XMLport Overview

2/17/2021 • 2 minutes to read • Edit Online

An XMLport is composed of the following items:

- An XMLport object
- An XMLport schema
- A Request page
- Properties, triggers, and code

XMLport object

You create an XMLport object in the AL Language development environment to define the schema of an XML document. You can export and import data between an external source and Dynamics 365 Business Central with XMLports. For more information, see XMLport Object.

XMLport schema

In order to define the underlying structure of the imported or exported document, you use the XMLport schema. An XMLport schema determines which data is exported from or imported to Dynamics 365 Business Central database tables and the format and structure of the files used. You build the XMLport schema by adding nodes. For more information, see Defining a XMLport Schema.

Request page

Request pages are dialog boxes that enable the user to set a filter on the data, sort the data, or choose whether to export or import the data. For more information, see Request Pages.

Unlike report request pages, XMLport request pages cannot be bookmarked by users from the user interface.

XMLport properties, triggers, and code

XMLport objects include triggers, methods, and properties that can be used to work with the object. For more information, see XMLport Data Type and XMLport Triggers.

When you design XMLports, you must set the value of the Format Property (XMLports) and the Direction Property. The Format Property (XMLports) indicates the type of file that you want to import or export and the Direction Property value indicates whether the XMLport will be used for import or export.

For more information about data consistency and validation against possible errors when using XMLports, see the blog post Importing and exporting valid data using XMLports in Dynamics 365 Business Central.

XMLport Object

2/17/2021 • 2 minutes to read • Edit Online

XMLports are used to export and import data between an external source and Dynamics 365 Business Central. Sharing data between different computer systems is seamless when it is shared in an XML format. Working with XML files can be tedious so the details of how the XML file is handled are encapsulated in XMLports.

To use an XMLport to import or export data, you first create an XMLport object. Once created, you can run the XMLport from a page or codeunit object.

You can design XMLports to include a request page, which is a dialog box that enables the user to set a filter on the data, sort the data, or choose whether to export or import the data. For more information about request pages, see Request Pages.

XMLport example

The following example shows a page extension of the **Permission Sets** page that adds an action to the specified page calling the XMLport **ExportPermissionSet**. The XMLport exports the permission set data to an XML file.

```
pageextension 50111 PermissionSetExporter extends "Permission Sets"
{
    actions
    {
        addafter(Permissions)
        {
            action(ExportPermissionSet)
            {
                Promoted = true;
                PromotedCategory = New;
                trigger OnAction();
                begin
                    Xmlport.Run(50112, false, false);
                end;
            }
        }
    }
}

xmlport 50112 ExportPermissionSet
{
    Format = xml;

    schema
    {
        textelement(PermissionSets)
        {
            tableElement(PSet; "Aggregate Permission Set")
            {
                SourceTableView = WHERE ("App Name" = FILTER (<> ''));
                XmlName = 'PermissionSet';
                fieldattribute(RoleID; pset."Role ID") { }
                fieldattribute(RoleName; pset.Name) { }
                tableelement(P; "Tenant Permission")
                {
                    XmlName = 'Permission';
                    LinkTable = pset;
                    LinkFields = "Role ID" = FIELD ("Role ID");
```

```
                    textelement(ObjectType)
                    {
                        trigger onbeforePassvariable();
                        var
                            int: Integer;
                        begin
                            int := p."Object Type";
                            ObjectType := format(int);
                        end;
                    }
                    textelement(ObjectID)
                    {
                        trigger onbeforePassvariable();
                        var
                            int: Integer;
                        begin
                            int := p."Object ID";
                            ObjectID := format(int);
                        end;
                    }
                    textelement(ReadPermission)
                    {
                        trigger onbeforePassvariable();
                        var
                            int: Integer;
                        begin
                            int := p."Read Permission";
                            ReadPermission := format(int);
                        end;
                    }
                    textelement(InsertPermission)
                    {
                        trigger onbeforePassvariable();
                        var
                            int: Integer;
                        begin
                            int := p."Insert Permission";
                            InsertPermission := format(int);
                        end;
                    }
                    textelement(ModifyPermission)
                    {
                        trigger onbeforePassvariable();
                        var
                            int: Integer;
                        begin
                            int := p."Modify Permission";
                            ModifyPermission := format(int);
                        end;
                    }
                    textelement(DeletePermission)
                    {
                        trigger onbeforePassvariable();
                        var
                            int: Integer;
                        begin
                            int := p."Delete Permission";
                            DeletePermission := format(int);
                        end;
                    }
                    textelement(ExecutePermission)
                    {
                        trigger onbeforePassvariable();
                        var
                            int: Integer;
                        begin
                            int := p."Execute Permission";
                            ExecutePermission := format(int);
                        end;
```

```
                    }
                    textelement(SecurityFilter)
                    {
                        trigger onbeforePassvariable();
                        begin
                            SecurityFilter := format(p."Security Filter");
                        end;
                    }
                }
            }
        }
    }
}
```

Defining an XMLport schema

2/17/2021 • 2 minutes to read • Edit Online

You use an XMLport object to export and import data between an external source and Dynamics 365 Business Central. The schema determines which and how data is extracted from or inserted into the Dynamics 365 Business Central database tables through an XMLport. For more information, see XMLport Object.

You build the XMLport schema from nodes. A node can be:

- A text element
- A text attribute
- A table element
- A field element
- A field attribute

You nest nodes inside other nodes in order to define the structure of the XMLport schema. Use the following keywords to define the structure.

KEYWORD	DESCRIPTION
`textelement`	Defines a new text element in the XMLport. It is used for XML elements that do not map to a database item or when the database does not need the information.
`textattribute`	Defines a new text attribute in the XMLport. It is used for XML attributes that do not map to a database item or when the database does not need the information.
`tableelement`	Defines a new table element in the XMLport. It is used for XML elements that map to a table in the database, which is specified in the SourceTable Property. When the XMLport is run, the code nested inside the table element is iterated for all records in the underlying table.
`fieldelement`	Defines a new field element in the XMLport. It is used for XMLport elements that map to a field in the database, which is specified in the SourceField Property. You must specify it inside the parent table element of the field.
`fieldattribute`	Defines a new field attribute in the XMLport. It is used for XMLport attributes that map to a field in the database, which is specified in the SourceField Property.

NOTE

There can only be one `<root>` node, which must be an element. If the Format Property is set to **Xml**, it must be a `textelement` node.

There can be several attributes for a single element and their order does not matter. Attribute nodes must be specified inside the element nodes they refer to and before other element nodes. They cannot have nested

element nodes.

Snippet support

Typing the shortcut `txmlport` will create the basic layout for an XMLport object when using the AL Language extension in Visual Studio Code.

Example

The following example adds the `Customer` table as a table element, the `Address` field as a field element and the `County` and `City` fields as field attributes.

```
schema
{
    textelement(Customers)
    {
        tableelement(Customer; Customer)
        {
            fieldelement(Address; Customer.Address)
            {
                fieldattribute(County; Customer.County){}
                fieldattribute(City; Customer.City){}
            }
        }
    }
}
```

For more information about designing XMLports, see XMLport Overview.

For more information about data consistency and validation against possible errors when using XMLports, see the blog post Importing and exporting valid data using XMLports in Dynamics 365 Business Central.

XMLport Overview

Using Namespaces with XMLports

2/17/2021 • 2 minutes to read • Edit Online

The external system that provides or consumes AL Language development environment data as XML might require that the XML documents include namespaces. Namespaces are used to avoid element name conflicts. In these cases, you must add namespaces on the XMLport to make it compatible with the XML schema that is used by the external system.

> **NOTE**
>
> Namespace-related properties are only available when the Format Property is set to **Xml**.

For example, the following code is a portion of a simple XML document for transferring sales order information. The XML includes namespaces for mapping fields from the `Sales Header` table.

```
<?xml version="1.0" encoding="UTF-16"?>
<Root xmlns="urn:bc:schema:all" xmlns:bcField="urn:bc:schema:field" xmlns:bcTable="urn:bc:schema:table">
  <bcTable:SalesHeader>
    <bcField:DocType>Order</bcField:DocType>
    <bcField:DocNo>101005</bcField:DocNo>
    <bcField:SellToCustNo>30000</bcField:SellToCustNo>
    <bcField:SellToCustName>John Haddock Insurance Co.</bcField:SellToCustName>
    <bcField:BillToCustNo>30000</bcField:BillToCustNo>
    <bcField:BillToCustName>John Haddock Insurance Co.</bcField:BillToCustName>
  </bcTable:SalesHeader>
...
</Root>
```

Each namespace has the syntax *xmlns:prefix="namespacename"*.

- The *namespacename* is a string of characters, often referred to as a Uniform Resource Identifier (URI), which uniquely identifies an Internet resource. This is typically a Uniform Resource Locator (URL) or Universal Resource Name (URN).
- The *prefix* is a short string of characters that acts as an alias for the namespace name. The prefix is applied to specific elements in the XML document. The example includes the prefixes `bcField` and `bcTable`.
- A namespace that does not include a prefix declares the default namespace. In the example, the default namespace is urn:bc:schema:all. The default prefix is applied to all the elements that do not include a prefix.

You declare the namespaces used in the XMLport using the Namespaces Property. For each namespace, you specify a prefix and a namespace name. You can declare a default namespace by defining an empty prefix `""`. In the XML documents exported or imported by the XMLport, the namespaces declarations are only supported in the `<root>` element.

You then apply the namespaces to XMLport elements by setting the NamespacePrefix Property of the element to one of the namespace prefixes declared in the Namespaces Property. This property only applies to `textelement`, `tableelement` and `fieldelement` nodes, otherwise it will be ignored.

You can also specify a default namespace using the DefaultNamespace Property and setting the UseDefaultNamespace Property to **true**. Note that there can only be one default namespace, so if you specify

the default namespace in the Namespaces Property, you must set the DefaultNamespace Property to **false**.

Request Pages

2/17/2021 • 4 minutes to read • Edit Online

A request page is a page that is run before the report or XMLport starts to execute. Request pages enable end users to specify options and filters for a report and an XMLport. Request pages are defined as part of designing a Report object and an XMLport object. The syntax is shown further down in this topic. You design the filters on request pages by using the following report and XMLport properties:

PROPERTY	DESCRIPTION
RequestFilterHeading Property	Sets a caption for the request page tab that is related to a report's data item or an XMLport's table element.
RequestFilterHeadingML Property	Sets the text used as a RequestFilterHeading Property for a request page tab.
RequestFilterFields Property	Specifies which fields are automatically included on the tab of the request page that is related to a report's data item or an XMLport's table element. The user can set filters on these fields.

NOTE

Request pages for XMLports are not supported by the Business Central Web client in versions prior to Dynamics 365 Business Central 2019 release wave 2. If you try to run an XMLport with a Request page from the web client in these versions, you receive an error that the XMLport page type is not supported. Alternatively, XMLport request pages do work in the Dynamics NAV Client connected to Business Central.

By default, a request page is displayed, unless the UseRequestPage is set to `false`; then the report or XMLport will start to print as soon as it is run. In this case, end users can't cancel the report or XMLport run. It is still possible to cancel the report or XMLport, but some pages may print.

By default, without having set anything else, a request page will always display the following buttons:

- Send to
- Print
- Preview
- Cancel

Additionally, you can add more options on the request page to allow the end user to filter the data displayed.

Filtering on request pages

The fields that you define as `RequestFilterFields` are shown on the request page and can be used for filtering the data before viewing or printing the report.

NOTE

Only on the Windows client, filtering is possible even if `RequestFilterFields` is not set.

Defining the `RequestFilterFields` property in the `dataitem()` part of the report code is done as illustrated in the following code example:

```
report 50103 "Customer List"
{
    CaptionML = ENU = 'Customer List';
    RDLCLayout = 'Customer List Report.rdl'; // if Word use WordLayout property
    dataset
    {
        dataitem(Customer; Customer)
        {
            RequestFilterFields = "No.", "Search Name", "Customer Posting Group";
...
```

> **NOTE**
>
> We recommend that you add fields that the end-users of the report will frequently set filters on.

For more information about the report object, see Report Object.

Defining the `RequestFilterFields` property in the `tableelement()` part of an XMLport is done in a similar way:

```
XMLport 50104 "Export Customer List"
{
    CaptionML = ENU = 'Export customer List';
    Direction = Export;
    schema
    {
        textelement(root)
        {
            XmlName = 'Root';
            tableelement(Customer; Customer)
            {
                RequestFilterFields = "No.", "Search Name", "Customer Posting Group";
...
```

For more information about the XMLport object, see XMLport Object.

By default, for every data item in the report and table element in a XMLport, a FastTab for defining filters and sorting is created on the request page. To remove a FastTab from a request page, do not define any `RequestFilterFields` for the data item or table element and set the DataItemTableView property in a report or the SourceTableView property in an XMLport to define sorting. The request page is displayed, but there is no tab for this data item or table element.

If a `DataItemTableView` or `SourceTableView` is not defined, then end users can select a sort field and sort order at runtime.

In a complex report or XMLport that uses data from several tables, the functionality may depend on a specific key and sort order. Design your reports and XMLports so that end users can't change the sort order in a way that affects their functionality.

For data items and table elements whose source table contains calculated fields, such as amounts and quantities, the **Filter totals by:** section is automatically included on the request page, which allows you to adjust various dimensions that influence calculations.

> **TIP**
> For information about how to enter filter criteria on the request page, see Filtering in the Business Central application help.

Defining a `requestpage` section

On reports, in addition to defining the filter options by setting the `RequestFilterFields` property, you can add a `requestpage` section. In this section, you can set the SaveValues property to `true` in order to save the values that the end user enters on the request page. When the report is run again, the end user will have the option to use previously defined filters. You can also add a `layout` to the request page, specifying an **Options** section to perform checks.

> **NOTE**
> With request pages that have `SaveValues = true`, users can preview the report multiple times in the client and the request page remains open. If `SaveValues = false` or omitted, a **Preview & Close** action appears on the request page. In this case, the request page closes once the report has been previewed.

```
...
requestpage
    {
        SaveValues = true;

        layout
        {
            area(content)
            {
                group(Options)
                {
                    Caption = 'Options';
                    field(PostingDate; PostingDateReq)
                    {
                        ApplicationArea = Basic, Suite;
                        Caption = 'Posting Date';
                        ToolTip = 'Specifies the posting date for the invoice(s) that the batch job creates.
This field must be filled in.';
                    }
                }
            }
        }

        trigger OnOpenPage()
        begin
            if PostingDateReq = 0D then
                PostingDateReq := WorkDate;
        end;

        var
            PostingDateReq: Date;
    }
...
```

XMLport Triggers

2/17/2021 • 2 minutes to read • Edit Online

The following triggers apply to XMLports.

XMLport triggers

XMLPORT TRIGGER	RUNS
OnAfterAssignField Trigger	Runs after a field has been assigned a value and before it is validated and imported. This trigger is only used to import data.
OnAfterAssignVariable Trigger	Runs after the value defined in the XML document is assigned to the text variable. This trigger is only used to import data.
OnAfterGetField Trigger	Runs after a field is passed to the XML document. This trigger is only used to export data.
OnAfterGetRecord (XMLports) Trigger	Runs after a record is retrieved from a table and before it is exported to the XML document. This trigger is only used to export data.
OnAfterInitRecord Trigger	Runs after a record is loaded. This trigger is only used to import data.
OnAfterInsertRecord Trigger	Runs after a record has been inserted into a database table. This trigger is only used to import data.
OnAfterModifyRecord Trigger	Runs after a record has been modified. The trigger is used to import data.
OnBeforeInsertRecord Trigger	Runs after a record has been loaded and before it is inserted into a database table. This trigger is only used to import data.
OnBeforeModifyRecord Trigger	Runs before a record is modified. This trigger is used to import data.
OnBeforePassField Trigger	Runs before a field is passed to the XML document. This trigger is only used to export data.

XMLPORT TRIGGER	RUNS
OnBeforePassVariable Trigger	Runs after the source expression has been formatted into a text variable and before the text variable is passed to the XML document. This trigger is only used to export data.
OnInitXMLport Trigger	Executes when the XMLport is loaded and before any table views and filters are set.
OnPreXMLport Trigger	Runs after the table views and filters are set and before the XMLport is run.
OnPostXMLport Trigger	Runs after the XMLport is run.
OnPreXMLItem Trigger	Runs after the table is initialized and before you start exporting data to an XML object. This trigger only applies to XMLport elements that have a source type of Table. This trigger is only used to export data.

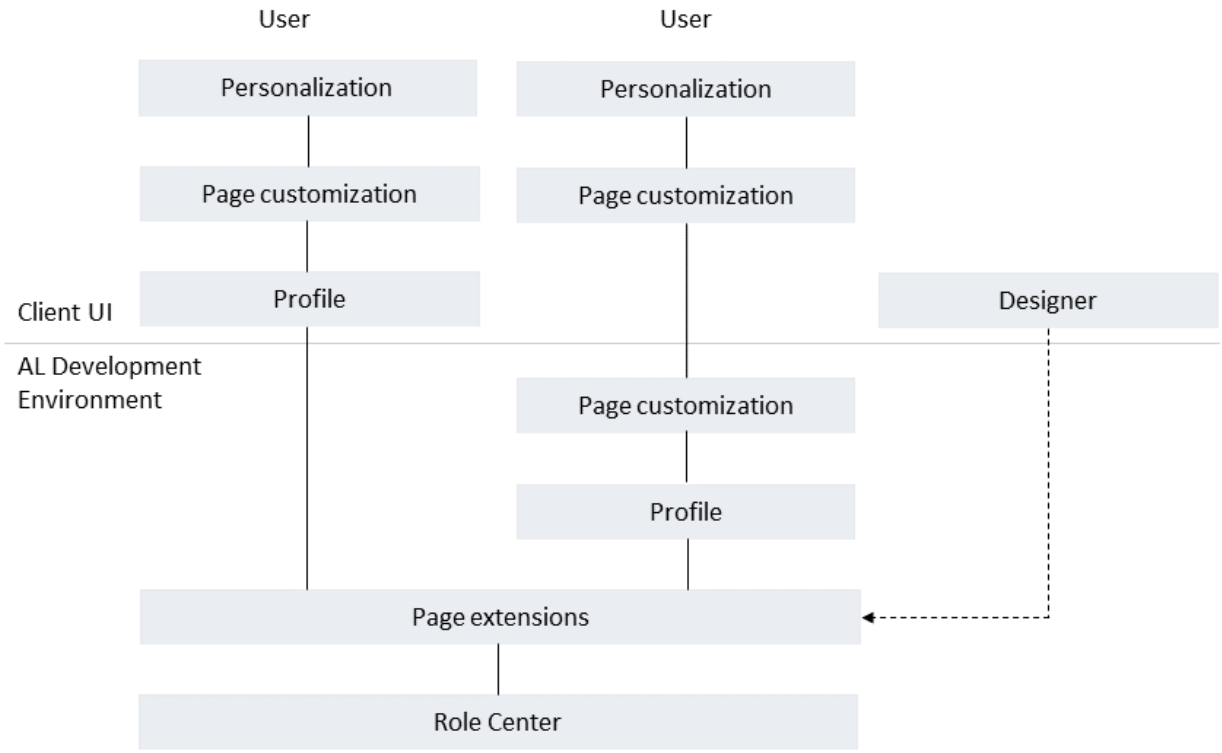
Customizing the User Interface for User Roles

2/17/2021 • 2 minutes to read • Edit Online

The strength of Business Central is its role-tailored experience that helps users focus on the work that is important to them. Business Central offers several features for developers, application administrators, and end-users, that can be used to customize the the pages that users work with in the client. These features customize the pages on different layers, as illustrated in the following figure. Some customization is done in AL extensions, while others can be done from the client.



Role Centers

The Role Center is first layer of customization. The Role Center is the user's entry point and home page for Business Central, displaying information that is pertinent to the user's role in the company and enabling them to easily navigate to relevant pages for viewing data and performing tasks. You can develop several different Role Centers, where each Role Center is customized to the profile of the intended users.

A Role Center is created in AL by the `rolecenter` page type.

For more information, see Designing Role Centers.

Page extensions and designer

A page extension object extends a page object by adding, moving or hiding UI elements that are defined in the page's source code. Page extensions can be created in Visual Studio Code or from the client using Designer. Changes made by page extensions affect the UI for all users, regardless of which profile they belong to.

Profiles and page customizations

A *profile* is the mechanism that makes a Role Center and its associated pages available to users in the client and enables you to build an individual experience for the specific user role. In the client, profiles are referred to as

Roles. Users sign in to the client under a specific role, which they can switch from the **My Settings** page. Different profiles can use the same Role Center. Profiles can be created as part of an extension by writing AL code or they can be created from the client by a user who has the proper permissions, typically an administrator or consultant.

On top of the profile are *page customizations*. Page customizations modify the layout of elements on specific pages. For example, you can move or hide actions, fields, columns on list, or entire parts; exactly the same modifications that can be done using personalization. The page customizations will be seen by all users of the profile. Like profiles, page customizations can be made in AL as part of an extension or from the client by modifying the profile. Customizations that are made from the client will take precedence over the customizations in AL.

For more information about profiles and page customization in AL, see Designing Profiles. For information about using the client, Customizing the Workspace for Profiles (Roles) in the Business Central Application Help.

Personalization

The last layer of customization is personalization. This is done strictly in the client by end-users for customizing their own workspaces. The changes that users make take precedent over page customizations made on the profile. The changes will only be seen by the user; not other users. For more information, see Personalizing Your Workspace in the Business Central Application Help.

Designing Profiles

2/17/2021 • 3 minutes to read • Edit Online

A profile is the mechanism that makes a Role Center page and its associated pages and reports available to users in the client. It enables you to build an individual experience for users based on their role in the company by customizing the pages that they use to perform the daily tasks. In the client, profiles are referred to as **Roles**. When users sign in to Business Central, they are doing so under a specific role. Users can switch the role from the **My Settings** page.

Creating profiles in AL involves two different object types: profile object and page customization object.

Profile objects

A profile object specifies an ID for the profile, a display name that appears in the client, a role center page, and the page customization objects that apply to the profile. Different profiles can use the same Role Center page.

Page customization object

A page customization object specifies layout and action modifications to a specific page object. For example, you can move actions, fields, columns on list, or entire parts. The modifications apply only to the profile that they are used with. The page customizations will be seen by all users of the profile.

To make the modifications, you use placement keywords in the `layout` and `actions` sections.

The same page customization objects can used in different profile objects. A profile object does not necessarily use any page customization objects, but a page customization has no effect without being associated with a profile object.

Example

The following example creates a profile object that uses the `Business Manager` role center page. It uses two page customization objects; one that modifies the **Business Manager Role Center** page and another that modifies the **Customer List** page.

```
profile TheBoss
{
    Description = 'This is the profile for the Boss';
    RoleCenter = "Business Manager";
    Customizations = MyCustomization1, MyCustomization1;
    Caption = 'Boss';
}

pagecustomization Configuration1 customizes "Business Manager Role Center"
{
  actions
  {
    // Hides the Customers action
    modify(Customers)
    {
      Visible = false;
    }
  }
}

pagecustomization MyCustomization customizes "Customer List"
{
    layout
    {
      {
        // Moves the Balance (LCY) column after the Phone No. column
        moveafter("Phone No.";"Balance (LCY)")
      }
    }
}
```

Using the client to create AL profiles and page customizations

Creating profiles and page customizations can also be done from the client. This will typically be done by administrators or consultants to create new profiles or fine-tune the page customizations that provided by extensions. However, as a developer, you can also leverage the client to make profiles and page customizations in AL extensions. For more information, see Using the Client to Create Profiles and Page Customizations.

Translating profiles

A profile's `Caption` and `ProfileDescription` properties appear in the client user-interface, so you will typically want to translate these into different languages. Like other objects, this is done by creating XLIFF files for the different languages from the source language. The generated XLIFF file contains a `<source>` tag for both the `Caption` and `ProfileDescription` to which you can add a `<target>` tag for the translated text. For more information, see Working with Translation Files.

For example, the following code is the content of an XLIFF file for translating the example profile mentioned above from its source language, en-US, to the target language da-DK.

```
<xliff version="1.2" xmlns="urn:oasis:names:tc:xliff:document:1.2"
xmlns:xsi="https://www.w3.org/2001/XMLSchema-instance"
xsi:schemaLocation="urn:oasis:names:tc:xliff:document:1.2 xliff-core-1.2-transitional.xsd">
  <file datatype="xml" source-language="en-US" target-language="da-DK" original="profiles">
    <body>
      <group id="body">
        <trans-unit id="Profile 3523819904 - Property 4111922599" size-unit="char" translate="yes"
xml:space="preserve">
          <source>The Boss</source>
          <target>Chefen</target>
          <note from="Developer" annotates="general" priority="2"></note>
          <note from="Xliff Generator" annotates="general" priority="3">Profile TheBoss - Property
ProfileDescription</note>
        </trans-unit>
        <trans-unit id="Profile 3523819904 - Property 2879900210" size-unit="char" translate="yes"
xml:space="preserve">
          <source>Boss</source>
          <target>Chef</target>
          <note from="Developer" annotates="general" priority="2"></note>
          <note from="Xliff Generator" annotates="general" priority="3">Profile TheBoss - Property
Caption</note>
      </group>
    </body>
  </file>
</xliff>
```

Profile Object

2/17/2021 • 2 minutes to read • Edit Online

The profile object in Dynamics 365 Business Central allows you to build an individual experience for each user profile. The Profile object performs a validation to check whether the specified role center page exists, and page customization objects exists, when you define a new profile object. On a page customization you can add changes to the page layout, and actions; but you cannot add variables, procedures, or triggers.

> **NOTE**
>
> Page customizations only apply to the RoleCenter they are specified for. In order to see them, in Dynamics 365 Business Central under **My Settings**, **Role Center** change to the specific RoleCenter that a page customization is defined for.

> **NOTE**
>
> Extension objects can have a name with a maximum length of 30 characters.

> **NOTE**
>
> `showMyCode` does not apply to profiles. Profiles defined in an extension with `showMyCode` set to `false` can still be copied using Designer.

Snippet support

Typing the shortcut `tprofile` will create the basic layout for a profile object when using the AL Language extension in Visual Studio Code.

> **TIP**
>
> Use **Ctrl+Space** to trigger IntelliSense and get assistance on code completion, parameter info, quick info, and member lists.

Profile example

The following profile object example creates a profile for the `MyRoleCenter` Role Center, which is available in the **Role Explorer** in the UI and available to end-users. The profile also depends on the customization `MyCustomization` and modifies the layout of the **Customer List** to make the `Name` field invisible using the `modify` method. For more information, see Profile Properties.

```
profile MyProfile
{
    Description = 'Some internal comment that only the Dev can see';
    Caption = 'My User-friendly Name';
    ProfileDescription = 'A detailed description of who is this profile for, why/how to use it (etc)';
    RoleCenter = MyRoleCenter;
    Enabled = true;
    Promoted = true;
    Customizations = MyCustomization;
}

pagecustomization MyCustomization customizes "Customer List"
{
    layout
    {
        modify(Name)
        {
            Visible = false;
        }
    }
}
```

Pages Overview
Page Customization Object

Page Customization Object

2/17/2021 • 2 minutes to read • Edit Online

The page customization object in Dynamics 365 Business Central allows you to add changes to the layout and actions on page that are accessible for a profile. See Using keywords to place actions and controls for how to place actions and controls on a page customization object.

The page customization object has more restrictions than the page extension object; when you define a new page customization object, you cannot add variables, procedures, or triggers.

> **NOTE**
> A single page customization can be used with multiple profiles within the same extension. Page customizations only apply to the RoleCenters they are specified for. In order to view or changes the RoleCenters in the client, go to **My Settings** > **Role Center**.

> **NOTE**
> Extension objects can have a name with a maximum length of 30 characters.

> **NOTE**
> Modifying actions in Cue groups on page extensions is not supported.

> **NOTE**
> `showMyCode` does not apply to page customizations. Page customizations defined in an extension with `showMyCode` set to `false` can still be copied using Designer.

Snippet support

Typing the shortcut `tpagecust` will create the basic layout for a page customization object when using the AL Language extension in Visual Studio Code.

> **TIP**
> Use **Ctrl+Space** to trigger IntelliSense and get assistance on code completion, parameter info, quick info, and member lists.

Views

Views in Dynamics 365 Business Central are used on list pages to define a different view of the data on a given page. Views can be defined for Pages, Page Extensions, and Page Customization. For more information, see Views.

Page customization example

The following page customization example `MyCustomization` makes changes to **Customer List**. By using the `moveafter` method, `Blanket Orders` is moved after the `Orders` action item. And the `modify` method is used to hide the `NewSalesBlanketOrder` action item.

```
profile TheBoss
{
    Description = 'The Boss';
    RoleCenter = "Business Manager Role Center";
    Customizations = MyCustomization;
    Caption = 'Boss';
}

pagecustomization MyCustomization customizes "Customer List"
{
    actions
    {
        moveafter(Orders; "Blanket Orders")

        modify(NewSalesBlanketOrder)
        {
            Visible = false;
        }

    }
}
```

You can use the same page customization on another profile within the same extension package by referencing its name from the profile definition, for example:

```
profile TheSalesman
{
    ProfileDescription = 'The Boss';
    RoleCenter = "Sales Manager Role Center";
    Customizations = MyCustomization;
    Caption = 'Salesman';
}
```

Using the Client to Create Profiles and Page Customizations

2/17/2021 • 5 minutes to read • Edit Online

APPLIES TO: Business Central 2019 release wave 2 and later

Besides creating profiles and page customizations by writing AL code, you can use the client. The client is a useful alternative, because you work with the user interface just as the users would. This method is especially advantageous for consultants, application administrators, and less technical users.

Overview

For detailed instructions on how to use the client to create and modify profiles, see the following articles in the Business Central application help:

- Create Profiles
- Customize Pages for Profiles.

A consequence of using the client is that profile changes apply only to the tenant. Extension-based profiles and customizations, by contrast, are available for all tenants. However, the client lets you export user-created profiles and page customizations from a tenant, then import them on another tenant.

Profiles created in the client are marked as **(user-created)** profiles. The export and import functionality lets you:

- Backup profile and page customizations locally.
- Make further changes to profiles and page customizations away from the production environment.
- Replicate profiles and page customizations on other environments and tenants.
- Preview changes in sandbox environments before going into production.

> **IMPORTANT**
> You can't use the import functionality to migrate legacy profiles from Dynamics NAV or early versions of Business Central.

Exporting profiles

When you export profiles, the system exports all user-defined profiles and page customizations that have been made in the tenant. It doesn't export profiles and page customizations introduced by extensions.

To export profiles from the client, open the **Profiles (Roles)** page, and select the **Export Profiles** action. A zip file is downloaded to your computer. The file is referred to as a *profile package*.

Once you have the profile package, you can import it as-is to another tenant. Or, you extract the files and make more changes to profiles and page customizations. When you're done, you compress the files into a profile package again and import it on tenants.

> **NOTE**
>
> To export profiles, a user requires read permission to the **Profiles** page and table as a minimum. This capability allows normal users to hand over profiles to others for troubleshooting.

Importing profiles

Importing profiles lets you add new profiles and page customizations on a tenant or replace existing ones. To import profiles, do the following steps:

1. Get the profile package that contains the new or modified profiles.
2. Before you import a package, we recommend that you export the current profiles so you have a copy.
3. Open the **Profiles (Roles)** page, select the **Import Profiles** action, and follow the instructions to import the profile package.

   You don't have to import all profiles contained in the package. You can select specific profiles.

When you replace a profile, signed-in users of the profile may be interrupted briefly.

> **IMPORTANT**
>
> To import profiles, you must be assigned the **SUPER** or **D365 Profile Mgmt** permission set.

Working with the profile package and files

A profile package is a zip file that contains profile and page customizations in separate files. These files basically contain AL source code. The following table provides an overview of the file types in a profile package.

FILE TYPE	DESCRIPTION
app.json	A required configuration file that includes dependencies to the base application and system application. In most cases, you shouldn't modify this file after exporting it. The app.json must be included in the profile package that you import.
profile.json	A required configuration file that specifies information about the profiles in the package. In most cases, you shouldn't modify this file after exporting it. The profile.json must be included in the profile package that you import.
profile file	An AL file for a user-created profile. There's a separate file for each profile. A profile file has the format `Profile._<profile ID>_.al`.
profile extension file	An AL file for customizations made to an extension-based profile. These file types have the format `ProfileExtension._<profile ID>_.al`.
page customization file	An AL file that specifies all customizations made to a page for a specific profile. A page customization file has the format `PageCustomization._[page name]_.Configuration\ <number\>.al` .

The sections that follow explain a bit more about the file types and creating the profile package.

Profile files

Each user-created profile is exported to a separate AL file. This file contains the `profile` object that defines the profile's ID, name, and Role Center. It also includes references to the page customizations it uses. For example, let's say you created a profile with the ID **MyProfile** that uses the role center page **9022 Business Manager Role Center**. You then customized the Business Manager Role Center itself and the **Customer** list page. The exported profile package would contain a file called **PROFILE.MyProfile.al**. This file would include the following code:

```
profile MyProfile
{
  CaptionML = ENU='My Profile';
  Enabled = true;
  ProfileDescriptionML = ENU='This is my sample profiles';
  Promoted = true;
  RoleCenter = 9022;
  Customizations = Configuration1; Configuration2;
}
```

The `Customizations` property identifies the page customization objects used by the profile.

Profile extension files

Customizations made to extension-based profiles are exported to a profile extension file. This file includes a `profileextension` object that specifies two types of information, depending on the changes:

- Properties that specify metadata like, the CaptionML, ProfileDescriptionML, and RoleCenter.
- References to configuration files that define page customizations.

For example, let's say you changed the description and customized the **Customer** page for the **Business Manager** profile that is provided by the Base Application extension. The profile package would then contain the file **ProfileExtension._BUSINESS MANAGER.al**. This file will contain code similar to the following code:

```
profileextension BUSINESSMANAGER_1 extends "BUSINESS MANAGER"
{
  CaptionML = ENU='Business Manager';
  Enabled = true;
  ProfileDescriptionML = ENU='My changed functionality for managers in charge of keeping the business viable
by determining product and company direction.';
  Promoted = false;
  RoleCenter = 9022;
  Customizations = Configuration3;
}
```

`Configuration3` is a reference to a page customization file for the **Customer** page. For more information, see the next section.

Page customization files

Page customizations made to user-created profiles and extension-based profiles are exported to AL files that include a `pagecustomization` object. This object defines each modification to the page. Referring to the examples above, the zip file would include three files:

- PageCustomization.*Business Manager Role Center*.Configuration1.al
- PageCustomization.*Customer List*.Configuration2.al
- PageCustomization.*Customer List*.Configuration3.al

The files would include code similar to the following code:

PageCustomization.*Business Manager Role Center*Configuration1.al

```
pagecustomization Configuration1 customizes "Business Manager Role Center"
{
  layout
  {
    modify(Control16)
    {
    Visible = false;
    }
  }
  actions
  {
  }
}
```

PageCustomization.*Customer List*Configuration2.al

```
pagecustomization Configuration2 customizes "Customer List"
{
  layout
  {
    modify("Balance (LCY)")
    {
    Visible = false;
    }
  }
  actions
  {
  }
}
```

PageCustomization.*Customer List*Configuration3.al

```
pagecustomization Configuration3 customizes "Customer List"
{
  layout
  {
    modify("Balance Due (LCY)")
    {
    Visible = false;
    }
  }
  actions
  {
  }
}
```

Creating a profile package for import

After you make modifications to exported profiles and page customizations, you'll have to create the profile package before you can import the changes.

The profile package doesn't have to contain the same files that were originally exported. But it must contain the app.json and profile.json files. Otherwise, you can't import the package. To create the profile package, just compress the files into a zip folder.

Web Client URL

2/17/2021 • 10 minutes to read • Edit Online

There are several parameters that you can add to the Web client URL to manipulate what is displayed in the client. For example, you can open a specific company, target a specific page, report, or table. The following URL displays page **9305 Sales Order List** for the CRONUS International Ltd. company:

```
https://businesscentral.dynamics.com/?company=CRONUS%20International%20Ltd.&page=9305
```

The following URL opens report **5 Receivables – Payables** for the same company:

```
https://businesscentral.dynamics.com/?company=CRONUS%20International%20Ltd.&report=5
```

This article describes how you can construct URLs. A well-constructed URL can be useful for including in other sources, such as emails or Word documents, or sending as hyperlinks to other users.

> **IMPORTANT**
> Certain data in the URL, such as filters, could be considered sensitive information. Use discretion if you distribute URLs that contain filters, or if it's possible, exclude this information from the address.

URL Syntax

The Web client URL has the following syntax:

```
https://<hostname>[/<aadtenantid>][/<environmentname>]/?[company=<companyname>]&[page|query|report|table=
<ID>]&[tenant=<tenantID>]&[mode=<View|Edit|Create>]&[profile=<profileID>]&[customize]&[bookmark=<bookmark>]&
[captionhelpdisabled=<0|1>]&[showribbon=<0|1>]&[shownavigation=<0|1>]&[showuiparts=<0|1>]&[showheader=
<0|1>]&[isembedded=1]&[pagesize=<number of lines>]&[redirect<0|1>]&[extension=<extensionID>]
```

The URL consists of two parts; the hostname part and the query string. The hostname part includes the protocol (https) and the hostname. The query string part includes everything after `<hostname>`. The query string determines what content to target.

Syntax Key

The following table describes the notation that is used to indicate the syntax.

NOTATION	DESCRIPTION
Text without brackets	Parameters that you must type as shown.
`<>`	A placeholder for values that you must supply. Don't include the brackets in the address.
`[]`	Optional parameters. Don't include the brackets in the address.

NOTATION	DESCRIPTION
`|`	A set of values from which to choose. Use one of the options and don't include `|` in the address.

Building the URL

Use the following guidelines to write URL syntax and create a URL:

- You can place parameters in any order after `/?`. For example, the following URLs will yield the same results.

```
https://businesscentral.dynamics.com/?company=CRONUS%20International%20Ltd.&page=9305&mode=View
```

```
https://businesscentral.dynamics.com/?page=9305&mode=View&company=CRONUS%20International%20Ltd.
```

- Separate parameters after `/?` with the ampersand symbol (`&`).
- Use `%20` for any spaces in values, or similar escape sequences for other characters that can't be used in URLs.
- Enclose values in single quotation marks (`''`) if they're unescaped.

URL Parameters

The following table describes the parameters of the URL for displaying a page.

PARAMETER	DESCRIPTION
`https`	Specifies the Internet protocol to use. Only `https` is supported.
`hostname`	Specifies the hostname for Dynamics 365, for example, `businesscentral.dynamics.com`.
`<aadtenantid>`	Specifies the unique identifier for an Azure Active Directory (AAD) tenant. The value can be formatted as a GUID or domain name. It's useful to people who work across multiple AAD organizations, such as delegated administrators, support personnel, or external accountants. It allows explicitly targeting an AAD tenant. If this parameter is omitted, you'll be directed to the primary AAD tenant or the same AAD tenant that you're currently signed in to.
`<environmentname>`	(online only) Specifies the display name of sandbox or production environment to target.
`company`	The name of the company in Dynamics 365 that you want to target. If you only have one company, then you can omit this parameter.
`page`	Opens a page object.

PARAMETER	DESCRIPTION
`query`	Opens a query object. **Note:** The TopNumberOfRows property is ignored when the query opens in the browser.
`report`	Opens a report object.
`table`	Opens a table object. Opening a table requires special permissions. For more information about opening a table, see Viewing Table Data.
`ID`	The ID of the page, report, or table to open.
`tenant`	(on-premises only) Specifies the ID of the tenant to connect to. Use this parameter when Web client is deployed in multitenant architecture. The tenant that you specify must be mounted on the Dynamics 365 Business Central service instance that the Web client connects to. For more information, see Multitenant Deployment Architecture.
`mode`	Specifies the mode in which to display the page when it opens. Once the page opens, you can switch modes as usual, unless restricted by the page itself. - `View` The page can only be viewed. The user can't change data on the page. **Note:** Worksheet page types only display in the edit mode, even if the value is set to `View`. - `Edit` The user can change data on the page. **Note:** To use the edit mode, the Editable Property of the page in Page Designer must be set to **Yes**. This mode isn't supported for pages of the type List, RoleCenter, and CardPart. If you set the value to `Edit`, pages of these types still display in the view mode. For List type pages, the user can modify the list by choosing **Edit List** on the page. - `Create` Opens a blank page that enables the user to create a new item. **Note:** The `Create` mode isn't supported for pages of the type CardPart, List, ListPart, RoleCenter, and Worksheet. For pages of the type CardPart, List, and ListPart, the page displays in the view mode. Don't use this mode for Worksheet pages; otherwise you'll get an error when you try to open the page.

PARAMETER	DESCRIPTION
`profile`	Specifies the ID of the profile to open, such as `accountant` or `order processor`. It's possible for two or more profiles have the same ID. Profiles can have a scope of either system or tenant. Also, tenant profiles can be either user-defined (added by using the **Profiles** page in the client) or extension-based (added by an extension). Among these different types, the IDs of some profiles might be the same. If there's more than one profile with the same ID as you provide, the profile is selected as follows: 1. If there's a matching system profile, it's used. 2. If there's a matching user-defined tenant profile, it's used. 3. If there's only one matching extension-based profile, it's used. 4. If there are two or more extensions-based profiles with the same ID, then the error message `More than one profile has the ID '<ID>' within the Tenant scope.` appears. In this case, you can't use the `profile` parameter for this profile.
`customize`	Opens the profile for customization, enabling you to change the layout of pages as seen by users of the profile. If you omit the `profile`, then the default profile opens. For more information, see Customizing the Workspace for Profiles (Roles) in the Business Central Application Help.
`bookmark`	Specifies a record in the underlying table of the page. The value of a bookmark is an alphanumeric string of characters, for example, `27%3bEgAAAAJ7CDAAMQA5ADAANQA4ADkAMw%3d%3`. For the page types Card, CardPart, and Document, the bookmark specifies the record that is shown in the page. For page types List, ListPart, and Worksheet, the bookmark specifies the record that is selected in the list on the page. **Important:** Bookmarks are generated automatically. You can only determine a value for the bookmark by displaying the page in the Web client and looking at its address. So, a bookmark is only relevant when the address you're working with was copied from another page instance.
`captionhelpdisabled`	Specifies that the ability to look up Help by selecting a field caption is disabled. If you want the Help look up from the field captions, either omit this parameter or set its value to `0`, such as `captionhelpdisabled=0`. If you don't want the Help lookup from field captions, set the value to `1`, such as `captionhelpdisabled=1`. **Note:** For this parameter to take effect, add it at the first request when the user signs in. Adding the parameter on an existing session has no effect.

PARAMETER	DESCRIPTION
`showribbon`	Specifies whether to show the action bar on pages when they open. To show the action bar, omit this parameter or use `showribbon=1`. To hide the action bar, use `showribbon=0`. When you hide the action bar, it will remain hidden as you move to different pages, until you refresh or reload the browser or use `showribbon=1` in the URL. Once you move to another page, the parameter is no longer shown in the URL, even though it's still in effect.
`shownavigation`	Specifies whether to show the navigation bar when the specified page opens. To show the navigation bar, omit this parameter or use `shownavigation=1`. To hide the navigation bar, use `shownavigation=0`. When you hide the navigation bar, it will remain hidden as you move to different pages, until you refresh or reload the browser or set `shownavigation=1` in the URL. Once you move to another page, the parameter is no longer shown in the URL, even though it's still in effect.
`showuiparts`	Specifies whether to show UI parts when the specified page opens. To show parts, omit this parameter or use `showuiparts=1`. To hide parts, use `showuiparts=0`. This parameter only affects parts that are shown in FactBoxes. Once you move to another page, the parameter is cleared.
`showheader`	Specifies whether to show the **Dynamics 365 Business Central** header and its functionality. To show the header, omit this parameter or use `showheader=1`. To hide the header, use `showheader=0`. The header is the bar at the top of pages. It gives access to the general functionality like **Tell Me**, **Notifications**, **My Settings**, and more. When the header is hidden, functionality that has a keyboard shortcut, like **Tell Me**, is still accessible by the shortcut. The parameter is preserved when you move to other pages and if you refresh or reload the browser. **Note:** Introduced in Business Central 2020 release wave 1, update 16.2.
`isembedded`	Specifies to open the Business Central Web client in the embedded mode. To set the embedded mode, use `isembedded=1`. This parameter is intended for use when Business Central Web client is embedded in another web application, like SharePoint. The embedded mode hides the **Dynamics 365 Business Central** header and adjusts how navigation works to suit the web application. For more information, see Embedding Business Central Web Client in Other Websites.

PARAMETER	DESCRIPTION
`pagesize`	Specifies the number of lines to display in a list. For example, `pagesize=10` specifies that 10 lines will be displayed. The default value, if the parameter isn't specified, is `20` The parameter applies only to pages that contain a `repeater` control. It's intended for use when Business Central Web client is embedded in another web application, like SharePoint. For more information, see Embedding Business Central Web Client in Other Websites.
`redirect`	Specifies whether users are presented with an option to download the Business Central Mobile App when they open the Web client in a mobile browser to improve the user experience. If you don't want to give users this option, set the value to `0`, such as `redirect=0`.
`extension`	Specifies the unique identifier (ID) of an extension that is deployed on the environment. This parameter is typically used during the development of the specified extension in a non-production environment. When this parameter is set, only the specified extension is available in the client, and the client opens in Designer. All other extensions are ignored and not visible. This parameter enables you to isolate and focus on the behavior of the specified extension only. An extension ID is a 32-digit GUID, such as `72CC5E27-BD97-4271-AF55-F77E4471E493`. You set this parameter using the format `extension={GUID}`, for example: `&extension={72CC5E27-BD97-4271-AF55-F77E4471E493}` You can determine an extension ID by opening the extension in Visual Studio Code and looking in the app.json file. Or, you can run the Get-NAVAppManifest cmdlet on the extension package.

Filtering Data on the Page

You can filter the data that is displayed in the page by using the filter parameter. The filter parameter let you display specific records from the underlying table of the page.

Example

The following address displays data in page 9305 only for the customer who has the **Sell-to Customer No.**=10000 and the **Location Code**=Blue.

```
https://businesscentral.dynamics.com/?company=CRONUS%20International%20Ltd.&page=9305&filter='Sell-to
Customer No.' IS '10000' AND 'Location Code' IS 'BLUE'
```

Filter Syntax

The filter has the following syntax.

```
&filter='<field>' IS '<value>'[ AND '<field>' IS '<value>']
```

Include a space or `%20` before and after the `IS` and `AND` operators. You can add the filter anywhere in the address after `/?`.

Filter Parameters

The following table describes the filter parameters.

PARAMETER	DESCRIPTION
`field`	The name of the table field on which to filter.
`IS`	Specifies the equal operator.
`value`	The value of the table field on which to filter.
`AND`	Use this parameter to specify more than one filter. It specifies an "and" operator for adding additional filters. Place `AND` between each additional filter. To be included in the page data, the table record must match values for all fields in the filter.

Linking to the Dynamics 365 Business Central App

2/17/2021 • 4 minutes to read • Edit Online

The protocol handler for the Business Central Mobile App lets you construct a URL for starting the app on a device, such as a phone or tablet. You can then distribute this URL by e-mail or from a Web page to the users.

The Business Central Mobile App URL is based on the *ms-businesscentral* URI scheme, which is registered automatically when the app is installed. Invoking a URL based on this scheme will start the app with the provided parameters.

Constructing the URL

To construct a URL, start with *ms-businesscentral* scheme, and then add additional parameters as needed. Some parameters are required and others are optional.

The structure of a Business Central Mobile App link is very similar to links for the Web client, and has the following syntax:

```
ms-businesscentral://[<hostname>][/<aadtenantid>][/sandbox]/[?<parameter>=<value>[&<parameter>=<value>]]
```

`[]` indicates an optional parameter; all other parameters are required.

`<>` indicate values that you must supply. Do not include the brackets in the address.

Parameters

The following table describes the parameters for the main part of the URL, which are the parameters up to and including `[/sandbox]/`.

PARAMETER	DESCRIPTION	EXAMPLE

hostname	Domain name for the Dynamics 365 Business Central solution or IP address of the computer/server that hosts it. This is required for an ISV Embed solution. For standard Business Central, you use `businesscentral.dynamics.com` or you can omit this parameter.	`ms-businesscentral://businesscentral.dynamics.com/`
		`ms-businesscentral:///`
		`ms-businesscentral://businesscentral.mysolution.com/`

aadtenantid	The unique identifier for an Azure Active Directory (AAD) tenant. The value can be formatted as a GUID or domain name. This is useful to those who work across multiple AAD organizations, such as delegated administrators, support personnel or external accountants, because it allows explicitly targeting an AAD tenant. If this is omitted, you will be directed to the primary AAD tenant or the same AAD tenant that you are currently signed in to.	`ms-businesscentral://businesscentral.mysolution.com/mysolutionaadtena`
sandbox	Specifies that the URL should target the Dynamics 365 Business Central sandbox environment instead of a production environment.	`ms-businesscentral:/businesscentral.dynamics.com/sandbox/` `ms-businesscentral://businesscentral.mysolution.com/sandbox/`

The following table describes the optional parameters that are indicated by `[?<parameter>=<value>[&<parameter>=<value>]]` in the syntax. These parameters are referred to as the *query parameters*.

PARAMETER	DESCRIPTION	EXAMPLE
page	The ID of the page that you want to open directly.	`ms-businesscentral:///?page=21` `ms-businesscentral://businesscentral.mysolution.com/?page=21`

PARAMETER	DESCRIPTION	EXAMPLE

bookmark	The bookmark of the record you want to open. The value of a bookmark is an alphanumeric string of characters, for example, `19%3bGwAAAAJ7BDEAMAAwADA%3d`.
	
	For the page types Card, CardPart, and Document, the bookmark specifies the record that is shown in the page. For page types List, ListPart, and Worksheet, the bookmark specifies the record that is selected in the list on the page.
	
	Important: Bookmarks are generated automatically. You can only determine a value for the bookmark by displaying the page in the client and looking at its address. Therefore, a bookmark is only relevant when the address you are working with has been copied from another instance of the page.
		`ms-businesscentral:///?bookmark=19%3bGwAAAAJ7BDEAMAAwADA%3d`
		
		`ms-businesscentral://businesscentral.mysolution.com/?bookmark=19%3bGwAAAAJ7BDEAMAAwADA%3d`

filter	The filter you want to apply to the page.
	
	The filter parameter enables you to display only records from the underlying table of the page that have specific values for one or more fields. For more information about filters, see Filtering Data on the Page.
		`ms-businesscentral:///?page9305&filter='No.'%20IS%20'1001'`
		
		`ms-businesscentral:///?page9305&filter='Sell-to-Customer-No.'%20IS%20'10000'%20AND%20'Location-Code'%20IS%20'BLUE'`
		
		`ms-businesscentral://businesscentral.mysolution.com/?page9305&filter='No.'%20IS%20'1001'`
		
		`ms-businesscentral://businesscentral.mysolution.com/?page9305&filter='Sell-to-Customer-No.'%20IS%20'10000'%20AND%20'Location-Code'%20IS%20'BLUE'`

profile	Specifies the ID of the profile to open, such as `accountant` or `order processor`.
	
	Be aware that it is possible for two or more profiles have the same ID. Profiles can have a scope of either system or tenant. In addition, tenant profiles can be either user-defined (added by using the **Profiles** page in the client) or extension-based (added by an extension). Among these different types, the IDs of some profiles might be the same. When there is more than one profile with the same ID as the one you provide, the process for launching the profile is as follows:
	1. If there is a matching system profile, it is used.
	2. If there is a matching user-defined tenant profile, it is used.
	3. If there is only one matching extension-based profile, it is used.
	4. If there are two or more extensions-based profiles with the same ID, then the error message `More than one profile has the ID '<ID>' within the Tenant scope.` appears. In this case, you cannot use the `profile` parameter for this profile.
		`ms-businesscentral:///?profile=BUSINESS%20%MANAGER`
		
		`ms-businesscentral://businesscentral.mysolution.com/?profile=BUSINESS%20%MANAGER`

PARAMETER	DESCRIPTION	EXAMPLE
`customize`	Opens the profile for customization, enabling you to change the layout of pages as seen by users of the profile. If you omit the `profile`, then the default profile opens. For more information, see Customizing the Workspace for Profiles (Roles) in the Business Central Application Help.	
company	The company that you want to open in the client. If not provided, the default company is used. CRONUS%20International%20Ltd.	`ms-businesscentral:///?'company=CRONUS%20International%20Ltd.'` `ms-businesscentral://businesscentral.mysolution.com/?'company=CRONUS%`
mode	Whether the page opens in view, edit, or create mode. `view` only lets you see the data on the page, not modify data. `edit` lets you to modify data on the page. `create` lets you to modify data on the page and add new entities.	`ms-businesscentral:///?page=21&mode=create` `ms-businesscentral://businesscentral.mysolution.com/?page=21&mode=create`

The query parameters can be in any order. However, the first parameter must be preceded by the `?` symbol, and any additional parameters must be preceded by the `&` symbol.

Introducing the Business Central Mobile App

Working with Translation Files

2/17/2021 • 4 minutes to read • Edit Online

Dynamics 365 Business Central is multilanguage enabled, which means that you can display the user interface (UI) in different languages. In Dynamics 365 Business Central this is done using XLIFF files, which is a standardized format used for computer-based translations.

Generating the XLIFF file

To add a new language to the extension that you have built, you must first enable the generation of XLIFF files. The XLIFF file extension is .xlf. The generated XLIFF file contains the strings that are specified in properties such as **Caption**, **CaptionML**, and **Tooltip**.

> **NOTE**
> To submit an app to AppSource, you must use XLIFF translation files.

In the app.json file of your extension, add the following line:

```
"features": [ "TranslationFile" ]
```

Now, when you run the build command (**Ctrl+Shift+B**) in Visual Studio Code, a `\Translations` folder will be generated and populated with the .xlf file that contains all the labels, label properties, and report labels that you are using in the extension. The generated .xlf file can now be translated.

> **IMPORTANT**
> Make sure to rename the translated file to avoid that the file is overwritten next time the extension is built.

By setting the `GenerateCaptions` flag in the app.json file, you specify that you want to generate captions based on the object name for pages, tables, reports, XMLports, request pages, and table fields. If the object already has a `Caption` or `CaptionML` property set, that value will be used, for table fields the `OptionCaption` is used. The syntax is the following:

```
"features": [ "TranslationFile", "GenerateCaptions" ]
```

GenerateLockedTranslations

APPLIES TO: Business Central 2020 release wave 2 and later

By setting the `GenerateLockedTranslations` flag in the app.json file, you specify that you want to generate `<trans-unit>` elements for locked labels in the XLIFF file. The default behavior is that these elements are not generated. For more information, see JSON Files.

```
"features": [ "GenerateLockedTranslations" ]
```

Label syntax

The label syntax is shown in the example below for the **Caption** property:

```
Caption = 'Developer translation for %1',  Comment = '%1 is extension name', locked = false, MaxLength=999;
```

> **NOTE**
>
> The `comment`, `locked`, and `maxLength` attributes are optional and the order is not enforced. For more information, see Label Data Type.

Use the same syntax for report labels:

```
labels
{
  LabelName='LabelText',Comment='Foo',MaxLength=999,Locked=true;
}
```

And the following is the syntax for **Label** data types:

```
var
a:Label'LabelText',Comment='Foo',MaxLength=999,Locked=true;
```

> **IMPORTANT**
>
> The **ML** versions of properties are **not** included in the .xlf file:
>
> - CaptionML
> - ConstValueML
> - InstructionalTextML
> - OptionCaptionML
> - PromotedActionCategoriesML
> - RequestFilterHeadingML
> - ToolTipML
>
> The TextConst Data Type is not included in the .xlf file either.

The XLIFF file

In the generated .xlf file, you can see a `<source>` element for each label. For the translation, you will now have to add the `target-language` and a `<target>` element per label. The `<trans-unit id>` attribute corresponds to the object ID in the extension. This is illustrated in the example below.

```
<?xml version="1.0" encoding="utf-8"?>
<xliff version="1.2" xmlns="urn:oasis:names:tc:xliff:document:1.2"
xmlns:xsi="https://www.w3.org/2001/XMLSchema-instance"
xsi:schemaLocation="urn:oasis:names:tc:xliff:document:1.2 xliff-core-1.2-transitional.xsd">
  <file datatype="xml" source-language="en-US" target-language="da-DK" original="ALProject16">
    <body>
      <group id="body">
        <trans-unit id="PageExtension 50110" maxWidth="999" size-unit="char" translate="yes"
xml:space="preserve">
          <source>Developer translation for %1</source>
          <target>Udvikleroversættelse for %1</target>
          <note from="Developer" annotates="general" priority="2">%1 is extension name</note>
          <note from="Xliff Generator" annotates="general" priority="3">PageExtension - PageExtension</note>
        </trans-unit>
      </group>
    </body>
  </file>
</xliff>
```

NOTE

You can have only one .xlf file per language. If you translate your extension to multiple languages, you must have a translation file per language. There is no enforced naming on the file, but a suggested good practice is to name it `<extensionname>.<language>.xlf`.

When the extension is built and published, you change the language of Dynamics 365 Business Central to view the UI in the translated language.

Translating other extensions

To translate other extensions, for example, adding translations to the Base Application, you must reference the project to be translated using the `dependencies` section in the app.json file. For more information, see JSON Files. When you have the dependencies added, you can add xliff files in your current project that translates the object captions of the referenced extension. Create a directory named **Translations** in the root of the extension, and place the translated xliff file there. When your extension is then built and published, change the language of Dynamics 365 Business Central to view the UI in the translated language.

Translation and Localization apps

NOTE

The following section only applies to versions released before Business Central 2019 release wave 2.

The .xlf files approach cannot be used for translating the base application. If you are working on a translation or localization app (for example for a country/region localization), you must take the .txt file containing the base application translation, and place the file in the root folder of your extension. When the extension is compiled, the .txt file is then packaged with the extension.

We recommend that you use only one .txt file per language. There is no enforced naming on the .txt files, but a suggested good practice is to name it `<extensionname>.<language>.txt`.

For more information about importing and exporting .txt files, see How to: Add Translated Strings By Importing and Exporting Multilanguage Files in Dynamics NAV.

Introducing the Dynamics 365 Business Central Mobile App

2/17/2021 • 3 minutes to read • Edit Online

The app displaying the Business Central tablet client and Business Central phone client is targeted at users in small and medium sized businesses that want to access data from a tablet or a phone. The main advantages of this offering are portability and flexibility, which allows end users to perform tasks when they are away from their desk. Having a Dynamics 365 Business Central solution that runs on a smaller device also brings it in the hands of many more users and your app is easy to distribute.

> **IMPORTANT**
>
> The Business Central tablet client and Business Central phone client do not replace the Business Central Web client. Instead, they offer a touch interface for a limited set of application scenarios compared to the Business Central Web client.

The Business Central Web client supports more complex business processes and heavier data entry than it is possible on the Business Central tablet client and Business Central phone client. Business Central is also designed for intensive use, and the user can have multiple windows open at the same time, but this is neither possible in Business Central phone client or Business Central tablet client. For more information, see Differences and Limitations When Developing Pages for the Business Central Mobile App.

The design for the Business Central tablet client is optimized for the touch experience and reduced use of the on-screen keyboard. On the other hand, the design for the Business Central phone client is about touch optimization, given its smaller screen size. The Business Central phone client layout is designed to support one-hand and both hands use, which allows the important data and buttons to be available within thumbs reach.

> **NOTE**
>
> In this documentation, you will see mentions of Business Central tablet client, Business Central phone client, and *Dynamics 365 Business Central Mobile App*. Business Central tablet client and Business Central phone client describe the interface tailored to the category of mobile device, which is one of the tools available for developers for designing mobile solutions, whereas *Dynamics 365 Business Central Mobile App* is the common name for the app across all devices; the end result made with these tools.

Considering the user scenarios

When you design your solution for the Business Central tablet client and the Business Central phone client, you must make sure that scenarios are simple enough to be meaningful and usable. The tablet and phone designs are meant for lighter tasks and are useful, for example, for traveling salespeople or service technicians who need a portable, online, easy-to-use app that provides an overview, for example, of daily tasks and items in stock.

Depending on the scenarios that your tablet and phone solution will support, it will either make sense to create a new Role Center for tablet and phone only, or share the same Role Center across all of the client types. In some cases, it can make sense to have a user sign in with two different profiles, one for a desktop client and one for mobile devices. In other cases, duplicating pages and designing specific duplicates to be device-oriented is the best solution.

If you have existing page objects that you want to make available on Business Central tablet client or Business Central phone client, we strongly recommend that you plan time to evaluate carefully which actions, sections,

and fields will be needed for the user scenarios you want to enable. Fields and actions that are not needed should not be visible to users of your app. The UI must be simplified significantly to work well on a small device. For more information, see Designing for Different Screen Sizes on Tablet and Phone.

Supported credential types

Business Central tablet client and Business Central phone client support the same credential types as Business Central Web client. For more information, see Authentication and Credential Types.

Differences and Limitations When Developing Pages for the Dynamics 365 Business Central Mobile App

Deciding on Your Tablet and Phone Strategy

2/17/2021 • 3 minutes to read • Edit Online

To offer users a great mobile experience, you must decide on a strategy for how to accomplish this based on an analysis of your users' needs. This topic explains the different options for developing for the Business Central tablet client and Business Central phone client, but the documentation you will find in this section is primarily focused on the first of these scenarios.

Mobile app development strategy

This section briefly describes some of the options that exist for Dynamics 365 Business Central.

DEVELOPMENT STRATEGY	WHAT ALSO TO CONSIDER	EXAMPLES	FOR MORE INFORMATION, SEE
Business Central platform Use the AL Language development environment to modify and extend the Business Central tablet client and Business Central phone client.This scenario resembles developing for Business Central Web client. The main advantages of this strategy are: - Extending and modifying Business Central tablet and phone clients is useful for a minimal learning curve and a reduction of development costs; scenarios automatically work on multiple operating systems without having to worry about the maintenance. - You can reuse existing investments in Dynamics 365 Business Central page objects, business logic, and javascript-based client add-ins. Ideal for user scenarios which can be achieved by using simple application pages.	Dynamics 365 Business Central only supports a specific number of page types, and this can be a limitation in some type of development projects.	- For salespeople tracking customers, looking up item details, and capturing orders. - For technicians on the road using and re-ordering spare parts. - For simple approval scenarios.	Introducing the Dynamics 365 Business Central Mobile App Getting Started Developing for the Dynamics 365 Business Central Mobile App

DEVELOPMENT STRATEGY	WHAT ALSO TO CONSIDER	EXAMPLES	FOR MORE INFORMATION, SEE
Power App Use the Power Apps platform connected to Business Central either using the Business Central connector in Power Apps or custom connector and access your modify data.	The standard Business Central connector for Power Apps only supports built in APIs, so you may need to use custom connector feature to access your custom APIs.	For field salesforce in need of user experience that is more customized or tightly connected to 3rd party software or hardware.	Connecting to Your Business Central Data to Build a Business App Using Power Apps Create a canvas app from a template in Power Apps
Connected mobile app Based on OData web services or SOAP web services technologies, write an app that interacts with Dynamics 365 Business Central. Visual Studio includes project templates for this kind of app. This strategy applies when you want to build a highly customized app with your own UI design that takes advantage of all the rich features which native apps provide.	Cost to learn development tools and languages outside AL, preparing new development environments. Cost of licensing any of these tools, and having to maintain code for different operating systems.	A simple touch interface for users to scan their access card for time registration.	OData Web Services Data Modification OData Web Services SOAP Web Services Web Services

Remarks

If you are developing using the AL language, use a browser for continuous development and test of the Business Central tablet client and the Business Central phone client solution that you are working on. Switching to running in a browser is an easy and efficient way to test what new and modified pages look like. Running the Business Central tablet client and Business Central phone client in a browser is only recommended for development scenarios. For more information, see Opening the Dynamics 365 Business Central Tablet or Phone Client from a Browser.

Getting Started Developing for the Dynamics 365 Business Central Mobile App
Introducing the Business Central Mobile App

Getting Started Developing for the Dynamics 365 Business Central Mobile App

2/17/2021 • 2 minutes to read • Edit Online

The Business Central tablet client and Business Central phone client are built on the same framework as the Business Central Web client, such that they are all based on the same Dynamics 365 Business Central pages. Developing for Business Central tablet client and Business Central phone client is not much different from developing pages for Business Central Web client either, since it is also done from the AL Language development environment.

Steps for Developing for the Business Central tablet client and Business Central phone client

The first step to take when you are developing for the Business Central tablet client and Business Central phone client is to consider the design and implementation of the solution:

- What is the business scenario that you want to support?
- Do you want to extend your existing data model?
- Should the solution work well on both a desktop computer, on the tablet and also on a phone?
- What design should the Role Center that will be the central dashboard for the solution have?

Understanding the business scenario is important to build the best solution. Design your solution for users who are most typically occasional users who need an overview of their daily work status and perform relatively simple or light data entry. Many of these preparations resemble those for developing for Business Central Web client, but in an even smaller scale.

Once the data model, users, permissions, and profiles are in place, you can start developing the Role Center. You can either reuse an existing Role Center or create a new one. This will depend on the business scenario. The Business Central tablet client and the Business Central phone client are designed to be smart about laying out the same Role Center depending on the display target.

When developing for the Business Central phone client you want to think even more about design and usability on a very small screen. On the phone the app will always by default start a page in view mode, meaning that the user actively must switch to edit mode.

There are some best practices and limitations to consider in particular caused by the smaller screen size and touch experience. For more information, see Differences and Limitations When Developing Pages for the Dynamics 365 Business Central Mobile App. On devices that run the Business Central Mobile App and have a camera and location capability you also have a couple of additional options. For more information, see Implementing the Camera in AL and Implementing Location in AL.

To complete designing your Business Central Mobile App solution, you should consider offering users Help, to guide them through pages or workflows. For more information about adding help to your solution, see Extend, Customize, and Collaborate on the Help for Dynamics 365 Business Central.

The next steps are to consider how to deploy your solution and how to distribute it to your customers. After you have completed your solution, you can send an e-mail to the users to let them know that they can download Dynamics 365 Business Central from the relevant store and include the organization URL and sign-in information. For more information, see Linking to the Dynamics 365 Business Central Mobile App.

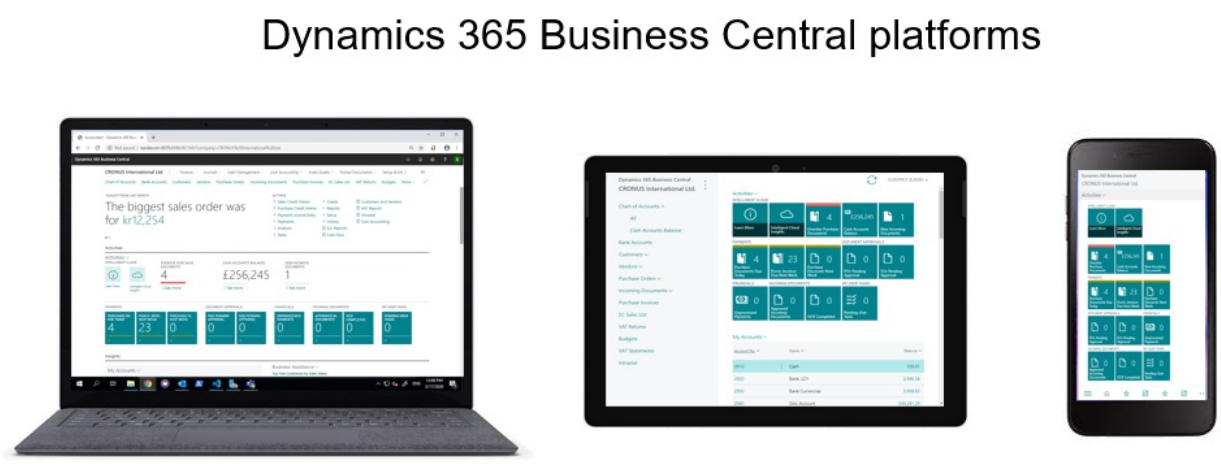
Differences and Limitations When Developing Pages for the Dynamics 365 Business Central Mobile App

Designing for Different Screen Sizes on Tablet and Phone

2/17/2021 • 2 minutes to read • Edit Online

When designing application pages for the Business Central tablet client and the Business Central phone client, it is best practice to consider the size of the tablets or phones that your end users have access to. It is an advantage if the solution works well on both small and large screen sizes, but we also recommend that you consider thoroughly the most frequently used screen sizes for your end user experience.

Designing for small screens can be more challenging, because pages will show fewer fields, columns, and tiles. Therefore, a good way to identify issues on how your application pages are displayed is to test on the smallest supported screen size.



Form factor considerations

Users can scroll both the navigation and the content area of the Business Central Mobile App on a tablet to access all data for a given page. However, it is recommended that the scrolling in the navigation bar is minimal. The navigation bar is the area on the left-hand side of Business Central Mobile App and it is designed to provide easy access to important information and tasks that the user should not lose sight of when scrolling on the content area.

On phones the Business Central Mobile App displays only one part at a time on the Role Center. On the Home page, the Activity tiles are always displayed first, and you navigate through the bottom menu to explore the content area.

Guidance for page element types on smallest tablet devices

The following table provides a list of elements that fit in the page content or the app bar without scrolling.

PAGE TYPE	DISPLAYS ON SMALLEST TABLET DEVICE
RoleCenter	4 tiles in 1 group, or 2 groups together with 2 tiles
List Pages	5 columns of type Text50 or 8 columns of type Text20

PAGE TYPE	DISPLAYS ON SMALLEST TABLET DEVICE
Card Pages	- CardPage Factbox with up to 15 fields - 2 CardPage Factboxes with up to 6 fields each - Activities Factboxes with 4 tiles in 1 group, or 2 groups together with 2 tiles
Document Pages	- CardPage Factbox with up to 15 fields - 2 CardPage Factboxes with up to 6 fields each - Activities Factboxes with 4 tiles in 1 group, or 2 groups together with 2 tiles

Testing using a browser

Using a browser you can test how your application pages will look on various device sizes. For more information, see Opening the Business Central Tablet or Phone Client from a Browser.

When running Business Central tablet client or Business Central phone client in a browser, you can use Microsoft Edge Developer Tools to emulate different screen sizes. For more information, see Microsoft Edge Developer Tools.

Differences and Limitations When Developing Pages for the Business Central Mobile App

2/17/2021 • 4 minutes to read • Edit Online

Developing for the Business Central tablet client and Business Central phone client is similar to developing for the Business Central Web client. However, there some natural limitations on tablets and phones, such as not having a physical keyboard and mouse, as well as a smaller screen.

Differences and limitations overview

The following table describes some of the most common differences and limitations that you might experience when developing for Business Central tablet client and Business Central phone client.

CONCEPT	ON TABLET	ON PHONE	EXAMPLE	RECOMMENDATION/ REMARKS
Activity groups	Only the **Home** activity group is shown.	Only the **Home** activity group is shown.	**Home** and **Posted Documents** on the `Sales Order Processor` Role Center.	Design pages to expose the workflows needed by the user. For example, configure the profile to show the important list pages under the **Home** activity group. Alternatively, consider designing a new Role Center if the activities for the activity group greatly vary from activities in other activity group.
Selecting multiple records in lists	Not available.	Not available.	`Ctrl+A` or `Ctrl+Click` on rows in a list using Business Central Web client.	Avoid scenarios requiring selecting multiple rows on a list. Also, try to minimize actions on lists.
Actions in the action bar	Only Promoted actions are shown.	Only Promoted actions are shown.	On the `Small Business` Role Center.	Use the development environment to promote actions. Alternatively, configure the profile and add actions to the Home tab.
FactBoxes	Not shown on List pages or Worksheet pages.	Not shown on List pages or Worksheet pages.	`Customer` list on the `Small Business` Role Center.	Make sure the same information is visible on the corresponding card page of the given record.

CONCEPT	ON TABLET	ON PHONE	EXAMPLE	RECOMMENDATION/ REMARKS
Advanced filters	No column-specific filtering is available.	No column-specific filtering is available.	On the `Customer` list page.	Send data to Excel and do the complex filtering there.
Tell Me	Not available yet.	Not available yet.	On Business Central Web client.	Design pages to expose the workflows needed by the user. For example via list places, tiles or actions.
Role Explorer	Not available yet.	Not available yet.	On Business Central Web client.	Design pages to expose the workflows needed by the user. For example via list places, tiles or actions.
Fields in FastTabs	Fields in FastTabs on list pages are not shown. Only the repeater control is shown in the content area of the page.	Not available.		Design List pages to avoid having important columns on the far right of the column list. Assume you have no control over how many columns are displayed and consider that only the first few columns will be made visible.
Select from full list	Not available on lookups. Users are not able to run actions on a lookup page, and they cannot access the full set of records.	Not available on lookups. Users are not able to run actions on a lookup page, and they cannot access the full set of records.	On the `Item Card` when selecting the **Base Units of Measure**.	Make sure the appropriate columns are visible on the lookup. The user is still able to filter, scroll, and search through the lookup.
Search across list columns	Partly supported. Search will not include FlowFields.	Partly supported. Search will not include FlowFields.	On the `Customer` list page.	
Lookups	Available.	Available, with the difference that advanced and simple lookups behave similarly on the phone. The lookup will not bring up the card, show FactBoxes, or any field groups.	See examples on the `Customer Card` page.	
Matrix controls	Not available.	Not available.	See example in `G/L Budget`.	

CONCEPT	ON TABLET	ON PHONE	EXAMPLE	RECOMMENDATION/ REMARKS
File download	Available. Cannot download multiple files at the same time.	Available. Cannot download multiple files at the same time.	`Trial Balance` report in the **Print to Excel** check box.	
Worksheet pages	Available.	Not available; an error message is displayed.	`Sales Price` Worksheet or `Cash Flow` Worksheet.	Run this type of page from the Business Central Web client, or Business Central tablet client.
Lists	Available.	Available, with the difference that these are displayed in a brick layout with a number of differences and limitations. For an overview, see Displaying Data as Tiles.	Customers or Sales Orders pages.	
Indentation in repeater controls	Available.	Not available. The repeater control will be rendered as a regular flat brick layout.	Chart of Accounts and Contacts List pages.	
Scope of actions	Available.	Available, but there are some behavioral differences regarding the Scope Property. Also, see Defining Action Scope for Business Central Pages.		
Automatic input focus on first editable field of a page	Not available.	Not available.	`Customer Card` page. In the Web client, focus will automatically be on the first editable field (such as the `Name` field), enabling you to change the value right away. In the Tablet or Phone client, this field will not be in focus; instead, you will have to manually select the field first in order to make changes.	The reason for this behavior is to prevent the in-app keyboard from initially displaying and occupying screen space.

Opening the Business Central Tablet or Phone Client from a Browser

2/17/2021 • 2 minutes to read • Edit Online

You can open the Business Central tablet client or the Business Central phone client by using a browser from a device that has a network connection. This can make it easier to test your solution during the design phase.

> **IMPORTANT**
>
> The steps in this article illustrates how you can open the Business Central tablet client in a browser. The syntax and options for opening Business Central phone client in a browser are the same; just replace *tablet* with *phone* in the examples later in this section.

To open Business Central tablet client in a browser

1. Open the web browser.
2. In the address box of the browser, type one of the following URLs.

TO OPEN	URL	EXAMPLE
The Role Center for the default company	*https://ComputerName:Port/WebServerInstance/tablet* Or (for multitenant deployments) *https://ComputerName:Port/WebServerInstance/tablet?tenant=TenantID*	https://MyBCWeb:8080/BC160/tablet
The Role Center for a specific company	*https://ComputerName:Port/WebServerInstance/tablet?company=CompanyName* Or *https://ComputerName:Port/WebServerInstance/tablet?tenant=TenantID&company=CompanyName*	https://MyBCWeb:8080/BC160/tablet?company=CRONUS%20International%20Ltd.
A specific page	*https://ComputerName:Port/WebServerInstance/tablet?page=ID* Or *https://ComputerName:Port/WebServerInstance/tablet?tenant=TenantID&page=ID*	https://MyBCWeb:8080/BC160/tablet?page=22

TO OPEN	URL	EXAMPLE
A specific report	*https://ComputerName:Port/WebServerInstance/tablet?report=ID* Or *https://ComputerName:Port/WebServerInstance/tablet?tenant=TenantID&report=ID*	https://MyBCWeb:8080/BC160/tablet?report=8
A specific profile	*https://ComputerName:Port/WebServerInstance/tablet?profile=ProfileID* Or *https://ComputerName:Port/WebServerInstance/tablet?tenant=TenantID&profile=ProfileID*	https://MyBCWeb:8080/BC160/tablet?profile=Small-Business

Substitute the following parameters:

- **ComputerName** with the name of the computer that is running the Business Central Web Server components.
- **Port** with the port number that you configured for the Business Central Web Server components during installation.
- **WebServerInstance** with the virtual directory alias under which the Business Central tablet client or the Business Central phone client exists on the web server. For more information, see Installing Business Central Using Setup.
- **TenantID** with the name of the tenant that you want to connect to. This parameter is only required when Business Central is deployed in a multitenant architecture. The tenant that you specify must be mounted on the Business Central Server instance that the Business Central Web client connects to. For more information, see Multitenant Deployment Architecture.
- **CompanyName** with the name of the company in Business Central. This parameter is optional and is only needed if you want to open a different company than the one specified in **My Settings**.
- **ID** with the ID that is assigned to the page or report in Business Central.
- **ProfileID** with the ID that is assigned to the profile in Business Central.

Introducing the Dynamics 365 Business Central Mobile App

Develop a Sales Rep Role Center for the Tablet Client

2/17/2021 • 3 minutes to read • Edit Online

In this example, you will learn how to create a new Role Center for the Business Central tablet client. Developing for the Business Central tablet client occurs in the AL Language development environment and is not much different from developing for one of the other Business Central clients. This example will concentrate on how to build a Role Center for a sales representative, which links to already existing page objects, but combined in a way so that it works well on the tablet.

About this example

This example illustrates the following tasks:

- Creating a Role Center page
- Adding existing pages to the Role Center
- Adding actions to pages from the Role Center
- Testing the Role Center page

Prerequisites

To complete this example, you will need:

- Business Central installed with a developer license
- Business Central Web Server components
- CRONUS International Ltd. demonstration database
- A supported browser. For more information, see System Requirements for Dynamics 365 Business Central 2020 Release Wave 1

Story

Simon is a partner developer working for CRONUS International Ltd. Nancy is a Sales Representative at Contoso Consulting. Simon has to build a new Role Center to support Nancy in her job. When at work, Nancy spends part of her time on the road with only her tablet available on customer visits. Nancy needs access to KPIs on the front page. She needs easy access to filter for the customers who she will visit. When at the customer site, she creates sales quotes. Simon wants to build a Role Center that can be used on a tablet and he wants to reuse as much code and as many page objects as possible.

The following code illustrates how Simon implements the Role Center.

```
page 50106 "Sales Rep Role Center"
{
    PageType = RoleCenter;

    layout
    {
        // Add already existing pages to help Nancy access activities, customers, and charts to the Role
Center.
        area(RoleCenter)
        {
            part("O365 Activities"; "O365 Activities")
            {
            }

            part("My Customers"; "My Customers")
            {
            }

            part("Generic Chart"; "Generic Chart")
            {
            }

            part("Trial Balance"; "Trial Balance")
            {
            }
        }
    }

    // Add actions that link to other pages, which Nancy uses in her daily work on the tablet.
    actions
    {
        area(Creation)
        {
            action("Sales Quote")
            {
                Caption = 'New';
                RunObject = Page "Sales Quote";
                Image = Quote;
                Promoted = true;
            }

            action("Customer List")
            {
                Caption = 'Customers';
                RunObject = Page "Customer List";
                Promoted = true;
                //  Sales Quote as an action item available from the action pane in the New group
                PromotedCategory = New;
            }

            action("Item List")
            {
                Caption = 'Items';
                RunObject = Page "Item List";
                Promoted = true;
                PromotedCategory = New;
            }
        }
    }
}
```

For more information about the specifics of Role Center structure and design, see Designing Role Centers.

Simon now wants to test the Sales Rep Role Center that he created, and for testing purposes he uses a browser window. He enters a URL that specifically opens the page 50006 from tablet.aspx. His URL now resembles this: *https://MyBCWeb:8080/BC160/tablet.aspx?page=50006*. For more information, see Opening the Business

Central Tablet or Phone Client from a Browser.

Next steps

Nancy now has a Role Center that gives her access to most of the information that she needs when she is on the road. The next step for Simon is to refine the Sales Rep Role Center by adding more functionality, for example, the ability to retrieve more lists or making sure that Nancy can smoothly continue to work when she is back at the office on her desktop computer.

Instrumenting an Application for Telemetry

2/17/2021 • 2 minutes to read • Edit Online

This article describes how you can implement custom telemetry signals in your application for emitting telemetry data.. This data can then be collected and visualized for analyzing the application against the desired business goals, troubleshooting, and more.

Telemetry overview

One aspect of event logging is collecting data about how the application and your deployment infrastructure is working in order to diagnose conditions and troubleshoot problems that affect operation and performance. For example, this type of event logging includes Business Central Server events and trace events like SQL and AL method (function) traces.

Another aspect of logging is *telemetry*, which is collecting data about how your application functions and how it is being used in production. Telemetry can tell you about specific activities that users perform within the application in the production environment. Telemetry is also a useful tool for troubleshooting, especially instances where you are not able to reproduce the conditions experienced by the user or have no access to the user's environment. Telemetry can be divided into different levels or categories, like: telemetry for engineering, telemetry about the business, telemetry for customers.

Creating custom telemetry signal

There are two different resources where telemetry trace signals can be sent for monitoring and analyzing: Event Log and Microsoft Azure Application Insights. By default, the Business Central application is instrumented to emit several system telemetry trace signals to these destinations. Custom telemetry trace signals enable you to send telemetry data from anywhere in the application code to either of these destinations.

The procedure for creating custom telemetry signals is different for each resource. Your choice might also depend on whether you are developing for Business Central online or on-premises.

REOURCE	DESCRIPTION	ONLINE	ON-PREMISES	MORE INFORMATION

REOURCE	DESCRIPTION	ONLINE	ON-PREMISES	MORE INFORMATION
Application Insights	Create custom telemetry signals that are sent to an Application Insights resource in Azure. Application Insights is a service hosted within Azure that gathers telemetry data for analysis and presentation. Extension developers can specify whether the signal is only sent to the extension publisher or also to the VAR partner telemetry resource. You create these custom trace signals by using the LOGMESSAGE method in code.	✓	✓	See...
Event Log	Create custom telemetry trace signals that are sent to the Event Log of the Business Central Server machine. You create these custom trace signals by using the SENDTRACETAG method in code.		✓	See...

NOTE

Using Application Insights is recommended.

Creating Custom Telemetry Traces for Application Insights Monitoring

2/17/2021 • 4 minutes to read • Edit Online

APPLIES TO: Business Central 2020 release wave 2 and later

This article explains how to develop extensions to send custom telemetry trace signals to Azure Application Insights for viewing and analyzing.

You can add AL code in extensions to emit messages about activities or operations that users do within the application. At runtime, the messages can be picked up by an Application Insights resource, which you set up in beforehand. In Application Insights, the custom telemetry events are stored in the *traces* table.

Set up Application Insights

An Application Insights resource can be configured in two places:

- In the app.json file of the extension.

  For more information, see Enabling Application Insight on an Extension.

- In the tenant on the Business Central Server service/server.

  For more information, see Enabling Application Insights.

When you create a custom telemetry trace signal, you can specify a telemetry scope. The telemetry scope enables you to send an signal only to the Application Insights resource specified in the extension's app.json. Or to all available resources.

> **NOTE**
> Having Application Insights resources configured is not required to create custom signals in AL code.

Create a custom telemetry trace signal

To create a custom telemetry trace signal, use a LOGMESSAGE method in AL code where you want to trigger the signal. The LOGMESSAGE method defines the information that is sent to Application Insights for a specific operation or activity.

There are two variations of the LOGMESSAGE method. The difference is that one method uses a dictionary object to define custom dimensions for the trace signal. The other method includes two overloads so you don't have to construct a dictionary. You can use these methods in any object, trigger, or method. The methods have the following signatures:

Using a dictionary

The LOGMESSAGE method for using a dictionary for dimensions has the following signature:

```
Session.LogMessage(EventId: String, Message: String, Verbosity: Verbosity, DataClassification:
DataClassification, TelemetryScope: TelemetryScope, CustomDimensions: Dictionary of [Text, Text])
```

Using dimension overloads

The LOGMESSAGE method for using dimension overloads has the following signature:

```
Session.LogMessage(EventId: String, Message: String, Verbosity: Verbosity, DataClassification:
DataClassification, TelemetryScope: TelemetryScope, Dimension1: String, Value1: String [, Dimension2:
String] [, Value2: String])
```

Setting the parameters

Use the parameters to build the dimensions, or columns, that will show for the trace in Application Insights. `Message` and `Verbosity` will appear as general dimensions. All other parameters appear as custom dimensions.

