Development and Administration for Dynamics 365 Business Central

2/17/2021 • 5 minutes to read • Edit Online

Dynamics 365 Business Central is a complete enterprise resource planning (ERP) software solution for mid-sized organizations that is fast to implement, easy to configure, and simple to use. Right from the start, simplicity has guided — and continues to guide — innovations in product design, development, implementation, and usability. Users can customize and administrate their Business Central experience in the product. Other tasks for administration and development require a more specialized profile, and in this *Development and Administration* section, you can find more technical information, including information about developing for Dynamics 365 Business Central using the AL Language extension and Visual Studio Code.

Get started with development and administration documentation

The content in this section of the Docs.microsoft.com site is intended for people who are Business Central resellers, administrators, or developers, and people who want to get started with Business Central development or administration. If you are a functional consultant or user of Business Central, check out the Business Functionality Help instead.

Resources for an administrator

As a system administrator, IT professional, or superuser, you have tools available for you to configure, update, and maintain a Business Central solution. The tools and processes are somewhat different depending on whether Business Central is deployed online or on-premises. It also depends on whether you are an internal administrator, or you work for a partner.

The following table outlines recommended content for you to get started:

LINK	DESCRIPTION
Deployment of Dynamics 365 Business Central	Describes the difference between making Business Central available online and on-premises.
Administration of Business Central Online as an internal administrator	Learn about resources that are available to you as the system administrator, IT professional, or superuser of a Business Central customer.
Administration of Business Central Online as a partner	Learn about resources that are available to you as a Business Central reselling partner.
The Business Central Administration Center	Learn about the administration center and what you can do there.
Technical Support for Dynamics 365 Business Central	Learn about the tools that are available to you to help you troubleshoot your customers' Business Central.
Managing Technical Support	Learn about how to handle support requests.

LINK	DESCRIPTION
Administration of Business Central On-Premises	Learn about resources that are available to you as the system administrator, IT professional, or superuser of Business Central on-premises.
Configuring the Help Experience	Learn about your options for deploying Help for Business Central.

Resources for a developer

You can extend Business Central with add-on apps, vertical or horizontal solutions, and with integration to other products and services.

The following table outlines recommended content for you to get started:

LINK	DESCRIPTION
Developer learning paths on Microsoft Learn	Provides links to role-specific training.
Development in AL	Get an understanding of the basics and terms you will encounter while working in Visual Studio Code with the AL extension.
Getting Started with AL	Learn how to set up a development environment.
The SMB Opportunity for App Publishers	Learn about the business opportunity for building your app on top of Business Central.
Get Started with Building Apps	Learn how to get started as a partner.

Resources for a reseller

Enroll in the CSP program

The Cloud Solution Provider (CSP) program helps your company to be more involved in your customers' businesses, beyond reselling licenses. In CSP, you can choose to enroll as an *indirect reseller* or a *direct bill partner*.

In most cases, you will enroll as an *indirect reseller* and then work with an *indirect provider*, also referred to as a *distributor*, who then manages all interaction with Microsoft in terms of licensing and technology, so that you can focus on sales and support. If you decide to enroll as a *direct bill partner* in order to fully own the end-to-end relationship with both customers and Microsoft, make sure that you meet the eligibility requirements. For more information, see Enroll in the Cloud Solution Provider program in the Microsoft Partner Center content.

The Microsoft Partner Center is a generic portal where partners can sell and manage customer subscriptions for Microsoft services, such as Microsoft 365, Azure, Dynamics 365, and others, as well as for some third-party products. For more information, see the Partner Center documentation.

Some indirect providers (distributors) provide their resellers with a custom portal that optimizes and enhances the experience beyond the Partner Center. They can also provide indirect resellers with an API to automate some of the customer onboarding steps. Contact your indirect provider to find out more.

Both indirect resellers and direct bill partners can access and support their customers' Business Central by setting up a reseller relationship with them.

To service customers in a specific country, your partner company's Azure Active Directory (Azure AD) tenant and CSP account must be registered in the regional CSP market that covers that country. For more information, see Cloud Solution Provider program regional markets and currencies.

> **NOTE**
>
> When you buy Business Central offers on behalf of your CSP customers, the CSP offer must be available in both your own tenant's country and in your customer's tenant's country. For example, if your tenant is located in Slovakia and the customer's tenant is in Germany, you will not be able to sell Dynamics 365 Business Central Premium to that customer, because this offer is currently not available in Slovakia.
>
> Similarly, if your tenant is located in Germany and the customer's tenant is in Slovakia, you will not be able to sell Dynamics 365 Business Central Premium to that customer, because this offer is currently not available in Slovakia.

The following table outlines recommended content for you to get started:

LINK	DESCRIPTION
Get Started as a Reseller of Business Central Online	Landing page for readiness for resellers.
Business Central on Microsoft Learn	Provides links to role-specific training.
Enroll in the Cloud Solution Provider program	Describes the different models for selling in the Cloud Solution Provider (CSP) program so you can determine which works best with your business.

Other roles and profiles

Business Central supports the same profiles and roles as other Dynamics 365 services. If you see yourself as a solution architect or functional consultant, for example, Business Central has functionality and content for you. Look around in the Help & Support section here, for example, ramp up on features in the business functionality content, or learn how you can integrate this with other products.

If you are completely new to Business Central, we recommend you take the Get started learning path.

The SMB Opportunity for App Publishers

2/17/2021 • 4 minutes to read • Edit Online

Our mission is to empower every individual and every organization on the planet to achieve more. This is particularly key for the 78 million small and mid-sized businesses (SMB) worldwide that increasingly want focus on tech intensity to be more resilient, more capable of transforming their products and services to face the constant changes and challenges in the marketplace. To embrace growth, every organization will have to have a business application which breaks down the silos of data, processes and workflow in their operations. This enables employees to respond to daily challenges and opportunities with agility. Market research shows that the business applications opportunity for software companies in the SMB space is predicted to be 51 billion dollars by 2025. As a developer, you want to make sure you bet on the winning platform. The BizApps market growth in this area is 17%; however Dynamics 365 platform growth has been growing at 47%!

Dynamics 365 Business Central

Dynamics 365 Business Central is an all-in-one business management solution that connects operations for small to mid-sized business. It ensures business continuity with a cloud solution that connects sales, service, finance, and operations to help teams adapt faster and deliver result. Business Central provides app publishers with a modern business platform that you can easily connect to, extend and build on — with little to no code required.

Microsoft AppSource

Microsoft AppSource is part of Microsoft's commercial marketplace where customers can find, try and get business solutions apps. It is the launch pad for your joint go-to-market activities with Microsoft and a flywheel for business growth. Using launch promotion, demand generation, and joint sales and marketing, your offer portfolio on AppSource can be the centerpiece of your cloud business engine.

In November 2020, Microsoft AppSource had more than 3 million monthly active users and more than +20.000 apps. Specifically for Business Central, there are more than 1000 apps available, and the number is growing fast.

Go-to Market Scenarios

As an AppSource publisher you can focus on these scenarios with Business Central and Microsoft AppSource:

- Connect
- Extend, or
- Embed

Connect

Connect your existing online service with Business Central through a powerful API. Here are a few examples which of existing connect apps which you can find on AppSource:

- Square payments, which allow you take payments with a Square terminal.
- Certify which allows users to post expense reports using Certify.com
- Scaptify, which connects your Shopify store with Business Central

Learn more about the API to build connect apps: Getting Started Developing Connect Apps

Extend

You can extend the default capabilities in Business Central to add extra productivity features or industry functionality to fit the needs of your customer base. The possibilities are plentiful.

In countries where Business Central is not localized by Microsoft, you can extend Business Central based on local requirements to respond to the regulatory and or competitive needs of that market.

Here are a few examples of some apps that extend Business Central:

- E-Ship and E-Receive from Lanham Associates, which extends warehouse management with barcoding and labelling, scanning functionality and interfaces with carriers and weigh scales.
- Continia Document Capture, which is an end-to-end solution for document recognition, invoice approval and digital archiving
- Philippines localization from Pasi, which computes the withholding tax as mandated by the Philippine government for both customers and vendors.
- SwissSalary 365, which is a certified and flexible payroll app that's intuitive and easy to use for the Swiss market

Learn more on how to build your app: Getting Started with AL

Embed

Embed Business Central as an integral component in an end-to-end industry solution. Here are a few examples of embed solutions available on Microsoft AppSource:

- 4PS construct, an all-in one solution for construction. 4PS has specifically developed an integrated software solution based on the Microsoft platform and tailored for construction, civil engineering, mechanical and electrical, service and maintenance, house builders and equipment rental companies
- LS Central from LS Retail. The complete, unified commerce online platform to manage your entire retail and food service operations
- Dynamics Empire Online, cegeka-dsa's open, secure and innovative real estate solution.

Learn more about embed apps: Embed app overview

Consultancy services

An increasing number of business users find web more convenient for buying where they can research, deploy and manage apps. Therefore, next to providing Apps, a publisher can also market consultancy services on Microsoft AppSource to connect with buyers. The provided content in these offers could be assessments, briefings, workshops, proof of concepts and implementations. In general the services are typically fixed in scope and duration, they are offered at a fixed price or free and have a defined outcome.

Here are a few examples of Consultancy services provided by publishers:

- Unified Commerce Readiness Intro: 1-Hr Assessment In this 1 hour assessment, LS Retail assesses how a 4-day engagement helps them with implementing their Unified Commerce Cloud solution based on Microsoft Dynamics 365.
- NAV-X Commission Mgt Gold 4-Hr Implementation in this 4 hour implementation workshop, NAV-X supports the customers in implementing their commission management app.

Get Started with Building Apps

Get Started with Building Apps

2/17/2021 • 8 minutes to read • Edit Online

Dynamics 365 Business Central is a business management solution that helps companies connect their financials, sales, services, and operations to streamline business processes, improve customer interactions and make better decisions. With this modern business platform, you can easily and quickly tailor, extend, and build applications so they fit your specific needs with little to no code development.

Build a line-of-business app, such as for a specific industry, process, or department such as HR, finance, marketing, or operations. Then, publish your app to the Microsoft commercial marketplace, where customers can find and try your app, and get in touch with you. For more information, see What is the Microsoft commercial marketplace?.

Learn how you can become a Business Central app publisher in six steps in this article.

Step 1: Become a partner

Becoming a Microsoft partner gives you access to the Microsoft resources needed to build, market, and sell your apps. You don't have to be a Microsoft partner to begin developing your apps. But all of the steps below are required to gain access to the programs that enable you to publish, market, and sell your apps for Business Central.

Obtain your work account

Your work account or work email is the email address provided to you by your company. This email is usually in the format `you@yourcompany.com`. More information on work accounts can be found here.

Join the Microsoft Partner Network

Microsoft Partner Network (MPN) membership unlocks our best resources to differentiate your business, take your product to market, and sell your solutions. To become a partner, you must join the Microsoft Partner Network (MPN), at which time you will be assigned an MPN ID. MPN membership is free to all partners; you can enroll in the MPN here.

Once signed up, you will get an MPN ID – your gateway to access all the membership resources and benefits for your partnership with Microsoft. There is no cost to obtain a MPN ID as a Network member, and with options to upgrade to an Action Pack subscription or work toward a competency, you can access even more benefits.

Set up your Partner Center account

Once you have joined the Microsoft Partner Network (MPN), you can set up your Partner Center (PC) account. The Microsoft Partner Center is a generic portal where partners can sell and manage customer subscriptions for Microsoft services, such as Microsoft 365, Azure, Dynamics 365, and others, as well as for some third-party products. For more information, see the Partner Center documentation.

Your Partner Center account provides you with access to pricing information, tools and services, and enables you to manage admin credentials for your company's work account. Partner Center is also where you can purchase or renew subscriptions to Microsoft Action Packs, create a business profile to receive and manage sales leads from Microsoft, and see if you qualify for co-selling opportunities.

Step 2: Register as a publisher

The first step to becoming a publisher is to register in Partner Center (PC). PC is where you submit your apps for publication, promote your apps, and manage your offers. To begin the registration process, you must complete

these steps. One of our team members will follow up to help you complete your registration. Once registered, you can access PC.

For more information, see Partner Center Account.

PartnerSource Business Center (PSBC) account

Developing apps requires you to be known as Business Central developer and requires you to have a unique development license file with a specific object range.

To obtain an object range for developing a Business Central, you must first have access to PartnerSource Business Center (PSBC). You have access to PSBC if you have one of the following agreements:

- An active Partner Registration Agreement (PRA)
- A Registered Solution Program Addendum (RSPA)

The relevant contract can be requested through your local Regional Operations Center (ROC) Contracts and Agreements Team below:

- mbscon@microsoft.com if you are based in Europe, the Middle East, or Africa
- mbsagree@microsoft.com if you are based in the Americas
- mbslques@microsoft.com if you are based in the Asia Pacific region.

Step 3: Your unique app specifications

Requesting an object range

When you develop an app for Business Central, you must request access to an object range that holds a certain number of objects for your solution. To avoid overlap between objects used in different solution, each partner is assigned a number of objects in a unique object range. For example, a partner is assigned the object range 70,001,000 – 70,001,999. The object range gives them 1000 numbered objects that they can use to develop Business Central solutions.

Depending on where you will deploy your Business Central solution, online or on-premises, you can use different licensing methods and object ranges.

There are currently two available ranges that you can request. Both have some characteristics to keep in mind:

- *RSP Object Range* (ID range 1,000,000-69,999,999)

  This object range is tied to the RSP Program details.

  > **IMPORTANT**
  > We currently advise new publishers to *not* request an RSP object range

- *App Object Range* (ID range 70,000,000-74,999,999)

  This object range was originally designed just for apps in the Microsoft commercial marketplace to be used in Business Central online.

  > **IMPORTANT**
  > We currently advise new publishers to request an app object range.

Currently, you can implement apps developed in both the *RSP range* and the *app object range* in Business

Central online and on-premises, as well as partner-hosted.

You can request an object range by downloading the object range request form here. After completion, send them to your Regional Operational Center (ROC) for processing:

- mbscon@microsoft.com if you are based in Europe, the Middle East, or Africa
- mbsagree@microsoft.com if you are based in the Americas
- mbslques@microsoft.com if you are based in the Asia Pacific region.

Downloading your development license file

After your Regional Operational Center has processed your Agreements and Object Range Request forms, download your company's unique developer license from PartnerSource Business Center. Find it in the license key configuration section under the developer tools section.

Register your unique prefix or suffix

In your extension, the name of each new application object must contain a prefix or suffix. This rule applies to all objects. Email d365val@microsoft.com with a prioritized list of three-letter affixes of your choice. You must also submit your MPN ID and the publisher name that you will use for the app.

Step 4: Getting access to preview bits

Get access to preview builds by joining Microsoft Collaborate.

In Microsoft Collaborate, you get access to a set of Business Central builds:

- The current major version
- An upcoming major version
- Daily builds

You must have the following prerequisites to register on Microsoft Collaborate:

- Azure Active Directory (Azure AD).

  > **NOTE**
  > If you have Microsoft 365, then your company most likely has Azure AD

- Azure AD Global Administrator permission

  > **NOTE**
  > To find out if your company has an Azure AD account, check with your system administrator.

Step 4 A: How your Global Administrator must register for Collaborate

Only your company's Global Administrator can start the onboarding to Collaborate. They must register at https://aka.ms/Collaborate, choose the **Get Started** action, and then complete the registration form.

The administrator can then add the relevant colleagues.

Optional Step: Add your coworkers to Microsoft Collaborate

To add coworkers:

1. Sign in to Microsoft Collaborate with your Global Administrator account at aka.ms/Collaborate.
2. Choose the  icon in the top-right corner of the page, click on account settings, and choose **user**

management.

3. Choose the grey **ADD USERS** button, and leave the default choice to **Add existing users** as-is. Now you can search for the user(s) that you want to add to Collaborate. To add them you need to select them from the menu, and then click the grey **ADD SELECTED** button.

4. You have successfully added your coworkers to Collaborate. Users can now sign in to Microsoft Collaborate using the following link: aka.ms/Collaborate

Step 4 B: Getting access to the available builds and engagements

Once you have successfully registered on Microsoft Collaborate, Microsoft must assign you to the right programs and engagements before you can see the preview bits. Contact Dyn365BEP@microsoft.com and provide them with information about the relevant users. the following table illustrates the type of information that you must submit:

PUBLISHER DISPLAY NAME	MPN ID	FIRST NAME	LAST NAME	WORK ACCOUNT EMAIL
Contoso	12345	Eugenia	Lopez	Eugenia.Lopez@Contoso.com
Contoso	12345	Quincy	Watson	Quincy.Watson@Contoso.com

After sending the email, expect a response from Microsoft within 1-2 business days.

Step 5: Resources while you develop your solution

Find below some guiding resources on how to develop your apps for Business Central.

- Microsoft Learn

  Learn new skills and discover the power of Microsoft products with step-by-step guidance. Start your journey today by exploring our learning paths and modules.

- Microsoft Docs

  Find The developer and administration content on Microsoft Docs

- Join the conversation

  In the dedicated Yammer network, join the conversation on developing apps

- Join the monthly Office hour calls

  Join the monthly Office hour calls to learn more about a hot topic

- Get coaching from experts

  Need help with developing your apps? There is a community of ISV Development Centers specialized in Business Central ready to engage with you.

Set up Azure DevOps for your development processes

Optionally, use the CI/CD workshop document at https://aka.ms/cicdhol if you want to do it yourself. Alternatively, choose between vendors offering tools or services around DevOps.

Talk to one of the ISV Development Centers for guidance.

Step 6: Publish your app in the Microsoft commercial marketplace

Once your app is ready for submission, you can list your app in the Microsoft commercial marketplace by submitting it in Partner Center. For more information, see Create a Dynamics 365 Business Central offer.

Before you submit, we recommend that you review the technical validation checklist and marketing validation checklist. The two articles list all requirements that you **must meet before you submit** an app for validation. If you do not meet these mandatory requirements, your extension will fail validation

The Lifecycle of Apps and Extensions for Business Central

2/17/2021 • 6 minutes to read • Edit Online

When you build an app or extension to Business Central and get that published to AppSource, it becomes an app like so many others - the app itself can be updated, and the platform that it sits on, Business Central online itself, will also get updated. But what happens after your app gets published?

When your app has passed all of our validations and has gone live to App Source, customers can install your extension and use it for their business. But you are expected to keep it compliant with the service and update it if something changes.

The following sections describe the different upgrade scenarios that we have seen play out as we update Business Central. For more information about your responsibility for keeping your app updated and the resources that are available to you, see Maintain AppSource Apps and Per-Tenant Extensions.

Scenario 1: Business Central service update

You don't need to make any bug fixes, feature adds, or app changes to your app. It continues to work fine without any interaction on your part.

Impact of service updates

The monthly service upgrades to Business Central do not impact your app. Your app just gets moved along and no upgrade code from your app needs to get used. Business Central itself gets upgraded on your tenant, and once complete, the customer sees no difference with your app.

Scenario 2: App update

You (our partner) add some features to your app and also some minor bug fixes. The app is submitted for validation. The app passes validation and gets checked into the service. This is now the active app for any new tenants and also for existing tenants that have never had your app installed before

Impact of app updates

Customers can either do an uninstall and then reinstall on their own, or they can ask their partner do it on their behalf from the Extension Management window within Business Central. Otherwise, they would have to wait until our every 6-month major release. That is the only time we do a force upgrade of extensions (except for critical bug hotfix extension updates)

Scenario 3: Reported bugs in your app

You (our partner) has various customers report some bugs that are impacting their usage of the app. The bugs aren't critical but they are important. The partner makes the fixes in the app and resubmits for validation. The app passes validation and gets checked into the service. This is now the active app for any new tenants and also for existing tenants that have never had your app installed before

Impact of bugs

We still do not force the upgrade of this app to this latest version on all of the tenants. Some tenants may not be using the functionality that includes this bug and continue to work fine on the current version of the app. Therefore, you should work directly with all of the impacted customer tenants to uninstall and reinstall to get the latest app version that contains fixes for the bug.

Scenario 4: Critical bug in your app

If a bug which leads to core functionality being broken or data loss/corruption/misrepresentation is found in the application, and the issue prevents customers from performing time-critical tasks, the validation and deployment of the application can be prioritized. The partner must create a support ticket for this case and they must immediately provide a fixed app for validation through Partner Center. The validation team makes this a top priority and does validation as soon as possible. If the fixed application passes validation, it will be checked into the service and will become available for environment administrators to install.

Scenario 5: Microsoft feature breaks your app

Microsoft has to break your app file for a needed Business Central core change. Some reasons for breaking could be security, bugs in the underlying code, high priority feature adds, and so on. Keep in mind, we do our very best to not break your app through our changes. We try and find proper ways of doing the changes without breaking your app. However, if we can't find a proper (non-breaking) way, then we could break your app. This won't be as likely in a minor update release (unless a security change is required on our part and that is the change that breaks you), but it can be more likely in our major (every 6-month) releases.

Impact of breaking changes

Here is our process when this takes place:

- First of all, Microsoft will not make a breaking change in the production environment at any point. Therefore, existing tenants are not expected to see this breaking change occur.
- When we make a breaking change, we do it in a build branch that is for a future release (monthly service minor or major release)
- We notify the partner in advance and give the partner ample time to fix their app, get it validated, and have it ready
- The fixed app will already be in our service and slotted as required for when your tenant is to be moved to the Business Central release that has the app breaking change
- As a result, the customer (tenant owner) should never see their Business Central break. Because the tenant gets moved from one monthly service update of Business Central to another, the tenant is being upgraded to the release of ours that breaks the specific app. However, our service detects that there is a new required version of that app (your fixed version). Therefore, we auto install the fixed version of the app for the tenant

Conclusions

You're responsible for your app. You own the process of updating the app and providing upgrade code if the schema changes between versions of the app.
If a customer uninstalls your app, and then installs it again later, then when they install the app the second time, they get the latest version from AppSource.

How Microsoft handles your app

When Microsoft upgrades a tenant with a service update, your app is tested against the new service version. If the app breaks, Microsoft rolls back to the previous healthy state. Your customer never learns that anything was about to break.

When a tenant uninstalls and reinstalls an extension via the Extension Management page or AppSource, there is platform logic that determines whether an *Install* or an *Upgrade* must take place. We detect which version of the extension the tenant previously had installed and perform the appropriate action. Therefore, the result of manually uninstalling/installing the extension is the exact same as an automated upgrade.

Additionally, there will not be any data loss during uninstall, install, or upgrade actions. Data for extensions is stored in its own tables in the tenant database. Before an extension gets installed, it first get synchronized on the tenant database. This step is implicit and happens automatically when a tenant installs an extension. This

synchronization process creates the database tables for the extension. Once the extension is installed and the tenant is using it, extension-specific data will get stored in these tables.

When an extensions gets uninstalled, these tables do not get removed. Therefore, when the extension gets reinstalled (or upgraded), the data is still available. You do not need to worry about data loss for choosing the uninstall/install route. However, do keep in mind that if any actions are being performed on the tenant while the extension is uninstalled, the extension's events and such will not be firing, and your app may miss the creation of new data. Try to perform the uninstall/install while the tenant is not online.

For more information, see When apps or PTEs cannot be updated by Microsoft.

Update Lifecycle for Customizations of Business Central Online

2/17/2021 • 2 minutes to read • Edit Online

When you create a tenant-specific customization, or an extension that is scoped to a single Business Central environment (often referred to as per-tenant extensions), you must take the lifecycle of the extension into consideration. For more information about the extension lifecycle and events that can cause incompatibilities between the extension and base application, see The Lifecycle of Apps and Extensions for Business Central.

You are responsible for your extension. You own the process of updating the extension and providing upgrade code if the schema changes between versions of the Business Central base application. When an update is available for your Business Central environment, all extensions, both AppSource extensions and tenant customizations, must be compatible with the next version of the base application before the update can be installed on the environment. You are responsible for ensuring that your extensions are compatible with the update version.

In this article, we describe the process for ensuring update compatibility for tenant customizations.

Automated Extension Validation

An automated service validates all tenant customizations before an update is marked for a scheduled update of an environment. This validation compares the extension's dependencies with the updated version of the Business Central application to see if any changes caused incompatibilities with the new version.

If the validation service discovers any tenant customizations that are not compatible with the update, an email notification is sent to the tenant administrators listed on the **Notification recipients** tab of the Business Central administration center. For more information, see Managing Tenant Notifications.

> **IMPORTANT**
> At least one email address must be specified as a notification recipient to receive the update notifications. If you do not speciy an email address, you will not be notified of updates and other changes to the tenant.

The email notification provides information on the incompatible extension, detail on which properties must be updated, and steps to bring the extension into compatibility.

Update Failure Notification

If a Business Central environment has an extension that is not compatible with the update version, the update cannot be applied. If an update fails due to an incompatible extension, a notification is sent to the tenant administrators listed on the **Notification recipients** tab of the Business Central administration center.

The notification is similar to that provided by the automated extension validation. It provides information on the incompatible extension, detail on which properties must be updated, and steps to bring the extension into compatibility.

Automatic Extension Removal

The publisher of an extension must maintain compatibility with the new release of Business Central. An extension that is not compatible with the update within 90 days of the first notification of incompatibility will be

removed, and then the environment will be updated.

Maintain AppSource Apps and Per-Tenant Extensions in Business Central Online

2/17/2021 • 7 minutes to read • Edit Online

As a partner, keeping your apps and per-tenant extensions (PTEs) up to date is your responsibility. Business Central is regularly updated with major and minor releases. These updates provide customers with a business application that is always compliant, secure, and enriched with new platform and application functionality. Often customers choose Business Central because of this promise of having an always up-to-date business solution.

To not break this promise, developers that bring apps to Microsoft AppSource, and resellers that provide PTEs to respond to the unique needs of customers, have a responsibility to align their code to the Microsoft release rhythm.

An inability for Microsoft to update tenants because of publishers incompatible code causes serious disruption in the service and must be avoided since it impacts the trustworthiness of the service and customer satisfaction.

Resources

To help app publishers keep up with their update responsibilities, Microsoft provides the following resources:

- Release plans about what's new and planned

  For more information, see Dynamics 365 release plans.

- Access to pre-release bits

  Business Central partners have access to the next major, next minor, and daily pre-release bits in Docker. These bits can be used to test apps against upcoming updates.

- Information about what will be deprecated

  With all Business Central releases, Microsoft controls and regulates breaking changes with major releases and communicates upcoming breaking changes at least one year in advance. If developers missed this above info, the compiler in Visual Studio Code also warns for potential controls that will become obsolete in future versions and how to deal with them.

- Policy definitions and terms

  The publisher agreement and the commercial marketplace certification policies describe the responsibilities of app providers for how to publish and maintain apps in the Microsoft monthly rhythm.

  When a PTE gets installed, the publisher also agrees to the terms to keep that code current and updatable.

- Training and coaching

  Microsoft provides a set of tools, training, and documentation to help partners find the info they need to keep up with these responsibilities on continuous integration and continuous deployment. External providers, including ISV Development Centers, MasterVARs, and training centers, can provide in-person training and coaching.

- Service notifications

  Business Central online will support app and PTE publishers with extra warnings about potential technical incompatibility. If publishers respond to these notifications in due timing and avoid incompatibilities

repeatedly, Microsoft will stand with these publishers to help where needed. If a publisher includes a telemetry key in their app, then, starting with 2020 release wave 2, Business Central also provides publishers with telemetry about upgrade failures that happen in production because of issues in the publisher's upgrade code.

If publishers lack to keep their code updatable, they risk that ultimately their apps or PTEs will be removed from the customer's tenant, and this will most likely result in important data not being captured as it should. For apps, this also means removal from the marketplace.

Since resellers are the first line contact point for customers, they carry responsibility to explain what it means to load code in a customer's environment. The best way is to explain this is with terms.

We advise these terms include topics like intellectual property rights, upgrade responsibilities, associated costs to keep code updatable, support options, data privacy, and so on.

Pre-release publisher support to keep apps and PTEs compatible and up-to date

Publishers have several tools available for them to keep their code in good shape. Not least, a Public Preview release is made available approximately one month before the announced release date for a major release. In that Public Preview release time frame, Business Central will automatically test and notify publishers of existing apps and PTEs running in production on technical incompatibility with the upcoming release.

> **IMPORTANT**
> Microsoft tests code based on technical compatibility. As the publisher, you are still responsible for all functional and logical validation.

When apps or PTEs cannot be updated by Microsoft

This section describes the processes that are initiated during and after upgrade attempts of code provided by publishers of apps or PTEs.

- **T1 – T30**: Microsoft alerts administrators, resellers, and ISVs

  Shortly after a service update of Business Central online (Day **T**), Microsoft will initiate daily updates attempts on all tenants. In these update attempts, the publisher's provided upgrade code is triggered and run. These attempts run repeatedly in a time frame of approximately one month until the upgrade is successful. For more information, see Major Updates of Business Central Online.

  With every unsuccessful upgrade attempt, stakeholders will receive notifications. Customers and their reselling partners can follow these notifications in the Business Central administration center.

  ISVs who provide third-party AppSource apps might not be listed in the customer's admin center. The reseller will in most cases have worked with the ISV to test compatibility, but after two weeks (Day **T+15**) of failed upgrade attempts, the Microsoft AppSource team will also send the app provider a warning message that action within the next few days is required.

  This message will explain that if they fail to respond correctly, their app will be removed from AppSource at Day **T+30**.

- **T30 – T60**: Microsoft alerts the customer

  After one month of failed upgrade attempts (Day **T+30**), the customers will be notified again that apps or PTEs are incompatible with the new version of Business Central, and that no further automatic upgrade attempts will be planned until further notice. Although the publisher's code continues to run on an

outdated version of Business Central online, the customer must work with their reseller to resolve these issues immediately so that the tenant can be updated. Next to messages in the Business Central administration center, all users in the customer's tenant will also get more active warning about the incompatibilities when they use the product in the browser or their mobile device.

For AppSource apps, if no appropriate action or follow-up was taken by the publisher since the release (**T - T+30days**), the app will be removed from AppSource. This means no new customer will be able to install the app in a new tenant. The main reason for removing an app from the marketplace is to ensure that no new customers will be affected by incompatibilities with the latest version of the base product, Business Central.

If the publisher wants to have their app available again, they must mitigate all existing incompatibility issues and go through the full validation process again.

If the source of the incompatibility has been resolved by the publisher, they'll have to submit a support request to schedule a new set of upgrade attempts for any tenants that are blocked because of this incompatibility. They'll also have to work with their resellers to inform them about the compatibility resolution.

- **T60 – T150**: Microsoft initiates the customer wind-down period

  If the incompatibility issues are not resolved at **T+60**, and the publisher remained unresponsive to the request to resolve the incompatibility, Microsoft may choose to send out a wind-down communication to the customer about removal of the publisher's code.

  This communication will share that the code from the publisher will be removed in *90* days (**T+150**).

  During this wind-down time, the customer and their reselling partner are fully responsible for finding a solution on how to proceed in this situation. If the customer decides to leave Business Central, or decides to use another publisher, they can access their data by exporting the database, use RapidStart Services, or copy data to Excel. For more information, see Exporting Your Business Data to Excel in the business functionality content.

  Microsoft may also choose to remove all existing apps by this publisher from AppSource and block the publisher from publishing new apps for Business Central.

  If this wind-down period is initiated, and the customer was able to fix the incompatible issues with their reseller and potential publishers, it will be at Microsoft discretion if the publisher's code will be removed from Business Central or not.

Get notified about incompatibilities by Microsoft

It is crucial for you to keep contact details correctly up to date. We advise you to use global team aliases instead of individual mail addresses. Here are the mail addresses that we'll use in the above process:

- PTE publishers

  The mail addresses specified in the Business Central administration center; this could be both a customer user and a partner user.

- App publishers

  The mail addresses specified during App publication in the partner center during app publication as support and engineering contact details.

- Customers

  The mail addresses specified in the Business Central administration center; this could be both a customer and a partner user.

Microsoft Responsibilities for Apps on Business Central online

2/17/2021 • 2 minutes to read • Edit Online

Business Central online is a cloud service for small to medium-sized businesses that is built on and for Microsoft Azure. Business Central brings together the business management solution, business intelligence, infrastructure, computing, and database services in a single offering that enables organizations to run horizontal or industry-specific apps from Independent Software Vendors (ISVs), without the hassle of managing infrastructure.

The Business Central online model distinguishes specific roles and responsibilities for partner-provided vertical solutions, system integrators, resellers, and Microsoft throughout the life cycle of the service. Microsoft maintains the Business Central service by deploying, actively monitoring, and servicing the customers' production tenants that are running on the service. This includes allocating the required system infrastructure to run the service and proactively communicating to customers about the service's health (which is done through the Service Health dashboard in the Microsoft 365 Admin Portal).

Microsoft responsibilities in the Business Central service include:

AREA	RESPONSIBILITIES
Infrastructure	• Storage and database capacity management • High availability and disaster recovery • Platform security and compliance • Infrastructure capacity, scaling in response to demand • Infrastructure management and deployment • Data center networking, power, and cooling
Base application and platform	• Availability and security • Diagnostics, patches, updates, hotfixes, and updates • Monitoring and first-line support for partners building apps
Lifecyle Services portal (EmbedApp program)	• Development, deployment, and support of the portal functionality • High availability and disaster recovery • Monitoring, updating and patching • First-line support for partners

Components and Capabilities

2/17/2021 • 2 minutes to read • Edit Online

When you build an app for Business Central, be it an Embed App or an AppSource app, you must be aware of which components and deployment steps are provided by Microsoft and which you must provide.

Components

Base application

The base application is the Business Central application provided by Microsoft, customized and extended to fit the needs of a market segment that an app wants to serve. Major releases and cumulative updates (CUs) of the base application are publicly available on Microsoft Download and as artifacts for use with Docker.

Pre-released versions of the base application are available as artifacts for participants of the "Ready and Go" program via Microsoft Collaborate for use with Docker. Although we recommend always using the latest version of the base application, partners can choose any version they need. The only requirement is that the partner makes sure that the base application version that they base their app on is available in Business Central online production environments.

AppSource apps must specify the dependency of a specific base application in the settings for their app. In contrast, the base application is an optional part of an Embed App package. If the partner has implemented all required functionality in their library extensions, they do not have to include the base application itself with the Embed App. Instead they should specify, in the metadata of the Embed App, which version of the Business Central base application they are targeting, just like an AppSource app.

Microsoft recommends all partners to move towards a model where the code-customization of the base application is not used. Keep track of new capabilities in the base application and platform in the release plans.

Platform

Partners who build apps for Business Central online must make sure that it is compatible with a supported version of Business Central platform.

The Microsoft platform is updated in the following way:

- Minor updates

  Microsoft will ship minor platform updates monthly and major platform updates every six months. Minor updates can include bug fixes and improvements which should not affect the compatibility of the platform with the previous version of the application. In rare situations, partners may be asked to recompile their solution to work with a minor update of a Business Central platform.

- Major updates

  Major updates will include changes that can require partners to perform a technical upgrade to make their application work with the new version of the platform. For more information, see the Dynamics 365 release plans

Ecosystem

Business Central online is part of a rich ecosystem of other Microsoft and 3rd party services, which partners and customers can decide to take advantage of.

The following integration capabilities of the Business Central can be considered:

INTEGRATION CAPABILITY	STATUS
Dynamics 365 API endpoint	Available if the base application objects are unchanged
Outlook Add-in	Available
Power BI	Available if the customer has a Power BI license
Power Automate	Available if the customer has a Power Automate license
Power Apps	Available
Microsoft 1st party integration apps included with Business Central (Yodlee, Quick Books, OCR, AMC, and others)	Available, but in many cases the partner must set up a separate agreement with these service providers
Azure machine learning	Available if the partner has an Azure ML subscription
Integration with Dynamics 365 Sales	Available
Microsoft Graph	Currently under evaluation
Accountant Hub	Available in specific countries

Embed App Overview

Add your App to AppSource

2/17/2021 • 2 minutes to read • Edit Online

AppSource is a market place where partners can provide marketing details, such as descriptions, whitepapers, or videos about their app for Business Central.

Embed App partners can choose to promote themselves and their Embed App on AppSource.

> **IMPORTANT**
>
> Unlike all other apps, solutions that are part of the Embed App program are not uploaded to AppSource itself. Instead, the app package is uploaded, deployed and tested via Lifecycle Services. AppSource in this case is used for the marketing purposes, not as a repository of Apps.
>
> All other apps do submit their app to App Source. For more information, see Technical Validation Checklist and Marketing Validation Checklist.

Marketing Validation Checklist

2/17/2021 • 3 minutes to read • Edit Online

The storefront details on AppSource is the first impression that prospects get regarding your offer. First impressions last, so make sure to invest some time in developing the content on the storefront, so it gives a good impression from the beginning. Failing to do so will jeopardize the hard work you put in, when developing your offer, likely leaving the prospect confused or looking elsewhere. Accordingly, we recommend you put in the time, effort and due diligence when developing this content.

You use Partner Center to submit your offer to AppSource. In the following, you can find information on all the marketing-related items that you need to fill out in Partner Center prior to submitting your app to AppSource. Follow this marketing validation checklist and get your app passed on the first submission.

What do I need to know before I begin?

You need to have the following three items in mind, when you are creating your storefront and marketing material.

ITEM	REQUIREMENT	DETAILS
Branding	Make sure to read the branding guidelines carefully before you start referencing the product name.	Read more
Language	Discover what to consider for each storefront detail when it comes to language.	Read more
Microsoft images	Make sure not to use any Microsoft images (e.g., Business Central icon or Dynamics 365 logo).	Read more

How do I fill out the marketing section in Partner Center?

The following section walks you through the marketing-related components, that is, *offer setup*, *properties*, *offer listing*, and *availability*, which you need to fill out in Partner Center prior to submitting your app to AppSource.

Offer Setup

ITEM	REQUIREMENT	DETAILS
App type	Read more about the types of apps you can submit to AppSource.	Read more
Contact type	How do you want potential customers to interact with your offer?	Read more
Test drive	If you choose “free trial” as the contact type of your offer, you need to enable a test drive.	Read more

ITEM	REQUIREMENT	DETAILS
Customer leads	Provide connection details to the CRM system where you would like to send customer leads.	Read more

Properties

ITEM	REQUIREMENT	DETAILS
Categories	Choose a primary, a secondary, and up to four subcategories.	Read more
Industries	Choose up to two industries for your offer.	Read more
App version	Specify the version number of your offer.	Read more
Terms and conditions	Outline the terms and conditions that the customer must accept before they can use your offer.	Read more

Offer listing

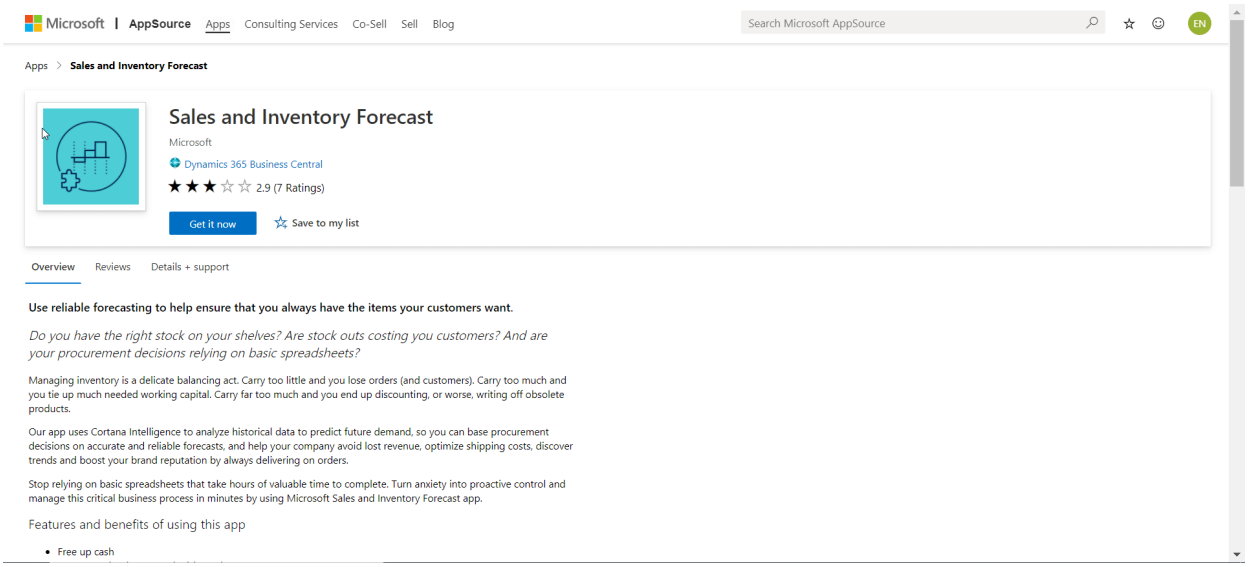
ITEM	REQUIREMENT	DETAILS
Offer name	Enter a descriptive name for the offer.	Read more
Offer summary	A single sentence summarizing the purpose or function of the offer.	Read more
Description text	Make an elaborate and compelling description that outlines the benefits and usage scenarios of your offer (include supported editions, countries, and languages).	Read more
Search keywords	Add search keywords to help users find your offer when they search in the marketplace.	Read more
Products your app work with	Add specific products that your app works with.	Read more
Help link	The link to your offer's learning resources.	Read more
Privacy policy link	The link to your offer's privacy policy.	Read more
Support link	The link to your offer's support page.	Read more
Supporting documents	Add supporting sales and marketing assets such as white papers, brochures, checklists, or PowerPoint presentations.	Read more

ITEM	REQUIREMENT	DETAILS
Logos	Upload a large size logo file with dimensions between 216 pixels x 216 pixels and 350 pixels x 350 pixels.	Read more
Screenshots	Provide a minimum of 3 screenshots that showcase your offer.	Read more
Videos (optional)	Add up to 4 videos that demonstrate your offer. These should be hosted on an external video service.	Read more

Availability

ITEM	REQUIREMENT	DETAILS
Markets (countries)	Choose the markets that your app is available in (make sure that it resembles the supported countries paragraph in the description text).	Read more
Hide key	The hide key is a token that is used to view the preview of your offer in AppSource before going live.	Read more

How does my offer look when it's live on AppSource?



Marketing Validation FAQ

2/17/2021 • 2 minutes to read • Edit Online

Where do I state the countries, editions and languages that my offer supports?

You are required to state the countries, editions and languages that your offer supports in the very bottom of your offer's description text. You can use the following format:

Supported Editions:

The app supports the Essentials and Premium Editions of Microsoft Dynamics 365 Business Central.

Supported Countries:

Canada, Mexico and United States

Supported Languages: This app is available in English (United States) and Spanish (Mexico).

Do you have any tips and tricks for what I should write in the description text?

Yes. We have detailed guidelines and good advice about that here.

How do I refer correctly to the product?

When you mention the product, both throughout your description text, as well as in your marketing material, you need to refer to the product, in the following way:

First mentions: Microsoft Dynamics 365 Business Central

Secondary mentions: Dynamics 365 Business Central

Subsequent mentions: Business Central

Therefore, you cannot use any abbreviations such as "MS Dyn 365 BC" or "Microsoft Dynamics NAV".

What are the requirements for my offer's help and support page?

You are required to submit two distinct pages for support and help i.e. they cannot be the same. You can see what you have to include on both pages in the table below.

HELP	SUPPORT
Learning material such as FAQs, step by step guides, video tutorials, webinars etc.	At least two contact options (e.g. e-mail, phone, chat) and a defined SLA for how much time it takes before you answer to support inquires.

Can I use the Microsoft Dynamics 365 Business Central logo?

No, you cannot use the Business Central logo, as it's a Microsoft trademarked logo. However, you can use the "Get it from Microsoft AppSource" badge, which you can find here.

See Also

Marketing Validation Checklist

Technical Validation

2/17/2021 • 7 minutes to read • Edit Online

Below you will find a checklist of all requirements that you **must meet before submitting** an extension for validation. You will also find a description of how the Business Central Validation team is performing technical and manual validation and how you can implement a validation pipeline to perform the same technical validation yourself.

Technical Validation Checklist

If you do not meet these mandatory requirements, your extension will fail validation. To get code validation helping you bring your extension package to AppSource, you can enable the **AppSourceCop** code analyzer. For more information, see Using the Code Analysis Tool.

REQUIREMENT	EXAMPLE/GUIDANCE
Develop your extension in Visual Studio Code.	Developing AL Language extensions
The app.json file has mandatory settings that you must include. Here you can also read more about dependency syntax and multiple countries per a single app syntax.	Mandatory app.json settings
Coding of `Date` must follow a specific format (**no longer region-specific**)	Use the format `yyyymmddD`. For example, `20170825D`.
Remote services (including all Web services calls) can use either HTTP or HTTPS. However, HTTP calls are only possible by using the HttpRequest AL type.	Guidance on HTTP use
Only JavaScript based Web client add-ins are supported. The zipping process is handled automatically by the compiler. Simply include the new AL `controladdin` type, JavaScript sources, and build the app.	Control Add-Ins
The .app file must be digitally signed.	Signing an APP Package File
The user scenario document must contain detailed steps for all setup and user validation testing.	User Scenario Documentation
Set the application areas that apply to your controls. Failure to do so will result in the control not appearing in Dynamics 365 Business Central.	Application Area guidance
Permission set(s) must be created by your extension and when marked, should give the user all setup and usage abilities. A user must not be required to have SUPER permissions for setup and usage of your extension.	Exporting Permission Sets Managing Users and Permissions
Before submitting for validation, ensure that you can publish/sync/install/uninstall/reinstall your extension. **This must be done in a Dynamics 365 Business Central environment**.	How to publish your app

REQUIREMENT	EXAMPLE/GUIDANCE
Thoroughly test your extension in a Dynamics 365 Business Central environment.	Testing Your Extension
Do not use `OnBeforeCompanyOpen` or `OnAfterCompanyOpen`	Replacement Options
Include the proper upgrade code allowing your app to successfully upgrade from version to version.	Upgrading Extensions
Pages and code units that are designed to be exposed as Web services must not generate any UI that would cause an exception in the calling code.	Web Services Usage
You are required to prefix or suffix the **Name** of your fields and objects. This eliminates collision between apps.	Prefix/Suffix Guidelines
We strongly recommend you are using automated testing, using the AL Test Toolkit. You are not required to include the test package with your extension.	Testing the Advanced Sample Extension
DataClassification is required for fields of all tables/table extensions. Property must be set to other than `ToBeClassified`.	Classifying Data
You must use the Profile object to add profiles instead of inserting them into the **Profiles** table.	Profile Object
Use `addfirst` and `addlast` for placing your actions on Business Central pages. This eliminates breaking your app due to Business Central core changes.	Placing Actions and Controls

Technical validation performed by the Business Central validation team

The primary responsibility of the technical validation is to ensure that the Business Central online service is stable and that the apps can be installed and run without destabilizing the service.

The technical validation is for a large part automated and will validate the steps described in the technical checklist above through some pipelines.

The submitted apps will be extracted and investigated following this list:

1. The apps are investigated. All dependencies must be included in the submission. We will lookup prior versions of the apps in the depot. If your app has a dependency on a third party app in AppSource, you should not include this, we will locate it in the depot. **Any unresolved dependencies will cause the submission to be rejected.**
2. If the version numbers haven't changed and the countries haven't changed, the validation is skipped and **the apps will not be updated.**
3. App.json is investigated for mandatory fields. **If mandatory fields are missing, the submission is rejected.**
4. Affixes for the submission are located. **If affixes haven't been registered or cannot be located, the submission is rejected.**
5. Business Central Artifacts are located for the version the apps is submitted for (*Current*, *NextMinor*, or

NextMajor).

6. For every country in the submission list, we perform the same validation:
   - A sandbox container based on the Business Central Artifacts with the right country version is created.
   - Any dependency apps not included in the submission are installed. **If any installation fails, the submission is rejected.**
   - In order of dependencies, all apps in the submission are tested using AppSourceCop analyzer. For more information, see AppSourceCop Analyzer
     - If any **breaking changes are identified, the submission is rejected.**
     - If mandatory affixes **are not included on all object names, the submission is rejected.**
   - In order of dependencies, all prior versions of the apps are published and installed. **If any installation fails, the submission is rejected.**
   - In order of dependencies, all new versions of the apps are published and upgrade is run (apps must be digitally signed, else they won't install). **If any installation/upgrade fails, the submission is rejected.**
   - A simple connection test is run; opening a role center and check simple actions and pages. If the connection test fails, **the submission investigated and potentially rejected.**
7. If all country validations succeed and no errors are found then **the submission is accepted.**

> **IMPORTANT**
> Microsoft recommends that all partners are performing the same checks as described above before submitting apps for validation to maximize chances of validation success.

Running technical validation yourself

With the latest version of BcContainerHelper, you can run a single command, which should perform the same validation steps and give you a good indication of whether your apps will pass validation or not:

```
$validationResults = Run-AlValidation `
    -licenseFile "path/url to license file" `
    -validateCurrent `
    -installApps @( "path/url to your foreign dependencies, apps which will not be part of the validation
(or blank if this is the first)" ) `
    -previousApps @( "path/url to your previous version of the .app files (or blank if this is the first)" )
`
    -apps @( "path/url to the new version of the .app files" ) `
    -countries @( "countries you want to validate against (f.ex. us,ca)" ) `
    -affixes @( "affixes you own (f.ex. fab,con)" ) `
    -supportedCountries @( "supported countries (f.eks. us,ca)" )
$validationResults | Write-Host -ForegroundColor Red
```

All array parameters can also be specified as a comma-separated string. For more information, you can also check this blog post Run-AlValidation and Run-AlCops.

Please include app and all library apps in both previousApps and apps and please include all countries on which you want to validate.

> **NOTE**
> The Run-AlValidation cannot see whether the affixes to specify have been correctly registered with Microsoft using your MPN ID and app publisher name, please make sure registration is in place.

IMPORTANT

The Computer on which you run this command must have Docker and the latest BcContainerHelper PowerShell module installed and be able to run Business Central on Docker.

If you are having issues with Business Central on Docker, you might be able to find help here: https://freddysblog.com/2020/10/12/troubleshooting-business-central-on-docker.

You can use https://aka.ms/getbc?artifacturl=bcartifacts%2fsandbox%2f%2fus%2flatest to create an Azure VM, which has all prerequisites installed to run Business Central on Docker.

NOTE

Microsoft recommends that all partners set up DevOps processes to ensure that this validation process happend automatically and regularly.

You can find resources for how to set up a build pipeline, which performs all these steps here: https://aka.ms/cicdhol and you can find sample repositories, performing these steps here:

- https://dev.azure.com/businesscentralapps/HelloWorld.AppSource (for Azure DevOps)
- https://github.com/BusinessCentralApps/HelloWorld.AppSource (for GitHub Actions)

Manual validation performed by the Business Central validation team

The primary responsibility of the manual validation is to ensure that the apps are working as described.

Manual validation is not done on all submissions. They will be done as sample tests.

For manual validation, we spin up a container with the right artifacts (same as used during technical validation) and the necessary apps are installed. Rapidstart packages needed for the manual test are installed.

The manual test validation document is run manually and if the document doesn't match the app functionality the submission is rejected.

IMPORTANT

Microsoft recommends that all partners are performing the manual validation as the last check before submitting for validation.

This can be done either in online sandbox environments or in sandbox docker containers.

Developing AL Language extensions

How to Make Compelling Videos

2/17/2021 • 9 minutes to read • Edit Online

Why use video? It is well worth investing time and resources to create marketing videos for your app, it is taken seriously in a business environment.

Reasons why video is a superior medium

- Videos offers a very rich, stimulating communication medium that engages multiple senses.
- Video engages the mind and triggers emotions, which makes it more compelling than text-based content.
- Our brains have an easier time processing visual stories than bullet points or straight facts.

A recent Demand Gen survey indicated that 58% of B2B buyers consume video content, while Hyperfine media states that 59% of executives would rather watch video than read text. Also, 50% of executives look for more information after seeing a product/service in a video.

Speak to Specific Personas in your videos

You should create a video for each of the three core personas in the company:

- WHY persona: Owner/executive/leadership
- HOW: Business line manager
- WHAT: IT buyer, User

A horizontal generic message that attempts to speak to everyone will likely not reach anyone in an emotionally engaging way. Wasting a prospect's time by requiring him/her to listen to irrelevant data or information will only create frustration and lead him/her to form a negative bias towards your company.

Choose the video format that is relevant for the audience that you want to target

Video type 1: "Why" video

How to set up "Why" videos

- Recommended length: 60-90 seconds
- Purpose:
  - Your video should clearly communicate WHY prospects need to buy your solution now.
- Focus:
  - Make sure the prospect is the hero of the story, not you or your company. Prospects are not interested in hearing about your company at this stage. They are simply trying to determine if what you offer is of value to THEM.
  - Your video should speak to the principal challenges and goals of your core decision-maker persona.
  - Describe the desired end state they will achieve by using your app.
  - A client/customer speaking about the benefits they received from your app is far more credible and compelling than anyone from your organization.
    - Don't only rely on "features" to acquire new customers.

How to speak to a WHY persona in a video

- Target audience:
  - Owner/executive/leadership
  - They have limited time and financial resources as well as many competing priorities and resource requirements
  - You need to elevate the discussion to a strategic level, where you highlight market share, competitiveness, profitability, differentiation, revenue loss, and more.
- Message:
  - The question you must answer beyond a doubt is WHY should they invest the time and money to buy your app? What will they get out of it?
  - Why should they spend money on a new system now? Can't they put it off?
  - The WHY messaging teaches people something and it is industry specific and results oriented, as well as being memorable. It engages the emotional/limbic brain and leads to meaningful action.

Video type 2: "How & What" video

How to set up "How and What product videos"

- Recommended length: Up to 3 minutes.
- Purpose:
  - This video goes into greater depth communicating the main benefits of your app as well as HOW you solve your prospects' problems. You can include some WHAT content. • Focus:
  - Demonstrating the proof of your claims is critical during this video.
  - Show very specific dashboards or visually show how you address prospect challenges.
  - If possible, use contrast to create desire and a sense of urgency. For example, you could show a complex, ugly data-filled forecast spreadsheet next to a beautiful visual dashboard stating "your sales forecast before and after."

How to speak to a HOW persona: (Business line manager)

- Target audience: Business Line Manager
  - HOW focuses on the operational benefits your solution will provide and HOW your organization will support the implementation.
  - Speaking to the HOW persona starts to separate you from the pack. • Message: o HOW content is VISUAL in nature and ACTION oriented. It allows your prospects to identify with you at a FUNCTIONAL business level and to Add-on with you. It provides evidence that your organization has relevant industry experience. Tribal acceptance increases, while risk decreases.
  - HOW messaging begins to appeal to the limbic brain because it is focused primarily on emotional business pains and problems.

How to speak to a WHAT persona: (IT buyer, User)

- Target audience: IT-buyer, User
  - WHAT people are often tasked with finding a solution and are important influencers in the decision, but they are not the financial decision makers, and their opinions are easily overturned by HOW and WHY people in the organization.
  - Therefore, don't invest all of your marketing time, money, and effort into providing content just for them.
- Message:
  - You need to survive the WHAT inquisition and provide information about product-related features, functionality, and data so that prospects clearly understand your solution offering.
  - However, this will seldom trigger an emotional response and, therefore, it is likely there will be little or

no emotional engagement with your content.

- WHAT content is binary. WHAT content is a commodity. WHAT content is boring. Logical WHAT content is a necessary evil because many prospects initially go looking for it, but stopping here means remaining relevant only to WHAT personas.

Video type 3: "Getting started" video

How to set up "Getting started videos"

- Recommended length: 2–3 minutes maximum.
- Purpose: This video should prove it is quick and easy to get up and running with your app.
- Target: What personas (Users, It buyers)

Video type 4: "Customer testimony" video

How to set up "Customer testimonial videos" - Recommended length: Up to 2 minutes

- Purpose:
  - Social reinforcement: Customer stories are the best proof of gain.
- Focus:
  - A story coming directly from your client in the form of a testimonial is stronger than having your prospects take your word for it. If prospects see that other similar people orcompanies have already purchased your solution, then their natural response will be to more readily accept it as a solution for themselves.

Video tips

How to structure your video and practical things to keep in mind when producing videos

How to structure the flow in your video?

- Gain immediate attention in the first 10 seconds of the video Stimulate curiosity by include a hook phrase/comment that will elude to solving a pain point. Ask questions about the prospects' core business challenges or ask about something they would like to do but can't accomplish today.
- Highlight the prospects' problems: Use an empathetic approach when describing their current situation and demonstrate that you understand their current business challenges. They must relate to this if they are to continue watching.
- Give them new learning Teach them something they don't know. Demonstrate you have expertise and knowledge about their business or industry that they might not. Show you can offer strategic value to them.
- Paint a picture of a desired outcome they would love to have or state they crave to experience Highlight the benefits, rewards, and value they will enjoy after they purchase from you. Include both what it looks like and how it will feel.
- Prove what you're saying is true Prospects don't trust us when we say our products are great. Include objective and credible proof in the form of data, charts, graphs, quotes, statistics, or testimonials as evidence of your claims.
- Ask them to take action Include a call to action at the end of all videos. When viewers watch your videos, they should feel inspired to take the next step towards purchasing. Tell them what to do next and include an interactive link to the next step in the buying cycle. Use scarcity to compel them to action. Provide a timelimited offer or, for example, say it is "only for the first 20 customers".

Practical things to keep in mind when producing and distributing your video

Does and don't when producing your video

- Don’t make the video too long As our attention span is 8 seconds the ideal length of video is 90 seconds (minimum 30 seconds/maximum 2 minutes).
- Add interactivity where possible Overlay text, charts, animation, questions etc. Visually call out key messages.
- Make sure your audio is high quality.
- Make your video easily shareable
- Enable your video to be shared on multiple media. Track views and attention span. Observe and measure viewer patterns so that you can learn from prospects’ actual behaviors and then improve future content.

How to make a good narrative that speak to the right persona in the right way?

- Your narrative should have a beginning, middle, and end.
  - Lead with a story, not with your app or the technology.
  - Don’t turn your videos into a product pitch.
  - You’ll build more brand affinity and trust by shedding light on a problem your prospects care about rather than by pitching your solutions to them directly.
- The brain is on alert at the beginning of the video and at the end.
  - Make sure the first and last ten seconds are compelling, memorable, and interesting.
- Speak directly to a particular persona in the second person.
  - Do not talk about them in the third person, and avoid using terms like “our clients” and “companies”; instead, use “you” language as often as possible.
  - Use a lot of industry specific vocabulary, terminology, and visuals. If possible, film onsite at a customer’s location rather than in your office or in a studio.
- Speak to a particular persona:
  - Do not try to appeal to everyone at once, as you may not fully engage anyone with this approach.
  - Keep your delivery casual and authentic to instill trust. Speak directly to the prospect as if you were having a fireside chat
  - The prospect should be the hero of the story, i.e. do not speak about you and your company.
- Ask rhetorical questions that stimulate pain and anxiety in your prospects in order to demonstrate that you understand their business problems.
  - For example: Are your margins decreasing? Having cash flow problems because you can’t collect payments sooner than 90 days? Had another large write off? Lost an important customer recently due to a late delivery?
- Use visual and auditory language to help the prospect imagine a new possible future.
  - For example: “imagine seeing” , “picture yourself”, or “ how would you like to hear your clients say…” and so on.
- Use contrast whenever possible.
  - Compare prospects’ experience now versus what it could be after the implementation of your solution.
  - Call out your competitive differentiators while anchoring your solution in prospects’ minds so that they can compare all others against the bar you set.

How to make a good narrative that speak to the right persona in the right way?

- Where possible, use tangible, concrete language.
  - Include quantifiable proof in the form of data or visual pictures.
  - No vague claims like “transform your business with the cloud”. This is an emotionless statement.
- Providing customer references and testimonials is much more compelling and effective than selling your company or product yourself.
  - Let others speak for you. A customer testimonial video will always be more believable and compelling than a video of you saying the same thing.

- Surprise and delight them.
    - Use humor to make them smile. We take ourselves and our problems too seriously. Be warm, memorable, and unique.

Guideline on Creating an Effective Sales Landing Page for Your App

2/17/2021 • 10 minutes to read • Edit Online

Building a landing page that drives a successful buying transaction

Microsoft will drive qualified traffic to AppSource. Though, once a prospect becomes aware of your app, it will be your job to guide them through to a successful buying transaction. Deliberately mapping and architecting the buying journey is critical to ensure a high level of engagement and conversion. Only presenting your app's features and functionality, or just providing a free trial, will not ensure prospects will become buyers. For this you need to have a good landing page that is built to help you capture attention, accelerate your customer acquisition process, and drive buying behavior. The recommendations on this page will help you do so.

Examples of how other partners have implemented our best practices

To inspire you in creating a good landing page for your app, two of our valued partners, LS Retail and Industry Built, have offered to provide a sample of what a best practice landing page for a Microsoft Dynamics 365 Business Central partner could look like.

Have a look at their app landing pages and use them as inspiration to build your own landing page:

- Industry Built's Build Food app
- LS Retail's LS Express Start app

In the following checklist, we have "broken down" the elements, on their landing pages in order to showcase best practices on design and messaging. More specifically, we are looking into layout and structure elements, content elements, visual elements, anxiety reducing elements and support elements.

Additionally, we have provided specific recommendations on how to apply these elements to help you increase conversion and maximize the effectiveness of your product's sales landing page.

We urge you to review and implement these best practices on your landing page – in so doing you will contribute in providing the Microsoft community of customers with a consistent buying experience across publishers.

Layout and structure elements

ELEMENT	DESCRIPTION	EXAMPLE
Company	Include the company logo on the page	
App name & app logo	Include a visual logo of your product name and a one sentence positioning statement.	
Top menu choices	Use clean, straightforward and descriptive menu options.	

ELEMENT	DESCRIPTION	EXAMPLE
Search box	Include a search box so visitors can quickly find what they are looking for.	
Emotional tribal anchor photos	Visuals create an emotional Add-onion. The brain skims over non-emotional photos.	
Visual	Make your page easy to scan, with lots of strong visual imagery.	

Logo

- The upper-left corner of the landing page is the most valuable section of the entire landing page.
- Place your company logo in this location.

If you need help formulating a positioning statement, try the value proposition generator located at here.

- There should ideally be 5 or fewer choices; do not include more than 7 options.
- The menu text should state what the prospect gains if they click on the menu item
- The text should be written from their perspective, not yours.

Recommended menu items:

- How to Buy, Benefits Gained, Why Us, and Contact.

The upper-right corner of the page is usually an ideal spot

- Faces evoke more emotion than landscapes or machines, and so on.
- Include a happy customer that looks similar to your prospect in terms of age, demographic, and industry, and which shows them dealing with the issues that your prospect can relate to.
- Try not to use stock photos of people or objects.

Engagement

- Too much text forces the brain to skim, skip, and exit. Text engages the logical, analytical brain, but not the emotional brain.
- Keep it clean and straightforward in terms of design and layout. Use lots of pictures, graphs, and screen shots to enhance engagement.

Content elements: Text and messaging

ELEMENT	DESCRIPTION	EXAMPLE	
Include a headline question	Get your prospects' attention by asking them a compelling pain-based question that they can relate to.	"Struggling to manage your ingredient inventory and fretting over allergens?"	

ELEMENT	DESCRIPTION	EXAMPLE	
	You want the prospect to mentally say "YES" as often as possible and to peak their curiosity enough to read more.		
	Your questions should be intriguing and customer-centric.		
	In general, 8 out of 10 people will read headline copy, but only 2 out of 10 will read the rest.		
Microsoft Dynamics 365 product description	Somewhere on the landing page, make sure you include the standard Microsoft Dynamics 365 Business Central product description provided by Microsoft *This is a requirement because your product is adding value to and building on this foundational solution.*	*Insert this paragraph:* Microsoft Dynamics 365 Business Central is a comprehensive business management solution for small and medium-size businesses (SMBs) that have outgrown their basic accounting software. From day one, this new application makes ordering, selling, invoicing, and reporting easier and faster. Dynamics 365 Business Central is deeply integrated with Microsoft 365 and includes built-in intelligence, so it is easy to use and helps users make better business decisions.	
Messaging (Address their pains)	Pain is a strong motivator of action.		
	- Identify 1-3 key sources of the client's most prominent pain early on the page.		
	- Call out the fears that are likely to be holding them back.		
	- Your landing page text and messaging should predominantly focus on the pain the prospect is experiencing, and NOT the features of your product or service.		

ELEMENT	DESCRIPTION	EXAMPLE	
Clearly demonstrate to your prospects that you genuinely understand their industry and unique business problems.	- Describe the business challenges they are facing now and the ways their revenue growth, margins, productivity and so on, are being negatively impacted by not taking action now.		

ELEMENT	DESCRIPTION	EXAMPLE
Messaging (Product benefits)	Paint a clear, visual and desirable picture of what is possible.	
	Describe the most significant benefits and rewards that your prospect will realize after purchase.	- For example, "Save time and money (benefits) by having a system that does all the tracking and calculations for you (features)."
	- Don't only list features and app functionality, start with the benefit first, then you can follow with the features.	
	- Paint a picture of a possible experience the prospect will immediately desire.	
Clearly articulate a compelling desired outcome	- If possible, use industry-specific language and vocabulary to resonate with your prospect deeply.	
	- Choose a particular persona to speak to directly.	
	- Engage prospects by speaking directly to them using first person "you" language.	

ELEMENT	DESCRIPTION	EXAMPLE
Messaging (Prove your claims)	Include specific calls-to-action on your app page.	"Reduce how long it takes to set up your recipes in the morning from 1 hour to 10 minutes."
	Don't make general and abstract claims.	

- Use data as often as possible to support your statements.

If you make specific claims, support your claims with proof, while Quantifying impacts and gains.

- The more specific and concrete your promise of value is, the better.
- Abstract concepts such as "more efficiency, more productivity, transform your business" are not emotionally

impactful or convincing and do not compel a prospect to act.

Target market - If you support multiple countries or languages, this is a key selling feature. • Find a way to show this visually.

ELEMENT	DESCRIPTION	EXAMPLE
Messaging (Compelling call-to-action)	Include specific calls-to-action on your app page	

- This can be your free trial; a time-limited special price; a scheduled walk-through demonstration; and so on.
- The words "free" and "save" are highly emotional words in the English language, so they should be used.
- Use bright colors, such as orange, yellow, or red, to call attention to your buttons.

Button text should use benefit language rather than descriptive language.

- For example, instead of "Download" write "Click here to start saving money now."
- Try not to send prospects away from your page – always have an embedded next step in your call to action that brings them back to your landing page.

ELEMENT	DESCRIPTION	EXAMPLE
Messaging (Create a sense of urgency by teaching the prospects)	Help your prospect gain a sense of urgency to buy by teaching them one thing about how they can be more efficient or profitable now.	Your bakery profitability will decrease over the next five years due to an increase of 3% in the cost of key inputs, such as wheat and sugar. Want to know five key strategies that can help you mitigate this challenge? Click here to find out how to preserve your profit margin

- Show them how their performance in one key business area is below that of their competitors.
- For an example you can provide a quick online self-assessment, a top-10 tips blog post, and much more. Visual elements

ELEMENT	DESCRIPTION	EXAMPLE	
Pictures (Differentiation comparison images)	Show them, don't tell them	Show the before and after state.	

- This is a visual image of how your prospects do things now versus how they will be able to do it in the future.
- You are not telling them but showing them using a visual.

ELEMENT	DESCRIPTION	EXAMPLE
Compelling proof screen shots	Visually demonstrate all the claims that you are making.	Quickly and easily view inventory items

- Graphic dashboards are the most effective method.
- Zoom in on the main benefit-related features.
- Make sure it is readable, and the benefit is obvious.
- Include a caption.
- Data should be industry specific so that it resonates with the viewer.

You want prospects to see how their data/process would look in your system.

ELEMENT	DESCRIPTION	EXAMPLE
Videos (Tell your story using videos not text)	Include as many videos as possible.	

- Videos have a much higher level of engagement and viewing time and convey much more than you can ever say with words.

Include at least one customer testimonial video on your app landing page.

- Your client should speak specifically about the pains they had before and the benefits they gained after, not product features. It should be all about your customers, not you.

Include one product demonstration video.

- See the video best practices https://aka.ms/ReadyToGo.

Elements that reduce anxiety and risk, while increasing trust

ELEMENT	DESCRIPTION	EXAMPLE
Customer testimonials	Don't sell your product; let your customers do that for you.	

- Social proof is more credible and trustworthy to prospects. The purpose of testimonials is to reduce the buyer's anxiety and fear.

Your testimonials should answer the following questions:

- "Will this work for my situation?"
- "What benefit will I really get if I buy this?"
- "Is this going to be too hard?"
- "How long is this going to take?"
- "Can I trust this company?"

ELEMENT	DESCRIPTION	EXAMPLE
Reduce risk	Prospects are afraid of being scammed and taken advantage of on the internet. They are naturally cautious and highly suspect.	Source: Microsoft.com

- You want to convert prospects to buyers.
- Make it easy for them to buy, while reducing their anxiety. Transparency is the key to building trust.
- Make sure that you include a link to a BUY NOW page, which includes full pricing details.
- Give them a compelling offer they cannot refuse. Offer a time-limited trial or special pricing discount if they buy in 30 days.
- Use scarcity to compel action. Offer a 100% money-back guarantee.

We recommend providing three offerings, optimized for three different customer segments. For more recommendations on pricing, see the pricing guide located at https://mbspartner.microsoft.com/BFI/Topic/64

ELEMENT	DESCRIPTION	EXAMPLE
Live chat	Include live chat, with a photo of one of your team members smiling at an appropriate time to increase conversion, such as when a prospect clicks the back button on your pricing page.	

- Include their name if possible to build trust.

Support elements: Interactivity and contact options

ELEMENT	DESCRIPTION	EXAMPLE
SHORT lead capture form	Include a lead capture form on your page.	

- Only ask for their name and email address, you can get the rest later.
- Your forms should not have more than 4 or 5 fields to fill out. You have not yet earned the right or enough trust to ask for too much information at this point.

Most lead capture forms are way too long, demanding, and intimidating, and have low completion rates.

> **NOTE**
> Nobody has the time or is willing to fill out an annoying form, which is of no value to them, especially if it is purely self-serving from your standpoint.

ELEMENT	DESCRIPTION	EXAMPLE
Contact	Provide prospects with different contact options based on their readiness to interact with you.	

- Ideally, include a phone number and an email address with an employee photo.
- This alone could double your conversion rate.

ELEMENT	DESCRIPTION	EXAMPLE
AppSource app page link & social share	Include a link back to your listing on AppSource, so the prospect can return when ready.	Return to AppSource

- Also, enable visitors to share and forward your app with others!

ELEMENT	DESCRIPTION	EXAMPLE
Close them! Add a get started button	Include a very specific call-to-action button with the option to buy or try.	

Embed App Overview

2/17/2021 • 4 minutes to read • Edit Online

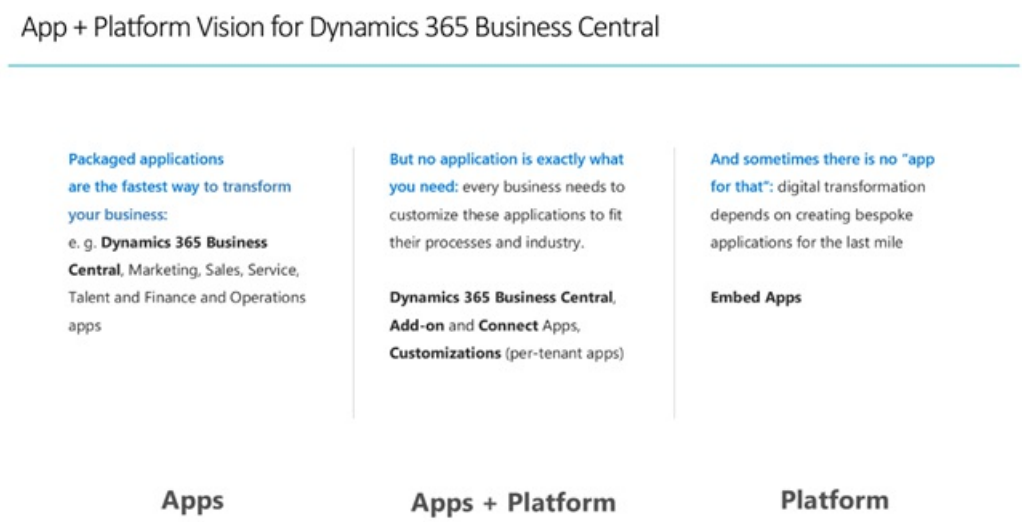
Embed App is a term that defines an end-to-end solution meeting the specific needs of a vertical or micro-vertical industry.

Dynamics 365 Business Central plays a vital role in the Embed App, as Business Central is embedded as an integral part of the overall solution.

Some examples of an Embed App include:

- A Dentist solution
- A Real Estate Agent solution
- A Food Processing solution

An Embed App refers to what is being provided to a given customer segment, unrelated to how the solution is being implemented or architected. An Embed App can be built using AL, in other words extension, code-customization, and a combination of extensions and code-customization.



Components

On a high level, an Embed App is a package that consists of the following parts:

- Library extensions

  This is the functionality of the Embed App that is implemented by the ISV partner in a form of extensions.

- Third party extensions

  These are add-on extensions coming from other ISVs that contribute to and enhance the Embed App. The extensions are validated to be compatible by the Embed App owner.

- Extended metadata

  This includes additional Embed App properties that are specific to this type of app and not otherwise available for other types of apps (see the list below).

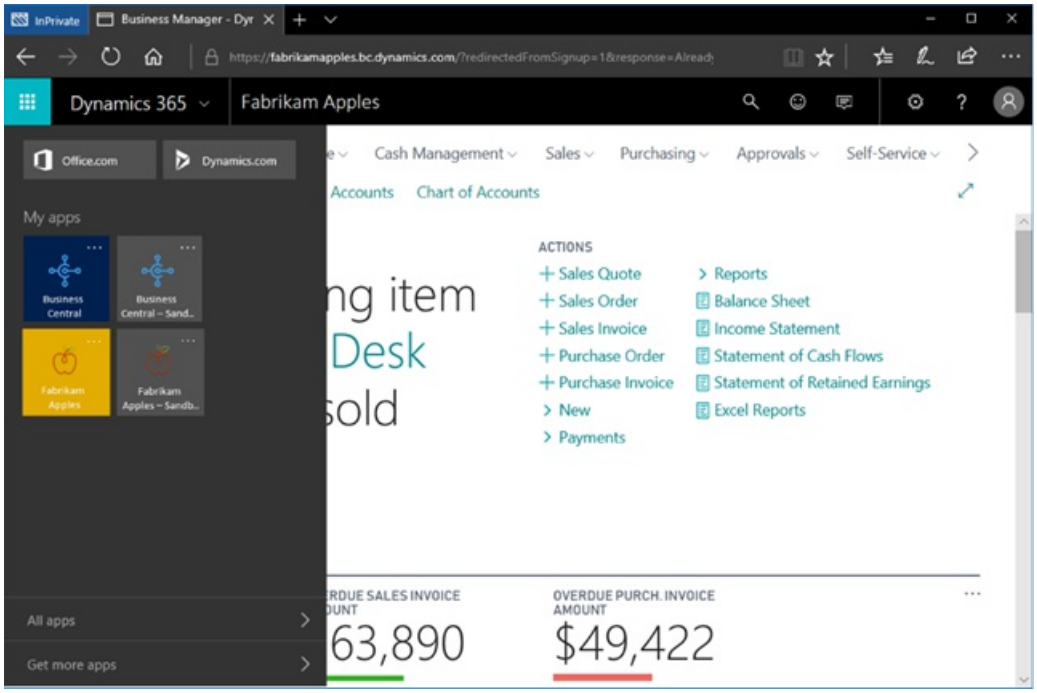
- Base application and tenant template (optional)

The following capabilities are only available for the Embed App and not for other types of Business Central apps (Connect and Add-on).

Partner Branding

The Embed App will promote the partner's brand in several places:

- Web Client and Web Service URLs
  - Client: `https://[application name].bc.dynamics.com`
  - Web Services: `https://[application name].api.bc.dynamics.com`
- Name, image, and icon on the provisioning page of the Fixed Client Endpoint
- Splash screen of the client
- Title bar of the browser tab (for example, "Fabrikam Apples")
- A dedicated product tile, icon, and short marketing description in the Dynamics shell (https://home.dynamics.com)
- In-product messages (such as pop-up errors, warnings, notifications)



Exclusivity

The partner can control which third party apps can be installed for their Embed App.

- Safe listing of the 3rd party apps - no other apps will be possible to install, except the ones explicitly approved by the partner
- App install/uninstall controlled by the partner
- The partner can choose to allow a customer to install other extensions from the AppSource, but this will be an explicit partner decision, not the default behavior

Code-customizations of the base application

Partners can choose to bring their own code-customized base application as an Embed App for several reasons:

- Shortening time-to-market ("lift and shift" approach).

  The partner's current solution is a significantly customized version of the Dynamics NAV application and it will require substantial time and effort to migrate it into extensions. A partner can lift their solution as-is (upgraded to a supported platform) to Business Central service and start offering it to their new and prospective customers. Then, they can gradually start moving their functionality into extensions to achieve the benefits that come with the extension model. The earliest version of the Business Central

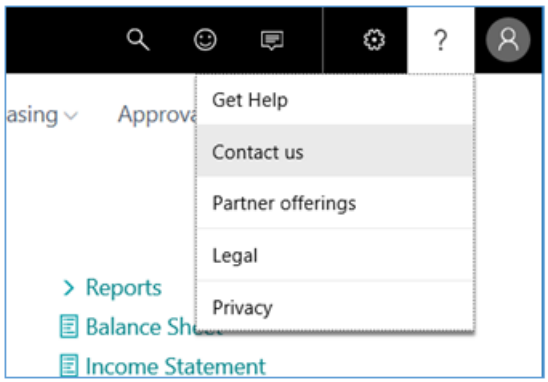
application you can bring to the service is version 16.

- Usage of .NET interoperability and custom assemblies.

  Partners that use .NET interoperability in their current application to address multiple business scenarios. Although extensions today allow a number of these scenarios to be implemented in AL, they don't and cannot cover for all possible scenarios of .NET usage. Therefore, the partner can choose to import the required .NET add-ins into the Add-ins table of the base application, and these add-ins will automatically be deployed into the environment where they will be running.

Additional settings (metadata)

- An Embed App is the property of the partner, so the customers of the Embed App must be able to find the partner's own legal, privacy, contact, community and feedback links (not Microsoft links) when they work with the app:



- Safe listed domains for embedding Embed App pages into other web sites, including SharePoint ("frame ancestors")
- Target version of Dynamics 365 Business Central platform
- Target version of Dynamics 365 Business Central base application (if not included with the Embed App)
- Azure KeyVault account for storing application secrets, such as accounts for connecting to 1-3rd party services
- Base application + tenant template. This is an optional component of an Embed App. The partner can choose to include it or simply specify which version of the Dynamics 365 Business Central base application the Embed App should use as a base application.

At this stage, within the extensions and base application, the partner can work in their own Object ID range.

Platform version availability

Microsoft is going to make new versions of the Business Central platform available to Embed App partners through the Lifecycle Services portal (LCS). The partner will then have to pick the platform they want to use for deployment of their solution.

Deploying versions

When a partner deploys a solution through the LCS portal, they can pick from the last three available versions of the platform (minor and major). Every newly released minor or major platform update will be added to the list and simultaneously one older version will be removed form that list.

Any existing deployments, running on platform versions that are older than 3 updates, will enter a grace period of 30 days. And after that, if the deployment is not upgraded, it will be moved out of the standard SLA.

Qualification and Onboarding of Partners to the Embed App Program

2/17/2021 • 2 minutes to read • Edit Online

If you as a software development partner are interested in developing an app that meets the description of Embed App in Embed App Overview, your app must meet qualification requirements. The main criteria for Embed App onboarding at this point are:

- Partner must provide all day, every day support. Their customers do not get to call Microsoft support. They always call the partner.
- Partner must live up to the standards for user assistance and documentation that are outlined in Dynamics 365 Business Central User Assistance Model. Good user assistance is part of Embed App success and uptake, and it also lowers the work load on their support center.
- Partner is committed to stay on the supported platform.
- Partner provides an SLA for requests from Microsoft towards the partner
- Partners must have a support agreement with Microsoft

Apps with a code-customized base application will have additional volume (number of users) requirements associated with it.

When an Embed App is qualified for onboarding to Business Central online, the partner must provide the following information about the Embed App to the Microsoft's onboarding team:

- The name of the application to be used for the client and web service URL. For example, an ISV for the *fabrikamapples* app would provide the following information:
  - Client: `https://fabrikamapples.bc.dynamics.com`
  - Web Services: `https://fabrikamapples.api.bc.dynamics.com`
- Entitlements for their application objects, per license type. For more information, see Licensing in Dynamics 365 Business Central.

The rest of the information will be included with the Embed App package that the partner deploys through LifeCycle Services.

Creating Deployment Packages for Embed Apps

2/17/2021 • 13 minutes to read • Edit Online

To deploy an Embed App, you'll need a deployment package and your apps. This article describes how to create a deployment package for an Embed App.

The apps are the individual extensions that make up your application. Apps are delivered as .app files, which you upload to the App Repository via the App Management API. For information about this task, see App Management API.

Once you've created the deployment package and uploaded your apps, you then upload the deployment package to a registered project in Microsoft Lifecycle Services.

Deployment package overview

Creating a deployment package prepares the Embed app code and data for deployment on Business Central Online service. The deployment package is a .zip file that contains components required for any Embed app.

At a high level, a deployment package consists of the following components:

- ISV branding elements, like images, icons, names, and so on
- An application database and tenant template databases as BACPAC files
- A manifest-json file that provides additional metadata and deployment instructions

The deployment package has the following structure:

```
[FOLDER] branding/
  - favicon.ico
  - splash.png (or .gif)
  - splash_narrow.png (or .gif)
  - header.png (or .gif)

[FOLDER] databases/
  - app.bacpac
  - tenant.bacpac

manifest.json
```

The following sections explain how to build the deployment package.

Creating the database BACPACs using Docker

We strongly recommend you run Business Central on Docker using the BCContainerHelperPowerShell module to prepare the BACPAC files.

> **IMPORTANT**
> You must only use the sandbox artifacts (Get-BcArtifactUrl -type sandbox) for your online deployments.

With the Docker container, you can:

- Attach your own database and publish necessary extensions into the application database
- Synchronize the schema of the tenant template database with the schema defined in the application

- Ensure that all objects are compiled
- Test your solution before creating the deployment package.

For more information about these and other things you can do, see BCContainerHelperPowerShell module.

About the databases

Business Central Online service runs exclusively in multi-tenant mode. Each customer environment is a separate database, but sharing the same application. So the deployment package has to include two databases, which are compiled into BACPAC format:

- App.bacpac - includes the application database. The application database contains your application data, like permissions, entitlements, report layouts, and so on.
- Tenant.bacpac - includes the tenant template database, which may also contain initial tenant data.

Requirements for the application database

REQUIREMENT	CONDITION	DESCRIPTION
Running on a supported Business Central platform	Always	The Business Central platform is updated monthly. You're responsible for updating the Embed App to operate with the updated version of Business Central. The Embed App must run on a supported build (platform) of Business Central, namely, the current version of Business Central or one of the two immediately preceding versions. The immediately preceding versions can be both minor and major versions of Business Central. Earlier versions of Business Central platform are out of support and can't be used for Embed app deployments.
Unique Base Application ID, Name, and Publisher	If any change is applied to the Microsoft Base Application objects	Create and assign your own unique App ID for it in the app.json file. Also, change the Publisher property and the Application name to your own in the app.json file. You can't use the original values of the Microsoft Base Application unless you've extracted all your customizations from that app into your own app(s).
Use System Application	Always	Your Embed app must be built on top of the Microsoft System Application. The System Application must not be customized and must be used as a dependency for your customized or non-customized Base Application.

REQUIREMENT	CONDITION	DESCRIPTION
Use `Microsoft_Application.app` file	If you use customized Base Application	Use `Microsoft_Application.app` to encapsulate references to your own customized Base Application, instead of referencing that app as a direct dependency in each extension separately. This will also allow other apps (like AppSource apps) to refer to your solution via the `Microsoft_Application.app`. For more information about the `Microsoft_Application.app`, see The Microsoft_Application.app File.
Solution prefix or suffix	Always	Register a prefix or suffix to be used by your solution. Apply the prefix or suffix to all objects, while you're still preparing your apps on-premise. The prefix or suffix must be used for all your app objects and also for your tables, controls, fields, actions, and groups that remain inside of Microsoft's Base Application. There's no need to apply this prefix or suffix to Microsoft objects and fields in the customized Base Application. Fore more information about requesting and using prefixes and suffixes, see Benefits and Guidelines for using a Prefix or Suffix. Once your apps are deployed to Business Central service, it won't be possible to rename fields and objects, because it would be a breaking change. Breaking changes aren't permitted in the online version of Business Central. While still preparing your apps on-prem, you can use the Sync-NAVApp cmdlet with `-Force` parameter to add prefix or suffix to your objects and fields.

REQUIREMENT	CONDITION	DESCRIPTION
Entitlements	Always	It's important that the application database also contains Microsoft unmodified records in the following tables: • Membership Entitlement • Entitlement Set • Entitlement No users can sign in to your service if these tables are empty. You can't add new records or modify existing records in these tables. For more information about these tables, see Business Central entitlements explained. The entitlements can be copied from the standard Business Central Demo Database available in sandbox Docker containers. Make sure you update the entitlements when you uptake a new version of Business Central application. Consult the entitlements documentation and parameters provided for the `Clean-BCContainerDatabase` and `New-BCContainer` commands included with the BcContainerHelperPowerShell module.
Permissions	Always	The application database must contain Microsoft unmodified records in the following tables: • Permission Set • Permission You can't modify the existing records in these tables. If you need to add your own permission sets and permissions for the objects used by your own solution, include these with your extension instead. For more information, see Exporting Permission Sets. Don't include customer-specific permission sets and permissions in your database, these permissions must be added within the customer environment instead. For more information, see how to create or modify a permission set in the Business Central Application help.

REQUIREMENT	CONDITION	DESCRIPTION
Custom .NET add-ins	If your solution uses custom .NET Server components (.NET add-ins)	Import components into the **Add-in** table in the application database. You register the control add-ins, import and manage the files by using the New-NAVAddin cmdlet, Set-NAVAddin cmdlet, Get-NAVAddin, or Remove-NAVAddin cmdlets from the Business Central Administration Shell. **IMPORTANT** Using custom .NET Server components option is being deprecated. So refactor your code to remove custom .NET components as soon as you can. For example, use Azure Functions instead.

Requirements to the tenant template database

While you are testing your Embed app solution in a Docker container, you can publish and install all the apps you need for your customers. When you're done testing, we recommend you to uninstall (including removing the data) and unpublish all apps, including Microsoft apps, before you export the application and tenant template databases.

Instead of keeping the apps pre-published and pre-installed in your databases, they must be uploaded to the service by using the App Management API and listed in the `[apps]` section of the `manifest.json` file. This way the apps will be automatically published and installed later, during deployment, following the list you provide in the `manifest.json` file that you include with your deployment package.

We recommend you to use RapidStart packages to populate the new companies with the demo data or initial setup data.

Exporting application and tenant databases

You export the databases to BACPACformat by usingthe `Export-BCContainerDatabasesAsBacpac` command from the BcContainerHelperPowerShell module.

We strongly recommend using this command for creating the BACPAC files you're planning to deploy to the Business Central service. To simplify exporting the data, the command also does a number of clean-up stepson the databases. It cleans up sessions,database connection, list of tenants, imported license, and more. It also verifies that the schemas of the application and tenant databases are synchronized, which is essential for deployment.We keep enhancing this commandwith more cleanup and validation steps as we discover BACPAC-related issues with deployments. So, remember to update the BcContainerHelperPowerShell module for every new iteration.

Providing deployment instructions in the manifest.json

The manifest.json file, supplied within the deployment package, contains important properties used by the deployment routine to configure the application version according to the Embed app ISV requirements.

SETTING	TYPE	DESCRIPTION
manifestSchemaVersion	String, `<major>.<minor>`	Schema version of the manifest. Current manifest schema version is 3.0.

SETTING	TYPE	DESCRIPTION
id	GUID	Unique ID of the Embed solution. Used for informational purposes, not used in the runtime. As a best practice it's recommended to use the Id of your main app in this field.
name	String	Short marketing name of the app. Used for informational purposes, not used in the runtime.
description	String	Short marketing description of the app. Used for informational purposes, not used in the runtime.
publisher	String	Name of the ISV organization that owns the Embed app. Used for informational purposes, not used in the runtime.
version	String. `<major>.<minor>.<build>.<revision>`	Version of the deployment package being uploaded. This version is displayed in the Application Version list in LCS, it has no other purpose or application in the runtime. Remember to update this version for every new deployment, so you can distinguish the deployments in the LCS UI.
branding	Object	Object that contains paths to the branding elements of the ISV included with the deployment package. See the `"branding"` section below.
databases	Object	Object that contains paths to the application and tenant template BACPAC files of the ISV solution included with the deployment package. See the `"databases"` section below.
links	Object	Object that contains paths to various URLs to be used in the Business Central Web Client. See the `"links"` section below.
apps	Array	Array that contains the list of apps and their dependencies, which are uploaded by the ISV via the App Management API. See the `"apps"` section below.

"branding"

SETTING	TYPE	DESCRIPTION

SETTING	TYPE	DESCRIPTION
productName	String	Official marketing name of your Embed app. This name will be displayed in the title bar of the Business Central Web Client.
productNameShort	String	Short version of Embed app marketing name. It's displayed in the areas of the UI where full Product Name can't be displayed.
marketingName	String	Longer (full) marketing name of your Embed app.
images	Object	Object that contains paths to the branding images included with the package. See the `"images"` section below.

"images"

SETTING	TYPE	DESCRIPTION
appleTouchIconPath	String	Format: PNG. Dimensions: 114x114
faviconPath	String	Format: ICO. Dimensions 16x16, 32x32, 48x48 & 64x64. Used on the Browser tab and bookmark icon.
headerPath	String	Formats: PNG, GIF. Dimensions: 558x107. Displayed on "Minimal Layout" pages, like the Microsoft Office add-in sign-in; Authentication / Permission errors ("You don't have access to Business Central", "You've successfully signed out.")
splashLandscapePath	String	Formats: PNG, GIF. Dimensions: 2048x272. Splash screen on devices with large screen space, for example, full screen browser, tablet in landscape mode.
splashPortraitPath	String	Formats: PNG, GIF. Dimensions: 960x320. Splash screen on devices with limited screen space, for example, small browser, phones, tablets in portrait orientation.

"databases"

SETTING	TYPE	DESCRIPTION
applicationBacpacPath	String	Path to the application database (.bacpac) included with the deployment package.

SETTING	TYPE	DESCRIPTION
tenantTemplateBacpacPath	String	Path to the tenant template database (.bacpac) included with the deployment package.

"links"

SETTING	TYPE	DESCRIPTION
baseHelpUrl	String	Link to your online Help server or web page.
baseHelpSearchUrl	String	Link to your online Help server or web page.
communityUrl	String	Link to your community blog page.
feedbackUrl	String	Link to your product feedback page.
legalUrl	String	Link to your product legal and privacy terms.
signInHelpUrl	String	Link to your sign-in help URL.
comingSoonUrl	String	Link to your product announcements page.
blogUrl	String	Link to your product blog page.
contactSalesUrl	String	Link to your sales page.

"apps"

This section of the manifest.json file must list all the apps used by your solution and their dependencies. Even if the dependency app belongs to a different publisher, for example Microsoft, you must include it. This list will be used by the deployment routine to publish and install these apps to your service and for your environments.

SETTING	TYPE	DESCRIPTION
id	String	Unique ID of the app. Use the same Id as listed in the app.json file.
name	String	Name of the app. Use the same Name as listed in the app.json file.
publisher	String	Name of the ISV organization that owns the app. Use the same Publisher as listed in the app.json file.

SETTING	TYPE	DESCRIPTION
initialVersion	String	Minimum required and compatible version of the app. If `"allowedUpdates"` is set to `"none"`, then the exact version of the app you specify must be available in the App Repository. In this case, a full initial version number must be specified. For other `"allowedUpdates"` values, it's enough that an app with a higher or equal [build].[revision] part of the version is available in the App Repository. You don't need to specify a full version number -- [major].[minor] and [major].[minor].[revision] are also accepted. This applies to the App versions uploaded either by you or by other publishers who own the apps.

SETTING	TYPE	DESCRIPTION
allowedUpdates	Enum	Allowed values: none, hotfix, minor, all. You can set up rules that determine which app version to use for the new signups. You can also specify whether updating of the installed app is allowed. • `"none"`: It won't be possible to apply any new versions to this app inline (only side by side). Only the application version that exactly matches the specified initial version number will be used for the new signups. • `"hotfix"`: You allow hot fixing this app with newer hotfix versions, that is, versions with a higher build and revision numbers than in the `"initialVersion"`, but with the same major and minor version. New signups and environments you upgrade to this deployment will automatically get the latest available hotfix version of the app installed. • `"minor"`: Customers can view and install newer applicable minor (or hotfix) versions of the app via the Business Central Administration Center. New signups and environments that you upgrade to this deployment will automatically get the latest available hotfix version of the app installed. Minor updates won't be automatically installed. They must be installed by the newly signed-up customers using the Business Central Administration Center. • `"all"`: Customers can view and install all newer applicable versions of the app via the Business Central Administration Center. New signups and environments that you upgrade to this deployment will automatically get the latest available hotfix version of the app installed.
blockUninstall	Boolean	Allow or disallow the app to be uninstalled using the Extension Management page.

SETTING	TYPE	DESCRIPTION
publishOnly	Boolean	Specifies whether to only publish (`true`) that app to the service. Customers can then install it manually from the Extension Management page. If `false` , the app is automatically installed for all new environments and environments updated to this deployment.

Sample manifest

Sample of the manifest.json file.

```
{
  "manifestSchemaVersion":"3.0",
  "id": "201e5067-99cc-4974-900a-b50bd4fbe777",

                {
                    "id":  "63ca2fa4-4f03-4f2b-a480-172fef340d3f",
                    "initialVersion":  "16.1",
                    "name":  "System Application",
                    "publisher":  "Microsoft",
                    "allowedUpdates":"hotfix",
                    "publishOnly":  false,
                    "blockUninstall":  true
                },
                {
                    "id":  "201e5067-99cc-4974-900a-b50bd4fbe777",
                    "initialVersion":  "16.1.5",
                    "name":  "Fabrikam Rentals Add-on",
                    "publisher":  "Fabrikam",
```

```
                    "allowedUpdates":"minor",
                    "publishOnly":  false,
                    "blockUninstall":  true
                },
                {
                    "id":  "201e5067-99cc-4974-900a-b50bd4fbe777",
                    "initialVersion":  "16.1.50043.50321",
                    "name":  "Fabrikam Rentals",
                    "publisher":  "Fabrikam",
                    "allowedUpdates":"minor",
                    "publishOnly":  false,
                    "blockUninstall":  true
                }
            ]
}
```

Creating the deployment package zip file

After you have all the components of the deployment package ready, you can package them into a .zip archive. The deployment package (.zip) can't include any additional subfolders and files and must have the following structure:

```
[FOLDER] branding/
  - favicon.ico
  - splash.png (or .gif)
  - splash_narrow.png (or .gif)
  - header.png (or .gif)

[FOLDER] databases/
  - app.bacpac
  - tenant.bacpac

manifest.json
```

Now, you can deploy your package to Business Central Online service. See Managing Embed Apps in Microsoft Lifecycle Services for more information.

Managing Embed Apps in Microsoft Lifecycle Services

Managing an Business Central Embed App in Microsoft Lifecycle Services

2/17/2021 • 7 minutes to read • Edit Online

Microsoft provides essential functionality within Microsoft Lifecycle Services collaboration portal (LCS) to support qualified ISVs in managing the Embed App based on Business Central online.

Creating LCS project

In LCS, you should create a project for each Embed App and each country you would like to deploy to Business Central service. You provide the list of countries where you want to run your Embed app during onboarding. You can only deploy your solution to the country that is already supported in the Business Central online service. Find the list of supported countries here: https://aka.ms/bccountries.

Before you can create a project, you need to unlock a corresponding Private Preview feature. Once you sign in to LCS, select the **Preview feature management** action. Then on the Preview feature management page, select the "+" action to add a new preview feature using a preview code. In the **Preview code** field, enter the code you received from Microsoft during onboarding. You should now see the "Microsoft Dynamics 365 Business Central (SaaS)" feature on the list of the private preview features on this page.

> **IMPORTANT**
>
> Even though the project will be created by one user, every user you are planning to add to your LCS project will have to activate the "Microsoft Dynamics 365 Business Central (SaaS)" feature using the same preview code you received from Microsoft. Without this activation, the users you add to your LCS project will run into permissions issues when trying to open the LCS project that you created.

Navigate back to the main page and start creating a new project by selecting the "+" action. Choose **Migrate, create solutions, and learn** category as the purpose of the project. On the next page, provide the project name.

> **NOTE**
>
> You will have to create a separate project for each country, even if your Embed app is going to be exactly the same. Therefore we recommend that you use the name of your Embed app appended by the country code as the name of your project, for example "Fabrikam Rentals, DK", "Fabrikam Rentals, US" and so on.

Next, provide a short description for your project (optional), select **Microsoft Dynamics NAV** as the product name and **Microsoft Dynamics 365 Business Central (SaaS)** as the product version. Select the **Create** button to complete creation of the project.

After you create the project, send its ID to the e-mail alias specified on the main project page for safe listing purposes. You can find the project ID in the URL displayed in your browser, such as `https://lcs.dynamics.com/V2/NavProjectDashboard/[projectID]`

Once your LCS project ID has been safe listed by Microsoft, you can start performing deployments of your solution to Business Central service.

Deploying the Embed App

Prerequisites

Before deploying the Embed App, complete the following tasks:

1. Create the deployment package for the Embed App.

   The deployment package is a .zip file that contains components required for any Embed app. For more information, see Creating Deployment Packages for Embed Apps.

2. Upload your apps into the App Repository

   Upload new versions of your own apps into the App Repository using the App Management API. Don't upload Microsoft apps or apps from other ISVs. The Microsoft team regularly uploads Microsoft apps and AppSource apps to this repository, so you don't have to. For more information, see App Management API.

Upload the deployment package

Once you have the deployment package and uploaded the apps, you can upload the Embed App deployment package into the **Asset library** within your LCS project.

1. In your LCS project, select the **Asset library** action to navigate to the Asset library page.
2. Select the **+** action to open the **Upload Software deployable package file** wizard.
3. Provide the **Name** and **Description** (optional) for your package.

   The asset name you provide will be displayed on the Application Version list inside your project.

4. Select the **Add the file** action to select and upload the deployment package.
5. Wait for the package to get uploaded, then select the **Confirm** button to close the upload wizard.

Start the Embed App deployment

Now, start deploying the package you uploaded in the **Asset library** by doing the following steps:

1. Go to the **Rings** section of your project.
2. Select **Maintain** menu, then select **Deploy** action to open the **Deploy package** wizard.
3. Select the package you want to deploy in the **Package name** field.
4. Select the **Target platform**, then select **Deploy** button to start the deployment.

The deployment routine will pull the apps that are listed in the `[apps]` section of the `manifest.json` file in your deployment package from the App Repository. It will then publish and install the apps based on the instructions you provided in the `manifest.json` file.

After the environment is successfully provisioned, its status on the list of application versions will be set to **Deployed**. To allow sign-ups to be directed to this application version, you select the **Use for new tenants** check box. You can only have one application version marked this way at a time.

> **IMPORTANT**
>
> The Business Central platform is updated monthly. You are responsible for updating the Embed App to operate with the updated version of Business Central. The Embed App must run on a supported build of Business Central, for example, the current version of Business Central or one of the two immediately preceding versions. The immediately preceding versions can be both minor and major versions of Business Central. The list of supported versions is displayed in the LCS portal on the **Deploy package wizard** in the **Target platform** field. The versions, which aren't displayed on that list are out of support. You customers running on these versions can't be serviced at the service levels set forth in the published Service Level Agreement.

Onboarding customers and creating environments

Partners who support an Embed App based on Business Central online can onboard customers in two ways:

- Using the self-service IW sign-up – for acquiring a free evaluation version of the app.
- Through the Microsoft Partner Center Cloud Solution Provider (CSP) program by contacting the partner - for acquiring a paid production version of the Embed App.

Tenant provisioning is happening automatically (just-in-time) on the first attempt to sign in to the solution.

Navigating to `https://businesscentral.dynamics.com` will trigger provisioning of the Business Central tenant, while navigating to `https://[application name].bc.dynamics.com` will trigger provisioning of the tenant running on the *application name* application.

Self-Service (IW) sign-up - evaluation

The Embed App partner can choose to allow customers to use a self-service sign-up (also known as IW sign-up and viral sign-up) for their Embed App. In that case, the partner must prepare a sign-up URL that will redirect the Microsoft 365 sign-up flow to their application URL. The sign-up URL must have the following format:

```
https://signup.microsoft.com/signup?sku=6a4a1628-9b9a-424d-bed5-4118f0ede3fd&ru=https%3A%2F%2F[application name].bc.dynamics.com%2F%3FredirectedFromSignup%3D1
```

The partner can then pass the URL to their customers, either from the partner's own marketing page or in a welcome e-mail, for example.

To work with an Embed App, the customers would use a URL that looks something like this:

- Client: `https://[application name].bc.dynamics.com`
- Web Services: `https://[application name].api.bc.dynamics.com`

In contrast, to work with Business Central, they would use these URLs:

- Client: `https://businesscentral.dynamics.com`
- Web Services: `https://api.businesscentral.dynamics.com`

Once you've established the reseller relationship with the customer and added Business Central subscriptions with required number of licenses for them, you must use your own branded Embed app URL to sign in their environment and Business Central Administration center.

To create a new production environment for your customers, go to this URL:

```
https://[your application family].bc.dynamics.com/[Customer's Azure AD Tenant ID]/Production
```

To open your customer's Business Central Administration center, go to this URL:

```
https://[your application family].bc.dynamics.com/[Customer's Azure AD Tenant ID]/admin
```

Each environment that you signed up for the Embed App is then displayed on the Tenant list part in your LCS project. On this part, you can find more details about the environment, including the name and the URL to sign in to each one. You can see which environments are running on which application version by selecting application version on the list.

Monitoring the Embed app

In the LCS portal, you get access to various logs for the activities that you do in the portal:

- Deployment: logs of deployment of the application versions
- Tenant provisioning: logs of creation of the new customer environments

- Tenant upgrades: logs of customer environments upgrades
- Application errors: errors that are displayed to the customers when they work with the Embed app functionality

To get to these logs, in the Rings section of your project, select **Maintain** menu and then select **Monitor** action.

On the **Ring monitoring** page, first select the **Category**, depending on the operation for which you want to retrieve the logs. Then set the **Period (min)** field to the number of minutes back in time, for which you want to see the logs. Don't use the **All** category.

> **NOTE**
> The logs typically appear in LCS with a delay of 15 minutes.

For easier troubleshooting, we recommend exporting the logs to a CSV file, using **Export to CSV** action, and then analyzing them in Microsoft Excel instead.

It's important to always review the logs before submitting any issues to Microsoft. When reporting issues, attach the relevant logs in TXT or CSV format, don't use screenshots.

Using Application Family in Embed App

2/17/2021 • 2 minutes to read • Edit Online

Business Central service is a part of rich ecosystem of surrounding applications and services. One of the prominent Embed App capabilities is to promote and use the ISV brand in various places of the overall service experience.

During onboarding, the ISV provides the application family name. The application family helps identify their solution among other Business Central apps and Embed App's of other ISVs.

The following table describes different aspects of using the application family when interacting with Business Central components and surrounding services.

AREA	HOW TO USE WITH THE EMBED APPLICATION FAMILY	ADDITIONAL DETAILS
Business Central Web client	Use the application family in the URL: `[application family].bc.dynamics.com`	Web Client URL
Business Central web services	Use the application family in the URL: `[application family].api.bc.dynamics.com`	Introduction to automation APIs
Business Central mobile app	Use the application family in the URL: `ms-businesscentral://[application family].bc.dynamics.com/`	Getting Business Central on Your Mobile Device
Business Central administration center	Application family is displayed for each environment	The Business Central Administration Center
In-code URL generation (GETURL)	GETURL returns the branded endpoint, including the application family.	GetUrl Method
Development endpoint for Visual Studio Code	To publish and debug apps in a Sandbox environment, use the "applicationFamily" property in the launch.json file	JSON Files
Microsoft AppSource	To install AppSource apps, use the branded URL with the following parameters: `https://[application family].bc.dynamics.com/?noSignUpCheck=1&filter=%27ID%27%20IS%20%27[APP ID]%27&page=2503`	Installing apps by selecting a direct app link in AppSource (for example, "Get it now" or "Free trial") isn't supported. This action redirects to the standard Business Central URL.
Microsoft Power BI	Supported for connecting to the environment data from Power BI and embedding Power BI pages in the Business Central Web client.	Enabling Your Business Data for Power BI

AREA	HOW TO USE WITH THE EMBED APPLICATION FAMILY	ADDITIONAL DETAILS
Outlook Add-in	Not supported	Using Business Central as your Business Inbox in Outlook
Excel Add-in	Supported	Setting up the Excel Add-In for Editing Business Central Data
CDS integration	Supported	Integrating with Microsoft Dataverse
Power Automate, Power Apps, Logic apps	Business Central standard connector currently can't be used (support is coming soon). The ISV needs to build a custom connector. The custom connector is required anyway, also for the Business Central environments, if you want to include data from other tables that aren't included with the standard Business Central connector.	Custom connector FAQ for Azure Logic Apps, Power Automate, and Power Apps
Cloud Migration Tool	Supported	Migrating On-Premises Data to Business Central Online

Application Access Management for the Embed App

2/17/2021 • 4 minutes to read • Edit Online

In this article, you'll learn how you can control which customers can create online environments based on your Embed App application family, by enabling your resellers (VARS) to use the Application Management API.

Overview

Both Business Central and Embed Apps are distributed by Cloud Solution Provider (CSP) resellers. Embed Apps use standard Business Central licenses—the same licenses used for Business Central. So any reseller who sells Business Central can also create online environments that run on your Embed App by default.

As an Embed App owner, you'll want to control which customers and which resellers can create online environments based on your Embed App application. You'd also like to allow these resellers to control whether customers have access to both Business Central and your Embed App or only to the Embed App.

To support these capabilities, two features are available, depending on your role:

ROLE	WHAT YOU CAN DO
Embed App ISV	Enable application access management for all environments in your LCS project. Register VARs to give them access to the Application Access Management API.
VAR	Once you've been registered by the Embed App ISV, you can allow or block access to the Embed App or Business Central app for specific customers.

Embed App ISV: Enable application access management and register VARs

Follow these steps to provide your VARs with access to the Application Access Management API. Once they have access, they can use the API to enable or disable the creation of online environments based on your Embed App application.

Preparation

- Prepare the VAR for the change

  Once you enable application access management in your LCS project, any existing customers already using your Embed App will be blocked from access to their Embed App environments by default. It also won't be possible to create new environments based on your Embed App application for any new or existing customers. The VAR will have to explicitly enable the access for each customer by using the API explained in the section below.Make sure you coordinate this change with your VARs.

- Get the VAR's CSP organizational ID (Microsoft ID). You'll need this ID for registration.

  The VAR can find their Microsoft ID in Partner Center, on the **Account Settings** > **Organizational profile** page.

Enable application access management and register VARs

1. Go to Lifecycle Services and open your project.
2. Select the **Manage VARs** tile.
3. On the **Manage VARs access** page, specify if VARs must be able to approve customers.

> **IMPORTANT**
> This step enables application access management. Once you have allowed VARs to approve customers, it won't take effect until you save the change. Be aware that once you save, any existing VAR customers already using your Embed App and any new customers will be blocked from access by default, until the VAR explicitly enables the app for them.

4. Now you start to register VARs. Select **+Add**.
5. On the **Register new VAR Tenant**, enter the VAR's Microsoft ID in the **Tenant ID** box.
6. Enter a description in the **Description** box to make it easier for you to identify the VAR.
7. Select **Add**.
8. Select **Save** when done.

Once a VAR is registered, they can start to enable and disable the Embed App for their customers using the Application Management API.

Disabling and enabling application access management

In your LCS project, you can specify that VARs can or cannot approve customers without having to remove VARs from the list. This capability is useful if you need to temporarily allow access to all VARs and all customers. For example, suppose a VAR is registered but they're not ready to use the API yet.

> **IMPORTANT**
> If you specify that VARs cannot approve customers, even if the VARs are still listed on the **Manage VARs access** page, the environment access settings made by VARs for their customers will be ignored. The existing access settings will be enforced again once you allow the VARs to approve customers again and save the changes.

VAR: Manage customer access to the Embed App environments

As a VAR, once you've been registered by your ISV, you must explicitly give every customer access to create Embed App environments. Access is given by using the application access management API. The required steps are outlined in the sections that follow.

Prerequisite: Register an application for in your Azure Active Directory tenant

You only have to do this step once. In your Azure Active Directory (Azure AD) tenant, register an application that has delegated permission to the Dynamics 365 Business Central API. You'll use this application to call theBusiness Central Administration Center APIfor each customerthat you want to onboard.

Apart from registering an application, you'll also need an access token. For more information, see Setting up Azure Active Directory (AAD) based authentication and Getting an access token.

Onboarding customers

With application access management enabled, the typical process for getting customers up and running on a Embed App environment is as follows:

1. Connect with the customer using Partner Center:

   a. Establish reseller relationship with the customer
   b. Add necessary Business Central subscriptions
   c. Assign Business Central licenses to the customer users.

   For more information, see Connect with customers.

2. Control access to Embed App and Business Central application using the application access management API:

   a. Enable the customer to create environments based on the Embed App
   b. Block the customer from creating environments based on the Business Central application.

   For more information, see Application Access Management API. The article explains the API calls that you can make to get the list oftheavailable Embed Apps and enable or disable a specific Embed Appfor the customer.

   This work is done using your AAD application and delegated admin access and credentials.

3. Create the first Embed App environment for the customer by signing in to it for the first time, using the branded Embed App URL:

   ```
   https://[application family].bc.dynamics.com/[Customer Azure Active Directory Tenant ID]/Production
   ```

Application Access Management API
Using Application Family Managing an Business Central Embed App in Microsoft Lifecycle Services

Application Access Management API

2/17/2021 • 2 minutes to read • Edit Online

As a **Delegated Tenant Admin**, you can manage access to application families available in the service. The application family is Business Central or Embed App applications that may be provisioned through the service.

You can get the list of applications that are available to the customer tenant. From this list you can determine, by setting the access property, for which applications an environment may be created on the tenant.

Get List Of Manageable Applications

Returns a list of manageable applications by family and country code.

```
GET /admin/v2.3/manageableapplications
```

Response

Returns a wrapped array of applications.

```
{
  "value": [
    {
      "applicationFamily":  string, // The name of the family for a given Business Central offered
application. (Typically this will just be "BusinessCentral")
      "access":  boolean, // Indicates if the tenant has access to the application family/country code
combination
      "countryCode": string, // The country code of the application.
    }
  ]
}
```

Example (PowerShell)

```
$url = "https://api.businesscentral.dynamics.com/admin/v2.3"
$result = Invoke-WebRequest -Uri "$($url)/manageableapplications" -Headers @{"Authorization" = "Bearer
$token"} | ConvertFrom-Json
Write-Host $($result.value | ConvertTo-Json)
```

Control the access to Applications

Pass the application family name in the URL and a boolean in the body.

- True - enables the access.
- False - disables the access.

```
Content-Type: application/json
PUT /admin/v2.3/manageableapplications/{applicationFamily}/countries/{countryCode}
```

Route Parameters

`applicationFamily` - The name of the family for a given Business Central offered application. (Typically this value will just be "BusinessCentral")

`countryCode` - Country code for the targeted application.

Body

```
{
  <boolean> // Desired access state
}
```

> **NOTE**
> It is not possible to disable the access to an application family for the AAD tenant which already has an environment created in that family.

Expected Error Codes

`invalidInput` - the targeted property in invalid in some way

- target: {targeted tenant's AAD Id} - attempt to remove access to an application but the targeted tenant already has an environment in that application

`resourceDoesNotExist` - couldn't find the targeted application

Example (PowerShell)

```
$url = "https://api.businesscentral.dynamics.com/admin/v2.3"
$country = 'DK'
$applicationFamily = 'frentals'
$access = "true"
Invoke-WebRequest -Uri "$($url)/manageableapplications/$($applicationFamily)/countries/$($country)"  -
Headers @{"Authorization" = "Bearer $token"} -Body $access -Method Put -ContentType "application/json"
```

Using Application Family

App Management for ISVs

2/17/2021 • 2 minutes to read • Edit Online

INTRODUCED IN: Business Central 2020 release wave 1

Each Business Central environment is built as a collection of apps. These apps include Microsoft apps and apps from AppSource that reselling partners have installed for customers. The apps are working together to provide customers with a broad set of features to address their various business, market, and industry needs.

As an authorized ISV, you can deliver your functionality or your services as apps in AppSource. For more information, see Get Started with Building Apps. To help you manage your apps running in different customer Business Central environments, Business Central provides the App Management API.

About the App Management API

The App Management API is a REST-based API. It requires that you're an authorized ISV and your apps have been registered by Microsoft. Once registered, you access the API by using this global endpoint: https://apps.businesscentral.dynamics.com.

You can use the API for the following operations:

- Make major, minor, and hotfix app updates available to customers for installation from the Business Central administration center.

  You make the updates available by uploading them to the App Repository. The new app versions will then be available on Manage Apps page of the Business Central administration.

- Retrieve the list of the customers' environments that have your app installed.
- Schedule the automatic deployment of the app hotfixes for their customers' environments.

The App Management API lets you apply modern continuous integration (CI), continuous deployment (CD), and DevOps practices to your work, for example:

- Automate operations by using Microsoft Azure DevOps Services or other available process automation tools.
- Organize role-based access control.
- Manage your apps at scale, in multiple geo locations, supported by advanced and well-controlled build, test, and release flows.

For more information about the API, see App Management API.

> **NOTE**
>
> Currently, direct access to the API is only available for the ISVs working with the Embed apps; not Add-on and Connect apps. To manage versions of Add-on and Connect apps, you use Partner Center to upload the new app versions to **Business Central** offers. The apps will undergo a technical and marketing validation before becoming available on AppSource. After passing validation, the new versions are made available in Business Central administration center to the customers that have these apps installed.

Legal information

The apps that are stored in the App Repository are governed by the Microsoft Publisher Agreement. For more information, see Publishing your business application.

The App Management API is governed by Microsoft APIs Terms of Use. For more information, see Microsoft APIs Terms of Use

INTRODUCED IN: Business Central 2020 release wave 1

Entities

App

Description

The `app` entity represents a Business Central App that has been registered with the service and so it can be managed via the API. The `app` entity contains some basic metadata about the app, such as:

- its ID
- the Azure Active Directory Tenant ID of the publisher's organization
- which Azure location the respective .app files and other metadata should be stored in.

> **NOTE**
> An app doesn't refer to any specific .app file or version of the app.

Properties

NAME	DESCRIPTION	SCHEMA
ID	The ID of the app. The ID must remain the same across all app versions.	string (uuid)
publisher	The publisher's name.	string
publisherAadTenantId	The ID of the Azure Active Directory tenant that represents the publisher's organization.	string (uuid)
publisherContactEmail	The publisher's contact e-mail address.	string
storageLocation	The Azure location in which data related to this app should be stored.	string
_etag	The entity tag that contains a value unique to the entity's current state.	string

Available Endpoints

List apps

Lists all apps that match the provided (optional) filter that the current `principal` can access.

```
GET https://apps.businesscentral.dynamics.com/v1.0/apps?$filter=<odata_filter>
```

Parameters

TYPE	NAME	DESCRIPTION	SCHEMA
query	$filter	Restricts the set of items returned.	OData filter

Example Request

```
GET https://apps.businesscentral.dynamics.com/v1.0/apps?$filter=storageLocation eq 'West Europe'
```

Example Response

```
{
    "value": [
        {
            "id": "36d697e1-1982-43a5-9927-7f8f2a3eb361",
            "publisher": "Contoso",
            "publisherAadTenantId": "49cf52d4-fc10-41af-91ab-2d7cd011db47",
            "publisherContactEmail": "publisher@contoso.com",
            "storageLocation": "West Europe",
            "_etag": "5c47bfb0-d80c-4780-99ed-c3a3d38ac539"
        }
    ]
}
```

Country

The `country` entity represents a country that an `app` is available in.
A country is represented by its ISO 3166-1 alpha-2 (2-letter) country code.
Specific versions of Business Central Apps can be made available for specific countries.

Properties

NAME	DESCRIPTION	SCHEMA
countryCode	The ISO 3166-1 alpha-2 (2-letter) code for the country.	string
_etag	The entity tag that contains a value unique to the entity's current state.	string

Available Endpoints

List countries

Lists all countries the specified `app` has been made available in.

```
GET https://apps.businesscentral.dynamics.com/v1.0/apps/{appId}/countries
```

Parameters

TYPE	NAME	DESCRIPTION	SCHEMA
path	appId	The ID of the app to list the countries for.	string (uuid)

Example Request

```
GET https://apps.businesscentral.dynamics.com/v1.0/apps/41a68924-7fcf-4fd0-9200-f10f36a2e213/countries
```

Example Response

```
{
    "value": [
        {
            "countryCode": "US",
            "_etag": "f6039211-0dea-481a-80a5-38498dcea011"
        },
        {
            "countryCode": "DK",
            "_etag": "bb8f8166-a6cc-4562-b135-0b13257b032f"
        }
    ]
}
```

Get country

Gets the `country` with the specified country code in the specified `app`.

```
GET https://apps.businesscentral.dynamics.com/v1.0/apps/{appId}/countries/{countryCode}
```

Parameters

TYPE	NAME	DESCRIPTION	SCHEMA
path	appId	The ID of the app that the country belongs to.	string (uuid)
path	countryCode	The ISO 3166-1 alpha-2 (2-letter) code of the country.	string

Example Request

```
GET https://apps.businesscentral.dynamics.com/v1.0/apps/41a68924-7fcf-4fd0-9200-f10f36a2e213/countries/US
```

Example Response

```
{
    "countryCode": "US",
    "_etag": "f6039211-0dea-481a-80a5-38498dcea011"
}
```

Add or update country

Adds a new `country` to the specified `app` or updates an existing one.

```
PATCH https://apps.businesscentral.dynamics.com/v1.0/apps/{appId}/countries/{countryCode}
```

Parameters

TYPE	NAME	DESCRIPTION	SCHEMA
path	appId	The ID of the app that the country belongs to.	string (uuid)

TYPE	NAME	DESCRIPTION	SCHEMA
path	countryCode	The ISO 3166-1 alpha-2 (2-letter) code of the country to add.	string
body	country	The country properties that should be added or updated.	Country

Example Request

```
PATCH https://apps.businesscentral.dynamics.com/v1.0/apps/41a68924-7fcf-4fd0-9200-f10f36a2e213/countries/AT

{
    "countryCode": "AT"
}
```

Example Response

```
{
    "countryCode": "AT",
    "_etag": "584915f0-6319-4aab-a23c-743c0c4d9aeb"
}
```

Principal

Description

The `principal` entity represents an Azure Active Directory user or application that has some level of access to an `app`.
Principal can have different roles that determine which actions they're allowed to do. The currently supported roles are:

- `Owner` - Owners are allowed to do all available actions on all entities.
- `Contributor` - Contributors have similar permissions to owners, except that they aren't allowed to add/update principals.
- `Reader` - Readers can read information about the various entities, but can't add/update anything.

Properties

NAME	DESCRIPTION	SCHEMA
aadTenantId	The ID of the Azure Active Directory Tenant the principal belongs to.	string (uuid)
id	The ID of Azure Active Directory user/application.	string (uuid)
roles	The list of roles the principal has assigned.	string[]
type	The principal type.	enum (User, Application)

NAME	DESCRIPTION	SCHEMA
_etag	The entity tag that contains a value unique to the entity's current state.	string

Available Endpoints

List principals

Lists all `principal`s that match the provided filter within the specified `app`.

```
GET https://apps.businesscentral.dynamics.com/v1.0/apps/{appId}/principals?$filter=<odata_filter>
```

Parameters

TYPE	NAME	DESCRIPTION	SCHEMA
path	appId	The ID of the app to list the principals for.	string (uuid)
query	$filter	Restricts the set of items returned.	OData filter

Example Request

```
GET https://apps.businesscentral.dynamics.com/v1.0/apps/41a68924-7fcf-4fd0-9200-f10f36a2e213/principals?
$filter=type eq 'User' and 'Owner' in roles
```

Example Response

```
{
    "value": [
        {
            "id": "c07b7af3-8c9a-4bb1-9a0b-03692ba98d6d",
            "type": "User",
            "aadTenantId": "0c1cbce0-b823-4acf-be2f-1ac3a4e81c21",
            "roles": [
                "Owner"
            ],
            "_etag": "c99541ab-a0d2-4807-86f8-e1eb1853eb4f"
        }
    ]
}
```

Get principal by ID

Gets the `principal` with the specified ID in the specified `app`.

```
GET https://apps.businesscentral.dynamics.com/v1.0/apps/{appId}/principals/{id}
```

Parameters

TYPE	NAME	DESCRIPTION	SCHEMA
path	appId	The ID of the app that the principal belongs to.	string (uuid)
path	id	The ID of the principal.	string (uuid)

Example Request

```
GET https://apps.businesscentral.dynamics.com/v1.0/apps/41a68924-7fcf-4fd0-9200-
f10f36a2e213/principals/c07b7af3-8c9a-4bb1-9a0b-03692ba98d6d
```

Example Response

```
{
    "id": "c07b7af3-8c9a-4bb1-9a0b-03692ba98d6d",
    "type": "User",
    "aadTenantId": "0c1cbce0-b823-4acf-be2f-1ac3a4e81c21",
    "roles": [
        "Owner"
    ],
    "_etag": "c99541ab-a0d2-4807-86f8-e1eb1853eb4f"
}
```

Remove principal

Removes the `principal` with the specified ID in the specified `app`.
Note: Only principals with the `Owner` role are allowed to remove principals.

```
DELETE https://apps.businesscentral.dynamics.com/v1.0/apps/{appId}/principals/{id}
```

Parameters

TYPE	NAME	DESCRIPTION	SCHEMA
path	appId	The ID of the app that the principal belongs to.	string (uuid)
path	id	The ID of the principal.	string (uuid)

Example Request

```
DELETE https://apps.businesscentral.dynamics.com/v1.0/apps/41a68924-7fcf-4fd0-9200-
f10f36a2e213/principals/c07b7af3-8c9a-4bb1-9a0b-03692ba98d6d
```

Add or update principal

Adds or updates the specified `principal` that belongs to the specified `app`. **Note:** Only principals with the `Owner` role are allowed to add or update principals. **Note:** The `aadTenantId` field should only be specified in the request body when the principal being added is of type `User`.

```
PATCH https://apps.businesscentral.dynamics.com/v1.0/apps/{appId}/principals/{id}
```

Parameters

TYPE	NAME	DESCRIPTION	SCHEMA
path	appId	The ID of the app that the principal belongs to.	string (uuid)
path	id	The ID of the principal to add or update.	string (uuid)

TYPE	NAME	DESCRIPTION	SCHEMA
body	principal	The properties that should be added or updated.	Principal

Example Request

```
PATCH https://apps.businesscentral.dynamics.com/v1.0/apps/41a68924-7fcf-4fd0-9200-
f10f36a2e213/principals/c07b7af3-8c9a-4bb1-9a0b-03692ba98d6d

{
    "aadTenantId":  "20ba9ed9-d37b-4db0-ade4-f64322ad7c02",
    "Type":  "User",
    "roles":  [
                  "Reader"
              ]
}
```

When using `Type:"Application"`, the `aadTenantId` must not be used.

Example Response

```
{
    "id": "c07b7af3-8c9a-4bb1-9a0b-03692ba98d6d",
    "type": "User",
    "aadTenantId": "0c1cbce0-b823-4acf-be2f-1ac3a4e81c21",
    "roles": [
        "Reader"
    ],
    "_etag": "a98992bf-d7f6-460b-83bb-1498459a6a75"
}
```

Version

Description

A `version` represents an .app file that has been uploaded for a specific `country` in an `app`.
If a version of an app should be available in multiple countries, then the .app file needs to be uploaded to each country separately.

Properties

Version

NAME	DESCRIPTION	SCHEMA
appId	The ID of the app.	string (uuid)
availability	The version's availability.	enum (Preview, Available, Deprecated)
buildVersion	The build number of the version.	integer (int32)
countryCode	The country that the version was uploaded for.	string
dependencies	The dependencies of the uploaded package.	Dependency[]
majorVersion	The major number of the version.	integer (int32)

NAME	DESCRIPTION	SCHEMA
minorVersion	The minor number of the version.	integer (int32)
name	The name of the app.	string
packageId	The ID of the uploaded package.	string (uuid)
publisher	The publisher of the app.	string
revisionVersion	The revision number of the version.	integer (int32)
status	The version's status.	enum (Uploading, Uploaded, UploadFailed)
uploadedOn	The UTC date and time the version was uploaded on.	string (date-time)
version	The version of the app.	string
_etag	The entity tag that contains a value unique to the entity's current state.	string

Dependency

NAME	DESCRIPTION	SCHEMA
appId	The dependency app ID.	string (uuid)
name	The dependency app name.	string
publisher	The dependency app publisher.	string
version	The minimum version of the dependency.	string
incompatibleFromVersion	The initial app version of the dependency that is no longer compatible with the dependent app. If this value is set then it means that versions greater or equal to it are considered incompatible.	string

List versions

Lists all `versions` that match the provided filter.

```
GET https://apps.businesscentral.dynamics.com/v1.0/apps/{appId}/countries/{countryCode}/versions?$filter=
<odata_filter>
```

Parameters

TYPE	NAME	DESCRIPTION	SCHEMA

TYPE	NAME	DESCRIPTION	SCHEMA
path	appId	The ID of the app to list the versions for.	string (uuid)
path	countryCode	The code of the country to list the versions for.	string
query	$filter	Restricts the set of items returned.	OData filter

Example Request

```
GET https://apps.businesscentral.dynamics.com/v1.0/apps/41a68924-7fcf-4fd0-9200-
f10f36a2e213/countries/US/versions?$filter=MajorVersion eq 16 and MinorVersion eq 0
```

Example Response

```
{
    "value": [
        {
            "version": "16.0.1.2",
            "appId": "41a68924-7fcf-4fd0-9200-f10f36a2e213",
            "countryCode": "US",
            "packageId": "01d39741-8ab1-4fcc-b353-d9208ba475e3",
            "publisher": "Example Publisher",
            "name": "ExampleApp",
            "uploadedOn": "2019-07-09T11:54:45.5414576Z",
            "availability": "Available",
            "status": "Uploaded",
            "dependencies": [
                {
                    "appId": "1914cafc-93b9-46fd-b825-707f1743caee",
                    "name": "Example Dependency",
                    "publisher": "Other Publisher",
                    "version": "1.0.0.0"
                }
            ],
            "majorVersion": 16,
            "minorVersion": 0,
            "buildVersion": 1,
            "revisionVersion": 2,
            "_etag": "50fec40a-99b6-4743-bbe7-42e95cde2cfa"
        }
    ]
}
```

Upload version

Uploads an .app file into the specified `app` and `country` based on the provided package contents.

```
POST https://apps.businesscentral.dynamics.com/v1.0/apps/{appId}/countries/{countryCode}/versions
```

> **IMPORTANT**
> Make sure that you registered your app with the service and added a country to it, before you attempt to upload the app version.

Parameters

TYPE	NAME	DESCRIPTION	SCHEMA
path	appId	The ID of the app.	string (uuid)
path	countryCode	The country code.	string
body	requestData	The request data.	Upload Version Request

Upload version request

NAME	DESCRIPTION	SCHEMA
initialAvailability	The initial availability that the uploaded app version should have.	enum (Preview, Available, Deprecated)
packageContents	The base64-encoded contents of the package (.app file) to upload.	string (byte)

Example Request

```
POST https://apps.businesscentral.dynamics.com/v1.0/apps/41a68924-7fcf-4fd0-9200-
f10f36a2e213/countries/US/versions

{
    "initialAvailability": "Preview",
    "packageContents": <contents>
}
```

Example Response

```
{
    "version": "16.0.1.2",
    "appId": "41a68924-7fcf-4fd0-9200-f10f36a2e213",
    "countryCode": "US",
    "packageId": "01d39741-8ab1-4fcc-b353-d9208ba475e3",
    "publisher": "Example Publisher",
    "name": "ExampleApp",
    "uploadedOn": "2019-07-09T11:54:45.5414576Z",
    "availability": "Preview",
    "status": "Uploaded",
    "dependencies": [
        {
            "appId": "1914cafc-93b9-46fd-b825-707f1743caee",
            "name": "Example Dependency",
            "publisher": "Other Publisher",
            "version": "1.0.0.0"
        }
    ],
    "majorVersion": 16,
    "minorVersion": 0,
    "buildVersion": 1,
    "revisionVersion": 2,
    "_etag": "50fec40a-99b6-4743-bbe7-42e95cde2cfa"
}
```

Get version

Gets the `version` in the specified `app` and `country`.

```
GET
https://apps.businesscentral.dynamics.com/v1.0/apps/{appId}/countries/{countryCode}/versions/{versionNumber}
```

Parameters

TYPE	NAME	DESCRIPTION	SCHEMA
path	appId	The ID of the app.	string (uuid)
path	countryCode	The country code.	string
path	versionNumber	The version number.	string

Example Request

```
GET https://apps.businesscentral.dynamics.com/v1.0/apps/41a68924-7fcf-4fd0-9200-
f10f36a2e213/countries/US/versions/16.0.1.2
```

Example Response

```
{
    "version": "16.0.1.2",
    "appId": "41a68924-7fcf-4fd0-9200-f10f36a2e213",
    "countryCode": "US",
    "packageId": "01d39741-8ab1-4fcc-b353-d9208ba475e3",
    "publisher": "Example Publisher",
    "name": "ExampleApp",
    "uploadedOn": "2019-07-09T11:54:45.5414576Z",
    "availability": "Preview",
    "status": "Uploaded",
    "dependencies": [
        {
            "appId": "1914cafc-93b9-46fd-b825-707f1743caee",
            "name": "Example Dependency",
            "publisher": "Other Publisher",
            "version": "1.0.0.0"
        }
    ],
    "majorVersion": 16,
    "minorVersion": 0,
    "buildVersion": 1,
    "revisionVersion": 2,
    "_etag": "50fec40a-99b6-4743-bbe7-42e95cde2cfa"
}
```

Update version

Updates the `version` in the specified `app` and `country` with the provided updated data.

Note: only some properties can be updated.

```
PATCH
https://apps.businesscentral.dynamics.com/v1.0/apps/{appId}/countries/{countryCode}/versions/{versionNumber}
```

Parameters

TYPE	NAME	DESCRIPTION	SCHEMA
path	appId	The ID of the app that the version belongs to.	string (uuid)

TYPE	NAME	DESCRIPTION	SCHEMA
path	countryCode	The country code.	string
path	versionNumber	The version number of the version to update.	string
body	version	The properties that should be updated.	Version

Example Request

Marking an app version as deprecated.

```
PATCH https://apps.businesscentral.dynamics.com/v1.0/apps/41a68924-7fcf-4fd0-9200-
f10f36a2e213/countries/US/versions/16.0.1.2

{
    "availability": "Deprecated"
}
```

Example Request

Marks older versions of your app as incompatible with a dependency app, starting with a specific version. In such cases, make sure you upload another version of your app that is compatible with the new version of the dependency app.

```
PATCH https://apps.businesscentral.dynamics.com/v1.0/apps/41a68924-7fcf-4fd0-9200-
f10f36a2e213/countries/US/versions/16.0.1.2

{
    "dependencies": [
        {
            "appId": "63ca2fa4-4f03-4f2b-a480-172fef340d3f",
            "incompatibleFromVersion": "16.0.0.0"
        }
    ]
}
```

Example Response

```
{
    "version": "16.0.1.2",
    "appId": "41a68924-7fcf-4fd0-9200-f10f36a2e213",
    "countryCode": "US",
    "packageId": "01d39741-8ab1-4fcc-b353-d9208ba475e3",
    "publisher": "Example Publisher",
    "name": "ExampleApp",
    "uploadedOn": "2019-07-09T11:54:45.5414576Z",
    "availability": "Deprecated",
    "status": "Uploaded",
    "dependencies": [
        {

            "name": "Example Dependency",
            "publisher": "Other Publisher",
            "version": "1.0.0.0"
        }
    ],
    "majorVersion": 16,
    "minorVersion": 0,
    "buildVersion": 1,
    "revisionVersion": 2,
    "_etag": "3c0f1fd2-266e-491b-82e3-74f09a975267"
}
```

Environment

Description

Represents a customer's `environment` that has a specific `version` of an `app` installed.

Properties

NAME	DESCRIPTION	SCHEMA
aadTenantId	The ID of the customer's Azure Active Directory tenant.	string (uuid)
appId	The ID of the installed app.	string (uuid)
applicationFamily	The environment's application family.	string
countryCode	The country code the environment belongs to.	string
locationName	The Azure location the environment is in.	string
name	The environment's name.	string
type	The environment's type.	enum (Production, Sandbox)
version	The version of the installed app.	string

List environments

Lists the `environment`s in the specified `app` and `country` that have the app installed.

```
GET https://apps.businesscentral.dynamics.com/v1.0/apps/{appId}/countries/{countryCode}/environments
```

Parameters

TYPE	NAME	DESCRIPTION	SCHEMA
path	appId	The ID of the app.	string (uuid)
path	countryCode	The country code.	string
query	$filter	Restricts the set of items returned.	OData filter

Example Request

```
GET https://apps.businesscentral.dynamics.com/v1.0/apps/41a68924-7fcf-4fd0-9200-
f10f36a2e213/countries/US/environments?$filter=version eq '16.0.1.2'
```

Example Response

```
{
    "value": [
        {
            "aadTenantId": "539a833c-4e6a-42d8-a081-27fa9d810424",
            "version": "16.0.1.2",
            "appId": "41a68924-7fcf-4fd0-9200-f10f36a2e213",
            "countryCode": "US",
            "applicationFamily": "Business Central",
            "locationName": "West Europe",
            "name": "MyCustomer",
            "type": "Production"
        }
    ]
}
```

Environment Hotfix

Description

An `environment hotfix` represents the action of pushing out an update (new `version`) of an `app` to a customer's `environment` as part of fixing a critical issue.
Only `version`s where the major and minor components haven't changed can be pushed as hotfixes.

Properties

NAME	DESCRIPTION	SCHEMA
appId	The ID of the app.	string (uuid)
completedOn	Date and time (UTC) when the hotfix was applied.	string (date-time)
countryCode	The country code.	string
createdOn	Date and time (UTC) when the hotfix request was created.	string (date-time)

NAME	DESCRIPTION	SCHEMA
environmentAadTenantId	The ID of the customer's Azure Active Directory tenant.	string (uuid)
environmentApplicationFamily	The environment's application family.	string
environmentName	The environment's name.	string
errorMessage	The error message provided when the hotfix was unable to be applied.	string
id	The ID hotfix request.	string (uuid)
ignoreUpgradeWindow	Determines whether the environment's upgrade window should be ignored when applying the hotfix.	boolean
runAfter	Date and time (UTC) after which hotfix should start to be applied.	string (date-time)
sourceAppVersion	The version of the app that was installed before the hotfix was applied.	string
startedOn	Date and time (UTC) when the hotfix started to be applied.	string (date-time)
status	Status.	enum (Scheduled, Running, Succeeded, Failed, Canceled, Skipped)
targetAppVersion	The version of the app containing the fixes that should be applied. The value is the version that the app will be updated to.	string

List environment hotfixes

Lists all the hotfix operations that were requested for a specific `app` and `country`.

```
GET https://apps.businesscentral.dynamics.com/v1.0/apps/{appId}/countries/{countryCode}/environmentHotfixes?
$filter=<odata_filter>
```

Parameters

TYPE	NAME	DESCRIPTION	SCHEMA
path	appId	The ID of the app.	string (uuid)
path	countryCode	The country code.	string
query	$filter	Restricts the set of items returned.	OData filter

Example Request

```
GET https://apps.businesscentral.dynamics.com/v1.0/apps/41a68924-7fcf-4fd0-9200-
f10f36a2e213/countries/US/environmentHotfixes?$filter=targetAppVersion eq '16.0.1.2'
```

Example Response

```
{
    "value": [
        {
            "id": "db311b6a-062e-4756-b17e-73aeb89c45cc",
            "environmentAadTenantId": "539a833c-4e6a-42d8-a081-27fa9d810424",
            "sourceAppVersion": "16.0.0.5",
            "targetAppVersion": "16.0.1.2",
            "status": "Scheduled",
            "createdOn": "2020-03-05T15:41:20.6468128Z",
            "runAfter": "2020-03-05T17:30:00.0000000Z",
            "appId": "41a68924-7fcf-4fd0-9200-f10f36a2e213",
            "countryCode": "US",
            "environmentApplicationFamily": "Business Central",
            "environmentName": "MyCustomer",
            "environmentType": "Production"
        }
    ]
}
```

Get environment hotfix

Gets an `environment hotfix` operation by its ID.

This endpoint can be used to track the status/outcome of a hotfix request.

```
GET
https://apps.businesscentral.dynamics.com/v1.0/apps/{appId}/countries/{countryCode}/environmentHotfixes/{id}
```

Parameters

TYPE	NAME	DESCRIPTION	SCHEMA
path	appId	The ID of the app.	string (uuid)
path	countryCode	The country code.	string
path	id	The ID of the hotfix request.	string (uuid)

Example Request

```
GET https://apps.businesscentral.dynamics.com/v1.0/apps/41a68924-7fcf-4fd0-9200-
f10f36a2e213/countries/US/environmentHotfixes/db311b6a-062e-4756-b17e-73aeb89c45cc
```

Example Response

```
{
    "id": "db311b6a-062e-4756-b17e-73aeb89c45cc",
    "environmentAadTenantId": "539a833c-4e6a-42d8-a081-27fa9d810424",
    "sourceAppVersion": "16.0.0.5",
    "targetAppVersion": "16.0.1.2",
    "status": "Scheduled",
    "createdOn": "2020-03-05T15:41:20.6468128Z",
    "runAfter": "2020-03-05T17:30:00.0000000Z",
    "appId": "41a68924-7fcf-4fd0-9200-f10f36a2e213",
    "countryCode": "US",
    "environmentApplicationFamily": "Business Central",
    "environmentName": "MyCustomer",
    "environmentType": "Production"
}
```

Schedule environment hotfix

Schedules a hotfix for a specific `environment` to the specified `version`.
The hotfix operation ID that is returned can be used to track the status/outcome of the operation (see: Get environment hotfix).

```
POST https://apps.businesscentral.dynamics.com/v1.0/apps/{appId}/countries/{countryCode}/environmentHotfixes
```

Parameters

TYPE	NAME	DESCRIPTION	SCHEMA
path	appId	The ID of the app.	string (uuid)
path	countryCode	The country code.	string
body	environmentHotfix	Environment hotfix to schedule.	Environment Hotfix

Example Request

```
POST https://apps.businesscentral.dynamics.com/v1.0/apps/41a68924-7fcf-4fd0-9200-
f10f36a2e213/countries/US/environmentHotfixes

{
    "environmentAadTenantId": "539a833c-4e6a-42d8-a081-27fa9d810424",
    "targetAppVersion": "16.0.1.2",
    "runAfter": "2020-03-05T17:30:00.0000000Z",
    "environmentApplicationFamily": "Business Central",
    "environmentName": "MyCustomer",
    "environmentType": "Production"
}
```

Example Response

```
{
    "id": "db311b6a-062e-4756-b17e-73aeb89c45cc",
    "environmentAadTenantId": "539a833c-4e6a-42d8-a081-27fa9d810424",
    "sourceAppVersion": "16.0.0.5",
    "targetAppVersion": "16.0.1.2",
    "status": "Scheduled",
    "createdOn": "2020-03-05T15:41:20.6468128Z",
    "runAfter": "2020-03-05T17:30:00.0000000Z",
    "appId": "41a68924-7fcf-4fd0-9200-f10f36a2e213",
    "countryCode": "US",
    "environmentApplicationFamily": "Business Central",
    "environmentName": "MyCustomer",
    "environmentType": "Production"
}
```

Update environment hotfix

Updates an existing `environment hotfix` operation.
It can currently only be used to cancel a requested hotfix that hasn't yet started running.

```
PATCH
https://apps.businesscentral.dynamics.com/v1.0/apps/{appId}/countries/{countryCode}/environmentHotfixes/{id}
```

Parameters

TYPE	NAME	DESCRIPTION	SCHEMA
path	appId	The ID of the app.	string (uuid)
path	countryCode	The country code.	string
path	id	The ID of the hotfix request.	string (uuid)
body	environmentHotfix	Environment hotfix properties to update.	Environment Hotfix

Example Request

```
PATCH https://apps.businesscentral.dynamics.com/v1.0/apps/41a68924-7fcf-4fd0-9200-
f10f36a2e213/countries/US/environmentHotfixes/db311b6a-062e-4756-b17e-73aeb89c45cc

{
    "status": "Canceled"
}
```

Example Response

```
{
    "id": "db311b6a-062e-4756-b17e-73aeb89c45cc",
    "environmentAadTenantId": "539a833c-4e6a-42d8-a081-27fa9d810424",
    "sourceAppVersion": "16.0.0.5",
    "targetAppVersion": "16.0.1.2",
    "status": "Canceled",
    "createdOn": "2020-03-05T15:41:20.6468128Z",
    "runAfter": "2020-03-05T17:30:00.0000000Z",
    "appId": "41a68924-7fcf-4fd0-9200-f10f36a2e213",
    "countryCode": "US",
    "environmentApplicationFamily": "Business Central",
    "environmentName": "MyCustomer",
    "environmentType": "Production"
}
```

Getting detailed error messages

To get detailed error messages from t API calls, wrap the calls in a try-catch block, as shown in the following PowerShell example:

```
try {
    Invoke-WebRequest ....
}
catch [System.Net.WebException]
{
    $Exception = $_.Exception
    $respStream = $Exception.Response.GetResponseStream()
    $reader = New-Object System.IO.StreamReader($respStream)
    $respBody = $reader.ReadToEnd() | ConvertFrom-Json | ConvertTo-Json -Depth 100
    $reader.Close();
    Write-Error $Exception.Response.Headers["ms-correlation-x"]
    Write-Error $Exception.Message
    Write-Error $respBody -ErrorAction Stop
}
```

Please make sure you provide full output in textual format when reporting the issues to Microsoft.

Get Started as a Reseller of Business Central Online

2/17/2021 • 9 minutes to read • Edit Online

If you want to build your business on Dynamics 365 Business Central online, you must get set up as a reseller in the Microsoft Partner Center. In this article, we take you through the first four steps in your journey.

Step 1: Become a partner

Becoming a Microsoft partner gives you access to the Microsoft resources needed to sell solutions. The steps in this section below are required to gain access to the programs that enable are intended to help you get set up to sell Business Central.

In order to be able to service Business Central licenses and provide help and support to your customers, your company must have a Microsoft Partner ID (MPN ID), and you must enroll in the Cloud Solution Provider (CSP) program.

Join the Microsoft Partner Network

Microsoft Partner Network (MPN) membership unlocks our best resources to differentiate your business, take your product to market, and sell your solutions. To become a partner, you must join the Microsoft Partner Network (MPN), at which time you will be assigned an MPN ID. MPN membership is free to all partners; you can enroll in the MPN here.

Once signed up, you will get an MPN ID – your gateway to access all the membership resources and benefits for your partnership with Microsoft. There is no cost to obtain a MPN ID as a Network member, and with options to upgrade to an Action Pack subscription or work toward a competency, you can access even more benefits.

Set up your Partner Center account

Once you have joined the Microsoft Partner Network (MPN), you can set up your Partner Center (PC) account. The Microsoft Partner Center is a generic portal where partners can sell and manage customer subscriptions for Microsoft services, such as Microsoft 365, Azure, Dynamics 365, and others, as well as for some third-party products. For more information, see the Partner Center documentation.

Your Partner Center account provides you with access to pricing information, tools and services, and enables you to manage admin credentials for your company's work account. Partner Center is also where you can purchase or renew subscriptions to Microsoft Action Packs, create a business profile to receive and manage sales leads from Microsoft, and see if you qualify for co-selling opportunities.

Enroll in the CSP program

The Cloud Solution Provider (CSP) program helps your company to be more involved in your customers' businesses, beyond reselling licenses. In CSP, you can choose to enroll as an *indirect reseller* or a *direct bill partner*.

In most cases, you will enroll as an *indirect reseller* and then work with an *indirect provider*, also referred to as a *distributor*, who then manages all interaction with Microsoft in terms of licensing and technology, so that you can focus on sales and support. If you decide to enroll as a *direct bill partner* in order to fully own the end-to-end relationship with both customers and Microsoft, make sure that you meet the eligibility requirements. For more information, see Enroll in the Cloud Solution Provider program in the Microsoft Partner Center content.

The Microsoft Partner Center is a generic portal where partners can sell and manage customer subscriptions for Microsoft services, such as Microsoft 365, Azure, Dynamics 365, and others, as well as for some third-party products. For more information, see the Partner Center documentation.

Some indirect providers (distributors) provide their resellers with a custom portal that optimizes and enhances the experience beyond the Partner Center. They can also provide indirect resellers with an API to automate some of the customer onboarding steps. Contact your indirect provider to find out more.

Both indirect resellers and direct bill partners can access and support their customers' Business Central by setting up a reseller relationship with them.

To service customers in a specific country, your partner company's Azure Active Directory (Azure AD) tenant and CSP account must be registered in the regional CSP market that covers that country. For more information, see Cloud Solution Provider program regional markets and currencies.

> **NOTE**
>
> When you buy Business Central offers on behalf of your CSP customers, the CSP offer must be available in both your own tenant's country and in your customer's tenant's country. For example, if your tenant is located in Slovakia and the customer's tenant is in Germany, you will not be able to sell Dynamics 365 Business Central Premium to that customer, because this offer is currently not available in Slovakia.
>
> Similarly, if your tenant is located in Germany and the customer's tenant is in Slovakia, you will not be able to sell Dynamics 365 Business Central Premium to that customer, because this offer is currently not available in Slovakia.

In the Microsoft Partner Center documentation, you can learn how to request a reseller relationship with customers, assign licenses to users, and create new subscriptions. Business Central is one of the subscriptions that you can create, and there are Business Central-specific license types that you can assign to users.

You must also assign certain roles to users in your own organization so that they can support your customers.

Add users from your own organization

In most cases, your partner company includes employees with different responsibilities, and you can assign different roles depending on people's responsibility. This way, you can be very explicit about who from your staff can access your customers' data, for example.

For each user, you can assign permissions for 2 categories of tasks:

- Managing your organization's account

  This controls access to the functionality of the Partner Center portal

- Assisting your customers

  This controls access to your customers' environments

When you establish a reseller relationship with a customer in Partner Center, you must specify which people from your organization will assist that customer's tenant as either *Admin agent* or *Helpdesk agent*. These users can manage implementation, support, and troubleshooting tasks for your customers. Once the reseller relationship with a customer is established, they will be able to login into the Business Central environments of the customer without a license. The number of partner users that can access customer environments is not restricted.

Both roles will provide your users with exactly the same level of access to the customer's Business Central environment. However, they have very different capabilities to manage the customer's Active Directory and other subscriptions that the customer might have. For more information, see Admin roles.

This way of accessing customer resources is called *delegated administration*, and the partner users are therefore called *delegated administrators* or *delegated admins* in daily shorthand. For more information, see Delegated Administrator Access to Business Central Online.

> **NOTE**
>
> These users cannot provide accounting services for the customers. For this purpose, the customers must use the **External Accountant** license, which is also available via CSP.

Caution

In the Microsoft 365 admin center and Microsoft Azure Management portal, both customers and partners can invite external users (guests) into their Active Directory. When a partner user is added as a guest to the customer's Azure AD, they can no longer log in as a delegated admin into the customer's Business Central. In order to log in, the local user (guests or native) must have a valid Business Central license assigned to them.

Step 2: Go to market

When you become a Microsoft Partner Network member, you gain access to membership benefits that can help you build and grow your business. For more information, see Explore your Go-To-Market with Microsoft offers in the Partner Center docs.

As a Dynamics 365 reseller, you benefit from Microsoft's investments in an always up-to-date modern platform, you can bundle recognized apps from the Microsoft commercial marketplace into an offering that fits the needs of your customers, reach more customers by using Microsoft's commercial marketplace to promote your packaged consulting service offerings or customization services, and streamline your own processes and build tools with Power BI, Power Automate, and Power Apps connected to Business Central.

Specifically for going to market with Business Central, Microsoft provides resources and guidance on the Business Applications for small and medium-sized businesses (SMBs) site. For more information, see Business Central Go-To-Market resources.

Step 3: Give powerful demos

You can create a trial environment based on content in cdx.transform.microsoft.com.

For more information, see Preparing Demonstration Environments of Dynamics 365 Business Central.

Step 4: Help your customers get started

When you onboard customers to Business Central, you have access to their account as a delegated administrator and can help them get things set up. For more information, see Administration of Business Central Online.

Connect with customers

As a CSP partner, you can manage a customer's subscriptions and services on their behalf in the Partner Center by establishing a reseller relationship with your customers. If they already have an account, such as if they currently use Microsoft 365, other Dynamics 365 apps, or PowerApps, for example, you can send them an invitation straight from the Partner Center. For more information, see Connect with customers in Partner Center (indirect providers/distributors) and Connect with customers (indirect resellers).

When the customer's internal administrator receives the invitation link and navigates to it, they must acknowledge that they have read the Microsoft Customer Agreement and that they can authorize you as their reseller on behalf of their organization. For more information, see Confirm customer acceptance of the Microsoft Customer Agreement.

When a customer accept this reseller relationship, delegated administration privileges are granted to the partner. For more information, see Delegated Administrator Access to Business Central Online.

If you are working as an indirect reseller, your indirect provider (distributor) must associate your customers with

you in their Partner Center.

The customer can decide to remove their partner's delegated admin privileges from their tenant, but still retain the relationship with their partner for subscription and license renewal purposes. Removing delegated admin privileges will block the partner's access to the customer's Business Central. The access can be restored if the partner sends the reseller relationship request to the customer again.

If the customer wants to cancel their relationship with their partner, the partner must remove the relationship in Partner Center.

Get Business Central right for the customer

The default version of Business Central is just that - a default version. In many cases, you'll enhance the default version with apps from the Microsoft commercial marketplace. But you can also customize pages for a profile and change which UI elements are visible. For more information, see Customize Business Central in the business functionality content.

If your customer wants more tweaks, you can create customizations of profiles and pages in code. For more information, see Customizing the User Interface for User Roles in the developer content.

Step 5: Configure the support experience

As a Business Central reselling partner, you are an administrator of your customers' Business Central tenants, and you are the first line of support. This means that you will get requests for support from your customers that you must triage, investigate, and either resolve or escalate to Microsoft. For more information, see Technical Support for Business Central.

Step 6: Maintain your customers' Business Central

As a Business Central reselling partner, you are the administrator of the Business Central tenants of your customers. You are expected to help your customers maintain their solution, including setting the upgrade window, monitoring telemetry, updating customizations, and managing apps.

For more information, see Administration of Business Central Online and The Business Central Administration Center.

FAQ for Developing in AL

2/17/2021 • 2 minutes to read • Edit Online

This topic contains a number of frequently asked questions and answers to these questions.

How do I get started?

For an overview of developing apps for Dynamics 365 Business Central, see aka.ms/GetStartedWithApps

Next, follow the Getting Started with AL to set up the tools.

Which version of the AL Language extension should I use?

For Dynamics 365 Business Central cloud sandboxes you must use the AL Language extension available in the Visual Studio Code Marketplace.

For the latest Developer Preview releases you must use the AL Language extension that is available in the *next major* artifact through the "Ready! for Dynamics 365 Business Central" program on Microsoft Collaborate.

How do I enable the debugger?

To read about enabling debugging in AL, see here Debugging. To read about snapshot debugging, see Snapshot Debugging.

Can I create something similar to Menusuites?

In the AL Language extension, the concept of Menusuites is not supported. The two primary purposes of Menusuites are:

- Making pages searchable
- Making pages accessible through a navigation structure

The first purpose can be achieved in Extensions by using the new properties added to Pages and Reports. For more information, see Adding Pages and Reports to Search.

The second purpose can be achieved by extending the Navigation Pane page and/or by adding Actions to other existing pages that can serve as a navigation starting point. For more information, see Adding Menus to the Navigation Pane.

How do I upgrade Extensions V1 to Extensions V2?

For information on upgrading, see the following topics: Upgrading Extensions v2 and Converting from Extensions v1 to Extensions v2.

File APIs are not available in Extensions V2. What do I do?

Code that relies on temporary files must be rewritten to rely on `InStream` and `OutStream` types. Code that relies on permanent files must be rewritten to use another form of permanent storage.

DotNet types are not available in Extensions V2. What now?

For cloud solutions .NET interop is not available due to safety issues in running arbitrary .NET code on cloud

servers.

With the AL Language extension, you can find AL types that replace the most typical usages of .NET like HTTP, JSON, XML, StringBuilder, Dictionaries, and Lists. Many .NET usages can be replaced directly by the AL types resulting in much cleaner code. For more information, see HTTP, JSON, TextBuilder, and XML API Overview.

For things that are not possible to achieve in AL code, the recommendation is to use Azure Functions to host the DLL or C# code previously embedded and call that service from AL.

Extensions published from Visual Studio Code or created using Designer have disappeared from a sandbox environment. Why?

Extensions that have been published to a sandbox environment from Visual Studio Code or created using Designer are removed when the sandbox environment is updated or relocated within our service. However, the data of an app is not removed, so you only have to re-publish and install the app to make it available.

For more information, see Sandbox Environments.

FAQ about Library and Dependency Apps in Business Central

2/17/2021 • 2 minutes to read • Edit Online

This section contains answers to frequently asked questions about library apps and dependency apps in Business Central.

What is a library app?

A library app contains common code that other apps depend on. If you are going to have multiple AppSource apps that all share common code, such as licensing, registration,and so on, you can put that common code into a library app and have the AppSource apps depend on the library app.

How does the library app get installed to a tenant?

A library app does not appear on AppSource. It only lives in Business Central. Our service is built to install the library apps behind the scenes. Here is how it works. Customers finds an app they want to install on AppSource. That customer does not know the app even has library app(s). When they click to install the app, our service looks into that apps json/manifest to see if it first needs to install any library/dependency apps it may depend on. If so, it installs them first before installing the main AppSource app.

What is a dependency app?

A dependency app isn't much different from a library app. A dependency app does have its own offer on AppSource. For example, you might have AppSource "App A" that serves a purpose on its own and is listed on AppSource. You then also have "App B" as its own offer on AppSource but it does depend on code within "App A" and needs "App A" to be installed before it can be installed. This is really the only difference though. Behind the scenes, library and dependency apps behave the same when it comes to walking that dependency chain and auto installing any app the top-level app depends on.

Can I have multiple library apps for my AppSource app?

Yes. Just make sure you list all library apps as dependencies within the AppSource app json file/manifest.

When I get the latest updated version of my app, why don't I get the updated library/dependency apps that my AppSource app depends on?

Currently, updating of apps does not handle the library/dependency chain. This work is planned for a future release. For now, you need to uninstall and reinstall the library/dependency apps as well.

What are the validation requirements for library apps

Library apps only get validated technically, but don't go through any type of marketing validation. Also, the library apps are expected to be covered by the user scenarios and tests that you submit for the core app. The technical requirements are described here.

FAQ about Testing your Business Central App

2/17/2021 • 4 minutes to read • Edit Online

This section contains answers to frequently asked questions about testing your app when you submit an app for Business Central.

Since my app goes through validation, do I really need to thoroughly test my app?

Yes. It is your app and you are the expert, so you should have a vested interest in high quality. The main goal of validation is to ensure app code is meeting requirements and policy. The testing done during validation is only to ensure good user experience on the most common app scenarios. We do not test every scenario of an app. Using customers to find bugs is not the proper approach.

Is it ok to submit my app for validation before we complete our own testing?

No. Please do not submit your app for validation until it has been 100% tested. This will lead to many delays in the validation process otherwise. Also, it wastes time and resources.

Is it ok to test my AppSource app in an on-premises environment?

No. You must test your app using Business Central online. Although Business Central online and on-premises are very similar, they are not the exact same. If you only test on-premises, invariably issues will be found in our validation testing.

Does it really matter what version of Business Central I test on before submitting my app for validation?

Yes. It is critical that you always test on the latest version at the time when you are ready to submit for validation. Testing on the wrong version usually leads to validation failure. For example, let's say the latest version of Business Central is 15.4 at the time when you submit for validation You tested on 15.0. The product has changed between those versions, and deprecated features or other changes could result in your app behavior changing.

We recommend that you consider using Docker containers. Use the `Get-BcArtifactUrl` function in the BCContainerHelper PowerShell module to give you the artifact URL for the latest sandbox build for the specified country. You don't have to figure out what product version is active at time of submission. That function does it for you.

How thorough should our testing be?

You should always test with 100% coverage, or at least as close to 100% as you can get. The testing should be a combination of automated and manual tests. The apps with good testing infrastructure behind them are the most successful.

Do I have to test on every country that I intend to support with my app?

Yes. If you support multiple countries, test your app on every country. Each country's code base is slightly

different from both the base application and other countries. It is critical to make sure that the app publishes, syncs, and installs on every country you support. Because an app installs fine on one country doesn't mean it will publish/install fine on another. We have seen many times where it passes on one but fails on another during our validation.

Do you have recommendations on maintenance testing of our apps?

Yes. You should be testing your apps against our various build branches. Through Docker, you have access to our latest public sandbox builds and through the "Ready! for Dynamics 365 Business Central" program on Microsoft Collaborate you can also get access to *Next Minor* and *Next Major* builds. Test often, especially against the *Next Minor* build. This allows you to catch any bugs that may arise from core changes in the product.

I only made minor code changes in my updated app. Can I test just these changes?

No. You should always test 100% coverage no matter what. Testing only what you changed is not the correct approach. Even minor changes can lead to breaking changes where you least expect it.

Do I need to do upgrade testing?

Yes, this is a must. If an app fails to upgrade, customers are unable to get your updated app. This is one of the common failures we see today in validations. You should want your app upgrade to work optimally.

Any recommendations on upgrade testing?

Test the upgrade with extensive app data included. Many of the upgrade failures for customers are data related. The upgrade fails because specific data scenarios were not considered for testing. Or worse, the upgrade succeeds, and data is lost.

Do I only need to do upgrade testing from previous version to current?

No. It is very important you test from various previous versions of your app. This is because we do not automatically upgrade apps for minor releases. You could have a tenant back on version 1.0.0.0 of your app and have to jump all the way to version 1.0.0.5. We don't guarantee direct upgrades of apps from their most previous version.

FAQ about Updating your Business Central App

2/17/2021 • 5 minutes to read • Edit Online

This section contains answers to frequently asked questions about updating your app for Business Central.

Is it the same process for an app update as the first version?

Yes. You upload the updated app file into Partner Center and submit as normal. It goes through a more scaled-back validation process than your original version, but it does get validated. If it fails validation, it comes back to you for fixing. If it passes validation, it gets checked into Business Central.

What are some "need to know" considerations with an updated app?

When you submit an updated version of your app, you must increase the version number in the app's json/manifest files. Business Central doesn't allow overwrites. So we need the version number increased for us to check the updated app into our service upon it passing validation.

Never change the app's App ID in the json/manifest files. This is must stay the same across versions for various reasons, not least for upgrade reasons.

When is my updated app available for tenants to install?

As soon as your updated app passes validation and is checked into our service, it then becomes the active version (for whatever the current Business Central version is at that time). Even though your offer might still show as in progress in Partner Center, the updated app is active and ready to install. Also, even though your version number in AppSource might show as older, tenants will still get this latest updated version. For example, your updated version might be version 1.0.0.5. And in AppSource it might still show 1.0.0.1. Tenants will get the version 1.0.0.5.

What version of Business Central is my updated app compatible with?

When you submit your app for validation, we validate it against the latest version at that point in time. Once the app passes validation, it is then checked into our service and configured for that version of Business Central, unless a newer version has been released in the meanwhile. For example, if you submit your app and the latest version of Business Central at that time is 16.1, your app will then be compatible and configured for 16.1. When versions 16.2, 16.3, and so on roll out, your app is automatically configured for the latest version. Tenants that are on earlier versions of Business Central will not get that updated version. They still however can install the previous versions of your app. They will get the version of your app that is configured for the version of Business Central that their tenant is on.

When tenants have their Business Central version upgraded, do apps ever get automatically updated?

For minor releases, we do not auto-update apps. This is because of customer feedback and them not wanting their apps auto updated. The only exception to this is if an app will be broken in a minor release due to changes in the base product. In this case, we configure that app in our service as required. When tenants then get upgraded to that minor release, if they have that app, it then gets updated automatically. This is to avoid the app being broken for the customer.

For major releases, we do auto-update every app on every tenant to the app's latest available version. We

consider major releases to be our "refresh" releases.

How do tenants that already have an existing version of my app get my latest updated version?

By uninstalling and reinstalling the app. When doing the reinstall, it calls into our service and finds the latest active version of an app. There is a new **Manage Apps** page in the Business Central administration center that will soon allow updating of AppSource apps without having to do uninstall and reinstall.

Do I have to submit an updated version of my app for the major releases?

No. The only reason you would need to submit an updated version of your app for a major release is if your app is going to be broken in that release. If your app will not be broken, then your latest available version of the app will be rolled over to that major release.

How frequent should I submit updated versions of my app?

We recommend that you bundle more bug fixes and features so that your app doesn't have to be updated frequently. This has been voiced by our Business Central customers. They do not want to be constantly updating their apps in their tenants. We recommend a minimum 1-month app update cadence.

What if I have a critical hotfix?

We treat critical hotfixes with the utmost importance. We do have a process around this. Additional information on this hotfix process can be found here.

If I make changes to the library app, must I also submit an update for the AppSource app?

You would upload the updated library app to Partner Center, leave the main app as is, and submit for validation. We then see that the main app has not changed and only validate the library app.

But wouldn’t I need to change the dependency in my main app’s json to reference the updated library app file?

No. The version number in the dependency listing in the json file to an app is a minimum version. The main app is essentially saying, "I need version 1.0.0.1 or greater" of the library app. For example, the AppSource app lists version 1.0.0.1 for the library app, and that means that it can also use version 1.0.0.2.

Why don't I see the updated version of my app in my sandbox tenant?

Your tenant is on an older version of Business Central and has not yet been upgraded to the latest version of Business Central. The latest updated version of your app is only compatible with the latest Business Central version and later. If you upgrade your tenant to the latest version, you can then update your app.

FAQ about Managing and Submitting your Business Central Offer

2/17/2021 • 2 minutes to read • Edit Online

This section contains answers to frequently asked questions about managing the offer in Partner Center when you submit an app for Business Central.

If I click the Go Live button, does that mean my app will go live to AppSource?

No. This button is deceiving, and I wish it were worded differently. When you click this button, it triggers our validation process and puts your app into our validation queue.

What should I know about the Review and publish button?

This is the button you should click when you want to submit your app for validation each time. Once you click the button, it takes you to a Review and publish page. Make sure all checkboxes are marked on that page. This pulls in all changed data into our validation queuing system properly.

I only made marketing changes. Will my app have to go through technical validation?

No. If you do not change your app in a submission, we skip technical validation.

Marketing Validation FAQ

2/17/2021 • 2 minutes to read • Edit Online

Where do I state the countries, editions and languages that my offer supports?

You are required to state the countries, editions and languages that your offer supports in the very bottom of your offer's description text. You can use the following format:

Supported Editions:

The app supports the Essentials and Premium Editions of Microsoft Dynamics 365 Business Central.

Supported Countries:

Canada, Mexico and United States

Supported Languages: This app is available in English (United States) and Spanish (Mexico).

Do you have any tips and tricks for what I should write in the description text?

Yes. We have detailed guidelines and good advice about that here.

How do I refer correctly to the product?

When you mention the product, both throughout your description text, as well as in your marketing material, you need to refer to the product, in the following way:

First mentions: Microsoft Dynamics 365 Business Central

Secondary mentions: Dynamics 365 Business Central

Subsequent mentions: Business Central

Therefore, you cannot use any abbreviations such as "MS Dyn 365 BC" or "Microsoft Dynamics NAV".

What are the requirements for my offer's help and support page?

You are required to submit two distinct pages for support and help i.e. they cannot be the same. You can see what you have to include on both pages in the table below.

HELP	SUPPORT
Learning material such as FAQs, step by step guides, video tutorials, webinars etc.	At least two contact options (e.g. e-mail, phone, chat) and a defined SLA for how much time it takes before you answer to support inquires.

Can I use the Microsoft Dynamics 365 Business Central logo?

No, you cannot use the Business Central logo, as it's a Microsoft trademarked logo. However, you can use the "Get it from Microsoft AppSource" badge, which you can find here.

Update Lifecycle for AppSource Apps FAQ

2/17/2021 • 5 minutes to read • Edit Online

Please see the following sections for frequently asked questions regarding updating apps on AppSource.

I want to submit an updated version of my app. What is the process for that?

For any updated version of your app (small or large changes), you follow the same submission as your original version. It must go through the same validation process. The following are the steps that you must follow:

- Increase the version number of your app within it's json/manifest file.
- Do not change the app's AppID within it's json/manifest file. That needs to remain the same for life of the app
- Include an upgrade codeunit and ensure that it works.
- Upload the app file to your existing Partner Center offer.
- In Partner Center, edit the version field to match what is now in your updated app file.
- Make any other edits in Partner Center as needed.
- Submit for validation.
- Validation takes place as normal (against current production version of Business Central at time of submission):
  - Code review is needed for avoiding violations and ensuring requirements are met.
  - Test validation is scaled back for updated versions.

What happens when my updated app passes validation?

The app is checked into our service and becomes the active version for that current production release of Business Central. If a tenant is already upgraded to the current release, they can install this updated version of your app.

Does Microsoft now update my app (to this latest updated version) on all tenants that already have a previous version?

Microsoft will only force update apps during the 2 major releases (release wave 1 and 2). For these releases, each tenant will have their AppSource apps force updated to the latest available versions in our service.

How do I update the apps on my tenant for minor releases then?

If a tenant wants to update the apps on their tenant during the minor releases, the tenant admin needs to handle this. Here are the steps you follow to update your apps:

- Login to your Business Central Web client instance.
- Navigate to the **Extension Management** page.
- Find the app and uninstall it.
- Reinstall the app.

That gives you the latest available version in our service.

How often should I submit updates of my app?

Our recommendation is to pack more bug fixes and features into less frequent updates. Try to avoid frequent submissions containing very few changes. Being on a more frequent cadence than Business Central (monthly) is not advised. This leads to lower churn to production tenants.

What if a customer reports a critical bug in my app and needs an immediate hotfix version of my app?

We do have a fast track validation process for situations like this. These types of situations become top priority in our queue. A very quick validation takes place with the goal of having the hotfix in our service that same day. The following is the hotfix process:

- Fully test the hotfix version of your app to ensure it fixes the problem and to make sure no other issues are introduced.
- Submit the app via Partner Center per the normal process.
- Email rweigel@microsoft.com to notify him of the hotfix situation.
- Provide justification as to why this is critical. Some definitions of critical being:
  - App is causing the tenant to be unresponsive or unusable with no workaround
  - App is serving a critical business process and that process cannot be executed without a fix
- If justification proves to be critical, hotfix process can proceed.
- Quick Validation takes place ASAP and app is uploaded to our service.
- Tenants can now install this version of your app.

> **NOTE**
> Please ensure that you are only using this process for critical situations. Do not try to use it for minor bug fixes.

Do you have any tips for us when submitting updates of our app?

Yes, we have some valuable tips we would like to share. These are tips that can save you time in the validation process. They will help lead to fewer (and possibly zero) failures during validation. Most importantly; they will lead to fewer issues being found in production by customers.

- Follow the checklist, for more information see Technical Validation Checklist. The checklist is ever evolving and requirements might change or be added. You might miss something from the checklist, leading to validation failure and delaying the passing of your updated app.
- Use AppSourceCop, for more information see Using the Code Analysis Tool. This helps to catch any missing prefix/suffix and DataClassification. Too often we see these fail the updated versions of apps.
- Sign your app. This fails many app validations. We try to publish the app during validation and it is not properly code-signed leading to failure to publish.
- Publish and install your app. This is another big validation failure we see too often.
- Test your app's functionality with 100% coverage. You are the expert on the app and know it best. If you are only testing a small percentage of your app, customers will most likely find issues resulting in you having to update your app more often. And if customers are the ones finding your app issues, they may decide to uninstall it. You should have a vested interest in providing a quality app.
- Test the upgrade of your app. upgrade from the previous version to this latest. Your updated app will not pass validation until the upgrade works. If it fails in our validation, we will return it to you, leading to a delay in it going to our service.

NOTE

The tips that we provide above are for your benefit to pass validation the first time through each submission. And to emphasize these points, think of the delays that can arise when you do not follow these tips. If you submit, it can take a couple days before we validate the app. Once we validate it, if all is good, it should pass quickly. If we find issues that lead us to fail the validation, we send the app back to you as you have to make fixes. It could then take you days to properly fix. Next time you submit, your app does not go to the front of the queue. It begins at the bottom again which means it could be another couple days before we validate it again. By following our tips above, you can avoid those delays. Spend a bit more time up front finding those issues yourself, leading to a quicker path to our service.

FAQ About the Windows Client and Business Central

2/17/2021 • 5 minutes to read • Edit Online

The first releases of Business Central on premises included an installed client derived from Dynamics NAV. Starting with 2019 release wave 2, this legacy component, referred to as "the Windows client", will no longer be available for Business Central. Find answers for some of the most common questions here.

I have heard "modern clients only". What is this about?

Businesses and users want to be reassured that only the newest, most advanced, and up-to-date tools are being used to access their data. With Business Central 2019 release wave 2, released October 2019, users switch to the **modern experience** in the browser ("the web client"), the Android or iOS mobile apps, or the Windows 10 desktop app, which are available through the respective stores.

Connecting the Windows client to Business Central is not supported in Business Central 2019 release wave 2 and onwards.

Why is Microsoft discontinuing the Windows client?

Our customers must feel comfortable that the tools they use are fit for new hardware, operating systems, and changing environments. We have accelerated our investment in speed and productivity features for the modern clients, thereby achieving a major milestone in its transformation into a world-class desktop experience for both new and expert users.

While the Windows client was inherently bound to the Windows operating system, the modern clients allow us to reach more customers and more users within an organization, no matter their platform or device of choice. The latest technologies allow us to innovate at a rapid pace and respond to accelerating compliance requirements, the changing technology landscape, and requests from the community. In addition, the lower installation footprint on client devices makes it easier for IT departments and hosters to maintain and support their user base.

When is the Windows client discontinued in Business Central?

From **October 2019**, with Business Central 2019 release wave 2.

It was first announced in 2018 at various conferences and then with a detailed timeline earlier in 2019. For more information, see Business Central April 2019 Update and the road ahead.

Will the Windows client still be supported in older releases of Business Central and Dynamics NAV?

Yes. You can safely continue to use the Windows client on premises and receive support as long as you follow the lifecycle policy for your on-premises installations of Business Central. For more information, see Lifecycle FAQ - Dynamics.

The Windows client **remains supported** for the Business Central April 2019 release and all earlier releases of Business Central on premises and Dynamics NAV, in accordance with the support lifecycle process.

Does this impact me if I use Business Central online?

No. This change only impacts on-premises installations because the Windows client was only available on premises.

Does this impact me if I use Business Central on premises?

Yes. When you **choose to upgrade** to Business Central 2019 release wave 2 or later, you must switch to access Business Central using one of the modern clients. The most popular choice on desktop computers is the web-browser client where your browser is pointing to an on-premises web server using a URL, such as this example (not active): `https://myserver.mydomain.com/BC170`

What if I really want to have an installable component or at least an icon on my desktop?

You can always add a browser shortcut on your desktop or pin the web page with Business Central to your Windows task bar. Alternatively, the Business Central Windows 10 desktop app, which is available from Microsoft Store, is a great way to access Business Central both online and on-premises. To get the app, go to Microsoft Dynamics 365 Business Central in the store.

How does this impact mobile?

There is **no impact** on mobile apps for Business Central as they are already part of the modern-client family. For more information about the mobile apps, seeGetting Business Central on Your Mobile Device.

Can I still work with Business Central data in Excel?

Yes. There are multiple ways to work with Business Central and Excel, including the following:

- The Open in Excel feature that downloads any list as an Excel file for your processing or reporting
- The Edit in Excel feature that allows you to edit almost any list-based data in Excel and publish it back to Business Central

For more information, see Viewing and Editing in Excel From Business Central. For instructions on how to configure it for on-premises, see Setting up the Excel Add-In for Editing Business Central Data.

Note that the legacy, COM-based Excel plugin that used to be included on the installation media is no longer supported.

Can I still use the same Outlook add-in?

Yes. This change does not impact the Outlook add-in. In fact, the modern Outlook add-in is based on the same familiar web experience. For more information, see Using Business Central as your Business Inbox in Outlook.

What happened to C/SIDE, the legacy development environment?

In line with the retirement of the Windows client, Business Central 2019 release wave 2 marks a milestone as the first release without the legacy development environment (also known as C/SIDE). The modern developer experience, which is based on Visual Studio Code and the new AL language, supports developing large apps, such as the base application from Microsoft.

Therefore, C/SIDE is discontinued for Business Central going forward. Partners enjoy tremendous productivity and performance gains after moving to the newest tools. For more information, see Development in AL.

Which features are available in the modern clients and where can I find the roadmap?

Business Central is a highly adaptable modern business management solution. It is rich in features and options and is continuously being enhanced. The roadmap is best represented by the release plans, which are updated every six months. For more information, see Overview of Dynamics 365 Business Central 2019 release wave 2.

FAQ about Connecting to Business Central Online from On-Premises Solutions

2/17/2021 • 7 minutes to read • Edit Online

This section contains answers to frequently asked questions about connecting on-premises solutions to Business Central online.

> **TIP**
> Check the tips in this article if your organization is not yet ready to migrate to Business Central online but still wants to enjoy some of the benefits of the cloud. The same tips apply to when you are migrating to the cloud and are running the migration tool. For more information, see Running the Cloud Migration Tool.

Which products and versions are supported for this connection?

The current version of Business Central can connect the following products in order to provide intelligent insights:

- Dynamics GP (supported major versions)
- Business Central on-premises

  Currently, you can migrate to Business Central online from versions 14, 15, 16, and 17.

If you are currently on a version of Dynamics NAV, you must upgrade to Business Central on-premises, and then switch to Business Central online. For more information, see Upgrading from Dynamics NAV to Business Central online.

System requirements

To connect to the cloud through Business Central, the on-premises solution must use SQL Server 2016 or a later version, and the database must have compatibility level 130 or higher. The on-premises solution must also be one of the supported versions.

How is my on-premises data replicated to my Business Central online tenant?

Data is replicated using an Azure service called Azure Data Factory (ADF). ADF is a service that is always running within the Business Central online service manager. When you have connected to the intelligent cloud, a data pipeline is created in the ADF service so that data can flow from your on-premises solution to your Business Central online tenant. If your data source is a local SQL Server instance, you will also be asked to configure a self-hosted integration runtime (SHIR). The runtime is installed locally and manages the communication between the cloud services and your on-premises data without opening any ports or firewalls.

Are there any limits on the amount or type of data will replicate?

There are no restrictions on the type of data that can be replicated. In the current version of Business Central, the migration tool is by default limited to migrate databases up to 80 GB. If your database is larger than 80 GB, we recommend that you reduce the number of companies that you are migrating data for. You can specify which companies to include in the migration in the assisted setup wizard.

If you want to add more companies after the first selection of companies, you can add additional companies in the **Cloud Migration Management** page in Business Central online. For more information, see Adding a tenant to an existing runtime service, or updating companies.

If you are looking at migrating databases larger than 80 GB, we recommend that you contact the support team and work with them to make sure that the migration is successful.

Is my SQL connection string required to set up the connection?

Yes. The SQL connection string is passed to Azure Data Factory, where it is encrypted and delivered to your Self-Hosted Integration Runtime. The connection string is used to communicate with your SQL Server instance during the data replication process. For more information, see How do I find my SQL connection string?.

How do I find my SQL connection string?

Find the connection string to your SQL database in SQL Management Studio or Visual Studio. The user name and password defined in the connection requires a SQL Authenticated user name/password. Your connection string will look something like this:

Server=tcp:{ServerName},1433;Initial Catalog={DatabaseName};Persist Security Info=False; User ID={UserName};Password={Password};MultipleActiveResultSets=False;Encrypt=True;TrustServerCertificate=True;Connection Timeout=30;

How do I find the Integration Runtime name?

Find the Integration Runtime name in the Microsoft Integration Runtime Manager, which you can find in your Windows system tray or by searching for the program. You must type the name. You will not be able to copy and paste the name.

I am a hosting partner - do I need to configure the Self-Hosted Runtime Service for each tenant?

No, there is no limit on the number of tenants that can be added to your Self-Hosted Integration Runtime. Each added tenant will have a dedicated pipeline created.

Will data from tables with code customizations replicate?

No, only tables that are available in both your on-premises solution and your Business Central online tenant will replicate. Any customization must be made into an extension and installed on both your on-premises solution and your Business Central online tenant to replicate.

Why are my permissions restricted in the Business Central online tenant?

When you connect your on-premises solution to Business Central online for intelligent insights, all existing users are automatically added to the *Intelligent Cloud* user group, unless they have the SUPER permission set. In this configuration, your on-premises solution is the master where all business transactions take place. The Business Central online environment is read-only, and the data is used to generate intelligent business insights based on your on-premises data for you. We restrict permissions to prevent users from accidentally entering transactions or updating master records only to have that information overwritten and lost when data replication takes place.

Can I 'turn off' my intelligent cloud?

You can switch off your connection to the Business Central online environment at any point. Once you disable

your intelligent cloud configuration, your on-premises solution and the Business Central online tenant will become independent of one another. If you switch off the connection, and you want to use your Business Central online environment as your primary solution to run and manage your business, you must reassign permissions to provide read/write access to the relevant users.

For more information, see Managing Users and Permissions.

Will my on-premises users and permissions replicate?

No. Since you are not required to configure your on-premises solution with Azure Active Directory (Azure AD), we cannot guarantee a mapping between on-premises users and users in your Business Central online tenant. Business Central online requires Azure AD accounts, and users must be manually added. All permissions must be granted in the Business Central tenant, independent from your on-premises permissions.

For more information, see Managing Users and Permissions.

Can I view insights from cloud services in my on-premises solution?

Yes, the **Intelligent Cloud Insights** page can be hosted within your on-premises solution if that is one of the currently supported solutions. Each user will need to have a Business Central license to view the data.

Can you export to Excel, modify the contents, and import the data back in?

You can export the list to Excel from the Business Central online tenant, but since the data is read-only you cannot make changes and import it again.

Is the data replication only one way?

Yes, data is only replicated from the on-premises solution to your Business Central online tenant.

Is there a cost to connect to the intelligent cloud?

Currently, the only costs associated with the intelligent cloud are your named user license costs. For more information, see the Business Central Licensing Guide (download).

Why did my Role Center change after configuring the intelligent cloud?

To keep the Role Center experience as clean as possible and avoid permission errors, we automatically hide actions that would generate a permission error for the user.

Should I uninstall all my Business Central extensions?

Not necessarily. Most extensions will run without issues in the online environment. You may want to consider uninstalling extensions that send data to an external service to avoid potential duplicated calls to that service. It is a best practice to test any extension in a sandbox tenant configured for the Business Central online environment that you are connecting to.

How do I build an extension that enables data replication?

The extension must be created in the same manner as any other extension. For data to replicate, you must add a **ReplicateData** property to your table and set the value to *True*. If your extension connects with an external service and you want to restrict any service calls from your Business Central online tenant, a good practice

would be to store the connection information in a separate table and set the **ReplicateData** property to *False*. This would enable you to keep the extension installed but prevent it from making any type of service calls from the read-only Business Central tenant. Once the extension is installed in Business Central online and on-premises, the data will begin to replicate.

Resources for Help and Support for Dynamics 365 Business Central

2/17/2021 • 8 minutes to read • Edit Online

As a Business Central partner, you have access to resources that can help you support your Business Central customers, and you have access to resources that can help you be more productive as a partner.

This page outlines the resources available to you.

Product Help

The functionality in the default version of Business Central is described on the Docs.microsoft.com site as described in the following table.

NAME	LOCATION	DESCRIPTION
Business functionality docs	/dynamics365/business-central	Use this library to learn about business functionality.
Development and administration docs	/dynamics365/business-central/dev-itpro/	Use this content to learn how to extend, customize, and administrate Business Central.

AL developer documentation

In the Development in AL section, you find descriptions of processes such as compilation and debugging, and conceptual information about object types such as tables and events.

The reference documentation of the AL language publishes under the AL Programming umbrella. This content is partly generated automatically from code, but currently most of the reference content is maintained by hand. Use the following landing pages to quickly find the reference content that you need:

- Methods
  - Data Types and Methods in AL
- Properties
  - Properties Overview
- Triggers
  - Triggers Overview
- Objects
  - Table object
  - Table extension object
  - Page object
  - Page extension object
  - Page customization object
  - Report object
  - XMLport object
  - Query object
  - Codeunit object
  - Profile object

- Control add-in object

Product versions and Help versions

In general, the Business Central content on the docs.microsoft.com site reflects the latest version of Business Central online with limited support for earlier versions.

If you support Business Central on-premises, your solution might be one or two versions older than the latest version. This means that the content in the business functionality documentation might describe functionality that your users do not have access to. For a better experience, we recommend that you take a copy of our content at the time when that reflected the version that your on-premises solution is based on and deploy that to your own website. For more information, see the On-premises deployments section in the Configure the Help Experience article.

Customize and extend the user assistance

If you customize or extend Business Central, you are expected to also customize the user assistance so that users will have access to content that can help them get started, get unblocked, and learn more. For more information, see User Assistance Model and Configure the Help Experience.

Support

As a Business Central reselling partner, you are an administrator of your customers' Business Central tenants, and you are the first line of support. You can customize the support experience, and you have access to information that can help you troubleshoot any issues that your customers report.

For more information, see Technical Support.

Training

You and your customers can find free eLearning content on the Microsoft Learn landing page for Business Central with suggested collections for getting started, managing financials, and extending Business Central.

The Learn site also includes role-specific learning paths for developers, administrators, and functional consultants.

Additionally, partners in the Business Central community offer training and books.

Resources

As a partner, you can keep on top of current and upcoming capabilities, and you can share Microsoft's roadmap with your prospects, for example. This section provides links to places to keep track of for people who are new to Business Central as well as for people who have been working with the product for years.

This article provides information about the following types of resources:

- How to get started as a partner
- Where to learn about current and upcoming capabilities
- How to make a feature request
- Where to find blog posts
- Where to find communities
- Where to file bugs and issues
- Where to contribute to code or docs
- Where to ask non-product related questions

Get set up as a partner

If you are not already a Microsoft partner, your company must get set up, and so must you as an employee. For

more information, see Get Started as a Reseller of Business Central Online and Get Started with Building Apps.

Learn about current or upcoming capabilities

You can learn about current and coming capabilities through a number of different resources as outlined in the following table.

NAME	LOCATION	DESCRIPTION
Release plans	https://docs.microsoft.com/dynamics365/release-plans/	Get an overview of upcoming and recently released capabilities in Business Central and other Dynamics 365 apps.
Business functionality	https://docs.microsoft.com/dynamics365/business-central/across-business-functionality	Use this content to learn about business functionality in the default version of Business Central.
Development in the AL language	https://docs.microsoft.com/dynamics365/business-central/dev-itpro/developer	Use this content to learn how to extend and customize Business Central using the native AL language.
Administrative tasks	https://docs.microsoft.com/dynamics365/business-central/dev-itpro/administration/	Use this content to learn how to administer Business Central online.
Development in the AL language	https://docs.microsoft.com/dynamics365/business-central/dev-itpro/developer	Use this content to learn how to extend and customize Business Central.
Security in Business Central	https://docs.microsoft.com/dynamics365/business-central/dev-itpro/security/	Use this content to help you understand and improve the security of Business Central.
Compliance	https://docs.microsoft.com/dynamics365/business-central/compliance/compliance-overview	Use this content to learn about compliance in relation to Business Central.
Performance	https://docs.microsoft.com/dynamics365/business-central/dev-itpro/performance	Use this content to learn how to extend and customize Business Central.
Integrating with Business Central using web services	https://docs.microsoft.com/dynamics365/business-central/dev-itpro/webservices/	Use this content to learn how to integrate Business Central with other products by using web services.
Migrate to Business Central online	https://docs.microsoft.com/dynamics365/business-central/dev-itpro/upgrade/upgrading-to-business-central-online	Use this content to learn how you can move an on-premises solution to Business Central online.
Features not implemented in on-premises deployments	https://docs.microsoft.com/dynamics365/business-central/dev-itpro/features-not-implemented-on-premises	Use this content to learn which capabilities in Business Central online are not available in Business Central on-premises deployments.

NAME	LOCATION	DESCRIPTION
The Business Central learning catalog	https://docs.microsoft.com/dynamics365/business-central/readiness/readiness-learning-catalog	Get an overview of role-specific training material from Microsoft.
Free eLearning	https://docs.microsoft.com/learn/dynamics365/business-central	Free Business Central collections and learning paths on Microsoft Learn

Share an idea about a new feature you'd like to have

On the Dynamics 365 Ideas site, you can provide suggestions for new feature and capabilities. Your input goes directly to Business Central's engineering backlog for investigation and prioritization.

Make sure to search through the list of submitted suggestions, as chances are that someone already submitted something similar and might have already received votes. Vote if an idea already has been submitted to get it prioritized on the team's backlog.

Business Central blog posts

The Dynamics 365 blog is where Microsoft publishes announcements, updates, and tips and tricks, including for Business Central.

NAME	LOCATION	DESCRIPTION
Business Central on the Dynamics 365 blog	https://cloudblogs.microsoft.com/dynamics365/it/product/business-central/	Use this blog to learn about opportunities, processes, and tools for the Business Central partner community. Some older blog posts are still available on the Community site for partners or the Community site for business users.

Business Central communities

On the Business Central Community site, you have access to the Business Central Forum. You can use this forum to submit a question and learn from other Business Central community members. MVPs, partners, and Microsoft employees participate in the conversations.

You can also join the BCUG/NAVUG User Group for Dynamics 365 Business Central and Dynamics NAV, which is a user-led, user-driven community of more than 26,000 users, partners, and MVPs.

Summary of where to file bugs and issues

As a partner, you have different support channels depending on what type of issue you want support for. The following list outlines the various channels.

ISSUE TYPE	SITE
Submit support request on behalf of your Business Central online customers	Start at the Business Central administration center where you can easily submit a support request in the Power Platform admin center
Report bug in a preview or beta version	The MS Collaborate site
Collaboration on the AL language and developer experience	The AL Developer Preview GitHub repo

ISSUE TYPE	SITE
As an ISV, report an issue in production code, such as a problem with Microsoft's application, upgrade, or telemetry	The Partner Center - choose the **Support** section, start a partner request, search for *Business Central*, and then choose the relevant category for *Product Support* > *Business Central Development* and submit your support request.
Report bug in supported in-market versions of Business Central on-premises	The Support for business site

> **IMPORTANT**
> To submit support requests on behalf of your customer, you must be a delegated admin on the customer tenant. If your company is a CSP direct bill partner, you must have *Advanced* or *Premier* support plan.

For more information, see Technical Support for Dynamics 365 Business Central.

Engage with us on GitHub

GitHub brings together communities of developers and other contributors to discover, share, and build software. Here are some useful repositories for Business Central:

- Microsoft AL

  For collaboration on the AL development environment in Visual Studio Code, use the GitHub repo here: https://github.com/microsoft/al

- Microsoft AL application add-ons

  There are a couple of ways to engage with us in the https://github.com/microsoft/ALAppExtensions repo:

  - You can grab the code and contribute to the published apps.
  - If you're building your own app and need something specific from us, such as an event, you can help improve the general extensibility of the business logic.

- NAV Docker

  Use this repo to collaborate around the source code and the scripts of the generic docker image for Business Central: https://github.com/Microsoft/nav-docker

- BcContainerHelper/NavContainerHelper

  Use this repo to collaborate around the source code and the scripts of BcContainerHelper PowerShell module for Business Central: https://github.com/Microsoft/NavContainerHelper

- Documentation

  The product Help and developer and administration content is based on GitHub as well, and you can collaborate and extend the docs. The GitHub repos are:

  - Product Help (English US): https://github.com/MicrosoftDocs/dynamics365smb-docs
  - Developer and administration content: https://github.com/MicrosoftDocs/dynamics365smb-devitpro-pb

  For more information, see Extend, Customize, and Collaborate on the Help.

Non-product related questions

On occasion, as a partner, you will run into questions that are not directly related to the product. The following list outlines how to get answers to those questions.

FOR QUESTIONS RELATED TO	CONTACT
Problems with listing or publishing apps to AppSource due to Commercial Marketplace issues	The Partner Center - choose the **Support** section, start a partner request, search for *Business Central*, and then choose the relevant category for *Commercial Marketplace* and submit your support request.
Licensing or PSBC agreements	Email MBS Orders or MBS Agreements, respectively
Microsoft Partner Network, Partner Center, Cloud Solution Provider program	The Partner Center Support site
Payments, credit terms, checks, wire, or similar	Email MBS Accounting
Technical issues with PSBC, PartnerSource, or Order Central	Email IT MBS Support
Incentives	Email CSA Team
Cloud Solution Provider incentives	Email Online Channel Incentives Support
CSA/Ocina escalations	Email NAOC Channel Incentives Escalations
Volume licensing	The Call Logging Tool site or email Online Licensing

Trials

Giving prospects access to a pre-configured trial of Business Central is an elegant way to introduce them to Business Central. You can use the standard trial provided by Microsoft, or you can prepare your own including relevant extensions.

For more information, see Preparing Demonstration Environments.

Technical Support for Dynamics 365 Business Central

2/17/2021 • 4 minutes to read • Edit Online

Each customer of Business Central has a partner who assists with technical support when requested by the internal administrator. As a Business Central reselling partner, you are an administrator of your customers' Business Central tenants, and you are the first line of support. This means that you will get requests for support from your customers that you must triage, investigate, and either resolve or escalate to Microsoft.

In this section, you can learn about the tools that are available to you to help you troubleshoot your customers' Business Central.

Configuring the support experience

Because you are the first line of support for your customers, you must make it easy for them to contact you. To that end, there is a section in the Help and Support page in your customers' Business Central tenants where they can find this information.

> **IMPORTANT**
>
> You must have set up users in your own tenant in Partner Center as either *Admin agent* or *Helpdesk agent*, and they must have *delegated administration* privileges in your customer's Business Central to support the customer. For more information, see Delegated Administrator Access to Business Central Online.

To supply your support contact information in the administration center

1. In the Business Central administration center, choose the environment that you want to specify your contact details for, such as *Production*, and then, in the **Support** menu, choose **Manage Support Contact**.
2. Fill in the **Name**, **Email address**, and the **Website** fields, so that your users know how to contact you for technical support.
3. Optionally, choose the **Apply to all environments** checkbox if you want to add the same details to all related environments for this tenant.

Your customer can now contact you if they experience problems that they cannot resolve themselves. If you also cannot resolve a reported issue, you can escalate the issue to Microsoft. For more information, see Managing Technical Support.

On-premises deployments

In on-premises deployments of Business Central, the **Help and Support** page does not contain the section for contacting technical support. Instead, you can enter an agreement with your customer's administrator about how and when to contact you.

There are two other links in the **Help and Support** page that you can customize:

- Blog

  Specifies a link to where your customers can access a blog about their solution

- Coming soon

  Specifies a link to where your customers can access a roadmap for future changes

If you choose to not modify these settings, then the links go to Microsoft's blog and release notes.

For more information, see Configuring Business Central Web Server Instances.

Getting support for extension issues

As a partner, you must identify if the issue is caused by application logic or platform behavior:

- If the issue is caused by application logic, you must identify the publisher of the extension.
- If the extension is a per-tenant extension, as a partner, you must fix the issue.
- If the extension is an AppSource extension, you must contact the AppSource partner that developed the extension.
- If the extension is published by Microsoft, you must contact Microsoft support.

Troubleshooting and support

The Business Central administration center is your primary tool to support your customers. However, you can also log in to the customer's Business Central as the delegated admin for troubleshooting.

For more information, see Managing Technical Support.

Summary of where to file bugs and issues

As a partner, you have different support channels depending on what type of issue you want support for. The following list outlines the various channels.

ISSUE TYPE	SITE
Submit support request on behalf of your Business Central online customers	Start at the Business Central administration center where you can easily submit a support request in the Power Platform admin center
Report bug in a preview or beta version	The MS Collaborate site
Collaboration on the AL language and developer experience	The AL Developer Preview GitHub repo
As an ISV, report an issue in production code, such as a problem with Microsoft's application, upgrade, or telemetry	The Partner Center - choose the **Support** section, start a partner request, search for *Business Central*, and then choose the relevant category for *Product Support > Business Central Development* and submit your support request.
Report bug in supported in-market versions of Business Central on-premises	The Support for business site

IMPORTANT

To submit support requests on behalf of your customer, you must be a delegated admin on the customer tenant. If your company is a CSP direct bill partner, you must have *Advanced* or *Premier* support plan.

TIP

When you submit your first support ticket as a partner, you must specify details about your company's support plan. If you or your colleagues do not know these details, contact your Microsoft rep.

Non-product related questions

On occasion, as a partner, you will run into questions that are not directly related to the product. The following list outlines how to get answers to those questions.

FOR QUESTIONS RELATED TO	CONTACT
Problems with listing or publishing apps to AppSource due to Commercial Marketplace issues	The Partner Center - choose the **Support** section, start a partner request, search for *Business Central*, and then choose the relevant category for *Commercial Marketplace* and submit your support request.
Licensing or PSBC agreements	Email MBS Orders or MBS Agreements, respectively
Microsoft Partner Network, Partner Center, Cloud Solution Provider program	The Partner Center Support site
Payments, credit terms, checks, wire, or similar	Email MBS Accounting
Technical issues with PSBC, PartnerSource, or Order Central	Email IT MBS Support
Incentives	Email CSA Team
Cloud Solution Provider incentives	Email Online Channel Incentives Support
CSA/Ocina escalations	Email NAOC Channel Incentives Escalations
Volume licensing	The Call Logging Tool site or email Online Licensing

Dynamics 365 Business Central User Assistance Model

2/17/2021 • 7 minutes to read • Edit Online

The Business Central user assistance model is based on the following principles:

- Get started

  Default values and setup wizards makes it easy to start using Business Central with your own data, in-product videos give new users a quick introduction to how the product works, and Home pages give easy access to key tasks so users can easily get started with work every day.

- Get unblocked

  Embedded user assistance implemented as tooltips answers most immediate questions about what fields and actions do.

- Learn more

  The Help menu and the tooltips provide context-sensitive links to Help articles with more information.

Apps, extensions, and customizations are expected to follow the same model by applying tooltips to controls on page objects, and by providing links to Help for their functionality. For more information about customizing and extending the user assistance, see Extend, Customize, and Collaborate on the Help and Configure the Help Experience.

In this article, we'll talk about the user assistance model itself and what it does.

Help users get started

The user assistance concept of *Get Started* is not just about getting started with Business Central on the first day. It's also about getting started all the other days, and about getting started with infrequent and unfamiliar tasks.

Assistance in the shape of wizards is helpful for set up or filling in data for a complicated report, for example. Home pages that are designed for a particular role or job help users get started with their daily work – they can easily get to their most important tasks, and that means that Business Central helps them get their work done more efficiently.

Help users get unblocked

Even the best designed user interface can still be confusing to some. It can be difficult to predict what users will find confusing, and that is why the base application includes descriptions for all controls and actions that can be accessed when you choose the caption of the control or action. In combination with descriptive captions and instructional text, these tooltips, or callouts, are our current implementation of *embedded user assistance*, which is an important principle in today's world of software design.

The tooltips help users unblock themselves by providing an answer to the most likely questions the users might have, such as "What data can I input here?" or "What is the data used for?". Keep tooltips in mind when you develop the user interface of your solution.

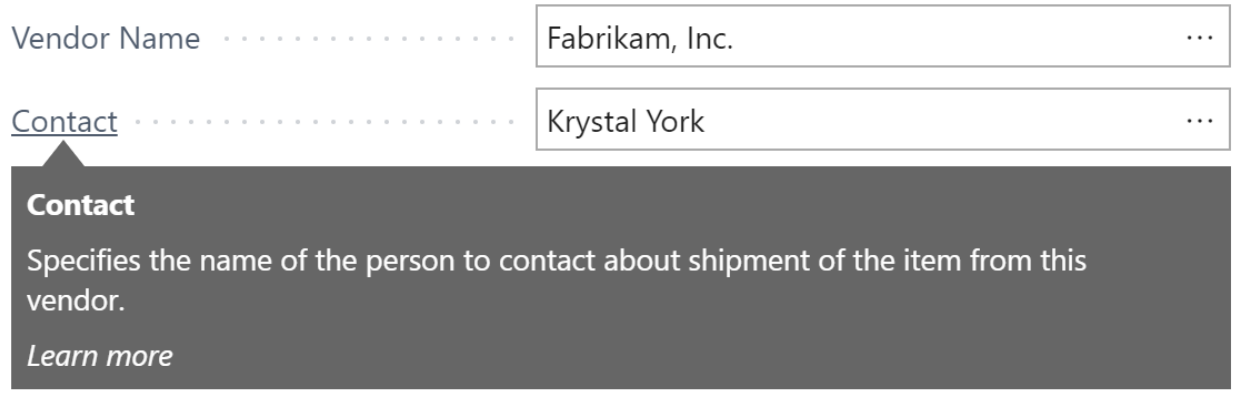

Table fields can be read-only in one page and editable in another so the tooltips describe the difference. In Business Central, this type of "What is this field?"-content is embedded in the page objects, and resource files can be used for translated user interfaces. For more information, see Working with Translation Files.

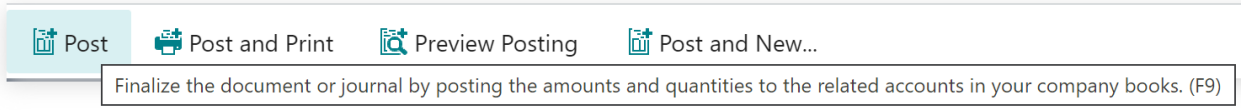
Most tooltips end with an automatically generated link to *learn more* as described in the Help users learn more section; however, tooltips for actions do not have *Learn more* links:



Users can always use the Ctrl+F1 keyboard shortcut to access the *learn more* content that is configured for the currently-selected item in the user interface.

The tooltips in Business Central are conceptually similar to *field descriptions* in Dynamics 365 Finance and related apps, and *flyouts* in the Fluent Design guidelines. Business Central does not have the equivalent of teaching tips that you can add to your solution, though our platform includes a few flyouts of the same type.

Guidelines for tooltip text

The Microsoft user assistance model requires a tooltip for all controls of type Action and Field that exist on page objects. Follow these guidelines:

- If the control is a field, begin with the verb *Specifies*.
- If the control is an action, begin with a verb in the imperative form , such as *Calculate* or *View*.
- Include the most valuable information that users need to perform the task(s) that the field or action supports.

  For example, for the **Post** action, do not write *Post the document*. Write, for example, *Update ledgers with the amounts and quantities on the document or journal lines*.
- Describe complex options in tooltips for option fields.

  Use a colon to call out the option name and its description. See example 3 below.
- Try to not exceed 200 characters including spaces.

  This makes the tooltip easier to scan so the user can get unblocked quickly. However, the UI will render longer tooltip text if you want to provide more detailed user assistance.
- Do not use line breaks in the tooltip text.

  The tooltip cannot render formatting or line breaks.

Examples:

CONTROL NAME	TOOLTIP
Password field	Specifies your company's password to the service that converts bank data. The password that you enter in this field must be the same as on the service provider's sign-on page. (175 characters including spaces)
Entries action	View the history of transactions that have been posted for the customer. (72 characters including spaces)
Account Type field	Specifies the purpose of the account. Total: Used to total a series of balances on accounts from many different account groupings. To use Total, leave this field blank. Begin-Total: A marker for the beginning of a series of accounts to be totaled that ends with an End-Total account. End-Total: A total of a series of accounts that starts with the preceding Begin-Total account. The total is defined in the Totaling field. (522 characters including spaces)

Help users learn more

The content that Microsoft publishes under the user assistance concept of *Learn more* is intended to answer those questions that the user interface (including the tooltips) cannot answer, such as where that page fits into the bigger workflow, or what comes next, or what would be the alternative. Users can access this content either through the *Learn more* link in tooltips, or by using the *Ctrl+F1* keyboard shortcut. For more information, see Configure Context-Sensitive Help.

The base version of Business Central uses content that is published to an online library (Docs.microsoft.com/dynamics365/business-central) so that it can also serve as onboarding material and as feature overviews that you can share with prospects. The content is written in MarkDown, and our source files are available in a public GitHub repo that you can extend and customize for your customers.

There are repos in GitHub for the source content and each of the languages that Microsoft translates to. For more information, see Extend, Customize, and Collaborate on the Help.

For the base version of Business Central, free online learning is also available on Microsoft Learn. For more information, see the Business Central Learning Catalog.

Feedback and contributions

On docs.microsoft.com, each article has two buttons at the end of the article. The *Product feedback* button sends you to the Ideas site, and the *Sign in to give documentation feedback* button lets you submit feedback about the content through GitHub. In both cases, you must create an account if you do not already have one. For *product feedback*, you must sign in with your work or organizational email account. For *access to GitHub*, you can use any email address when you create an account.

We welcome your contributions, both as pull requests with suggestions or corrections to the content, and as GitHub Issues with bugs or questions. However, we can only accept feedback and contributions to the content in the *dynamics365smb-docs* repo and we cannot address issues or questions about the product.

> **IMPORTANT**
> Microsoft only accepts pull requests to the *dynamics365smb-docs* repo, not the language-specific repos. If you have feedback about translations, you can report a GitHub issue in the relevant repo.

Microsoft also accepts contributions and feedback about the development and administration content through

the dynamics365smb-devitpro-pb. This repo does not have translation repos associated with it, but other than that, the same rules apply as for the *dynamics365smb-docs* repo.

For more information, see Extend, Customize, and Collaborate on the Help.

Working in MarkDown

If you fork one of our repos, you will be authoring in MarkDown. We recommend that you learn the basics by referring to the Docs Markdown reference section in the Docs Contributor Guide.

The Docs Authoring Pack for VS Code can aid with MarkDown authoring and validation in Visual Studio Code. However, you can also use other text editors to edit MarkDown.

For other tips and tricks, see Extend, Customize, and Collaborate on the Help and Blog post: Collaborate on content for Business Central.

Translate the Help

If you want to deliver a localization app, or if you want to deliver your functionality in more than one country, you will want to translate the Help. We suggest that you take a look at the Microsoft Dynamics 365 Translation Service, which is available as preview in Microsoft Dynamics Life Cycle Services. For more information, see Translate documentation files.

The user interface text, including the tooltips, is translated as part of the application. For more information, see Working with Translation Files.

Style

At Microsoft, we are in process of simplifying and unifying our style guides. To get to know the Microsoft style, use the Microsoft Writing Style Guide as a good starting point. The Business Central follows most of the guidelines in the Microsoft Writing Style Guide with exceptions for industry terminology and other product-specific issues.

Configuring the Help Experience for Dynamics 365 Business Central

2/17/2021 • 6 minutes to read • Edit Online

The default version of Business Central comes with conceptual overviews and other articles that publish to the https://docs.microsoft.com/dynamics365/business-central/ site. This location is accessible from the Help menu and through the Learn More links in all tooltips. Each extension that you add will include its own tooltips and links to Help.

But what if you want to deploy Business Central locally? Or if you have a vertical solution so that you want to refer your customers to your own website for Help? Or if you have a legacy Help collection based on the Dynamics NAV Help Server? These and other scenarios are also supported in Business Central.

Apps for online tenants

When you build an app for Business Central using the AL developer experience, you are expected to comply with the Business Central user assistance model. The user assistance model requires the use of tooltips and context-sensitive links to Help content that is hosted on a website. For more information, see the Deploy content to your website section and the Configure Context-Sensitive Help article.

> **TIP**
> The website does not have to be publicly accessible, but it must be accessible to all users of the solution that it supports.

You can add Microsoft's content to your website, or you can deploy just your own content. The choice is yours and depends on the requirements of your users, the size of your app, and the amount of customization you want to make. The custom Help toolkit includes tools that can help you prepare and deploy content. For more information, see Custom Help Toolkit.

On-premises deployments

For deploying Business Central on-premises, you can choose between using the legacy Dynamics NAV Help Server and an online website, and you can configure different Help experience for each Business Central Web Server instance. Help Server is a simple website that requires your Help to be in a specific format (HTML files), while the online website can host any content that you want to make available. Your choice depends on the needs of your solution and your users. If you add configuration for an online library, you must remove any settings for Help Server.

> **IMPORTANT**
> The legacy Dynamics NAV Help Server component will be deprecated. We recommend that you invest in a different type of website. For more information, see the 2020 release wave 2 release plan and Custom Help Toolkit.

TIP

The content on the https://docs.microsoft.com/dynamics365/business-central/ site and in the various GitHub repos reflects the latest version of Business Central, unless otherwise specified.

We recommend that you get your version of Microsoft's content close to the time the subsequent major version of Business Central becomes available. For example, if you are deploying version 16.4, you should have taken a snapshot of the content in GitHub before version 17.0 became available.

