ServerInstance <server instance name> -KeyName "EnableTaskScheduler" -
   KeyValue false
   ```

   Be sure to re-enable task scheduler after upgrade if needed.

4. Restart the server instance.

   ```
   Restart-NAVServerInstance -ServerInstance <server instance name>
   ```

Task 7: Import License

Import the version 16 partner license. To import the license, use the Import-NAVServerLicense cmdlet:

```
Import-NAVServerLicense $-ServerInstance <server instance name> -LicenseFile <path>
```

Restart the server instance.

Task 8: Increase application version

This task is optional, but it's recommended. You can choose to skip it for now and do it later. In this task, you'll increase the application_version that's stored in ndodbproperty table of the application database. The application version isn't changed automatically.

The application version serves two purposes:

- Enables running the Start-NAVDataUpgrade cmdlet later. The application version is compared with the tenant's version. If the application version is greater, a data upgrade can be run. If you skip this task, you'll have to use the `-SkipAppVersionCheck` switch with Start-NAVDataUpgrade cmdlet in Task 11.
- The application version is shown in the client on the **Help and Support** page. This task ensures that page displays the latest application version.

The version has the format `major.minor.build.revision`, such as, '14.3.14824.1'. As a minimum, you increase the revision by 1. However, we recommend setting the value to application build number for the version 16 update. You can get this number from the Released Updates for Microsoft Dynamics 365 Business Central 2020 Release Wave 1 on-premises page.

1. To see the current application version, run the Get-NAVApplication cmdlet:

   ```
   Get-NAVApplication -ServerInstance <server instance name>
   ```

2. To change the application version, run the Set-NAVApplication cmdlet:

   ```
   Set-NAVApplication -ServerInstance <server instance name> -ApplicationVersion <new application
   version> -Force
   ```

   For example:

   ```
   Set-NAVApplication -ServerInstance BC160 -ApplicationVersion 16.0.38071.0 -Force
   ```

Task 9: Publish symbols and DestinationAppsForMigrations

In this task, you'll publish the platform symbols and the extensions configured as DestinationAppsForMigration.

1. Publish version 16 system symbols extension.

   The symbols extension contains the required platform symbols that the base application depends on. The symbols extension package is called **System.app**. You find it where the **AL Development Environment** is installed. The default path is C:\Program Files (x86)\Microsoft Dynamics 365 Business Central\160\AL Development Environment.

   ```
   Publish-NAVApp -ServerInstance  <server instance name> -Path "<path to system.app>" -PackageType
   SymbolsOnly
   ```

   What are symbols?

2. Publish the first version of the table migration extension, which is the version that contains the table objects.

```
Publish-NAVApp -ServerInstance <server instance name> -Path "<path to extension .app file>"
```

3. Publish the empty versions of the following extensions:

   - **System Application** extension
   - **Base Application** extension
   - Customization extensions (if any).

   This step publishes the extensions you created in Task 3. Publish the extensions using the Publish-NAVApp, like in the previous steps. Except if the extensions aren't signed, use the `-SkipVerification` switch parameter.

4. Restart the server instance.

```
Restart-NAVServerInstance -ServerInstance <server instance name>
```

Task 10: Synchronize tenant

In this task, you'll synchronize the tenant's database schema with any schema changes in the application database and extensions.

If you have a multitenant deployment, do these steps for each tenant.

1. (Multitenant only) Mount the tenant to the version 15 server instance.

   To mount the tenant, use the Mount-NAVTenant cmdlet:

```
Mount-NAVTenant -ServerInstance <server instance name> -DatabaseName <database name> -DatabaseServer
<database server>\<database instance> -Tenant <tenant ID> -AllowAppDatabaseWrite
```

   IMPORTANT

   You must use the same tenant ID for the tenant that was used in the old deployment; otherwise you'll get an error when mounting or syncing the tenant. If you want to use a different ID for the tenant, you can either use the `-AlternateId` parameter now or after upgrading, dismount the tenant, then mount it again using the new ID and the `OverwriteTenantIdInDatabase` parameter.

   NOTE

   For upgrade, we recommend that you use the `-AllowAppDatabaseWrite` parameter. After upgrade, you can dismount and mount the tenant again without the parameter if needed.

   At this stage, the tenant state is OperationalWithSyncPending.

2. Synchronize the tenant with the application database.

   Use the Sync-NAVTenant cmdlet:

```
Sync-NAVTenant -ServerInstance <server instance name> -Mode Sync -Tenant <tenant ID>
```

   With a single-tenant deployment, you can omit the `-Tenant` parameter and value.

3. Synchronize the tenant with the table migration extension.

Use the Sync-NAVApp cmdlet:

```
Sync-NAVApp -ServerInstance <server instance name> -Tenant <tenant ID> -Name "<table migration
extension>" -Version <extension version>
```

This step creates empty tables in the database for the table objects defined in the table migration extension. When completed, the table migration extension takes ownership of the table. In SQL Server, you'll notice that the table names will be suffixed with the extension ID. At this point, the tenant state is OperationalDataUpgradePending.

> **TIP**
> To verify the tenant state, run Get-NAVTenant cmdlet with the `-ForceRefresh` switch:
>
> `Get-NAVTenant <server instance> -Tenant <default> -ForceRefresh`

4. Synchronize the empty versions of system application, base application, and customization extensions that you published in Task 9.

Task 11: Install DestinationAppsForMigration and move tables

In this task, you run a data upgrade on tables to handle data changes made by platform and extensions. The step installs table migration extension. It moves data from the old tables to the new tables owned by the table migration extension.

1. To run the data upgrade, use the Start-NavDataUpgrade cmdlet:

   ```
   Start-NAVDataUpgrade -ServerInstance <server instance name> -Tenant <tenant ID> -
   FunctionExecutionMode Serial -SkipCompanyInitialization [-SkipAppVersionCheck]
   ```

   You only need to use the -SkipAppVersionCheck if you didn't increase the application version in Task 8. This step will automatically install the table migration extension.

2. To view the progress of the data upgrade, you can run Get-NavDataUpgrade cmdlet with the `-Progress` switch.

3. Install the empty versions of the system, base, and custom extensions that you published in Task 9.

   To install the extension, you use the Install-NAVApp cmdlet.

   ```
   Install-NAVApp -ServerInstance <BC16 server instance> -Name "<name>" -Version <extension version>
   ```

4. (Multitenant only) Repeat steps 1 and 2 for each tenant.

Task 12: Publish final extensions

This step starts the second phase of the data upgrade. You'll publish the second version of the table migration extension and the production versions of extensions. The production extensions include the new versions of Microsoft System Application, Base Application extension, and customization extensions. The extension packages for Microsoft extensions are on the installation media (DVD). Customization extensions include the extension versions that you created in Task 1, not the empty versions.

Publish extensions using the Publish-NAVApp cmdlet like you did in previous steps.

```
Publish-NAVApp -ServerInstance <server instance name> -Path "<path to extension .app file>"
```

Publish the extensions in the following order:

1. Second version of the table migration extension, which is the empty version with the migration.json file.
2. Microsoft System Application

   Publish the Microsoft_System Application.app extension package file that is in the **Applications\System Application\Source** folder of installation media (DVD).
3. Microsoft Base Application

   Publish the Microsoft_Base Application.app extension package file that is in the **Applications\BaseApp\Source** folder of installation media (DVD).

   > **NOTE**
   > The other .app files in this folder, like Microsoft_Danish language (Denmark).app, are extensions that add translations for a specific language. By publishing and installing these extensions, you add the capability of showing the base application in another language. These extensions aren't required to complete the upgrade and can be published and installed later.
4. Customization extensions.
5. Microsoft and third-party extensions.

   The Microsoft extensions are in the **Applications** folder of installation media (DVD).

Task 13: Synchronize final extensions

Synchronize the newly published extensions using the Sync-NAVApp cmdlet like you did in previous steps.

```
Sync-NAVApp -ServerInstance <server instance name> -Tenant <tenant ID> -Name "<table migration extension>" -
Version <extension version>
```

Synchronize the extensions in the following order:

1. Microsoft System Application
2. Microsoft Base Application
3. Microsoft and third-party extensions
4. Customization extensions
5. Second version of the table migration extension

> **IMPORTANT**
> Synchronize extensions in the order of dependencies. The migration extension must be synchronized last. This step will change table ownership to the system and base application.

Task 14: Upgrade on table migration extension

Run data upgrade on the table migration extension by using the Start-NAVAppDataUpgrade cmdlet. For example:

```
Start-NAVAppDataUpgrade -ServerInstance <server instance> -Name "<table migration extension>" -version
<version 2>
```

Task 15: Upgrade final extensions

The final step is to upgrade to the new extension versions in the following order. Use the Start-NAVAppDataUpgrade cmdlet like you did in the previous task.

Run the data upgrade on the extensions in the following order:

1. Microsoft System Application.
2. Microsoft Base Application.
3. Customization, Microsoft, and third-party extensions.

   For customization extensions, only do this task for those extensions that have an empty version currently installed on the tenant (see Task 11). If you have a customization extension for which you didn't create and publish an empty version, complete the next task for these extensions.

Task 16: Install remaining customization extensions

Complete this task for cutomizations extension that you created in Task 1, but create and publish an empty version first.

To install each extension, run the Install-NAVApp cmdlet:

```
Install-NAVApp -ServerInstance <BC16 server instance> -Name "<name>" -Version <extension version>
```

Task 17: Upgrade control add-ins

The Business Central Server installation includes new versions of the Microsoft-provided Javascript-based control add-ins that must be upgraded.

- Microsoft.Dynamics.Nav.Client.BusinessChart
- Microsoft.Dynamics.Nav.Client.FlowIntegration
- Microsoft.Dynamics.Nav.Client.OAuthIntegration
- Microsoft.Dynamics.Nav.Client.PageReady
- Microsoft.Dynamics.Nav.Client.PowerBIManagement
- Microsoft.Dynamics.Nav.Client.RoleCenterSelector
- Microsoft.Dynamics.Nav.Client.SocialListening
- Microsoft.Dynamics.Nav.Client.SatisficationSurvey
- Microsoft.Dynamics.Nav.Client.TimelineVisualization
- Microsoft.Dynamics.Nav.Client.VideoPlayer
- Microsoft.Dynamics.Nav.Client.WebPageViewer
- Microsoft.Dynamics.Nav.Client.WelcomeWizard

To upgrade the control add-ins from the client, do the following steps:

1. Open the Business Central client.
2. Search for and open the **Control Add-ins** page.
3. Choose **Actions** > **Control Add-in Resource** > **Import**.

4. Locate and select the .zip file for the control add-in and choose **Open**.

   The .zip files are located in the **Add-ins** folder of the Business Central Server installation. There's a subfolder for each add-in. For example, the path to the Business Chart control add-in is `C:\Program Files\Microsoft Dynamics 365 Business Central\160\Service\Add-ins\BusinessChart\Microsoft.Dynamics.Nav.Client.BusinessChart.zip`.

5. After you've imported all the new control add-in versions, restart Business Central Server instance.

Alternatively, you can use the Set-NAVAddin cmdlet of the Business Central Administration Shell. For example, the following commands update the control add-ins installed by default. Modify the commands to suit:

```
$InstanceName = 'BC160'
$ServicesAddinsFolder = 'C:\Program Files\Microsoft Dynamics 365 Business Central\160\Service\Add-ins'
Set-NAVAddIn -ServerInstance $InstanceName -AddinName 'Microsoft.Dynamics.Nav.Client.BusinessChart' -
PublicKeyToken 31bf3856ad364e35 -ResourceFile ($AppName = Join-Path $ServicesAddinsFolder
'BusinessChart\Microsoft.Dynamics.Nav.Client.BusinessChart.zip')
Set-NAVAddIn -ServerInstance $InstanceName -AddinName 'Microsoft.Dynamics.Nav.Client.FlowIntegration' -
PublicKeyToken 31bf3856ad364e35 -ResourceFile ($AppName = Join-Path $ServicesAddinsFolder
'FlowIntegration\Microsoft.Dynamics.Nav.Client.FlowIntegration.zip')
Set-NAVAddIn -ServerInstance $InstanceName -AddinName 'Microsoft.Dynamics.Nav.Client.OAuthIntegration' -
PublicKeyToken 31bf3856ad364e35 -ResourceFile ($AppName = Join-Path $ServicesAddinsFolder
'OAuthIntegration\Microsoft.Dynamics.Nav.Client.OAuthIntegration.zip')
Set-NAVAddIn -ServerInstance $InstanceName -AddinName 'Microsoft.Dynamics.Nav.Client.PageReady' -
PublicKeyToken 31bf3856ad364e35 -ResourceFile ($AppName = Join-Path $ServicesAddinsFolder
'PageReady\Microsoft.Dynamics.Nav.Client.PageReady.zip')
Set-NAVAddIn -ServerInstance $InstanceName -AddinName 'Microsoft.Dynamics.Nav.Client.PowerBIManagement' -
PublicKeyToken 31bf3856ad364e35 -ResourceFile ($AppName = Join-Path $ServicesAddinsFolder
'PowerBIManagement\Microsoft.Dynamics.Nav.Client.PowerBIManagement.zip')
Set-NAVAddIn -ServerInstance $InstanceName -AddinName 'Microsoft.Dynamics.Nav.Client.RoleCenterSelector' -
PublicKeyToken 31bf3856ad364e35 -ResourceFile ($AppName = Join-Path $ServicesAddinsFolder
'RoleCenterSelector\Microsoft.Dynamics.Nav.Client.RoleCenterSelector.zip')
Set-NAVAddIn -ServerInstance $InstanceName -AddinName 'Microsoft.Dynamics.Nav.Client.SatisfactionSurvey' -
PublicKeyToken 31bf3856ad364e35 -ResourceFile ($AppName = Join-Path $ServicesAddinsFolder
'SatisfactionSurvey\Microsoft.Dynamics.Nav.Client.SatisfactionSurvey.zip')
Set-NAVAddIn -ServerInstance $InstanceName -AddinName 'Microsoft.Dynamics.Nav.Client.SocialListening' -
PublicKeyToken 31bf3856ad364e35 -ResourceFile ($AppName = Join-Path $ServicesAddinsFolder
'SocialListening\Microsoft.Dynamics.Nav.Client.SocialListening.zip')
Set-NAVAddIn -ServerInstance $InstanceName -AddinName 'Microsoft.Dynamics.Nav.Client.VideoPlayer' -
PublicKeyToken 31bf3856ad364e35 -ResourceFile ($AppName = Join-Path $ServicesAddinsFolder
'VideoPlayer\Microsoft.Dynamics.Nav.Client.VideoPlayer.zip')
Set-NAVAddIn -ServerInstance $InstanceName -AddinName 'Microsoft.Dynamics.Nav.Client.WebPageViewer' -
PublicKeyToken 31bf3856ad364e35 -ResourceFile ($AppName = Join-Path $ServicesAddinsFolder
'WebPageViewer\Microsoft.Dynamics.Nav.Client.WebPageViewer.zip')
Set-NAVAddIn -ServerInstance $InstanceName -AddinName 'Microsoft.Dynamics.Nav.Client.WelcomeWizard' -
PublicKeyToken 31bf3856ad364e35 -ResourceFile ($AppName = Join-Path $ServicesAddinsFolder
'WelcomeWizard\Microsoft.Dynamics.Nav.Client.WelcomeWizard.zip')
```

Post-upgrade tasks

1. Uninstall the table migration extension.
2. Enable task scheduler on the server instance.
3. (Multitenant only) For tenants other than the tenant that you use for administration purposes, if you mounted the tenants using the `-AllowAppDatabaseWrite` parameter, dismount the tenants, then mount them again without using the `-AllowAppDatabaseWrite` parameter.
4. If you want to use data encryption as before, enable it.

   For more information, see Managing Encryption and Encryption Keys.

Optionally, if you exported the encryption key instead of disabling encryption earlier, import the encryption key file to enable encryption.

5. Grant users permission to the *Open in Excel* and *Edit in Excel* actions.

   Version 16 introduces a system permission that protects these two actions. The permission is granted by the system object **6110 Allow Action Export To Excel**. Because of this change, users who had permission to these actions before upgrading, will lose permission. To grant permission again, do one of the following steps:

   - Assign the **EXCEL EXPORT ACTION** permission set to appropriate users.
   - Add the system object **6110 Allow Action Export To Excel** permission directly to appropriate permission sets.

   For more information about working with permission sets and permissions, see Export and Import Permission Sets.

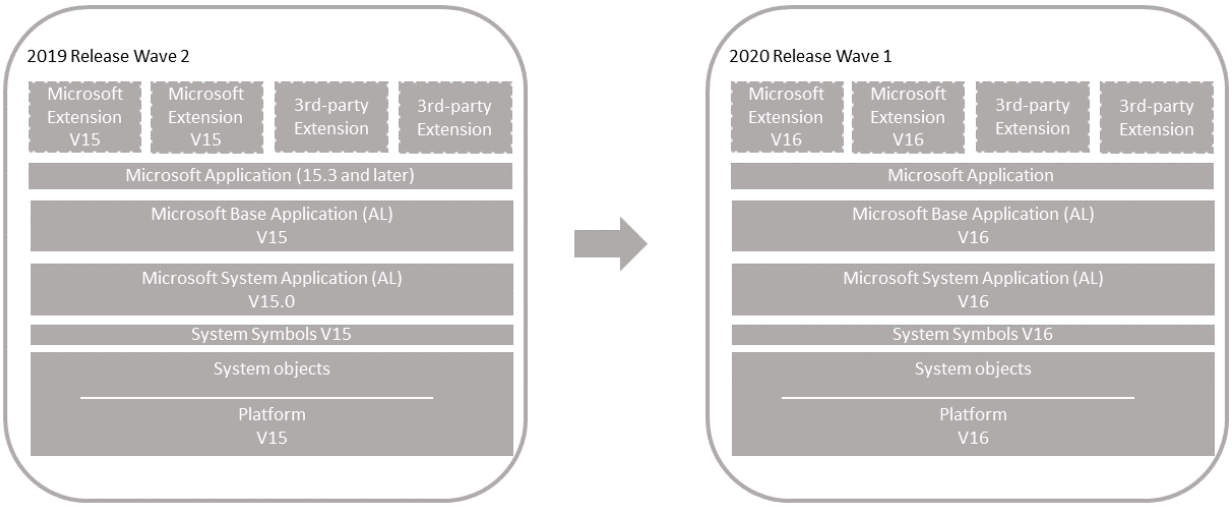
Upgrading Version 15 Base Application to Version 16

2/17/2021 • 13 minutes to read • Edit Online

Use this scenario if you have a Business Central 2019 release wave 2 solution that uses the Microsoft System and Base applications.



Single-tenant and multitenant deployments

The process for upgrading the similar for a single-tenant and multitenant deployment. However, there are some inherent differences. With a single-tenant deployment, the application code and business data are in the same database. In a multitenant deployment, application code is in a separate database (the application database) than the business data (tenant). In the procedures that follow, for a single-tenant deployment, consider references to the *application database* and *tenant database* as the same database. Steps are marked as *Single-tenant only* or *Multitenant only* where applicable.

Prerequisites

1. Your version 15 is compatible with version 16.

   There are several updates for version 15. The updates have a compatible version 16 update. For more information, see Dynamics 365 Business Central Upgrade Compatibility Matrix. For example, if your solution is currently running 15.5, you can't upgrade to 16.0. You must wait until 16.1 is available.

2. Disable data encryption.

   If the current server instance uses data encryption, disable it. You can enable it again after upgrading.

   For more information, see Managing Encryption and Encryption Keys.

   Instead of disabling encryption, you can export the current encryption key, which you'll then import after upgrade. However, we recommend disabling encryption before upgrading.

Task 1: Install version 16

1. Download the latest available update for Business Central 2020 (version 16) that is compatible with your version 15.

   For more information, see Dynamics 365 Business Central Upgrade Compatibility Matrix.

2. Before you install version 16, it can be useful to create desktop shortcuts to the version 15.0 tools, such

as the Business Central Server Administration tool, Business Central Administration Shell, and Dynamics NAV Development Shell because the Start menu items for these tools will be replaced with the version 16 tools.

3. Install Business Central version 16 components.

   You'll have to keep version 15 installed to complete some steps in the upgrade process. When you install version 16, you must either specify different port numbers for components (like the Business Central Server instance and web services) or you must stop the version 15.0 Business Central Server instance before you run the installation. Otherwise, you'll get an error that the Business Central Server failed to install.

   For more information, see Installing Business Central Using Setup.

Task 2: Prepare version 15 databases

1. Make backup of the databases.
2. Start Business Central Administration Shell for version 15 as an administrator.
3. (Single-tenant only) Uninstall all extensions from the old tenants.

   In this step, you uninstall the Base Application, System Application (if used), and any other extensions that are currently installed on the database.

   a. Get a list of installed extensions.

      This step is optional, but it can be useful to the names and versions of the extensions.

      To get a list of installed extensions, use the Get-NAVAppInfo cmdlet.

      ```
      Get-NAVAppInfo -ServerInstance <server instance name> -Tenant <tenant ID>
      ```

      For a single-tenant deployment, set the `<tenant ID>` to default.

   b. Uninstall the extensions.

      To uninstall an extension, you use the Uninstall-NAVApp cmdlet.

      ```
      Uninstall-NAVApp -ServerInstance <server instance name> -Name <extensions name> -Tenant
      <tenant ID> -Version <extension version> -Force
      ```

      Replace `<extension name>` and `<extension version>` with the exact name and version the published System Application.

      For example, together with the Get-NAVApp cmdlet, you can uninstall all extensions with a single command:

      ```
      Get-NAVAppInfo -ServerInstance <server instance name> -Tenant <tenant ID>| % { Uninstall-
      NAVApp -ServerInstance <server instance name> -Tenant <tenant ID> -Name $_.Name -Version
      $_.Version -Force}
      ```

4. Unpublish all system symbols.

   To unpublish symbols, use the Unpublish-NAVAPP cmdlet with the `-SymbolsOnly` switch.

```
Get-NAVAppInfo -ServerInstance <BC15 server instance> -SymbolsOnly | % { Unpublish-NAVApp -
ServerInstance <BC15 server instance> -Name $_.Name -Version $_.Version }
```

What are symbols?

5. (Multitenant only) Dismount the tenants from the application server instance.

   To dismount a tenant, use the Dismount-NAVTenant cmdlet:

```
Dismount-NAVTenant -ServerInstance <server instance name> -Tenant <tenant ID>
```

6. Stop the server instance.

```
Stop-NAVServerInstance -ServerInstance <server instance name>
```

Task 3: Convert version 15 database

This task runs a technical upgrade on the application database to convert it from the version 15 platform to the version 16 platform. The conversion updates the system tables of the database to the new schema (data structure). It provides the latest platform features and performance enhancements.

1. Start Business Central Administration Shell for version 16 as an administrator.
2. Run the Invoke-NAVApplicationDatabaseConversion cmdlet to start the conversion:

```
Invoke-NAVApplicationDatabaseConversion -DatabaseServer <database server name>\<database server
instance> -DatabaseName "<database name>"
```

   When completed, a message like the following displays in the console:

```
DatabaseServer      : .\BCDEMO
DatabaseName        : Demo Database BC (15-0)
DatabaseCredentials :
DatabaseLocation    :
Collation           :
```

Task 4: Configure version 16 server

When you installed version 16 in **Task 1**, a version 16 Business Central Server instance was created. In this task, you change server configuration settings that are required to complete the upgrade. Some of the changes are only required for version 15 to version 16 upgrade and can be reverted after you complete the upgrade.

1. Set the server instance to connect to the application database.

```
Set-NAVServerConfiguration -ServerInstance <server instance name> -KeyName DatabaseName -KeyValue "
<database name>"
```

   In a single tenant deployment, this command will mount the tenant automatically. For more information, see Connecting a Server Instance to a Database.

2. Disable task Scheduler on the server instance for purposes of upgrade.

```
Set-NavServerConfiguration -ServerInstance <server instance name> -KeyName "EnableTaskScheduler" -
KeyValue false
```

Be sure to re-enable task scheduler after upgrade if needed.

3. Restart the server instance.

```
Restart-NAVServerInstance -ServerInstance <server instance name>
```

Task 5: Import version 16 license

1. Use the Import-NAVServerLicense to upload the version 16 license to the database.

```
Import-NAVServerLicense -ServerInstance <server instance name> -LicenseFile <path and file name>
```

2. Restart the server instance.

```
Restart-NAVServerInstance -ServerInstance <server instance name>
```

Task 6: Publish symbols and extensions

In this task, you'll publish the platform symbols and extensions. As minimum, you publish the new base application and system application extensions from the installation media (DVD). You also publish new versions of any Microsoft extensions and third-party extensions that were used on your old deployment.

Publishing an extension adds the extension to the application database that is mounted on the server instance. Once published, it's available for installing on tenants. This task updates internal tables, compiles the components of the extension behind-the-scenes, and builds the necessary metadata objects that are used at runtime.

The steps in this task continue to use the Business Central Administration Shell for version 16 that you started in the previous task.

1. Publish version 16 system symbols extension.

   The symbols extension contains the required platform symbols that the base application depends on. The symbols extension package is called **System.app**. You find it where the **AL Development Environment** is installed. The default path is C:\Program Files (x86)\Microsoft Dynamics 365 Business Central\160\AL Development Environment.

```
Publish-NAVApp -ServerInstance  <server instance name> -Path "<path to system.app>" -PackageType
SymbolsOnly
```

   What are symbols?

2. Publish the **System Application** extension (Microsoft_System Application.app).

   You find the (Microsoft_System Application.app in the **Applications\System Application\Source** folder of installation media (DVD).

```
Publish-NAVApp -ServerInstance <server instance name> -Path "<path to Microsoft_System
Application.app>"
```

What is the System Application?

3. Publish the Business Central base application extension (Microsoft_Base Application.app).

   The **Base Application** extension contains the application business objects. You find the (Microsoft_Base Application.app in the **Applications\BaseApp\Source** folder of installation media (DVD).

   ```
   Publish-NAVApp -ServerInstance <server instance name> -Path "<path to Microsoft_Base
   Application.app>"
   ```

4. Publish the Microsoft_Application extension (when coming from 15.2 and earlier only).

   The Microsoft_Application extension is a new extension introduced in 15.3. For more information about this extension, see The Microsoft_Application.app File.

   ```
   Publish-NAVApp -ServerInstance <server instance name> -Path "<path to Microsoft_Application.app>"
   ```

5. Publish the new versions of Microsoft extensions.

   In this step, you publish new versions of Microsoft extensions that were used on your version 15 deployment. You find the extensions in the **Applications** folder of the installation media (DVD).

   ```
   Publish-NAVApp -ServerInstance <server instance name> -Path "<path to Microsoft extension>"
   ```

   For example:

   ```
   Publish-NAVApp -ServerInstance BC150 -Path
   "C:\W1DVD\Applications\SalesAndInventoryForecast\Source\SalesAndInventoryForecast.app"
   ```

6. Publish new versions of 3rd-party extensions.

   If you have new versions of these extensions, built on the Business Central version 16, then publish the new versions.

   ```
   Publish-NAVApp -ServerInstance BC160 -Path "<path to extension>"
   ```

7. Recompile extensions not build on version 16.

   This step pertains to any published extension versions that aren't built on version 16, which you want to reinstall on tenants. These extensions must be recompiled to work with version 16. To recompile the extensions, use the Repair-NAVApp cmdlet:

   ```
   Repair-NAVApp -ServerInstance <server instance> -Name <extension name> -Version <extension name>
   ```

   For example, to recompile all extensions that are not published by Microsoft, you could run the following command:

   ```
   Get-NAVAppInfo -ServerInstance <server instance> | Where-Object {$_.Publisher -notlike 'Microsoft'} |
   Repair-NAVApp
   ```

   Restart the Business Central Server when completed.

Task 7: Synchronize tenant

You'll synchronize the tenant's database schema with any schema changes in the application database and extensions. If you have a multitenant deployment, do these steps for each tenant.

1. (Multitenant only) Mount the tenant to the version 15 server instance.

   To mount the tenant, use the Mount-NAVTenant cmdlet:

   ```
   Mount-NAVTenant -ServerInstance <server instance name> -DatabaseName <database name> -DatabaseServer
   <database server>\<database instance> -Tenant <tenant ID> -AllowAppDatabaseWrite
   ```

   > **IMPORTANT**
   > You must use the same tenant ID for the tenant that was used in the old deployment; otherwise you'll get an error when mounting or syncing the tenant. If you want to use a different ID for the tenant, you can either use the `-AlternateId` parameter now or after upgrading, dismount the tenant, then mount it again using the new ID and the `OverwriteTenantIdInDatabase` parameter.

   > **NOTE**
   > For upgrade, we recommend that you use the `-AllowAppDatabaseWrite` parameter. After upgrade, you can dismount and mount the tenant again without the parameter if needed.

   At this stage, the tenant state is OperationalWithSyncPending.

2. Synchronize the tenant with the application database.

   Use the Sync-NAVTenant cmdlet:

   ```
   Sync-NAVTenant -ServerInstance <server instance name> -Mode Sync -Tenant <tenant ID>
   ```

   With a single-tenant deployment, you can omit the `-Tenant` parameter and value.

3. Synchronize the tenant with the **System Application** extension.

   Use the Sync-NAVApp cmdlet:

   ```
   Sync-NAVApp -ServerInstance <server instance name> -Tenant <tenant ID> -Name "System Application" -
   Version <extension version>
   ```

   Replace `<extension version>` with the exact version of the published System Application. To get the version, you can use the Get-NAVAppInfo cmdlet.

4. Synchronize the tenant with the Business Central Base Application extension.

   ```
   Sync-NAVApp -ServerInstance <server instance name> -Tenant <tenant ID> -Name "Base Application" -
   Version <extension version>
   ```

   Replace `<extension version>` with the exact version of the published Base Application.

5. Synchronize the tenant with the Application extension (when coming from 15.2 and earlier only).

```
Sync-NAVApp -ServerInstance <server instance name> -Tenant <tenant ID> -Name "Application"
```

6. Synchronize the tenant with Microsoft and 3rd-party extensions.

   For each extension, run the Sync-NAVApp cmdlet:

   ```
   Sync-NAVApp -ServerInstance BC150 -Tenant default -Name "<extension name>" -Version <extension
   version>
   ```

Task 8: Upgrade data

In this task, you run a data upgrade for extensions.

Single tenant

Run the data upgrade on extensions in order of dependency.

1. Run the data upgrade for the system application, followed by the base application.

   To run the data upgrade, use the Start-NavDataUpgrade cmdlet:

   ```
   Start-NAVAppDataUpgrade -ServerInstance <server instance name> -Name "<extension name>" -Version
   <extension version>
   ```

   This step will automatically install the new system application and base application versions on the tenant.

2. Upgrade the new versions of Microsoft extensions and third-party extensions.

   Complete this task to upgrade any Microsoft and third-party extension used in the old deployment to new versions on the installation media. The new versions are in the **Application** folder of the DVD. There's a folder for each extension. The extension package (.app file) is in the **Source** folder.

   a. Install **Application** extension (when comping from 15.2 and earlier only).

      You'll have to install the **Application** extension first, otherwise you can't upgrade Microsoft extensions.

      ```
      Install-NAVApp -ServerInstance <server instance name> -Tenant <tenant ID> -Name "Application"
      ```

   b. For each extension, run Start-NAVAppDataUpgrade cmdlet.

      This step will also automatically install the new extension version on the tenant.

Multitenant

On each tenant, run the Start-NavDataUpgrade cmdlet as follows to change the version number:

```
Start-NAVDataUpgrade -ServerInstance <server instance name> -Tenant <tenant ID> -FunctionExecutionMode
Serial -SkipAppVersionCheck
```

Task 9: Install 3rd-party extensions

Complete this task to install third-party extensions for which a new version wasn't published. For each extension, run the Install-NAVApp cmdlet:

```
Install-NAVApp -ServerInstance <server instance name> -Name <extension name> -Version <extension version>
```

Task 10: Upgrade control add-ins

The Business Central Server installation includes new versions of the Microsoft-provided Javascript-based control add-ins, like Microsoft.Dynamics.Nav.Client.BusinessChart, Microsoft.Dynamics.Nav.Client.VideoPlayer, and more. If your solution uses any of these control add-ins, upgrade them to the latest version.

To upgrade the control add-ins from the client, do the following steps:

1. Open the Business Central client.
2. Search for and open the **Control Add-ins** page.
3. Choose **Actions** > **Control Add-in Resource** > **Import**.
4. Locate and select the .zip file for the control add-in and choose **Open**.

   The .zip files are located in the **Add-ins** folder of the Business Central Server installation. There's a subfolder for each add-in. For example, the path to the Business Chart control add-in is
   ```
   C:\Program Files\Microsoft Dynamics 365 Business Central\160\Service\Add-ins\BusinessChart\Microsoft.Dynamics.Nav.Client.BusinessChart.zip
   ```
   .
5. After you've imported all the new control add-in versions, restart Business Central Server instance.

Alternatively, you can use the Set-NAVAddin cmdlet of the Business Central Administration Shell. For example, the following commands update the control add-ins installed by default. Modify the commands to suit:

```
$InstanceName = 'BC160'
$ServicesAddinsFolder = 'C:\Program Files\Microsoft Dynamics 365 Business Central\160\Service\Add-ins'
Set-NAVAddIn -ServerInstance $InstanceName -AddinName 'Microsoft.Dynamics.Nav.Client.BusinessChart' -
PublicKeyToken 31bf3856ad364e35 -ResourceFile ($AppName = Join-Path $ServicesAddinsFolder
'BusinessChart\Microsoft.Dynamics.Nav.Client.BusinessChart.zip')
Set-NAVAddIn -ServerInstance $InstanceName -AddinName 'Microsoft.Dynamics.Nav.Client.FlowIntegration' -
PublicKeyToken 31bf3856ad364e35 -ResourceFile ($AppName = Join-Path $ServicesAddinsFolder
'FlowIntegration\Microsoft.Dynamics.Nav.Client.FlowIntegration.zip')
Set-NAVAddIn -ServerInstance $InstanceName -AddinName 'Microsoft.Dynamics.Nav.Client.OAuthIntegration' -
PublicKeyToken 31bf3856ad364e35 -ResourceFile ($AppName = Join-Path $ServicesAddinsFolder
'OAuthIntegration\Microsoft.Dynamics.Nav.Client.OAuthIntegration.zip')
Set-NAVAddIn -ServerInstance $InstanceName -AddinName 'Microsoft.Dynamics.Nav.Client.PageReady' -
PublicKeyToken 31bf3856ad364e35 -ResourceFile ($AppName = Join-Path $ServicesAddinsFolder
'PageReady\Microsoft.Dynamics.Nav.Client.PageReady.zip')
Set-NAVAddIn -ServerInstance $InstanceName -AddinName 'Microsoft.Dynamics.Nav.Client.PowerBIManagement' -
PublicKeyToken 31bf3856ad364e35 -ResourceFile ($AppName = Join-Path $ServicesAddinsFolder
'PowerBIManagement\Microsoft.Dynamics.Nav.Client.PowerBIManagement.zip')
Set-NAVAddIn -ServerInstance $InstanceName -AddinName 'Microsoft.Dynamics.Nav.Client.RoleCenterSelector' -
PublicKeyToken 31bf3856ad364e35 -ResourceFile ($AppName = Join-Path $ServicesAddinsFolder
'RoleCenterSelector\Microsoft.Dynamics.Nav.Client.RoleCenterSelector.zip')
Set-NAVAddIn -ServerInstance $InstanceName -AddinName 'Microsoft.Dynamics.Nav.Client.SatisfactionSurvey' -
PublicKeyToken 31bf3856ad364e35 -ResourceFile ($AppName = Join-Path $ServicesAddinsFolder
'SatisfactionSurvey\Microsoft.Dynamics.Nav.Client.SatisfactionSurvey.zip')
Set-NAVAddIn -ServerInstance $InstanceName -AddinName 'Microsoft.Dynamics.Nav.Client.SocialListening' -
PublicKeyToken 31bf3856ad364e35 -ResourceFile ($AppName = Join-Path $ServicesAddinsFolder
'SocialListening\Microsoft.Dynamics.Nav.Client.SocialListening.zip')
Set-NAVAddIn -ServerInstance $InstanceName -AddinName 'Microsoft.Dynamics.Nav.Client.VideoPlayer' -
PublicKeyToken 31bf3856ad364e35 -ResourceFile ($AppName = Join-Path $ServicesAddinsFolder
'VideoPlayer\Microsoft.Dynamics.Nav.Client.VideoPlayer.zip')
Set-NAVAddIn -ServerInstance $InstanceName -AddinName 'Microsoft.Dynamics.Nav.Client.WebPageViewer' -
PublicKeyToken 31bf3856ad364e35 -ResourceFile ($AppName = Join-Path $ServicesAddinsFolder
'WebPageViewer\Microsoft.Dynamics.Nav.Client.WebPageViewer.zip')
Set-NAVAddIn -ServerInstance $InstanceName -AddinName 'Microsoft.Dynamics.Nav.Client.WelcomeWizard' -
PublicKeyToken 31bf3856ad364e35 -ResourceFile ($AppName = Join-Path $ServicesAddinsFolder
'WelcomeWizard\Microsoft.Dynamics.Nav.Client.WelcomeWizard.zip')
```

At this point, the upgrade is complete, and you can open the client.

Post-upgrade tasks

1. Enable task scheduler on the server instance.
2. (Multitenant only) For tenants other than the tenant that you use for administration purposes, if you mounted the tenants using the `-AllowAppDatabaseWrite` parameter, dismount the tenants, then mount them again without using the `-AllowAppDatabaseWrite` parameter.
3. If you want to use data encryption as before, enable it.

   For more information, see Managing Encryption and Encryption Keys.

   Optionally, if you exported the encryption key instead of disabling encryption earlier, import the encryption key file to enable encryption.
4. Change application version.

   (Optional) This task isn't required for installing the update. However, it might be useful for support purposes and answering a common question about the application version.

   On the **Help and Support** page in the client, you'll see an application version, such as 16.0.2345.6. For an explanation of the number, see Version numbers in Business Central. This version isn't updated automatically when you install an update. If you want the version to reflect the version of the update or your own version, you change it manually.

We recommend setting the value to application build number for the version 15 update. You get the number from the Released Updates for Microsoft Dynamics 365 Business Central 2020 Release Wave 1 on-premises.

a. Run the Set-NAVApplication cmdlet:

```
Set-NAVApplication -ServerInstance <server instance name> -ApplicationVersion <new application
version> -Force
```

For example:

```
Set-NAVApplication -ServerInstance BC160 -ApplicationVersion 16.0.38071.0 -Force
```

b. Run the Sync-NAVTenant cmdlet to synchronize the tenant with the application database.

```
Sync-NAVTenant -ServerInstance <server instance name> -Mode Sync -Tenant <tenant ID>
```

With a single-tenant deployment, you can omit the `-Tenant` parameter and value.

c. Run the Start-NavDataUpgrade cmdlet to change the version number:

```
Start-NAVDataUpgrade -ServerInstance <server instance name> -Tenant <tenant ID>
```

5. Grant users permission to the *Open in Excel* and *Edit in Excel* actions.

   Version 16 introduces a system permission that protects these two actions. The permission is granted by the system object **6110 Allow Action Export To Excel**. Because of this change, users who had permission to these actions before upgrading, will lose permission. To grant permission again, do one of the following steps:

   - Assign the **EXCEL EXPORT ACTION** permission set to appropriate users.
   - Add the system object **6110 Allow Action Export To Excel** permission directly to appropriate permission sets.

   For more information about working with permission sets and permissions, see Export and Import Permission Sets.

Code Conversion from C/AL to AL

2/17/2021 • 11 minutes to read • Edit Online

This article explains how to convert a Business Central (version 14) C/AL code-customized on-premises solution to AL code.

You'll use this procedure as part of the upgrade process when going from version 14 to a later version, like 15, 16, or 17.

Before you start

Get familiar with the basics of setting up and developing in Visual Studio Code and AL, see Developing Extensions in AL.

> **NOTE**
> Moving on-premise C/AL code customizations to Dynamics 365 Business Central online, requires converting these to AL extensions. This could include converting the C/AL deltas to AL extension code as a starting point, as outlined in The Txt2Al Conversion Tool.

Also, review the Known Issues for information about issues that may affect the upgrade.

Breaking changes

When converting from C/AL to AL, it's important that you don't introduce any breaking schema changes to the database. Otherwise, you won't be able to synchronize the new extension with the database.

Task 1: Import the test library into your C/AL solution

If your solution uses Microsoft (1st-party) extensions, you'll have to convert the test library from C/AL to AL. The reason for this is that the Microsoft extensions rely on the test symbols. The easiest way is to import the **CALTestLibraries.W1.fob** file into the old database. This file is available on the version 14 installation media (DVD) in the **TestToolKit** folder.

You can do this using the (Dynamics NAV Development Environment). For more information, see Exporting and Importing Objects.

Task 2: Compile all the objects in your C/AL solution

Compiling all the objects is a prerequisite for a successful and complete export. To compile objects, you can use either of the following tools:

- C/SIDE (Dynamics NAV Development Environment). See Compiling Objects.
- Compile-NAVApplicationObject cmdlet of the Dynamics NAV Development Shell. Make sure to run this cmdlet as an administrator.

Task 3: Export the application objects to the new TXT syntax

Once the application compiles, you must export all C/AL application objects, except system tables and codeunits (IDs in the 2000000000 range), to the new TXT format. The exported objects will be used as input to the Txt2AL conversion tool. To export objects, use the Export-NAVApplicationObject cmdlet of the Dynamics NAV Development Shell. it's important to:

- Omit omit all system objects, which have IDs in the 2000000000 range.
- Use the `ExportToNewSyntax` switch to export the objects in a syntax that is compatible with the Txt2Al conversion tool.

The Export-NAVApplicationObject cmdlet will export all objects to a single .txt file. If you imported the test library objects into the database, then you'll export the base application objects and the test library separately. Later, you'll create a separate AL project for each set of files.

For example, do the following steps:

1. Export the custom base application objects.
   a. Create a folder for storing the exported base application objects to TXT files (for example, c:\export2al\baseapplication).

   b. Run the following commands to export tha application objects, but omitting the system objects and test library objects.

```
Export-NAVApplicationObject -DatabaseServer .\BCDEMO -DatabaseName "Demo Database BC (14-0)" -
ExportToNewSyntax -Path "c:\export2al\baseapplication\exportedbc14app-part1.txt" -Filter
'Id=1..129999'
```

```
Export-NAVApplicationObject -DatabaseServer .\BCDEMO -DatabaseName "Demo Database BC (14-0)" -
ExportToNewSyntax -Path "c:\export2al\baseapplication\exportedbc14app-part2.txt" -Filter
'Id=140000..1999999999'
```

```
Export-NAVApplicationObject -DatabaseServer .\BCDEMO -DatabaseName "Demo Database BC (14-0)" -
ExportToNewSyntax -Path "c:\export2al\baseapplication\exportedbc14testobjects.txt" -Filter
'Id=130400..130416'
```

2. Export the test library objects.
   a. Create a folder for storing the exported test library objects to TXT files (for example, c:\export2al\testlibrary).

   b. Run the following commands to export the test library objects only

```
Export-NAVApplicationObject -DatabaseServer .\BCDEMO -DatabaseName "Demo Database BC (14-0)" -
ExportToNewSyntax -Path "c:\export2al\testlibrary\bc14testlibrary-part1.txt" -Filter
'Id=130000..130399'
```

```
Export-NAVApplicationObject -DatabaseServer .\BCDEMO -DatabaseName "Demo Database BC (14-0)" -
ExportToNewSyntax -Path "c:\export2al\testlibrary\bc14testlibrary-part2.txt" -Filter
'Id=130440..139999'
```

Task 4: Create a declaration file for custom .NET assemblies (optional)

If your solution contains .NET interoperability code and control add-ins, you can create a file that contains the declarations to the assemblies. This file will be used when you convert the C/AL TXT files to AL in the next step. Alternatively, after the conversion, you'll have to manually add the declarations to objects that use the assemblies.

To create the file, use a text editor or Visual Studio code to create a file that contains the assembly declarations as follows:

```
dotnet

{
    assembly("Microsoft.Dynamics.Nav.Client.BusinessChart")
    {

type("Microsoft.Dynamics.Nav.Client.BusinessChart.BusinessChartAddIn";"Microsoft.Dynamics.Nav.Client.Busines
sChart")
        {
            IsControlAddIn = true;
        }

        // Other control add-ins in this assembly
    }

    // Other assemblies containing control add ins
}
```

Save the file with any name and the extension **.al**, for example **mydotnet.al**. Make a note of the path because you'll use it in the next step.

Task 5: Convert the C/AL TXT files to AL

With C/AL exported to the new TXT format, you now convert the code to AL using the The Txt2Al Conversion Tool. The Txt2Al creates .al files for each object in the TXT files. Similar to **Task 3**, if you imported the test library objects into the database, then you'll convert the base application objects and the test library separately.

Get the Txt2AL conversion tool

The Txt2Al conversion tool (txt2al.exe) is only available with version 14, which is the last version to support C/AL. Use this version of the tool no matter what later version you may eventually be upgrading to. The AL objects created by the tool will be compatible with later versions.

You find the txt2al.exe on the installation media (DVD) in the "DVD\RoleTailoredClient\program files\Microsoft Dynamics NAV\140\RoleTailored Client" folder. Or, it's installed locally with Dynamics NAV Development Environment, for example, in the "C:\Program Files (x86)\Microsoft Dynamics 365 Business Central\140\RoleTailored Client" folder.

Run the Txt2AL conversion tool

1. Convert the base application TXT files to AL.

    a. Create a folder for storing the AL files for base application objects (for example, c:\export2al\baseapplication\al).

    b. Start a command prompt as administrator, and navigate to the folder that contain txt2al.exe file.

    By default, the location is C:\Program Files (x86)\Microsoft Dynamics 365 Business Central\140\RoleTailored Client.

    c. Run the txt2al command:

    ```
    txt2al --source=C:\export2al\baseapplication --target=C:\export2al\baseapplication\al --
    injectDotNetAddIns --dotNetAddInsPackage=C:\export2al\dotnet\mydotnet.al --dotNetTypePrefix=BC
    --rename
    ```

    If your solution contains .NET interoperability code, the following Txt2Al command line parameters are used to achieve a conversion that requires less manual intervention:

    - `--injectDotNetAddIns` injects the definition of standard .NET add-ins in the resulting .NET

package. The standard .NET add-ins are a set of add-ins that are embedded into the platform.

- `--dotNetAddInsPackage` should be used to point the conversion tool to an AL file containing declarations for the .NET types that represent .NET control addins. Use this to inject a custom set of .NET control add-in declarations. This parameter is only required if you completed **Task 4**, and you set it to point to the location of the dotnet.al file.

  > **NOTE**
  > If you are interested in migrating your localization resources, you should use the `--addLegacyTranslationInfo` switch to instruct Txt2Al to generate information about the legacy IDs of the translation code.

- `--dotNetTypePrefix` specifies a prefix to be used for all .NET type aliases created during the conversion. This will ensure that no naming conflicts occur with existing types. In the example, `BC` is the prefix.

- `--rename` renames the output files to prevent clashes with the source .txt files.

When completed, there will be an .al file for each object.

2. Convert the test library TXT files to AL.

   This is similar to the previous step.

   a. Create a folder for storing the AL files for base application objects (for example, c:\export2al\baseapplication\al).

   b. Run the txt2al command:

   ```
   txt2al --source=C:\export2al\testlibrary --target=C:\export2al\testlibrary\al --
   injectDotNetAddIns --dotNetTypePrefix=BCTest --rename
   ```

   Use a different value for the `--dotNetTypePrefix` than you did for the base application.

Task 6: Create a new application database for development

To build your base application, you'll create a new application database on the Business Central version 15, 16, or 17 platform. This will only be used during development.

1. Start the Business Central Administration Shell for version 16 as an administrator.
2. Run the New-NAVApplicationDatabase cmdlet to create the database. For example:

   ```
   New-NAVApplicationDatabase -DatabaseServer .\BCDEMO -DatabaseName MyDBforupgrade
   ```

3. Connect your Business Central Server instance to the database. See Connecting a Business Central Server Instance to a Database.

   ```
   Set-NAVServerConfiguration -ServerInstance BC -KeyName DatabaseName -KeyValue "MyDBforupgrade"
   ```

4. Restart the server instance.