PARAMETER	DESCRIPTION	DIMENSION
EventID	A text string that assigns an identifier to the telemetry trace signal. The tag can consist of letters, numbers, and special characters. Try to make your tags unique. For example, use at least 8 characters or a prefix, like Cronus-0001 and Cronus-0002.	eventId
Message	A text string that specifies the descriptive message for the telemetry trace signal.	message

Verbosity*	An enumeration that specifies the severity level of the telemetry trace signal. The value can be `Critical`, `Error`, `Warning`, `Normal`, or `Verbose`.	severityLevel
		
		`4` = `Critical`
		`3` = `Error`
		`2` = `Warning`
		`1` = `Normal`
		`0` = `Verbose`

DataClassification*	A DataClassification data type that assigns a classification to the telemetry trace signal. For more information, see Data Classifications.	dataClassification
TelemetryScope	Scope of emitting the telemetry. • `extensionpublisher` sends the custom signal only to the Application Insight resource specified in the extension's app.json file • `all` sends the custom signal to Application Insight resource specified in the extension's app.json file and on the tenant.	telemetryScope
CustomDimensions	A dictionary of text that defines the custom dimensions for the trace signal in Application Insights.	
Dimension1	A text string that specifies the name of the custom dimension.	
Value1	A text string that specifies the value of Dimension1.	

PARAMETER	DESCRIPTION	DIMENSION
Dimension2	A text string that specifies the name of the custom dimension.	
Value2	A text string that specifies the value of Dimension2.	

Examples

The following code snippets create simple telemetry trace signals. They create a critical-level telemetry signal that is scoped to the signal publisher. For a simple test of this code, add it to the `OnRun` trigger of a codeunit, and then run the codeunit.

Using a dictionary:

```
trigger OnRun();
var
    CustDimension: Dictionary of [Text, Text];
begin
    CustDimension.Add('result', 'failed');
    CustDimension.Add('reason', 'critical error in code');
    LogMessage('MyExt-0001', 'This is a critical error message', Verbosity::Normal,
DATACLASSIFICATION::SystemMetadata, TelemetryScope::ExtensionPublisher, CustDimension);
end;
```

Using an overload:

```
trigger OnRun();
begin
    LogMessage('MyExt-0001', 'This is a critical error message', Verbosity::Critical,
DATACLASSIFICATION::SystemMetadata, TelemetryScope::ExtensionPublisher, 'result', 'failed', 'reason',
'critical error in code');
end;
```

Design considerations

- For Business Central on-premises, the **Diagnostic Trace Level** setting on the Business Central Server instance controls which signals are sent, based on their severity level.

  If the **Diagnostic Trace Level** is set to **Warning** for example, then **Normal** and **Verbose** signals won't be sent to Application Insights. For more information, see Configuring Business Central Server - General.

- For privacy reasons, events that have a `DataClassification` other than `SystemMetadata` aren't sent to Application Insight resources set up on the tenant. During development of your extension, it's good practice to have a privacy review of the use of LOGMESSAGE calls to ensure that customer data isn't mistakenly leaked into Application Insights resources.

LOGMESSAGE method
Monitoring and Analyzing Telemetry

Sending Extension Telemetry to Azure Application Insights

2/17/2021 • 2 minutes to read • Edit Online

APPLIES TO: Business Central 2020 release wave 2 and later

This article describes how to develop an extension to send telemetry data to Azure Application Insights for monitoring and analyzing. Business Central emits telemetry data for several operations that occur when extension code is run. You can configure an extension to send this telemetry data to a specific Application Insights resource on Microsoft Azure. For an overview about the telemetry with Application Insights, see Monitoring and Analyzing Telemetry.

This feature targets publishers of per-tenant extensions to give them insight into issues in their extensions before partners and customers report them.

Get an Application Insights resource in Azure

The first thing to do is to create an Application Insights resource in Azure if you don't have one. For more information, see Create an Application Insights resource.

The Application Insights resource is assigned an instrumentation key, which you can see on the **Overview** page for the resource in Azure. Copy this key because you'll need it to enable Application Insights in the extension.

Add the Application Insights Key to the extension's app.json

The next step is to add the `"applicationInsightsKey"` setting the extension's app.json as shown:

```
"applicationInsightsKey":"<instrumenation key>"
```

Replace `<instrumenation key>` with your key.

When done, build the extension package, then publish and install it as usual. When the extension is run from Business Central, Application Insights gathers the telemetry data for viewing and analyzing.

LogMessage Method

Creating Custom Telemetry Events for Event Log Monitoring

2/17/2021 • 3 minutes to read • Edit Online

APPLIES TO: Business Central On-Premises.

This article explains how to create custom telemetry trace events in AL code that will be sent to the Event Log of the Business Central Server machine.

> **NOTE**
> The SENDTRACETAG method is marked as obsolete in Business Central 2020 release wave 2 (v17). You can still use it, but we recommend that you send traces to Application Insights using the LOGMESSAGE method instead. For more information, see Creating Custom Telemetry Traces for Application Insights Monitoring.

Create custom telemetry events

To create a custom telemetry event, you use the SENDTRACETAG method in code. You can use the SENDTRACETAG method in any object, trigger, or method. The SENDTRACETAG method has the following syntax:

```
SENDTRACETAG(Tag, Category, Verbosity, Message[, DataClassification])
```

You use the parameters to define the information about the telemetry trace event. This information is can be consumed by event logging tools, and presented in different ways.

PARAMETER	DESCRIPTION
Tag	A text string that assigns an identifier to the telemetry trace event. The tag can consist of letters, numbers, and special characters. Business Central system telemetry events use an auto-generated, auto-incremented, 7-character tag that includes numbers and letters, such as 000002Q. and 000013P. Try to make your tags unique from these telemetry event tags by, for example, using at least 8 characters or a prefix, like Cronus-0001 and Cronus-0002.
Category	A text string that assigns the telemetry trace event to a category that you define. For example, you could have a category for upgrading, user activity, or reporting.
Verbosity	An enumeration that specifies the severity level of the telemetry trace event. The value can be Critical, Error, Warning, Normal, or Verbose. This severity level can be used by Business Central Server to filter out lower-level telemetry trace events from being emitted. See Viewing and collecting telemetry data.
Message	A text string that specifies the descriptive message for the telemetry trace event.

PARAMETER	DESCRIPTION
DataClassification	A DataClassification data type that assigns a classification to the telemetry trace event. For more information, see Data Classifications.

For example, the following code creates simple telemetry trace events for the five different severity levels.

```
SENDTRACETAG('Cronus-0001', 'Action', VERBOSITY::Critical, 'This is a critical message.',
DATACLASSIFICATION::CustomerContent);
SENDTRACETAG('Cronus-0002', 'Action', VERBOSITY::Error, 'This is an error message.',
DATACLASSIFICATION::EndUserIdentifiableInformation);
SENDTRACETAG('Cronus-0003', 'Action', VERBOSITY::Warning, 'This is a warning message.',
DATACLASSIFICATION::AccountData);
SENDTRACETAG('Cronus-0004', 'Action', VERBOSITY::Normal, 'This is an informational message.',
DATACLASSIFICATION::OrganizationIdentifiableInformation);
SENDTRACETAG('Cronus-0005', 'Action', VERBOSITY::Verbose, 'This is a verbose message.',
DATACLASSIFICATION::SystemMetadata);
```

For a simple test of this code, add it to the `OnRun` trigger of a codeunit, and then run the codeunit. Of course, you can also call the code from other objects, triggers or functions as well.

View and collect telemetry data

Viewing and collecting telemetry data is done the same way as with other trace events emitted by Business Central, for example, by using tools like Event Viewer, Performance Monitor, PerfView, or logman.

- In Event Viewer, telemetry trace events can be viewed from **Applications and Services Logs**, in the **Microsoft** > **DynamicsNAV** > **Common** folder. The custom telemetry trace events are recorded in the **Admin** folder. You should be aware that only events with severity level of Warning, Error, and Critical will appear.

  For more information, see Monitoring Business Central Server Events Using Event Viewer.

- With other tools like Performance Monitor, PerfView, and logman, you can collect telemetry data by using **Microsoft-DynamicsNAV-Common** as the event trace provider.

  For more information, see Get Started Monitoring Events.

> **IMPORTANT**
> The Business Central Server instance includes a configuration setting called **Diagnostic Trace Level** (`TraceLevel` in the customsettings.config file) that enables you to specify the lowest severity level of telemetry events to be recorded in the event log, or even turn off telemetry event logging altogether. If you do not see the expected events, then verify the Business Central Server instance configuration with an administrator. For information, see Configuring Business Central Server.

Exporting Permission Sets

2/17/2021 • 2 minutes to read • Edit Online

Permission sets that exist in Dynamics 365 Business Central can be exported and packaged for your extension directly from the client, instead of defining XML by hand.

To export permission sets from Dynamics 365 Business Central

1. In Dynamics 365 Business Central, search for **Permission Sets**, and then choose the relevant link.
2. On the **Permission Sets** page, choose the permissions that you want to export, and then choose **Export Selected Permissions**.
3. In the **Export Permission Sets** dialog, choose to export permission sets only for the application, only for the tenant, or for both.
4. Save the file to your extension folder.
5. Delete the permission sets from Dynamics 365 Business Central.

You can generate a permission set file which contains permissions to all the files in your extension. This will make it easier to start setting up permissions for your app. You can do this by simply creating an extension with some objects as described below.

To export permission sets using Visual Studio Code

1. In Visual Studio Code, open your extension with objects; pages, reports, tables, queries, codeunits, and/or XMLports.
2. Open the command palette using the `Ctrl+Shift+P` keys and select the **AL: Generate permission set containing current extension objects** command.

   > **NOTE**
   > If you do this repeatedly, Visual Studio Code will probe for overwriting the file, there is no support for merging manual corrections into newly generated content.

3. Publish the app.

Now, you have the XML file with default permissions to all your objects.

Example from Visual Studio Code

The following example illustrates the generated .xml file from **MyProject** which contains a table with objectID 50106 and two object types are generated; `<ObjectType>0</ObjectType>` is `TableData` and `<ObjectType>1</ObjectType>` is `Table`.

> **NOTE**
> The maximum length of the RoleID attribute is 20 characters. If the RoleID exceeds this length, then the XML schema validation fails and the corresponding permission set file is not included in the resulting app package. You will get a warning in the Visual Studio output panel.

```
<?xml version="1.0" encoding="utf-8"?>
<PermissionSets>
  <PermissionSet RoleID="MyProject" RoleName="MyProject">
    <Permission>
      <ObjectID>50106</ObjectID>
      <ObjectType>0</ObjectType>
      <ReadPermission>1</ReadPermission>
      <InsertPermission>1</InsertPermission>
      <ModifyPermission>1</ModifyPermission>
      <DeletePermission>1</DeletePermission>
      <ExecutePermission>0</ExecutePermission>
      <SecurityFilter />
    </Permission>
    <Permission>
      <ObjectID>50106</ObjectID>
      <ObjectType>1</ObjectType>
      <ReadPermission>0</ReadPermission>
      <InsertPermission>0</InsertPermission>
      <ModifyPermission>0</ModifyPermission>
      <DeletePermission>0</DeletePermission>
      <ExecutePermission>1</ExecutePermission>
      <SecurityFilter />
    </Permission>
 </PermissionSet>
 </PermissionSets>
```

Object type mapping

The mapping of object types in the XML such as `<ObjectType>0</ObjectType>` generated from Visual Studio Code is the following:

OBJECT TYPE	NUMBER
TableData	0
Table	1
Report	3
Codeunit	5
XMLPort	6
Page	8
Query	9
FieldNumber	11
PageExtension	14
TableExtension	15
Enum	16
EnumExtension	17

OBJECT TYPE	NUMBER
Profile	18
ProfileExtension	19

Getting started with Microsoft .NET Interoperability from AL

2/17/2021 • 2 minutes to read • Edit Online

You can call .NET type members, including methods, properties, and constructors, from AL code. In this article we will guide you through the process of creating an extension that uses .NET types.

> **IMPORTANT**
>
> .NET Interoperability is only available on-premise. If you want to use this functionality, you must set the `"target": "OnPrem"` in the `app.json` file. For more information, see JSON Files.

Enabling .NET Interoperability

.NET interoperability can only be used by applications that target on-premise deployments. See JSON Files for more information on how to set the correct compilation target and Compilation Scope Overview.

Declaring a .NET package

Using a .NET type in AL is a two-step process. First, you must declare the type in a **dotnet** package, and then reference it from code using the **DotNet** type.

You start by declaring an empty **dotnet** package in your extension. See the example snippet below.

```
dotnet
{

}
```

It is recommended to have only one package per extension that contains all the .NET types which you will be using.

You continue by adding a declaration of the assembly that you will be referencing. For this example, we will use the `mscorlib` assembly that contains the core .NET types. A **dotnet** package can contain an unlimited number of assembly declarations. The name of the assembly must be the one defined in the assembly's manifest. See the following example snippet.

```
dotnet
{
    assembly(mscorlib)
    {
    }
}
```

By default, the compiler only knows about the location of the `mscorlib` assembly. You can reference any compatible assembly by providing the compiler with a path to the assembly's containing folder. This can be achieved by adding the path to assembly's containing folder to the `"al.assemblyProbingPaths"` setting. Open the Command Palette **Ctrl+Shift+P** and choose either **User Settings** or **Workspace Settings** and specify the `al.assemblyProbingPaths` setting. For example:

```
"al.assemblyProbingPaths": [
        "./.netpackages",
        "C:/Program Files/Assemblies"
    ]
```

> **NOTE**
> Any update to an assembly's code is not automatically detected by the compiler. If an assembly has changed, then you must restart your development environment.

You continue by adding a reference to a type from the referenced assembly. In this example, we will use `System.DateTime` from `mscorlib` and we will give it the alias `MyDateTime`. The type must be referenced using its fully-qualified name. The alias is used for referencing the .NET type from code. If an alias is not provided, the compiler will use the .NET type name. A .NET assembly declaration can contain any number of type declarations. See the example below.

```
dotnet
{
    assembly(mscorlib)
    {
        type(System.DateTime; MyDateTime){}
    }
}
```

Using a .NET type from AL code

From this point on, we can reference the .NET type from AL code using its given alias, as shown in the example below.

```
dotnet
{
    assembly(mscorlib)
    {
        type(System.DateTime; MyDateTime){}
    }
}

pageextension 50100 CustomerListExt extends "Customer List"
{
    trigger OnOpenPage();
    var
        now: DotNet MyDateTime;
    begin
        now := now.UtcNow();
        Message('Hello, world! It is: ' + now.ToString());
    end;
}
```

Publishing your extension

The AL Language extension, including the AL compiler, and the server to which you publish your code are completely decoupled. When publishing, the server re-compiles your code and tries to resolve all the references to external assemblies. In order for the compilation to succeed, the server must be able to locate and load all the referenced assemblies and types.

The server will search the global assembly cache (GAC), the **Add-ins** folder, and the **Add-in** table. You must

manually install any custom assembly in one of these locations.

.NET Control Add-Ins

2/17/2021 • 3 minutes to read • Edit Online

In Dynamics 365 Business Central on-premises you can use existing .NET and Javascript control add-ins from the AL Language through .NET interoperability. It is recommended that you convert your existing .NET and Javascript add-ins to native AL control add-ins that are supported both on-premises and in the cloud. For more information about native AL control add-ins, see Control Add-In Object.

To declare the usage of a .NET or Javascript add-in in AL, you need three critical pieces of information about the .NET type that represent the interface of the add-in. These are the name of the assembly containing the add-in, the name of the control add-in, and the name of the class that implements the control add-in. We will show how to retrieve this information for the `Microsoft.Dynamics.Nav.Client.PingPong` control add-in that ships with Business Central.

The name of the assembly can be retrieved from the AssemblyName element in the `.csproj` file associated with the .NET project that represents the control add-in. In this case the name of the assembly is `Microsoft.Dynamics.Nav.Client.PingPong`.

> **NOTE**
> If you do not have access to the `.csproj file`, you can determine the name of the assembly by following the instructions in How to: Determine an Assembly's Fully Qualified Name.

The following code sample contains the stub definition of the `Microsoft.Dynamics.Nav.Client.PingPong` .NET add-in.

```
namespace Microsoft.Dynamics.Nav.Client.PingPong
{

/// <summary>
/// Add-in for pinging the server from the client. The client will respond with a pong.
/// </summary>
[ControlAddInExport("Microsoft.Dynamics.Nav.Client.PingPong")]
public class PingPongAddIn : WinFormsControlAddInBase
{

        /// <summary>
        /// Event will be fired when the AddIn is ready for communication through its API
        /// </summary>
        [ApplicationVisible]
        public event MethodInvoker AddInReady;

        /// <summary>
        /// Event will be fired when the specified time by the ping has elapsed.
        /// </summary>
        [ApplicationVisible]
        public event MethodInvoker Pong;

        /// <summary>
        /// Starts the ping process.
        /// </summary>
        /// <param name="milliseconds">Number of milliseconds before ponging.</param>
        /// <remarks>If a milliseconds are less than the minimum then the MinimumValue is used.</remarks>
        [ApplicationVisible]
        public void Ping(int milliseconds)
        {
            ...
        }
}

}
```

The next needed piece of information is the namespace-qualified name of the type annotated with the `ControlAddInExport` attribute. This is the type that provides the implementation of the control add-in and which exposes members annotated with the `ApplicationVisible` attribute to the AL runtime. In this example this is `Microsoft.Dynamics.Nav.Client.PingPong.PingPongAddIn`.

The `ControlAddInExport` attribute's constructor takes as an argument the name of the control add-in, as represented in the runtime, and in existing C/AL code. In this example, the name of the control add-in is `Microsoft.Dynamics.Nav.Client.PingPong`. This was the last component needed to construct a declaration for this .NET control add-in in AL. The name of the assembly is used in creating the `assembly` construct, the namespace-qualified name of the type is used as the first element in the `type` declaration, and the name of the control add-in is used as the alias of the type. You complete the declaration by setting the `IsControlAddIn` property to true. This property is used to tell the AL compiler to treat the given type declaration as a .NET control add-in declaration.

Remember to add the setting **"AL: Assembly Probing Paths"** in the **User Settings** or **Workspace Settings** specifying the path of the folder containing the assembly so that the compiler can access it. For more information, see Getting started with Microsoft .NET Interoperability from AL.

```
dotnet
{
    assembly("Microsoft.Dynamics.Nav.Client.PingPong")
    {
        type("Microsoft.Dynamics.Nav.Client.PingPong.PingPongAddIn"; PingPongAddIn)
        {
            IsControlAddIn = true;
        }
    }
}
```

You can now use the `Microsoft.Dynamics.Nav.Client.PingPong` from AL, just as you use a native control add-in.

```
page 50100 MyPage
{
    layout
    {
        area(Content)
        {
            usercontrol(PingPongControl; PingPongAddIn)
            {
                trigger Pong()
                begin
                    Message('Pong received.');
                end;

                trigger AddInReady()
                begin
                    Message('Ready');
                end;
            }
        }
    }
}
```

Remarks

Only members of the .NET type implementing the control add-in that are annotated with the `ApplicationVisibleAttribute` will be accessible from AL. Usages of .NET control add-ins in C/AL are automatically converted to AL by the Txt2Al conversion tool, but the code will only compile, if you manually insert the declaration of the control add-in, as outlined above.

If within the same project you have a native AL control add-in and a .NET add-in with the same name, the .NET add-in will be the one used.

Subscribing to Events in a .NET Framework Type

2/17/2021 • 2 minutes to read • Edit Online

With .NET Framework interoperability in Dynamics 365 Business Central objects, you can configure a DotNet variable to subscribe to events that are published by a .NET Framework type. Events are handled by triggers in the AL code of the Business Central object.

You start by declaring in AL the usage of two .NET types from the `System` assembly. The first type is `System.Timers.Timer` and it will be used to generate .NET events. The second one is called `System.Timers.ElapsedEventArgs` and it is required for creating a subscriber to the `Elapsed` event emitted by the `Timer` type.

```
dotnet
{
    assembly(System)
    {
        type(System.Timers.Timer; MyTimer) {}
        type(System.Timers.ElapsedEventArgs; MyElapsedEventArgs) {}
    }
}
```

You can only subscribe to events that are emitted by global variables of the .NET type marked with the `WithEvents` attribute. For all the global variables that are marked with this attribute, the compiler will expose the events available on the type as triggers on the variable. The syntax for declaring these triggers is `{VariableName}::{EventName}(...ParameterList)`, but IntelliSense will offer suggestions for the event name and autocomplete the parameter list.

```
pageextension 50101 CustomerListExt extends "Customer List"
{
    var
        [WithEvents]
        timer: DotNet MyTimer;

    trigger OnOpenPage()
    begin
        SetupTimer();
    end;

    procedure SetupTimer()
    begin
        timer := timer.Timer(2000);
        timer.AutoReset := true;
        timer.Enabled := true;
        timer.Start();
    end;

    trigger timer::Elapsed(sender: Variant; e: DotNet MyElapsedEventArgs)
    begin
     // Print a message when this event is published
        Message('%1', e.SignalTime());
        timer.Stop();
    end;
}
```

Serializing .NET Framework Types

2/17/2021 • 6 minutes to read • Edit Online

In Microsoft .NET Framework, serialization is the process of converting an object into a format that can be transmitted across a network connection. Microsoft .NET Framework interoperability uses serialization for communication between client-side .NET Framework objects and server-side .NET Framework objects. When you configure DotNet variables in a Dynamics 365 Business Central object, you can specify .NET Framework objects to target either the Business Central Windows client or Business Central Server. In some cases, a client-side object and a server-side object must communicate and share data, such as return values and parameters. The serialization occurs when the following conditions are true:

- When a server-side object is assigned to a client-side object, and vice-versa.
- When a server-side object is passed as a parameter in a method call from the server to a client-side object, and vice-versa.

Serialization requires that the .NET Framework types that are used by the DotNet variables are serializable. Many types in the Microsoft .NET Framework class library are already serializable. If you are using a .NET Framework type that cannot be serialized, then you must modify the type to make it serializable.

> **IMPORTANT**
> For the Business Central Web client, you cannot implement Microsoft .NET Framework interoperability objects that target the client.

Making a Type Serializable

There are two ways that you can make a .NET Framework type serializable. You can implement basic serialization by applying the System.SerializableAttribute attribute to the type or you can implement custom serialization by using System.Runtime.Serialization.ISerializable interface.

Basic Serialization Using SerializableAttribute

Basic serialization uses the .NET Framework to automatically serialize an object. To implement basic serialization on a type, you decorate the type with the SerializableAttribute class as shown in the following example.

```
[Serializable]
public class MyObject
{
    code
}
```

This method requires that you have access to the source code of the .NET Framework assembly.

Basic Serialization of Date Fields

You can use basic serialization only if all data fields in the type are serializable. Fields that are calculated at runtime cannot be serialized. If a field cannot be serialized, then at runtime, the serialization process will throw an exception and the AL code execution will fail.

You can exclude fields from the serialization process by decorating the field with the System.NonSerializedAttribute class.

Custom Serialization Using ISerializable Interface

With custom serialization, you can create an object that controls the serialization of types in another object. This method is useful when you do not have access to the source code of the assembly that contains the .NET Framework types that you are implementing with .NET Framework interoperability. The custom object specifies which types will be serialized and how serialization will be done.

To implement custom serialization, you create a class that implements the ISerializable interface, and decorate the class with SerializableAttribute. In most cases, you must also implement the System.Runtime.Serialization.ISerializable.GetObjectData method and a special constructor that is used when the source object is deserialized. You use the **GetObjectData** method to populate the SerializationInfo the data that is required to serialize the source object at runtime.

The common language runtime calls the constructor during deserialization to construct a replica of the source object. The constructor takes two parameters, a **SerializationInfo** type and a System.Runtime.Serialization.StreamingContext type. The **StreamingContext** parameter describes the source and destination of a given serialized stream.

Custom Serialization Example

The following code example demonstrates a custom serialization object that implements the basic functionality that is required for compliance with the **ISerializable** interface. In the first procedure of this example, you create a .NET Framework assembly that includes a serializable type. In the second procedure, in the Business Central development environment, you create a codeunit that includes two DotNet variables for the serializable type. You set one variable to target the Business Central Windows client and the other to target the Business Central Server. In AL code, you add code that transfers the value for the DotNet variable on the Business Central Server to the Business Central Windows client. You will also add code that verifies that the data transfer is successful.

To create the custom serialization object

1. In Microsoft Visual Studio, create a C# Class Library project called *SerializationSample*.
2. Add the following code.

```
using System;
using System.Runtime.Serialization;

[Serializable]
public class SerializeWithInterface : ISerializable
{
     // Defines a field that will not be serialized.
     [NonSerialized]
     private string notSerializedField;
     // Defines two fields that will be serialized.
     private int serializedIntField;
     private string serializedStringField;
     // Specifies literal field names.
     private const string serializedIntFieldName = “serializedIntField”;
     private const string serializedStringFieldName = “serializeStringField”;

     // Defines a default constructor that initializes the object with default values.
     public SerializeWithInterface()
     {
          this.serializedIntField = 1;
          this.notSerializedField = string.Empty;
          this.serializedStringField = string.Empty;
     }

     // Defines the protected constructor that is required by the ISerializable interface.
     // Data is stored in the SerializationInfo argument and is extracted using the GetValue method.
     protected SerializeWithInterface(SerializationInfo si, StreamingContext context)
     {
          this.serializedStringField = (string)si.GetValue(serializedStringFieldName, typeof(string));
          this.serializedIntField = (int)si.GetValue(serializedIntFieldName, typeof(int));
     }

     // Fills the SerializationInfo object with data that must to be sent to the replicated object.
     // Data is stored in the dictionary using the AddValue method.
     // The SerializationInfo object is a key/value dictionary.
     // The name you use to store the value must match the name used in the constructor.
     // For this reason, a string constant is used.
     public void GetObjectData(SerializationInfo info, StreamingContext context)
     {
          info.AddValue(serializedStringFieldName, this.serializedStringField);
          info.AddValue(serializedIntFieldName, this.serializedIntField);
     }

     // Remaining class implementation is irrelevant for the serialization process.
     // The SerializedStringField property is used by AL code to verify that the contained data is
transferred between the server and client.
     // SerializedStringField gets or sets the internal serialized string field.
     public string SerializedStringField
     {
          get { return this.serializedStringField; }
          set { this.serializedStringField = value; }
     }
 }
```

3. Build the project.
4. Copy the SerializationSample.dll to the **Add-ins** folder of the Business Central Windows client and Business Central Server installation folders.

By default, the path of the Business Central Windows client installation folder is C:\Program Files (x86)\Microsoft Dynamics 365 Business Central\160\RoleTailored Client\Add-ins.

By default, the path of the Business Central Server installation folder is C:\Program Files\Microsoft Dynamics 365 Business Central\130\Service\Add-ins.

To test the serialization object

1. In the AL Development Environment, add the following code.

```
dotnet
{
     assembly(SerializationSample)
     {
          type(SerializationSample.SerializeWithInterface; SerializeWithInterface){}
     }
}

codeunit 50101 SerializationSample
{
    procedure Testing()
    var
        ServerObject: DotNet SerializeWithInterface;
        ClientObject: DotNet SerializeWithInterface;

    begin
        // Constructor that instantiates the ServerObject object on the server.
        ServerObject := ServerObject.SerializeWithInterface();
        // Constructor that instantiates the ClientObject object on the server.
        ClientObject := ClientObject.SerializeWithInterface();
        // Assign unique values to the data members in the two objects.
        ServerObject.SerializedStringField := 'ServerSide';
        ClientObject.SerializedStringField := 'ClientSide';
        // Transfer the server object to the client object using serialization.
        ClientObject := ServerObject;
        // Test if the objects contain the same data.
        If ClientObject.SerializedStringField <> ServerObject.SerializedStringField then
            Error('Client object does not match the server object.');
            Message('Server data has been serialized to the client object.');
    end;
}
```

The line that contains assignment of the **ServerObject** to the **ClientObject** causes the serialization process to run. When completed, the message **Server data has been serialized to the client object** appears, which verifies that the server object has been transferred to the client object.

Implementing the Camera in AL

2/17/2021 • 3 minutes to read • Edit Online

You can access the camera of a device from the Business Central Web client in the browser and from the Business Central Mobile App. This allows the user to take pictures and handle them directly from the same device, and in that way, improve accuracy of capturing data closest to the source, and reduce end-to-end time to perform tasks.

You can also add access to the camera to a specific page from the AL Language development environment. For a Dynamics 365 Business Central existing implementation of this, see the `Picture` factbox on the `Item Card`, which lets you take a picture of a specific item and store it together with the item.

> **IMPORTANT**
>
> The camera access is only available on devices that have a camera.

Example

This example illustrates how to implement the camera capability on a page in AL. The example implements three actions to take a picture: **Take Picture**, **Take Picture High Quality**, and **Take Picture Low Quality**. However, it does not include code that saves the picture to the database.

The example also shows how to specify options for the camera functionality such as picture quality or source type. For more information about the different options that can be set for the camera, see CameraOptions Overview.

> **NOTE**
>
> To enable the camera functionality, it is required that you add the path of the folder containing the `"Microsoft.Dynamics.Nav.ClientExtensions"` assembly on the **AI: Assembly Probing Paths** setting on the **User Settings** or **Workspace Settings** so the compiler can access it. For more information, see Getting started with Microsoft .NET Interoperability from AL.

The following code will create two variables; the `CameraAvailable` variable is a **Boolean** that checks whether the current device has a camera. The `Camera` variable is a **DotNet** type that gets instantiated by adding code to the `OnOpenPage` trigger. Then, it will add the actions to the page that lets the user start the camera. Finally, the trigger `Camera::PictureAvailable` is defined to handle the incoming picture.

```
page 50101 "Card with Camera Capability"
{

    Caption = 'Card Page';
    PageType = Card;
    RefreshOnActivate = true;
    SourceTable = "Test Table";

    layout
    {
        area(content)
        {
            //...
        }
```

```
    }

    actions
    {

        area(Processing)
        {
            action(TakePicture)
            {
                Visible = CameraAvailable;
                Promoted = true;
                PromotedCategory = Process;
                PromotedIsBig = true;
                Image = Camera;

                trigger OnAction()
                begin
                    Camera.RequestPictureAsync();
                end;
            }

            action(TakePictureHigh)
            {
                Visible = CameraAvailable;
                Promoted = true;
                PromotedCategory = Process;
                PromotedIsBig = true;
                Image = Camera;

                trigger OnAction()
                begin
                    CameraOptions := CameraOptions.CameraOptions();
                    CameraOptions.Quality := 100;
                    Camera.RequestPictureAsync(CameraOptions);
                end;
            }

            action(TakePictureLow)
            {
                Visible = CameraAvailable;
                Promoted = true;
                PromotedCategory = Process;
                PromotedIsBig = true;
                Image = Camera;

                trigger OnAction()
                begin
                    CameraOptions := CameraOptions.CameraOptions();
                    CameraOptions.Quality := 10;
                    Camera.RequestPictureAsync(CameraOptions);
                end;
            }
        }

    }

    trigger OnOpenPage()
    begin
        // The IsAvailable() enables the camera functionality based on its presence.
        if Camera.IsAvailable() then begin
            Camera := Camera.Create();
            CameraAvailable := True;
        end;
    end;

    // The PictureName contains the name of the file including its extension on the device.
    // The naming scheme depends on the device platform.
    // The PictureFilePath contains the path to the picture in a temporary folder on the server for the
current user.
```

```
    // The PictureAvailable trigger handles the picture for when the camera has captured it and it has been
uploaded.
    trigger Camera::PictureAvailable(PictureName: Text; PictureFilePath: Text)
    begin
        IncomingFile.Open(PictureFilePath);
        Message('Picture size: %1', IncomingFile.Len());
        IncomingFile.Close();
        // It is important to clean up by using the File.Erase command to avoid accumulating image files.
        File.Erase(PictureFilePath);
    end;

    var
        [RunOnClient]
        [WithEvents]
        Camera: DotNet UT_CameraProvider;
        CameraOptions: DotNet UT_CameraOptions;
        // Checks whether the current device has a camera.
        CameraAvailable: Boolean;
        IncomingFile: File;
}

dotnet
{
    assembly("Microsoft.Dynamics.Nav.ClientExtensions")
    {

        type("Microsoft.Dynamics.Nav.Client.Capabilities.CameraProvider"; "UT_CameraProvider")
        {

        }

        type("Microsoft.Dynamics.Nav.Client.Capabilities.CameraOptions"; "UT_CameraOptions")
        {

        }
    }
}
```

WithEvents property

Implementing Location in AL

2/17/2021 • 2 minutes to read • Edit Online

You can access the location information of a device from the Business Central Web client in the browser and from the Business Central Mobile App. This functionality could be useful in scenarios such as calculating routes from the current location or planning the next round of customer visits based on their addresses.

You can also add access to location information to a specific page from the AL Language development environment. For a Dynamics 365 Business Central existing implementation of this, see the `Show On Map` link on the `Customer Card`, which displays a map that shows where your customer is located based on the GPS coordinates and gives directions to reach its location.

> **IMPORTANT**
> Location information is only available on devices that are able to obtain location coordinates, such as using GPS capabilities.

Example

This example illustrates how to implement the location capability on a page in AL. The example implements a **GetLocation** action on a page that returns the coordinates of the current customer's address, but does not save this information to the database.

The example also shows how to specify options for the location functionality such as setting a timeout or enabling high accuracy. For more information about the different options that can be set for location, see LocationOptions Overview.

> **NOTE**
> To enable the location functionality, it is required that you add the path of the folder containing the `"Microsoft.Dynamics.Nav.ClientExtensions"` assembly on the **AL: Assembly Probing Paths** setting on the **User Settings** or **Workspace Settings** so the compiler can access it. For more information, see Getting started with Microsoft .NET Interoperability from AL.

The following code will create two variables; the `LocationAvailable` variable is a **Boolean** that checks whether the current device has location capabilities. The `Location` variable is a **DotNet** type that gets instantiated by adding code to the `OnOpenPage` trigger. Then, it will add an action to the page that lets the user retrieve the location information. Finally, the trigger `Location::LocationChanged` is defined to handle the incoming location information.

```
page 50101 "Card with Location Capability"
{

    Caption = 'Card Page';
    PageType = Card;
    RefreshOnActivate = true;
    SourceTable = "Test Table";

    layout
    {
        area(content)
        {
```

```
            //...
        }
    }

    actions
    {
        area(Processing)
        {
            action(GetLocation)
            {
                Visible = LocationAvailable;
                Promoted = true;
                PromotedCategory = Process;
                PromotedIsBig = true;
                Image = Map;

                trigger OnAction()
                begin
                    LocationOptions := LocationOptions.LocationOptions;
                    LocationOptions.EnableHighAccuracy();
                    Location.RequestLocationAsync();
                end;
            }
        }

    }

    trigger OnOpenPage()
    begin
        if Location.IsAvailable() then begin
            Location := Location.Create();
            LocationAvailable := true;
        end;
    end;

    trigger Location::LocationChanged(Location: DotNet Location)
    begin
        // Location.Status can be:
        //      0 = Available
        //      1 = NoData (no data could be obtained)
        //      2 = TimedOut (location information not obtained in due time)
        //      3 = NotAvailable (for example user denied app access to location)
        if Location.Status = 0 then
            Message('Your position: %1 %2', Location.Coordinate.Latitude, Location.Coordinate.Longitude)
        else
            Message('Position not available');
    end;

    var
        [RunOnClient]
        [WithEvents]
        Location: DotNet LocationProvider;
        LocationAvailable: Boolean;
        LocationOptions: DotNet UT_LocationOptions;
}

dotnet
{
    assembly("Microsoft.Dynamics.Nav.ClientExtensions")
    {

        type("Microsoft.Dynamics.Nav.Client.Capabilities.LocationProvider"; LocationProvider)
        {

        }

        type("Microsoft.Dynamics.Nav.Client.Capabilities.Location"; Location)
        {
```

```
        }

        type("Microsoft.Dynamics.Nav.Client.Capabilities.LocationOptions"; UT_LocationOptions)
        {

        }
    }
}
```

For information about troubleshooting access to location information, see Troubleshooting: Camera and Location.

Testing the Application Overview

2/17/2021 • 7 minutes to read • Edit Online

Before you release your Business Central application, you should test its functionality to ensure it works as expected. Testing is an iterative process. It's important to create repeatable tests, and helpful to create tests that can be automated. This article describes the features in Business Central that help you test the business logic in your application, and it provides some best practices for testing.

For a walkthrough concerning advanced extension testing, see Testing the Advanced Extension Sample.

Business Central includes the below features to help you test your application.

Environment testing support and limitations

The extent to which you can run automated tests will depend on your Business Central solution type and environment. The following table gives an overview.

BUSINESS CENTRAL SOLUTION	ENVIRONMENT	TESTING ALLOWED	MORE DETAILS
Online	Production		Running tests isn't allowed because it might have an adverse effect on your business. Testing can incidentally invoke external systems, like CDS, PayPal, and web hook subscriptions. Invoking these systems may slow down the solution for other users or cause data corruption.
	Sandbox	✔	You can use a sandbox environment to run tests manually to verify functionality on an environment. Running a large number of tests or tests that take a long time (more than 15 minutes per test method) isn't allowed. It's recommended that you don't run tests more that one or two hours a day.

BUSINESS CENTRAL SOLUTION	ENVIRONMENT	TESTING ALLOWED	MORE DETAILS
On-premises	Production	✅	For Business Central on-premises, running automated tests is only possible with a Partner license or a license that includes the Application Builder module. You can disable the ability to run tests by turning off **Enable Test Automation** (TestAutomationEnabled) on the Business Central Server instance. For more information, see Configuring Business Central Server - General Settings.
	Container-based development environment	✅	This setup should be the default environment for running large number of tests or setting up CI/CD gates. For more information, see Running a Container-Based Development Environment or Running Tests In Containers.

Test Codeunits and Test Methods

You write tests as AL code in methods of codeunits that are configured to be test codeunits. Test codeunits have the SubType Property set to **Test**. There are three types of methods that you can add in a test codeunit: test, handler, and normal. Each method type is used for a specific purpose and behaves differently. When a test codeunit runs, it executes the **OnRun** trigger, and then executes each test method in the codeunit. The outcome of a test method is either SUCCESS or FAILURE.

This pattern doesn't apply to test isolation and isn't recommended as a method for running tests.

For more information about test codeunits and test methods, see Test Codeunits and Test Methods.

Test Runner Codeunits

You use test runner codeunits to manage the execution of test codeunits and to integrate with other test management, execution, and reporting frameworks. By integrating with a test management framework, you can automate your tests and enable them to run unattended.

Test runner codeunits are codeunits that have the SubType Property set to **TestRunner**.

Test runner codeunits include the following triggers:

- OnRun Trigger
- OnBeforeTestRun Trigger
- OnAfterTestRun Trigger

In the **OnRun** trigger you enter the code to run the codeunits. It runs when you execute the codeunit and before the test methods run. You can use the **OnBeforeTestRun** and the **OnAfterTestRun** triggers to do preprocessing and postprocessing, such as initialization or logging test results.

For more information about test runner codeunits, see Test Runner Codeunits.

> **TIP**
> You can reuse test runners from Test Runner module in the Microsoft/ALAppExtensions GitHub repo. You can also use the repo to request for the new functionality.

Test Pages

Test pages mimic actual pages but don't present any UI on a client computer. Test pages let you test the code on a page by using AL to simulate user interaction with the page.

There are two types of test pages:

- TestPage, which is a regular page and can be any kind of page. It includes page parts and subpages as well.
- TestRequestPage, which represents the request page on a report.

You access the page's fields and properties or a field by using the dot notation. You open and close test pages, do actions on the test page, and navigate around the test page by using AL methods. For more information, see Testing Pages.

UI Handlers

To create tests that can be automated, you must handle cases when user interaction is requested by code that is being tested. UI handlers run instead of the requested UI. UI handlers provide the same exit state as the UI. For example, a method that has the ConfirmHandler Attribute set handles Confirm Method calls. If code that is being tested calls the Confirm Method, then the **ConfirmHandler** method is called instead of the Confirm Method. You write code in the **ConfirmHandler** method to verify that the expected question is displayed by the Confirm Method. You write AL code to return the relevant reply.

You create a specific handler for each page that you want to handle and a specific report handler for each report that you want to handle.

If you run a test codeunit from a test runner codeunit, then any unhandled UI in the test methods of the test codeunit causes a failure of the test. If you do not run the test codeunit from a test runner codeunit, then any unhandled UI is displayed as it typically would.

For more information, see Creating Handler Methods.

ASSERTERROR Keyword

You use `AssertError` statements in test methods to test how your application behaves under failing conditions. These statements are called positive and negative tests. The `AssertError` keyword specifies that an error is expected at run time in the statement that follows the `AssertError` keyword.

If a simple or compound statement that follows the `AssertError` keyword causes an error, then execution successfully continues to the next statement in the test method. You can get the error text of the statement by using the GETLASTERRORTEXT Method.

If a statement that follows the `AssertError` keyword doesn't cause an error, then the `AssertError` statement

causes the following error and the test method that is running produces a FAILURE result.

> **IMPORTANT**
> Use ASSERTERROR in test code only. It isn't allowed or supported in production code.

Example

To create a test method to test the result of a failure of a CheckDate method that you've defined, you can use the following code. This example requires that you create a method called CheckDate. This method checks whether the date is valid for the customized application. You also create the following text constant, *Date* variable InvalidDate, and *Text* variable InvalidDateErrorMessage.

```
InvalidDate := 010184D;
InvalidDateErrorMessage := 'The date is outside the valid date range.';
ASSERTERROR CheckDate(InvalidDate);
if GETLASTERRORTEXT <> InvalidDateErrorMessage then
  ERROR('Unexpected error: %1', GETLASTERRORTEXT);
```

Testing Best Practices

We recommend the following best practices for designing your application tests:

- Test code should be kept separate from the code that is being tested. That way, you can release the tested code to a production environment without releasing the test code.
- Test code should test that the code works as intended both under successful and failing conditions. These tests are called positive and negative tests. The positive tests validate that the code being tested works as intended under successful conditions. The negative tests validate that the code being tested work as intended under failing conditions.
    1. In positive tests, the test method should validate the results of application calls, such as return values, state changes, or database transactions.
    2. In negative tests, the test method should validate that the intended errors occur, error messages are presented, and data has the expected values.
- Automated tests shouldn't require user intervention.
- Tests should leave the system in the same well-known state as when the test started. This way, you can rerun the test or run other tests in any order and always start from the same state.
- Test execution and reporting should be fast and able to integrate with the test management system. This way, the tests can be used as check-in tests or other build verification tests. These other tests typically run on unattended servers.
- Create test methods that follow the same pattern:
    1. Initialize and set up the conditions for the test.
    2. Invoke the business logic that you want to test.
    3. Validate that the business logic worked as expected.
- Only use hardcoded values in tests when you really need it. For all other data, consider using random data.

    For example, you want to test the `Ext. Doc. No. Mandatory` field in the `Purchases & Payables Setup` table. To do this, you need to create and post typical purchase invoice. The typical purchase invoice line specifies

an amount. For most tests, it doesn't matter exactly what amount. For inspiration, see the use of the **GenerateRandomCode** method in the tests that are included in the **TestToolkit** folder on the Business Central product media. For more information, see Random Test Data.

> **TIP**
> Use the Any module in the Microsoft/ALAppExtensions GitHub repo to generate pseudo-random values during test set-up. This module generates the same set of numbers, allowing you to reproduce test failures.

- Tests should be readable and fast to execute. We recommend that test codeunits run under 2 minutes, and that you don't add more than 100 test methods to the codeunit.

Creating Test Codeunits and Test Methods

2/17/2021 • 2 minutes to read • Edit Online

In Dynamics 365 Business Central, you can create test codeunits and create test methods in the test codeunits.

Test codeunits are codeunits that have the SubType Property set to **Test**. You write tests as Al code in the methods inside of the test codeunits. There are three types of methods that you can add in a test codeunit: test, handler, and normal. Each method type is used for a specific purpose and behaves differently. When a test codeunit runs, it runs the **OnRun** trigger, and then runs each test method in the codeunit.

By default, each test method runs in a separate database transaction, but you can use the TransactionModel Property on test methods and the TestIsolation Property on test runner codeunits to control the transactional behavior.

The results of a test codeunit and of the individual test methods are displayed in a message window, but you can use the OnAfterTestRun Trigger on a test runner codeunit to capture the results. The outcome of a test method is either SUCCESS or FAILURE. If any error is raised by either the code that is being tested or the test code, then the global outcome of the test codeunit is FAILURE and the error is included in the results log file.

The difference between a normal codeunit and a test codeunit is their execution at runtime. When a normal codeunit is run, if one of its methods fails, then the codeunit is terminated. When a test codeunit is run, even if the outcome of one test method is FAILURE, the next test methods are still run.

The methods in a test codeunit can be one of the following types:

TYPE	DESCRIPTION	
Test method	You use test methods that include AL code that tests the business logic in the application, where each method covers a transaction. You declare the Test Attribute on the method.	
Handler method	You use handler methods to automate tests by handling instances when user interaction is required by the code that is being tested by the test method. In these instances, the handler method is run instead of the requested user interface. The handler method should simulate the user interaction for the test case, such as validating messages, making selections, or entering values. You declare a handler type attribute on the method. For more information, see Creating Handler Methods	
Normal method	You use normal methods to structure the test code by using the same design practices and principles as methods in other codeunits of the application. You declare the Normal Attribute on the method.

Creating Test Runner Codeunits

2/17/2021 • 2 minutes to read • Edit Online

You can create test runner codeunits to manage the execution of test codeunits and to integrate with test management or test reporting frameworks. By integrating with a test management framework, you can automate your tests and enable them to run unattended.

To create a test runner codeunit, create a codeunit and set the SubType Property to **TestRunner**.

To specify what changes in the database you want to roll back after the tests in the test runner codeunit execute, set the TestIsolation Property.

Test runner codeunits include the following triggers:

- OnRun Trigger
- OnBeforeTestRun Trigger
- OnAfterTestRun Trigger

In the **OnRun** trigger you enter the code to run the codeunits. It runs when you execute the codeunit and before the test methods run. You can use the **OnBeforeTestRun** and the **OnAfterTestRun** triggers to perform preprocessing and postprocessing, such as initialization or logging test results. If you implement the **OnBeforeTestRun** trigger, then it executes before each test method executes. If you implement the **OnAfterTestRun** trigger, then it executes after each test method executes and also suppresses the automatic display of the results message.

> **WARNING**
> The **OnBeforeTestRun** and **OnAfterTestRun** triggers always run in their own transactions, regardless of the value of the TestIsolation Property, the value of the TransactionModel Property, or the outcome of a test method.

Example

This sample codeunit runs three test codeunits in the automated application test libraries.

```
codeunit 50101 TestRunnerCodeunit
{
    Subtype = TestRunner;

    trigger OnRun()
    begin
        Codeunit.RUN(Codeunit::"ERM Vendor Statistics");
        Codeunit.RUN(Codeunit::"ERM Sales Quotes");
        Codeunit.RUN(Codeunit::"ERM Dimension");

    end;
}
```

You may want to define your test suite in a table and then write code in the test runner codeunit to iterate through items in the table and run each test codeunit. In that case, you can make use of the following example.

```
codeunit 50102 TestRunnerCodeunit
{
    Subtype = TestRunner;

    trigger OnRun()
    var
        EnabledTestCodeunit: Record "CAL Test Enabled Codeunit";
        Object: Record "Object";
    begin
        if EnabledTestCodeunit.FINDSET then
            repeat
                if Object.GET(ObjectType::Codeunit, '', EnabledTestCodeunit."Test Codeunit ID") then
                    CODEUNIT.RUN(EnabledTestCodeunit."Test Codeunit ID");
            until EnabledTestCodeunit.NEXT = 0

    end;
}
```

Testing the Application

Testing Pages

2/17/2021 • 3 minutes to read • Edit Online

You use test page objects to simulate user interactions with the application. You can:

- View or change the value of a field on a test page.
- View the data on page parts.
- View or change the value of a field on a subpage.
- Filter the data on a test page.
- Perform any actions that are available on the page.
- Navigate to different records.

You can create and open a test page in the following ways:

- Declare a test page variable and then write AL code to open the test page by using one of the following methods:
  - OpenNew Method (TestPage)
  - OpenEdit Method (TestPage)
  - OpenView Method (TestPage)
- Create a **PageHandler** or **ModalPageHandler** method that has a test page parameter.
- Write AL code to trap a call to open a test page by using the Trap Method (TestPage).

> **NOTE**
> You must consider how you set the TransactionModel Property to simulate the scenario that you want to test and to return the database to its initial state after the test.

> **NOTE**
> Test methods and code on test pages run on the Dynamics 365 Business Central Server instance, even though they simulate client interactions.

For more information about the AL methods that you use on a test page, see TestPage Data Type.

Accessing Fields on Test Pages

You access the fields on a test page by using the dot notation. For example, if you have a test page variable named `CustomerCard` that represents the `Customer Card` page, then to access the `Name` field on the test page, you write `CustomerCard.Name` in your code.

These fields are instances of the TestField Data Type, so you can use the corresponding AL methods to work with them. For example, if you have a test page variable named `CustomerCard` that represents the `Customer Card` page, then to assign the value of the `No.` field to a variable named `CustNo`, you write `CustNo := CustomerCard."No.".Value` in your code. To write a value in the `Address` field of a `Customer Card` page,

you write `CustomerCard.Address.Value := '<address>'` in your code.

Accessing Page Parts and Subpages

You access page parts and subpages on a test page by using the dot notation.

These are instances of the TestPart Data Type, so you can use the corresponding AL methods to work with them.

For example, to compare the value of the `No.` field on a page to the value of the `No` . field on a FactBox on the page, you can write the following code.

```
if CustomerCard."No.".Value <> CustomerCard."Sales Hist. Sell-to FactBox"."No.".Value then
  error("Page part data is not updated.");
```

Filtering Data on Test Pages

To filter the data that can be accessed on a test page, you use AL methods correspoding to the TestFilter Data Type instances. For example, to filter the customers on the `Customer List` page based on a range of values in the `No.` field, you can write the following code.

```
CustomerList.Filter.SetFilter("No.", '20000..30000');
```

Invoking Actions on Test Pages

Any action that is available on a page is also available on the test page that mimics that page. You access page actions by using the dot notation and the Invoke Method.

These are instances of the TestAction Data Type, so you can use the corresponding AL methods to work with them. To access built-in actions, such as Yes, No, OK, or Cancel you can also call the Yes Method, No Method, Ok Method and Cancel Method respectively, directly in the test page.

Navigating Among Records

To simulate moving to different items on a list page or moving to different records on a card page, you use one of the following navigation methods:

- Next Method (TestPage)
- Previous Method (TestPage)
- First Method (TestPage)
- Last Method (TestPage)
- GoToRecord Method (TestPage))
- GoToKey Method (TestPage)
- FindFirstField Method (TestPage)
- FindNextField Method (TestPage)
- FindPreviousField Method (TestPage)

Creating Handler Methods

2/17/2021 • 3 minutes to read • Edit Online

You can create test codeunits, test methods, and test pages to test your application. We recommend that you create tests that can be automated. To create automated tests, you must write code to handle all UI interactions so that the tests do not require user interaction when they are running. To do this, you create special handler methods.

You can use the following handler methods:

METHOD TYPE	PURPOSE	SIGNATURE	
MessageHandler	Handles **Message** statements.	< *Function name*> (< *Message*> : Text[1024])	
ConfirmHandler	Handles **Confirm** statements.	< *Function name*> (< *Question*> : Text[1024]; var < *Reply*> : Boolean)	
StrMenuHandler	Handles **StrMenu** statements.	< *Function name*> (< *Options* : Text[1024]; var < *Choice*> : Integer; < *Instruction*> : Text[1024])	
PageHandler	Handles specific pages that are not run modally.	< *Function name*> (var < *Page*> : Page < *page id*>) < *Function name*> (var < *Page*> : TestPage < *testpage id*>)	
ModalPageHandler	Handles specific pages that are run modally.	< *Function name*> (var < *Page*> : Page < *page id*>; var < *Response*> : Action) < *Function name*> (var < *Page*> : Page < *testpage id*>)	
ReportHandler	Handles specific reports. If you create a **ReportHandler** method, then that method replaces all code for running the report, including the request page, and a **RequestPageHandler** is not called. Only create a **RequestPageHandler** if you are not using a ReportHandler.	< *Function name*> (var < *Report*> : Report < *report id*>)	

METHOD TYPE	PURPOSE	SIGNATURE	
FilterPageHandler	Handles a specific filter page. The FilterPageHandler tests the UI that is generated by a FilterPageBuilder Data Type.	< *Function name* > (var < *Record1* > : RecordRef)[, var < *Record2* > : RecordRef] [, ...]): Boolean	
RequestPageHandler	Handles the request page of a specific report.	< *Function name* > (var < *RequestPage* > : TestRequestPage)	
HyperlinkHandler	Handles specific hyperlinks.	< *Function name* > (< *Hyperlink* > : Text[1024])	
SendNotificationHandler	Handles **Send** statements.	< *Function name* > (< *TheNotification* >: Notification): Boolean	
RecallNotificationHandler	Handles **Recall**	< *Function name* > (< *TheNotification* >: Notification): Boolean	
SessionSettingsHandler	Handles **RequestSessionUpdate** statements.	< *Function name* > (var < *SessionSettings* >: SessionSettings): Boolean	

How to create a handler method

To create a handler method, you set one of the handler attributes on a method. You must use the method signature specified for the handler attribute that you are using, as illustrated in this code example.

```
[MessageHandler]
procedure MessageHandler(Message: Text[1024])
begin
    Assert.IsTrue(StrPos(Message, MSG_HAS_BEEN_CREATED) > 0, Message);
end;
```

The parameters of the methods that are being handled are passed as parameters to the handler methods. For example, when **Message** is called in a test method, the parameter of the **Message** method is passed as the parameter of the **MessageHandler** method. For page and report handlers, the page, report, or request page is passed as the parameter of the **PageHandler**, **ModalPageHandler**, **ReportHandler**, or **RequestPageHandler**.

You can call handler methods from methods that have the Test Attribute and then specify the handler methods that it will use in the HandlerFunctions Attribute. The code inside the test method should simulate that the UI was actually raised and some values entered or some actions were taken. You can specify more than one handler method by separating the handler method names with a comma.

> **NOTE**
> Every handler method that you enter in the HandlerFunctions Attribute of a test method must be called at least one time in the test method. If you run a test method that has a handler method listed that is not called, then the test fails.

The following example shows a test method that uses the HandlerFunctions Attribute to call the

MessageHandler method.

```
[Test]
[HandlerFunctions('MessageHandler')]
procedure ApproveRequestForPurchCreditMemo()
var
    PurchHeader: Record "Purchase Header";
begin
    ApproveRequestForPurchDocument(PurchHeader."Document Type"::"Credit Memo");
end;
```

Application Testing Example: Testing Purchase Invoice Discounts

2/17/2021 • 4 minutes to read • Edit Online

Before you release a customized Dynamics 365 Business Central application to a production environment, you must test the application. This walkthrough demonstrates how to use the test codeunits and test libraries to test an application.

About this example

You have modified codeunit 70, Purch-Calc.Discount, which is a codeunit in the CRONUS International Ltd. database. You want to test the functionality of the customized codeunit before you offer the customized application for sale. You create a new test codeunit with new test methods to test the Purch-Calc.Discount codeunit. During development, You use the application test libraries to help write a test with fewer lines of code.

Prerequisites

To complete this example, you will need:

- Dynamics 365 Business Central with a developer license.
- The CRONUS International Ltd. demo data company.
- To import the Test Toolkit.

Task 1: Create the test codeunit and method

1. Create a new codeunit and specifies that it is a test codeunit.
2. Define the scenario that you want to verify, and add a test method to test the Purch-Calc.Discount functionality.

   > **TIP**
   > By default, methods in test codeunits are test methods unless you specify otherwise.

Guidelines

- In this example, the name of the test method consists of the tested functionality, Purchase Invoice Discount Calculation, and relevant parameters that affect the test result. We recommend that you follow this naming pattern for your test methods also. In our example, the following parameters are introduced:
- `PInv` for the document that is tested, purchase invoices. You can apply the same test to purchase orders or purchase credit memos. Also, we recommend that you have mirrored sets of tests for the sales area.
- `Above`. It is a good practice to have tests for positive and negative scenarios. In this test, Isaac wants to check that discount come into effect when the document amount is above a minimum amount. But the amount in the document can be also less than or equal to the minimum amount.
- Isaac first defines the test scenario [SCENARIO], then details it with the GIVEN-THEN-WHEN notation. Finally, he adds the AL code.The code in this test method prepares the test data by setting a random discount percent, a minimum amount, and a document amount. Then, it creates a purchase document

with a line and runs the Purch-Calc.Discount codeunit, which contains the code that is being tested. Finally, it verifies the results of running the Purch-Calc.Discount codeunit and raises an error if the results are not as expected.

- You can create additional test methods in this test codeunit to test other aspects of vendor discounts. These test methods should include negative tests, which validate that the code being tested works as intended under failing conditions.

Task 2: Create a helper method

The next task is to create a helper method that generates data for the test. The helper method can be reused if you decide to extend test coverage.

Guidelines

- The code in the helper method prepares data for the test by creating a new vendor, setting up the invoice discount, and creating a purchase document with an item. Because this helper method is not specific to the test itself, you can reuse it for similar tests. For example, you can call it with other parameters and create a purchase credit memo, or set up 0% discount, or create a document where the total amount is less than the minimum amount that is specified in **Vendor Invoice Disc.** table.

> **NOTE**
> This test code does not guarantee that the state of the database after you run the test is the same as the state of the database before you run the test.

Code

```
codeunit 50111 "ERM Vendor Discount"
{
    // Specifies the codeunit to be a test codeunit
    Subtype = Test;

    trigger OnRun()
    begin

    end;

    // Makes the method a test method
    [Test]

    // Adds the test logic to the test method
    procedure PurchInvDiscCalculationPInvAbove()

    var
        PurchLine: Record "Purchase Line";
        MinAmount: Decimal;
        DocAmount: Decimal;
        DiscountPct: Decimal;
        PurchCalcDisc: Codeunit "Purch.-Calc.Discount";

    begin
        // [SCENARIO] "Inv. Discount Amount" should be calculated on Purchase Invoice (in LCY), where
Invoice amount is
        // above the minimal amount required for invoice discount calculation.
        // [GIVEN] Vendor with invoice discount percentage "D" for minimal amount "A" in LCY
        // [GIVEN] Create purchase invoice with one line and amount >"A"
        DiscountPct := RandomNumberGenerator.RandDec(100, 5);
        MinAmount := RandomNumberGenerator.RandDec(1000, 2);
        DocAmount := MinAmount + RandomNumberGenerator.RandDec(100, 2);
        CreatePurchDocument(PurchLine, PurchLine."Document Type"::Invoice, DocAmount, MinAmount,
```

```
DiscountPct);
        // [WHEN] Calculate invoice discount for purchase document (line)
        PurchCalcDisc.RUN(PurchLine);
        // [THEN] "Inv. Discount Amount" = Amount "A" * discount "D" / 100
        PurchLine.Find;
        Assert.AreEqual(Round(PurchLine."Line Amount" * DiscountPct / 100), PurchLine."Inv. Discount
Amount", PurchInvDiscErr);
    end;

    // Creates the test helper method
    local procedure CreatePurchDocument(var PurchLine: Record "Purchase Line"; DocumentType: Option;
DocAmount: Decimal; MinAmount: Decimal; DiscountPct: Decimal)

    var
        VendorInvoiceDisc: Record "Vendor Invoice Disc.";
        PurchaseHeader: Record "Purchase Header";
        VendorNo: Code[30];

    begin
        // Create vendor
        VendorNo := LibraryPurchase.CreateVendorNo;
        // Create vendor invoice discount
        VendorInvoiceDisc.Init;
        VendorInvoiceDisc.Code := VendorNo;
        VendorInvoiceDisc.Validate("Currency Code", '');
        VendorInvoiceDisc.Validate("Minimum Amount", MinAmount);
        VendorInvoiceDisc.Validate("Discount %", DiscountPct);
        VendorInvoiceDisc.Insert(TRUE);
        // Create purchase line
        LibraryPurchase.CreatePurchaseDocumentWithItem(PurchaseHeader, Purchline, DocumentType, VendorNo,
'', 1, '', 0D);
        PurchLine.Validate("Direct Unit Cost", DocAmount);
        PurchLine.Modify(TRUE);
    end;

    var
        RandomNumberGenerator: Codeunit "Library - Random";
        LibraryPurchase: Codeunit "Library - Purchase";
        Assert: Codeunit Assert;
        myInt: Integer;
        PurchInvDiscErr: Label 'The Purchase Invoice Discount Amount was not calculated correctly.';

}
```

The Performance Toolkit Extension

2/17/2021 • 10 minutes to read • Edit Online

This extension is built for independent solution vendors (ISVs) and value added resellers (VARs) who develop vertical solutions and customize Business Central for their customers. In this type of collaboration, things often change between released versions on both sides, so it's important that ISVs and VARs can ensure that new versions of their solutions don't introduce performance regressions as the volume of users grows. To help, the Performance Toolkit lets developers simulate workloads in realistic scenarios to compare performance between builds of their solutions.

In short, the Performance Toolkit helps answer questions such as, "Does my solution for Business Central support X number of users doing this, that, and the other thing at the same time?" It doesn't answer questions such as, "How many orders can Business Central process per hour?"

> **IMPORTANT**
> You can use the toolkit only in sandbox environments and Docker images. You cannot use it in a production tenant.

Components of the Performance Toolkit

The Performance Toolkit is two extensions, the **Performance Toolkit**, which is available for free on AppSource, and **BCPT-SampleTests**, which you can download from the ALAppExtensions repository on GitHub. To get the full benefit of the toolkit, we recommend that you download and install both extensions. Combined, the extensions provide the following:

- A framework for defining a set of tests or scenarios to run in parallel. The framework also logs results and lets you import and export suite definitions.
- Predefined test suites that cover basic scenarios, which can also serve as inspiration for other suites that suit your customer environments.
- A command line tool that must be installed on a client computer. To simulate multiple users signing in and using pages, you must start those scenarios from outside Business Central. The command line tool will run the number of concurrent client sessions that is specified in the suit. For more information, see Starting the Run from PowerShell.

Single and Multiple Sessions

Typically, you'll want to run the suite for multiple sessions at the same time. After you configure the suite, you can do that by using the **Start** action. However, if you want to do light-weight testing, for example, early in the development phase, you can choose the **Start in Single Run mode** action to run your suite just once, and as fast as possible. Single Run mode lets you monitor the number of SQL statements between runs and define baselines, and gives you quick feedback that can help identify regressions early on.

You can run up to 125 sessions at the same time for a test suite. The **Total No. of Sessions** field shows how many sessions will be created when you run the suite.

Running in the Background and Foreground

On the suite lines, the **Run in Foreground** check box lets you run tests in sequence, rather than in parallel. You can also use it in combination with background tasks, but that will run each session individually. You can only run one session in the foreground at a time.

> **NOTE**
> If you use Single Run mode and run in the foreground, you don't need to go to PowerShell to run the test.

Configuring a Suite

The settings to configure a suite depend on the environment that you want to simulate. The following procedure provides an example for testing multiple sessions, but the steps also apply to a single run.

To configure a suite

1. Search for **BCPT Suites**, and then choose the related link.
2. Choose **New** to open the BCPT Suite page.
3. In the **Code**, **Description**, and **Tag** fields, provide an identifier, some information about the test, and a tag that you can use to find the results of the suite on the Log Entries page.
4. Define timing for the run.
   a. The **1 Work Day Corresponds to** field works with the **Duration (minutes)** field to update the **Work Date Starts at** field, and you use it to test processes that have deadlines, such as payments. The duration can be up to 240 minutes.
   b. The **Default Min. User Delay** and **Default Max. User Delay** fields in the header let you simulate pauses between actions. You must specify a delay. Between each iteration, for example when creating sales orders, you can define a **Delay** (Delay between iterations) before the test starts on the next sales order. The delay can be **Fixed** or **Random**. Delays are not included the results for run times.
5. Specify the base version to compare.

   > **TIP**
   > To change the value in the **Base Version** field, you might need to turn on Edit mode.

6. Configure lines for the suite.

   > **TIP**
   > The lines will contain some of the settings from the header. Updating the values on the lines will also update the header.

   a. On the **BCPT Suite Lines** FastTab, choose the codeunits to run.
   b. In the **Parameters** field, enter a parameter to define iterations such as, for example, creating lines on documents. For example, a parameter **Lines=10** will create 10 lines on a document.
   c. In the **No. of Sessions** field, enter the number of concurrent users to simulate.
   d. Optional: If you want to run in Single Run mode, or you want to run one of the sessions without applying settings such as minimum and maximum delays, choose the **Run in Foreground** check box. For more information, see Running in the Background and Foreground.

Starting the Run from PowerShell

After you have installed the binaries and scripts and configured your suite, you can create the credential object and run the tests from PowerShell by using the following commands

To create the credential object, run the following command:

```
$Credential = New-Object PSCredential -ArgumentList <user email>,(ConvertTo-SecureString -String <password>
-AsPlainText -Force)
```

To start tests in a Business Central online sandbox, run the following command:

```
RunBCPTTests.ps1 -Environment PROD -AuthorizationType AAD -Credential $Credential -SandboxName <sandbox
name> -TestRunnerPage 149002 -SuiteCode "TRADE-50U"
```

> **NOTE**
>
> When you start tests from PowerShell, there is a two second delay between new sessions.

Analyzing Results

When a run has completed, you can view the results on the lines on the **BCPT Suite Lines** FastTab. For more information, see Analyzing the Results.

Troubleshooting log entries

After running the suite, you can choose **Log Entries** to see what happened. Use the **Show Errors** and **Show sessions running at the same time as this** actions to apply filters to the results. For example, filtering can help troubleshoot errors by showing what a user was doing when an error occurred. By default, the page is filtered to show the latest version, but you can change or remove the filter if you want to compare runs. You can use the **Open in Excel** action to build dashboards that can help visualize performance results.

Log entries are listed in the order that they were created, which means that the different scenarios are mixed. Each run is identified by the value in the **Version No.** fields.

The **Operation** column shows the individual measurements, where the term *Scenario* is used for running the codeunit without the user wait time. The **No. of SQL Statements** column includes the SQL statements that were issued by the scenario and system activities, such as retrieving metadata. The counts exclude the log entries themselves. To drill down to a single session, filter on the **Session No.** field or choose **Open in Excel** to create a pivot table and pivot chart for deeper analysis.

Example: Evaluate SQL calls and timing in Single Run mode

This example shows how to use Single Run mode for performance regression testing (PRT) between changes to code, to evaluate SQL calls and timing. Often, when developing a new extension, you start out with limited code and may want to wait to do a larger benchmark test with simulated concurrent users until you're closer to having a full, end-to-end scenario. You can use the **Start in Single Run Mode** action to perform a limited test, for example, on a new extension. Single Run mode will still provide things like a baseline, the ability to run the test in the background, and give you instant feedback.

The data that the runs generate is persisted in the database. If the database is maintained, you can set previous runs as baseline.

To run a test in Single Run mode

The following steps provide an example of how to run a PRT in Single Run mode.

1. On the **BCPT Suites** page, choose **New**.

2. In the **Code** field, enter a name for the test suite. In this example, we'll use **PreTest**.
3. In the **Tag** field, enter something that will make it easy to identify the suite later when you analyze the results.
4. The fields for duration and delays are not used for Single Run mode, so we'll leave their default values.
5. On the BCPT Suit Lines FastTab, choose the test suite for your component.
6. In this example, we're calculating the total weight of the items on a sales order, so we'll use the **Sales Order** page test with a parameter that creates four lines. The parameter looks as follows: Lines=4.
7. Clear the **Run in Foreground** check box. This will run the test suite in a background thread.
8. Choose **Start in Single Run mode**.
9. To set your baseline after the run completes, in the **Base Version** field, enter **1**.

> **TIP**
> If you run the test again you'll have delta values in the test case line. For more information, see Analyzing the Results. You can reset the baseline to any version, and run as many test as needed.

Analyzing the results

The results of the PRT are shown on the **BCPT Suite Lines** FastTab. The following tables describe the fields that show results of the current run, the results of the baseline, and the delta between the two.

FIELDS FOR CURRENT RUN	DESCRIPTION
No. of Iterations	How many times it ran. this will remain 1 as we use the Start In single Run Mode.
Total Duration in (ms)	How long it took to complete one iteration.
Average duration	Equal to **Total Duration in (ms)** field for the first run, but after you run test multiple times it's a result of the sum of runs since your baseline.
No. of SQL statements	The number of SQL statements generated for one run.
Avg. No. of SQL Statements	Similar to the duration fields, for the first run this will be the same as the **No. of SQL statements** field, but will become averaged after subsequent runs.

The following table describes the fields related to the baseline.

FIELDS FOR BASELINE	DESCRIPTION
No. of Iterations Base	Not relevant for PRTs in Single Run mode.
Total Duration Base (ms)	The total duration of the baseline run.
Avg. Duration Base (ms)	Not relevant for PRTs in Single Run mode.
Avg. No. of SQL Statements Base	The number of SQL statements in your base run.

The following table describes the fields that show the delta between the run and the baseline.

FIELDS FOR THE DELTA	DESCRIPTION
Change in No. of SQL statements (%)	The difference, as a percent, between a baseline and the latest run.
Changes in Duration (%)	The change in measured time between a baseline and the latest run.

> **NOTE**
> The first iteration of any scenario running will show higher number of SQL Statements because nothing has been cached.

Writing Test Cases (codeunits)

A test case is a codeunit of either a **Normal** or **Test** subtype. If the subtype is Normal, the test scenario should be defined in the OnRun trigger because the Performance Toolkit uses the codeunit to run the testcase.

To interact with pages and make the tests more realistic, define a codeunit of the subtype **Test**, as shown in the example for codeunit BCPT Open Item List. Codeunit BCPT Test Context is an interface for running tests. Tests can use the StartScenario amd EndScenario functions on the BCPT Test Context codeunit to log when a scenario that is being measured started and stopped. To simulate user delays, the UserWait() function should be called while moving between fields to make the tests more realistic. The BCPT Test Context codeunit also exposes the parameters that are set on the test codeunit to the test suite. When using Business Central, an implicit Commit() is called for every interaction, and that should be simulated in the tests by calling an explicit Commit().

Rules and Guidelines for AL Code

2/17/2021 • 4 minutes to read • Edit Online

This page defines the rules and guidelines to follow when writing AL code in an extension package for Dynamics 365 Business Central. The rules and guidelines are grouped according to two importance levels: critical errors that must be resolved, and important errors that should be resolved. Errors that are not resolved must include an explanation and justification for the error.

Critical errors

- Code uses encryption key functions such as IMPORTENCRYPTIONKEY, EXPORTENCRYPTIONKEY, CREATEENCRYPTIONKEY, and DELETEENCRYPTIONKEY. (It is fine to use the ENCRYPT and DECRYPT methods.)
- Code uses ASSERTERROR.
- External data connections do not properly handle sensitive data.
- It does not encrypt sensitive table data. (i.e. credit card info, passwords, etc.).

Important errors

- Temporary files are not cleaned up after use.
- Code uses codeunits that require printers to be selected.
- Code uses a specific time zone or locale.

Common pitfalls

To help you save time, we're sharing a list of the top 15 common pitfalls that regularly lead to app validation failures.

1. Prefix/Suffix missing

   One of the app requirements is for you to reserve a prefix/suffix for your app. This is needed to ensure a healthy app ecosystem by avoiding collision amongst apps. This common failure occurs due to not setting your prefix/suffix in some or all required places. For more information, see Benefits and Guidelines for using a Prefix or Suffix.

2. DataClassification missing or set incorrectly

   Due to GDPR requirements, fields of field class *Normal* must use the DataClassification property, and its value must be different from *ToBeClassified*. This applies to fields in tables and table extensions. Use the AppSourceCop tool for detecting this.

3. Required translation files missing

   There are many countries today that where Dynamics 365 Business Central is available, and that you can support as well with your app. For specifying additional languages, we no longer support Caption ML. You must use xliff translation files instead. For more information, see Working with Translation Files. Microsoft provides a free translation tool that you can access from https://lcs.dynamics.com. To support a specific country, you must include a translation file per for each language code. For example, to support Switzerland, you must provide fr-CH, de-CH, and it-CH.

4. Missing permission sets

Your app must provide one or more permission sets so that users can use your app's functionality. Your app must never require the SUPER permission set.

5. Permission errors

   For your app to be a good citizen in Dynamics 365 Business Central, permission errors must not appear unless it is a necessary reason for showing the error.
   It is acceptable to throw an error to a user that does not have your permission set marked and tries to access your page object. It is not acceptable to throw an error to that same user trying to access Business Central pages in the base application, or to throw an error to a user who is not trying to access your app's functionality.

6. Missing application area tagging

   Tag in which part your app participates. Pages, controls, actions, and fields will not appear in Dynamics 365 Business Central if the Application Area property has not been set.

7. Usage Category not set

   You enable a page or report to be available through search in Dynamics 365 Business Central by using the UsageCategory property. For more information, see Using Tell Me to Find Features and Information.

8. OnCompany procedure

   Due to their performance impact, *OnBeforeCompanyOpen* and *OnAfterCompanyOpen* cannot be used. For more information, see Replacing OnBeforeCompanyOpen and OnAfterCompanyOpen.

9. Upgrade procedures

   Make sure that your app can be upgraded properly. For more information, see Upgrading extensions.

10. Profiles

    Do not insert into the Profile table. Use the Profile object instead.

11. App file not properly code signed

    Your app file must be digitally signed with a certificate from a third-party certification authority trusted by Windows.

12. You tested your app on an obsolete Dynamics 365 Business Central version (or never even tested it)

    Make sure that your app is properly tested on the correct version. For more information, see Current Build - Developing for Dynamics 365 Business Central on the Collaborate site.

13. You tested using SUPER permissions

    You tested your app, but your user had SUPER permissions. This can hide critical errors. You must test with a user that doesn't have the SUPER permissions. The user must have the ESSENTIAL license. For more information, see Testing your Extension.

14. User scenario document unclear

    Our validation team is testing your app functionality manually, so we need to be able to understand the core functionality of your app. If your user scenario document is missing important details that are needed for us to properly walk through your app's setup and usage scenarios, we cannot validate your app successfully. For more information, see User Scenario Documentation.

15. The .json file is incorrect

    There are many values in the app.json file that may not be mandatory to compile your app, but are mandatory for your app to be in AppSource. For example, your app cannot be published to a production

tenant if the **target** value is set to *OnPrem*. It must be set to *Cloud*. For information, see JSON Files.

Best Practices for AL

2/17/2021 • 4 minutes to read • Edit Online

This page defines some of the best practices to follow when writing AL code for Dynamics 365 Business Central. These best practices are additional to rules and guidelines that are caught during compilation of AL code. We recommend following these best practices when developing extensions in AL to ensure consistency and discoverability on file, object, and method naming, as well as better readability of written code.

> **NOTE**
> If a best practice is not mentioned here, the PreCal rules listed here apply.

Extension structure

An extension is fully contained in a single folder. This folder often contains multiple files, such as `app.json` and `launch.json` files, perhaps an image file representing the extension's logo, various folders for source; "\src", other resources; "\res", and a test folder; "\test" folder. The extension does not need to follow a flat structure, which means that, depending on the amount of application files, additional folders can be used in the "src" or "test" folders to group objects based on their functionality, which can help make maintaining a large .al project easier.

File naming

Each file name has object names with only characters [A-Za-z0-9], object type, and dot al, for file type. In your extension, the name of each new application object (table, page, codeunit), can contain a prefix or suffix.

The CodeCop analyzer suggests that the object name is part of the file name, which is encouraged as a best practice. Adding any affixes to the file names is voluntary.

> **NOTE**
> If you are submitting an app to AppSource, you must follow the guidance in the Technical Validation Checklist.

File naming notation

Follow the syntax for file naming as shown below:

FULL OBJECTS	EXTENSIONS
`<ObjectNameSuffix>.<FullTypeName>.al`	`<ObjectNameSuffix>.<FullTypeName>Ext.al`
`<PrefixObjectName>.<FullTypeName>.al`	`<PrefixObjectName>.<FullTypeName>Ext.al`
`<ObjectNameExcludingAffix>.<FullTypeName>.al`	`<ObjectNameExcludingAffix>.<FullTypeName>Ext.al`

Type map

Use the listed abbreviations for each type of object in the file naming:

OBJECT	ABBREVIATION
Page	Page
Page Extension	PageExt
Page Customization	PageCust
Codeunit	Codeunit
Table	Table
Table Extension	TableExt
XML Port	Xmlport
Report	Report
Request Page	RequestPage
Query	Query
Enum	Enum
Enum Extension	EnumExt
Control Add-ins	ControlAddin
Dotnet	Dotnet
Profile	Profile
Interface	Interface

Examples of object naming

Table

```
table 70000000 MyPrefixSalesperson
```

Page

```
page 70000000 MyPrefixSalesperson
```

Page extension

```
actions
{
    addafter(ApprovalEntries)
    {
        action(MyPrefixVacation)
```

Codeunit

```
codeunit 70000000 MyPrefixSalesperson
```

File naming examples

For the listed objects above, these are examples of the file naming.

OBJECT NAME	FILE NAME
codeunit 70000000 MyPrefixSalesperson	`MyPrefixSalesperson.Codeunit.al`
page 70000000 MyPrefixSalesperson	`MyPrefixSalesperson.Page.al`
page 70000000 MyPrefixSalesperson extends "Customer Card"	`MyPrefixSalesperson.PageExt.al`

Formatting

We recommend keeping your AL code properly formatted as follows:

- Use all lowercase letters for reserved language keywords. Built-in methods and types are not included in this rule because they are written using Pascal case.
- Use four spaces for indentation.
- Curly brackets are always on a new line. If there is one property, put it on a single line.

The following example illustrates these formatting rules.

```
page 123 PageName
{
    actions
    {
        area(Processing)
        {
            action(ActionName)
            {
                trigger OnAction()
                begin
                end;
            }
        }
    }

    var
        TempCustomer: Record Customer temporary;

    [EventSubscriber(ObjectType::Page, Page::"Item Card", 'OnAfterGetCurrRecordEvent', '', false, false)]
    local procedure OnOpenItemCard(var rec: Record Item)
    var
        OnRecord: Option " ", Item, Contact;
    begin
        EnablePictureAnalyzerNotification(rec."No.", OnRecord::Item);
    end;
}
```

The AL Language extension offers users the option to automatically format their source code. For more information on how to use it, see AL Formatter.

Line length

In general, there is no restriction on line length, but lengthy lines can make the code unreadable. We recommend that you keep your code easily scannable and readable.

Object naming

Object names are prefixed. They start with the feature/group name, followed by the logical name as in these two examples:

- `Intrastat extension validation codeunit for Denmark`
- `codeunit 123 "IntrastatDK Validation"`

> **NOTE**
> The "MS - " prefix is not required.

File structure

Inside an .al code file, the structure for all objects must follow the sequence below:

1. Properties
2. Object-specific constructs such as
   - Table fields
   - Page layout
   - Actions
   - Triggers
3. Global variables
   - Labels
   - Global variables
4. Methods

Referencing

In AL, objects are referenced by their object name, not by their ID.

Example

```
Page.RunModal(Page::"Customer Card", ...)

var
    Customer: Record Customer;
```

Variable and field naming

For variables they must:

- Be named using PascalCase
- Have the `Temp` prefix if they are temporary variables
- Include the object name in the name (for objects)

Furthermore:

- Field and variable names should not include wildcard symbols, such as `%` and `&`. This might break features such as export using Excel or RapidStart.

- Name fields using aA-zZ and 0-9 and use Caption and xliff files to display the field appropriately. For more information, see Working with Translation Files.
- Using English as the language for naming improves the ability to troubleshoot issues that may arise.

Example

```
TempCustomer: Record Customer temporary;
Vendor: Record Vendor;
```

Method declaration

To declare a method, follow the guidelines below:

- Include a space after a semicolon when declaring multiple arguments.
- Semicolons can be used at the end of the signature/method header. If you use a snippet, the semicolons are not automatically added.
- Methods are named as variables using Pascal case. However, this is not a mandatory rule.
- There must be a blank line between method declarations. If you format your code using the AL Formatter tool, the auto-formatter sets the blank line between procedures.

Example

```
local procedure MyProcedure(Customer: Record Customer; Int: Integer)
begin
end;

// space

local procedure MyProcedure2(Customer: Record Customer; Int: Integer)
begin
end;
```

Calling methods

When calling a method, include one space after each command if you are passing multiple parameters. Parentheses must be specified when you are making a method call or system call such as: `Init()`, `Modify()`, `Insert()` etc.

Example

```
MyProcedure();
MyProcedure(1);
MyProcedure(1, 2);
```

Type definition (colon)

When declaring a variable or a parameter, the name of that variable or parameter must be immediately followed by a colon, then a single space, and then the type of the variable/parameter as illustrated in the example below.

```
var
    Number: Integer;

local procedure MyProcedure(a: Integer; b: Integer): Integer
```

Best Practices for Deprecation of Code in the Base App

2/17/2021 • 2 minutes to read • Edit Online

This topic provides guidelines that describe how code in the Base App is obsoleted. The topic describes some best practices that Microsoft is using for obsoleting code, and is meant as a non-enforced guidance and best practice. You can use this topic as an inspiration on how to set up a best practice for your own code. For obsoleting code, preprocessor statements in AL can be used. For more information, see Directives in AL.

Obsoleting Code

When we obsolete code, we:

- Add the preprocessor statements `#if`, `#else`, and `#endif` surrounding the code to be obsoleted.
- Use one of the following preprocessor symbols, where the pattern is `CLEAN<Version>`, such as `CLEAN15`, `CLEAN16`, `CLEAN17`, and `CLEAN18`.

  > **NOTE**
  > These symbols are not shipped with the product.

- The version to use in the symbol matches the `<major>` of the `ObsoleteTag`. For example:
  - If a method is to be removed, then we are using `#if not`

```
#if not CLEAN18
    [Obsolete('Replaced by SetParameters().', '18.0')]
    procedure SetParams(NewAnalysisArea: Option Sales,Purchase,Inventory; NewReportName:
Code[10]; NewLineTemplateName: Code[10]; NewColumnTemplateName: Code[10])
    begin
        SetParameters("Analysis Area Type".FromInteger(NewAnalysisArea), NewReportName,
NewLineTemplateName, NewColumnTemplateName);
    end;
#endif
```

  - If an action is to be removed, then we are also using `#if not`

```
#if not CLEAN17
    action("Social Listening Setup")
    {
        ApplicationArea = All;
        Caption = 'Social Engagement Setup';
        RunObject = page "Social Listening Setup";
        Visible = false;
        ObsoleteState = Pending;
        ObsoleteReason = 'Microsoft Social Engagement has been discontinued.';
        ObsoleteTag = '17.0';
    }
#endif
```

  - If a table is to be removed, then we'll use `#if #else #endif`

```
table 1808 "Aggregated Assisted Setup"
{
    Access = Internal;
    Caption = 'Aggregated Assisted Setup';
#if CLEAN16
    ObsoleteState = Removed;
#else
    ObsoleteState = Pending;
#endif
    ObsoleteReason = 'Data available in Assisted Setup already- extensions also register in
the same table.';
    ObsoleteTag = '16.0';
```

- If a table is to be marked as `Temporary`, then we'll use `#if #else #endif`

```
table 5503 "Acc. Schedule Line Entity"
{
    Caption = 'Acc. Schedule Line Entity';
    // TableType = Temporary;
#if CLEAN17
    TableType = Temporary;
#else
    ObsoleteState = Pending;
    ObsoleteReason = 'Table will be marked as TableType=Temporary. Make sure you are not using
this table to store records';
    ObsoleteTag = '17.0';
#endif
```

In order to have the compiler take the new 'clean' code path, the symbols must be defined. This is done in the `app.json` file with the following setting. For more information, see JSON Files.

```
"preprocessorSymbols": [ "CLEAN15", "CLEAN16", "CLEAN17", "CLEAN18" ]
```

> **IMPORTANT**
> A best practice is to change this locally to make sure everything compiles, run tests locally, and submit test jobs.

Fixing code when objects are removed

If an action or other code element points to a now removed object, then the guidance is to:

- Ensure that the action is obsoleted.
- Add preprocessor statements to fix the issue.
  - If code points to an obsoleted method, then use directives to put in the fixed code.
  - If code points to an obsoleted table/field, then use directives to put in the fixed code.

Benefits and Guidelines for using a Prefix or Suffix

2/17/2021 • 3 minutes to read • Edit Online

In your extension, the name of each new application object (table, page, codeunit), must contain a prefix or suffix. This rule applies to all objects. You can use the Caption values for what you decide to display to the user. When you modify a core Dynamics 365 object using a table extension or a page extension, the prefix/suffix must be defined at the control/field/action/group level.

Examples

Declare your objects with a prefix as shown in the following examples.

Table

```
table 70000000 MyPrefixSalesperson
```

```
table 70000001 SalespersonMySuffix
```

Page

```
page 70000000 MyPrefixSalesperson
```

```
page 70000001 SalespersonMySuffix
```

Page extension

```
actions
{
    addafter(ApprovalEntries)
    {
        action(MyPrefixVacation)
```

```
actions
{
    addafter(ApprovalEntries)
    {
        action(VacationMySuffix)
```

Codeunit

```
codeunit 70000000 MyPrefixSalesperson
```

```
codeunit 70000001 SalespersonMySuffix
```

Benefits

Apps in AppSource are required to register and use a prefix or a suffix. Only in vary rare cases will apps run into naming conflicts.