Online library

To display content from an website that hosts your user assistance content, specify the URL in the settings for the Business Central Web Server. The navsettings.json file must contain the following setting in the `ApplicationIdSettings` element:

```
{
  "NAVWebSettings": {
    // [...more keys]
  },
  "ApplicationIdSettings": {
    //BaseHelpUrl:  The location of Help for this application.,
    "BaseHelpUrl": "https://mysite.com/{0}/documentation/",
     // [...more keys]
  }
}
```

NOTE

Replace the value of the BaseHelpUrl key with the URL for your own website. The parameter, {0}, represents the locale of the browser that the user is using, such as en-us or da-dk, and is set automatically at runtime.

For more information, see Configuring Business Central Web Server Instances.

TIP

The website does not have to be publicly accessible, but it must be accessible to all users of the solution that it supports.

Help Server

If you want to use Help Server, then you must specify the server and port in the installation options. The Help Server website can also serve as a starting point for adding a library to your existing website, for example.

The navsettings.json file must contain the following settings in the `NAVWebSettings` element:

```
{
  "NAVWebSettings": {
    //HelpServer: Name of the Dynamics NAV Help Server to connect to.,
    "HelpServer": "https://myserver.com",
    //HelpServerPort:  The listening TCP port for the Dynamics NAV Help Server. Valid range: 1-65535,
    "HelpServerPort": "49000",
    // [...more keys]
  },
  "ApplicationIdSettings": {
    // [...more keys]
  }
}
```

In the example, `https://myserver.com` represents the URL to the Help Server instance. For more information, see Configuring Microsoft Dynamics NAV Help Server in the developer and adminstration content for Dynamics NAV.

> **IMPORTANT**
>
> If you use Help Server, the UI-to-Help mapping functionality that is described in Configure Context-Sensitive Help does not work. Neither does the original Help lookup mechanism that was based on filenames that reflected the object IDs, such as N_123.htm for the page object with the ID 123. For more information, see Blog post: Reusing classic object-based Help on your Dynamics 365 Business Central Help Server.

> **TIP**
>
> If you are upgrading from Microsoft Dynamics NAV 2017, you can reuse your existing Help Server content by simply replacing the product name and make any other changes that apply to your Business Central environment.

You can also still download the files that were made available for Microsoft Dynamics NAV 2017. The download consists of 45 CAB files with the content from the Dynamics NAV 2016 DVD rebranded to Microsoft Dynamics NAV 2017. There are CAB files with the W1 application Help translated into each of the supported languages plus the local functionality for the country/region where that language is spoken. There are also CAB files with local functionality in English. The files were published as a single download so each administrator could choose exactly the files that they needed at the time. For more information, see Microsoft Dynamics NAV 2017 Classic Help Download.

> **IMPORTANT**
>
> Specifically for the preview of Business Central in India, the installation of Help Server fails due to missing files on the installation media. The solution is to install Help Server without the HTML files for local functionality and instead pick up the content from GitHub. For more information, see Get updates from Microsoft.

Deploy content to your website

Business Central has no firm requirements for the website that hosts your online library for your Business Central online or on-premises. You can deploy your content using any tool and process, such as Azure Static Web Apps, Azure App Service, a website that can render MarkDown files using a customization of the DocFx Flavored MarkDown engine, or third-party services such as MkDocs.

You can see an example of how to deploy content to an Azure web app in the article Deploy custom help to Azure, which supports the custom Help toolkit for Dynamics 365 Finance, Dynamics 365 Supply Chain Management, and Dynamics 365 Commerce. That article also describes how you can build a search service for your website. This is currently not relevant for Business Central, but you might find the guidance helpful anyway.

Use the HtmlFromRepoGenerator tool tool in the custom Help toolkit to clone a repo and generate the corresponding HTML files automatically. If, instead, you want to create your own tooling and processes around DocFx, which is an open-source tool for converting markdown files, you can see examples in the Build HTML files section of the contributor guide.

Fork the Microsoft repos, and customize or extend the content

If you want to customize or extend the Microsoft Help, you can fork our public repo for either the source repo in English (US) at https://github.com/MicrosoftDocs/dynamics365smb-docs, or one of the repos that contain translations. For more information, see Extend, Customize, and Collaborate on the Help and Custom Help Toolkit.

Configure Context-Sensitive Help

2/17/2021 • 6 minutes to read • Edit Online

A key pillar of helping users help themselves is to give them access to Help for the particular part of Business Central that they are working in.

App-level configuration

Specify where the Help for your functionality is published in the *contextSensitiveHelpUrl* property in the app.json file. For example, if you publish your content to `https://mysite.com/documentation`:

```
"contextSensitiveHelpUrl": "https://mysite.com/documentation/",
```

In this example, when the user is using your app's functionality, the *contextSensitiveHelpUrl* property specifies that the links to Help will go to the *mysite.com* site. When the user is using functionality from the base application, then the Help calls will go to the *docs.microsoft.com* site.

If your app only supports a limited number of locales, you can specify that as well as shown in the following example:

```
"contextSensitiveHelpUrl": "https://mysite.com/{0}/documentation/",
"supportedLocales": [
  "en-GB", "en-IE
],
```

The *contextSensitiveHelpUrl* and *supportedLocales* properties specify that the links to the Help for page objects in this app must go to the *mysite.com* site, but that the site only supports those two languages. All other Help calls from objects in this app will go to the default locale on the specified webserver, in this case the equivalent of `https://mysite.com/en-GB/documentation/my-feature`.

Help calls for Microsoft objects will continue to go to the *docs.microsoft.com* site.

Localization apps

Specifically for localization apps that translate Business Central into languages that are not offered by Microsoft, the app.json file must be set to specify the destination of links to Help as shown in the following example:

```
"helpBaseUrl": "https://mysite.com/{0}/documentation/",
"supportedLocales": [
  "ca-es"
],
```

The *helpBaseUrl* and *supportedLocales* properties specify that the links to the Help must go to the *mysite.com* site when the user is using the product in Catalan. If the user switches the application language to English (US), then the Help calls will go to the *docs.microsoft.com* site.

Page-level configuration

Your target website is expected to have a default page that will display if nothing else is specified. But for each page or page extension in your app, you can specify the Help page that describes this page or the fields that the

page extension adds to the page. You can do that using the *ContextSensitiveHelpPage* property as shown in the following example:

```
page 50101 "Reward Card"
{
    PageType = Card;
    SourceTable = Reward;
    ContextSensitiveHelpPage = 'sales-rewards';

}
```

In this example, the app contains a page object that is mapped to the *sales-rewards* Help file on the website that the app.json specifies. As a result, the *Learn more* link in the tooltips for this page will go to the equivalent of `https://mysite.com/documentation/sales-rewards`.

Similarly, the following code example shows a page extension object that sets the *ContextSensitiveHelpPage* property so that the *Learn more* link in tooltips for the fields that this page extension adds to the Customer Card will go to the `https://mysite.com/documentation/sales-rewards` rather than the default location at docs.microsoft.com:

```
pageextension 50104 "Customer Card Ext" extends "Customer Card"
{
    ContextSensitiveHelpPage = 'sales-rewards';
    layout
    {...}
}
```

You can use the ContextSensitiveHelpPage property to direct Help calls from multiple page objects or actions to the same article. For example, Microsoft has chosen to group the context-sensitive links depending on the granularity of the Help for specific area in the base application. If the Help for a specific area is made more granular, then the context-sensitive Help mapping is updated accordingly.

Your target website is expected to have a default page that will display if no other page is appropriate. For every page where *ContextSensitiveHelpPage* is not set, this default Help page will be shown.

For page extensions, the value of the *ContextSensitiveHelpPage* property will apply only to the controls that the page extension adds to the extended page objects. For example, if your page extension adds two new controls to the base application's Customer Card page, then the *Learn more* links in the tooltips for those two controls will go to the Help page that you have specified. The *Learn more* links in the rest of the controls will go to the default Help that is specified in the base application. This way, multiple apps can extend the same page object and each apply their own content-sensitive Help link without overwriting the context-sensitive links for other apps.

> **NOTE**
>
> The app.json file also contains a *help* property that is used by AppSource to specify the link that describes the app or solution.

How it works for the base application

In the current version of Business Central, the context-sensitive links to Help for the base application is based on a different UI-to-Help mapping that is stored in table 2000000198 **Page Documentation**. In this table, all page objects in the default version of Business Central are listed, and have a target Help article associated with each of them. Multiple page objects can be associated with the same Help article, such as when a specific workflow involves multiple pages.

The base URL to the location of the target articles that are listed in table 2000000198 **Page Documentation** is

specified at the app level as https://docs.microsoft.com/dynamics365/business-central/. In an extension, you can overrule this URL so that all calls for Help go to your site instead. This is especially important for localization apps where all context-sensitive Help calls for that app's language must go to the provider's website. For more information, see Configuring the Help Experience.

Adding page-level UI-to-Help mapping to the system table

You can run a script that populates the **Page Documentation** table with a mapping for Microsoft's page objects and your own page objects. This is useful if you want to reuse legacy Dynamics NAV Help for your Business Central on-premises deployment.

Caution

While it is possible to reuse the Dynamics NAV legacy Help with the legacy Dynamics NAV Help Server, and to populate the system table, **Page Documentation**, we recommend that you convert any existing content to the Business Central format, and that you fork our GitHub repos. For more information, see Extend, Customize, and Collaborate on the Help for Dynamics 365 Business Central and Migrate Legacy Help to the Dynamics 365 Business Central Format.

In the following example, you have chosen not to apply context-sensitive Help links to your page objects and instead you want to overwrite the UI-to-Help mapping that Microsoft has made in the system table.

Let's assume that the current mapping is:

PAGE ID	PAGE NAME	REGION/COUNTRY	RELATIVE PATH
4	Payment Terms	W1	sales-manage-sales
11300	Financial Journal	BE	how-to-create-financial-journals

You want to replace the values of the fields in the **Relative Path** column with classic page-level Help files:

PAGE ID	PAGE NAME	REGION/COUNTRY	RELATIVE PATH
4	Payment Terms	W1	N_4
11300	Financial Journal	BE	N_11300

Once you have done this mapping, you can apply it to the **Page Documentation** table by using a script that updates the table in the SQL Server database, for example.

You can find a couple of suggestions for how to go about this in our blog post, Blog post: Reusing classic object-based Help on your Dynamics 365 Business Central Help Server.

Migrate Legacy Help to the Dynamics 365 Business Central Format

2/17/2021 • 5 minutes to read • Edit Online

Business Central implements a user assistance model where tooltips explain all fields and actions, and articles with conceptual descriptions of functionality are published to a website. If you are building an app, you are expected to comply with this model. However, there are many ways in which you can migrate and reuse your existing Help within this model.

Reusing existing web content

When you move to Business Central, you can reuse your existing product Help solution in most situations, especially if the content is already published to an *online library*, which is an internal or external website. In that case, all you have to do is to add that website to the configuration of Business Central online or on-premises. For more information, see Configuring the Help Experience.

More specifically, if you have content that you created for Dynamics NAV, then you can choose to reuse that content for your Business Central solution.

For example, you have a Dynamics NAV Help Server website with HTML files that describe your solution according to the Microsoft Dynamics NAV 2013 R2 documentation model and format. You can reuse the Help Server website and rebrand the website and the content. You then connect your Business Central solution with the Help Server website. For more information, see Configuring the Help Experience.

Business Central does not support the field-based approach to context-sensitive Help that Dynamics NAV 2017 and earlier versions use. Instead, you must use the Business Central page-based approach to context-sensitive Help. You do not have to convert your existing Help, but you do need to make the content available. For more information, see the Converting existing content section.

> **NOTE**
> For apps for Business Central online, you must apply tooltips to controls and actions in both page objects and page extensions, and you must supply context-sensitive links. For more information, see Configuring the Help Experience.

Converting existing content

If your existing content is in a different format, such as PDF files, Word documents, or printed manuals, you must decide if you want to keep the content as-is, or if you want to convert it to a format that can be accessed from inside Business Central. There are third-party tools available that can help you migrate your content, depending on the current format and the target format.

For example, if you are migrating your solution from Dynamics GP, you might have content in PDF files. You can choose to convert the content to MarkDown as described in the Moving to MarkDown section, and then publish to a new online library on your current website.

Migrating from Dynamics NAV

If you are migrating your solution from Microsoft Dynamics NAV 2013 R2 or later versions of Dynamics NAV, then you most likely have been using the Dynamics NAV Help Server, and your Help content is in HTML format. That means that you can reuse your existing content as-is, you can use the Custom Help Toolkit to get new HTML files to supplement your existing content, or you can use publicly available third-party solutions to

convert some or all of your HTML files to MarkDown if you want to follow similar processes to the ones the Microsoft team follows. For more information, see the Moving to MarkDown section.

If you are migrating from an earlier version of Dynamics NAV, then you can choose to first migrate to the Microsoft Dynamics NAV 2013 R2 format, and then migrate again to MarkDown. For more information, see Upgrading Your Existing Help Content in the legacy docs for Microsoft Dynamics NAV 2013 R2.

Converting legacy Dynamics NAV field Help to tooltips

Tooltips play an important role as part of the Business Central user assistance model, and we encourage you to apply tooltips to your controls and actions as well.

If you would like to reuse text from your Dynamics NAV Help for table fields, the FieldTopicTextExtractor tool can extract the first paragraph from your Dynamics NAV Help topics for table fields. The resulting spreadsheet will help you copy and paste the text from your Dynamics NAV Help topics into the ToolTip property of your controls.

Mapping the table fields to page controls is not always straightforward because the same table is often used by two or more pages. As a result, the page ID can be many numbers away from the table ID. It requires knowledge of the actual solution to determine which tooltips are relevant for which pages. The **FieldTopicTextExtractor** tool generates an Excel file that you can use for this purpose, since you can sort and filter, and then copy content in Excel.

In the base application, tooltips are in the page objects, so, at Microsoft, we edit code to edit tooltips. You do not have to do the same. You can choose to work with tooltips in the translation files or straight in the .AL files. Different solutions require different processes, so pick the process that is more efficient for you. We chose to associate the "What is this field?"-content with the user interface, meaning the controls on page objects. In the Dynamics NAV Help model, we chose a different approach, focusing on the database structure. Both approaches have their advantages and disadvantages, but the Business Central user assistance model currently focuses on the user interface with tooltips on page objects. For more information, see User Assistance Model.

For more information, see Working with Application Objects as Text Files in the docs for Microsoft Dynamics NAV 2016, How to Add Translated Strings By Importing and Exporting Multilanguage Files in the docs for Microsoft Dynamics NAV 2018, and Working with Translation Files for Business Central.

Moving to MarkDown

Converting your existing content to MarkDown can be done using third-party tools, including but not limited to PanDoc or the Writage plugin for Word.

Once you have converted your content to MarkDown, we recommend storing your content in a repository, such as a Git repo in Azure DevOps, a private or public repo in GitHub, or a project in MkDocs. You can use open-source tools such as DocFx to generate content for your website. In general, working in MarkDown means that you have access to a world of open-source tools and do not have a hard dependency on Microsoft providing you with tools. The Custom Help Toolkit can help you prepare content for publishing. For more information, see Custom Help Toolkit.

If you do not yet have a website that you publish content to, then there are several ways in which you can create such a site. The MkDocs project generates a website for you, but you can also work with a web designer to build a site to host your content. We recommend deploying to an Azure web app.

Custom Help Toolkit

2/17/2021 • 2 minutes to read • Edit Online

Microsoft has published a GitHub repository with scripts and tools that can help you prepare customized Help for your Business Central solution. This Help content can then be accessed from the user interface through the *Learn more* links as described in Configure Context-Sensitive Help. You are welcome to use any tools or processes to build and deploy content; this toolkit is intended to help you in some of the steps that are required.

The GitHub repository includes source code for the tools, and we welcome contributions and feedback to collaborate on improving the toolkit.

Tools in the toolkit

The toolkit is available at https://github.com/microsoft/dynamics365smb-custom-help. The repo contains the following tools as well as the source code for the tools:

- HtmlFromRepoGenerator tool

  For more information, see Custom Help Toolkit: The HtmlFromRepoGenerator tool

- Dynamics NAV field Help conversion scripts

  For more information, see Custom Help Toolkit: The FieldTopicTextExtractor tool

- HtmlLocaleChanger tool

  For more information, see Custom Help Toolkit: The HtmlLocaleChanger tool

Custom Help

Depending on your solution, you are expected to deploy Help to a website that can be accessed by users of your solution. For more information, see User Assistance Model and Configuring the Help Experience for Dynamics 365 Business Central.

Custom Help Toolkit: The HtmlFromRepoGenerator tool

2/17/2021 • 4 minutes to read • Edit Online

The custom help toolkit includes the **HtmlFromRepoGenerator** tool that gets Microsoft's content in MarkDown files and converts it to HTML files. You can then deploy the HTML files to a website.

The HtmlFromRepoGenerator tool is a wrapper around the DocFx component that Microsoft uses to generate HTML files for the Docs.microsoft.com site. You can write your own scripts around this component, and maybe you already have that in place. If you don't, then the HtmlFromRepoGenerator tool can help you get started. Run the tool from a command prompt, use the examples as inspiration but remember to update the paths to suit your configuration.

Use the HtmlFromRepoGenerator tool to get MarkDown files and generate HTML files

HtmlFromRepoGenerator.exe provides functionality that supports the creation of custom Help based on source files from Microsoft. You can use HtmlFromRepoGenerator.exe to:

- Clone a Microsoft documentation repository (repo)
- Update links to files that are no longer in the clone
- Update the **ms.locale** value to match the language options that are supported by Business Central
- Generate HTML files that can be used for publishing to your own website

  The HTML files will be generated in the **business-central\d365businesscentral** subfolder, such as *D:\BC\de-DE\business-central\d365businesscentral*. This name of the subfolder is set in the docfx.json file in the en-US source repo. The tool applies the `<meta name="robots" content="NOINDEX, NOFOLLOW">` tag to the HTML files, so if you use the tool to process your own content, you should remove these tags from your files but leave the tags in your version of Microsoft's content.

  The files are generated based on stylesheets and templates that are part of the tool.

- Compare a localized Microsoft repo to the en-US repo to identify differences and update links accordingly

  The en-US repo includes files that are required for building the various localized versions, including the very important docfx.json file that sets the output location and certain metadata settings, some of which are important for the Docs.microsoft.com site only. For more information, see Get content from the GitHub repos.

Syntax

Here is the syntax for HtmlFromRepoGenerator.exe:

```
HtmlFromRepoGenerator.exe --Out <path> [--DoNotClone <true|false>] [--Repo <URL>] [--RemoveGitFolder
<true|false>] [--LogsDir <.\logs>] [--EnRepo <URL>] [--EnOut <path>] [--Lng <language code>] [--Rtl] [--?[--
]]
```

The following table provides an explanation of the parameters:

PARAMETER	DESCRIPTION
Out	Specifies the folder where your existing clone is, or the folder to clone the repo to, such as D:\BC. If you run HtmlFromRepoGenerator to clone a repo, this folder must not already exist.
DoNotClone	Set this parameter when you run the tool against a previously cloned repo.
Repo	Specifies the repo URL. Optional if you run the tool based on a previously cloned repo. Examples of Microsoft documentation repo URLs include `https://github.com/MicrosoftDocs/dynamics365smb-docs` for English (US) and `https://github.com/MicrosoftDocs/dynamics365smb-docs-pr.de-de` for German (Germany).
RemoveGitFolder	Specifies whether to remove the `.git` folder.
LogsDir	Specifies the folder to save logs files to.

The following additional parameters are used when the tool is run against the localized Microsoft documentation repos:

PARAMETER	DESCRIPTION
EnRepo	Specifies the URL of the en-US repo. Optional if you run the tool on a previously cloned repo. The Microsoft documentation repo URL for English (US) is https://github.com/MicrosoftDocs/dynamics365smb-docs.
EnOut	Specifies the folder where the en-US repo exists, or the folder to clone it to. This folder must not already exist if you run the tool based on a previously cloned repo.
Lng	Specifies the language value to use for `ms.locale` metadata in the generated HTML files. If this parameter is not set, the tool uses en-US.
Rtl	Set this parameter if the language uses right-to-left (RTL) formatting. Examples of RTL languages include Arabic and Hebrew.

Examples

> **NOTE**
> The Microsoft repos contain many files, so the process takes several minutes. If you run the tool against multiple localization repos, the process takes longer.

The following example clones the en-US repo and generates HTML files.

```
HtmlFromRepoGenerator.exe --out "D:\BC\en-US" --repo "https://github.com/MicrosoftDocs/dynamics365smb-docs"
--LogsDir D:\BC\logs\en-US
```

The following example uses a previously cloned en-US repo and generates HTML files.

```
HtmlFromRepoGenerator.exe --out "D:\BC\en-US" --DoNotClone --LogsDir D:\BC\logs\en-US
```

The following example clones both the de-DE and en-US repos, and generates HTML files for de-DE.

```
HtmlFromRepoGenerator.exe --out "D:\BC\de-DE" --repo "https://github.com/MicrosoftDocs/dynamics365smb-docs-
pr.de-de" --EnRepo "https://github.com/MicrosoftDocs/dynamics365smb-docs" --EnOut "D:\BC\en-US" --lng "de-
DE" --LogsDir D:\BC\logs\de-DE
```

The following example uses previously cloned de-DE and en-US repos to generate HTML files for de-DE. Make sure that the de-DE repo is up to date if you use an existing cloned repo.

```
HtmlFromRepoGenerator.exe --out "D:\BC\de-DE" --DoNotClone --enOut "D:\BC\en-US" --lng "de-DE" --LogsDir
D:\BC\logs\de-DE
```

IMPORTANT

Do not run HtmlFromRepoGenerator.exe repeatedly on a previously-cloned repo. HtmlFromRepoGenerator modifies the links during processing, so running HtmlFromRepoGenerator more than once on the same content will result in incorrect links. If you want to rerun HtmlFromRepoGenerator, either use HtmlFromRepoGenerator to create a new clone of the repo, or revert all local changes to your existing clone.

Modifying the styling of the generated HTML files

The tool generates the HTML files based a set of predefined templates. In most cases, you can modify the stylesheets in the `styles` folder to modify the appearance of your content.

For advanced scenarios, you can modify the templates used by the HtmlFromRepoGenerator tool. The source files are included in the *SourceCode* folder in the GitHub repo. The templates are in the *SourceCode\HtmlFromRepoGenerator\HtmlFromRepoGenerator\HtmlFromRepoGenerator\Resources* subfolder.

NOTE

If you modify the templates, you must rebuild HtmlFromRepoGenerator.exe using Visual Studio or similar.

For more information, see Introduction to DocFX Template System.

Custom Help Toolkit

Custom Help Toolkit: The HtmlLocaleChanger tool

2/17/2021 • 2 minutes to read • Edit Online

The custom help toolkit includes the **HtmlLocaleChanger** tool that can process HTML files containing Help content for Business Central to change the metadata for language.

HTML files published by Microsoft for documentation contain the ms.locale metadata which describes the language of the content. Depending on the website that you deploy your content to, the value can be used to switch between different translations of the content. For example, on the docs.microsoft.com site, the value specifies if the version of the article that is published under the URL `https://docs.microsoft.com/de-de/dynamics365/business-central` is in fact in German (Germany) or in another language, such as English. The same value is also used in the translation process.

Use the HtmlLocaleChanger tool to align locales

The **HtmlLocaleChanger** tool can update your HTML files with a new value for the *ms.locale* entry in the metadata for the specified files. For example, if you have HTML files for German (Germany) and you want to make the same content available in German (Austria), then copy the files to a new folder, and then run the tool to change the setting from *ms.locale: de-de* to *ms.locale:de-at*.

Here is the syntax for HtmlLocaleChanger.exe:

```
HtmlLocaleChanger.exe --h <path> --l <locale> --v <true|false>
```

Here is an explanation of the parameters:

PARAMETER	DESCRIPTION
h	Specifies the path to the HTML files that you want to process.
l	Specifies the new locale for the HTML files.
v	**true** to enable verbose logging; otherwise **false**.

Example

The following example changes the original locale to *de-at* with verbose logging:

```
HtmlLocaleChanger.exe --h D:\BC\de --l de-at --v
```

In the example, the `D:\BC\de` folder contains HTML files with the locale *de-de*, and the command changes that locale setting to *de-at*. You can now publish the relevant HTML files to your website in both locales.

Custom Help Toolkit
Custom Help Toolkit: The HtmlFromRepoGenerator tool

Custom Help Toolkit: The FieldTopicTextExtractor tool

2/17/2021 • 2 minutes to read • Edit Online

If you are migrating a solution from Dynamics NAV to Business Central, you can use this tool to export the text contained in the first paragraph of field-level Help topics for Microsoft Dynamics NAV 2018 or earlier versions. You can then use these paragraphs as tooltip text in your Business Central solution.

> **NOTE**
> The tool does not import the tooltip text directly into your Business Central page objects. Instead it creates a spreadsheet that will make it easier to reuse the text from field-level Help topics in your Business Central solution.

Use the FieldTopicTextExtractor tool to extract content Excel

Use the **FieldTopicTextExtractor** tool to populate an Excel workbook with the field IDs and the corresponding first paragraph from a set of HTML topics from the Dynamics NAV field-level Help. The Dynamics NAV field topics have a name in the format `T_10_20.html` for field 20 on table 10. The name of the resulting Excel spreadsheet will be in the format Field_topic_summaries*.xlsx.

Here is the syntax for FieldTopicTextExtractor.exe:

```
FieldTopicTextExtractor.exe --n --o
```

Here is an explanation of the parameters:

PARAMETER	DESCRIPTION
n	Specifies the path to the HTML files with Dynamics NAV field topics.
o	Specifies the path where the Excel spreadsheet must be created.

Examples

The following example extracts the introductory paragraph from T_*.htm files in D:\NAV to an Excel spreadsheet with the name Field_topic_summaries*.xlsx in D:\BC:

```
NavFieldsTooltips.exe --n D:\NAV --o D:\BC
```

After extracting the Dynamics NAV field topic text

Excel makes it easy to bulk-apply and bulk-edit strings because you can sort and filter data. If you work with dedicated technical writers, then they are probably more efficient if they can work with tooltip text in Excel prior to adding tooltip text to your Business Central solution. You can also take the opportunity to revise the text. For more information, see Guidelines for tooltip text.

Before you import the tooltips into your solution, map the original field IDs to page control IDs in your Business Central solution. It requires knowledge of the actual solution to determine which tooltips are relevant for which pages, and Excel is very handy to help you in this process.

Migrate Legacy Help to the Business Central Format

Extend, Customize, and Collaborate on the Help for Dynamics 365 Business Central

2/17/2021 • 18 minutes to read • Edit Online

The source files for the Help for the base application are available in public GitHub repos so that you can easily extend and customize the content for your customers. In this section, you can learn about working with the GitHub repos and MarkDown files. You can also find guidance in the Docs Contributor Guide.

> **TIP**
> If you want to get Microsoft's content and deploy it to your own website with or without customizations, see Custom Help Toolkit.

Get content from the GitHub repos

There are repos in GitHub for the source content and each of the languages that Microsoft translates to. The dynamics365smb-docs repo contains the source content in English (US). If you want access to the content in other languages, navigate to the relevant repo - the names follow this pattern: `dynamics365smb-docs-pr.<language>-<country>`, such as dynamics365smb-docs-pr.da-DK for the Danish version.

You can use the HtmlFromRepoGenerator tool to get the latest version of Microsoft's content and generate HTML files that you can then customize. The tool handles the GitHub work for you, but you will still have to understand the basics of the Microsoft GitHub repos.

When Microsoft publishes an update to the content, the *live* branch in the corresponding GitHub repo is updated. The source repo is updated at least weekly; however, the related language-specific repos are updated less frequently, based on when new translations are made available. You can use the Custom Help Toolkit to get the current version of Microsoft's content and prepare HTML files for customization. Alternatively, if you customize the Microsoft content based on MarkDown, you can use scripts to get the current version. The GitHub platform and tooling will help you manage any potential merge conflicts if you have made changes to the same files as Microsoft has. For more information, see Set up Git repository locally for documentation in the Docs Authoring Guide and Fork a repo in the Help for GitHub.

> **TIP**
> You do not have to get acquainted with GitHub if you just want to get the Microsoft content in HTML format to deploy to a website, for example. You do not even have to get a GitHub account, as shown in the Getting by without GitHub section. However, in many scenarios, you might want to join us in GitHub for closer collaboration and easy of extensibility.

If you fork one of our repos, you can choose to update your fork with regular updates from the Microsoft repo.

For guidance about what the Microsoft-provided content for Business Central is all about, see User Assistance Model.

The remaining sections of this article are intended for people who do **not** use the Custom Help Toolkit - and for the curious. See the following table to find what you want to learn more about.

What the GitHub repos contain

Microsoft's GitHub *dynamics365smb-docs* repos for Business Central Help contain the following folders:

- archive

  Contains files that are not published but kept for backwards compatibility use internally at Microsoft. You can ignore this folder.

- business-central

  Contains files that are relevant for Business Central

- media-source

  Contains source files for some of the pictures that are used in the Business Central content

- Templates

  Contains a template that you can use if you build HTML files for the legacy Dynamics NAV Help Server website

The repos also contain files in the root of the repos that are used internally by Microsoft for managing the content on the docs.microsoft.com site and on GitHub. They are not relevant for the purpose of extending or customizing the content.

> **TIP**
> The Business Central installation media still contain CAB files for Help Server; however, the latest content is always available in the GitHub repos. If you find that the CAB files are outdated, or if they do not contain the files that you expect, get the latest files from GitHub. For more information, see the Get updates from Microsoft and Get the content without a GitHub account sections, respectively.

If you want to contribute to the developer and administration content, clone or fork the

`https://github.com/MicrosoftDocs/dynamics365smb-devitpro-pb` repo

Get updates from Microsoft

Microsoft makes frequent changes to the Business Central content, and those changes show up in the public GitHub repos. The base repo, MicrosoftDocs/dynamics365smb-docs, is updated weekly, and the translations are updated monthly. When you decide it is time to get the latest version of the content from Microsoft, you can do that using GitBash or GitHub Desktop. In the Help for GitHub, you can see an example of how this works in GitBash. In GitHub Desktop, just use the *Merge into current branch* menu item to pull changes from the origin into your fork.

However, if your solution is available in more than one country, then you are likely to want to make content available in multiple languages. Microsoft has a GitHub repo for each supported language, but the configuration files are only available in the English (US) source repo, MicrosoftDocs/dynamics365smb-docs.

The following script was developed by a Danish partner in order to get the Microsoft source for a number of languages, copy media files to the localization repos, and then build HTML files. The script is provided in agreement with the partner without further support.

```
$languages = $("da-dk","de-ch","de-de")
$git = "C:\Program Files\Git\cmd\git.exe"
$docfx = "C:\GitHub\DocFx\docfx.exe"
$365docs = "C:\GitHub\MSFT\dynamics365smb-docs"
$langDir = "c:\Working\help\dynamics365smb-docs-pr."

Start-Process -FilePath $git -ArgumentList "clone --single-branch --branch live
https://github.com/MicrosoftDocs/dynamics365smb-docs.git" -WorkingDirectory "C:\working\help" -Wait
foreach ($language in $languages)
{
    $arguments = $("clone --single-branch --branch live https://github.com/MicrosoftDocs/dynamics365smb-
docs-pr." + $language + ".git")
    Start-Process -FilePath $git -ArgumentList $arguments -WorkingDirectory "C:\working\help" -Wait
    Copy-Item $($365docs + "\business-central\docfx.json") $($langDir + $language + "\business-central")
    Copy-Item $($365docs + "\business-central\media") $($langDir + $language + "\business-central") -Recurse
-Force
    Copy-Item $($365docs + "\business-central\LocalFunctionality") $($langDir + $language + "\business-
central") -Recurse -Force
    Copy-Item $($365docs + "\Templates") $($langDir + $language) -Recurse -Force
    Set-Content -Path $($langDir + $language + "\business-central\docfx.json") -Value (get-content -Path
$($365docs + "\business-central\docfx.json"))
    Start-Process -FilePath $docfx -ArgumentList $("C:\working\help\dynamics365smb-docs-pr." + $language +
"\business-central\docfx.json" + " --output c:\working\output\" + $language)
}
```

For more information, see the Build HTML files section.

Because the Microsoft repos are public, you do not need a valid GitHub account in order to get the content. However, we recommend that your organization has a system account with access to GitHub at a minimum.

Get started with GitHub

To join Microsoft in the world of GitHub and MarkDown, there are new terminology and tools to get used to. The following list outlines the main steps, but you can find additional content, tools, and ideas in the GitHub documentation and other forums.

1. Fork the right repo

   You cannot work directly in the Business Central repos in the MicrosoftDocs GitHub org, such as the dynamics365smb-docs repo. The first thing you need to do is create a fork of the repo under your GitHub account. A fork is a copy of this repo that lets you work freely on the content without affecting the MicrosoftDocs/dynamics365smb-docs repo.

Alternatively, you can *clone* the Microsoft repo. This is useful if you don't intend to customize Microsoft's content, for example. But in many cases, *forking* the repo is more preferable.

For more information, see Set up your GitHub account and Set up Git repository locally for documentation in the Docs Authoring Guide.

> **TIP**
> You are not required to make your GitHub repos public. When you fork a public repo, you can specify in the settings for the new repo if the repo is public, private, or available only to specific GitHub accounts.

2. Install GitHub Desktop (optional) and clone your forked repo.

   GitHub Desktop makes is easy to work and collaborate with repos locally from your own desktop. For more information, see GitHub Desktop.

3. Get hold of your favorite MarkDown editor, and start making changes.

   The help content is stored in the *business-central* folder of the repo. Articles use a syntax for formatting text called Markdig Flavored Markdown, which is CommonMark compliant. To learn more about working with markdown, see Getting started with writing and formatting on GitHub.

   If you want to work locally, you can edit using any text editor. Just save the file as a .md type. Here are two good tools that provide you with some nice features, including a preview of how the content will be rendered in HTML:

   - Visual Studio Code

     Add the Docs Authoring Pack for Visual Studio Code, which gives you spell checker, MarkDown validation, and many other productivity features

   - Atom

     Atom has spell check and is good for managing many files

Internally at Microsoft, some authors use Code, others use Atom, and for light-weight work, we tend to just edit the content in the browser. You can find more guidance for how to get started with MarkDown in the Docs Contributor Guide. This guide is published by the team that built the Docs.microsoft.com site where the Business Central team publishes their docs.

Contributing

A benefit of GitHub is the ability for you to contribute to the core content that the Microsoft team provides in the dynamics365smb-docs repo. For example, you might have a new article that you think would be beneficial or you might have a correction to an existing article. If you would like to contribute to the MicrosoftDocs/dynamics365smb-docs repo, you create a *pull request* from your repo to the MicrosoftDocs/dynamics365smb-docs repo. The Microsoft team will then review the request and include the changes as appropriate.

> **NOTE**
> Microsoft accepts pull requests to the *dynamics365smb-docs* repo only, not the language-specific repos. If you have feedback about translations, you can report a GitHub issue in the relevant repo.

To create a pull request to the MicrosoftDocs/dynamics365smb-docs repo by using GitHub Desktop, do the following:

1. Commit the changes to your repo that you want to include in the pull request.

2. Choose **Sync** to push the changes up to your repo on GitHub.
3. When the sync is completed, choose **Pull Request**, make sure that the pull request points at the *live* branch, and then choose **Pull Request**.

Get the content without a GitHub account

If you do not want to collaborate with Microsoft on the content, you can get the latest version of the content from GitHub without a GitHub account. For example, if you want content that is newer than the content on the Business Central installation media, you can get the latest by simply downloading the content of the relevant GitHub repo, which you can do without a GitHub account - the Microsoft repos are public so that anyone can always get to them. Use the HtmlFromRepoGenerator tool, create your own scripts, or follow this process to fork a repo manually.

To get files without a GitHub account

1. Go to the relevant GitHub repo, such as this one for German: https://github.com/MicrosoftDocs/dynamics365smb-docs-pr.de-de/.

   You can see in the browser when the content was last updated.

2. Choose the green **Clone or download** button, and then choose **Download ZIP**.

3. Open the downloaded *dynamics365smb-docs-pr.de-de-live.zip* file and extract to a relevant location.

   Now you have a copy of Microsoft's content. Next, you can generate HTML files for use on your website as described in the Build HTML files section.

Build HTML files

For publishing to your own website, you can use the HtmlFromRepoGenerator tool that is part of the custom Help toolkit for Business Central to clone a repo and generate the corresponding HTML files.

Alternatively, you can create your own tooling and processes around DocFx, which is an open-source tool for converting markdown files. This section provides some guidance on how you can use DocFx to publish HTML files from your fork of one of the Microsoft repos. You can find additional tips in the Custom Help Toolkit article.

> **TIP**
> You can also use DocFx to generate content for the legacy Dynamics NAV Help Server. In that case, use the NAV docfx.json file from dynamics365smb-docs.

1. Install DocFx on your computer.

   DocFx is a command line tool, but you can also run it from a PowerShell script.

   You must provide a .JSON file that defines certain build settings, including the output folder in which to store the generated HTML files. We suggest that you use the docfx.json configuration file from the dynamics365smb-docs repo. For more information, see Getting Started with DocFX.

2. To change settings in the docfx.json file, open the docfx.json file from the folder containing your local clone in your preferred editor.

   The following table describes key parameters for you to customize.

PROPERTY	DESCRIPTION

PROPERTY	DESCRIPTION
dest	Specifies the output folder of the generated HTML files, such as `c:\Working\output\`.
template	Specifies the templates that the HTML files will be generated after. The default for Microsoft is blank, but the value can be a string or an array.
globalMetadata	Contains metadata that will be applied to every file, in key-value pair format. We encourage you to use this property to apply the `ROBOTS: NOINDEX, NOFOLLOW` metadata to each HTML file. The intent is that search engines will find Microsoft's original content on the docs.microsoft.com site rather than any customizations that you and hundreds of other may have published. For an example, see the NAVdocfx.json file. If you use the NAVdocfx.json file to build HTML files for non-Microsoft functionality, then change the value of the `ROBOTS` property. You can also add other global metadata, or metadata that applies to specific subfolders.
fileMetadata	Contains metadata that will be applied to specific files, based on the specified parameters, in key-value pair format. The default is currently blank.
markdownEngineName	Specifies the "flavor" of MarkDown to use to build the HTML files. The default is `markdig`.

For more information, see the Properties for build section in the DocFx user manual.

The docfx.json files in the Microsoft repos have additional settings for the docs.microsoft.com site. If you build the HTML files based on the docfx.json in the Microsoft repos, make sure that you have configured it for your needs.

3. If you have cloned a localization repo such as dynamics365smb-docs-pr.da-dk, you must also clone the dynamics365smb-docs repo and copy the content of the \business-central\media\ folder.

   The localization repos only contain the files that are translated into the relevant languages. Microsoft does not translate all illustrations; therefore, the localization repos do not contain the many untranslated images, screenshots, and other illustrations. If you build a localization repo as-is, then the HTML files will have broken links to the missing illustrations.

   In the sample script described above, the following command copies the media folder:

   ```
   Copy-Item $($365docs + "\business-central\media") $($langDir + $language + "\business-central") -
   Recurse -Force
   ```

4. Go to your desktop and open a command prompt.
5. Go to the docfx installation folder.
6. Run the equivalent of the following command:

   ```
   docfx "c:\GitHub\MSFT\dynamics365smb-docs\business-central\docfx.json"
   ```

The files are generated as .html files and stored in the output location that is specified in the docfx.json file.

> **IMPORTANT**
>
> Depending on the website that the HTML files will be deployed to, you might not be able to use the table of contents file (TOC.html) that is generated in this process. That file is structured based on the configuration of the https://docs.microsoft.com site. If you use the legacy Dynamics NAV Help Server, then you must use the ToC.xml file instead.

The table of contents on the docs.microsoft.com site is currently a MarkDown file, TOC.md, but we are planning to convert it to a YAML file in order to be more compliant with the docs.microsoft.com site. Once we have converted the TOC.md file to TOC.yml, you will still be able to use DocFx.exe to build HTML files, but you will have to port your customizations of the TOC.md file to the new YAML format.

The root of the MicrosoftDocs repos contain files that are related to internal Microsoft processes, such as `.openpublishing.build.ps1`. These scripts are used to validate and preview content, but they rely on internal Microsoft resources that are not publicly available. The `.openpublishing.redirection.json` file lists files that were published to the docs.microsoft.com site but have been deprecated later. As part of standard website practices, the docs.microsoft.com site uses redirection to avoid broken links when a page is deleted, and the `.openpublishing.redirection.json` file provides the mapping for redirection.

For inspiration for how to build your own help website, see How-to: Customize DFM Engine in the DocFx user manual and the Azure App Service documentation.

For tips and tricks about writing in MarkDown, see the Authoring Guide.

Links to anchors across languages

If your website supports two or more locales, you can use DocFx to generate HTML files for the relevant languages. However, you may experience problems with links to anchors, also known as bookmarks.

For example, if your content has a link from article1.md to a specific section in article2.md, that link would be formatted like this: `[My translated subheading](article2.md#my-translated-subheading)`. Then, when you run DocFx to generate HTML files in Danish, DocFx will convert that link to `[Min oversatte overskrift](article2.md#min-oversatte-overskrift)`. That is not a problem because the link will work in both English and Danish.

But if you then want to use that link elsewhere, the link only works for one of the languages because the anchor changed its name in the Danish translation. If you link to that subheading in article2 from your marketing site or support site, or if you use it as the value of the ContextSensitiveHelpPage property, then it only works in English.

To work around this problem, we recommend that you create explicit anchors by tagging your subheading to give it a *fixed anchor*. The following example illustrates how that would look in MarkDown:

```
### <a name="subheading"></a>My translated subheading
```

You would then be able to use the same link across all locales:
`[My translated subheading](article2.md#subheading)`, which would render in HTML as `myurl.com/docs/article2#subheading` across all languages.

For more information, see Using hashtag in cross reference in the GitHub documentation.

> **NOTE**
>
> Adding fixed anchors is only relevant if you want to generate a link to a subheading that works consistently across languages.

Alternatively, you can add a post-processing step to the script that you use to run DocFx to change the equivalent of `<h3 id=da-DK-anchor-name>` with `<h3 id=en-US-anchor-name>`. In this example, the step would change `<h3 id=min-oversatte-overskrift'>` to `<h3 id=my-translated-subheading'>`.

Known issues with Microsoft's content

Microsoft's content in the various GitHub repos is optimized for the docs.microsoft.com site and the tools that are used for this site. If you reuse Microsoft's content, you may experience a number of known issues, depending on how you publish your content. This section describes recommended steps to work around these issues.

Docs are not available for a specific version

Microsoft's public GitHub repos reflect the latest version of Business Central. If you want to deploy help for an earlier version of Business Central on-premises, then you can use the HTML files on the installation media. If you find that that particular version is missing content, then please check the following sections for suggested workarounds.

Broken links

If you deploy Microsoft's content to a website, your tools or your users will report that some links do not work. The links result in a 404 error or similar. These errors are caused by Microsoft having deleted the target files due to rework of the content. On the docs.microsoft.com site, we have tools that automatically handle links to deleted files through redirection. But if you deploy Microsoft's content to your own website, you will not have the same redirection.

We run periodic tests to catch these errors, but if you do see an error that is caused by a file not existing anymore, check the `.openpublishing.redirection.json` file in the root of the source repo. This file is used by the docs.microsoft.com site to manage redirection when a file is deprecated. For example, if you get an error that *"finance-how-to-set-up-sepa-direct-debit.md does not exist"*, then you can see in the `.openpublishing.redirection.json` file that the article has been deprecated and replaced by *finance-collect-payments-with-sepa-direct-debit.md*. You can replace the link in the file that is looking for *finance-how-to-set-up-sepa-direct-debit.md* to link to *finance-collect-payments-with-sepa-direct-debit.md* instead.

> **TIP**
> Use the HtmlFromRepoGenerator tool to manage this for you.

ToC.xml for Help Server is different from the TOC.md file

Microsoft does not currently maintain the ToC.xml file and does not add new features to it. While the Help Server component is still supported, it will be deprecated in 2021 release wave 1. As a result, it contains links that are broken as described in the previous section.

Translated content is not available

Microsoft creates content in English (US) that then gets translated into the Microsoft-provided target languages. The translations are available in the relevant localization repos within a few weeks.

Translate the content

You can use the Dynamics 365 Translation Service (DTS) to translate your own or the Microsoft-provided content into other languages. The service is hosted in Lifecycle Services and currently supports translation of content in Word documents and HTML files. For more information, see Translate documentation files.

To translate content for either Business Central or Dynamics NAV, choose Dynamics NAV as the product as shown in the following illustration:

Authoring Guide for Dynamics 365 Business Central

2/17/2021 • 9 minutes to read • Edit Online

If you are contributing to the Business Central Help, or if you are customizing and extending the Microsoft content for your own solution, you will probably want to use the same tools, processes, and style guide that Microsoft uses.

Resources

- The Microsoft Writing Style Guide is published online

  The content on the Docs.microsoft.com site generally follows the Microsoft Writing Style Guide. The content for Business Central varies in certain ways, partly with product-specific terminology, and a generally more conservative approach to contractions, for example.

- Extend, Customize, and Collaborate on the Help shows you the basics of collaborating on content for Business Central
- The Docs Contributor Guide has many tips and tricks for authoring in MarkDown
- The Docs Authoring Pack for Visual Studio Code adds productivity tools to Visual Studio Code

Write for accessibility

At Microsoft, we write for accessibility, which also means that the same content applies to interactions with the software across devices, regardless of input method, for example. For more information, see Describing interactions with UI in the Microsoft Writing Style Guide.

The accessibility requirements also impacts metadata for illustrations, such as the following:

```
:::image type="content" source="media/illustration.png" alt-text="Text used by screen readers":::
```

Most of Microsoft's articles use a different MarkDown formatting for illustrations, such as the following:

```
![Lightbulb that opens the Tell Me feature](media/ui-search/search_small.png "Tell me what you want to do")
```

Both formats are valid MarkDown, and both formats are supported by DocFx.exe. For more information, see Images in the Docs Contributor Guide.

Authoring in MarkDown

The Business Central content is styled using a MarkDown syntax as described below. Extended guidance is available in the MarkDown Reference section in the Docs Contributor Guide.

Headings

Use `#` for headings. For more information, see Headings in the Docs Contributor Guide.

In the source files for the Business Central content, which publishes as English (US) on the Docs.microsoft.com site, the title of an article is expected to use Title Case (capitalize each word, except prepositions) whereas subsequent headings use Sentence case (capitalize the first word, only). The Microsoft Writing Style Guide recommends a different approach.

Metadata

The content on the Docs.microsoft.com site includes metadata that is used by the site and feeds our internal telemetry dashboards. The metadata is required for Microsoft's content but not necessarily for content that extends or customizes Microsoft's content.

However, some metadata is recommended as a best practice as outlined in the following table.

METADATA TAG	DESCRIPTION
title	Used by search engines. Recommended length of 60-70 characters, including spaces. We recommend that the title metadata is the same as the first heading in the article.
description	Used by search engines. Recommended length of 100-160 characters, including spaces.
author	GitHub account of the main contributor to the article.
ROBOTS	Please apply this tag if you customize one of Microsoft's articles and deploy that to your website. By applying the metadata `ROBOTS: NOINDEX, NOFOLLOW`, you help make sure that search engines will find the original article rather than your customized version. Users of your Help will still be able to find the customized article through context-sensitive Help links and other links.

Bulleted lists

Use `-` or `*` to create bullets as shown in the following example:

```
The following options are available:

- first option
- second option
- third option
```

> **TIP**
> It doesn't matter if you use `-` or `*`, but the current version of the Docs Authoring Pack requires each article to use one or the other and not mix them up.

As a best practice, the MarkDown validation in the current version of the Docs Authoring Pack recommends a blank line between options in a bulleted list for better readability in MarkDown.

Ordered lists

Use numbers for ordered lists. Do not add spaces between the lines.

```
1. Choose the ![Lightbulb that opens the Tell Me feature](media/ui-search/search_small.png "Tell me what you
want to do") icon, enter **Payment Journal**, and then choose the related link.
2. In the **Payment Journal** window, on the first journal line, enter the relevant information about the
payment entry.
3. To apply a single vendor ledger entry:
4. In the **Applies-to Doc. No.** field, choose the field to open the **Apply Vendor Entries** window.
```

Bold and italics syntax

Use `**bold**` and `*italics*`

Tables

For tables in the body, use the markdown syntax. The Docs Authoring Pack for Visual Studio Code has a shortcut for adding a table, and you can also use Tables Generator.

```
| To   | See                       |
|------|---------------------------|
|<text>|<link>|
| | |
| | |
```

MarkDown syntax for nested tables is limited, so we recommend using HTML-syntax for nested tables in ordered and unordered lists use HTML-syntax.

Placeholders

Rather than repeating text in two or more articles, use *includes*. For more information, see Included Markdown files.

For Business Central, we use includes for boilerplate text, for content that is repeated in more than one article, and for the product name. That way, we can make changes in just one location - and so can you.

> **TIP**
> In the dynamics365smb-docs repo, the includes are in the `business-central\includes` subfolder.
>
> In December 2020, the two placeholders for the product name, prodshort.md and prodlong.md, were renamed to prod_short.md and prod_long.md. The change solved a problem internally at Microsoft, because we have a tool that helps identify spelling error, and that tool generated warnings for prodshort.md and prodlong.md.

Comment syntax

Useful for sections that are not ready and will not pass build checks.

```
<!-- Comments -->
```

Examples:

```
<!-- [Managing Payables](payables-manage-payables.md)-->
<!-- This is a paragraph that spans more lines and I can just put the comment tag
at the beginning and end of it -->
```

Links

Ordinary link to a different topic in the same folder

These links have the format `[link text](filename.md)`.

Example: `[Managing Payables](payables-manage-payables.md)`

Link to a topic in a subfolder of the source topic

These links have the format `[link text](subfolder/filename.md)`.

For example, you want to link to payables-manage-payables.md from ui-work-general-journals.md, where the folder structure is as follows:

- articles

    - ui-work-general-journals.md
- ManagePayables
    - payables-manage-payables.md

Here is the link: `[Manage Payables](ManagePayables/payables-manage-payables.md)`

Link to a topic in a different folder than source topic

These links have the format `[link text](../folder/filename.md)`.

For example, you want to link to payables-manage-payables.md from receivables-manage-receivables.md, where the folder structure is as follows:

- articles
    - ManageReceivables
        - receivables-manage-receivables.md
        - ui-work-general-journals.md
        - ManagePayables
            - payables-manage-payables.md

Here is the link: `[Manage Payables](../ManagePayables/payables-manage-payables.md)`

Link to a place in the same article

From within an article, you can create a link to a specific heading in the same article. You can create the link like other links except with the following format:

`[link text](#target-heading)`

target-heading is the text of the heading that you want to link to, except it is all lowercase and spaces between words are replaced with hyphens. For example, here is the link:
`[How Autoscaling Works](#how-autoscaling-works)`

To the heading: `## How Autoscaling Works`

Link to a place in a different article

From an article, you can create a link to a specific heading in another article. You can create the link like other links except with the following format:

`[link text](targetarticlename#target-heading)`

targetarticlename is the file name of the article, including the .md file type. target-heading is the text of the heading that you want to link to, except it is all lowercase and spaces between words are replaced with hyphens.

For example, to link to the heading "How autoscaling works" in the article Autoscaling.md, add the following code: `[How autoscaling works](Autoscaling.md#how-autoscaling-works)`

Links to anchors across languages

If your website supports two or more locales, you can use DocFx to generate HTML files for the relevant languages. However, you may experience problems with links to anchors, also known as bookmarks.

For example, if your content has a link from article1.md to a specific section in article2.md, that link would be formatted like this: `[My translated subheading](article2.md#my-translated-subheading)`. Then, when you run DocFx to generate HTML files in Danish, DocFx will convert that link to `[Min oversatte overskrift](article2.md#min-oversatte-overskrift)`. That is not a problem because the link will work in both English and Danish.

But if you then want to use that link elsewhere, the link only works for one of the languages because the anchor changed its name in the Danish translation. If you link to that subheading in article2 from your marketing site or

support site, or if you use it as the value of the ContextSensitiveHelpPage property, then it only works in English.

To work around this problem, we recommend that you create explicit anchors by tagging your subheading to give it a *fixed anchor*. The following example illustrates how that would look in MarkDown:

```
### <a name="subheading"></a>My translated subheading
```

You would then be able to use the same link across all locales:
`[My translated subheading](article2.md#subheading)`, which would render in HTML as
`myurl.com/docs/article2#subheading` across all languages.

For more information, see Using hashtag in cross reference in the GitHub documentation.

> **NOTE**
> Adding fixed anchors is only relevant if you want to generate a link to a subheading that works consistently across languages.

Line breaks (soft return)

In the editor, add two blank spaces at the end of the sentence and hit return. This is used in the See Also list. (See Also must be heading 2.)

Continue steps after a non-step para

Enter four spaces in front of the non-step para. Otherwise, the non-step para will restart the step sequence.

TOC

The TOC structure of the TOC.md file is as follows:

```
#[Overview](overview.md)
 ##[Topic 1](topic-1.md)
 ##[Topic 2](topic-2.md)
 ##[Topic 3](topic-3.md)
 ##[Topic 4](topic-4.md)
```

Standard phrases

All fields in Business Central have tooltips; therefore, do not document fields in Help. To refer readers to the tooltips, use this standard phrase where relevant:

> "Choose a field to read a short description of the field or link to more information."

For more information, see Business Central User Assistance Model.

Recycle content

Rather than copy-pasting content that you want to surface in two or more places, use *includes*. For more information, see Included Markdown files in the Docs Contributor Guide.

Topic titles

- Use imperative verb form for step-based topics ("Pay vendors").
- Use gerund verb form for conceptual, non-step topics. ("Paying Vendors")
- Use nouns for highest-level topics. ("Sales")

File naming

Rules

- No spaces or punctuation characters. Use hyphens to separate the words in the file name.
- Use all lowercase letters
- No more than 80 characters - this is a publishing system limit
- Use action verbs that are specific such as develop, buy, build, troubleshoot. No -ing words.
- No small words - don't include a, and, the, in, or, etc.
- All files must be in markdown and use the .md file extension.

Examples

TOPIC TITLE	NAMING
Select a Company	ui-how-select-company.md
Enter Criteria in Filters	ui-enter-criteria-filters.md
Troubleshooting: Record Locked by Another User	ui-troubleshoot-record-locked-another-user.md
Changing Basic Settings	ui-change-basic-settings.md
Sales	sales-manage-sales.md
Set Up Currencies	finance-setup-currencies.md
Set Up Purchasers	purchases-how-setup-purchasers.md
Understanding Session Timeouts	admin-understand-session-timeouts.md
Manage Data Encryption	admin-manage-data-encryption.md

Country-specific content

To simplify content localization and translation, country-specific articles live in country-specific folders. The TOC entries live under the "Local Functionality" parent node.

Blog post: Collaborate on content for Business Central

Administration of Business Central Online

2/17/2021 • 13 minutes to read • Edit Online

As an administrator, you can manage Business Central online tenants both as an internal administrator, who is typically an employee of the company that bought the Business Central subscription, and as an administrator from the reselling partner company. Some of the tools are the same, and some tools are available to partners only. Here you can learn which tools are available to you as an administrator.

Administration as an internal administrator

Internal administrators are the system administrators, IT professionals, or superusers of the customer's company, who are assigned the **Global admin** role in the Microsoft 365 admin center. For more information, see About admin roles in the Microsoft 365 admin content.

Administration in Business Central

As the internal administrator, you can add users and grant permissions. For more information, see Create Users According to Licenses and Assign Permissions to Users and Groups in the business functionality content for Business Central.

As an internal administrator you have **read-only** access to all areas of Business Central. You will have this access even if your organization decides not to continue with Business Central and cancels the subscription. That way, you, as the internal administrator, can export relevant data, while no one else in your organization has a license to sign in and use Business Central.

> **IMPORTANT**
>
> You must have a Business Central license in order to set up integration to other products, or perform any other tasks in Business Central, except the two mentioned above. For information about licensing, see Microsoft Dynamics 365 Business Central Licencing Guide.

For other tasks, you can access the Business Central administration center, where you can manage upgrade schedules and other tasks. For more information, see The Business Central Administration Center.

You can also use telemetry to track usage and monitor user sessions, for example. For more information, see Monitoring and Analyzing Telemetry and Managing Sessions.

Administration of a trial

If your organization has signed up for a Business Central trial, you can extend the free trial, and you can start the process of finding a reselling partner to help you get a subscription. For more information, see Dynamics 365 Business Central Trials and Subscriptions.

Administration in the Microsoft 365 admin center

The **Global admin** role makes you an administrator of your organization's Microsoft 365 tenant. This means that you can manage the subscription, add or remove users, and assign or remove licenses in the Microsoft 365 admin center. For more information, see Microsoft 365 Admin help center.

Collaboration with reselling partners

When your organization subscribes to Business Central, you have a relationship with an authorized partner of Microsoft. The partner company assists with licensing, configuration, and other tasks. They can also help you get telemetry about your Business Central environment.

The partner will have access to your tenant as a *delegated administrator*. You can configure their access to your data. For more information, see Managing delegated permissions as an internal administrator.

If your organization decides to switch to another partner, you must take the following steps:

1. Ask your current partner to remove the reseller relationship with you in the Partner Center
2. Remove their delegated administration privileges
    a. In the Microsoft 365 admin center, under **Settings**, choose **Partner relationships**, and then select the partner of interest
    b. In the details pane, choose **Remove delegated admin**
    c. In the confirmation pane, choose **Remove**

    You must also disable their user accounts from your Business Central.
3. Remove any settings in the Business Central administration center if the partner did not already clear their settings.

    For more information, see Internal administrators.
4. Add your new partner to your subscription, and work with them to get them set up

Unsubscribing from Business Central

If the organization decides not to continue with Business Central, you can then cancel the subscription.

In the Microsoft 365 admin portal, you can remove licenses from users. As the administrator, you can remove a trial subscription from your company's account. But to cancel a paid subscription, you must contact your reselling partner, and they can cancel the relevant subscription in the Partner Center.

For more information, see Unsubscribe or Remove Business Central in the business functionality content for Business Central.

Administration as a partner

As a Business Central reselling partner, you are the administrator of the Business Central tenants of your customers. You have access to the administration tools of their Microsoft 365 account and their Business Central administration center where you can specify update windows. You can also log into their Business Central as a *delegated administrator* if you want to reproduce errors.

Join the Microsoft Partner Network

Microsoft Partner Network (MPN) membership unlocks our best resources to differentiate your business, take your product to market, and sell your solutions. To become a partner, you must join the Microsoft Partner Network (MPN), at which time you will be assigned an MPN ID. MPN membership is free to all partners; you can enroll in the MPN here.

Once signed up, you will get an MPN ID – your gateway to access all the membership resources and benefits for your partnership with Microsoft. There is no cost to obtain a MPN ID as a Network member, and with options to upgrade to an Action Pack subscription or work toward a competency, you can access even more benefits.

Set up your Partner Center account

Once you have joined the Microsoft Partner Network (MPN), you can set up your Partner Center (PC) account. The Microsoft Partner Center is a generic portal where partners can sell and manage customer subscriptions for Microsoft services, such as Microsoft 365, Azure, Dynamics 365, and others, as well as for some third-party products. For more information, see the Partner Center documentation.

Your Partner Center account provides you with access to pricing information, tools and services, and enables you to manage admin credentials for your company's work account. Partner Center is also where you can

purchase or renew subscriptions to Microsoft Action Packs, create a business profile to receive and manage sales leads from Microsoft, and see if you qualify for co-selling opportunities.

Enroll in the CSP program

The Cloud Solution Provider (CSP) program helps your company to be more involved in your customers' businesses, beyond reselling licenses. In CSP, you can choose to enroll as an *indirect reseller* or a *direct bill partner*.

In most cases, you will enroll as an *indirect reseller* and then work with an *indirect provider*, also referred to as a *distributor*, who then manages all interaction with Microsoft in terms of licensing and technology, so that you can focus on sales and support. If you decide to enroll as a *direct bill partner* in order to fully own the end-to-end relationship with both customers and Microsoft, make sure that you meet the eligibility requirements. For more information, see Enroll in the Cloud Solution Provider program in the Microsoft Partner Center content.

The Microsoft Partner Center is a generic portal where partners can sell and manage customer subscriptions for Microsoft services, such as Microsoft 365, Azure, Dynamics 365, and others, as well as for some third-party products. For more information, see the Partner Center documentation.

Some indirect providers (distributors) provide their resellers with a custom portal that optimizes and enhances the experience beyond the Partner Center. They can also provide indirect resellers with an API to automate some of the customer onboarding steps. Contact your indirect provider to find out more.

Both indirect resellers and direct bill partners can access and support their customers' Business Central by setting up a reseller relationship with them.

To service customers in a specific country, your partner company's Azure Active Directory (Azure AD) tenant and CSP account must be registered in the regional CSP market that covers that country. For more information, see Cloud Solution Provider program regional markets and currencies.

> **NOTE**
>
> When you buy Business Central offers on behalf of your CSP customers, the CSP offer must be available in both your own tenant's country and in your customer's tenant's country. For example, if your tenant is located in Slovakia and the customer's tenant is in Germany, you will not be able to sell Dynamics 365 Business Central Premium to that customer, because this offer is currently not available in Slovakia.
>
> Similarly, if your tenant is located in Germany and the customer's tenant is in Slovakia, you will not be able to sell Dynamics 365 Business Central Premium to that customer, because this offer is currently not available in Slovakia.

In the Microsoft Partner Center documentation, you can learn how to request a reseller relationship with customers, assign licenses to users, and create new subscriptions. Business Central is one of the subscriptions that you can create, and there are Business Central-specific license types that you can assign to users.

You must also assign certain roles to users in your own organization so that they can support your customers.

Add users from your own organization

In most cases, your partner company includes employees with different responsibilities, and you can assign different roles depending on people's responsibility. This way, you can be very explicit about who from your staff can access your customers' data, for example.

For each user, you can assign permissions for 2 categories of tasks:

- Managing your organization's account

  This controls access to the functionality of the Partner Center portal

- Assisting your customers

This controls access to your customers' environments

When you establish a reseller relationship with a customer in Partner Center, you must specify which people from your organization will assist that customer's tenant as either *Admin agent* or *Helpdesk agent*. These users can manage implementation, support, and troubleshooting tasks for your customers. Once the reseller relationship with a customer is established, they will be able to login into the Business Central environments of the customer without a license. The number of partner users that can access customer environments is not restricted.

Both roles will provide your users with exactly the same level of access to the customer's Business Central environment. However, they have very different capabilities to manage the customer's Active Directory and other subscriptions that the customer might have. For more information, see Admin roles.

This way of accessing customer resources is called *delegated administration*, and the partner users are therefore called *delegated administrators* or *delegated admins* in daily shorthand. For more information, see Delegated Administrator Access to Business Central Online.

> **NOTE**
> These users cannot provide accounting services for the customers. For this purpose, the customers must use the **External Accountant** license, which is also available via CSP.

Connect with customers

As a CSP partner, you can manage a customer's subscriptions and services on their behalf in the Partner Center by establishing a reseller relationship with your customers. If they already have an account, such as if they currently use Microsoft 365, other Dynamics 365 apps, or PowerApps, for example, you can send them an invitation straight from the Partner Center. For more information, see Connect with customers in Partner Center (indirect providers/distributors) and Connect with customers (indirect resellers).

When the customer's internal administrator receives the invitation link and navigates to it, they must acknowledge that they have read the Microsoft Customer Agreement and that they can authorize you as their reseller on behalf of their organization. For more information, see Confirm customer acceptance of the Microsoft Customer Agreement.

When a customer accept this reseller relationship, delegated administration privileges are granted to the partner. For more information, see Delegated Administrator Access to Business Central Online.

If you are working as an indirect reseller, your indirect provider (distributor) must associate your customers with you in their Partner Center.

Acting as a delegated administrator

As a reselling partner, you have delegated administration access to their Business Central and other services. For more information, see Delegated Administrator Access to Business Central Online.

Manage technical support

As a reselling partner, you must be the first line of support for your Business Central customers. You must set up your support contact information, and help the internal administrators troubleshoot any issues that users find. For more information, see Managing Technical Support.

Extending trials

An organization can sign up for a free trial of Business Central. When they first sign up for Business Central, they get access to an evaluation version that does not include all capabilities in Business Central. They can then switch to the 30 day trial experience to enable all capabilities.

However, sometimes a 30 day trial is not enough to decide if they want to buy Business Central. In that case, they can extend their trial with an additional 30 days. For more information, see Need More Time to Decide Whether to Subscribe? in the business functionality content for Business Central.

> **NOTE**
> If you are a reselling partner, we recommend that you set up demo environments for prospects that need longer time to decide if they want to buy Business Central. You can also use demo environments to help customers train their employees, for example. Using the 30 days trials for training should be limited to just that short period. However, demo environments cannot be used for production. For more information, see Preparing Demonstration Environments.

If the prospect wants to extend the trial further than those 30 days, they must contact a partner. The partner can extend it another 30 days if the delegated administrator signs into the prospect's Business Central and runs the **Extend Trial Period** guide.

After those additional 30 days, the prospect must either purchase Business Central or abandon Business Central. At this point, they will have had up to 90 days with the trial experience.

> **TIP**
> As a reselling partner, you can suggest your prospects sign up for a trial, but you can also help set up a customized demonstration environment based on a sandbox environment or a trial environment. In both cases, you can easily add or remove functionality based on your prospects' expectations. For more information, see Preparing Demonstration Environments.

The Dynamics 365 Business Central Premium Trial

In the Partner Center, you can find a special license type called the **Dynamics 365 Business Central Premium Trial** license, which is a very different way to give a prospect or an existing customer a trial experience using their own data. If you assigned the **Dynamics 365 Business Central Premium Trial** license to a customer's account in the Partner Center, then that also expires after 30 days. You cannot extend the Premium trial, but you can add one more Premium trial license to give the customer an extra 30 days of trial. But when the second Premium trial expires, then the customer must either convert their trial to a paid subscription, or they must sign up for the viral trial as described above.

For more information, see Offer your customers trials of Microsoft products in the Partner Center documentation. If you have technical difficulties assigning this license, contact Partner Center support. For more information, see Report problems with Partner Center.

Caution

Make sure you understand the limitations of this type of trial, before you offer it to a prospect or customer. It is easy to convert this type of trial to a paid subscription, but if the prospect needs more than 30 days to decide, or if they want to add more than 25 users, then the viral trial is probably a better fit for them.

Data and access when a trial or subscription ends

Trials can expire, and so can a apid subscription, such as if the customer does not renew the subscription or stops payments, or if the customer cancels the subscription.

When a trial or a subscription expires, two special periods kick in:

- *Grace period*
- *Data retention period*

The *grace period* is a period of 30 days when the customer can still access the product without any restrictions. After the grace period, the subscription enters the *data retention period*, which is another 90 days during which

only the admin users of the Azure Active Directory tenant can login into the product. After those 90 days, Microsoft deletes the data automatically.

This policy is general across Microsoft's online offerings, as you can see in this example from Microsoft 365: What happens to my data and access when my Microsoft 365 for business subscription ends?.

Get Started as a Reseller of Business Central Online

2/17/2021 • 9 minutes to read • Edit Online

If you want to build your business on Dynamics 365 Business Central online, you must get set up as a reseller in the Microsoft Partner Center. In this article, we take you through the first four steps in your journey.

Step 1: Become a partner

Becoming a Microsoft partner gives you access to the Microsoft resources needed to sell solutions. The steps in this section below are required to gain access to the programs that enable are intended to help you get set up to sell Business Central.

In order to be able to service Business Central licenses and provide help and support to your customers, your company must have a Microsoft Partner ID (MPN ID), and you must enroll in the Cloud Solution Provider (CSP) program.

Join the Microsoft Partner Network

Microsoft Partner Network (MPN) membership unlocks our best resources to differentiate your business, take your product to market, and sell your solutions. To become a partner, you must join the Microsoft Partner Network (MPN), at which time you will be assigned an MPN ID. MPN membership is free to all partners; you can enroll in the MPN here.

Once signed up, you will get an MPN ID – your gateway to access all the membership resources and benefits for your partnership with Microsoft. There is no cost to obtain a MPN ID as a Network member, and with options to upgrade to an Action Pack subscription or work toward a competency, you can access even more benefits.

Set up your Partner Center account

Once you have joined the Microsoft Partner Network (MPN), you can set up your Partner Center (PC) account. The Microsoft Partner Center is a generic portal where partners can sell and manage customer subscriptions for Microsoft services, such as Microsoft 365, Azure, Dynamics 365, and others, as well as for some third-party products. For more information, see the Partner Center documentation.

Your Partner Center account provides you with access to pricing information, tools and services, and enables you to manage admin credentials for your company's work account. Partner Center is also where you can purchase or renew subscriptions to Microsoft Action Packs, create a business profile to receive and manage sales leads from Microsoft, and see if you qualify for co-selling opportunities.

Enroll in the CSP program

The Cloud Solution Provider (CSP) program helps your company to be more involved in your customers' businesses, beyond reselling licenses. In CSP, you can choose to enroll as an *indirect reseller* or a *direct bill partner*.

In most cases, you will enroll as an *indirect reseller* and then work with an *indirect provider*, also referred to as a *distributor*, who then manages all interaction with Microsoft in terms of licensing and technology, so that you can focus on sales and support. If you decide to enroll as a *direct bill partner* in order to fully own the end-to-end relationship with both customers and Microsoft, make sure that you meet the eligibility requirements. For more information, see Enroll in the Cloud Solution Provider program in the Microsoft Partner Center content.

The Microsoft Partner Center is a generic portal where partners can sell and manage customer subscriptions for Microsoft services, such as Microsoft 365, Azure, Dynamics 365, and others, as well as for some third-party products. For more information, see the Partner Center documentation.

Some indirect providers (distributors) provide their resellers with a custom portal that optimizes and enhances the experience beyond the Partner Center. They can also provide indirect resellers with an API to automate some of the customer onboarding steps. Contact your indirect provider to find out more.

Both indirect resellers and direct bill partners can access and support their customers' Business Central by setting up a reseller relationship with them.

To service customers in a specific country, your partner company's Azure Active Directory (Azure AD) tenant and CSP account must be registered in the regional CSP market that covers that country. For more information, see Cloud Solution Provider program regional markets and currencies.

> **NOTE**
>
> When you buy Business Central offers on behalf of your CSP customers, the CSP offer must be available in both your own tenant's country and in your customer's tenant's country. For example, if your tenant is located in Slovakia and the customer's tenant is in Germany, you will not be able to sell Dynamics 365 Business Central Premium to that customer, because this offer is currently not available in Slovakia.
>
> Similarly, if your tenant is located in Germany and the customer's tenant is in Slovakia, you will not be able to sell Dynamics 365 Business Central Premium to that customer, because this offer is currently not available in Slovakia.

In the Microsoft Partner Center documentation, you can learn how to request a reseller relationship with customers, assign licenses to users, and create new subscriptions. Business Central is one of the subscriptions that you can create, and there are Business Central-specific license types that you can assign to users.

You must also assign certain roles to users in your own organization so that they can support your customers.

Add users from your own organization

In most cases, your partner company includes employees with different responsibilities, and you can assign different roles depending on people's responsibility. This way, you can be very explicit about who from your staff can access your customers' data, for example.

For each user, you can assign permissions for 2 categories of tasks:

- Managing your organization's account

  This controls access to the functionality of the Partner Center portal

- Assisting your customers

  This controls access to your customers' environments

When you establish a reseller relationship with a customer in Partner Center, you must specify which people from your organization will assist that customer's tenant as either *Admin agent* or *Helpdesk agent*. These users can manage implementation, support, and troubleshooting tasks for your customers. Once the reseller relationship with a customer is established, they will be able to login into the Business Central environments of the customer without a license. The number of partner users that can access customer environments is not restricted.

Both roles will provide your users with exactly the same level of access to the customer's Business Central environment. However, they have very different capabilities to manage the customer's Active Directory and other subscriptions that the customer might have. For more information, see Admin roles.

This way of accessing customer resources is called *delegated administration*, and the partner users are therefore called *delegated administrators* or *delegated admins* in daily shorthand. For more information, see Delegated Administrator Access to Business Central Online.

> **NOTE**
>
> These users cannot provide accounting services for the customers. For this purpose, the customers must use the **External Accountant** license, which is also available via CSP.

Caution

In the Microsoft 365 admin center and Microsoft Azure Management portal, both customers and partners can invite external users (guests) into their Active Directory. When a partner user is added as a guest to the customer's Azure AD, they can no longer log in as a delegated admin into the customer's Business Central. In order to log in, the local user (guests or native) must have a valid Business Central license assigned to them.

Step 2: Go to market

When you become a Microsoft Partner Network member, you gain access to membership benefits that can help you build and grow your business. For more information, see Explore your Go-To-Market with Microsoft offers in the Partner Center docs.

As a Dynamics 365 reseller, you benefit from Microsoft's investments in an always up-to-date modern platform, you can bundle recognized apps from the Microsoft commercial marketplace into an offering that fits the needs of your customers, reach more customers by using Microsoft's commercial marketplace to promote your packaged consulting service offerings or customization services, and streamline your own processes and build tools with Power BI, Power Automate, and Power Apps connected to Business Central.

Specifically for going to market with Business Central, Microsoft provides resources and guidance on the Business Applications for small and medium-sized businesses (SMBs) site. For more information, see Business Central Go-To-Market resources.

Step 3: Give powerful demos

You can create a trial environment based on content in cdx.transform.microsoft.com.

For more information, see Preparing Demonstration Environments of Dynamics 365 Business Central.

Step 4: Help your customers get started

When you onboard customers to Business Central, you have access to their account as a delegated administrator and can help them get things set up. For more information, see Administration of Business Central Online.

Connect with customers

As a CSP partner, you can manage a customer's subscriptions and services on their behalf in the Partner Center by establishing a reseller relationship with your customers. If they already have an account, such as if they currently use Microsoft 365, other Dynamics 365 apps, or PowerApps, for example, you can send them an invitation straight from the Partner Center. For more information, see Connect with customers in Partner Center (indirect providers/distributors) and Connect with customers (indirect resellers).

When the customer's internal administrator receives the invitation link and navigates to it, they must acknowledge that they have read the Microsoft Customer Agreement and that they can authorize you as their reseller on behalf of their organization. For more information, see Confirm customer acceptance of the Microsoft Customer Agreement.

When a customer accept this reseller relationship, delegated administration privileges are granted to the partner. For more information, see Delegated Administrator Access to Business Central Online.

If you are working as an indirect reseller, your indirect provider (distributor) must associate your customers with

you in their Partner Center.

The customer can decide to remove their partner's delegated admin privileges from their tenant, but still retain the relationship with their partner for subscription and license renewal purposes. Removing delegated admin privileges will block the partner's access to the customer's Business Central. The access can be restored if the partner sends the reseller relationship request to the customer again.

If the customer wants to cancel their relationship with their partner, the partner must remove the relationship in Partner Center.

Get Business Central right for the customer

The default version of Business Central is just that - a default version. In many cases, you'll enhance the default version with apps from the Microsoft commercial marketplace. But you can also customize pages for a profile and change which UI elements are visible. For more information, see Customize Business Central in the business functionality content.

If your customer wants more tweaks, you can create customizations of profiles and pages in code. For more information, see Customizing the User Interface for User Roles in the developer content.

Step 5: Configure the support experience

As a Business Central reselling partner, you are an administrator of your customers' Business Central tenants, and you are the first line of support. This means that you will get requests for support from your customers that you must triage, investigate, and either resolve or escalate to Microsoft. For more information, see Technical Support for Business Central.

Step 6: Maintain your customers' Business Central

As a Business Central reselling partner, you are the administrator of the Business Central tenants of your customers. You are expected to help your customers maintain their solution, including setting the upgrade window, monitoring telemetry, updating customizations, and managing apps.

For more information, see Administration of Business Central Online and The Business Central Administration Center.

Country/regional availability and supported languages

2/17/2021 • 4 minutes to read • Edit Online

This page lists the countries/regions where Dynamics 365 Business Central is available and which languages are supported.

> **NOTE**
> In countries where Microsoft has not delivered a localization, partners can build localizations using translation and localization apps that are published on AppSource. These apps are built on top of the international (W1) version of Dynamics 365 Business Central.

The following table provides the list of all countries/regions where Dynamics 365 Business Central is available or in planning for future availability, and states whether the localization is provided by Microsoft or partner(s).

Countries and regions

COUNTRY/REGION	LOCALIZED BY	AVAILABILITY	ENVIRONMENT COUNTRY IN TENANT ADMIN CENTER
Australia	Microsoft	Available	AU
Austria	Microsoft	Available	AT
Belgium	Microsoft	Available	BE
Brazil	Partner	Available	BR
Canada	Microsoft	Available	CA
Colombia	Partner	Available	CO
Croatia	Partner	Available	HR
Czechia	Microsoft	Available	CZ
Denmark	Microsoft	Available	DK
Estonia	Partner	Available	EE
Faroe Islands (Denmark)	Microsoft	Available	DK
Finland	Microsoft	Available	FI
France	Microsoft	Available	FR
Germany	Microsoft	Available	DE

COUNTRY/REGION	LOCALIZED BY	AVAILABILITY	ENVIRONMENT COUNTRY IN TENANT ADMIN CENTER
Greenland (Denmark)	Microsoft	Available	DK
Hong Kong SAR	Partner	Available	HK
Hungary	Partner	Available	HU
Iceland	Microsoft	Available	IS
Ireland	Partner	Available	IE
Indonesia	Partner	Available	ID
India	Microsoft	Preview	IN
Italy	Microsoft	Available	IT
Japan	Partner	Available	JP
Latvia	Partner	Available	LV
Lithuania	Partner	Available	LT
Malaysia	Partner	Available	MY
Mexico	Microsoft	Available	MX
Netherlands	Microsoft	Available	NL
New Zealand	Microsoft	Available	NZ
Norway	Microsoft	Available	NO
Peru	Partner	Available	PE
Philippines	Partner	Available	PH
Poland	Partner	Available	PL
Portugal	Partner	Available	PT
Russia **(on-premises only)**	Microsoft	Available	(Not listed)
Serbia	Partner	Available	RS
Singapore	Partner	Available	SG
Slovenia	Partner	Available	SI
South Africa	Partner	Available	ZA

COUNTRY/REGION	LOCALIZED BY	AVAILABILITY	ENVIRONMENT COUNTRY IN TENANT ADMIN CENTER
South Korea	Partner	Available	KR
Spain	Microsoft	Available	ES
Sweden	Microsoft	Available	SE
Switzerland	Microsoft	Available	CH
Taiwan	Partner	Available	TW
Thailand	Partner	Available	TH
United Arab Emirates	Partner	Available	AE
United Kingdom	Microsoft	Available	GB
United States	Microsoft	Available	US
Vietnam	Partner	Available	VN

Important information regarding planned availability

Due to the nature of the joint effort where Microsoft is providing the international (W1) cloud service and partners are providing localization app(s), the above planned availability estimates represent the earliest possible availability and can be exceeded if localization partners have not successfully published their app(s) to AppSource by this time.

Supported languages

To maximize productivity Dynamics 365 Business Central supports many languages. It is important to know that language support requires translation of *platform* captions and *application* captions (UI). Translated platform captions are provided by Microsoft for all supported languages. Application languages are provided by both Microsoft and partners, depending on the language.

Application languages delivered by Microsoft are provided as language apps, available on AppSource, that can be installed if needed. Partners can also provide application translation for any platform supported language. To use one of these languages the app publisher must be contacted through AppSource.

This table gives an overview of supported languages and how application languages are provided.

LANGUAGE	LOCALE	TRANSLATION APP PROVIDED BY
Bulgarian	bg-BG	Partner, Available on AppSource (pending)
Czech (Czech Republic)	cs-CZ	Microsoft, Available on AppSource
Danish (Denmark)	da-DK	Microsoft, Available on AppSource
German (Austria)	de-AT	Microsoft, Available on AppSource

LANGUAGE	LOCALE	TRANSLATION APP PROVIDED BY
German (Switzerland)	de-CH	Microsoft, Available on AppSource
German (Germany)	de-DE	Microsoft, Available on AppSource
English (Australian)	en-AU	Microsoft, Available on AppSource
English (Canada)	en-CA	Microsoft, Available on AppSource
English (Great Britain)	en-GB	Microsoft, Available on AppSource
English (New Zealand)	en-NZ	Microsoft, Available on AppSource
English (United States)	en-US	Built-in
English (South Africa)	en-ZA	Supported by platform, no app available
Spanish (Spain)	es-ES	Microsoft, Available on AppSource
Spanish (Mexico)	es-MX	Microsoft, Available on AppSource

Traditional Chinese (Taiwan)	zh-TW	Partner, Available on AppSource
Vietnamese (Vietnam)	vi-VN	Partner, Available on AppSource

NOTE

Application translations provided by Microsoft cover features in the international version (W1). Local functionality is not translated to all languages and will be provided in English and native language, as has been done historically. As a result, you may experience a mix of translations if using Dynamics 365 Business Central in a foreign language.

Checklist for Submitting Your App

Delegated Administrator Access to Business Central Online

2/17/2021 • 5 minutes to read • Edit Online

As a Business Central reselling partner, you must set up your employees to work in Partner Center, and you must assign employees to support your customers. When you request a reseller relationship with a customer, you can choose to include *delegated administration* privileges for Azure Active Directory (Azure AD) and Office 365 in the request email that you send to the customer.

You must already have set up users in your own tenant in Partner Center so that the **Assists your customers as** field specifies the relevant role for this user to be able to login in to your customers' Business Central environments as either *Admin agent* or *Helpdesk agent*. These roles are used when the customer accepts the relationship, so you can assign the right people to the customer's Azure AD tenant.

When a customer grants the delegated administration privilege to a partner:

- The **Admin Agent** group is assigned to the **Global Administrator** role in the customer's Azure AD tenant.
- The **Helpdesk Agent** group is assigned to the **Helpdesk Administrator** role in the customer's Azure AD tenant.

Based on the roles assigned, members of both groups can sign in to the customer's Azure AD tenant, Microsoft 365 services, Business Central administration center, and Business Central tenants by using their partner credentials. For more information, see Delegated admin privileges in Azure AD in the Partner Center documentation.

For certain tasks, you can access the Business Central administration center, which is a powerful tool for you to manage your customers' tenants. From the administration center, you can manage upgrades and access the tenants as the delegated administrator. For more information, see The Business Central Administration Center.

> **TIP**
> Always include the domain or the Azure Active Directory ID of the customer in the URL when you log in as a *delegated admin*, such as in `https://businesscentral.dynamics.com/contoso.com/admin`. This way, you always know exactly which customer you are trying to access.

Caution

In the Microsoft 365 admin center and Microsoft Azure Management portal, both customers and partners can invite external users (guests) into their Active Directory. When a partner user is added as a guest to the customer's Azure AD, they can no longer log in as a delegated admin into the customer's Business Central. In order to log in, the local user (guests or native) must have a valid Business Central license assigned to them.

Restricted access to Business Central as delegated administrator

When you sign in to your customers' Business Central as the *delegated administrator* from the Business Central administration center, you have access to all areas of their Business Central. However, because you are not registered as a regular user, there are certain tasks that you cannot do.

The following tasks are *not* available to the delegated administrator:

- Set up jobs to run as scheduled tasks in the job queue

- Use the **Edit in Excel** action or interact with Business Central data in Excel using the Business Central add-in for Excel.

  You can still use the **Open in Excel** action to view data in Excel.

- Use the **Invite External Accountant** assisted setup guide

  Instead, you can add the external user in the Azure portal and assign this user the **External Accountant** license.

- Change the experience to Premium

- Use the **Cloud Migration Setup** assisted setup guide to migrate data from Business Central on-premises to Business Central online

  Instead, a user who is assigned the SUPER permission set in Business Central can run the assisted setup guide.

- Access a web service by using a Web Service Access key.

Managing delegated permissions as a partner

Delegated administrators are not visible in the customer's Azure AD user list and cannot be managed by the customer's internal admin. However, when a delegated admin logs into a Business Center environment on behalf of a customer, they are automatically created as a user inside the Business Central environment. This means that the actions performed by a delegated admin are logged in Business Central, such as posting documents and, associated with their user ID.

If a customer removes delegated permissions from you, you can still manage their subscription from the Partner Center, such as adding or removing licenses for their subscription, but you will no longer be able to log into and manage their Business Central environment, Azure AD, and other services. You will also not be able to manage their users (add/remove/assign licenses) from the **Customer** page in the Partner Center.

Managing delegated permissions as an internal administrator

As a Microsoft customer organization, you can have multiple partners registered as your resellers. It is not unusual for a single organization to use one partner as the delegated admin for their Microsoft 365 subscription and another for Business Central, for example. However, as soon as the delegated administration right is granted in the Microsoft 365 admin center, you cannot restrict partner access to a specific service only. The delegated admin access applies to all Microsoft services that your organization subscribes to.

If you do not need delegated admin help continuously, you can restrict access for the partner users into your environment. There are two approaches that you can use to restrict delegated admin access to a Business Center environment:

- Disable a specific delegated admin user within the Business Central environment. For more information, see How to remove a user's access.
- Revoke delegated administration rights from all partner users at once in the Microsoft 365 admin center, without breaking the reseller relationship with the partner.

In the Microsoft 365 admin center, internal administrators can find information about their partner relationships in the Settings/Partner Relationship menu. On the same page, you can remove delegated permissions from the partner, to restrict their access to Business Central and other services, while still keeping the reseller relationship with them.

If you then want to allow access to your environment again, you can ask the partner to share the "Request a reseller relationship" invitation link with you again.

For more information, see Customers delegate administration privileges to partners.

Licensing in Dynamics 365 Business Central

2/17/2021 • 3 minutes to read • Edit Online

Business Central licenses can only be purchased through CSP. Microsoft offers several types of paid licenses (users):

- Essential
- Premium
- Team Member
- External Accountant

Customers can also subscribe for an evaluation version by using self-service sign-up (also known as IW or viral sign-up). This subscription comes with 10000 licenses and allows customers to evaluate the functionality of Business Central using non-production companies.

Business Central does not use the classic Dynamics NAV license files (*.flf). Instead, permissions are generated based on entitlements.

We define license permissions (per object) in the **Entitlements** table. Entitlements are grouped in the **Entitlement Set** table, and then each entitlement set is associated with one of the four Azure Active Directory (Azure AD) service plans.

This means that when a user purchases, for example, an Essential license and tries to sign in to Business Central, we retrieve the user's service plan (in this case Essential) from Azure AD and then load the corresponding entitlements as license permissions.

> **NOTE**
>
> For more information about the different types of licenses and how licensing works in Business Central, see the Dynamics 365 Licensing Guide, which you can download from https://go.microsoft.com/fwlink/?LinkId=866544.

Entitlements and user groups

Entitlements are permissions that describe which objects in Business Central a customer is entitled to use according to their Azure Active Directory role or the license they purchased from Microsoft.

The **User Group Plan** table stores the mapping between the service plans and the user groups. Based on this mapping, the service determines which user group is assigned to a user by default when a user logs in to Business Central for the first time. The user group assigns a specific license (or makes the user a member of a specific Azure AD role).

When a user logs in to Business Central, the service applies the intersection of the entitlements that are associated with the user's service plan (or Azure AD role) and the permissions that are defined for that user. Entitlements always have higher priority over permissions. For example, even is the user is given SUPER permissions by the admin but has the Team Member license assigned – the user can still only access the objects defined by the Team Member entitlements.

You can verify how entitlements, licenses, and user groups work together by looking at the **Effective Permissions** page, which you can access from the **User** page. For more information, see Create Users According to Licenses in the business functionality content for Business Central.

Entitlements in production and sandbox environments

In versions earlier than 2020 release wave 2 (version 17.0), entitlements are only enforced in production environments so that prospective and existing customers could explore the functionality of the Premium subscription in a sandbox environment without having to purchase a Premium license.

However, partners that create and test their extensions using sandbox environments of that type could miss errors in their code that would be related to entitlements or access, so that those issues would not be found until they deployed their extensions to the production environments.

Also, you can explore such functionality by creating an evaluation company in either a production or a sandbox environment using the free evaluation subscription that is available from https://dynamics.microsoft.com/en-us/business-central. Alternatively, you can use the **Business Central Premium - Trial** subscription that is available through the CSP program as described here. By using these subscription types, customers and partners can explore the capabilities included with the Premium subscription.

With 2020 release wave 2, the license checks for entitlements are now also enforced in the sandbox environments.

Reassigning licenses

The licensing terms in the Online Services Terms document do not allow temporary assignment of a license that belongs to one user to another user.

Most, but not all, licenses can be reassigned. Except as permitted in this paragraph or in the Online Service-specific Terms, the customer cannot reassign a license on a short-term basis, meaning within 90 days of the latest assignment. The customer can reassign a license on a short-term basis to cover a user's absence or the unavailability of a device that is out of service. Reassignment of a license for any other purpose must be permanent. When a customer reassigns a license from one device or user to another, they must block access and remove any related software from the former device or from the former user's device.

Operational Limits for Business Central Online

2/17/2021 • 6 minutes to read • Edit Online

To ensure the availability and quality of Business Central services, there are limits on certain operations. This article describes the limits and, in some cases, the strategy behind them.

> **TIP**
> Telemetry is gathered on some of the operations that have a limit. The telemetry provides insight into operations for which limits were exceeded. For more information, see Monitoring and Analyzing Telemetry.

Client connection limits

SETTING	DESCRIPTION	LIMIT
Reconnect period	The time during which a client can reconnect to the service after being disconnected.	10 minutes

Data handling limits

SETTING	DESCRIPTION	LIMIT
Max items in object graph	The maximum number of objects to serialize or deserialize.	10,000
Max file size	The maximum size of files that can be uploaded to or downloaded from the service.	350 MB
Maximum stream read size	The maximum number of bytes that can be read from a stream (InStream object) in a single AL read operation. Examples include READ or InStream.READTEXT method calls. This setting pertains to UTF-8 and UTF-16 text encoding; not MS-DOS encoding.	1,000,000 bytes

Database connection limits

SETTING	DESCRIPTION	VALUE
Search timeout	The time (in seconds) that a search operation on lists in the client continues before it's stopped. When the limit is reached, the following message displays in the client: **Searching for rows is taking too long. Try to search or filter using different criteria.**	10 seconds

SETTING	DESCRIPTION	VALUE
SQL command timeout	The contextual time-out for a SQL command.	30 minutes
SQL connection idle timeout	The time that a SQL connection can remain idle before being closed.	5 minutes
SQL connection timeout	The time to wait for the service to connect to the database. When the time is exceeded, the attempt is canceled and an error occurs. This setting also applies to begin, rollback, and commit of transactions.	1.5 minutes
Long running SQL query threshold	The amount of time that an SQL query can run before a warning telemetry event occurs. If this threshold is exceeded, the following event is logged: Action completed successfully, but it took longer than the given threshold.	1000 ms

Asynchronous task limits

SETTING	DESCRIPTION	LIMIT
Maximum concurrent running scheduled tasks	The maximum number of tasks that can run simultaneously for an environment. If there are many jobs running at the same time, you might experience that the response time for clients gets slower. If the value is too low, it might take longer for scheduled tasks to process.	3
Page background task default timeout	The default amount of time that page background tasks can run before being canceled. Page background tasks can be also given a timeout value when enqueued at runtime. This limit is used when no timeout is provided when the page background task is enqueued.	2 minutes
Page background task max timeout	The maximum amount of time that page background tasks can run before being canceled. Page background tasks can be also given a timeout value when enqueued at runtime. If a page background task is enqueued with a timeout greater than this limit, this limit is ignored.	10 minutes

SETTING	DESCRIPTION	LIMIT
ChildSessionsMaxConcurrency	The maximum number of child sessions that can run concurrently per parent session. When the value is exceeded, additional child sessions will be queued and run when a slot becomes available as other child sessions are finished.	5
ChildSessionsMaxQueueLength	The maximum number of child sessions that can be queued per parent session. If the value is exceeded, an error occurs.	100

Report limits

SETTING	DESCRIPTION	LIMIT
Default max documents	The maximum number of documents that can be merged in report by default Users can override this setting on a report-basis from the report request page. If exceeded, the report will be canceled. Developers can override this setting by using MaximumDocumentCount property of a report. Client users can do the same when running a report from the report request page	200
Max documents	The maximum number of documents that can be merged in report. If exceeded, the report will be canceled.	500
Default max execution timeout	The maximum execution time that it can take to generate a report by default. Users can override this setting on a report-basis from the report request page. If exceeded, the report will be canceled. Developers can override this setting by using the ExecutionTimeout property of a report. Client users can do the same when running a report from the report request page.	6 hours
Max execution timeout	The maximum execution time that it can take to generate a report. If exceeded, the report will be canceled.	12 hours

SETTING	DESCRIPTION	LIMIT
Default max rows	The maximum number of rows that can be processed in a report by default. Users can override this setting on a report-basis from the report request page. If exceeded, the report will be canceled. Developers can override this setting by using the MaximumDataSetSize property of a report. Client users can do the same when running a report from the report request page.	500,000
Max rows	The maximum number of rows that can be processed in a report. If exceeded, the report will be canceled by the server.	1,000,000

Query limits

SETTING	DESCRIPTION	LIMIT
Max execution timeout	The maximum execution time that it can take to generate a query. If exceeded, the query will be canceled.	30 minutes
Max rows	The maximum number of rows that can be processed in a query. If exceeded, the query will be canceled.	1,000,000

OData request limits (per environment)

SETTING	DESCRIPTION	LIMIT
Max concurrent requests	The maximum number of OData V4 requests the server instance can actively process at the same time. Requests that exceed the limit will wait in the queue until a time slot becomes available.	5
Max connections	The maximum number of simultaneous OData requests on the server instance, including concurrent and queued requests. When the limit is exceeded, a 429 (Too Many Requests) error occurs.	100
Max page size	The maximum number of entities returned per page of OData results.	20,000 entities per page
Max request queue size	The maximum number of pending OData V4 requests waiting to be processed. When the limit is exceeded, a 429 (Too Many Requests) error occurs.	95

SETTING	DESCRIPTION	LIMIT
Rate	The number of OData requests per minute that are allowed. An HTTP response code `429 - Too Many Requests` is returned if limits are exceeded.	Sandbox: 300 requests/minute Production - 600 requests/minute
Operation timeout	The maximum amount of time that the service gives a single OData request. When the limit is exceeded, an HTTP response code `408 - Request Timeout` is returned. After 8 minutes, the session is canceled.	8 minutes

SOAP request limits (per environment)

SETTING	DESCRIPTION	LIMIT
Max concurrent requests	The maximum number of SOAP requests the server instance can actively process at the same time. Requests that exceed the limit will wait in the queue until a time slot becomes available.	5
Max connections	The maximum number of simultaneous SOAP requests on the server instance, including concurrent and queued requests. When the limit is exceeded, a `429 (Too Many Requests)` error occurs.	100
Max message size	The maximum permitted size of a SOAP web service requests	65,536 KB
Max request queue size	The maximum number of pending SOAP requests waiting to be processed. When the limit is exceeded, a 429 (Too Many Requests) error occurs.	95
Rate	Specifies how many SOAP requests per minute are allowed. An HTTP response code `429 - Too Many Requests` is returned if limits are exceeded.	Sandbox: 300 requests/minute Production: 600 requests/minute
Operation timeout	The maximum amount of time that the service gives to a single SOAP request. When the limit is exceeded, HTTP response code `408 - Request Timeout` is returned.	8 minutes

Major Updates of Business Central Online

2/17/2021 • 14 minutes to read • Edit Online

This article provides an overview of what you need to know about how a major Business Central update rolls out. It includes key dates, actions you need take, and answers some common questions.

Timelines for major updates

The following figure illustrates the key milestones and dates for rolling out a major update. The timeline and dates are loosely based on 2020 release wave 2. The same timeline applies to all other major updates, though dates will differ.

The following table describes the milestones with example dates for the two release waves in any given calendar year.

MILESTONE	EXAMPLE DATE WAVE 1	EXAMPLE DATE WAVE 2	DESCRIPTION
Update is available	April 1	October 1	The date when the new major version of Business Central becomes generally available
Update starts rolling out	April 15	October 15	The default date when Microsoft starts upgrading your environments. Once the update is scheduled, you can change that date, within allowed date range, to a date, which fits you better.
Last scheduled update date	May 31	November 30	The last date you can choose to extend your upgrade date to, typically 30 days after the update is available but extended to 60 days for 2020 release wave 2.

IMPORTANT

As announced in the blog post, in response to COVID-19, Microsoft made some changes to the update schedules in April, 2020. Specifically for Business Central, existing customers were given 60 days to upgrade after the new version was made generally available. The extended 60 days update window also applies to 2020 release wave 2 updates.

Dates and times differ significantly across countries and regions. Make sure that you have set up notifications in the Business Central administration center so that you're notified when the next major update is available.

Update is available

In the release plans, you can see when the next major update is generally available. Typically, the update is announced on the Dynamics 365 blog, and Microsoft starts rolling out the update to existing environments. On the same day, new customers signing up for a trial and all newly created environments (sandboxes and production) are directed to the new version.

The existing environments are scheduled to be updated to the new version gradually across the world. Microsoft strives to schedule all environments soon after the official release date, but for some environments, the update might not be available for a few weeks. In extreme cases, a given environment might be scheduled for update up to one month after the release date.

When the update becomes available for an environment, all notification recipients for that environment receive email notifications. A notification about the update availability is also shown in the Business Central administration center itself. Starting this day, you can set the date for when your environment should be updated via the Business Central administration center (schedule update). You can choose any date between that date and the date that is shown as the last available date for the update. The last available date can be between one and four weeks away. For more information, see Managing Major and Minor Updates of Business Central Online.

Behind the scenes

Starting from the official release date, Microsoft begins scheduling updates. Scheduling doesn't occur for all environments around the world simultaneously. During scheduling, Microsoft sets a default update date for each environment, typically 14 days in the future from the date when you received the notification. You can see this date in the environment details page in the Business Central administration center.

> **IMPORTANT**
>
> If you don't change the default date, **Microsoft updates the environment automatically** any day between the scheduled update date and the date that is shown as the last possible update date in your e-mail notification. If you don't want your environment to be updated automatically, change the update date to the one that fits you better.

You can change the default date set by Microsoft at any point of time, including changing it to the current date. In some cases, Microsoft can suspend or postpone all updates beyond this last possible date. For more information about what happens in such cases, see Postponed updates.

When the scheduled update date arrives, the update runs automatically within the update window that you've specified for this environment. All users will be disconnected from this environment, and all sign-in attempts during the update will be blocked with the message `Service is under maintenance`. We strongly encourage that you set an update window for all production environments so that updates don't start during business hours. For more information, see Set the update window for each environment.

> **NOTE**
>
> When you select a current date for your update, but the update window defined for this environment has already passed, the update will start within that time window, but on the following day to the one you defined for your environment. For example, if you're changing the Scheduled update date to the current date at 6pm, and your update window is set to 1 AM - 7 AM, the update will not start immediately, but around 1 AM on the next day.

Environments fail to update for various reasons, such as per-tenant extension compatibility issues, AppSource app compatibility issues, or internal update issues. Any environment that fails to update will be automatically restored to the original application version. Within one hour, the environments are automatically rescheduled for new update attempts for seven days. If you consider the issue resolved and want to try the update again, change the date to an earlier date or the current date.

If Microsoft can't do the update on the selected date, you'll be notified by email that the environment is rescheduled to be updated seven days later. You can change that date in the Business Central administration center to any other allowed date, including the current date.

Delayed scheduling of updates

In some cases, even after the update is available in your area, you may still not be able to set the update date (schedule environment update). This condition can happen for one of the following reasons:

- Your environment has not yet updated to the latest minor update of the previous version of Business Central. All environments must be updated to the last available minor update of the previous version of Business Central before they can be scheduled to be updated to the next major version. You can check the version information in the **Troubleshooting** section of the **Help and Support** page in Business Central as well as in the **Version Management** section in Business Central administration center. For more information, see Version numbers in Business Central.

  Microsoft is actively working on updating all environments to the latest minor update as soon as possible. In most cases, your environment will be scheduled for the major update soon, and you'll get a chance to change the date to the one that fits you better. In the unlikely situation that your environment is updated to the last minor update around or even after the last selectable update date, you'll still get a least seven days to schedule the update.

- You have just created a new sandbox environment as a copy of your production environment. In this case, the sandbox environment is created on the same version as the production environment it was copied from. If your newly created sandbox environment is running on the last minor update of the previous version, Microsoft will schedule it for update automatically within one hour.

  You'll receive email notification and will see the notification in Business Central administration centerwhen it happens. The scheduled update date for this environment will be set to seven days from the current date, so that you have enough time to change the date to one that fits you better (including the current date).

- Your per-tenant extensions are not compatible with the next major update.

  Before rolling out the next major update, as well as during the update, Microsoft routinely checks per-tenant extensions in all existing environments for compatibility with the next major update. When compatibility issues with the upcoming version are detected, email notifications that describe the detected issues are sent to the notification recipients.

  Ifyou discoverany such issues, apply the changes to your solution as usual using Visual Studio Code, and test the new appin a sandbox environment that runson the new major version (either in preview or officially available). If testscomplete successfully, upload the new app version into your production environment in the **Extension Management** page, setting the**Deploy to**field to**Nextmajorversion**.This way the compatible version of your app will beusedwhenyour environment is updated.For more information, see Deploying a Tenant Customization.

- The AppSource apps that are installed in your environment are not yet available for the next major version of Business CentralBusiness Central. While the AppSource apps are normally kept up-to-date by the partners who own them, it can happen that a particular app needs more time to prepare for the next major update and is not yet available for it. In this situation, please contact the app owner to understand their availability plans.

Postponed updates

In critical circumstances, Microsoft can decide to postpone the rollout of the updates, such as if a critical issue is discovered in the new major version that is being rolled out. While Microsoft is working on addressing the issue,

the updates will be postponed. You'll receive email notification about this, and you'll see the notification displayed in the Business Central administration center. The **Version Management** section for each environment will show the update rollout state as *Postponed*.

Not knowing the nature of the issue and the solution in advance, we can't predict when the updates will resume again. This means that neither the email nor the notification in Business Central administration center will contain the information about the expected resume date. Microsoft will be actively working on resuming updates as a matter of highest priority once the issue is addressed. You'll receive another email notification when updates have been resumed. The last available date will be prolonged by the number of days the update was postponed.

If it happens that you schedule the update of your environment on a date when the updates are postponed, your update will not be done. Microsoft will not send separate notification about this. You can reschedule the update to a later date, or you can wait until you have received the email notification that the updates have been resumed and schedule the update at that time. All environments that missed their scheduled update date will be rescheduled automatically to run the update within seven days from the date the updates were resumed, but you can change that date to any other allowed date, including the current date.

If you did not explicitly set a date for your environment update in the Business Central administration center, this environment will be picked up for updating automatically, shortly after the updates have been resumed. The update will of course still be executed within the specified update time window.

Prepare, test, and learn before the major update

You can prepare yourself, users, and any customizations by trying out the new version before your production environment is updated. You can do this in different ways as explained in the following sections.

Prepare for major updates by enabling select features earlier

Some new features can be enabled ahead of time on sandbox and production environments, giving you time to test and prepare for change. Most times, you can enable features weeks before preview environments for the major update are available.

When Microsoft releases features or feature design improvements as part of minor updates, some of these features are optional until the following major update. Administrators can turn these optional features on or off from the **Feature Management** page.

For more information, see Feature Management.

Prepare for major updates with preview environments

About one month before a major update, you can try out new functionality in preview environments. Preview environments are essentially Business Central online sandbox environments that you create on a preview version of the application. When you create the new sandbox environment, choose the preview version marked as *(Preview)* from the version list. This way, you get a new sandbox environment with a preview version of the application.

You must have access to Microsoft Collaborate in order to submit your feedback and report any potential issues that you discover in the preview version of the application. For more information about getting access to Collaborate, see Step 4: Getting access to preview bits.

> **NOTE**
> Previews roll out gradually across the world, so if the option is not showing up for you today, please try again tomorrow.

The newly created preview sandbox environment contains demonstration company data. Trying the preview on a copy of your current production data is not yet supported; nor is testing the upgrade from your current

version to the preview. However, you can use the newly created sandbox environment for exploring and learning the new product capabilities, as well as validating that your per-tenant extensions are still working as expected.

If you run your tests on a preview environment one month before the announced major release of Business Central, it is more likely that the coming updates of your production environments will go smoother. This way, you, your customers, and your code are better prepared for the official release.

We expect to update the preview version only if we discover critical issues before the major update is generally available for production environments. Apart from these potential fixes, we do not expect any further changes to the product between the preview and the official release. This means that you can start your testing and learning activities immediately, without waiting for the official release.

> **NOTE**
> You will be able to test the update on a copy of your production data in a sandbox environment when we release the new update in production in April or October, respectively. When the official release becomes available, you can continue your tests on that version. You will no longer be able to create new preview sandboxes.

> **IMPORTANT**
> The preview version as well as all sandbox environments that are based on it will be removed 30 days after the official release becomes available.

For more information, see Prepare for major updates with preview environments.

Prepare for major updates just before the production environment is updated

Starting on the date when you're notified that the new major update is available, you can test the new version by using a sandbox environment that you then schedule to be updated. Start by copying your production environment into a sandbox on the same version as your production environment. All newly created environments are automatically included in the update process within one hour, so you'll receive email notification that the update is available, and you'll be able to schedule the newly created sandbox for update within one hour after it was created. By default, the newly created environments are scheduled to run the update within seven days from the date they were created, but you can change that date to any other allowed date, including the current date.

If you change the update date to the current date, the update will start within the closest available update time window you specified for the environment. If you want to start the update of your sandbox environment immediately, you can set the update time window for this sandbox environment to be 24 hours.

If any errors are detected during the update, you'll receive email notification that describes the detected issues.

Any environments that fail to update due to per-tenant extension compatibility issues or any other issues will be automatically restored to the original application version. Within one hour, they are automatically rescheduled for another update attempt. Scheduled update date is again set to seven days in the future. If you address the compatibility issues earlier, you can change the date to an earlier date, including the current date. This pattern repeats until your environment is updated successfully.

Overview of the timeline for preparing for the next major update

The following table describes the suggested milestones with example dates for the two release waves in any given calendar year.

MILESTONE	EXAMPLE DATE WAVE 1	EXAMPLE DATE WAVE 2	DESCRIPTION

MILESTONE	EXAMPLE DATE WAVE 1	EXAMPLE DATE WAVE 2	DESCRIPTION
Previews are available	March 1	September 1	You create a new sandbox environment based on the new preview for test purposes. For more information, see Prepare for major updates with preview environments.
A few days before you know that the update is announced	March 31	September 30	You create a new sandbox environment based on your existing production environment (copy your production environment into a sandbox) and wait for it to be updated to the new version.
Update available in your region	April 6	October 5	The major update is made available. You're notified about it via e-mail. Go to the Business Central administration center and set the update date for your sandbox environment to the current date. The sandbox will be updated within the closest available update time window that you set for it. Now, you can test your existing extensions and your production data against the new version. We recommend that you set the update date for your production environment a few days or weeks in the future, to help make sure that it does not get updated automatically before you had a chance to test the new version and your extensions in your sandbox environment.
Preview sandboxes are deleted	May 1	November 1	30 days after the new major update is announced, the preview sandboxes are deleted. There will be no option to keep these sandboxes or export data from them.

The Business Central Administration Center

Version numbers in Business Central

2/17/2021 • 2 minutes to read • Edit Online

Business Central online and on-premises consists of different components that must work together. If you are a an enduser, this doesn't matter in the course of your normal work day. But if you are an administrator, knowing the version numbers is important for troubleshooting, development, and on-premises upgrade scenarios.

You can use the information about which version the tenant is on to help you troubleshoot an issue that a user has reported, for example. This information is listed in the **Troubleshooting** section of the **Help and Support** page in Business Central in the following format:

VERSION	EXAMPLE	DESCRIPTION
Platform <major>.<minor>.<build>.<revision>	16.0.12345.0	Specifies the full platform version, which includes client and server components.
Application <major>.<minor>.<build>.<revision>	16.1.23456.0	Specifies the full version number for the application, including the major version number and build number.

In the Business Central administration center, the version information is rendered slightly differently:

VERSION	EXAMPLE	DESCRIPTION
Platform <major>.<minor>	16.1	Specifies the major and minor version of the platform, which includes client and server components.
Application <major>.<minor>.<build>.<revision>	16.1.23456.0	Specifies the full version number for the application.

The numbers are updated based on Microsoft's builds. In the default version of Business Central online, platform and application have the same major version number but different build numbers. If you perform a technical upgrade of Business Central on-premises, then platform and application will have different versions.

The following list describes the meaning of each of the numbers in a full version number:

- `major` is the major version of Business Central
  - `16` is the Business Central 2020 release wave 1 update in April 2020 and forward
  - `15` is the Business Central 2019 release wave 2 update in October 2019 and forward
  - `14` is the Business Central April 2019 release
  - `13` is the Business Central October 2018 release
  - `12` is the April 2018 launch of Business Central
- `minor` is the monthly update number, such as 0, 1, or 5.
- `build` is the five digit build number, such as 23456.
- `revision` is set to 0 for the original release and can remain at 0. However, if the tenant is patched with a hotfix, then that build number can be applied.

In other words, if you see a version number such as `16.1.23456.26323`, then it means major version *16*, update number *1*, build number *23456*, and hotfix number *26323*.

The same version numbers are used to identify artifacts for running Business Central on Docker.

Administration of Business Central Online

Enabling Upcoming Features Ahead of Time

2/17/2021 • 7 minutes to read • Edit Online

This document describes how administrators can turn on new features using the Feature Management page.

About Feature Management

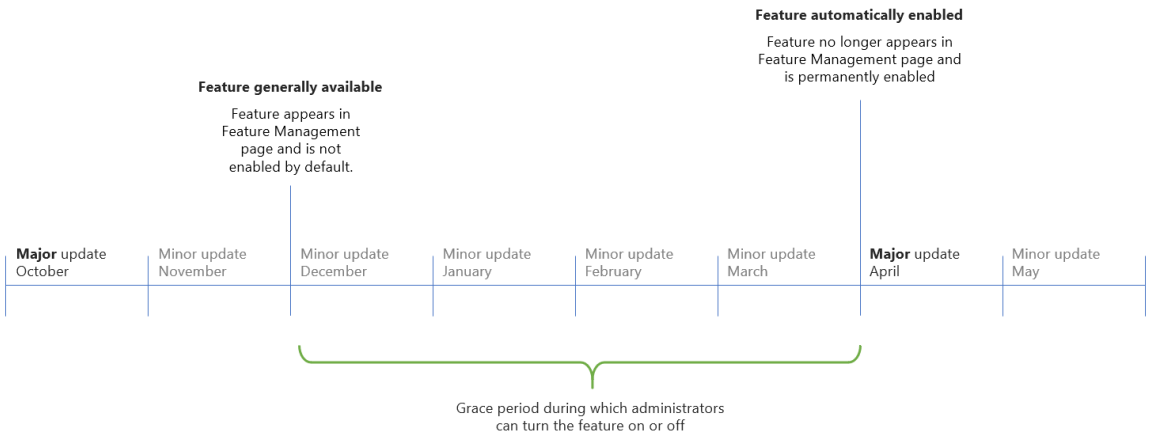
Some new features can be enabled ahead of time on sandbox and production environments. This capability allows you to benefit as early as possible from feature improvements and innovative new features. It gives you the time you need to test and prepare your organization for change.

When Microsoft releases features or feature design improvements as part of minor updates, some features aren't immediately enabled. Administrators can learn about these features and independently enable each feature from the **Feature Management** page. Once a feature is enabled, it becomes available for all users on that environment no matter how they access Business Central.

These features are only optional for a while. The option period typically starts from the minor update in which they're made generally available. The period ends when the features become mandatory and are automatically enabled in a later major update. To see the approximate date and service update when each feature is expected to become mandatory, see the **Automatically enabled from** field in the **Feature Management** page. After this date, the feature will no longer appear in the Feature Management page and can no longer be turned off.

> **IMPORTANT**
>
> The projected timeline for a feature is subject to change (see Microsoft policy).

Example timeline for an optional feature



Learn about What's new and planned.
Learn about new features available in the last minor update.

TIP

To prepare for an upcoming feature, consider enabling the feature on a sandbox environment that has a copy of production data. Invite business users to test out the change using real-world tasks. Once you and your users are satisfied with the change, you can then enable it on production environments where they can immediately benefit from that feature.

How to enable an optional feature

1. Sign in to your environment and navigate to the **Feature Management** page, or use this link: https://businesscentral.dynamics.com/?page=2610.
2. If the page isn't editable, choose **Edit List** from the action menu.
3. For any row in the list, set the **Enabled for** field to *All users*.

As soon as you enable the feature, any user that signs in to that environment experiences the change. You won't necessarily experience the change yourself until you sign out and sign in again, or start a new session.

TIP

You can try out the feature for yourself without enabling it for all users by choosing the **Try it out** link. This will open a new browser tab with the feature enabled for that session. Any new sessions in your browser will also have the feature temporarily turned on. To stop trying the feature, close your browser window or sign out.

Features that can't be turned off

Some features or feature improvements may permanently affect the state and capabilities of Business Central and can't be safely reverted. These irreversible features can't be turned off again after they've been enabled. Before you enable an irreversible feature on a production environment, we recommend that you first enable and evaluate it on a sandbox environment that has a copy of production data.

NOTE

When you choose to enable an irreversible feature, a warning dialog that describes the consequences is displayed. Choose **Yes** to proceed with permanently enabling the feature on that environment.

Scheduling Data Updates for New Features

Enabling application features that change the user experience or update data can be a disruptive process, and you might want to go at your own pace by scheduling an update per company, for example, for a time that is after your users have been trained for the new experiences.

You can schedule a data update on the **Feature Management** page by choosing the **Schedule**action, or by choosing **All Users** in the **Enable for** column. Both of those actions start the **Feature Data Update** setup guide, which allows you to review the affected data and schedule the update process. When the data update process is completed, the feature is enabled in the company where you ran the data update.

NOTE

For a feature that requires data update, data is created based on the data for the existing feature. The data for the existing feature may remain available, however, it is not synchronized with data for the new feature. Therefore, we recommend that you use one feature or the other, but not both.

FAQ about Feature Management

There are no features listed as optional. Did I do something wrong?

There may be periods where no optional features have been made available, which is perfectly normal. There will likely be few or no features listed in the **Feature Management** page immediately after a major update.

Will all new features eventually be listed on the Feature Management list?

No. We carefully select applicable features based on different criteria so that only a manageable subset of new features will appear in the list. Selected features are primarily those features that change the visuals or behaviors of the user interface and which require significant effort for business users to adjust to.

Are these features still under development or in beta/preview?

No. Features listed in the Feature Management page are considered ready and generally available. Most of these features are automatically enabled on newly provisioned environments for new customers to benefit from.

Does Microsoft provide support for optional features?

Yes. Features that are listed in the **Feature Management** page are considered ready. They follow the standard support lifecycle for the service update in which they're first made available.

Will Business Central notify me closer to the date when a feature becomes mandatory?

No. Users and administrators don't receive any in-app or email notifications about approaching dates for features becoming automatically enabled.

Do these features show in the Microsoft 365 admin center Message center?

At this time, new Business Central features are not listed in Message center.

How is feature management different to the Early Access program?

The Early Access program that is used by some Dynamics 365 apps makes a large set of new features available two months before a major update. It allows customers to enable those features in production. The most significant difference is that the Early Access program features are always two months before the major update.

How is feature management different to preview environments?

Preview environments are Business Central online sandbox environments that include all new platform and application features that will later be made available with the major update. The most significant difference is that a preview environment includes all new features bundled together. You don't have the opportunity to select which feature to enable and test.

How is feature management different to Application Areas?

Application areas are a concept where developers specify differentiated user experiences in the business application. By using application areas, developers can show or hide individual controls on a page. Like feature management, application areas concept also puts administrators in control of selecting the preferred experience tier. One difference is that there's no time period during which application areas can be optionally enabled. Another difference is that they only apply to business application controls.

Can resellers, ISVs, and developers contribute to the list of features?

No. At this time, feature management is only for features released by Microsoft.

Can I enable a feature for a single user?

No. Business Central doesn't provide the ability to enable a feature for a single user or group of users. Enabled features apply to all users of an environment.

I don't see a link to try out an optional feature. Is something wrong?

Some features don't provide a way to try out the feature for yourself and won't display a **Try it out** link. Before you enable these features, we recommend you first enable and test the features on a sandbox environment that has a copy of production data.

Are optional features also optional on new environments?

Yes. Most optional features are enabled by default on new environments for new customers to benefit from. Administrators can still turn any of these features off from the Feature Management page. Some features are

irreversible and are not enabled by default.

Are optional features automatically enabled on sandbox environments?

When you create a new sandbox environment with a copy of production data, your choice of enabled features is also copied to the sandbox. When you create a fresh sandbox, each feature is enabled by default, unless a feature is irreversible.

Is feature management applicable to on-premises deployments of Business Central?

Yes. You can turn optional features on or off in a similar way.

Major updates of Business Central Online

Managing Technical Support

2/17/2021 • 12 minutes to read • Edit Online

If users report that they are having a problem with Business Central, superusers and the internal administrator can often find a solution. The internal administrator can find technical information in the **Help and Support** page as described in the following sections, and they can then escalate relevant issues to the reselling partner.

The reselling partner can log in to their customer's Business Central as the delegated admin for troubleshooting, such as by creating a sandbox environment based on production data, and then troubleshooting in that environment.

Both internal administrators and the reselling partner can use the Business Central administration center to manage environments and updates.

Internal administrators

As the internal administrator, you can work with users to identify solutions or workarounds, such as missing setup, missing permissions, and other issues in Business Central. If users are not sure if their Business Central is working as intended, they can check the Help and Learn content for the intended behavior. For more technical problems, administrators can find technical information in the **Help and Support** page to help with this investigation. For more information, see the Finding technical information section.

Internal administrators can also create sandbox environments for deeper troubleshooting, for example, before they decide to contact their partner for technical support. The partner must have specified their support contact details in the **Help and Support** page.

Delegated administrators

Each customer of Business Central has a partner who assists with technical support when requested by the internal administrator. As the partner, you must have specified support contact details in the **Help and Support** page. For more information, see Configuring the support experience.

> **IMPORTANT**
>
> You must have set up users in your own tenant in Partner Center as either *Admin agent* or *Helpdesk agent*, and they must have *delegated administration* privileges in your customer's Business Central to support the customer. For more information, see Delegated Administrator Access to Business Central Online.

The delegated administrator can access the customer's Business Central for further troubleshooting, and they can use the Business Central administration center to analyse telemetry, create a sandbox environment for debugging, or an extra production environment for step-by-step reproduction, for example.

If the partner cannot find a solution, they can request support from Microsoft. For more information, see the Escalating support issues to Microsoft section.

Extend trials

Another task for a delegated admin is to help with extending trials. For more information, see Extending trials.

Cleaning up settings

If you end the relationship with a customer, you must remove certain settings while you still have access to that customer's Business Central administration center. These settings include the following:

- Support contact details

  For more information, see To supply your support contact information in the administration center.

- Notification recipients

  For more information, see Tenant Notifications.

- Application Insights key (if this was set up by the partner)

  For more information, see Environment Telemetry in the Business Central administration center.

Finding technical information

For Business Central online, administrators have access to a range of tools for troubleshooting. Depending on the type of problem, administrators can troubleshoot in Business Central, or they can use the Business Central administration center to analyze telemetry, for example.

In this section, we provide an overview of the most useful tools for troubleshooting the problems that users are reporting. In many cases, administrators will want to create a sandbox environment based on the production environment where users are reporting problems. That way, the administrators can troubleshoot without disturbing normal work.

- The Help and Support page

  Each company in any Business Central environment has a **Help and Support** page that can be accessed from the the question mark in the top right corner. Here you can access the latest error message, which, for example, is useful if your users complain of a confusing error message such as *Sorry, we just updated this page. Please close and reopen.*. For more information, see The Help and Support page section.

- Page inspection

  Business Central includes a page inspection feature that lets you get details about a page, providing insight into the page design, the different elements that comprise the page, and the source behind the data it displays. For more information, see Inspecting and Troubleshooting Pages.

- Environment telemetry in the Business Central administration center

  In the Business Central administration center, you can view telemetry of top-level AL events, and any errors resulting from calls through the telemetry stack. For more information, see Environment telemetry.

- Troubleshoot in a sandbox environment

  In the Business Central administration center, you can create sandbox environments for safe debugging and troubleshooting. For more information, see Sandbox environments.

- Use the Event Recorder

  Using the Event Recorder, you can record the events that are published and raised while performing the actions of your scenario. For more information, see Discoverability of Events.

- Check the data in the database

  You can view table objects in Business Central. This lets you to see the data in all rows and columns of a specific table, including any columns that are added by table extensions. From the Business Central administration center, you can also launch a list of all tables, sorted by storage size. For more information, see Viewing Table Data.

- Analyze long running operations in Application Insights

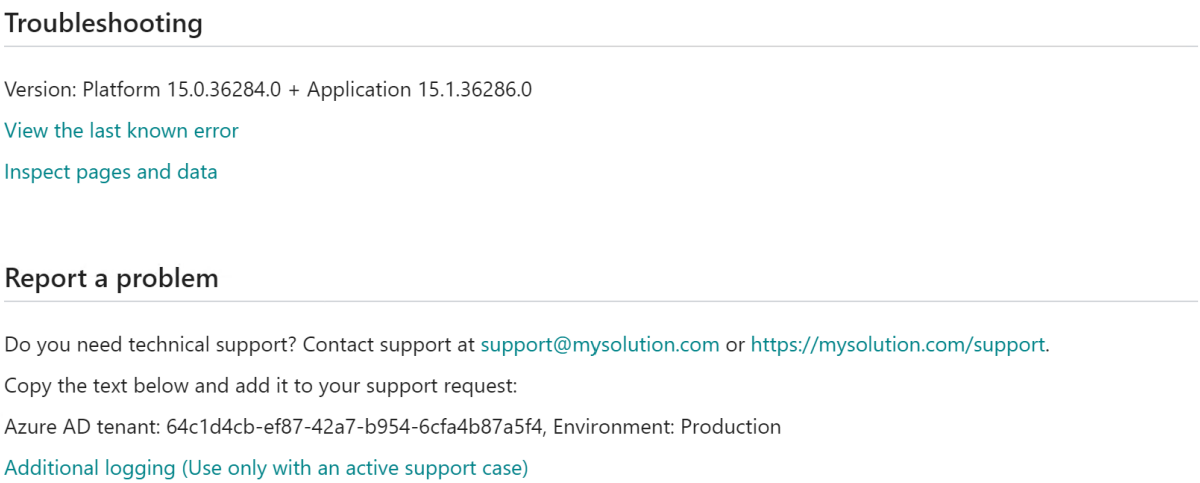
Set up Application Insights so that any SQL query that takes longer than 1000 milliseconds to execute will be sent to your Application Insights resource. For more information, see Analyzing long running operations in Application Insights.

- Debug your app or pre-tenant extension

  With Visual Studio Code and the AL Language extension you get an integrated debugger to help you inspect your code to verify that your application can run as expected. For more information, see Debugging in AL.

The Help and Support page in the Business Central company

The **Help and Support** page is a powerful tool for administrators to find technical information about Business Central, both online and on-premises. The **Troubleshooting** section gives easy access to the most recent error message, and it has a link to inspect pages for further troubleshooting.



Also in the **Help and Support** page, users can see support contact information, provided that this has been set up. For more information, see To supply your support contact information in the administration center. The **Help and Support** page also shows which version of Business Central, the specific environment is on.

For Business Central online, internal and delegated administrators also have access to this information in the Business Central administration center. You can use the Business Central administration center to easily navigate to the different environments in a tenant, and you can create sandbox environments that can help troubleshoot any issues reported by users. For more information, see The Business Central Administration Center.

Azure Active Directory tenant

When the internal administrator wants to contact the partner for support, then the **Help and Support** page encourages them to include information about their Azure Active Directory tenant ID in the email. This information is shown in the **Troubleshooting** section at the bottom of the **Help and Support** page.

The delegated administrator can use that to identify the tenant in the Partner Center and in the Business Central administration center for troubleshooting.

Version

You can use the information about which version the tenant is on to help you troubleshoot the issue that the customer has reported, for example. This information is also listed in the **Troubleshooting** section of the **Help and Support** page. For more information, see Version numbers in Business Central.

Last known error

The link behind the sentence *View the last known error* will find and show the most recent error message that was was generated by the application code. This includes errors from field validation, posting routines, and other code behind business functionality.

The information that you can get from this link includes the following:

- Text

  This is the error message that the user sees, either in a dialog window or next to a user interface element that cannot render, for example.

- Code

  This is the code snippet that threw the error.

- Callstack

  This shows how the error was triggered.

- Object

  This shows information about the runtime objects.

The link cannot open errors that were generated by the platform. So if you suspect that the issue is caused by the platform, you can try to reproduce the error in a sandbox environment before you contact Microsoft for support. For more information, see Create a sandbox environment.

> **TIP**
> If your users complain of a confusing error message such as *Sorry, we just updated this page. Please close and reopen.*, then you can often find the underlying problem either in this last known error, or by analyzing telemetry in the Business Central administration center. For example, in the case of the *Sorry, we just updated this page. Please close and reopen.* message, the underlying problem is often that two users are trying to modify the same data. So if both users open the same sales order, and both change a field, then one of them will see the *Sorry, we just updated this page. Please close and reopen.* message, because Business Central saves changes as soon as you move to the next field or close the page.

Escalating support issues to Microsoft

Sometimes the tenant has run into a problem that the partner cannot resolve. In those cases, the delegated admin can use the Partner Center or the Business Central administration center to submit a support request to Microsoft.

Both internal and delegated administrators can access Business Central administration center, and then, in the **Support** menu, choose the **New Support Request** button. This logs you in to the Power Platform Admin Center. Here, you can launch the **New Support Request** guide that will help you identify potential solutions or workarounds based on how you fill in the various fields.

In the Power Platform Admin Center, both internal and delegated administrators can explore different solutions based on the keywords that they specify.

> **NOTE**
> The internal administrator cannot contact Microsoft directly. If you are an internal admin and suspect that something is wrong with your Business Central, you must contact your partner for next steps.

Submitting support requests on behalf of your customer

As the delegated administrator, if you are logged into the Business Central administration center, you can use the **New Support Request** link in the **Support** menu to submit a support request on behalf of your customer.

> **TIP**
>
> Alternatively, you can use customer-specific URLs such as `https://admin.powerplatform.microsoft.com/account/login/[customer tenant ID]`.

To start the process of submitting a new support request from the Business Central administration center

1. On the **Environments** tab of the Business Central administration center, choose the relevant environment to open the environment details.
2. In the **Support** menu, choose **New Support Request**.

   This opens a new browser tab so that you can submit the support request in the Power Platform Admin Center.

In the Power Platform Admin Center, you are automatically logged in with information about the customer tenant that you are working on behalf of. Create a new support request and fill in the fields as appropriate, but remember to use the **See solutions** button to find potential guidance or workarounds. Based on your search keywords, links to suggested documentation are shown on the **Solutions** tab.

You can find most of the necessary information in the Business Central administration center, including the tenant ID and the Business Central version numbers. For more information, see View solutions or enter a support request through the new support center in the Power Platform administration content.

> **IMPORTANT**
>
> Your company must be registered as a partner in order to submit a support request to Microsoft, and you must have the ASfP (Advanced Support for Partners) support plan. The support person can be a member of the **Helpdesk agent** group in the customer's Azure AD tenant or a global administrator. For more information, see Delegated Administrator Access to Business Central Online. Your service account manager can get you more information about getting the ASfP, and, if you already have a support plan, they can get the contract information and access ID that you must specify when you submit a new support request on behalf of your customer.

Microsoft Support will keep you updated on the status of your support request. You can also see the status in the Power Platform Admin Center. For more information, see Power Platform Admin Center.

To start the process of submitting a new support request from the Partner Center

You can also start the process from the Partner Center, where you can choose the customer you want to open a case on, and then follow the support request work flow. This will redirect the delegated administrator to the Power Platform admin center in the context of the customer's tenant.

However, you might need information from the Business Central administration center, which is why we recommend that route. For more information, see Report problems on behalf of a customer in the Partner Center content.

Report customer outages

When a customer has a situation where no users can log in to Business Central, you must take immediate action. Outages are frustrating but rare, so make sure that you verify that the users are not unable to log in due to problems with their network connection, for example. For more information, see How do I check my online service health? in the Power Platform administration content.

Internal and delegated administrators can report this outage to Microsoft by using the **Report Production Outage** action for the relevant production environment in the Business Central administration center. This action creates a support ticket for Microsoft with all the information that is needed to begin steps to resolve the issue.

> **NOTE**
> This option is not available in sandbox environments.

To report an outage

1. On the **Environments** tab of the Business Central administration center, choose the relevant environment to open the environment details.
2. In the action ribbon, choose **Support**, and then choose **Report Production Outage**.
3. In the **Report Production Outage** pane, choose the outage type:
   - Unable to log on (all users)
   - Cannot access API/Web Service
4. Enter your name, email address, and phone number. This information will be included in the support ticket.
5. Choose **Next**.
6. In the next pane, provide details about the outage, including which browsers users have tried to log in with, any companies that you can log into, and errors and correlation IDs. This information will be included in the support ticket.
7. Finally, add the date and time when the outage began. This information will also flow to the support ticket.
8. Choose the consent checkbox, and then choose **Report**.

A support request ticket is then created, and you will see a dialog box with the ticket ID. You can then monitor progress in the **Reported Outages** section. From there, you can access the tickets in the Partner Center. For more information, see the Microsoft Partner Center documentation.

Special Permission Sets

2/17/2021 • 2 minutes to read • Edit Online

The following permission sets have special definitions that you should be aware of as you implement permissions and security for Business Central users.

PERMISSION SET	DEFINITION
SUPER	Can read, use, update, and delete all data and all application objects in the scope of your license. Business Central requires that at least one user is assigned this permission set in each database. The first user created is automatically assigned the SUPER Permission Set You can't modify permissions for the SUPER permission set.
SUPER (DATA)	Can read, use, update, and delete all data. You typically assign this permission set to an accounting manager who needs to work with all data but doesn't need to change Business Central. **Note:** This permission set is available only for Business Central on-premises.
SECURITY	Manage the permission sets that are assigned to your account. When assigned this permission set, you can: • Create new users and assign them any permission set that is also assigned to your account. • Remove a permission set from a user as long as the permission set is also assigned to your account. • Modify individual permission granted by a permission set as long as the permission set is also assigned to your account. The idea behind this permission set is to prohibit you from granting users more permissions than you have. The permission set is useful for SUPER users or global administrators who want to delegate permission management to team administrators. For example, a sales manager can assign permissions in sales area to sales people, sales assistant, sales coordinator, and so on.
BASIC	Grants Read access to almost all application tables and all system tables. The main purpose of this permission set is to enable the service to open and show all pages.

PERMISSION SET	DEFINITION
FOUNDATION	A prerequisite for all other permission sets. The FOUNDATION permission set grants access to system tables and application setup tables that are required for most application features to work. **Note:** This permission set is recommended when using the UI Elements Removal feature to automatically remove UI elements according to user permissions. For more information, see Removing Elements from the User Interface According to Permissions. **Note:** This permission set is available only for Business Central on-premises.

Removing Elements from the User Interface According to Permissions

Setting up the Excel Add-In for Editing Business Central Data

2/17/2021 • 9 minutes to read • Edit Online

You can set up the Business Central deployment to support an Excel add-in that enables users in the Business Central client to work with data from list pages in Excel. Users can get fresh data from Business Central into Excel and push updated data from Excel to Business Central.

Without this add-in, users can open a list page in Excel from the **Open in Excel** action on the page. But the **Open in Excel** action doesn't allow them to push changed data back to Business Central. When this add-in is set up, the **Open in Excel** action is replaced by the **Edit in Excel** action. The add-in is based on the Microsoft Dynamics Office Add-In.

> **NOTE**
> The Excel add-in is not available in the mobile apps.

This article provides guidance for how to configure Business Central so that users can edit data in Excel.

> **NOTE**
> This article does not apply to the older Excel add-in that was available for installation with the Dynamics NAV Client connected to Business Central client by using the Business Central Setup in versions older than 2019 release wave 2.

Deploy the Excel add-in for Business Central online

For Business Central online, the administrator can deploy the add-in for all users. But users can also install the add-in themselves, provided they have permission to configure their Office experience.

> **TIP**
> In some organizations, administrators cannot deploy add-ins centrally. For more information, see Determine if Centralized Deployment of add-ins works for your organization.

To deploy the Excel add-in for all users

1. As the administrator, sign in to the Microsoft commercial website and find the add-in at https://appsource.microsoft.com/product/office/WA104379629.
2. Choose the **Get it now** button.

   You'll be redirected to the Microsoft 365 admin center.
3. In the left panel, go to **Settings**, and then choose **Add-ins**.
4. In the **Configure add-in** pane, specify which users to grant access to the add-in.
5. Save your changes.

When users now choose the **Edit in Excel** action, the add-in will launch as a pane in Excel. Each user will be automatically logged in and connected to their Business Central, but if a user cannot connect automatically, you

can unblock them by asking them to follow the steps in the To configure the connection section.

To add the Excel add-in locally

1. Open Excel, and then open any Excel workbook.
2. On the **Insert** menu, choose **Office Add-ins**, and then choose **Admin managed** or **Store** as appropriate.
3. Search for *Dynamics Office Add-In*, and then install the add-in.

When the add-in is installed, it shows up as a panel in Excel. Next, you must configure the connection.

To configure the connection

1. In the Dynamics 365 Excel add-in, choose **Add server information**, and then in the **Server URL** field, enter `https://exceladdinprovider.smb.dynamics.com`.
2. Choose the OK button, and then confirm that the app reloads.
3. When prompted, sign in with your Azure Active Directory account.
4. Optionally, choose the environment and company that you want to connect to.

The add-in is now connected to your Business Central, and you can edit data and publish the changes to Business Central.

> **TIP**
> If the workbook is not automatically saved to the user's OneDrive, then recommend them to save all workbooks that they export from Business Central. When they open the workbook again, the connection is still available, so they do not have to configure the connection again.

> **NOTE**
> In certain deployments, the administrator must configure network access to unblock the Excel add-in. For more information, see Preparing Your Network for the Excel Add-In.

Troubleshooting

Sometimes, users run into problems with the Excel add-in. In this section, we provide tips for how to unblock users in certain circumstances.

ISSUE	SOLUTION OR WORKAROUND	COMMENTS
The add-in doesn't start	Check if the add-in is deployed centrally, or if the user is blocked from installing it locally.	The admin can configure Office so that users cannot acquire add-ins. In those cases, the admin must deploy the add-in centrally. For more information, see Deploy add-ins in the admin center.
Data does not load into Excel	Test the connection by opening another list in Excel from Business Central. Alternatively, open the workbook in Excel in a browser.	If the user has specified a company name that contains special characters, the add-in might not be able to connect.
Data can't publish back to Business Central.	Test the connection by opening the workbook in Excel in a browser.	Sometimes an extension can block the publishing job. If the page is extended or customized, remove the extensions, and then try again.

ISSUE	SOLUTION OR WORKAROUND	COMMENTS
The dates are wrong	Excel might show times and dates in a different format than Business Central. This does not make them wrong, and the data in Business Central will not get messed up.	

Deploy the Excel add-in for Business Central on-premises

Your on-premises deployment must meet the following prerequisites:

- Azure Active Directory (Azure AD) used to authenticate users.

  The Business Central Server instance, clients, and users must be configured for Azure Active Directory (Azure AD) authentication.

  For more information, see Authenticating Users with Azure Active Directory.

- OData enabled and uses Secure Sockets Layer (SSL) for authentication.

  For more information, see Using Security Certificates with Business Central On-Premises.

- Business Central Web Server installed and configured to use SSL (https).

  For more information, see Install Business Central and Configure SSL to Secure the Connection to Web Client.

- If your deployment is multitenant, Business Central Web client must accept host names for tenants.

  For more information, see Configure the Web Server to Accept Host Names for Tenants.

- Business Central client computers have a supported version of Excel.

  For more information, see System Requirements.

Expose the Business Central application Web API in Azure AD

APPLIES TO: Business Central On-Premises

When Business Central is configured for Azure AD authentication, the Business Central application is registered as an application in an Azure AD. Before the Excel add-in can be configured, you must configure the Business Central application in Azure AD to expose its Web API.

For information about how to expose the Web API, see Quickstart: Configure an application to expose web APIs.

Register and configure an Azure AD application for the Excel Add-in in Microsoft Azure

APPLIES TO: Business Central On-Premises

When Azure AD authentication was set up for your Business Central deployment, an Azure AD tenant was created in Microsoft Azure, and an application for Business Central was registered in the tenant. The Excel add-in requires that you add (register) a separate Azure AD application in the Azure AD tenant.

1. Register an Azure AD application for the Excel add-in.

   You add the Azure AD application by using the Azure portal. For guidelines, see Register your application with your Azure Active Directory tenant.

   When you add an application to an Azure AD tenant, you must specify the following information:

SETTING	DESCRIPTION
Name	The name of your application as it will display to your users, such as *Excel Add-in for Business Central*.
Supported account types	Specifies which accounts that you would like your application to support. For purposes of this article, select **Accounts in this organizational directory only**.
Redirect URI	Specifies the type of application that you're registering and the redirect URI (or reply URL) for your application. Select the type to **Web**, and in the redirect URL box, enter URL for signing in to the Business Central Web client, for example `https://localhost:443/BC170/SignIn`. The URI has the format `https://<domain or computer name>/<webserver-instance>/SignIn`, such as `https://cronusinternationltd.onmicrosoft.com/BC170/SignIn` or `https://MyBcWebServer/BC170/Signin`. **Important** The portion of the reply URL after the domain name (in this case `BC170/SignIn`) is case-sensitive, so make sure that the web server instance name matches the case of the web server instance name as it is defined on IIS for your Business Central Web Server installation.

When completed, the **Overview** displays in the portal for the new Excel Add-in application.

2. Grant the Excel add-in application permission to access the Business Central application Web API.

   Give the Azure AD application for the Excel add-in delegated permission to access the Business Central application Web API in Azure AD (which you exposed earlier in this article). This permission allows users of the Excel add-in to access the OData web services to read and write data.

   a. From the application's **Overview**, select **API Permissions**.
   b. Select the **Add a permission**
   c. On the **APIs my organization uses**, select the Business Central application.
   d. Select **Delegated permission**.
   e. Select the permission from the list, and then select **Add Permission**.

   For information, see Quickstart: Configure a client application to access web APIs.

3. Configure OAuth2 authentication in the Excel add-in.

   The Excel add-in requires OAuth2 implicit grant flow to be enabled on the Excel Add-in application. You configure OAuth2 in the manifest file for the Excel Add-in application. From the application's **Overview**, select **Manifest**, and then set `"oauth2AllowIdTokenImplicitFlow"` and `"oauth2AllowImplicitFlow"` to `true`:

   ```
   "oauth2AllowIdTokenImplicitFlow": true,
   "oauth2AllowImplicitFlow": true,
   ```

4. In the manifest, add the following URL entry to the `"replyUrlsWithType":`:

```
{
    "url": "https://az689774.vo.msecnd.net/dynamicsofficeapp/v1.3.0.0/*",
    "type": "Web"
}
```

Remember to add a comma before or after this entry, depending on where you add it in the list.

5. Copy the **Application (Client) ID** that is assigned to Excel add-in application.

   You can get this value from the **Overview** page for the application. You'll need it to configure the Business Central Server instance.

This completes the work you have to do in the Azure portal. The final configuration is to add the Excel add-in to the Business Central Server instances.

Configure the Business Central Server Instances

APPLIES TO: Business Central On-Premises

You add the Excel add-in to the Business Central Server instances in your deployment. You can use either the Business Central Server Administration tool or Set-NAVServerConfiguration cmdlet in the Business Central Administration Shell.

1. In the Business Central Server Administration tool, in the **Azure Active Directory** section, set the **Excel add-in AAD client ID** field to the application (client) ID for the Excel add-in application that you copied from the Azure portal.

   If you use the Set-NAVServerConfiguration cmdlet, set the `ExcelAddInAzureActiveDirectoryClientId` key.

2. In the **Client Services** section, set the **Web Client Base URL** field to the base URL of the Business Central Web client.

   This value is the root portion of all URLs that are used to access pages in the web client. The value must have the format `https://[hostname:port]/[instance]`, such as `https://MyBCWebServer/BC` or `https://cronusinternationltd.onmicrosoft.com/BC170`.

   If using the **Set-NAVServerConfiguration** cmdlet, set the `PublicWebBaseUrl` key.

3. In the **OData Services** section, set the **OData Base URL** field to the public URL for accessing OData services.

   The URL must have the following format `https://<hostname>:<port>/<instance>/ODataV4/`, such as `https://localhost:7048/BC170/ODataV4/`.

   With the **Set-NAVServerConfiguration** cmdlet, set the `PublicODataBaseUrl` key.

Prepare devices and network for the Excel Add-In

Network services such as proxies or firewalls must allow routing between each client device on which the Add-In is installed and a number of service endpoints. For a list of endpoints, see Preparing your network for the Excel Add-In.

Use the Excel Add-In

Your users can now use the Excel add-in. When a list page shows the **Edit in Excel** action, then users can open lists, such as the **Customers** page, in Excel and work with the data there. They use the add-in to update data in Business Central and get fresh data from the database. For more information, see Viewing and Editing in Excel From Business Central.

Preparing Your Network for the Excel Add-In

2/17/2021 • 2 minutes to read • Edit Online

As the administrator of Business Central online or on-premises, you can deploy an add-in so that users can work with their Business Central data in the Excel desktop app. This article includes information that helps administrators configure advanced device and network settings for the Excel add-in for Business Central when your network requirements block the add-in.

Network endpoints required by the Excel add-in

The Excel add-in must have access to Business Central for it to function and synchronize business data. Network services, such as proxies or firewalls, must allow routing between each client device on which the add-in is installed and the following services that are published by Microsoft:

- `https://az689774.vo.msecnd.net`
- `https://dc.services.visualstudio.com`
- `https://exceladdinprovider.smb.dynamics.com`
- `https://api.businesscentral.dynamics.com`

> **NOTE**
>
> Your API endpoint URL can be different from these default values. For example, if your environment is based on a vertical solution by Fabrikam, your API endpoint is `https://fabrikam.api.bc.dynamics.com`. These vertical solutions have API endpoints that are based on the format of `ApplicationName`*.api.bc.dynamics.com*. You can check if an environment uses such a URL in the Business Central Administration Center.

Managing an Business Central Embed App in Microsoft Lifecycle Services

Setting up App Key Vaults for Business Central Online

2/17/2021 • 3 minutes to read • Edit Online

APPLIES TO: Business Central 2020 release wave 2 and later

AppSource apps for Business Central can be developed to get secrets from Azure Keys Vaults. The app key vault feature is readily available for use on the service by all App Source apps. However, there are some onboarding tasks required.

> **IMPORTANT**
> With Business Central online, App key vaults can only be used with AppSource apps. They're not supported with per-tenant extensions.

> **TIP**
> You must also specify secrets in a key vault if you deploy Business Central as part of the Embed App program. Especially if you must support the Outlook add-in, in which case you must specify secrets for TEMPORARYDOCUMENTSTORAGEACCOUNT and TEMPORARYDOCUMENTSTORAGEKEY.

For more information about developing extensions with key vaults, see Using Key Vault Secrets in Business Central Extensions.

Create the Azure Key Vault with secrets

In this task, you create a key vault in Azure, and add the secrets that you want to make available to your extensions. An extension can use up to two key vaults, so you can create more than one.

There are different ways to create an Azure key vault. For example, you can use the Azure portal, Azure CLI, and more.

The easiest way is to use the Azure portal. For instructions, see Quickstart: Set and retrieve a secret from Azure Key Vault using the Azure portal.

For using other methods, see Azure Key Vault Developer's Guide.

Provision the key reader application in your Azure AD tenant

Your Business Central online solution is configured to use an Azure AD application for reading key vault secrets. The application is called **Dynamics 365 Business Central ISV Key Vault Reader**. Microsoft manages the key vault reader application, however, there are a couple tasks that you have to do to enable it. First, the application must be provisioned on your Azure AD tenant, as described here.

To provision the key vault reader application, use the Azure Active Directory PowerShell module.

1. Open Windows PowerShell as an administrator.
2. Install the Azure Active Directory PowerShell module.

```
Install-Module AzureAD
```

3. Import the Azure AD module.

```
Import-Module AzureAD
```

4. Connect to your Business Central Azure AD tenant.

   a. Run the following command:

   ```
   Connect-AzureAD
   ```

   b. Provide your sign-in name and password when prompted.

5. Create an Azure AD service principal using the following command:

```
New-AzureADServicePrincipal -AppId 7e97dcfb-bcdd-426e-8f0a-96439602627a
```

`7e97dcfb-bcdd-426e-8f0a-96439602627a` is the Application (client) ID of Microsoft's centralized Azure AD application.

This step provisions the application in your Azure AD tenant, where it now "lives" together with your key vaults.

Grant the key vault reader application permission to your key vaults

The next task is to grant the key vault reader application permission to read secrets from your key vaults. The steps in this task are done from the Azure portal.

1. Open the key vault in the portal.
2. Select **Access policies**, then **Add Access Policy**.
3. Set **Secret Permissions** to **Get**.
4. Choose **Select principal**, and on the right, search for either the application (client) ID **7e97dcfb-bcdd-426e-8f0a-96439602627a** or the display name **Dynamics 365 Business Central ISV Key Vault Reader**.
5. Select **Add**, then **Save**.

Contact Microsoft to enable the App Key Vault feature

Send an email to bcappkeyvaultonboard@microsoft.com to start the onboarding process. Do this step before you publish your updated extension to Partner Center.

The onboarding process involves a manual verification step that verifies that you own the AAD tenant that contains the key vaults.

Provide the following information in the email:

- Your AAD tenant ID. Obtain this information from the Azure portal by going to the Azure Active Directory Overview page.
- Your AppSource extensions, including names and App IDs, that should be enabled to read secrets from your key vaults.
- Optionally, a screenshot from the Azure portal showing the key vault and its access policies. The screenshot can help Microsoft catch configuration mistakes early in the process.

Upgrading AppSource Apps in Production

2/17/2021 • 2 minutes to read • Edit Online

When an updated version of an AppSource app becomes the active version in the Dynamics 365 Business Central service, tenants do not automatically get this updated version. This upgrade must be done manually by getting the latest version of the app in AppSource.

To upgrade an AppSource app

Follow the steps below to update a tenant to the latest version of any AppSource app.

1. Log in to the Dynamics 365 Business Central browser client.
2. In the **Tell Me** box, enter **Extension Management**, and then choose the related link.
3. Locate the app that you want to update.
4. Under **Manage**, choose **Uninstall**.
5. Go to AppSource and then install the app again.

Production and Sandbox Environments

2/17/2021 • 6 minutes to read • Edit Online

You can create environments of different types. Which type of environment to choose depends on what you need it for.

Production environments

Production environments are meant to be precisely that: Environments that a business can run their daily business in Business Central in, deployed on performance tiers in Azure with a guaranteed high level of availability and support.

Production environments are backed up automatically and frequently to help protect business data. For more information, see How often are production databases backed up?.

You can create additional production environments for training or performance testing, for example. However, for training purposes, in many cases organizations will prefer to create a sandbox environment with production data. You can also create additional production environments to support offices in different countries.

> **NOTE**
>
> The Premium and Essential subscription types give each Business Central customer one production environment and three sandbox environment free of extra charge. If the customer requires more production environments, they can buy additional environments through their CSP partner. Each additional production environment comes with three additional sandbox environments and 4 GB additional, tenant-wide database capacity.

Administrators can create the additional environments in the Business Central administration center. The environments can be created and used in any country or region where Business Central is available, including the countries or regions where the customer's existing environments are running. The environments quota is applied when you try to create a new environment, or copy an existing environment, in the Business Central administration center.

Sandbox environments

Sandbox environments are meant to be precisely that: Environments that you can play around with, use as a testbed for development, and delete at will. You can deploy apps straight from Visual Studio Code to a sandbox environment, and you can attach a debugging session to a sandbox.

> **IMPORTANT**
>
> Apps that are published to a sandbox from the development environment or created using Designer are published within the scope of the service node that hosts the environment. When the sandbox is upgraded, these apps are removed because the environment is moved to another node that is running the new version. However, the data of the app is not removed, so you only have to re-publish and install the app to make it available.
> Apps that are uploaded to the environments of both types (production and sandbox) using the **Upload Extension** action from the **Extension Management** page are published within a global scope. When the environment is upgraded or moved, these apps are downloaded to the service node and installed, which means that they will not disappear.

You can also safely use sandboxes for training, such as for following a learning path from Microsoft Learn, because it's a safe environment to experiment with. If anything goes wrong, you just delete the sandbox and

start over.

> **IMPORTANT**
> The automatic backup that applies to production environments does not apply to sandbox environments. If you want to export data from a sandbox environment, you can use Excel or RapidStart, but you cannot request a database export.

You can create a sandbox environment that includes data from your production environment for debugging purposes, for example. But if you want to run performance tests, or similar benchmarking, the sandbox is not reliable enough for that purpose. This is because sandboxes run in a different performance tier on Azure than production environments. Instead, create a dedicated environment based on the Production environment type - this gives you the exact experience and performance that users will experience in the actual production environment.

Sandbox environments are handy for certain types of development scenarios because the debugging endpoint is open by default. This means that you can attach Visual Studio Code to a running system and debug through running code. It also allows you to publish directly to the environment from Code.

If your organization has more than one sandbox environment, you can switch between environments by opening the App Launcher, choosing the Dynamics 365 tile, then choose the Business Central Sandbox tile. The sandbox environment picker shows the available sandboxes, so choose the one that you want to switch to.

> **NOTE**
> The Premium and Essential subscription types give each Business Central customer one production environment and three sandbox environment free of extra charge. If the customer requires more production environments, they can buy additional environments through their CSP partner. Each additional production environment comes with three additional sandbox environments and 4 GB additional, tenant-wide database capacity.

Administrators can create the additional environments in the Business Central administration center. The environments can be created and used in any country or region where Business Central is available, including the countries or regions where the customer's existing environments are running. The environments quota is applied when you try to create a new environment, or copy an existing environment, in the Business Central administration center.

Precautions for sandbox environments with production data

If a sandbox is created with a copy of a production environment, a number of precautions are taken for that sandbox:

- The job queue is automatically stopped
- Any base application integration settings are cleared
- Outbound HTTP calls from extensions are blocked by default and must be approved for each extension

  To enable outbound HTTP calls, go to the **Extension Management** page in Business Central, and choose **Configure**. Then, on the **Extension Settings** page, make sure that **Allow HttpClient Requests** is selected. This setting must be enabled for each extension.

- Any General Data Protection Regulation (GDPR) action must be handled separately and repeated for the sandbox. There is no synchronization with the production environment after the sandbox has been created.

  The internal administrator has the same tools and responsibilities for a sandbox environment as they do for a production environment. As a data processor, Business Central offers the same level of data protection and data handling restrictions that we apply to production environments.

Pre-sales performance evaluation

If you want to provide a prospect with an online environment where you want to demonstrate the performance and reliability of Business Central online in addition to demonstrating functionality, you must take a few extra steps.

To demonstrate the functionality of the default version of Business Central, without focusing on performance, you can quite simply use your own trial experience based on a Microsoft 365 demo account. We recommend that you show the full functionality of the default version by switching the tenant to the 30 day trial and the associated My Company. You can then enable the *Premium* user experience in the new My Company's **Company Information** page, populate the new company with the data required for their evaluation scenarios, and present the environment to the prospect.

To demonstrate the functionality of the service, with a focus on performance, you can take the same step as outlined above, but then also sign up the prospect for the Business Central Premium Trial offer that is available through your CSP access in the Partner Center, wait 24 hours, and then run your performance evaluation. For more information, see Preparing Test Environments of Dynamics 365 Business Central.

That 30 day trial is as close to an actual production environment performance as you can get. You only have those 29 days to run your tests and convince the prospect, of course, but provided that you have prepared everything in advance, it should give you time enough.

If the prospect is convinced and decides to buy Business Central, you can then either let them keep the environment that they are currently using, or create a new production environment for them. If the tenant is yours rather than the prospect's, then a new tenant will be provided to them.

For more information about performance and Business Central, see Performance Overview.

Creating default sandbox environments

A single, default sandbox environment can also be created in the Business Central application. For more information, see How to: Create a Sandbox Environment.

Preparing Demonstration Environments of Dynamics 365 Business Central

2/17/2021 • 8 minutes to read • Edit Online

As a Business Central reselling partner, you might want to have an environment that you can show prospects as part of pre-sales demonstrations. Depending on your requirements, you have several different options that are described in this article.

Microsoft 365 demo plus Business Central

For repeatable demos that showcase Business Central together with Microsoft apps and services in an independent Azure organization (tenant) that you fully control, get a Microsoft 365 demo account that you create on https://aka.ms/CDX, which has replaceddemos.microsoft.com. You have access to the site if you are enrolled with the Microsoft Partner Center.

Such Microsoft demo accounts give you environments that you can use for demos and training without the risk of introducing changes to an existing production environment, for example. For more information about demo accounts in general, see Offer your customers trials of Microsoft products in the Partner Center documentation.

To get a demo environment based on Microsoft 365 content packs

1. Log in to aka.ms/cdx using your partner account.
2. Choose the **My Environments** tab, and then, under **My tenants**, choose the **Create Tenant** button.
3. As the type, choose **Quick Tenant**.
4. As the period, choose either a quarter or a full year.

   Your account in CDX has access to a limited quota of tenants that can last three months or a full year. For more information, see the CDX FAQ.
5. As the location, choose the region that is closest to your location.

   This determines the location in which the tenant is deployed, but you will be able to add Business Central environments to it for any country/region afterwards.
6. Choose one of the available content packs and then choose the **Create Tenant** button.

   You can choose the **Dynamics 365 Business Central** content pack if the location you specified is *North America*, *Asia/Pacific*, or *Europe, Middle East, Africa*. This content pack includes demonstration users and Microsoft 365 licenses.

   You can also choose any of the other content packs that might better match your prospects' industry or interests, such as the **Microsoft 365 Business Premium Demo Content** or **Microsoft Teams for Consumer Goods** content packs. These content packs give you a dedicated demonstration organization in Azure that includes multiple demo users with Microsoft 365 licenses.

   > **NOTE**
   > When demand for a specific content pack is high, the **Create Tenant** button is disabled, and you must choose a different content pack.

Next, you sign up for a Business Central trial.

7. In an dedicated browser window, go to the https://dynamics.microsoft.com/business-central/ page, choose the **Get started** button, and then choose the **Sign up now** button.

   Use the new administrator account that you got as part of your demo account, typically called something like `admin@CRMbc123456.onmicrosoft.com`, or `admin@contoso.onmicrosoft.com`.

   > **TIP**
   > We recommend that you use profiles in the Microsoft Edge browser rather than InPrivate or Incognito browser mode. For more information, see Microsoft Edge documentation.

By now, you have a dedicated demonstration organization in Azure that includes multiple demo users with Microsoft 365 licenses, and a Business Central environment.

The initial Business Central demo environment comes with two companies:

- The CRONUS demonstration company
- An empty company with the name*My Company*, but it might have a different display name for demo purposes

You can keep using the demonstration company until the tenant expires, provided that you use it at least a couple of times per week. However, if you start the trial experience or switch to the empty *My Company*, that experience will expire after 30 days. At that point, you canextend the trial, create a new environment, or you can return to the CRONUS demonstration company.

You can now enable the *Premium* user experience in the new My Company's **Company Information** page, populate the new company with the data required for their evaluation scenarios, and present the environment to the prospect.

> **IMPORTANT**
> Environments that are based on Microsoft 365 demo accounts are intended for demonstration and training purposes. If a prospect uses such an environment to help run their business, then they risk losing their company data when demo environment or the Microsoft 365 demo account expires. If a prospect wants to use Business Central to help run their business, they should sign up for a trial using their own email account. For more information, see Dynamics 365 Business Central Trials and Subscriptions in the business functionality content for Business Central.

Customize the demo environment

Because you are logged in as the global administrator of the demonstration tenant, you can access the Microsoft 365 administration center. The following list illustrates the types of work that your demo account can do:

- Subscribe to additional apps and services that may be relevant to your demos
- Configure apps and services by accessing their administration centers
- Modify or add user accounts, and assign licenses
- Set up the organizational profile to reflect your prospect's business and brand

Your administrator account also gives you access to the Business Central administration center, where you can make further customizations, such as the following:

- Create additional environments within the available quota, depending on your needs.

  For example, you can create a Business Central environment for a specific country/region, or create a

dedicated sandbox that you then apply your solution to, such as by deploying your app straight from Visual Studio Code. For more information, seeManaging Environments.

- Specify the update window and date for your environments, so that planned updates will not interfere with your demos.
- Add your own email address to the list of notification recipients, so that you will be informed of upgrades to your Business Central environments or any issues that may impact your planned demos.
- Try out new functionality in preview environments that are available about two months before a major update. For more information, seePrepare for major updates with preview environments.

With your administrator account, you can install apps from AppSource, and you can set up integrations between Business Central and other services. For example, you can add the Business Central app for Microsoft Teams, and you can run the**Set up your Business Inbox in Outlook**assisted setup guide on behalf of the organization. For more information, seeUsing Business Central as your Business Inbox in Outlook. You can also add Dynamics 365 Customer Service,Dynamics 365 Sales,Power Automate,Power Apps, and many more.

Some content packs provide additional demonstration data for non-administrator accounts, such as example channels and conversations in Microsoft Teams that can reduce the time needed to customize the experience for a demo. You can log in with the demo user account, often called `meganb@M365B123456.onmicrosoft.com`, or something similar, for the non-administrator experience.

Use profiles in Microsoft Edge

If you demo in the new Microsoft Edge browser, you can easily switch between different browser profiles. That way, you do not have to use private mode for browsing, and you can let Microsoft Edge save passwords and sites to any of your browser profiles, including a Microsoft 365 demo account. Business Central also performs well in the Microsoft Edge for even better demos. You can also switch the page layout to *Focused* to minimize demo distraction. For more information, see Microsoft Edge documentation.

> **TIP**
> We recommend that you connect to a low-latency network for a faster response time during demos, and that you always plug in your laptop if you are about to demo anything. Performance impact may vary depending on your device and choice of browser, but being plugged in generally helps overall snappiness.

Pre-sales performance evaluation

If you want to provide a prospect with an online environment where you want to demonstrate the performance and reliability of Business Central online in addition to demonstrating functionality, you must take a few extra steps.

To demonstrate the functionality of the default version of Business Central, without focusing on performance, you can quite simply use your own trial experience based on a Microsoft 365 demo account. We recommend that you show the full functionality of the default version by switching the tenant to the 30 day trial and the associated My Company. You can then enable the *Premium* user experience in the new My Company's **Company Information** page, populate the new company with the data required for their evaluation scenarios, and present the environment to the prospect.

To demonstrate the functionality of the service, with a focus on performance, you can take the same step as outlined above, but then also sign up the prospect for the Business Central Premium Trial offer that is available through your CSP access in the Partner Center, wait 24 hours, and then run your performance evaluation. For more information, see Preparing Test Environments of Dynamics 365 Business Central.

That 30 day trial is as close to an actual production environment performance as you can get. You only have those 29 days to run your tests and convince the prospect, of course, but provided that you have prepared everything in advance, it should give you time enough.

If the prospect is convinced and decides to buy Business Central, you can then either let them keep the environment that they are currently using, or create a new production environment for them. If the tenant is yours rather than the prospect's, then a new tenant will be provided to them.

For more information about performance and Business Central, see Performance Overview.

Adding a Business Central trial to your prospect's organization

The easiest way to give a prospect a demonstration of Business Central online, is to quite simply ask them to sign up for a trial from the https://dynamics.microsoft.com/business-central/ page. This way, the prospect will be able to explore the default version of Business Central on their own or together with you.

This type of environment can be useful if you want to demonstrate the general user interface, for example, or talk about how they can add capabilities with apps from AppSource.

> **NOTE**
> If you want to show the prospect the full capabilities in Business Central, you must ask them to change the user experience to Premium in the **Company Information** page. For more information, see Change Which Features are Displayed.

If a prospect has signed up for a free trial, and they use Business Central to help run their business, then they must decide whether to subscribe within the first 60 days. If they extend their trial once, and they are still not sure, they must contact a partner.

However, in many cases, you will probably prefer to show prospects more tailored experiences with your own trial as described in the Microsoft 365 demo plus Business Central section.

Offer your customers trials of Microsoft products

Preparing Test Environments of Dynamics 365 Business Central

2/17/2021 • 2 minutes to read • Edit Online

As a Business Central reselling partner, you might want to have an environment that you can use for testing or pre-sales demonstrations. You can create such environments based on free 30 day trials, or you can set up a dedicated environment if you have a Business Central subscription yourself.

Test environments based on a 30 day trial

This type of environment can be useful if you want to run benchmark tests, for example. The following procedure requires CSP access in Partner Center. If you do not have CSP access, you can work with your CSP distributor to do this for you. For more information, see the Partner Center documentation.

To create a test environment based on a 30 day trial

1. In Partner Center, create a new test customer with any test domain, such as *contoso.onmicrosoft.com*. For more information, see Add a new customer in the Partner Center docs.

   a. Fill in the fields as described in the following list:

FIELD	VALUE
Country	<Your country>
Subscription	*Dynamics 365 Business Central Premium Trial* This will give you 25 Premium licenses for 30 days for free

   b. Make a note of the Admin credentials that are shown on the last page of the customer creation wizard. You will need these credentials later.

2. In Partner Center, once the test customer has been created, create a new test user. For more information, see Create user accounts for a customer in the Partner Center documentation.

3. Assign that user 1 Premium license.

   > **NOTE**
   > It may take up to 10 minutes for the available licenses to show up on the **Users** page.

   Also, make a note of the user credentials shown on the last page of the user creation wizard. You will use this information in step 55

4. In the **Service Management** section, choose the **Dynamics 365 Business Central** link.

   This opens the Business Central administration center at the equivalent of the following URL:
   `https://businesscentral.dynamics.com/contoso.onmicrosoft.com/admin`

   In the Business Central administration center, you can create new production and sandbox environments for the test customer.

> **TIP**
> Always include the domain or the Azure Active Directory ID of the customer in the URL when you login as a *delegated admin*. This way, you always know exactly which customer you are trying to access.

5. Access Business Central as the local user that you created in step 2.

   a. Open another browser window in InPrivate or Incognito mode. This way, you can make sure that you are not logging in with your own credentials.

   > **TIP**
   > We recommend that you use profiles in the Microsoft Edge browser instead. For more information, see Microsoft Edge documentation.

   b. Go to *https://businesscentral.dynamics.com/*, and then, when you are asked to sign in, use the credentials of the user you created in step 2.

The Business Central environment is created automatically when you use the environment URL to login the first time.

Prepare for major updates with preview environments

About two months before a major update, you can try out new functionality in preview environments. For more information, see Prepare for major updates with preview environments.

Prepare for major updates with preview environments

2/17/2021 • 4 minutes to read • Edit Online

About one month before a major update, you can try out new functionality in preview environments. Preview environments are essentially Business Central online sandbox environments that you create on a preview version of the application. When you create the new sandbox environment, choose the preview version marked as *(Preview)* from the version list. This way, you get a new sandbox environment with a preview version of the application.

You must have access to Microsoft Collaborate in order to submit your feedback and report any potential issues that you discover in the preview version of the application. For more information about getting access to Collaborate, see Step 4: Getting access to preview bits.

> **NOTE**
> Previews roll out gradually across the world, so if the option is not showing up for you today, please try again tomorrow.

The newly created preview sandbox environment contains demonstration company data. Trying the preview on a copy of your current production data is not yet supported; nor is testing the upgrade from your current version to the preview. However, you can use the newly created sandbox environment for exploring and learning the new product capabilities, as well as validating that your per-tenant extensions are still working as expected.

If you run your tests on a preview environment one month before the announced major release of Business Central, it is more likely that the coming updates of your production environments will go smoother. This way, you, your customers, and your code are better prepared for the official release.

We expect to update the preview version only if we discover critical issues before the major update is generally available for production environments. Apart from these potential fixes, we do not expect any further changes to the product between the preview and the official release. This means that you can start your testing and learning activities immediately, without waiting for the official release.

> **NOTE**
> You will be able to test the update on a copy of your production data in a sandbox environment when we release the new update in production in April or October, respectively. When the official release becomes available, you can continue your tests on that version. You will no longer be able to create new preview sandboxes.

> **IMPORTANT**
> The preview version as well as all sandbox environments that are based on it will be removed 30 days after the official release becomes available.

Practice and test

Once you have the preview, start using it:

1. Review the new functionality. Try it out, and begin training employees on the new features that are coming.

2. Validate your extensions.

   Upload and install your extensions into the sandbox environments created on the preview version and run through the functionality. Verify that the customization continues to work and is compatible with the new version.

   In rare cases, if you discover any changes required for your per-tenant extension to become compatible with the next release, apply the changes to your app, test it again on a sandbox environment running on a preview version. Then, if tests complete successfully, upload the app into your production environment, setting **Deploy to** field to **Next major version**. This way the compatible version of your app will be used when you schedule upgrade of your production environment to the new major update once it becomes available.

3. Test the quality. If you run into issues related to the preview, please provide feedback on Collaborate.

Finally, as always, if you have ideas for features you would like to see in future releases of Business Central, let us know at https://aka.ms/bcideas.

Provide feedback on the preview

We need your feedback on the preview! Let us know about your experiences with the new version. You can provide feedback on Microsoft Collaborate:

1. Browse to aka.ms/collaborate
2. If you have not registered before, please complete the registration form to access Collaborate
3. Choose **Engagements**, and then choose **Join**
4. Under the **Ready! for Dynamics 365 Business Central program**, find **2020 release wave 2 Preview** in the list of available engagements, and choose **Join**

Once you have joined the preview engagement, you can submit your feedback by filling in the form. You must specify if you are reporting a technical issue, a translation issue, or a documentation issue. The default severity is set to 3, which is the normal severity for most defects and means that the system is not crashing and users are not blocked from doing their work, but you can change that. When we have triaged your issue, you can see changes in Collaborate.

> **TIP**
> If you get stuck trying to join Collaborate, please contact dyn365bep@microsoft.com with as many details about the error that you got and other circumstances.

Monitoring and Analyzing Telemetry

2/17/2021 • 4 minutes to read • Edit Online

APPLIES TO: Business Central 2019 release wave 2 and later

Business Central emits telemetry data for various activities and operations on tenants and extensions. Whether running Business Central Online or On-premises, you can set up your tenants to send telemetry to Application Insights. Application Insights is a service hosted within Azure that gathers telemetry data for analysis and presentation. For more information, see What is Application Insights?. Monitoring telemetry gives you a look at the activities and general health of your tenants. It helps you diagnose problems and analyze operations that affect performance.

Tenant-level and extension-level telemetry

Application Insights can be enabled on two different levels: tenant and extension. When enabled on the tenant, either for a Business Central online tenant or on-premises Business Central Server instance, telemetry is emitted to a single Application Insights resource for gathering data on tenant-wide operations.

With Business Central 2020 release wave 2 and later, Application Insights can also be enabled on a per-extension basis. An Application Insights key is set in the extension's manifest (app.json file). At runtime, certain events related to the extension are emitted to the Application Insights resource. This feature targets publishers of per-tenant extensions to give them insight into issues in their extension before partners and customers report them.

Available telemetry

In Application Insights, telemetry from Business Central is logged as traces. Currently, Business Central offers telemetry on the following operations:

AREA	DESCRIPTION	ONLINE	ON-PREMISES	EXTENSION SUPPORT	MORE INFORMATION
App key vault secrets	Provides information about the retrieval of secrets from Azure Key Vaults by extensions.	✓ [1]	✓ [1]	✓	See...
Authorization	Provides information about user sign-in attempts. Information includes success or failure indication, reason for failure, user type, and more.	✓			See...

[1]This signal is only emitted to the Application Insights resource that's specified in the extension.

[2]Introduced in Business Central 2020 release wave 1, version 16.3. For extension telemetry, this signal was introduced in 2020 release wave 2, version 17.1.

Enabling Application Insights

Sending telemetry data to Application Insights requires you have an Application Insights resource in Azure. Once you have the Application Insights resource, you can start to configure your tenants and extensions to send telemetry data to your Application Insights resource. The configuration is different for Online and On-premises:

- For Business Central Online, Application Insights is enabled by using the Administration Center. For more information, see Enable Sending Telemetry to Application Insights.
- For Business Central On-premises, see Enable Sending Telemetry to Application Insights.
- For extensions, see Sending Extension Telemetry to Azure Application Insights.

Viewing telemetry data in Application Insights

Telemetry from Business Central is stored in Azure Monitor Logs in the *traces* table. You can view collected data by writing log queries. Log queries are written in the Kusto query language (KQL). For more information, see Logs in Azure Monitor and Overview of log queries in Azure Monitor.

As a simple example, do the following steps:

1. In the Azure portal, open your Application Insights resource.
2. In the **Monitoring** menu, select **Logs**.
3. On the **New Query** tab, type the following to get the last 100 traces:

```
traces
| take 100
| sort by timestamp desc
```

About Custom Dimensions

Each trace includes a `customDimensions` column. The `customDimensions` column, in turn, includes a set dimensions that contain metrics specific to the trace. Each of these custom dimensions has a limit of 8000 characters. If a dimension's value exceeds 8000 characters, additional dimensions will be added to the trace for containing the excess characters. There can be up to two additional parameters, each with a maximum 8000 characters. The additional dimensions will have the names that `<custom_dimension_name>_1` and `<custom_dimension_name>_2`, where `<custom_dimension_name>` is the name of the original dimension. For example, if the custom dimension is `extensionCompilationDependencyList`, then the additional dimensions would be `extensionCompilationDependencyList_1` and `extensionCompilationDependencyList_2`.

> **NOTE**
>
> The 8000 character limit is governed by the Application Insights API.

Application Insights sample code

On the Business Central BCTech repository on GitHub, samples of KQL code are available to make it easy to get started using Application Insights.

For more information, see Business Central BCTech repository on GitHub.

Analyzing App Key Vault Secret Trace Telemetry

2/17/2021 • 6 minutes to read • Edit Online

APPLIES TO: Business Central 2020 release wave 2 and later

App key vault telemetry gathers information about the acquisition of secrets in Azure Key Vaults by extensions at runtime. For an overview of app key vaults and secrets, see Using App Key Vaults with Business Central Extensions.

The app key vault secret process has two operations: *initialization* and *retrieval*. The telemetry data provides information about the success or failure for each of these operations. There are various conditions that cause a failure. The failure messages provide insight into the cause of the failure, helping you identify, troubleshoot, and resolve issues.

Initialization

Initialization is the first stage. It verifies the configuration of the app key vault provider in the extension and on the service. This stage is initiated by the `TryInitializeFromCurrentApp` method call in the extension code. Some conditions that cause failures in this stage include:

- The extension doesn't specify a key vault in it's app.json file.
- The Azure Key Vault Client Identity settings are incorrect. For example, it could be that the application (client) ID that you specified for the key vault reader application in Azure is wrong.
- The Business Central Server lacks permission to the private key of the Azure Key Vault client certificate.

Retrieval

Retrieval is the second stage, and occurs after a successful initialization. In this stage, the service tries to get a secret from a specified key vault. This stage is initiated by the `GetSecret` method call in the extension code. Some conditions that cause failures include:

- The secret name requested by the extension is doesn't exist or isn't valid.
- The key vault doesn't exist.
- The application ID doesn't have permission to read from the key vault.

For more information about using key vault secrets with extensions, see App Key Vaults with Business Central Extensions.

App Key Vault secret initialization succeeded

Occurs when an extension secret was successfully initialized.

General dimensions

DIMENSION	DESCRIPTION OR VALUE
message	**App Key Vault initialization succeeded: '{keyVaultUri}'.**
severityLevel	1

Custom dimensions

DIMENSION	DESCRIPTION OR VALUE
alObjectId	Specifies the ID of the AL object that was run by request.
alObjectName	Specifies the name of the AL object that was run by request.
alObjectType	Specifies the type of AL object that was run by request.
alStackTrace	The stack trace in AL.
clientType	Specifies the type of client that executed the request, such as **Background** or **Web**. For a list of the client types, see ClientType Option Type.
component	**Dynamics 365 Business Central Server**.
componentVersion	Specifies the version number of the component that emits telemetry (see the component dimension.)
deprecatedKeys	A comma-separated list of all the keys that have been deprecated. The keys in this list are still supported but will eventually be removed in the next major release. We recommend that update any queries that use these keys to use the new key name.
eventId	**RT0014**
extensionId	Specifies the AppID of the extension that requested the secret.
extensionName	Specifies the name of the extension that requested the secret.
extensionPublisher	Specifies the publisher of the extension that requested the secret.
extensionVersion	Specifies the version of the extension that requested the secret.
keyVaultUrls	Specifies the DNS name of the Azure key vault that was used in the request. The keyVaultUris are specified in the app.json file of the extension.
telemetrySchemaVersion	Specifies the version of the Business Central telemetry schema.

App Key Vault initialization failed

Occurs when a key vault failed to be initialized.

General dimensions

DIMENSION	DESCRIPTION OR VALUE
message	**App Key Vault initialization failed.**

DIMENSION	DESCRIPTION OR VALUE
severityLevel	3

Custom dimensions

DIMENSION	DESCRIPTION OR VALUE
alObjectId	Specifies the ID of the AL object that was run by request.
alObjectName	Specifies the name of the AL object that was run by request.
alObjectType	Specifies the type of AL object that was run by request.
alStackTrace	The stack trace in AL.
clientType	Specifies the type of client that executed request, such as **Background** or **Web**. For a list of the client types, see ClientType Option Type.
component	**Dynamics 365 Business Central Server**.
componentVersion	Specifies the version number of the component that emits telemetry (see the component dimension.)
deprecatedKeys	A comma-separated list of all the keys that have been deprecated. The keys in this list are still supported but will eventually be removed in the next major release. We recommend that update any queries that use these keys to use the new key name.
eventId	**RT0015**
extensionId	Specifies the AppID of the extension that requested the secret.
extensionName	Specifies the name of the extension that requested the secret.
extensionPublisher	Specifies the publisher of the extension that requested the secret.
extensionVersion	Specifies the version of the extension that requested the secret.
failureReason	Specifies the error that occurred.
telemetrySchemaVersion	Specifies the version of the Business Central telemetry schema.

App Key Vault secret retrieval succeeded

Occurs when a secret used by an extension is successfully retrieved from an Azure Key Vault.

General dimensions

DIMENSION	DESCRIPTION OR VALUE
message	**App Key Vault secret retrieval succeeded from key vault '{keyVaultUri}'.**
severityLevel	1

Custom dimensions

DIMENSION	DESCRIPTION OR VALUE
alObjectId	Specifies the ID of the AL object that was run by request.
alObjectName	Specifies the name of the AL object that was run by request.
alObjectType	Specifies the type of AL object that was run by request.
alStackTrace	The stack trace in AL.
clientType	Specifies the type of client that executed the SQL Statement, such as **Background** or **Web**. For a list of the client types, see ClientType Option Type.
component	**Dynamics 365 Business Central Server**.
componentVersion	Specifies the version number of the component that emits telemetry (see the component dimension.)
deprecatedKeys	A comma-separated list of all the keys that have been deprecated. The keys in this list are still supported but will eventually be removed in the next major release. We recommend that update any queries that use these keys to use the new key name.
eventId	**RT0016**
extensionId	Specifies the AppID of the extension that requested the secret.
extensionName	Specifies the name of the extension that requested the secret.
extensionPublisher	Specifies the publisher of the extension that requested the secret.
extensionVersion	Specifies the version of the extension that requested the secret.
keyVaultUrl	Specifies the DNS name of the Azure key vault that was used in the request. The keyVaultUris are specified in the app.json file of the extension.
telemetrySchemaVersion	Specifies the version of the Business Central telemetry schema.

App Key Vault secret retrieval failed

Occurs when an extension failed to retrieve a secret from a specified Azure key vault.

General dimensions

DIMENSION	DESCRIPTION OR VALUE
message	**App Key Vault secret retrieval failed from key vault '{keyVaultUri}'.**
severityLevel	**3**

Custom dimensions

DIMENSION	DESCRIPTION OR VALUE
alObjectId	Specifies the ID of the AL object that was run by request.
alObjectName	Specifies the name of the AL object that was run by request.
alObjectType	Specifies the type of AL object that was run by request.
alStackTrace	The stack trace in AL.
clientType	Specifies the type of client that executed the SQL Statement, such as **Background** or **Web**. For a list of the client types, see ClientType Option Type.
component	**Dynamics 365 Business Central Server**.
componentVersion	Specifies the version number of the component that emits telemetry (see the component dimension.)
deprecatedKeys	A comma-separated list of all the keys that have been deprecated. The keys in this list are still supported but will eventually be removed in the next major release. We recommend that update any queries that use these keys to use the new key name.
eventId	**RT0017**
extensionId	Specifies the AppID of the extension that requested the secret.
extensionName	Specifies the name of the extension that requested the secret.
extensionPublisher	Specifies the publisher of the extension that requested the secret.
extensionVersion	Specifies the version of the extension that requested the secret.

DIMENSION	DESCRIPTION OR VALUE
keyVaultUrl	Specifies the DNS name of the Azure key vault that was used in the request. The keyVaultUris are specified in the app.json file of the extension.
telemetrySchemaVersion	Specifies the version of the Business Central telemetry schema.

Analyzing Authorization Trace Telemetry

2/17/2021 • 10 minutes to read • Edit Online

APPLIES TO: Business Central 2019 release wave 2 and later

Authorization telemetry provides information about the authorization of users when they try to sign in to Business Central. This telemetry data can help you identify problems a user might experience when signing in.

Authorization signals are emitted in two stages of sign-in. The first stage is the initial authorization, before the CompanyOpen trigger is run. In this stage, the system verifies that the user account is enabled in the tenant and has the correct entitlements. The telemetry data includes:

- Success or failure of the sign-in attempt
- Reason for failure
- Type of user (such as normal, administrator, or delegated user)
- Whether the user belongs to the tenant or is an invited user

The next stage occurs after a successful authorization attempt, when trying to open the company (that is, when the CompanyOpen trigger run). The telemetry data indicates whether the company opened successfully or failed (for some reason).

> **NOTE**
> Business Central 2020 release wave 1, version 16.1, introduces changes to some `operation_Name` and `message` dimension values. The differences from earlier versions are indicated in the following sections.

AuthorizationSucceeded(PreOpenCompany)

Occurs when a user has been successfully authorized.

General dimensions

DIMENSION	DESCRIPTION OR VALUE
message	Version 16.1 and later: **AuthorizationSucceeded(PreOpenCompany)** Before Version 16.1: **Authorization steps prior to the open company trigger succeeded.**
operation_Name	**AuthorizationSucceeded(PreOpenCompany)** **Note:** The use of the `operation_Name` column was deprecated in version 16.1. In future versions, data won't be stored in this column. So in version 16.1 and later, use the custom dimension column `eventID` column custom in Kusto queries instead of `operation_Name`.
severityLevel	1

Custom dimensions

DIMENSION	DESCRIPTION OR VALUE
authorizationStatus	**Succeeded**
aadTenantId	Specifies that Azure Active Directory (Azure AD) tenant ID used for Azure AD authentication. For on-premises, if you aren't using Azure AD authentication, this value is **common**.
component	**Dynamics 365 Business Central Server**.
componentVersion	Specifies the version number of the component that emits telemetry (see the component dimension.)
environmentName	Specifies the name of the tenant environment. See Managing Environments.
environmentType	Specifies the environment type for the tenant, such as **Production**, **Sandbox**, **Trial**. See Environment Types
entitlementSetIds	Specifies the entitlements that the user has in Business Central.
eventId	**RT0003**
guestUser	**true** indicates that the user is a guest user on the tenant. **false** indicates the user belongs to the tenant.
telemetrySchemaVersion	Specifies the version of the Business Central telemetry schema.
userType	Specifies whether the user is a **Delegated_admin**, **Internal_Admin**, or **Normal user**. See UserType.

UserType

VALUE	DESCRIPTION	SEE MORE
Delegated_admin	Indicates that the user is a delegated administrator on the tenant. Delegated administrators are typically reserved for partners. Delegated administrator privileges are granted to users by the customer. You grant these privileges by setting up a Partner Relationship in the Microsoft Partner Center.	Delegated Administrator Access to Business Central Online Customers delegate administration privileges to partners
Internal_Admin	Indicates that the user is an internal administrator on the tenant. As an internal administrator, the user is assigned the **Global admin** role in the Microsoft 365 admin center.	Administration as an internal administrator in Business Central Assign admin roles in Microsoft 365 admin center
Normal user	Indicates that the user is a normal user in the tenant, based on the license.	Create Users According to Licenses

> **NOTE**
>
> The client type is not known when the server emits the pre-open company events (RT0001 and RT0003). You need to join to data for the events RT0002/RT0004 if you need both userType and clientType.

AuthorizationFailed(PreOpenCompany)

Occurs when a user sign-in has failed authorization.

General dimensions

DIMENSION	DESCRIPTION OR VALUE
message	Version 16.1 and later (depending on the cause): • **AuthorizationFailed(PreOpenCompany): User is disabled.** • **AuthorizationFailed(PreOpenCompany): User has no entitlements.** Before Version 16.1: **Authorization steps prior to the open company trigger failed, see failureReason column for details.**
operation_Name	**Authorization Failed (Pre Open Company)** **Note:** The use of the `operation_Name` column was deprecated in version 16.1. In future versions, data won't be stored in this column. So in version 16.1 and later, use the custom dimension column `eventID` column custom in Kusto queries instead of `operation_Name`.
severityLevel	3

Custom dimensions

DIMENSION	DESCRIPTION OR VALUE
authorizationStatus	**Failed**
failureReason	Specifies why the sign-in failed. See Troubleshooting failures section for details.
guestUser	**true** indicates that the user is a guest user on the tenant. **false** indicates the user belongs to the tenant.
eventId	**RT0001**
userType	Specifies whether the user is a **Delegated_admin**, **Internal_Admin**, or **Normal user**. See UserType.

Troubleshooting failures

The user was successfully authenticated in Azure Active Directory but the user account is disabled in Business Central.

This message occurs when the user's account is valid, but the account is disabled. If you open the user account in Business Central, you'll see the **State** field is set to **Disabled**.

Resolution

Enable the user account by setting the **State** field to **Enabled**. For more information, see Create Users According to Licenses.

A user successfully authenticated in Azure Active Directory but the user does not have any entitlements in Business Central.

This message occurs if the user has an account, but the account hasn't been assigned any entitlements.

Entitlements are part of the license. Entitlements are permissions that describe which objects in Business Central a user can use, according to their Azure Active Directory role or license. For an explanation of entitlements, see Business Central entitlements explained

Resolution

Entitlements are assigned to the user account in the Microsoft 365 admin center or Microsoft Partner Center. They aren't assigned in Business Central. To assign entitlements to a user, see one of the following articles:

- From Microsoft 365 admin center, see Add users individually or in bulk to Microsoft 365.
- From the Microsoft Partner Center, see User management tasks for customer accounts.

Authorization Succeeded (Open Company)

Occurs when the company has opened successfully.

General dimensions

DIMENSION	DESCRIPTION OR VALUE
message	Version 16.1 and later: **Authorization Succeeded (Open Company)** Before version 16.1: **Authorization steps in the open company trigger succeeded.**
operation_Name	**Authorization Succeeded (Open Company)** **Note:** The use of the `operation_Name` column was deprecated in version 16.1. In future versions, data won't be stored in this column. So in version 16.1 and later, use the custom dimension column `eventID` column custom in Kusto queries instead of `operation_Name`.
severityLevel	1

Custom dimensions

DIMENSION	DESCRIPTION OR VALUE
authorizationStatus	**Success**
aadTenantId	Specifies that Azure Active Directory (Azure AD) tenant ID used for Azure AD authentication. For on-premises, if you aren't using Azure AD authentication, this value is **common**.
clientType	Specifies the type of client that opened the session, such as **Background** or **Web**. For a list of the client types, see ClientType Option Type.

DIMENSION	DESCRIPTION OR VALUE
companyName	Specifies the display name of the Business Central company for which the report was run.
component	**Dynamics 365 Business Central Server**.
componentVersion	Specifies the version number of the component that emits telemetry (see the component dimension.)
environmentName	Specifies the name of the tenant environment. See Managing Environments.
environmentType	Specifies the environment type for the tenant, such as **Production**, **Sandbox**, **Trial**. See Environment Types
eventId	**RT0004**
result	**Success**
serverExecutionTime	Specifies the amount of time it took the server to open the company**. The time has the format hh:mm:ss.sssssss. Doesn't apply to the **Cancellation report generation** trace.
sqlExecutes	Specifies the number of SQL statements that the report executed**. Doesn't apply to the **Cancellation report generation** trace.
sqlRowsRead	Specifies the number of table rows that were read by the SQL statements**. Doesn't apply to the **Cancellation report generation** trace.
telemetrySchemaVersion	Specifies the version of the Business Central telemetry schema.
totalTime	Specifies the amount of time it took to open the company**. The time has the format hh:mm:ss.sssssss. Doesn't apply to the **Cancellation report generation** trace.

** From telemetrySchemaVersion **0.6** and onwards, this value also includes the CompanyOpen operation.

Authorization Failed (Open Company)

Occurs when a company has failed to open.

General dimensions

DIMENSION	DESCRIPTION OR VALUE
message	Version 16.1 and later (depending on the cause): • **Authorization Failed (Open Company): Invalid company name.** • **Authorization Failed (Open Company): User has no permission to company.** • **Authorization Failed (Open Company): The tenant is locked.** • **Authorization Failed (Open Company): The license has expired or the trial period has ended.** • **Authorization Failed (Open Company): The user's license is not valid for use on production companies.** Before version 16.1: **Authorization steps in the open company trigger failed, see failureReason column for details.**
operation_Name	**Authorization Failed (Open Company)** **Note:** The use of the `operation_Name` column was deprecated in version 16.1. In future versions, data won't be stored in this column. So in version 16.1 and later, use the custom dimension column `eventID` column custom in Kusto queries instead of `operation_Name`.
severityLevel	3

Custom dimensions

DIMENSION	DESCRIPTION OR VALUE
authorizationStatus	**Failed**
companyName	Specifies the name of the company that the user tried to open.
failureReason	Specifies why the sign-in failed. See Troubleshooting failures section for details.
eventId	**RT0002**

Troubleshooting failures

The company name is not valid, because the name is either empty or exceeds the maximum allowed length.

This message occurs when a user tries to sign in to a company whose name exceeds the maximum allowed length.

Resolution

This message typically occurs when a user tries to access a specific company in Business Center by entering a URL in the browser address, for example, `https://businesscentral.dynamics.com/?company=CRONUS%20International%20Ltd.`. If the name exceeds 30 characters, then this message occurs. Make sure that the user has the proper name of the company.

The user does not have permission to access the company.

This message occurs when a user account in Business Central doesn't have the proper permissions to the company.

Resolution

In Business Central, open the user account and modify the permissions the user to give them access to the company. For more information, see Assign Permissions to Users and Groups.

> **TIP**
> A good starting point is to look at the **Effective Permissions** that the user has on the company. You can do this from the user card by selecting **Effective Permissions** and setting the **Company** to the company in question.

The company doesn't exist.

This message occurs when a user tries to sign in to a company, but the company isn't found in Business Central.

Resolution

This message typically occurs when a user tries to access a specific company in Business Center by entering a URL in the browser address, for example, `https://businesscentral.dynamics.com/?company=CRONUS%20International%20Ltd.`. Make sure that the user has the proper name of the company.

User cannot open the company because the tenant is locked.

This message indicates that the tenant has been locked by Microsoft, typically for security reasons like preventing repeated malicious sign-in attempts. The tenant isn't accessible by any user.

Resolution

For help with resolving this issue, read the following articles or contact Microsoft Support:

- Troubleshoot account lockout problems with an Azure AD Domain Services managed domain
- "It looks like your account has been blocked" error when signing in to Microsoft 365

The user can't sign in to the company because the assigned license has expired or the trial period has ended.

This message occurs for one the following reasons:

- The license being used has expired.
- The license was trial license and the trial period has ended. Trial licenses are typically assigned when customers subscribe for an evaluation version by using self-service sign-up (also known as IW or viral sign-up). This license has a time limit.

Resolution

Renew the existing license or obtain a new license. Licenses are purchased through the Cloud Solution Provider (CSP) program. For more information, see the Cloud Service Provider site and the Microsoft Dynamics 365 Business Central Licensing Guide.

You can't open the company, because it is a production company. Your license isn't valid for use on production companies.

This message occurs because the license doesn't allow the user to open production companies. For example, the user may be using a trial license that is only valid on the evaluation version.

Resolution

Obtain a license that can be used on production companies. Licenses are purchased through the Cloud Solution Provider (CSP) program. For more information, see the Cloud Service Provider site and the Microsoft Dynamics 365 Business Central Licensing Guide.

Analyzing Company Lifecycle Trace Telemetry

2/17/2021 • 11 minutes to read • Edit Online

INTRODUCED IN: Business Central 2020 release wave 1, version 16.1

Company lifecycle telemetry gathers data about the success or failure of the following company-related operations:

- creating a company
- copying a company
- deleting a company

Failed operations result in a trace log entry that includes a reason for the failure.

Company created

Occurs when the company has been successfully created.

General dimensions

DIMENSION	DESCRIPTION OR VALUE
message	**Company created: {companyName}** `{companyName}` indicates the name of the new company.
severityLevel	1

Custom dimensions

DIMENSION	DESCRIPTION OR VALUE
aadTenantId	Specifies that Azure Active Directory (Azure AD) tenant ID used for Azure AD authentication. For on-premises, if you aren't using Azure AD authentication, this value is **common**.
clientType	Specifies the type of client that executed the SQL Statement, such as **Background** or **Web**. For a list of the client types, see ClientType Option Type.
companyName	Specifies the display name of the Business Central company.
component	**Dynamics 365 Business Central Server**
componentVersion	Specifies the version number of the component that emits telemetry (see the component dimension.)
deprecatedKeys	Specifies a comma-separated list of all the keys that have been deprecated. The keys in this list are still supported but will eventually be removed in the next major release. We recommend that update any queries that use these keys to use the new key name.

DIMENSION	DESCRIPTION OR VALUE
environmentName	Specifies the name of the tenant environment. See Managing Environments.
environmentType	Specifies the environment type for the tenant, such as **Production**, **Sandbox**, **Trial**. See Environment Types
eventId	**LC0001**
result	**Success**
serverExecutionTime	Specifies the amount of time it took the server to create the company. The time has the format hh:mm:ss.sssssss.
sqlExecutes	Specifies the number of SQL statements that were executed.
sqlRowsRead	Specifies the number of table rows that were read by the SQL statements.
telemetrySchemaVersion	Specifies the version of the Business Central telemetry schema.
totalTime	Specifies the amount of time it took to create the company. The time has the format hh:mm:ss.sssssss.

Company creation canceled

Occurs when creating a company was canceled.

General dimensions

DIMENSION	DESCRIPTION OR VALUE
message	**Company creation canceled: {companyName}** `{companyName}` indicates the name of the company being created.
severityLevel	2

Custom dimensions

DIMENSION	DESCRIPTION OR VALUE
aadTenantId	Specifies that Azure Active Directory (Azure AD) tenant ID used for Azure AD authentication. For on-premises, if you aren't using Azure AD authentication, this value is **common**.
clientType	Specifies the type of client that executed the SQL Statement, such as **Background** or **Web**. For a list of the client types, see ClientType Option Type.
companyName	Specifies the display name of the Business Central company.

DIMENSION	DESCRIPTION OR VALUE
component	**Dynamics 365 Business Central Server**.
componentVersion	Specifies the version number of the component that emits telemetry (see the component dimension.)
deprecatedKeys	Specifies a comma-separated list of all the keys that have been deprecated. The keys in this list are still supported but will eventually be removed in the next major release. We recommend that update any queries that use these keys to use the new key name.
environmentType	Specifies the environment type for the tenant, such as **Production**, **Sandbox**, **Trial**. See Environment Types
eventId	**LC0002**
failureReason	**Operation was canceled**
result	**Failure**
serverExecutionTime	Specifies the amount of time it took the server create the company before being canceled. The time has the format hh:mm:ss.sssssss.
sqlExecutes	Specifies the number of SQL statements that were executed by the operation.
sqlRowsRead	Specifies the number of table rows that were read by the SQL statements.
telemetrySchemaVersion	Specifies the version of the Business Central telemetry schema.
totalTime	Specifies the amount of time used to create the company before being canceled. The time has the format hh:mm:ss.sssssss.

Company creation failed

Occurs when a company failed to be created.

General dimensions

DIMENSION	DESCRIPTION OR VALUE
message	**Company creation failed: {companyName}** `{companyName}` indicates the name of the company being created.
severityLevel	1

Custom dimensions

DIMENSION	DESCRIPTION OR VALUE
aadTenantId	Specifies that Azure Active Directory (Azure AD) tenant ID used for Azure AD authentication. For on-premises, if you aren't using Azure AD authentication, this value is **common**.
clientType	Specifies the type of client that executed the SQL Statement, such as **Background** or **Web**. For a list of the client types, see ClientType Option Type.
companyName	Specifies the display name of the Business Central company.
component	**Dynamics 365 Business Central Server**.
componentVersion	Specifies the version number of the component that emits telemetry (see the component dimension.)
deprecatedKeys	Specifies a comma-separated list of all the keys that have been deprecated. The keys in this list are still supported but will eventually be removed in the next major release. We recommend that update any queries that use these keys to use the new key name.
environmentType	Specifies the environment type for the tenant, such as **Production**, **Sandbox**, **Trial**. See Environment Types
eventId	**LC0003**
failureReason	Specifies the exception that indicates the cause of the failure.
result	**Failure**
serverExecutionTime	Specifies the amount of time it took the server create the company before it failed. The time has the format hh:mm:ss.ssssss.
sqlExecutes	Specifies the number of SQL statements that were executed by the operation.
sqlRowsRead	Specifies the number of table rows that were read by the SQL statements.
telemetrySchemaVersion	Specifies the version of the Business Central telemetry schema.
totalTime	Specifies the amount of time used to create the company before it failed. The time has the format hh:mm:ss.ssssss.

Company copied

Occurs when a company has been copied from another company successfully.

General dimensions

DIMENSION	DESCRIPTION OR VALUE
message	**Company copied: {companyNameSource} to {companyNameDestination}** • `{companyNameSource}` is name of the company that was copied. • `{companyNameDestination}` is the name of new company that was created.
severityLevel	2

Custom dimensions

DIMENSION	DESCRIPTION OR VALUE
aadTenantId	Specifies that Azure Active Directory (Azure AD) tenant ID used for Azure AD authentication. For on-premises, if you aren't using Azure AD authentication, this value is **common**.
clientType	Specifies the type of client that executed the SQL Statement, such as **Background** or **Web**. For a list of the client types, see ClientType Option Type.
companyNameDestination	Specifies the name of the new company.
companyNameSource	Specifies the name of the Business Central company.
component	**Dynamics 365 Business Central Server**.
componentVersion	Specifies the version number of the component that emits telemetry (see the component dimension.)
deprecatedKeys	Specifies a comma-separated list of all the keys that have been deprecated. The keys in this list are still supported but will eventually be removed in the next major release. We recommend that update any queries that use these keys to use the new key name.
environmentType	Specifies the environment type for the tenant, such as **Production**, **Sandbox**, **Trial**. See Environment Types
eventId	**LT0004**
result	**Success**
serverExecutionTime	Specifies the amount of time it took the server to copy the company. The time has the format hh:mm:ss.sssssss.
sqlExecutes	Specifies the number of SQL statements that were executed by the operation.
sqlRowsRead	Specifies the number of table rows that were read by the SQL statements.

DIMENSION	DESCRIPTION OR VALUE
telemetrySchemaVersion	Specifies the version of the Business Central telemetry schema.
totalTime	Specifies the amount of time it took to copy the company. The time has the format hh:mm:ss.sssssss.

Company copy canceled

Occurs when a copying a company was canceled.

General dimensions

DIMENSION	DESCRIPTION OR VALUE
message	**Company copied canceled: {source company name} to {destination company name}** • `{companyNameSource}` is name of the company that was being copied. • `{companyNameDestination}` is the name of new company that was being created.
severityLevel	2

Custom dimensions

DIMENSION	DESCRIPTION OR VALUE
aadTenantId	Specifies that Azure Active Directory (Azure AD) tenant ID used for Azure AD authentication. For on-premises, if you aren't using Azure AD authentication, this value is **common**.
clientType	Specifies the type of client that executed operation, such as **Background** or **Web**. For a list of the client types, see ClientType Option Type.
companyName	Specifies the display name of the Business Central company.
component	**Dynamics 365 Business Central Server**.
componentVersion	Specifies the version number of the component that emits telemetry (see the component dimension.)
environmentType	Specifies the environment type for the tenant, such as **Production**, **Sandbox**, **Trial**. See Environment Types
eventId	**LC0005**
failureReason	**Operation was canceled**.
result	**Failure**

DIMENSION	DESCRIPTION OR VALUE
serverExecutionTime	Specifies the amount of time it took the server to copy the company. The time has the format hh:mm:ss.sssssss.
sqlExecutes	Specifies the number of SQL statements that were executed.
sqlRowsRead	Specifies the number of table rows that were read by the SQL statements.
telemetrySchemaVersion	Specifies the version of the Business Central telemetry schema.
totalTime	Specifies the amount of time used to do the operation. The time has the format hh:mm:ss.sssssss.

Company copy failed

Occurs when a company failed to be copied from another company.

General dimensions

DIMENSION	DESCRIPTION OR VALUE
message	**Company copy failed: {companyNameSource} to {companyNameDestination}** • `{companyNameSource}` is name of the company that was being copied. • `{companyNameDestination}` is the name of new company that was being created.
severityLevel	3

Custom dimensions

DIMENSION	DESCRIPTION OR VALUE
aadTenantId	Specifies that Azure Active Directory (Azure AD) tenant ID used for Azure AD authentication. For on-premises, if you aren't using Azure AD authentication, this value is **common**.
clientType	Specifies the type of client that executed the SQL Statement, such as **Background** or **Web**. For a list of the client types, see ClientType Option Type.
companyName	Specifies the display name of the Business Central company.
component	**Dynamics 365 Business Central Server**.
componentVersion	Specifies the version number of the component that emits telemetry (see the component dimension.)
environmentType	Specifies the environment type for the tenant, such as **Production**, **Sandbox**, **Trial**. See Environment Types

DIMENSION	DESCRIPTION OR VALUE
eventId	**LC0006**
failureReason	Specifies the exception that indicates the cause of the failure.
result	**Failure**
serverExecutionTime	Specifies the amount of time on the server. The time has the format hh:mm:ss.sssssss.
sqlExecutes	Specifies the number of SQL statements that were executed.
sqlRowsRead	Specifies the number of table rows that by the SQL statements.
telemetrySchemaVersion	Specifies the version of the Business Central telemetry schema.
totalTime	Specifies the amount of time used to create the company before it failed. The time has the format hh:mm:ss.sssssss.

Company deleted

Occurs when a company has been deleted successfully.

General dimensions

DIMENSION	DESCRIPTION OR VALUE
message	**Company deleted: {companyName}** `{companyName}` indicates the name of the company that was deleted.
severityLevel	1

Custom dimensions

DIMENSION	DESCRIPTION OR VALUE
aadTenantId	Specifies that Azure Active Directory (Azure AD) tenant ID used for Azure AD authentication. For on-premises, if you aren't using Azure AD authentication, this value is **common**.
clientType	Specifies the type of client that executed the SQL Statement, such as **Background** or **Web**. For a list of the client types, see ClientType Option Type.
companyName	Specifies the display name of the Business Central company.
component	**Dynamics 365 Business Central Server**.
componentVersion	Specifies the version number of the component that emits telemetry (see the component dimension.)

DIMENSION	DESCRIPTION OR VALUE
environmentType	Specifies the environment type for the tenant, such as **Production**, **Sandbox**, **Trial**. See Environment Types
eventId	**LC0007**
result	**Success**
serverExecutionTime	Specifies the amount of time it took on server. The time has the format hh:mm:ss.ssssss.
sqlExecutes	Specifies the number of SQL statements that the operation executed.
sqlRowsRead	Specifies the number of table rows that were read by the SQL statements.
telemetrySchemaVersion	Specifies the version of the Business Central telemetry schema.
totalTime	Specifies the amount of time it took to delete the company. The time has the format hh:mm:ss.sssssss.

Company deletion canceled

Occurs when deleting a company failed was canceled.

General dimensions

DIMENSION	DESCRIPTION OR VALUE
message	**Company deletion canceled: {companyName}** `{companyName}` indicates the name of the company that was being deleted.
severityLevel	2

Custom dimensions

DIMENSION	DESCRIPTION OR VALUE
aadTenantId	Specifies that Azure Active Directory (Azure AD) tenant ID used for Azure AD authentication. For on-premises, if you aren't using Azure AD authentication, this value is **common**.
clientType	Specifies the type of client that executed the SQL Statement, such as **Background** or **Web**. For a list of the client types, see ClientType Option Type.
companyName	Specifies the display name of the Business Central company.
component	**Dynamics 365 Business Central Server**.

DIMENSION	DESCRIPTION OR VALUE
componentVersion	Specifies the version number of the component that emits telemetry (see the component dimension.)
environmentType	Specifies the environment type for the tenant, such as **Production**, **Sandbox**, **Trial**. See Environment Types
eventId	**LC0008**
failureReason	**Operation was canceled**
result	**Failure**
serverExecutionTime	Specifies the amount of time it took on server. The time has the format hh:mm:ss.sssssss.
sqlExecutes	Specifies the number of SQL statements that executed by the operation.
sqlRowsRead	Specifies the number of table rows that were read by the SQL statements.
telemetrySchemaVersion	Specifies the version of the Business Central telemetry schema.
totalTime	Specifies the amount of time used to delete the company before being canceled. The time has the format hh:mm:ss.sssssss.

Company deletion failed

Occurs when a company failed to be deleted.

General dimensions

DIMENSION	DESCRIPTION OR VALUE
message	**Company deletion failed: {companyName}** `{companyName}` indicates the name of the company that was being deleted.
severityLevel	3

Custom dimensions

DIMENSION	DESCRIPTION OR VALUE
aadTenantId	Specifies that Azure Active Directory (Azure AD) tenant ID used for Azure AD authentication. For on-premises, if you aren't using Azure AD authentication, this value is **common**.

DIMENSION	DESCRIPTION OR VALUE
clientType	Specifies the type of client that executed the SQL Statement, such as **Background** or **Web**. For a list of the client types, see ClientType Option Type.
companyName	Specifies the display name of the Business Central company.
component	**Dynamics 365 Business Central Server**.
componentVersion	Specifies the version number of the component that emits telemetry (see the component dimension.)
environmentType	Specifies the environment type for the tenant, such as **Production**, **Sandbox**, **Trial**. See Environment Types
eventId	**LC0009**
failureReason	Specifies the exception that caused the failure.
result	**Failed**
serverExecutionTime	Specifies the amount of time it took on server. The time has the format hh:mm:ss.sssssss.
sqlExecutes	Specifies the number of SQL statements that executed by the operation.
sqlRowsRead	Specifies the number of table rows that were read by the SQL statements.
telemetrySchemaVersion	Specifies the version of the Business Central telemetry schema.
totalTime	Specifies the amount of time used to delete the company before it failed. The time has the format hh:mm:ss.sssssss.

Analyzing Configuration Package Lifecycle Trace Telemetry

2/17/2021 • 4 minutes to read • Edit Online

APPLIES TO: Business Central 2020 release wave 2, version 17.2, and later

Configuration package telemetry gathers data about the following operations on configuration packages:

- Export
- Import
- Apply
- Delete

For information about working with configuration packages, see Prepare a Configuration Package in the Business Central Application Help.

Configuration package export started

Occurs when an export operation on a configuration package is started.

General dimensions

DIMENSION	DESCRIPTION OR VALUE
message	**Configuration package export started: {alPackageCode}**
severityLevel	**1**

Custom dimensions

DIMENSION	DESCRIPTION OR VALUE
eventId	**AL0000E3F**
alExecutionId	Specifies the ID of the export operation.
alObjectId	**8614**, which is the ID of the base application codeunit that handles the export of configuration packages.
alObjectName	**Config. XML Exchange**, which is the name of the base application codeunit that handles the export of configuration packages.
alObjectType	**CodeUnit**
alPackageCode	Specifies the ID of the configuration package being exported.

Common custom dimensions

The following table explains additional custom dimensions that are common to all configuration package traces.

DIMENSION	DESCRIPTION OR VALUE
aadTenantId	Specifies that Azure Active Directory (Azure AD) tenant ID used for Azure AD authentication. For on-premises, if you aren't using Azure AD authentication, this value is **common**.
alCategory	**RapidStart**
alDataClassification	**SystemMetadata**
component	**Dynamics 365 Business Central Server**.
componentVersion	Specifies the version number of the component that emits telemetry (see the component dimension.)
environmentType	Specifies the environment type for the tenant, such as **Production**, **Sandbox**, **Trial**. See Environment Types.
telemetrySchemaVersion	Specifies the version of the Business Central telemetry schema.

Configuration package exported successfully

Occurs when an export operation on a configuration package completes successfully.

General dimensions

DIMENSION	DESCRIPTION OR VALUE
message	**Configuration package exported successfully: {alPackageCode}**
severityLevel	1

Custom dimensions

DIMENSION	DESCRIPTION OR VALUE
eventId	**AL0000E3G**
alExecutionId	Specifies the ID of the export operation.
alExecutionTimeInMs	Specifies the number of milliseconds it took to complete the export operation.
alObjectId	**8614**, which is the ID of the base application codeunit that handles the export of configuration packages.
alObjectName	**Config. XML Exchange**, which is the name of the base application codeunit that handles the export of configuration packages.
alObjectType	**CodeUnit**

DIMENSION	DESCRIPTION OR VALUE
alPackageCode	Specifies the ID of the configuration package that was exported.
See common custom dimensions	

Configuration package import started

Occurs when an import operation on a configuration package is started.