```
Restart-NAVServerInstance -ServerInstance BC
```

Task 7: Create and build an AL project for custom base application

In this task, you'll create a AL project in Visual Studio code that you'll use for building your custom base application extension based on your converted C/AL application.

1. If you haven't already, install Visual Studio Code and the latest AL Language extension for version 15, 16, or 17 as outlined in Getting Started with AL.

2. Configure Visual Studio Code for optimal performance with AL projects.

   This step is optional, but recommended. For more information, see Optimize Visual Studio Code for Editing and Building.

3. In Visual Studio Code, from the **Command Palette**, select the **AL Go!** command to create a new project.

   Specify the path for the project, and set the **Target Platform** to **4.0 Business Central 2019 release wave 2** or **5.0 Business Central 2020 release wave 1**. When prompted to select your server, choose **Your own server**.

4. Create a **.alpackages** folder in the root folder of the project and then copy the system (platform) symbols extension (System.app file) to the folder.

   The System.app file is located where you installed the AL Development Environment, which by default is the C:\Program Files (x86)\Microsoft Dynamics 365 Business Central<150, 160, or 170>\AL Development Environment folder. This package contains the symbols for all the system tables and codeunits.

5. Delete the **HelloWorld.al** sample file from the project.

6. Modify the `settings.json` file of Visual Studio Code to configure the assembly probing path.

   Change `"al.assemblyProbingPaths": ["./.netpackages"]` to point to all the folders that contain .NET assemblies that are used by your project. Here is an example that contains the most typical paths:

   ```
   "al.assemblyProbingPaths": [
   "C:\\Program Files\\Microsoft Dynamics 365 Business Central\\150",
   "C:\\Program Files (x86)\\Microsoft Dynamics 365 Business Central\\150\\RoleTailored Client",
   "C:\\Program Files (x86)\\Reference Assemblies\\Microsoft\\Framework\\.NETFramework\\v4.7.2",
   "C:\\Program Files (x86)\\Reference Assemblies\\Microsoft\\WindowsPowerShell\\3.0"
   ]
   ```

   For more information about the settings.json, see User and Workspace Settings.

   > **NOTE**
   > Adding assemblies to the folders in your assembly probing paths is not automatically detected by the compiler. You must restart Visual Studio Code for the changes to be detected.

7. Modify the `app.json` for the project as follows:

   - **Important** The ID, name, and publisher, and version of the custom base application must match the Business Central base application. Set the parameters to the following values`:

```
"appId": "437dbf0e-84ff-417a-965d-ed2bb9650972",
"name": "Base Application",
"publisher": "Microsoft",
"version": "14.5.0.0"
```

We recommend that you set the "version" to the same version as the C/AL application.

- Add the setting `"target": "OnPrem"` somewhere in the file.
- Change the `idRange` to include all the IDs used by your base application (or leave blank).
- Delete the values in the `dependencies` parameter.

8. Copy all of the base application AL files generated in the previous task (**Task 5**) to the root folder of your project.
9. Open the **dotnet.al** file for the project, and make the following changes:
   - Delete all instances of `Version = '14.0.0.0';` for **Microsoft.Dynamics.Nav** assembly declarations.
   - For the `DocumentFormat.OpenXml` assembly declaration, remove the `version` and `culture` keys and set `PublicKeyToken = '8fb06cb64d019a17'`.

   ```
   assembly("DocumentFormat.OpenXml")
   {
       PublicKeyToken = '8fb06cb64d019a17';
       ...
   ```
10. Delete objects that are related to the client debugger client.

    Debugging from the client has been discontinued, and replaced by AL Debugger. The version 14 debugger objects are not supported on version 15, 16, or 17. To avoid compilation errors, delete the following objects:

    - Debugger.Page.al
    - DebuggerBreakpointCondition.Page.al
    - DebuggerBreakpointList.Page.al
    - DebuggerCallstackFactBox.Page.al
    - DebuggerCodeViewer.Page.al
    - DebuggerManagement.Codeunit.al
    - DebuggerVariableList.Page.al
    - DebuggerWatchValueFactBox.Page.al
    - SessionList.Page.al

    You might also have to remove references to `SessionList` in ChangeGlobalDimensions.Codeunit.al.
11. Build and compile your project (press Ctrl+Shift+B).

    The AL compiler will issue errors for constructs that are not valid. Fix any errors that occur, and build again.

> **TIP**
> If you are maintaining your C/AL solution going forward, we recommend that you fix errors in C/AL objects and convert to AL again. This makes it future changes easier to foward push changes because code bases will be similar.

When all errors are fixed, the custom base application package (.app) will be created.

Task 8: Create and build an AL project for the test library

If you converted the test library form C/AL to AL, you'll now create and build a project for test library, similar to what you did for the base application.

a. Follow steps 1 through 5 in **Task 7** to create an AL project for the test library.

b. As with base application project, you have to modify the `app.json` file, but in this case, you have to change the version and add a dependency on the base application that you created.

- Set the `"version"` to the old application version, such as `14.5.0.0`.
- Set the `"dependencies"` to include information about your custom the base application.

```
"dependencies": [
{
    "appId": "437dbf0e-84ff-417a-965d-ed2bb9650972",
    "publisher": "Microsoft",
    "name": "Base Application",
    "version": "14.5.0.0"
}
],
```

- Set the `target` to `OnPrem`.
- Change the `idRange` to include all the IDs used by your test application (or leave blank).

c. Copy all of the AL files that you generated for the test library in **Task 5** to the root folder of your project.

d. Open the **dotnet.al** file for the project, and make the following changes:

- Delete all instances of `Version = '14.0.0.0';` for **Microsoft.Dynamics.Nav** assembly declarations.

e. Build the project.

Next Steps

If you are performing a technical upgrade from version 14.0 to version 15, 16, or 17, return to the technical upgrade step where you left off.

- Technical Upgrade to version 15.0
- Technical Upgrade to to version 16.0
- Technical Upgrade to to version 17.0

Developing Extensions

Migrating Tables and Fields Between Extensions

2/17/2021 • 4 minutes to read • Edit Online

INTRODUCED IN: Business Central 2019 Release Wave 2, update 15.3, for on-premises only

Data migration allows you to move table and field data between extensions. The concepts and processes in this article apply to large-scale and small-scale data migrations. A large-scale migration is typically upgrade scenario, like upgrading from Business Central version 14 to version 16. Small-scale migrations are scenarios where you want to move a limited number of objects from one extension to another.

Overview

The move is divided into two phases: development and deployment. However, before you begin, you have to determine the direction of the migration within the dependency graph.

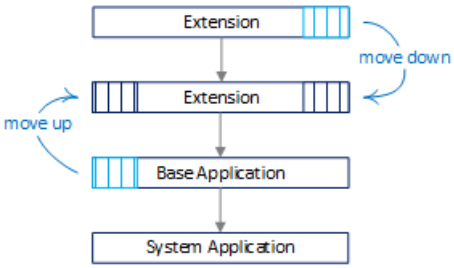
Limitations

- The concepts discussed in this article pertain only to AL. They're not supported in C/AL.
- You can only move fields from a table object to a table extension or move entire tables from one extension to another.
- You can't:
  - Move table extensions to other extensions.
  - Merge multiple table extensions into one extension.
  - Split table extensions into multiple extensions.

  Although you can't use this feature for these scenarios, you can achieve the scenarios by other means, which require more manual work. Examples include obsoleting, copying/re-IDing/renaming, moving data, and more.

Determining the migration direction in the dependency graph

The process to migrate tables and fields to another extension depends on the migration's direction in the dependency graph. The following figure illustrates a simplified extension dependency graph. From top to bottom, an extension is dependent on any extension below it in the graph.



When to move down

Typical move-down scenarios include:

- Moving to a shared extension.

  You want to move common tables to a separate extension that other extensions can have a dependency on.

- Transitioning from a customized base application extension with its own ID to an extension on top of the

Microsoft Base Application.

You have a customized base application extension with its own ID. You want to transition to the Microsoft Base Application. In this case, customizations remain in the current extension. Base objects are removed and ownership transferred to Microsoft Base Application.

This scenario is typical for embed ISV apps and on premises solutions moving to the cloud. It's also relevant for solutions that will remain on-premises for the foreseeable future. Use it to refactor code customizations into cleaner, standard base with extensions as part of upgrading.

For more information, see Moving Tables and Fields to Extension Down the Dependency Graph.

When to move up

Typical move-up scenarios include:

- Splitting an extension in two, with one dependent on the other.
- Extracting the system application from the base application.
- Transitioning from a customized base application extension with Microsoft ID to the Microsoft Base Application.

  You have a customized base application extension that reuses the Microsoft application ID. You want to transition to the standard Microsoft Base Application. In this case, customizations are moved out of the base application up into new extensions. The new extensions have new application IDs and dependencies to the standard Microsoft base application. The customization objects are removed from the custom base application and ownership transferred to the new extensions.

For more information, see Moving Tables and Fields to Extension Up the Dependency Graph.

Development

Development involves making application code changes required for the move. In short, the work involves:

- Creating the *releasing extension* version

  You create a new version of the original extension. This new version contains the tables or fields you want to keep in the extension. The tables and fields that you want to move are deleted from this extension. They're moved to the *receiving extension*.

- Creating the *receiving extension*

  You create new extension that includes the table and fields that you want moved. It essentially includes those tables and fields deleted from the releasing extension.

The key to the move is the *migration.json* file. You add the file to the project for the releasing extension. This file provides a pointer to the ID of new receiving extension where tables and fields are to be moved to. The *migration.json* is used in the deployment phase. Its purpose is to transfer ownership of tables and fields in the database from one extension to another. For more information, see Migration.json File.

Deployment

The deployment phase is when the data is migrated to new tables in the database. In this phase, ownership of tables and fields is switched from one extension to another. Deployment involves publishing, syncing, upgrading, and installing extensions.

The order that you synchronize extensions is important:

- The receiving extensions must be synchronized first.

- The releasing extensions, which include those extensions that include the migration.json file, must be synchronized last.

  These extensions are synchronized last because the tables are moved during the synchronization of the releasing extensions. At the end of the synchronization process, the system checks for breaking changes introduced by the extension. If the extension isn't synchronized last, breaking changes will be detected.

Moving Tables and Fields to Extensions Down the Dependency Graph

2/17/2021 • 3 minutes to read • Edit Online

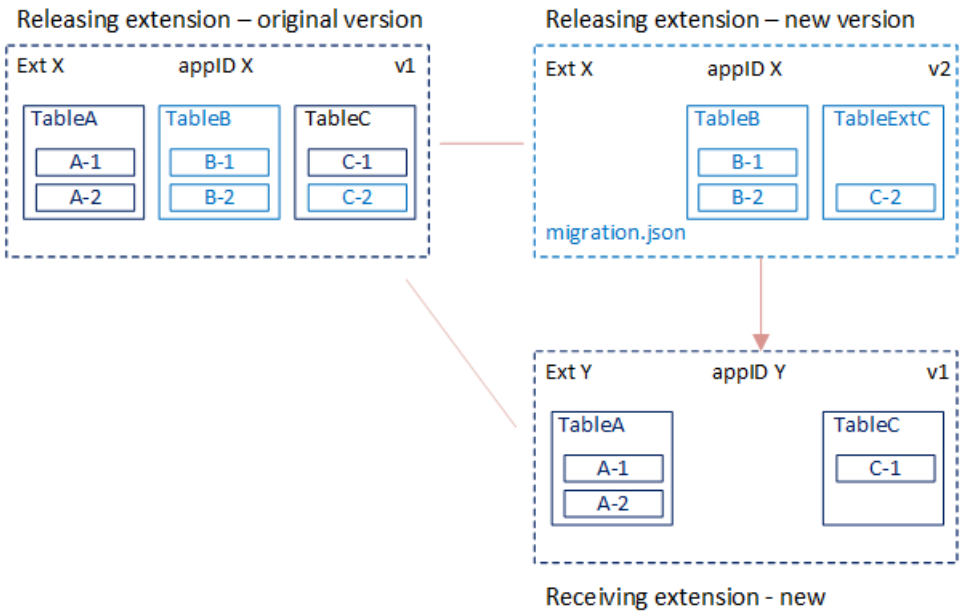
INTRODUCED IN: Business Central 2019 Release Wave 2, update 15.3, for on-premises only

This article explains how to move tables and fields from an extension to another extension that is down the dependency graph.

> **TIP**
> For more information about the general concepts for moving tables and fields between extensions, see Migrating Tables and Fields Between Extensions. This article explains the the difference between moving up and down the dependency graph.

Overview

The steps in this article are based on the example illustrated in the following figure. Although your scenario is different, the concept and process are much the same.



In the example, **TableB** and **Field C-2** are customizations. You'll keep these elements in the original extension, but create a new version without **TableA** and **TableC**. You'll move **TableA** and **TableC** down the dependency chain to a new, separate extension.

Prerequisite

If you're moving enum type fields, then your solution must be running on Business Central 2020 release wave 1, version 16.5 or later. For more information, see Known Issues.

Create receiving extension (Ext Y)

The receiving extension will contain the table and fields that you want to move. In this example, these objects

include **TableA** and **TableC**.

1. Create an AL project for the receiving extension.
2. Add a table object definition for **TableA**.

   The table definition (schema) must include the full schema of the releasing extension **Ext X**, with the same field definitions. You can add new fields.
3. Add a table object definition for **TableC**.

   The table definition (schema) must include the full schema of the releasing extension **Ext X**, with the same field definitions, except don't include field **C-2**. You can add new fields.
4. Make a note of the `ID` of the new extension. You'll use this ID in the next task.

   For purposes of the example, the ID is `11111111-aaaa-2222-bbbb-333333333333`.
5. Compile the extension package.

Create new version of releasing extension (Ext X v2)

1. In the releasing extension AL project, add a migration.json file that points to the ID of the target extension.

   ```
   {
   "apprules": [
       {
           "id": "11111111-aaaa-2222-bbbb-333333333333"
       }
   ]
   }
   ```

   For more information, see The Migration.json File.
2. Modify the app.json file as follows:

   - Ensure that `"target": "OnPrem"`.
   - Increase the `"version"` value.
   - In the `"dependencies"` parameter, set up a dependency on the new receiving extension **Ext Y**.

   For more information, see App.json file.
3. Complete the following steps for **TableC**.

   a. Add a table extension object **TableExtC**.
   b. In table extension object **TableExtC**, add a field definition for field **C-2** that matches its definition in the original **TableC** object.
   c. Delete the original **TableC** object.
4. Delete the entire table object for **TableA**.
5. Compile a new version of the extension package.

Deploy extensions

1. Uninstall the old version of the releasing extension **Ext X**.
2. Publish the new receiving extension **Ext Y** and releasing extension version **Ext X v2**.
3. Synchronize the receiving extension **Ext Y**.

This step creates empty database tables for **TableA** and **TableC** that are owned by the receiving extension **Ext Y**.

> **IMPORTANT**
>
> The receiving extension must always be synchronized first.

4. Synchronize the new version of the releasing extension **Ext X v2**.

   This step first reads rules in the migration.json file of the extension, then does the following operations in the database:

   - Creates a companion table for field **C-2** of the table extension object **TableExtC**.
   - Copies data from column **C-2** in the original **TableC** to new companion table **TableExtC**.
   - Temporarily renames the new empty tables **TableA** and **TableC** made by receiving extension **Ext Y**.
   - Renames the original tables **TableA** and **TableC** that include the data. Instead of including the ID of the releasing extension **Ext X**, the names are changed to include the ID of the receiving extension **Ext Y**. This step essentially transfers ownership from **Ext X** to **Ext Y**.
   - Deletes the unused column for **C-2** in the original table **TableC**.
   - Deletes the empty, renamed tables of **Ext Y**.
5. Install the receiving extension **Ext Y**.
6. Run Start-NAVAppDataUpgrade cmdlet on the new releasing extension version **Ext X v2**.

   This step basically installs the new extension version. You run a data upgrade because an earlier version has been installed and is still published.

Moving Tables and Fields to Extensions Up the Dependency Graph

2/17/2021 • 5 minutes to read • Edit Online

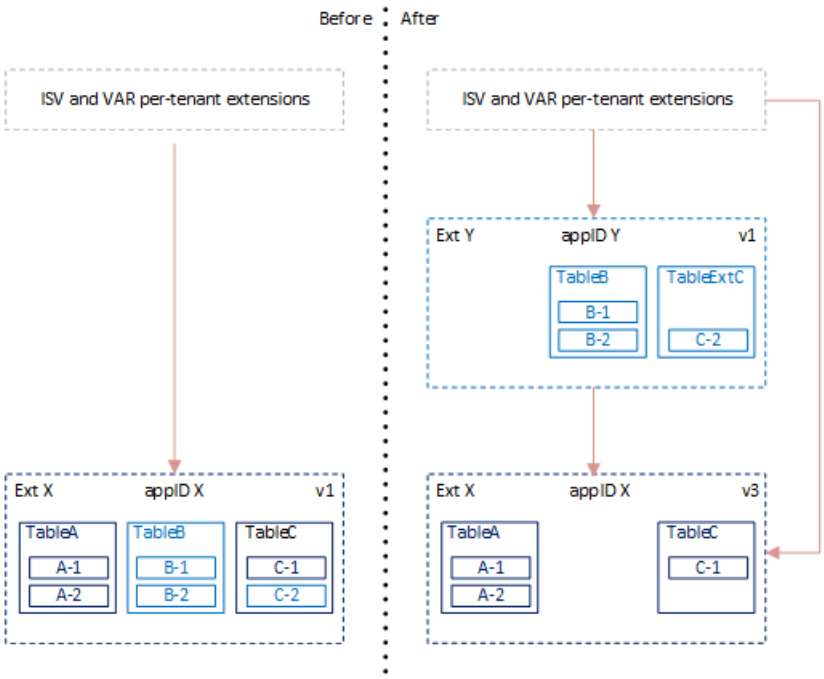
INTRODUCED IN: Business Central 2019 Release Wave 2, update 15.3, for on-premises only

This article explains how to move tables and fields from an extension to another extension that is up the dependency graph.

> **TIP**
> For more information about the general concepts for moving tables and fields between extensions, see Migrating Tables and Fields Between Extensions. This article explains the the difference between moving up and down the dependency graph.

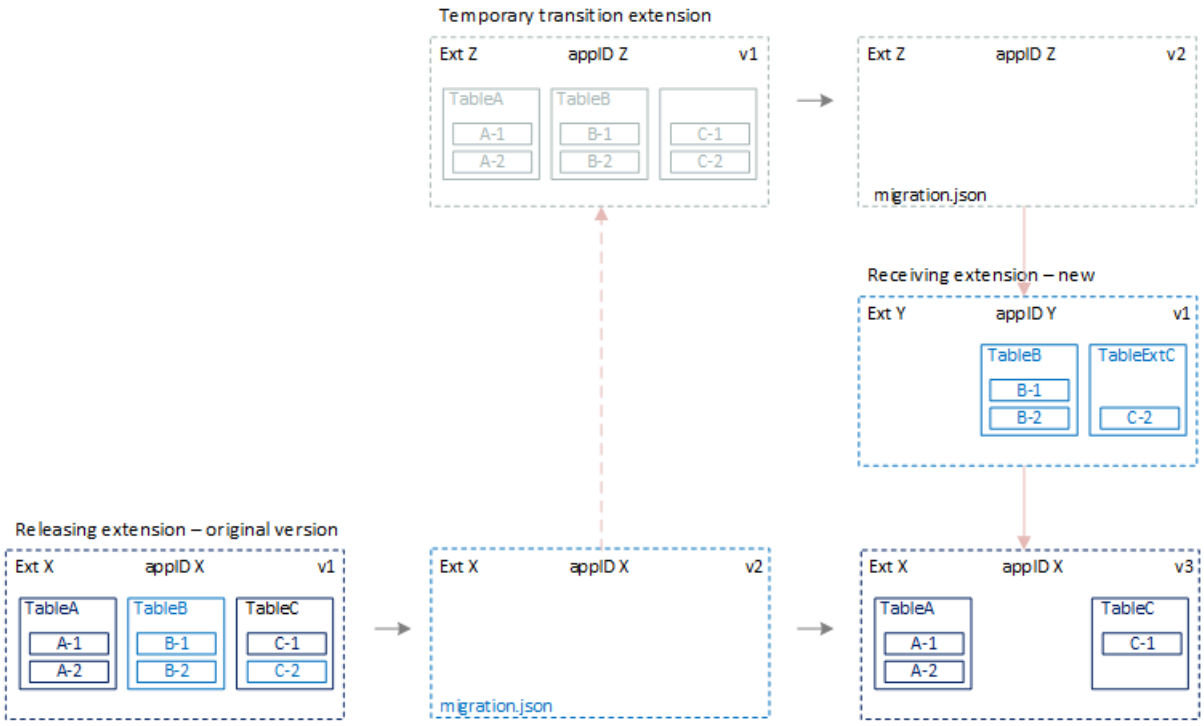
Overview

The steps are based on the example illustrated in the following figure. Although your scenario is different, the concept and process are much the same.



In the example, **TableB** and **Field C-2** are customizations. You'll move these elements from the original extension up to a new extension. This new extension will have a dependency on the original extension. You'll keep **TableA** and **TableC** in the original extension.

To accommodate data migration, you'll have to create an extension that is only used for deployment. This extension is **Ext Z** in the figure. There are two stages of deployment:



- In the first stage, **Ext Z** temporarily takes ownership of tables and fields from **Ext X**.
- In the second stage, **Ext Z** releases ownership to extensions **Ext X** and **Ext Y**. You uninstall and unpublish transition extension **Ext Z** when you finish deployment.

This process is a two-step process because we only support moving down the dependency graph. So instead, the concept is to first move the tables' ownership to an extension above the receiving extensions in the dependency graph. Then, the extensions are moved down. This concept essentially turns the process into a two-step, move-down process.

Ext Z is used just as a temporary extension for moving ownership. So, it only includes schema objects. As a result, customers can't run on the tenant until both steps have been done.

> **NOTE**
> You can only use this process for on-premise solutions.

Prerequisite

If you're moving enum type fields, then your solution must be running on Business Central 2020 release wave 1, version 16.5 or later. For more information, see Known Issues.

Create transition extension (Ext Z v1)

The transition extension will contain replicas of all table object definitions in the releasing extension, except logic code. In the illustration, these objects include **TableA**, **TableB**, and **TableC** and current their field definitions. The transition extension is **Ext Z**.

1. Create an AL project for the transition extension.
2. Add a table object that exactly matches the table object definitions for **TableA**, **TableB**, and **TableC** in the releasing extension.
3. Compile the extension package.
4. Make a note of the `ID` of the new extension. You'll use this ID in the next task.

For purposes of the example, the ID is `11111111-aaaa-2222-bbbb-333333333333`. The value for your extension will be different.

Create empty version of releasing extension (Ext X v2)

In this step, you create a new version of the releasing extension that doesn't contain any objects. It only contains a `migration.json` file that points to **Ext Z**.

1. In the releasing extension AL project, add a migration.json file that points to the ID of the transition extension **Ext Z**.

   ```
   {
   "apprules": [
       {
           "id": "11111111-aaaa-2222-bbbb-333333333333"
       }
   ]
   }
   ```

   For more information, see The Migration.json File.

2. Delete all objects from the extension. The objects include **TableA**, **TableB**, and **TableC**.
3. In the app.json file, increase the `version` value. Ensure that `"target": "OnPrem"`.
4. Compile a new version of the extension package.

Create receiving extension (Ext Y v1)

You now create a new extension that contains the customization you want to move from the releasing. In this example, the customizations include **TableB** and a **TableExtC**.

1. Create an AL project for **Ext Y**.
2. In the app.json file, set up a dependency on the releasing extension **Ext X**.
3. Add a table definition and code for **TableB** that exactly matches the definition in the original releasing extension.
4. Add a table extension object called **TableExtC**. Then, add a field definition for field **C-2** that matches its definition in the original **TableC** object of the releasing extension.
5. Compile the extension package.
6. Make a note of the `ID` of the new extension. You'll use this ID in the next task.

   For purposes of the example, the ID is `44444444-cccc-5555-dddd-666666666666`. The value for your extension will be different.

Create final version of releasing extension (Ext X v3)

In this step, you create another version of the releasing extension **Ext X**. This version will contain the objects and code that you want to finally publish.

1. Create an AL project for **Ext X**.
2. Add a table definition and code for **TableA** that exactly matches the definition in the original releasing extension.
3. Add a table object for **TableC** and field definition for **C-1** that matches the definitions in the original

TableC object of the releasing extension.

4. In the app.json file, increase the `version` value.
5. Compile the extension package.
6. Make a note of the `ID` of the extension. You'll use this ID in the next task.

   For purposes of the example, the ID is `77777777-eeee-8888-ffff-999999999999`. The value for your extension will be different.

Create new empty version of transition extension (Ext Z v2)

In this step, you create a new version of **Ext Z** that only contains a `migration.json` file. This `migration.json` file points the IDS of **Ext X** and **Ext Y**. The file is used to release ownership.

1. In the extension AL project, add a migration.json file that points to the IDs of the releasing extension **Ext X** and receiving extension **Ext Y**.

   ```
   {
   "apprules": [
       {
           "id": "77777777-eeee-8888-ffff-999999999999"
       }
       {
           "id": "44444444-cccc-5555-dddd-666666666666"
       }
   ]
   }
   ```

   For more information, see The Migration.json File.

2. Delete the object definitions for **TableA**, **TableB**, and **TableC**.
3. In the app.json file, increase the `version` value.
4. Compile the extension package.

Deploy the extensions

1. Uninstall the current version of the releasing extension **Ext X**.
2. Complete the following steps for the first stage of deployment:

   a. Publish the transition extension **Ext Z** and empty version of **Ext X v2**.

   b. Synchronize the transition extension **Ext Z**.

      This step creates empty database tables **TableA**, **TableB**, and **TableC** that are owned by **Ext Z**.

      > **IMPORTANT**
      > Extensions receiving table objects must be synced first. Extension releasing/giving away table objects must be synced last.

   c. Synchronize the releasing extension **Ext X v2**.

      This step will read the migration.json of the extension. Then transfer ownership of the original tables **TableA**, **TableB**, and **TableC** to **Ext Z**.

3. Complete the following steps for the second stage of deployment:

    a. Publish the next version for **Ext Z v2** and **Ext X v3**, and the first version of **Ext Y**.

    b. Synchronize the extensions in the following order: **Ext X v3**, **Ext Y v1**, and **Ext Z v2**.

        Synchronize **Ext Z v2** last. When you synchronize **Ext Z v2**, ownership of the tables is transferred from **Ext Z** to **Ext X** and **Ext Y**.

4. Run Start-NAVAppDataUpgrade cmdlet on the new releasing extension version**Ext X v3**.

    This step basically installs the new extension version. You run a data upgrade because an earlier version has been installed and is still published.

5. Install the new receiving extension **Ext Y v1**.

6. Unpublish both versions of **Ext Z**.

DestinationAppsForMigration

2/17/2021 • 3 minutes to read • Edit Online

DestinationAppsForMigration is a Business Central Server instance setting. It's primarily used when upgrading from version 14. It's part of data upgrade process for transitioning application features from C/AL to AL extensions.

What this setting does

The DestinationAppsForMigration setting serves the following purposes:

1. Supports moving entire tables from C/AL to AL.

   When you transition your solution from C/AL to AL, you can move entire tables from the C/AL application to separate AL extensions. In the tenant database, the ownership of the tables must be transferred to the extensions. The DestinationAppsForMigration setting is used to do this transfer, which is done when the tenant is synchronized. As a result, in the database, the table names will be suffixed with the ID of the extension. For example, `[dbo].[CRONUS International Ltd_$VAT Clause]` changes to `[dbo].[CRONUS International Ltd_$VAT Clause$437dbf0e-84ff-417a-965d-ed2bb9650972]`. In this case, `437dbf0e-84ff-417a-965d-ed2bb9650972` is the extension's ID.

   To successfully move a table automatically: This scenario requires that:

   - Table ID in AL must be the same ID as was in the C/AL.
   - The table definition (schema) must match the existing schema. Or, if there are schema changes, they must be additive only.

     If this condition isn't met, it won't prohibit the move to the extension. But, the data upgrade may fail because of the breaking changes.

2. Runs upgrade code and installs extensions automatically during upgrade.

   The server instance essentially runs the Start-NAVDataUpgrade cmdlet. However, unlike normally, it doesn't invoke the OnInstall codeunit. It invokes the upgrade codeunit directly instead.

   When you run the data upgrade on a tenant, the server runs the upgrade code for the base and system application extensions. These extensions will then be automatically installed on the tenant.

3. Enables republishing and reinstalling extensions that haven't been built on the latest platform. For example, extensions that haven't been compiled on version 15 or 16.

   These extensions don't include base or system application dependencies in their manifests (app.json file). These extensions typically include the third-party extensions used on your version 14 solution. The DestinationAppsForMigration setting will resolve references to the Microsoft base application and system application for the extensions. When an extension is published, the system will automatically modify its manifest to include a dependency on the base and system applications.

   The destinationappsformigration process only inserts dependencies, which allows you to resolve dependencies. If the extension introduces breaking changes, it will fail.

TIP

If you moving a table and fields from one extension to another, this move is considered an AL to AL move. For this move, you use the migration.json file. For more information, see Migrating Tables and Fields Between Extensions.

How to set it up

You can only set the DestinationAppsForMigration by using the Set-NAVServerConfiguration cmdlet. To specify an extension, you must know the extension's ID, name, and publisher. The following code snippet shows the syntax for setting the DestinationAppsForMigration:

```
Set-NAVServerConfiguration -ServerInstance <server instance name> -KeyName "DestinationAppsForMigration" -
KeyValue '[{"appId":"<GUID>, "name":"<Extension name>", "publisher": "<Publisher>"},{"appId":"<GUID>,
"name":"<Extension name>", "publisher": "<Publisher>"}]'
```

For example, the following command specifies the Microsoft system and base applications and a custom extension named My Extension.

```
Set-NAVServerConfiguration -ServerInstance <server instance name> -KeyName "DestinationAppsForMigration" -
KeyValue '[{"appId":"63ca2fa4-4f03-4f2b-a480-172fef340d3f", "name":"System Application", "publisher":
"Microsoft"},{"appId":"437dbf0e-84ff-417a-965d-ed2bb9650972", "name":"Base Application", "publisher":
"Microsoft"},{"appId":"e3d1b010-7f32-4370-9d80-0cb7e304b6f0", "name":"My Extension", "publisher": "Me"}]'
```

IMPORTANT

The order of the extensions is important. You specify the extensions according to the dependency graph. For example, the system application must be before the base application.

FAQ

What extensions should I include?

In short, include any new extension, or in other words, any extensions that have never published and installed on the tenant. Typically:

- New extensions for existing objects that were moved from C/AL. The base application and system application are good examples.
- New extensions that add new objects to the application.
- Old extensions that are still compiled on version 14. Third-party extensions for which you don't have access to source code would typically fall into this category.

My extension only includes new objects that were never in C/AL. Can I include this extension?

Yes. You can use this mechanism to install any extension together with the Microsoft system or base application. For example, Microsoft publishes extensions for upgrade tests and the library assert that had no objects in the C/AL base application.

My extension is standalone, that is, it's not dependent on the system or base application. Can or should I include it?

It depends. For the setting to have any effect, you also include the system and base applications. If you use global triggers, you can add it to the list so it can listen to the triggers.

How many extensions can I include?

As many as you like. There's no limit or performance impact.

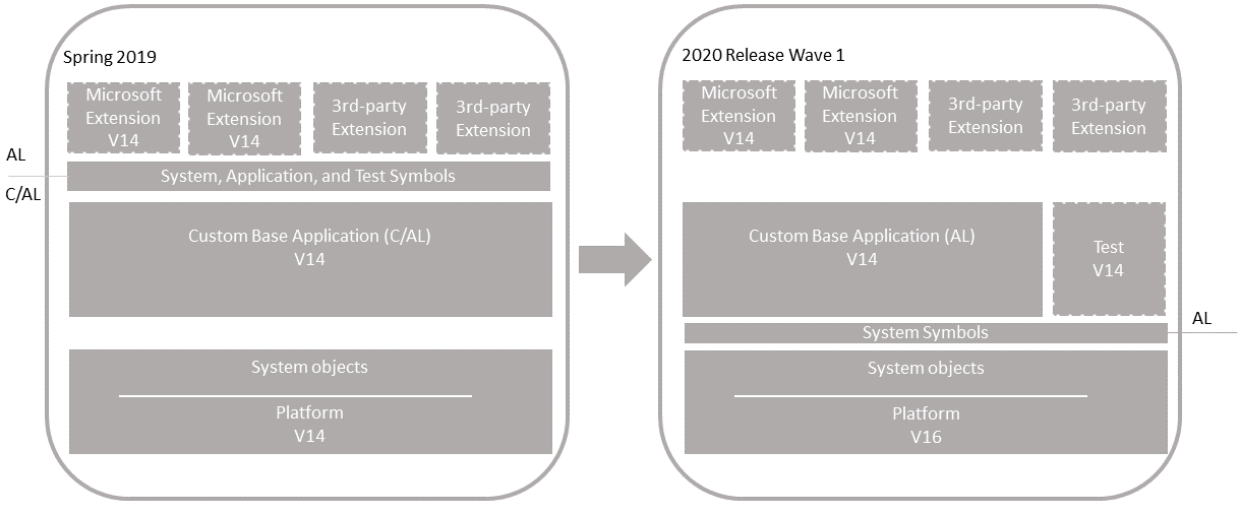
Technical Upgrade From Version 14 to Version 16

2/17/2021 • 12 minutes to read • Edit Online

Use this process when you have a code customized Business Central application (version 14) that you want to upgrade to the Business Central 2020 release wave 1 platform (version 16). This process won't upgrade the application to the latest version. You'll convert the entire application from C/AL to an AL base application extension.



Single-tenant and multitenant deployments

The process for upgrading is similar for a single-tenant and multitenant deployment. However, there are some inherent differences. With a single-tenant deployment, the application and business data are included in the same database. While with a multitenant deployment, application code is in a separate database (the application database) than the business data (tenant). In the procedures that follow, for a single-tenant deployment, consider references to the *application database* and *tenant database* as the same database. Steps are marked as *Single-tenant only* or *Multitenant only* where applicable.

Prerequisites

1. Upgrade to Business Central Spring 2019 (version 14).

   There are several updates for version 14. When upgrading from Business Central Fall 2018 (version 13) or Dynamics NAV, upgrade to the latest version 14 update that has a compatible version 16 update. For more information, see Dynamics 365 Business Central Upgrade Compatibility Matrix.

   If your solution is already on version 14, then you don't have to upgrade to the latest version 16 update.

   To download the latest update, go to Released Cumulative Updates for Microsoft Dynamics 365 Business Central Spring 2019 Update on-premises.

   For information, see Upgrading to Dynamics 365 Business Central On-Premises.

2. Disable data encryption.

   If the current server instance uses data encryption, disable it. You can enable it again after upgrading.

   For more information, see Managing Encryption and Encryption Keys.

   Instead of disabling encryption, you can export the current encryption key, which you'll then import after upgrade. However, we recommend disabling encryption before upgrading.

Task 1: Install version 16

1. Before you install version 16, it can be useful to create desktop shortcuts to the version 14.0 tools, such as the Business Central Server Administration tool, Business Central Administration Shell, and Dynamics NAV Development Shell because the Start menu items for these tools will be replaced with the version 16.0 tools.

2. Install all components of version 16.

   You'll have to keep version 14.0 installed, because you'll need the it to complete the C/AL to AL conversion in this process. Therefore, when you install version 16, you must either specify different port numbers for components during installation or stop the version 14.0 Business Central Server instance before you run the installation. Otherwise, you'll get an error that the Business Central Server failed to install.

   For more information, see Installing Business Central Using Setup.

3. Copy the version 14 **CodeViewer** add-in to the version 16.0 server installation

   a. Find the **CodeViewer** folder in the **Add-ins** folder of the version 14 RoleTailored client installation. By default, the folder path is C:\Program Files (x86)\Microsoft Dynamics 365 Business Central\140\RoleTailored Client\Add-ins.

   b. Copy the folder to the **Add-ins** folder of the version 16 server installation. By default, the folder path is C:\Program Files\Microsoft Dynamics 365 Business Central\160\Service\Add-ins. Replace the existing folder and files, if any.

   CodeViewer is no longer used in version 16. But it's required because of references that exist in the converted application. If you omit this step, you might get compilation errors later.

Task 2: Convert your v14 C/AL application to AL

For more information, see Code Conversion from C/AL to AL.

Task 3: Rewrite code for obsoleted system tables

In version 17, a number of tables have been deprecated and replaced by new tables compared to version 14. You must rewrite code that uses the deprecated tables to use the new tables. For a list of the deprecated tables and new tables, see Deprecated Tables.

Task 4: Prepare databases

In this task, you prepare the application and tenant databases for the upgrade.

1. Make backup of the database.

2. Make sure that you have the extension packages for all published extensions.

   You'll need these packages later to publish and install the extensions again.

3. Uninstall all extensions from the old tenants.

   Run the Business Central Administration Shell for version 14.0 as an administrator. Use the Uninstall-NAVApp cmdlet to uninstall an extension. For example, together with the Get-NAVAppInfo cmdlet, you can uninstall all extensions with a single command:

```
Get-NAVAppInfo -ServerInstance <BC14 server instance> -Tenant <tenant ID> | % { Uninstall-NAVApp -
ServerInstance <BC14 server instance> -Name $_.Name -Version $_.Version -Tenant <tenant ID>}
```

If you have a single tenant deployment, you can omit the `-Tenant` parameter and value.

4. Unpublish all extensions from the application server instance.

   To unpublish extensions, use the Unpublish-NAVAPP cmdlet. Together with the Get-NAVAppInfo cmdlet, you can uninstall all extensions from the tenant using a single command:

   ```
   Get-NAVAppInfo -ServerInstance <BC14 server instance> | % { Unpublish-NAVApp -ServerInstance <BC14
   server instance> -Name $_.Name -Version $_.Version }
   ```

5. Unpublish all system, test, and application symbols.

   To unpublish symbols, use the Unpublish-NAVAPP cmdlet. You can unpublish all symbols by using the Get-NAVAppInfo cmdlet with the `-SymbolsOnly` switch as follows:

   ```
   Get-NAVAppInfo -ServerInstance <BC14 server instance> -SymbolsOnly | % { Unpublish-NAVApp -
   ServerInstance <BC14 server instance> -Name $_.Name -Version $_.Version }
   ```

   What are symbols?

6. (Multitenant only) Dismount the tenants from the application server instance.

   To dismount a tenant, use the Dismount-NAVTenant cmdlet:

   ```
   Dismount-NAVTenant -ServerInstance <BC14 server instance> -Tenant <tenant ID>
   ```

7. Stop the server instance.

   ```
   Stop-NAVServerInstance -ServerInstance <BC14 server instance>
   ```

Task 5: Convert version 14.0 application database

This task runs a technical upgrade on the application database. A technical upgrade converts the database from the version 14.0 platform to the version 16.0 platform. This conversion updates the system tables of the database to the new schema (data structure). It also provides the latest platform features and performance enhancements.

1. Start Business Central Administration Shell for version 16.0 as an administrator.
2. Run the Invoke-NAVApplicationDatabaseConversion cmdlet to start the conversion:

   ```
   Invoke-NAVApplicationDatabaseConversion -DatabaseServer <database server>\<database instance> -
   DatabaseName "<BC14 database name>"
   ```

   When completed, a message like the following displays in the console:

```
DatabaseServer      : .\BCDEMO
DatabaseName        : Demo Database BC (14-0)
DatabaseCredentials :
DatabaseLocation    :
Collation           :
```

Task 6: Configure version 16 server

When you installed version 16 in **Task 1**, a version 16 Business Central Server instance was created. In this task, you change server configuration settings that are required to complete the upgrade. Some of the changes are only required for version 14 to version 16.0 upgrade and can be reverted after you complete the upgrade.

1. Set the server instance to connect to the application database.

   ```
   Set-NAVServerConfiguration -ServerInstance <BC15 server instance> -KeyName DatabaseName -KeyValue "
   <BC14 database name>"
   ```

   In a single tenant deployment, this command mounts the tenant automatically. For more information, see Connecting a Server Instance to a Database.

2. Disable task scheduler on the server instance for purposes of upgrade.

   ```
   Set-NavServerConfiguration -ServerInstance <BC16 server instance> -KeyName "EnableTaskScheduler" -
   KeyValue false
   ```

   Be sure to re-enable task scheduler after upgrade if needed.

3. Restart the server instance.

   ```
   Restart-NAVServerInstance -ServerInstance <BC16 server instance>
   ```

Task 7: Publish system symbols, base application, and test library extensions

In this task, you'll publish extensions to the version 16.0 server instance. Publishing adds the extension to the application database that is mounted on the server instance. The extension is then available for installing on tenants later. It updates internal tables, compiles the components of the extension behind-the-scenes, and builds the necessary metadata objects that are used at runtime.

The steps in this task continue to use the Business Central Administration Shell for version 16.0 that you started in the previous task.

1. Publish the system symbols extension for version 16.

   The symbols extension contains the required platform symbols that the base application depends on. The symbols extension package is called **System.app**. You find it where the **AL Development Environment** is installed. The default installation path is C:\Program Files (x86)\Microsoft Dynamics 365 Business Central\160\AL Development Environment.

   ```
   Publish-NAVApp -ServerInstance <BC16 server instance> -Path "<path to the System.app file>" -
   PackageType SymbolsOnly
   ```

2. Publish the custom base application extension that you created in **Task 2**.

```
Publish-NAVApp -ServerInstance <BC16 server instance> -Path "<path to the base application extension
package file>"
```

3. Publish the test library extension if you created one in **Task 2**.

```
Publish-NAVApp -ServerInstance <BC16 server instance> -Path "<path to the test library extension
package file>"
```

Task 8: Synchronize tenant

This task updates the tenant database schema with schema changes in system objects and application objects.

If you have a multitenant deployment, run these steps for each tenant (replacing `<tenant ID>` with the appropriate tenant ID).

1. (Multitenant only) Mount the tenant to the version 16 server instance.

   To mount the tenant, use the Mount-NAVTenant cmdlet:

```
Mount-NAVTenant -ServerInstance <BC16 server instance> -DatabaseName "<BC14 database name>" -
DatabaseServer <database server>\<database instance> -Tenant <tenant ID> -AllowAppDatabaseWrite
```

> **IMPORTANT**
> You must use the same tenant ID for the tenant that was used in the old deployment; otherwise you will get an error when mounting or syncing the tenant. If you want to use a different ID for the tenant, you can either use the `-AlternateId` parameter now or after upgrading, dismount the tenant, then mount it again using the new ID and the `OverwriteTenantIdInDatabase` parameter.

> **NOTE**
> For upgrade, we recommend that you use the `-AllowAppDatabaseWrite` parameter. After upgrade, you can dismount and mount the tenant again without the parameter if needed.

2. Synchronize the tenant to the system objects.

   Use the Sync-NAVTenant cmdlet:

```
Sync-NAVTenant -ServerInstance <BC16 server instance> -Tenant <tenant ID> -Mode Sync
```

   With a single-tenant deployment, you can omit the `-Tenant` parameter and value.

   At this stage, the tenant state is **Operational**.

Task 9: Install base and test applications

You'll synchronize the tenant to the custom base application and test library extension (if any). When you synchronize the tenant, extensions take ownership of the tables in the SQL Database.

If you have a multitenant deployment, run these steps for each tenant (replacing `<tenant ID>` with the appropriate tenant ID).

1. Synchronize the tenant to the base application extension (Base Application).

   Use the Sync-NAVApp cmdlet:

   ```
   Sync-NAVApp -ServerInstance <BC16 server instance> -Name "Base Application" -Version <extension
   version> -tenant <tenant ID>
   ```

   With this step, the base app takes ownership of the database tables. When completed, in SQL Server, the table names will be suffixed with the base app extension ID.

2. Install custom base application extension on the tenant.

   To install the extension, you use the Install-NAVApp cmdlet.

   ```
   Install-NAVApp -ServerInstance <BC16 server instance> -Name "Base Application" -Version <extension
   version>
   ```

   At this point, the base application is upgraded to the version 16 platform and is operational. You can open the application in the client.

3. Synchronize and install the test library extension.

   This step is like what you did for the custom base application in steps 3 and 4.

Task 10: Configure version 16 server for app migration

In this task, you configure the version 16 server so that the Microsoft and third-party extensions that were installed in the version 14 deployment can be reinstalled. You'll configure the `DestinationAppsForMigration` parameter of the serve instance with information about the custom base application and test library. Specifically, you need the ID, name, and publisher assigned to these extensions. With the `DestinationAppsForMigration` parameter set, when you publish the Microsoft and third-party extensions, the server instance will automatically modify the manifest of the extensions to include the dependency on the base application and test library extension, allowing them to be published. For more information about this setting, see DestinationAppsForMigration.

1. Get the ID, name, and publisher of the custom base application and test library.

   ```
   Get-NAVAppInfo -ServerInstance <BC15 server instance>
   ```

2. Set the `DestinationAppsForMigration` parameter for the server instance configuration to include the information about the custom base application and test library (if used). For example:

   ```
   Set-NAVServerConfiguration -ServerInstance <BC16 server instance> -KeyName
   "DestinationAppsForMigration" -KeyValue '[{"appId":"437dbf0e-84ff-417a-965d-ed2bb9650972",
   "name":"Base Application", "publisher": "Microsoft"},{"appId":"<test library extension app ID>",
   "name":"<test library extension name>", "publisher": "<test library publisher>"}]'
   ```

3. Restart the server instance.

Task 11: Publish and install extensions

Now, you can install the Microsoft and 3rd-party extensions that were installed on the tenant before the upgrade.

1. Publish the old extension versions.

```
Publish-NAVApp -ServerInstance <BC16 server instance> -Path "<path to extension package file>"
```

You only need to do this step once.

2. Synchronize the extension.