Per-tenant extensions are not required to use a prefix or suffix, but we strongly recommend that you do so. You can use *pte* as prefix or suffix to avoid conflicts with AppSource apps or base objects.

> **NOTE**
> If your per-tenant extension causes a conflict with a new object in the base application or an updated AppSource app, then the per-tenant extension will be required to make the change.

General rules

- The prefix/suffix must be at least 3 characters
- The object/field name must start or end with the prefix/suffix
- If a conflict arises, the one who registered the prefix/suffix always wins
- For your own pages/tables/codeunits, you must set the prefix/suffix at the top object level
- For pages/tables in the base application or other apps that you extend, you must set the prefix/suffix at the top object level and also at the control/field/action level
- Use the AppSourceCop tool to find all missing prefixes and/or suffixes. Configuration options for this tool can be found here. The Rules section explains the different checks that the analyzer will do. For prefix/suffix detection, refer to the Configuration section. It explains how to set your prefix in the AppSourceCop.json file.

Examples – per-tenant extension

Let's say that you're creating a per-tenant extension, **myext** and you want to future-proof the naming by applying the prefix or suffix *pte*, which you are not required to register.

Let's look at some examples:

PREFIXES	SUFFIXES
pte-myext-salespersoncode	salespersoncode-myext-pte
pte_myext_salespersoncode	salespersoncode_myext_pte
pte myext salesperson code	salesperson code myext pte
pteMyExtSalesPersonCode	SalesPersonCodeMyExtPte

Examples - AppSource app

Alternatively, let's say your company is Fabrikam, and you're building an app called *Rentals*. First thing, you email d365val@microsoft.com and register *fab* as your company affix.

> **TIP**
> It is always a good idea to supply a few suggestions in priority order to avoid back and forth communication.

> **NOTE**
> For AppSource validation file names are not enforced; only object names.

A registered affix must be 3 letters, no more, no less, and you must provide the publisher name, which you will be using in app.json when you apply for an affix.

Once you get confirmation from Microsoft, you are free to use object and field names that start with *fab* or end with *fab*. Here are some examples:

PREFIXES	SUFFIXES
fab-salespersoncode	salespersoncode-fab
fab_salespersoncode	salespersoncode_fab
fab salespersoncode	salespersoncode fab
FabSalesPersonCode	SalesPersonCodefab

At Fabrikam, another team is building another app, so you request a special affix for your app so that the two Fabrikam apps can be kept apart. In this scenario, you do not have to register anything with Microsoft, as long as you do this with your company affix. Here are some examples:

PREFIXES	SUFFIXES
fab-rentals-salespersoncode	salespersoncode-rentals-fab
fab_rentals_salespersoncode	salespersoncode_rentals_fab
fab rentals salesperson code	salesperson code rentals fab
FabRentalsSalesPersonCode	SalesPersonCodeRentalsfab

In this scenario, your appSourceCop.json configuration will specify something like `fab-rentals` and `rentals-fab` as values for `mandatoryaffixes`, even though only *fab* was registered with Microsoft.

> **IMPORTANT**
> You are not required to change any already registered affixes; you can continue using these affixes. The guidelines above only apply to new registrations.

> **TIP**
> Contact us at d365val@microsoft.com to reserve the prefix/suffix of your choosing.

Instrumenting an Application for Telemetry

2/17/2021 • 2 minutes to read • Edit Online

This article describes how you can implement custom telemetry signals in your application for emitting telemetry data.. This data can then be collected and visualized for analyzing the application against the desired business goals, troubleshooting, and more.

Telemetry overview

One aspect of event logging is collecting data about how the application and your deployment infrastructure is working in order to diagnose conditions and troubleshoot problems that affect operation and performance. For example, this type of event logging includes Business Central Server events and trace events like SQL and AL method (function) traces.

Another aspect of logging is *telemetry*, which is collecting data about how your application functions and how it is being used in production. Telemetry can tell you about specific activities that users perform within the application in the production environment. Telemetry is also a useful tool for troubleshooting, especially instances where you are not able to reproduce the conditions experienced by the user or have no access to the user's environment. Telemetry can be divided into different levels or categories, like: telemetry for engineering, telemetry about the business, telemetry for customers.

Creating custom telemetry signal

There are two different resources where telemetry trace signals can be sent for monitoring and analyzing: Event Log and Microsoft Azure Application Insights. By default, the Business Central application is instrumented to emit several system telemetry trace signals to these destinations. Custom telemetry trace signals enable you to send telemetry data from anywhere in the application code to either of these destinations.

The procedure for creating custom telemetry signals is different for each resource. Your choice might also depend on whether you are developing for Business Central online or on-premises.

REOURCE	DESCRIPTION	ONLINE	ON-PREMISES	MORE INFORMATION

REOURCE	DESCRIPTION	ONLINE	ON-PREMISES	MORE INFORMATION
Application Insights	Create custom telemetry signals that are sent to an Application Insights resource in Azure. Application Insights is a service hosted within Azure that gathers telemetry data for analysis and presentation. Extension developers can specify whether the signal is only sent to the extension publisher or also to the VAR partner telemetry resource. You create these custom trace signals by using the LOGMESSAGE method in code.	✓	✓	See...
Event Log	Create custom telemetry trace signals that are sent to the Event Log of the Business Central Server machine. You create these custom trace signals by using the SENDTRACETAG method in code.		✓	See...

NOTE

Using Application Insights is recommended.

Monitoring Business Central Server Events

Testing your Extension

2/17/2021 • 4 minutes to read • Edit Online

Several key things lead to your Dynamics 365 Business Central extension passing the Microsoft validation process. However, one of the most important checks you can do is to take the time and test your extension before submitting it for validation. This allows you to catch some of the basic errors that could lead to validation failures. The following list calls out key points, and the sections below provide more context.

- Always test in a Dynamics 365 Business Central online environment. If you test in an on-premises deployment, you might miss errors that would be seen online.
- Ensure that your extension can be published without code signing errors. You **must not** use the `-skipverification` flag.
- The extension should be able to be installed without errors.
- If you are using the **Assisted Setup**, ensure that you can use your wizard to completion without errors.
- Walk through the setup and usage of your extension to verify it works as expected (**remember to test as a user that does not have SUPER permissions**).
- Check that you can uninstall and unpublish your extension without any errors.
- Make sure you can republish and reinstall your extension without any errors.

Use the correct Dynamics 365 Business Central version

Use Docker for your development and testing. At least, run your full test in Dynamics 365 Business Central online at least once before submitting for validation. We use Docker, and this ensures that you will be testing on the same as what we validate your app on.

If you test in an on-premises deployment, you might miss errors that would be seen online.

Make sure that you use the correct artifacts for Docker to set up the correct Dynamics 365 Business Central version number. Use the function `Get-BCArtifactUrl` in the BcContainerHelper module to retrieve the artifactUrl of the current version. If you test on a build that is older or much newer than the current version, your app will most likely fail validation.

Also make sure that you refresh the Docker instance each time you want to submit. If you haven't run your Docker script to refresh for months, then you are on a much older build.

Use the correct data when you test your app

When we validate apps, we use the base CRONUS demo data. This of course is there for some countries and you don't have to do anything additional to receive that demo data. However, for countries that are empty and don't include demo data, you must import the CRONUS evaluation demo data. Not the International CRONUS data, the evaluation demo data. We do not use custom data and we do not use any other data. We always use the base evaluation demo data. To get this same data (if you don't have it by default), you follow these instructions:

1. Search for **Configuration Packages**, and then choose the link.
2. Choose **Process > Import Predefined Package**.
3. Click the link for **GB.ENU.EVALUATION**.

   That will start processing. You will see the process bar.
4. If there are popups at all, just choose **Yes** or **OK**.

5. Once the process is complete, choose the **Apply Package** button, and then choose **Yes**.
6. Again, if any popups or anything just click through them.
7. Once it completes, sign out of Business Central and then sign back in again.
8. You now have data.

Use the right user for your testing

Do not do your testing with a user that has SUPER permissions marked. The SUPER user can do all without issue and you won't catch your true app bugs. No live customer will have several users marked with this permission set. Therefore, we cannot test with it. You need to setup a user in your test environment that only has the BUS FULL ACCESS permission set, LOCAL, and any of your own permission sets. For information on how to set up this user, see this blog Enabling Premium Experience in Business Central Sandbox Containers.

Testing your app

Now it is time to test your app. The following are all things you must do as part of your testing effort.

- Test your app in its entirety. We expect you to test 100% of the functionality of your app. Testing just a few areas of your app will not suffice. Test everything.
- We are not going to test 100% of the functionality of your app. We expect you to be doing that.
- If the testing works for you, it will most likely work for us.
- Ensure that no permission errors are thrown for any of your app's functionality.
- With the ESSENTIAL user (before you assign your permission sets to it), make sure that the user can still use the core Business Central without facing permission errors. You must allow that user to do things such as accessing the Customer card, posting sales order, and so on.

Maintaining your app

Although we do regular testing of your app when we prepare a new version of Dynamics 365 Business Central, we expect you to do the same on your end. You have access to the same builds that we do through the Collaborate program. You can do more thorough testing than we can because you know your app the best. By doing this testing, you can catch future Dynamics 365 Business Central changes that may impact or break your app. Catching these changes in advance leaves less risk for customers to run into them.

You should be doing regular testing against our next minor (monthly) and next major (bi-annual) release branches that ports into our monthly service updates. To test against these builds, sign into aka.ms/collaborate, navigate to packages, and locate the package named **Working With Business Central Insider Builds**. The package contains a Shared Access Signature token with which you can download artifacts of future releases for use with Docker.

User Scenario Documentation

2/17/2021 • 3 minutes to read • Edit Online

One of the keys to a successful extension validation is a document that guides the tester through the setup and usage of the extension. You must include a document that helps Microsoft test some of the key scenarios of your extension. We want to ensure that we are validating the functionality in the correct manner. Following are some key points to keep in mind when writing the user scenario document.

- Be as detailed as possible. No detail is too small. If a field needs a specific value, include that value in your document.
- Keep the inexperienced user in mind. You know your app well, but other users Microsoft does not.
- Use screenshots as much as possible. They provide a good picture of what you want the user to accomplish.
- Provide all prerequisite and setup steps required for successful test scenario completion.
    - If your app requires setup of its own, include those details.
    - If any setup is extensive, consider using the import of Rapid Start packages.
    - If your app has a dependency on non-standard settings in the core default version of Business Central, include those details. The Microsoft-provided demo data might not have everything that your app needs to work properly.
- Include the most important functionality scenarios of your extension. We are not looking to test your entire extension, but we do want to ensure we are validating the most used aspects of your app.
    - Do not give a summary as to what these scenarios do. List step by step details instead. Again, the tester doing the validation might not have the same product knowledge as you do.
    - It should be possible for the inexperienced tester to **complete the user scenario test in less than 20 minutes** (after installation and startup).

> **NOTE**
> This is not the same as the requirement to include Help for your functionality. For more information about getting started with extending and customizing the Business Central user assistance, see User assistance model.

Use the correct Business Central version

We recommend that you use Docker as a guide for writing your user scenario document. This way, you can take screenshots and other visuals that really help the tester walk through your validation. Keep these things in mind:

- Do not base your user document on an on-premises environment. Business Central on-premises deployments can have different windows, data, and so on. As a result, your document can lead to confusion and differences in our results.
- Use the correct Business Central version. If you are basing your document on a build that is months old, many things could now be different in the latest production environment. This also can lead to much confusion. For more information, see Current Build - Developing for Dynamics 365 Business Central on the Collaborate site.
- Use the correct data for your document. Do not submit a document based on custom data that our testers will not have access to. You should always base your documents on the base demo CRONUS data and then

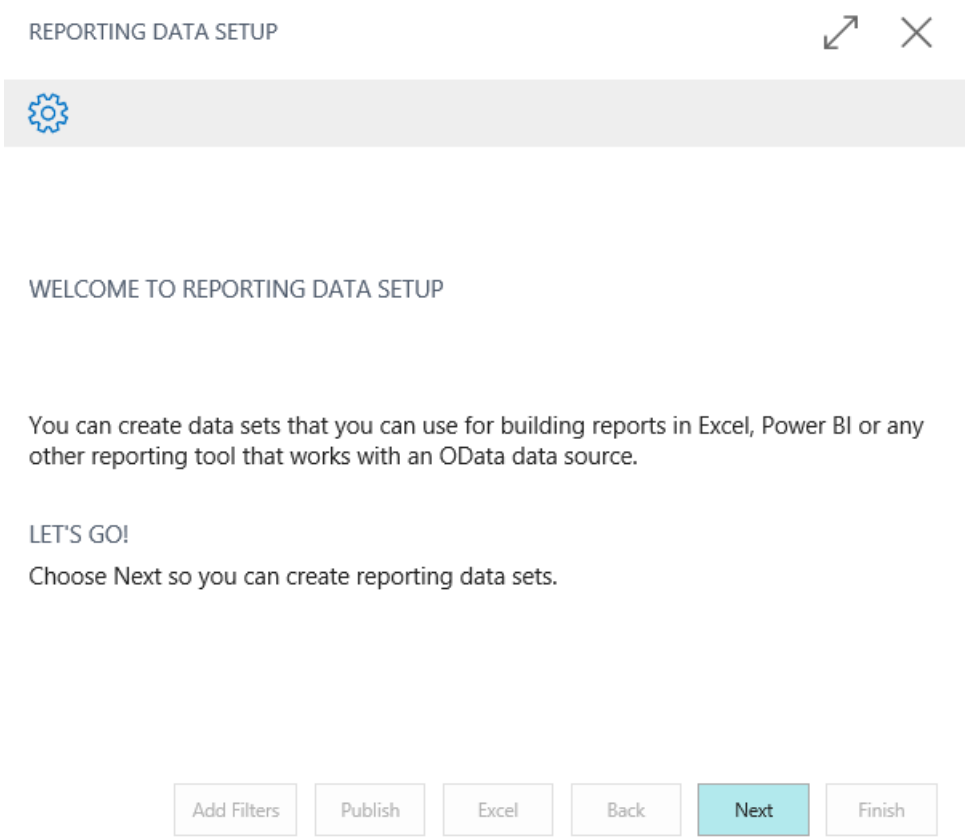
include Rapid Start packages with any additional data.

- If your app's functionality is different per country, provide that important information. Some of the steps might be different (for your app) between US and DK. If that is the case, mention that in the document.

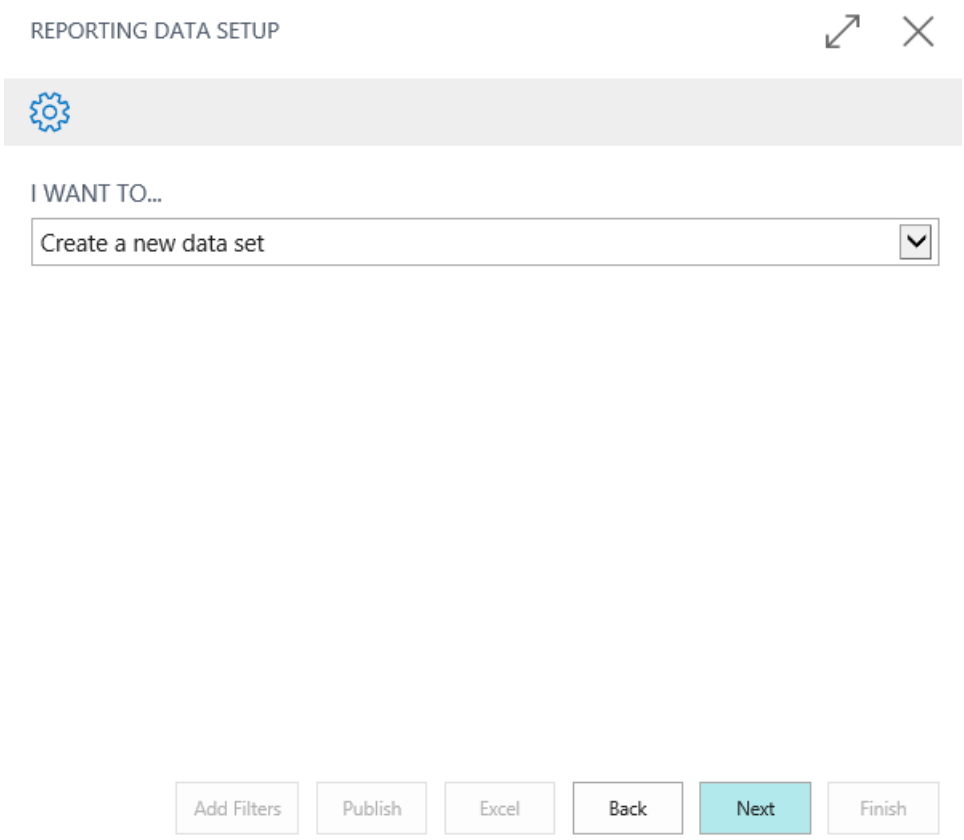
Example

Here is an example of the level of detail we are looking for, based on running the Assisted Setup wizard:

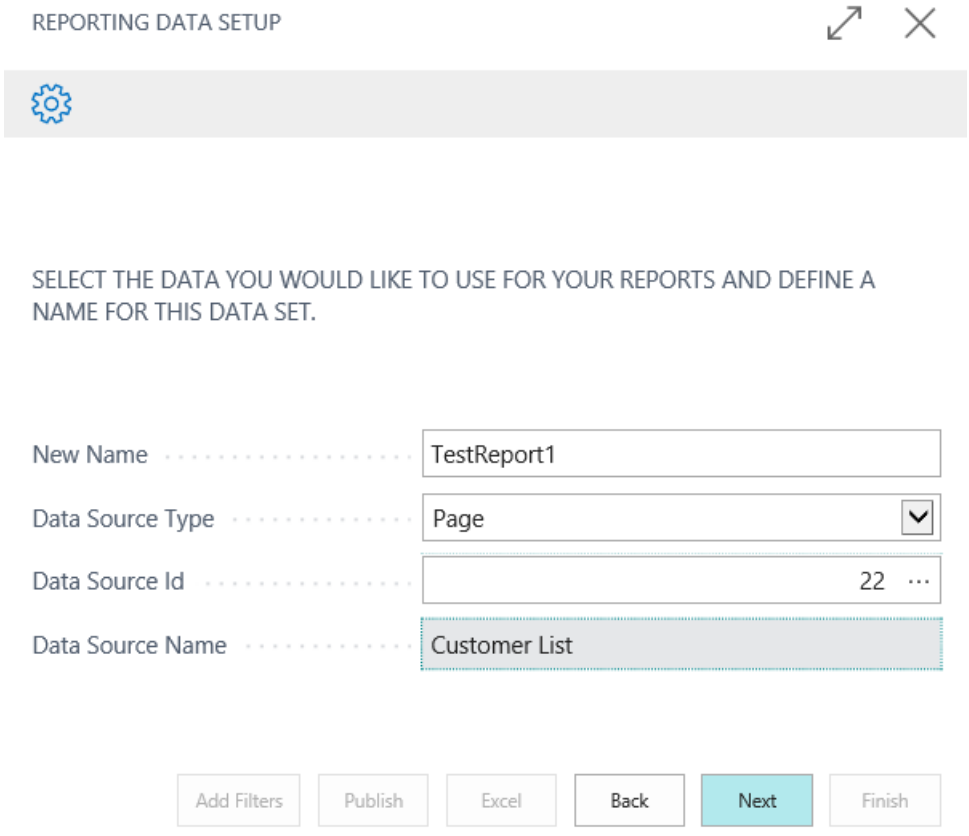
1. On the Home Page, click the **Setup & Extensions** dropdown
2. Click **Assisted Setup**
3. Click the **Set up reporting data** link
4. This will launch the wizard for this process



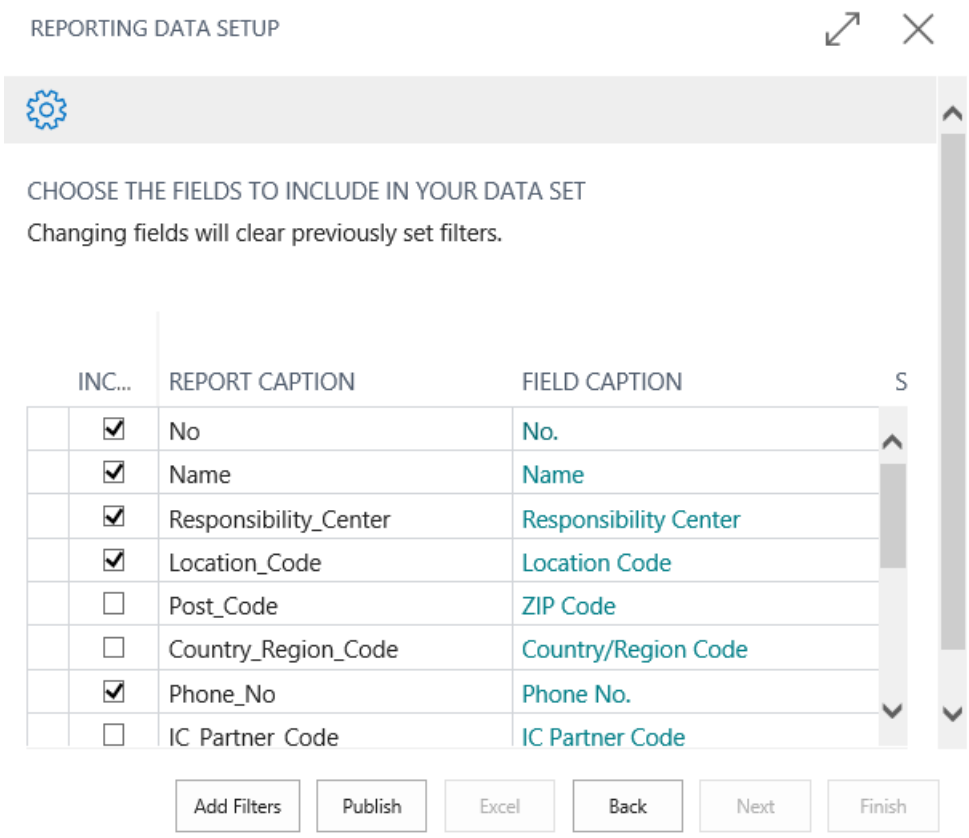
5. Click **Next**



6. Click **Next**
7. New Name = TestReport1
8. Data Source Type = Page
9. Data Source Id = 22
10. Data Source Name = Customer List



11. Click **Next**



12. Click **Publish**

Restrictions on UI for Objects Exposed as Web Services

2/17/2021 • 2 minutes to read • Edit Online

Pages and code units that are designed to be exposed as Web services must not generate any UI that would cause an exception in the calling code.

SUMMARY AND INTENT: When writing code for Web services, you must not use end-user confirmation dialog boxes, message boxes, or any other page constructs in the code. Because a Web service runs independently of a user interface, running this type of code causes the code to throw an exception. The exception can be caught and handled, but the Web service will not complete.

RESOURCES: For more information, see Microsoft Dynamics NAV Web Services.

HOW TO COMPLY: Ensure that code for pages and code units that are being exposed as Web services do not use any end-user confirmation dialog boxes or message boxes.

TEST METHODOLOGY: To verify this requirement, the following tests will be performed:

1. Identify the pages and code units that are exposed as Web services during the installation of the extension.
2. Using code inspection, verify that methods from the following table are not used by the pages and code units published by the installation without conditional code that is based on GUIALLOWED=FALSE or CurrFieldNo=0 circumventing their call.

AL METHOD	APPLIES TO
CONFIRM	Codeunit/page
STRMENU	Codeunit/page
(Page RunModal)	Page
Page of type Confirmation Dialog	Page
(Request page)	Page
ERROR	Codeunit/page
BEEP	Codeunit/page
YIELD	Codeunit/page

Additionally, when running the page or code unit as a Web service, the following exception should never occur:

Microsoft.Dynamics.Nav.Types.Exceptions.NavNCLCallbackNotAllowedException: Callback functions are not allowed.

Replacing OnBeforeCompanyOpen and OnAfterCompanyOpen

2/17/2021 • 2 minutes to read • Edit Online

To improve the login time for Dynamics 365 Business Central, extensions should no longer use the **OnBeforeCompanyOpen** and **OnAfterCompanyOpen** events. Following are some recommended patterns to use in place of these events.

- Move the code to the actual usage of the extension.
- Code written on the subscribers that are called from these triggers must be safe. Every **GET**, **MODIFY**, **DELETE**, and **INSERT** operation must be written with `IF THEN`, to avoid raising conditions that could prevent user from signing in.
- The code should start with check `IF NOT GUIALLOWED THEN EXIT;` to avoid impacting Web services code. Other checks to exit early should be added to the beginning of the code so that login performance is not affected.
- If the extension is subscribing to **OnBeforeCompanyOpen** or **OnAfterCompanyOpen** in order to perform some long-running data update, then either call **Update** when the extension gets called in code for the first time or apply the new task scheduler pattern for Update 6 and later. This applies to code that is not crucial.

  ```
  // Add 15s
  TASKSCHEDULER.CREATETASK(CODEUNIT::"Job Queue User Handler",0,TRUE,COMPANYNAME,CURRENTDATETIME +
  15000);
  ```

- If you are inserting data for a newly created company, we recommend subscribing to **OnCompanyInitialize** from Codeunit 2 instead. Use Installation or Upgrade code for the extension, or to set up on the first usage and if this is not possible only then it should be **OnCompanyInitialize** be used to populate data for new companies. This runs after every upgrade.

Building an Advanced Sample Extension

2/17/2021 • 16 minutes to read • Edit Online

It is required to submit tests with your extension in order to pass validation. This walkthrough builds an advanced sample extension which is used as the foundation for writing a test which you can read about in the Testing the Advanced Sample Extension topic. If you are new to building extensions, we suggest that you get familiar with Building your first sample extension that uses new objects and extension objects.

For information about submitting your app to AppSource, see Checklist for Submitting Your App.

This walkthrough will guide you through all the steps that you must follow to create the sample extension in AL. The final result can be published, installed, and tested on your sandbox. After you have built your extension, you must write the test for it.

About this walkthrough

This walkthrough illustrates the following tasks:

- Developing a sample extension that uses codeunits, tables, card pages, list pages, navigate page (Assisted Setup) actions, and events and it includes tooltips and links to context-sensitive Help.
- Creating extension objects that can be used to modify page and table objects.
- Initializing the database during the installation of the extension.
- Developing a sample test that tests external calls to a service, events, permissions, actions, navigate page (Assisted Setup), and other modified pages.
- Running the sample test using the Test Tool.

Prerequisites

To complete this walkthrough, you will need:

- The Dynamics 365 Business Central tenant
- Visual Studio Code
- The AL Language extension for Visual Studio Code

For more information on how to get started with your first extension for Dynamics 365 Business Central, see Getting Started. It is recommended to try out simpler examples, before starting this walkthrough.

Customer Rewards extension overview

This sample extension enables the ability to set up any number of reward levels and the minimum number of rewards points required to attain that level. When the sample extension is installed, customers begin to accrue one reward point per sales order. When no reward levels are set up, the customer's reward level is set to 'NONE' even though the customer may have reward points. To begin using the sample extension, the user must accept the extension terms and activate the extension by entering a valid activation code using the **Customer Rewards Assisted Setup Wizard**. Following all the steps of this walkthrough allows you to publish the extension on your tenant and create a possible new feature for your customers.

Developing the sample Customer Rewards extension

In the following section, you will be adding the objects that are needed for the Customer Rewards extension.

Customer Rewards table objects

First, we will get started with the table objects that store the data.

Reward Level table object

The following code adds a new table 50100 **Reward Level** for storing reward level information set up by the user. The table consists of two fields: **Level** and **Minimum Reward Points**.

```
table 50100 "Reward Level"
{
    fields
    {
        field(1; Level; Text[20]) { }

        field(2; "Minimum Reward Points"; Integer)
        {
            MinValue = 0;
            NotBlank = true;

            trigger OnValidate();
            var
                tempPoints: Integer;
                RewardLevel: Record "Reward Level";
            begin
                tempPoints := "Minimum Reward Points";
                RewardLevel.SetRange("Minimum Reward Points", tempPoints);
                if RewardLevel.FindFirst then
                    Error('Minimum Reward Points must be unique');
            end;
        }
    }

    keys
    {
        key(PK; Level)
        {
            Clustered = true;
        }
        key("Minimum Reward Points"; "Minimum Reward Points") { }
    }

    trigger OnInsert();
    begin

        Validate("Minimum Reward Points");
    end;

    trigger OnModify();
    begin
        Validate("Minimum Reward Points");
    end;
}
```

Activation Code Information table object

The following code adds a new table 50101 **Activation Code Information** for storing activation information for the extension. The table consists of three fields: **ActivationCode**, **Date Activated**, and **Expiration Date**.

```
table 50101 "Activation Code Information"
{
    fields
    {
        field(1; ActivationCode; Text[14])
        {
            Description = 'Activation code used to activate Customer Rewards';
        }

        field(2; "Date Activated"; Date)
        {
            Description = 'Date Customer Rewards was activated';
        }

        field(3; "Expiration Date"; Date)
        {
            Description = 'Date Customer Rewards activation expires';
        }
    }

    keys
    {
        key(PK; ActivationCode)
        {
            Clustered = true;
        }
    }
}
```

Customer Rewards Mgt. Setup table object

The following code adds a new table 50102 **Customer Rewards Mgt. Setup** for storing information about the codeunit that should be used to handle events in the extension. This enables us to mock events in our sample test. The table consists of two fields: **Primary Key** and **Customer Rewards Ext. Mgt. Codeunit ID**.

```
table 50102 "Customer Rewards Mgt. Setup"
{
    fields
    {
        field(1; "Primary Key"; Code[10])
        {
        }

        field(2; "Customer Rewards Ext. Mgt. Codeunit ID"; Integer)
        {
            TableRelation = "CodeUnit Metadata".ID;
        }
    }

    keys
    {
        key(PK; "Primary Key")
        {
            Clustered = true;
        }
    }
}
```

Customer Rewards table extension objects

Customer table extension object

The **Customer** table, like many other tables, is part of the Dynamics 365 Business Central service and it cannot be modified directly by developers. To add additional fields or to change properties on this table, developers

must create a new type of object; a table extension. The following code creates a table extension for the**Customer**table and adds the **RewardPoints** field.

```
tableextension 50100 "CustomerTable Ext." extends Customer
{
    fields
    {
        field(10001; RewardPoints; Integer)
        {
            MinValue = 0;
        }
    }
}
```

Customer Rewards page objects

For each page object, you can specify the target Help page that describes the feature that the page object is part of. The `ContextSensitiveHelpPage` property on the page object works together with the link that is specified in the app.json file. For more information, see Configure Context-Sensitive Help.

Customer Rewards Wizard page object

The following code adds the50100 **Customer Rewards Wizard**page that enables the user to accept the terms for using the extension as well as activating the extension. The page consists of a welcome step, an activation step, and a finish step. The welcome step has a checkbox for the Terms of Use that must be enabled. The activation step has a text box where the activation code must be entered for validation. A valid activation code for this sample extension is any 14 character alphanumeric code.

```
page 50100 "Customer Rewards Wizard"
{
    // Specifies that this page will be a navigate page.
    PageType = NavigatePage;
    Caption = 'Customer Rewards assisted setup guide';
    ContextSensitiveHelpPage = 'sales-rewards';

    layout
    {
        area(content)
        {
            group(MediaStandard)
            {
                Caption = '';
                Editable = false;
                Visible = TopBannerVisible;

                field("MediaResourcesStandard.""Media Reference"""; MediaResourcesStandard."Media
Reference")
                {
                    ApplicationArea = All;
                    Editable = false;
                    ShowCaption = false;
                }
            }

            group(FirstPage)
            {
                Caption = '';
                Visible = FirstPageVisible;

                group("Welcome")
                {
                    Caption = 'Welcome';
                    Visible = FirstPageVisible;

                    group(Introduction)
```

```
                    {
                        Caption = '';
                        InstructionalText = 'This Customer Rewards extension is a sample extension. It adds
rewards tiers support for Customers.';
                        Visible = FirstPageVisible;

                        field(Spacer1; '')
                        {
                            ApplicationArea = All;
                            ShowCaption = false;
                            Editable = false;
                            MultiLine = true;
                        }
                    }

                    group("Terms")
                    {
                        Caption = 'Terms of Use';
                        Visible = FirstPageVisible;

                        group(Terms1)
                        {

Rewards Level List page object

The following code adds the50101 **Rewards Level List**page that enables the user to view, edit, or add new reward levels and their corresponding minimum required points. The code example includes tooltips for controls and a relative link to context-sensitive Help.

```
page 50101 "Rewards Level List"
{
    PageType = List;
    ContextSensitiveHelpPage = 'sales-rewards';
    SourceTable = "Reward Level";
    SourceTableView = sorting ("Minimum Reward Points") order(ascending);

    layout
    {
        area(content)
        {
            repeater(Group)
            {
                field(Level; Level)
                {
                    ApplicationArea = All;
                    Tooltip = 'Specifies the level of reward that the customer has at this point.';
                }

                field("Minimum Reward Points"; "Minimum Reward Points")
                {
                    ApplicationArea = All;
                    Tooltip = 'Specifies the number of points that customers must have to reach this
level.';
                }
            }
        }
    }

    trigger OnOpenPage();
    begin

        if(not CustomerRewardsExtMgt.IsCustomerRewardsActivated) then
            Error(NotActivatedTxt);
    end;

    var
        CustomerRewardsExtMgt: Codeunit "Customer Rewards Ext. Mgt.";
        NotActivatedTxt: Label 'Customer Rewards is not activated';
}
```

Customer Rewards page extension objects

Customer card page extension object

A page extension object can be used to add new functionality to pages that are part of the Dynamics 365 Business Central service. The following page extension object extends the **Customer Card** page object by

adding two field controls: **RewardLevel** and **RewardPoints** after the **Name** field control on the page. The fields are added in the layout section.

```
pageextension 50100 "Customer Card Ext." extends "Customer Card"
{
    layout
    {
        addafter(Name)
        {
            field(RewardLevel; RewardLevel)
            {
                ApplicationArea = All;
                Caption = 'Reward Level';
                Description = 'Reward level of the customer.';
                ToolTip = 'Specifies the level of reward that the customer has at this point.';
                Editable = false;
            }

            field(RewardPoints; RewardPoints)
            {
                ApplicationArea = All;
                Caption = 'Reward Points';
                Description = 'Reward points accrued by customer';
                ToolTip = 'Specifies the total number of points that the customer has at this point.';
                Editable = false;
            }
        }
    }

    trigger OnAfterGetRecord();
    var
        CustomerRewardsMgtExt: Codeunit "Customer Rewards Ext. Mgt.";
    begin
        // Get the reward level associated with reward points
        RewardLevel := CustomerRewardsMgtExt.GetRewardLevel(RewardPoints);
    end;

    var
        RewardLevel: Text;
}
```

Customer list page extension object

A page extension object can be used to add new functionality to pages that are part of the Dynamics 365 Business Central service. The following page extension object extends the **Customer List** page object by adding one action control; **Reward Levels** to the **Customer** group on the page.

```
pageextension 50101 "Customer List Ext." extends "Customer List"
{
    actions
    {
        addfirst("&Customer")
        {
            action("Reward Levels")
            {
                ApplicationArea = All;
                Image = CustomerRating;
                Promoted = true;
                PromotedCategory = Process;
                PromotedIsBig = true;
                ToolTip = 'Open the list of reward levels.';

                trigger OnAction();
                begin
                    if CustomerRewardsExtMgt.IsCustomerRewardsActivated then
                        CustomerRewardsExtMgt.OpenRewardsLevelPage
                    else
                        CustomerRewardsExtMgt.OpenCustomerRewardsWizard;
                end;
            }
        }
    }

    var
        CustomerRewardsExtMgt: Codeunit "Customer Rewards Ext. Mgt.";
}
```

Customer Rewards codeunit objects

Customer Rewards Install Logic codeunit object

The following code adds the50100 **Customer Rewards Install Logic**codeunit that initializes the default codeunit that will be used for handling events. Because this is an install codeunit, it has its **Subtype** property set to **Install**. The **OnInstallAppPerCompany** trigger is run when the extension is installed for the first time and the same version is re-installed.

```
codeunit 50100 "Customer Rewards Install Logic"
{
    // Customer Rewards Install Logic
    Subtype = Install;

    trigger OnInstallAppPerCompany();
    begin
        SetDefaultCustomerRewardsExtMgtCodeunit;
    end;

    procedure SetDefaultCustomerRewardsExtMgtCodeunit();
    var
        CustomerRewardsExtMgtSetup: Record "Customer Rewards Mgt. Setup";
    begin
        CustomerRewardsExtMgtSetup.DeleteAll;
        CustomerRewardsExtMgtSetup.Init;
        // Default Customer Rewards Ext. Mgt codeunit to use for handling events
        CustomerRewardsExtMgtSetup."Customer Rewards Ext. Mgt. Codeunit ID" := Codeunit::"Customer Rewards
Ext. Mgt.";
        CustomerRewardsExtMgtSetup.Insert;
    end;
}
```

Customer Rewards Ext. Mgt. codeunit object

The50101 **Customer Rewards Ext. Mgt.** codeunit encapsulates most of the logic and functionality required

for the Customer Rewards extension. This codeunit contains examples of how we can use events to react to specific actions or behavior that occur within our extension. In this sample extension, there is the need to make a call to an external service or API to validate activation codes entered by the user. Typically, you may do this by defining procedures that take in the activation code and then make calls to the API. Instead of using that approach, we use events in AL. Let us look at the following code from the codeunit.

```
    // Activates Customer Rewards if activation code is validated successfully
    procedure ActivateCustomerRewards(ActivationCode: Text): Boolean;
    var
        ActivationCodeInfo: Record "Activation Code Information";
    begin
        // raise event
        OnGetActivationCodeStatusFromServer(ActivationCode);
        exit(ActivationCodeInfo.Get(ActivationCode));
    end;

    // publishes event
    [IntegrationEvent(false, false)]
    procedure OnGetActivationCodeStatusFromServer(ActivationCode: Text);
    begin
    end;

    // Subscribes to OnGetActivationCodeStatusFromServer event and handles it when the event is raised
    [EventSubscriber(ObjectType::Codeunit, Codeunit::"Customer Rewards Ext. Mgt.",
'OnGetActivationCodeStatusFromServer', '', false, false)]
    local procedure OnGetActivationCodeStatusFromServerSubscriber(ActivationCode: Text);
    var
        ActivationCodeInfo: Record "Activation Code Information";
        ResponseText: Text;
        Result: JsonToken;
        JsonRepsonse: JsonToken;

    begin
        if not CanHandle then
            exit; // use the mock
        // Get response from external service and update activation code information if successful
        if(GetHttpResponse(ActivationCode, ResponseText)) then begin
            JsonRepsonse.ReadFrom(ResponseText);

            if(JsonRepsonse.SelectToken('ActivationResponse', Result)) then begin

                if(Result.AsValue().AsText() = 'Success') then begin

                    if(ActivationCodeInfo.FindFirst()) then
                        ActivationCodeInfo.Delete;

                    ActivationCodeInfo.Init;
                    ActivationCodeInfo.ActivationCode := ActivationCode;
                    ActivationCodeInfo."Date Activated" := Today;
                    ActivationCodeInfo."Expiration Date" := CALCDATE('<1Y>', Today);
                    ActivationCodeInfo.Insert;
                end;
            end;
        end;
    end;

    // Helper method to make calls to a service to validate activation code
    local procedure GetHttpResponse(ActivationCode: Text; var ResponseText: Text): Boolean;
    begin
        // You will typically make external calls / http requests to your service to validate the activation
code
        // here but for the sample extension we simply return a successful dummy response
        if ActivationCode = '' then
            exit(false);

        ResponseText := DummySuccessResponseTxt;
        exit(true);
    end;
```

We define an event publisher method **OnGetActivationCodeStatusFromServer** that accepts the activation code entered by the user as a parameter, and, a subscriber method **OnGetActivationCodeStatusFromServerSubscriber** to listen for and handle the event. When the

ActivateCustomerRewards procedure is run, the **OnGetActivationCodeStatusFromServer** event is raised. Because the **EventSubscriberInstance** property for the codeunit is set to **Static-Automatic** by default, the **OnGetActivationCodeStatusFromServerSubscriber** procedure is called. In this procedure, we handle the raised event by first checking if the current codeunit has been defined for handling this event. If the codeunit can handle the event, the **GetHttpResponse** helper procedure is called to validate the activation code. Depending on the response, Customer Rewards is activated or not.

By using events when the extension makes external calls to a service, we are able to mock the behavior of what happens when events are raised. This becomes particularly useful when writing tests for the extension.

For more information about events, see Events in Microsoft Dynamics 365 Business Central.

Below is the full code for this codeunit.

```
codeunit 50101 "Customer Rewards Ext. Mgt."
{
    var
        DummySuccessResponseTxt: Label '{"ActivationResponse": "Success"}', Locked = true;
        NoRewardlevelTxt: Label 'NONE';

    // Determines if the extension is activated
    procedure IsCustomerRewardsActivated(): Boolean;
    var
        ActivationCodeInfo: Record "Activation Code Information";
    begin
        if not ActivationCodeInfo.FindFirst then
            exit(false);

        if(ActivationCodeInfo."Date Activated" <= Today) and(Today <= ActivationCodeInfo."Expiration Date")
then
            exit(true);
        exit(false);
    end;

    // Opens the Customer Rewards Assisted Setup Guide
    procedure OpenCustomerRewardsWizard();
    var
        CustomerRewardsWizard: Page "Customer Rewards Wizard";
    begin
        CustomerRewardsWizard.RunModal;
    end;

    // Opens the Reward Level page
    procedure OpenRewardsLevelPage();
    var
        RewardsLevelPage: Page "Rewards Level List";
    begin
        RewardsLevelPage.Run;
    end;

    // Determines the correponding reward level and returns it
    procedure GetRewardLevel(RewardPoints: Integer) RewardLevelTxt: Text;
    var
        RewardLevelRec: Record "Reward Level";
        MinRewardLevelPoints: Integer;
    begin
        RewardLevelTxt := NoRewardlevelTxt;

        if RewardLevelRec.IsEmpty then
            exit;
        RewardLevelRec.SetRange("Minimum Reward Points", 0, RewardPoints);
        RewardLevelRec.SetCurrentKey("Minimum Reward Points"); // sorted in ascending order

        if not RewardLevelRec.FindFirst then
            exit;
        MinRewardLevelPoints := RewardLevelRec."Minimum Reward Points";
```

```
        if RewardPoints >= MinRewardLevelPoints then begin
            RewardLevelRec.Reset;
            RewardLevelRec.SetRange("Minimum Reward Points", MinRewardLevelPoints, RewardPoints);
            RewardLevelRec.SetCurrentKey("Minimum Reward Points"); // sorted in ascending order
            RewardLevelRec.FindLast;
            RewardLevelTxt := RewardLevelRec.Level;
        end;
    end;

    // Activates Customer Rewards if activation code is validated successfully
    procedure ActivateCustomerRewards(ActivationCode: Text): Boolean;
    var
        ActivationCodeInfo: Record "Activation Code Information";
    begin
        // raise event
        OnGetActivationCodeStatusFromServer(ActivationCode);
        exit(ActivationCodeInfo.Get(ActivationCode));
    end;

    // publishes event
    [IntegrationEvent(false, false)]
    procedure OnGetActivationCodeStatusFromServer(ActivationCode: Text);
    begin
    end;

    // Subscribes to OnGetActivationCodeStatusFromServer event and handles it when the event is raised
    [EventSubscriber(ObjectType::Codeunit, Codeunit::"Customer Rewards Ext. Mgt.",
'OnGetActivationCodeStatusFromServer', '', false, false)]
    local procedure OnGetActivationCodeStatusFromServerSubscriber(ActivationCode: Text);
    var
        ActivationCodeInfo: Record "Activation Code Information";
        ResponseText: Text;
        Result: JsonToken;
        JsonRepsonse: JsonToken;
    begin
        if not CanHandle then
            exit; // use the mock

        // Get response from external service and update activation code information if successful
        if(GetHttpResponse(ActivationCode, ResponseText)) then begin
            JsonRepsonse.ReadFrom(ResponseText);

            if(JsonRepsonse.SelectToken('ActivationResponse', Result)) then begin

                if(Result.AsValue().AsText() = 'Success') then begin

                    if(ActivationCodeInfo.FindFirst()) then
                        ActivationCodeInfo.Delete;

                    ActivationCodeInfo.Init;
                    ActivationCodeInfo.ActivationCode := ActivationCode;
                    ActivationCodeInfo."Date Activated" := Today;
                    ActivationCodeInfo."Expiration Date" := CALCDATE('<1Y>', Today);
                    ActivationCodeInfo.Insert;

                end;
            end;
        end;
    end;

    // Helper method to make calls to a service to validate activation code
    local procedure GetHttpResponse(ActivationCode: Text; var ResponseText: Text): Boolean;
    begin
        // You will typically make external calls / http requests to your service to validate the activation
code
        // here but for the sample extension we simply return a successful dummy response
        if ActivationCode = '' then
            exit(false);
```

```
            exit(false);

        ResponseText := DummySuccessResponseTxt;
        exit(true);
    end;

    // Subcribes to the OnAfterReleaseSalesDoc event and increases reward points for the sell to customer in
posted sales order
    [EventSubscriber(ObjectType::Codeunit, Codeunit::"Release Sales Document", 'OnAfterReleaseSalesDoc', '',
false, false)]
    local procedure OnAfterReleaseSalesDocSubscriber(VAR SalesHeader: Record "Sales Header"; PreviewMode:
Boolean; LinesWereModified: Boolean);
    var
        Customer: Record Customer;
    begin
        if SalesHeader.Status <> SalesHeader.Status::Released then
            exit;

        Customer.Get(SalesHeader."Sell-to Customer No.");
        Customer.RewardPoints += 1; // Add a point for each new sales order
        Customer.Modify;
    end;

    // Checks if the current codeunit is allowed to handle Customer Rewards Activation requests rather than
a mock.
    local procedure CanHandle(): Boolean;
    var
        CustomerRewardsExtMgtSetup: Record "Customer Rewards Mgt. Setup";
    begin
        if CustomerRewardsExtMgtSetup.Get then
            exit(CustomerRewardsExtMgtSetup."Customer Rewards Ext. Mgt. Codeunit ID" = CODEUNIT::"Customer
Rewards Ext. Mgt.");
        exit(false);
    end;
}
```

Conclusion

At this point, the Customer Rewards sample extension can be published and installed on your sandbox. To continue writing tests for the sample extension, see Testing the Advanced Sample Extension.

Testing the Advanced Sample Extension

2/17/2021 • 28 minutes to read • Edit Online

It is required to submit tests with your extension in order to pass validation. This walkthrough builds on the advanced sample extension which you can read about here Building an Advanced Sample Extension. If you are new to building extensions, we suggest that you get familiar with Building your first sample extension that uses new objects and extension objects. This walkthrough goes through how you develop the test for the sample CustomerRewards extension.

For information about submitting your app to AppSource, see Checklist for Submitting Your App.

Prerequisites

To complete this walkthrough, you will need:

- Dynamics 365 Business Central Docker container-based development environment For more information, see Get started with the Container Sandbox Development Environment and Running a Container-Based Development Environment
- Visual Studio Code
- The AL Language extension for Visual Studio Code

Identifying the areas of the extension that need to be tested

Before writing tests for your extension, you need to identify all the areas of the extension that need to be tested.

- Ensure that your tests cover all the setup and usage scenario steps found in the user scenario document. This includes Assisted Setup, pages, fields, actions, events, and other controls and objects used by your extension.
- The CRONUS demo company will be used for the purpose of this walkthrough. If your app requires setup within the core product or any additional data, remember to include that in your tests.
- As part of your tests, remember to include tests that verify that the extension works as expected for **a user that does not have SUPER permissions**. For more information, see Special Permission Sets.
- Your tests **should not make any requests to an external service**. Mock your external calls to prevent this from happening.

In the sample test we will consider the following:

- Logic in our **Install** codeunit.
- **Assisted Setup - Customer Rewards Wizard** page. We will verify that the wizard behaves as expected. It can be used to completion without errors. The Assisted Setup contains code that mimics making calls to an external service or API. Because our tests cannot make requests to an external service, we will mock the requests and the responses.
- **Reward Level** page. We will verify that the page behaves as expected when the user opens it whether Customer Rewards is activated or not.
- **Customer List** page. We will verify that our new **Reward Levels** action exists on the page and that it behaves as expected whether the extension is activated or not.
- **Customer Card** page. We will verify that the page has the **Reward Level** and **Reward Points** field that we added.
- **New Customer** should have zero reward points and corresponding reward level if defined.

- Different scenarios involving Customers and Sales Orders to verify that **Reward Points** work as expected and that reward levels for reward points work as defined by the user.
- Each test will also verify that the extension works for a user that does not have SUPER permissions.

Writing the tests

We will first create a new project (CustomerRewardsTest) for the tests. You are required to separate the CustomerRewards extension and the tests into separate projects.

Before we can start writing the tests for the extension, we need to do the following:

- Specify the dependencies between the extension (CustomerRewards) and the test (CustomerRewardsTest) projects.
  Our CustomerRewardsTest project will be referencing objects from the CustomerRewards project and so we will need to specify this in the `dependencies` setting in the CustomerRewardsTest project's app.json file. The `dependencies` setting takes a list of dependencies, where each dependency specifies the `appId`, `name`, `publisher`, and `version` of the base project/package that the current project/package will depend on.

> **NOTE**
> Another prerequisite is to update the app.json with a dependency to the test toolkit.

```
{
 ...
 "dependencies": [
   {
     "appId": "c228bdcf-7112-480b-a832-da81971b6feb",
     "name": "CustomerRewards",
     "publisher": "Microsoft",
     "version": "1.0.0.0"
   }
 ],
 "test": "13.0.0.0"
  ...
}
```

For more information, see JSON Files.

After setting the `dependencies` value, you will be prompted to download the symbols from the base project/package if they are not present.

Application Test Toolkit

We will be using the Application Test Toolkit to automate and run the tests that we write. The toolkit includes:

- Codeunits with test functions to test various application areas.
- Codeunits with generic and application-specific functions to reduce duplication of test code.
- Application objects for running application tests such as the **Test Tool** page.

In order to install the Application Test Toolkit:

1. Open the BCContainerHelper prompt found on the Desktop. You will see a list of functions that you can run on the container.
2. Run the `Import-TestToolkitToBCContainer` function with `-containerName` parameter to import the test toolkit

into the application database.

```
Import-TestToolkitToBCContainer -containerName <name-of-container>
```

Alternatively, if you use the `New-BCContainer` function from the BCContainerHelper PowerShell module to create your containers on Docker, you can add the `-includeTestToolkit` flag. This will install the Application Test Toolkit during the creation of your container.

Without further configuration, the Import-TestToolkitToBCContainer and New-BCContainer with -includeTestToolkit will install the framework, the libraries, and all base application tests. Both the Import-TestToolkitToBCContainer and New-BCContainer cmdlets support two additional parameters, which limits the number of apps installed:

- `-includeTestFrameworkOnly` installs the Test Framework only. This option includes the Test Runner and low-level functions such as *Any* and *Assert*.
- `-includeTestLibrariesOnly` installs the Test Framework and the Test Libraries only. Beside the Test Framework, this option includes functionality that is shared between base application tests.

Describing your tests

To help you design the relevant tests for your functionality, you can write scenarios that outline what you want to test, and you can write test criteria in the GIVEN-WHEN-THEN format. By adding comments based on feature, scenario, and GIVEN-WHEN-THEN, you add structure to your test code and make tests readable.

The following sections provide an overview of the tags that we recommend you to use.

FEATURE Tag

```
// [FEATURE] [<FeatureTag1>][<FeatureTagN>]
```

`FeatureTag` represents the name of the feature, application area, functional area, or another aspect of the application. This list of tags must point to an area of your solution that is touched by the test. Order tags in descending importance. Start with the most important tags referring to the WHEN or THEN steps. The `[FEATURE]` tag can be set for the whole test codeunit. This means all tests in this codeunit will inherit the list of tags set there. If a test is supposed to have the same list of tags as the codeunit has, you do not have to add the `[FEATURE]` tag for this test. Add the tags only if the test has something specific to say.

SCENARIO Tag

```
// [SCENARIO <ScenarioID>] <TestDescription>`
```

`ScenarioID` links the test to a work item for the functionality. For example, if you use Visual Studio Online or Team Foundation Server, `[SCENARIO 12345]` represents a work item with the ID 12345.

TestDescriptionrepresents a short description of the purpose of the test, such as *Annie can apply a deferral template to a purchase order*.

GIVEN-WHEN-THEN Tags

The `GIVEN-WHEN-THEN` tags provide a framework for the specific test criteria.

TAG	DESCRIPTION

TAG	DESCRIPTION
GIVEN	Describes one step in setting up the test. If you feel a need to add an AND, you should probably add a separate GIVEN. In most of cases, in order to run an action under test, you must prepare the database. Tests can be complex, so you can add more than one GIVEN. They can come in one block or comment particular lines of code. Do not try to repeat code and comment each line. Instead, add information of a higher level that would be valuable when reading without the test code.
WHEN	Describes the action under test. A test is to test one thing. There should be only one WHEN in a test. It is the line of code that changes the state of something that we are going to verify. If you feel a need to add more than one WHEN followed by different verification, you should split this test in two or more tests.
THEN	Describes what is verified by the test. All tests must have a verification part. If there is no verification, the test does not test anything. You can add more than one THEN tag.

We can now begin writing the tests for the extension.

MockCustomerRewardsExtMgt codeunit object

The50102 **MockCustomerRewardsExtMgt**codeunit contains all the code that mocks the process of validating the activation code for Customer Rewards. Because we cannot make requests to external services in the tests, we define a subscriber method **MockOnGetActivationCodeStatusFromServerSubscriber** for handling the **OnGetActivationCodeStatusFromServer** event when it is raised in the **Customer Rewards Ext. Mgt.** codeunit. The **EventSubscriberInstance** property for this codeunit is set to **Manual** so that we can control when the subscriber function is called. We want the subscriber method to be called only during our tests. We also define a Setup procedure that modifies the **Customer Rewards Ext. Mgt. Codeunit ID** in the **Customer Rewards Mgt. Setup** table so that the actual **OnGetActivationCodeStatusFromServerSubscriber** will not handle **OnGetActivationCodeStatusFromServer** event when it is raised.

```
codeunit 50102 MockCustomerRewardsExtMgt

{

    // When set to Manual subscribers in this codeunit are bound to an event by calling the BINDSUBSCRIPTION
method.
    // This enables you to control which event subscriber instances are called when an event is raised.
    // If the BINDSUBSCRIPTION method is not called, then nothing will happen when the published event is
raised.

    EventSubscriberInstance = Manual;
    var
        DummyResponseTxt: Text;
        DummySuccessResponseTxt: Label '{"ActivationResponse": "Success"}', Locked = true;
        DummyFailureResponseTxt: Label '{"ActivationResponse": "Failure"}', Locked = true;

    // Mocks the response text for testing success and failure scenarios

    procedure MockActivationResponse(Success: Boolean);
    begin
        if Success then
            DummyResponseTxt := DummySuccessResponseTxt
        else
            DummyResponseTxt := DummyFailureResponseTxt;
    end;
```

```
    // Modifies the default Customer Rewards Ext. Mgt codeunit to this codeunit to prevent the
    // OnGetActivationCodeStatusFromServerSubscriber in Customer Rewards Ext. Mgt from handling
    // the OnGetActivationCodeStatusFromServer event when it is raised

    procedure Setup();
    var
        CustomerRewardsExtMgtSetup: Record "Customer Rewards Mgt. Setup";
    begin
        CustomerRewardsExtMgtSetup.Get;
        CustomerRewardsExtMgtSetup."Customer Rewards Ext. Mgt. Codeunit ID" :=
Codeunit::MockCustomerRewardsExtMgt;
        CustomerRewardsExtMgtSetup.Modify;
    end;

    // Subscribes to OnGetActivationCodeStatusFromServer event and handles it when the event is raised

    [EventSubscriber(ObjectType::Codeunit, Codeunit::"Customer Rewards Ext. Mgt.",
'OnGetActivationCodeStatusFromServer', '', false, false)]

    local procedure MockOnGetActivationCodeStatusFromServerSubscriber(ActivationCode: Text);
    var
        ActivationCodeInfo: Record "Activation Code Information";
        ResponseText: Text;
        Result: JsonToken;
        JsonRepsonse: JsonToken;
    begin
        if(MockGetHttpResponse(ActivationCode, ResponseText)) then begin
            JsonRepsonse.ReadFrom(ResponseText);

            if(JsonRepsonse.SelectToken('ActivationResponse', Result)) then begin
                if(Result.AsValue().AsText() = 'Success') then begin
                    if ActivationCodeInfo.FindFirst then
                        ActivationCodeInfo.Delete;
                        ActivationCodeInfo.Init;
                        ActivationCodeInfo.ActivationCode := ActivationCode;
                        ActivationCodeInfo."Date Activated" := Today;
                        ActivationCodeInfo."Expiration Date" := CALCDATE('<1Y>', Today);
                        ActivationCodeInfo.Insert;
                end;
            end;
        end;
    end;

    // Mocks making calls to external service

    local procedure MockGetHttpResponse(ActivationCode: Text; var ResponseText: Text): Boolean;
    begin
        if ActivationCode = '' then
            exit(false);

        ResponseText := DummyResponseTxt;

        exit(true);
    end;
}
```

Customer Rewards Test codeunit object

A test codeunit must have its **Subtype** property set to **Test** and the test methods must be decorated with the `[Test]` attribute. When a test codeunit runs, it executes the **OnRun** trigger, and then executes each test method in the codeunit. By default, each test function runs in a separate database transaction, but you can use the **TransactionModel** attribute on test methods to control the transactional behavior. The outcome of a test method is either SUCCESS or FAILURE. If any error is raised by either the code that is being tested or the test code, then the outcome is FAILURE and the error is included in the results log file. Even if the outcome of one

test method is FAILURE, the next test methods are still executed.

In addition to the Application Test Toolkit, the following features are available to help you test your extension:

Test pages

Test pages mimic actual pages, but do not present any UI on a client computer. Test pages let you test the code on a page by using AL to simulate user interaction with the page. You can access the fields on a page and the properties of a page or a field by using the dot notation. You can open and close test pages, perform actions on the test page, and navigate around the test page by using AL methods.

UI handlers

To create tests that can be automated, you must handle cases when user interaction is requested by code that is being tested. UI handlers run instead of the requested UI. UI handlers provide the same exit state as the UI. For example, a test method that has a ConfirmHandler handles CONFIRM method calls. If code that is being tested calls the CONFIRM method, then the ConfirmHandler method is called instead of the CONFIRM method. You write code in the ConfirmHandler method to verify that the expected question is displayed by the CONFIRM method and you write AL code to return the relevant reply. The following table describes the available UI handlers.

FUNCTION TYPE	SYNTAX EXAMPLE	PURPOSE	
MessageHandler	`[MessageHandler]` `procedure MessageHandler(Msg : Text[1024]);`	This handler is called when a message function is invoked in the code. The parameter type, **Text**, contains the text of the function.	
ConfirmHandler	`[ConfirmHandler]` `procedure ConfirmHandlerNo(Question: Text[1024]; var Reply: Boolean);`	This handler is called when a confirm function is invoked in the code. The parameter type, **Text**, contains the text of the function and the parameter **Reply** if the response to confirm is *yes* or *no*.	
StrMenuHandler	`[StrMenuHandler]` `procedure StrMenuHandler(Option: Text[1024]; var Choice: Integer; Instruction: Text[1024]);`	This handler is called when a StrMenu function is invoked in code. The parameter type, **Text**, contains the text of the function and **Choice** is the option chosen in the StrMenu. **Options** is the list of the different option values and **Instruction** is the leading text.	
PageHandler	`[PageHandler]` `procedure MappingPageHandler(var MappingPage: TestPage 1214);`	This handler is called when a non-modal page is invoked in the code. **TestPage** is the specific page in this case.	

FUNCTION TYPE	SYNTAX EXAMPLE	PURPOSE	
ModalPageHandler	`[ModalPageHandler]` `procedure DevSelectedObjectPageHandler(var DevSelectedObjects: TestPage 89015);`	This handler is called when a modal page is invoked in the code. **TestPage** is the specific page in this case.	
ReportHandler	`[ReportHandler]` `procedure VendorListReportHandler(var VendorList: Report 301);`	This handler is called when a report is invoked in the code. **Report** is the specific report in this case.	
RequestPageHandler	`[RequestPageHandler]` `procedure SalesInvoiceReportRequestPageHandler(var SalesInvoice: TestRequestPage 206);`	This handler is called when a report is invoked in the code. **TestRequestPage** refers to the specific report ID.	

You must create a specific handler for each page that you want to handle. Any unhandled UI in the test methods of the test codeunit causes a failure of the test.

ASSERTERROR statement

When you test your extension, you should test that your code performs as expected under both successful and failing conditions. These are called positive and negative tests. To test how your extension performs under failing conditions, you can use the ASSERTERROR keyword. The ASSERTERROR keyword specifies that an error is expected at run time in the statement that follows the ASSERTERROR keyword. If a simple or compound statement that follows the ASSERTERROR keyword causes an error, then execution successfully continues to the next statement in the test function. If a statement that follows the ASSERTERROR keyword does not cause an error, then the ASSERTERROR statement itself fails with an error, and the test function that is running produces a FAILURE result.

The50103 **Customer Rewards Test** codeunit contains all the tests for the Customer Rewards extension. For each test method, we follow the following pattern:

- Initialize and set up the conditions for the test.
- Invoke the business logic that you want to test.
- Validate that the business logic performed as expected.

Let us look some of the sample tests.

TestOnInstallLogic Test

This test verifies that the logic we defined in our Install codeunit works as expected. We first call a helper method **Initialize** which initializes and cleans up any objects that will be needed for the test. The Initialize method also binds our mock codeunit **MockCustomerRewardsExtMgt** to our test codeunit so that any events raised during our test can be handled by the subscriber methods specified in our mock codeunit.

Next, we invoke the **SetDefaultCustomerRewardsExtMgtCodeunit** method, which is the method defined in our Install codeunit.

And finally, we verify using the **Assert** codeunit from the Application Test Toolkit, that the **Customer Rewards Mgt. Setup** table contains the expected codeunit ID.

TestCustomerRewardsWizardActivationPageErrorsWhenInvalidActivationCodeEntered Test

This is one of the tests that focus on the **Customer Rewards Assisted Setup Guide**. The test verifies that an

error message is displayed when a not valid activation code is entered in the wizard.

First, **Initialize** is called to clean up previous state and bind our mock subscriber methods to the test codeunit. Additionally, we set our MockActivationResponse to return FAILURE since we are mocking a not valid validation of the activation code. We also use the **Library - Lower Permissions** codeunit to restrict the users permission to one that does not have the SUPER permission.

Next, we open the **Customer Rewards Wizard** by using a Customer Rewards Wizard, the TestPage object is used to mimic the actual page. On the page, the activation code is entered and then the Activate action is invoked.

And finally, we verify that an error message is displayed because the validation of the activation code failed. If no other error is reported then we are also able to conclude that the functionality in this test can be run without the need for a SUPER permission.

TestRewardLevelsActionExistsOnCustomerListPage Test

This test verifies that the new **Reward Levels** action exists on the Customer List page.

TestCustomerHasBronzeRewardLevelAfterPostedSalesOrders Test

This is one of the tests that considers the interaction between Customers, Sales Orders, and Reward Levels. This test verifies that when two sales orders are made for a new customer, that customer accrues two reward points. Consequently, he attains the corresponding reward level for two points, which is the BRONZE reward level.

First, the test is initialized by calling Initialize. The extension is activated and then a BRONZE reward level for two points or more is set up in the **Reward Level** table.

Next, a new **Customer** is created using the **LibrarySales** codeunit from the Application Test Toolkit. And then, the **LibrarySales** codeunit is used again to create and post two sales orders for the previously created customer.

Finally, to verify that the customer got the correct reward points and level, we open the **Customer Card** using its corresponding TestPage and then verify the values in the **Reward Points** and **Reward Level** fields.

There are many more areas that we look at in the sample test. See the full codeunit below for the rest of the tests.

```
codeunit 50103 "Customer Rewards Test"

{
    // [FEATURE] [Customer Rewards]

    Subtype = Test;
    TestPermissions = Disabled;

    var
        Assert: Codeunit Assert;
        LibraryLowerPermissions: Codeunit "Library - Lower Permissions";
        LibrarySales: Codeunit "Library - Sales";
        MockCustomerRewardsExtMgt: Codeunit MockCustomerRewardsExtMgt;
        ActivatedTxt: Label 'Customer Rewards should be activated';
        NotActivatedTxt: Label 'Customer Rewards should not be activated';
        BronzeLevelTxt: Label 'BRONZE';
        SilverLevelTxt: Label 'SILVER';
        GoldLevelTxt: Label 'GOLD';
        NoLevelTxt: Label 'NONE';

    [Test]

    procedure TestOnInstallLogic();
    var
        CustomerRewardsExtMgtSetup: Record "Customer Rewards Mgt. Setup";
        CustomerRewardsInstallLogic: Codeunit "Customer Rewards Install Logic";
```

```
    begin
        // [Scenario] Check default codeunit is specified for handling events on install
        // [Given] Customer Rewards Mgt. Setup table

        Initialize;

        // [When] Install logic is run
        CustomerRewardsInstallLogic.SetDefaultCustomerRewardsExtMgtCodeunit;

        // [Then] Default Customer Rewards Ext. Mgt codeunit is specified
        Assert.AreEqual(1, CustomerRewardsExtMgtSetup.Count, 'CustomerRewardsExtMgtSetup must have exactly
one record.');

        CustomerRewardsExtMgtSetup.Get;

        Assert.AreEqual(Codeunit::"Customer Rewards Ext. Mgt.", CustomerRewardsExtMgtSetup."Customer Rewards
Ext. Mgt. Codeunit ID", 'Codeunit does not match default');

    end;

    [Test]

    procedure TestCustomerRewardsWizardTermsPage();
    var
        CustomerRewardsWizardTestPage: TestPage "Customer Rewards Wizard";

    begin
        // [Scenario] Check Terms Page on Wizard
        // [Given] The Customer Rewards Wizard
        Initialize;

        // Using permissions that do not include SUPER
        LibraryLowerPermissions.SetO365BusFull;

        // [When] The Wizard is opnened
        CustomerRewardsWizardTestPage.OpenView;

        // [Then] The terms page and fields behave as expected
        Assert.IsFalse(CustomerRewardsWizardTestPage.EnableFeature.AsBoolean, 'Enable feature should be
unchecked');
        Assert.IsFalse(CustomerRewardsWizardTestPage.ActionNext.Visible, 'Next should not be visible');
        Assert.IsFalse(CustomerRewardsWizardTestPage.ActionBack.Visible, 'Back should not be visible');
        Assert.IsFalse(CustomerRewardsWizardTestPage.ActionFinish.Enabled, 'Finish should be disabled');

        CustomerRewardsWizardTestPage.EnableFeature.SetValue(true);

        Assert.IsTrue(CustomerRewardsWizardTestPage.EnableFeature.AsBoolean, 'Enable feature should be
checked');
        Assert.IsTrue(CustomerRewardsWizardTestPage.ActionNext.Visible, 'Next should be visible');
        Assert.IsFalse(CustomerRewardsWizardTestPage.ActionFinish.Enabled, 'Finish should be disabled');

        CustomerRewardsWizardTestPage.Close;
    end;

    [Test]
    procedure TestCustomerRewardsWizardActivationPageErrorsWhenNoActivationCodeEntered();
    var
        CustomerRewardsExtMgt: Codeunit "Customer Rewards Ext. Mgt.";
        CustomerRewardsWizardTestPage: TestPage "Customer Rewards Wizard";

    begin
        // [Scenario] Error message when user tries to activate Customer Rewards without activation code.
        // [Given] The Customer Rewards Wizard
        Initialize;

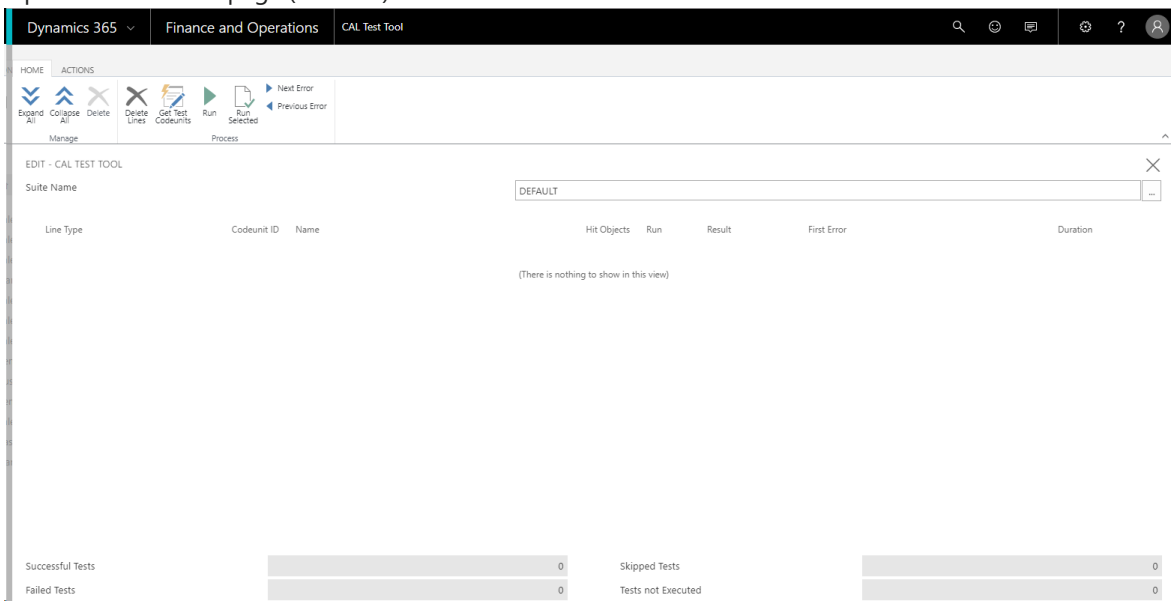
    [PageHandler]
    procedure RewardsLevelListlPageHandler(var RewardsLevelList: TestPage "Rewards Level List");
    begin
    end;
}
```

At this point you can publish and run your tests on your tenant by pressing Ctrl+F5.

Run the tests

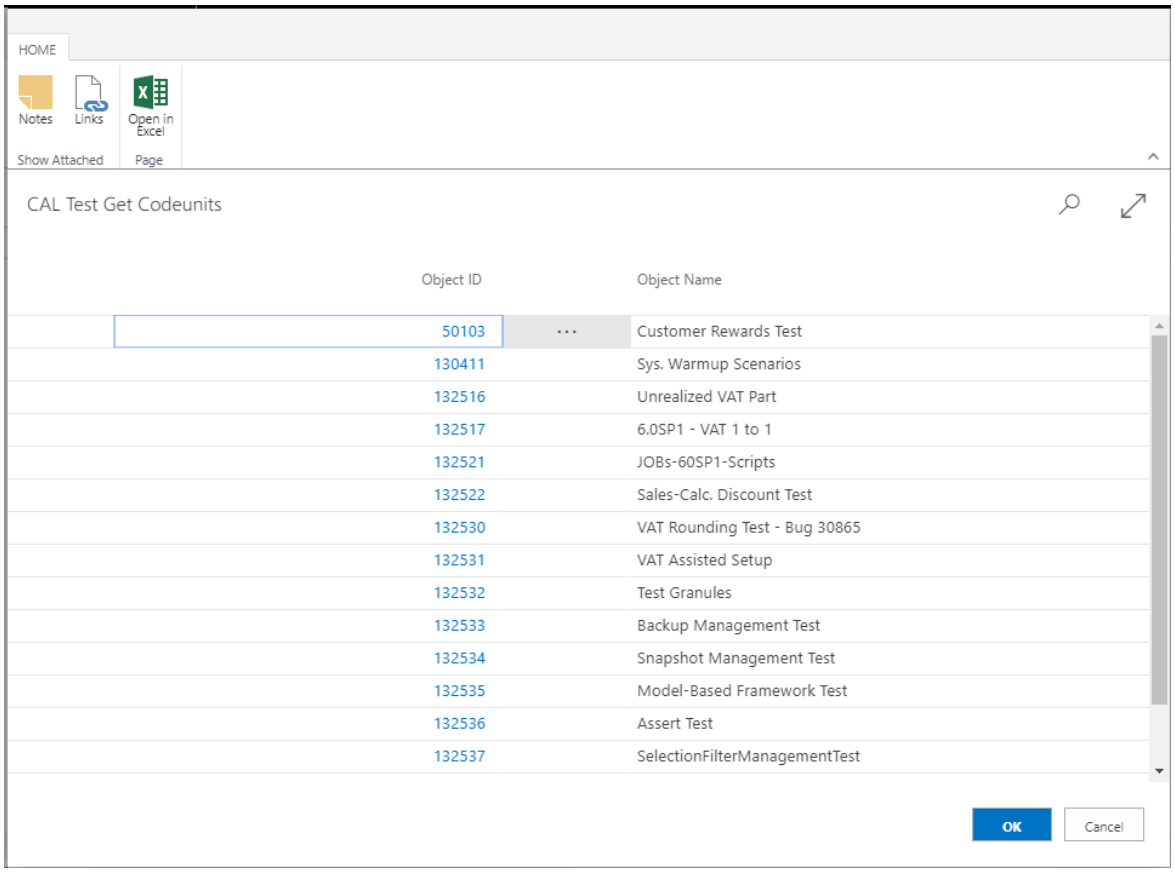
In order to run the tests, follow the steps below.

1. Open the **Test Tool** page (130401).



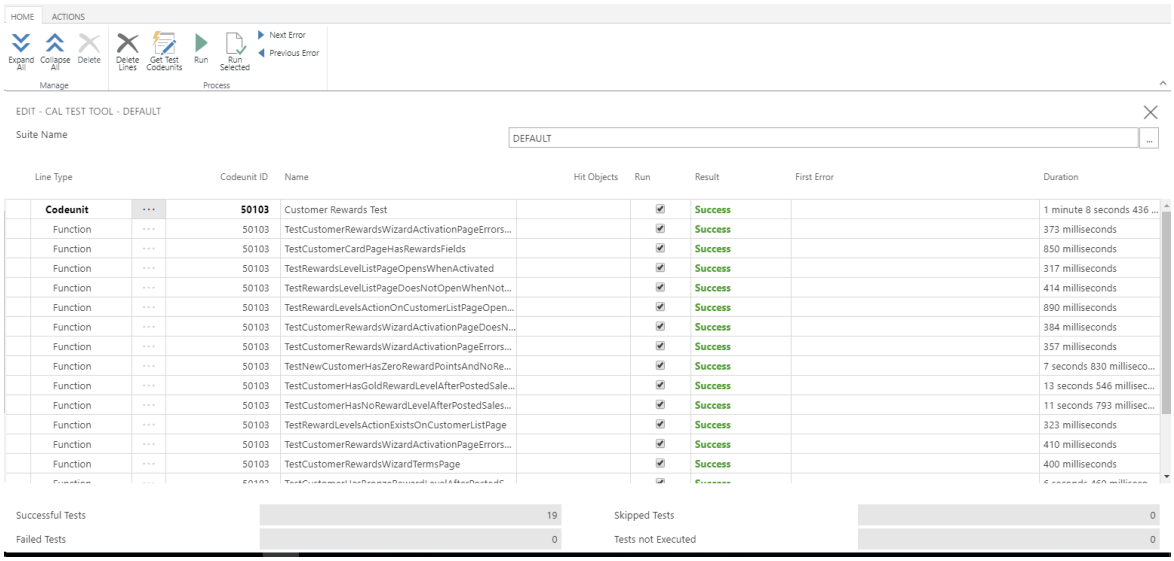
2. Choose **Get Test Codeunits** and then choose **Select Test Codeunits**.

3. Select your test codeunits and then choose the **OK** button.



You can now see all the test methods from your test codeunits.

4. Now, choose **Run** or **Run Selected** to run all the tests in the test codeunit or only the selected tests. The **Result** column indicates whether a test was a SUCCESS or FAILURE. A summary is also presented at the bottom of the page.



Failing Tests

Let us look at what to do if you have a failing test. To create a failing test, we will modify the **SetDefaultCustomerRewardsExtMgtCodeunit** method in codeunit 50100 **Customer Rewards Install Logic** to the following:

```
procedure SetDefaultCustomerRewardsExtMgtCodeunit();
    var
        CustomerRewardsExtMgtSetup: Record "Customer Rewards Mgt. Setup";

    begin
        CustomerRewardsExtMgtSetup.DeleteAll;
        CustomerRewardsExtMgtSetup.Init;
        // Default Customer Rewards Ext. Mgt codeunit to use for handling events
        // Changing
        // CustomerRewardsExtMgtSetup."Customer Rewards Ext. Mgt. Codeunit ID" := Codeunit::"Customer
Rewards Ext. Mgt.";
        // To
        CustomerRewardsExtMgtSetup."Customer Rewards Ext. Mgt. Codeunit ID" := 0;
        CustomerRewardsExtMgtSetup.Insert;
    end;
```

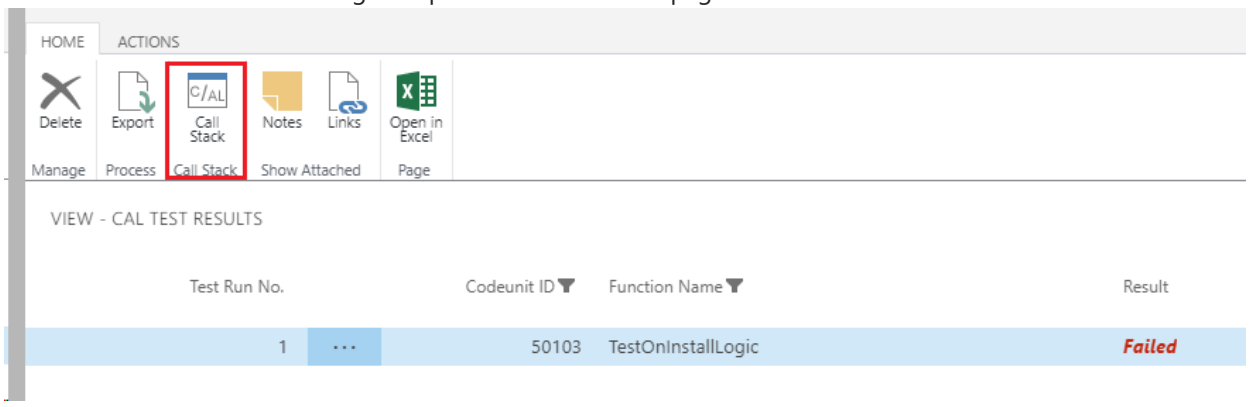
Now, anytime the **SetDefaultCustomerRewardsExtMgtCodeunit** method in the install codeunit is run, the **Customer Rewards Ext. Mgt. Codeunit ID** in the **Customer Rewards Mgt. Setup** table will be set to 0.

Press Ctrl+F5 to publish the updated tests to your tenant and then run them.

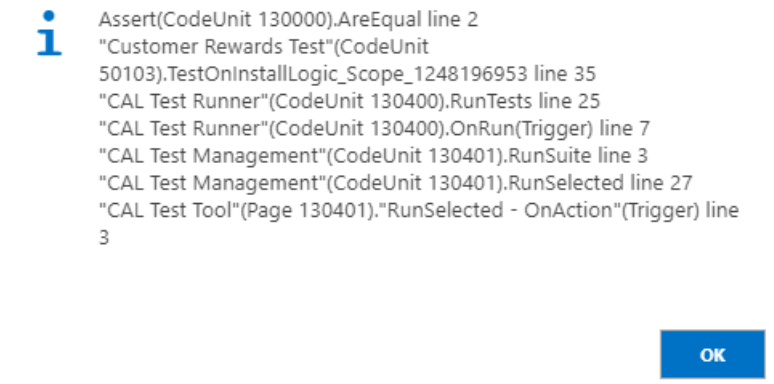
The test TestOnInstallLogic should now have a Failure result with the error message:

```
"Assert.AreEqual failed. Expected:<50101> (Integer). Actual:<0> (Integer). Codeunit does not match default."
```

The error message shows that the actual result in one of our Assert statements differed from what was expected. According to the error message, the Assert statement was expecting a value of 50101 but actually got a value of 0. We can also tell where in our code this is happening because of the message; "Codeunit does not match default", which we defined earlier when we wrote our tests. If we had no idea where the error occurred, we can click on the error message to open the **Test Results** page and then choose the **Call Stack** action.



Choosing the **Call Stack** action will give you a message alert that contains an ordered list of method calls up to the one that caused the error.



The list of method calls is arranged from the most recent at the top to the oldest at the bottom. In our example, we can tell that the `Assert(CodeUnit 130000).AreEqual` (the first on the list) was the last method to be run, indicating where the error was found. Because we did not modify the Assert codeunit, then the wrong values or results must have been passed to it. The next item on the list, `"Customer Rewards Test"(CodeUnit 50103).TestOnInstallLogic_Scope_1248196953` line 35 points to the method that was run before the final one that caused the error. This time, it is in the TestOnInstallLogic method of codeunit 50103 Customer Rewards Test after line 35.

```
35      CustomerRewardsExtMgtSetup.Get;
36      Assert.AreEqual(Codeunit::"Customer Rewards Ext. Mgt.", CustomerRewardsExtMgtSetup."Customer Rewards Ext. Mgt. Codeunit ID", 'Codeunit does not match default');
37  end;
```

On line 36 of codeunit 50103 **Customer Rewards Test**, we can see the Assert statement that throws the error. We tested that the result should be `Codeunit::"Customer Rewards Ext. Mgt."` which is 50101, when our install logic is run, however, the result of the test indicated that we got a result of 0. This implies that our install logic is not working as expected. To fix this, we need to examine all the previous lines of code in the method to figure out where we went wrong. This will lead us to line 31, where the **SetDefaultCustomerRewardsExtMgtCodeunit** method call is made.

```
31      CustomerRewardsInstallLogic.SetDefaultCustomerRewardsExtMgtCodeunit;
```

When you go into the **SetDefaultCustomerRewardsExtMgtCodeunit** method, codeunit 50100 **Customer Rewards Install Logic**, you will see the change we made to cause the test to fail. Revert it so that `CustomerRewardsExtMgtSetup."Customer Rewards Ext. Mgt. Codeunit ID"` now stores `Codeunit::"Customer Rewards Ext. Mgt."`, instead of 0. Publish the updated extension and tests to your tenant and run the tests again. The test **TestOnInstallLogic** should pass now because the actual result matches what is expected.

Conclusion

At this point, the Customer Rewards sample extension can be published and installed on your sandbox.

AL Language Extension Configuration

Programming in AL

2/17/2021 • 2 minutes to read • Edit Online

AL is the programming language that is used for manipulating data (such as retrieving, inserting, and modifying records) in a Dynamics 365 Business Central database, and controlling the execution of the various application objects, such as pages, reports, or codeunits.

With AL, you can create business rules to ensure that the data which is stored in the database is meaningful and consistent with the way customers do business. Through AL programming, you can:

- Add new data or transfer data from one table to another, for example, from a journal table to a ledger table.
- Combine data from multiple tables into one report or display it on one page.

Where to write AL code

Almost every object in Dynamics 365 Business Central contains triggers where you can add your AL code. Triggers exist for the following objects:

- Tables and table extensions
- Table fields
- Pages and page extensions
- Reports
- Data items
- XMLports
- Queries

You can initiate the execution of your AL code from the following:

- Actions
- Any object that has an instantiation of the object that contains AL code. An example of an instantiation is a variable declaration.

> **NOTE**
> If the AL code is in a `local` method, then you cannot run it from another object.

Variable declarations

Variables in AL are declared using the `var` keyword, and the syntax looks like this:

```
var
        myInt: Integer;
```

If you have multiple variables of the same type, these can be declared in one line, such as:

```
var
        myInt, nextInt, thirdInt : Integer;
        isValid, doCheck : Boolean;
```

The `protected` keyword can be used to make variables accessible between tables and table extensions and between pages and page extensions. For more information, see Protected Variables.

Guidelines for placing AL code

We recommend the following guidelines for AL code:

- In general, write the code in codeunits instead of on the object on which it operates. This promotes a clean design and provides the ability to reuse code. It also helps enforce security. For example, typically users do not have direct access to tables that contain sensitive data, such as the **General Ledger Entry** table, nor do they have permission to modify objects. If you put the code that operates on the general ledger in a codeunit, give the codeunit access to the table, and give the user permission to run the codeunit, then you will not compromise the security of the table and the user will be able to access the table.
- If you must put code on an object instead of in a codeunit, then put the code as close as possible to the object on which it operates. For example, put code that modifies records in the triggers of the table fields.

Reusing code

Reusing code makes developing applications both faster and easier. More importantly, if you organize your AL code as suggested, your applications will be less prone to errors. By centralizing the code, you will not unintentionally create inconsistencies by performing the same calculation in many places, for example, in several triggers that have the same table field as their source expression. If you have to change the code, you could either forget about some of these triggers or make a mistake when you modify one of them.

AL Simple Statements

2/17/2021 • 5 minutes to read • Edit Online

AL simple statements are single-line statements that are executed sequentially and do not alter the flow of execution of code. This article explains some of the simple statements in AL.

Assignment statements

Assignment statements assign a value to a variable. The value that you assign to the variable is an AL expression. It can be a constant or a variable, or it can consist of multiple elements of AL expressions. If you use a method call as the value to assign to a variable in an assignment statement, then the value that is assigned is the return value of the method.

You use the ":=" operator for assignment statements.

Example

The following example assigns a constant integer value to an integer variable that you have defined.