General dimensions

DIMENSION	DESCRIPTION OR VALUE
message	**Configuration package import started: {alPackageCode}**
severityLevel	1

Custom dimensions

DIMENSION	DESCRIPTION OR VALUE
eventId	**AL0000E3H**
alExecutionId	Specifies the ID of the import operation.
alObjectId	**8614**, which is the ID of the base application codeunit that handles the import of configuration packages.
alObjectName	**Config. XML Exchange**, which is the name of the base application codeunit that handles the import of configuration packages.
alObjectType	**CodeUnit**
alPackageCode	Specifies the ID of the configuration package being imported.
See common custom dimensions	

Configuration package imported successfully

Occurs when an import operation on a configuration package completes successfully.

General dimensions

DIMENSION	DESCRIPTION OR VALUE
message	**Configuration package imported successfully: {alPackageCode}**
severityLevel	1

Custom dimensions

DIMENSION	DESCRIPTION OR VALUE
eventId	**AL0000E3I**
alExecutionTimeInMs	Specifies the number of milliseconds it took to complete the import operation.
alExecutionId	Specifies the ID of the import operation.
alPackageCode	Specifies the ID of the configuration package that was imported.
alObjectId	**8614**, which is the ID of the base application codeunit that handles the import of configuration packages.
alObjectName	**Config. XML Exchange**, which is the name of the base application codeunit that handles the import of configuration packages.
alObjectType	**CodeUnit**
See common custom dimensions	

Configuration package apply started

Occurs when an apply operation on a configuration package is started.

General dimensions

DIMENSION	DESCRIPTION OR VALUE
message	**Configuration package apply started: {alPackageCode}**
severityLevel	1

Custom dimensions

DIMENSION	DESCRIPTION OR VALUE
eventId	**AL0000E3N**
alExecutionId	Specifies the ID of the apply operation.
alObjectId	**8611**, which is the ID of the base application codeunit that handles applying configuration packages.
alObjectName	**Config. Package Management**, which is the name of the base application codeunit that handles applying configuration packages.
alObjectType	**CodeUnit**

DIMENSION	DESCRIPTION OR VALUE
alPackageCode	Specifies the ID of the configuration package being applied.
See common custom dimensions	

Configuration package applied successfully

Occurs when an apply operation on a configuration package completes successfully.

General dimensions

DIMENSION	DESCRIPTION OR VALUE
message	**Configuration package applied successfully: {alPackageCode}**
severityLevel	1

Custom dimensions

DIMENSION	DESCRIPTION OR VALUE
eventId	**AL0000E3O**
alExecutionId	Specifies the ID of the apply operation.
alExecutionTimeInMs	Specifies the number of milliseconds it took to complete the apply operation.
alErrorCount	Specifies the number of errors that occurred when applying the configuration package.
alFieldCount	Specifies the number of fields that were included in the migration table of the applied configuration package.
alObjectId	**8611**, which is the ID of the base application codeunit that applies configuration packages.
alObjectName	**Config. Package Management**, which is the name of the base application codeunit that applies configuration packages.
alObjectType	**CodeUnit**
alPackageCode	Specifies the ID of the configuration package that was applied.
alRecordCount	Specifies the number of records that were included in the applied configuration package.
See common custom dimensions	

Configuration package deleted successfully

Occurs when a configuration package is deleted successfully.

General dimensions

DIMENSION	DESCRIPTION OR VALUE
message	**Configuration package deleted successfully: {alPackageCode}**
severityLevel	1

Custom dimensions

DIMENSION	DESCRIPTION OR VALUE
eventId	**AL0000E3P**
alObjectId	**8611**, which is the ID of the base application codeunit that deletes configuration packages.
alObjectName	**Config. Package Management**, which is the name of the base application codeunit that handles deleting configuration packages.
alObjectType	**CodeUnit**
alPackageCode	Specifies the ID of the configuration package that was deleted.
See common custom dimensions

Analyzing Database Lock Timeout Trace Telemetry

2/17/2021 • 5 minutes to read • Edit Online

INTRODUCED IN: Business Central 2020 release wave 1, version 16.0

Database lock timeout telemetry gathers information about database locks that have timed out. The telemetry data allows you to troubleshoot what caused these locks.

In the client, when a lock has timed out, the user is presented with a message, similar to the following message:

The operation could not complete because a record in the [table name] table was locked by another user. Please retry the activity.

Two types of trace events are emitted to Application Insights:

- The first is a **Database lock timed out** event. This event includes general information about the lock request. This event includes information like the AL object and code that is impacted by the lock, the extension involved, and more.
- The **Database lock timed out** event then triggers one or more **Database lock snapshot** events. **Database lock snapshot** events provide details about SQL sessions that hold database locks at the time of lock timeout, including the session that caused the lock timeout. These events include specific details about the SQL lock request on the database, like the type, status, mode, and the table.

> **TIP**
> When analyzing database lock timeout telemetry, it's useful to look at combined data from the **Database lock timed out** event and **Database lock snapshot** events. You can combine data from different events by using *joins* in your Kusto queries. For an example, see LockTimeouts.kql in the **Microsoft/BCTech** repository on GitHub. For more general information about using joins, see Joins in Azure Monitor log queries in the Microsoft Azure documentation.

Database lock timed out

Occurs when a database lock has timed out.

General dimensions

DIMENSION	DESCRIPTION OR VALUE
message	**Database lock timed out**
severityLevel	3

Custom dimensions

DIMENSION	DESCRIPTION OR VALUE
aadTenantId	Specifies that Azure Active Directory (Azure AD) tenant ID used for Azure AD authentication. For on-premises, if you aren't using Azure AD authentication, this value is **common**.

DIMENSION	DESCRIPTION OR VALUE
alExecutingMethodScope	Specifies the AL action that is running the transaction that caused the lock.
alObjectId	Specifies the ID of the running AL object that requested the lock.
alObjectName	Specifies the name of the running AL object that requested the lock. not shown
alObjectType	Specifies the type of the running AL object that requested the lock, such as a page or report.
alStackTrace	The stack trace in AL.
clientType	Specifies the type of client that executed the SQL Statement, such as **Background** or **Web**. For a list of the client types, see ClientType Option Type.
companyName	Specifies the display name of the Business Central company.
component	**Dynamics 365 Business Central Server**
componentVersion	Specifies the version number of the component that emits telemetry (see the component dimension.)
deprecatedKeys	Specifies a comma-separated list of all the keys that have been deprecated. The keys in this list are still supported but will eventually be removed in the next major release. We recommend that update any queries that use these keys to use the new key name.
eventId	**RT0012**
environmentName	Specifies the name of the tenant environment. See Managing Environments.
environmentType	Specifies the environment type for the tenant, such as **Production**, **Sandbox**, **Trial**. See Environment Types
extensionId	Specifies the AppID of the extension that was involved in the lock.
extensionName	Specifies the name of the extension that was involved in the lock.
extensionVersion	Specifies the version of that was involved in the lock.
sessionId	Specifies the ID of the session that requested the lock.
snapshotId	Specifies the ID of the database snapshot. This ID is used to identify associated **Database lock snapshot** trace events.

DIMENSION	DESCRIPTION OR VALUE
sqlServerSessionId	Specifies the ID of the SQL server session that requested the lock.
telemetrySchemaVersion	Specifies the version of the Business Central telemetry schema.

Database lock snapshot

Occurs when a database lock has timed out. Each **Database lock snapshot** trace event is associated with a specific **Database lock timed out** trace event.

General dimensions

DIMENSION	DESCRIPTION OR VALUE
message	**Database lock snapshot: {snapshotId}** The value of the `{snapshotId}` maps to the `snapshotId` dimension of the **Database lock timed out** trace event that triggered this event.
severityLevel	3

Custom dimensions

DIMENSION	DESCRIPTION OR VALUE
aadTenantId	Specifies that Azure Active Directory (Azure AD) tenant ID used for Azure AD authentication. For on-premises, if you aren't using Azure AD authentication, this value is **common**.
alExecutingMethodScope	Specifies the AL action that is running the transaction that caused the lock.
alObjectId	Specifies the ID of the running AL object that requested the lock.
alObjectName	Specifies the name of the running AL object that requested the lock.
alObjectType	Specifies the type of the running AL object that requested the lock, such as a page or report.
alStackTrace	The stack trace in AL.
component	**Dynamics 365 Business Central Server**
componentVersion	Specifies the version number of the component that emits telemetry (see the component dimension.)

DIMENSION	DESCRIPTION OR VALUE
deprecatedKeys	Specifies a comma-separated list of all the keys that have been deprecated. The keys in this list are still supported but will eventually be removed in the next major release. We recommend that update any queries that use these keys to use the new key name.
eventId	**RT0013**
environmentName	Specifies the name of the tenant environment. See Managing Environments.
environmentType	Specifies the environment type for the tenant, such as **Production**, **Sandbox**, **Trial**. See Environment Types
extensionId	Specifies the AppID of the extension that was involved in the lock.
extensionName	Specifies the name of the extension that was involved in the lock.
extensionVersion	Specifies the version of that was involved in the lock.
sessionId	Specifies the ID of the session that requested the lock.
snapshotId	Specifies the ID of the database snapshot. All messages in the snapshot share this ID.
sqlLockRequestMode	Specifies the lock mode that determines how concurrent transactions can access the resource. For more information, see Lock Modes.
sqlLockRequestStatus	Specifies the current status of the lock, which can be one of the following values: • `CNVRT` - means that the lock is transitioning from another mode, but the conversion is blocked by another process that holds a lock with a conflicting mode. • `GRANT` - means that the lock is active. • `WAIT` - means that the lock is blocked by another process that holds a lock with a conflicting mode.
sqlLockResourceType	Specifies the database resource affected by the lock. For example, `DATABASE`, `FILE`, `OBJECT`, `PAGE`, `KEY`, and more.
sqlServerSessionId	Specifies the ID of the SQL server session that requested the lock.
sqlTableName	Specifies the name of table on which the lock was held.
telemetrySchemaVersion	Specifies the version of the Business Central telemetry schema.

Analyzing Email Trace Telemetry

2/17/2021 • 2 minutes to read • Edit Online

APPLIES TO: Business Central 2020 release wave 2, update 17.2, and later

Email telemetry gathers data about the following operations:

- An email was sent successfully
- An attempt to send an email failed

Before you can collect this data, you'll have to set up email. For more information, see Set Up Email in the Business Central application help.

Email sent successfully

Occurs when an email was successfully sent from the client.

General dimensions

DIMENSION	DESCRIPTION OR VALUE
message	**Email sent successfully**
severityLevel	**1**

Custom dimensions

DIMENSION	DESCRIPTION OR VALUE
aadTenantId	Specifies that Azure Active Directory (Azure AD) tenant ID used for Azure AD authentication. For on-premises, if you aren't using Azure AD authentication, this value is **common**.
alCategory	**Email**
alConnector	Specifies the email-provider connector used to send the email. Possible values include: • Current User • Microsoft 365 • SMTP • Other custom connectors installed by extensions. The connector is specified on the email accounts that are set up in Business Central. For more information, see Adding Email Accounts.
alDataClassification	**SystemMetadata**
alEmailMessageID	Specifies the GUID assigned to email, like C7A56676-9F3F-4044-90F0-D7F3196AC366.
alObjectId	**8888**, which is the ID of the system application codeunit that sends emails.

DIMENSION	DESCRIPTION OR VALUE
alObjectName	**Email Dispatcher**, which is the name of the system application codeunit that sends the emails.
alObjectType	**CodeUnit**
component	**Dynamics 365 Business Central Server**.
componentVersion	Specifies the version number of the component that emits telemetry (see the component dimension.)
environmentName	Specifies the name of the tenant environment. See Managing Environments. This dimension isn't included for Business Central on-premises environments.
environmentType	Specifies the environment type for the tenant, such as **Production**, **Sandbox**, **Trial**. See Environment Types
eventId	**AL0000CTV**
telemetrySchemaVersion	Specifies the version of the Business Central telemetry schema.

Failed to send email

Occurs when an email failed to be sent from the client.

General dimensions

DIMENSION	DESCRIPTION OR VALUE
message	**Failed to send email.**
severityLevel	**1**

Custom dimensions

DIMENSION	DESCRIPTION OR VALUE
aadTenantId	Specifies that Azure Active Directory (Azure AD) tenant ID used for Azure AD authentication. For on-premises, if you aren't using Azure AD authentication, this value is **common**.
alCategory	**Email**
alConnector	Specifies the email-provider connector used to send the email. Possible values include: • Current User • Microsoft 365 • SMTP • Other custom connectors installed by extensions. The connector is specified on the email accounts that are set up in Business Central. For more information, see Adding Email Accounts.

DIMENSION	DESCRIPTION OR VALUE
alDataClassification	**SystemMetadata**
alEmailMessageID	Specifies the GUID assigned to email, like C7A56676-9F3F-4044-90F0-D7F3196AC366.
alObjectId	**8888**, which is the ID of the system application codeunit that sends emails.
alObjectName	**Email Dispatcher**, which is the name of the system application codeunit that sends the emails.
alObjectType	**CodeUnit**
component	**Dynamics 365 Business Central Server**.
componentVersion	Specifies the version number of the component that emits telemetry (see the component dimension.)
environmentName	Specifies the name of the tenant environment. See Managing Environments. This dimension isn't included for Business Central on-premises environments.
environmentType	Specifies the environment type for the tenant, such as **Production**, **Sandbox**, **Trial**. See Environment Types
eventId	**AL0000CTP**
telemetrySchemaVersion	Specifies the version of the Business Central telemetry schema.

TIP

You can also view failed emails in the **Email Outbox** page in the Business Central client.

Analyzing Extension Lifecycle Trace Telemetry

2/17/2021 • 30 minutes to read • Edit Online

INTRODUCED IN: Business Central 2020 release wave 1, version 16.3. For extension telemetry, this signal was introduced in 2020 release wave 2, version 17.1

Extension lifecycle telemetry gathers data about the success or failure of the following extension-related operations:

- Compiling an extension
- Synchronizing an extension
- Publishing an extension
- Installing an extension
- Updating an extension
- Uninstalling an extension
- Unpublishing an extension

Failed operations result in a trace log entry that includes a reason for the failure.

Data is gathered when the operations are done using:

- Extension Management page in the client.
- Manage Apps page in the Business Central administration center.
- Extension management PowerShell cmdlets from the Business Central Administration Shell.

Behavior overview

- Compiling, publishing, and unpublishing extensions

  Data for these operations is only recorded for extensions that are published in the tenant scope.

  - For on-premises, it includes extensions that are published by running the Publish-NAVApp cmdlet with the `-Scope Tenant` parameter.
  - For online, it includes per-tenant extensions uploaded from the **Extension Management** page in the client. It doesn't include Microsoft extensions or AppSource extensions.

- Synchronizing extensions

  - For on-premises, data for this operation is recorded when an extension is synchronized by using the Sync-NAVApp cmdlet.
  - For online, data is recorded when an extension is installed from the **Extension Management** page in the client. Or, when upgraded from the Manage Apps page in the Business Central administration center.

- Installing and uninstalling extensions

  - For on-premises, data for these operations is recorded when an extension is installed or uninstalled by using the Install-NAVApp cmdlet or Uninstall-NAVApp cmdlet. Or, when an extension is installed or uninstalled from the **Extension Management** page in the client.
  - For on-premises, data for these operations is recorded when an extension is installed or uninstalled from the **Extension Management** page in the client.

- Updating an extension
  - For on-premises, data for this operation is recorded when an extension is upgraded by using the Start-NAVAppDataUpgrade cmdlet.
  - For online, data is recorded when an extension is updated from the Manage Apps page in the Business Central administration center.
- For some operations, you might experience that certain custom dimensions aren't available.

  The reason is that custom dimensions are added to the signal gradually, as the information is retrieved. If the operation fails before the custom dimension is retrieved, it isn't included in the result.

  For example, if you try to uninstall an extension using the Ininstall-NAVApp cmdlet, and the specified extension name is wrong, the operation fails. In this case, the `extensionid` and `extensionVersion` will be excluded from the results.

ENVIRONMENT/SERVER-SIDE OPERATIONS

Extension compiled successfully

Occurs when an extension compiles successfully on the service. An extension compiles when it's published or when it's repaired by using the Repair-NAVApp cmdlet.

General dimensions

DIMENSION	DESCRIPTION OR VALUE
message	**Extension compiled successfully: {extensionName} version {extensionVersion} by {extensionPublisher} ({extensionId})**
severityLevel	**1**

Custom dimensions

DIMENSION	DESCRIPTION OR VALUE
aadTenantId	Specifies that Azure Active Directory (Azure AD) tenant ID used for Azure AD authentication. For on-premises, if you aren't using Azure AD authentication, this value is **common**.
component	**Dynamics 365 Business Central Server**.
componentVersion	Specifies the version number of the component that emits telemetry (see the component dimension.)
deprecatedKeys	Specifies a comma-separated list of all the keys that have been deprecated. The keys in this list are still supported but will eventually be removed in the next major release. We recommend that update any queries that use these keys to use the new key name.
environmentType	Specifies the environment type for the tenant, such as **Production**, **Sandbox**, **Trial**. See Environment Types
eventId	**LC0020**

DIMENSION	DESCRIPTION OR VALUE
extensionCompilationDependencyList	Specifies details about the extensions on which the compiled extension has dependencies. **Note:** If the value exceeds 8000 characters, one or two additional dimensions will be included in the trace to cover the complete dependency list. For more information, see About Custom Dimensions.
extensionCompilationResult	**Compilation succeeded without errors or warnings.**
extensionName	Specifies the name of the extension that was compiled.
extensionId	Specifies the AppID of the extension that was compiled.
extensionPublishedAs	Specifies whether the compiled extension was published as one of the following options: • **Dev** - published from the AL development environment. • **Global** - published to the global scope. • **Tenant** - published to the tenant scope.
extensionPublisher	Specifies the extension's publisher.
extensionScope	Specifies whether the extension was published to one of the following scopes: • **Global** - the extension can be installed on all tenants connected the service instance. • **Tenant** - the extension can only be installed on the tenant to which it was published. .
extensionVersion	Specifies the version of the compiled extension.
result	**Success**
serverExecutionTime	Specifies the amount of time it took the server to complete the request. The time has the format hh:mm:ss.sssssss.
totalTime	Specifies the amount of time it took to process the request. The time has the format hh:mm:ss.sssssss.
telemetrySchemaVersion	Specifies the version of the Business Central telemetry schema.

Extension failed to compile

Occurs when an extension failed to compile on the service. An extension compiles when it's published or when it's repaired by using the Repair-NAVApp cmdlet.

General dimensions

DIMENSION	DESCRIPTION OR VALUE
message	**Extension failed to compile: {extensionName} version {extensionVersion} by {extensionPublisher} ({extensionId})**
severityLevel	**3**

Custom dimensions

DIMENSION	DESCRIPTION OR VALUE
aadTenantId	Specifies that Azure Active Directory (Azure AD) tenant ID used for Azure AD authentication. For on-premises, if you aren't using Azure AD authentication, this value is **common**.
component	**Dynamics 365 Business Central Server**.
componentVersion	Specifies the version number of the component that emits telemetry (see the component dimension.)
deprecatedKeys	Specifies a comma-separated list of all the keys that have been deprecated. The keys in this list are still supported but will eventually be removed in the next major release. We recommend that update any queries that use these keys to use the new key name.
environmentType	Specifies the environment type for the tenant, such as **Production**, **Sandbox**, **Trial**. See Environment Types
eventId	**LC0021**
extensionCompilationDependencyList	Specifies details about the extensions on which the compiled extension has dependencies. **Note:** If the value exceeds 8000 characters, one or two additional dimensions will be included in the trace to cover the complete dependency list. For more information, see About Custom Dimensions.
extensionCompilationResult	Specifies details about the error that occurred during compilation.
extensionName	Specifies the name of the extension that failed to compile.
extensionId	Specifies the AppID of the extension that failed to compile.
extensionPublishedAs	Specifies whether the extension was published as one of the following options: • **Dev** - published from the AL development environment. • **Global** - published to the global scope. • **Tenant** - published to the tenant scope.
extensionPublisher	Specifies the extension's publisher.

DIMENSION	DESCRIPTION OR VALUE
extensionScope	Specifies whether the extension was published to one of the following scopes: • **Global** - the extension can be installed on all tenants connected the service instance. • **Tenant** - the extension can only be installed on the tenant to which it was published. .
extensionVersion	Specifies the version of the compiled extension.
failureReason	Specifies the error that occurred when compiling the extension.
result	**Failure**
serverExecutionTime	Specifies the amount of time it took the server to complete the request. The time has the format hh:mm:ss.sssssss.
totalTime	Specifies the amount of time it took to process the request. The time has the format hh:mm:ss.sssssss.
telemetrySchemaVersion	Specifies the version of the Business Central telemetry schema.

Extension published successfully

Occurs when an extension published successfully on the service.

General dimensions

DIMENSION	DESCRIPTION OR VALUE
message	**Extension published successfully: {extensionName} version {extensionVersion} by {extensionPublisher} ({extensionId})**
severityLevel	1

Custom dimensions

DIMENSION	DESCRIPTION OR VALUE
aadTenantId	Specifies that Azure Active Directory (Azure AD) tenant ID used for Azure AD authentication. For on-premises, if you aren't using Azure AD authentication, this value is **common**.
component	**Dynamics 365 Business Central Server**.
componentVersion	Specifies the version number of the component that emits telemetry (see the component dimension.)

DIMENSION	DESCRIPTION OR VALUE
deprecatedKeys	Specifies a comma-separated list of all the keys that have been deprecated. The keys in this list are still supported but will eventually be removed in the next major release. We recommend that update any queries that use these keys to use the new key name.
environmentType	Specifies the environment type for the tenant, such as **Production**, **Sandbox**, **Trial**. See Environment Types
eventId	**LC0014**
extensionId	Specifies the AppID of the extension that was published.
extensionIsRad	Specifies whether the extension that was RAD published. **True** indicates the extension was RAD published. **False** indicates normal publishing. RAD (Rapid Application Development) publishing is done from the AL development environment. RAD publishing is a partial publishing operation that only publishes objects application objects that have changed during development. For more information, see Working with Rapid Application Development.
extensionName	Specifies the name of the extension that published.
extensionId	Specifies the AppID of the extension that published.
extensionPublishedAs	Specifies whether the extension was published as one of the following options: • **Dev** - published from the AL development environment. • **Global** - published to the global scope. • **Tenant** - published to the tenant scope.
extensionPublisher	Specifies the extension's publisher.
extensionScope	Specifies whether the extension was published to one of the following scopes: • **Global** - the extension can be installed on all tenants connected the service instance. • **Tenant** - the extension can only be installed on the tenant to which it was published. .
extensionVersion	Specifies the version of the published extension.
result	**Success**
serverExecutionTime	Specifies the amount of time it took the server to complete the request. The time has the format hh:mm:ss.sssssss.
sqlExecutes	Specifies the number of SQL statements that the request executed.

DIMENSION	DESCRIPTION OR VALUE
sqlRowsRead	Specifies the number of table rows that were read by the SQL statements.
telemetrySchemaVersion	Specifies the version of the Business Central telemetry schema.
totalTime	Specifies the amount of time it took to process the request. The time has the format hh:mm:ss.sssssss.

Extension failed to publish

Occurs when an extension failed publish on the service.

General dimensions

DIMENSION	DESCRIPTION OR VALUE
message	**Extension failed to publish: {extensionName} version {extensionVersion} by {extensionPublisher} ({extensionId})**
severityLevel	**3**

Custom dimensions

DIMENSION	DESCRIPTION OR VALUE
aadTenantId	Specifies that Azure Active Directory (Azure AD) tenant ID used for Azure AD authentication. For on-premises, if you aren't using Azure AD authentication, this value is **common**.
component	**Dynamics 365 Business Central Server**.
componentVersion	Specifies the version number of the component that emits telemetry (see the component dimension.)
deprecatedKeys	Specifies a comma-separated list of all the keys that have been deprecated. The keys in this list are still supported but will eventually be removed in the next major release. We recommend that update any queries that use these keys to use the new key name.
environmentType	Specifies the environment type for the tenant, such as **Production**, **Sandbox**, **Trial**. See Environment Types
eventId	**LC0015**
extensionId	Specifies the AppID of the extension that was published.

DIMENSION	DESCRIPTION OR VALUE
extensionIsRad	Specifies whether the extension that was RAD published. **True** indicates the extension was RAD published. **False** indicates normal publishing. RAD (Rapid Application Development) publishing is done from the AL development environment. RAD publishing only is a partial publishing operation that only publishes objects application objects that have changed during development. For more information, see Working with Rapid Application Development.
extensionName	Specifies the name of the extension that published.
extensionId	Specifies the AppID of the extension that published.
extensionPublishedAs	Specifies whether the extension was published as one of the following options: • **Dev** - published from the AL development environment. • **Global** - published to the global scope. • **Tenant** - published to the tenant scope.
extensionPublisher	Specifies the extension's publisher.
extensionScope	Specifies whether the extension was published to one of the following scopes: • **Global** - the extension can be installed on all tenants connected the service instance. • **Tenant** - the extension can only be installed on the tenant to which it was published. .
extensionVersion	Specifies the version of the published extension.
failureReason	Specifies the error that occurred when publishing.
result	**Failure**
serverExecutionTime	Specifies the amount of time it took the server to complete the request. The time has the format hh:mm:ss.sssssss.
sqlExecutes	Specifies the number of SQL statements that the request executed.
sqlRowsRead	Specifies the number of table rows that were read by the SQL statements.
telemetrySchemaVersion	Specifies the version of the Business Central telemetry schema.
totalTime	Specifies the amount of time it took to process the request. The time has the format hh:mm:ss.sssssss.

Extension unpublished successfully

Occurs when an extension was unpublished successfully on the service.

General dimensions

DIMENSION	DESCRIPTION OR VALUE
message	**Extension unpublished successfully: {extensionName} version {extensionVersion} by {extensionPublisher} ({extensionId})**
severityLevel	1

Custom dimensions

DIMENSION	DESCRIPTION OR VALUE
aadTenantId	Specifies that Azure Active Directory (Azure AD) tenant ID used for Azure AD authentication. For on-premises, if you aren't using Azure AD authentication, this value is **common**.
component	**Dynamics 365 Business Central Server**.
componentVersion	Specifies the version number of the component that emits telemetry (see the component dimension.)
deprecatedKeys	Specifies a comma-separated list of all the keys that have been deprecated. The keys in this list are still supported but will eventually be removed in the next major release. We recommend that update any queries that use these keys to use the new key name.
environmentType	Specifies the environment type for the tenant, such as **Production**, **Sandbox**, **Trial**. See Environment Types
eventId	**LC0018**
extensionId	Specifies the AppID of the extension that was unpublished.
extensionName	Specifies the name of the extension that was unpublished.
extensionId	Specifies the AppID of the extension that was unpublished.
extensionPublishedAs	Specifies whether the extension was published as one of the following options: • **Dev** - published from the AL development environment. • **Global** - published to the global scope. • **Tenant** - published to the tenant scope.
extensionPublisher	Specifies the extension's publisher.

DIMENSION	DESCRIPTION OR VALUE
extensionScope	Specifies whether the extension was published to one of the following scopes: • **Global** - the extension can be installed on all tenants connected the service instance. • **Tenant** - the extension can only be installed on the tenant to which it was published. .
extensionVersion	Specifies the version of the unpublished extension.
result	**Success**
serverExecutionTime	Specifies the amount of time it took the server to complete the request. The time has the format hh:mm:ss.sssssss.
sqlExecutes	Specifies the number of SQL statements that the request executed.
sqlRowsRead	Specifies the number of table rows that were read by the SQL statements.
telemetrySchemaVersion	Specifies the version of the Business Central telemetry schema.
totalTime	Specifies the amount of time it took to process the request. The time has the format hh:mm:ss.sssssss.

Extension failed to un-publish

Occurs when an extension fails to unpublish on the service.

General dimensions

DIMENSION	DESCRIPTION OR VALUE
message	**Extension failed to un-publish: {extensionName} version {extensionVersion} by {extensionPublisher} ({extensionId})**
severityLevel	**3**

Custom dimensions

DIMENSION	DESCRIPTION OR VALUE
aadTenantId	Specifies that Azure Active Directory (Azure AD) tenant ID used for Azure AD authentication. For on-premises, if you aren't using Azure AD authentication, this value is **common**.
component	**Dynamics 365 Business Central Server**.
componentVersion	Specifies the version number of the component that emits telemetry (see the component dimension.)

DIMENSION	DESCRIPTION OR VALUE
deprecatedKeys	Specifies a comma-separated list of all the keys that have been deprecated. The keys in this list are still supported but will eventually be removed in the next major release. We recommend that update any queries that use these keys to use the new key name.
environmentType	Specifies the environment type for the tenant, such as **Production**, **Sandbox**, **Trial**. See Environment Types
eventId	**LC0019**
extensionId	Specifies the AppID of the extension that failed to unpublish.
extensionName	Specifies the name of the extension that failed to unpublish.
extensionPublishedAs	Specifies whether the extension was published as one of the following options: • **Dev** - published from the AL development environment. • **Global** - published to the global scope. • **Tenant** - published to the tenant scope.
extensionPublisher	Specifies the extension's publisher.
extensionScope	Specifies whether the extension was published to one of the following scopes: • **Global** - the extension can be installed on all tenants connected the service instance. • **Tenant** - the extension can only be installed on the tenant to which it was published. .
extensionVersion	Specifies the version of the unpublished extension.
failureReason	Specifies the error that occurred when unpublishing.
result	**Failure**
serverExecutionTime	Specifies the amount of time it took the server to complete the request. The time has the format hh:mm:ss.sssssss.
sqlExecutes	Specifies the number of SQL statements that the request executed.
sqlRowsRead	Specifies the number of table rows that were read by the SQL statements.
telemetrySchemaVersion	Specifies the version of the Business Central telemetry schema.
totalTime	Specifies the amount of time it took to process the request. The time has the format hh:mm:ss.sssssss.

TENANT OPERATIONS

Extension synchronized successfully

Occurs when an extension synchronizes successfully on the tenant.

General dimensions

DIMENSION	DESCRIPTION OR VALUE
message	**Extension synchronized successfully: {extensionName} version {extensionVersion} by {extensionPublisher} ({extensionId})**
severityLevel	1

Custom dimensions

DIMENSION	DESCRIPTION OR VALUE
aadTenantId	Specifies that Azure Active Directory (Azure AD) tenant ID used for Azure AD authentication. For on-premises, if you aren't using Azure AD authentication, this value is **common**.
component	**Dynamics 365 Business Central Server**.
componentVersion	Specifies the version number of the component that emits telemetry (see the component dimension.)
deprecatedKeys	Specifies a comma-separated list of all the keys that have been deprecated. The keys in this list are still supported but will eventually be removed in the next major release. We recommend that update any queries that use these keys to use the new key name.
environmentName	Specifies the name of the tenant environment. See Managing Environments.
environmentType	Specifies the environment type for the tenant, such as **Production**, **Sandbox**, **Trial**. See Environment Types
eventId	**LC0012**
extensionId	Specifies the AppID of the extension that was synchronized.
extensionName	Specifies the name of the extension that was synchronized.
extensionPublishedAs	Specifies whether the extension was published as one of the following options: • **Dev** - published from the AL development environment. • **Global** - published to the global scope. • **Tenant** - published to the tenant scope.
extensionPublisher	Specifies the extension's publisher.

DIMENSION	DESCRIPTION OR VALUE
extensionScope	Specifies whether the extension was published to one of the following scopes: • **Global** - the extension can be installed on all tenants connected the service instance. • **Tenant** - the extension can only be installed on the tenant to which it was published. .
extensionSynchronizationMode	Specifies whether the extension was synchronized in one of the following modes: • **Add** - The database schema defined by the objects in the extension are added to the database schema of the tenant database. This mode is typically used mode after you publish an extension for the first time. • **Clean** - The database schema defined by all versions of the extension will be removed from the database and all data is lost. This mode is typically used when an extension will no longer be used and all versions unpublished. • **Development** - This mode is acts similar to Add, except it is intended for use during development. It lets you to sync the same version of an extension that is already published. However, to run this mode, only one version the App can be currently published. • **ForceSync** - This mode like **Add** except it supports destructive schema changes (like removing fields, renaming them, changing their datatypes, and more). It is typically used during development, and is the mode used when an extension is published and installed from the AL development environment. For more information about the modes, see Sync-NAVApp cmdlet -Mode.
extensionVersion	Specifies the version of the extension was synchronized.
result	**Success**
serverExecutionTime	Specifies the amount of time it took the server to complete the request. The time has the format hh:mm:ss.sssssss.
sqlExecutes	Specifies the number of SQL statements that the request executed.
sqlRowsRead	Specifies the number of table rows that were read by the SQL statements.
telemetrySchemaVersion	Specifies the version of the Business Central telemetry schema.
totalTime	Specifies the amount of time it took to process the request. The time has the format hh:mm:ss.sssssss.

Extension synchronized failed

Occurs when an extension fails to synchronize on the tenant.

General dimensions

DIMENSION	DESCRIPTION OR VALUE
message	**Extension failed to synchronize: {extensionName} version {extensionVersion} by {extensionPublisher} ({extensionId})**
severityLevel	1

Custom dimensions

DIMENSION	DESCRIPTION OR VALUE
aadTenantId	Specifies that Azure Active Directory (Azure AD) tenant ID used for Azure AD authentication. For on-premises, if you aren't using Azure AD authentication, this value is **common**.
component	**Dynamics 365 Business Central Server**.
componentVersion	Specifies the version number of the component that emits telemetry (see the component dimension.)
deprecatedKeys	Specifies a comma-separated list of all the keys that have been deprecated. The keys in this list are still supported but will eventually be removed in the next major release. We recommend that update any queries that use these keys to use the new key name.
environmentName	Specifies the name of the tenant environment. See Managing Environments.
environmentType	Specifies the environment type for the tenant, such as **Production**, **Sandbox**, **Trial**. See Environment Types
eventId	**LC0013**
extensionId	Specifies the AppID of the extension that failed to synchronize.
extensionName	Specifies the name of the extension that failed to synchronize.
extensionPublishedAs	Specifies whether the extension was published as one of the following options: • **Dev** - published from the AL development environment. • **Global** - published to the global scope. • **Tenant** - published to the tenant scope.
extensionPublisher	Specifies the extension's publisher.

DIMENSION	DESCRIPTION OR VALUE
extensionScope	Specifies whether the extension was published to one of the following scopes: • **Global** - the extension can be installed on all tenants connected the service instance. • **Tenant** - the extension can only be installed on the tenant to which it was published. .
extensionSynchronizationMode	Specifies whether the extension was synchronized in one of the following modes: • **Add** - The database schema defined by the objects in the extension are added to the database schema of the tenant database. This mode is typically used mode after you publish an extension for the first time. • **Clean** - The database schema defined by all versions of the extension will be removed from the database and all data is lost. This mode is typically used when an extension will no longer be used and all versions unpublished. • **Development** - This mode is acts similar to Add, except it is intended for use during development. It lets you to sync the same version of an extension that is already published. However, to run this mode, only one version the App can be currently published. • **ForceSync** - This mode like **Add** except it supports destructive schema changes (like removing fields, renaming them, changing their datatypes, and more). It is typically used during development, and is the mode used when an extension is published and installed from the AL development environment. For more information about the modes, see Sync-NAVApp cmdlet -Mode.
extensionVersion	Specifies the version of the extension was synchronized.
failureReason	Specifies the error that occurred when synchronizing the extension.
result	**Failure**
serverExecutionTime	Specifies the amount of time it took the server to complete the request. The time has the format hh:mm:ss.sssssss.
sqlExecutes	Specifies the number of SQL statements that the request executed.
sqlRowsRead	Specifies the number of table rows that were read by the SQL statements.
telemetrySchemaVersion	Specifies the version of the Business Central telemetry schema.
totalTime	Specifies the amount of time it took to process the request. The time has the format hh:mm:ss.sssssss.

Extension installed successfully

Occurs when an extension installs successfully on a tenant.

General dimensions

DIMENSION	DESCRIPTION OR VALUE
message	**Extension installed successfully: {extensionName} version {extensionVersion} by {extensionPublisher} ({extensionId})**
severityLevel	1

Custom dimensions

DIMENSION	DESCRIPTION OR VALUE
aadTenantId	Specifies that Azure Active Directory (Azure AD) tenant ID used for Azure AD authentication. For on-premises, if you aren't using Azure AD authentication, this value is **common**.
component	**Dynamics 365 Business Central Server**.
componentVersion	Specifies the version number of the component that emits telemetry (see the component dimension.)
deprecatedKeys	Specifies a comma-separated list of all the keys that have been deprecated. The keys in this list are still supported but will eventually be removed in the next major release. We recommend that update any queries that use these keys to use the new key name.
environmentName	Specifies the name of the tenant environment. See Managing Environments.
environmentType	Specifies the environment type for the tenant, such as **Production**, **Sandbox**, **Trial**. See Environment Types
eventId	**LC0010**
extensionId	Specifies the AppID of the extension that was installed.
extensionName	Specifies the name of the extension that failed to synchronize.
extensionPublishedAs	Specifies whether the extension was published as one of the following options: • **Dev** - published from the AL development environment. • **Global** - published to the global scope. • **Tenant** - published to the tenant scope.
extensionPublisher	Specifies the extension's publisher.

DIMENSION	DESCRIPTION OR VALUE
extensionScope	Specifies whether the extension was published to one of the following scopes: • **Global** - the extension can be installed on all tenants connected the service instance. • **Tenant** - the extension can only be installed on the tenant to which it was published. .
extensionVersion	Specifies the version of the extension was installed.
result	**Success**
serverExecutionTime	Specifies the amount of time it took the server to complete the request. The time has the format hh:mm:ss.sssssss.
sqlExecutes	Specifies the number of SQL statements that the request executed.
sqlRowsRead	Specifies the number of table rows that were read by the SQL statements.
telemetrySchemaVersion	Specifies the version of the Business Central telemetry schema.
totalTime	Specifies the amount of time it took to process the request. The time has the format hh:mm:ss.sssssss.

Extension failed to install

Occurs when an extension failed to install on a tenant.

General dimensions

DIMENSION	DESCRIPTION OR VALUE
message	**Extension failed to install: {extensionName} version {extensionVersion} by {extensionPublisher} ({extensionId})**
severityLevel	**3**

Custom dimensions

DIMENSION	DESCRIPTION OR VALUE
aadTenantId	Specifies that Azure Active Directory (Azure AD) tenant ID used for Azure AD authentication. For on-premises, if you aren't using Azure AD authentication, this value is **common**.
component	**Dynamics 365 Business Central Server**.
componentVersion	Specifies the version number of the component that emits telemetry (see the component dimension.)

DIMENSION	DESCRIPTION OR VALUE
deprecatedKeys	Specifies a comma-separated list of all the keys that have been deprecated. The keys in this list are still supported but will eventually be removed in the next major release. We recommend that update any queries that use these keys to use the new key name.
environmentName	Specifies the name of the tenant environment. See Managing Environments.
environmentType	Specifies the environment type for the tenant, such as **Production**, **Sandbox**, **Trial**. See Environment Types
eventId	**LC0011**
extensionId	Specifies the AppID of the extension that failed to uninstall.
extensionName	Specifies the name of the extension that failed to uninstall.
extensionPublishedAs	Specifies whether the extension was published as one of the following options: • **Dev** - published from the AL development environment. • **Global** - published to the global scope. • **Tenant** - published to the tenant scope.
extensionPublisher	Specifies the extension's publisher.
extensionScope	Specifies whether the extension was published to one of the following scopes: • **Global** - the extension can be installed on all tenants connected the service instance. • **Tenant** - the extension can only be installed on the tenant to which it was published. .
extensionVersion	Specifies the version of the extension was installed.
failureReason	Specifies the error that occurred when the extension was installed.
result	**Failed**
serverExecutionTime	Specifies the amount of time it took the server to complete the request. The time has the format hh:mm:ss.sssssss.
sqlExecutes	Specifies the number of SQL statements that the request executed.
sqlRowsRead	Specifies the number of table rows that were read by the SQL statements.
telemetrySchemaVersion	Specifies the version of the Business Central telemetry schema.

DIMENSION	DESCRIPTION OR VALUE
totalTime	Specifies the amount of time it took to process the request. The time has the format hh:mm:ss.sssssss.

Extension un-installed successfully

Occurs when an extension is successfully uninstalled from a tenant.

General dimensions

DIMENSION	DESCRIPTION OR VALUE
message	**Extension un-installed successfully: {extensionName} version {extensionVersion} by {extensionPublisher} ({extensionId})**
severityLevel	1

Custom dimensions

DIMENSION	DESCRIPTION OR VALUE
aadTenantId	Specifies that Azure Active Directory (Azure AD) tenant ID used for Azure AD authentication. For on-premises, if you aren't using Azure AD authentication, this value is **common**.
component	**Dynamics 365 Business Central Server**.
componentVersion	Specifies the version number of the component that emits telemetry (see the component dimension.)
deprecatedKeys	Specifies a comma-separated list of all the keys that have been deprecated. The keys in this list are still supported but will eventually be removed in the next major release. We recommend that update any queries that use these keys to use the new key name.
doNotSaveData	Specifies whether the uninstall operation was run with option not to save the data in database table fields that are added by the extension. When using the Uninstall-NAVApp cmdlet, this condition is set with the -DoNotSaveData switch parameter.
environmentName	Specifies the name of the tenant environment. See Managing Environments.
environmentType	Specifies the environment type for the tenant, such as **Production**, **Sandbox**, **Trial**. See Environment Types
eventId	**LC0016**
extensionId	Specifies the AppID of the extension that was uninstalled.
extensionName	Specifies the name of the extension that was uninstalled.

DIMENSION	DESCRIPTION OR VALUE
extensionPublishedAs	Specifies whether the extension was published as one of the following options: • **Dev** - published from the AL development environment. • **Global** - published to the global scope. • **Tenant** - published to the tenant scope.
extensionPublisher	Specifies the extension's publisher.
extensionScope	Specifies whether the extension was published to one of the following scopes: • **Global** - the extension can be installed on all tenants connected the service instance. • **Tenant** - the extension can only be installed on the tenant to which it was published. .
extensionVersion	Specifies the version of the extension was uninstalled.
result	**Success**
serverExecutionTime	Specifies the amount of time it took the server to complete the request. The time has the format hh:mm:ss.sssssss.
sqlExecutes	Specifies the number of SQL statements that the request executed.
sqlRowsRead	Specifies the number of table rows that were read by the SQL statements.
telemetrySchemaVersion	Specifies the version of the Business Central telemetry schema.
totalTime	Specifies the amount of time it took to process the request. The time has the format hh:mm:ss.sssssss.

Extension failed to un-install

Occurs when an extension failed to uninstall on a tenant.

General dimensions

DIMENSION	DESCRIPTION OR VALUE
message	**Extension failed to un-install: {extensionName} version {extensionVersion} by {extensionPublisher} ({extensionId})**
severityLevel	**3**

Custom dimensions

DIMENSION	DESCRIPTION OR VALUE
aadTenantId	Specifies that Azure Active Directory (Azure AD) tenant ID used for Azure AD authentication. For on-premises, if you aren't using Azure AD authentication, this value is **common**.
component	**Dynamics 365 Business Central Server**.
componentVersion	Specifies the version number of the component that emits telemetry (see the component dimension.)
deprecatedKeys	Specifies a comma-separated list of all the keys that have been deprecated. The keys in this list are still supported but will eventually be removed in the next major release. We recommend that update any queries that use these keys to use the new key name.
doNotSaveData	Specifies whether the uninstall operation was run with option not to save the data in database table fields that are added by the extension. When using the Uninstall-NAVApp cmdlet, this condition is set with the -DoNotSaveData switch parameter.
environmentName	Specifies the name of the tenant environment. See Managing Environments.
environmentType	Specifies the environment type for the tenant, such as **Production**, **Sandbox**, **Trial**. See Environment Types
eventId	**LC0017**
extensionId	Specifies the AppID of the extension that failed to uninstall.
extensionName	Specifies the name of the extension that failed to uninstall.
extensionPublishedAs	Specifies whether the extension was published as one of the following options: • **Dev** - published from the AL development environment. • **Global** - published to the global scope. • **Tenant** - published to the tenant scope.
extensionPublisher	Specifies the extension's publisher.
extensionScope	Specifies whether the extension was published to one of the following scopes: • **Global** - the extension can be installed on all tenants connected the service instance. • **Tenant** - the extension can only be installed on the tenant to which it was published. .
extensionVersion	Specifies the version of the extension that failed to uninstall.

DIMENSION	DESCRIPTION OR VALUE
failureReason	Specifies the error that occurred when the extension was uninstalled.
result	**Failure**
serverExecutionTime	Specifies the amount of time it took the server to complete the request. The time has the format hh:mm:ss.sssssss.
sqlExecutes	Specifies the number of SQL statements that the request executed.
sqlRowsRead	Specifies the number of table rows that were read by the SQL statements.
telemetrySchemaVersion	Specifies the version of the Business Central telemetry schema.
totalTime	Specifies the amount of time it took to process the request. The time has the format hh:mm:ss.sssssss.

Extension updated successfully

Occurs when an extension updates successfully on the service.

> **NOTE**
> Data is also recorded for any upgrade code that was run. For more information, see Analyzing Extension Update Trace Telemetry.

General dimensions

DIMENSION	DESCRIPTION OR VALUE
message	**Extension updated successfully: {extensionName} version {extensionVersion} by {extensionPublisher}**
severityLevel	1

Custom dimensions

DIMENSION	DESCRIPTION OR VALUE
aadTenantId	Specifies that Azure Active Directory (Azure AD) tenant ID used for Azure AD authentication. For on-premises, if you aren't using Azure AD authentication, this value is **common**.
component	**Dynamics 365 Business Central Server**.
componentVersion	Specifies the version number of the component that emits telemetry (see the component dimension.)

DIMENSION	DESCRIPTION OR VALUE
deprecatedKeys	Specifies a comma-separated list of all the keys that have been deprecated. The keys in this list are still supported but will eventually be removed in the next major release. We
environmentName	Specifies the name of the tenant environment. See Managing Environments.
environmentType	Specifies the environment type for the tenant, such as **Production**, **Sandbox**, **Trial**. See Environment Types
eventId	**LC0022**
extensionCulture	Specifies the language version for which the extension that was upgraded. The value is a language culture name, such as **en-US** or **da-DK**. If a language wasn't specified when the extension was installed, then en-US is used by default.
extensionId	Specifies the AppID of the extension that failed to uninstall.
extensionName	Specifies the name of the extension that was being upgraded.
extensionPublisher	Specifies the extension's publisher.
extensionVersion	Specifies the new version of the extension being upgraded.
extensionVersionFrom	Specifies the old version of the extension being upgraded.
result	**Success**
serverExecutionTime	Specifies the amount of time it took the server to complete the request. The time has the format hh:mm:ss.sssssss.
sqlExecutes	Specifies the number of SQL statements that the request executed.
sqlRowsRead	Specifies the number of table rows that were read by the SQL statements.
telemetrySchemaVersion	Specifies the version of the Business Central telemetry schema.
totalTime	Specifies the amount of time it took to process the request. The time has the format hh:mm:ss.sssssss.

Extension failed to update

Occurs when an extension failed to update on the service.

> **NOTE**
> Data is also recorded for any upgrade code that was run. For more information, see Analyzing Extension Update Trace Telemetry.

General dimensions

DIMENSION	DESCRIPTION OR VALUE
message	**Extension failed to update: {extensionName} version {extensionVersion} by {extensionPublisher} ({extensionId})**
severityLevel	**3**

Custom dimensions

DIMENSION	DESCRIPTION OR VALUE
aadTenantId	Specifies that Azure Active Directory (Azure AD) tenant ID used for Azure AD authentication. For on-premises, if you aren't using Azure AD authentication, this value is **common**.
component	**Dynamics 365 Business Central Server**.
componentVersion	Specifies the version number of the component that emits telemetry (see the component dimension.)
deprecatedKeys	Specifies a comma-separated list of all the keys that have been deprecated. The keys in this list are still supported but will eventually be removed in the next major release. We recommend that update any queries that use these keys to use the new key name.
environmentName	Specifies the name of the tenant environment. See Managing Environments.
environmentType	Specifies the environment type for the tenant, such as **Production**, **Sandbox**, **Trial**. See Environment Types
eventId	**LC0023**
extensionCulture	Specifies the language version for which the extension that was upgraded. The value is a language culture name, such as **en-US** or **da-DK**. If a language wasn't specified when the extension was installed, then en-US is used by default.
extensionId	Specifies the AppID of the extension that failed to uninstall.
extensionName	Specifies the name of the extension that was being upgraded.
extensionPublisher	Specifies the extension's publisher.
extensionVersion	Specifies the new version of the extension being upgraded.

DIMENSION	DESCRIPTION OR VALUE
extensionVersionFrom	Specifies the old version of the extension being upgraded.
failureReason	Specifies the error that occurred during upgrade.
result	**Failure**
serverExecutionTime	Specifies the amount of time it took the server to complete the request. The time has the format hh:mm:ss.sssssss.
sqlExecutes	Specifies the number of SQL statements that the request executed.
sqlRowsRead	Specifies the number of table rows that were read by the SQL statements.
telemetrySchemaVersion	Specifies the version of the Business Central telemetry schema.
totalTime	Specifies the amount of time it took to process the request. The time has the format hh:mm:ss.sssssss.

Analyzing Extension Update Trace Telemetry

2/17/2021 • 2 minutes to read • Edit Online

INTRODUCED IN: Business Central 2020 release wave 1, version 16.2

Extension upgrade telemetry gathers information about failures that occur during extension upgrades. Specifically, it provides information about exceptions that are thrown by code run by upgrade codeunits. The trace events include the following information:

- The codeunit that threw the exception.
- AL stack trace.
- Exception message.

This data can help you identify, troubleshoot, and resolve issues with per-tenant and AppSource extensions that are blocking data upgrade.

Extension Update Failed: exception raised in extension

Occurs when an extension upgrade fails because of an exception in an upgrade codeunit.

General dimensions

DIMENSION	DESCRIPTION OR VALUE
message	**Extension Update Failed: exception raised in extension {extensionName} by {extensionPublisher} (updating to version {extensionTargetedVersion})**
severityLevel	**3**

Custom dimensions

DIMENSION	DESCRIPTION OR VALUE
aadTenantId	Specifies that Azure Active Directory (Azure AD) tenant ID used for Azure AD authentication. For on-premises, if you aren't using Azure AD authentication, this value is **common**.
alObjectId	Specifies the ID of the AL object that was run by request.
alStackTrace	The stack trace in AL.
companyName	The display name of the Business Central company that was used at time of execution.
component	**Dynamics 365 Business Central Server**.
componentVersion	Specifies the version number of the component that emits telemetry (see the component dimension.)

DIMENSION	DESCRIPTION OR VALUE
deprecatedKeys	A comma-separated list of all the keys that have been deprecated. The keys in this list are still supported but will eventually be removed in the next major release. We recommend that update any queries that use these keys to use the new key name.
environmentName	Specifies the name of the tenant environment. See Managing Environments.
environmentType	Specifies the environment type for the tenant, such as **Production**, **Sandbox**, **Trial**. See Environment Types
eventId	**RT0010**
extensionName	Specifies the name of the extension that was being upgraded.
extensionId	Specifies the AppID of the extension that was being upgraded.
extensionTargetedVersion	Specifies the new version of the extension being upgraded.
extensionVersion	Specifies the old version of the extension being upgraded.
failureReason	Specifies the exception that was thrown by the upgrade code. Some exception messages can contain customer data. As a precaution, Business Central only emits information that's classified as SystemMetadata. Exception messages that contain other data classifications, like customer data, are not shown. Instead, the following message is shown: "Message not shown because the NavBaseException(string, Exception, bool) constructor was used."
failureType	**DataUpdate**
telemetrySchemaVersion	Specifies the version of the Business Central telemetry schema.

Analyzing Field Monitoring Telemetry

2/17/2021 • 3 minutes to read • Edit Online

APPLIES TO: Business Central 2020 release wave 2 (update 17.1) and later

Keeping sensitive data secure and private is a core concern for most businesses. To add a layer of security, you can monitor important fields when someone changes a value. For example, you might want to know if someone changes your company's IBAN number.

To gather this data, you'll have to start field monitoring and specify the fields that you want to monitor. For more information, see Auditing Changes in Business Central - Monitoring Sensitive Fields in the Application help.

Telemetry is then logged for the following operations:

- When field monitoring is stopped or started
- When a field is added or removed for monitoring
- When a field value is changed

Sensitive field monitor status changed

Occurs when the field monitor feature is started or stopped in the company.

General dimensions

DIMENSION	DESCRIPTION OR VALUE
message	**Sensitive field monitor status has changed to {almonitorStatus}**
severityLevel	**1**

Custom dimensions

DIMENSION	DESCRIPTION OR VALUE
aadTenantId	Specifies that Azure Active Directory (Azure AD) tenant ID used for Azure AD authentication. For on-premises, if you aren't using Azure AD authentication, this value is **common**.
alDataClassification	**SystemMetadata**
almonitorStatus	**Yes** - the field monitor feature was started. **No** the field monitor feature was stopped.
alObjectId	**1392**
alObjectName	**Monitor Sensitive Field**
alObjectType	**CodeUnit**
component	**Dynamics 365 Business Central Server**

DIMENSION	DESCRIPTION OR VALUE
componentVersion	Specifies the version number of the component that emits telemetry (see the component dimension.)
deprecatedKeys	Specifies a comma-separated list of all the keys that have been deprecated. The keys in this list are still supported but will eventually be removed in the next major release. We recommend that update any queries that use these keys to use the new key name.
environmentName	Specifies the name of the tenant environment. See Managing Environments. This dimension isn't included for Business Central on-premises environments.
environmentType	Specifies the environment type for the tenant, such as **Production**, **Sandbox**, **Trial**. See Environment Types. This dimension isn't included for Business Central on-premises environments.
eventId	**AL0000DD3**
extensionName	Specifies the name of the base application.
extensionId	Specifies the ID of the base extension.
extensionPublisher	Specifies the publisher of the extension.
extensionVersion	Specifies the version of the base application.
telemetrySchemaVersion	Specifies the version of the Business Central telemetry schema.

Sensitive field value has changed

Occurs the value of a monitored field has changed in the company.

General dimensions

DIMENSION	DESCRIPTION OR VALUE
message	**Sensitive field value has changed: {alfieldCaption} in table {altableCaption}**
severityLevel	1

Custom dimensions

DIMENSION	DESCRIPTION OR VALUE
aadTenantId	Specifies that Azure Active Directory (Azure AD) tenant ID used for Azure AD authentication. For on-premises, if you aren't using Azure AD authentication, this value is **common**.

DIMENSION	DESCRIPTION OR VALUE
alDataClassification	**SystemMetadata**
alfieldCaption	Specifies the name of the field that was changed.
altableCaption	Specifies the name of the table that the changed field is included.
alObjectId	**1392**
alObjectName	**Monitor Sensitive Field**
alObjectType	**CodeUnit**
component	**Dynamics 365 Business Central Server**
componentVersion	Specifies the version number of the component that emits telemetry (see the component dimension.)
deprecatedKeys	Specifies a comma-separated list of all the keys that have been deprecated. The keys in this list are still supported but will eventually be removed in the next major release. We recommend that update any queries that use these keys to use the new key name.
environmentName	Specifies the name of the tenant environment. See Managing Environments. This dimension isn't included for Business Central on-premises environments.
environmentType	Specifies the environment type for the tenant, such as **Production**, **Sandbox**, **Trial**. See Environment Types. This dimension isn't included for Business Central on-premises.
eventId	**AL0000CTE**
extensionName	Specifies the name of the base application.
extensionId	Specifies the ID of the base extension.
extensionPublisher	Specifies the publisher of the extension.
extensionVersion	Specifies the version of the base application.
telemetrySchemaVersion	Specifies the version of the Business Central telemetry schema.

NOTE

Changes to fields in the following tables are always logged:

- Fields in the **Field Monitoring Setup** table. Many of the fields are included on the **Field Monitoring Setup** page.
- Fields in the **Change Log Setup (Field)** table. Many of the fields are included on the **Field Monitoring Worksheet** page.
- The **Contact Email** field in the **User** table.

Analyzing Job Queue Lifecycle Trace Telemetry

2/17/2021 • 3 minutes to read • Edit Online

APPLIES TO: Business Central 2020 release wave 2, version 17.2, and later

Job queue lifecycle telemetry gathers data about the following operations:

- A job queue entry was enqueued.
- A job queue entry was started.
- A job queue entry finished. Provides information as to whether it was successful or failed.

For information about creating and managing job queue entries, see Use Job Queues to Schedule Tasks in the Business Central application help.

Job queue entry enqueued

Occurs when a job queue entry is sent to the job queue to eventually be run. A job queue entry is sent to the queue when its status is changed from **On Hold** to **Ready** or if it's a recurring job queue entry. Recurring job queue entries are automatically enqueued after each run.

General dimensions

DIMENSION	DESCRIPTION OR VALUE
message	**Job queue entry enqueued: {alJobQueueId}**
severityLevel	**1**

Custom dimensions

The following table explains custom dimensions that are specific to this trace.

DIMENSION	DESCRIPTION OR VALUE
eventId	**AL0000E24**
alJobQueueId	Specifies the ID of the job queue entry.
alJobQueueIsRecurring	Specifies whether the job queue is recurring. **Yes** indicates it's recurring. **No** indicates it's not recurring.
alJobQueueObjectId	Specifies the ID of the object that the job queue entry runs.
alJobQueueObjectType	Specifies the type of the object that the job queue entry runs, for example **Report** or **Codeunit**.
alJobQueueStatus	**Ready** indicates it's a non-recurring job queue entry or the first run of a recurring job queue entry that's ready to run. **On Hold with Inactivity Timeout** indicates it's a recurring job query entry that's ready to run.

Common custom dimensions

The following table explains additional custom dimensions that are common to all job queue entry traces.

DIMENSION	DESCRIPTION OR VALUE
aadTenantId	Specifies that Azure Active Directory (Azure AD) tenant ID used for Azure AD authentication. For on-premises, if you aren't using Azure AD authentication, this value is **common**.
alCategory	**AL JobQueueEntries**
alDataClassification	**SystemMetadata**
alObjectId	**1351**, which is the ID of the system application codeunit that subscribes to the telemetry events.
alObjectName	**Telemetry Subscribers**, which is the name of the system application codeunit that subscribes to the telemetry events.
alObjectType	**CodeUnit**
component	**Dynamics 365 Business Central Server**.
componentVersion	Specifies the version number of the component that emits telemetry (see the component dimension.)
deprecatedKeys	A comma-separated list of all the keys that have been deprecated. The keys in this list are still supported but will eventually be removed in the next major release. We recommend that update any queries that use these keys to use the new key name.
environmentName	Specifies the name of the tenant environment. See Managing Environments.
environmentType	Specifies the environment type for the tenant, such as **Production**, **Sandbox**, **Trial**. See Environment Types
extensionName	Specifies the name of the extension that contains the object run by the job queue entry.
extensionId	Specifies the ID of the extension that contains the object run by the job queue entry.
extensionVersion	Specifies the version of the extension that contains the object run by the job queue entry.
telemetrySchemaVersion	Specifies the version of the Business Central telemetry schema.

Job queue entry started

Occurs when a job queue entry starts to run.

General dimensions

DIMENSION	DESCRIPTION OR VALUE
message	**Job queue entry started: {alJobQueueId}**
severityLevel	**1**

Custom dimensions

The following table explains custom dimensions that are specific to this trace.

DIMENSION	DESCRIPTION OR VALUE
eventId	**AL0000E25**
alJobQueueId	Specifies the ID of the job queue entry.
alJobQueueObjectId	Specifies the ID of the object that the job queue entry runs.
alJobQueueObjectType	Specifies the type of the object that the job queue entry runs, for example **Report** or **Codeunit**.
alJobQueueStatus	**In Process**
See common custom dimensions	

Job queue entry finished

Occurs when a job queue entry finishes running.

General dimensions

DIMENSION	DESCRIPTION OR VALUE
message	**Job queue entry finished: {alJobQueueId}**
severityLevel	**1**

Custom dimensions

DIMENSION	DESCRIPTION OR VALUE
eventId	**AL0000E26**
alJobQueueExecutionTimeInMs	Specifies how many milliseconds it took to run the job queue entry.
alJobQueueId	Specifies the ID of the job queue entry.
alJobQueueObjectId	Specifies the ID of the object that the job queue entry runs.
alJobQueueObjectType	Specifies the type of the object that the job queue entry runs, for example **Report** or **Codeunit**.

DIMENSION	DESCRIPTION OR VALUE
alJobQueueResult	**Success** indicates that the job queue entry ran successfully. **Fail** indicates that an error occurred when running the job queue.
alJobQueueStatus	**Finished** indicates that a non-recurring job queue entry has completed. **On Hold with Inactivity Timeout** indicates that a recurring the job queue entry completed.
See common custom dimensions

Analyzing Long Running AL Methods Telemetry

2/17/2021 • 3 minutes to read • Edit Online

APPLIES TO: Business Central 2020 release wave 2 and later, version 17.1

The Business Central Server server will emit telemetry about the execution time of long running AL methods, including the time spent in the database. The signal also includes a breakdown of how much time each event subscriber added to the total time. As a partner, this data gives you insight into bad performing code and enables you to troubleshoot performance issues caused by extensions.

> **NOTE**
> To collect this telemetry for Business Central on-premises, the **AL Function Timing** and **AL Function Logging Threshold - Application Insights** settings must be configured on the Business Central Server instance. For more information, see Configuring Business Central Server. With Business Central online, this telemetry is enabled with a specific threshold on a case-by-case basis by the service.

General dimensions

The following table explains the general dimensions included in the trace. The table lists the dimensions that are specific to Business Central.

DIMENSION	DESCRIPTION OR VALUE
message	**Operation exceeded time threshold (AL method)**
severityLevel	2

CustomDimensions

This table describes the different dimensions of a **Operation exceeded time threshold (AL method)** operation.

COLUMN (KEY)	DESCRIPTION OR VALUE
aadTenantId	Specifies that Azure Active Directory (Azure AD) tenant ID when using Azure AD authentication. For on-premises, if you aren't using Azure AD authentication, this value is **common**.
alMethod	The name of the long running AL method.
alObjectId	The type of the AL object that executed the AL method.
alObjectName	The name of the AL object that executed the AL method.
alObjectType	The type of the AL object that executed the AL method.
alStackTrace	The stack trace in AL.

COLUMN (KEY)	DESCRIPTION OR VALUE
clientType	Specifies the type of client that executed the AL method, such as Background or Web. For a list of the client types, see ClientType Option Type.
companyName	The display name of the Business Central company that was used at time of execution.
component	**Dynamics 365 Business Central Server**
componentVersion	Specifies the version number of the component that emits telemetry (see the component dimension.)
deprecatedKeys	A comma-separated list of all the keys that have been deprecated. The keys in this list are still supported but will eventually be removed in the next major release. We recommend that update any queries that use these keys to use the new key name.
environmentType	Specifies the environment type of the Business Central solution, such as Production or Sandbox.
environmentName	Specifies the environment name of the Business Central solution, such as Production or Sandbox.
eventId	**RT0018**
executionTime	Specifies the total time that it took to execute the AL method. The value has the format hh:mm:ss.sssssss.
extensionInfo	Specifies information about individual extensions that contributed to the execution time spent in the call stack up until the point at which the long-running threshold was exceeded and the trace was emitted. The following information is included for each extension: • `id` - the ID of the extension. • `extensionName` - the name of the extension. • `extensionVersion` - the version of the extension. • `extensionPublisher` - the publisher of the extension. • `subscriberExecutionCount` - the number of event subscribers executed in this extension. • `executionTime` - the total execution time for this extension in the call stack. The value has the format hh:mm:ss.sssssss.
extensionName	Specifies the name of the extension that was currently executing when the long-running threshold was exceeded and the trace was emitted.
extensionPublisher	Specifies the publisher of the extension that was currently executing when the long-running threshold was exceeded and the trace was emitted.

COLUMN (KEY)	DESCRIPTION OR VALUE
extensionVersion	Specifies the version of the extension that was currently executing when the long-running threshold was exceeded and the trace was emitted.
extensionId	Specifies the ID of the extension that was currently executing when the long-running threshold was exceeded and the trace was emitted.
longRunningThreshold	Specifies the time that defines a long-running AL method, after which the trace is emitted. The value has the format hh:mm:ss.sssssss.
telemetrySchemaVersion	Specifies the version of the Business Central telemetry schema.

Analyzing Long Running Operation (SQL Query) Telemetry

2/17/2021 • 4 minutes to read • Edit Online

A SQL query that takes longer than 1000 milliseconds to execute will be sent to your Application Insights resource.

To get a quick overview, you can go the Application Insights Overview dashboard.

> **NOTE**
> With Business Central On-premises, you can change the threshold that defines long running queries. For more information, see Defining Long Running SQL Queries Threshold.

There are multiple reasons that affect the time it takes SQL queries to run. For example, the database could be waiting for a lock to be released. Or, the database is executing an operation that does badly because of missing indexes. Sometimes you can look at the SQL statement that was generated by the code to see what caused the delay. This information is found in the **CustomDimension** data, specifically the **AL Stack Trace** column.

Dimensions in Application Insights

This table explains the columns included in long running query events emitted to Application Insights. Bold text indicates that the value of the columns is a constant. Some columns are standard for Application Insights. These columns are indicated by *Application Insights*.

COLUMN	DESCRIPTION OR VALUE
timestamp	Specifies the date and time that the long running query event occurred, such as 2019-08-20T07:23:07.9996696Z
message	Version 16.1 and later: **Operation exceeded time threshold (SQL query)** Before version 16.1: **Action took longer than expected**
severityLevel	**2** (This level indicates a warning. Long running queries are always recorded as warnings)
itemType	**trace**
customDimensions	(see table that follows)
operation_Name	**Long Running Operation (SQL Query)** **Note:** The use of the `operation_Name` column was deprecated in version 16.1. In future versions, data won't be stored in this column. So in version 16.1 and later, use the custom dimension column `eventID` column custom in Kusto queries instead of `operation_Name`.
operation_Id	Specifies the GUID assigned to the client operation. An operation is created whenever the user does something in the client, such as selecting an action.
operation_ParentId	Currently this column is the same as the operation_Id. This behavior might change in a future release.
session_Id	Specifies the GUID of the client session. When a client makes a connection to the Business Central Server instance, a session is created and assigned an ID.
client_Type	*Application Insights*
client_IP	*Application Insights*
client_City	*Application Insights*
client_StateOrProvince	*Application Insights*
client_CountryOrRegion	*Application Insights*
cloud_RoleName	Specifies the display name of Business Central tenant. For on-premises, this value is the same as the cloud_RoleInstance.
cloud_RoleInstance	Specifies the name of Business Central tenant.

COLUMN	DESCRIPTION OR VALUE
appId	*Application Insights*
appName	*Application Insights*
iKey	*Application Insights*
sdkVersion	*Application Insights*

CustomDimensions

This table describes the different dimensions of a **Long Running Operation (SQL Query)** operation.

COLUMN (KEY)	DESCRIPTION OR VALUE
extensionVersion	Specifies the version of the extension.
telemetrySchemaVersion	Specifies the version of the Business Central telemetry schema.
componentVersion	Specifies the version number of the component that emits telemetry (see the component dimension.)
environmentType	Specifies the environment type of the Business Central solution, such as Production or Sandbox.
environmentName	Specifies the environment name of the Business Central solution, such as Production or Sandbox.
extensionName	Specifies the name of the extension.
alObjectType	The type of the AL object that executed the SQL statement
alObjectName	The name of the AL object that executed the SQL statement
alStackTrace	The stack trace in AL.
companyName	The display name of the Business Central company that was used at time of execution.
extensionId	Specifies the AppID of the extension.
eventId	**RT0005** This dimension was introduced in Business Central 2020 release wave 1, version 16.1.
aadTenantId	Specifies that Azure Active Directory (Azure AD) tenant ID when using Azure AD authentication. For on-premises, if you aren't using Azure AD authentication, this value is **common**.
clientType	Specifies the type of client that executed the SQL Statement, such as Background or Web. For a list of the client types, see ClientType Option Type.
alObjectId	The type of the AL object that executed the SQL statement.
component	Specifies the Business Central Server instance name and the platform version.
executionTime	Specifies the time that it took to execute the SQL statement**. The value has the format hh:mm:ss.sssssss.
longRunningThreshold	Specifies the amount of time that an SQL query can run before a warning event is recorded. The value has the format hh:mm:ss.sssssss. This threshold is controlled by the Business Central Server configuration setting called SqlLongRunningThreshold.
sqlStatement	Specifies the SQL statement that was executed for the long running query. The value is limited to 8192 characters. If the value exceeds 8192 characters, it will be truncated in manner that still provides the most pertinent information.
deprecatedKeys	A comma-separated list of all the keys that have been deprecated. The keys in this list are still supported but will eventually be removed in the next major release. We recommend that update any queries that use these keys to use the new key name.

** From telemetrySchemaVersion **0.6** and onwards, this value also includes the CompanyOpen operation.

Example

The following code snippet shows an example of the CustomDimensions.

Analyzing Page View Telemetry

2/17/2021 • 4 minutes to read • Edit Online

INTRODUCED IN: Business Central 2020 release wave 1, version 16.3

Page view telemetry gathers data about the pages that users open in the Business Central client. Each page view tells you how long it took to open the page, information about the user's environment, and more.

Use the data to gather statistics about system usage and also troubleshoot performance issues caused by the users' environments.

> **NOTE**
> In Application Insights, telemetry about page views is logged to the **pageViews** table and not the **traces** table like other Business Central traces. This also means that you can use the built-in pages in the **Usage** feature of the Application Insights to investigate how users interact with the Business Central environment. For more information, see Usage analysis with Application Insights.

Page opened: {alObjectName}

Occurs when a page has been opened in the client.

General dimensions

The pageViews table is a built-in table in Application Insights. Here are some of the fields most used in analysis of the signal:

FIELD	DESCRIPTION OR VALUE
client_Browser	Browser running on the client device.
client_OS	Operating system of the client device.
client_Type	Type of the client device.
duration	Number of milliseconds it took the application to handle the page view.
url	URL of the page view.
name	Name of the page opened in the client
session_id	An identifier for the session. Can be used to create a timeline of page views happening in the session

All fields are documented here: Application Insights PageViews Schema

Custom dimensions

DIMENSION	DESCRIPTION OR VALUE

DIMENSION	DESCRIPTION OR VALUE
aadTenantId	Specifies that Azure Active Directory (Azure AD) tenant ID used for Azure AD authentication. For on-premises, if you aren't using Azure AD authentication, this value is **common**.
alObjectId	Specifies the ID of the page object that was opened.
alObjectName	Specifies the name of the page object that was opened.
alObjectType	**Page**
clientType	Specifies the type of client that opened the page such as **Background** or **Web**. For a list of the client types, see ClientType Option Type.
companyName	The display name of the Business Central company that was used when the page opened.
component	**Dynamics 365 Business Central Server**.
componentVersion	Specifies the version number of the component that emits telemetry (see the component dimension.)
deprecatedKeys	A comma-separated list of all the keys that have been deprecated. The keys in this list are still supported but will eventually be removed in the next major release. We recommend that update any queries that use these keys to use the new key name.
designerLevel	Specifies the design level in which the page was opened. This dimension provides additional insight when the `hostType` dimension is **Designer**. • **None** The page wasn't opened in a design mode. This value is shown when the `hostType` dimension is a value other than **Designer** • **Personalization** The page opened in the personalizing mode for tailoring the page in the user's workspace only. See Personalize Your Workspace. • **Configuration** The page opened in customizing mode for tailoring the page for all users of a specific profile. See Customizing Pages for Profiles. • **Development** The page opened in design mode for developing and modifying the page from the client for all users. See Using Designer. • **Inspector** The page opened in page inspection mode for viewing page information like source table, source extension, and filters. See Inspecting Pages. • **All** - the page was opened in the personalization, configuration, development, and inspector modes.

DIMENSION	DESCRIPTION OR VALUE
deviceLocale	Specifies the preferred language that's configured for the device that opened the page. For example, this dimension could show the language setting of a browser used to view the page. The value is a language code, such as **en-US** or **da-DK**.
deviceScreenResolution	Specifies the display resolution of the device that opened the page. The value is given as {width}×{height}, with the units in pixels. For example, **1024×768** means the width is 1024 pixels and the height is 768 pixels.
environmentName	Specifies the name of the tenant environment. See Managing Environments.
environmentType	Specifies the environment type for the tenant, such as **Production**, **Sandbox**, **Trial**. See Environment Types
eventID	**CL0001** (note that this is different from other signals where the dimension is called *eventId*)
expandedFastTabs	Specifies the FastTabs on the page that were expanded when the page opened.
factboxExpanded	Specifies whether the FactBox area was shown or hidden when the page was opened. **true** indicates that the FactBox was shown. **false** indicates that the FactBox was hidden.
hostType	Specifies the host that loads the page. • **DeviceApp** The page was loaded by a Business Central mobile app, from a desktop, tablet, or phone. • **Officeadd-in** The page was loaded by Office application, like Excel or Outlook. • **Designer** The page was loaded by the in-client designer, used for changing page layout. The designer has different modes. Each mode provides a different level of page customization, as specified in the `designerLevel` dimension. • **ShimBrowser** The page was loaded by the UWP (Universal Windows Platform) application. • **Browser** The page was loaded by web browser, like Microsoft Edge or Google Chrome.
message	**Page opened: {alObjectName}**
pageIsModal	Specifies whether the page was opened as a modal page. **true** indicates that the page was opened as a modal page; otherwise, **false**.

DIMENSION	DESCRIPTION OR VALUE
pageMode	Specifies whether the page was opened in one of the following modes: • **View** indicates the page was opened for viewing only • **Edit** indicates the page was opened for making changes • **Create** indicates the page was opened for creating a new entity. • **Select** indicates the page was opened for selecting an existing entity. • **Delete** indicates the page was opened for deleting an entity. The mode in which a page opened determined by different things, like the RunPageMode Property or the URL used to open the page.
pageType	Specifies the type of page, such as **Card**, **List**, **Document**, and more. For a complete list of page types and descriptions, see Page Types and Layouts.
refUri	Specifies the URI of the page.
telemetrySchemaVersion	Specifies the version of the Business Central telemetry schema.

Analyzing Permission Changes Trace Telemetry

2/17/2021 • 4 minutes to read • Edit Online

APPLIES TO: Business Central 2020 release wave 2, version 17.2, and later

Permission changes telemetry gathers data about the following operations on permission sets:

- A user-defined permission set was added or removed
- A link between a user-defined permission set and system permission set was added or removed
- A permission set was assigned to or removed from a user or user group

For information about managing permission sets, see Assign Permissions to Users and Groups.

User-defined permission set added

Occurs when a user-defined permission set is created.

General dimensions

DIMENSION	DESCRIPTION OR VALUE
message	**User-defined permission set added: {alPermissionSetId}**
severityLevel	**1**

Custom dimensions

DIMENSION	DESCRIPTION OR VALUE
eventId	**AL0000E2A**
alNumberOfUserDefinedPermissionSets	Specifies the total number of user-defined permission sets.
alPermissionSetId	Specifies the ID assigned to the permission set.

Common custom dimensions

The following table explains additional custom dimensions that are common to all permission traces.

DIMENSION	DESCRIPTION OR VALUE
aadTenantId	Specifies that Azure Active Directory (Azure AD) tenant ID used for Azure AD authentication. For on-premises, if you aren't using Azure AD authentication, this value is **common**.
alCategory	**AL PermissionSet**
alDataClassification	**SystemMetadata**
alObjectId	**1351**, which is the ID of the system application codeunit that subscribes to the telemetry events.

DIMENSION	DESCRIPTION OR VALUE
alObjectName	**Telemetry Subscribers**, which is the name of the system application codeunit that subscribes to the telemetry events.
alObjectType	**CodeUnit**
component	**Dynamics 365 Business Central Server**.
componentVersion	Specifies the version number of the component that emits telemetry (see the component dimension.)
environmentType	Specifies the environment type for the tenant, such as **Production**, **Sandbox**, **Trial**. See Environment Types.
telemetrySchemaVersion	Specifies the version of the Business Central telemetry schema.

User-defined permission set removed

Occurs when a user-defined permission set is deleted.

General dimensions

DIMENSION	DESCRIPTION OR VALUE
message	**User-defined permission set removed: {alPermissionSetId}**
severityLevel	**1**

Custom dimensions

DIMENSION	DESCRIPTION OR VALUE
eventId	**AL0000E2B**
alNumberOfUserDefinedPermissionSets	Specifies the total number of user-defined permission sets.
alPermissionSetId	Specifies the ID of the permission set that was deleted.
See common custom dimensions	

Permission set link added

Occurs when a user-defined permission set is created from a copy of a system permission set, and the **Notify on Changed Permission Set** option is selected. The **Notify on Changed Permission Set** option creates a link between the system permission set and the user-defined permission set.

General dimensions

DIMENSION	DESCRIPTION OR VALUE

DIMENSION	DESCRIPTION OR VALUE
message	**Permission set link added: {alSourcePermissionSetId} -> {alLinkedPermissionSetId}**
severityLevel	**1**

Custom dimensions

DIMENSION	DESCRIPTION OR VALUE
eventId	**AL0000E28**
alSourcePermissionSetId	Specifies the ID of the system permission set that was copied to create the user-defined permission set.
alLinkedPermissionSetId	Specifies the ID of the user-defined permission that was created from a copy of the system permission set.
alNumberOfUserDefinedPermissionSetLinks	Specifies the total number of user-defined permission sets that are linked to system permission sets.
See common custom dimensions	

Permission set link removed

Occurs when a user-defined permission set, which is linked to a system permission set, is deleted.

General dimensions

DIMENSION	DESCRIPTION OR VALUE
message	**Permission set link removed {alSourcePermissionSetId} -> {alLinkedPermissionSetId}**
severityLevel	**1**

Custom dimensions

DIMENSION	DESCRIPTION OR VALUE
eventId	**AL0000E29**
alSourcePermissionSetId	Specifies the ID of the system permission set that the deleted user-defined permission set was linked to.
alLinkedPermissionSetId	Specifies the ID of the deleted user-defined permission set.
alNumberOfUserDefinedPermissionSetLinks	Specifies the total number of user-defined permission sets that are linked to system permission sets.
See common custom dimensions	

Permission set assigned to user

Occurs when a permission set is assigned to a user.

General dimensions

DIMENSION	DESCRIPTION OR VALUE
message	**Permission set assigned to user: {alPermissionSetId}**
severityLevel	**1**

Custom dimensions

DIMENSION	DESCRIPTION OR VALUE
eventId	**AL0000E2C**
alPermissionSetId	Specifies the ID of the permission set that was assigned to a user.
See common custom dimensions	

Permission set removed from user

Occurs when a permission set is removed from a user.

General dimensions

DIMENSION	DESCRIPTION OR VALUE
message	**Permission set removed from user: {alPermissionSetId}**
severityLevel	**1**

Custom dimensions

DIMENSION	DESCRIPTION OR VALUE
eventId	**AL0000E2D**
alPermissionSetId	Specifies the ID of the permission set that was removed from the user.
See common custom dimensions	

Permission set assigned to user group

Occurs when a permission set is assigned to a user group.

General dimensions

DIMENSION	DESCRIPTION OR VALUE
message	**Permission set assigned to user group: {alPermissionSetId}**
severityLevel	**1**

Custom dimensions

DIMENSION	DESCRIPTION OR VALUE
eventId	**AL0000E2E**
alPermissionSetId	Specifies the ID of the permission set that was assigned to the user group.
alUserGroupId	Specifies the ID of the user group that the permission set was assigned to.
See common custom dimensions	

Permission set removed from user group

Occurs when a permission set is removed from a user.

General dimensions

DIMENSION	DESCRIPTION OR VALUE
message	**Permission set removed from user group: {alPermissionSetId}**
severityLevel	**1**

Custom dimensions

DIMENSION	DESCRIPTION OR VALUE
eventId	**AL0000E2F**
alPermissionSetId	Specifies the ID of the permission set that was removed from the user group.
alUserGroupId	Specifies the ID of the user group that the permission set was removed from.
See common custom dimensions

Analyzing Report Generation Telemetry

2/17/2021 • 10 minutes to read • Edit Online

INTRODUCED IN: Business Central 2020 release wave 1

Report generation telemetry gathers data about reports that are run on the service. It provides information about whether the report dataset generation succeeded, failed, or was canceled. For each report, it tells you how long it ran, how many SQL statements it executed, and how many rows it consumed.

You use this data to gather statistics to help identify slow-running reports.

Success report generation

Occurs when a report dataset generates without any errors.

General dimensions

The following table explains the general dimensions of this trace.

DIMENSION	DESCRIPTION OR VALUE
operation_Name	**Success report generation** **Note:** The use of the `operation_Name` column was deprecated in version 16.1. In future versions, data won't be stored in this column. So in version 16.1 and later, use the custom dimension column `eventID` column custom in Kusto queries instead of `operation_Name`.
message	Version 16.1 and later: **Report rendered: {report ID} - {report name}** Before version 16.1: **The report {report ID} '{report name}' rendered successfully**
severityLevel	**1**

Custom dimensions

DIMENSION	DESCRIPTION OR VALUE
aadTenantId	Specifies that Azure Active Directory (Azure AD) tenant ID used for Azure AD authentication. For on-premises, if you aren't using Azure AD authentication, this value is **common**.
alObjectId	Specifies the ID of the report object that was run.
alObjectName	Specifies the name of the report object that was run.
alObjectType	**Report**.
alStackTrace	The stack trace in AL.

DIMENSION	DESCRIPTION OR VALUE
clientType	Specifies the type of client that executed the SQL Statement, such as **Background** or **Web**. For a list of the client types, see ClientType Option Type.
companyName	Specifies the display name of the Business Central company for which the report was run.
component	**Dynamics 365 Business Central Server**.
componentVersion	Specifies the version number of the component that emits telemetry (see the component dimension.)
deprecatedKeys	Specifies a comma-separated list of all the keys that have been deprecated. The keys in this list are still supported but will eventually be removed in the next major release. We recommend that update any queries that use these keys to use the new key name.
environmentName	Specifies the name of the tenant environment. See Managing Environments.
environmentType	Specifies the environment type for the tenant, such as **Production**, **Sandbox**, **Trial**. See Environment Types
eventId	**RT0006** This dimension was introduced in Business Central 2020 release wave 1, version 16.1.
extensionId	Specifies the appID of the extension that the report object belongs to.
extensionName	Specifies the name of the extension that the report object belongs to.
extensionVersion	Specifies the version of the extension that the report object belongs to.
numberOfRows	Specifies the number of rows/records generated for the report dataset.
reportingEngine	Specifies the reporting engine used to generate the report, such as **ProcessingOnly**, **Rdlc**, or **Word**. This dimension was added in version 17.3
result	**Success**
serverExecutionTime	Specifies the amount of time it took the service to complete the request[1]. The time has the format hh:mm:ss.sssssss.
sqlExecutes	Specifies the number of SQL statements that the report executed[1].

DIMENSION	DESCRIPTION OR VALUE
sqlRowsRead	Specifies the number of table rows that were read by the SQL statements[1].
telemetrySchemaVersion	Specifies the version of the Business Central telemetry schema.
totalTime	Specifies the amount of time it took for the system to generate the dataset and render the report[1]. The time has the format hh:mm:ss.sssssss.

From telemetrySchemaVersion **0.6** and onwards, this value also includes the CompanyOpen operation.

Failed report generation

This operation occurs when the report dataset couldn't be generated because of an error.

General dimensions

The following table explains the general dimensions of the **Failed report generation** operation.

DIMENSION	DESCRIPTION OR VALUE
message	Version 16.1 and later: **Report rendering failed: {report ID} - {report name}** Before version 16.1: **The report {report ID} '{report name}' couldn't be rendered**
operation_Name	**Failed report generation** **Note:** The use of the `operation_Name` column was deprecated in version 16.1. In future versions, data won't be stored in this column. So in version 16.1 and later, use the custom dimension column `eventID` column custom in Kusto queries instead of `operation_Name`.
severityLevel	**3**

Custom dimensions

DIMENSION	DESCRIPTION OR VALUE
aadTenantId	Specifies that Azure Active Directory (Azure AD) tenant ID used for Azure AD authentication. For on-premises, if you aren't using Azure AD authentication, this value is **common**.
alObjectId	Specifies the ID of the report object that was run.
alObjectName	Specifies the name of the report object that was run.
alObjectType	**Report**.
alStackTrace	The stack trace in AL.

DIMENSION	DESCRIPTION OR VALUE
cancelReason[2]	Specifies why the report was canceled.
clientType	Specifies the type of client that executed the SQL Statement, such as **Background** or **Web**. For a list of the client types, see ClientType Option Type.
companyName	Specifies the display name of the Business Central company for which the report was run.
component	**Dynamics 365 Business Central Server**.
componentVersion	Specifies the version number of the component that emits telemetry (see the component dimension.)
deprecatedKeys	Specifies a comma-separated list of all the keys that have been deprecated. The keys in this list are still supported but will eventually be removed in the next major release. We recommend that update any queries that use these keys to use the new key name.
environmentName	Specifies the name of the tenant environment. See Managing Environments.
environmentType	Specifies the environment type for the tenant, such as **Production**, **Sandbox**, **Trial**. See Environment Types
eventId	**RT0006** This dimension was introduced in Business Central 2020 release wave 1, version 16.1.
extensionId	Specifies the appID of the extension that the report object belongs to.
extensionName	Specifies the name of the extension that the report object belongs to.
extensionVersion	Specifies the version of the extension that the report object belongs to.
numberOfRows	Specifies the number of rows/records generated for the report dataset.
result	Specifies the title of the exception that was thrown, such as **NavNCLDialogException**.
serverExecutionTime	Specifies the amount of time used by service on the request. The time has the format hh:mm:ss.sssssss.
sqlExecutes	Specifies the number of SQL statements that the report executed.
sqlRowsRead	Specifies the number of table rows that were read by the SQL statements.

DIMENSION	DESCRIPTION OR VALUE
telemetrySchemaVersion	Specifies the version of the Business Central telemetry schema.
totalTime	Specifies the amount of time used to generate the dataset and render the report before it failed. The time has the format hh:mm:ss.sssssss.

[2] Available in Business Central 2020 release wave 2 and later only.

Analyzing report generation failures

When a report fails to generate, the `result` column in the CustomDimensions will include the title of the exception that was thrown by the service or the AL code.

Cancellation report generation

This operation occurs when the report dataset generation was canceled. There are various conditions that can cancel a report. The **Cancellation report generation** operation emits different trace messages for each condition.

General dimensions

The following table explains the general dimensions of the **Cancellation report generation** operation.

DIMENSION	DESCRIPTION OR VALUE
operation_Name	**Cancellation report generation** **Note:** The use of the `operation_Name` column was deprecated in version 16.1. In future versions, data won't be stored in this column. So in version 16.1 and later, use the custom dimension column `eventID` column custom in Kusto queries instead of `operation_Name`.
message	Specifies the reason why the report was canceled. See Analyzing cancellation messages section for details.
severityLevel	2

Custom dimensions

DIMENSION	DESCRIPTION OR VALUE
aadTenantId	Specifies that Azure Active Directory (Azure AD) tenant ID used for Azure AD authentication. For on-premises, if you aren't using Azure AD authentication, this value is **common**.
alObjectId	Specifies the ID of the report object that was run.
alObjectName	Specifies the name of the report object that was run.
alObjectType	**Report**.
alStackTrace	The stack trace in AL.

DIMENSION	DESCRIPTION OR VALUE
clientType	Specifies the type of client that executed the SQL Statement, such as **Background** or **Web**. For a list of the client types, see ClientType Option Type.
companyName	Specifies the display name of the Business Central company for which the report was run.
component	**Dynamics 365 Business Central Server**.
componentVersion	Specifies the version number of the component that emits telemetry (see the component dimension.)
deprecatedKeys	Specifies a comma-separated list of all the keys that have been deprecated. The keys in this list are still supported but will eventually be removed in the next major release. We recommend that update any queries that use these keys to use the new key name.
environmentName	Specifies the name of the tenant environment. See Managing Environments.
environmentType	Specifies the environment type for the tenant, such as **Production**, **Sandbox**, **Trial**. See Environment Types
eventId	**RT0007** This dimension was introduced in Business Central 2020 release wave 1, version 16.1.
extensionId	Specifies the appID of the extension that the report object belongs to.
extensionName	Specifies the name of the extension that the report object belongs to.
extensionVersion	Specifies the version of the extension that the report object belongs to.
telemetrySchemaVersion	Specifies the version of the Business Central telemetry schema.

Analyzing report cancellations

The cancellation messages indicate events that caused the report to be canceled. The telemetry can help identify slow-running reports - reports that take longer than expected to run and generate a large number of rows.

> **NOTE**
> The service evaluates cancellation events in a specific order, and the evaluation is done every five seconds. For more information, see Report Generation and Cancellation Flow.

Cancellation event received. Requesting cancellation of the action.

This message occurs when the session canceled a report as it was being generated.

Received a cancellation request from the user. Requesting cancellation of the action.

This message occurs when a user canceled a report in the client as it was being generated.

The action took longer to complete ({0}) than the specified threshold ({1}). Requesting cancellation of the action.

The service is configured to cancel reports if they take longer to generate than a set amount of time. With Business Central online, you can't change the threshold. With Business Central on-premises, you change the threshold by setting the **Max Execution Timeout** parameter on the Business Central Server instance. There's no timeout for on-premises by default. For more information, see Configuring Business Central Server.

The rendering of the word report has been cancelled because it took longer than the specified threshold ({0})"

This message occurs when a report that based on a Word layout takes longer to generate than the specified threshold. The event is only relevant for Business Central online. There's no timeout for on-premises.

The number of processed rows exceeded ({0} rows) the maximum number of rows ({1} rows). Requesting cancellation of the action.

The service is configured to cancel reports if they generate more than a set number of rows. With Business Central online, you can't change this threshold. With Business Central on-premises, you change the threshold by setting the **Max Rows** parameter on the Business Central Server instance. There's no limit on rows for on-premises by default. For more information, see Configuring Business Central Server.

Report cancelled but a commit occurred

This operation occurs when the report dataset generation was canceled but a COMMIT operation occurred before the cancellation. This pattern isn't recommended. Reconsider the report design.

General dimensions

The following table explains the general dimensions of the **Report cancelled but a commit occurred** operation.

DIMENSION	DESCRIPTION OR VALUE
message	The report <ID> '<Name>' is being canceled, but a COMMIT() has been performed. This can lead to data inconsistency if the report is not idempotent
severityLevel	2

Custom dimensions

DIMENSION	DESCRIPTION OR VALUE
aadTenantId	Specifies that Azure Active Directory (Azure AD) tenant ID used for Azure AD authentication. For on-premises, if you aren't using Azure AD authentication, this value is **common**.
alObjectId	Specifies the ID of the report object that was run.
alObjectName	Specifies the name of the report object that was run.
alObjectType	**Report**.
alStackTrace	The stack trace in AL.
cancelReason	The reason why the report was cancelled
clientType	Specifies the type of client that executed the SQL Statement, such as **Background** or **Web**. For a list of the client types, see ClientType Option Type.

DIMENSION	DESCRIPTION OR VALUE
companyName	Specifies the display name of the Business Central company for which the report was run.
component	**Dynamics 365 Business Central Server**.
componentVersion	Specifies the version number of the component that emits telemetry (see the component dimension.)
deprecatedKeys	Specifies a comma-separated list of all the keys that have been deprecated. The keys in this list are still supported but will eventually be removed in the next major release. We recommend that update any queries that use these keys to use the new key name.
environmentName	Specifies the name of the tenant environment. See Managing Environments.
environmentType	Specifies the environment type for the tenant, such as **Production**, **Sandbox**, **Trial**. See Environment Types
eventId	**RT0011** This dimension was introduced in Business Central 2020 release wave 1, version 16.1.
extensionId	Specifies the appID of the extension that the report object belongs to.
extensionName	Specifies the name of the extension that the report object belongs to.
extensionPublisher	Specifies the name of the extension publisher that the report object belongs to.
extensionVersion	Specifies the version of the extension that the report object belongs to.
telemetrySchemaVersion	Specifies the version of the Business Central telemetry schema.

Analyzing Incoming Web Services Request Telemetry

2/17/2021 • 5 minutes to read • Edit Online

INTRODUCED IN: Business Central 2020 release wave 1

Web services telemetry gathers data about SOAP, OData, and API requests through the service. It provides information like the request's endpoint, time to complete, the SQL statements run, and more.

As a developer, you use the data to learn about conditions that you can change to improve performance. The following table provides some examples:

CONDITION	ANALYSIS
A web service request results in a long running SQL query	Adjust or fine-tune code.
Web service requests to a specific endpoint read more rows than requests to the other endpoints	Consider adding filtering to limit the rows that are read.
Fewer API type requests compared with other types	With SOAP and OData requests, computation resources are used on UI elements that aren't relevant. Instead of exposing normal pages as web service endpoints, use the built-in API pages. API pages are optimized for this scenario.
High number of requests to endpoints that include Power BI	This condition may indicate excessive Power BI integration.

For more performance guidelines, see Writing efficient Web Services.

> **NOTE**
> Business Central online and on-premises are configured with various limits on web service requests. For example, there is a request timeout and a maximum connections limit. For online, you can't change these limits, but it is helpful to know what the limits are. See Current API Limits. For on-premises, you change the limits on the Business Central Server instance. See Configuring Business Central Server. Web service calls that exceed the timeout limit result in a **408 - Request Timeout**. These calls are recorded in Application Insights with a totalTime that is equal to the timeout threshold.

General dimensions

The following table explains the general dimensions included in an incoming **Web Services Call** trace. The table lists the dimensions that are specific to Business Central.

DIMENSION	DESCRIPTION OR VALUE
operation_Name	**Web Services Call** **Note:** The use of the `operation_Name` column was deprecated in version 16.1. In future versions, data won't be stored in this column. So in version 16.1 and later, use the custom dimension column `eventID` column custom in Kusto queries instead of `operation_Name`.

DIMENSION	DESCRIPTION OR VALUE
message	Version 16.1 and later (depending on the type): • **Web service called (API): {endpoint}** • **Web service called (ODataV4): {endpoint}** • **Web service called (ODataV3): {endpoint}** • **Web service called (SOAP): {endpoint}** Before version 16.1: • **Received a web service request of type API** • **Received a web service request of type ODataV4** • **Received a web service request of type ODataV3** • **Received a web service request of type SOAP**
severityLevel	**1**

Custom dimensions

The following table explains the custom dimensions included in a **Web Services Call** trace.

DIMENSION	DESCRIPTION OR VALUE
aadTenantId	Specifies that Azure Active Directory (Azure AD) tenant ID used for Azure AD authentication. For on-premises, if you aren't using Azure AD authentication, this value is **common**.
alObjectId	Specifies the ID of the AL object that was run by request.[1]
alObjectName	Specifies the name of the AL object that was run by the request.[1]
alObjectType	Specifies the type of the AL object that was run by the request.[1]
category	Specifies the service type. Values include: **API**, **ODataV4**, **ODataV3**, and **SOAP**.
component	**Dynamics 365 Business Central Server**
componentVersion	Specifies the version number of the component that emits telemetry (see the component dimension.)
deprecatedKeys	A comma-separated list of all the keys that have been deprecated. The keys in this list are still supported but will eventually be removed in the next major release. We recommend that update any queries that use these keys to use the new key name.
endpoint	Specifies the endpoint for the request.
environmentName	Specifies the name of the tenant environment. See Managing Environments.
environmentType	Specifies the environment type for the tenant, such as **Production**, **Sandbox**, **Trial**. See Environment Types
eventId	**RT0008** This dimension was introduced in Business Central 2020 release wave 1, version 16.1.
httpHeaders	Introduced in version 16.3. Specifies the http headers set in the request.

DIMENSION	DESCRIPTION OR VALUE
httpMethod	Introduced in version 16.3. Specifies the HTTP method used in the request. Values include: POST, GET, PUT, PATCH, orDELETE.
httpStatusCode	Introduced in version 16.3. Specifies the http status code returned when a request has completed. This dimension further indicates whether request succeeded or not, and why. Use it to verify whether there was an issue with a request even though the request was logged as successful. The dimension displays one of the following values: • **200** OK. The request succeeded. • **401** Access denied. The user who made the request doesn't have proper permissions. For more information, see Web Services Authentication and Assign Permissions to Users and Groups. • **404** Not found. The given endpoint was not valid. For more information, see Publishing a Web Service • **408** Request timed out. The request took longer to complete than the threshold configured for the service. For information about this threshold in Business Central online, see OData request limits. For on-premises, the timeout is determined by the ODataServicesOperationTimeout setting of the Business Central Server. For more information, see Configuring Business Central Server • **429** Too Many Requests. The request exceeded the maximum simultaneous requests allowed on the service. For information about this threshold in Business Central online, see OData request limits. For on-premises, the timeout is determined by the ODataMaxConnections setting of the Business Central Server. For more information, see Configuring Business Central Server This dimension was introduced in Business Central 2020 release wave 1, version 16.3. This dimension is not populated for SOAP endpoints.
serverExecutionTime	Specifies the amount of time it took the server to complete the request**. The time has the format hh:mm:ss.sssssss.
sqlExecutes	Specifies the number of SQL statements that the request executed.[1] [2]
sqlRowsRead	Specifies the number of table rows that were read by the SQL statements.[1] [2]
totalTime	Specifies the amount of time it took to process the request.[2] The time has the format hh:mm:ss.sssssss.
telemetrySchemaVersion	Specifies the version of the Business Central telemetry schema.

[1]This dimension isn't relevant for $metadata calls, like `https://localhost:7048/BC/ODataV4/$metadata`, so it won't be in the trace.

[2]From telemetrySchemaVersion **0.6** and onwards, this value also includes the CompanyOpen operation.

Analyzing Outgoing Web Service Request Telemetry

2/17/2021 • 3 minutes to read • Edit Online

APPLIES TO: Business Central 2020 release wave 2 and later

Outgoing web service request telemetry gathers data about outgoing web service requests sent using the AL HTTPClient module. As a partner, the data gives you insight into the execution time and failures that happen in external services that your environment and extensions depend on. Use the data to monitor environments for performance issues caused by external services, and be more proactive in preventing issues from occurring.

General dimensions

The following table explains the general dimensions included in an outgoing **Web Services Call (Outgoing)** trace. The table lists the dimensions that are specific to Business Central.

DIMENSION	DESCRIPTION OR VALUE
message	**Web Service Called (Outgoing): {endpoint}**
severityLevel	**1**

Custom dimensions

The following table explains the custom dimensions included in a **Web Services Call** trace.

DIMENSION	DESCRIPTION OR VALUE
aadTenantId	Specifies that Azure Active Directory (Azure AD) tenant ID used for Azure AD authentication. For on-premises, if you aren't using Azure AD authentication, this value is **common**.
alAuthenticationMethod	Specifies the user authentication used by the Business Central service . Values include: Windows, UserName, NavUserPassword, AccessControlService. For more information about the authentication types, see Authentication and Credential Types.
alHttpTimeout	Specifies the timeout defined for the request. The timeout is the time to wait before a request gets canceled. The value has the format hh:mm:ss. The timeout is defined either by the NavHttpClientMaxTimeout setting on the Business Central Server instance or by a TimeOut method call in extension code. The TimeOut method call takes precedence.
alObjectId	Specifies the ID of the AL object that made the request.
alObjectName	Specifies the name of the AL object that made the request.
alObjectType	Specifies the type of the AL object that made the request.
companyName	Specifies the display name of the Business Central company from which the request was made.
component	**Dynamics 365 Business Central Server**
componentVersion	Specifies the version number of the component that emits telemetry (see the component dimension.)
deprecatedKeys	A comma-separated list of all the keys that have been deprecated. The keys in this list are still supported but will eventually be removed in the next major release. We recommend that update any queries that use these keys to use the new key name.
endpoint	Specifies the endpoint for the request. The endpoint is cleaned to include only the base URI.
environmentName	Specifies the name of the tenant environment. See Managing Environments.
environmentType	Specifies the environment type for the tenant, such as **Production**, **Sandbox**, **Trial**. See Environment Types
eventId	**RT0019**
extensionId	Specifies the appID of the extension that made the request.
extensionName	Specifies the name of the extension that made the request.
extensionVersion	Specifies the version of the extension that made the request.

DIMENSION	DESCRIPTION OR VALUE
httpHeaders	Introduced in version 17.2. Specifies the http headers set in the request.
httpMethod	Specifies the HTTP method used in the outgoing request. Values include: POST, GET, PUT, PATCH, orDELETE.
httpReturnCode	**Deprecated in version 17.2. Use the dimension httpStatusCode instead.** Specifies the http status code returned when a request has completed. This dimension further indicates whether request succeeded or not, and why. Use it to verify whether there was an issue with a request even though the request was logged as successful. The dimension displays one of the following values: • **200** OK. The request succeeded. • **404** Not found. The given endpoint wasn't valid.
httpStatusCode	Specifies the http status code returned when a request has completed. This dimension further indicates whether request succeeded or not, and why. Use it to verify whether there was an issue with a request even though the request was logged as successful. The dimension displays one of the following values: • **200** OK. The request succeeded. • **404** Not found. The given endpoint wasn't valid.
serverExecutionTime	Specifies the amount of time it took the server to complete the request, including the time to open the company. The time has the format hh:mm:ss.sssssss.
totalTime	Specifies the amount of time it took to process the request, including the time to open the company. The time has the format hh:mm:ss.sssssss.
telemetrySchemaVersion	Specifies the version of the Business Central telemetry schema.

Example trace

The following code snippet is a CustomDimensions example:

```
{"Telemetry schema version":"0.2","telemetrySchemaVersion":"0.2","Component version":"17.0.15765.0","Environment type":"Production","componentVersion":"17.0.15

Analyzing Web Service Access Key Telemetry

2/17/2021 • 3 minutes to read • Edit Online

APPLIES TO: Business Central 2020 release wave 2, version 17.3, and later

The Business Central emits telemetry data about the success or failure of authenticating web service access keys on web service requests.

In a future release, web service access key feature will be deprecated. As a partner or customer, this data lets you monitor the use of web service access keys on your environments in preparation for this change.

For information about web service access keys, see How to use an Access Key for SOAP and OData Web Service Authentication.

Authentication with web service key succeeded

Occurs when a web service access key was authenticated successfully.

General dimensions

The following table explains the general dimensions included in the trace. The table lists the dimensions that are specific to Business Central.

DIMENSION	DESCRIPTION OR VALUE
message	**Authentication with Web Service Key succeeded: {endpoint}**
severityLevel	**1**

Custom dimensions

The following table explains the custom dimensions included in the trace.

DIMENSION	DESCRIPTION OR VALUE
aadTenantId	Specifies that Azure Active Directory (Azure AD) tenant ID used for Azure AD authentication. For on-premises, if you aren't using Azure AD authentication, this value is **common**.
alObjectId	Specifies the ID of the AL object that was run by request.
authenticationStatus	**Succeeded**
authenticationType	Specifies whether the service uses NavUserPassword or AccessControl (Azure AD) authentication.
category	Specifies the service type. Values include: **Api**, **ODataV4**, **ODataV3**, and **SOAP**.
component	**Dynamics 365 Business Central Server**
componentVersion	Specifies the version number of the component that emits telemetry (see the component dimension.)

DIMENSION	DESCRIPTION OR VALUE
deprecatedKeys	A comma-separated list of all the keys that have been deprecated. The keys in this list are still supported but will eventually be removed in the next major release. We recommend that update any queries that use these keys to use the new key name.
endpoint	Specifies the endpoint for the request. Private and sensitive information is omitted from the endpoint.
environmentType	Specifies the environment type for the tenant, such as **Production**, **Sandbox**, **Trial**. See Environment Types
eventId	**RT0020** This dimension was introduced in Business Central 2020 release wave 1, version 16.1.
telemetrySchemaVersion	Specifies the version of the Business Central telemetry schema.

Authentication with web service key failed

Occurs when a web service access key failed to authenticate.

General dimensions

The following table explains the general dimensions included in the trace. The table lists the dimensions that are specific to Business Central.

DIMENSION	DESCRIPTION OR VALUE
message	**Authentication with Web Service Key failed: {endpoint}**
severityLevel	**3**

Custom dimensions

The following table explains the custom dimensions included in the trace.

DIMENSION	DESCRIPTION OR VALUE
aadTenantId	Specifies that Azure Active Directory (Azure AD) tenant ID used for Azure AD authentication. For on-premises, if you aren't using Azure AD authentication, this value is **common**.
alObjectId	Specifies the ID of the AL object that was run by request.
authenticationStatus	**Failed**
authenticationType	Specifies whether the service uses NavUserPassword or AccessControl (Azure AD) authentication.
category	Specifies the service type. Values include: **Api**, **ODataV4**, **ODataV3**, and **SOAP**.
component	**Dynamics 365 Business Central Server**

DIMENSION	DESCRIPTION OR VALUE
componentVersion	Specifies the version number of the component that emits telemetry (see the component dimension.)
deprecatedKeys	A comma-separated list of all the keys that have been deprecated. The keys in this list are still supported but will eventually be removed in the next major release. We recommend that update any queries that use these keys to use the new key name.
endpoint	Specifies the endpoint for the request. Private and sensitive information is omitted from the endpoint.
environmentType	Specifies the environment type for the tenant, such as **Production**, **Sandbox**, **Trial**. See Environment Types
eventId	**RT0021**
failureReason	Specifies the exception that was thrown by the server. Some exception messages can contain customer data. As a precaution, Business Central only emits information that's classified as SystemMetadata. Exception messages that contain other data classifications, like customer data, are not shown. Instead, the following message is shown: "Message not shown because the NavBaseException(string, Exception, bool) constructor was used."
telemetrySchemaVersion	Specifies the version of the Business Central telemetry schema.

Example trace

The following code snippet is a CustomDimensions example:

```
{"component":"Dynamics 365 Business Central
Server","category":"Api","AadTenantId":"common","environmentType":"Production","Component":"Dynamics 365 Business Central

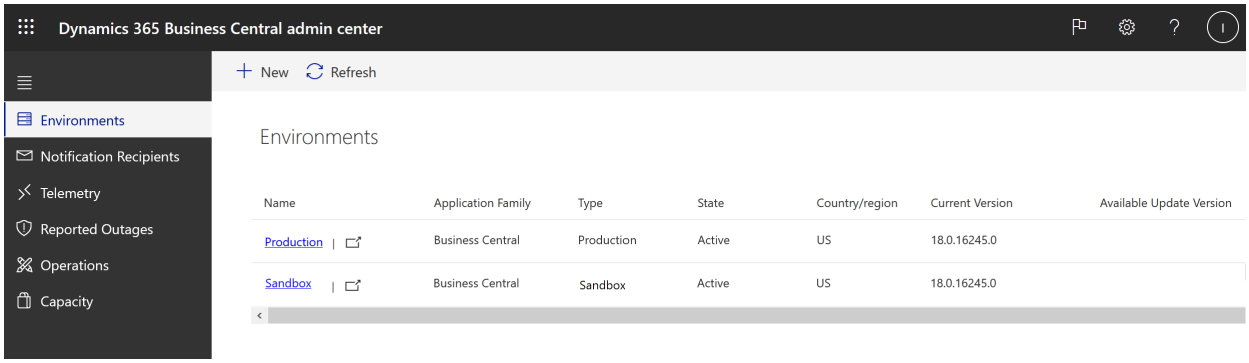
The Business Central Administration Center

2/17/2021 • 3 minutes to read • Edit Online

The Business Central administration center provides a portal for administrators to do administrative tasks for a Business Central tenant. Here, administrators can:

- view and work with production and sandbox environments for the tenant.
- set up upgrade notifications.
- view telemetry for events on the tenant.



Access to the administration center

The following users are authorized to access the Business Central administration center:

- Internal tenant administrators
- Admin agent
- Helpdesk agent

Internal administrators are users who are assigned the **Global admin** role or the **Dynamics 365 Admin** role in the Microsoft 365 admin center. These users are typically system administrators, IT professionals, or super users at the customer's company. For more information, see About admin roles in the Microsoft 365 admin content.

The *admin agent* and *helpdesk agent* roles are assigned through the Microsoft Partner Center for the partner that is associated with the tenant. These roles can access the Business Central tenant as *delegated administrators*. For more information, see Administration of Business Central Online.

Internal administrators

As the internal administrator, you can choose the link in the **Settings** menu when you're signed in to Business Central.

Alternatively, you can access the administration center from the URL, use the following pattern but replace *[TENANT_ID]* with the tenant ID of your Business Central:

```
https://businesscentral.dynamics.com/[TENANT_ID]/admin
```

TIP

The tenant ID is shown in the **Help and Support** page in your Business Central.

In the administration center, you can create and monitor environments. This is also where you manage the people who must be notified of administrative events for your tenant.

Your partner can help you set up telemetry for production environments, including integration with Application Insights in Azure.

Cleaning up settings

If your organization decides to switch to another partner, you must make sure that some settings that your current partner made in your Business Central administration center are removed. This includes the following settings:

- Support contact details
  1. In the Business Central administration center, choose the relevant environment, and then, in the **Support** menu, choose **Manage Support Contact**.
  2. Verify that the values in the **Name**, **Email address**, and the **Website** fields are still relevant; if not, then delete or modify the values.
- Notification recipients
  1. In the Business Central administration center, on the left side, choose **Notification recipients**
  2. Verify that the list of email addresses are still relevant; if not, then delete or modify the values.
- Application Insights key (if this was set up by the partner)
  1. In the Business Central administration center, choose the relevant environment, and then, in the top menu, choose **Application Insights Key**.
  2. Remove the value of the **Instrumentation Key**

When you establish a relationship with a new partner, they will fill in these fields again.

Partner access to the administration center

As a partner, you can access the administration center from the Partner Dashboard in the Microsoft Partner Center:

1. Log into the Partner Dashboard.
2. Select the **Customers** link in the navigation pane.
3. Select the customer tenant that you want to do administrative tasks for.
4. Select **Service Management**.
5. Under the **Administer Services** heading, select Dynamics 365 Business Central.

You can also get to the administration center by using the URL of a tenant, as described in the previous section.

In the Business Central administration center, you can specify support information, create and remove environments, and submit support request for your customer.

From the Business Central administration center, you can access your customer's Business Central for troubleshooting, for example.

> **NOTE**
> As the partner, there are certain tasks that you cannot do in your customers' Business Central. For more information, see Acting as a delegated administrator.

Managing Environments

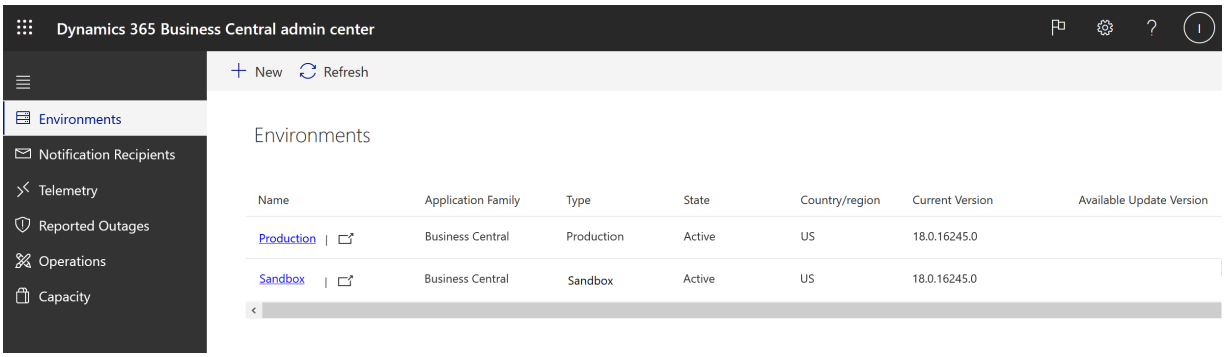
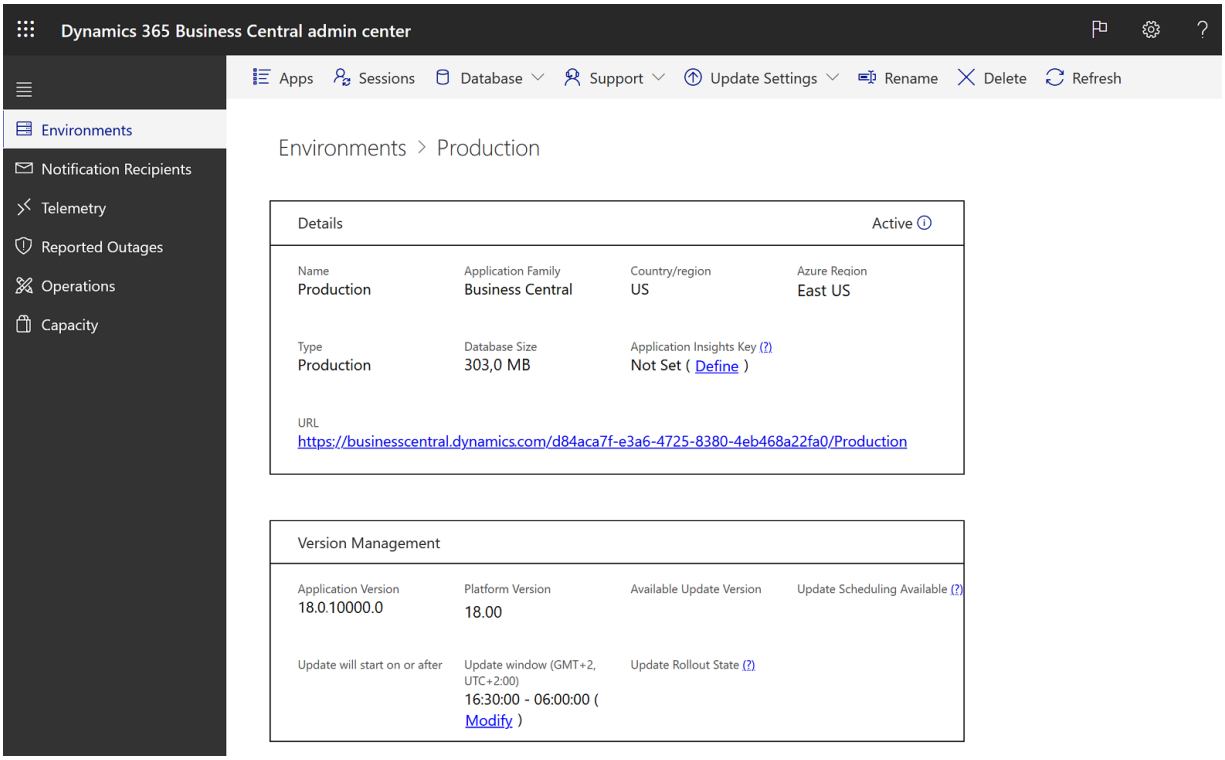
2/17/2021 • 21 minutes to read • Edit Online

The **Environments** tab of the Business Central administration center provides you with an overview of the Business Central production and sandbox environments for the tenant, and you can manage updates for each environment.



Viewing details for an environment

In the environments list, you can view more details by choosing the link in the **Name** column.



Types of environments

You can create environments of different types. Which type of environment to choose depends on what you need it for. For more information, see Production and Sandbox Environments.

Production environments

Production environments are meant to be precisely that: Environments that a business can run their daily business in Business Central in, deployed on performance tiers in Azure with a guaranteed high level of availability and support.

Production environments are backed up automatically and frequently to help protect business data. For more information, see How often are production databases backed up?.

You can create additional production environments for training or performance testing, for example. However, for training purposes, in many cases organizations will prefer to create a sandbox environment with production data. You can also create additional production environments to support offices in different countries.

> **NOTE**
> The Premium and Essential subscription types give each Business Central customer one production environment and three sandbox environment free of extra charge. If the customer requires more production environments, they can buy additional environments through their CSP partner. Each additional production environment comes with three additional sandbox environments and 4 GB additional, tenant-wide database capacity.

Administrators can create the additional environments in the Business Central administration center. The environments can be created and used in any country or region where Business Central is available, including the countries or regions where the customer's existing environments are running. The environments quota is applied when you try to create a new environment, or copy an existing environment, in the Business Central administration center.

Sandbox environments

Sandbox environments are meant to be precisely that: Environments that you can play around with, use as a testbed for development, and delete at will. You can deploy apps straight from Visual Studio Code to a sandbox environment, and you can attach a debugging session to a sandbox.

> **IMPORTANT**
> Apps that are published to a sandbox from the development environment or created using Designer are published within the scope of the service node that hosts the environment. When the sandbox is upgraded, these apps are removed because the environment is moved to another node that is running the new version. However, the data of the app is not removed, so you only have to re-publish and install the app to make it available.
> Apps that are uploaded to the environments of both types (production and sandbox) using the **Upload Extension** action from the **Extension Management** page are published within a global scope. When the environment is upgraded or moved, these apps are downloaded to the service node and installed, which means that they will not disappear.

You can also safely use sandboxes for training, such as for following a learning path from Microsoft Learn, because it's a safe environment to experiment with. If anything goes wrong, you just delete the sandbox and start over.

> **IMPORTANT**
> The automatic backup that applies to production environments does not apply to sandbox environments. If you want to export data from a sandbox environment, you can use Excel or RapidStart, but you cannot request a database export.

You can create a sandbox environment that includes data from your production environment for debugging purposes, for example. But if you want to run performance tests, or similar benchmarking, the sandbox is not reliable enough for that purpose. This is because sandboxes run in a different performance tier on Azure than production environments. Instead, create a dedicated environment based on the Production environment type - this gives you the exact experience and performance that users will experience in the actual production environment.

Sandbox environments are handy for certain types of development scenarios because the debugging endpoint is open by default. This means that you can attach Visual Studio Code to a running system and debug through running code. It also allows you to publish directly to the environment from Code.

If your organization has more than one sandbox environment, you can switch between environments by opening the App Launcher, choosing the Dynamics 365 tile, then choose the Business Central Sandbox tile. The sandbox environment picker shows the available sandboxes, so choose the one that you want to switch to.

> **NOTE**
>
> The Premium and Essential subscription types give each Business Central customer one production environment and three sandbox environment free of extra charge. If the customer requires more production environments, they can buy additional environments through their CSP partner. Each additional production environment comes with three additional sandbox environments and 4 GB additional, tenant-wide database capacity.

Administrators can create the additional environments in the Business Central administration center. The environments can be created and used in any country or region where Business Central is available, including the countries or regions where the customer's existing environments are running. The environments quota is applied when you try to create a new environment, or copy an existing environment, in the Business Central administration center.

Pre-sales performance evaluation

If you want to provide a prospect with an online environment where you want to demonstrate the performance and reliability of Business Central online in addition to demonstrating functionality, you must take a few extra steps.

To demonstrate the functionality of the default version of Business Central, without focusing on performance, you can quite simply use your own trial experience based on a Microsoft 365 demo account. We recommend that you show the full functionality of the default version by switching the tenant to the 30 day trial and the associated My Company. You can then enable the *Premium* user experience in the new My Company's **Company Information** page, populate the new company with the data required for their evaluation scenarios, and present the environment to the prospect.

To demonstrate the functionality of the service, with a focus on performance, you can take the same step as outlined above, but then also sign up the prospect for the Business Central Premium Trial offer that is available through your CSP access in the Partner Center, wait 24 hours, and then run your performance evaluation. For more information, see Preparing Test Environments of Dynamics 365 Business Central.

That 30 day trial is as close to an actual production environment performance as you can get. You only have those 29 days to run your tests and convince the prospect, of course, but provided that you have prepared everything in advance, it should give you time enough.

If the prospect is convinced and decides to buy Business Central, you can then either let them keep the environment that they are currently using, or create a new production environment for them. If the tenant is yours rather than the prospect's, then a new tenant will be provided to them.

For more information about performance and Business Central, see Performance Overview.

Create a new production environment

The Business Central administration center provides an easy method for creating environments for the tenant. For example, if you have been using a production environment for training purposes, and you've decided to start using Business Central to run the business, you can delete the original production environment and then create a new production environment.

> **NOTE**
> The Premium and Essential subscription types give each Business Central customer one production environment and three sandbox environment free of extra charge. If the customer requires more production environments, they can buy additional environments through their CSP partner. Each additional production environment comes with three additional sandbox environments and 4 GB additional, tenant-wide database capacity.

Administrators can create the additional environments in the Business Central administration center. The environments can be created and used in any country or region where Business Central is available, including the countries or regions where the customer's existing environments are running. The environments quota is applied when you try to create a new environment, or copy an existing environment, in the Business Central administration center.

To create a production environment:

1. On the **Environments** tab of the Business Central administration center, choose the **New** action on the action ribbon.
2. In the **Create Environment** pane, in the **Environment Type** list, choose **Production**.
3. In the **Country** list, select the country for the environment. The specified country determines the localization for the environment and the Azure region in which the environment is created and stored.
4. Select **Create**.

When the new production environment is created, it will be based on the latest production version of Business Central.

Create a new sandbox environment

A sandbox environment is a non-production instance of Business Central. Isolated from production, a sandbox environment is the place to safely explore, learn, demo, develop, and test the service without the risk of affecting the data and settings of your production environment.

> **IMPORTANT**
> Make sure that you understand the limitations of a sandbox before you create a new sandbox environment. For more information, see Sandbox environments section.

To create a sandbox environment:

1. On the **Environments** tab of the Business Central administration center, choose the **New** action on the action ribbon.
2. In the **Create Environment** pane, specify a name for the new environment.
3. In the **Create Environment** pane, in the **Environment Type** list, choose **Sandbox**.
4. Specify if you want the sandbox environment to contain a copy of another environment. If you choose this option, you must specify which environment to copy.

   When you create a sandbox environment as a copy of another environment, the new environment is created on the same application version as the environment that you are copying. The new environment will contain all per-tenant extensions and AppSource extensions that are installed and published in the original environment that is being copied.

   If a sandbox is created with a copy of a production environment, a number of precautions are taken for that sandbox:

   - The job queue is automatically stopped

- Any base application integration settings are cleared
- Outbound HTTP calls from extensions are blocked by default and must be approved for each extension

  To enable outbound HTTP calls, go to the **Extension Management** page in Business Central, and choose **Configure**. Then, on the **Extension Settings** page, make sure that **Allow HttpClient Requests** is selected. This setting must be enabled for each extension.
- Any General Data Protection Regulation (GDPR) action must be handled separately and repeated for the sandbox. There is no synchronization with the production environment after the sandbox has been created.

  The internal administrator has the same tools and responsibilities for a sandbox environment as they do for a production environment. As a data processor, Business Central offers the same level of data protection and data handling restrictions that we apply to production environments.

5. In the **Country** list, select the country for the environment. The specified country determines the localization for the environment and the Azure region in which the environment is created and stored.
6. Choose the relevant application version for the new sandbox environment from the **Version** list if more than one version is available.
7. Select **Create**.

> **NOTE**
> The sandbox environment won't be accessible until the **State** shows *Active*.

To delete a sandbox environment, choose the environment on the **Environments** tab of the Business Central administration center, and then choose **Delete** on the action ribbon.

Selecting a version for a new sandbox environment

If you create a sandbox that isn't a copy of an existing environment, you must specify an application version for the new environment. The version list will show the latest *production* version, which is the version used for new production environments.

The version list may also have one or more *preview* versions. Preview versions are early release candidates of upcoming releases of Business Central that are made available specifically for sandbox environments. This list gives you access to review new functionality, validate extension compatibility, and other general testing of the upcoming release.

When you create a sandbox environment on a preview version, the environment will automatically be updated to new preview versions when they become available. However, the environment won't be updated to the production version. Once a sandbox environment is on a preview version, it must stay on a preview version until it's deleted. The environment can also be deleted if an update between preview versions fails. We recommend that preview versions are used only for temporary testing of an upcoming release.

Managing Sessions

The **Manage Sessions** page displays information about active sessions on an environment and lets you cancel selected sessions.

To open the page, select **Manage Sessions**. Use the **Show session details** check box to show more or fewer details.

Cancel sessions

Canceling a session is sometimes the only way to unblock a customer. For example, a long-running report is locking data in a table, preventing warehouse employees from working.

To cancel a session, select it from the list and then select **Cancel selected sessions**.

Restoring an environment

> **NOTE**
> This feature is in preview. It might change or be removed in the future updates.

Database backups are an essential part of any business continuity and disaster recovery strategy, because they protect your data from corruption or deletion. Business Central online service uses Azure SQL Database as the underlying database backup technology for its environments. All databases are protected by automated backups that are continuously created and maintained by the Azure SQL service. The backup retention period for Business Central databases is set to 30 days for both production and sandbox environments.For more information about this backup process, see Automated backups - Azure SQL Database & SQL Managed Instance.

As an administrator, you can restore an existing environment from a time in the past, within the 30-day retention period. An environment can only be restored within the same Business Central version (minor and major).

Users who can restore environments

Permission to restore environments is limited to specific types of users: internal and delegated administrators. The following users are allowed to restore environments.

- Delegated administrators from reselling partners
- Administrators from the organization that subscribes to Business Central online

Also, these users must have the **D365 BACKUP/RESTORE** permission set assigned to their user account in the environment they're trying to export.

For more information about permissions sets and user groups, see Assign Permissions to Users and Groups.

Considerations and limitations

- Environments can only be restored if the customer has a paid Business Central subscription.
- Each environment can be restored up to 10 times in a calendar month.
- It's not possible to use the Business Central administration center to restore an environment that was previously deleted.

  If you end up in the situation where you need to restore a deleted environment, contact Microsoft Support for help. In such cases, Microsoft doesn't guarantee a restore operation will succeed or all data and extensions will be available in the restored database. So before you decide to delete an environment, it's important to ensure that the environment is no longer needed.
- An environment can only be restored within the same Azure region and country (Business Central localization) as the original environment.
- A production environment can be restored to either a **Production** or **Sandbox** type environment. A sandbox environment can only be restored a **Sandbox** type environment.
- When restoring a sandbox environment, all development extensions (that is, extensions published directly from Visual Studio Code) won't be available in the restored environment—even if they were present at the point-in-time you're restoring to). Additionally, any per-tenant extensions that depend on such development extensions will also not be available.

- Per-tenant extensions you may have uploaded that target the **next** version of the Business Central won't be available in the restored environment—even if they were uploaded at the point-in-time you're restoring to. Per-tenant extensions that were already installed will be available in the restored environment.
- Every AppSource and Business Central app in the restored environment will have the latest available hotfix installed automatically—even if the hotfix was introduced after the point-in-time you're restoring to.

Before you restore an environment

Here are a few important things to do when you're planning to restore an environment:

- Make sure you communicate the plan to restore an environment within your organization upfront, in good time.
- Typically, you want to stop users and external integrations from using the environment during restoration. Consider doing the following actions in the environment you're planning to restore:
  - Remove access to the environment for non-essential users, but make sure required users, like administrators, keep access. For more information, see Remove a user's access to the system.
  - Put all job queues to on hold. For more information, see Use Job Queues to Schedule Task.
- Consider renaming the environment. The users and external integrations won't be able to access it by its old name.

  When restoring an environment, you'll create a new environment that the database backup will be restored to. You can't use the same name for two environments of the same customer. So if you want the restored environment to have the same name as the original environment, rename the original environment before you run the restore operation. For example, you could change the name to include DONOTUSE.

  For more information, see Renaming an environment.

Restore an environment

To restore an environment, you'll have to provide a name for the environment and a date/time from which to restore the database.

1. Select **Environments** and then open the environment you want to restore.
2. Select **Restore**.
3. In the **Restore Environment** pane, specify the date and time in the past to which you want to restore the environment.
4. Select the type to be used for the restored environment.
5. Specify a name for the restored environment.
6. Select **Restore**.

   If there's no backup available for date and time you chose, select the available nearest backup, when prompted. This situation can occur, for example, if the environment was being updated to a new minor or major version during the specified time.

   > **NOTE**
   >
   > For newly created environments it may take up to 30 min for the backups to be initialized, so you may not be able to restore an environment if you have just created it.

7. When the process starts, you can go to the list of your environments and see the status of the restored environment. At first, you'll see the new environment with state **Preparing**. The original environment state remains as **Active**.

   The restore operation duration is affected by several factors. For large or highly active databases, the restore might take several hours. You can find more details about the factors that affect the recovery time at Recovery time.

   Once the restore is completed, the environment state will change to **Active**. If the restore operation fails, you can find the failure details on the **Operations** page. In this case, delete the failed environment, and then try to restore again. Contact Microsoft Support if the issue persists.

After you restore an environment

After restoring an environment, you should inspect and adjust data to prepare it for users. Consider enforcing these steps during this period:

- Remove access to the environment for non-essential users, but make sure required users, like administrators, keep access.
- Put all job queues in the restored environment to on hold immediately after restore.
- If needed, you can upload the per-tenant extensions targeting the next version of Business Central again.

The original environment will remain available and isn't affected by the restore operation. You can then get back to the original environment if you need to look up data. Or maybe you'll have to migrate some data to the restored environment. You can, for example, migrate data by using Business Central RapidStart services. For more information, see Migrate Customer Data.

> **IMPORTANT**
> You can restore your production environment into a new production environment even if doing so results in exceeding your number of environments or database capacity quotas. You can however only exceed this quota by one extra production environment, regardless of how many production environments you have available for your subscription. This capability is provided as an exception, to ensure that you can always restore your production environment in critical situations. You must return within your quota within 30 days following the restore by either removing the original production environment or by purchasing an additional production environment. Before removing the environment, we recommend you export the environment to an Azure storage container in case you need to access some data at a later point. This exception isn't available for restoring from and to sandbox environments.

When you're satisfied with the data in the restored database, enable the users, start the job queues, and let your organization know that the restore process is now completed and they can again use the environment.

Renaming an environment

> **NOTE**
> This feature is in preview. It might change or be removed in the future updates.

You can change the name of any environment. The name uniquely identifies the environment from your other environments. Before you change a name, you must consider that the name also is part of the environment's URL. The URL is used in links to the environment in various ways. So changing the name can have significant impact.

The renaming of an environment is logged and shown in the operations log.

Before you rename an environment

- Read the Environment rename considerations section to understand the consequences of renaming an

environment.

- Make sure you notify all your users, including any external service integrations you may have, about the upcoming URL change. It will let them prepare to update their references.
- Determine the best time to do the renaming. Renaming an environment requires a restart to the environment. We recommend doing this operation when no users are active in Business Central.

Rename an environment

1. Select **Environments**, then select the environment you want to rename.
2. On the **Environment Details** page, select **Rename**.
3. On **Rename environment** page, read the information.
4. Enter the new name, and then select **Rename**.
5. Confirm your intent to rename the environment.

At this point, the environment state will first change to **Preparing | Rename Scheduled**, then to **Active** again when the rename has been completed. The new name will be available immediately. The environment will no longer be accessible using the old environment name.

You can also review the log for the Rename operation on the **Operations** page afterwards.

Environment rename considerations

Changing the environment name can affect many scenarios and integrations. In the early stages of a customer implementation, it may be a low risk operation. But renaming an environment that's been used by customers for a while or integrated with many external services and components is risky. So carefully plan for it.

Here are some areas where the environment name is used, which will be affected when you change the environment name. Consider these areas and plan your communication before attempting to rename an environment:

- Web client URL, including links to web client bookmarked by users
- Deep links to specific pages within Business Central created by users or shared by them via e-mails, internal documentation or training portals, Teams channels, Word, and Excel documents. They're often exchanged among users in the same company, across companies, across environments, across tenants. Links created by users as desktop shortcuts. Links sent or created before the name change will no longer work after the name change.
- Integrations that embed the web client, for example, SharePoint apps composed of Business Central pages
- Integrations that launch the web client
- Partner-developed mobile apps, web applications, and so on. These apps likely originate from partners outside the customer's organization where the admin can't update URLS.
- Mobile apps, including Windows 10 store app for desktop/tablet. Affects only users who have modified the protocol handler to force the app to connect to environment with name other than "production". If the user keeps working with "production" on the mobile app (which is default now), and the admin renames the environment from "prod2" to "myprod", the mobile user isn't affected. Otherwise, the app would throw an error, and the user would have to exit using a newly created protocol handler link.
- Browser cache. Business Central stores the URL, including environment name, in some of its cached data. This data is cached browser-side, that is, in the user's browser and across devices. Admins typically don't have access or control this data cache. When users lose their cache, they lose the link modifications to all their pages and preferences.
- Web services URL, potentially affecting external integrations that use OData or SOAP
- Business Central add-ins and integrations with other Microsoft services

    - Outlook Add-in. The Add-In manifest that is saved to Exchange Server, either per-organization or per-user, includes the environment name.
    - Excel Add-in. Each user's Excel worksheet stores the environment name.
    - Power BI. All reports, including the default reports deployed from the Role Center, built before the rename will be affected. Also, Power BI apps installed before the rename would be affected. There's no automatic way to repair these items. The partner or user would have to manually update the connections.
    - Power Apps/Automate. All apps and flows built before rename would be affected with no automatic way to repair. The partner or user would have to manually update the connections.
    - CDS. CDS Virtual Entity setup stores environment name.
- Development scenarios
    - Publish to sandbox environment from Visual Studio Code. The launch.json file of extensions might contain the sandbox name, if different from "default". The files require source code updates.
    - CI/CD pipelines for test and deployment could be impacted by environment renames.
- Azure Application Insights logs and metrics

Log of administrative operations

The **Operations** section of Business Central administration center provides a log of operations that internal administrators and delegated administrators from the partner have made in the Business Central administration center or through the admin center API. Currently, the log includes the following operations: renaming environments restoring environments.

Use this log to see which operations were created and when. You can also access detailed error messages in this log, should any operation fail.

Managing Apps

2/17/2021 • 5 minutes to read • Edit Online

INTRODUCED IN: Business Central 2020 release wave 1

A Business Central environment is built as a collection of apps. These apps include Microsoft apps and third-party apps, for example, apps from AppSource. The apps work together to provide customers with a broad set of features to address their various business, market, and industry needs.

Updates are frequently made available for these apps by Microsoft, partners, and ISVs. App updates add new features and fix known problems. To keep your environment up to date and running smoothly, you should check for and install the latest updates regularly.

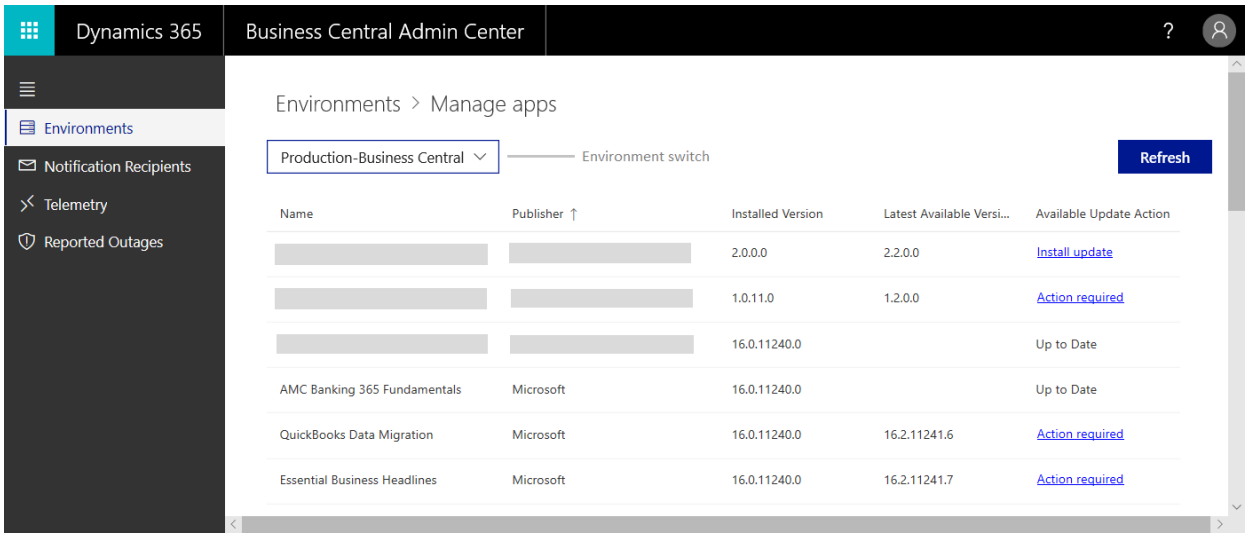
To help you manage app updates, the administration center includes the **Manage Apps** page.

Like other features in the administration center, this functionality can be used by the partner (delegated administrator) or a local customer admin.

> **NOTE**
> In the current version, it's not possible to install new apps, either main apps or their dependencies (library apps), by using the **Manage Apps**. To install the apps, continue using the **Extension Management** page within your Business Central environment.

Get an overview and check for updates

Open the **Manage Apps** page from the environment details page. Choose **Environments** > select the environment > **Manage Apps**.



The **Manage Apps** lists all the apps installed on the environment and indicates whether updates are available. When first opened, the system will start checking for updates. Wait for this operation to complete.

> **IMPORTANT**
> When an ISV provides a new version of their AppSource app, Microsoft validates it against the latest, currently available version of Business Central at the time. If the new app version passes validation, it's made available for the customers' environments that are running on that version of Business Central and greater. So if you're not seeing an AppSource app update in the list, your environment may not yet be running on the version the app was registered for.

When completed, if an update is available for an app, there are two indications:

- The **Latest Available Version** column contains the new version number of the app.
- The **Available Update Action** column contains one of the following actions:

ACTIONS	DESCRIPTIONS
Action required	This action means that you have to do something before you install the update for the app. For example, you may have to first update another app or install a new app. Select the link and read the **Requirements for App Updates** pane to see what is required. For more information, see Resolving requirements for app updates.
Install update	This action means that the app is ready to install. Select the link to start the installation.

Install an app update - the flow

We recommend you always install and test an app update on a Sandbox environment first. Make sure the app update won't disrupt the operational flow or cause problems for the users.

The following steps provide the general flow for updating an app.

1. If you don't have a sandbox environment, create one. For more information, see Create a new sandbox environment.
2. Open the Sandbox environment and select **Manage Apps**.
3. On the **Manage Apps**, find the app in the list that you want to update.
4. If the **Available Update Action** column for the app shows the **Action required** link, resolve the update requirements.

   See Resolving requirements for app updates.
5. When the **Available Update Action** column for the app shows **Install update**, select this action to install the new version of the app.

   > **IMPORTANT**
   > The update will be applied immediately after you accept the confirmation dialogue. The users can continue working during update installation, but depending on the app changes coming with the update, they may receive a message asking them to log out and login again. It is therefore recommended that you apply the updates outside of working hours.
6. Wait for the app to be installed.

   Select **Refresh** occasionally to check the status.

- If the app installs successfully, the new version displays in the **Installed version** column and the **Available Update Action** column is **Up to date**.
- If the installation fails the **Available Update Action** column changes to **Update failed**. See What to do when an update fails.

7. If the app update succeeded, sign in the Sandbox environment and test the new app version.
8. If the app update works as expected on the Sandbox, switch to the production environment, and repeat the installation steps for the app update.

> **TIP**
> Use the environment switch box at the top of the page to quickly change to your production environment.

Resolve requirements for app updates

For apps that have dependencies on other apps, you may have to update or install the dependency apps. The **Requirements for App Updates** page provide this information. The requirements are divided into two categories: **Update requirements** and **Install requirements**.

After you resolve all requirements, the app that you want to update will be ready to install.

Update requirements

The **Update requirements** category lists existing dependency apps the have updates to be installed. To resolve these requirements, do the following steps for each app:

1. Return to the **Manage Apps** page.
2. Find the app in the list and select **Install update**.
3. Wait for **Available update action** column to change to **Up to date**.

Install requirements

The **Install requirements** category lists dependency apps that haven't been installed yet. For example, a new app was introduced that app update depends on.

You can't, however, install a new app from the **Manage App** page. Use the **Extension Management** page in the client instead. Completing this step will resolve the requirement. For more information, see Installing an Extension.

What happens when an app update is installed?

The new app version is starting to install immediately, following the confirmation dialogue. The new app version will be published, synchronized, and updated in the background. This process usually doesn't take long, and users won't be interrupted. However, we still recommend you to install the updates outside of working hours.

What do I do when an update fails?

When the installation of an app update fails, the **Available Update Action** column will display the **Update failed** action. Select this action to get more information. The **App Update Details** pane provides some details about update and what might have caused the failure.

Sometimes the update could fail because of a transient problem. Select **Retry** to try to install the update again. If the installation continues to fail, contact your ISV. You can find the support details of each ISV on their app page on AppSource. Contact Microsoft support if the app publisher is **Microsoft**.

TIP

When reporting issues to Microsoft Support, always provide the **Operation ID** displayed in the error message. This will help expedite the investigations.

Managing Capacity

2/17/2021 • 4 minutes to read • Edit Online

To help customers manage and plan their storage costs on an ongoing basis, the Business Central administration center includes the **Capacity** page. The **Capacity** page provides an overview of the total database and file storage usage, with details about the storage used by every environment. The page also displays the currently used and the maximum allowed number of production and sandbox environments available for the customer.

Customers can purchase additional database capacity and environments via their reselling partner by using the following add-ons:

- Dynamics 365 Business Central Database Capacity
- Dynamics 365 Business Central Additional Environment Add-on

Number of environments

Business Central administrators can create multiple sandbox and production type environments for various purposes, like:

- Creating more business branches
- Moving into more countries
- Expanding within their current country
- Development
- Testing changes
- Learning new product capabilities

Every Business Central customer with Business Central Premium or Essential subscriptions can use one production environment and three sandbox environments, at no extra charge.

> **NOTE**
> Existing customers with Business Central Premium or Essentials subscriptions purchased before October 1st 2020 will keep their existing environment entitlements for a period of 1 year until October 1st 2021 or until their subscription is renewed or ended, whichever occurs last. This won't increase their overall database storage capacity and won't enable extra sandbox environments. These benefits are only activated with the production environments purchased by the customers separately.

Customers can also choose to purchase any number of additional production environments via their CSP partner. Each production environment comes with three additional sandbox environments.

Production and sandbox environments can be created and used in any country where Business Central service is available, also in the country where the default Business Central environments are located. Additional environments can be created by customers, administrators, and partners by using the Business Central administration center.

When customer administrators create users in Microsoft 365 Admin Center and assign them Business Central licenses, each user, by default, gets access to all Business Central environments (sandbox and production) under the same single Business Central license, still acting within the scope of their license within each of these environments. Administrators can limit users' access to any particular environment by changing their permissions, or by removing users' access within that environment.

Storage

Storage capacity usage of Business Central is represented by **Database** and **File** on the **Capacity** page.

Business Central customers can use up to 80 GB of database storage capacity across all of their environments (production and sandbox), meaning that the sum of database capacity usage of all of their environments must not exceed 80 GB.

Some businesses have unique scenarios that may require additional storage. For those organizations that need more space, there is an option to purchase extra database capacity as an add-on to their existing Business Central subscriptions through their reselling CSP partner. Every add-on increases overall database capacity quota by 1 GB.

Every additional production environment purchased by the customer also increases tenant-wide database capacity quota by 4 GB.

> **TIP**
> Use the **Capacity** page to help manage the migration when you migrate to Business Central online. That way, you know if your migration will bring you close to or over the current limits on database size, for example.

Storage usage by environment

The **Storage usage by environment** section of the **Capacity** page provides a tenant-level view of where your organization is using storage capacity. Here you can see how much database and file storage is used by each environment. For each of your environments, you can also navigate to the Table Information page within Business Central, which let's you see the distribution of data size across tables.

> **NOTE**
> Only the environments running on version 17 (2020 release wave 2) and later are included in the database capacity calculations.

The **File usage** storage is calculated based on the size of the content of the following tables:

- Tenant Media
- Tenant Media Thumbnails

The content of the other tables is counted towards the **Database usage** storage.

> **IMPORTANT**
> When you uninstall extensions, you have a choice of deleting or leaving the extension data in the database. If you decide not to delete the data when uninstalling extensions, this data will be counted in the overall database storage you use.

Exceeding capacity quotas

Exceeding the paid database storage limit won't interrupt transaction processing within the existing environments. The existing environments that organically grow and eventually exceed the quota will still be accessible and available for the customers to continue their business operations.

However, once the capacity limits are exceeded, the customers won't be able to create new environments or copy their existing environments until the storage used by the existing environments is decreased to fit the quota or additional capacity is purchased.

Administrative actions are currently not limited by the File storage, however similar restrictions will be applied

to the File storage with one of the next releases of Business Central.

Reducing Data Stored in Databases

There are a few things that you can do to reduce the amount of data stored in a database to keep it under its current limit. For more information, see Reducing Data Stored in Databases.

Managing Tenant-Specific Notifications

2/17/2021 • 2 minutes to read • Edit Online

Notifications are sent by email for administrative events that occur on the tenant. For example, notifications are sent when a major update is available for tenant environments, when an environment update has succeeded or failed, or when extensions require changes to be compatible with an upcoming release. When these and other similar events occur on the tenant, an email is sent to the notification recipients for the tenant.

Notification recipients

Notifications are sent to all email addresses that are listed in the **Notification recipients** list of the Business Central administration center. The list is managed manually by adding and removing recipients to ensure the right individuals are notified of the event.

> **NOTE**
>
> It is important that *at least* one administrator's email address has been entered as a notification recipient to ensure proper awareness of events requiring administrative attention.

> **IMPORTANT**
>
> To not miss update notifications from Microsoft, you must verify that the e-mails are not redirected to a spam folder by your e-mail software. The notifications are sent from the Microsoft Partner Center address, `msftpc@microsoft.com` and contain `Dynamics 365 Business Central` in the subject line.

Cleaning up settings

If you end the relationship with a customer where you have set up your email address as a notification recipient, you must remove the email address while you still have access to that customer's Business Central administration center.

Managing Updates in the Business Central Admin Center

2/17/2021 • 3 minutes to read • Edit Online

Business Central environments are updated according to the Business Central roadmap with two major updates in April and October each year, and monthly service updates. For more information, see Dynamics 365 Release Plans.

Updates of the base application and platform are managed by Microsoft. As an internal administrator or as a partner, you can use the Business Central administration center to specify certain parameters of the timing of updates for each environment, and you can specify the people who must receive notifications of when an update is available. You can also help prepare your solution and your users by creating preview environments so that you can get acquainted with new functionality in the product. For more information, see Major Updates of Business Central Online.

Set the update window for each environment

The update window for an environment defines a window of time during the day in which the environment can be updated. When an update is rolling out to Business Central online, regardless of whether it's the monthly service update or a major update, the update will be applied to an environment within the time frame that the update window defines. This helps to ensure that updates are applied outside of the normal business hours of the organization, for example.

The update window must be a minimum of six hours.

> **NOTE**
> Desktop users who are signed in during the update will receive an alert in Business Central.

To set the update window for an environment:

1. On the **Environments** tab of the Business Central administration center, choose the **Name** of the relevant environment to open the environment details.
2. Choose the **Set update window** action on the **Update** list on the action ribbon.
3. In the **Set update window** pane, specify the start time and the end time for the update window for the environment.

   > **NOTE**
   > The update window must be a minimum of six hours.

4. Choose **Save**.

Schedule an update date

Specifically for major updates, you can choose a specific date on which the environment is updated. The **Update version** field in the **Version Management** section of the environment details also displays the version number of the available update version.

To schedule an update date:

1. On the **Environments** tab of the Business Central administration center, choose the **Name** of the relevant environment to open the environment details.
2. Choose the **Schedule Update** action on the **Update** list on the action ribbon.
3. In the **Schedule Environment Update** pane, specify the update date.

   > **NOTE**
   > The specified date must be within a given date range that is shown in the pane.

4. Choose **Schedule Update**.

If an administrator has chosen the **Schedule Update** action but not set a date, then the update is applied automatically to each tenant environment with a default date range. The default date range is communicated in advance to tenant administrators through administrative notifications. You can then choose to override that with a custom date by following the steps that are provided above. Not selecting an update date does not prevent the environment from being updated.

Get notified of updates

For updates for which the option is available for tenant administrators to schedule the update date, a notification is sent to the notification recipients listed on the **Notification recipients** tab of the Business Central administration center. For more information, see Managing Tenant Notifications.

> **IMPORTANT**
> To not miss update notifications from Microsoft, you must add notification recipients and verify that the e-mails are not redirected to a spam folder by your e-mail software. The notifications are sent from the Microsoft Partner Center address, `msftpc@microsoft.com` and contain `Dynamics 365 Business Central` in the subject line.

Scheduling environment updates is *not* available for monthly service updates. For these, the update is applied to tenant environments as it becomes available. No notifications are sent to tenant administrators prior to the update. Notifications are sent only after the update is applied.

Exporting Databases

2/17/2021 • 5 minutes to read • Edit Online

APPLIES TO: Business Central 2019 release wave 2 and later

From the Business Central administration center, you can export the database for Business Central online environments as BACPAC files to an Azure storage container.

Considerations before you begin

- You can only request a database export for production environments. If you want to export data from a sandbox environment, you can use Excel or RapidStart.
- You must have explicit permission to export databases. For more information, see the Users who can export databases section.
- You can't export your database to an Azure premium storage account. The steps in this article are only supported on Azure standard storage accounts.

Setting up Azure storage

Before you can export the file, you must first set up the Azure storage account container that the BACPAC file will be exported to.

Creating the storage account

The first step is to create an Azure standard storage account, if you don't already have one. To set up the export, you must first have a subscription to Microsoft Azure and access to the Azure portal.

For more information setting up an Azure storage account, see Create a storage account.

Generating a shared access signature (SAS)

The next step is to generate a shared access signature (SAS) that provides secure delegated access to your storage account. Business Central uses the signature to write the BACPAC file to your storage account.

To generate a shared access signature (SAS)

1. On the Azure storage account, choose **Shared access signature** in the navigation pane.
2. In the **Allowed services** section of the shared access signature pane, select **Blob**, and clear the other options.
3. In the **Allowed resource types** section, select **Container** and **Object**, and clear the other options.
4. In the **Allowed permissions** section, mark **Read**, **Write**, **Delete**, and **Create**, and clear the other options.
5. Select a start and end date and time for the SAS. A minimum expiration window of 24 hours from the initiation of the export is required.

> **TIP**
> It is a best practice to use near-term expiration for the account's SAS. To reduce risk of a compromised storage account, set the end date and time no later than what is needed for you to complete the database export operation. However, the SAS must be valid for a minimum of 24 hours.

6. In the **Allowed protocols** section, select **HTTPS only**.
7. Select **Generate SAS and connection string**.
8. Copy the **Blob service SAS URL**.

For more information on generating and using a SAS, see Grant limited access to Azure Storage resources using shared access signatures (SAS).

Creating the database export

When you've created the Azure storage account and generated the SAS URI, you can then create the export file from the Business Central administration center.

1. On the Environments list page, choose the relevant production environment to view the environment details.
2. On the action ribbon of the environment details, choose **Database**, and then choose **Create Database Export**.
3. In the **File Name** field, specify a name for the export file, or leave the default value.
4. In the **SAS URI** field, specify the **Blob service SAS URL** value that you copied in the previous section.
5. In the **Container Name** field, enter the name of the container in the Azure storage account to which you want the BACPAC file exported. If you've already created a container in your Azure storage account, you can enter the name of that container here. Otherwise, if the name that is specified in the **Container Name** field doesn't already exist in the Azure storage account, it will be created for you.

Once the export operation begins, the BACPAC file is generated and exported to the indicated Azure storage account. The operation may take several minutes to several hours depending on the size of the database. You can close the browser window with the Business Central administration center during the export. When the export completes, you can access the export file in the defined container in your Azure storage account. Optionally, you can import the data into a new database in Azure SQL Database or SQL Server for further processing. For more information, see Quickstart: Import a BACPAC file to a database in Azure SQL Database.

> **NOTE**
> There is a limit to the number of times you can export the database for each environment in any given month. The **Create Database Export** pane includes information about the number of exports still remaining that month.

Viewing the export history

All database export activity is logged for auditing purposes. To view the history, choose **Database**, then choose **View Export History** on the environment details page of the environment.

Users who can export databases

Permission to export databases is limited to specific types of users: internal and delegated administrators. The following users are allowed to export databases.

- Delegated administrators from reselling partners
- Administrators from the organization that subscribes to Business Central online

Also, these users must have the **D365 BACKUP/RESTORE** permission set assigned to their user account in the environment they're trying to export.

For more information about permissions sets and user groups, see Assign Permissions to Users and Groups.

Using the exported data

The BACPAC file contains data that is customer-specific business data. Technically, Business Central online is a multitenant deployment, which means that each customer tenant has their own business database while the data that defines the application is in a shared application database.

This means that if you want to export the data in order to change the customer's Business Central from an online deployment to an on-premises deployment, you must also get the application data from the installation media from the same version of Business Central that the online tenant is using. You can see the version number in the Business Central administration center or the **Help and Support** page in the customer's Business Central.

> **IMPORTANT**
> While you can import the downloaded BACPAC file into your own SQL Server instance, Microsoft does not provide support for creating a working on-premises environment from the BACPAC that you download from Business Central online.

For more information, see Quickstart: Import a BACPAC file to a database in Azure SQL Database, Migrating to Single-Tenancy From Multitenancy, and When to choose on-premises deployment.

Environment Telemetry in the Business Central administration center

2/17/2021 • 3 minutes to read • Edit Online

The Business Central administration center provides telemetry for the tenant environments to enable troubleshooting and support for the tenant. The Telemetry tab provides telemetry of top-level AL events, and any errors resulting from calls through the telemetry stack.

To filter the telemetry for an environment:

1. Select a base point-in-time for the timestamp of the telemetry messages.
2. Enter a number of minutes before or after the base point-in-time to set a range of time for the timestamp. A negative number indicates a number of minutes before the base point-in-time, and a positive number indicates a number of minutes following the base point-in-time. For example, a value of *-15* filters messages to a timestamp range of up to 15 minutes before the base point-in-time.
3. Choose the message type.
4. Choose the environment.
5. Select **Filter**.

> **TIP**
> If your users complain of a confusing error message such as *Sorry, we just updated this page. Please close and reopen.*, then you can often find the underlying problem by analyzing telemetry in the Business Central administration center. For example, in the case of the *Sorry, we just updated this page. Please close and reopen.* message, the underlying problem is often that two users are trying to modify the same data. So if both users open the same sales order, and both change a field, then one of them will see the *Sorry, we just updated this page. Please close and reopen.* message, because Business Central saves changes as soon as you move to the next field or close the page.

Sending telemetry to Microsoft Azure Application Insights

APPLIES TO: Business Central 2019 release wave 2 and later

You can set up your environments to send telemetry to Application Insights. Application Insights is a service hosted within Azure that gathers telemetry data for analysis and presentation. For more information, see What is Application Insights?.

For an overview of the telemetry types that are currently emitted, see Monitoring and Analyzing with Telemetry.

> **IMPORTANT**
> Currently, emitting data to Azure Application Insights resources in Germany regions, like **(Europe) Germany West Central** or **(Europe) Germany North** , doesn't work. Until this issue is fixed, the mitigation is to create an Azure Application Insights resource in a region outside of Germany. Then, when the issue has been fixed, move the resource to the preferred region.

Enable Application Insights

1. If you don't already have one, get a subscription to Microsoft Azure.
2. Create an Application Insights resource in Azure.

The Application Insights resource will be assigned an instrumentation key. Copy this key because you'll need it to enable Application Insights in the Business Central administration center.

The Application Insights resource can be in any Azure tenant that is accessible to your organization. For example, a delegated administrator from the reselling partner is the person analyzing the telemetry. But this person might not have access rights the customer's Azure instance. This scenario enables the partner to send the telemetry to their own Application Insights instance.

> **TIP**
> You can use the same Application Insights resource for multiple tenants and their different environments.

For more information, see Create an Application Insights resource.

3. In the Business Central administration center, select **Environments**, and then select the environment that you want to change.

> **IMPORTANT**
> The next steps require a restart to the environment, which is triggered automatically after step 5. Plan to do this during non-working hours to avoid disruptions.

4. On the **Environment** page, the **Application Insights Key** field shows if the environment already uses application insights.

   To enable application insights, choose the **Define** caption, and then, in the **Set Application Insights Key** pane, choose the **Enable application insights** field and enter the instrumentation key in the **Instrumentation Key** field.

> **NOTE**
> In version 15 and 16, to enable application insights, choose the **Application Insights Key** action, and then specify the instrumentation key.

5. Choose the **Save** button.

Cleaning up settings

If the Application Insights resource is tied to your partner account, and you end the relationship with a customer where you have set up telemetry based on your account's instrumentation key, you must remove the instrumentation key while you still have access to that customer's Business Central administration center.

The Business Central Administration Center API

2/17/2021 • 33 minutes to read • Edit Online

The Business Central administration center API enables administrators to programmatically do administrative tasks for a Business Central tenant. With the API, administrators can, for example:

- Query and work with production and sandbox environments for the tenant.
- Set up administrative notifications.
- View telemetry for events on the tenant.

For more information about administrative capabilities, see The Business Central Administration Center. This article describes the API contracts for these administrative capabilities.

> **IMPORTANT**
>
> For delegated admin access, you must add the Azure Active Directory (Azure AD) application to the **AdminAgents** group. If the Azure AD application is not added, the consent flow will show an error such as *Need pre-consent*. For more information, see Pre-consent your app for all your customers in the Graph documentation.

Location

The Business Central administration center API is located at the following URL: https://api.businesscentral.dynamics.com.

Setting up Azure Active Directory (Azure AD) based authentication

Sign in to the Azure portal to register your client application as an app and enable it to call the Business Central administration center API.

1. Follow the instructions in the Integrating applications with Azure Active Directory article. The next steps elaborate on some of the specific settings you must enable.
2. Give the application a **Name**, such as **Business Central Web Service Client**.
3. For **Application type**, choose either **Native** or **Web app/API** depending on your scenario. The code examples below assume **Native**.
4. Choose a **Redirect URI**. If it's a **Native** app, you can choose for example: **BusinessCentralWebServiceClient://auth**. If it's a **Web app/API** app, set the value to the actual URL of the web application.
5. During the registration of the app, make sure to go to **Settings**, and then under **API ACCESS**, choose **Required permissions**. Choose **Add**, and then under **Add API Access**, choose **Select an API** and search for the **Dynamics 365** option. Choose **Dynamics 365**, select **Delegated permissions**, and then choose the **Done** button.

   > **NOTE**
   >
   > If **Dynamics 365** doesn't show up in search, it's because the tenant doesn't have any knowledge of Dynamics 365. To make it visible, an easy way is to register for a free trial for Dynamics 365 Business Central with a user from the directory.

6. Make a note of both the **Application ID** and the **Redirect URI**. They'll be needed later.

Getting an access token

HTTP requests sent to the Business Central administration center API must include the Authorization HTTP header, and the value must be an access token.

The following examples show how to obtain such a token using PowerShell. Using C# is straightforward.

PowerShell example without prompt:

```
   $cred = [Microsoft.IdentityModel.Clients.ActiveDirectory.UserPasswordCredential]::new($UserName,
$Password)
   $ctx =
[Microsoft.IdentityModel.Clients.ActiveDirectory.AuthenticationContext]::new("https://login.windows.net/$Ten
antName")
   $token =
[Microsoft.IdentityModel.Clients.ActiveDirectory.AuthenticationContextIntegratedAuthExtensions]::AcquireToke
nAsync($ctx, "https://api.businesscentral.dynamics.com", <Application ID>,
$cred).GetAwaiter().GetResult().AccessToken
```

PowerShell example with prompt:

```
   $ctx =
[Microsoft.IdentityModel.Clients.ActiveDirectory.AuthenticationContext]::new("https://login.windows.net/$ten
antName")
   $redirectUri = New-Object -TypeName System.Uri -ArgumentList <Redirect URL>
   $platformParameters = New-Object -TypeName
Microsoft.IdentityModel.Clients.ActiveDirectory.PlatformParameters -ArgumentList
([Microsoft.IdentityModel.Clients.ActiveDirectory.PromptBehavior]::Always)
   $token = $ctx.AcquireTokenAsync("https://api.businesscentral.dynamics.com", <Application ID>,
$redirectUri, $platformParameters).GetAwaiter().GetResult().AccessToken
```

Error Format

If an error occurs during the execution of an API method, it will respond back with an error object. While the specifics of any error will vary from endpoint to endpoint and by the error, the error object returned should adhere to the following structure. When an error occurs that doesn't fit this structure, it typically indicates that an error occurred in sending the request or during authentication of the request. For example, it could be that the API hasn't yet received the request.

Error Response Object:

```
{
"code": string, // A stable error code describing the type an nature of the error. Ex: EnvironmentNotFound
"message": string, // A message with a readable description of the error and cause. Intended to assist with
debugging or troubleshooting the API, it's not intended to be displayed.
("target": string), // Optional - Provides information about what part of a request caused the error. Ex:
The name of a property on the request body.
("extensionData": {...}), // Optional - A key/value dictionary object containing additional information
about the error.
("clientError": [ // Optional - A nested list of error objects containing more details about the error
encountered. For instance, this may be used if multiple errors are encountered to list them all out.
  {
    "code": string,
    "message": string,
    "target": string,
    "extensionData": {...},
    "clientError": [...]
  })
]
}
```

General unhandled errors

All unknown and unhandled errors that aren't covered by the lists above will use the error code: **Unknown**

Environments

Environments are the instances of the application that have been set up for the tenant. An instance can be of either a production type or a sandbox type. The environment APIs can be used to:

- Get information about the environments currently set up for the tenant
- Get information about the used storage and allowed quotas
- Create a new environment using sample data or as a sandbox copy of the production environment
- Delete an environment.

> **NOTE**
> Special care should be taken when deleting a production environment as the data will not be recoverable

Get environments and Get environments by application family

Returns a list of all the environments for the tenant.

```
GET /admin/v2.3/applications/environments
```

Returns a list of the environments for the specified application family.

```
GET /admin/v2.3/applications/{applicationFamily}/environments
```

Route Parameters

`applicationFamily` - Family of the environment's application as is. (for example, "BusinessCentral)

Response

Returns a wrapped array of environments.

```
{
  "value":
  [
    {
      "friendlyName": string, // Display name of the environment
      "type": string, // Environment type (for example, "Sandbox", "Production")
      "name": string, // Environment name, unique within an application family
      "countryCode": string, // Country/Region that the environment is deployed in
      "applicationFamily": string, // Family of the environment (for example, "BusinessCentral")
      "aadTenantId": Guid, // Id of the Azure Active Directory tenant that owns the environment
      "applicationVersion": string, // The version of the environment's application
      "status": string, // (enum | "NotReady", "Removing", "Preparing", "Active")
      "webClientLoginUrl": string, // Url to use to log into the environment,
      "webServiceUrl": string, // Url to use to access the environment's service API
      "locationName": string, // The Azure location where the environment's data is stored
      "platformVersion": string, // The version of the environment's Business Central platform
      "ringName": string, // Name of the environment's logical ring group (such as  Prod, Preview)
      "appInsightsKey": string // The environment's key for Azure Application Insights
    }
  ]
}
```

Expected Error Codes

`applicationTypeDoesNotExist` - the provided value for the application family wasn't found

Get environment by application family and name

Returns the properties for the provided environment name if it exists.

```
GET /admin/v2.3/applications/{applicationFamily}/environments/{environmentName}
```

Route Parameters

`applicationFamily` - Family of the environment's application as is. (for example, "BusinessCentral")

`environmentName` - Name of the targeted environment

Response

Returns a single environment if exists.

```
{
  "friendlyName": string, // Display name of the environment
  "type": string, // Environment type (for example, "Sandbox", "Production")
  "name": string, // Environment name, unique within an application family
  "countryCode": string, // Country/Region that the environment is deployed in
  "applicationFamily": string, // Family of the environment (for example, "BusinessCentral")
  "aadTenantId": Guid, // Id of the Azure Active Directory tenant that owns the environment
  "applicationVersion": string, // The version of the environment's application
  "status": string, // (enum | "NotReady", "Removing", "Preparing", "Active")
  "webClientLoginUrl": string, // Url to use to log into the environment,
  "webServiceUrl": string, // Url to use to access the environment's service API
  "locationName": string, // The Azure location where the environment's data is stored
  "platformVersion": string, // The version of the environment's Business Central platform
  "ringName": string, // Name of the environment's logical ring group (such as  Prod, Preview)
  "appInsightsKey": string // The environment's key for Azure Application Insights
}
```

Expected Error Codes

`environmentNotFound` - the targeted environment couldn't be found

- `target: {applicationFamily}/{environmentName}`

Create new environment

Creates a new environment with sample data.

```
Content-Type: application/json
PUT /admin/v2.3/applications/{applicationFamily}/environments/{environmentName}
```

Route Parameters

`applicationFamily` - Family to create the new environment within. (for example, "BusinessCentral")

`environmentName` - The name of the new environment. See the section below about valid environment names to see what values are allowed.

Body

```
{
  "environmentType": string, // The type of environment to create (enum | "Production", "Sandbox")
  "countryCode": string, // The country to create the environment within
  ("ringName": string), // Optional - The logical ring group to create the environment within. Currently
only Sandbox type environments may be created in a 'Preview' ring. If not provided then the production ring
will be used.
  ("applicationVersion": Version), // Optional - The version of the application the environment should be
created on. If not provided then the latest available version will be used.
}
```

> **NOTE**
>
> The values for the `countryCode`, `ringName`, and `applicationVersion` properties should be derived from the API endpoints described in the Available Applications section below.

Response

Returns newly created environment.

```
{
  "friendlyName": string, // Display name of the environment
  "type": string, // Environment type (for example, "Sandbox", "Production")
  "name": string, // Environment name, unique within an application family
  "countryCode": string, // Country/Region that the environment is deployed in
  "applicationFamily": string, // Family of the environment (for example, "BusinessCentral")
  "aadTenantId": Guid, // Id of the Azure Active Directory tenant that owns the environment
  "applicationVersion": string, // The version of the environment's application
  "status": string, // (enum | "NotReady", "Removing", "Preparing", "Active")
  "webClientLoginUrl": string, // Url to use to log into the environment,
  "webServiceUrl": string, // Url to use to access the environment's service API
  "locationName": string, // The Azure location where the environment's data is stored
  "platformVersion": string, // The version of the environment's Business Central platform
  "ringName": string, // Name of the environment's logical ring group (such as  Prod, Preview)
  "appInsightsKey": string // The environment's key for Azure Application Insights
}
```

Expected Error Codes

`DoesNotExist` - the provided value for the application family wasn't found

`destinationApplicationServiceNotFound` -- a suitable destination service couldn't be found to put the environment. Occurs if missing or if the tenant doesn't have access to the target application.

`invalidInput` - the targeted property in invalid in some way

- target: {countryCode} - the country code property can't be null or whitespace
- target: {environmentName} - the environment name property can't be null or whitespace

- target: {environmentType} - the environment type property can't be null or whitespace, and must be a valid value (Production or Sandbox)
- target: {ringName} - attempt to create a production environment on a non-production ring
- target: {applicationVersion} - the version property must be a valid version string (major.minor.build.revision)

`requestBodyRequired` - the request body must be provided

`resourceDoesNotExist` - the targeted property doesn't exist

- target: {ringName} - a ring with the provided name wasn't found

`resourceExists` an environment with the same name already exists

`environmentNameNotValid` - the environment name can't be a reserved value, must be less than 30 characters, must start with an alpha character and consist only of alpha, numberical, underscore (_), or dash (-) characters

`cannotCreateNamedEnvironment` - environments with names other than 'Production' or 'Sandbox' aren't supported on the targeted version.

`tenantAlreadyProvisioning` - can't create a new environment because another environment is currently in the process of being created.

`applicationFamilyNotAccessible` - the calling tenant doesn't have access to the targeted application family and country code

`environmentReservationFailed` -- another environment within the same application family already has this name

`maximumNumberOfEnvironmentsAllowedReached` - the limit on the number of allowed environments of the provided type has been reached

`maximumStorageCapacityUsageReached` - the limit of the storage capacity usage has been reached

Copy environment

Creates a new environment with a copy of another environment's data.

```
Content-Type: application/json
POST /admin/v2.3/applications/{applicationFamily}/environments/{sourceEnvironmentName}
```

Route Parameters

`applicationFamily` - Family of the source environment's application. (for example, "BusinessCentral")

`sourceEnvironmentName` - Name of the environment to copy from.

Body

```
{
  "environmentName": string, // The name of the new environment.
  "type": string // The type of environment to create. Currently only the value "Sandbox" is supported.
}
```

Response

Returns newly copied environment.

```
{
  "friendlyName": string, // Display name of the environment
  "type": string, // Environment type (for example, "Sandbox", "Production")
  "name": string, // Environment name, unique within an application family
  "countryCode": string, // Country/Region that the environment is deployed in
  "applicationFamily": string, // Family of the environment (for example, "BusinessCentral")
  "aadTenantId": Guid, // Id of the Azure Active Directory tenant that owns the environment
  "applicationVersion": string, // The version of the environment's application
  "status": string, // (enum | "NotReady", "Removing", "Preparing", "Active")
  "webClientLoginUrl": string, // Url to use to log into the environment,
  "webServiceUrl": string, // Url to use to access the environment's service API
  "locationName": string, // The Azure location where the environment's data is stored
  "platformVersion": string, // The version of the environment's Business Central platform
  "ringName": string, // Name of the environment's logical ring group (such as  Prod, Preview)
  "appInsightsKey": string // The environment's key for Azure Application Insights
}
```

Expected Error Codes

`applicationTypeDoesNotExist` - the provided value for the application family wasn't found

`destinationApplicationServiceNotFound` -- a suitable destination service couldn't be found to put the environment. Occurs if missing or if tenant doesn't have access rights to the target application.

`environmentNotFound` - the targeted environment couldn't be found

- target: {applicationFamily}/{sourceEnvironmentName}```

`invalidInput` - the targeted property in invalid in some way

- target: {environmentName} - the environment name property can't be null or whitespace```
- target: {type} - the type property can't be null or whitespace, and must be a valid value (Currently only Sandbox)```

`requestBodyRequired` - the request body must be provided

`resourceExists` an environment with the same name already exists

`environmentNameNotValid` - the environment name can't be a reserved value, must be fewer than 30 characters, must start with an alpha character and consist only of alpha, numerical, underscore (_), or dash (-) characters

`cannotCreateNamedEnvironment` - environments with names other than 'Production' or 'Sandbox' aren't supported on the targeted version.

`tenantAlreadyProvisioning` - can't create a copy of an environment because another environment is currently in the process of being created.

`conflictingDeveloperExtensions` - The source environment contains 'uploaded' extensions that are already published to the destination service as 'developer' extensions. This condition will cause conflicts.

```
extensionData:
{
    "conflictingExtensions": [{
        "appId": guid, // The id of the conflicting extension
        "name": string, // The name of the conflicting extension
        "publisher": string, // The name of the person or group who published the conflicting extension
        "version": string, // The version of the conflicting extension
        "developerEnvironmentName": string // The name of the environment if the conflicting extension
exists in another environment owned by the tenant requesting the copy operation
    }],
    "sameAadTenant": bool, // Indicates if the conflicts occur on an environment that is owned by the same
tenant that is requesting the copy operation
}
```

`environmentReservationFailed` -- another environment within the same application family already has the same name

`maximumNumberOfEnvironmentsAllowedReached` - the limit on the number of allowed environments of the provided type has been reached

`maximumStorageCapacityUsageReached` - the limit of the storage capacity usage has been reached

Delete environment

Deletes the specified environment. Warning: A production environment shouldn't be deleted.

```
DELETE /admin/v2.3/applications/{applicationFamily}/environments/{environmentName}
```

Route Parameters

`applicationFamily` - Family of the environment's application. (for example "BusinessCentral")

`environmentName` - Name of the environment to delete.

> **NOTE**
> The Create, Copy, and Delete operations are asynchronous. The response objects are returned before the underlying operation has completed. The final results of the operation are reflected in the 'status' field of the environment that the operations affect. In practice this means that polling of the 'Get Environments' endpoints must be done to determine if the given operation was successful.

Expected Error Codes

`invalidStatusCannotDeleteTenant` - can't delete the environment in its current state

`tenantDeletionInProgress` - environment is already in the process of being deleted

`ambiguousRequest` - multiple environments with the same name were found

`environmentNotFound` - the targeted environment couldn't be found

- target: {applicationFamily}/{environmentName}

Get used storage of an environment by application family and name

Returns used storage properties for the provided environment name if it exists.

```
GET /admin/v2.3/applications/{applicationFamily}/environments/{environmentName}/usedstorage
```

Route Parameters

`applicationFamily` - Family of the environment's application as is. (for example, "BusinessCentral")

`environmentName` - Name of the targeted environment

Response

Returns used storage information of a single environment if exists.

```
{
  "environmentType": string, // Environment type (for example, "Sandbox", "Production")
  "environmentName": string, // Environment name, unique within an application family
  "applicationFamily": string, // Family of the environment (for example, "BusinessCentral")
  "fileStorageInKilobytes": int, // Used file storage in kilobytes
  "databaseStorageInKilobytes": int // Used database storage in kilobytes
}
```

> **NOTE**
>
> If an error occurs when calculating file storage or database storage the corresponding property will be -1.

Expected Error Codes

`environmentNotFound` - the targeted environment couldn't be found

- `target: {applicationFamily}/{environmentName}`

Get used storage for all environments

Returns a list of used storage objects for all the environments.

```
GET /admin/v2.3/environments/usedstorage
```

Response

Returns a wrapped array of used storage objects.

```
{
  "value":
  [
    {
       "environmentType": string, // Environment type (for example, "Sandbox", "Production")
       "environmentName": string, // Environment name, unique within an application family
       "applicationFamily": string, // Family of the environment (for example, "BusinessCentral")
       "fileStorageInKilobytes": int, // Used file storage in kilobytes
       "databaseStorageInKilobytes": int // Used database storage in kilobytes
    }
  ]
}
```

Get allowed quotas

Returns different types of quotas and their limits.

```
GET /admin/v2.3/environments/quotas
```

Response

Returns quotas object.

```
{
  "productionEnvironmentsCount": int, // Maximum allowed number of production environments
  "sandboxEnvironmentsCount": string, // Maximum allowed number of sandbox environments
  "fileStorageInKilobytes": int, // Maximum allowed file storage in kilobytes
  "databaseStorageInKilobytes": int // Maximum allowed database storage in kilobytes
}
```

Available Applications

Get information about the currently available application families, countries, rings, and versions that environments can be created on. The API endpoints here should be utilized to determine what values can be used for environment creation or copying

Applications and corresponding Countries with Rings

Get a list of the currently available application families, the available countries within those families, and the available rings within the countries.

```
GET /admin/v2.3/applications/
```

Response

```
{
  "value": [
    {
      "applicationFamily": string, // The name of the family for a given Business Central offered
application. (Typically this will just be "BusinessCentral")
      "countriesringDetails": {
          "countryCode": string, // Code for a country that the application family supports creating
environments within.
          "rings": [{ // A list of logical ring groupings where environments can be created
            "name": string, // The API name of the ring (for example, PROD, PREVIEW)
            "productionRing": bool, // Indicates that the ring is a production ring. Currently there should
only be one production ring within a country.
            "friendlyName": string, // The display friendly name of the ring
          }]
      }
    }
  ]
}
```

Ring details with Versions

Gets a list of the currently available Versions that an environment can be created on within a logical ring group.

```
GET /admin/v2.3/applications/{applicationFamily}/Countries/{countryCode}/Rings/{ringName}
```

Route Parameters

`applicationFamily` - Family of the ring's application. (for example, "BusinessCentral")

`countryCode` - Code for the ring's country.

`ringName` - Name of the ring to inspect.

Response

```
{
  "value": [ // A list of the available application versions within the ring that environments can be
created on
    "<version string>",
    "<version string>",
    ...
  ]
}
```

Environment Settings

Allows you to manage environment specific settings such as the environment's AppInsights key or the update window. That is, the timeframe is considered 'ok' for updates (and thus downtime) to occur.

Get Update Settings

Returns the update settings for the environment.

```
GET /admin/v2.3/applications/{applicationFamily}/environments/{environmentName}/settings/upgrade
```

Route Parameters

`applicationFamily` - Family of the environment's application as is. (for example "BusinessCentral")

`environmentName` - Name of the targeted environment

Response

Returns the environment's update settings, or "null" if none exist

```
{
  "preferredStartTimeUtc": datetime, // Specifies the start of an environment's update window.
  "preferredEndTimeUtc": datetime, // Specifies the end of environment's update window.
}
```

> **NOTE**
> The `date` components of the values are ignored, only the time components are used.

Expected Error Codes

`environmentNotFound` - the targeted environment couldn't be found

- target: {applicationFamily}/{environmentName}

Put Update Settings

Sets the update window start and end times.

```
Content-Type: application/json
PUT /admin/v2.3/applications/{applicationFamily}/environments/{environmentName}/settings/upgrade
```

Route Parameters

`applicationFamily` - Family of the environment's application as is. (for example "BusinessCentral")

`environmentName` - Name of the targeted environment

Body

```
{
  "preferredStartTimeUtc": datetime, // Start of environment update window
  "preferredEndTimeUtc": datetime, // End of environment update window
}
```

Response

Returns the updated settings

```
{
  "preferredStartTimeUtc": datetime, // Start of environment update window
  "preferredEndTimeUtc": datetime, // End of environment update window
}
```

> **NOTE**
>
> The `date` components of the values are ignored, only the time components are used.

Expected Error Codes

`environmentNotFound` - the targeted environment couldn't be found

- target: {applicationFamily}/{environmentName}

- **invalidRange**: - the targeted logical range is invalid in some way

- target: "Preferred Upgrade Window" - the specified window is too small

`requestBodyRequired` - the request body must be provided

Put AppInsights key

Sets the key an environment uses for Azure AppInsights.

> **IMPORTANT**
>
> This process requires a restart to the environment, which is triggered automatically when you call this API. Plan to do this during non-working hours to avoid disruptions.

```
Content-Type: application/json
POST /admin/v2.3/applications/{applicationFamily}/environments/{environmentName}/settings/appinsightskey
```

Route Parameters

`applicationFamily` - Family of the environment's application as is. (for example, "BusinessCentral")

`environmentName` - Name of the targeted environment

Body

```
{
  "key": string, // The Application Insights key for the environment
}
```

Expected Error Codes

`environmentNotFound` - the targeted environment couldn't be found

- target: {applicationFamily}/{environmentName}

`requestBodyRequired` - the request body must be provided

`cannotSetAppInsightsKey` - the targeted environment's status isn't 'Active'

Telemetry

Telemetry includes the top-level AL events and any returned errors logged from the service. These events can provide necessary information and errors that can be used to troubleshoot issues happening in the tenant's environment.

Get Environment Telemetry

Returns the telemetry information for the provided environment and filters. it's recommended that you provide start and end time parameters to return a manageable data set.

```
GET /admin/v2.3/applications/{applicationFamily}/environments/{environmentName}/telemetry?startDateUtc=
{start}&endDateUtc={end}&logCategory={cat}
```

Route Parameters

`applicationFamily` - Family of the environment's application as is. (for example, "BusinessCentral")

`environmentName` - Name of the targeted environment

Query parameters

`start` : datetime // The start of the telemetry entry time window to query
`end` : datetime // The end of the telemetry entry time window to query
`cat` : (All or 0) // Category of telemetry to query

Response

Returns the telemetry logs and with data column headers.

```
{
  "queryColumns": [
    {
      "name": string, // Column display name
      "ordinal": int, // Index of the column in the data set
      "dataType": ( string or 0 | numeric or 1 | datetime or 2 )
      "expectations": (none or 0 | wide or 1) // Flags enum value
    }
  ],
  "queryResults": object[][] // Raw query data results
}
```

Expected Error Codes

`applicationTypeDoesNotExist` - the provided value for the application family wasn't found

`environmentNotFound` - the targeted environment couldn't be found

- target: {applicationFamily}/{environmentName}

`invalidInput` - the targeted property in invalid in some way

- target: {logCategory} - the provided log category isn't a valid value

Notifications

Notifications are sent to the recipient email addresses set up for the tenant. For example, notifications are sent for update availability, successful updates, update failures, and extension validations.

Get Notification Recipients

Returns a list of notification recipients.

```
GET /admin/v2.3/settings/notification/recipients
```

Response

Returns a wrapped array of recipients.

```
{
  "value":
  [
    {
      "id": GUID, // Unique identifier of the recipient
      "email": string, // Email address of the recipient
      "name": string // Full name of the recipient
    }
  ]
}
```

Expected Error Codes

`tenantNotFound` - the calling tenant information couldn't be found

Create Notification Recipient

Create a new notification recipient.

```
Content-Type: application/json
PUT /admin/v2.3/settings/notification/recipients
```

Body

```
{
  "email": string, // Email address of the recipient
  "name": string // Full name of the recipient
}
```

Response

Returns the newly created recipient.

```
{
  "id": GUID, // Unique identifier of the recipient
  "email": string, // Email address of the recipient
  "name": string // Full name of the recipient
}
```

Expected Error Codes

`invalidInput` - the targeted property in invalid in some way

- target: {name} - the name property can't be null or whitespace
- target: {email} - the email property can't be null or whitespace

`requestBodyRequired` - the request body must be provided

`tenantNotFound` - the calling tenant information couldn't be found

Delete Notification Recipient

Deletes an existing notification recipient.

```
DELETE /admin/v2.3/settings/notification/recipients/{id}
```

Route Parameters

`id` - The unique identifier of the notification recipient to delete.

Expected Error Codes

`invalidInput` - the targeted property in invalid in some way

- target: {id} - provided id can't be the empty guid

`tenantNotFound` - the calling tenant information couldn't be found

Get Notification Settings

Returns the full set of notification settings including the list of recipients.

```
GET /admin/v2.3/settings/notification
```

Response

Returns the notification settings.

```
{
  "aadTenantId": GUID, // AAD Tenant ID of the caller
  "recipients": [
    {
      "id": GUID, // Unique identifier of the recipient
      "email": string, // Email address of the recipient
      "name": string // Full name of the recipient
    }
  ]
}
```

Expected Error Codes

`tenantNotFound` - the calling tenant information couldn't be found

Reschedule Updates

Allows for the management of scheduled updates such as rescheduling the update to a run on or after a specific date within a provided range.

Get Scheduled Update

Get information about updates that have already been scheduled for a specific environment.

```
GET /admin/v2.3/applications/{applicationFamily}/environments/{environmentName}/upgrade
```

Route Parameters

`applicationFamily` - Family of the environment's application as is. (for example, "BusinessCentral")

`environmentName` - Name of the targeted environment

Response

Returns information about the scheduled update for that environment.

```
{
  "environmentName": string, // The name of the targeted environment.
  "applicationFamily": string, // Family of the environment. (for example, "BusinessCentral")
  "sourceVersion": string, // The current version of the environment's application.
  "targetVersion": string, // The version of the application that the environment will update to.
  "canTenantSelectDate": boolean, // Indicates if a new update date can be selected.
  "didTenantSelectDate": boolean, // Indicates if the tenant has selected the current date for the update.
  "earliestSelectableUpgradeDate": datetime, // Specifies the earliest date that can be chosen for the
update.
  "latestSelectableUpgradeDate": datetime, // Specifies the latest date that can be chosen for the update.
  "upgradeDate": datetime, // The currently selected scheduled date of the update.
  "updateStatus": string, // The current status of the environment's update. (enum | "Scheduled" or
"Running")
  "ignoreUpgradeWindow": boolean, // Indicates if the environment's update window will be ignored
  "isActive": boolean, // Indicates if the update is activated and is scheduled to occur.
}
```

Expected Error Codes

`applicationTypeDoesNotExist` - the provided value for the application family wasn't found

`environmentNotFound` - the targeted environment couldn't be found

- target: {applicationFamily}/{environmentName}

Reschedule Update

Reschedule an update, if able.

```
Content-Type: application/json
PUT /admin/v2.3/applications/{applicationFamily}/environments/{environmentName}/upgrade
```

Route Parameters

`applicationFamily` - Family of the environment's application as is. (for example, "BusinessCentral")

`environmentName` - Name of the targeted environment

Body

```
{
  "runOn": datetime, // Sets the date that the upgrade should be run on.
  "ignoreUpgradeWindow": boolean // Specifies if the upgrade window for the environment should be respected.
}
```

Expected Error Codes

`applicationTypeDoesNotExist` - the provided value for the application family wasn't found

`requestBodyRequired` - the request body must be provided

`resourceDoesNotExist` - no upgrade is currently scheduled for the targeted environment

`entityValidationFailed` - some unhandled error occurred in the validation of the request

`environmentNotFound` - the targeted environment couldn't be found

- target: {applicationFamily}/{environmentName}

Support Settings

Allows for the management of support settings, such as changing the contact, for a specific environment

Get Support Contact

Get information about the support contact for a specified environment.

```
GET /admin/v2.3/support/applications/{applicationFamily}/environments/{environmentName}/supportcontact
```

Route Parameters

`applicationFamily` - Family of the environment's application as is. (for example, "BusinessCentral")

`environmentName` - Name of the targeted environment

Response

Returns information about the support contact for that environment.

```
{
  "name": string, // The name of the support contact.
  "email": string, // The email address of the support contact.
  "url": string, // A freeform url for additional support contact information such as a support website.
}
```

Expected Error Codes

`applicationTypeDoesNotExist` - the provided value for the application family wasn't found

`environmentNotFound` - the targeted environment couldn't be found

- target: {applicationFamily}/{environmentName}

`resourceDoesNotExist` - couldn't find the necessary information to communicate with the targeted environment's API

`businessCentralCommunicationException` - an unhandled error occurred when communicating with the targeted environment's API

Set Support Contact

Sets the support contact information for a specified environment

```
Content-Type: application/json
PUT /admin/v2.3/support/applications/{applicationFamily}/environments/{environmentName}/supportcontact
```

Route Parameters

`applicationFamily` - Family of the environment's application as is. (for example, "BusinessCentral")

`environmentName` - Name of the targeted environment

Body

```
{
  "name": string, // The name of the support contact.
  "email": string, // The email address of the support contact.
  "url": string, // A freeform url for additional support contact information such as a support website.
}
```

Response

Returns the newly updated support contact information.

```
{
  "name": string, // The name of the support contact.
  "email": string, // The email address of the support contact.
  "url": string // A freeform url for additional support contact information such as a support website.
}
```

Expected Error Codes

`applicationTypeDoesNotExist` - the provided value for the application family wasn't found

`environmentNotFound` - the targeted environment couldn't be found

- target: {applicationFamily}/{environmentName}

`requestBodyRequired` - the request body must be provided

`resourceDoesNotExist` - couldn't find the necessary information to communicate with the targeted environment's API

`businessCentralCommunicationException` - an unhandled error occurred when communicating with the targeted environment's API

Environment Outage Reporting

Enables the ability to report that an environment isn't accessible and may require attention

Get Outage Types

Gets the list of supported categories of outages

```
GET /admin/v2.3/support/outageTypes
```

Response

Returns a list with information about the supported outage types for reporting

```
{
  "value": [
    {
      "outageType": string, // The identifier of the outage type.
      "name": string, // A displayable name for the outage type.
      "description": string, // A displayable description for the outage type.
    }]
}
```

Expected Error Codes

`cannotGetOutages` - an unhandled error occurred when trying to acquire the outage types

`tenantNotFound` - the calling tenant information couldn't be found

Get Outage Questions

Gets the list of metadata about questions that need to be answered when reporting an environment outage

```
GET /admin/v2.3/support/outageTypes/{outageType}/outageQuestions
```

Response

Returns the list of question metadata for the provided outage type

```
{
  "value": [
    {
      "sequence": int, // The order in which the question should be answered
      "parentId": int, // The identifier of a toggle question whose value indicates if this question should
be shown. that is if the parent value is 'true' then this question should also be answered
      "id": string, // The unique identifier of the question
      "defaultValue": string, // The default value of the question if it has no value
      "questionType": string, // (enum | "None", "Toggle", "TextField", "DateTime")
      "questionText": string, // The question's text to display
      "required": bool, // Indicates if the question must have a value
      "onText": string, // Toggle type only - display text for when the question is toggled to 'true'
      "offText": string, // Toggle type only - display text for when the question is toggled to 'false'
      "multiline": bool // Indicates if the value is intended to contain multi-line text
    }]
}
```

Expected Error Codes

`cannotGetOutageQuestions` - an unhandled error occurred when trying to acquire the outage types

`tenantNotFound` - the calling tenant information couldn't be found

Get Reported Outages

Gets the list of outages that have been previously reported

```
GET /admin/v2.3/support/reportedoutages
```

Response

Returns the list of outages reported across all environments for the calling tenant

```
{
  "value": [
    {
      "TenantId": string, // The id of the tenant who reported the outage.
      "EnvironmentId": string, // The id of the environment that was reported to have been unavailable.
      "CreatedDate": dateTime, // The date that the report was created.
      "State": string, // The current state of the outage report.
      "MsaasTicketId": string, // The identifier of the MSaaS ticket that is associated with the outage
report.
      "IcmTicketId": string, // The identifier of the IcM ticket that is associated with the outage report.
      "AppVersion": string, // The version of the environment's application at the time of the outage
report.
      "PlatformVersion": string, // The version of the environment's platform at the time of the outage
report.
      "OutageType": string, // The category of the reported outage.
    }]
}
```

Expected Error Codes

`cannotGetReportedOutages` - an unhandled error occurred when trying to acquire the reported outages

`tenantNotFound` - the calling tenant information couldn't be found

Report Outage

Initiates an outage report indicating that an environment isn't accessible

```
Content-Type: application/json
POST /admin/v2.3/support/applications/{applicationFamily}/environments/{environmentName}/reportoutage
```

Route Parameters

`applicationFamily` - Family of the environment's application as is. (for example, "BusinessCentral")

`environmentName` - Name of the targeted environment

Body

```
{
  "outageType": string, // The category of the outage being reported.
  "outageQuestionAnswers": [{ // The collection of answers to the questions associated with the outage type.
    "id": string, // The identifier of the question being answered.
    "answer": string // The answered value of the question.
  }],
  ("contact": string), // (Optional) - The name of the person whose to contact with updates on the outage
report
  ("email": string), // (Optional) - An email to contact with updates on the outage report
  ("phone": string), // (Optional) - A phone number to contact with updates on the outage report
  ("appVersion": string), // (Optional) - If known, the version of the targeted environment's application
  ("platformVersion": string) //(Optional) - If known, the version of the targeted environment's platform
}
```

Response

Returns information about the created outage report

```
{
    "creationStatus": string, // The status of the request to create an outage report. (enum | "Unknown",
"Created", "UpdatedExisting", "Error")
    "msaasCaseNumber": string, // The identifier of the MSaaS ticket that is associated with the outage
report.
}
```

Expected Error Codes

`requestBodyRequired` - the request body must be provided

`environmentNotFound` - the targeted environment couldn't be found

- target: {applicationFamily}/{environmentName}

`failedToReportOutage` - an unhandled error occurred when trying to report the outage

Environment Database Export

Allows for the export of an environment's Azure database. Databases are exported to an Azure Storage account provided by you. There is a limit to the number of exports that can be done within a month as shown by the 'metrics' endpoint below.

Get Export Metrics

Gets information about the number of exports allowed per month and the amount remaining.

```
GET /admin/v2.3/exports/applications/{applicationFamily}/environments/{environmentName}/metrics
```

Route Parameters

`applicationFamily` - Family of the environment's application as is. (for example, "BusinessCentral")

`environmentName` - Name of the targeted environment

Response

Returns the metrics around the current month's database exports.

```
{
  "exportsPerMonth": int, // The total number of allowed exports of the targeted environment every month.
  "exportsRemainingThisMonth": int, // The number of exports remaining for the targeted environment that can
be performed this month.
}
```

Expected Error Codes

`environmentNotFound` - the targeted environment couldn't be found

- target: {applicationFamily}/{environmentName}

Start Environment Database Export

Starts the export of an environment's database to a provided Azure storage account

```
Content-Type: application/json
POST /admin/v2.3/exports/applications/{applicationFamily}/environments/{environmentName}
```

Route Parameters

`applicationFamily` - Family of the environment's application as is. (for example, "BusinessCentral")

`environmentName` - Name of the targeted environment

Body

```
{
  "storageAccountSasUri": string, // An Azure SAS uri pointing at the Azure storage account where the
database will be exported to. The uri must have (Read | Write | Create | Delete) permissions
  "container": string, // The name of the container that will be created by the process to store the
exported database.
  "blob": string, // The name of the blob within the container that the database will be exported to.
Databases are exported in the .bacpac format so a filename ending with the '.bacpac' suffix is typical.
}
```

Expected Error Codes

`environmentNotFound` - the targeted environment couldn't be found

- target: {applicationFamily}/{environmentName}

`requestBodyRequired` - the request body must be provided

`exportFailed` - the export failed because the target environment's version was too old, it wasn't a production environment, the requesting tenant is a trial, the calling user doesn't have permissions to export, or the quota of allowed exports has been used up

Get Export History

Gets information about the exports that have been done within a provided time frame, for which environment, and by whom.

```
POST /admin/v2.3/exports/history?start={startTime}&end={endTime}
```

Query parameters

`startTime` - datetime // The start of the export history entry time window to query
`endTime` - datetime // The end of the export history entry time window to query

Response

Returns a detailed list of the database exports that occurred within the provided timeframe of the `start` and `end` query parameters

```
{
  "applicationType": string, // Family of the environment. (for example, "BusinessCentral")
  "applicationVersion": string, // The version of the environment's application at the time of the export.
  "blob": string, // The name of the blob that the environment's database was exported to.
  "container": string, // The name of the Azure storage account container that the environment's database
was exported within.
  "country": string, // The country code of the environment.
  "environmentName": string, // The name of the environment that was exported.
  "storageAccount": string, // The name of the Azure storage account that the environent's database was
exported to.
  "time": dateTime, // The time that the environment's database was exported.
  "user": string // The user who initiated the export process.
}
```

NOTE

All datetime values are in UTC

Case-Invariant blocked environment names

All environment types

- invoicing
- api
- error
- navwinclient
- clickonce
- tablet
- phone
- reset
- getapp
- signout
- addremotehost
- deployment
- health
- home
- notsupported
- officeaddin
- remotesignin
- shell service
- admin

Production Environment Types

- sandbox

Sandbox Environment Types

- production

App Management

INTRODUCED IN: Business Central 2020 release wave 1

Manage the apps that are installed on the environment.

Get Installed Apps

Get information about apps that are installed on the environment.

```
GET /admin/v2.3/applications/{applicationFamily}/environments/{environmentName}/apps
```

Route Parameters

`applicationFamily` - Family of the environment's application as is. (for example, "BusinessCentral")

`environmentName` - Name of the targeted environment.

Response

Returns information about the apps installed on the environment.

```
{
    "value":
    [
        {
            "id": Guid, // Id of the installed app
            "name": string, // Name of the installed app
            "publisher": string, // Publisher of the installed app
            "version": string, // Version of the installed app
            "state": string, // (enum | "Installed", "UpdatePending", "Updating")
            "lastOperationId": Guid, // Id of the last update operation that was performed for this app
            "lastUpdateAttemptResult": string // (enum | "Failed", "Succeeded", "Canceled", "Skipped")
        }
    ]
}
```

Get Available App Updates

Get information about new app versions that are available for apps currently installed on the environment.

```
GET /admin/v2.3/applications/{applicationFamily}/environments/{environmentName}/apps/availableUpdates
```

Route Parameters

`applicationFamily` - Family of the environment's application as is. (for example, "BusinessCentral")

`environmentName` - Name of the targeted environment.

Response

```
{
    "value":
    [
        {
            "id": Guid, // Id of the app
            "name": string, // Name of the app
            "publisher": string, // Publisher of the app
            "version": string, // New version available of the app
            "requirements": // List of other apps that need to be installed or updated before this app can
be updated
            [
                {
                    "id": Guid, // Id of the app
                    "name": string, // Name of the app
                    "publisher": string, // Publisher of the app
                    "version": string, // Version the required app needs to be updated to or installed
                    "type": string // (enum | "Install", "Update")
                }
            ]
        }
    ]
}
```

Schedule an App Update

Schedules the installation of an app update version. The update will be installed as soon as a time slot is available.

```
Content-Type: application/json
POST /admin/v2.3/applications/{applicationFamily}/environments/{environmentName}/apps/{appId}/update
```

Route Parameters

`applicationFamily` - Family of the environment's application as is. (for example, "BusinessCentral")

`environmentName` - Name of the targeted environment.

`appId` - Id of the targeted app.

Body

```
{
    "targetVersion": string // Version the installed app should be updated to
    "allowPreviewVersion": bool // Indicates whether to allow updating to an app version that is marked as a
Preview by the ISV (exact version must be specified in the targetVersion)
}
```

Response (app operation)

Returns information about the scheduled app update request.

```
{
    "id": Guid, // Id of the operation used for tracking the update request
    "createdOn": string, // Date and time the request was created
    "status": string, // (enum | "Scheduled", "Running", "Succeeded", "Failed", "Canceled", "Skipped")
    "targetVersion": string, // Version the installed app will be updated to
    "type": string // The type of app operation
}
```

Get App Operations

Gets information about app update operations for the specified app.

```
GET
/admin/v2.3/applications/{applicationFamily}/environments/{environmentName}/apps/{appId}/operations/[{operat
ionId}]
```

Route Parameters

`applicationFamily` - Family of the environment's application as is. (for example, "BusinessCentral")

`environmentName` - Name of the targeted environment.

`appId` - Id of the targeted app.

`operationId` - Id of the app update operation. Used for getting information about a specific operation.

Response

Returns the list of app update operations for the specified app. *Note*: `operationId` is provided, the single operation is returned instead.

```
{
    "value":
    [
        {
            "id": Guid,  // Id of the operation
            "createdOn": string, // Date and time the request was created
            "startedOn": string, // Date and time the installation process started
            "completedOn": string, // Date and time the installation process completed
            "status": string, // (enum | "Scheduled", "Running", "Succeeded", "Failed", "Canceled",
"Skipped")
            "sourceVersion": string, // Version of the app that was installed before the installation
process started
            "targetVersion": string, // Version the installed app will be updated to
            "type": string, // The type of app operation
            "errorMessage": string // The error message provided when update installation fails
        }
    ]
}
```

Session Management

INTRODUCED IN: Business Central 2020 release wave 1

Manage the active sessions on an environment.

Get active sessions

Gets active sessions for an environment.

```
GET /admin/v2.3/applications/{applicationFamily}/environments/{environmentName}/sessions
```

Response

```
{
    value: [
        {
            environmentName: string,
            applicationFamily: string,
            sessionId: int,
            userId: string,
            clientType: string,
            logOnDate: string,
            entryPointOperation: string,
            entryPointObjectName: string,
            entryPointObjectId: string,
            entryPointObjectType: string,
            currentObjectName: string,
            currentObjectId: int,
            currentObjectType: string,
            currentOperationDuration: long
        }
        ,...
    ]
}
```

Get session details

Gets session information for a specific session id.

```
GET /admin/v2.3/applications/{applicationFamily}/environments/{environmentName}/sessions/{sessionId}
```

Response

```
{
    environmentName: string,
    applicationFamily: string,
    sessionId: int,
    userId: string,
    clientType: string,
    logOnDate: string,
    entryPointOperation: string,
    entryPointObjectName: string,
    entryPointObjectId: string,
    entryPointObjectType: string,
    currentObjectName: string,
    currentObjectId: int,
    currentObjectType: string,
    currentOperationDuration: long
}
```

Stop and delete a session

Terminates and deletes an active session.

```
DELETE /admin/v2.3/applications/{applicationFamily}/environments/{environmentName}/sessions/{sessionId}
```

Introduction to automation APIs

2/17/2021 • 4 minutes to read • Edit Online

Automation APIs provide capability for automating company setup through APIs. Once the tenants have been created, the automation APIs can be used, in order to hydrate the tenant - to bring the tenant up to a desired state. Usually this involves creating a new company on the tenant, running RapidStart packages, installing extensions, adding users to user groups and assigning permission sets to users.

Delegated admin credentials and Dynamics 365 Business Central users with permissions, can call the APIs.

> **IMPORTANT**
>
> For delegated admin access, you must add the Azure Active Directory (Azure AD) application to the **AdminAgents** group. If the Azure AD application is not added, the consent flow will show an error such as *Need pre-consent*. For more information, see Pre-consent your app for all your customers in the Graph documentation.

Automation APIs are placed in the `microsoft/automation` API namespace. In all the examples below, parameters are marked in parenthesis `{}`. Make sure that only valid parameters are passed.

Create a company

To create a company, an automationCompany endpoint is available. To create a Company issue a POST request as shown in the following example.

```
POST https://api.businesscentral.dynamics.com/v2.0/{environment
name}/api/microsoft/automation/2.0/companies({companyId})/automationCompanies
Authorization: Bearer {token}
Content-type: application/json
{
    "name": "CRONUS",
    "displayName": "CRONUS",
    "businessProfileId": ""
}
```

The {companyId} must be the ID of an valid company on the tenant. Issue a GET automationCompany request to fetch existing companies.

> **NOTE**
>
> The company which is created will not be initialized.

To rename a company, issue a PATCH automationCompanies.

Upload and apply a RapidStart package

RapidStart is uploaded, installed, and applied using the APIs described below. RapidStart operations can be time consuming. To get the current status of the RapidStart packages and running operations issue a GET configurationPackages as shown in the following example.

```
GET https://api.businesscentral.dynamics.com/v2.0/{environment
name}/api/microsoft/automation/2.0/companies({companyId})/configurationPackages

Authorization: Bearer {token}
```

In the response, status for the import and apply status will be shown, as well as information about the RapidStart package.

Insert RapidStart

First step is to create the configuration package, by issuing a POST configurationPackages in the Dynamics 365 Business Central tenant. Once the configuration package is created, the RapidStart package can be uploaded. See the example below.

```
POST https://api.businesscentral.dynamics.com/v2.0/{environment
name}/api/microsoft/automation/2.0/companies({companyId})/configurationPackages

Authorization: Bearer {token}
Content-type: application/json
{
    "code":"{SAMPLE}",
    "packageName": "{SAMPLE}"
}
```

Upload RapidStart package

Once the configuration package is created, a RapidStart package can be uploaded with a PATCH configurationPackages. See the example below.

```
PATCH https://api.businesscentral.dynamics.com/v2.0/{environment
name}/api/microsoft/automation/2.0/companies({companyId})/configurationPackages({Id})/file('{SAMPLE}')/conte
nt

Authorization: Bearer {token}
Content-type: application/octet-stream
If-Match: *
Body: RapidStart file.
```

Import and apply RapidStart package

Once uploaded, the RapidStart package needs to be imported by issuing a POST on the bound action Microsoft.NAV.import.

```
POST https://api.businesscentral.dynamics.com/v2.0/{environment
name}/api/microsoft/automation/2.0/companies({companyId})/configurationPackages({Id})/Microsoft.NAV.import

Authorization: Bearer {token}
```

When the RapidStart package is imported it can applied with a POST on bound action Microsoft.NAV.apply.

```
POST https://api.businesscentral.dynamics.com/v2.0/{environment
name}/api/microsoft/automation/2.0/companies({companyId})/configurationPackages({Id})/Microsoft.NAV.apply

Authorization: Bearer {token}
```

Managing users, user groups, and permission sets

The automation APIs enable users to be set up in Dynamics 365 Business Central.

Modifying user properties

Get the current user properties by issuing a GET users. This will get the UserSecurityId needed on subsequent requests.

To modify the user, create a PATCH user request as shown in the example below.

```
PATCH https://api.businesscentral.dynamics.com/v2.0/{environment
name}/api/microsoft/automation/v1.0/companies({id})/users({userSecurityId})
Content-type: application/json
If-Match:*
{
    "state": "Enabled",
    "expiryDate": "2035-01-01T21:03:53.444Z"
}
```

Assign user permissions and user groups

To assign users to a user group, issue a POST request against the **userGroupMembers** entity. See the example below.

```
POST https://api.businesscentral.dynamics.com/v2.0/{environment
name}/api/microsoft/automation/2.0/companies({companyId})/users({userSecurityId})/userGroupMembers

Authorization: Bearer {token}
{
    "code": "D365 EXT. ACCOUNTANT",
    "companyName" :"CRONUS USA, Inc."
}
```

To retrieve the list of user groups issue a GET userGroups. This will return the information that you need for the payload above.

Assigning permission sets is identical to adding users to user groups. GET permissionSet returns information about the available permission sets. To assign a permissionSet issue a POST userPermission as shown in the following example.

```
POST https://api.businesscentral.dynamics.com/v2.0/{environment
name}/api/microsoft/automation/2.0/companies({companyId})/users({userSecurityId})/userPermissions

Authorization: Bearer {token}
{
    "id": "SECURITY"
}
```

Removing the permissionSet from the user is done by issuing a DELETE userPermissions on the users entity.

Handling tenant extensions

Add-on extensions which are already published to the tenant can be installed and uninstalled. Per-tenant extensions can be uploaded and installed. To get the list of all extensions on the tenant, issue a GET extensions. This will return the packageId needed for installing and uninstalling extensions.

Installing and uninstalling published add-on extensions

There are two bound actions available on the **extensions** endpoint: `Microsoft.NAV.install` and `Microsoft.NAV.uninstall`.

Issue a POST extension using the bound actions. See the example below.

```
POST https://api.businesscentral.dynamics.com/v2.0/{environment
name}/api/microsoft/automation/2.0/companies({companyId})/extensions({packageId})/Microsoft.NAV.install

Authorization: Bearer {token}
```

Upload and install a per-tenant extension

Issue a PATCH against the **extensionUpload** endpoint to upload and install the extension.

> **NOTE**
>
> Installing per-tenant extensions using Automation APIs is only possible in SaaS.

Uninstalling the extension can be done through the bound action Microsoft.NAV.uninstall, as with the add-on extensions.

Monitoring extension installation progress

To view ongoing extension installation status, issue GET extensionDeploymentStatus as shown in the following example.

```
GET https://api.businesscentral.dynamics.com/v2.0/{environment
name}/api/microsoft/automation/v1.0/companies({companyId})/extensionDeploymentStatus
```

Automation API overview

Automation Overview

2/17/2021 • 2 minutes to read • Edit Online

The following table provides an overview of the available resource types on a Dynamics 365 Business Central tenant. For an overview of how to use the automation APIs, see Introduction to Automation APIs.

RESOURCE TYPE	DESCRIPTION
automationCompany resource type	Represents an automationCompany resource type in Dynamics 365 Business Central.
company resource type	Represents a company resource type in Dynamics 365 Business Central.
configurationPackages resource type	Represents a configurationPackage resource type in Dynamics 365 Business Central.
extension resource type	Represents an extension resource type in Dynamics 365 Business Central.
extensionDeploymentStatus resource type	Represents a extensionDeploymentStatus resource type in Dynamics 365 Business Central.
permissionSet resource type	Represents a permissionSet resource type in Dynamics 365 Business Central.
user resource type	Represents a user resource type in Dynamics 365 Business Central.
userGroup resource type	Represents a userGroup resource type in Dynamics 365 Business Central.
userGroupMember resource type	Represents a userGroupMember resource type in Dynamics 365 Business Central.
userPermission resource type	Represents a userPermissions resource type in Dynamics 365 Business Central.