```
Sync-NAVApp -ServerInstance <BC16 server instance> -Name "<extension name>" -Version <extension
version> -tenant <tenant ID>
```

3. Install the extension:

```
Install-NAVApp -ServerInstance <BC16 server instance> -Name "<extension name>" -Version <extension
version> -tenant <tenant ID>
```

4. Repeat steps 2 and 3 for each extension and on each tenant.

Now, your application is fully upgraded to the version 16 platform.

Task 12: Upgrade control add-ins

The Business Central Server installation includes new versions of the Microsoft-provided Javascript-based control add-ins, like Microsoft.Dynamics.Nav.Client.BusinessChart, Microsoft.Dynamics.Nav.Client.VideoPlayer, and more. If your solution uses any of these control add-ins, upgrade them to the latest version.

To upgrade the control add-ins from the client, do the following steps:

1. Open the Business Central client.
2. Search for and open the **Control Add-ins** page.
3. Choose **Actions** > **Control Add-in Resource** > **Import**.
4. Locate and select the .zip file for the control add-in and choose **Open**.

   The .zip files are located in the **Add-ins** folder of the Business Central Server installation. There's a subfolder for each add-in. For example, the path to the Business Chart control add-in is `C:\Program Files\Microsoft Dynamics 365 Business Central\160\Service\Add-ins\BusinessChart\Microsoft.Dynamics.Nav.Client.BusinessChart.zip`.

5. After you've imported all the new control add-in versions, restart Business Central Server instance.

Alternatively, you can use the Set-NAVAddin cmdlet of the Business Central Administration Shell. For example, the following commands update the control add-ins installed by default. Modify the commands to suit:

```
$InstanceName = 'BC160'
$ServicesAddinsFolder = 'C:\Program Files\Microsoft Dynamics 365 Business Central\160\Service\Add-ins'
Set-NAVAddIn -ServerInstance $InstanceName -AddinName 'Microsoft.Dynamics.Nav.Client.BusinessChart' -
PublicKeyToken 31bf3856ad364e35 -ResourceFile ($AppName = Join-Path $ServicesAddinsFolder
'BusinessChart\Microsoft.Dynamics.Nav.Client.BusinessChart.zip')
Set-NAVAddIn -ServerInstance $InstanceName -AddinName 'Microsoft.Dynamics.Nav.Client.FlowIntegration' -
PublicKeyToken 31bf3856ad364e35 -ResourceFile ($AppName = Join-Path $ServicesAddinsFolder
'FlowIntegration\Microsoft.Dynamics.Nav.Client.FlowIntegration.zip')
Set-NAVAddIn -ServerInstance $InstanceName -AddinName 'Microsoft.Dynamics.Nav.Client.OAuthIntegration' -
PublicKeyToken 31bf3856ad364e35 -ResourceFile ($AppName = Join-Path $ServicesAddinsFolder
'OAuthIntegration\Microsoft.Dynamics.Nav.Client.OAuthIntegration.zip')
Set-NAVAddIn -ServerInstance $InstanceName -AddinName 'Microsoft.Dynamics.Nav.Client.PageReady' -
PublicKeyToken 31bf3856ad364e35 -ResourceFile ($AppName = Join-Path $ServicesAddinsFolder
'PageReady\Microsoft.Dynamics.Nav.Client.PageReady.zip')
Set-NAVAddIn -ServerInstance $InstanceName -AddinName 'Microsoft.Dynamics.Nav.Client.PowerBIManagement' -
PublicKeyToken 31bf3856ad364e35 -ResourceFile ($AppName = Join-Path $ServicesAddinsFolder
'PowerBIManagement\Microsoft.Dynamics.Nav.Client.PowerBIManagement.zip')
Set-NAVAddIn -ServerInstance $InstanceName -AddinName 'Microsoft.Dynamics.Nav.Client.RoleCenterSelector' -
PublicKeyToken 31bf3856ad364e35 -ResourceFile ($AppName = Join-Path $ServicesAddinsFolder
'RoleCenterSelector\Microsoft.Dynamics.Nav.Client.RoleCenterSelector.zip')
Set-NAVAddIn -ServerInstance $InstanceName -AddinName 'Microsoft.Dynamics.Nav.Client.SatisfactionSurvey' -
PublicKeyToken 31bf3856ad364e35 -ResourceFile ($AppName = Join-Path $ServicesAddinsFolder
'SatisfactionSurvey\Microsoft.Dynamics.Nav.Client.SatisfactionSurvey.zip')
Set-NAVAddIn -ServerInstance $InstanceName -AddinName 'Microsoft.Dynamics.Nav.Client.SocialListening' -
PublicKeyToken 31bf3856ad364e35 -ResourceFile ($AppName = Join-Path $ServicesAddinsFolder
'SocialListening\Microsoft.Dynamics.Nav.Client.SocialListening.zip')
Set-NAVAddIn -ServerInstance $InstanceName -AddinName 'Microsoft.Dynamics.Nav.Client.VideoPlayer' -
PublicKeyToken 31bf3856ad364e35 -ResourceFile ($AppName = Join-Path $ServicesAddinsFolder
'VideoPlayer\Microsoft.Dynamics.Nav.Client.VideoPlayer.zip')
Set-NAVAddIn -ServerInstance $InstanceName -AddinName 'Microsoft.Dynamics.Nav.Client.WebPageViewer' -
PublicKeyToken 31bf3856ad364e35 -ResourceFile ($AppName = Join-Path $ServicesAddinsFolder
'WebPageViewer\Microsoft.Dynamics.Nav.Client.WebPageViewer.zip')
Set-NAVAddIn -ServerInstance $InstanceName -AddinName 'Microsoft.Dynamics.Nav.Client.WelcomeWizard' -
PublicKeyToken 31bf3856ad364e35 -ResourceFile ($AppName = Join-Path $ServicesAddinsFolder
'WelcomeWizard\Microsoft.Dynamics.Nav.Client.WelcomeWizard.zip')
```

Task 13: Post-upgrade

1. Enable task scheduler on the server instance.
2. (Multitenant only) For tenants other than the tenant that you use for administration purposes, if you mounted the tenants using the `-AllowAppDatabaseWrite` parameter, dismount the tenants, then mount them again without using the `-AllowAppDatabaseWrite` parameter.
3. If you want to use data encryption as before, enable it.

   For more information, see Managing Encryption and Encryption Keys.

   Optionally, if you exported the encryption key instead of disabling encryption earlier, import the encryption key file to enable encryption.
4. Grant users permission to the *Open in Excel* and *Edit in Excel* actions.

   Version 16 introduces a system permission that protects these two actions. The permission is granted by the system object **6110 Allow Action Export To Excel**. Because of this change, users who had permission to these actions before upgrading, will lose permission. To grant permission again, do one of the following steps:

   - If you have a version 16 application, export the **EXCEL EXPORT ACTION** permission set. Then, import it to your application and add it to appropriate users.
   - Add the system object **6110 Allow Action Export To Excel** permission directly to appropriate

permission sets.

For more information about working with permission sets and permissions, see Export and Import Permission Sets.

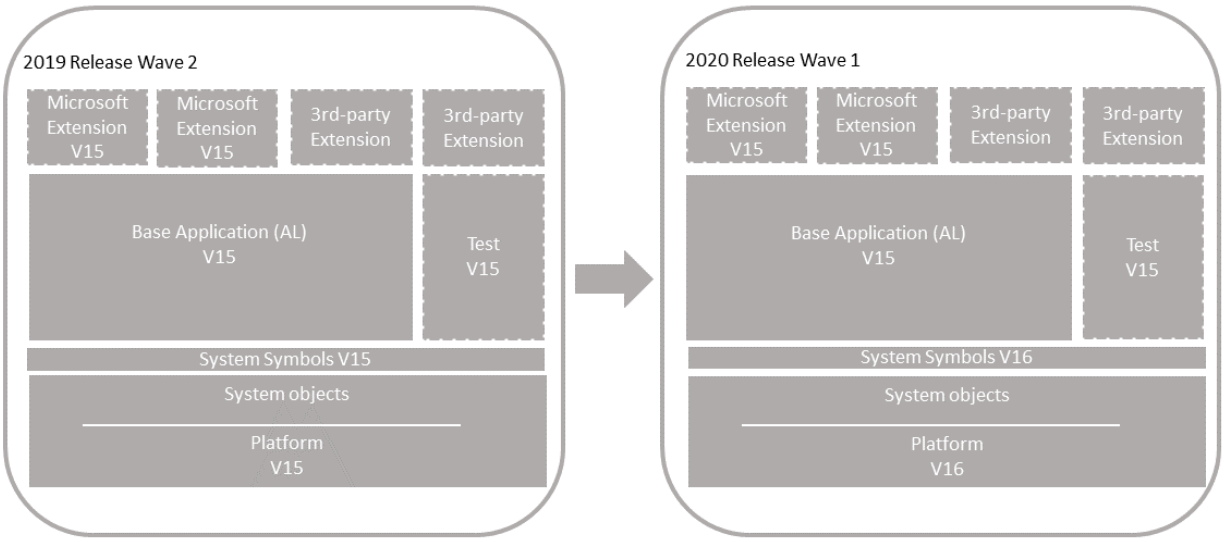
Technical Upgrade from Version 15 to Version 16

2/17/2021 • 9 minutes to read • Edit Online

Use this process to upgrade from Business Central 2019 release wave 2 (version 15) to the Business Central 2020 release wave 1 platform (version 16). This process won't upgrade the application to the latest version.



Single-tenant and multitenant deployments

The process for upgrading is similar for a single-tenant and multitenant deployment. However, there are some inherent differences. With a single-tenant deployment, the application and business data are included in the same database. While with a multitenant deployment, application code is in a separate database (the application database) than the business data (tenant). In the procedures that follow, for a single-tenant deployment, consider references to the *application database* and *tenant database* as the same database. Steps are marked as *Single-tenant only* or *Multitenant only* where applicable.

Prerequisites

1. Your version 15 platform is compatible with version 16.

   There are several updates for version 15. The updates have a compatible version 16 update. For more information, see Dynamics 365 Business Central Upgrade Compatibility Matrix. For example, if your solution is currently running 15.5, you can't upgrade to 16.0. You must wait until 16.1 is available.

2. Disable data encryption.

   If the current server instance uses data encryption, disable it. You can enable it again after upgrading.

   For more information, see Managing Encryption and Encryption Keys.

   Instead of disabling encryption, you can export the current encryption key, which you'll then import after upgrade. However, we recommend disabling encryption before upgrading.

Task 1: Install version 16

1. Before you install version 16, it can be useful to create desktop shortcuts to the version 15.0 tools, such as the Business Central Server Administration tool, Business Central Administration Shell, and Dynamics NAV Development Shell because the Start menu items for these tools will be replaced with the version 16.0 tools.

2. Install version 16 components.

   You can keep version 15 component installed, but it is not required. If you do, when you install version 16, you must either specify different port numbers for components during installation or stop the version 15.0 Business Central Server instance before you run the installation. Otherwise, you'll get an error that the Business Central Server failed to install.

   For more information, see Installing Business Central Using Setup.

Task 2: Rewrite code for obsoleted system tables

In version 16, a number of tables have been deprecated and replaced by new tables. You must rewrite code that uses the deprecated tables to use the new tables. For a list of the deprecated tables and new tables, see Deprecated Tables.

Task 3: Prepare databases

In this task, you prepare the application and tenant databases for the upgrade.

1. Make backup of the database.
2. Make sure that you have the extension packages for all published extensions.

   You'll need these packages later to publish and install the extensions again.

3. (Single-tenant only) Uninstall all extensions from the old tenants.

   Run the Business Central Administration Shell for version 15.0 as an administrator. Use the Uninstall-NAVApp cmdlet to uninstall an extension. For example, together with the Get-NAVAppInfo cmdlet, you can uninstall all extensions with a single command:

   ```
   Get-NAVAppInfo -ServerInstance <BC15 server instance> | % { Uninstall-NAVApp -ServerInstance <BC15 server instance> -Name $_.Name -Version $_.Version }
   ```

4. Unpublish all system, test, and application symbols.

   To unpublish symbols, use the Unpublish-NAVAPP cmdlet. You can unpublish all symbols by using the Get-NAVAppInfo cmdlet with the `-SymbolsOnly` switch as follows:

   ```
   Get-NAVAppInfo -ServerInstance <BC15 server instance> -SymbolsOnly | % { Unpublish-NAVApp -ServerInstance <BC15 server instance> -Name $_.Name -Version $_.Version }
   ```

   What are symbols?

5. (Multitenant only) Dismount the tenants from the application server instance.

   To dismount a tenant, use the Dismount-NAVTenant cmdlet:

   ```
   Dismount-NAVTenant -ServerInstance <BC15 server instance> -Tenant <tenant ID>
   ```

6. Stop the server instance.

   ```
   Stop-NAVServerInstance -ServerInstance <BC15 server instance>
   ```

Task 4: Convert the version 15.0 application database

This task runs a technical upgrade on the application database. A technical upgrade converts the database from the version 15.0 platform to the version 16.0 platform. This conversion updates the system tables of the database to the new schema (data structure). It also provides the latest platform features and performance enhancements.

> **IMPORTANT**
> The conversion does not modify the application objects, but it will remove any modifications that you have made to system tables. After the conversion you will no longer be able to use it with Business Central 14.

1. Start Business Central Administration Shell for version 16.0 as an administrator.
2. Run the Invoke-NAVApplicationDatabaseConversion cmdlet to start the conversion. In a multitenant deployment, run this cmdlet against the application database.

   ```
   Invoke-NAVApplicationDatabaseConversion -DatabaseServer <database server>\<database instance> -
   DatabaseName "<BC15 database name>"
   ```

   When completed, a message like the following displays in the console:

   ```
   DatabaseServer      : .\BCDEMO
   DatabaseName        : Demo Database BC (15-0)
   DatabaseCredentials :
   DatabaseLocation    :
   Collation           :
   ```

Task 5: Configure version 16 server

When you installed version 16 in **Task 1**, a version 16 Business Central Server instance was created. In this task, you change server configuration settings that are required to complete the upgrade. Some of the changes are only required for version 15 to version 16.0 upgrade and can be reverted after you complete the upgrade.

1. Set the server instance to connect to the application database.

   ```
   Set-NAVServerConfiguration -ServerInstance <BC15 server instance> -KeyName DatabaseName -KeyValue "
   <BC15 database name>"
   ```

   In a single tenant deployment, this command mounts the tenant automatically. For more information, see Connecting a Server Instance to a Database.

2. Disable task scheduler on the server instance for purposes of upgrade.

   ```
   Set-NavServerConfiguration -ServerInstance <BC16 server instance> -KeyName "EnableTaskScheduler" -
   KeyValue false
   ```

   Be sure to re-enable task scheduler after upgrade if needed.

3. Restart the server instance.

   ```
   Restart-NAVServerInstance -ServerInstance <BC16 server instance>
   ```

Task 6: Publish new system symbols

Use the Publish-NAVApp cmdlet to publish the new symbols extension package. This package is called **System.app**. If you've installed the **AL Development Environment**, you find the file in the installation folder. By default, the folder path is C:\Program Files (x86)\Microsoft Dynamics 365 Business Central\160\AL Development Environment.

```
Publish-NAVApp -ServerInstance <BC16 server instance> -Path "<path to the System.app file>" -PackageType
SymbolsOnly
```

Task 7: Recompile published extensions

Compile all published extensions against the new platform.

1. To compile an extension, use the Repair-NAVApp cmdlet, For example:

   ```
   Repair-NAVApp -ServerInstance <server instance> -Name <extension name> -Version <extension name>
   ```

   To compile all published extensions at once, you can use this command:

   ```
   Get-NAVAppInfo -ServerInstance <server instance> | Repair-NAVApp
   ```

2. Restart the server instance.

   ```
   Restart-NAVServerInstance -ServerInstance <server instance>
   ```

Task 8: Synchronize tenant

1. (Multitenant only) Mount the tenant to the new Business Central Server instance.

   You'll have to do this step and the next for each tenant. For more information, see Mount or Dismount a Tenant.

2. Synchronize the tenant.

   Use the Sync-NAVTenant cmdlet:

   ```
   Sync-NAVTenant -ServerInstance <server instance> -Tenant <tenant ID> -Mode Sync
   ```

   For a single-tenant deployment, you can either set the `<tenant ID>` to `default` or omit the `-Tenant <tenant ID>` parameter. For more information about syncing, see Synchronizing the Tenant Database and Application Database.

Task 9: Reinstall extensions

Skip this task for a multitenant environment. In this task, you reinstall the same extensions that were installed on the tenant before.

To install an extension, you use the Install-NAVApp cmdlet.

1. If your solution uses the System Application, install this first.

   ```
   Install-NAVApp -ServerInstance <server instance> -Name "System Application" -Version <extension
   version>
   ```

Replace `<extension version>` with the exact version of the published System Application.

2. Install the Base Application.

```
Install-NAVApp -ServerInstance <server instance> -Name "Base Application" -Version <extension
version>
```

   Replace `<extension version>` with the exact version of the published System Application.

3. (Upgrading from 15.3 and later) Install the Application extension.

   This extension was introduced in 15.3. For more information about it see The Microsoft_Application.app File.

```
Install-NAVApp -ServerInstance <server instance> -Name "Application" -Version <extension version>
```

   Replace `<extension version>` with the exact version of the published System Application.

4. Install other extensions, including Microsoft and third-party extensions.

```
Install-NAVApp -ServerInstance <server instance name> -Name <extension name> -Version <extension
version>
```

At this point, your solution has been updated to the latest platform.

Task 10: Upgrade control add-ins

The Business Central Server installation includes new versions of the Microsoft-provided Javascript-based control add-ins, like Microsoft.Dynamics.Nav.Client.BusinessChart, Microsoft.Dynamics.Nav.Client.VideoPlayer, and more. If your solution uses any of these control add-ins, upgrade them to the latest version.

To upgrade the control add-ins, do the following steps:

1. Open the Business Central client.
2. Search for and open the **Control Add-ins** page.
3. Choose **Actions** > **Control Add-in Resource** > **Import**.
4. Locate and select the .zip file for the control add-in and choose **Open**.

   The .zip files are located in the **Add-ins** folder of the Business Central Server installation. There's a subfolder for each add-in. For example, the path to the Business Chart control add-in is

```
C:\Program Files\Microsoft Dynamics 365 Business Central\160\Service\Add-
ins\BusinessChart\Microsoft.Dynamics.Nav.Client.BusinessChart.zip
```

   .

5. After you've imported all the new control add-in versions, restart Business Central Server instance.

Alternatively, you can use the Set-NAVAddin cmdlet of the Business Central Administration Shell. For example, the following commands update the control add-ins installed by default. Modify the commands to suit:

```
$InstanceName = 'BC160'
$ServicesAddinsFolder = 'C:\Program Files\Microsoft Dynamics 365 Business Central\160\Service\Add-ins'
Set-NAVAddIn -ServerInstance $InstanceName -AddinName 'Microsoft.Dynamics.Nav.Client.BusinessChart' -
PublicKeyToken 31bf3856ad364e35 -ResourceFile ($AppName = Join-Path $ServicesAddinsFolder
'BusinessChart\Microsoft.Dynamics.Nav.Client.BusinessChart.zip')
Set-NAVAddIn -ServerInstance $InstanceName -AddinName 'Microsoft.Dynamics.Nav.Client.FlowIntegration' -
PublicKeyToken 31bf3856ad364e35 -ResourceFile ($AppName = Join-Path $ServicesAddinsFolder
'FlowIntegration\Microsoft.Dynamics.Nav.Client.FlowIntegration.zip')
Set-NAVAddIn -ServerInstance $InstanceName -AddinName 'Microsoft.Dynamics.Nav.Client.OAuthIntegration' -
PublicKeyToken 31bf3856ad364e35 -ResourceFile ($AppName = Join-Path $ServicesAddinsFolder
'OAuthIntegration\Microsoft.Dynamics.Nav.Client.OAuthIntegration.zip')
Set-NAVAddIn -ServerInstance $InstanceName -AddinName 'Microsoft.Dynamics.Nav.Client.PageReady' -
PublicKeyToken 31bf3856ad364e35 -ResourceFile ($AppName = Join-Path $ServicesAddinsFolder
'PageReady\Microsoft.Dynamics.Nav.Client.PageReady.zip')
Set-NAVAddIn -ServerInstance $InstanceName -AddinName 'Microsoft.Dynamics.Nav.Client.PowerBIManagement' -
PublicKeyToken 31bf3856ad364e35 -ResourceFile ($AppName = Join-Path $ServicesAddinsFolder
'PowerBIManagement\Microsoft.Dynamics.Nav.Client.PowerBIManagement.zip')
Set-NAVAddIn -ServerInstance $InstanceName -AddinName 'Microsoft.Dynamics.Nav.Client.RoleCenterSelector' -
PublicKeyToken 31bf3856ad364e35 -ResourceFile ($AppName = Join-Path $ServicesAddinsFolder
'RoleCenterSelector\Microsoft.Dynamics.Nav.Client.RoleCenterSelector.zip')
Set-NAVAddIn -ServerInstance $InstanceName -AddinName 'Microsoft.Dynamics.Nav.Client.SatisfactionSurvey' -
PublicKeyToken 31bf3856ad364e35 -ResourceFile ($AppName = Join-Path $ServicesAddinsFolder
'SatisfactionSurvey\Microsoft.Dynamics.Nav.Client.SatisfactionSurvey.zip')
Set-NAVAddIn -ServerInstance $InstanceName -AddinName 'Microsoft.Dynamics.Nav.Client.SocialListening' -
PublicKeyToken 31bf3856ad364e35 -ResourceFile ($AppName = Join-Path $ServicesAddinsFolder
'SocialListening\Microsoft.Dynamics.Nav.Client.SocialListening.zip')
Set-NAVAddIn -ServerInstance $InstanceName -AddinName 'Microsoft.Dynamics.Nav.Client.VideoPlayer' -
PublicKeyToken 31bf3856ad364e35 -ResourceFile ($AppName = Join-Path $ServicesAddinsFolder
'VideoPlayer\Microsoft.Dynamics.Nav.Client.VideoPlayer.zip')
Set-NAVAddIn -ServerInstance $InstanceName -AddinName 'Microsoft.Dynamics.Nav.Client.WebPageViewer' -
PublicKeyToken 31bf3856ad364e35 -ResourceFile ($AppName = Join-Path $ServicesAddinsFolder
'WebPageViewer\Microsoft.Dynamics.Nav.Client.WebPageViewer.zip')
Set-NAVAddIn -ServerInstance $InstanceName -AddinName 'Microsoft.Dynamics.Nav.Client.WelcomeWizard' -
PublicKeyToken 31bf3856ad364e35 -ResourceFile ($AppName = Join-Path $ServicesAddinsFolder
'WelcomeWizard\Microsoft.Dynamics.Nav.Client.WelcomeWizard.zip')
```

Task 11: Post-upgrade

1. Enable task scheduler on the server instance.
2. (Multitenant only) For tenants other than the tenant that you use for administration purposes, if you mounted the tenants using the `-AllowAppDatabaseWrite` parameter, dismount the tenants, then mount them again without using the `-AllowAppDatabaseWrite` parameter.
3. If you want to use data encryption as before, enable it.

   For more information, see Managing Encryption and Encryption Keys.

   Optionally, if you exported the encryption key instead of disabling encryption earlier, import the encryption key file to enable encryption.
4. Grant users permission to the *Open in Excel* and *Edit in Excel* actions.

   Version 16 introduces a system permission that protects these two actions. The permission is granted by the system object **6110 Allow Action Export To Excel**. Because of this change, users who had permission to these actions before upgrading, will lose permission. To grant permission again, do one of the following steps:

   - If you have a version 16 application, export the **EXCEL EXPORT ACTION** permission set. Then, import it to your application and add it to appropriate users.
   - Add the system object **6110 Allow Action Export To Excel** permission directly to appropriate

permission sets.

For more information about working with permission sets and permissions, see Export and Import Permission Sets.

Business Central 14.X to 15.X compatibility matrix

Installing a Business Central 2020 Release Wave 1 Update

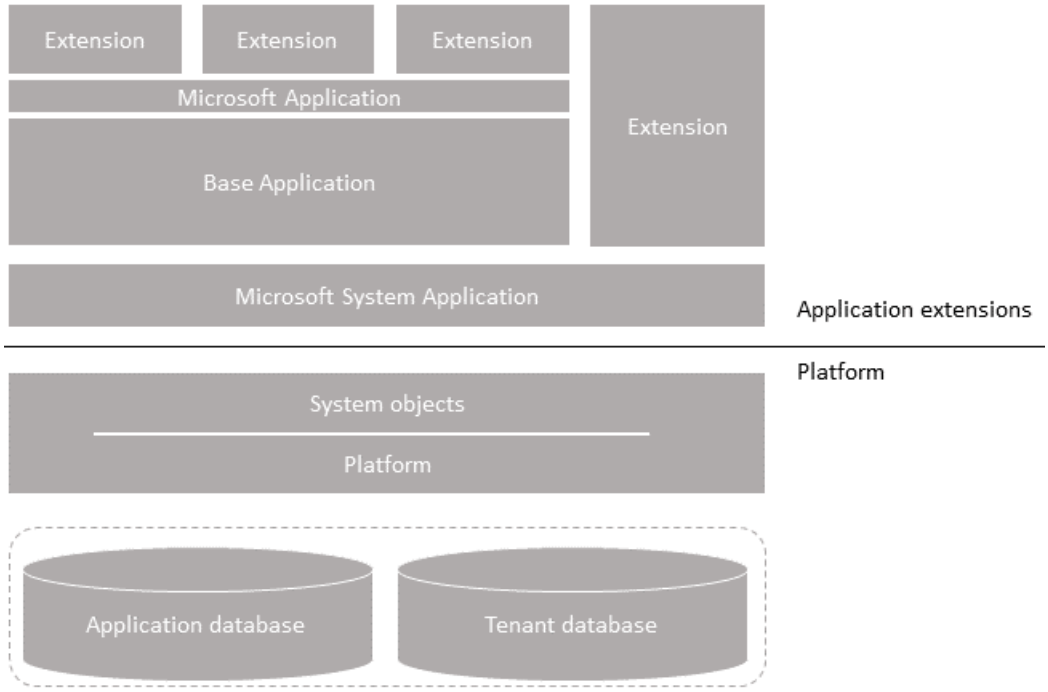
2/17/2021 • 17 minutes to read • Edit Online

This article describes how to install an update for Business Central on-premises. An update is a set of files that includes all hotfixes and regulatory features that have been released for Business Central.

You can choose to update only the platform or both the platform and application code. The installation guidelines are separated into PLATFORM tasks and APPLICATION tasks.

Overview

The following figure provides a high-level representation of a Business Central solution and the components that are involved in the installation of an update.



The databases store the application metadata and business data. If you have a single-tenant deployment, this data is stored in a single database. A multitenant deployment stores the application metadata in the application database and the business data in one or more tenant databases.

Application stack

The application includes AL extensions that define the objects and code that makes up the business logic. For example, objects include tables, report, pages, codeunits, and more. Each extension is compiled and delivered as an .app file, which is published to the Business Central Server instance.

- System Application extension

  The Microsoft System Application extension includes functionality that isn't directly related the business logic. For more information, see Overview of the System Application. When using the Microsoft Base Application, your solution uses the System Application. With a custom Base Application, your solution may or may not use the System Application. If it doesn't, you can skip any steps in this article related to the System Application.

- Base application extension

  As a minimum, the solution always includes the Base Application. The Base Application contains the objects (such as table, pages, codeunits, and reports) that define the business logic and functionality of the solution. The Base Application can be either the Microsoft Base Application or a customized Base Application. The Microsoft Base Application is the standard application that is on the installation media (DVD). A customized Base Application is an application that includes customized code.

- Application extension

  The Application extension logically encapsulates all of the extensions making up a solution, for example, version `16.0.0.0` of the base and system application package files, and it provides a convenient way to define and refer to this solution identity. This extension is required for Microsoft extensions, but is optional for third-party extensions. For more information, see The Microsoft_Application.app File.

- Customization extensions

  Customization extensions add functionality and features to the Base Application or System Application. Extensions can be either Microsoft extensions or third-party extensions. Microsoft extensions are available on the DVD. Third-party extensions are extensions developed by your organization or by another organization, like an ISV.

Single-tenant and multitenant deployments

The process for upgrading is similar for a single-tenant and multitenant deployment. However, there are some inherent differences. With a single-tenant deployment, the application and business data are included in the same database. While with a multitenant deployment, application code is in a separate database (the application database) than the business data (tenant). In the procedures that follow, for a single-tenant deployment, consider references to the *application database* and *tenant database* as the same database. Steps are marked as *Single-tenant only* or *Multitenant only* where applicable.

Platform versus application update

A platform update doesn't change the application. It involves converting your databases to the new platform and recompiling the existing extensions to ensure that they're compatible with the new platform.

An application update involves:

- Publishing new versions of extensions that include the latest application modifications
- Synchronizing the databases with any schema change introduced by the new extensions
- Updating affected data.

The installation media (DVD) includes new versions of Microsoft's Base Application, System Application, and extensions. The DVD also includes the AL source code for the Microsoft Base Application. This code useful if you have a custom base application. You can use the code to compare and merge updates into your application. You'll only have to recompile third-party extensions that you don't have a new version to publish.

PREPARATION

Download update package

The first thing to do is to download the update package that matches your Business Central solution.

1. Go to the list of available updates for your on-premises version of Business Central. Then, choose the update that you want.

2. From the update page, under the **Resolution** section, select the link for downloading the update, and follow the instructions.

3. On the computer where you downloaded the update .zip file, extract the all the files to a selected location.

   When extracted, the update includes the DVD folder. This folder contains the full Business Central product. For example, the folder includes the Business Central installation program (setup.exe), tools for upgrading to the platform, and the Microsoft extensions.

When this step is completed, you can continue to update your Business Central solution to the new platform and application.

Prepare existing databases

1. Back up your databases.
2. Run the Business Central Administration Shell as an administrator.
3. (Single-tenant only) Uninstall all extensions from the all tenants.

   In this step, you uninstall the Base Application, System Application (if used), and any other extensions that are currently installed on the database.

   a. Get a list of installed extensions.

      This step is optional, but it can be useful to the names and versions of the extensions.

      To get a list of installed extensions, use the Get-NAVAppInfo cmdlet.

      ```
      Get-NAVAppInfo -ServerInstance <server instance name>
      ```

   b. Uninstall the extensions.

      To uninstall an extension, you use the Uninstall-NAVApp cmdlet.

      ```
      Uninstall-NAVApp -ServerInstance <server instance name> -Tenant <tenant ID> -Name <extensions
      name> -Version <extension version> -Force
      ```

      Replace `<extension name>` and `<extension version>` with the exact name and version the installed extension. For single-tenant deployment, set `<tenant ID>` to `default` or omit the `-Tenant` parameter.

      For example, together with the Get-NAVApp cmdlet, you can uninstall all extensions with a single command:

      ```
      Get-NAVAppInfo -ServerInstance <server instance name> -Tenant <tenant ID> | % { Uninstall-
      NAVApp -ServerInstance <server instance name> -Tenant <tenant ID> -Name $_.Name -Version
      $_.Version -Force}
      ```

4. Unpublish the existing system symbols.

   To unpublish the system symbols, use the Unpublish-NAVApp cmdlet as follows:

   ```
   Unpublish-NAVApp -ServerInstance <server instance> -Name System -version <version>
   ```

   What are symbols?.

5. (Multitenant only) Dismount the tenants from the application database.

   To dismount a tenant, use the Dismount-NAVTenant cmdlet:

```
Dismount-NAVTenant -ServerInstance <server instance> -Tenant <tenant ID>
```

Install Business Central components

From the installation media (DVD), run setup.exe to uninstall the current Business Central components and install the Business Central components included in the update.

1. Stop the Business Central Server instance.

```
Stop-NAVServerInstance -ServerInstance <server instance>
```

2. Run setup.exe to uninstall your current version of Business Central.
3. Run setup.exe again to install components of the update.
   a. Follow setup pages until you get to the **Microsoft Dynamics 365 Business Central Setup** page.
   b. Select **Advanced installation options** > **Choose an installation option** > **Custom**.
   c. On the **Customize the installation** page, select the following components as a minimum:
      - AL Development Environment (optional but recommended)
      - Server
      - Web Server Components.
   d. Select **Next**.
   e. On the **Specify parameters** page, set the fields as needed.

      IMPORTANT
      Clear the **SQL Database** field so that it is blank. At this time, do not set this to the database that you want to update; otherwise, the installation of the Business Central Server will fail. You will connect the database to the Business Central Server later after it is converted to the new platform.

   f. Select **Apply** to complete the installation.

For more information, see Installing Business Central Using Setup.

PLATFORM UPDATE

Follow the next few tasks to convert your database to the new platform of the update. A multitenant deployment includes the application and tenant databases. The conversion updates the system tables of the database to the new schema (data structure) and provides the latest platform features and performance enhancements.

Also, to ensure that the existing published extensions work on the new platform, you'll recompile the extensions.

Convert existing database to new platform

1. Run the Business Central Administration Shell as an administrator.
2. Run the Invoke-NAVApplicationDatabaseConversion cmdlet to start the database conversion to the new platform.

```
Invoke-NAVApplicationDatabaseConversion -DatabaseServer <database server name>\<database server
instance> -DatabaseName "<database name>" [-Force]
```

For example, in a single tenant deployment:

```
Invoke-NAVApplicationDatabaseConversion -DatabaseServer .\BCDEMO -DatabaseName "Demo Database BC (16-
0)"
```

In a multitenant deployment, run this cmdlet against the application database and use the `-Force` parameter. For example:

```
Invoke-NAVApplicationDatabaseConversion -DatabaseServer .\BCDEMO -DatabaseName "BC16 Application" -
Force
```

When completed, a message like the following displays in the console:

```
DatabaseServer      : .\BCDEMO
DatabaseName        : Demo Database BC (16-0)
DatabaseCredentials :
DatabaseLocation    :
Collation           :
```

NOTE

Depending on the update that you're installing, you might get a message similar to the following:

```
Invoke-NAVApplicationDatabaseConversion : A technical upgrade of database <database name> on
server '.\<database instance>' cannot be run, because the database's application version 'NNNNNN'
is greater than or equal to the platform version 'NNNNNN'
```

This is not an error, and you can continue installing the update. This message is recorded as a warning in the event log as well. This message indicates that the application database is already compatible with the new platform, which happens when the update does not make any schema changes to the system tables.

Connect server instance to database

1. (Multitenant only) Enable the server instance as a multitenant instance:

```
Set-NAVServerConfiguration -ServerInstance <server instance> -KeyName Multitenant -KeyValue true
```

2. Connect the server instance to connect to the database.

```
Set-NAVServerConfiguration -ServerInstance <server instance> -KeyName DatabaseName -KeyValue "
<database name>"
```

In a multitenant deployment, the database is the application database. For more information, see Connecting a Server Instance to a Database.

3. Restart the server instance.

```
Restart-NAVServerInstance -ServerInstance <server instance>
```

Publish the new system symbols

Use the Publish-NAVApp cmdlet to publish the new symbols extension package. This package is called **System.app**. If you've installed the **AL Development Environment**, you find the file in the installation folder. By default, the folder path is C:\Program Files (x86)\Microsoft Dynamics 365 Business Central\160\AL Development Environment. Or, it's also on the installation media (DVD) in the ModernDev\program files\Microsoft Dynamics NAV\160\AL Development Environment folder.

```
Publish-NAVApp -ServerInstance <server instance> -Path "<path to the System.app file>" -PackageType
SymbolsOnly
```

Recompile published extensions

Compile all published extensions against the new platform.

> **NOTE**
> If you plan on updating the application you can skip this step for extensions for which you have new versions built on the new platform. For example, this includes Microsoft extensions that are on the DVD.

1. To compile an extension, use the Repair-NAVApp cmdlet, For example:

   ```
   Repair-NAVApp -ServerInstance <server instance> -Name <extension name> -Version <extension name>
   ```

   To compile all published extensions at once, you can use this command:

   ```
   Get-NAVAppInfo -ServerInstance <server instance> | Repair-NAVApp
   ```

2. Restart the server instance.

   ```
   Restart-NAVServerInstance -ServerInstance <server instance>
   ```

Synchronize tenant

1. (Multitenant only) Mount the tenant to the new Business Central Server instance.

   You'll have to do this step and the next for each tenant. For more information, see Mount or Dismount a Tenant.

2. Synchronize the tenant.

   Use the Sync-NAVTenant cmdlet:

   ```
   Sync-NAVTenant -ServerInstance <server instance> -Tenant <tenant ID> -Mode Sync
   ```

   For a single-tenant deployment, you can either set the `<tenant ID>` to `default` or omit the `-Tenant <tenant ID>` parameter. For more information about syncing, see Synchronizing the Tenant Database and Application Database.

NOTE

At this point, if you want to update the application, you can skip the next step and proceed APPLICATION.

(Single-tenant only) Reinstall extensions

In this task, you reinstall the same extensions that were installed on the tenant before. If you're planning on updating the application, then skip this step.

To install an extension, you use the Install-NAVApp cmdlet.

1. If your solution uses the System Application, install this first.

   ```
   Install-NAVApp -ServerInstance <server instance> -Name "System Application" -Version <extension version>
   ```

   Replace `<extension version>` with the exact version of the published System Application.

2. Install the Base Application.

   ```
   Install-NAVApp -ServerInstance <server instance> -Name "Base Application" -Version <extension version>
   ```

   Replace `<extension version>` with the exact version of the published Base Application.

3. Install the Application extension as needed.

   ```
   Install-NAVApp -ServerInstance <server instance> -Name "Application" -Version <extension version>
   ```

   Replace `<extension version>` with the exact version of the published Application extension.

4. Install other extensions, including Microsoft and third-party extensions.

   ```
   Install-NAVApp -ServerInstance <server instance name> -Name <extension name> -Version <extension version>
   ```

At this point, your solution has been updated to the latest platform.

IMPORTANT

If your solution uses any Microsoft control add-ins, you must upgrade the add-ins to the latest version. Go to Upgrade control add-ins under **Post Upgrade** section.

APPLICATION UPDATE

Follow the next tasks to update the application code to the new features and hotfixes. The tasks include publishing new versions of the System Application, Base Application, and add-on extensions.

You publish the System Application extension only if it was used in old solution. Add-on extensions include Microsoft and third- party extensions that were used in the old solution.

> **NOTE**
> If a license update is required for a regulatory feature, customers can download an updated license from CustomerSource (see How to Download a Microsoft Dynamics 365 Business Central License from CustomerSource), and partners can download their customers' updated license from VOICE (see How to Download a Microsoft Dynamics 365 Business Central Customer License from VOICE).

Upgrade System Application

Follow these steps if your existing solution uses the Microsoft System Application. Otherwise, you can skip this procedure.

1. Publish the **System Application** extension (Microsoft_System Application.app).

   You find the (Microsoft_System Application.app in the **Applications\System Application\Source** folder of installation media (DVD).

   ```
   Publish-NAVApp -ServerInstance <server instance name> -Path "<path to Microsoft_System
   Application.app>"
   ```

2. Synchronize the tenant(s) with the **System Application** extension (Microsoft_System Application):

   Use the Sync-NAVApp cmdlet:

   ```
   Sync-NAVApp -ServerInstance <server instance name> -Tenant <tenant ID> -Name "System Application" -
   Version <extension version>
   ```

   Replace `<extension version>` with the exact version of the published System Application.

   > **TIP**
   > To get a list of all published extensions, along with their names and versions, use the Get-NAVAppInfo cmdlet.

3. Run the data upgrade on the System Application.

   To run the data upgrade, use the Start-NavAppDataUpgrade cmdlet:

   ```
   Start-NAVAppDataUpgrade -ServerInstance <server instance name> -Tenant <tenant ID> -Name "System
   Application" -Version <extension version>
   ```

   Upgrading data updates the data in the tables of the tenant database to the schema changes made to tables of the System Application.

Upgrade Base Application

Microsoft Base Application

Follow these steps if your existing solution uses the Microsoft Base Application.

1. Publish the Business Central Base Application extension (Microsoft_Base Application.app).

   The **Base Application** extension contains the application business objects. You find the Microsoft_Base Application.app in the **Applications\BaseApp\Source** folder of installation media (DVD).

```
Publish-NAVApp -ServerInstance <server instance name> -Path "<path to Microsoft_Base
Application.app>"
```

2. Synchronize the tenant with the Business Central Base Application extension (Microsoft_BaseApp):

   ```
   Sync-NAVApp -ServerInstance <server instance name> -Tenant <tenant ID> -Name "Base Application" -
   Version <extension version>
   ```

   Replace `<extension version>` with the exact version of the published Base Application.

   With this step, the base app takes ownership of the database tables. When completed, in SQL Server, the table names will be suffixed with the base app extension ID. This process can take several minutes.

3. Run the data upgrade on the Base Application.

   To run the data upgrade, use the Start-NavAppDataUpgrade cmdlet:

   ```
   Start-NAVAppDataUpgrade -ServerInstance <server instance name> -Tenant <tenant ID> -Name "Base
   Application" -Version <extension version>
   ```

   Upgrading data updates the data in the tables of the tenant database to the schema changes made to tables of the Base Application.

Upgrade custom Base Application

With a custom Base Application, you may want the new application features and hotfixes in the Microsoft Base Application. If so, you'll have to merge the modifications made in the Microsoft Base Application into your custom Base Application. Then, create a new version of your custom Base Application.

The source code for the new Microsoft Base Application version is in the **Base Application.Source.zip** file. This file is on the installation media (DVD), in the **Applications\BaseApp\Source** folder. You can compare this source code with the source code of the previous Microsoft Base Application and your custom application source. Then merge the code into a new custom application version.

After you've created the new version of your custom application, you publish it to the application server instance. Then, you synchronize and run the data upgrade on the tenants.

Upgrade Microsoft extensions

If your old solution used Microsoft extensions, then you upgrade these extensions to the new versions that are available on the Business Central installation media (DVD). The new versions are in the **Applications** folder, which contains a subfolder for each extension. The extension package (.app file) that you need for publishing the extension is in the **Source** folder, for example, **Applications\SalesAndInventoryForecast\Source\SalesAndInventoryForecast.app**.

The general steps for this task are listed below. For detailed steps, see Publishing, Upgrading, and Installing Extensions During Upgrade.

Publish and install Microsoft_Application extension

The Microsoft_Application extension was introduced in 15.3. In short, it's used to contain the dependency declarations on the system and base application extensions. For more information about this extension, see The Microsoft_Application.app File.

1. Publish the Microsoft_Application.app package.

   The installation media path to the extension package (.app file) is

Applications\Application\Source\Microsoft_Application.app"

```
Publish-NAVApp -ServerInstance <server instance name> -Path "<folder path>\Microsoft_Application.app"
```

2. Synchronize the tenant database with the schema changes of the Microsoft_Application extension.

```
Sync-NavApp -ServerInstance <server instance name> -Tenant <tenant ID> -Name <extension name> -Tenant
<tenant ID>
```

3. Upgrade the Microsoft_Application extension on your tenants.

```
Start-NAVAppDataUpgrade -ServerInstance <server instance name> -Tenant <tenant ID> -Name Application
```

Publish and install Microsoft extensions

Complete these steps for each Microsoft extension that you want to upgrade.

1. Publish the new extension versions from the installation media (DVD).

```
Publish-NAVApp -ServerInstance <server instance name> -Path <path to extension package file>
```

2. Synchronize the tenant database with the schema changes of the extensions.

```
Sync-NavApp -ServerInstance <server instance name> -Tenant <tenant ID> -Name <extension name> -
Version <extension version>
```

3. Upgrade the data associated with the Microsoft extensions. This step will automatically install the new version on the tenant

```
Start-NAVAppDataUpgrade -ServerInstance <server instance name> -Tenant <tenant ID> -Name <extension
name> -Version <extension version>
```

Upgrade Third-Party extensions

If the old solution used third-party extensions, and you still want to use them, they must be compiled to work on the new platform. For more information, see Recompile published extensions. You then reinstall the extensions on tenants using the Install-NAVApp cmdlet.

As an alternative, if you have the source for these extensions, you can build and compile a new version of the extension in the AL development environment. Then, you upgrade to the new version as described in the previous task.

Post Upgrade

Upgrade control add-ins

The Business Central Server installation includes new versions of the Microsoft-provided Javascript-based control add-ins, like Microsoft.Dynamics.Nav.Client.BusinessChart, Microsoft.Dynamics.Nav.Client.VideoPlayer, and more. If your solution uses any of these control add-ins, upgrade them to the latest version.

To upgrade the control add-ins, do the following steps:

1. Open the Business Central client.

2. Search for and open the **Control Add-ins** page.
3. Choose **Actions** > **Control Add-in Resource** > **Import**.
4. Locate and select the .zip file for the control add-in and choose **Open**.

   The .zip files are located in the **Add-ins** folder of the Business Central Server installation. There's a subfolder for each add-in. For example, the path to the Business Chart control add-in is

   ```
   C:\Program Files\Microsoft Dynamics 365 Business Central\160\Service\Add-ins\BusinessChart\Microsoft.Dynamics.Nav.Client.BusinessChart.zip
   ```

   .
5. After you've imported all the new control add-in versions, restart Business Central Server instance.

Alternatively, you can use the Set-NAVAddin cmdlet of the Business Central Administration Shell. For example, the following commands update the control add-ins installed by default. Modify the commands to suit:

```
$InstanceName = 'BC160'
$ServicesAddinsFolder = 'C:\Program Files\Microsoft Dynamics 365 Business Central\160\Service\Add-ins'
Set-NAVAddIn -ServerInstance $InstanceName -AddinName 'Microsoft.Dynamics.Nav.Client.BusinessChart' -
PublicKeyToken 31bf3856ad364e35 -ResourceFile ($AppName = Join-Path $ServicesAddinsFolder
'BusinessChart\Microsoft.Dynamics.Nav.Client.BusinessChart.zip')
Set-NAVAddIn -ServerInstance $InstanceName -AddinName 'Microsoft.Dynamics.Nav.Client.FlowIntegration' -
PublicKeyToken 31bf3856ad364e35 -ResourceFile ($AppName = Join-Path $ServicesAddinsFolder
'FlowIntegration\Microsoft.Dynamics.Nav.Client.FlowIntegration.zip')
Set-NAVAddIn -ServerInstance $InstanceName -AddinName 'Microsoft.Dynamics.Nav.Client.OAuthIntegration' -
PublicKeyToken 31bf3856ad364e35 -ResourceFile ($AppName = Join-Path $ServicesAddinsFolder
'OAuthIntegration\Microsoft.Dynamics.Nav.Client.OAuthIntegration.zip')
Set-NAVAddIn -ServerInstance $InstanceName -AddinName 'Microsoft.Dynamics.Nav.Client.PageReady' -
PublicKeyToken 31bf3856ad364e35 -ResourceFile ($AppName = Join-Path $ServicesAddinsFolder
'PageReady\Microsoft.Dynamics.Nav.Client.PageReady.zip')
Set-NAVAddIn -ServerInstance $InstanceName -AddinName 'Microsoft.Dynamics.Nav.Client.PowerBIManagement' -
PublicKeyToken 31bf3856ad364e35 -ResourceFile ($AppName = Join-Path $ServicesAddinsFolder
'PowerBIManagement\Microsoft.Dynamics.Nav.Client.PowerBIManagement.zip')
Set-NAVAddIn -ServerInstance $InstanceName -AddinName 'Microsoft.Dynamics.Nav.Client.RoleCenterSelector' -
PublicKeyToken 31bf3856ad364e35 -ResourceFile ($AppName = Join-Path $ServicesAddinsFolder
'RoleCenterSelector\Microsoft.Dynamics.Nav.Client.RoleCenterSelector.zip')
Set-NAVAddIn -ServerInstance $InstanceName -AddinName 'Microsoft.Dynamics.Nav.Client.SatisfactionSurvey' -
PublicKeyToken 31bf3856ad364e35 -ResourceFile ($AppName = Join-Path $ServicesAddinsFolder
'SatisfactionSurvey\Microsoft.Dynamics.Nav.Client.SatisfactionSurvey.zip')
Set-NAVAddIn -ServerInstance $InstanceName -AddinName 'Microsoft.Dynamics.Nav.Client.SocialListening' -
PublicKeyToken 31bf3856ad364e35 -ResourceFile ($AppName = Join-Path $ServicesAddinsFolder
'SocialListening\Microsoft.Dynamics.Nav.Client.SocialListening.zip')
Set-NAVAddIn -ServerInstance $InstanceName -AddinName 'Microsoft.Dynamics.Nav.Client.VideoPlayer' -
PublicKeyToken 31bf3856ad364e35 -ResourceFile ($AppName = Join-Path $ServicesAddinsFolder
'VideoPlayer\Microsoft.Dynamics.Nav.Client.VideoPlayer.zip')
Set-NAVAddIn -ServerInstance $InstanceName -AddinName 'Microsoft.Dynamics.Nav.Client.WebPageViewer' -
PublicKeyToken 31bf3856ad364e35 -ResourceFile ($AppName = Join-Path $ServicesAddinsFolder
'WebPageViewer\Microsoft.Dynamics.Nav.Client.WebPageViewer.zip')
Set-NAVAddIn -ServerInstance $InstanceName -AddinName 'Microsoft.Dynamics.Nav.Client.WelcomeWizard' -
PublicKeyToken 31bf3856ad364e35 -ResourceFile ($AppName = Join-Path $ServicesAddinsFolder
'WelcomeWizard\Microsoft.Dynamics.Nav.Client.WelcomeWizard.zip')
```

Update application version

This task isn't required for installing the update. However, it might be useful for support purposes and answering a common question about the application version. The **Help and Support** page in the client displays an application version, such as 16.1.2345.6. This version number isn't updated automatically when you install an update.

However, the Business Central Server includes a configuration setting called **Solution Version Extension** (SolutionVersionExtension). This setting lets you specify an extension whose version number will show as the Application Version on the client's **Help and Support** page. Typically, you'd use the extension considered to be

your solution's base application. You set **Solution Version Extension** to ID of the extension. For example, if your solution uses the Microsoft Base Application, set the value to `437dbf0e-84ff-417a-965d-ed2bb9650972`.

You can set **Solution Version Extension** by using the Business Central Server Administration tool or the Set-NAVServerConfiguration cmdlet of the Business Central Administration Shell.

The following example uses the Set-NAVServerConfiguration cmdlet to set the **Solution Version Extension** to the Microsoft Base Application:

```
Set-NAVServerConfiguration -ServerInstance <server instance name> -KeyName SolutionVersionExtension -
KeyValue 437dbf0e-84ff-417a-965d-ed2bb9650972 -ApplyTo All
```

For more information about how to configure a server instance, see Configuring Business Central Server.

Upgrading to Dynamics 365 Business Central 2020 Release Wave 2

2/17/2021 • 2 minutes to read • Edit Online

Business Central 2020 release wave 2 (version 17) is the third major release that is fully AL-based. Business Central 2019 release wave 2 (version 15) marked the release in which C/AL was replaced by AL. The classic development environment, known as C/SIDE, was deprecated. From an application perspective, Business Central is now extension-based only. The Business Central base application is delivered as an AL extension. Also, application functionality that isn't related to the business logic has been moved into separate modules. These modules are combined into an extension known as the System Application. This change will influence how you do the upgrade compared to earlier releases.

Upgrade path

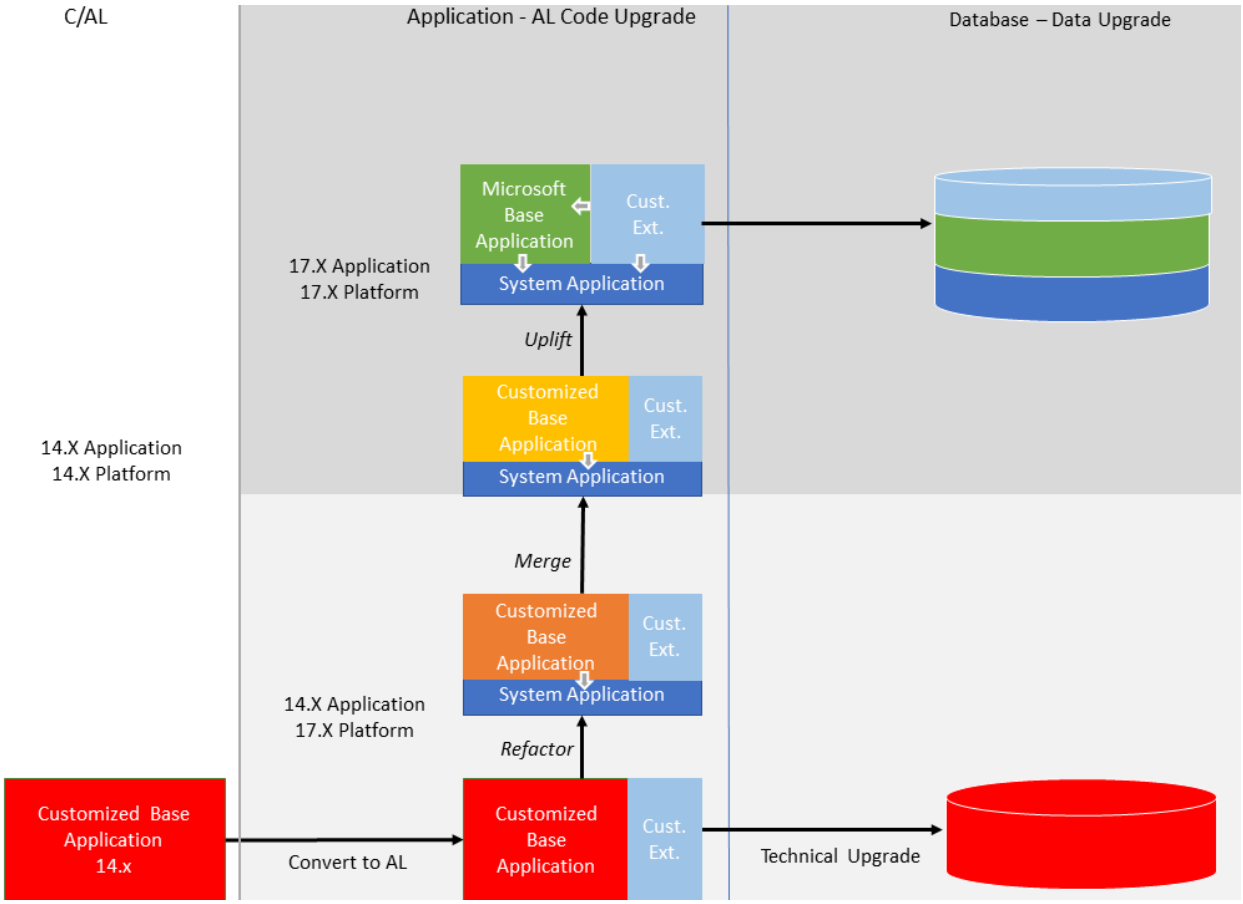
Depending on your current version, a direct upgrade to version 17 isn't always possible. You may have to first upgrade to an intermediate version. The following table describes the upgrade paths for supported versions:

SOURCE VERSION	PATH	COMMENT
• Microsoft Dynamics NAV 2015 (version 8) • Microsoft Dynamics NAV 2016 (version 9) • Microsoft Dynamics NAV 2017 (version 10) • Microsoft Dynamics NAV 2018 (version 11) • Business Central October 2018 (version 13)	1. Business Central Spring 2019 (version 14) 2. Business Central 2020 Release Wave 2 (version 17)	This path requires you convert your application from C/AL to AL.
• Business Central Spring 2019 (version 14) • Business Central 2019 Release Wave 2 (version 15) • Business Central 2020 release wave 1 (version 16)	Direct to version 17	

Your current version doesn't have to be the latest update for the version. However, for intermediate versions, use to the latest available update.

Upgrade overview

When upgrading your Business Central Spring 2019 (version 14) solution to version 17, the goal is to move towards a full uptake of the Business Central base and system applications, as they are, and migrating code customizations to add-on extensions. There are different upgrade levels that you follow to get to this state, as illustrated in the following figure. We recommend that you refactor to the system application as a minimum.



Technical Upgrade

Although it's recommend to refactor to the system application as a minimum, you can do a technical upgrade only. A technical upgrade changes the database so that it works on the latest Business Central platform. The conversion updates the system tables of the old database to the new schema (data structure). It provides you with the latest platform features and performance enhancements.

When upgrading from version 14, part of the technical upgrade process includes converting your customized base application from C/AL to AL.

New and changed features

There are several new and changed platform and application features available in Business Central 2020 release wave 2. These changes affect users, administrators, and developers. For an overview of these features, see Overview of Dynamics 365 Business Central 2020 release wave 2.

To take advantage of these features, you'll have to do an application code upgrade, not just a technical (platform) upgrade.

Deprecated features

Before you upgrade, review the following articles to get an overview of features deprecated in this release:

- Deprecated Tables
- Deprecated Features in W1

  From this article, use the links in the table of content to view deprecated features specific to local versions

Migrating from on-premises to online

For information about migrating an on-premises solution to online, see Migrate to Business Central Online from

Business Central On-premises.

Dynamics 365 Business Central Upgrade Compatibility Matrix

Dynamics 365 Business Central Upgrade Compatibility Matrix

2/17/2021 • 2 minutes to read • Edit Online

You can upgrade Business Central Spring 2019 (version 14) directly to 2019 release wave 2 (version 15) or to 2020 release wave 1 (version 16). And, of course, you can upgrade 2019 release wave 2 directly to 2020 release wave 1 (version 16). For an overview of the supported paths, see Supported Upgrade Paths.

However, minor updates are regularly made available for each major release, like 14.1 or 15.2. When upgrading, it's important to target an update version that's compatible with your current version.

Before choosing the target version

Before you choose the target version for your upgrade, read the Some Known Issues article. This article will describe issues in Business Central versions that affect upgrade.

Version 14 compatibility

The following table lists the Business Central 14 versions and the minimum 15, 16, and 17 version that's compatible for upgrade.

VERSION 14	VERSION 15	VERSION 16	VERSION 17
14.0 (GA and cumulative update 01)	15.0	16.0	17.0
14.3 (cumulative update 02)	15.0	16.0	17.0
14.4 (cumulative update 03)	15.0	16.0	17.0
14.5 (cumulative update 04)	15.0	16.0	17.0
14.6 (cumulative update 05)	15.1	16.0	17.0
14.7 (cumulative update 06)	15.2	16.0	17.0
14.8 (cumulative update 07)	15.3	16.0	17.0
14.9 (cumulative update 08)	15.3	16.0	17.0
14.10 (cumulative update 09)	15.4	16.0	17.0
14.11 (cumulative update 10)	15.5	16.0	17.0
14.12 (cumulative update 11)	15.6	16.1	17.0

VERSION 14	VERSION 15	VERSION 16	VERSION 17
14.13 (cumulative update 12)	15.7	16.2	17.0
14.14 (cumulative update 13)	15.8	16.3	17.0
14.15 (cumulative update 14)	15.9	16.4	17.0
14.16 (cumulative update 15)	15.10	16.5	17.0
14.17 (cumulative update 16)	15.11	16.6	17.0
14.18 (cumulative update 17)	15.12	16.7	17.1
14.19 (cumulative update 18)	15.13	16.8	17.2
14.20 (cumulative update 19)	15.14	16.9	17.3
14.21 (cumulative update 20)	15.15	16.10	17.4
14.22 (cumulative update 21)[1]	15.16	16.11	17.5

For example, you can upgrade version 14.0 to any 15 or 16 version. You can only upgrade version 14.11 to version 15.5 (or later) or version 16.0 (or later).

To see the available updates for Business Central 2019 Release Wave 2, see Released Updates for Microsoft Dynamics 365 Business Central 2019 Release Wave 2 on-premises.

[1]The compatible upgrade versions for this version aren't available yet. If you are currently operating on this version, you'll have to wait until the next round of updates before you upgrade.

Version 15 compatibility

The following table lists the Business Central 15 versions and the minimum 16 and 17 version that's compatible for upgrade.

VERSION 15	VERSION 16	VERSION 17
15.0 to 15.4	16.0	17.0
15.5	16.1	17.0
15.6	16.2	17.0
15.7	16.3	17.0

VERSION 15	VERSION 16	VERSION 17
15.8	16.4	17.0
15.9	16.5	17.0
15.10	16.6	17.0
15.11	16.7	17.1
15.12	16.8	17.2
15.13	16.9	17.3
15.14	16.10	17.4
15.15[1]	16.11	17.5

To see the available updates for Business Central 2020 Release Wave 1, see Released Updates for Microsoft Dynamics 365 Business Central 2020 Release Wave 1 on-premises.

Version 16 compatibility

The following table lists the Business Central 16 versions and the minimum 17 version that's compatible for upgrade.

VERSION 16	VERSION 17
16.0 to 16.5	17.0
16.6	17.1
16.7	17.2
16.8	17.3
16.9	17.4
16.10[1]	17.5

To see the available updates for Business Central 2020 Release Wave 2, see Released Updates for Microsoft Dynamics 365 Business Central 2020 Release Wave 2 on-premises.

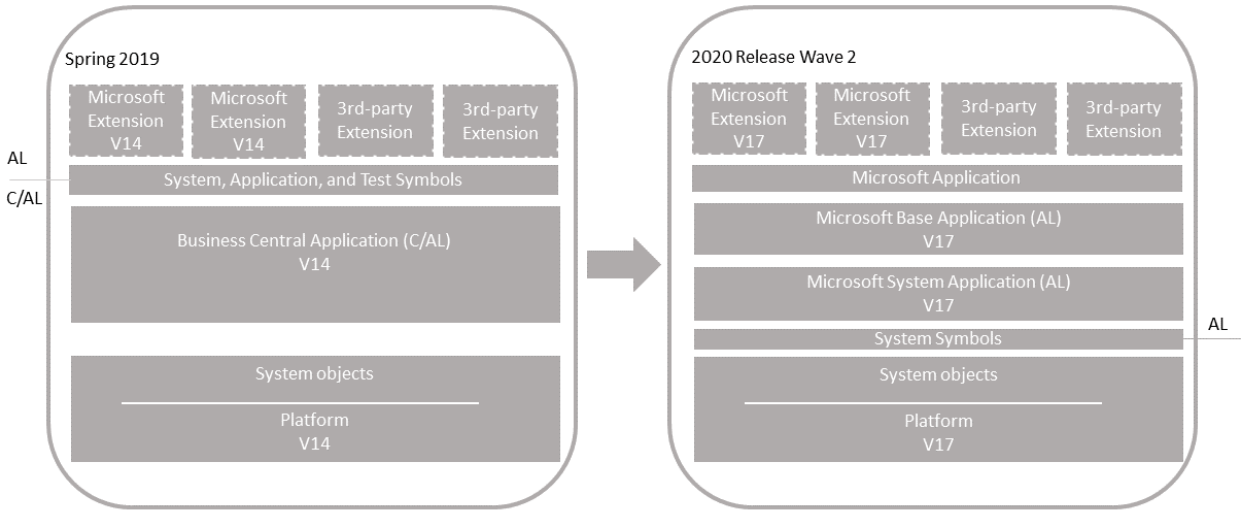
Upgrading to Business Central

Upgrading Unmodified C/AL Application to Version 17

2/17/2021 • 15 minutes to read • Edit Online

Use this scenario if you have a Business Central Spring 2019 (version 14) application or earlier that doesn't include any code customization. Your solution might include Microsoft (first party) extensions and customization extensions (3rd-party). With this upgrade, you'll replace the C/AL base application with the new Microsoft System and Base Application extensions. The result will be a fully upgraded Business Central 2020 release wave 1 (version 17) application and platform.



Single-tenant and multitenant deployments

The process for upgrading the similar for a single-tenant and multitenant deployment. However, there are some inherent differences. With a single-tenant deployment, the application code and business data are in the same database. In a multitenant deployment, application code is in a separate database (the application database) than the business data (tenant). In the procedures that follow, for a single-tenant deployment, consider references to the *application database* and *tenant database* as the same database. Steps are marked as *Single-tenant only* or *Multitenant only* where applicable.

Prerequisite

1. Upgrade to Business Central Spring 2019 (version 14).

   - If your solution is already on version 14, then no action on this step is required.
   - If you're upgrading from Business Central Fall 2018 (version 13) or Dynamics NAV, we recommend you upgrade to the latest update for version 14 that has a compatible update for version 17. For more information, see Dynamics 365 Business Central Upgrade Compatibility Matrix.

   To download the latest update, go to Released Cumulative Updates for Microsoft Dynamics 365 Business Central Spring 2019 Update on-premises.

   For information about how to do the upgrade, see Upgrading to Dynamics 365 Business Central On-Premises.

2. Disable data encryption.

   If the current server instance uses data encryption, disable it. You can enable it again after upgrading.

For more information, see Managing Encryption and Encryption Keys.

Instead of disabling encryption, you can export the current encryption key, which you'll then import after upgrade. However, we recommend disabling encryption before upgrading.

Task 1: Install version 17

1. Download the latest available update for version 17 that is compatible with your version 14.

   To download the latest update, go to Released Updates for Microsoft Dynamics 365 Business Central 2020 Release Wave 2 on-premises.

   The guidelines in this article assume that you're running the latest available update.

2. Before you install version 17, it can be useful to create desktop shortcuts to the version 14.0 tools, such as the Business Central Server Administration tool, Business Central Administration Shell, and Dynamics NAV Development Shell because the Start menu items for these tools will be replaced with the version 17 tools.

3. Install Business Central version 17 components.

   You'll have to keep version 14 installed to complete some steps in the upgrade process. When you install version 17, you must either specify different port numbers for components (like the Business Central Server instance and web services) or stop the version 14.0 Business Central Server instance before you run the installation. Otherwise, you'll get an error that the Business Central Server failed to install.

   For more information, see Installing Business Central Using Setup.

Task 2: Prepare version 14 databases

1. Make backup of the databases.

2. Start Business Central Administration Shell for version 14 as an administrator.

3. Uninstall all extensions from the old tenants.

   In this step, you uninstall any extensions that are currently installed on the database.

   a. Get a list of installed extensions.

      This step is optional, but it can be useful to the names and versions of the extensions.

      To get a list of installed extensions, use the Get-NAVAppInfo cmdlet.

      ```
      Get-NAVAppInfo -ServerInstance <server instance name> -Tenant <tenant ID>
      ```

      For a single-tenant deployment, set the `<tenant ID>` to default.

   b. Uninstall the extensions.

      To uninstall an extension, you use the Uninstall-NAVApp cmdlet.

      ```
      Uninstall-NAVApp -ServerInstance <server instance name> -Name <extensions name> -Tenant
      <tenant ID> -Version <extension version> -Force
      ```

      Replace `<extension name>` and `<extension version>` with the exact name and version the published System Application.

      For example, together with the Get-NAVApp cmdlet, you can uninstall all extensions with a single

command:

```
Get-NAVAppInfo -ServerInstance <server instance name> -Tenant <tenant ID>| % { Uninstall-
NAVApp -ServerInstance <server instance name> -Tenant <tenant ID> -Name $_.Name -Version
$_.Version -Force}
```

4. Unpublish all extensions from the application server instance.

   To unpublish an extension, use the Unpublish-NAVApp cmdlet:

   ```
   Unpublish-NAVApp -ServerInstance <server instance name> -Name <extension name> -Version <extension
   version>
   ```

   Together with the Get-NAVAppInfo cmdlet, you can unpublish all extensions by using a single command:

   ```
   Get-NAVAppInfo -ServerInstance <BC14 server instance> | % { Unpublish-NAVApp -ServerInstance <BC14
   server instance> -Name $_.Name -Version $_.Version }
   ```

5. Unpublish all system, test, and application symbols.

   To unpublish symbols, use the Unpublish-NAVAPP cmdlet with the `-SymbolsOnly` switch.

   ```
   Get-NAVAppInfo -ServerInstance <BC14 server instance> -SymbolsOnly | % { Unpublish-NAVApp -
   ServerInstance <BC14 server instance> -Name $_.Name -Version $_.Version }
   ```

   What are symbols?

6. (Multitenant only) Dismount the tenants from the application server instance.

   To dismount a tenant, use the Dismount-NAVTenant cmdlet:

   ```
   Dismount-NAVTenant -ServerInstance <server instance name> -Tenant <tenant ID>
   ```

7. Stop the server instance.

   ```
   Stop-NAVServerInstance -ServerInstance <server instance name>
   ```

Task 3: Convert the version 14 database

This task runs a technical upgrade on the application database to convert it from the version 14 platform to the version 17 platform. The conversion updates the system tables of the database to the new schema (data structure). It provides the latest platform features and performance enhancements.

1. Start Business Central Administration Shell for version 17 as an administrator.
2. Run the Invoke-NAVApplicationDatabaseConversion cmdlet to start the conversion:

   ```
   Invoke-NAVApplicationDatabaseConversion -DatabaseServer <database server name>\<database server
   instance> -DatabaseName "<database name>"
   ```

   When completed, a message like the following displays in the console:

```
DatabaseServer      : .\BCDEMO
DatabaseName        : Demo Database BC (14-0)
DatabaseCredentials :
DatabaseLocation    :
Collation           :
```

Task 4: Configure version 17 server for DestinationAppsForMigration

When you installed version 17 in **Task 1**, a version 17 Business Central Server instance was created. In this task, you change server configuration settings that are required to complete the upgrade. Some of the changes are only required for version 14 to version 17.0 upgrade and can be reverted after you complete the upgrade.

1. Set the server instance to connect to the application database.

   ```
   Set-NAVServerConfiguration -ServerInstance <server instance name> -KeyName DatabaseName -KeyValue "
   <database name>"
   ```

   In a single tenant deployment, this command will mount the tenant automatically. For more information, see Connecting a Server Instance to a Database.

2. Configure the server instance for migrate extensions to the use the new base application and system application extensions.

   ```
   Set-NAVServerConfiguration -ServerInstance <server instance name> -KeyName
   "DestinationAppsForMigration" -KeyValue '[{"appId":"63ca2fa4-4f03-4f2b-a480-172fef340d3f",
   "name":"System Application", "publisher": "Microsoft"},{"appId":"437dbf0e-84ff-417a-965d-
   ed2bb9650972", "name":"Base Application", "publisher": "Microsoft"}]'
   ```

   This setting serves the following purposes:

   - When you run the data upgrade on a tenant, the server will run the data upgrade for the base and system application extensions. The base and system applications will be automatically installed on the tenant also.
   - Lets you republish extensions that haven't been built on version 17. The extensions typically include the third-party extensions that were used in your version 14. When you publish the extensions, the extension manifests are automatically modified with a dependency on the base and system applications.

   For more information about this setting, see DestinationAppsForMigration.

3. Disable task scheduler on the server instance for purposes of upgrade.

   ```
   Set-NavServerConfiguration -ServerInstance <server instance name> -KeyName "EnableTaskScheduler" -
   KeyValue false
   ```

   Be sure to re-enable task scheduler after upgrade if needed.

4. Restart the server instance.

   ```
   Restart-NAVServerInstance -ServerInstance <server instance name>
   ```

Task 5: Import version 17 license

If you have a new Business Central partner license, make sure that it has been uploaded to the database.

1. To upload the license, use the Import-NAVServerLicense cmdlet:

```
Import-NAVServerLicense -ServerInstance <server instance name> -LicenseFile <path and file name>
```

2. Restart the server instance.

```
Restart-NAVServerInstance -ServerInstance <server instance name>
```

For more information, see Uploading a License File for a Specific Database.

Task 6: Publish symbols and extensions

In this task, you'll publish the platform symbols and extensions. As minimum, you publish the new base application and system application extensions from the installation media (DVD). You also publish new versions of any Microsoft extensions and third-party extensions that were used on your old deployment.

Publishing an extension adds the extension to the application database that is mounted on the server instance. Once published, it's available for installing on tenants. This task updates internal tables, compiles the components of the extension behind-the-scenes, and builds the necessary metadata objects that are used at runtime.

The steps in this task continue to use the Business Central Administration Shell for version 14 that you started in the previous task.

1. Publish version 17 system symbols extension.

   The symbols extension contains the required platform symbols that the base application depends on. The symbols extension package is called **System.app**. You find it where the **AL Development Environment** is installed. The default path is C:\Program Files (x86)\Microsoft Dynamics 365 Business Central\170\AL Development Environment.

```
Publish-NAVApp -ServerInstance  <server instance name> -Path "<path to system.app>" -PackageType
SymbolsOnly
```

   What are symbols?

2. Publish the **System Application** extension (Microsoft_System Application.app).

   You find the (Microsoft_System Application.app in the **Applications\System Application\Source** folder of installation media (DVD).

```
Publish-NAVApp -ServerInstance <server instance name> -Path "<path to Microsoft_System
Application.app>"
```

   What is the System Application?

3. Publish the Business Central base application extension (Microsoft_Base Application.app).

   The **Base Application** extension contains the application business objects. You find the (Microsoft_Base Application.app in the **Applications\BaseApp\Source** folder of installation media (DVD).

```
Publish-NAVApp -ServerInstance <server instance name> -Path "<path to Microsoft_Base
Application.app>"
```

4. Publish the Microsoft_Application extension

   The Microsoft_Application extension is a new extension introduced in 15.3. For more information about this extension, see The Microsoft_Application.app File.

   ```
   Publish-NAVApp -ServerInstance <server instance name> -Path "<folder path>\Microsoft_Application.app"
   ```

5. Publish the new versions of Microsoft extensions.

   In this step, you publish new versions of Microsoft extensions that were used on your version 14 deployment. You find the extensions in the **Applications** folder of the installation media (DVD).

   ```
   Publish-NAVApp -ServerInstance <server instance name> -Path "<path to Microsoft extension>"
   ```

   For example:

   ```
   Publish-NAVApp -ServerInstance BC170 -Path
   "C:\W1DVD\Applications\SalesAndInventoryForecast\Source\SalesAndInventoryForecast.app"
   ```

6. Publish 3rd-party extensions.

   Publish 3rd-party extensions that were used on your version 14 solution. If you have new versions of these extensions, built on the Business Central version 17, then publish the new versions. Otherwise, republish the same versions that were previously published in the old deployment.

   ```
   Publish-NAVApp -ServerInstance <server instance name> -Path "<path to extension>"
   ```

Task 7: Restart server instance

Restart the Business Central Server to free up resources for completing the upgrade.

```
Restart-NAVServerInstance -ServerInstance <server instance name>
```

This step is important, otherwise you might experience issues when you run the data upgrade.

Task 8: Synchronize tenant

In this task, you'll synchronize the tenant's database schema with any schema changes in the application database and extensions.

If you have a multitenant deployment, do these steps for each tenant.

1. (Multitenant only) Mount the tenant to the version 17 server instance.

   To mount the tenant, use the Mount-NAVTenant cmdlet:

   ```
   Mount-NAVTenant -ServerInstance <server instance name> -DatabaseName <database name> -DatabaseServer
   <database server>\<database instance> -Tenant <tenant ID> -AllowAppDatabaseWrite
   ```

> **IMPORTANT**
>
> You must use the same tenant ID for the tenant that was used in the old deployment; otherwise you'll get an error when mounting or syncing the tenant. If you want to use a different ID for the tenant, you can either use the `-AlternateId` parameter now or after upgrading, dismount the tenant, then mount it again using the new ID and the `OverwriteTenantIdInDatabase` parameter.

> **NOTE**
>
> For upgrade, we recommend that you use the `-AllowAppDatabaseWrite` parameter. After upgrade, you can dismount and mount the tenant again without the parameter if needed.

At this stage, the tenant state is OperationalWithSyncPending.

2. Synchronize the tenant with the application database.

   Use the Sync-NAVTenant cmdlet:

   ```
   Sync-NAVTenant -ServerInstance <server instance name> -Mode Sync -Tenant <tenant ID>
   ```

   With a single-tenant deployment, you can omit the `-Tenant` parameter and value.

3. Synchronize the tenant with the **System Application** extension.

   Use the Sync-NAVApp cmdlet:

   ```
   Sync-NAVApp -ServerInstance <server instance name> -Tenant <tenant ID> -Name "System Application" -
   Version <extension version>
   ```

   Replace `<extension version>` with the exact version of the published System Application. To get the version, you can use the Get-NAVAppInfo cmdlet.

4. Synchronize the tenant with the **Base Application** extension.

   ```
   Sync-NAVApp -ServerInstance <server instance name> -Tenant <tenant ID> -Name "Base Application" -
   Version <extension version>
   ```

   Replace `<extension version>` with the exact version of the published Base Application.

5. Synchronize the tenant with the **Application** extension.

   ```
   Sync-NAVApp -ServerInstance <server instance name> -Tenant <tenant ID> -Name "Application"
   ```

6. Synchronize the tenant with Microsoft and 3rd-party extensions.

   For each extension, run the Sync-NAVApp cmdlet:

   ```
   Sync-NAVApp -ServerInstance <server instance name> -Tenant default -Name "<extension name>" -Version
   <extension version>
   ```

TIP

When you synchronize an extension, the extension takes ownership of any tables that it includes. In SQL Server, you'll notice that the table names will be suffixed with the extension ID. For example, Base Application tables will have `437dbf0e-84ff-417a-965d-ed2bb9650972` in the name. In addition, the systemId column is added to application tables that are not already part of an extension.

Task 9: Upgrade data

In this task, you run a data upgrade on tables to handle data changes made by platform and extensions.

If you have a multitenant deployment, do these steps for each tenant.

1. Upgrade the data to the platform, system application, and base application.

   a. To run the data upgrade, use the Start-NavDataUpgrade cmdlet:

   ```
   Start-NAVDataUpgrade -ServerInstance <server instance name> -Tenant <tenant ID> -
   FunctionExecutionMode Serial -SkipAppVersionCheck
   ```

   b. To view the progress of the data upgrade, you can run Get-NavDataUpgrade cmdlet with the `-Progress` switch.

   This step will automatically install the base application and system application on the tenant.

2. Upgrade the new versions of Microsoft extensions and third-party extensions.

   Complete this task to upgrade any Microsoft extension and third-party extension. Microsoft extensions used in the old deployment to new versions on the installation media. The new versions are in the **Application** folder of the DVD. There's a folder for each extension. The extension package (.app file) is in the **Source** folder.

   a. Install **Application** extension.

   You'll have to install the **Application** extension first, otherwise you can't upgrade Microsoft extensions.

   ```
   Install-NAVApp -ServerInstance <server instance name> -Tenant <tenant ID> -Name "Application"
   ```

   b. For each extension, run Start-NAVAppDataUpgrade cmdlet:

   ```
   Start-NAVAppDataUpgrade -ServerInstance <server instance name> -Name "<extension name>" -
   Version <extension version>
   ```

   This step will also automatically install the new extension version on the tenant.

3. (Multitenant only) Repeat steps 1 through 3 for each tenant.

Task 10: Install 3rd-party extensions

Complete this task to install third-party extensions for which a new version wasn't published. For each extension, run the Install-NAVApp cmdlet:

```
Install-NAVApp -ServerInstance <server instance name> -Name <extension name> -Version <extension version>
```

Task 11: Upgrade control add-ins

The Business Central Server installation includes new versions of the Microsoft-provided Javascript-based control add-ins, like Microsoft.Dynamics.Nav.Client.BusinessChart, Microsoft.Dynamics.Nav.Client.VideoPlayer, and more. If your solution uses any of these control add-ins, upgrade them to the latest version.

To upgrade the control add-ins from the client, do the following steps:

1. Open the Business Central client.
2. Search for and open the **Control Add-ins** page.
3. Choose **Actions** > **Control Add-in Resource** > **Import**.
4. Locate and select the .zip file for the control add-in and choose **Open**.

   The .zip files are located in the **Add-ins** folder of the Business Central Server installation. There's a subfolder for each add-in. For example, the path to the Business Chart control add-in is

   ```
   C:\Program Files\Microsoft Dynamics 365 Business Central\170\Service\Add-ins\BusinessChart\Microsoft.Dynamics.Nav.Client.BusinessChart.zip
   ```

   .
5. After you've imported all the new control add-in versions, restart Business Central Server instance.

Alternatively, you can use the Set-NAVAddin cmdlet of the Business Central Administration Shell. For example, the following commands update the control add-ins installed by default. Modify the commands to suit:

```
$InstanceName = 'BC170'
$ServicesAddinsFolder = 'C:\Program Files\Microsoft Dynamics 365 Business Central\170\Service\Add-ins'
Set-NAVAddIn -ServerInstance $InstanceName -AddinName 'Microsoft.Dynamics.Nav.Client.BusinessChart' -
PublicKeyToken 31bf3856ad364e35 -ResourceFile ($AppName = Join-Path $ServicesAddinsFolder
'BusinessChart\Microsoft.Dynamics.Nav.Client.BusinessChart.zip')
Set-NAVAddIn -ServerInstance $InstanceName -AddinName 'Microsoft.Dynamics.Nav.Client.FlowIntegration' -
PublicKeyToken 31bf3856ad364e35 -ResourceFile ($AppName = Join-Path $ServicesAddinsFolder
'FlowIntegration\Microsoft.Dynamics.Nav.Client.FlowIntegration.zip')
Set-NAVAddIn -ServerInstance $InstanceName -AddinName 'Microsoft.Dynamics.Nav.Client.OAuthIntegration' -
PublicKeyToken 31bf3856ad364e35 -ResourceFile ($AppName = Join-Path $ServicesAddinsFolder
'OAuthIntegration\Microsoft.Dynamics.Nav.Client.OAuthIntegration.zip')
Set-NAVAddIn -ServerInstance $InstanceName -AddinName 'Microsoft.Dynamics.Nav.Client.PageReady' -
PublicKeyToken 31bf3856ad364e35 -ResourceFile ($AppName = Join-Path $ServicesAddinsFolder
'PageReady\Microsoft.Dynamics.Nav.Client.PageReady.zip')
Set-NAVAddIn -ServerInstance $InstanceName -AddinName 'Microsoft.Dynamics.Nav.Client.PowerBIManagement' -
PublicKeyToken 31bf3856ad364e35 -ResourceFile ($AppName = Join-Path $ServicesAddinsFolder
'PowerBIManagement\Microsoft.Dynamics.Nav.Client.PowerBIManagement.zip')
Set-NAVAddIn -ServerInstance $InstanceName -AddinName 'Microsoft.Dynamics.Nav.Client.RoleCenterSelector' -
PublicKeyToken 31bf3856ad364e35 -ResourceFile ($AppName = Join-Path $ServicesAddinsFolder
'RoleCenterSelector\Microsoft.Dynamics.Nav.Client.RoleCenterSelector.zip')
Set-NAVAddIn -ServerInstance $InstanceName -AddinName 'Microsoft.Dynamics.Nav.Client.SatisfactionSurvey' -
PublicKeyToken 31bf3856ad364e35 -ResourceFile ($AppName = Join-Path $ServicesAddinsFolder
'SatisfactionSurvey\Microsoft.Dynamics.Nav.Client.SatisfactionSurvey.zip')
Set-NAVAddIn -ServerInstance $InstanceName -AddinName 'Microsoft.Dynamics.Nav.Client.SocialListening' -
PublicKeyToken 31bf3856ad364e35 -ResourceFile ($AppName = Join-Path $ServicesAddinsFolder
'SocialListening\Microsoft.Dynamics.Nav.Client.SocialListening.zip')
Set-NAVAddIn -ServerInstance $InstanceName -AddinName 'Microsoft.Dynamics.Nav.Client.VideoPlayer' -
PublicKeyToken 31bf3856ad364e35 -ResourceFile ($AppName = Join-Path $ServicesAddinsFolder
'VideoPlayer\Microsoft.Dynamics.Nav.Client.VideoPlayer.zip')
Set-NAVAddIn -ServerInstance $InstanceName -AddinName 'Microsoft.Dynamics.Nav.Client.WebPageViewer' -
PublicKeyToken 31bf3856ad364e35 -ResourceFile ($AppName = Join-Path $ServicesAddinsFolder
'WebPageViewer\Microsoft.Dynamics.Nav.Client.WebPageViewer.zip')
Set-NAVAddIn -ServerInstance $InstanceName -AddinName 'Microsoft.Dynamics.Nav.Client.WelcomeWizard' -
PublicKeyToken 31bf3856ad364e35 -ResourceFile ($AppName = Join-Path $ServicesAddinsFolder
'WelcomeWizard\Microsoft.Dynamics.Nav.Client.WelcomeWizard.zip')
```

At this point, the upgrade is complete, and you can open the client.

Post-upgrade tasks

1. Enable task scheduler on the server instance.
2. (Multitenant only) For tenants other than the tenant that you use for administration purposes, if you mounted the tenants using the `-AllowAppDatabaseWrite` parameter, dismount the tenants, then mount them again without using the `-AllowAppDatabaseWrite` parameter.
3. If you want to use data encryption as before, enable it.

   For more information, see Managing Encryption and Encryption Keys.

   Optionally, if you exported the encryption key instead of disabling encryption earlier, import the encryption key file to enable encryption.
4. Change application version.

   (Optional) This task isn't required for installing the update. However, it might be useful for support purposes and answering a common question about the application version.

   On the **Help and Support** page in the client, you'll see an application version, such as 14.0.2345.6. For an explanation of the number, see Version numbers in Business Central. This version isn't updated automatically when you install an update. If you want the version to reflect the version of the update or your own version, you change it manually.

   We recommend setting the value to application build number for the version 17 update. You get the number from the Released Updates for Microsoft Dynamics 365 Business Central 2020 Release Wave 2 on-premises.

   a. Run the Set-NAVApplication cmdlet:

   ```
   Set-NAVApplication -ServerInstance <server instance name> -ApplicationVersion <new application
   version> -Force
   ```

   For example:

   ```
   Set-NAVApplication -ServerInstance BC170 -ApplicationVersion 17.0.38071.0 -Force
   ```

   b. Run the Sync-NAVTenant cmdlet to synchronize the tenant with the application database.

   ```
   Sync-NAVTenant -ServerInstance <server instance name> -Mode Sync -Tenant <tenant ID>
   ```

   With a single-tenant deployment, you can omit the `-Tenant` parameter and value.

   c. Run the Start-NavDataUpgrade cmdlet to change the version number:

   ```
   Start-NAVDataUpgrade -ServerInstance <server instance name> -FunctionExecutionMode Serial -Tenant
   <tenant ID>
   ```
5. Grant users permission to the *Open in Excel* and *Edit in Excel* actions.

   Version 17 introduces a system permission that protects these two actions. The permission is granted by the system object **6110 Allow Action Export To Excel**. Because of this change, users who had permission to these actions before upgrading, will lose permission. To grant permission again, do one of the following steps:

- Assign the **EXCEL EXPORT ACTION** permission set to appropriate users.
- Add the system object **6110 Allow Action Export To Excel** permission directly to appropriate permission sets.

For more information about working with permission sets and permissions, see Export and Import Permission Sets.

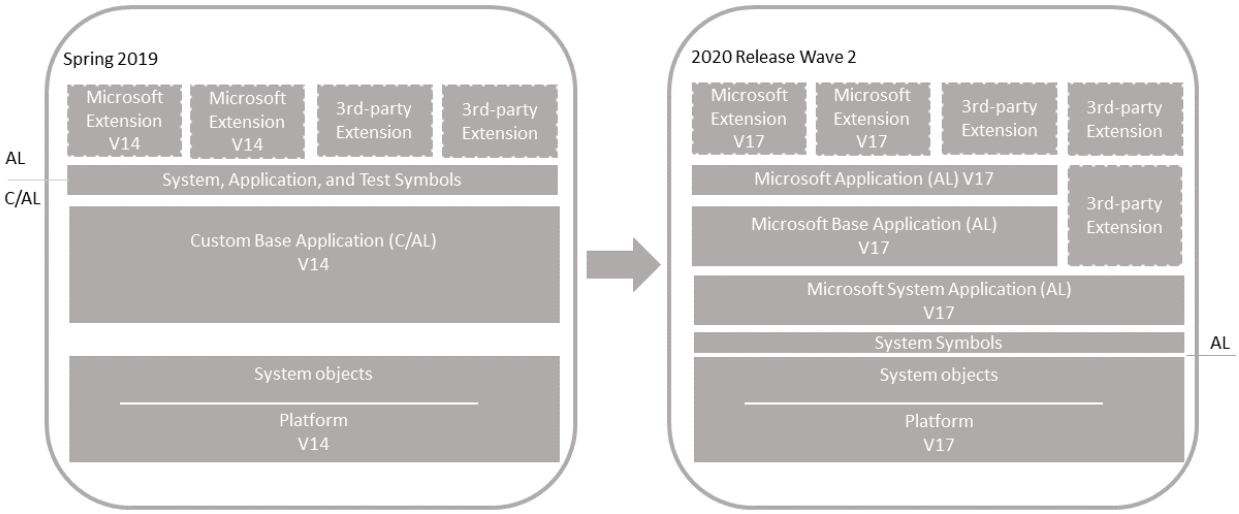
Upgrading Customized C/AL Application to Microsoft Base Application Version 17

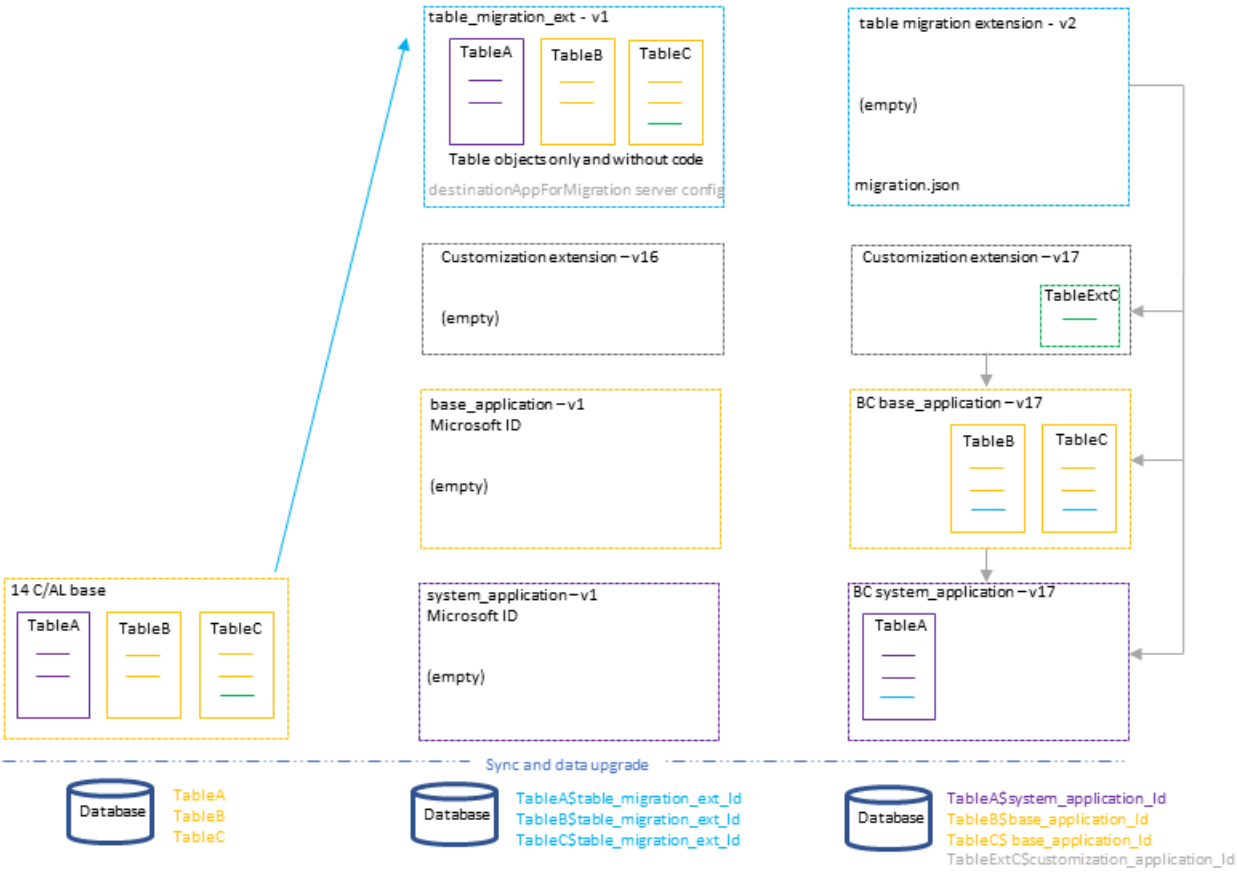
2/17/2021 • 20 minutes to read • Edit Online

This article describes how to upgrade a customized version 14 application to a version 17 solution that uses the Microsoft Base Application.



Overview

The upgrade is divided into two sections: Application Upgrade and Data Upgrade. The Application Upgrade section deals with upgrading the application code. For the application upgrade, you'll have to create several extensions. Some of these extensions are only used for upgrade purposes. The Data Upgrade section deals with upgrading the data on tenants - publishing, syncing, and installing extensions. For this scenario, the data upgrade consists of two phases for migrating data from the current tables to extension-based tables. The following figure illustrates the upgrade process.



The process uses two special features for migrating tables and data to extensions:

- destinationappsformigration server setting

  The *destinationappsformigration* setting is a configuration setting on the Business Central Server. In short, it's used to transfer ownership of the existing tables to the table migration extension. For more information, see DestinationAppsForMigration.

- migration.json file

  The *migration.json* file is used to migrate tables and fields from one extension to another. In this case, migration is from the table migration extension to system and base application tables. For more information about the migration.json, see The Migration.json File.

Single-tenant and multitenant deployments

The process for upgrading is similar for a single-tenant and multitenant deployment. However, there are some inherent differences. With a single-tenant deployment, the application and business data are included in the same database. While with a multitenant deployment, application code is in a separate database (the application database) than the business data (tenant). In the procedures that follow, for a single-tenant deployment, consider references to the *application database* and *tenant database* as the same database. Steps are marked as *Single-tenant only* or *Multitenant only* where applicable.

Prerequisites

1. Your version 14 is compatible with version 17.

   There are several updates for version 14. The updates have a compatible version 17 update. For more information, see Dynamics 365 Business Central Upgrade Compatibility Matrix.

2. The version 14 Dynamics NAV Development Shell and Business Central Administration Shell are installed.

3. Get the required version of the txt2al conversion tool.

   During the upgrade, you'll use the txt2al conversion tool to convert existing tables to the AL syntax. You'll

need to use a version of txt2al conversion tool that supports the `--tableDataOnly` parameter. This parameter was first introduced in version 14.12 (cumulative update 11, platform 14.0.41862). So if you're upgrading from version 14.11 (cumulative update 10) or earlier, you'll have to download the txt2al conversion tool from a later version 14 update. See Released Cumulative Updates for Microsoft Dynamics 365 Business Central Spring 2019 Update on-premises.

Install version 17

1. Download the latest available update for Dynamics 365 Business Central (version 17) that is compatible with your version 14.

   For more information, see Dynamics 365 Business Central Upgrade Compatibility Matrix.

2. Before you install version 17, it can be useful to create desktop shortcuts to the version 14.0 tools, such as the Business Central Server Administration tool, Business Central Administration Shell, and Dynamics NAV Development Shell because the Start menu items for these tools will be replaced with the version 17 tools.

3. Install Business Central version 17 components.

   You'll have to keep version 14 installed to complete some steps in the upgrade process. When you install version 17, you must either specify different port numbers for components (like the Business Central Server instance and web services) or stop the version 14.0 Business Central Server instance before you run the installation. Otherwise, you'll get an error that the Business Central Server failed to install.

   For more information, see Installing Business Central Using Setup.

APPLICATION UPGRADE

This section describes how to upgrade the application code. This work involves creating various extensions.

Task 1: Move code customizations to extensions

The first step, and the largest step, is to create extensions for the customizations compared to the Microsoft base application.

- Create extensions for the target platform **6.0 Business Central 2020 release wave 2**.
- Include dependencies for the Microsoft System, Base, and Application extensions for version 17.0.0.0.

Task 2: Create table migration extension

In this step, you create an extension that consists only of the non-system table objects from your custom base application. The table objects will only include the properties and field definitions. They won't include AL code on triggers or methods. This extension is an interim extension used only during the upgrade.

You'll create two versions of this extension. The first version contains the table objects. The second version, is an empty extension that contains a migrate.json file.

Create the first version

1. Create a folder where you'll store exported txt files for tables (for example, C:\export2al\bc14tablesonly).

2. Start the Dynamics NAV Development Shell for version 14.

3. Run the Export-NAVApplicationObject cmdlet to export only tables from the database.

```
Export-NAVApplicationObject -DatabaseServer .\BCDEMO -DatabaseName "Demo Database BC (14-0)" -
ExportToNewSyntax -Path "C:\export2al\bc14tablesonly\exportedbc14-tables.txt" -Filter
'Type=Table;Id=1..1999999999'
```

4. Use the txt2al conversion tool to convert the exported tables to the AL syntax. Use the `--tableDataOnly` parameter to include table and field definitions only.

   a. Create a folder for storing the AL files for base application objects (for example, C:\export2al\bc14tablesonly\al).

   b. Start a command prompt as an administrator, and navigate to the folder that contains txt2al.exe file.

      By default, the location is C:\Program Files (x86)\Microsoft Dynamics 365 Business Central\140\RoleTailored Client.

   c. Run the txt2al command:

```
txt2al --source=C:\export2al\bc14tablesonly --target=C:\export2al\bc14tablesonly\al --tableDataOnly
```

   For more information about this tool, see The Txt2Al Conversion Tool.

   > **NOTE**
   > If the `--tableDataOnly` parameter isn't available, you'll need a later version ot the txt2al conversion tool. For more information, see Prerequisites.

5. Make sure you've installed the latest AL Extension for Visual Studio Code from the version 17 DVD.

   For more information, see Getting Started with AL.

6. In Visual Studio Code, create an AL project for table migration extension using the **AL: Go!** command.

   Set the target platform to **6.0 Business Central 2020 release wave 2**.

7. Configure the project's app.json file:

   - Set the `"name"`, `"publisher"`, and `"version"`. You can use any valid values.
   - Delete the `"application"` parameter.
   - Clear the `"dependencies"`.
   - Set the `"idRanges"` to cover the table object IDs or clear all values.
   - Add the `"target"` parameter and set it to `"Onprem"`.

   Make a note of the `"id"` setting value, which is the ID assigned to the table migration extension. You'll use this ID later in the process. **Don't** use the ID in the following example. It's for illustration purposes only.

```
{
  "id": "11111111-aaaa-2222-bbbb-333333333333",
  "name": "bc14tablesonly",
  "publisher": "My publisher",
  "version": "1.0.0.0",
  "brief": "",
  "description": "",
  "privacyStatement": "",
  "EULA": "",
  "help": "",
  "url": "",
  "logo": "",
  "dependencies": [],
  "screenshots": [],
  "platform": "17.0.0.0",
  "idRanges": [  ],
  "contextSensitiveHelpUrl": "https://bc14tablesonly.com/help/",
  "showMyCode": true,
  "runtime": "6.0",
  "target": "OnPrem"
}
```

8. Create an `.alpackages` folder in the root folder of the project and then copy the version 17 system symbols extension (System.app file) to the folder.

   The System.app file is located where you installed the AL Development Environment. By default, the folder path is C:\Program Files (x86)\Microsoft Dynamics 365 Business Central\170\AL Development Environment. This package contains the symbols for all the system tables and codeunits.

9. Add the AL files for tha tables that you converted earlier to the root folder for the project.

   The folder used in this article is C:\export2al\bc14tablesonly\al.

   > **IMPORTANT**
   > If you're upgrading a **CH** or **NA** local version (14.18 or later), you'll have to rename the primary keys in some tables. For more information, see Known Issues.

10. Build the extension package for the first version.

    To build the extension package, press Ctrl+Shift+B. This step creates an .app file for your extension. The file name has the format <publisher>_<name>_<version>.app.

Create the second version

1. In Visual Studio Code, create a new file called migration.json file and add it to the project's root folder.
2. In the migration.json, include rules for the Microsoft base application, system application, and your customization extensions.