```
Count := 1;
```

Example

The following example assigns a value that consists of a constant, an operator, and a variable.

```
Amount := 2 * Price;
```

Example

The following example assigns the return value of the Open Method (File) to a Boolean variable that you have defined.

> **NOTE**
> This method is supported only in Business Central on-premises.

```
OK := TestFile.Open('C:\temp\simple.xml');
```

The return value of the `Open` method is optional. If you do not handle the return value in your code, then a run-time error occurs when a method returns **false**. The following example causes a run-time error if the file `C:\temp\simple.xml` cannot be opened.

```
TestFile.Open('C:\temp\simple.xml');
```

You can handle the return value by using an if-then statement.

```
if TestFile.Open('C:\temp\simple.xml') then begin
  // continue running
else
  Error(Text001);
```

Method statements

You use method statements to execute either built-in system methods or user-defined (custom) methods. Method calls may include parameters, which are passed to the method. For more information, see Calling Methods.

AssertError statements

You use AssertError statements in test methods to test how your application behaves under failing conditions. The AssertError keyword specifies that an error is expected at run time in the statement that follows the AssertError keyword.

If a simple or compound statement that follows the AssertError keyword causes an error, then execution successfully continues to the next statement in the test method. You can get the error text of the statement by using the GetLastErrorText method.

If a statement that follows the AssertError keyword does not cause an error, then the AssertError statement causes the following error and the test method that is running produces a FAILURE result:

```
TestAsserterrorFail: FAILURE

An error was expected inside an AssertError statement.
```

Example

To create a test method to test the result of a failure of a `CheckDate` method that you have defined, you can use the following code. This example requires that you create a method called `CheckDate` to check whether the date is valid for the customized application.

```
InvalidDate := 19000101D;
InvalidDateErrorMessage := Text001;
AssertError CheckDate(InvalidDate);

IF GetLastErrorText <> InvalidDateErrorMessage then
  Error('Unexpected error: %1', GetLastErrorText);
```

This example requires the following variables.

```
var
    InvalidDate : Date;
    InvalidDateErrorMessage : Text;
    Text001 : Label 'The date is outside the valid date range.';
```

With statements (to be deprecated)

IMPORTANT

Using the `with` statement is being deprecated with Dynamics 365 Business Central 2020, release wave 2. With this release it is a warning, which will become an error in a future release.
Using `with` statements introduces possible uniqueness collisions when multiple extensions contribute to the same objects because it allows working with members using just simple names instead of qualifying them. To avoid this going forward, we are marking the use of `with`, be it implicit or explicit as warnings. With this release, you can use a quick action to fix these files, as well as suppress obsolete warnings for now. Code that contains `with` statements will, however, need to be refactored before `with` statements are compiled with errors. For more information, see Deprecating Explicit and Implicit With Statements. For information about using directives in code, see Directives in AL and Pragma ImplicitWith Directive in AL.

The following syntax shows a with-do statement.

```
with <Record> do
  <Statement>
```

When you work with records, addressing is created as record name, dot (period), and field name:

<Record>.<Field>

If you work continuously with the same record, then you can use `with` statements. When you use a `with` statement, you can only specify the record name one time.

Within the scope of *<Statement>*, fields in *<Record>* can be addressed without having to specify the record name.

You can nest several `with` statements. If you have identical names, then the inner `with` statement overrules the outer `with` statement.

Example

This example shows two ways to write the same code that creates a record variable that you can commit later.

```
CustomerRec."No." := '1234';
CustomerRec.Name := 'Windy City Solutions';
CustomerRec."Phone No." := '555-444-333';
CustomerRec.Address := '1241 Druid Avenue';
CustomerRec.City := 'Windy City';
Message('A variable has been created for this customer.');
```

This example requires the following variables.

```
var
    CustomerRec : Record Customer;
```

The following example shows another way to create a record variable that you can commit later:

```
with CustomerRec do begin
  "No." := '1234';
  Name := 'Windy City Solutions';
  "Phone No." := '555-444-333';
  Address := '1241 Druid Avenue';
  City := 'Windy City';
  Message('A variable has been created for this customer.');
end;
```

Programming conventions

Within `with-do` blocks, do not repeat the name of the object by using the member variable or method.

If you nest a `with-do` block within another explicit or implicit `with-do` block, then the `with-do` block that you create within another `with-do` block must always be attached to a variable of the same type as the variable that is attached to the surrounding `with-do` block. Otherwise, it can be difficult to see what variable that a member variable or method refers to. For example, implicit `with-do` blocks occur in table objects and in pages that have been attached to a record.

Example

The following example demonstrates nested `with-do` blocks. Both `with-do` blocks are attached to a Customer Ledger Entry record variable.

```
with CustLedgEntry do begin
  Insert;
  ...;
  with CustLedgEntry2 do begin
    Insert;
    ...;
  end;
end;
```

Incorrect example

The following example demonstrates incorrect code in which you cannot directly tell which record variable that the MyField field refers to.

```
with CustLedgEntry do begin
  ...;
  with VendLedgEntry do begin
    MyField := <Some Value>;
    ...;
  end;
end;
```

AL Control Statements

2/17/2021 • 13 minutes to read • Edit Online

AL code consists of one or more statements, which are executed sequentially in top-down order. However, you will often need to control the direct top-down flow of the execution. One or more statements may have to be repeated more than once, or you may have to make the execution of a certain statement conditional. To do this, you use control structures.

The control structures in AL are divided into the following main groups, as described in this article:

- AL Compound Statements
- AL Conditional Statements
- AL Repetitive Statements

> **NOTE**
> In the following sections conventions for how to structure and align AL code are presented to introduce best practices. In many cases the structure is not necessary to get the code to compile, but rather to improve readability.

AL compound statements

In some cases, the AL syntax only lets you use a single statement. However, if you have to execute more than one simple statement, the statements can be written as a compound statement by enclosing the statements between the `begin` and `end` keywords.

```
begin
    <Statement 1>;
    <Statement 2>;
    ..
    <Statement n>;
end;
```

The individual statements are separated by a semicolon. In AL, a semicolon is used to separate statements and not, as in other programming languages, as a terminator symbol for a statement. Nevertheless, an extra semicolon before an end does not cause an error because it is interpreted by the compiler as an empty statement.

Blocks

The begin-end structure is also called a *block*. Blocks can be very useful to refer to the other control structures in AL.

When begin follows then, else, or do, it should be on the same line and preceded by one space character.

Example

```
if (x = y) and (a = b) then begin
    x := a;
    y := b;
end;
```

Example

```
if (xxx = yyyyyyyyyy) and
    (aaaaaaaaaa = bbb)
then begin
    x := a;
    x := y;
    a := y;
end else begin
    y := x;
    y := a;
end;
```

AL conditional statements

You use conditional statements to specify a condition and one or more commands to execute if the condition is evaluated as true or false. There are two types of conditional statements in AL:

- if-then-else, where there are two choices
- case, where there are more than two choices

If-then else statements

if-then-else statements have the following syntax.

```
if <Condition> then
    <Statement1>
[else
    <Statement2>]
```

If `<Condition>` is true, then `<Statement1>` is executed. If `<Condition>` is false, then `<Statement2>` is executed.

The square brackets around else `<Statement2>` mean that this part of the statement is optional. The else statement is used when different actions are executed depending on how `<Condition>` is evaluated.

You can build more complex control structures by nesting if-then-else statements. The following example is a typical if-then-else statement.

```
if <Condition1> then
    if <Condition2> then
        <Statement1>
    else
        <Statement2>
```

If `<Condition1>` is false, then nothing is executed. If `<Condition1>` and `<Condition2>` are both true, then `<Statement1>` is executed. If `<Condition1>` is true and `<Condition2>` is false, then `<Statement2>` is executed.

> **NOTE**
> A semicolon in front of an else statement is not allowed.

Reading several nested if-then-else statements can be very confusing but generally, an else statement belongs to the last if statement that lacks an else statement.

Programming conventions

- If and then should be on the same line. else should be on a separate line.
- If there are many or long expressions, then should be on a new line and be aligned with if.

- When you write if expressions with then and else parts, write them so that the then result is more probable than the else one.
- If the last statement in the then part of an if-then-else statement is an exit or an error, do not continue with an else statement.

Example

```
if x = y then
    x := x + 1
else
    x := -x - 1;
```

Example

```
if (xxxxxxxxxx = yyy) and
    (aaa = bbbbbbbbbb)
then
    x := a
else
    y := b;
```

Example

```
if x <> y then
    exit(true);
x := x * 2;
y := y - 1;
```

Incorrect example

```
if x < y then
    exit(true)
else begin
    x := x * 2;
    y := y - 1;
end;
```

Example

The following example shows an if-then statement without the optional else statement.

```
if Amount < 1000 then
    Total := Total + Amount;
```

Example

The following example shows a nested if-then-else statement.

```
...
if Amount < 1000 then begin
    if I > J then
        Max := I
    else
        Max := J;
    Amount := Amount * Max;
    end;
else
...
```

Case statements

Case statements have the following syntax.

```
case <Expression> of
    <Value set 1>:
        <Statement 1>;
    <Value set 2>:
        <Statement 2>;

    <Value set n>:
        <Statement n>;
[else
    <Statement n+1>]
end;
```

In this definition, `<Expression>` cannot be a record and `<Value set>` must be an expression or a range.

Case statements are also called multiple option statements and are typically used when you must choose between more than two different actions. The method of the case statement is as follows:

- The `<Expression>` is evaluated, and the first matching value set executes the associated statement, if there is one.
- If no value set matches the value of the expression and the optional else part has been omitted, then no action is taken. If the optional else part is used, then the associated statement is executed.

The data type of the value sets must be the same as the data type of `<Expression>` or at least be convertible to the same data type.

In most cases, the data type of the value sets are converted to the date type of the evaluated expression. The only exception is if the evaluated expression is a Code variable. If the evaluated expression is a Code variable, then the value sets are not converted to the Code data type.

> **NOTE**
> This type conversion can cause an overflow at run time if the resulting data type cannot hold the values of the datasets.

For more information about Code variables, see Code Data Type.

Programming conventions

When you use a case statement, indent the value sets by four character spaces. If you have two or more value sets on the same line, then separate them by commas without spaces. The last value set on a line is immediately followed by a colon without a preceding space. The action starts on the line after the value set and is further indented by four character spaces. If there is a begin, then it should be put on a separate line unless it follows else. If a begin follows an else, then it should be on the same line as else.

If there are more than two alternatives, use a case statement. Otherwise, use an if-then-else statement.

Example

```
case Field of
    Field::A:
        begin
            x := x + 1;
            y := -y - 1;
        end;
    Field::B:
        x := y;
    Field::C,Field::D:
        y := x;
    else begin
        y := x;
        a := b;
    end;
end;
```

Example

The following AL code prints various messages depending on the value of *Number*. If the value of *Number* does not match any of the entries in the case structure, then the else entry is used as the default.

```
case Number of
    1,2,9:
        message('1, 2, or 9.');
    10..100:
        message('In the range from 10 to 100.');
else
    message('Neither 1, 2, 9, nor in the range from 10 to 100.');
end;
```

Example

The following AL code shows how value sets in a case statement are evaluated if the expression is a Code data type.

```
MyCode := 'ABC';
case MyCode of
    'abc':
        message('This message is not displayed.');
    'def':
        message('This message is not displayed.');
else
    message('The value set does not match the expression.');
end;
```

This example requires that you create the following code data type variable.

```
var
    MyCode : Code[10];
```

The value set 'abc' is not converted because the evaluated expression MyCode is a code variable.

AL repetitive statements

A repetitive statement is also known as a loop. The following table shows the looping mechanisms in AL.

LOOPING MECHANISM	DESCRIPTION

LOOPING MECHANISM	DESCRIPTION
for	Repeats the inner statement until a counter variable equals the maximum or minimum value specified.
foreach	Repeats the inner statement for each statement in a List, XmlNodeList, XmlAttributeCollection, or JsonArray.
while	Repeats the inner statement as long as the specified condition is **true**. The statement in a loop of this kind is repeated 0 or more times.
repeat	Repeats the inner statements until the specified conditions evaluate to **true**. The statements in a loop of this kind are always executed at least one time.

For-to and for-downto control structure

The following syntax shows the for-to and for-downto statement.

```
for <Control Variable> := <Start Number> to <End Number> do
    <Statement>
```

```
for <Control Variable> := <Start Number> downto <End Number> do
    <Statement>
```

The data type of `<Control Variable>`, `<Start Number>`, and `<End Number>` must be Boolean, number, time, or date.

Use for-to and for-downto statements when you want to execute code a specific number of times. The *<Control Variable>* controls the number of times that the code of the inner statement is executed according to the following:

- In a for-to loop statement, the `<Control Variable>` value is increased by one after each iteration. The inner `<Statement>` is executed repeatedly until the `*<Start Number>*` value is greater than the `*<End Number>*` value.
- In a for-downto loop statement, the `<Control Variable>` value is decreased by one after each iteration. The inner `<Statement>` is executed repeatedly until the `<Start Number>` value is less than the `<End Number>` value.

> **NOTE**
> When the for statement is executed, `<Start Number>` and `<End Number>` are converted to the same data type as `<Control Variable>` if it is required. This type conversion can cause a run-time error.

> **NOTE**
> If the value of the `<Control Variable>` is changed inside the for loop, then the behavior is not predictable. Furthermore, the value of the `<Control Variable>` is undefined outside the scope of the for loop.

Example 1

The following code initiates a for loop that uses the integer control variable named Count.

```
for Count := 1000 to 100000000000000 do
```

This example requires the following Integer data type variable.

```
var
    Count : Integer;
```

When this statement is executed, a run-time error occurs because the start and end values are converted to the same data type as the Count control variable. Count has been declared as an integer variable. The end number 100000000000000 is outside the valid range for integers, and an error occurs.

Example 2

The following example shows how to nest for statements.

Set the Dimensions property of variable A to 5;7.

The following for statements could be used to initialize every element in a 5x7 array with the value 23.

```
for I := 1 to 5 do
    for J := 1 to 7 do
        A[I,J] := 23;
```

This example requires the following Integer data type variables.

```
var
    I : Integer;
    J : Integer;
```

Foreach control structure

You can use the foreach statement to iterate through List, XmlNodeList, XmlAttributeCollection, and JsonArray expressions. The foreach statement has the following syntax.

```
foreach <Element> in <List> do
    <Statement>
```

The `<List>` variable must be of the List, XmlNodeList, XmlAttributeCollection, or JsonArray type. The `<Element>` variable must be a data type that is compatible with elements specified by the `<List>`.

The following code example iterates through a list of customer names and returns each customer name in a message.

```
procedure PrintCustomerNames(customerNames : List of [Text]);
var
    customerName : Text;
begin
    foreach customerName in customerNames do
        message(customerName);
end;
```

While-do control structure

The following syntax shows the while-do statement.

```
while <Condition> do
    <Statement>
```

If `<Condition>` is true, then `<Statement>` is executed repeatedly until `<Condition>` becomes false. If `<Condition>` is false from the start, then `<*Statement>` is never executed.

The while do statement can be used when some code should be repeated as long as an expression is true.

Programming conventions

When there is only one condition, put while and do on the same line. Put the statements on separate lines and indented by two spaces.

When there are multiple conditions, put the conditions on separate lines and indented by two spaces and put do on a separate line that is aligned with while.

Example

```
while <expr> do
    <Statement>;
```

Example

```
while <expr> do begin
    <Statement>;
    <Statement>;
end;
```

Example

```
while <expr> and
      <expr> and
      <expr>
do begin
    <Statement>;
    <Statement>;
end;
```

Example

The following AL code increases the variable I until it equals 1000 and displays a message when it is finished.

```
while I < 1000 do
    I := I + 1;
message(format(I));
```

This example requires the following integer data type variable.

```
var
    I : integer
```

Repeat-until control structure

The following syntax shows the repeat-until statement.

```
repeat
    <Statements> until <Condition>
```

`<Statements>` is executed repeatedly until `<Condition>` is true.

The repeat until control structure resembles the while control structure. The difference is that because the repeat until statement is executed from left to right, the `<Statements>` is always executed at least one time, regardless of what the `<Condition>` is evaluated to. This contrasts with the while control structure, which performs the evaluation before the `<Statement>` is executed. In the while control structure, if the first evaluation of `<Condition>` returns false, then no statements are executed.

Programming conventions

Always put repeat on a separate line.

Example

```
if x < y then begin
    repeat
        x := x + 1;
        a := a - 1;
    until x = y;
        b := x;
end;
```

Example

This code uses a repeat-until loop to count the number of entries in the Customer table.

```
Count := 0;
if Customer.find('-') then
repeat
    Count := Count + 1;
until Customer.next <= 0;
message('The Customer table contains %1 records.',Count);
```

This example requires the following variables.

```
var
    Count : Integer;
    Customer : Record Customer;
```

The `find` method finds the first entry in the table. Each time NEXT is called, it steps one record forward. When NEXT equals 0, there are no more entries in the table. The loop is exited, and a message displays how many entries were found.

Exit statement

The exit statement is used to control the flow of the execution. The following syntax shows an exit statement.

```
exit([<Value>])
```

An exit statement is used to interrupt the execution of a AL trigger. The interruption occurs even when the code is executed inside a loop or a similar structure. The exit statement is also used when a local method should return a value.

Using exit without a parameter in a local method corresponds to using the parameter value 0. The AL method will return the value 0 or '' (empty string).

A compile-time error occurs if exit is called by using a return parameter from either of the following:

- System-defined triggers.

- Local methods that do not return a value.

Example

The following example shows the use of the exit statement in a local method. Assume that the if statement is used to detect an error. If the error condition is met, then execution is stopped and the local method returns the error code 1.

```
for I := 1 to 1000 do begin
    if Amount[I] < Total[I] then
        exit(1);
    A[I] := Amount[I] + Total[I];
end;
```

Break statement

You use the break statement to terminate the iterative statement in which it appears.

```
break;
```

You typically use the break statement in the repeating statements such as for, while, or repeat to stop an iteration or loop when certain conditions are met.

> **NOTE**
> The break statement is different than the Break Method (Report, XMLport). Although both stop an iteration or loop, the break method will also terminate the trigger in which it is run.

Example

The following AL code increases the variable I by one for each iteration, and terminates the iteration when I equals 10.

```
while Count < 1000 do
    begin
    Count := Count + 1;
    message(FORMAT(Count));
    if Count = 10 then
        break;
    end;
end;
```

This example requires the following integer data type variable.

```
var
    I : integer
```

AL Essential Methods

AL methods

2/17/2021 • 5 minutes to read • Edit Online

Like other languages, AL methods are a fundamental programming element. A method, also known as a procedure, is a named group of statements that perform an operation or task. Depending on the scope, methods can be run, or *called*, from the same object in which they are declared or from other parts of the application.

There are two types of methods: system methods (built-in) and user-defined (custom) methods.

- Built-in methods are part of the platform. Built-in methods can be used for different purposes, such as string handling, text formatting, database handling, and so on. For information about the available built-in methods, see AL method Reference and Essential AL methods.
- Custom methods are specialized methods for your application to bind the objects, such as tables, pages, and codeunits, together to form a unified whole. You can create special methods for use anywhere in the database.

Declaring methods

The method declaration defines the method and has the following syntax:

```
[Attributes(arguments list)]
local procedure <method_name>(parameter list) <return_value_name> : <data_type>[<length>]
```

Snippet support

Typing the shortcut `tprocedure` will create the basic structure for a method when using the AL Language extension in Visual Studio Code.

Attributes (optional)

An attribute is a modifier on a method declaration that specifies information that controls the method's use and behavior. Adding an attribute on a method declaration is also known as *decorating* a method. For example, decorating a method with the Integration attribute sets the method to be an event publisher. An attribute can have one or more arguments that set properties for the method instance.

Attributes are placed before the method. For information about the available attributes, see Method Attributes.

Local and global scope

A method can be a *local* method or *global* method. A local method can only be accessed or called from inside the object in which it is declared. A global method can be called from inside the object in which it is declared and from other objects.

To declare a local method, start the declaration with `local`:

```
local procedure Mymethod();
```

To declare a global method, *omit* `local`:

```
procedure Mymethod();
```

Parameters (optional)

A parameter is one or more variables or expressions that are sent to the method through the method call. The parameter provides information to the method, and the method can modify that information. In the method declaration, you place the parameters in parentheses `()`. If there is more than one parameter, the parameters are separated by semicolons. A parameter is defined by a data type. Some data types, such as `Record`, require an additional subtype.

For example, the following method declaration includes two parameters: `MyCustomer` and `MyDimension`:

```
procedure  Mymethod(MyCustomer : Record Customer;var MyDimension : ARRAY [2] OF Boolean)
```

Return values (optional)

A method can return data that can be then coded against. A return value is defined by a name (optional), data type, and optional length depending on the data type.

For example, if the return value is a Text DataType, the text might have a length of 50.

```
    procedure MyMethod() ReturnValue: Text[50]
        var result : Text[50];
    begin
        // do something important where result is calculated
        ReturnValue := result;
    end;
```

Calling methods

You can run, or call, a built-in or a custom method by using its name in a method call statement. When a method is called the current application sequence is suspended and the code on the method is run. When the method code is completed, the application code sequence returns to where the method was called from. How the method is called determines what happens when it returns.

A method can be used as part of an expression. For example, the following code uses a method named `CalculatePrice` as an expression:

```
TotalCost := Quantity * CalculatePrice;
```

In this case, the `CalculatePrice` method must return a value that is used in evaluating the expression. This return value is then multiplied by the Quantity variable and that result is assigned to the TotalCost variable.

A method can also be run by using a method call statement. This statement only calls the method and does not return any value. The following is an example of calling a method named `MyRunMethod`:

```
if Quantity > 5 then
MyRunMethod;
```

The `MyRunMethod` returns no data back to the calling code.

Parameters

In a method call, the parameters are separated by commas, and the optional parameters may be omitted starting from the right. For example, this means that if a method has three optional parameters, then you cannot omit the second parameter without omitting the third parameter.

You can specify that a parameter is passed to a method by value or by reference.

- If a parameter is passed by value, then a copy of the variable is passed to the method. Any changes that the method makes to the value of the variable are local changes that affect only the copy, not the variable itself.
- If a parameter is passed by reference, then a reference to the variable is passed to the method. The method can change the value of the variable itself.

Example 1

The following shows the syntax for a method. The first example shows a method with two mandatory parameters.

```
method(Parameter1, Parameter2)
```

Some built-in methods have optional parameters, the syntax is shown below. The optional parameters may be omitted starting from the right.

```
method([Optional1] [, Optional2] [, Optional3])
```

The method that uses the syntax above can be called by using the following code.

```
method(Optional1, Optional2)
```

Example 2

ABS is an example of an AL method that has a fixed number of parameters (1).

```
Value := -1033; //A negative integer value
PositiveValue := ABS(Value); //Calculate the positive value 1033
```

Example 3

The method `DMY2DATE` is an example of a method that can be called by using a variable number of parameters.

```
NewDate := DMY2DATE(5, 11, 1992); //Returns the date November 5, 1992
```

Depending on the use of the `DMY2DATE` method, one, two, or three parameters can be passed to the method because the second and third parameters are optional. When the second and third parameters are not used, values from the system date are used as default values.

Example 4

You can assign the return value of a method to a variable.

```
ReturnVal := MyMethod(Param1);
```

Example 5

In this example, `MyMethod` returns a Boolean value. You can use the return value in a conditional statement.

```
if (MyMethod(Param1)) then
  <Statement1>
else
  <Statement2>
```

Preprocessor Directives in AL

2/17/2021 • 2 minutes to read • Edit Online

APPLIES TO: Business Central 2020 release wave 2 and later

In AL, like in other programming languages, preprocessor directives can be used to make code conditional, to suppress warnings, or to enable expand and collapse in code. Preprocessor directives can be divided into the following groups. For more information about each type, use the links provided below.

- Conditional directives
- Regions
- Pragmas

Any code can be made conditional, including table fields, and checked using a conditional directive. To check code using a conditional directive, you must define a symbol to check. A symbol returns a boolean value; `true` or `false`. Symbols can be defined at the beginning of a source file and the scope of the specific symbol is the file that it is defined within. You can also define symbols in the `app.json` file, and then the scope is global for the extension.

> **NOTE**
> Built-in symbols are currently not supported in AL. Symbols must be defined in a specific file or in the `app.json` file.

Conditional directives

The following conditional preprocessor directives are supported in AL.

CONDITIONAL PREPROCESSOR DIRECTIVE	DESCRIPTION
#if	Specifies the beginning of a conditional clause. The `#endif` clause ends it. Compiles the code between the directives if the specified symbol being checked is defined.
#else	Specifies a compound conditional clause. If none of the preceding clauses evaluates to `true`, the compiler will evaluate code between `#else` and `#endif`.
#elif	Combines `else` and `if`. If `#elif` is `true` the compiler evaluates all code between `#elif` and the next conditional directive.
#endif	Specifies the end of a conditional clause that begins with `#if`.
#define	Defines a symbol that can be used to specify conditions for a compilation. For example, `#define DEBUG`. The scope of the symbol is the file that it was defined in.
#undef	Undefines a symbol.

Defining symbols

Symbols can be defined globally in the `app.json` file. A symbol can also be defined using the `#define` directive in code, but if symbols are defined in the `app.json` file, they can be used globally. The following example defines `DEBUG` as a global symbol. This can then be used from code as illustrated in the Conditional code example below. A symbol has a boolean value, that means it evaluates to `true` or `false`.

```
"preprocessorSymbols": [ "DEBUG" ]
```

For more information, see JSON Files.

Example

```
#if DEBUG
    trigger OnOpenPage()
    begin
        Message('Only in debug versions');
    end;
#endif
```

Deprecating Explicit and Implicit With Statements
Best Practices for Deprecation of Code in the Base App

Region Directive in AL

2/17/2021 • 2 minutes to read • Edit Online

APPLIES TO: Business Central 2020 release wave 2 and later

Region

The `#region` directive is used to mark a block of code that you can expand or collapse. This can, for example, be useful for larger files for better readability or for focusing on code that you are currently working on. The `#endregion` specifies the end of a `#region` block of code.

Syntax

```
#region code
```

```
#endregion
```

Remarks

A `#region` block must be terminated with a `#endregion` directive.

A `#region` block cannot overlap with an `#if` block. However, a `#region` block can be nested in an `#if` block, and an `#if` block can be nested in a `#region` block.

Example

In this example the `#region` directive makes a code block that is up for refactoring collapsible.

```
#region Ugly code - let's not look at this
    procedure UglyCode()
    begin
        // No one should look at this
    end;
#endregion
```

Pragma Directive in AL

2/17/2021 • 2 minutes to read • Edit Online

APPLIES TO: Business Central 2020 release wave 2 and later

Pragma

The `#pragma` directive gives the compiler special instructions for the compilation of the file in which it appears. The `#pragma` directive has a number of actions that can be used with the pragma instructions below, these are `disable`, `restore`, and `enable`.

AL supports the following pragma instructions:

- Pragma ImplicitWith
- Pragma Warning

Using Access Modifiers in AL

2/17/2021 • 2 minutes to read • Edit Online

Access modifiers are used to set accessibility of tables, table fields, codeunits, and queries, which controls whether the object can be used from other code in your module or other modules. Access modifiers in AL are designed to create solid APIs, by limiting the symbols that dependant modules can take a reference on. Limiting the API surface can hide implementation details and allow for later refactoring of code without breaking external code.

You set the object accessibility by using the Access Property. If the `Access` property is not specified; default is `Public`.

> **NOTE**
> In AL access modifiers are primarily intended for designing APIs and *cannot* be used as a security boundary.

Access modifiers

The access modifiers that are available in AL are:

ACCESS MODIFIER	DESCRIPTION
`internal`	The object or field can be accessed only by code in the same module, but not from another module. **Note:** This accessibility level is controlled by the `internalsVisibleTo` setting. For more information, see JSON Files
`local`	The field can be accessed only by code in the same table or table extension where the field is defined. **Note:** Applies to tables fields only.
`protected`	The field can be accessed only by code in the same table or tableextensions of that table. **Note:** Applies to table fields only.
`public`	The object or field can be accessed by any other code in the same module and in other modules that references it. **Note:** This is the default value.

Setting access to `internal` is linked to the JSON Files setting `internalsVisibleTo`.

> **IMPORTANT**
> Access modifiers are only taken into consideration at compile time. For example, at compile time, a table with `Access = Internal` cannot be used from other modules that do not have access to the internals of the module where the table is defined, but at runtime, any module can access the table by using reflection-based mechanisms such as `RecordRef`, or `TransferFields`. And the `OnRun` trigger can be run on `internal` codeunits by using `Codeunit.Run`. Setting the object accessibility level as `Access = Internal;` *cannot* be used as a security boundary. Also see JSON Files.

Access Property

XML Comments in Code

2/17/2021 • 3 minutes to read • Edit Online

APPLIES TO: Business Central 2020 release wave 2 and later

In Dynamics 365 Business Central, you can add documentation to your code by including XML elements in special comment fields directly in the source code before the block of code that the comment refers to. The documentation comment must immediately precede a user-defined type that it annotates, for example a codeunit, table, or interface, or a member such as a field or method. The syntax for adding XML comments in your code is triple slashes `///` followed by one of the supported XML tags. There is IntelliSense support for writing documentation comments. Most importantly providing a template documentation comment when writing the third slash in the triple slash.

Documentation comments are visible when hovering over source symbols, in completion lists, and in signature help. By adding XML comments in code, you can improve readability, add useful information about the implementation, and help others take over code that you wrote. With XML comments you also enable IntelliSense in Visual Studio Code on the AL objects that you add in your code as a help to other developers, working with or extending your code. This means that when you have built an extension and someone extends this code, they will get inline documentation when they call the given object.

> **NOTE**
> Integration with documentation generator tools like DocFx and SandCastle is currently not supported.

> **NOTE**
> If you have the `showMyCode` setting in the app.json file set to `false` and download an app package; the app package will not contain any XML comments.

Supported XML tags

The following table lists the XML elements that are supported for AL.

TOP-LEVEL XML TAG	DESCRIPTION	SYNTAX
`<summary>`	A summary of the object	`<summary>description</summary>`
`<param>`	Used in method declarations to describe one or more parameters defined in the method. For each parameter, specify the name and a description.	`<param name="name">description</param>`
`<returns>`	Used in method declarations to describe the return value of the method.	`<returns>description</returns>`
`<example>`	Used to specify an example of how to use a given codeunit or object.	`<example>description</example>`

TOP-LEVEL XML TAG	DESCRIPTION	SYNTAX
`<remarks>`	Used to supplement information given in the `<summary>` section.	`<remarks>description</remarks>`

FORMATTING XML TAG	DESCRIPTION	SYNTAX
`<paramref>`	Specifies a reference to a parameter in a `<summary>` or `<remarks>` block.	`<paramref name="name"/>`
`<para>`	Allows structuring text inside a `<summary>`, `<remarks>`, or `<returns>` tag.	`<para>paragraph</para>`
`<b>`	Allows formatting text as **bold** inside a top-level tag.	`<b>bold</b>`
`<i>`	Allows formatting text as *italic* inside a top-level tag.	`<i>italic</i>`
`<c>`	Specifies that text within a description should be marked as code inside a top-level tag.	`<c>inline code</c>`
`<code>`	Specifies that multiline text within a description should be marked as code inside a top-level tag.	`<code>code block</code>`
`<list>`	Specifies a list formatted as a bulleted or numbered list, or as a table in a `<summary>` or `<remarks>` block.	`<list type="bullet|number|table">`. See full List syntax below.

List syntax

```
<list type="bullet|number|table">
    <listheader>
        <term>term</term>
        <description>description</description>
    </listheader>
    <item>
        <term>term</term>
        <description>description</description>
    </item>
</list>
```

Example

The following example is taken from the *Email.Codeunit.al* file in the System Application. In this example, the parameter `EmailMessageId` is documented using the `<param>` syntax.

```
/// <summary>
/// Provides functionality to create and send e-mails.
/// </summary>

codeunit 8901 "Email"
{
    Access = Public;

    /// <summary>
    /// Enqueues an email in the outbox to be sent in the background.
    /// </summary>
    /// <param name="EmailMessageId">The ID of the email to enqueue</param>
    procedure Enqueue(EmailMessageId: Guid)
    begin
        EmailImpl.Enqueue(EmailMessageId);
    end;
...
```

Special symbols

For special symbols, such as angle brackets, to appear in text of a documentation comment, use the HTML encoding of `<` and `>` which is `<` and `>` respectively. The following example illustrates how.

```
/// <summary>
/// This property always returns a value &lt; 1.
/// </summary>
```

Developing Extensions in AL
Pages Overview

FAQ for Developing in AL

2/17/2021 • 2 minutes to read • Edit Online

This topic contains a number of frequently asked questions and answers to these questions.

How do I get started?

For an overview of developing apps for Dynamics 365 Business Central, see aka.ms/GetStartedWithApps

Next, follow the Getting Started with AL to set up the tools.

Which version of the AL Language extension should I use?

For Dynamics 365 Business Central cloud sandboxes you must use the AL Language extension available in the Visual Studio Code Marketplace.

For the latest Developer Preview releases you must use the AL Language extension that is available in the *next major* artifact through the "Ready! for Dynamics 365 Business Central" program on Microsoft Collaborate.

How do I enable the debugger?

To read about enabling debugging in AL, see here Debugging. To read about snapshot debugging, see Snapshot Debugging.

Can I create something similar to Menusuites?

In the AL Language extension, the concept of Menusuites is not supported. The two primary purposes of Menusuites are:

- Making pages searchable
- Making pages accessible through a navigation structure

The first purpose can be achieved in Extensions by using the new properties added to Pages and Reports. For more information, see Adding Pages and Reports to Search.

The second purpose can be achieved by extending the Navigation Pane page and/or by adding Actions to other existing pages that can serve as a navigation starting point. For more information, see Adding Menus to the Navigation Pane.

How do I upgrade Extensions V1 to Extensions V2?

For information on upgrading, see the following topics: Upgrading Extensions v2 and Converting from Extensions v1 to Extensions v2.

File APIs are not available in Extensions V2. What do I do?

Code that relies on temporary files must be rewritten to rely on `InStream` and `OutStream` types. Code that relies on permanent files must be rewritten to use another form of permanent storage.

DotNet types are not available in Extensions V2. What now?

For cloud solutions .NET interop is not available due to safety issues in running arbitrary .NET code on cloud

servers.

With the AL Language extension, you can find AL types that replace the most typical usages of .NET like HTTP, JSON, XML, StringBuilder, Dictionaries, and Lists. Many .NET usages can be replaced directly by the AL types resulting in much cleaner code. For more information, see HTTP, JSON, TextBuilder, and XML API Overview.

For things that are not possible to achieve in AL code, the recommendation is to use Azure Functions to host the DLL or C# code previously embedded and call that service from AL.

Extensions published from Visual Studio Code or created using Designer have disappeared from a sandbox environment. Why?

Extensions that have been published to a sandbox environment from Visual Studio Code or created using Designer are removed when the sandbox environment is updated or relocated within our service. However, the data of an app is not removed, so you only have to re-publish and install the app to make it available.

For more information, see Sandbox Environments.

Using the Code Analysis Tool

2/17/2021 • 3 minutes to read • Edit Online

This topic shows how you can use static code analysis tool on an AL project from within Visual Studio Code.

Enabling code analysis

First, follow the steps below to create a simple project in AL.

1. Press **Alt + A, Alt + L** to create a new project.
2. Open the Command Palette **Ctrl+Shift+P** and choose either **User Settings** or **Workspace Settings**.
3. Copy the setting `al.enableCodeAnalysis` to the settings file and set it to `true`: `"al.enableCodeAnalysis": true`.
4. Copy the setting `al.codeanalyzers` to the settings file and then use **Ctrl+Space** to pick from the available code analyzers. Separate the list of code analyzers with commas. For more information about the available analyzers, see AppSourceCop, CodeCop, PerTenantExtensionCop, and UICop.

At this point, the selected analyzers will be run on your project. Next, add some code to the project that will, in the following example, be used to demonstrate a violation of the AA0001 **"There must be exactly one space character on each side of a binary operator such as := + - AND OR =."** code analysis rule.

> **NOTE**
> By default, code analysis is run in the background.

Adding your own code to the project

In the Visual Studio Code Explorer, open the `HelloWorld.al` file and replace the existing code with the following:

```
pageextension 50100 CustomerListExt extends "Customer List"
{
    trigger OnOpenPage();
    var
        result: Integer;
    begin
        // The following line will trigger the warning
        // AA0001 "There must be exactly one space character on each side
        // of a binary operator such as := + - AND OR =."
        result := 2+2;
        Message('2 + 2 = ' + Format(result));
    end;
}
```

Viewing the results of the code analysis

The code analysis tools will run in the background. You will see the faulty expression underlined and the warning **"There must be exactly one space character on each side of '+'."** will be displayed if you mouse over the underlined code. You can also view the list of issues by selecting the **View** tab of Visual Studio Code and choosing the **Problems** option.

Using the **Ctrl+Shift+B** shortcut to build your project will run the code analysis tools on the entire project and

the detected issues will be displayed in the **Output** window of Visual Studio Code. For more information about AL keyboard shortcuts, see Keyboard shortcuts.

Code analyzers

A code analyzer is a library that builds on the compiler's functionality to offer enhanced analysis of the syntax and semantics of your code at build time. The AL Language extension for Visual Studio Code contains four analyzers:

- **CodeCop** is an analyzer that enforces the official AL Coding Guidelines. For more information about the CodeCop rules, see CodeCop Analyzer Rules.
- **PerTenantExtensionCop** is an analyzer that enforces rules that must be respected by extensions meant to be installed for individual tenants. For more information about the PerTenantExtensionCop rules, see PerTenantExtensionCop Analyzer Rules.
- **AppSourceCop** is an analyzer that enforces rules that must be respected by extensions meant to be published to Microsoft AppSource. For more information about the AppSourceCop rules, see AppSourceCop Analyzer Rules.
- **UICop** is an analyzer that enforces rules that must be respected by extensions meant to customize the Web Client. For more information about the UserInterfaceCop rules, see UICop Analyzer Rules.

Enabling code analysis on large projects

In order to improve performance when running code analysis on large projects, you can switch off running code analysis in the background. To do so, open the Command Palette **Ctrl+Shift+P** and choose either **User Settings** or **Workspace Settings**. Then, specify the setting `"al.backgroundCodeAnalysis": false`.

Ruleset for the Code Analysis Tool

2/17/2021 • 2 minutes to read • Edit Online

In an AL project, you can use a custom ruleset file to specify how code analysis will report the issues it encounters. Different settings can affect how rules are applied and each ruleset file name must follow the pattern `<name>.ruleset.json` to benefit from IntelliSense in Visual Studio Code.

> **NOTE**
> Use the `truleset` and `trule` snippets provided by the AL Language extension to create your ruleset.

The following table describes the schema of a ruleset object:

SETTING	MANDATORY	TYPE	VALUE
name	Yes	String	The name of the ruleset.
description	No	String	The description of the ruleset. You can use this to document the purpose of the ruleset.
generalAction	No	Error | Warning | Info | Hidden	The action to apply to all the diagnostics that have rules defined in this file or in other files that have a **Default** action specified and to all the diagnostics generated by the current set of analyzers that do not have a rule defined. If an included file has a stricter **generalAction**, that one will be used.
includedRuleSets	No	Array of **IncludedRuleSet**	List of external ruleset files to include in the current ruleset. The order in which the files are processed is undefined.
rules	No	Array of **Rule**	Collection of rules to apply to diagnostics generated by analyzers.

An **IncludedRuleSet** is a complex JSON object that defines the inclusion of an external ruleset file in the current ruleset, and has the following properties:

SETTING	MANDATORY	TYPE	VALUE

SETTING	MANDATORY	TYPE	VALUE
path	Yes	String	The path to the included file. For includes specified in the file to which the **al.ruleSetPath** is set, the path can be absolute or relative to the project folder. For files included from the root ruleset file, the path is relative to the file. Adding an entry to the ruleset path and saving it will automatically be applied to all projects that are using the ruleset.
action	Yes	Error | Warning | Info | Hidden | None | Default	The action to apply for all the diagnostics that have an action specified in the included ruleset that is different from **None** and **Hidden**.

A **Rule** is a complex JSON object that specifies how you can process a specific diagnostic. A **Rule** object has the following properties:

SETTING	MANDATORY	TYPE	VALUE
id	Yes	String	The string that uniquely identifies a diagnostic.
action	Yes	Error | Warning | Info | Hidden | None	The action to apply if the diagnostic is emitted. There cannot be two rules with the same id and different actions in the same rule file.

Examples

The following example shows a ruleset that sets the severity of rule **AA0001 : There must be exactly one space character on each side of a binary operator such as := + - AND OR =.** provided by the **CodeCop** analyzer to **Error**.

```
{
    "name": "Company ruleset",
    "description": "These rules must be respected by all the AL code written within the company.",
    "rules": [
        {
            "id": "AA0001",
            "action": "Error",
            "justification": "This diagnostic helps to improve readability. It must be respected in all
cases."
        }
    ]
}
```

The following example shows a project-specific ruleset that extends a company-wide ruleset contained in the file **company.ruleset.json** and sets the severity of the rule **AA0005 : Only use BEGIN..END to enclose**

compound statements. provided by the **CodeCop** analyzer to **Info**.

```
{
    "name": "Personal Project ruleset",
    "description": "A list of project specific rules",
    "includedRuleSets": [
        {
            "action": "Default",
            "path": "./company.ruleset.json"
        }
    ],
    "rules": [
        {
            "id": "AA0005",
            "action": "Info",
            "justification": "For this specific project, this diagnostic should be informational."
        }
    ]
}
```

Using the Code Analysis Tools with the Ruleset

2/17/2021 • 3 minutes to read • Edit Online

This topic shows how you can use a custom ruleset to customize the severity of diagnostics produced by the code analysis tools that are part of the AL Language extension for Visual Studio Code.

Using rulesets with code analysis

First, create a simple project in AL.

1. Press **Alt + A, Alt + L** to create a new project.
2. Open the Command Palette by using the **Ctrl+Shift+P** shortcut and choose either **User Settings** or **Workspace Settings**.
3. Copy the setting `al.enableCodeAnalysis` to the settings.json file and set it to `true`: `"al.enableCodeAnalysis": true`.
4. Copy the setting `al.codeanalyzers` to the settings file and then use **Ctrl+Space** to pick from the available code analyzers. Separate the list of code analyzers with commas. For more information about the available analyzers, see AppSourceCop, CodeCop, PerTenantExtensionCop, and UICop.

At this point, the selected analyzers will be run on your project. Next, add some code to the project that will, in the following example, be used to demonstrate violations of the AA0001 **"There must be exactly one space character on each side of a binary operator such as := + - AND OR =."** code analysis rule.

Add your own code to the project

In the Visual Studio Code Explorer, open the `HelloWorld.al` file and replace the existing code with the following:

```
pageextension 50100 CustomerListExt extends "Customer List"
{
    trigger OnOpenPage();
    var
        result: Integer;
    begin
        // The following line will trigger the warning
        // AA0001 "There must be exactly one space character on each side
        // of a binary operator such as := + - AND OR =."
        result := 2+2;
        Message('2 + 2 = ' + Format(result));
    end;
}
```

On the **View** tab of Visual Studio Code, select the **Problems** option and you will see a warning with the message **"There must be exactly one space character on each side of '+'."**. In this case, the problem can be fixed by running the AL Formatter command. For more information, see AL Formatter.

Creating and customizing a ruleset

To create and customize a ruleset of your own, follow the next steps:

1. On the **File** tab in Visual Studio Code, choose **New File**.
2. Save the empty file with a name, for example `<name>.ruleset.json` and make a note of the file path.

3. Add the following code to the `<name>.ruleset.json` file:

```
{
    "name": "My Custom ruleset",
    "rules": [
        {
            "id": "AA0001",
            "action": "None"
        }
    ]
}
```

4. In your project settings set **al.ruleSetPath** to the path to the `<name>.ruleset.json` file, relative to the project root. For more information about custom rules, see Ruleset for the Code Analysis Tool.

> **NOTE**
>
> Use the `truleset` and `trule` snippets provided by the AL Language extension to create your ruleset. The ruleset will be applied to all the analyzers enabled for the current project. For more information about selectively enabling analyzers, see Using the Code Analysis Tools.

Running the code analysis

The code analysis will run in the background and you will see the warning **"There must be exactly one space character on each side of '+'."** disappear from the **Problems** option in Visual Studio Code.

To trigger a new compilation manually, use the **Ctrl+Shift+B** shortcut to build your project. For more information about AL keyboard shortcuts, see Keyboard shortcuts.

Limitations

Changing the contents of the ruleset file will not be detected by the AL Language extension. To see the effects of changing the ruleset file, you can try any of the following:

- Reload the window.
- In the project settings, change the **al.ruleSetPath** setting to an invalid path. Save the settings file, change back the setting, and save it.

AppSourceCop Analyzer Rules

2/17/2021 • 9 minutes to read • Edit Online

AppSourceCop is an analyzer that enforces rules that must be respected by extensions meant to be published to Microsoft AppSource.

Rules

ID	TITLE	CATEGORY	DEFAULT SEVERITY
AS0001	Tables and table extensions that have been published must not be deleted.	Upgrade	Error
AS0002	Fields must not be deleted.	Upgrade	Error
AS0003	The previous version of the extension could not be found.	Upgrade	Error
AS0004	Fields must not change type, since dependent extensions may break	Upgrade	Error
AS0005	Fields must not change name	Upgrade	Error
AS0006	Tables that have been published must not change name.	Upgrade	Error
AS0009	Key fields must not be changed	Upgrade	Error
AS0010	Keys must not be deleted, since dependent extensions may break	Upgrade	Error
AS0011	An affix is required	Extensibility	Error
AS0013	The field identifier must be within the allowed range	Extensibility	Error
AS0014	The project manifest must contain the allocated identifier range	Extensibility	Error
AS0015	TranslationFile must be enabled.	Extensibility	Error

ID	TITLE	CATEGORY	DEFAULT SEVERITY
AS0016	Fields of field class 'Normal' must use the DataClassification property and its value should be different from ToBeClassified	Extensibility	Error
AS0018	A procedure belonging to the public API cannot be removed	Upgrade	Error
AS0019	Event attributes cannot be removed	Upgrade	Error
AS0020	The type of events cannot be changed.	Upgrade	Error
AS0021	An argument in an event attribute cannot be changed to false.	Upgrade	Error
AS0022	An external scope cannot be removed	Upgrade	Error
AS0023	A return type cannot be modified in external procedures	Upgrade	Error
AS0024	Parameters cannot be removed or added in external procedures	Upgrade	Error
AS0025	Parameters cannot be modified, renamed, or removed from events.	Upgrade	Error
AS0026	The type and subtype of parameters cannot be modified in events and external procedures	Upgrade	Error
AS0027	Modifying the array size of a parameter in events and external procedures is not allowed	Upgrade	Error
AS0028	Reducing the array size of a parameter in events and external procedures is not allowed	Upgrade	Error
AS0029	Pages and PageExtensions that have been published must not be deleted, since dependent extensions may break	Upgrade	Error

ID	TITLE	CATEGORY	DEFAULT SEVERITY
AS0030	Pages that have been published must not be renamed.	Upgrade	Error
AS0031	Actions that have been published must not be deleted.	Upgrade	Error
AS0032	Controls that have been published must not be deleted/	Upgrade	Error
AS0033	Views that have been published must not be deleted.	Upgrade	Error
AS0034	Unsupported table property change	Upgrade	Error
AS0036	Unsupported table field property change	Upgrade	Error
AS0038	Unsupported table key property change	Upgrade	Error
AS0039	Removing properties that cause destructive changes is not allowed	Upgrade	Error
AS0041	Table field property changes that cause destructive changes must not be removed	Upgrade	Error
AS0042	Table key property changes that cause destructive changes must not be removed	Upgrade	Error
AS0043	Unique keys must not be deleted	Upgrade	Error
AS0044	Property changes that cause destructive changes are not allowed	Upgrade	Error
AS0047	The extension name is too long.	Extensibility	Error
AS0048	The publisher name is too long.	Extensibility	Error

ID	TITLE	CATEGORY	DEFAULT SEVERITY
AS0049	The access modifier of an application object cannot be changed to a value that provides less access	Extensibility	Error
AS0050	The extensibility of an application object cannot be removed	Extensibility	Error
AS0051	Manifest property is required for AppSource submission	Extensibility	Error
AS0052	The property 'url' must be set to a valid URL	Extensibility	Error
AS0053	The compilation target of an application must be a value that is allowed in a multi-tenant SaaS environment	Extensibility	Error
AS0054	The AppSourceCop configuration must specify the set of affixes used by the application	Configuration	Error
AS0055	The AppSourceCop configuration must specify the list of countries targeted by the application	Configuration	Hidden
AS0056	The country codes specified in the 'supportedCountries' property must be valid ISO 3166-1 alpha-2 codes	Configuration	Warning
AS0057	Translations must be provided for all the locales in which the application will be available	Extensibility	Hidden
AS0058	Only use AssertError in Test Codeunits	Extensibility	Error
AS0059	Reserved database tables are read-only in a multi-tenant environment	Extensibility	Error
AS0060	Unsafe methods cannot be invoked in an AppSource application	Extensibility	Error
AS0061	Procedures must not subscribe to CompanyOpen events	Extensibility	Error

ID	TITLE	CATEGORY	DEFAULT SEVERITY
AS0062	Page controls and actions must use the ApplicationArea property	Extensibility	Error
AS0063	Removing a var modifier in events is not allowed	Upgrade	Error
AS0064	Interface implementations that have been published must not be deleted.	Upgrade	Error
AS0065	Interfaces that have been published must not be deleted.	Upgrade	Error
AS0066	A new method to an interface that has been published must not be added.	Upgrade	Error
AS0067	Adding an interface to an enum that has been published must have a default implementation.	Upgrade	Error
AS0068	Changing a table extension's target is not allowed.	Upgrade	Error
AS0069	An enum field replacing an option field should have at least the same number of members.	Upgrade	Error
AS0070	An enum field replacing an option field should preserve the member names.	Upgrade	Error
AS0071	An enum field replacing an option field should preserve the member ordinal values.	Upgrade	Error
AS0072	The ObsoleteTag property and the Tag in the Obsolete attribute must be set to the next release version.	Design	Hidden
AS0073	Obsolete Tag must be set.	Design	Hidden
AS0074	The Obsolete Tag must be the same across branches.	Design	Hidden
AS0075	Obsolete Reason must be set.	Design	Warning

ID	TITLE	CATEGORY	DEFAULT SEVERITY
AS0076	Obsolete Tag format.	Design	Hidden
AS0077	Adding a var modifier in events is not allowed	Upgrade	Warning
AS0078	Adding or removing a var modifier in external procedures is not allowed	Upgrade	Warning
AS0079	An affix is required for procedures defined in extension objects.	Extensibility	Warning
AS0080	Fields must not decrease in length	Upgrade	Error
AS0081	InternalsVisibleTo should not be used as a security feature.	Extensibility	Warning
AS0082	It is not allowed to rename an enum value.	Upgrade	Error
AS0083	It is not allowed to delete a value from an enum.	Upgrade	Error
AS0084	The ID range assigned to the extension must be within the allowed range	Extensibility	Error
AS0085	The 'application' property must be used instead of explicit dependencies	Extensibility	Warning
AS0086	Fields must not increase in length	Upgrade	Warning
AS0087	Translations of enum value captions must not contain commas	Extensibility	Warning
AS0088	Objects with an ID that can be referenced and which have been published must not be deleted.	Upgrade	Error
AS0089	Objects that can be referenced and which have been published must not be deleted.	Upgrade	Error
AS0090	Objects that can be referenced and which have been published must not be renamed.	Upgrade	Error

ID	TITLE	CATEGORY	DEFAULT SEVERITY
AS0091	One or more dependencies of the previous version of the extension could not be found.	Upgrade	Error
AS0092	The 'applicationInsightsKey' property must specify the AAD instrumentation key.	Configuration	Warning

NOTE

Several rules enforced by the AppSourceCop analyzer are incompatible with rules enforced by the PerTenantExtensionCop. Make sure to enable only one of these at a time.

NOTE

Failing to comply with the rules whose default severity is set to `Error` will fail the submission of your extension to the AppSource marketplace. It is recommended, but not mandatory to comply with the rules whose severity is marked as `Warning` or `Info`.

Configuration

The AppSourceCop analyzer can be further configured by adding a file named `AppSourceCop.json` in the project's root folder. The AL Language extension will offer IntelliSense for this file.

The following table describes the settings in the `AppSourceCop.json` file:

SETTING	MANDATORY	VALUE
name	No	The name of a previous version of this package with which you want to compare the current package for breaking changes.
publisher	No	The publisher of a previous version of this package with which you want to compare the current package for breaking changes.
version	Yes	The version of a previous version of this package with which you want to compare the current package for breaking changes.
mandatoryAffixes	No	Affixes that must be prepended or appended to the name of all new application objects, extension objects, and fields.
supportedCountries	No	The set of country codes, in the alpha-2 ISO 3166 format, in which the application will be available.

SETTING	MANDATORY	VALUE
targetVersion	No	Specifies the next Major.Minor version of the extension in the current branch in order to validate the ObsoleteTag values with AS0072. This is only relevant when the default obsoleteTagPattern '(\d+)\.(\d+)' is used. This property is being deprecated in favor of obsoleteTagVersion.
obsoleteTagVersion	No	Specifies the next Major.Minor version of the extension in the current branch in order to validate the ObsoleteTag values with AS0072. This is only relevant when the default obsoleteTagPattern '(\d+)\.(\d+)' is used.
obsoleteTagPattern	No	The Obsolete tag pattern used by AS0076. This should be a valid regular expression. By default, the pattern '(\d+)\.(\d+)' is used.
obsoleteTagPatternDescription	No	A human-readable description for the ObsoleteTagPattern regular expression. This is used in diagnostics reported by AS0076. By default, 'Major.Minor' is used.
baselinePackageCachePath	No	The path to the folder containing the baseline and its dependencies with which you want to compare the current package for breaking changes. By default, the package cache path for the current project is used (see 'al.packageCachePath' setting).

The `name`, `publisher`, `version` properties are used for specifying a previous version of the current package. This package must be located in the baseline package cache folder of your extension. This cache can be specified using the `baselinePackageCachePath` property. If this property is not specified, the dependency package cache path of the extension will be used instead. The `al.packageCachePath` setting allows you to specify the path to the folder that will act as the cache for the dependencies symbol files used by your project. AppSourceCop will compare the previous version of your extension with its current version and will report any breaking changes introduced by the current package.

The `mandatoryAffixes` property specifies strings that must be prepended or appended to the names of all new objects, extension objects and fields. By using these affixes, you can prevent clashes between objects added by your extension and objects added by other extensions.

The `supportedCountries` property specifies the codes that correspond to the countries for which the product allows AppSource submissions. For more information, see Availability and supported Countries/Regions and Translations

The properties `obsoleteTagVersion`, `obsoleteTagPattern`, and `obsoleteTagPatternDescription` can be used to enable additional validation on object obsoletion. These are not required for AppSource submissions.

Example

In the following example, we will configure AppSourceCop to validate that all new elements have a name that contains one of the specified affixes.

> **NOTE**
> Make sure that code analysis is enabled and `${AppSourceCop}` is specified in the list of enabled code analyzers. For more information see AL Language Extension Configuration.

We start by creating the default "Hello world" extension.

```
pageextension 50100 CustomerListExt extends "Customer List"
{
    trigger OnOpenPage();
    begin
        begin
            Message('App published: Hello world');
        end;
    end;
}
```

We continue by adding the configuration file `AppSourceCop.json` in the project's root folder and setting its content to the following.

```
{
    "mandatoryAffixes": [ "Foo", "Bar" ]
}
```

> **IMPORTANT**
> If you are running a multi-root workspace environment, you must have one `AppSourceCop.json` file in the root folder of each of the projects. For more information, see Working with multiple AL project folders within one workspace.

You are immediately greeted by the following error message:

```
AS0011: The identifier 'CustomerListExt' must have at least one of the mandatory affixes 'Foo, Bar'.
```

Prepending **Foo** to the name of the page extension object will fix this error and prevent clashes between this page extension and page extensions added by other developers.

> **NOTE**
> It is still possible to use the `mandatoryPrefix` and `mandatorySuffix` properties in the `AppSourceCop.json`. For more information see AS0011.

CodeCop Analyzer Rules

2/17/2021 • 5 minutes to read • Edit Online

CodeCop is an analyzer that enforces the official AL Coding Guidelines.

Rules

ID	TITLE	CATEGORY	DEFAULT SEVERITY
AA0001	There must be exactly one space character on each side of a binary operator such as := + - AND OR =.	Readability	Warning
AA0002	There must be no space character.	Readability	Warning
AA0003	There must be exactly one space character between the NOT operator and its argument.	Readability	Warning
AA0005	Only use BEGIN..END to enclose compound statements.	Readability	Warning
AA0008	Function calls should have parenthesis even if they do not have any parameters.	Readability	Warning
AA0013	When BEGIN follows THEN, ELSE, DO, it should be on the same line, preceded by one space character.	Readability	Warning
AA0018	The END, IF, REPEAT, UNTIL, FOR, WHILE, and CASE statement should always start a line.	Readability	Warning
AA0021	Variable declarations should be ordered by type.	Readability	Warning
AA0022	Substitute the IF THEN ELSE structure with a CASE.	Readability	Warning
AA0040	Avoid using nested WITH statements.	Readability	Warning
AA0072	The name of variables and parameters must be suffixed with the type or object name.	Readability	Info

ID	TITLE	CATEGORY	DEFAULT SEVERITY
AA0073	The name of temporary variable must be prefixed with Temp.	Readability	Warning
AA0074	TextConst and Label variable names should have an approved suffix.	Readability	Warning
AA0087	Lowering permissions should only be used in tests	Design	Warning
AA0100	Do not have identifiers with quotes in the name.	Design	Warning
AA0101	Use camel case property values in pages of type API.	Design	Warning
AA0102	Use camel case name for field controls in pages of type API.	Design	Warning
AA0103	Use camel case property values in queries of type API.	Design	Warning
AA0104	Use camel case name for column controls in queries of type API.	Design	Warning
AA0105	PagePart controls must not refer to parent pages.	Design	Error
AA0106	A page of type API can only refer to the same subpage once.	Design	Error
AA0131	String parameters must match placeholders.	Design	Warning
AA0136	Do not write code that will never be hit.	Design	Warning
AA0137	Do not declare variables that are unused.	Design	Warning
AA0139	Do not assign a text to a target with smaller size.	Design	Warning
AA0150	Do not declare parameters by reference if their values are never changed.	Design	Warning
AA0161	Only use AssertError in Test Codeunits.	Design	Warning

ID	TITLE	CATEGORY	DEFAULT SEVERITY
AA0175	Only find record if you need to use it.	Design	Warning
AA0181	The FindSet() or Find() methods must be used only in connection with the Next() method.	Design	Warning
AA0189	Only use a correct values of ApplicationArea.	Design	Warning
AA0194	Only write actions that have an effect.	Design	Warning
AA0198	Do not use identical names for local and global variables.	Design	Warning
AA0199	Use only a correct order for ApplicationArea.	Design	Warning
AA0200	When ApplicationArea is set to 'All', no other values for ApplicationArea should be specified.	Design	Warning
AA0201	When ApplicationArea is set to 'Basic', you must also specify 'Suite'.	Design	Warning
AA0462	The CalcDate should only be used with DataFormula variables. Alternatively the string should be enclosed using the <> symbols.	Localizability	Warning
AA0202	To avoid confusion, do not give local variables the same name as fields, methods or actions in the same scope.	Design	Warning
AA0203	To avoid confusion, do not give methods the same name as fields or actions in the same scope.	Design	Warning
AA0204	To avoid confusion, do not give global variables the same name as fields, methods or actions in the same scope.	Design	Warning
AA0205	Variables must be initialized before usage.	Design	Warning

ID	TITLE	CATEGORY	DEFAULT SEVERITY
AA0206	The value assigned to a variable must be used.	Design	Warning
AA0207	The EventSubscriber method must be local.	Design	Warning
AA0210	Avoid non-indexed fields into filtering.	Design	Info
AA0211	Avoids a runtime error from using CalcFields on a field that is not a FlowField or a field of type Blob.	Design	Warning
AA0213	Obsoleted object must have a state 'Pending' or 'Removed' and a justification specifying why this field is being obsoleted.	Design	Warning
AA0214	The local record should be modified before saving to the database.	Design	Warning
AA0215	Follow the style guide about the best practices for naming.	Readability	Warning
AA0216	Use a text constant for passing user messages and errors without concatenations.	Localizability	Warning
AA0217	Use a text constant or label for format string in StrSubstNo.	Localizability	Warning
AA0218	You must write a tooltip in the Tooltip property for all controls of type Action and Field that exist on page objects.	Localizability	Warning
AA0219	The Tooltip property of Fields must start with 'Specifies'.	Localizability	Warning
AA0220	The value of the Tooltip property of Fields must be filled.	Localizability	Warning
AA0221	You must specify a OptionCaption property for all fields which source expressions is not a table field.	Localizability	Warning

ID	TITLE	CATEGORY	DEFAULT SEVERITY
AA0222	SIFT index should not be used on primary or unique key.	Design	Warning
AA0223	The value of the OptionCaption property of Fields must be filled in.	Localizability	Warning
AA0224	The count of option captions specified in the OptionCaption property is wrong.	Localizability	Warning
AA0225	You must specify a caption in the Caption property for Fields that exist on page objects.	Localizability	Warning
AA0226	The value of the Caption property of Fields must be filled in.	Localizability	Warning
AA0227	Optional return value should not be omitted in upgrade codeunits.	Design	Warning
AA0228	The local method must be used; otherwise removed.	Design	Warning
AA0230	Version should not be specified for internal assemblies.	Design	Warning
AA0231	StrSubstNo or string concatenation must not be used as a parameter in the Error method.	Design	Warning
AA0232	The FlowField of a table should be indexed.	Design	Info
AA0233	Use Get(), FindFirst() and FindLast() without Next() method.	Design	Warning
AA0235	When using 'OnInstallPerCompany' you should also add 'Company - Initialize'::'OnCompanyInitialize' event subscriber.	Design	Info
AA0237	The name of non-temporary variables must not be prefixed with Temp.	Readability	Warning

ID	TITLE	CATEGORY	DEFAULT SEVERITY
AA0240	Email and Phone No must not be present in any part of the source code.	Design	Warning
AA0241	Use all lowercase letters for reserved language keywords.	Readability	Warning
AA0448	You must use the FieldCaption method instead of the FieldName method and TableCaption method instead of TableName method.	Localizability	Warning
AA0470	Placeholders should have a comment explaining their content.	Localizability	Warning
AA0242	Limit JIT loads by selecting all fields for load.	Design	Warning

Isolated Storage

2/17/2021 • 2 minutes to read • Edit Online

Isolated Storage is a data storage that provides isolation between extensions, so that you can keep keys/values in one extension from being accessed from other extensions. Keys/values in the Isolated Storage are accessible through an API. The involved option type is DataScope Option Type.

The methods supported for IsolatedStorage are:

METHOD	DESCRIPTION	FOR MORE INFORMATION, SEE
Set(String, String, [DataScope])	Sets the value associated with the specified key within the extension.	Set(String, String, [DataScope]) Method
Get(String, [DataScope], var Text)	Gets the value associated with the specified key within the extension.	Get(String, [DataScope], var Text) Method
Contains(String, [DataScope])	Determines whether the storage contains a value with the specified key within the extension.	Contains(String, [DataScope]) Method
Delete(String, [DataScope])	Deletes the value with the specified key from the isolated storage within the extension.	ISOLATEDSTORAGE.DELETE Method
SetEncrypted(String, String, [DataScope])	Encrypts and sets the value associated with the specified key. The input string cannot exceed a length of 215 plain characters; be aware that special characters take up more space.	SetEncrypted(String, String, [DataScope]) Method

DataScope Option Type

File Handling and Text Encoding

2/17/2021 • 4 minutes to read • Edit Online

There are several AL methods that you can use to open files, import and export files to and from Dynamics 365 Business Central, and more. For a list of methods, see File Data Type.

The following are recommended best practices for working with files:

- Use fully qualified paths to eliminate ambiguity.
- Be aware of operating system file access restrictions when designing applications that use files. Consider which users have access to files and directories and what Access Control List (ACL) that you need to apply to file directories.

Text encoding

Text encoding is the process of transforming bytes of data into readable characters for users of a system or program. When you import a file as text or as a stream, the text encoding format ensures that all the language-specific characters are represented correctly in Dynamics 365 Business Central. When you export a file as text or as a stream, the text encoding format ensures that all the language-specific characters are represented correctly in the system or program that will read the exported file.

Encoding formats

You can specify text encoding for the following objects.

OBJECT OR DATA TYPE	FOR MORE INFORMATION, SEE
XMLports	TextEncoding Property (XMLports)
File	OPEN Method (File)
BLOB	CREATEINSTREAM Method (BLOB) CREATEOUTSTREAM Method (BLOB)

There are several industry text encoding formats and different systems support different formats. Internally, Dynamics 365 Business Central uses Unicode encoding. For exporting and importing data with an XMLport, it supports MS-DOS, UTF-8, UTF-16, and Windows encoding formats.

Data is imported and exported as follows:

- When data is imported from an external file, it is read using the format that is specified by the **TextEncoding** property or parameter, and then converted to Unicode in Dynamics 365 Business Central.
- When data is exported to an external file, it is converted from Unicode in Dynamics 365 Business Central, and then written to the file in the format that is specified by the **TextEncoding** property or parameter.

You should set the text encoding to the encoding format that is compatible with the system or program that you will be exporting to or importing from. The following sections describe the available text encoding formats.

MS-DOS encoding format

MS-DOS encoding, which is also referred to as OEM encoding, is an older format than UTF-8 and UTF-16, but it

is still widely supported.

MS-DOS encoding requires a different character set for each language. When the property is set to MS-DOS, text is encoded by using the system locale language of the computer that is running Dynamics 365 Business Central service instance. So if you use MS-DOS encoding, you should set the system locale language of server instance computer to match the language of the data that is being imported or exported. For example, if an XMLport includes text in Danish, then you should set the system locale language of the server instance computer to Danish before the XMLport is run.

You should choose **MS-DOS** with XMLports that were created in earlier versions of Dynamics 365 Business Central.

UTF-8 encoding format

UTF-8 encoding is a Unicode Transformation Format that uses one byte (8 bits) to encode each character. UTF-8 is based on the Unicode character set, which includes most characters of all languages in a single character set.

Unlike MS-DOS, when you use UTF-8, you do not have to consider the language settings of Dynamics 365 Business Central service instance or the external system or program that will read or write the data.

UTF-8 is compatible with ASCII so that it will understand files written in ASCII format.

UTF-8 is the most common encoding format and the recommended setting if you are not sure of the format that is supported by the system that you are integrating with.

UTF-16 encoding format

UTF-16 encoding resembles UTF-8 except that UTF-16 uses 2 bytes (16 bits) to encode each character. UTF-16 is also based on the Unicode character set, so you do not have to consider the language setting of Dynamics 365 Business Central service instance or the external system or program that reads or writes the data.

UTF-16 includes two encoding schemes which mandate the byte order: UTF-16LE and UTF-16BE. The schemas are supported as follows:

- When exporting, the file is written using UTF-16LE encoding.
- When importing, the file is read using the UTF-16, UTF-16LE, or UTF-16BE, depending on encoding scheme of the file itself.

A UTF-16 encoded file will typically be larger than the same file encoded with UTF-8, except for Eastern language character sets, which will typically be smaller.

UTF-16 is incompatible with ASCII so that it will not understand files written in ASCII format.

Windows format

Windows encoding is also referred to as ANSI encoding. If you set the text encoding to **Windows**, you can import and export text files that are based on the Windows codepage on the user's computer. As a result, you do not have to consider the language setting of Dynamics 365 Business Central service instance computer or the external system or program that reads or writes the data.

For example, if an XMLport can import bank files from a foreign bank in addition to a domestic bank, use Windows encoding instead of MS-DOS encoding to avoid changing the language of Dynamics 365 Business Central service instance computer.

Windows encoding is compatible with ASCII so that it will understand files written in ASCII format.

FlowFields

2/17/2021 • 2 minutes to read • Edit Online

FlowFields display the result of the calculation described in the CalcFormula Property. For example, the **Account Balance** field in the General Ledger Account table shows the balance of the account and is calculated as the sum of the NetAmount fields for all General Journal entries in the account.

FlowFields increase performance in activities such as calculating the balance of your customers. In traditional database systems, this involves a series of accesses and calculations before a result is available. By using FlowFields, the result is immediately available. You can further optimize the performance of Flowfields by enabling or disabling SIFT. For more information, see SumIndexField Technology (SIFT).

FlowFields are not physical fields that are stored in the database. They are a description of a calculation and a location for the result to be displayed. Because the information in FlowFields exists only at run time, values in FlowFields are automatically initialized to 0 (zero). To update a FlowField, use the CalcFields Method (Record). If a FlowField is the direct source expression of a control on a page, then the FlowField is automatically calculated when the page is displayed.

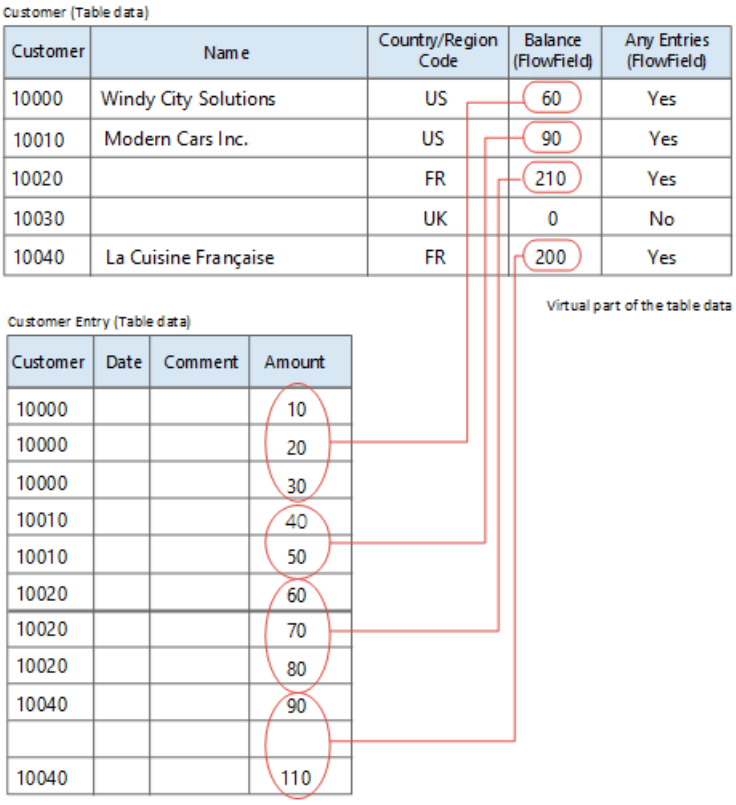
FlowField types

There are seven types of FlowFields. Each is described in the following table.

FLOWFIELD TYPE	FIELD TYPE	DESCRIPTION
Sum	Decimal, Integer, BigInteger, or Duration	The sum of a specified set in a column in a table.
Average	Decimal, Integer, BigInteger, or Duration	The average value of a specified set in a column in a table.
Exist	Boolean	Indicates whether any records exist in a specified set in a table.
Count	Integer	The number of records in a specified set in a table.
Min	Any	The minimum value in a column in a specified set in a table.
Max	Any	The maximum value in a column in a specified set in a table.
Lookup	Any	Looks up a value in a column in another table.

Example

Consider the Customer table in the following illustration. This table contains two FlowFields. The field named **Any Entries** is a FlowField of the Exist type, and the **Balance** field is a FlowField of the Sum type.



The figure shows that the value in the Balance FlowField for customer number 10000 (Windy City Solutions) is retrieved from the Amount column in the Customer Entry table. The value is the sum of the amount fields for the entries that have the customer number 10000.

```
Sum = 10 + 20 + 30 = 60.
```

The values shown in the **Balance** column in the Customer table for customers 10010, 10020, and 10040 are found in the same way. For customer number 10030 the value is 0 (zero), as there are no entries in the Customer Entry table that have a Customer No. that equals 10030.

In this example, the Balance FlowField in the Customer table reflects the sum of a specific subset of the Amount fields in the Customer Entry table. How the calculation of a FlowField is to be made, is defined in a calculation formula. The calculation formula for the **Balance** field is:

```
Sum("Customer Entries".Amount WHERE(CustNo=FIELD(CustNo)))
```

Correspondingly, the **Any Entries** field, which indicates whether any entries exist, has the following definition:

```
Exist("Customer Entries" WHERE(CustNo=FIELD(CustNo)))
```

Create FlowFields and FlowFilters

Create FlowFields and FlowFilters

2/17/2021 • 3 minutes to read • Edit Online

This topic describes the procedure and the properties used to create FlowFields and FlowFilters.

A FlowField performs a set of calculations and displays the results immediately. A FlowFilter displays the results based on the user input to calculate the filtered values that will affect the calculation of a FlowField. The FlowFields and FlowFilters are not physical fields; these fields act as a virtual field which does not actually exist in the database. They are a description of a calculation and a location for the result to be displayed which is typically derived in the CalcFormula Property.

For more information about the FlowField type, see FlowFields, and for more information about the FlowFilter type, see FlowFilter Overview.

Classifying the field type

In order to create FlowFields and FlowFilters, you must first classify the field type by using the FieldClass Property. For more information, see FieldClass Property. By classifying the field as a FlowField or a FlowFilter type, you enable the fields to act as a virtual field whose value can be dynamically derived based on the calculation formula.

Calculation formula

A FlowField type is always associated with a calculation formula that determines how the FlowField is calculated. Likewise, the FlowFilter type is associated with the calculation formula. To perform the calculations by using the FlowField and FlowFilter type, you must derive those fields in the calculation formula which you classify in the table. You can choose from several methods of calculations including sum (total), average, maximum value, minimum value, record count, lookup, and more, by using the CalcFormula Property. For more information about the syntax and formulas, see Calculation Formulas and the CalcFormula Property.

Example

In the following example, `MyTable` sets the `Global Dimension 1 Filter` and `Global Dimension 2 Filter` fields whose values are based only on the dimension values included in the filter. Also, some of the following fields formulate the currency filter to one single currency because you do not store the filter value on the entries, hence you define the `Currency Filter` as a FlowFilter type. `Total Amount`, `Amount upper bound`, `Amount lower bound`, `First Entry`, and `Customer Balance` are classified as a FlowField type and here you specify the calculations. These fields display the results immediately based on the filters that you apply in the user interface.

```
table 50123 MyTable
{
    fields
    {
        field(1;MyField; Decimal)
        {
            Description='New field';
        }

        field(2;"No."; Code[20])
        {
            Description='Serial number of the service';
        }
```

```
        field(3;"Global Dimension 1 Filter"; Code[20])
        {
            FieldClass = FlowFilter;
        }

        field(4;"Global Dimension 2 Filter"; Code[20])
        {
            FieldClass = FlowFilter;
        }

        field(5;"Currency Filter"; Code[10])
        {
            FieldClass = FlowFilter;
        }

        field(6; "Total Amount"; Decimal)
        {
            FieldClass = FlowField;
            CalcFormula = Sum("Detailed Cust. Ledg. Entry"."Amount (LCY)"
            WHERE ("Customer No."=Field("No."),
            "Initial Entry Global Dim. 1"=Field("Global Dimension 1 Filter"),
            "Initial Entry Global Dim. 2"=Field("Global Dimension 2 Filter"),
            "Currency Code"=Field("Currency Filter")
            ) );
        }

        field(7; "Amount upper bound"; Decimal)
        {
            FieldClass = FlowField;
            CalcFormula = max ("Detailed Cust. Ledg. Entry"."Amount (LCY)"
            WHERE ("Customer No." = Field ("No."),
            "Initial Entry Global Dim. 1" = Field ("Global Dimension 1 Filter"),
            "Initial Entry Global Dim. 2" = Field ("Global Dimension 2 Filter"),
            "Currency Code" = Field ("Currency Filter")
            ));
        }

        field(8; "Amount lower bound"; Decimal)
        {
            FieldClass = FlowField;
            CalcFormula = min ("Detailed Cust. Ledg. Entry"."Amount (LCY)"
            WHERE ("Customer No." = Field ("No."),
            "Initial Entry Global Dim. 1" = Field ("Global Dimension 1 Filter"),
            "Initial Entry Global Dim. 2" = Field ("Global Dimension 2 Filter"),
            "Currency Code" = Field ("Currency Filter")
            ));
        }

        field(9; "First entry"; Boolean)
        {
            CalcFormula = exist (Customer where (Payments = const (0),
                                                 "No." = field ("No.")));
            FieldClass = FlowField;
            Caption = 'Specifies whether it is the customer''s first entry';
        }

        field(10; "Customer Balance"; Decimal)
        {
            FieldClass = FlowField;
            CalcFormula = lookup (Customer.Balance where ("No." = field ("No.")));
        }
    }
}
```

SumIndexField Technology (SIFT)

2/17/2021 • 2 minutes to read • Edit Online

SumIndexField Technology (SIFT) lets you quickly calculate the sums of numeric data type (Decimal, Integer, BigInteger, and Duration) columns in tables, even in tables with thousands of records. SIFT is used to optimize the performance of FlowFields and query results in a Business Central application. SIFT involves performing a series of database calls and calculations before arriving at a result. The topics in this section describes how SIFT is implemented in Business Central.

SIFT and SQL Server

2/17/2021 • 2 minutes to read • Edit Online

A SumIndexField is always associated with a key and each key can have a maximum of 20 SumIndexFields associated with it. In this topic, a key that has at least one SumIndexField associated with it is a SIFT key.

> **IMPORTANT**
> Any field that has a numeric data type of Decimal, Integer, BigInteger, or Duration, can be associated with a key as a SumIndexField.

Implementing SIFT

Business Central uses *Indexed Views* to maintain SIFT totals. Indexed views are a standard SQL Server feature. An indexed view is like a SQL Server view except that the contents have been materialized (computed and stored) to speed up the retrieval of data. For more information about indexed views, see SQL Server Documentation.

Business Central creates one indexed view for each SIFT key that is enabled. When you create a SIFT key for a table, you must set the MaintainSIFTIndex Property for that key to **True** to enable the SIFT key and create the indexed view. After SQL Server has created the indexed view, it maintains the contents of the view when any changes are made to the base table. If you set the MaintainSIFTIndex Property for that key to **False**, SQL Server drops the indexed view and stops maintaining the totals.

The indexed view that is generated for a SIFT key is always created at the level of finest granularity. Therefore, if you create a SIFT key for `AccountNo., PostingDate`, the database will store an aggregated value for each account for each date. This means that in the worst case scenario, 365 records must be summed to generate the total for each account for a year.

The following is an example of how Business Central creates an indexed view for a SIFT key that consists of the **AccountNo.** and **PostingDate** fields with a total for the **Amount** field.

```
CREATE VIEW GLEntry$VSIFT$1 AS
SELECT SUM(Amount) as SUM$Amount, AccountNo, PostingDate
FROM GLEntry
GROUP BY AccountNo, PostingDate
;

CREATE UNIQUE CLUSTERED INDEX VSIFTIDX ON
GLEntry$VSIFT$1(AccountNo, PostingDate)
;
```

The following AL code example retrieves a total.

```
GLEntry.SETCURRENTKEY("G/L Account No.","Posting Date");
GLEntry.SETRANGE("G/L Account No.",'1110');
GLEntry.SETRANGE("Posting Date",DMY2DATE(1,1,2007),DMY2DATE(15,12,2007));
GLEntry.CALCSUMS(Amount);
```

The following code example shows how the same total is retrieved through an indexed view.

```
SELECT SUM(SUM$Amount)
FROM GLEntry$VSIFT$1 WITH(NOEXPAND)
WHERE AccountNo=?
AND PostingDate>=?
AND PostingDate<=?
```

SIFT and Performance

Tuning and Tracing

2/17/2021 • 2 minutes to read • Edit Online

As a result of using indexed views, SIFT keys are exposed to SQL Server tracing and tuning tools. For example, the SQL Server profiler can display information about which indexed views are maintained for a specific table. This makes it easy for you to assess the cost of maintaining SIFT keys and allows you to make informed decisions about any adjustments that might be required.

SIFT Keys

When data is inserted, updated, or deleted in a table, the SIFT keys that have been defined and enabled for that table are maintained. Maintaining these SIFT indexes has performance overhead. The size of the performance overhead depends on the number of keys and SumIndexFields that have been defined for each table. You should therefore give careful consideration to the number of SIFT keys that you define and only maintain the SIFT keys that are important for your application.

There is no need to maintain a SIFT key for a total that is only used periodically and can be easily generated by a report. You can still program Business Central to calculate the SIFT based totals even if the SIFT key is disabled. The calculation is performed directly on the base table.

You should consider combining indexes wherever possible.

Example

Maintaining two SIFT keys:

1. Key: "WareHouseId, ItemId, Color" SumField: "OnStock"
2. Key: "WareHouseId, ItemId, Size" SumField: "OnStock"

If there are only a few combinations of Size and Color (for example, less than 200), then one combined index/SIFT key should be sufficient.

1. The Combined Key:
2. "WareHouseId, ItemId, Color, Size" SumFIeld: "OnStock"

When you set the MaintainSIFTIndex Property of a key to **True**, this will be the SIFT key and create the indexed view to support it. However, disabling the SIFT key by setting MaintainSIFTIndex Property to **False** can improve performance in certain circumstances. Setting this property to **False** means that the SIFT functionality must be implemented by calculating the totals online instead of using the precalculated sums that are maintained by SIFT.

FlowFields

SIFT and Performance

2/17/2021 • 2 minutes to read • Edit Online

This topic looks at the factors you must take into consideration when you deal with SIFT and performance.

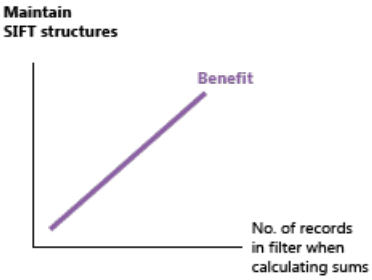
Performance Factors to Consider

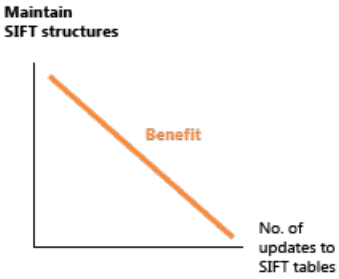
The factors that you must take into consideration when you deal with any performance problems that arise include:

- Designing your SIFT indexes optimally.
- Supporting too many SIFT indexes will affect performance.
- Having unnecessary date fields in the SIFT indexes of the base table will affect performance because they create three times as many entries as an ordinary field.
- Supporting too many fields in the SIFT indexes will also affect performance.
- The fields in the SIFT index that are used most regularly in queries must be positioned to the left in the SIFT index. Usually, the field that contains the greatest number of unique values must be placed on the left, with the field that contains the second greatest number of unique values on the right and so on. Integer fields generally contain the greatest number of unique values and Option fields contain a relatively small number of values.

Consider the costs and the benefits of maintaining SIFT indexes.

COST	BENEFIT
Updates to the SIFT indexes	Fast calculation of sums
Potential locking conflicts	





You can prevent the SIFT indexes from being updated by setting the MaintainSIFTIndex Property of the index in the base table to **False**. This means that you no longer benefit from SIFT's ability to calculate sums quickly. However, the SIFT functionality is still available. If the base table does not grow or only grows slowly, there is no need to set the MaintainSIFTIndex Property to **True** for any indexes that contain SumIndexFields. If the base table does grow, you should set the MaintainSIFTIndex Property to **True** for any indexes that contain SumIndexFields.

In Business Central , changes have been made to improve performance when accessing the database. One of these changes is that Business Central automatically maintains a count for all SIFT indexes. For more information about how this affects the **Count** and **Average** methods on FlowFields, see CalcFields Method. For more information about other data access changes, see Data Access.

IMPORTANT

It is important that you remember to perform tests every time you make any changes to the SIFT structures. You must ensure that the changes that you have made do not cause problems in any other areas of the application. You must also ensure that your changes do not have a negative effect on performance.

Number Sequences in Business Central

2/17/2021 • 2 minutes to read • Edit Online

APPLIES TO: Business Central 2019 release wave 2 and later

In AL, you can create and manage number sequences that generate numeric identifiers for data and records. Business Central number sequences are built on SQL Server number sequences, which means that they are not associated with any tables. Instead, the application code references the number sequence object and coordinates the values across records.

The numbers in a number sequence are generated in ascending order at a defined interval. Numbers are used sequentially, but numbers can be skipped. This means that numbers used on records in tables can have gaps. These gaps, for example, can occur when transactions are rolled back or numbers are allocated but not used.

Number sequences and number series in the application

Unlike number sequences, number series are specially designed for scenarios where you have to use a continuous numbering system on transactional records. This typically includes documents such as purchase orders, sales orders, and invoices. The drawback of using continuous numbers is that when a number is requested by a transaction, the **No Series Line** table in the database is locked until the transaction completes. This can potentially block other users from being able to work.

However, number series also include an option called **Allow Gaps in Nos.**. This option actually uses number sequences in the underlying code, and allows you to implement non-continuous, non-blocking numbering. So, if there are no regulatory requirements for using continuous numbering, you can improve performance by allowing gaps and using a number sequence instead. Customer cards, sales quotes, and warehouse activities are examples of entities that typically do not require continuous numbering.

For more information about number series, see Create Number Series in the Business Central application help.

Creating and managing number sequences in AL

To create and manage number sequences, you use the `NumberSequence` data type and the following methods.

METHOD NAME	DESCRIPTION
[Insert(String, BigInteger][, BigInteger], [Boolean])	Creates a number sequence in the database, with the given parameters.
Exists(String[, Boolean])	Checks whether a specific number sequence exists.
Delete(String[, Boolean])	Deletes a specific number sequence.
Next(String[, Boolean])	Retrieves the next value from the number sequence.
Current(String[, Boolean])	Gets the current value from the number sequence, without doing any increment. The value is retrieved out of transaction. The value will not be returned on transaction rollback.

Examples

```
// Creates a NumberSequence object that starts with the value '0' and increments by '1'
NumberSequence.Insert('DefaultSequence');

// Creates a NumberSequence object that starts with the value '10' and increments by '1'
NumberSequence.Insert('StartsWithTenSequence', 10);

// Creates a NumberSequence object that starts with the value '0' and increments by '10'
NumberSequence.Insert('StartsWithZeroIncrementTenSequence', 0, 10);

// Creates a NumberSequence object that starts with the value '0', increments by '10', and is company-
specific
NumberSequence.Insert('MyCompanySequence', 0, 1, true);

// Verifies whether a specific NumberSequence object exists, and if so, deletes it

if NumberSequence.Exists('MySequence', true) then
    NumberSequence.Delete('MySequence',true);

// Gets and returns the current value in a NumberSequence object
number := NumberSequence.Current('MySequence',true);

// Gets and returns the next value in a NumberSequence object
number := NumberSequence.Next('MySequence',true);
```

Extensible Enums

2/17/2021 • 3 minutes to read • Edit Online

An enumeration type, also known as an enum in programming, is a keyword used to declare a type that consists of a set of named constants. The list of named constants is called the enumeration list. Enums can be used as table fields, local and global variables, and parameters.

To declare an `enum` in AL you must specify an ID and a name. The enumeration list consists of values and each of the values are declared with an ID and a value. The value ID is the ordinal value on the enumeration list and must be unique. The following example shows the declaration of an enum, which can be extended, and has the four values; **None**, **Bronze**, **Silver**, and **Gold**.