Introduction to Automation APIs

Using Service-to-Service Authentication with Automation APIs

2/17/2021 • 2 minutes to read • Edit Online

APPLIES TO: Business Central 2020 release wave 2 and later (Online)

Starting with Business Central 2020 release wave 2, version 17, service-to-service authentication is enabled for Automation APIs. Service-to-service authentication enables external services to connect as an application, without impersonating normal users.

Usage and setup overview

Automation APIs provide capability for automating company setup through APIs. The automation APIs are used to hydrate tenants, that is, to bring them to an initial state. Service-to-service authentication is intended only for the hydration of companies.

The **D365 Automation** entitlements give access to APIs in the `/api/microsoft/automation` route by using the OAuth client credentials flow. An application token with the `Automation.ReadWrite.All` scope is needed for accessing Business Central Automation APIs.

To enable service-to-service authentication, you'll have to do two things:

- Register an application in your Azure Active Directory tenant for authenticating API calls against Business Central.
- Set up the Azure AD application in Business Central.

These tasks are described in the sections that follow.

Task 1: Register an Azure AD application for authentication to Business Central

Complete these steps to register an application in your Azure AD tenant for service-to-service authentication.

1. Sign in to the Azure portal.
2. Register an application for Business Central in Azure Active Directory tenant.

   Follow the general guidelines at Register your application with your Azure Active Directory tenant.

   When you add an application to an Azure AD tenant, you must specify the following information:

SETTING	DESCRIPTION
Name	Specify a unique name for your application.
Supported account types	Select either **Accounts in this organizational directory only (Microsoft only - Single tenant)** or **Accounts in any organizational directory (Any Azure AD directory - Multitenant)**.
Redirect URI	Leave this option empty.

When completed, an **Overview** displays in the portal for the new application.

3. Create a client secret for the registered application as follows:

   a. Select **Certificates & secrets** > **New client secret**.

   b. Add a description, select a duration, and select **Add**.

   For the latest guidelines about adding client secrets in Azure AD, see Add credentials in the Azure documentation.

4. Grant the registered application **Automation.ReadWrite.All** permission to the **Dynamics 365 Business Central** API as follows:

   a. Select **API permissions** > **Add a permission** > **Microsoft APIs**.

   b. Select **Dynamics 365 Business Central**.

   c. Select **Application permissions**, select **Automation.ReadWrite.All**, then select **Add permissions**.

   When completed, the **API permissions** page will include the following entry:

API / PERMISSION NAME	TYPE	DESCRIPTION
Dynamics 365 Business Central / Automation.ReadWrite.All	Application	Full access to automation

   For the latest guidelines about adding permissions in Azure AD, see Add permissions to access your APIs in the Azure documentation.

Task 2: Set up the Azure AD application in Business Central

Complete these steps to set up the Azure AD application for service-to-service authentication in Business Central.

1. In the Business Central client, search for **AAD Applications** and open the page.
2. Select **New**.

   The **AAD Application Card** opens.

3. In the **Client ID** field, enter the **Application (Client) ID** for the registered application in Azure AD from task 1.
4. Fill in the **Description** field.
5. Set the **State** to **Enabled**.
6. Assign permissions to objects as needed.

   For more information, Assign Permissions to Users and Groups.

   > **TIP**
   > The system permission set and user group called **Dynamics 365 Automation** provide access to most typical objects used with automation.

7. Select **Grant Consent** and follow the wizard to the complete the setup.

TIP

Pre-consent can be done by adding the AAD application to the **Adminagents** group in the partner tenant. For more information, see Pre-consent your app for all your customers in the Graph documentation.

Trials and Sign-ups for Business Central Online

2/17/2021 • 4 minutes to read • Edit Online

You can invite customers and prospects to sign up for any number of Dynamics 365 apps, including Business Central online and partner solutions based on Business Central, using the same account ID. These apps will run side-by-side with each other, will use different URLs, and will be displayed as separate tiles on the *home.dynamics.com* portal.

This means that you can show prospects a preview of what you are offering based on trials of Business Central and other Dynamics 365 apps.

Prospects and trials

Prospects can contact you if they have signed up for the Business Central free trial. This means that you can become their CSP partner. For more information, see Connect with customers.

Alternatively, you can create a more tailored trial environment based on the Business Central content pack on the cdx.transform.microsoft.com site. For more information, see Preparing Demonstration Environments of Dynamics 365 Business Central.

Some types of trials can be extended beyond 30 days. The following table outlines the types of trials that you can offer prospects:

SCENARIO	TRIAL PERIOD	CAN BE EXTENDED	CAN BE USED FOR PRODUCTION
Prospect signs up for the free trial with their work or school email account, and then switches to My Company for a 30 day trial. Their trial is based on the **Dynamics 365 Business Central for IWs** license.	30 days	Yes Once through the in-product notification + once by the partner	Yes
Partner assigns the **Dynamics 365 Business Central Premium Trial** license to an existing client in Partner Center so that they can try out the Business Central full experience in My Company	30 days	No The partner can assign a new **Dynamics 365 Business Central Premium Trial** license for a second 30 days trial	Yes
Partner creates a test customer and assigns the **Dynamics 365 Business Central Premium Trial** license to that in Partner Center. Then they invite a client or prospect to that trial.	30 days	No The partner can assign a new **Dynamics 365 Business Central Premium Trial** license for a second 30 days trial	Yes

At any point during their trial experience, when they are ready, you can convert their trial to a paid subscription using the Partner Center dashboard. For more information, see Converting trials to paid subscriptions.

The Dynamics 365 Business Central Premium Trial

In the Partner Center, you can find a special license type called the **Dynamics 365 Business Central Premium Trial** license, which is a very different way to give a prospect or an existing customer a trial experience using their own data. If you assigned the **Dynamics 365 Business Central Premium Trial** license to a customer's account in the Partner Center, then that also expires after 30 days. You cannot extend the Premium trial, but you can add one more Premium trial license to give the customer an extra 30 days of trial. But when the second Premium trial expires, then the customer must either convert their trial to a paid subscription, or they must sign up for the viral trial as described above.

For more information, see Offer your customers trials of Microsoft products in the Partner Center documentation. If you have technical difficulties assigning this license, contact Partner Center support. For more information, see Report problems with Partner Center.

Caution

Make sure you understand the limitations of this type of trial, before you offer it to a prospect or customer. It is easy to convert this type of trial to a paid subscription, but if the prospect needs more than 30 days to decide, or if they want to add more than 25 users, then the viral trial is probably a better fit for them.

Extending trials

An organization can sign up for a free trial of Business Central. When they first sign up for Business Central, they get access to an evaluation version that does not include all capabilities in Business Central. They can then switch to the 30 day trial experience to enable all capabilities.

However, sometimes a 30 day trial is not enough to decide if they want to buy Business Central. In that case, they can extend their trial with an additional 30 days. For more information, see Need More Time to Decide Whether to Subscribe? in the business functionality content for Business Central.

> **NOTE**
>
> If you are a reselling partner, we recommend that you set up demo environments for prospects that need longer time to decide if they want to buy Business Central. You can also use demo environments to help customers train their employees, for example. Using the 30 days trials for training should be limited to just that short period. However, demo environments cannot be used for production. For more information, see Preparing Demonstration Environments.

If the prospect wants to extend the trial further than those 30 days, they must contact a partner. The partner can extend it another 30 days if the delegated administrator signs into the prospect's Business Central and runs the **Extend Trial Period** guide.

After those additional 30 days, the prospect must either purchase Business Central or abandon Business Central. At this point, they will have had up to 90 days with the trial experience.

> **TIP**
>
> As a reselling partner, you can suggest your prospects sign up for a trial, but you can also help set up a customized demonstration environment based on a sandbox environment or a trial environment. In both cases, you can easily add or remove functionality based on your prospects' expectations. For more information, see Preparing Demonstration Environments.

Embed Apps and signing customers up

Specifically for partners that are in the Embed App program, signing up customers works differently. For more information, see Onboarding customers and creating environments.

Embed App Overview

Deploying a Tenant Customization

2/17/2021 • 4 minutes to read • Edit Online

When you have finished developing and testing your tenant customization, you must deploy the extension (.app file) containing the customization to your customer's production tenant. You must be able to log into the customer's tenant as a user with permissions to the **Extension Management** page to complete the deployment.

Use the **Upload Extension** action to deploy the extension. The extension can be deployed for the current version or for the next version of the service. In most cases it is sufficient to select the current version, unless you have developed the extension specifically for the next version.

> **NOTE**
> When you deploy an .app file for the next version, the extension will be queued up to be deployed as part of the customer's tenant being upgraded to the next version. You can typically use this in a situation where you have built an upgrade of the extension to work with the next version.

The extension you are deploying could be the initial release of the customization or an upgrade to a previous version. You must use the same steps for uploading a new extension or an extension upgrade. The service will determine if the extension needs to be upgraded based on the extension's app ID and version.

Steps for deploying your .app file

1. Log into your customer's Dynamics 365 Business Central tenant.
2. Open the **Extension Management** page.
3. Choose the **Upload Extension** action.
4. Select the browse button to select the .app file to upload. Browse to and select the extension's .app file.
5. Select if you want to deploy for the current version (most common) or next version. Select the language for the deployment.
6. Choose the **Deploy** button.
7. The extension will be deployed in the background.
   To check the status of the deployment, choose **Deployment Status** and then view the status of the extension deployment. Select the row to see additional details.
   In the deployment status details there is a **Refresh** button in the actions you must press to retrieve the most recent status and details.
8. When the extension has been successfully deployed, choose the **Refresh** button to see the new extension in the list of installed extensions.

Extension uniqueness requirements

If you are developing and deploying an updated version of a previously-deployed extension, you must keep the app ID the same and increase the version number to successfully upgrade the extension. The deployment services require that uploaded extension packages be unique across all tenants based on several sets of keys:

- Package ID
- App ID + Version
- Name + Publisher + Version

> **NOTE**
>
> These parameters are defined in the app.json file of the extension. For more information, see JSON files.

If you have successfully deployed an extension to a tenant, and then recompile the extension's source code without updating version number, this generates a new extension package file with a new package ID. If you try to upload this new extension package file to a different tenant, the upload will fail with the error similar to `An extension with same App ID and version has already been uploaded. Resolve and deploy again.`. Similarly, if an extension failed to deploy, and you try to upload a new extension package with the same version number, the upload will fail as well.

When developing a per-tenant extension from the same source code as an extension for multiple tenants, we recommend that you adjust the App ID, Name, Publisher, and Version of the extension for each tenant to maintain uniqueness. You may deploy the same extension package to multiple tenants if the package ID, app ID, name, publisher, and version are all the same.

If, when creating a new sandbox environment as a copy of a production environment, you receive a message indicating that the environment creation failed due to an existing development extension, it is related to violation of uniqueness requirements for extension packages.

Typically this situation is the result of the production environment being copied having an extension package installed with the same app ID, name, publisher, and version as a development extension published to another sandbox environment within the same application service. To resolve this situation, remove the development extension by unpublishing it via the Extension Management page of the other sandbox environment once you have made sure you have a backup of the extension development files. After this is completed you can attempt to copy a production environment to a sandbox again. It is recommended that when you create the extension package for distribution, you use a different app ID than that used for your development extension, which will help you avoid this conflict between your development sandbox and your customer's production and sandbox environments.

Upgrades and per-tenant extensions

In some cases, a customer's production environment that includes a per-tenant extension cannot be upgraded automatically by Microsoft. In those cases Microsoft contacts the reselling partner and provides guidance for how to update the extension. However, if the extension remains impossible to upgrade, Microsoft will wait for 90 days and then uninstall the extension and force-upgrade the tenant.

Technical Support for Dynamics 365 Business Central

2/17/2021 • 4 minutes to read • Edit Online

Each customer of Business Central has a partner who assists with technical support when requested by the internal administrator. As a Business Central reselling partner, you are an administrator of your customers' Business Central tenants, and you are the first line of support. This means that you will get requests for support from your customers that you must triage, investigate, and either resolve or escalate to Microsoft.

In this section, you can learn about the tools that are available to you to help you troubleshoot your customers' Business Central.

Configuring the support experience

Because you are the first line of support for your customers, you must make it easy for them to contact you. To that end, there is a section in the Help and Support page in your customers' Business Central tenants where they can find this information.

> **IMPORTANT**
>
> You must have set up users in your own tenant in Partner Center as either *Admin agent* or *Helpdesk agent*, and they must have *delegated administration* privileges in your customer's Business Central to support the customer. For more information, see Delegated Administrator Access to Business Central Online.

To supply your support contact information in the administration center

1. In the Business Central administration center, choose the environment that you want to specify your contact details for, such as *Production*, and then, in the **Support** menu, choose **Manage Support Contact**.
2. Fill in the **Name**, **Email address**, and the **Website** fields, so that your users know how to contact you for technical support.
3. Optionally, choose the **Apply to all environments** checkbox if you want to add the same details to all related environments for this tenant.

Your customer can now contact you if they experience problems that they cannot resolve themselves. If you also cannot resolve a reported issue, you can escalate the issue to Microsoft. For more information, see Managing Technical Support.

On-premises deployments

In on-premises deployments of Business Central, the **Help and Support** page does not contain the section for contacting technical support. Instead, you can enter an agreement with your customer's administrator about how and when to contact you.

There are two other links in the **Help and Support** page that you can customize:

- Blog

  Specifies a link to where your customers can access a blog about their solution

- Coming soon

  Specifies a link to where your customers can access a roadmap for future changes

If you choose to not modify these settings, then the links go to Microsoft's blog and release notes.

For more information, see Configuring Business Central Web Server Instances.

Getting support for extension issues

As a partner, you must identify if the issue is caused by application logic or platform behavior:

- If the issue is caused by application logic, you must identify the publisher of the extension.
- If the extension is a per-tenant extension, as a partner, you must fix the issue.
- If the extension is an AppSource extension, you must contact the AppSource partner that developed the extension.
- If the extension is published by Microsoft, you must contact Microsoft support.

Troubleshooting and support

The Business Central administration center is your primary tool to support your customers. However, you can also log in to the customer's Business Central as the delegated admin for troubleshooting.

For more information, see Managing Technical Support.

Summary of where to file bugs and issues

As a partner, you have different support channels depending on what type of issue you want support for. The following list outlines the various channels.

ISSUE TYPE	SITE
Submit support request on behalf of your Business Central online customers	Start at the Business Central administration center where you can easily submit a support request in the Power Platform admin center
Report bug in a preview or beta version	The MS Collaborate site
Collaboration on the AL language and developer experience	The AL Developer Preview GitHub repo
As an ISV, report an issue in production code, such as a problem with Microsoft's application, upgrade, or telemetry	The Partner Center - choose the **Support** section, start a partner request, search for *Business Central*, and then choose the relevant category for *Product Support > Business Central Development* and submit your support request.
Report bug in supported in-market versions of Business Central on-premises	The Support for business site

IMPORTANT

To submit support requests on behalf of your customer, you must be a delegated admin on the customer tenant. If your company is a CSP direct bill partner, you must have *Advanced* or *Premier* support plan.

TIP

When you submit your first support ticket as a partner, you must specify details about your company's support plan. If you or your colleagues do not know these details, contact your Microsoft rep.

Non-product related questions

On occasion, as a partner, you will run into questions that are not directly related to the product. The following list outlines how to get answers to those questions.

FOR QUESTIONS RELATED TO	CONTACT
Problems with listing or publishing apps to AppSource due to Commercial Marketplace issues	The Partner Center - choose the **Support** section, start a partner request, search for *Business Central*, and then choose the relevant category for *Commercial Marketplace* and submit your support request.
Licensing or PSBC agreements	Email MBS Orders or MBS Agreements, respectively
Microsoft Partner Network, Partner Center, Cloud Solution Provider program	The Partner Center Support site
Payments, credit terms, checks, wire, or similar	Email MBS Accounting
Technical issues with PSBC, PartnerSource, or Order Central	Email IT MBS Support
Incentives	Email CSA Team
Cloud Solution Provider incentives	Email Online Channel Incentives Support
CSA/Ocina escalations	Email NAOC Channel Incentives Escalations
Volume licensing	The Call Logging Tool site or email Online Licensing

Migrating On-Premises Data to Business Central Online

2/17/2021 • 3 minutes to read • Edit Online

Organizations that run their workloads on-premises but are looking to move to the cloud can easily migrate to Business Central online. By moving to the cloud, users get the benefits of cloud scenarios such as Machine Learning, Power BI, Power Automate, and others to drive suggested actions.

First, get started with Business Central online tenant here.

The cloud migration tool in Business Central online supports migration from specific versions of specific software. For more information, see the following articles:

- Migrate to Business Central Online from Business Central On-premises
- Migrate to Business Central Online from Dynamics GP
- Upgrading from Dynamics NAV to Business Central Online

Data migration

Data migration is the process of securely migrating data from your on-premises SQL Server instance to your Business Central online tenant. The process uses the Azure Data Factory (ADF) to migrate the data between databases directly, meaning it does not look at any permissions within the applications you are transferring data between, only SQL permissions.

> **TIP**
> Before you start the migration process, please update statistics and reorganize indexes on all tables on the source database. This will ensure that the migration runs as fast as possible. For more information, see the documentation for sp_updatestats (Transact-SQL) and Resolve index fragmentation by reorganizing or rebuilding indexes.

To migrate data, in the target company in your Business Central online tenant, run the Cloud Migration Setup assisted setup wizard.

> **IMPORTANT**
> You must be signed in as an administrator of the Business Central online tenant and the Microsoft 365 tenant.

Once the wizard is complete and data migration is activated, an initial data migration will happen at the scheduled time. Alternatively, you can trigger the data migration process manually.

> **TIP**
> You can migrate the data that you want to take with you to the cloud. But if your Business Central online storage exceeds 80 GB, some administrative tasks are disabled. We recommend that you consider reducing the amount of data that you migrate so that it is less than 30 GB in each migration run. For example, reduce the number of companies that you are migrating data for, or delete outdated data in tables that contain log entries and archived records. Also, review how you can manage database capacity in a Business Central online environment.

Data is migrated table by table, and success and failures are tracked for each table. If a table fails to migrate, the

error will be captured, and the migration moves on to the next table until completed. Tables will fail to migrate if they cannot be found, or if the schema does not match between the cloud and the on-premises tables.

The initial data migration time can vary depending factors such as the amount of data to migrate, your SQL Server configuration, and your connection speeds. The initial migration will take the longest amount of time to complete because all data is migrating. After the initial migration, only changes in data will be migrated so they should run more quickly. You do not need to run the migration process more than once if you don't want to, but if you are running the migration while users are still using the on-premises system you will need to run at least one more migration in order to ensure all data was moved to the cloud before you start transacting in the cloud tenant.

Running the Cloud Migration Tool

2/17/2021 • 11 minutes to read • Edit Online

The **Set up Cloud Migration** assisted setup guide helps administrators migrate data from supported on-premises solutions to their Business Central online tenant as part of the migration to the cloud.

The cloud migration tool supports migration from specific versions of specific software. For more information, see the following articles:

- Migrate to Business Central Online from Business Central On-premises
- Migrate to Business Central Online from Dynamics GP
- Upgrading from Dynamics NAV to Business Central Online

Use the same assisted setup to set up a connection to the intelligent cloud but still remain on-premises. For the list of on-premises solutions that currently supported for connecting to the intelligent cloud, see Which products and versions are supported for connecting to the intelligent cloud? in the FAQ.

In the following sections, you're working in your Business Central online tenant and connecting it to your on-premises database. Either because you are migrating from on-premises to online, or because you are connecting to the intelligent cloud.

> **TIP**
> In migration scenarios, we recommend that you start the migration by running the assisted setup from a company other than the company that you are migrating data to. For example, you can log into the demonstration company, CRONUS, and start the process there. This way, you can make sure that all users are logged out of the original company and the target company.

Best practices

This section provides best practices and recommendations for migrating to the cloud.

> **IMPORTANT**
> You must be signed in as an administrator of the Business Central online tenant and the Microsoft 365 tenant.

- As a best practice, test this configuration in your sandbox environment before making changes to a production tenant.

  For more information, see Managing Environments.

- Any existing data in your Business Central tenant will be overwritten with data from your on-premises solution, or source, once the data migration process is run.

  If you do not want data in your Business Central online tenant to be overwritten, do not configure the connection.

- All users that do not have *SUPER* permissions will be automatically reassigned to the intelligent cloud user group. This will limit them to read-only access within the Business Central tenant. See more below.

- If your data source is Business Central on-premises, several stored procedures will be added to the SQL Server instance that you define. These stored procedures are required to migrate data from your SQL Server database to the Azure SQL server associated with your Business Central tenant.

- Consider reducing the amount of data that you migrate.

  You can migrate the data that you want to take with you to the cloud. But if your Business Central online

storage exceeds 80 GB, some administrative tasks are disabled. We recommend that you consider reducing the amount of data that you migrate so that it is less than 30 GB in each migration run. For example, reduce the number of companies that you are migrating data for, or delete outdated data in tables that contain log entries and archived records. Also, review how you can manage database capacity in a Business Central online environment.

You can specify which companies to include in the migration in the assisted setup wizard, and you can view the migration status of each company in the Cloud Migration Management page.

If you want to add more companies after the first selection of companies, you can add additional companies in the **Cloud Migration Management** page in the Business Central online tenant. For more information, see Adding a tenant to an existing runtime service, or updating companies. But use the Capacity section of the Business Central administration center to keep track of how much data you migrate.

In certain cases, the customer wants to migrate very large amounts of data. In those cases, you must first run the assisted setup once to create a pipeline, and then contact Support to increase the limitations on your Business Central online tenant. For more information, see Escalating support issues to Microsoft. We are continually working on improving and optimizing the migration tool for larger database sizes, and since 2020 release wave 2, customers can buy additional environments, for example.

- Before you set up the cloud migration, make sure that at least one user in the system has *SUPER* permissions. This is the only user that will be allowed to make changes in the Business Central tenant.
- Configuring the cloud environment will have no impact on any users or data in your on-premises solution.

To begin configuring the connection, navigate to the assisted setup page and launch the **Set up Cloud Migration** assisted setup guide.

> **TIP**
> If you are using Business Central on-premises, the same setup guide is also available in your on-premises solution. You will automatically be redirected to your Business Central online tenant to continue the configuration process.

The Set up Cloud Migration assisted setup guide

When you choose the **Set up Cloud Migration** assisted setup, it launches the **Data Migration Setup** guide, which consists of up to six pages that take you through the process of connecting your solution to the Business Central online tenant.

1. Welcome and Consent page

   This page provides an overview of what the wizard will do. You must agree to the displayed warning message before you can continue to the next step.

2. Product selection

   On this page, specify the on-premises solution that you want to replicate data from. All supported sources will appear in the list. If you don't see your product, navigate to the **Manage Extensions** page, and then verify that the intelligent cloud extension for your on-premises solution is installed.

   To set up migration from the previous version of Business Central, in the **Data Migration Setup** dialog, choose *Dynamics 365 Business Central (Previous Version)* as the product.

   > **TIP**
   > Use the migration tool to migrate from the latest version of Business Central or the previous version. If your current version is older than the previous version, then you must upgrade your on-premises solution. For more information, see Supported Upgrade Paths to Dynamics 365 Business Central Releases.

3. SQL Connection

   If the product you selected requires a SQL connection, this page will be presented. Other source applications may require different information to connect to them. This page will display the connection information based on the product that you specified in the previous page. This is defined from the installed extensions for the product you have selected.

FIELD	DESCRIPTION
SQL Connection	**SQL Server**, which is your locally installed SQL Server instance, or **Azure SQL**.

SQL Connection string	You must specify the connection string to your SQL Server, including the name of the server that SQL Server is running on, and the name of the instance, the database, and the relevant user account. For example, `Server=MyServer\BCDEMO;Database=BC170;UID=MySQLAccount;PWD=MyPassW`, if you're migrating from Business Central on-premises, version 17. For more information, see the SQL Server blog. The following snippets illustrate a couple of connection strings with different formats:
	`Server={Server Name\Instance Name};Initial Catalog={Database Name};UserID={SQL Authenticated UserName};Password={SQL Authenticated Password};`
	`Server={Server Name\Instance Name};Database={Database Name};User Id={SQL Server Authenticated UserName};Password={SQL Server Authenticated Password};`
	The SQL connection string is passed to Azure Data Factory (ADF), where it is encrypted and delivered to your Self-Hosted Integration Runtime and used to communicate with your SQL Server instance during the data migration process.

Integration runtime name	If your SQL connection is **SQL Server**, you must specify the runtime service that will be used to replicate the data from the defined source to your Business Central online tenant. The integration runtime must be running on the machine that holds the SQL Server database. If you don't already have a runtime service, leave the field empty, and then choose the **Next** button. Once you choose **Next**, a new pipeline will be created in the Azure service. This takes less than a minute to complete, in most cases. If you want to test your SQL string, open the **Microsoft Integration Runtime Configuration Manager**, and then choose the **Diagnostics** menu option. From there, you can test to see if the connection is good. If you are a hosting partner, you may have multiple tenants running on the same integration runtime service. Each tenant will be isolated in their own data pipeline. To add tenants to an existing integration runtime service, enter the name of the existing integration runtime service into this field. The integration runtime name can be found in the Microsoft Integration Runtime Manager. For more information, see Create and configure a self-hosted integration runtime.

   If you left the *Integration runtime name* field empty, a new page appears from where you can download the self-hosted integration runtime that you must install. Follow the instructions on the page.

4. Company Selection

   From the list of companies from your on-premises solution, the source of the migration, select the

companies you want to migrate data for. If the company does not exist in your Business Central online tenant, it will be automatically created for you.

> **NOTE**
> This process may take several minutes depending on the number of companies that need to be created.

5. Enable & Scheduling Migration

   The final page in the wizard allows you to enable the migration process and create a schedule for when the data migration should occur. These settings are also available within your Business Central tenant on the **Cloud Migration Management** page. You have the option to schedule migrations daily or weekly.

> **TIP**
> We recommend that you schedule your data migration for off-peak business hours since it can take many hours to run, depending on the amount of data.
>
> We also recommend that you make sure that all users are logged out of both the source company and the target company.

Once you have migrated the data that you want to migrate to Business Central online, you end the migration by disabling cloud migration in the **Cloud Migration Setup** page. This is an important step, because each time someone runs the migration, outstanding documents for vendors and customers, general ledger account numbers, inventory items, and any other changes made in the target company in Business Central online are overwritten. If you are not migrating but using the assisted setup guide to connect to the intelligent cloud, you can adjust the migration schedule.

> **NOTE**
> The amount of time the migration will take to complete depends on the amount of data, your SQL configuration, and your connection speed. Subsequent migrations will complete more quickly because only changed data is migrating.

Adding a tenant to an existing runtime service, or updating companies

There are some scenarios where it will be necessary for you to run the cloud migration setup wizard more than once.

One example is if you want to change the companies you replicate data for. If the companies in your on-premises solution have changed, either added or deleted, or you want to change the companies to migrate, run the assisted setup wizard again. Alternatively, choose the additional companies in the **Cloud Migration Management** page.

Another example is that if you are a hosting partner and want to add tenants to your existing runtime service.

In both examples, you will be making updates to an existing runtime service. When you get to the point of the wizard where you can specify an existing runtime services name, open the Microsoft Integration Runtime Service Manager and enter the runtime name in the field in the wizard; you will not be allowed to copy/paste. The runtime service will identify that you are making updates to an existing service and will not create a new one.

Complete the steps in the wizard to update the runtime service. If the change was related to adding tenants to an existing service, a new data pipeline will be created for that tenant. Changing your migration schedule or regenerating an Azure Data Factory (ADF) key may be done using the **Cloud Migration Management** page in your Business Central cloud tenant. For more information, see Managing the Migration to the Cloud.

User groups and permission sets

When running as connected with an on-premises solution, the Business Central online tenant will be read-only with few exceptions. Because the on-premises solution is your primary application for running your business, including activities such as data entry, tax reporting, and sending invoices, these tasks must be completed in the on-premises solution. We limit the amount of data that you can enter in your Business Central tenant to data that is not migrated. Otherwise any data that was written to the tenant database would be continuously overwritten during the migration process.

To make setting up this read-only tenant more efficient, we created a new *Intelligent Cloud* user group and an *Intelligent Cloud* permission set. Once the cloud migration environment is configured, all users without SUPER permissions will be automatically assigned to the *Intelligent Cloud* user group. Only users with SUPER permissions will be allowed to make modifications to the system at this point.

> **NOTE**
> Before you configure the a connection from on-premises to Business Central, make sure that at least one user in each company is assigned SUPER permissions.

Users that are reassigned to the *Intelligent Cloud* user group will have access to read ALL data by default. If you need to further restrict what data a user should be able to read, the SUPER user may create new user groups and permissions sets and assign users accordingly. It is highly recommended to create any new permissions sets from a copy of the *Intelligent Cloud* permission set and then take away permissions you do not want users to have.

> **WARNING**
> If you grant insert, modify or delete permissions to any resource in the application that was set to read-only, it could have a negative impact on the data in the Business Central cloud tenant. If this occurs, you may have to clear all your data and rerun a full migration to correct this.

Extensions

It is highly recommended that you test the impact of any extension in a sandbox environment before having it installed in your production Business Central tenant to help avoid any data failures or untended consequences.

Managing the Migration to the Cloud

2/17/2021 • 5 minutes to read • Edit Online

You can connect your on-premises solution to your Business Central online tenant for the purpose of migrating your data to the cloud. Once you have set up this configuration, you can manage your cloud environment and data migration from the **Cloud Migration Management** page in Business Central online.

> **NOTE**
>
> To manage migrations and run the migration tool, you must have the SUPER permission set in Business Central and be an administrator of the Microsoft 365 tenant. .

Cloud Migration Management

The **Cloud Migration Management** page provides information about your data migration runs as well as the ability to manage your migration services, for example.

The page provides a view of the status of all migration runs. You can view the time the migration ran and the status of each migration. If you have set up a schedule, you can also see when the next migration is scheduled to run. The **Migration Information** tiles show the number of migrated tables and the number of tables that did not migrate due to warnings or errors. Choose a tile to drill into additional details and guidance to correct any errors.

There is also a tile that shows tables that are not migrated due to problems with the data. For example, tables with permissions are not migrated from on-premises solutions because permissions work differently between online and on-premises.

The following table describes the actions that you can run from the page:

ACTION	DESCRIPTION
Manage Schedule	Opens a page where you can set the migration schedule without having to run the assisted setup wizard again.
Run Migration Now	Choose this to start the data migration manually. This can be helpful if you received errors in the scheduled data migration, you corrected the errors, and you now want to push updated data to the cloud outside of a normally scheduled run. The migration can also be used for subsequent runs after the initial migration. On subsequent runs, the migration tool will only migrate changes that have happened since the previous migration was run. Change tracking is used to identify what data should be moved in those subsequent runs.
Refresh Status	If a migration run is in progress, you can choose to refresh status to update the page. If the run is complete, the status will update using the refresh status action without having to close the window and reopen it.

ACTION	DESCRIPTION
Reset Cloud Data	You may run into instances where you need to reset your cloud data. This option will clear all data in your cloud tenant and enable you to start over with data migration. Only run this process if you want to start the migration process all over from the beginning. If you need to clear data in your cloud tenant, and you have connectivity issues that persist for more than 7 days, you must contact customer support. They will create a ticket to have your tenant data cleared. This process should *only* be done if you want to start the data migration all over and bring all data from on-premises to your cloud tenant.
Get Runtime Service Key	Returns the existing runtime key.
Reset Runtime Service Key	If at any time you suspect that your Self-Hosted Integration Runtime key is no longer secure, you can choose this option to regenerate a new key. A new key will be generated for you and automatically be updated in the Self Host Integration Runtime service.
Disable Cloud Migration	Opens a guide that helps you through a checklist of instructions to disable the cloud migration configuration. Once the steps in this process are complete, you can use your Business Central online tenant as your primary solution.
Check for Update	If there have been changes to the migration service, we will publish the new service. This action will check to see if a new service has been published. The check will display the version of the service you are currently running and then also display the latest service published. You will then have the option to update your solution. We recommend that you update the solution if a newer version has been published.
Select Companies to Migrate	If your database contains more than one company, you this action to specify which company or companies to schedule a migration run for. For example, you're migrating a very large database with multiple companies, so you break down the migration in several runs by including one or a few companies in each migration run. You can see the estimated size of each company
Define User Mappings	This option is available when you log in to a particular company that has been migrated. This action should be done in one of the companies you have migrated. This action gives you a list of the users that were in your on-premises environment, and then gives you a list of your Microsoft 365 users, so that you can map the two together. This process renames the **Name** field on the **User Card** to match the user name in your on-premises solution. It is not a required step, but if you use some of the processes in Business Central that work in conjunction with the user name, such as timesheets, you may want to map users. Timesheets are visible based on the user name you are logged in as in Business Central.

ACTION	DESCRIPTION
Setup Checklist	When you are ready to use your Business Central online tenant as your main system, the tables that were not migrated must be set up or defined as needed. The checklist page shows recommended steps to complete your migration to the cloud.
Azure Data Lake	This option is available if the Business Central online tenant is connected to Dynamics GP. For more information, see Migrate Dynamics GP to Azure Data Lake.

Company initialization

When a company is created in Business Central, no one can access it until it has been initialized. If you are familiar with Dynamics NAV, then you are used to this step happening automatically during the upgrade process, for example. But it's not quite the same with Business Central online. Starting with 2020 release wave 2, when a migration run completes, you are prompted to view a list of companies that were not initialized yet so that you can start the initialization. You can choose to mark a company as already initialized, such as if it was initialized in an earlier migration run. Technically, the initialization runs as a scheduled task in the job queue, and the status is automatically updated in the list of companies when a task completes.

> **NOTE**
> When you schedule an initialization in the **Hybrid Companies** list, then you cannot make any modifications to the company until the initialization task completes.

Migrate to Business Central Online from Business Central On-premises

2/17/2021 • 3 minutes to read • Edit Online

Your Business Central on-premises solution can have an identical twin in a Business Central online tenant. Use this twin to migrate to the cloud, or use it to connect to intelligent cloud scenarios. The migration can be started quite easily from the assisted setup wizard in your on-premises solution.

> **NOTE**
>
> Currently, you can migrate to Business Central online from versions 14, 15, 16, and 17. Alternatively, you can upgrade to the current version and then migrate to the cloud. For more information, see Supported Upgrade Paths to Business Central Releases.

To verify that you are running on a version that supports this migration, in the Business Central administration center, open the environment that you intend to migrate your data to, and then choose the **Apps** action. Make sure that these apps have the latest updates installed:

- Intelligent Cloud Base
- Business Central Intelligent Cloud

If you are migrating from an earlier supported version, you must also make sure that the following apps are updated:

- Business Central Cloud Migration – Previous Release
- Business Central Cloud Migration – Previous Release [code for your country-specific version]

For more information, see Managing Apps.

Migrating data from extensions

When your on-premises solution is connected to the cloud, it is highly recommended that you test the impact of any extension in a sandbox environment before you install the extensions in your Business Central production tenant to help avoid any data failures or unintended consequences.

In order to support data migration, tables and table extensions must specify if data from that table must be migrated or not. By default, the **ReplicateData** property is set to *Yes* so that, by default, any extension that is installed in the Business Central cloud tenant will have all its tables migrated.

In certain circumstances, you may want to not migrate all data. Here are a few examples:

- The extension is installed in the Business Central online tenant but not in the Business Central on-premises solution

  In this case, Business Central will attempt to migrate the data but show a warning. Since the extension is not installed on-premises, any table related to that extension table will not migrate, and warning notifications will appear in the cloud migration status page.

  If you own the extension, we recommend that you set the **ReplicateData** property to *No* on the extension tables. If you do not, and if you want data to migrate, install the extension in both your Business Central cloud tenant and your on-premises solution. If you do not want data to migrate, uninstall the

extension from your Business Central cloud tenant.

- The extension references a base table

  This can cause your base table to appear empty when you view data in your Business Central cloud tenant. If that happens, uninstall the extension from your Business Central cloud tenant, and then run the cloud migration process again.

Data that is not migrated

During the data migration process, Business Central does not migrate most system tables, users, and permissions.

Upgrading to a new version of Business Central

If you upgrade to a new version of Business Central on-premises, including a cumulative update, then you must update the extensions as well. Depending on your on-premises solution, your Business Central tenant contains different extensions for the cloud migration. For more information, see Business Central Intelligent Cloud Extensions.

> **IMPORTANT**
> In your Business Central online tenant, install, publish, or upgrade the **Intelligent Cloud Base** extension first, and then the product-specific extension or extensions.

Also, at the end of the upgrade, you must make sure that the `applicationVersion` field in the `ndo$tenantdatabaseproperty` table is set to the right version. If the field is blank, or if it is set to an older version than the migration tool supports, the migration cannot run. For more information, see Post-upgrade tasks.

Migrate to Business Central Online from Dynamics GP

2/17/2021 • 9 minutes to read • Edit Online

An assisted setup guide in Business Central can help you migrate data from Dynamics GP. You can migrate data from Dynamics GP 2015 on SQL Server 2012 and later versions of Dynamics GP and SQL Server.

> **IMPORTANT**
>
> Migrating from Dynamics GP using the **Cloud Migration Setup** assisted setup guide is currently only supported for the following markets: United States, Canada, United Kingdom, Australia.

Migrated data

When you migrate from Dynamics GP, the following information is migrated from Dynamics GP to Business Central online:

1. Chart of Accounts master records

   The account number in Business Central will be mapped from the main account segment from Dynamics GP. Remaining account segments are then defined as dimensions in Business Central. The assisted setup guide asks the user to enter a segment for *Global Dimension 1* and *Global Dimension 2*. If your chart of accounts in Dynamics GP has more than 2 segments outside of the main segment, the other segments are automatically set up as shortcut dimensions (3-8). You can verify the setup in the **General Ledger Setup** page in Business Central.

   Account Summary transactions are generated and posted for open and history years that were set up in Dynamics GP. The summary amounts are created based on the fiscal periods set up in Dynamics GP.

   Let us look at an example of an account from Dynamics GP:

ACCOUNT IN DYNAMICS GP	YEAR	NAME	AMOUNT
000-1100-00 Cash	Year 2019		
		Period 1	250.00
		Period 2	117.00
		Period 3	340.00
000-1100-01 Cash	Year 2019		
		Period 1	240.00
		Period 2	102.00
		Period 3	501.00

ACCOUNT IN DYNAMICS GP	YEAR	NAME	AMOUNT
000-4000-00 Sales	Year 2019		
		Period 1	490.00
		Period 2	219.00
		Period 3	841.00

The migration creates two accounts in Business Central, number 1100 and number 4000. New dimensions are also added with the names 000, 00, and 01. General journal transactions are created as follows:

TRANSACTION DATE	ACCOUNT NO.	AMOUNT	DIMENSIONS
1/31/2019	1100	250.00	Dimension 000, 00
1/31/2019	1100	240.00	Dimension 000, 01
1/31/2019	4000	490.00	Dimension 000, 00
2/28/2019	1100	117.00	Dimension 000, 00
2/28/2019	1100	102.00	Dimension 000, 01
2/28/2019	4000	219.00	Dimension 000, 00
3/31/2019	1100	340.00	Dimension 000, 00
3/31/2019	1100	501.00	Dimension 000, 01
3/31/2019	4000	841.00	Dimension 000, 00

The data migration generates dimensions on that account based on the different segments. User will see a *Department* dimension with the values *000*, *100*, and *200*, respectively. A second dimension, *Division*, will show the values *00*, *01*, and *02*, respectively.

2. Customer master records and outstanding transactions from the Receivables module

   In the setup wizard, you can choose to migrate all customers from Dynamics GP or only active customers. This allows you to not migrate over customers that have been marked as inactive. We also have added bringing all addresses from the customer over into Business Central. All of the addresses on the customer will be setup as shipping addresses in Business Central. That will allow the end user to choose the address needed when entering transactions after the migration.

   We also bring over outstanding receivables transactions. These transactions will be brought in with the amount remaining in Dynamics GP. For example, if an invoice for $1000 was entered into Dynamics GP, and it has been partially paid and has a remaining balance of $400, the new invoice created in Business Central will be for $600 as that is the amount remaining to be paid. We bring over all transaction types from Receivables Management.

3. Vendor master records and outstanding transactions from the Payables module

In the setup wizard, you can choose to migrate all vendors from Dynamics GP or only active vendors. This allows you to not migrate over vendors that have been marked as inactive. We also have added bringing all addresses from the vendor over into Business Central. All of the addresses on the vendor will be setup as order addresses in Business Central. That will allow the end user to choose the address needed when entering transactions after the migration.

We also bring over outstanding Payables transactions. These transactions will be brought in with the amount remaining in Dynamics GP. For example, if an invoice for $1000 was entered into Dynamics GP, and it has been partially paid and has a remaining balance of $400, the new invoice created in Business Central will be for $600 as that is the amount remaining to be paid. We bring over all transaction types from Payables Management.

You can also bring over Open Purchase Orders. When we migrate purchase orders, we are looking at the items and the quantities remaining on those items to determine what we will bring over as an open purchase order. If an item is fully received and invoiced that item will not migrate. By bringing over open purchase orders, you do not have to enter outstanding transactions from the purchase order aspect.

4. Inventory items

   Inventory is imported with the cost valuation method that was selected when the company setup wizard was run. Currently, the data migration brings in the quantity on hand for the items at the time of migration. This quantity is brought into the blank location.

5. Historical data from Receivables, Payables, Sales Order Processing, Purchase Order Processing, and Inventory

   This data can be used in Power BI reports and Power Apps. In Business Central online, the data is included in the SmartList views in the Customers, Vendors, and Items lists. Technically, the data is stored in table extensions.

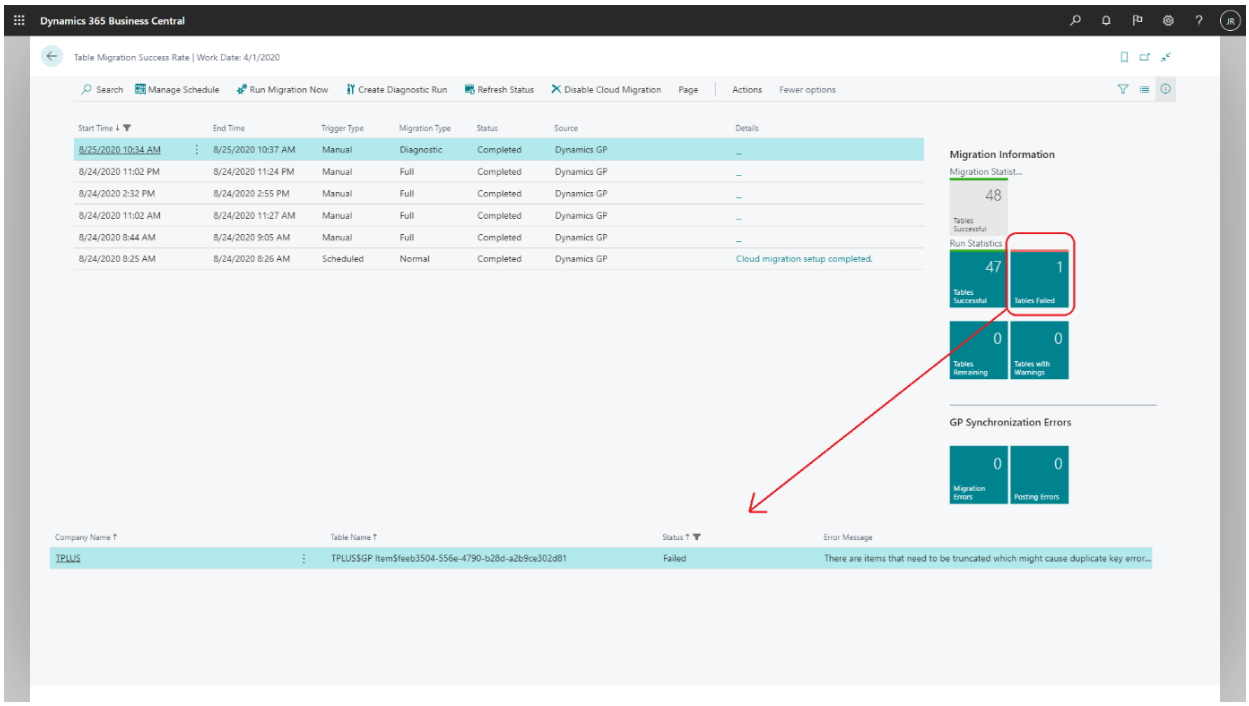
6. Checkbooks and outstanding transactions in Bank Reconciliation. We strongly recommend that you reconcile your checkbooks before you run the migration process to Business Central as we will bring over transactions that have not been reconciled during the migration process.

Diagnostics run

In the **Cloud Migration Management** page, you can create a diagnostics run to do more data validation/verification before the migration is run so that you can decrease the risk of a failed migration.

The maximum field length is different in Dynamics GP (30) and Business Central (20), and the diagnostics run checks for issues and shows warnings. The tool also checks item numbers to look for duplicates based on the character limit, and it checks to make sure there are no blank posting accounts that are needed for posting of transactions with the migration.

Here is an example of what you might see when you run a diagnostic run:



Migration tool support for Australia

Starting with 2020 release wave 2, organizations in Australia can migrate from Dynamics GP to an Australian version of Business Central online.

The process to run the migration in an Australian Business Central online is the same as running a migration in the other supported countries. However, there is some setup that needs to be done before the migration can be run. To make the changes to the setup, you must run through the cloud migration wizard. When the wizard setup is complete, and companies are fully set up, you must log into the companies that you are planning to migrate and make the following changes

- With transactions that are being migrated, we bring over totals on the invoices for the customers so GST information is already included in the transactions. You must turn off the GST and Adjustment Mandatory features in the **General Ledger Setup** page to allow the transactions to post during the migration. After the migration is complete, you can turn both GSP and Adjustment Mandatory back on so that new transactions that are entered in Business Central online will use this functionality.
- Within the posting process there is validation to look for a blank VAT business posting group and VAT product posting group. This combination isn't setup by default and is needed for the migration. So add a VAT posting configuration in the **VAT Posting Setup** page with blank values for the **VAT Bus Posting Group** and **VAT Prod. Posting Group** fields.

Move your Dynamics GP database to Azure Data Lake

Starting with 2020 release wave 2, you can create a copy of the Dynamics GP database in Azure Data Lake so that you have it for future reference after the migration to Business Central online. To take advantage of this functionality, there are some pieces that must be set up before the migration process. A customer is not required to copy their database to Azure Data Lake, but there are several benefits to being able to do so, including having access to the historical data that is not migrated by the migration tool. For an introduction to Azure Data Lake, see azure.microsoft.com.

To create an Azure Data Lake storage account, you log in to your Azure subscription (or sign up for an Azure subscription). Once logged into the Azure portal, you can create a storage account. Under the **Access Keys** section of the information about your storage account in the Azure portal, you can see the keys that you must provide in the cloud migration wizard in Business Central. For more information about Azure Data Lake and

setting up a storage account, see Azure documentation.

To move to Azure Data Lake

1. In your Business Central online tenant, choose the icon, enter **Cloud Migration Management**, and then choose the related link.

2. Choose the **Azure Data Lake** action.

   The **Azure Data Lake Migration Setup** guide takes you through the steps to connect your on-premises Dynamics GP database and your storage in Azure Data Lake. You must have created an Azure Data Lake storage account before launching the assisted setup, and you must have access to the storage account name and storage account key.

3. When the setup completes, you can monitor the progress of moving your data from on-premises to Azure Data Lake in the **Cloud Migration Management** page in Business Central.

If you go back to the Azure portal, you can see the data that was moved from your Dynamics GP database to Azure Data Lake. Under the containers section of the Data Lake storage, a new *gp-database* folder contains the company/system databases, and sub-folders contain the series folder and data files.

The database folder in Azure Data Lake will always be set as *gp-database*. If you want to rename it, you can do so after the migration has competed. The same applies to the various sub-folders. The folders created follow the standard naming convention of the *series* folders in Dynamics GP. An additional folder, *3rd Party*, will be created, and any files that haven't be mapped to a folder will reside in there. You can modify the content in the folders after the migration has completed.

If an Azure Data Lake migration has already been run in the Business Central company and you launch a second run, the migration tool will check to see if a *gp-database* folder exists. If you still want to run the migration again, you must delete the *gp-database* folder and its contents before you can run the wizard again.

At the end of the migration, you have a completely copy of your Dynamics GP database in the cloud with all the advantages of having access to historical data without having to maintain a server on-premises.

Important Information and Considerations for Before Upgrading to Dynamics 365 Business Central Spring 2019 and Later Versions

2/17/2021 • 5 minutes to read • Edit Online

Depending on which version you are upgrading from, and the degree to which your solution differs from the standard version of Business Central, you may want to prepare your solution for the upgrade. This topic provides important information and tips for things to consider when you prepare to upgrade to Business Central.

Migrate from Dynamics NAV to Business Central online

You can upgrade to Business Central online from supported versions of Dynamics NAV on-premises, provided that your application customization is handled by extensions. Any data from tables with code customizations cannot be carried forward from Dynamics NAV.

> **NOTE**
> Upgrade your solution to Business Central Spring 2019 (version 14) or later, and then migrate to Business Central online.

The process consists of two parts:

- Upgrade from Dynamics NAV to Business Central using the tools described in Upgrading to Business Central on-premises (version 14). For more information, see Supported Upgrade Paths to Dynamics 365 Business Central Releases.
- Convert non-standard functionality and customizations to apps and per-tenant extensions. For more information, see Deploying a Tenant Customization.
- Run the cloud migration tool as described in Running the Cloud Migration Tool, and then switch to use Business Central online going forward.

Upgrading from Dynamics NAV

This section lists specific changes between Dynamics NAV and Business Central.

Codeunit 1 has been deprecated and replaced

Dynamics NAV included codeunit **1 ApplicationManagement**. In Business Central, this codeunit has been retired, and new 'system' codeunits have been introduced in the 2 billion range.

For information, see Transitioning from Codeunit 1 to System Codeunits.

V1 Extensions have been discontinued

With Business Central, extensions V1 are no longer supported for on-premise installations. As a result, any custom extensions V1 must be converted to extensions V2 in the old environment before upgrading to Business Central.

For information about how to convert to extensions V2, see Converting Extensions V1 to Extensions V2.

MenuSuite not used for page and report search

With Business Central, the MenuSuite is no longer used to control whether a page or report can be found in the

search feature of the Web client. This is now determined by specific properties on the page and report objects. As part of the application code upgrade process, you change these properties on existing pages and reports used by the MenuSuite to ensure that they are still searchable from the Web client. For more information, see Making Pages and Reports Searchable After an Upgrade.

Dynamics 365 Sales integration

Because of changes in Dynamics 365 Sales and the integration since pervious releases, if your application is integrating with Dynamics 365 Sales, then you must perform a full upgrade instead of just a technical upgrade.

New and changed application features

There a several new and changed application features available in Business Central April 2019 for users, administrators, and developers. For an overview of these features, see Overview of Dynamics 365 Business Central April '19 release.

To take advantage of these all these features, you will have to perform an application code upgrade, not just a technical (platform) upgrade.

Changes to profiles in the CRONUS International Ltd. demonstration database and promoted actions

With the Business Central April 2019 release, profiles that are part of the CRONUS International Ltd. demonstration database, such as the **Sales Order Processor** profile, customize fewer pages compared to earlier releases. For customers that rely on these profiles, their users might experience slight differences in the layout of actions in the action bar on pages. Additionally, the layout of promoted actions on over 380 core application pages has been fine-tuned.

To ensure that users are not disrupted by these changes, we recommend that administrators and partners who are upgrading a customer to Business Central April 2019, review the layout of promoted actions when combined with their own code and profile customization.

Names of variables

Business Central introduces new methods and statements. If your solution includes variables where the name is now used by a standard AL method or statement such as REGISTERTABLECONNECTION or FOREACH, you must change the variables before you upgrade to Business Central. Alternatively, you can enclose the variable names in quotation marks. If you do not, and you import an object that has this code in text format, you cannot compile the object.

Deprecated or redesigned functionality

If you are upgrading a solution that depends on functionality that is deprecated or changed in the default version of Business Central, you must verify that the upgrade codeunits migrate data correctly. See the See Also section for links to descriptions of deprecated functionality.

Deprecated fields and fields marked as obsolete

Sometimes Microsoft will refactor code so that fields are no longer used, or the functionality is moved from the base application to an extension, for example. Typically, the upgrade toolkit will manage the upgrade impact, but for transparency, you can find a list of fields that are deprecated in the current release or marked to be obsolete in a later release. For more information, see Deprecated Fields, and Fields Marked as Obsolete.

Upgrade codeunits

When you introduce changes to the database schema, Business Central will check if these changes are

destructive or not. If the database check indicates that the change may lead to data deletion, such as if you are dropping a table column so that the contents of that column will be deleted, this is considered a destructive change. You will be prompted to handle the situation using upgrade codeunits.

Company names

If a company name includes a special character, an error may display during the upgrade. In this context, special characters include the following:
[~ @ # $ % & * ( ) . ! % - + / = ?]

If you are going to upgrade a database where one or more company name includes a special character, we recommend that you rename the company before you start the upgrade process. After the upgrade is successfully finished, you can rename the company again.

System tables with non-English names

In older versions of Dynamics NAV, you could translate the columns in system tables to a language other than English. Starting with version 3.0, we advised heavily against this, and versions later than Microsoft Dynamics NAV 2013 R2 require that all columns in all system tables are in English. As a result, if you try to open a database with non-English system tables in Microsoft Dynamics NAV 2013 R2 or later, an error displays, saying that one or more columns do not exist.

Make sure that all objects where compiled in a development environment with the right .ETX and .STX files. You can verify that you are running in the correct environment with English (US) as the base language by opening the **ndo$dbproperty** table in SQL Server Management Studio. In the **Identifiers** column, the word `Object` must be written exactly as shown here.

FAQ about Connecting to Business Central Online from On-Premises Solutions

2/17/2021 • 7 minutes to read • Edit Online

This section contains answers to frequently asked questions about connecting on-premises solutions to Business Central online.

> **TIP**
> Check the tips in this article if your organization is not yet ready to migrate to Business Central online but still wants to enjoy some of the benefits of the cloud. The same tips apply to when you are migrating to the cloud and are running the migration tool. For more information, see Running the Cloud Migration Tool.

Which products and versions are supported for this connection?

The current version of Business Central can connect the following products in order to provide intelligent insights:

- Dynamics GP (supported major versions)
- Business Central on-premises

  Currently, you can migrate to Business Central online from versions 14, 15, 16, and 17.

If you are currently on a version of Dynamics NAV, you must upgrade to Business Central on-premises, and then switch to Business Central online. For more information, see Upgrading from Dynamics NAV to Business Central online.

System requirements

To connect to the cloud through Business Central, the on-premises solution must use SQL Server 2016 or a later version, and the database must have compatibility level 130 or higher. The on-premises solution must also be one of the supported versions.

How is my on-premises data replicated to my Business Central online tenant?

Data is replicated using an Azure service called Azure Data Factory (ADF). ADF is a service that is always running within the Business Central online service manager. When you have connected to the intelligent cloud, a data pipeline is created in the ADF service so that data can flow from your on-premises solution to your Business Central online tenant. If your data source is a local SQL Server instance, you will also be asked to configure a self-hosted integration runtime (SHIR). The runtime is installed locally and manages the communication between the cloud services and your on-premises data without opening any ports or firewalls.

Are there any limits on the amount or type of data will replicate?

There are no restrictions on the type of data that can be replicated. In the current version of Business Central, the migration tool is by default limited to migrate databases up to 80 GB. If your database is larger than 80 GB, we recommend that you reduce the number of companies that you are migrating data for. You can specify which companies to include in the migration in the assisted setup wizard.

If you want to add more companies after the first selection of companies, you can add additional companies in the **Cloud Migration Management** page in Business Central online. For more information, see Adding a tenant to an existing runtime service, or updating companies.

If you are looking at migrating databases larger than 80 GB, we recommend that you contact the support team and work with them to make sure that the migration is successful.

Is my SQL connection string required to set up the connection?

Yes. The SQL connection string is passed to Azure Data Factory, where it is encrypted and delivered to your Self-Hosted Integration Runtime. The connection string is used to communicate with your SQL Server instance during the data replication process. For more information, see How do I find my SQL connection string?.

How do I find my SQL connection string?

Find the connection string to your SQL database in SQL Management Studio or Visual Studio. The user name and password defined in the connection requires a SQL Authenticated user name/password. Your connection string will look something like this:

Server=tcp:{ServerName},1433;Initial Catalog={DatabaseName};Persist Security Info=False; User ID={UserName};Password={Password};MultipleActiveResultSets=False;Encrypt=True;TrustServerCertificate=True;Connection Timeout=30;

How do I find the Integration Runtime name?

Find the Integration Runtime name in the Microsoft Integration Runtime Manager, which you can find in your Windows system tray or by searching for the program. You must type the name. You will not be able to copy and paste the name.

I am a hosting partner - do I need to configure the Self-Hosted Runtime Service for each tenant?

No, there is no limit on the number of tenants that can be added to your Self-Hosted Integration Runtime. Each added tenant will have a dedicated pipeline created.

Will data from tables with code customizations replicate?

No, only tables that are available in both your on-premises solution and your Business Central online tenant will replicate. Any customization must be made into an extension and installed on both your on-premises solution and your Business Central online tenant to replicate.

Why are my permissions restricted in the Business Central online tenant?

When you connect your on-premises solution to Business Central online for intelligent insights, all existing users are automatically added to the *Intelligent Cloud* user group, unless they have the SUPER permission set. In this configuration, your on-premises solution is the master where all business transactions take place. The Business Central online environment is read-only, and the data is used to generate intelligent business insights based on your on-premises data for you. We restrict permissions to prevent users from accidentally entering transactions or updating master records only to have that information overwritten and lost when data replication takes place.

Can I 'turn off' my intelligent cloud?

You can switch off your connection to the Business Central online environment at any point. Once you disable

your intelligent cloud configuration, your on-premises solution and the Business Central online tenant will become independent of one another. If you switch off the connection, and you want to use your Business Central online environment as your primary solution to run and manage your business, you must reassign permissions to provide read/write access to the relevant users.

For more information, see Managing Users and Permissions.

Will my on-premises users and permissions replicate?

No. Since you are not required to configure your on-premises solution with Azure Active Directory (Azure AD), we cannot guarantee a mapping between on-premises users and users in your Business Central online tenant. Business Central online requires Azure AD accounts, and users must be manually added. All permissions must be granted in the Business Central tenant, independent from your on-premises permissions.

For more information, see Managing Users and Permissions.

Can I view insights from cloud services in my on-premises solution?

Yes, the **Intelligent Cloud Insights** page can be hosted within your on-premises solution if that is one of the currently supported solutions. Each user will need to have a Business Central license to view the data.

Can you export to Excel, modify the contents, and import the data back in?

You can export the list to Excel from the Business Central online tenant, but since the data is read-only you cannot make changes and import it again.

Is the data replication only one way?

Yes, data is only replicated from the on-premises solution to your Business Central online tenant.

Is there a cost to connect to the intelligent cloud?

Currently, the only costs associated with the intelligent cloud are your named user license costs. For more information, see the Business Central Licensing Guide (download).

Why did my Role Center change after configuring the intelligent cloud?

To keep the Role Center experience as clean as possible and avoid permission errors, we automatically hide actions that would generate a permission error for the user.

Should I uninstall all my Business Central extensions?

Not necessarily. Most extensions will run without issues in the online environment. You may want to consider uninstalling extensions that send data to an external service to avoid potential duplicated calls to that service. It is a best practice to test any extension in a sandbox tenant configured for the Business Central online environment that you are connecting to.

How do I build an extension that enables data replication?

The extension must be created in the same manner as any other extension. For data to replicate, you must add a **ReplicateData** property to your table and set the value to *True*. If your extension connects with an external service and you want to restrict any service calls from your Business Central online tenant, a good practice

would be to store the connection information in a separate table and set the **ReplicateData** property to *False*. This would enable you to keep the extension installed but prevent it from making any type of service calls from the read-only Business Central tenant. Once the extension is installed in Business Central online and on-premises, the data will begin to replicate.

Migrating On-Premises Data to Business Central Online

Troubleshooting Cloud Migration

2/17/2021 • 6 minutes to read • Edit Online

In this article, you learn how to troubleshoot problems that you may experience with the cloud migration of Business Central. For the cloud migration to work properly, there are certain requirements that must be met on the online and on-premises databases. The following sections talk about these requirements, how you can check them, and correct them as needed.

SQL Server compatibility level

> Database: on-premises

The SQL Server compatibility level must be 130 or higher.

To check the compatibility level run following query:

```
SELECT compatibility_level FROM sys.databases WHERE name = 'YourDatabaseName';
```

To change the compatibility level, run this query:

```
ALTER DATABASE YourDatabaseName SET COMPATIBILITY_LEVEL = 130;
```

> **NOTE**
> You may also get the following error when compatibility level isn't set to the expected value: "A database operation failed with the following error: Invalid length parameter passed to the LEFT or SUBSTRING function."

Migration user

> Database: on-premises

Make sure that the database user that the Integration Runtime uses to connect to your database has access to the database.

You can verify the database user, for example, by running the following command using Microsoft PowerShell ISE.

```
sqlcmd -S 'ServerName\ServerInstance' -d 'DatabaseName' -U 'UserID' -P 'Password' -Q 'select * from [dbo].
[CRONUS USA, Inc_$Accounting Period$437dbf0e-84ff-417a-965d-ed2bb9650972]'
```

Change tracking

> Database: on-premises

Change tracking must be enabled on the database. It should be enabled automatically. However, if you see an error like **Change tracking is not enabled on table <number>** during migration, you'll have to enable it

manually.

To enable change tracking on your database, run the following query:

```
ALTER DATABASE [YOUR DATABASE] SET CHANGE_TRACKING = ON (CHANGE_RETENTION = 2 DAYS, AUTO_CLEANUP = ON)
```

To enable change tracking on specific tables, run the following query:

```
ALTER TABLE [YOUR TABLE] ENABLE CHANGE_TRACKING
```

User permissions

> Database: online

If a user has problems managing a cloud migration, like starting migration, initializing companies, or migrating data from earlier versions, check that:

- The user has a Business Central license (Essentials or Premium, depending on their solution). We recommend using free Dynamics 365 Business Central Premium Trial subscription for this user.
- The user is assigned the SUPER permission set.

Users without a license, such as internal administrators or delegated administrators, aren't allowed to run the migration.

Self-Hosted Integration Runtime

> Database: on-premises

- Ensure that you're running the latest, compatible version of Microsoft Integration Runtime (IR).

  You can check for and download the latest version from the Microsoft Download Center.

  When downloading and installing Integration Runtime, choose version 5 (IntegrationRuntime_5.x.x.x.msi) only if your machine runs .NET Framework Runtime 4.7.2. Otherwise, or if in doubt, choose version 4 (IntegrationRuntime_4.x.x.x.msi).

  > **IMPORTANT**
  > Running Integration Runtime v5 on a machine that doesn't have .NET Framework Runtime 4.7.2 can cause timeouts when connecting to the on-premise SQL Server, which will break the cloud migration setup.

  Before you install a new Integration Runtime version, uninstall the old version. When you uninstall the old version, choose to delete the user data (such as authentication key and data source credentials) when prompted. Then, install the Integration Runtime again and connect it to the online environment using the new authentication key.

- If you get a "Failed to enable your replication." error when running the**Data Migration Setup** assisted setup, check the IR logs.

  You view the logs by using the **Microsoft Integration Runtime Configuration Manager**, which was installed on-premises as part of the IR installation. Launch **Microsoft Integration Runtime Configuration Manager**, select the **Diagnostics** tab, then select **View Logs** action. You can also use the **Test Connection** feature on the page to verify that your user can connect to the database.

- Synchronization errors can sometimes occur because IR is installed on a laptop or desktop computer where the hibernate feature is turned on.

  The computer where IR is installed ideally shouldn't be switched off, go to sleep, or hibernate. If these conditions happen, the IR may get into an error state. In this case, we recommend that you reinstall the IR and turn off sleep hibernate on the computer.

- Make sure the machine, which you use for hosting IR has plenty of memory (RAM) available. Migration can be interrupted by your machine running out of memory, and you can find this issue described in the IR log. To prevent this situation, avoid running too many migrations simultaneously using the same IR. Every additional parallel migration slows down the overall progress considerably.

If you experience problems with Microsoft Integration Runtime, also see Troubleshoot self-hosted integration runtime.

Migrating between multiple source and destination databases

> Database: online and on-premises

- If you migrate several on-prem databases to several online environments, it's possible to reuse the same IR for these migrations.

  Once you've successfully connected and migrated data into one online environment, you can reuse the IR for another environment. To reuse an IR, enter its name in **Integration Runtime Name** field of **Data Migration Setup** assisted setup, instead of leaving the field blank.

- Use a restored backup when migrating the same on-premise database to different online environments.

  Cloud migration stores some data in the on-premise database. So using the same on-premise database to migrate into another online environment can affect the next synchronization run. If you need to migrate to several online environments, we recommend you make a backup of the on-premise database before enabling the data migration. Then, restore the on-premise database to this backup before setting up migration to another online environment.

- Avoid running several migrations of the same on-prem database to different online environment at the same time.

  If you need to do this type of migration, then migrate data sequentially. First, migrate data into the online environment and disable the migration. Then restore the on-prem database from backup and enable the migration again by providing a connection string to this database. You can use the same Integration Runtime and Authorization key.

- Don't try to migrate data from several on-premise databases into the same online environment at the same time.

  For example, you may have two companies, where each company is in its own on-premise database. If you need to do this type of migration, the migrate data sequentially. First, migrate data from one database into the online environment and disable the migration. Then set up the migration in the same online environment, provide a new connection string to the next on-prem database. You can use the same Integration Runtime and Authorization key.

Product version

> Database: online

- When running the**Data Migration Setup** assisted setup, make sure to select the right product that you

want to migrate from. Depending on which Cloud Migration apps you've installed, the assisted setup will let you choose from three options:

OPTION	WHEN TO USE
Dynamics 365 Business Central	Select this option if you're migrating from the Business Central latest version, currently version 17
Dynamics 365 Business Central - Previous Version	Select this option if you're migrating from the an earlier supported version. Currently, you can migrate to Business Central online from versions 14, 15, 16, and 17.
Dynamics GP	Select this option if you're migrating from the Dynamics GP product.

- When migrating data from Business Central, check the `applicationVersion` field in the `$ndo$tenantdatabaseproperty` table. Set this field to the correct version in the SQL if it's blank or not up to date. The migration code uses the field's value for the following reasons:
  - Verifies that you're migrating from a supported version
  - Verifies that you've selected the right product version in the **Data Migration Setup** assisted setup, like Dynamics 365 Business Central or Dynamics 365 Business Central - Previous Version.
  - Determines which upgrade code will be executed.

    If that field is blank, the migration can't run.

Disabling the Cloud Migration

> Database: online

When you've completed the migration, disable cloud migration by using the **Disable Cloud Migration** action on the **Cloud Migration Management** page. This action properly disengages the synchronization and cleans up the Azure Data Factory resources deployed for this migration.

> **IMPORTANT**
> Just uninstalling the Cloud Migration apps, even with the option to remove the data, won't disable the migration in the same way. If you don't disable **Cloud Migration**, users will experience permission-related errors when they try to modify records in the migrated companies.

Update 17.4 for Microsoft Dynamics 365 Business Central online 2020 release wave 2

2/17/2021 • 2 minutes to read • Edit Online

Would you like to know what has changed in update 17.4? Below you'll find an overview and relevant links to what has been done on hotfixes and regulatory features in this update. In addition, we have gathered some good to know information and links, you might find interesting.

Hotfixes

Find an overview of hotfixes in this article.

Feature changes

- Use recurring journals to allocate balances by dimension values
- The Busines Central app for Microsoft Teams reaches General Availability

Release Plan

If you want to get a comprehensive overview of what's new and planned for Business Central online for the entire 2020 release wave 2 (release from October 2020 through March 2021), find the link to the release plan here.

Upgrade to 17.4

Please note that new customers will automatically get the latest builds of Business Central (17.4). If you are an existing partner/customer, you will receive an email notification as soon as your environment has been upgraded.

Good to know

OData V3 will be removed with 2021 Wave 1
As previously announced, OData Version 3.0 (V3) has been deprecated since April 2020 and support for it will be removed in Dynamics 365 Business Central 2021 release wave 1. OData V4 is the current recommended version of OData and current integrations needs to move to OData V4. To identify incoming OData V3 requests, enable and use the Web Service Request telemetry that's available to partners. Notifications has also been sent via M365 Message Center to tenants with identified usage.

Release Plan for wave 1 2021 is out
The release plan for Dynamics 365 Busines Central wave 1 2021 is now live! You can find an overview of all the new and planned features here.

Basic Authentication
Basic Authentication (Web Service Access Key) removal for Business Central online has been postponed until April 2022. We see that some integrations needs more time to move from Web Service Access Key usage to OAuth. PowerShell samples on how to connect to Business Central is published on GitHub.

Business Central Office Hours Calls in February
Make sure to join the office hours calls around 'Power Platform Integration, Power Apps, and Dataverse' on February 9 and 'Performance Toolkit and Telemetry; How to deploy for performance' on February 23. Register

and stay tuned for the upcoming calls: https://aka.ms/BCOfficeHours.

It's time to switch your Dynamics 365 Business Central browser to Microsoft Edge

On April 2, 2021, Microsoft will remove Internet Explorer 11 and Microsoft Edge Legacy browsers from the list of supported browsers for the Business Central modern clients. Read the details, how it applies to you and actions to take here.

Update 17.3 for Microsoft Dynamics 365 Business Central online 2020 release wave 2

2/17/2021 • 2 minutes to read • Edit Online

Would you like to know what has changed in update 17.3? Below you'll find an overview and relevant links to what has been done on hotfixes and regulatory features in this update. In addition, we have gathered some good to know information and links, you might find interesting.

Hotfixes

Find an overview of hotfixes in this article.

Feature changes

- Restoring environments in Business Central admin center
- Use Shortcut dimensions in G/L Entries for Financial reporting
- Signal from web service key authentication added to Application Insights telemetry for partners
- Handle Price List Exceptions with Allow Updating Defaults

Release Plan

If you want to get a comprehensive overview of what's new and planned for Business Central online for the entire 2020 release wave 2 (release from October 2020 through March 2021), find the link to the release plan here.

Upgrade to 17.3

Please note that new customers will automatically get the latest builds of Business Central (17.3). If you are an existing partner/customer, you will receive an email notification as soon as your environment has been upgraded.

Good to know

Basic Authentication

Basic Authentication (Web Service Access Key) removal for Business Central online has been postponed until April 2022. We see that some integrations needs more time to move from Web Service Access Key usage to OAuth. PowerShell samples on how to connect to Business Central is published on GitHub.

Snapshot debugging is now enabled in production environments

From version 17.2 and forward it is now possible to use snapshot debugging to investigate production environments. For more information, see the help page or view the Virtual Event for 2020 Wave 2 release recording on the What's New in Visual Studio and AL, covering snapshot debugging in details.

Business Central Office Hours Calls in January

Make sure to join the office hours calls around 'Customer Migration Tooling' on January 12 and 'Power Platform Integration – Power BI' on January 26. Register and stay tuned for the upcoming calls: https://aka.ms/BCOfficeHours.

Want to improve the performance of Business Central?

Visit https://aka.ms/bcperformance and learn about best practices, dos and don'ts and different ways to make

changes with a performance impact. The Performance Tuning Guide will help you understand and improve the performance of Business Central whether you are a functional consultant, a developer, or an administrator.

It's time to switch your Dynamics 365 Business Central browser to Microsoft Edge

On April 2, 2021, Microsoft will remove Internet Explorer 11 and Microsoft Edge Legacy browsers from the list of supported browsers for the Business Central modern clients. Read the details, how it applies to you and actions to take here.

Update 17.2 for Microsoft Dynamics 365 Business Central online 2020 release wave 2

2/17/2021 • 2 minutes to read • Edit Online

Would you like to know what has changed in update 17.2? Below you'll find an overview and relevant links to what has been done on hotfixes and regulatory features in this update. In addition, we have gathered some good to know information and links, you might find interesting.

Hotfixes

Find an overview of hotfixes in this article.

Feature changes

- Application Performance Improvements
- Signal from job queue execution added to Application Insights telemetry for partners
- Signal from permission changes to added to Application Insights telemetry for partners
- Signal from the retention policy feature added to Application Insights telemetry for partners
- Signal from the sensitive field audit feature added to Application Insights telemetry for partners
- Signal from the email feature added to Application Insights telemetry for partners
- Signal from application packages lifecycle added to Application Insights Telemetry for partners
- Snapshot Debugging

Release Plan

If you want to get a comprehensive overview of what's new and planned for Business Central online for the entire 2020 release wave 2 (release from October 2020 through March 2021), find the link to the release plan here.

Upgrade to 17.2

Please note that new customers will automatically get the latest builds of Business Central (17.2). If you are an existing partner/customer, you will receive an email notification as soon as your environment has been upgraded.

Small update for Business Central mobile app

A small update for the Business Central mobile app (with added languages and some fixes) is being released to the app stores on all three platforms (Windows, iOS, and Android). Please remember to update the Business central app on your device (version 3.1.12032 or later). Direct links: Windows (Microsoft Store), iOS (Apple's App Store), Android (Google's Play Store).

Migrate directly from version 14, 15, and 16 to Business Central online

Business Central includes a cloud migration tool that administrators can use to migrate customer data from on-premises databases to Business Central online. Starting now, the Cloud Migration app also supports migration from the earlier on-premises versions of Business Central, with the latest cumulative update applied: Migrate directly from versions 14.x, 15.x, and 16.x to version 17.x. This helps customers reduce their costs of migrating to the Business Central cloud significantly, as they can skip upgrading their on-premises environments to the latest version of Business Central and just migrate the data, including all historical transactions. The Cloud Migration app now includes all the necessary data upgrade logic to convert the data from the previous versions to the data structure of 2020 release wave 2 (version 17.0). Learn more here.

Update 17.1 for Microsoft Dynamics 365 Business Central online 2020 release wave 2

2/17/2021 • 3 minutes to read • Edit Online

Would you like to know what has changed in update 17.1? Below you'll find an overview and relevant links to what has been done on hotfixes and regulatory features in this update. In addition, we have gathered some good to know information and links, you might find interesting.

Hotfixes

Find an overview of hotfixes in this article.

Feature changes

- Enhanced email capabilities
- Notify users of high-risk changes in selected setup fields
- Use new sales pricing experience
- Control how Account Schedules for core financial reports are generated
- Improved VAT Registration no. lookup
- Extension lifecycle telemetry in Application Insights for ISVs
- Use environmentType and environmentName launch.json properties instead of obsoleted sandboxName
- Symbols can be downloaded with a snapshot initialize launch.json configuration, using above environment properties

Release Plan

If you want to get a comprehensive overview of what's new and planned for Business Central online for the entire 2020 release wave 2 (release from October 2020 through March 2021), find the link to the release plan here.

Upgrade to 17.1

Please note that new customers will automatically get the latest builds of Business Central (17.1). If you are an existing partner/customer, you will receive an email notification as soon as your environment has been upgraded.

Good to know

NEW! Migrate directly from version 14, 15, and 16 to Business Central online
Business Central includes a cloud migration tool that administrators can use to migrate customer data from on-premises databases to Business Central online. Starting now, the Cloud Migration app also supports migration from the earlier on-premises versions of Business Central, with the latest cumulative update applied: Migrate directly from versions 14.x, 15.x, and 16.x to version 17.x. This helps customers reduce their costs of migrating to the Business Central cloud significantly, as they can skip upgrading their on-premises environments to the latest version of Business Central and just migrate the data, including all historical transactions. The Cloud Migration app now includes all the necessary data upgrade logic to convert the data from the previous versions to the data structure of 2020 release wave 2 (version 17.0). Learn more here.

Database size when migrating from Business Central on-prem to online

We have increased the limit we apply to the database size from 30 Gb to 80 Gb when migrating from Business Central on-prem to Business Central online using the Cloud Migration tool. If you are looking at migrating a larger database, we recommend that you contact the support team and work with them to make sure that the migration is successful. Learn more here and read about running the cloud migration tool here.

Watch what's new sessions on demand

Watch the sessions from the Business Central Launch Event in October. Register and get access to 30+ sessions here.

Snapshot debugging

Snapshot debugging has now been enabled for sandbox environments. It will be enabled in production in a later minor. Learn more here.

Apps are moving to office.com

The home for all your business applications across Dynamics 365 and Microsoft Power Platform is moving to office.com, where you'll find the Business Central tiles for production and sandbox environments. Learn more here.

Easy access to production or sandbox environments from the mobile app

Users of mobile devices can now choose between their sandbox and production environments without the need to use the pre-crafted URL as before. Partners running their own apps based on Business Central can also let their users explore it from mobile devices. Learn more here.

Unblock multifactor authentication for mobile apps

We have updated core authentication components of the mobile app to support multifactor authentication. Enabling such flow in the user setting on your Microsoft 365 account and then using it on a mobile device (via an SMS code, authenticator app, or more) is now possible after updating the Business Central mobile app to version 3.0 or higher. Learn more here.

Update 16.5 for Microsoft Dynamics 365 Business Central online 2020 release wave 1

2/17/2021 • 2 minutes to read • Edit Online

Would you like to know what has changed in update 16.5? Below you'll find an overview and relevant links to what has been done on hotfixes and regulatory features in this update. In addition, we have gathered some good to know information and links, you might find interesting.

Feature changes

- Delete extension data

Release Plan

If you want to get a comprehensive overview of what's new and planned for Business Central online for the entire 2020 release wave 1 (release from April 2020 through September 2020), find the link to the release plan here.

For a list of next wave release plans, see the 2020 release wave 2 release plan.

Upgrade to 16.5

Please note that new customers will automatically get the latest builds of Business Central (16.5). If you are an existing partner/customer, you will receive an email notification as soon as your environment has been upgraded.

Good to know

It's time to switch your Dynamics 365 Business Central browser to Microsoft Edge
On April 2, 2021, Microsoft will remove Internet Explorer 11 and Microsoft Edge Legacy browsers from the list of supported browsers for the Business Central modern clients. Read the details, how it applies to you and actions to take here.

Leveraging IoT data in Dynamics 365 Business Central
Make sure to read the blog about getting started with leveraging the Internet of Things (IoT) data in Dynamics 365 Business Central using services from Microsoft Azure is easier than you may think.

Support for an unlimited number of production and sandbox environments
With 2020 release wave 2 (October), we're introducing the ability for customers to buy additional Business Central production environments to expand their business. More environments will open up new opportunities like creating more business branches, moving into more countries, or expanding within their current country, read more here.

Running a Container-Based Development Environment
From 16.4 and onwards Microsoft will stop producing docker images and instead publish builds as artifacts, which can be used together with the generic Docker image to run the image you want. Read more here.

Update 16.4 for Microsoft Dynamics 365 Business Central online 2020 release wave 1

2/17/2021 • 2 minutes to read • Edit Online

Update 16.2 for Microsoft Dynamics 365 Business Central online 2020 release wave 1

2/17/2021 • 2 minutes to read • Edit Online

Would you like to know what has changed in update 16.2?
Below you'll find an overview and relevant links to what has been done on hotfixes and regulatory features in this update. In addition, we have gathered some good to know information and links, you might find interesting.

Hotfixes

Link to Hotfixes

Feature changes

- Migrate data from Business Central 14.x on-premises to Business Central 15.x online
- Update error telemetry in Application Insights for partners
- New URL parameter hides web client header
- Improved user experience to keep things from going wrong
- Use modern authentication to connect to Microsoft Dataverse and Dynamics 365 Sales
- Installing AppSource apps updates in the Business Central administration center – please note gradual availability! Until the feature is generally available, some AppSource apps can't be updated using this feature. For information about the timeline, see here

Release Plan

If you want to get a comprehensive overview of what's new and planned for Business Central online for the entire 2020 release wave 1 (release from April 2020 through September 2020), find the link to the release plan here.

Upgrade to 16.2

Please note that new customers will automatically get the latest builds of Business Central (16.2). If you are an existing partner/customer, you will receive an email notification as soon as your environment has been upgraded.

Good to know

A change to the Web client header
The top-most header in the Business Central Web client and desktop app have been updated to align with other Microsoft 365 and Dynamics 365 apps. The most notable change is to the height of the header that has now been reduced to 48 pixels.

Warning of performance impact when using configuration packages to import data
Configuration packages were designed to speed up the implementation of new companies. In case a customer wants to use Configuration Packages as a quick way to import data -sometimes big data- from other systems to Business Central, this small feature analyzes if the import will bring data to a new company or not and, depending of that and the size of the package, alerts the user that the performance of its tenant could be affected suggesting other ways to import or request partner help.

Update 15.3 for Microsoft Dynamics 365 Business Central 2019 online release wave 2

2/17/2021 • 2 minutes to read • Edit Online

Would you like to know what has changed in update 15.3? Below you'll find an overview and relevant links to what has been done on hotfixes and regulatory features in this update.

Hotfixes

Link to Hotfixes

Feature changes

- View Your Reference and External Document No. on sales documents
- Skip empty lines in the Account Schedule report
- MICR fonts available in Business Central online
- New events to unblock printer extensions in Business Central online
- Bookmarking a report
- Sign-in attempt telemetry in Application Insights for partners

Release Plan

If you want to get a comprehensive overview of what's new and planned for Business Central online for the entire wave 2 (release from October 2019 through March 2020), find the link to the release plan here

Upgrade to 15.3

Please note that new customers will automatically get the latest builds of Business Central (15.3). If you are an existing partner/customer, you will receive an email notification as soon as your environment has been upgraded.

Good to know

- Changes to Browser Cookie Policy
  Avoid disruption by following these steps to prepare for tighter security policies starting February 2020 in Google Chrome and Microsoft Edge. For more information, see Preparing Dynamics NAV or Dynamics 365 Business Central for Upcoming Changes to Browser Cookie Policy.

- Using Internet Explorer
  From Update 15.3 onwards, users who access Business Central from Internet Explorer will receive a notification suggesting they consider a different browser. Users who switch to a modern browser, such as Microsoft Edge, typically observe improved performance and a generally smoother experience. Learn more about our supported and recommended browsers for Business Central on premises and online.

- To support partners who are interested in monetizing the app they have published to AppSource, update 15.3 comes with new options. These options allow partners to understand number, type and state of Business Central licenses in the current tenant as well as number of allocated seats. That data enables the partner to implement user-based billing into their apps. To learn more, see Azure AD Licensing.

- Visit our new aka.ms/bcperformance page and start your learning about Business Central performance.

Update 15.2 for Microsoft Dynamics 365 Business Central 2019 online release wave 2

2/17/2021 • 2 minutes to read • Edit Online

Would you like to know what has changed in update 15.2? Below you'll find an overview and relevant links to what has been done on hotfixes and regulatory features in this update.

Hotfixes

Link to Hotfixes

Feature changes

- Add the Name 2 field to customer and vendor cards
- Include job information in archived sales and purchase documents
- Use VAT clauses on different document types
- View item availability by unit of measure
- View the number of general journal lines

Release Plan

If you want to get a comprehensive overview of what's new and planned for Business Central online for the entire wave 2 (release from October 2019 through March 2020), find the link to the release plan here

Upgrade to 15.2

Please note that new customers will automatically get the latest builds of Business Central (15.2). If you are an existing partner/customer, you will receive an email notification as soon as your environment has been upgraded.

Good to know

Please find an overview of new "How to videos" recently published on Dynamics 365 YouTube channel for the Business users and the Functional Consultants. These videos complement the extensive MS Learn and Documentation content already available for Business Central.

- How to set up an inventory location
- How to create purchase order
- How to email documents
- How to set up documents sending profiles
- How to setup categories
- How to set up customer approval workflow
- How to open a new fiscal year (part of payment methods)

Building Your First Sample Extension With Extension Objects, Install Code, and Upgrade Code

2/17/2021 • 16 minutes to read • Edit Online

This walkthrough will guide you through all the steps that you must follow to create a sample extension in AL. New objects and extension objects will be added to the base application for a simple reward feature for customers. Every section of this exercise includes code that serves for installing, customizing, or upgrading this sample extension. The final result can be published and installed on your tenants.

About this walkthrough

This walkthrough illustrates the following tasks:

- Developing a sample extension with a table, a card page, and a list page.
- Deploying the sample extension to your development sandbox environment.
- Using the Dynamics 365 Business Central Designer to modify visual aspects of the extension.
- Creating extension objects that can be used to modify page and table objects.
- Initializing the database during the installation of the extension.
- Upgrading and preserving data during the upgrade of the extension.

Prerequisites

To complete this walkthrough, you will need:

- The Dynamics 365 Business Central tenant.
- Visual Studio Code.
- The AL Language extension for Visual Studio Code.

For more information on how to get started with your first extension for Dynamics 365 Business Central, see Getting Started.

Rewards extension overview

The extension enables the ability to assign one of three reward levels to customers: GOLD, SILVER, and BRONZE. Each reward level can be assigned a discount percentage. Different types of objects available within the AL development environment will build the foundation of the user interface, allowing the user to edit the information. If you look for another option to update the layout of a page, you can use the Designer drag-and-drop interface. Additionally, this exercise contains the install code that will create the base for the reward levels. The upgrade code is run to upgrade the extension to a newer version and it will change the BRONZE level to ALUMINUM. Following all the steps of this walkthrough allows you to publish the extension on your tenant and create a possible new feature for your customers.

Reward table object

The following code adds a new table **50100 Reward** for storing the reward levels for customers. The table consists of three fields: **Reward ID**, **Description**, and **Discount Percentage**. For example, the **Description**

field must contain a value of type text and it cannot exceed the limit of 250 characters. The second field contains three properties that are used to set the range of the discount percentage assigned to every customer. Properties can be created for every field, depending on the scope.

> **TIP**
>
> Type `ttable` followed by the Tab key. This snippet will create a basic layout for a table object.

```
table 50100 Reward
{
    DataClassification = ToBeClassified;

    fields
    {
        // The "Reward ID" field represents the unique identifier
        // of the reward and can contain up to 30 Code characters.
        field(1;"Reward ID";Code[30])
        {
            DataClassification = ToBeClassified;
        }

        // The "Description" field can contain a string
        // with up to 250 characters.
        field(2;Description;Text[250])
        {
            // This property specified that
            // this field cannot be left empty.
            NotBlank = true;
        }

        // The "Discount Percentage" field is a Decimal numeric value
        // that represents the discount that will
        // be applied for this reward.
        field(3;"Discount Percentage";Decimal)
        {
            // The "MinValue" property sets the minimum value for the "Discount Percentage"
            // field.
            MinValue = 0;

            // The "MaxValue" property sets the maximum value for the "Discount Percentage"
            // field.
            MaxValue = 100;

            // The "DecimalPlaces" property is set to 2 to display discount values with
            // exactly 2 decimals.
            DecimalPlaces = 2;
        }
    }

    keys
    {
        // The field "Reward ID" is used as the primary key of this table.
        key(PK;"Reward ID")
        {
            // Create a clustered index from this key.
            Clustered = true;
        }
    }
}
```

For more information about table properties, see Table Properties.

Reward card page object

The following code adds a new page **50101 Reward Card** for viewing and editing the different reward levels that are stored in the new **Reward** table. Pages are the primary object that a user will interact with and have a different behavior based on the type of page that you choose. The **Reward Card** page is of type Card and it is used to view and edit one record or entity from the **Reward** table.

> **TIP**
> Use the snippet `tpage, Page` to create the basic structure for the page object.

```
page 50101 "Reward Card"
{
    // The page will be of type "Card" and will render as a card.
    PageType = Card;

    // The page will be part of the "Tasks" group of search results.
    UsageCategory = Tasks;

    // The source table shows data from the "Reward" table.
    SourceTable = Reward;

    // The layout describes the visual parts on the page.
    layout
    {
        area(content)
        {
            group(Reward)
            {
                field("Reward Id";"Reward ID")
                {
                    // ApplicationArea sets the application area that
                    // applies to the page field and action controls.
                    // Setting the property to All means that the control
                    // will always appear in the user interface.
                    ApplicationArea = All;
                }

                field(Description;Description)
                {
                    ApplicationArea = All;
                }

                field("Discount Percentage";"Discount Percentage")
                {
                    ApplicationArea = All;
                }
            }
        }
    }
}
```

For more information about the types of pages in AL, see Pages Overview.

Reward list page object

The following code adds the **50102 Reward List** page that enables users to view the contents of the **Reward** table and edit specific records by selecting them and viewing them in the **Reward Card** page.

TIP

Use the snippet `tpage, Page of type list` to create the basic structure for the page object.

```
page 50102 "Reward List"
{
    // Specify that this page will be a list page.
    PageType = List;

    // The page will be part of the "Lists" group of search results.
    UsageCategory = Lists;

    // The data of this page is taken from the "Reward" table.
    SourceTable = Reward;

    // The "CardPageId" is set to the Reward Card previously created.
    // This will allow users to open records from the list in the "Reward Card" page.
    CardPageId = "Reward Card";

    layout
    {
        area(content)
        {
            repeater(Rewards)
            {
                field("Reward ID";"Reward ID")
                {
                    ApplicationArea = All;
                    ToolTip = 'Specifies the level of reward that the customer has at this point.';
                }

                field(Description;Description)
                {
                    ApplicationArea = All;
                }

                field("Discount Percentage";"Discount Percentage")
                {
                    ApplicationArea = All;
                }
            }
        }
    }
}
```

After you have created the objects, update the **startupObjectId** in the `launch.json` file to 50102, the ID of the **Reward List** page and select the Ctrl+F5 shortcut to see the new page in your sandbox environment. You will be asked to sign in to your Business Central, if you have not already done so.

TIP

Information about your sandbox environment and other environments is stored as configurations in the `launch.json` file. For more information, see JSON Files.

Designer

Dynamics 365 Business Central Designer works in the browser and allows modifying the current page. It enables users to add existing table fields, move fields around, or remove fields from the page. Users can make changes to display the information they need, where they need it by using drag-and-drop components.
To show how the Designer changes the design of a page, you begin by adding two new fields to the **Reward**

table. These fields will be used later on to exemplify the Designer's properties.

```
field(4;"Minimum Purchase";Decimal)
{
    MinValue = 0;
    DecimalPlaces = 2;
}

field(5;"Last Modified Date";Date)
{
    // The "Editable" property sets a value that indicates whether the field can be edited
    // through the UI.
    Editable = false;
}
```

The **Last Modified Date** field requires constant changes to remain accurate. To keep it updated, triggers will be used. Triggers are predefined methods that are executed when certain actions happen. They are added by default when you use the `ttable` template, but you can also use the `ttriger` snippet to add them manually. Now you can add code to the triggers.

```
    // "OnInsert" trigger executes when a new record is inserted into the table.
    trigger OnInsert();
    begin
        SetLastModifiedDate();
    end;

    // "OnModify" trigger executes when a record in the table is modified.
    trigger OnModify();
    begin
        SetLastModifiedDate();
    end;

    // "OnDelete" trigger executes when a record in the table is deleted.
    trigger OnDelete();
    begin
    end;

    // "OnRename" trigger executes when a record in a primary key field is modified.
    trigger OnRename();
    begin
        SetLastModifiedDate();
    end;

    // On the current record, the value of the "Last Modified Date" field to the current
    // date.
    local procedure SetLastModifiedDate();
    begin
        Rec."Last Modified Date" := Today();
    end;
```

From this point, changes to the **Reward Card** page can be done either manually by adding the code below in Visual Studio Code or by using the Designer's functions to add the same fields. Both ways lead to the same results, but the Designer speeds up the process.

```
field("Minimum Purchase";"Minimum Purchase")
{
    ApplicationArea = All;
}

field("Last Modified Date";"Last Modified Date")
{
    ApplicationArea = All;
}
```

Using the F6 key shortcut in Visual Studio Code launches the browser and enters the Designer. You can also use the Designer from the Business Central client, by selecting  **Designer**.

> **NOTE**
> Every time you start designing, you create a new extension and the changes you make in the Designer will apply to all users.

To add the same fields and customize the **Reward Card** page, follow the next steps:

- Navigate to the **Reward Card** page by choosing **+ new**.
- Enter the Designer mode from the UI and select **More** from the Designer bar.
- Select **Field** from the Designer bar to show the list of available fields.
- Drag the **Minimum Purchase** and **Last Modified Date** fields from the list onto the page in the **Reward group**.
- Choose the **Reward** in the group caption to enable the value to be edited. Change the caption to **Info** and press **Enter**.

After making these adjustments, finish up your design by choosing **Stop Designing**, which allows you to name the extension with an option to download code, and save the extension for the tenant. If you choose not to download the code at the end, you can still pull the changes via the **Alt+F6** key shortcut from Visual Studio Code. You can also uninstall the extension by opening the **Extension Management** page.
For more information about Designer, see Designer.

Customer table extension object

The **Customer** table, like many other tables, is part of the Dynamics 365 Business Central service and it cannot be modified directly by developers. To add additional fields or to change properties on this table, developers must create a new type of object, a table extension. The following code creates a table extension for the **Customer** table and adds the `Reward ID` field.

> **TIP**
> Use the snippet `ttableext` to create a basic structure for the table extension object.

```
tableextension 50103 "Customer Ext" extends Customer
{
    fields
    {
        field(50100;"Reward ID";Code[30])
        {
            // Set links to the "Reward ID" from the Reward table.
            TableRelation = Reward."Reward ID";

            // Set whether to validate a table relationship.
            ValidateTableRelation = true;

           // "OnValidate" trigger executes when data is entered in a field.
            trigger OnValidate();
            begin

            // If the "Reward ID" changed and the new record is blocked, an error is thrown.
                if (Rec."Reward ID" <> xRec."Reward ID") and
                    (Rec.Blocked <> Blocked::" ") then
                begin
                    Error('Cannot update the rewards status of a blocked customer.')
                end;
            end;
        }
    }
}
```

Customer card page extension object

A page extension object can be used to add new functionality to pages that are part of the Dynamics 365 Business Central service. The following page extension object extends the **Customer Card** page object by adding a field control, **Reward ID**, to the **General group** on the page. The field is added in the layout section, while in the actions section the code adds an action to open the **Reward List** page.

> **TIP**
> Use the shortcuts `tpageext` to create the basic structure for the page extension object.

```
pageextension 50104 "Customer Card Ext" extends "Customer Card"
{
    layout
    {
        // The "addlast" construct adds the field control as the last control in the General
        // group.
        addlast(General)
        {
            field("Reward ID";"Reward ID")
            {
                ApplicationArea = All;

                // Lookup property is used to provide a lookup window for
                // a text box. It is set to true, because a lookup for
                // the field is needed.
                Lookup = true;
            }
        }
    }

    actions
    {
        // The "addfirst" construct will add the action as the first action
        // in the Navigation group.
        addfirst(Navigation)
        {
            action("Rewards")
            {
                ApplicationArea = All;

                // "RunObject" sets the "Reward List" page as the object
                // that will run when the action is activated.
                RunObject = page "Reward List";
            }
        }
    }
}
```

At this point, reward levels can be created and assigned to customers. To do that, update the `startupObjectId` value in launch.json to 21 and select the Ctrl+F5 key to open the page.

Help links

This app is relatively straightforward, but we want users of your app to be able to get unblocked and learn more just like all other users of Business Central. First, configure your app to get context-sensitive links to Help, and then apply tooltips to the fields in your pages.

Configure context-sensitive links to Help

At an app level, you can specify where the Help for your functionality is published in the app.json file. Then, for each page in your app, you specify which Help file on that website is relevant for that particular page. For more information, see Configure Context-Sensitive Help.

Open the app.json file, and then change the value of the `contextSensitiveHelpUrl` property to point at the right location on your website. In this example, you publish Help for your app at *https://mysite.com/documentation*.

```
"contextSensitiveHelpUrl": "https://mysite.com/documentation/",
```

Next, you set the ContextSensitiveHelpPage property for the **Reward Card** and **Reward List** pages:

```
    // The target Help topic is hosted on the website that is specified in the app.json file.
    ContextSensitiveHelpPage = 'sales-rewards';
```

The following example illustrates the properties for the **Reward List** page after you have specified the context-sensitive Help page.

```
page 50102 "Reward List"
{
    // Specify that this page will be a list page.
    PageType = List;

    // The page will be part of the "Lists" group of search results.
    UsageCategory = Lists;

    // The target Help topic is hosted on the website that is specified in the app.json file.
    ContextSensitiveHelpPage = 'sales-rewards';

    // The data of this page is taken from the "Reward" table.
    SourceTable = Reward;

    // The "CardPageId" is set to the Reward Card previously created.
    // This will allow users to open records from the list in the "Reward Card" page.
    CardPageId = "Reward Card";

...
```

You can specify the same relative link for **Reward Card**, **Reward List**, and the customization of the **Customer** page, or you can specify different targets. For more information, see Page-level configuration.

Add tooltips

Even the best designed user interface can still be confusing to some. It can be difficult to predict specifically what users will find confusing, and that is why the base application includes tooltips for all controls and actions. For more information, see Help users get unblocked.

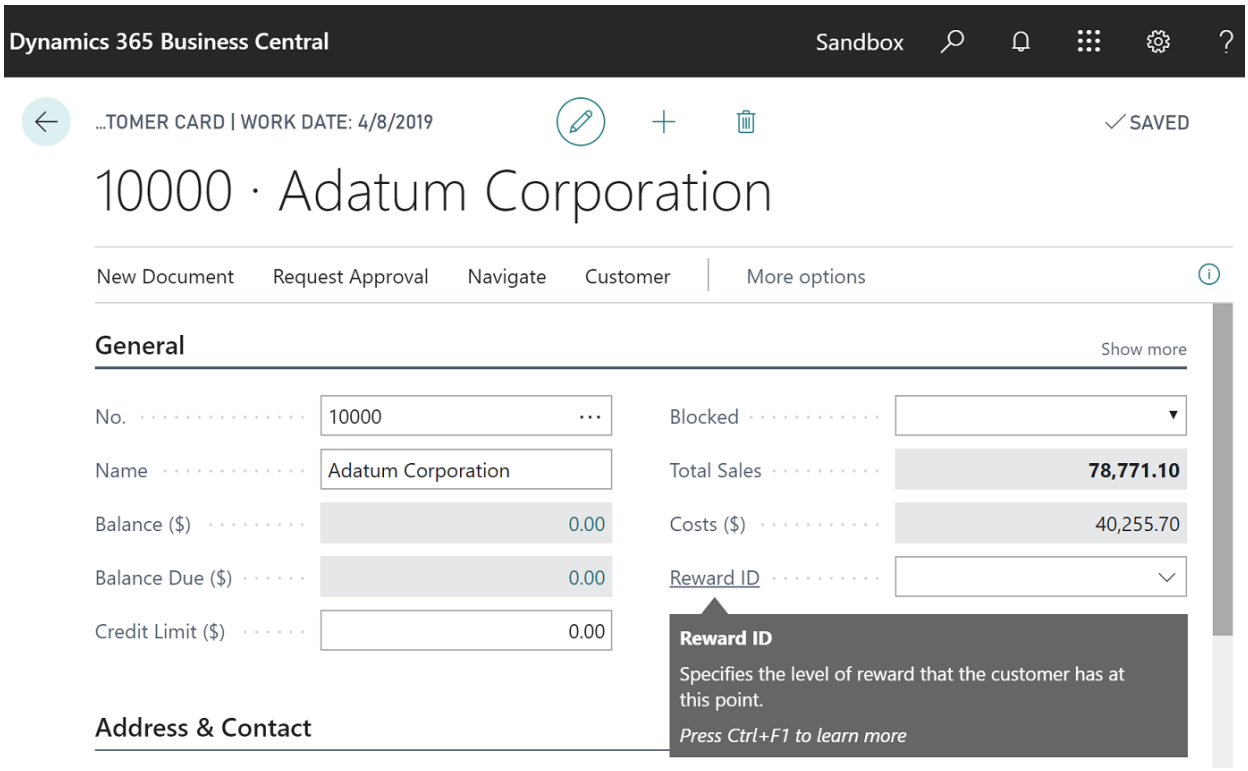
For the purposes of this walkthrough, add the following tooltip to the properties of the **Reward ID** field on all three pages:

```
ToolTip = 'Specifies the level of reward that the customer has at this point.';
```

The following example illustrates the tooltip:

```
field("Reward ID";"Reward ID")
{
ApplicationArea = All;
ToolTip = 'Specifies the level of reward that the customer has at this point.';
}
```

If you now deploy the app, you will be able to read the tooltip text for the **Reward ID** field, and if you choose the *Learn more* link or press Ctrl+F1, a new browser tab opens the equivalent of `https://mysite.com/documentation/sales-rewards`.



Install code

After installing the extension, the **Reward List** page is empty. This is the result of the fact that the **Reward** table is also empty. Data can be entered manually into the **Reward** table by creating new records from the **Reward List** page. However, this task slows down the process, especially because the **Reward** table should be initialized with a standard number of reward levels when the extension is installed. To solve this, install codeunits can be used. A codeunit is an object that can be used to encapsulate a set of related functionality represented by procedures and variables. An install codeunit is a codeunit with the Subtype property set to Install. This codeunit provides a set of triggers that are executed when the extension is installed for the first time and when the same version is re-installed.

In this example, the following install codeunit initializes the **Reward** table with three records representing the 'GOLD', 'SILVER', and 'BRONZE' reward levels.

> **TIP**
> Use the shortcuts `tcodeunit` to create the basic structure for the codeunit.

```
codeunit 50105 RewardsInstallCode
{
    // Set the codeunit to be an install codeunit.
    Subtype = Install;

    // This trigger includes code for company-related operations.
    trigger OnInstallAppPerCompany();
    var
        Reward : Record Reward;
    begin
        // If the "Reward" table is empty, insert the default rewards.
        if Reward.IsEmpty() then begin
            InsertDefaultRewards();
        end;
    end;

    // Insert the GOLD, SILVER, BRONZE reward levels
    procedure InsertDefaultRewards();
    begin
        InsertRewardLevel('GOLD', 'Gold Level', 20);
        InsertRewardLevel('SILVER', 'Silver Level', 10);
        InsertRewardLevel('BRONZE', 'Bronze Level', 5);
    end;

    // Create and insert a reward level in the "Reward" table.
    procedure InsertRewardLevel(ID : Code[30]; Description : Text[250]; Discount : Decimal);
    var
        Reward : Record Reward;
    begin
        Reward.Init();
        Reward."Reward ID" := ID;
        Reward.Description := Description;
        Reward."Discount Percentage" := Discount;
        Reward.Insert();
    end;

}
```

For more information about install code, see Writing Extension Install Code.

Upgrade code

When you upgrade an extension to a newer version, if any modifications to the existing data are required to support the upgrade, you must write upgrade code in an upgrade codeunit. In this example, the following upgrade codeunit contains code that changes the BRONZE reward level to customer records to ALUMINUM. The upgrade codeunit will run when you run the Start-NAVAppDataUpgrade cmdlet.

> **IMPORTANT**
>
> Remember to increase the `version` number of the extension in the app.json file.

```
codeunit 50106 RewardsUpgradeCode
{
    // An upgrade codeunit includes AL methods for synchronizing changes to a table definition
    // in an application with the business data table in SQL Server and migrating existing
    // data.
    Subtype = Upgrade;

    // "OnUpgradePerCompany" trigger is used to perform the actual upgrade.
    trigger OnUpgradePerCompany();
    var
        InstallCode : Codeunit RewardsInstallCode;
        Reward : Record Reward;

        // "ModuleInfo" is the current executing module.
        Module : ModuleInfo;
    begin
        // Get information about the current module.
        NavApp.GetCurrentModuleInfo(Module);

        // If the code needs to be upgraded, the BRONZE reward level will be changed into the
        // ALUMINUM reward level.
        if Module.DataVersion.Major = 1 then begin
            Reward.Get('BRONZE');
            Reward.Rename('ALUMINUM');
            Reward.Description := 'Aluminum Level';
            Reward.Modify();
        end;
    end;
}
```

For more information about writing and running upgrade code, see Upgrading Extension.

Instrumenting your app with telemetry

Business Central emits telemetry data for several operations that occur when extension code is run. Create an Application Insights resource in Azure if you don't have one. For more information, see Create an Application Insights resource. Now, add the Application Insights Key to the extension manifest (app.json file):

```
"applicationInsightsKey":["<instrumenation key>"]
```

Replace `<instrumenation key>` with your key.

You can configure your extension to send this data to a specific Application Insights resource on Microsoft Azure. For more information, see Sending Extension Telemetry to Azure Application Insights.

Conclusion

This walkthrough demonstrated how an extension can be developed. The main AL objects and extension objects were used to store the reward levels, to view, and to edit them. The Designer was introduced as an alternative to modify visual aspects of page objects and to customize them from the web client instead of using code. Up to this point, the table and the page objects were empty, but the install codeunits were added and allowed to initialize the **Reward** table with a standard number of reward levels when the extension was installed. An upgrade code section was also included in this exercise to create a full picture of all processes involved when an extension is built. As a result, a user is enabled to assign one of the three reward levels to a customer and to change this scenario by upgrading the version of the extension.

TIP

To try building a more advanced Customer Rewards sample extension, see Building an Advanced Sample Extension.

Using Designer

2/17/2021 • 9 minutes to read • Edit Online

When developing extensions in the AL development environment, you have a wide range of possibilities. Designer in Dynamics 365 Business Central complements the development experience in Visual Studio Code. It provides an easy and convenient way to make immediate changes to your design by dragging and dropping the components on the page.

IMPORTANT

Designer is currently only available from a Dynamics 365 Business Central sandbox.
Every time you start designing, you're effectively creating a new extension. Your changes are *immediately visible to other users* in the sandbox environment.
Designer *cannot be used by multiple users at the same time* in sandboxes.

NOTE

Extensions created using Designer are removed when the sandbox environment is updated or relocated within our service. Thus, you should not rely on using the sandbox environment as a source control for these Designer extensions, but remember to frequently download and backup the Designer extension source. For more information, see Production and Sandbox Environments.

Designer capabilities

Here is a quick overview of capabilities in **Designer**:

FEATURES	APPLIES TO
Add components	fields, columns, actions in navigation bar
Move components	fields, columns, cues, parts, actions, and action groups
Remove components	fields, columns, cues, parts, actions, and action groups
Hide and unhide components	parts
Change field importance, like showing in collapsed FastTab header or under **Show More**	fields
Exclude field from Quick Entry	fields, columns
Set freeze pane and clear freeze pane	columns
Adjust column width	columns
Edit caption	FastTabs, cards, FactBoxes
Save extension/download code	general

FEATURES	APPLIES TO
Preview design	general

Important points to note

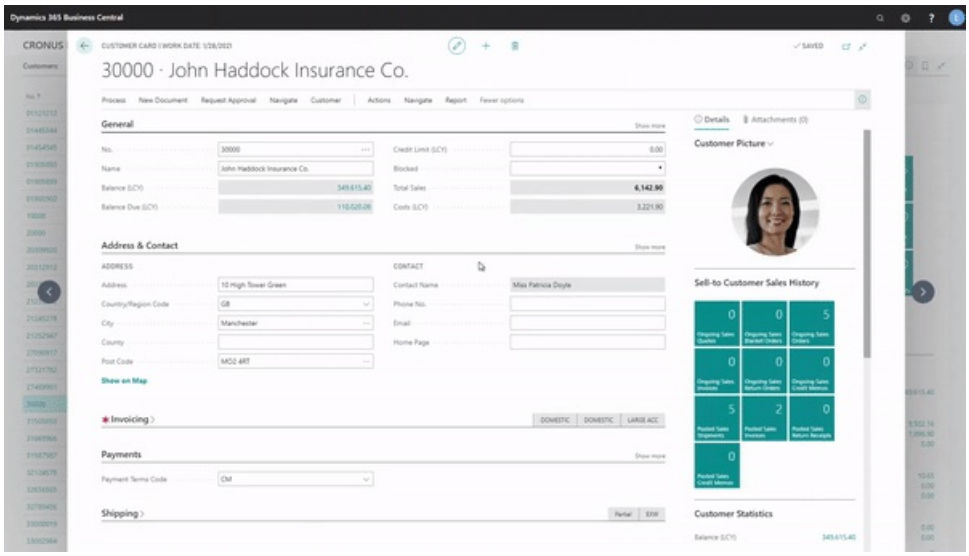
- Every time you start designing, you're effectively creating a new extension. Your changes are immediately visible to other users.
- The changes you make in Designer will apply to **all** users.
- You cannot remove specific fields that are bound to a page and a field must belong to an underlying table.
- You can only add fields, columns, or tiles to its applicable view from list, tall tiles, and wide tiles views. Some components can't be moved using drag-and-drop and are restricted to the view that they are in.
- You can only add fields/columns, from a predefined list, which is based on the source table. You can't create new ones.
- In the client, users can change many of these settings for their workspace only by using personalization. For more information, see Personalizing Your Workspace.

Start and stop designing

In the Business Central client, you start Designer by choosing **Designer** in the top-right corner of any page that you want to make modifications to, and start designing using drag-and-drop components. In Visual Studio Code, you can start Designer by using the **F6** shortcut, which launches a browser that opens the Business Central client in Designer.

After you are done with the changes, choose **Stop Designing**. You can name the extension and download code to save it for the tenant. Once you're done, the extension is automatically installed. If you choose to download the code, the project will be downloaded as a .zip folder. You extract the files and open the folder from Visual Studio Code, where you can deploy it as you would do with any other extension.

If you choose not to download the code at the end, you can still pull the code using the **Alt+F6** shortcut. You can also uninstall the extension from the **Extension Management** page or even download the source from there.



Drag-and-drop components

In Designer, you design and modify the current page. You can display existing table fields, move fields around, remove fields from the page, hide and move actions, and more. You can make changes to display the information by using drag-and-drop components.

Working with fields

To add a field or column to a page, in the banner, choose **More**, and then choose **Field**. A pane to the right appears that lets you add fields. Here you can see all of the table fields that are available for the specific page. The table fields displayed are based on the underlying table or tables. The field can have a status of **Placed**, which means that the field already exists on the page. A status of **Ready** means that the field doesn't already exist on the page. To add a field, drag and drop it to the wanted location.

If you want to remove a field or column, select the arrowhead indicator or on the component, and then choose **Remove**.

You can edit the caption of a FastTab for a group of fields by selecting the caption and start writing. A caption should provide a short and clear description.

Setting the freeze pane

Set freeze pane locks one or more columns to the left, even when you scroll horizontally. You can set the freeze pane, by selecting the arrowhead indicator or of the column that you want as the last column of the freeze pane, and then choose **Set Freeze Pane**. If you want to set the freeze pane back to its original designed location, select the arrowhead indicator or for the current freeze pane column, and then choose **Clear Freeze Pane**.

Setting the Importance on a field

Fields on non-list type pages, such as card and document type pages, include Designer options for setting the importance. The following table describes the options for setting the importance in Designer and how it corresponds to the Importance property in the page code.

OPTION	DESCRIPTION	IMPORTANCE PROPERTY VALUE
Show under "Show more"	Sets the field so that it appears only when the user selects **Show more**.	Additional
Show always	Sets the field to always display on the page. The field displays regardless of whether the user selects **Show more** or **Show less**. The field won't show in the FastTab heading if the FastTab is collapsed.	Standard
Show when collapsed	Sets the field to always display on the page. The field displays regardless of whether the user selects **Show more** or **Show less**. The fields will also display in the header of the FastTab if the FastTab is collapsed.	Promoted

Setting the Quick Entry on fields

You can use Designer to set the QuickEntry property on a field. The **QuickEntry** property determines whether the field is skipped when users press the **Enter** key to navigate through fields on a page. You use Quick Entry to help accelerate keyboard data entry by focusing only those fields a user typically needs to fill in.

To set the QuickEntry property from Designer, select the field or column heading, and then choose either **Include in Quick Entry** (sets the **QuickEntry** property to `true`) or **Exclude from Quick Entry** (sets the

QuickEntry property to `false`).

For more information about Quick Entry, from a user perspective, see Accelerating Data Entry Using Quick Entry in the Business Central Application Help.

Working with the Navigation Menu and Navigation Bar

Designer lets you add actions that link to pages and reports in the navigation bar using the bookmark icon on the target page or report. The bookmark icon is also available in the Tell Me window.

> **NOTE**
> Bookmarking is only available for pages and reports that are discoverable from Tell Me. For more information on how to make pages and reports searchable, see Adding Pages and Reports to Tell me.

This allows the user to efficiently create multiple links and build up the set of important or commonly used links for a specific profile in the Role Center navigation bar. For more information about bookmarking, see Bookmark a Link to a Page or Report on Your Role Center in the Business Central Application Help.

You can also move actions to reorder them in the navigation bar, or move them into groups or subgroups to design the Navigation Menu.

Hiding and showing Parts

Designer lets you hide and unhide part controls in a page directly from the client. When you select the **Hide** option on a part, it will be grayed out and will disappear from the page when you quit Designer mode. Similarly, you can select **Show** on a grayed part control to make it visible again to the user.

The extension generated when the user hides or shows a part overrides the Visible Property in code. For more information on how the **Visible Property** affects the visibility of a control, see UI Customization and Visibility of Controls.

Working with Actions

Designer lets you make changes to the actions that are defined in the action bar of a page. You can move, remove, hide, and show individual actions or action groups.

> **NOTE**
> You cannot modify actions that are defined on pages that are shown in parts, such as in FactBoxes or embedded lists.

> **TIP**
> In Designer, to run an action as normal, select the action and press **Ctrl+Click**.

Remove, hide, and show actions and groups

Actions and actions groups that are already hidden appear dimmed. To change the state of an action or action group, select it, and then choose one of the following options:

OPTION	WHAT IT DOES
Remove	This option is available for the actions that are shown only in a promoted category. Or actions that are shown in both a promoted category and another action menu. Choosing **Remove** deletes the action from the selected location so that it no longer appears. If the action is only shown in the promoted category, it will automatically be shown in the action menu where it's originally defined. You cannot remove actions on a Role Center page; you can only hide them.
Hide	This option is available for actions or action groups that currently are shown only in an action menu (not in a promoted category). Like **Remove**, choosing **Hide** will make the action or action group disappear from the action bar in the client. However, in Designer, the action or action group appears dimmed.
Show	This option appears if the action or action group has been previously hidden (dimmed). Choosing this option will make the action or action group appear in the action bar.

Move actions and action groups

Designer lets you move actions within the action bar. For example, you can:

- Move an action from an action menu to a promoted category.
- Move an action from one promoted category to another.
- Move an action within an action group or to a different action group.

To move an action or action group, drag and drop it to the wanted location, just like with fields and columns.

- You can move individual actions into the promoted categories, but you can't change the order of the actions in the category.
- You cannot move an action group into a promoted category.
- To move an action or action group into an empty action group, drag the action or action group to the target group and drop it in the **Drop an action here** box.
- On Role Center pages, you can't move actions among the different areas that are defined by the `area(creation)`, `area(processing)`, and `area(reporting)` controls.

Preview design on different display targets

The display type icons let you preview the changes you made on desktop, tablet, and phone clients. This way you can make sure that your design will work on the intended display target(s). You can flip to display tablet and phone designs in portrait and landscape orientation.

Controlling user access to Designer

Accessing Designer is controlled on a user or user group basis by the **D365 EXTENSION MGT** permission set. If a user is assigned this permission set, then Designer is available for the user in the client. To prohibit a user

from using Designer, just remove the user from the **D365 EXTENSION MGT** permission set.

> **NOTE**
>
> It is important that the **D365 EXTENSION MGT** permission set does not have a *company* specified; otherwise the user will not be able to access Designer.

Keyboard Shortcuts

2/17/2021 • 2 minutes to read • Edit Online

The following table provides an overview of some of the shortcut key combinations that you can use when you are working in Visual Studio Code. For a complete overview, see Key Bindings for Visual Studio Code.

General in Visual Studio Code

KEYBOARD SHORTCUT	ACTION
Ctrl+Shift+P	Show All Commands
Alt+F6	Download source code
Alt+A Alt+L	AL Go! Generates a HelloWorld project
Ctrl+Shift+B	Package
F5	Publish
Ctrl+F5	Build and publish without debugging. **Note:** The keyboard shortcut has a different meaning when debugging.
F6	Publish and open Designer
Ctrl+F2	Update the compiler used by the service tier(s)

Editing in Visual Studio Code

KEYBOARD SHORTCUT	ACTION
Ctrl+Space	Look up suggestions for the current object
Ctrl+X	Cut
Ctrl+C	Copy
Ctrl+V	Paste
Ctrl+F2	Select all occurrences
F12	Go to definition
Alt+F12	Peek definition
Shift+F12	Show references
Ctrl+Shift+Space	Look up parameter hints

KEYBOARD SHORTCUT	ACTION
Ctrl+K Ctrl+C	Add line comment
Ctrl+K Ctrl+U	Remove line comment
Ctrl+Shift+P	Show all commands
F2	Rename (use **Enter** to rename, use **Shift+Enter** to preview)
Shift+Alt+E	Look up events and insert event subscriber in code for a selected event.

Errors in Visual Studio Code

KEYBOARD SHORTCUT	ACTION
F8	Move to the next error or warning
Shift+F8	Move to the previous error or warning

Compile in Visual Studio Code

KEYBOARD SHORTCUT	ACTION
Ctrl+Shift+B	Compile and build the solution
Ctrl+F5	Build and deploy

Debugging in Visual Studio Code

For topics on debugging in AL, see Debugging and Snapshot Debugging.

KEYBOARD SHORTCUT	ACTION
F5	Start debugging session
Ctrl+F5	Publish without building. **Note:** The keyboard shortcut has a different meaning when not debugging.
Ctrl+Alt+F5	Start RAD publishing without debugging
Alt+F5	Start RAD with debugging
F7	Start a snapshot debugging session
Shift+F7	List all available snapshots

The AL Formatter

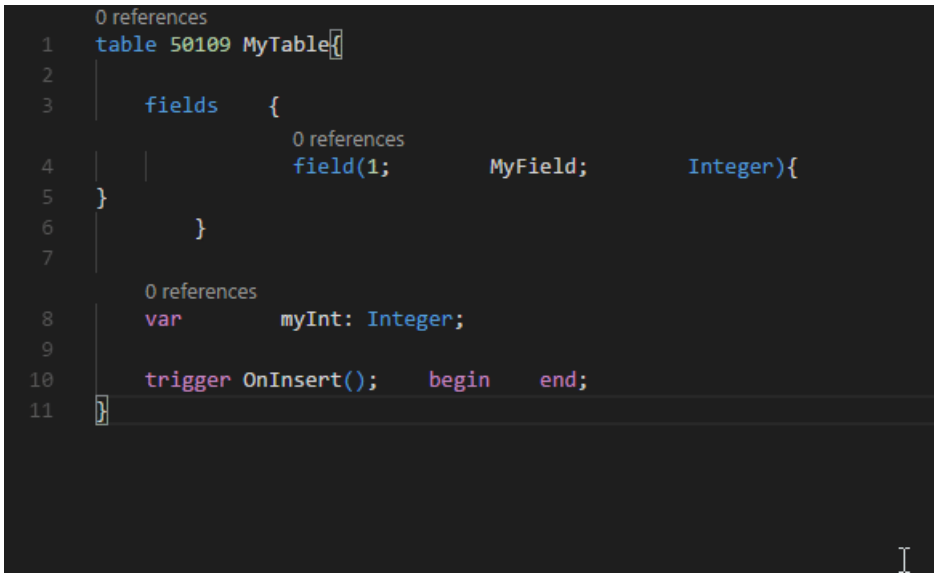
2/17/2021 • 2 minutes to read • Edit Online

The AL Language extension offers users the option to automatically format their source code. This capability increases the usability of the editor by allowing developers to instantly fix the indentation and formatting of their code. The auto-formatter analyzes the syntax tree of the AL code that you are formatting and, using rules developed based on the coding and style guidelines for AL, inserts and removes whitespace from key points in the document to make it more readable.

> **NOTE**
>
> The rules used by the auto-formatter cannot be configured by the user. This limitation is present to allow for a uniform style to be used throughout the community of AL developers.

Invoking the AL formatter

The auto-formatter can be invoked to format an entire AL document or a pre-selected range. In an existing project, open the document that you want to format, right-click inside the document, and select **Format Document**. In the default configuration for Visual Studio Code, the command can be run using the shortcut **Alt+Shift+F**.



To format a range, in an already opened project, open the document that you want to modify, select the specific range to format, right-click, and select **Format Selection**. In the default configuration for Visual Studio Code, the command can be run using the shortcut **Ctrl+K**, **Ctrl+F**.

AL Outline View

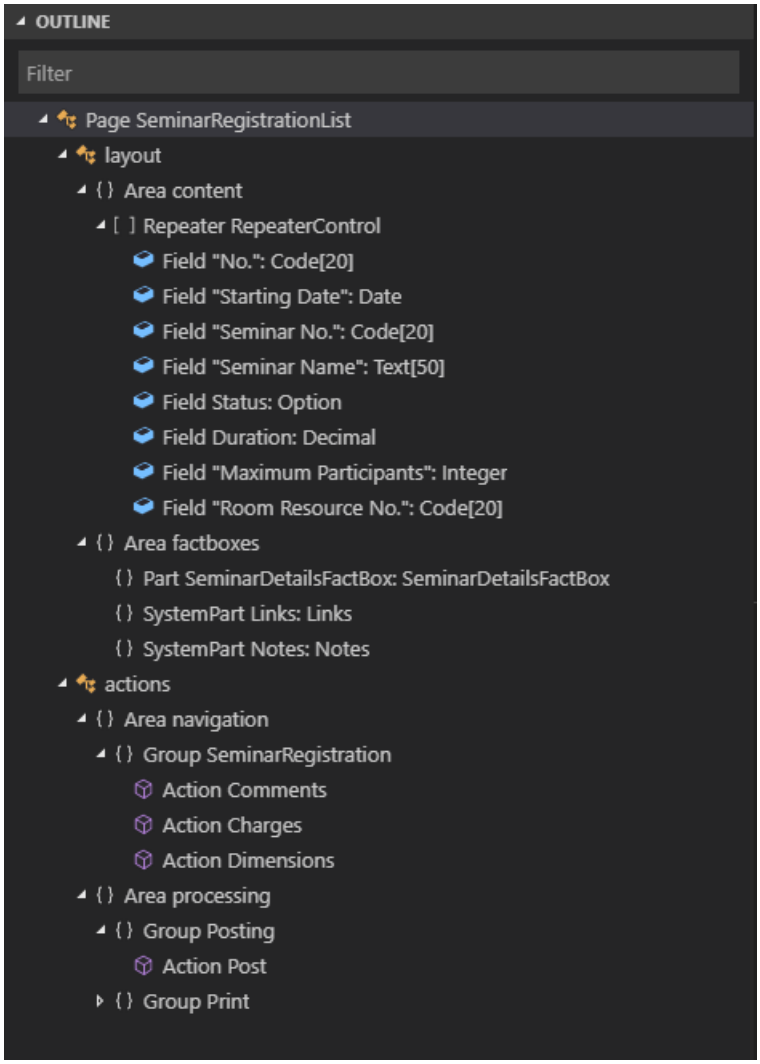
2/17/2021 • 2 minutes to read • Edit Online

Working with the AL Language extension you have access to the **Outline** view. The **Outline** view is a separate section in the lower left corner, right under the **Explorer** view.

The **Outline** view is enabled by default and shows the symbol tree of the currently active cursor, it also allows you to filter as you type. Double-clicking on any node makes your cursor jump to the selected definition or keyword. The **Outline** view will also display any errors in your project for easy inspection.



You manage the look and feel of the **Outline** view by defining a number of settings, that are all enabled by default. To set these, press **Ctrl+Shift+P**, and then choose **Preferences: Open Settings (UI)** for workspace settings, or choose **Preferences: Open User Settings** for user settings. Under **Extensions**, and **AL Language extension configuration** you will find the settings that are available for the AL Language extension for the `settings.json` file.

- `outline.icons` - Outline elements displayed with icons
- `outline.problems.enabled` - Show errors and warnings on outline elements
- `outline.problems.badges` - Badges displayed for errors and warnings
- `outline.problems.colors` - Colors used for errors and warnings

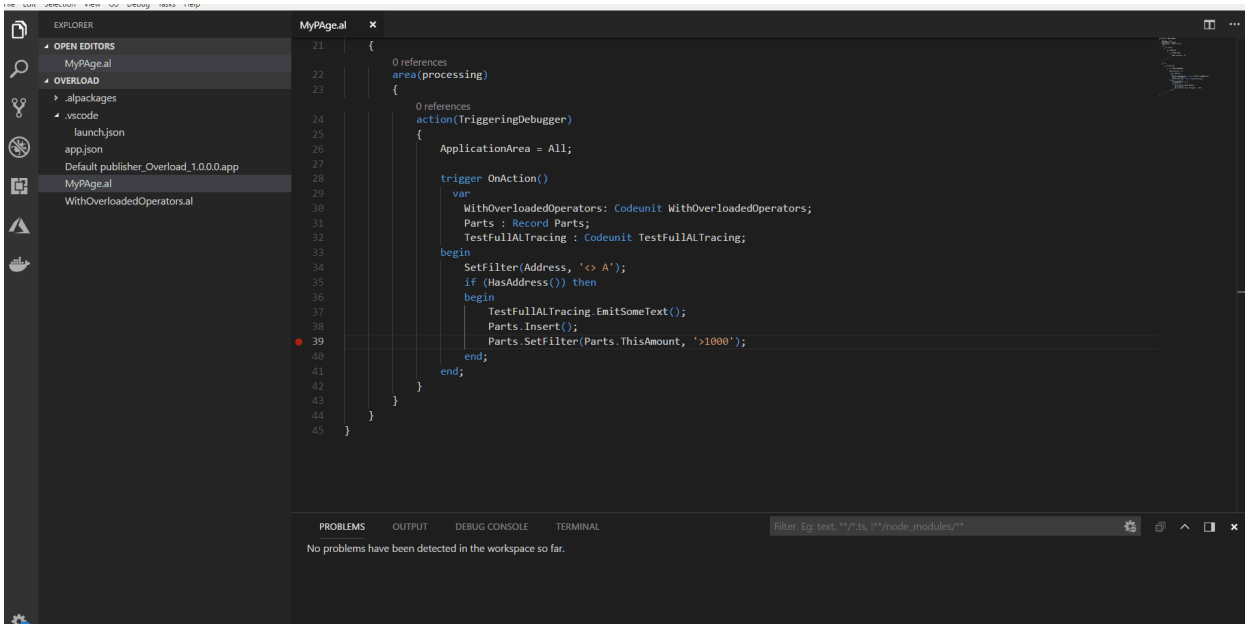
AL Code Navigation

2/17/2021 • 2 minutes to read • Edit Online

When you develop an AL extension, you may want to navigate around the source code frequently. To jump around the code or to access the reference code, you use the Go To Definition feature in Visual Studio Code.

Go To Definition

The **Go to Definition** feature navigates to the source of a type and opens the result in a new tab. You can use the `F12` shortcut key or right-click and select the **Go to Definition** feature from the right-click menu. The **Go to Definition** opens the source in the `.dal` format which contains the base application code. For example, the base application code may contain table metadata and application methods. In the following illustration, the Address type and the HasAddress type opens the `Customer.dal` file and locates the reference code of those types by using the Go To Definition feature.



With **Go to Definition**, you can step into the referenced code and set breakpoints on the external code and base application code. For more information, see Debugging in AL.

You can always use **Go to Definition** on Dynamics 365 Business Central code. However, if you want to use it on other extensions, the extension package which is now referenced, when originally published, must have the `showMyCode` property set to `true`. For example, if A is referencing B you can only use the Go To Definition on types of B, if B, when it was published, had the `showMyCode` flag set to `true`. For more information, see Security Setting and IP Protection.

Runtime 5.2 and Go to Definition

From runtime 5.2 and onwards, **Go to Definition** will resolve sources from the downloaded application dependency. You can navigate from within a symbol source file (.dal) to another symbol source file. For example, you can use **Go to Definition** from the `Customer` source DAL file in the Base App to the `Customer List` DAL source also defined in the Base App.

The following conditions still apply:

- **Go to Definition** is forward only. This is due how Visual Studio Code handles preview documents (DAL

files). There is no backward navigation support for preview files within Visual Studio Code. This means that if you navigate from your AL file to the `Customer` DAL source, and from there to the `Customer List` DAL source, and you issue a backward navigation (**Alt+Left arrow**), you will get back to the AL file and not what you would have expected; the `Customer` DAL source.

- Transitive references can only be resolved if the symbol app that defines the reference is a dependency on the project that contains the entry point for the **Go to Definition** symbol. For example, assume that you are in `HelloWorld.al` and want to **Go to Definition** on the `Car` table defined in the `Car.app` which is a dependency on your app. Then navigation will open the `CarTable.dal` preview file. And assume that from here you want to **Go to Definition** on `CarDistributor` table defined in the `CarDistributor.app` which is a dependency on `Car.app`, but *not* a dependency on the `HelloWorld.app`. In this case the source code **Go to Definition** will not work.

For more information about code navigation in Visual Studio Code, see Code Navigation.

AL Code Actions

AL Code Actions

2/17/2021 • 2 minutes to read • Edit Online

The AL Language extension offers users the option to help fix issues in code. **Code Actions** is a Visual Studio Code feature providing the user with possible corrective actions right next to an error or warning. If actions are available, a light bulb appears next to the error or warning. When the user clicks the light bulb (or presses **Ctrl+.**), a list of available code actions is presented.

In AL Language extension these code actions are available in the current version:

- Multiple IF to CASE converting code action.
- Spell check code action.
- Interface implementer.
- Make method local.
- Use parenthesis for method call.
- Fix explicit `with` statements.
- Fix implicit with statements.

To enable AL Code Actions

1. Open the Command Palette by pressing **Ctrl+Shift+P** and then open the `settings.json` file.
2. Enter the setting `al.enableCodeActions` and set it to `true` like this `"al.enableCodeActions": true`
3. Save the settings file. You have now enabled code actions on your project.

Alternatively:

1. Open the Settings Page, **Ctrl+,** and choose either **User Settings** or **Workspace Settings** depending on which scope you want the code actions to apply to.
2. Navigate to **Extensions > AL Language extension configuration**.
3. Click on the **Enable Code Actions** checkbox. You have now enabled code actions on your project.

Object Ranges in Business Central

2/17/2021 • 2 minutes to read • Edit Online

When you develop an app for Business Central online, you must request an object range in terms of licensing. Developing for Business Central is done using Visual Studio Code with the AL Language extension.

There are currently two available ranges that you can request. Both have some characteristics to keep in mind:

- *RSP Object Range* (ID range 1,000,000-69,999,999)

  This object range is tied to the RSP Program details.

  > **IMPORTANT**
  > We currently advise new publishers to *not* request an RSP object range

- *App Object Range* (ID range 70,000,000-74,999,999)

  This object range was originally designed just for apps in the Microsoft commercial marketplace to be used in Business Central online.

  > **IMPORTANT**
  > We currently advise new publishers to request an app object range.

Currently, you can implement apps developed in both the *RSP range* and the *app object range* in Business Central online and on-premises, as well as partner-hosted.

For more information, see Requesting an object range.

The following sections describe the different object ranges that you can find in the base application and extensions.

0-49,999

This range is assigned to Business Central base app functionality and must not be used in extensions or customizations.

50,000-99,999

This range is for customizations, and for test purposes. For Business Central online, a partner can develop an extension tailored to the individual tenant to fit the needs. The partner will develop this either by using a sandbox tenant or by obtaining a Docker image. Once the development is done, the extension can be deployed to the individual tenant.

Also, use this range as part of training and similar, such as if you are using a sandbox tenant or a build of Business Central on Docker.

100,000-999,999

The objects in this range are mainly designed when the Microsoft team localizes Business Central for a specific country or region. These objects cannot be used by partners.

1,000,000-69,999,999

This object range is intended for the Registered Solution Program (RSP). The partner can choose to use this range for developing extensions that can be used in Business Central online or on-premises. When used in Business Central online, these extensions are obtained as apps from appsource.microsoft.com.

70,000,000-74,999,999

Partners can obtain IDs in this range for extensions for Business Central online. These extensions are obtained as apps from appsource.microsoft.com.

For more information, see Get Started with Building Apps.

Download the Business Central licensing guide here.

Differences in the Development Environments

2/17/2021 • 3 minutes to read • Edit Online

Coming from the Dynamics NAV Development Environment and C/SIDE, there are some differences and optimizations that you should familiarize yourself with. The following sections go through some of these changes, but is in no way an exhaustive list.

> **TIP**
> A very useful tool working in Visual Studio Code, is IntelliSense which gives you a list of options in the current context. To activate IntelliSense from anywhere in the code, press **Ctrl+Shift**.

General development approach

While you could change the existing Dynamics NAV source code using C/SIDE, the best approach to developing with the AL Language development environment is to work with Extensions only. That means that you can extend the existing code by adding new functionality or integrating your code using Events, but it is not possible to change existing code, for example in codeunits.

With Business Central 2019 release wave 2, the possibility to change or "code-customize" the base application was introduced for on-premises installations, but at the same time it was announced that at some point in the future, the extension model will be the only option and code-customization will no longer be possible.

Data types

C/SIDE	AL LANGUAGE DEVELOPMENT ENVIRONMENT
Dates are parsed based on culture settings.	Locale independent and supports only: `yyyy-mm-ddD`.
Boolean values could be expressed as **yes/no**.	Boolean values are expressed as **true/false**.
For tables, integers could allow decimal values. For example, 5.0 converts to an integer, 5.4 throws an error at runtime.	For tables, Min, Max, InitValue numbers with a fraction are expressed as `decimal`, thus they are not a valid integer data type.
The largest constant integer could be `999999999999999`.	Transforms to `999'999'999'999'999.0`, a decimal value. In AL, this can be expressed as `999999999999999.0` or `999999999999999L`.

Syntax updates

C/SIDE	AL LANGUAGE DEVELOPMENT ENVIRONMENT
The token for multilanguage comment is @@@.	A multilanguage comment is marked with `Comment`.

Several properties have been renamed, to mention some:

C/SIDE	AL LANGUAGE DEVELOPMENT ENVIRONMENT
AutoFormatExpr	AutoFormatExpression
DataCaptionExpr	DataCaptionExpression
Layout	GridLayout
ProviderID	Provider

> **NOTE**
> Property values are considered syntax elements; thus they should follow the standard AL escaping rules.

Multilanguage properties

With the introduction of .xliff files, the ML properties, such as **CaptionML** and **TooltipML** are not used for this translation method. Use the equivalent properties instead, such as **Caption** and **Tooltip**, then make sure the manifest is set up to generate the `/Translations` folder and use the generated .xliff files for translations of the extension. For more information, see Working with Translation Files.

Pages

The `ActionContainer` elements in AL have been renamed; the following table lists the renamed elements:

C/SIDE	AL LANGUAGE DEVELOPMENT ENVIRONMENT
ActionItems	`Processing`
ActivityButtons	`Sections`
HomeItems	`Embedding`
NewDocumentItems	`Creation`
RelatedInformation	`Navigation`
Reports	`Reporting`

For instance, `area(Sections)` can be defined inside the `actions` section of the page.

Likewise, `Container` and `ContainerType` elements in C/SIDE have been renamed to `area(Content|FactBoxes|RoleCenter)` and can be defined inside the `layout` section of the page.

> **NOTE**
> For backwards compatibility we continue to support adding non-part pages as parts. We do, however, recommend that you redesign your page to only use Card part or List part, as we may remove support in a future update.

For syntax examples, see Page Object and Page Extension Object.

Naming

Controls, actions, and methods names must be unique on pages. In C/SIDE, you could create a Part control with the same name as a method, which would give you an error at runtime. This is now prevented, by disallowing duplicates. Similarly, trigger and trigger event names are disallowed on matching application object types. Likewise, actions and fields could have same names before, but that would have prevented page testability access, and will now throw a compilation error.

> **NOTE**
> Name on Controls and Actions on Pages is now mandatory.

Property dependencies

Some properties require that you set another property. An example is `PromotedCategory`, which requires that you have enabled the property `Promoted`. The following table lists some of the properties that have this dependency.

PROPERTY	DEPENDS ON THE PROPERTY...
PromotedCategory	Promoted
PromotedIsBig	Promoted
ValidateTableRelation	TableRelation
SourceTableTemporary	SourceTable
RunPageMode	RunObject

Limited functionality

The `InitValue` property of type `Duration` is not allowed in the AL Language Development Environment. The `InitValue` of type `DateTime` only allows for the value `0DT`.

Adding Help Links from Pages, Reports, and XMLports

2/17/2021 • 2 minutes to read • Edit Online

When creating new pages, you can specify which Help file to open if the user selects the *Learn more* links in the UI of Business Central.

The context-sensitive Help link is generated based on a configuration setting in the `app.json` file and the name of the relevant Help file that you specify as part of the metadata for the page object. For more information, see Configure Context-Sensitive Help.

Examples

The following examples show how you can specify the *ContextSensitiveHelpPage* property from new pages, reports, and XMLports:

```
page 50100 MyPageWithHelp
{
    ContextSensitiveHelpPage = 'sales-rewards';
}
```

```
report 50100 MyReportWithHelp
{
    requestpage
    {
        ContextSensitiveHelpPage = 'sales-rewards';
    }
}
```

```
xmlport 50100 XmlPortWithHelp
{
    requestpage
    {
        ContextSensitiveHelpPage = 'sales-rewards';
    }
}
```

In all three examples, the ContextSensitiveHelpPage property is set to point at the same Help files. This is because all three example objects support the same feature that is explained in the *sales-rewards* Help topic. In your app, you can choose to structure the Help differently.

Working with Translation Files

2/17/2021 • 4 minutes to read • Edit Online

Dynamics 365 Business Central is multilanguage enabled, which means that you can display the user interface (UI) in different languages. In Dynamics 365 Business Central this is done using XLIFF files, which is a standardized format used for computer-based translations.

Generating the XLIFF file

To add a new language to the extension that you have built, you must first enable the generation of XLIFF files. The XLIFF file extension is .xlf. The generated XLIFF file contains the strings that are specified in properties such as **Caption**, **CaptionML**, and **Tooltip**.

> **NOTE**
> To submit an app to AppSource, you must use XLIFF translation files.

In the app.json file of your extension, add the following line:

```
"features": [ "TranslationFile" ]
```

Now, when you run the build command (**Ctrl+Shift+B**) in Visual Studio Code, a `\Translations` folder will be generated and populated with the .xlf file that contains all the labels, label properties, and report labels that you are using in the extension. The generated .xlf file can now be translated.

> **IMPORTANT**
> Make sure to rename the translated file to avoid that the file is overwritten next time the extension is built.

By setting the `GenerateCaptions` flag in the app.json file, you specify that you want to generate captions based on the object name for pages, tables, reports, XMLports, request pages, and table fields. If the object already has a `Caption` or `CaptionML` property set, that value will be used, for table fields the `OptionCaption` is used. The syntax is the following:

```
"features": [ "TranslationFile", "GenerateCaptions" ]
```

GenerateLockedTranslations

APPLIES TO: Business Central 2020 release wave 2 and later

By setting the `GenerateLockedTranslations` flag in the app.json file, you specify that you want to generate `<trans-unit>` elements for locked labels in the XLIFF file. The default behavior is that these elements are not generated. For more information, see JSON Files.

```
"features": [ "GenerateLockedTranslations" ]
```

Label syntax

The label syntax is shown in the example below for the **Caption** property:

```
Caption = 'Developer translation for %1',  Comment = '%1 is extension name', locked = false, MaxLength=999;
```

> **NOTE**
>
> The `comment`, `locked`, and `maxLength` attributes are optional and the order is not enforced. For more information, see Label Data Type.

Use the same syntax for report labels:

```
labels
{
  LabelName='LabelText',Comment='Foo',MaxLength=999,Locked=true;
}
```

And the following is the syntax for **Label** data types:

```
var
a:Label'LabelText',Comment='Foo',MaxLength=999,Locked=true;
```

> **IMPORTANT**
>
> The **ML** versions of properties are **not** included in the .xlf file:
>
> - CaptionML
> - ConstValueML
> - InstructionalTextML
> - OptionCaptionML
> - PromotedActionCategoriesML
> - RequestFilterHeadingML
> - ToolTipML
>
> The TextConst Data Type is not included in the .xlf file either.

The XLIFF file

In the generated .xlf file, you can see a `<source>` element for each label. For the translation, you will now have to add the `target-language` and a `<target>` element per label. The `<trans-unit id>` attribute corresponds to the object ID in the extension. This is illustrated in the example below.

```
<?xml version="1.0" encoding="utf-8"?>
<xliff version="1.2" xmlns="urn:oasis:names:tc:xliff:document:1.2"
xmlns:xsi="https://www.w3.org/2001/XMLSchema-instance"
xsi:schemaLocation="urn:oasis:names:tc:xliff:document:1.2 xliff-core-1.2-transitional.xsd">
  <file datatype="xml" source-language="en-US" target-language="da-DK" original="ALProject16">
    <body>
      <group id="body">
        <trans-unit id="PageExtension 50110" maxWidth="999" size-unit="char" translate="yes"
xml:space="preserve">
          <source>Developer translation for %1</source>
          <target>Udvikleroversættelse for %1</target>
          <note from="Developer" annotates="general" priority="2">%1 is extension name</note>
          <note from="Xliff Generator" annotates="general" priority="3">PageExtension - PageExtension</note>
        </trans-unit>
      </group>
    </body>
  </file>
</xliff>
```

NOTE

You can have only one .xlf file per language. If you translate your extension to multiple languages, you must have a translation file per language. There is no enforced naming on the file, but a suggested good practice is to name it `<extensionname>.<language>.xlf`.

When the extension is built and published, you change the language of Dynamics 365 Business Central to view the UI in the translated language.

Translating other extensions

To translate other extensions, for example, adding translations to the Base Application, you must reference the project to be translated using the `dependencies` section in the app.json file. For more information, see JSON Files. When you have the dependencies added, you can add xliff files in your current project that translates the object captions of the referenced extension. Create a directory named **Translations** in the root of the extension, and place the translated xliff file there. When your extension is then built and published, change the language of Dynamics 365 Business Central to view the UI in the translated language.

Translation and Localization apps

NOTE

The following section only applies to versions released before Business Central 2019 release wave 2.

The .xlf files approach cannot be used for translating the base application. If you are working on a translation or localization app (for example for a country/region localization), you must take the .txt file containing the base application translation, and place the file in the root folder of your extension. When the extension is compiled, the .txt file is then packaged with the extension.

We recommend that you use only one .txt file per language. There is no enforced naming on the .txt files, but a suggested good practice is to name it `<extensionname>.<language>.txt`.

For more information about importing and exporting .txt files, see How to: Add Translated Strings By Importing and Exporting Multilanguage Files in Dynamics NAV.

Instrumenting an Application for Telemetry

2/17/2021 • 2 minutes to read • Edit Online

This article describes how you can implement custom telemetry signals in your application for emitting telemetry data.. This data can then be collected and visualized for analyzing the application against the desired business goals, troubleshooting, and more.

Telemetry overview

One aspect of event logging is collecting data about how the application and your deployment infrastructure is working in order to diagnose conditions and troubleshoot problems that affect operation and performance. For example, this type of event logging includes Business Central Server events and trace events like SQL and AL method (function) traces.

Another aspect of logging is *telemetry*, which is collecting data about how your application functions and how it is being used in production. Telemetry can tell you about specific activities that users perform within the application in the production environment. Telemetry is also a useful tool for troubleshooting, especially instances where you are not able to reproduce the conditions experienced by the user or have no access to the user's environment. Telemetry can be divided into different levels or categories, like: telemetry for engineering, telemetry about the business, telemetry for customers.

Creating custom telemetry signal

There are two different resources where telemetry trace signals can be sent for monitoring and analyzing: Event Log and Microsoft Azure Application Insights. By default, the Business Central application is instrumented to emit several system telemetry trace signals to these destinations. Custom telemetry trace signals enable you to send telemetry data from anywhere in the application code to either of these destinations.

The procedure for creating custom telemetry signals is different for each resource. Your choice might also depend on whether you are developing for Business Central online or on-premises.

REOURCE	DESCRIPTION	ONLINE	ON-PREMISES	MORE INFORMATION

REOURCE	DESCRIPTION	ONLINE	ON-PREMISES	MORE INFORMATION
Application Insights	Create custom telemetry signals that are sent to an Application Insights resource in Azure. Application Insights is a service hosted within Azure that gathers telemetry data for analysis and presentation. Extension developers can specify whether the signal is only sent to the extension publisher or also to the VAR partner telemetry resource. You create these custom trace signals by using the LOGMESSAGE method in code.	✓	✓	See...
Event Log	Create custom telemetry trace signals that are sent to the Event Log of the Business Central Server machine. You create these custom trace signals by using the SENDTRACETAG method in code.		✓	See...

NOTE

Using Application Insights is recommended.

Monitoring Business Central Server Events

The SMB Opportunity for App Publishers

2/17/2021 • 4 minutes to read • Edit Online

Our mission is to empower every individual and every organization on the planet to achieve more. This is particularly key for the 78 million small and mid-sized businesses (SMB) worldwide that increasingly want focus on tech intensity to be more resilient, more capable of transforming their products and services to face the constant changes and challenges in the marketplace. To embrace growth, every organization will have to have a business application which breaks down the silos of data, processes and workflow in their operations. This enables employees to respond to daily challenges and opportunities with agility. Market research shows that the business applications opportunity for software companies in the SMB space is predicted to be 51 billion dollars by 2025. As a developer, you want to make sure you bet on the winning platform. The BizApps market growth in this area is 17%; however Dynamics 365 platform growth has been growing at 47%!

Dynamics 365 Business Central

Dynamics 365 Business Central is an all-in-one business management solution that connects operations for small to mid-sized business. It ensures business continuity with a cloud solution that connects sales, service, finance, and operations to help teams adapt faster and deliver result. Business Central provides app publishers with a modern business platform that you can easily connect to, extend and build on — with little to no code required.

Microsoft AppSource

Microsoft AppSource is part of Microsoft's commercial marketplace where customers can find, try and get business solutions apps. It is the launch pad for your joint go-to-market activities with Microsoft and a flywheel for business growth. Using launch promotion, demand generation, and joint sales and marketing, your offer portfolio on AppSource can be the centerpiece of your cloud business engine.

In November 2020, Microsoft AppSource had more than 3 million monthly active users and more than +20.000 apps. Specifically for Business Central, there are more than 1000 apps available, and the number is growing fast.

Go-to Market Scenarios

As an AppSource publisher you can focus on these scenarios with Business Central and Microsoft AppSource:

- Connect
- Extend, or
- Embed

Connect

Connect your existing online service with Business Central through a powerful API. Here are a few examples which of existing connect apps which you can find on AppSource:

- Square payments, which allow you take payments with a Square terminal.
- Certify which allows users to post expense reports using Certify.com
- Scaptify, which connects your Shopify store with Business Central

Learn more about the API to build connect apps: Getting Started Developing Connect Apps

Extend

You can extend the default capabilities in Business Central to add extra productivity features or industry functionality to fit the needs of your customer base. The possibilities are plentiful.

In countries where Business Central is not localized by Microsoft, you can extend Business Central based on local requirements to respond to the regulatory and or competitive needs of that market.

Here are a few examples of some apps that extend Business Central:

- E-Ship and E-Receive from Lanham Associates, which extends warehouse management with barcoding and labelling, scanning functionality and interfaces with carriers and weigh scales.
- Continia Document Capture, which is an end-to-end solution for document recognition, invoice approval and digital archiving
- Philippines localization from Pasi, which computes the withholding tax as mandated by the Philippine government for both customers and vendors.
- SwissSalary 365, which is a certified and flexible payroll app that's intuitive and easy to use for the Swiss market

Learn more on how to build your app: Getting Started with AL

Embed

Embed Business Central as an integral component in an end-to-end industry solution. Here are a few examples of embed solutions available on Microsoft AppSource:

- 4PS construct, an all-in one solution for construction. 4PS has specifically developed an integrated software solution based on the Microsoft platform and tailored for construction, civil engineering, mechanical and electrical, service and maintenance, house builders and equipment rental companies
- LS Central from LS Retail. The complete, unified commerce online platform to manage your entire retail and food service operations
- Dynamics Empire Online, cegeka-dsa's open, secure and innovative real estate solution.

Learn more about embed apps: Embed app overview

Consultancy services

An increasing number of business users find web more convenient for buying where they can research, deploy and manage apps. Therefore, next to providing Apps, a publisher can also market consultancy services on Microsoft AppSource to connect with buyers. The provided content in these offers could be assessments, briefings, workshops, proof of concepts and implementations. In general the services are typically fixed in scope and duration, they are offered at a fixed price or free and have a defined outcome.

Here are a few examples of Consultancy services provided by publishers:

- Unified Commerce Readiness Intro: 1-Hr Assessment In this 1 hour assessment, LS Retail assesses how a 4-day engagement helps them with implementing their Unified Commerce Cloud solution based on Microsoft Dynamics 365.
- NAV-X Commission Mgt Gold 4-Hr Implementation in this 4 hour implementation workshop, NAV-X supports the customers in implementing their commission management app.

Learn more about Consultancy Services.

Get Started with Building Apps

Get Started with Building Apps

2/17/2021 • 8 minutes to read • Edit Online

Dynamics 365 Business Central is a business management solution that helps companies connect their financials, sales, services, and operations to streamline business processes, improve customer interactions and make better decisions. With this modern business platform, you can easily and quickly tailor, extend, and build applications so they fit your specific needs with little to no code development.

Build a line-of-business app, such as for a specific industry, process, or department such as HR, finance, marketing, or operations. Then, publish your app to the Microsoft commercial marketplace, where customers can find and try your app, and get in touch with you. For more information, see What is the Microsoft commercial marketplace?.

Learn how you can become a Business Central app publisher in six steps in this article.

Step 1: Become a partner

Becoming a Microsoft partner gives you access to the Microsoft resources needed to build, market, and sell your apps. You don't have to be a Microsoft partner to begin developing your apps. But all of the steps below are required to gain access to the programs that enable you to publish, market, and sell your apps for Business Central.

Obtain your work account

Your work account or work email is the email address provided to you by your company. This email is usually in the format `you@yourcompany.com`. More information on work accounts can be found here.

Join the Microsoft Partner Network

Microsoft Partner Network (MPN) membership unlocks our best resources to differentiate your business, take your product to market, and sell your solutions. To become a partner, you must join the Microsoft Partner Network (MPN), at which time you will be assigned an MPN ID. MPN membership is free to all partners; you can enroll in the MPN here.

Once signed up, you will get an MPN ID – your gateway to access all the membership resources and benefits for your partnership with Microsoft. There is no cost to obtain a MPN ID as a Network member, and with options to upgrade to an Action Pack subscription or work toward a competency, you can access even more benefits.

Set up your Partner Center account

Once you have joined the Microsoft Partner Network (MPN), you can set up your Partner Center (PC) account. The Microsoft Partner Center is a generic portal where partners can sell and manage customer subscriptions for Microsoft services, such as Microsoft 365, Azure, Dynamics 365, and others, as well as for some third-party products. For more information, see the Partner Center documentation.

Your Partner Center account provides you with access to pricing information, tools and services, and enables you to manage admin credentials for your company's work account. Partner Center is also where you can purchase or renew subscriptions to Microsoft Action Packs, create a business profile to receive and manage sales leads from Microsoft, and see if you qualify for co-selling opportunities.

Step 2: Register as a publisher

The first step to becoming a publisher is to register in Partner Center (PC). PC is where you submit your apps for publication, promote your apps, and manage your offers. To begin the registration process, you must complete

these steps. One of our team members will follow up to help you complete your registration. Once registered, you can access PC.

For more information, see Partner Center Account.

PartnerSource Business Center (PSBC) account

Developing apps requires you to be known as Business Central developer and requires you to have a unique development license file with a specific object range.

To obtain an object range for developing a Business Central, you must first have access to PartnerSource Business Center (PSBC). You have access to PSBC if you have one of the following agreements:

- An active Partner Registration Agreement (PRA)
- A Registered Solution Program Addendum (RSPA)

The relevant contract can be requested through your local Regional Operations Center (ROC) Contracts and Agreements Team below:

- mbscon@microsoft.com if you are based in Europe, the Middle East, or Africa
- mbsagree@microsoft.com if you are based in the Americas
- mbslques@microsoft.com if you are based in the Asia Pacific region.

Step 3: Your unique app specifications

Requesting an object range

When you develop an app for Business Central, you must request access to an object range that holds a certain number of objects for your solution. To avoid overlap between objects used in different solution, each partner is assigned a number of objects in a unique object range. For example, a partner is assigned the object range 70,001,000 – 70,001,999. The object range gives them 1000 numbered objects that they can use to develop Business Central solutions.

Depending on where you will deploy your Business Central solution, online or on-premises, you can use different licensing methods and object ranges.

There are currently two available ranges that you can request. Both have some characteristics to keep in mind:

- *RSP Object Range* (ID range 1,000,000-69,999,999)

  This object range is tied to the RSP Program details.

  > **IMPORTANT**
  > We currently advise new publishers to *not* request an RSP object range

- *App Object Range* (ID range 70,000,000-74,999,999)

  This object range was originally designed just for apps in the Microsoft commercial marketplace to be used in Business Central online.

  > **IMPORTANT**
  > We currently advise new publishers to request an app object range.

Currently, you can implement apps developed in both the *RSP range* and the *app object range* in Business

Central online and on-premises, as well as partner-hosted.

You can request an object range by downloading the object range request form here. After completion, send them to your Regional Operational Center (ROC) for processing:

- mbscon@microsoft.com if you are based in Europe, the Middle East, or Africa
- mbsagree@microsoft.com if you are based in the Americas
- mbslques@microsoft.com if you are based in the Asia Pacific region.

Downloading your development license file

After your Regional Operational Center has processed your Agreements and Object Range Request forms, download your company's unique developer license from PartnerSource Business Center. Find it in the license key configuration section under the developer tools section.

Register your unique prefix or suffix

In your extension, the name of each new application object must contain a prefix or suffix. This rule applies to all objects. Email d365val@microsoft.com with a prioritized list of three-letter affixes of your choice. You must also submit your MPN ID and the publisher name that you will use for the app.

Step 4: Getting access to preview bits

Get access to preview builds by joining Microsoft Collaborate.

In Microsoft Collaborate, you get access to a set of Business Central builds:

- The current major version
- An upcoming major version
- Daily builds

You must have the following prerequisites to register on Microsoft Collaborate:

- Azure Active Directory (Azure AD).

  > **NOTE**
  > If you have Microsoft 365, then your company most likely has Azure AD

- Azure AD Global Administrator permission

  > **NOTE**
  > To find out if your company has an Azure AD account, check with your system administrator.

Step 4 A: How your Global Administrator must register for Collaborate

Only your company's Global Administrator can start the onboarding to Collaborate. They must register at https://aka.ms/Collaborate, choose the **Get Started** action, and then complete the registration form.

The administrator can then add the relevant colleagues.

Optional Step: Add your coworkers to Microsoft Collaborate

To add coworkers:

1. Sign in to Microsoft Collaborate with your Global Administrator account at aka.ms/Collaborate.
2. Choose the  icon in the top-right corner of the page, click on account settings, and choose **user**

management.

3. Choose the grey **ADD USERS** button, and leave the default choice to **Add existing users** as-is. Now you can search for the user(s) that you want to add to Collaborate. To add them you need to select them from the menu, and then click the grey **ADD SELECTED** button.

4. You have successfully added your coworkers to Collaborate. Users can now sign in to Microsoft Collaborate using the following link: aka.ms/Collaborate

Step 4 B: Getting access to the available builds and engagements

Once you have successfully registered on Microsoft Collaborate, Microsoft must assign you to the right programs and engagements before you can see the preview bits. Contact Dyn365BEP@microsoft.com and provide them with information about the relevant users. the following table illustrates the type of information that you must submit:

PUBLISHER DISPLAY NAME	MPN ID	FIRST NAME	LAST NAME	WORK ACCOUNT EMAIL
Contoso	12345	Eugenia	Lopez	Eugenia.Lopez@Contoso.com
Contoso	12345	Quincy	Watson	Quincy.Watson@Contoso.com

After sending the email, expect a response from Microsoft within 1-2 business days.

Step 5: Resources while you develop your solution

Find below some guiding resources on how to develop your apps for Business Central.

- Microsoft Learn

  Learn new skills and discover the power of Microsoft products with step-by-step guidance. Start your journey today by exploring our learning paths and modules.

- Microsoft Docs

  Find The developer and administration content on Microsoft Docs

- Join the conversation

  In the dedicated Yammer network, join the conversation on developing apps

- Join the monthly Office hour calls

  Join the monthly Office hour calls to learn more about a hot topic

- Get coaching from experts

  Need help with developing your apps? There is a community of ISV Development Centers specialized in Business Central ready to engage with you.

Set up Azure DevOps for your development processes

Optionally, use the CI/CD workshop document at https://aka.ms/cicdhol if you want to do it yourself. Alternatively, choose between vendors offering tools or services around DevOps.

Talk to one of the ISV Development Centers for guidance.

Step 6: Publish your app in the Microsoft commercial marketplace

Once your app is ready for submission, you can list your app in the Microsoft commercial marketplace by submitting it in Partner Center. For more information, see Create a Dynamics 365 Business Central offer.

Before you submit, we recommend that you review the technical validation checklist and marketing validation checklist. The two articles list all requirements that you **must meet before you submit** an app for validation. If you do not meet these mandatory requirements, your extension will fail validation

Marketing Validation Checklist

2/17/2021 • 3 minutes to read • Edit Online

The storefront details on AppSource is the first impression that prospects get regarding your offer. First impressions last, so make sure to invest some time in developing the content on the storefront, so it gives a good impression from the beginning. Failing to do so will jeopardize the hard work you put in, when developing your offer, likely leaving the prospect confused or looking elsewhere. Accordingly, we recommend you put in the time, effort and due diligence when developing this content.

You use Partner Center to submit your offer to AppSource. In the following, you can find information on all the marketing-related items that you need to fill out in Partner Center prior to submitting your app to AppSource. Follow this marketing validation checklist and get your app passed on the first submission.

What do I need to know before I begin?

You need to have the following three items in mind, when you are creating your storefront and marketing material.

ITEM	REQUIREMENT	DETAILS
Branding	Make sure to read the branding guidelines carefully before you start referencing the product name.	Read more
Language	Discover what to consider for each storefront detail when it comes to language.	Read more
Microsoft images	Make sure not to use any Microsoft images (e.g., Business Central icon or Dynamics 365 logo).	Read more

How do I fill out the marketing section in Partner Center?

The following section walks you through the marketing-related components, that is, *offer setup*, *properties*, *offer listing*, and *availability*, which you need to fill out in Partner Center prior to submitting your app to AppSource.

Offer Setup

ITEM	REQUIREMENT	DETAILS
App type	Read more about the types of apps you can submit to AppSource.	Read more
Contact type	How do you want potential customers to interact with your offer?	Read more
Test drive	If you choose “free trial” as the contact type of your offer, you need to enable a test drive.	Read more

ITEM	REQUIREMENT	DETAILS
Customer leads	Provide connection details to the CRM system where you would like to send customer leads.	Read more

Properties

ITEM	REQUIREMENT	DETAILS
Categories	Choose a primary, a secondary, and up to four subcategories.	Read more
Industries	Choose up to two industries for your offer.	Read more
App version	Specify the version number of your offer.	Read more
Terms and conditions	Outline the terms and conditions that the customer must accept before they can use your offer.	Read more

Offer listing

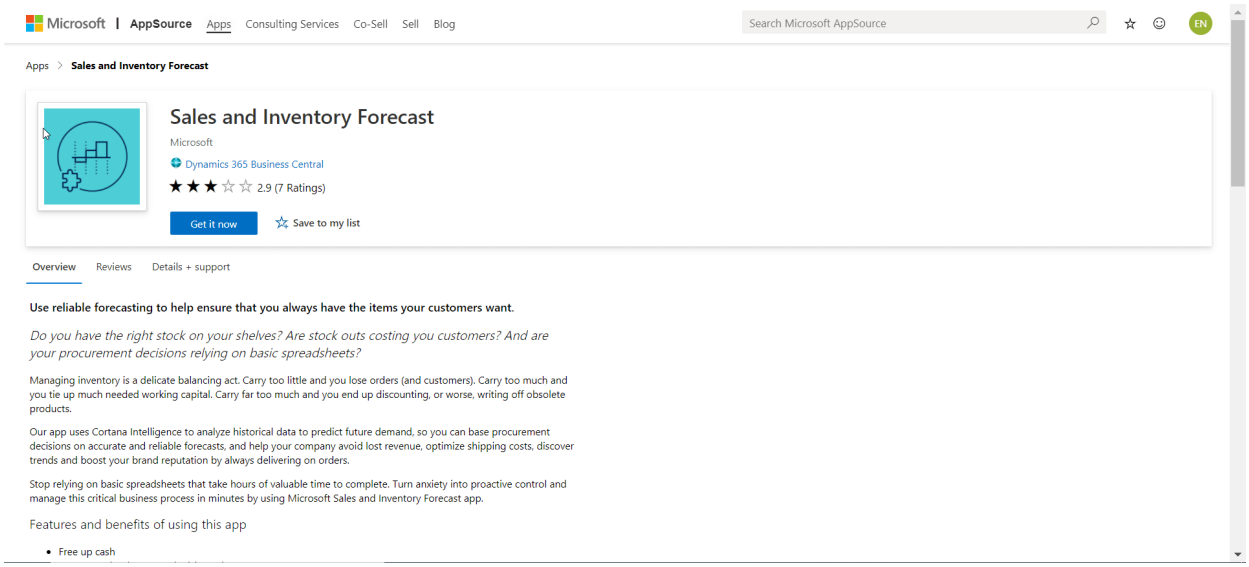
ITEM	REQUIREMENT	DETAILS
Offer name	Enter a descriptive name for the offer.	Read more
Offer summary	A single sentence summarizing the purpose or function of the offer.	Read more
Description text	Make an elaborate and compelling description that outlines the benefits and usage scenarios of your offer (include supported editions, countries, and languages).	Read more
Search keywords	Add search keywords to help users find your offer when they search in the marketplace.	Read more
Products your app work with	Add specific products that your app works with.	Read more
Help link	The link to your offer's learning resources.	Read more
Privacy policy link	The link to your offer's privacy policy.	Read more
Support link	The link to your offer's support page.	Read more
Supporting documents	Add supporting sales and marketing assets such as white papers, brochures, checklists, or PowerPoint presentations.	Read more

ITEM	REQUIREMENT	DETAILS
Logos	Upload a large size logo file with dimensions between 216 pixels x 216 pixels and 350 pixels x 350 pixels.	Read more
Screenshots	Provide a minimum of 3 screenshots that showcase your offer.	Read more
Videos (optional)	Add up to 4 videos that demonstrate your offer. These should be hosted on an external video service.	Read more

Availability

ITEM	REQUIREMENT	DETAILS
Markets (countries)	Choose the markets that your app is available in (make sure that it resembles the supported countries paragraph in the description text).	Read more
Hide key	The hide key is a token that is used to view the preview of your offer in AppSource before going live.	Read more

How does my offer look when it's live on AppSource?



Technical Validation

2/17/2021 • 7 minutes to read • Edit Online

Below you will find a checklist of all requirements that you **must meet before submitting** an extension for validation. You will also find a description of how the Business Central Validation team is performing technical and manual validation and how you can implement a validation pipeline to perform the same technical validation yourself.

Technical Validation Checklist

If you do not meet these mandatory requirements, your extension will fail validation. To get code validation helping you bring your extension package to AppSource, you can enable the **AppSourceCop** code analyzer. For more information, see Using the Code Analysis Tool.

REQUIREMENT	EXAMPLE/GUIDANCE
Develop your extension in Visual Studio Code.	Developing AL Language extensions
The app.json file has mandatory settings that you must include. Here you can also read more about dependency syntax and multiple countries per a single app syntax.	Mandatory app.json settings
Coding of `Date` must follow a specific format (**no longer region-specific**)	Use the format `yyyymmddD`. For example, `20170825D`.
Remote services (including all Web services calls) can use either HTTP or HTTPS. However, HTTP calls are only possible by using the HttpRequest AL type.	Guidance on HTTP use
Only JavaScript based Web client add-ins are supported. The zipping process is handled automatically by the compiler. Simply include the new AL `controladdin` type, JavaScript sources, and build the app.	Control Add-Ins
The .app file must be digitally signed.	Signing an APP Package File
The user scenario document must contain detailed steps for all setup and user validation testing.	User Scenario Documentation
Set the application areas that apply to your controls. Failure to do so will result in the control not appearing in Dynamics 365 Business Central.	Application Area guidance
Permission set(s) must be created by your extension and when marked, should give the user all setup and usage abilities. A user must not be required to have SUPER permissions for setup and usage of your extension.	Exporting Permission Sets Managing Users and Permissions
Before submitting for validation, ensure that you can publish/sync/install/uninstall/reinstall your extension. **This must be done in a Dynamics 365 Business Central environment**.	How to publish your app

REQUIREMENT	EXAMPLE/GUIDANCE
Thoroughly test your extension in a Dynamics 365 Business Central environment.	Testing Your Extension
Do not use `OnBeforeCompanyOpen` or `OnAfterCompanyOpen`	Replacement Options
Include the proper upgrade code allowing your app to successfully upgrade from version to version.	Upgrading Extensions
Pages and code units that are designed to be exposed as Web services must not generate any UI that would cause an exception in the calling code.	Web Services Usage
You are required to prefix or suffix the **Name** of your fields and objects. This eliminates collision between apps.	Prefix/Suffix Guidelines
We strongly recommend you are using automated testing, using the AL Test Toolkit. You are not required to include the test package with your extension.	Testing the Advanced Sample Extension
DataClassification is required for fields of all tables/table extensions. Property must be set to other than `ToBeClassified`.	Classifying Data
You must use the Profile object to add profiles instead of inserting them into the **Profiles** table.	Profile Object
Use `addfirst` and `addlast` for placing your actions on Business Central pages. This eliminates breaking your app due to Business Central core changes.	Placing Actions and Controls

Technical validation performed by the Business Central validation team

The primary responsibility of the technical validation is to ensure that the Business Central online service is stable and that the apps can be installed and run without destabilizing the service.

The technical validation is for a large part automated and will validate the steps described in the technical checklist above through some pipelines.

The submitted apps will be extracted and investigated following this list:

1. The apps are investigated. All dependencies must be included in the submission. We will lookup prior versions of the apps in the depot. If your app has a dependency on a third party app in AppSource, you should not include this, we will locate it in the depot. **Any unresolved dependencies will cause the submission to be rejected.**
2. If the version numbers haven't changed and the countries haven't changed, the validation is skipped and **the apps will not be updated.**
3. App.json is investigated for mandatory fields. **If mandatory fields are missing, the submission is rejected.**
4. Affixes for the submission are located. **If affixes haven't been registered or cannot be located, the submission is rejected.**
5. Business Central Artifacts are located for the version the apps is submitted for (*Current*, *NextMinor*, or

NextMajor).

6. For every country in the submission list, we perform the same validation:
   - A sandbox container based on the Business Central Artifacts with the right country version is created.
   - Any dependency apps not included in the submission are installed. **If any installation fails, the submission is rejected.**
   - In order of dependencies, all apps in the submission are tested using AppSourceCop analyzer. For more information, see AppSourceCop Analyzer
     - If any **breaking changes are identified, the submission is rejected.**
     - If mandatory affixes **are not included on all object names, the submission is rejected.**
   - In order of dependencies, all prior versions of the apps are published and installed. **If any installation fails, the submission is rejected.**
   - In order of dependencies, all new versions of the apps are published and upgrade is run (apps must be digitally signed, else they won't install). **If any installation/upgrade fails, the submission is rejected.**
   - A simple connection test is run; opening a role center and check simple actions and pages. If the connection test fails, **the submission investigated and potentially rejected.**
7. If all country validations succeed and no errors are found then **the submission is accepted.**

> **IMPORTANT**
> Microsoft recommends that all partners are performing the same checks as described above before submitting apps for validation to maximize chances of validation success.

Running technical validation yourself

With the latest version of BcContainerHelper, you can run a single command, which should perform the same validation steps and give you a good indication of whether your apps will pass validation or not:

```
$validationResults = Run-AlValidation `
    -licenseFile "path/url to license file" `
    -validateCurrent `
    -installApps @( "path/url to your foreign dependencies, apps which will not be part of the validation
(or blank if this is the first)" ) `
    -previousApps @( "path/url to your previous version of the .app files (or blank if this is the first)" )
`
    -apps @( "path/url to the new version of the .app files" ) `
    -countries @( "countries you want to validate against (f.ex. us,ca)" ) `
    -affixes @( "affixes you own (f.ex. fab,con)" ) `
    -supportedCountries @( "supported countries (f.eks. us,ca)" )
$validationResults | Write-Host -ForegroundColor Red
```

All array parameters can also be specified as a comma-separated string. For more information, you can also check this blog post Run-AlValidation and Run-AlCops.

Please include app and all library apps in both previousApps and apps and please include all countries on which you want to validate.

> **NOTE**
> The Run-AlValidation cannot see whether the affixes to specify have been correctly registered with Microsoft using your MPN ID and app publisher name, please make sure registration is in place.

IMPORTANT

The Computer on which you run this command must have Docker and the latest BcContainerHelper PowerShell module installed and be able to run Business Central on Docker.

If you are having issues with Business Central on Docker, you might be able to find help here: https://freddysblog.com/2020/10/12/troubleshooting-business-central-on-docker.

You can use https://aka.ms/getbc?artifacturl=bcartifacts%2fsandbox%2f%2fus%2flatest to create an Azure VM, which has all prerequisites installed to run Business Central on Docker.

NOTE

Microsoft recommends that all partners set up DevOps processes to ensure that this validation process happend automatically and regularly.

You can find resources for how to set up a build pipeline, which performs all these steps here: https://aka.ms/cicdhol and you can find sample repositories, performing these steps here:

- https://dev.azure.com/businesscentralapps/HelloWorld.AppSource (for Azure DevOps)
- https://github.com/BusinessCentralApps/HelloWorld.AppSource (for GitHub Actions)

Manual validation performed by the Business Central validation team

The primary responsibility of the manual validation is to ensure that the apps are working as described.

Manual validation is not done on all submissions. They will be done as sample tests.

For manual validation, we spin up a container with the right artifacts (same as used during technical validation) and the necessary apps are installed. Rapidstart packages needed for the manual test are installed.

The manual test validation document is run manually and if the document doesn't match the app functionality the submission is rejected.

IMPORTANT

Microsoft recommends that all partners are performing the manual validation as the last check before submitting for validation.

This can be done either in online sandbox environments or in sandbox docker containers.

Developing AL Language extensions

How to Make Compelling Videos

2/17/2021 • 9 minutes to read • Edit Online

Why use video? It is well worth investing time and resources to create marketing videos for your app, it is taken seriously in a business environment.

Reasons why video is a superior medium

- Videos offers a very rich, stimulating communication medium that engages multiple senses.
- Video engages the mind and triggers emotions, which makes it more compelling than text-based content.
- Our brains have an easier time processing visual stories than bullet points or straight facts.

A recent Demand Gen survey indicated that 58% of B2B buyers consume video content, while Hyperfine media states that 59% of executives would rather watch video than read text. Also, 50% of executives look for more information after seeing a product/service in a video.

Speak to Specific Personas in your videos

You should create a video for each of the three core personas in the company:

- WHY persona: Owner/executive/leadership
- HOW: Business line manager
- WHAT: IT buyer, User

A horizontal generic message that attempts to speak to everyone will likely not reach anyone in an emotionally engaging way. Wasting a prospect's time by requiring him/her to listen to irrelevant data or information will only create frustration and lead him/her to form a negative bias towards your company.

Choose the video format that is relevant for the audience that you want to target

Video type 1: "Why" video

How to set up "Why" videos

- Recommended length: 60-90 seconds
- Purpose:
  - Your video should clearly communicate WHY prospects need to buy your solution now.
- Focus:
  - Make sure the prospect is the hero of the story, not you or your company. Prospects are not interested in hearing about your company at this stage. They are simply trying to determine if what you offer is of value to THEM.
  - Your video should speak to the principal challenges and goals of your core decision-maker persona.
  - Describe the desired end state they will achieve by using your app.
  - A client/customer speaking about the benefits they received from your app is far more credible and compelling than anyone from your organization.
    - Don't only rely on "features" to acquire new customers.

How to speak to a WHY persona in a video

- Target audience:
  - Owner/executive/leadership
  - They have limited time and financial resources as well as many competing priorities and resource requirements
  - You need to elevate the discussion to a strategic level, where you highlight market share, competitiveness, profitability, differentiation, revenue loss, and more.
- Message:
  - The question you must answer beyond a doubt is WHY should they invest the time and money to buy your app? What will they get out of it?
  - Why should they spend money on a new system now? Can't they put it off?
  - The WHY messaging teaches people something and it is industry specific and results oriented, as well as being memorable. It engages the emotional/limbic brain and leads to meaningful action.

Video type 2: "How & What" video

How to set up "How and What product videos"

- Recommended length: Up to 3 minutes.
- Purpose:
  - This video goes into greater depth communicating the main benefits of your app as well as HOW you solve your prospects' problems. You can include some WHAT content. • Focus:
  - Demonstrating the proof of your claims is critical during this video.
  - Show very specific dashboards or visually show how you address prospect challenges.
  - If possible, use contrast to create desire and a sense of urgency. For example, you could show a complex, ugly data-filled forecast spreadsheet next to a beautiful visual dashboard stating "your sales forecast before and after."

How to speak to a HOW persona: (Business line manager)

- Target audience: Business Line Manager
  - HOW focuses on the operational benefits your solution will provide and HOW your organization will support the implementation.
  - Speaking to the HOW persona starts to separate you from the pack. • Message: o HOW content is VISUAL in nature and ACTION oriented. It allows your prospects to identify with you at a FUNCTIONAL business level and to Add-on with you. It provides evidence that your organization has relevant industry experience. Tribal acceptance increases, while risk decreases.
  - HOW messaging begins to appeal to the limbic brain because it is focused primarily on emotional business pains and problems.

How to speak to a WHAT persona: (IT buyer, User)

- Target audience: IT-buyer, User
  - WHAT people are often tasked with finding a solution and are important influencers in the decision, but they are not the financial decision makers, and their opinions are easily overturned by HOW and WHY people in the organization.
  - Therefore, don't invest all of your marketing time, money, and effort into providing content just for them.
- Message:
  - You need to survive the WHAT inquisition and provide information about product-related features, functionality, and data so that prospects clearly understand your solution offering.
  - However, this will seldom trigger an emotional response and, therefore, it is likely there will be little or

no emotional engagement with your content.

- WHAT content is binary. WHAT content is a commodity. WHAT content is boring. Logical WHAT content is a necessary evil because many prospects initially go looking for it, but stopping here means remaining relevant only to WHAT personas.

Video type 3: "Getting started" video

How to set up "Getting started videos"

- Recommended length: 2–3 minutes maximum.
- Purpose: This video should prove it is quick and easy to get up and running with your app.
- Target: What personas (Users, It buyers)

Video type 4: "Customer testimony" video

How to set up "Customer testimonial videos" - Recommended length: Up to 2 minutes

- Purpose:
  - Social reinforcement: Customer stories are the best proof of gain.
- Focus:
  - A story coming directly from your client in the form of a testimonial is stronger than having your prospects take your word for it. If prospects see that other similar people orcompanies have already purchased your solution, then their natural response will be to more readily accept it as a solution for themselves.

Video tips

How to structure your video and practical things to keep in mind when producing videos

How to structure the flow in your video?

- Gain immediate attention in the first 10 seconds of the video Stimulate curiosity by include a hook phrase/comment that will elude to solving a pain point. Ask questions about the prospects' core business challenges or ask about something they would like to do but can't accomplish today.
- Highlight the prospects' problems: Use an empathetic approach when describing their current situation and demonstrate that you understand their current business challenges. They must relate to this if they are to continue watching.
- Give them new learning Teach them something they don't know. Demonstrate you have expertise and knowledge about their business or industry that they might not. Show you can offer strategic value to them.
- Paint a picture of a desired outcome they would love to have or state they crave to experience Highlight the benefits, rewards, and value they will enjoy after they purchase from you. Include both what it looks like and how it will feel.
- Prove what you're saying is true Prospects don't trust us when we say our products are great. Include objective and credible proof in the form of data, charts, graphs, quotes, statistics, or testimonials as evidence of your claims.
- Ask them to take action Include a call to action at the end of all videos. When viewers watch your videos, they should feel inspired to take the next step towards purchasing. Tell them what to do next and include an interactive link to the next step in the buying cycle. Use scarcity to compel them to action. Provide a timelimited offer or, for example, say it is "only for the first 20 customers".

Practical things to keep in mind when producing and distributing your video

Does and don't when producing your video

- Don’t make the video too long As our attention span is 8 seconds the ideal length of video is 90 seconds (minimum 30 seconds/maximum 2 minutes).
- Add interactivity where possible Overlay text, charts, animation, questions etc. Visually call out key messages.
- Make sure your audio is high quality.
- Make your video easily shareable
- Enable your video to be shared on multiple media. Track views and attention span. Observe and measure viewer patterns so that you can learn from prospects’ actual behaviors and then improve future content.

How to make a good narrative that speak to the right persona in the right way?

- Your narrative should have a beginning, middle, and end.
  - Lead with a story, not with your app or the technology.
  - Don’t turn your videos into a product pitch.
  - You’ll build more brand affinity and trust by shedding light on a problem your prospects care about rather than by pitching your solutions to them directly.
- The brain is on alert at the beginning of the video and at the end.
  - Make sure the first and last ten seconds are compelling, memorable, and interesting.
- Speak directly to a particular persona in the second person.
  - Do not talk about them in the third person, and avoid using terms like “our clients” and “companies”; instead, use “you” language as often as possible.
  - Use a lot of industry specific vocabulary, terminology, and visuals. If possible, film onsite at a customer’s location rather than in your office or in a studio.
- Speak to a particular persona:
  - Do not try to appeal to everyone at once, as you may not fully engage anyone with this approach.
  - Keep your delivery casual and authentic to instill trust. Speak directly to the prospect as if you were having a fireside chat
  - The prospect should be the hero of the story, i.e. do not speak about you and your company.
- Ask rhetorical questions that stimulate pain and anxiety in your prospects in order to demonstrate that you understand their business problems.
  - For example: Are your margins decreasing? Having cash flow problems because you can’t collect payments sooner than 90 days? Had another large write off? Lost an important customer recently due to a late delivery?
- Use visual and auditory language to help the prospect imagine a new possible future.
  - For example: “imagine seeing” , “picture yourself”, or “ how would you like to hear your clients say…” and so on.
- Use contrast whenever possible.
  - Compare prospects’ experience now versus what it could be after the implementation of your solution.
  - Call out your competitive differentiators while anchoring your solution in prospects’ minds so that they can compare all others against the bar you set.

How to make a good narrative that speak to the right persona in the right way?

- Where possible, use tangible, concrete language.
  - Include quantifiable proof in the form of data or visual pictures.
  - No vague claims like “transform your business with the cloud”. This is an emotionless statement.
- Providing customer references and testimonials is much more compelling and effective than selling your company or product yourself.
  - Let others speak for you. A customer testimonial video will always be more believable and compelling than a video of you saying the same thing.

- Surprise and delight them.
    - Use humor to make them smile. We take ourselves and our problems too seriously. Be warm, memorable, and unique.

Guideline on Creating an Effective Sales Landing Page for Your App

2/17/2021 • 10 minutes to read • Edit Online

Building a landing page that drives a successful buying transaction

Microsoft will drive qualified traffic to AppSource. Though, once a prospect becomes aware of your app, it will be your job to guide them through to a successful buying transaction. Deliberately mapping and architecting the buying journey is critical to ensure a high level of engagement and conversion. Only presenting your app's features and functionality, or just providing a free trial, will not ensure prospects will become buyers. For this you need to have a good landing page that is built to help you capture attention, accelerate your customer acquisition process, and drive buying behavior. The recommendations on this page will help you do so.

Examples of how other partners have implemented our best practices

To inspire you in creating a good landing page for your app, two of our valued partners, LS Retail and Industry Built, have offered to provide a sample of what a best practice landing page for a Microsoft Dynamics 365 Business Central partner could look like.

Have a look at their app landing pages and use them as inspiration to build your own landing page:

- Industry Built's Build Food app
- LS Retail's LS Express Start app

In the following checklist, we have "broken down" the elements, on their landing pages in order to showcase best practices on design and messaging. More specifically, we are looking into layout and structure elements, content elements, visual elements, anxiety reducing elements and support elements.

Additionally, we have provided specific recommendations on how to apply these elements to help you increase conversion and maximize the effectiveness of your product's sales landing page.

We urge you to review and implement these best practices on your landing page – in so doing you will contribute in providing the Microsoft community of customers with a consistent buying experience across publishers.

Layout and structure elements

ELEMENT	DESCRIPTION	EXAMPLE
Company	Include the company logo on the page	
App name & app logo	Include a visual logo of your product name and a one sentence positioning statement.	
Top menu choices	Use clean, straightforward and descriptive menu options.	

ELEMENT	DESCRIPTION	EXAMPLE
Search box	Include a search box so visitors can quickly find what they are looking for.	
Emotional tribal anchor photos	Visuals create an emotional Add-onion. The brain skims over non-emotional photos.	
Visual	Make your page easy to scan, with lots of strong visual imagery.	

Logo

- The upper-left corner of the landing page is the most valuable section of the entire landing page.
- Place your company logo in this location.

If you need help formulating a positioning statement, try the value proposition generator located at here.

- There should ideally be 5 or fewer choices; do not include more than 7 options.
- The menu text should state what the prospect gains if they click on the menu item
- The text should be written from their perspective, not yours.

Recommended menu items:

- How to Buy, Benefits Gained, Why Us, and Contact.

The upper-right corner of the page is usually an ideal spot

- Faces evoke more emotion than landscapes or machines, and so on.
- Include a happy customer that looks similar to your prospect in terms of age, demographic, and industry, and which shows them dealing with the issues that your prospect can relate to.
- Try not to use stock photos of people or objects.

Engagement

- Too much text forces the brain to skim, skip, and exit. Text engages the logical, analytical brain, but not the emotional brain.
- Keep it clean and straightforward in terms of design and layout. Use lots of pictures, graphs, and screen shots to enhance engagement.

Content elements: Text and messaging

ELEMENT	DESCRIPTION	EXAMPLE	
Include a headline question	Get your prospects' attention by asking them a compelling pain-based question that they can relate to.	"Struggling to manage your ingredient inventory and fretting over allergens?"	

ELEMENT	DESCRIPTION	EXAMPLE	
	You want the prospect to mentally say "YES" as often as possible and to peak their curiosity enough to read more.		
	Your questions should be intriguing and customer-centric.		
	In general, 8 out of 10 people will read headline copy, but only 2 out of 10 will read the rest.		
Microsoft Dynamics 365 product description	Somewhere on the landing page, make sure you include the standard Microsoft Dynamics 365 Business Central product description provided by Microsoft *This is a requirement because your product is adding value to and building on this foundational solution.*	*Insert this paragraph:* Microsoft Dynamics 365 Business Central is a comprehensive business management solution for small and medium-size businesses (SMBs) that have outgrown their basic accounting software. From day one, this new application makes ordering, selling, invoicing, and reporting easier and faster. Dynamics 365 Business Central is deeply integrated with Microsoft 365 and includes built-in intelligence, so it is easy to use and helps users make better business decisions.	
Messaging (Address their pains)	Pain is a strong motivator of action.		
	- Identify 1-3 key sources of the client's most prominent pain early on the page.		
	- Call out the fears that are likely to be holding them back.		
	- Your landing page text and messaging should predominantly focus on the pain the prospect is experiencing, and NOT the features of your product or service.		

ELEMENT	DESCRIPTION	EXAMPLE	
Clearly demonstrate to your prospects that you genuinely understand their industry and unique business problems.	- Describe the business challenges they are facing now and the ways their revenue growth, margins, productivity and so on, are being negatively impacted by not taking action now.		

ELEMENT	DESCRIPTION	EXAMPLE
Messaging (Product benefits)	Paint a clear, visual and desirable picture of what is possible.	
	Describe the most significant benefits and rewards that your prospect will realize after purchase.	- For example, "Save time and money (benefits) by having a system that does all the tracking and calculations for you (features)."
	- Don't only list features and app functionality, start with the benefit first, then you can follow with the features.	
	- Paint a picture of a possible experience the prospect will immediately desire.	
Clearly articulate a compelling desired outcome	- If possible, use industry-specific language and vocabulary to resonate with your prospect deeply.	
	- Choose a particular persona to speak to directly.	
	- Engage prospects by speaking directly to them using first person "you" language.	

ELEMENT	DESCRIPTION	EXAMPLE
Messaging (Prove your claims)	Include specific calls-to-action on your app page.	"Reduce how long it takes to set up your recipes in the morning from 1 hour to 10 minutes."
	Don't make general and abstract claims.	

- Use data as often as possible to support your statements.

If you make specific claims, support your claims with proof, while Quantifying impacts and gains.

- The more specific and concrete your promise of value is, the better.
- Abstract concepts such as "more efficiency, more productivity, transform your business" are not emotionally

impactful or convincing and do not compel a prospect to act.

Target market - If you support multiple countries or languages, this is a key selling feature. • Find a way to show this visually.

ELEMENT	DESCRIPTION	EXAMPLE
Messaging (Compelling call-to-action)	Include specific calls-to-action on your app page	

- This can be your free trial; a time-limited special price; a scheduled walk-through demonstration; and so on.
- The words "free" and "save" are highly emotional words in the English language, so they should be used.
- Use bright colors, such as orange, yellow, or red, to call attention to your buttons.

Button text should use benefit language rather than descriptive language.

- For example, instead of "Download" write "Click here to start saving money now."
- Try not to send prospects away from your page – always have an embedded next step in your call to action that brings them back to your landing page.

ELEMENT	DESCRIPTION	EXAMPLE
Messaging (Create a sense of urgency by teaching the prospects)	Help your prospect gain a sense of urgency to buy by teaching them one thing about how they can be more efficient or profitable now.	Your bakery profitability will decrease over the next five years due to an increase of 3% in the cost of key inputs, such as wheat and sugar. Want to know five key strategies that can help you mitigate this challenge? Click here to find out how to preserve your profit margin

- Show them how their performance in one key business area is below that of their competitors.
- For an example you can provide a quick online self-assessment, a top-10 tips blog post, and much more. Visual elements

ELEMENT	DESCRIPTION	EXAMPLE	
Pictures (Differentiation comparison images)	Show them, don't tell them	Show the before and after state.	

- This is a visual image of how your prospects do things now versus how they will be able to do it in the future.
- You are not telling them but showing them using a visual.

ELEMENT	DESCRIPTION	EXAMPLE
Compelling proof screen shots	Visually demonstrate all the claims that you are making.	Quickly and easily view inventory items

- Graphic dashboards are the most effective method.
- Zoom in on the main benefit-related features.
- Make sure it is readable, and the benefit is obvious.
- Include a caption.
- Data should be industry specific so that it resonates with the viewer.

You want prospects to see how their data/process would look in your system.

ELEMENT	DESCRIPTION	EXAMPLE
Videos (Tell your story using videos not text)	Include as many videos as possible.	

- Videos have a much higher level of engagement and viewing time and convey much more than you can ever say with words.

Include at least one customer testimonial video on your app landing page.

- Your client should speak specifically about the pains they had before and the benefits they gained after, not product features. It should be all about your customers, not you.

Include one product demonstration video.

- See the video best practices https://aka.ms/ReadyToGo.

Elements that reduce anxiety and risk, while increasing trust

ELEMENT	DESCRIPTION	EXAMPLE
Customer testimonials	Don't sell your product; let your customers do that for you.	

- Social proof is more credible and trustworthy to prospects. The purpose of testimonials is to reduce the buyer's anxiety and fear.

Your testimonials should answer the following questions:

- "Will this work for my situation?"
- "What benefit will I really get if I buy this?"
- "Is this going to be too hard?"
- "How long is this going to take?"
- "Can I trust this company?"

ELEMENT	DESCRIPTION	EXAMPLE
Reduce risk	Prospects are afraid of being scammed and taken advantage of on the internet. They are naturally cautious and highly suspect.	Source: Microsoft.com

- You want to convert prospects to buyers.
- Make it easy for them to buy, while reducing their anxiety. Transparency is the key to building trust.
- Make sure that you include a link to a BUY NOW page, which includes full pricing details.
- Give them a compelling offer they cannot refuse. Offer a time-limited trial or special pricing discount if they buy in 30 days.
- Use scarcity to compel action. Offer a 100% money-back guarantee.

We recommend providing three offerings, optimized for three different customer segments. For more recommendations on pricing, see the pricing guide located at https://mbspartner.microsoft.com/BFI/Topic/64

ELEMENT	DESCRIPTION	EXAMPLE
Live chat	Include live chat, with a photo of one of your team members smiling at an appropriate time to increase conversion, such as when a prospect clicks the back button on your pricing page.	

- Include their name if possible to build trust.

Support elements: Interactivity and contact options

ELEMENT	DESCRIPTION	EXAMPLE
SHORT lead capture form	Include a lead capture form on your page.	

- Only ask for their name and email address, you can get the rest later.
- Your forms should not have more than 4 or 5 fields to fill out. You have not yet earned the right or enough trust to ask for too much information at this point.

Most lead capture forms are way too long, demanding, and intimidating, and have low completion rates.

> **NOTE**
> Nobody has the time or is willing to fill out an annoying form, which is of no value to them, especially if it is purely self-serving from your standpoint.

ELEMENT	DESCRIPTION	EXAMPLE
Contact	Provide prospects with different contact options based on their readiness to interact with you.	

- Ideally, include a phone number and an email address with an employee photo.
- This alone could double your conversion rate.

ELEMENT	DESCRIPTION	EXAMPLE
AppSource app page link & social share	Include a link back to your listing on AppSource, so the prospect can return when ready.	Return to AppSource

- Also, enable visitors to share and forward your app with others!

ELEMENT	DESCRIPTION	EXAMPLE
Close them! Add a get started button	Include a very specific call-to-action button with the option to buy or try.	

Getting Started with C/SIDE and AL for On-Premises

2/17/2021 • 2 minutes to read • Edit Online

To get started with a mixed development environment of C/SIDE and AL, you must follow the steps below.

Steps to install Business Central on-premises with C/SIDE and AL development environment

1. Install Business Central on-premises and make sure to include the **AL Development Environment**.
2. Download Visual Studio Code.
3. From Visual Studio Code, locate **Extensions** in the left navigation bar, and then choose **Install from vsix**.
4. Browse to the equivalent folder of `C:\Program Files (x86)\Microsoft Dynamics 365 Business Central\160\AL Development Environment` and then choose **Install**.
5. Now, press **Alt+A, Alt+L** to trigger the **AL Go!** command, choose a project, the target platform, and then choose **Your own server**.
6. Authenticate with the credentials you use for signing into Business Central on-premises.
7. In the launch.json file, update the `"server": "https://localhost"` setting with the URL for server running Business Central on-premises and save the file.
8. In the app.json file, add the `"target": "OnPrem"` setting.
9. Now, use the Business Central Administration Console to ensure that the settings on the **Development** tab are set as follows:
   - **Allowed Extension Target Level** is set to **OnPrem**.
   - **Enable Developer Service Endpoint** checkbox is selected.
   - **Enable Loading Application Symbol References at Server Startup** checkbox is selected.
10. Make sure to read and ensure any additional settings here Running C/SIDE and AL Side-by-Side.

> **TIP**
> For information about which sandboxes you can choose, see Sandbox Environments for Dynamics 365 Business Central Development.

> **NOTE**
> Build and get inspired by our sample library on GitHub.

FAQ for Developing in AL

Running C/SIDE and AL Side-by-Side

2/17/2021 • 3 minutes to read • Edit Online

Business Central on-premises supports development using both C/SIDE and AL, as well as Designer side-by-side. When new objects are added or changed in C/SIDE these changes must be reflected in the symbol download in Visual Studio Code using the AL Language extension. To enable this reflection, a command and argument called `generatesymbolreference` has been added to finsql.exe and you can run it as illustrated below.

Get started generating symbols and compiling all objects

Open a command prompt **Run as administrator** and change to the directory where the finsql.exe file has been installed as part of Dynamics NAV Development Environment.

Use the `generatesymbolreference` command specified with the database and server name to add symbol references to the **Object Metadata** table for the specified database.

Given the `generatesymbolreference` command, C/SIDE will traverse all the objects in the database and generate symbols for them. This command should be run at least once to generate the initial set of symbols to which incremental updates can be applied.

Syntax example

```
finsql.exe Command=generatesymbolreference, Database=<DatebaseName>, ServerName=<ServerName>\<Instance>
```

For example:

```
finsql.exe Command=generatesymbolreference, Database="Demo Database NAV (11-0)", ServerName=.\NAVDEMO
```

> **TIP**
> The finsql.exe includes several parameters that you can set to suit you environment. For more information, see Using the Development Environment from the Command Prompt.

This is a lengthy operation. When you run the command, the console returns to an empty command prompt, and does not display or provide any indication about the status of the run. However, the finsql.exe may still be running in the background. It can take several minutes for the run to complete, and the symbols will not be generated until such time. You can see whether the finsql.exe is still running by using Task Manager and looking on the **Details** tab for **finsql.exe**.

When the process ends, a file named **navcommandresult.txt** is saved to the Dynamics NAV Client connected to Business Central installation folder. If the command succeeded, the file will contain text like `[0] [06/12/17 14:36:17] The command completed successfully in '177' seconds.` If the command failed, another file named **naverrorlog.txt** will be generated. This file contains details about the error(s) that occurred.

NOTE

The symbol references are stored in the **Symbol Reference** column of the **Object Metadata** table of the database. For on-premises installations, if you experience problems with generating symbols, check the information in the naverrorlog.txt file.

Continuously generate symbols each time you compile objects in C/SIDE

The `generatesymbolreference` flag enables incremental symbol generation through the UI or through the compile command passed on the command line. To update the symbols for a set of objects from the UI, start C/SIDE with the `generatesymbolreference` flag, make any desired modifications to your application objects, and compile them.

NOTE

Use `generatesymbolreference` set to yes as a command line argument each time you start finsql.exe to have all compilations add a symbol reference to the **Object Metadata** table. The default setting of the argument is no.

NOTE

If you make changes in C/SIDE and start the C/SIDE development environment without the `generatesymbolreference` flag set to `yes`, the symbols downloaded from Visual Studio Code will not reflect your changes.

Syntax example

```
finsql.exe generatesymbolreference=yes
```

This flag is also a part of the `Compile-NavApplicationObject` PowerShell command and you can use it to compile and generate symbols on a filtered set of application objects through PowerShell. This alternative should be considered if you do not work with the UI in C/SIDE. For more information about it, see Compile-NavApplicationObject.

Business Central on-premises server setting

In addition to the symbol generation setting you have chosen above, you must enable the Business Central on-premises server setting.

1. Go to **Business Central Administration**.
2. Scroll to the **Development** tab and expand the tab.
3. Choose the **Edit** button, and then select the **Enable loading application symbols at server startup** checkbox.

IMPORTANT

This setting must be enabled to allow any symbol generation. If the setting is not enabled, the `generatesymbolreference` setting does not have any effect.

Creating Runtime Packages for Business Central On-Premises

2/17/2021 • 2 minutes to read • Edit Online

If you want to distribute extensions, you can generate runtime packages that do not contain AL code, but only the final artifacts used by the server at runtime. Runtime packages thereby allow you to protect the intellectual property represented by your AL source code.

When the runtime package is generated on the server, the developer license is checked for permissions to the used extension IDs. The extension in a runtime package can then be installed on servers that do not have a developer license; the server only needs permissions to run the objects, but not to modify or insert them.

Start using runtime packages

The first step in using runtime packages is to have an extension developed and published to an on-premise instance. Next, use the following PowerShell command to connect to the server, find the extension, and download the runtime package.

```
Get-NavAppRuntimePackage
```

For more information about this cmdlet, see Get-NAVAppRuntimePackage cmdlet.

The following example gets the NAV App runtime package with the provided name and version.

```
Get-NAVAppRuntimePackage -ServerInstance DynamicsNAV -AppName 'Proseware SmartApp' -Version 2.3.4.500 -Path
'Prosware SmartApp_2.3.4.500_runtime.app'
```

For publishing and installing the package, use the Publish-NavApp and the Install-NAVApp PowerShell cmdlets.

Limitations

The limitation of runtime packages is that they only work for on-premise installations and therefore cannot be submitted to AppSource. Moreover, debugging into an extension to view the source code is not allowed by default; the `ShowMyCode` flag is by default set to `false`.

> **NOTE**
> Runtime packages are guaranteed to work only if published to a platform with the same version as the one where they were produced.

> **NOTE**
> If you set the `ShowMyCode` flag to `true` when running the `Get-NavAppRuntimePackage` cmdlet, you can enable debugging and you thereby also allow viewing the source code.

Sandbox Environments for Dynamics 365 Business Central Development

2/17/2021 • 2 minutes to read • Edit Online

To get started developing for Dynamics 365 Business Central it is important to understand the different options you have at hand. You can either choose to run a sandbox environment deployed as a Dynamics 365 Business Central service, or you can run a container-based image either hosted as an Azure VM or locally. Both options provide the AL development tools; the container-based sandbox additionally provides access to the C/SIDE development tools. You can also choose to run a sandbox environment with production data using the **Business Central Admin Center**. For more information, see Business Central Admin Center.

> **NOTE**
> Extensions that have been published to a sandbox environment from Visual Studio Code or created using Designer are removed when the environment is updated or relocated within our service. For more information, see Production and Sandbox Environments.

> **IMPORTANT**
> It is not supported to publish, from Visual Studio Code, an extension with the same identifiers as an extension published to AppSource. Identifiers include the combination of appID and version or name, publisher, and version. If you do publish such an extension, it can be removed at any time.

Development sandbox overview

The following table outlines the most important capabilities on the offered development sandbox environments for Dynamics 365 Business Central.

CAPABILITY	ONLINE SANDBOX	CONTAINER SANDBOX
Deployment	Dynamics 365 Cloud Service managed by Microsoft	Azure VM or on-premises managed by ISV/VAR
Production data	Manually uploaded using Rapid Start packages. Or, available through the Business Central Admin Center.	Manually uploaded using Rapid Start packages
Production services	Manually configured	Not available
Cost	Part of the Business Central subscription	Locally hosted - free, Azure-hosted - cost incurred
Development	Full capabilities of the development environment. Designer functionality, such as: Add/Remove components, Move components, Set/clear Freeze pane, Edit captions	Full capabilities of the development environment. Designer functionality, such as: Add/Remove components, Move components, Set/clear Freeze pane, Edit captions

CAPABILITY	ONLINE SANDBOX	CONTAINER SANDBOX
Tools	Visual Studio Code, Designer	Visual Studio Code, Designer, on-premise tools such as SQL Server Management Studio, and C/SIDE.
Debugging	Enabled	Enabled
Database access	No	Yes
Extensions	Must be manually installed.	Must be manually installed.
From AppSource	Available.	Not available.
From File	Available.	Available.
From Visual Studio Code	Available.	Available.

Getting started

Based on the overview above and the requirements for your development environment, you can get started with a sandbox by following the links below:

- Online Sandbox with Demo Data
- Online Sandbox with Production Data
- Container Sandbox

Get started with the Container Sandbox Development Environment

2/17/2021 • 3 minutes to read • Edit Online

Dynamics 365 Business Central offers a container-based image environment that enables access to the AL development environment.

You set up a container sandbox by running the **Container Sandbox Environment** page from Dynamics 365 Business Central. You will have to decide whether you want an Azure-hosted or locally hosted container sandbox. See the next section for details.

> **TIP**
> Dynamics 365 Business Central also offers an online sandbox. For more information, see Sandbox Environments for Dynamics 365 Business Central Development.

Choosing an Azure-hosted or local-hosted container sandbox

When you set up the container sandbox, you can choose to host the sandbox on Microsoft Azure or on a local computer. Both environments offer the same capabilities and use Docker to provide the infrastructure for the container-based application. The difference is:

- With Azure hosting, Docker is installed and configured for you. However, Azure hosting requires that you sign up for an Azure subscription, and additional costs may be incurred for each container sandbox.
- Local hosting requires that your computer is running Windows 10, Windows Server 2016, or Windows Server 2019, and you install and configure Docker before setting up the container sandbox.

Set up an Azure-hosted container sandbox

1. If you you do not already have one, sign up for an Azure subscription.

   To get a free subscription and read more information, see https://azure.microsoft.com.

2. In Dynamics 365 Business Central, choose the icon, enter **Container Sandbox Environment**, and then select the relevant link.

3. Choose **Host in Azure**. If prompted, enter the user name and password of your Azure subscription.

   The Azure portal opens to display a custom deployment form.

4. Fill out the required fields on the form, and then select **Purchase**.

> **NOTE**
> You must set the **Accept Eula** setting to **Yes** in order to continue.

Set up a local-hosted container sandbox

1. If not already done, install Docker.

   To install and configure Docker, choose the version of Docker that is appropriate for the host operating

system:

- For Windows 10, use Docker Community Edition. For more information, see Install instructions.
- For Windows Server, use Docker Enterprise Edition. For more information, see Install instructions.

2. In Dynamics 365 Business Central, choose the  icon, enter **SANDBOX ENVIRONMENT (CONTAINER)**, and then select the relevant link.
3. Choose **Host Locally**.
4. Save the **CreateBCSandbox.ps1** file to your computer.
5. Run Windows PowerShell ISE as an administrator.
6. Open the **CreateBCSandbox.ps1** file.
7. Set the `$containername = ''` variable to the name that you want to give the container, for example `$containername = 'mybc'`.

   This name is only used internally in your envirorment for identification purposes.
8. Set the `$accept_eula = ''` variable to `'$true'`.
9. Press F5 to run the script.

   The console pane displays the progress of the script. When the script has completed successfully, information like the following will display:

```
...
Container IP Address: 172.22.147.63
Container Hostname  : mybc
Container Dns Name  : mybc
Web Client          : http://mybc/BC/
Dev. Server         : http://mybc
Dev. ServerInstance : BC

Files:
http://test:8080/ALLanguage.vsix

Initialization took 116 seconds
Ready for connections!
Reading CustomSettings.config from mybc
Creating Desktop Shortcuts for mybc
```

10. Write down or copy the following parameter/values from the console: `Dev. Server`, `Dev. ServerInstance`, and `Files`. You will need this information later to set up Visual Studio Code for extension development.

You now have a container sandbox set up on your computer. The following shortcuts have been added to your desktop:

- **<Container name> Web Client** - opens the Web client for the your application in the container.
- **<Container name> PowerShell Prompt** - opens a Windows PowerShell prompt in the container. This gives you access to the Dynamics NAV (/powershell/business-central/overview), which you can run against the container sandbox environment.
- **<Container name>Command Prompt** - opens a Windows command prompt in the container.

For more information about working with a container sandbox, see Running a Container-Based Development Environment.

Set up Visual Studio Code

After the container sandbox is set up, you must set up Visual Studio Code for extension development. To do this,

you need the values for `Dev. Server`, `Dev. ServerInstance`, and `Files` parameters that you retrieved from the Windows PowerShell ISE console when you ran the **CreateBCSandbox.ps1** script.

1. In Visual Studio Code, go to **Extensions**, and install the AL Language extension from the Marketplace. You now have the AL Language extension enabled.
2. In Visual Studio Code, press **Ctrl+Shift+P** and then choose **AL Go!**.
3. Choose where to create the project, and then choose the **Your own server** option.
4. Open the generated `launch.json` file, update the `"server"` setting with the value of the `Dev. Server` parameter and the `"serverInstance"` setting with the value of the `Dev. ServerInstance` to reflect the container you just created. For example:

   ```
   "server": "http://mybc",
   "serverInstance": "BC",
   "authentication": "Windows",
   ```

5. Save the launch.json file.

You have now set up Visual Studio Code with the AL Language extension.

AL Development Environment

Working with Development Sandboxes and Entitlements

2/17/2021 • 4 minutes to read • Edit Online

The experience that a user has in Dynamics 365 Business Central depends on the purchased subscription plan. In Dynamics 365 Business Central, there are two main plans; the Essential and the Premium plan, plus a few more. For more information, see Licensing in Dynamics 365 Business Central. For detailed information about the Essential and Premium plans, see Business Central on the Microsoft Dynamics 365 site.

When you develop in a Docker sandbox, the Essential experience is automatically assigned to you (you set the experience on the **Company Information** page), which makes it difficult to test how a user with the Premium plan assigned will experience what you have developed.

> **NOTE**
> There is no license check in a Docker Sandbox except for on Purchase and Sales documents. There is a different behavior in these documents as the **TEAMMEMBER** license has partial access. In particular Invoices, Orders, Quotes and Credit Memos share the same table and the **TEAMMEMBER** license has access only to Quotes.

Setup for users with different plans

To mimic users with a specific subscription plan assigned, you can set them up with the user groups as detailed in the table below. When you add user to the group, the permission sets defined for the group will apply to the user. For more information, see To group users in user groups.

> **NOTE**
> In the table below *non-default* means not assigned by default, but the plan allows this to be assigned to the user.