```
{
    "apprules": [
        {
            "id": "63ca2fa4-4f03-4f2b-a480-172fef340d3f"
        },
        {
            "id": "437dbf0e-84ff-417a-965d-ed2bb9650972"
        },
        {
            "id": "<NNNNNNNN-NNNN-NNNN-NNNN-NNNNNNNNNNNN>"
        },
        {
            "id": "<NNNNNNNN-NNNN-NNNN-NNNN-NNNNNNNNNNNN>"
        }
    ]
}
```

In the example code:

- `63ca2fa4-4f03-4f2b-a480-172fef340d3f` identifies the system application extension
- `437dbf0e-84ff-417a-965d-ed2bb9650972` identifies the base application extension
- The two other IDs are examples that identify other new customization extensions you might have. Replace or remove these entries as needed.

For more information about the migration.json, see The Migration.json File.

3. Delete the AL object files.
4. Increase the `version` in the app.json file.
5. Build the extension package for the second version.

   To build the extension package, press Ctrl+Shift+B.

Task 3: Create empty extensions System, Base, and customization extensions

Create two empty extensions: one for the Microsoft base application and another for the System Application. Also, create an empty extension for each new customization extension. The only file in the extension project that is required is an app.json.

You can create the empty extension like any other extension by adding an AL project in Visual Studio Code:

1. In Visual Studio Code, select **View** > **Command Palette** > **AL: Go!** and follow instructions.
2. Delete the HelloWorld.al sample file from the project.
3. Modify the app.json file.

   The important settings in the app.json file are: `"id"`, `"name"`, `"version"`, `"publisher"`, `"dependencies"`, and `"runtime"`.

   - The `id` and `name` must match the value used by Microsoft's extensions.
   - Set the `version` to any version lower than 17.0.0.0, like 14.0.0.0.
   - You'll also have to include the `"publisher"`. You can use your own publisher name or `"Microsoft"`.
   - Remove all other settings. It's important that there are no `"dependencies"` set.
   - Set the `runtime` to `"6.0"`.

   The app.json files for the **System Application** and **Base Application** extensions, should look similar to following examples:

System Application

```
"id": "63ca2fa4-4f03-4f2b-a480-172fef340d3f",
"name": "System Application",
"publisher": "Microsoft",
"version": "14.0.0.0",
"runtime": "6.0"
```

Base Application

```
"id": "437dbf0e-84ff-417a-965d-ed2bb9650972",
"name": "Base Application",
"publisher": "Microsoft",
"version": "14.0.0.0",
"runtime": "6.0"
```

4. Build and compile the extension package. To build the extension package, press Ctrl+Shift+B.

> **TIP**
> This step is only required if you need to trigger a data upgrade on these extensions, which you'll do by running Start-NavAppDataUpgrade on these extensions in Task 14. For the scenario in this article, at a minimum this step is required for the System and Base Applications. You can skip this step for any customization extensions that do not not include upgrade code.

DATA UPGRADE

Task 4: Prepare databases

1. Make backup of the databases.
2. Disable data encryption.

   If the current server instance uses data encryption, disable it. You can enable it again after upgrading.

   For more information, see Managing Encryption and Encryption Keys.

   Instead of disabling encryption, you can export the current encryption key, which you'll then import after upgrade. However, we recommend disabling encryption before upgrading.
3. Start Business Central Administration Shell for version 14 as an administrator.
4. (Single-tenant only) Uninstall all extensions from the tenants.

   To uninstall an extension, you use the Uninstall-NAVApp cmdlet. For example, you can uninstall all extensions with a single command:

```
Get-NAVAppInfo -ServerInstance <server instance name> -Tenant <tenant ID>| % { Uninstall-NAVApp -
ServerInstance <server instance name> -Tenant <tenant ID> -Name $_.Name -Version $_.Version -Force}
```

5. (Single-tenant only) Unpublish all extensions from the application server instance.

   To unpublish an extension, use the Unpublish-NAVApp cmdlet. For example, you can unpublish all extensions by using a single command:

```
Get-NAVAppInfo -ServerInstance <BC14 server instance> | % { Unpublish-NAVApp -ServerInstance <BC14
server instance> -Name $_.Name -Version $_.Version }
```

6. Unpublish all system, test, and application symbols.

   To unpublish symbols, use the Unpublish-NAVAPP cmdlet with the `-SymbolsOnly` switch.

   ```
   Get-NAVAppInfo -ServerInstance <BC14 server instance> -SymbolsOnly | % { Unpublish-NAVApp -
   ServerInstance <BC14 server instance> -Name $_.Name -Version $_.Version }
   ```

   What are symbols?

7. (Multitenant only) Dismount the tenants from the application server instance.

   To dismount a tenant, use the Dismount-NAVTenant cmdlet:

   ```
   Dismount-NAVTenant -ServerInstance <server instance name> -Tenant <tenant ID>
   ```

8. Stop the server instance.

   ```
   Stop-NAVServerInstance -ServerInstance <server instance name>
   ```

Task 5: Convert version 14 database

This task runs a technical upgrade on the application database. The task converts the database from the version 14 platform to the version 17 platform. The conversion updates the system tables of the database to the new schema (data structure). It provides the latest platform features and performance enhancements.

1. Start Business Central Administration Shell for version 17 as an administrator.
2. Run the Invoke-NAVApplicationDatabaseConversion cmdlet to start the conversion:

   ```
   Invoke-NAVApplicationDatabaseConversion -DatabaseServer <database server name>\<database server
   instance> -DatabaseName "<database name>"
   ```

   When completed, a message like the following displays in the console:

   ```
   DatabaseServer      : .\BCDEMO
   DatabaseName        : Demo Database BC (14-0)
   DatabaseCredentials :
   DatabaseLocation    :
   Collation           :
   ```

Task 6: Configure version 17 server for DestinationAppsForMigration

In this step, you configure the version 17 server instance. In particular, you configure it to migrate the table migration extension that you created earlier. The migration is controlled by the `DestinationAppsForMigration` setting for the server instance. For more information about the `DestinationAppsForMigration` setting, see DestinationAppsForMigration.

1. Set the server instance to connect to the application database.

```
Set-NAVServerConfiguration -ServerInstance <server instance name> -KeyName DatabaseName -KeyValue "
<database name>"
```

In a single tenant deployment, this command will mount the tenant automatically. For more information, see Connecting a Server Instance to a Database.

2. Configure the `DestinationAppsForMigration` setting of the server instance to table migration extension.

   You'll need the ID, name, and publisher for the table migration extension that you created in **Task 2**.

   ```
   Set-NAVServerConfiguration -ServerInstance <server instance name> -KeyName
   "DestinationAppsForMigration" -KeyValue '[{"appId":"<table migration extension ID>", "name":"<table
   migration extension>", "publisher": "<publisher>"}]'
   ```

   For example:

   ```
   Set-NAVServerConfiguration -ServerInstance BC -KeyName "DestinationAppsForMigration" -KeyValue
   '[{"appId":"11111111-aaaa-2222-bbbb-333333333333", "name":"bc14tablesonly", "publisher": "My
   publisher"}]'
   ```

   > **NOTE**
   > You can add multiple extensions to this setting.

3. Disable task scheduler on the server instance for purposes of upgrade.

   ```
   Set-NavServerConfiguration -ServerInstance <server instance name> -KeyName "EnableTaskScheduler" -
   KeyValue false
   ```

   Be sure to re-enable task scheduler after upgrade if needed.

4. Restart the server instance.

   ```
   Restart-NAVServerInstance -ServerInstance <server instance name>
   ```

Task 7: Import License

Import the version 17 partner license. To import the license, use the Import-NAVServerLicense cmdlet:

```
Import-NAVServerLicense -ServerInstance <server instance name> -LicenseFile <path>
```

Restart the server instance.

Task 8: Publish symbols and DestinationAppsForMigrations

In this task, you'll publish the platform symbols and the extensions configured as DestinationAppsForMigration.

1. Publish version 17 system symbols extension.

   The symbols extension contains the required platform symbols that the base application depends on. The symbols extension package is called **System.app**. You find it where the **AL Development Environment** is installed. The default path is C:\Program Files (x86)\Microsoft Dynamics 365 Business

Central\170\AL Development Environment.

```
Publish-NAVApp -ServerInstance  <server instance name> -Path "<path to system.app>" -PackageType
SymbolsOnly
```

What are symbols?

2. Publish the first version of the table migration extension, which is the version that contains the table objects.

```
Publish-NAVApp -ServerInstance <server instance name> -Path "<path to extension .app file>"
```

3. Publish the empty versions of the following extensions:

   - **System Application** extension
   - **Base Application** extension
   - Customization extensions (if any).

   This step publishes the extensions you created in Task 3. Publish the extensions using the Publish-NAVApp, like in the previous steps. Except if the extensions aren't signed, use the `-SkipVerification` switch parameter.

4. Restart the server instance.

```
Restart-NAVServerInstance -ServerInstance <server instance name>
```

Task 9: Synchronize tenant

In this task, you'll synchronize the tenant's database schema with any schema changes in the application database and extensions.

If you have a multitenant deployment, do these steps for each tenant.

1. (Multitenant only) Mount the tenant to the version 15 server instance.

   To mount the tenant, use the Mount-NAVTenant cmdlet:

```
Mount-NAVTenant -ServerInstance <server instance name> -DatabaseName <database name> -DatabaseServer
<database server>\<database instance> -Tenant <tenant ID> -AllowAppDatabaseWrite
```

> **IMPORTANT**
> You must use the same tenant ID for the tenant that was used in the old deployment; otherwise you'll get an error when mounting or syncing the tenant. If you want to use a different ID for the tenant, you can either use the `-AlternateId` parameter now or after upgrading, dismount the tenant, then mount it again using the new ID and the `OverwriteTenantIdInDatabase` parameter.

> **NOTE**
> For upgrade, we recommend that you use the `-AllowAppDatabaseWrite` parameter. After upgrade, you can dismount and mount the tenant again without the parameter if needed.

At this stage, the tenant state is OperationalWithSyncPending.

2. Synchronize the tenant with the application database.

   Use the Sync-NAVTenant cmdlet:

   ```
   Sync-NAVTenant -ServerInstance <server instance name> -Mode Sync -Tenant <tenant ID>
   ```

   With a single-tenant deployment, you can omit the `-Tenant` parameter and value.

3. Synchronize the tenant with the table migration extension. This extension is the tables-only extension you created in task 2.

   Use the Sync-NAVApp cmdlet:

   ```
   Sync-NAVApp -ServerInstance <server instance name> -Tenant <tenant ID> -Name "<table migration
   extension>" -Version <extension version>
   ```

   This step creates empty tables in the database for the table objects defined in the table migration extension. When completed, the table migration extension takes ownership of the table. In SQL Server, you'll notice that the table names will be suffixed with the extension ID. At this point, the tenant state is OperationalDataUpgradePending.

   TIP

   To verify the tenant state, run Get-NAVTenant cmdlet with the `-ForceRefresh` switch:

   `Get-NAVTenant <server instance> -Tenant <default> -ForceRefresh`

4. Synchronize the empty versions of system application, base application, and customization extensions that you published in Task 8.

Task 10: Install DestinationAppsForMigration and move tables

In this task, you run a data upgrade on tables to handle data changes made by platform and extensions. The step installs table migration extension. It moves data from the old tables to the new tables owned by the table migration extension.

1. To run the data upgrade, use the Start-NavDataUpgrade cmdlet:

   ```
   Start-NAVDataUpgrade -ServerInstance <server instance name> -Tenant <tenant ID> -
   FunctionExecutionMode Serial -SkipAppVersionCheck
   ```

2. To view the progress of the data upgrade, you can run Get-NavDataUpgrade cmdlet with the `-Progress` switch.

   When completed, the table migration extension will be installed.

3. Install the empty versions of the system, base, and custom extensions that you published in Task 8.

   To install the extension, you use the Install-NAVApp cmdlet.

   ```
   Install-NAVApp -ServerInstance <server instance name> -Name "<name>" -Version <extension version>
   ```

4. (Multitenant only) Repeat steps 1 and 2 for each tenant.

Task 11: Publish final extensions

This step starts the second phase of the data upgrade. You'll publish the second version of the table migration extension and the production versions of extensions. The production extensions include the new versions of Microsoft System Application, Base Application extension, and customization extensions. The extension packages for Microsoft extensions are on the installation media (DVD). Customization extensions include the extension versions that you created in Task 1, not the empty versions.

Publish extensions using the Publish-NAVApp cmdlet like you did in previous steps.

```
Publish-NAVApp -ServerInstance <server instance name> -Path "<path to extension .app file>"
```

Publish the extensions in the following order:

1. Second version of the table migration extension, which is the empty version with the migration.json file.
2. Microsoft System Application

   Publish the Microsoft_System Application.app extension package file that is in the **Applications\System Application\Source** folder of installation media (DVD).
3. Microsoft Base Application

   Publish the Microsoft_Base Application.app extension package file that is in the **Applications\BaseApp\Source** folder of installation media (DVD).

   > **NOTE**
   > The other .app files in this folder, like Microsoft_Danish language (Denmark).app, are extensions that add translations for a specific language. By publishing and installing these extensions, you add the capability of showing the base application in another language. These extensions aren't required to complete the upgrade and can be published and installed later.
4. Customization extensions.
5. Application extension.
6. Microsoft and third-party extensions.

   The Microsoft extensions are in the **Applications** folder of installation media (DVD).

Task 12: Synchronize final extensions

Synchronize the newly published extensions using the Sync-NAVApp cmdlet like you did in previous steps.

```
Sync-NAVApp -ServerInstance <server instance name> -Tenant <tenant ID> -Name "<extension name>" -Version
<extension version>
```

Synchronize the extensions in the following order:

1. Microsoft System Application
2. Microsoft Base Application
3. Microsoft Application
4. Microsoft and third-party extensions
5. Customization extensions
6. Second version of the table migration extension (empty version)

IMPORTANT

Synchronize extensions in the order of dependencies. The migration extension must be synchronized last. This step will change table ownership to the system and base application.

Task 13: Upgrade empty table migration extension

Run data upgrade on the table migration extension (empty version) by using the Start-NAVAppDataUpgrade cmdlet. For example:

```
Start-NAVAppDataUpgrade -ServerInstance <server instance> -Name "<table migration extension>" -version
<version 2>
```

Task 14: Upgrade and install final extensions

The final step is to upgrade to the new extension versions in the following order. Use the Start-NAVAppDataUpgrade or Install-NAVApp cmdlets like you did in the previous task.

Run the data upgrade on the extensions in the following order:

1. Upgrade the Microsoft System Application extension.
2. Upgrade the Microsoft Base Application extension.
3. Install the Microsoft Application extension
4. Upgrade customization extensions, Microsoft, and third-party extensions.

   For customization extensions, only do this task for those extensions that have an empty version currently installed on the tenant (see **Task 11**). If you have a customization extension for which you didn't create and publish an empty version, complete the next task to install these extensions.

Task 15: Install remaining customization extensions

Complete this task for customizations extension that you created in Task 1, but create and publish an empty version first.

To install each extension, run the Install-NAVApp cmdlet:

```
Install-NAVApp -ServerInstance <server instance name> -Name "<name>" -Version <extension version>
```

Task 16: Upgrade control add-ins

The Business Central Server installation includes new versions of the Microsoft-provided Javascript-based control add-ins that must be upgraded.

- Microsoft.Dynamics.Nav.Client.BusinessChart
- Microsoft.Dynamics.Nav.Client.FlowIntegration
- Microsoft.Dynamics.Nav.Client.OAuthIntegration
- Microsoft.Dynamics.Nav.Client.PageReady
- Microsoft.Dynamics.Nav.Client.PowerBIManagement
- Microsoft.Dynamics.Nav.Client.RoleCenterSelector
- Microsoft.Dynamics.Nav.Client.SocialListening

- Microsoft.Dynamics.Nav.Client.SatisficationSurvey
- Microsoft.Dynamics.Nav.Client.TimelineVisualization
- Microsoft.Dynamics.Nav.Client.VideoPlayer
- Microsoft.Dynamics.Nav.Client.WebPageViewer
- Microsoft.Dynamics.Nav.Client.WelcomeWizard

To upgrade the control add-ins from the client, do the following steps:

1. Open the Business Central client.
2. Search for and open the **Control Add-ins** page.
3. Choose **Actions** > **Control Add-in Resource** > **Import**.
4. Locate and select the .zip file for the control add-in and choose **Open**.

   The .zip files are located in the **Add-ins** folder of the Business Central Server installation. There's a subfolder for each add-in. For example, the path to the Business Chart control add-in is
   `C:\Program Files\Microsoft Dynamics 365 Business Central\170\Service\Add-ins\BusinessChart\Microsoft.Dynamics.Nav.Client.BusinessChart.zip`
   .
5. After you've imported all the new control add-in versions, restart Business Central Server instance.

Instead, you can use the Set-NAVAddin cmdlet of the Business Central Administration Shell. For example, the following commands update the control add-ins installed by default. Modify the commands to suit:

```
$InstanceName = 'BC170'
$ServicesAddinsFolder = 'C:\Program Files\Microsoft Dynamics 365 Business Central\170\Service\Add-ins'
Set-NAVAddIn -ServerInstance $InstanceName -AddinName 'Microsoft.Dynamics.Nav.Client.BusinessChart' -
PublicKeyToken 31bf3856ad364e35 -ResourceFile ($AppName = Join-Path $ServicesAddinsFolder
'BusinessChart\Microsoft.Dynamics.Nav.Client.BusinessChart.zip')
Set-NAVAddIn -ServerInstance $InstanceName -AddinName 'Microsoft.Dynamics.Nav.Client.FlowIntegration' -
PublicKeyToken 31bf3856ad364e35 -ResourceFile ($AppName = Join-Path $ServicesAddinsFolder
'FlowIntegration\Microsoft.Dynamics.Nav.Client.FlowIntegration.zip')
Set-NAVAddIn -ServerInstance $InstanceName -AddinName 'Microsoft.Dynamics.Nav.Client.OAuthIntegration' -
PublicKeyToken 31bf3856ad364e35 -ResourceFile ($AppName = Join-Path $ServicesAddinsFolder
'OAuthIntegration\Microsoft.Dynamics.Nav.Client.OAuthIntegration.zip')
Set-NAVAddIn -ServerInstance $InstanceName -AddinName 'Microsoft.Dynamics.Nav.Client.PageReady' -
PublicKeyToken 31bf3856ad364e35 -ResourceFile ($AppName = Join-Path $ServicesAddinsFolder
'PageReady\Microsoft.Dynamics.Nav.Client.PageReady.zip')
Set-NAVAddIn -ServerInstance $InstanceName -AddinName 'Microsoft.Dynamics.Nav.Client.PowerBIManagement' -
PublicKeyToken 31bf3856ad364e35 -ResourceFile ($AppName = Join-Path $ServicesAddinsFolder
'PowerBIManagement\Microsoft.Dynamics.Nav.Client.PowerBIManagement.zip')
Set-NAVAddIn -ServerInstance $InstanceName -AddinName 'Microsoft.Dynamics.Nav.Client.RoleCenterSelector' -
PublicKeyToken 31bf3856ad364e35 -ResourceFile ($AppName = Join-Path $ServicesAddinsFolder
'RoleCenterSelector\Microsoft.Dynamics.Nav.Client.RoleCenterSelector.zip')
Set-NAVAddIn -ServerInstance $InstanceName -AddinName 'Microsoft.Dynamics.Nav.Client.SatisfactionSurvey' -
PublicKeyToken 31bf3856ad364e35 -ResourceFile ($AppName = Join-Path $ServicesAddinsFolder
'SatisfactionSurvey\Microsoft.Dynamics.Nav.Client.SatisfactionSurvey.zip')
Set-NAVAddIn -ServerInstance $InstanceName -AddinName 'Microsoft.Dynamics.Nav.Client.SocialListening' -
PublicKeyToken 31bf3856ad364e35 -ResourceFile ($AppName = Join-Path $ServicesAddinsFolder
'SocialListening\Microsoft.Dynamics.Nav.Client.SocialListening.zip')
Set-NAVAddIn -ServerInstance $InstanceName -AddinName 'Microsoft.Dynamics.Nav.Client.VideoPlayer' -
PublicKeyToken 31bf3856ad364e35 -ResourceFile ($AppName = Join-Path $ServicesAddinsFolder
'VideoPlayer\Microsoft.Dynamics.Nav.Client.VideoPlayer.zip')
Set-NAVAddIn -ServerInstance $InstanceName -AddinName 'Microsoft.Dynamics.Nav.Client.WebPageViewer' -
PublicKeyToken 31bf3856ad364e35 -ResourceFile ($AppName = Join-Path $ServicesAddinsFolder
'WebPageViewer\Microsoft.Dynamics.Nav.Client.WebPageViewer.zip')
Set-NAVAddIn -ServerInstance $InstanceName -AddinName 'Microsoft.Dynamics.Nav.Client.WelcomeWizard' -
PublicKeyToken 31bf3856ad364e35 -ResourceFile ($AppName = Join-Path $ServicesAddinsFolder
'WelcomeWizard\Microsoft.Dynamics.Nav.Client.WelcomeWizard.zip')
```

Post-upgrade tasks

1. Uninstall the table migration extension.
2. Enable task scheduler on the server instance.
3. (Multitenant only) For tenants other than the tenant that you use for administration purposes, if you mounted the tenants using the `-AllowAppDatabaseWrite` parameter, dismount the tenants, then mount them again without using the `-AllowAppDatabaseWrite` parameter.
4. If you want to use data encryption as before, enable it.

   For more information, see Managing Encryption and Encryption Keys.

   Optionally, if you exported the encryption key instead of disabling encryption earlier, import the encryption key file to enable encryption.
5. Change application version.

   (Optional) This task isn't required for installing the update. However, it might be useful for support purposes and answering a common question about the application version.

   On the **Help and Support** page in the client, you'll see an application version, such as 14.0.2345.6. For an explanation of the number, see Version numbers in Business Central. This version isn't updated automatically when you install an update. If you want the version to reflect the version of the update or your own version, you change it manually.

   We recommend setting the value to application build number for the version 17 update. You get the number from the Released Updates for Microsoft Dynamics 365 Business Central 2020 Release Wave 2 on-premises.

   a. Run the Set-NAVApplication cmdlet:

   ```
   Set-NAVApplication -ServerInstance <server instance name> -ApplicationVersion <new application
   version> -Force
   ```

   For example:

   ```
   Set-NAVApplication -ServerInstance BC170 -ApplicationVersion 17.0.38071.0 -Force
   ```

   b. Run the Sync-NAVTenant cmdlet to synchronize the tenant with the application database.

   ```
   Sync-NAVTenant -ServerInstance <server instance name> -Mode Sync -Tenant <tenant ID>
   ```

   With a single-tenant deployment, you can omit the `-Tenant` parameter and value.

   c. Run the Start-NavDataUpgrade cmdlet to change the version number:

   ```
   Start-NAVDataUpgrade -ServerInstance <server instance name> -FunctionExecutionMode Serial -Tenant
   <tenant ID>
   ```
6. Grant users permission to the *Open in Excel* and *Edit in Excel* actions.

   Version 17 introduces a system permission that protects these two actions. The permission is granted by the system object **6110 Allow Action Export To Excel**. Because of this change, users who had permission to these actions before upgrading, will lose permission. To grant permission again, do one of

the following steps:

- Assign the **EXCEL EXPORT ACTION** permission set to appropriate users.
- Add the system object **6110 Allow Action Export To Excel** permission directly to appropriate permission sets.

For more information about working with permission sets and permissions, see Export and Import Permission Sets.

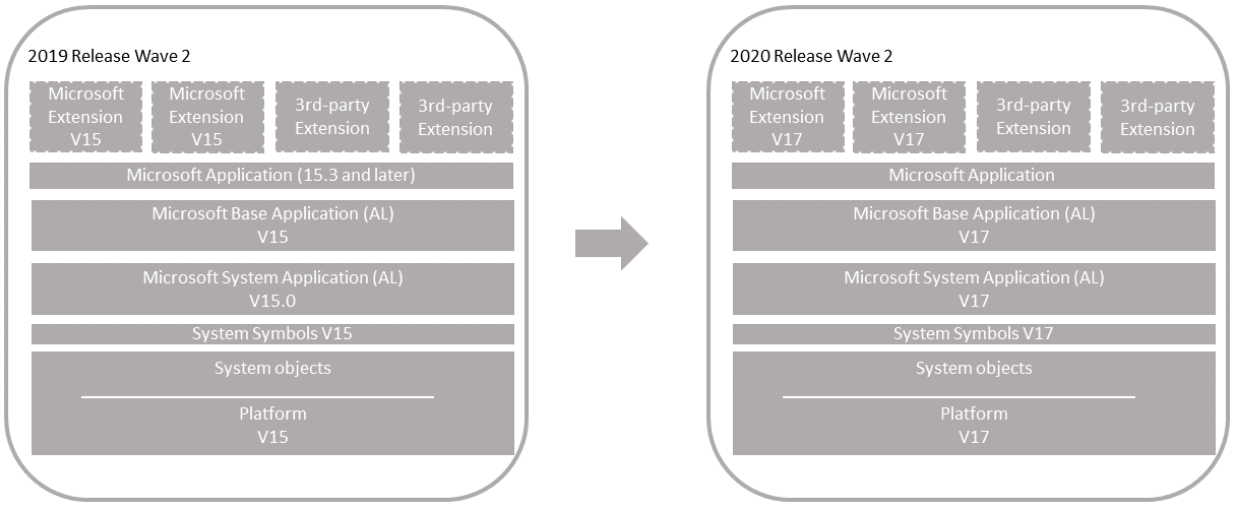
Upgrading Version 15 Base Application to Version 17

2/17/2021 • 13 minutes to read • Edit Online

Use this scenario if you have a Business Central 2019 release wave 2 solution that uses the Microsoft System and Base applications.



Single-tenant and multitenant deployments

The process for upgrading the similar for a single-tenant and multitenant deployment. However, there are some inherent differences. With a single-tenant deployment, the application code and business data are in the same database. In a multitenant deployment, application code is in a separate database (the application database) than the business data (tenant). In the procedures that follow, for a single-tenant deployment, consider references to the *application database* and *tenant database* as the same database. Steps are marked as *Single-tenant only* or *Multitenant only* where applicable.

Prerequisites

1. Your version 15 is compatible with version 17.

   There are several updates for version 15. The updates have a compatible version 17 update. For more information, see Dynamics 365 Business Central Upgrade Compatibility Matrix. For example, if your solution is currently running 15.5, you can't upgrade to 17.0. You must wait until 17.1 is available.

2. Disable data encryption.

   If the current server instance uses data encryption, disable it. You can enable it again after upgrading.

   For more information, see Managing Encryption and Encryption Keys.

   Instead of disabling encryption, you can export the current encryption key, which you'll then import after upgrade. However, we recommend disabling encryption before upgrading.

Task 1: Prepare version 15 databases

1. Make backup of the databases.
2. Start Business Central Administration Shell for version 15 as an administrator.
3. (Single-tenant only) Uninstall all extensions from the old tenants.

In this step, you uninstall the Base Application, System Application (if used), and any other extensions that are currently installed on the database.

a. Get a list of installed extensions.

   This step is optional, but it can be useful to the names and versions of the extensions.

   To get a list of installed extensions, use the Get-NAVAppInfo cmdlet.

   ```
   Get-NAVAppInfo -ServerInstance <server instance name> -Tenant <tenant ID>
   ```

   For a single-tenant deployment, set the `<tenant ID>` to default.

b. Uninstall the extensions.

   To uninstall an extension, you use the Uninstall-NAVApp cmdlet.

   ```
   Uninstall-NAVApp -ServerInstance <server instance name> -Name <extensions name> -Tenant
   <tenant ID> -Version <extension version> -Force
   ```

   Replace `<extension name>` and `<extension version>` with the exact name and version the published System Application.

   For example, together with the Get-NAVApp cmdlet, you can uninstall all extensions with a single command:

   ```
   Get-NAVAppInfo -ServerInstance <server instance name> -Tenant <tenant ID>| % { Uninstall-
   NAVApp -ServerInstance <server instance name> -Tenant <tenant ID> -Name $_.Name -Version
   $_.Version -Force}
   ```

4. Unpublish all system symbols.

   To unpublish symbols, use the Unpublish-NAVAPP cmdlet with the `-SymbolsOnly` switch.

   ```
   Get-NAVAppInfo -ServerInstance <BC15 server instance> -SymbolsOnly | % { Unpublish-NAVApp -
   ServerInstance <BC15 server instance> -Name $_.Name -Version $_.Version }
   ```

   What are symbols?

5. (Multitenant only) Dismount the tenants from the application server instance.

   To dismount a tenant, use the Dismount-NAVTenant cmdlet:

   ```
   Dismount-NAVTenant -ServerInstance <server instance name> -Tenant <tenant ID>
   ```

6. Stop the server instance.

   ```
   Stop-NAVServerInstance -ServerInstance <server instance name>
   ```

Task 2: Install version 17

1. Download the latest available update for Business Central 2020 release wave 2 (version 17) that is compatible with your version 15.

For more information, see Dynamics 365 Business Central Upgrade Compatibility Matrix.

2. Before you install version 17, it can be useful to create desktop shortcuts to the version 15.0 tools, such as the Business Central Server Administration tool, Business Central Administration Shell, and Dynamics NAV Development Shell because the Start menu items for these tools will be replaced with the version 17 tools.

3. Install Business Central version 17 components.

   You'll keep version 15 installed to complete some steps in the upgrade process. When you install version 17, you must either specify different port numbers for components (like the Business Central Server instance and web services) or you must stop the version 15.0 Business Central Server instance before you run the installation. Otherwise, you'll get an error that the Business Central Server failed to install.

   For more information, see Installing Business Central Using Setup.

Task 3: Convert version 15 database

This task runs a technical upgrade on the application database to convert it from the version 15 platform to the version 17 platform. The conversion updates the system tables of the database to the new schema (data structure). It provides the latest platform features and performance enhancements.

1. Start Business Central Administration Shell for version 17 as an administrator.

2. Run the Invoke-NAVApplicationDatabaseConversion cmdlet to start the conversion:

   ```
   Invoke-NAVApplicationDatabaseConversion -DatabaseServer <database server name>\<database server
   instance> -DatabaseName "<database name>"
   ```

   When completed, a message like the following displays in the console:

   ```
   DatabaseServer      : .\BCDEMO
   DatabaseName        : Demo Database BC (15-0)
   DatabaseCredentials :
   DatabaseLocation    :
   Collation           :
   ```

Task 4: Configure version 17 server

When you installed version 17 in **Task 2**, a version 17 Business Central Server instance was created. In this task, you change server configuration settings that are required to complete the upgrade. Some of the changes are only required for version 15 to version 17 upgrade and can be reverted after you complete the upgrade.

1. Set the server instance to connect to the application database.

   ```
   Set-NAVServerConfiguration -ServerInstance <server instance name> -KeyName DatabaseName -KeyValue "
   <database name>"
   ```

   In a single tenant deployment, this command will mount the tenant automatically. For more information, see Connecting a Server Instance to a Database.

2. Disable task Scheduler on the server instance for purposes of upgrade.

   ```
   Set-NavServerConfiguration -ServerInstance <server instance name> -KeyName "EnableTaskScheduler" -
   KeyValue false
   ```

Be sure to re-enable task scheduler after upgrade if needed.

3. Restart the server instance.

```
Restart-NAVServerInstance -ServerInstance <server instance name>
```

Task 5: Import version 17 license

1. Use the Import-NAVServerLicense to upload the version 17 license to the database.

```
Import-NAVServerLicense -ServerInstance <server instance name> -LicenseFile <path and file name>
```

2. Restart the server instance.

```
Restart-NAVServerInstance -ServerInstance <server instance name>
```

Task 6: Publish symbols and extensions

In this task, you'll publish the platform symbols and extensions. As minimum, you publish the new base application and system application extensions from the installation media (DVD). You also publish new versions of any Microsoft extensions and third-party extensions that were used on your old deployment.

Publishing an extension adds the extension to the application database that is mounted on the server instance. Once published, it's available for installing on tenants. This task updates internal tables, compiles the components of the extension behind-the-scenes, and builds the necessary metadata objects that are used at runtime.

The steps in this task continue to use the Business Central Administration Shell for version 17 that you started in the previous task.

1. Publish version 17 system symbols extension.

   The symbols extension contains the required platform symbols that the base application depends on. The symbols extension package is called **System.app**. You find it where the **AL Development Environment** is installed. The default path is C:\Program Files (x86)\Microsoft Dynamics 365 Business Central\170\AL Development Environment.

```
Publish-NAVApp -ServerInstance  <server instance name> -Path "<path to system.app>" -PackageType
SymbolsOnly
```

   What are symbols?

2. Publish the **System Application** extension (Microsoft_System Application.app).

   You find the (Microsoft_System Application.app in the **Applications\System Application\Source** folder of installation media (DVD).

```
Publish-NAVApp -ServerInstance <server instance name> -Path "<path to Microsoft_System
Application.app>"
```

   What is the System Application?

3. Publish the Business Central base application extension (Microsoft_Base Application.app).

The **Base Application** extension contains the application business objects. You find the (Microsoft_Base Application.app in the **Applications\BaseApp\Source** folder of installation media (DVD).

```
Publish-NAVApp -ServerInstance <server instance name> -Path "<path to Microsoft_Base
Application.app>"
```

4. Publish the Microsoft_Application extension.

   The Microsoft_Application extension is a new extension introduced in 15.3. For more information about this extension, see The Microsoft_Application.app File.

   ```
   Publish-NAVApp -ServerInstance <server instance name> -Path "<path to Microsoft_Application.app>"
   ```

5. Publish the new versions of Microsoft extensions.

   In this step, you publish new versions of Microsoft extensions that were used on your version 15 deployment. You find the extensions in the **Applications** folder of the installation media (DVD).

   ```
   Publish-NAVApp -ServerInstance <server instance name> -Path "<path to Microsoft extension>"
   ```

   For example:

   ```
   Publish-NAVApp -ServerInstance BC170 -Path
   "C:\W1DVD\Applications\SalesAndInventoryForecast\Source\SalesAndInventoryForecast.app"
   ```

6. Publish new versions of 3rd-party extensions.

   If you have new versions of these extensions, built on the Business Central version 17, then publish the new versions.

   ```
   Publish-NAVApp -ServerInstance <server instance name> -Path "<path to extension>"
   ```

7. Recompile extensions not build on version 17.

   This step pertains to any published extension versions that aren't built on version 17, which you want to reinstall on tenants. These extensions must be recompiled to work with version 17. To recompile the extensions, use the Repair-NAVApp cmdlet:

   ```
   Repair-NAVApp -ServerInstance <server instance> -Name <extension name> -Version <extension name>
   ```

   For example, to recompile all extensions that are not published by Microsoft, you could run the following command:

   ```
   Get-NAVAppInfo -ServerInstance <server instance> | Where-Object {$_.Publisher -notlike 'Microsoft'} |
   Repair-NAVApp
   ```

   Restart the Business Central Server when completed.

Task 7: Synchronize tenant

You'll synchronize the tenant's database schema with any schema changes in the application database and extensions. If you have a multitenant deployment, do these steps for each tenant.

1. (Multitenant only) Mount the tenant to the version 15 server instance.

   To mount the tenant, use the Mount-NAVTenant cmdlet:

   ```
   Mount-NAVTenant -ServerInstance <server instance name> -DatabaseName <database name> -DatabaseServer
   <database server>\<database instance> -Tenant <tenant ID> -AllowAppDatabaseWrite
   ```

   IMPORTANT

   You must use the same tenant ID for the tenant that was used in the old deployment; otherwise you'll get an error when mounting or syncing the tenant. If you want to use a different ID for the tenant, you can either use the `-AlternateId` parameter now or after upgrading, dismount the tenant, then mount it again using the new ID and the `OverwriteTenantIdInDatabase` parameter.

   NOTE

   For upgrade, we recommend that you use the `-AllowAppDatabaseWrite` parameter. After upgrade, you can dismount and mount the tenant again without the parameter if needed.

   At this stage, the tenant state is OperationalWithSyncPending.

2. Synchronize the tenant with the application database.

   Use the Sync-NAVTenant cmdlet:

   ```
   Sync-NAVTenant -ServerInstance <server instance name> -Mode Sync -Tenant <tenant ID>
   ```

   With a single-tenant deployment, you can omit the `-Tenant` parameter and value.

3. Synchronize the tenant with the **System Application** extension.

   Use the Sync-NAVApp cmdlet:

   ```
   Sync-NAVApp -ServerInstance <server instance name> -Tenant <tenant ID> -Name "System Application" -
   Version <extension version>
   ```

   Replace `<extension version>` with the exact version of the published System Application. To get the version, you can use the Get-NAVAppInfo cmdlet.

4. Synchronize the tenant with the Business Central Base Application extension.

   ```
   Sync-NAVApp -ServerInstance <server instance name> -Tenant <tenant ID> -Name "Base Application" -
   Version <extension version>
   ```

   Replace `<extension version>` with the exact version of the published Base Application.

5. Synchronize the tenant with the Application extension.

   ```
   Sync-NAVApp -ServerInstance <server instance name> -Tenant <tenant ID> -Name "Application"
   ```

6. Synchronize the tenant with Microsoft and 3rd-party extensions.

   For each extension, run the Sync-NAVApp cmdlet:

```
Sync-NAVApp -ServerInstance <server instance name> -Tenant default -Name "<extension name>" -Version
<extension version>
```

Task 8: Upgrade data

In this task, you run a data upgrade for extensions.

Single tenant

Run the data upgrade on extensions in order of dependency.

1. Run the data upgrade for the system application, followed by the base application.

   To run the data upgrade, use the Start-NavDataUpgrade cmdlet:

   ```
   Start-NAVAppDataUpgrade -ServerInstance <server instance name> -Name "<extension name>" -Version
   <extension version>
   ```

   This step will automatically install the new system application and base application versions on the tenant.

2. Upgrade the new versions of Microsoft extensions and third-party extensions.

   Complete this task to upgrade any Microsoft and third-party extension used in the old deployment to new versions on the installation media. The new versions are in the **Application** folder of the DVD. There's a folder for each extension. The extension package (.app file) is in the **Source** folder.

   a. Install **Application** extension (when comping from 15.2 and earlier only).

      You'll have to install the **Application** extension first, otherwise you can't upgrade Microsoft extensions.

      ```
      Install-NAVApp -ServerInstance <server instance name> -Tenant <tenant ID> -Name "Application"
      ```

   b. For each extension, run Start-NAVAppDataUpgrade cmdlet.

      This step will also automatically install the new extension version on the tenant.

Multitenant

On each tenant, run the Start-NavDataUpgrade cmdlet as follows:

```
Start-NAVDataUpgrade -ServerInstance <server instance name> -Tenant <tenant ID> -FunctionExecutionMode
Serial -SkipAppVersionCheck
```

This command will upgrade and install the extensions on the tenant.

Task 9: Install 3rd-party extensions

Complete this task to install third-party extensions for which a new version wasn't published. For each extension, run the Install-NAVApp cmdlet:

```
Install-NAVApp -ServerInstance <server instance name> -Name <extension name> -Version <extension version>
```

Task 10: Upgrade control add-ins

The Business Central Server installation includes new versions of the Microsoft-provided Javascript-based control add-ins, like Microsoft.Dynamics.Nav.Client.BusinessChart, Microsoft.Dynamics.Nav.Client.VideoPlayer, and more. If your solution uses any of these control add-ins, upgrade them to the latest version.

To upgrade the control add-ins from the client, do the following steps:

1. Open the Business Central client.
2. Search for and open the **Control Add-ins** page.
3. Choose **Actions** > **Control Add-in Resource** > **Import**.
4. Locate and select the .zip file for the control add-in and choose **Open**.

   The .zip files are located in the **Add-ins** folder of the Business Central Server installation. There's a subfolder for each add-in. For example, the path to the Business Chart control add-in is

   ```
   C:\Program Files\Microsoft Dynamics 365 Business Central\170\Service\Add-ins\BusinessChart\Microsoft.Dynamics.Nav.Client.BusinessChart.zip
   ```

   .
5. After you've imported all the new control add-in versions, restart Business Central Server instance.

Alternatively, you can use the Set-NAVAddin cmdlet of the Business Central Administration Shell. For example, the following commands update the control add-ins installed by default. Modify the commands to suit:

```
$InstanceName = 'BC170'
$ServicesAddinsFolder = 'C:\Program Files\Microsoft Dynamics 365 Business Central\170\Service\Add-ins'
Set-NAVAddIn -ServerInstance $InstanceName -AddinName 'Microsoft.Dynamics.Nav.Client.BusinessChart' -
PublicKeyToken 31bf3856ad364e35 -ResourceFile ($AppName = Join-Path $ServicesAddinsFolder
'BusinessChart\Microsoft.Dynamics.Nav.Client.BusinessChart.zip')
Set-NAVAddIn -ServerInstance $InstanceName -AddinName 'Microsoft.Dynamics.Nav.Client.FlowIntegration' -
PublicKeyToken 31bf3856ad364e35 -ResourceFile ($AppName = Join-Path $ServicesAddinsFolder
'FlowIntegration\Microsoft.Dynamics.Nav.Client.FlowIntegration.zip')
Set-NAVAddIn -ServerInstance $InstanceName -AddinName 'Microsoft.Dynamics.Nav.Client.OAuthIntegration' -
PublicKeyToken 31bf3856ad364e35 -ResourceFile ($AppName = Join-Path $ServicesAddinsFolder
'OAuthIntegration\Microsoft.Dynamics.Nav.Client.OAuthIntegration.zip')
Set-NAVAddIn -ServerInstance $InstanceName -AddinName 'Microsoft.Dynamics.Nav.Client.PageReady' -
PublicKeyToken 31bf3856ad364e35 -ResourceFile ($AppName = Join-Path $ServicesAddinsFolder
'PageReady\Microsoft.Dynamics.Nav.Client.PageReady.zip')
Set-NAVAddIn -ServerInstance $InstanceName -AddinName 'Microsoft.Dynamics.Nav.Client.PowerBIManagement' -
PublicKeyToken 31bf3856ad364e35 -ResourceFile ($AppName = Join-Path $ServicesAddinsFolder
'PowerBIManagement\Microsoft.Dynamics.Nav.Client.PowerBIManagement.zip')
Set-NAVAddIn -ServerInstance $InstanceName -AddinName 'Microsoft.Dynamics.Nav.Client.RoleCenterSelector' -
PublicKeyToken 31bf3856ad364e35 -ResourceFile ($AppName = Join-Path $ServicesAddinsFolder
'RoleCenterSelector\Microsoft.Dynamics.Nav.Client.RoleCenterSelector.zip')
Set-NAVAddIn -ServerInstance $InstanceName -AddinName 'Microsoft.Dynamics.Nav.Client.SatisfactionSurvey' -
PublicKeyToken 31bf3856ad364e35 -ResourceFile ($AppName = Join-Path $ServicesAddinsFolder
'SatisfactionSurvey\Microsoft.Dynamics.Nav.Client.SatisfactionSurvey.zip')
Set-NAVAddIn -ServerInstance $InstanceName -AddinName 'Microsoft.Dynamics.Nav.Client.SocialListening' -
PublicKeyToken 31bf3856ad364e35 -ResourceFile ($AppName = Join-Path $ServicesAddinsFolder
'SocialListening\Microsoft.Dynamics.Nav.Client.SocialListening.zip')
Set-NAVAddIn -ServerInstance $InstanceName -AddinName 'Microsoft.Dynamics.Nav.Client.VideoPlayer' -
PublicKeyToken 31bf3856ad364e35 -ResourceFile ($AppName = Join-Path $ServicesAddinsFolder
'VideoPlayer\Microsoft.Dynamics.Nav.Client.VideoPlayer.zip')
Set-NAVAddIn -ServerInstance $InstanceName -AddinName 'Microsoft.Dynamics.Nav.Client.WebPageViewer' -
PublicKeyToken 31bf3856ad364e35 -ResourceFile ($AppName = Join-Path $ServicesAddinsFolder
'WebPageViewer\Microsoft.Dynamics.Nav.Client.WebPageViewer.zip')
Set-NAVAddIn -ServerInstance $InstanceName -AddinName 'Microsoft.Dynamics.Nav.Client.WelcomeWizard' -
PublicKeyToken 31bf3856ad364e35 -ResourceFile ($AppName = Join-Path $ServicesAddinsFolder
'WelcomeWizard\Microsoft.Dynamics.Nav.Client.WelcomeWizard.zip')
```

At this point, the upgrade is complete, and you can open the client.

Post-upgrade tasks

1. Enable task scheduler on the server instance.

2. (Multitenant only) For tenants other than the tenant that you use for administration purposes, if you mounted the tenants using the `-AllowAppDatabaseWrite` parameter, dismount the tenants, then mount them again without using the `-AllowAppDatabaseWrite` parameter.

3. If you want to use data encryption as before, enable it.

   For more information, see Managing Encryption and Encryption Keys.

   Optionally, if you exported the encryption key instead of disabling encryption earlier, import the encryption key file to enable encryption.

4. Change application version.

   (Optional) This task isn't required for installing the update. However, it might be useful for support purposes and answering a common question about the application version.

   On the **Help and Support** page in the client, you'll see an application version, such as 15.0.2345.6. For an explanation of the number, see Version numbers in Business Central. This version isn't updated automatically when you install an update. If you want the version to reflect the version of the update or your own version, you change it manually.

   We recommend setting the value to application build number for the version 17 update. You get the number from the Released Updates for Microsoft Dynamics 365 Business Central 2020 Release Wave 2 on-premises.

   a. Run the Set-NAVApplication cmdlet:

   ```
   Set-NAVApplication -ServerInstance <server instance name> -ApplicationVersion <new application
   version> -Force
   ```

   For example:

   ```
   Set-NAVApplication -ServerInstance BC170 -ApplicationVersion 17.0.38071.0 -Force
   ```

   b. Run the Sync-NAVTenant cmdlet to synchronize the tenant with the application database.

   ```
   Sync-NAVTenant -ServerInstance <server instance name> -Mode Sync -Tenant <tenant ID>
   ```

   With a single-tenant deployment, you can omit the `-Tenant` parameter and value.

   c. Run the Start-NavDataUpgrade cmdlet to change the version number:

   ```
   Start-NAVDataUpgrade -ServerInstance <server instance name> -FunctionExecutionMode Serial -Tenant
   <tenant ID>
   ```

5. Grant users permission to the *Open in Excel* and *Edit in Excel* actions.

   Version 17 introduces a system permission that protects these two actions. The permission is granted by the system object **6110 Allow Action Export To Excel**. Because of this change, users who had permission to these actions before upgrading, will lose permission. To grant permission again, do one of the following steps:

- Assign the **EXCEL EXPORT ACTION** permission set to appropriate users.
- Add the system object **6110 Allow Action Export To Excel** permission directly to appropriate permission sets.

For more information about working with permission sets and permissions, see Export and Import Permission Sets.

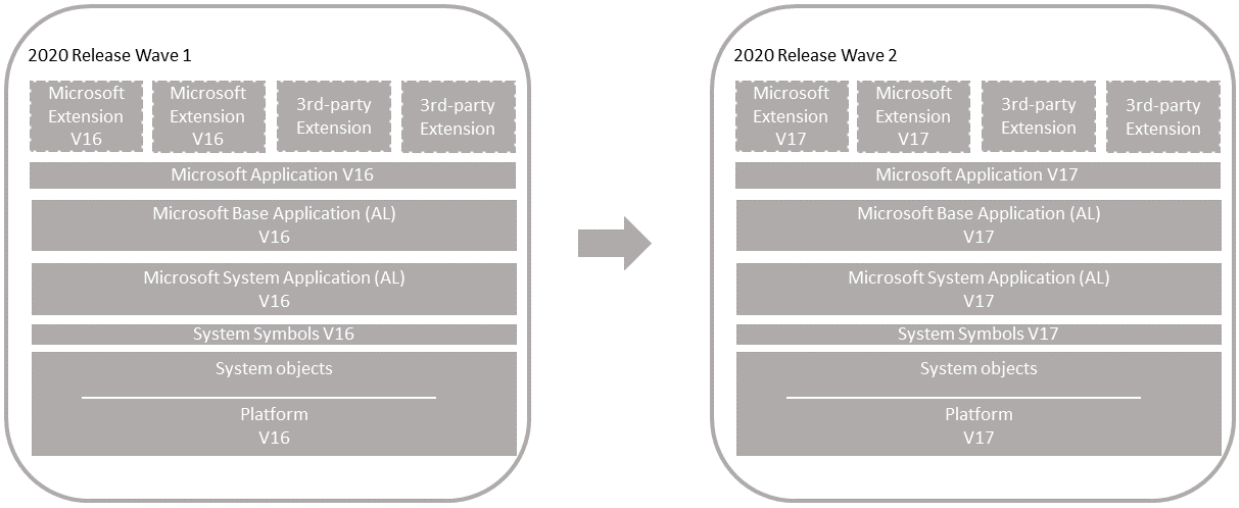
Upgrading Extensions

Upgrading Version 16 Microsoft System and Base Application to Version 17

2/17/2021 • 12 minutes to read • Edit Online

Use this scenario if you have a Business Central 2020 release wave 1 solution that uses the Microsoft System and Base applications.



Single-tenant and multitenant deployments

The process for upgrading the similar for a single-tenant and multitenant deployment. However, there are some inherent differences. With a single-tenant deployment, the application code and business data are in the same database. In a multitenant deployment, application code is in a separate database (the application database) than the business data (tenant). In the procedures that follow, for a single-tenant deployment, consider references to the *application database* and *tenant database* as the same database. Steps are marked as *Single-tenant only* or *Multitenant only* where applicable.

Prerequisites

1. Your version 16 is compatible with version 17.

   There are several updates for version 16. The updates have a compatible version 17 update. For more information, see Dynamics 365 Business Central Upgrade Compatibility Matrix. For example, if your solution is currently running 16.6, you can't upgrade to 17.0. You must wait until 17.1 is available.

2. Disable data encryption.

   If the current server instance uses data encryption, disable it. You can enable it again after upgrading.

   For more information, see Managing Encryption and Encryption Keys.

   Instead of disabling encryption, you can export the current encryption key, which you'll then import after upgrade. However, we recommend disabling encryption before upgrading.

Task 1: Prepare version 16 databases

1. Make backup of the databases.

2. Start Business Central Administration Shell for version 16 as an administrator.

3. (Single-tenant only) Uninstall all extensions from the old tenants.

   In this step, you uninstall the Base Application, System Application (if used), and any other extensions that are currently installed on the database.

   a. Get a list of installed extensions.

      This step is optional, but it can be useful to the names and versions of the extensions.

      To get a list of installed extensions, use the Get-NAVAppInfo cmdlet.

      ```
      Get-NAVAppInfo -ServerInstance <server instance name> -Tenant <tenant ID>
      ```

      For a single-tenant deployment, set the `<tenant ID>` to default.

   b. Uninstall the extensions.

      To uninstall an extension, you use the Uninstall-NAVApp cmdlet.

      ```
      Uninstall-NAVApp -ServerInstance <server instance name> -Name <extensions name> -Tenant
      <tenant ID> -Version <extension version> -Force
      ```

      Replace `<extension name>` and `<extension version>` with the exact name and version the published System Application.

      For example, together with the Get-NAVApp cmdlet, you can uninstall all extensions with a single command:

      ```
      Get-NAVAppInfo -ServerInstance <server instance name> -Tenant <tenant ID>| % { Uninstall-
      NAVApp -ServerInstance <server instance name> -Tenant <tenant ID> -Name $_.Name -Version
      $_.Version -Force}
      ```

4. Unpublish all system symbols.

   To unpublish symbols, use the Unpublish-NAVAPP cmdlet with the `-SymbolsOnly` switch.

   ```
   Get-NAVAppInfo -ServerInstance <BC15 server instance> -SymbolsOnly | % { Unpublish-NAVApp -
   ServerInstance <BC15 server instance> -Name $_.Name -Version $_.Version }
   ```

   What are symbols?

5. (Multitenant only) Dismount the tenants from the application server instance.

   To dismount a tenant, use the Dismount-NAVTenant cmdlet:

   ```
   Dismount-NAVTenant -ServerInstance <server instance name> -Tenant <tenant ID>
   ```

6. Stop the server instance.

   ```
   Stop-NAVServerInstance -ServerInstance <server instance name>
   ```

Task 2: Install version 17

1. Download the latest available update for Business Central 2020 (version 17) that is compatible with your

version 16.

For more information, see Dynamics 365 Business Central Upgrade Compatibility Matrix.

2. Before you install version 17, it can be useful to create desktop shortcuts to the version 16.0 tools, such as the Business Central Server Administration tool, Business Central Administration Shell, and Dynamics NAV Development Shell because the Start menu items for these tools will be replaced with the version 16 tools.

3. Install Business Central version 17 components.

   You can keep version 16 installed to complete some steps in the upgrade process. When you install version 17, you must either specify different port numbers for components (like the Business Central Server instance and web services) or you must stop the version 16.0 Business Central Server instance before you run the installation. Otherwise, you'll get an error that the Business Central Server failed to install.

   For more information, see Installing Business Central Using Setup.

Task 3: Convert version 16 database

This task runs a technical upgrade on the application database to convert it from the version 16 platform to the version 17 platform. The conversion updates the system tables of the database to the new schema (data structure). It provides the latest platform features and performance enhancements.

1. Start Business Central Administration Shell for version 17 as an administrator.

2. Run the Invoke-NAVApplicationDatabaseConversion cmdlet to start the conversion:

   ```
   Invoke-NAVApplicationDatabaseConversion -DatabaseServer <database server name>\<database server
   instance> -DatabaseName "<database name>"
   ```

   When completed, a message like the following displays in the console:

   ```
   DatabaseServer      : .\BCDEMO
   DatabaseName        : Demo Database BC (16-0)
   DatabaseCredentials :
   DatabaseLocation    :
   Collation           :
   ```

Task 4: Configure version 17 server

When you installed version 17 in **Task 2**, a version 17 Business Central Server instance was created. In this task, you change server configuration settings that are required to complete the upgrade. Some of the changes are only required for version 16 to version 17 upgrade and can be reverted after you complete the upgrade.

1. Set the server instance to connect to the application database.

   ```
   Set-NAVServerConfiguration -ServerInstance <server instance name> -KeyName DatabaseName -KeyValue "
   <database name>"
   ```

   In a single tenant deployment, this command will mount the tenant automatically. For more information, see Connecting a Server Instance to a Database.

2. Disable task Scheduler on the server instance for purposes of upgrade.