```
enum 50121 Loyalty
{
    Extensible = true;

    value(0; None) { }
    value(1; Bronze) { }
    value(2; Silver) { }
    value(3; Gold)
    {
        Caption = 'Gold Customer';
    }
}
```

NOTE

While enums and enumextension objects have object IDs, these are not enforced by the license. In previous versions they reused the range for tables, and were checked against the license at deployment time, but this is no longer the case. Uniqueness validation is now enforced during installation, which will fail if an enum object ID clashes with an already installed enum. Thus, as always, it is important that you use object IDs in your assigned range. This is enforced for AppSource apps, but not for per-tenant extensions, or on-premise. The enum does not have to use the same ID as the table it is put on.

IMPORTANT

Only enums with the Extensible Property set to **true** can be extended.

Enumextension object

Enums can be extended in order to add more values to the enumeration list in which case the `Extensible` property must be set to `true`. The syntax for an enum extension, which extends the **Loyalty** enum with the value **Diamond**, is shown below.

```
enumextension 50130 LoyaltyWithDiamonds extends Loyalty
{
    value(50130; Diamond)
    {
        Caption = 'Diamond Level';
    }
}
```

Usage

When referencing a defined enum from code, you use the syntax as illustrated below.

`enum Loyalty`

If you want to define an enum as a table field type, use the syntax illustrated below:

```
field(50100; Loyal; enum Loyalty) {}
```

Or, as a variable:

```
var
    LoyaltyLevel: enum Loyalty;
```

In code, you address a specific enum value like in the following example:

```
codeunit 50140 EnumUsage
{
    procedure Foo(p: enum Loyalty)
    var
        LoyaltyLevel: enum Loyalty;
    begin
        if p = p::Gold then begin
            LoyaltyLevel := p;
        end;
    end;
}
```

Example

The following example illustrates how to define an enum extension of `TypeEnum`, using this in a table extension `TableWithRelationExt` and displaying this as a control on a new page.

```
enumextension 50133 TypeEnumExt extends TypeEnum
{
    value(10; Resource) { }
}

tableextension 50135 TableWithRelationExt extends TableWithRelation
{
    fields
    {
        modify(Relation)
        {
            TableRelation = if (Type = const (Resource)) Resource;
        }
    }
}

page 50133 PageOnRelationTable
{
    SourceTable = TableWithRelation;
    SourceTableView = where (Type = const (Resource));
    PageType = List;

    layout
    {
        area(Content)
        {
            repeater(MyRep)
            {
                field(Id; Id)
                {
                    ApplicationArea = All;
                }
                field(Type; Type)
                {
                    ApplicationArea = All;
                }
                field(Relation; Relation)
                {
                    ApplicationArea = All;
                }
            }
        }
    }
}
```

TIP

For another example of how to extend the usage of the `TableRelation` property in connection with enums, see TableRelation Property.

Business Central On-Premises

If you want to extend an existing Dynamics 365 on-premises enum, it is possible to mark a table field in C/SIDE as extensible. To enable running C/SIDE and AL side-by-side, see Running C/SIDE and AL Side-by-Side.

Table field options in C/SIDE have three properties to enable enum support:

PROPERTY NAME	DATA TYPE
Extensible	Boolean, default value is **No**.

PROPERTY NAME	DATA TYPE
EnumTypeId	Integer
EnumTypeName	Text

Some table fields share options that are semantically identical. In those cases the **EnumTypeId** and **EnumTypeName** must be the same across all the fields. There is no design or runtime check for collision of IDs, but loading generated symbols, see Running C/SIDE and AL Side-by-Side, into the compiler will show collision errors.

Conversions

Conversion to and from `enum` is more strict than for `Options` in C/SIDE.

- An enum can be assigned/compared to an enum of the same type.
- To be backwards compatible we support conversion to/from any `Option` for now.

For information about assigment compatibility, see AssignmentCompatibility Property.

Protected Variables

2/17/2021 • 2 minutes to read • Edit Online

APPLIES TO: Business Central 2019 release wave 2 and later

The `protected` keyword can be used to make variables accessible between tables and table extensions and between pages and page extensions. If you want to only expose some variables as `protected`, you must create two sections of `var` declarations. See the syntax below.

Syntax

```
protected var
        myInt: Integer; // protected var

var
        myLocalInt: Integer; // local var
```

Example

The example below illustrates how to declare and use a protected variable.

```
page 50100 MyPage
{
    SourceTable = Customer;
    PageType = Card;

    layout
    {
        area(Content)
        {
            group(General)
            {
                field(Name; Name)
                {
                    ApplicationArea = All;
                }
            }
            group(Advanced)
            {
                Visible = ShowBalance;

                field(Balance; Balance)
                {
                    ApplicationArea = All;
                }
            }
        }
    }

    protected var
        [InDataSet]
        ShowBalance: Boolean;
}

pageextension 50101 MyPageExt extends MyPage
{
    layout
    {
```

```
    {
        addlast(Content)
        {
            group(MoreBalance)
            {
                Visible = ShowBalance; // ShowBalance from MyPage

                field("Balance (LCY)"; "Balance (LCY)")
                {
                    ApplicationArea = All;
                }
            }
        }

    }

    actions
    {
        addlast(Navigation)
        {
            action(ToggleBalance)
            {
                ApplicationArea = All;
                trigger OnAction()
                begin
                    ShowBalance := not ShowBalance; // Toggle ShowBalance from MyPage.
                end;
            }
        }
    }
}
```

Working with Labels

2/17/2021 • 2 minutes to read • Edit Online

Labels are string constants displayed in the Business Central client that can be translated into multiple languages, such as captions, descriptions, or messages. This way, the user interface can be displayed in different languages. For more information on how translation is carried out in Dynamics 365 Business Central, see Multilanguage development.

Label syntax

Labels have a specific syntax defined by a text constant followed by three optional parameters. They must be comma-separated, but the order of the parameters is not enforced. The parameters that you can set are described in the following table.

PARAMETER	TYPE	DESCRIPTION
Comment	Text	Used for general comments about the label, specifically about the placeholders in that label.
Locked	Boolean	When Locked is set to **true**, the label should not be translated. Default value is **false**.
MaxLength	Integer	Determines how much of the label is used. If no maximum length is specified, the string can be any length.

Using labels

A label can take the form of four different AL structures. It can be the property value of certain page and report properties, the label data type variable and a report or a page label. The different possibilities are explained in more detail below.

Properties

The label syntax is used in properties that are set to display text on the user interface. It applies to the following properties:

- Caption Property
- ToolTip Property
- OptionCaption Property
- AdditionalSearchTerms Property
- InstructionalText Property
- PromotedActionCategories Property
- RequestFilterHeading Property

The following example shows the label syntax when it is used as property value for the **Caption** property.

```
Caption = 'Developer translation for %1',  Comment = '%1 is extension name', locked = false, MaxLength=999;
```

Report labels

Report labels are used by RDL and Word report layouts as, for example, the caption for a field, the title for a chart, or the title for the report itself. For a code example on how to use report labels for an RDL layout, see Walkthrough: Designing a Report from Multiple Tables.

Report labels are defined inside the `labels` control of a report object, as shown in the code sample below.

```
labels
{
  LabelName1='LabelText1',Comment='Foo',MaxLength=999,Locked=true;
  LabelName2 = 'LabelText2',Comment='Foo',Locked=false;
}
```

Page labels

Page labels are used to display plain text on a page, such as instructions or informative texts. You can find several examples of page labels in the Rapidstart Services Wizard in page `"Config. Wizard"`.

Page labels are defined by a `label(Name)` control inside the `area(Content)` part of a page. The following code shows how to define a page label.

```
label(BeforeSetupCloseMessage)
{
    ApplicationArea = Basic, Suite;
    Caption = 'If you still need to change setup data, do not change the profile.'
}
```

Label data type

The Label Data Type denotes a string variable used to define error messages, questions, captions, tokens, or other text constants displayed to the user.

The following code sample illustrates how to use the **Label** data type.

```
var
a:Label'LabelText',Comment='Foo',MaxLength=999,Locked=true;
```

The **Label** variable names should have an approved suffix. For more information, see CodeCop Rule AA0074.

Table Object

2/17/2021 • 2 minutes to read • Edit Online

Tables are the core objects used to store data in Dynamics 365 Business Central. No matter how data is registered in the product - from a web service to a finger swipe on the phone app, the results of that transaction will be recorded in a table.

The structure of a table has four sections:

- The first block contains metadata for the overall table, such as the table type.
- The fields section describes the data elements that make up the table, such as their name and the type of data they can store.
- The keys section contains the definitions of the keys that the table needs to support.
- The final section details the triggers and code that can run on the table.

IMPORTANT

Only tables with the Extensible Property set to **true** can be extended.

NOTE

Extension objects can have a name with a maximum length of 30 characters.

IMPORTANT

System and virtual tables can't be extended. System tables are created in the ID range of 2.000.000.000 and above. For more information about object ranges, see Object Ranges.

Snippet support

Typing the shortcut `ttable` will create the basic layout for a table object when using the AL Language extension in Visual Studio Code.

TIP

Use **Ctrl+Space** to trigger IntelliSense and get assistance on code completion, parameter info, quick info, and member lists.

Table example

This table stores address information and it has four fields; `Address`, `Locality`, `Town/City`, and `County`.

```
table 50104 Address
{
    Caption = 'Sample table';
    DataPerCompany = true;

    fields
    {
        field(1; Address; Text[50])
        {
            Description = 'Address retrieved by Service';
        }
        field(2; Locality; Text[30])
        {
            Description = 'Locality retrieved by Service';
        }
        field(3; "Town/City"; Text[30])
        {
            Description = 'Town/City retrieved by Service';
        }
        field(4; County; Text[30])
        {
            Description = 'County retrieved by Service';

            trigger OnValidate();
            begin
                ValidateCounty(County);
            end;

        }
    }
    keys
    {
        key(PrimaryKey; Address)
        {
            Clustered = TRUE;
        }
    }

    var
        Msg: Label 'Hello from my method';

    trigger OnInsert();
    begin

    end;

    procedure MyMethod();
    begin
        Message(Msg);
    end;
}
```

System fields

The Dynamics 365 Business Central platform will automatically add several system fields to tables. For more information, see System Fields.

Table, Table Fields, and Table Extension Properties

Table Extension Object

2/17/2021 • 2 minutes to read • Edit Online

The table extension object allows you to add additional fields or to change some properties on a table provided by the Dynamics 365 Business Central service. In this way, you can add data to the same table and treat it as a single table. For example, you may want to create a table extension for a retail winter sports store. In your solution you want to have `ShoeSize` as an additional field on the customer table. Adding this as an extension allows you to write code for the customer record and also include values for the `ShoeSize`.

Along with defining other fields, the table extension is where you write trigger code for your additional fields.

When developing a solution for Dynamics 365 Business Central , you will follow the code layout for a table extension as shown in the example below.

IMPORTANT

Only tables with the Extensible Property set to **true** can be extended.

NOTE

Extension objects can have a name with a maximum length of 30 characters.

IMPORTANT

System and virtual tables cannot be extended. System tables are created in the ID range of 2.000.000.000 and above. For more information about object ranges, see Object Ranges.

IMPORTANT

Extending tables from Dynamics 365 for Sales is currently not supported.

Snippet support

Typing the shortcut `ttableext` will create the basic layout for a table extension object when using the AL Language extension in Visual Studio Code.

Properties

Using a table extension allows you to overwrite some properties on fields in the base table. For a list of Table properties, see Table and Table Extension Properties.

Table extension syntax

```
tableextension Id MyExtension extends MyTargetTable
{
    fields
    {
        // Add changes to table fields here
    }

    var
        myInt: Integer;
}
```

Table extension example

This table extension object extends the Customer table object by adding a field `ShoeSize`, with ID 50116 and the data type `Integer`. It also contains a procedure to check if the `ShoeSize` field is filled in.

```
tableextension 50115 RetailWinterSportsStore extends Customer
{
    fields
    {
        field(50116;ShoeSize;Integer)
        {
            trigger OnValidate();
            begin
                if (rec.ShoeSize < 0) then
                begin
                   message('Shoe size not valid: %1', rec.ShoeSize);
                end;
            end;
        }
    }

    procedure HasShoeSize() : Boolean;
    begin
        exit(ShoeSize <> 0);
    end;

    trigger OnBeforeInsert();
    begin
        if not HasShoeSize then
            ShoeSize := Random(42);
    end;
}
```

Table Keys

Table Keys

2/17/2021 • 7 minutes to read • Edit Online

The database management system, which is SQL Server, keeps track of data in a table using a primary key. The primary key is composed of up to 16 fields in a record. The combination of values in fields in the primary key makes it possible to uniquely identify each record.

A table definition in AL can contain a list of keys. A key is a sequence of one or more field IDs from the table. Up to 40 keys can be associated to a table.

Primary keys

The first key in the list of keys in a table definition is the primary key.

The primary key determines the logical order in which records are stored, regardless of their physical placement.

Logically, records are stored sequentially in ascending order and are sorted by the primary key. Before adding a new record to a table, SQL Server checks if the information in the record's primary key fields is unique and only then inserts the record into the correct logical position. Records are sorted dynamically so the database is always structurally correct. This allows for fast data manipulation and retrieval.

The primary key is always active, and SQL Server keeps the table sorted in primary key order and rejects records with duplicate values in primary key fields. Therefore, the values in the primary key must always be unique. Note that it is not the value in each field in the primary key that must be unique, but it is the combination of values in all fields that make up the primary key.

> **NOTE**
>
> In the development environment, it is technically possible to create a primary key based on up to 20 fields. However, because of SQL Server limitations, only the first 16 are used.

Secondary keys

Any keys defined after the primary key in the list of keys in a table definition are called *secondary keys*.

A secondary key is implemented on SQL Server using an additional structure that is called an *index*. This is like an index that is used in textbooks. A textbook index alphabetically lists important terms at the end of a book. Next to each term are page numbers. You can quickly search the index to find a list of page numbers (addresses), and you can locate the term by searching the specified pages. The index is an exact indicator that shows where each term occurs in the textbook.

When you define a secondary key and mark it as enabled, an index is automatically maintained on SQL Server. The index reflects the sorting order that is defined by the key. Several secondary keys can be active at the same time.

A secondary key can be changed to be disabled, which does not occupy database space, and does not use time during updates to maintain its index. Disabled keys can be re-enabled, although this can be time-consuming because SQL Server must scan the whole table to rebuild the index.

The fields that make up the secondary keys do not always contain unique data, and SQL Server does not reject records with duplicate data in secondary key fields. If two or more records contain identical information in the

secondary key, then SQL Server uses the primary key for the table to resolve this conflict.

Unique secondary keys

A key definition includes the Unique property that you can use to create a unique constraint on the table in SQL Server. A unique key ensures that records in a table do not have identical field values. With a unique key, when table is validated, the key value is checked for uniqueness. If the table includes records with duplicate values, the validation fails. Another benefit of unique indexes is providing information to the query optimizer that helps produce more efficient execution plans.

Like primary keys, you can create unique secondary keys that are comprised of multiple fields. In this case, it's the combination of the values in the secondary key that must be unique. For example, if you have a **Customer** table, you could create a unique key for the **Name**, **Address**, and **City** fields to make sure that there are no customers that have the same combination of values for these fields.

Unlike primary keys, it is possible to define multiple unique secondary keys on a table.

> **NOTE**
> The `Unique` property is not supported in table extension objects.

System keys

There is always a unique secondary key on the **SystemId** field.

Clustered and non-clustered keys

A key definition includes the Clustered property that you use to create a clustered index. A clustered index determines the physical order in which records are stored in the table. Based on the key value, records are sorted in ascending order. Using a clustered key can speed up the retrieval of records.

There can be only one clustered index per table. By default the primary is configured as a clustered key.

> **NOTE**
> The `Clustered` property is not supported in table extension objects.

Sort orders and secondary keys

The following example shows how the primary key influences the sort order when a secondary key is active. The Customer table includes four entries (records), and the records in the Customer table have two fields: Customer Number and Customer Name.

The following is the key list for the Customer table.

KEY	KEY TYPE	DEFINITION
1	Primary	Customer Number
2	Secondary	Customer Name

When you sort by the primary key, the Customer table resembles the following table.

CUSTOMER NUMBER	CUSTOMER NAME

CUSTOMER NUMBER	CUSTOMER NAME
001	Customer C
002	Customer A
003	Customer B
004	Customer C

If you select the secondary key for sorting, then the order is based on the contents of the Customer Name field. Because the contents of these fields are not unique, the records must be sub-sorted according to the primary key.

CUSTOMER NAME	CUSTOMER NUMBER
Customer A	002
Customer B	003
Customer C	001
Customer C	004

> **NOTE**
> The two records that have the same Customer Name value are sorted by Customer Number.

How keys affect performance

Searching for specific data is easier if several keys have been defined and maintained for the table that holds the desired data. The indexes for each key provide specific views that enable quick, flexible searches. There are advantages and disadvantages to using many keys, as demonstrated in the following table.

IF YOU	PERFORMANCE IMPROVES WHEN YOU	PERFORMANCE SLOWS WHEN YOU
Increase the number of secondary keys that are marked as active.	Retrieve data in several different sorting sequences because the data is already sorted.	Enter data because indexes for each secondary key must be maintained.
Decide to use only a few keys.	Enter data because a minimal number of indexes are maintained.	Retrieve data. You may have to define or reactivate the secondary keys to get the appropriate sorting. Depending on the size of the database, this can take some time, because the index must be rebuilt.

The decision whether to use a few or many keys is not easy. The choice of appropriate keys and the number of active keys to use should be the best compromise between maximizing the speed of data retrieval and maximizing the speed of data updates (operations that insert, delete, or modify data). In general, it may be worthwhile to deactivate complex keys if they are rarely used.

The overall speed depends on the following factors:

- Size of the database.
- Number of active keys.
- Complexity of the keys.
- Number of records in your tables.
- Speed of your computer and its hard disk.

Defining new keys

You define keys in AL code of a table object. To define keys, add the `keys` keyword after the `fields` definition, and then add a `key` keyword for each key:

```
keys
{
    key(Name; Fields)
    {

    }
    key(Name; Fields)
    {

    }
}
```

Replace `Name` with descriptive text that you want to use to identify the key. Replace `Field` with the name of a field that you want to use as the key. If you want to include multiple fields in a single key, separate each field with a comma.

The first `key` keyword defines the primary key. Subsequent `key` keywords define secondary keys.

Key properties

There are several properties that configure the behavior of a key, such as the Enabled, Clustered, and Unique properties:

```
keys
{
    key(PrimaryKey; ID)
    {
        Clustered = true;
    }
    key(CustomerInfo; Name,Address,City)
    {
        Unique = true;
    }
   key(Currency; Currency Code)
    {
        Enabled = false;
    }
}
```

For a more information about the different key properties, see Key Properties.

Restrictions on key modifications

When developing a new version of an extension, be aware of the following restrictions to avoid schema synchronization errors that prevent you from publishing the new version:

- Do not delete primary keys.
- Do not add or remove primary key fields, nor change their order.
- Do not change properties of existing primary keys.
- Do not add additional unique keys.
- Do not add additional clustered keys.
- Do not add keys that are fields of the base table.

Page Object

2/17/2021 • 2 minutes to read • Edit Online

Pages are the main way to display and organize visual data in Dynamics 365 Business Central. They are the primary object that a user will interact with and have a different behavior based on the type that you choose. Pages are designed independently of the device they are to be rendered on, and in this way the same page can be reused across phone, tablet, and web clients.

The structure of a page is hierarchical and breaks down in to three sections. The first block contains metadata for the overall page; the type of the page and the source table it is showing data from. The next section; the layout, describes the visual parts on the page. The final section details the actions that are published on the page.

When developing a solution for Dynamics 365 Business Central, you will follow the code layout for a page as shown in the page example below, but for more details on the individual controls and properties that are available, see Page Property Overview.

If you want to, for example, add functionality to a page that already exists in Business Central, you can create a page extension object that changes an existing page object. For more information, see Page Extension Object. Depending on how much you want to change on an existing page, you can also create a page customization object, which offers modifications on actions and layout. For more information, see Page Customization Object.

> **IMPORTANT**
> Only pages with the Extensible Property set to **true** can be extended.

> **NOTE**
> Extension objects can have a name with a maximum length of 30 characters.

Snippet support

Typing the shortcut `tpage` will create the basic layout for a page object when using the AL Language extension in Visual Studio Code.

> **TIP**
> Use **Ctrl+Space** to trigger IntelliSense and get assistance on code completion, parameter info, quick info, and member lists.

Views

Views in Dynamics 365 Business Central are used on list pages to define a different view of the data on a given page. Views can be defined for Pages, Page Extensions, and Page Customization. For more information, see Views.

Page example

```
page 50101 SimpleCustomerCard
{
    PageType = Card;
    SourceTable = Customer;
    ContextSensitiveHelpPage = 'my-feature';

    layout
    {
        area(content)
        {
            group(General)
            {
                field("No."; "No.")
                {
                    ApplicationArea = All;
                    CaptionML = ENU = 'Hello';

                    trigger OnValidate()
                    begin
                        if "No." < '' then
                            Message('Number too small')
                    end;
                }

                field(Name; Name)
                {
                    ApplicationArea = All;
                }
                field(Address; Address)
                {
                    ApplicationArea = All;
                }
            }
        }
    }
    actions
    {
        area(Navigation)
        {
            action(NewAction)
            {
                ApplicationArea = All;
                RunObject = codeunit "Document Totals";
            }
        }
    }
}
```

Page Extension Object

2/17/2021 • 4 minutes to read • Edit Online

The page extension object extends a Dynamics 365 Business Central page object and adds or overrides the functionality.

The structure of a page is hierarchical and breaks down into three sections. The first block contains metadata for the overall page; the type of the page and the source table it is showing data from. The next section; the layout, describes the visual parts on the page. The final section details the actions that are published on the page.

For more information about the Page and Page Extension objects, see Pages Overview.

IMPORTANT

Only pages with the Extensible Property set to **true** can be extended.

NOTE

Extension objects can have a name with a maximum length of 30 characters.

IMPORTANT

The API page type should not be extended by creating a page extension object. Instead, create a new API by adding a page object.

NOTE

Modifying actions in Cue groups on page extensions is not supported.

Snippet support

Typing the shortcut `tpageext` will create the basic layout for a page extension object when using the AL Language extension in Visual Studio Code.

TIP

Use **Ctrl+Space** to trigger IntelliSense and get assistance on code completion, parameter info, quick info, and member lists.

Views

Views in Dynamics 365 Business Central are used on list pages to define a different view of the data on a given page. Views can be defined for Pages, Page Extensions, and Page Customization. For more information, see Views.

Using keywords to place actions and controls

You can use the following keywords in the `layout` section to place and move fields and groups on the page extension. Similarly, in the `actions` section, you use these keywords to place actions in the ribbon.

KEYWORDS	SYNTAX	APPLIES TO
`addfirst`	`addfirst(Anchor)`	**Anchor**: areas and groups
`addlast`	`addlast(Anchor)`	**Anchor**: areas and groups
`addafter`	`addafter(Anchor)`	**Anchor**: controls, actions, and groups
`addbefore`	`addbefore(Anchor)`	**Anchor**: controls, actions, and groups
`movefirst`	`movefirst(Anchor; Target1, Target2)`	**Anchor**: area, group **Target**: list of actions or list of controls
`movelast`	`movelast(Anchor; Target1, Target2)`	**Anchor**: area, group **Target**: list of actions or list of controls
`moveafter`	`moveafter(Anchor; Target1, Target2)`	**Anchor**: controls, actions, and groups **Target**: list of actions or list of controls
`movebefore`	`movebefore(Anchor; Target1, Target2)`	**Anchor**: controls, actions, and groups **Target**: list of actions or list of controls
`modify`	`modify(Target)`	**Target**: controls, actions, and groups

Example

To modify the existing fields and groups on a page, you use the `modify` keyword. See the code snippet below for `addlast`, `modify` and `action` syntax. In the following example, the `actions` section creates a new group in the ribbon and places it last in the `Creation` group.

```
pageextension 70000020 CustomerCardExtension extends "Customer Card"
{
    layout
    {
        // Adding a new control field 'ShoeSize' in the group 'General'
        addlast(General)
        {
            field("Shoe Size"; ShoeSize)
            {
                Caption = 'Shoe size';

                trigger OnValidate();
                begin
                    if ShoeSize < 10 then
                        Error('Feet too small');
                end;
            }
        }

        // Modifying the caption of the field 'Address 2'
        modify("Address 2")
        {
            Caption = 'New Address 2';
        }

        // Moving the two fields 'CreditLimit' and 'CalcCreditLimitLCYExpendedPct'
        // to be the first ones in the 'Balance' group.
        movefirst(Balance; CreditLimit, CalcCreditLimitLCYExpendedPct)
    }
    actions
    {
        // Adding a new action group 'MyNewActionGroup' in the 'Creation' area
        addlast(Creation)
        {
            group(MyNewActionGroup)
            {
                action(MyNewAction)
                {
                    Caption = 'My New Action';

                    trigger OnAction();
                    begin
                        Message('My message');
                    end;
                }
            }
        }
    }
}

tableextension 70000020 CustomerTableExtension extends Customer
{
    fields
    {
        // Adding a new table field in the 'Customer' table
        field(50100; ShoeSize; Integer) { }
    }
}
```

Page extension examples

In the following example, we use a table extension to extend the Customer table with a new field named `ShoeSize` of the datatype Integer. Then we create a page extension object that extends the Customer Card page object by adding a field control `ShoeSize` to the `General` group on the page. The field control is added as the

last control in the group using the `addlast` method. The example also illustrates how to add a display-only control to the page. In the actions area, you can see what the syntax looks like for actions that execute triggers and actions that run objects.

```
tableextension 50115 RetailWinterSportsStore extends Customer
{
    fields
    {
        field(50116;ShoeSize;Integer)
        {
            Caption = 'ShoeSize';

            trigger OnValidate();
            begin
                if (rec.ShoeSize < 0) then
                begin
                   message('Shoe size not valid: %1', rec.ShoeSize);
                end;
            end;
        }
    }

    procedure HasShoeSize() : Boolean;
    begin
        exit(ShoeSize <> 0);
    end;

    trigger OnBeforeInsert();
    begin
        if not HasShoeSize then
            ShoeSize := Random(42);
    end;
}

pageextension 50110 CustomerCardExtension extends "Customer Card"
{
    layout
    {
        addlast(General)
        {
            // control with underlying datasource
            field("Shoe Size"; ShoeSize)
            {
                ApplicationArea = All;

                trigger OnValidate();
                begin
                    if ShoeSize < 10 then
                        Error('Feet too small');
                end;
            }

            // display-only control (without underlying datasource)
            field(ShoesInStock; 10)
            {
                ApplicationArea = All;
                Caption = 'Shoes in stock';

            }
        }

        modify("Address 2")
        {
            Caption = 'New Address 2';
        }
    }
```

```
    actions
    {
        addlast(Creation)
        {
            group(MyActionGroup)
            {
                Action(MyAction1)
                {
                    ApplicationArea = All;
                    Caption = 'Hello!';

                    trigger OnAction();
                    begin
                        Message('My message');
                    end;
                }

                Action(MyAction2)
                {
                    ApplicationArea = All;

                    // Run page to test how actions work
                    RunObject = page "Absence Registration";
                }
            }
        }
    }
}
```

You can reference Report and XMLPort objects and use these objects in the **RunObject** property, as well as, declare variables of the types **Report** and **XMLPort** and call AL methods on them. This page extension object extends the Customer List page object by adding two actions; the first action calls the **Customer - List** report, the second action calls the **Export Contact** XMLPort.

```
pageextension 50114 AddCustomerReport extends "Customer List"
{
    actions
    {
        AddLast("&Customer")
        {
            action("Customer List Report")
            {
                trigger OnAction();
                var
                    rep : Report "Customer - List";
                begin
                    rep.Run;
                end;
            }

            action("Export Contact List")
            {
                trigger OnAction();
                var
                    xml : XmlPort "Export Contact";
                begin
                    xml.Run;
                end;
            }
        }
    }
}
```

Page Customization Object

2/17/2021 • 2 minutes to read • Edit Online

The page customization object in Dynamics 365 Business Central allows you to add changes to the layout and actions on page that are accessible for a profile. See Using keywords to place actions and controls for how to place actions and controls on a page customization object.

The page customization object has more restrictions than the page extension object; when you define a new page customization object, you cannot add variables, procedures, or triggers.

> **NOTE**
> A single page customization can be used with multiple profiles within the same extension. Page customizations only apply to the RoleCenters they are specified for. In order to view or changes the RoleCenters in the client, go to **My Settings** > **Role Center**.

> **NOTE**
> Extension objects can have a name with a maximum length of 30 characters.

> **NOTE**
> Modifying actions in Cue groups on page extensions is not supported.

> **NOTE**
> `showMyCode` does not apply to page customizations. Page customizations defined in an extension with `showMyCode` set to `false` can still be copied using Designer.

Snippet support

Typing the shortcut `tpagecust` will create the basic layout for a page customization object when using the AL Language extension in Visual Studio Code.

> **TIP**
> Use **Ctrl+Space** to trigger IntelliSense and get assistance on code completion, parameter info, quick info, and member lists.

Views

Views in Dynamics 365 Business Central are used on list pages to define a different view of the data on a given page. Views can be defined for Pages, Page Extensions, and Page Customization. For more information, see Views.

Page customization example

The following page customization example `MyCustomization` makes changes to **Customer List**. By using the `moveafter` method, `Blanket Orders` is moved after the `Orders` action item. And the `modify` method is used to hide the `NewSalesBlanketOrder` action item.

```
profile TheBoss
{
    Description = 'The Boss';
    RoleCenter = "Business Manager Role Center";
    Customizations = MyCustomization;
    Caption = 'Boss';
}

pagecustomization MyCustomization customizes "Customer List"
{
    actions
    {
        moveafter(Orders; "Blanket Orders")

        modify(NewSalesBlanketOrder)
        {
            Visible = false;
        }

    }
}
```

You can use the same page customization on another profile within the same extension package by referencing its name from the profile definition, for example:

```
profile TheSalesman
{
    ProfileDescription = 'The Boss';
    RoleCenter = "Sales Manager Role Center";
    Customizations = MyCustomization;
    Caption = 'Salesman';
}
```

Report Object

2/17/2021 • 3 minutes to read • Edit Online

Reports are used to print or display information from a database. You can use a report to structure and summarize information, and to print documents, such as sales quotes and invoices.

Creating a report consists of two primary tasks; the first task is to create the underlying data model and the next is to define the visual layout that displays the data. The report object defines the underlying data model and specifies which database tables and fields to pull data from. When the report is run, that data is displayed in a specified layout; the visual layout, which determines the content and format of a report when it is viewed and printed.

For more information about defining database tables and fields, see Defining a Report Dataset. For more information about the Report data type, see Report Data Type.

You build the layout of a report by arranging data items and columns, and specifying the general format, such as text font and size. There are two types of report layouts; client report definition, also called RDL layouts and Word layouts. RDL layouts are defined in Visual Studio Report Designer or Microsoft SQL Server Reporting Services Report Builder. Word layouts are created using Word. Word layouts are based on a Word document that includes a custom XML part representing the report dataset.

> **NOTE**
> Extension objects can have a name with a maximum length of 30 characters.

Snippet support

Typing the shortcut `treport` will create the basic layout for a report object when using the AL Language extension in Visual Studio Code.

> **TIP**
> Use **Ctrl+Space** to trigger IntelliSense and get assistance on code completion, parameter info, quick info, and member lists.

Report example

The following example is a report that prints the list of customers. The report object defines a dataset of columns from the Customer table. For more information on creating a Word Layout report, see Creating a Report.

```
report 50103 "Customer List"
{
  CaptionML=ENU='Customer List';
  DefaultLayout = RDLC; // if Word use WordLayout property
  RDLCLayout = 'MyRDLReport.rdl';

  dataset
  {
    dataitem(Customer;Customer)
    {
      RequestFilterFields="No.","Search Name","Customer Posting Group";
```

```
        column(COMPANYNAME;COMPANYNAME)
        {
        }
        column(CurrReport_PAGENO;Customer."no.")
        {
        }
        column(Customer_TABLECAPTION_CustFilter;TABLECAPTION + ': ' + CustFilter)
        {
        }
        column(CustFilter;CustFilter)
        {
        }
        column(Customer_No;"No.")
        {
        }
        column(Customer_Customer_Posting_Group;"Customer Posting Group")
        {
        }
        column(Customer_Customer_Disc_Group;"Customer Disc. Group")
        {
        }
        column(Customer_Invoice_Disc_Code;"Invoice Disc. Code")
        {
        }
        column(Customer_Customer_Price_Group;"Customer Price Group")
        {
        }
        column(Customer_Fin_Charge_Terms_Code;"Fin. Charge Terms Code")
        {
        }
        column(Customer_Payment_Terms_Code;"Payment Terms Code")
        {
        }
        column(Customer_Salesperson_Code;"Salesperson Code")
        {
        }
        column(Customer_Currency_Code;"Currency Code")
        {
        }
        column(Customer_Credit_Limit_LCY;"Credit Limit (LCY)")
        {
          DecimalPlaces=0:0;
        }
        column(Customer_Balance_LCY;"Balance (LCY)")
        {
        }
        column(CustAddr_1;CustAddr[1])
        {
        }
        column(CustAddr_2;CustAddr[2])
        {
        }
        column(CustAddr_3;CustAddr[3])
        {
        }
        column(CustAddr_4;CustAddr[4])
        {
        }
        column(CustAddr_5;CustAddr[5])
        {
        }
        column(Customer_Contact;Contact)
        {
        }
        column(Customer_Phone_No;"Phone No.")
        {
        }
        column(CustAddr_6;CustAddr[6])
        {
```

```
      {
      }
      column(CustAddr_7;CustAddr[7])
      {
      }
      column(Customer_ListCaption;Customer_ListCaptionLbl)
      {
      }
      column(CurrReport_PAGENOCaption;CurrReport_PAGENOCaptionLbl)
      {
      }
      column(Customer_NoCaption;FIELDCAPTION("No."))
      {
      }
      column(Customer_Customer_Posting_GroupCaption;Customer_Customer_Posting_GroupCaptionLbl)
      {
      }
      column(Customer_Customer_Disc_GroupCaption;Customer_Customer_Disc_GroupCaptionLbl)
      {
      }
      column(Customer_Invoice_Disc_CodeCaption;Customer_Invoice_Disc_CodeCaptionLbl)
      {
      }
      column(Customer_Customer_Price_GroupCaption;Customer_Customer_Price_GroupCaptionLbl)
      {
      }
      column(Customer_Fin_Charge_Terms_CodeCaption;FIELDCAPTION("Fin. Charge Terms Code"))
      {
      }
      column(Customer_Payment_Terms_CodeCaption;Customer_Payment_Terms_CodeCaptionLbl)
      {
      }
      column(Customer_Salesperson_CodeCaption;FIELDCAPTION("Salesperson Code"))
      {
      }
      column(Customer_Currency_CodeCaption;Customer_Currency_CodeCaptionLbl)
      {
      }
      column(Customer_Credit_Limit_LCYCaption;FIELDCAPTION("Credit Limit (LCY)"))
      {
      }
      column(Customer_Balance_LCYCaption;FIELDCAPTION("Balance (LCY)"))
      {
      }
      column(Customer_ContactCaption;FIELDCAPTION(Contact))
      {
      }
      column(Customer_Phone_NoCaption;FIELDCAPTION("Phone No."))
      {
      }
      column(Total_LCY_Caption;Total_LCY_CaptionLbl)
      {
      }

      trigger OnAfterGetRecord();
      begin
        CalcFields("Balance (LCY)");
        FormatAddr.FormatAddr(
          CustAddr,Name,"Name 2",'',Address,"Address 2",
          City,"Post Code",County,"Country/Region Code");
      end;

    }
  }

  requestpage
  {
    SaveValues=true;
    ContextSensitiveHelpPage = 'my-feature';
    layout
```

```
    layout
    {
    }

    actions
    {
    }
  }

  labels
  {
      LabelName = 'LabelText', Comment = 'Foo', MaxLength = 999, Locked = true;
  }

  trigger OnPreReport();
  var
    CaptionManagement : Codeunit 42;
  begin
    CustFilter := CaptionManagement.GetRecordFiltersWithCaptions(Customer);
  end;

  var
    FormatAddr : Codeunit 365;
    CustFilter : Text;
    CustAddr : ARRAY [8] OF Text[50];
    Customer_ListCaptionLbl : Label 'Customer - List';
    CurrReport_PAGENOCaptionLbl : Label 'Page';
    Customer_Customer_Posting_GroupCaptionLbl : Label 'Customer Posting Group';
    Customer_Customer_Disc_GroupCaptionLbl : Label 'Cust./Item Disc. Gr.';
    Customer_Invoice_Disc_CodeCaptionLbl : Label 'Invoice Disc. Code';
    Customer_Customer_Price_GroupCaptionLbl : Label 'Price Group Code';
    Customer_Payment_Terms_CodeCaptionLbl : Label 'Payment Terms Code';
    Customer_Currency_CodeCaptionLbl : Label 'Currency Code';
    Total_LCY_CaptionLbl : Label 'Total (LCY)';

Profile Object

2/17/2021 • 2 minutes to read • Edit Online

The profile object in Dynamics 365 Business Central allows you to build an individual experience for each user profile. The Profile object performs a validation to check whether the specified role center page exists, and page customization objects exists, when you define a new profile object. On a page customization you can add changes to the page layout, and actions; but you cannot add variables, procedures, or triggers.

> **NOTE**
>
> Page customizations only apply to the RoleCenter they are specified for. In order to see them, in Dynamics 365 Business Central under **My Settings**, **Role Center** change to the specific RoleCenter that a page customization is defined for.

> **NOTE**
>
> Extension objects can have a name with a maximum length of 30 characters.

> **NOTE**
>
> `showMyCode` does not apply to profiles. Profiles defined in an extension with `showMyCode` set to `false` can still be copied using Designer.

Snippet support

Typing the shortcut `tprofile` will create the basic layout for a profile object when using the AL Language extension in Visual Studio Code.

> **TIP**
>
> Use **Ctrl+Space** to trigger IntelliSense and get assistance on code completion, parameter info, quick info, and member lists.

Profile example

The following profile object example creates a profile for the `MyRoleCenter` Role Center, which is available in the **Role Explorer** in the UI and available to end-users. The profile also depends on the customization `MyCustomization` and modifies the layout of the **Customer List** to make the `Name` field invisible using the `modify` method. For more information, see Profile Properties.

```
profile MyProfile
{
    Description = 'Some internal comment that only the Dev can see';
    Caption = 'My User-friendly Name';
    ProfileDescription = 'A detailed description of who is this profile for, why/how to use it (etc)';
    RoleCenter = MyRoleCenter;
    Enabled = true;
    Promoted = true;
    Customizations = MyCustomization;
}

pagecustomization MyCustomization customizes "Customer List"
{
    layout
    {
        modify(Name)
        {
            Visible = false;
        }
    }
}
```

Codeunit Object

2/17/2021 • 2 minutes to read • Edit Online

A codeunit is a container for AL code that you can use in many application objects. You typically implement business logic in codeunits and call the codeunit from the object that needs to perform that specific logic.

Snippet support

Typing the shortcut `tcodeunit` will create the basic layout for a codeunit object when using the AL Language extension in Visual Studio Code.

Codeunit example

This codeunit example checks whether a given customer has registered a shoe size. If not, the customer is assigned a shoe size of 42.

The codeunit can be used both as a direct call to `codeunit.run(customer)` or as a call to the procedure inside the codeunit `createcustomer.CheckSize(customer)`.

```
codeunit 50113 CreateCustomer
{
    TableNo = Customer;
    trigger OnRun();
    begin
        CheckSize(Rec);
    end;
    procedure CheckSize(var Cust : Record Customer)
    begin
        if not Cust.HasShoeSize() then
            Cust.ShoeSize := 42;
    end;
}
```

Query Object

2/17/2021 • 3 minutes to read • Edit Online

Business Central query objects enable you to retrieve records from one or more tables and then combine the data into rows and columns in a single dataset. Query objects can also perform calculations on data, such finding the sum or average of all values in a column of the dataset.

There are two types of query objects: normal and API. This article describes normal query objects, which can be used to display data in the user interface. API query objects are used to generate web service endpoints and cannot be displayed in the user interface. For information about creating a query of the type API, see API Query Type.

Creating a query object

A query object is comprised mainly of two different types of elements: dataitems and columns. A dataitem specifies the table to retrieve records from. A column specifies a field of the table to include in the resulting dataset of a query. The basic steps to create a query object are as follows:

1. Add the `query` keyword, followed by the `elements` control.
2. Build the dataset by adding `dataitem` controls and `column` controls within the `elements` control.

   The hierarchy of the `dataitem` and `column` controls is important because it will determine the sequence in which data items are linked, which in turn will control the results. Working from top-to-bottom, you start by adding the `dataitem` control for first table that you want in the dataset, then add `column` controls for each table field that you want to include in the dataset. For the next table, you add another `dataitem` control that is embedded within the first `dataitem` control, then add `column` controls as needed. You continue this pattern for additional tables and fields.
3. When you have specified the dataitem and column elements, create links and joins between the `dataitem` elements.

   Dataitem links and joins determine which records to include in the dataset based on the values of a common field between dataitems. You set a link between one or more fields of the dataitem tables with the DataItemLink Property and you define the type of the link using the SQLJoinType Property. Both properties must be set on the lower dataitem of the query object. For more information, see Linking and Joining Data Items.

The following shows the basic structure of a query object.

```
query ID Name
{

    elements
    {
        dataitem(DataItem1; Table1)
        {
            column(Column1; Field1)
            {
            }
            column(Column2; Field2)
            {
            }
            dataitem(DataItem2; Table2)
            {
                // Sets a link between FieldY of Table2 and FieldX of Table1.
                DataItemLink = FieldY = DataItem1.FieldX;
                //The dataset contains records from Table1 and Table2 where a match is found between FieldY
and FieldX.
                SqlJoinType = InnerJoin;

                column(Column1; Field1)
                {
                }
                dataitem(DataItem3; Table3)
                {
                    DataItemLink = FieldZ = DataItem2.FieldY;
                    SqlJoinType = InnerJoin;
                    column(Column1; Field1)
                    {
                    }
                }
            }
        }
    }
}
```

NOTE

Extension objects can have a name with a maximum length of 30 characters.

Snippet support

Typing the shortcut `tquery` will create the basic layout for a Query object when using the AL Language extension in Visual Studio Code.

TIP

Use **Ctrl+Space** to trigger IntelliSense and get assistance on code completion, parameter info, quick info, and member lists.

Query example

The following example shows a query that displays a list of customers with sales and profit figures. The query primarily retrieves fields from the **Customer** table, but also displays fields from the **Salesperson Purchaser** and **Country Region** tables.

The query also uses the DataItemLink property to create a link between the **Customer** table, **Salesperson**

Code field and the **Salesperson Purchaser** table, **Code** fields and a link between the **Customer** table, **Country/Region Code** field and the **Country/Region** table, **Code** field.

```
query 50102 "Top Customer Overview"
{
    QueryType = Normal;
    Caption = 'Top Customer Overview';

    elements
    {
        dataitem(Customer; Customer)
        {
            column(Name; Name)
            {
            }
            column(No; "No.")
            {
            }
            column(Sales_LCY; "Sales (LCY)")
            {
            }
            column(Profit_LCY; "Profit (LCY)")
            {
            }
            column(Country_Region_Code; "Country/Region Code")
            {
            }
            column(City; City)
            {
            }
            column(Global_Dimension_1_Code; "Global Dimension 1 Code")
            {
            }
            column(Global_Dimension_2_Code; "Global Dimension 2 Code")
            {
            }
            column(Salesperson_Code; "Salesperson Code")
            {
            }
            dataitem(Salesperson_Purchaser; "Salesperson/Purchaser")
            {
                DataItemLink = Code = Customer."Salesperson Code";
                column(SalesPersonName; Name)
                {
                }
                dataitem(Country_Region; "Country/Region")
                {
                    DataItemLink = Code = Customer."Country/Region Code";
                    column(CountryRegionName; Name)
                    {
                    }
                }
            }
        }
    }
}
```

IMPORTANT

You cannot run a query that gets data from both the application database and the business data database. This also applies to single-tenant deployments so that you do not have to rewrite queries if you decide to export the application. For a description of which tables are considered part of the application database, see Separating Application Data from Business Data.

XMLport Object

2/17/2021 • 2 minutes to read • Edit Online

XMLports are used to export and import data between an external source and Dynamics 365 Business Central. Sharing data between different computer systems is seamless when it is shared in an XML format. Working with XML files can be tedious so the details of how the XML file is handled are encapsulated in XMLports.

To use an XMLport to import or export data, you first create an XMLport object. Once created, you can run the XMLport from a page or codeunit object.

You can design XMLports to include a request page, which is a dialog box that enables the user to set a filter on the data, sort the data, or choose whether to export or import the data. For more information about request pages, see Request Pages.

XMLport example

The following example shows a page extension of the **Permission Sets** page that adds an action to the specified page calling the XMLport **ExportPermissionSet**. The XMLport exports the permission set data to an XML file.

```
pageextension 50111 PermissionSetExporter extends "Permission Sets"
{
    actions
    {
        addafter(Permissions)
        {
            action(ExportPermissionSet)
            {
                Promoted = true;
                PromotedCategory = New;
                trigger OnAction();
                begin
                    Xmlport.Run(50112, false, false);
                end;
            }
        }
    }
}

xmlport 50112 ExportPermissionSet
{
    Format = xml;

    schema
    {
        textelement(PermissionSets)
        {
            tableElement(PSet; "Aggregate Permission Set")
            {
                SourceTableView = WHERE ("App Name" = FILTER (<> ''));
                XmlName = 'PermissionSet';
                fieldattribute(RoleID; pset."Role ID") { }
                fieldattribute(RoleName; pset.Name) { }
                tableelement(P; "Tenant Permission")
                {
                    XmlName = 'Permission';
                    LinkTable = pset;
                    LinkFields = "Role ID" = FIELD ("Role ID");
```

```
                    textelement(ObjectType)
                    {
                        trigger onbeforePassvariable();
                        var
                            int: Integer;
                        begin
                            int := p."Object Type";
                            ObjectType := format(int);
                        end;
                    }
                    textelement(ObjectID)
                    {
                        trigger onbeforePassvariable();
                        var
                            int: Integer;
                        begin
                            int := p."Object ID";
                            ObjectID := format(int);
                        end;
                    }
                    textelement(ReadPermission)
                    {
                        trigger onbeforePassvariable();
                        var
                            int: Integer;
                        begin
                            int := p."Read Permission";
                            ReadPermission := format(int);
                        end;
                    }
                    textelement(InsertPermission)
                    {
                        trigger onbeforePassvariable();
                        var
                            int: Integer;
                        begin
                            int := p."Insert Permission";
                            InsertPermission := format(int);
                        end;
                    }
                    textelement(ModifyPermission)
                    {
                        trigger onbeforePassvariable();
                        var
                            int: Integer;
                        begin
                            int := p."Modify Permission";
                            ModifyPermission := format(int);
                        end;
                    }
                    textelement(DeletePermission)
                    {
                        trigger onbeforePassvariable();
                        var
                            int: Integer;
                        begin
                            int := p."Delete Permission";
                            DeletePermission := format(int);
                        end;
                    }
                    textelement(ExecutePermission)
                    {
                        trigger onbeforePassvariable();
                        var
                            int: Integer;
                        begin
                            int := p."Execute Permission";
                            ExecutePermission := format(int);
                        end;
```

```
                    }
                    textelement(SecurityFilter)
                    {
                        trigger onbeforePassvariable();
                        begin
                            SecurityFilter := format(p."Security Filter");
                        end;
                    }
                }
            }
        }
    }
}
```

Control Add-In Object

2/17/2021 • 4 minutes to read • Edit Online

The control add-in object allows you to add custom functionality to Dynamics 365 Business Central. A control add-in is a custom control, or visual element, for displaying and modifying data within an iframe or a page. For example, a control add-in can display the content of a webpage, visualize data as a chart or on a map, or host a custom web application. Control add-ins can exchange data with the Dynamics 365 server on various data types and respond to user interaction to raise events that execute additional AL code.

Control add-in properties

In the control add-in definition, you must set the `Scripts` property to include scripts in the control add-in. The scripts could be local files in the package or references to external files using the HTTP or the HTTPS protocol. With the `StartupScript` property, you can call a special script that runs when the page you've implemented the control add-in on, is loaded. These settings initialize the control add-in. With the `Images` and `StyleSheet` properties, you can specify additional styling to the control add-in. For more information about some of the control add-in properties, see:

- Images
- Scripts
- StartupScript
- StyleSheets
- RecreateScript
- RefreshScript

Sizing of the control add-in

Control add-ins can either have fixed dimensions or dynamically adapt to the available space on the screen. By controlling the sizing of an add-in, you ensure the add-in and the surrounding content on the page remain optimal on smaller display targets such as the phone or when users resize the browser. The following properties are available for you to specify how the sizing of the control add-in should behave.

- HorizontalShrink
- HorizontalStretch
- MinimumHeight
- MinimumWidth
- MaximumHeight
- MaximumWidth
- RequestedHeight
- RequestedWidth
- VerticalShrink
- VerticalStretch

Control add-in considerations and limitations

Designing control add-ins that provide the best possible experience can require some additional planning, design, and implementation. The following considerations and limitations will help you design add-ins that look and feel seamlessly integrated with both Dynamics 365 Business Central online and on-premises.

- Respond to touch events so that mobile users or users on devices supporting touch input can also use the add-in.
- Design content that is responsive and can flow, resize, or reorganize naturally based on the available space.
- Consider the accessibility needs of users, for example by implementing keyboard access and support for screen readers.
- Use the Style guidelines to apply a choice of colors, typefaces, and font sizes that match that of Dynamics 365 Business Central. For more information, see Control Add-in Style Guide.
- Provide language translation and other localizations that match the current user language in Dynamics 365 Business Central.
- In extensions for Business Central online, don't reference font files in stylesheets, because the fonts won't display in client. Instead, do one of the following:
  - Reference the font files from some other source such as a public or private CDN.
  - Base64 encode the fonts and include the encoded fonts in the CSS file.

Control add-in syntax example

The following control add-in syntax shows how to implement small customizations of the layout and functionality of a page.

```
// The controladdin type declares the new add-in.
controladdin SampleAddIn
{
    // The Scripts property can reference both external and local scripts.
    Scripts = 'https://cdnjs.cloudflare.com/ajax/libs/knockout/3.4.2/knockout-debug.js',
              'main.js';
    // The StartupScript is a special script that the web client calls once the page is loaded.
    StartupScript = 'startup.js';

    // Specifies the StyleSheets that are included in the control add-in.
    StyleSheets = 'skin.css';

    // Specifies the Images that are included in the control add-in.
    Images = 'image.png';

    // The procedure declarations specify what JavaScript methods could be called from AL.
    // In main.js code, there should be a global function CallJavaScript(i,s,d,c)
{Microsoft.Dynamics.NAV.InvokeExtensibilityMethod('CallBack', [i, s, d, c]);}
    procedure CallJavaScript(i: integer; s: text; d: decimal; c: char);

    // The event declarations specify what callbacks could be raised from JavaScript by using the webclient
API:
    // Microsoft.Dynamics.NAV.InvokeExtensibilityMethod('CallBack', [42, 'some text', 5.8, 'c'])
    event Callback(i: integer; s: text; d: decimal; c: char);
}
```

The `controladdin` object is then invoked as a `usercontrol` on a page called **PageWithAddIn**.

```
page 50130 PageWithAddIn
{
    layout
    {
        area(Content)
        {
             // The control add-in can be placed on the page using usercontrol keyword.
            usercontrol(ControlName; SampleAddIn)
            {

                ApplicationArea = All;

                 // The control add-in events can be handled by defining a trigger with a corresponding
name.
                trigger Callback(i: integer; s: text; d: decimal; c: char)
                begin
                    Message('Got from js: %1, %2, %3, %4', i, s, d, c);
                end;
            }
        }
    }

    actions
    {
        area(Creation)
        {
            action(CallJavaScript)
            {
                ApplicationArea = All;

                trigger OnAction();
                begin

                    // The control add-in methods can be invoked via a reference to the usercontrol.
                    CurrPage.ControlName.CallJavaScript(5, 'text', 6.3, 'c');
                end;
            }
        }
    }
}
```

Loading static resources using AJAX requests

You can design a control add-in to load static resources from the add-in package by using AJAX requests. For example, the control add-in could load HTML content and inject it into add-in's HTML structure. In this case, you must use the `withCrendentials` property set to `true` in the AJAX request. Otherwise, the request won't contain the necessary context and important cookies required by the Business Central service, and it may fail in production. This concept is illustrated in the following examples.

Wrong:

```
$.get(url).done(function(response) { } );
```

Correct:

```
$.ajax({
     url: url,
     xhrFields: {
          withCredentials: true
    }
)).done(function(data) {
    $("#controlAddIn).text(data);
});
```

Data Types and Methods in AL

2/17/2021 • 9 minutes to read • Edit Online

The following data types are available as part of the AL Language. Each data type has various methods that support it. For more information about a data type and its methods, select a link in the table.

TYPE	DESCRIPTION
BigInteger	Stores very large whole numbers that range from -9,223,372,036,854,775,807 to 9,223,372,036,854,775,807.
BigText	Handles large text documents.
Blob	Is a complex data type. Variables of this data type differ from normal numeric and string variables in that BLOBs have a variable length. The maximum size of a BLOB(binary large object) is 2 GB.
Boolean	Indicates true or false.
Byte	Stores a single, 8-bit character as a value in the range 0 to 255. You can easily convert this data type from a number to a character and vice versa. This means you can use mathematical operators on Byte variables.
Char	Stores a single, 16-bit character as a value in the range 0 to 65535. You can convert this data type from a number to a character and vice versa. This means you can use mathematical operators on Char variables.
Code	Denotes a special type of string that is converted to uppercase and removes any trailing or leading spaces.
Codeunit	Is a container for AL code that you can use from other application objects.
CompanyProperty	Provides language support for company properties.
Database	Provides access to common database functionality.
Date	Denotes a date ranging from January 1, 1753 to December 31, 9999.
DateFormula	Represents a date formula that has the same capabilities as an ordinary input string for the CALCDATE Method (Date). The DateFormula data type is used to provide multilanguage capabilities to the CALCDATE Method (Date).
DateTime	Denotes a date and time ranging from January 1, 1753, 00:00:00.000 to December 31, 9999, 23:59:59.999. An undefined or blank DateTime is specified by 0DT.

TYPE	DESCRIPTION
Debugger	Enables communication with a debugger.
Decimal	Denotes decimal numbers ranging from -999,999,999,999,999.99 to +999,999,999,999,999.99.
Dialog	Represents a dialog window.
Dictionary	Represents an unordered collection of keys and values. The Dictionary data type is optimized for fast lookup of values.
DotNet	Represents an unspecified .NET type.
Duration	Represents the difference between two DateTimes. This value can be negative. It is stored as a 64-bit integer. The integer value is the number of milliseconds during the duration.
Enum	Represents the text content of an element or attribute.
ErrorInfo	Provides a structure for grouping information about an error.
FieldRef	Identifies a field in a table and gives you access to this field.
File	Represents a file.
FilterPageBuilder	Stores filter configurations for a filter page. A filter page is a dynamic page type that contains one or more filter controls that enables users to set filters on fields of the underlying tables.
Guid	Represents a 16 byte binary data type. This data type is used for the global identification of objects, programs, records, and so on. The important property of a GUID is that each value is globally unique. The value is generated by an algorithm, developed by Microsoft, which assures this uniqueness.
HttpClient	Provides a data type for sending HTTP requests and receiving HTTP responses from a resource identified by a URI.
HttpContent	Represents an HTTP entity body and content headers.
HttpHeaders	Is a collection of headers and their values.
HttpRequestMessage	Represents an HTTP request message.
HttpResponseMessage	Represents a HTTP response message including the status code and data.
InStream	Is a generic stream object that you can use to read from or write to files and BLOBs. You can define the internal structure of a stream as a flat stream of bytes. You can assign one stream to another. Reading from and writing to a stream occurs sequentially.

TYPE	DESCRIPTION
Integer	Stores whole numbers with values that range from -2,147,483,647 to 2,147,483,647.
IsolatedStorage	Provides data isolation for extensions.
Any	This data type can be substituted by any other data type.
JsonArray	Is a container for any well-formed JSON array. A default JsonArray contains an empty JSON array.
JsonObject	Is a container for any well-formed JSON object. A default JsonObject contains an empty JSON object.
JsonToken	Is a container for any well-formed JSON data. A default JsonToken object contains the JSON value of NULL.
JsonValue	Is a container for any well-formed fundamental JSON value. A default JsonValue is set to the JSON value of NULL.
KeyRef	Identifies a key in a table and the fields in this key.
Label	Denotes a string constant that can be optionally translated into multiple languages.
List	Represents a strongly typed list of ordered objects that can be accessed by index. Contrary to the Array data type, a List is unbounded, such that its dimension does not need to be specified upon declaration.
Media	Encapsulates media files, such as image .jpg and .png files, in application database tables. The Media data type can be used as a table field data type, but cannot be used as a variable or parameter. The Media data type enables you to import a media file to the application database and reference the file from records, making it possible to display the media file in the client user interface. You can also export media from the database to files and streams.
MediaSet	Encapsulates media, such as images, in application database tables.
ModuleDependencyInfo	Provides information about a dependent module.
ModuleInfo	Represents information about an application consumable from AL.
NavApp	Provides information about a NavApp.
None	Is used implicitly when a method does not return a value.
Notification	Provides a programmatic way to send non-intrusive information to the user interface (UI) in the Business Central Web client.

TYPE	DESCRIPTION
NumberSequence	Is a complex data type for creating and managing number sequences in the database.
SessionInformation	Is a complex data type for exposing Session information into AL.
Option	Denotes an option value. In the code snippet below, you can see how the Option data type is declared.
OutStream	Is a generic stream object that you can use to write to files and BLOBs.
Page	Contains a number of simpler elements called controls. Controls are used to display information to the user or receive information from the user.
ProductName	An application can have a full name, marketing name, and short name. The PRODUCTNAME functions enable you to retrieve these name variations.
Query	Enables you to retrieve data from multiple tables and combine the data in single dataset.
RecordId	Contains the table number and the primary key of a table.
RecordRef	References a record in a table.
Report	Is used to display, print, or process information from a database.
RequestPage	Is a page that is run before the report starts to execute. Request pages enable end-users to specify options and filters for a report.
Session	Represents a Microsoft Dynamics Business Central session.
SessionSettings	Is a complex data type for passing user personalization settings for a client session as an object. The object contains properties that correspond to the fields in the system table **2000000073 User Personalization**, including: App ID, Company, Language ID, Locale ID, Profile ID, Scope, and Time Zone. You can use the AL methods of the SessionSettings data type to get, set, and send the user personalization settings for the current client session.
String	Denotes a sequence of characters. It can be represented by a string literal, a text value or a code value.
System	Is a complex data type.
Record	Is a complex data type.
TaskScheduler	Is a complex data type for creating and managing tasks in the task scheduler, which runs codeunits at scheduled times.

TYPE	DESCRIPTION
TestAction	Represents a test action on a page.
TestField	Represents a testable field on a page.
TestFilter	Represents a test filter on a page.
TestFilterField	Represents the type of a field filter in a test filter on a page or on a request page.
TestPage	Represents a variable type that can be used to test Page Application Objects.
TestPart	Represents a variable type that can be used to test Page Application Objects of type Part.
TestRequestPage	Stores test request pages. A test request page part is a logical representation of a request page on a report. A test request page does not display a user interface (UI). The subtype of a test request page is the report whose request page you want to test.
Text	Denotes a text string.
TextConst	Denotes a multi-language string constant.
TextBuilder	Represents a lighweight wrapper for the .Net implementation of StringBuilder.
Time	Denotes a time ranging from 00:00:00.000 to 23:59:59.999. An undefined or blank time is specified by 0T.
Variant	Represents an AL variable object. The AL variant data type can contain many AL data types.
Version	Represents a version matching the format: Major.Minor.Build.Revision .
WebServiceActionContext	Represents an AL WebServiceActionContext.
XmlAttribute	Represents an XML attribute.
XmlAttributeCollection	Represents a collection of XML attributes.
XmlCData	Represents a CData section.
XmlComment	Represents an XML comment.
XmlDeclaration	Represents an XML declaration.
XmlDocument	Represents an XML document.
XmlDocumentType	Represents an XML document type.

TYPE	DESCRIPTION
XmlElement	Represents an XML element.
XmlNamespaceManager	Represents a namespace manager that can be used to resolve, add and remove namespaces to a collection. It also provides scope management for these namespaces.
XmlNameTable	Represents a table of atomized string objects.
XmlNode	Represents a XML node which can either be for instance an XML attribute, an XML element or a XML document.
XmlNodeList	Represents a collection of XML nodes.
Xmlport	XmlPorts are used to export or import data between an external source and a Microsoft Dynamics Business Central database.
XmlProcessingInstruction	Represents a processing instruction, which XML defines to keep processor-specific information in the text of the document.
XmlReadOptions	Represents the options configuring how XML is loaded from a data source.
XmlText	Represents the text content of an element or attribute.
XmlWriteOptions	Represents the options configuring how XML is saved.
Action	Represents the action that the user took on the page.
ClientType	Represents the type of the client executing the operation.
CommitBehavior	Specifies whether commit is allowed within the scope of the method.
DataClassification	Sets the classification of the data in the table or field.
DataScope	Identifies the scope of stored data in the isolated storage.
DefaultLayout	The default layout to be used by a report.
ErrorType	Represents the type of error.
ExecutionContext	Represents the context in which a session is running. In certain scenarios, for example during upgrade, the system will run a session in a special context for a limited time.
ExecutionMode	The execution mode of the current session.
FieldClass	Represents the type of a field class.
FieldType	Represents the type of a table field.

TYPE	DESCRIPTION
NotificationScope	Specifies the context in which the notification appears in the client.
ObjectType	The different types of objects.
PageBackgroundTaskErrorLevel	Specifies how an error in the page background task appears in the client.
ReportFormat	Specifies the format of the report.
SecurityFilter	Specifies how security filters are applied to the record.
TableConnectionType	Use variables of this data type to specify the type of connection to an external database.
TelemetryScope	Represents the emission scope of the telemetry signal.
TestPermissions	Specifies a value that can be used to determine which permission sets are used on tests that are run by test codunits or test functions.
TextEncoding	Represents a file encoding.
TransactionModel	Represents a test transaction model.
TransactionType	Represents a transaction type.
Verbosity	Represents the security level of events.
WebServiceActionResultCode	Represents a web service action status code.

Array Methods

2/17/2021 • 2 minutes to read • Edit Online

An array is a data structure that contains a number of variables which are accessed through computed indices. The variables contained in an array, also called the elements of the array, are all of the same type, and this type is called the element type of the array.

An array has a rank which determines the number of indices associated with each array element. The rank of an array is also referred to as the dimensions of the array. An array with a rank of one is called a single-dimensional array. An array with a rank greater than one is called a multi-dimensional array. Specific sized multi-dimensional arrays are often referred to as two-dimensional arrays, three-dimensional arrays, and so on. Each dimension of an array has an associated length which is an integral number greater than or equal to zero. The maximum number of dimensions is 10 and the total number of elements in all dimensions is 1,000,000.

The length of a dimension determines the valid range of indices for that dimension. For a dimension of length N, indices can range from **1 to N** inclusive. The total number of elements in an array is the product of the lengths of each dimension in the array. If one or more of the dimensions of an array have a length of zero, the array is considered to be empty.

Syntax

The syntax for declaring an array of a specific type is the following:

```
Array [Dimension] of Type;
```

The `Dimension` is a comma-delimited list of integer literals greater than 0, where each integer defines the number of elements in that dimension.

The `Type` is the element type of the array.

Code example

The following code sample shows the declaration of an array with a simple element type.

```
ArrayOfInteger: Array [10] of Integer;
```

The following code sample shows the declaration of an array with an element type of a fixed length.

```
ArrayOfCode: Array [10] of Code[20];
ArrayOfText: Array [10] of Text[20];
```

The following code sample shows the declaration of an array with a complex element type.

```
ArrayOfCodeunits: Array [10] of Codeunit 10;
ArrayOfQueryes: Array [10] of Query "My Query";
ArrayOfTemporaryRecords: Array [10] of Record 10 Temporary;
ArrayOfDotNetVariables: Array [10] of DotNet String;
```

Methods

The following AL methods for arrays are available:

ArrayLen Method
CompressArray Method
CopyArray Method

Essential AL Methods

2/17/2021 • 2 minutes to read • Edit Online

Although there are hundreds of methods in AL, there are several methods that you will use more often than the others. This does not mean that the rest of the methods are obsolete or that you will never use them. However, it does mean that if you are very familiar with this small set of essential methods, you will be able to accomplish many tasks when you are programming in AL. When you want to add more specialized functionality to your applications, you can learn about more of the methods.

The topics in this section describe the most common AL methods. For more details about all of the AL methods, see AL Method Reference.

- Get, Find, and Next Methods
- SetCurrentKey, SetRange, SetFilter, GetRangeMin, and GetRangeMax Methods
- Insert, Modify, ModifyAll, Delete, and DeleteAll Methods
- LockTable Method
- Field Calculation Methods
- Progress Windows, Message, Error, and Confirm Methods
- StrMenu Method

AL Method Reference

Get, Find, and Next Methods

2/17/2021 • 3 minutes to read • Edit Online

The following methods are used to search for records:

- `Get`
- `Find`
- `Next`

These methods are some of the most frequently used AL methods. When you search for records, you must know the difference between Get and Find and to know how to use Find and Next in conjunction.

> **TIP**
> When using these methods, consider using the partial records methods to improve performance, especially when looping through several records or when table extensions are defined on the table. For more information, see Using Partial Records.

Get method

The Get Method (Record) retrieves one record based on values of the primary key fields.

Get has the following syntax.

```
[Ok :=] Record.Get([Value],...)
```

For example, if the **No.** field is the primary key of the **Customer** table and if you have created a record variable called **CustomerRec** that has a subtype of Customer, then you can use Get in the following way.

```
CustomerRec.Get('4711');
```

The result is that the record of customer 4711 is retrieved.

Get produces a run-time error if it fails and the return value is not checked by the code. In the previous example, the actual code that you write should resemble the following.

```
if CustomerRec.GET('4711') then
.... // Do some processing.
else
.... // Do some error processing.
```

Get searches for a record, regardless of the current filters, and it does not change any filters. Get always searches through all the records in a table.

GetBySystemId method

APPLIES TO: Business Central 2019 release wave 2 and later

The GetBySystemId(Guid) retrieves a record based on the value of its **SystemId** field.

GetBySystemId has the following syntax:

```
RecordExists :=   Record.GetBySystemId(SystemId: Guid)
```

The following example gets the record that has the SystemId `5286305A-08A3-E911-8180-001DD8B7338E`:

```
var
    Customer: Record Customer;
    Text000: Label 'Customer was found.';
begin
    If Customer.GetBySystemId('{5286305A-08A3-E911-8180-001DD8B7338E}') then
    Message(Text000);
end;
```

Similar to the Get method, GetBySystemId searches for a record, regardless of the current filters, and it does not change any filters. Get always searches through all the records in a table.

Find methods

The Find Method (Record) locates a record in a table that is based on the values stored in the keys.

Find has the following syntax.

```
Ok := Record.Find([Which])
```

The *Which* parameter specifies how to perform the search. You can search for values that are greater than, less than, or equal to the key value, or for the first or last record in a table.

The important differences between Get and Find are as follows:

- Find uses the current filters.
- Find can look for records where the key value is equal to, greater than, or smaller than the search string.
- Find can find the first or the last record, depending on the sort order defined by the current key.

When you are developing applications in a relational database, there are often one-to-many relationships defined between tables. An example could be the relationship between an **Item** table, which registers items, and a **Sales Line** table, which registers the detailed lines from sales orders. One record in the **Sales Line** table can only be related to one item, but each item can be related to any number of sales line records. You would not want an item record to be deleted as long as there are still open sales orders that include the item. You can use Find to check for open sales orders.

The OnDelete trigger of the **Item** table includes the following code that illustrates using Find.

```
SalesOrderLine.SetCurrentKey(Type,"No.");
SalesOrderLine.SetRange(Type,SalesOrderLine.Type::Item);
SalesOrderLine.SetRange("No.","No.");
if SalesOrderLine.Find('-') then
    Error(Text001,TableCaption,"No.",SalesOrderLine."Document Type");
```

If you want to find the first record in a table or set, then use the FindFirst Method (Record). If you want to find the last record in a table or set, then use the FindLast Method (Record).

Next method

The Next Method (Record) is often used with FIND to step through the records of a table.

Next has the following syntax.

```
Steps := Record.Next([Steps])
```

In the following example, Find is used to go to the first record of the table. Next is used to step through every record, until there are no more. When there are no more records, Next returns 0 (zero).

```
if (Rec.FindSet) then
repeat
  // process record
until (Rec.Next = 0);
```

Creating Handler Methods

2/17/2021 • 3 minutes to read • Edit Online

You can create test codeunits, test methods, and test pages to test your application. We recommend that you create tests that can be automated. To create automated tests, you must write code to handle all UI interactions so that the tests do not require user interaction when they are running. To do this, you create special handler methods.

You can use the following handler methods:

METHOD TYPE	PURPOSE	SIGNATURE	
MessageHandler	Handles **Message** statements.	< *Function name*> (< *Message*> : Text[1024])	
ConfirmHandler	Handles **Confirm** statements.	< *Function name*> (< *Question*> : Text[1024]; var < *Reply*> : Boolean)	
StrMenuHandler	Handles **StrMenu** statements.	< *Function name*> (< *Options* : Text[1024]; var < *Choice*> : Integer; < *Instruction*> : Text[1024])	
PageHandler	Handles specific pages that are not run modally.	< *Function name*> (var < *Page*> : Page < *page id*>) < *Function name*> (var < *Page*> : TestPage < *testpage id*>)	
ModalPageHandler	Handles specific pages that are run modally.	< *Function name*> (var < *Page*> : Page < *page id*>; var < *Response*> : Action) < *Function name*> (var < *Page*> : Page < *testpage id*>)	
ReportHandler	Handles specific reports. If you create a **ReportHandler** method, then that method replaces all code for running the report, including the request page, and a **RequestPageHandler** is not called. Only create a **RequestPageHandler** if you are not using a ReportHandler.	< *Function name*> (var < *Report*> : Report < *report id*>)	

METHOD TYPE	PURPOSE	SIGNATURE	
FilterPageHandler	Handles a specific filter page. The FilterPageHandler tests the UI that is generated by a FilterPageBuilder Data Type.	<*Function name*>(var <*Record1*> : RecordRef)[, var <*Record2*> : RecordRef] [, ...]): Boolean	
RequestPageHandler	Handles the request page of a specific report.	<*Function name*>(var <*RequestPage* > : TestRequestPage)	
HyperlinkHandler	Handles specific hyperlinks.	<*Function name*> (<*Hyperlink*> : Text[1024])	
SendNotificationHandler	Handles **Send** statements.	<*Function name*> (< *TheNotification*>: Notification): Boolean	
RecallNotificationHandler	Handles **Recall**	<*Function name*> (< *TheNotification*>: Notification): Boolean	
SessionSettingsHandler	Handles **RequestSessionUpdate** statements.	<*Function name*>(var <*SessionSettings*>: SessionSettings): Boolean	

How to create a handler method

To create a handler method, you set one of the handler attributes on a method. You must use the method signature specified for the handler attribute that you are using, as illustrated in this code example.

```
[MessageHandler]
procedure MessageHandler(Message: Text[1024])
begin
    Assert.IsTrue(StrPos(Message, MSG_HAS_BEEN_CREATED) > 0, Message);
end;
```

The parameters of the methods that are being handled are passed as parameters to the handler methods. For example, when **Message** is called in a test method, the parameter of the **Message** method is passed as the parameter of the **MessageHandler** method. For page and report handlers, the page, report, or request page is passed as the parameter of the **PageHandler**, **ModalPageHandler**, **ReportHandler**, or **RequestPageHandler**.

You can call handler methods from methods that have the Test Attribute and then specify the handler methods that it will use in the HandlerFunctions Attribute. The code inside the test method should simulate that the UI was actually raised and some values entered or some actions were taken. You can specify more than one handler method by separating the handler method names with a comma.

> **NOTE**
> Every handler method that you enter in the HandlerFunctions Attribute of a test method must be called at least one time in the test method. If you run a test method that has a handler method listed that is not called, then the test fails.

The following example shows a test method that uses the HandlerFunctions Attribute to call the

MessageHandler method.

```
[Test]
[HandlerFunctions('MessageHandler')]
procedure ApproveRequestForPurchCreditMemo()
var
    PurchHeader: Record "Purchase Header";
begin
    ApproveRequestForPurchDocument(PurchHeader."Document Type"::"Credit Memo");
end;
```

Handling Errors using Try Methods

2/17/2021 • 2 minutes to read • Edit Online

Try methods in AL enable you to handle errors that occur in the application during code execution. For example, with try methods, you can provide more user-friendly error messages to the end user than those thrown by the system.

> **NOTE**
> Try Methods are available from runtime version 2.0.

Behavior and usage

The main purpose of try methods is to catch errors/exceptions that are thrown by Business Central or exceptions that are thrown during .NET Framework interoperability operations. Try methods catch errors similar to a conditional Codeunit.Run method call, except try method calls do not require that write transactions are committed to the database, and changes to the database that are made with a try method are not rolled back.

Database write transactions in try methods

Because changes made to the database by a try method are not rolled back, you should not include database write transactions within a try method. By default, the Business Central Server configuration prevents you from doing this. If a try method contains a database write transaction, a runtime error occurs.

Handling errors with a return value

A method that is designated as a try method has a Boolean return value (**true** or **false**), and has the construction `OK:= MyTrymethod`. A try method cannot have a user-defined return value.

- If a try method call does not use the return value, the try method operates like an ordinary method and errors are exposed as usual.
- If a try method call uses the return value in an `OK:=` statement or a conditional statement such as `if-then`, errors are caught. The try method returns `true` if no error occurs; `false` if an error occurs.

> **NOTE**
> The return value is not accessible within the try method itself.

Getting details about errors

You can use the GetLastErrorText method to obtain errors that are generated by Business Central. To get details of exceptions that are generated by .NET Framework objects, you can use the GetLastErrorObject method to inspect the `Exception.InnerException` property.

Creating a try method

To create a try method, add a method in the AL code of an object such as a codeunit as usual, and then set the TryFunction Attribute property to **true**.

Example 1

The following simple example illustrates how the try method works. First, create a codeunit that has a local method `MyTrymethod`. Add the following code on the `OnRun` trigger and `MyTrymethod` method.

```
trigger OnRun()
begin
    MyTrymethod;
    message('Everything went well');
end;
```

```
local procedure MyTryMethod()
begin
    error('An error occurred during the operation');
end;
```

When you run this codeunit, the execution of the `OnRun` trigger stops. The error message `An error occurred during the operation` is thrown in the UI.

Now, set the TryFunction Attribute of the `MyTrymethod` method. Then, add code to the `OnRun` trigger to handle the return value of the try method:

```
[TryFunction]
local procedure MyTryMethod()
begin
    error('An error occurred during the operation');
end;

trigger OnRun()
begin
    if MyTryMethod then
        message('Everything went well')
    else
        message('Something went wrong')
end;
```

When you run the codeunit, instead of stopping the execution of the `OnRun` trigger when the error occurs, the error is caught and the message `Something went wrong` is returned.

Progress Windows, Message, Error, and Confirm Methods

2/17/2021 • 4 minutes to read • Edit Online

You can use several specialized methods to display messages and gather input. We recommend that you use pages to ensure that your application has a consistent user interface. However, there are situations where you may want to use the dialog methods instead of pages. The most important uses of the dialog methods are as follows:

- To display a window that indicates the progress of some processing that may take a long time.
- To stop the running program to display an error Message.
- To let the user confirm a choice before the program continues running.

You can also use the StrMenu method to create pages that present options to the user. It is much faster to use this method than to design a page which only presents a limited set of options to the user. For more information about the StrMenu method, see StrMenu Method.

Best practices for user messages

We recommend the following guidelines for writing messages for end users:

- Write messages correctly according to the grammatical rules for your language.
- Do not use backslashes to indicate line breaks in a message. Line formatting is completed automatically. The only exception is in the Open Method (Dialog). You must use backslashes for the message to be aligned correctly.
- Use the FieldCaption Method (Record) and TableCaption Method (Record) whenever possible to return names of fields and tables as strings so that the user can always recognize a term that indicates a field or table name. The only exception to this is in Open Method (Dialog). In this method, you can use the field name directly. Otherwise, it can be difficult to align correctly. If you refer to a field name without using the FieldCaption method, then type the field name without any single or double quotation marks.
- Try to write all messages on only one line. If you want to use more than one line, then start each new line after a period instead of in the middle of a sentence.
- Do not enter the text directly in the AL code. Instead, enter it as a label so that the message can be translated.

Creating a window to indicate progress

If you have an application that performs some processing that can take a long time to complete, then you should consider displaying a window that informs the user of the progress that is being made. It is always a good idea to inform the user that processes are still running.

A **Cancel** button is automatically added to every dialog window and gives the user the opportunity to stop the processing.

In some applications, you may want to create a window in which each field is updated when the program is running. For example, the fields in the window display the count of the number of postings made. In another application, you may want to display information about the record that is currently being processed. For

example, the field in the window displays the number of the account that is currently being processed.

To create this kind of progress window, you use the Dialog data type.

Message method

The Message Method (Dialog) displays a message in a window that remains open until the user chooses the **OK** button.

The Message method has the following syntax.

```
Message(String [, Value1, ...]);
```

The Message method runs asynchronously, which means that the Message is not run until the method from which it was called ends or another method requests user input. The method is useful for notifying the user that some processing has been successfully completed.

For an example of the Message method, see codeunit 83 in the CRONUS International Ltd. demonstration database. The code in the OnRun trigger converts a quote into a sales order and then displays a Message. The Message is generated by the following code.

```
var
    Text001 : Label 'Quote %1 has been changed to order %2';

Message(Text001,"No.",SalesHeader2."No.");
```

> **NOTE**
> Unlike the progress window, the Message method does not require that you first declare a variable of type Dialog. The Message method creates a window of its own.

Error method

The Error Method (Dialog) is very similar to the Message method except that when the user has acknowledged the Message from an Error method, execution ends. The Error method is also similar to the FieldError method. For more information, see CalcFields, CalcSums, FieldError, FieldName, Init, TestField, and Validate Methods.

The Error method has the following syntax.

```
Error(String [, Value1, ...]);
```

Confirm method

The Confirm Method (Dialog) is used just like the Message method to display a Message. However, unlike the Message method, the Confirm method has a required return value.

The Confirm method has the following syntax.

```
Ok := Dialog.Confirm(String [, Default] [, Value1] ,...);
```

The following example shows how to use the Confirm method.

```
if Confirm('Do you want to post the journal lines and print report %1?', False, ReportID) then
    Message('Posting')
else begin
    Message('No Posting');
    exit;
end;
```

The False parameter in the Confirm statement means that No is the default.

Dialog Data Type

Creating Test Codeunits and Test Methods

2/17/2021 • 2 minutes to read • Edit Online

In Dynamics 365 Business Central, you can create test codeunits and create test methods in the test codeunits.

Test codeunits are codeunits that have the SubType Property set to **Test**. You write tests as Al code in the methods inside of the test codeunits. There are three types of methods that you can add in a test codeunit: test, handler, and normal. Each method type is used for a specific purpose and behaves differently. When a test codeunit runs, it runs the **OnRun** trigger, and then runs each test method in the codeunit.

By default, each test method runs in a separate database transaction, but you can use the TransactionModel Property on test methods and the TestIsolation Property on test runner codeunits to control the transactional behavior.

The results of a test codeunit and of the individual test methods are displayed in a message window, but you can use the OnAfterTestRun Trigger on a test runner codeunit to capture the results. The outcome of a test method is either SUCCESS or FAILURE. If any error is raised by either the code that is being tested or the test code, then the global outcome of the test codeunit is FAILURE and the error is included in the results log file.

The difference between a normal codeunit and a test codeunit is their execution at runtime. When a normal codeunit is run, if one of its methods fails, then the codeunit is terminated. When a test codeunit is run, even if the outcome of one test method is FAILURE, the next test methods are still run.

The methods in a test codeunit can be one of the following types:

TYPE	DESCRIPTION	
Test method	You use test methods that include AL code that tests the business logic in the application, where each method covers a transaction. You declare the Test Attribute on the method.	
Handler method	You use handler methods to automate tests by handling instances when user interaction is required by the code that is being tested by the test method. In these instances, the handler method is run instead of the requested user interface. The handler method should simulate the user interaction for the test case, such as validating messages, making selections, or entering values. You declare a handler type attribute on the method. For more information, see Creating Handler Methods	
Normal method	You use normal methods to structure the test code by using the same design practices and principles as methods in other codeunits of the application. You declare the Normal Attribute on the method.

Method Attributes

2/17/2021 • 2 minutes to read • Edit Online

An attribute is modifier on a method declaration that specifies information that controls the method's use and behavior. Adding an attribute on a method declaration is also known as *decorating* a method. For example, decorating a method with the `Integration` attribute sets the method to be an event publisher. An attribute can have one or more arguments that set properties for the method instance.

In AL, attributes are placed before the method, and have the following syntax:

```
[Attribute_Name(ArgumentName : data_type, ArgumentName : data_type)]
```

For example, the Integration attribute has two arguments, and the syntax is:

```
[Integration(IncludeSender : Boolean, GlobalVarAccess : Boolean)]
```

Attributes

The following method attributes are available:

- CommitBehavior Attribute
- Business Attribute
- ConfirmHandler Attribute
- EventSubscriber Attribute
- FilterPageHandler Attribute
- HandlerFunctions Attribute
- HyperlinkHandler Attribute
- InDataSet Attribute
- IntegrationEvent Attribute
- InternalEvent Attribute
- MessageHandler Attribute
- ModalPageHandler Attribute
- NonDebuggable Attribute
- Normal Attribute
- Obsolete Attribute
- PageHandler Attribute
- RecallNotificationHandler Attribute
- ReportHandler Attribute
- RequestPageHandler Attribute
- Scope Attribute
- SendNotificationHandler Attribute
- SessionSettingsHandler Attribute
- StrMenuHandler Attribute
- Test Attribute
- TestPermissions Attribute

- TryFunction Attribute

Procedure overload

2/17/2021 • 2 minutes to read • Edit Online

Procedure overload enables developers to create multiple procedures with the same name, but with different signatures, on the same application object. Conceptually, overloaded procedures are used to execute the same task on a different set of arguments. When an overloaded procedure is called, a specific implementation of that procedure, appropriate to the context of the call, will be run.