USER NAME THE TYPE OF SUBSCRIPTION PLAN ASSIGNED TO THE GIVEN USER	USER GROUPS
EXTERNAL ACCOUNTANT Dynamics 365 Business Central External Accountant	D365 EXT. ACCOUNTANT D365 EXTENSION MGT (non-default) D365 TROUBLESHOOT (non-default) D365 SECURITY (non-default)
PREMIUM Dynamics 365 Business Central Premium Dynamics 365 Business Central for IWs	D365 BUS PREMIUM D365 EXTENSION MGT (non-default) D365 TROUBLESHOOT (non-default) D365 SECURITY (non-default)
ESSENTIAL Dynamics 365 Business Central Essential	D365 BUS FULL ACCESS D365 EXTENSION MGT (non-default) D365 TROUBLESHOOT (non-default) D365 SECURITY (non-default)

USER NAME THE TYPE OF SUBSCRIPTION PLAN ASSIGNED TO THE GIVEN USER	USER GROUPS
INTERNALADMIN Internal Administrator (Microsoft 365 Global administrator role)	D365 INTERNAL ADMIN D365 TROUBLESHOOT D365 BACKUP/RESTORE D365 SECURITY (non-default)

DEVICE Dynamics 365 Business Central Device	D365 FULL ACCESS D365 EXTENSION MGT (non-default) D365 BUS PREMIUM (non-default)* D365 TROUBLESHOOT (non-default) D365 SECURITY (non-default) *) Please note: usage need to be according to terms in Licensing Guide
DELEGATEDADMIN Delegated Admin agent - Partner Delegated Helpdesk agent - Partner	D365 EXTENSION MGT D365 FULL ACCESS D365 RAPIDSTART D365 BACKUP/RESTORE D365 TROUBLESHOOT D365 SECURITY (non-default)

TIP

For more information about how to choose a user experience, see Changing Which Features are Displayed.

Assigning the Premium plan to test users

Depending on how you are running your Docker sandbox, you assign the experience in different ways.

Azure VMs

If you use https://aka.ms/bcsandbox to create your Dynamics 365 Business Central Sandbox Container Azure VM, the Azure Resource Manager template has two fields; **Assign Premium Plan** and **Create Test Users**, which by default are set to **Yes**.

Assign Premium Plan specifies whether or not your admin user should be assigned a Premium plan. **Create Test Users** specifies whether or not you want the setup to include test users.

BCContainerHelper

If you are using `New-BCContainer` to create your Dynamics 365 Business Central Sandbox container, you must make sure that you are using version 0.2.8.3 or later.

Use the switch `assignPremiumPlan` on `New-BCContainer` like this:

```
New-BCContainer -accept_eula -updateHosts -containerName test -artifactUrl (Get-BCArtifactUrl -country us) -
assignPremiumPlan
```

This assigns the Premium plan to your default admin user. Internally this just adds a record to the **User Plan** table.

To create the test users, you must call the `Setup-BCContainerTestUsers` method:

```
Setup-BCContainerTestUsers containerName test -tenant default -password $securePassword
```

specifying the container and the password that you want to use for the new users.

Internally, the `Setup-BCContainerTestUsers` downloads an app which exposes an API, publishes and installs the app, and then invokes the `CreateTestUsers` API with the password needed. After this, the app is uninstalled and unpublished.

If you want to see code behind the app, it is available here.

Docker run

If you are using Docker run to run your containers, you have a little more work to do.

First of all, you must override the `SetupNavUsers.ps1` by sharing a local folder to `c:\run\my` in the container and place a file called `SetupNavUsers.ps1` in that folder with the following content:

```
# Invoke default behavior
. (Join-Path $runPath $MyInvocation.MyCommand.Name)

Get-NavServerUser -serverInstance $ServerInstance -tenant default |? LicenseType -eq "FullUser" | ForEach-
Object {
    $UserId = $_.UserSecurityId
    Write-Host "Assign Premium plan for $($_.Username)"
    Invoke-Sqlcmd -ErrorAction Ignore -ServerInstance 'localhost\SQLEXPRESS' -Query "USE [$TenantId]
    INSERT INTO [dbo].[User Plan$63ca2fa4-4f03-4f2b-a480-172fef340d3f] ([Plan ID],[User Security ID]) VALUES
('{8e9002c0-a1d8-4465-b952-817d2948e6e2}','$userId')"
}
```

This will assign the Premium plan to the admin user in the database.

> **TIP**
> To set up test users, you can clone the createtestusers repository and modify the code to create the users on the `oninstall` trigger with the password that you want.

JSON Files

2/17/2021 • 15 minutes to read • Edit Online

In an AL project there are two JSON files; the `app.json` file and the `launch.json` file that are generated automatically when you start a new project. The `app.json` file contains information about the extension that you are building, such as publisher information and specifies the minimum version of base application objects that the extension is built on. Often the `app.json` file is referred to as the manifest. The `launch.json` file contains information about the server that the extension launches on.

> **NOTE**
> For information about data migration and creating a `migration.json` file, see The Migration.json File.

> **IMPORTANT**
> The `rad.json` and the `snapshots.json` files should not be modified.

App.json file

The following table describes the settings in the `app.json` file. For an example `app.json` file, see Business Central Performance Toolkit.

SETTING	MANDATORY	VALUE
id	Yes	The unique ID of the extension. When the `app.json` file is automatically created, the ID is set to a new GUID value. **Note:** The appId is used at runtime to bind table names contained in the application. Changing the appId will result in data from old tables not being used.
name	Yes	The unique extension name.
publisher	Yes	The name of your publisher, for example: **NAV Partner, LLC**.
brief	No, but required for AppSource submission	Short description of the extension.
description	No, but required for AppSource submission	Longer description of the extension.
version	Yes	The version of the app package.
privacyStatement	No, but required for AppSource submission	URL to the privacy statement for the extension.
EULA	No, but required for AppSource submission	URL to the license terms for the extension.

SETTING	MANDATORY	VALUE
help	No, but required for AppSource submission	URL to an online description of the extension. The link is used in AppSource and can be the same as the value of the `contextSensitiveHelpUrl` property or a different link, such as a link to your marketing page.
url	No, but required for AppSource submission	URL of the extension package.
logo	No, but required for AppSource submission	Relative path to the app package logo from the root of the package.
dependencies	No	List of dependencies for the extension package. For example: `"dependencies": [ {"id": "4805fd15-75a5-46a2-952f-39c1c4eab821", "name": "WeatherLibrary", "publisher": "Microsoft", "version": "1.0.0.0"},{}]` . **Note:** For dependencies to the System Application and Base Application these are no longer listed as explicit dependencies, but captured in the `application` setting as a reference to the application package. Must be filled in with the version number of the Application package. See `application` below. **Note:** The version specified defines the minimum version for the dependency. At runtime and when downloading symbols, the latest version of the dependency satisfying the specified name, publisher and, minimum version will be returned. When `runtime` is set to 4.0 or earlier, use `appId` instead of `id`.
screenshots	No	Relative paths to any screenshots that should be in the extension package.
platform	Yes, if system tables are referenced in the extension	The minimum supported version of the platform symbol package file, for example: "16.0.0.0". See the Symbols for the list of object symbols contained in the platform symbol package file.

SETTING	MANDATORY	VALUE
application	Yes, if base application is referenced in the extension	The supported version of the system and base application package file, for example: "16.0.0.0". The file name of this reference is Microsoft_Application.app and the `name` is `Application`. For code-customized base applications, the Microsoft_Application.app file can be modified to reference the code-customized base application instead. It is important to keep `"name": "Application"` in the extension, but information about publisher can be changed and the .app file can be renamed. For more information, see The Microsoft_Application.app File.
idRange	Yes	For example: `"idRange": {"from": 50100,"to": 50149}`. A range for application object IDs. For all objects outside the range, a compilation error will be raised. When you create new objects, an ID is automatically suggested.
idRanges	Yes	For example: `"idRanges": [{"from": 50100,"to": 50200},{"from": 50202,"to": 50300}]`. A list of ranges for application object IDs. For all objects outside the ranges, a compilation error will be raised. When you create new objects, an ID is automatically suggested. You must use *either* the `idRange` *or* the `idRanges` setting. Overlapping ranges are not allowed and will result in a compilation error.
showMyCode	No	This is by default set to `false` and not visible in the manifest. To enable viewing the source code when debugging into an extension, add the following setting: `"showMyCode": true`

SETTING	MANDATORY	VALUE
target	No	By default this is `Cloud`. The setting currently has the following options: `Internal`, `Extension`, `OnPrem`, and `Cloud`. The `Internal` and `Extension` settings are being deprecated with runtime 4.0 and replaced by the `OnPrem` and `Cloud` respectively. For on-premises, you can set this to `OnPrem` to get access to otherwise restricted APIs and .NET Interop. The Business Central Server setting must then also be set to `OnPrem`. **Note:** System tables that have the Scope property set to `Internal` / `OnPrem` cannot be accessed from extensions that have `target` set to `Cloud` / `External` through direct reference or through RecordRef. For more information, see Compilation Scope Overview
contextSensitiveHelpUrl	No, but required for AppSource submission	The URL for the website that displays context-sensitive Help for the objects in the app, such as `https://mysite.com/documentation/`. If the app does not support all locales currently supported by Business Central, then include a parameter for the locale in this URL, `/{0}/`, and also specify the relevant locales in the `supportedLocales` setting.
helpBaseUrl	No	The URL for the website that overtakes all Help for the specified locales. This property is intended for localization apps specifically since the setting overwrites the default URL of `/{0}/dynamics365/business-central`. If you set this value, you must also specify one or more languages in the `supportedLocales` setting.
supportedLocales	No	The list of locales that are supported in your Help if different from all locales. The value on the list is inserted into the URL defined in the `contextSensitiveHelpUrl` and `helpBaseUrl` properties. The first locale on the list is default. An example is `"supportedLocales": ["da-DK", "en-US"]` for an app that supports only Danish and English (US).

SETTING	MANDATORY	VALUE
runtime	Yes	The version of the runtime that the project is targeting. The project can be published to the server with an earlier or the same runtime version. The available options are: `1.0` - Business Central April 2018 Release `2.0` - Business Central Fall '18 Release `3.0` - Business Central Spring '19 Release `4.0` - Business Central 2019 release wave 2 `5.0` - Business Central 2020 release wave 1 `6.0` - Business Central 2020 release wave 2 `6.1` - Business Central 2020 release wave 2 update 17.1 `6.2` - Business Central 2020 release wave 2 update 17.2 `6.3` - Business Central 2020 release wave 2 update 17.3 `6.4` - Business Central 2020 release wave 2 update 17.4
features	No	Specifies a list of options. The `TranslationFile` option generates a `\Translations` folder that is populated with the .xlf file that contains all the labels, label properties, and report labels that you are using in the extension. The `GenerateCaptions` option depends on the `TranslationFile` setting. It generates captions for objects that do not have a `Caption` or `CaptionML` specified, these are then written to the .xlf file. The `GenerateLockedTranslations` flag is used to generate `<trans-unit>` elements in the XLIFF file for locked labels. The syntax is `"features": [ "TranslationFile", "GenerateCaptions", "GenerateLockedTranslations" ]`. For more information, see Working with Translation Files. When the `NoImplicitWith` flag is specified, `ImplicitWith` will be disabled by default. This flag is useful when all code has been rewritten to avoid any future usage of `ImplicitWith`. For more information, see Pragma ImplicitWith and Deprecating Explicit and Implicit With Statements.

SETTING	MANDATORY	VALUE
internalsVisibleTo	No	Specifies a list of modules that have access to the objects that are marked as `Internal` using the **Access** property from the current module. The syntax is `{ "appId": "d6c3f231-08d3-4681-996f-261c06500e1a", "name": "TheConsumer", "publisher": "Microsoft"}]`. For more information see Access Property and InternalEvent Attribute. **Note:** Using `internalsVisibleTo` in Business Central online will throw a warning from AppSourceCop and PTECop. `Access = Internal` is *not* designed as a security boundary, but for API development.
propagateDependencies	No	Specifies whether the dependencies of this project should be propagated as direct dependencies of projects that depend on this one. Default is `false`. If set to `true` then any dependencies of the current package will be visible to consumers of the package. For example, if A depends on B that depends on C, by default, A will not be able to use types defined in C. If B has `"propagateDependencies" : "true"`, then A will be able to use types defined in C without taking a direct dependency. **Note:** `propagateDependencies` applies to all dependencies, there is no option to exclude specific dependencies.
preprocessorSymbols	No	Defines any symbols to use with preprocessor directives. The syntax is `"preprocessorSymbols": [ "DEBUG" ]`. For more information, see Preprocessor Directives in AL.
applicationInsightsKey	No	The instrumentation key of the Azure Application Insights resource for monitoring operations, for example, like app secrets retrieval by extensions. For more information, see Monitoring and Analyzing Telemetry.
keyVaultUrls	No	List of URLs of key vaults that the extension from which the extension can retrieve secrets. For example: `"keyVaultUrls":[ "https://myfirstkeyvault.vault.azure.net "https://mysecondkeyvault.vault.azure.ne ]`. For more information, see App Key Vaults.

SETTING	MANDATORY	VALUE
suppressWarnings	No	Specifies that warnings issued by, for example, a specific analyzer rule should not be shown in the **Output** window. Syntax is `"suppressWarnings": [<warning ID>,<warning ID2>,...]`. For example `"suppressWarnings": [ "AL0458" ]`. It is also possible to use `#pragma` directives for suppressing warnings for specific areas of code. For more information, see Pragma Warning Directive and Suppressing Warnings.

Launch.json file

The following table describes the settings in the `launch.json` file. The `launch.json` file has two configurations depending on whether the extension is published to a local server or to the cloud.

Publish to local server settings

SETTING	MANDATORY	VALUE
name	Yes	"Your own server"
type	Yes	Must be set to `".al"`. Required by Visual Studio Code.
request	Yes	Request type of the configuration. Can be set to `"launch"` or `"attach"`. Required by Visual Studio Code. For more information, see Attach and Debug Next.
server	Yes	The HTTP URL of your server, for example: `"https://localhost|serverInstance"`
port	No	The port assigned to the development service.
serverInstance	Yes	The instance name of your server, for example: `"US"`
authentication	Yes	Specifies the server authentication method and can be set to `"UserPassword"`, `"Windows"`, or `"AAD"`. Currently, AAD authentication is supported only for Dynamics 365 Business Central sandboxes. AAD authentication cannot be used for on-premise servers.
startupObjectType	No	Specifies whether the object to open after publishing is a Page type (`"Page"`) or Table type (`"Table"`) object. The default is `"Page"`.

SETTING	MANDATORY	VALUE
startupObjectId	No	Specifies the ID of the object to open after publishing. Only objects of type Page and Table are currently supported.
schemaUpdateMode	No	Specifies the data synchronization mode when you publish an extension to the development server, for example: `"schemaUpdateMode": "Recreate"` The default value is Synchronize. For more information, see Retaining table data after publishing This feature is not supported in Dynamics NAV.
environmentType	No	Specifies which type of environment to use to connect to Business Central. Possible values are `OnPrem`, `Sandbox`, or `Production`.
environmentName	No	Specifies which named production or sandbox environment to use in cases where multiple sandboxes are owned by the same tenant.
breakOnError	No	Specifies whether to break on errors when debugging. The default value is `true`.
breakOnNext	No	Specifies the session type that the server will connect to. The options are: `WebserviceClient` - web API-based client including ODdata and SOAP clients, `WebClient` - standard web client, `Background` - background sessions, such as job queues, see Task Scheduler. This setting applies to Attach and Debug Next and to Snapshot Debugging. For *Attach* debugging, `breakOnNext` defines the next client session that the debug engine will attach to for the same user who has initiated an attach debug session from Visual Studio Code. For *Snapshot* debugging, `breakOnNext` defines the next session to hook AL code execution recording for a given user on a tenant, or if this is not specified with the userId in the configuration settings; the first user on the tenant.
breakOnRecordWrite	No	Specifies if the debugger breaks on record changes. The default value is `false`.

SETTING	MANDATORY	VALUE
launchBrowser	No	Specifies whether to open a new tab page in the browser when publishing the AL extension (Ctrl+F5). The default value is `false`. If the value is not specified or set to `true`, the session is started. If the value is explicitly set to `false`, the session is not started unless you launch your extension in debugging mode.
enableSqlInformationDebugger	Yes	Specifies whether the debugger shows the SQL information. The default value is `true`. For more information, see Debugging SQL behavior.
enableLongRunningSqlStatements	Yes	Specifies whether the debugger enables long running SQL statements in the debugger window.
longRunningSqlStatementsThreshold	Yes	Sets the number of milliseconds spent before a SQL statement is considered as long running in the debugger.
numberOfSqlStatements	Yes	Sets the number of SQL statements to be shown in the debugger.
dependencyPublishingOption	No	Available options are: `Default` - set dependency publishing will be applied `Ignore` - dependency publishing is ignored `Strict` - dependency publishing will fail if there are any apps that directly depend on the startup project and these apps are not part of the workspace. For more information, see Working with multiple projects and project references.
disableHttpRequestTimeout	No	Specifies if the default setting for HTTP request timeout in Visual Studio Code is switched off. The default value is `false`. If the value is set to `true` requests can run without timeout.

attach	No	Sets the session to attach to. There are two options;
		`Attach to the next client on the cloud sandbox`
		and
		`Attach to the next client on your server`
		. Use the first option to attach to a cloud session, and the second option to attach to a local server. For more information, see Attach and Debug Next.

SETTING	MANDATORY	VALUE
forceUpgrade	No	Always run upgrade codeunits, even if the version number of the extension is the same as an already installed version. This can be useful for troubleshooting upgrade issues. **Note:** The `forceUpgrade` setting requires the package ID to be changed.
useSystemSession	No	Runs install and upgrade codeunits in a system session. This will prevent debugging install and upgrade codeunits.
snapshotFileName	No	Specifies the snapshot file name used when snapshot debugging files are saved. For more information, see Snapshot Debugging.

Publish to cloud settings

SETTING	MANDATORY	VALUE
name	Yes	"Microsoft cloud sandbox"
type	Yes	Must be set to `"al"`. Required by Visual Studio Code.
request	Yes	Request type of the configuration. Must be set to `"launch"`. Required by Visual Studio Code.
startupObjectType	No	Specifies whether the object to open after publishing is a Page type (`"Page"`) or Table type (`"Table"`) object. The default is `"Page"`.
startupObjectId	No	Specifies the ID of the object to open after publishing. Only objects of type Page and Table are currently supported.
tenant	No	Specifies the tenant to which the package is deployed. If you specify multiple configurations, a drop-down of options will be available when you deploy. This parameter must contain a tenant AAD domain name, for example `mycustomer.onmicrosoft.com`.
environmentType	No	Specifies which type of environment to use to connect to Business Central. Possible values are `OnPrem`, `Sandbox`, or `Production`.

SETTING	MANDATORY	VALUE
environmentName	No	Specifies which named production or sandbox environment to use in cases where multiple sandboxes are owned by the same tenant.
applicationFamily	No (Yes for Embed apps)	The application family in the cloud server, for example `Fabrikam`. This property is reserved for Embed apps.
breakOnError	No	Specifies whether to break on errors when debugging. The default value is `true`.
breakOnNext	No	Specifies the session type that the server will connect to. The options are: `WebserviceClient` - web API-based client including OData and SOAP clients, `WebClient` - standard web client, `Background` - background sessions, such as job queues, see Task Scheduler. This setting applies to Attach and Debug Next and to Snapshot Debugging. For *Attach* debugging, `breakOnNext` defines the next client session that the debug engine will attach to for the same user who has initiated an attach debug session from Visual Studio Code. For *Snapshot* debugging, `breakOnNext` defines the next session to hook AL code execution recording for a given user on a tenant, or if this is not specified with the userId in the configuration settings; the first user on the tenant.
breakOnRecordWrite	No	Specifies if the debugger breaks on record changes. The default value is `false`.
launchBrowser	No	Specifies whether to open a new tab page in the browser when publishing the AL extension (Ctrl+F5). The default value is `false`. If the value is not specified or set to `true`, the session is started. If the value is explicitly set to `false`, the session is not started unless you launch your extension in debugging mode.
enableSqlInformationDebugger	Yes	Specifies whether the debugger shows the SQL information. The default value is `true`. For more information, see Debugging SQL behavior.

SETTING	MANDATORY	VALUE
enableLongRunningSqlStatements	Yes	Specifies whether the debugger enables long running SQL statements in the debugger window.
longRunningSqlStatementsThreshold	Yes	Sets the number of milliseconds spent before a SQL statement is considered as long running in the debugger.
numberOfSqlStatements	Yes	Sets the number of SQL statements to be shown in the debugger.
dependencyPublishingOption	No	Available options are: `Default` - set dependency publishing will be applied `Ignore` - dependency publishing is ignored `Strict` - dependency publishing will fail if there are any apps that directly depend on the startup project and these apps are not part of the workspace. For more information, see Working with multiple projects and project references.
disableHttpRequestTimeout	No	Specifies if the default setting for HTTP request timeout in Visual Studio Code is switched off. The default value is `false`. If the value is set to `true` requests can run without timeout.

attach	No	Sets the session to attach to. There are two options;
		`Attach to the next client on the cloud sandbox`
		and
		`Attach to the next client on your server`
		. Use the first option to attach to a cloud session, and the second option to attach to a local server. For more information, see Attach and Debug Next.

The Migration.json File

2/17/2021 • 2 minutes to read • Edit Online

INTRODUCED IN: Business Central 2019 Release Wave 2, update 15.3, for on-premises only

Data migration allows you to move table and field data between extensions. The `migration.json` file provides a pointer to the ID of an app that one or more tables will be moved to. This allows you to move table and field data from, for example, a code-customization on the base application to an extension of the base application. The `migration.json` file can be added into the app project of an extension that a table is moved from to specify the ID of the app that the table will be moved to. It can, for example, be placed at the root of the AL project. The `migration.json` file must be created manually following the steps and syntax as described below.

In the extension `app.json` file, ensure that `"target": "OnPrem"`. For more information, see JSON Files.

Creating the migration.json file

1. In the root folder of the app project that will migrate data to a different app project, choose **New File**.
2. Name the file `migration.json`.
3. Edit the file by adding one or more IDs inside the `"apprules":[]` section, such as the following:

```
{
    "apprules": [
        {
            "id": "12345678-abcd-abcd-abcd-1234567890ab"
        }
    ]
}
```

4. Save the `migration.json` file in the project.

You now have the migration file in place for the data migration from one app project to another. This will be used for performing the data migration steps. For more information, see Migrating Tables and Fields Between Extensions.

Migrating Tables and Fields Between Extensions

AL Language Extension Configuration

2/17/2021 • 2 minutes to read • Edit Online

APPLIES TO: Business Central 2019 release wave 2 and later

The AL Language extension has a number of settings that can be specified for a specific user or for a workspace. To activate the settings, press **Ctrl+Shift+P**, and then choose **Preferences: Open Settings (UI)** for workspace settings, or choose **Preferences: Open User Settings** for user settings. Under **Extensions**, and **AL Language extension configuration** you will find the settings that are available for the AL Language extension. For tips on how to optimize Visual Studio Code, see Optimizing Visual Studio Code for AL Development.

Settings

The following table describes the user and workspace settings for the AL Language extension:

SETTING	VALUE
Assembly Probing Paths	Sets the list of directory paths where the compiler searches for referenced .NET assemblies. For example: `"al.assemblyProbingPaths": ["./.netpackages", "C:/Program Files/Assemblies"]`
Browser	Specifies the browser in which to open the Business Central client when launching the application from Visual Studio Code.
Code Analyzers	Sets the list of paths to code analyzers to use for performing code analysis. For example : `"al.codeAnalyzers": ["${AppSourceCop}", "${CodeCop}"]` .
Compilation Options	Specifies the compilation options; `generateReportLayout`, which controls whether report layout files are generated during build and `parallel`, which controls whether to use concurrent builds. Both options are default set to `true`.
Editor Services Log Level	Sets the logging verbosity level for the AL Language Editor Services host executable. Possible values are `Verbose`, `Normal`, `Warning`, and `Error`.
Editor Services Path	Specifies the path to the Editor Services host executable.
Enable Code Actions	Specifies whether code actions should be enabled for all source files in the current project. Default is `false`.
Enable Code Analysis	Specifies whether code analysis should be performed for all source files in the current project. Default is `false`. If this is set to `true`, you must specify the **Code Analyzers** setting with the list of code analyzers to use.

SETTING	VALUE
Incognito	Specifies whether to open the browser in Incognito/InPrivate mode when launching the application from Visual Studio Code. This option will take effect only if the **Browser** option is set to a non-default value.
Package Cache Path	Sets the directory path where reference symbol packages are located.
Rule Set Path	Sets the path to the file containing the customized rules to use when running code analysis.
Incremental Build	Specifies whether a project, when it is built using **Ctrl+Shift+B**, **Ctrl+F5**, or **F5**, will reuse the last known tracked compilation which will enhance the compilation time significantly. For more information about project to project references, see Working with multiple projects and project references. **Note:** Setting this to `true` will not do an end-to-end build, as it is depending on an already-compiled state. To get a clean, full build, this flag must be set to `false`. Default is `false`.
Snapshot Output Path	Sets the directory path where snapshot files are saved. Default is `./.snapshots`.
Snapshot Debugging Path	Sets the directory path where the snapshot debugger sources are located. Default is `./.snapshot`.

Security Setting and IP Protection

2/17/2021 • 2 minutes to read • Edit Online

When developing an extension, your code is by default protected against downloading or debugging. Read below about the security setting and adding Intellectual Property (IP) protection against downloading or debugging into an extension to see the source code in the extensions.

The extension development package provides a pre-configured setting for IP protection against viewing or downloading the code of the extensions. However, this setting can also be controlled in the manifest; the `app.json` file.

IP protection setting

When you start a new project, an `app.json` file is generated automatically, which contains the information about the extension that you are building on. The `app.json` file contains a setting called `showMyCode`, which controls whether it is possible to debug into the extension, when that extension is taken as a dependency. The default value of this property is set to **false**. This means that debugging into an extension or going to definition to view the code is not allowed. For a more refined setting, you can specify the `NonDebuggable` attribute on methods and variables. For more information, see NonDebuggable Attribute.

`showMyCode` does not apply to Profiles, Page Customizations and Views, because these objects cannot define any custom logic in procedures or triggers. The code for Profiles, Page Customizations, and Views defined in an extension with `showMyCode` set to **false** can then still be accessed and copied using Designer.

> **NOTE**
> The `showMyCode` setting is not visible in the `app.json` file when it is generated. If you want to change the value, you must add the setting as shown in the code snippet below.

> **NOTE**
> Even though `showMyCode` is set to **false**, you will still be able to view that code if an extension is deployed through Visual Studio Code, as opposed to deploying using a cmdlet or via AppSource.

Changing the IP protection setting

If you want to allow debugging into an extension to view the source code, you can add the `showMyCode` property in the `app.json` file and set the property value to **true**. For example, if a developer develops extension A and he or someone else on the team develops extension B, and B depends on A, then debugging B will only step into the code for A if a method from A is called and if the `ShowMyCode` flag is set to **true** in the app.json for extension A as shown in the example below:

```
"showMyCode": true
```

By adding this setting, you *enable debugging* into an extension to view the source code when that extension is set as a dependency.

Developing for Multiple Platform Versions

2/17/2021 • 2 minutes to read • Edit Online

The AL language extension is compatible with multiple platform versions. You can install the AL Language extension from the Visual Studio Code marketplace and use it to develop solutions for Dynamics 365 Business Central.

Defining the platform version

To set the platform version, add the **runtime** property in the `app.json` file. This attribute defines the platform version that the extension is targeting. Depending on the platform version, some features become available, while some features are not supported. For example, OData-bound actions can only be used when the platform version is 2.0 or higher.

> **NOTE**
> The AL Language extension is not compatible with Dynamics NAV 2018 version backwards. For Dynamics NAV 2018 development, the traditional method should be used. You must install the Visual Studio Code extension from the `ALLanguage.vsix` file shipped on the DVD.

Version compatibility

The following two elements are compared when you publish an extension.

1. The runtime version of the extension defined in the app.json file.
2. The runtime version of the platform that the extension is targeting.

In the app.json file, set the extension **runtime** version lower than the platform version. When you set the extension to a higher **runtime** version, the extension package may contain certain features that the platform may not support which would result in an error. Therefore, you must lower the extension runtime version than the one that platform supports in order to publish your extension.

Things to be aware of

1. An error will be thrown when you publish an extension with a higher runtime version than the one that platform supports. For example, if you set the runtime value to `2.0`, you get the following error message.

   ```
   The runtime version of the extension package is currently set to '2.0'. The runtime version must be set to '1.0' or earlier in the app.json file in order to install the extension package on this platform.
   ```

2. When you lower the extension runtime version, you may get warnings about the newest features not supported by the earlier versions of the platform.

3. A best-effort compilation is made when you publish an extension compiled with a lower runtime version. This is allowed in order to avoid recompilation of the extension package every time you upgrade the platform.

Optimizing Visual Studio Code for AL Development

2/17/2021 • 2 minutes to read • Edit Online

Visual Studio Code is built to handle many smaller, dependent projects, and not one large project, however, as the base application is not yet split into modules or components that allows managing the code in smaller projects, we recommend the following performance optimizations.

Open your `settings.json` file in the project (or global settings if you prefer that) pressing **Ctrl+Shift+P**. Set:

- `"al.enableCodeAnalysis": false` to turn off code analysis completely, read more here Using the Code Analysis Tool.
- `"al.backgroundCodeAnalysis": false` to turn off running code analysis in the background, but code analysis will be enabled when building with **Ctrl+Shift+B**. This is an alternative if analyzers are required with `"al.enableCodeAnalysis": true`.
- `"al.enableCodeActions": false` to turn off AL Code Actions, read more here AL Code Actions.
- `"al.incrementalBuild": true` to allow the compiler to reuse the existing background compilation for creating the package.
- `"editor.codeLens": false` to turn off code lens in Visual Studio Code, see Code Navigation.
- Add the build folder to the exclusion list for Windows Defender.

Best Practices for AL

Compilation Scope Overview

2/17/2021 • 2 minutes to read • Edit Online

In Dynamics 365 Business Central there are different layers of controlling what can be published to the server and accessed from within a project.

Configuring extension target on the server

By setting the **Allowed Extension Target Level** flag in the server configuration, you control what can be published to the server by setting the **Cloud** or **OnPrem** flag. For more information, see Configuring Business Central Server.

Configuring extension target for an extension

In the manifest of an extension (the app.json file), you can set the **target** property to specify the compilation target of an extension. The available values are `Internal`, `Extension`, `OnPrem`, and `Cloud`.

> **IMPORTANT**
> The `Internal` and `Extension` values have been deprecated starting with runtime 4.0 and replaced by the `OnPrem` and `Cloud` respectively.

The `target` property informs the compiler which APIs can be used within the current project.

- If you specify `"target":"OnPrem"` you can use any platform APIs and .NET types. This is the most permissive target. It is only if you specify this target that you can use methods marked with `Scope('OnPrem')` or tables with the property Scope (Tables) set to `OnPrem`.
- If you specify `"target":"Cloud"` you can only use APIs that are safe for use in a cloud environment. If the target is set to `Cloud`, the extension cannot use any method marked with `Scope('OnPrem')` or table with the property `Scope` set to `OnPrem`, even if those elements are declared within the same extension. For example, if you have two extensions; A and B. Extension A has an app.json target setting `"target": "OnPrem"` and defines a method with the Scope Attribute set to `[Scope('OnPrem')]`. Extension B has a dependency on extension A and extension B has an app.json target setting `"target": "Cloud"` and tries to call the method in extension A marked with scope `OnPrem`, you will get a compile error when you are trying to compile extension B. For more information, see JSON Files.

Methods and tables scope

Methods can be marked with the `[Scope()]` attribute to specify the compilation target and tables can be marked with the `Scope` property. Both instruct the compiler which target the method or table can be used in. For more information, see Scope Attribute and Scope (Table) Property.

Scope (Table) Property

Debugging

2/17/2021 • 7 minutes to read • Edit Online

The process of finding and correcting errors is called *debugging*. With Visual Studio Code and the AL Language extension you get an integrated debugger to help you inspect your code to verify that your application can run as expected. You start a debugging session by pressing **F5**. For more information about Debugging in Visual Studio Code, see Debugging.

An alternative to classic debugging, is snapshot debugging, which allows you to record running code, and later debug it. For more information, see Snapshot Debugging.

> **IMPORTANT**
> To enable debugging in versions before Business Central April 2019, the `NetFx40_LegacySecurityPolicy` setting in the Microsoft.Dynamics.Nav.Server.exe.config file must be set to **false**. This requires a server restart.

> **IMPORTANT**
> To use the development environment and debugger, you must make sure that port `7049` is available.

There are a number of limitations to be aware of:

- "External code" can only be debugged if the code has the `showMyCode` flag set. For more information, see Security Setting and IP Protection.
- The debugger launches a new client instance each time you press **F5**. If you close the debugging session, and then start a new session, this new session will rely on a new client instance. We recommend that you close the Web client instances when you close a debugging session.
- Pausing the debugging session is not supported.

To control table data synchronization between each debugging session, see Retaining table data after publishing.

> **TIP**
> To be able to debug an online environment with an Embed app published in it, make sure to specify the `applicationFamily` parameter in your launch.json file. You define the application family for your Embed app during onboarding.

Breakpoints

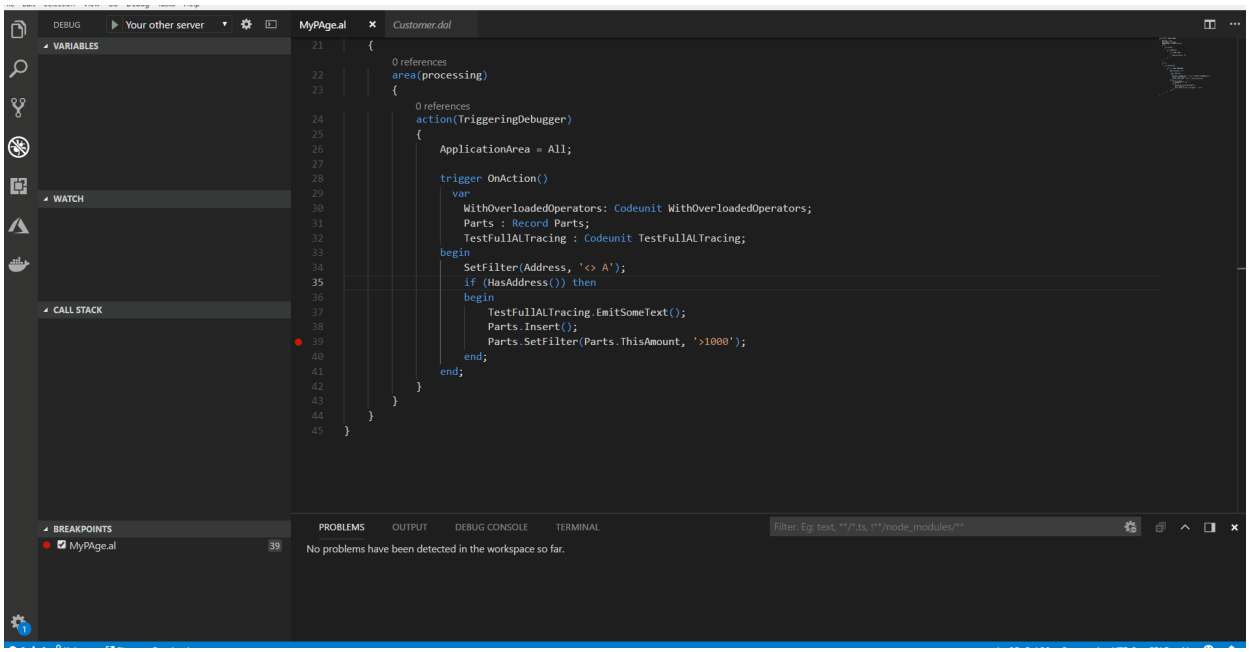
The basic concept in debugging is the *breakpoint*, which is a mark that you set on a statement. When the program flow reaches the breakpoint, the debugger stops execution until you instruct it to continue. Without any breakpoints, the code runs without interruption when the debugger is active. You can set a breakpoint by using the **Debug Menu** in Visual Studio Code. For more information, see Debugging Shortcuts.

Set breakpoints on the external code that is not part of your original project. You can step into the base application code by using the **Go to Definition** feature, and set breakpoints on the referenced code which is generally a `.dal` file. To set a breakpoint on the external code or base application code, you do the following:

- Use **Go to Definition** which opens the "external file" and then a breakpoint can be set.

- Using the debugger, step into the code, and then set a breakpoint.

In the following video illustration, the `Customer.dal` is an external file. A breakpoint is set in the `Customer.dal` file which is referenced from your AL project to stop execution at the marked point.



For more information about **Go to Definition**, see AL Code Navigation.

Break on errors

Specify if the debugger breaks on the next error by using the `breakOnError` property. If the debugger is set to `breakOnError`, then it stops execution both on errors that are handled in code and on unhandled errors.

The default value of the `breakOnError` property is **true**, which means the debugger stops execution that throws an error by default. To skip the error handling process, set the `breakOnError` property to **false** in the `launch.json` file.

> **TIP**
> If the debugging session takes longer, you can refresh the session by pressing the **Ctrl+Shift+P** keys, and select **Reload Window**.

Break on record changes

Specify if the debugger breaks on record changes by using the `breakOnRecordWrite` property. If the debugger is set to break on record changes, then it breaks before creating, modifying, or deleting a record. The following table shows each record change and the AL methods that cause each change.

RECORD CHANGE	AL METHODS
Create a new record	Insert Method (Record)
Update an existing record	Modify Method (Record), ModifyAll Method (Record), Rename Method (Record)
Delete an existing record	Delete Method (Record), DeleteAll Method (Record)

The default value of the `breakOnRecordWrite` property is **false**, which means that the debugger is not set to break on record changes by default. To break on record changes, you can set the `breakOnRecordWrite` property to **true** in the `launch.json` file. For more information, see JSON Files.

Debugging large size variable values

Variables that contain values that are larger than 1024 bytes are truncated (`...`) and cannot be fully inspected from the **VARIABLES** window. In order to inspect a large size variable value, instead use the **DEBUG CONSOLE** and write the name or qualified name of a variable to inspect at the prompt and then press **Enter**.

Attach and Debug Next

If you do not want to publish and invoke functionality to debug it, you can instead attach a session to a specified server and await a process to trigger the breakpoint you have set. For more information, see Attach and Debug Next.

Debugging shortcuts

KEYSTROKE	ACTION
F5	Start debugging
Ctrl+F5	Start without debugging
Shift+F5	Stop debugging
Ctrl+Shift+F5	Start debugging without publishing. Using this command on a changed, but not published code may trigger false existing breakpoints. For example, if you modify method "foo", add two lines and put a breakpoint on the second line and then start debugging without publishing, that breakpoint will not be hit, or if it is hit is not your new code that it breaks. If it breaks, it will break on the line that the server thinks the breakpoint is, based on the last published code.
Alt+F5	Start RAD with debugging. For more information, see Working with Rapid Application Development.
F10	Step over
F11	Step into
Shift+F11	Step out
F12	Go To Definition

For more shortcuts, see Debugging in Visual Studio Code. For working with Snapshot Debugging, see Snapshot Debugging.

Debugging SQL behavior

Traditionally, debugging AL has been about examining behavior of the language runtime, for example, looking into the content of local variables at a breakpoint. As of Business Central April 2019, the AL debugger also offers

the capability to examine the impact that your AL code has on the Business Central database. The `enableSQLInformationDebugger` setting enables this functionality. For more information, see JSON Files.

View database statistics

In the **VARIABLES** pane in debugger, expand the **<Database statistics>** node to get insights such as the current network latency between the Business Central Server and the Business Central database, the total number of SQL statements executed, and the total number of rows read, as well as insights into the most recent SQL statements executed by the server. The following insights are part of the database statistics:

INSIGHT	DESCRIPTION
Current SQL latency (ms)	When the debugger hits a breakpoint, the Business Central Server will send a short SQL statement to the database and measure how long time it takes. The value is in milliseconds.
Number of SQL Executes	This number shows the total number of SQL statements executed in the debugging session since the debugger was started.
Number of SQL Rows Read	This number shows the total number of rows read from the Business Central database in the debugging session since the debugger was started.

> **TIP**
> You can also get database insights from the AL runtime by using the SqlStatementsExecuted() and SqlRowsRead() methods.

View SQL statement statistics

The database insights also let you peek into the most recent and the latest long running SQL statements executed by the server. To view a list if these, expand either the **<Last Executed SQL Statements>** or **<Last Long Running SQL Statements>** node. The following insights are part of the SQL statement statistics:

INSIGHT	DESCRIPTION
Statement	The SQL statement that the AL server sent to the Business Central database. You can copy this into other database tools, such as SQL Server Management Studio, for further analysis.
Execution time (UTC)	The timestamp (in UTC) of when the SQL statement was executed. You can use this to infer whether the SQL statement was part of the AL code between current and last breakpoint (if set).
Duration (ms)	The duration in milliseconds of the total execution time of the SQL statement measured inside the Business Central Server. You can use this to analyze whether you are missing indexes (Business Central keys), or to experiment with performance of database partitioning and/or compression.
Approx. Rows Read	This number shows the approximate number of rows read from the Business Central database by the SQL statement. You can use this to analyze whether you are missing filters.

The number of SQL statements tracked by the debugger can be configured in the Business Central Server. The

default value is 10.

> **NOTE**
>
> For Business Central on-premises, the Business Central Server instance has several configuration settings that control the SQL statistics that are gathered and then displayed in debugger, like whether long running SQL statements or SQL statements are shown. If you are not seeing the insights that you expect to see in debugger, check the server configuration. For more information, see Configuring Business Central Server.

NonDebuggable attribute

The ability to debug certain methods and/or variables can be restricted. For more information, see NonDebuggable Attribute.

Snapshot Debugging

2/17/2021 • 8 minutes to read • Edit Online

> **NOTE**
> With Business Central 17.2 - Snapshot Debugging is available in production cloud environments.

Snapshot debugging allows a delegated admin to record AL code that runs on the server, and once it has run, debug the recorded *snapshot* in Visual Studio Code. For a delegated admin to create and download a snapshot file that exists on the server on behalf of an end-user, the delegated admin must be part of the **D365 Snapshot Debug** permission group. For more information, see Assign Permissions to Users and Groups. One of the advantages of snapshot debugging is that it provides the ability to inspect code execution and variables in the production environment in a cloud service, on a specified user session.

Snapshot debugging introduces the concept of *snappoints*. A snappoint is a breakpoint in Visual Studio Code that is set when creating a snapshot, they do not, however, stop execution of code like when using regular debugging. Snappoints instruct execution to log the state at the breakpoint for later offline inspection. Snapshot debugging will record AL code as it runs on the server, but will only collect variable information on:

- Snappoints
- AL exceptions

> **IMPORTANT**
> To enable snapshot debugging it is very important that the symbols on the tenant match the symbols on the server. This is not automatically detected, and must be manually checked. In this release, you can ensure this by copying the specific sandbox and download symbols from that copy. Furthermore, any code that snappoints are set in, must have been deployed, otherwise debugging will not work. For more information, see the section Downloading symbols on the snapshot debugger endpoint.

Snapshot debugging keyboard shortcuts

In the following sections you can read more about how to initialize, view the status, and finalize a snapshot debugging session. For these actions, the following keyboard shortcuts are useful to familiarize yourself with. For additional keyboard shortcuts, see Keyboard Shortcuts.

KEYBOARD SHORTCUT	ACTION
F7	Start a snapshot debugging session
Shift+F7	List all available snapshots
Alt+F7	Finish a snapshot debugging session

Initializing a snapshot debugging session

From Visual Studio Code, you start a snapshot by creating a snapshot configuration file. There are two template configurations for a snapshot, which are accessed by selecting **Add Configuration** in Visual Studio Code.

- AL: Initialize a snapshot debugging session locally
- AL: Initialize a snapshot debugging session on cloud

Choose whether to run the session on a cloud service or locally. The configuration file will now contain the following information:

SETTING	DESCRIPTION
`userId`	The GUID of the user on whose behalf a snapshot debugging will be started. For on-premises, this can also be the user name in user password authentication scenarios. The user must be able to start, or have a session type opened that is specified in the `breakOnNext` parameter. For more information, see JSON Files.
`sessionId`	A session ID for the user specified above in `userId`.
`snapshotVerbosity`	Determines how much execution context to be recorded. If **SnapPoint** is specified, then only methods that hit a snappoint will be recorded.

When a configuration is defined, a snapshot debugging session can be initialized by pressing **Ctrl+Shift+P** and then selecting **AL:Initialize Snapshot Debugging** or by pressing **F7**.

To record the AL execution, the server will now wait for a connection to happen where the following rules apply:

- If a `sessionId` is specified for a userId for a given tenant then it will be that session that will be snapshot debugged.
- If only a `userId` is specified for a given tenant then the next session that is specified in the `breakOnNext` configuration parameter is snapshot debugged.
- If no `userId` is specified then the next session on a given tenant that validates the `breakOnNext` parameter will be snapshot debugged.

Once a snapshot debugging session is initialized the snapshot debugging session counter on the status-bar will be updated and look like this:

Status of a snapshot debugging session

Clicking on the status bar icon or pressing **Shift+F7** will bring up a list of all available snapshots.
The status list will show the state of a snapshot-debugged session.

A snapshot debugging session can be in one of the three states:

- **Initialized** - A request is issued and the server is waiting for the next session to be snapshot debugged based on the above rules.
- **Started** - You have attached to an end-user session to snapshot debug.
- **Finished** - When the snapshot debugging session has finished.
- **Downloaded** - When the snapshot file is downloaded.

Finishing a snapshot debugging session

You finish a snapshot debugging session by pressing **Alt+F7**. This brings up all snapshot sessions that have

been started. Choosing one will close the session debugging on the server and download the snapshot file.

> **IMPORTANT**
> The snapshot file can contain customer privacy data and must therefore be handled according to privacy compliance and should be deleted when it is not needed anymore.

Snapshot debugging sessions that have produced a snapshot file can be debugged. The location of a snapshot file is controlled by the `al.snapshotOutputPath` configuration parameter. By default it is local to the current workspace and it is called `./.snapshots`. For more information, see AL Language Extension Configuration.

Downloading symbols on the snapshot debugger endpoint

In order to download symbols on a production server, you need permission related entries:

- Be a delegated admin
- The read-only access to the **Published Application** table emphasized in the **D365 EXTENSION MGT** permission set should also be granted.

Debugging requires that symbols on the server are matched with the symbols that the user has locally. If this is not the case, and you set a breakpoint on a given line in Visual Studio Code, the line of code may differ from what is on the server.

Symbols download is using the **snapshotInitialize** debug configuration settings in Visual Studio Code, which is set up when you choose either **AL: Initialize a snapshot debugging session locally** or **AL: Initialize a snapshot debugging session on cloud**.

```
{
            "name": "snapshotInitialize: MyServer",
            "type": "al",
            "request": "snapshotInitialize",
            "environmentType": "OnPrem",
            "server": "http://localhost",
            "serverInstance": "BC170",
            "authentication": "UserPassword",
            "breakOnNext": "WebClient"
        },
```

> **IMPORTANT**
> Debugging requires that symbols on the server are matched with the symbols that the user has locally. If this is not the case, and you set a breakpoint on a given line in Visual Studio Code, the line of code may differ from what is on the server. This is why you must download symbols from production servers for snapshot debugging in order for a breakpoint set on one line to match with what the server understands of this line. This is to avoid a scenario where you set a breakpoint in a DAL file on line 12, but line 12 on the server is an empty line or a completely different line if the symbols are not the same.

Debugging a snapshot file

There are two user actions that will start snapshot debugging:

- Creating a new launch debug configuration and specifying the snapshot file name in the `snapshotFileName` configuration setting. This is the only setting that is needed besides the type, request, and name.
- Clicking on the status icon or by pressing **Shift+F7** and selecting a finished snapshot-debugged session.

Once a snapshot debugging session starts in Visual Studio Code, code execution will stop at the first snappoint. AL exceptions will be treated as snappoints, with the only difference that they cannot be removed by user actions. Other snappoints are just regular breakpoints that can be removed or re-added by user actions. If no snappoints are specified the first recorded methods; the first line is the entry breakpoint.

The user can set breakpoints and continue execution to that breakpoint for testing, for example, if a line is hit, but it is the snappoint that carries the real information.

Snapshot debugging versus regular debugging

Snapshot debugging is almost the same as a regular debugging with the differences mentioned in the following:

SNAPSHOT VERSUS REGULAR DEBUGGING
Breakpoints can be added and removed and they will be hit if given a breakpoint; the breakpoint is in the execution context of a recorded state. This means that if walking the execution stack for a breakpoint and the next stepped line is reached, then the code will break on the breakpoint.
A snappoint is a breakpoint in Visual Studio Code that is set when creating a snapshot, they do not, however, stop execution of code like when using regular debugging. Snappoints instruct execution to log the state at the breakpoint for later offline inspection.
You can always navigate through all the breakpoints with **Continue** (F5). The order may not be the same as the execution order on the Business Central server. This is due to the fact that some calls on the server are AL calls with non-walkable stacks. Some are direct server calls on the server like triggers. A snapshot debugging session on the Business Central server can only record AL calls and walk AL stack traces.
This is also true when stepping. The rule of thumb is that breakpoints within the reach are hit first, and if there are none; the next line is hit. Breakpoints on triggers may not always qualify as code within reach.
Variable data is only shown on snappoints.
If there are no frames available snapshot debugging will stop.
Stepping out of triggers with no recorded stack information will move execution to the first recorded method's first line. This may be very far from the user's execution of interest. For example, stepping out from an `OnOpenPage` trigger with a snappoint may land on deep inside base code execution where recording has started. Navigating with **F5** will start over breakpoint resolution, thus this is an exit strategy from a scenario like this.
A snappoint may resolve as a non-reachable breakpoint if there was no execution state on the server hitting the snappoint.
A snapshot debugger session with a Business Central server will be closed if not attached to after 30 minutes.
If a snapshot debugger session is started, it has to be finished after 10 minutes.

Attach and Debug Next

2/17/2021 • 2 minutes to read • Edit Online

APPLIES TO: Business Central 2019 release wave 2 and later

If you do not want to publish and invoke functionality to debug it, you can instead attach a session to a specified server and await a process to trigger the breakpoint you have set. Then debugging starts when the code that the breakpoint is set on is hit. This is particularly useful for debugging Web API sessions.

> **NOTE**
> To use the attach functionality, you must make sure that your app is published with **Ctrl+F5** first, or with **Alt+Ctrl+F5** for RAD publishing, before you start the debugging session with **F5**. To debug using attach, you must make sure to debug on a *new* session. Creating a new server session from the client can be achieved for example by launching a new client session. Pressing **F5** (Refresh) in a browser may not create a new server session, because it is cached, but if a session is expired and refreshed that will create a new session.

> **IMPORTANT**
> Only the user who starts a Visual Studio Code attach session can issue the Web request on the server.

Attach configuration

You activate the attach functionality by creating a new configuration in the `launch.json` file. The configuration has two flavors; **Attach to the next client on the cloud sandbox** and **Attach to the next client on your server**. Use the first option to attach to a cloud session, and the second option to attach to a local server.

In the attach configuration, the `breakOnNext` setting specifies the next client to break on when the debugging session starts and allows only one option. The available options are: `WebServiceClient`, `WebClient`, and `Background`. The example below illustrates a configuration for a local server.

```
...
{
            "name": "My attach to local server",
            "type": "al",
            "request": "attach",
            "server": "https://localhost",
            "serverInstance": "BC160",
            "authentication": "Windows",
            "breakOnError": true,
            "breakOnRecordWrite": false,
            "enableSqlInformationDebugger": true,
            "enableLongRunningSqlStatements": true,
            "longRunningSqlStatementsThreshold": 500,
            "numberOfSqlStatements": 10,
            "breakOnNext": "WebClient"
        }
...
```

Attach support

The following configurations for attach are supported:

BUSINESS CENTRAL	WEB CLIENT	WEB SERVICE CLIENT	BACKGROUND SESSION
On-premises	Supported	Supported	Supported
Sandbox	Not supported	Supported	Not supported

To start an attach session

1. In Visual Studio Code, under **Debug**, choose **Add configuration**.
2. Choose whether to attach to a cloud or a local session.
   The `launch.json` file is now populated with the correct attach configuration settings. If you selected a local session, change the default settings to point to your local server in the `server` and `serverInstance` settings.
3. Set `breakOnNext` to specify the client type on which to break.
4. In your code, set at least one breakpoint using **Debug** from the toolbar, choose **New breakpoint**, and then choose which type of breakpoint to add. You can always add more breakpoints while debugging.
5. It is important to make sure to publish your app by pressing **Ctrl+F5**, alternatively **Alt+Ctrl+F5** for RAD publishing. Your app *will not be* published if you only press **F5**.

   > **IMPORTANT**
   > If you modify the app code during the debugging session, make sure to re-publish the app using **Ctrl+F5**.

6. After publishing the app, press **F5** to start a debugging session.

   > **NOTE**
   > If you have more attach configuration settings, you must first select which configuration to start.

7. Debug and inspect the code. You can add more breakpoints while debugging.
8. Stop the attach debugging session by selecting **Detach** in the Visual Studio Code toolbar.

Working with Rapid Application Development

2/17/2021 • 2 minutes to read • Edit Online

Working with Visual Studio Code and Dynamics 365 Business Central you can benefit from Rapid Application Development (RAD) on large code projects. RAD allows faster development on projects with a large number of files by doing a delta compilation and publishing only on those application objects that have changed during development in Visual Studio Code. RAD publishing is an interim state and does not replace a full publish.

How RAD works

The files that have been changed by the application developer within Visual Studio Code are persisted in a special RAD (.rad) file during builds. This file is saved in the .vscode folder of the code project. RAD changes are the changes of application objects within a RAD session. Only application objects, page customization objects, and profile objects are handled for RAD. RAD changes will not be persisted during save, only during build, publish, and debug.

> **IMPORTANT**
>
> The `rad.json` file should not be modified.

> **IMPORTANT**
>
> If you change many files and close Visual Studio Code without a build (**Ctrl+Shift+B**), publish (**Ctrl+F5**, **Ctrl+Shift+F5**) or debug (**F5**, **Shift+F5**) all the RAD changes will be lost. This means that if you, in the next Visual Studio Code session perform a RAD publishing, this is done on the latest changes and not the prior changes. This can lead to an incomplete published package if it succeeds. It is therefore a best practice to do a regular publish. You can always check the RAD file in the code project to see what application objects are going to be changed during publishing.

In scenarios when application IDs are renamed, or refactored it is also a best practice to first do a full publishing, and then a RAD publishing for the consecutive changes. RAD does not check for application ID changes and ID changes can occur in a wrongly published application.

A RAD published file will not contain the following files that are normally packaged during regular publishing:

- Translation files
- Permission files
- Custom word and report rdl layout files
- Table data
- Web service definitions

These files will need to be re-generated with full publishing (**Ctrl+F5**). A RAD file will be deleted as a result of a successful publishing.

> **NOTE**
>
> If RAD publishing fails, then you must do a full publishing before performing another RAD publishing. The final state of an application must be built using full publishing, and never with RAD publishing.

RAD shortcuts

There are two commands for starting a RAD-based action.

SHORTCUT	DESCRIPTION
Ctrl+Alt+F5	Start RAD publishing without debugging.
Alt+F5	Start RAD with debugging.

Debugging

Signing an APP Package File

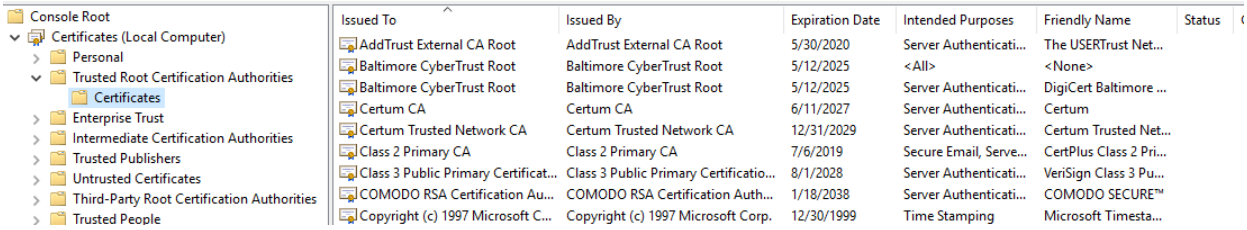
2/17/2021 • 3 minutes to read • Edit Online

Code signing is a common practice for many applications. It is the process of digitally signing a file to verify the author and that the file has not been tampered with since it was signed. The signature of the APP package file is verified during the publishing of the extension using the `Publish-NAVApp` cmdlet. For more technical information on signing, see Authenticode.

> **NOTE**
>
> If you want to publish an unsigned extension package in your on-premise environment, you need to explicitly state that by using the -*SkipVerification* parameter on the `Publish-NAVApp` cmdlet. An extension without a valid signature will not be published on AppSource.

The signing of an APP package file must be performed on a computer that has Dynamics 365 Business Central installed. If you are running Dynamics 365 Business Central on Docker for your development environment, that environment will meet this requirement. You must also have the certificate that will be used for signing on the computer. The certificate must include code signing as the intended purpose. It is recommended that you use a certificate purchased from a third-party certificate authority.

> **IMPORTANT**
>
> If you publish the extension as an app on AppSource, the APP package file must be signed using a certificate purchased from a Certification Authority that has its root certificates in Microsoft Windows. You can obtain a certificate from a range of certificate providers, including but not limited to GoDaddy, DigiCert, and Symantec, see the image below.



Steps for signing your .app file

1. Prepare your computer for signing.
2. Make sure that you sign the .app file on a computer that has Dynamics 365 Business Central installed.
3. Copy the certificate that you purchased from a third-party certificate authority to a folder on the computer. The example uses a pfx version of the certificate. If the certificate you purchased is not in a pfx format, create a PFX file. The file path for the sample command is `C:\Certificates\MyCert.pfx`. (Optionally, create your own certificate for local test or development purposes using the Self-signed certificate information).
4. Install a signing tool such as SignTool or SignCode to the computer. The sample command will use SignTool.
5. Copy your extensions .app file to the computer if it is not already on the computer. The file path for the sample command is `C:\NAV\Proseware.app`.
6. Run the command to sign the .app file.
7. The following example signs the Proseware.app file with a time stamp using the certificate in the password-protected MyCert.pfx file. The command is run on the computer that was prepared for the signing. Once the command has been run, the Proseware.app file has been modified with a signature. This file is then used

when publishing the extension.

```
SignTool sign /f C:\Certificates\MyCert.pfx /p MyPassword /t
http://timestamp.verisign.com/scripts/timestamp.dll “C:\NAV\Proseware.app”
```

IMPORTANT

It is recommended to use a time stamp when signing the APP package file. A time stamp allows the signature to be verifiable even after the certificate used for the signature has expired. For more information, see Time Stamping Authenticode Signatures. Depending on the certification authority, you may need to acquire a specific certificate in order to time stamp, an Extended Validation certificate from DigiCert for example.

NOTE

If you are using the BCContainerHelper PowerShell module to run Dynamics 365 Business Central on Docker, you can use the function `Sign-BCContainerApp` to perform all the steps above.

Self-signed certificate

For testing purposes and on-premise deployments, it is acceptable to create your own self-signed certificate using the New-SelfSignedCertificate cmdlet in PowerShell on Windows 10 or MakeCert.

The following example illustrates how to create a new self-signed certificate for code signing:

```
New-SelfSignedCertificate –Type CodeSigningCert –Subject “CN=ProsewareTest”
```

The following MakeCert command is used to create a new self-signed certificate for code signing:

```
Makecert –sk myNewKey –n “CN=Prosewaretest” –r –ss my
```

AL Development Environment

Working with multiple AL project folders within one workspace

2/17/2021 • 2 minutes to read • Edit Online

Visual Studio Code offers the multi-root workspace feature which enables grouping different project folders into one workspace. The AL Language extension also supports the multi-root functionality and allows you to work with multiple AL folders including roots and projects within one workspace.

Working with multiple project folders

Go through the following steps to work simultaneously on several related projects.

1. On the **File** tab of Visual Studio Code, select **Add Folder to Workspace...** .
2. Save the workspace file if you plan to open it again.
   This will create a `code-workspace` file that contains an array of folders with either absolute or relative paths. If you want to share your workspace files, choose the relative paths.
3. Modify the settings of your files in the **Settings** editor. You can change your user settings, global workspace settings, or individual folder settings.

For more information about multi-root workspaces in Visual Studio Code, see Multi-root Workspaces.

Grouping a set of disparate project folders into one workspace

It is not mandatory to use only AL-based roots. Different kinds of projects can be mixed, and each AL project will have its configuration values for the following settings:

- `al.packageCachePath`
- `al.enableCodeAnalysis`

The `al.packageCachePath` setting allows you to specify the path to a folder that will act as the cache for the symbol files used by your project. It can be specified in the **User Settings**, **Workspace Settings**, or **Project Settings**. The `al.enableCodeAnalysis` setting allows you to enable the execution of code analyzers on your project. It can likewise be specified in the **User Settings**, **Workspace Settings**, or **Project Settings**. For more information, see AL Language Extension Configuration.

Working with Multiple Projects and Project References

Working with Multiple Projects and Project References

2/17/2021 • 4 minutes to read • Edit Online

APPLIES TO: Business Central 2019 release wave 2 and later

A project reference in an AL-based workspace is defined as a dependency in the `app.json` file and exists as a project in the workspace. There is no special visual representation of a project reference.

> **IMPORTANT**
>
> A *project reference* is the full `id`, `name`, `publisher`, and `version` of an existing project in the workspace. This is contrary to an application reference where it is enough to specify a minimal version.

In the example below, the project called **Leaf** defines two dependencies to the projects **Middle** and **Root**. Since both **Root** and **Middle** are projects in the workspace they are considered project references.

The advantage of working with project references is that there is no need to download the symbols for a project reference. They are there as the symbols for the reference project and will be resolved as they are modified. For example, if you add a new method to a codeunit in the **Root** project and reference the codeunit in the **Leaf** project, the method will automatically resolve as you touch the **Leaf** project.

When a project is built with **Ctrl+Shift+B** the following will happen:

1. The .app file is copied to the `.alpackages` folder of all projects that depend on it.
2. All project references that might be "dirty" are also built.

> **NOTE**
>
> If reference resolution stops working then building the project reference and re-initializing the workspace using **Reload Window** resolves references.

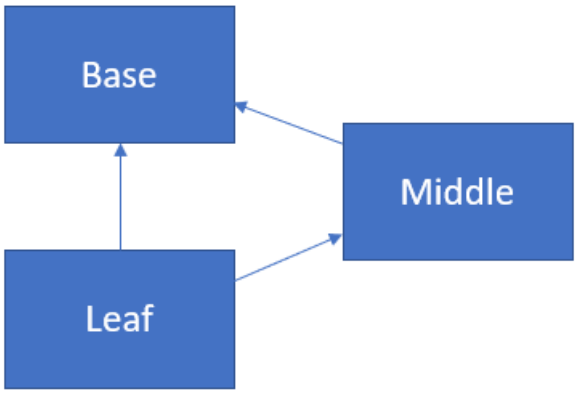
Publishing changes

With the introduction of project references the publishing logic in a workspace has changed. Publishing, either with **Ctrl+F5** or RAD publishing using **Alt+Ctrl+F5**, will do a set publishing of all the projects that have changed with defining a startup project. The startup project is always the active project. What does this mean?

A project is considered changed if any of its application objects have changed in the sense that the application object already is in the `rad.json` or will be in the `rad.json` once the project has been built. This means that if

you change an application object, you save it, and then close Visual Studio Code, but have not built, the `rad.json` will not be updated and then the project will not be considered "dirty".

For example, in a workspace with three projects; **Leaf**, **Middle**, and **Base**. **Leaf** depends on **Middle** and **Base**, and **Middle** depends on **Base** as illustrated below:



Assuming that:

1. All three projects; **Leaf**, **Base**, and **Middle** have changed.
2. The **Leaf** project is the current project that is published.

Then all three projects; **Base**, **Middle**, and **Leaf** will be part of the set that will be published.

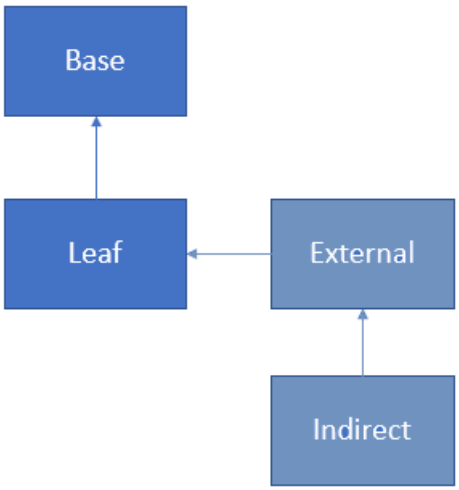
In a scenario where **Middle** has not changed, but **Leaf** is still the startup project, then only **Base** and **Leaf** will be published.

A new file is created to package set dependencies called `*.dep.app`. This is the file that gets transferred to the server and it is deleted if publishing of the dependency set is successful.

Server publishing changes

Although server publishing is an internal step, it does have an impact on the dependency publishing and is useful to know.

For example, in a workspace with two projects; **Leaf** depends on **Base**, and **External** and **Indirect** are projects outside of the workspace as illustrated below:



Assuming that:

1. A workspace exists with **Leaf** and **Base** as workspace projects.
2. **Base** is published.

3. On the server **Base**, **Leaf**, **External**, and **Indirect** are already installed apps.

The following happens on the server:

- All apps that depend on **Base** will be uninstalled, including **External** and **Indirect** dependency.
- Any other app that directly depend on **Base** and are not published in the global scope - in this case **Leaf** and **External** - are unpublished.
- **Base** will be uninstalled, unpublished, and then published.
- **Leaf** and **External** will be published, installed and then compiled against the newly published **Base**. Important to notice here is that the **Extenal** app also will be published.

Launch.json file setting

To control how dependency publishing is performed on the server, the `launch.json` file has a setting `dependencyPublishingOption` with the following options:

SETTING	DESCRIPTION
Default	Set dependency publishing will be applied.
Ignore	Dependency publishing is ignored. This setting should be used cautiously, see note below.
Strict	Dependency publishing will fail if there are any installed apps that depend on the startup project.

> **NOTE**
> With the `Ignore` setting only **Leaf** will be published against what has already been published on the server for **Middle** and **Base**. If a change has been done on **Base** that would break **Leaf**, even though local compilation would pass, the server compilation will fail in this scenario. The benefit of using this option is to gain publishing time when **Base** is a large project. Assuming that **Base** is published, then **Leaf** and **Middle** will be left untouched on the server. Only runtime errors will reveal if **Base** has broken **Middle** and **Leaf**.

Incremental Build setting

If the `al.incrementalBuild` setting is set to `true` on workspaces with project to project refernces, all resolution will happen from the referenced project, instead of happening from an app in the `\packagecache` folder which will enhance the build time. For more information, see AL Language Extension Configuration.

The Lifecycle of Apps and Extensions for Business Central

2/17/2021 • 6 minutes to read • Edit Online

When you build an app or extension to Business Central and get that published to AppSource, it becomes an app like so many others - the app itself can be updated, and the platform that it sits on, Business Central online itself, will also get updated. But what happens after your app gets published?

When your app has passed all of our validations and has gone live to App Source, customers can install your extension and use it for their business. But you are expected to keep it compliant with the service and update it if something changes.

The following sections describe the different upgrade scenarios that we have seen play out as we update Business Central. For more information about your responsibility for keeping your app updated and the resources that are available to you, see Maintain AppSource Apps and Per-Tenant Extensions.

Scenario 1: Business Central service update

You don't need to make any bug fixes, feature adds, or app changes to your app. It continues to work fine without any interaction on your part.

Impact of service updates

The monthly service upgrades to Business Central do not impact your app. Your app just gets moved along and no upgrade code from your app needs to get used. Business Central itself gets upgraded on your tenant, and once complete, the customer sees no difference with your app.

Scenario 2: App update

You (our partner) add some features to your app and also some minor bug fixes. The app is submitted for validation. The app passes validation and gets checked into the service. This is now the active app for any new tenants and also for existing tenants that have never had your app installed before

Impact of app updates

Customers can either do an uninstall and then reinstall on their own, or they can ask their partner do it on their behalf from the Extension Management window within Business Central. Otherwise, they would have to wait until our every 6-month major release. That is the only time we do a force upgrade of extensions (except for critical bug hotfix extension updates)

Scenario 3: Reported bugs in your app

You (our partner) has various customers report some bugs that are impacting their usage of the app. The bugs aren't critical but they are important. The partner makes the fixes in the app and resubmits for validation. The app passes validation and gets checked into the service. This is now the active app for any new tenants and also for existing tenants that have never had your app installed before

Impact of bugs

We still do not force the upgrade of this app to this latest version on all of the tenants. Some tenants may not be using the functionality that includes this bug and continue to work fine on the current version of the app. Therefore, you should work directly with all of the impacted customer tenants to uninstall and reinstall to get the latest app version that contains fixes for the bug.

Scenario 4: Critical bug in your app

If a bug which leads to core functionality being broken or data loss/corruption/misrepresentation is found in the application, and the issue prevents customers from performing time-critical tasks, the validation and deployment of the application can be prioritized. The partner must create a support ticket for this case and they must immediately provide a fixed app for validation through Partner Center. The validation team makes this a top priority and does validation as soon as possible. If the fixed application passes validation, it will be checked into the service and will become available for environment administrators to install.

Scenario 5: Microsoft feature breaks your app

Microsoft has to break your app file for a needed Business Central core change. Some reasons for breaking could be security, bugs in the underlying code, high priority feature adds, and so on. Keep in mind, we do our very best to not break your app through our changes. We try and find proper ways of doing the changes without breaking your app. However, if we can't find a proper (non-breaking) way, then we could break your app. This won't be as likely in a minor update release (unless a security change is required on our part and that is the change that breaks you), but it can be more likely in our major (every 6-month) releases.

Impact of breaking changes

Here is our process when this takes place:

- First of all, Microsoft will not make a breaking change in the production environment at any point. Therefore, existing tenants are not expected to see this breaking change occur.
- When we make a breaking change, we do it in a build branch that is for a future release (monthly service minor or major release)
- We notify the partner in advance and give the partner ample time to fix their app, get it validated, and have it ready
- The fixed app will already be in our service and slotted as required for when your tenant is to be moved to the Business Central release that has the app breaking change
- As a result, the customer (tenant owner) should never see their Business Central break. Because the tenant gets moved from one monthly service update of Business Central to another, the tenant is being upgraded to the release of ours that breaks the specific app. However, our service detects that there is a new required version of that app (your fixed version). Therefore, we auto install the fixed version of the app for the tenant

Conclusions

You're responsible for your app. You own the process of updating the app and providing upgrade code if the schema changes between versions of the app.
If a customer uninstalls your app, and then installs it again later, then when they install the app the second time, they get the latest version from AppSource.

How Microsoft handles your app

When Microsoft upgrades a tenant with a service update, your app is tested against the new service version. If the app breaks, Microsoft rolls back to the previous healthy state. Your customer never learns that anything was about to break.

When a tenant uninstalls and reinstalls an extension via the Extension Management page or AppSource, there is platform logic that determines whether an *Install* or an *Upgrade* must take place. We detect which version of the extension the tenant previously had installed and perform the appropriate action. Therefore, the result of manually uninstalling/installing the extension is the exact same as an automated upgrade.

Additionally, there will not be any data loss during uninstall, install, or upgrade actions. Data for extensions is stored in its own tables in the tenant database. Before an extension gets installed, it first get synchronized on the tenant database. This step is implicit and happens automatically when a tenant installs an extension. This

synchronization process creates the database tables for the extension. Once the extension is installed and the tenant is using it, extension-specific data will get stored in these tables.

When an extensions gets uninstalled, these tables do not get removed. Therefore, when the extension gets reinstalled (or upgraded), the data is still available. You do not need to worry about data loss for choosing the uninstall/install route. However, do keep in mind that if any actions are being performed on the tenant while the extension is uninstalled, the extension's events and such will not be firing, and your app may miss the creation of new data. Try to perform the uninstall/install while the tenant is not online.

For more information, see When apps or PTEs cannot be updated by Microsoft.

Maintain AppSource Apps and Per-Tenant Extensions

Update Lifecycle for Customizations of Business Central Online

2/17/2021 • 2 minutes to read • Edit Online

When you create a tenant-specific customization, or an extension that is scoped to a single Business Central environment (often referred to as per-tenant extensions), you must take the lifecycle of the extension into consideration. For more information about the extension lifecycle and events that can cause incompatibilities between the extension and base application, see The Lifecycle of Apps and Extensions for Business Central.

You are responsible for your extension. You own the process of updating the extension and providing upgrade code if the schema changes between versions of the Business Central base application. When an update is available for your Business Central environment, all extensions, both AppSource extensions and tenant customizations, must be compatible with the next version of the base application before the update can be installed on the environment. You are responsible for ensuring that your extensions are compatible with the update version.

In this article, we describe the process for ensuring update compatibility for tenant customizations.

Automated Extension Validation

An automated service validates all tenant customizations before an update is marked for a scheduled update of an environment. This validation compares the extension's dependencies with the updated version of the Business Central application to see if any changes caused incompatibilities with the new version.

If the validation service discovers any tenant customizations that are not compatible with the update, an email notification is sent to the tenant administrators listed on the **Notification recipients** tab of the Business Central administration center. For more information, see Managing Tenant Notifications.

> **IMPORTANT**
> At least one email address must be specified as a notification recipient to receive the update notifications. If you do not speciy an email address, you will not be notified of updates and other changes to the tenant.

The email notification provides information on the incompatible extension, detail on which properties must be updated, and steps to bring the extension into compatibility.

Update Failure Notification

If a Business Central environment has an extension that is not compatible with the update version, the update cannot be applied. If an update fails due to an incompatible extension, a notification is sent to the tenant administrators listed on the **Notification recipients** tab of the Business Central administration center.

The notification is similar to that provided by the automated extension validation. It provides information on the incompatible extension, detail on which properties must be updated, and steps to bring the extension into compatibility.

Automatic Extension Removal

The publisher of an extension must maintain compatibility with the new release of Business Central. An extension that is not compatible with the update within 90 days of the first notification of incompatibility will be

removed, and then the environment will be updated.

Maintain AppSource Apps and Per-Tenant Extensions in Business Central Online

2/17/2021 • 7 minutes to read • Edit Online

As a partner, keeping your apps and per-tenant extensions (PTEs) up to date is your responsibility. Business Central is regularly updated with major and minor releases. These updates provide customers with a business application that is always compliant, secure, and enriched with new platform and application functionality. Often customers choose Business Central because of this promise of having an always up-to-date business solution.

To not break this promise, developers that bring apps to Microsoft AppSource, and resellers that provide PTEs to respond to the unique needs of customers, have a responsibility to align their code to the Microsoft release rhythm.

An inability for Microsoft to update tenants because of publishers incompatible code causes serious disruption in the service and must be avoided since it impacts the trustworthiness of the service and customer satisfaction.

Resources

To help app publishers keep up with their update responsibilities, Microsoft provides the following resources:

- Release plans about what's new and planned

  For more information, see Dynamics 365 release plans.

- Access to pre-release bits

  Business Central partners have access to the next major, next minor, and daily pre-release bits in Docker. These bits can be used to test apps against upcoming updates.

- Information about what will be deprecated

  With all Business Central releases, Microsoft controls and regulates breaking changes with major releases and communicates upcoming breaking changes at least one year in advance. If developers missed this above info, the compiler in Visual Studio Code also warns for potential controls that will become obsolete in future versions and how to deal with them.

- Policy definitions and terms

  The publisher agreement and the commercial marketplace certification policies describe the responsibilities of app providers for how to publish and maintain apps in the Microsoft monthly rhythm.

  When a PTE gets installed, the publisher also agrees to the terms to keep that code current and updatable.

- Training and coaching

  Microsoft provides a set of tools, training, and documentation to help partners find the info they need to keep up with these responsibilities on continuous integration and continuous deployment. External providers, including ISV Development Centers, MasterVARs, and training centers, can provide in-person training and coaching.

- Service notifications

  Business Central online will support app and PTE publishers with extra warnings about potential technical incompatibility. If publishers respond to these notifications in due timing and avoid incompatibilities

repeatedly, Microsoft will stand with these publishers to help where needed. If a publisher includes a telemetry key in their app, then, starting with 2020 release wave 2, Business Central also provides publishers with telemetry about upgrade failures that happen in production because of issues in the publisher's upgrade code.

If publishers lack to keep their code updatable, they risk that ultimately their apps or PTEs will be removed from the customer's tenant, and this will most likely result in important data not being captured as it should. For apps, this also means removal from the marketplace.

Since resellers are the first line contact point for customers, they carry responsibility to explain what it means to load code in a customer's environment. The best way is to explain this is with terms.

We advise these terms include topics like intellectual property rights, upgrade responsibilities, associated costs to keep code updatable, support options, data privacy, and so on.

Pre-release publisher support to keep apps and PTEs compatible and up-to date

Publishers have several tools available for them to keep their code in good shape. Not least, a Public Preview release is made available approximately one month before the announced release date for a major release. In that Public Preview release time frame, Business Central will automatically test and notify publishers of existing apps and PTEs running in production on technical incompatibility with the upcoming release.

> **IMPORTANT**
> Microsoft tests code based on technical compatibility. As the publisher, you are still responsible for all functional and logical validation.

When apps or PTEs cannot be updated by Microsoft

This section describes the processes that are initiated during and after upgrade attempts of code provided by publishers of apps or PTEs.

- **T1 – T30**: Microsoft alerts administrators, resellers, and ISVs

  Shortly after a service update of Business Central online (Day **T**), Microsoft will initiate daily updates attempts on all tenants. In these update attempts, the publisher's provided upgrade code is triggered and run. These attempts run repeatedly in a time frame of approximately one month until the upgrade is successful. For more information, see Major Updates of Business Central Online.

  With every unsuccessful upgrade attempt, stakeholders will receive notifications. Customers and their reselling partners can follow these notifications in the Business Central administration center.

  ISVs who provide third-party AppSource apps might not be listed in the customer's admin center. The reseller will in most cases have worked with the ISV to test compatibility, but after two weeks (Day **T+15**) of failed upgrade attempts, the Microsoft AppSource team will also send the app provider a warning message that action within the next few days is required.

  This message will explain that if they fail to respond correctly, their app will be removed from AppSource at Day **T+30**.

- **T30 – T60**: Microsoft alerts the customer

  After one month of failed upgrade attempts (Day **T+30**), the customers will be notified again that apps or PTEs are incompatible with the new version of Business Central, and that no further automatic upgrade attempts will be planned until further notice. Although the publisher's code continues to run on an

outdated version of Business Central online, the customer must work with their reseller to resolve these issues immediately so that the tenant can be updated. Next to messages in the Business Central administration center, all users in the customer's tenant will also get more active warning about the incompatibilities when they use the product in the browser or their mobile device.

For AppSource apps, if no appropriate action or follow-up was taken by the publisher since the release (**T - T+30days**), the app will be removed from AppSource. This means no new customer will be able to install the app in a new tenant. The main reason for removing an app from the marketplace is to ensure that no new customers will be affected by incompatibilities with the latest version of the base product, Business Central.

If the publisher wants to have their app available again, they must mitigate all existing incompatibility issues and go through the full validation process again.

If the source of the incompatibility has been resolved by the publisher, they'll have to submit a support request to schedule a new set of upgrade attempts for any tenants that are blocked because of this incompatibility. They'll also have to work with their resellers to inform them about the compatibility resolution.

- **T60 – T150**: Microsoft initiates the customer wind-down period

  If the incompatibility issues are not resolved at **T+60**, and the publisher remained unresponsive to the request to resolve the incompatibility, Microsoft may choose to send out a wind-down communication to the customer about removal of the publisher's code.

  This communication will share that the code from the publisher will be removed in *90* days (**T+150**).

  During this wind-down time, the customer and their reselling partner are fully responsible for finding a solution on how to proceed in this situation. If the customer decides to leave Business Central, or decides to use another publisher, they can access their data by exporting the database, use RapidStart Services, or copy data to Excel. For more information, see Exporting Your Business Data to Excel in the business functionality content.

  Microsoft may also choose to remove all existing apps by this publisher from AppSource and block the publisher from publishing new apps for Business Central.

  If this wind-down period is initiated, and the customer was able to fix the incompatible issues with their reseller and potential publishers, it will be at Microsoft discretion if the publisher's code will be removed from Business Central or not.

Get notified about incompatibilities by Microsoft

It is crucial for you to keep contact details correctly up to date. We advise you to use global team aliases instead of individual mail addresses. Here are the mail addresses that we'll use in the above process:

- PTE publishers

  The mail addresses specified in the Business Central administration center; this could be both a customer user and a partner user.

- App publishers

  The mail addresses specified during App publication in the partner center during app publication as support and engineering contact details.

- Customers

  The mail addresses specified in the Business Central administration center; this could be both a customer and a partner user.

Update Lifecycle for AppSource Apps FAQ

2/17/2021 • 5 minutes to read • Edit Online

Please see the following sections for frequently asked questions regarding updating apps on AppSource.

I want to submit an updated version of my app. What is the process for that?

For any updated version of your app (small or large changes), you follow the same submission as your original version. It must go through the same validation process. The following are the steps that you must follow:

- Increase the version number of your app within it's json/manifest file.
- Do not change the app's AppID within it's json/manifest file. That needs to remain the same for life of the app
- Include an upgrade codeunit and ensure that it works.
- Upload the app file to your existing Partner Center offer.
- In Partner Center, edit the version field to match what is now in your updated app file.
- Make any other edits in Partner Center as needed.
- Submit for validation.
- Validation takes place as normal (against current production version of Business Central at time of submission):
  - Code review is needed for avoiding violations and ensuring requirements are met.
  - Test validation is scaled back for updated versions.

What happens when my updated app passes validation?

The app is checked into our service and becomes the active version for that current production release of Business Central. If a tenant is already upgraded to the current release, they can install this updated version of your app.

Does Microsoft now update my app (to this latest updated version) on all tenants that already have a previous version?

Microsoft will only force update apps during the 2 major releases (release wave 1 and 2). For these releases, each tenant will have their AppSource apps force updated to the latest available versions in our service.

How do I update the apps on my tenant for minor releases then?

If a tenant wants to update the apps on their tenant during the minor releases, the tenant admin needs to handle this. Here are the steps you follow to update your apps:

- Login to your Business Central Web client instance.
- Navigate to the **Extension Management** page.
- Find the app and uninstall it.
- Reinstall the app.

That gives you the latest available version in our service.

How often should I submit updates of my app?

Our recommendation is to pack more bug fixes and features into less frequent updates. Try to avoid frequent submissions containing very few changes. Being on a more frequent cadence than Business Central (monthly) is not advised. This leads to lower churn to production tenants.

What if a customer reports a critical bug in my app and needs an immediate hotfix version of my app?

We do have a fast track validation process for situations like this. These types of situations become top priority in our queue. A very quick validation takes place with the goal of having the hotfix in our service that same day. The following is the hotfix process:

- Fully test the hotfix version of your app to ensure it fixes the problem and to make sure no other issues are introduced.
- Submit the app via Partner Center per the normal process.
- Email rweigel@microsoft.com to notify him of the hotfix situation.
- Provide justification as to why this is critical. Some definitions of critical being:
  - App is causing the tenant to be unresponsive or unusable with no workaround
  - App is serving a critical business process and that process cannot be executed without a fix
- If justification proves to be critical, hotfix process can proceed.
- Quick Validation takes place ASAP and app is uploaded to our service.
- Tenants can now install this version of your app.

> **NOTE**
> Please ensure that you are only using this process for critical situations. Do not try to use it for minor bug fixes.

Do you have any tips for us when submitting updates of our app?

Yes, we have some valuable tips we would like to share. These are tips that can save you time in the validation process. They will help lead to fewer (and possibly zero) failures during validation. Most importantly; they will lead to fewer issues being found in production by customers.

- Follow the checklist, for more information see Technical Validation Checklist. The checklist is ever evolving and requirements might change or be added. You might miss something from the checklist, leading to validation failure and delaying the passing of your updated app.
- Use AppSourceCop, for more information see Using the Code Analysis Tool. This helps to catch any missing prefix/suffix and DataClassification. Too often we see these fail the updated versions of apps.
- Sign your app. This fails many app validations. We try to publish the app during validation and it is not properly code-signed leading to failure to publish.
- Publish and install your app. This is another big validation failure we see too often.
- Test your app's functionality with 100% coverage. You are the expert on the app and know it best. If you are only testing a small percentage of your app, customers will most likely find issues resulting in you having to update your app more often. And if customers are the ones finding your app issues, they may decide to uninstall it. You should have a vested interest in providing a quality app.
- Test the upgrade of your app. upgrade from the previous version to this latest. Your updated app will not pass validation until the upgrade works. If it fails in our validation, we will return it to you, leading to a delay in it going to our service.

NOTE

The tips that we provide above are for your benefit to pass validation the first time through each submission. And to emphasize these points, think of the delays that can arise when you do not follow these tips. If you submit, it can take a couple days before we validate the app. Once we validate it, if all is good, it should pass quickly. If we find issues that lead us to fail the validation, we send the app back to you as you have to make fixes. It could then take you days to properly fix. Next time you submit, your app does not go to the front of the queue. It begins at the bottom again which means it could be another couple days before we validate it again. By following our tips above, you can avoid those delays. Spend a bit more time up front finding those issues yourself, leading to a quicker path to our service.

FAQ about Managing and Submitting your Business Central Offer

2/17/2021 • 2 minutes to read • Edit Online

This section contains answers to frequently asked questions about managing the offer in Partner Center when you submit an app for Business Central.

If I click the Go Live button, does that mean my app will go live to AppSource?

No. This button is deceiving, and I wish it were worded differently. When you click this button, it triggers our validation process and puts your app into our validation queue.

What should I know about the Review and publish button?

This is the button you should click when you want to submit your app for validation each time. Once you click the button, it takes you to a Review and publish page. Make sure all checkboxes are marked on that page. This pulls in all changed data into our validation queuing system properly.

I only made marketing changes. Will my app have to go through technical validation?

No. If you do not change your app in a submission, we skip technical validation.

FAQ about Library and Dependency Apps in Business Central

2/17/2021 • 2 minutes to read • Edit Online

This section contains answers to frequently asked questions about library apps and dependency apps in Business Central.

What is a library app?

A library app contains common code that other apps depend on. If you are going to have multiple AppSource apps that all share common code, such as licensing, registration,and so on, you can put that common code into a library app and have the AppSource apps depend on the library app.

How does the library app get installed to a tenant?

A library app does not appear on AppSource. It only lives in Business Central. Our service is built to install the library apps behind the scenes. Here is how it works. Customers finds an app they want to install on AppSource. That customer does not know the app even has library app(s). When they click to install the app, our service looks into that apps json/manifest to see if it first needs to install any library/dependency apps it may depend on. If so, it installs them first before installing the main AppSource app.

What is a dependency app?

A dependency app isn't much different from a library app. A dependency app does have its own offer on AppSource. For example, you might have AppSource "App A" that serves a purpose on its own and is listed on AppSource. You then also have "App B" as its own offer on AppSource but it does depend on code within "App A" and needs "App A" to be installed before it can be installed. This is really the only difference though. Behind the scenes, library and dependency apps behave the same when it comes to walking that dependency chain and auto installing any app the top-level app depends on.

Can I have multiple library apps for my AppSource app?

Yes. Just make sure you list all library apps as dependencies within the AppSource app json file/manifest.

When I get the latest updated version of my app, why don't I get the updated library/dependency apps that my AppSource app depends on?

Currently, updating of apps does not handle the library/dependency chain. This work is planned for a future release. For now, you need to uninstall and reinstall the library/dependency apps as well.

What are the validation requirements for library apps

Library apps only get validated technically, but don't go through any type of marketing validation. Also, the library apps are expected to be covered by the user scenarios and tests that you submit for the core app. The technical requirements are described here.

FAQ about Testing your Business Central App

2/17/2021 • 4 minutes to read • Edit Online

This section contains answers to frequently asked questions about testing your app when you submit an app for Business Central.

Since my app goes through validation, do I really need to thoroughly test my app?

Yes. It is your app and you are the expert, so you should have a vested interest in high quality. The main goal of validation is to ensure app code is meeting requirements and policy. The testing done during validation is only to ensure good user experience on the most common app scenarios. We do not test every scenario of an app. Using customers to find bugs is not the proper approach.

Is it ok to submit my app for validation before we complete our own testing?

No. Please do not submit your app for validation until it has been 100% tested. This will lead to many delays in the validation process otherwise. Also, it wastes time and resources.

Is it ok to test my AppSource app in an on-premises environment?

No. You must test your app using Business Central online. Although Business Central online and on-premises are very similar, they are not the exact same. If you only test on-premises, invariably issues will be found in our validation testing.

Does it really matter what version of Business Central I test on before submitting my app for validation?

Yes. It is critical that you always test on the latest version at the time when you are ready to submit for validation. Testing on the wrong version usually leads to validation failure. For example, let's say the latest version of Business Central is 15.4 at the time when you submit for validation You tested on 15.0. The product has changed between those versions, and deprecated features or other changes could result in your app behavior changing.

We recommend that you consider using Docker containers. Use the `Get-BcArtifactUrl` function in the BCContainerHelper PowerShell module to give you the artifact URL for the latest sandbox build for the specified country. You don't have to figure out what product version is active at time of submission. That function does it for you.

How thorough should our testing be?

You should always test with 100% coverage, or at least as close to 100% as you can get. The testing should be a combination of automated and manual tests. The apps with good testing infrastructure behind them are the most successful.

Do I have to test on every country that I intend to support with my app?

Yes. If you support multiple countries, test your app on every country. Each country's code base is slightly

different from both the base application and other countries. It is critical to make sure that the app publishes, syncs, and installs on every country you support. Because an app installs fine on one country doesn't mean it will publish/install fine on another. We have seen many times where it passes on one but fails on another during our validation.

Do you have recommendations on maintenance testing of our apps?

Yes. You should be testing your apps against our various build branches. Through Docker, you have access to our latest public sandbox builds and through the "Ready! for Dynamics 365 Business Central" program on Microsoft Collaborate you can also get access to *Next Minor* and *Next Major* builds. Test often, especially against the *Next Minor* build. This allows you to catch any bugs that may arise from core changes in the product.

I only made minor code changes in my updated app. Can I test just these changes?

No. You should always test 100% coverage no matter what. Testing only what you changed is not the correct approach. Even minor changes can lead to breaking changes where you least expect it.

Do I need to do upgrade testing?

Yes, this is a must. If an app fails to upgrade, customers are unable to get your updated app. This is one of the common failures we see today in validations. You should want your app upgrade to work optimally.

Any recommendations on upgrade testing?

Test the upgrade with extensive app data included. Many of the upgrade failures for customers are data related. The upgrade fails because specific data scenarios were not considered for testing. Or worse, the upgrade succeeds, and data is lost.

Do I only need to do upgrade testing from previous version to current?

No. It is very important you test from various previous versions of your app. This is because we do not automatically upgrade apps for minor releases. You could have a tenant back on version 1.0.0.0 of your app and have to jump all the way to version 1.0.0.5. We don't guarantee direct upgrades of apps from their most previous version.

FAQ about Updating your Business Central App

2/17/2021 • 5 minutes to read • Edit Online

This section contains answers to frequently asked questions about updating your app for Business Central.

Is it the same process for an app update as the first version?

Yes. You upload the updated app file into Partner Center and submit as normal. It goes through a more scaled-back validation process than your original version, but it does get validated. If it fails validation, it comes back to you for fixing. If it passes validation, it gets checked into Business Central.

What are some "need to know" considerations with an updated app?

When you submit an updated version of your app, you must increase the version number in the app's json/manifest files. Business Central doesn't allow overwrites. So we need the version number increased for us to check the updated app into our service upon it passing validation.

Never change the app's App ID in the json/manifest files. This is must stay the same across versions for various reasons, not least for upgrade reasons.

When is my updated app available for tenants to install?

As soon as your updated app passes validation and is checked into our service, it then becomes the active version (for whatever the current Business Central version is at that time). Even though your offer might still show as in progress in Partner Center, the updated app is active and ready to install. Also, even though your version number in AppSource might show as older, tenants will still get this latest updated version. For example, your updated version might be version 1.0.0.5. And in AppSource it might still show 1.0.0.1. Tenants will get the version 1.0.0.5.

What version of Business Central is my updated app compatible with?

When you submit your app for validation, we validate it against the latest version at that point in time. Once the app passes validation, it is then checked into our service and configured for that version of Business Central, unless a newer version has been released in the meanwhile. For example, if you submit your app and the latest version of Business Central at that time is 16.1, your app will then be compatible and configured for 16.1. When versions 16.2, 16.3, and so on roll out, your app is automatically configured for the latest version. Tenants that are on earlier versions of Business Central will not get that updated version. They still however can install the previous versions of your app. They will get the version of your app that is configured for the version of Business Central that their tenant is on.

When tenants have their Business Central version upgraded, do apps ever get automatically updated?

For minor releases, we do not auto-update apps. This is because of customer feedback and them not wanting their apps auto updated. The only exception to this is if an app will be broken in a minor release due to changes in the base product. In this case, we configure that app in our service as required. When tenants then get upgraded to that minor release, if they have that app, it then gets updated automatically. This is to avoid the app being broken for the customer.

For major releases, we do auto-update every app on every tenant to the app's latest available version. We

consider major releases to be our "refresh" releases.

How do tenants that already have an existing version of my app get my latest updated version?

By uninstalling and reinstalling the app. When doing the reinstall, it calls into our service and finds the latest active version of an app. There is a new **Manage Apps** page in the Business Central administration center that will soon allow updating of AppSource apps without having to do uninstall and reinstall.

Do I have to submit an updated version of my app for the major releases?

No. The only reason you would need to submit an updated version of your app for a major release is if your app is going to be broken in that release. If your app will not be broken, then your latest available version of the app will be rolled over to that major release.

How frequent should I submit updated versions of my app?

We recommend that you bundle more bug fixes and features so that your app doesn't have to be updated frequently. This has been voiced by our Business Central customers. They do not want to be constantly updating their apps in their tenants. We recommend a minimum 1-month app update cadence.

What if I have a critical hotfix?

We treat critical hotfixes with the utmost importance. We do have a process around this. Additional information on this hotfix process can be found here.

If I make changes to the library app, must I also submit an update for the AppSource app?

You would upload the updated library app to Partner Center, leave the main app as is, and submit for validation. We then see that the main app has not changed and only validate the library app.

But wouldn’t I need to change the dependency in my main app’s json to reference the updated library app file?

No. The version number in the dependency listing in the json file to an app is a minimum version. The main app is essentially saying, "I need version 1.0.0.1 or greater" of the library app. For example, the AppSource app lists version 1.0.0.1 for the library app, and that means that it can also use version 1.0.0.2.

Why don't I see the updated version of my app in my sandbox tenant?

Your tenant is on an older version of Business Central and has not yet been upgraded to the latest version of Business Central. The latest updated version of your app is only compatible with the latest Business Central version and later. If you upgrade your tenant to the latest version, you can then update your app.

Writing Extension Install Code

2/17/2021 • 2 minutes to read • Edit Online

There might be certain operations outside of the extension code itself that you want run when an extension is installed. These operations could include, for example, populating empty records with data, service callbacks and telemetry, version checks, and messages to users. To do these types of operations, you write extension install code. Extension install code is run when:

- An extension is installed for the first time.
- An uninstalled version is installed again.

This enables you to write different code for initial installation and reinstallation.

How to write install code

You write install logic in an *install* codeunit. This is a codeunit that has the SubType property set to **Install**. An install codeunit supports two system triggers on which you can add the install code.

TRIGGER	DESCRIPTION
OnInstallAppPerCompany()	Includes code for company-related operations. Runs once for each company in the database.
OnInstallAppPerDatabase()	Includes code for database-related operations. Runs once in the entire install process.

The install codeunit becomes an integral part of the extension version. You can have more than one install codeunit. However, be aware that there is no guarantee on the order of execution of the different codeunits. If you do use multiple install units, make sure that they can run independently of each other.

Install codeunit syntax

The following code illustrates the basic syntax and structure of an install codeunit:

```
codeunit [ID] [NAME]
{
    Subtype=Install;

    trigger OnInstallAppPerCompany()
    begin
        // Code for company related operations
    end;

    trigger OnInstallAppPerDatabase()
    begin
        // Code for database related operations
    end;

}
```

TIP

Use the shortcuts `tcodeunit` and `ttrigger` to create the basic structure for the codeunit and trigger.

Get information about an extension

Each extension version has a set of properties that contain information about the extension, including: AppVersion, DataVersion, Dependencies, Id, Name, and Publisher. This information can be useful when installing. For example, one of the more important properties is the `DataVersion` property, which tells you what version of data you are dealing with. These properties are encapsulated in a `ModuleInfo` data type. You can access these properties by through the `NAVApp.GetCurrentModuleInfo()` and `NAVAPP.GetModuleInfo()` methods. For more information, see NavApp Data Type

Install codeunit example

This example uses the `OnInstallAppPerDatabase()` trigger to check whether the data version of the previous extension version is compatible for the upgrade.

```
codeunit 50100 MyInstallCodeunit
{
    Subtype=Install;

    trigger OnInstallAppPerDatabase();
    var
        myAppInfo : ModuleInfo;
    begin
        // Get info about the currently executing module
        NavApp.GetCurrentModuleInfo(myAppInfo);

        // A 'DataVersion' of 0.0.0.0 indicates a 'fresh/new' install
        if myAppInfo.DataVersion = Version.Create(0,0,0,0) then
            HandleFreshInstall
        else
            // If not a fresh install, then we are Re-installing the same version of the extension
            HandleReinstall;
    end;

    local procedure HandleFreshInstall();
    begin
        // Do work needed the first time this extension is ever installed for this tenant.
        // Some possible usages:
        // - Service callback/telemetry indicating that extension was installed
        // - Initial data setup for use
    end;

    local procedure HandleReinstall();
    begin
        // Do work needed when reinstalling the same version of this extension back on this tenant.
        // Some possible usages:
        // - Service callback/telemetry indicating that extension was reinstalled
        // - Data 'patchup' work, for example, detecting if new 'base' records have been
        //   changed while you have been working 'offline'.
        // - Setup 'welcome back' messaging for next user access.
    end;
}
```

Building Your First Sample Extension With Extension Objects, Install Code, and Upgrade Code

Upgrading Extensions

2/17/2021 • 12 minutes to read • Edit Online

This article provides information about how to make a newer version of extension upgrade available on tenants. The first phase of the process is to develop the extension for upgrading. In this phase, you add code to upgrade data from the previous extension version. Once you have the upgrade code in place, you can publish and synchronize the new version, and the run the data upgrade.

> **NOTE**
>
> An *upgrade* is defined as enabling an extension that has a greater version number, as defined in the app.json file, than the current installed extension version.

Writing upgrade code

When you develop a new extension version, you must consider the data from the previous version. You have to determine the modifications that must be made to the data to make it compatible with the current version. For example, maybe the new version adds a new field that needs default values set for existing records. Or, the new version adds new tables that must be linked to existing records. To address this type of data handling, you must write upgrade code for the extension version. If there are no data changes between the extension versions, you don't need to write upgrade code. All data that isn't modified by upgrade code will automatically be available when the process completes.

You write upgrade logic in an upgrade codeunit, which is a codeunit whose SubType property is set to **Upgrade**. An upgrade codeunit supports several system triggers on which you can add data upgrade code. These triggers are invoked when you run the data upgrade process on the new extension.

The upgrade codeunit becomes an integral part of the extension and may be modified as needed for later versions. You can have more than one upgrade codeunit. There's a set order to the sequence of the upgrade triggers, but the execution order of the different codeunits isn't guaranteed. If you do use multiple upgrade units, make sure that they can run independently of each other.

Upgrade triggers

The following table describes the upgrade triggers and lists them in the order in which they're invoked.

TRIGGER	DESCRIPTION	FAILS THE UPGRADE ON ERROR
OnCheckPreconditionsPerCompany() and OnCheckPreconditionsPerDatabase()	Used to check that certain requirements are met before the upgrade can be run.	Yes
OnUpgradePerCompany() and OnUpgradePerDatabase()	Used to do the actual upgrade.	Yes
OnValidateUpgradePerCompany() and OnValidateUpgradePerDatabase()	Used to check that the upgrade was successful.	Yes

`PerCompany` triggers are run once for each company in the database, where each trigger is executed within its own system session for the company.

`PerDatabase` triggers are run once in the entire upgrade process, in a single system session that doesn't open

any company.

> **NOTE**
> These triggers are also available in upgrade codeunits for the base application, not just for extensions.

Upgrade codeunit syntax

The following code illustrates the basic syntax and structure of an upgrade codeunit:

```
codeunit [ID] [NAME]
{
    Subtype=Upgrade;

    trigger OnCheckPreconditionsPerCompany()
    begin
        // Code to make sure company is OK to upgrade.
    end;

    trigger OnUpgradePerCompany()
    begin
        // Code to perform company related table upgrade tasks
    end;

    trigger OnValidateUpgradePerCompany()
    begin
        // Code to make sure that upgrade was successful for each company
    end;
}
```

> **TIP**
> Use the shortcuts `tcodeunit` and `ttrigger` to create the basic structure for the codeunit and trigger.

Controlling when upgrade code runs

In most cases, it's important, that upgrade code isn't run more than once. There are a couple ways that you can control when upgrade code runs. You can either use extension version data or upgrade tags. These two methods are described in the sections follow. The method you choose will depend on the complexity of your solution. Use the following table as a guideline:

SCENARIO	VERSION NUMBER	UPGRADE TAGS
Large application with many versions		x
Extension version changes frequently, for example more than once a year		x
Version is set manually	x	
When checking whether it's a first-time installation. In this case, comparing with 0.0.0.0	x	
Fixing a broken upgrade		x

Using extension version data to control upgrade code

Each extension version has a set of properties that contain information about the extension, including: `AppVersion`, `DataVersion`, `Dependencies`, `Id`, `Name`, and `Publisher`. This information can be useful when upgrading. For more information, see JSON Files.

The `AppVersion` is one of the available properties and its value differs depending on the context of the code being run:

- Normal operation: `AppVersion` represents the value of the currently installed extension.
- Installation code: `AppVersion` represents the version of the extension you're trying to install.
- Upgrade code: `AppVersion` represents the version of the extension that you're upgrading to (in other words, the 'newer' version).

Another one of the more important properties is the `DataVersion` property, that represents the value of most recently installed/uninstalled/upgraded version of the extension, meaning that it reflects the most recent version of the data on the system, be that from the currently installed, or a previously uninstalled extension. The `DataVersion` property value differs depending on the context of the code being run:

- Normal operation: `DataVersion` represents the version of the currently installed extension, in which case it's identical to the `AppVersion` property.
- Installation code:
  - Reinstallation (applying the same version): `DataVersion` represents the version of the extension you're trying to install (identical to the `AppVersion` property).
  - New installation: `DataVersion` represents the value of '0.0.0.0' that's used to indicate there's no data.
- Upgrade code:
  - The version of the extension you're upgrading from. Either what was last uninstalled, or what is currently installed.

All these properties are encapsulated in a `ModuleInfo` data type. You can access these properties through the `NAVApp.GetCurrentModuleInfo()` and `NAVApp.GetModuleInfo()` methods. For more information, see NavApp Data Type.

Upgrade codeunit example

This example uses the `OnCheckPreconditionsPerDatabase()` trigger to check whether the data version of the previous extension version is compatible for the upgrade before restoring the archived data of the old extension.

```
codeunit 50100 MyUpgradeCodeunit
{
    Subtype=Upgrade;

    trigger OnCheckPreconditionsPerDatabase();
    var
        myInfo : ModuleInfo;
    begin
        if NavApp.GetCurrentModuleInfo(myInfo) then
            if myInfo.DataVersion = Version.Create(1, 0, 0, 1) then
                error('The upgrade isn't compatible');
    end;

    trigger OnUpgradePerDatabase()
    begin
        NavApp.RestoreArchiveData(Database::"TableName");
    end;
}
```

Using upgrade tags to control upgrade code

Although you can control upgrade code by checking versions, this pattern becomes difficult with larger applications that have many versions. The risk of something going wrong increases. If your solution includes the Microsoft system application, another way is to use *upgrade tags*. Upgrade tags provide a more robust and resilient way of controlling the upgrade process. They provide a way to track upgrade methods have been run to prevent executing the same upgrade code twice. Tags can also be used to skip the upgrade methods for a specific company or to fix an upgrade that went wrong.

Implementation behind upgrade tags

Upgrade tags are implemented as part the **Upgrade Tags** module of the system application. The module provides an API that you can code against to control your upgrade code.

> **TIP**
> If you want to implement your own upgrade tagging functionality, or get a better understanding of the code behind implementation in the system application, see Upgrade Tags in the ALAppExtensions repository on GitHub.

The **Upgrade Tags** module consists of several AL objects. In particular, it includes codeunit 9999 "Upgrade Tag" for creating and handling upgrade tags and table 9999 "Upgrade Tags" for storing them.

Codeunit 9999 "Upgrade Tag" includes the following methods:

METHOD	DESCRIPTION
`HasUpgradeTag(Tag: Code[250]; TagCompanyName: Code[30]): Boolean`	Verifies whether a specific upgrade tag exists. `Tag` is the code to check. `TagCompanyName` is the name of the company for which to check the existence of the tag. Returns `true` if the `Tag` with the given code exists.
`SetUpgradeTag(NewTag: Code[250])`	Specifies the tag to save.
`SetAllUpgradeTags()`	Sets all upgrade tags in a new company. This method is called from codeunit 2 "Company Initialize" in the base application.
`SetAllUpgradeTags(NewCompanyName: Code[30])`	Sets all upgrade tags in a new company. This method is called from report 357 "Copy Company" in the base application.

The codeunit also publishes the following events:

EVENT	DESCRIPTION
`OnGetPerCompanyUpgradeTags(var PerCompanyUpgradeTags: List of [Code[250]])`	Subscribe to this event to register an upgrade tag for OnUpgradePerCompany upgrade method for a new company. `PerCompanyUpgradeTags` specifies a list of tags to insert. Tags that already exist won't be inserted.
`OnGetPerDatabaseUpgradeTags(var PerDatabaseUpgradeTags: List of [Code[250]])`	Subscribe to this event to register an upgrade tag for OnUpgradePerDatabase upgrade method for a new company. `PerDatabaseUpgradeTags` specifies a list of tags to insert. Tags that already exist won't be inserted.

How to use upgrade tags

The following steps provide the general pattern for using an upgrade tag on upgrade code.

> **IMPORTANT**
> Use upgrade tags only for upgrade purposes only.

1. Use the following construct around the upgrade code to check for and add an upgrade tag.

```
// Check whether upgrade tag exists
if UpgradeTag.HasUpgradeTag(UpgradeTagValue) then
  exit;

// Upgrade code

// Add the new upgrade tag using SetUpgradeTag or SetAllUpgradeTags
UpgradeTag.SetUpgradeTag(UpgradeTagValue);
```

   You can use any value for the upgrade tag, but we recommend that you use the convention [CompanyPrefix]-[ID]-[Description]-[YYYYMMDD], for example, ABC-1234-MyExtensionUpgrade-20201206.

2. Add code to register the upgrade tag for new companies that might eventually be created.

   This step ensures that the upgrade code isn't run on the first upgrade because of a missing tag.

   To register the tag, subscribe to the `OnGetPerCompanyUpgradeTags` or `OnGetPerDatabaseUpgradeTags` events.

```
[EventSubscriber(ObjectType::Codeunit, Codeunit::"Upgrade Tag", 'OnGetPerCompanyUpgradeTags', '',
false, false)]
local procedure OnGetPerCompanyTags(var PerCompanyUpgradeTags: List of [Code[250]]);
begin
    PerCompanyUpgradeTags.Add(UpgradeTagValue);
end;
```

   This step isn't necessary if the tag is added by calling the `SetAllUpgradeTags` method.

3. Add code to register the upgrade tag for first-time installations of the extension.

   The step ensures that the upgrade code isn't run on first upgrade because of missing tag.

   To register the tag, call the `SetUpgradeTag` method on the `OnInstallAppPerCompany` and `OnInstallAppPerDatabase` triggers in the extension's install codeunit.

```
codeunit 50100 InstallCodeunit
{
    Subtype=Install;

    trigger OnInstallAppPerCompany()
    var
        UpgradeTag: Codeunit "Upgrade Tag";
    begin
        if not UpgradeTag.HasUpgradeTag(UpgradeTagValue) then
            UpgradeTag.SetUpgradeTag(UpgradeTagValue);
    end;
}
```

> **NOTE**
>
> Instead of registering tags individually, call the `SetAllUpgradeTags` method as opposed to `SetUpgradeTag`. This will register automatically register new tags as they're added.

For more information about extension install code, see Writing Extension Install Code.

Design considerations

1. Keep tags simple by limiting nesting tags to two levels. Complicated if statements can lead to problems.
2. Implement additional safety checks to avoid data corruption, even though you're using upgrade tags. For example, when copying obsolete fields to new fields, make sure the new fields have a default or blank. This check adds safety if upgrade tags introduce data issues.

Example

The following code is a simple example of an upgrade codeunit. For this example, the original extension extended the **Customer** table with a **Shoesize** field. In the new version of the extension, the **Shoesize** field has been removed ObsoleteState=removed), and replaced by a new field **ABC - Customer Shoesize**. The upgrade code will copy data from **Shoesize** field to the **ABC - Customer Shoesize**. An upgrade tag ensures that code doesn't run more than once, and data isn't overwritten on future upgrades. The example also uses a separate codeunit to define the upgrade tag so that they aren't hard-coded, but within methods.

```
codeunit 50100 "ABC Upgrade Shoe Size"
{
    Subtype = Upgrade;

    trigger OnUpgradePerCompany()
    var
        ABCUpgradeTagDefinitions: Codeunit "ABC Upgrade Tag Definitions";
        UpgradeTagMgt: Codeunit "Upgrade Tag";
    begin

        // Check whether the tag has been used before, and if so, don't run upgrade code
        if UpgradeTagMgt.HasUpgradeTag(ABCUpgradeTagDefinitions.GetABCShoeSizeUpgradeTag()) then
            exit;

        // Run upgrade code
        UpgradeShoeSize();

        // Insert the upgrade tag in table 9999 "Upgrade Tags" for future reference
        UpgradeTagMgt.SetUpgradeTag(ABCUpgradeTagDefinitions.GetABCShoeSizeUpgradeTag());
    end;

    local procedure UpgradeShoeSize()
    var
        Customer: Record Customer;
    begin

        if not Customer.FindSet() then
            exit;

        repeat
            // Make sure that target field is blank because you're copying obsolete=removed field to new
field
            // Additional safety check
            if Customer."ABC - Customer Shoesize" <> 0 then
                Error('ShoeSize must be blank, the value is already assigned');

            // Avoid blank modifies - it is a performance hit and slows down the upgrade
            if Customer."ABC - Customer Shoesize" <> Customer.Shoesize then begin
                Customer."ABC - Customer Shoesize" := Customer.Shoesize;
                Customer.Modify();
            end;
        until Customer.Next() = 0;
    end;
}

codeunit 50101 "ABC Upgrade Tag Definitions"
{
    // Register the new upgrade tag for new companies when they are created.
    [EventSubscriber(ObjectType::Codeunit, Codeunit::"Upgrade Tag", 'OnGetPerCompanyUpgradeTags', '', false,
false)]
    local procedure OnGetPerCompanyTags(var PerCompanyUpgradeTags: List of [Code[250]]);
    begin
        PerCompanyUpgradeTags.Add(GetABCShoeSizeUpgradeTag());
    end;

    // Use methods to avoid hard-coding the tags. It is easy to remove afterwards because it's compiler-
driven.
    procedure GetABCShoeSizeUpgradeTag(): Text
    begin
        exit('ABC-1234-ShoeSizeUpgrade-20201125');
    end;

}
```

Protecting sensitive code from running during upgrade

The extension might initiate code that you don't want to run during upgrade. The changes done to the data stored in the database will be rolled back. However, things like calls to external web services or physical printing can't be rolled back. Also, some code, like scheduling tasks, might throw an error and fail the upgrade.

For example, let's say the extension runs code that prints a check after a purchase invoice is posted for buying shoes. If the upgrade fails, the purchase invoice is rolled back. But the check will still be printed, unless you have implemented a mechanism to prevent printing.

To avoid this situation, use the session `ExecutionContext`. Depending on the scenario, the system runs a session in a special context for a limited time, which can be either `Normal`, `Install`, `Uninstall`, or `Upgrade`. You get the `ExecutionContext` by calling the GetExecutionContext method. For example, referring the example for printing checks, you could add something like the following code to verify the ExecutionContent before printing the check:

```
[EventSubscriber(ObjectType::Codeunit, Codeunit::"Purch.-Post", 'OnAfterPurchInvHeaderInsert', '', false,
false)]
local procedure PrintCheckWhenPurchasingShoes(var PurchHeader: Record "Purchase Header"; var PurchInvHeader:
Record "Purch. Inv. Header")
begin
    // Check whether global context is upgrade or installation of extension
    if Session.GetExecutionContext() <> ExecutionContext::Normal then
        // Check whether code is triggered by the extension
        if Session.GetCurrentModuleExecutionContext() <> ExecutionContext::Normal then
            // Something is wrong, so you want to abort here because the code doesn't raise the
EnqueuePrintingCheck trigger
            Error('Check can't be printed')
        else begin
            // Other code is invoking the upgrade, so use Job queue or similar mechanism to roll back if
upgrade fails
            EnqueuePrintingCheck(PurchInvHeader);
            exit;
        end;

    CallWebServiceToPrintCheck(PurchInvHeader);
end;
```

Running the upgrade for the new extension version

To upgrade to the new extension version, you use the Sync-NavApp and Start-NAVAppDataUpgrade cmdlets of the Business Central Administration Shell. These cmdlets synchronize table schema changes in the extension with the SQL database and run the data upgrade code.

1. Publish the new extension version. For simplicity, this example assumes the extension isn't signed, which isn't allowed with Dynamics 365 and isn't recommended with an on-premise production environment.

   ```
   Publish-NAVApp -ServerInstance BC -Path .\ProswareStuff_1.7.1.0.app -SkipVerification
   ```

   This step validates the extension syntax against server instance, and stages it for synchronizing.

2. Synchronize the new extension version with the database.

   ```
   Sync-NAVApp -ServerInstance BC -Name ProswareStuff -Version 1.7.1.0
   ```

   This step synchronizes the database with any table schema changes in the extension; it adds the tables from the extension to the tenant.

3. Run a data upgrade.

```
Start-NAVAppDataUpgrade -ServerInstance BC -Name ProswareStuff -Version 1.7.1.0
```

This step runs the upgrade logic that is defined by the upgrade codeunits in the extension. This step will uninstall the current extension version and enable the new version instead.

Publishing and Installing an Extension v2.0

2/17/2021 • 2 minutes to read • Edit Online

To make your extension available to tenant users requires three basic tasks: publish the extension package to the Dynamics 365 Business Central server instance, synchronize the extension with the tenant database, and install the extension on the tenant.

> **NOTE**
> This article describes how to publish and install the first version of an extension. If you want to publish an install newer version of an extension, see Upgrading Extensions.

Publish and synchronize an extension

Publishing an extension to a Dynamics 365 Business Central server instance adds the extension to the application database that is mounted on the server instance, making it available for installation on tenants of the server instance. Publishing updates internal tables, compiles the components of the extension behind-the-scenes, and builds the necessary metadata objects that are used at runtime.

Synchronizing an extension updates the database schema of the tenant database with the database schema that is defined by the extension objects. If a table or table extension is included in the extension, the respective full or companion table is created in the tenant database.

To publish and synchronize an extension

1. Start the Dynamics NAV Administration Shell.
2. To publish the extension, run the Publish-NAVApp cmdlet.

   The cmdlet takes as parameters the Dynamics 365 Business Central service instance that you want to install to and the .app package file that contains the extension. The following example publishes the extension **MyExtension.app** to the **YourDynamicsNAVServer** instance.

   ```
   Publish-NAVApp -ServerInstance YourDynamicsNAVServer -Path ".\MyExtension.app"
   ```

   > **NOTE**
   > If you are publishing a version 16.0 Microsoft extension, you'll have to include the `-SkipVerification` parameter. Otherwise, you will get the error "Publish-NAVApp : You cannot publish an extension that has not been code signed.". This issue is fixed in later versions.

3. To synchronize the schema of a tenant database to the extension, run the Sync-NavApp cmdlet.

   The following example synchronizes the extension **MyExtension** with version number 1.0.0.0:

   ```
   Sync-NavApp -ServerInstance YourDynamicsNAVServer -Name ExtensionName -Version 1.0.0.0 -Tenant
   TenantID
   ```

   Replace `TenantID` with the tenant ID of the database. If you don't have a multitenant server instance, use `default` or omit this parameter.

The extension can now be installed on tenants.

Install an extension

After you publish and synchronize an extension, you can install it on tenants. The extension is then available to users in the client. Installing an extension can be done from the Dynamics 365 client or Dynamics NAV Administration Shell.

> **NOTE**
> Installing an extension will run any installation code that is built-in to the extension. Installation code could, for example, perform operations like populating empty records with data, service callbacks and telemetry, version checks, and messages to users. For more information, see Writing Extension Install Code.

To install an extension by using Dynamics NAV Administration Shell

1. Start the Dynamics NAV Administration Shell.
2. To install the extension on one or more tenants, use the `Install-NAVApp` cmdlet.

   The following example installs the extension **My Extension** for Tenant1 and Tenant3. In single-tenant deployments, you either specify `default` as the tenant ID, or you omit the `-Tenant` parameter.

   ```
   Install-NAVApp -ServerInstance YourDynamicsNAVServer -Name "My Extension" -Tenant Tenant1, Tenant3
   ```

To install an extension by using the client

1. In Dynamics 365 Business Central, use search to open the **Extension Management** page.

   In the **Extension Management** window, you can view the extensions that are published to your server. For each extension, you can see the current installation status.
2. Choose an extension to see additional information and to install the extension.
3. Review and accept the license agreement.
4. Choose the **Install** button to install the extension.

Upgrading AppSource Apps in Production

2/17/2021 • 2 minutes to read • Edit Online

When an updated version of an AppSource app becomes the active version in the Dynamics 365 Business Central service, tenants do not automatically get this updated version. This upgrade must be done manually by getting the latest version of the app in AppSource.

To upgrade an AppSource app

Follow the steps below to update a tenant to the latest version of any AppSource app.

1. Log in to the Dynamics 365 Business Central browser client.
2. In the **Tell Me** box, enter **Extension Management**, and then choose the related link.
3. Locate the app that you want to update.
4. Under **Manage**, choose **Uninstall**.
5. Go to AppSource and then install the app again.

Generating Delta files

2/17/2021 • 2 minutes to read • Edit Online

You can use the `Compare-NAVApplicationObject` PowerShell cmdlet to generate .delta files from two versions of a set of application objects. For more information about the PowerShell cmdlet, see Compare-NAVApplicationObject.

The cmdlet has a `ExportToNewSyntax` switch that allows generating .delta files that can be used as a starting point for creating extensions. Setting the `ExportToNewSyntax` flag generates .delta files that contain additional information needed to generate the correct structure and layout of extension objects.

> **IMPORTANT**
> The Txt2Al conversion tool will reject .delta files that were generated without using the -ExportToNewSyntax flag.

Using the `ExportToNewSyntax` switch for the `Compare-NAVApplicationObject` cmdlet produces a .delta file that can be converted to an extension.

The ExportToNewSyntax flag

PARAMETER	DESCRIPTION
Type	SwitchParameter
Aliases	None
Position	Named
Default value	None
Accept pipeline input	False
Accept wildcard characters	False

Example

```
Compare-NAVApplicationObject -OriginalPath "C:\PageWith2Controls.txt" -ModifiedPath
"C:\PageWith3Controls.txt" -ExportToNewSyntax
```

Exporting data for Extensions

2/17/2021 • 2 minutes to read • Edit Online

For your extension to run properly, configuration and starting data such as permission sets and table data may be needed. An extension can include the following types of data that can be imported for the tenant during the installation of the extension.

- Permission sets
- Web services
- Starting table data
- Custom report layouts

The data must be exported into files to be included in the extension. To use the export functions you must use a container sandbox environment for Dynamics 365 Business Central. For more information, see Get started with the Container Sandbox Development Environment.

To export permission sets

1. Open the Business Central Development Shell.
2. Export the relevant permission set using the `Export-NAVAppPermissionSet` cmdlet to export the permission set to a file. For example, the following command exports the BASIC permission set.

   ```
   Export-NAVAppPermissionSet -ServerInstance DynamicsNAV160 -Path '.\PermissionSet.xml' -PermissionSetId
   BASIC
   ```

   NOTE

   Export each permission set to a separate XML file.

3. Add the exported permission set files to the Visual Studio Code project that contains your extension.

   WARNING

   If you do not include a permission set with your extension, only users with the SUPER permission set will be able to use the extension.

To export web services

1. Open the Business Central Development Shell.
2. Export the relevant web service using the `Export-NAVAppTenantWebService` cmdlet to export the web service to a file. The following command exports the Customer Card page.

   ```
   Export-NAVAppTenantWebService -ServerInstance DynamicsNAV160 -Path TenantWebService.xml -ServiceName
   Customer -ObjectType Page -ObjectId 21
   ```

   NOTE

   Export each web service to a separate XML file.

3. Add the exported web services files to the Visual Studio Code project that contains your extension.

To export table data

1. Open the Business Central Development Shell.
2. Export the relevant data using the `Export-NAVAppTableData` cmdlet to export the data to a file. This includes setting the path to a folder where you want the .navxdata file created. A data file in the format of TAB.navxdata will be created. (Example: TAB10000.navxdata).

   ```
   Export-NAVAppTableData -ServerInstance DynamicsNAV160 -Path 'C:\NAVAppTableData' -TableId 10000
   ```

   > **NOTE**
   > Export the data for each table to a separate XML file.

3. Add the exported table data files to the Visual Studio Code project that contains your extension.
4. Call the procedure in a Codeunit with the Subtype property `Install` or `Upgrade` and specify the table ID in the `NavApp.LoadPackageData` procedure as shown in the following example.

   ```
   codeunit 50100 MyExtensionUpgrade
   {
       Subtype = Upgrade;
       trigger OnUpgradePerDatabase()
       begin
           NavApp.LoadPackageData(50100);
       end;
   }
   ```

   > **WARNING**
   > An extension can only include table data for new tables that are added as part of the extension.

To export custom report layouts

1. Open the Business Central Development Shell.
2. Export the relevant report layouts using the `Export-NAVAppReportLayout` cmdlet to export to a file:

   ```
   Export-NAVAppReportLayout -ServerInstance DynamicsNAV160 -Path .\ReportLayout.xml -LayoutId 1
   ```

   > **NOTE**
   > Export each custom report layout to a separate XML file.

3. Add the exported custom report files to the Visual Studio Code project that contains your extension.

The Txt2Al Conversion Tool

2/17/2021 • 4 minutes to read • Edit Online

The Txt2Al conversion tool allows you to take C/AL objects, which were created in Dynamics NAV or Business Central Spring 2019 (version 14), and convert them into the new .al format. The .al format is used when developing extensions for Dynamics 365 Business Central. Converting the objects consists of following two steps:

1. Exporting the objects from C/SIDE in a cleaned .txt format.
2. Converting the objects to the new syntax.

Where to get the Txt2Al conversion tool

The Txt2Al conversion tool (txt2al.exe) is only available with version 14, which is the last version to support C/AL. Use this version no matter what later version you may eventually be upgrading to. The AL objects created by the tool will be compatible with later versions.

You find the txt2al.exe on the installation media (DVD) in the "DVD\RoleTailoredClient\program files\Microsoft Dynamics NAV\140\RoleTailored Client" folder. Or, it's installed locally with Dynamics NAV Development Environment, for example, in the "C:\Program Files (x86)\Microsoft Dynamics 365 Business Central\140\RoleTailored Client" folder.

Using the Txt2Al conversion tool

To run the Txt2Al conversion tool, follow the steps outlined below.

1. Start with a clean Dynamics NAV database and compile the database.
   It's **very** important that you compile the database to get the right result in the next step.
2. Make an export of **all the baseline objects** in the command line using the following syntax:
   ```
   finsql.exe Command=ExportToNewSyntax, File=<filename.txt>, Database="<databasename>", ServerName=
   <servername> ,Filter=Type=table;ID=<tableID>
   ```
   The following example exports the table **225** from the Demo Database NAV (13-0) database:
   ```
   finsql.exe Command=ExportToNewSyntax, File=exportedBaselineObjects.txt, Database="Demo Database NAV (13-
   0)", ServerName=.\NAVDEMO ,Filter=Type=table;ID=225
   ```
3. Import your solution using the import option in C/SIDE and compile the database.
   It's **very** important that you compile the database to get the right result in the next step.
4. Export all **new and/or modified** objects using the following syntax:
   ```
   finsql.exe Command=ExportToNewSyntax, File=<filename.txt>, Database="<databasename>", ServerName=
   <servername> ,Filter=Type=table;ID=<tableID>
   ```
   The following example exports the table **231** from the Demo Database NAV (13-0) database:
   ```
   finsql.exe Command=ExportToNewSyntax, File=exportedNewModifiedObjects.txt, Database="Demo Database NAV
   (13-0)", ServerName=.\NAVDEMO ,Filter=Type=table;ID=231
   ```
5. Run the Set-ObjectPropertiesFromMenuSuite cmdlet, which will convert MenuSuite information on pages and reports in the generated AL objects to enable them for search. For more information, see Making Pages and Reports Searchable in the Web client
6. Create .delta files using the Compare-NAVApplicationObject PowerShell script. For more information, see Generating DELTA Files.
7. Go to the *\Program Files(x86)\Microsoft Dynamics 365 Business Central\140\RoleTailored Client* folder and locate the **txt2al.exe** converter tool.
8. Run the tool from the command line using the following syntax:

```
txt2al --source --target --rename --type --extensionStartId --injectDotNetAddIns --dotNetAddInsPackage --
dotNetTypePrefix --translationFormat --addLegacyTranslationInfo
```

Parameters

PARAMETER	DESCRIPTION
--source=Path	Required. The path of the directory containing the .delta files.
--target=Path	Required. The path of the directory into which the converted AL files will be placed.
--rename	Rename the output files to prevent clashes with the source .txt files.
--type=ObjectType	The type of object to convert. Allowed values: Codeunit, Table, Page, Report, Query, XmlPort
--extensionStartId	The starting numeric ID of the extension objects (Default: 70000000). It will be incremented by 1 for each extension object.
--stacktrace	Display the stack trace of exceptions raised during the conversion.
--help	Show help screen.
--injectDotNetAddIns	Inject the definition of standard .NET add-ins in the resulting .NET package. The standard .NET add-ins are a set of add-ins that are embedded into the platform.
--dotNetAddInsPackage=Path	Specify the path to an AL file that contains a definition for a .NET package containing .NET type declarations that should be included in the .NET package definition that's produced by the conversion. This parameter should be used to inject a custom set of .NET control add-in declarations. The file should contain something similar to the example shown below.
--multithreaded	Run using multiple threads. This parameter improves performance but results in non-repeatable extension numbers and .xlf content.
--dotNetTypePrefix	Specify a prefix to be used for all .NET type aliases created during the conversion.
--translationFormat=ObjectType	Specify the format to use when generating translation files. The allowed values are: Xliff, Lcg.
--addLegacyTranslationInfo	Add information to the translation file that can be used to migrate existing translations/translated resources. During conversion, XLIFF files from all the ML properties in the app are extracted. If this switch is set, a comment is added in the generated XLIFF that specifies what the ID of the translation item would be in C/SIDE. This acts as a mapping that allows you to convert existing translation resources for your app.

PARAMETER	DESCRIPTION
--runtime	Specify the target runtime for the converted AL. The default is the latest supported runtime. The string should be in a format similar to `major.minor`.
--objectFileNamePattern	Specify the pattern for naming AL files that contain AL objects by using the following placeholders: `{name}` - object name, `{type}` - object type, `{id}` - object ID. This parameter only takes effect if `--rename` is specified. The default is `{name}.{type}`.
--extensionObjectFileNamePattern	Specify the pattern for naming AL files containing AL extension objects by using the following placeholders: `{name}` - extension object name, `{type}` - extension object type, `{id}` - object ID, `{targetName}` - the name of the object being extended, `{targetId}` - the ID of the object being extended. This parameter only takes effect if `--rename` is specified. The default is `{name}.{type}-{targetName}`.
--format	Format the converted AL code using the standard formatter.
--dataClassificationDefaulting	Specify the DataClassification property for all table fields that don't have it specified. For more information, see DataClassification Property.
--tableDataOnly	For table objects, specifies to convert only the table and field definitions, including properties. Methods and trigger code isn't included. **Note:** This parameter was first introduced in Business Central version 14.2 (cumulative update 11) and Business Central version 15.5.

NOTE

It's recommended to only use the conversion tool for export. Importing objects that have been exported can damage your application.

TIP

You can use the Dynamics NAV Development Shell cmdlet `Export-NAVApplicationObject` with the `-ExportToNewSyntax` flag set instead of using finsql. From the command prompt in the Dynamics NAV Development Shell, run `Get-Help Export-NAVApplicationObject -full` to see the full syntax.

Converting Extensions V1 to Extensions V2

2/17/2021 • 5 minutes to read • Edit Online

Extensions are a programming model where functionality is defined as an addition to existing objects and defines how they are different or modify the behavior of the solution. This article explains the steps involved in converting V1 extensions, written in C/SIDE. to V2 extensions; written using the AL Language extension for Visual Studio Code. The overall steps for the conversion are:

1. Convert the source code from C/AL to the AL syntax.
2. Complete the development of the extension in AL syntax.
3. Write upgrade code to restore and modify data from the V1 Extension tables.
4. Build the extension.
5. Uninstall the V1 extension, and publish and run upgrade on the V2 extension.

> **IMPORTANT**
> Converting extensions V1 to extensions V2 can only be done on Business Central Spring 2019 (version 14) and earlier versions. It isn't supported on later Business Central versions, because it requires a working C/AL base application and several ArchiveData functions, which are not available in later versions.

Convert the source code from V1 to V2

To convert the source code, you must use the Txt2Al conversion tool. The Txt2Al conversion tool allows you to take existing application objects that have been exported in .txt format and convert them into the new .al format. The .al format is used when developing extensions for Business Central. For more information about converting the source code, see Txt2Al Conversion Tool.

Complete the development of the extension

When the source code has been converted using the Txt2Al conversion tool, open the project folder in Visual Studio Code, and then modify or add code to the new version as needed. For more information about getting started with Visual Studio Code and the AL Language extension, see Getting Started with AL.

You might run into compilation errors, which can typically be caused by:

- Object IDs that have changed. The conversion tool tries to convert your code into the object ID range allowed for Extensions V2.
- Field or control names look different; the AL syntax requires names, this means that no empty or default names are allowed.
- Menu suites do not exist in Extensions V2.
- .NET references are not allowed; there is no support for .NET types. Instead you must use the classes that replace .NET calls. For more information, see Reference.

IMPORTANT

In the `app.json` file, keep the ID the same as in the V1 extension. Also, make sure to increase the version number.

The version number has the format `Major.Minor.Build.Revision`, for example `1.5.0.0`. To increase the version number, you must increase the value of `Major`, `Minor`, or `Build` by at least one, for example `1.5.1.0` or `1.6.0.0`.

To use `NAVAPP.RestoreArchiveData()` method for upgrading, you must not change the IDs of the tables that are being restored; this means that tables from your V1 extension must have the same IDs in the V2 extensions.

Write upgrade code to move data from V1 Extensions

Just like with V1 extensions, you have to write code to handle data in tables during upgrade. Writing code for the V1-to-V2 extension upgrade is very similar to the code that you have been writing for V1 Extensions. The differences are:

- Instead of adding code to normal codeunit, you write code in an upgrade codeunit, which is a codeunit whose SubType property is set to **Upgrade**.
- Instead of adding code to the user-defined methods `OnNavAppUpgradePerDatabase()` or `OnNavAppUpgradePerCompany()`, you add code to one or more of the following system triggers for data upgrade. These triggers are invoked when a data upgrade is started. The following table lists the upgrade triggers in the order in which they run.

TRIGGER	DESCRIPTION
OnCheckPreconditionsPerCompany() or OnCheckPreconditionsPerDatabase()	Used to check that certain requirements are met in order to run.
OnUpgradePerCompany() or OnUpgradePerDatabase()	Used to run the actual upgrade work
OnValidateUpgradePerCompany() or OnValidateUpgradePerDatabase()	Used to check that the upgrade was successful

However, for this one-time conversion, all of the same **NAVAPP** system methods you used in V1 extensions work with V2 extensions and can be called from any of the upgrade triggers.

METHOD	DESCRIPTION
`NAVAPP.DeleteArchiveData(70000000)`	Deletes the archived data from table 70000000.
`NAVAPP.GetArchiveRecordRef(70000000, archRef)`	Gets a record ref to the archived data from table 70000000.
`archVersion := NAVAPP.GetArchiveVersion()`	Gets the version of the archived data from the old extension.
`NAVAPP.RestoreArchiveData(70000000)`	Restores the data from the archive of table 70000000.

By using these methods, you can restore or move all your data from the old V1 extension into the new V2 by running an upgrade.

IMPORTANT

To use `NAVAPP.RestoreArchiveData()`, you must not change the IDs of the tables that are being restored; this means that tables from your V1 extension must have the same IDs in the V2 extensions.

Example

This code illustrates a simple upgrade codeunit for restoring the V1 extension data for extension table `70000000`.

```
codeunit 70000001 MyExtensionUpgrade
{
    Subtype=Upgrade;

    trigger OnUpgradePerDatabase();
    begin
        NAVAPP.RestoreArchiveData(70000000);
    end;
}
```

TIP

Typing the shortcut `ttrigger` in Visual Studio Code will create the basic structure for a trigger.

Build the extension package

Press Ctrl+Shift+B to compile and build the extension complete with the application objects and upgrade codeunit.

Run the upgrade

The final task of the conversion is to publish the V2 extension, and run the data upgrade. The following steps use an example that upgrades a V1 extension that is called 'ProsewareStuff' and has the version '1.5.0.0.'. The V1 extension is published, installed, and populated with data. The V2 extension has the same name (and ID), but it has the version '1.5.1.0'. The Dynamics 365 Business Central service instance is called 'DynamicsNAV', and there is only one tenant.

The steps use the Dynamics NAV Server Administration tool.

1. Uninstall the V1 extension.

   ```
   Uninstall-NAVApp -ServerInstance NAV -Name ProsewareStuff -Version 1.5.0.0
   ```

   This removes the tables from the SQL Server database and archives extension data.

   IMPORTANT

   The V1 extension must be uninstalled before upgrading it to a V2 extension.

2. Publish the V2 extension. This example assumes the extension is not signed.

   ```
   Publish-NAVApp -ServerInstance DynamicsNAV -Path .\ProswareStuff_1.5.1.0.app -SkipVerification
   ```

   This validates the extension syntax against server instance, and stages it for syncing.

3. Synchronize the V2 extension with the database.

```
Sync-NAVApp -ServerInstance NAV -Name ProswareStuff -Version 1.5.1.0
```

   This adds tables from V2 extension to SQL database.

4. Run the upgrade process to handle archived data from the V1 extension.

```
Start-NAVAppDataUpgrade -ServerInstance NAV -Name ProswareStuff -Version 1.5.1.0
```

   This runs the upgrade logic defined by the upgrade codeunit in the extension, and installs the new V2 extension.

5. (optional) Unpublish the V1 extension.

```
Unpublish-NAVApp -ServerInstance NAV -Name ProswareStuff -Version 1.5.0.0
```

   This removes the unused extension package from server.

Going forward

The upgrade code unit becomes an integral part of the extension. The **NAVAPP** methods were mainly be used for the conversion from V1 to V2. After converting the extension, you should begin to write upgrade code as described in Upgrading Extensions.

AL Development Environment

The Microsoft_Application.app File

2/17/2021 • 3 minutes to read • Edit Online

The Microsoft_Application.app file is included with Business Central and is located in the `\Applications\Application\Source` folder. The `Microsoft_Application.app` file logically encapsulates all of the extensions making up a solution, for example, version `16.0.0.0` of the base and system application package files, and it provides a convenient way to define and refer to this solution identity.

> **NOTE**
>
> In previous versions the references to base and system application were stated explicitly under `dependencies` in the `app.json` file of the extension. Instead you must now use the `Application` version property in the `app.json` file. For more information, see JSON Files.

The file name of the reference is `Microsoft_Application.app` and in the app.json file of the application package file, the name is `Application`. For code-customized base applications that have their own appId, the `Microsoft_Application.app` file can be modified to reference the appId of the code-customized base applications instead. This allows any extensions that are dependent on the `Application` to resolve to the custom appId.

> **NOTE**
>
> The partner who redefines the application must ensure that extensions that are dependent on the `Application` compile and work. This can be ensured, for example, by not introducing any breaking changes.

> **IMPORTANT**
>
> If you have modified the `Microsoft_Application.app` file, you can rename the file name, and change information about the `publisher`, but it is important to keep `"name": "Application"` in the extension, which is what is being checked for in terms of symbols references. It is also important to keep the `propagateDependencies` set to `true`. The `version` must be set to the version of the Microsoft base application with which it is compatible.

Changing the app.json file for a code-customized base application

The `app.json` file of the `Microsoft_Application.app` file looks like the following example for Business Central version 15.3.

```
{
    "id":  "c1335042-3002-4257-bf8a-75c898ccb1b8",
    "name":  "Application",
    "publisher":  "Microsoft",
    "version":  "15.3.40074.40254",
    "propagateDependencies":  true,
    "logo":  "ExtensionLogo.png",
    "privacyStatement":  "https://go.microsoft.com/fwlink/?LinkId=724009",
    "EULA":  "https://go.microsoft.com/fwlink/?linkid=2009120",
    "help":  "https://go.microsoft.com/fwlink/?linkid=2104024",
    "url":  "https://go.microsoft.com/fwlink/?LinkId=724011",
    "dependencies":  [
                         {
                             "appId":  "437dbf0e-84ff-417a-965d-ed2bb9650972",
                             "name":  "Base Application",
                             "publisher":  "Microsoft",
                             "version":  "15.3.0.0"
                         },
                         {
                             "appId":  "63ca2fa4-4f03-4f2b-a480-172fef340d3f",
                             "name":  "System Application",
                             "publisher":  "Microsoft",
                             "version":  "15.3.0.0"
                         }
                     ],
    "screenshots":  [

                    ],
    "platform":  "15.0.0.0",
    "showMyCode":  true,
    "brief":  "Application (W1)"
}
```

If you have a code-customized base application, the file can be edited to reflect the dependency to this instead. To do so, update the `"dependencies": []` section and change the `"appId": "437dbf0e-84ff-417a-965d-ed2bb9650972"` to the `appId` of your code-customized base application. You can update the `"name"` and `"publisher"` information to match too.

```
...
"dependencies":  [
                         {
                             "appId":  "<appId of the code-customized base app>",
                             "name":  "Customized Base Application",
                             "publisher":  "PartnerSolutions",
                             "version":  "15.3.0.0"
                         },
                         ...
                     ],
...
```

Uptaking the Application app

The Application app logically encapsulates apps making up a solution (such as Base Application and System Application), and provides an abstraction to protect the AppSource and PTE extensions running on top of that solution from not being able to resolve dependencies to these apps.

When using it, future refactoring of the referenced solution; like extracting some areas into separate apps, or changes to the identities of the apps which comprise the solution, will not be forcing all other dependent apps to change or add new apps to their dependencies, as these dependencies will be resolved implicitly via the reference to the Application app.

Additionally, it is meant to simplify the on-premises upgrade scenarios, when customizations are extracted from the Base Application into extensions. And finally it makes it possible to make the same apps available not only to the Business Central customers, but also to the customers of the rich, vertical solutions called Embed Apps, which are also running in the Business Central service.

To enable these benefits, all you need to do, as an AppSource or PTE app owner, is to add the `"application"` property in the `app.json` file of your app and provide the minimum Microsoft Base Application version that this app is compatible with. For more information, see JSON Files. Also, you need to remove the direct dependencies to the Base Application and System Application from the `app.json` file. See the following example:

```
{
    "id":  "e5645aaf-74be-453a-ab50-2e34ec3ee53c",
    "name":  "Fabrikam Gadgets Management",
    "publisher":  "Fabrikam",
    "version":  "15.3.41056.29085",
    "logo":  "ExtensionLogo.png",
    "privacyStatement":  "https://go.microsoft.com/fwlink/?LinkId=724009",
    "EULA":  "https://go.microsoft.com/fwlink/?linkid=2009120",
    "help":  "https://go.microsoft.com/fwlink/?linkid=2104024",
    "url":  "https://go.microsoft.com/fwlink/?LinkId=724011",
    "application": "15.3.0.0",
    "dependencies":  [
                     ],
    "screenshots":  [

                    ],
    "platform":  "15.0.0.0",
    "showMyCode":  true,
    "brief":  "Fabrikam Gadgets Mgt."
}
```

IMPORTANT

Soon up-taking the Application app will also be a mandatory requirement for AppSource apps, enforced by the AppSource technical validation. Thus it is highly recommended to change the existing AppSource apps at first convenience, for example with your next planned app update, and adopt the `"application"` property for all new AppSource apps. We also recommend up-taking the Application app for the customized Base Applications on-premise, and per-tenant-extensions (PTEs) that you use in the Business Central online environments.

Publishing a Code-Customized Base Application for Business Central On-Prem

2/17/2021 • 4 minutes to read • Edit Online

APPLIES TO: Business Central 2019 release wave 2 and later

This topic describes the steps and development environment configuration settings that are needed in order to customize the Base Application code in Dynamics 365 Business Central on-premises and publish the code-customized Base Application to the local server.

> **IMPORTANT**
> Instead of code-customizing the Base Application, it is *strongly* recommended to create extensions whenever possible.

> **NOTE**
> The steps in this topic are not validated against a Docker environment. If you are running the on-premises installation and development from Docker, there can be dependencies and other steps that you need to take into consideration.

Prerequisites

Make sure to have the following prerequisites installed to be able to follow the steps in this topic.

- Dynamics 365 Business Central on-premises with the AL Language Development Environment option installed
- Visual Studio Code
- The AL Language extension

To publish a code customization for Business Central on-premises

1. Get the Base Application source from the `/Applications/BaseApp/Source` folder on the DVD.
2. Unzip the *BaseApplication.source.zip* file and open the source folder in Visual Studio Code. This folder contains all of the base application objects and an `app.json` file with the settings enabled for `OnPrem`.
3. Now, you must configure your `launch.json` file settings to the local server. For more information, see JSON Files.
4. Next, download symbols for the Base Application using **Ctrl+Shift+P** and then choose **Download Symbols**.
5. Customize the Base Application. In this example, we will just modify the text in the **Name** field on the **Customer Card** page to be **Strong**. So, in the `CustomerCard.Page.al` file, we specify the following extra line of code:

```
...
field(Name; Name)
{
    ApplicationArea = All;
    Importance = Promoted;
    ShowMandatory = true;

    Style = Strong;       // Show name in bold

    ToolTip = 'Specifies the customer''s name. This name will appear on all sales documents for the
customer.';

    trigger OnValidate()
    begin
        CurrPage.SaveRecord;
    end;
}
...
```

6. Use the Business Central Administration Console to ensure that the settings for developing for on-premises are correctly set. On the **Development** tab these must be:
   - **Allowed Extension Target Level** is set to **OnPrem**.
   - **Enable Developer Service Endpoint** checkbox is selected.
7. In the `app.json` file, in the `dependencies` section, make sure that `version` is set to the version of the System Application found in the project under `.alpackages`. For example:

```
"dependencies": [
    {
    "appId": "63ca2fa4-4f03-4f2b-a480-172fef340d3f",
    "publisher": "Microsoft",
    "name": "System Application",
    "version": "16.0.10037.0"
    }
],
```

8. Configure **User Settings** or **Workspace Settings** to include the following paths for the `"al.assemblyProbingPaths"` setting. For more information, see AL Language Extension Configuration.

```
"al.assemblyProbingPaths": [
    "C:\\Program Files\\Microsoft Dynamics 365 Business Central\\170",
    "C:\\Program Files (x86)\\Microsoft Dynamics 365 Business Central\\170",
    "C:\\Program Files (x86)\\Reference Assemblies\\Microsoft\\Framework\\.NETFramework\\v4.8",
    "C:\\Program Files (x86)\\Reference Assemblies\\Microsoft\\WindowsPowerShell"
],
```

9. For improved performance when working with a large project like the Base Application, see the Optimize Visual Studio Code Editing and Building Performance topic.
10. Next, you must uninstall all extensions from the command line. If you at this point try to just publish the extension from Visual Studio Code you will get the following error:

```
The request for path /BC170/dev/apps?SchemaUpdateMode=synchronize&DependencyPublishingOption=ignore
failed with code 422. Reason: The extension could not be deployed because it is already deployed on
another tenant.
```

    You get the error because the extensions are installed in the `global` scope. If you want to publish an extension from Visual Studio Code, within the `developer` scope, you will have to first uninstall and then unpublish the extensions from the command line.

Ideally, you should uninstall the application that you want to update and all its dependencies. To uninstall the Base Application use the following cmdlet:

```
Uninstall-NavApp -Name "Base Application" -ServerInstance BC170 -Force
```

Use the `-Force` parameter to uninstall all dependencies.

> **NOTE**
>
> Alternatively, uninstall everything using the following cmdlet.
>
> ```
> Get-NAVAppInfo -ServerInstance BC170 | %{Uninstall-NAVApp -Name $_.Name -ServerInstance BC170 -
> Force}
> ```

11. Having uninstalled, the next step is to unpublish the application and all of its dependencies. This needs to happen before we can publish it. The following command can be used if there are no dependencies to the Base Application:

    ```
    Unpublish-NavApp -Name "Base Application" -ServerInstance BC170
    ```

    But if there are dependencies on the Base Application this will give an error. To solve this, you must unpublish all the applications with dependencies on the Base Application. This is easier to do using a script that recursively removes the dependencies. Use Windows PowerShell ISE to create a new script with the following lines of code:

    ```
    function UnpublishAppAndDependencies($ServerInstance, $ApplicationName)
    {
         Get-NAVAppInfo -ServerInstance $ServerInstance | Where-Object {
        # If the dependencies of this extension include the application that we want to unpublish, it
    means we have to unpublish this application first.
        (Get-NavAppInfo -ServerInstance $ServerInstance -Name $_.Name).Dependencies | Where-Object
    {$_.Name -eq $ApplicationName}
     } | ForEach-Object {
        UnpublishAppAndDependencies $ServerInstance $_.Name
     }

     Unpublish-NavApp -ServerInstance $ServerInstance -Name $ApplicationName
    }

    function UninstallAndUnpublish($ServerInstance, $ApplicationName)
    {
        Uninstall-NavApp -ServerInstance $ServerInstance -Name $ApplicationName -Force
        UnpublishAppAndDependencies $ServerInstance  $ApplicationName

    }

    UninstallAndUnpublish -ServerInstance "BC170" -ApplicationName "Base Application"
    ```

12. Save the script as **unpublish.ps1**.

13. Run the script from the PowerShell commandline to handle the uninstall and unpublishing of the Base Application and its dependencies: `.\unpublish.ps1`

    > **NOTE**
    >
    > Use `"dependencyPublishingOption": "Ignore"` in the `launch.json` file to only publish this extension. For more information, see JSON Files.

14. Import a license with rights to publish the extension. For example:

```
Import-NAVServerLicense -ServerInstance BC170 -LicenseFile "C:\Users\mylicense.flf"
```

15. Press **Ctrl+F5** to publish the modified Base Application as an extension from Visual Studio Code.

The Base Application is now published with the small customization of bolding the text in the **Name** field on the **Customer Card** page.

Extending Application Areas

2/17/2021 • 5 minutes to read • Edit Online

Application areas represent a feature in the system that offers developers, administrators, and users the ability to define differentiated user experiences.

Application areas are mapped to controls to show or hide them on page objects to enable more or fewer business scenarios.

Extending application areas and the experience tier

In this example you will:

- Add a new application area in the **Application Area Setup** table.
- Enable the application area in the **OnInstallAppPerCompany** trigger.
- Extend the experience tier in the **OnGetExperienceAppArea** event.
- Modify the experience tier (optional).
- Validate the application area in the **OnValidateApplicationAreas**.

> **IMPORTANT**
> The code used in this example is still under active development and might be subject to change in the future.

The following example extends the **Customer List** page. The field **ExampleField** is added and it is followed by a series of properties. The **ApplicationArea** property sets the application areas that apply to the control and in this code, **ExampleAppArea** is assigned to it.

> **IMPORTANT**
> If your extension fails to use **ApplicationArea** in any controls or actions, they will not be visible when you use an experience tier.

The **OnOpenPage** trigger will display the message only if **ApplicationArea** is enabled.

```
pageextension 50100 CustomerListExt extends "Customer List"
{
    layout
    {
        addafter(Name)
        {
            field(ExampleField; "Name 2")
            {
                Caption = 'Example Field';
                ApplicationArea = ExampleAppArea;
                ToolTip = 'This is a field added by an example extension';
                Importance = Promoted;
            }
        }
    }

    trigger OnOpenPage()
    var
        EnableExampleExtension : Codeunit "Enable Example Extension";
    begin
        if EnableExampleExtension.IsExampleApplicationAreaEnabled() then
            Message('App published: Example Extension');
    end;
}
```

Adding an application area

To add an application area, the **Application Area Setup** table must be extended. A new boolean field is added and the name of this field will be used in the attribute that you want to be tagged with this application area. This particular case, in the code below, is an exception, because space is used inside it. Usually, spaces are omitted in the application area attribute. At this point, the extension has an application area but it still needs to be enabled.

```
tableextension 50100 "Application Area Setup" extends "Application Area Setup"
{
    fields
    {
        // Spaces in field name are omitted in the ApplicationArea attribute
        // e.g. ApplicationArea = ExampleAppArea;
        field(50100;"Example App Area";Boolean)
        {
        }
    }
}
```

The codeunit **Install Example Extension** is of the subtype Install and it enables the application area inside the **OnInstallAppPerCompany** trigger.

```
codeunit 50101 "Install Example Extension"
{
    Subtype = Install;

    trigger OnInstallAppPerCompany()
    var
        EnableApplicationArea : Codeunit "Enable Example Extension";
    begin
        if(EnableApplicationArea.IsExampleApplicationAreaEnabled()) then
            exit;

        EnableApplicationArea.EnableExampleExtension();

        // Add your code here
    end;
}
```

The registration of the application area inside an experience tier is made inside the **OnGetEssentialExperienceAppArea**. There are different versions of this event, one for each experience tier and in this case, Essential is chosen. This will make the extension visible inside the Essential experience and the event exposes an **Application Area Setup** temporary record; **TempApplicationAreaSetup**, to the **Application Area Setup** table. At this point, to enable the application area, this must be set to true.

> **NOTE**
>
> This event is important because it is called every single time an experience tier is reset, which can happen because of many reasons.

Another thing that is possible inside these methods is to modify the experience tier. You can also modify other application areas, such as creating an extension that extends the Fixed Assets functionality. By subscribing to **OnValidateApplicationAreas**, the application area inside an experience tier is validated. **OnValidateApplicationAreas** is guaranteed to be executed after the events in the **OnGet*ExperienceAppArea** family. The validation is necessary in the presence of extensions concurrently manipulating the same application areas.

In case a needed application area is not enabled, the suggested action is to show an error and turn off the extension to avoid unintended behavior. However, if the functionality controlled by this application area is of secondary importance and its loss does not affect the rest of the extension, it is also appropriate to keep the extension enabled.

```
codeunit 50100 "Enable Example Extension"
{
    // Extend and modify Essential experience tier with "Example App Area"
    [EventSubscriber(ObjectType::Codeunit, Codeunit::"Application Area Mgmt.",
'OnGetEssentialExperienceAppAreas', '', false, false)]
    local procedure RegisterExampleExtensionOnGetEssentialExperienceAppAreas(var TempApplicationAreaSetup:
Record "Application Area Setup" temporary)
    begin
        TempApplicationAreaSetup."Example App Area" := true;
        // Modify other application areas here
    end;

    // Validate that application areas needed for the extension are enabled
    [EventSubscriber(ObjectType::Codeunit, Codeunit::"Application Area Mgmt.", 'OnValidateApplicationAreas',
'', false, false)]
    local procedure VerifyApplicationAreasOnValidateApplicationAreas(ExperienceTierSetup: Record "Experience
Tier Setup"; TempApplicationAreaSetup: Record "Application Area Setup" temporary)
    begin
        if ExperienceTierSetup.Essential then
            if not TempApplicationAreaSetup."Example App Area" then
                Error('Example App Area should be part of Essential in order for the Example Extension to
work.');
    end;

    // Helpers .....................................................................
    procedure IsExampleApplicationAreaEnabled() : Boolean
    var
        ApplicationAreaSetup: Record "Application Area Setup";
        ApplicationAreaMgmtFacade: Codeunit "Application Area Mgmt. Facade";
    begin
        if ApplicationAreaMgmtFacade.GetApplicationAreaSetupRecFromCompany(ApplicationAreaSetup,
CompanyName()) then
            exit(ApplicationAreaSetup."Example App Area");
    end;

    procedure EnableExampleExtension()
    var
        ApplicationAreaMgmtFacade: Codeunit "Application Area Mgmt. Facade";
    begin
        ApplicationAreaMgmtFacade.RefreshExperienceTierCurrentCompany();
    end;
}
```

Adding Advanced application area to the Essentials and Premium experiences using an extension

If you are familiar with Dynamics NAV you will have noticed that Dynamics 365 Business Central is not exposing all the controls/actions that you find in Dynamics NAV. These controls have been hidden so far by using the application area **Advanced**, which is not assigned to any experiences. For more information, see FAQ.

Most of these fields will become available/visible soon, but until then you will have to create an extension to get (almost) the same experience as you have in Dynamics NAV. See the example below.

> **IMPORTANT**
>
> Adding the application area **Advanced** to the experience will mean that you lose some of the simplification made to pages. For example, you will see more actions duplicated on many pages, compared to Business Central where the experience is intended to be simpler than in Dynamics NAV. You must also consider that we plan to re-tag the **Advanced** actions/controls and add them to the **Essentials** and/or **Premium** experiences in a future release.

To enable Advanced in an extension

Depending on which experience you want to enable **Advanced** for you can subscribe to `OnGetEssentialExperienceAppAreas` or `OnGetPremiumExperienceAppAreas`. If you have defined your own experience you must subscribe to `OnSetExperienceTier`.

The experiences are additive so you only need to subscribe to one of the events. For example, to enable **Essentials** and **Premium** experiences you only need to subscribe to `OnGetEssentialExperienceAppAreas`.

```
codeunit 50102 EnableAdvancedApplicationArea
{
    [EventSubscriber(ObjectType::Codeunit, Codeunit::"Application Area Mgmt. Facade",
'OnGetEssentialExperienceAppAreas','', false, false)]
    local procedure EnableAdvancedApplicationAreaOnGetEssentialExperienceAppAreas(var
TempApplicationAreaSetup : record 9178 temporary)
    begin
        TempApplicationAreaSetup.Advanced := true
    end;

    [EventSubscriber(ObjectType::Codeunit, Codeunit::"Application Area Mgmt. Facade",
'OnGetPremiumExperienceAppAreas','', false, false)]
    local procedure EnableAdvancedApplicationAreaOnGetPremiumExperienceAppAreas(var TempApplicationAreaSetup
: record 9178 temporary)
    begin
        TempApplicationAreaSetup.Advanced := true
    end;

    [EventSubscriber(ObjectType::Codeunit, Codeunit::"Application Area Mgmt. Facade",
'OnSetExperienceTier','', false, false)]
    local procedure EnableAdvancedApplicationAreaOnSetExperienceTier(ExperienceTierSetup : record 9176;var
TempApplicationAreaSetup : record 9178 temporary;var ApplicationAreasSet : boolean)
    begin
        TempApplicationAreaSetup.Advanced := true
    end;
}
```

Application areas advantages and disadvantages

If you decide to code application areas as an extension, there are some aspects that must be considered. Application areas enable hiding entire business scenarios and you can have the same code base, which makes it possible to quickly modify the UI for different business scenarios or audiences. However, tagging errors as missing tags or incorrect tags will occur and every single control will need to be tagged.

Extending Item Charge Distribution Methods

2/17/2021 • 5 minutes to read • Edit Online

To ensure correct valuation, your inventory items must carry any added costs, such as freight, physical handling, insurance, and transportation that you incur when purchasing or selling the items.

Users can add these costs by adding a Charge (Item) line to the involved purchase or sales document. For more information, see Use Item Charges to Account for Additional Trade Costs in application help.

Item charges are distributed over other item lines in the document according to a distribution method. Dynamics 365 Business Central offers four distribution methods out of the box: **Equally**, **By Amount**, **By Weight**, and **By Volume**. This article explains how to remove or add item charge distribution methods. The article describes the method for purchases. The steps are similar for sales, except the events are located in codeunit 5807, **Item Charge Assgnt. (Sales)**.

To enable extension of item charges distribution methods, two events can be found in codeunit 5805, **Item Charge Assgnt. (Purch.)**. The work consists of the following two tasks:

1. In the **OnBeforeShowSuggestItemChargeAssignStrMenu** event, you manipulate the options that are presented to users. You can remove, add, and change the order of the options.
    - Keep in mind that other extensions may also manipulate the options.
    - You should not assume that an option will exist, nor should you write code that may remove an option added by another extension.
2. In the **OnAssignItemCharges** event, you distribute the item charge amount over the item lines according to your new distribution method.
    - You must verify that the option selected by the user is your new option. If it is not, then exit without taking action.
    - When you have distributed the amount over the lines, you must set the ItemChargesAssigned boolean to true. If you do not set this boolean to true, an error will occur.

The following procedures show how to extend the item charges distribution methods:

1. Add a new option to the item charges distribution methods in the **OnBeforeShowSuggestItemChargeAssignStrMenu** event.
2. Add a new distribution method for item charges.
3. Call the new distribution method in the **OnAssignItemCharges** event.

The procedures are based on an example where the **By Fairy Dust** option is added to the string menu (STRMENU) and added to the CASE statement.

> **NOTE**
> To complete this example you will have to add a new field **Fairy Dust** to the **Purchase Line** table and other relevant tables and pages.

To add a new option to the item charges distribution methods

Create a new codeunit and add an event subscriber to the **OnBeforeShowSuggestItemChargeAssignStrMenu** event.

```
codeunit 50100 "Item Ch. Assign by Fairy Dust"
{
    var
        ByFairyDustTok: Label 'By Fairy Dust';

    local procedure AssignByFairyDustMenuText(): Text
    begin
        exit(ByFairyDustTok)
    end;

    [EventSubscriber(ObjectType::Codeunit, Codeunit::"Item Charge Assgnt. (Purch.)",
'OnBeforeShowSuggestItemChargeAssignStrMenu', '', false, false)]
    local procedure AddByFairyDustOnBeforeShowSuggestItemChargeAssignStrMenu(PurchLine: Record "Purchase
Line"; var SuggestItemChargeMenuTxt: Text; var SuggestItemChargeMessageTxt: Text; var Selection: Integer)
    begin
        // if 'By Fairy Dust' is not in the menu options, add it at the end
        if StrPos(SuggestItemChargeMenuTxt, AssignByFairyDustMenuText) = 0 then begin
            SuggestItemChargeMenuTxt += ',' + AssignByFairyDustMenuText;
            // make the last option ('By Fairy Dust') the default selection
            Selection := StrLen(DelChr(SuggestItemChargeMenuTxt, '=', DelChr(SuggestItemChargeMenuTxt, '=',
',','))) + 1;
        end;
    end;
}
```

To add a new distribution method for item charges

In the new codeunit, add functions to distribute the charges over the item lines.

```
    local procedure AssignByFairyDust(var ItemChargeAssignmentPurch: Record "Item Charge Assignment
(Purch)"; Currency: Record Currency; TotalQtyToAssign: Decimal; TotalAmtToAssign: Decimal);
    var
        TempItemChargeAssgntPurch: Record "Item Charge Assignment (Purch)" temporary;
        LineArray: array[2] OF Decimal;
        TotalFairyDust: Decimal;
        QtyRemaining: Decimal;
        AmountRemaining: Decimal;
    begin
        // copy lines to temp variable and calculate total Fairy Dust
        repeat
            if not ItemChargeAssignmentPurch.PurchLineInvoiced then begin
                TempItemChargeAssgntPurch.Init();
                TempItemChargeAssgntPurch := ItemChargeAssignmentPurch;
                TempItemChargeAssgntPurch.Insert(false);
                GetItemValues(TempItemChargeAssgntPurch, LineArray);
                TotalFairyDust := TotalFairyDust + (LineArray[2] * LineArray[1]);
            end;
        until ItemChargeAssignmentPurch.Next = 0;

        if TempItemChargeAssgntPurch.Findset(true) then
            repeat
                // Calculate Fairy Dust to assign to the line
                GetItemValues(TempItemChargeAssgntPurch, LineArray);
                if TotalFairyDust <> 0 then
                    TempItemChargeAssgntPurch."Qty. to Assign" :=
                      (TotalQtyToAssign * LineArray[2] * LineArray[1]) / TotalFairyDust + QtyRemaining
                else
                    TempItemChargeAssgntPurch."Qty. to Assign" := 0;

                // Assign Fairy Dust to the line and calculate the remaining Fairy Dust to assign
                ItemChargeAssignmentPurch.Get(
                  TempItemChargeAssgntPurch."Document Type",
                  TempItemChargeAssgntPurch."Document No.",
                  TempItemChargeAssgntPurch."Document Line No.",
                  TempItemChargeAssgntPurch."Line No.");
```

```
                ItemChargeAssignmentPurch."Qty. to Assign" := Round(TempItemChargeAssgntPurch."Qty. to
Assign", 0.00001);
                ItemChargeAssignmentPurch."Amount to Assign" :=
                  ItemChargeAssignmentPurch."Qty. to Assign" * ItemChargeAssignmentPurch."Unit Cost" +
AmountRemaining;
                AmountRemaining := ItemChargeAssignmentPurch."Amount to Assign" -
                  Round(ItemChargeAssignmentPurch."Amount to Assign", Currency."Amount Rounding Precision");
                QtyRemaining := TempItemChargeAssgntPurch."Qty. to Assign" - ItemChargeAssignmentPurch."Qty.
to Assign";
                ItemChargeAssignmentPurch."Amount to Assign" :=
                  Round(ItemChargeAssignmentPurch."Amount to Assign", Currency."Amount Rounding Precision");
                ItemChargeAssignmentPurch.Modify(false);

            until TempItemChargeAssgntPurch.Next = 0;
        TempItemChargeAssgntPurch.DeleteAll(false);
    end;

    procedure GetItemValues(TempItemChargeAssgntPurch: Record "Item Charge Assignment (Purch)" temporary;
var DecimalArray: Array[2] OF Decimal);
    var
        PurchaseLine: Record "Purchase Line";
        PurchRcptLine: Record "Purch. Rcpt. Line";
        ReturnShptLine: Record "Return Shipment Line";
        TransferRcptLine: Record "Transfer Receipt Line";
        SalesShptLine: Record "Sales Shipment Line";
        ReturnRcptLine: Record "Return Receipt Line";
    begin
        // Get the Fairy Dust for the line
        Clear(DecimalArray);
        with TempItemChargeAssgntPurch do
            case "Applies-to Doc. Type" of
                "Applies-to Doc. Type"::Order,

                        DecimalArray[2] := PurchaseLine."Fairy Dust";
                    end;
                "Applies-to Doc. Type"::Receipt:
                    begin
                        PurchRcptLine.Get("Applies-to Doc. No.", "Applies-to Doc. Line No.");
                        DecimalArray[1] := PurchRcptLine.Quantity;
                        DecimalArray[2] := PurchRcptLine."Fairy Dust";
                    end;

                "Applies-to Doc. Type"::"Return Receipt":
                    begin
                        ReturnRcptLine.Get("Applies-to Doc. No.", "Applies-to Doc. Line No.");
                        DecimalArray[1] := ReturnRcptLine.Quantity;
                        DecimalArray[2] := ReturnRcptLine."Fairy Dust";
                    end;
                "Applies-to Doc. Type"::"Return Shipment":
                    begin
                        ReturnShptLine.Get("Applies-to Doc. No.", "Applies-to Doc. Line No.");
                        DecimalArray[1] := ReturnShptLine.Quantity;
                        DecimalArray[2] := ReturnShptLine."Fairy Dust";
                    end;
                "Applies-to Doc. Type"::"Transfer Receipt":
                    begin
                        TransferRcptLine.Get("Applies-to Doc. No.", "Applies-to Doc. Line No.");
                        DecimalArray[1] := TransferRcptLine.Quantity;
                        DecimalArray[2] := TransferRcptLine."Fairy Dust";
                    end;
                "Applies-to Doc. Type"::"Sales Shipment":
                    begin
                        SalesShptLine.Get("Applies-to Doc. No.", "Applies-to Doc. Line No.");
```

```
                    DecimalArray[1] := SalesShptLine.Quantity;
                    DecimalArray[2] := SalesShptLine."Fairy Dust";
                end;
            end;
    end;
```

To call the new distribution method

In the new codeunit, add a subscriber to the **OnAssignItemCharges** event.

```
    [EventSubscriber(ObjectType::Codeunit, Codeunit::"Item Charge Assgnt. (Purch.)", 'OnAssignItemCharges',
'', false, false)]
    local procedure AssignByFairyDustOnAssignItemCharges(SelectionTxt: Text; var ItemChargeAssignmentPurch:
Record "Item Charge Assignment (Purch)"; Currency: Record Currency; PurchaseHeader: Record "Purchase
Header"; TotalQtyToAssign: Decimal; TotalAmtToAssign: Decimal; VAR ItemChargesAssigned: Boolean);
    begin
        // if item charges are already assigned, exit
        if ItemChargesAssigned then
            exit;
        // if the user did not choose 'By Fairy Dust', exit
        if not (SelectionTxt = AssignByFairyDustMenuText) then
            exit;
        // assign item charges by fairy dust
        AssignByFairyDust(ItemChargeAssignmentPurch, Currency, TotalQtyToAssign, TotalAmtToAssign);
        // charges have been assigned
        ItemChargesAssigned := true;
    end;
```

Extending Price Calculations

2/17/2021 • 15 minutes to read • Edit Online

If you record special prices and line discounts for sales and purchases, Dynamics 365 Business Central can automatically calculate prices on sales and purchase documents, and on job and item journal lines. The price is the lowest permissible price with the highest permissible line discount on a given date. Dynamics 365 Business Central automatically calculates the price when it inserts the unit price and the line discount percentage for items on new document and journal lines. For more information, see Price Calculation.

2020 release wave 1 introduces a second implementation of price calculations that will be available as an alternative to the calculations that were available in 2019 release wave 2 and earlier versions. This new implementation has the advantage that it is much easier to extend, for example, with new calculations.

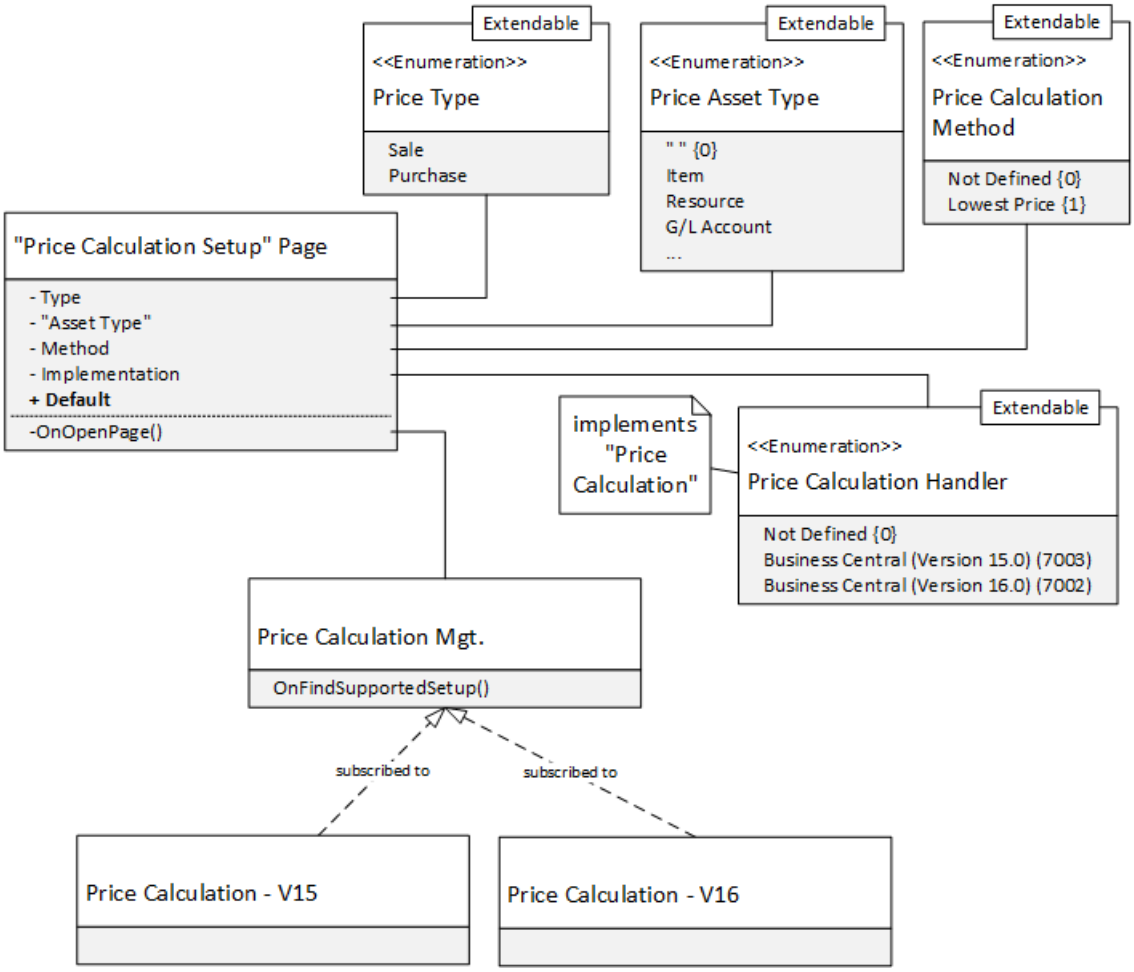
Price calculations that were available in 2019 release wave 2 are unchanged. The new calculations in 2020 release wave 1 are an alternative implementation that you can extend.

> **NOTE**
> The new price calculation capabilities in 2020 release wave 1 exist in code only, and do not include any user experience. We will provide that in an upcoming release. For now, to use the new capability you must create your own page.

This topic describes how price calculations are implemented in 2020 release wave 1 (referred to as "Business Central Version 16" in the illustrations), and provides comparisons with 2019 release wave 2 (referred to as "Business Central Version 15" in the illustrations) to show what we have changed. It also provides some examples of how you can extend price calculations in 2020 release wave 1.

Price Calculation Setup

Price calculation are based on the **Price Calculation Setup** table, where you can choose an existing implementation, as shown in the following image.



The Price Calculation Setup table has the Code field as its primary key. The value of the field is calculated by combining the values in the Method, Type, Asset Type, and Implementation fields. For example, it is '[1-1-0]-7003' for the setup line when the following fields contain the following values:

- Method contains Lowest Price
- Type contains Sale
- Asset Type contains All
- Implementation is Business Central (Version 15.0)"

You can have multiple setups with the same combination of method, type, and asset type. The implementation value should always be different though, because each implementation provides different calculations. The default implementation is defined by the Default field. For example, in 2020 release wave 1 the following setups are available:

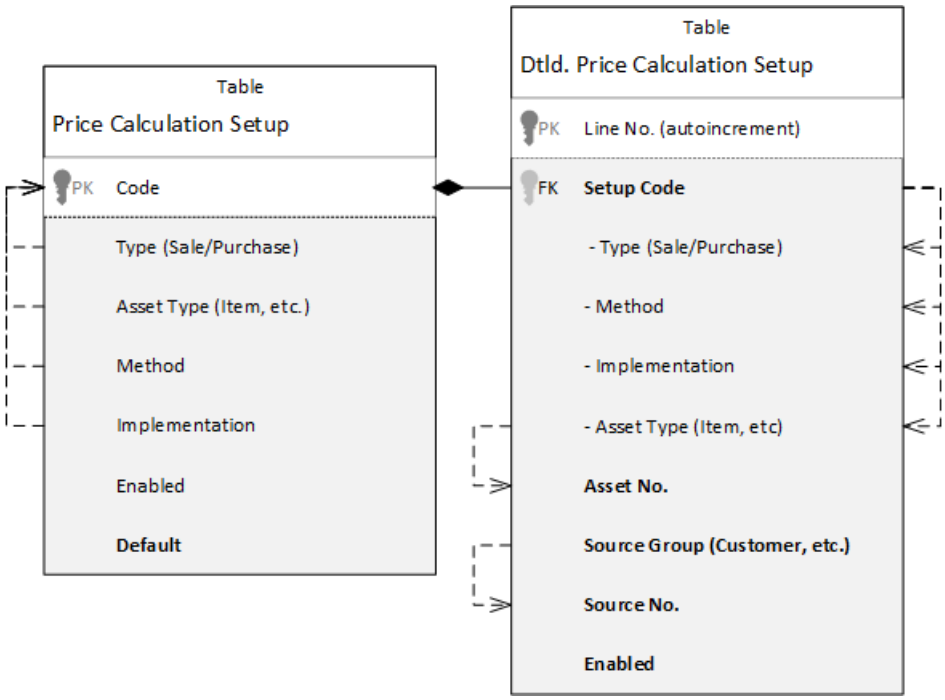
METHOD	TYPE	ASSET TYPE	IMPLEMENTATION	DEFAULT
Lowest Price	Sale	All	Business Central (Version 15.0)	X
Lowest Price	Sale	All	Business Central (Version 16.0)	

By default, all sales lines use the "Business Central (Version 15.0)" implementation to calculate prices, unless the second line has detailed setup lines that define exceptions.

The Price Calculation method on the document line searches for a setup that that has a matching combination of the method, the price type, and asset type on the document line. The method then searches for detailed lines that contain exceptions for the combination of a source group (Customer, Vendor, and Job) and an asset (Item, Resource, and so on) on the document line. If we find a matching setup we use its implementation for price

calculation. If there is no matching setup exception, we use the default implementation.

For example, let's say we have a line on a sales order for Customer 20000 contains item 1000. The default implementation for the sale of any asset is "Business Central (Version 15.0)," but "Business Central (Version 16.0)" implementation contains a detailed setup line for Item 1000. That means that the "Business Central (Version 16.0)" implementation will calculate the price. Detailed setup records are to be entered by users and only make sense for the non-default setup records. The following image shows the relation between the setup line and the detailed setup.



For the Business Central (Version 15.0) implementation, you can only edit the Default field. The records are inserted by the codeunits that subscribe to the OnFindSupportedSetup() event in the Price Calculation Mgt. codeunit. The two price calculation implementation codeunits add pairs of such records, one for the sale of assets and another for purchases. Because the Price Calculation Setup table is extensible, you can add new fields to the key by subscribing to the OnAfterDefineCode() event.

Price Type

The Type field is an extensible Price Type enum that contains the following values:

- Any (0)
- Sale (1)
- Purchase (2)

The values are part of the composite key in the Price Calculation Setup table. Sales and service lines use the Sale type, purchase lines use the Purchase type, and job or item journal lines use both for calculating price and cost. The Any value is the default value, and is used when a line contains both a price and a cost.

Asset Type

The "Asset Type" field is an extensible "Price Asset Type" enum that contains the following values:

- All (0)
- Item (10)
- Item Discount Group (20)
- Resource (30)
- Resource Group (40)
- Service Cost (50)

- G/L Account (60)

The Asset Type is part of the composite key in the Price Calculation Setup table. If the only setup record contains "Asset Type" - All it means that there is no need in special price calculation implementations per asset type. The default implementation will be used regardless of an asset type in the document line. If you need different implementations you must add a setup lines with another asset type. For example, the following table shows a Resource Pricing implementation with a Resource asset type.

METHOD	TYPE	ASSET TYPE	IMPLEMENTATION	DEFAULT
Lowest Price	Sale	All	Business Central (Version 15.0)	X
Lowest Price	Sale	Resource	Resource Pricing	X

Because only one record has the combination of Lowest Price, Sale, and Resource it will be the default. If a sales line sells a resource, its price will be calculated by Resource Pricing implementation. All other assets will use the "Business Central (Version 15.0)" implementation.

Price Calculation Method

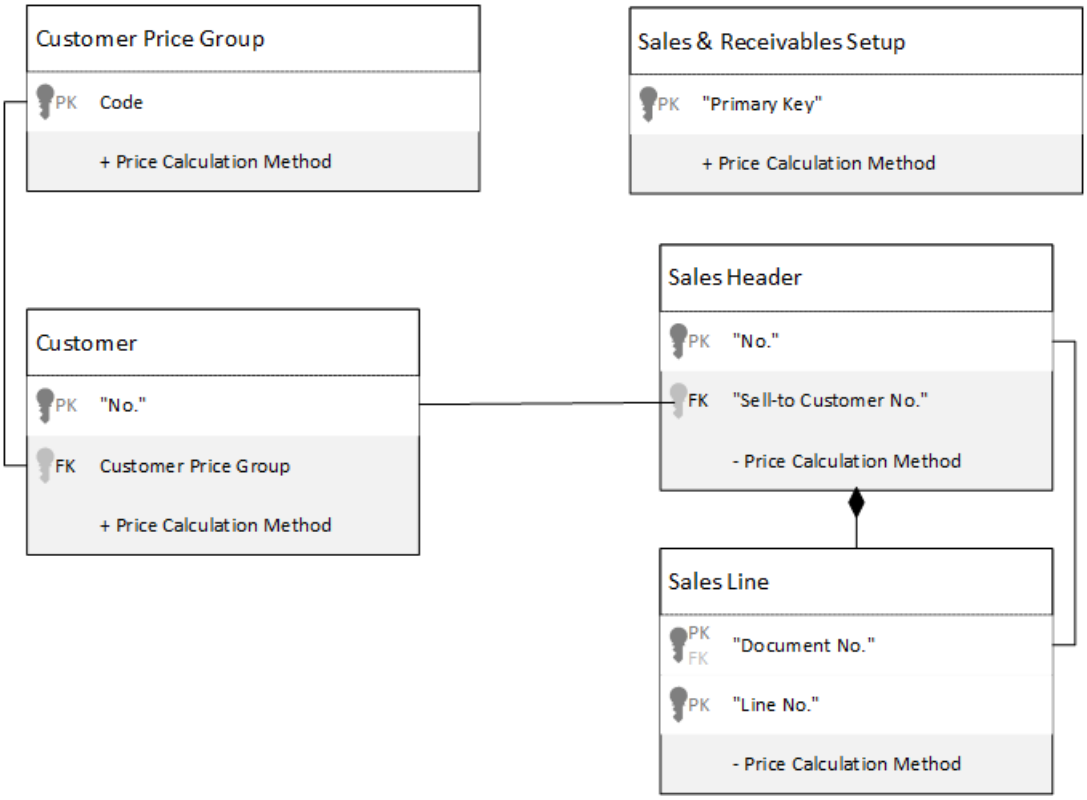
The Method field is an extensible Price Calculation Method enum that contains the following values:

- Not defined (0)
- Lowest Price (1)

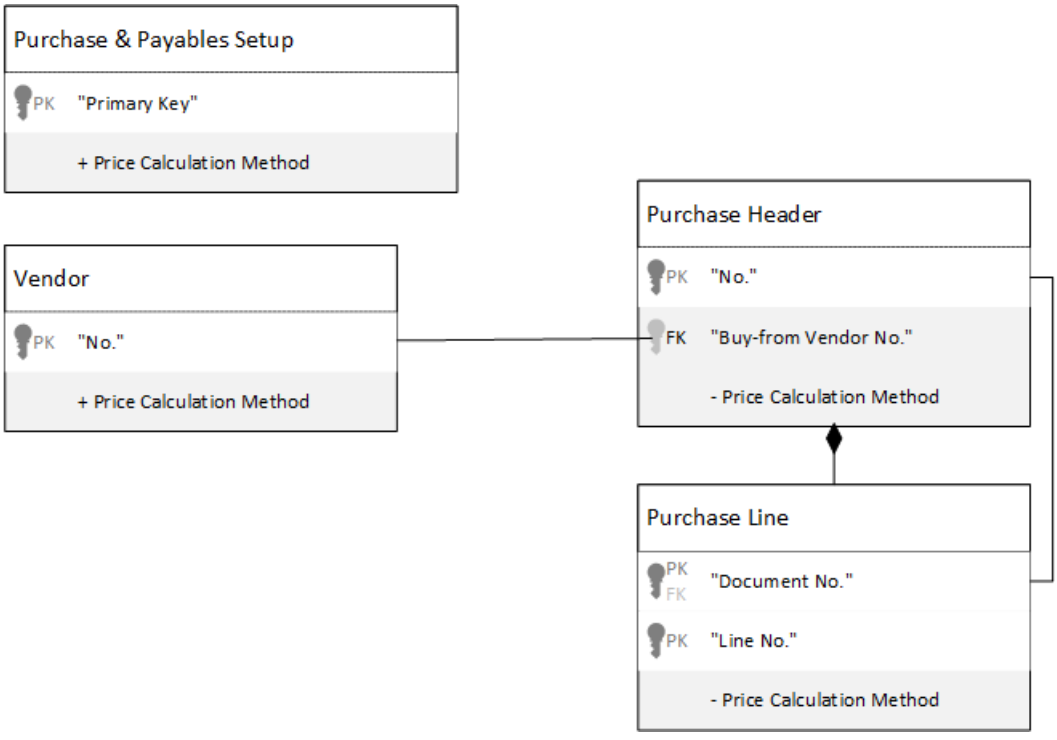
The method value is part of the composite key in the Price Calculation Setup table. A sales document line inherits the method value from the sales header, which in turn inherits it from one of the following, depending on where it's defined:

- Customer
- Customer price group
- Sales & Receivable Setup table

The Sales & Receivable Setup table defines the default method, Lowest Price, for all sales prices. If you want to use a different method, you can specify it on a customer price group or a customer. You cannot edit the method on sales document headers or lines.



The Purchase & Payables Setup table also defines the default method for all purchase prices. You can redefine it for a certain vendor. You cannot edit the method on purchase document headers or lines.



Data Structure Comparison

The Business Central (Version 15.0) calculation uses the following tables that store information about prices, costs, and discounts:

- table7002"SalesPrice"
- table7004"SalesLineDiscount"
- table7012"PurchasePrice"
- table7014"PurchaseLineDiscount"
- table201"ResourcePrice"

- table1014"JobG/LAccountPrice"
- table1013"JobItemPrice"
- table1012"JobResourcePrice"

The Business Central (Version 16.0) calculation uses the following table:

- table7001"PriceListLine"

Table7001"PriceListLine" is compatible with all tables used by the Business Central (Version 15.0) calculation. It contains the set of CopyFrom() methods that convert the data from the tables to the Price List Line table.

If you extended the Business Central (Version 15.0) tables you must also extend the Price List Line table and the CopyFrom() methods by subscribing to special events. Here's are examples that extend the Sales Price table with a Document No. field.

```
tableextension 50010 "Document No in Sales Price" extends "Sales Price"
{
    fields
    {
        field(50000; "Document No."; Code[20])
        { }
    }
}
```

Now we'll extend the Price List Line table with the same field.

```
tableextension 50011 "Doc. No in Price List Line" extends "Price List Line"
{
    fields
    {
        field(50000; "Document No."; Code[20])
        { }
    }
}
```

Now we'll subscribe to the 'OnCopyFromSalesPrice' event to copy data from "Sales Price" to "Price List Line" table.

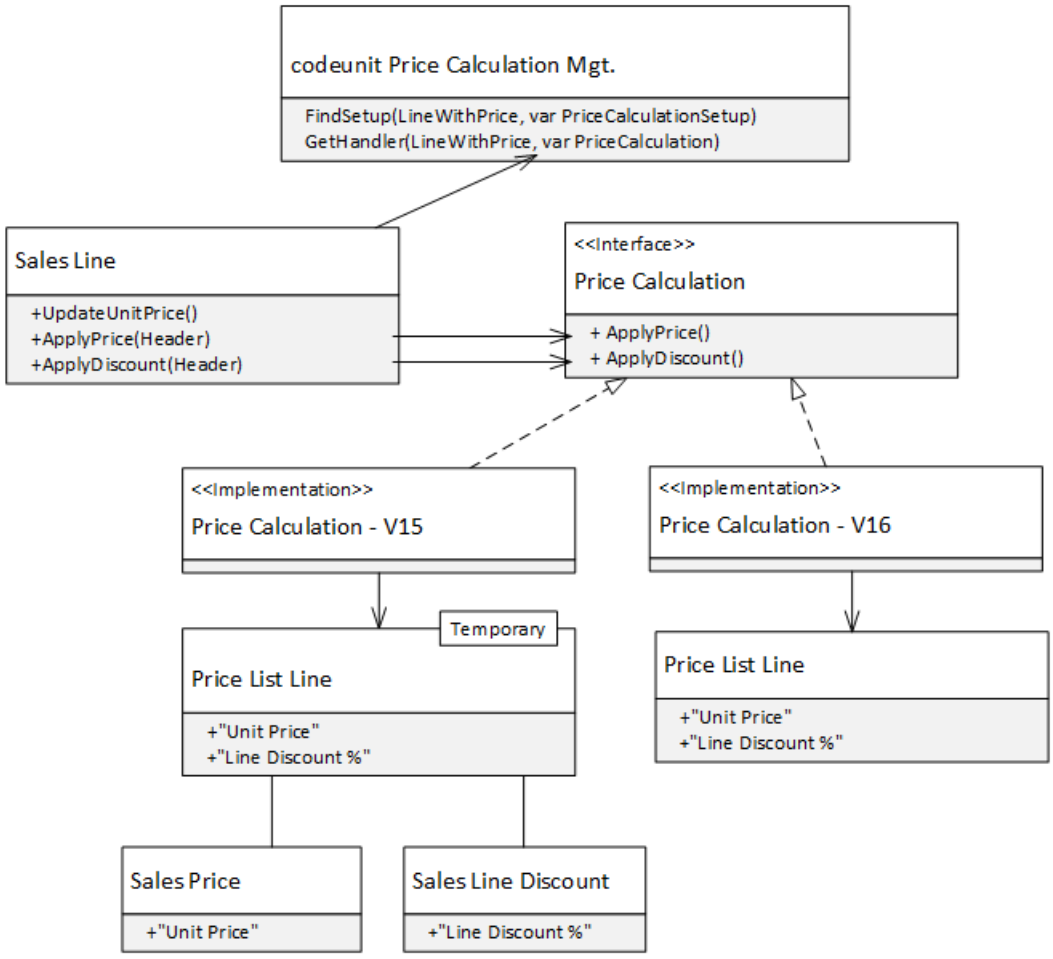
```
codeunit 50012 "Copy DocumentNo to Price List"
{
    [EventSubscriber(ObjectType::Codeunit, Codeunit::CopyFromToPriceListLine, 'OnCopyFromSalesPrice', '',
false, false)]
    procedure CopyFromSalesPriceHandler(var SalesPrice: Record "Sales Price"; var PriceListLine: Record
"Price List Line");
    begin
        PriceListLine."Document No." := SalesPrice."Document No.";
    end;
}
```

The Price Calculation Method field is added to all tables that need calculated prices and discounts:

- table 37 "Sales Line"
- table 5902 "Service Line"
- table 39 "Purchase Line"
- table 246 "Requisition Line"
- table 83 "Item Journal Line"
- table 753 "Standard Item Journal Line"

- table 210 "Job Journal Line"
- table 1003 "Job Planning Line"

The following image shows the schema of how the methods called in the Sales Line table get the price and discount amounts from either the Sales Price or Price List Line tables.



Interface Objects

AL interface objects are important for extensibility. They define the capabilities that are available to an object, and allow implementations to differ as long as they comply with the interface requirements. For more information, see Interfaces in AL.

Price calculation uses the following AL interface objects:

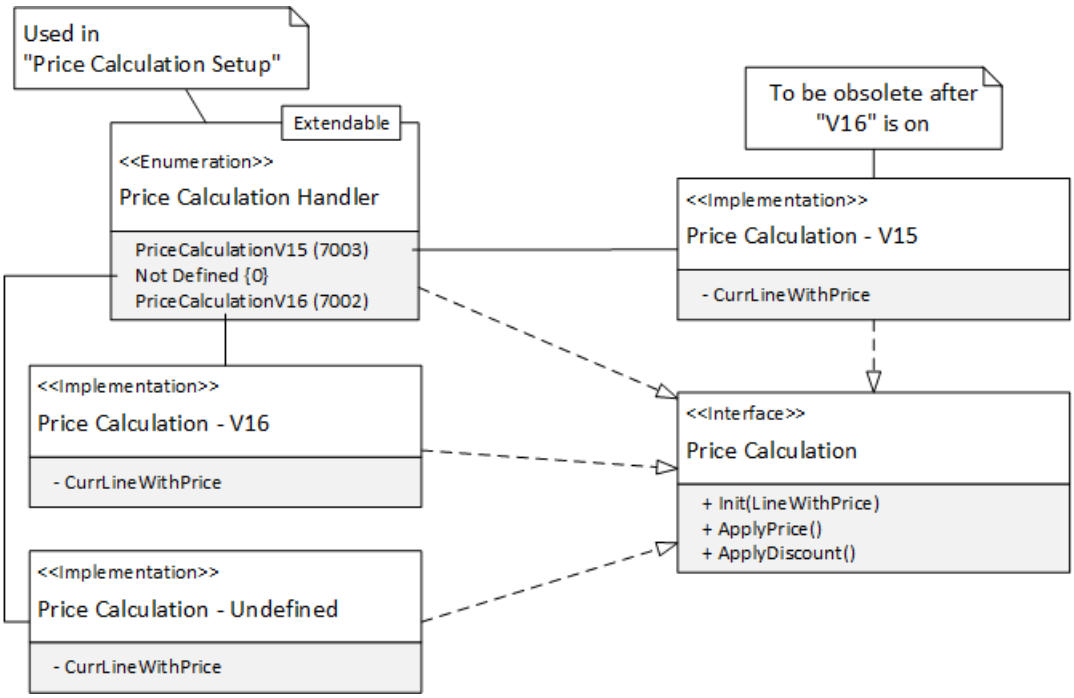
- Price Calculation
- Line With Price
- Price Source Group
- Price Source

Price Calculation

The Price Calculation interface defines methods that calculate amounts and discount percentages on journal and document lines.

In Business Central (Version 15.0) and earlier, the Price Calculation – V15 interface implementation calls the Sales Price Calc. Mgt. and Purch. Price Calc. Mgt. codeunits to calculate prices. In Business Central (Version 15.0), the implementation codeunit is Price Calculation – V16. This codeunit works the same as "Price Calculation – V15" but is based on a different price line table and makes it easier to extend price calculations.

The Price Calculation - Undefined implementation is used when the setup line does not contain a match for the document line. This implementation will display a message that states the combination that is missing.



You can add a new implementation codeunit or reuse one as a starting point and rewrite it as needed. For the new codeunit, you must extend the Price Calculation Handler enum that implements Price Calculation interface and is used in the Price Calculation Setup table.

```
enumextension 50000 "SpecialPriceHandler" extends "Price Calculation Handler"
{
    value(50000; "Special Price")
    {
        Implementation = "Price Calculation" = "Price Calc. - Special Price";
    }
}
```

Afterwards you can insert a record in the Price Calculation Setup table and set the new implementation as the default.

The following code in codeunit 7001 "Price Calculation Mgt." returns a Price Calculation interface that initialized with the instance of the Line With Price interface that depends on the setup record:

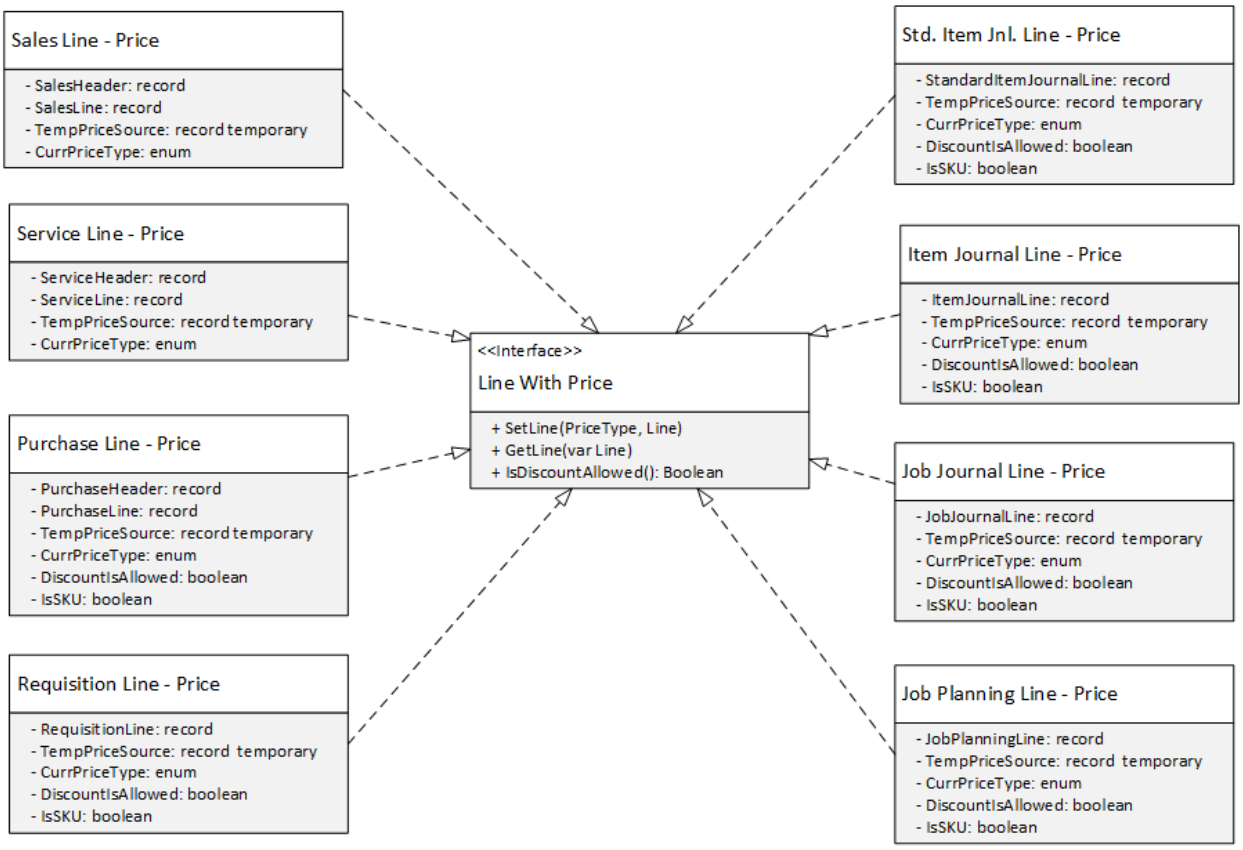
```
procedure GetHandler(
    LineWithPrice: Interface "Line With Price";
    var PriceCalculation: Interface "Price Calculation") Result: Boolean;
    var
        PriceCalculationSetup: Record "Price Calculation Setup";
    begin
        Result := FindSetup(LineWithPrice, PriceCalculationSetup);
        PriceCalculation := PriceCalculationSetup.Implementation;
        PriceCalculation.Init(LineWithPrice, PriceCalculationSetup);
    end;
```

After the price calculation implementation is defined the document line typically calls the methods in the interfrace that calculate the price and discount. The following code is used in the Sales Line table:

```
var
    Line: Variant;
begin
    PriceCalculation.ApplyDiscount();
    PriceCalculation.ApplyPrice(CalledByFieldNo);
    PriceCalculation.GetLine(Line);
    Rec := Line;
end;
```

Line With Price

The Line With Price interface defines methods for lines that require the calculation of a price, cost, and line discount. The following image shows the codeunits that implement this interface.



The following example shows a typical use of the codeunits in the Sales Line table.

```
 var
    PriceCalculationMgt: codeunit "Price Calculation Mgt.";
    PriceCalculation: Interface "Price Calculation";
    SalesLinePrice: Codeunit "Sales Line - Price";
    PriceType: Enum "Price Type";
begin
    SalesLinePrice.SetLine(PriceType::Sale, SalesHeader, Rec);
    PriceCalculationMgt.GetHandler(SalesLinePrice, PriceCalculation);
end;
```

The SalesLinePrice codeunit is declared directly because this is the sales line context. The instance is initialized by the interface's SetLine() method, and then passed to the GetHandler() method for PriceCalculation initialization because all Price Calculation implementation codeunits include an instance of the Line With Price interface, which stores data about document and journal lines. The following example shows how to declare the interface variable.

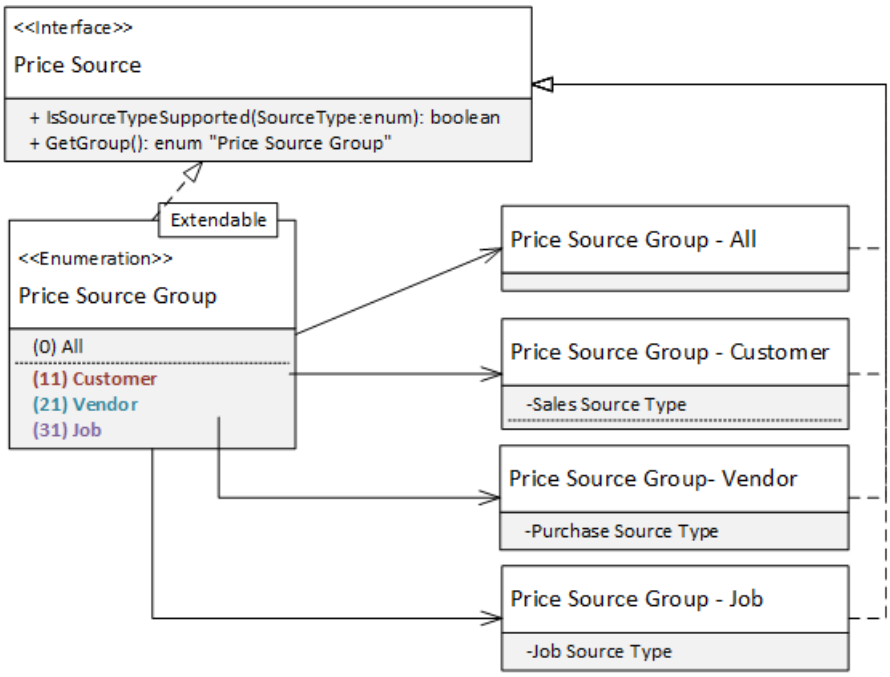
```
    var
        CurrLineWithPrice: Interface "Line With Price";
```

Price Source Group

The Price Source Group interface defines methods for a generic price source group. The Price Source Group enum defines the list of supported source groups, as follows:

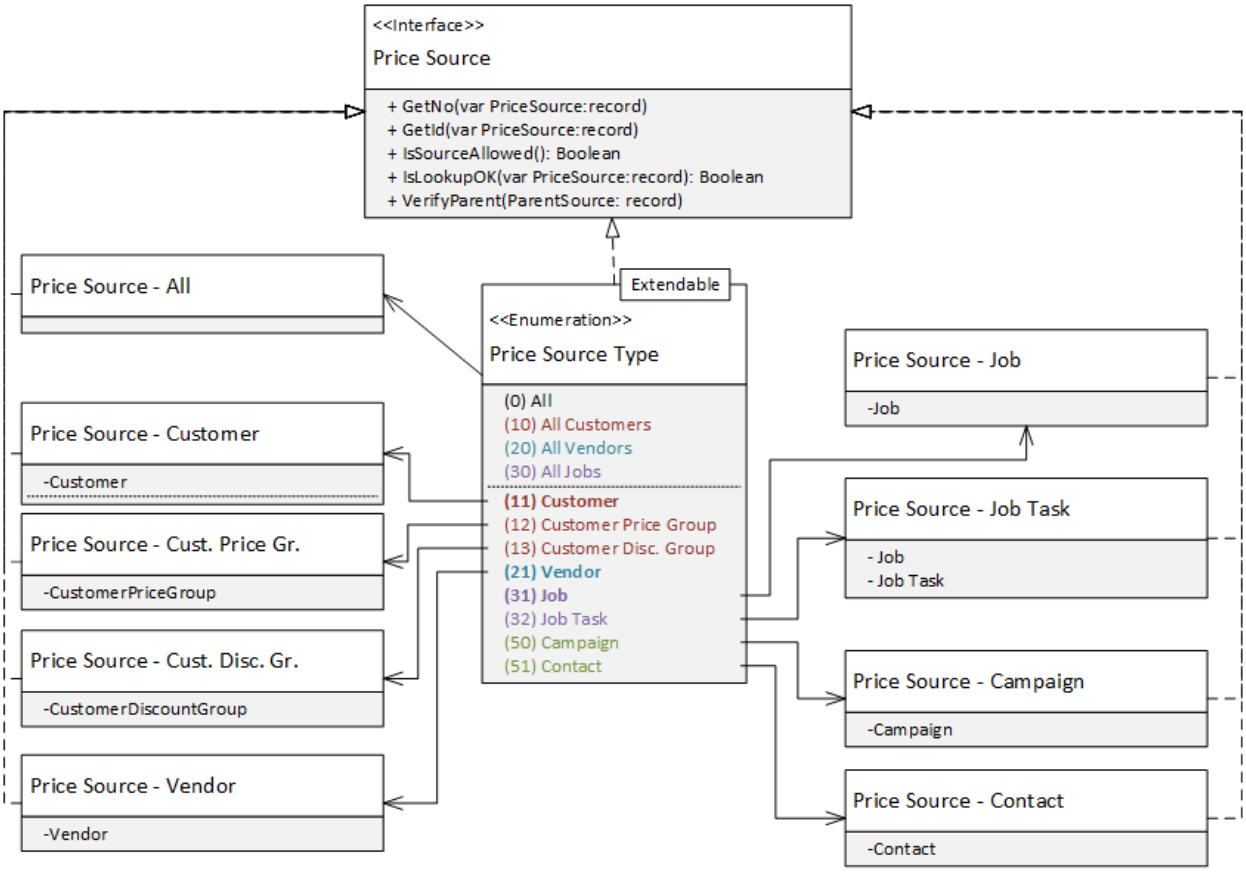
- All (0)
- Customer (11)
- Vendor (21)
- Job (31)

This enum is the subset of the Price Source Type enum. Both enums implement the Price Source Group interface. The interface helps to link the Price Source Type enum with the Sale Price Source Type, Purchase Price Source Type, and Job Price Source Type enums.



Price Source

The Price Source interface defines methods for price sources, such as vendors or customers. The list of supported sources is defined by the Price Source Type enum. The interface is used in the Price Source table to validate the primary key fields and look up respective tables, as shown in the following table.



Example

The Price Source enum implements the Price Source interface and defines Price Source - Customer as the implementation for the value Customer.

```
enum 7003 "Price Source Type" implements "Price Source", "Price Source Group"
    value(11; Customer)
    {
        Implementation = "Price Source" = "Price Source - Customer",
                   "Price Source Group" = "Price Source Group - Customer";
    }
```

The Price Source table has a public method LookupNo() that opens a different page depending on the Source Type value. The PriceSourceInterface variable gets the implementation value from the Source Type enum value and then calls the interface's IsLookupOK(Rec) method.

```
table 7005 "Price Source"
    var
        PriceSourceInterface: Interface "Price Source";

    procedure LookupNo() Result: Boolean;
    begin
        PriceSourceInterface := "Source Type";
        Result := PriceSourceInterface.IsLookupOK(Rec);
    end;
```

Because the source type Customer implementation is the "Price Source - Customer" codeunit, the interface calls its IsLookupOK() method and then opens the Customer List page.

```
codeunit 7032 "Price Source - Customer" implements "Price Source"

    procedure IsLookupOK(var PriceSource: Record "Price Source"): Boolean
    begin
        if Customer.Get(PriceSource."Source No.") then;
        if Page.RunModal(Page::"Customer List", Customer) = ACTION::LookupOK then begin
            PriceSource.Validate("Source No.", Customer."No.");
            exit(true);
        end;
    end;
```

Example of Extended Price Calculations

You can extend price calculations, for example, to include other sources or use calculations that allow for combinations and dependencies. The following sections provide an example.

Example: Change an Item Price When Combined with Another Item

Let's say we want to make the price of one item depend on whether it's sold individually or bundled with one or more other items. We'll use software licenses in this example, but the same principles apply in other scenarios.

> **NOTE**
> The prices, names, and combinations in this example are completely fictional and intended only to support the scenario described here. They do not reflect anything in the real-world.

We have the following licenses in our price list. If you buy 70061 or 70062 alone their prices do not change. However, let's say that we want to offer discounts when one license is purchased along with another. For example, we want to sell 70064 at a reduced monthly rate when it's purchased in combination with 70061 or 70062. Our list would then look like this.

ASSET NUMBER	NAME	MONTHLY BASE PRICE PER USER	BUNDLE PRICE
70061	BC Premium	$100	N/A
70062	BC Essentials	$75	N/A
70063	BC Team Member	$8	N/A
70064	Sales Professional	$65	$15 and $16 when bundled with 70061 or 70062.
70065	Customer Service Pro	$50	$20 and $21 when bundled with 70061 or 70062.

The following image shows an example of a Sales Line page that is extended with the Attached to Line No. field. Notice that the prices are changed based on the combinations of licenses.

Type	No.	Description	Location Code	Quantity	Attach To Line No.	Qty. to Assemble to Order	Reserved Quantity	Unit of Measure Code	Unit Price Excl. VAT
Item	70061	BC Premium	BLUE	2	0		_	PCS	100.00
Item	70062	BC Essential	BLUE	4	0		_	PCS	75.00
Item	70063	BC Team member	BLUE	10	0		_	PCS	8.00
Item	70064	Sales professional	BLUE	9	0		_	PCS	65.00
Item	70065	Customer Service Pro	BLUE	4	0		_	PCS	50.00
→ Item	70064	Sales professional	BLUE	2	10000		_	PCS	20.00
Item	70065	Customer Service Pro	BLUE	1	20000		_	PCS	16.00
Item	70064	Sales professional	BLUE	2	20000		_	PCS	21.00
Item	70065	Customer Service Pro	BLUE	4	10000		_	PCS	15.00

Let's look at some sample extensions that will implement this for us.