```
Set-NavServerConfiguration -ServerInstance <server instance name> -KeyName "EnableTaskScheduler" -
KeyValue false
```

Be sure to re-enable task scheduler after upgrade if needed.

3. Restart the server instance.

```
Restart-NAVServerInstance -ServerInstance <server instance name>
```

Task 5: Import version 17 license

1. Use the Import-NAVServerLicense to upload the version 17 license to the database.

```
Import-NAVServerLicense -ServerInstance <server instance name> -LicenseFile <path and file name>
```

2. Restart the server instance.

```
Restart-NAVServerInstance -ServerInstance <server instance name>
```

Task 6: Publish symbols and extensions

In this task, you'll publish the platform symbols and extensions. As minimum, you publish the new base application and system application extensions from the installation media (DVD). You also publish new versions of any Microsoft extensions and third-party extensions that were used on your old deployment.

Publishing an extension adds the extension to the application database that is mounted on the server instance. Once published, it's available for installing on tenants. This task updates internal tables, compiles the components of the extension behind-the-scenes, and builds the necessary metadata objects that are used at runtime.

The steps in this task continue to use the Business Central Administration Shell for version 16 that you started in the previous task.

1. Publish version 17 system symbols extension.

   The symbols extension contains the required platform symbols that the base application depends on. The symbols extension package is called **System.app**. You find it where the **AL Development Environment** is installed. The default path is C:\Program Files (x86)\Microsoft Dynamics 365 Business Central\170\AL Development Environment.

```
Publish-NAVApp -ServerInstance  <server instance name> -Path "<path to system.app>" -PackageType
SymbolsOnly
```

   What are symbols?

2. Publish the **System Application** extension (Microsoft_System Application.app).

   You find the (Microsoft_System Application.app in the **Applications\System Application\Source** folder of installation media (DVD).

```
Publish-NAVApp -ServerInstance <server instance name> -Path "<path to Microsoft_System
Application.app>"
```

What is the System Application?

3. Publish the Business Central base application extension (Microsoft_Base Application.app).

   The **Base Application** extension contains the application business objects. You find the (Microsoft_Base Application.app in the **Applications\BaseApp\Source** folder of installation media (DVD).

   ```
   Publish-NAVApp -ServerInstance <server instance name> -Path "<path to Microsoft_Base
   Application.app>"
   ```

4. Publish the Microsoft_Application extension.

   For more information about this extension, see The Microsoft_Application.app File.

   ```
   Publish-NAVApp -ServerInstance <server instance name> -Path "<path to Microsoft_Application.app>"
   ```

5. Publish the new versions of Microsoft extensions.

   In this step, you publish new versions of Microsoft extensions that were used on your version 16 deployment. You find the extensions in the **Applications** folder of the installation media (DVD).

   ```
   Publish-NAVApp -ServerInstance <server instance name> -Path "<path to Microsoft extension>"
   ```

   For example:

   ```
   Publish-NAVApp -ServerInstance BC170 -Path
   "C:\W1DVD\Applications\SalesAndInventoryForecast\Source\SalesAndInventoryForecast.app"
   ```

6. Publish new versions of 3rd-party extensions.

   If you have new versions of these extensions, built on the Business Central version 17, then publish the new versions.

   ```
   Publish-NAVApp -ServerInstance BC170 -Path "<path to extension>"
   ```

7. Recompile extensions not build on version 17.

   This step pertains to any published extension versions that aren't built on version 16, which you want to reinstall on tenants. These extensions must be recompiled to work with version 16. To recompile the extensions, use the Repair-NAVApp cmdlet:

   ```
   Repair-NAVApp -ServerInstance <server instance> -Name <extension name> -Version <extension name>
   ```

   For example, to recompile all extensions that are not published by Microsoft, you could run the following command:

   ```
   Get-NAVAppInfo -ServerInstance <server instance> | Where-Object {$_.Publisher -notlike 'Microsoft'} |
   Repair-NAVApp
   ```

   Restart the Business Central Server when completed.

Task 7: Synchronize tenant

You'll synchronize the tenant's database schema with any schema changes in the application database and extensions. If you have a multitenant deployment, do these steps for each tenant.

1. (Multitenant only) Mount the tenant to the version 17 server instance.

   To mount the tenant, use the Mount-NAVTenant cmdlet:

   ```
   Mount-NAVTenant -ServerInstance <server instance name> -DatabaseName <database name> -DatabaseServer
   <database server>\<database instance> -Tenant <tenant ID> -AllowAppDatabaseWrite
   ```

   IMPORTANT

   You must use the same tenant ID for the tenant that was used in the old deployment; otherwise you'll get an error when mounting or syncing the tenant. If you want to use a different ID for the tenant, you can either use the `-AlternateId` parameter now or after upgrading, dismount the tenant, then mount it again using the new ID and the `OverwriteTenantIdInDatabase` parameter.

   NOTE

   For upgrade, we recommend that you use the `-AllowAppDatabaseWrite` parameter. After upgrade, you can dismount and mount the tenant again without the parameter if needed.

   At this stage, the tenant state is OperationalWithSyncPending.

2. Synchronize the tenant with the application database.

   Use the Sync-NAVTenant cmdlet:

   ```
   Sync-NAVTenant -ServerInstance <server instance name> -Mode Sync -Tenant <tenant ID>
   ```

   With a single-tenant deployment, you can omit the `-Tenant` parameter and value.

3. Synchronize the tenant with the **System Application** extension.

   Use the Sync-NAVApp cmdlet:

   ```
   Sync-NAVApp -ServerInstance <server instance name> -Tenant <tenant ID> -Name "System Application" -
   Version <extension version>
   ```

   Replace `<extension version>` with the exact version of the published System Application. To get the version, you can use the Get-NAVAppInfo cmdlet.

4. Synchronize the tenant with the Business Central Base Application extension.

   ```
   Sync-NAVApp -ServerInstance <server instance name> -Tenant <tenant ID> -Name "Base Application" -
   Version <extension version>
   ```

   Replace `<extension version>` with the exact version of the published Base Application.

5. Synchronize the tenant with the Application extension.

   ```
   Sync-NAVApp -ServerInstance <server instance name> -Tenant <tenant ID> -Name "Application"
   ```

6. Synchronize the tenant with Microsoft and 3rd-party extensions.

   For each extension, run the Sync-NAVApp cmdlet:

   ```
   Sync-NAVApp -ServerInstance BC150 -Tenant default -Name "<extension name>" -Version <extension
   version>
   ```

Task 8: Upgrade data

In this task, you run a data upgrade for extensions.

Single tenant

Run the data upgrade on extensions in order of dependency.

1. Run the data upgrade for the System Application, followed by the Base Application.

   To run the data upgrade, use the Start-NavDataUpgrade cmdlet:

   ```
   Start-NAVAppDataUpgrade -ServerInstance <server instance name> -Name "<extension name>" -Version
   <extension version>
   ```

   This step will automatically install the new system application and base application versions on the tenant.

2. Upgrade the new versions of Microsoft extensions and third-party extensions.

   Complete this task to upgrade any Microsoft and third-party extension used in the old deployment to new versions on the installation media. The new versions are in the **Application** folder of the DVD. There's a folder for each extension. The extension package (.app file) is in the **Source** folder.

   For each extension, run Start-NAVAppDataUpgrade cmdlet. First, run the data upgrade for the Application extension, then run it for other Microsoft extensions and third-party extensions.

   This step will also automatically install the new extension version on the tenant.

Multitenant

On each tenant, run the Start-NavDataUpgrade cmdlet as follows:

```
Start-NAVDataUpgrade -ServerInstance <server instance name> -Tenant <tenant ID> -FunctionExecutionMode
Serial -SkipAppVersionCheck
```

This command will upgrade and install the extensions on the tenant.

Task 9: Install 3rd-party extensions

Complete this task to install third-party extensions for which a new version wasn't published. For each extension, run the Install-NAVApp cmdlet:

```
Install-NAVApp -ServerInstance <server instance name> -Name <extension name> -Version <extension version>
```

Task 10: Upgrade control add-ins

The Business Central Server installation includes new versions of the Microsoft-provided Javascript-based control add-ins, like Microsoft.Dynamics.Nav.Client.BusinessChart, Microsoft.Dynamics.Nav.Client.VideoPlayer, and more. If your solution uses any of these control add-ins, upgrade them to the latest version.

To upgrade the control add-ins from the client, do the following steps:

1. Open the Business Central client.
2. Search for and open the **Control Add-ins** page.
3. Choose **Actions** > **Control Add-in Resource** > **Import**.
4. Locate and select the .zip file for the control add-in and choose **Open**.

   The .zip files are located in the **Add-ins** folder of the Business Central Server installation. There's a subfolder for each add-in. For example, the path to the Business Chart control add-in is

   ```
   C:\Program Files\Microsoft Dynamics 365 Business Central\160\Service\Add-ins\BusinessChart\Microsoft.Dynamics.Nav.Client.BusinessChart.zip
   ```

   .
5. After you've imported all the new control add-in versions, restart Business Central Server instance.

Alternatively, you can use the Set-NAVAddin cmdlet of the Business Central Administration Shell. For example, the following commands update the control add-ins installed by default. Modify the commands to suit:

```
$InstanceName = 'BC170'
$ServicesAddinsFolder = 'C:\Program Files\Microsoft Dynamics 365 Business Central\170\Service\Add-ins'
Set-NAVAddIn -ServerInstance $InstanceName -AddinName 'Microsoft.Dynamics.Nav.Client.BusinessChart' -
PublicKeyToken 31bf3856ad364e35 -ResourceFile ($AppName = Join-Path $ServicesAddinsFolder
'BusinessChart\Microsoft.Dynamics.Nav.Client.BusinessChart.zip')
Set-NAVAddIn -ServerInstance $InstanceName -AddinName 'Microsoft.Dynamics.Nav.Client.FlowIntegration' -
PublicKeyToken 31bf3856ad364e35 -ResourceFile ($AppName = Join-Path $ServicesAddinsFolder
'FlowIntegration\Microsoft.Dynamics.Nav.Client.FlowIntegration.zip')
Set-NAVAddIn -ServerInstance $InstanceName -AddinName 'Microsoft.Dynamics.Nav.Client.OAuthIntegration' -
PublicKeyToken 31bf3856ad364e35 -ResourceFile ($AppName = Join-Path $ServicesAddinsFolder
'OAuthIntegration\Microsoft.Dynamics.Nav.Client.OAuthIntegration.zip')
Set-NAVAddIn -ServerInstance $InstanceName -AddinName 'Microsoft.Dynamics.Nav.Client.PageReady' -
PublicKeyToken 31bf3856ad364e35 -ResourceFile ($AppName = Join-Path $ServicesAddinsFolder
'PageReady\Microsoft.Dynamics.Nav.Client.PageReady.zip')
Set-NAVAddIn -ServerInstance $InstanceName -AddinName 'Microsoft.Dynamics.Nav.Client.PowerBIManagement' -
PublicKeyToken 31bf3856ad364e35 -ResourceFile ($AppName = Join-Path $ServicesAddinsFolder
'PowerBIManagement\Microsoft.Dynamics.Nav.Client.PowerBIManagement.zip')
Set-NAVAddIn -ServerInstance $InstanceName -AddinName 'Microsoft.Dynamics.Nav.Client.RoleCenterSelector' -
PublicKeyToken 31bf3856ad364e35 -ResourceFile ($AppName = Join-Path $ServicesAddinsFolder
'RoleCenterSelector\Microsoft.Dynamics.Nav.Client.RoleCenterSelector.zip')
Set-NAVAddIn -ServerInstance $InstanceName -AddinName 'Microsoft.Dynamics.Nav.Client.SatisfactionSurvey' -
PublicKeyToken 31bf3856ad364e35 -ResourceFile ($AppName = Join-Path $ServicesAddinsFolder
'SatisfactionSurvey\Microsoft.Dynamics.Nav.Client.SatisfactionSurvey.zip')
Set-NAVAddIn -ServerInstance $InstanceName -AddinName 'Microsoft.Dynamics.Nav.Client.SocialListening' -
PublicKeyToken 31bf3856ad364e35 -ResourceFile ($AppName = Join-Path $ServicesAddinsFolder
'SocialListening\Microsoft.Dynamics.Nav.Client.SocialListening.zip')
Set-NAVAddIn -ServerInstance $InstanceName -AddinName 'Microsoft.Dynamics.Nav.Client.VideoPlayer' -
PublicKeyToken 31bf3856ad364e35 -ResourceFile ($AppName = Join-Path $ServicesAddinsFolder
'VideoPlayer\Microsoft.Dynamics.Nav.Client.VideoPlayer.zip')
Set-NAVAddIn -ServerInstance $InstanceName -AddinName 'Microsoft.Dynamics.Nav.Client.WebPageViewer' -
PublicKeyToken 31bf3856ad364e35 -ResourceFile ($AppName = Join-Path $ServicesAddinsFolder
'WebPageViewer\Microsoft.Dynamics.Nav.Client.WebPageViewer.zip')
Set-NAVAddIn -ServerInstance $InstanceName -AddinName 'Microsoft.Dynamics.Nav.Client.WelcomeWizard' -
PublicKeyToken 31bf3856ad364e35 -ResourceFile ($AppName = Join-Path $ServicesAddinsFolder
'WelcomeWizard\Microsoft.Dynamics.Nav.Client.WelcomeWizard.zip')
```

At this point, the upgrade is complete, and you can open the client.

Post-upgrade tasks

1. Enable task scheduler on the server instance.
2. (Multitenant only) For tenants other than the tenant that you use for administration purposes, if you

mounted the tenants using the `-AllowAppDatabaseWrite` parameter, dismount the tenants, then mount them again without using the `-AllowAppDatabaseWrite` parameter.

3. If you want to use data encryption as before, enable it.

   For more information, see Managing Encryption and Encryption Keys.

   Optionally, if you exported the encryption key instead of disabling encryption earlier, import the encryption key file to enable encryption.

4. Change application version.

   (Optional) This task isn't required for installing the update. However, it might be useful for support purposes and answering a common question about the application version.

   On the **Help and Support** page in the client, you'll see an application version, such as 16.0.2345.6. For an explanation of the number, see Version numbers in Business Central. This version isn't updated automatically when you install an update. If you want the version to reflect the version of the update or your own version, you change it manually.

   We recommend setting the value to application build number for the version 17 update. You get the number from the Released Updates for Microsoft Dynamics 365 Business Central 2020 Release Wave 2 on-premises.

   a. Run the Set-NAVApplication cmdlet:

   ```
   Set-NAVApplication -ServerInstance <server instance name> -ApplicationVersion <new application
   version> -Force
   ```

   For example:

   ```
   Set-NAVApplication -ServerInstance BC160 -ApplicationVersion 16.0.38071.0 -Force
   ```

   b. Run the Sync-NAVTenant cmdlet to synchronize the tenant with the application database.

   ```
   Sync-NAVTenant -ServerInstance <server instance name> -Mode Sync -Tenant <tenant ID>
   ```

   With a single-tenant deployment, you can omit the `-Tenant` parameter and value.

   c. Run the Start-NavDataUpgrade cmdlet to change the version number:

   ```
   Start-NAVDataUpgrade -ServerInstance <server instance name> -FunctionExecutionMode Serial -Tenant
   <tenant ID>
   ```

Code Conversion from C/AL to AL

2/17/2021 • 11 minutes to read • Edit Online

This article explains how to convert a Business Central (version 14) C/AL code-customized on-premises solution to AL code.

You'll use this procedure as part of the upgrade process when going from version 14 to a later version, like 15, 16, or 17.

Before you start

Get familiar with the basics of setting up and developing in Visual Studio Code and AL, see Developing Extensions in AL.

> **NOTE**
> Moving on-premise C/AL code customizations to Dynamics 365 Business Central online, requires converting these to AL extensions. This could include converting the C/AL deltas to AL extension code as a starting point, as outlined in The Txt2Al Conversion Tool.

Also, review the Known Issues for information about issues that may affect the upgrade.

Breaking changes

When converting from C/AL to AL, it's important that you don't introduce any breaking schema changes to the database. Otherwise, you won't be able to synchronize the new extension with the database.

Task 1: Import the test library into your C/AL solution

If your solution uses Microsoft (1st-party) extensions, you'll have to convert the test library from C/AL to AL. The reason for this is that the Microsoft extensions rely on the test symbols. The easiest way is to import the **CALTestLibraries.W1.fob** file into the old database. This file is available on the version 14 installation media (DVD) in the **TestToolKit** folder.

You can do this using the (Dynamics NAV Development Environment). For more information, see Exporting and Importing Objects.

Task 2: Compile all the objects in your C/AL solution

Compiling all the objects is a prerequisite for a successful and complete export. To compile objects, you can use either of the following tools:

- C/SIDE (Dynamics NAV Development Environment). See Compiling Objects.
- Compile-NAVApplicationObject cmdlet of the Dynamics NAV Development Shell. Make sure to run this cmdlet as an administrator.

Task 3: Export the application objects to the new TXT syntax

Once the application compiles, you must export all C/AL application objects, except system tables and codeunits (IDs in the 2000000000 range), to the new TXT format. The exported objects will be used as input to the Txt2AL conversion tool. To export objects, use the Export-NAVApplicationObject cmdlet of the Dynamics NAV Development Shell. it's important to:

- Omit omit all system objects, which have IDs in the 2000000000 range.
- Use the `ExportToNewSyntax` switch to export the objects in a syntax that is compatible with the Txt2Al conversion tool.

The Export-NAVApplicationObject cmdlet will export all objects to a single .txt file. If you imported the test library objects into the database, then you'll export the base application objects and the test library separately. Later, you'll create a separate AL project for each set of files.

For example, do the following steps:

1. Export the custom base application objects.
   a. Create a folder for storing the exported base application objects to TXT files (for example, c:\export2al\baseapplication).
   b. Run the following commands to export tha application objects, but omitting the system objects and test library objects.

```
Export-NAVApplicationObject -DatabaseServer .\BCDEMO -DatabaseName "Demo Database BC (14-0)" -
ExportToNewSyntax -Path "c:\export2al\baseapplication\exportedbc14app-part1.txt" -Filter
'Id=1..129999'
```

```
Export-NAVApplicationObject -DatabaseServer .\BCDEMO -DatabaseName "Demo Database BC (14-0)" -
ExportToNewSyntax -Path "c:\export2al\baseapplication\exportedbc14app-part2.txt" -Filter
'Id=140000..1999999999'
```

```
Export-NAVApplicationObject -DatabaseServer .\BCDEMO -DatabaseName "Demo Database BC (14-0)" -
ExportToNewSyntax -Path "c:\export2al\baseapplication\exportedbc14testobjects.txt" -Filter
'Id=130400..130416'
```

2. Export the test library objects.
   a. Create a folder for storing the exported test library objects to TXT files (for example, c:\export2al\testlibrary).
   b. Run the following commands to export the test library objects only

```
Export-NAVApplicationObject -DatabaseServer .\BCDEMO -DatabaseName "Demo Database BC (14-0)" -
ExportToNewSyntax -Path "c:\export2al\testlibrary\bc14testlibrary-part1.txt" -Filter
'Id=130000..130399'
```

```
Export-NAVApplicationObject -DatabaseServer .\BCDEMO -DatabaseName "Demo Database BC (14-0)" -
ExportToNewSyntax -Path "c:\export2al\testlibrary\bc14testlibrary-part2.txt" -Filter
'Id=130440..139999'
```

Task 4: Create a declaration file for custom .NET assemblies (optional)

If your solution contains .NET interoperability code and control add-ins, you can create a file that contains the declarations to the assemblies. This file will be used when you convert the C/AL TXT files to AL in the next step. Alternatively, after the conversion, you'll have to manually add the declarations to objects that use the assemblies.

To create the file, use a text editor or Visual Studio code to create a file that contains the assembly declarations as follows:

```
dotnet

{
    assembly("Microsoft.Dynamics.Nav.Client.BusinessChart")
    {

type("Microsoft.Dynamics.Nav.Client.BusinessChart.BusinessChartAddIn";"Microsoft.Dynamics.Nav.Client.Busines
sChart")
        {
            IsControlAddIn = true;
        }

        // Other control add-ins in this assembly
    }

    // Other assemblies containing control add ins
}
```

Save the file with any name and the extension **.al**, for example **mydotnet.al**. Make a note of the path because you'll use it in the next step.

Task 5: Convert the C/AL TXT files to AL

With C/AL exported to the new TXT format, you now convert the code to AL using the The Txt2Al Conversion Tool. The Txt2Al creates .al files for each object in the TXT files. Similar to **Task 3**, if you imported the test library objects into the database, then you'll convert the base application objects and the test library separately.

Get the Txt2AL conversion tool

The Txt2Al conversion tool (txt2al.exe) is only available with version 14, which is the last version to support C/AL. Use this version of the tool no matter what later version you may eventually be upgrading to. The AL objects created by the tool will be compatible with later versions.

You find the txt2al.exe on the installation media (DVD) in the "DVD\RoleTailoredClient\program files\Microsoft Dynamics NAV\140\RoleTailored Client" folder. Or, it's installed locally with Dynamics NAV Development Environment, for example, in the "C:\Program Files (x86)\Microsoft Dynamics 365 Business Central\140\RoleTailored Client" folder.

Run the Txt2AL conversion tool

1. Convert the base application TXT files to AL.

   a. Create a folder for storing the AL files for base application objects (for example, c:\export2al\baseapplication\al).

   b. Start a command prompt as administrator, and navigate to the folder that contain txt2al.exe file.

      By default, the location is C:\Program Files (x86)\Microsoft Dynamics 365 Business Central\140\RoleTailored Client.

   c. Run the txt2al command:

      ```
      txt2al --source=C:\export2al\baseapplication --target=C:\export2al\baseapplication\al --
      injectDotNetAddIns --dotNetAddInsPackage=C:\export2al\dotnet\mydotnet.al --dotNetTypePrefix=BC
      --rename
      ```

      If your solution contains .NET interoperability code, the following Txt2Al command line parameters are used to achieve a conversion that requires less manual intervention:

      - `--injectDotNetAddIns` injects the definition of standard .NET add-ins in the resulting .NET

package. The standard .NET add-ins are a set of add-ins that are embedded into the platform.

- `--dotNetAddInsPackage` should be used to point the conversion tool to an AL file containing declarations for the .NET types that represent .NET control addins. Use this to inject a custom set of .NET control add-in declarations. This parameter is only required if you completed **Task 4**, and you set it to point to the location of the dotnet.al file.

  > **NOTE**
  > If you are interested in migrating your localization resources, you should use the `--addLegacyTranslationInfo` switch to instruct Txt2Al to generate information about the legacy IDs of the translation code.

- `--dotNetTypePrefix` specifies a prefix to be used for all .NET type aliases created during the conversion. This will ensure that no naming conflicts occur with existing types. In the example, `BC` is the prefix.

- `--rename` renames the output files to prevent clashes with the source .txt files.

When completed, there will be an .al file for each object.

2. Convert the test library TXT files to AL.

   This is similar to the previous step.

   a. Create a folder for storing the AL files for base application objects (for example, c:\export2al\baseapplication\al).

   b. Run the txt2al command:

   ```
   txt2al --source=C:\export2al\testlibrary --target=C:\export2al\testlibrary\al --
   injectDotNetAddIns --dotNetTypePrefix=BCTest --rename
   ```

   Use a different value for the `--dotNetTypePrefix` than you did for the base application.

Task 6: Create a new application database for development

To build your base application, you'll create a new application database on the Business Central version 15, 16, or 17 platform. This will only be used during development.

1. Start the Business Central Administration Shell for version 16 as an administrator.
2. Run the New-NAVApplicationDatabase cmdlet to create the database. For example:

   ```
   New-NAVApplicationDatabase -DatabaseServer .\BCDEMO -DatabaseName MyDBforupgrade
   ```

3. Connect your Business Central Server instance to the database. See Connecting a Business Central Server Instance to a Database.

   ```
   Set-NAVServerConfiguration -ServerInstance BC -KeyName DatabaseName -KeyValue "MyDBforupgrade"
   ```

4. Restart the server instance.

```
Restart-NAVServerInstance -ServerInstance BC
```

Task 7: Create and build an AL project for custom base application

In this task, you'll create a AL project in Visual Studio code that you'll use for building your custom base application extension based on your converted C/AL application.

1. If you haven't already, install Visual Studio Code and the latest AL Language extension for version 15, 16, or 17 as outlined in Getting Started with AL.

2. Configure Visual Studio Code for optimal performance with AL projects.

   This step is optional, but recommended. For more information, see Optimize Visual Studio Code for Editing and Building.

3. In Visual Studio Code, from the **Command Palette**, select the **AL Go!** command to create a new project.

   Specify the path for the project, and set the **Target Platform** to **4.0 Business Central 2019 release wave 2** or **5.0 Business Central 2020 release wave 1**. When prompted to select your server, choose **Your own server**.

4. Create a **.alpackages** folder in the root folder of the project and then copy the system (platform) symbols extension (System.app file) to the folder.

   The System.app file is located where you installed the AL Development Environment, which by default is the C:\Program Files (x86)\Microsoft Dynamics 365 Business Central<150, 160, or 170>\AL Development Environment folder. This package contains the symbols for all the system tables and codeunits.

5. Delete the **HelloWorld.al** sample file from the project.

6. Modify the `settings.json` file of Visual Studio Code to configure the assembly probing path.

   Change `"al.assemblyProbingPaths": ["./.netpackages"]` to point to all the folders that contain .NET assemblies that are used by your project. Here is an example that contains the most typical paths:

   ```
   "al.assemblyProbingPaths": [
   "C:\\Program Files\\Microsoft Dynamics 365 Business Central\\150",
   "C:\\Program Files (x86)\\Microsoft Dynamics 365 Business Central\\150\\RoleTailored Client",
   "C:\\Program Files (x86)\\Reference Assemblies\\Microsoft\\Framework\\.NETFramework\\v4.7.2",
   "C:\\Program Files (x86)\\Reference Assemblies\\Microsoft\\WindowsPowerShell\\3.0"
   ]
   ```

   For more information about the settings.json, see User and Workspace Settings.

   > **NOTE**
   > Adding assemblies to the folders in your assembly probing paths is not automatically detected by the compiler. You must restart Visual Studio Code for the changes to be detected.

7. Modify the `app.json` for the project as follows:

   - **Important** The ID, name, and publisher, and version of the custom base application must match the Business Central base application. Set the parameters to the following values`:

```
"appId": "437dbf0e-84ff-417a-965d-ed2bb9650972",
"name": "Base Application",
"publisher": "Microsoft",
"version": "14.5.0.0"
```

We recommend that you set the "version" to the same version as the C/AL application.

- Add the setting `"target": "OnPrem"` somewhere in the file.
- Change the `idRange` to include all the IDs used by your base application (or leave blank).
- Delete the values in the `dependencies` parameter.

8. Copy all of the base application AL files generated in the previous task (**Task 5**) to the root folder of your project.
9. Open the **dotnet.al** file for the project, and make the following changes:
   - Delete all instances of `Version = '14.0.0.0';` for **Microsoft.Dynamics.Nav** assembly declarations.
   - For the `DocumentFormat.OpenXml` assembly declaration, remove the `version` and `culture` keys and set `PublicKeyToken = '8fb06cb64d019a17'`.

   ```
   assembly("DocumentFormat.OpenXml")
   {
       PublicKeyToken = '8fb06cb64d019a17';
       ...
   ```
10. Delete objects that are related to the client debugger client.

    Debugging from the client has been discontinued, and replaced by AL Debugger. The version 14 debugger objects are not supported on version 15, 16, or 17. To avoid compilation errors, delete the following objects:

    - Debugger.Page.al
    - DebuggerBreakpointCondition.Page.al
    - DebuggerBreakpointList.Page.al
    - DebuggerCallstackFactBox.Page.al
    - DebuggerCodeViewer.Page.al
    - DebuggerManagement.Codeunit.al
    - DebuggerVariableList.Page.al
    - DebuggerWatchValueFactBox.Page.al
    - SessionList.Page.al

    You might also have to remove references to `SessionList` in ChangeGlobalDimensions.Codeunit.al.
11. Build and compile your project (press Ctrl+Shift+B).

    The AL compiler will issue errors for constructs that are not valid. Fix any errors that occur, and build again.

> **TIP**
> If you are maintaining your C/AL solution going forward, we recommend that you fix errors in C/AL objects and convert to AL again. This makes it future changes easier to foward push changes because code bases will be similar.

When all errors are fixed, the custom base application package (.app) will be created.

Task 8: Create and build an AL project for the test library

If you converted the test library form C/AL to AL, you'll now create and build a project for test library, similar to what you did for the base application.

a. Follow steps 1 through 5 in **Task 7** to create an AL project for the test library.

b. As with base application project, you have to modify the `app.json` file, but in this case, you have to change the version and add a dependency on the base application that you created.

- Set the `"version"` to the old application version, such as `14.5.0.0`.
- Set the `"dependencies"` to include information about your custom the base application.

```
"dependencies": [
{
    "appId": "437dbf0e-84ff-417a-965d-ed2bb9650972",
    "publisher": "Microsoft",
    "name": "Base Application",
    "version": "14.5.0.0"
}
],
```

- Set the `target` to `OnPrem`.
- Change the `idRange` to include all the IDs used by your test application (or leave blank).

c. Copy all of the AL files that you generated for the test library in **Task 5** to the root folder of your project.

d. Open the **dotnet.al** file for the project, and make the following changes:

- Delete all instances of `Version = '14.0.0.0';` for **Microsoft.Dynamics.Nav** assembly declarations.

e. Build the project.

Next Steps

If you are performing a technical upgrade from version 14.0 to version 15, 16, or 17, return to the technical upgrade step where you left off.

- Technical Upgrade to version 15.0
- Technical Upgrade to to version 16.0
- Technical Upgrade to to version 17.0

Developing Extensions

Migrating Tables and Fields Between Extensions

2/17/2021 • 4 minutes to read • Edit Online

INTRODUCED IN: Business Central 2019 Release Wave 2, update 15.3, for on-premises only

Data migration allows you to move table and field data between extensions. The concepts and processes in this article apply to large-scale and small-scale data migrations. A large-scale migration is typically upgrade scenario, like upgrading from Business Central version 14 to version 16. Small-scale migrations are scenarios where you want to move a limited number of objects from one extension to another.

Overview

The move is divided into two phases: development and deployment. However, before you begin, you have to determine the direction of the migration within the dependency graph.

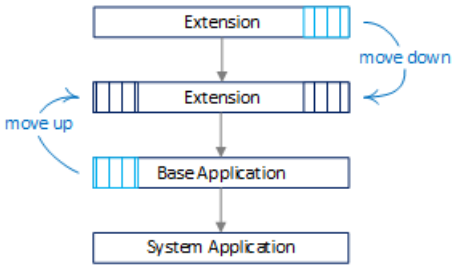
Limitations

- The concepts discussed in this article pertain only to AL. They're not supported in C/AL.
- You can only move fields from a table object to a table extension or move entire tables from one extension to another.
- You can't:
  - Move table extensions to other extensions.
  - Merge multiple table extensions into one extension.
  - Split table extensions into multiple extensions.

  Although you can't use this feature for these scenarios, you can achieve the scenarios by other means, which require more manual work. Examples include obsoleting, copying/re-IDing/renaming, moving data, and more.

Determining the migration direction in the dependency graph

The process to migrate tables and fields to another extension depends on the migration's direction in the dependency graph. The following figure illustrates a simplified extension dependency graph. From top to bottom, an extension is dependent on any extension below it in the graph.



When to move down

Typical move-down scenarios include:

- Moving to a shared extension.

  You want to move common tables to a separate extension that other extensions can have a dependency on.

- Transitioning from a customized base application extension with its own ID to an extension on top of the

Microsoft Base Application.

You have a customized base application extension with its own ID. You want to transition to the Microsoft Base Application. In this case, customizations remain in the current extension. Base objects are removed and ownership transferred to Microsoft Base Application.

This scenario is typical for embed ISV apps and on premises solutions moving to the cloud. It's also relevant for solutions that will remain on-premises for the foreseeable future. Use it to refactor code customizations into cleaner, standard base with extensions as part of upgrading.

For more information, see Moving Tables and Fields to Extension Down the Dependency Graph.

When to move up

Typical move-up scenarios include:

- Splitting an extension in two, with one dependent on the other.
- Extracting the system application from the base application.
- Transitioning from a customized base application extension with Microsoft ID to the Microsoft Base Application.

  You have a customized base application extension that reuses the Microsoft application ID. You want to transition to the standard Microsoft Base Application. In this case, customizations are moved out of the base application up into new extensions. The new extensions have new application IDs and dependencies to the standard Microsoft base application. The customization objects are removed from the custom base application and ownership transferred to the new extensions.

For more information, see Moving Tables and Fields to Extension Up the Dependency Graph.

Development

Development involves making application code changes required for the move. In short, the work involves:

- Creating the *releasing extension* version

  You create a new version of the original extension. This new version contains the tables or fields you want to keep in the extension. The tables and fields that you want to move are deleted from this extension. They're moved to the *receiving extension*.

- Creating the *receiving extension*

  You create new extension that includes the table and fields that you want moved. It essentially includes those tables and fields deleted from the releasing extension.

The key to the move is the *migration.json* file. You add the file to the project for the releasing extension. This file provides a pointer to the ID of new receiving extension where tables and fields are to be moved to. The *migration.json* is used in the deployment phase. Its purpose is to transfer ownership of tables and fields in the database from one extension to another. For more information, see Migration.json File.

Deployment

The deployment phase is when the data is migrated to new tables in the database. In this phase, ownership of tables and fields is switched from one extension to another. Deployment involves publishing, syncing, upgrading, and installing extensions.

The order that you synchronize extensions is important:

- The receiving extensions must be synchronized first.

- The releasing extensions, which include those extensions that include the migration.json file, must be synchronized last.

  These extensions are synchronized last because the tables are moved during the synchronization of the releasing extensions. At the end of the synchronization process, the system checks for breaking changes introduced by the extension. If the extension isn't synchronized last, breaking changes will be detected.

Moving Tables and Fields to Extensions Down the Dependency Graph

2/17/2021 • 3 minutes to read • Edit Online

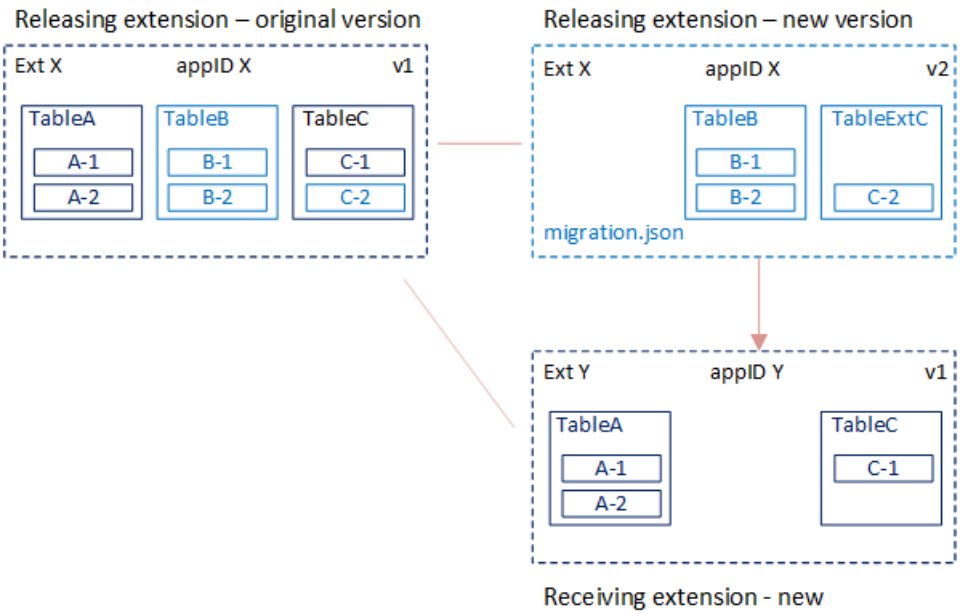
INTRODUCED IN: Business Central 2019 Release Wave 2, update 15.3, for on-premises only

This article explains how to move tables and fields from an extension to another extension that is down the dependency graph.

> **TIP**
> For more information about the general concepts for moving tables and fields between extensions, see Migrating Tables and Fields Between Extensions. This article explains the the difference between moving up and down the dependency graph.

Overview

The steps in this article are based on the example illustrated in the following figure. Although your scenario is different, the concept and process are much the same.



In the example, **TableB** and **Field C-2** are customizations. You'll keep these elements in the original extension, but create a new version without **TableA** and **TableC**. You'll move **TableA** and **TableC** down the dependency chain to a new, separate extension.

Prerequisite

If you're moving enum type fields, then your solution must be running on Business Central 2020 release wave 1, version 16.5 or later. For more information, see Known Issues.

Create receiving extension (Ext Y)

The receiving extension will contain the table and fields that you want to move. In this example, these objects

include **TableA** and **TableC**.

1. Create an AL project for the receiving extension.
2. Add a table object definition for **TableA**.

   The table definition (schema) must include the full schema of the releasing extension **Ext X**, with the same field definitions. You can add new fields.
3. Add a table object definition for **TableC**.

   The table definition (schema) must include the full schema of the releasing extension **Ext X**, with the same field definitions, except don't include field **C-2**. You can add new fields.
4. Make a note of the `ID` of the new extension. You'll use this ID in the next task.

   For purposes of the example, the ID is `11111111-aaaa-2222-bbbb-333333333333`.
5. Compile the extension package.

Create new version of releasing extension (Ext X v2)

1. In the releasing extension AL project, add a migration.json file that points to the ID of the target extension.

   ```
   {
   "apprules": [
       {
           "id": "11111111-aaaa-2222-bbbb-333333333333"
       }
   ]
   }
   ```

   For more information, see The Migration.json File.
2. Modify the app.json file as follows:

   - Ensure that `"target": "OnPrem"`.
   - Increase the `"version"` value.
   - In the `"dependencies"` parameter, set up a dependency on the new receiving extension **Ext Y**.

   For more information, see App.json file.
3. Complete the following steps for **TableC**.

   a. Add a table extension object **TableExtC**.
   b. In table extension object **TableExtC**, add a field definition for field **C-2** that matches its definition in the original **TableC** object.
   c. Delete the original **TableC** object.
4. Delete the entire table object for **TableA**.
5. Compile a new version of the extension package.

Deploy extensions

1. Uninstall the old version of the releasing extension **Ext X**.
2. Publish the new receiving extension **Ext Y** and releasing extension version **Ext X v2**.
3. Synchronize the receiving extension **Ext Y**.

This step creates empty database tables for **TableA** and **TableC** that are owned by the receiving extension **Ext Y**.

> **IMPORTANT**
>
> The receiving extension must always be synchronized first.

4. Synchronize the new version of the releasing extension **Ext X v2**.

   This step first reads rules in the migration.json file of the extension, then does the following operations in the database:

   - Creates a companion table for field **C-2** of the table extension object **TableExtC**.
   - Copies data from column **C-2** in the original **TableC** to new companion table **TableExtC**.
   - Temporarily renames the new empty tables **TableA** and **TableC** made by receiving extension **Ext Y**.
   - Renames the original tables **TableA** and **TableC** that include the data. Instead of including the ID of the releasing extension **Ext X**, the names are changed to include the ID of the receiving extension **Ext Y**. This step essentially transfers ownership from **Ext X** to **Ext Y**.
   - Deletes the unused column for **C-2** in the original table **TableC**.
   - Deletes the empty, renamed tables of **Ext Y**.
5. Install the receiving extension **Ext Y**.
6. Run Start-NAVAppDataUpgrade cmdlet on the new releasing extension version **Ext X v2**.

   This step basically installs the new extension version. You run a data upgrade because an earlier version has been installed and is still published.

Moving Tables and Fields to Extensions Up the Dependency Graph

2/17/2021 • 5 minutes to read • Edit Online

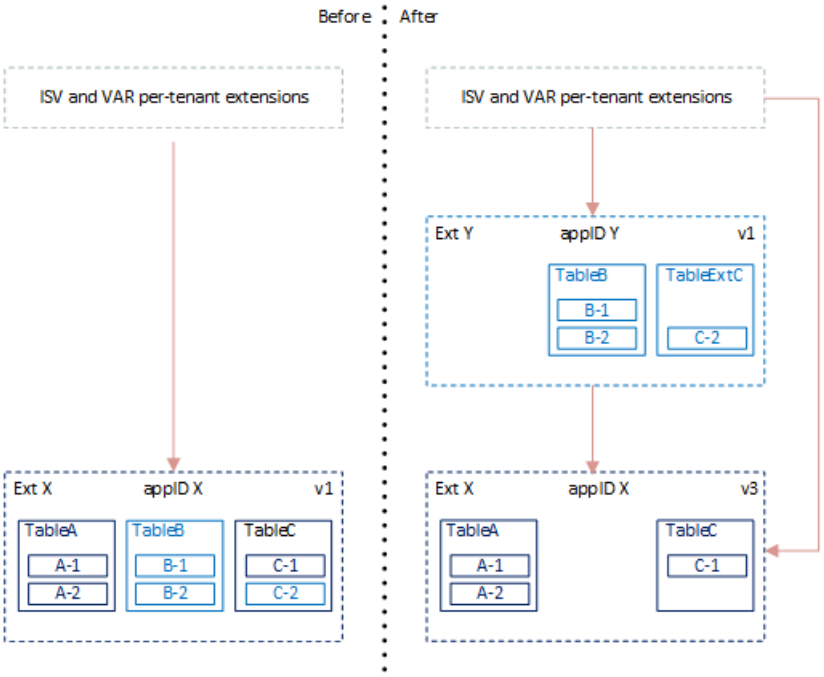
INTRODUCED IN: Business Central 2019 Release Wave 2, update 15.3, for on-premises only

This article explains how to move tables and fields from an extension to another extension that is up the dependency graph.

> **TIP**
> For more information about the general concepts for moving tables and fields between extensions, see Migrating Tables and Fields Between Extensions. This article explains the the difference between moving up and down the dependency graph.

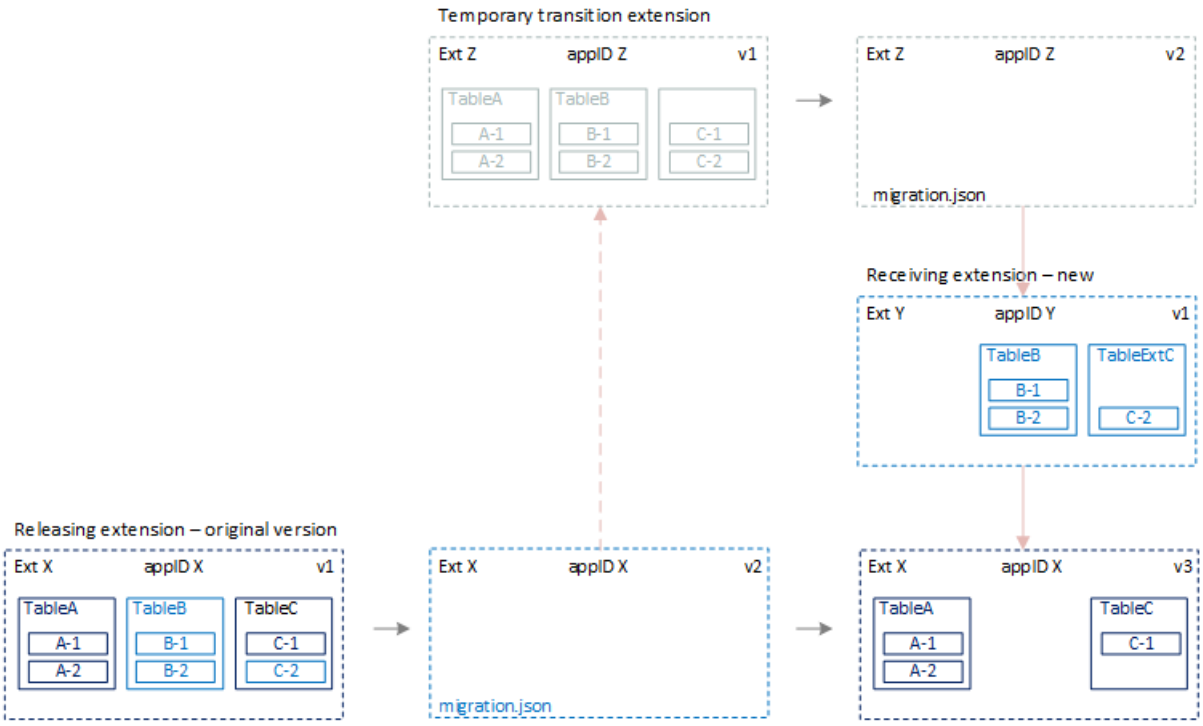
Overview

The steps are based on the example illustrated in the following figure. Although your scenario is different, the concept and process are much the same.



In the example, **TableB** and **Field C-2** are customizations. You'll move these elements from the original extension up to a new extension. This new extension will have a dependency on the original extension. You'll keep **TableA** and **TableC** in the original extension.

To accommodate data migration, you'll have to create an extension that is only used for deployment. This extension is **Ext Z** in the figure. There are two stages of deployment:



- In the first stage, **Ext Z** temporarily takes ownership of tables and fields from **Ext X**.
- In the second stage, **Ext Z** releases ownership to extensions **Ext X** and **Ext Y**. You uninstall and unpublish transition extension **Ext Z** when you finish deployment.

This process is a two-step process because we only support moving down the dependency graph. So instead, the concept is to first move the tables' ownership to an extension above the receiving extensions in the dependency graph. Then, the extensions are moved down. This concept essentially turns the process into a two-step, move-down process.

Ext Z is used just as a temporary extension for moving ownership. So, it only includes schema objects. As a result, customers can't run on the tenant until both steps have been done.

> **NOTE**
> You can only use this process for on-premise solutions.

Prerequisite

If you're moving enum type fields, then your solution must be running on Business Central 2020 release wave 1, version 16.5 or later. For more information, see Known Issues.

Create transition extension (Ext Z v1)

The transition extension will contain replicas of all table object definitions in the releasing extension, except logic code. In the illustration, these objects include **TableA**, **TableB**, and **TableC** and current their field definitions. The transition extension is **Ext Z**.

1. Create an AL project for the transition extension.
2. Add a table object that exactly matches the table object definitions for **TableA**, **TableB**, and **TableC** in the releasing extension.
3. Compile the extension package.
4. Make a note of the `ID` of the new extension. You'll use this ID in the next task.

For purposes of the example, the ID is `11111111-aaaa-2222-bbbb-333333333333`. The value for your extension will be different.

Create empty version of releasing extension (Ext X v2)

In this step, you create a new version of the releasing extension that doesn't contain any objects. It only contains a `migration.json` file that points to **Ext Z**.

1. In the releasing extension AL project, add a migration.json file that points to the ID of the transition extension **Ext Z**.

   ```
   {
   "apprules": [
       {
           "id": "11111111-aaaa-2222-bbbb-333333333333"
       }
   ]
   }
   ```

   For more information, see The Migration.json File.

2. Delete all objects from the extension. The objects include **TableA**, **TableB**, and **TableC**.

3. In the app.json file, increase the `version` value. Ensure that `"target": "OnPrem"`.

4. Compile a new version of the extension package.

Create receiving extension (Ext Y v1)

You now create a new extension that contains the customization you want to move from the releasing. In this example, the customizations include **TableB** and a **TableExtC**.

1. Create an AL project for **Ext Y**.

2. In the app.json file, set up a dependency on the releasing extension **Ext X**.

3. Add a table definition and code for **TableB** that exactly matches the definition in the original releasing extension.

4. Add a table extension object called **TableExtC**. Then, add a field definition for field **C-2** that matches its definition in the original **TableC** object of the releasing extension.

5. Compile the extension package.

6. Make a note of the `ID` of the new extension. You'll use this ID in the next task.

   For purposes of the example, the ID is `44444444-cccc-5555-dddd-666666666666`. The value for your extension will be different.

Create final version of releasing extension (Ext X v3)

In this step, you create another version of the releasing extension **Ext X**. This version will contain the objects and code that you want to finally publish.

1. Create an AL project for **Ext X**.

2. Add a table definition and code for **TableA** that exactly matches the definition in the original releasing extension.

3. Add a table object for **TableC** and field definition for **C-1** that matches the definitions in the original

TableC object of the releasing extension.

4. In the app.json file, increase the `version` value.
5. Compile the extension package.
6. Make a note of the `ID` of the extension. You'll use this ID in the next task.

   For purposes of the example, the ID is `77777777-eeee-8888-ffff-999999999999`. The value for your extension will be different.

Create new empty version of transition extension (Ext Z v2)

In this step, you create a new version of **Ext Z** that only contains a `migration.json` file. This `migration.json` file points the IDS of **Ext X** and **Ext Y**. The file is used to release ownership.

1. In the extension AL project, add a migration.json file that points to the IDs of the releasing extension **Ext X** and receiving extension **Ext Y**.

   ```
   {
   "apprules": [
       {
           "id": "77777777-eeee-8888-ffff-999999999999"
       }
       {
           "id": "44444444-cccc-5555-dddd-666666666666"
       }
   ]
   }
   ```

   For more information, see The Migration.json File.

2. Delete the object definitions for **TableA**, **TableB**, and **TableC**.
3. In the app.json file, increase the `version` value.
4. Compile the extension package.

Deploy the extensions

1. Uninstall the current version of the releasing extension **Ext X**.
2. Complete the following steps for the first stage of deployment:

   a. Publish the transition extension **Ext Z** and empty version of **Ext X v2**.

   b. Synchronize the transition extension **Ext Z**.

      This step creates empty database tables **TableA**, **TableB**, and **TableC** that are owned by **Ext Z**.

      > **IMPORTANT**
      > Extensions receiving table objects must be synced first. Extension releasing/giving away table objects must be synced last.

   c. Synchronize the releasing extension **Ext X v2**.

      This step will read the migration.json of the extension. Then transfer ownership of the original tables **TableA**, **TableB**, and **TableC** to **Ext Z**.

3. Complete the following steps for the second stage of deployment:

    a. Publish the next version for **Ext Z v2** and **Ext X v3**, and the first version of **Ext Y**.

    b. Synchronize the extensions in the following order: **Ext X v3**, **Ext Y v1**, and **Ext Z v2**.

    Synchronize **Ext Z v2** last. When you synchronize **Ext Z v2**, ownership of the tables is transferred from **Ext Z** to **Ext X** and **Ext Y**.

4. Run Start-NAVAppDataUpgrade cmdlet on the new releasing extension version**Ext X v3**.

    This step basically installs the new extension version. You run a data upgrade because an earlier version has been installed and is still published.

5. Install the new receiving extension **Ext Y v1**.

6. Unpublish both versions of **Ext Z**.

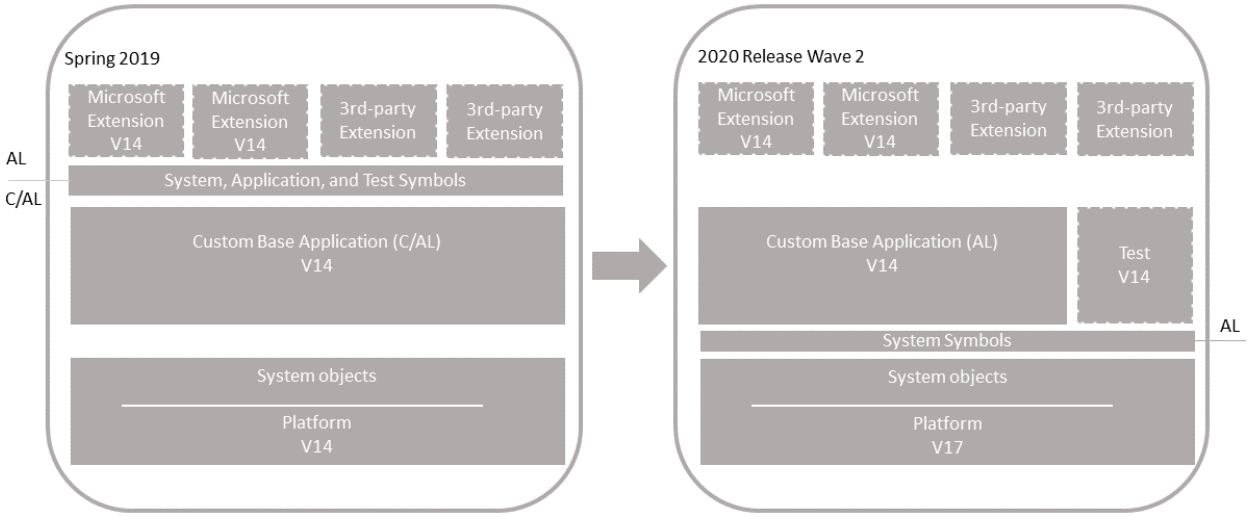
Technical Upgrade From Version 14 to Version 17

2/17/2021 • 11 minutes to read • Edit Online

Use this process when you have a code customized Business Central application (version 14) that you want to upgrade to the Business Central 2020 release wave 2 platform (version 17). This process won't upgrade the application to the latest version. You'll convert the entire application from C/AL to an AL base application extension.



Single-tenant and multitenant deployments

The process for upgrading is similar for a single-tenant and multitenant deployment. However, there are some inherent differences. With a single-tenant deployment, the application and business data are included in the same database. While with a multitenant deployment, application code is in a separate database (the application database) than the business data (tenant). In the procedures that follow, for a single-tenant deployment, consider references to the *application database* and *tenant database* as the same database. Steps are marked as *Single-tenant only* or *Multitenant only* where applicable.

Prerequisites

1. Upgrade to Business Central Spring 2019 (version 14).

   There are several updates for version 14. When upgrading from Business Central Fall 2018 (version 13) or Dynamics NAV, upgrade to the latest version 14 update that has a compatible version 17 update. For more information, see Dynamics 365 Business Central Upgrade Compatibility Matrix.

   If your solution is already on version 14, then you don't have to upgrade to the latest version 17 update.

   To download the latest update, go to Released Cumulative Updates for Microsoft Dynamics 365 Business Central Spring 2019 Update on-premises.

   For information, see Upgrading to Dynamics 365 Business Central On-Premises.

2. Disable data encryption.

   If the current server instance uses data encryption, disable it. You can enable it again after upgrading.

   For more information, see Managing Encryption and Encryption Keys.

   Instead of disabling encryption, you can export the current encryption key, which you'll then import after upgrade. However, we recommend disabling encryption before upgrading.

Task 1: Install version 17

1. Before you install version 17, it can be useful to create desktop shortcuts to the version 14.0 tools, such as the Business Central Server Administration tool, Business Central Administration Shell, and Dynamics NAV Development Shell because the Start menu items for these tools will be replaced with the version 17.0 tools.

2. Install all components of version 17.

   You'll have to keep version 14.0 installed, because you'll need the it to complete the C/AL to AL conversion in this process. Therefore, when you install version 17, you must either specify different port numbers for components during installation or stop the version 14.0 Business Central Server instance before you run the installation. Otherwise, you'll get an error that the Business Central Server failed to install.

   For more information, see Installing Business Central Using Setup.

3. Copy the version 14 **CodeViewer** add-in to the version 17.0 server installation

   a. Find the **CodeViewer** folder in the **Add-ins** folder of the version 14 RoleTailored client installation. By default, the folder path is C:\Program Files (x86)\Microsoft Dynamics 365 Business Central\140\RoleTailored Client\Add-ins.

   b. Copy the folder to the **Add-ins** folder of the version 17 server installation. By default, the folder path is C:\Program Files\Microsoft Dynamics 365 Business Central\170\Service\Add-ins. Replace the existing folder and files, if any.

   CodeViewer is no longer used in version 17. But it's required because of references that exist in the converted application. If you omit this step, you might get compilation errors later.

Task 2: Convert your v14 C/AL application to AL

For more information, see Code Conversion from C/AL to AL.

Task 3: Prepare databases

In this task, you prepare the application and tenant databases for the upgrade.

1. Make backup of the database.

2. Make sure that you have the extension packages for all published extensions.

   You'll need these packages later to publish and install the extensions again.

3. Uninstall all extensions from the old tenants.

   Run the Business Central Administration Shell for version 14.0 as an administrator. Use the Uninstall-NAVApp cmdlet to uninstall an extension. For example, together with the Get-NAVAppInfo cmdlet, you can uninstall all extensions with a single command:

   ```
   Get-NAVAppInfo -ServerInstance <BC14 server instance> -Tenant <tenant ID> | % { Uninstall-NAVApp -
   ServerInstance <BC14 server instance> -Name $_.Name -Version $_.Version -Tenant <tenant ID>}
   ```

   If you have a single tenant deployment, you can omit the `-Tenant` parameter and value.

4. Unpublish all extensions from the application server instance.

   To unpublish extensions, use the Unpublish-NAVAPP cmdlet. Together with the Get-NAVAppInfo cmdlet,

you can uninstall all extensions from the tenant using a single command:

```
Get-NAVAppInfo -ServerInstance <BC14 server instance> | % { Unpublish-NAVApp -ServerInstance <BC14
server instance> -Name $_.Name -Version $_.Version }
```

5. Unpublish all system, test, and application symbols.

   To unpublish symbols, use the Unpublish-NAVAPP cmdlet. You can unpublish all symbols by using the Get-NAVAppInfo cmdlet with the `-SymbolsOnly` switch as follows:

   ```
   Get-NAVAppInfo -ServerInstance <BC14 server instance> -SymbolsOnly | % { Unpublish-NAVApp -
   ServerInstance <BC14 server instance> -Name $_.Name -Version $_.Version }
   ```

   What are symbols?

6. (Multitenant only) Dismount the tenants from the application server instance.

   To dismount a tenant, use the Dismount-NAVTenant cmdlet:

   ```
   Dismount-NAVTenant -ServerInstance <BC14 server instance> -Tenant <tenant ID>
   ```

7. Stop the server instance.

   ```
   Stop-NAVServerInstance -ServerInstance <BC14 server instance>
   ```

Task 4: Convert version 14.0 application database

This task runs a technical upgrade on the application database. A technical upgrade converts the database from the version 14.0 platform to the version 17.0 platform. This conversion updates the system tables of the database to the new schema (data structure). It also provides the latest platform features and performance enhancements.

1. Start Business Central Administration Shell for version 17.0 as an administrator.
2. Run the Invoke-NAVApplicationDatabaseConversion cmdlet to start the conversion:

   ```
   Invoke-NAVApplicationDatabaseConversion -DatabaseServer <database server>\<database instance> -
   DatabaseName "<BC14 database name>"
   ```

   When completed, a message like the following displays in the console:

   ```
   DatabaseServer      : .\BCDEMO
   DatabaseName        : Demo Database BC (14-0)
   DatabaseCredentials :
   DatabaseLocation    :
   Collation           :
   ```

Task 5: Configure version 17 server

When you installed version 17 in **Task 1**, a version 17 Business Central Server instance was created. In this task, you change server configuration settings that are required to complete the upgrade. Some of the changes are only required for version 14 to version 17.0 upgrade and can be reverted after you complete the upgrade.

1. Set the server instance to connect to the application database.

   ```
   Set-NAVServerConfiguration -ServerInstance <BC17 server instance> -KeyName DatabaseName -KeyValue "
   <BC14 database name>"
   ```

   In a single tenant deployment, this command mounts the tenant automatically. For more information, see Connecting a Server Instance to a Database.

2. Disable task scheduler on the server instance for purposes of upgrade.

   ```
   Set-NavServerConfiguration -ServerInstance <BC17 server instance> -KeyName "EnableTaskScheduler" -
   KeyValue false
   ```

   Be sure to re-enable task scheduler after upgrade if needed.

3. Restart the server instance.

   ```
   Restart-NAVServerInstance -ServerInstance <BC17 server instance>
   ```

Task 6: Upload Business Central partner license

If you have a new Business Central partner license, make sure that it has been uploaded to the database. To upload the license, use the Import-NAVServerLicense cmdlet:

```
Import-NAVServerLicense -ServerInstance <BC17 server instance> -LicenseFile "<path to the license>"
```

For more information, see Uploading a License File for a Specific Database.

Task 7: Publish system symbols, base application, and test library extensions

In this task, you'll publish extensions to the version 17.0 server instance. Publishing adds the extension to the application database that is mounted on the server instance. The extension is then available for installing on tenants later. It updates internal tables, compiles the components of the extension behind-the-scenes, and builds the necessary metadata objects that are used at runtime.

The steps in this task continue to use the Business Central Administration Shell for version 17.0 that you started in the previous task.

1. Publish the system symbols extension for version 17.

   The symbols extension contains the required platform symbols that the base application depends on. The symbols extension package is called **System.app**. You find it where the **AL Development Environment** is installed. The default installation path is C:\Program Files (x86)\Microsoft Dynamics 365 Business Central\170\AL Development Environment.

   ```
   Publish-NAVApp -ServerInstance <BC17 server instance> -Path "<path to the System.app file>" -
   PackageType SymbolsOnly
   ```

2. Publish the custom base application extension that you created in **Task 2**.

```
Publish-NAVApp -ServerInstance <BC17 server instance> -Path "<path to the base application extension
package file>"
```

3. Publish the test library extension if you created one in **Task 2**.

```
Publish-NAVApp -ServerInstance <BC17 server instance> -Path "<path to the test library extension
package file>"
```

Task 8: Synchronize tenant

This task updates the tenant database schema with schema changes in system objects and application objects.

If you have a multitenant deployment, run these steps for each tenant (replacing `<tenant ID>` with the appropriate tenant ID).

1. (Multitenant only) Mount the tenant to the version 17 server instance.

   To mount the tenant, use the Mount-NAVTenant cmdlet:

```
Mount-NAVTenant -ServerInstance <BC17 server instance> -DatabaseName "<BC14 database name>" -
DatabaseServer <database server>\<database instance> -Tenant <tenant ID> -AllowAppDatabaseWrite
```

> **IMPORTANT**
> You must use the same tenant ID for the tenant that was used in the old deployment; otherwise you will get an error when mounting or syncing the tenant. If you want to use a different ID for the tenant, you can either use the `-AlternateId` parameter now or after upgrading, dismount the tenant, then mount it again using the new ID and the `OverwriteTenantIdInDatabase` parameter.

> **NOTE**
> For upgrade, we recommend that you use the `-AllowAppDatabaseWrite` parameter. After upgrade, you can dismount and mount the tenant again without the parameter if needed.

2. Synchronize the tenant to the system objects.

   Use the Sync-NAVTenant cmdlet:

```
Sync-NAVTenant -ServerInstance <BC17 server instance> -Tenant <tenant ID> -Mode Sync
```

   With a single-tenant deployment, you can omit the `-Tenant` parameter and value.

   At this stage, the tenant state is **Operational**.

Task 9: Install base and test applications

You'll synchronize the tenant to the custom base application and test library extension (if any). When you synchronize the tenant, extensions take ownership of the tables in the SQL Database.

If you have a multitenant deployment, run these steps for each tenant (replacing `<tenant ID>` with the appropriate tenant ID).

1. Synchronize the tenant to the base application extension (Base Application).

   Use the Sync-NAVApp cmdlet:

   ```
   Sync-NAVApp -ServerInstance <BC17 server instance> -Name "Base Application" -Version <extension
   version> -tenant <tenant ID>
   ```

   With this step, the base app takes ownership of the database tables. When completed, in SQL Server, the table names will be suffixed with the base app extension ID.

2. Install custom base application extension on the tenant.

   To install the extension, you use the Install-NAVApp cmdlet.

   ```
   Install-NAVApp -ServerInstance <BC17 server instance> -Name "Base Application" -Version <extension
   version>
   ```

   At this point, the base application is upgraded to the version 17 platform and is operational. You can open the application in the client.

3. Synchronize and install the test library extension.

   This step is like what you did for the custom base application in steps 1 and 2.

Task 10: Publish and install extensions

Now, you can install the Microsoft and 3rd-party extensions that were installed on the tenant before the upgrade.

1. Publish the old extension versions.

   ```
   Publish-NAVApp -ServerInstance <BC17 server instance> -Path "<path to extension package file>"
   ```

   You only need to do this step once.

2. Synchronize the extension.

   ```
   Sync-NAVApp -ServerInstance <BC17 server instance> -Name "<extension name>" -Version <extension
   version> -tenant <tenant ID>
   ```

3. Install the extension:

   ```
   Install-NAVApp -ServerInstance <BC17 server instance> -Name "<extension name>" -Version <extension
   version> -tenant <tenant ID>
   ```

4. Repeat steps 2 and 3 for each extension and on each tenant.

Now, your application is fully upgraded to the version 17 platform.

Task 11: Upgrade control add-ins

The Business Central Server installation includes new versions of the Microsoft-provided Javascript-based control add-ins, like Microsoft.Dynamics.Nav.Client.BusinessChart, Microsoft.Dynamics.Nav.Client.VideoPlayer, and more. If your solution uses any of these control add-ins, upgrade them to the latest version.

To upgrade the control add-ins from the client, do the following steps:

1. Open the Business Central client.
2. Search for and open the **Control Add-ins** page.
3. Choose **Actions** > **Control Add-in Resource** > **Import**.
4. Locate and select the .zip file for the control add-in and choose **Open**.

   The .zip files are located in the **Add-ins** folder of the Business Central Server installation. There's a subfolder for each add-in. For example, the path to the Business Chart control add-in is `C:\Program Files\Microsoft Dynamics 365 Business Central\170\Service\Add-ins\BusinessChart\Microsoft.Dynamics.Nav.Client.BusinessChart.zip`.
5. After you've imported all the new control add-in versions, restart Business Central Server instance.

Alternatively, you can use the Set-NAVAddin cmdlet of the Business Central Administration Shell. For example, the following commands update the control add-ins installed by default. Modify the commands to suit:

```
$InstanceName = 'BC170'
$ServicesAddinsFolder = 'C:\Program Files\Microsoft Dynamics 365 Business Central\170\Service\Add-ins'
Set-NAVAddIn -ServerInstance $InstanceName -AddinName 'Microsoft.Dynamics.Nav.Client.BusinessChart' -
PublicKeyToken 31bf3856ad364e35 -ResourceFile ($AppName = Join-Path $ServicesAddinsFolder
'BusinessChart\Microsoft.Dynamics.Nav.Client.BusinessChart.zip')
Set-NAVAddIn -ServerInstance $InstanceName -AddinName 'Microsoft.Dynamics.Nav.Client.FlowIntegration' -
PublicKeyToken 31bf3856ad364e35 -ResourceFile ($AppName = Join-Path $ServicesAddinsFolder
'FlowIntegration\Microsoft.Dynamics.Nav.Client.FlowIntegration.zip')
Set-NAVAddIn -ServerInstance $InstanceName -AddinName 'Microsoft.Dynamics.Nav.Client.OAuthIntegration' -
PublicKeyToken 31bf3856ad364e35 -ResourceFile ($AppName = Join-Path $ServicesAddinsFolder
'OAuthIntegration\Microsoft.Dynamics.Nav.Client.OAuthIntegration.zip')
Set-NAVAddIn -ServerInstance $InstanceName -AddinName 'Microsoft.Dynamics.Nav.Client.PageReady' -
PublicKeyToken 31bf3856ad364e35 -ResourceFile ($AppName = Join-Path $ServicesAddinsFolder
'PageReady\Microsoft.Dynamics.Nav.Client.PageReady.zip')
Set-NAVAddIn -ServerInstance $InstanceName -AddinName 'Microsoft.Dynamics.Nav.Client.PowerBIManagement' -
PublicKeyToken 31bf3856ad364e35 -ResourceFile ($AppName = Join-Path $ServicesAddinsFolder
'PowerBIManagement\Microsoft.Dynamics.Nav.Client.PowerBIManagement.zip')
Set-NAVAddIn -ServerInstance $InstanceName -AddinName 'Microsoft.Dynamics.Nav.Client.RoleCenterSelector' -
PublicKeyToken 31bf3856ad364e35 -ResourceFile ($AppName = Join-Path $ServicesAddinsFolder
'RoleCenterSelector\Microsoft.Dynamics.Nav.Client.RoleCenterSelector.zip')
Set-NAVAddIn -ServerInstance $InstanceName -AddinName 'Microsoft.Dynamics.Nav.Client.SatisfactionSurvey' -
PublicKeyToken 31bf3856ad364e35 -ResourceFile ($AppName = Join-Path $ServicesAddinsFolder
'SatisfactionSurvey\Microsoft.Dynamics.Nav.Client.SatisfactionSurvey.zip')
Set-NAVAddIn -ServerInstance $InstanceName -AddinName 'Microsoft.Dynamics.Nav.Client.SocialListening' -
PublicKeyToken 31bf3856ad364e35 -ResourceFile ($AppName = Join-Path $ServicesAddinsFolder
'SocialListening\Microsoft.Dynamics.Nav.Client.SocialListening.zip')
Set-NAVAddIn -ServerInstance $InstanceName -AddinName 'Microsoft.Dynamics.Nav.Client.VideoPlayer' -
PublicKeyToken 31bf3856ad364e35 -ResourceFile ($AppName = Join-Path $ServicesAddinsFolder
'VideoPlayer\Microsoft.Dynamics.Nav.Client.VideoPlayer.zip')
Set-NAVAddIn -ServerInstance $InstanceName -AddinName 'Microsoft.Dynamics.Nav.Client.WebPageViewer' -
PublicKeyToken 31bf3856ad364e35 -ResourceFile ($AppName = Join-Path $ServicesAddinsFolder
'WebPageViewer\Microsoft.Dynamics.Nav.Client.WebPageViewer.zip')
Set-NAVAddIn -ServerInstance $InstanceName -AddinName 'Microsoft.Dynamics.Nav.Client.WelcomeWizard' -
PublicKeyToken 31bf3856ad364e35 -ResourceFile ($AppName = Join-Path $ServicesAddinsFolder
'WelcomeWizard\Microsoft.Dynamics.Nav.Client.WelcomeWizard.zip')
```

Task 12: Post-upgrade

1. Enable task scheduler on the server instance.
2. (Multitenant only) For tenants other than the tenant that you use for administration purposes, if you mounted the tenants using the `-AllowAppDatabaseWrite` parameter, dismount the tenants, then mount

them again without using the `-AllowAppDatabaseWrite` parameter.

3. If you want to use data encryption as before, enable it.

   For more information, see Managing Encryption and Encryption Keys.

   Optionally, if you exported the encryption key instead of disabling encryption earlier, import the encryption key file to enable encryption.

4. Grant users permission to the *Open in Excel* and *Edit in Excel* actions.

   Version 17 introduces a system permission that protects these two actions. The permission is granted by the system object **6110 Allow Action Export To Excel**. Because of this change, users who had permission to these actions before upgrading, will lose permission. To grant permission again, do one of the following steps:

   - Export the **EXCEL EXPORT ACTION** permission set. Then, import it to your application and add it to appropriate users.
   - Add the system object **6110 Allow Action Export To Excel** permission directly to appropriate permission sets.

   For more information about working with permission sets and permissions, see Export and Import Permission Sets.

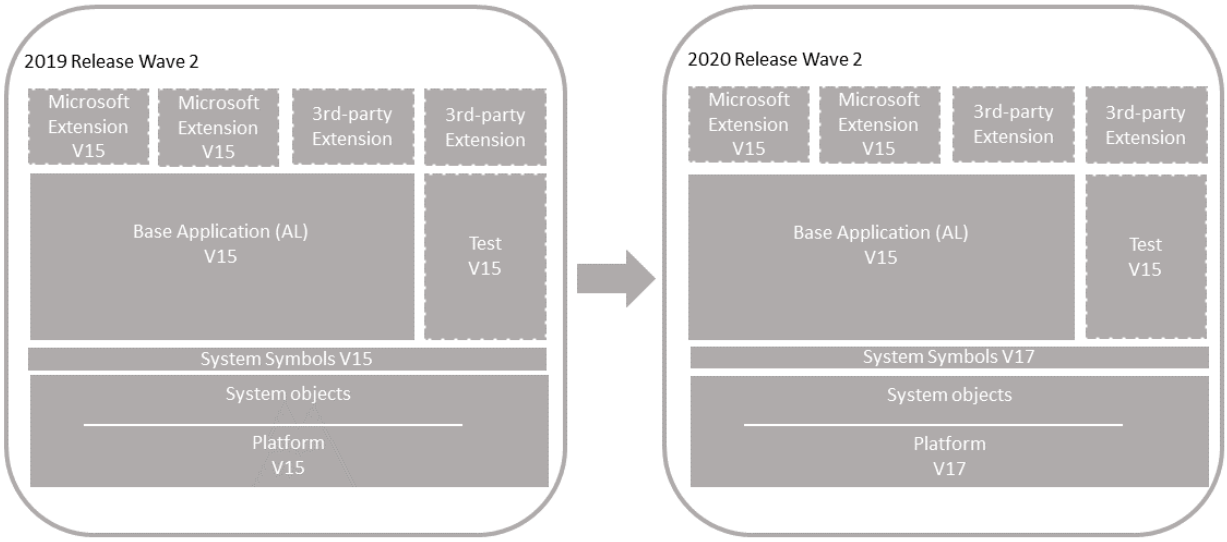
Business Central 14.X to 15.X compatibility matrix

Technical Upgrade from Version 15 to Version 17

2/17/2021 • 10 minutes to read • Edit Online

Use this process to upgrade from Business Central 2019 release wave 2 (version 15) to the Business Central 2020 release wave 1 platform (version 17). This process won't upgrade the application to the latest version.



Single-tenant and multitenant deployments

The process for upgrading is similar for a single-tenant and multitenant deployment. However, there are some inherent differences. With a single-tenant deployment, the application and business data are included in the same database. While with a multitenant deployment, application code is in a separate database (the application database) than the business data (tenant). In the procedures that follow, for a single-tenant deployment, consider references to the *application database* and *tenant database* as the same database. Steps are marked as *Single-tenant only* or *Multitenant only* where applicable.

Considerations

In version 17, a number of tables have been deprecated and replaced by new tables compared to version 15. For a list of these tables and the corresponding new tables, see Deprecated Tables. Code that uses the deprecated table or tables, must be rewritten to use the tables. In this article, this work is done under Task 2.

Prerequisites

1. Your version 15 platform is compatible with version 17.

   There are several updates for version 15. The updates have a compatible version 17 update. For more information, see Dynamics 365 Business Central Upgrade Compatibility Matrix. For example, if your solution is currently running 15.11, you can't upgrade to 17.0. You must wait until 17.1 is available.

2. Disable data encryption.

   If the current server instance uses data encryption, disable it. You can enable it again after upgrading.

   For more information, see Managing Encryption and Encryption Keys.

   Instead of disabling encryption, you can export the current encryption key, which you'll then import after upgrade. However, we recommend disabling encryption before upgrading.

Task 1: Install version 17

1. Before you install version 17, it can be useful to create desktop shortcuts to the version 15.0 tools, such as the Business Central Server Administration tool, Business Central Administration Shell, and Dynamics NAV Development Shell because the Start menu items for these tools will be replaced with the version 17.0 tools.

2. Install version 17 components.

   You'll keep version 15 component installed for now. When you install version 17, you must either specify different port numbers for components during installation or stop the version 15.0 Business Central Server instance before you run the installation. Otherwise, you'll get an error that the Business Central Server failed to install.

   For more information, see Installing Business Central Using Setup.

APPLICATION

Task 2: Rewrite code to handle obsoleted system tables

In version 17, several tables have been deprecated and replaced by new tables, compared to version 15. For a list of these tables and the corresponding new tables, see Deprecated Tables. Code that uses the deprecated tables, must be rewritten to use the tables. This change will typically affect your base application or the Microsoft System Application, if you're using it.

For the base application or system application extensions, you'll have to create a new version that uses the new tables. The basic steps are as follows:

1. Create AL project in Visual Studio Code for the system and/or base application.

   If you're using the Microsoft System Application, start with this project first.

2. Include the source files of the current version in the project.

3. Copy the version 17 System symbols (System.app) file to the **.alpackages** folder of the project.

   You'll find the System.app file on the installation media (DVD) for version 17 or in the **AL Development Environment** installation folder. By default, the folder is C:\Program Files (x86)\Microsoft Dynamics 365 Business Central\170\AL Development Environment.

   For the base application, also include the extension package (.app) for the new version of the Microsoft System Application, if you're using it.

4. Modify the app.json:

   - Increase `"version"` number. You have to increase the version so you can run a data upgrade later in this process.
   - Set `"runtime"` to `6.0`
   - Set `"platform"` to `17.0.0.0`
   - Set `"target"` to `OnPrem`

   For more information about the app.json file, see App.json file.

5. In the **dotnet.al** files in the project, find and delete all instances of `Version = '15.0.0.0';` in **Microsoft.Dynamics.Nav** and **Microsoft.Dynamics.Framework** assembly declarations.

6. Rewrite code that references the deprecated table to reference the new tables.

   Try to build the project first to see what errors you get. Then, resolve the errors.

7. Compile and build the new version of the extension.

DATA

Task 3: Prepare databases

In this task, you prepare the application and tenant databases for the upgrade.

1. Make backup of the database.
2. Make sure that you have the extension packages for all published extensions.

   You'll need these packages later to publish and install the extensions again.
3. (Single-tenant only) Uninstall all extensions from the old tenants.

   Run the Business Central Administration Shell for version 15.0 as an administrator. Use the Uninstall-NAVApp cmdlet to uninstall an extension. For example, together with the Get-NAVAppInfo cmdlet, you can uninstall all extensions with a single command:

   ```
   Get-NAVAppInfo -ServerInstance <BC15 server instance> | % { Uninstall-NAVApp -ServerInstance <BC15
   server instance> -Name $_.Name -Version $_.Version }
   ```
4. Unpublish all system, test, and application symbols.

   To unpublish symbols, use the Unpublish-NAVAPP cmdlet. You can unpublish all symbols by using the Get-NAVAppInfo cmdlet with the `-SymbolsOnly` switch as follows:

   ```
   Get-NAVAppInfo -ServerInstance <BC15 server instance> -SymbolsOnly | % { Unpublish-NAVApp -
   ServerInstance <BC15 server instance> -Name $_.Name -Version $_.Version }
   ```

   What are symbols?
5. (Multitenant only) Dismount the tenants from the application server instance.

   To dismount a tenant, use the Dismount-NAVTenant cmdlet:

   ```
   Dismount-NAVTenant -ServerInstance <BC15 server instance> -Tenant <tenant ID>
   ```
6. Stop the server instance.

   ```
   Stop-NAVServerInstance -ServerInstance <BC15 server instance>
   ```

Task 4: Convert the version 15.0 application database

This task runs a technical upgrade on the application database. A technical upgrade converts the database from the version 15.0 platform to the version 17.0 platform. This conversion updates the system tables of the database to the new schema (data structure). It also provides the latest platform features and performance enhancements.

> **IMPORTANT**
> The conversion does not modify the application objects, but it will remove any modifications that you have made to system tables. After the conversion you will no longer be able to use it with Business Central 14.

1. Start Business Central Administration Shell for version 17.0 as an administrator.

2. Run the Invoke-NAVApplicationDatabaseConversion cmdlet to start the conversion. In a multitenant deployment, run this cmdlet against the application database.

```
Invoke-NAVApplicationDatabaseConversion -DatabaseServer <database server>\<database instance> -
DatabaseName "<BC15 database name>"
```

When completed, a message like the following displays in the console:

```
DatabaseServer      : .\BCDEMO
DatabaseName        : Demo Database BC (15-0)
DatabaseCredentials :
DatabaseLocation    :
Collation           :
```

Task 5: Configure version 17 server

When you installed version 17 in **Task 1**, a version 17 Business Central Server instance was created. In this task, you change server configuration settings that are required to complete the upgrade. Some of the changes are only required for version 15 to version 17.0 upgrade and can be reverted after you complete the upgrade.

1. Set the server instance to connect to the application database.

```
Set-NAVServerConfiguration -ServerInstance <BC17 server instance> -KeyName DatabaseName -KeyValue "
<BC15 database name>"
```

In a single tenant deployment, this command mounts the tenant automatically. For more information, see Connecting a Server Instance to a Database.

2. Disable task scheduler on the server instance for purposes of upgrade.

```
Set-NavServerConfiguration -ServerInstance <BC17 server instance> -KeyName "EnableTaskScheduler" -
KeyValue false
```

Be sure to re-enable task scheduler after upgrade if needed.

3. Restart the server instance.

```
Restart-NAVServerInstance -ServerInstance <BC17 server instance>
```

Task 6: Import version 17 license

1. Use the Import-NAVServerLicense to upload the version 17 license to the database.

```
Import-NAVServerLicense -ServerInstance <server instance name> -LicenseFile <path and file name>
```

2. Restart the server instance.

```
Restart-NAVServerInstance -ServerInstance <server instance name>
```

Task 7: Publish new system symbols

Use the Publish-NAVApp cmdlet to publish the new symbols extension package. This package is called **System.app**. If you've installed the **AL Development Environment**, you find the file in the installation folder. By default, the folder path is C:\Program Files (x86)\Microsoft Dynamics 365 Business Central\170\AL Development Environment.

```
Publish-NAVApp -ServerInstance <BC17 server instance> -Path "<path to the System.app file>" -PackageType
SymbolsOnly
```

Task 8: Publish new extension versions

Publish the new versions of the system and base application extensions.

```
Publish-NAVApp -ServerInstance <BC17 server instance> -Path "<path to .app file for system or base
application>"
```

Task 9: Recompile published extensions

Compile all other published extensions, except the Microsoft System Application and you're base application, against the new platform.

1. To compile an extension, use the Repair-NAVApp cmdlet, For example:

   ```
   Repair-NAVApp -ServerInstance <server instance> -Name <extension name> -Version <extension name>
   ```

   To compile all published extensions at once, you can use this command:

   ```
   Get-NAVAppInfo -ServerInstance <server instance> | Repair-NAVApp
   ```

2. Restart the server instance.

   ```
   Restart-NAVServerInstance -ServerInstance <server instance>
   ```

Task 10: Synchronize tenant

1. (Multitenant only) Mount the tenant to the new Business Central Server instance.

   You'll have to do this step and the next for each tenant. For more information, see Mount or Dismount a Tenant.

2. Synchronize the tenant.

   Use the Sync-NAVTenant cmdlet:

   ```
   Sync-NAVTenant -ServerInstance <server instance> -Tenant <tenant ID> -Mode Sync
   ```

   For a single-tenant deployment, you can either set the `<tenant ID>` to `default` or omit the `-Tenant <tenant ID>` parameter. For more information about syncing, see Synchronizing the Tenant Database and Application Database.

3. Synchronize the system application extension, then the base application.

```
Sync-NAVApp -ServerInstance <server instance> -Name <extension name> version <extension version> -
Tenant <tenant ID>
```

Task 11: Run upgrade to install system and base applications

Instead of directly installing the system amd base applications, you'll have to run a data upgrade because previous versions of these extensions were installed.

To do this, run the Start-NAVAppDataUpgrade cmdlet on each extension. Start with the system application, then the base application.

```
Start-NAVAppDataUpgrade -ServerInstance <server instance> -Name <extension name> version <extension version>
-Tenant <tenant ID>
```

This will run the data upgrade and install the extensions on the tenant.

Task 12: Reinstall other extensions

In this step, you install the remaining extensions that were previously installed on your tenant before upgrading. To install an extension, you use the Install-NAVApp cmdlet.

```
Install-NAVApp -ServerInstance <server instance> -Name "System Application" -Version <extension version>
```

If your previous tenant including the **Application** extension, install this extension first.

Task 13: Upgrade control add-ins

The Business Central Server installation includes new versions of the Microsoft-provided Javascript-based control add-ins, like Microsoft.Dynamics.Nav.Client.BusinessChart, Microsoft.Dynamics.Nav.Client.VideoPlayer, and more. If your solution uses any of these control add-ins, upgrade them to the latest version.

To upgrade the control add-ins, do the following steps:

1. Open the Business Central client.
2. Search for and open the **Control Add-ins** page.
3. Choose **Actions** > **Control Add-in Resource** > **Import**.
4. Locate and select the .zip file for the control add-in and choose **Open**.

   The .zip files are located in the **Add-ins** folder of the Business Central Server installation. There's a subfolder for each add-in. For example, the path to the Business Chart control add-in is

   ```
   C:\Program Files\Microsoft Dynamics 365 Business Central\170\Service\Add-
   ins\BusinessChart\Microsoft.Dynamics.Nav.Client.BusinessChart.zip
   ```

   .
5. After you've imported all the new control add-in versions, restart Business Central Server instance.

Alternatively, you can use the Set-NAVAddin cmdlet of the Business Central Administration Shell. For example, the following commands update the control add-ins installed by default. Modify the commands to suit:

```
$InstanceName = 'BC170'
$ServicesAddinsFolder = 'C:\Program Files\Microsoft Dynamics 365 Business Central\170\Service\Add-ins'
Set-NAVAddIn -ServerInstance $InstanceName -AddinName 'Microsoft.Dynamics.Nav.Client.BusinessChart' -
PublicKeyToken 31bf3856ad364e35 -ResourceFile ($AppName = Join-Path $ServicesAddinsFolder
'BusinessChart\Microsoft.Dynamics.Nav.Client.BusinessChart.zip')
Set-NAVAddIn -ServerInstance $InstanceName -AddinName 'Microsoft.Dynamics.Nav.Client.FlowIntegration' -
PublicKeyToken 31bf3856ad364e35 -ResourceFile ($AppName = Join-Path $ServicesAddinsFolder
'FlowIntegration\Microsoft.Dynamics.Nav.Client.FlowIntegration.zip')
Set-NAVAddIn -ServerInstance $InstanceName -AddinName 'Microsoft.Dynamics.Nav.Client.OAuthIntegration' -
PublicKeyToken 31bf3856ad364e35 -ResourceFile ($AppName = Join-Path $ServicesAddinsFolder
'OAuthIntegration\Microsoft.Dynamics.Nav.Client.OAuthIntegration.zip')
Set-NAVAddIn -ServerInstance $InstanceName -AddinName 'Microsoft.Dynamics.Nav.Client.PageReady' -
PublicKeyToken 31bf3856ad364e35 -ResourceFile ($AppName = Join-Path $ServicesAddinsFolder
'PageReady\Microsoft.Dynamics.Nav.Client.PageReady.zip')
Set-NAVAddIn -ServerInstance $InstanceName -AddinName 'Microsoft.Dynamics.Nav.Client.PowerBIManagement' -
PublicKeyToken 31bf3856ad364e35 -ResourceFile ($AppName = Join-Path $ServicesAddinsFolder
'PowerBIManagement\Microsoft.Dynamics.Nav.Client.PowerBIManagement.zip')
Set-NAVAddIn -ServerInstance $InstanceName -AddinName 'Microsoft.Dynamics.Nav.Client.RoleCenterSelector' -
PublicKeyToken 31bf3856ad364e35 -ResourceFile ($AppName = Join-Path $ServicesAddinsFolder
'RoleCenterSelector\Microsoft.Dynamics.Nav.Client.RoleCenterSelector.zip')
Set-NAVAddIn -ServerInstance $InstanceName -AddinName 'Microsoft.Dynamics.Nav.Client.SatisfactionSurvey' -
PublicKeyToken 31bf3856ad364e35 -ResourceFile ($AppName = Join-Path $ServicesAddinsFolder
'SatisfactionSurvey\Microsoft.Dynamics.Nav.Client.SatisfactionSurvey.zip')
Set-NAVAddIn -ServerInstance $InstanceName -AddinName 'Microsoft.Dynamics.Nav.Client.SocialListening' -
PublicKeyToken 31bf3856ad364e35 -ResourceFile ($AppName = Join-Path $ServicesAddinsFolder
'SocialListening\Microsoft.Dynamics.Nav.Client.SocialListening.zip')
Set-NAVAddIn -ServerInstance $InstanceName -AddinName 'Microsoft.Dynamics.Nav.Client.VideoPlayer' -
PublicKeyToken 31bf3856ad364e35 -ResourceFile ($AppName = Join-Path $ServicesAddinsFolder
'VideoPlayer\Microsoft.Dynamics.Nav.Client.VideoPlayer.zip')
Set-NAVAddIn -ServerInstance $InstanceName -AddinName 'Microsoft.Dynamics.Nav.Client.WebPageViewer' -
PublicKeyToken 31bf3856ad364e35 -ResourceFile ($AppName = Join-Path $ServicesAddinsFolder
'WebPageViewer\Microsoft.Dynamics.Nav.Client.WebPageViewer.zip')
Set-NAVAddIn -ServerInstance $InstanceName -AddinName 'Microsoft.Dynamics.Nav.Client.WelcomeWizard' -
PublicKeyToken 31bf3856ad364e35 -ResourceFile ($AppName = Join-Path $ServicesAddinsFolder
'WelcomeWizard\Microsoft.Dynamics.Nav.Client.WelcomeWizard.zip')
```

Task 14: Post-upgrade

1. Enable task scheduler on the server instance.
2. (Multitenant only) For tenants other than the tenant that you use for administration purposes, if you mounted the tenants using the `-AllowAppDatabaseWrite` parameter, dismount the tenants, then mount them again without using the `-AllowAppDatabaseWrite` parameter.
3. If you want to use data encryption as before, enable it.

   For more information, see Managing Encryption and Encryption Keys.

   Optionally, if you exported the encryption key instead of disabling encryption earlier, import the encryption key file to enable encryption.
4. Grant users permission to the *Open in Excel* and *Edit in Excel* actions.

   Version 17 introduces a system permission that protects these two actions. The permission is granted by the system object **6110 Allow Action Export To Excel**. Because of this change, users who had permission to these actions before upgrading, will lose permission. To grant permission again, do one of the following steps:

   - If you have a version 17 application, export the **EXCEL EXPORT ACTION** permission set. Then, import it to your application and add it to appropriate users.
   - Add the system object **6110 Allow Action Export To Excel** permission directly to appropriate

permission sets.

For more information about working with permission sets and permissions, see Export and Import Permission Sets.

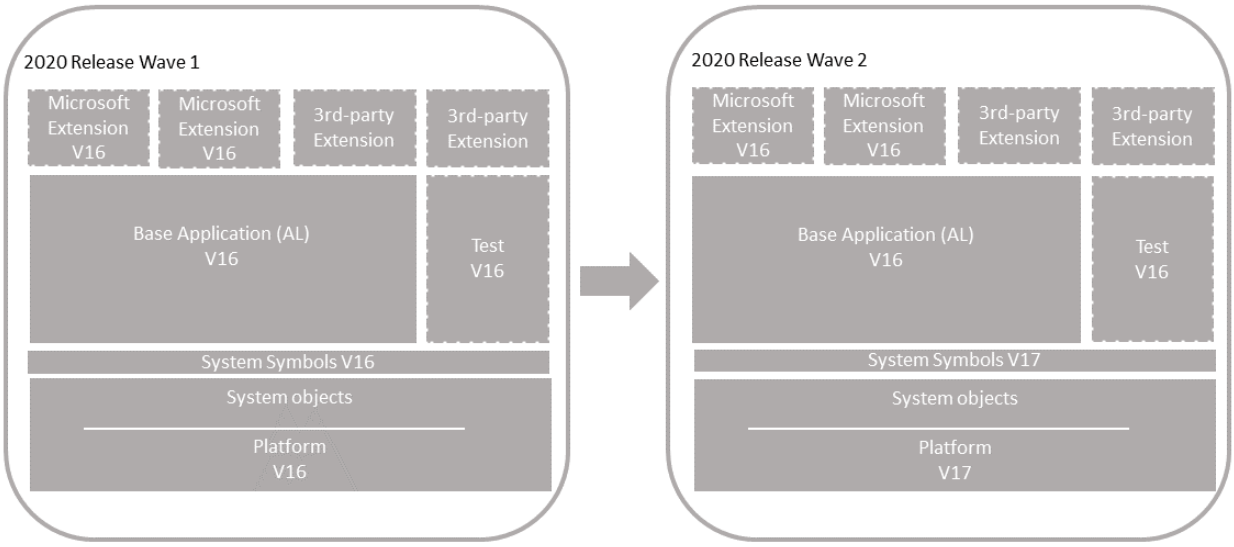
Upgrading to Business Central
Business Central Compatibility Matrix

Technical Upgrade from Version 16 to Version 17

2/17/2021 • 8 minutes to read • Edit Online

Use this process to upgrade from Business Central 2020 release wave 1 (version 16) to the Business Central 2020 release wave 2 platform (version 17). This process won't upgrade the application to the latest version.



Single-tenant and multitenant deployments

The process for upgrading is similar for a single-tenant and multitenant deployment. However, there are some inherent differences. With a single-tenant deployment, the application and business data are included in the same database. While with a multitenant deployment, application code is in a separate database (the application database) than the business data (tenant). In the procedures that follow, for a single-tenant deployment, consider references to the *application database* and *tenant database* as the same database. Steps are marked as *Single-tenant only* or *Multitenant only* where applicable.

Prerequisites

1. Your version 16 platform is compatible with version 17.

   There are several updates for version 16. The updates have a compatible version 17 update. For more information, see Dynamics 365 Business Central Upgrade Compatibility Matrix. For example, if your solution is currently running 16.6, you can't upgrade to 17.0. You must wait until 17.1 is available.

2. Disable data encryption.

   If the current server instance uses data encryption, disable it. You can enable it again after upgrading.

   For more information, see Managing Encryption and Encryption Keys.

   Instead of disabling encryption, you can export the current encryption key, which you'll then import after upgrade. However, we recommend disabling encryption before upgrading.

Task 1: Prepare databases

In this task, you prepare the application and tenant databases for the upgrade.

1. Make backup of the database.

3. (Single-tenant only) Uninstall all extensions from the old tenants.

   Run the Business Central Administration Shell for version 16.0 as an administrator. Use the Uninstall-NAVApp cmdlet to uninstall an extension. For example, together with the Get-NAVAppInfo cmdlet, you can uninstall all extensions with a single command:

   ```
   Get-NAVAppInfo -ServerInstance <BC16 server instance> | % { Uninstall-NAVApp -ServerInstance <BC16
   server instance> -Name $_.Name -Version $_.Version }
   ```

4. Unpublish all system, test, and application symbols.

   To unpublish symbols, use the Unpublish-NAVAPP cmdlet. You can unpublish all symbols by using the Get-NAVAppInfo cmdlet with the `-SymbolsOnly` switch as follows:

   ```
   Get-NAVAppInfo -ServerInstance <BC16 server instance> -SymbolsOnly | % { Unpublish-NAVApp -
   ServerInstance <BC16 server instance> -Name $_.Name -Version $_.Version }
   ```

   What are symbols?

5. (Multitenant only) Dismount the tenants from the application server instance.

   To dismount a tenant, use the Dismount-NAVTenant cmdlet:

   ```
   Dismount-NAVTenant -ServerInstance <BC16 server instance> -Tenant <tenant ID>
   ```

6. Stop the server instance.

   ```
   Stop-NAVServerInstance -ServerInstance <BC16 server instance>
   ```

Task 2: Install version 17

1. Before you install version 17, it can be useful to create desktop shortcuts to the version 16.0 tools, such as the Business Central Server Administration tool, Business Central Administration Shell, and Dynamics NAV Development Shell because the Start menu items for these tools will be replaced with the version 17.0 tools.

2. Install version 17 components.

   You'll keep version 16 installed for now. When you install version 17, you must either specify different port numbers for components (like the Business Central Server instance and web services) or stop the version 16.0 Business Central Server instance before you run the installation. Otherwise, you'll get an error that the Business Central Server failed to install.

   For more information, see Installing Business Central Using Setup.

Task 3: Copy Dynamics Online Connect add-in

The Dynamics Online Connect add-in has been deprecated in version 17. As a result, it has been removed from the DVD and is no longer installed as part of the Business Central Server. However, when doing a technical upgrade, it is still required for the old System Application. To meet this requirement, copy the **Add-ins\Connect** folder of the version 16 server installation to the **Add-ins** folder of the version 17 server installation.

Task 4: Convert the version 16.0 application database

This task runs a technical upgrade on the application database. A technical upgrade converts the database from the version 16.0 platform to the version 17.0 platform. This conversion updates the system tables of the database to the new schema (data structure). It also provides the latest platform features and performance enhancements.

> **IMPORTANT**
> The conversion does not modify the application objects, but it will remove any modifications that you have made to system tables. After the conversion you will no longer be able to use it with Business Central 14.

1. Start Business Central Administration Shell for version 17.0 as an administrator.
2. Run the Invoke-NAVApplicationDatabaseConversion cmdlet to start the conversion. In a multitenant deployment, run this cmdlet against the application database.

   ```
   Invoke-NAVApplicationDatabaseConversion -DatabaseServer <database server>\<database instance> -
   DatabaseName "<BC16 database name>"
   ```

   When completed, a message like the following displays in the console:

   ```
   DatabaseServer      : .\BCDEMO
   DatabaseName        : Demo Database BC (16-0)
   DatabaseCredentials :
   DatabaseLocation    :
   Collation           :
   ```

Task 5: Configure version 17 server

When you installed version 17 in **Task 1**, a version 17 Business Central Server instance was created. In this task, you change server configuration settings that are required to complete the upgrade. Some of the changes are only required for version 16 to version 17.0 upgrade and can be reverted after you complete the upgrade.

1. Set the server instance to connect to the application database.

   ```
   Set-NAVServerConfiguration -ServerInstance <BC17 server instance> -KeyName DatabaseName -KeyValue "
   <BC17 database name>"
   ```

   In a single tenant deployment, this command mounts the tenant automatically. For more information, see Connecting a Server Instance to a Database.

2. Disable task scheduler on the server instance for purposes of upgrade.

   ```
   Set-NavServerConfiguration -ServerInstance <BC17 server instance> -KeyName "EnableTaskScheduler" -
   KeyValue false
   ```

   Be sure to re-enable task scheduler after upgrade if needed.

3. Restart the server instance.

   ```
   Restart-NAVServerInstance -ServerInstance <BC17 server instance>
   ```

Task 6: Upload Business Central partner license

If you have a new Business Central partner license, make sure that it has been uploaded to the database. To upload the license, use the Import-NAVServerLicense cmdlet:

```
Import-NAVServerLicense -ServerInstance <BC17 server instance> -LicenseFile "<path to the license>"
```

For more information, see Uploading a License File for a Specific Database.

Task 7: Publish new system symbols

Use the Publish-NAVApp cmdlet to publish the new symbols extension package. This package is called **System.app**. If you've installed the **AL Development Environment**, you find the file in the installation folder. By default, the folder path is C:\Program Files (x86)\Microsoft Dynamics 365 Business Central\170\AL Development Environment.