Reasons for using procedure overload

Overloaded procedures give programmers the flexibility to call a procedure with similar semantics for different types of data. At the same time, overloaded procedures remove the need for abusing the Variant data type for the purpose of processing different types of data in a similar manner and allows the developer to write strongly-typed code and rely on the compiler for validation.

Remarks

Overload resolution is performed by using procedure signatures to find the best match. The signature of a procedure is represented by its name and the type, order, and number of parameters. The return type of a procedure is not part of the procedure's signature.

Example

The following example shows how a **ToString** method can be implemented with and without using procedure overloads.
In the first code snippet, a **ToString** procedure is implemented. This takes a Variant value and inspects the type of the value to delegate to different implementations. If the caller passes a value of a different type than Integer, Date, and Text, an empty string will be returned. This can lead to bugs that will only show up at runtime.

```
codeunit 10 Stringifier
{
    local procedure TextToString(value : Text) : Text;
    begin
        Exit(value);
    end;

    local procedure DateToString(value : Date) : Text;
    begin
        Exit(Format(value));
    end;

    local procedure IntegerToString(value : Integer) : Text;
    begin
        Exit(Format(value));
    end;

    procedure ToString(value: Variant) : Text;
    begin
        if value.IsInteger then
            Exit(IntegerToString(value))
        else if value.IsDate then
                Exit(DateToString(value))
        else if value.IsText then
                Exit(TextToString(value))
        else
            Exit('');
    end;
}
```

In the second code snippet, we overload the ToString procedure for Text, Date and Integer. At this point, it is not possible for a caller to call a ToString method with a different type other than Integer, Date, or Text. This will catch the bug above at compile time.

```
codeunit 10 StringifierWithOverloads
{
    procedure ToString(value : Text) : Text;
    begin
        Exit(value);
    end;

    procedure ToString(value : Date) : Text;
    begin
        Exit(Format(value));
    end;

    procedure ToString(value : Integer) : Text;
    begin
        Exit(Format(value));
    end;
}
```

Joker Data Type

2/17/2021 • 2 minutes to read • Edit Online

`Joker` is an *internal* data type that is not exposed to AL developers. Joker can replace any other type and represents a wildcard. In certain cases, `Joker` plays the role of a generic T which is inferred from the type of the left-hand side of the invocation expression, in other cases, it is inferred from another parameter.

The following illustrates examples of how `Joker` is used in AL.

```
procedure SetRange(Field: Joker, [FromValue: Joker], [ToValue: Joker])
```

```
procedure SetFilter(Field: Joker, String: Text, [Value: Joker, ...])
```

```
procedure SetAscending(Field: Joker, Ascending: Boolean)
```

Action Option Type

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Represents the action that the user took on the page.

Members

MEMBER	DESCRIPTION
None	Represents the result of running a page.
OK	Represents the result of the user closing a page window by performing one of the following actions: - Chooses the **OK** button. - Chooses the **X** button when there was no **Cancel** button on the window. - Presses the Esc key when there is no **Cancel** button on the window.
Cancel	Represents the result of the user closing a page window by performing one of the following actions: - Chooses the **Cancel** button. - Chooses the **X** button when there is a **Cancel** button on the window. - Presses the Esc key when there is a **Cancel** button on the window
LookupOK	Represents the result of the user closing a lookup window by performing one of the following actions: - Chooses the **OK** button. - Chooses an item in the Lookup window.
LookupCancel	Represents the result of the user closing a lookup window by choosing the **Cancel** button.
Yes	Represents the result of the user closing a confirmation window by choosing the **Yes** button.
No	Represents the result of the user closing a confirmation window by performing one of the following actions: - Chooses the No button. - Chooses the X button. - Presses the Esc key.
RunObject	Represents the result of the user selecting an option that ran another object.

MEMBER	DESCRIPTION
RunSystem	Represents the result of the user selecting an option that ran an external program.

ClientType Option Type

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Represents the type of the client executing the operation.

Members

MEMBER	DESCRIPTION
Background	A background session.
ChildSession	A child session.
Desktop	A desktop client.
Management	A management client.
NAS	A NAS client.
OData	A NAS client.
Phone	Microsoft Dynamics Business Central Phone client.
SOAP	A SOAP client.
Tablet	Microsoft Dynamics Business Central Tablet client.
Web	Microsoft Dynamics Business Central Web client.
Windows	Microsoft Dynamics Business Central Windows client.
Current	Microsoft Dynamics Business Central Windows client.
Default	The default client.
ODataV4	A ODataV4 client.
Api	An API client.
Teams	Microsoft Teams client.

DataClassification Option Type

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Sets the classification of the data in the table or field.

Members

MEMBER	DESCRIPTION
CustomerContent	Content directly provided/created by admins and users.
ToBeClassified	Content that has not yet been given a classification. This is the initial value when table or field is created.
EndUserIdentifiableInformation	(EUII) Data that identifies or could be used to identify the user of a Microsoft service. EUII does not contain Customer content.
AccountData	Customer billing information and payment instrument information, including administrator contact information, such as tenant administrator's name, address, or phone number.
EndUserPseudonymousIdentifiers	(EUPI) An identifier created by Microsoft tied to the user of a Microsoft service. When EUPI is combined with other information, such as a mapping table, it identifies the end user. EUPI does not contain information uploaded or created by the customer (Customer content or EUII).
OrganizationIdentifiableInformation	(OII) Data that can be used to identify a tenant, generally config or usage data. This data is not linkable to a user and does not contain Customer content.
SystemMetadata	Data generated while running the service or program that is not linkable to a user or tenant.

FieldType Option Type

2/17/2021 • 3 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Represents the type of a table field.

Members

MEMBER	DESCRIPTION
Boolean	Assumes the values true or false. When formatted, a Boolean field is shown as "Yes" or "No". The size of the corresponding SQL data type, TINYINT, is 1 byte.
Integer	Denotes an integer between -2,147,483,647 and 2,147,483,647. The size of the corresponding SQL data type, INTEGER, is 4 bytes.
BigInteger	A 64-bit integer.
Decimal	A decimal number between -10^63 and 10^63. The exponent ranges from -63 to 63. Decimal numbers are held in memory with 18 significant digits. The representation of a decimal number is a Binary Coded Decimal (BCD). The size of the corresponding SQL data type, DECIMAL(38,20), is 17 bytes. We recommend that you construct decimals that operate on numbers in the range of +/- 999,999,999,999,999.99. You can construct larger numbers in some cases, but overflow, truncation or loss of precision can occur.
Option	An option field is defined by using an option string, which is a comma-separated list of strings that represent each valid value of the field. This string is used when a field of type Option is formatted and its value is converted into a string.
Text	Any alphanumeric string. The field must be defined to be between 1 and 250 characters. The number of bytes used by a text field equals (number of characters + 1) * 2. The additional character is used for the string terminating character, which is '0' in Unicode. The size of a Unicode character is 2 bytes. Therefore, you multiply the number of characters by two to get the size.
Code	An alphanumeric string, which is right-justified if the contents are numbers only. If letters or blanks occur among the numbers, the contents are left-aligned. All letters are converted to uppercase upon entry.

MEMBER	DESCRIPTION
DateTime	Represents a point in time as a combined date and time. The datetime is stored in the database as Coordinated Universal Time (UTC) and is always displayed as local time in Dynamics 365 Business Central.
Time	Any time in the range 00:00:00 to 23:59:59.999. A time field contains 1 plus the number of milliseconds since 00:00:00 o'clock, or 0 (zero), an undefined time.
Date	A date value in the range from January 1, 1753 to December 31, 9999. An undefined date is expressed as 0. All dates have a corresponding closing date. The system considers the closing date for a given date as a period that follows the given date but comes before the next normal date; that is, a closing date is sorted immediately after the corresponding normal date but before the next normal date.
DateFormula	Used to verify the date entered by the user.
Duration	Represents the difference between two points in time, in milliseconds. This value can be negative.
Guid	Globally unique identifier (GUID).
RecordId	Unique record identifier.
TableFilter	This data type is used to apply a filter to another table. Currently, this can only be used to apply security filters from the Permission table.
Blob	Binary Large Object. Used to store bitmaps and memos. Notice that the BLOB is not stored in the record, but in the BLOB area of the table.
Media	A complex type that encapsulates media files, such as image .jpg and .png files, in application database tables. The Media data type can be used as a table field data type, but cannot be used as a variable or parameter.
MediaSet	A complex type that encapsulates media, such as images, in application database tables. The MediaSet data type can be used as a table field data type, but cannot be used as variable or parameter.

TestPermissions Option Type

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Specifies a value that can be used to determine which permission sets are used on tests that are run by test codunits or test functions.

Members

MEMBER	DESCRIPTION
InheritFromTestCodeunit	Is only relevant for test methods; not test codeunits. It specifies that a test method uses the TestPermissions property setting of the test codeunit to which it belongs. If you use this value on a test codunit, the property will resolve to Restrictive at runtime.
Restrictive	Does not perform any operations or have any specific behavior. Instead, you programmatically define what each value does, and the permissions sets it applies at runtime, by adding code in a test runner codeunit.
NonRestrictive	Does not perform any operations or have any specific behavior. Instead, you programmatically define what each value does, and the permissions sets it applies at runtime, by adding code in a test runner codeunit.
Disabled	Does not perform any operations or have any specific behavior. Instead, you programmatically define what each value does, and the permissions sets it applies at runtime, by adding code in a test runner codeunit.

TransactionModel Option Type

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Represents a test transaction model.

Members

MEMBER	DESCRIPTION
AutoCommit	The transaction automatically commits after the Test method has run.
AutoRollback	The transaction is automatically rolled back after the Test method has run.
None	No write-transaction is open in the test-method code, and writes will fail. The transaction model mirrors the model used by the "real" client. Every call from the TestPage to the "server" has its own transaction.

See Also

Getting Started with AL
Developing Extensions

TransactionType Option Type

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Represents a transaction type.

Members

MEMBER	DESCRIPTION
UpdateNoLocks	This is an update transaction. Modifications can occur within the transaction. All read operations are performed with READ UNCOMMITTED locking until the table is either modified by a write operation or locked with the LOCKTable Method (Record). From this point until the end of the transaction, all read operations are performed with UPDLOCK locking. This transaction type improves concurrency for all tables that users access within the transaction by delaying locking as much as it can. However, the disadvantage is that you must know when to lock the tables for the required transaction behavior.
Update	This is an update transaction. Modifications can occur within the transaction. All read operations are performed with REPEATable READ locking until the table is either modified by any write operation or locked with the LOCKTable method. From this point forward, all read operations are performed with UPDLOCK locking. This transaction type provides full transaction isolation from the start of the transaction, regardless of the lock status of tables that users access within the transaction.
Snapshot	This is a read-only transaction. Modifications cannot occur within the transaction. All read operations are performed with REPEATable READ locking. Therefore, shared locks are added on all data and are maintained until the end of the transaction. This prevents other transactions from modifying any rows that have been read by the current transaction.
Browse	This is a read-only transaction. Modifications cannot occur within the transaction. All read operations are performed with READ UNCOMMITTED locking. Therefore, no locks are added and locks that are added by other sessions are not honored. This means that the transaction may read uncommitted data.
Report	Report option maps to one of the basic options. This enables a report to use the most concurrent read-only form of data access for the connected server. When you use Dynamics 365 Business Central database server, it maps to Snapshot and when you use SQL Server, it maps to Browse.

BigInteger Data Type

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Stores very large whole numbers that range from -9,223,372,036,854,775,807 to 9,223,372,036,854,775,807.

Remarks

This data type is a 64-bit integer.

You must add an L to the constant definition to inform AL that the integer must be interpreted and treated as a BigInteger.

If you assign -9,223,372,036,854,775,808 directly to a BigInteger variable, then you get an error when you try to compile the code. However, you can indirectly assign -9,223,372,036,854,775,808 to a BigInteger variable by using the following code.

```
BigIntegerVar := -9223372036854775807L;
BigIntegerVar := BigIntegerVar - 1;
```

If you try to indirectly assign a value that is smaller than -9,223,372,036,854,775,808, or larger than 9,223,372,036,854,775,807, then you get a run-time error.

Example

```
BI := 1L;
BI := 455500000000L;
```

Developing Extensions

BigText Data Type

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Handles large text documents.

The following methods are available on instances of the BigText data type.

METHOD NAME	DESCRIPTION
AddText(String [, Integer])	Adds a text string to a BigText variable.
AddText(BigText [, Integer])	Adds a text string to a BigText variable.
GetSubText(var Text, Integer [, Integer])	Gets part of a BigText variable.
GetSubText(var BigText, Integer [, Integer])	Gets part of a BigText variable.
Length()	Retrieves the length of the text stored in this BigText instance.
Read(InStream)	Streams a BigText object that is stored as a BLOB in a table to a BigText variable.
TextPos(String)	Gets the position at which a specific string first occurs in this BigText instance.
Write(OutStream)	Streams a BigText object to a BLOB field in a table.

Remarks

This data type cannot be shown in a message window or be seen in the Debugger. The maximum length of a BigText variable is 2,147,483,647 characters and this corresponds to 2 GB. You can use the BigText methods to manipulate a BigText variable, for example to extract part of a BigText variable or to add a text string to a BigText variable. The normal string methods cannot be used with a BigText variable.

Developing Extensions

BigText.AddText Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Adds a text string to a BigText variable.

Syntax

```
BigText.AddText(String: String [, Position: Integer])
```

Parameters

BigText Type: BigText An instance of the BigText data type.

String
Type: String
The string that will be added to the BigText variable. If this parameter is empty, then the BigText variable is not modified.

Position
Type: Integer
This is an optional parameter that defines the position in the BigText variable where the string is inserted. If this parameter is omitted, then the string is added at the end of the BigText variable. If this parameter is less than one, then a run-time error occurs. If this parameter is greater than the length of the BigText variable, then the string is added at the end of the BigText variable.

Remarks

Variable can be inserted anywhere in *BigText* or added at the end of the *BigText*.

The first character in a *BigText* variable is position 1.

To delete the content in a *BigText* variable, use the Clear Method. The following code shows the syntax for the method: `Clear(BigText)`

> **NOTE**
> If you use AddText to add multiple BigText strings to what is presented as a single string, you can experience performance problems. The same applies to other repetitive uses of AddText. This is due to the implementation of the BigText data type, which relies on a String object that is immutable. You can avoid this issue by refactoring the code to reduce the number of additions or deletions. Alternatively, you can change your implementation to use the System.Text.StringBuilder class instead. For more information, see Immutability and the StringBuilder Class in the MSDN Library.

Example 1

The following examples show how to use the AddText method. The specified text is inserted into the BigText string at the specified position. In these examples, the initial content of the *BigText* variable is `ABCDEFG`. These examples require that you create the following variable.

```
var
    MyBigText: BigText;
```

The following example inserts the string 'ZZZ' after the character B in the MyBigText variable because 3 is specified for *Position*.

```
// Example 1
MyBigText.AddText('ABCDEFG');
MyBigText.AddText('ZZZ', 3); // Returns the subtext ABZZZCDEFG.
```

Example 2

The following example appends the string 'ZZZ' at the end of the MyBigText variable because the number specified for *Position* is greater than the length of the MyBigText variable.

```
// Example 2
MyBigText.AddText('ABCDEFG');
MyBigText.AddText('ZZZ', 15); // Returns the subtext ABCDEFGZZZ.
```

Example 3

In the following example, the content of the MyBigText variable is unchanged because the specified variable is an empty string.

```
// Example 3
MyBigText.AddText('ABCDEFG');
MyBigText.AddText('', 1); // Returns the subtext ABCDEFG.
```

Example 4

In the following example, the method returns an error because 0 is specified for *Position*.

```
// Example 4
MyBigText.AddText('ABCDEFG');
MyBigText.AddText('ZZZ', 0); // Returns an error.
```

BigText.AddText Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Adds a text string to a BigText variable.

Syntax

```
BigText.AddText(String: BigText [, Position: Integer])
```

Parameters

BigText Type: BigText An instance of the BigText data type.

String
Type: BigText
The string that will be added to the BigText variable. If this parameter is empty, then the BigText variable is not modified.

Position
Type: Integer
This is an optional parameter that defines the position in the BigText variable where the string is inserted. If this parameter is omitted, then the string is added at the end of the BigText variable. If this parameter is less than one, then a run-time error occurs. If this parameter is greater than the length of the BigText variable, then the string is added at the end of the BigText variable.

Remarks

Variable can be inserted anywhere in *BigText* or added at the end of the *BigText*.

The first character in a *BigText* variable is position 1.

To delete the content in a *BigText* variable, use the Clear Method. The following code shows the syntax for the method: `Clear(BigText)`

> **NOTE**
> If you use AddText to add multiple BigText strings to what is presented as a single string, you can experience performance problems. The same applies to other repetitive uses of AddText. This is due to the implementation of the BigText data type, which relies on a String object that is immutable. You can avoid this issue by refactoring the code to reduce the number of additions or deletions. Alternatively, you can change your implementation to use the System.Text.StringBuilder class instead. For more information, see Immutability and the StringBuilder Class in the MSDN Library.

Example 1

The following examples show how to use the AddText method. The specified text is inserted into the BigText string at the specified position. In these examples, the initial content of the *BigText* variable is `ABCDEFG`. These examples require that you create the following variable.

```
var
    MyBigText: BigText;
```

The following example inserts the string 'ZZZ' after the character B in the MyBigText variable because 3 is specified for *Position*.

```
// Example 1
MyBigText.AddTEXT('ABCDEFG');
MyBigText.AddTEXT('ZZZ', 3); // Returns the subtext ABZZZCDEFG.
```

Example 2

The following example appends the string 'ZZZ' at the end of the MyBigText variable because the number specified for *Position* is greater than the length of the MyBigText variable.

```
// Example 2
MyBigText.AddText('ABCDEFG');
MyBigText.AddText('ZZZ', 15); // Returns the subtext ABCDEFGZZZ.
```

Example 3

In the following example, the content of the MyBigText variable is unchanged because the specified variable is an empty string.

```
// Example 3
MyBigText.AddText('ABCDEFG');
MyBigText.AddText('', 1); // Returns the subtext ABCDEFG.
```

Example 4

In the following example, the method returns an error because 0 is specified for *Position*.

```
// Example 4
MyBigText.AddText('ABCDEFG');
MyBigText.AddText('ZZZ', 0); // Returns an error.
```

BigText.GetSubText Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Gets part of a BigText variable.

Syntax

```
[Length := ]  BigText.GetSubText(var Variable: Text, Position: Integer [, Length: Integer])
```

Parameters

BigText Type: BigText An instance of the BigText data type.

Variable
Type: Text
The sub text of the BigText that is retrieved. This is the actual text that is returned.

Position
Type: Integer
The position in the BigText variable that the sub text is to be retrieved from. If this parameter is less than one, then a run-time error occurs. If this parameter is greater than the length of the BigText variable, then an empty string is returned. If the value of this parameter plus the value of the Length parameter is greater than the length of the BigText variable, then the remainder of the BigText variable from the position specified by this parameter is returned.

Length
Type: Integer
The length of the sub text that should be retrieved. This parameter is optional. If this parameter is omitted the function retrieves a sub text that starts at Position and runs to the end of the BigText variable. If this parameter is less than 0, then a run-time error occurs. If the value of the Position parameter plus the value of this parameter is greater than the length of the BigText variable, then the remainder of the BigText variable from the position specified by this parameter is returned.

Return Value

Length Type: Integer The length of the result text.

Remarks

The first character in a BigText variable is position 1.

To delete the content in a BigText variable use the Clear Method. The following code snippet shows the syntax for the clear method. `Clear(BigText)`.

Example 1

The following examples demonstrate how to use the GetSubText method. This example requires that you create

the following global variables and text constant.

```
var
    MyBigText: BigText;
    VarSubText: Text;
    Text000: Label 'VarSubText = %1';
```

The following example initializes the content of the MyBigText variable with the text `ABCDEFG`. The method starts from the third position (the character C) in the MyBigText variable and retrieves two characters. The result is the subtext CD. This is because the number 2 is specified for *Length* .

```
MyBigText.AddText('ABCDEFG');
MyBigText.GetSubText(VarSubText, 3, 2); // Returns CD.
Message(Text000, VarSubText);
```

Example 2

The following example initializes the content of the MyBigText variable with the text `ABCDEFG`. The method returns an error because zero is specified for *Position*.

```
MyBigText.AddText('ABCDEFG');
MyBigText.GetSubText(VarSubText, 0, 4); // Returns an error.
Message(Text000, VarSubText);
```

Example 3

The following example initializes the content of the MyBigText variable with the text `ABCDEFG`. The method returns an error because a negative number is specified for *Length*.

```
MyBigText.AddText('ABCDEFG');
MyBigText.GetSubText(VarSubText, 5, -2); // Returns an error.
Message(Text000, VarSubText);
```

Example 4

The following example initializes the content of the MyBigText variable with the text `ABCDEFG`. The method returns an empty string because the number specified for *position* is greater than the length of the MyBigText variable.

```
MyBigText.AddText('ABCDEFG');
MyBigText.GetSubText(VarSubText, 15, 4); // Returns an empty string.
Message(Text000, VarSubText);
```

Example 5

The following example initializes the content of the MyBigText variable with the text `ABCDEFG`. The method starts from the forth position (the character D) and retrieves all the characters in the MyBigText string. The result is the subtext DEFG. This is because the number specified for *Length* is greater than the length of the MyBigText variable.

```
MyBigText.AddText('ABCDEFG');
MyBigText.GetSubText(VarSubText, 4, 15); // Returns DEFG.
Message(Text000, VarSubText);
```

BigText.GetSubText Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Gets part of a BigText variable.

Syntax

```
[Length := ]  BigText.GetSubText(var Variable: BigText, Position: Integer [, Length: Integer])
```

Parameters

BigText Type: BigText An instance of the BigText data type.

Variable

Type: BigText

The sub text of the BigText that is retrieved. This is the actual text that is returned.

Position

Type: Integer

The position in the BigText variable that the sub text is to be retrieved from. If this parameter is less than one, then a run-time error occurs. If this parameter is greater than the length of the BigText variable, then an empty string is returned. If the value of this parameter plus the value of the Length parameter is greater than the length of the BigText variable, then the remainder of the BigText variable from the position specified by this parameter is returned.

Length

Type: Integer

The length of the sub text that should be retrieved. This parameter is optional. If this parameter is omitted the method retrieves a sub text that starts at Position and runs to the end of the BigText variable. If this parameter is less than 0, then a run-time error occurs. If the value of the Position parameter plus the value of this parameter is greater than the length of the BigText variable, then the remainder of the BigText variable from the position specified by this parameter is returned.

Return Value

Length Type: Integer The length of the result text.

Remarks

The first character in a BigText variable is position 1.

To delete the content in a BigText variable use the Clear Method. The following code snippet shows the syntax for the clear method. `Clear(BigText)`.

Example 1

The following examples demonstrate how to use the GetSubText method. This example requires that you create

the following global variables and text constant.

```
var
    MyBigText: BigText;
    VarSubText: Text;
    Text000: Label 'VarSubText = %1';
```

The following example initializes the content of the MyBigText variable with the text `ABCDEFG`. The method starts from the third position (the character C) in the MyBigText variable and retrieves two characters. The result is the subtext CD. This is because the number 2 is specified for *Length* .

```
MyBigText.AddText('ABCDEFG');
MyBigText.GetSubText(VarSubText, 3, 2); // Returns CD.
Message(Text000, VarSubText);
```

Example 2

The following example initializes the content of the MyBigText variable with the text `ABCDEFG`. The method returns an error because zero is specified for *Position*.

```
MyBigText.AddText('ABCDEFG');
MyBigText.GetSubText(VarSubText, 0, 4); // Returns an error.
Message(Text000, VarSubText);
```

Example 3

The following example initializes the content of the MyBigText variable with the text `ABCDEFG`. The method returns an error because a negative number is specified for *Length*.

```
MyBigText.AddText('ABCDEFG');
MyBigText.GetSubText(VarSubText, 5, -2); // Returns an error.
Message(Text000, VarSubText);
```

Example 4

The following example initializes the content of the MyBigText variable with the text `ABCDEFG`. The method returns an empty string because the number specified for *position* is greater than the length of the MyBigText variable.

```
MyBigText.AddText('ABCDEFG');
MyBigText.GetSubText(VarSubText, 15, 4); // Returns an empty string.
Message(Text000, VarSubText);
```

Example 5

The following example initializes the content of the MyBigText variable with the text `ABCDEFG`. The method starts from the forth position (the character D) and retrieves all the characters in the MyBigText string. The result is the subtext DEFG. This is because the number specified for *Length* is greater than the length of the MyBigText variable.

```
MyBigText.AddText('ABCDEFG');
MyBigText.GetSubText(VarSubText, 4, 15); // Returns DEFG.
Message(Text000, VarSubText);
```

BigText.Length Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Retrieves the length of the text stored in this BigText instance.

Syntax

```
Length :=   BigText.Length()
```

> **NOTE**
> This method can be invoked using property access syntax.

Parameters

BigText Type: BigText An instance of the BigText data type.

Return Value

Length Type: Integer The length of the text stored in this BigText instance.

Remarks

To delete the content in a BigText variable use the Clear Method. The syntax for the Clear method is shown in the following code snippet: `Clear(BigText)`.

Example

The following example demonstrates how to retrieve the length of a BigText variable.

In this example, the BigText variable is initialized with the text 'ABCDEFG'. The length, which is 7, is stored in the VarLength variable and displayed in a message box.

```
var
    MyBigText: BigText;
    VarLength: Text;
    Text000: Label 'VarLength = %1';
begin
    MyBigText.AddText('ABCDEFG');
    VarLength := MyBigText.Length;
    Message(Text000, VarLength);
end;
```

BigText.Read Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Streams a BigText object that is stored as a BLOB in a table to a BigText variable.

Syntax

```
[Ok := ]  BigText.Read(InStream: InStream)
```

Parameters

BigText Type: BigText An instance of the BigText data type.

InStream
Type: InStream
The InStream object type that you use to stream a BLOB to a BigText variable.

Return Value

Ok Type: Boolean **true** if the read transaction was successful, otherwise **false**.

Remarks

To delete the content in a BigText variable, use the Clear Method.

```
Clear(BigText)
```

Example

This example shows how to stream a BigText that is stored as a BLOB in a table to a BigText variable.

```
var
    Bstr: BigText;
    Istream: InStream;
    EmployeeRec: Record Employee;
begin
    EmployeeRec.Find('-');
    EmployeeRec.CalcFields(Picture);
    EmployeeRec.Picture.CreateInStream(Istream);
    Bstr.Read(Istream);
end;
```

Use the CalcFields Method (Record) to calculate the BlobField. A BlobField is a binary large object (maximum size 2 GB) and must be calculated if you want to use it in AL or display it in the application.

See Also

BigText.TextPos Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Gets the position at which a specific string first occurs in this BigText instance.

Syntax

```
Position :=   BigText.TextPos(String: String)
```

Parameters

BigText Type: BigText An instance of the BigText data type.

String
Type: String
The text string to search for in the BigText variable. If this parameter is empty, then 0 is returned.

Return Value

Position Type: Integer The position at which a specific string first occurs in this BigText instance.

Remarks

The first character in a *BigText* variable is position 1.

Example 1

The following examples show how to use the TextPos Method. These examples require that you create the following global variables and text constant.

```
var
    MyBigText: BigText;
    VarPosition: Text;
    Text000: Label 'VarPosition = %1';
```

The following examples first initialize the content of the *BigText* variable with the text `ABCDEFG`.

In this example, the first occurrence of the character B (the first character of the specified text) is found in the second position in the MyBigText variable so the method returns 2. The return value is stored in the variable VarPosition and displayed in a message box.

```
MyBigText.AddText('ABCDEFG');
VarPosition := MyBigText.TextPos('BCD'); // Returns 2.
Message(Text000, VarPosition);
```

Example 2

In the following example, the method returns 0 because the specified string is not found in the MyBigText variable. The return value is stored in the variable VarPosition and displayed in a message box.

```
MyBigText.AddText('ABCDEFG');
VarPosition := MyBigText.TextPos(''); // Returns 0.
Message(Text000, VarPosition);
```

Example 3

In the following example, the method returns 0 because the specified string is not found in the MyBigText variable. The return value is stored in the variable VarPosition and displayed in a message box.

```
MyBigText.AddText('ABCDEFG');
VarPosition := MyBigText.TextPos('XYZ'); // Returns 0.
Message(Text000, VarPosition);
```

BigText.Write Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Streams a BigText object to a BLOB field in a table.

Syntax

```
[Ok := ]  BigText.Write(OutStream: OutStream)
```

Parameters

BigText Type: BigText An instance of the BigText data type.

OutStream
Type: OutStream
The stream to which you write a BigText.

Return Value

Ok Type: Boolean **true** if the write transaction was successful, otherwise **false**.

Remarks

To delete the content in a BigText variable, use the Clear Method.

```
Clear(BigText)
```

Example

This example shows how to stream a BigText to a BLOB field in a table.

```
var
    Bstr: BigText;
    Ostream: OutStream;
    ItemRec: Record Item;
begin
    Bstr.AddText('This is the text string that we want to store in a BLOB field.');
    ItemRec.Picture.CreateOutStream(Ostream);
    Bstr.Write(Ostream);
    ItemRec.Insert;
end;
```

Blob Data Type

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Is a complex data type. Variables of this data type differ from normal numeric and string variables in that BLOBs have a variable length. The maximum size of a BLOB(binary large object) is 2 GB.

The following methods are available on instances of the Blob data type.

METHOD NAME	DESCRIPTION
CreateInStream(InStream [, TextEncoding])	Creates an InStream object for a binary large object (BLOB). This enables you to read data from the BLOB.
CreateOutStream(OutStream [, TextEncoding])	Creates an OutStream object for a binary large object (BLOB). This enables you to write data to the BLOB.
Export(String)	Exports a binary large object (BLOB) to a file.
HasValue()	Determines whether a binary large object (BLOB) has a value.
Import(String)	Imports a binary large object (BLOB) from a file.
Length()	Returns the number of bytes in the binary large object (BLOB).

Remarks

Use BLOBs to store memos (text), pictures (bitmaps), or user-defined types.

> **NOTE**
> You cannot view text that is stored in BLOBs from the development environment.

You can read from and write to BLOBs by creating input and output streams, respectively. To do so, use CreateInStream method (BLOB) and CreateOutStream method (BLOB).

Blob.CreateInStream Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Creates an InStream object for a binary large object (BLOB). This enables you to read data from the BLOB.

Syntax

```
Blob.CreateInStream(InStream: InStream [, Encoding: TextEncoding])
```

Parameters

Blob Type: Blob An instance of the Blob data type.

InStream
Type: InStream
The InStream object type that has been created.

Encoding
Type: TextEncoding
The encoding that will be used by the stream.

Optionally, you can specify the encoding on the stream. By specifying the File Handling and Text Encoding, you ensure that all the language-specific characters are represented correctly in Dynamics 365 when you read data and write data. The following example illustrates how you can set the encoding to Windows when you create a stream for a BLOB field.

```
MyTable.MyBLOBfield.CreateInStream(MyStream, TextEncoding::WINDOWS);
```

For more information, see File Handling and Text Encoding.

Blob.CreateOutStream Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Creates an OutStream object for a binary large object (BLOB). This enables you to write data to the BLOB.

Syntax

```
Blob.CreateOutStream(OutStream: OutStream [, Encoding: TextEncoding])
```

Parameters

Blob Type: Blob An instance of the Blob data type.

OutStream
Type: OutStream
The OutStream object type that has been created.

Encoding
Type: TextEncoding
The encoding that will be used by the stream.

Optionally, you can specify the encoding on the stream. By specifying the File Handling and Text Encoding, you ensure that all the language-specific characters are represented correctly in Dynamics 365 when you read data and write data. The following example illustrates how you can set the encoding to Windows when you create a stream for a BLOB field.

```
MyTable.MyBLOBfield.CreateOutStream(MyStream, TextEncoding::WINDOWS);
```

For more information, see File Handling and Text Encoding.

Blob.Export Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Exports a binary large object (BLOB) to a file.

Syntax

```
[ExportName := ]  Blob.Export(Name: String)
```

Parameters

Blob Type: Blob An instance of the Blob data type.

Name
Type: String
The path and name of the BLOB that you want to export. When you enter the path, consider these shortcuts:

- You can omit the drive letter if the command is located on the current drive.
- You can omit the full path if the command is located in the current directory.
- You can enter only the subdirectory name if the command is located in a subdirectory of the current directory.

Return Value

ExportName Type: String The name of the created file.

Blob.HasValue Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Determines whether a binary large object (BLOB) has a value.

Syntax

```
HasValue :=   Blob.HasValue()
```

NOTE

This method can be invoked using property access syntax.

Parameters

Blob Type: Blob An instance of the Blob data type.

Return Value

HasValue Type: Boolean **True** if the BLOB has a value; otherwise **false**.

See Also

Blob Data Type
Getting Started with AL
Developing Extensions

Blob.Import Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Imports a binary large object (BLOB) from a file.

Syntax

```
[ImportName := ]  Blob.Import(Name: String)
```

Parameters

Blob Type: Blob An instance of the Blob data type.

Name
Type: String
The path and name of the BLOB that you want to import. When you enter the path, consider the following shortcuts:

- You can omit the drive letter if the command is located on the current drive.
- You can omit the full path if the command is located in the current directory.
- You can enter only the subdirectory name if the command is located in a subdirectory of the current directory.

Return Value

ImportName Type: String The name of the imported file.

Byte Data Type

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Stores a single, 8-bit character as a value in the range 0 to 255. You can easily convert this data type from a number to a character and vice versa. This means you can use mathematical operators on Byte variables.

Example

The following example assumes that you have a Byte variable named B and a Text variable named S.

You can assign a constant string of the length 1 to a Byte variable, as shown in the first line of the following code example. You can assign a single character in a Text or Code variable to a Byte variable, as shown in the second line of the following code example. You can assign a numeric value to a Byte variable, as shown in the third line of the following code example. This causes the Byte variable to contain the character from the ASCII character set that corresponds to the numeric ASCII code.

```
B := 'A';
B := S[2];
B := 65;
```

You cannot assign a character to a position greater than the position of the null terminator. For example, if the value of the text variable *MyText* is 'abc', then the null terminator is at position 4 and the following assignment causes a run-time error to occur.

```
MyText[5] := 'e';
```

See Also

Getting Started with AL
Developing Extensions

Char Data Type

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Stores a single, 16-bit character as a value in the range 0 to 65535. You can convert this data type from a number to a character and vice versa. This means you can use mathematical operators on Char variables.

Example

The following example assumes that you have a Char variable named C and a Text or Code variable named S.

You can assign a constant string of the length 1 to a Char variable, as shown in the first line of the following code example. You can assign a single Char in a Text or Code variable to a Char variable, as shown in the second line of the following code example. You can assign a numeric value to a Char variable, as shown in the third line of the following code example.

```
C := 'A';
C := S[2];
C := 65;
```

You cannot assign a Char to a position greater than the position of the null terminator. For example, if the value of the Text variable *MyText* is 'abc', then the null terminator is at position 4 and the following assignment causes a run-time error to occur.

```
MyText[5] := 'e';
```

See Also

Getting Started with AL
Developing Extensions

Code Data Type

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Denotes a special type of string that is converted to uppercase and removes any trailing or leading spaces.

Remarks

The length of a Code variable equals the number of characters in the text without leading or trailing spaces.

You must specify the length of a Code variable or field. The maximum length of a Code variable is 1024 characters. The maximum length of a Code field in a table is 2048 characters. A Code variable cannot be null. The Code data type supports Unicode.

You can index any character position in a string, such as A[65]. The resulting value will be a Char Data Type. You cannot assign a char to a position in the code variable greater than the current length of the variable +1.

Fields that contain a date formula must not have data type Code. Instead, use the DateFormula Data Type. All fields that contain a date formula with data type Code must be converted into data type DateFormula.

Example

This example shows some typical examples of code string assignments. In these examples, assume that the variable c is a code variable with a maximum length of 4.

```
c := 'ABC';
// Results in variable c, which contains 'ABC'
// and is 3 characters in length.
c := '1';
// Results in variable c, which contains '1'
// and is 1 character in length.
c := '';
// Results in variable c, which contains '' (empty string)
// and is zero (0) characters in length.
c := ' 2 ';
// Results in variable c, which contains '2'
// and is 1 character in length.
```

Codeunit Data Type

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Is a container for AL code that you can use from other application objects.

The following methods are available on the Codeunit data type.

METHOD NAME	DESCRIPTION
Run(Integer [, var Record])	Loads and runs the unit of AL code you specify. To use this method, you can specify a table associated with the codeunit when you defined the codeunit properties. This allows you to pass a variable with the method. The transaction that the codeunit contains is always committed due to the Boolean return value.

The following methods are available on instances of the Codeunit data type.

METHOD NAME	DESCRIPTION
Run(var Record)	Loads and executes the unit of AL code that you specify.

Codeunit.Run Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Loads and runs the unit of AL code you specify. To use this method, you can specify a table associated with the codeunit when you defined the codeunit properties. This allows you to pass a variable with the method. The transaction that the codeunit contains is always committed due to the Boolean return value.

Syntax

```
[Ok := ]  Codeunit.Run(Number: Integer [, var Record: Record])
```

Parameters

Number

Type: Integer

An integer data type that identifies the unit of AL code. If the codeunit you specify does not exist, a run-time error occurs. If you run the codeunit with a record from a table other than the one it is associated with, a run-time error occurs.

Record

Type: Record

This optional parameter identifies a record. This parameter is a record data type.

Return Value

Ok Type: Boolean **true** if the operation was successful; otherwise **false**. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

Example

This example runs two codeunits. The first uses a record parameter. The second is defined without a source table.

```
var
    FiscalYearCloseInstance: Codeunit "Fiscal Year-Close";
    AppMgmtInstance: Codeunit ApplicationManagement;
    AccountRecord: Record "Accounting Period";
begin
    AccountRecord.Init;
    if not FiscalYearCloseInstance.Run(AccountRecord) then
      Error('Codeunit run failed (with record).');
    if not AppMgmtInstance.Run then
      Error('Codeunit run failed.');
end;
```

Codeunit.Run Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Loads and executes the unit of AL code that you specify.

Syntax

```
[Ok := ]  Codeunit.Run(var Record: Record)
```

Parameters

Codeunit Type: Codeunit An instance of the Codeunit data type.

Record
Type: Record
A record from the table that is associated with the codeunit.

Return Value

Ok Type: Boolean **true** if the operation was successful; otherwise **false**. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

CompanyProperty Data Type

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Provides language support for company properties.

The following methods are available on the CompanyProperty data type.

METHOD NAME	DESCRIPTION
DisplayName()	Gets the current company display name.
UrlName()	Gets the string that represents the company name in a URL.

See Also

Getting Started with AL
Developing Extensions

CompanyProperty.DisplayName Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Gets the current company display name.

Syntax

```
DisplayName :=   CompanyProperty.DisplayName()
```

Return Value

DisplayName Type: String The display name of the company as specified in the **Display Name** field in the **Company** table. If no display name is specified, the company name that is stored in the **Name** field is returned.

CompanyProperty.UrlName Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Gets the string that represents the company name in a URL.

Syntax

```
UrlName :=   CompanyProperty.UrlName()
```

Return Value

UrlName Type: String The company name in a URL.

Database Data Type

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Provides access to common database functionality.

The following methods are available on the Database data type.

METHOD NAME	DESCRIPTION
ChangeUserPassword(String, String)	Changes the password for the current user.
CheckLicenseFile(Integer)	Checks a key in the license file of the system.
Commit()	Ends the current write transaction.
CompanyName()	Gets the current company name.
CopyCompany(String, String)	Creates a new company and copies all data from an existing company in the same database.
CurrentTransactionType([TransactionType])	Gets the current transaction type and sets a new type to be assigned.
DataFileInformation(Boolean, var Text, var Text, var Boolean, var Boolean, var Boolean, var Text, var DateTime, var Record)	Specifies data from a file that has been exported from a database.
ExportData(Boolean, var Text [, String] [, Boolean] [, Boolean] [, Boolean] [, Record])	Exports data from the database to a file. The data is not deleted from the database.
GetDefaultTableConnection(TableConnectionType)	Gets the default table connection based on the specified connection type. You must already have registered a table connection of this type.
HasTableConnection(TableConnectionType, String)	Verifies if a connection to an external database exists based on the specified name.
ImportData(Boolean, var Text [, Boolean] [, Boolean] [, Record])	Imports data from a file that has been exported from a database.
LockTimeout([Boolean])	Determines whether the lock time-out setting is set to On. You can also use this method to override the default setting.
RegisterTableConnection(TableConnectionType, String, String)	Registers a table connection to an external database.
SelectLatestVersion()	Forces the latest version of the database to be used.
SerialNumber()	Gets a string that contains the serial number of the license file for your system.

METHOD NAME	DESCRIPTION
ServiceInstanceId()	Gets the ID of the service instance.
SessionId()	Gets the ID of the current session.
SetDefaultTableConnection(TableConnectionType, String [, Boolean])	Establishes a connection to an external database based on a previously registered connection of the specified type.
SetUserPassword(Guid, String)	Sets a password for the user iwith the given user security ID. If the given password is blank, an empty string will be stored instead of a password hash. This will prevent the user from logging in using a password. Only SUPER can call this method. Passwords cannot be set for the empty GUID or for the default Super ID.
SID([String])	Retrieves the security identifier (SID) of a Windows user account.
TenantId()	Gets the ID of the tenant that has started the current session. Use this method when your code must be specific about which tenant database to access in a multitenant deployment. For example, if your code imports data into a cache, you can make a cache tenant-specific by using the tenant ID as a key. Also, if you want to write code that saves documents, you can include the tenant ID in the file name or location, for example. In those cases, you can use the TENANTID method in combination with the CompanyName method to identify the company and the tenant database.
UnregisterTableConnection(TableConnectionType, String)	Unregisters a table connection to an external database.
UserId()	Gets the user name of the user account that is logged on to the current session.
UserSecurityId()	Gets the unique identifier of the user that is logged on to the current session.

Database.ChangeUserPassword Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Changes the password for the current user.

> **NOTE**
> This method is supported only in Business Central on-premises.

Syntax

```
[Ok := ]  Database.ChangeUserPassword(OldPassword: String, NewPassword: String)
```

> **NOTE**
> This method can be invoked without specifying the data type name.

Parameters

OldPassword
Type: String
The old password for the user.

NewPassword
Type: String
The new password for the user.

Return Value

Ok Type: Boolean **true** if the operation was successful; otherwise **false**. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

See Also

Database Data Type

Developing Extensions

Database.CheckLicenseFile Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Checks a key in the license file of the system.

> **NOTE**
> This method is supported only in Business Central on-premises.

Syntax

```
Database.CheckLicenseFile(KeyNumber: Integer)
```

> **NOTE**
> This method can be invoked without specifying the data type name.

Parameters

KeyNumber
Type: Integer
The number of the key you want to check.

Remarks

The license file turns on or off different system capabilities. Use this method to check a key in the file for the current user. If the user has no access rights to the object, a message is displayed and the process is terminated.

If you omit this method, the user will have the ability to continue regardless of whether the appropriate license file is open.

Database.Commit Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Ends the current write transaction.

Syntax

```
Database.Commit()
```

> **NOTE**
> This method can be invoked without specifying the data type name.

Remarks

When a codeunit begins, it automatically enables write transactions to be performed. When an AL code module completes, it automatically ends the write transaction by committing the updates made by the AL code.

This means that if you want the codeunit to perform a single write transaction, it is automatically handled for you. However, if you want the codeunit to perform multiple write transactions, you must use the Commit method to end one write transaction before you can start the next. The COMMIT method separates write transactions in an AL code module.

Example

The following pseudo-code example contains two write transactions. When it begins, a write transaction is automatically started. Using the Commit method, you end the first write transaction and prepare for the second. When the code completes, the second write transaction automatically ends.

```
BeginWriteTransactions
(AL Statements) // Transaction 1
COMMIT
(AL Statements) // Transaction 2
EndWriteTransactions
```

Database.CompanyName Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Gets the current company name.

Syntax

```
Name :=   Database.CompanyName()
```

NOTE

This method can be invoked using property access syntax.

NOTE

This method can be invoked without specifying the data type name.

Return Value

Name Type: String The name of the company, or an empty string if no company has been selected.

Example

```
var
    CompName: Text[1024];
    Text000: Label 'The name is %1.';
begin
    CompName := CompanyName;
    Message(Text000, CompName);
end;
```

Developing Extensions

Database.CopyCompany Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Creates a new company and copies all data from an existing company in the same database.

Syntax

```
[Ok := ]  Database.CopyCompany(SourceName: String, DestinationName: String)
```

> **NOTE**
> This method can be invoked without specifying the data type name.

Parameters

SourceName
Type: String
The name of the company that you want to copy data from.

DestinationName
Type: String
The name of the company that you want to create and copy data to. The company name can have a maximum of 30 characters. If the database collation is case-sensitive, you can have one company called Company and another called Company. However, if the database is case-insensitive, you cannot create companies with names that differ only by case.

Return Value

Ok Type: Boolean **true** if the operation was successful; otherwise **false**. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

Remarks

Links and notes on records are not copied to the new company.

Example

The following example is based on the **Copy Company** batch job, which is part of the CRONUS. The batch job takes the Company system table as a data item and uses the **Name** field as the value of the *SourceName* parameter. The value of the *DestinationName* parameter is specified in the **New Company Name** field in the request page, which is represented by the `NewCompanyName` variable.

```
CopyCompany(Name, NewCompanyName);
```

Database.CurrentTransactionType Method

2/17/2021 • 3 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Gets the current transaction type and sets a new type to be assigned.

Syntax

```
[TransactionType := ]  Database.CurrentTransactionType([TransactionType: TransactionType])
```

NOTE

This method can be invoked using property access syntax.

NOTE

This method can be invoked without specifying the data type name.

Parameters

TransactionType

Type: TransactionType

The type of transaction to be set for the next transaction.

Return Value

TransactionType Type: TransactionType The type of transaction for the next transaction.

Remarks

This method sets the transaction type for the next transaction that starts when you are using Microsoft SQL Server. The transaction type determines the extent of locking that is performed on data in SQL Server tables and indexes. It also determines whether modifications to data can occur within the transaction. The following basic transaction types are available:

- Browse
- Snapshot
- UpdateNoLocks
- Update
- Report

The Report transaction type maps to one of the other basic transaction types. For more information about the behavior of the transaction types, see TransactionType Property.

Using CurrentTransactionType to set a transaction type from within a currently active transaction does not affect the transaction type. You must set the transaction type before a transaction starts, which occurs at the first

database call in a trigger or in a codeunit. If you set the current transaction type to a less isolated transaction behavior, for example, if you try to change an Update transaction to a Browse transaction, the method call is ignored. If you try to change the current transaction type to a more isolated transaction behavior, for example, from Browse to Update, you will receive an error message.

Example 1

In Example 1, CurrentTransactionType is used to set the required behavior of the next transaction in the database.

```
//Example 1
CurrentTransactionType := TransactionType::UpdateNoLocks;
```

Example 2

In Example 2, CurrentTransactionType is used to return the transaction type setting for the current transaction.

```
//Example 2
if CurrentTransactionType = TransactionType::UpdateNoLocks then...
```

Example 3

Examples 3 and 4 show how to use the CurrentTransactionType method to set the transaction type for two separate transactions.

When you set the transaction type as in Example 3, you will get an update (or write) transaction using Serializable behavior, which means that modifications are allowed within this transaction. SQL Server will guarantee the serializability of the transaction by placing the appropriate locks when you read from the table in the database.

```
//Example 3
CurrentTransactionType := TransactionType::Update;
```

Example 4

Examples 3 and 4 show how to use the CurrentTransactionType method to set the transaction type for two separate transactions.

When you set the transaction type as in Example 4, you will get a read-only, non-locking transaction. This means that no modifications are allowed within this transaction and that SQL Server does not add any locks. It is also possible to read any uncommitted data.

```
//Example 4
CurrentTransactionType := TransactionType::Browse;
```

Example 5

In Example 5, the initial transaction type is UpdateNoLocks. This is usually the default transaction type for a trigger. When you try to change the transaction type from UpdateNoLocks to Browse, which is a less isolated transaction type, the method call is ignored. The current transaction type remains UpdateNoLocks. After the first Table.Get line, again, when you try to change the transaction type from UpdateNoLocks to Browse, the method

call is ignored. The current transaction type remains UpdateNoLocks. Next, when you try to change the transaction type from UpdateNoLocks to Update, which is a more isolated transaction type, the method call causes an error message to be generated. The current transaction type remains UpdateNoLocks. After the Commit Method, you can set a new transaction type and change it again if it is required. After the second Table.Get line, the CurrentTransactionType method call is ignored. The transaction type remains Update.

```
//Example 5
OnInsert
CurrentTransactionType := TransactionType::Browse;
Table.Get;
CurrentTransactionType := TransactionType::Browse;
CurrentTransactionType := TransactionType::Update;
Commit;
CurrentTransactionType := TransactionType::Browse;
CurrentTransactionType := TransactionType::Update;
Table.Get;
CurrentTransactionType := TransactionType::Browse;
OnInsert.RETURN
Commit;
```

Example 6

In Example 6, the initial transaction type is UpdateNoLocks. The first two times that you try to change to a less isolated transaction type, the method call is ignored. Finally, when you try to change to a more isolated transaction type, the method call causes an error message to be generated.

```
//Example 6
CodeUnit
CurrentTransactionType := TransactionType::Snapshot;
Report 1
CurrentTransactionType := TransactionType::Browse;
Report 2
CurrentTransactionType := TransactionType::Update;
```

Database.DataFileInformation Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Specifies data from a file that has been exported from a database.

> **NOTE**
> This method is supported only in Business Central on-premises.

Syntax

```
[Ok := ]  Database.DataFileInformation(ShowDialog: Boolean, var FileName: Text, var Description: Text, var
HasApplication: Boolean, var HasApplicationData: Boolean, var HasGlobalData: Boolean, var tenantId: Text,
var exportDate: DateTime, var CompanyRecord: Record)
```

> **NOTE**
> This method can be invoked without specifying the data type name.

Parameters

ShowDialog
Type: Boolean
Specifies if you want to display a dialog box where the user can confirm the action.

FileName
Type: Text
Specifies the name and location of the file that you want to read information from. The file must have been exported from a database.

Description
Type: Text

HasApplication
Type: Boolean
Specifies if the file contains application objects. Create a variable of type Boolean to specify this parameter.

HasApplicationData
Type: Boolean
Specifies if the file contains the data that defines the application in the database. This includes the permissions, permission sets, profiles, and style sheets. Create a variable of type Boolean to specify this parameter.

HasGlobalData
Type: Boolean
Specifies if the file contains global, non-company specific data. Create a variable of type Boolean to specify this parameter.

tenantId

Type: Text

Specifies the tenant ID of the database that the data was exported from. Create a variable of type Text to specify this parameter.

exportDate

Type: DateTime

Specifies the date and time when the data was exported. Create a variable of type DateTime to specify this parameter.

CompanyRecord

Type: Record

Specifies the company or companies in the file.

Return Value

Ok Type: Boolean **true** if the operation was successful; otherwise **false**. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

Database.ExportData Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Exports data from the database to a file. The data is not deleted from the database.

> **NOTE**
> This method is supported only in Business Central on-premises.

Syntax

```
[Ok := ]  Database.ExportData(ShowDialog: Boolean, var FileName: Text [, Description: String] [,
IncludeApplication: Boolean] [, IncludeApplicationData: Boolean] [, IncludeGlobalData: Boolean] [,
CompanyRecord: Record])
```

> **NOTE**
> This method can be invoked without specifying the data type name.

Parameters

ShowDialog
Type: Boolean
Specifies if you want to display a dialog box where the user can confirm the action.

FileName
Type: Text
Specifies the name and location of the file that the data must be exported to. The file must have the .navdata extension.

Description
Type: String
Specifies a description for the exported data.

IncludeApplication
Type: Boolean
Specifies if you want to export the application objects. Create a variable of type Boolean to specify this parameter.

IncludeApplicationData
Type: Boolean
Specifies if you want to export the data that defines the application in the database. This includes the permissions, permission sets, profiles, and style sheets. Create a variable of type Boolean to specify this parameter.

IncludeGlobalData
Type: Boolean

Specifies if you want to export global, non-company specific data. Create a variable of type Boolean to specify this parameter.

CompanyRecord
Type: Record
Specifies the company or companies that must be imported.

Return Value

Ok Type: Boolean **true** if the operation was successful; otherwise **false**. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

Database.GetDefaultTableConnection Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Gets the default table connection based on the specified connection type. You must already have registered a table connection of this type.

Syntax

```
Name :=   Database.GetDefaultTableConnection(Type: TableConnectionType)
```

> **NOTE**
> This method can be invoked without specifying the data type name.

Parameters

Type
Type: TableConnectionType
The type of table connection as defined in the TableType property.

Return Value

Name Type: String

See Also

Database Data Type
Getting Started with AL
Developing Extensions

Database.HasTableConnection Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Verifies if a connection to an external database exists based on the specified name.

Syntax

```
Ok :=   Database.HasTableConnection(Type: TableConnectionType, Name: String)
```

> **NOTE**
> This method can be invoked without specifying the data type name.

Parameters

Type
Type: TableConnectionType
Specifies the type of table connection as defined in the TableType property.

Name
Type: String
The name of the external table connection. You must already have registered a table connection with this name.

Return Value

Ok Type: Boolean **true** if a connection to an external database exists for the specified name, otherwise **false**.

See Also

Developing Extensions

Database.ImportData Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Imports data from a file that has been exported from a database.

> **NOTE**
> This method is supported only in Business Central on-premises.

Syntax

```
[Ok := ]  Database.ImportData(ShowDialog: Boolean, var FileName: Text [, IncludeApplicationData: Boolean] [,
IncludeGlobalData: Boolean] [, CompanyRecord: Record])
```

> **NOTE**
> This method can be invoked without specifying the data type name.

Parameters

ShowDialog
Type: Boolean
Specifies if you want to display a dialog box where the user can confirm the action.

FileName
Type: Text
Specifies the name and location of the file that must be imported. The file must have been exported from a database .
IncludeApplicationData
Type: Boolean

Specifies if you want to import the data that defines the application in the database. This includes the permissions, permission sets, profiles, and style sheets. Create a variable of type Boolean to specify this parameter. To import application objects, you must use the Import-NAVData Windows PowerShell cmdlet.

IncludeGlobalData
Type: Boolean

Specifies if you want to import global, non-company specific data. Create a variable of type Boolean to specify this parameter.

CompanyRecord
Type: Record
Specifies the company or companies that must be imported.

Return Value

Ok Type: Boolean **true** if the operation was successful; otherwise **false**. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

Database.LockTimeout Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Determines whether the lock time-out setting is set to On. You can also use this method to override the default setting.

Syntax

```
[LockTimeout := ]  Database.LockTimeout([LockTimeout: Boolean])
```

NOTE

This method can be invoked using property access syntax.

NOTE

This method can be invoked without specifying the data type name.

Parameters

LockTimeout

Type: Boolean

The new setting for whether the lock time-out is on.

Return Value

LockTimeout Type: Boolean This value shows whether to use a lock time-out.

Remarks

This method has been designed specifically for use in long-running processes that should not be terminated because of a lock time-out, for example batch jobs that run overnight.

When the AL code has finished running, the default setting is used again. This method does not change the duration of a lock time-out.

Database.RegisterTableConnection Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Registers a table connection to an external database.

Syntax

```
Database.RegisterTableConnection(Type: TableConnectionType, Name: String, Connection: String)
```

> **NOTE**
> This method can be invoked without specifying the data type name.

Parameters

Type

Type: TableConnectionType

Specifies the type of table connection as defined in the TableType property.

Name

Type: String

Specifies the name of the connection in your code, or the name of the primary key field on the table.

Connection

Type: String

Specifies the connection to the external database.

See Also

Database Data Type
Getting Started with AL
Developing Extensions

Database.SelectLatestVersion Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Forces the latest version of the database to be used.

Syntax

```
Database.SelectLatestVersion()
```

> **NOTE**
> This method can be invoked without specifying the data type name.

Remarks

This method makes sure that the data displayed is the most current data in the database. The method clears all non-locked records from the client cache, thereby ensuring that you read the most recent data. The method also clears the current client session's cache for the CaptionClassTranslate strings. The strings will then be reevaluated by the **CaptionClassTranslate** method trigger in codeunit 42.

> **WARNING**
> Clearing the cache and reading data directly from the database adversely affects performance.

Developing Extensions

Database.SerialNumber Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Gets a string that contains the serial number of the license file for your system.

Syntax

```
String :=   Database.SerialNumber()
```

NOTE

This method can be invoked using property access syntax.

NOTE

This method can be invoked without specifying the data type name.

Return Value

String Type: String The serial number.

Example

```
var
    SN: Text[30];
    Text000: Label 'The serial number for this software package is:%1.';
begin
    SN := SerialNumber;
    Message(Text000, SN);
end;
```

The output of this example is as follows:

The serial number for this software package is:

W1-ZA-002-6R75A-7

NOTE

The serial number depends on your licensed version of Dynamics 365. The serial number shown here is an example.

Database.SetDefaultTableConnection Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Establishes a connection to an external database based on a previously registered connection of the specified type.

Syntax

```
Database.SetDefaultTableConnection(Type: TableConnectionType, Name: String [, Scoped: Boolean])
```

> **NOTE**
> This method can be invoked without specifying the data type name.

Parameters

Type
Type: TableConnectionType
The type of table connection as defined in the TableType property.

Name
Type: String
The name of the external table connection. You must already have registered a table connection with this name.

Scoped
Type: Boolean
If true, when the method ends where you have used SETDEFAULTTableCONNECTION, the default table connection returns to the value it had before. Use the Scope parameter when you want to use a specific table connection for a specific task and then return to the normal configuration.

Database.SetUserPassword Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Sets a password for the user iwith the given user security ID. If the given password is blank, an empty string will be stored instead of a password hash. This will prevent the user from logging in using a password. Only SUPER can call this method. Passwords cannot be set for the empty GUID or for the default Super ID.

> **NOTE**
> This method is supported only in Business Central on-premises.

Syntax

```
[Ok := ]  Database.SetUserPassword(USID: Guid, Password: String)
```

> **NOTE**
> This method can be invoked without specifying the data type name.

Parameters

USID
Type: Guid
User security ID of the user for which to set the password.

Password
Type: String
The password to set for the user.

Return Value

Ok Type: Boolean **true** if the operation was successful; otherwise **false**. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

Database.SID Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Retrieves the security identifier (SID) of a Windows user account.

> **NOTE**
> This method is supported only in Business Central on-premises.

Syntax

```
SID :=   Database.SID([UserAccount: String])
```

> **NOTE**
> This method can be invoked without specifying the data type name.

Parameters

UserAccount
Type: String
The Windows user account for which you want to get the SID. You must specify a domain and user name, such as 'cronus\simon'.

Return Value

SID Type: String The SID of the specified Windows user account.

Remarks

If you create a page for adding Windows logins, then you must use the SID method to retrieve the SID for the user account so that you can enter the new login into the Windows Login table.

This method runs only on the computer that is running Dynamics 365 Business Central service. If you call this method from the client computer, then no action occurs.

Example

```
var
    NewSID: Text[119];
    UserAccount: Text[132];
begin
    UserAccount := 'cronus\simon';
    NewSID := SID(UserAccount);
end;
```

Database.TenantId Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Gets the ID of the tenant that has started the current session. Use this method when your code must be specific about which tenant database to access in a multitenant deployment. For example, if your code imports data into a cache, you can make a cache tenant-specific by using the tenant ID as a key. Also, if you want to write code that saves documents, you can include the tenant ID in the file name or location, for example. In those cases, you can use the TENANTID method in combination with the CompanyName method to identify the company and the tenant database.

Syntax

```
ID :=   Database.TenantId()
```

> **NOTE**
> This method can be invoked without specifying the data type name.

Return Value

ID Type: String The ID of the tenant that has started the current session.

Database.UnregisterTableConnection Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Unregisters a table connection to an external database.

Syntax

```
Database.UnregisterTableConnection(Type: TableConnectionType, Name: String)
```

> **NOTE**
> This method can be invoked without specifying the data type name.

Parameters

Type

Type: TableConnectionType

Specifies the type of table connection as defined in the TableType property. If the table is of type ExternalSQL, UNREGISTERTableCONNECTION rolls back the current transaction.

Name

Type: String

Specifies the name of the connection in your code, or the name of the primary key field on the table.

Database.UserId Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Gets the user name of the user account that is logged on to the current session.

Syntax

```
ID :=   Database.UserId()
```

NOTE

This method can be invoked using property access syntax.

NOTE

This method can be invoked without specifying the data type name.

Return Value

ID Type: String This string contains the value of the User Name field in table 2000000120, the User table, for the current user.

Example

```
User := UserId;
Message('The system was started by %1', User);
```

The following is an example of the output of the previous code:

The system was started by cronus\simon.

Database.UserSecurityId Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Gets the unique identifier of the user that is logged on to the current session.

Syntax

```
USID :=   Database.UserSecurityId()
```

NOTE

This method can be invoked without specifying the data type name.

Return Value

USID Type: Guid The ID that is assigned to the user by the application. This is the value of the User Security ID field in table 2000000120, the User table, for the current user.

Date Data Type

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Denotes a date ranging from January 1, 1753 to December 31, 9999.

The displayed text format of the date is determined by your Region and Language Format setting in Windows.

Undefined dates

An undefined or blank date is specified by 0D. The undefined date is considered to be before all other dates.

Normal dates and closing dates

All normal dates have a corresponding closing date. The closing date for a given date is defined as a period of time that follows a given normal date and precedes the next normal date.

Syntax

The syntax for defining DateTime format follows the ISO standard.

- The syntax for defining Date format is `yyyymmddD`, where `D` is a mandatory letter. For example, `20180325D`, read as the 25th of March, 2018.

To assign a normal date to a variable, use the following format: `yyyymmddD`.

Storing dates in the SQL server database

SQL Server stores information about both date and time in columns of the DateTime types. For date fields, Dynamics 365 Business Central uses only the date and uses a constant value for the time. For a normal date, this constant value contains 00:00:00:000. For a closing date, it contains 23:59:59:000.

The Dynamics 365 Business Central undefined date is represented by the earliest valid date in SQL Server. The earliest valid date in SQL Server for a DateTime is 01-01-1753 00:00:00:000.

If you store a date in the database that is outside the valid range for a SQL DateTime, a run-time error occurs.

Example

This example shows a valid assignment of date. This example is compiled and run on a computer with the regional format set to English (United States).

```
var
    Date1: Date;
begin
    Date1 := 20180612D;
    Message(Format(Date1));
end;
```

The message window displays the following:

06/12/2018

Getting Started with AL
Developing Extensions

DateFormula Data Type

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Represents a date formula that has the same capabilities as an ordinary input string for the CALCDATE Method (Date). The DateFormula data type is used to provide multilanguage capabilities to the CALCDATE Method (Date).

Remarks

When a date calculation formula is stored in a DateFormula field, it is converted to a generic, non-language dependent format. When a date calculation formula is retrieved from a DateFormula field, it is converted to a valid date conversion string for the currently selected language.

To assign a value to a DateFormula data type, whether it is a field or a variable, you must use the EVALUATE Method.

Example

This example requires that you create a DateFormulaVariable variable that is a DateFormula data type.

```
if Format(DateFormulaVariable) = ' ' then
  Evaluate(DateFormulaVariable, '1W');
```

You must use the Format Method to make a comparison with a text string. If you do not use this method, then the IF statement will fail because you cannot compare a DateFormula data type with a Text data type.

Developing Extensions

DateTime Data Type

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Denotes a date and time ranging from January 1, 1753, 00:00:00.000 to December 31, 9999, 23:59:59.999. An undefined or blank DateTime is specified by 0DT.

The displayed text format of a DateTime is determined by your Regional and Language Options in Windows.

Remarks

A DateTime is stored in the database as Coordinated Universal Time (UTC). UTC is the international time standard (formerly Greenwich Mean Time, or GMT). Zero hours UTC is midnight at 0 degrees longitude.

The DateTime is always displayed as local time in Dynamics 365 Business Central. Local time is determined by the time zone regional settings used by your computer. You must always enter DateTimes as local time. When you enter a DateTime as local time, it is converted to UTC using the current settings for the time zone and daylight savings time.

The DateTime data type does not support closing dates.

By default, DateTimes are displayed using the standard display format. When you use the standard display format, seconds and milliseconds are not displayed until you select the DateTime field. Furthermore, if you export your data using an XMLport or by writing it to a file, the seconds and milliseconds are not exported unless you specify that DateTime fields use another format and display this information. For more information about how DateTime objects are displayed and the formats that are available, see Format Property.

The only constant available when you use the DateTime data type is the undefined DateTime, 0DT. To assign a constant value to a DateTime variable you must use the CreateDateTime method.

If you use a date that is outside the valid date range, a run-time error occurs.

Syntax

The syntax for defining DateTime format follows the ISO standard.

- The syntax for defining Date format is `yyyymmddD`, where `D` is a mandatory letter. For example, `20180325D`, read as the 25th of March, 2018.
- The syntax for defining Time format is `hhmmssT`, where `T` is the time designator. For example, `093125H`, read as 9:13:25.

SQL Server

In SQL Server, the earliest permitted DateTime is January 1, 1753, 00:00:00.000. The latest permitted DateTime is December 31, 9999, 23:59:59.999. If you store a date in the database that is outside the valid range for a SQL DateTime, a runtime error occurs.

CurrentDateTime Method

Format Property

Debugger Data Type

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Enables communication with a debugger.

> **NOTE**
> This data type is supported only in Business Central on-premises.

The following methods are available on the Debugger data type.

METHOD NAME	DESCRIPTION
Activate()	Activates the debugger and attaches the debugger to the next session that is started.
Attach(Integer)	Activates the debugger and attaches it to the specified session.
Break()	Breaks code execution of a debugging session.
BreakOnError(Boolean)	Sets whether the debugger breaks on errors.
BreakOnRecordChanges(Boolean)	Breaks execution before a change to a record occurs.
Continue()	Executes code until the next breakpoint or until execution ends.
Deactivate()	Deactivates the debugger.
DebuggedSessionID()	Gets the ID of the previous session that the debugger was attached to.
DebuggingSessionID()	Gets the ID of the session that the debugger is currently attached to.
EnableSqlTrace(Integer [, Boolean])	Enables or verifies SQL tracing. If you enable SQL tracing, then SQL Server events for selected sessions on the server instance are collected.
GetLastErrorText()	Gets the last error that occurred in the debugger.
IsActive()	Indicates whether the debugger is active.
IsAttached()	Specifies if the debugger is attached to a session.
IsBreakpointHit()	Specifies if a breakpoint is hit in a debugging session.

METHOD NAME	DESCRIPTION
SkipSystemTriggers(Boolean)	Enables the debugger to skip code that is inside system triggers.
StepInto()	Executes a method call and then stops at the first line of code inside the method.
StepOut()	Enables debugging to return to the calling method after it steps into a method call.
StepOver()	Executes a method call and then stops at the first line outside the method call.
Stop()	Stops execution as if the code hits an error.

> **NOTE**
> The Dynamics 365 Business Central Debugger is an example of a debugger application that is built using tables, pages, codeunits, and the AL debugger methods.

Debugger.Activate Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0 until version 4.0 where it was deprecated.*

Activates the debugger and attaches the debugger to the next session that is started.

Syntax

```
[Ok := ]  Debugger.Activate()
```

Return Value

Ok Type: Boolean **true** if the operation was successful; otherwise **false**. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

See Also

Debugger Data Type
Getting Started with AL
Developing Extensions

Debugger.Attach Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0 until version 4.0 where it was deprecated.*

Activates the debugger and attaches it to the specified session.

Syntax

```
[Ok := ]  Debugger.Attach(SessionID: Integer)
```

Parameters

SessionID

Type: Integer

The ID of the session that you want to attach the debugger to.The session can be any of the following:

- Windows client
- Web client
- NAS services session
- SOAP web services client session
- OData web services client session
- Background session

Return Value

Ok Type: Boolean **true** if the operation was successful; otherwise **false**. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

Remarks

The **Attach** method behaves like the **Debug** action on the **Sessions** page. You can call the **Attach** method to activate the debugger.

Debugger.Break Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0 until version 4.0 where it was deprecated.*

Breaks code execution of a debugging session.

Syntax

```
[Ok := ]  Debugger.Break()
```

Return Value

Ok Type: Boolean **true** if the operation was successful; otherwise **false**. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

If you omit this optional return value and if the break is not set successfully, then a run-time error occurs. If you include the return value, then you must handle any errors.

Developing Extensions

Debugger.BreakOnError Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0 until version 4.0 where it was deprecated.*

Sets whether the debugger breaks on errors.

Syntax

```
[Ok := ]  Debugger.BreakOnError(Ok: Boolean)
```

Parameters

Ok

Type: Boolean

Specifies whether the debugger breaks on errors.

Return Value

Ok Type: Boolean **true** if the operation was successful; otherwise **false**. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

If you omit this optional return value and if the break is not set successfully, then a run-time error occurs. If you include the return value, then you must handle any errors.

Remarks

The debugger must be attached to a session when you run the BreakOnError method.

Example

This example shows how to implement the code for an action on a page that sets the break on error setting to **true**. You can use this code example in the OnAction trigger of that action. This code example requires that you create a Boolean variable named *Value*.

```
Value := true;
Debugger.BreakOnError(Value);
```

Debugger.BreakOnRecordChanges Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0 until version 4.0 where it was deprecated.*

Breaks execution before a change to a record occurs.

Syntax

```
[Ok := ]  Debugger.BreakOnRecordChanges(Ok: Boolean)
```

Parameters

Ok

Type: Boolean

Specifies whether the debugger should break execution when a change to a record occurs. If Ok is true, then the debugger breaks before creating, updating, or deleting a record.

Return Value

Ok Type: Boolean **true** if the operation was successful; otherwise **false**. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

If you omit this optional return value and if the break is not set successfully, then a run-time error occurs. If you include the return value, then you must handle any errors.

Debugger.Continue Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0 until version 4.0 where it was deprecated.*

Executes code until the next breakpoint or until execution ends.

Syntax

```
[Ok := ]  Debugger.Continue()
```

Return Value

Ok Type: Boolean **true** if the operation was successful; otherwise **false**. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

If you omit this optional return value and if the break is not set successfully, then a run-time error occurs. If you include the return value, then you must handle any errors.

Debugger.Deactivate Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0 until version 4.0 where it was deprecated.*

Deactivates the debugger.

Syntax

```
[Ok := ]  Debugger.Deactivate()
```

Return Value

Ok Type: Boolean **true** if the operation was successful; otherwise **false**. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

If you omit this optional return value and if the break is not set successfully, then a run-time error occurs. If you include the return value, then you must handle any errors.

Debugger.DebuggedSessionID Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0 until version 4.0 where it was deprecated.*

Gets the ID of the previous session that the debugger was attached to.

Syntax

```
SessionID :=   Debugger.DebuggedSessionID()
```

Return Value

SessionID Type: Integer

The session ID that the debugger is currently attached to.

See Also

Debugger Data Type

Developing Extensions

Debugger.EnableSqlTrace Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Enables or verifies SQL tracing. If you enable SQL tracing, then SQL Server events for selected sessions on the server instance are collected.

Syntax

```
[IsEnabled := ]  Debugger.EnableSqlTrace(SessionID: Integer [, NewIsEnabled: Boolean])
```

Parameters

SessionID

Type: Integer

The ID of the session for which you want to enable the SQL trace, or for which you want to verify if tracing is enabled.If you specify 0 and you specify the NewIsEnabled parameter, then tracing is enabled for all existing sessions and all new sessions on the current server instance. If you specify 0 and you omit the NewIsEnabled parameter, then the function returns true if tracing is enabled for new sessions on the current server instance. If the session ID that you specify does not exist and you specify the NewIsEnabled parameter, then a run-time error occurs. If the session ID that you specify does not exist and you do not specify the NewIsEnabled parameter, then the function returns false.

NewIsEnabled

Type: Boolean

If you specify the optional NewIsEnabled parameter, then the method sets whether tracing is enabled. true if you want to enable tracing for the specified session; false if you want to disable tracing. If you omit the NewIsEnabled parameter, then the function verifies if tracing is enabled.

Return Value

IsEnabled Type: Boolean

Remarks

You use Microsoft SQL Server Profiler to view traces. For more information, see Using SQL Server Profiler. To start SQL Server Profiler, in **SQL Server Management Studio**, on the **Tools** menu, choose **SQL Server Profiler**.

You can also enable and disable SQL tracing by using the **Start Full SQL Tracing** and **Stop Full SQL Tracing** buttons on the **Session List** page.

Debugger.GetLastErrorText Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0 until version 4.0 where it was deprecated.*

Gets the last error that occurred in the debugger.

Syntax

```
String :=   Debugger.GetLastErrorText()
```

Return Value

String Type: String The text string that was contained in the last error message that was generated by Microsoft Dynamics Business Central. If no error has occurred, then the function returns an empty string.

Debugger.IsActive Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0 until version 4.0 where it was deprecated.*

Indicates whether the debugger is active.

Syntax

```
Ok :=   Debugger.IsActive()
```

Return Value

Ok Type: Boolean

Remarks

When the debugger is activated, it is in one of the following states:

- Attached to a session.
- Waiting to attach to a session.

Debugger.SkipSystemTriggers Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0 until version 4.0 where it was deprecated.*

Enables the debugger to skip code that is inside system triggers.

Syntax

```
[Ok := ]  Debugger.SkipSystemTriggers(Ok: Boolean)
```

Parameters

Ok

Type: Boolean

Specifies if the debugger should skip system triggers.

Return Value

Ok Type: Boolean **true** if the operation was successful; otherwise **false**. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

If you omit this optional return value and if the break is not set successfully, then a run-time error occurs. If you include the return value, then you must handle any errors.

Debugger.StepInto Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0 until version 4.0 where it was deprecated.*

Executes a method call and then stops at the first line of code inside the method.

Syntax

```
[Ok := ]  Debugger.StepInto()
```

Return Value

Ok Type: Boolean **true** if the operation was successful; otherwise **false**. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

If you omit this optional return value and if the break is not set successfully, then a run-time error occurs. If you include the return value, then you must handle any errors.

Debugger.StepOut Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0 until version 4.0 where it was deprecated.*

Enables debugging to return to the calling method after it steps into a method call.

Syntax

```
[Ok := ]  Debugger.StepOut()
```

Return Value

Ok Type: Boolean **true** if the operation was successful; otherwise **false**. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

If you omit this optional return value and if the break is not set successfully, then a run-time error occurs. If you include the return value, then you must handle any errors.

Decimal Data Type

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Denotes decimal numbers ranging from -999,999,999,999,999.99 to +999,999,999,999,999.99.

Example 1

The following are examples of decimal values.

```
546.88
3425.57
```

Example 2

The following is not a decimal, but rather an Integer Data Type.

```
342
```

Limits on Decimal Data Type Variables

The Decimal data type is mapped to the Microsoft .NET Framework common language runtime (CLR) Decimal data type, which controls and the precision and limits for variables.

The following table shows the limits for variables of type `Decimal`.

LIMIT	VALUE
Maximum format value. This is the maximum value that can be: - Formatted into a TEXT variable by the Format function. - Input from the UI or XMLPorts. - Assigned directly in source code.	+/- 999,999,999,999,999.99
Maximum field data type value. This is the maximum value that a field variable in a record can hold while not being persisted.	+/- 999,999,999,999,999.99
Maximum persisted value. This is the maximum value that can be stored in the database.	Can read previous stored values but cannot store values outside the formatting range since field variables cannot be assigned values outside the formatting range.

LIMIT	VALUE
Maximum calculating value. This is the maximum value that can be calculated by code statements while not assigning to a field variable, storing to the database, or formatting to a text variable.	+/- 79,228,162,514,264,337,593,543,950,335
Scaling factor (digits after decimal point) for calculating values	28 For example, 7.9228162514264337593543950335

The maximum safe value that will work on all Business Central versions of is +/- 999,999,999,999,999.99.

It is possible to assign to a variable the maximum value that can be formatted and then multiply that variable by a large positive number, thereby generating a greater value. However, we do not recommend doing this. If you do, you will get errors if you attempt to format this variable to a text variable or assign the variable to a field variable in a record.

Dialog Data Type

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Represents a dialog window.

The following methods are available on the Dialog data type.

METHOD NAME	DESCRIPTION
Confirm(String [, Boolean] [, Any,...])	Creates a dialog box that prompts the user for a yes or no answer. The dialog box is centered on the screen.
Error(String [, Any,...])	Displays an error message and ends the execution of AL code.
Error(ErrorInfo)	Displays an error message and ends the execution of AL code.
LogInternalError(String, DataClassification, Verbosity)	Log internal errors for telemetry.
LogInternalError(String, String, DataClassification, Verbosity)	Log internal errors for telemetry.
Message(String [, Any,...])	Displays a text string in a message window.
StrMenu(String [, Integer] [, String])	Creates a menu window that displays a series of options.

The following methods are available on instances of the Dialog data type.

METHOD NAME	DESCRIPTION
Close()	Closes a dialog window that has been opened by the Open method.
HideSubsequentDialogs([Boolean])	Specifies that subsequent child dialogs are not shown.
Open(String [, var Any,...])	Opens a dialog window.
Update([Integer] [, Any])	Updates the value of a '#'-or '@' field in the active window.

Dialog.Confirm Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Creates a dialog box that prompts the user for a yes or no answer. The dialog box is centered on the screen.

Syntax

```
Ok :=   Dialog.Confirm(String: String [, Default: Boolean] [, Value1: Any,...])
```

NOTE

This method can be invoked without specifying the data type name.

Parameters

String

Type: String

Specifies the string that is displayed in the dialog box. Use a backslash (\) to indicate a new line. The string can be a text constant that is enabled for multilanguage functionality.

Default

Type: Boolean

Specifies the default button. If you do not specify a default button, then No is used as the default button.

Value1

Type: Any

Return Value

Ok Type: Boolean

Remarks

The message window is automatically sized. The height of the window corresponds to the number of lines and the width corresponds to the length of the longest line.

We recommend that you always end `Confirm` messages with a question mark. For more information about best practices for end-user messages, see Progress Windows, Message, Error, and Confirm Methods.

Example

In the following example, the Dialog.Confirm method prompts the user for a **true** or **false** answer.

```
var
    Question: Text;
    Answer: Boolean;
    CustomerNo: Integer;
    Text000: Label 'Exit without saving changes to customer %1?';
    Text001: Label 'You selected %1.';
begin
    CustomerNo := 01121212;
    Question := Text000;
    Answer := Dialog.Confirm(Question, true, CustomerNo);
    Message(Text001, Answer);
end;
```

The first dialog box shows:

Exit without saving changes to customer 1121212?

If you select the default **true** value, then the second dialog box is shown:

You selected true.

Dialog.Error Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Displays an error message and ends the execution of AL code.

Syntax

```
Dialog.Error(Message: String [, Value: Any,...])
```

> **NOTE**
> This method can be invoked without specifying the data type name.

Parameters

Message

Type: String

This string contains the text of the error message you want to display to the user. Use percent signs (%) or number signs (#) to insert variable values into the string. Place the percent or number signs where you want to substitute the variable value. The string can be a text constant that is enabled for multilanguage functionality.

Value

Type: Any

Any variable or expression to be inserted in String. You can insert up to 10 values. For '#'-type fields, the value is truncated according to the total number of number-sign characters in String. For '%'-type fields, the full length of the value is printed.

Dialog.Error Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 3.0.*

Displays an error message and ends the execution of AL code.

> **NOTE**
>
> This method is supported only in Business Central on-premises.

Syntax

```
Dialog.Error(Message: ErrorInfo)
```

> **NOTE**
>
> This method can be invoked without specifying the data type name.

Parameters

Message

Type: ErrorInfo

The ErrorInfo structure that contains error message, error type, verbosity, and data classification.

See Also

Dialog.LogInternalError Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 6.0.*

Log internal errors for telemetry.

> **NOTE**
> This method is supported only in Business Central on-premises.

Syntax

```
Dialog.LogInternalError(Message: String, DataClassificationInstance: DataClassification, VerbosityInstance: Verbosity)
```

> **NOTE**
> This method can be invoked without specifying the data type name.

Parameters

Message
Type: String
This string contains the text of the error message you want to log into telemetry. It is not what the user will get, they will only get a generic error message.

DataClassificationInstance
Type: DataClassification
Sets the classification of the data in the error message.

VerbosityInstance
Type: Verbosity
Represents the security level of events.

Dialog.LogInternalError Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 6.0.*

Log internal errors for telemetry.

> **NOTE**
> This method is supported only in Business Central on-premises.

Syntax

```
Dialog.LogInternalError(Message: String, SubstitutionString: String, DataClassificationInstance:
DataClassification, VerbosityInstance: Verbosity)
```

> **NOTE**
> This method can be invoked without specifying the data type name.

Parameters

Message
Type: String
This string contains the text of the error message you want to log into telemetry. Use a percent sign (%) to insert a variable value into the string. Place the percent where you want the system to substitute the variable value. You may only insert one variable value. It is not what the user will get, they will only get a generic error message.

SubstitutionString
Type: String
This string replaces a percent sign in the "Message" Parameter.

DataClassificationInstance
Type: DataClassification
Sets the classification of the data in the error message.

VerbosityInstance
Type: Verbosity
Represents the security level of events.

Dialog.Message Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Displays a text string in a message window.

Syntax

```
Dialog.Message(String: String [, Value: Any,...])
```

> **NOTE**
> This method can be invoked without specifying the data type name.

Parameters

String

Type: String

This string contains the text you want the system to display in the message window. Use a backslash (\) to start a new line. Use percent signs (%) to insert variable values into the string. Place the percent where you want the system to substitute the variable value. The string can be a text constant that is enabled for multilanguage functionality.

Value

Type: Any

Any type of AL variable you want to insert into String. You can insert up to 10 values.

Remarks

When a message statement in the AL code is executed, the message is not immediately displayed. Instead, it is displayed after the AL code is finished executing or after the AL code pauses to wait for user interaction.

The window is automatically sized to hold the longest line of text and the total number of lines.

For NAS sessions or Dynamics 365 sessions (including NAS) that are started by the StartSession Method (Sessions), messages are recorded in the event log of the computer that is running Dynamics 365 Business Central service. The message entries have the ID 100 and type Information.

Programming Guidelines

We recommend the following guidelines for messages:

- Always end a message with a period.
- Supply the user with a message when the system has finished performing a task.
- Write the message in past tense.

For more information, see Progress Windows, Message, Error, and Confirm Methods.

Example

This example shows how to use the `Message` method.

```
begin
        Message('App published: Hello world');

        Text := 'ABCDE';
        Number := 12345.678;

        // The backslash indicates a new line.
        // You can concatenate strings using the + operator.
        // You can insert variable values using the % symbol.
        Message(Text000 + Text001 + '%1\' + Text002 + '%2\', Number, Text);
    end;

    var
        Text: Text;
        Number: Decimal;
        Text000: Label 'You can use message windows to display text and numbers: \';
        Text001: Label 'The number: ';
        Text002: Label 'The text: ';
```

The message window reads:

You can use message windows to display text and numbers:

The number: 12,345.678

The text: ABCDE

Dialog.StrMenu Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Creates a menu window that displays a series of options.

Syntax

```
OptionNumber :=   Dialog.StrMenu(OptionMembers: String [, DefaultNumber: Integer] [, Instruction: String])
```

NOTE

This method can be invoked without specifying the data type name.

Parameters

OptionMembers

Type: String

A comma-separated string. Each substring in OptionString specifies an option on the menu. The string can be a text constant that is enabled for multilanguage functionality.

DefaultNumber

Type: Integer

Use this optional parameter to determine a default option, which is highlighted. The options are numbered 1, 2, 3, 4, and so on. If you omit this optional parameter, the first option (1) is used as the default.

Instruction

Type: String

Use this optional parameter to add a description to the option values.

Return Value

OptionNumber Type: Integer The number of the menu option that the user selected. If the user presses the Esc key to exit the menu, zero (0) is returned.

Example

This example shows how to use the Dialog.StrMenu method.

```
var
    Options: Text[30];
    Selected: Integer;
    Text000: Label 'Save,Delete,Exit,Find';
    Text001: Label 'You selected option %1.';
    Text002: Label 'Choose one of the following options:';
begin
    Options := Text000;
    // Sets the default to option 3
    Selected := Dialog.StrMenu(Options, 3, Text002);
    Message(Text001, Selected);
end;
```

The menu window displays the following text:

Choose one of the following options:

Save

Delete

Exit

Find

Option 3, **Exit**, is highlighted. The option that the user selects is stored in the variable *Selected*. The user receives following message:

You selected option 3.

Dialog.Close Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Closes a dialog window that has been opened by the Open method.

Syntax

```
Dialog.Close()
```

> **NOTE**
> This method can be invoked without specifying the data type name.

Parameters

Dialog Type: Dialog An instance of the Dialog data type.

Remarks

If `Close` is used on a dialog window that is not open, a run-time error will occur. The dialog windows of an object are automatically closed when the object terminates.

Dialog Data Type
Getting Started with AL
Developing Extensions

Dialog.HideSubsequentDialogs Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Specifies that subsequent child dialogs are not shown.

Syntax

```
[HideSubsequentDialogs := ]  Dialog.HideSubsequentDialogs([HideSubsequentDialogs: Boolean])
```

NOTE

This method can be invoked using property access syntax.

NOTE

This method can be invoked without specifying the data type name.