The first table extension adds a new field named Attach to Line No. to the Sales Line table and recalculates pricing when we make a change. This field will let us create the combinations that determine our discounts. It also copies the GetPriceCalculationHandler() function from the Sales Line table.

```
tableextension 50001 "Attach Price" extends "Sales Line"
{
    fields
    {
        field(50001; "Attach To Line No."; Integer)
        {
            trigger OnValidate()
            var
                PriceCalculation: Interface "Price Calculation";
            begin
                GetPriceCalculationHandler(PriceCalculation);
                ApplyPrice(FieldNo("Attach To Line No."), PriceCalculation);
            end;
        }
    }

    local procedure GetPriceCalculationHandler(var PriceCalculation: Interface "Price Calculation")
    var
        SalesHeader: Record "Sales Header";
        PriceCalculationMgt: codeunit "Price Calculation Mgt.";
        SalesLinePrice: Codeunit "Sales Line - Price";
        PriceType: Enum "Price Type";
    begin
        SalesHeader.Get("Document Type", "Document No.");
        SalesLinePrice.SetLine(PriceType::Sale, SalesHeader, Rec);
        PriceCalculationMgt.GetHandler(SalesLinePrice, PriceCalculation);
    end;
}
```

The following page extension adds the Attach Line No. field to the Sales order page (subform).

```
pageextension 50001 "Attach Price" extends "Sales Order Subform"
{
    layout
    {
        addAfter(Quantity)
        {
            field("Attach To Line No."; "Attach To Line No.")
            {
                ApplicationArea = Basic, Suite;
            }
        }
    }
}
```

The following table extension adds the Attach to Item No. field to the "Price List line" table.

```
tableextension 50002 "Attach To Price - Line" extends "Price List Line"
{
    fields
    {
        field(50001; "Attach To Item No."; Code[20])
        {
        }
    }
}
```

The following table extension adds the Attach to Item No. field to the "Price Calculation Buffer" table.

```
tableextension 50003 "Attach To Price - Buffer" extends "Price Calculation Buffer"
{
    fields
    {
        field(50001; "Attach To Item No."; Code[20])
        {
        }
    }
}
```

The calculation that links these three new fields is based on the following events:

- OnAfterSetFilters() – Sets the filter on the price list line when searching for the price.
- OnAfterFillBuffer() – Copies the value from the sales line to the buffer.
- FindItemToAttachToInLine() - Defines the value of the item number stored in the sales line that we attach to.

```
codeunit 50004 "Attached Price Mgt."
{
    [EventSubscriber(ObjectType::Codeunit, Codeunit::"Price Calculation Buffer Mgt.", 'OnAfterSetFilters',
'', false, false)]
    procedure OnAfterSetFilters(var PriceListLine: Record "Price List Line"; AmountType: Enum "Price Amount
Type"; var PriceCalculationBuffer: Record "Price Calculation Buffer"; ShowAll: Boolean);
    begin
        PriceListLine.SetRange("Attach To Item No.", PriceCalculationBuffer."Attach To Item No.");
    end;

    [EventSubscriber(ObjectType::Codeunit, Codeunit::"Sales Line - Price", 'OnAfterFillBuffer', '', false,
false)]
    procedure OnAfterFillBuffer(var PriceCalculationBuffer: Record "Price Calculation Buffer"; SalesHeader:
Record "Sales Header"; SalesLine: Record "Sales Line");
    begin
        PriceCalculationBuffer."Attach To Item No." := FindItemToAttachToInLine(SalesLine);
    end;

    local procedure FindItemToAttachToInLine(CurrSalesLine: Record "Sales Line"): Code[20]
    var
        SalesLine: Record "Sales Line";
    begin
        if SalesLine.Get(CurrSalesLine."Document Type", CurrSalesLine."Document No.", CurrSalesLine."Attach
To Line No.") then
            exit(SalesLine."No.");
    end;
}
```

The new price calculation capabilities are not available in the user interface. When a page does become available, either, from Microsoft or one that you develop yourself, you can use the following sample code to

extend the page with a new control.

```
    field("Attach To Item No."; "Attach To Item No.")
    { }
```

Extending Application Areas

Extending Pages Previously Based on the Date Virtual Table

2/17/2021 • 2 minutes to read • Edit Online

INTRODUCED IN: Business Central 2020 release wave 1

Pages that previously had the **Date** virtual table as their source table have been redesigned so that they are based on buffer tables instead. This way, base application pages such as **Item Availability Lines** and **Res. Availability Lines** can now be extended.

To perform extensions on such pages, you must first extend the underlying buffer table. Then you create a method that calculates and updates the values of the extended fields and subscribe it to the **OnAfterCalcLine** event of the page.

Example

The following example illustrates how to add two new fields, `"Add. -Currency Debit Amount"` and `"Add. -Currency Credit Amount"`, to the **G/L Account Balance Lines** page, which used to be based on the **Date** table.

The first step is to create a Table Extension object and add the two fields, `"Add.-Currency Debit Amount"` and `"Add.-Currency Credit Amount"`, to the **G/L Account Balance Buffer** source table. Then you create a Page Extension object to display the fields in the **G/L Account Balance Lines** page. This is shown in the following code.

```
tableextension 50001 GLAccBalanceBufferExt extends "G/L Acc. Balance Buffer"
{
    fields
    {
        field(50001; "Add.-Currency Debit Amount"; Decimal)
        {

        }
        field(50002; "Add.-Currency Credit Amount"; Decimal)
        {

        }
    }
}

pageextension 50001 GLAccountBalanceLinesExt extends "G/L Account Balance Lines"
{
    layout
    {
        addlast(Control1)
        {

            field(AddCurrencyDebitAmount; "Add.-Currency Debit Amount")
            {

                ApplicationArea = Basic, Suite;
                Caption = 'Debit Amount (ACY)';
            }

            field(AddCurrencyCreditAmount; "Add.-Currency Credit Amount")
            {
                ApplicationArea = Basic, Suite;
                Caption = 'Credit Amount (ACY)';
            }
        }
    }
}
```

The subscriber method `GLAccountBalanceLinesOnAfterCalcLine` computes the values of the `"Add.-Currency Credit Amount"` and `"Add.-Currency Debit Amount"` fields and updates the **G/L Acc. Balance Buffer** table. This method is called when the **OnAfterCalcLine** event in the **G/L Account Balance Lines** page is raised.

```
codeunit 50001 GLAccountBalanceLinesExt
{
    // Subscribe to OnAfterCalcLine event
    [EventSubscriber(ObjectType::Page, Page::"G/L Account Balance Lines", 'OnAfterCalcLine', '', false,
false)]
    local procedure GLAccountBalanceLinesOnAfterCalcLine(var GLAccount: Record "G/L Account"; var
GLAccBalanceBuffer: Record "G/L Acc. Balance Buffer")
    begin

        // Calculate values
        GLAccount.CalcFields("Add.-Currency Credit Amount", "Add.-Currency Debit Amount");

        // Assign calculated values to the new fields of the buffer table
        GLAccBalanceBuffer."Add.-Currency Debit Amount" := GLAccount."Add.-Currency Debit Amount";
        GLAccBalanceBuffer."Add.-Currency Credit Amount" := GLAccount."Add.-Currency Credit Amount";

    end;
}
```

Overview of the System Application

2/17/2021 • 3 minutes to read • Edit Online

The System Application contains modules that interact with the Dynamics 365 Business Central platform and online ecosystem to support the business logic in the Base Application. If you are developing extensions or add-ons for Dynamics 365 Business Central, you will probably need to use one or more of the objects in the modules.

This topic provides an overview of the modules in the System Application. For more details about each module, and to get a look at the code, choose the **ReadMe** link for the module to visit our AL AppExtensions repository on GitHub.

> **NOTE**
>
> The modules in the System Application represent a significant change in what's happening under the hood in Dynamics 365 Business Central. We are aware that the changes we have made will introduce breaking changes, so we have made a list of those that we know about, which includes suggestions for solutions. To view the breaking changes list, see Breaking Changes.
>
> We will continue to enhance the System Application in future releases. If you find something you think we should add, visit our Dynamics 365 Application Ideas page. If you want us to improve something, go to the AL AppExtensions repository and submit a pull request for it.

Overview of the Modules in the System Application

The list of modules is growing continuously. The following table lists and describes the modules that are available now.

MODULE	DESCRIPTION	LINK TO README
Assisted Setup	Contains all pages that are used by assisted setup guides.	ReadMe
Auto Format	Formats the appearance decimal data types.	ReadMe
Azure AD Graph	Interface for the Azure AD Graph API.	ReadMe
Azure AD Licensing	Access information about the subscribed SKUs and the corresponding service plans.	ReadMe
Azure AD Plan	Provides methods for retrieving and managing user plans in Azure Active Directory.	ReadMe
Azure AD Tenant	Retrieves information about the Azure Active Directory tenant.	ReadMe
Azure AD User Management	Provides functionality for managing Azure Active Directory users.	ReadMe

MODULE	DESCRIPTION	LINK TO README
Azure AD User	Retrieves and updates a user from the Azure AD Graph API.	ReadMe
Azure Key Vault	Stores Azure Key Vault secrets for deployments.	ReadMe
BLOB Storage	Stores and manages data in a binary format.	ReadMe
Base64 Convert	Converts text and from base 64.	ReadMe
Caption Class	Defines how the CaptionClass property displays captions.	ReadMe
Client Type Management	Allows testing of code that relies on different types of clients.	ReadMe
Confirm Management	Determines whether a confirm dialog displays when logic is run.	ReadMe
Cryptography Management	Contains the capabilities for encryption and hashing.	ReadMe
Cues and KPIs	Provides setup pages and interface methods to manage cues.	ReadMe
Data Classification	Handles data classification for objects that might contain sensitive information.	ReadMe
Data Compression	Compresses and uncompresses data in a binary format.	ReadMe
Date-Time Dialog	Provides helper functions for entering date-time values.	ReadMe
Default Role Center	Supports the default RoleCenter selection.	ReadMe
DotNet Aliases	Defines aliases for .NET classes.	ReadMe
Environment Information	Contains helper methods for getting information about the tenant and general settings.	ReadMe
Extension Management	Provides the tools needed to manage an extension.	ReadMe
Field Selection	Looks up fields.	ReadMe
Filter Tokens	Provides helper functions to manage filter texts.	ReadMe

MODULE	DESCRIPTION	LINK TO README
Headlines	Helps with constructing the text for headlines.	ReadMe
Language	Changes the language for Windows and applications.	ReadMe
Manual Setup	Contains functions and events used by manual setup pages.	ReadMe
Math	Provides constants and static methods for trigonometric, logarithmic, and other common mathematical functions.	ReadMe
Object Selection	Look up page for all of the application objects, including objects from installed extensions.	ReadMe
Page Summary Provider	Contains functionality for providing summary data for a given page in Microsoft Teams.	ReadMe
Password	Sets and verifies passwords.	ReadMe
Printer Management	Contains functionality that enables a user to manage printers.	ReadMe
Record Link Management	Provides helper functions for RecordLinks.	ReadMe
Recurrence Schedule	Calculates when the next event will occur.	ReadMe
Satisfaction Survey	Shows a satisfaction survey.	ReadMe
Secrets	Contains secret providers for reading secrets from the key vault that is specified by an extension or from other secret providers.	ReadMe
Server Settings	Exposes methods that get settings from the server configuration file.	ReadMe
System Initialization	Runs non-business logic on user log-ins.	ReadMe
Tenant License State	Retrieves the current state of the tenant license.	ReadMe
Translation	Gets and stores language translations.	ReadMe
Upgrade Tags	Provides functionality for ensuring that the upgrade code is run only one time.	ReadMe

MODULE	DESCRIPTION	LINK TO README
User Log-In Times	Keeps track of when users sign in.	ReadMe
User Permissions	Exposes functionality to check and alter User Permission sets.	ReadMe
User Selection	Looks up and selects registered users.	ReadMe
Video	Looks up and plays videos.	ReadMe
Web Service Management	Provides the tools needed to manage web services.	ReadMe

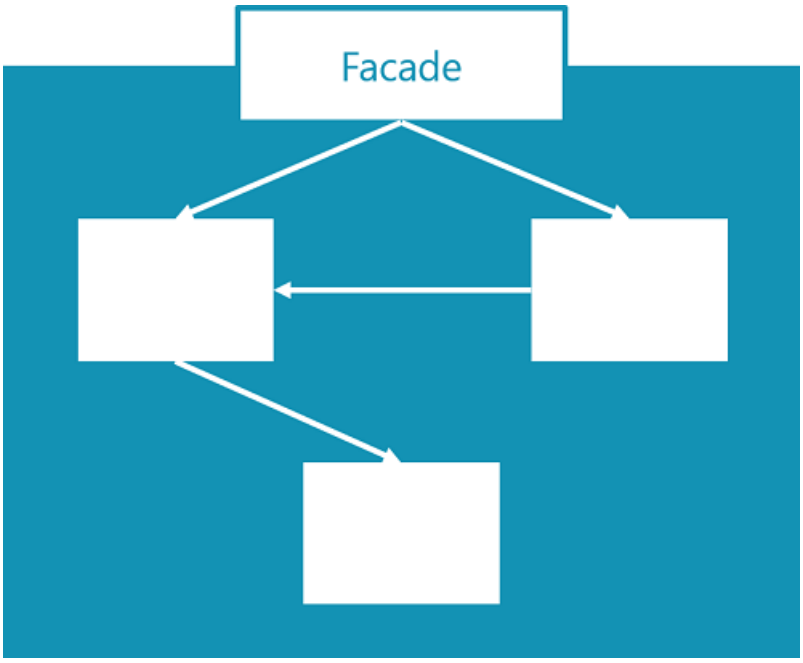
Module Architecture

2/17/2021 • 5 minutes to read • Edit Online

Though the internal architecture of modules can, and most likely will, differ, there are rules that ensure consistency and reliability in the architecture of application modules. To reduce coupling and increase consistency, every module is a separate entity that has a publicly accessible facade, while the internal implementation is not public, as shown in the following image:



The following sections describe the design principles for modules.

One Module, One Project

Modules are independent projects and have their own app.json files. For details about the contents of the app.json file, see Project Setup.

Packaging and Layering

Modules can belong to a specific package, or functional layer. A module becomes part of a layer when it's added to the folder structure of the layer's package. A module can belong to several packages because the module is a package of its own, and can be bundled into larger functional layering packages.

Dependencies

Dependencies to other modules can only be taken to modules in the same functional layer or to lower layers. For example, a module in the Core Application can only take dependencies to modules in the Core Application or System Application, but never to extensions.

Target Environment

Every module must initially target the most restrictive environment, which is the cloud environment. If unsafe operations are required, those should result in a System Application module where the unsafe operations are wrapped with safe APIs. That is done by setting the **Target** to **OnPrem**. Modules in layers above the System Application must have **Target** set to **Cloud** in the **app.json** file.

Object Accessibility

Only facade codeunits, pages, and tables required in the public API of the module can be accessible. Internal implementation details must be marked as such by setting the access modifier to Internal, i.e. entities can be accessed within the module but cannot be called from outside the module.

Facade Codeunits

Every module must have a facade that meets the following rules:

- Access must be **Public**. It should be set explicitly to emphasize that this is a facade or an API-like codeunit that exposes the core functionality in the module.
- All integration and business event publishers must be in the facade as internal functions. This prevents them from being invoked outside the module.
- Event publishers should be marked as internal. Exceptions must be documented.
- All external methods go in the facade.
- Facades cannot contain logic or local functions.
- Because the facade is the codeunit that other modules reference, it should have a short, meaningful name. Internal implementation codeunits can be suffixed with "Impl," for example, because they are not referenced outside the module.

Business Logic

Implementation codeunits contain the business logic. Pages and tables can contain code, but should do so only when it's absolutely required.

Extensibility

Extensibility must be thought into the internal implementation of every module. If a module should not be extensible, the **Extensibility** property on tables, pages, and enums must be set to **False** to prevent those objects from being extended.

Functions and fields in extensible tables and pages must have an access modifier, as described in the following table.

ACCESS	DESCRIPTION
Local	Accessed only by code in the same table or table extension where the function or field is defined.
Internal	Accessed only by code in the same module, but not from another module.
Protected	Accessed only by code in the same table or table/page extensions of that table.
Public	Accessed by any other code in the same module and in other modules that reference it.

Documentation

Every publicly accessible object must be documented. For more information, see Documentation.

Tests

Every module's public API must be tested according to Microsoft standards. For more information, see Testing.

Single Instance

Use single instance only when it's required, or if the module is expected to be called frequently.

.NET

If a .NET type is an integral part of the module and is not referenced elsewhere, the alias for that type must be defined in the module. If the .NET type is used in different modules, then the alias for it must be defined in the DotNet Aliases module.

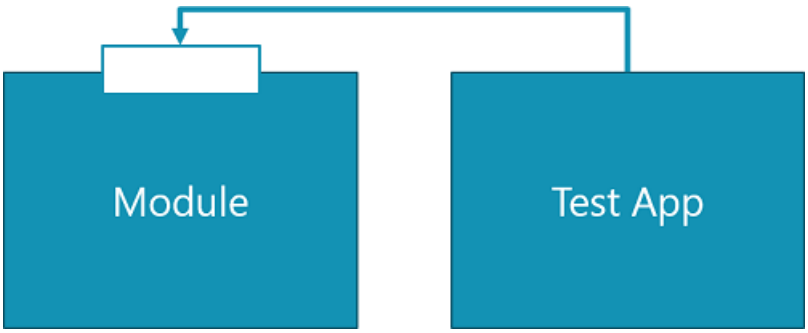
Project Setup

Every module begins with a project setup that includes the following:

- **Module Name**: If the module represents an entity, name the module after the entity. If the module does not represent an entity, give it a name that describes what it does. Module names can be singular or plural, depending on whether they handle one or more entities or tasks.
- **Location**: Determine which layer the module belongs to, and create a subfolder in a folder in that layer. For example, *Modules**System**My Module*).
- **Source Code**: Add the source code of the module in a src subfolder. For example, *Modules**System**My Module**src*).

Testing

Every module must be tested through a separate test module. Only public functions that are exposed through the facade, or other public objects such as pages, tables, xmlports, and queries, are tested by the test module.



The test module should have the same name as the module it tests, but be placed in a separate layer/package that contains tests for all modules in the layer. For example, *Modules****System Tests***My Module*). Test code cannot reside in the same layer folder structure as the module, or within the module, because it must not be executable or part of a production environment.

Documentation Guidelines

It's important that you document your module. The following sections provide some guidelines.

Modules

The app.json file for each module must contain a user-friendly title, a short brief, and a description that states its purpose.

Public API

Every publicly accessible object must have developer facing documentation that follows the XML documentation comments standard.

Public Objects

Public objects, such as codeunits, tables, pages, and so on, must have a summary that states what the object is used for.

```
/// <summary>
/// Lorem ipsum dolor sit amet, consectetur adipiscing elit.
/// </summary>
```

Public Functions

Public functions must have a summary, a parameter description, and a return value description. The following is an example.

```
/// <summary>
/// Maecenas sodales posuere ligula eu maximus.
/// </summary>
/// <param name="Lorem">The current language ID</param>
/// <param name="ipsum ">The CaptionClass expression to resolve</param>
/// <returns> Fusce in tristique massa, tincidunt tempor libero.</returns>
```

Getting Started with Modules in the System Application

2/17/2021 • 2 minutes to read • Edit Online

This topic provides information about requirements for working with modules in the System Application.

AL

Get familiar with development in AL. For more information, see Getting Started with AL.

Git

Familiarize yourself with Git. For a quick introduction, see git - the simple guide.

Setup Environment

For details about how to set up an environment for AL development, see Set up your environment.

Building a new module

Have you decided to build a new module? For more information, see Create a new module.

Modifying an existing module

Want to improve an existing module? For more information, see Change a module.

Have an issue?

Please open an issue.

Create a module

Set Up an Environment for Developing a Module

2/17/2021 • 3 minutes to read • Edit Online

This topic describes how to set up an environment for developing a module in the System Application.

Requirements

- You must have a GitHub account.
- You are familiar with the basics of Git, and have the application available. You will use Git to access the GitHub repository.
- Docker is installed. You will use it to run Business Central as a self-contained application.
- BcContainerHelper is installed. You will use it to create a Docker container.
- Demo or Partner license for Business Central

Get the Repository On Your Local Machine

1. Open the ALAppExtensions Repository, and choose Fork to create a fork of the repository.
2. Choose **Code**, and then copy the URL under code to clone the forked repository.

   The URL looks like https://github.com/<*username*>/ALAppExtensions.git, and <*username*> is your GitHub username.
3. Open PowerShell, and then open the directory in which you want to keep the repository files.
4. Run the **git clone** command. Replace <*URL*> with the URL you copied in step 3.
5. Open VS Code, and then go to the **System Modules** folder in the cloned repository.
6. Run the **code ALAppExtensions/Modules/System** command.
7. In the **System** folder, open the **app.json** and note the **version** that is listed. You will need that in step 3 in the process of setting up a Docker container.

Set Up a Business Central Docker Container

1. In PowerShell, import the **BcContainerHelper** module by running the **Import-Module BcContainerHelper** command. This loads the functions from the module.
2. Run the **New-BcContainerWizard** command. This opens a new PowerShell window and allows you to configure your AL Language development environment container.
3. Complete the steps in the wizard. Make the following changes to the default values.
   a. On the **Local Docker Container or Azure VM** step, choose a local docker container.
   b. On the **Authentication, Username/Password Authentication** step, choose options **a**, **b** or **c**.
   c. On the **Container Name** step, enter a name.
   d. On the **Version** step, choose options **e** or **f**, depending on whether you want a sandbox or on-premesis build.
      - Enter the version from `ALAppExtensions/Modules/System/app.json` after selecting option **e** or **f**.
   e. Country, US is fine.

f. Test Toolkit, if you have a partner license, you may choose any option. If you only have a demo license, choose option **d**, **No Test Toolkit**.

g. Premium Plan, not required.

h. Create Test Users, not required.

i. AL Base App Development, we will need this as we will work on the System Application.

j. Export AL Base App, not required as we will not be working on BaseApp.

k. AL Language Extension, not required.

l. License, put in the path to your license file.

m. Database, default option a.

n. Multitenant, non-multitenant setup.

o. We will then put in ! to use the default option choices for the rest of the options.

4. At the end of the configuration, you should be presented with the following script:

```
$containerName = 'mydemo'
$password = 'P@ssw0rd'
$securePassword = ConvertTo-SecureString -String $password -AsPlainText -Force
$credential = New-Object pscredential 'admin', $securePassword
$auth = 'UserPassword'
$artifactUrl = Get-BcArtifactUrl -type 'OnPrem' -country 'w1' -select 'Latest'
$licenseFile = '<Path to license file>'
New-BcContainer -accept_eula `
    -containerName $containerName `
    -credential $credential `
    -auth $auth `
    -artifactUrl $artifactUrl `
    -includeTestToolkit `
    -includeTestLibrariesOnly `
    -licenseFile $licenseFile `
    -includeAL -doNotExportObjectsToText `
    -updateHosts
```

> **NOTE**
>
> If you copy the script, remember to update the path to the license file ($licenseFile). Also, if you are using a demo license, remove the **-includeTestToolkit** and **-includeTestLibrariesOnly** options. 5. Run the script to create the Docker container. This can take some time if you are running it for the first time.

Module Architecture

Create a New Module in the System Application

2/17/2021 • 4 minutes to read • Edit Online

This topic provides an overview of how to create a new module in the System Application.

Requirements

1. Familiarity with development in AL. For more information, see AL Development.
2. Your development environment is ready. For more information, see Development Environment.

> **NOTE**
>
> Your environment must have the correct symbols. Go get those, in Visual Studio Code, press **F1**, and then choose **AL: Download Symbols**. Also, make a note of the **server** and **serverInstance** settings. You will add that information to the launch.json file.

Create a New Module

The following sections provide an example of how to contribute a new module. The example is based on the XmlWriter module, which is published in the AlAppExtensions repository. That contribution added a wrapper module to provide support for the XmlWriter, and the steps in this topic will recreate the pull request for the XmlWriter module. If you want to view the original pull request, it's available here: Pull Request 7876.

Set Up Visual Studio Code for Module Development

Open the **launch.json**, file and update the **server**, **serverInstance**, and **authentication** settings, as described in Set Up Your Development Environment.

```
"server": "https://YourDockerContainerName",
"serverInstance": "BC",
"authentication": "Windows",
```

Open the **settings.json** file, and update the **al.assemblyProbingPaths**, as described in Set Up a Development Environment.

Create a Branch

To create a branch, run the **git checkout -b "YourFeatureBranchName"** command. Afterward, you can start creating a new module.

Create a New Module

Before you create a new module, make sure you are familiar with the general architecture of system modules. For more information, see Module Architecture.

We'll start by creating a new folder named **XmlWriter** in the **System** folder, where we will add an app.json file. The app.json file will contain the general details of the module.

```
    {
        "id":  "215b484f-9fbf-437c-bc6e-67e2c0f283b0",
        "name":  "XMLWriter",
        "publisher":  "Microsoft",
        "brief":  "Write XML quickly with System.Xml.XmlTextWriter.",
        "description":  "Provides a fast, non-cached, forward-only way to create streams or files with XML
data that conforms to guidelines for W3C Extensible Markup Language (XML) 1.0 and Namespaces.",
        "version":  "17.0.0.0",
        "privacyStatement":  "https://go.microsoft.com/fwlink/?linkid=724009",
        "EULA":  "https://go.microsoft.com/fwlink/?linkid=2009120",
        "help":  "https://go.microsoft.com/fwlink/?linkid=2103698",
        "url":  "https://go.microsoft.com/fwlink/?linkid=724011",
        "logo":  "",
        "dependencies":  [
            {
                "id":  "7e3b999e-1182-45d2-8b82-d5127ddba9b2",
                "name":  "DotNet Aliases",
                "publisher":  "Microsoft",
                "version":  "17.0.0.0"
            }
        ],
        "screenshots":  [],
        "platform":  "17.0.0.0",
        "idRanges":  [
            {
                "from":  1483,
                "to":  1484
            }
        ],
        "target":  "OnPrem",
        "contextSensitiveHelpUrl":  "https://docs.microsoft.com/dynamics365/business-central/"
    }
```

NOTE

After we finish developing our module, we will need to update the app.json file to ensure that the **versions** and **idRanges** are correct. We can easily verify the version by checking the app.json in other modules in the System Application. The idRanges must reflect the IDs used in the module.

Next, create the **src** folder under **System/XmlWriter**. This folder will contain our source code. We will create an internal implementation codeunit named **XmlWriterImpl.Codeunit.al** in the **src** folder.

After adding the implementation functions, the implementation codeunit will look as follows.

```
codeunit 1484 "XmlWriter Impl"
{
    Access = Internal;

    procedure WriteStartDocument()
    begin
        StringBuilder := StringBuilder.StringBuilder();
        StringWriter := StringWriter.StringWriter(StringBuilder);
        XmlTextWriter := XmlTextWriter.XmlTextWriter(StringWriter);
        XmlTextWriter.WriteStartDocument();
    end;

    procedure WriteEndDocument()
    begin
        XmlTextWriter.WriteEndDocument();
    end;

    procedure ToBigText(var XmlBigText: BigText)
    begin
        XmlTextWriter.WriteString(XmlBigText);
    end;

    var
        StringBuilder: DotNet StringBuilder;
        StringWriter: DotNet StringWriter;
        XmlTextWriter: DotNet XmlTextWriter;
}
```

Now that we have created our implementation codeunit, we must add public functions in a facade codeunit with the functionality that we want to expose. Because the functions are public, we must ensure that these are tested and documented. To do this, we need to create a facade codeunit. In this example, we'll name the codeunit **XmlWriter.Codeunit.al**. The functions call the corresponding functions in the implementation codeunit.

The following is an example of the facade codeunit named **XmlWriter.Codeunit.al** that includes public functions and documentation.

```
/// <summary>
/// Provides helper functions for System.Xml.XmlWriter
/// </summary>
codeunit 1483 "XmlWriter"
{
    Access = Public;

    /// <summary>
    /// Creates the XmlWriter Document
    /// </summary>
    procedure WriteStartDocument()
    begin
        XmlWriterImpl.WriteStartDocument();
    end;

    /// <summary>
    /// Closes any open elements or attributes and puts the writer back in the Start state.
    /// </summary>
    procedure WriteEndDocument()
    begin
        XmlWriterImpl.WriteEndDocument();
    end;

    /// <summary>
    /// Writes the text within XmlWriter to the BigText variable.
    /// </summary>
    /// <param name="XmlBigText">The BigText the XmlWriter has to be write to.</param>
    procedure ToBigText(var XmlBigText: BigText)
    begin
        Clear(XmlBigText);
        XmlWriterImpl.ToBigText(XmlBigText)
    end;

    var
        XmlWriterImpl: Codeunit "XmlWriter Impl";
}
```

Now that we have now exposed the functions, the next step is to add tests. To do that, we'll create a new folder under **System Tests**, **XmlWriter**. We will also create an app.json file for the module details and an **src** folder for our test code.

We will add the following new file under **System Tests/XmlWriter/src**, **XmlWriterTest.Codeunit.al**.

```
    codeunit 139911 "Xml Writer Test"
    {
        Subtype = Test;

        var
            Assert: Codeunit "Library Assert";

        [Test]
        procedure TestWriteStartDocument()
        var
            XmlWriter: Codeunit "XmlWriter";
            XmlBigText: BigText;
        begin
            // [GIVEN] Initialized XmlWriter
            XmlWriter.WriteStartDocument();

            // [THEN] Get XmlDocument to text
            XmlWriter.ToBigText(XmlBigText);
            Assert.AreEqual('<?xml version="1.0" encoding="utf-16"?>', Format(XmlBigText), 'Unexpected text
when creating a Xml Document with XmlWriter');
        end;

        [Test]
        procedure TestWriteEndDocumentNoElement()
        var
            XmlWriter: Codeunit "XmlWriter";
        begin
            // [GIVEN] Initialized XmlWriter with root element
            XmlWriter.WriteStartDocument();

            // [WHEN] Write end document
            // [THEN] Expected error to be thrown
            asserterror XmlWriter.WriteEndDocument();
            Assert.ExpectedError('A call to System.Xml.XmlTextWriter.WriteEndDocument failed with this
message: Document does not have a root element.');
        end;
    }
```

After running the tests successfully, changes are complete.

Commit and push your changes and open a PR

- To commit your changes, run the **git commit -m "Your message"** command.
- To push your changes, run the **git push** command.

You can now go to your Github fork and open a pull request in the AlAppExtensions repository.

Module Architecture

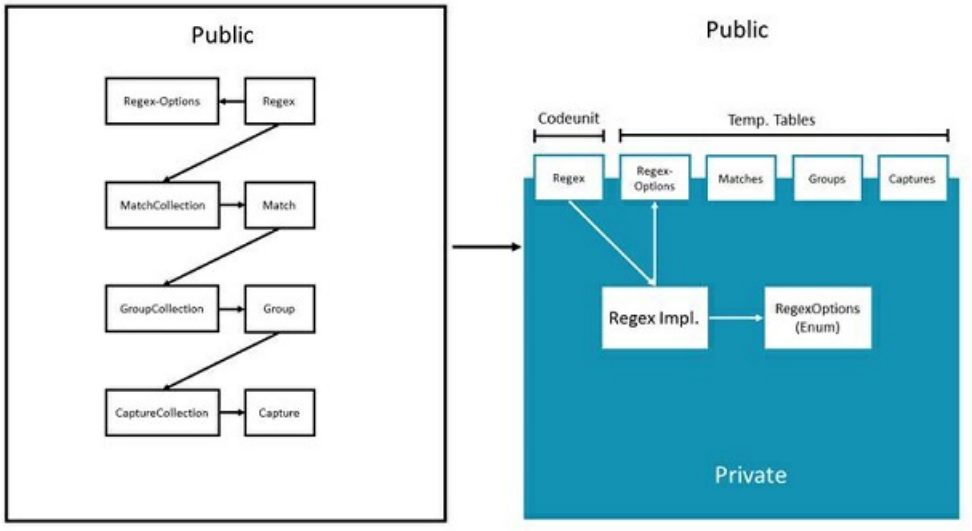
Create a .NET Wrapper Module

2/17/2021 • 4 minutes to read • Edit Online

This topic provides a description of how to contribute a .NET wrapper module to Business Central, using the Regex module as an example. The Regex module is published in the AlAppExtensions repository, and if you aren't already familiar with the Regex class in .NET, see the .NET documentation.

Converting the Regex architecture

In .NET, the Regex class provides functionality for regular expressions. You can implement the functionality in a similar way as a system module by creating a Regex codeunit that provides an interface and an internal Regex implementation that contains the logic.



Wrapping a .NET method

For some methods, you can wrap the .NET method in AL in an internal codeunit and expose the procedure to the facade. For example, you can wrap the IsMatch method as follows.

```
/// <summary>
/// Provides functionality to use regular expressions to match text, split text, replace text etc.
/// </summary>
codeunit 3960 Regex
{
    Access = Public;

    var
        RegexImpl: Codeunit "Regex Impl.";

    /// <summary>
    /// Indicates whether the regular expression finds a match in the input string.
    /// </summary>
    /// <param name="Input">The string to search for a match.</param>
    /// <param name="Pattern">A regular expression pattern to match.</param>
    /// <returns>True if the regular expression finds a match; otherwise, false.</returns>
    procedure IsMatch(Input: Text; Pattern: Text): Boolean
    begin
        exit(RegexImpl.IsMatch(Input, Pattern));
    end;
}
```

```
codeunit 3961 "Regex Impl."
{
    Access = Internal;

    var
        DotNetRegex: DotNet Regex;

    procedure IsMatch(Input: Text; Pattern: Text): Boolean
    begin
        Regex(Pattern);
        exit(DotNetRegex.IsMatch(Input))
    end;
}
```

Codeunits in method signatures

Not all .NET Regex classes map so directly to system modules, however. The .NET Regex class also includes classes such as Match, Group, and Capture, that are used to represent results for regular expression matches. While it's tempting to wrap these classes in codeunits and use those to output results, you should avoid that because procedure signatures should not contain codeunits. Instead, use temporary tables to model these classes. The following code example shows how to implement the Match class in a temporary table.

```
/// <summary>
/// Provides a representation of Regex Matches that models Match objects in .Net
/// </summary>

/// <remark>
/// For more information, visit https://docs.microsoft.com/en-
us/dotnet/api/system.text.regularexpressions.match?view=netcore-3.1.
/// </remark>
table 3965 Matches
{
    TableType = Temporary;
    Extensible = false;

    fields
    {
        field(1; MatchIndex; Integer)
        {
            Description = 'The index of the match in the table.';
        }
        field(2; Index; Integer)
        {
            Description = 'The position in the original string where the first character of the captured
substring is found.';
        }
        field(3; ValueBlob; Blob)
        {
            Access = Internal;
            Description = 'Gets the captured substring from the input string.';
        }
        field(4; Length; Integer)
        {
            Description = 'Gets the length of the captured substring.';
        }
        field(5; Success; Boolean)
        {
            Description = 'Gets a value indicating whether the match is successful.';
        }
    }
}
```

The temporary table has all the normal table procedures, and can be extended with procedures if needed. Now we can write the Match objects, output by .NET, to this table.

```
codeunit 3961 "Regex Impl."
{
    Access = Internal;

    var
        DotNetRegex: DotNet Regex;
        DotNetMatchCollection: DotNet MatchCollection;

    procedure Match(Input: Text; Pattern: Text; var Matches: Record Matches)
    begin
        Regex(Pattern);
        DotNetMatchCollection := DotNetRegex.Matches(Input);
        InsertMatch(Matches);
    end;
}
```

Avoiding Constructors

The .NET Regex class includes multiple constructors, but we should not expose them in the facade. We can, however, use constructors internally, as the code previous code example shows.

Removing constructors from a class can cause overloads. One way to get around that is to use the argument-table pattern. For example, you can construct a temporary table with all optional parameters and internally implement the logic to apply them.

The .NET Regex class contains three constructors that we want to support:

- Regex(Pattern)
- Regex(Pattern, RegexOptions)
- Regex(Pattern, RegexOptions, MatchTimeout)

In .NET, RegexOptions is an enum with options for matching the pattern (case-sensitivity, ignoring whitespace, and so on), and MatchTimeout sets a time-out interval for matching. The following example shows how to add those options to a temporary table.

```
/// <summary>
/// Table with options to use with Regular Expressions
/// </summary>
table 3966 "Regex Options"
{
    Extensible = false;
    TableType = Temporary;

    fields
    {
        field(1; IgnoreCase; Boolean)
        {
            DataClassification = SystemMetadata;
            Description = 'Specifies case-insensitive matching.';
        }
        field(2; Multiline; Boolean)
        {
            DataClassification = SystemMetadata;
            Description = 'Changes the meaning of ^ and $ so they match at the beginning and end
respectively of any line.';
        }

        ...

        field(10; MatchTimeoutInMs; Integer)
        {
            DataClassification = SystemMetadata;
            Description = 'A time-out interval in milliseconds, to indicate when the matching should time
out.';
            InitValue = -1; // Indicates no time-out
        }
    }
}
```

This temporary table makes it straightforward to add overloads to the facade. For each method, there is one procedure without an options parameter, and one overload with an options table. The following example illustrates that for the Match procedure.

```
/// <summary>
    /// Searches the input string for the first occurrence of the specified regular expression, using the
specified matching options.
    /// </summary>
    /// <param name="Input">The string to search for a match.</param>
    /// <param name="Pattern">A regular expression pattern to match.</param>
    /// <param name="Match">The Match object to write information about the match to.</param>
    procedure Match(Input: Text; Pattern: Text; var Matches: Record Matches)
    begin
        RegexImpl.Match(Input, Pattern, Matches);
    end;

    /// <summary>
    /// Searches the input string for the first occurrence of the specified regular expression, using the
specified matching options.
    /// </summary>
    /// <param name="Input">The string to search for a match.</param>
    /// <param name="Pattern">A regular expression pattern to match.</param>
    /// <param name="RegexOptions">A combination of the enumeration values that provide options for
matching.</param>
    /// <param name="Match">The Match object to write information about the match to.</param>
    procedure Match(Input: Text; Pattern: Text; var RegexOptions: Record "Regex Options"; var Matches:
Record Matches)
    begin
        RegexImpl.Match(Input, Pattern, RegexOptions, Matches);
    end;
```

Change a Module in the System Application

2/17/2021 • 5 minutes to read • Edit Online

This topic provides an overview of how to change an existing module.

Requirements

1. Familiarity with development in AL. For more information, see AL Development.
2. Your local repository and development environment are ready. For more information, see Set Up an Environment for Developing a Module.

> **NOTE**
>
> Your environment must have the correct symbols. Go get those, in Visual Studio Code, press **F1**, and then choose **AL: Download Symbols**. Also, make a note of the **server** and **serverInstance** settings. You will add that information to the launch.json file.

Your changes must follow the guidelines for module architecture. For more information, see Module Architecture. When changing an existing module, do not introduce breaking changes, that is, make sure that you do not break existing functionality. Existing tests must still pass, and you should add new tests for the functionality that you change or add.

Set Up Visual Studio Code for Module Development

Open the **launch.json**, file and update the **server**, **serverInstance**, and **authentication** settings, as described in Set Up Your Development Environment.

```
    "server": "https://YourDockerContainerName",
    "serverInstance": "BC",
    "authentication": "Windows",
```

Open the **settings.json** file, and update the **al.assemblyProbingPaths**, as described in Set Up Your Development Environment.

Create a Branch

To create a branch, run the **git checkout -b "YourFeatureBranchName"** command. Afterward, you can start creating a new module.

Change an Existing Module

The following sections provide an example of how to contribute to an existing module. The example is based on a previous contribution to the Base64 Convert module, which has been published in the AlAppExtensions repository. The contribution added support for text encodings other than UTF8. If you're interested, you can view the original pull request at Pull Request 7676.

Make Changes to a Module

Before making changes, make sure you are familiar with the general architecture of system modules. For more information, see Module Architecture. You can also check out the article titled How to add a system module for an example of creating a full system module.

We'll start by adding the functions that we need to support different text encodings to the internal

implementation codeunit. We'll add the following functions to the **System/Base64 Convert/src/Base64ConvertImpl.Codeunit.al** implementation codeunit:

```
    procedure ToBase64(String: Text; TextEncoding: TextEncoding): Text
    begin
        exit(ToBase64(String, false, TextEncoding, 0));
    end;

    procedure ToBase64(String: Text; TextEncoding: TextEncoding; Codepage: Integer): Text
    begin
        exit(ToBase64(String, false, TextEncoding, Codepage));
    end;

    procedure ToBase64(String: Text; InsertLineBreaks: Boolean; TextEncoding: TextEncoding): Text
    begin
        exit(ToBase64(String, InsertLineBreaks, TextEncoding, 0));
    end;

    procedure ToBase64(String: Text; InsertLineBreaks: Boolean; TextEncoding: TextEncoding; Codepage:
Integer): Text
    var
        Convert: DotNet Convert;
        Encoding: DotNet Encoding;
        Base64FormattingOptions: DotNet Base64FormattingOptions;
        Base64String: Text;
    begin
        if String = '' then
            exit('');

        if InsertLineBreaks then
            Base64FormattingOptions := Base64FormattingOptions.InsertLineBreaks
        else
            Base64FormattingOptions := Base64FormattingOptions.None;
        case TextEncoding of
            TextEncoding::UTF16:
                Base64String := Convert.ToBase64String(Encoding.Unicode().GetBytes(String),
Base64FormattingOptions);
            TextEncoding::MSDos,
            TextEncoding::Windows:
                Base64String := Convert.ToBase64String(Encoding.GetEncoding(CodePage).GetBytes(String),
Base64FormattingOptions);
            else
                Base64String := Convert.ToBase64String(Encoding.UTF8().GetBytes(String),
Base64FormattingOptions);
        end;

        exit(Base64String);
    end;

    procedure FromBase64(Base64String: Text; TextEncoding: TextEncoding): Text
    begin
        exit(FromBase64(Base64String, TextEncoding, 1252));
    end;

    procedure FromBase64(Base64String: Text; TextEncoding: TextEncoding; CodePage: Integer): Text
    var
        Convert: DotNet Convert;
        Encoding: DotNet Encoding;
        OutputString: Text;
    begin
        if Base64String = '' then
            exit('');

        case TextEncoding of
            TextEncoding::UTF16:
                OutputString := Encoding.Unicode().GetString(Convert.FromBase64String(Base64String));
            TextEncoding::MSDos,
            TextEncoding::Windows:
```

```
            TextEncoding::Windows:
                OutputString :=
Encoding.GetEncoding(CodePage).GetString(Convert.FromBase64String(Base64String));
            else
                OutputString := Encoding.UTF8().GetString(Convert.FromBase64String(Base64String));
        end;
        exit(OutputString);
    end;
```

We also need to update some of the existing functions in **System/Base64 Convert/src/Base64ConvertImpl.Codeunit.al**, while making sure that they keep the same functionality:

```
    procedure ToBase64(String: Text): Text
    begin
        exit(ToBase64(String, false));
    end;

    procedure ToBase64(String: Text; InsertLineBreaks: Boolean): Text
    begin
        exit(ToBase64(String, InsertLineBreaks, TextEncoding::UTF8, 0));
    end;

    procedure FromBase64(Base64String: Text): Text
    begin
        exit(FromBase64(Base64String, TextEncoding::UTF8, 0));
    end;
```

We have changed the implementation codeunit, and avoided breaking existing functionality by keeping the same behavior for existing functions.

Now we'll add public functions in the facade codeunit with the functionality that we want to expose. Because the functions are public, we need to ensure that they are documented and tested. The functions call the corresponding functions in the implementation codeunit. We add the following functions to **System/Base64 Convert/src/Base64Convert.Codeunit.al**:

```
    /// <summary>
    /// Converts the value of the input string to its equivalent string representation that is encoded with
base-64 digits.
    /// </summary>
    /// <param name="String">The string to convert.</param>
    /// <param name="TextEncoding">The TextEncoding for the input string.</param>
    /// <returns>The string representation, in base-64, of the input string.</returns>
    procedure ToBase64(String: Text; TextEncoding: TextEncoding): Text
    begin
        exit(Base64ConvertImpl.ToBase64(String, TextEncoding));
    end;

    /// <summary>
    /// Converts the value of the input string to its equivalent string representation that is encoded with
base-64 digits.
    /// </summary>
    /// <param name="String">The string to convert.</param>
    /// <param name="TextEncoding">The TextEncoding for the input string.</param>
    /// <param name="Codepage">The Codepage if TextEncoding is MsDos or Windows.</param>
    /// <returns>The string representation, in base-64, of the input string.</returns>
    procedure ToBase64(String: Text; TextEncoding: TextEncoding; Codepage: Integer): Text
    begin
        exit(Base64ConvertImpl.ToBase64(String, TextEncoding, Codepage));
    end;

    /// <summary>
    /// Converts the specified string, which encodes binary data as base-64 digits, to an equivalent regular
string.
    /// </summary>
    /// <param name="Base64String">The string to convert.</param>
    /// <param name="TextEncoding">The TextEncoding for the input string.</param>
    /// <returns>Regular string that is equivalent to the input base-64 string.</returns>
    /// <error>The length of Base64String, ignoring white-space characters, is not zero or a multiple of 4.
</error>
    /// <error>The format of Base64String is invalid. Base64String contains a non-base-64 character, more
than two padding characters,
    /// or a non-white space-character among the padding characters.</error>
    procedure FromBase64(Base64String: Text; TextEncoding: TextEncoding): Text
    begin
        exit(Base64ConvertImpl.FromBase64(Base64String, TextEncoding));
    end;

    /// <summary>
    /// Converts the specified string, which encodes binary data as base-64 digits, to an equivalent regular
string.
    /// </summary>
    /// <param name="Base64String">The string to convert.</param>
    /// <param name="TextEncoding">The TextEncoding for the inout string.</param>
    /// <param name="Codepage">The Codepage if TextEncoding is MsDos or Windows.</param>
    /// <returns>Regular string that is equivalent to the input base-64 string.</returns>
    /// <error>The length of Base64String, ignoring white-space characters, is not zero or a multiple of 4.
</error>
    /// <error>The format of Base64String is invalid. Base64String contains a non-base-64 character, more
than two padding characters,
    /// or a non-white space-character among the padding characters.</error>
    procedure FromBase64(Base64String: Text; TextEncoding: TextEncoding; Codepage: Integer): Text
    begin
        exit(Base64ConvertImpl.FromBase64(Base64String, TextEncoding, Codepage));
    end;
```

We have now exposed the functions. The next steps are to ensure that existing tests pass, and then add new tests for the functionality that we added.

After verifying that the tests pass, we'll add the following tests to the **System Tests/Base64 Convert/src/Base64ConvertTest.Codeunit.al** file.

```
    [Test]
    procedure StringToBase64UTF16Test()
    var
        ConvertedText: Text;
    begin
        // [SCENARIO] A string variable is converted to base-64 string, binary representation is kept in
UTF16

        // [WHEN] The string is converted
        ConvertedText := Base64Convert.ToBase64(SampleUTF16Txt, TextEncoding::UTF16);

        // [THEN] The converted value is correct
        Assert.AreEqual(Base64SampleUTF16Txt, ConvertedText, ConvertionToBase64UTF16Err);
    end;

    [Test]
    procedure FromBase64UTF16StringTest()
    var
        ConvertedText: Text;
    begin
        // [SCENARIO] A base-64 string with UTF16 encoding is converted to a regular string

        // [WHEN] The base-64 string is converted
        ConvertedText := Base64Convert.FromBase64(Base64SampleUTF16Txt, TextEncoding::UTF16);

        // [THEN] The converted value is correct
        Assert.AreEqual(SampleUTF16Txt, ConvertedText, ConvertionFromBase64UTF16Err);
    end;
```

Commit and Push Changes, and Open a Pull Request

To submit your changes, follow these steps:

1. To commit your changes, run the **git commit -m "Your message"** command.
2. To push your changes, run the **git push** command.

You can now go to your GitHub fork and open a pull request in the AlAppExtensions repository.

Deprecating Explicit and Implicit With Statements

2/17/2021 • 6 minutes to read • Edit Online

APPLIES TO: Business Central 2020 release wave 2 and later

The extensibility model and the AL programming language is a successor to the C/AL language. And the `with` statement has up until now been supported in AL. While using the `with` statement might make code harder to read, it can also prevent code in Business Central online from being upgraded without changes to the code or even worse - upgraded, but with changed behavior. We distinguish between two types of with statements; the explicit type of `with` using the keyword, and the implicit with which is not expressed directly in code. The next sections describe these one by one.

The explicit with statement

In Business Central online your code is recompiled when the platform and application versions are upgraded. The recompilation ensures that it is working and the recompile regenerates the runtime artifacts to match the new platform. Breaking changes without due warning are not allowed, but the use of the `with` statement makes it impossible, as Microsoft, to make even additive changes in a completely non-breaking way. This problem is not alone isolated to changes made by Microsoft; any additive change has the potential to break a `with` statement in consuming code.

The following example illustrates code written using the `with` statement; referred to in this context as the explicit `with`.

```
codeunit 50140 MyCodeunit
{
    procedure DoStuff()
    var
        Customer: Record Customer;
    begin
        with Customer do begin
            // Do some work on the Customer record.
            Name := 'Foo';

            if IsDirty() then
                Modify();
        end;
    end;

    local procedure IsDirty(): Boolean;
    begin
        exit(false);
    end;
}
```

The `DoStuff()` procedure processes work on the Customer record and calls a local procedure `IsDirty()` to check whether to update the record or not. Looking at the code above it looks like it does nothing since `IsDirty()` returns `false` - assuming that the `IsDirty()` call (line 11) is in fact calling the local `IsDirty()` procedure.

Symbol lookup

Considering the above code sample again, what would happen to that code if `IsDirty` was added to the base

application between two releases? To understand that we need to take a look at how compilers turn syntax into symbols. When the AL compiler meets the `IsDirty` call it must bind the syntax name to a procedure symbol.

When the AL compiler searches for the symbol `IsDirty()` in the sample above it will search in following order:

1. Customer table
   - User-defined members on the Customer table and Customer table extensions
   - Platform-defined members, for example, `FindFirst()` or `Modify()`
2. MyCodeunit codeunit
   - User-defined members, for example, `IsDirty()`
   - Platform-defined members
3. Globally defined members

The first time the search for `IsDirty` finds the name IsDirty, it will not continue to the next top-level group. That means that if a procedure named `IsDirty` is introduced in the Customer table (platform or application) that procedure will be found instead of the procedure in `MyCodeunit`.

The solution for the *explicit* `with` is to stop using it. Using the `with` statement can make your code vulnerable to upstream changes. The example below illustrates how to rewrite the sample in The explicit with statement:

```
// Safe version
codeunit 50140 MyCodeunit
{
    procedure DoStuff()
    var
        Customer: Record Customer;
    begin
        // Do some work on the Customer record.
        Customer.Name := 'Foo';

        if IsDirty() then
            Customer.Modify();
    end;

    local procedure IsDirty(): Boolean;
    begin
        exit(false);
    end;
}
```

The implicit with statement

The implicit with is injected automatically by the compiler in certain situations. The next sections describe, how this works on codeunits and pages.

Codeunits

When a codeunit has the `TableNo` property set, there is an implicit with around the code inside the `OnRun` trigger. This is indicated with the comments in the code example below.

```
codeunit 50140 MyCodeunit
{
    TableNo = Customer;

    trigger OnRun()
    begin
        // with Rec do begin
        SetRange("No.", '10000', '20000');
        if Find() then
            repeat
            until Next() = 0;

        if IsDirty() then
            Error('Something is not clean');
        // end;
    end;

    local procedure IsDirty(): Boolean;
    begin
        exit(false);
    end;
}
```

Similar to the The explicit with statement, the code looks like it will call the local `IsDirty` method, but depending on the Customer table, extensions to the Customer table, and built-in methods that may not be the case. If any of these implement an `IsDirty` method with an identical signature that returns `true`, then the example above will fail with an error. If an `IsDirty` method with a different signature is implemented, then this code will not compile and will fail to upgrade.

Pages

Pages on tables have the same type of implicit with, but around the entire object. Everywhere inside the page object the fields and methods from the source tables are directly available without any prefix.

```
page 50143 ImplicitWith
{
    SourceTable = Customer;

    layout
    {
        area(Content)
        {
            field("No."; "No.") { }
            field(Name; Name)
            {
                trigger OnValidate()
                begin
                    Name := 'test';
                end;
            }
        }
    }

    trigger OnInit()
    begin
        if IsDirty() then Insert()
    end;

    local procedure IsDirty(): Boolean
    begin
        exit(Name <> '');
    end;
}
```

On pages it is not only the code in triggers and procedures that is spanned by the implicit with on the source `Rec`; also the source expressions for the fields are covered.

Warnings and using pragma

From Business Central 2020 release wave 2 we begin to warn about the use of explicit and implicit with for extensions that are targeting the cloud. There are two different warnings: `AL0604` and `AL0606`.

> **NOTE**
> The warnings will become errors with a future release. We will at the earliest remove with statement support from the Business Central 2021 release wave 2.

AL0606 - use of explicit with

The warning has a Quick Fix code action that allows you to convert the statement(s) inside the `with` statement to fully-qualified statements, this means statements as shown in The explicit with statement.

AL0604 - use of implicit with

Just qualifying with `Rec.` will not solve this problem. The `IsDirty()` will still be vulnerable to upstream change. We want to remove the implicit with, but also offer an opt-in model to avoid forcing everyone to upgrade their code at once.

The solution for that is to introduce pragmas in AL. A pragma is an instruction to the compiler on how it should understand the code. The pragma instructs the compiler not to create an implicit with for the `Rec` variable.

The following shows the syntax for the implicit with pragma. The pragma must be used before the beginning of the codeunit or page. For more information, see Pragma Directive and Pragma ImplicitWith.

```
#pragma implicitwith disable|restore
```

The fixed example under Pages will then look like this:

```
#pragma implicitwith disable
page 50143 ImplicitWith
{
    SourceTable = Customer;

    layout
    {
        area(Content)
        {
            field("No."; Rec."No.") { }
            field(Name; Rec.Name)
            {
                trigger OnValidate()
                begin
                    Rec.Name := 'test';
                end;
            }
        }
    }

    trigger OnInit()
    begin
        if IsDirty() then Rec.Insert()
    end;

    local procedure IsDirty(): Boolean
    begin
        exit(Name <> '');
    end;
}
#pragma implicitwith restore
```

The Quick Fix code actions will automatically insert the pragma before and after the fixed object.

> **TIP**
> Remember to **Enable Code Actions** in the settings for the AL Language extension. For more information, see Code Actions.

In the `app.json` file, you can set the `NoImplicitWith` flag to disable implicit with when you have rewritten all code. For more information, see JSON Files.

Suppressing warnings

There are two ways of suppressing warnings to unclutter warnings while working on other issues and then afterwards you can fix the warnings at your own pace.

suppressWarnings setting

Warnings can be suppressed globally in an extension by specifying this in the `app.json` file. For more information, see AL Language Extension Configuration. The syntax is:

```
"suppressWarnings": [ "AL0606", "AL0604" ]
```

Pragmas

It is also possible to use `#pragma` to suppress individual warnings for one or more lines of code. For more information, see Pragma Warning.

```
#pragma warning disable AL0606
    // No AL0606 will be shown for code here.
    with Customer do begin
        Name := 'Foo';
        Insert();
    end;

#pragma warning restore AL0606
// Suppression of AL0606 is restored to global state.
```

Events in AL

2/17/2021 • 3 minutes to read • Edit Online

The use of events is a proven and established programming concept that can ease application upgrade and limit or even eliminate the need for code modifications in customized applications because of application platform changes.

You can use events to design the application to react to specific actions or behavior that occur. Events enable you to separate customized functionality from the application business logic. By using events in the application where customizations are typically made, you can lower the cost of code modifications and upgrades to the original application.

- Code modifications to customized functionality can be made without having to modify the original application.
- Changes to the original application code can be made with minimal impact on the customizations.

Events can be used for different purposes, such as generating notifications when certain behavior occurs or the state of an entity changes, distributing information, and integrating with external systems and applications. For example, in the CRONUS International Ltd. demonstration database, events are used extensively for workflow and Dynamics 365 for Sales integration.

The following table describes all the different event types:

EVENT TYPES	DESCRIPTION
BusinessEvent	Specifies the method to be business type event publisher.
IntegrationEvent	Specifies the method to be integration type event publisher.
InternalEvent	Specifies the method to be an internal event publisher.
Global	Global events are predefined system events.
Trigger	Trigger events are published by the runtime.

The process for implementing these events is slightly different. To learn about the different types, see Event Types.

How events work

The basic principle is that you program events in the application to run customized behavior when they occur. Events in AL are modeled after Microsoft .NET Framework. There are three major participants involved in events: the *event*, a *publisher*, and a *subscriber*.

- An *event* is the declaration of the occurrence or change in the application. An event is declared by an AL method, which is referred to as an *event publisher function*. An event publisher method is comprised of a signature only and does not execute any code.
- A *publisher* is the object that contains event publisher method that declares the event. The publisher exposes an event in the application to subscribers, essentially providing them with a hook-up point in the application.

Publishing an event does not actually do anything in the application apart from making the event available for subscription. The event must be raised for subscribers to respond. An event is raised by adding logic to the application that calls into the publisher to invoke the event (the event publisher method).

Partners or subsystems can then take advantage of the published event in their solutions. An ISV that delivers vertical solutions, and Microsoft itself, are the typical providers of published events.

Business and integration type events must be explicitly published and raised, which means that you must create event publisher functions and add them to objects manually. On the other hand, trigger events, which occur on table and page operations, are published and raised implicitly by the system at runtime. Therefore, no coding is required to publish them.

- A *subscriber* listens for and handles a published event. A subscriber is an AL method that subscribes to a specific event publisher method and includes the logic for handling the event. When an event is raised, the subscriber method is called and its code is run. A subscriber enables partners to hook into the core application functionality without having to do traditional code modifications. Any Dynamics 365 solution provider, which also includes Microsoft, can use event subscribers.

There can by multiple subscribers to a single event publisher method. However, a publisher has no knowledge of subscribers, if any. Subscribers can reside in different parts of the application than publishers.

How to implement events

Implementing events consists of the following tasks:

1. Publish the event.

   For business and integration events, create and configure a method in an application object to be an event publisher method. For more information, see Publishing Events. This is not required for trigger events because these are automatically published by the system.

2. Raise the event.

   Add code that calls the event publisher method. For more information, see Raising Events. This is not required for trigger events because these are raised automatically by the system.

3. Subscribe to the event.

   At the consumer end, add one or more subscriber methods that subscribe to published events when they are raised. For more information, see Subscribing to Events.

Event Types

2/17/2021 • 7 minutes to read • Edit Online

Dynamics 365 Business Central supports different types of events for different purposes.

Business events

A business event is a custom event that is raised by AL code. It defines a formal contract that carries an implicit promise not to change in future releases. It is the expectation that business events are published by solution ISVs, including Microsoft.

Business events can be compared with publicly released APIs on which 3rd party solution providers develop integrations and additions. Therefore, the downstream cost of making changes to a business event implementation can be considerable for those who use the event in their applications. There may be some cases where changes are required; however, you should keep these to an absolute minimum.

Development considerations

A typical business event reflects changes in "state" with regards to a process. This makes them very well suited for workflow. An example of a business event could be when a sales order has been posted. It is important to note that business events should not be tied to the implementation-details, such as the tables or fields in which the data is stored. Preferably, the event publisher developer should be free to change the implementation, while still keeping the business event intact. To learn about the syntax and example on how to use the BusinessEvent type, see BusinessEvent Attribute.

Business events should be documented with the solution, including the before-state and after-state of the events.

Integration events

An integration event is also a custom event that is raised by AL code, like a business event, except that it does not carry the same promise of not changing, nor does it have the restriction not to expose implementation details.

The main purpose of integration events is to enable the integration of other solutions with Dynamics 365 Business Central without having to perform traditional code modifications.

Development considerations

An integration event can be changed to a business event later. At which time, it must adhere to the same implied contract and commitment as any business event. It can also simply be designed-in hook points for external add-ons. To learn about the syntax and example on how to use the IntegrationEvent type, see IntegrationEvent Attribute.

Global events

Global events are predefined system events that are automatically raised by various base application codeunits. For example, codeunit 40 **LoginManagement** includes several global method triggers, such as CompanyOpen, CompanyClose, and GetSystemIndicator. For most of these global method triggers, there are one or two global events: a before and after event. For example, there is an OnBeforeCompanyOpen event and an OnAfterCompanyOpen event. The global events are defined as integration event publishers by local methods in the following codeunits.

CODEUNIT ID	CODEUNIT NAME	EVENT
40	LoginInManagement	OnRoleCenterOpen
		OnAfterLogInEnd
		OnBeforeLogInStart
		OnBeforeCompanyOpen
		OnAfterCompanyOpen
		OnBeforeCompanyClose
		OnAfterCompanyClose
42	TextManagement	OnBeforeMakeTextFilter
		OnAfterMakeDateTimeFilter
		OnAfterMakeDateFilter
		OnAfterMakeTextFilter
		OnAfterMakeTimeFilter
42	CaptionManagement	OnAfterCaptionClassTranslate
44	ReportManagement	OnAfterGetPrinterName
		OnAfterDocumentPrintReady
		OnAfterGetPaperTrayForReport
		OnAfterHasCustomLayout
		OnAfterSetupPrinters
		OnAfterSubstituteReport
45	AutoFormatManagement	OnAfterAutoFormatTranslate
49	GlobalTriggerManagement	OnAfterGetGlobalTableTriggerMask
		OnAfterOnGlobalInsert
		OnAfterOnGlobalModify
		OnAfterOnGlobalDelete
		OnAfterOnGlobalRename

CODEUNIT ID	CODEUNIT NAME	EVENT
		OnAfterGetDatabaseTableTriggerSetup
		OnAfterOnDatabaseInsert
		OnAfterOnDatabaseModify
		OnAfterOnDatabaseDelete
		OnAfterOnDatabaseRename
		OnBeforeOnDatabaseInsert
		OnBeforeOnDatabaseModify
		OnBeforeOnDatabaseDelete
		OnBeforeOnDatabaseRename

Trigger events

Unlike business and integration events which must be programmed, trigger events are predefined events. Trigger events are published by the runtime and they cannot be raised programmatically. There are two types of trigger events: database trigger events and page trigger events.

> **NOTE**
> Trigger events do not appear as methods in AL for a table or page object.

Database trigger events

Trigger events are automatically raised by the system when it performs database operations on a table object, such as deleting, inserting, modifying, and renaming a record, as defined in a table. Trigger events are closely associated with the table triggers for database operations: OnDelete, OnInsert, OnModify, OnRename, and OnValidate (for fields). For each database operation, there is a "before" and "after" trigger event with a fixed signature.

Available Database Trigger Events

The following table describes the available database trigger events:

DATABASE TRIGGER EVENT WITH SIGNATURE	DESCRIPTION
`OnBeforeDeleteEvent(VAR Rec: Record; RunTrigger: Boolean)`	Executed before a record is deleted from a table.
`OnAfterDeleteEvent(VAR Rec: Record; RunTrigger: Boolean)`	Executed after a record is deleted from a table.
`OnBeforeInsertEvent(VAR Rec: Record; RunTrigger: Boolean)`	Executed before a record is inserted in a table.

DATABASE TRIGGER EVENT WITH SIGNATURE	DESCRIPTION
`OnAfterInsertEvent(VAR Rec : Record; RunTrigger : Boolean)`	Executed after a record is inserted in a table.
`OnBeforeModifyEvent(VAR Rec : Record; VAR xRec : Record; RunTrigger : Boolean)`	Executed before a record is modified in a table.
`OnAfterModifyEvent(VAR Rec : Record; VAR xRec : Record; RunTrigger : Boolean)`	Executed after a record is modified in a table.
`OnBeforeRenameEvent(VAR Rec : Record; VAR xRec : Record; RunTrigger : Boolean)`	Executed before a record is renamed in a table.
`OnAfterRenameEvent(VAR Rec : Record; VAR xRec: Record; RunTrigger : Boolean)`	Executed after a record is renamed in a table.
`OnBeforeValidateEvent(VAR Rec : Record; VAR xRec : Record; CurrentFieldNo : Integer)`	Executed before a field is validated when its value has been changed.
`OnAfterValidateEvent(VAR Rec : Record; VAR xRec : Record; CurrentFieldNo : Integer)`	Executed after a field is validated when its value has been changed.

The following table describes the parameters of the trigger events:

PARAMETER	TYPE	DESCRIPTION
Rec	Record	The table that raises the event.
xRec	Record	The table that raises the event.
RunTrigger	Boolean	Specifies whether to execute the code in the event trigger when it is invoked. If this parameter is true, the code will be executed. If this parameter is false, then the code is not executed.
CurrentFieldNo	Integer	The number of the field that raises the event.

Order of Event Execution

The relative order of execution of database trigger events, table triggers, and database operations is as follows:

ORDER	ITEM	EXAMPLE
1	Trigger event (before)	OnBeforeDeleteEvent
2	Table trigger	OnDelete
3	Global table trigger in codeunit	OnDatabaseDelete
4	Database operations	Delete the record
5	Trigger event (after)	OnAfterDeleteEvent

Page trigger events

Page Trigger events are raised automatically by the system when it performs certain operations in a page object. Page trigger events are closely associated with the standard page triggers, such as OnOpenPage. OnClosePage, and OnAction.

Available Page Trigger Events

The following table describes the available page trigger events:

TRIGGER EVENT WITH SIGNATURE	DESCRIPTION
`OnBeforeActionEvent(VAR Rec : Record)`	Executed before the OnAction Trigger, which is called when a user selects an action on the page.
`OnAfterActionEvent(VAR Rec : Record)`	Executed after the OnAction Trigger, which is called when a user selects an action on the page.
`OnAfterGetCurrRecordEvent(VAR Rec : Record)`	Executed after the OnAfterGetCurrRecord Trigger, which is called after the current record is retrieved from the table.
`OnAfterGetRecordEvent(VAR Rec : Record)`	Executed after the OnAfterGetRecord Trigger, which is called after the record is retrieved from the table but before it is displayed to the user.
`OnBeforeValidateEvent(VAR Rec : Record, VAR xRec : Record)`	Executed before the OnValidate (Page fields) Trigger, which is called when a field loses focus after its value has been changed.
`OnAfterValidateEvent(VAR Rec : Record, VAR xRec : Record)`	Executed after the OnValidate (Page fields) Trigger, which is called when a field loses focus after its value has been changed.
`OnClosePageEvent(VAR Rec : Record)`	Executed after the OnClosePage Trigger, which is called when page closes after the OnQueryClosePage trigger is executed.
`OnDeleteRecordEvent(VAR Rec : Record, VAR AllowDelete : Boolean)`	Executed after the OnDeleteRecord Trigger, which is called before a record is deleted from a table.
`OnInsertRecordEvent(VAR Rec : Record, BelowxRec : Boolean, VAR xRec : Record, VAR AllowInsert : Boolean)`	Executed after the OnInsertRecord Trigger, which is called before a record is inserted in a table.
`OnModifyRecordEvent(VAR Rec : Record, VAR xRec : Record, VAR AllowModify : Boolean)`	Executed after the OnModifyRecord Trigger, which is called before a record is modified in a table.
`OnNewRecordEvent(VAR Rec: Record, BelowxRec : Boolean, VAR xRec : Record)`	Executed after the OnNewRecord Trigger, which is called before a new record is initialized.
`OnOpenPageEvent(VAR Rec : Record)`	Executed after the OnOpenPage Trigger, which is called after a page is initialized and run.
`OnQueryClosePageEvent(VAR Rec : Record, VAR AllowClose : Boolean)`	Executed after the OnQueryClosePage Trigger, which is called as a page closes and before the OnClosePage Trigger executes.

The following table describes the parameters of the trigger events:

PARAMETER	TYPE	DESCRIPTION
Rec	Record	The table that used page that raises the event.
xRec	Record	The table that used page that raises the event.
AllowDelete	Boolean	Specifies whether the OnDeleteRecord trigger call was successful and the record can be deleted. If this parameter is true, the code will be executed. If this parameter is false, then the code is not executed.
AllowModify	Boolean	Specifies whether the OnModifyRecord trigger call was successful and the record can be modified. If this parameter is true, the code will be executed. If this parameter is false, then the code is not executed.
BelowxRec	Boolean	Specifies whether the new record was inserted after the last record in the table (xRec).
AllowClose	Boolean	Specifies whether to the page can close. If this parameter is true, the code will be executed. If this parameter is false, then the code is not executed.

Publishing Events

2/17/2021 • 3 minutes to read • Edit Online

The first phase of implementing an event is publishing the event. Publishing an event exposes it in the application. It provides hook up points for subscribers to register to the event, and eventually handle the event if it's raised. An event is published by adding an AL method that is set up as an event publisher.

- Business and integration events require that you manually create an event publisher method for each event that you want to publish. An event publisher method declares the event in the application and makes it available for subscription. However, it doesn't raise the event. After an event is published, you can raise it in your application from where event subscribers can react and handle the event.
- Trigger events don't require that you create publisher methods. Trigger events are predefined event publisher methods that are called automatically at runtime. So trigger events are readily available to subscribers by default.

Creating an event publisher method to publish business and integration events

You create an event publisher method the same way you create any method in AL. But there are specific attributes that you set to make it an event publisher. Additionally, an event publisher method has the following requirements and restrictions that you must follow, otherwise you can't compile your code changes:

- An event publisher method can't include any code except comments.
- An event publisher method can't have a return value, variables, or text constants.

The following procedure provides an outline of the tasks that are involved in creating an event publisher method for declaring an event.

To create an event publisher method

1. Decide where you want to include the event publisher method.

   You can include an event publisher method in the AL code of any object type, such as codeunit, page, or table. You can create a new object or use an existing object.

   > **IMPORTANT**
   > If you include the event publisher method in a page object, the page must have a source table. Otherwise, you can't successfully create an event subscriber method to subscribe to the event.

2. Add an AL method to the object.

   If you don't want the event publisher to be raised from other objects than the one defining it, make it a local method by affixing it with `local`. The event still remains available to event subscribers from other objects.

   Give the method a name that has the format *On[Event]*, where *[Event]* is text that indicates what occurred, such as `OnAddressLineChanged`.

3. Decorate the method with either the Integration attribute or Business attribute as follows:

```
[IntegrationEvent(IncludeSender : Boolean, GlobalVarAccess : Boolean)]
```

or

```
[BusinessEvent(IncludeSender : Boolean)]
```

> **TIP**
> Use the `teventint` snippet for an integration event or the `teventbus` snippet for a business event to get started.

For more information about integration and business events, see Event Types.

4. Add parameters to the method as needed.

   You can include as many parameters of any type as necessary.

   Make sure to expose enough information. Parameters enable subscriber methods to add value to the application. However, don't expose unnecessary parameters that may constrain you from changing or extending methodically in the future.

You can now add code to the application that raises the event by calling the event publisher method. You can also create subscriber methods that handle the event when it's raised.

Example

This example creates the codeunit **50100 MyPublishers** to publish an integration event. The event is published by adding the global method called `OnAddressLineChanged`. The event takes a single text data type parameter.

> **NOTE**
> This example is part of a larger, simple scenario where when users change the address of a customer on the page **21 Customer Card**, you want to check that the address doesn't include a plus sign (+). If it does, you want to display a message. To accomplish this, you will publish an event that is raised when the **Address** field on **Customer Card** is changed, and add an event subscriber method to that includes logic that checks the address value and returns a message to the user if it contains a plus sign. For a complete description of this scenario and all the code involved, see Event Example.

```
codeunit 50100 MyPublishers
{
    [IntegrationEvent(false, false)]
    procedure OnAddressLineChanged(line : Text[100]);
    begin
    end;
}
```

The next step is to raise this event in the application. To see an example for how this event is raised, go to Raising Event Example.

Raising Events
Subscribing to Events

Raising Events

2/17/2021 • 2 minutes to read • Edit Online

After an event has been published by an event publisher method, you can modify the application to raise the event where it is needed. Subscribers of an event will not react on the event until it is raised in the application.

To raise an event, you add logic in AL code of the application to call the event publisher method that declares the event. The procedure for calling the event publisher method is the same as calling any other method in AL.

When the code that calls the event publisher method is run, all event subscriber methods that subscribe to the event are run. If there are multiple subscribers, the subscriber methods are run one at a time in no particular order. You cannot specify the order in which the subscriber methods are called.

If there are no subscribers to the published event, then the line of code that calls the event publisher method is ignored and not executed.

Snippet support

Typing the shortcut `teventsub` will create the basic event subscriber syntax when using the AL Language extension in Visual Studio Code.

> **TIP**
>
> Typing the keyboard shortcut `Ctrl + space` displays IntelliSense to help you fill in the attribute arguments and to discover which events are available to use.

Example

This example uses a page extension object **50100 MyCustomerExt** to modify the page **21 Customer Card** so that an event is raised when a user changes the **Address** field. This example assumes that the event has already been published by the event publisher method `OnAddressLineChanged` in a separate codeunit called **50100 MyPublishers**.

> **NOTE**
>
> This example is part of a larger, simple scenario where when users change the address of a customer on the page **21 Customer Card**, you want to check that the address does not include a plus sign (+). If it does, you want to return a message to the user. For a description of this scenario and all the code involved, see Event Example.

In the code that follows, the page extension object modifies the `OnBeforeValidate` trigger of the **Customer Card** page to raise the event `OnAddressLineChanged` which includes the new value of the **Address** field.

```
pageextension 50100 MyCustomerExt extends "Customer Card"
{
    layout
    {
        modify(Address)
        {
            trigger OnBeforeValidate();
            var
                Publisher: Codeunit MyPublishers;
            begin
                Publisher.OnAddressLineChanged(Address);
            end;
        }
    }
}
```

To learn about how the event used in this example is published, see Publishing Events Example.

The next step would be to subscribe to the event to handle to condition. To see an example of how to subscribe to this event, see Subscribing to Events Example.

Subscribing to Events

2/17/2021 • 5 minutes to read • Edit Online

To handle events, you design event subscribers. Event subscribers determine what actions to take in response to an event that has been raised. An event subscriber is a method that listens for a specific event that is raised by an event publisher. The event subscriber includes code that defines the business logic to handle the event. When the published event is raised, the event subscriber is called and its code is run.

Subscribing to an event tells the runtime that the subscriber method must be called whenever the publisher method is run, either by code (as with business and integration events) or by the system (as with trigger events). The runtime establishes the link between an event raised by the publisher and its subscribers, by looking for event subscriber methods.

There can be multiple subscribers to the same event from various locations in the application code. When an event is raised, the subscriber methods are run one at a time in no particular order. You can't specify the order in which the subscriber methods are called.

Creating an event subscriber method

You create an event subscriber method just like other methods except that you specify properties that set up the subscription to an event publisher. The procedure is slightly different for database and page trigger events than business and integration events. Business and integration events are raised by event publisher methods in application code. Trigger events are predefined system events that are raised automatically on tables and pages.

For an explanation about the different types, see Event Types.

To create an event subscriber method

1. Decide which codeunit to use for the event subscriber method.

   You can create a new codeunit or use an existing one.

2. Add an AL method to the codeunit.

   We recommend that you give the method a name that indicates what the subscriber does, and has the format *[Action][Event]*. *[Action]* is text that describes what the method does. *[Event]* is the name of the event publisher method to which it subscribes.

3. Add code to the method for handling the event.

4. Decorate the event subscriber method with the EventSubscriber attribute.

   ```
   [EventSubscriber(ObjectType::<Event Publisher Object Type>, <Event Publisher Object>, '<Published
   Event Name>', '<Published Event Element Name>', <SkipOnMissingLicense>, <SkipOnMissingPermission>)]
   ```

   Set the arguments according to the following table. For optional arguments, if you don't want to set a value, use an empty value (`''`). In this case, the default value, if any, is used.

ARGUMENT	DESCRIPTION	OPTIONAL

ARGUMENT	DESCRIPTION	OPTIONAL
`<Event Publisher Object Type>`	Specify the type of object that publishes the event. This argument can be `Codeunit`, `Page`, `Report`, `Table`, or `XMLPort`.	no
`<Event Publisher Object>`	Specify the object that publishes the event. You can set this argument to the ID, such as `50100`, or the recommended way is to use the object name by using the syntax `<Object Type>::"<Object Name>"`, such as `Codeunit::"MyPublishers"`, or for database triggers `Database::"Customer"`.	no
`<Published Event Name>`	Specify the name of method that publishes the event in the object that is specified by the `<Event Publisher Object>` parameter.	no
`<Published Event Element Name>`	Specifies the table field that the trigger event pertains to. This argument only requires a value for database trigger events, that is, when the `<Event Publisher Object Type>` is set to `Table` and the `<Published Event Name>` argument is a validate trigger event, such as `OnAfterValidateEvent`.	no
`<SkipOnMissingLicense>`	Set to `true` to skip the event subscriber method call if the user's license doesn't cover the event subscriber codeunit. If `false`, an error is thrown and the code execution stops. `false` is the default.	yes
`<SkipOnMissingPermission>`	Set to `true` to skip the event subscriber method call if the user doesn't have the correct permissions the event subscriber codeunit. If `false`, an error is thrown and the code execution stops. `false` is the default.	yes

TIP

There are couple things that can make defining an event subscriber method easier. You can use the `teventsub` snippet to get started. Then, typing the keyboard shortcut `Ctrl + space` displays IntelliSense to help you fill the attribute arguments and discover which events are available. Or, use the Shift+Alt+E keyboard shortcut to look up the event you want to subscribe to and insert the code.

5. Optionally, set the codeunit's **EventSubscriberInstance** property to specify how the event subscriber method will be bound to the instance of this codeunit.

   For more information, see EventSubscriberInstance Property.

Example 1

This example creates the codeunit **50101 MySubscribers** to subscribe to an event that has been published by the event publisher method called `OnAddressLineChanged` in the codeunit **50100 MyPublishers**. The event is raised by a change to the **Address** field on page **21 Customer Card**. This example assumes:

- The codeunit **50100 MyPublishers** with the event publisher method `OnAddressLineChanged` already exists. For an example, see Publishing Event Example.
- The code for raising the `OnAddressLineChanged` event has been added to the **Customer Card** page. For an example, see Raising Event Example.

The following code creates a codeunit called **50101 MySubscribers** that includes an event subscriber method, called `CheckAddressLine`. The method includes code for handling the published event.

```
codeunit 50101 MySubscribers
{
    EventSubscriberInstance = StaticAutomatic;

    [EventSubscriber(ObjectType::Codeunit, Codeunit::"MyPublishers", 'OnAddressLineChanged', '', true,
true)]
    procedure CheckAddressLine(line : Text[100]);
    begin
        if (STRPOS(line, '+') > 0) then begin
            MESSAGE('Can''t use a plus sign (+) in the address [' + line + ']');
        end;
    end;
}
```

> **NOTE**
>
> This example is part of a larger, simple scenario where when users change the address of a customer on the page **21 Customer Card**, you want to check that the address does not include a plus sign (+). If it does, you want to return a message to the user. For a description of this scenario and all the code involved, see Event Example.

Example 2

This example achieves the same as example 1, except it subscribes to the page trigger event `OnBeforeValidateEvent` on the `Address` field instead. By using the page trigger, you avoid creating an event publisher and adding code to raise the event. The event is raised automatically by the system.

```
codeunit 50101 MySubscribers
{
    EventSubscriberInstance = StaticAutomatic;

    [EventSubscriber(ObjectType::Page, Page::"Customer Card", 'OnBeforeValidateEvent', 'Address', true,
true)]
    local procedure CheckAddressLine(var Rec : Record Customer)
    begin
        if (STRPOS('Rec.Address', '+') > 0) then begin
            MESSAGE('Can''t use a plus sign (+) in the address [' + 'Address' + ']');
        end;
    end;
}
```

Discoverability of Events

2/17/2021 • 2 minutes to read • Edit Online

You subscribe to events to extend application and interact with the base application and other extensions. This topic describes how to discover events that you can subscribe to without writing the code manually. Using the **Event Recorder**, you can record the events that are published and raised while performing the actions of your scenario. For example, record the events raised when you post a purchase order and identify the events that you need for your extension. You can retrieve the events in the form of AL snippet code and use them in Visual Studio Code directly.

Using the Event Recorder

You can launch the event recorder session from Dynamics 365 Business Central. It can be accessed in the following two ways:

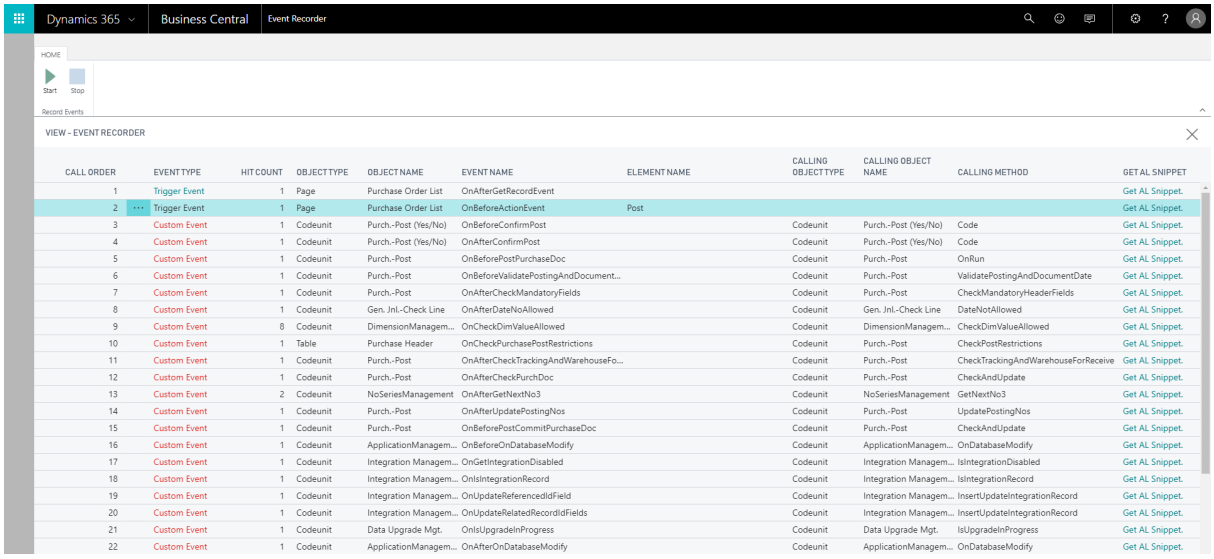
- In Dynamics 365 Business Central, search for **Event Recorder**.
- In Visual Studio Code, use the `Ctrl+Shift+P` keys and select the **Open Event Recorder** command to open the **Event Recorder** page in the Dynamics 365 Business Central web client.

> **NOTE**
>
> The event recorder captures all events that are raised in the same session. If the actions performed by the user are in another session, then the event recorder will not capture them.

How to record events

The following steps describe how to record events when you are on the **Event Recorder** page.

1. On the **Event Recorder** page, in the upper right corner, choose **Open this page in a new window**.
2. Then on the **Event Recorder** page, choose **Record Events**, and then choose the **Start** button.
3. In the original window, perform all the actions that you want to record while the event recorder session is on. For example, post a purchase order.
4. After you have performed the actions of your scenario, navigate back to the window that has the **Event Recorder** page open and click the **Stop** button to finish recording.
   All the events raised while performing the actions of your scenario are recorded and can be viewed on as shown below.



CALL ORDER	EVENT TYPE	HIT COUNT	OBJECT TYPE	OBJECT NAME	EVENT NAME	ELEMENT NAME	CALLING OBJECT TYPE	CALLING OBJECT NAME	CALLING METHOD	GET AL SNIPPET
1	Trigger Event	1	Page	Purchase Order List	OnAfterGetRecordEvent					Get AL Snippet.
2	Trigger Event	1	Page	Purchase Order List	OnBeforeActionEvent	Post				Get AL Snippet.
3	Custom Event	1	Codeunit	Purch.-Post (Yes/No)	OnBeforeConfirmPost		Codeunit	Purch.-Post (Yes/No)	Code	Get AL Snippet.
4	Custom Event	1	Codeunit	Purch.-Post (Yes/No)	OnAfterConfirmPost		Codeunit	Purch.-Post (Yes/No)	Code	Get AL Snippet.
5	Custom Event	1	Codeunit	Purch.-Post	OnBeforePostPurchaseDoc		Codeunit	Purch.-Post	OnRun	Get AL Snippet.
6	Custom Event	1	Codeunit	Purch.-Post	OnBeforeValidatePostingAndDocument...		Codeunit	Purch.-Post	ValidatePostingAndDocumentDate	Get AL Snippet.
7	Custom Event	1	Codeunit	Purch.-Post	OnAfterCheckMandatoryFields		Codeunit	Purch.-Post	CheckMandatoryHeaderFields	Get AL Snippet.
8	Custom Event	1	Codeunit	Gen. Jnl.-Check Line	OnAfterDateNoAllowed		Codeunit	Gen. Jnl.-Check Line	DateNotAllowed	Get AL Snippet.
9	Custom Event	8	Codeunit	DimensionManagem...	OnCheckDimValueAllowed		Codeunit	DimensionManagem...	CheckDimValueAllowed	Get AL Snippet.
10	Custom Event	1	Table	Purchase Header	OnCheckPurchasePostRestrictions		Codeunit	Purch.-Post	CheckPostRestrictions	Get AL Snippet.
11	Custom Event	1	Codeunit	Purch.-Post	OnAfterCheckTrackingAndWarehouseFo...		Codeunit	Purch.-Post	CheckTrackingAndWarehouseForReceive	Get AL Snippet.
12	Custom Event	1	Codeunit	Purch.-Post	OnAfterCheckPurchDoc		Codeunit	Purch.-Post	CheckAndUpdate	Get AL Snippet.
13	Custom Event	2	Codeunit	NoSeriesManagement	OnAfterGetNextNo3		Codeunit	NoSeriesManagement	GetNextNo3	Get AL Snippet.
14	Custom Event	1	Codeunit	Purch.-Post	OnAfterUpdatePostingNos		Codeunit	Purch.-Post	UpdatePostingNos	Get AL Snippet.
15	Custom Event	1	Codeunit	Purch.-Post	OnBeforePostCommitPurchaseDoc		Codeunit	Purch.-Post	CheckAndUpdate	Get AL Snippet.
16	Custom Event	1	Codeunit	ApplicationManagem...	OnBeforeOnDatabaseModify		Codeunit	ApplicationManagem...	OnDatabaseModify	Get AL Snippet.
17	Custom Event	1	Codeunit	Integration Managem...	OnGetIntegrationDisabled		Codeunit	Integration Managem...	IsIntegrationDisabled	Get AL Snippet.
18	Custom Event	1	Codeunit	Integration Managem...	OnIsIntegrationRecord		Codeunit	Integration Managem...	IsIntegrationRecord	Get AL Snippet.
19	Custom Event	1	Codeunit	Integration Managem...	OnUpdateReferencedIdField		Codeunit	Integration Managem...	InsertUpdateIntegrationRecord	Get AL Snippet.
20	Custom Event	1	Codeunit	Integration Managem...	OnUpdateRelatedRecordIdFields		Codeunit	Integration Managem...	InsertUpdateIntegrationRecord	Get AL Snippet.
21	Custom Event	1	Codeunit	Data Upgrade Mgt.	OnIsUpgradeInProgress		Codeunit	Data Upgrade Mgt.	IsUpgradeInProgress	Get AL Snippet.
22	Custom Event	1	Codeunit	ApplicationManagem...	OnAfterOnDatabaseModify		Codeunit	ApplicationManagem...	OnDatabaseModify	Get AL Snippet.

5. Choose **Get AL Snippet** to get the event subscription code in AL. You can use the AL snippet code in Codeunits to subscribe to those events.

> **NOTE**
>
> The recorded events are not saved. When you refresh the page, the recorded events disappear.

For more information on how to subscribe to events, see Subscribing to Events.

Recorded Events

All the recorded events display in the order they were called. The Event Recorder page provides information on the events that were raised including the details whether the raised events were trigger events or custom events. The custom events are either Business Events or Integration Events. For more information, see Event Types.

You can identify the Event types, additionally, you can discover which object types and methods raised the events with the details like calling methods, object types, and object names. For more information about Events, see Events in AL.

Event Example

2/17/2021 • 2 minutes to read • Edit Online

This article includes a simple code example to explain how to use Business Central events. The example uses an event to verify a customer's address. When a user changes the address of a customer on the page **21 Customer Card**, an event is used to check that the address doesn't include a plus sign (+). If it does, a message is displayed in the client. In this example, you'll add code that:

- Publishes an event that is raised when the **Address** field on **Customer Card** is changed.
- Raises the event from the **Customer Card** page
- Subscribes to the event to check the address value and return a message to the user if it contains a plus sign.

```
// The following code creates codeunit that publishes the `OnAddressLineChanged` event.

codeunit 50100 MyPublishers
{
    [IntegrationEvent(false, false)]
    procedure OnAddressLineChanged(line: Text[100])
    begin
    end;
}

// The following code extends the Customer Card page to raise the `OnAddressLineChanged` event
// when the Address field is changed.
pageextension 50100 MyCustomerExt extends "Customer Card"
{
    layout
    {
        modify(Address)
        {
            trigger OnBeforeValidate();
            var
                Publisher: Codeunit MyPublishers;
            begin
                Publisher.OnAddressLineChanged(Address);
            end;
        }
    }
}

// The following code creates an event subscriber codeunit.
// It declares the `CheckAddressLine` event subscriber that listens for OnAddressLineChanged event.
// The event subscriber displays a message in the client when '+' is used in the **Address** field.

codeunit 50101 MySubscribers
{
    //Set the event subscribers to bind automatically to the event
    EventSubscriberInstance = StaticAutomatic;

    [EventSubscriber(ObjectType::Codeunit, Codeunit::"MyPublishers", 'OnAddressLineChanged', '', true,
true)]
    procedure CheckAddressLine(line: Text[100]);
    begin
        if (STRPOS(line, '+') > 0) then begin
            MESSAGE('Can''t use a plus sign (+) in the address [' + line + ']');
        end;
    end;
}
```

TIP

This example binds the event subscriber automatically to the event. You can also bind the event subscriber manually, by setting the EventSubscriberInstance property. For more information, including an example, see EventSubscriberInstance property.

Walkthrough: Implementing New Workflow Events and Responses

2/17/2021 • 12 minutes to read • Edit Online

If a business scenario requires a workflow event or a workflow response that is not supported in a Business Central solution, you must implement it by extending the application code.

In the **Workflow** page, the workflow administrator creates a workflow by listing the involved steps on the lines. Each step consists of a workflow event, moderated by event conditions, and a workflow response, customized by response options. You define workflow steps by filling fields on workflow lines from fixed lists of event and response values representing scenarios that are supported by the application code. For more information, see Set Up Workflows in the business functionality content.

The following procedure describes how to add a new workflow event and a new workflow response and then register the involved object relations, so that the new elements can be used in workflows. You can then share your code as an app or a per-tenant extension, for example. The workflow administrator can then select the new workflow event and response from the **Workflow** page to incorporate them in new or existing workflow steps.

> **IMPORTANT**
>
> To ensure that custom workflow records are upgraded correctly, you must add new workflow events, workflow responses, and workflow table relations to dedicated extension points, as described in this procedure. During an upgrade to the next version, the libraries of workflow events, responses, and table relations are removed and then recreated with the latest content from Microsoft. By adding your custom workflow records using subscriptions to the Microsoft-provided extension points, you ensure that your custom record library gets recreated after an upgrade.

> **NOTE**
>
> This topic refers to two types of events:
>
> - *Workflow event*: An occurrence in the application that users in the client can select from the **Workflow** page to define workflow steps. For more information, see Workflows in Dynamics 365 Business Central in the business functionality content.
> - *Event*: The declaration of the occurrence or change in the application. Workflow events typically subscribe to events. For more information, see Events in AL.

The development work involved in creating a new workflow event and a related workflow response consists of the following tasks, as a minimum:

1. Create a workflow event
    a. Create a workflow event code that identifies the workflow event
    b. Add the workflow event code to the **Workflow Event** table
    c. Create and publish an event that the workflow event subscribes to
    d. Raise the event
    e. Subscribe to the event and implement the workflow event
2. Create a workflow response

a. Create a workflow response code that identifies the workflow response

b. Add the workflow response code to the **Workflow Response** table

c. Implement the workflow response

d. Enable that the workflow response can be executed

e. Add a new workflow response option

3. Register workflow event/response combinations needed for the new workflow response
4. Register workflow event hierarchies needed for the new workflow event
5. Creating table relations between entities used when the new workflow event and response are used

> **NOTE**
> Data and code samples in this procedure refer loosely to a workflow step of sending a notification when a purchase header is posted. However, the procedure alone does not result in a complete solution. The purpose of the walkthrough is simply to illustrate the process.

Workflow event

In this section, we'll create a code to identify the workflow event, add the workflow event to the library, create an event that the workflow event subscribes to, raise the event, and then subscribe to the event and implement the workflow event.

Each subsection takes you through the discrete steps.

To create a workflow event code that identifies the workflow event

1. Create a new .al file, such as MyWorkflowEvents.codeunit.al, and add a codeunit that will be used for new workflow events. Name it to reflect that it is used to identify the new workflow event, such as `MyWorkflowEvents`.
2. Add a method in the codeunit. Optionally, use the shortcut `teventint`. Name the method to reflect that it is used to identify the workflow event, such as `MyWorkflowEventCode`, and make it take 128 characters of code as a parameter.

> **TIP**
> The terminology can be a bit confusing here. This method is not an *AL event*. It's a method that declares the *workflow event*, and it will subscribe to an *AL event* that, when triggered, will trigger the *workflow event*.

Your MyWorkflowEvents.codeunit.al file now looks like this:

```
codeunit 50101 MyWorkflowEvents
{
    procedure MyWorkflowEventCode(): code[128];
    begin
    end;
}
```

To add the workflow event code to the Workflow Event table

1. Create another method in the codeunit. Name it to reflect that it is used to add the workflow event to the library, such as `AddMyWorkflowEventsToLibrary`.

This method will subscribe to the `OnAddWorkflowEventsToLibrary` method in the `Workflow Event Handling` codeunit in the base application, so you must set the EventSubscriber attribute, and you must add code that handles the event.

The following code illustrates the new method in the `MyWorkflowEvents` codeunit:

```
    [EventSubscriber(ObjectType::Codeunit, Codeunit::"Workflow Event Handling",
'OnAddWorkflowEventsToLibrary', '', true, true)]
    procedure AddMyWorkflowEventsToLibrary()
    var
        WorkflowEventHandling: Codeunit"Workflow Event Handling";
    begin
        WorkflowEventHandling.AddEventToLibrary(MyWorkflowEventCode(), Database::"Purchase Header", 'My
workflow event description', 0, false);
    end;
```

To publish an event that the workflow event subscribes to

1. Create another codeunit, such as MyEvents.codeunit.al, and add a method that publishes your event. Name the method to reflect that it is used as the publisher event, such as `OnAfterPostPurchaseHeader`.

   ```
   codeunit 50102 MyEvents
   {
       [IntegrationEvent(false, false)]
       procedure OnAfterPostPurchaseHeader(PurchaseHeader: Record "Purchase Header")
       begin
       end;
   }
   ```

   Select the event type that is relevant for the workflow event, such as Integration. For more information, see Event Types.

To raise the event

1. Create an object or an extension object to add the code that will raise the event that triggers the workflow event, such as the `Purch.-Post` codeunit.

   The following code raises the event by extending the `Purchase Order` page object in a new file, `MyPurchOrder.PageExt.al`.

   ```
   pageextension 50100 WFW_PurchaseOrder extends "Purchase Order"
    {
        layout
        {
            modify(Status)
            {
                trigger OnBeforeValidate();
                var
                    MyEvents: Codeunit MyEvents;
                begin
                    MyEvents.OnAfterPostPurchaseHeader(Rec)
                end;
            }
        }
    }
   ```

   For more information, see Raising Events.

To subscribe to the event and implement the workflow event

1. Go back to the MyWorkflowEvents.codeunit.al file file and add another method in the `MyWorkflowEvents` codeunit. Name the new method to reflect that it is used to subscribe to and implement the workflow event, such as `RunWorkflowOnAfterPostPurchaseHeader`.

The following code illustrates the new workflow event that subscribes to your previously created event:

```
[EventSubscriber(ObjectType::Codeunit, Codeunit::MyEvents, 'OnAfterPostPurchaseHeader', '', true, true)]
local procedure RunWorkflowOnAfterPostPurchaseHeader(var PurchaseHeader: Record "Purchase Header")
var
    WorkflowManagement: Codeunit "Workflow Management";
begin
    WorkflowManagement.HandleEvent(MyWorkflowEventCode, PurchaseHeader);
end;
```

Another task that you can perform at this point is to specify which filter fields appear in the **Workflow Event Conditions** page.

For more information, see Subscribing to Events.

You have now created a new workflow event. Next, we'll create a new workflow response that relates to the workflow event.

Workflow response

Create a new .al file, such as MyWorkflowResponses.codeunit.al, with code to identify the workflow response, add the workflow response code to the library, implement the workflow response, and then enable that the workflow response can be executed.

To create a workflow response code that identifies the workflow response

1. Add a new codeunit that will be used for the new workflow responses. Name it to reflect that it handles your new responses, such `MyWorkflowResponses`.

2. Add a method in the codeunit. Name the method to reflect that it is used to identify the workflow response, such as `MyWorkflowResponseCode` with a return value of code (128).

To add the workflow response code to the Workflow Response table

1. Add another method in the codeunit that will be the event subscriber. Name it to reflect that it is used to add the workflow response to the library, such as `AddMyWorkflowResponsesToLibrary` and set it to subscribe to the OnAddWorkflowResponsesToLibrary `method in the` Workflow Response Handling` codeunit.

```
 [EventSubscriber(ObjectType::Codeunit, Codeunit::"Workflow Event Handling",
'OnAddWorkflowEventPredecessorsToLibrary', '', false, false)]
 local procedure AddWorkflowEventHierarchiesToLibrary(EventFunctionName: Code[128])
 begin
 end;
```

2. Add a local variable for the codeunit:

```
[...]
var
WorkflowResponseHandling: Codeunit "Workflow Response Handling";
```

3. In the method, write code that registers the response, so that you end up with something like the following code.

```
 [EventSubscriber(ObjectType::Codeunit, Codeunit::"Workflow Response Handling",
'OnAddWorkflowResponsesToLibrary', '', true, true)]
 local procedure AddMyWorkflowResponsesToLibrary()
 var
     WorkflowEventHandling: codeunit "Workflow Event Handling";
 begin
     WorkflowResponseHandling.AddResponseToLibrary(MyWorkflowResponseCode, Database::"Purchase
Header", 'Send a notification.', 'GROUP 0');
     End
 end;
```

NOTE

In the To add a new workflow response option section, you will change the GROUP value to *50100*. This way, you'll be able to see the workflow in action.

The codeunit now looks something like this:

```
codeunit 50103 MyWorkflowResponses
{
    procedure MyWorkflowResponseCode(): code[128];
    begin
    end;

    [EventSubscriber(ObjectType::Codeunit, Codeunit::"Workflow Response Handling",
'OnAddWorkflowResponsesToLibrary', '', true, true)]
    local procedure AddMyWorkflowResponsesToLibrary()
    var
        WorkflowResponseHandling: Codeunit "Workflow Response Handling";
    begin
        WorkflowResponseHandling.AddResponseToLibrary(MyWorkflowResponseCode, Database::"Purchase Header",
'Send a notification.', 'GROUP 0');
    end;
}
```

To implement the workflow response

1. Create another method in the codeunit. Name it to reflect that it is used to implement the workflow response, such as `MyWorkflowResponse`, that takes a parameter based on the Purchase Header table.
2. In the method, write code that handles the response, so that you end up with something like the following code.

```
procedure MyWorkflowResponse(PurchaseHeader: Record "Purchase Header")
begin
    Message('Status change on: %1 %2', PurchaseHeader."Document Type", PurchaseHeader."No.");
end;
```

To enable that the workflow response can be executed

1. Create another method in the codeunit that subscribes to the `OnExecuteWorkflowResponse` event on the `Workflow ResponseHandling` codeunit. Name it to reflect that it is used to enable the new workflow response to be executed alongside existing workflow responses, such as `ExecuteMyWorkflowResponses`.
2. In the event subscriber method, write code that enables the response, so that you end up with something like the following code.

```
[EventSubscriber(ObjectType::Codeunit, Codeunit::"Workflow Response Handling",
'OnExecuteWorkflowResponse', '', true, true)]
procedure ExecuteMyWorkflowResponses(ResponseWorkflowStepInstance: Record "Workflow Step Instance";
var ResponseExecuted: Boolean; var Variant: Variant; xVariant: Variant)
var
    WorkflowResponse: record "Workflow Response";
begin
    if WorkflowResponse.GET(ResponseWorkflowStepInstance."Function Name") then
        case WorkflowResponse."Function Name" of
            MyWFResponseCode:
                BEGIN
                    MyWorkflowResponse(Variant);
                    ResponseExecuted := TRUE;
                END;
        END;
end;
```

You'll update this method in step 8 in the next section.

To add a new workflow response option

1. Create a table extension object that extends table 1523, **Workflow Step Argument**, such as MyWorkflowStepArgument.TableExt.al.
2. Add a field that reflects your new response option, such as **My New Response Option**.

```
tableextension 50100 WFW_WorkflowStepArgument extends "Workflow Step Argument"
{
    fields
    {
        field(50100; "My New Response Option"; Text[100])
        {
        }
    }
}
```

3. Create a page extension object that extends page 1523, **Workflow Response Options**, such as MyworkflowStepArgument.PageExt.al.
4. Add a group and a control for the new field.

```
pageextension 50101 WFW_WorkflowResponseOptions extends "Workflow Response Options"
{
    layout
    {
        addlast(content)
        {
            group(Group50100)
            {
                Visible = Rec."Response Option Group" = 'GROUP 50100';
                ShowCaption = false;

                field(MyNewResponseOption; Rec."My New Response Option")
                {
                    ApplicationArea = All;
                }
            }
        }
    }
}
```

Here, the **Visibility** property of the group is set to `"Response Option Group" = 'GROUP 51000'`, but you can

set it to another value.

5. Go back to MyWorkflowResponses.codeunit.al and the ´AddMyWorkflowResponsesToLibrary` method.
6. In the method code, change `'GROUP 0'` to `'GROUP 50100'`.

```
[EventSubscriber(ObjectType::Codeunit, Codeunit::"Workflow Response Handling",
'OnAddWorkflowResponsesToLibrary', '', true, true)]
local procedure AddMyWorkflowResponsesToLibrary()
var
    WorkflowResponseHandling: Codeunit "Workflow Response Handling";
begin
    WorkflowResponseHandling.AddResponseToLibrary(MyWorkflowResponseCode, Database::"Purchase
Header", 'Send a notification.', 'GROUP 50100');
end;
```

7. To use the new option in the `MyWorkflowResponse` method, proceed to add a local parameter and a local variable and show a message as the response.

```
 local procedure MyWorkflowResponse(PurchaseHeader: Record "Purchase Header"; WorkflowStepInstance:
Record "Workflow Step Instance")
 var
     WorkflowStepArgument: Record "Workflow Step Argument";
 begin
     if WorkflowStepArgument.Get(WorkflowStepInstance.Argument) then;

     Message('Status change on: %1 %2.\%3', PurchaseHeader."Document Type", PurchaseHeader."No.",
WorkflowStepArgument."My New Response Option")
 end;
```

8. In the `ExecuteMyWorkflowResponses` method, make the following code change:

   Change from this code: `MyWorkflowResponse(Variant);`

   Change to this code: `MyWorkflowResponse(Variant,ResponseWorkflowStepInstance);`

   You have now created the actual workflow event and response. Proceed to perform various tasks that enable them to be used in workflows.

Register workflow event/response combinations

In this section, you'll add new workflow event/response combinations to table 1509 **WF Event/Response Combination** so that they appear correctly in the **Workflow Events** and **Workflow Responses** pages.

To register workflow event/response combinations needed for the new workflow response

1. Open the codeunit that you created in the Workflow response section, `My Workflow Responses`.
2. Create another method in the codeunit that subscribes to the `OnAddWorkflowResponsePredecessorsToLibrary` event on the `Workflow Response Handling` codeunit . Name it to reflect that it is used to add the workflow event/response combinations to table 1509 **WF Event/Response Combination**, such as `AddMyWorkflowEventResponseCombinationsToLibrary`.

```
[EventSubscriber(ObjectType::Codeunit, Codeunit::"Workflow Response Handling",
'OnAddWorkflowResponsePredecessorsToLibrary', '', false, false)]
local procedure AddMyworkflowEventOnAddWorkflowResponsePredecessorsToLibrary(ResponseFunctionName:
Code[128])
var
    MyWorkflowEvents: Codeunit MyWorkflowEvents;
    WorkflowResponseHandling: Codeunit "Workflow Response Handling";
begin
    Case ResponseFunctionName of
        MyWorkflowResponseCode():
            WorkflowResponseHandling.AddResponsePredecessor(MyWorkflowResponseCode(),
MyWorkflowEvents.MyWorkflowEventCode());
    End
end;
```

In the method, write code that registers event/response combinations that you want to support in your application, using a CASE statement, such as the code in the example above.

You can also do this work from the user interface on page 1507 **Workflow-Event-Response-Combinations**.

Register workflow event hierarchies

In this section, you'll add new workflow event/event combinations to table 1509 **WF Event/Response Combination** so that they workflow events appear in the correct hierarchy in the **Workflow Events** page.

To register workflow event hierarchies needed for the new workflow event

1. Go back to the MyWorkflowEvents.codeunit.al file with the codeunit that you created in the To create a workflow event code that identifies the workflow event section, `My Workflow Events`.
2. Create another method in the codeunit that subscribes to the `OnAddWorkflowEventPredecessorsToLibrary` event on the `Workflow Event Handling` codeunit. Name it to reflect that it is used to add the workflow event hierarchies to table 1509 **WF Event/Response Combination**, such as `AddWorkflowEventHierarchiesToLibrary`.

```
[EventSubscriber(ObjectType::Codeunit, Codeunit::"Workflow Event Handling",
'OnAddWorkflowEventPredecessorsToLibrary', '', false, false)]
local procedure AddWorkflowEventHierarchiesToLibrary(EventFunctionName: Code[128])
var
    WorkflowEventHandling: codeunit "Workflow Event Handling";
begin
    Case EventFunctionName of
        MyWorkflowEventCode():
            //WorkflowEventHandling.AddEventPredecessor(MyWorkflowEventCode(),
WorkflowEventHandling./*[Add your predecessor event code]*/);
            ;
    End
end;
```

In the method, write code that registers event hierarchies that you want to support in your application, using a CASE statement, such as the code in the example above.

You can also do this work from the user interface on page 1506 **Workflow-Event-Hierarchies**.

Create table relations

Workflows events can be executed on different types of records. To keep track of these, you must define relations between the involved records. In this section, you'll create relationships between the entities that are

used when the new workflow event and response are used.

To create table relations between entities that are processed when the new workflow event and response are used in workflows

1. Got back to the MyWorkflowEvents.codeunit.al file with the codeunit that you created in the To create a workflow event code that identifies the workflow event section, `My Workflow Events`.

2. Create another method in the codeunit that subscribes to the `OnAddWorkflowTableRelationsToLibrary` event on the `Workflow Event Handling` codeunit. Name it to reflect that it is used add workflow table relations in table 1505 **Workflow Table Relation**, such as `AddWorkflowTableRelationsToLibrary`.

   ```
   [EventSubscriber(ObjectType::Codeunit, Codeunit::"Workflow Event Handling",
   'OnAddWorkflowTableRelationsToLibrary', '', false, false)]
   local procedure AddWorkflowTableRelationsToLibrary()
   var
       WorkflowSetup: Codeunit "Workflow Setup";
   begin
       WorkflowSetup.InsertTableRelation(Database::"Purchase Header", 1, Database::"Approval Entry", 2);
   end;
   ```

   In the method, write code that registers table relations that you want to support in your application, such as the example above.

   You can also do this work from the user interface on page 1509 **Workflow Table-Relations**.

You have now enabled a new workflow scenario by implementing the required workflow event and response in the application code. The workflow administrator can now select the workflow event and workflow response from the **Workflow** page to define new or edit existing workflows. For more information, see Set Up Workflows in the business functionality content.

Notifications

2/17/2021 • 5 minutes to read • Edit Online

Notifications provide a programmatic way to send non-intrusive information to the User Interface (UI) in the Web client. Notifications differ from messages initiated by the **Message** method. Messages are modal, which means users are typically required to address the message and take some form of corrective action before they continue working. On the other hand, notifications are non-modal. Their purpose is to give users information about a current situation, but do not require any immediate action or block users from continuing with their current task. For example, you could have a notification that a customer's credit limit is exceeded.

Notifications in the UI

In the UI, notifications appear in the **Notification** bar (similar to validation errors) at the top of the page on which a user is currently working. The user can then choose to dismiss the notification, which clears it. Or, if actions are defined on notification, the user can choose one of the actions.

- There can be multiple notifications. The notifications appear in chronological order from top to bottom.
- Notifications remain for the duration of the page instance or until the user dismisses them or takes action on them.
- Notifications that are defined on sub-pages, for example in parts and FactBoxes, appear in the same **Notification** bar.
- Validation errors on the page will be shown first.

Notifications in the development environment

By using the **Notification** and **NotificationScope** data types and methods in AL, you can add code to send notifications to users. The following table provides an overview of the available methods. The sections that follow provide additional information about how to create notifications.

METHOD	DESCRIPTION
Message	Specifies the content of the notification that appears in the UI.
Scope	Specifies the scope in which the notification appears.
Send	Sends the notification to be displayed by the client.
AddAction	Adds an action on the notification.
SetData	Sets a data property value for the notification
GetData	Gets a data property value from the notification.
Recall	Recalls a sent notification.

Creating and sending a notification

You create a notification by using the **Message** and **Send** methods. The **Message** method defines the message

part of the notification. When the **Send** method is called, the notification is sent to the client and content of the message is displayed.

```
MyNotification.Message := 'This is a notification';
MyNotification.Send();
```

The **Send** method call should be the last statement in the notification code, after any **AddAction** or **SetData** method calls for the notification instance.

Defining the notification scope

The scope determines where the notification is broadcast in the client. There are two different scopes: *LocalScope* and *GlobalScope*.

- A *LocalScope* notification appears in context of the user's current task, that is, on the page the user is currently working on. *LocalScope* is the default.
- A *GlobalScope* notification is not directly related to the current task, and will appear regardless of which the page the user is viewing.

  > **NOTE**
  > *GlobalScope* is currently not supported. This will be implemented in a future release.

The following code creates a notification in the *LocalScope*:

```
MyNotification.Message := 'This is a notification';
MyNotification.Scope := NotificationScope::LocalScope;
MyNotification.Send();
```

Adding actions on a notification

You add actions on notifications by using the **AddAction** method. This method provides a way for you to create interactive notifications. By default, users have the option to dismiss the notifications. However, there might be cases where you want to provide users with different actions that they can take to address the notification, like opening an associated page for modifying data.

Conceptually, a notification action calls a method in a specified codeunit, passing the notification object in the call. The method includes the business logic for handling the action.

```
MyNotification.Message := 'This is a notification';
MyNotification.Scope := NotificationScope::LocalScope;
MyNotification.AddAction('Action 1',Codeunit::"Action Handler",'RunAction1');
MyNotification.AddAction('Action 2',Codeunit::"Action Handler",'RunAction2');
MyNotification.Send();
```

The basic steps for adding an action are as follows:

1. Create a global method in a new or existing codeunit. The method must have a **Notification** data type parameter for receiving the notification object.
2. Add AL code to the method for handling the action.
3. Specify the codeunit and method in the **AddAction** method call.

IMPORTANT

You can have more than one action on a notification. A LocalScope notification can have up to 3 actions. A GlobalScope notification can have up to 2 actions.

Sending data with a notification

You use the **SetData** and **GetData** methods to add data to a notification, which is typically needed when actions are invoked. The **SetData** method sets, or adds, data to the notification. The data is defined as text in a key-value pair. With the **GetData** method, you can then retrieve the data again.

The following code sets data for a notification:

```
MyNotification.Message := 'This is a notification';
MyNotification.Scope := NotificationScope::LocalScope;
MyNotification.SetData('Created',Format(CurrentDateTime,0,9));
MyNotification.SetData('ID',Format(CreateGuid(),0,9));
MyNotification.AddAction('Action 1',Codeunit::"Action Handler",'RunAction1');
MyNotification.AddAction('Action 2',Codeunit::"Action Handler",'RunAction2');
MyNotification.Send();
```

The following code gets the data for a notification:

```
DataValue := MyNotification.GetData('Created');
DataValue := MyNotification.GetData('ID');
```

Example

This simple example illustrates how notifications work and provides some insight into how you can use them. This example extends page **42 Sales Order** of the CRONUS International Ltd. demonstration database according to the following:

- The code compares a customer's balance with their credit limit. If the balance exceeds the credit limit, a notification is sent to the client.
- The notification includes an action, which has the caption **Change credit limit**, that opens page **21 Customer Card**. This enables the user to increase the credit limit.

To complete the example, follow these steps:

1. Create a page extension object that extends page **42 Sales Order**, and add the notification code on the **OnOpenPage** trigger.

```
pageextension 50100 CreditBalanceNotification extends "Sales Order"
{

    trigger OnOpenPage()
    var
        Customer: Record Customer;
        CreditBalanceNotification: Notification;
        OpenCustomer: Text;
        Text003: Label 'The current balance exceeds the credit limit.';
        Text004: Label 'Change credit limit';
    begin
        Customer.Get("Sell-to Customer No.");
        if Customer."Balance (LCY)" > Customer."Credit Limit (LCY)" then begin
            //Create the notification
            CreditBalanceNotification.Message(Text003);
            CreditBalanceNotification.Scope := NotificationScope::LocalScope;
            //Add a data property for the customer number
            CreditBalanceNotification.SetData('CustNumber', Customer."No.");
            //Add an action that calls the ActionHandler codeunit, which you define in the next step.
            CreditBalanceNotification.AddAction('Text004', Codeunit::"ActionHandler",
'OpenCustomer');
            //Send the notification to the client.
            CreditBalanceNotification.Send();
        end;
    end;
}
```

2. Create a codeunit called **ActionHandler** for handling the notification action. Add a global method called **OpenCustomer** that has a **Notification** data type parameter called **CreditBalanceNotification** for receiving the Notification object, and include the following code on the method:

```
codeunit 50100 ActionHandler
{
    trigger OnRun()
    begin

    end;

    procedure OpenCustomer(CreditBalanceNotification: Notification)
    var
        CustNumber: Text;
        CustNo: Text;
        CustRec: Record Customer;
        CustPage: Page "Customer Card";
    begin
        //Get the customer number data from the SetData() call.
        CustNo := CreditBalanceNotification.GetData(CustNumber);
        // Open the Customer Card page for the customer.
        if CustRec.Get(CustNo) then begin
            CustPage.SetRecord(CustRec);
            CustPage.Run();
        end else begin
            Error('Could not find Customer: ' + CustNo);
        end;
    end;
}
```

Task Scheduler

2/17/2021 • 2 minutes to read • Edit Online

The task scheduler enables you to control when certain operations or processes (in other words *tasks*) are run. Basically, a task is a codeunit or report that is scheduled to run at a specific data and time. Tasks run in a background session between the Dynamics 365 Business Central service instance and database. Behind the scenes, the task scheduler is used by the job queue to process job queue entries that are created and managed from the clients.

In AL code, you create and manage tasks by using the AL methods that are available for the **TASKSCHEDULER** data type.

METHOD	DESCRIPTION	FOR MORE INFORMATION, SEE
CreateTask	Adds a task to run a codeunit at a specified date and time.	CreateTask Method
SetTaskReady	Sets a task to the **Ready** state. A task cannot run until it is **Ready**.	SetTaskReady Method
TaskExists	Checks whether a specific task exists.	TaskExists Method
CancelTask	Cancels a scheduled task.	CancelTask Method

How task scheduler works

To set up a task, you create a codeunit that contains the logic that you want to run at a scheduled time. Optionally, you can create a second codeunit that contains the logic to handle the task if an error occurs for any reason. This codeunit is referred to as a *failure codeunit*. Once you have the codeunits, you can add AL code to the application that calls the CREATETASK method to schedule a task to run the codeunits. The CreateTask method can also specify the earliest date to run the task, and whether the task is in the ready state.

Task flow

Here is an overview of the process that a task goes through:

1. After you add a task, the task is recorded in table **2000000175 Scheduled Task** of the database.
2. If the task is in the ready state, when the scheduled time occurs, a new background session is started and the task codeunit is run.

   You can view the session in the table **2000000111 Session Event**.
3. If an error occurs, the following happens:

   a. If a failure codeunit is not specified, then the retry flow is initiated.

   b. If a failure codeunit has been specified, the error is passed in a call to the failure codeunit, and the failure codeunit is run.

      If the failure codeunit does not handle the error or fails itself, then the retry flow is initiated.

Error conditions and retry process

A task can fail under the following conditions:

- The company cannot be opened.
- A SQL connection or transient error occurred with the database.
- The Dynamics 365 Business Central service instance restarted while the task was being run.

When an error occurs, unless the task is interrupted by the failure codeunit, the server instance will rerun the task according to the following retry flow:

1. Two minutes after the first failure.
2. Four minutes after the second failure.
3. Fifteen minutes after the third failure and any subsequent failures up to a maximum of 10 times, after which the task is canceled.

About task sessions and permissions

The task runs in a background session, which means that there is no user interface. The behavior is similar to that of the STARTSESSION method, where any dialog boxes that would normally appear are suppressed. For more information about specific dialog boxes, see StartSession method.

The session runs by using the same user/credentials that are used when calling AL code. The user must have appropriate permissions to the codeunit and any other objects that are associated with the operation of the codeunit.

Using App Key Vaults with Business Central Extensions

2/17/2021 • 2 minutes to read • Edit Online

APPLIES TO: Business Central 2020 release wave 2 and later

Some Business Central extensions make web service calls to non-Business Central services. For example, one extension might call Azure Storage to read/write blobs. Another extension might call the extension publisher's web service to do an operation.

These web service calls are typically authenticated, which means the extension must provide a credential in the call. The credentials enable the other service to accept or reject the call. You can consider the credentials as a kind of secret to the extension. A secret shouldn't be leaked to customers, partners, or anybody else. So where can the extension get the secret from? Here is where Azure Key Vault is used. Azure Key Vault is a cloud service that works as a secure secrets store. It provides centralized storage for secrets, enabling you to control access and distribution of the secrets.

> **NOTE**
> For Business Central online, the app key vault feature is only supported for AppSource extensions.

Getting started

Getting extensions to use secrets from Azure Key Vault involves two areas of work: setting up and configuring Azure Key Vaults and developing the extensions to use secrets from Azure Key Vault.

Setting up and configuring Azure Key Vaults

An extension can retrieve secrets from one or two different Azure Key Vaults. These key vaults must be created in Azure, and the Business Central service configured to access key vaults. The setup process is different for online and on-premises. For more information, see:

- Setting up App Key Vaults for Business Central online
- Setting up App Key Vaults for Business Central on-premises

Developing the extensions to use secrets from Azure Key Vault

Once you have an Azure Key Vault, you can develop Business Central extensions to retrieve secrets from the key vault. In short, this work involves specifying the key vault's URL and adding code to retrieve a secret from the key vault.

For more information, see Using App Key Vault Secrets in Extensions.

Setting up App Key Vaults for Business Central Online

2/17/2021 • 3 minutes to read • Edit Online

APPLIES TO: Business Central 2020 release wave 2 and later

AppSource apps for Business Central can be developed to get secrets from Azure Keys Vaults. The app key vault feature is readily available for use on the service by all App Source apps. However, there are some onboarding tasks required.

> **IMPORTANT**
> With Business Central online, App key vaults can only be used with AppSource apps. They're not supported with per-tenant extensions.

> **TIP**
> You must also specify secrets in a key vault if you deploy Business Central as part of the Embed App program. Especially if you must support the Outlook add-in, in which case you must specify secrets for TEMPORARYDOCUMENTSTORAGEACCOUNT and TEMPORARYDOCUMENTSTORAGEKEY.

For more information about developing extensions with key vaults, see Using Key Vault Secrets in Business Central Extensions.

Create the Azure Key Vault with secrets

In this task, you create a key vault in Azure, and add the secrets that you want to make available to your extensions. An extension can use up to two key vaults, so you can create more than one.

There are different ways to create an Azure key vault. For example, you can use the Azure portal, Azure CLI, and more.

The easiest way is to use the Azure portal. For instructions, see Quickstart: Set and retrieve a secret from Azure Key Vault using the Azure portal.

For using other methods, see Azure Key Vault Developer's Guide.

Provision the key reader application in your Azure AD tenant

Your Business Central online solution is configured to use an Azure AD application for reading key vault secrets. The application is called **Dynamics 365 Business Central ISV Key Vault Reader**. Microsoft manages the key vault reader application, however, there are a couple tasks that you have to do to enable it. First, the application must be provisioned on your Azure AD tenant, as described here.

To provision the key vault reader application, use the Azure Active Directory PowerShell module.

1. Open Windows PowerShell as an administrator.
2. Install the Azure Active Directory PowerShell module.

```
Install-Module AzureAD
```

3. Import the Azure AD module.

```
Import-Module AzureAD
```

4. Connect to your Business Central Azure AD tenant.

   a. Run the following command:

   ```
   Connect-AzureAD
   ```

   b. Provide your sign-in name and password when prompted.

5. Create an Azure AD service principal using the following command:

```
New-AzureADServicePrincipal -AppId 7e97dcfb-bcdd-426e-8f0a-96439602627a
```

`7e97dcfb-bcdd-426e-8f0a-96439602627a` is the Application (client) ID of Microsoft's centralized Azure AD application.

This step provisions the application in your Azure AD tenant, where it now "lives" together with your key vaults.

Grant the key vault reader application permission to your key vaults

The next task is to grant the key vault reader application permission to read secrets from your key vaults. The steps in this task are done from the Azure portal.

1. Open the key vault in the portal.
2. Select **Access policies**, then **Add Access Policy**.
3. Set **Secret Permissions** to **Get**.
4. Choose **Select principal**, and on the right, search for either the application (client) ID **7e97dcfb-bcdd-426e-8f0a-96439602627a** or the display name **Dynamics 365 Business Central ISV Key Vault Reader**.
5. Select **Add**, then **Save**.

Contact Microsoft to enable the App Key Vault feature

Send an email to bcappkeyvaultonboard@microsoft.com to start the onboarding process. Do this step before you publish your updated extension to Partner Center.

The onboarding process involves a manual verification step that verifies that you own the AAD tenant that contains the key vaults.

Provide the following information in the email:

- Your AAD tenant ID. Obtain this information from the Azure portal by going to the Azure Active Directory Overview page.
- Your AppSource extensions, including names and App IDs, that should be enabled to read secrets from your key vaults.
- Optionally, a screenshot from the Azure portal showing the key vault and its access policies. The screenshot can help Microsoft catch configuration mistakes early in the process.

Configuring Business Central Server

Setting up App Key Vaults for Business Central On-premises

2/17/2021 • 7 minutes to read • Edit Online

APPLIES TO: Business Central 2020 release wave 2 and later

Business Central extensions can be developed to get secrets from Azure Keys Vaults. This article describes the tasks required to set up Azure Keys Vaults for storing extension secrets and configure them in your Business Central deployment.

For more information about developing extensions with key vaults, see Using Key Vault Secrets in Business Central Extensions.

Prerequisites

To complete the tasks in this article, you need:

- An Azure subscription with an Active Directory tenant.

  You sign up for an Azure subscription at https://azure.microsoft.com. For information about getting an Azure AD tenant, see How to get an Azure Active Directory tenant.

- A security certificate

  Later, you'll have to register and configure an application in Azure AD for reading key vaults. This step requires a certificate. The certificate is used to prove the application's identity when requesting upon request. For a production environment, obtain a certificate from a certification authority or trusted provider.

  In a test environment, if you don't have a certificate, then you can create your own self-signed certificate. For example, on the Business Central server computer, start Windows PowerShell as an administrator. Then at the prompt, run the following commands:

  ```
  $cert = New-SelfSignedCertificate -Subject "BusinessCentralKeyVaultReader" -Provider "Microsoft
  Strong Cryptographic Provider"
  $cert.Thumbprint
  Export-Certificate -Cert $cert -FilePath c:\certs\BusinessCentralKeyVaultReader.cer
  ```

  These commands add a certificate called BusinessCentralKeyVaultReader to the computer's **LocalMachine** > **Personal (My)** certificate store.

Create the Azure Key Vault with secrets

Now, you create one or more key vaults in Azure, and add the secrets that you want to make available to your extensions. An extension can be set up with one or two key vaults.

There are different ways to create an Azure key vault. For example, you can use the Azure portal, Azure CLI, and more.

- The easiest way is to use the Azure portal. For instructions, see Quickstart: Set and retrieve a secret from Azure Key Vault using the Azure portal.

  After you create the key vault, add the secrets.

- For using other methods, see Azure Key Vault Developer's Guide.

Register a key vault reader application in Azure AD

Next, register an application on your Azure AD tenant for reading secrets from the key vaults. When Azure AD authentication was set up, an Azure AD tenant was created in Azure. Reading key vaults requires a separate application registration with the Azure AD tenant. You can use an existing application.

The steps in this task are done from the Azure portal.

1. Sign in to Azure portal at portal.azure.com and set the portal to your Azure Active Directory tenant.
2. Register an Azure AD application for the reading key vault.

   You add the new application by using the Azure portal. For guidelines, see Register your application with your Azure Active Directory tenant.

   When you add an application to an Azure AD tenant, you must specify the following information:

SETTING	DESCRIPTION
Name	The name of your application as it will display to your users, such as *Business Central Key Vault Reader*.
Supported account types	Specifies which accounts that you would like your application to support. For purposes of this article, select **Accounts in this organizational directory only**.

   When completed, the **Overview** displays in the portal for the new application.

   Copy the **Application (client) ID**. You'll use this information later.
3. Upload the security certificate to the registered application.

   In this step, you upload the certificate file that you obtained as part of the prerequisites.

   Go to the key vault reader application overview page. Select **Certificates & secrets** > **Upload certificate**. Follow the instructions to locate and upload the certificate.

Grant the key vault reader application permission to key vaults

In this task, you grant the key vault reader application permission to read secrets from your key vaults.

The steps in this task are done from the Azure portal.

1. Open the key vault in the portal.
2. Select **Access policies**, then **Add Access Policy**.
3. Set **Secret Permissions** to **Get**.
4. Choose **Select principal**, and on the right, search for either **Application (client) ID** or display name for the key vault reader application.
5. Select **Add**.
6. Select **Save**.

At this point, the work in Azure is finished.

Configure the Business Central Server to use the Apps Key Vault feature

Next, you configure the Business Central Server instance to use the key vault reader application and its certificate, which you registered in Azure AD, for authenticating to the key vaults.

If you're running a container-based environment, you have two options for configuring the server instance. You can either do it manually or use the Set-BcContainerKeyVaultAadAppAndCertificate script. Using the Set-BcContainerKeyVaultAadAppAndCertificate script is simpler and recommended.

Configure a container-based Business Central Server instance

If you are running a container-based environment, use the Set-BcContainerKeyVaultAadAppAndCertificate.ps1 script that is available in the NAV Container Helper GitHub repository at https://github.com/microsoft/navcontainerhelper/blob/master/ContainerHandling/Set-BcContainerKeyVaultAadAppAndCertificate.ps1.

Manually configure a Business Central Server instance

To complete this task, you'll need the user name of the service account that runs the Business Central Server.

1. If not already done, import your key vault certificate and its private keys to the local certificate store for the Business Central server computer.

   You can import the certificate either using the MMC snap-in or Import-PfxCertificate cmdlet from a Windows PowerShell prompt.

   For example, the following PowerShell command installs a certificate to the local machine's personal store:

   ```
   Import-PfxCertificate -FilePath "C:\certificates\BusinessCentralKeyVaultReader.pfx" -Password
   (ConvertTo-SecureString -String "pfxpassword" -AsPlainText -Force) -CertStoreLocation
   Cert:\LocalMachine\My\
   ```

2. Give the service account used by the Business Central Server instance permission to access the certificates private key.

   To do this using the MMC:

   a. Open the MMC snap-in for certificates. See How to: View Certificates with the MMC Snap-in.

   b. Expand the **Certificates (Local Computer)** node, expand the **Personal** node, and then select the **Certificates** subfolder.

   c. In the right pane, right-click the certificate, select **All Tasks**, and then choose **Manage Private Keys**.

   d. In the **Security** dialog box, choose **Add**.

   e. In the **Select Users, Computers, Service Accounts, or Groups** dialog box, enter the name of the dedicated domain user account that is associated with Business Central Server, for example, NETWORK SERVICE. Then, choose the **OK** button.

   f. In the **Full Control** field, select **Allow**, and then choose the **OK** button.

3. Make a note of the certificate thumbprint because you'll need it in the next step. See How to: Retrieve the Thumbprint of a Certificate.

4. Configure the Business Central Server instance.

   Now, you'll configure App Key Vault settings on the server instance. The following table describes the settings that you must configure:

SETTING (KEY NAME)	VALUE
Client Certificate Store Location (AzureKeyVaultClientCertificateStoreLocation)	Set to the certificate store location where key vault certificate was stored. Example: LocalMachine
Client Certificate Store Name (AzureKeyVaultClientCertificateStoreName)	Set to the certificate store name where key vault certificate was stored. Example: MY
Client Certificate Thumbprint (AzureKeyVaultClientCertificateThumbprint)	Set to the thumbprint for the key vault certificate. Example: 649419e4fbb87340f5a0f995e605b74c5f6d943e
Client ID (AzureKeyVaultClientId)	Set to the **Application (client) ID** of the key vault reader application registered in your Azure AD tenant. Example: ed4129d9-b913-4514-83db-82e305163bec
Enable Publisher Validation (AzureKeyVaultAppSecretsPublisherValidationEnabled)	Specifies whether extensions can only use key vaults that belong to their publishers. Enabling this setting (`true`) blocks attempts in AL to read secrets from another publisher's key vault. When extensions that use key vault secrets are published, you must provide your Azure AD tenant ID, which is done by using the Publish-NAVApp cmdlet with the `-PublisherAzureActiveDirectoryTenantId` parameter. **Important** We recommend that you only set it to `false` if you trust all extensions that will be installed. For more information, see App Key Vaults - Security considerations. Example: true

You can configure the instance using the Business Central Server Administration tool or Set-NAVServerConfiguration cmdlet.

To use the Set-NAVServerConfiguration cmdlet, start the Business Central Administration Shell as an administrator, and run the following commands one at a time. Replace brackets with your own values.

```
Set-NAVServerConfiguration -ServerInstance <serverInstance> -KeyName
AzureKeyVaultClientCertificateStoreLocation -KeyValue <certificate store location>
Set-NAVServerConfiguration -ServerInstance <serverInstance> -KeyName
AzureKeyVaultClientCertificateStoreName -KeyValue <certifcate store>
Set-NAVServerConfiguration -ServerInstance <serverInstance> -KeyName
AzureKeyVaultClientCertificateThumbprint -KeyValue <certificate thumbprint>
Set-NAVServerConfiguration -ServerInstance <serverInstance> -KeyName AzureKeyVaultClientId -KeyValue
<application ID of key vault reader app in Azure>
Set-NAVServerConfiguration -ServerInstance <serverInstance> -KeyName
AzureKeyVaultAppSecretsPublisherValidationEnabled -KeyValue <true|false>
Restart-NAVServerInstance -ServerInstance <serverInstance>
```

At this point, you can run your extensions that use key vault secrets to read secrets from key vault.

TIP

If your on-premises solution uses the ImportStreamWithUrlAccess method, you must have set up an Azure blob storage account and stored the account name and account keys in the current subscription's Azure KeyVault using the identifiers TEMPORARYDOCUMENTSTORAGEACCOUNT and TEMPORARYDOCUMENTSTORAGEKEY. That way, your users can use the integration with Outlook.

Using Key Vault Secrets in Business Central Extensions

2/17/2021 • 6 minutes to read • Edit Online

APPLIES TO: Business Central 2020 release wave 2 and later

This article describes how to code an extension to retrieve secrets from Azure Key Vaults. Secrets are typically used when the extensions calls a web service. For an overview of app key vaults and secrets, see Using App Key Vaults with Extensions.

Developing an extension to use secrets from a key vault involves two tasks, as described in this article:

- Specifying the Azure Key Vault in the extension's manifest.
- Adding code to retrieve the secrets from the key vault.

Preparation

- Using secrets requires that you have at least one Azure Key Vault with secrets set up and configured for use by the service. If you don't already have an Azure Key Vault, see Setting up App Key Vaults for Business Central online or Setting up App Key Vaults for Business Central on-premises.
- For coding, you'll need the URI the Azure Key Vault that stores the secret and the name of the secret itself. If you don't have this information, you can get it from Azure portal. For instructions, see Quickstart: Set and retrieve a secret from Azure Key Vault using the Azure portal.

Specify the Azure Key Vault in extensions

You specify the key vaults for an extension in the extension's manifest file (app.json). To specify a key vault, you add the `"keyVaultUrls"` to the app.json, and set the value to the key vault's URL. For example, the following code snippet specifies a key vault that has the URI `https://mykeyvault.vault.azure.net`:

```
"keyVaultUrls":[
"https://mykeyvault.vault.azure.net"
]
```

You can specify up to two key vaults in the app.json, as shown in the following example code snippet:

```
"keyVaultUrls":[
"https://myfirstkeyvault.vault.azure.net",
"https://mysecondkeyvault.vault.azure.net"
]
```

Specifying two key vaults ensures a higher availability of secrets, especially if created in two different Azure regions. At runtime, the Business Central platform will iterate both key vaults until the secret is successfully retrieved. If one of the key vaults is unavailable for any reason, the extension will continue to execute because the other key vault will most likely be available.

Add code to retrieve secrets from the key vault

Next, you add code to the extension for reading secrets from the key vault at runtime. To read secrets, you use

the **Secrets** module of the System Application. Specifically, you'll use codeunit **3800 "App Key Vault Secret Provider"**. This codeunit includes two methods:

METHOD	DESCRIPTION
`TryInitializeFromCurrentApp(): Boolean`	Identifies the calling extension and initializes the codeunit with the key vaults specified in the extension's manifest.
`GetSecret(SecretName: Text, var SecretValue: Text): Boolean`	Retrieves the value of a specific secret from one of the app's key vaults.

Look at the following example for a simple page object. The code retrieves the value of the secret named **MySecret** in app key vault:

```
page 50100 HelloWorldPage
{
    var
        SecretProvider: Codeunit "App Key Vault Secret Provider";
        SecretValue: Text;

    trigger OnOpenPage();
    begin
        if SecretProvider.TryInitializeFromCurrentApp() then begin
            if SecretProvider.GetSecret('MySecret', SecretValue) then
                Message('Retrievedsecret:' + SecretValue)
            else
                Message('Failed to retrieve secret')
        end
        else
            Message('ERROR:' + GetLastErrorText());
    end;
}
```

The call to the `TryInitializeFromCurrentApp` method determines the extension that is currently being executed, then determines the extension's key vaults as specified in the extension manifest. After initialization, the `GetSecret` call reads secrets from the key vault.

Security considerations

Keep the following information in mind when you use the App Key Vault feature with your extensions.

Mark methods as NonDebuggable

When your code works with secrets, whether from a key vault or from Isolated Storage, block the ability to debug relevant methods by using the NonDebuggable Attribute. It prevents other partners from debugging into your code and seeing the secrets.

Don't pass the App Key Vault Secret Provider to untrusted code

Once the **App Key Vault Secret Provider** codeunit has been initialized, it can be used to get secrets.

- If you pass the codeunit to another method, then that method is also able use it.
- If you pass the codeunit to a method in another extension, then the other extension can also use the secret provider to get secrets.

These conditions may not be what you want, so be careful who you pass the secret provider to.

Enable publisher validation

For on-premises deployments, you can configure Business Central Server to run with or without publisher validation of key vault secret providers. Publisher validation is controlled by the server's **Enable Publisher**

Validation (AzureKeyVaultAppSecretsPublisherValidationEnabled) configuration setting. The validation is a runtime operation that ensures extensions use only key vaults that belong to their publishers. It essentially blocks attempts in AL to read secrets from another publisher's key vault.

How it works

Publisher validation is done by comparing the key vault's Azure AD tenant ID with the extension publisher's Azure AD tenant ID. It works this way:

1. When an extension is published by using the Publish-NAVApp cmdlet, the publisher can provide their Azure AD tenant ID by setting the `-PublisherAzureActiveDirectoryTenantId` parameter:

   ```
   Publish-NavApp -ServerInstance <server instance> -Path <path to extension package> -
   PublisherAzureActiveDirectoryTenantId <Azure AD tenant ID GUID>
   ```

   > **NOTE**
   > An error won't occur if `-PublisherAzureActiveDirectoryTenantId` isn't set. There is nothing preventing you from publishing the extension at this point.

2. When the extension runs, it tries to initialize the **App Key Vault Secret Provider** codeunit.
3. The system compares the key vault's Azure AD tenant ID with the Azure AD tenant ID published with the extension:
   - If they match, initialization succeeds.
   - If they don't match, an error occurs.

Turning off publisher validation

Publisher validation is turned on by default, which is the recommended setting. If it's turned off, the server instance won't do any additional validation to ensure extensions have the right to read secrets from the key vaults that they specify. This condition implies some risk of unauthorized access to key vaults that you should be aware of. So, don't turn off publisher validation unless you trust the extensions that can be potentially installed.

For information about how to turn publisher validation on or off, see Configuring Business Central Server.

Monitoring and troubleshooting

Compiling and publishing

If you get errors when you compile or publish your extension, the most likely reasons are:

- You're using an old Visual Studio Code AL extension. Upgrade to the latest AL extension.
- Your extension targets an older runtime. Make sure that the `"runtime"` value in the app.json file is at least `"6.0"`.
- You're running an old version of Business Central Server. Upgrade to at least version 17.0.

Runtime

For runtime operations, there are two sources that you can use for gathering details:

- Windows Event Log of the machine running the Business Central Server.
- Application Insights.

These sources provide details about retrieving secrets from key vaults, for calls to the `TryInitializeFromCurrentApp` and `GetSecret` methods from an extension.

Using Application Insights

You can set up extensions to emit telemetry to an Application Insights resource in Azure.

1. Create an Application Insights resource in Azure if you don't have one.

   The Application Insights resource will be assigned an instrumentation key. Copy this key because you'll need it to enable Application Insights in the Business Central administration center.

   For more information, see Create an Application Insights resource.

2. In the app.json file of the extension, add the `"applicationInsightsKey"`:

```
"applicationInsightsKey":["<instrumenation key>"]
```

3. Now, you can run your extensions and view data in Application Insights.

   For more information, see Viewing telemetry data in Application Insights and Analyzing App Key Vault Secret Trace Telemetry.

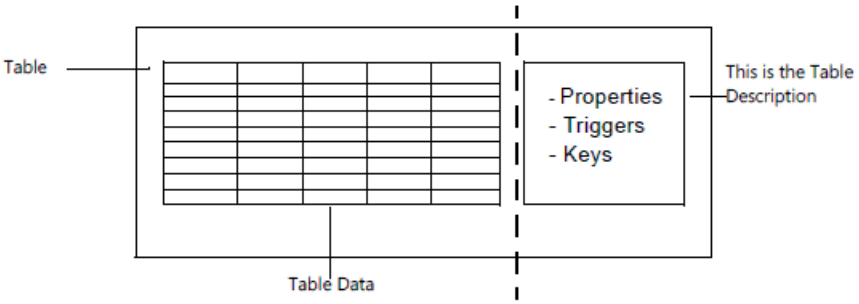
Tables Overview

2/17/2021 • 2 minutes to read • Edit Online

Tables are the fundamental objects in any database. They are the objects in which you store and manipulate data. This is true no matter what kind of data you need to manage. When you create a new database, you begin by building the tables. Later, you create pages and reports in order to access and view the data in the tables.

A table can be visualized as a two-dimensional matrix, consisting of columns and rows. The following illustration shows a table where each row is a record and each column is a field.

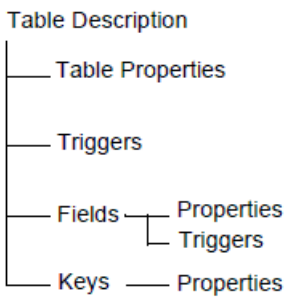
A table consists of two parts: the table data and a table description. The table data is the part users often think of as comprising the database, because it contains the actual records with their data fields. The layout and properties of those fields, however, are specified by the table description. The table description is not directly visible to the user. The following illustration shows how the table data and the table description together form a table.



When you design a table, you assign a number of characteristics to it, such as a name, an ID number, and the fields it contains. You also assign a number of characteristics (such as name, ID number, data type, and initial value) to each field. When you design a new table, you also specify which keys you want the system to maintain. All these characteristics are stored in the table description when you save your table design.

The information in the table description is used by SQL Server and occasionally by database users who need information about the table structure. The table description makes the database flexible, as it lets the system access tables with different structures. The database can extract the definitions of the table structure from the table description and thereby correctly access any table.

The following illustration shows that a table description contains properties, triggers, fields, and keys and shows how these are related.



The table description contains some properties that are related to the table, others that are related to the fields in the table, and other properties related to keys. You can also see that triggers are defined both for the table and for the fields in the table.

Creating tables

In AL code, you can create new tables or modify existing tables. Read more about creating and modifying tables in the following sections.

TO	SEE
Create a new table object	Table Object
Modify an existing table object	Table Extension Object
Decide which field data type you want to apply to your data	Field Data Types
Apply table and field properties	Table and Table Extension Properties
Set primary and secondary table keys	Table Keys

Using triggers in database design

Dynamics 365 Business Central supports setting up actions to take place in response to specific events. These are known as triggers. The following topics help to explain how Dynamics 365 Business Central implements this feature of database design.

TO	SEE
Learn about the set of triggers that Dynamics 365 Business Central supports for tables and fields.	Table and Field Triggers

Creating relationships between tables

In Dynamics 365 Business Central, the primary way to establish a connection between tables is to use the **TableRelation** property. The following topics go into detail about how this works.

Developing Extensions in AL

Table Object

2/17/2021 • 2 minutes to read • Edit Online

Tables are the core objects used to store data in Dynamics 365 Business Central. No matter how data is registered in the product - from a web service to a finger swipe on the phone app, the results of that transaction will be recorded in a table.

The structure of a table has four sections:

- The first block contains metadata for the overall table, such as the table type.
- The fields section describes the data elements that make up the table, such as their name and the type of data they can store.
- The keys section contains the definitions of the keys that the table needs to support.
- The final section details the triggers and code that can run on the table.

IMPORTANT

Only tables with the Extensible Property set to **true** can be extended.

NOTE

Extension objects can have a name with a maximum length of 30 characters.

IMPORTANT

System and virtual tables can't be extended. System tables are created in the ID range of 2.000.000.000 and above. For more information about object ranges, see Object Ranges.

Snippet support

Typing the shortcut `ttable` will create the basic layout for a table object when using the AL Language extension in Visual Studio Code.

TIP

Use **Ctrl+Space** to trigger IntelliSense and get assistance on code completion, parameter info, quick info, and member lists.

Table example

This table stores address information and it has four fields; `Address`, `Locality`, `Town/City`, and `County`.

```
table 50104 Address
{
    Caption = 'Sample table';
    DataPerCompany = true;

    fields
    {
        field(1; Address; Text[50])
        {
            Description = 'Address retrieved by Service';
        }
        field(2; Locality; Text[30])
        {
            Description = 'Locality retrieved by Service';
        }
        field(3; "Town/City"; Text[30])
        {
            Description = 'Town/City retrieved by Service';
        }
        field(4; County; Text[30])
        {
            Description = 'County retrieved by Service';

            trigger OnValidate();
            begin
                ValidateCounty(County);
            end;

        }
    }
    keys
    {
        key(PrimaryKey; Address)
        {
            Clustered = TRUE;
        }
    }

    var
        Msg: Label 'Hello from my method';

    trigger OnInsert();
    begin

    end;

    procedure MyMethod();
    begin
        Message(Msg);
    end;
}
```

System fields

The Dynamics 365 Business Central platform will automatically add several system fields to tables. For more information, see System Fields.

Table Keys
Table, Table Fields, and Table Extension Properties

System Fields

2/17/2021 • 5 minutes to read • Edit Online

System fields are fields that are automatically included in every table object by the platform. Dynamics 365 Business Central includes the following system fields:

- SystemId
- Data audit fields
- Timestamp

System fields are assigned numbers in the range 2000000000-2147483647. This range is reserved for system fields. You'll get a design-time error if you give a field a number in this range.

SystemId field

APPLIES TO: Business Central 2019 release wave 2 and later

The **SystemId** field is a GUID data type field that specifies a unique, immutable (read-only) identifier for records in the table. The **SystemId** field has the following characteristics and behavior:

- All records must have a value in the **SystemId** field.
- You can assign your own value when a record is inserted in the database. Otherwise, the platform will automatically generate and assign a value.
- Once the **SystemId** has been set, it can't be changed.
- There's always a unique secondary key on the **SystemId** field to ensure records don't have identical field values.
- The **SystemId** field is given the field number 2000000000.

The **SystemId** field is exposed in the platform code and for AL code, allowing you to code against it. For example:

- The Insert(Boolean, Boolean) lets you specify the **SystemId** value for a record, instead of using one assigned by the platform:

```
myRec.SystemId := '{B6666666-F5A2-E911-8180-001DD8B7338E}';
myRec.Insert(true, true);
```

- The GetBySystemId(Guid) uses the **SystemId** to get a record:

```
id := myRec.GetBySystemId('{B6666666-F5A2-E911-8180-001DD8B7338E}';
```

- The SystemIdNo() gets the field number used by the **SystemId** field in the table:

```
myRec.OPEN(DATABASE::MyTable);
SystemIdFieldNo := myRec.SystemIdNo();
```

- The TableRelation lets you use the **SystemId** field to set up table relationships:

```
field(1; MyField; Guid)
{
    DataClassification = ToBeClassified;
    TableRelation = Customer.SystemId;
}
```

- The **SystemId** field can be used as a binding key to an API:

```
page 50100 "Customer Entity"
{
    PageType = API;
    ApplicationArea = All;
    UsageCategory = Administration;
    SourceTable = Customer;
    ODataKeyFields = SystemId;
    ...
```

APPLIES TO: Business Central 2020 release wave 2 and later

- If the **SystemId** field is specified in a Web Service POST request, the OData stack persists the value in the database.
- The **SystemId** field can be used as part of a (non-primary) key.
- You can show the **SystemId** field as a field on a page.
- You can link FactBoxes/page parts using the **SystemId** field.

Data audit fields

APPLIES TO: Business Central 2020 release wave 2 and later

Every table in Business Central includes the following four system fields, which can be used for auditing records:

FIELD NAME (IN AL)	COLUMN NAME (IN DATABASE)	DATA TYPE	FIELD NUMBER	DESCRIPTION
SystemCreatedAt	$systemCreatedAt	DateTime	2000000001	Specifies the data and time that the record was created.
SystemCreatedBy	$systemCreatedBy	GUID	2000000002	Specifies security ID (SID) of the user that created the record.
SystemModifiedAt	$systemModifiedAt	DateTime	2000000003	Specifies the data and time that the record was last modified.
SystemModifiedBy	$systemModifiedBy	GUID	2000000004	Specifies the SID of the user that last modified the record

Runtime characteristics

At runtime, the data audit fields have the following characteristics and behavior:

The platform will automatically generate and assign values according to the following triggers:

- After all OnBeforeInsert and OnBeforeModify triggers are run

- After the OnInsert and OnModify triggers are run
- Before all OnAfterInsert and OnAfterModify triggers are run

> **NOTE**
> You can assign the values, but the values written to the database are always provided by the platform.

Fields are populated as follows:

- When a new record is created, before calling Insert, the audit fields are given blank GUIDs and blank dates as values.
- When a record is first inserted, the fields are populated with actual values.

  The $systemCreatedBy and $systemModifiedBy fields are given the same value. So are the $systemCreatedAt and $systemModifiedAt fields.

  The $systemCreatedBy and $systemCreatedAt fields won't change after this point.
- When a record is updated, the $systemModifiedBy and $systemModifiedAt fields are changed.

The platform won't populate audit field values in these cases:

- Copying company. The values in the tables of the company being copied stay the same, and the values are copied to the tables of the new company.
- Synchronizing the table schema with the application.

> **NOTE**
> Audit fields can't be imported with configuration packages.

In AL

The data audit fields are exposed in AL code. As a developer, the audit fields give you an easy and performant way to program against historical data. For example, you can write AL queries that return data changes since a specific date and time.

The following methods are available on the RecordRef data type:

METHOD	DESCRIPTION
SystemCreatedAtNo	Gets the field number that is used by the **SystemCreatedAt** field.
SystemCreatedByNo	Gets the field number that is used by the **SystemCreatedBy** field.
SystemModifiedAtNo	Gets the field number that is used by the **SystemModifiedAt** field.
SystemModifiedByNo	Gets the field number that is used by the **SystemModifiedBy** field.

There are a couple points of interest you should know:

- If a record is copied into a temporary table, the data audit field values are copied as well. The values aren't changed by the server when calling a modify or insert method.

- It's possible to use audit fields in a key. The platform doesn't automatically index these fields in any way.

Timestamp field

The **timestamp** field contains row version numbers for records, as maintained in SQL Server. The **timestamp** field is hidden. But, you can expose it by using SqlTimestamp Property. You're then able to write code against it, add filters, and so on, similar to any other field in a table. However, you can't write to the **timestamp** field.

A typical use of the **timestamp** field is for synchronizing data changes in tables. It lets you identify records that have changed since the last synchronization. For example, you can read all the records in a table, then store the highest **timestamp** value. Later, you can query and retrieve records that have a higher **timestamp** value than the stored value.

Expose the timestamp field

1. Add a field that has the data type `BigInteger`.

   Specify a name for the field, such as `Record Time Stamp`. You can specify any valid name for field, but you can't use `timestamp` because it's a reserved name.

2. Set the `SqlTimestamp` property to `true`.

   For example:

```
field(3; "Record Time Stamp"; BigInteger)
{
    SqlTimestamp = true;
}
```

Alternatively, you can use a FieldRef Data Type variable to access the timestamp value of a record, as follows:

1. Create a RecordRef Data Type variable that references the record in a table for which you want to retrieve its timestamp.

2. Use the Field Method on the **RecordRef** variable to get the **FieldRef** for the field that has the number 0. This field contains the timestamp value.

The following example shows how to retrieve the timestamp value for the first record in the `Customer` table. **RecordRef** and **FieldRef** are RecordRef Data Type and FieldRef Data Type variables, respectively.

```
RecordRef.Open(DATABASE::Customer);
RecordRef.FindFirst();
FieldRef := RecordRef.Field(0);
Message(Format(FieldRef.Value()));
```

Table Extension Object

2/17/2021 • 2 minutes to read • Edit Online

The table extension object allows you to add additional fields or to change some properties on a table provided by the Dynamics 365 Business Central service. In this way, you can add data to the same table and treat it as a single table. For example, you may want to create a table extension for a retail winter sports store. In your solution you want to have `ShoeSize` as an additional field on the customer table. Adding this as an extension allows you to write code for the customer record and also include values for the `ShoeSize`.

Along with defining other fields, the table extension is where you write trigger code for your additional fields.

When developing a solution for Dynamics 365 Business Central , you will follow the code layout for a table extension as shown in the example below.

IMPORTANT

Only tables with the Extensible Property set to **true** can be extended.

NOTE

Extension objects can have a name with a maximum length of 30 characters.

IMPORTANT

System and virtual tables cannot be extended. System tables are created in the ID range of 2.000.000.000 and above. For more information about object ranges, see Object Ranges.

IMPORTANT

Extending tables from Dynamics 365 for Sales is currently not supported.

Snippet support

Typing the shortcut `ttableext` will create the basic layout for a table extension object when using the AL Language extension in Visual Studio Code.

Properties

Using a table extension allows you to overwrite some properties on fields in the base table. For a list of Table properties, see Table and Table Extension Properties.

Table extension syntax

```
tableextension Id MyExtension extends MyTargetTable
{
    fields
    {
        // Add changes to table fields here
    }

    var
        myInt: Integer;
}
```

Table extension example

This table extension object extends the Customer table object by adding a field `ShoeSize`, with ID 50116 and the data type `Integer`. It also contains a procedure to check if the `ShoeSize` field is filled in.

```
tableextension 50115 RetailWinterSportsStore extends Customer
{
    fields
    {
        field(50116;ShoeSize;Integer)
        {
            trigger OnValidate();
            begin
                if (rec.ShoeSize < 0) then
                begin
                   message('Shoe size not valid: %1', rec.ShoeSize);
                end;
            end;
        }
    }

    procedure HasShoeSize() : Boolean;
    begin
        exit(ShoeSize <> 0);
    end;

    trigger OnBeforeInsert();
    begin
        if not HasShoeSize then
            ShoeSize := Random(42);
    end;
}
```

Setting Relationships Between Tables

2/17/2021 • 2 minutes to read • Edit Online

It is common to distinguish among the following types of relationships between tables in relational database design:

- One-to-many relationships
- Many-to-many relationships
- One-to-one relationships

The one-to-many relationship is the most common. If your database design model indicates that you need to set up a many-to-many relationship, then your design is probably inefficient. You can typically break down a many-to-many relationship into two one-to-many relationships. A one-to-one relationship is usually not optimal and can often be avoided by combining the two tables.

Using relationships

If your database contains tables with related data, then you can define a relationship between them. You relate tables by specifying one or more fields that contain the same value in related records. These matching fields often have the same name in each table. You can use relationships to:

- Validate data entries
- Perform lookup functions in other tables
- Propagate changes automatically from one table to other tables

Table relationships and the TableRelation property

Table relationships are defined in the AL Language development environment using the **TableRelation** property. This property allows you to define both simple and advanced table relations.

> **NOTE**
> You can define a relationship only to a field that is a member of the primary key group.

Advanced table relations are typically prefixed with a conditional statement and include filters. The following syntax is for table relations.

```
<TableRelation> =
   <TableName>[.<FieldName>] [WHERE(<TableFilters>)] |
   if (<Conditions>) <TableName>[.<FieldName>]
   [WHERE(<TableFilters>)] else <TableRelation>
<Conditions> ::=
   <TableFilters>
<TableFilters> ::=
   [<TableFilter> {,<TableFilter>}]
<TableFilter> ::=
   <DstFieldName>=CONST(<FieldConst>) |
   <DstFieldName>=FILTER(<Filter>)
```

For example:

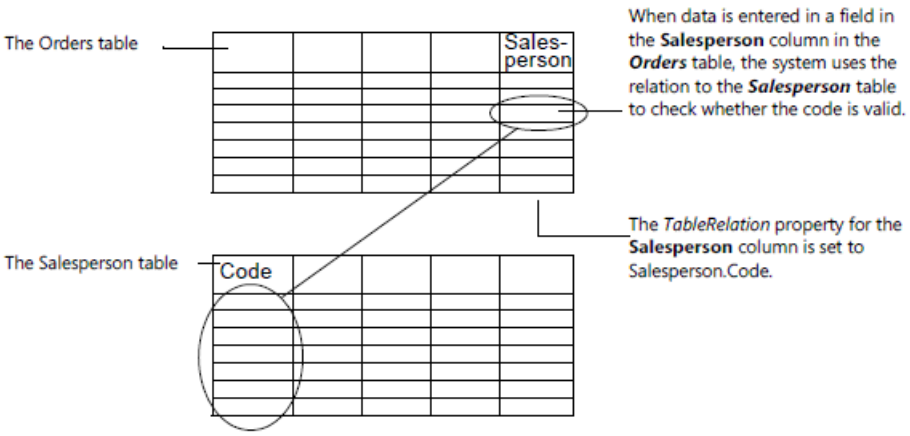
```
table 50120 TableWithRelation
{
  fields
  {
    field(1; Id; Integer) { }
    field(2; Type; enum TypeEnum) { }
    field(3; Relation; Code[20])
    {
      TableRelation =
        if (Type = const (Customer)) Customer
        else if (Type = const (Item)) Item;
    }
  }
}
```

The following table describes each of the symbols.

SYMBOL	DESCRIPTION
TableName	Specifies the related table.
FieldName	Specifies a field in the related table.
Conditions	Table relations can be conditional.
TableFilters	A list of table filters.
TableFilter	A constant expression or a filter expression.
DstFieldName	Specifies the destination field name.
Filter	A filter expression, such as 10|20..30.

Examples of table relationships

For example, you have an **Orders** table that stores orders and a **Salesperson** table that stores the names of all salespeople in your company. In the **Orders** table, you can include a **Salesperson** field that identifies the salesperson. By setting up a relationship between these two tables, you can check whether the **Salesperson** field in the **Orders** table contains a valid code.



For example, you have a **Vendors** table with all your vendors and a **Currency Code** table. You can create a relationship between a **Currency Code** field in the **Vendors** table and the **Currency Code** table. This will allow users to look up information about valid currency codes.

Furthermore, if you change one of the currency codes in the **Currency Code** table, then the change is automatically propagated to all tables that refer to this code.

Viewing Table Data

2/17/2021 • 2 minutes to read • Edit Online

For developers, administrators, and support personnel, it can be useful to inspect table data in the tenant database, particularly when debugging or troubleshooting. To support this need, you can view table objects in the Web client. This lets you to see the data in all rows and columns of a specific table, including any columns that are added by table extensions.

- In a production environment, administrators and support can view a table directly from the Web client.
- From the Business Central administration center, you can launch a list of all tables, sorted by storage size. For more information, see Storage usage by environment.
- In a development environment, in addition to viewing a table directly from the Web client, developers can view a table automatically when they publish/debug an AL project from Visual Studio Code.

> **NOTE**
> The table appears as read-only in the client, so modifications, insertions, and deletions cannot be made.

> **IMPORTANT**
> Data in the tables can be sensitive. Make sure that you follow your organization's guidelines for handling such data.

Required permissions

Whether viewing the table directly from the client or from Visual Studio Code, your Dynamics 365 user account must have the following permissions:

- Read permission on the table that you want to view.
- Execution permission (direct) on the System object **1350 Run table**.

Any end-user that is assigned these permissions will be able to view that table in the browser.

For information about assigning permissions, see Manage Users and Permissions.

View a table object directly from the client

To view a table, you add the `table=<TableID>` parameter to the client's address (URL), replacing `<TableID>` with the ID of the table that you want to view.

For example, if your URL starts with `https://businesscentral.dynamics.com`, then to view table **18 Customer** in your current company, you could use the following URL:

```
https://businesscentral.dynamics.com/?table=18
```

Or for a specific company, such as "CRONUS Inc.":

```
https://businesscentral.dynamics.com/?company=CRONUS%20Inc.&table=18
```

Note the use of `&` when `table=<TableID>` is not located directly after the domain name.

View a table object from an AL project in Visual Studio Code

You can configure an AL project to view a table when you publish or debug the project (pressing **F5** or **Ctrl+F5**).

In the `launch.json` file for the project, set the `"startupObjectType"` parameter to `"table"` and the `"startupObjectId"` parameter to the ID of the table. For example:

```
{
    "version": "1.0.0",
    "configurations": [
        {
            "type": "al",
            "request": "launch",
            "name": "Publish to Microsoft cloud sandbox",
            "serverInstance": "dynamics",
            "startupObjectType": "Table"
            "startupObjectId": 18
        }
    ]
}
```

For more information about the `launch.json` file, see Launch.json file.

Constraints

You cannot view virtual tables or the following system tables:

Managing Capacity

Insert, Modify, ModifyAll, Delete, and DeleteAll Methods

2/17/2021 • 4 minutes to read • Edit Online

The following methods maintain the database by adding, modifying, and removing records:

- Insert
- Modify
- ModifyAll
- Delete
- DeleteAll

These methods are some of the most frequently used AL methods.

Some of these methods return an optional Boolean value that indicates whether the method succeeded. If you do not handle the return value in your code, a run-time error occurs when a method returns **false**. If you handle the return value by testing its value in an **if** statement, no error will occur, and you must take corrective action in the code.

Insert method

The Insert method inserts a record in a table. Insert has the following syntax.

```
[Ok := ]  Record.Insert([RunTrigger: Boolean[, InsertWithSystemId: Boolean]])
```

A record must be assigned a **SystemId**. You have the option to assign your own value or have the platform assign an auto-generated value. The following example inserts a new record, with the **SystemId**, **No.**, and **Name** fields specified in the assigned values, while other fields will have their default values. If the **No.** field is the primary key of the **Customer** table, then the record will be inserted in the **Customer** table unless the table already contains a record with the same primary key. In this case you receive an error message because the return value is not tested.

```
var
    Customer: Record Customer;
begin
    Customer.Init;
    Customer.SystemId := '{B6666666-F5A2-E911-8180-001DD8B7338E}';
    Customer."No." := '4711';
    Customer.Name := 'Andrew Dixon';
    Customer.Insert(false, true);
end;
```

IMPORTANT

After the **SystemId** has been set on a record, it cannot be changed.

Modify method

Modify modifies a record that already exists. For more information, see Modify Method. Modify has the

following syntax.

```
[Ok :=] Record.Modify([RunTrigger])
```

Modify returns an optional Boolean value. It returns **true** if the record to be modified exists; otherwise, it returns **false**.

The following example changes the name of customer 4711 to Richard Roe. This example requires that you create the following variable.

VARIABLE	DATA TYPE	SUBTYPE
Customer	Record	Customer

```
Customer.Get('4711');
Customer.Name := 'Richard Roe';
Customer.Modify;
```

ModifyAll method

ModifyAll performs a bulk update of records. For more information, see ModifyAll Method.

ModifyAll has the following syntax.

```
Record.ModifyAll(Field, NewValue [, RunTrigger])
```

ModifyAll uses the current filters. This means that you can perform the update on a specified set of records in a table. ModifyAll returns no value, nor does it cause an error if the set of records to be changed is empty.

In the following example, the `SetRange` statement selects the records where Salesperson Code is PS. The ModifyAll statement changes the Salesperson Code of these records to JR. The example requires that you create the following variable.

VARIABLE	DATA TYPE	SUBTYPE
Customer	Record	Customer

```
Customer.SetRange("Salesperson Code",'PS','PS');
Customer.ModifyAll("Salesperson Code",'JR');
```

Delete method

Delete deletes a record from the database. For more information, see Delete Method Delete has the following syntax.

```
[Ok :=] Record.Delete([RunTrigger])
```

The record that you want to delete must be specified by using the values in the primary key fields before you call this method. This means that Delete does take filters into consideration.

The following example shows how to use Delete to delete the record for customer number 4711. This example

requires that you create the following variable.

VARIABLE	DATA TYPE	SUBTYPE
Customer	Record	Customer

```
Customer."No." := '4711';
Customer.Delete;
```

Delete returns an optional Boolean value. It returns **true** if the record could be found; otherwise, it returns **false**. Unless you test this value in your code, a run-time error occurs when Delete fails.

When you are developing your own applications, you should consider the following scenario:

1. Retrieve a record from the database.
2. Perform various checks to determine whether the record should be deleted.
3. If step 2 indicated that you should delete the record, then delete it.

This can cause problems in a multi-user environment. Another user can modify or delete the same record between your performing steps 2 and 3. If the record is modified, then perhaps the new contents of the record would have changed your decision to delete it. If it has been deleted by the other user, you can get a run-time error if you have just verified that the record existed (in step 1). If the design of your application indicates that you can encounter this problem, you should consider using the LockTable method. LockTable should be used sparingly because this method degrades performance. For more information about the LockTable method, see LockTable Method.

DeleteAll method

DeleteAll deletes all the records that are specified by the filter settings. If no filters are applied, it deletes all the records in the table. For more information, see DeleteAll Method DeleteAll has the following syntax.

```
Record.DeleteAll([RunTrigger])
```

The following example deletes all the records from the **Customer** table where the Salesperson Code is PS. This example requires that you create the following variable.

VARIABLE	DATA TYPE	SUBTYPE
Customer	Record	Customer

```
Customer.SetRange("Salesperson Code", 'PS', 'PS');
Customer.DeleteAll;
```

NOTE

When you use DeleteAll (true), a copy of the AL variable with its initial values is created. This means that when you use DeleteAll(true) to run the OnDelete trigger, all the changes that were made to the variables in the method or codeunit that is making the call cannot be seen in the OnDelete trigger. If you want to see the changes that you made to the variables, you must use Delete(true) in a loop. There is no difference in performance between using DeleteAll(true) and using Delete(true) in a loop.

SystemId Field

Get, Find, and Next Methods

2/17/2021 • 3 minutes to read • Edit Online

The following methods are used to search for records:

- `Get`
- `Find`
- `Next`

These methods are some of the most frequently used AL methods. When you search for records, you must know the difference between Get and Find and to know how to use Find and Next in conjunction.

> **TIP**
> When using these methods, consider using the partial records methods to improve performance, especially when looping through several records or when table extensions are defined on the table. For more information, see Using Partial Records.

Get method

The Get Method (Record) retrieves one record based on values of the primary key fields.

Get has the following syntax.

```
[Ok :=] Record.Get([Value],...)
```

For example, if the **No.** field is the primary key of the **Customer** table and if you have created a record variable called **CustomerRec** that has a subtype of Customer, then you can use Get in the following way.

```
CustomerRec.Get('4711');
```

The result is that the record of customer 4711 is retrieved.

Get produces a run-time error if it fails and the return value is not checked by the code. In the previous example, the actual code that you write should resemble the following.

```
if CustomerRec.GET('4711') then
.... // Do some processing.
else
.... // Do some error processing.
```

Get searches for a record, regardless of the current filters, and it does not change any filters. Get always searches through all the records in a table.

GetBySystemId method

APPLIES TO: Business Central 2019 release wave 2 and later

The GetBySystemId(Guid) retrieves a record based on the value of its **SystemId** field.

GetBySystemId has the following syntax:

```
RecordExists :=   Record.GetBySystemId(SystemId: Guid)
```

The following example gets the record that has the SystemId `5286305A-08A3-E911-8180-001DD8B7338E`:

```
var
    Customer: Record Customer;
    Text000: Label 'Customer was found.';
begin
    If Customer.GetBySystemId('{5286305A-08A3-E911-8180-001DD8B7338E}') then
    Message(Text000);
end;
```

Similar to the Get method, GetBySystemId searches for a record, regardless of the current filters, and it does not change any filters. Get always searches through all the records in a table.

Find methods

The Find Method (Record) locates a record in a table that is based on the values stored in the keys.

Find has the following syntax.

```
Ok := Record.Find([Which])
```

The *Which* parameter specifies how to perform the search. You can search for values that are greater than, less than, or equal to the key value, or for the first or last record in a table.

The important differences between Get and Find are as follows:

- Find uses the current filters.
- Find can look for records where the key value is equal to, greater than, or smaller than the search string.
- Find can find the first or the last record, depending on the sort order defined by the current key.

When you are developing applications in a relational database, there are often one-to-many relationships defined between tables. An example could be the relationship between an **Item** table, which registers items, and a **Sales Line** table, which registers the detailed lines from sales orders. One record in the **Sales Line** table can only be related to one item, but each item can be related to any number of sales line records. You would not want an item record to be deleted as long as there are still open sales orders that include the item. You can use Find to check for open sales orders.

The OnDelete trigger of the **Item** table includes the following code that illustrates using Find.

```
SalesOrderLine.SetCurrentKey(Type,"No.");
SalesOrderLine.SetRange(Type,SalesOrderLine.Type::Item);
SalesOrderLine.SetRange("No.","No.");
if SalesOrderLine.Find('-') then
    Error(Text001,TableCaption,"No.",SalesOrderLine."Document Type");
```

If you want to find the first record in a table or set, then use the FindFirst Method (Record). If you want to find the last record in a table or set, then use the FindLast Method (Record).

Next method

The Next Method (Record) is often used with FIND to step through the records of a table.

Next has the following syntax.

```
Steps := Record.Next([Steps])
```

In the following example, Find is used to go to the first record of the table. Next is used to step through every record, until there are no more. When there are no more records, Next returns 0 (zero).

```
if (Rec.FindSet) then
repeat
  // process record
until (Rec.Next = 0);
```

Temporary Tables

2/17/2021 • 4 minutes to read • Edit Online

A temporary table is a temporary variable that holds a table. A temporary table is used as a buffer or intermediate storage for table data.

You can use a temporary table just like you use a database table. The differences between a temporary table and a database table are as follows:

- A temporary table data is not stored in the database. It's only held in memory until the table is closed.
- The write transaction principle that applies to a database table does not apply to a temporary table.

Advantage of using a temporary table

The advantage of using a temporary table is that all the interaction with a temporary table occurs on Dynamics 365 Business Central. A temporary table reduces the load on both the network and the SQL database server.

When you want to do many operations on the data in a specific table in the database, you can load the data into a temporary table when you modify it. Loading the data into a temporary table speeds up the process because all the operations are done in memory on the Business Central Server.

Creating and using a temporary table

There are three ways to implement a temporary table:

- Setting the TableType property on the table object to **Temporary**.
- Using a temporary record variable.
- Setting the SourceTableTemporary property on a page.

Whichever way you choose, you must create the table object that defines the fields, like any other table object. The differences are explained in the following sections.

> **TIP**
> Temporary tables retain system fields, like SystemID and data audit fields. For more information, see System Fields.

Setting the TableType to Temporary

APPLIES TO: Business Central 2020 release wave 2 and later

With this implementation, a physical table is not created in the database. In the table object, set the `TableType` property to `Temporary`:

```
table 50100 MyTable
{
    DataClassification = ToBeClassified;
    TableType = Temporary;

    fields

    ...
}
```

This implementation has the same effect as using a temporary record variable or setting the SourceTableTemporary property on a page. But the advantage is that the table schema isn't synchronized with the database. So it does not have restrictions on breaking schema changes, like removing a field, changing its data type or length.

It will also improve the performance of BACPAC generation using the sqlpackage command-line tool, compared to temporary tables based on temporary record variables and pages. For more information, see Performance of BACPAC generation.

Changing the table type

You can change from **Normal** to **Temporary**, and the other way around. When changing **Normal** to **Temporary** the table, you will have to synchronize the extension with the database. This step will remove the table from the database. So if the table contains data, you will have to synchronize the schema using the ForceSync mode.

Using a temporary record variable

With this implementation, a physical table is not created in the database. You create a global or local variable of the type record and set the Temporary Property next to it. The variable that holds a temporary table is defined just like any other global or local variable. The syntax is shown in the following example:

```
var
    TempInvoicePostBuffer: Record "Invoice Post. Buffer" temporary;
```

You manipulate the temporary table variable as you would with any other database table. For example, you can apply filters and do searches. For more information about the operations you can do, see Record Data Type.

Using a SourceTableTemporary property on page objects

Another option for temporary tables is to set the SourceTableTemporary on all pages that use the table. This implementation will also use a physical table in the database.

```
page 50100 MyPage
{
    PageType = Card;
    ApplicationArea = All;
    UsageCategory = Administration;
    SourceTable = TableName;
    SourceTableTemporary = true;

    layout

    ...
}
```

Temporary tables on reports and XMLPorts

You can also use temporary tables for storing the data set that is returned by a report object or that is imported by an XMLPort. To do so, set the **UseTemporary property** to **true** on the relevant report data item or XMLPort table element. For more information, see UseTemporary Property (XMLports) and UseTemporary Property (Reports).

It's useful to use a temporary table for a report when the column data is not mapped directly to a field in the database but is instead the result of a process or operation, such as an aggregation of data from several columns. If a temporary table is not used, the data must be handled by AL code.

For XMLPorts, if the data that you are importing has a different structure than the table in Dynamics 365 Business Central that you want to insert it into, you can import the data into a temporary table. You can then modify the data before inserting it into the database.

Retaining table data after publishing

2/17/2021 • 3 minutes to read • Edit Online

When developing an extension, you debug several times using the F5 shortcut key, and you also test your app by adding some sample data every time. To simplify the extension development process in Business Central, you can synchronize the sample data specified in the extension when you do subsequent publishing from Visual Studio Code.

How data synchronization works

The data synchronization between each publish is controlled by the `schemaUpdateMode` setting, which is specified in the `launch.json` file. This setting consists of three options; **Synchronize**, **Recreate**, and **ForceSync**.

The default value for `schemaUpdateMode` is set to the **Synchronize** mode, which means that every time you publish an extension to the development server, the data you entered previously stays. If you do not want to synchronize the sample data with each publish, you can change the `schemaUpdateMode` setting from `Synchronize` to, for example, `Recreate` with the syntax shown in the example below.

```
{
    "type": "al",
    "request": "launch",
    "name": "your own server",
    "server": "https://localhost",
    "serverInstance": "Nav",
    "authentcation": "UserPassword",
    "startupobjectId": 22,
    "schemaUpdateMode": "Recreate"
}
```

Recreate mode

When you set the schema update mode to **Recreate**, all the tables and table extensions are recreated at every publish, which means that all the data in those tables are lost. This means that you will get empty records when you publish your extension.

ForceSync mode

ForceSync is similar to the existing Synchronize schema update mode, but contains more freedom to make schema changes while retaining data. To enable this mode, set `schemaUpdateMode` to `"ForceSync"` and then set the `"version"` parameter in the app.json file to a fixed number. Data will be preserved in almost all cases with the exception of changing the main table's primary key, in which case the data from the extension tables will be lost. Field renames are allowed and supported in this mode, but the data can only be preserved if you maintain the same ID for the field. If you change both the name and the ID of the field then the data will be lost.

> **IMPORTANT**
> This schema update mode is only meant for testing and development and should never be used in production.

In addition to the `launch.json` file setting, the **ForceSync** switch is available through the PowerShell cmdlet `Sync-NavApp –Mode ForceSync`.

Things to be aware of

Synchronize is the default schema update mode for syncing the database and the extension. There are some key factors to consider when you work with the **Synchronize** mode.

- After publishing, the field data and the primary key information synchronizes with all the tables and the table extensions. This means that you can do additions easily, but not deletions. Breaking changes are never supported in synchronize mode. For example, you can add a field and sync that with the extension just by pressing the F5 shortcut key, but if a field is removed then the table data cannot be synchronized. If you, during development, for example, discover that you no longer want field **X**, and you then mark field **X** as obsolete, you may still want to write an upgrade codeunit to move the data from the obsolete field to a new field **Y** that you introduce. Later, the obsoleted field will not be available. But if you do not want the data, you can choose to use the **Recreate** mode instead.

- When you make changes to the data types, you can only *enlarge* the unit size, and *not decrease* the unit size. For example, you can set a text type from `Code[20]` to `Code[50]` or `Text[32]` to `Text[87]`, and you cannot set a text type from `Code[50]` to `Code[30]` or `Text[87]` to `Text[40]`.

- Making major table structural changes could lead to compilation errors. For example, if you want to update a primary key. In this case, the table data cannot be synchronized, and if you want to publish the extension, you must change the `schemaUpdateMode` to `Recreate`.

- For extensions built on Business Central Spring 2019 or earlier, if a table field has the `SqlDataType` set to a value other than `Varchar` (which is the default), you must delete the `SqlDataType` property on the field, otherwise, you will will not be able to successfully synchronize the extension.

  If the `SqlDataType` property is still needed, you will have to create a new table in the extension that has the same definition as the original table, and write upgrade code that migrates the data from the original table to the new table. For more information, see Writing upgrade code.

  Alternatively, if this is a development scenario, you can synchronize the extension using the ForceSync or Recreate mode.

Classifying Data in Dynamics 365

2/17/2021 • 5 minutes to read • Edit Online

Dynamics 365 includes development features for tagging business data with specific classifications. Specifically, this includes data that is stored in table fields of the database and telemetry data that is emitted from the application.

About Data Classification

Classifying data serves different purposes. It can make data easier and more efficient to locate and retrieve, and also help to add another layer of protection and security for handling private and sensitive data. It can supplement your process for making the application compliant with legislative and regulatory requirements for collecting, storing, and using personal information.

> **IMPORTANT**
>
> You should consider the data classification features offered in Dynamics 365 as the first layer of classification - done by developers (Dynamics 365 and partners) on customizations, add-ons, and extensions. The second layer is to classify the sensitivity of the data itself. For more information, see Classifying Data Sensitivity. It is also important to consider end-users, and how they handle data they provide and that is made available to them.

What are the different data classifications?

The following table describes the different classifications that you can apply to data:

DATA CLASSIFICATION	DESCRIPTION	EXAMPLE
CustomerContent	Content directly provided/created by admins and users.	• Customer generated BLOB or structured storage data • Customer-owned/provided secrets (passwords, certificates, encryption keys, storage keys)
EndUserIdentifiableInformation	(EUII) Data that identifies or could be used to identify the user of a Microsoft service. EUII does not contain Customer content.	• User name or display name (DOMAIN\UserName) • User principle name (name@company.com) • User-specific IP address
AccountData	Customer billing information and payment instrument information, including administrator contact information, such as tenant administrator's name, address, or phone number.	• Tenant administrator contact information (for example, tenant administrator's name, address, e-mail address, phone number) • Customer's provisioning information

DATA CLASSIFICATION	DESCRIPTION	EXAMPLE
EndUserPseudonymousIdentifiers	(EUPI) An identifier created by Microsoft tied to the user of a Microsoft service. When EUPI is combined with other information, such as a mapping table, it identifies the end user. EUPI does not contain information uploaded or created by the customer (Customer content or EUII)	• User GUIDs, PUIDs, or SIDs • Session IDs
OrganizationIdentifiableInformation	(OII) Data that can be used to identify a tenant, generally config or usage data. This data is not linkable to a user and does not contain Customer content.	• Tenant ID (non-GUID) • Domain name in e-mail address (xxx@contoso.com) or other tenant-specific domain information
SystemMetadata	Data generated while running the service or program that is not linkable to a user or tenant.	• Database table names, database column names, entity names

Classifying data in tables and fields

Table objects and field controls include the `DataClassification` property that you can use to tag data with one of the classifications previously described.

Dynamics 365 operates with some standard rules for classification:

- When you add a new field to a table, the field is assigned an initial value of **ToBeClassified**.
- FlowField and FlowFilter fields are automatically set to the **SystemMetadata** data classification. This cannot be changed.
- Existing tables and fields (except for FlowFields and FlowFilters) in an application that has been upgraded from a Dynamics 365 version without the `DataClassification` property, will automatically be assigned the **CustomerContent** classification.

> **IMPORTANT**
> Microsoft is providing this `DataClassification` property as a matter of convenience only. It is your responsibility to classify the data appropriately and comply with any laws and regulations that are applicable to you. Microsoft disclaims all responsibility towards any claims related to your classification of the data.

For more information about this property, see DataClassification Property.

Data classification on upgrade

When you upgrade an application from a Dynamics 365 version that does not contain the `DataClassification` property, existing tables and fields (except for FlowFields and FlowFilters) will automatically be assigned the **CustomerContent** classification. You can then access the `DataClassification` property on these tables and fields, and change the classification as needed. FlowFields and FlowFilters will be assigned the **SystemMetadata** classification automatically.

IMPORTANT

After upgrade or import of objects, using fob files, that introduce new tables and/or fields, make sure to synchronize new tables and/or fields to enable Data Sensitivity Classification by running **SyncAllFields** method in `Data Classification Mgt.` Codeunit (Codeunit 1750). No action is needed when extensions are installed, as installation of extension automatically triggers **SyncAllFields** method. See example below.

Run the script below from Developer Shell:

```
Invoke-NAVCodeunit -Tenant <TenantID> -CompanyName <CompanyName> -CodeunitID 1750 -MethodNAme
'SyncAllFields' -ServerIntance <ServerInstance>
```

Bulk-classifying data

The Field Data Classification report, which is described in the *Viewing current field classifications* section in this topic, provides an overview of the data classifications for fields. The report also lets you assign data classifications for more than one field. For example, this is useful if you are assigning classifications for the first time, or have changed several fields and want to update their classifications. You can bulk-edit classifications only for fields in AL Language development environment. The script does not update fields in extensions.

To bulk-edit classifications, export the report to Excel, update the classifications, and then save your changes. Then, in Windows PowerShell, run the following commands to run the `Import-Module` script and set the classifications on the fields.

To run the script from the default folder on the DVD, run:

```
Import-Module WindowsPowerShellScripts\DataClassification\DataClassification.psm1
```

To update the `DataClassification` property, run the following command. Replace <FilePath> with the full path to the client files. For example, C:\Program Files\Microsoft Dynamics 365 Business Central\160\RoleTailored Client.

```
Set-FieldDataClassificationFromExcelFile -ExcelFilePath "C:\BC\W1 Fields (Main).xlsx" -SheetName 'Field Data
Classification' -RTCFolder "<FilePath>" -DBName BC2 -OutputFolder C:\BC2\Classifications
```

Viewing current field classifications

To view the data classification on all fields, you can do one of the following:

- From the client, search for and open the **Data Classification Worksheet** page.
- Create a page that has the virtual table **Field** (ID 2000000041) as its source, and open the page in the client.

Classifying data in custom telemetry trace events

Custom telemetry trace events are defined by calls to the **SENDTRACETAG** method in the application code. The **SENDTRACETAG** method includes an optional parameter called `DataClassification` that you can use to tag the telemetry trace event with a data classification.

For more information, see SendTraceTag and Instrumenting an Application for Telemetry.

Integrating Microsoft Dataverse for Extension Development

2/17/2021 • 2 minutes to read • Edit Online

NOTE

Effective November 2020:

- Common Data Service has been renamed to Microsoft Dataverse. Learn more
- Some terminology in Microsoft Dataverse has been updated. For example, *entity* is now *table* and *field* is now *column*. Learn more

Develop extensions and streamline the workflow by synchronizing Microsoft Dataverse data with Dynamics 365 Business Central.

For developing extensions to integrate with sales data, you simply enable the tables used in Microsoft Dataverse. The extension development process includes the following set of properties in Dynamics 365 Business Central to enable field mapping. You can enable the field mapping by using the following properties. The tables are extensible, so that you can update Microsoft Dataverse with data as well.

Associated table and field properties

The following properties are used for integrating with Microsoft Dataverse:

PROPERTIES	APPLIES TO	DESCRIPTION
TableType Property	Tables	Specifies the table type. This enables the table to integrate with the external database. For example, `CDS`.
ExternalName Property	Tables, Fields	Specifies the name of the original table in the external database when used as a table property. Specifies the field name of the corresponding field specified in the external table when used as a field property.
ExternalAccess Property	Fields	Specifies the access to the underlying Microsoft Dataverse table when Microsoft Dataverse tables are generated using the **AL Table Proxy Generator** tool, see AL Proxy Table Generator
ExternalType Property	Fields	Specifies the data type of the corresponding column in the Microsoft Dataverse table.

PROPERTIES	APPLIES TO	DESCRIPTION
OptionMembers Property	Fields	Sets the option values for a field, text box, or variable.
OptionOrdinalValues Property	Fields	Specifies the list of option values. You can set this property, if the **ExternalType** is set to **Picklist**.

Enabling the table

Typically in Microsoft Dataverse, tables handle the internal processes. In order to access to the underlying Microsoft Dataverse table, you use the `TableType` property and select the value called **CDS**. This enables the table as an integration table for integrating Dynamics 365 Business Central with Microsoft Dataverse. The table is mainly based on a table in Microsoft Dataverse, such as the Accounts table.

Snippet support

Typing the shortcut `ttable` will create the basic layout for a table object when using the AL Language extension in Visual Studio Code.

Example

In the following example, the `SalesIntegration` table uses the `TableType` and `ExternalName` properties to link the underlying **Microsoft Dataverse** table for mapping the columns from the `Sales` table with the specified fields.

```
table 50100 SalesIntegration
{
    TableType = CDS;
    ExternalName = 'Sales';

    fields
    {
        field(1; ActualSales; Integer)
        {
            ExternalName = 'ActualSale';
            ExternalAccess = Full;
            ExternalType = 'String';
        }

        field(2; SalesCategories; Option)
        {
            ExternalName='SalesCategory';
            ExternalAccess = Read;
            ExternalType = 'Picklist';
            OptionMembers = Manufacturing, Marketing, Support;
            OptionOrdinalValues = -1, 1, 2;
        }
    }
}
```

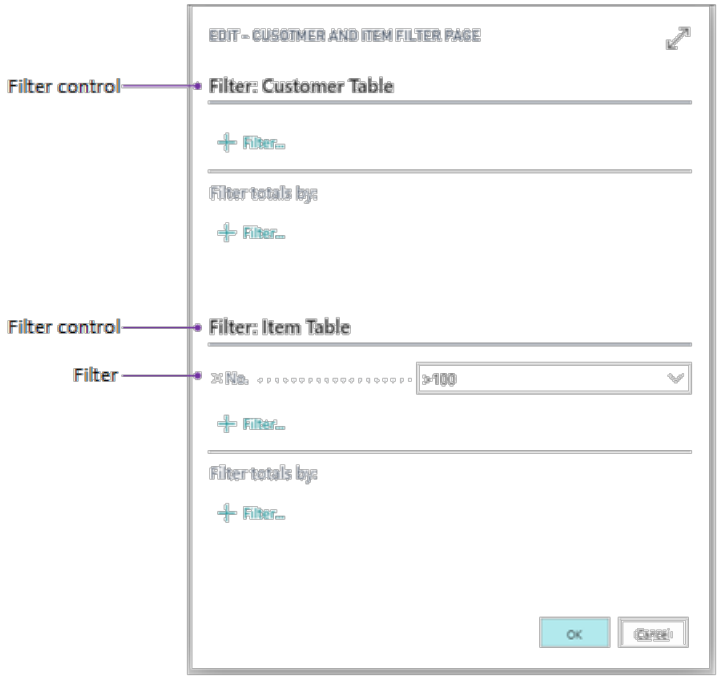
Creating Filter Pages for Filtering Tables

2/17/2021 • 2 minutes to read • Edit Online

In AL code, you can use the FilterPageBuilder data type to create a filter page that enables users to set filters on multiple tables. Filter pages contain one or more filter controls, where each filter control can be used to set filters on a specific table. In the Business Central client, filter pages are generated at runtime and run in a modal dialog box. The following figure illustrates a filter page that filters on the **Item** table.



To create a filter page, you use AL code and the methods that are available for the FilterPageBuilder Data Type. The following code example shows the code that creates the filter page in the figure.

```
var
    varItem: Record Item;
    varFilterPageBuilder: FilterPageBuilder;
begin
    varFilterPageBuilder.AddTable('Customer Table', Database::Customer);
    varFilterPageBuilder.AddRecord('Item Table', varItem);
    varFilterPageBuilder.Addfield('Item Table', varItem."No.", '>100');
    varFilterPageBuilder.PageCaption := 'Customer and Item Filter Page';
    varFilterPageBuilder.RunModal();
end;
```

Formatting Decimal Values in Fields

2/17/2021 • 5 minutes to read • Edit Online

This article describes how you can format the decimal values that appear in fields on table, pages and reports. For example, you can change how the data appears in a Cue on the Role Center page. To format data, you use a combination of the AutoFormatType Property, AutoFormatExpression Property, and DecimalPlaces Property of the field. These properties work together to enable you to specify the following:

- Display amounts and unit amounts in another currency.
- Specify the number of decimal places.
- Specify whether to display a thousand separator.
- Specify characters before and after the value, such as currency signs or %.

Implementation overview

When a field is used on a page or report, you can set the **AutoFormatType** and **AutoFormatExpr** properties directly on the page field or report field (column), or you can set them on the underlying table field. If you specify the properties on the table field, then the format applies wherever the field is used. Specifying the properties on the page or report field will only apply the format to the specific page or report. If you specify the properties on the table field and the page or report field, then the settings on the page or report field take precedence.

When you use the **AutoFormatType** and **AutoFormatExpression** properties to format a field, two events are raised by the system codeunit **45 Auto Format**: OnResolveAutoFormat and OnAfterResolveAutoFormat.

Setting up data formatting

The settings for the **AutoFormatType**, **AutoFormatExpression**, and **DecimalPlaces** properties will depend on the type of data that is displayed, for example, this could be currency amounts, unit amounts, simple decimals, or ratios. For the most part, the **AutoFormatType** property is the primary setting, which in turn determines the options for setting the **DecimalPlaces** and **AutoFormatExpr** properties.

If the **AutoFormatType** is not set or is set to an incorrect property value, then the default setting is used, regardless of whether the **AutoFormatExpression** or **DecimalValues** properties are set. The default setting uses `AutoFormatType = 1` and `AutoFormatExpression = ''`.

The following tables describes how to set each of the properties to achieve the format that you want.

Setting the DecimalPlaces property

With the following set up, the **AutoFormatExpression** property is ignored.

AUTOFORMATTYPE PROPERTY	DECIMALPLACES PROPERTY	USAGE DESCRIPTION

AUTOFORMATTYPE PROPERTY	DECIMALPLACES PROPERTY	USAGE DESCRIPTION

0	Set to the number of decimal places that you want to display for the value.	Use this configuration when you want to format the decimal value according the Standard Format 0 (which is the default format) with a specific number of decimal places.
		
		For example, if the value is a US decimal `-76543.21` and you set the **DecimalPlaces** property to `0`, then the value appears as **76,543**. The properties will look like this:
		
		`AutoFormatType = 0;`
		`DecimalPlaces = '0';`

Setting the AutoFormatExpression property

With the following setup, the **DecimalPlaces** property is ignored.

AUTOFORMATTYPE PROPERTY	AUTOFORMATEXPRESSION PROPERTY	USAGE DESCRIPTION

1	Set to return a currency code, such as USD or IDR. The blank currency code `''` denotes LCY and is the default value.	Use this configuration when you want to format the data as an amount. For example, a sales order will use two decimals when the currency is defined as US dollar and no decimals when the currency is defined as IDR (Indonesian rupiah). For example:
		
		`AutoFormatType = 1;`
		`AutoFormatExpression = 'IDR';`

2	Set to return a currency code such as USD or IDR. The blank currency code `''` denotes LCY and is the default value.	This is similar to the previous configuration where the **AutoFormatType** property is set to `1`, except you use this configuration when you want to format the data as a unit amount.

AUTOFORMATTYPE PROPERTY	AUTOFORMATEXPRESSION PROPERTY	USAGE DESCRIPTION

10	Set to the property according to the following syntax:
	`'[SubType][,<currencycode or expression>[,<PrefixedText>]]'`
	`SubType` can be `1`, `2`, another number, or omitted:
	`1` sets the value to an amount type (see 1 above). `2` sets the value to a unit amount type (see 2 above). The syntax for these two settings is:
	`'SubType,<currencycode[, <PrefixedText>]'`
	If you omit the subtype or use a number other than 1 or 2, the syntax is:
	`'<CustomNumber>, <expression>[, <PrefixedText>]'`
	where `<expression>` sets the precision and one of the standard formats. For more information, see Standard Formats.
		Use SubType `1` to add the currency symbol and use the amount type precision. You use SubType `2` for unit amount precision. For example, set the property to `'1,USD'` to add the **$** symbol, like **$543.21**.
		`AutoFormatType = 10;`
		`AutoFormatExpression = '1,USD';`
		If you omit the SubType, you can use this configuration to customize the format based on one of the standard formats. This option enables you to specify characters before and after the decimal value, such as currency signs **$** and percent **%**.
		For example, if you want to prefix the decimal value with a **$**, include a thousand separator, and have a maximum of two decimal places, such as **$76,453.21**, then you can set the properties to:
		`AutoFormatType = 10;`
		`AutoFormatExpression = '$<precision, 2:2><standard format, 0>'`
		If you want to display the decimal value as a percentage, then you can add `%` at the end of the setting. For example:
		`AutoFormatType = 10;`
		`AutoFormatExpression = '<precision, 1:1><standard format,0>%'`
		When you include a `%` at the end of the setting, then the decimal value is assumed to be the ratio, and the decimal value will be multiplied by 100. For example, a value of 0.98 will be formatted to **98%**.

11	Set the property to the standard format as explained below. For example: `'<Precision,3:3><Standard Format,0>'`	Use this option when you want full control over the formatting. The format string will be applied exactly as specified in the AutoFormatExpr property.

Precision

The precision determines the minimum and maximum number of decimal points for values. The precision takes the format `<precision,minimum:maximum>`. For example, `<precision,minimum:maximum>` sets the data with a minimum of 2 and a maximum of 3 decimal places.

Standard formats

The following table describes the standard formats that are available for the **AutoFormatExpr** property when the **AutoFormatType** property is set to 10.

STANDARD FORMAT	FORMAT DESCRIPTION	EUROPE DECIMAL EXAMPLE	US DECIMAL EXAMPLE
0	<Sign> <Integer Thousand> <Point or Comma> <Decimals>	-76.543,21	-76,543.21
1	<Sign> <Integer> <Point or Comma> <Decimals>	-76543,21	-76543.21
2	<Sign> <Integer> <Point or Comma> <Decimals>	-76543.21	-76543.21
3	<Integer Thousand> <Point or Comma> <Decimals> <Sign>	76.543,21-	76,543.21-
4	<Integer> <Decimals> <Point or Comma> <Sign>	76543,21-	76543.21-
9	XML format	-76543.21	-76543.21

Working With Media on Records

2/17/2021 • 7 minutes to read • Edit Online

This topic describes how you can upload media, such as an image, to the database for displaying with records in the client. There are two ways that you can do this:

- Use a BLOB data type

You add media to a BLOB data type field on the record. For more information, see BLOB Data Type.

- Use a Media or MediaSet data type

This way enables you to store media in system tables of the database, and then reference the media from application records. For example, you can:

- Display media with records in list type pages, when the page is viewed in the **Tile** layout. For more information, see Displaying Data as Tiles.
- Display media on a card type page for a record.
- Display media in a report.

Using the Media or MediaSet data type provides better performance than using a BLOB data type and is more flexible in its design. With a BLOB data type, each time the media is rendered in the client, it is retrieved from the SQL database server, which requires extra bandwidth and affects performance. With the Media and MediaSet data types, the client uses media ID to cache the media data, which in turn improves the response time for rendering the media in the user interface.

Using Media and Media Sets on records

Table fields support two data types for adding media to records: **Media** and **MediaSet**. With these data types, you can import media directly from a file to a record, or media can be passed to the record in an InStream object. Imported media is stored as an object in the system table **2000000184 Tenant Media** of the tenant database. Each media object is assigned a unique identifier (ID).

Media data type

The **Media** data type associates a record with a single media object. For example, you can use this data type to display an image with each record in a list type page.

If a media object is added to Media data type field, the field references the media object by its ID.

MediaSet data type

The **MediaSet** data type associates a record with one or more media objects. This enables you to set up a collection or catalog of media for a record. For example, you can use this data type to set up a slide show of images for a record in a card type page.

If a media object is added to **MediaSet** data type field, the media object is assigned to a media set in the system table **2000000183 Tenant Media Set**. The media set is assigned a unique identifier, which is then referenced from the field. The media set is created with the first file media object that you add on the record. Any additional media objects for the record are then associated with the same media set.

Indexing of media objects in a media set

A media set is an ordered list of media objects, determined by the order in which the media objects were added to the media set. This order cannot be changed. To identify this order, each media object is assigned an index number, starting a 1. This means that the first media added gets the index 1, the second media gets the index 2, and so on. If a media object is removed from the set, the list is re-indexed accordingly.

> **NOTE**
> If a **MediaSet** data type field is used in a report object, then only the first associated media file is displayed in the generated report.

Supported Media (MIME) types

The media type, also referred to as the MIME (Multipurpose Internet Mail Extensions) type, is an Internet standard to describe the contents of a file. Internet browsers use the MIME type to determine how to handle the file. The Media and MediaSet datatypes support all recognized MIME types.

A MIME type is defined by two parts, the *type* and *subtype*, where the format is `type/subtype`. For example, the MIME type for a JPEG image is image/jpeg. There are several types, including image, application, audio, video, text, and more. Each MIME type is associated with one or more acceptable file extensions. The following table lists some of the more common MIME types and their file extensions.

MIME TYPE	FILE EXTENSION
image/bmp	bmp
image/jpeg	jpeg, jpg, jpe
image/gif	gif
application/msword	doc
application/octet-stream	json
application/vnd.openxmlformats-officedocument.wordprocessingml.document	docx
application/vnd.ms-excel	xls
application/vnd.openxmlformats-officedocument.spreadsheetml.sheet	xlsx
application/vnd.ms-powerpoint	ppt
application/vnd.openxmlformats-officedocument.presentationml.presentation	pptx
application/pdf	pdf
application/xml	xml
audio/mpeg	mp3
audio/x-wav	wav

MIME TYPE	FILE EXTENSION
video/mp4	mp4
video/x-msvideo	avi
text/html	htm, html
text/plain	txt

> **NOTE**
>
> GIF type is not supported on reports. If you want to display an image on a report, use another supported type.
>
> Files with extensions that are not recognized are also supported and can be imported. These are stored as BLOBs (binary larger objects).

General procedure for adding media to records

The general procedure for setting up media on records is as follows:

1. Obtain the media file or files that you want to use on the record.
2. In AL, modify the table object to include a field that has the data type **Media** or **MediaSet**.
3. Add AL code that imports the media on the field.

   The **Media** and **MediaSet** data types support several methods that you can use to manage the media on records. See the next section for a complete list of methods with a link to more details, such as usage, parameters and sample code.

   For example, you can create a codeunit that calls one of the import methods, or add a page action that calls one of the methods.

AL methods

To get an overview of the methods that are related to the Media and MediaSet data types, see Media Data Type and MediaSet Data Type.

Automatic deletion of unused Media objects

When a table record that contains a media object is deleted, the OnDelete trigger gets the media or media set's ID, and uses the ID to look for other references to the media object from the same field index in the same table. If no other references are found, the media object is assumed to be unreferenced and it is deleted. The runtime will not look in all tables in the database to see if a media object is referenced elsewhere, because doing this would decrease performance and result in costly SQL table scans. If media objects are to be shared between tables, they should be shared through a reference table or by sharing the media set field content as described in the next section.

Sharing Media objects between different tables

To maintain data integrity related to media object, it's important to notice that the Media and MediaSet data types are complex data types that are referenced by an ID. The ID is stored in the record field that contains the media object. If a simple copy operation is performed to copy the media object from one media set field to another, the ID is copied to the new field. However, the application does not know that the media object is

referenced in two different fields, which causes issues when a row that contains the media ID is deleted.

To avoid unintentionally deleting referenced media objects, media sharing should be done by using the INSERT method to insert the media (by its ID) into the new media set field. This will create the correct (new) MediaSet records in the system tables, which means that the media object in one field will not be deleted if media object in the other field is deleted.

Example

This example copies a media set field called `MediaSetField` in table `mediaSourceTable` to a field in another table `mediaTargetTable`. The `FOR` loop will iterate all media objects in the source, and then insert their ID in the target field.

```
for index := 1 to mediaSourceTable.MediaSetField.COUNT do
 mediaTargetTable.MediaSetField.INSERT(mediaSourceTable.MediaSetField.ITEM(index));
MediaTargetTable.Modify(true);
```

This will create a new media set that contains the shared media object references. When you delete the media set (by deleting the MediaTargetTable record), the runtime will detect that the media object is used in multiple media sets, and therefore will not delete the media objects. The media objects might eventually be deleted when the runtime cannot find other references.

> **IMPORTANT**
> The simple field copy statement `mediaTargetTable.MediaSetField := mediaSourceTable.MediaSetField;` can only be used if `mediaTargetTable` is declared as the same record subtype as `mediaSourceTable`, and the target and source field IDs are the same.

Using Partial Records

2/17/2021 • 5 minutes to read • Edit Online

APPLIES TO: Business Central 2020 release wave 2 and later

The partial records capability in Business Central allows for loading a subset of normal table fields when accessing a SQL based data source. Using partial records improves performance of objects like reports and OData pages - objects whose source code loops through records. It's particularly beneficial when table extensions are used in the application.

Accessing a data source from AL code is typically done by using the record's methods GET, FIND, NEXT, and so on. Without using partial records, the runtime loads all normal fields when accessing the data source. Using the partial records API, you can now select a set of fields and only load them.

API Overview

To accommodate partial record loading, the following methods are available on both the RecordRef and Record data type in AL. These methods operate on the record instance that they're called on, changing the set of fields to load until otherwise altered. The methods are divided into two groups: methods that pertain to subsequent loads and methods that pertain to the currently loaded record.

Subsequent load methods

METHOD	DESCRIPTION	SEE MORE
SetLoadFields	Specifies a set of fields to be initially loaded when the record is retrieved from its data source. A call to this method will overwrite any fields that were previously set to load.	Record.SetLoadFields RecordRef.SetLoadFields
AddLoadFields	Adds fields to the current set of fields to be initially loaded when the record is retrieved from its data source. Subsequent calls to this method won't overwrite fields that were previously selected for loading.	Record.AddLoadFields RecordRef.AddLoadFields

Current load methods

METHOD	DESCRIPTION	SEE MORE
AreFieldsLoaded	Checks whether the specified fields are all initially loaded.	Record.AreFieldsLoaded RecordRef.AreFieldsLoaded
LoadFields	Accesses the table's corresponding data source to load the specified fields.	Record.LoadFields RecordRef.LoadFields

A record instance that has been previously loaded with fields can be reset to a non-partial load either by calling Record.SetLoadFields without any parameters, or by calling Reset. After being reset, subsequent loads will behave as if SetLoadFields hadn't previously been called on the record instance.

Example

The following code shows a way to load only a single field from the **Item** table for computing the arithmetic mean.

```
procedure ComputeArithmeticMean(): Decimal;
var
    Item: Record Item;
    SumTotal: Decimal;
    Counter: Integer;
begin
    Item.SetLoadFields(Item."Standard Cost");
    if Item.FindSet() then begin
        repeat
            SumTotal += Item."Standard Cost";
            Counter += 1;
        until Item.Next() = 0;
        exit(SumTotal / Counter);
    end;
end
```

Notice that the call to SetLoadFields occurs before the data fetching operations. This call determines which fields are needed for the FindSet call. You use the same pattern for AddLoadFields calls.

Usage guidelines

This feature gives you the ability to limit the fields that load for a record to only those fields that are necessary. In general, loading fewer fields will make operations faster. But the most significant performance gains can be seen with table extensions - by not loading unnecessary fields in table extensions. Table extensions that don't have any fields for loading won't be part of the data join, which saves time.

> **TIP**
> Testing on the previous example code showed that the execution time for loading only the "Standard Cost" field was nine times faster than loading all normal fields. Your performance numbers will vary depending on the machine and the setup with the SQL database.

For performance reasons, it's not recommended to use partial records on a record that will do inserts, deletes, renames, transferfields, or copies to temporary records. All these operations require that all fields on the record are loaded, so the platform will emit a JIT load if they're not already loaded. A JIT load requires to access the data source again, this cost is larger than the gains of loading fewer fields. For this reason, the feature is especially advantageous in reading-based scenarios.

Reports and OData pages

Currently, the platform implicitly uses partial records when fetching data for reports and calling pages through OData.

For reports, the fields that are selected for loading are fields setup as columns in the report data set. If a report accesses a field that isn't in the data set, it's beneficial to do one of the following to avoid just-in-time (JIT) loading:

- Add the field as a column in the data set.
- Add the field on the OnPreDataItem trigger.

  The following example code snippet illustrates how to use the AddLoadFields method on a report's

OnPreDataItem trigger to add a field for loading:

```
trigger OnPreDataItem()
begin
    CurrencyDataItem.AddLoadFields(CurrencyDataItem."ISO Numeric Code");
end;

trigger OnAfterGetRecord()
begin
    if (CurrencyDataItem."ISO Numeric Code" <> 'DKK') then begin
        CurrReport.Skip();
    end;
end;
```

The same issue arises for pages called through OData. If a field isn't requested for the OData output, it won't be loaded. In this case, it's beneficial to add the fields using the AddLoadFields method in the OnOpenPage trigger.

Just-in-time (JIT) loading

When a record is loaded as a partial record, the obvious question is: What happens when accessing a field that hasn't been selected for loading?". The answer is JIT loading. The platform, in such a case, does an implicit GET on the record and loads out the missing field.

When JIT loading occurs, another access to the data source is required. These operations tend to be fast because they're GET calls. GET calls can often be served by the server's data cache or can be resolved as a clustered index operation on the database.

A JIT load may fail for multiple reasons, like:

- The record has been modified between the original load and the subsequent JIT load.
- The record has been deleted between the original load and the subsequent JIT load.
- The record has been renamed between the original load and the subsequent JIT load.

Iterating over records

When iterating over records in the database, an enumerator is created based on selected fields. Then, a row is fetched when NEXT is called. This behavior is an optimization that allows for large parts of the operation to be done only once.

Certain operations will invalidate the enumerator and force the creation of a new one, which adds some overhead. As long as the enumerator isn't invalidated too frequently, this model is an effective optimization. When accessing fields that aren't loaded, the platform does a JIT load, followed by an update of the enumerator. This process eliminates the need to trigger a JIT load on subsequent iterations.

When passing a record by value, without using a VAR, a new copy of the record is created. The original record and its copy don't share filters, fields selected for load, and so on. So accessing an unloaded field will trigger a JIT load. But it won't update the enumerator, which means future iterations will also require JIT load.

There are a few options to remedy this situation:

- Pass the record reference using VAR parameter allows for updating of enumerator.
- Call AddLoadFields(fieldnames) on the original record before passing by value.
- Before calling FIND, GET, NEXT, and so on, use the SetLoadFields(fieldnames) to set all fields needed for load.

FAQ for Partial Records

2/17/2021 • 2 minutes to read • Edit Online

This article answers some of the most typical questions about the partial records capability in Business Central.

Do I need to change any code to keep my solution functional?

No. If a field that's not selected for loading is accessed, the data will be fetched automatically for the current record. The field will then be selected for loading on future requests by using this record instance. However, you may still get the message *Record has been modified by another user*, like you could before. But now, the message can also appear in read-only scenarios where the record isn't locked.

Where is "Partial Records" applied? To all records instances?

Currently, the partial records capability is only implicitly used on report data items and OData pages. The behavior for all other record instances is as before, that is, all fields will be loaded. However, as an AL developer, use in your own code to improve performance in looping code.

What happens when accessing fields not selected for load?

The platform will load any fields not selected for loading when accessed, making it seem like the field was already loaded.

What happens if the record has been modified or deleted in between the original load and JIT load?

The platform will validate that either the record is unchanged, or no change has been made to read fields.

What's a JIT load?

The platform determines that a field, which isn't currently loaded, is needed. Then it loads the field.

Can I optimize my code, so that I can avoid an extra database call to load my field?

Yes. You can add your field to the list of fields selected for loading by using the AddLoadFields method.