```
Publish-NAVApp -ServerInstance <BC17 server instance> -Path "<path to the System.app file>" -PackageType
SymbolsOnly
```

Task 8: Recompile published extensions

Compile all published extensions against the new platform.

1. To compile an extension, use the Repair-NAVApp cmdlet, For example:

   ```
   Repair-NAVApp -ServerInstance <server instance> -Name <extension name> -Version <extension name>
   ```

   To compile all published extensions at once, you can use this command:

   ```
   Get-NAVAppInfo -ServerInstance <server instance> | Repair-NAVApp
   ```

2. Restart the server instance.

   ```
   Restart-NAVServerInstance -ServerInstance <server instance>
   ```

Task 9: Synchronize tenant

1. (Multitenant only) Mount the tenant to the new Business Central Server instance.

   You'll have to do this step and the next for each tenant. For more information, see Mount or Dismount a Tenant.

2. Synchronize the tenant.

   Use the Sync-NAVTenant cmdlet:

   ```
   Sync-NAVTenant -ServerInstance <server instance> -Tenant <tenant ID> -Mode Sync
   ```

   For a single-tenant deployment, you can either set the `<tenant ID>` to `default` or omit the `-Tenant <tenant ID>` parameter. For more information about syncing, see Synchronizing the Tenant Database and Application Database.

Task 10: Reinstall extensions

Skip this task for a multitenant environment. In this task, you reinstall the same extensions that were installed on the tenant before.

To install an extension, you use the Install-NAVApp cmdlet.

1. If your solution uses the System Application, install this first.

   ```
   Install-NAVApp -ServerInstance <server instance> -Name "System Application" -Version <extension version>
   ```

   Replace `<extension version>` with the exact version of the published System Application.

2. Install the Base Application.

   ```
   Install-NAVApp -ServerInstance <server instance> -Name "Base Application" -Version <extension version>
   ```

   Replace `<extension version>` with the exact version of the published System Application.

3. Install the Application extension.

   ```
   Install-NAVApp -ServerInstance <server instance> -Name "Application" -Version <extension version>
   ```

   Replace `<extension version>` with the exact version of the published Application extension.

   For more information about the Application extension, see The Microsoft_Application.app File.

4. Install other extensions, including Microsoft and third-party extensions.

   ```
   Install-NAVApp -ServerInstance <server instance name> -Name <extension name> -Version <extension version>
   ```

At this point, your solution has been updated to the latest platform.

Task 11: Upgrade control add-ins

The Business Central Server installation includes new versions of the Microsoft-provided Javascript-based control add-ins, like Microsoft.Dynamics.Nav.Client.BusinessChart, Microsoft.Dynamics.Nav.Client.VideoPlayer, and more. If your solution uses any of these control add-ins, upgrade them to the latest version.

To upgrade the control add-ins, do the following steps:

1. Open the Business Central client.
2. Search for and open the **Control Add-ins** page.
3. Choose **Actions** > **Control Add-in Resource** > **Import**.
4. Locate and select the .zip file for the control add-in and choose **Open**.

   The .zip files are located in the **Add-ins** folder of the Business Central Server installation. There's a subfolder for each add-in. For example, the path to the Business Chart control add-in is `C:\Program Files\Microsoft Dynamics 365 Business Central\170\Service\Add-ins\BusinessChart\Microsoft.Dynamics.Nav.Client.BusinessChart.zip`.

5. After you've imported all the new control add-in versions, restart Business Central Server instance.

Alternatively, you can use the Set-NAVAddin cmdlet of the Business Central Administration Shell. For example, the following commands update the control add-ins installed by default. Modify the commands to suit:

```
$InstanceName = 'BC170'
$ServicesAddinsFolder = 'C:\Program Files\Microsoft Dynamics 365 Business Central\170\Service\Add-ins'
Set-NAVAddIn -ServerInstance $InstanceName -AddinName 'Microsoft.Dynamics.Nav.Client.BusinessChart' -
PublicKeyToken 31bf3856ad364e35 -ResourceFile ($AppName = Join-Path $ServicesAddinsFolder
'BusinessChart\Microsoft.Dynamics.Nav.Client.BusinessChart.zip')
Set-NAVAddIn -ServerInstance $InstanceName -AddinName 'Microsoft.Dynamics.Nav.Client.FlowIntegration' -
PublicKeyToken 31bf3856ad364e35 -ResourceFile ($AppName = Join-Path $ServicesAddinsFolder
'FlowIntegration\Microsoft.Dynamics.Nav.Client.FlowIntegration.zip')
Set-NAVAddIn -ServerInstance $InstanceName -AddinName 'Microsoft.Dynamics.Nav.Client.OAuthIntegration' -
PublicKeyToken 31bf3856ad364e35 -ResourceFile ($AppName = Join-Path $ServicesAddinsFolder
'OAuthIntegration\Microsoft.Dynamics.Nav.Client.OAuthIntegration.zip')
Set-NAVAddIn -ServerInstance $InstanceName -AddinName 'Microsoft.Dynamics.Nav.Client.PageReady' -
PublicKeyToken 31bf3856ad364e35 -ResourceFile ($AppName = Join-Path $ServicesAddinsFolder
'PageReady\Microsoft.Dynamics.Nav.Client.PageReady.zip')
Set-NAVAddIn -ServerInstance $InstanceName -AddinName 'Microsoft.Dynamics.Nav.Client.PowerBIManagement' -
PublicKeyToken 31bf3856ad364e35 -ResourceFile ($AppName = Join-Path $ServicesAddinsFolder
'PowerBIManagement\Microsoft.Dynamics.Nav.Client.PowerBIManagement.zip')
Set-NAVAddIn -ServerInstance $InstanceName -AddinName 'Microsoft.Dynamics.Nav.Client.RoleCenterSelector' -
PublicKeyToken 31bf3856ad364e35 -ResourceFile ($AppName = Join-Path $ServicesAddinsFolder
'RoleCenterSelector\Microsoft.Dynamics.Nav.Client.RoleCenterSelector.zip')
Set-NAVAddIn -ServerInstance $InstanceName -AddinName 'Microsoft.Dynamics.Nav.Client.SatisfactionSurvey' -
PublicKeyToken 31bf3856ad364e35 -ResourceFile ($AppName = Join-Path $ServicesAddinsFolder
'SatisfactionSurvey\Microsoft.Dynamics.Nav.Client.SatisfactionSurvey.zip')
Set-NAVAddIn -ServerInstance $InstanceName -AddinName 'Microsoft.Dynamics.Nav.Client.SocialListening' -
PublicKeyToken 31bf3856ad364e35 -ResourceFile ($AppName = Join-Path $ServicesAddinsFolder
'SocialListening\Microsoft.Dynamics.Nav.Client.SocialListening.zip')
Set-NAVAddIn -ServerInstance $InstanceName -AddinName 'Microsoft.Dynamics.Nav.Client.VideoPlayer' -
PublicKeyToken 31bf3856ad364e35 -ResourceFile ($AppName = Join-Path $ServicesAddinsFolder
'VideoPlayer\Microsoft.Dynamics.Nav.Client.VideoPlayer.zip')
Set-NAVAddIn -ServerInstance $InstanceName -AddinName 'Microsoft.Dynamics.Nav.Client.WebPageViewer' -
PublicKeyToken 31bf3856ad364e35 -ResourceFile ($AppName = Join-Path $ServicesAddinsFolder
'WebPageViewer\Microsoft.Dynamics.Nav.Client.WebPageViewer.zip')
Set-NAVAddIn -ServerInstance $InstanceName -AddinName 'Microsoft.Dynamics.Nav.Client.WelcomeWizard' -
PublicKeyToken 31bf3856ad364e35 -ResourceFile ($AppName = Join-Path $ServicesAddinsFolder
'WelcomeWizard\Microsoft.Dynamics.Nav.Client.WelcomeWizard.zip')
```

Task 12: Post-upgrade

1. Enable task scheduler on the server instance.
2. (Multitenant only) For tenants other than the tenant that you use for administration purposes, if you mounted the tenants using the `-AllowAppDatabaseWrite` parameter, dismount the tenants, then mount them again without using the `-AllowAppDatabaseWrite` parameter.
3. If you want to use data encryption as before, enable it.

   For more information, see Managing Encryption and Encryption Keys.

   Optionally, if you exported the encryption key instead of disabling encryption earlier, import the encryption key file to enable encryption.

Installing a Business Central 2020 Release Wave 2 Update

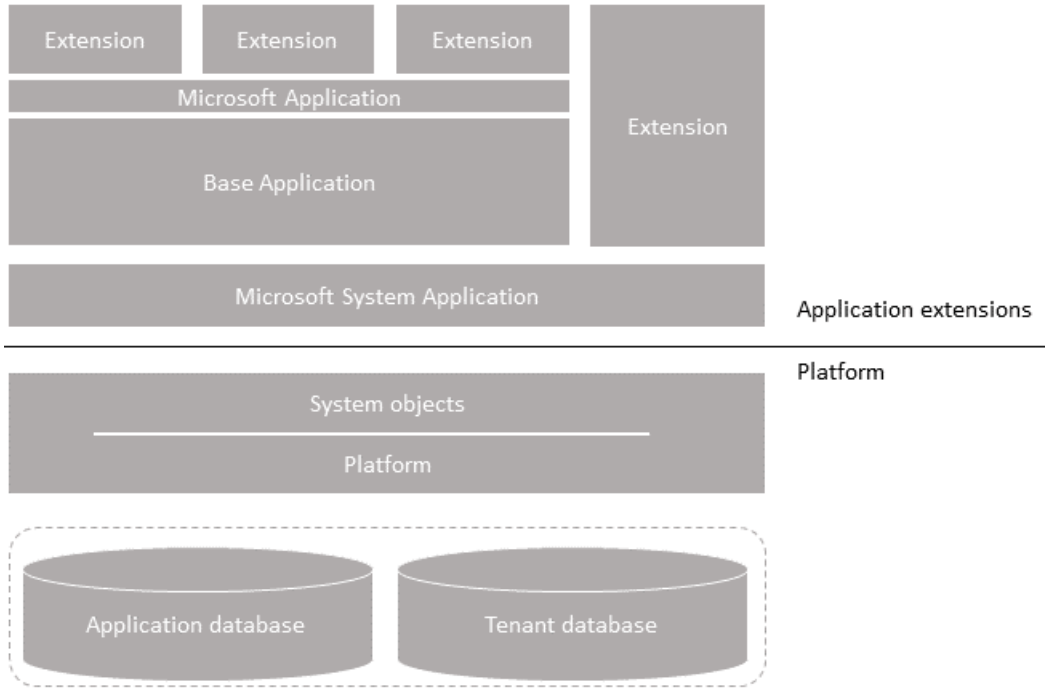
2/17/2021 • 17 minutes to read • Edit Online

This article describes how to install an update for Business Central on-premises. An update is a set of files that includes all hotfixes and regulatory features that have been released for Business Central.

You can choose to update only the platform or both the platform and application code. The installation guidelines are separated into PLATFORM tasks and APPLICATION tasks.

Overview

The following figure provides a high-level representation of a Business Central solution and the components that are involved in the installation of an update.



The databases store the application metadata and business data. If you have a single-tenant deployment, this data is stored in a single database. A multitenant deployment stores the application metadata in the application database and the business data in one or more tenant databases.

Application stack

The application includes AL extensions that define the objects and code that makes up the business logic. For example, objects include tables, report, pages, codeunits, and more. Each extension is compiled and delivered as an .app file, which is published to the Business Central Server instance.

- System Application extension

  The Microsoft System Application extension includes functionality that isn't directly related the business logic. For more information, see Overview of the System Application. When using the Microsoft Base Application, your solution uses the System Application. With a custom Base Application, your solution may or may not use the System Application. If it doesn't, you can skip any steps in this article related to the System Application.

- Base application extension

  As a minimum, the solution always includes the Base Application. The Base Application contains the objects (such as table, pages, codeunits, and reports) that define the business logic and functionality of the solution. The Base Application can be either the Microsoft Base Application or a customized Base Application. The Microsoft Base Application is the standard application that is on the installation media (DVD). A customized Base Application is an application that includes customized code.

- Application extension

  The Application extension logically encapsulates all of the extensions making up a solution, for example, version `16.0.0.0` of the base and system application package files, and it provides a convenient way to define and refer to this solution identity. This extension is required for Microsoft extensions, but is optional for third-party extensions. For more information, see The Microsoft_Application.app File.

- Customization extensions

  Customization extensions add functionality and features to the Base Application or System Application. Extensions can be either Microsoft extensions or third-party extensions. Microsoft extensions are available on the DVD. Third-party extensions are extensions developed by your organization or by another organization, like an ISV.

Single-tenant and multitenant deployments

The process for upgrading is similar for a single-tenant and multitenant deployment. However, there are some inherent differences. With a single-tenant deployment, the application and business data are included in the same database. While with a multitenant deployment, application code is in a separate database (the application database) than the business data (tenant). In the procedures that follow, for a single-tenant deployment, consider references to the *application database* and *tenant database* as the same database. Steps are marked as *Single-tenant only* or *Multitenant only* where applicable.

Platform versus application update

A platform update doesn't change the application. It involves converting your databases to the new platform and recompiling the existing extensions to ensure that they're compatible with the new platform.

An application update involves:

- Publishing new versions of extensions that include the latest application modifications
- Synchronizing the databases with any schema change introduced by the new extensions
- Updating affected data.

The installation media (DVD) includes new versions of Microsoft's Base Application, System Application, and extensions. The DVD also includes the AL source code for the Microsoft Base Application. This code useful if you have a custom base application. You can use the code to compare and merge updates into your application. You'll only have to recompile third-party extensions that you don't have a new version to publish.

PREPARATION

Download update package

The first thing to do is to download the update package that matches your Business Central solution.

1. Go to the list of available updates for your on-premises version of Business Central. Then, choose the update that you want.

2. From the update page, under the **Resolution** section, select the link for downloading the update, and follow the instructions.

3. On the computer where you downloaded the update .zip file, extract the all the files to a selected location.

   When extracted, the update includes the DVD folder. This folder contains the full Business Central product. For example, the folder includes the Business Central installation program (setup.exe), tools for upgrading to the platform, and the Microsoft extensions.

When this step is completed, you can continue to update your Business Central solution to the new platform and application.

Prepare existing databases

1. Back up your databases.
2. Run the Business Central Administration Shell as an administrator.
3. (Single-tenant only) Uninstall all extensions from the all tenants.

   In this step, you uninstall the Base Application, System Application (if used), and any other extensions that are currently installed on the database.

   a. Get a list of installed extensions.

      This step is optional, but it can be useful to the names and versions of the extensions.

      To get a list of installed extensions, use the Get-NAVAppInfo cmdlet.

      ```
      Get-NAVAppInfo -ServerInstance <server instance name>
      ```

   b. Uninstall the extensions.

      To uninstall an extension, you use the Uninstall-NAVApp cmdlet.

      ```
      Uninstall-NAVApp -ServerInstance <server instance name> -Tenant <tenant ID> -Name <extensions
      name> -Version <extension version> -Force
      ```

      Replace `<extension name>` and `<extension version>` with the exact name and version the installed extension. For single-tenant deployment, set `<tenant ID>` to `default` or omit the `-Tenant` parameter.

      For example, together with the Get-NAVApp cmdlet, you can uninstall all extensions with a single command:

      ```
      Get-NAVAppInfo -ServerInstance <server instance name> -Tenant <tenant ID> | % { Uninstall-
      NAVApp -ServerInstance <server instance name> -Tenant <tenant ID> -Name $_.Name -Version
      $_.Version -Force}
      ```

4. Unpublish the existing system symbols.

   To unpublish the system symbols, use the Unpublish-NAVApp cmdlet as follows:

   ```
   Unpublish-NAVApp -ServerInstance <server instance> -Name System -version <version>
   ```

   What are symbols?.

5. (Multitenant only) Dismount the tenants from the application database.

   To dismount a tenant, use the Dismount-NAVTenant cmdlet:

```
Dismount-NAVTenant -ServerInstance <server instance> -Tenant <tenant ID>
```

Install Business Central components

From the installation media (DVD), run setup.exe to uninstall the current Business Central components and install the Business Central components included in the update.

1. Stop the Business Central Server instance.

```
Stop-NAVServerInstance -ServerInstance <server instance>
```

2. Run setup.exe to uninstall your current version of Business Central.
3. Run setup.exe again to install components of the update.
   a. Follow setup pages until you get to the **Microsoft Dynamics 365 Business Central Setup** page.
   b. Select **Advanced installation options** > **Choose an installation option** > **Custom**.
   c. On the **Customize the installation** page, select the following components as a minimum:
      - AL Development Environment (optional but recommended)
      - Server
      - Web Server Components.
   d. Select **Next**.
   e. On the **Specify parameters** page, set the fields as needed.

      IMPORTANT
      Clear the **SQL Database** field so that it is blank. At this time, do not set this to the database that you want to update; otherwise, the installation of the Business Central Server will fail. You will connect the database to the Business Central Server later after it is converted to the new platform.

   f. Select **Apply** to complete the installation.

For more information, see Installing Business Central Using Setup.

PLATFORM UPDATE

Follow the next few tasks to convert your database to the new platform of the update. A multitenant deployment includes the application and tenant databases. The conversion updates the system tables of the database to the new schema (data structure) and provides the latest platform features and performance enhancements.

Also, to ensure that the existing published extensions work on the new platform, you'll recompile the extensions.

Convert existing database to new platform

1. Run the Business Central Administration Shell as an administrator.
2. Run the Invoke-NAVApplicationDatabaseConversion cmdlet to start the database conversion to the new platform.

```
Invoke-NAVApplicationDatabaseConversion -DatabaseServer <database server name>\<database server
instance> -DatabaseName "<database name>" [-Force]
```

For example, in a single tenant deployment:

```
Invoke-NAVApplicationDatabaseConversion -DatabaseServer .\BCDEMO -DatabaseName "Demo Database BC (17-
0)"
```

In a multitenant deployment, run this cmdlet against the application database and use the `-Force` parameter. For example:

```
Invoke-NAVApplicationDatabaseConversion -DatabaseServer .\BCDEMO -DatabaseName "BC17 Application" -
Force
```

When completed, a message like the following displays in the console:

```
DatabaseServer      : .\BCDEMO
DatabaseName        : Demo Database BC (17-0)
DatabaseCredentials :
DatabaseLocation    :
Collation           :
```

NOTE

Depending on the update that you're installing, you might get a message similar to the following:

```
Invoke-NAVApplicationDatabaseConversion : A technical upgrade of database <database name> on
server '.\<database instance>' cannot be run, because the database's application version 'NNNNNN'
is greater than or equal to the platform version 'NNNNNN'
```

This is not an error, and you can continue installing the update. This message is recorded as a warning in the event log as well. This message indicates that the application database is already compatible with the new platform, which happens when the update does not make any schema changes to the system tables.

Connect server instance to database

1. (Multitenant only) Enable the server instance as a multitenant instance:

```
Set-NAVServerConfiguration -ServerInstance <server instance> -KeyName Multitenant -KeyValue true
```

2. Connect the server instance to connect to the database.

```
Set-NAVServerConfiguration -ServerInstance <server instance> -KeyName DatabaseName -KeyValue "
<database name>"
```

In a multitenant deployment, the database is the application database. For more information, see Connecting a Server Instance to a Database.

3. Restart the server instance.

```
Restart-NAVServerInstance -ServerInstance <server instance>
```

Publish the new system symbols

Use the Publish-NAVApp cmdlet to publish the new symbols extension package. This package is called **System.app**. If you've installed the **AL Development Environment**, you find the file in the installation folder. By default, the folder path is C:\Program Files (x86)\Microsoft Dynamics 365 Business Central\170\AL Development Environment. Or, it's also on the installation media (DVD) in the ModernDev\program files\Microsoft Dynamics NAV\170\AL Development Environment folder.

```
Publish-NAVApp -ServerInstance <server instance> -Path "<path to the System.app file>" -PackageType SymbolsOnly
```

Recompile published extensions

Compile all published extensions against the new platform.

> **NOTE**
> If you plan on updating the application you can skip this step for extensions for which you have new versions built on the new platform. For example, this includes Microsoft extensions that are on the DVD.

1. To compile an extension, use the Repair-NAVApp cmdlet, For example:

   ```
   Repair-NAVApp -ServerInstance <server instance> -Name <extension name> -Version <extension name>
   ```

   To compile all published extensions at once, you can use this command:

   ```
   Get-NAVAppInfo -ServerInstance <server instance> | Repair-NAVApp
   ```

2. Restart the server instance.

   ```
   Restart-NAVServerInstance -ServerInstance <server instance>
   ```

Synchronize tenant

1. (Multitenant only) Mount the tenant to the new Business Central Server instance.

   You'll have to do this step and the next for each tenant. For more information, see Mount or Dismount a Tenant.

2. Synchronize the tenant.

   Use the Sync-NAVTenant cmdlet:

   ```
   Sync-NAVTenant -ServerInstance <server instance> -Tenant <tenant ID> -Mode Sync
   ```

   For a single-tenant deployment, you can either set the `<tenant ID>` to `default` or omit the `-Tenant <tenant ID>` parameter. For more information about syncing, see Synchronizing the Tenant Database and Application Database.

NOTE

At this point, if you want to update the application, you can skip the next step and proceed APPLICATION.

(Single-tenant only) Reinstall extensions

In this task, you reinstall the same extensions that were installed on the tenant before. If you're planning on updating the application, then skip this step.

To install an extension, you use the Install-NAVApp cmdlet.

1. If your solution uses the System Application, install this first.

   ```
   Install-NAVApp -ServerInstance <server instance> -Name "System Application" -Version <extension version>
   ```

   Replace `<extension version>` with the exact version of the published System Application.

2. Install the Base Application.

   ```
   Install-NAVApp -ServerInstance <server instance> -Name "Base Application" -Version <extension version>
   ```

   Replace `<extension version>` with the exact version of the published Base Application.

3. Install the Application extension as needed.

   ```
   Install-NAVApp -ServerInstance <server instance> -Name "Application" -Version <extension version>
   ```

   Replace `<extension version>` with the exact version of the published Application extension.

4. Install other extensions, including Microsoft and third-party extensions.

   ```
   Install-NAVApp -ServerInstance <server instance name> -Name <extension name> -Version <extension version>
   ```

At this point, your solution has been updated to the latest platform.

IMPORTANT

If your solution uses any Microsoft control add-ins, you must upgrade the add-ins to the latest version. Go to Upgrade control add-ins under **Post Upgrade** section.

APPLICATION UPDATE

Follow the next tasks to update the application code to the new features and hotfixes. The tasks include publishing new versions of the System Application, Base Application, and add-on extensions.

You publish the System Application extension only if it was used in old solution. Add-on extensions include Microsoft and third- party extensions that were used in the old solution.

> **NOTE**
> If a license update is required for a regulatory feature, customers can download an updated license from CustomerSource (see How to Download a Microsoft Dynamics 365 Business Central License from CustomerSource), and partners can download their customers' updated license from VOICE (see How to Download a Microsoft Dynamics 365 Business Central Customer License from VOICE).

Upgrade System Application

Follow these steps if your existing solution uses the Microsoft System Application. Otherwise, you can skip this procedure.

1. Publish the **System Application** extension (Microsoft_System Application.app).

   You find the (Microsoft_System Application.app in the **Applications\System Application\Source** folder of installation media (DVD).

   ```
   Publish-NAVApp -ServerInstance <server instance name> -Path "<path to Microsoft_System
   Application.app>"
   ```

2. Synchronize the tenant(s) with the **System Application** extension (Microsoft_System Application):

   Use the Sync-NAVApp cmdlet:

   ```
   Sync-NAVApp -ServerInstance <server instance name> -Tenant <tenant ID> -Name "System Application" -
   Version <extension version>
   ```

   Replace `<extension version>` with the exact version of the published System Application.

   > **TIP**
   > To get a list of all published extensions, along with their names and versions, use the Get-NAVAppInfo cmdlet.

3. Run the data upgrade on the System Application.

   To run the data upgrade, use the Start-NavAppDataUpgrade cmdlet:

   ```
   Start-NAVAppDataUpgrade -ServerInstance <server instance name> -Tenant <tenant ID> -Name "System
   Application" -Version <extension version>
   ```

   Upgrading data updates the data in the tables of the tenant database to the schema changes made to tables of the System Application.

Upgrade Base Application

Microsoft Base Application

Follow these steps if your existing solution uses the Microsoft Base Application.

1. Publish the Business Central Base Application extension (Microsoft_Base Application.app).

   The **Base Application** extension contains the application business objects. You find the Microsoft_Base Application.app in the **Applications\BaseApp\Source** folder of installation media (DVD).

```
Publish-NAVApp -ServerInstance <server instance name> -Path "<path to Microsoft_Base
Application.app>"
```

2. Synchronize the tenant with the Business Central Base Application extension (Microsoft_BaseApp):

   ```
   Sync-NAVApp -ServerInstance <server instance name> -Tenant <tenant ID> -Name "Base Application" -
   Version <extension version>
   ```

   Replace `<extension version>` with the exact version of the published Base Application.

   With this step, the base app takes ownership of the database tables. When completed, in SQL Server, the table names will be suffixed with the base app extension ID. This process can take several minutes.

3. Run the data upgrade on the Base Application.

   To run the data upgrade, use the Start-NavAppDataUpgrade cmdlet:

   ```
   Start-NAVAppDataUpgrade -ServerInstance <server instance name> -Tenant <tenant ID> -Name "Base
   Application" -Version <extension version>
   ```

   Upgrading data updates the data in the tables of the tenant database to the schema changes made to tables of the Base Application.

Upgrade custom Base Application

With a custom Base Application, you may want the new application features and hotfixes in the Microsoft Base Application. If so, you'll have to merge the modifications made in the Microsoft Base Application into your custom Base Application. Then, create a new version of your custom Base Application.

The source code for the new Microsoft Base Application version is in the **Base Application.Source.zip** file. This file is on the installation media (DVD), in the **Applications\BaseApp\Source** folder. You can compare this source code with the source code of the previous Microsoft Base Application and your custom application source. Then merge the code into a new custom application version.

After you've created the new version of your custom application, you publish it to the application server instance. Then, you synchronize and run the data upgrade on the tenants.

Upgrade Microsoft extensions

If your old solution used Microsoft extensions, then you upgrade these extensions to the new versions that are available on the Business Central installation media (DVD). The new versions are in the **Applications** folder, which contains a subfolder for each extension. The extension package (.app file) that you need for publishing the extension is in the **Source** folder, for example, **Applications\SalesAndInventoryForecast\Source\SalesAndInventoryForecast.app**.

The general steps for this task are listed below. For detailed steps, see Publishing, Upgrading, and Installing Extensions During Upgrade.

Publish and install Microsoft_Application extension

The Microsoft_Application extension was introduced in 15.3. In short, it's used to contain the dependency declarations on the system and base application extensions. For more information about this extension, see The Microsoft_Application.app File.

1. Publish the Microsoft_Application.app package.

   The installation media path to the extension package (.app file) is

Applications\Application\Source\Microsoft_Application.app"

```
Publish-NAVApp -ServerInstance <server instance name> -Path "<folder path>\Microsoft_Application.app"
```

2. Synchronize the tenant database with the schema changes of the Microsoft_Application extension.

```
Sync-NavApp -ServerInstance <server instance name> -Tenant <tenant ID> -Name <extension name> -Tenant
<tenant ID>
```

3. Upgrade the Microsoft_Application extension on your tenants.

```
Start-NAVAppDataUpgrade -ServerInstance <server instance name> -Tenant <tenant ID> -Name Application
```

Publish and install Microsoft extensions

Complete these steps for each Microsoft extension that you want to upgrade.

1. Publish the new extension versions from the installation media (DVD).

```
Publish-NAVApp -ServerInstance <server instance name> -Path <path to extension package file>
```

2. Synchronize the tenant database with the schema changes of the extensions.

```
Sync-NavApp -ServerInstance <server instance name> -Tenant <tenant ID> -Name <extension name> -
Version <extension version>
```

3. Upgrade the data associated with the Microsoft extensions. This step will automatically install the new version on the tenant

```
Start-NAVAppDataUpgrade -ServerInstance <server instance name> -Tenant <tenant ID> -Name <extension
name> -Version <extension version>
```

Upgrade Third-Party extensions

If the old solution used third-party extensions, and you still want to use them, they must be compiled to work on the new platform. For more information, see Recompile published extensions. You then reinstall the extensions on tenants using the Install-NAVApp cmdlet.

As an alternative, if you have the source for these extensions, you can build and compile a new version of the extension in the AL development environment. Then, you upgrade to the new version as described in the previous task.

Post Upgrade

Upgrade control add-ins

The Business Central Server installation includes new versions of the Microsoft-provided Javascript-based control add-ins, like Microsoft.Dynamics.Nav.Client.BusinessChart, Microsoft.Dynamics.Nav.Client.VideoPlayer, and more. If your solution uses any of these control add-ins, upgrade them to the latest version.

To upgrade the control add-ins, do the following steps:

1. Open the Business Central client.

2. Search for and open the **Control Add-ins** page.
3. Choose **Actions** > **Control Add-in Resource** > **Import**.
4. Locate and select the .zip file for the control add-in and choose **Open**.

   The .zip files are located in the **Add-ins** folder of the Business Central Server installation. There's a subfolder for each add-in. For example, the path to the Business Chart control add-in is `C:\Program Files\Microsoft Dynamics 365 Business Central\170\Service\Add-ins\BusinessChart\Microsoft.Dynamics.Nav.Client.BusinessChart.zip`.
5. After you've imported all the new control add-in versions, restart Business Central Server instance.

Alternatively, you can use the Set-NAVAddin cmdlet of the Business Central Administration Shell. For example, the following commands update the control add-ins installed by default. Modify the commands to suit:

```
$InstanceName = 'BC170'
$ServicesAddinsFolder = 'C:\Program Files\Microsoft Dynamics 365 Business Central\170\Service\Add-ins'
Set-NAVAddIn -ServerInstance $InstanceName -AddinName 'Microsoft.Dynamics.Nav.Client.BusinessChart' -
PublicKeyToken 31bf3856ad364e35 -ResourceFile ($AppName = Join-Path $ServicesAddinsFolder
'BusinessChart\Microsoft.Dynamics.Nav.Client.BusinessChart.zip')
Set-NAVAddIn -ServerInstance $InstanceName -AddinName 'Microsoft.Dynamics.Nav.Client.FlowIntegration' -
PublicKeyToken 31bf3856ad364e35 -ResourceFile ($AppName = Join-Path $ServicesAddinsFolder
'FlowIntegration\Microsoft.Dynamics.Nav.Client.FlowIntegration.zip')
Set-NAVAddIn -ServerInstance $InstanceName -AddinName 'Microsoft.Dynamics.Nav.Client.OAuthIntegration' -
PublicKeyToken 31bf3856ad364e35 -ResourceFile ($AppName = Join-Path $ServicesAddinsFolder
'OAuthIntegration\Microsoft.Dynamics.Nav.Client.OAuthIntegration.zip')
Set-NAVAddIn -ServerInstance $InstanceName -AddinName 'Microsoft.Dynamics.Nav.Client.PageReady' -
PublicKeyToken 31bf3856ad364e35 -ResourceFile ($AppName = Join-Path $ServicesAddinsFolder
'PageReady\Microsoft.Dynamics.Nav.Client.PageReady.zip')
Set-NAVAddIn -ServerInstance $InstanceName -AddinName 'Microsoft.Dynamics.Nav.Client.PowerBIManagement' -

```

Update application version

This task isn't required for installing the update. However, it might be useful for support purposes and answering a common question about the application version. The **Help and Support** page in the client displays an application version, such as 16.1.2345.6. This version number isn't updated automatically when you install an update.

However, the Business Central Server includes a configuration setting called **Solution Version Extension** (SolutionVersionExtension). This setting lets you specify an extension whose version number will show as the Application Version on the client's **Help and Support** page. Typically, you'd use the extension considered to be

your solution's base application. You set **Solution Version Extension** to ID of the extension. For example, if your solution uses the Microsoft Base Application, set the value to `437dbf0e-84ff-417a-965d-ed2bb9650972`.

You can set **Solution Version Extension** by using the Business Central Server Administration tool or the Set-NAVServerConfiguration cmdlet of the Business Central Administration Shell.

The following example uses the Set-NAVServerConfiguration cmdlet to set the **Solution Version Extension** to the Microsoft Base Application:

```
Set-NAVServerConfiguration -ServerInstance <server instance name> -KeyName SolutionVersionExtension -
KeyValue 437dbf0e-84ff-417a-965d-ed2bb9650972 -ApplyTo All
```

For more information about how to configure a server instance, see Configuring Business Central Server.

Some Known Issues in Dynamics 365 Business Central On-premises

2/17/2021 • 6 minutes to read • Edit Online

This article describes some known issues in Business Central versions. These issues can impact installation, upgrade, and various operations of Business Central on-premises.

> **NOTE**
> The article doesn't include a complete list of known issues. Instead, it addresses some common issues that you might experience or might consider when upgrading to a version. If you're aware of issues that aren't in this article, or you'd like more help, see Resources for Help and Support.

Primary key mismatch between converted tables in local 14 versions and Microsoft Base Application

> Applies to: 14.18-14.x, 15.12-15.x, 16.7-16.x, 17.1-17.x

Problem

In some local versions, new table objects were added as part of a minor update. In version 14, which is still C/AL based, the primary keys of these tables are unnamed. When you convert the tables from CAL to AL using the txt2AL tool, primary keys are given the name `Key1`. In version 15, 16, and 17, which is fully AL-based, these tables have been moved to Microsoft base application extension, and the primary keys have the name `PK`. This difference can cause problems when you upgrade to use the Microsoft Base Application because it introduces breaking changes.

The affected local versions and tables include:

LOCAL 14 VERSION	TABLES
CH	• QRBill Buffer • QRBill Billing Detail • QRBill Billing Info • QRBill Layout QRBill • QRBill Setup • VAT Reg. No. Srv. Template • VAT Registration Log Details
NA	• VAT Reg. No. Srv. Template • VAT Registration Log Details

> **NOTE**
> You don't experience this problem with table objects in other Microsoft extension because the primary keys are named `KEY1`.

Impact

If you don't resolve this conflict, you'll experience problems when upgrading a customized version 14 (C/AL) application to the Microsoft Base Application.

For example, consider the following articles:

- Upgrading Customized C/AL Application to Microsoft Base Application Version 16
- Upgrading Customized C/AL Application to Microsoft Base Application Version 17

During this upgrade process, you'll create two versions of an extension referred to as the *table migration* extension. This extension is used for transferring ownership of existing tables in the database to other extensions. The first version contains table objects. The second version contains a migration.json file instead of the table objects. When you try synchronize the second version of the table migration extension (Task 13.5 or Task 12.6), you'll get the following errors for each affected table:

```
Table <table name> :: The previous primary key 'Key1' cannot be located. Changing the primary key is not
allowed.
```

```
Table <table name> :: Introducing a new key 'PK' as the primary key is not allowed. Please make the key
'Key1' the primary key again.
```

Workaround

To avoid these errors, after converting the version 14 tables to AL, rename instances of the primary key `Key1` to `PK` in the affected table objects before building your extensions.

- If you're following the upgrade articles listed above, do this change as part of Task 2. If you've already published the first table migration extension with the wrong key names, we recommend restore the databases and go through the upgrade again, starting from Task 2.
- You should also make these changes if you're only doing a technical upgrade, so you won't run into problems later if eventually uptake the Microsoft Base Application.

For each affected table object, do the following steps:

1. Open the .al file.
2. Locate the primary key definition. For example:

```
keys
{
    key(Key1; "Primary key")
    {
        Clustered = true;
    }
}
```

3. Change the name from `Key1` to `PK`. For example:

```
keys
{
    key(PK; "Primary key")
    {
        Clustered = true;
    }
}
```

Enum type fields not transferred as part of schema migration between extensions

> Applies to: 15.3-15.11, 16.0-16.4

Problem

The table migration feature fails to transfer data from a table object to a table extension object that introduces an enumeration.

> **NOTE**
> The table migration feature was introduced in version 15.3. For more information, see Migrating Tables and Fields Between Extensions.

Impact

You'll experience this issue in the following scenarios:

- Upgrading a customized version 14 solution to version 15 or 16
- Migrating data from one extension to another.

The issue occurs when synchronizing extensions. You'll get an error similar to one of the following messages:

```
Sync-NAVApp : The metadata object Enum <ID> was not found.
```

```
Message App Sync Exception -- Microsoft.Dynamics.Nav.Types.NavMetadataNotFoundException: The metadata object
Enum <ID> was not found.
```

Workaround

- If you're upgrading from version 14, use 15.12 (or later) or 16.5 (or later) as the target version.
- If you're migrating data between extensions, upgrade your solution to 15.12 (or later) or 16.5 (or later).

$systemModifiedAt fields in tables not populated during upgrade

> Applies to: 14.0-14.x

Problem

Business Central version 17 introduced data audit fields on tables. When you upgrade from version 15 or 16, the $systemModifiedAt field is populated with values from field **5120 ModifiedOn** in table **5151 Integration Record**. However, this mapping doesn't work in a version 14-to-17 upgrade.

Impact

When upgrading from version 14 to version 17, the $systemModifiedAt field will be blank.

Workaround

Upgrade to version 15 or 16 before upgrading to version 17.

Wrong .NET assemblies for external connected services

> Applies to: 16.5

Problem

Version 16.5 includes the wrong .NET 4.5 assemblies for connecting to external services that use OAuth, like Common Data Service.

Impact

In the Business Central client, you can set up external service connections from the **Service Connections** page.

When you try to set up a connection, it will fail because Business Central can't obtain an access token for connecting to the service.

In the client, you'll get an error similar to the following message:

```
Failed to acquire authorization token for <service>.
```

In the event log, you'll see an error similar to the following message:

```
Could not load file or assembly 'Microsoft.Identity.Client, Version=4.14.0, Culture=neutral,
PublicToken=0a613f4dd989e8e' or one of its dependencies. The located assembly's manifest location does not
match the assembly reference.
```

Workaround

There are two workarounds for this issue:

1. Upgrade to 16.6 or later.
2. Install the required assemblies:
   a. Go to https://www.nuget.org/packages/Microsoft.Identity.Client/4.14.0.
   b. Under **Info**, select **Download package**.
   c. Extract the contents of the nupkg file to a folder.

      There are different ways to extract the content of nupkg file. An easy way is to change the file extension from *.nupkg* to *.zip*. Then, extract the files like you would do with any .zip file.

   d. Copy the files in the **\lib\net45** folder to the **Service** folder of the Business Central Server installation. Replace the existing files when prompted.

      The default folder is C:\Program Files\Microsoft Dynamics 365 Business Central\160\Service.

   e. Restart the Business Central Server instance.

Help Server for India preview missing files

> Applies to: 17.x

Problem

The installation media (DVD) is missing required HTML files for the Help Server.

Impact

The Help Server installation will fail.

Workaround

Install Help Server without the HTML files for local functionality, then pick up the content from GitHub instead. For more information, see Get updates from Microsoft.

Business Central Server Administration tool doesn't work for multitenant server instances

> Applies to: 17.0-17.1

If a Business Central Server instance is configured as a multitenant instance, you can't manage the tenants by using the Business Central Server Administration tool.

Impact

When you try to use the **Tenant** node in the Business Central Server Administration tool, you get a message: The MMC has detected an error in the snap-in and will unload it. This message is followed by:

```
FX:{ba484c42-ed9a-0170-925f-23e64e686fd0}
```

```
Value cannot be null.
```

```
Parameter name: objectToValidate at Microsoft.ManagementConsole.BaseCollection.OnValidate(Object
objectToValidate, Boolean testForDuplicate) at

requestInfo) at Microsoft.ManagementConsole.Executive.SnapInRequestOperation.ProcessRequest() at
Microsoft.ManagementConsole.Executive.Operation.OnThreadTransfer(SimpleOperationCallback callback)
```

Workaround

Use the Business Central Administration Shell. This error is fixed in later updates.

Upgrading to Business Central

Migrate Legacy Help to the Dynamics 365 Business Central Format

2/17/2021 • 5 minutes to read • Edit Online

Business Central implements a user assistance model where tooltips explain all fields and actions, and articles with conceptual descriptions of functionality are published to a website. If you are building an app, you are expected to comply with this model. However, there are many ways in which you can migrate and reuse your existing Help within this model.

Reusing existing web content

When you move to Business Central, you can reuse your existing product Help solution in most situations, especially if the content is already published to an *online library*, which is an internal or external website. In that case, all you have to do is to add that website to the configuration of Business Central online or on-premises. For more information, see Configuring the Help Experience.

More specifically, if you have content that you created for Dynamics NAV, then you can choose to reuse that content for your Business Central solution.

For example, you have a Dynamics NAV Help Server website with HTML files that describe your solution according to the Microsoft Dynamics NAV 2013 R2 documentation model and format. You can reuse the Help Server website and rebrand the website and the content. You then connect your Business Central solution with the Help Server website. For more information, see Configuring the Help Experience.

Business Central does not support the field-based approach to context-sensitive Help that Dynamics NAV 2017 and earlier versions use. Instead, you must use the Business Central page-based approach to context-sensitive Help. You do not have to convert your existing Help, but you do need to make the content available. For more information, see the Converting existing content section.

> **NOTE**
> For apps for Business Central online, you must apply tooltips to controls and actions in both page objects and page extensions, and you must supply context-sensitive links. For more information, see Configuring the Help Experience.

Converting existing content

If your existing content is in a different format, such as PDF files, Word documents, or printed manuals, you must decide if you want to keep the content as-is, or if you want to convert it to a format that can be accessed from inside Business Central. There are third-party tools available that can help you migrate your content, depending on the current format and the target format.

For example, if you are migrating your solution from Dynamics GP, you might have content in PDF files. You can choose to convert the content to MarkDown as described in the Moving to MarkDown section, and then publish to a new online library on your current website.

Migrating from Dynamics NAV

If you are migrating your solution from Microsoft Dynamics NAV 2013 R2 or later versions of Dynamics NAV, then you most likely have been using the Dynamics NAV Help Server, and your Help content is in HTML format. That means that you can reuse your existing content as-is, you can use the Custom Help Toolkit to get new HTML files to supplement your existing content, or you can use publicly available third-party solutions to

convert some or all of your HTML files to MarkDown if you want to follow similar processes to the ones the Microsoft team follows. For more information, see the Moving to MarkDown section.

If you are migrating from an earlier version of Dynamics NAV, then you can choose to first migrate to the Microsoft Dynamics NAV 2013 R2 format, and then migrate again to MarkDown. For more information, see Upgrading Your Existing Help Content in the legacy docs for Microsoft Dynamics NAV 2013 R2.

Converting legacy Dynamics NAV field Help to tooltips

Tooltips play an important role as part of the Business Central user assistance model, and we encourage you to apply tooltips to your controls and actions as well.

If you would like to reuse text from your Dynamics NAV Help for table fields, the FieldTopicTextExtractor tool can extract the first paragraph from your Dynamics NAV Help topics for table fields. The resulting spreadsheet will help you copy and paste the text from your Dynamics NAV Help topics into the ToolTip property of your controls.

Mapping the table fields to page controls is not always straightforward because the same table is often used by two or more pages. As a result, the page ID can be many numbers away from the table ID. It requires knowledge of the actual solution to determine which tooltips are relevant for which pages. The **FieldTopicTextExtractor** tool generates an Excel file that you can use for this purpose, since you can sort and filter, and then copy content in Excel.

In the base application, tooltips are in the page objects, so, at Microsoft, we edit code to edit tooltips. You do not have to do the same. You can choose to work with tooltips in the translation files or straight in the .AL files. Different solutions require different processes, so pick the process that is more efficient for you. We chose to associate the "What is this field?"-content with the user interface, meaning the controls on page objects. In the Dynamics NAV Help model, we chose a different approach, focusing on the database structure. Both approaches have their advantages and disadvantages, but the Business Central user assistance model currently focuses on the user interface with tooltips on page objects. For more information, see User Assistance Model.

For more information, see Working with Application Objects as Text Files in the docs for Microsoft Dynamics NAV 2016, How to Add Translated Strings By Importing and Exporting Multilanguage Files in the docs for Microsoft Dynamics NAV 2018, and Working with Translation Files for Business Central.

Moving to MarkDown

Converting your existing content to MarkDown can be done using third-party tools, including but not limited to PanDoc or the Writage plugin for Word.

Once you have converted your content to MarkDown, we recommend storing your content in a repository, such as a Git repo in Azure DevOps, a private or public repo in GitHub, or a project in MkDocs. You can use open-source tools such as DocFx to generate content for your website. In general, working in MarkDown means that you have access to a world of open-source tools and do not have a hard dependency on Microsoft providing you with tools. The Custom Help Toolkit can help you prepare content for publishing. For more information, see Custom Help Toolkit.

If you do not yet have a website that you publish content to, then there are several ways in which you can create such a site. The MkDocs project generates a website for you, but you can also work with a web designer to build a site to host your content. We recommend deploying to an Azure web app.