Parameters

Dialog Type: Dialog An instance of the Dialog data type.

HideSubsequentDialogs

Type: Boolean

A value specifying whether to hide subsequent dialogs.

Return Value

HideSubsequentDialogs Type: Boolean **True** if HideSubsequentDialogs is set to true; otherwise, false.

Remarks

You must call the `HideSubsequentDialogs` method on the dialog variable before the Open Method. Until the Open Method is called on this variable, calls on other dialog variables will behave as normal.

Example

The following code illustrates how the `HideSubsequentDialogs` method works with two dialog variables.

```
var
  MyDialog1 : Dialog;
  MyDialog2 : Dialog;
  Text000 : Label 'additional text';
  begin

    // The HideSubsequentDialogs method is used on MyDialog1 dialog.
    MyDialog1.HideSubsequentDialogs := true;

    // When MyDialog1 dialog opens, it will register as the root dialog.
    MyDialog1.Open('Dialog 1');
    Sleep(2000);

    // MyDialog2 dialog will not open. However, the code associated with the Open call will run as if it was
actually opened.
    MyDialog2.Open('Dialog 2');
    Sleep(2000);

    // Updating MyDialog2 dialog will have no effect
    MyDialog2.Update(1, Text000);
    Sleep(2000);

    // MyDialog1 dialog will open
    MyDialog1.Open('Dialog 1 #1', Text000);
    Sleep(2000);

    // As soon as MyDialog1 dialog is closed, other can be reopened and they will no longer be hidden
    MyDialog1.Close;

    MyDialog2.Open('Dialog 2');
    Sleep(2000);

  end;
```

Dialog.Open Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Opens a dialog window.

Syntax

```
Dialog.Open(String: String [, var Variable1: Any,...])
```

NOTE

This method can be invoked without specifying the data type name.

Parameters

Dialog Type: Dialog An instance of the Dialog data type.

String

Type: String

This string contains the text that you want to display in the window. Use a backslash (\) to start a new line. Use number signs (#) to insert variable values into the string. Place the number signs where you want to substitute the variable value. Place a number in the part of the string where a variable value will be substituted (for example, #1####) to be able to reference this field for updating. The number of # characters in the string indicates the length of the field. You can update the fields using the UPDATE method (Dialog) or by letting the user edit the values.

Variable1

Type: Any

Use these optional parameters to specify variables for field1, field2, and so on in the String.

Remarks

Dialog windows that are opened by an object are closed when the object terminates.

Dialog windows are automatically sized to hold the longest line of text and the total number of lines.

We recommend the following guidelines:

- Enter messages as text constants.
- Write messages using active voice. For example, write "Processing items" instead of writing "Items are being processed."
- Align the # field to the left with at least one space character between the text and the variable.

NOTE

With the Dynamics NAV Client connected to Business Central, you can use @ characters instead of # characters for the *String* parameter to display the value as percentage and a progress indicator. The percentage value that is displayed is the percentage of the variable value from 0 to 9999. This is not supported in the Business Central Web client.

Example 1

This example shows how to use the dialog.Open method.

```
var
    MyDialog: Dialog;
    MyNext: Integer;
    Text000: Label 'Counting to 4 #1:';
begin
    MyNext := 0;
    MyDialog.Open(Text000,MyNext);
    repeat
      // Do some processing.
      Sleep(1000);
      MyNext := MyNext + 1;
      MyDialog.Update(); // Update the field in the dialog.
    until MyNext = 4;
    Sleep(1000);
    MyDialog.Close();
end;
```

The dialog window opens and displays this text:

Counting to 4: 0

Every one second, the dialog window updates with the new value of *MyNext* until it reaches 4, then the dialog window closes.

Example 2

This example shows how to use the dialog.Open method to display a progress indicator in the Dynamics NAV Client connected to Business Central. The progress indicator will not display in the Business Central Web client.

```
var
    MyDialog: Dialog;
    MyNext: Integer;
    Text000: Label 'Progress from 0 to 9999 #1#####';
begin
    MyNext := 0;
    MyDialog.Open(Text000,MyNext);
    repeat
      // Do some processing.
      MyNext := MyNext + 1;
      MyDialog.Update(); // Update the field in the dialog.
    until MyNext = 9999;
    Sleep(1000);
    MyDialog.Close();
end;
```

The dialog window opens and displays the progress indicator and percentage.

Dialog.Update Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Updates the value of a '#'-or '@' field in the active window.

Syntax

```
Dialog.Update([Number: Integer] [, Value: Any])
```

> **NOTE**
> This method can be invoked without specifying the data type name.

Parameters

Dialog Type: Dialog An instance of the Dialog data type.

Number
Type: Integer
Each '#' or '@' field has a specific number. The Number argument tells into which field the Value should be inserted. If you omit this parameter, then all '#' or '@' fields in the active window are updated.

Value
Type: Any
This value or expression can be any simple AL data type such as Boolean, Option, Integer, Decimal, Date, Time, Text, and Code. If you omit this value, then the value from the variable in the Open method (Dialog)] call is used.

Remarks

Dialog windows that are opened by an object are closed when the object terminates.

Dialog windows are automatically sized to hold the longest line of text and the total number of lines.

We recommend the following guidelines:

- Enter messages as text constants.
- Write messages using active voice. For example, write "Processing items" instead of writing "Items are being processed."
- Align the # field to the left with at least one space character between the text and the variable.

> **NOTE**
> With the Dynamics NAV Client connected to Business Central, you can use @ characters instead of # characters for the *String* parameter to display the value as percentage and a progress indicator. The percentage value that is displayed is the percentage of the variable value from 0 to 9999. This is not supported in the Business Central Web client.

Dictionary Data Type

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Represents an unordered collection of keys and values. The Dictionary data type is optimized for fast lookup of values.

The following methods are available on instances of the Dictionary data type.

METHOD NAME	DESCRIPTION
Add(TKey, TValue)	Adds the specified key and value to the dictionary.
ContainsKey(TKey)	Determines whether the Dictionary contains the specified key.
Count()	Gets the number of key/value pairs contained in the Dictionary.
Get(TKey, var TValue)	Gets the value associated with the specified key.
Get(TKey)	Gets the value associated with the specified key.
Keys()	Gets a collection containing the keys in the Dictionary.
Remove(TKey)	Removes the value with the specified key from the Dictionary.
Set(TKey, TValue)	Sets the value associated with the specified key.
Set(TKey, TValue, var TValue)	Sets the value associated with the specified key.
Values()	Gets a collection containing the values in the Dictionary.

Remarks

Each addition to the dictionary consists of a value, and its associated key. Every key in a Dictionary must be unique. A key cannot be null, but a value can be, only when the value type is a reference type.

The Dictionary data type does not support holding instantiated records. For this purpose, use temporary tables.

WARNING

Previously in C/AL, one would have typically used an in-memory temporary table to create a key-value data structure, as shown in the code below. In AL you use the Dictionary Data Type instead.

```
IF KeyCacheRec.Get('Some Value') THEN
    Complete data stack execution;
```

Example

In the following example, the variable `counter` represents the Dictionary data type to store a value representing the number of occurrences for each character in the `customerName`. Using the `Get` method, you get the number of occurrences for the character at position `i`. If `i` returns **false**, it means there is no value associated with that character, so you add the value 1. If `i` returns **true**, it means the value already exists, so you add `c + 1` to the value. The `Add` method adds the {key:value} pair to the Dictionary.

```
procedure CountCharactersInCustomerName(customerName: Text; var counter: Dictionary of [Char, Integer]);
var
    i : Integer;
    c : Integer;
begin

    for i := 1 to StrLen(customerName) do
    begin
        if counter.Get(customerName[i], c) then
            counter.Set(customerName[i], c + 1)
        else
            counter.Add(customerName[i], 1);
    end;
end;
```

Dictionary.Add Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Adds the specified key and value to the dictionary.

Syntax

```
[Ok := ]  Dictionary.Add(Key: TKey, Value: TValue)
```

Parameters

Dictionary Type: Dictionary An instance of the Dictionary data type.

Key
Type: TKey
The key of the element to add.

Value
Type: TValue
The value of the element to add.

Return Value

Ok Type: Boolean **true** if the operation was successful; otherwise **false**. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

Dictionary.ContainsKey Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Determines whether the Dictionary contains the specified key.

Syntax

```
Ok :=   Dictionary.ContainsKey(Key: TKey)
```

Parameters

Dictionary Type: Dictionary An instance of the Dictionary data type.

Key
Type: TKey
The key to locate in the Dictionary.

Return Value

Ok Type: Boolean **true** if the Dictionary contains an element with the specified key, otherwise **false**.

Dictionary.Count Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Gets the number of key/value pairs contained in the Dictionary.

Syntax

```
Count :=   Dictionary.Count()
```

NOTE

This method can be invoked using property access syntax.

Parameters

Dictionary Type: Dictionary An instance of the Dictionary data type.

Return Value

Count Type: Integer The number of key/value pairs contained in the Dictionary.

Dictionary.Get Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Gets the value associated with the specified key.

Syntax

```
[Ok := ]  Dictionary.Get(Key: TKey, var Value: TValue)
```

Parameters

Dictionary Type: Dictionary An instance of the Dictionary data type.

Key
Type: TKey
The key of the value to get. If the specified key is not found an error will be reported.

Value
Type: TValue
The value associated with the specified key.

Return Value

Ok Type: Boolean **true** if the operation was successful; otherwise **false**. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

Dictionary.Get Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Gets the value associated with the specified key.

Syntax

```
Value :=   Dictionary.Get(Key: TKey)
```

Parameters

Dictionary Type: Dictionary An instance of the Dictionary data type.

Key
Type: TKey
The key of the value to get. If the specified key is not found an error will be reported.

Return Value

Value Type: TValue The value associated with the specified key. If the specified key is not found, an error will be raised.

Dictionary.Remove Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Removes the value with the specified key from the Dictionary.

Syntax

```
[Ok := ]  Dictionary.Remove(Key: TKey)
```

Parameters

Dictionary Type: Dictionary An instance of the Dictionary data type.

Key
Type: TKey
The key of the element to remove.

Return Value

Ok Type: Boolean **true** if the element is successfully removed; otherwise, **false**. This method also returns **false** if the given key was not found in the original Dictionary.

Dictionary.Set Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Sets the value associated with the specified key.

Syntax

```
Dictionary.Set(Key: TKey, Value: TValue)
```

Parameters

Dictionary Type: Dictionary An instance of the Dictionary data type.

Key
Type: TKey
The key of the value to set.

Value
Type: TValue
The value that will be associated with the specified key.

Dictionary.Set Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Sets the value associated with the specified key.

Syntax

```
[Replaced := ]  Dictionary.Set(Key: TKey, Value: TValue, var OldValue: TValue)
```

Parameters

Dictionary Type: Dictionary An instance of the Dictionary data type.

Key
Type: TKey
The key of the value to set.

Value
Type: TValue
The value that will be associated with the specified key.

OldValue
Type: TValue
The value that was previously associated with the specified key.

Return Value

Replaced Type: Boolean **true** if the Dictionary contained a value associated with the given key that was replaced with the new value, otherwise **false**.

Duration Data Type

2/17/2021 • 2 minutes to read • Edit Online

> **Version**: *Available from runtime version 1.0.*

Represents the difference between two DateTimes. This value can be negative. It is stored as a 64-bit integer. The integer value is the number of milliseconds during the duration.

The following are examples of durations:

DateTime-DateTime=Duration

DateTime-Duration=DateTime

DateTime+Duration=DateTime

Example

This example shows how to calculate the difference between two DateTimes. This example is run on a computer with the Current Format in the Regional and Language Options set to English (United States).

```
var
    DateTime1: DateTime;
    DateTime2: DateTime;
    Duration: Duration;
begin
    DateTime1 := CreateDateTime(20090101D, 080000T); // January 1, 2009 at 08:00:00 AM
    DateTime2 := CreateDateTime(20090505D, 133001T); // May 5, 2009 at 1:30:01 PM
    Duration := DateTime2 - DateTime1;
    Message(Format(Duration));
end;
```

The message window displays the following:

124 days 4 hours 30 minutes 1 second

Enum.FromInteger Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 4.0.*

Returns an enum with the integer value

Syntax

```
Enum with integer value :=   Enum.FromInteger(Value: Integer)
```

Parameters

Value

Type: Integer

Return Value

Enum with integer value Type: Any

Example

```
enum 50130 YesNo
{
    value(0; Yes) { }
    value(10; No) { }
}

codeunit 50130 YesNoTest
{
    procedure Test();
    var
        Answer: enum YesNo;
    begin
        Answer := YesNo.FromInteger(10); // Ordinal value for 'No'
        if Answer = YesNo::No then
            Message('Success');
    end;
}
```

Enum.Names Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 4.0.*

Gets the value names

Syntax

```
List of enum value names :=   Enum.Names()
```

Return Value

List of enum value names Type: List of [Text]

See Also

Enum.Ordinals Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 4.0.*

Gets the ordinal numbers/ID's for the values

Syntax

```
List of ordinals :=   Enum.Ordinals()
```

Return Value

List of ordinals Type: List of [Integer]

See Also

Enum.AsInteger Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 4.0.*

Get the enum value as an integer value.

Syntax

```
The Enum Value as an Integer value :=   Enum.AsInteger()
```

Parameters

Enum Type: Enum An instance of the Enum data type.

Return Value

The Enum Value as an Integer value Type: Integer

ErrorInfo Data Type

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 3.0.*

Provides a structure for grouping information about an error.

> **NOTE**
> This data type is supported only in Business Central on-premises.

The following methods are available on instances of the ErrorInfo data type.

METHOD NAME	DESCRIPTION
DataClassification([DataClassification])	Specifies the severity level of the error. Values include 'Critical', 'Error', 'Warning', 'Normal', and 'Verbose'
ErrorType([ErrorType])	Specifies type of the error. 'Client' shows the specified message in the client and sends it to telemetry. 'Internal' shows a generic message in the client and sends the specified message to telemetry.
Message([String])	Specifies the message that will be sent to telemetry. For a 'Client' error type, the message will also be appear in the client.
Verbosity([Verbosity])	Specifies the severity level of the error. This can determine whether the error should be sent to telemetry (which is based on the trace level setting of the server).

ErrorInfo.DataClassification Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 3.0.*

Specifies the severity level of the error. Values include 'Critical', 'Error', 'Warning', 'Normal', and 'Verbose'

Syntax

```
[DataClassification := ]  ErrorInfo.DataClassification([DataClassification: DataClassification])
```

> **NOTE**
> This method can be invoked using property access syntax.

Parameters

ErrorInfo Type: ErrorInfo An instance of the ErrorInfo data type.

DataClassification
Type: DataClassification
The data classification of the content in the message.

Return Value

DataClassification Type: DataClassification The current data classification of the ErrorInfo.

ErrorInfo.ErrorType Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 3.0.*

Specifies type of the error. 'Client' shows the specified message in the client and sends it to telemetry. 'Internal' shows a generic message in the client and sends the specified message to telemetry.

Syntax

```
[ErrorType := ]  ErrorInfo.ErrorType([ErrorType: ErrorType])
```

> **NOTE**
> This method can be invoked using property access syntax.

Parameters

ErrorInfo Type: ErrorInfo An instance of the ErrorInfo data type.

ErrorType
Type: ErrorType
The error type of the error.

Return Value

ErrorType Type: ErrorType The current error type of the ErrorInfo.

ErrorInfo.Message Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 3.0.*

Specifies the message that will be sent to telemetry. For a 'Client' error type, the message will also be appear in the client.

Syntax

```
[Message := ]  ErrorInfo.Message([Message: String])
```

NOTE

This method can be invoked using property access syntax.

Parameters

ErrorInfo Type: ErrorInfo An instance of the ErrorInfo data type.

Message

Type: String

The message of the the ErrorInfo

Return Value

Message Type: String The current message of the ErrorInfo.

ErrorInfo.Verbosity Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 3.0.*

Specifies the severity level of the error. This can determine whether the error should be sent to telemetry (which is based on the trace level setting of the server).

Syntax

```
[Verbosity := ]  ErrorInfo.Verbosity([Verbosity: Verbosity])
```

> **NOTE**
> This method can be invoked using property access syntax.

Parameters

ErrorInfo Type: ErrorInfo An instance of the ErrorInfo data type.

Verbosity
Type: Verbosity
The verbosity that the error should be sent with.

Return Value

Verbosity Type: Verbosity The current verbosity of the ErrorInfo.

FieldRef Data Type

2/17/2021 • 4 minutes to read • Edit Online

> **Version**: *Available from runtime version 1.0.*

Identifies a field in a table and gives you access to this field.

The following methods are available on instances of the FieldRef data type.

METHOD NAME	DESCRIPTION
Active()	Checks whether the field that is currently selected is enabled.
CalcField()	Updates FlowFields in a record.
CalcSum()	Calculates the total of all values of a SumIndexField in a table.
Caption()	Gets the current caption of a field as a String.
Class()	Gets the value of the FieldClass Property of the field that is currently selected. This method returns an error if no field is selected.
EnumValueCount()	Gets the number of Enum values (or Option members) from the Enum metadata for the field that is currently selected.
FieldError([String])	Stops the execution of the code, causing a run-time error, and creates an error message for a field.
GetEnumValueCaption(Integer)	Gets an Enum value (or Option member) caption for the from the Enum metadata for the field that is currently selected.
GetEnumValueCaptionFromOrdinalValue(Integer)	Gets an Enum value (or Option member) caption for the from the Enum metadata for the field that is currently selected.
GetEnumValueName(Integer)	Gets an Enum value (or Option member) name from the Enum metadata for the field that is currently selected.
GetEnumValueNameFromOrdinalValue(Integer)	Gets an Enum value (or Option member) name from the Enum metadata for the field that is currently selected.
GetEnumValueOrdinal(Integer)	Gets the Enum value (or Option member) ordinal value from the Enum metadata for the field that is currently selected.
GetFilter()	Gets the filter that is currently applied to the field referred to by FieldRef.
GetRangeMax()	Gets the maximum value in a range for a field.
GetRangeMin()	Gets the minimum value in a range for a field.

METHOD NAME	DESCRIPTION
Length()	Gets the maximum size of the field (the size specified in the DataLength property of the field). This method is usually used for finding the defined length of code and text fields.
Name()	Gets the name of a field as a string.
Number()	Gets the number of a field as an integer.
OptionCaption()	Gets the option caption of the field that is currently selected.
OptionMembers()	Gets the list of options that are available in the field that is currently selected.
OptionString()	The 'OptionString' property has been deprecated and will be removed in the future. Use the 'OptionMembers' property instead.
Record()	Gets the RecordRef of the field that is currently selected. This method returns an error if no field is selected.
Relation()	Finds the table relationship of a given field.
SetFilter(String [, Any,...])	Assigns a filter to a field that you specify.
SetRange([Any] [, Any])	Sets a simple filter on a field, such as a single range or a single value.
TestField()	Determines whether the contents of a field matches a given value. If the contents differ from the given value, an error message is displayed.
TestField(Byte)	Determines whether the contents of a field matches a given value. If the contents differ from the given value, an error message is displayed.
TestField(Boolean)	Determines whether the contents of a field matches a given value. If the contents differ from the given value, an error message is displayed.
TestField(Char)	Determines whether the contents of a field matches a given value. If the contents differ from the given value, an error message is displayed.
TestField(Option)	Determines whether the contents of a field matches a given value. If the contents differ from the given value, an error message is displayed.
TestField(Integer)	Determines whether the contents of a field matches a given value. If the contents differ from the given value, an error message is displayed.
TestField(BigInteger)	Determines whether the contents of a field matches a given value. If the contents differ from the given value, an error message is displayed.
TestField(Decimal)	Determines whether the contents of a field matches a given value. If the contents differ from the given value, an error message is displayed.

METHOD NAME	DESCRIPTION
TestField(Guid)	Determines whether the contents of a field matches a given value. If the contents differ from the given value, an error message is displayed.
TestField(String)	Determines whether the contents of a field matches a given value. If the contents differ from the given value, an error message is displayed.
TestField(Label)	Determines whether the contents of a field matches a given value. If the contents differ from the given value, an error message is displayed.
TestField(Text)	Determines whether the contents of a field matches a given value. If the contents differ from the given value, an error message is displayed.
TestField(Code)	Determines whether the contents of a field matches a given value. If the contents differ from the given value, an error message is displayed.
TestField(Date)	Determines whether the contents of a field matches a given value. If the contents differ from the given value, an error message is displayed.
TestField(DateTime)	Determines whether the contents of a field matches a given value. If the contents differ from the given value, an error message is displayed.
TestField(Time)	Determines whether the contents of a field matches a given value. If the contents differ from the given value, an error message is displayed.
TestField(Variant)	Determines whether the contents of a field matches a given value. If the contents differ from the given value, an error message is displayed.
TestField(Enum)	Determines whether the contents of a field matches a given value. If the contents differ from the given value, an error message is displayed.
TestField(Any)	Determines whether the contents of a field matches a given value. If the contents differ from the given value, an error message is displayed.
Type()	Gets the data type of the field that is currently selected.
Validate([Any])	Use this method to enter a new value into a field and have the new value validated by the properties and code that have been defined for that field.
Value([Any])	Sets or gets the value of the field that is currently selected. This method returns an error if no field is selected.

FieldRef.Active Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Checks whether the field that is currently selected is enabled.

Syntax

```
Ok :=   FieldRef.Active()
```

NOTE

This method can be invoked using property access syntax.

Parameters

FieldRef Type: FieldRef An instance of the FieldRef data type.

Return Value

Ok Type: Boolean

Remarks

Each field in a record can be set as enabled or disabled in the table description. You cannot use a disabled field because disabled fields cannot contain data.

This method is like the FieldActive Method (Record).

Example

The following example opens table 18 (Customer) as a RecordRef variable that is named Recref. The Field Method (RecordRef) uses Recref to create a FieldRef variable that is named MyFieldRef. MyFieldRef sets a reference to the first field (field 1) in the table. The SetRange Method (FieldRef) sets a filter that selects record 30000. The Field Method (RecordRef) selects the record and then loops through fields 1 through 6. For each field, the Active method determines whether the field is enabled. If the field is enabled, a message that states that the field is enabled is displayed. Otherwise, a message that states that the field is not enabled is displayed.

NOTE

You can use the name of the table instead of the table number to open the table by using the following syntax:

```
Recref.Open\(DATABASE::Customer\)
```

```
var
    Recref: RecordRef;
    MyFieldRef: FieldRef;
    i: Integer;
    Text000: Label 'Field %1 is enabled.';
    Text001: Label 'Field %1 is not enabled.';
begin
    Recref.Open(18);
    MyFieldRef := Recref.Field(1);
    MyFieldRef.SetRange('30000');
    Recref.Find('-');
    for i := 1 to 5 do begin
      MyFieldRef := Recref.FieldIndex(i);
      if MyFieldRef.Active then
        Message(Text000, i)
      else begin
        Message(Text001, i)
      end;
    end;
end;
```

FieldRef.CalcField Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Updates FlowFields in a record.

Syntax

```
[Ok := ]  FieldRef.CalcField()
```

Parameters

FieldRef Type: FieldRef An instance of the FieldRef data type.

Return Value

Ok Type: Boolean **true** if the operation was successful; otherwise **false**. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

Remarks

FlowFields are virtual fields. The values in these fields are not saved in the table. This means that you must use the CalcFields method to update them. For example, if you retrieve a record using the Find Method (RecordRef) and Next Method (RecordRef) methods, the FlowFields in those records are set to zero (0). Then, you can call `FieldRef.CalcField`, to calculate the value in one of the FlowFields.

When a FlowField is a direct source expression of a control on a page or a report, the calculation is automatically performed. You can also use the CALCFieldS method to calculate binary large objects (BLOBs). For more information, see BLOB Data Type.

This method is similar to the CalcFields Method (Record) method.

Example

The following example opens table 18 (Customer) as a RecordRef variable that is named CustRecordref. The Find Method (RecordRef) selects the first record in the table and then loops through all the records until no records could be found. For each record, the Field Method (RecordRef) creates a FieldRef variable that is named MyFieldref for the Balance Due field (field 66), which is a flow field. The CalcField method is called to update the field before the customer ID and the balance due are displayed. Otherwise, the balance due for every record will be set to 0.

```
var
    CustRecordref: RecordRef;
    MyFieldRef: FieldRef;
    Count: Integer;
    Text000: Label '%1: \\Balance Due: %2.';
begin
    Count := 0;
    CustRecordref.Open(18);
    if CustRecordref.Find('-') then
      repeat
        MyFieldRef := CustRecordref.Field(66);
        MyFieldRef.CalcField;
        Message(Text000, CustRecordref.RecordId, MyFieldRef);
        Count := Count + 1;
      until CustRecordref.Next = 0;
end;
```

FieldRef.CalcSum Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Calculates the total of all values of a SumIndexField in a table.

Syntax

```
[Ok := ]  FieldRef.CalcSum()
```

Parameters

FieldRef Type: FieldRef An instance of the FieldRef data type.

Return Value

Ok Type: Boolean **true** if the operation was successful; otherwise **false**. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

Remarks

This method is like the CalcSums Method (Record) method. This method operates only on records that meet the conditions of any filters associated with the record.

If possible, the CalcSum method uses SumIndexField Technology (SIFT). SIFT is used only if the following conditions are true:

- The Dynamics 365 key contains the fields that are used in the filters that are defined for the FlowField.
- The SumIndexFields on the Dynamics 365 key contain the field to which the FieldRef parameter refers.
- The MaintainSIFTIndex Property is set to **true**.

> **NOTE**
> By default this property is set to **true** for all keys.

For Dynamics 365 Business Central, CalcSum execution is decoupled from Dynamics 365 SIFT index definitions. This means that if any of the conditions for using SIFT indexes are not true, then Dynamics 365 traverses all records in the base table to perform the calculation instead of using SIFT. This can reduce the number of required SIFT indexes, which can improve performance. In earlier versions of Dynamics 365, if the conditions for using SIFT indexes were not true and the **MaintainSIFTIndex** property was enabled, then you received an error when you called the CalcSum method. This provided a degree of protection in earlier versions against accidentally requesting a sorting for which no index existed. In Dynamics 365 Business Central, an index is not required to support a certain sorting, but sorting without an index could lead to bad performance if a search returns a large result set, which would then have to be sorted before the first row is returned.

Example

This example sets a RecordRef variable to refer to table 21, the **Cust. Ledger Entry** table. Next, it creates a reference to field 18, the **Sales (LCY)** field, in the **Cust. Ledger Entry** table and assigns the field reference to a FieldRef variable. The **Sales (LCY)** field is a decimal field and is one of the SumIndexFields on a Dynamics 365 key in the **Cust. Ledger Entry** table. The code displays the original Value of the FieldRef variable, then calls the CalcSum method and displays the calculated value of the field.

```
var
    MyFieldRef: FieldRef;
    MyRecRef: RecordRef;
begin
    MyRecRef.Open(21);
    MyFieldRef := MyRecRef.Field(18);
    Message('Before CalcSum, Sales (LCY) is %1.', MyFieldRef.Value);
    MyFieldRef.CalcSum;
    Message('After CalcSum, Sales (LCY) is %1.', MyFieldRef.Value);
end;
```

On a computer that has the regional format set to English (United States), the first message window displays the following:

Before CalcSum, Sales (LCY) is 0.

The second message window displays the following:

After CalcSum, Sales (LCY) is 55,162.67.

CalcSum Method (Record)
AL Database Methods and Performance on SQL Server

FieldRef.Caption Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Gets the current caption of a field as a String.

Syntax

```
Caption :=   FieldRef.Caption()
```

NOTE

This method can be invoked using property access syntax.

Parameters

FieldRef Type: FieldRef An instance of the FieldRef data type.

Return Value

Caption Type: String

Remarks

The Caption method returns the caption of a field. Caption first looks for a CaptionML Property. If it does not find one, it will use the Name Property. This means that Caption is enabled for multilanguage functionality.

This method is similar to the FieldCaption Method (Record).

Example

The following example opens table 18 (Customer) as a RecordRef variable that is named CustomerRecref. The code uses the Field Method (RecordRef) to loop through field 1 through 9 and creates a FieldRef variable that is named MyFieldRef. For each field, the Caption method retrieves the caption of the field, stores it in the varCaption variable and displays it in a message box.

```
var
    MyFieldRef: FieldRef;
    CustomerRecref: RecordRef;
    varCaption: Text;
    i: Integer;
    Text000: Label 'The caption for field %1 is "%2"';
begin
    CustomerRecref.Open(18);
    for i := 1 to 9 do begin
      MyFieldRef := CustomerRecRef.Field(i);
      varCaption := MyFieldRef.Caption;
      Message(Text000, i, varCaption);
    end;
    CustomerRecref.Close;
end;
```

FieldRef.Class Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Gets the value of the FieldClass Property of the field that is currently selected. This method returns an error if no field is selected.

Syntax

```
Class :=   FieldRef.Class()
```

NOTE

This method can be invoked using property access syntax.

Parameters

FieldRef Type: FieldRef An instance of the FieldRef data type.

Return Value

Class Type: FieldClass

Remarks

The FieldRef refers to the field that you are interested in.

The Class method returns the class as an Option. However, you cannot assign the class to an Option variable directly. Instead, you must use the Evaluate Method. The Evaluate method has a variable parameter to which the value is assigned and a string parameter. You use the forMAT method to convert the result of the FieldRef.Class method to Text, and then use the Evaluate method to convert the Text to an Option.

Example 1

In this example, the return value of the Class method is converted to Text and then converted to an Option. The value of the **OptionString** property of OptionVar is Normal,FlowFilter,FlowField.

```
var
    OptionVar: Option;
    FldRef: FieldRef;
begin
    Evaluate(OptionVar,Format(FldRef.Class));
end;
```

Example 2

In this example, the return value of the Class method is converted to Text and then converted to an Option. This

example uses the Field virtual table instead of an Option variable. The Field virtual table has a Class field, which is an Option and already has the correct OptionString.

```
var
    FieldRec: Record Field;
    FldRef: FieldRef;
begin
    Evaluate(FieldRec.Class,Format(FldRef.Class));
end;
```

FieldRef.EnumValueCount Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 4.0.*

Gets the number of Enum values (or Option members) from the Enum metadata for the field that is currently selected.

Syntax

```
Number of Enum values :=   FieldRef.EnumValueCount()
```

Parameters

FieldRef Type: FieldRef An instance of the FieldRef data type.

Return Value

Number of Enum values Type: Integer The number of Enum values.

See Also

FieldRef Data Type
Getting Started with AL
Developing Extensions

FieldRef.FieldError Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Stops the execution of the code, causing a run-time error, and creates an error message for a field.

Syntax

```
FieldRef.FieldError([Text: String])
```

Parameters

FieldRef Type: FieldRef An instance of the FieldRef data type.

Text

Type: String

Use this optional parameter to include the text of the error message. If this parameter is not present, default text will be used.

Remarks

Similar to a run-time error, this method causes any transaction to be ended automatically.

This method is like the FieldError Method for the Record data type. For examples, see FieldError Method (Record).

Example

The following example opens table 18 (Customer) as a RecordRef variable that is named CustomerRecref. The CustomerName variable is initialized with a blank text. `CustomerRecref.Field` creates a FieldRef that is named MyFieldRef for field1 (No.) and selects record 30000. Field 2 (Name) is then selected for record 30000. If the CustomerName variable is a blank text, then `MyFieldRef.FieldError` is executed and an error message is displayed. The text in Text000 text constant is inserted into the error message that is displayed by Dynamics 365.

```
var
    MyFieldRef: FieldRef;
    CustomerRecref: RecordRef;
    CustomerName: Text;
    Text000: Label 'cannot be blank';
begin
    CustomerRecref.Open(18);
    CustomerName := '';
    MyFieldRef := CustomerRecref.Field(1);
    MyFieldRef.Value('30000');
    MyFieldRef := CustomerRecref.Field(2);
    if CustomerName = '' then
      MyFieldRef.FieldError(Text000)
    else
      //Do some processing
end;
```

This code example displays the following error message:

Name cannot be blank in Customer No.="30000".

Programming Guidelines

We recommend the following guidelines for error messages:

- Describe what is wrong and how to solve the problem.
- Write a short descriptive message. Do not use more words than necessary.
- Note that a period is automatically inserted at the end of a FieldError.
- Use a text constant for the *Text* parameter.

For more information, see Progress Windows, Message, Error, and Confirm Methods.

FieldRef.GetEnumValueCaption Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 7.0.*

Gets an Enum value (or Option member) caption for the from the Enum metadata for the field that is currently selected.

Syntax

```
The Enum value caption :=   FieldRef.GetEnumValueCaption(Index: Integer)
```

Parameters

FieldRef Type: FieldRef An instance of the FieldRef data type.

Index

Type: Integer

The index in the list of Enum values to get the Enum value (or Option member) caption for. The index is 1-based.

Return Value

The Enum value caption Type: String The Enum value caption.

FieldRef.GetEnumValueCaptionFromOrdinalValue Method

2/17/2021 • 2 minutes to read • Edit Online

> **Version**: *Available from runtime version 7.0.*

Gets an Enum value (or Option member) caption for the from the Enum metadata for the field that is currently selected.

Syntax

```
The Enum value caption :=   FieldRef.GetEnumValueCaptionFromOrdinalValue(Ordinal: Integer)
```

Parameters

FieldRef Type: FieldRef An instance of the FieldRef data type.

Ordinal
Type: Integer
The Enum value's ordinal value to get the Enum value (or Option member) caption for.

Return Value

The Enum value caption Type: String The Enum value caption.

FieldRef.GetEnumValueName Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 4.0.*

Gets an Enum value (or Option member) name from the Enum metadata for the field that is currently selected.

Syntax

```
The Enum value name :=   FieldRef.GetEnumValueName(Index: Integer)
```

Parameters

FieldRef Type: FieldRef An instance of the FieldRef data type.

Index
Type: Integer
The index in the list of Enum values to get the Enum value (or Option member) name for. The index is 1-based.

Return Value

The Enum value name Type: String The Enum value name.

Example

```
procedure GetOptionNo(Value: Text; FieldRef: FieldRef): Integer
    var
        FieldRefValueVar: Variant;
        FieldRefValueInt: Integer;
    begin
        if (Value = '') and (FieldRef.GetEnumValueName(1) = ' ') then
            exit(0);

        FieldRefValueVar := FieldRef.Value();
        FieldRefValueInt := -1;
        if Evaluate(FieldRef, Value) then begin
            FieldRefValueInt := FieldRef.Value();
            FieldRef.Value(FieldRefValueVar);
        end;

        exit(FieldRefValueInt);
    end;
```

FieldRef.GetEnumValueNameFromOrdinalValue Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 4.0.*

Gets an Enum value (or Option member) name from the Enum metadata for the field that is currently selected.

Syntax

```
The Enum value name or empty if the ordinal value doesn't exist :=
FieldRef.GetEnumValueNameFromOrdinalValue(Ordinal: Integer)
```

Parameters

FieldRef Type: FieldRef An instance of the FieldRef data type.

Ordinal

Type: Integer

The Enum value's ordinal value to get the Enum value (or Option member) name for.

Return Value

The Enum value name or empty if the ordinal value doesn't exist Type: String The Enum value name.

Example

```
procedure OptionNoExists(var FieldRef: FieldRef; OptionValue: Text): Boolean
    var
        OptionNo: Integer;
    begin
        if Evaluate(OptionNo, OptionValue) then
            exit((FieldRef.GetEnumValueNameFromOrdinalValue(OptionNo) <> '') or
((FieldRef.GetEnumValueNameFromOrdinalValue(OptionNo) = '') and (OptionNo = 0)));

        exit(false);
    end;
```

FieldRef.GetEnumValueOrdinal Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 4.0.*

Gets the Enum value (or Option member) ordinal value from the Enum metadata for the field that is currently selected.

Syntax

```
The Enum value ordinal value :=   FieldRef.GetEnumValueOrdinal(Index: Integer)
```

Parameters

FieldRef Type: FieldRef An instance of the FieldRef data type.

Index

Type: Integer

The index in the list of Enum ordinal values to get the Enum value (or Option member) ordinal value for. The index is 1-based.

Return Value

The Enum value ordinal value Type: Integer The ordinal value.

FieldRef.GetFilter Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Gets the filter that is currently applied to the field referred to by FieldRef.

Syntax

```
String :=   FieldRef.GetFilter()
```

NOTE

This method can be invoked using property access syntax.

Parameters

FieldRef Type: FieldRef An instance of the FieldRef data type.

Return Value

String Type: String

Remarks

See also GetFilters Method (RecordRef), SetFilter Method (FieldRef), and SetRange Method (FieldRef).

This method is like the GetFilter Method (Record).

Example

The following example opens the Customer table as a RecordRef variable that is named CustomerRecref. The Field Method (RecordRef) creates a FieldRef for the first field (No.) and stores the reference in the MyFieldRef variable. The GetFilter method retrieves the filters that are set on the No. field and stores the value in the Filters1 variable. The value of any filter that is set is displayed in a message box. The SetFilter Method (FieldRef) sets the filter that selects records from 10000 to 40000 in the No. field. The GetFilter method retrieves and stores the filter in the Filter2 variable and displays it in a message. The value in the Filter1 variable is blank because no filter is set. The value in Filter2 is 10000..40000 because of the filter that is set by the SetFilter Method (FieldRef).

```
var
    MyFieldRef: FieldRef;
    CustomerRecref: RecordRef;
    Filters1: Text;
    Filters2: Text;
    Text000: Label 'Filter before filters set: %1.';
    Text001: Label 'Filter after filters set: %1.';
begin
    CustomerRecref.Open(Database::Customer);
    MyFieldRef := CustomerRecref.Field(1);
    Filters1 := MyFieldRef.GetFilter;
    Message(Text000, Filters1);
    MyFieldRef.SetFilter('10000..40000');
    Filters2 := MyFieldRef.GetFilter;
    Message(Text001, Filters2);
end;
```

FieldRef.GetRangeMax Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Gets the maximum value in a range for a field.

Syntax

```
Value :=   FieldRef.GetRangeMax()
```

> **NOTE**
> This method can be invoked using property access syntax.

Parameters

FieldRef Type: FieldRef An instance of the FieldRef data type.

Return Value

Value Type: Any

Remarks

This method is like the GetRangeMax Method (Record) method.

Example

The following example opens the Customer table as RecordRef variable, creates a FieldRef for the first field (No.) and stores the reference in the MyFieldRef variable. The SetFilter Method (FieldRef) sets a filter that selects records in the range 10000 to 40000 from the No. field. The GetRangeMax method retrieves and stores the maximum value that was set in the filter, stores the value in the varMax variable and displays it in a message box. The varMax variable contains 40000 which is the maximum value that is set in the filter.

```
var
    MyFieldRef: FieldRef;
    CustomerRecref: RecordRef;
    varMax: Text;
    Text000: Label 'The maximum value in the filter is %1.';
begin
    CustomerRecref.Open(Database::Customer);
    MyFieldRef := CustomerRecref.Field(1);
    MyFieldRef.SetFilter('10000..40000');
    varMax := MyFieldRef.GetRangeMax();
    Message(Text000, varMax);
end;
```

FieldRef.GetRangeMin Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Gets the minimum value in a range for a field.

Syntax

```
Value :=   FieldRef.GetRangeMin()
```

NOTE

This method can be invoked using property access syntax.

Parameters

FieldRef Type: FieldRef An instance of the FieldRef data type.

Return Value

Value Type: Any

Remarks

This method is like the GetRangeMin Method (Record) method.

Example

The following example opens the Customer table as RecordRef variable, creates a FieldRef for the first field (No.) and stores the reference in the MyFieldRef variable. The SetFilter Method (FieldRef) sets a filter that selects records in the range 10000 to 40000 from the No. field. The GetRangeMin method retrieves and stores the minimum value that is set in the filter, stores the value in the varMin variable and displays it in a message box. The varMin variable contains 10000 which is the minimum value that is set in the filter.

```
var
    MyFieldRef: FieldRef;
    CustomerRecref: RecordRef;
    varMin: Text;
    Text000: Label 'The minimum value in the filter is %1.';
begin
    CustomerRecref.Open(Database::Customer);
    MyFieldRef := CustomerRecref.Field(1);
    MyFieldRef.SetFilter('10000..40000');
    varMin := MyFieldRef.GetRangeMin();
    Message(Text000, varMin);
end;
```

FieldRef.Length Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Gets the maximum size of the field (the size specified in the DataLength property of the field). This method is usually used for finding the defined length of code and text fields.

Syntax

```
Length :=   FieldRef.Length()
```

NOTE

This method can be invoked using property access syntax.

Parameters

FieldRef Type: FieldRef An instance of the FieldRef data type.

Return Value

Length Type: Integer

Remarks

For Text and Code fields this method returns the defined length. For other types of fields, it returns the fixed byte size, for example, Integer fields returns 4.

Example

The following example opens the Customer table as a RecordRef variable. The Field Method (RecordRef) creates a FieldRef for any specified field and stores the reference in the MyFieldRef variable. The LENGTH method retrieves the maximum size of the field and stores the value in the varLength variable. The value that is stored in the varLength is displayed in a message box.

```
var
    MyFieldRef: FieldRef;
    CustomerRecref: RecordRef;
    varLength: Integer;
    varFieldNo: Integer;
    Text000: Label 'The maximum size of the field is %1.';
begin
    varFieldNo := 1;
    CustomerRecref.Open(Database::Customer);
    MyFieldRef := CustomerRecref.Field(varFieldNo);
    varLength := MyFieldRef.Length();
    Message(Text000, varLength);
end;
```

FieldRef.Name Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Gets the name of a field as a string.

Syntax

```
Name :=   FieldRef.Name()
```

NOTE

This method can be invoked using property access syntax.

Parameters

FieldRef Type: FieldRef An instance of the FieldRef data type.

Return Value

Name Type: String

Remarks

The Caption Method (FieldRef, TestPage Field) method retrieves the Caption Property of a field. To enable your application for multilanguage functionality, you must use the FieldCaption Method (Record) instead.

This method is similar to the FieldName Method (Record).

Example

The following example opens the Customer table as a RecordRef variable that is named CustomerRecref. The Field Method (RecordRef) creates a reference to the fields in the table and stores the FieldRef in the MyFieldRef variable. The code loops through field 1 through 5. For each field, the Name method retrieves the name of the field and stores the value in the varName variable. The field number and the value in the varName variable are displayed in a message box.

```
var
    MyFieldRef: FieldRef;
    CustomerRecref: RecordRef;
    varName: Text;
    i: Integer;
    Text000: Label 'The name of field %1 is "%2".\\';
begin
    for i := 1 to 5 do begin
        CustomerRecref.Open(Database::Customer);
        MyFieldRef := CustomerRecref.Field(i);
        varName := MyFieldRef.Name;
        Message(Text000, i, varName);
        CustomerRecref.Close;
    end;
end;
```

FieldRef.Number Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Gets the number of a field as an integer.

Syntax

```
No :=   FieldRef.Number()
```

NOTE

This method can be invoked using property access syntax.

Parameters

FieldRef Type: FieldRef An instance of the FieldRef data type.

Return Value

No Type: Integer

Remarks

This method is like the FieldNo Method (Record) method.

Example

The following example displays the caption and the field number of the first 10 fields in the Location table. The Location table is open as a RecordRef Data Type object and the reference is stored in the LocationRecref variable. The FieldIndex variable that stores the field index is initialized to 0. The LocationRecref variable uses the FieldIndex Method (RecordRef) to create a FieldRef that is named MyFieldRef for the specified field index. MyFiledRef now references the field that is specified by the FieldIndex. MyFieldref is then used to display the number and caption of the field The Number Method (FieldRef) method retrieves the field number. This is repeated for the first ten fields in the table.

```
var
    MyFieldRef: FieldRef;
    LocationRecref: RecordRef;
    FieldIndex: Integer;
begin
    LocationRecref.Open(DATABASE::Location);
    FieldIndex := 0;
    repeat
      FieldIndex  := FieldIndex + 1;
      MyFieldRef := LocationRecref.FieldIndex(FieldIndex);
      Message('Field Number: %1  Field Caption: %2.' , MyFieldRef.Number, MyFieldRef.Caption);
    until FieldIndex = 10;
end;
```

FieldRef.OptionCaption Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Gets the option caption of the field that is currently selected.

Syntax

```
OptionCaption :=   FieldRef.OptionCaption()
```

> **NOTE**
> This method can be invoked using property access syntax.

Parameters

FieldRef Type: FieldRef An instance of the FieldRef data type.

Return Value

OptionCaption Type: String

Remarks

The option caption of the field is returned as a comma-separated string.

If the field is not an Option, an empty string is returned.

This method returns an error if no field is selected.

Example

The following example opens the Item table as a RecordRef variable that is named ItemRecref. and creates a reference to field 19 (Price/Profit Calculation field), which is an Option field. The OptionCaption method retrieves the caption of the option field and displays the options as a comma-separated list.

```
var
    MyFieldRef: FieldRef;
    ItemRecref: RecordRef;
    OptionCaption: Text;
begin
    ItemRecref.Open(Database::Item);
    MyFieldRef := ItemRecref.Field(19);
    OptionCaption := MyFieldRef.OptionCaption;
    Message('%1', OptionCaption);
end;
```

FieldRef.OptionMembers Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Gets the list of options that are available in the field that is currently selected.

Syntax

```
OptionMembers :=   FieldRef.OptionMembers()
```

NOTE

This method can be invoked using property access syntax.

Parameters

FieldRef Type: FieldRef An instance of the FieldRef data type.

Return Value

OptionMembers Type: String

See Also

FieldRef.OptionString Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0 until version 1.0 where it was deprecated.*

The 'OptionString' property has been deprecated and will be removed in the future. Use the 'OptionMembers' property instead.

Syntax

```
OptionMembers :=   FieldRef.OptionString()
```

NOTE

This method can be invoked using property access syntax.

Parameters

FieldRef Type: FieldRef An instance of the FieldRef data type.

Return Value

OptionMembers Type: String

Remarks

All the options for this field are returned as a comma separated-string.

This method returns an error if no field is selected.

If the field is not an option an empty string is returned.

Example

The following example opens the Item table with RecordRef variable that is named ItemRecref and creates a reference to field 19 (Price/Profit Calculation), which is an Options field. The OptionString method retrieves the options in the field and displays them as a comma-separated list.

```
var
    MyFieldRef: FieldRef;
    ItemRecref: RecordRef;
    OptionString: Text;
begin
    ItemRecref.Open(Database::Item);
    MyFieldRef := ItemRecref.Field(19);
    OptionString := MyFieldRef.OptionString;
    Message(' %1', OptionString);
end;
```

FieldRef.Record Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Gets the RecordRef of the field that is currently selected. This method returns an error if no field is selected.

Syntax

```
Record :=   FieldRef.Record()
```

Parameters

FieldRef Type: FieldRef An instance of the FieldRef data type.

Return Value

Record Type: RecordRef

Example

The following example opens the Item table as a RecordRef variable that is named ItemRecref, creates a reference to field 1 (No.), and stores the value in the variable named MyFieldRef. The Record method uses the MyFieldRef variable to return the RecordRef of field 1 and stores the reference in a variable named MyRecRef. `MyRecRef.Number` returns the table that the selected field belongs to.

```
var
    MyFieldRef: FieldRef;
    ItemRecref: RecordRef;
    MyRecRef: RecordRef;
    Text000: Label 'The selected field is from table %1.';
begin
    ItemRecref.Open(Database::Item);
    MyFieldRef := ItemRecref.Field(1);
    MyRecRef := MyFieldRef.Record;
    Message(Text000, MyRecRef.Number);
end;
```

FieldRef.Relation Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Finds the table relationship of a given field.

Syntax

```
TableNumber :=   FieldRef.Relation()
```

> **NOTE**
> This method can be invoked using property access syntax.

Parameters

FieldRef Type: FieldRef An instance of the FieldRef data type.

Return Value

TableNumber Type: Integer

Remarks

You can use this method for several purposes such as to determine lookups or to check to see if you have permission to read from a table.

This method is similar to the Relation Method (Record).

Example

The following example opens table 37, the Sales Line table, as a RecordRef variable and creates a reference to field 2 (Sell-to Customer No.). The FieldRef Data Type of field 2 is stored in the MyFieldRef variable. The RELATION method retrieves the number of the table that has a relation with the Sell-To-Customer field (field 2). The table number is stored the varRelation variable and displayed in the message box.

```
var
    MyFieldRef: FieldRef;
    SaleRecref: RecordRef;
    varRelation: Integer;
    Text000: Label 'Field 2 in the Sales Line (37) table has a relation with table %1.';
begin
    SaleRecref.Open(37);
    MyFieldRef := SaleRecref.Field(2);
    varRelation := MyFieldRef.Relation;
    Message(Text000, varRelation);
end;
```

FieldRef.SetFilter Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Assigns a filter to a field that you specify.

Syntax

```
FieldRef.SetFilter(String: String [, Value: Any,...])
```

Parameters

FieldRef Type: FieldRef An instance of the FieldRef data type.

String
Type: String
The filter expression. A valid expression consists of alphanumeric characters and one or more of the following operators: <, >, , &, |, and =. You can use replacement fields (%1, %2, and so on) to insert values at run time.

Value
Type: Any
Replacement values to insert in replacement fields in the filter expression. The data type of Value must match the type of FieldRef.

Remarks

If the method is called with a field for which a filter already exists, the filter is removed before a new one is set. You can construct filters using the following operators.

OPERATOR	DESCRIPTION
..	Range
&	And
|	Or
<	Less than
<=	Less than or equal to
>	Greater than
>=	Greater than or equal to
<>	Different from
*	Forms a part of value

OPERATOR	DESCRIPTION
@	Case-insensitive

This method is like the SetFilter Method (Record) method.

Example

The following example opens the Customer table as a RecordRef variable that is named CustomerRecref. The Field Method (RecordRef) creates a FieldRef for the first field (No.) and stores the reference in the MyFieldRef variable. The GetFilter Method (FieldRef) retrieves the filters that are set on the No. field and stores the value in the Filter1 variable. The value of any filter that is set is displayed in a message box. The SetFilter method sets a filter that selects records from 10000 to 40000 in the No. field. The GetFilter Method (FieldRef) retrieves and stores the new filter in the Filter2 variable and displays it in a message. The value in the Filter1 variable is blank because no filter is set. The value in Filter2 is 10000..40000 because of the filter that is set by the SetFilter method.

```
var
    MyFieldRef: FieldRef;
    CustomerRecref: RecordRef;
    Filter1: Text;
    Filter3: Text;
    Text000: Label 'Filter before filters set: %1.';
    Text001: Label 'Filter after filters set: %1.';
begin
    CustomerRecref.Open(Database::Customer);
    MyFieldRef := CustomerRecref.Field(1);
    Filter1 := MyFieldRef.GetFilter;
    Message(Text000, Filter1);
    MyFieldRef.SetFilter('10000..40000');
    Filter2 := MyFieldRef.GetFilter;
    Message(Text001, Filter2);
end;
```

FieldRef.SetRange Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Sets a simple filter on a field, such as a single range or a single value.

Syntax

```
FieldRef.SetRange([FromValue: Any] [, ToValue: Any])
```

Parameters

FieldRef Type: FieldRef An instance of the FieldRef data type.

FromValue
Type: Any
The lower limit of the range. The data type of FromValue must match the data type of the field referred to by FieldRef.

ToValue
Type: Any
The upper limit of the range. If you omit this parameter, the FromValue you specified is used. The data type of ToValue must match the data type of the field referred to by FieldRef.

Remarks

The SetRange method provides a quick way to set a simple filter on a field. If you call this method by using a field that already has a filter, that filter is removed before the new filter is set.

If you omit all of the optional parameters, all filters set for that field are removed. The SetRange method fails if no field is selected.

This method is like the SetRange Method (Record) method.

Example

The following example opens the Customer table as a RecordRef object, creates a reference to the first (No.) field, and stores the reference in the MyFieldRef variable. The SetRange method sets a filter that selects all records from 10000 to 40000 in the No. field. The Find Method (RecordRef) searches and selects the first record in the filter and counts the number of records that are found. The number of records is stored in the Count variable. The process is repeated by looping through all the records in the filter until no more records are found. The number of records that are found in the range is stored in the Count variable and displayed in a message box.

```
var
    MyFieldRef: FieldRef;
    CustomerRecref: RecordRef;
    Count: Integer;
    Text000: Label '%1 records were retrieved.';
begin
    CustomerRecref.Open(Database::Customer);
    MyFieldRef := CustomerRecref.Field(1);
    MyFieldRef.SetRange('10000' , '40000');
    Count := 0;
    if CustomerRecref.Find('-') then
      repeat
        Count := Count + 1;
      until CustomerRecref.Next = 0;
    Message(Text000 , Count);
end;
```

FieldRef.TestField Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Determines whether the contents of a field matches a given value. If the contents differ from the given value, an error message is displayed.

Syntax

```
FieldRef.TestField()
```

Parameters

FieldRef Type: FieldRef An instance of the FieldRef data type.

Remarks

This method is like the TestField Method (Record) method.

Example 1

The following example opens the Customer table as a RecordRef variable that is named CustomerRecref, created a reference to the first field (No) and stores the reference in the MyFieldRef variable. The Value Method (FieldRef, TestPage Field) sets the No. field to a blank text. The TestField method determines whether the contents of the field match 10000, the specified value. In this case, the content does not match so the Dynamics 365 throws an exception. If the there is a match, no exception is thrown.

```
var
    MyFieldRef: FieldRef;
    CustomerRecref: RecordRef;
begin
    CustomerRecref.Open(Database::Customer);
    MyFieldRef := CustomerRecref.Field(1);
    MyFieldRef.Value := '';
    MyFieldRef.TestField('10000');
end;
```

In this example, the Dynamics 365 displays following error message:

No. must be equal to 10000 in Customer: No.=. Current value is ''.

Example 2

If the value of the No. field is set to a value other than 10000, Dynamics 365 displays the following error message:

No. must be equal to 10000 in Customer: No.=AAA10000. Current value is 'AAA 10000'.

```
CustomerRecref.Open(DataBase::Customer);
MyFieldRef := CustomerRecref.Field(1);
MyFieldRef.Value := 'AAA 10000';
MyFieldRef.TestField('10000');
```

FieldRef.TestField Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Determines whether the contents of a field matches a given value. If the contents differ from the given value, an error message is displayed.

Syntax

```
FieldRef.TestField(Value: Byte)
```

Parameters

FieldRef Type: FieldRef An instance of the FieldRef data type.

Value

Type: Byte

The value that you want to compare with the contents of the field referred to by FieldRef. The data type of Value must match the type of the field. If you include Value and the contents of the field do not match, an error message is displayed. If you omit Value and the content of the field is zero or blank (empty string), an error message is displayed.

FieldRef.TestField Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Determines whether the contents of a field matches a given value. If the contents differ from the given value, an error message is displayed.

Syntax

```
FieldRef.TestField(Value: Option)
```

Parameters

FieldRef Type: FieldRef An instance of the FieldRef data type.

Value

Type: Option

The value that you want to compare with the contents of the field referred to by FieldRef. The data type of Value must match the type of the field. If you include Value and the contents of the field do not match, an error message is displayed. If you omit Value and the content of the field is zero or blank (empty string), an error message is displayed.

Determines whether the contents of a field matches a given value. If the contents differ from the given value, an error message is displayed.

Syntax

```
FieldRef.TestField(Value: BigInteger)
```

Parameters

FieldRef Type: FieldRef An instance of the FieldRef data type.

Value

Type: BigInteger

The value that you want to compare with the contents of the field referred to by FieldRef. The data type of Value must match the type of the field. If you include Value and the contents of the field do not match, an error message is displayed. If you omit Value and the content of the field is zero or blank (empty string), an error message is displayed.

Determines whether the contents of a field matches a given value. If the contents differ from the given value, an error message is displayed.

Syntax

```
FieldRef.TestField(Value: Decimal)
```

Parameters

FieldRef Type: FieldRef An instance of the FieldRef data type.

Value

Type: Decimal

The value that you want to compare with the contents of the field referred to by FieldRef. The data type of Value must match the type of the field. If you include Value and the contents of the field do not match, an error message is displayed. If you omit Value and the content of the field is zero or blank (empty string), an error message is displayed.

FieldRef.Type Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Gets the data type of the field that is currently selected.

Syntax

```
Type :=   FieldRef.Type()
```

> **NOTE**
> This method can be invoked using property access syntax.

Parameters

FieldRef Type: FieldRef An instance of the FieldRef data type.

Return Value

Type Type: FieldType

Example

The following example opens the Customer table as a RecordRef variable that is named CustomerRecref. The code loops through fields 1 to 5 and creates a FieldRef that is named MyFieldRef for each field that is selected. `MyFieldRef.Type` retrieves the data of each field and displays it in a message box.

```
var
    MyFieldRef: FieldRef;
    CustomerRecref: RecordRef;
    varType: Variant;
    Text000: Label 'Field %1 is a %2 data type.';
begin
    CustomerRecref.Open(Database::Customer);
    for i := 1 to 5 do begin
      MyFieldRef := CustomerRecref.Field(i);
      Message(Text000, i, MyFieldRef.Type);
    end;
END;
```

FieldRef.Validate Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Use this method to enter a new value into a field and have the new value validated by the properties and code that have been defined for that field.

Syntax

```
FieldRef.Validate([NewValue: Any])
```

Parameters

FieldRef Type: FieldRef An instance of the FieldRef data type.

NewValue
Type: Any
The value to insert in the field.

Remarks

The Validate method first checks any TableRelation Property, and then executes the OnValidate (Fields) Trigger of the field.

If you omit *NewValue*, the method validates the current value.

This method is like the Validate Method (Record).

Example

The following example opens table 17 (G/L Entry) as a RecordRef that is named EntryRecref. The FindFirst Method (RecordRef) searches for the first record in the table. The Field Method (RecordRef) sets the field to 3, which is the G/L Account No. field. The **VALIDATE** method validates and inserts the specified value (1210) into the field. The Modify Method (RecordRef) modifies the table. A message that indicates the G/L Account No. field has changed is displayed. To show that the code in the **OnValidate** trigger is executed, design the **G/L Entry** table and add the following code to the **G/L Account No. – OnValidate** trigger:

```
Message('The OnValidate trigger is called.');
```

```
var
    MyFieldRef: FieldRef;
    EntryRecref: RecordRef;
    Text000: Label 'The G/L Account No. for record %1 is %2.';
    Text001: Label 'The G/L Account No. for record %1 has changed to %2.';
begin
    EntryRecref.Open(17);
    if EntryRecref.FindFirst then begin
      MyFieldRef := EntryRecref.Field(3);
      Message(Text000, EntryRecref.RecordId, MyFieldRef.Value);
      MyFieldRef.Validate('1210');
      EntryRecref.Modify;
      Message(Text001, EntryRecref.RecordId, MyFieldRef.Value);
    end;
end;
```

See Also

FieldRef Data Type
Getting Started with AL
Developing Extensions

FieldRef.Value Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Sets or gets the value of the field that is currently selected. This method returns an error if no field is selected.

Syntax

```
[Value := ]  FieldRef.Value([NewValue: Any])
```

> **NOTE**
> This method can be invoked using property access syntax.

Parameters

FieldRef Type: FieldRef An instance of the FieldRef data type.

NewValue
Type: Any

Return Value

Value Type: Any

Remarks

If you omit NewValue, the method returns the current value of the field.

If you want to format the value of a FieldRef you must use `Format(FieldRef)` instead of `Format(FieldRef.Value)`.

Example

The following example opens table 18, the **Customer** table, a RecordRef variable that is named CustomerRecref. The Field Method (RecordRef) creates a FieldRef for the first field (No.). The reference to the field is stored in the MyFieldRef variable. The Active Method (FieldRef) method determines whether the field is enabled. If the field is enabled, then the record that is identified by the number in the CustomerNo variable is selected. The MyFieldRef variable is updated to refer to the second field (Name). Then the value in the second field is changed to Contoso. The Modify Method (RecordRef) modifies the record in the table to reflect the change. `MyFieldRef.Value` retrieves the new name and displays it in message box.

```
var
    MyFieldRef: FieldRef;
    CustomerRecref: RecordRef;
    CustomerNo: Code;
    Text000: Label 'Customer name has changed to %1.';
begin
    CustomerNo := '50000';
    CustomerRecref.Open(18);
    MyFieldRef := CustomerRecref.Field(1);
    if MyFieldRef.Active then begin
      MyFieldRef.Value(CustomerNo);
      MyFieldRef := CustomerRecref.Field(2);
      MyFieldRef.Value('Contoso');
      CustomerRecref.Modify;
      Message(Text000, MyFieldRef.Value);
    end;
end;
```

File Data Type

2/17/2021 • 3 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Represents a file.

The following methods are available on the File data type.

METHOD NAME	DESCRIPTION
Copy(String, String)	Copies a file.
Download(String, String, String, String, var Text)	Sends a file from a server computer to the client computer. The client computer is the computer that is running the Windows client or the computer that is running a browser that accesses the web client.
DownloadFromStream(InStream, String, String, String, var Text)	Sends a file from server computer to the client computer. The client computer is the computer that is running the Windows client or the computer that is running the browser that accesses the web client.
Erase(String)	Deletes a file.
Exists(String)	Determines whether a file exists.
GetStamp(String, var Date [, var Time])	Gets the exact time that a file was last written to.
IsPathTemporary(String)	Validates whether the given path is located in the current users temporary folder within the current service.
Rename(String, String)	Renames an ASCII or binary file.
SetStamp(String, Date [, Time])	Sets a timestamp for a file.
Upload(String, String, String, String, var Text)	Sends a file from the client computer to the server computer. The client computer is the computer that is running the Windows client or the computer that is running a browser that accesses the web client.
UploadIntoStream(String, String, String, var Text, var InStream)	Sends a file from the client computer to the corresponding server. The client computer is the computer that is running the Windows client or the computer that is running a browser that accesses the web client.

The following methods are available on instances of the File data type.

METHOD NAME	DESCRIPTION
Close()	Closes a file that has been opened by the Open method (File).

METHOD NAME	DESCRIPTION
Create(String [, TextEncoding])	Creates an Automation object.
CreateInStream(InStream)	Creates an InStream object for a file. This enables you to import or read data from the file.
CreateOutStream(OutStream)	Creates an OutStream object for a file. This enables you to export or write data to the file.
CreateTempFile([TextEncoding])	Creates a temporary file. This enables you to save data of any format to a temporary file. This file has a unique name and will be stored in a temporary file folder.
Len()	Gets the length of an ASCII or binary file.
Name()	Gets the name of an ASCII or binary file.
Open(String [, TextEncoding])	Opens an ASCII or binary file. This method does not create the file if it does not exist.
Pos()	Gets the current position of the file pointer in an ASCII or binary file.
Read(var Any)	Reads from an MS-DOS encoded file or binary file.
Seek(Integer)	Sets a file pointer to a new position in an ASCII or binary file.
TextMode([Boolean])	Sets whether a file should be opened as an ASCII file or a binary file. Gets the current setting of this option for a file.
Trunc()	Truncate an ASCII or binary file to the current position of the file pointer.
Write(Boolean)	Writes to an MS-DOS encoded file or binary file.
Write(Byte)	Writes to an MS-DOS encoded file or binary file.
Write(Char)	Writes to an MS-DOS encoded file or binary file.
Write(Integer)	Writes to an MS-DOS encoded file or binary file.
Write(BigInteger)	Writes to an MS-DOS encoded file or binary file.
Write(Decimal)	Writes to an MS-DOS encoded file or binary file.
Write(Guid)	Writes to an MS-DOS encoded file or binary file.
Write(Text)	Writes to an MS-DOS encoded file or binary file.
Write(Code)	Writes to an MS-DOS encoded file or binary file.
Write(Label)	Writes to an MS-DOS encoded file or binary file.
Write(BigText)	Writes to an MS-DOS encoded file or binary file.

METHOD NAME	DESCRIPTION
Write(Date)	Writes to an MS-DOS encoded file or binary file.
Write(Time)	Writes to an MS-DOS encoded file or binary file.
Write(DateTime)	Writes to an MS-DOS encoded file or binary file.
Write(DateFormula)	Writes to an MS-DOS encoded file or binary file.
Write(Duration)	Writes to an MS-DOS encoded file or binary file.
Write(Option)	Writes to an MS-DOS encoded file or binary file.
Write(Record)	Writes to an MS-DOS encoded file or binary file.
Write(RecordId)	Writes to an MS-DOS encoded file or binary file.
Write(String)	Writes to an MS-DOS encoded file or binary file.
Write(Any)	Writes to an MS-DOS encoded file or binary file.
WriteMode([Boolean])	Use this method before you use Open method (File)] to set or test whether you can write to a file in later calls.

File.Copy Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Copies a file.

> **NOTE**
> This method is supported only in Business Central on-premises.

Syntax

```
[Ok := ]  File.Copy(FromName: String, ToName: String)
```

> **NOTE**
> This method can be invoked without specifying the data type name.

Parameters

FromName
Type: String
The name of the file that you want to make a copy of, including its path. When you enter the path, consider these shortcuts:

- You can omit the drive designation if the file is located on the current drive.
- You can omit the full path if the file is located in the current directory.
- You can enter only the subdirectory name if the file is located in a subdirectory of the current directory.

ToName
Type: String
The name that you want to assign to the copy that includes its path. When you enter the path, consider these shortcuts:

- You can omit the drive designation if the file is located on the current drive.
- You can omit the full path if the file is located in the current directory.
- You can enter only the subdirectory name if the file is located in a subdirectory of the current directory.

Return Value

Ok Type: Boolean **true** if the operation was successful; otherwise **false**. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

Remarks

If you do not use the return value and the file cannot be copied, a run-time error will occur. If you do include the

return value in your code, you must handle any errors yourself.

Example

The following example copies a file that is named OldFile from a folder that is named Old on drive C to a folder that is named New. If the file is copied, a message is displayed and the program continues. Otherwise, an error occurs. This example assumes that you have created the following file 'c:\Old\' OldFile.

```
 var
    OldFile: Text;
    NewFile: Text;
begin
    OldFile := 'old.txt';
    NewFile := 'new.txt';
    if File.Copy('c:\Old\' + OldFile, 'c:\New\' + NewFile) then
      // Continue your program.
      Message('The file was copied.');
    else
      // Handle the error.
      Message('The file was not copied.');
end;
```

File.Download Method

2/17/2021 • 3 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Sends a file from a server computer to the client computer. The client computer is the computer that is running the Windows client or the computer that is running a browser that accesses the web client.

> **NOTE**
> This method is supported only in Business Central on-premises.

Syntax

```
[Ok := ]  File.Download(FromFile: String, DialogTitle: String, ToFolder: String, ToFilter: String, var
ToFile: Text)
```

> **NOTE**
> This method can be invoked without specifying the data type name.

Parameters

FromFile
Type: String
The name of the file on the server computer that you want to download to the client computer.

DialogTitle
Type: String
The title that you want to display in the dialog box for downloading the file. This parameter is not supported by the web client. The title is determined by the end-user's browser.

ToFolder
Type: String
The default folder in which to save the file to be downloaded. The folder name is displayed in the dialog box for downloading the file. The folder can be changed by the user. This parameter is not supported by the web client. By default, the files are saved to the default download location that is configured in the end-user's browser.

ToFilter
Type: String
The type of file that can be downloaded to the client computer. The type is displayed in the dialog box for downloading the file. This parameter is not supported by the web client.

ToFile
Type: Text
The name to give the downloaded file. This is the default file name that is shown in the dialog box for downloading the file. This value can be changed by the user.

Return Value

Ok Type: Boolean **true** if the operation was successful; otherwise **false**. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

Remarks

> **NOTE**
> On devices that run Apple iOS, such as iPad, you can only download a file if the Apple iOS device on which you are downloading the file has an application which supports the file type.

Files are saved to the default download location that is configured in the end-user's browser.

The business logic is run on the computer that is running Dynamics 365 Business Central service and not on the client. Files are created on the computer that is running Dynamics 365 Business Central service and not locally on the client computer.

Upload Method (File) and UploadIntoStream Method (File) are used to send a file from the client to a Dynamics 365 Business Central service instance.

Download Method (File) and DownloadFromStream Method (File) are used to send a file from a Dynamics 365 Business Central service instance to the client.

We recommend that you use the methods in codeunit **419 File Management** to upload and download files.

> **NOTE**
> Internet browsers can only handle one file per request. Therefore, with the Web client, if this method is called in a repetitive statement (or loop) that generates multiple files, only the last file will be sent to the browser. Alternatively, when designing for the Web client, bundle the files in an archive file (.zip), for example, by using the methods found in codeunit **419 File Management**. For more details about this design pattern, see Multi-File Download. Although this article is written for Dynamics NAV, it is still relevant for Business Central. The methods in codeunit 419 are not external, therefore cannot be used in extensions. Instead, when developing extensions in AL, use the external methods of codeunit **425 Data Compression**. The approach is similar.

Example

This example shows how to use the Download method.

```
 var
    ToFile: Text;
begin
    ToFile := 'ToFile.txt';
    Download('FromFile.txt','Download file','C:\','Text file(*.txt)|*.txt',ToFile);
end;
```

File.DownloadFromStream Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Sends a file from server computer to the client computer. The client computer is the computer that is running the Windows client or the computer that is running the browser that accesses the web client.

Syntax

```
[Ok := ]  File.DownloadFromStream(InStream: InStream, DialogTitle: String, ToFolder: String, ToFilter:
String, var ToFile: Text)
```

NOTE

This method can be invoked without specifying the data type name.

Parameters

InStream

Type: InStream

An InStream that you want to use to send the data in a file on Business Central Server to a file on the client computer.

DialogTitle

Type: String

The title that you want to display in the dialog box for downloading the file. This parameter is not supported by the web client. The title is determined by the end-user's browser.

ToFolder

Type: String

The default folder in which to save the file to be downloaded. The folder name is displayed in the dialog box for downloading the file. The folder can be changed by the user. This parameter is not supported by the web client. By default, files are saved to the default download location that is configured in the end-user's browser.

ToFilter

Type: String

The type of file that can be downloaded to the client computer. The type is displayed in the dialog box for downloading the file. This parameter is not supported by the web client.

ToFile

Type: Text

The name to give the downloaded file. This is the default file name that is shown in the dialog box for downloading the file. This value, can be changed by the user.

Return Value

Ok Type: Boolean **true** if the operation was successful; otherwise **false**. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

Remarks

> **NOTE**
> On devices that run Apple iOS, such as iPad, you can only download a file if the Apple iOS device on which you are downloading the file has an application that supports the file type.

The business logic runs on the computer that is running Dynamics 365 Business Central service and not on the client. Files are created on a Dynamics 365 service and not locally on the client computer. When you write code, you must consider where files are created.

Use Upload Method (File) and UploadIntoStream Method (File) to send a file from a client to a Dynamics 365 Business Central service instance.

Use Download Method (File) and DownloadFromStream Method (File) to send a file from a Dynamics 365 Business Central service instance to a client.

We recommend that you use the methods in codeunit **419 File Management** to upload and download files.

> **NOTE**
> Internet browsers can only handle one file per request. Therefore, with the Web client, if this method is called in a repetitive statement (or loop) that generates multiple files, only the last file will be sent to the browser. Alternatively, when designing for the Web client, bundle the files in an archive file (.zip), for example, by using the methods found in codeunit **419 File Management**. For more details about this design pattern, see Multi-File Download. Although this article is written for Dynamics NAV, it is still relevant for Business Central. The methods in codeunit 419 are not external, therefore cannot be used in extensions. Instead, when developing extensions in AL, use the external methods of codeunit **425 Data Compression**. The approach is similar.

Example

```
 var
    TempFile: File;
    NewStream: InsTream;
    ToFileName: Variant;
begin
    TempFile.CreateTempFile();
    TempFile.Write('abc');
    TempFile.CreateInStream(NewStream);
    ToFileName := 'SampleFile.txt';
    DownloadFromStream(NewStream,'Export','','All Files (*.*)|*.*',ToFileName);
end;
```

File.Erase Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Deletes a file.

> **NOTE**
> This method is supported only in Business Central on-premises.

Syntax

```
[Ok := ]  File.Erase(Name: String)
```

> **NOTE**
> This method can be invoked without specifying the data type name.

Parameters

Name
Type: String
The name of the file that you want to delete, including the path. When you enter the path, consider these shortcuts:

- You can omit the drive designation if the file is located on the current drive.
- You can omit the full path if the file is located in the current directory.
- You can enter only the subdirectory name if the file is located in a subdirectory of the current directory.

Return Value

Ok Type: Boolean **true** if the operation was successful; otherwise **false**. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

If the user who runs this method does not have the required permission to delete the file or if the file is read-only, then the file is not deleted.

Example

The following example deletes the file that is named C:\TestFolder\NewTestFile.txt.This example assumes that you have created the file on your computer.

```
Erase('C:\TestFolder\NewTestFile.txt');
```

File.Exists Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Determines whether a file exists.

> **NOTE**
> This method is supported only in Business Central on-premises.

Syntax

```
[Ok := ]  File.Exists(Name: String)
```

> **NOTE**
> This method can be invoked without specifying the data type name.

Parameters

Name
Type: String
The name of the file that you want to check. This includes the path. When you enter the path, consider these shortcuts:

- You can omit the drive designation if the file is located on the current drive.
- You can omit the full path if the file is located in the current directory.
- You can enter only the subdirectory name if the file is located in a subdirectory of the current directory.

Return Value

Ok Type: Boolean **true** if the server instance has access to the file; otherwise **false**. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

Example

The following example uses the Exists method to determine whether the specified file exists. If the file exists, then the WriteMode Method (File) allows the file to be open for writing. The Open Method (File) opens the file, the Write Method (File) writes the text "Hello World" to the file, and then the Close Method (File) method closes the file. If the file does not exist, an error message is displayed. This example assumes that you have created the following file C:\TestFolder\TestFile2.txt.

```
 var
    TestFile: File;
    FileName: Text;
begin
    FileName := 'C:\TestFolder\TestFile2.txt';
    if exists(FileName) then begin
      TestFile.WriteMode(true);
      TestFile.Open(FileName);
      TestFile.Write('Hello World');
      TestFile.Close;
    end else
        Message('%1 does not exist.', FileName);
end;
```

File.GetStamp Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Gets the exact time that a file was last written to.

> **NOTE**
> This method is supported only in Business Central on-premises.

Syntax

```
[Ok := ]  File.GetStamp(Name: String, var Date: Date [, var Time: Time])
```

> **NOTE**
> This method can be invoked without specifying the data type name.

Parameters

Name
Type: String
The name of the file, including the path. When you enter the path, consider these shortcuts:

- You can omit the drive designation if the file is located on the current drive.
- You can omit the full path if the file is located in the current directory.
- You can enter only the subdirectory name if the file is located in a subdirectory of the current directory.

Date
Type: Date
The date that the file was last written to.

Time
Type: Time
The time that the file was last written to. Optional.

Return Value

Ok Type: Boolean **true** if the operation was successful; otherwise **false**. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

Example

The following example gets the date and time that a file was written to and displays the data in a message box. The code example assumes that you have created the file 'C:\MyFolder\MyText.txt'. This example requires that you create the following global variables and text constant.

```
 var
    varDate: Date;
    varTime: Time;
    varFileName: Text;
    Text000: Label 'This document was last written to on %1 at %2.';
begin
    varFileName := 'C:\MyFolder\MyText.txt';
    GetStamp(VarFileName, varDate, varTime);
    Message(Text000, varDate, varTime);
end;
```

File.IsPathTemporary Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 2.0.*

Validates whether the given path is located in the current users temporary folder within the current service.

> **NOTE**
> This method is supported only in Business Central on-premises.

Syntax

```
[Ok := ]  File.IsPathTemporary(Name: String)
```

> **NOTE**
> This method can be invoked without specifying the data type name.

Parameters

Name
Type: String
The name of the file, including the path.

Return Value

Ok Type: Boolean **true** if the name point to a location is the users temporary folder within the current service; **false** otherwise. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

File.Rename Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Renames an ASCII or binary file.

> **NOTE**
> This method is supported only in Business Central on-premises.

Syntax

```
[Ok := ]  File.Rename(OldName: String, NewName: String)
```

> **NOTE**
> This method can be invoked without specifying the data type name.

Parameters

OldName
Type: String
The current name of the file that you want to change, including its path. When you enter the path, consider these shortcuts:

- You can omit the drive designation, if the file is located on the current drive.
- You can omit the full path, if the file is located in the current directory.
- You can enter only the subdirectory name, if the file is located in a subdirectory of the current directory.

NewName
Type: String
The new name that you want to assign to the file, including its path. When you enter the path, consider these shortcuts:

- You can omit the drive designation, if the file is located on the current drive.
- You can omit the full path, if the file is located in the current directory.
- You can enter only the subdirectory name, if the file is located in a subdirectory of the current directory.

Return Value

Ok Type: Boolean **true** if the operation was successful; otherwise **false**. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

Remarks

Typically, the return value is **false** if the file does not exist, or if the file is a system or hidden file.

Example

The following example changes the name of a text file that is named Testfile.txt to NewTestFile.txt. The path of the file that is renamed is C:\TestFolder\Testfile.txt. The name and path are stored in the varOldFile variable. The new name and path of the file are stored the varNewfile variable. The RENAME method uses the variables to change the name of the file. This example assumes that you have created the following file on your computer: C:\TestFolder\Testfile.txt.

```
 var
    varOldfile: Text;
    varNewfile: Text;
begin
    varOldfile := 'C:\TestFolder\Testfile.txt' ;
    varNewfile := 'C:\TestFolder\NewTestFile.txt';
    Rename(varOldfile, varNewfile);
end;
```

File.SetStamp Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Sets a timestamp for a file.

> **NOTE**
> This method is supported only in Business Central on-premises.

Syntax

```
[Ok := ]  File.SetStamp(Name: String, Date: Date [, Time: Time])
```

> **NOTE**
> This method can be invoked without specifying the data type name.

Parameters

Name
Type: String
The name of the file, including its path. When you enter the path, keep in mind these shortcuts:

- You can omit the drive designation, if the file is located on the current drive.
- You can omit the full path, if the file is located in the current directory.
- You can enter only the subdirectory name, if the file is located in a subdirectory of the current directory.

Date
Type: Date
The date that you want stamped on the file.

Time
Type: Time
The time that you want stamped on the file.

Return Value

Ok Type: Boolean **true** if the operation was successful; otherwise **false**. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

Example

The following example sets timestamp for that a file that is named varFileName. The date and time are set to the current date and on your computer respectively. The code example assumes that you have created the following file: 'C:\MyFolder\MyText.txt'. The following example requires that you create the following global variables and text constant.

```
 var
    varFileName: Text;
    varDate: Date;
    varTime: Time;
    Text000: Label 'The timestamp for this file is Date: %1 Time: %2.';
begin
    VarFileName := 'C:\MyFolder\MyText.txt';
    varDate := Today;
    varTime := Time;
    SetStamp(VarFileName, varDate, varTime);
    Message(Text000, varDate, varTime);
end;
```

File.Upload Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Sends a file from the client computer to the server computer. The client computer is the computer that is running the Windows client or the computer that is running a browser that accesses the web client.

> **NOTE**
> This method is supported only in Business Central on-premises.

Syntax

```
[Ok := ]  File.Upload(DialogTitle: String, FromFolder: String, FromFilter: String, FromFile: String, var
ToFile: Text)
```

> **NOTE**
> This method can be invoked without specifying the data type name.

Parameters

DialogTitle

Type: String

The title that you want to display in the dialog box for uploading the file. This parameter is not supported by the web client. The title is determined by the end-user's browser.

FromFolder

Type: String

The name of the folder that is displayed in the dialog box. This is the default value, and the user can change it. This parameter is not supported by the web client. The browser uses the folder that was last accessed.

FromFilter

Type: String

The type of file that can be uploaded to the server. In the Windows client, the type is displayed in the upload dialog box, so that the user can only select files of the specified type. For the web client, a user can try to upload any file type but an error occurs if the file is not the specified type.

FromFile

Type: String

The default file that you want to upload to the service. The name displays in the dialog box for uploading the file. The user can change the file. This parameter is not supported by the web client.

ToFile

Type: Text

The path and file name to give the uploaded file. If you do not provide a path, or you upload the file that uses web client, then the file is uploaded to the following folder on the computer that is running the server:

\ProgramData\Microsoft\Microsoft Dynamics NAV\110\Server\MicrosoftDynamicsNAVServer$DynamicsNAV110\users\ServiceAccount

Return Value

Ok Type: Boolean **true** if the operation was successful; otherwise **false**. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

Remarks

> **NOTE**
> This method is not supported on devices that run Apple iOS, such as iPad. The dialog box for uploading a file displays, but it is disabled and the user cannot select a file.

The business logic is run on the Dynamics 365 Business Central service and not on the client. Files are created on the Dynamics 365 Business Central service and not locally on the client.

Upload Method (File) and UploadIntoStream Method (File) are used to send a file from the client to a Dynamics 365 Business Central service.

Download Method (File) and DownloadFromStream Method (File) are used to send a file from a Dynamics 365 Business Central service to the client.

We recommend that you use the methods in codeunit 419, File Management, to upload and download files.

Example

```
Upload('Upload file','C:\','Text file(*.txt)|*.txt','Test.txt',varTest);
```

See Also

File Data Type

Developing Extensions

File.UploadIntoStream Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Sends a file from the client computer to the corresponding server. The client computer is the computer that is running the Windows client or the computer that is running a browser that accesses the web client.

Syntax

```
[Ok := ]  File.UploadIntoStream(DialogTitle: String, FromFolder: String, FromFilter: String, var FromFile:
Text, var InStream: InStream)
```

NOTE

This method can be invoked without specifying the data type name.

Parameters

DialogTitle

Type: String

The text displayed in the title bar of the Open dialog box. This parameter is not supported by the web client. The title is determined by the end-user's browser.

FromFolder

Type: String

The path of the folder that is displayed in the File Open dialog box. This is the default folder, but the user can browse to any available location. This parameter is not supported by the web client. By default, the browser uses the folder that was last accessed.

FromFilter

Type: String

The type of file that can be uploaded to the server. In the Windows client, the type is displayed in the upload dialog box, so the user can only select files of the specified type. For the web client, a user can try to upload any file type but an error occurs if the file is not the specified type.

FromFile

Type: Text

The default file to upload to the service. The name displays in the dialog box for uploading the file. The user can change the file. This parameter is not supported by the web client.

InStream

Type: InStream

Return Value

Ok Type: Boolean **true** if the operation was successful; otherwise **false**. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

Remarks

> **NOTE**
>
> This method is not supported on devices that run Apple iOS, such as iPad. The dialog box for uploading a file displays, but it is turned off and the user cannot select a file.

The business logic runs on the Dynamics 365 Business Central service and not on the client. Files are created on Dynamics 365 Business Central service and not locally on the client computer.

Use Upload Method (File) and UploadIntoStream Method (File) to send a file from the client to the Dynamics 365 Business Central service.

Use Download Method (File) and DownloadFromStream Method (File) to send a file from the Dynamics 365 Business Central service to the client.

We recommend that you use the methods in codeunit 419, File Management, to upload and download files.

Example

```
 var
    FileName: Text;
    NVInStream: InStream;
begin
    FileName := 'c:\SomeFile.txt';
    UploadIntoStream('Import','',' All Files (*.*)|*.*',FileName,NVInStream);
end;
```

File.Close Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Closes a file that has been opened by the Open method (File).

> **NOTE**
> This method is supported only in Business Central on-premises.

Syntax

```
File.Close()
```

> **NOTE**
> This method can be invoked without specifying the data type name.

Parameters

File Type: File An instance of the File data type.

Remarks

If the file is not open, a run-time error will occur.

Example

The following example determines whether the specified file exists. If it exists, the WriteMode Method (File) allows the file to be open for writing. The Open Method (File) opens the file, the Write Method (File) writes the text "Hello World" to the file, and then the Close method closes the file. If the file does not exist, an error message is displayed. This example assumes that you have created the following file C:\TestFolder\TestFile2.txt.

```
var
    FileName: Text;
    TestFile: File;
begin
    FileName := 'C:\TestFolder\TestFile2.txt';
    if Exists(FileName) then begin
      TestFile.WriteMode(true);
      TestFile.Open(FileName);
      TestFile.Write('Hello World');
      TestFile.Close;
    end else
    Message('%1 does not exist.', FileName);
end;
```

See Also

File Data Type

File.Create Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Creates an Automation object.

> **NOTE**
> This method is supported only in Business Central on-premises.

Syntax

```
[Ok := ]  File.Create(Name: String [, Encoding: TextEncoding])
```

> **NOTE**
> This method can be invoked without specifying the data type name.

Parameters

File Type: File An instance of the File data type.

Name
Type: String

Encoding
Type: TextEncoding

Return Value

Ok Type: Boolean **true** if the operation was successful; otherwise **false**. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

Remarks

If the TextMode Method (File) returns **true** and you read or write to the file, text is put in the buffer.

If the TextMode Method (File) method returns **false**, binary information is put in the buffer.

If you call Create on a File variable that refers to an open file, the method does not automatically close the existing file and create the new file. You must explicitly call the Close Method (File) to close the existing file. Otherwise, a run-time error occurs.

Example

The following example creates a file that is named TestFile.txt in the path C:\TestFolder\. The TestFile variable stores the file and path that is created. If the file is created, a message that states that the file is created is displayed. Otherwise, an error message is displayed. This example requires that you create the following global

variable.

```
 var
    TestFile: File;
begin
    if TestFile.Create('C:\TestFolder\TestFile.txt') then begin
      Message('%1 is created', TestFile.Name);
    end else
    Error('The file could not be created');
end;
```

File.CreateInStream Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Creates an InStream object for a file. This enables you to import or read data from the file.