Which fields can be selected not to be loaded?

Any field that isn't a FlowField, FlowFilter, Primary Key, Timestamp, SystemId, Audit Fields, or Blobs.

How do partial records interact with table extensions?

When no fields from a table extension are selected for loading, then table extension data isn't joined, which saves time.

What's the performance overhead of determining the fields necessary for a record?

For reports, a calculation takes place at compile time and once per data item type per report execution. For OData pages, the calculation takes place at compile time and once per request segment.

Compared to the time it takes to fetch data, the overhead is insignificant.

Can I disable partial records in certain scenarios?

- With Business Central on-premises, you can turn off partial records by using **Enable Partial Records** setting of Business Central Server. See Configuring Business Central Server .
- With Business Central online, you can call the SetLoadFields method with no fields. Calling an empty SetLoadFields method will revert the behavior to what it was before Business Central 2020 release wave 2.

Migrating Tables and Fields Between Extensions

2/17/2021 • 4 minutes to read • Edit Online

INTRODUCED IN: Business Central 2019 Release Wave 2, update 15.3, for on-premises only

Data migration allows you to move table and field data between extensions. The concepts and processes in this article apply to large-scale and small-scale data migrations. A large-scale migration is typically upgrade scenario, like upgrading from Business Central version 14 to version 16. Small-scale migrations are scenarios where you want to move a limited number of objects from one extension to another.

Overview

The move is divided into two phases: development and deployment. However, before you begin, you have to determine the direction of the migration within the dependency graph.

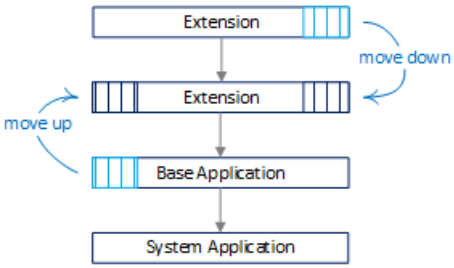
Limitations

- The concepts discussed in this article pertain only to AL. They're not supported in C/AL.
- You can only move fields from a table object to a table extension or move entire tables from one extension to another.
- You can't:
  - Move table extensions to other extensions.
  - Merge multiple table extensions into one extension.
  - Split table extensions into multiple extensions.

  Although you can't use this feature for these scenarios, you can achieve the scenarios by other means, which require more manual work. Examples include obsoleting, copying/re-IDing/renaming, moving data, and more.

Determining the migration direction in the dependency graph

The process to migrate tables and fields to another extension depends on the migration's direction in the dependency graph. The following figure illustrates a simplified extension dependency graph. From top to bottom, an extension is dependent on any extension below it in the graph.



When to move down

Typical move-down scenarios include:

- Moving to a shared extension.

  You want to move common tables to a separate extension that other extensions can have a dependency on.

- Transitioning from a customized base application extension with its own ID to an extension on top of the

Microsoft Base Application.

You have a customized base application extension with its own ID. You want to transition to the Microsoft Base Application. In this case, customizations remain in the current extension. Base objects are removed and ownership transferred to Microsoft Base Application.

This scenario is typical for embed ISV apps and on premises solutions moving to the cloud. It's also relevant for solutions that will remain on-premises for the foreseeable future. Use it to refactor code customizations into cleaner, standard base with extensions as part of upgrading.

For more information, see Moving Tables and Fields to Extension Down the Dependency Graph.

When to move up

Typical move-up scenarios include:

- Splitting an extension in two, with one dependent on the other.
- Extracting the system application from the base application.
- Transitioning from a customized base application extension with Microsoft ID to the Microsoft Base Application.

  You have a customized base application extension that reuses the Microsoft application ID. You want to transition to the standard Microsoft Base Application. In this case, customizations are moved out of the base application up into new extensions. The new extensions have new application IDs and dependencies to the standard Microsoft base application. The customization objects are removed from the custom base application and ownership transferred to the new extensions.

For more information, see Moving Tables and Fields to Extension Up the Dependency Graph.

Development

Development involves making application code changes required for the move. In short, the work involves:

- Creating the *releasing extension* version

  You create a new version of the original extension. This new version contains the tables or fields you want to keep in the extension. The tables and fields that you want to move are deleted from this extension. They're moved to the *receiving extension*.

- Creating the *receiving extension*

  You create new extension that includes the table and fields that you want moved. It essentially includes those tables and fields deleted from the releasing extension.

The key to the move is the *migration.json* file. You add the file to the project for the releasing extension. This file provides a pointer to the ID of new receiving extension where tables and fields are to be moved to. The *migration.json* is used in the deployment phase. Its purpose is to transfer ownership of tables and fields in the database from one extension to another. For more information, see Migration.json File.

Deployment

The deployment phase is when the data is migrated to new tables in the database. In this phase, ownership of tables and fields is switched from one extension to another. Deployment involves publishing, syncing, upgrading, and installing extensions.

The order that you synchronize extensions is important:

- The receiving extensions must be synchronized first.

- The releasing extensions, which include those extensions that include the migration.json file, must be synchronized last.

  These extensions are synchronized last because the tables are moved during the synchronization of the releasing extensions. At the end of the synchronization process, the system checks for breaking changes introduced by the extension. If the extension isn't synchronized last, breaking changes will be detected.

Moving Tables and Fields to Extensions Down the Dependency Graph

2/17/2021 • 3 minutes to read • Edit Online

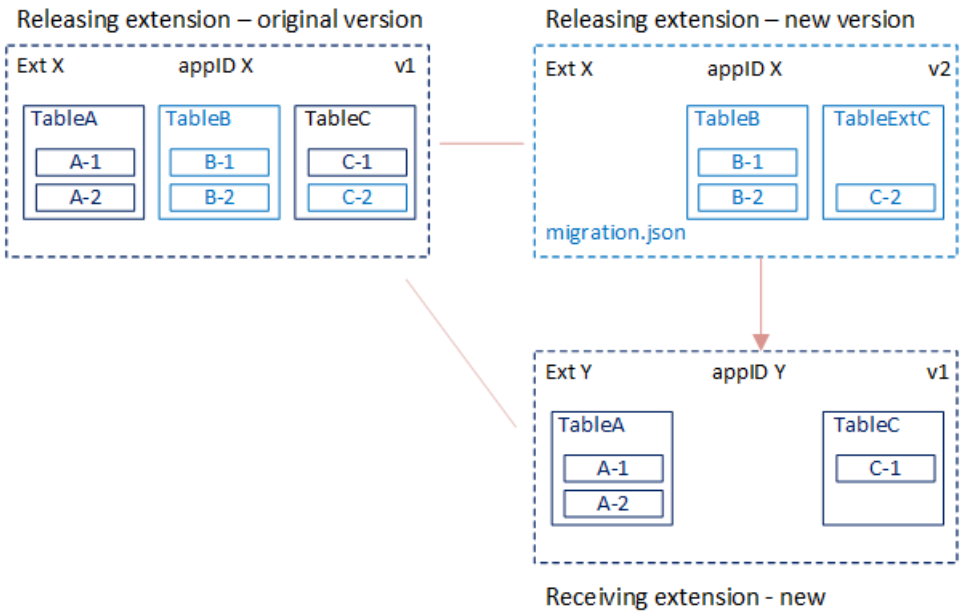
INTRODUCED IN: Business Central 2019 Release Wave 2, update 15.3, for on-premises only

This article explains how to move tables and fields from an extension to another extension that is down the dependency graph.

> **TIP**
> For more information about the general concepts for moving tables and fields between extensions, see Migrating Tables and Fields Between Extensions. This article explains the the difference between moving up and down the dependency graph.

Overview

The steps in this article are based on the example illustrated in the following figure. Although your scenario is different, the concept and process are much the same.



In the example, **TableB** and **Field C-2** are customizations. You'll keep these elements in the original extension, but create a new version without **TableA** and **TableC**. You'll move **TableA** and **TableC** down the dependency chain to a new, separate extension.

Prerequisite

If you're moving enum type fields, then your solution must be running on Business Central 2020 release wave 1, version 16.5 or later. For more information, see Known Issues.

Create receiving extension (Ext Y)

The receiving extension will contain the table and fields that you want to move. In this example, these objects

include **TableA** and **TableC**.

1. Create an AL project for the receiving extension.
2. Add a table object definition for **TableA**.

   The table definition (schema) must include the full schema of the releasing extension **Ext X**, with the same field definitions. You can add new fields.
3. Add a table object definition for **TableC**.

   The table definition (schema) must include the full schema of the releasing extension **Ext X**, with the same field definitions, except don't include field **C-2**. You can add new fields.
4. Make a note of the `ID` of the new extension. You'll use this ID in the next task.

   For purposes of the example, the ID is `11111111-aaaa-2222-bbbb-333333333333`.
5. Compile the extension package.

Create new version of releasing extension (Ext X v2)

1. In the releasing extension AL project, add a migration.json file that points to the ID of the target extension.

   ```
   {
   "apprules": [
       {
           "id": "11111111-aaaa-2222-bbbb-333333333333"
       }
   ]
   }
   ```

   For more information, see The Migration.json File.
2. Modify the app.json file as follows:

   - Ensure that `"target": "OnPrem"`.
   - Increase the `"version"` value.
   - In the `"dependencies"` parameter, set up a dependency on the new receiving extension **Ext Y**.

   For more information, see App.json file.
3. Complete the following steps for **TableC**.

   a. Add a table extension object **TableExtC**.
   b. In table extension object **TableExtC**, add a field definition for field **C-2** that matches its definition in the original **TableC** object.
   c. Delete the original **TableC** object.
4. Delete the entire table object for **TableA**.
5. Compile a new version of the extension package.

Deploy extensions

1. Uninstall the old version of the releasing extension **Ext X**.
2. Publish the new receiving extension **Ext Y** and releasing extension version **Ext X v2**.
3. Synchronize the receiving extension **Ext Y**.

This step creates empty database tables for **TableA** and **TableC** that are owned by the receiving extension **Ext Y**.

> **IMPORTANT**
>
> The receiving extension must always be synchronized first.

4. Synchronize the new version of the releasing extension **Ext X v2**.

   This step first reads rules in the migration.json file of the extension, then does the following operations in the database:

   - Creates a companion table for field **C-2** of the table extension object **TableExtC**.
   - Copies data from column **C-2** in the original **TableC** to new companion table **TableExtC**.
   - Temporarily renames the new empty tables **TableA** and **TableC** made by receiving extension **Ext Y**.
   - Renames the original tables **TableA** and **TableC** that include the data. Instead of including the ID of the releasing extension **Ext X**, the names are changed to include the ID of the receiving extension **Ext Y**. This step essentially transfers ownership from **Ext X** to **Ext Y**.
   - Deletes the unused column for **C-2** in the original table **TableC**.
   - Deletes the empty, renamed tables of **Ext Y**.
5. Install the receiving extension **Ext Y**.
6. Run Start-NAVAppDataUpgrade cmdlet on the new releasing extension version **Ext X v2**.

   This step basically installs the new extension version. You run a data upgrade because an earlier version has been installed and is still published.

Moving Tables and Fields to Extensions Up the Dependency Graph

2/17/2021 • 5 minutes to read • Edit Online

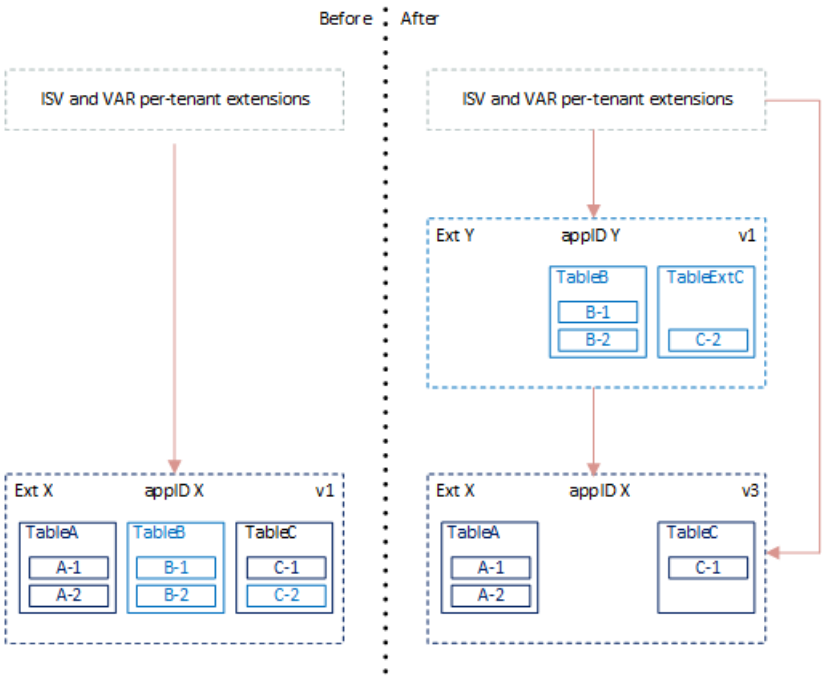
INTRODUCED IN: Business Central 2019 Release Wave 2, update 15.3, for on-premises only

This article explains how to move tables and fields from an extension to another extension that is up the dependency graph.

> **TIP**
> For more information about the general concepts for moving tables and fields between extensions, see Migrating Tables and Fields Between Extensions. This article explains the the difference between moving up and down the dependency graph.

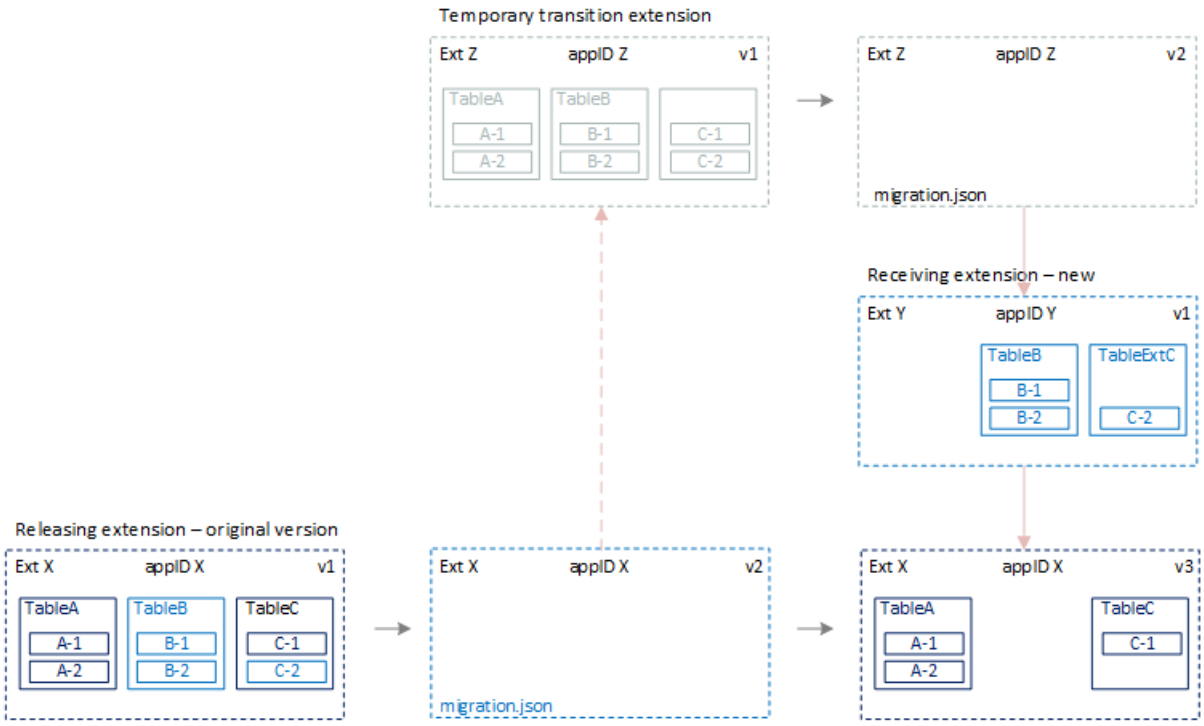
Overview

The steps are based on the example illustrated in the following figure. Although your scenario is different, the concept and process are much the same.



In the example, **TableB** and **Field C-2** are customizations. You'll move these elements from the original extension up to a new extension. This new extension will have a dependency on the original extension. You'll keep **TableA** and **TableC** in the original extension.

To accommodate data migration, you'll have to create an extension that is only used for deployment. This extension is **Ext Z** in the figure. There are two stages of deployment:



- In the first stage, **Ext Z** temporarily takes ownership of tables and fields from **Ext X**.
- In the second stage, **Ext Z** releases ownership to extensions **Ext X** and **Ext Y**. You uninstall and unpublish transition extension **Ext Z** when you finish deployment.

This process is a two-step process because we only support moving down the dependency graph. So instead, the concept is to first move the tables' ownership to an extension above the receiving extensions in the dependency graph. Then, the extensions are moved down. This concept essentially turns the process into a two-step, move-down process.

Ext Z is used just as a temporary extension for moving ownership. So, it only includes schema objects. As a result, customers can't run on the tenant until both steps have been done.

> **NOTE**
> You can only use this process for on-premise solutions.

Prerequisite

If you're moving enum type fields, then your solution must be running on Business Central 2020 release wave 1, version 16.5 or later. For more information, see Known Issues.

Create transition extension (Ext Z v1)

The transition extension will contain replicas of all table object definitions in the releasing extension, except logic code. In the illustration, these objects include **TableA**, **TableB**, and **TableC** and current their field definitions. The transition extension is **Ext Z**.

1. Create an AL project for the transition extension.
2. Add a table object that exactly matches the table object definitions for **TableA**, **TableB**, and **TableC** in the releasing extension.
3. Compile the extension package.
4. Make a note of the `ID` of the new extension. You'll use this ID in the next task.

For purposes of the example, the ID is `11111111-aaaa-2222-bbbb-333333333333`. The value for your extension will be different.

Create empty version of releasing extension (Ext X v2)

In this step, you create a new version of the releasing extension that doesn't contain any objects. It only contains a `migration.json` file that points to **Ext Z**.

1. In the releasing extension AL project, add a migration.json file that points to the ID of the transition extension **Ext Z**.

   ```
   {
   "apprules": [
       {
           "id": "11111111-aaaa-2222-bbbb-333333333333"
       }
   ]
   }
   ```

   For more information, see The Migration.json File.

2. Delete all objects from the extension. The objects include **TableA**, **TableB**, and **TableC**.
3. In the app.json file, increase the `version` value. Ensure that `"target": "OnPrem"`.
4. Compile a new version of the extension package.

Create receiving extension (Ext Y v1)

You now create a new extension that contains the customization you want to move from the releasing. In this example, the customizations include **TableB** and a **TableExtC**.

1. Create an AL project for **Ext Y**.
2. In the app.json file, set up a dependency on the releasing extension **Ext X**.
3. Add a table definition and code for **TableB** that exactly matches the definition in the original releasing extension.
4. Add a table extension object called **TableExtC**. Then, add a field definition for field **C-2** that matches its definition in the original **TableC** object of the releasing extension.
5. Compile the extension package.
6. Make a note of the `ID` of the new extension. You'll use this ID in the next task.

   For purposes of the example, the ID is `44444444-cccc-5555-dddd-666666666666`. The value for your extension will be different.

Create final version of releasing extension (Ext X v3)

In this step, you create another version of the releasing extension **Ext X**. This version will contain the objects and code that you want to finally publish.

1. Create an AL project for **Ext X**.
2. Add a table definition and code for **TableA** that exactly matches the definition in the original releasing extension.
3. Add a table object for **TableC** and field definition for **C-1** that matches the definitions in the original

TableC object of the releasing extension.

4. In the app.json file, increase the `version` value.
5. Compile the extension package.
6. Make a note of the `ID` of the extension. You'll use this ID in the next task.

   For purposes of the example, the ID is `77777777-eeee-8888-ffff-999999999999`. The value for your extension will be different.

Create new empty version of transition extension (Ext Z v2)

In this step, you create a new version of **Ext Z** that only contains a `migration.json` file. This `migration.json` file points the IDS of **Ext X** and **Ext Y**. The file is used to release ownership.

1. In the extension AL project, add a migration.json file that points to the IDs of the releasing extension **Ext X** and receiving extension **Ext Y**.

   ```
   {
   "apprules": [
       {
           "id": "77777777-eeee-8888-ffff-999999999999"
       }
       {
           "id": "44444444-cccc-5555-dddd-666666666666"
       }
   ]
   }
   ```

   For more information, see The Migration.json File.

2. Delete the object definitions for **TableA**, **TableB**, and **TableC**.
3. In the app.json file, increase the `version` value.
4. Compile the extension package.

Deploy the extensions

1. Uninstall the current version of the releasing extension **Ext X**.
2. Complete the following steps for the first stage of deployment:

   a. Publish the transition extension **Ext Z** and empty version of **Ext X v2**.

   b. Synchronize the transition extension **Ext Z**.

      This step creates empty database tables **TableA**, **TableB**, and **TableC** that are owned by **Ext Z**.

      > **IMPORTANT**
      > Extensions receiving table objects must be synced first. Extension releasing/giving away table objects must be synced last.

   c. Synchronize the releasing extension **Ext X v2**.

      This step will read the migration.json of the extension. Then transfer ownership of the original tables **TableA**, **TableB**, and **TableC** to **Ext Z**.

3. Complete the following steps for the second stage of deployment:

    a. Publish the next version for **Ext Z v2** and **Ext X v3**, and the first version of **Ext Y**.

    b. Synchronize the extensions in the following order: **Ext X v3**, **Ext Y v1**, and **Ext Z v2**.

        Synchronize **Ext Z v2** last. When you synchronize **Ext Z v2**, ownership of the tables is transferred from **Ext Z** to **Ext X** and **Ext Y**.

4. Run Start-NAVAppDataUpgrade cmdlet on the new releasing extension version**Ext X v3**.

    This step basically installs the new extension version. You run a data upgrade because an earlier version has been installed and is still published.

5. Install the new receiving extension **Ext Y v1**.

6. Unpublish both versions of **Ext Z**.

The Migration.json File

2/17/2021 • 2 minutes to read • Edit Online

INTRODUCED IN: Business Central 2019 Release Wave 2, update 15.3, for on-premises only

Data migration allows you to move table and field data between extensions. The `migration.json` file provides a pointer to the ID of an app that one or more tables will be moved to. This allows you to move table and field data from, for example, a code-customization on the base application to an extension of the base application. The `migration.json` file can be added into the app project of an extension that a table is moved from to specify the ID of the app that the table will be moved to. It can, for example, be placed at the root of the AL project. The `migration.json` file must be created manually following the steps and syntax as described below.

In the extension `app.json` file, ensure that `"target": "OnPrem"`. For more information, see JSON Files.

Creating the migration.json file

1. In the root folder of the app project that will migrate data to a different app project, choose **New File**.
2. Name the file `migration.json`.
3. Edit the file by adding one or more IDs inside the `"apprules":[]` section, such as the following:

```
{
    "apprules": [
        {
            "id": "12345678-abcd-abcd-abcd-1234567890ab"
        }
    ]
}
```

4. Save the `migration.json` file in the project.

You now have the migration file in place for the data migration from one app project to another. This will be used for performing the data migration steps. For more information, see Migrating Tables and Fields Between Extensions.

Pages Overview

2/17/2021 • 7 minutes to read • Edit Online

In Dynamics 365 Business Central, pages are the main way to display and organize data. Pages are the primary object that a user will interact with and have a different behavior based on the type of page that you choose. Pages are designed independently of the device they are to be rendered on, and in this way the same page can be reused across phone, tablet, and web clients.

A page is defined in code as an object composed of controls, properties, actions, and triggers. You can also use Designer in Dynamics 365 Business Central to create a page. For more information, see Using Designer.

Whether you are creating a new page, or extending an existing page, you will add a new .al file to your project and describe the page object in code. The difference is basically that for a new page, you need to define the entire page, whereas when modifying an existing page, you only add the extra functionality or modify the existing.

The structure of a page is hierarchical and breaks down in to three sections. The first block contains metadata for the overall page. The metadata describes the page type and the source table it is showing data from. The next section; the layout, describes the visual parts on the page. The final section details the actions that are published on the page.

Furthermore, the page has properties. Properties work in the same way for pages as they do for other Dynamics 365 Business Central objects. For more information, see Page Properties.

> **TIP**
> For information about designing pages, see Page Types and Layouts.

Page metadata

For a new page object, you must at least specify the type of page; `PageType` and the data source; `SourceTable` of the page. And you can also set other metadata at the beginning of the declaration of the page object.

```
page 50102 PageName
{
    PageType = List;
    SourceTable = TableName;
    Editable = true;
    ContextSensitiveHelpPage = 'feature-overview';
    ...
}
```

Types of pages

Which page type you choose depends on the application task that you want to support, the content that you want to display, and how you want to display it. The Role Center page is the main or home page and it helps the user focus on the most important daily tasks and activities. Other types of pages, such as list pages or card pages are typically linked from the home page for easy access. The following page types are available:

PAGE TYPE	DESCRIPTION

PAGE TYPE	DESCRIPTION
RoleCenter	The Role Center page is the main page.
Card	A Card page is used to view and edit one record or entity from a table.
CardPart	A Card Part page is used in a FactBox on another page to view or edit additional fields associated with a selected entity in the page.
List	A List page displays content from a table in a list format.
ListPart	Similar to a List page, a List Part page displays content from a table in a list format. The difference is that you use the List part page as another page in a FactBox or as a part of the Role Center page.
ListPlus	A ListPlus page displays content from a table in a list format. The difference from a List page is that the main content is a ListPart, not a Repeater group as the List has it.
Document	A Document page usually consists of two separate pages combined into one, with one page nested in the other. A Document page is suitable for use when you want to display data from two tables that are linked together.
WorkSheet	You use a Worksheet page type for creating worksheet or journal task pages.
ConfirmationDialog	You use the ConfirmationDialog page to display messages or prompt users with a confirmation before they continue with the task that they are working on.
StandardDialog	The StandardDialog is a simple page type that you use when users only need to input data and do not need to perform other actions from the page.
NavigatePage	You use a Navigate page type to create a wizard that leads the user through a sequence of steps for completing a task.
HeadlinePart	You use a HeadlinePart page type to display a set of changing headlines on a Role Center.
API	Pages of this type are used to generate web service endpoints and cannot be shown in the user interface. This page type should not be extended by creating a page extension object. Instead, create a new API by adding a page object.

NOTE

For backwards compatibility we continue to support adding non-part pages as parts. We do, however, recommend that you redesign your page to only use Card part or List part, as we may remove support in a future update.

Page layout

The page layout of the page object determines what the page will look like and is specified in the `layout` section. The `layout` contains one or more `area` sections that define a certain placement on the page.

You can choose between the following `area` categories:

AREA TYPE	PLACEMENT ON THE PAGE
`Content`	The content area displays the content of, for example, a RoleCenter or a List page.
`FactBoxes`	The FactBox area is placed to the right-most side of a page. Displays content related to an item on the main content page.
`RoleCenter`	The RoleCenter is the main page of the application and is used for quick access to frequently used information and tasks.

Page actions

All pages contain menu items and navigation controls called actions. In Dynamics 365 Business Central, actions are displayed at the top of each page in the ribbon or in the navigation pane. The `actions` section of the page describes what the user is able to do on a page and must be designed with the user's need for process support in mind.

Actions can be displayed in the ribbon of all pages and grouped together under the following actions tabs:

- Home
- Actions
- Navigate
- Report

Creating actions can include adding activity buttons/cues to a page, configuring navigation items on a user role center, or adding Reports to a page. To learn how you can enable users to quickly locate the actions they want to use, see Actions.

Adding Help to the page objects

The Business Central user assistance model expects your solution to include tooltips and links to context-sensitive Help. For more information, see User Assistance Model.

Context-sensitive Help

To apply context-sensitive Help to your app, you specify a URL to your Help library in the app.json file, and you then set the relevant target Help files as property values for each of your page objects and page extension objects. Between them, these two settings then give users access to context-sensitive Help for the features in your app at runtime. For more information, see Configure Context-Sensitive Help.

Tooltips

In combination with descriptive captions and instructional text, tooltips are our current implementation of *embedded user assistance*, which is an important principle in today's world of software design. The tooltips are there to help users unblock themselves by providing an answer to the most likely questions the users might have, such as "What data can I input here?" or "What is the data used for?".

The base application has set the Tooltip property for all controls on (almost) all page objects. Most system

actions also include tooltips so that users get a consistent experience. Your extensions are expected to also include tooltips for the same reason. For more information, see ToolTip Property.

Instructional text

The base application has applied instructional text to setup guides and certain other types of page objects. Your extensions are expected to also include instructional text to setup guides for the same reason. For more information, see InstructionalText Property.

Example

The following example shows how you can apply user assistance and link to Help in a page object:

```
page 50101 "Reward Card"
{
    PageType = Card;
    SourceTable = Reward;
    ContextSensitiveHelpPage = 'sales-rewards';

    layout
    {
        area(content)
        {
            group(Reward)
            {
                InstructionalText = 'Fill in the fields so that you can reward customers with discounts.';
                field("Reward Id"; "Reward ID")
                {
                    ApplicationArea = All;
                    ToolTip = 'Specifies the unique ID of the reward.';
                }

                field(Description; Description)
                {
                    ApplicationArea = All;
                    ToolTip = 'Specifies what this type of reward is used for.';
                }

                field("Discount Percentage"; "Discount Percentage")
                {
                    ApplicationArea = All;
                    ToolTip = 'Specifies the impact of the reward on the customer''s price.';
                }
            }
        }
    }
}
```

In this example, the app.json file has specified a link to where the *sales-rewards* target file is published, such as `"contextSensitiveHelpUrl": "https://mysite.com/documentation"`.

Best practices for designing pages

We recommend that you simplify the user experience by reducing what users see by default. You can promote the information that the users most frequently need to see and hide the less important information. For example:

- Place common tasks in the ribbon
- Organize information pages under FastTabs and, by default, hide the FastTabs that are infrequently visited.
- Use one to three FactBoxes on a page to provide supplementary information and a place for adding notes
- Add a target Help file for context-sensitive Help for the feature that the page object supports

Page Object

2/17/2021 • 2 minutes to read • Edit Online

Pages are the main way to display and organize visual data in Dynamics 365 Business Central. They are the primary object that a user will interact with and have a different behavior based on the type that you choose. Pages are designed independently of the device they are to be rendered on, and in this way the same page can be reused across phone, tablet, and web clients.

The structure of a page is hierarchical and breaks down in to three sections. The first block contains metadata for the overall page; the type of the page and the source table it is showing data from. The next section; the layout, describes the visual parts on the page. The final section details the actions that are published on the page.

When developing a solution for Dynamics 365 Business Central, you will follow the code layout for a page as shown in the page example below, but for more details on the individual controls and properties that are available, see Page Property Overview.

If you want to, for example, add functionality to a page that already exists in Business Central, you can create a page extension object that changes an existing page object. For more information, see Page Extension Object. Depending on how much you want to change on an existing page, you can also create a page customization object, which offers modifications on actions and layout. For more information, see Page Customization Object.

> **IMPORTANT**
> Only pages with the Extensible Property set to **true** can be extended.

> **NOTE**
> Extension objects can have a name with a maximum length of 30 characters.

Snippet support

Typing the shortcut `tpage` will create the basic layout for a page object when using the AL Language extension in Visual Studio Code.

> **TIP**
> Use **Ctrl+Space** to trigger IntelliSense and get assistance on code completion, parameter info, quick info, and member lists.

Views

Views in Dynamics 365 Business Central are used on list pages to define a different view of the data on a given page. Views can be defined for Pages, Page Extensions, and Page Customization. For more information, see Views.

Page example

```
page 50101 SimpleCustomerCard
{
    PageType = Card;
    SourceTable = Customer;
    ContextSensitiveHelpPage = 'my-feature';

    layout
    {
        area(content)
        {
            group(General)
            {
                field("No."; "No.")
                {
                    ApplicationArea = All;
                    CaptionML = ENU = 'Hello';

                    trigger OnValidate()
                    begin
                        if "No." < '' then
                            Message('Number too small')
                    end;
                }

                field(Name; Name)
                {
                    ApplicationArea = All;
                }
                field(Address; Address)
                {
                    ApplicationArea = All;
                }
            }
        }
    }
    actions
    {
        area(Navigation)
        {
            action(NewAction)
            {
                ApplicationArea = All;
                RunObject = codeunit "Document Totals";
            }
        }
    }
}
```

Page Extension Object

2/17/2021 • 4 minutes to read • Edit Online

The page extension object extends a Dynamics 365 Business Central page object and adds or overrides the functionality.

The structure of a page is hierarchical and breaks down into three sections. The first block contains metadata for the overall page; the type of the page and the source table it is showing data from. The next section; the layout, describes the visual parts on the page. The final section details the actions that are published on the page.

For more information about the Page and Page Extension objects, see Pages Overview.

IMPORTANT

Only pages with the Extensible Property set to **true** can be extended.

NOTE

Extension objects can have a name with a maximum length of 30 characters.

IMPORTANT

The API page type should not be extended by creating a page extension object. Instead, create a new API by adding a page object.

NOTE

Modifying actions in Cue groups on page extensions is not supported.

Snippet support

Typing the shortcut `tpageext` will create the basic layout for a page extension object when using the AL Language extension in Visual Studio Code.

TIP

Use **Ctrl+Space** to trigger IntelliSense and get assistance on code completion, parameter info, quick info, and member lists.

Views

Views in Dynamics 365 Business Central are used on list pages to define a different view of the data on a given page. Views can be defined for Pages, Page Extensions, and Page Customization. For more information, see Views.

Using keywords to place actions and controls

You can use the following keywords in the `layout` section to place and move fields and groups on the page extension. Similarly, in the `actions` section, you use these keywords to place actions in the ribbon.

KEYWORDS	SYNTAX	APPLIES TO
`addfirst`	`addfirst(Anchor)`	**Anchor**: areas and groups
`addlast`	`addlast(Anchor)`	**Anchor**: areas and groups
`addafter`	`addafter(Anchor)`	**Anchor**: controls, actions, and groups
`addbefore`	`addbefore(Anchor)`	**Anchor**: controls, actions, and groups
`movefirst`	`movefirst(Anchor; Target1, Target2)`	**Anchor**: area, group **Target**: list of actions or list of controls
`movelast`	`movelast(Anchor; Target1, Target2)`	**Anchor**: area, group **Target**: list of actions or list of controls
`moveafter`	`moveafter(Anchor; Target1, Target2)`	**Anchor**: controls, actions, and groups **Target**: list of actions or list of controls
`movebefore`	`movebefore(Anchor; Target1, Target2)`	**Anchor**: controls, actions, and groups **Target**: list of actions or list of controls
`modify`	`modify(Target)`	**Target**: controls, actions, and groups

Example

To modify the existing fields and groups on a page, you use the `modify` keyword. See the code snippet below for `addlast`, `modify` and `action` syntax. In the following example, the `actions` section creates a new group in the ribbon and places it last in the `Creation` group.

```
pageextension 70000020 CustomerCardExtension extends "Customer Card"
{
    layout
    {
        // Adding a new control field 'ShoeSize' in the group 'General'
        addlast(General)
        {
            field("Shoe Size"; ShoeSize)
            {
                Caption = 'Shoe size';

                trigger OnValidate();
                begin
                    if ShoeSize < 10 then
                        Error('Feet too small');
                end;
            }
        }

        // Modifying the caption of the field 'Address 2'
        modify("Address 2")
        {
            Caption = 'New Address 2';
        }

        // Moving the two fields 'CreditLimit' and 'CalcCreditLimitLCYExpendedPct'
        // to be the first ones in the 'Balance' group.
        movefirst(Balance; CreditLimit, CalcCreditLimitLCYExpendedPct)
    }
    actions
    {
        // Adding a new action group 'MyNewActionGroup' in the 'Creation' area
        addlast(Creation)
        {
            group(MyNewActionGroup)
            {
                action(MyNewAction)
                {
                    Caption = 'My New Action';

                    trigger OnAction();
                    begin
                        Message('My message');
                    end;
                }
            }
        }
    }
}

tableextension 70000020 CustomerTableExtension extends Customer
{
    fields
    {
        // Adding a new table field in the 'Customer' table
        field(50100; ShoeSize; Integer) { }
    }
}
```

Page extension examples

In the following example, we use a table extension to extend the Customer table with a new field named `ShoeSize` of the datatype Integer. Then we create a page extension object that extends the Customer Card page object by adding a field control `ShoeSize` to the `General` group on the page. The field control is added as the

last control in the group using the `addlast` method. The example also illustrates how to add a display-only control to the page. In the actions area, you can see what the syntax looks like for actions that execute triggers and actions that run objects.

```
tableextension 50115 RetailWinterSportsStore extends Customer
{
    fields
    {
        field(50116;ShoeSize;Integer)
        {
            Caption = 'ShoeSize';

            trigger OnValidate();
            begin
                if (rec.ShoeSize < 0) then
                begin
                   message('Shoe size not valid: %1', rec.ShoeSize);
                end;
            end;
        }
    }

    procedure HasShoeSize() : Boolean;
    begin
        exit(ShoeSize <> 0);
    end;

    trigger OnBeforeInsert();
    begin
        if not HasShoeSize then
            ShoeSize := Random(42);
    end;
}

pageextension 50110 CustomerCardExtension extends "Customer Card"
{
    layout
    {
        addlast(General)
        {
            // control with underlying datasource
            field("Shoe Size"; ShoeSize)
            {
                ApplicationArea = All;

                trigger OnValidate();
                begin
                    if ShoeSize < 10 then
                        Error('Feet too small');
                end;
            }

            // display-only control (without underlying datasource)
            field(ShoesInStock; 10)
            {
                ApplicationArea = All;
                Caption = 'Shoes in stock';

            }
        }

        modify("Address 2")
        {
            Caption = 'New Address 2';
        }
    }
```

```
    actions
    {
        addlast(Creation)
        {
            group(MyActionGroup)
            {
                Action(MyAction1)
                {
                    ApplicationArea = All;
                    Caption = 'Hello!';

                    trigger OnAction();
                    begin
                        Message('My message');
                    end;
                }

                Action(MyAction2)
                {
                    ApplicationArea = All;

                    // Run page to test how actions work
                    RunObject = page "Absence Registration";
                }
            }
        }
    }
}
```

You can reference Report and XMLPort objects and use these objects in the **RunObject** property, as well as, declare variables of the types **Report** and **XMLPort** and call AL methods on them. This page extension object extends the Customer List page object by adding two actions; the first action calls the **Customer - List** report, the second action calls the **Export Contact** XMLPort.

```
pageextension 50114 AddCustomerReport extends "Customer List"
{
    actions
    {
        AddLast("&Customer")
        {
            action("Customer List Report")
            {
                trigger OnAction();
                var
                    rep : Report "Customer - List";
                begin
                    rep.Run;
                end;
            }

            action("Export Contact List")
            {
                trigger OnAction();
                var
                    xml : XmlPort "Export Contact";
                begin
                    xml.Run;
                end;
            }
        }
    }
}
```

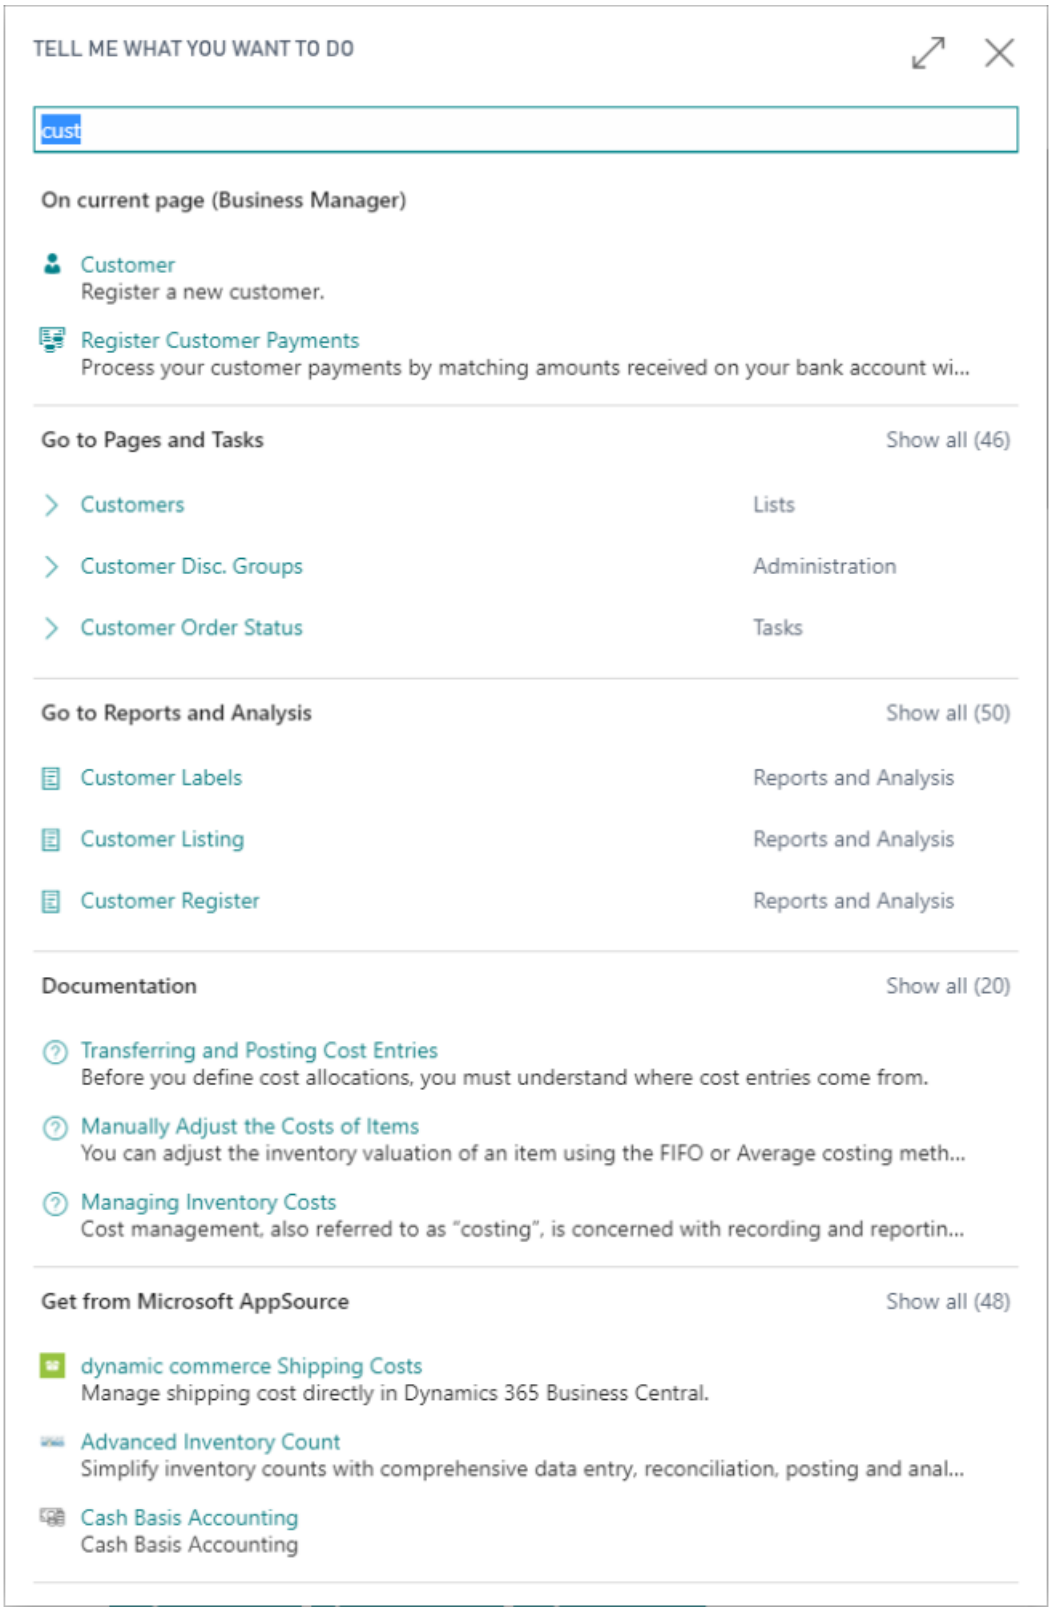
Adding Pages and Reports to Tell me

2/17/2021 • 3 minutes to read • Edit Online

The Business Central client includes the **Tell me** feature that lets users find objects and online help articles by entering search terms. When you have added a page or a report in your extension, you most likely want it to be discoverable to users in **Tell me**. In AL, you make a page or report searchable from **Tell me** by setting the UsageCategory property in code. The **UsageCategory** setting will make the page or report searchable, and the value chosen for the setting will further sub categorize the item.



Tell me finds pages and reports by searching the captions that are specified on page and report objects by the CaptionML property.

Working with the UsageCategory property

When you create a Page or a Report, you add the UsageCategory Property. If the **UsageCategory** is set to **None**, or if you do not specify **UsageCategory**, the page or report will not show up when you search in Dynamics 365 Business Central.

UsageCategory property values

The values for the **UsageCategory** property are listed below. The sub category will help the user navigate through the search results and it is a best practice to be consistent when categorizing the pages and the reports that you add. A consistent approach will help guiding the user and improve productivity.

VALUE	DESCRIPTION
None	The page or report is not included in search.
Lists	The page or report is listed as **Lists** under the **Pages and Tasks** category.
Tasks	The page or report is listed as **Tasks** under the **Pages and Tasks** category.
ReportsAndAnalysis	The page or report is listed as **Reports and Analysis** under the **Reports and Analysis** category.
Documents	The page or report is listed as **Documents** under the **Reports and Analysis** category.
History	The page or report is listed as **Archive** under the **Reports and Analysis** category.
Administration	The page or report is listed as **Administration** under the **Pages and Tasks** category.

Adding additional search terms

You can specify other words or phrases that can help users find a page or report by using the AdditionalSearchTerms and AdditionalSearchTermsML properties. If the page or report is searchable by **Tell me** (that is, th **UsageCategory** property is set a value other than `None`), the search terms specified by these properties are used in addition to the caption of the page or report. These properties are useful when the caption does not always reflect what users will look for. A good example of this in Business Central is pages and reports associated with **Item**. Users unfamiliar with Business Central might look for 'product' or 'merchandise' instead of 'item'.

> **NOTE**
>
> For Business Central on-premises, the Business Central Web Server configuration file (navsettings.json) includes a setting called `UseAdditionalSearchTerms` that enables or disables the use of additional search terms by the **Tell me**. For more information, see Configuring Business Central Web Server Instances.

Example

The following example creates a `SimpleItemList` page and sets a `UsageCategory` property to the page, so that the `SimpleItemList` page is discoverable through search using the **Tell me** feature. Also, the example sets the `AdditionalSearchTerms` property to add two search terms for the page.

```
page 50210 SimpleItemList
{
    PageType = List;
    SourceTable = Item;
    UsageCategory = Lists;
    AccessByPermission = page SimpleItemList = X;
    ApplicationArea = All;
    AdditionalSearchTerms = 'product, merchandise';

    layout
    {
        area(content)
        {
            group(General)
            {
                field("No.";"No.") {}
                field(Name;Name) {}
                field(Description;Description) {}
            }
        }
    }
}
```

Optional settings

In addition to making a page or report searchable, you can control the access of an object by providing **Read**, **Insert**, **Modify**, **Delete**, and **Execute** (RIMDX) permissions by adding the AccessByPermission property. Likewise, control the application area access on the specified object by adding the ApplicationArea Property.

The **AccessByPermission** property and **ApplicationArea** property are the optional settings, which can be applied with the **UsageCategory** property. These settings are used to set restrictions on an object when you enable the Search functionality.

Working in the Dynamics NAV Development Environment

> **NOTE**
> Dynamics NAV Development Environment is **DISCONTINUED AFTER:** Business Central Spring 2019.

If you are using the Dynamics NAV Development Environment, you can also set **UsageCategory**, **AdditionalSearchTerms**, **AccessByPermission**, and **ApplicationArea** properties on pages and reports to control their search.

After you change these properties by using the Dynamics NAV Development Environment, before the changes take effect in the client, you must run **Build Object Search Index** from the **Tools** menu.

Designing Role Centers

2/17/2021 • 8 minutes to read • Edit Online

The strength of Dynamics 365 is its role-tailored experience that helps users focus on the work that is important to them. The Role Center is an integral part of the role-tailored experience. And as a developer, role-tailoring should be the foundation for your Role Center design.

About the Role Center

The Role Center is the user's entry point and home page for Dynamics 365. You can develop several different Role Centers, where each Role Center is customized to the profile of the intended users. For example, you could have Role Centers that target the different levels within an organization, such business owners, department leads, and information workers.

Role Centers are based on a user-centric design model. You should design a Role Center to give users quick access to the information that is most important to them in their daily work - displaying information that is pertinent to their role in the company and enabling them to easily navigate to relevant pages for viewing data and performing tasks.

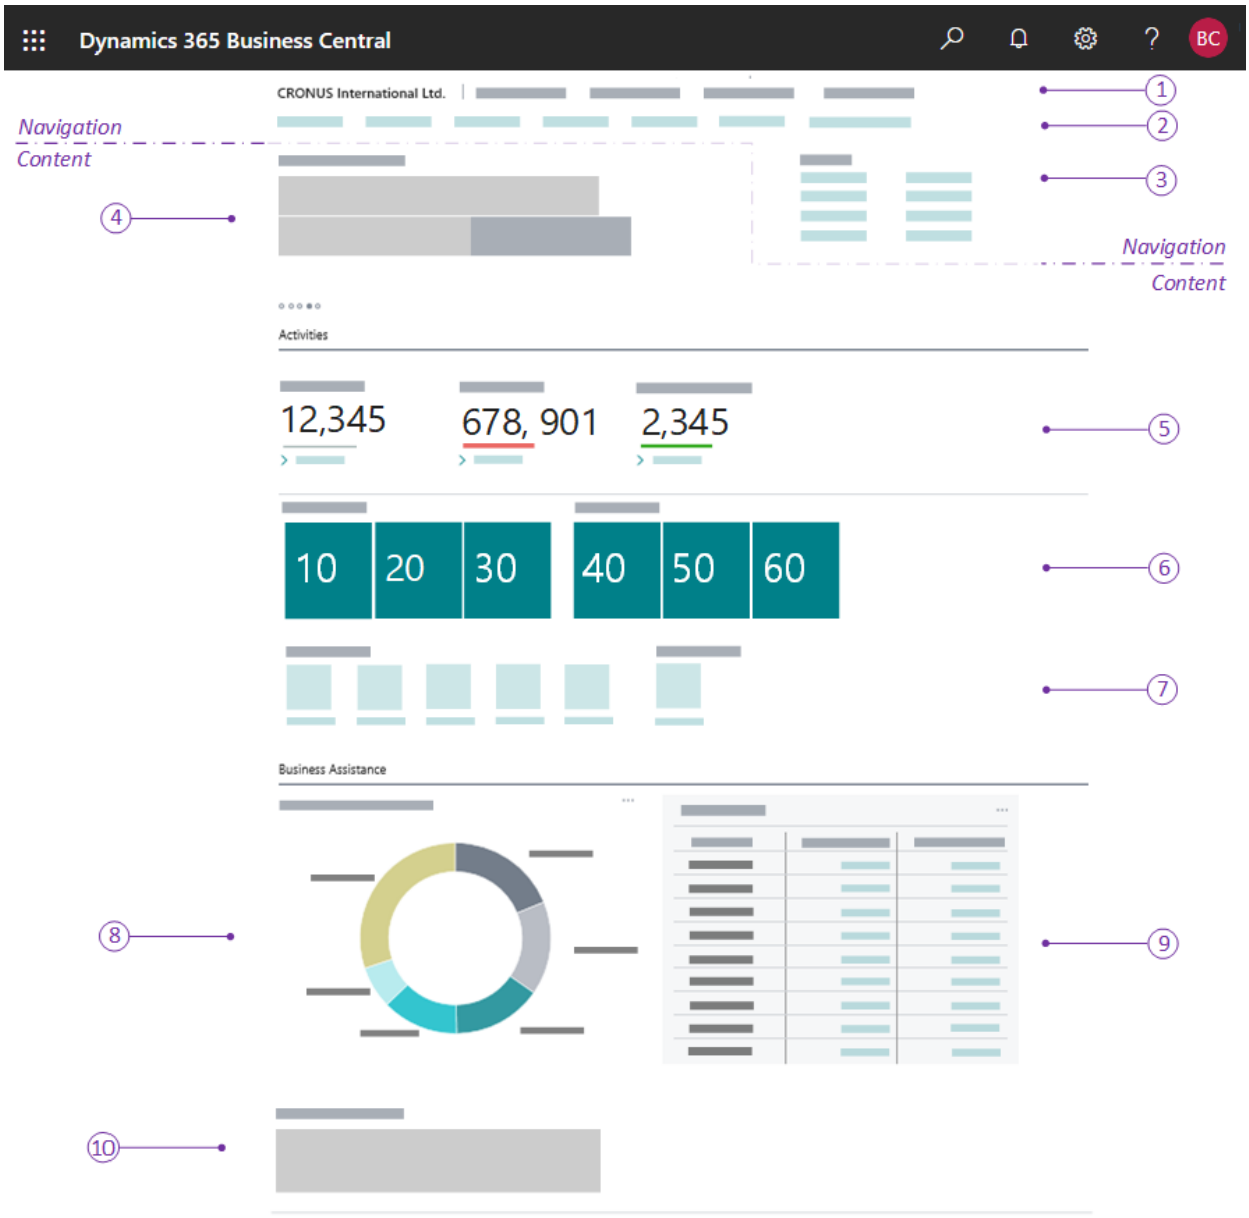
Customizing a Role Center from the client

In the client, users who work across multiple roles can easily switch Role Centers to shift their focus to different tasks. Users can also personalize their Role Centers by rearranging or hiding content as they like. For more information, see Personalizing Your Workspace.

As a developer or administrator, you can use Designer to customize a Role Center the same way that individual users personalize their own workspaces. The difference is that changes you make are applied to all users assigned to the Role Center. For more information, see Using Designer.

Role Center structure

A Role Center is defined by page that has the PageType property set to `RoleCenter`. The Role Center page is divided into two main areas: navigation/actions area and content area. The following figure illustrates the general layout and elements of a Role Center page.



For a simple code example of a role center page, see Simple Role Center Code Example.

Navigation and Actions area

The navigation and actions area appears at the top of the Role Center page, and provides links to other objects, such as pages, reports, and codeunits. You define the navigation area by adding actions to the Role Center page code, under the `actions` control in the page code. The navigation and actions area is subdivided into smaller areas by using different `area()` controls as described in the following table:

NO.	AREA	DESCRIPTION	USAGE GUIDELINES

NO.	AREA	DESCRIPTION	USAGE GUIDELINES
1	Navigation menus	The top-level navigation consists of one or more root menu items that expand to display links to other pages. The links can be grouped into sub-menus, enabling you to create a logical hierarchy. The pages targeted by the links will open in the content area of the Role Center. You define this area with an `area(Sections)` control in the page code.	The top-level navigation should provide access to relevant entity lists for the role's areas of business. For example, typical root items for a business manager could be finance, sales, and purchasing. You should place the root items in order of importance, starting from the left.
2	Navigation bar	The second-level navigation displays a flat list of links to other pages. The pages targeted by the links will open in the content area of the Role Center. You define this area with an `area(embedding)` control in the page code.	You should use these items to link to users' most useful entity lists in their business process. For example, with a business manager, these could be links to customers, sales orders, and bank accounts. You should place items in the order that reflects the business process sequence. Try to limit the number of second-level items, and consider placing items in the top-level navigation instead, if the number gets too large.
3	Action bar	The actions bar provides links to pages, reports, and codeunits. The links can be displayed on the root-level or grouped in a sub-menu. The objects targeted by these links will open in a separate window in front of the Role Center page. You can define the actions by using the three different `area()` controls that are described below:	The action area is designed for running the most important or most often used tasks and operations required by users. Actions will typically target card type pages that enable users to create new entities, such as customers, invoices, and sales orders, or run reports. Place the most important action at the root-level, and group closely related actions in a sub-menu.
		`area(creation)` - Actions in this control will appear first in the action area, and will display with a plus (+) icon.	Use this control to target pages that enable the user to create new entities.

NO.	AREA	DESCRIPTION	USAGE GUIDELINES
		`area(processing)` - Actions in this control will appear after the `area(creation)` items. You can group actions in sub-menus by using a `group` control.	Use this control to target pages that are associated with the work flow for processing documents, such as payments or sales orders. Use the `group` control to organize similar actions under a common parent.
		`area(reporting)` - Actions in this control will appear last in the action area. They display with a default report icon.	Use this control to target report objects.

For more information about navigation, see Adding to Navigation.

Behavioral points of interest

- The order of the `area()` controls in the page code is not important. However, the order of the individual actions and groups is important because they will appear in the order in which they appear in page code.
- In page code, if the first part in the content area is a Headline part, then in the client, the actions area will be automatically positioned either to the right of the Headline part or after the Headline part, depending on the browser window size. If the first part is not a Headline, the actions area will appear directly after the navigation area, and extend the width of the workspace.

Content area

The content area consists of one or more parts that display content from other pages. Unlike the navigation and actions area that is completely defined in the Role Center page code, the content area consists of self-contained, independent page part objects that can be used across Role Centers and in other pages. You define the content area by adding a `layout` control in the page code, and then a `part` control for each individual part to display.

The following table describes some of the most common parts for Role Centers, as illustrated in the previous figure.

NO.	ELEMENT	DESCRIPTION	MORE INFORMATION	
4	Headline	Displays a series of automatically changing headlines that provide users with up-to-date information and insight into the business and daily work. This is created by a `HeadlinePart` page type.	Creating Role Center Headlines	

NO.	ELEMENT	DESCRIPTION	MORE INFORMATION	
5	Wide data cues	A set of cues for displaying large numbers, like monetary values. This is created by using a `cuegroup` control on a `CardPart` page type, where the Layout property is set to `wide`.	Wide Cues	
6	Data cues	Provide a visual representation of aggregated business data, such as the number of open sales invoices or the total sales for the month. These are created by using a `cuegroup` control on a `CardPart` page type.	Creating Cues	
7	Action cues	Tiles that link to tasks or operations, like opening another page, starting a video, targeting another URL, or running code. These are created by using a `cuegroup` control on a `CardPart` page type	Action Tiles	
8	Chart	A graphical and interactive representation of your business data that can be sourced by a custom business chart control add-in or an embedded Power BI report.		
9	CardPart or ListPart page	Displays data fields in a form or tabular layout.	Page Object	
10	Control add-in	Displays custom content by using HTML-based control add-in.	Control Add-in Object	

Behavioral points of interest

- In general, the parts will appear in the client according to the order in which they are defined in the Role

Center page code and will automatically rearrange horizontally and vertically to fill the available workspace.

- However, in the Web client, page parts that contain cues are automatically grouped under a common **Activities** section, no matter where they are placed in the code. All other page parts are grouped under the **Business Assistance** section. Within **Activities** and **Business Assistance** sections, the parts will arrange according to the order in which they are defined in the page code.

Development tips for overall page design

- Do not apply grouping to parts in the content area because this prevents parts from flowing to fill the available space. This gives the best experience to users with different screen resolutions or those on mobile devices.
- To achieve the best readability and discoverability, place Headlines first, followed by cues, and then the remaining parts.
- You cannot add custom logic directly to a Role Center page code. Code is limited to defining navigation, actions, and parts. All other code is ignored.
- Role Centers can be highly specialized, in the fact that all navigation, actions, and content is optional. For example, you could have a single part that fills the entire workspace.

Design for all display targets

- Role Center pages are also the primary entry point on mobile devices. Mobile devices will display the same content as the Web client, but is presented in a different way to suit how users hold and interact with their mobile device.
- You can preview how your Role Center will look on mobile devices directly in Designer.
- Some limitations on mobile devices include the following:
  - On tablets, there is a limit on the number of cues that can be displayed.
  - On phones, there is a limit on the number of parts in the content area that can be displayed.
  - Role Center pages cannot be displayed when they are embedded in Outlook or SharePoint.

Using the Role Center in the client

To use or test the new Role Center in the client, you must first associate the Role Center page with a profile. Profiles define user roles and each profile is associated with a single Role Center page. Create a new profile object that references your page. Then, go to **My Settings** and select the new profile.

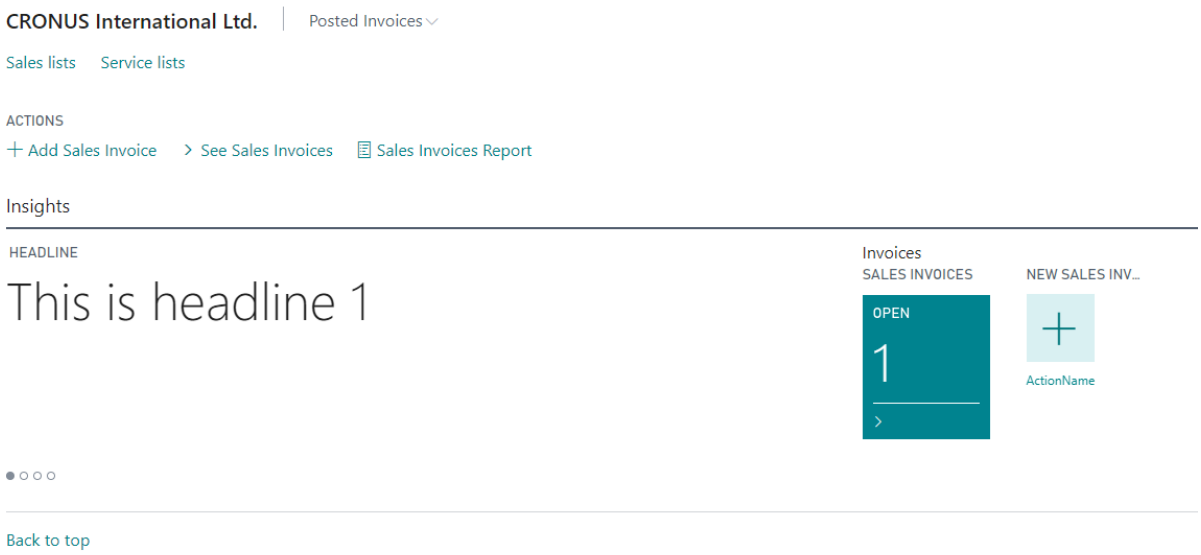
Simple Role Center Code Example

2/17/2021 • 2 minutes to read • Edit Online

The AL code in this article creates a simple Role Center customized for users assigned to a new profile.



For a more detailed explanation of Role Centers, see Designing Role Centers.

This example uses the **RoleCenterHeadline** page code example to display the headline and the **SalesInvoiceCuePage** page and the following code example for the Cue and Action tile.

```
page 50125 MyRoleCenter
{
    PageType = RoleCenter;
    Caption = 'My Role Center';

    layout
    {
        area(RoleCenter)
        {
            group(Group1)
            {
                part(Part1; RoleCenterHeadline)
                {
                    ApplicationArea = All;
                }

                part(Part2; SalesInvoiceCuePage)
                {
                    Caption = 'Invoices';
                }
            }
        }
    }

    actions
    {
        area(Sections)
        {
            group(PostedInvoices)
            {
                Caption = 'Posted Invoices';
```

```
            Caption = 'Posted Invoices';
            Image = RegisteredDocs;
            action(PostedServiceInvoices)
            {
                Caption = 'Posted Service Invoices';
                RunObject = Page "Posted Service Invoices";
                ApplicationArea = All;
            }

            action(PostedSalesInvoices)
            {
                Caption = 'Posted Sales Invoices';
                RunObject = Page "Posted Sales Invoices";
                ApplicationArea = All;
            }

            group(SalesDocuments)
            {
                Caption = 'Sales Documents';
                action("Sales Document Entity")
                {
                    ApplicationArea = All;
                    RunObject = page "Sales Document Entity";
                }
                action("Sales Document Line Entity")
                {
                    ApplicationArea = All;
                    RunObject = page "Sales Document Line Entity";
                }
            }
        }
    }

    area(Embedding)
    {

        action(Sales)
        {
            Caption = 'Sales lists';
            RunObject = Page "Sales list";
            ApplicationArea = All;
        }

        action(Services)
        {
            Caption = 'Service lists';
            RunObject = Page "Service list";
            ApplicationArea = All;

        }

    }

    area(Processing)
    {
        action(SeeSalesInvoices)
        {
            Caption = 'See Sales Invoices';
            RunObject = Page "Posted Sales Invoices";
        }

    }

    area(Creation)
    {
        action(AddSalesInvoice)
        {
            Caption = 'Add Sales Invoice';
            Image = NewInvoice;
```

```
                Image = NewInvoice;
                RunObject = Page "Sales Invoice";
                RunPageMode = Create;
            }
        }

        area(Reporting)
        {
            action(SalesInvoicesReport)
            {
                Caption = 'Sales Invoices Report';
                Image = "Report";
                RunObject = Report "Sales - Invoice";
            }
        }
    }
}

// Creates a profile that uses the Role Center
profile MyProfile
{
    ProfileDescription = 'Sample Profile';
    RoleCenter = MyRoleCenter;
    Caption = 'My profile';
}
```

Adding Menus to the Navigation and Actions Area

2/17/2021 • 3 minutes to read • Edit Online

The navigation area appears at the top of the Dynamics 365 Business Central window, and contains multiple sections that enable users to quickly navigate and perform actions in Dynamics 365 Business Central. In the client, the navigation area is separated into three separate areas: navigation menu, navigation area, and actions area. For an illustration that identifies the different areas in a Role Center, see Designing Role Centers. In AL, these areas are defined by the `area()` control, as described in the sections that follow.

Adding to the navigation menu

The top-level navigation area is referred to as the navigation menu. The navigation menu contains one or more root menu items that expand to display a set of links to pages, and other objects like reports, XMLPorts, and codeunits. These links are defined by `action()` controls. You can also group `action()` controls in sub-menus. This enables you to create a logical hierarchy that matches the needs of the user role. The pages targeted by the links in the navigation menu will open in the content area of the Role Center.

> **NOTE**
> The Dynamics NAV Client connected to Business Central doesn't support sub-menus in the navigation menu.

You define the navigation menu by using an `area(Sections)` control in the page code.

Example

The example below adds the root menu item called `My Customers` to the navigation menu of the **Sales Order Processor** Role Center. The `My Customers` menu item contains two actions, the `Customer Bank Account List` and `Customer Ledger Entries` actions, which open corresponding page objects. The `My Customers` menu item also includes a group that contains two other actions, which open sales-related documents.

```
pageextension 50120 ExtendNavigationArea extends "Order Processor Role Center"
{

    actions
    {
        addlast(Sections)
        {
            group("My Customers")
            {
                action("Customer Bank Account List")
                {
                    RunObject = page "Customer Bank Account List";
                    ApplicationArea = All;
                }
                 action("Customer Ledger Entries")
                {
                    RunObject = page "Customer Ledger Entries";
                    ApplicationArea = All;
                }

                // Creates a sub-menu
                group("Sales Documents")
                {
                    action("Sales Document Entity")
                    {
                        ApplicationArea = All;
                        RunObject = page "Sales Document Entity";
                    }
                    action("Sales Document Line Entity")
                    {
                        ApplicationArea = All;
                        RunObject = page "Sales Document Line Entity";
                    }
                }
            }
        }
    }
}
```

You can also enable pages and reports to appear in the Dynamics 365 Business Central search for a quick navigational support. For more information, see Adding Pages and Reports to Tell Me.

Adding to the navigation bar

The second-level navigation is referred to as the navigation bar. The navigation bar offers a flat list of links to other pages. These should be the most relevant pages needed for a user's business process. We recommend to have only the most important items on this level and to place the others in the top-level navigation instead.

You define the navigation bar by using an `area(Embedding)` control in the page code.

Example

The following code adds a new link to the navigation bar by defining this area with an `area(Embedding)` control in the page code. The object targeted in this case is the `Sales Cycles` page and it will appear as the last one.

```
...
addlast(Embedding)
{
    action("Sales Cycles")
    {
        RunObject = page "Sales Cycles";
        ApplicationArea = All;
    }
}
```

Adding to actions

The actions area displays the most important or most often used tasks and operations required by users. It contains links to pages, reports, and codeunits. The links are placed on the root-level, and they can be grouped in a submenu.

You can define the actions by using three different `area()` controls.

The first action area that appears at the top of the Role Center page is `area(Creation)`. The following example adds the item last, and it allows opening the `Sales Journal` page.

Example

```
...
addlast(Creation)
{
    action("Sales Journal")
    {
        ApplicationArea = All;
        RunObject = page "Sales Journal";
    }
}
```

The actions in the `area(Processing)` control appears after the `area(Creation)` items. The example below shows how you can use the group control to organize similar actions under a common parent. The created group is placed at the end of this action area, and it targets pages needed for processing sales documents.

Example

```
...
addlast(Processing)
{
    group(Documents)
    {
        action("Sales Document Entity")
        {
            ApplicationArea = All;
            RunObject = page "Sales Document Entity";
        }
        action("Sales Document Line Entity")
        {
            ApplicationArea = All;
            RunObject = page "Sales Document Line Entity";
        }
    }
}
```

The actions in the `area(Reporting)` control will appear last in the action area and they display with a default report icon. This control's purpose is to target report objects and the following example opens the

`Customer Sales Statistics` report.

Example

```
...
addlast(Reporting)
{
    action("Customer Statistics")
    {
        ApplicationArea = All;
        RunObject = report "Customer Sales Statistics";
    }
}
```

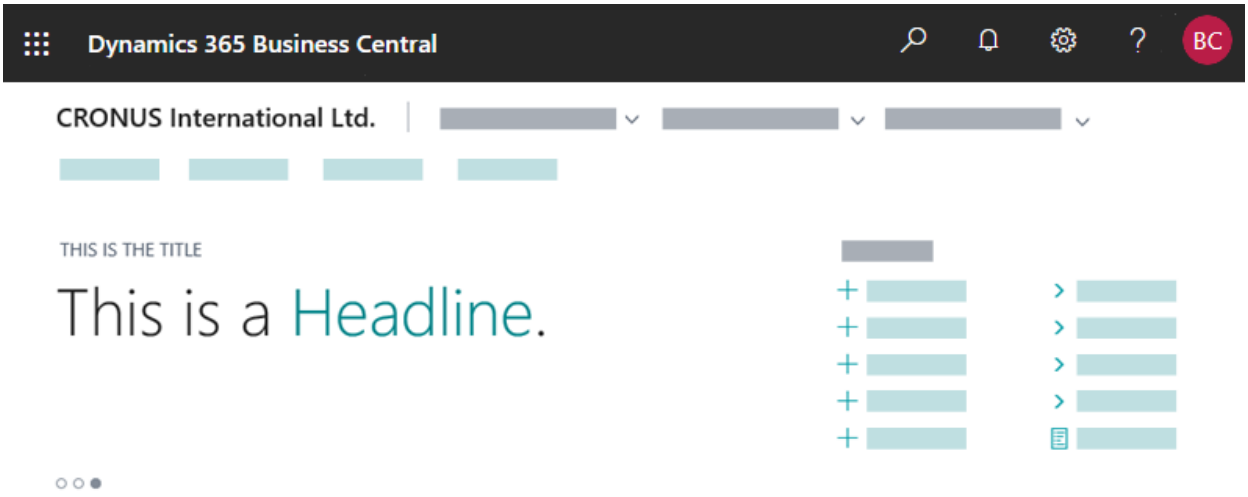
Adding Pages and Reports to Tell Me

Creating a Role Center Headline

2/17/2021 • 5 minutes to read • Edit Online

You can set up a Role Center to display a series of headlines, where headlines appear one at a time for a predefined period of time before displaying the next.



The headlines can provide users with up-to-date information and insight into the business and daily work. Typical categories of headlines might include:

- My performance
- My workday
- Organizational health
- Productivity tips
- Cross-tenant insights (performance relative to peers)
- Getting started information

> **IMPORTANT**
> Headlines will only appear in the Web client; they will not be shown on other client types.

Design concept

In development

In short, the Headline is basically a page that contains one or more fields. The page must be the **HeadlinePart** type page. Each field defines an individual headline to be displayed. The source for a field can be an expression or a field in an underlying table.

- The **HeadlinePart** page is designed for Role Centers, that is, pages that have the type **RoleCenter**. If you use a **HeadlinePart** page on another page type, the part will not render in the client.
- Using the OnDrillDown trigger, headlines can be made interactive, meaning that users can select the headline to dig deeper into numbers or values that are shown in the headline or link to another page or URL.
- You can dynamically toggle visibility of a specific headline, for example based on its relevancy, by setting the Visible property on the field.

- There are only a few field properties that apply to fields that are used on a **HeadlinePart** type page, including Expression, Visible, ApplicationArea, Drilldown, and DrillDownPageID. All other properties are ignored.

In the client

The Role Center will start by displaying the first visible headline that is defined on the HeadlinePart page. The headline will appear for 5 seconds, then the next headline will appear for 5 seconds, and so on. When all the headlines have been displayed, it will cycle back to the first headline, and continue from there.

- If a headline is interactive, users can select the headline to open the target defined in the headline.
- Users can pause on a headline by pointing to it.
- Users can manually switch among headlines by selecting a corresponding dot that is displayed under the headlines.
- Users can personalize their Role Center to show or hide the Headline part as they like.

Creating a HeadlinePart page

1. Implement the logic that resolves field expressions for the headlines that you will use on the page.

   You can apply more flexible and complex patterns, such as having data tables drive the text, drill-down and relevance engine for headlines.

2. Create a page that has the PageType property set to `HeadlinePart`.

3. For each headline, add a field, and set the Expression property. The order of the fields, determines the order in which they appear.

   The following example shows the AL code for a simple **HeadlinePart** page that consists of four fields that display static text.

```
page 50100 RoleCenterHeadline
{
PageType = HeadLinePart;

layout
{
    area(content)
    {
        field(Headline1; hdl1Txt)
        {

        }
        field(Headline2; hdl2Txt)
        {

        }
        field(Headline3; hdl3Txt)
        {

        }
        field(Headline4; hdl4Txt)
        {

        }
    }
}

var
    hdl1Txt: Label 'This is headline 1';
    hdl2Txt: Label 'This is headline 2';
    hdl3Txt: Label 'This is headline 3';
    hdl4Txt: Label 'This is headline 4';
}
```

4. You can now add the **HeadlinePart** page to the **RoleCenter** page.

Constructing Headlines with the Expression property

The `Expression` property supports the following syntax that enables you to specify a title for the headline, the headline text itself, and emphasize a string of text in the headline:

```
'<qualifier>Title</qualifier><payload>This is the <emphasize>Headline</emphasize>.</payload>'
```

TAG	DESCRIPTION
`<qualifier></qualifier>`	Specifies the title that appears above the headline. If you omit this tag, the text **HEADLINE** will be used by default.
`<payload></payload>`	Specifies the actual headline text.
`<emphasize></emphasize>`	Applies the style to the text.

The `Expression` property must evaluate to the correct syntax. For example, looking back at the previous example, the label `hdl1Txt` could be:

```
hdl1Txt: Label '<qualifier>The first headline</qualifier><payload>This is the <emphasize>Headline
1</emphasize>.</payload>';
```

Making headlines interactive

You can use the OnDrillDown trigger of a headline field to link the headline to more details or relevant information about what is shown in the headlines. For example, if the headline announced the largest sales order for the month, you could set up the headline to open a page that shows a sorted list of sales order for the month.

The following code uses the OnDrillDown trigger to link `Headline1` to the Dynamics 365 online help.

```
field(Headline1; hdl1Txt)
{
    trigger OnDrillDown()
    var
        DrillDownURLTxt: Label 'https://go.microsoft.com/fwlink/?linkid=867580', Locked = True;
    begin
        Hyperlink(DrillDownURLTxt)
    end;
}
```

Changing the visibility of headlines

You can use the Visible property to show or hide headlines that are defined on the **HeadlinePart** page. With the `Visible` property, you can show or hide the control either statically by setting the property to **true** or **false**, or dynamically by using a `Boolean` variable.

Static visibility

With static visibility, you can simply set the `Visible` property on specific fields. For example, following code hides `Headline3`:

```
{
    field(Headline1; hdl1Txt)
    {

    }
    field(Headline2; hdl2Txt)
    {

    }
    field(Headline3; hdl3Txt)
    {
         Visible=false;
    }
    field(Headline4; hdl4Txt)
    {
    }
}
```

By adding fields under `Group` controls, you can hide or show more than one headline by setting the `Visible` property on the `Group` control. For example, the following code hides headings `Headline3` and `Headline4`:

```
group(Group1)
{
    field(Headline1; hdl1Txt)
    {
    }
    field(Headline2; hdl2Txt)
    {

    }
    }
group(Group2)
{
    Visible=false;
    field(Headline3; hdl3Txt)
    {
    }
    field(Headline4; hdl4Txt)
    {
    }
}
```

> **IMPORTANT**
> Unlike other page types, the `group` control has no effect on the UI on pages of type **HeadlinePart**. Its primary purpose is to enable developers to group headlines for controlling visibility.

Dynamic visibility

With dynamic visibility, you can show or hide a headline based on a condition that evaluates to `true` or `false`.

- To dynamically show or hide a headline when the **HeadlinePart** page opens, the headline field must be in `group` control, and you set the `Visible` property on the `group` control to the `Boolean` variable that determines the visibility. For example, you could add code on the page's `OnAfterGetRecord` trigger that evaluates the relevance of displaying `Headline3` and results in a `Boolean` variable being set to `true` or `false`.
- To dynamically show or hide a headline while a page is open, you set the `Visible` property on the `field` control to the `Boolean` variable that determines the visibility.

```
group(Group1)
{
    field(Headline1; hdl1Txt)
    {
    }
    field(Headline2; hdl2Txt)
    {

    }
    }
group(Group2)
{
    // Determines visibility when the page opens
    Visible=ShowHeadline3;
    field(Headline3; hdl3Txt)
    {
        // Determines visibility while the page is open
        Visible=ShowHeadline3;
    }
    field(Headline4; hdl4Txt)
    {
    }
}
```

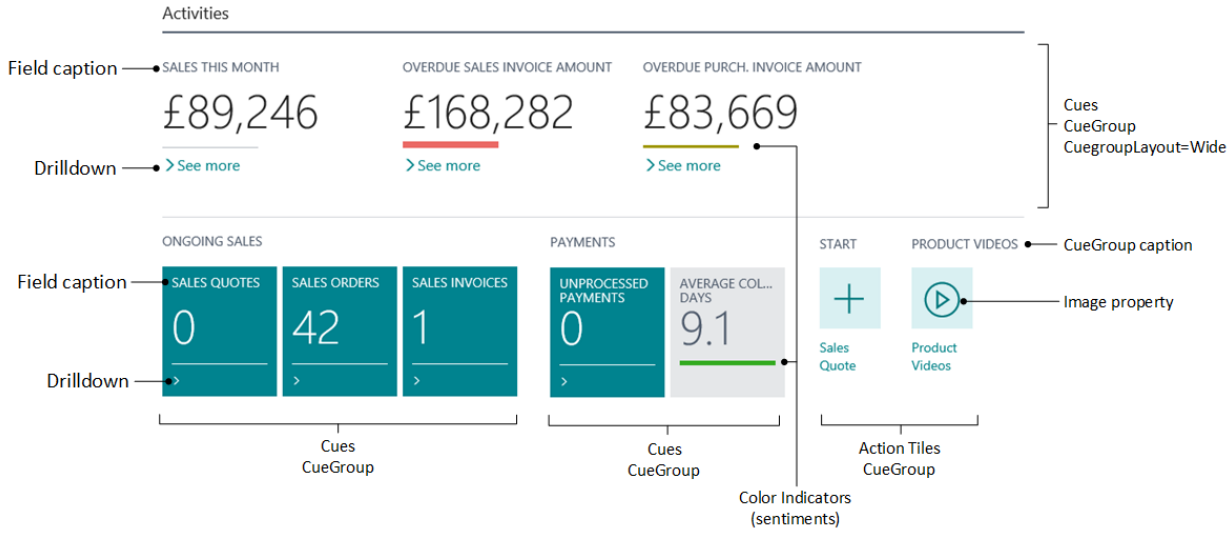
Creating Cues and Action Tiles on Role Centers

2/17/2021 • 7 minutes to read • Edit Online

This article provides an overview of Cues and Action tiles, and the tasks involved in creating and customizing them for displaying on Role Centers, as illustrated in the following figure:



NOTE

Modifying actions in Cue groups on page extensions is not supported.

Designing Cues

A Cue provides a visual representation of aggregated business data, such as the number of open sales invoices or the total sales for the month. Cues are interactive, meaning that you can select the Cue to drill down to data or open another page, run code, and more. Cues display data that is contained in a table field. This can be raw data or calculated data.

Normal and wide layout

There are two layout options that influence how Cues appear in the client: *normal* and *wide*.

- The *normal* layout displays Cues as tiles. With this layout, Cue groups are automatically arranged to fill in the width of the workspace, which means there can be more than one group horizontally across the workspace.
- The *wide* layout is designed to display large values, such as monetary values. The wide layout gives you a way emphasize a group of Cues. Wide and normal Cue groups can be interleaved. However, wide groups that precede all normal groups will appear in their own section of the workspace, spanning the entire width - providing space for the large values. Wide groups that are placed after normal groups will behave just like the normal layout groups. With this in mind, it is good practice to place Cue groups that use the wide layout, above those that use the normal layout. The wide layout is specified by setting the CuegroupLayout property to `wide`.

> **NOTE**
>
> The wide layout is only supported in the Web client.
>
> The Caption and CaptionML properties of the `cuegroup` control are ignored when the layout is wide.

Supported data types

You can only base Cues on integer and decimal data types. Other data types are not supported and will not display in a Cue.

FlowFields versus normal fields

A Cue can be based on a FlowField or Normal field. If you base the Cue on a FlowField, then you add the logic that calculates the data for the Cue to the CalcFormula property of the FlowField. If you use a Normal field, then you will typically add the logic that calculates the Cue data to an AL trigger or method. Unlike a FlowField, where data is extracted from tables, a Normal field enables you to extract data from other objects such as queries.

Creating a Cue

The implementation of a Cue involves the following elements:

- A table object with a field that holds the data that is contained in the Cue at runtime.
- A page object that contains the table field and displays the Cue in the client.
- Logic that calculates the data to display in the Cue at runtime.

The logic can consist of a combination of AL code and objects, such as tables, queries, and codeunits. How and where you implement the logic will depend on whether the Cue is based on a FlowField or Normal field and what you want to achieve.

> **NOTE**
>
> The examples in this section will set up a Cue that extracts the number of open sales invoices from the **Sales Header** table.

Create a table for Cue data

The first thing that you must do is to create a table that contains fields that will hold the calculated data to display in the Cues at runtime.

1. Create a table object or use an existing one.
2. Add fields for the Cue data.

   For each Cue that you want to display on the page, you must add a **Field** control in the table object. When you add the **Field** control, specify the following properties:

   - Set the Data Type property to **Decimal**, **Integer**, or **Text**, depending on the type of data the Cue will display.
   - Set the FieldClass property to **FlowField** or **Normal**.

     If field is a FlowField, then set the `CalcFormula` property to calculate the Cue data. For more information, see Calculation Formulas and the CalcFormula Property.
3. Add a primary key field for FlowFields.

   A table must have at least one data field. Because a **FlowField** is based on a calculation, it not considered an actual data field. Therefore, if the Cue table only includes FlowFields, you must add "dummy" primary

key field that does not yield any data.

To add primary key, for example, add a field with the name **Primary Key**, and then set its data type to **Code**.

Example

```
table 50100 SalesInvoiceCueTable
{
    DataClassification = ToBeClassified;

    fields
    {
        field(1;PrimaryKey; Code[250])
        {

            DataClassification = ToBeClassified;
        }
        field(2; SalesInvoicesOpen ; Integer)
        {
            FieldClass = FlowField;
            CalcFormula = count("Sales Header" where("Document Type"=Filter(Invoice), Status=FILTER(Open)));

        }
    }

    keys
    {
        key(PK; PrimaryKey)
        {
            Clustered = true;
        }
    }
}
```

Add Cues to a Page object

After you have a table for holding the Cue data, you create a page that you associate the table, and then add Cue fields on the page. Typically, you will create Card Part type page that will be part of the Role Center page. Cues are arranged into one or more groups on the page. Each group will have its own caption.

1. Create a page object that has the SourceTable property set to the Cue data table.
2. Add a `cuegroup` control.
3. Under the `cuegroup` control, for each Cue that you want to display, add a `field` control.
4. If you want to set the `cuegroup` to use the wide layout, set the `CuegroupLayout` property to `wide`.

   Repeat steps 2-4 to add additional Cue groups.

5. Initialize the Cue fields.

   You must initialize the Cue fields on the page. To do this, for example, you can add the following AL code to the OnOpenPage Trigger.

```
      RESET;
    if not get then begin
        INIT;
        INSERT;
    end;
```

Example

```
page 50105 SalesInvoiceCuePage
{
    PageType = CardPart;
    SourceTable = SalesInvoiceCueTable;

    layout
    {
        area(content)
        {
            cuegroup(SalesCueContainer)
            {
                Caption='Sales Invoices';
                // CuegroupLayout=Wide;
                field(SalesCue; SalesInvoicesOpen)
                {
                    Caption='Open';
                    DrillDownPageId="Sales Invoice List";
                }
            }
        }
    }

    trigger OnOpenPage();
    begin
        RESET;
        if not get then begin
            INIT;
            INSERT;
        end;
    end;
}
```

Designing Action tiles

Action tiles promote an action or operation to the user on the Role Center. Action tiles act as links that perform a task or operation, like opening another page, starting a video, targeting an another resource or URL, or running code. They will arrange on the workspace just like that use the normal layout.

Similar to Cues, Actions tile can be grouped together, under a common caption, by using the `cuegroup` control. The difference is that instead adding field controls under the `cuegroup` control, you create Action tiles by adding actions to the `cuegroup` control.

Create an Action tile

1. Develop or locate the functionality that you want to Action tile to perform.

For example, create the page object that you want the Action tile to open, add AL code that you want the Action tile to run, find the URL to the video.

2. Open the page on which you want to display the Action tiles. For example, this could be the page that you created in the previous task.

3. In the location where you want the Action group, add a `cuegroup` control.

4. Configure the control to the desired operation.

   For example, if it should open a page, set the control's RunObject property to the appropriate page. Or, set it to call a function or method.

Example

The following code adds an Action tile that opens **Sales Invoice** page.

```
cuegroup(SalesActionontainer)
{
    Caption='New Sales Invoice';

    actions
    {

        action(ActionName)
        {
            RunObject=page "Sales Invoice";
            Image=TileNew;

            trigger OnAction()
            begin

            end;
        }
    }
}
```

Styling an Action tile

You can use the Image property on an `action` control to change the look of the Action tile. For Action tiles, the `Image` property supports several standard values that start with the text `Tile`, such as `TileNew` and `TileYellow`. These values change the Action's background color and icon as follows:

- A value that has the format `Tile[color]` will set the Action tile to use the circle icon and a background that is specified by `[color]`. For example, `TileBlue` will display a circle icon in a blue background.
- A value that has the format `Tile[picture]` will set the Action tile to use an icon that is specified by `[picture]` and a neutral background color. For example, `TileCamera` will display a camera icon on the neutral background.

> **NOTE**
> If you use a value that is not valid or recognized, the Action tile will default to display the circle icon on the neutral background.

Page Types and Layouts

2/17/2021 • 14 minutes to read • Edit Online

Understanding how Business Central displays a page dependent on its *page type* is important to be able to create a good user experience. There are also several page properties and variations of the page structures that can help create an intuitive and efficient user interface.

In the following we are focusing on how pages appear when a user accesses Business Central from a desktop browser. But it is an important point that the same page types apply across the different form factors of apps, and that the Business Central page type layouts automatically adapt to work well on different devices, e.g. on a phone or a tablet.

Understanding page types

Choosing the right page type is the first step when creating or modifying a page. The next step is to organize the page contents to suit its purpose in your solution. We recommend that you design pages based on the user tasks that you want to support.

The following table provides an overview of the page types supported in Business Central, their typical uses, and basic characteristics. To specify the page type, use the `PageType` property. For more information, see PageType Property.

PAGE TYPE	EXAMPLES OF USE	MAIN DATA DISPLAY	CHARACTERISTICS
`RoleCenter`	Overview of business performance and the start page for a specific user profile.	Defined by the embedded parts.	A collection of parts (Cues, KPIs, etc.) and the contents of the navigation pane.
`Card`	Master, reference, and set up data management. Card page example	Single entity	Titled entity with FastTabs. May embed parts.
`Document`	Transaction and other document management.	Single entity	Titled entity with FastTabs. Should have the document lines ListPart immediately follow the header section(s).
`ListPlus`	Statistics, details, and related data management.	Single entity	Titled entity with at least one `ListPart`. Can have fields above or below the part(s).
`List`	Entity overviews and navigation, and inline editing of simple entities. List page example	Collection of entities/entries	A single list with a caption. May have field groups and subpages above and below the list's `Repeater`.
`Worksheet`	Line-based data entry tasks (such as journals) and inquiries.	Collection of entities	A single list or table with a caption. May have field groups and subpages above and below the worksheet's `Repeater`.

PAGE TYPE	EXAMPLES OF USE	MAIN DATA DISPLAY	CHARACTERISTICS
`StandardDialog`	Routine dialog that starts or progresses a task.	Single or collection	A cancelable dialog with an instruction to the user. Can have one or more groups of fields, a list, and parts.
`ConfirmationDialog`	Confirmative or exceptional dialog, such as warnings.	Single or collection	A Yes/No dialog with an instruction to the user. Can have one or more groups of fields, a list, and parts.
`NavigatePage`	Multi-step dialog (also known as a "Wizard").	Single or collection	Can have one or more groups of fields, a list, and parts.
`CardPart`	A page that is embedded in another page, such as in a FactBox.	Single entity	Single group of fields representing fields in a FastTab.
`ListPart`	A page that is embedded in another page, such as in a FactBox.	Collection of entities/entries	Single `Repeater` representing columns in a list or table. Can have fields above or below the repeater.
`HeadlinePart`	A page that is embedded in a `RoleCenter` page to display relevant insights from across the business.	Single entity	Single group of fields representing headlines.

The two principal categories of page types

A fundamental characteristic of a page type is how it relates to the data presented on the page. Two principal ways exist: *entity*-oriented (typical for the `Card` page type) and *collection*-oriented (typical for the `List` page type.)

`CARD`, `DOCUMENT`, AND `LISTPLUS`	`LIST` AND `WORKSHEET`
	The **entity-oriented** page types have actions (in top and in action bar) that affect the entity or context given by the title of the page.	The **collection-oriented** page types provide actions in action bar (and on the rows' action menu) that take effect on the selected row(s) in the collection.

Entity-oriented pages

In Business Central, entity-oriented pages are used to support users when their tasks revolve around a single business entity. The most typical entity-oriented page is the `Card`, which provides details about a single customer or other master data, and the `Document`, which represents a single transaction, or other important business event, e.g. a sales transaction.

`ListPlus` is also an entity-oriented page type. Unlike `Card` and `Document` pages, the `ListPlus` page type is for pages that have a prominent `ListPart` and either few or no header fields.

The `CardPart` page type is an entity-oriented page type for inclusion in another page, for example, in a FactBox.

> **NOTE**
>
> Since entity-oriented pages represent a *single* entity, such as a customer or an item, we recommend that you do not use a `Repeater` group in the construction of entity-oriented pages. If you do, some of the repeater's features may not work properly, and it may not get the expected size. However, an entity-oriented page *can* embed a list part page that, in turn, contains a repeater control.

Collection-oriented pages

In Business Central, collection-oriented pages are used to support users when their tasks involve multiple entities or records at the same time. The most typical collection-oriented page type is the `List` (for example showing customers, items, and so on.) from which the user can seek out the entities to work with.

The `Worksheet` is the other prominent collection-oriented page type, suited for data entry (for example, in journal pages) and other tasks related to managing a set of entities/entries based on custom fields above and/or below the collection.

The `ListPart` page type is a collection-oriented page type for inclusion in another page, for example, in a FactBox.

Dialog pages

The page types in Business Central that are available exclusively for displaying dialogs, such as the `StandardDialog` and `ConfirmationDialog` page types, can represent an entity *or* a collection. The title caption and actions are suited for both types.

Composing pages

Within a page, the developer can combine page fields into groups. This can help the user overview the page by placing related fields together. And within a group, *subgroups* can further increase the structure of the data displayed in a page.

Besides adding fields and groups to a page, it is possible to embed another page of type `CardPart` or `ListPart`. (These two page types can in turn not embed other pages.)

When pages are created that embed parts, Business Central divides the available screen real estate between the page's groups of fields and any embedded pages. Screen space is divided between field groups and embedded pages such that the user can get access to the full contents of the page and collapse/expand specific sections of interest.

How space allocation takes place for a given page depends on the chosen page type, the structure of page contents (field groups and page parts), and on the size of the browser window.

A page is Content + Actions + FactBoxes

For all pages (excluding `RoleCenter`, dialogs, and part pages) there is a common structure to the areas of a page where content, FactBoxes, and actions can be displayed.

The `content` area provides rich layout capabilities, which are described in the coming sections. The `FactBoxes` area is limited to showing a list of parts, usually in a vertical arrangement. The header consists of the title, action bar, and controls for filtering, views, and so on.

For more information about page areas, see Pages Overview.

Field groups and page parts

In the following sections you find descriptions of typical page layouts, recommendations for how to organize the contents, and illustrations of the principles by which the sections of page share screen real estate. The types of content on a page are illustrated this way:

SYMBOL	SECTION	NOTES
	Group of fields, or CardPart	Appears on the page as a FastTab, with fields wrapped in one or more columns.
	ListPart	List or table layout, with integrated action bar.
	Repeater	List or table layout.

Sizing of page sections

The groups of fields and page parts making up a page are rendered when the user opens the page.

Dependent on the size of the available screen real estate, for example, in the browser window on a desktop computer, Business Central sizes the sections automatically to make the most of the space.

There are three different ways a section's size are determined.

SYMBOL	LAYOUT BEHAVIOR	NOTES
	Size to content	Enclosing page will use a scrollbar if needed.

SYMBOL	LAYOUT BEHAVIOR	NOTES
	Size to content within certain limits	The part will use a scrollbar if content exceeds available space.
	Size to fill space	The part will use a scrollbar if content exceeds available space.

Which of the section sizing behavior is used is dependent on the chosen page type. For each of the page types described in the sections below, we present the typical layouts, and the way that the sections are sized.

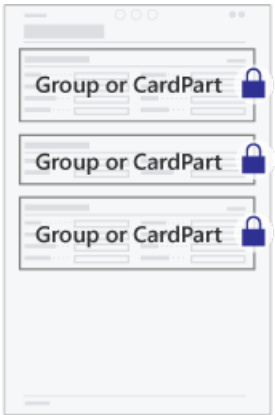
Card and Document page layouts

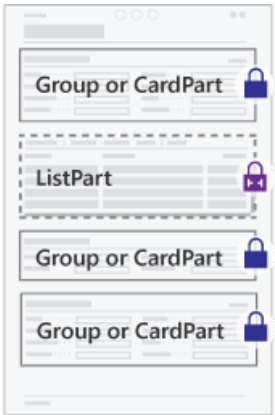
The primary purpose of Card pages is to support users managing master and reference data, such as Customer, Vendor, and Item entities. (The name *Card* refers to how this kind of business data was kept on paper cards in filing cabinets before being computerized.) The Card page type is also often used for setup pages.

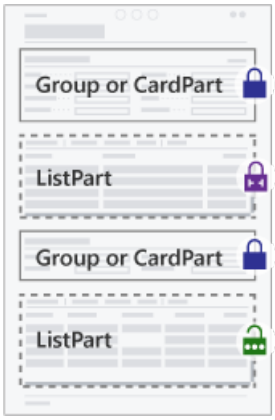
The Document pages' primary purpose is to represent a transaction or other important event in the domain of business. Document pages are the computerized counterpart to paper-based documents (quotes, invoices, orders, etc.), and as such, document pages often have associated workflow or audit trail requirements.

Below are examples of Card and Document page compositions, showing how space is divided. Parts can be combined in more ways than shown here to suit different scenarios.

Card layouts

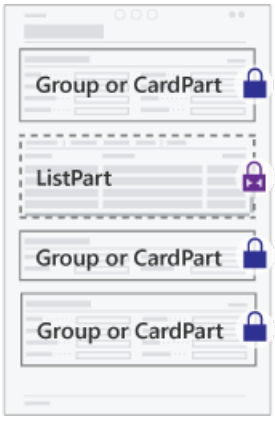
EXAMPLE 1	EXAMPLE 2	EXAMPLE 3
Sections are placed vertically from top to bottom of the page.	A ListPart can be embedded. In this case, the ListPart's height is limited.	When a ListPart is embedded as the last part on the page, it will expand to fill space.
		


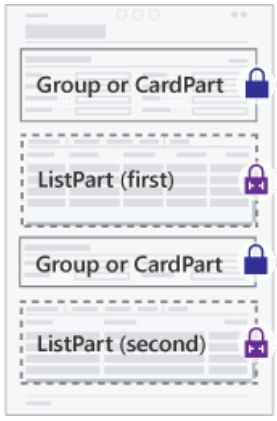


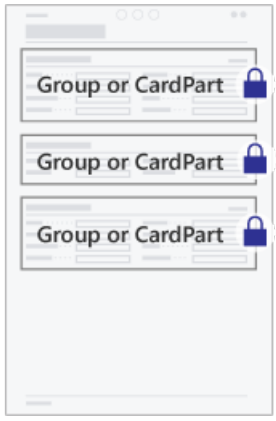


Document layouts

EXAMPLE 1	EXAMPLE 2	EXAMPLE 3
Sections are placed vertically from top to bottom of the page. The lines ListPart comes after the header section(s).	Multiple ListParts can be embedded. In this case, the first ListPart is allowed the most space.	When no ListPart is embedded, the Document layout follows the Card layout exactly.

EXAMPLE 1	EXAMPLE 2	EXAMPLE 3
		






> **NOTE**
>
> The Document page type allows the first ListPart on the page to use additional vertical space before showing a scrollbar. This allows more space for showing the document lines without requiring the user to scroll.

The well-designed card or document page

From the user's perspective, the following are qualities of a well-designed card or document page:

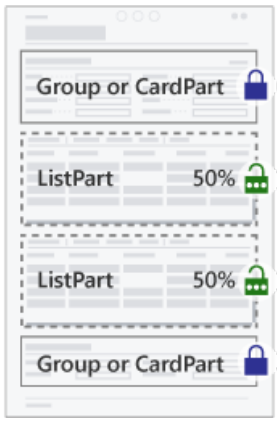
- Uses the page type `Card` if the page represents master or reference data, or is a setup page.
- Uses the page type `Document` if the page represents a transaction or other important event in the domain of business.
- Has a page title that clearly identifies the data represented in the page.
- Is optimized for overview by organizing data in FastTabs and marking relevant fields as `Promoted` or `Additional`.
- Favors header fields and other important fields by placing them in a FastTab titled General that come first on the page.
- Has one or two FactBoxes to give relevant statistics and quick access to related documents.
- For Document pages, a FastTab titled *Lines* comes second on the page with the document lines.

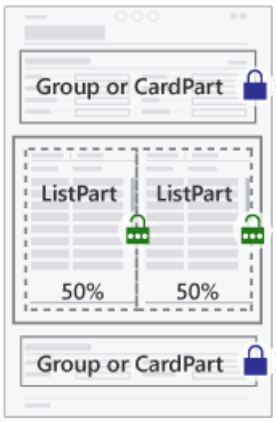
ListPlus page layouts

The ListPlus pages' primary purpose is to support users in managing or browsing a collection of data, or entries, related to a specific business entity or event. For example, the *Customer Sales* page is a ListPlus page that shows sales numbers for a customer and providing dedicated viewing options for sales analysis.

The ListPlus page type is a versatile means to support analysis and management tasks in a specific entity context (named by the page title). ListPlus pages can show persistent data about the entity/event in addition to giving options for how data is viewed or filtered.

A ListPlus page should generally not contain a repeater control but will typically embed a `ListPart` page that in turn embeds a repeater. In addition, a ListPlus page can embed groups of fields and cardparts. Below are examples of ListPlus page compositions, showing how space is divided. Parts can be combined in more ways than shown here to suit different scenarios.

EXAMPLE 1	EXAMPLE 2	EXAMPLE 3
Page sections are placed from top to bottom. The first ListPart fills vertical space.	When placing two or more ListParts, they'll share available vertical space.	When placing two ListParts in a group, they share horizontal space.
		




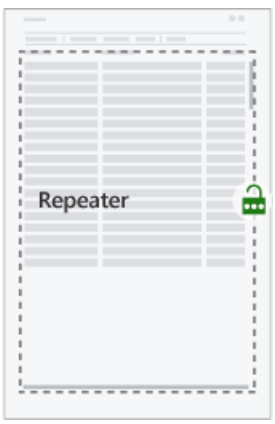
From the user's perspective, the following are qualities of a well-designed ListPlus page:

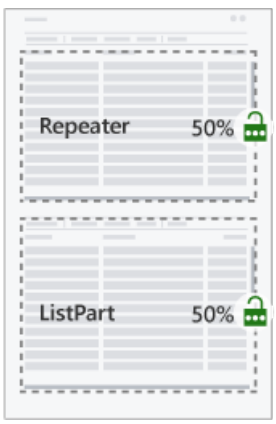
- Has a page title that clearly identifies the context for the information presented in the page.
- Is optimized for showing one set of details, and giving the user means to work with them.
- Presents information in the page in such a way that the hierarchy can be understood when read from top to bottom.
- If present, fields that control which data is presented in another FastTab come before that FastTab.
- If present, fields that show data dependent on the chosen row (in the ListPart) come after the ListPart.

List page layouts

List pages support users viewing and finding specific entities or entries in a collection. Lists that are editable have cells available for data entry and update.

List pages must contain a single `Repeater` group. In addition, a list can embed groups of fields, card parts, and list parts. Below are examples of list page compositions, showing how space is divided. Parts can be combined in more ways than shown here to suit different scenarios.

EXAMPLE 1	EXAMPLE 2	EXAMPLE 3
The repeater control assumes full vertical space.	When a field group or cardpart is embedded, space for repeater is reduced.	When a listpart is embedded, space is shared equally between part and repeater.
		




From the user's perspective, the following are qualities of a well-designed List page:

- Defines a set of columns that is optimized for viewing and filtering the given collection. Optimize the column order for data entry if the list is editable.
- Has a page title that clearly names or identifies the collection of entities/entries presented.
- If a summary or additional detail related to the selected row are shown, these appear below the list.
- If custom viewing options are available, these appear above the list.
- Has one or two FactBoxes to give essential collection statistics, and relevant related details for the selected row.

Worksheet page layouts

A Worksheet page lets users view and manage a collection of entries in tabular or matrix form. It is well suited for cases when a custom filter or a set of default field values is the basis for users' understanding of the collection, such as with journals (where the user selects a batch) and inquiry pages (where the user forms a query).

Use a Worksheet page (instead of a List page) when there are header fields that determine or subdivide a collection, i.e. the user must make a choice in the header field before the repeater has data to show at all. Or when there are header fields that represent default values for data entry in the repeater.

> **NOTE**
> The Worksheet page type doesn't support the same part and group compositions as the List page type.

Worksheet pages must contain a single `Repeater` group. In addition, a worksheet can embed groups of fields, cardparts, and listparts. Below are examples of list page compositions, showing how space is divided. Parts can be combined in more ways than shown here to suit different scenarios.

EXAMPLE 1	EXAMPLE 2	EXAMPLE 3
The repeater control takes full vertical space, but leaving space for a group or CardPart above.	A group, CardPart, or ListPart can be embedded below the repeater that then assumes the remaining vertical space.	Groups and/or parts are embedded above and below, leaving the remaining vertical space for the repeater.
		

From the user's perspective, the following are qualities of a well-designed worksheet page:

- Defines a set of columns that is optimized for overviewing and managing the given collection. Columns are ordered relative to their importance.
- Has fields above the grid that specify filtering options or specify the default values effective during data entry

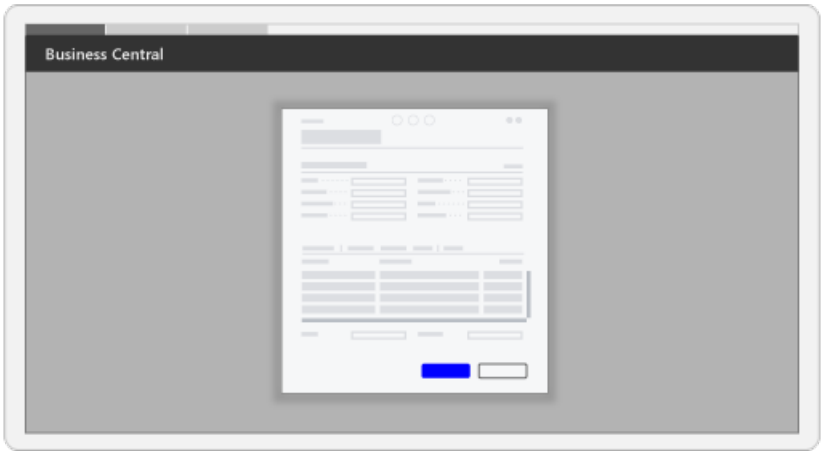
and editing in the grid.

- If summary fields or additional details of the selected row are shown, these appear below the repeater.

Dialog page layouts

Some page types in Business Central are available exclusively for displaying dialogs, such as the `StandardDialog` and `ConfirmationDialog` page types. In addition, there are programmatic ways in AL to display a dialog to the user with the Dialog data type, as well as dialogs defined as report request pages.

It is also possible to use the common page types (`Card` , `Document` , `List` , etc.) to present a dialog to the user. In this case, pages are created, composed, and can embed the same elements, as when displayed ordinarily. Presenting the page to the user as a dialog requires certain AL code that activates the dialog mode. When this happens, the page is shown with dismiss buttons in the page footer.



Generally, Business Central displays dialogs on the screen in a frame that is more narrow and not taking up full vertical height, compared to how pages appear ordinarily. Aside from that, pages lay out their contents according to the same principles, whether displayed as a dialog or not.

Given the size of the screen where the dialog appears, more or less of the page contents will be visible without scrolling. When a page contains a lot of content, it is possible for the user to increase the dialog size with the maximize button.

> **NOTE**
> The dialogs created from the ConfirmationDialog and StandardDialog page types are not currently providing a maximize button.

Designing List Pages

2/17/2021 • 8 minutes to read • Edit Online

The *List* page type displays records from an underlying table, either as rows and columns or as individual tiles.

You design list pages when you want to provide users with a collection of data, enabling them to get an overview of and find entities to work with, such as customers, vendors, or sales orders. Typically, a list page will link to an associated card page that lets users view or modify specific entities in the list.

There are different ways to incorporate a list page into that application:

- Make the list page available from the navigation of a Role Center page.

  This gives users quick access to the page. With this implementation, the list page opens in the content area of the Role Center page, where the Role Center's navigation area is still present and accessible at the top of the page. For more information about Role Centers, see Designing Role Centers.

- Make the list page available from an action on another page.

  With this implementation, the list page opens in a separate window in front of the current page.

- Make the list page searchable from the **Tell me what you want to do** feature.

  With this implementation, the list page also opens in a separate window. For more information, see Adding Pages and Reports to Search.

Customizing a list pages from the client

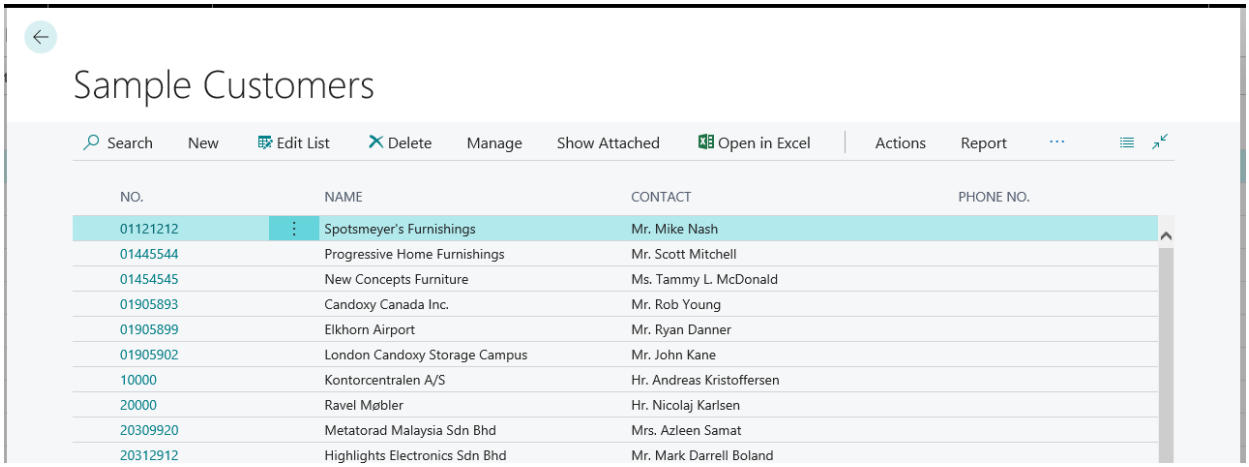
In the client, users can personalize list pages by rearranging or hiding records or FactBoxes as they like. For more information, see Personalizing Your Workspace.

As a developer or administrator, you can use Designer to customize the list page the same way that individual users personalize their own work spaces. The difference is that changes you make are applied to all users. For more information, see Using Designer.

Simple List Page Code Example

2/17/2021 • 2 minutes to read • Edit Online

The AL code in this article creates a simple list page that displays records from an existing table.



For a more detailed explanation of the list page, see Designing List Pages.

```
page 50111 SampleCustomerList
{
    PageType = List;
    ApplicationArea = All;

    // Specifies the page to display records from the Customer table.
    SourceTable = Customer;

    // Makes the page searchable from the Tell me what you want to do feature.
    UsageCategory = Lists;

    // Specifies the card page Sample Customers to be uses for modifying or creating new customer records.
    CardPageId = 50112;

    // Sets the title of the page to Sample Customers.
    Caption = 'Sample Customers';

    layout
    {
        area(Content)
        {
            // Sets the No., Name, Contact, and Phone No. fields in the Customer table to be displayed as
columns in the list.
            repeater(Group)
            {
                field("No."; "No.")
                {
                    ApplicationArea = All;

                }
                field(Name; Name)
                {
                    ApplicationArea = All;

                }
                field(Contact; Contact)
                {
                    ApplicationArea = All;
                }
```

```
                field(Phone; "Phone No.")
                {
                    ApplicationArea = All;

                }
            }
        }

    }

    actions
    {
        // Adds an action on the Actions menu of the action bar that opens the page Customer Ledger Entries.
        area(Processing)
        {
            action("Ledger Entries")
            {
                ApplicationArea = All;
                RunObject = page "Customer Ledger Entries";
                trigger OnAction();
                begin

                end;
            }
        }

        // Promotes an action for creating a sales quote to promoted action menu called New.
        area(Creation)
        {
            action("New Sales Quote")
            {
                ApplicationArea = All;
                RunObject = page "Sales Quote";
                Promoted = true;
                PromotedCategory = New;
                Image = NewSalesQuote;
                trigger OnAction();
                begin

                end;
            }
        }

        // Adds an action on the Report menu that opens the Top 10 List report.
        area(Reporting)
        {
            action("Top 10 List")
            {
                ApplicationArea = All;
                RunObject = report "Customer - Top 10 List";
                trigger OnAction();
                begin

                end;
            }
        }
    }
}
```

Working with Repeater Controls

2/17/2021 • 3 minutes to read • Edit Online

A repeater is a control used to define a list of records from the source table of a page. These are displayed as rows and columns, where each row is a record and each column is a field.

You add a `repeater()` control within the `area(Content)` control of a page, and then you nest a `field()` control for each of the fields from the table specified in the SourceTable Property that you want to include. The order of the field controls determines the order in which they appear on the page.

A list is a characteristic element of the layout of pages of the type **List** and **ListPart**. You define the type of a page using the PageType Property. List pages are designed for using a single `repeater()` control, which must be defined at the beginning of the content area. If you include more than one repeater or another control like a group or grid, the page might not behave as expected. If you want to design a page that includes controls in the content area other than a repeater, then try using a **Worksheet** page type instead. For more information, see Pages Types and Layout.

Pages of the type **API** are also designed to integrate a repeater control, but they cannot be displayed in the user interface.

The following figure illustrates how a list created by a repeater is displayed in the Web Client.

NO.	NAME	CONTACT	PHONE NO.
01121212	Spotsmeyer's Furnishings	Mr. Mike Nash	
01445544	Progressive Home Furnishings	Mr. Scott Mitchell	
01454545	New Concepts Furniture	Ms. Tammy L. McDonald	
01905893	Candoxy Canada Inc.	Mr. Rob Young	
01905899	Elkhorn Airport	Mr. Ryan Danner	
01905902	London Candoxy Storage Campus	Mr. John Kane	
10000	Kontorcentralen A/S	Hr. Andreas Kristoffersen	
20000	Ravel Møbler	Hr. Nicolaj Karlsen	
20309920	Metatorad Malaysia Sdn Bhd	Mrs. Azleen Samat	
20312912	Highlights Electronics Sdn Bhd	Mr. Mark Darrell Boland	

NOTE

The Web client does not support displaying Repeater controls that contain other Parts or FlowFilter fields.

How to customize a list

You can make various changes to customize the appearance of the list in a page and determine which data is displayed. This can be done using AL code or directly from the Web Client.

To the improve the visibility and readability of the list you can set some properties at control and field level. For example, you can specify the width of a column using the Width Property or set row indentation using the IndentationColumn Property and the IndentationControls Property.

You should also consider limiting the number of columns and enabling a freeze column, by setting the FreezeColumn Property, as well as applying filters to display only the most relevant data and minimize scrolling. This is particularly important when it comes to mobile devices, where there are restrictions as to how much content can be shown. You can also do this by defining a new view on a page. For more information, see Views.

Alternatively, you can add, move or hide fields and make adjustments like modifying the column width, directly from the user interface. To apply these changes you use the Designer tool. For more information, see Using

Designer. If these changes are meant for your own workspace, then you use the Personalize tool. For more information, see Personalizing Your Workspace. To sort the data and apply filters you can use the Filter Pane from the page. For more information, see Sorting, Searching, and Filtering.

You can also use the Tile View to display records as tiles (or bricks) instead of as rows and optimize the space and readability of data. For more information on how to customize the tile view, see Displaying Data as Tiles.

Example

The following example shows how the repeater control is used to define a list page for the Customer table.

```
page 50111 SampleCustomerList
{
    PageType = List;
    ApplicationArea = All;
    SourceTable = Customer;
    UsageCategory = Lists;
    CardPageId = 50112;
    Caption = 'Sample Customers';

    layout
    {
        area(Content)
        {
            // Sets the No., Name, Contact, and Phone No. fields in the Customer table to be displayed as
columns in the list.
            repeater(Group)
            {
                field("No."; "No.")
                {
                    ApplicationArea = All;

                }
                field(Name; Name)
                {
                    ApplicationArea = All;

                }
                field(Contact; Contact)
                {
                    ApplicationArea = All;
                }

                field(Phone; "Phone No.")
                {
                    ApplicationArea = All;

                }
            }
        }
    }

    actions
    {
        area(Processing)
        {
            action("Ledger Entries")
            {
                ApplicationArea = All;
                RunObject = page "Customer Ledger Entries";
                trigger OnAction();
                begin

                end;
            }
        }
    }

}
```

You can use page customizations to modify the layout of a page for concrete users. The following code hides the `"Phone No."` column from the users with `Accountant` profile.

```
profile Accountant
{
    Description = 'Functionality for finance staff performing any AR or AP work and managerial reporting.';
    RoleCenter = "Accountant Role Center";
    Customizations = MyCustomization;
}

pagecustomization MyCustomization customizes "Customer List"
{
    layout
    {
        modify("Phone No.")
        {
            Visible = false;
        }
    }
}
```

Displaying Data as Tiles for Lists

2/17/2021 • 3 minutes to read • Edit Online

In the client, on `List` type pages, users can view the page in the tile view. The tile view shows records as tiles (or bricks) instead of as rows. Tiles optimize space and readability of data. Tiles are especially useful for images, like on a page that show items, customers, and contacts. Business Central also provides Microsoft Teams integration, which enables users to display an interactive, visual representation of records in a Teams chat. These features both use the same design concept, which is based defining a `Brick` field group on the an entities source table.

By default, the tile view will display the first five fields that are defined in page's `repeater` control. This article describes how you can customize the tile view for list type pages.

> **NOTE**
> The `Brick` field group is also used to define the fields that appear when a record is shown in a Microsoft Teams conversation. For more information, see Extending Teams Cards.

Tile view in the client

To switch between the list and tile view, users selecting the **View layout options** icon in the action bar of the page. If tiles contain a media field type, then there are two tile view options: **Tiles** and **Tall Tiles**. The same information is displayed except with **Tall Tiles**, images are larger and display at the top of the tiles.

Tiles are interactive. A context menu is available in the upper right corner. The context menu contains the actions that are defined for the record, like in the list view. To drill down to a card page for a record, the user selects the tile.

Customizing the tile view in AL

You specify the data that you want shown in the tile view in the source table of the page by adding a `Field Group` that has the name `Brick`:

```
fieldgroups
{
    fieldgroup(Brick; <field 1>, <field 2>, <field 3>, <field 4>, <field 5>)
    {

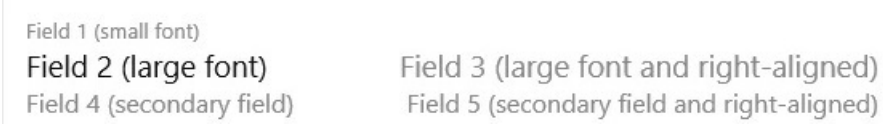
    }
}
```

There's no limit on the number fields that you can display in a tile. However, we recommend that you limit tiles to five data fields and one image field.

> **IMPORTANT**
> By default, the `Field Group` named `DropDown` is interpreted as `Brick` when a `Brick` definition has not been set. The `DropDown` is typically set on entities such as customer, vendor, and items. For more information, see Field Groups (Drop-Down Controls).

Field layout in tiles

The order of the fields determines how they appear in the layout of the tile, no matter the order in the page object. Depending on the number of columns that you define in the `Field Group`, the layout will dynamically change. This concept is illustrated in the following figure:



The fields 2 and 3 are shown in a large font. These fields should typically contain data that identifies the brick. For example, in the **Customers** list, the **Customer Name** and **Balance** are displayed in fields 2 and 3.

Including images in tiles

To display an image in the brick, you include a `Media` data type field in the `Field Group` definition. You don't have to include a field control for the media field in the page object, because the image will be shown in the tile view automatically.

The image will be displayed on the left side of the tile (or at the top in the **Tall Tiles** view), whatever its position in the `Field Group` definition. If an image doesn't exist for a certain record, a default picture is displayed instead.

For information including media on records, see Working With Media on Records.

Styling text in tiles

Like the list view, the tile view supports the Style Property and StyleExpr Property. You apply these properties on the page field controls. These properties, for example, let you mark numbers as favorable or unfavorable.

Example

The following code is a simple example of a table that includes `Field Group` control for displaying data in the tile view of a list page.

```
Table 50100 MyTable
{

    fields
    {
        field(1; Number; Integer)
        {
        }

        field(2; Description; Text[50])
        {
        }
        field(3; Inventory; Integer)
        {
        }
        field(4; Image; Media)
        {
        }
    }

    keys
    {
        key(PK; Number)
        {
        }
    }

    fieldgroups
    {
        fieldgroup(Brick; Number, Description, Inventory, Image)
        {
```

```
        }
    }
}

page 50100 MyListPage
{
    PageType = List;
    ApplicationArea = All;
    UsageCategory = Lists;
    SourceTable = BrickTableTest;
    Editable = true;
    CardPageId = MyCardPage;

    layout
    {
        area(Content)
        {
            repeater(GroupName)
            {
                field(Number; Number)
                {
                    ApplicationArea = All;
                }
                field(Description; Description)
                {
                    ApplicationArea = All;
                }
                field(Inventory; Inventory)
                {
                    ApplicationArea = All;
                    Style = Attention;
                }
            }
        }
    }
}
```

Views

2/17/2021 • 3 minutes to read • Edit Online

Views in Dynamics 365 Business Central are used on list pages to define a different view of the data on a given page. Views can be defined for Pages, Page Extensions, and Page Customization. Views are defined on page extension objects to provide an alternative view of data and/or layout on an existing page, and in views on page customization objects, they can be used to provide an alternative view for a certain profile.

A view offers:

- Filtering on multiple table fields on the source table defined for the page.
- Sorting of the data on multiple table fields, but only in one direction; either *ascending* or *descending*.
- Layout changes, modifying page columns, moving them, etc.

Views are defined directly in code, on the list page that they modify. The defined view or views are available to the user through **Filter Pane** on a page and appear in the sequence that they are defined in code.

> **NOTE**
> `showMyCode` does not apply to views. Views defined in an extension with `showMyCode` set to `false` can still be copied using Designer.

Snippet support

Typing the shortcut `tview` will create the basic layout for a view when using the AL Language extension in Visual Studio Code.

Filtering and sorting

You can filter on the data in a view by using the `Filters` property. The following is an example of the syntax:

```
Filters = where ("Balance (LCY)" = filter (> 500), Name = filter ('G*'));
```

For more information, see Filters.

You can sort on the data in a view by using the `OrderBy` property. The following is an example of the syntax:

```
OrderBy = ascending ("Balance (LCY)", Name);
```

For more information, see OrderBy.

> **NOTE**
> All filters are applied to the table field(s), not the page field(s), which allows filtering on a table field not shown on the page.

View example

The following example shows a page customization of the **Customer List** page, which is available for a specific

role center only; the **My Role Center**. Change the role center view under **My Settings**. The definition of the view adds a caption which is displayed on the left side in the UI. The view sorts the customer balance in ascending mode and the view modifies the layout by moving the customer balance first and adding a freeze column after it.

> **IMPORTANT**
> The definition of the `view` section must come after any definition of layout and actions, otherwise you will get a compilation error.

```
profile MyProfile
{
    Description = 'My Role Center';
    RoleCenter = "Order Processor Role Center";
    Customizations = MyCustomization;
}

pagecustomization MyCustomization customizes "Customer List"
{
    layout
    {
        // Change the layout of the page
    }

    actions
    {
        // Add any actions to the page
    }

    views
    {
        addfirst
        {
            view(BalanceLCY)
            {
                Caption = 'Ordered Balance LCY';
                OrderBy = ascending ("Balance (LCY)");

                layout
                {
                    // Change the layout of the view

                    movefirst(Control1; "Balance (LCY)")

                    modify(Control1)
                    {
                        FreezeColumn = "Balance (LCY)";

                    }
                }
            }
        }
    }
}
```

Limitations

In general, views can in several ways be compared to page customizations. These are the limitations of views:

- For views you can modify the same control properties as for page customization objects independently of where the view has been defined (page, page extension, or page customization level). This is validated by the

compiler.

- It is not possible to use variables or methods in a view. When writing client-side expressions for properties like **Visibility**, it will only be possible to use constant values or table field references. This is validated by the compiler.
- It is not possible to create new controls for a page from a view.

Adding Custom Filter Tokens

2/17/2021 • 3 minutes to read • Edit Online

In the client, when filtering lists using the filter pane, users can enter filter tokens, which are special words that resolve to one or more values. This powerful feature makes filtering easier by reducing the need to navigate to other pages to look up values to enter as filter criteria.

There are several useful filter tokens available in Business Central. For example, entering **%mycustomers** in a **Customer No.** field will resolve to the set of customers in the user's **My Customers** list such as `1001|1002`, making it easy to find relevant sales orders for customers 1001 and 1002.

You can add custom filter tokens and make these available in any language and across the application. To add your custom filter token, you need to define the token word that users will enter as filter criteria, and define a handler that resolves the token to a concrete value at runtime. For more information, see Filter Tokens in our ALAppExtensions repository on GitHub.

Defining the token word and the handler

To create the token word, start by defining a multi-language text string for your word. Subscribe to the `OnResolveTextFilterToken` event associated with the `MakeTextFilter` method from the `Filter Tokens` codeunit. In the event subscriber, if the value of the `TextFilter` parameter contains the token string, process its value and construct the final filter string. If the filter string must contain multiple values, you must handle the operators that join them by adding the `|` filter symbol (OR operation). Complete the operation by setting the value of the `TextFilter` parameter to the value of the final filter string.

> **TIP**
> Filter criteria will often contain symbols along with filter tokens. We recommend that you only modify the filter token you have introduced and preserve the rest of the filter string.

Example

This example shows how you can use the guidelines above to create the **%MYTOKEN** filter token. This will return a filter with the accounts marked as favorite by the user.

> **NOTE**
> To keep this sample short and simple, the entire filter string is overwritten.

```
codeunit 50101 MyAccountFilterTokenSimple
{
    [EventSubscriber(ObjectType::Codeunit, Codeunit::"Filter Tokens", 'OnResolveTextFilterToken', '', true,
true)]
    local procedure FilterMyAccounts(TextToken: Text; var TextFilter: Text; var Handled: Boolean)
    var
        MyAccount: Record "My Account";
        MaxCount: Integer;
    begin
        if StrLen(TextToken) < 3 then
            exit;

        if StrPos(UpperCase('MYTOKEN'), UpperCase(TextToken)) = 0 then
            exit;

       Handled := true;

        MaxCount := 20;
        MyAccount.SetRange("User ID", UserId());

        if MyAccount.FindSet() then begin
            MaxCount -= 1;
            TextFilter := MyAccount."Account No.";

            if MyAccount.Next() <> 0 then
                repeat
                    MaxCount -= 1;
                    TextFilter += '|' + MyAccount."Account No.";
                until (MyAccount.Next() = 0) or (MaxCount <= 0);
        end;
    end;

}
```

To try it out in the client, open the `Charts of Accounts` page, filter on **No.** field, and type in a substring that starts the same way with the chosen token word, like **%MYTO**.

Design considerations

Resolving tokens is intended to be fast, simple, and reliable. When implementing event subscribers to resolve filter tokens, keep in mind that these events can be triggered from any user task in Business Central, and in some cases may be triggered repeatedly such as when searching across columns. To improve usability and reduce the impact on performance, do consider the following practices:

- Avoid implementing tokens that are only relevant to few business tasks, or assume they are used in the context of a specific page.
- Avoid implementing tokens that are time-consuming to resolve. Examples of this include looking up records in large or poorly indexed tables, or fetching data from a remote service.
- Avoid implementing tokens that are complex or unreliable and may result in error.
- Avoid displaying pages, dialogs or any other form of interactive UI.

Sorting, Searching and Filtering Lists

Designing Indented Hierarchy Lists

2/17/2021 • 4 minutes to read • Edit Online

This article explains how to indent specific rows in a list.

Overview

Using the indentation properties in AL, you can display rows in a parent-child structure.

A row that's indented from a row above is considered a *child* of that row. The row above is considered the *parent*. Indenting rows can help organize related records in the list and make it more readable for the user.

You can display indented hierarchy lists on any page type, including List pages, Worksheets, and ListParts. Pages can also be editable.

There are two kinds of indented hierarchy lists: fixed and collapsible. In a fixed hierarchy, rows that are indented are always shown. In a collapsible, users can collapse and expand parent rows to show and hide child records.

Setting up a fixed indented hierarchy

In a fixed hierarchy, child rows are always shown, as illustrated in the following figure.

In the figure, indentation is applied to the second column. Setting up the fixed indented hierarchy involves configuring two properties on the page object: IndentColumn and IndentationControls.

- The IndentationColumn Property determines which records get indented and by how much. You set the property to either a field in the page's source table or to a variable. The important thing, is that property resolves to an integer. This integer determines the indentation level.
- The IndentationControls property specifies which column in the list gets indented. You can only specify one column.

Example

In this example, you indent records based on the value of the **Indent** column and apply the indentation to **Name** column. You set the IndentationColumn and IndentationControls on the repeater of the page, as shown in the following code:

```
page 50100 MyPage
{
    PageType = List;
    ApplicationArea = All;
    UsageCategory = Lists;
    SourceTable = MyTable;
    Editable = true;

    layout
    {
        area(Content)
        {
            repeater(Control1)
            {
                IndentationColumn = Indent;// IndentationColumn = IndentVariable;
                IndentationControls = Name;

                field(Number; Number)
                {
                }
                field(Name; Name)
                {
                }
                field(Indent; Indent)
                {
                }
            }
        }
    }

    //trigger OnAfterGetRecord()
        //begin
          //IndentVariable := Indent;
        //end;

        //var
           //IndentVariable: Integer;
}
```

You can achieve the same results using a variable instead of the table field for the IndentationColumn property. Look at the commented lines of code in the example above.

For a more detailed implementation example, see the Chart of Accounts page in the base application (link requires sign-in to Business Central online).

Setting up a collapsible indented hierarchy

In a collapsible hierarchy, users can collapse and expand parent rows to show and hide child records.

Setting up a collapsible hierarchy is similar to the fixed indented list, except for the properties that you set. A collapsible hierarchy involves three properties: IndentColumn, ShowsAsTree, and TreeInitialState.

- Like in fixed indented hierarchy, the IndentationColumn Property is an integer data type field or variable that determines which records get indented and by how much.

- The ShowAsTree Property makes the hierarchy collapsible.
- The TreeInitialState Property, which is optional, specifies whether the list is collapsed or expanded when the page opens.

Unlike fixed indented lists, a collapsible hierarchy always indents the left-most visible column in the repeater. The IndentationControls property is ignored. If users customize the page by moving another column first, the moved column will be indented instead.

Example

In this example, you'll indent records based on the value of the **Indent** column. Records will indent on the **Number** column and parent records will be collapsible. You add the IndentationColumn, ShowAsTree, and TreeInitialState properties to the pages' repeater:

```
page 50100 MyPage
{
    PageType = List;
    ApplicationArea = All;
    UsageCategory = Lists;
    SourceTable = MyTable;
    Editable = true;

    layout
    {
        area(Content)
        {
            repeater(Control1)
            {
                IndentationColumn = Indent; // IndentationColumn = IndentVariable;
                ShowAsTree = true;
                TreeInitialState = CollapseAll;

                field(Number; Number)
                {
                }
                field(Name; Name)
                {
                }
                field(Indent; Indent)
                {
                }
            }
        }
    }

    //trigger OnAfterGetRecord()
        //begin
          //IndentVariable := Indent;
        //end;

        //var
           //IndentVariable: Integer;
}
```

You can achieve the same results using a variable instead of the table field for the IndentationColumn property. Look at the commented lines of code in the example above.

For a more detailed implementation example, see the Assisted Setup page in the base application (link requires sign-in to Business Central online).

Collapsed or Expanded lists

Users can change whether the page opens with rows collapsed or expanded, essentially overriding the TreeInitialState property. They change the behavior by selecting the **Toggle Expand All / Collapse All** button

in the header of the first column, or using the button in the top-left corner of the repeater. It stays this way, until they delete personalization on the page.

Design and behavior considerations

When using an indented hierarchy, consider the following behavior:

- When indentation is specified, it's no longer possible to use sorting on the columns in the repeater control or display the list as tiles.
- Right-aligned data in columns, such as the integer data type, won't appear as indented.
- Indentation is used to visually communicate structure, without modifying the table of records itself. There's no tightly defined *parent-child* relationship between records, so you must implement additional logic if records need to relate together. For example, if a user deletes a parent record, Business Central won't delete all of its child records.
- Indenting records in a list doesn't automatically apply any additional styling to emphasize parent records and distinguish them from child records. You can implement styling using style expressions. For example, you could format all fields on parent records to display bold values. Learn more about StyleExpr Property.

Designing Card and Document Pages

2/17/2021 • 7 minutes to read • Edit Online

The *card* page type displays selected fields from an underlying table. The *document* page type is very similar in structure to the card page, but in addition to fields, it also includes a part that includes another page, called a sub-page.

Card pages

You design card pages when you want to enable users to view, create, and modify records (master and reference data) in a table, such as a customer, vendor, or item.

Document pages

Design document pages when you want to represent a transaction or other important event in the domain of business. Document pages are the computerized counterpart to paper-based documents, such as quotes, invoices, orders, and so on. As such, document pages often have associated workflow or audit trail requirements.

Associate with a list page

Both page types are typically associated with list pages (like the customers or sales orders list) that uses the same table as their source. From the list page, users can select a record and open it the card or document page for viewing and editing.

Customizing a card and document pages from the client

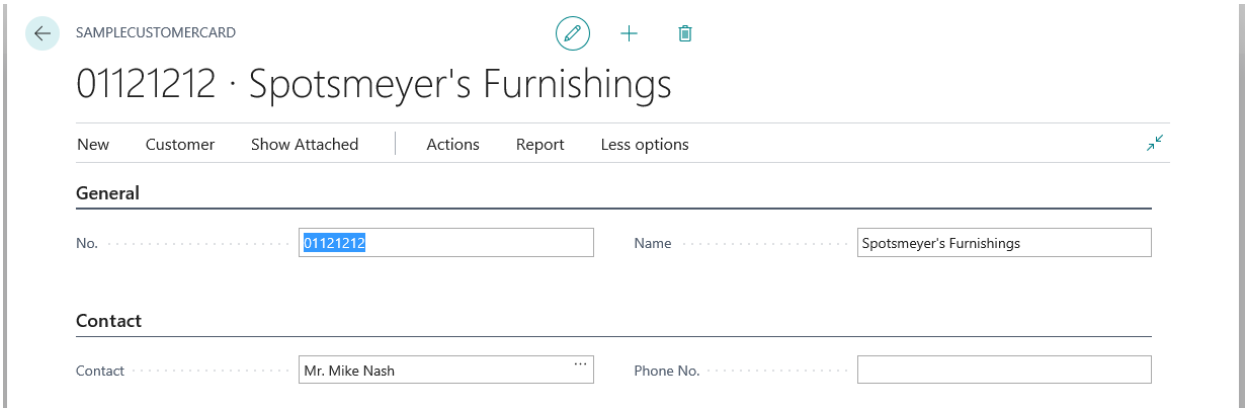
In the client, users can personalize card pages by rearranging or hiding content as they like. For more information, see Personalizing Your Workspace.

As a developer or administrator, you can use Designer to customize a card and document page the same way that individual users personalize their own work spaces. The difference is that changes you make are applied to all users. For more information, see Using Designer.

Simple Card Page Code Example

2/17/2021 • 2 minutes to read • Edit Online

The AL code in this article creates a simple card page that displays records from an existing table.



For a more detailed explanation of the list page, see Designing Card and Document Pages.

```
page 50112 SampleCustomerCard
{
    PageType = Card;
    ApplicationArea = All;
    UsageCategory = Administration;
    SourceTable = Customer;

    //Defines the names for promoted categories for actions.
    PromotedActionCategories = 'New,Process,Report,Manage,New Document,Request Approval,Customer';

    layout
    {
        area(Content)
        {
            //Defines a FastTab that has the heading 'General'.
            group(General)
            {
                field("No."; "No.")
                {
                    ApplicationArea = All;

                }
                field(Customer; Name)
                {
                    ApplicationArea = All;

                }
            }

            //Defines a FastTab that has the heading 'Contact'.
            group(Contact)
            {
                field(Name; Contact)
                {
                    ApplicationArea = All;

                }
                field(Phone; "Phone No.")
                {
                    ApplicationArea = All;
```

```
                }
            }
        }
    }

    actions
    {
        area(Processing)
        {

            //Defines action that display under the 'Actions' menu.
            action("New Sales Quote")
            {
                ApplicationArea = All;
                RunObject = page "Sales Quote";
                Promoted = true;
                PromotedCategory = New;
                Image = NewSalesQuote;
                trigger OnAction();
                begin

                end;
            }
            action("Banks Account")
            {
                ApplicationArea = All;
                RunObject = page "Customer Bank Account List";
                Promoted = true;

                //Promotes the action to the category named 'Customer'.
                PromotedCategory = Category7;
                Image = BankAccount;
                trigger OnAction();
                begin

                end;
            }

        }
        area(Reporting)
        {

            //Defines action that display under the 'Report' menu.
            action("Statement")
            {
                ApplicationArea = All;
                RunObject = codeunit "Customer Layout - Statement";
                trigger OnAction();
                begin

                end;
            }
        }
    }
    var
        myInt: Integer;
}
```

Page Parts Overview

2/17/2021 • 5 minutes to read • Edit Online

Parts are a special category of page designed to be embedded within another page. The hosting page can be composed of one or more page parts. Parts are useful when designing richer user experiences, by displaying information from a table that is different from the source table of the hosting page. Using parts is a great way to reuse your code across multiple pages.

Hosting parts on a page

The following table illustrates how parts could be creatively arranged on a page to deliver unique experiences.

ILLUSTRATION OF PAGE PATTERN	EXPLANATION
	Pages of type **Role Center** are typically composed of multiple pages parts. These parts typically display business headlines, KPIs, and other cues to help users get an overview of their work.
	Most page types can display a number of FactBoxes in the FactBox pane, that display information related to the current record.

ILLUSTRATION OF PAGE PATTERN	EXPLANATION
	Pages of type **Document** are used to model transactional data that typically consists of a header and detailed lines. Since these records come from different tables, a part is used to display lines that originate from a related table.
	Related lists can be displayed above each other. This pattern is a common pattern allowing one list to be filled by the selected record of another list. **Note:** We're working on adding guidance for more optimal layouts.

ILLUSTRATION OF PAGE PATTERN	EXPLANATION
	When records from two tables need to be compared together, parts can be displayed side by side. **Note:** We're working on adding guidance for more optimal layouts.

Different types of parts

Business Central offers different types of parts that display data in a specific way.

PAGETYPE	PURPOSE	HOSTING PAGE TYPES
ListParts	Display a list of records.	Role Centers; FactBoxes on pages of type Card, Document, Worksheet, List, ListPlus; Tabular step in a Wizard; Subpage on a Document page.
CardParts	Flexible canvas that can be used to display almost any page controls, such as fields, cue tiles, charts, images, or control add-ins.	Role Centers; FactBoxes on pages of type Card, Document, Worksheet, List, ListPlus; Step in a Wizard.
HeadlineParts	Display relevant insights from across the business.	Role Centers only.

Adding a part to a page

To add a part to a page in Visual Studio Code, you add a part control on the hosting page object that references the page part object. The part control also defines a small set of properties, such as the caption that will accompany the part. This allows separation of responsibility: the page part object defines self-contained functionality, whilst the hosting page defines how the container of the part should behave without knowledge of its' functionality.

For more information about the properties of a part control, see Page Properties.

Design considerations

Part size

The size of a part is automatically determined by the user interface and will vary depending on where the part has been embedded on the page, other content surrounding the part, and the overall available space of the

display target. Developers can't specify the preferred, minimum, or maximum height or width of a part.

Part actions

A part can define actions that operate on the fields within the part or navigate to another page. The area in which a part is embedded on a page determines how the action menu is displayed.

- In the `FactBoxes` or `RoleCenter` area of the hosting page, parts display a condensed action menu.
- In the `Content` area of the hosting page, parts will only display an expanded action menu if they satisfy the following rules:
  - parts are hosted on a card or document page.
  - parts aren't placed within a FastTab.

Collapsed or expanded parts

The area in which a part is embedded on a page determines whether the part can be collapsed.

- In the `FactBoxes` or `RoleCenter` area of the hosting page, parts can't be collapsed.
- In the `Content` area of the hosting page, parts can only be collapsed if they satisfy the following rules:
  - parts are hosted on a task dialog, card, or document page.
  - parts aren't placed within a FastTab.

Dynamics 365 Business Central automatically determines whether parts are initially displayed as expanded or collapsed. For example, when a document page is opened the first time, the first two parts or FastTabs are automatically expanded and all other parts and FastTabs are shown as collapsed to provide an optimal starting experience. Users can change the state of a part to be expanded or collapsed directly within the user interface, but developers can't specify the starting state.

Choosing the visibility of parts

Parts can be hidden on the hosting page to provide an optimal starting experience. For example, a part could be hidden because it contains secondary content, or content that is needed by only some categories of users. To hide a part, set the **Visible** property of the part to `false` on the hosting page.

When you design a page with hidden parts, users can choose to display those parts again using personalization and role customization features in the user interface. Parts can be made visible programmatically using an expression, for example, depending on whether the feature has been set up by administrators. Learn more about Dynamic Visibility of Controls.

> **NOTE**
> Parts embedded on Role Center pages can't be made visible using expressions, because the hosting Role Center page can't execute code.

Using page background tasks

Like other page types, you can design a part page to use one or more page background tasks. However, unlike other page types, a part page won't display any data until all page background tasks have completed. For more information about this behavior, see Designing part pages for page background tasks.

Good to know

- Parts can either represent self-contained functionality, or can be contextual and exchange information with the hosting page.
- A part can't be hosted within another part. Business Central allows a maximum of one level of page nesting.
- Parts can't be placed within repeater controls.
- Parts aren't intended to be displayed on their own without a hosting page.

Working with List Parts

2/17/2021 • 2 minutes to read • Edit Online

A *ListPart* page is a type of page part used to display a list of records embedded within another page. It consists of a repeater, which presents the records of the source table as rows and columns, and optionally, of an action bar.

A list part can be contained in Role Centers, in the FactBox and content area of other pages, in a tabular step in a Wizard and as a subpage in a Document page. Depending on the type of the hosting page, a list part is subject to different design constraints, which determine its position and dimensions. For more information, see Design Considerations.

Creating a list part

To create a list part, you create a page object, set the PageType Property to `ListPart` and specify the source table. A list part page uses a single `repeater` control, located inside `area(Content)`, where you specify the `field` controls that you want to display. The structure is similar to that of a `List` page, except that there is no FactBox section, since part pages cannot host other parts. For more information, see List Page Structure.

Adding a list part to a page

To place the list part in a page, you add a `part` control to the hosting page and associate it with the list part page object. Here you can also define additional properties. These will only apply to the container of the list part, whose functionality is independent from the hosting page.

Example

The following code sample illustrates how to create a `ListPart` page, `"Pending Shipments"`, and how to integrate it in the card page `"Customer Card"`.

```
page 50101 "Pending Shipments"
{
    PageType = ListPart;
    SourceTable = "Sales Header";
    // Filter on the sales orders that are pending completion.
    SourceTableView = WHERE("Completely Shipped" = CONST(False));

    layout
    {
        area(Content)
        {
            repeater(General)
            {
                field("No."; "No.")
                {
                    ApplicationArea = All;
                }
                field("Order Date"; "Order Date")
                {
                    ApplicationArea = All;
                }
                field("Location Code"; "Location Code")
                {
                    ApplicationArea = All;
                }
            }
        }
    }
}

page 50102 "Customer Card"
{
    PageType = Card;
    SourceTable = Customer;

    layout
    {
        area(Content)
        {
            group(General)
            {
                field("No."; "No.")
                {
                    ApplicationArea = All;
                }
                field(Name; Name)
                {
                    ApplicationArea = All;
                }
            }
            group(Shipments)
            {
                part("Pending Shipments"; "Pending Shipments")
                {
                    // Filter on the sales orders that relate to the customer in the card page.
                    SubPageLink = "Sell-to Customer No." = FIELD("No.");
                }
            }
        }
    }
}
```

Page Parts Overview

Working with Card Parts

2/17/2021 • 2 minutes to read • Edit Online

A *CardPart* page is a type of page part embedded within another page used to display additional data relevant to the page that hosts it. It can display the data in the form of almost any page control, such as fields, cue tiles, charts, images, or control add-ins. You can also define actions to operate on the card part page.

A card part can be placed in Role Centers, in the FactBox and content area of other pages or in a tabular step in a Wizard. Depending on the type of the hosting page, a card part is subject to different design constraints, which determine its position and dimensions. For more information, see Design Considerations.

Creating a card part

To create a card part, you create a page object, set the PageType Property to `CardPart` and specify the source table. You can nest different controls inside the `area(Content)` control depending on how you want to display the data. The controls you can specify are the following.

CONTROL	DEFINITION
`field`	Defines a field. It can also be used to display an image.
`cuegroup`	Defines a group of cue tiles. For more information, see Designing Cues.
`chartpart`	Defines a chart.
`usercontrol`	Defines a control add-in. For more information, see Control Add-In Object.

Adding a card part to a page

To place a card part in a page, you add a `part` control to the hosting page and associate it with the card part page object. Here you can also define additional properties. These will only apply to the container of the card part, whose functionality is independent from the hosting page.

Example

The following code sample illustrates how to create a `CardPart` page, `"Customer Sales History"`, and how to integrate it in the FactBox area of the card page `"Customer Card"`.

```
page 50101 "Customer Sales History"
{
    PageType = CardPart;
    SourceTable = Customer;

    layout
    {
        area(Content)
        {
            // Display data as cue tiles
            cuegroup(Overview)
            {
```

```
                field("No. of Quotes"; "No. of Quotes")
                {
                    ApplicationArea = All;
                    // Make the cue interactive
                    DrillDownPageID = "Sales Quotes";
                }
                field("No. of Orders"; "No. of Orders")
                {
                    ApplicationArea = All;
                    DrillDownPageID = "Sales Order List";
                }
                field("No. of Invoices"; "No. of Invoices")
                {
                    ApplicationArea = All;
                    DrillDownPageID = "Sales Invoice List";
                }
            }
        }
    }
}

page 50102 "Customer Card"
{
    PageType = Card;
    SourceTable = Customer;

    layout
    {
        area(Content)
        {
            group(General)
            {
                field("No."; "No.")
                {
                    ApplicationArea = All;
                }
                field(Name; Name)
                {
                    ApplicationArea = All;
                }

            }
        }

        // Display the card part in the Factbox area
        area(FactBoxes)
        {
            part("Customer Sales History"; "Customer Sales History")
            {
                // Filter on the sales history that relate to the customer in the card page.
                SubPageLink = "No." = FIELD("No.");
            }
        }
    }
}
```

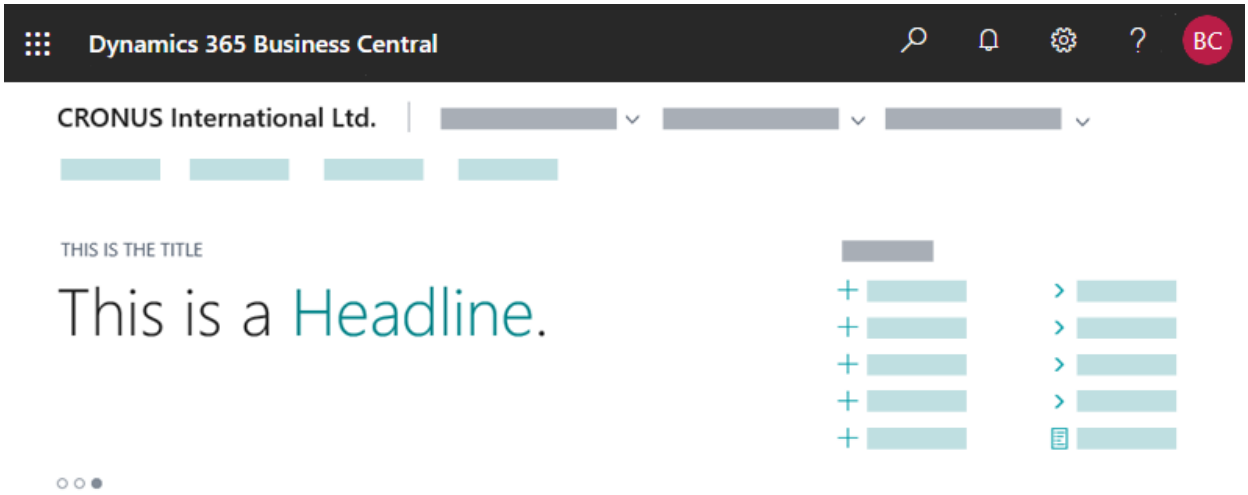
Creating a Role Center Headline

2/17/2021 • 5 minutes to read • Edit Online

You can set up a Role Center to display a series of headlines, where headlines appear one at a time for a predefined period of time before displaying the next.



The headlines can provide users with up-to-date information and insight into the business and daily work. Typical categories of headlines might include:

- My performance
- My workday
- Organizational health
- Productivity tips
- Cross-tenant insights (performance relative to peers)
- Getting started information

> **IMPORTANT**
> Headlines will only appear in the Web client; they will not be shown on other client types.

Design concept

In development

In short, the Headline is basically a page that contains one or more fields. The page must be the **HeadlinePart** type page. Each field defines an individual headline to be displayed. The source for a field can be an expression or a field in an underlying table.

- The **HeadlinePart** page is designed for Role Centers, that is, pages that have the type **RoleCenter**. If you use a **HeadlinePart** page on another page type, the part will not render in the client.
- Using the OnDrillDown trigger, headlines can be made interactive, meaning that users can select the headline to dig deeper into numbers or values that are shown in the headline or link to another page or URL.
- You can dynamically toggle visibility of a specific headline, for example based on its relevancy, by setting the Visible property on the field.

- There are only a few field properties that apply to fields that are used on a **HeadlinePart** type page, including Expression, Visible, ApplicationArea, Drilldown, and DrillDownPageID. All other properties are ignored.

In the client

The Role Center will start by displaying the first visible headline that is defined on the HeadlinePart page. The headline will appear for 5 seconds, then the next headline will appear for 5 seconds, and so on. When all the headlines have been displayed, it will cycle back to the first headline, and continue from there.

- If a headline is interactive, users can select the headline to open the target defined in the headline.
- Users can pause on a headline by pointing to it.
- Users can manually switch among headlines by selecting a corresponding dot that is displayed under the headlines.
- Users can personalize their Role Center to show or hide the Headline part as they like.

Creating a HeadlinePart page

1. Implement the logic that resolves field expressions for the headlines that you will use on the page.

   You can apply more flexible and complex patterns, such as having data tables drive the text, drill-down and relevance engine for headlines.

2. Create a page that has the PageType property set to `HeadlinePart`.

3. For each headline, add a field, and set the Expression property. The order of the fields, determines the order in which they appear.

   The following example shows the AL code for a simple **HeadlinePart** page that consists of four fields that display static text.

```
page 50100 RoleCenterHeadline
{
PageType = HeadLinePart;

layout
{
    area(content)
    {
        field(Headline1; hdl1Txt)
        {

        }
        field(Headline2; hdl2Txt)
        {

        }
        field(Headline3; hdl3Txt)
        {

        }
        field(Headline4; hdl4Txt)
        {

        }
    }
}

var
    hdl1Txt: Label 'This is headline 1';
    hdl2Txt: Label 'This is headline 2';
    hdl3Txt: Label 'This is headline 3';
    hdl4Txt: Label 'This is headline 4';
}
```

4. You can now add the **HeadlinePart** page to the **RoleCenter** page.

Constructing Headlines with the Expression property

The `Expression` property supports the following syntax that enables you to specify a title for the headline, the headline text itself, and emphasize a string of text in the headline:

```
'<qualifier>Title</qualifier><payload>This is the <emphasize>Headline</emphasize>.</payload>'
```

TAG	DESCRIPTION
`<qualifier></qualifier>`	Specifies the title that appears above the headline. If you omit this tag, the text **HEADLINE** will be used by default.
`<payload></payload>`	Specifies the actual headline text.
`<emphasize></emphasize>`	Applies the style to the text.

The `Expression` property must evaluate to the correct syntax. For example, looking back at the previous example, the label `hdl1Txt` could be:

```
hdl1Txt: Label '<qualifier>The first headline</qualifier><payload>This is the <emphasize>Headline
1</emphasize>.</payload>';
```

Making headlines interactive

You can use the OnDrillDown trigger of a headline field to link the headline to more details or relevant information about what is shown in the headlines. For example, if the headline announced the largest sales order for the month, you could set up the headline to open a page that shows a sorted list of sales order for the month.

The following code uses the OnDrillDown trigger to link `Headline1` to the Dynamics 365 online help.

```
field(Headline1; hdl1Txt)
{
    trigger OnDrillDown()
    var
        DrillDownURLTxt: Label 'https://go.microsoft.com/fwlink/?linkid=867580', Locked = True;
    begin
        Hyperlink(DrillDownURLTxt)
    end;
}
```

Changing the visibility of headlines

You can use the Visible property to show or hide headlines that are defined on the **HeadlinePart** page. With the `Visible` property, you can show or hide the control either statically by setting the property to **true** or **false**, or dynamically by using a `Boolean` variable.

Static visibility

With static visibility, you can simply set the `Visible` property on specific fields. For example, following code hides `Headline3`:

```
{
    field(Headline1; hdl1Txt)
    {

    }
    field(Headline2; hdl2Txt)
    {

    }
    field(Headline3; hdl3Txt)
    {
         Visible=false;
    }
    field(Headline4; hdl4Txt)
    {
    }
}
```

By adding fields under `Group` controls, you can hide or show more than one headline by setting the `Visible` property on the `Group` control. For example, the following code hides headings `Headline3` and `Headline4`:

```
group(Group1)
{
    field(Headline1; hdl1Txt)
    {
    }
    field(Headline2; hdl2Txt)
    {

    }
    }
group(Group2)
{
    Visible=false;
    field(Headline3; hdl3Txt)
    {
    }
    field(Headline4; hdl4Txt)
    {
    }
}
```

IMPORTANT

Unlike other page types, the `group` control has no effect on the UI on pages of type **HeadlinePart**. Its primary purpose is to enable developers to group headlines for controlling visibility.

Dynamic visibility

With dynamic visibility, you can show or hide a headline based on a condition that evaluates to `true` or `false`.

- To dynamically show or hide a headline when the **HeadlinePart** page opens, the headline field must be in `group` control, and you set the `Visible` property on the `group` control to the `Boolean` variable that determines the visibility. For example, you could add code on the page's `OnAfterGetRecord` trigger that evaluates the relevance of displaying `Headline3` and results in a `Boolean` variable being set to `true` or `false`.
- To dynamically show or hide a headline while a page is open, you set the `Visible` property on the `field` control to the `Boolean` variable that determines the visibility.

```
group(Group1)
{
    field(Headline1; hdl1Txt)
    {
    }
    field(Headline2; hdl2Txt)
    {

    }
    }
group(Group2)
{
    // Determines visibility when the page opens
    Visible=ShowHeadline3;
    field(Headline3; hdl3Txt)
    {
        // Determines visibility while the page is open
        Visible=ShowHeadline3;
    }
    field(Headline4; hdl4Txt)
    {
    }
}
```

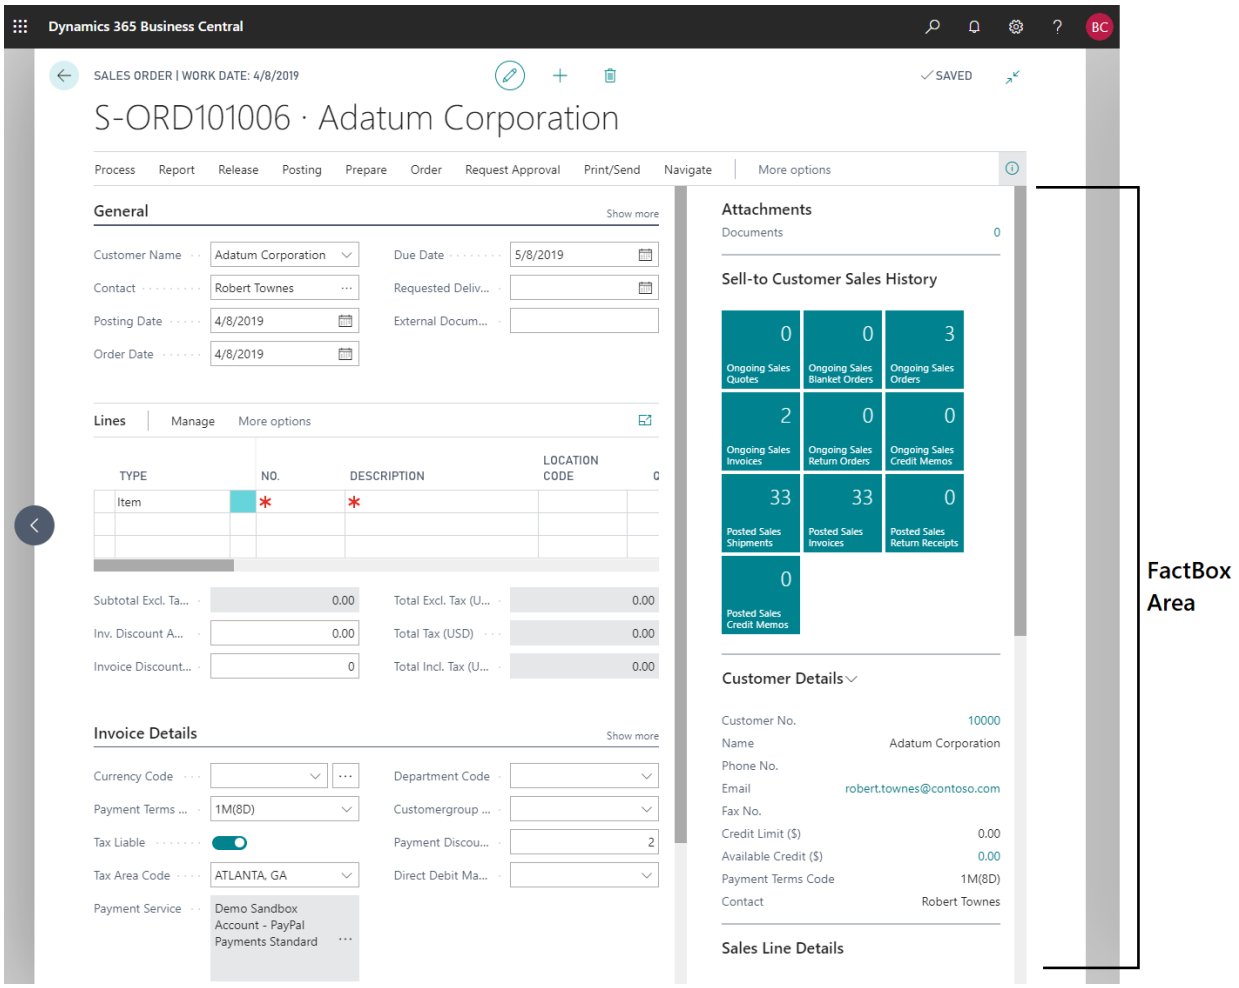
Adding a FactBox to a Page

2/17/2021 • 6 minutes to read • Edit Online

A FactBox is the area that is located on the right-most side of a page and it is divided into one or more parts that are arranged vertically. This area is used to display content including other pages, charts, and system parts such as Notes, and Links. Typically, you can use a FactBox to display information that is related to an item on the main content page. For example, on a page that shows a sales order list, you can use a FactBox to show sell-to customer sales history for a selected sales order in the list as shown below.



The following list highlights a few categories of FactBoxes:

- Show related records/fields which are modeled as ListParts or CardParts.
- Show related KPIs which are modeled as CardParts with charts or Cues. For more information, see Designing Role Centers.
- Visualize related data or display from external sources which are modeled as CardParts containing a Client AddIn. For example, Bing maps, PowerBI, Microsoft Social Engagement, and more.

Adding a FactBox area to a page

You define the FactBox by adding a FactBox area container control to the page. The FactBox area control acts as a placeholder to which you can add different parts for the FactBox. You can add a FactBox area control on the following page types.

- Card

- Document
- ListPlus
- List
- Worksheet

> **NOTE**
> Only one FactBox area control is allowed on a page.

> **WARNING**
> You can add a part to the FactBox area that displays an existing page of the CardPart or ListPart type only. If you attempt to use another page type, you will get an error.

Example

```
page 50100 "Simple Customercard Page"
{
    PageType = Card;

    layout
    {
        area(FactBoxes)
        {
            part(MyPart; "Acc. Sched. KPI Web Srv. Lines")
            {
                ApplicationArea = All;
                SubPageView = SORTING ("Acc. Schedule Name");
            }
            systempart(Links; Links)
            {
                ApplicationArea = All;
            }
            systempart(Notes; Notes)
            {
                ApplicationArea = All;
            }
        }
    }
}
```

> **TIP**
> When used on Lists, FactBoxes can be used to show information about the entire list, or more contextually about the user's current selection; the currently selected rows. You can control the filter which gets passed to the FactBox that determines its contextual contents.

System Parts

There are two system parts that you can define by using the `systempart()` keyword: `Links` and `Notes`:

VALUE	DESCRIPTION

VALUE	DESCRIPTION
Links	Allows the user to add links to a URL or path on the record shown in the page. For example, on an Item card, a user can add a link to the supplier's item catalog. The links will appear with the record when it is viewed. When a user chooses a link, the target file opens.
Notes	Allows the user to write a note on the record shown in the page. For example, when creating a sales order, a user can add a note about the order. The note will appear with the item when it is viewed.

NOTE

The `systempart` keyword also includes an `Outlook` and `MyNotes` value, for example, `systempart(Outlook; Outlook)`. These values are only supported by the Dynamics NAV Client connected to Business Central (which has been deprecated after Business Central Spring 2019). These values are ignored in the Business Central Web client.

Filtering data that is displayed on a page in a FactBox

In many cases, you want to change the content that is displayed on the page in the FactBox based on the content of the main page. For example, if the main page is a Customer List, you can have a FactBox that includes the Customer Details page that shows information about a customer. When a user selects a customer in the Customer List, the Customer Details page displays information about the selected customer. To implement this functionality, you set up a table filter that associates a field in the table that is used by the Customer Details page with a field in the table that is used by the Customer List page, as shown in the example below. You can also filter on a constant value or set of conditions.

Example

```
page 50101 "Simple Customerlist Page"
{
    PageType = List;
    SourceTable = Customer;

    layout
    {
        area(content)
        {
            repeater(Control)
            {
                field("No."; "No.")
                {
                    ApplicationArea = All;
                }
            }

        }

        area(FactBoxes)
        {
            part(CustomerList; "Customer Details FactBox")
            {
                ApplicationArea = All;
                SubPageLink = "No." = FIELD ("No.");
            }
        }
    }
}
```

Performance considerations

Having a page composed of multiple FactBox pages that each process data from different sources can degrade performance. To improve responsiveness and the time it takes to load the page, Business Central 2020 release wave 2 and later optimizes the sequence in which content is loaded. The sequence is as follows:

1. Content on the hosting page is loaded first, and users can immediately begin interacting with it.
2. The FactBox pane is loaded next, where each FactBox is loaded independently in sequence starting from the top.
   a. FactBoxes having the `Visible` property evaluate to `false` won't be loaded.
   b. FactBoxes that aren't within view are only loaded when the user scrolls them into view. If the FactBox pane is collapsed, no FactBoxes are loaded until the user expands the FactBox pane.

Below are some practical tips to help you make the most of this optimization:

- Consider hiding any FactBoxes that represent secondary content that only some users will require. Learn more about Choosing the Visibility of Parts.
- For FactBoxes that require heavy processing, consider processing in the page background task. Learn more about Using Page Background Tasks.
- Avoid having triggers on the hosting page that call into a FactBox because this condition forces the FactBox to ignore performance optimizations and load along with the content of the hosting page, adding to the total loading time.

FAQ about performance

Are any FactBox triggers run when the FactBox is hidden?

No. The trigger is only run when the FactBox is visible and within the user's view.

How often are triggers run if the FactBox pane is expanded, collapsed, and then expanded again?

In this scenario, the `OnOpenPage` trigger is only run the first time. Once a FactBox is loaded, it isn't loaded again

for as long as the page remains open.

Are FactBoxes processed asynchronously?

No. This optimization is simply a controlled sequence in which triggers are run, still within the same session as the hosting page. For more information about asynchronous processing in the background, see Designing page parts for page background tasks.

Does this optimization work with SubPageLink or SubPageView properties?

The use of these properties has no effect on the sequence of loading content on a page. Using properties such as `SubPageView` is preferred to writing trigger code to update a FactBox.

Does this optimization apply to parts that aren't FactBoxes?

This optimization doesn't apply to Role Center pages. When parts are used in the content area of a page, such as on a Card page, they aren't loaded if their `Visible` property evaluates to `false`.

Can I force a FactBox to load along with page content?

There's no AL API to force FactBoxes to load along with the content of the hosting page.

Can I set the FactBox pane to start collapsed on all pages?

No. The default state of the FactBox pane is set by the Business Central platform and modifed by the user.

Does the experience vary on different browsers?

Each browser has its own definition of whether a FactBox is considered within view or not. For example, opening Business Central in a new browser tab and quickly switching back to the original tab may pause loading of any FactBoxes in the new tab.

Does this optimization apply to other form factors?

This applies to desktop, tablet, and phone clients.

Field Arrangement on FastTabs

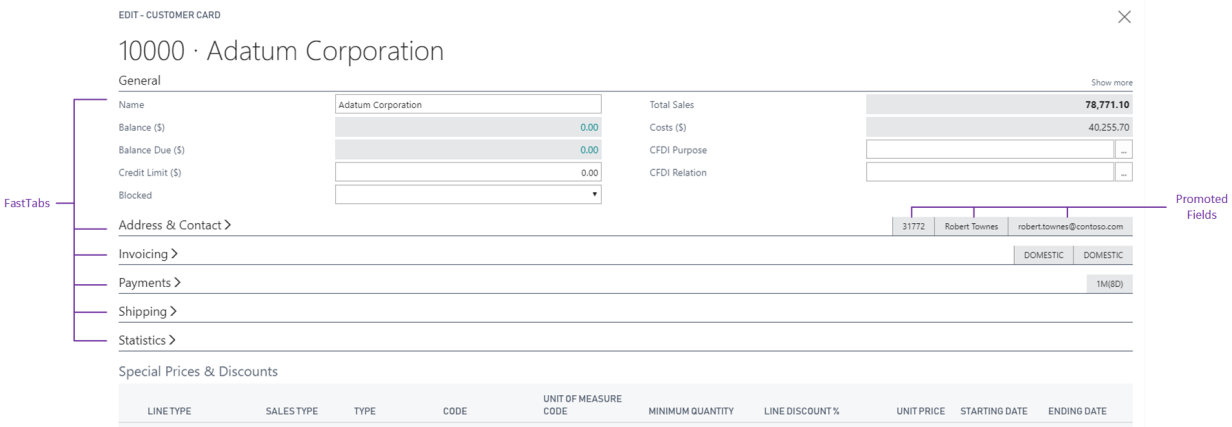
2/17/2021 • 3 minutes to read • Edit Online

FastTabs in Dynamics 365 Business Central allow users to find key information on a page by displaying the data in separate groups. This article describes how individual fields are arranged on a FastTab and ways that you can change the layout.

Organizing data using FastTabs helps users to find key information quickly, while at the same time giving an overview of areas that otherwise would remain hidden. For example, the customer card page displays customer information in the following categories: General, Communication, Invoicing, Payments, Shipping, and Foreign Trade. Each category is a separate FastTab that can be expanded or collapsed, making it easier for users to focus on one subject at a time. On task pages, a FastTab typically represents a single step in a task.

How fields are arranged on a FastTab of a page

By default, a FastTab is divided into two columns for containing fields. Fields are automatically distributed between the left and right columns based on their order in the `layout` section of the page. Starting with the first field in the Page Layout and working downward, fields are positioned in the left column and then in the right column. The area that is occupied by the fields in each column is as equal as possible. Field captions are positioned to the left of fields.



Pages automatically adjust to the available space on the screen. If horizontal space is reduced, a FastTab will adapt and distribute fields into a single column. Similarly, a FastTab will automatically distribute fields into more than two columns to take advantage of wider screens.

FastTab example

Creating a FastTab is easy. A FastTab is a group control directly within the `content` area of a card, document, or task page. The following example shows how you can create a FastTab containing a pair of fields.

```
page 50101 SimpleCustomerCard
{
    PageType = Card;
    SourceTable = Customer;

    layout
    {
        area(content)
        {
            group(GeneralFastTab)
            {
                CaptionML = ENU = 'General';

                field(Name; Name)
                {
                    ApplicationArea = All;
                }
                field(Address; Address)
                {
                    ApplicationArea = All;
                }
            }
        }
    }
}
```

Collapsed or Expanded FastTabs

Dynamics 365 Business Central automatically determines whether FastTabs are initially displayed as expanded or collapsed. For example, when a document page is opened the first time, the first two parts or FastTabs are automatically expanded. All other parts or FastTabs are shown as collapsed to provide an optimal starting experience. Users can change the state of a FastTab to be expanded or collapsed directly within the user interface, but developers can't specify the starting state.

Choosing how to show fields in a FastTab

If a FastTab is expanded, you see all the fields. If it's collapsed, you just see the summary line. The summary line is the header that displays a name for the group, such as 'Communication'. It can also include important fields such as 'E-mail'. Promoting fields to the summary line enables you to present key information to the user, even if the FastTab is collapsed. You can also specify fields that only appear when the users select the **Show more** action on the FastTab. You promote a field or display it only when **Show more** is selected by setting the Importance property of the field.

> **NOTE**
>
> If a group doesn't specify the **CaptionML** property or this is set to an empty value, it's considered to be a group used only for structural purposes. This includes FastTabs. Structural FastTabs look and behave differently, for example, they can't be collapsed by users unless they include the **Show more** action.

Organizing compound content in a FastTab

By using a Group control within a FastTab, you can group fields by similarity. This pattern also gives you control over how fields are distributed between the left and right columns. When you group fields on a FastTab, the groups are distributed evenly between the left and right columns. Fields aren't.

Similarly, page parts placed within a FastTab are distributed evenly between the columns. For example, a FastTab containing two ListParts may be used to display two lists side by side for easier comparison. Learn more about

Page parts.

Manually arranging fields in multiple rows and columns

Using the GridLayout or FixedLayout controls, you can arrange fields in multiple rows and columns in a grid-like format. These controls define a static layout that doesn't automatically adapt to the available space on the screen. It's recommended to use these controls only when you're sure your users will access them on larger screens. For more information, see Arranging Fields Using Grid and Fixed Controls.

Arranging Fields in Rows and Columns Using the Grid Control

2/17/2021 • 3 minutes to read • Edit Online

By default, fields in a FastTab are arranged automatically in two columns that are based on the number of fields. For more information, see Field Arrangement on a FastTab. You can use a Grid control or a Fixed control to arrange fields in rows and columns on a page and design it to look like a grid-like format or a matrix-like format. To understand the differences between the two controls to help you determine which control to use, see Comparing Grid and Fixed controls.

> **NOTE**
> Grid control for arranging page fields is partially supported.

Using the **Grid** control, you can arrange the fields manually in one or more rows and columns. The **Grid** control gives you the following options:

- Set up your grid row-by-row or column-by-column.
- Span a field across multiple rows and columns.
- Show or hide field captions.

Setting-up fields in rows and columns in a FastTab

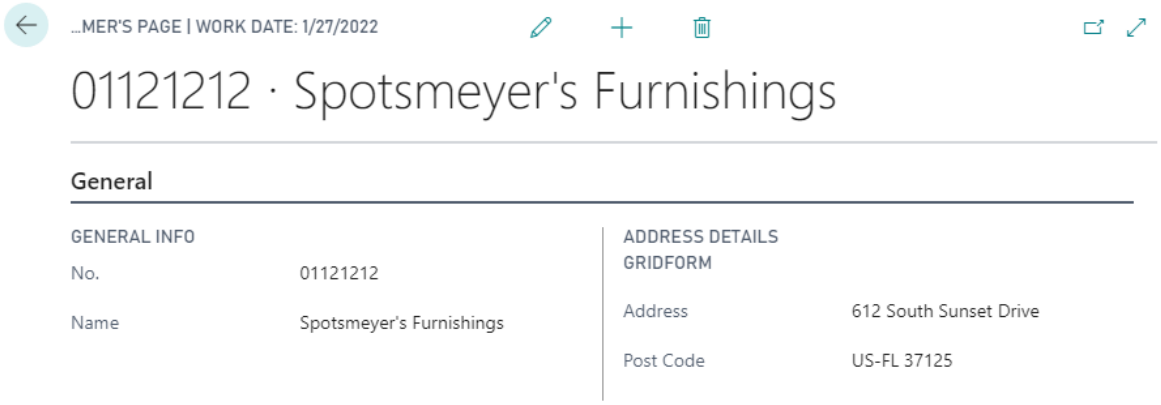
To set up a grid in row-by-row or column-by-column format, you define the **Grid** control in a FastTab of a page. You must define the **Grid** control in a group and specify how you want to arrange the fields by using the **GridLayout** property. For more information, see GridLayout Property.

Example

The following example demonstrates how to structure a page in a grid-like format.

```
page 50113 "Customers Page"
{
    PageType = Card;
    SourceTable = Customer;
    layout
    {
        area(content)
        {
            group(General)
            {
                grid(MyGrid)
                {
                    group("General Info")
                    {
                        field("No."; "No.")
                        {
                            ApplicationArea = All;
                        }
                        field(Name; Name)
                        {
                            ApplicationArea = All;
                        }
                        field("E-Mail"; "E-Mail")
                        {
                            ShowCaption = false;
                            ApplicationArea = All;
                        }
                    }
                    group("Address Details")
                    {
                        grid(Grid2)
                        {
                            group(GridForm)
                            {
                                field(Address; Address)
                                {
                                    ApplicationArea = All;
                                }
                                field("Post Code"; "Post Code")
                                {
                                    ApplicationArea = All;
                                }
                            }
                        }
                    }
                }
            }
        }
    }
}
```

The following screenshot shows how the resulting page looks like from the Web client.

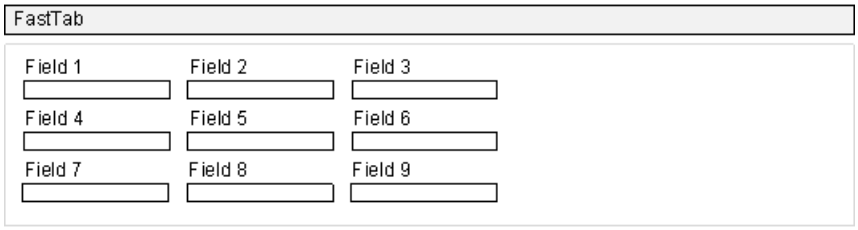


Setting fields to span multiple rows and columns

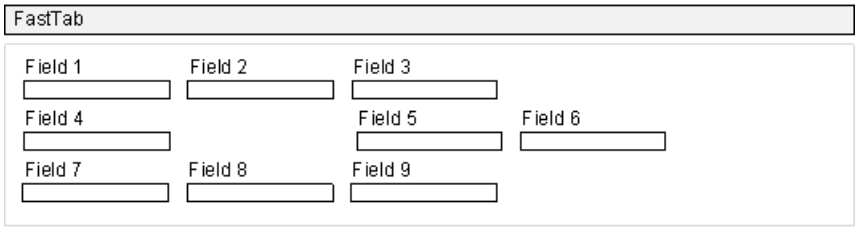
You can set a field to span multiple rows or columns. When you set a field to span multiple rows, the field occupies the cells in the rows below it, and existing fields in the occupied cells are moved to the right. When you set a field to span multiple columns, the field occupies the cells in the columns to the left, and existing fields in the occupied cells are moved to the right. You can also set a field to span multiple rows and columns.

> **IMPORTANT**
> The Dynamics 365 Business Central web client does not support row and column spanning for fields. If the page displays in the Dynamics 365 Business Central web client, the fields appear without spanning.

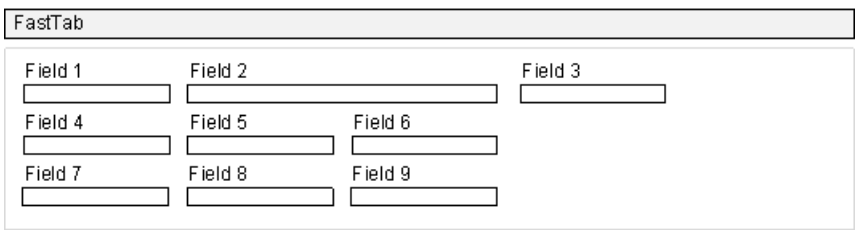
For example, the following figure illustrates a **Grid** control that consists of six fields arranged in three rows.



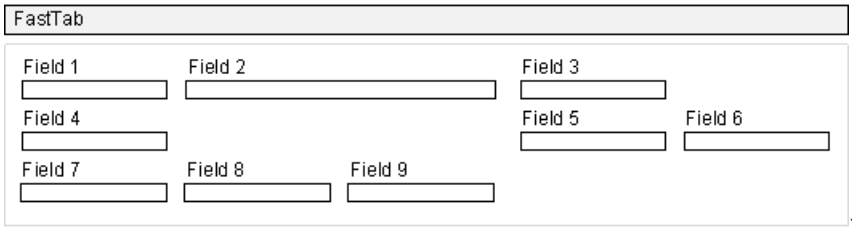
If you set **Field 2** to span two rows, then the following layout is displayed:



When you set a field to span multiple columns, the field occupies the cells in the columns to the right, and existing fields in the occupied cells are moved to the right. Using the previous **Grid** example, if you set **Field 2** to span two columns instead of two rows, the following layout is displayed:



You can also set a field to span multiple rows and columns. For example, if you set **Field 2** to span two rows and two columns, the following layout is displayed:



To set a field to span rows and columns

When you set the **Grid** control, the fields of that group can be set to span rows or columns.

- To set a field to span one or more rows, set the value of the **RowSpan** property to the number of rows. For more information, see RowSpan Property.
- To set a field to span one or more columns, set the value of the **ColumnSpan** property to the number of columns. For more information, see ColumnSpan Property.

> **NOTE**
>
> The **RowSpan** and **ColumnSpan** properties on fields in the grid layout are not supported in the Dynamics 365 Business Central web client. The **Rows** layout on the grid control itself is not supported.

Hiding field captions

You can hide the caption of a group or a field. To hide the caption of a field, set the value of the **ShowCaption** property to **False**. For more information, see ShowCaption Property.

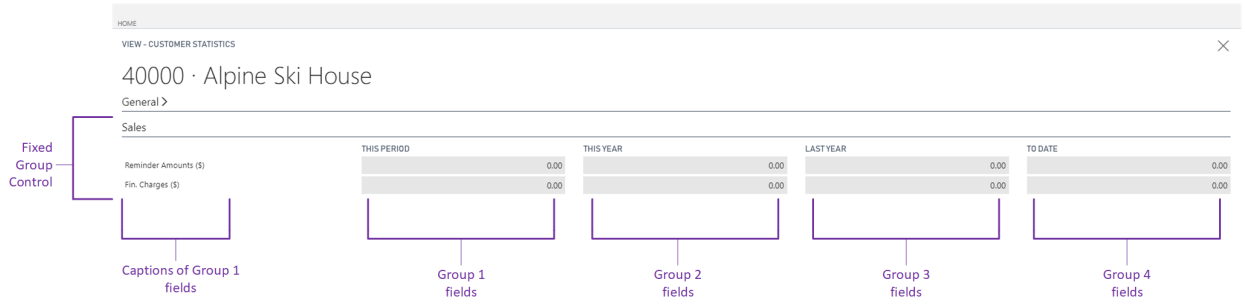
Arranging Fields in Rows and Columns Using the Fixed Control

2/17/2021 • 3 minutes to read • Edit Online

By default, fields on a FastTab are arranged automatically in two columns based on the number of fields. For more information on how the fields are placed on a page, see Field Arrangement on a Fasttab. To manually arrange fields, you can either use a Grid control to design the page to look like a grid-like format, or a Fixed control to design the page to look like a matrix-like format. To understand the differences between the two controls to help you determine which control to use, see Comparing Grid and Fixed controls.

How Fixed control works

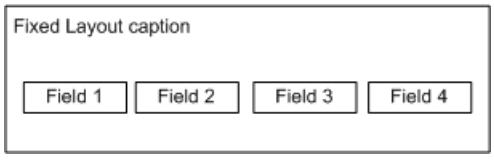
You use the Fixed control to arrange page fields in rows and columns to form a matrix-like layout except that the Fixed control contains a specific number of fields, and a matrix can contain an unspecified number of fields. A Fixed group control is typically used to display statistical data. The following illustration shows an example of a page that uses a Fixed control to show sales totals for different time periods.



You can also use a Fixed control to display information in the details section of a Worksheet page. If you are using the CRONUS International Ltd. demonstration database, then you can see examples of these uses in page 151, Customer Statistics, and page 40, Item Journal.

Adding fields

You can add fields directly in the Fixed control. However, when you add fields directly in the Fixed control, all the fields will display in an equal size and the larger fields will get compressed. The following illustration shows the resulting field layout on a page.



Grouping fields in a Fixed control

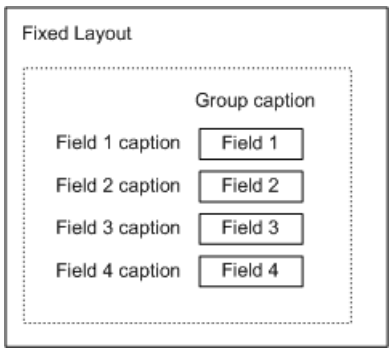
By placing the fields in a Fixed control throughout a group control, you can define separate rows and columns to create a matrix-like arrangement. The group control caption appears as the column header, and the field control captions appear as the row headers. If you add two more group controls that contain fields, then the layout on the page will display like a table format.

Example

The following AL code uses **Fixed** control to display four fields on a page inside the group called Fixed Layout.

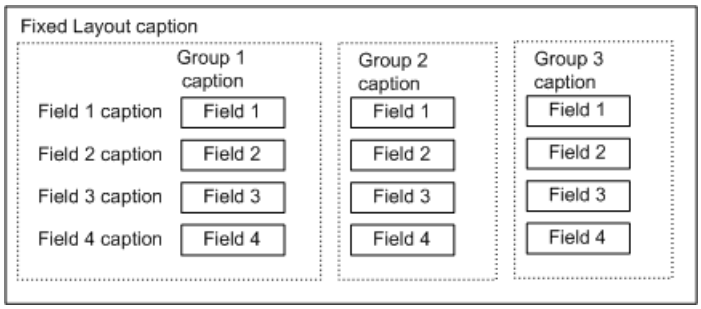
```
page 50114 "Fixed Control Example"
{
    layout
    {
        area(content)
        {
            group("Fixed Layout")
            {
                fixed(DefiningFixedControl)
                {
                    group("Group Caption")
                    {
                        field("Field 1"; "Field 1")
                        {
                            ApplicationArea = All;
                        }
                        field("Field 2"; "Field 2")
                        {
                            ApplicationArea = All;
                        }
                        field("Field 3"; "Field 3")
                        {
                            ApplicationArea = All;
                        }
                        field("Field 4"; "Field 4")
                        {
                           ApplicationArea = All;
                        }
                    }
                }
            }
        }
    }
   var
        "Field 1": Integer;
        "Field 2": Integer;
        "Field 3": Integer;
        "Field 4": Integer;
}
```

The following illustration shows the resulting field layout on a page.



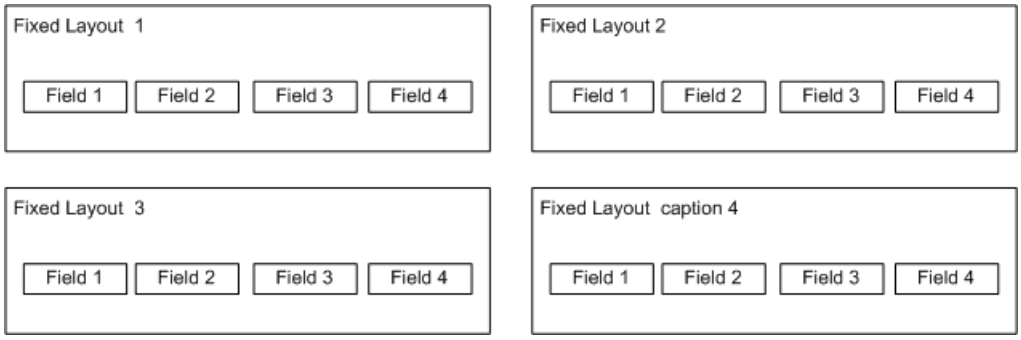
The group control caption appears as the column header, and the field control captions appear as the row headers. If you add two more group controls that contain fields, then the layout on the page will resemble the following illustration.

> **NOTE**
>
> Only the captions of fields in the first column define the row headings. Therefore, only the field captions for the first group control appear. The field captions in other group controls are ignored.



Using multiple Fixed controls

You can also set up more than one Fixed control in a group control. The page area will then divide the fields into two columns that contain the separate Fixed fields. For example, the following illustration shows the page layout if you have four Fixed controls.



> **NOTE**
>
> The fields in the Fixed controls in the illustration are not in a group control. If they were in a group control, then they would follow the same principle as described in the previous section about how to group fields.

> **IMPORTANT**
>
> In previous versions, having a Fixed control directly under a content area was supported. However, in Dynamics 365 Business Central, you must make sure that the Fixed control is nested in a Group control. For more information, see Supported Structure for Using the Grid and Fixed Controls.

Editing fields in a Fixed control

Fields in a fixed layout are not editable even if the **Editable** property is set to **true**. However, if the field drills down to a page where the field source is defined, then you can modify the field. For more information, see Editable Property.

Field Groups (Drop-Down Controls)

2/17/2021 • 2 minutes to read • Edit Online

A field group in table or table extension objects defines the fields to display in a drop-down control on pages that use the table.

In a table object, you define field groups by first adding a `fieldgroups` control, and then adding one or more `fieldgroup(<Name>; <Field>)` keyword for each group, where:

- `<Name>` can be either `DropDown`, for adding fields to the drop-down control, or `Brick` to display data as tiles.
- `<Field>` is a comma-separated list of the fields, by name, to include in the group.

> **NOTE**
> A field group can also be used to specify fields that display when list type pages are shown in the tile view. For more information, see Displaying Data as Tiles.

```
fieldgroups
{
  fieldgroup(DropDown; Field1, Field2)
  {

  }
  fieldgroup(Brick; Field1, Field2)
  {

  }
}
```

> **NOTE**
> The `fieldgroups` keyword cannot be inserted before the `key` control.

> **IMPORTANT**
> The syntax for using a DropDown, must be exactly `DropDown` with the right capitalization.

In a table extension object, the `fieldgroups` control allows you to add more fields to a field group defined for the table object. This can be done by using the `addlast(<name>; <field>)` keyword.

> **WARNING**
> The server will remove the duplicates, if multiple extensions attempt to add the same field more than once. A field can only be added to the field group once.

Define fields for a drop-down control

You define a field to include in a drop-down control by using the `DropDown` field group name in the keyword.

The following example illustrates how to add the field

```
tableextension 50100 CustomerExercise extends Customer
{
    fields
    {
        field(50100; "V02Max"; Decimal) { }
    }

    fieldgroups
    {
        addlast(DropDown; V02Max) { }
    }
}
```

Field Calculation Methods

2/17/2021 • 5 minutes to read • Edit Online

The following methods perform various actions on fields:

- CalcFields
- CalcSums
- FieldError
- FieldName
- Init
- TestField
- Validate

CalcFields method

CalcFields updates FlowFields. FlowFields are automatically updated when they are the direct source expressions of controls, but they must be explicitly calculated when they are part of a more complex expression. For more information about Flowfields, see FlowFields.

CalcFields has the following syntax.

```
[Ok :=] Record.CalcFields(Field1, [Field2],...);
```

When you use FlowFields in AL methods, you must use the CalcFields method to update them.

In the following example, the SETRANGE method sets a filter and then the CalcFields method calculates the Balance and Balance Due fields by using the current filter and performing the calculations that are defined as the CalcFormula properties of the FlowFields. This example requires that you create the following variable.

VARIABLE	DATA TYPE	SUBTYPE
Customer	Record	Customer

```
Customer.Get('01454545');
Customer.SetRange("Date Filter",0D,TODAY);
Customer.CalcFields(Balance,"Balance Due");
Message('The Balance is %1 and your Balance Due is %2',Customer.Balance,Customer."Balance Due");
```

The following message is displayed:

The Balance is 342,529.44 and your Balance Due is 342,529.44

CalcSums method

CalcSums calculates the sum of one or more fields that are SumIndexFields in the record.

CalcSums has the following syntax.

```
[Ok :=] Record.CalcSums (Field1, [Field2],...);
```

For CalcSums, a key that contains the SumIndexFields must be selected as the current key. Similar to CalcFields, CalcSums uses the current filter settings when it performs the calculation.

In the following example, an appropriate key is selected, some filters are set, the calculation is performed and then a message is displayed. This example requires that you create the following variable.

VARIABLE	DATA TYPE	SUBTYPE
custledgerentry	Record	Cust. Ledger Entry

```
custledgerentry.SetCurrentKey("Customer No.");
custledgerentry.SetRange("Customer No.",'10000','50000');
custledgerentry.SetRange("Posting Date",0D,TODAY);
custledgerentry.CalcSums("Sales (LCY)");
Message('%1 calculated sales',custledgerentry."Sales (LCY)");
```

FieldError method

FieldError triggers a run-time error after it displays a field-related error message.

FieldError has the following syntax.

```
Record.FieldError(Field, [Text]);
```

This method is very similar to the Error method. However, in the FieldError method, if the name of a field is changed, for example, translated to another language, in the Table Designer, the message from the FieldError method will reflect the current name of the field.

The following examples show how to use the FieldError method. These examples require that you create the following variable.

VARIABLE	DATE TYPE	SUBTYPE
Item	Record	Item

```
Item.Get('70000');
If Item.Class <> 'HARDWARE' then
   Item.FieldError(Class);
```

If item 70000 has a Class other than HARDWARE, then you receive the following error message:

Class must not be OTHER in Item No. ='70000'.

If the text or code field contains the empty string, then you receive the following error message:

You must specify Class in Item No.='70000'.

If the field is a numeric field and is empty, it is treated as if it contains the value 0 (zero), and then you receive the following error message:

Class must not be 0 in Item No.='70000'.

You can change the default text that is displayed in the error message. The following example shows how to use the FieldError method and change the default text. This example requires that you create the following variable.

VARIABLE	DATA TYPE
Class	Code

```
if Item.Class < '4711' then
   Item.FieldError(Class,'must be greater than 4711');
```

The following error message is displayed:

Class must be greater than 4711 in Item No.='70000'.

FieldName

FieldName returns the name of a field. It has the following syntax.

```
Name := Record.FieldName(Field);
```

You could just use the name of the field. However, using FieldName lets you create messages that always contain the name of the field, even if the name of the field is changed.

This example shows how to use FieldName together with FieldError.

```
FieldError(Quantity,'must not be less than ' + FieldName("Quantity Shipped"));
```

Init

Init initializes a record. It has the following syntax.

```
Record.Init();
```

If a default value for a field has been defined by using the **InitValue** property, this value is used for the initialization. Otherwise, the default value of each data type is used.

> **NOTE**
> Init does not initialize the fields of the primary key.

TestField method

TestField tests whether a field contains a specific value. It has the following syntax.

```
Record.TestField(Field, [Value]);
```

If the test fails, that is, if the field does not contain the specified value, an error message is displayed and a run-time error is triggered. This means that any changes that were made to the record are discarded. If the value that you test against is an empty string, the field must have a value other than blank or 0 (zero).

The following example tests the Language Code field for customer number 10000 in the Customer table and tests whether the Language Code is ZX. This example requires that you create the following variable.

VARIABLE	DATA TYPE	SUBTYPE
customer	Record	Customer

```
customer.Get('10000');
customer.TestField("Language Code",'ZX');
```

Validate method

Validate calls the OnValidate trigger of a field. It has the following syntax.

```
Record.Validate(Field [, NewValue]);
```

When you enter an account number in a ledger, code in a table trigger is executed to transfer the name of the account from the chart of accounts. If you enter an account number in a batch job, the code which transfers the name of the account is not automatically executed. The following example executes the appropriate field-level trigger code. This example requires that you create the following variable.

VARIABLE	DATA TYPE	SUBTYPE
GeneralLedgerEntry	Record	G/L Entry

```
GeneralLedgerEntry.Validate("G/L AccountNo", '100');
```

This corresponds to the following code.

```
GeneralLedgerEntry."G/L AccountNo" := '100';
GeneralLedgerEntry.Validate("G/L AccountNo");
```

The `Validate` method is useful for centralizing processing, which makes your application easier to maintain.

For example, if the OnValidate trigger of the Total Amount field performs a calculation that uses values from three other fields as operands, the calculation must be performed again if the contents of any one of these fields changes. You should avoid entering the calculation formula in the OnValidate triggers of each field because this can create errors if the calculation formula has to be changed later and you have to update the code in all the triggers. Instead, you should enter the calculation formula in the OnValidate trigger of only one of the fields and call this trigger code from the OnValidate triggers of the other fields.

Formatting Decimal Values in Fields

2/17/2021 • 5 minutes to read • Edit Online

This article describes how you can format the decimal values that appear in fields on table, pages and reports. For example, you can change how the data appears in a Cue on the Role Center page. To format data, you use a combination of the AutoFormatType Property, AutoFormatExpression Property, and DecimalPlaces Property of the field. These properties work together to enable you to specify the following:

- Display amounts and unit amounts in another currency.
- Specify the number of decimal places.
- Specify whether to display a thousand separator.
- Specify characters before and after the value, such as currency signs or %.

Implementation overview

When a field is used on a page or report, you can set the **AutoFormatType** and **AutoFormatExpr** properties directly on the page field or report field (column), or you can set them on the underlying table field. If you specify the properties on the table field, then the format applies wherever the field is used. Specifying the properties on the page or report field will only apply the format to the specific page or report. If you specify the properties on the table field and the page or report field, then the settings on the page or report field take precedence.

When you use the **AutoFormatType** and **AutoFormatExpression** properties to format a field, two events are raised by the system codeunit **45 Auto Format**: OnResolveAutoFormat and OnAfterResolveAutoFormat.

Setting up data formatting

The settings for the **AutoFormatType**, **AutoFormatExpression**, and **DecimalPlaces** properties will depend on the type of data that is displayed, for example, this could be currency amounts, unit amounts, simple decimals, or ratios. For the most part, the **AutoFormatType** property is the primary setting, which in turn determines the options for setting the **DecimalPlaces** and **AutoFormatExpr** properties.

If the **AutoFormatType** is not set or is set to an incorrect property value, then the default setting is used, regardless of whether the **AutoFormatExpression** or **DecimalValues** properties are set. The default setting uses `AutoFormatType = 1` and `AutoFormatExpression = ''`.

The following tables describes how to set each of the properties to achieve the format that you want.

Setting the DecimalPlaces property

With the following set up, the **AutoFormatExpression** property is ignored.

AUTOFORMATTYPE PROPERTY	DECIMALPLACES PROPERTY	USAGE DESCRIPTION

AUTOFORMATTYPE PROPERTY	DECIMALPLACES PROPERTY	USAGE DESCRIPTION

0	Set to the number of decimal places that you want to display for the value.	Use this configuration when you want to format the decimal value according the Standard Format 0 (which is the default format) with a specific number of decimal places.
		
		For example, if the value is a US decimal `-76543.21` and you set the **DecimalPlaces** property to `0`, then the value appears as **76,543**. The properties will look like this:
		
		`AutoFormatType = 0;`
		`DecimalPlaces = '0';`

Setting the AutoFormatExpression property

With the following setup, the **DecimalPlaces** property is ignored.

AUTOFORMATTYPE PROPERTY	AUTOFORMATEXPRESSION PROPERTY	USAGE DESCRIPTION

1	Set to return a currency code, such as USD or IDR. The blank currency code `''` denotes LCY and is the default value.	Use this configuration when you want to format the data as an amount. For example, a sales order will use two decimals when the currency is defined as US dollar and no decimals when the currency is defined as IDR (Indonesian rupiah). For example:
		
		`AutoFormatType = 1;`
		`AutoFormatExpression = 'IDR';`

2	Set to return a currency code such as USD or IDR. The blank currency code `''` denotes LCY and is the default value.	This is similar to the previous configuration where the **AutoFormatType** property is set to `1`, except you use this configuration when you want to format the data as a unit amount.

AUTOFORMATTYPE PROPERTY	AUTOFORMATEXPRESSION PROPERTY	USAGE DESCRIPTION

10	Set to the property according to the following syntax:
	`'[SubType][,<currencycode or expression>[,<PrefixedText>]]'`
	`SubType` can be `1`, `2`, another number, or omitted:
	`1` sets the value to an amount type (see 1 above). `2` sets the value to a unit amount type (see 2 above). The syntax for these two settings is:
	`'SubType,<currencycode[, <PrefixedText>]'`
	If you omit the subtype or use a number other than 1 or 2, the syntax is:
	`'<CustomNumber>, <expression>[, <PrefixedText>]'`
	where `<expression>` sets the precision and one of the standard formats. For more information, see Standard Formats.
		Use SubType `1` to add the currency symbol and use the amount type precision. You use SubType `2` for unit amount precision. For example, set the property to `'1,USD'` to add the **$** symbol, like **$543.21**.
		`AutoFormatType = 10;`
		`AutoFormatExpression = '1,USD';`
		If you omit the SubType, you can use this configuration to customize the format based on one of the standard formats. This option enables you to specify characters before and after the decimal value, such as currency signs **$** and percent **%**.
		For example, if you want to prefix the decimal value with a **$**, include a thousand separator, and have a maximum of two decimal places, such as **$76,453.21**, then you can set the properties to:
		`AutoFormatType = 10;`
		`AutoFormatExpression = '$<precision, 2:2><standard format, 0>'`
		If you want to display the decimal value as a percentage, then you can add `%` at the end of the setting. For example:
		`AutoFormatType = 10;`
		`AutoFormatExpression = '<precision, 1:1><standard format,0>%'`
		When you include a `%` at the end of the setting, then the decimal value is assumed to be the ratio, and the decimal value will be multiplied by 100. For example, a value of 0.98 will be formatted to **98%**.

11	Set the property to the standard format as explained below. For example: `'<Precision,3:3><Standard Format,0>'`	Use this option when you want full control over the formatting. The format string will be applied exactly as specified in the AutoFormatExpr property.

Precision

The precision determines the minimum and maximum number of decimal points for values. The precision takes the format `<precision,minimum:maximum>`. For example, `<precision,minimum:maximum>` sets the data with a minimum of 2 and a maximum of 3 decimal places.

Standard formats

The following table describes the standard formats that are available for the **AutoFormatExpr** property when the **AutoFormatType** property is set to 10.

STANDARD FORMAT	FORMAT DESCRIPTION	EUROPE DECIMAL EXAMPLE	US DECIMAL EXAMPLE
0	<Sign> <Integer Thousand> <Point or Comma> <Decimals>	-76.543,21	-76,543.21
1	<Sign> <Integer> <Point or Comma> <Decimals>	-76543,21	-76543.21
2	<Sign> <Integer> <Point or Comma> <Decimals>	-76543.21	-76543.21
3	<Integer Thousand> <Point or Comma> <Decimals> <Sign>	76.543,21-	76,543.21-
4	<Integer> <Decimals> <Point or Comma> <Sign>	76543,21-	76543.21-
9	XML format	-76543.21	-76543.21

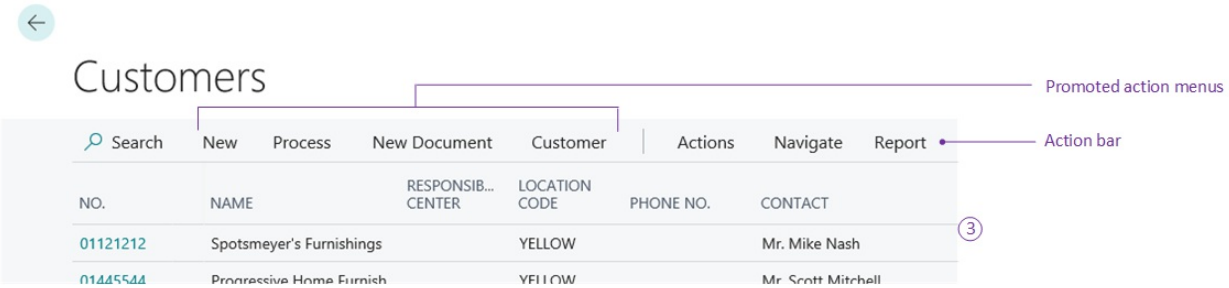
Actions Overview

2/17/2021 • 6 minutes to read • Edit Online

In Dynamics 365 Business Central, actions are displayed at the top of each page, referred to as the action bar. In this topic, you learn about different types of actions, and how you can enable users to quickly locate the actions they want to use.

The actions can be displayed in different menus on the action bar.



You can choose from the following action menus to place the actions in the specified area.

AREA	SYNTAX	USED ON	DESCRIPTION	EXAMPLE
Actions menu	`area(processing)`	Role Center, list, card, and task pages	User tasks	Post a sales order
New document group in Actions menu	`area(creation)`	List, card, Role Center pages, and task pages	Actions that appear under the New group. Opens a new Dynamics 365 document.	New sales invoice
Navigate menu	`area(navigation)`	List, card, and task pages	Links to other pages in Dynamics 365 Business Central.	Prices
Report menu	`area(reporting)`	Role Center, list, card, and task pages	A list of available reports.	Customer Top 10 List

The following actions are related to the Role Center page.

AREA	SYNTAX	USED ON	DESCRIPTION	EXAMPLE
Navigation menus	`area(sections)`	Role Center pages	The top-level navigation consists of one or more root items that expand to display a submenu of links to other pages.	Posted sales invoices
Navigation bar	`area(embedding)`	Role Center pages	The second-level navigation displays a flat list of links to other pages.	Customers

For more information about actions used on the role center page, see Designing Role Centers.

> **TIP**
> If you used to work in Microsoft Dynamics NAV, you can get an overview of the mapping between actions in the Differences in the Development Environments topic.

Types of Actions

Each page has a different set of actions depending on the page type, and the processes that the page supports. In order to create the appropriate set of actions for a particular page, you should have a good understanding of your customer's business processes.

Each process in an organization has several actions associated with it. You should try to create a full set of actions that mirror all tasks and processes that are performed.

Example: The Sales Orders list page at CRONUS International contains all actions related to processing sales orders. During user configuration and personalization, some of these actions may be hidden or promoted to the ribbon. Therefore, you must create a full set of actions for the customer.
Pages can have the following actions as described in each section below.

Actions menu

The Actions menu is a displayed in the action bar on all page types, and contains relevant tasks for the current page. Typically, you add processing tasks and creation tasks in the Actions menu. To add processing actions such as posting a sale order, you must use the `processing` action area. They are regular daily tasks. Therefore, they must be on the Actions menu. For examples on how to add actions to the Actions menu, see Adding Actions to a Page.

Some examples from the Customer page are as follows:

- Sales Invoice
- Sales Quote
- Sales Credit Memo
- Ledger Entries
- Invoice Discounts
- Prices
- Line Discounts

You can add actions to the Actions menu, group actions together under action sub menus, or promote them to the ribbon. For examples of how to use actions, see Page Object and Page Extension Object.

New Document menu

The New Document menu is often displayed both as a top-level menu in the actions bar and as a sub menu in the Actions menu. You can use this menu to open new documents within Dynamics 365. You can add an action to create a new document such as creating a new sales invoice. This action displays in a separate menu called **New document** in the Actions menu. To add to the New document menu, you must use the `creation` action area.

Example: On the Customers page, if the order processor wants to create a new invoice, she can open the new page directly from the Actions menu. This is useful as she creates new sales invoices daily.

Navigate menu

The Navigate menu is displayed after the Actions menu in the action bar. Rather than providing tasks for the user, this menu provides additional information by taking the user to a specific page in Dynamics 365. To add a page link in the Navigate menu, you must use the `navigation` action area. These actions act like a bookmark to enable quick access to view a page.

> **NOTE**
> You should not add a Navigation action to a Role Center page.

Report menu

The Report menu is displayed after the Navigate menu in the action bar. The Reports menu lists the reports most relevant to a page. If a user does not require a Report menu, then the menu is hidden. Sometimes it is relevant to promote the most important reports to the top-level in the action bar to save the user from too many clicks. To create an action in the Report menu, you must use the `reporting` action area.

Promoted Actions

Promoted actions are actions that are set up on the Actions, Navigate, or Reports menus in the action bar, but are also configured to display in custom menus in the action bar. Although the actions are set up on the Actions, Navigate, or Report menus, you can choose to hide them on these menus and only show them in custom menus . For more information on how to add promoted actions, promoted categories and example, see Promoted Actions.

Grouping Actions in Sub-Menus

Within the different areas, you can create sub-menus to a group of actions and improve navigation. You create a sub-menu by adding a `group()` control, as shown in the following example:

```
actions
{
    area(Report)
    {
        action(Report 1)
        {
            RunObject = report "Report1";
        }

        // Adds a sub-menu called "Group1" to the Report menu.
        group(Group1)
        {
            // Adds the action "Report 2" to the My Label sub-menu.
            action(Action2)
            {
                RunObject = report "Report2";
            }
            // Adds a sub-menu called "Group2" to the Group1 sub-menu.
            group(Group2)
            {
                // Adds the action "Report 3" to the Group1 sub-menu.
                action(Action3)
                {
                    RunObject = report "Report3";
                }
            }
        }
    }
}
```

NOTE

Prior to Dynamics 365 Business Central 2019 Wave 2, in the client, sub-menus were automatically placed before single actions on the same level. This means, for example, group **Group2** appears before the action **Report 2**.

Actions at runtime

An action can trigger code to run, such as posting a document or otherwise modifying a record in a table. When a user chooses an action, one of the following pieces of logic will happen in addition to the code that the action itself triggers:

- If the page is empty and no longer shows any records, the page is re-initialized with default values.
- If the page does show records, and the current state is within the page filters boundary, the **OnAfterGetRecord** trigger is executed on the page.
- If the current record that the page showed is now outside the filter but there are other records within the filter, the **OnFindRecord** trigger is called and the **OnAfterGetRecord** trigger is run on the next record with the given filters.

The logic runs in the transaction that the action triggered. This can cause the application code to result in users locking the whole table when they thought they were only modifying one record.

To avoid users accidentally locking tables, you can use the SetSelectionFilter method before your code passes the record variable to the processing codeunit, for example. The following code example illustrates the code on the OnAction trigger on an action on a page.

```
if confirm('Are you sure you want to call this codeunit?', true) then begin
    CurrPage.SetSelectionFilter(Rec);
    codeunit.Run(50000, Rec);
end;
```

Pages Overview

Adding Actions to a Page

2/17/2021 • 4 minutes to read • Edit Online

This topic shows how to create new actions, how to add actions to a page, and how to preview them in the Dynamics 365 web client. In Dynamics 365, actions can be displayed in the action bar of all pages and grouped together under the following actions menus:

- Promoted action categories
- Actions
- Navigate
- Report

Before putting an action on a page you should think about the business processes that the action supports. For example, on page 42, the Sales Orders list page, the Actions button contains actions for all tasks related to processing sales orders. Creating these actions can make it easier for the order processor to perform their daily tasks, such as posting sales orders and creating new customer orders.

For more information about different types of actions and where to use them, see Actions Overview.

> **TIP**
> After you have added actions to a page, you can use Designer to alter the actions, like moving an action to or from a promoted category, hiding and action or action group, and more. For more information, see Using Designer.

To add Actions to a Page

The page actions are displayed on the header section. There are multiple tabs to help navigate to the right item.

In order to add actions to the action bar, you must use the keywords with Anchors or Targets. These keywords are used to place and move the actions around in the tab groups. For more information about adding, moving, and modifying actions, see Using Keywords to Place Actions and Controls.

> **NOTE**
> Actions can only be linked to a page, or to a group control. Actions cannot be linked to fields, or parts on a page.

Set an icon to an action

Dynamics 365 Business Central includes images that you can use on actions in command bar menus and promoted actions on the ribbon. To add an image to an action, you add the **Image** property and you must provide the name of the image you that want to use from the Dynamics 365 Business Central Action icon library. By default, the size of images is 16 pixels high by 16 pixels wide. For promoted actions, you can choose to display larger images that are 32 pixels high and 32 pixels wide. For more information, see Image Property.

Example

The following example shows how to use different action areas on a **page object of the PageType Card**. These actions will display in the following menus in the action bar.

1. Actions menu: The `area(Processing)` action area is used to display the action in the Actions menu. This action uses the **Promoted** and **PromotedCategory** properties in order to display the action in the promoted

actions menu called **Process**.

2. New Document group: The `area(Creation)` action area is used to display the action in the **New document** group in the Actions menu. Also, this action uses the **Image** property to display a form icon instead of a default icon.
3. Navigate menu: The `area(Navigation)` action area is used to display the action in the Navigate tab. This action and other actions in this example uses the **RunObject** property to assign a page to the action.
4. Report menu: The `area(Reporting)` action area is used to display this action in the Report menu, and also a Group control is added as a submenu to this menu. It sets the **Caption** property to make the action group visible in the Reports menu.

```
page 50110 PageName
{
    PageType = Card;

    actions
    {
        // Adds the action called "My Actions" to the Action menu
        area(Processing)
        {
            action("My Actions")
            {
                Promoted = true;
                PromotedCategory = Process;
                ApplicationArea = All;
                trigger OnAction()
                begin
                    Message('Hello World');
                end;
            }
        }

        area(Creation)
        {
            // Adds the action "My New document" to the New Document group in the Actions menu.
            action("My New document")
            {
                ApplicationArea = All;
                RunObject = page "Customer Card";
                Image = "1099Form";
            }
        }

        area(Navigation)
        {
            // Adds the action called "My Navigate" to the Navigate menu.
            action("My Navigate")
            {
                ApplicationArea = All;
                RunObject = page "Customer Card";
            }
        }

        area(Reporting)
        {
            // Adds a submenu called "My Label" to the Report menu.
            group(NewSubGroup)
            {
                Caption = 'My label';
                group(MyGroup)
                {
                    // Adds the action "My Report" to the My Label submenu.
                    action("My Report")
                    {
                        ApplicationArea = All;
                        RunObject = page "Customer Card";
                    }
                }
            }
        }
    }
}
```

> **NOTE**
>
> Actions can be assigned to a page by setting the RunObject property, or by adding a trigger to a Codeunit. For more information, see RunObject Property and Codeunit Triggers.

The promoted action menus are always displayed first so the promoted actions provide quick access to common tasks, and users do not have to browse through a menu to access them. Add the Promoted property to add actions to the a promoted action menu. For more information on how to add promoted actions, promoted categories, and examples, see Promoted Actions.

You can assign different icons for your actions from the Dynamics 365 image library. For more information, see Image Property.

Promoted Actions

Promoted Actions

2/17/2021 • 4 minutes to read • Edit Online

Promoted actions are actions that are set up on the Actions, Navigate, or Report menus in the action bar, but are also configured to display on the Home tab. Although the actions are set up on the Actions, Navigate, or Report tabs, you can choose to hide them on these menus and only show them on the Home tab.

The following table describes where you can use promoted actions.

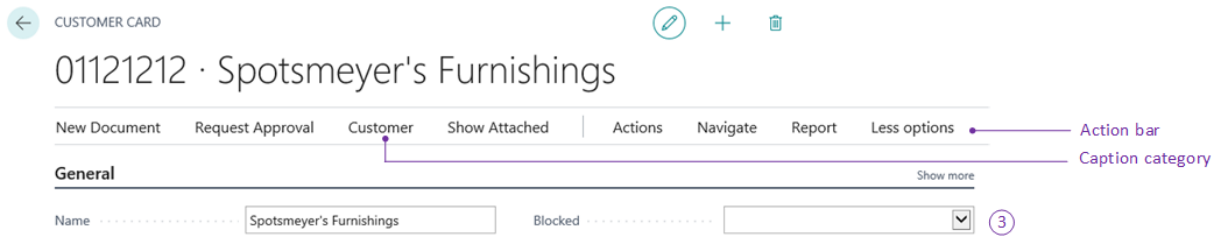
ACTION TYPE	USED ON	DESCRIPTION	EXAMPLE
Promoted Actions	List, card, Role Center pages, and task pages	Provide quick access to common tasks that appear under the Home tab.	Post and print a sales order

You can promote any command from the existing actions menus to the ribbon. If there are no promoted actions, the ribbon remains hidden. To promote an action on the Home tab, you set the **Promoted** property of the action. If you want to display the action only on the Home tab, then you add an additional step to set the **PromotedOnly** property. For more information, see Promoted Property and PromotedOnly Property.

Promote actions by category

Promoted actions can be grouped. You can add promoted actions by different grouped categories. Typically, promoted actions are displayed in the ribbon of the role center client. You can organize promoted actions into different categories, where each category is indicated by a caption in the ribbon. You define up to 10 categories for a page. The following figure illustrates a page that has promoted actions under the following categories.

- New Document
- Request Approval
- Customer



You assign a promoted action to a category by setting the **PromotedCategory** property of the action. By default, these category names correspond to the captions that are displayed for the category on the page in Dynamics 365 Business Central. You will typically want to change the captions, especially the Category4 through Category10 captions. See the table below for the default **PromotedCategory** values. To change the default captions, set the **PromotedActionCategories** property. You type the values of the **PromotedActionCategories** where each caption is separated with a comma as shown below:

```
PromotedActionCategories =
'New_caption,Process_caption,report_caption,category4_caption,category5_caption,category6_caption,category7_
caption,category8_caption,category9_caption,category10_caption';
```

The position of the caption in the list determines its corresponding category setting in the **PromotedCategory**

property for the actions as described in the table below.

PROMOTEDACTIONCATEGORIES CAPTION POSITION	DEFAULT PROMOTEDCATEGORY VALUES	EXAMPLE
First	New	*New_caption*
Second	Process	*Process_caption*
Third	Report	*Report_caption*
Fourth	Category4	*Category4_caption*
Fifth	Category5	*Category5_caption*
Sixth	Category6	*Category6_caption*
Seventh	Category7	*Category7_caption*
Eighth	Category8	*Category8_caption*
Ninth	Category9	*Category9_caption*
Tenth	Category10	*Category10_caption*

You can change category captions on a page-by-page basis and for each Dynamics 365 Business Central Windows client language.

For more information about these properties, see PromotedCategory Property and PromotedActionCategories Property.

Assigning an icon to the promoted actions

Each promoted action has an icon associated with it. You can accept a default icon, or choose your own from the Dynamics 365 Business Central image library by using the **Image** property, where each promoted action has an icon associated with it. Also, you can use a larger icon that makes it more prominent to the user by using the **PromotedIsBig** property. For more information, see Image Property and PromotedIsBig Property.

Example

The example shows how to promote actions on a Customers page using different properties:

1. The actions in the example are promoted to display in the **New Document**, **Request Approval** and **Customer** groups on the Home tab.
2. The **Sales Quote** and **Sales Invoice** actions are promoted to the ribbon and grouped in a category called **New Document**.
3. The `PromotedCategory` value; `Category5` corresponds the caption position in the `PromotedActionCateogories` value with the **New Document** caption.
4. Each promoted action in the example is assigned to a unique icon. Additionally, to display bigger icons, the **Sales Quote** and **Contact** actions are set with the `PromotedIsBig` property.
5. The **Sales Quote** and **Send Approval Request** actions are set to appear only on the Home tab.

```

            {
                Promoted = true;
                PromotedCategory = Category5;  // PromotedActionCategories = New Document
                PromotedOnly = true;
                PromotedIsBig = true;
                Image = NewSalesQuote;
                ApplicationArea = All;
                trigger OnAction()
                begin
                    Message('Create sales quote');
                end;
            }
            action("Sales Invoice")
            {
                Promoted = true;
                PromotedCategory = Category5;  // PromotedActionCategories = New Document
                Image = SalesInvoice;
                ApplicationArea = All;
                trigger OnAction()
                begin
                end;
            }
        }
        area(Processing)
        {
            action("Send Approval Request")
            {
                Promoted = true;
                PromotedOnly = true;
                PromotedCategory = Category6;  // PromotedActionCategories = Request Approval
                Image = SendApprovalRequest;
                ApplicationArea = All;
                trigger OnAction()
                begin
                end;
            }
            action("Cancel Approval Request")
            {
                Promoted = true;
                PromotedCategory = Category6;  // PromotedActionCategories = Request Approval
                Image = CancelApprovalRequest;
                ApplicationArea = All;
                trigger OnAction()
                begin
                end;
            }
        }
        area(Navigation)
        {
            action(Contact)
            {
                Promoted = true;
                PromotedCategory = Category7;  // PromotedActionCategories = Customer
                PromotedIsBig = true;
                Image = CustomerContact;
                ApplicationArea = All;
                trigger OnAction()
                begin
                end;
            }
            action("Account Details")
            {
```

```
            {
                Promoted = true;
                PromotedCategory = Category7;  // PromotedActionCategories = Customer
                Image = Account;
                ApplicationArea = All;
                trigger OnAction()
                begin
                end;
            }
        }
    }
}
```

Page Background Tasks

2/17/2021 • 17 minutes to read • Edit Online

APPLIES TO: Business Central 2019 release wave 2 and later

To improve the performance of a page, you can develop the page to run read-only computations and long processes asynchronously in background tasks. Background tasks make a page quicker to open and more responsive, faster for users to enter information. Users aren't blocked from working while waiting for the computations to finish. Typical places where you might use background tasks are on cues and pages in FactBoxes.

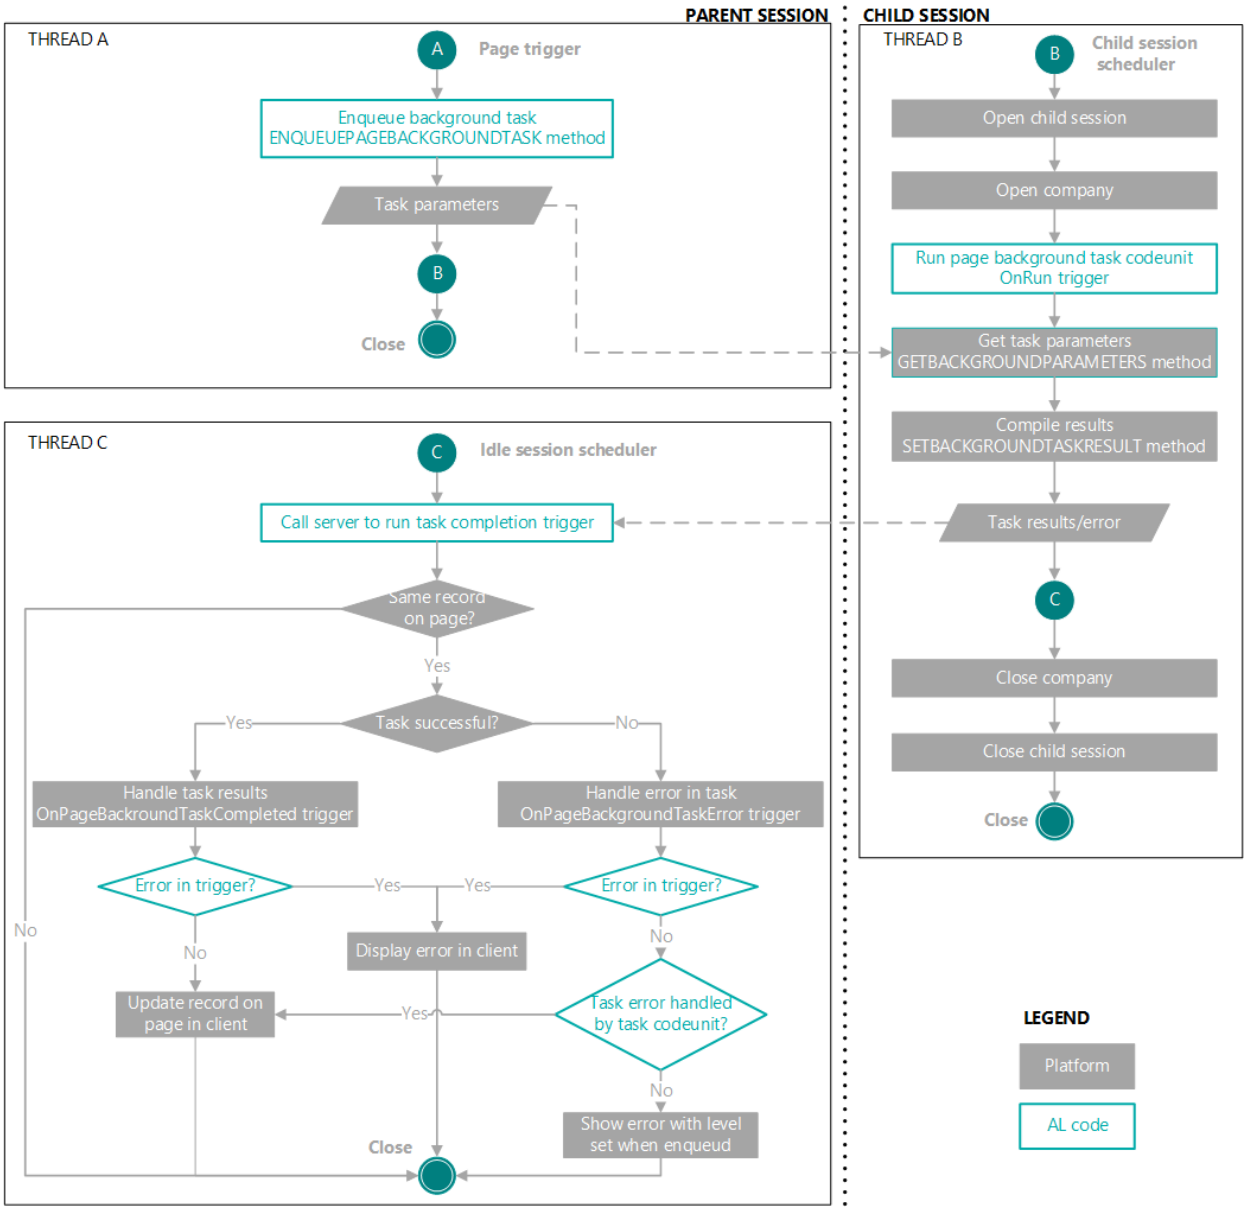
About background tasks

When a page opens in the client, a session is established between the page and the Business Central Server instance. Consider this session as the *parent session*. As a user works on the page, the user can sometimes be blocked from continuing until a process has completed. This situation is where background tasks can be beneficial.

A page background task is a *child session* that runs processes from a codeunit in the background. The user can continue to work on the page while the task runs. It's similar to other background sessions. The difference is that when the process completes, the child session is ended. The parent session is notified with results of the task. Then, the client will handle the results on the Business Central Server instance.

Background task flow

A background task is a multithread operation between the parent and child sessions. The following diagram illustrates the flow of a background task. In the illustration, the threads start in the order: THREAD A, THREAD B, THREAD C.



Background task characteristics and behavior

A page background task has the following characteristics:

- Does read-only operations; it can't write to or lock the database.
- Runs on the same Business Central Server instance as the parent session.
- The parameters that are passed to and returned from page background task are in the form of a `dictionary<string, string>`.
- Calls `OpenCompany` and executes in its own transaction.
- The callback triggers can't execute UI operations, except notifications and control updates.
- If the calling page or session closes or the current record is changed, the background task is canceled.
- It has a default and maximum timeout, which cancels the task automatically.
- Doesn't insert session event records; it relies on the parent session event records.
- Runs isolated from the parent session. Apart from the completion and error triggers, it can't call back to the parent session.
- There's a limit on the number of background tasks per session. If there are more tasks than the threshold specified per session, then the requests are queued.
- Executed synchronously from web services.
- Not counted as part of the license calculation.

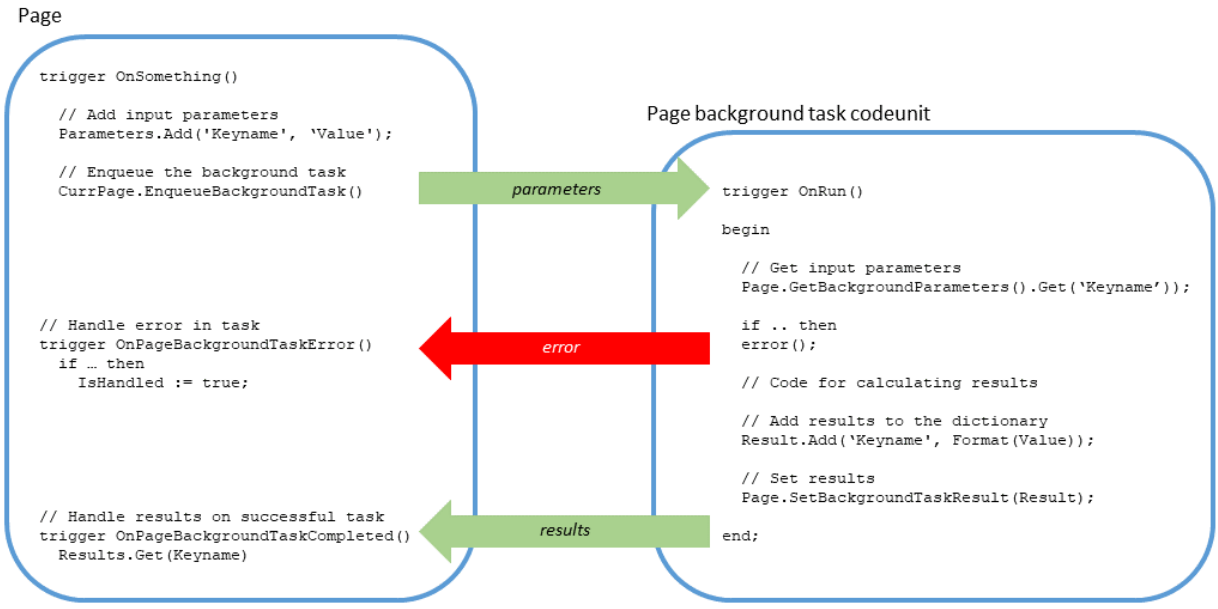
Background tasks API

The API for background tasks includes the following methods and triggers:

TYPE	NAME	DESCRIPTION
Methods	EnqueueBackgroundTask	Creates and queues a background task that runs the specified codeunit (without a UI) in a child session of the page session. If the task completes successfully, the **OnPageBackgroundTaskCompleted** trigger is invoked. If an error occurs, the **OnPageBackgroundTaskError** trigger is invoked. If the page is closed before the task completes, the task is canceled.
	GetBackgroundParameters	Gets the page background task input parameters.
	SetBackgroundTaskResult	Sets the page background task result as a dictionary. When the task is completed, the OnPageBackgroundCompleted trigger will be invoked on the page with this result dictionary
	RunPageBackgroundTask	Runs the page background task codeunit in the current session.
	CancelBackgroundTask	Attempt to cancel a page background task.
Triggers	OnPageBackgroundTaskCompleted	Runs after a page background task has successfully completed.
	OnPageBackgroundTaskError	Runs when an error occurs in a page background task.

How to create a page background task

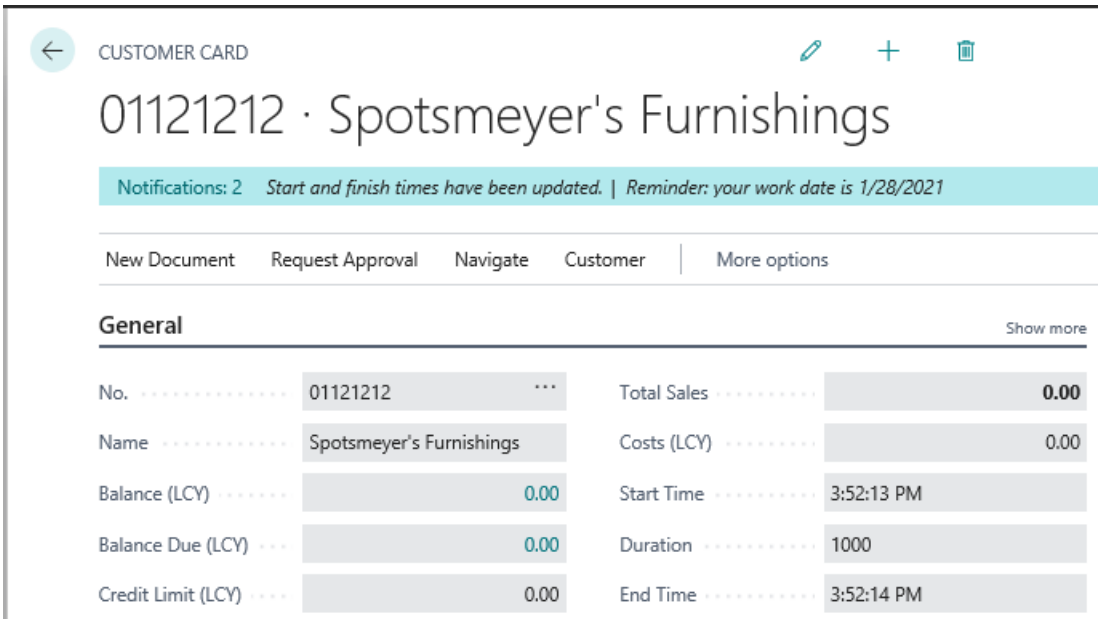
The following figure illustrates the application objects and code involved in creating a background task. The code has been simplified for demonstration purposes.



The general steps are as follows:

1. Create a background task codeunit that includes the logic that you want to run in the background.
2. On the page, complete the following steps:
   a. Add code that creates (or *enqueues*) the page background task at runtime.
   b. Add code to the OnPageBackgroundTaskCompleted trigger to handle the results of the background task and update the UI.
   c. Add code to the OnPageBackgroundTaskError trigger to handle errors that occur in the background task.

These steps are described in more details in the following sections. To help explain page background tasks, the sections use a simple example. The example extends the **Customer** card page to include a page background task. The task gets the current system time, waits a specified number of milliseconds, and gets the system time again. The page is extended with three new fields: **Start Time**, **Duration**, and **End Time**. In the page UI, these fields are updated with results of the background task, along with a notification when the task completes.



Creating a background task codeunit

You create a codeunit that does the computations that you want to run in the background. You'll also have to include code that collects the results of computations and passes them back to the calling page for handling.

The background task codeunit is a standard codeunit, which you create like any other codeunit, except it has the following characteristics:

- The OnRun() trigger is invoked without a record.
- It can't display any UI.
- It can only read from the database; not write to the database. If there's code that attempts to write to the database at runtime, an error occurs. The error informs the user that they don't have permission to do the operation on the table. For example, if the code tried to insert a record, an error similar to the following message would occur: `You don't have the following permissions on TableData 50125: Insert`.
- Casting must be manually written in code by using Format() and Evaluate() methods.

For general information about creating a codeunit, see Codeunit Object.

Getting the input parameters from the page background task

When a page background task is enqueued, it can include a set of parameters that can be used in the computations that are done in the background task codeunit. The parameters are a collection of key and value pairs. The parameters are passed as a dictionary of text to the codeunit's OnRun trigger when the page background task session starts.

To get the parameters, call the GETBACKGROUNDPARAMETERS method:

```
Parameters :=  Page.GetBackgroundParameters()
```

Use the EVALUATE method to convert the parameters to the required data type calculations.

Defining and setting the results

The results that are computed by the codeunit must be in the form of a dictionary of text. When the codeunit completes successfully, the results are passed to the parent session in a call to the `OnPageBackgroundCompleted` trigger, which will be explained later in this article.

The basic steps for defining the results are as follows:

1. Define a variable of the data type `Dictionary of [Text, Text]` for holding the results.
2. Use the Add to add key-value pairs for the results to the dictionary.
3. Call the SETBACKGROUNDTASKRESULT method to set the results in the background task.

   ```
   Page.SetBackgroundTaskResult(Result: Dictionary[Text, Text])
   ```

Example

In this example, the page background task codeunit is used to get the current system time. Then, after waiting a short period of time, it gets the system time again. The waiting period is defined by an input parameter (called `Wait`) that was passed to the background task from the parent session.

```
codeunit 50100 PBTWaitCodeunit
{
    trigger OnRun()
    var
        Result: Dictionary of [Text, Text];
        StartTime: Time;
        WaitParam: Text;
        WaitTime: Integer;
        EndTime: Time;
    begin
        if not Evaluate(WaitTime, Page.GetBackgroundParameters().Get('Wait')) then
            Error('Could not parse parameter WaitParam');

        StartTime := System.Time();
        Sleep(WaitTime);
        EndTime := System.Time();

        Result.Add('started', Format(StartTime));
        Result.Add('waited', Format(WaitTime));
        Result.Add('finished', Format(EndTime));

        Page.SetBackgroundTaskResult(Result);
    end;
}
```

Enqueuing a background task on the page

To create a page background task, you call the ENQUEUEBACKGROUNDTASK method from the page code to run the page background task codeunit. The basics steps are as follows:

1. Define any input parameters for the background task.

   The ENQUEUEBACKGROUNDTASK method can pass parameters to the background task that can be used as input to the task. Input parameters must have the data type `Dictionary of [Text, Text]`. For example, the following code defines a `Dictionary of [Text, Text]` variable and adds a single key and value pair to dictionary on the variable.

   ```
   var
       TaskParameters: Dictionary of [Text, Text];
   begin

       TaskParameters.Add('Wait', '1000');
     ...
   end
   ```

2. Define a global variable of the data type `Integer` that will be used to assign the background task an identification number.

   You don't have to assign a value to this variable. The ID is assigned automatically when the background task is enqueued.

3. Call the ENQUEUEBACKGROUNDTASK method.

   First, determine where in the code that you want to call the background task from. Typically, you call the ENQUEUEBACKGROUNDTASK method from a page trigger.

IMPORTANT

It's important that the ID of the current record of the page remains static after the ENQUEUEBACKGROUNDTASK method call is made and while the background task is running; otherwise the task will be cancelled. For this reason, we recommend that you don't enqueue the background task from the `OnOpenPage` or `OnValidate` triggers. Instead, use the `OnAfterGetCurrRecord` trigger.

Once you've determined the location, add the following code to enqueue the background task:

```
CurrPage.EnqueueBackgroundTask(TaskID, CodeunitId, Parameters, Timeout, ErrorLevel)
```

PARAMETER	DESCRIPTION	REQUIRED
`TaskId`	The variable that is defined for the task ID. This variable must be a global variable.	Yes
`CodeunitId`	The ID of the background task codeunit.	Yes
`Parameters`	The dictionary variable that is defined for the input parameters to the background task	No
`Timeout`	The number of milliseconds that the page background task can run before it's automatically canceled. You can set it to run for a maximum of 600,000 ms (10 minutes). When the task is canceled, the `OnPageBackgroundTaskError` trigger is called. By default, the task timeout is controlled by the **Page Background Task Default Timeout** and **Page Background Task Max Timeout** settings on the server instance. For more information, see Timeout. **Note:** You can add code to re-enqueue a task when an error occurs. For more information, see Re-enqueuing background tasks.	No

PARAMETER	DESCRIPTION	REQUIRED
`ErrorLevel`	The severity level for unhandled errors that occur in the background task. The severity level will determine how the errors are shown in the client UI. Values include: • `PageBackgroundTaskErrorLevel::Ignore` specifies that errors are ignored and have no effect in the client. • `PageBackgroundTaskErrorLevel::Warning` gives errors a severity level of warning. Warnings appear as a notification in the client. • `PageBackgroundTaskErrorLevel::Error` gives errors a severity level of error. Errors appear as a notification in the client. This value is the default.	No

Re-enqueuing background tasks

There are some scenarios where you want to enqueue a page background task again, after it's been initially enqueued. For example:

- You want to refresh the data on the page, like a part in a FactBox.
- You want to re-enqueue a task if it times out. When a page background task exceeds the specified timeout, the background task is canceled and an error with error code **ChildSessionTaskTimeout** occurs.

To re-enqueue a page background task, call the ENQUEUEBACKGROUNDTASK method on either the `OnPageBackgroundTaskCompleted` or `OnPageBackgroundTaskError` triggers, depending on your scenario. For detailed examples, see the PageBackgroundTask.AutoRefresh project in the BCTech GitHub repository.

> **NOTE**
>
> Use this pattern cautiously to avoid endless looping and applying excessive load on the server. Also, consider the **Child Sessions Max Queue Length** limit of the server instance. If this limit is exceeded, enqueuing will fail.

Design considerations and limitations

- The enqueued page background task stores the record ID of the current page. If the current record ID on the page changes, or the page is closed, the task is canceled.
- On list pages, it's recommended not to enqueue a page background task from `OnAfterGetRecord` trigger, unless you're aware of the consequences. If you enqueue a page background task from the `OnAfterGetRecord` , the task will be immediately canceled after the first row is retrieved. The reason is that the `OnAfterGetRecord` trigger is called on every row. Because the record changes for each row, the page background task is canceled when the trigger runs after the first row.
- By default, only five page background tasks can be run simultaneously for a parent session. If there are more than five, they're queued and run when a slot becomes available as other tasks finish. If you're using version 15.2 or later, you can increase or decrease this value by changing the **Child Sessions Max Concurrency** setting of the server instance. You can also change the **Child Sessions Max Queue Length** setting to specify the maximum number of child sessions that can be queued per parent session of a page background

task. If this value is exceeded, an error occurs. For more information, see Configuring Business Central Server - Asynchronous Processing. the Page.Rec is different.

Example

The following example extends **Customer Card** page of the base application to include three fields for displaying times that are calculated in a page background task.

```
pageextension 50100 CustomerCardExt extends "Customer Card"
{
    layout
    {
        addlast(General)
        {

            field(starttime;starttime)
            {
                ApplicationArea = All;
                Caption = 'Start Time';
                Editable = false;
            }

            field(durationtime;durationtime)
            {
                ApplicationArea = All;
                Caption = 'Duration';
                Editable = false;
            }

            field(endtime;endtime)
            {
                ApplicationArea = All;
                Caption = 'End Time';
                Editable = false;
            }
        }
    }

    var
        // Global variable used for the TaskID
        WaitTaskId: Integer;

        // Variables for the three fields on the page
        starttime: Text;
        durationtime: Text;
        endtime: Text;

    trigger OnAfterGetCurrRecord()
    var
        //Defines a variable for passing parameters to the background task
        TaskParameters: Dictionary of [Text, Text];
    begin
         TaskParameters.Add('Wait', '1000');

        CurrPage.EnqueueBackgroundTask(WaitTaskId, Codeunit::PBTWaitCodeunit, TaskParameters, 1000,
PageBackgroundTaskErrorLevel::Warning);
    end;
}
```

Coding the background task completion trigger to handle the results

When a page background task completes successfully, the `OnPageBackgroundTaskComplete` trigger of the page in the parent session is called, and the results of the task are passed to the trigger. The results are passed as a

dictionary of text. You add code to the trigger to handle the results. This operation typically includes updating the record in the page UI with the calculated values and caching the results in the database. The `OnPageBackgroundTaskComplete` trigger has the following signature:

```
trigger OnPageBackgroundTaskCompleted(TaskId: Integer; Results: Dictionary of [Text, Text])
```

PARAMETER	DESCRIPTION
`TaskId`	The ID that is assigned to the background task.
`Results`	The results of the background task

Design considerations and limitations

- Use the value of `TaskID` parameter assigned by the ENQUEUEBACKGROUNDTASK method call to identify a specific task.
- The client user must have the appropriate write permission to cache results in the database.
- Calling the UPDATE method has no effect in the trigger.
- Except for notifications, the trigger can't render UI in the client.

Example

The following example modifies the `OnPageBackgroundTaskCompleted` trigger to update the page with the started and finished times that were calculated in the page background task, and displays a notification that the times have been updated.

```
trigger OnPageBackgroundTaskCompleted(TaskId: Integer; Results: Dictionary of [Text, Text])
var
    started: Text;
    waited: Text;
    finished: Text;
    PBTNotification: Notification;
begin
    if (TaskId = WaitTaskId) then begin
        Evaluate(started, Results.Get('started'));
        Evaluate(waited, Results.Get('waited'));
        Evaluate(finished, Results.Get('finished'));

        starttime := started;
        durationtime := waited;
        endtime := finished;
        PBTNotification.Message('Start and finish times have been updated.');
        PBTNotification.Send();
    end;
end;
```

Handling errors

Within the page background task flow, errors can occur in three different locations:

- The page background task codeunit.

  > **NOTE**
  > A background task timeout will also result in an error.

- The `OnPageBackgroundTaskError` trigger of the page.

- The `OnPageBackgroundTaskCompleted` trigger of the page.

With errors that occur in the page background codeunit, you can control how the errors affect the client UI and the resultant data. For example, some errors are more severe than others. Users should be notified when an error occurs in some cases. Other times, the error can be ignored.

Errors that occur while executing the `OnPageBackgroundTaskError` or `OnPageBackgroundTaskCompleted` always display in the client with the severity level of error (`PageBackgroundTaskErrorLevel:Error`).

Handling errors that occur in the background task

When an error occurs in the page background task codeunit, the `OnPageBackgroundTaskError` trigger of the page in the parent session is automatically called with information about the error. To handle these errors, you can either use the `OnPageBackgroundTaskError` trigger as-is, that is with no custom code, or you can add custom code to the trigger to handle the errors separately.

The `OnPageBackgroundTaskError` trigger has the following signature:

```
trigger OnPageBackgroundTaskError(TaskId: Integer; ErrorCode: Text; ErrorText: Text; ErrorCallStack: Text;
var IsHandled: Boolean)
```

The following table describes the parameters of the trigger:

PARAMETER	DESCRIPTION
`TaskId`	Specifies the ID assigned to the background task.
`ErrorCode`	Specifies the error code assigned to the error that occurred in the background task, for example, `NDBCS:Deadlock` or `DB:FatalCode`. The error code is assigned by the Business Central Server instance.
`ErrorText`	Specifies the error message of the error that occurred in the background task.
`ErrorCallStack`	Specifies the error's call stack on the Business Central Server instance.
`IsHandled`	Specifies whether the error is handled. The default is `false`.

Using the `OnPageBackgroundTaskError` trigger as-is

If you want all errors that occur in the background task to be handled according to the severity level that was specified for the background task when it was enqueued, then don't add any code to the `OnPageBackgroundTaskError` trigger. In this case, the `ErrorLevel` parameter of the `ENQUEUEBACKGROUNDTASK` method call determines how the error is handled in the client.

- If the `ErrorLevel` is `PageBackgroundTaskErrorLevel:Ignore`, then error doesn't affect the client, and there's no indication on the page that the error occurred.
- If the `ErrorLevel` is `PageBackgroundTaskErrorLevel:Warning` or `PageBackgroundTaskErrorLevel:Error`, the error message displays as a notification on the page. There's currently no distinction in the notification as to whether the error is a warning or error.

For this implementation, you can either add the empty `OnPageBackgroundTaskError` trigger or omit the trigger entirely.

Customizing the OnPageBackgroundTaskError trigger

When `OnPageBackgroundTaskError` is called, it includes information about the error, such as the error code, error text, and call stack. You can add code to the trigger that handles errors based on this information. You do this by using the `IsHandled` boolean variable in your code:

- If `IsHandled` is set to `true`, the error thrown in the background task is ignored and handled by code that you add in the trigger. Here, you can add code to update the UI and associated record, similar to what can be done by `OnPageBackgroundTaskCompleted` trigger.
- If `IsHandled` is set to `false`, which is the default, the error in the background task is displayed in the client with the severity level that was specified by `ErrorLevel` parameter when the background task when was enqueued.

Example

The following example modifies the `OnPageBackgroundTaskError` trigger to display a more user-friendly notification in the client when the error `Could not parse parameter WaitParam` or timeout occurs in the page background task.

```
trigger OnPageBackgroundTaskError(TaskId: Integer; ErrorCode: Text; ErrorText: Text; ErrorCallStack: Text;
var IsHandled: Boolean)
var
    PBTErrorNotification: Notification;
begin
    if (ErrorCode = 'ChildSessionTaskTimeout') then begin
        IsHandled := true;
    PBTErrorNotification.Message('Something went wrong. The start and finish times haven''t been updated.');
    PBTErrorNotification.Send();
    end

    else if (ErrorText = 'Child Session task was terminated because of a timeout.') then begin
        IsHandled := true;
        PBTErrorNotification.Message('It took too long to get results. Try again.');
        PBTErrorNotification.Send();
    end
end;
```

Testing page background tasks

The TestPage data type includes the RUNBACKGROUNDTASK method that allows you to run unit tests for page background task codeunit. The following code is an example of a text codeunit that uses the RUNBACKGROUNDTASK method to test the page background task codeunit used in this article:

```
codeunit 50122 MyPBTCodeunit
{
    Subtype = Test;
    trigger OnRun()
    begin
        CustomerCard.OpenEdit();

        // Adds the parameters to be used as input to the background task
        TaskParameters.Add('Wait', '1000');

        // Runs the background task codeunit
        Results := CustomerCard.RunPageBackgroundTask(50100, TaskParameters);

        // Returns the results in the client
        Message('Start time: ' + '%1' + ', Duration :' + '%2' + ', Finished time: ' + '%3',
Results.Get('started'), Results.Get('waited'), Results.Get('finished'));
    end;

    var
        CustomerCard: TestPage "Customer Card";

        Results: Dictionary of [Text, Text];
        TaskParameters: Dictionary of [Text, Text];
}
```

Debugging page background tasks

Like with other code in the application, you debug page background tasks by using the integrated debugger (see Debugging). However, there are a couple limitations to be aware of:

- Only one session can be debugged at a time.
- If a breakpoint in a child session is hit, the child session will become the debugged session.
- Other sessions will continue to run normally.
- In other sessions, the breakpoints and error sessions will be ignored until the child session is completed.

Monitoring page background tasks

To monitor page background tasks, you can use the **# Active child session** performance counter and the event log.

The **# Active child session** performance counter monitors the number of active child sessions (page background tasks) on the Business Central Server instance.

In the event log, events that occur in the child session are recorded in the **Server > Admin** channel log and tagged with **Session type: ChildSession**. Events that occur in the parent session, such as in the `OnPageBackgroundTaskError` or `OnPageBackgroundTaskCompleted` triggers, are tagged with **Session type: Background**.

Designing part pages for page background tasks

Parts are a special category of page designed to be embedded within another page. Part type pages include ListPart, CardPart, and HeadlinePart. Like other page types, you can design a part page to use one or more page background tasks. However, unlike other page types, a part page won't display any data until all page background tasks have completed. This condition applies to synchronous data that's not reliant on the background tasks. In the user-interface, dashes (-) appear for field values while the page background tasks run. To work around this behavior, separate the synchronous data into a separate page part.

Page Parts Overview

API Page Type

2/17/2021 • 2 minutes to read • Edit Online

Pages of the type `API` are used to create versioned, webhook-supported, OData v4 enabled REST web services. This type of page cannot be displayed in the user interface, but is intended for building reliable integration services. When creating this page type, you must specify a number of properties that provide information for the web service endpoint. Use the snippet `tpage - Page of type API` to get the right template and the list of these properties automatically filled in. This page type cannot be extended by creating a page extension object. Instead, you must create a new API by adding a page object.

Pages of the type `API` can be used to develop a custom API. For more information, see Developing a Custom API.

Naming conventions

For the API page type, the following naming conventions exist:

- camelCase for naming attributes, tables, as well as APIPublisher, APIGroup, EntityName, and EntitySetName.
- Alphanumeric characters allowed (A-Z+a-z+0-9) in above elements.
- APIVersion follows the pattern vX.Y or beta.

At design time, the compiler will show warnings on casing violations and errors on naming violations. Once an API page is deployed, the corresponding $metadata is exposed on the endpoint of the page.

> **TIP**
> Use **Ctrl+Space** to trigger IntelliSense and get assistance on code completion, parameter info, quick info, and member lists.

Example of the API page type

The following page example publishes an API available at: `../contoso/app1/v2.0/companies({id})/customers`. The `APIVersion` can be specified as one version, or a list of versions, if the API is supported through multiple versions.

```
page 50120 MyCustomerApi
{
    PageType = API;
    Caption = 'My Customer API';
    APIPublisher = 'contoso';
    APIGroup = 'app1';
    APIVersion = 'v2.0', 'v1.0';
    EntityName = 'customer';
    EntitySetName = 'customers';
    SourceTable = Customer;
    DelayedInsert = true;

    layout
    {
        area(Content)
        {
            repeater(GroupName)
            {
                field(id; Id)
                {
                    Caption = 'ID';
                }
                field(name; Name)
                {
                    Caption = 'Name';
                }
            }
        }
    }
}
```

Inspecting and Troubleshooting Pages

2/17/2021 • 5 minutes to read • Edit Online

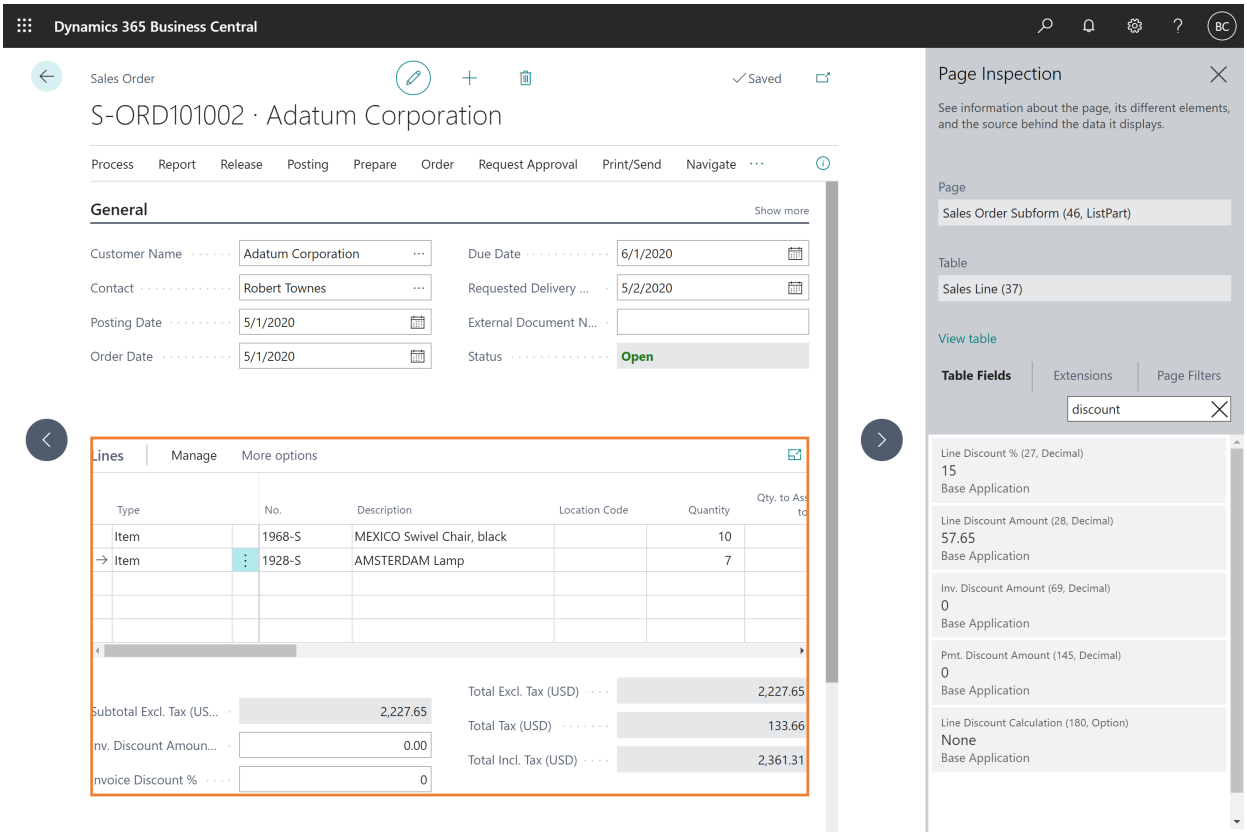
The Business Central Web client includes a page inspection feature that lets you get details about a page. Page inspection provides insight into the page design, the different elements that form the page, and the source behind the data it displays. Page inspection helps you:

- Learn the data model behind a page.
- Discover pages and parts that can be reused in your application design.
- Troubleshoot data issues without having to do tasks like copying the production database, viewing the entire source table, or digging into SQL.
- Debug the application, complementing Designer.

Working with Page Inspection

You start page inspection from the **Help & Support** page. Choose the question mark in the top-right corner, choose **Help & Support**, and then choose **Inspect pages and data**. Or, you can just use the keyboard shortcut **Ctrl+Alt+F1**.

The **Page inspection** pane opens on the side. The following figure illustrates the **Page Inspection** pane on the **Sales Order** page.



When the **Page Inspection** pane first opens, it shows information that pertains to the main page object.

Use the keyboard or pointing device to move focus to different elements on the page. When you select a FactBox or a part on the main page, a border will highlight the area. The **Page Inspection** pane then shows information about the selected element. For example, the previous figure shows information about the list part in the **Sales Order** page.

As you navigate to other pages in the application, the **Page Inspection** pane will automatically update with page information as you move along.

What Page Inspection Shows

The page inspection pane shows the information for the main page or page part, including:

- The page's source table (if any) and fields.
- Extensions that affect the page.
- Current filters applied to the page.

The following sections describe details about what is shown.

> **NOTE**
> If you do not see all details described below, you might not have the required permissions. For more information, see Controlling Access to Page Inspection Details.

> **TIP**
> To copy the values of a field or entity under one of the tabs to the clip board, select the field or entity and press Ctrl+C.

- Page
- Table
- Table Fields
- Extensions
- Page Filters

The **Page** field shows information about the main page or a selected (highlighted) subpage in a part. The field shows the following information:

- The name, as specified by its Name property
- The ID as specified by the ID property.
- The type, as specified by the PageType property.

Elements shown with limited information

- Role Center pages

  If a page has the type Role Center, the **Table** field doesn't appear. Because the Role Center consists of several parts, there's no more information shown. To see more details, select the different parts that make up the Role Center.

- Report request pages and previews

  If you open a report request page or preview for inspection, the only information shown in the Page Inspection pane is the report's name and ID.

- System parts, such as Links or Notes, and parts containing charts.

Control Add-in Style Guide

2/17/2021 • 5 minutes to read • Edit Online

This article offers a variety of stylistic definitions that are used throughout Dynamics 365, which you can apply to your control add-ins to create an experience that complements Dynamics 365.

Introduction

Control add-ins for Dynamics 365 extend a business solution by surfacing contextual functionality alongside business data. Control add-ins empower users to get more done without costly context switching, no matter which device they access Dynamics 365 from. Typical uses of control add-ins include unique data visualizations, surfacing controls from a third party service, or displaying related content from another data source.

Apart from the functionality, an important aspect of creating a control add-in is making sure the control add-in looks good and blends seamlessly into Dynamics 365. To achieve this, you should follow these basic principles:

- Apply similar patterns for command, navigation and presentation of data.
- Favor content over chrome
- Design for all platforms and input methods.
- Make it accessible to all users.
- Make it enjoyable and keep users in control.

Dynamics 365 uses a set of specific colors and fonts. You can employ these colors and fonts in your control add-ins to give it a style that matches the rest of client's user interface.

Colors

Choosing the right color gives the interface visual continuity. Color can be used to convey information to users, indicate interactivity, give feedback, and more. The following sections describe the colors used in Dynamics 365. The colors can be used on all aspects of a UI element, such background, border, text, and more.

Main colors

The following colors represent the Dynamics 365 theme main palette.

COLOR	NAME	USE	HEX VALUE
	Primary color	Prominent UI elements and areas.	#00B7C3
	Secondary color	UI elements and areas in default or subdued state.	#505C6D

Style colors

The following colors are used to express or accent conditions or user activity in the UI. For example, these colors are used as sentiments, or color indication, on Cues.

COLOR	DESCRIPTION	HEX VALUE
	Standard	#212121
	Accent	#00B7C3
	Strong	#212121
	Favorable	#35AB22
	Ambiguous	#9F9700
	Unfavorable	#EB6965
	Attention	#EB6965
	Subordinate	#A7ADB6

More palette colors

The following table includes additional colors that you can use in the UI.

COLOR	DESCRIPTION	HEX VALUE
	Yellow	#C9C472
	Green	#88CE81

COLOR	DESCRIPTION	HEX VALUE
	Red	#E97768
	Blue	#75B5E7
	Light green	#59CCB4
	Sky	75D8E7
	Egg	EEEA86
	Orange	#E89E63
	Violet	#DBBDEB
	Teal	#39B294
	Grass	#73BA5A
	Scarlet	#E65E6D

Chart colors

The following table describes the colors used in charts.

COLOR	DESCRIPTION	HEX VALUE
	-	#505C6D
	-	#008089
	Primary color	#00B7C3
	Yellow	#C9C472
	Red	#E97768
	Blue	#75B5E7
	Light green	#59CCB4
	Sky	75D8E7
	Egg	EEEA86
	Violet	#DBBDEB
	Teal	#39B294
	Grass	#73BA5A

Applying colors

To apply a color scheme to the control add-in, you specify CSS rule-sets that use the following properties:

PROPERTY	DESCRIPTION
`color`	Specifies font color.
`background-color`	Specifies background colors.
`border-color`	Specifies Border colors.

For example, to change the background of a part of your UI to use the `Secondary (#505C6D)` color, write the following CSS:

```
.my-ui-part {
    background-color: #505C6D;
}
```

If you want to change the text color of a caption to the Primary (#00B7C3) color, use the following CSS:

```
.my-caption {
    color: #00B7C3;
}
```

Typography

The main goal of typography is to provide clean and readable text in the user interface. Similar to colors, typography can also be used to convey or communicate conditions to the user.

Font Families

Dynamics 365 uses the following font families to specify the typeface and weight for text elements, such as headings, captions, messages, and so on:

EXAMPLE	NAME	VALUE
This is the Segoe UI font	Segoe UI	`"Segoe UI", "Segoe WP", Segoe, device-segoe, Tahoma, Helvetica, Arial, sans-serif`
This is the Segoe UI Light font	Segoe UI Light	`"Segoe UI Light", "Segoe WP Light", device-segoe-light, "Segoe WP Semilight", "Segoe UI", "Segoe WP", Segoe, Tahoma, Helvetica, Arial, sans-serif`
This is the Segoe UI Semi Light font	Segoe UI Semilight	`"Segoe UI Semilight", "Segoe WP Semilight", device-segoe-semilight, "Segoe UI", "Segoe WP", Segoe, Tahoma, Helvetica, Arial, sans-serif`
This is the Segoe UI Semibold font	Segoe UI Semibold	`"Segoe UI Semibold", "Segoe WP Semibold", device-segoe-semibold, "Segoe UI", "Segoe WP", Segoe, Tahoma, Helvetica, Arial, sans-serif`

Sizes

Dynamics 365 uses the following font sizes for text. The same font family on different clients may apply different sizes.

EXAMPLE	NAME	VALUE
This is 37.5pt	largest-plus-font-size	`37.5pt`
This is 30pt	largest-font-size	`30pt`
This is 22.5pt	large-plus-font-size	`22.5pt`
This is 18pt	large-font-size	`18pt`
This is 15pt	medium-plus-font-size	`15pt`
This is 13.5pt	medium-font-size	`13.5pt`
This is 12pt	small-plus-font-size	`12pt`
This is 10.5pt	small-font-size	`10.5pt`
This is 9pt	smallest-font-size	`9pt`

Applying Font Families and Sizes

To apply fonts and sizes to text elements in the UI, you need specify the following CSS properties:

- Font family. use property `font-family`.
- Font size. use property `font-size`.

For example, to change a UI element for the Web client to use the font family *Segoe UI Light* and the size *Small* (10.5pt), write the following CSS:

```
.my-ui-part {
    font-family: "Segoe UI Light", "Segoe WP Light", device-segoe-light, "Segoe WP Semilight", "Segoe UI",
"Segoe WP", Segoe, Tahoma, Helvetica, Arial, sans-serif;
    font-size: 10.5pt;
}
```

IMPORTANT

To ensure that the correct fonts are used on devices, do not omit fonts or change the order of the fonts.

Example

This examples illustrates how to use CSS to style a simple HTML UI part of a control add-in. The example includes three UI controls, as shown in the following HTML code:

```
<div class="addin">
    <div class="control">
        <div class="caption">Name:</div>
        <div class="value">
            <input type="text" name="name">
        </div>
    </div>

    <div class="control">
        <div class="caption">Surname:</div>
        <div class="value">
            <input type="text" name="name">
        </div>
    </div>

    <div class="control">
        <div class="submit">Submit</div>
    </div>
</div>
```

The following is CSS code for styling the controls, including padding, background colors, and fonts:

```
.addin {
    padding: 1em;
    background-color: #505C6D; /* Sets the background color to "Secondary" */
}

.addin .control {
     border-color: #00B7C3; /* Sets the border color to "Primary" */
}

.addin .control .caption {
    color: #00B7C3; /* Sets the captions to "Primary" */

    /* Segoe UI Light, small */
    font-family: "Segoe UI Light", "Segoe WP Light", device-segoe-light, "Segoe WP Semilight", "Segoe UI",
"Segoe WP", Segoe, Tahoma, Helvetica, Arial, sans-serif; /* Sets the font of the caption to ""Segoe UI
Light" */
    font-size: 10.5pt;
}

.addin .control .value {
    color: #008089; /* Tertiary shade 2 */

    /* Segoe UI, medium */
    font-family: "Segoe UI", "Segoe WP", Segoe, device-segoe, Tahoma, Helvetica, Arial, sans-serif;
    font-size: 12pt;
}

.addin .control .submit {
    color: white; /* Sets the caption text to "white" */
    background-color: #00B7C3; /* Sets the background to "Primary */

    /* Segoe UI Semibold, medium */
    font-family: "Segoe UI Semibold", "Segoe WP Semibold", device-segoe-semibold, "Segoe UI", "Segoe WP",
Segoe, Tahoma, Helvetica, Arial, sans-serif;
    font-size: 12pt;
    text-transform: uppercase; /* Sets the caption to use all uppercase letters */
}
```

Reports Overview

2/17/2021 • 2 minutes to read • Edit Online

You can use reports to print or display information from a database. Use reports to structure and summarize information to print documents, such as invoices. For example, create a report that lists all customers and orders that have been added by each customer. Also, create a report that is automatically filled with the relevant information for an invoice.

Reports can also be used to process data without printing or displaying content. For example, use a report to automate updating all prices in an item list. It can be easier to create a report to process data instead of a codeunit to do the same processing because you can use:

- Request page functionality to select options and filters for data items, which are available in a report but are difficult to add to a codeunit. For more information, see Request Pages.
- Report data items instead of writing code to open tables and retrieve records.
- Data modeling, which is available when you design reports.

Creating reports

Creating a report involves two primary tasks. First, you create a report object and design the dataset. The dataset determines the data that is extracted or calculated from the Dynamics 365 Business Central database tables that can be used in a report. After the dataset has been designed, you design the visual layout of the report. There are two types of report layouts that you can create: layouts using report definition language (RDL) and Word report layouts.

Getting started

The following table includes links to help you get started with designing the reports.

Report Design Overview

2/17/2021 • 2 minutes to read • Edit Online

A report is composed of the following items:

- A report object
- A report dataset
- A report layout
- A request page
- Properties, triggers, and code

You design a report by first defining the dataset, and then designing the visual layout.

Report object

You create a report object in the AL Language development environment to define the data model, or dataset of a report. You can structure and summarize information in a report and print documents, such as sales quotes and invoices. For more information, see Report Object.

Report dataset

In order to define the underlying data model, you use the report dataset. A report dataset determines the data that is extracted or calculated from the Dynamics 365 Business Central database tables that can be used in a report. You build the report dataset by adding data items and columns. For more information, see Report Dataset.

Report layouts

The visual layout determines the content and format of a report when it is viewed and printed. You build the layout of a report by arranging data items and columns and specifying the general format, such as text font and size. A report that is viewed, printed, or saved from a Dynamics 365 Business Central client must have a report layout. There are two types of report layouts: layouts using report definition language (RDL) and Word layouts.

RDL layout

To create an RDL layout report, you use Visual Studio Report Designer or Microsoft SQL Server Reporting Services Report Builder. For more information, see Creating an RDL Layout Report.

> **IMPORTANT**
>
> RDL layouts can result in slower performance with document reports, regarding actions that are related to the user interface (for example. like sending emails) compared to Word layouts. When developing layouts for document reports, we recommend that you design Word layouts instead of RDL. With Word layouts, reports are not impacted by the security constraints on sandbox appdomains like they are with RDL layouts. From a service perspective, RDL layouts are not trusted, so they will run in a sandbox appdomain that only lives for the current report invocation.

Word report layout

You create Word layouts by using a Word Document. Word layouts are based on a Word document that includes a custom XML parts that represents the report dataset. For more information, see Creating a Word Layout Report.

Report Object

2/17/2021 • 3 minutes to read • Edit Online

Reports are used to print or display information from a database. You can use a report to structure and summarize information, and to print documents, such as sales quotes and invoices.

Creating a report consists of two primary tasks; the first task is to create the underlying data model and the next is to define the visual layout that displays the data. The report object defines the underlying data model and specifies which database tables and fields to pull data from. When the report is run, that data is displayed in a specified layout; the visual layout, which determines the content and format of a report when it is viewed and printed.

For more information about defining database tables and fields, see Defining a Report Dataset. For more information about the Report data type, see Report Data Type.

You build the layout of a report by arranging data items and columns, and specifying the general format, such as text font and size. There are two types of report layouts; client report definition, also called RDL layouts and Word layouts. RDL layouts are defined in Visual Studio Report Designer or Microsoft SQL Server Reporting Services Report Builder. Word layouts are created using Word. Word layouts are based on a Word document that includes a custom XML part representing the report dataset.

> **NOTE**
> Extension objects can have a name with a maximum length of 30 characters.

Snippet support

Typing the shortcut `treport` will create the basic layout for a report object when using the AL Language extension in Visual Studio Code.

> **TIP**
> Use **Ctrl+Space** to trigger IntelliSense and get assistance on code completion, parameter info, quick info, and member lists.

Report example

The following example is a report that prints the list of customers. The report object defines a dataset of columns from the Customer table. For more information on creating a Word Layout report, see Creating a Report.

```
report 50103 "Customer List"
{
  CaptionML=ENU='Customer List';
  DefaultLayout = RDLC; // if Word use WordLayout property
  RDLCLayout = 'MyRDLReport.rdl';

  dataset
  {
    dataitem(Customer;Customer)
    {
      RequestFilterFields="No.","Search Name","Customer Posting Group";
```

```
        column(COMPANYNAME;COMPANYNAME)
        {
        }
        column(CurrReport_PAGENO;Customer."no.")
        {
        }
        column(Customer_TABLECAPTION_CustFilter;TABLECAPTION + ': ' + CustFilter)
        {
        }
        column(CustFilter;CustFilter)
        {
        }
        column(Customer_No;"No.")
        {
        }
        column(Customer_Customer_Posting_Group;"Customer Posting Group")
        {
        }
        column(Customer_Customer_Disc_Group;"Customer Disc. Group")
        {
        }
        column(Customer_Invoice_Disc_Code;"Invoice Disc. Code")
        {
        }
        column(Customer_Customer_Price_Group;"Customer Price Group")
        {
        }
        column(Customer_Fin_Charge_Terms_Code;"Fin. Charge Terms Code")
        {
        }
        column(Customer_Payment_Terms_Code;"Payment Terms Code")
        {
        }
        column(Customer_Salesperson_Code;"Salesperson Code")
        {
        }
        column(Customer_Currency_Code;"Currency Code")
        {
        }
        column(Customer_Credit_Limit_LCY;"Credit Limit (LCY)")
        {
          DecimalPlaces=0:0;
        }
        column(Customer_Balance_LCY;"Balance (LCY)")
        {
        }
        column(CustAddr_1;CustAddr[1])
        {
        }
        column(CustAddr_2;CustAddr[2])
        {
        }
        column(CustAddr_3;CustAddr[3])
        {
        }
        column(CustAddr_4;CustAddr[4])
        {
        }
        column(CustAddr_5;CustAddr[5])
        {
        }
        column(Customer_Contact;Contact)
        {
        }
        column(Customer_Phone_No;"Phone No.")
        {
        }
        column(CustAddr_6;CustAddr[6])
        {
```

```
    }
    column(CustAddr_7;CustAddr[7])
    {
    }
    column(Customer_ListCaption;Customer_ListCaptionLbl)
    {
    }
    column(CurrReport_PAGENOCaption;CurrReport_PAGENOCaptionLbl)
    {
    }
    column(Customer_NoCaption;FIELDCAPTION("No."))
    {
    }
    column(Customer_Customer_Posting_GroupCaption;Customer_Customer_Posting_GroupCaptionLbl)
    {
    }
    column(Customer_Customer_Disc_GroupCaption;Customer_Customer_Disc_GroupCaptionLbl)
    {
    }
    column(Customer_Invoice_Disc_CodeCaption;Customer_Invoice_Disc_CodeCaptionLbl)
    {
    }
    column(Customer_Customer_Price_GroupCaption;Customer_Customer_Price_GroupCaptionLbl)
    {
    }
    column(Customer_Fin_Charge_Terms_CodeCaption;FIELDCAPTION("Fin. Charge Terms Code"))
    {
    }
    column(Customer_Payment_Terms_CodeCaption;Customer_Payment_Terms_CodeCaptionLbl)
    {
    }
    column(Customer_Salesperson_CodeCaption;FIELDCAPTION("Salesperson Code"))
    {
    }
    column(Customer_Currency_CodeCaption;Customer_Currency_CodeCaptionLbl)
    {
    }
    column(Customer_Credit_Limit_LCYCaption;FIELDCAPTION("Credit Limit (LCY)"))
    {
    }
    column(Customer_Balance_LCYCaption;FIELDCAPTION("Balance (LCY)"))
    {
    }
    column(Customer_ContactCaption;FIELDCAPTION(Contact))
    {
    }
    column(Customer_Phone_NoCaption;FIELDCAPTION("Phone No."))
    {
    }
    column(Total_LCY_Caption;Total_LCY_CaptionLbl)
    {
    }

    trigger OnAfterGetRecord();
    begin
      CalcFields("Balance (LCY)");
      FormatAddr.FormatAddr(
        CustAddr,Name,"Name 2",'',Address,"Address 2",
        City,"Post Code",County,"Country/Region Code");
    end;

  }
}

requestpage
{
  SaveValues=true;
  ContextSensitiveHelpPage = 'my-feature';
  layout
```

```
    layout
    {
    }

    actions
    {
    }
  }

  labels
  {
      LabelName = 'LabelText', Comment = 'Foo', MaxLength = 999, Locked = true;
  }

  trigger OnPreReport();
  var
    CaptionManagement : Codeunit 42;
  begin
    CustFilter := CaptionManagement.GetRecordFiltersWithCaptions(Customer);
  end;

  var
    FormatAddr : Codeunit 365;
    CustFilter : Text;
    CustAddr : ARRAY [8] OF Text[50];
    Customer_ListCaptionLbl : Label 'Customer - List';
    CurrReport_PAGENOCaptionLbl : Label 'Page';
    Customer_Customer_Posting_GroupCaptionLbl : Label 'Customer Posting Group';
    Customer_Customer_Disc_GroupCaptionLbl : Label 'Cust./Item Disc. Gr.';
    Customer_Invoice_Disc_CodeCaptionLbl : Label 'Invoice Disc. Code';
    Customer_Customer_Price_GroupCaptionLbl : Label 'Price Group Code';
    Customer_Payment_Terms_CodeCaptionLbl : Label 'Payment Terms Code';
    Customer_Currency_CodeCaptionLbl : Label 'Currency Code';
    Total_LCY_CaptionLbl : Label 'Total (LCY)';
}
```

AL Development Environment

Defining a Report Dataset

2/17/2021 • 2 minutes to read • Edit Online

You use a report object in the AL Language development environment to define the data model, or dataset, of a report. The dataset determines the data that is extracted or calculated from the Dynamics 365 Business Central database tables that can be used in a report. For more information, see Report Object.

You build the report dataset from data items and columns. A data item is a table. A column can be:

- A field in a table
- A variable
- An expression
- A text constant

Typically, data items and columns correspond to fields in a table. When the report is run, each data item is iterated for all records in the underlying table. Filters are applied and the dataset is created. When a report is based on more than one table, you must set relations between the data items so that you can retrieve and organize the data.

Snippet support

Typing the shortcut `treport` will create the basic layout for a report object when using the AL Language extension in Visual Studio Code.

> **TIP**
> Use **Ctrl+Space** to trigger IntelliSense and get assistance on code completion, parameter info, quick info, and member lists.

Example

The following example adds the `Customer` table as the data item and the `CustomerName` and `CompanyName` as fields of a column to the report. For more information on creating a report, see Creating a Report.

```
dataset
{
    dataitem(Customer; Customer)
    {
        column(CustomerName; CustomerName)
        {
        }
        column(CompanyName; CompanyName)
        {
        }
    }
}
```

Reports Overview

Request Pages

2/17/2021 • 4 minutes to read • Edit Online

A request page is a page that is run before the report or XMLport starts to execute. Request pages enable end users to specify options and filters for a report and an XMLport. Request pages are defined as part of designing a Report object and an XMLport object. The syntax is shown further down in this topic. You design the filters on request pages by using the following report and XMLport properties:

PROPERTY	DESCRIPTION
RequestFilterHeading Property	Sets a caption for the request page tab that is related to a report's data item or an XMLport's table element.
RequestFilterHeadingML Property	Sets the text used as a RequestFilterHeading Property for a request page tab.
RequestFilterFields Property	Specifies which fields are automatically included on the tab of the request page that is related to a report's data item or an XMLport's table element. The user can set filters on these fields.

NOTE

Request pages for XMLports are not supported by the Business Central Web client in versions prior to Dynamics 365 Business Central 2019 release wave 2. If you try to run an XMLport with a Request page from the web client in these versions, you receive an error that the XMLport page type is not supported. Alternatively, XMLport request pages do work in the Dynamics NAV Client connected to Business Central.

By default, a request page is displayed, unless the UseRequestPage is set to `false`; then the report or XMLport will start to print as soon as it is run. In this case, end users can't cancel the report or XMLport run. It is still possible to cancel the report or XMLport, but some pages may print.

By default, without having set anything else, a request page will always display the following buttons:

- Send to
- Print
- Preview
- Cancel

Additionally, you can add more options on the request page to allow the end user to filter the data displayed.

Filtering on request pages

The fields that you define as `RequestFilterFields` are shown on the request page and can be used for filtering the data before viewing or printing the report.

NOTE

Only on the Windows client, filtering is possible even if `RequestFilterFields` is not set.

Defining the `RequestFilterFields` property in the `dataitem()` part of the report code is done as illustrated in the following code example:

```
report 50103 "Customer List"
{
    CaptionML = ENU = 'Customer List';
    RDLCLayout = 'Customer List Report.rdl'; // if Word use WordLayout property
    dataset
    {
        dataitem(Customer; Customer)
        {
            RequestFilterFields = "No.", "Search Name", "Customer Posting Group";
...
```

> **NOTE**
>
> We recommend that you add fields that the end-users of the report will frequently set filters on.

For more information about the report object, see Report Object.

Defining the `RequestFilterFields` property in the `tableelement()` part of an XMLport is done in a similar way:

```
XMLport 50104 "Export Customer List"
{
    CaptionML = ENU = 'Export customer List';
    Direction = Export;
    schema
    {
        textelement(root)
        {
            XmlName = 'Root';
            tableelement(Customer; Customer)
            {
                RequestFilterFields = "No.", "Search Name", "Customer Posting Group";
...
```

For more information about the XMLport object, see XMLport Object.

By default, for every data item in the report and table element in a XMLport, a FastTab for defining filters and sorting is created on the request page. To remove a FastTab from a request page, do not define any `RequestFilterFields` for the data item or table element and set the DataItemTableView property in a report or the SourceTableView property in an XMLport to define sorting. The request page is displayed, but there is no tab for this data item or table element.

If a `DataItemTableView` or `SourceTableView` is not defined, then end users can select a sort field and sort order at runtime.

In a complex report or XMLport that uses data from several tables, the functionality may depend on a specific key and sort order. Design your reports and XMLports so that end users can't change the sort order in a way that affects their functionality.

For data items and table elements whose source table contains calculated fields, such as amounts and quantities, the **Filter totals by:** section is automatically included on the request page, which allows you to adjust various dimensions that influence calculations.

TIP

For information about how to enter filter criteria on the request page, see Filtering in the Business Central application help.

Defining a `requestpage` section

On reports, in addition to defining the filter options by setting the `RequestFilterFields` property, you can add a `requestpage` section. In this section, you can set the SaveValues property to `true` in order to save the values that the end user enters on the request page. When the report is run again, the end user will have the option to use previously defined filters. You can also add a `layout` to the request page, specifying an **Options** section to perform checks.

NOTE

With request pages that have `SaveValues = true`, users can preview the report multiple times in the client and the request page remains open. If `SaveValues = false` or omitted, a **Preview & Close** action appears on the request page. In this case, the request page closes once the report has been previewed.

```
...
requestpage
    {
        SaveValues = true;

        layout
        {
            area(content)
            {
                group(Options)
                {
                    Caption = 'Options';
                    field(PostingDate; PostingDateReq)
                    {
                        ApplicationArea = Basic, Suite;
                        Caption = 'Posting Date';
                        ToolTip = 'Specifies the posting date for the invoice(s) that the batch job creates.
This field must be filled in.';
                    }
                }
            }
        }

        trigger OnOpenPage()
        begin
            if PostingDateReq = 0D then
                PostingDateReq := WorkDate;
        end;

        var
            PostingDateReq: Date;
    }
...
```

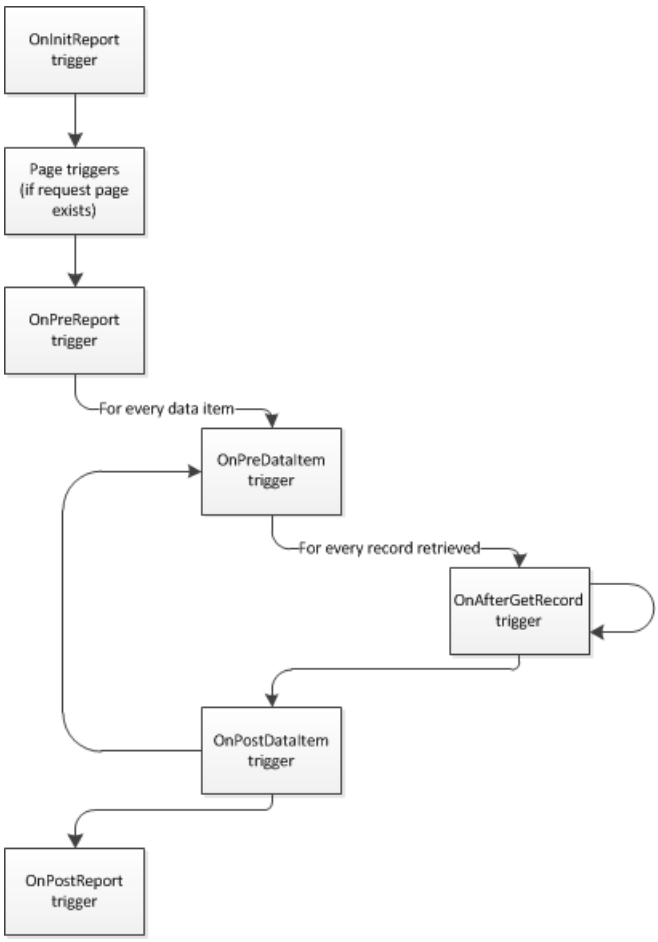
Report Triggers

2/17/2021 • 2 minutes to read • Edit Online

When you run a report, the report triggers are called in a specific order.

The following illustration describes the order of report triggers.



Report triggers

When you start the report run, the OnInitReport Trigger is called. If the OnInitReport doesn't end the processing of the report, then the request page for the report is run, if it's defined. The page triggers for the request page are called. On the request page, you select the options that you want for this report. You can also decide to cancel the report run. If you decide to continue, then the OnPreReport Trigger is called. At this point, no data has yet been processed. When the OnPreReport trigger has been run, the first data item is processed unless the processing of the report was ended in the OnPreReport trigger.

When the first data item has been processed, the next data item, if there's any, is processed in the same way. When there are no more data items, the OnPostReport Trigger is called to do any necessary post processing, for example, removing temporary files.

> **IMPORTANT**
>
> If you define two methods that have the same name, one defined in a report and the other in a table that is referenced by the report, you cannot invoke the defined in the report directly. By default, a call to the invokes the that is defined in the table. This behavior occurs when the is called from a source expression or a trigger.

How a data item is processed

Before the first record is retrieved, the OnPreDataItem Trigger is called, and after the last record has been processed, the OnPostDataItem Trigger is called.

Between these two triggers, the data item records are processed. Processing a record means executing the record triggers and outputting data. After a record is retrieved from the data item, the OnAfterGetRecord (Data Items) Trigger is called.

If there's an indented data item, then the records in this data item are processed.

When there are no more records to be processed in a data item, control returns to the point from which processing was started. For an indented data item, it's the next record of the data item on the next highest level. If the data item is already on the highest level, then control returns to the report.

Trigger execution with multiple previews

Business Central 2020 release wave 2 (version 17) introduced the ability to preview a report multiple times, without closing the request page. With this change, the execution flow of the report triggers is different.

When previewing a report, a new report instance is scheduled to run immediately. This new instance will rerun all of the report triggers, but won't execute any of the request page triggers.

This condition leads to the two important differences in the flow, which may influence your design:

1. The **OnInitReport** trigger is run once when opening the request page and again for every preview of the report. In some cases, it can mean that before the report is even executed, the **OnInitReport** trigger has already run twice.
2. The request page and the request page triggers won't be executed on every preview. The new report instances will receive the request page parameters from the initial request page.

For some reports, their design may make it impossible to run them as scheduled reports. It's possible to disable multiple previews and revert to the legacy preview behavior by setting the AllowScheduling property on the report object to `false`. This property was introduced in version 17.2.

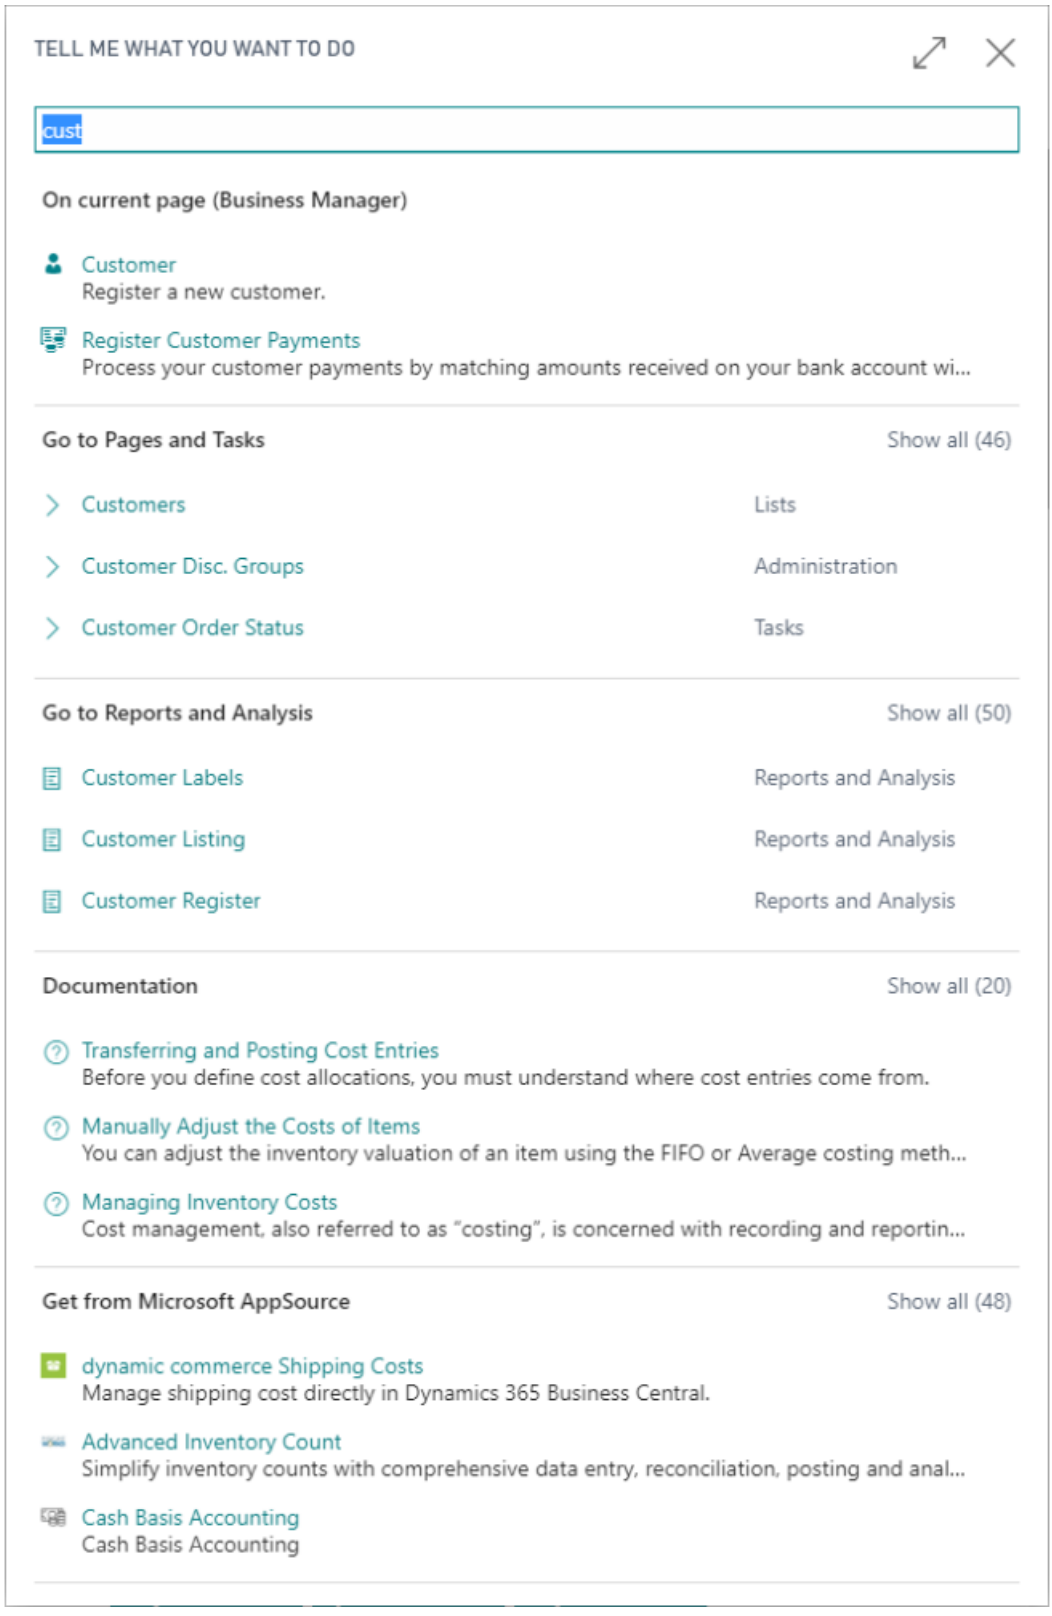
Adding Pages and Reports to Tell me

2/17/2021 • 3 minutes to read • Edit Online

The Business Central client includes the **Tell me** feature that lets users find objects and online help articles by entering search terms. When you have added a page or a report in your extension, you most likely want it to be discoverable to users in **Tell me**. In AL, you make a page or report searchable from **Tell me** by setting the UsageCategory property in code. The **UsageCategory** setting will make the page or report searchable, and the value chosen for the setting will further sub categorize the item.



Tell me finds pages and reports by searching the captions that are specified on page and report objects by the CaptionML property.

Working with the UsageCategory property

When you create a Page or a Report, you add the UsageCategory Property. If the **UsageCategory** is set to **None**, or if you do not specify **UsageCategory**, the page or report will not show up when you search in Dynamics 365 Business Central.

UsageCategory property values

The values for the **UsageCategory** property are listed below. The sub category will help the user navigate through the search results and it is a best practice to be consistent when categorizing the pages and the reports that you add. A consistent approach will help guiding the user and improve productivity.

VALUE	DESCRIPTION
None	The page or report is not included in search.
Lists	The page or report is listed as **Lists** under the **Pages and Tasks** category.
Tasks	The page or report is listed as **Tasks** under the **Pages and Tasks** category.
ReportsAndAnalysis	The page or report is listed as **Reports and Analysis** under the **Reports and Analysis** category.
Documents	The page or report is listed as **Documents** under the **Reports and Analysis** category.
History	The page or report is listed as **Archive** under the **Reports and Analysis** category.
Administration	The page or report is listed as **Administration** under the **Pages and Tasks** category.

Adding additional search terms

You can specify other words or phrases that can help users find a page or report by using the AdditionalSearchTerms and AdditionalSearchTermsML properties. If the page or report is searchable by **Tell me** (that is, th **UsageCategory** property is set a value other than `None`), the search terms specified by these properties are used in addition to the caption of the page or report. These properties are useful when the caption does not always reflect what users will look for. A good example of this in Business Central is pages and reports associated with **Item**. Users unfamiliar with Business Central might look for 'product' or 'merchandise' instead of 'item'.

> **NOTE**
>
> For Business Central on-premises, the Business Central Web Server configuration file (navsettings.json) includes a setting called `UseAdditionalSearchTerms` that enables or disables the use of additional search terms by the **Tell me**. For more information, see Configuring Business Central Web Server Instances.

Example

The following example creates a `SimpleItemList` page and sets a `UsageCategory` property to the page, so that the `SimpleItemList` page is discoverable through search using the **Tell me** feature. Also, the example sets the `AdditionalSearchTerms` property to add two search terms for the page.

```
page 50210 SimpleItemList
{
    PageType = List;
    SourceTable = Item;
    UsageCategory = Lists;
    AccessByPermission = page SimpleItemList = X;
    ApplicationArea = All;
    AdditionalSearchTerms = 'product, merchandise';

    layout
    {
        area(content)
        {
            group(General)
            {
                field("No.";"No.") {}
                field(Name;Name) {}
                field(Description;Description) {}
            }
        }
    }
}
```

Optional settings

In addition to making a page or report searchable, you can control the access of an object by providing **Read**, **Insert**, **Modify**, **Delete**, and **Execute** (RIMDX) permissions by adding the AccessByPermission property. Likewise, control the application area access on the specified object by adding the ApplicationArea Property.

The **AccessByPermission** property and **ApplicationArea** property are the optional settings, which can be applied with the **UsageCategory** property. These settings are used to set restrictions on an object when you enable the Search functionality.

Working in the Dynamics NAV Development Environment

> **NOTE**
> Dynamics NAV Development Environment is **DISCONTINUED AFTER:** Business Central Spring 2019.

If you are using the Dynamics NAV Development Environment, you can also set **UsageCategory**, **AdditionalSearchTerms**, **AccessByPermission**, and **ApplicationArea** properties on pages and reports to control their search.

After you change these properties by using the Dynamics NAV Development Environment, before the changes take effect in the client, you must run **Build Object Search Index** from the **Tools** menu.

Substituting Reports

2/17/2021 • 2 minutes to read • Edit Online

Contrary to pages and tables, extensibility is not yet supported for report objects in Business Central. Therefore, if you want to make any changes to the dataset or the layout of a base application report, you must create a new version of the report and apply the changes on the new object. Then you can override the base report with your own customized version by subscribing to the **OnAfterSubstituteReport** event published by **Codeunit 44 – ReportManagement**.

How to substitute a report for another report

To substitute a report, you create a method and subscribe it to the **OnAfterSubstituteReport** event, as shown in the code below. The `OnSubstituteReport` method replaces the report specified by the `ReportId` with the one given by the `NewReportId` parameter. In this example the `"Customer - List"` report will be substituted for `"My New Customer - List"`.

```
codeunit 50100 "Substitute Report"
{
    [EventSubscriber(ObjectType::Codeunit, Codeunit::ReportManagement, 'OnAfterSubstituteReport', '', false,
false)]
    local procedure OnSubstituteReport(ReportId: Integer; var NewReportId: Integer)
    begin
        if ReportId = Report::"Customer - List" then
            NewReportId := Report::"My New Customer - List";
    end;
}
```

For more information on how to subscribe to events, see Subscribing to Events.

When the **OnAfterSubstituteReport** event is raised, the event subscriber method is called and the substitution takes place.

> **NOTE**
> The event is called **OnAfterSubstituteReport** to match the pattern followed by other events in the **ReportManagement** codeunit, but the subscriber will be invoked before the substitution takes place.

The **OnAfterSubstituteReport** event is raised when:

1. The user activates a page action that runs the report to be substituted, that is, an action that has the RunObject Property set to the report.
2. The report is invoked from the **Tell Me** window.
3. The report is called by one of the following *static* methods:
   - Run Method
   - RunModal Method
   - SaveAsHtml Method
   - SaveAsXml Method
   - SaveAsPdf Method
   - SaveAsExcel Method

- SaveAsWord Method
- RunRequestPage Method
- Execute Method
- Print Method
- SaveAs Method

For more information about raising events, see Raising Events.

Good practices

- Consider using the same caption for both reports, given by the Caption Property. Consequently, any links and action captions that lead to the report will match the report itself. This is also relevant for bookmarks linked to a report, since they maintain the caption of the original report, even if it has been substituted for one with another caption.

- Consider enhancing the code of the subscriber method to check if the report has already been replaced with another extension. This is done by comparing the `ReportId` and `NewReportId` parameters before making the change, such that if the value of the `NewReportId` parameter is different from the value of the `ReportId` parameter and different from -1, it means that the report has already been substituted for another subscriber of the **OnAfterSubstituteReport** event.

> **IMPORTANT**
> Make sure that if a report is called on code, you use a compatible report to replace it to avoid run time errors.

Testing Reports

2/17/2021 • 2 minutes to read • Edit Online

Testing your report requires you to run it and to verify the data output. This practice helps you ensure that your customers are presented with complete and accurate data.

Before extensions, the output of a report was saved to a file, but extensions deployed to Dynamics 365 Business Central cannot access the file system and therefore must save the output of a report to a stream. Codeunit 131007 `Library - Report Dataset` offers a high-level API for running and testing the output of reports that does not require direct access to the file system.

Example

The following example shows how to initialize the codeunit 131007 `Library - Report Dataset` by using the `RunReportAndLoad` method. This method is preferred as it will run the report and initialize the `Library - Report DataSet` codeunit. To verify the output, call either the `AssertElementWithValueExists` or the `AssertElementWithValueNotExist` method. The other methods in the library should work as well if they do not contain "Tag" in the name. `RUNREQUESTPAGE` and `[RequestPageHandler]` are optional and you can use them when you want to open the request page.

> **TIP**
> If you want to run the report separately and load the data from the input stream manually, you can use the `LoadDataFromInstream` method.

```
codeunit 50105 MyReportTesting
{
    Subtype = Test;

    [Test]
    [HandlerFunctions('RemittanceAdviceJournalRequestPageHandler')]
    procedure TestingReports();
    var
        XmlParameters: Text;
        LibraryReportDataset: Codeunit "Library - Report Dataset";
        GenJournalLine: Record "Gen. Journal Line";
    begin
        // Run the Report Remittance Advice - Journal.
        XmlParameters := Report.RunRequestPage(Report::"Remittance Advice - Journal");
        LibraryReportDataset.RunReportAndLoad(Report::"Remittance Advice - Journal", GenJournalLine,
XmlParameters);

        // Verifying Total Amount on Report.
        LibraryReportDataset.AssertElementWithValueExists('Amt_GenJournalLine', GenJournalLine.Amount);
    end;

    [RequestPageHandler]
    procedure RemittanceAdviceJournalRequestPageHandler(var RemittanceAdviceJournal: TestRequestPage 399);
    begin
        // Empty handler used to close the request page. We use default settings.
    end;
}
```

Any changes done in the handler above will result in the `XmlParameters` being changed and applied

automatically when the report runs. Examples of the implementation in the existing tests are in `Codeunit 133770` and `Codeunit 134141`.

Remarks

TestRequestPage.SaveAsXML uses a different format than Report.SaveAsXML or Report.SaveAs by serializing the output of **Report Previewer**. This is a component that will be deprecated in the future and replaced with the new methods that can be used for the new tests. Another difference is that `TestRequestPage.SaveAsXML` requires files to be saved to disk and loaded, while other methods work in memory, making them more efficient.

> **NOTE**
>
> The existing tests still need support and the codeunit solves this problem by supporting both formats for now. `TestRequestPage.SaveAsXML` uses Tags for values, while the new format uses attributes. This means that you cannot use any public method that contains "Tag" in the name to test the reports generated in the memory.

Creating a Word Layout Report

2/17/2021 • 2 minutes to read • Edit Online

When you create a new report, there are two things you have to think about; defining the report dataset of data items and columns, and then designing the report layout. These steps will show how to create a very simple report based on a Word layout. For more information about the report object, see Report Object.

Create a Word layout report

To facilitate testing your report layout, the following simple example extends the Customer List page with a trigger that runs the report as soon as the Customer List page is opened.

1. Create a new extension to the **Customer List** page that contains code to run the report, as well as a simple report object by adding the following lines of code:

```
pageextension 50100 MyExtension extends "Customer List"
{
    trigger OnOpenPage();
    begin
        report.Run(Report::MyWordReport);
    end;
}

report 50124 MyWordReport
{
    DefaultLayout = Word;
    WordLayout = 'MyWordReport.docx';
}
```

2. Build the extension (**Ctrl+Shift+B**) to generate the MyWordReport.docx file.
3. Add the **Customer** table as the data item and the **Name** field as a column to the report by adding the following lines of code to the report. For more information about defining a dataset, see Report Dataset.

```
report 50124 MyWordReport
{
    DefaultLayout = Word;
    WordLayout = 'MyWordReport.docx';

    dataset
    {
        dataitem(Customer; Customer)
        {
            column(Name; Name)
            {

            }
        }
    }
}
```

4. Build the extension (**Ctrl+Shift+B**).
5. Open the generated report layout file in Word.
6. In Word, edit the layout using the **XML Mapping Pane** on the **Developer** tab.

> **NOTE**
>
> If you do not see the Developer tab, go to **Options**, then **Customize Ribbon**, and in the **Main tabs** section, select the **Developer** check box.

7. In Word, to the right, in the **Custom XML part** lookup, locate the report, and then open the layout.
8. Right-click on the **Customer** table, and in **Insert Content Control**, select **Repeating** to add the repeater data item.
9. Right-click on the **Name** field and in **Insert Content Control**, select **Plain Text** to add the column as a text box.
10. Save the report layout when you are done and then close it.
11. Back in Visual Studio Code, press **Ctrl+F5** to compile and run the report.

You will now see the generated report in preview mode.

> **NOTE**
>
> If the report layout is not generated, open the `settings.json` from Visual Studio Code. Use **Ctrl+Shift+P**, then choose **Preferences: Open User Settings**, locate the **AL Language extension**. Under **Compilation Options**, choose **Edit in settings.json** and add the following line:
>
> ```
> json "al.compilationOptions": { "generateReportLayout": true }
> ```

Creating an RDL Layout Report

Creating an RDL Layout Report

2/17/2021 • 2 minutes to read • Edit Online

When you create a new report for Dynamics 365 Business Central, there are two things you have to think about; defining the report dataset of data items and columns, and then designing the report layout. These steps will show you how to create a very simple report based on an RDL layout. For more information about the report object, see Report Object.

> **IMPORTANT**
>
> RDL layouts can result in slower performance with document reports, regarding actions that are related to the user interface (for example. like sending emails) compared to Word layouts. When developing layouts for document reports, we recommend that you design Word layouts instead of RDL. With Word layouts, reports are not impacted by the security constraints on sandbox app domains like they are with RDL layouts. From a service perspective, RDL layouts are not trusted, so they will run in a sandbox app domain that only lives for the current report invocation.

To create and modify RDL report layouts, you use SQL Server Report Builder or Visual Studio Report Designer. For information about required versions of these tools, see System Requirements.

Create an RDL layout report

To facilitate testing your report layout, the following simple example extends the Customer List page with a trigger that runs the report as soon as the Customer List page is opened.

1. Create a new extension to the Customer List page that contains code to run the report, as well as a simple report object by adding the following lines of code:

```
pageextension 50123 MyExtension extends "Customer List"
{
    trigger OnOpenPage();
    begin
        report.Run(Report::MyRdlReport);
    end;
}

report 50123 MyRdlReport
{
    DefaultLayout = RDLC;
    RDLCLayout = 'MyRDLReport.rdl';

}
```

2. Build the extension (**Ctrl+Shift+B**) to generate the MyRDLReport.rdl file.

3. Add the **Customer** table as the data item and the **Name** field as a column to the report by adding the following lines of code to the report:

```
report 50123 MyRdlReport
{
    DefaultLayout = RDLC;
    RDLCLayout = 'MyRDLReport.rdl';

    dataset
    {
        dataitem(Customer; Customer)
        {
            column(Name; Name)
            {
            }
        }
    }
}
```

4. Build the extension (**Ctrl+Shift+B**). The `MyRDLReport.rdl` file will be created in the root of the current project.
5. Open the generated report layout file in **Microsoft SQL Server Report Builder**.
6. Edit the layout by inserting a table.
7. Add the **Name** column from the **Datasets** folder into the table and save the .rdl file.
8. Back in Visual Studio Code, press **Ctrl+F5** to compile and run the report in Dynamics 365 Business Central.

You will now see the generated report in preview mode.

> **NOTE**
>
> If the report layout is not generated, open the `settings.json` from Visual Studio Code. Use **Ctrl+Shift+P**, then choose **Preferences: Open User Settings**, locate the **AL Language extension**. Under **Compilation Options**, choose **Edit in settings.json** and add the following line:
>
> ```
> "al.compilationOptions": {
>         "generateReportLayout": true
>     }

Creating a Word Layout Report

Walkthrough: Designing a Report from Multiple Tables

2/17/2021 • 22 minutes to read • Edit Online

A report object is composed of a report dataset and a visual layout. You design a report by first defining the dataset and then designing the visual layout. You define the dataset for reports directly in AL code. You design the layout in Visual Studio Report Designer or Microsoft SQL Server Reporting Services Report Builder for a RDL layout and in Microsoft Word for a Word layout. After you design a report, you can make it available to applications that are running on the Business Central Web client. A report can be designed from one table or multiple tables. This walkthrough demonstrates how to design a report from multiple tables.

About This Walkthrough

This walkthrough shows you how to design a report from the AL Language development environment and using Visual Studio Report Designer for designing an RDL layout.

This walkthrough illustrates the following tasks:

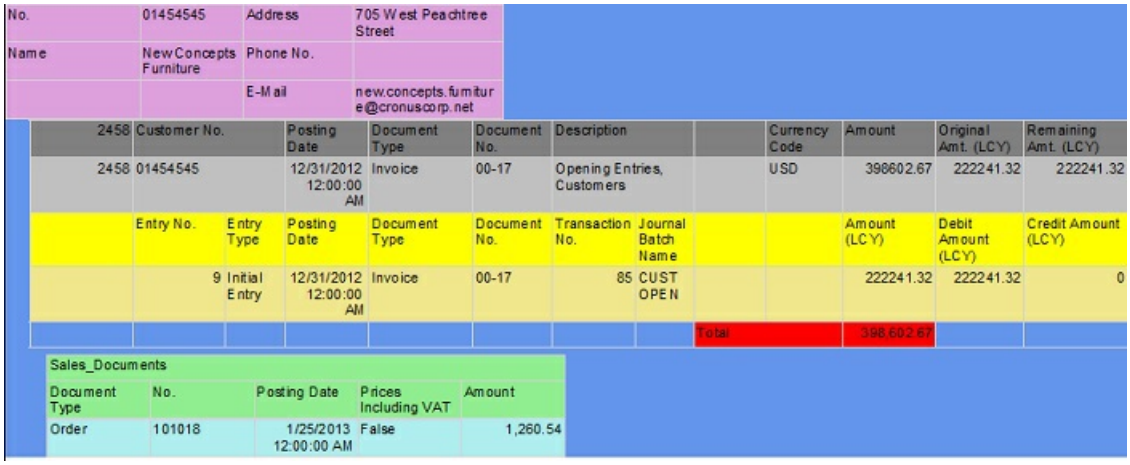
- Defining the dataset for multiple tables.
- Adding fields to a data item.
- Defining properties for the data items.
- Adding labels to a report.
- Design a client report definition (RDL) report layout in Visual Studio 2019.
- Setting filters to hide empty rows and fields in a report.
- Building and running a report.

Story

Viktor is a developer who is working for CRONUS International Ltd. Viktor has been asked by his manager to create a report that shows data from the `Customer` (ID 18), `Cust. Ledger Entry` (ID 21), `Detailed Cust. Ledger Entry` (ID 379), and the `Sales Header` (ID 36) tables. The report should meet the following requirements:

- The report must display customer information at the top of the report.
- For each customer, the report must show a list of ledger entries.
- For each ledger entry, the report must show a list of detailed ledger entries under the ledger entries.
- The report must display basic sales document headers information for the selected customer.
- Each section of the data for each customer must begin on a new page.
- The `Amount` field from the `Cust. Ledger Entry` table should be totaled and displayed for each customer.
- If there are no records to display, the report must not display that data sections. For example, if there are no sales documents for a customer, the sale header section must be skipped.
- Amount fields must not display zero values.
- The orientation of the report should be landscape.

The following illustration shows an example of the second page of the report.



No.	01454545	Address	705 West Peachtree Street
Name	New Concepts Furniture	Phone No.	
		E-Mail	new.concepts.furniture@cronuscorp.net

2458	Customer No.	Posting Date	Document Type	Document No.	Description		Currency Code	Amount	Original Amt. (LCY)	Remaining Amt. (LCY)
2458	01454545	12/31/2012 12:00:00 AM	Invoice	00-17	Opening Entries, Customers		USD	398602.67	222241.32	222241.32

	Entry No.	Entry Type	Posting Date	Document Type	Document No.	Transaction No.	Journal Batch Name			Amount (LCY)	Debit Amount (LCY)	Credit Amount (LCY)
	9	Initial Entry	12/31/2012 12:00:00 AM	Invoice	00-17	85	CUST OPEN			222241.32	222241.32	0
								Total		398,602.67		

Sales_Documents

Document Type	No.	Posting Date	Prices Including VAT	Amount
Order	101018	1/25/2013 12:00:00 AM	False	1,260.54

Defining the Dataset

Viktor starts by creating an empty report object by using the AL Language extension in Visual Studio Code. You can use the shortcut `treport` to create the basic layout for a report object.

He sets the DefaultLayout Property to **RDLC** to specify that he will use an RDL layout for the report and the RDLCLayout Property to `'MyRDLReport.rdl'`, the name of the rdl file he will use for the layout.

Viktor will now design the dataset to display customers and their transaction details. This is defined within the `dataset` part of the report object.

Adding Data Items and columns

The datasets for the data model will come from four tables: `Customer`, `Cust. Ledger Entry`, `Detailed Cust. Ledger Entry`, and `Sales Header`. Viktor will create a data item for each table with the `dataitem` control. Moreover, for each table, he will add the fields that he wants to display on the report. Each field is given by a `column` control, defined inside the corresponding data item.

The hierarchy of the `dataitem` and `column` controls is important because it will determine the sequence in which data items are linked, which in turn will control the results. Working from top-to-bottom, you start by adding the `dataitem` control for first table that you want in the dataset, then add column controls for each table field that you want to include in the dataset. For the next table, you add another `dataitem` control that is embedded within the first `dataitem` control, then add column controls as needed. You continue this pattern for additional tables and fields.

Defining Properties for the Data Items

Once Viktor has specified the dataitem and column elements he will define the appropriate properties. He sets the DataItemTableView Property in each data item to sort the table view based on a specific field.

He also sets the RequestFilterFields Property to automatically include a specific field on the filter tab of the request page. For more information about request pages, see Request Pages.

Now, Viktor uses the DataItemLink (Reports) Property to set a link between one or more fields of the dataitem tables. Links determine which records to include in the dataset based on the values of a common field between dataitems. This property must be set on the lower dataitem of the report object.

For each of the `column` controls he adds the IncludeCaption Property and sets it to **True**. This property specifies to include the caption of the fields in the dataset of a report.

Finally, he sets the PrintOnlyIfDetail Property to **True** on a data item to print data only if at least one of its child data items generates output.

Adding Labels to the Report

Viktor will now add labels to the report. You define the labels in the `label` part of the report. These labels will be used later as captions.

The following code exemplifies the code that Viktor has written for the report.

```
report 50101 "Report for Multiple Tables"
{
    //Make the report searchable from Tell me under the Administration category.
    UsageCategory = Administration;
    ApplicationArea = All;
    // Use an RDL layout.
    DefaultLayout = RDLC;
    // Specify the name of the file that the report will use for the layout.
    RDLCLayout = 'MyRDLReport.rdl';

    dataset
    {

        dataitem(Customer; Customer)
        {
            // Sort the table view based on the "No." field.
            DataItemTableView = Sorting("No.");
            // Include the "No." field on the filter tab of the request page.
            RequestFilterFields = "No.";
            // Print data only if at least one of the CustLedgerEntry and SalesHeader data items generates
output.
            PrintOnlyIfDetail = True;

            // For each field that you want to display you add a column control.
            column(No_Customer; "No.")
            {
                // Include the caption of the "No." field in the dataset of the report.
                IncludeCaption = true;
            }

            column(Name_Customer; Name)
            {
                IncludeCaption = true;

            }

            column(Phone_Customer; "Phone No.")
            {
                IncludeCaption = true;

            }

            column(Address_Customer; Address)
            {
                IncludeCaption = true;

            }

            column(EMail_Customer; "E-Mail")
            {
                IncludeCaption = true;

            }
            dataitem(CustLedger; "Cust. Ledger Entry")
            {

                DataItemTableView = sorting("Entry no.");
                // Set a filter on the child data item, **CustLedgerEntry** to select only the records where
the
                // value of `Customer."No."` field and the `"Customer Ledger Entry"."Customer No."` field
```

```
matches.
                DataItemLink = "Customer No." = field("No.");

                column(EntryNo_CustLedgerEntry; "Entry No.")
                {
                    IncludeCaption = true;

                }
                column(CustomerNo_CustLedgerEntry; "Customer No.")
                {
                    IncludeCaption = true;

                }
                column(PostingDate_CustLedgerEntry; "Posting Date")
                {
                    IncludeCaption = true;

                }
                column(DocumentType_CustLedgerEntry; "Document Type")
                {
                    IncludeCaption = true;

                }

                column(DocumentNo_CustLedgerEntry; "Document No.")
                {
                    IncludeCaption = true;

                }

                column(Description_CustLedgerEntry; Description)
                {
                    IncludeCaption = true;

                }

                column(CurrencyCode_CustLedgerEntry; "Currency Code")
                {
                    IncludeCaption = true;

                }

                column(Amount_CustLedgerEntry; Amount)
                {
                    IncludeCaption = true;

                }

                column(OriginalAmtLCY_CustLedgerEntry; "Original Amt. (LCY)")
                {
                    IncludeCaption = true;

                }

                column(RemainingAmtLCY_CustLedgEntry; "Remaining Amt. (LCY)")
                {
                    IncludeCaption = true;

                }

                dataitem(DetCustLedger; "Detailed Cust. Ledg. Entry")
                {

                    DataItemTableView = sorting("entry no.");
                    DataItemLink = "Cust. Ledger Entry No." = field("Entry No."), "Customer No." =
field("Customer No.");

                    column(EntryNo_DetailedCustLedgEntry; "Entry No.")
```

```
            {
                IncludeCaption = true;

            }

            column(EntryType_DetailedCustLedgEntry; "Entry Type")
            {
                IncludeCaption = true;

            }

            column(PostingDate_DetailedCustLedgEntry; "Posting Date")
            {
                IncludeCaption = true;

            }

            column(DocumentType_DetailedCustLedgEntry; "Document Type")
            {
                IncludeCaption = true;

            }

            column(DocumentNo_DetailedCustLedgEntry; "Document No.")
            {
                IncludeCaption = true;

            }

            column(AmountLCY_DetailedCustLedgEntry; "Amount (LCY)")
            {
                IncludeCaption = true;

            }

            column(TransactionNo_DetailedCustLedgEntry; "Transaction No.")
            {
                IncludeCaption = true;

            }

            column(JournalBatchName_DetailedCustLedgEntry; "Journal Batch Name")
            {
                IncludeCaption = true;

            }

            column(DebitAmountLCY_DetailedCustLedgEntry; "Debit Amount (LCY)")
            {
                IncludeCaption = true;

            }

            column(CreditAmountLCY_DetailedCustLedgEntry; "Credit Amount (LCY)")
            {
                IncludeCaption = true;

            }

        }
    }

    dataitem(SalesHeader; "Sales Header")
    {
        DataItemTableView = sorting("Document Type", "No.");
        DataItemLink = "Sell-to Customer No." = field("No.");

        column(DocumentType_SalesHeader; "Document Type")
        {
```

```
                {
                    IncludeCaption = true;

                }

                column(No_SalesHeader; "No.")
                {
                    IncludeCaption = true;

                }

                column(PostingDate_SalesHeader; "Posting Date")
                {
                    IncludeCaption = true;

                }

                column(PricesIncludingVAT_SalesHeader; "Prices Including VAT")
                {
                    IncludeCaption = true;

                }

                column(Amount_SalesHeader; Amount)
                {
                    IncludeCaption = true;

                }
            }

        }
    }

    // These labels will be used later as captions in the report layout.
    labels
    {
        Sales_Document_Caption = 'Sales Documents';
        Total_Caption = 'Total';
    }
}
```

Designing the Visual RDL Layout for the Report

Next, Viktor will design an RDL layout for the report by using Visual Studio Report Designer. He will set properties for the report and the report elements, format the report, and then add the data to the report.

To design the RDL layout for the report

1. Build the extension (Ctrl+Shift+B) to generate the `MyRDLReport.rdl` file, and then open the file with Visual Studio 2019.
2. Right-click anywhere outside the report (in the shaded area) and then choose **Add Page Header**.
3. Right-click anywhere outside the report (in the shaded area), and then choose **Report Properties**.
4. In the **Report Properties** window, choose the **Page Setup** tab. In the **Paper size** section, under **Orientation**, choose **Landscape**, and then choose the **OK** button.
5. On the **View** menu, choose **Toolbox**. Select the **List** control, and then choose the body of the report to add the **List** control to the report. This control will contain and group all the data.
6. Move the **List control** to the top of the report body and resize it to cover the whole report body.
7. Right-click the middle of the **List** controls, and then click on the box to open the **Rectangle Properties**.
8. In the **Rectangle Properties** window, choose the **Fill** tab, in the **Fill Color** list color pallet, select

Cornflower Blue from the color pallet, and then choose the **OK** button. You can choose any color.

> **NOTE**
> Changing the color of report elements helps you identify elements on the report preview. You can set different color properties for table header, detail rows, text boxes, and so on.

Viktor will set the properties of the **List** control to hold the dataset, group the data by Customer No. and set up how the groups should be displayed.

To set the list control properties

1. Select the **List** control, right-click the shaded border to the left of the **List** control, and then choose **Tablix Properties**.
2. In the **Tablix Properties** window, on the **General** tab, under **Dataset name**, select **DataSet_Result** from the drop-down list, and then choose the **OK** button.
3. Select the **List** control, right-click the shaded border to the left of the list control, choose **Row Group**, and then **Group Properties**.
4. In the **Group Properties** window, on the **General** tab, under **Group expressions:**, choose the **Add** button, and then select **[No_Customer]** from the **Group on:** drop-down list. This groups all the data in the List control by customer number.
5. On the **Page Breaks** tab, select **Between each instance of a group**, and then choose the **OK** button.

Viktor is now ready to add the customer data. The table will display one customer at a time, therefore Viktor must put all the fields into table header rows. The table data and footer rows will be disabled.

To add customer data

1. From the **Toolbox** pane, drag a **Table** control into the **List** control and resize the table to about the half the width of the list control. This table will contain the customer data.

   The following illustration shows the list control and the table.

   
   Note that the table contains two table rows, a header row (first row), and a data row (second row). The three parallel lines in the left border of the second row identify the data row.
2. Select any table row, right-click the shaded border, and then choose **Tablix Properties** to open the **Tablix Properties** window.
3. On the **General** tab, verify that the **Dataset name** field is set to **DataSet_Result**, and then choose the **OK** button.

   The table has three columns. Viktor will add a fourth column to the table to hold all the customer data.
4. Right-click the middle column header, choose **Insert Column**, and then select **Right** to insert the fourth column into the table.
5. Select the second table row (the data row), right-click the row, choose **Delete Rows** to delete the data row, and then choose the **OK** button in the **Delete Rows** window to delete the row and its associated

groups.

6. Select the remaining table row, right-click the shaded border on the left, choose **Insert Row**, and then choose **Below** to insert another table header row.
7. Repeat step 6 to insert a third table header row. There should now be three header rows in the table.
8. Right-click the first cell (row 1, column 1) in the table, and then choose **Expression** to open the **Expression** window.
9. In the **Category** column, select **Parameters**, in the **Item** column, verify that **All** is selected, and then in the **Values** column, double-click **No_CustomerCaption**. Verify that the **Set expression for: Value** box contains the following value: `=Parameters!No_CustomerCaption.Value`. This cell will display the customer No. caption in the report.
10. Modify the expression to `=First(Parameters!No_CustomerCaption.Value)`. Choose the **OK** button.

> **NOTE**
> All caption fields must begin with `=First` so that the first value for the caption fields in the data set is retrieved and used as caption. If the First function is not used, the report will return the current value for a field. The current value however may be incorrect. For example, the current value could be empty.

11. Right-click the second cell (row 1, column 2) in the table, and then choose **Expression** to open the **Expression** window.
12. In the **Category** column, select **Field(DataSet_Result)**, in the **Item** column verify that **All** is selected, and then in the **Values** column double-click **No_Customer**. Verify that the **Set expression for: Value** box contains the following value `=Fields!No_Customer.Value`. Choose the **OK** button. This cell will display the Customer No..
13. Repeat steps 8 through 12 to the enter captions and values in the following cells.

> **NOTE**
> Columns 1 and 3 will contain the captions and columns 2 and 4 will contain the values.

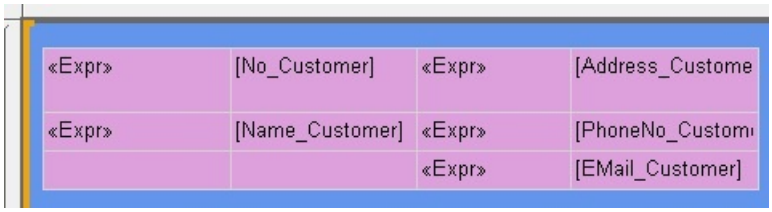
ROW	COLUMN	CAPTION	VALUE
2	1	Name_CustomerCaption	None
2	2	None	Name_Customer
1	3	Address_CustomerCaption	None
1	4	None	Address_Customer
2	3	PhoneNo_CustomerCaption	None
2	4	None	PhoneNo_Customer
3	3	Email_CustomerCaption	None

ROW	COLUMN	CAPTION	VALUE
3	4	None	Email_Customer

14. Select all table rows (not the whole table), and then on the **View** menu, choose **Properties Window** to open the **Properties** window in Visual Studio.

15. In the **Properties** window, under **Fill**, set the **BackgroundColor** property to **Plum**. You can choose any color.

    The layout that Viktor has designed to this point resembles the following illustration.



16. On the **Build** menu, choose **Build Web site** to build the project. Inspect the **Output** pane and make sure that there are no build errors. Close Visual Studio.

    > **NOTE**
    > It is a good practice to build the project periodically during the report design to make sure that there are no build errors.

    Viktor will run the report and preview what he has done to this point.

17. Go back to your project in Visual Studio Code and Reload the Window.

18. In the `launch.json` file set the `"startupObjectId"` to the **Id** of the report object and the `"startupObjectType"` to `Report`.

19. Press the `F5` key to run the report.

20. In the request page that is displayed, choose the **Preview** button to view the report. The first customer is displayed on the first page. If you page through the report, each customer is displayed on a separate page.

Viktor will now add the data for the customer ledger entries and detailed ledger entries. The entries will be put in a different table.

To add the data for ledger entry and detailed ledger entry

1. Open the `MyRDLReport.rdl` report in Microsoft Visual Studio.

2. From the **Toolbox**, drag a table control into the list control. Put the table under the table that contains the customer data.

   > **NOTE**
   > You may have to resize the report body and the list controls to make them larger.

3. Select the table, right-click the shaded border, choose **Tablix Properties**. On the **General** tab, verify that the **Dataset name** field is set to **DataSet_Result**, and then choose the **OK** button.

4. Select the table data row, choose **Insert Row** and then choose **Outside Group – Below**. This adds

another data row to the table. You now have one header row and two data rows.

5. Delete the first row (header row) in the table and then insert columns in the table so that the total number of columns is eleven.
6. Choose the first data row, right-click the shaded border to the left, choose **Add Group**, and then choose **Parent Group**.
7. In the **Tablix group** window, select **Group by**, select **EntryNo_CustLedgerEntry** from the drop-down list. Select **Add group header**, and then choose the **OK** button.
8. Right-click the first row, choose **Insert Row**, and then choose **Inside Group – Above**. This header will hold the captions for the Customer Ledger entries.
9. Right-click the cell in the row1, column 2, and then choose **Expression** to open the **Expression** window.
10. In the **Category** column, select **Parameters** and then in the **Values** column double-click **EntryNo_CustLedgerEntryCaption**. Note that the **Set expression for: Value** box contains the following value: `=Parameters!EntryNo_CustLedgerEntryCaption.Value`
11. Modify the expression to the following value: `=First(Parameters!EntryNo_CustLedgerEntryCaption.Value)`.
12. Repeat steps 9 through 11 to add captions for the table cells in the rest of the first row as shown in the following table.

COLUMN	CAPTION EXPRESSION
3	CustomerNo_CustLedgerEntryCaption
4	PostingDate_CustLedgerEntryCaption
5	DocumentType_CustLedgerEntryCaption
6	DocumentNo_CustLedgerEntryCaption
7	Description_CustLedgerEntryCaption
8	Skip this cell. You will use this cell later.
9	CurrencyCode_CustLedgerEntryCaption
10	Amount_CustLedgerEntryCaption
11	OriginalAmtLCY_CustLedgerEntryCaption
12	RemainingAmtLCY_CustLedgerEntryCaption

13. Right-click the left-most grouping cell (the cell that contains the **EntryNo_CustLedgerEntry** field) in the table, select **Text Box Properties**, in the Text Box Properties window, select the **Visibility** tab, under the **Change display options**, select the Hide option.
14. Select the first row in the table, in the **Properties** pane, under **Fill**, set the **BackgroundColor** property to **Dim Grey**.
15. Right-click the cell in the row2, column 2, and then choose **Expression** to open the **Expression** window.
16. In the **Category** column, select **Fields (DataSet_Result)**, in the **Values** column, double-click

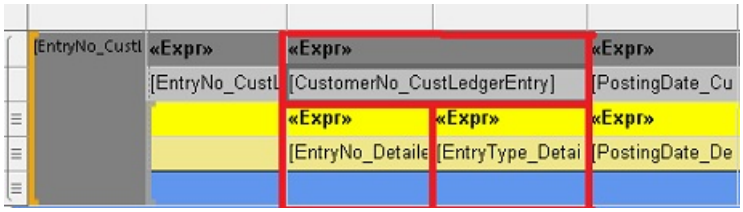
EntryNo_CustLedgerEntry, and then choose the **OK** button. Note that the **Set expression for: Value** box contains the following value: `=Fields!EntryNo_CustLedgerEntry.Value`

17. Repeat steps 15 and 16 for row 3 to add fields from the ledger entry dataset. Put the fields under the corresponding captions.
18. Select the row that you just filled and set the **BackgroundColor** property to **Silver**.
19. Build the project, inspect the **Output** pane, and make sure that there are no build errors.
20. Select the second table row, right-click the shaded border to the left, choose **Insert Row**, and then choose **Below**. The table should now have three group rows, one group data row, and one table footer row. This row will store the captions of **Detailed Cust. Ledg. Entry** data item.
21. Add the captions and fields for the **Detailed Cust. Ledger Entry table** as shown in the following table.

THIRD ROW (CAPTION)	FORTH ROW (FIELDS)
EntryNo_DetailedCustLedgEntryCaption	EntryNo_DetailedCustLedgEntry.Value
EntryType_DetailedCustLedgEntryCaption	EntryType_DetailedCustLedgEntry.Value
PostingDate_DetailedCustLedgEntryCaption.	PostingDate_DetailedCustLedgEntr.Value
DocumentType_DetailedCustLedgEntryCaption	DocumentType_DetailedCustLedgEntry.Value
DocumentNo_DetailedCustLedgEntryCaption	DocumentNo_DetailedCustLedgEnt.Value
TransactionNo_DetailedCustLedgEntryCaption	TransactionNo_DetailedCustLedgEntry.Value
JournalBatchName_DetailedCustLedgEntryCaption	JournalBatchName_DetailedCustLedgEntry.Value
AmountLCY_DetailedCustLedgEntryCaption	AmountLCY_DetailedCustLedgEntr.Value
DebitAmountLCY_DetailedCustLedgEntryCaption	DebitAmountLCY_DetailedCustLedgEntry.Value
CreditAmountLCY_DetailedCustLedgEntryCaption	CreditAmountLCY_DetailedCustLedgEntry.Value

22. Shrink the column that contains the **Customer No.** field of the Cust. Ledger Entry to about half of its size.
23. Right-click the column header that contains the **Customer No.** field, choose **Insert Column**, and then choose **Right**.
24. Select the cell that contains the **Customer No.** caption and the empty cell that you just created, and then choose **Merge Cells** to merge the two cells.
25. Repeat step 24 to merge the cell that contains the value of the **Customer No.** field and the empty cell that you created.
26. Assign the expression from the **EntryType** caption and field cells of the Detailed Cust. Ledg. Entry to the empty cell that you created to the right. You may have to have to cut the expressions and paste them into the empty cells.
27. Repeat 26 to move the **EntryNo** caption and field one cell to the right. This makes sure that the EntryNo and the EntryType data is located directly under the CustomerNo cell.

The following illustration shows EntryNo and the EntryType cells directly under the CustomerNo cell



28. Repeat steps through 27 to put the **Transaction No.** and **Journal Batch Name** captions and fields under the Description data. This creates a blank cell under the CurrencyCode field.

29. Select the third row and set the **BackgroundColor** property to **Yellow** and then set the **BackgroundColor** property of the fourth row to **Khaki**.

    Viktor will now hide all empty cells and add the totals to the footer row. To hide empty cells Viktor will add a filter that selects rows that have [EntryNo] value that are greater than zero.

To hide empty cells and add totals

1. Select the first row, right-click the shaded border to the left of the row, choose **Row Group**, and then choose **Group Properties**.

2. In the **Group Properties** window, select the **Filters** tab, and then choose the **Add** button.

3. Set **Expression** to **[EntryNo_CustLedgerEntry]**, change **Text** to **Integer**, set **Operator** to **>**, set **Value** to **0**, and then choose the **OK** button.

   The filter that is set applies to the other rows in the table.

4. In the **Group Properties** window, under the **Filters** tab, verify that the **Expression** box contains [EntryNo_CustLedgerEntry].

   Viktor will now add the total of the amount field to the footer row of the table, format the cells and hide the total cell if customer ledger entry is not available.

5. In the last row of the table, right-click the empty cell under the **Amount (LCY)** field, and then choose **Expression**.

6. In the **Category** column, select **Fields (DataSet_Result)**, in the **Values** column double-click **Amount_CustLedgerEntry**, and then change the expression in the **Set expression for: Value** box to the following value: `=Sum(Fields!Amount_CustLedgerEntry.Value)`. Choose the **OK** button.

7. In the **Properties** window, locate the **Format** property, choose the drop-down arrow and select **Expression**.

8. In the **Expression** window, enter the following formatting expression in **Set expression for: Value** box: `=Fields!Amount_CustLedgerEntryFormat.Value`. Choose the **OK** button.

   > **NOTE**
   > Alternatively, you set this value by double-clicking **Amount_CustLedgerEntryFormat** in the **Values** field of **Fields(DataSet)** category.

9. Select the two empty cells to the left of the total cell, right-click the cells, and then choose **Merge Cells**.

10. Right-click the merged cell, choose **Expression**, choose the **Parameters** category, and then set the caption to **Total_Caption**

11. Set the **BackgroundColor** property of the cells that contain the total and total caption to **Red**.

If you run the report now, the total amount cell will be displayed even if there are no ledger entries. Viktor will add an expression to hide the footer row when there are no ledger entries.

12. Select the last row, in the **Properties** window, locate the **Hidden** property, choose the drop-down arrow, and then choose **Expression**.
13. In the **Expression** window, in the **Set expression for: Hidden** box, enter the following expression to hide the row: `=Fields!EntryNo_CustLedgerEntry.Value = 0`. Choose the **OK** button. This hides the row if there are no entry values.
14. Right-click the left-most cell in the last table row, select **Text Box Properties**, select the **Visibility** tab, under **Change display options**, select the **Hide** option, and then choose the **OK** button.

The next step is to add the data from the **Sales Header** table.

To add the sales header data

1. From the **Toolbox**, drag a **Table** control to the **List** control, and then put the table control under the table that contains the **Cust. Ledger Entry** table
2. Right-click a column and add columns to create five columns for the table.
3. Delete the first header row from the table.
4. Right-click the data row, choose **Tablix Properties**, verify that the **DataSet name** is set to **DataSet_Result**, and then choose the **OK** button.
5. Right-click the data row, choose **Add Group**, and then choose **Parent Group** to open the **Tablix group** window.
6. Select the **Group by:** option and then choose the **fx** button to open the **Expression** window.
7. In the **Category** column, select **Parameters**, and then in the **Values**, column double-click **Sales_Document_Caption**. Verify that the **Set expression for: Value** box contains the following value: `=Parameters!Sales_Document_Caption.Value`. Choose the **OK** button.
8. In the **Tablix group** window, select **Add group header**, and then choose the **OK** button.
9. Right-click the first row in the table, choose **Insert Row**, and then choose **Inside Group – Above**.
10. Reduce the size of the first column, and then in the **Properties** window, under **Visibility**, set the **Hidden** property to **True**. This hides the first column.
11. In the first table row, merge all the cells except the first grouping cell.
12. Right-click the merged cell, and then choose **Expression**.
13. In the **Category** column, select **Parameters**, and then in the **Values** column double-click **Sales_Document_Caption**. Verify that the **Set expression for: Value** box contains the following value: `=Parameters!Sales_Document_Caption.Value`. Choose the **OK** button.
14. Modify the expression to `=First(Parameters!Sales_Document_Caption.Value)`.
15. Right-click the cell in row2, column 2, and then choose **Expression** to open the **Expression** window.
16. In the **Category** column, select **Parameters**, and then in the **Values** column double-click **DocumentType_SalesHeader**. Verify that the **Set expression for: Value** box contains the following value: `Parameters!DocumentType_SalesHeaderCaption.Value`.
17. Modify the expression to the following value: `=First(Parameters!DocumentType_SalesHeaderCaption.Value)` and then choose the **OK** button.

18. Right-click the cell that is under the caption that you just created, choose **Expression**. In the **Category** column, select **Fields (DataSet_Result)**, and then in the **Values** column double-click **DocumentType_SalesHeader**. Choose the **OK** button. Verify that the **Set expression for: Value** box contains the following value: `=Fields!DocumentType_SalesHeader.Value`

19. Repeat steps 15 through 18 and add the following captions and the corresponding fields.

CAPTION	CORRESPONDING FIELD
No_SalesHeaderCaption	No_SalesHeader
PostingDate_SalesHeaderCaption	PostingDate_SalesHeader
PricesIncludingVAT_SalesHeaderCaption	PricesIncludingVAT_SalesHeader
Amount_SalesHeaderCaption	Amount_SalesHeader

20. Select the first two rows and in the **Properties** window, set the **BackgroundColor** property to **Lime**.

21. Select the data row (last row), in the **Properties** window, set the **BackgroundColor** property to **Turquoise**.

    Viktor will now set a filter that hides empty rows.

To set a filter hide empty row

1. Select any row from this table, right-click the shaded border to the left of the table, and then choose **Tablix Properties**.

2. Choose the **Filters** tab and then choose the **Add** button.

3. In the **Expression** list box, select **No_SalesHeader**, set **Operator** to **>**, set **Value** to **0**, and then choose the **OK** button.

4. Save the report.

Building and Running the Report

Viktor will run the report to view how it looks like. For this, do the following:

1. Make sure that the `"startupObjectId"` is set to the **Id** of the report object and the `"startupObjectType"` to `Report` in the `launch.json` file.

2. Press the `F5` key to compile and run the report in Dynamics 365 Business Central.

3. If you have not disabled the UseRequestPage Property you will be shown a request page in the Web Client.

   The following illustration shows an example of the request page that is displayed when the report is run.

   If you choose the **Preview** button on the request page, the report will be displayed with the RLD layout just created.

Viktor can now add advanced features to the report. He can add features such as displaying the company name and logo on every page on the report. He might also want to add features that enable users to apply filters on the request page.

Formatting Decimal Values in Fields

2/17/2021 • 5 minutes to read • Edit Online

This article describes how you can format the decimal values that appear in fields on table, pages and reports. For example, you can change how the data appears in a Cue on the Role Center page. To format data, you use a combination of the AutoFormatType Property, AutoFormatExpression Property, and DecimalPlaces Property of the field. These properties work together to enable you to specify the following:

- Display amounts and unit amounts in another currency.
- Specify the number of decimal places.
- Specify whether to display a thousand separator.
- Specify characters before and after the value, such as currency signs or %.

Implementation overview

When a field is used on a page or report, you can set the **AutoFormatType** and **AutoFormatExpr** properties directly on the page field or report field (column), or you can set them on the underlying table field. If you specify the properties on the table field, then the format applies wherever the field is used. Specifying the properties on the page or report field will only apply the format to the specific page or report. If you specify the properties on the table field and the page or report field, then the settings on the page or report field take precedence.

When you use the **AutoFormatType** and **AutoFormatExpression** properties to format a field, two events are raised by the system codeunit **45 Auto Format**: OnResolveAutoFormat and OnAfterResolveAutoFormat.

Setting up data formatting

The settings for the **AutoFormatType**, **AutoFormatExpression**, and **DecimalPlaces** properties will depend on the type of data that is displayed, for example, this could be currency amounts, unit amounts, simple decimals, or ratios. For the most part, the **AutoFormatType** property is the primary setting, which in turn determines the options for setting the **DecimalPlaces** and **AutoFormatExpr** properties.

If the **AutoFormatType** is not set or is set to an incorrect property value, then the default setting is used, regardless of whether the **AutoFormatExpression** or **DecimalValues** properties are set. The default setting uses `AutoFormatType = 1` and `AutoFormatExpression = ''`.

The following tables describes how to set each of the properties to achieve the format that you want.

Setting the DecimalPlaces property

With the following set up, the **AutoFormatExpression** property is ignored.

AUTOFORMATTYPE PROPERTY	DECIMALPLACES PROPERTY	USAGE DESCRIPTION

AUTOFORMATTYPE PROPERTY	DECIMALPLACES PROPERTY	USAGE DESCRIPTION

0	Set to the number of decimal places that you want to display for the value.	Use this configuration when you want to format the decimal value according the Standard Format 0 (which is the default format) with a specific number of decimal places.
		
		For example, if the value is a US decimal `-76543.21` and you set the **DecimalPlaces** property to `0`, then the value appears as **76,543**. The properties will look like this:
		
		`AutoFormatType = 0;`
		`DecimalPlaces = '0';`

Setting the AutoFormatExpression property

With the following setup, the **DecimalPlaces** property is ignored.

AUTOFORMATTYPE PROPERTY	AUTOFORMATEXPRESSION PROPERTY	USAGE DESCRIPTION

1	Set to return a currency code, such as USD or IDR. The blank currency code `''` denotes LCY and is the default value.	Use this configuration when you want to format the data as an amount. For example, a sales order will use two decimals when the currency is defined as US dollar and no decimals when the currency is defined as IDR (Indonesian rupiah). For example:
		
		`AutoFormatType = 1;`
		`AutoFormatExpression = 'IDR';`

2	Set to return a currency code such as USD or IDR. The blank currency code `''` denotes LCY and is the default value.	This is similar to the previous configuration where the **AutoFormatType** property is set to `1`, except you use this configuration when you want to format the data as a unit amount.

AUTOFORMATTYPE PROPERTY	AUTOFORMATEXPRESSION PROPERTY	USAGE DESCRIPTION

10	Set to the property according to the following syntax:
	`'[SubType][,<currencycode or expression>[,<PrefixedText>]]'`
	`SubType` can be `1`, `2`, another number, or omitted:
	`1` sets the value to an amount type (see 1 above). `2` sets the value to a unit amount type (see 2 above). The syntax for these two settings is:
	`'SubType,<currencycode[, <PrefixedText>]'`
	If you omit the subtype or use a number other than 1 or 2, the syntax is:
	`'<CustomNumber>, <expression>[, <PrefixedText>]'`
	where `<expression>` sets the precision and one of the standard formats. For more information, see Standard Formats.
		Use SubType `1` to add the currency symbol and use the amount type precision. You use SubType `2` for unit amount precision. For example, set the property to `'1,USD'` to add the **$** symbol, like **$543.21**.
		`AutoFormatType = 10;`
		`AutoFormatExpression = '1,USD';`
		If you omit the SubType, you can use this configuration to customize the format based on one of the standard formats. This option enables you to specify characters before and after the decimal value, such as currency signs **$** and percent **%**.
		For example, if you want to prefix the decimal value with a **$**, include a thousand separator, and have a maximum of two decimal places, such as **$76,453.21**, then you can set the properties to:
		`AutoFormatType = 10;`
		`AutoFormatExpression = '$<precision, 2:2><standard format, 0>'`
		If you want to display the decimal value as a percentage, then you can add `%` at the end of the setting. For example:
		`AutoFormatType = 10;`
		`AutoFormatExpression = '<precision, 1:1><standard format,0>%'`
		When you include a `%` at the end of the setting, then the decimal value is assumed to be the ratio, and the decimal value will be multiplied by 100. For example, a value of 0.98 will be formatted to **98%**.

11	Set the property to the standard format as explained below. For example: `'<Precision,3:3><Standard Format,0>'`	Use this option when you want full control over the formatting. The format string will be applied exactly as specified in the AutoFormatExpr property.

Precision

The precision determines the minimum and maximum number of decimal points for values. The precision takes the format `<precision,minimum:maximum>`. For example, `<precision,minimum:maximum>` sets the data with a minimum of 2 and a maximum of 3 decimal places.

Standard formats

The following table describes the standard formats that are available for the **AutoFormatExpr** property when the **AutoFormatType** property is set to 10.

STANDARD FORMAT	FORMAT DESCRIPTION	EUROPE DECIMAL EXAMPLE	US DECIMAL EXAMPLE
0	<Sign><Integer Thousand><Point or Comma><Decimals>	-76.543,21	-76,543.21
1	<Sign><Integer><Point or Comma><Decimals>	-76543,21	-76543.21
2	<Sign><Integer><Point or Comma><Decimals>	-76543.21	-76543.21
3	<Integer Thousand><Point or Comma><Decimals><Sign>	76.543,21-	76,543.21-
4	<Integer><Decimals><Point or Comma><Sign>	76543,21-	76543.21-
9	XML format	-76543.21	-76543.21

Developing Printer Extensions in Business Central

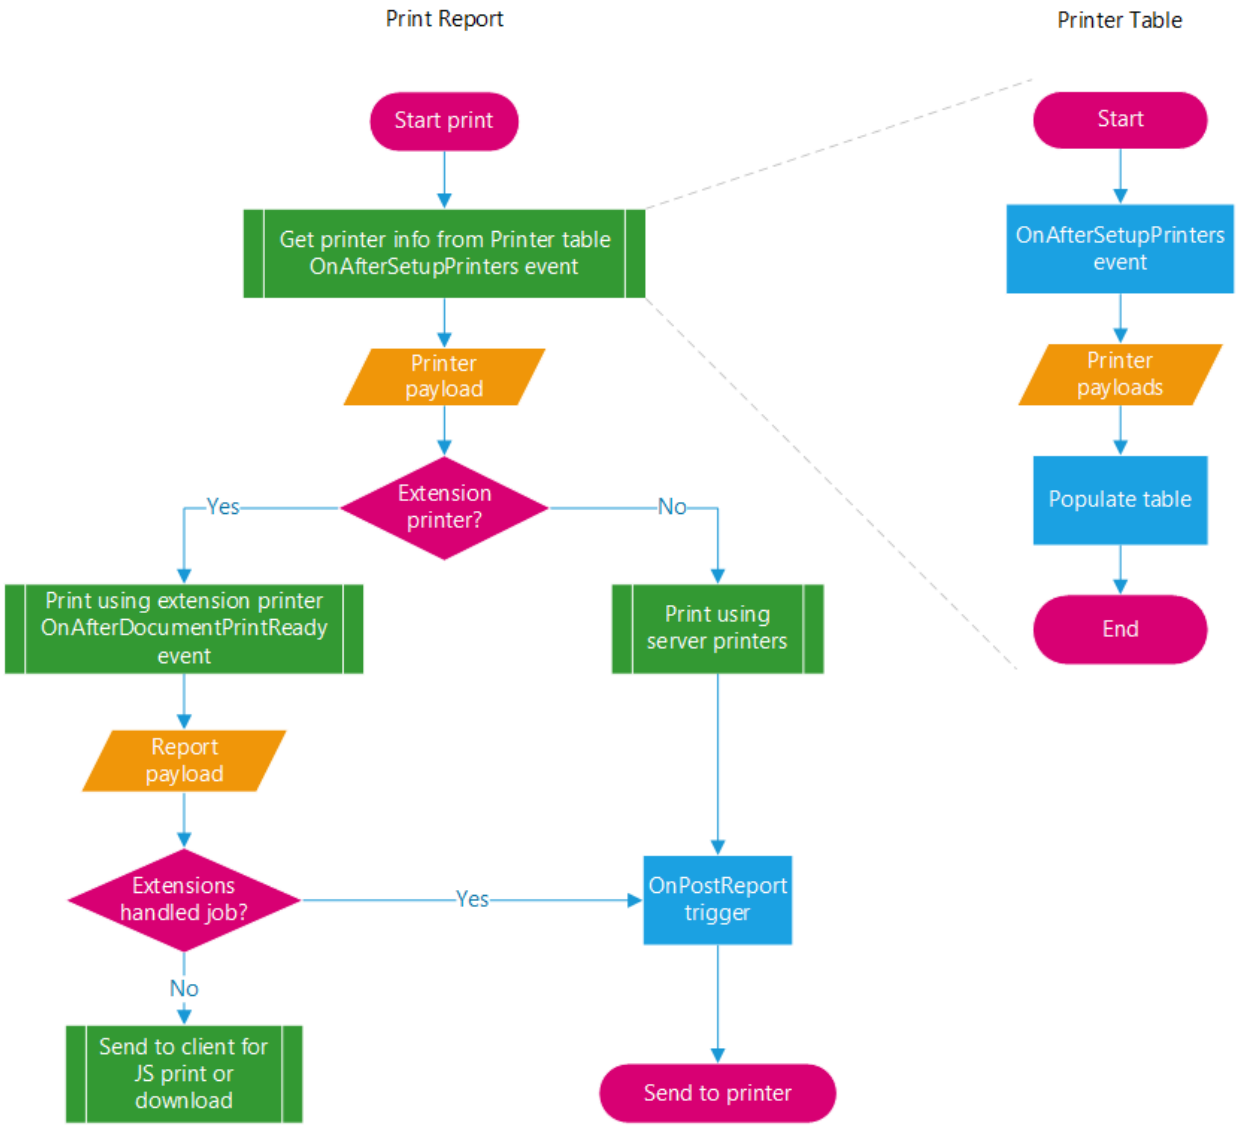
2/17/2021 • 3 minutes to read • Edit Online

This article provides an overview about how to add code that enables Business Central reports to be sent from the client directly to a web-connected printer, like an email printer or through a cloud printing service.

Without any customized code, there's no way to send a report directly to a printer for printing. The only way to print a report from the client is to download it first (as a .pdf file), and then send it to a printer. But you can create extensions that are designed to send reports to web-connected printers. For example, if you have an email printer, you create an extension that sends print jobs directly to the printer's email address.

Overview

To accommodate printing, the system publishes two events that you can subscribe to: OnAfterSetupPrinters and OnAfterDocumentPrintReady. The following figure illustrates the runtime execution of the events:



Throughout the print process, the system compiles the report into a PDF file and passes it in a stream object, then finally sends the PDF file the printer.

OnAfterSetupPrinters event

You subscribe to the OnAfterSetupPrinters event to set up different printers that users can use on reports, which

they select from the **Printer Selections** page. The OnAfterSetupPrinters event is a global integration event that is published from codeunit **44 Report Managements**. It has the following declaration:

```
[IntegrationEvent(false, false)]
local procedure OnAfterSetupPrinters(var Printers: Dictionary of [Text[250], JsonObject]);
```

The *Printers* parameter is a Dictionary of [Text, Text] type that includes a collection of key-value pairs that define different printer setups. The key specifies a name for the printer. The value is a JSON object that specifies settings supported by the printer. The settings include information like paper size, paper trays, default copies, and more. The JSON object is referred to as the *payload*.

The OnAfterSetupPrinters event is raised when the following operations occur:

- When you open a page that uses the virtual table **Printer** as its source.
- From page **64 Printer Selections** in the base application, when you access the **Printer Name** field for selecting a printer for a report. This field has a lookup to the **Printer** table.
- From a report request page, when you select the **Print** or **Preview** action for a report. But only if the report is set up to use a specific printer from the **Printer Selections** page.

OnAfterDocumentPrintReady

You subscribe to the OnAfterDocumentPrintReady event to specify what happens when the user selects the **Print** action on a report request page. You use OnAfterDocumentPrintReady event subscribers to provide instructions on how and where to send to the report for printing. For example, with email printing, the OnAfterDocumentPrintReady event subscriber would construct and send an email to a target printer.

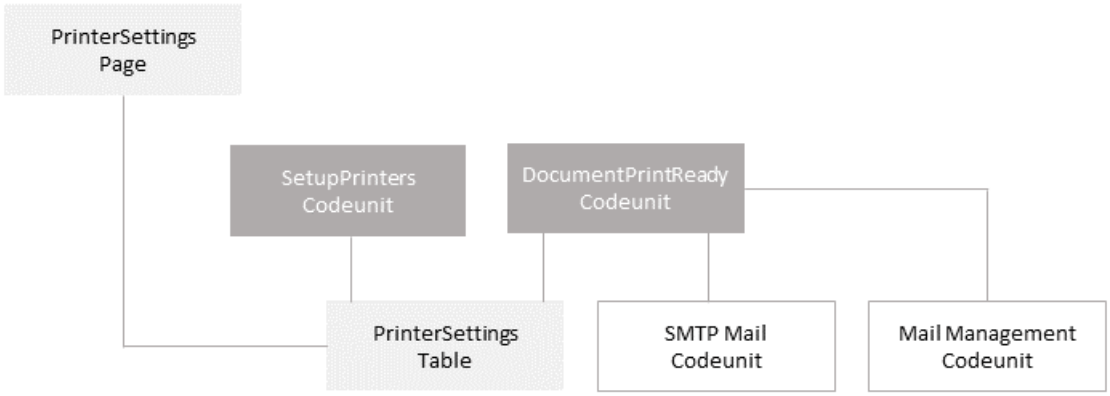
The OnAfterDocumentPrintReady event is also a global integration event that is published from codeunit **44 Report Managements**. It has the following declaration:

```
IntegrationEvent(false, false)]
local procedure OnAfterDocumentPrintReady(ObjectType: Option "Report","Page"; ObjectId: Integer;
ObjectPayload: JsonObject; DocumentStream: InStream; var Success: Boolean);
```

The event is raised when the use selects the **Print** action on the request page of a report. Two parameters of interest are *DocumentStream* and *ObjectPayload*. *DocumentStream* is an Upstream object that contains the report data to be printed. The *ObjectPayload* is a JsonObject type object that combines the printer payload and report metadata. The report metadata includes information like the company name, MIME type, views, and more. This combination is referred to as the *report payload*.

Development Overview

To develop a printer extension, you create codeunits that subscribe to the OnAfterSetupPrinters and OnAfterDocumentPrintReady events. Plus, you would typically add other objects to support the printing. For example, you could create a table that stores printer setups and a page that enables users to manage them.



For more information about using the OnAfterSetupPrinters and OnAfterDocumentPrintReady events to create a printer extension, see Creating a Printer Extension.

Creating a Printer Extension

2/17/2021 • 6 minutes to read • Edit Online

This article describes how to use the OnAfterSetupPrinters and OnAfterDocumentPrintReady events to set up different printers for reports.

Overview

This article uses a simplified printer extension example for sending reports to an email printer. The example creates a printer extension that sets up a single email printer. Users can then assign the printer to reports from the **Printer Selections** page in the client. In this article, you will:

- Create two codeunits, one that subscribes to the OnAfterSetupPrinters event and another that subscribes to the OnAfterDocumentPrintReady event.
- Use the **SMTP Mail** and **Mail Management** codeunits that are part of the base application for sending the report via email.

Set up printers using the OnAfterSetupPrinters event

This section describes how to use the OnAfterSetupPrinters event to set up a printer. When completed, users can select the printer from on the **Printer Selections** page.

Getting started

1. Create an AL project for the printer extension.

   See Getting Started with AL.

2. Create a codeunit to use for subscribing to the OnAfterSetupPrinters event.

3. Create a method that subscribes to the OnAfterSetupPrinters event.

   At this point, your code would look something like this:

   ```
   codeunit 50100 SetupPrinter
   {
       [EventSubscriber(ObjectType::Codeunit, Codeunit::"ReportManagement", 'OnAfterSetupPrinters', '',
   true, true)]
       procedure OnSetupPrinters(var Printers: Dictionary of [Text[250], JsonObject]);
       var

       begin

       end;
   }
   ```

   For more information about subscribing to events, see Subscribing to Events.

4. Now you can start adding code to the event subscriber method to create the printer payloads.

   In this example, you set up a printer named 'My Printer' that has two paper trays: A4 and Custom. There are two ways of setting values for a payload JSON object. You can add properties (key-value pairs) by using the Add method, as shown in the example. Or, you can use the ReadFrom method to read the JSON data from the string into a JsonObject variable (see Using ReadFrom to create the payload).

```
codeunit 50100 SetupPrinter
{
    [EventSubscriber(ObjectType::Codeunit, Codeunit::"ReportManagement", 'OnAfterSetupPrinters', '',
true, true)]
    procedure OnSetupPrinters(var Printers: Dictionary of [Text[250], JsonObject]);
    var
        Payload: JsonObject;
        PaperTrays: JsonArray;
        PaperTrayA4: JsonObject;
        PaperTrayCustom: JsonObject;
    begin
        // Step 1: Create the paper trays
        PaperTrayA4.Add('papersourcekind', 'Upper');
        PaperTrayA4.Add('paperkind', 'A4');

        PaperTrayCustom.Add('papersourcekind', 'Custom');
        PaperTrayCustom.Add('paperkind', 'Custom');
        PaperTrayCustom.Add('width', 236);
        PaperTrayCustom.Add('height', 322);
        PaperTrayCustom.Add('units', 'mm');

        // Step 2: Add the paper trays to the list of paper trays
        PaperTrays.Add(PaperTrayA4);
        PaperTrays.Add(PaperTrayCustom);

        // Step 3: Add the required parameters for the payload
        Payload.Add('version', 1);
        Payload.Add('papertrays', PaperTrays);

        // Step 4: Add the printer to the dictionary
        Printers.Add('My Printer', Payload);
    end;
}
```

5. At this point, you can compile your project, and publish/install the extension on the tenant to test the payload.

   Open the **Printer Selections** page in the client. You should see **My Printer** as an option in the **Printer Name** field. If there are errors with payload, you'll get an error when you try to open the **Printer Name** field. For more information, see Troubleshooting Printer Payload Errors.

About the printer payload

The event subscriber method has one parameter, which is a dictionary of printers. The key is a name of the printer. The value is a JSON object that is referred to as the payload. The payload specifies information about a specific printer. The payload includes several attributes in the following structure:

```
{
    "version": 1,
    "description":[default=""],
    "duplex":[default=false],
    "color":[default=false],
    "defaultcopies":[default=1],
    "papertrays":
    [
        {
            "papersourcekind":'Upper' | 1,
            "paperkind":'A4' | 9,
            "units":[default='HI'],
            "height":[default=0],
            "width":[default=0],
            "landscape":[default=false]
        }
    ]
}
```

There are few required attributes, such as `version` and `papertrays`. The `papertrays` attribute must contain at least one paper tray setup, which in turn must include the attributes `papersourcekind` and `paperkind`. For more information about the attributes, see Printer Payload.

Using the ReadFrom method to create the payload

The following example illustrates how to create a payload by using the ReadFrom method.

```
codeunit 50101 SetupPrinter2
{
    [EventSubscriber(ObjectType::Codeunit, Codeunit::"ReportManagement", 'OnAfterSetupPrinters', '', true,
true)]
    procedure SetupPrinters(var Printers: Dictionary of [Text[250], JsonObject]);
    var
        Payload: JsonObject;
    begin
        // Step 1: Read the payload from the text
        Payload.ReadFrom('{"version":1,"papertrays":[{"papersourcekind":"Upper","paperkind":"A4"},
{"papersourcekind":"Custom","paperkind":"Custom","width":236,"height":322,"units":"mm"}]}');

        // Step 2: Add the printer to the dictionary
        Printers.Add('My Printer', Payload);
    end;
}
```

Select the paper tray

A printer can have several paper trays. If a report doesn't specify which paper tray to use or the specified paper tray isn't present in the printer's setup, a default paper tray is used. The default paper tray is the first one defined in the `papertrays` list.

You can change the paper tray for an existing report by subscribing to the `OnAfterGetPaperTrayForReport` event and setting a value for a `DefaultPage` parameter.

```
[EventSubscriber(ObjectType::Codeunit, Codeunit::"ReportManagement", 'OnAfterGetPaperTrayForReport', '',
true, true)]
procedure GetPaperTrayForReport(ReportID: Integer; var FirstPage: Integer; var DefaultPage: Integer; var
LastPage: Integer)
```

As an alternative, if you're creating a new report, you can set a paper tray by specifying PaperSourceDefaultPage property.

```
report 50103 MyReport
{
    PaperSourceDefaultPage = Upper;
            ...
}
```

Handle print using the OnAfterDocumentPrintReady event

This section describes how to subscribe to the OnAfterDocumentPrintReady event. You subscribe to the OnAfterDocumentPrintReady event to define what happens when a user chooses to print a report. The event subscriber specifies how and where to send the report.

Getting started

1. Create a codeunit to use for subscribing to the OnAfterDocumentPrintReady event.
2. Create a method that subscribes to OnAfterDocumentPrintReady event.

   At this point, your code would look something like this:

   ```
   codeunit 50102 HandlePrintAction
   {
       [EventSubscriber(ObjectType::Codeunit, Codeunit::ReportManagement, 'OnAfterDocumentPrintReady',
   '', true, true)]
       procedure OnDocumentPrintReady(ObjectType: Option "Report","Page"; ObjectId: Integer;
   ObjectPayload: JsonObject; DocumentStream: InStream; var Success: Boolean);
       var

       begin

       end;
   }
   ```

   For more information about subscribing to events, see Subscribing to Events.

3. Now you can start adding code to the event subscriber method to handle the report payload and send the report.

   The following code sends a report by email to the printer that is named 'My Printer'. In this example, the printer's email address is 'myprinterb@businesscentral.onmicrosoft.com'.

```
codeunit 50101 SendReportByEmail
{
    [EventSubscriber(ObjectType::Codeunit, Codeunit::ReportManagement, 'OnAfterDocumentPrintReady',
'', true, true)]
    procedure OnDocumentPrintReady(ObjectType: Option "Report","Page"; ObjectId: Integer;
ObjectPayload: JsonObject; DocumentStream: InStream; var Success: Boolean);
    var
        SMTPMail: Codeunit "SMTP Mail";
        PrinterNameToken: JsonToken;
        PrinterName: Text;
        ObjectNameToken: JsonToken;
        ObjectName: Text;
        DocumentTypeToken: JsonToken;
        DocumentTypeParts: List of [Text];
        FileExtension: Text;
        MailManagement: Codeunit "Mail Management";
        SendFrom: Text;
        FileName: Text;
        Recipients: List of [Text];
    begin
        begin
            // Step 1: Before doing anything, it is important to check the current Success value
            if Success then
                exit;

            // Step 2: Make sure code only runs for reports
            if ObjectType = ObjectType::Report then begin

                // Step 3: Get report object payload information
                ObjectPayload.Get('printername', PrinterNameToken);
                PrinterName := PrinterNameToken.AsValue().AsText();
                if PrinterName = 'My Printer' then begin
                    ObjectPayload.Get('objectname', ObjectNameToken);
                    ObjectName := ObjectNameToken.AsValue().AsText();
                    ObjectPayload.Get('documenttype', DocumentTypeToken);

                    // Step 4: Build the email message
                    DocumentTypeParts := DocumentTypeToken.AsValue().AsText().Split('/');
                    FileExtension := DocumentTypeParts.Get(DocumentTypeParts.Count);
                    Recipients.Add('myprinterb@businesscentral.onmicrosoft.com');
                    SendFrom := MailManagement.GetSenderEmailAddress();
                    SMTPMail.CreateMessage('Sender', SendFrom, Recipients, 'Hello this is your
report', 'Please take a look');
                    SMTPMail.AddAttachmentStream(DocumentStream, ObjectName + '.' + FileExtension);

                    // Step 5: Send the email for print
                    SMTPMail.Send;
                    Success := true;
                    exit;
                end;
            end;
        end;
    end;
}
```

4. At this point, you can compile and publish/install the extension on a tenant to test.

   First, make sure that SMTP email is set up on the tenant (see Set Up Email in the Application Help).

   Then, on the **Printer Selections** page, set a report to use 'My Printer', and then run and print the report.

About the report payload

The event subscriber receives the printer payload and combines it with the report metadata, like the report's ID. This combination is the report payload. The content of the report itself is received as a stream object. You add code to define how and where to send the report payload for printing. In this example, it's sent as an email.

The report object payload is a JSON object that includes several parameters and values arranged in a specific structure, as shown in the following example

```
{
    "filterviews":
    [
        {"name":"Header","tableid":112,"view":"VERSION(1) SORTING(Field3) WHERE(Field3=1(103027))"},
        {"name":"Line","tableid":113,"view":"VERSION(1) SORTING(Field3,Field4) WHERE(Field4=1(0..10000))"},
        {"name":"ShipmentLine","tableid":7190,"view":"VERSION(1) SORTING(Field1,Field2,Field3)
WHERE(Field2=1(10000))"}
    ],
    "version":1,
    "objectname":"Standard Sales - Invoice",
    "objectid":1306,
    "documenttype":"application/pdf",
    "invokedby":"00000000-0000-0000-0000-000000000001",
    "invokeddatetime":"2020-01-17T15:33:52.48+01:00",
    "companyname":"CRONUS International Ltd.",
    "printername":"My Printer",
    "duplex":false,
    "color":false,
    "defaultcopies":1,
    "papertray":
    {
        "papersourcekind":257,
        "paperkind":0,
        "landscape":false,
        "units":0,
        "height":1268,
        "width":929
    }
}
```

The parameters can be read but not modified at runtime. For more information about the report payload, see Report Payload.

Queries in Business Central

2/17/2021 • 2 minutes to read • Edit Online

Queries enable you to retrieve records from one or more tables or data sources and then combine the data into rows and columns in a single dataset. Queries can also perform calculations on data, such as finding the sum or average of all values in a column of the dataset.

Query Types

There are two types of query objects: normal and API.

- A normal query retrieves records from business data tables in the Dynamics 365 Business Central database, and can be used to display data in the user interface. This type of query is created by a query object. For more information, Query Object.
- An API query is used to generate web service endpoints and this type of page cannot be displayed in the user interface. A query of the API type can be used to join data from different data sources. The data can only be viewed. For information about creating a query of the type API, see API Query Type.

Query usages

The following examples show how you can use queries in your Dynamics 365 Business Central application.

- Creating charts that are based on a query instead of a table.
- Saving a query as an .xml or .csv file. For example, you can use the SAVEASXML method to create an .xml file that contains the resulting dataset of a query. You can use the .xml file to integrate with external applications.
- Exposing data as an OData web service. You can register and publish a query as a web service in the same way that you can register and publish pages or codeunits as web services. You use the **Web Services** page to register and publish pages, codeunits, or queries. After you expose a query as a web service, you can import it into other applications.
- Using the query as a data source for a page. To do this, you have to copy the query resulting dataset into a temporary table and set it as the source table for the page.
- Using the query as a data source for a report. To do this, you have to copy the query resulting dataset into a temporary table which can then be used by the report.
- Performing calculations on data such as computing sums and averages. For more information see, Query Totals and Grouping.
- Replacing nested loops that use record variables to retrieve or to detect duplicate records. For more information, see Using Queries Instead of Record Variables.

Query Data Type

The query resulting dataset cannot be used directly by other objects such as pages and reports. Instead, you must create a Query Data Type instance and apply methods for handling the data from the query object. You must first call the OPEN Method to be able to perform actions such as reading the dataset or setting filters and you must use the CLOSE Method when you are finished. You can write this code in a codeunit, for example. The following example illustrates how to do this.

```
var
    MyQuery: Query "Customer SalesQuantity";
    Text000: Label 'Customer name = %1, Quantity = %2';
begin
    // Sets a filter to display only sales quantities greater than 20.
    MyQuery.SETFILTER(Quantity, '>20');
    // Runs the query.
    MyQuery.OPEN;
    // Reads each row in the dataset and displays a message with column values.
    // Stops reading when there are no more rows remaining in the dataset (READ is FALSE).
    while MyQuery.READ do
    begin
      MESSAGE(Text000, MyQuery.Name, MyQuery.Quantity);
    end;
    MyQuery.CLOSE;
end;
```

Query Object

2/17/2021 • 3 minutes to read • Edit Online

Business Central query objects enable you to retrieve records from one or more tables and then combine the data into rows and columns in a single dataset. Query objects can also perform calculations on data, such finding the sum or average of all values in a column of the dataset.

There are two types of query objects: normal and API. This article describes normal query objects, which can be used to display data in the user interface. API query objects are used to generate web service endpoints and cannot be displayed in the user interface. For information about creating a query of the type API, see API Query Type.

Creating a query object

A query object is comprised mainly of two different types of elements: dataitems and columns. A dataitem specifies the table to retrieve records from. A column specifies a field of the table to include in the resulting dataset of a query. The basic steps to create a query object are as follows:

1. Add the `query` keyword, followed by the `elements` control.
2. Build the dataset by adding `dataitem` controls and `column` controls within the `elements` control.

   The hierarchy of the `dataitem` and `column` controls is important because it will determine the sequence in which data items are linked, which in turn will control the results. Working from top-to-bottom, you start by adding the `dataitem` control for first table that you want in the dataset, then add `column` controls for each table field that you want to include in the dataset. For the next table, you add another `dataitem` control that is embedded within the first `dataitem` control, then add `column` controls as needed. You continue this pattern for additional tables and fields.
3. When you have specified the dataitem and column elements, create links and joins between the `dataitem` elements.

   Dataitem links and joins determine which records to include in the dataset based on the values of a common field between dataitems. You set a link between one or more fields of the dataitem tables with the DataItemLink Property and you define the type of the link using the SQLJoinType Property. Both properties must be set on the lower dataitem of the query object. For more information, see Linking and Joining Data Items.

The following shows the basic structure of a query object.

```
query ID Name
{

    elements
    {
        dataitem(DataItem1; Table1)
        {
            column(Column1; Field1)
            {
            }
            column(Column2; Field2)
            {
            }
            dataitem(DataItem2; Table2)
            {
                // Sets a link between FieldY of Table2 and FieldX of Table1.
                DataItemLink = FieldY = DataItem1.FieldX;
                //The dataset contains records from Table1 and Table2 where a match is found between FieldY
and FieldX.
                SqlJoinType = InnerJoin;

                column(Column1; Field1)
                {
                }
                dataitem(DataItem3; Table3)
                {
                    DataItemLink = FieldZ = DataItem2.FieldY;
                    SqlJoinType = InnerJoin;
                    column(Column1; Field1)
                    {
                    }
                }
            }
        }
    }
}
```

NOTE

Extension objects can have a name with a maximum length of 30 characters.

Snippet support

Typing the shortcut `tquery` will create the basic layout for a Query object when using the AL Language extension in Visual Studio Code.

TIP

Use **Ctrl+Space** to trigger IntelliSense and get assistance on code completion, parameter info, quick info, and member lists.

Query example

The following example shows a query that displays a list of customers with sales and profit figures. The query primarily retrieves fields from the **Customer** table, but also displays fields from the **Salesperson Purchaser** and **Country Region** tables.

The query also uses the DataItemLink property to create a link between the **Customer** table, **Salesperson**

Code field and the **Salesperson Purchaser** table, **Code** fields and a link between the **Customer** table, **Country/Region Code** field and the **Country/Region** table, **Code** field.

```
query 50102 "Top Customer Overview"
{
    QueryType = Normal;
    Caption = 'Top Customer Overview';

    elements
    {
        dataitem(Customer; Customer)
        {
            column(Name; Name)
            {
            }
            column(No; "No.")
            {
            }
            column(Sales_LCY; "Sales (LCY)")
            {
            }
            column(Profit_LCY; "Profit (LCY)")
            {
            }
            column(Country_Region_Code; "Country/Region Code")
            {
            }
            column(City; City)
            {
            }
            column(Global_Dimension_1_Code; "Global Dimension 1 Code")
            {
            }
            column(Global_Dimension_2_Code; "Global Dimension 2 Code")
            {
            }
            column(Salesperson_Code; "Salesperson Code")
            {
            }
            dataitem(Salesperson_Purchaser; "Salesperson/Purchaser")
            {
                DataItemLink = Code = Customer."Salesperson Code";
                column(SalesPersonName; Name)
                {
                }
                dataitem(Country_Region; "Country/Region")
                {
                    DataItemLink = Code = Customer."Country/Region Code";
                    column(CountryRegionName; Name)
                    {
                    }
                }
            }
        }
    }
}
```

IMPORTANT

You cannot run a query that gets data from both the application database and the business data database. This also applies to single-tenant deployments so that you do not have to rewrite queries if you decide to export the application. For a description of which tables are considered part of the application database, see Separating Application Data from Business Data.

Linking and Joining Data Items to Define the Query Dataset

2/17/2021 • 11 minutes to read • Edit Online

Business Central queries enable you to retrieve records from one or more tables and combine the specific records into rows in a single dataset. In AL, each table is specified as a data item. The data included in the dataset is a result of how the data items are linked and joined together.

> **TIP**
> The concept of linking and joining data items in AL is similar to Join clauses in SQL Select statements on tables in SQL Server. For those familiar with SQL Joins, when describing links and joins in AL, this article provides the equivalent SQL SELECT statement in most cases.

Sample Tables and Query

To demonstrate data item links and joins, this article uses the following sample tables and query.

Salesperson/Purchaser Table

The **Salesperson/Purchaser** table contains a list of salespersons. Each salesperson is identified by a unique code. The following is a simplified version of the **Salesperson/Purchaser** table for demonstration purposes.

CODE	NAME
AA	Annette
BB	Bart
DD	Debra
JJ	John

Sales Header Table

The **Sales Header** table contains a list of sales orders. Each sales order has a unique number, includes the name of the customer to sell to, and is assigned to a salesperson by the **Salesperson_Code** column. The following is a simplified version of the **Sales Header** table for demonstration purposes.

NO.	SELL-TO CUSTOMER NAME	SALESPERSON CODE
1000	Autohaus	AA
2000	Blanemark	DD
3000	Candoxy	JJ
4000	New Concepts	

Sample Query

The following query object links the **Sale Header** table with the **Salesperson/Purchaser** table on the **Salesperson_Code** and **Code** fields, as specified by the DataItemLink Property. In the example, the SQLJoinType Property is set to **InnerJoin**.

```
query 50100 "Sample Query"
{
    QueryType = Normal;
    Caption = 'Sales Overview';

    elements
    {
        dataitem(Salesperson_Purchaser; "Salesperson/Purchaser")
        {
            column(Salesperson; Name)
            {

            }
            dataitem(Sales_Header; "Sales Header")
            {
                DataItemLink = "Salesperson Code" = Salesperson_Purchaser.Code;
                // Change the SqlJoinType value to suit the desired results: LeftOuterJoin, InnerJoin,
RighOuterJoin, FullJoin, CrossJoin.
                SqlJoinType = InnerJoin;

                column(Order_Number; "No.")
                {

                }
                column(Sell_to_Customer; "Sell-to Customer Name")
                {

                }
            }
        }
    }
}
```

How to link and join data items

When you add data items to a query object in AL, you define them in a specific hierarchy, one after another, where each lower data item is embedded within the definition of the upper data item. The order of the data items determines the sequence in which data items are linked and joined to produce the results in the dataset.

In short, to join two data items, you set the DataItemLink and SqlJoinType properties on the lower data item in the query object.

Set the DataItemLink Property

The DataItemLink Property sets up a reference or association between one or more fields in the source table of a lower data item tables with a field in the source table of the upper data item. In a query, two data item tables typically will have columns that have values that are common to both tables. For example, the **Salesperson** table and **Sales Header** table have the **Code** column and **Salesperson_Code** column in common. To create a link between these two tables, you could set the DataItemLink property of the **Sales Header** data item as follows:

```
DataItemLink = "Salesperson Code" = Salesperson_Purchaser.Code;
```

The DataItemLink Property sets up an "equal to" (=) comparison condition between two columns of the data items. When the query is run, the query compares each row of the two data items to find records that having matching values for the columns. Records that have matching column values are combined into a row in the

resulting dataset. In some cases, there will be records that do not have matching values. You use the SqlJoinType Property to include records that do not have matching column values.

Set the SqlJoinType Property

The SqlJoinType Property the determines which records to combine into the results, based on the values of the fields that are linked by the DataItemLink property. You use this property to limit the records that are included in the resulting dataset based on the specified conditions. By default, the SqlJoinType property is `LeftOuterJoin`, so if you omit this property, a `LeftOuterJoin` is performed.

> **TIP**
> In SQL join statements, tables are designated as either left or right. In AL query objects, because data items are arranged vertically, when joining data items, the *left* corresponds to the upper data item (table) and *right* corresponds to the lower data item (table).

Linking More Than Two Data Items

A query links data items in the order that they appear in AL, starting from the top and then working downward. When you have more than two data items, lower data items are linked to the resulting dataset of the linked data items above it. For example, when you link the first two data items, the query generates a dataset. When you add another data item, it is linked to the dataset of the first linked pair of data items, where it applies the conditions that are specified by its DataItemLink Property and SqlJoinType Property. The following code adds another data item to the sample query:

```
query 50100 "Sample Query"
{
    QueryType = Normal;
    Caption = 'Sales Overview';

    elements
    {
        dataitem(Salesperson_Purchaser; "Salesperson/Purchaser")
        {
            column(Salesperson; Name)
            {

            }
            dataitem(Sales_Header; "Sales Header")
            {
                DataItemLink = "Salesperson Code" = Salesperson_Purchaser.Code;
                SqlJoinType = InnerJoin;

                column(Order_Number; "No.")
                {

                }
                column(Sell_to_Customer; "Sell-to Customer Name")
                {

                }
                dataitem(Sales_Line; "Sales Line")
                {
                    DataItemLink = "Sell-to Customer No." = Sales_Header."Sell-to Customer No.";
                }
            }
        }
    }
}
```

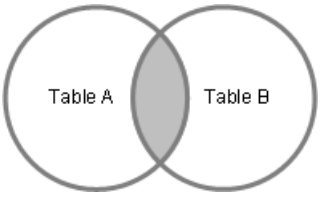
This pattern continues for each additional data item.

InnerJoin

`InnerJoin` creates a dataset by combining records from data item tables where a match is found between the columns that are linked by the DataItemLink Property of the lower data item. `Inner Join` uses an "equal to" comparison operator to match rows from the lower data item table with rows from the upper data item table that is based on the values of the linked columns.

- Each pair of matching records is combined into a row in the dataset.
- Records from the upper and lower data item tables that do not have a matching column in the lower data item table are excluded from the resulting dataset.

The following illustration shows an `InnerJoin` type between tables A and B. The shaded area indicates the records that are included in the resulting dataset.



Dataset Example

The following table shows the resulting dataset for an `InnerJoin` between the **Sales Header** table and **Salesperson/Purchaser** table in sample query.

SALESPERSON	ORDER_NUMBER	SELL_TO_CUSTOMER
Annette	1000	Autohaus
Debra	2000	Blanemark
John	3000	Candoxy

The records for **Bart** in the Salesperson table and **New Concepts** in the **Sales Header** table do not have matching records in the opposing table, so they are excluded from the resulting dataset.

SQL SELECT Statement for Inner Join

To specify an inner join with an SQL statement, you can do either of the following:

- Use a WHERE clause.
- Use the INNER JOIN condition with an ON clause.

The following two examples show how to create an inner join on the **Salesperson/Purchaser** and **Sales Header** tables with SQL statements. These two statements result in the same dataset.

```
SELECT "Salesperson/Purchaser".Name, "Sales Header"."No.", "Sales Header"."Sell-to Customer Name"
FROM "Salesperson/Purchaser" INNER JOIN "Sales Header"
  ON "Salesperson/Purchaser".Code = "Sales Header"."Salesperson Code"
```

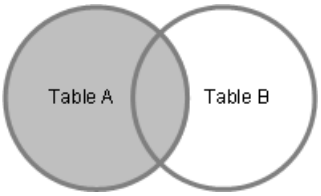
```
SELECT "Salesperson/Purchaser".Name, "Sales Header"."No.", "Sales Header"."Sell-to Customer Name"
FROM "Salesperson/Purchaser", "Sales Header"
WHERE "Salesperson/Purchaser".Code = "Sales Header"."Salesperson Code"
```

LeftOuterJoin

A `LeftOuterJoin` resembles the `InnerJoin` except that the resulting dataset set contains every record from the upper data item table, even if a record does not have a matching value in the lower data item for columns that are linked by the DataItemLink Property.

- For each record in the upper data item, a row is added in the dataset that combines columns from the upper and lower data item.
- When a record in the upper data item table has no matching record in the lower data item table, columns coming from the lower data item table have null values.

The following illustration shows a `LeftOuterJoin` type between tables A and B. The shaded area indicates the records that are included in the resulting dataset. In the sample query, the **Salesperson/Purchaser** table is considered the left table.



Dataset Example

The following table shows the resulting dataset for a `LeftOuterJoin` between the **Sales Header** table and **Salesperson/Purchaser** table in sample query.

SALESPERSON	ORDER_NUMBER	SELL_TO_CUSTOMER
Annette	1000	Autohaus
Bart	null	null
Debra	2000	Blanemark
John	3000	Candoxy

The record for **Bart** in the Salesperson/Purchaser table does not have a matching record in the **Sales Header** table, so a row is included but the columns from the **Sale Header** table are given null values. The record for **New Concepts** in the **Sale Header** table is not included in the resulting dataset because it does not have a matching column in the **Salesperson/Purchaser** table.

SQL SELECT Statement for Left Outer Join

To specify a left outer join with an SQL statement, you use the LEFT OUTER JOIN condition.

The following example shows how to create a left outer join on the **Salesperson/Purchaser** and **Sales Header** tables by using a SQL statement.

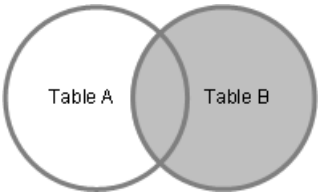
```
SELECT "Salesperson/Purchaser".Name, "Sales Header"."No.", "Sales Header"."Sell-to Customer Name"
FROM "Salesperson/Purchaser" LEFT OUTER JOIN "Sales Header"
  ON "Salesperson/Purchaser".Code = "Sales Header"."Salesperson Code"
```

RightOuterJoin

A `RightOuterJoin` resembles the inner join except that the resulting dataset set contains every record from the lower data item table, even if a record does not have a matching value in the upper data item for columns that are linked by the DataItemLink Property.

- For each record in the lower data item, a row is added in the dataset that combines columns from the lower and upper data item tables.
- When a record in the lower data item table has no matching record in the upper data item table, columns coming from the upper data item table have null values.

The following illustration shows a `RightOuterJoin` type between tables A and B. The shaded area indicates the records that are included in the resulting dataset.



Dataset Example

The following table shows the resulting dataset for a `RightOuterJoin` between the **Salesperson/Purchaser** table and **Sales Header** table in the sample query. The **Sales Header** table is considered the right table.

SALESPERSON	ORDER_NUMBER	SELL_TO_CUSTOMER
Annette	1000	Autohaus
Debra	2000	Blanemark
John	3000	Candoxy
null	4000	New Concept

The record for **New Concepts** in the Sales Header table does not have a matching record in the **Salesperson/Purchaser** table, so a row is included but the columns from the **Salesperson/Purchaser** table are given null values. The record for **Bart** in the **Salesperson/Purchaser** table is not included in the resulting dataset because it does not have a matching column in the **Sales Header** table.

SQL SELECT Statement for Right Outer Join

To specify a right outer join with an SQL statement, you use the RIGHT OUTER JOIN condition.

The following example shows how to create a right outer join on the **Salesperson/Purchaser** and **Sales Header** tables by using a SQL statement.

```
SELECT "Salesperson/Purchaser".Name, "Sales Header"."No.", "Sales Header"."Sell-to Customer Name"
FROM "Salesperson/Purchaser" RIGHT OUTER JOIN "Sales Header"
  ON "Salesperson/Purchaser".Code = "Sales Header"."Salesperson Code"
```

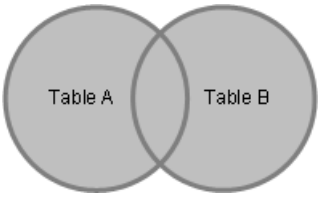
FullOuterJoin

A `FullOuterJoin` contains all the records from the upper data item table, and all records from the lower data item, including records that do not have a matching value for columns that are linked by the DataItemLink Property.

- Each pair of records from the data items that have matching column values are combined into a row in the dataset.
- Records from the upper data item table that do have a matching column are included in a row, where the columns from lower data item table have null values.

- Records from the lower data item table that do have a matching column are included in a row, where the columns from upper data item table have null values.

The following illustration shows a `FullOuterJoin` type between tables A and B. The shaded area indicates the records that are included in the resulting dataset.



Dataset Example

The following table shows the resulting dataset for a full outer join between the **Sales Header** table and **Salesperson/Purchaser** table in sample query.

SALESPERSON	ORDER_NUMBER	SELL_TO_CUSTOMER
Annette	1000	Autohaus
Bart	null	null
Debra	2000	Blanemark
John	3000	Candoxy
null	4000	New Concept

The records for **Bart** in the Salesperson/Purchaser table and **New Concepts** in the Sales Header table are included in a row, even though they not have matching values for columns.

SQL SELECT Statement for Full Outer Join

To specify a full outer join with an SQL statement, you use the FULL OUTER JOIN condition.

The following example shows how to create a full outer join on the **Salesperson/Purchaser** and **Sales Header** tables by using a SQL statement.

```
SELECT "Salesperson/Purchaser".Name, "Sales Header"."No.", "Sales Header"."Sell-to Customer Name"
FROM "Salesperson/Purchaser" FULL OUTER JOIN "Sales Header"
  ON "Salesperson/Purchaser".Code = "Sales Header"."Salesperson Code"
```

CrossJoin

A `CrossJoin` contains rows that combine each row from the upper data item table with each row from a lower data item table. Cross joins are also called Cartesian products. A cross join does not apply any comparisons between columns of data items, so the DataItemLink Property is left blank.

Dataset Example

The following table shows the resulting dataset for a `CrossJoin` between the **Sales Header** table and **Salesperson/Purchaser** table in sample query.

SALESPERSON	ORDER_NUMBER	SELL_TO_CUSTOMER
Annette	1000	Autohaus

SALESPERSON	ORDER_NUMBER	SELL_TO_CUSTOMER
Annette	2000	Blanemark
Annette	3000	Candoxy
Annette	4000	New Concept
Bart	1000	Autohaus
Bart	2000	Blanemark
Bart	3000	Candoxy
Bart	4000	New Concept
Debra	1000	Autohaus
Debra	2000	Blanemark
Debra	3000	Candoxy
Debra	4000	New Concept
John	1000	Autohaus
John	2000	Blanemark
John	3000	Candoxy
John	4000	New Concept

SQL SELECT Statement for Cross Join

To specify a cross join with a SQL statement, you can do either of the following:

- Use the CROSS JOIN condition
- Create an implicit join, which has no join condition, without using a WHERE clause

The following examples shows how to create a cross join of the **Salesperson/Purchaser** and **Sales Header** tables by using a SQL statement.

```
SELECT "Salesperson/Purchaser".Name, "Sales Header"."No.", "Sales Header"."Sell-to Customer Name"
FROM "Salesperson/Purchaser" CROSS JOIN "Sales Header"
```

```
SELECT "Salesperson/Purchaser".Name, "Sales Header"."No.", "Sales Header"."Sell-to Customer Name"
FROM "Salesperson/Purchaser", "Sales Header"
```

Query Object
Filtering Queries

Filtering in Query Objects

2/17/2021 • 8 minutes to read • Edit Online

You specify filters in a query to restrict the data in the resulting dataset. A filter applies conditions on fields in a table that is associated with the query. For a field to be included in the resulting dataset, a field must meet the conditions of the filter.

Overview

There are different ways to filter on fields of a query. You can set up filters on a field directly in the query object or use the AL filter methods that are outlined in the following table.

FILTER	DESCRIPTION
Filter directly on a data item in query object	You can set the DataItemTableFilter property of a data item to filter on a field in the table of the data item. You can apply the filter to any field in the table, not just fields that are defined as columns in the resulting dataset. A data item filter can't be overwritten from AL code. See Filtering on data items in a query object.
Filter directly on a column in a query object	You can set the ColumnFilter property of a `column` control to filter on the source field of the column. A filter on a column can be overwritten by the SETFILTER and SETRANGE methods from AL code. See Filtering on columns and filter rows in query object.
Add a filter row to a query object	A filter row lets you add a filter on a field that will not be included in the resulting dataset, but can be changed from AL code. To set up a row filter add a `filter` control referencing the filed that you want to filter and then set its ColumnFilter Property. A filter row is like a data item filter except a filter on a filter row can be overwritten by the SETFILTER and SETRANGE methods from AL code. See Filtering on columns and filter rows in query object.
Use SETFILTER or SETRANGE method calls	You can call the SETFILTER method method from AL code to set a filter on a field that is exposed through a column or filter row. The filter that is set by the **SETFILTER** method will overwrite any filter that is applied to a column or filter row on the same field by the ColumnFilter Property. You can call the SETRANGE method method from AL code to set a filter on a field that is exposed through a column or filter row. The filter that is set by the **SETRANGE** method will overwrite any filter that is applied to column or filter row on the same field. See Filtering using SETFILTER and SETRANGE methods.

Filtering on data items in a Query object

To specify filters on a data item, you set the DataItemTableFilter property of a data item. **DataItemTableFilter** property has the following syntax:

```
DataItemTableFilter = String;
```

Where `String` is the filter expression.

You can apply a filter on any field in a table, not just those fields that are represented by a column in the query object.

A data item filter is static which means that it can't be overwritten by the ColumnFilter Property, `filter` controls or by the SETFILTER or SETRANGE methods in AL code. If one of these filter types is applied to the same field as the data item filter, then the filters are combined. In logical terms, this combination corresponds to an "AND" operation. For example, if the data item filter applies a filter on a field to include values greater than 10 (>10) and a column filter applies a filter on the same field to include values less than fifty (<50), then the resultant filter includes values that are greater than 10 and less than fifty (10< value <50).

The DataItemTableFilter Property corresponds to a WHERE clause in an SQL SELECT statement. For more information, see Equivalent SQL SELECT Statements for Query Filters.

Example

The following query object links table `18 Customer` and table `37 Sales Line` to get the number of line items in each sales for customers. The **DataItemTableFilter** property is used to only include rows in which the number of line items is greater than 10.

```
query 50100 "Customer_Sales_Quantity"
{
    QueryType = Normal;

    elements
    {
        dataitem(C; Customer)
        {
            column(Customer_Number; "No.")
            {
            }

            column(Customer_Name; Name)
            {
            }

            dataitem(SL; "Sales Line")
            {
                DataItemLink = "Sell-to Customer No." = c."No.";
                SqlJoinType = InnerJoin;
                DataItemTableFilter = Quantity = filter(> 10);

                column(Qty; Quantity)
                {
                }
            }
        }
    }
}
```

Filtering on columns and filter rows in query object

Unlike data item filters, filters on a column or filter row are dynamic and can be overwritten from AL code at runtime by a call to the SETFILTER or SETRANGE method, if the method sets a filter on the same field.

You use filters on a column to filter on fields that are included in the dataset. To apply a filter on a column, you set the ColumnFilter Property of the column. You can apply a filter on any column, including aggregated columns that are applied an aggregate method by the Method Property. The **ColumnFilter** property has the following syntax:

```
ColumnFilter = String;
```

where `String` is the filter expression.

Adding a filter row

Use a filter row when you want to filter the query on a field, but you don't want to include the field in the dataset. For example, you might want to filter a date field on a specific date, but you don't want to include the date in the dataset. To set up a filter row, first add a `filter` element that specifies the table field on which you want to filter, Then, add the **ColumnFilter** property to set the conditions of the filter.

Example

The following query object links the `Customer` table and the `Sales Line` table and retrieves the total quantity of line items ordered for each customer. The query includes the following filters.

- A filter on the `Qty` column to include only records from the `Sales Line` table where the total quantity is less than 50.
- A filter on filter row for the `Location Code` field of the Sales Line table that includes only records where the location code is WHITE.

```
query 50100 "Customer_Sales_Quantity"
{
    QueryType = Normal;

    elements
    {
        dataitem(C; Customer)
        {
            column(Customer_Number; "No.")
            {
            }

            column(Customer_Name; Name)
            {
            }

            dataitem(SL; "Sales Line")
            {
                DataItemLink = "Sell-to Customer No." = c."No.";
                SqlJoinType = InnerJoin;
                DataItemTableFilter = Quantity = filter(> 10);

                column(Qty; Quantity)
                {
                    Method = Sum;
                    ColumnFilter = Qty = filter(< 50);
                }

                filter(Location_Code; "Location Code")
                {
                    ColumnFilter = Location_Code = const('White');
                }
            }
        }
    }
}
```

In an SQL SELECT statement, filters on a column or filter row that don't apply an aggregate method, as with the `Location_Code` filter row in the example, would correspond to a WHERE clause. Filters on a columns or filter rows that do apply a totals method, as with the `Quantity` column in the example, would correspond to a HAVING clause. For more information, see Equivalent SQL SELECT Statements for Query Filters.

Filtering using SETFILTER and SETRANGE methods

AL code includes the SETFILTER and SETRANGE methods that you can use to apply a filter on a field that is represented as a column or filter row in a query. The **SETFILTER** and **SETRANGE** methods enable you to set filters programmatically on a query at runtime. You use the **SETRANGE** method to filter on a range of values in a column or filter row. The **SETFILTER** method is more versatile than the **SETRANGE** method and enables you to filter a field based on a filter expression.

These methods will overwrite any filter on the same field that is set on a column or filter row by the `ColumnFilter` property. If a **SETFILTER** or **SETRANGE** method filters on the same field as a filter on a data item, as specified by the DataItemTableFilter Property, then the method filter and **DataItemTableFilter** property filter are combined.

Calling the SETFILTER and SETRANGE methods

You can call the **SETFILTER** and **SETRANGE** method from the AL code of the Business Central object that runs the query object or from the OnBeforeOpen Trigger of the query object.

To call the **SETFILTER** method, you use the following code.

```
Query.SetFilter(Column, String)
```

To call the **SETRANGE** method, you use the following code.

```
Query.SetRange(Column, FromValue, ToValue)
```

where:

- `Query` is a variable of the Query type that specifies the query object.
- `Column` is the name of the column or filter row as defined by its Name property.
- `String` is the filter expression.
- `FromValue` is the lower value of the range.
- `ToValue` is the higher value of the range.

For more information about these methods and important behavior, see SETFILTER method and SETRANGE method (Query).

Example

Referring to the query example in the previous sections, you can add the following code to the **OnBeforeOpen** trigger of the query object to change the filters on the `Quantity` column and the `Location\_Code` filter row to include quantities of in the range of 10 to 50 and a location code of RED.

```
trigger OnBeforeOpen()
begin
    currQuery.SETRANGE(Qty, 10, 50);
    currQuery.SETFILTER(Location_Code, '=RED');
end;
```

Equivalent SQL SELECT Statements for Query Filters

If you're familiar with SQL, then it is helpful to know how filtering in Business Central queries relates to SQL statements. To specify filters in an SQL statement, you use WHERE and HAVING clauses. The WHERE clause filters on fields. The HAVING clause filters on the results that have aggregated values as applied by of a totals method.

The following example shows the corresponding SQL SELECT statement for the previous data item filter example that links the `Customer` and `Sales Line` tables and filters on the `Quantity` field.

```
SELECT Customer."No.", Customer.Name, "Sales Line".Quantity
FROM Customer LEFT OUTER JOIN "Sales Line"
ON Customer."No." = "Sales Line".Sell-to Customer No.
WHERE "Sales Line"."Quantity" > 10
```

The following example shows the corresponding SQL SELECT statement for the previous column and filter row example that links the `Customer` and `Sales Line` tables and filters on the `Location Code` field and the total sum of the `Quantity` field.

```
SELECT Customer."No.", Customer.Name, SUM("Sales Line".Quantity) as Qty
FROM Customer LEFT OUTER JOIN "Sales Line"
  ON Customer."No." = "Sales Line".Sell-to Customer No.
WHERE "Sales Line"."Location Code" = WHITE
GROUP BY Customer."No."
HAVING Qty  50
```

Aggregating Data in Query Objects

2/17/2021 • 6 minutes to read • Edit Online

In a query object, you can use the Method property to do a calculation on the fields of a column and return the calculated value in the dataset. For example, you can sum all the fields in a column or find the average value. The `Method` property is set on `column` controls and can be set to any of the following aggregate methods.

AGGREGATE METHOD	DESCRIPTION
Sum	Calculates the sum of the values of the field in the designated column for all records that are selected as part of the grouped set.
Average	Calculates the average value of the field in the designated column for all records that are selected as part of the grouped set. When averaging fields that have an integer data type (such as `Integer` or `BigInteger`), integer division is used. The result isn't rounded, and the remainder is discarded. For example, 5÷2=2 instead of 2.5 (or 2 1/2).
Min	Retrieves the lowest value of the field in the designated column for all records that are selected as part of the grouped set.
Max	Retrieves the highest value of the field in the designated column for all records that are selected as part of the grouped set.
Count	Returns the number of records that are selected as part of the grouped set.

Setting up an aggregate method for a query column

Except for the `Count` method, you can only use an aggregate method (`Sum`, `Average`, `Min`, and `Max`) on a field that has a numeric data type of Decimal, Integer, BigInteger, or Duration. To set up an aggregate on a column, you set the column's Method Property.

```
column(Name; Field)
{
    Method = Sum|Average|Min|Max|Count;
}
```

Setting an aggregate method on a column will automatically group the resultant data set by the other columns in the query. Records that have matching values for the other columns are grouped together into a single row in the results. The aggregate method is then applied against the group and a summary value returned in the row. It's similar to the GROUP BY clause in SQL SELECT statements (see Creating Queries with Aggregates in SQL).

The aggregate methods and grouping are further explained in the following sections.

Sample Query

The following sample query object retrieves the number of line items in every sales order for each customer. The query links the **Customer** table and the **Sales Line** table. In its current state, the `Method` property is commented out so it doesn't implement any aggregate method.

```
query 50101 "Customer_Sales_Quantity"
{
    QueryType = Normal;
    // Sorts the results in descending order
    OrderBy = descending(Qty);

    elements
    {
        dataitem(C; Customer)
        {
            column(Customer_Number; "No.")
            {
            }

            column(Customer_Name; Name)
            {
            }

            dataitem(SL; "Sales Line")
            {
                DataItemLink = "Sell-to Customer No." = c."No.";
                SqlJoinType = InnerJoin;

                column(Qty; Quantity)
                {
                    // Change the value of the property to perform a different aggregate method on grouped
columns:
                    // Sum, Average, Max, Min, or Count
                    // Method = Sum|Average|Min|Max|Count;
                }
            }
        }
    }
}
```

The following table represents a simplified version of the resulting dataset for the sample query.

CUSTOMER_NUMBER	CUSTOMER_NAME	QTY
20000	Selangorian Ltd.	400
30000	Blanemark Hifi	350
20000	Selangorian Ltd.	300
40000	Deerfield Graphics	250
20000	Selangorian Ltd.	200
30000	Blanemark Hifi	150

The following sections explain how you can modify the query to implement the different aggregate methods by changing the value of the Method property.

Sum

The `Sum` method adds the values of all fields for the specified column within a group. To set up a `Sum` method on the **Quantity** column of the sample query, set the `Method` property to `Sum`. The query is automatically grouped by the **No.** and **Name** columns.

```
...
column(Qty; Quantity)
{
    Method = Sum;
}
...
```

Looking at the sample query, you can use `Sum` method to get the total number of items in sales orders for each customer. The following table illustrates the resulting dataset for the query.

CUSTOMER_NUMBER	CUSTOMER_NAME	QTY
20000	Selangorian Ltd.	900
30000	Blanemark Hifi	500
40000	Deerfield Graphics	250

Average

The `Average` method calculates the average value of the fields in the column within a group. To set up an Average method on the **Quantity** column of the sample query, set the `Method` property to `Average`. The query is automatically grouped by the **No.** and **Name** columns:

```
...
column(Qty; Quantity)
{
    Method = Average;
}
...
```

Looking at the sample query, you can use `Average` method to get the average number of items in sales orders for each customer. The following table illustrates the resulting dataset for the query.

CUSTOMER_NUMBER	CUSTOMER_NAME	QTY
20000	Selangorian Ltd.	300
30000	Blanemark Hifi	250
40000	Deerfield Graphics	250

Min

The `Min` method retrieves the lowest value of fields in the column within a group. To set up a `Min` method on the **Quantity** column of the sample query, set the `Method` property to `Min`. The name of the **Quantity** column automatically changes to **Min_Quantity** and the query is automatically grouped by the **No.** and **Name**

columns:

```
...
column(Qty; Quantity)
{
    Method = Min;
}
...
```

Looking at the sample query, you can use `Min` method to get the least number of items in sales orders for each customer. The following table illustrates the resulting dataset for the query.

CUSTOMER_NUMBER	CUSTOMER_NAME	QTY
40000	Deerfield Graphics	250
20000	Selangorian Ltd.	200
30000	Blanemark Hifi	150

Max

The `Max` method retrieves the highest value of fields in the column within a group. To set up a `Max` method on the **Quantity** column of the sample query, set the `Method` property to `Max`. The name of the **Quantity** column automatically changes to **Max_Quantity** and the query is automatically grouped by the **No.** and **Name** columns:

```
...
column(Qty; Quantity)
{
    Method = Max;
}
...
```

Looking at the sample query, you can use `Max` method to get the greatest number of items in sales orders for each customer. The following table illustrates the resulting dataset for the query.

CUSTOMER_NUMBER	CUSTOMER_NAME	QTY
20000	Selangorian Ltd.	400
30000	Blanemark Hifi	350
40000	Deerfield Graphics	250

Count

The `Count` method returns the number of records from the data item table that comprise a group in the dataset. Unlike the other aggregate methods, the `Count` method is not associated with a specific column. Records are identified and counted based on the primary key of the data item table. Referring to the sample query, you can use a `Count` method to get the number of open sales orders per customer.

To set up a `Count` method in the sample query, the `column` element definition cannot include a source table; only a name. Therefore, you can delete the reference to the `Quantity` field in the `column(Qty; Quantity)`

element and set the `Method` property to `Count`:

```
...
column(Qty)
{
    Method = Count;
}
```

Looking at the sample query, you can use `Count` method the number of sales orders for each customer. The following table illustrates the resulting dataset for the query.

CUSTOMER_NUMBER	CUSTOMER_NAME	QTY
20000	Selangorian Ltd.	3
30000	Blanemark Hifi	2
40000	Deerfield Graphics	1

In SQL SELECT statements, the Count method corresponds to a COUNT(*) or COUNT(field) clause.

Creating queries with aggregates in SQL

If you're familiar with SQL, then it's helpful to know how the aggregate methods in Business Central relate to SQL statements. To specify an aggregate method in an SQL statement, you add the method to the SELECT statement and then add a GROUP BY clause. To group results on columns, you add the GROUPED BY statement.

The following example shows how to use an SQL statement to create an inner join of the Customer table and Sales Line table, and a sum of items for each customer. The result is grouped by the **No.** and **Name** columns.

```
SELECT Customer."No.", Customer.Name, SUM("Sales Line".Quantity)
FROM Customer INNER JOIN "Sales Line"
  ON Customer."No." = "Sales Line"."Sell-to Customer No."
GROUP BY Customer."No.", Customer.Name
```

Retrieving Date Data in Queries

2/17/2021 • 4 minutes to read • Edit Online

When you have fields in a table that contain dates, you can use a date method to retrieve only the year, month, or day instead of including the date in the resulting dataset of a query.

Setting up a Date method on a query column

To set up a date method on a query column, set the Method Property to `Day`, `Month`, and `Year`.

> **IMPORTANT**
> You can only use a date method on fields that have a Date or DateTime data type. For additional information about how to use a date method on a field that has the DateTime data type, see Working with DateTime Data Types.

For more information about how to set up query columns and properties, see Query Object.

Sample table and query

This article uses the following sample table and query to demonstrate the different date methods.

Sample Sales Header table

The following table contains data about sales orders for customers. The **Order Date** field has the data type of Date and the format DD-MM-YYYY, where DD is the day, MM is the month, and YYYY is the year.

NO.	BILL-TO NAME	ORDER DATE
1000	Autohaus Meilberg KG	18-01-2019
5000	Autohaus Meilberg KG	21-05-2019
4000	Beef House	30-09-2017
3000	Deerfield Graphics Company	05-04-2018
3000	Deerfield Graphics Company	29-04-2018

> **NOTE**
> This is a simplified subset of the data that is found in table 36 Sales Header of the CRONUS International Ltd. demonstration database.

Sample query

The following query object retrieves data from the sample Sales Header table. The query includes a totals method that counts the total the number of records from the table included in the dataset.

```
query 50100 "Sample Data Query"
{
    QueryType = Normal;

    elements
    {
        dataitem(Sales_Header; "Sales Header")
        {
            column(Bill_to_Name; "Bill-to Name")
            {
            }

            column(Order_Date; "Order Date")
            {
                // Change the value of the property to Day, Month, or Year
                Method = Day;
            }

            column(Count_)
            {
                Method = Count;
            }
        }
    }
}
```

NOTE

A column that applies a date method is still part of the group unlike columns that apply an aggregate method.

Day method

The `Day` method retrieves the day from the date expression of a field value in the query column. The day is returned as an integer, in the range of 1 to 31, which represents the day of the month. If the day in the date expression is 0, then 1 is returned.

Example

The following table displays the resulting dataset for the sample query with the `Method` property of the `Order Date` column set to `Day`.

BILL_TO_NAME	DAY_ORDER_DATE	COUNT_
Autohaus Meilberg KG	18	1
Autohaus Meilberg KG	21	1
Beef House	30	1
Deerfield Graphics Company	5	1
Deerfield Graphics Company	29	1

Month method

The `Month` method retrieves the month from the date expression of a field value in the query column. The month is returned as an integer, in the range of 1 to 12, where 1 represents January and 12 represents

December. If the month in the date expression is 0, then 1 is returned.

Example

The following table displays the resulting dataset for the sample query with the `Method` property of the `Order Date` column set to `Month`.

BILL_TO_NAME	MONTH_ORDER_DATE	COUNT_
Autohaus Meilberg KG	1	1
Autohaus Meilberg KG	5	1
Beef House	9	1
Deerfield Graphics Company	4	2

Year method

The `Year` method gets the year from the date expression of a field value in the query column. The year is returned as an integer. If the year in the date expression is 0, then 1900 is returned.

Example

The following table displays the resulting dataset for the sample query with the `Method` property of the `Order Date` column set to `Year`

CUSTOMER NAME	YEAR_ORDER_DATE	COUNT_
Autohaus Meilberg KG	2019	2
Beef House	2017	1
Deerfield Graphics Company	2018	2

Working with DateTime Data Types

On the SQL server, date and time values are processed using Coordinated Universal Time (UTC). If your Business Central solution uses a time zone other than UTC and the field on which you apply the date method has a data type of DateTime, then there might be a difference between the date value that is returned in the dataset for the field and the actual day, month, or year for the field in the table. This occurs when the corresponding UTC date for a field falls on the next day or previous day because of the time of day and the time zone of Business Central solution. The following table includes examples of DateTime values for two time zones that will return days, months, and years in a dataset that differ from the values in the table.

TIME ZONE	DATE AND TIME IN BUSINESS CENTRAL	DAY RETURNED BY DAY METHOD	MONTH RETURNED BY MONTH METHOD	YEAR RETURNED BY YEAR METHOD
Pacific Time (UTC – 8:00:00)	12-31-2011 17:00:00	31	12	2018
Middle European Time (UTC +1:00:00)	01-01-2012 00:59:00	1	1	2019

The differences in day, month, or year occur because when a date and time value is retrieved from the Business

Central database table, it is converted from the regional settings of the Business Central solution to the UTC date and time. The day, month, or year is calculated on the SQL server, and then returned to the query dataset as an integer, which does not consider the regional settings of the Business Central solution.

To avoid this condition, you should use the date method on fields that have a Date data type instead of a DateTime data type whenever possible. You can also return the DateTime value and implement post processing for the day, month, and year as needed.

Using Queries Instead of Record Variables

2/17/2021 • 2 minutes to read • Edit Online

In scenarios where you want to read records from multiple tables, it can be a good idea to use a query instead of implementing code with record variables. Using a query can improve performance and also simplify the AL code that is required to perform the operation.

Code Example Using Record Variables

The following AL code shows an example of using record variables to retrieve and handle records from two tables. You could potentially use this code to track item movement. The code uses two record variables, `Item` and `ItemLedgerEntry`, to retrieve the first five records from table **27 Item** and table **32 Item Ledger Entry** where the **Entry Type** field equals **Sale**. The retrieved records are passed to and handled by the `OutputData` method.

```
begin
    count := 0;
    if Item.FINDSET then
        repeat
            PrevDate := 0D;
            TotalQty := 0;
            ItemLedgerEntry.SETCURRENTKEY("Item No.", "Posting Date");
            ItemLedgerEntry.SETRANGE("Item No.", Item."No.");
            ItemLedgerEntry.SETRANGE("Entry Type",
                ItemLedgerEntry."Entry Type"::Sale);
            if ItemLedgerEntry.FINDSET then
                repeat
                    if (ItemLedgerEntry."Posting Date" <> PrevDate) and (PrevDate <> 0D) then begin
                        OutputData(1, Item."No.", Item.Description, PrevDate, -TotalQty);
                        TotalQty := 0;
                        count := count + 1;
                    end;
                    PrevDate := ItemLedgerEntry."Posting Date";
                    TotalQty := TotalQty + ItemLedgerEntry.Quantity;
                until (ItemLedgerEntry.NEXT = 0) or (count >= 4);
            if PrevDate <> 0D then begin
                OutputData(1, Item."No.", Item.Description, PrevDate, -TotalQty);
                count := count + 1;
            end;
        until (Item.NEXT = 0) or (count >= 4);
end;
```

Corresponding Query Implementation

The following AL code represents a query object and additional code that will return the same results as the previous example that uses record variables.

```
query 50100 "Item Movements Query"
{
    QueryType = Normal;

    elements
    {
        // This dataitem corresponds to the `Item` record variable in the record variable example.
        dataitem(Item; Item)
        {
            column(No_; "No.")
            {
            }
            column(Description; Description)
            {
            }

            // This dataitem corresponds to the `ItemLedgerEntry` record variable in the record variable
example.
            dataitem(Item_Ledger_Entry; "Item Ledger Entry")
            {
                // The DataItemLink and  SqlJoinType settings correspond to the
`ItemLedgerEntry.SETRANGE("Item No.",Item."No.");` statement in the record variable example.
                DataItemLink = "Item No." = Item."No.";
                SqlJoinType = InnerJoin;

                filter(Entry_Type; "Entry Type")
                {
                }
                column(Posting_Date; "Posting Date")
                {
                }

                // The SUM corresponds to the `TotalQty := TotalQty + ItemLedgerEntry.Quantity;` statement
in the record variable example.
                column(Sum_Quantity; Quantity)
                {
                    Method = Sum;
                }
            }
        }
    }
}
```

Add the following code to a codeunit that will run the query.

```
var
    ItemMovements: Query "Item Movements"
begin
    ItemMovements.TopNumberOfRows(5);
    ItemMovements.SetRange(Entry_Type,ItemMovements.Entry_Type::Sale);
    ItemMovements.Open;
    while ItemMovements.Read do
      OutputData(2,
ItemMovements.Item_No,ItemMovements.Description,ItemMovements.Posting_Date,ItemMovements.Sum_Quantity);
end;
```

The `ItemMovements.TOPNUMBEROFROWS(5);` statement will include only the first 5 records in the resulting dataset and corresponds to implementing the `count` variable in the record-based code example.

The `OutputData` method performs the same operations as the `OutputData` method in the record variable example.

Accessing Columns of a Query Dataset

2/17/2021 • 2 minutes to read • Edit Online

If the query is in the reading state, you can retrieve the value of columns in the current active row of the dataset by using the following syntax in AL.

Syntax

```
ColumnValue := QueryVariable.ColumnName
```

- *QueryVariable* is a variable of the Query data type that specifies the query object.
- *ColumnName* is the name of the column in the query object.

Return Value

The data type of the field that is used by the column, unless the column applies a totaling method as specified by the Method Property. If the column applies a totaling method, then data type is an integer for the `Count` method and a decimal for all other totaling methods.

Returns the value of the column in the current active row.

Remarks

A column of a row can only be accessed after the query has been opened by using a call to the Open Method followed by a call to the Read Method. The current active row is the row that has been included in the query variable after the last call to Read Method.

Example

This example demonstrates how to access a column of a query dataset. When the query is run, each row in the dataset is read and message box is displayed that contains the value of a column in the row.

The following query object links table **18 Customer** and table **37 Sales Line**.

```
query 50123 "Customer_Sales_Quantity"
{
    QueryType = Normal;
    // Sets the results to only include the top forts the results in descending order
    TopNumberOfRows = 5;
    OrderBy = descending(Qty);

    elements
    {
        dataitem(C; Customer)
        {
            column(Customer_Number; "No.")
            {
            }

            column(Customer_Name; Name)
            {
            }

            dataitem(SL; "Sales Line")
            {
                DataItemLink = "Sell-to Customer No." = c."No.";
                SqlJoinType = InnerJoin;

                column(Qty; Quantity)
                {
                }
            }
        }
    }
}
```

The following codeunit opens the query, reads each row of dataset, and then displays a message that has the content of each row.

```
codeunit 50100 QueryColumnAccess
{
    trigger OnRun()
    begin

        // Sets a filter to display only sales quantities greater than 20.
        MyQuery.SETFILTER(Qty, '>20');
        // Runs the query.
        MyQuery.OPEN;
        // Reads each row in the dataset and displays a message with column values.
        // Stops reading when there are no more rows remaining in the dataset (READ is FALSE).
        while MyQuery.READ do begin
            MESSAGE(Text000, MyQuery.Customer_Name, MyQuery.Qty);
        end;
        // Closes the query.
        MyQuery.CLOSE;

    end;

    var
        MyQuery: Query "Customer_Sales_Quantity";

        Text000: Label 'Customer name = %1, Quantity = %2.';
}
```

API Query Type

2/17/2021 • 2 minutes to read • Edit Online

Queries of the type `API` are used to generate web service endpoints and this type of query cannot be used to display data in the user interface. A query of the API type can be used to join data from different data sources. The data can only be viewed. When creating this query type, you must specify a number of properties that provide information for the web service endpoint. Use the snippet `tquery - Query of type API` to get the right template and the list of these properties automatically filled in.

> **TIP**
> Use **Ctrl+Space** to trigger IntelliSense and get assistance on code completion, parameter info, quick info, and member lists.

Example of the API query type

The following query example publishes an API available at: `../contoso/app1/v1.0/companies({id})/customerSales`. The `APIVersion` can be specified as one version, or a list of versions, if the API is supported through multiple versions.

```
query 20000 "APIV1 - Customer Sales"
{
    QueryType = API;
    APIPublisher = 'contoso';
    APIGroup = 'app1';
    APIVersion = 'v1.0';
    Caption = 'customerSales', Locked = true;
    EntityName = 'customerSale';
    EntitySetName = 'customerSales';

    elements
    {
        dataitem(QueryElement1; Customer)
        {
            column(customerId; Id)
            {
                Caption = 'Id', Locked = true;
            }
            column(customerNumber; "No.")
            {
                Caption = 'No', Locked = true;
            }
            column(name; Name)
            {
                Caption = 'Name', Locked = true;
            }
            dataitem(QueryElement10; "Cust. Ledger Entry")
            {
                DataItemLink = "Customer No." = QueryElement1."No.";
                SqlJoinType = LeftOuterJoin;
                DataItemTableFilter = "Document Type" = FILTER (Invoice | "Credit Memo");
                column(totalSalesAmount; "Sales (LCY)")
                {
                    Caption = 'TotalSalesAmount', Locked = true;
                    Method = Sum;
                }
                filter(dateFilter; "Posting Date")
                {
                    Caption = 'DateFilter', Locked = true;
                }
            }
        }
    }
}
```

Interfaces in AL

2/17/2021 • 2 minutes to read • Edit Online

INTRODUCED IN: Business Central 2020 release wave 1

An interface in AL is similar to an interface in any other programming language; it is a syntactical contract that can be implemented by a non-abstract method. The interface is used to define which capabilities must be available for an object, while allowing actual implementations to differ, as long as they comply with the defined interface.

This allows for writing code that reduces the dependency on implementation details, makes it easier to reuse code, and supports a polymorphic way of calling object methods, which again can be used for substituting business logic.

The interface declares an interface name along with its methods, and codeunits that implement the interface methods, must use the `implements` keyword along with the interface name(s). The interface itself does not contain any code, only signatures, and cannot itself be called from code, but must be implemented by other objects.

The AL compiler checks to ensure that implementations adhere to assigned interfaces.

You can declare variables as a given interface to allow passing objects that implement the interface, and then call interface implementations on the passed object in a polymorphic manner.

Snippet support

Typing the shortcut `tinterface` will create the basic layout for an interface object when using the AL Language extension in Visual Studio Code.

Interface example

The following example defines an interface `IAddressProvider`, which has one method `getAddress` with a certain signature. The codeunits `CompanyAddressProvider` and `PrivateAddressProvider` both implement the `IAddressProvider` interface, and each define a different implementation of the `getAddress` method; in this case a simple variation of address value.

The `MyAddressPage` is a simple page with an action that captures the choice of address and calls, based on that choice, an implementation of the `IAddressProvider` interface.

```
interface IAddressProvider
{
    procedure GetAddress(): Text
}

codeunit 50200 CompanyAddressProvider implements IAddressProvider
{
    procedure GetAddress(): Text

    begin
        exit('Company address \ Denmark 2800')
    end;
}

codeunit 50201 PrivateAddressProvider implements IAddressProvider
{
```

```
    procedure GetAddress(): Text

    begin
        exit('My Home address \ Denmark 2800')
    end;
}

enum 50200 SendTo
{
    Extensible = true;

    value(0; Company)
    {
    }

    value(1; Private)
    {
    }
}

page 50200 MyAddressPage
{

    PageType = Card;
    ApplicationArea = All;
    UsageCategory = Administration;

    actions
    {
        area(Processing)
        {
            action(ActionName)
            {
                ApplicationArea = All;

                trigger OnAction()

                var
                    iAddressProvider: Interface IAddressProvider;

                begin
                    AddressproviderFactory(iAddressProvider);
                    Message(iAddressProvider.GetAddress());

                end;
            }

            action(SendToHome)
            {
                ApplicationArea = All;

                trigger OnAction()

                begin
                    sendTo := sendTo::Private
                end;
            }

            action(SendToWork)
            {
                ApplicationArea = All;

                trigger OnAction()

                begin
                    sendTo := sendTo::Company
                end;
            }
        }
```

```
    }

    local procedure AddressproviderFactory(var iAddressProvider: Interface IAddressProvider)
    var
        CompanyImplementer: Codeunit CompanyAddressProvider;
        PrivateImplementer: Codeunit PrivateAddressProvider;
    begin

        if sendTo = sendTo::Company then