> **NOTE**
> This method is supported only in Business Central on-premises.

Syntax

```
File.CreateInStream(InStream: InStream)
```

> **NOTE**
> This method can be invoked without specifying the data type name.

Parameters

File Type: File An instance of the File data type.

InStream
Type: InStream

Example

The following example imports data from an XML document to a table. The code uses the Open Method (File) to open the XML document named NewCustomer.xml from a folder named Import on the C drive. The CreateInStream Method (File) creates a data stream to get the data from the XML document into the table. The Import Method (XMLport) then imports, parses the data, and adds it as a record to the table by using an XMLport (50004). The Close Method (File) then closes the data stream. This example assumes that you have created a NewCustomer.xml file in a folder that is named Import on the C drive and you have created an XMLport and given it ID 50004.

```
 var
    ImportXmlFile: File;
    XmlINStream: InStream;
begin
    ImportXmlFile.Open('C:\Import\NewCustomer.xml');
    ImportXmlFile.CreateInStream(XmlINStream);
    XMLPORT.Import(50004, XmlINStream);
    ImportXmlFile.Close;
end;
```

File.CreateOutStream Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Creates an OutStream object for a file. This enables you to export or write data to the file.

> **NOTE**
> This method is supported only in Business Central on-premises.

Syntax

```
File.CreateOutStream(OutStream: OutStream)
```

> **NOTE**
> This method can be invoked without specifying the data type name.

Parameters

File Type: File An instance of the File data type.

OutStream
Type: OutStream

Example

The following example uses the CreateOUTSTREAM method to export data from a table to an XML document. The code uses the Create Method (File) to create an XML file that is named CustXmlFile.xml in a folder that is named xmlData on drive C. The CreateOUTSTREAM Method (File) opens a data stream to output the data from the table to the XML file. The Export Method (XMLport) then exports the data and saves it at the specified location. The Close Method (File) closes the data stream. This example assumes that you have created a folder named xmlData on drive C.

```
 var
    CustXmlFile: File;
    XmlStream: OutStream;
begin
    CustXmlFile.Create('C:\XmlData\Customer.xml');
    CustXmlFile.CreateOUTSTREAM(XmlStream);
    XMLPORT.Export(50002, XmlStream);
    CustXmlFile.Close;
end;
```

File.CreateTempFile Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Creates a temporary file. This enables you to save data of any format to a temporary file. This file has a unique name and will be stored in a temporary file folder.

> **NOTE**
> This method is supported only in Business Central on-premises.

Syntax

```
[Ok := ]  File.CreateTempFile([Encoding: TextEncoding])
```

> **NOTE**
> This method can be invoked without specifying the data type name.

Parameters

File Type: File An instance of the File data type.

Encoding
Type: TextEncoding

Return Value

Ok Type: Boolean

Remarks

You can use this method together with Name Method (File) and Close Method (File).

Example

This example creates a temporary file that has the text Hello and then deletes the file by using the File.Close method.

```
 var
    FileName: File;
begin
    FileName.CreateTempFile;
    FileName.Write('Hello');
    FileName.Close;
end;
```

File.Len Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Gets the length of an ASCII or binary file.

> **NOTE**
> This method is supported only in Business Central on-premises.

Syntax

```
Length :=   File.Len()
```

> **NOTE**
> This method can be invoked using property access syntax.

> **NOTE**
> This method can be invoked without specifying the data type name.

Parameters

File Type: File An instance of the File data type.

Return Value

Length Type: Integer

Remarks

This method is often used with Pos Method (File) and Seek Method (File).

Example

The following example opens a text file that is named 'C:\TestFolder\TestFile.txt' and contains the text 'Hello World'. The Seek Method (File) sets a pointer to position 6 in the file. The Read Method (File) reads the file and stores the retrieved contents in the varString variable. The LEN method retrieves the length of the file and stores it the varLength variable. The text that is read starts from the position of the pointer, so the text 'World' and the length of 12 are displayed in the message box. The length of the file is not affected by the Seek Method (File). This example assumes that you have created the text file that is named C:\TestFolder\TestFile.txt and contains the text 'Hello World'. This example requires that you create the following global variables.

```
var
   Testfile: File;
   varString: Text[200];
   varLength: Integer;
begin
   Testfile.Open('C:\TestFolder\TestFile.txt');
   Testfile.Seek(6);
   Testfile.Read(varString);
   varLength := Testfile.LEN;
   Message('The text is: %1. The length of the file is: %2', varString, varLength);
end;
```

File.Name Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Gets the name of an ASCII or binary file.

> **NOTE**
> This method is supported only in Business Central on-premises.

Syntax

```
Name :=   File.Name()
```

> **NOTE**
> This method can be invoked using property access syntax.

> **NOTE**
> This method can be invoked without specifying the data type name.

Parameters

File Type: File An instance of the File data type.

Return Value

Name Type: String

Remarks

You must use the Open Method (File) to open the file before you can use this method.

Example

The following example opens a text file that is named C:\TestFolder\TestFile.txt. The Name Method (File) retrieves the name and path of the text file and stores it in the varName variable. The value in the variable is displayed in a message box. This example assumes that you have created a text file named C:\TestFolder\TestFile.txt.

```
var
   Testfile: File;
   varName: Text;
begin
   TestFile.Open('C:\TestFolder\TestFile.txt');
   varName := TestFile.Name;
   Message('The name of the file is: %1',varName);
end;
```

File.Open Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Opens an ASCII or binary file. This method does not create the file if it does not exist.

> **NOTE**
> This method is supported only in Business Central on-premises.

Syntax

```
[Ok := ]  File.Open(Name: String [, Encoding: TextEncoding])
```

> **NOTE**
> This method can be invoked without specifying the data type name.

Parameters

File Type: File An instance of the File data type.

Name
Type: String

Encoding
Type: TextEncoding

Return Value

Ok Type: Boolean **true** if the operation was successful; otherwise **false**. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

Remarks

If you call Open on a file variable that refers to an open file, then the method does not automatically close the existing file and open the new file. You must explicitly call the Close Method (File) to close the existing file. If you call Open on a file that is already open, then a run-time error occurs.

Example

This example shows how to open an .xml file for reading in text mode. To use this example, you must create the simple.xml file at C:\temp and create the following variable.

```
var
   TestFile: File;
```

```
TestFile.TextMode(True);
TestFile.WriteMode(False);
TestFile.Open('C:\temp\simple.xml');
```

If you want to be explicit about the encoding of a file, you can set the *TextEncoding* parameter. The following code example replaces the last statement in the previous example.

```
TestFile.TextMode(True);
TestFile.WriteMode(False);
TestFile.Open('C:\temp\simple.xml', TextEncoding::Windows);
```

File.Pos Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Gets the current position of the file pointer in an ASCII or binary file.

> **NOTE**
> This method is supported only in Business Central on-premises.

Syntax

```
Position :=   File.Pos()
```

> **NOTE**
> This method can be invoked using property access syntax.

> **NOTE**
> This method can be invoked without specifying the data type name.

Parameters

File Type: File An instance of the File data type.

Return Value

Position Type: Integer

Remarks

This method is often used with Len Method (File) and Seek Method (File).

Example

The following example opens a text file that is named C:\TestFolder\TestFile.txt. The WriteMode Method (File) enables the file to be open in write mode. The POS method retrieves the position of the file pointer and stores it in the Position variable. When the file is open, the position of the pointer is 0 because a pointer is not set. The Seek Method (File) method sets a file pointer at position 5. After the Seek Method (File) is executed, the POS method returns 5 as the file pointer position. This example assumes that you have created a text file named C:\TestFolder\TestFile.txt.

```
 var
    Testfile: File;
    Position: Integer;
begin
    File.WriteMode(true);
    TestFile.Open('C:\TestFolder\TestFile.txt');
    Position := TestFile.Pos;
    Message('Pointer position before Seek: %1', Position);
    Testfile.Seek(5);
    Position := Testfile.POS;
    Message('Pointer position after Seek: %1', Position);
end;
```

File.Read Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Reads from an MS-DOS encoded file or binary file.

> **NOTE**
> This method is supported only in Business Central on-premises.

Syntax

```
[Read := ]  File.Read(var Read: Any)
```

> **NOTE**
> This method can be invoked without specifying the data type name.

Parameters

File Type: File An instance of the File data type.

Read
Type: Any
Streams a BigText object that is stored as a BLOB in a table to a BigText variable.

Return Value

Read Type: Integer If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

Remarks

To read from a file that is larger than 1024 bytes, use streams instead of the **File.Read** method.

MS-DOS encoding, which is also referred to as OEM encoding, is an older format than UTF-8 and UTF-16, but it is still widely supported. MS-DOS encoding was the only format that was supported by earlier versions of Dynamics 365.

MS-DOS encoding requires a different character set for each language. MS-DOS text is encoded to the internal Unicode data type by using the system locale language of the computer that is running Dynamics 365 Business Central service. If you read a file that uses MS-DOS encoding, then you must set the system locale language of the computer that is running Dynamics 365 Business Central service to match the language of the data in the file that is being read. For example, if the file contains text in Danish, then you must set the system locale language of the computer that is running Dynamics 365 Business Central service to Danish before you call the **Read** method (File) or Write Method (File).

We recommend that you use the File data type for files that were created in earlier versions of Dynamics 365.

To read or write files in Unicode or in other formats, we recommend that you use .NET Framework interoperability and use the System.IO Namespace.

Example

The following example opens a text file that is named C:\TestFolder\TestFile.txt. The READ method read the contents of the file and stores it in the String variable. The method returns the size of the text that was read, stores it in the varSize variable, and displays it in a message box. This example assumes that you have created a text file named C:\TestFolder\TestFile.txt that contains less than 500 bytes.

```
 var
    Testfile: File;
    String: Text[500];
    varSize: Integer;
begin
    TestFile.Open('C:\TestFolder\TestFile.txt');
    varSize := TestFile.Read(String);
    Message('The text "%1" is %2 bytes.', String, varSize);
end;
```

File.Seek Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Sets a file pointer to a new position in an ASCII or binary file.

> **NOTE**
> This method is supported only in Business Central on-premises.

Syntax

```
File.Seek(Position: Integer)
```

> **NOTE**
> This method can be invoked without specifying the data type name.

Parameters

File Type: File An instance of the File data type.

Position
Type: Integer
The position at which to set the pointer.

Remarks

This method is often used with Pos Method (File) and Len Method (File).

Example

The following example sets a pointer at position 20 in a file and truncates the file at the pointer position. The WriteMode Method (File) enables a file named C:\TestFolder\TestFile.txt to open in write mode. The Seek method sets a pointer at position 20 in the file and then the Trunc Method (File) truncates the contents of the file at the pointer position. This example assumes that you have created the text file C:\TestFolder\TestFile.txt.

```
 var
    TestFile: File;
begin
    TestFile.WriteMode(True);
    TestFile.Open('C:\TestFolder\TestFile.txt');
    TestFile.Seek(20);
    TestFile.Trunc;
end;
```

File.TextMode Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Sets whether a file should be opened as an ASCII file or a binary file. Gets the current setting of this option for a file.

NOTE

This method is supported only in Business Central on-premises.

Syntax

```
[Textmode := ]  File.TextMode([Mode: Boolean])
```

NOTE

This method can be invoked using property access syntax.

NOTE

This method can be invoked without specifying the data type name.

Parameters

File Type: File An instance of the File data type.

Mode
Type: Boolean

Return Value

Textmode Type: Boolean

Remarks

This method should be used before File.Open is used to open the file. If you use this method on a file that is already open, then an error occurs.

Example

The following example sets the TextMode to **true** when the file is open for writing. This means the file contents will be written to a text file that is named 'C:\TestFolder\TestFile.txt' by using ASCII characters. The WriteMode Method (File) and the Open Method (File) open the file for writing and the text 'Hello World' is written. The Close Method (File) closes the file after the file is written to. This example assumes that you have created a text file that is named C:\TestFolder\TestFile.txt.

```
var
    TestFile: File;
begin
    TestFile.TextMode(True);
    TestFile.WriteMode(True);
    TestFile.Open('C:\TestFolder\TestFile.txt');
    TestFile.Write('Hello World');
    TestFile.Close;
end;
```

File.Trunc Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Truncate an ASCII or binary file to the current position of the file pointer.

> **NOTE**
> This method is supported only in Business Central on-premises.

Syntax

```
File.Trunc()
```

> **NOTE**
> This method can be invoked without specifying the data type name.

Parameters

File Type: File An instance of the File data type.

Remarks

Typically, you use this method together with Seek Method (File). Use File.Seek to position the pointer in the file and then use File.Trunc to truncate the file at that point.

Example

The following example sets a pointer at position 20 in a file and truncates the file at the pointer position. The WriteMode Method (File) allows the file that is named C:\TestFolder\TestFile.txt to open in write mode. The Seek method sets a pointer at position 20 in the file and then the Trunc Method (File) truncates the contents at the pointer position. This example assumes that you have created a text file named C:\TestFolder\TestFile.txt. The file is then saved a truncated file.

```
 var
    TestFile: File;
begin
    TestFile.WriteMode(True);
    TestFile.Open('C:\TestFolder\TestFile.txt');
    TestFile.Seek(20);
    TestFile.Trunc;
end;
```

File.Write Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Writes to an MS-DOS encoded file or binary file.

> **NOTE**
> This method is supported only in Business Central on-premises.

Syntax

```
File.Write(Value: Boolean)
```

> **NOTE**
> This method can be invoked without specifying the data type name.

Parameters

File Type: File An instance of the File data type.

Value
Type: Boolean
The data that you want to write to the file.

Remarks

You must call the TextMode Method (File) before you call the Write method.

If TextMode Method (File) is set to **true** and *Value* is an integer, then the integer is written as text, followed by a new line character.

If *Value* is a record, each field is separated by a tab character.

If TextMode Method (File) is **false** and *Value* is an integer, an integer is written that is four bytes long.

MS-DOS encoding requires a different character set for each language. MS-DOS text is encoded to the internal Unicode data type by using the system locale language of the computer that is running Dynamics 365 Business Central service. If you write to a file that uses MS-DOS encoding, then you must set the system locale language of the computer that is running Dynamics 365 Business Central service to match the language of the data that you want to write to the file.

We recommend that you use the File data type for files that were created in earlier versions of Dynamics 365.

To read or write files in Unicode or in other formats, we recommend that you use .NET Framework interoperability and use the System.IO Namespace.

Example

The following example determines whether the specified file exists. If it exists, the WriteMode Method (File) allows the file to be open for writing. The Open Method (File) opens the file, the Write Method (File) writes the text "Hello World" to the file and then the Close Method (File) closes the file. If the file does not exist, then an error message is displayed. This example assumes that you have created the following file: C:\TestFolder\TestFile.txt.

```
var
  FileName: Text;
  TestFile: File;
  Bool: Boolean;
begin
  FileName := 'C:\TestFolder\TestFile.txt';
  if Exists(FileName) then begin
    TestFile.WriteMode(True);
    TestFile.Open(FileName);
    TestFile.Write(Bool);
    TestFile.Close;
  end else
    Message('%1 does not exit.', FileName);
end;
```

The following example determines whether the specified file exists. If it exists, the WriteMode Method (File) allows the file to be open for writing. The Open Method (File) opens the file, the Write Method (File) writes the text "Hello World" to the file and then the Close Method (File) closes the file. If the file does not exist, then an error message is displayed. This example assumes that you have created the following file: C:\TestFolder\TestFile.txt.

```
 var
    FileName: Text;
    TestFile: File;
    Txt: Text;
begin
    FileName := 'C:\TestFolder\TestFile.txt';
    if Exists(FileName) then begin
      TestFile.WriteMode(True);
      TestFile.Open(FileName);
      TestFile.Write(Txt);
      TestFile.Close;
    end else
      Message('%1 does not exit.', FileName);
end;
```

File.Write Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Writes to an MS-DOS encoded file or binary file.

> **NOTE**
> This method is supported only in Business Central on-premises.

Syntax

```
File.Write(Value: Code)
```

> **NOTE**
> This method can be invoked without specifying the data type name.

Parameters

File Type: File An instance of the File data type.

Value
Type: Code
The data that you want to write to the file.

Remarks

You must call the TextMode Method (File) before you call the Write method.

If TextMode Method (File) is set to **true** and *Value* is an integer, then the integer is written as text, followed by a new line character.

If *Value* is a record, each field is separated by a tab character.

If TextMode Method (File) is **false** and *Value* is an integer, an integer is written that is four bytes long.

MS-DOS encoding requires a different character set for each language. MS-DOS text is encoded to the internal Unicode data type by using the system locale language of the computer that is running Dynamics 365 Business Central service. If you write to a file that uses MS-DOS encoding, then you must set the system locale language of the computer that is running Dynamics 365 Business Central service to match the language of the data that you want to write to the file.

We recommend that you use the File data type for files that were created in earlier versions of Dynamics 365.

To read or write files in Unicode or in other formats, we recommend that you use .NET Framework interoperability and use the System.IO Namespace.

Example

The following example determines whether the specified file exists. If it exists, the WriteMode Method (File) allows the file to be open for writing. The Open Method (File) opens the file, the Write Method (File) writes the text "Hello World" to the file and then the Close Method (File) closes the file. If the file does not exist, then an error message is displayed. This example assumes that you have created the following file: C:\TestFolder\TestFile.txt. This example requires that you create the following global variables.

```
var
  FileName: Text;
  TestFile: File;
  Cde: Code;
begin
  FileName := 'C:\TestFolder\TestFile.txt';
  if Exists(FileName) then begin
    TestFile.WriteMode(True);
    TestFile.Open(FileName);
    TestFile.Write(Cde);
    TestFile.Close;
  end else
    Message('%1 does not exit.', FileName);
end;
```

The data that you want to write to the file.

Remarks

You must call the TextMode Method (File) before you call the Write method.

If TextMode Method (File) is set to **true** and *Value* is an integer, then the integer is written as text, followed by a new line character.

If *Value* is a record, each field is separated by a tab character.

If TextMode Method (File) is **false** and *Value* is an integer, an integer is written that is four bytes long.

MS-DOS encoding requires a different character set for each language. MS-DOS text is encoded to the internal Unicode data type by using the system locale language of the computer that is running Dynamics 365 Business Central service. If you write to a file that uses MS-DOS encoding, then you must set the system locale language of the computer that is running Dynamics 365 Business Central service to match the language of the data that you want to write to the file.

We recommend that you use the File data type for files that were created in earlier versions of Dynamics 365.

To read or write files in Unicode or in other formats, we recommend that you use .NET Framework interoperability and use the System.IO Namespace.

Example

The following example determines whether the specified file exists. If it exists, the WriteMode Method (File) allows the file to be open for writing. The Open Method (File) opens the file, the Write Method (File) writes the text "Hello World" to the file and then the Close Method (File) closes the file. If the file does not exist, then an error message is displayed. This example assumes that you have created the following file: C:\TestFolder\TestFile.txt.

```
 var
    FileName: Text;
    TestFile: File;
begin
    FileName := 'C:\TestFolder\TestFile.txt';
    if Exists(FileName) then begin
      TestFile.WriteMode(True);
      TestFile.Open(FileName);
      TestFile.Write('Hello World');
      TestFile.Close;
    end else
      Message('%1 does not exit.', FileName);
end;
```

File.Write Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Writes to an MS-DOS encoded file or binary file.

> **NOTE**
> This method is supported only in Business Central on-premises.

Syntax

```
File.Write(Value: Any)
```

> **NOTE**
> This method can be invoked without specifying the data type name.

Parameters

File Type: File An instance of the File data type.

Value
Type: Any
The data that you want to write to the file.

Remarks

You must call the TextMode Method (File) before you call the Write method.

If TextMode Method (File) is set to **true** and *Value* is an integer, then the integer is written as text, followed by a new line character.

If *Value* is a record, each field is separated by a tab character.

If TextMode Method (File) is **false** and *Value* is an integer, an integer is written that is four bytes long.

MS-DOS encoding requires a different character set for each language. MS-DOS text is encoded to the internal Unicode data type by using the system locale language of the computer that is running Dynamics 365 Business Central service. If you write to a file that uses MS-DOS encoding, then you must set the system locale language of the computer that is running Dynamics 365 Business Central service to match the language of the data that you want to write to the file.

We recommend that you use the File data type for files that were created in earlier versions of Dynamics 365.

To read or write files in Unicode or in other formats, we recommend that you use .NET Framework interoperability and use the System.IO Namespace.

Example

The following example determines whether the specified file exists. If it exists, the WriteMode Method (File) allows the file to be open for writing. The Open Method (File) opens the file, the Write Method (File) writes the text "Hello World" to the file and then the Close Method (File) closes the file. If the file does not exist, then an error message is displayed. This example assumes that you have created the following file: C:\TestFolder\TestFile.txt. This example requires that you create the following global variables.

```
var
  FileName: Text;
  TestFile: File;
begin
  FileName := 'C:\TestFolder\TestFile.txt';
  if Exists(FileName) then begin
    TestFile.WriteMode(True);
    TestFile.Open(FileName);
    TestFile.Write('Hello World');
    TestFile.Close;
  end else
    Message('%1 does not exit.', FileName);
end;
```

File.WriteMode Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Use this method before you use Open method (File)] to set or test whether you can write to a file in later calls.

> **NOTE**
> This method is supported only in Business Central on-premises.

Syntax

```
[Writemode := ]  File.WriteMode([Mode: Boolean])
```

> **NOTE**
> This method can be invoked using property access syntax.

> **NOTE**
> This method can be invoked without specifying the data type name.

Parameters

File Type: File An instance of the File data type.

Mode
Type: Boolean

Return Value

Writemode Type: Boolean

Remarks

You must call the TextMode Method (File) before you call the Write method.

If TextMode Method (File) is set to **true** and *Value* is an integer, then the integer is written as text, followed by a new line character.

If *Value* is a record, each field is separated by a tab character.

If TextMode Method (File) is **false** and *Value* is an integer, an integer is written that is four bytes long.

FilterPageBuilder Data Type

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Stores filter configurations for a filter page. A filter page is a dynamic page type that contains one or more filter controls that enables users to set filters on fields of the underlying tables.

The following methods are available on instances of the FilterPageBuilder data type.

METHOD NAME	DESCRIPTION
AddField(String, Any [, String])	Adds a table field to the filter control for a table on filter page.
AddField(String, FieldRef [, String])	Adds a table field to the filter control for a table on filter page.
AddFieldNo(String, Integer [, String])	Adds a table field to the filter control for a table on the filter page.
AddRecord(String, Record)	Adds a filter control for a table to a filter page. The table is specified by a record data type variable that is passed to the method.
AddRecordRef(String, RecordRef)	Adds a filter control for a table to a filter page. The table is specified by a RecordRef variable that is passed to the method. This creates a filter control on the filter page, where users can set filter table data.
AddTable(String, Integer)	Adds filter control for a table to a filter page.
Count()	Gets the number of filter controls that are specified in the FilterPageBuilder object instance.
GetView(String [, Boolean])	Gets the filter view (which defines the sort order, key, and filters) for the record in the specified filter control of a filter page. The view contains all fields in the filter control that have a default filter value.
Name(Integer)	Gets the name of a table filter control that is included on a filter page based on an index number that is assigned to the filter control.
PageCaption([String])	Gets or sets the FilterPageBuilder UI caption. Defaults to the resource text if not explicitly set.
RunModal()	Builds and runs the filter page that includes the filter controls that are stored in FilterPageBuilder object instance.

METHOD NAME	DESCRIPTION
SetView(String, String)	Sets the current filter view, which defines the sort order, key, and filters, for a record in a filter control on a filter page. The view contains all fields that have default filters, but does not contain fields without filters.

FilterPageBuilder.AddField Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Adds a table field to the filter control for a table on filter page.

Syntax

```
[Ok := ]  FilterPageBuilder.AddField(Name: String, Field: Any [, Filter: String])
```

Parameters

FilterPageBuilder Type: FilterPageBuilder An instance of the FilterPageBuilder data type.

Name
Type: String

Field
Type: Any
The name of the table field to add to the filter control for a table.

Filter
Type: String
A default filter on the field that is specified by the Field parameter.

Return Value

Ok Type: Boolean **true** if the field was added to the field list for the specified filter control; otherwise **false**. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

Remarks

If the filter page implementation will call a SetView Method, then the SetView Method must be called before the AddField method call, otherwise the filter that is specified by the *Filter* parameter will be cleared by SetView Method.

The filter that is specified by the *Filter* parameter will overwrite any previously defined filters for the field which were set by AddView method or read from the record or recordRef instance that defined the filter control.

Example

The following example initializes a filter page object that includes a filter control for the **Date** system table. The filter control has the caption of **Date record**. The example adds two fields of the **Date** record variable which will be available in the filter control on the filter page: **Period End** and **Period Start**. A default filter is set on the **Period End** field.

```
var
    varDateItem|: Text[30];
    varDateRecord: Record Date;
    varFilterPageBuilder: FilterPageBuilder;

begin
    varDateItem := 'Date record';
    varFilterPageBuilder.AddRecord(varDateItem, varDateRecord);
    varFilterPageBuilder.AddField(varDateItem, varDateRecord."Period End",'12122015D');
    varFilterPageBuilder.AddField(varDateItem, varDateRecord."Period Start");
    varFilterPageBuilder.RunModal();
end;
```

FilterPageBuilder.AddField Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 2.0.*

Adds a table field to the filter control for a table on filter page.

Syntax

```
[Ok := ]  FilterPageBuilder.AddField(Name: String, Field: FieldRef [, Filter: String])
```

Parameters

FilterPageBuilder Type: FilterPageBuilder An instance of the FilterPageBuilder data type.

Name
Type: String
The name that is assigned to the table in the filter control. This value must match the value of the Name parameter that was specified by AddTable, AddRecord, or AddRecordRef method that adds the table to the filter control.

Field
Type: FieldRef
The name of the table field to add to the filter control for a table.

Filter
Type: String
A default filter on the field that is specified by the Field parameter.

Return Value

Ok Type: Boolean **true** if the field was added to the field list for the specified filter control, otherwise **false**. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

Remarks

If the filter page implementation will call a SetView method, then the SetView method must be called before the AddField method call, otherwise the filter that is specified by the *Filter* parameter will be cleared by SetView.

The filter that is specified by the *Filter* parameter will overwrite any previously defined filters for the field which were set by AddView method or read from the record or recordRef instance that defined the filter control.

Example

The following example initializes a filter page object that includes a filter control for the **Date** system table. The filter control has the caption of **Date record**. The example adds two fields of the **Date** record variable which will be available in the filter control on the filter page: **Period End** and **Period Start**. A default filter is set on the **Period End** field.

```
var
    varDateItem: Text[30];
    varDateRecord: Record Date;
    varFilterPageBuilder: FilterPageBuilder;

begin
    varDateItem := 'Date record';
    varFilterPageBuilder.AddRecord(varDateItem, varDateRecord);
    varFilterPageBuilder.AddField(varDateItem, varDateRecord."Period End",'12122015D');
    varFilterPageBuilder.AddField(varDateItem, varDateRecord.);
    varFilterPageBuilder.RunModal();
end;
```

FilterPageBuilder.AddFieldNo Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Adds a table field to the filter control for a table on the filter page.

Syntax

```
[Ok := ]  FilterPageBuilder.AddFieldNo(Name: String, FieldNo: Integer [, Filter: String])
```

Parameters

FilterPageBuilder Type: FilterPageBuilder An instance of the FilterPageBuilder data type.

Name
Type: String
The name that is assigned to the table in the filter control. This value must match the value of the Name parameter that was specified by AddTable, AddRecord, or AddRecordRef method that adds the table to the filter control.

FieldNo
Type: Integer
The number that is assigned to the field in the table as specified by the Field No. Property.

Filter
Type: String
A default filter on the field that is specified by the Field parameter.

Return Value

Ok Type: Boolean **true** if the field was added to the field list for the specified filter control; otherwise **false**. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

Remarks

If the filter page implementation will call a SetView Method, then the SetView Method must be called before the AddFieldNo method call, otherwise the default filter that is specified by the *Filter* parameter for field, if any, will be cleared by SetView Method.

The filter that is specified by the *Filter* parameter will overwrite any previously defined filters for the field which were set by AddView method or read from the record or recordRef instance that defined the filter control.

Example

The following example initializes a filter page object that includes a filter control for the **Date** system table. The filter control has the caption of **Date record**. The example adds two fields of the **Date** record variable which will be available in the filter control on the filter page: **Period End** and **Period Start**. A default filter is set on the **Period End** field.

```
var
    varDateItem: Text[30];
    varDateRecord: Record Date;
    varFilterPageBuilder: FilterPageBuilder;

begin
    varDateItem := 'Date record';
    varFilterPageBuilder.AddRecord(varDateItem, varDateRecord);
    varFilterPageBuilder.AddFieldNo(varDateItem, varDateRecord.FieldNo(varDateRecord."Period
End"),'03032014D');
    varFilterPageBuilder.AddFieldNo(varDateItem, varDateRecord.FieldNo(varDateRecord."Period Start"));
    varFilterPageBuilder.RunModal();
end;
```

FilterPageBuilder.AddRecord Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Adds a filter control for a table to a filter page. The table is specified by a record data type variable that is passed to the method.

Syntax

```
[Name := ]  FilterPageBuilder.AddRecord(Name: String, Record: Record)
```

Parameters

FilterPageBuilder Type: FilterPageBuilder An instance of the FilterPageBuilder data type.

Name
Type: String
Assigns a name to the filter control for the table. The text displays as the caption for the filter control on the rendered filter page in the client.

Record
Type: Record
The record to use in the filter control.

Return Value

Name Type: String The text that is specified by the Name parameter. If an error occurs at runtime, an empty text string is returned. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

Remarks

In the filter page that is rendered in the client, the AddRecord method defines a filter control for the specified table where the user can set filters on specific fields in the table.

Fields in the table that already have filters are automatically included in the filter control. Filters in the record passed to the method will not be modified by any method in the FilterPageBuilder object.

Example

The following example initializes a filter page object that includes a filter control that uses the Date system table. The filter control has the caption of **Date record**. The example set two filters are on the **Date** record variable, which results in a filter control that includes two fields by default.

```
var
    varDateItem: Text[30];
    varDateRecord: Record Date;
    varFilterPageBuilder: FilterPageBuilder;

begin
    varDateItem := 'Date record';
    varDateRecord.SetFilter("Period End",'12122015D');
    varDateRecord.SetFilter("Period Start",'01012015D');
    varFilterPageBuilder.AddRecord(varDateItem, varDateRecord);
    varFilterPageBuilder.RunModal();

end;
```

FilterPageBuilder.AddRecordRef Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Adds a filter control for a table to a filter page. The table is specified by a RecordRef variable that is passed to the method. This creates a filter control on the filter page, where users can set filter table data.

Syntax

```
[Name := ]  FilterPageBuilder.AddRecordRef(Name: String, RecordRef: RecordRef)
```

Parameters

FilterPageBuilder Type: FilterPageBuilder An instance of the FilterPageBuilder data type.

Name
Type: String
Assigns a name to the filter control for the table. The text displays as the caption for the filter control on the rendered filter page in the client.

RecordRef
Type: RecordRef
The record reference to use in the filter control.

Return Value

Name Type: String The text that is specified by the Name parameter. If an error occurs at runtime, an empty text string is returned. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

Remarks

In the filter page that is rendered in the client, the AddRecordREF method defines a filter control for the specified table where the user can add and set the filters on the table.

Fields in the table that already have filters are automatically included in the filter control. Filters in the record reference passed to the method will not be modified by any method in the FilterPageBuilder object.

Example

The following example initializes a filter page object that includes a filter control that uses the Date system table. The filter control has the caption of **Date record**. The example set two filters are on the **Date** record variable, which results in a filter control that includes two fields by default.

```
var

    varDateItem: Text[30];
    varDateRecord: Record Date;
    varDateRecordRef: RecordRef;
    varFilterPageBuilder: FilterPageBuilder;

begin
    varDateItem := 'Date record';
    varDateRecord.SetFilter("Period End",'12122015D');
    varDateRecord.SetFilter("Period Start",'01012015D');
    varDateRecordRef.GetTable(varDateRecord);
    varFilterPageBuilder.AddRecordREF(varDateItem,varDateRecordRef);
    varFilterPageBuilder.RunModal();
end;
```

FilterPageBuilder.AddTable Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Adds filter control for a table to a filter page.

Syntax

```
[Name := ]  FilterPageBuilder.AddTable(Name: String, TableNo: Integer)
```

Parameters

FilterPageBuilder Type: FilterPageBuilder An instance of the FilterPageBuilder data type.

Name
Type: String
Assigns a name to the filter control for the table. The text displays as the caption for the filter control on the rendered filter page in the client.

TableNo
Type: Integer
The ID of the table object that you want to filter on.

Return Value

Name Type: String The text that is specified by the Name parameter. If an error occurs at runtime, an empty text string is returned. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

Remarks

In the filter page that is rendered in the client, the AddTable method defines a filter control for the specified table where the user can set filters on specific fields in the table.

You can use the **AddField Method** or AddFieldNo Method method to add field of the table to the filter control.

Example

The following example initializes a filter page object that includes a filter control that uses the Date system table. The filter control has the caption of **Date record**.

```
var
    varDateItem: Text[30];
    varFilterPageBuilder: FilterPageBuilder;

begin
    varDateItem := 'Date record';
    varFilterPageBuilder.AddTable(varDateItem, Database::Date);
    varFilterPageBuilder.RunModal();
end;
```

FilterPageBuilder.Count Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Gets the number of filter controls that are specified in the FilterPageBuilder object instance.

Syntax

```
Count :=   FilterPageBuilder.Count()
```

NOTE

This method can be invoked using property access syntax.

Parameters

FilterPageBuilder Type: FilterPageBuilder An instance of the FilterPageBuilder data type.

Return Value

Count Type: Integer The number of filter controls in the current FilterPageBuilder object instance.

Example

The following example uses the COUNT method on a filter page object that includes a two filter controls for the **Date** system table.

```
var
    varDateItem: Text[30];
    varCount: Integer;
    varFilterPageBuilder: FilterPageBuilder;

begin
    varDateItem := 'Date record';
    varFilterPageBuilder.AddTable(varDateItem + ' 1',DATABASE::Date);
    varFilterPageBuilder.AddTable(varDateItem + ' 2',DATABASE::Date);
    varCount := varFilterPageBuilder.Count;
    if varCount <> 2 then
      Error('There should be two controls in varFilterPageBuilder');
    varFilterPageBuilder.RunModal();
end;
```

FilterPageBuilder.GetView Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Gets the filter view (which defines the sort order, key, and filters) for the record in the specified filter control of a filter page. The view contains all fields in the filter control that have a default filter value.

Syntax

```
View :=   FilterPageBuilder.GetView(Name: String [, UseNames: Boolean])
```

Parameters

FilterPageBuilder Type: FilterPageBuilder An instance of the FilterPageBuilder data type.

Name

Type: String

The name of the filter control. This value must match the value of the Name parameter that was specified by AddTable, AddRecord, or AddRecordRef method that adds the table to the filter control.

UseNames

Type: Boolean

Specifies whether a field caption or field number should be returned. This parameter is optional. If this parameter is **true** (default value) or if it is empty, then the returned string contains references to field captions in the table with which the record is associated. If this parameter is **false**, then the returned string contains references to field numbers.

Return Value

View Type: String The view that is configured for the filter control that is identified by Name.

Example

The following example initializes a filter page object that includes a filter control for the **Date** system table. The filter control has the caption of **Date record**. The example adds two filter fields to the filter control on the filter page as the result of applying a default view. The GetView method is used to capture that filter view from the FilterPageBuilder object, and then apply it to the record.

```
var
    varDateItem: Text[300];
    varDateRecord: Record Date;
    varFilterPageBuilder: FilterPageBuilder;
    varDefaultView: Text[300];

begin
    varDateItem := 'Date record';
    varDateRecord.SetFilter("Period End", '12122015D');
    varDateRecord.SetFilter("Period Start", '01012015D');
    varDefaultView := varDateRecord.GetView;
    varFilterPageBuilder.AddTable(varDateItem, DATABASE::Date);
    varFilterPageBuilder.SetView(varDateItem, varDefaultView);
    if varFilterPageBuilder.RunModal = true then
      varDateRecord.SetView(varFilterPageBuilder.GetView(varDateItem));
      varFilterPageBuilder.RunModal();
end;
```

FilterPageBuilder.Name Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Gets the name of a table filter control that is included on a filter page based on an index number that is assigned to the filter control.

Syntax

```
Name :=   FilterPageBuilder.Name(Index: Integer)
```

Parameters

FilterPageBuilder Type: FilterPageBuilder An instance of the FilterPageBuilder data type.

Index

Type: Integer

The index of a filter control. The value must be in the range 1 to N, where N is the number of filter controls on the filter page.

Return Value

Name Type: String The name of the filter control.

Example

The following example initializes a filter page object that includes two filter controls for the **Date** system table. The NAME method returns the names of filter control in a message dialog box.

```
var
    varDateItem: Text[30];
    varCount: Integer;
    varIndex: Integer;
    varFilterPageBuilder: FilterPageBuilder;

begin
    varDateItem := 'Date record';
    varFilterPageBuilder.AddTable(varDateItem + ' 1', Database::Date);
    varFilterPageBuilder.AddTable(varDateItem + ' 2', Database::Date);
    varCount := varFilterPageBuilder.COUNT;
    if varCount <> 2 then
        Error('There should be two controls in FilterPageBuilder');
    for varIndex := 1 to varCount do
        Message('Control item %1 is named %2', varIndex, varFilterPageBuilder.Name(varIndex));
    varFilterPageBuilder.RunModal();
end;
```

FilterPageBuilder.PageCaption Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Gets or sets the FilterPageBuilder UI caption. Defaults to the resource text if not explicitly set.

Syntax

```
[PageCaption := ]  FilterPageBuilder.PageCaption([PageCaption: String])
```

NOTE

This method can be invoked using property access syntax.

Parameters

FilterPageBuilder Type: FilterPageBuilder An instance of the FilterPageBuilder data type.

PageCaption

Type: String

The value to set for the FilterPageBuilder UI caption.

Return Value

PageCaption Type: String The current value of the FilterPageBuilder UI caption.

Example

```
var
    varFilterPageBuilder: FilterPageBuilder;
    Customer: Record Customer;
    Item: Record Item;
    varDateItem: Text[30];
begin
    varFilterPageBuilder.AddRecord('Item Table', Item);
    varFilterPageBuilder.Addfield('Item Table', Item."No.", '>100');
    varFilterPageBuilder.PageCaption := 'Item Filter Page';
    varFilterPageBuilder.RunModal;
    Item.SetView(varFilterPageBuilder.Getview('Item Table'));
end;
```

FilterPageBuilder.RunModal Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Builds and runs the filter page that includes the filter controls that are stored in FilterPageBuilder object instance.

Syntax

```
[Ok := ]  FilterPageBuilder.RunModal()
```

Parameters

FilterPageBuilder Type: FilterPageBuilder An instance of the FilterPageBuilder data type.

Return Value

Ok Type: Boolean **true** if the operation was successful; otherwise **false**. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

Remarks

The page is run modally and includes an **OK** and **Cancel** button for closing to modal popup.

You can call the GetView Method method to retrieve the current filter view that is configured on the filter control and apply to the record.

Because the filter page runs modally in the context of where it was invoked from, users cannot bookmark a link to this page from the user interface.

Example

The following example initializes a filter page object that includes a filter control for the **Date** system table. The filter control has the caption of **Date record**. The example adds two filter fields to the filter control on the filter page as the result of applying a default view. The GetView Method is used to capture that filter view from the FilterPageBuilder object, and then apply it to the record.

```
var
    varDateItem: Text[300];
    varDateRecord: Record Date;
    varFilterPageBuilder: FilterPageBuilder;
    varDefaultView: Text[300];

begin
    varDateItem := 'Date record';
    varDateRecord.SetFilter("Period End", '20151212D');
    varDateRecord.SetFilter("Period Start", '20150101D');
    varDefaultView := varDateRecord.GetView;
    varFilterPageBuilder.AddTable(varDateItem, Database::Date);
    varFilterPageBuilder.SetView(varDateItem, varDefaultView);
    if varFilterPageBuilder.RunModal = true then
      varDateRecord.SetView(varFilterPageBuilder.GetView(varDateItem));
end;
```

FilterPageBuilder.SetView Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Sets the current filter view, which defines the sort order, key, and filters, for a record in a filter control on a filter page. The view contains all fields that have default filters, but does not contain fields without filters.

Syntax

```
[Ok := ]  FilterPageBuilder.SetView(Name: String, View: String)
```

Parameters

FilterPageBuilder Type: FilterPageBuilder An instance of the FilterPageBuilder data type.

Name

Type: String

The name that is assigned to the filter control. This value must match the value of the ItemName parameter that was specified by AddTable, AddRecord, or AddRecordRef method that adds the table to the filter control.

View

Type: String

The filter view to apply. This can be the output of the GetView method invoked on a Record or a RecordRef value.

Return Value

Ok Type: Boolean **true** if the operation was successful; otherwise **false**. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

Remarks

The SetView method will overwrite any previously defined filters for the fields that are also included in the view.

Example

The following example initializes a filter page object that includes a filter control for the **Date** system table. The filter control has the caption of **Date record**. The example adds two filter fields to the filter control on the filter page as the result of applying a default view from the GetView Method.

```
var
    varDateItem: Text[30];
    varDateRecord: Record Date;
    varFilterPageBuilder: FilterPageBuilder;
    varDefaultView: Text;

begin
    varDateItem := 'Date record';
    varDateRecord.SetFilter("Period End", '20151212D');
    varDateRecord.SetFilter("Period Start", '20150101D');
    varDefaultView := varDateRecord.GetView;
    varFilterPageBuilder.AddTable(varDateItem, Database::Date);
    varFilterPageBuilder.SetView(varDateItem, varDefaultView);
    varFilterPageBuilder.RunModal();
end;
```

Guid Data Type

2/17/2021 • 3 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Represents a 16 byte binary data type. This data type is used for the global identification of objects, programs, records, and so on. The important property of a GUID is that each value is globally unique. The value is generated by an algorithm, developed by Microsoft, which assures this uniqueness.

The GUID is a 16-byte binary data type that can be logically grouped into the following subgroups:

4byte-2byte-2byte-2byte-6byte.

The standard textual representation is {12345678-1234-1234-1234-1234567890AB}.

The virtual table OLE Control (2000000042) does not use the GUID data type. It uses a textual representation of the GUID in a text field instead. It is easier to make operations and references to this text field using the GUID data type than it is using the textual representation. The GUID data type is compatible with the existing textual representation.

The GUID data type is useful when you want to uniquely identify some data, so that it can be exchanged with external applications. For example, if you want to transfer an item catalog to an external application, you add a GUID field to the record in the table and use this as the primary reference when you communicate with the external application.

Compatibility

You can assign and compare the Text data type and the GUID data type. Assigning a Text to a GUID can be done as follows:

```
MyTableRec.MyGuid  :=  MyTableRec.MyText;
```

The supported formats of `MyText` are:

`'11111111-1111-1111-1111-111111111111'` `'{22222222-2222-2222-2222-222222222222}'`

Methods and properties

The following AL methods can be used with the GUID data type:

```
Guid := CreateGUID();
```

This method creates a new unique GUID value. The value can then be assigned to a field of the GUID data type or of the Text data type.

```
Ok := IsNullGUID(Guid);
```

This method is a convenient way to check if a value has already been assigned to a GUID. A NULL GUID (consisting only of zeroes) is valid, but should never be used for reference purposes.

A NULL GUID is valid but is not useful in a table. Therefore, the **AutoSplitKey** property is implemented for the GUID data type when it is used in a page. When GUID is selected as a primary key, **AutoSplitKey** is enabled for the page, and the GUID value remains NULL. When you create a new record, a valid GUID is created and assigned automatically.

The CreateGUID method and IsNullGUID method methods are available in the AL Symbol Menu under SYSTEM, Variables.

CreateGUID takes no arguments and returns a valid 16-byte GUID value. If the result is assigned to a TEXT variable or field, the value is converted to a string and follows the syntax explained earlier. The algorithm that generates the new GUID value uses Microsoft's CoCreateGuid method.

IsNullGUID takes a GUID value as a required argument and returns True/False depending on whether the GUID value is NULL. This method does not accept a Text value as an argument.

AutoSplitKey is a property, not a method and can be applied to pages. If you have defined a GUID field as part of the primary key, the **AutoSplitKey** property automatically generates a new valid GUID value. When a new record is created and the GUID field is left as NULL, the **AutoSplitKey** property ensures that a valid GUID value is automatically inserted into the field. If you then enter a NULL GUID into this record, for example, by using the Clear method, this new NULL GUID value is not automatically replaced by the **AutoSplitKey** property. The **AutoSplitKey** property only applies to new records.

Format

The GUID value can also be represented as text. You can use the standard AL methods Format and Evaluate to convert from GUID values to Text values. If you do not use the correct format when you edit a GUID value in its textual format, the following error message is displayed:

Invalid Format of GUID string. The correct format of the GUID string is {CDEF7890-ABCD-1234-ABCD-1234567890AB} where 0-9, A-F symbolizes hexadecimal digits.

HttpClient Data Type

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Provides a data type for sending HTTP requests and receiving HTTP responses from a resource identified by a URI.

The following methods are available on instances of the HttpClient data type.

METHOD NAME	DESCRIPTION
AddCertificate(String [, String])	Adds a certificate to the HttpClient class.
Clear()	Sets the HttpClient variable to the default value.
DefaultRequestHeaders()	Gets the default request headers which should be sent with each request.
Delete(String, var HttpResponseMessage)	Sends a DELETE request to delete the resource identified by the request URL.
Get(String, var HttpResponseMessage)	Sends a Get request to get the resource identified by the request URL.
GetBaseAddress()	Gets the base address of Uniform Resource Identifier (URI) of the Internet resource used when sending requests.
Post(String, HttpContent, var HttpResponseMessage)	Sends a POST request to the specified URI as an asynchronous operation.
Put(String, HttpContent, var HttpResponseMessage)	Sends a PUT request to the specified URI as an asynchronous operation.
Send(HttpRequestMessage, var HttpResponseMessage)	Sends an HTTP request as an asynchronous operation.
SetBaseAddress(String)	Sets the base address of Uniform Resource Identifier (URI) of the Internet resource used when sending requests.
Timeout([Duration])	Gets or sets the duration in milliseconds to wait before the request times out.
UseDefaultNetworkWindowsAuthentication()	Sets the HttpClient credentials to use the default network credentials for Windows authentication. If this method is invoked after any HTTP request has started; a runtime error occurs.
UseWindowsAuthentication(String, String [, String])	Sets the HttpClient credentials to use the specified network credentials for Windows authentication. If this method is invoked after any HTTP request has started; a runtime error occurs.

Remarks

The supported security protocols are controlled by the **SecurityProtocol** configuration setting. For more information, see Microsoft Dynamics 365 Business Central Server Configuration.

HttpClient.AddCertificate Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Adds a certificate to the HttpClient class.

Syntax

```
HttpClient.AddCertificate(Certificate: String [, Password: String])
```

Parameters

HttpClient Type: HttpClient An instance of the HttpClient data type.

Certificate
Type: String
The Base64 encoded certificate.
Password
Type: String
The certificate password.

Remarks

The certificate must be in base 64 format.

With the **AddCertificate** method you set the certificates that you want to be associated to the request of the http client connection. These have the only purpose of authenticating the client.

The system caches SSL sessions as they are created and attempts to reuse a cached session for a new request, if possible. When attempting to reuse an SSL session, it uses the first certificate that was added or tries to reuse an anonymous session if no certificates have been specified.

HttpClient.Clear Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Sets the HttpClient variable to the default value.

Syntax

```
HttpClient.Clear()
```

Parameters

HttpClient Type: HttpClient An instance of the HttpClient data type.

See Also

HttpClient Data Type
Getting Started with AL
Developing Extensions

HttpClient.DefaultRequestHeaders Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Gets the default request headers which should be sent with each request.

Syntax

```
CurrentDefaultRequestHeaders :=   HttpClient.DefaultRequestHeaders()
```

NOTE

This method can be invoked using property access syntax.

Parameters

HttpClient Type: HttpClient An instance of the HttpClient data type.

Return Value

CurrentDefaultRequestHeaders Type: HttpHeaders The default request headers which should be sent with each request.

Remarks

The HttpHeaders variable is a reference type. When you add a header to this variable, the default headers are changed. You cannot set another HttpHeaders object as a default header, you have to update the header fetched from HttpClient.

HttpClient.Delete Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Sends a Delete request to delete the resource identified by the request URL.

Syntax

```
[Ok := ]  HttpClient.Delete(Path: String, var Response: HttpResponseMessage)
```

Parameters

HttpClient Type: HttpClient An instance of the HttpClient data type.

Path
Type: String
The path the request is sent to.

Response
Type: HttpResponseMessage
The response received from the remote endpoint.

Return Value

Ok Type: Boolean Accessing the HttpContent property of HttpResponseMessage in a case when the request fails will result in an error. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

See Also

HttpClient.Get Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Sends a Get request to get the resource identified by the request URL.

Syntax

```
[Ok := ]  HttpClient.Get(Path: String, var Response: HttpResponseMessage)
```

Parameters

HttpClient Type: HttpClient An instance of the HttpClient data type.

Path
Type: String
The path the request is sent to.

Response
Type: HttpResponseMessage
The response received from the remote endpoint.

Return Value

Ok Type: Boolean Accessing the HttpContent property of HttpResponseMessage in a case when the request fails will result in an error. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

HttpClient.GetBaseAddress Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Gets the base address of Uniform Resource Identifier (URI) of the Internet resource used when sending requests.

Syntax

```
CurrentBaseAddress :=   HttpClient.GetBaseAddress()
```

NOTE

This method can be invoked using property access syntax.

Parameters

HttpClient Type: HttpClient An instance of the HttpClient data type.

Return Value

CurrentBaseAddress Type: String The base address of URI of the Internet resource used when sending requests.

HttpClient.Post Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Sends a POST request to the specified URI as an asynchronous operation.

Syntax

```
[Ok := ]  HttpClient.Post(Path: String, Content: HttpContent, var Response: HttpResponseMessage)
```

Parameters

HttpClient Type: HttpClient An instance of the HttpClient data type.

Path
Type: String
The path the request is sent to.
Content
Type: HttpContent
The HTTP request content sent to the server.

Response
Type: HttpResponseMessage
The response received from the remote endpoint.

Return Value

Ok Type: Boolean Accessing the HttpContent property of HttpResponseMessage in a case when the request fails will result in an error. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

HttpClient.Put Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Sends a PUT request to the specified URI as an asynchronous operation.

Syntax

```
[Ok := ]  HttpClient.Put(Path: String, Content: HttpContent, var Response: HttpResponseMessage)
```

Parameters

HttpClient Type: HttpClient An instance of the HttpClient data type.

Path
Type: String
The path the request is sent to.

Content
Type: HttpContent
The HTTP request content sent to the server.

Response
Type: HttpResponseMessage
The response received from the remote endpoint.

Return Value

Ok Type: Boolean Accessing the HttpContent property of HttpResponseMessage in a case when the request fails will result in an error. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

HttpClient.Send Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Sends an HTTP request as an asynchronous operation.

Syntax

```
[Ok := ]  HttpClient.Send(Request: HttpRequestMessage, var Response: HttpResponseMessage)
```

Parameters

HttpClient Type: HttpClient An instance of the HttpClient data type.

Request
Type: HttpRequestMessage
The HTTP request message to send.

Response
Type: HttpResponseMessage
The response received from the remote endpoint.

Return Value

Ok Type: Boolean Accessing the HttpContent property of HttpResponseMessage in a case when the request fails will result in an error. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

See Also

HttpClient Data Type

HttpClient.SetBaseAddress Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Sets the base address of Uniform Resource Identifier (URI) of the Internet resource used when sending requests.

Syntax

```
[Ok := ]  HttpClient.SetBaseAddress(NewBaseAddress: String)
```

Parameters

HttpClient Type: HttpClient An instance of the HttpClient data type.

NewBaseAddress
Type: String
The base address of the Uniform Resource Identifier (URI) of the Internet resource used when sending requests.

Return Value

Ok Type: Boolean **true** if the operation was successful; otherwise **false**. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

HttpClient.Timeout Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Gets or sets the duration in milliseconds to wait before the request times out.

Syntax

```
[CurrentTimeout := ]  HttpClient.Timeout([SetTimeout: Duration])
```

NOTE

This method can be invoked using property access syntax.

Parameters

HttpClient Type: HttpClient An instance of the HttpClient data type.

SetTimeout

Type: Duration

The duration in milliseconds to wait before the request times out.

Return Value

CurrentTimeout Type: Duration The duration in milliseconds to wait before the request times out.

Remarks

The *SetTimeout* duration is limited by the **NavHttpClientMaxTimeout** parameter that is configured for Business Central Server instance. If you set the duration to a value that is greater than the value of the **NavHttpClientMaxTimeout** parameter, a 'NavNclHttpClientTimeoutTooLargeException' error is thrown. The default value of the **NavHttpClientMaxTimeout** parameter is 00:05:00. To change the **NavHttpClientMaxTimeout** parameter, see Configuring Business Central Server.

HttpClient.UseDefaultNetworkWindowsAuthentication Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 3.0.*

Sets the HttpClient credentials to use the default network credentials for Windows authentication. If this method is invoked after any HTTP request has started; a runtime error occurs.

> **NOTE**
> This method is supported only in Business Central on-premises.

Syntax

```
[Result := ]  HttpClient.UseDefaultNetworkWindowsAuthentication()
```

Parameters

HttpClient Type: HttpClient An instance of the HttpClient data type.

Return Value

Result Type: Boolean **true** if the operation was successful; otherwise **false**. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

HttpClient.UseWindowsAuthentication Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 3.0.*

Sets the HttpClient credentials to use the specified network credentials for Windows authentication. If this method is invoked after any HTTP request has started; a runtime error occurs.

> **NOTE**
> This method is supported only in Business Central on-premises.

Syntax

```
[Result := ]  HttpClient.UseWindowsAuthentication(UserName: String, Password: String [, Domain: String])
```

Parameters

HttpClient Type: HttpClient An instance of the HttpClient data type.

UserName
Type: String
The Windows user name.
Password
Type: String
The password.
Domain
Type: String
The user's domain.

Return Value

Result Type: Boolean **true** if the operation was successful; otherwise **false**. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

HttpContent Data Type

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Represents an HTTP entity body and content headers.

The following methods are available on instances of the HttpContent data type.

METHOD NAME	DESCRIPTION
Clear()	Sets the HttpContent object to a default value. The content contains an empty string and empty headers.
GetHeaders(var HttpHeaders)	Gets the HTTP content headers as defined in RFC 2616.
ReadAs(var Text)	Reads the content into the provided text.
ReadAs(var InStream)	Reads the content into the provided text.
WriteFrom(Text)	Sets HttpContent content to the provided text or stream.
WriteFrom(InStream)	Sets HttpContent content to the provided text or stream.

An instance of HttpContent encapsulates the body and the associated headers of an HTTP request that will be sent to a remote endpoint or that is being received from a remote endpoint. The HttpContent data type is a value type. This means that when assigning an instance of HttpContent to a variable, a copy will be created.

Example

The following example illustrates how to use the HttpContent type to send a simple POST request containing JSON data.

```
codeunit 50110 MyCodeunit
{
    procedure MakeRequest(uri: Text; payload: Text) responseText: Text;
    var
        client: HttpClient;
        request: HttpRequestMessage;
        response: HttpResponseMessage;
        contentHeaders: HttpHeaders;
        content: HttpContent;
    begin
        // Add the payload to the content
        content.WriteFrom(payload);

        // Retrieve the contentHeaders associated with the content
        content.GetHeaders(contentHeaders);
        contentHeaders.Clear();
        contentHeaders.Add('Content-Type', 'application/json');

        // Assigning content to request.Content will actually create a copy of the content and assign it.
        // After this line, modifying the content variable or its associated headers will not reflect in
        // the content associated with the request message
        request.Content := content;

        request.SetRequestUri(uri);
        request.Method := 'POST';

        client.Send(request, response);

        // Read the response content as json.
        response.Content().ReadAs(responseText);
    end;
}
```

HttpContent.GetHeaders Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Gets the HTTP content headers as defined in RFC 2616.

Syntax

```
[Ok := ]  HttpContent.GetHeaders(var Headers: HttpHeaders)
```

Parameters

HttpContent Type: HttpContent An instance of the HttpContent data type.

Headers
Type: HttpHeaders
The HTTP headers associated with the content.

Return Value

Ok Type: Boolean Accessing the HttpContent property of HttpResponseMessage in a case when the request fails will result in an error. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

HttpContent.ReadAs Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Reads the content into the provided text.

Syntax

```
[Ok := ]  HttpContent.ReadAs(var OutputString: Text)
```

Parameters

HttpContent Type: HttpContent An instance of the HttpContent data type.

OutputString
Type: Text
The variable that will contain the HTTP content as a string.

Return Value

Ok Type: Boolean Accessing the HttpContent property of HttpResponseMessage in a case when the request fails will result in an error. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

HttpHeaders Data Type

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Is a collection of headers and their values.

The following methods are available on instances of the HttpHeaders data type.

METHOD NAME	DESCRIPTION
Add(String, String)	Adds the specified header and its value into the HttpHeaders collection. Validates the provided value.
Clear()	Sets the HttpHeaders variable to the default value.
Contains(String)	Checks if the specified header exists in the HttpHeaders collection.
GetValues(String, Array of [Text])	Gets the values for the specified key.
Remove(String)	Removes the specified header from the HttpHeaders collection.
TryAddWithoutValidation(String, String)	Adds the specified header and its value into the HttpHeaders collection. Doesn't validate the provided value.

HttpHeaders.Add Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Adds the specified header and its value into the HttpHeaders collection. Validates the provided value.

Syntax

```
[Ok := ]  HttpHeaders.Add(Name: String, Value: String)
```

Parameters

HttpHeaders Type: HttpHeaders An instance of the HttpHeaders data type.

Name
Type: String
The header to add to the collection.

Value
Type: String
The content of the header.

Return Value

Ok Type: Boolean **true** if the value was added successfully, otherwise **false**. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

HttpHeaders.GetValues Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Gets the values for the specified key.

Syntax

```
[Ok := ]  HttpHeaders.GetValues(Key: String, Values: Array of [Text])
```

Parameters

HttpHeaders Type: HttpHeaders An instance of the HttpHeaders data type.

Key
Type: String
The specified header.

Values
Type: Text
The specified header values.

Return Value

Ok Type: Boolean **true** if the specified header name and values are stored in the collection; otherwise **false**. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

HttpHeaders.Remove Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Removes the specified header from the HttpHeaders collection.

Syntax

```
[Ok := ]  HttpHeaders.Remove(Name: String)
```

Parameters

HttpHeaders Type: HttpHeaders An instance of the HttpHeaders data type.

Name
Type: String
The name of the header to remove from the collection.

Return Value

Ok Type: Boolean **true** if the element is successfully removed; otherwise, **false**. This method also returns **false** if the given header was not found in the HttpHeaders collection. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

HttpHeaders.TryAddWithoutValidation Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 3.0.*

Adds the specified header and its value into the HttpHeaders collection. Doesn't validate the provided value.

Syntax

```
[Ok := ]  HttpHeaders.TryAddWithoutValidation(Name: String, Value: String)
```

Parameters

HttpHeaders Type: HttpHeaders An instance of the HttpHeaders data type.

Name
Type: String
The header to add to the collection.
Value
Type: String
The content of the header.

Return Value

Ok Type: Boolean **true** if the value was added successfully, otherwise **false**. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

HttpRequestMessage Data Type

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Represents an HTTP request message.

The following methods are available on instances of the HttpRequestMessage data type.

METHOD NAME	DESCRIPTION
Content([HttpContent])	Gets or sets the contents of the HTTP message.
GetHeaders(var HttpHeaders)	Gets a reference to the collection of HTTP request headers.
GetRequestUri()	Gets the URI used for the HTTP request.
Method([String])	Gets or sets the method type as defined in the HTTP standard.
SetRequestUri(String)	Sets the URI used for the HTTP request.

NOTE

For performance reasons all HTTP, JSON, TextBuilder, and XML types are reference types, not value types. Reference types holds a pointer to the data elsewhere in memory, whereas value types store its own data.

HttpRequestMessage.Content Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Gets or sets the contents of the HTTP message.

Syntax

```
[CurrentContent := ]  HttpRequestMessage.Content([SetContent: HttpContent])
```

NOTE

This method can be invoked using property access syntax.

Parameters

HttpRequestMessage Type: HttpRequestMessage An instance of the HttpRequestMessage data type.

SetContent

Type: HttpContent

The contents of the HTTP message.

Return Value

CurrentContent Type: HttpContent The contents of the HTTP message.

HttpRequestMessage.GetHeaders Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Gets a reference to the collection of HTTP request headers.

Syntax

```
[Ok := ]  HttpRequestMessage.GetHeaders(var Headers: HttpHeaders)
```

Parameters

HttpRequestMessage Type: HttpRequestMessage An instance of the HttpRequestMessage data type.

Headers
Type: HttpHeaders
A variable that will contain a reference to the collection of HTTP request headers after the method completes successfully.

Return Value

Ok Type: Boolean **true** if the operation was completed successfully, otherwise **false**. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

HttpRequestMessage.GetRequestUri Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Gets the URI used for the HTTP request.

Syntax

```
RequestUri :=   HttpRequestMessage.GetRequestUri()
```

NOTE

This method can be invoked using property access syntax.

Parameters

HttpRequestMessage Type: HttpRequestMessage An instance of the HttpRequestMessage data type.

Return Value

RequestUri Type: String The URI used for the HTTP request.

See Also

HttpRequestMessage.Method Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Gets or sets the method type as defined in the HTTP standard.

Syntax

```
[CurrentMethod := ]  HttpRequestMessage.Method([NewMethod: String])
```

> **NOTE**
> This method can be invoked using property access syntax.

Parameters

HttpRequestMessage Type: HttpRequestMessage An instance of the HttpRequestMessage data type.

NewMethod
Type: String
The HTTP method used by the request message.

Return Value

CurrentMethod Type: String The HTTP method used by the request message. The default is the Get method.

HttpRequestMessage.SetRequestUri Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Sets the URI used for the HTTP request.

Syntax

```
[Ok := ]  HttpRequestMessage.SetRequestUri(RequestUri: String)
```

Parameters

HttpRequestMessage Type: HttpRequestMessage An instance of the HttpRequestMessage data type.

RequestUri
Type: String
The URI to use for the HTTP request.

Return Value

Ok Type: Boolean **true** if the URI was set successfully, otherwise **false**. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

HttpResponseMessage Data Type

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Represents a HTTP response message including the status code and data.

The following methods are available on instances of the HttpResponseMessage data type.

METHOD NAME	DESCRIPTION
Content()	Gets the contents of the HTTP response.
Headers()	Gets the HTTP response's HTTP headers.
HttpStatusCode()	Gets the status code of the HTTP response.
IsBlockedByEnvironment()	Gets a value that indicates if the HTTP response is the result of the environment blocking an outgoing HTTP request.
IsSuccessStatusCode()	Gets a value that indicates if the HTTP response was successful.
ReasonPhrase()	Gets the reason phrase which typically is sent by servers together with the status code.

Remarks

The size of the `HttpResponseMessage` is determined by the `HttpClient AL Function Response Size` setting on the Dynamics 365 Business Central server. The default value is `150`. For more information, see Microsoft Dynamics 365 Business Central Server Configuration.

> **NOTE**
> For performance reasons all HTTP, JSON, TextBuilder, and XML types are reference types, not value types. Reference types holds a pointer to the data elsewhere in memory, whereas value types store its own data.

HttpResponseMessage.IsBlockedByEnvironment Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 2.0.*

Gets a value that indicates if the HTTP response is the result of the environment blocking an outgoing HTTP request.

Syntax

```
IsBlockedByEnvironment :=   HttpResponseMessage.IsBlockedByEnvironment()
```

NOTE

This method can be invoked using property access syntax.

Parameters

HttpResponseMessage Type: HttpResponseMessage An instance of the HttpResponseMessage data type.

Return Value

IsBlockedByEnvironment Type: Boolean **true** if the HTTP response is the result of the environment blocking an outgoing HTTP request, otherwise **false**.

HttpResponseMessage.IsSuccessStatusCode Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Gets a value that indicates if the HTTP response was successful.

Syntax

```
IsSuccessStatusCode :=   HttpResponseMessage.IsSuccessStatusCode()
```

NOTE

This method can be invoked using property access syntax.

Parameters

HttpResponseMessage Type: HttpResponseMessage An instance of the HttpResponseMessage data type.

Return Value

IsSuccessStatusCode Type: Boolean A value that indicates if the HTTP response was successful. **true** if StatusCode was in the range 200-299; otherwise **false**.

InStream Data Type

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Is a generic stream object that you can use to read from or write to files and BLOBs. You can define the internal structure of a stream as a flat stream of bytes. You can assign one stream to another. Reading from and writing to a stream occurs sequentially.

The following methods are available on instances of the InStream data type.

METHOD NAME	DESCRIPTION
EOS()	Indicates whether an input stream has reached End of Stream (EOS).
Read(var Boolean [, Integer])	Reads a specified number of bytes from an InStream object. Data is read in binary format.
Read(var Byte [, Integer])	Reads a specified number of bytes from an InStream object. Data is read in binary format.
Read(var Char [, Integer])	Reads a specified number of bytes from an InStream object. Data is read in binary format.
Read(var Integer [, Integer])	Reads a specified number of bytes from an InStream object. Data is read in binary format.
Read(var BigInteger [, Integer])	Reads a specified number of bytes from an InStream object. Data is read in binary format.
Read(var Decimal [, Integer])	Reads a specified number of bytes from an InStream object. Data is read in binary format.
Read(var Guid [, Integer])	Reads a specified number of bytes from an InStream object. Data is read in binary format.
Read(var String [, Integer])	Reads a specified number of bytes from an InStream object. Data is read in binary format.
Read(var Any [, Integer])	Reads a specified number of bytes from an InStream object. Data is read in binary format.
ReadText(var Text [, Integer])	Reads text from an InStream object.

InStream.EOS Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Indicates whether an input stream has reached End of Stream (EOS).

Syntax

```
IsEOS :=   InStream.EOS()
```

NOTE

This method can be invoked using property access syntax.

Parameters

InStream Type: InStream An instance of the InStream data type.

Return Value

IsEOS Type: Boolean **true** if the stream has reached End of Stream; otherwise **false**.

Remarks

If you are reading data from an external component, EOS can return **false** even though no more data is available. This may occur if you have not called Read first.

Example

The following example opens the text file in a folder that is named MyFolder. The data in the text file is read into and input stream variable named StreamInTest. The InStream.EOS Method is used to determine whether the input stream has reached the end. If the stream has not reached the end, the stream is read into a text buffer, which indicates that the stream has not reached the end until the stream reaches the end. You must also create the following file 'c:\MyFolder\MyText.txt'.

```
 var
    StreamInTest: InStream;
    FileTest: File;
    Buffer: Text;
begin
    FileTest.Open('c:\MyFolder\MyText.txt');
    FileTest.CreateInStream(StreamInTest);
    while not StreamInTest.EOS do begin
      StreamInTest.ReadTet(Buffer);
      //Do some processing
      Message('Stream is still processing')
    end;
    Message('End of Stream');
end;
```

InStream.Read Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Reads a specified number of bytes from an InStream object. Data is read in binary format.

Syntax

```
[Read := ]  InStream.Read(var Variable: Boolean [, Length: Integer])
```

Parameters

InStream Type: InStream An instance of the InStream data type.

Variable
Type: Boolean

Length
Type: Integer
Describes the number of characters to be read. If you do not specify Length, the size of the variable is used. In the case of data types other than string, code, and binary, if you specify a length that differs from the size of the variable, you receive an error message.

Return Value

Read Type: Integer If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

Remarks

Read reads until the specified length or a zero byte. For more information about how zero bytes and line endings are read, see WRITE, WriteText, Read, and ReadTEXT Method Behavior Regarding Line Endings and Zero Terminators.

If the optional return value (*Read*) is not present and the data being read is less than the length requested to be read, then you receive an error message.

If the return value is present, then you must verify the validity of the data that has been read.

Example

The following example shows how to use the **Instream.Read** method to read data in binary format. The **Find** method finds the first record from the **Company Information** table. The **CalcFields** method retrieves the **Picture** field, which is a BLOB field. The **CreateInStream** method uses the recBinaries variable to create an InStream object that is named varInstream. The **varInstream.Read** method then reads three characters from the varInstream variable and stores the binary data in the varChars variable. The number of characters that is read is stored in the numChars variable. The binary data and the number of characters that is read are displayed in a message box.

```
 var
    recBinaries: Record "Company Information";
    varInstream: Instream;
    varChars: Text[50];
    numChars: Integer;
    Text000: Label 'Number of characters read: %1. Characters read: %2.';
begin
    recBinaries.Find('-');
    recBinaries.CalcFields(recBinaries.Picture);
    recBinaries.Picture.CreateInStream(varInstream);
    numChars := varInstream.Read(varChars,3);
    Message(Text000, numChars, varChars);
end;
```

InStream Data Type
Getting Started with AL
Developing Extensions

InStream.Read Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Reads a specified number of bytes from an InStream object. Data is read in binary format.

Syntax

```
[Read := ]  InStream.Read(var Variable: String [, Length: Integer])
```

Parameters

InStream Type: InStream An instance of the InStream data type.

Variable
Type: String

Length
Type: Integer
Describes the number of characters to be read. If you do not specify Length, the size of the variable is used. In the case of data types other than string, code, and binary, if you specify a length that differs from the size of the variable, you receive an error message.

Return Value

Read Type: Integer If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

Remarks

Read reads until the specified length or a zero byte. For more information about how zero bytes and line endings are read, see WRITE, WriteText, Read, and ReadTEXT Method Behavior Regarding Line Endings and Zero Terminators.

If the optional return value (*Read*) is not present and the data being read is less than the length requested to be read, then you receive an error message.

If the return value is present, then you must verify the validity of the data that has been read.

Example

The following example shows how to use the **Instream.Read** method to read data in binary format. The **Find** method finds the first record from the **Company Information** table. The **CalcFields** method retrieves the **Picture** field, which is a BLOB field. The **CreateInStream** method uses the recBinaries variable to create an InStream object that is named varInstream. The **varInstream.Read** method then reads three characters from the varInstream variable and stores the binary data in the varChars variable. The number of characters that is read is stored in the numChars variable. The binary data and the number of characters that is read are displayed in a message box.

```
 var
    recBinaries: Record "Company Information";
    varInstream: Instream;
    varChars: Text[50];
    numChars: Integer;
    Text000: Label 'Number of characters read: %1. Characters read: %2.';
begin
    recBinaries.Find('-');
    recBinaries.CalcFields(recBinaries.Picture);
    recBinaries.Picture.CreateInStream(varInstream);
    numChars := varInstream.Read(varChars,3);
    Message(Text000, numChars, varChars);
end;
```

InStream.Read Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Reads a specified number of bytes from an InStream object. Data is read in binary format.

Syntax

```
[Read := ]  InStream.Read(var Variable: Any [, Length: Integer])
```

Parameters

InStream Type: InStream An instance of the InStream data type.

Variable
Type: Any

Length
Type: Integer
Describes the number of characters to be read. If you do not specify Length, the size of the variable is used. In the case of data types other than string, code, and binary, if you specify a length that differs from the size of the variable, you receive an error message.

Return Value

Read Type: Integer If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

Remarks

Read reads until the specified length or a zero byte. For more information about how zero bytes and line endings are read, see WRITE, WriteText, Read, and ReadTEXT Method Behavior Regarding Line Endings and Zero Terminators.

If the optional return value (*Read*) is not present and the data being read is less than the length requested to be read, then you receive an error message.

If the return value is present, then you must verify the validity of the data that has been read.

Example

The following example shows how to use the **Instream.Read** method to read data in binary format. The **Find** method finds the first record from the **Company Information** table. The **CalcFields** method retrieves the **Picture** field, which is a BLOB field. The **CreateInStream** method uses the recBinaries variable to create an InStream object that is named varInstream. The **varInstream.Read** method then reads three characters from the varInstream variable and stores the binary data in the varChars variable. The number of characters that is read is stored in the numChars variable. The binary data and the number of characters that is read are displayed in a message box.

```
 var
    recBinaries: Record "Company Information";
    varInstream: Instream;
    varChars: Text[50];
    numChars: Integer;
    Text000: Label 'Number of characters read: %1. Characters read: %2.';

InStream.ReadText Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Reads text from an InStream object.

Syntax

```
[Read := ]  InStream.ReadText(var Variable: Text [, Length: Integer])
```

Parameters

InStream Type: InStream An instance of the InStream data type.

Variable
Type: Text
The variable that receives the characters that were read.
Length
Type: Integer
The number of characters to be read. If you do not specify this parameter, the maximum length of the string is used.

Return Value

Read Type: Integer The number of characters that were read. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

Remarks

ReadText reads the until the specified number of bytes, the maximum length of the string, a zero byte, or until the end of the line. For more information about how zero bytes and line endings are read, see Write, WriteText, Read, and ReadText Method Behavior Regarding Line Endings and Zero Terminators.

Data is read in text format.

If you do not use the optional return value and the data being read is less than the length requested to be read, an error message is displayed.

If you use the return value, you must verify the validity of the data that has been read.

Example

```
 var
    FileTest: File;
    StreamInTest: Instream;
    Txt: Text;
    Int: Integer;
begin
    FileTest.Open('c:\XMLDocs\NewTest.txt');
    FileTest.CreateInStream(StreamInTest);
    // Starting a loop
    while not (StreamInTest.EOS) do begin
      Int := StreamInTest.ReadText(Txt,100);
      Message(Txt + '\Size: ' + Format(Int));
    end;
    FileTest.Close();
end;
```

Integer Data Type

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Stores whole numbers with values that range from -2,147,483,647 to 2,147,483,647.

Remarks

In addition to representing whole numbers in this range, you can use integers to represent Boolean values. For Boolean values, 1 represents **true** and 0 represents **false**.

If you assign -2,147,483,648 directly to an Integer variable, then you get an error when you try to compile the code. However, you can indirectly assign -2,147,483,648 to an Integer variable by using the following code.

```
IntegerVar := -2147483647;
IntegerVar := IntegerVar - 1;
```

If you try to indirectly assign a value that is smaller than -2,147,483,648 or larger than 2,147,483,647, then you get a run-time error.

Example 1

The following are examples of integer values.

```
546
-3425
```

Example 2

The following example is a decimal and not an integer.

```
342.45
```

IsolatedStorage Data Type

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 2.0.*

Provides data isolation for extensions.

The following methods are available on the IsolatedStorage data type.

METHOD NAME	DESCRIPTION
Contains(String [, DataScope])	Determines whether the storage contains a value with the specified key.
Delete(String [, DataScope])	Deletes the value with the specified key from the isolated storage.
Get(String [, DataScope], var Text)	Gets the value associated with the specified key.
Get(String, var Text)	Gets the value associated with the specified key.
Set(String, String [, DataScope])	Sets the value associated with the specified key.
SetEncrypted(String, String [, DataScope])	Encrypts and sets the value associated with the specified key. The input string cannot exceed a length of 215 plain characters; be aware that special characters take up more space.

IsolatedStorage.Contains Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 2.0.*

Determines whether the storage contains a value with the specified key.

Syntax

```
HasValue :=   IsolatedStorage.Contains(Key: String [, DataScope: DataScope])
```

Parameters

Key

Type: String

The key to locate in the storage.

DataScope

Type: DataScope

The scope in which to check for the existence of a value with the given key. If a value is not passed in, the default value DataScope::Module will be used.

Return Value

HasValue Type: Boolean **true** if a value with the specified key exists in the storage, otherwise **false**.

See Also

IsolatedStorage Data Type

Developing Extensions

IsolatedStorage.Delete Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 2.0.*

Deletes the value with the specified key from the isolated storage.

Syntax

```
[Ok := ]  IsolatedStorage.Delete(Key: String [, DataScope: DataScope])
```

Parameters

Key
Type: String
The key of the value to remove.

DataScope
Type: DataScope
The scope from which to remove the value with the given key. If a value is not passed in, the default value DataScope::Module will be used.

Return Value

Ok Type: Boolean **true** if the value with the given key was successfully deleted from isolated storage, otherwise **false**. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

IsolatedStorage.Get Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 2.0.*

Gets the value associated with the specified key.

Syntax

```
[Ok := ]  IsolatedStorage.Get(Key: String [, DataScope: DataScope], var Value: Text)
```

Parameters

Key

Type: String

The key of the value to get. If the specified key is not found an error will be reported.

DataScope

Type: DataScope

The scope of the data to retrieve. If a value is not passed in, the default value DataScope::Module will be used.

Value

Type: Text

The value that is associated with the specified key.

Return Value

Ok Type: Boolean **true** if the value was retrieved successfully, otherwise **false**. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

See Also

IsolatedStorage.Get Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 2.0.*

Gets the value associated with the specified key.

Syntax

```
[Ok := ]  IsolatedStorage.Get(Key: String, var Value: Text)
```

Parameters

Key

Type: String

The key of the value to get. If the specified key is not found an error will be reported.

Value

Type: Text

The value that is associated with the specified key.

Return Value

Ok Type: Boolean **true** if the value was retrieved successfully, otherwise **false**. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

See Also

IsolatedStorage Data Type

IsolatedStorage.Set Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 2.0.*

Sets the value associated with the specified key.

Syntax

```
[Ok := ]  IsolatedStorage.Set(Key: String, Value: String [, DataScope: DataScope])
```

Parameters

Key
Type: String
The key of the value to set.

Value
Type: String
The value that will be associated with the specified key.

DataScope
Type: DataScope
The scope of the stored data. If a value is not passed in, the default value DataScope::Module will be used.

Return Value

Ok Type: Boolean **true** if the value was saved successfully, otherwise **false**. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

Remarks

The **Set** method initiates a write transaction, which means that it cannot be succeeded by code that opens a modal page. If you want to open a modal page, it must be done before the **Set** method is called.

IsolatedStorage.SetEncrypted Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 2.0.*

Encrypts and sets the value associated with the specified key. The input string cannot exceed a length of 215 plain characters; be aware that special characters take up more space.

Syntax

```
[Ok := ]  IsolatedStorage.SetEncrypted(Key: String, Value: String [, DataScope: DataScope])
```

Parameters

Key

Type: String

The key of the value to set.

Value

Type: String

The value that will be associated with the specified key.

DataScope

Type: DataScope

The scope of the stored data. If a value is not passed in, the default value DataScope::Module will be used.

Return Value

Ok Type: Boolean **true** if the value was saved successfully, otherwise **false**. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

JsonArray Data Type

2/17/2021 • 5 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Is a container for any well-formed JSON array. A default JsonArray contains an empty JSON array.

The following methods are available on instances of the JsonArray data type.

METHOD NAME	DESCRIPTION
Add(JsonToken)	Adds a new value at the end of the JsonArray.
Add(JsonArray)	Adds a new value at the end of the JsonArray.
Add(JsonObject)	Adds a new value at the end of the JsonArray.
Add(JsonValue)	Adds a new value at the end of the JsonArray.
Add(Boolean)	Adds a new value at the end of the JsonArray.
Add(Char)	Adds a new value at the end of the JsonArray.
Add(Byte)	Adds a new value at the end of the JsonArray.
Add(Option)	Adds a new value at the end of the JsonArray.
Add(Integer)	Adds a new value at the end of the JsonArray.
Add(BigInteger)	Adds a new value at the end of the JsonArray.
Add(Decimal)	Adds a new value at the end of the JsonArray.
Add(Duration)	Adds a new value at the end of the JsonArray.
Add(Date)	Adds a new value at the end of the JsonArray.
Add(Time)	Adds a new value at the end of the JsonArray.
Add(DateTime)	Adds a new value at the end of the JsonArray.
Add(String)	Adds a new value at the end of the JsonArray.
AsToken()	Converts the value in a JsonArray to a JsonToken data type.
Clone()	Creates a deep-copy of the JsonArray value.
Count()	Gets the number of elements in the JsonArray.
Get(Integer, var JsonToken)	Retrieves the value at the given index in the JsonArray.
IndexOf(JsonToken)	Determines the index of a specific value in the JsonArray.
IndexOf(JsonArray)	Determines the index of a specific value in the JsonArray.
IndexOf(JsonObject)	Determines the index of a specific value in the JsonArray.

METHOD NAME	DESCRIPTION
IndexOf(JsonValue)	Determines the index of a specific value in the JsonArray.
IndexOf(Boolean)	Determines the index of a specific value in the JsonArray.
IndexOf(Char)	Determines the index of a specific value in the JsonArray.
IndexOf(Byte)	Determines the index of a specific value in the JsonArray.
IndexOf(Option)	Determines the index of a specific value in the JsonArray.
IndexOf(Integer)	Determines the index of a specific value in the JsonArray.
IndexOf(BigInteger)	Determines the index of a specific value in the JsonArray.
IndexOf(Decimal)	Determines the index of a specific value in the JsonArray.
IndexOf(Duration)	Determines the index of a specific value in the JsonArray.
IndexOf(Date)	Determines the index of a specific value in the JsonArray.
IndexOf(Time)	Determines the index of a specific value in the JsonArray.
IndexOf(DateTime)	Determines the index of a specific value in the JsonArray.
IndexOf(String)	Determines the index of a specific value in the JsonArray.
Insert(Integer, JsonToken)	Inserts the value at the given index in the array while shifting all the values to the right by one position.
Insert(Integer, JsonArray)	Inserts the value at the given index in the array while shifting all the values to the right by one position.
Insert(Integer, JsonObject)	Inserts the value at the given index in the array while shifting all the values to the right by one position.
Insert(Integer, JsonValue)	Inserts the value at the given index in the array while shifting all the values to the right by one position.
Insert(Integer, Boolean)	Inserts the value at the given index in the array while shifting all the values to the right by one position.
Insert(Integer, Char)	Inserts the value at the given index in the array while shifting all the values to the right by one position.
Insert(Integer, Byte)	Inserts the value at the given index in the array while shifting all the values to the right by one position.
Insert(Integer, Option)	Inserts the value at the given index in the array while shifting all the values to the right by one position.
Insert(Integer, Integer)	Inserts the value at the given index in the array while shifting all the values to the right by one position.
Insert(Integer, BigInteger)	Inserts the value at the given index in the array while shifting all the values to the right by one position.
Insert(Integer, Decimal)	Inserts the value at the given index in the array while shifting all the values to the right by one position.
Insert(Integer, Duration)	Inserts the value at the given index in the array while shifting all the values to the right by one position.

METHOD NAME	DESCRIPTION
Insert(Integer, Date)	Inserts the value at the given index in the array while shifting all the values to the right by one position.
Insert(Integer, Time)	Inserts the value at the given index in the array while shifting all the values to the right by one position.
Insert(Integer, DateTime)	Inserts the value at the given index in the array while shifting all the values to the right by one position.
Insert(Integer, String)	Inserts the value at the given index in the array while shifting all the values to the right by one position.
Path()	Retrieves the JSON path of the array relative to the root of its containing tree.
ReadFrom(String)	Reads the JSON data from the string into a JsonArray variable.
ReadFrom(InStream)	Reads the JSON data from the stream into a JsonArray variable.
RemoveAt(Integer)	Removes the token at the given index.
SelectToken(String, var JsonToken)	Selects a JsonToken using a JPath expression.
Set(Integer, JsonToken)	Replaces the value at the given index with a new value.
Set(Integer, JsonObject)	Replaces the value at the given index with a new value.
Set(Integer, JsonArray)	Replaces the value at the given index with a new value.
Set(Integer, JsonValue)	Replaces the value at the given index with a new value.
Set(Integer, Boolean)	Replaces the value at the given index with a new value.
Set(Integer, Char)	Replaces the value at the given index with a new value.
Set(Integer, Byte)	Replaces the value at the given index with a new value.
Set(Integer, Option)	Replaces the value at the given index with a new value.
Set(Integer, Integer)	Replaces the value at the given index with a new value.
Set(Integer, BigInteger)	Replaces the value at the given index with a new value.
Set(Integer, Decimal)	Replaces the value at the given index with a new value.
Set(Integer, Duration)	Replaces the value at the given index with a new value.
Set(Integer, Date)	Replaces the value at the given index with a new value.
Set(Integer, Time)	Replaces the value at the given index with a new value.
Set(Integer, DateTime)	Replaces the value at the given index with a new value.
Set(Integer, String)	Replaces the value at the given index with a new value.
WriteTo(var Text)	Serializes and writes the JSON data of the JsonArray to a given Text object.

METHOD NAME	DESCRIPTION
WriteTo(OutStream)	Serializes and writes the JSON data of the JsonArray to a given OutStream object.

> **NOTE**
> For performance reasons all HTTP, JSON, TextBuilder, and XML types are reference types, not value types. Reference types holds a pointer to the data elsewhere in memory, whereas value types store its own data.

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Converts the value in a JsonArray to a JsonToken data type.

Syntax

```
Token :=   JsonArray.AsToken()
```

Parameters

JsonArray Type: JsonArray An instance of the JsonArray data type.

Return Value

Token Type: JsonToken

JsonArray.Clone Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Creates a deep-copy of the JsonArray value.

Syntax

```
Clone :=   JsonArray.Clone()
```

Parameters

JsonArray Type: JsonArray An instance of the JsonArray data type.

Return Value

Clone Type: JsonToken The Result will be a full, deep-copy of the Value.

JsonArray.Count Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Gets the number of elements in the JsonArray.

Syntax

```
Count :=   JsonArray.Count()
```

NOTE

This method can be invoked using property access syntax.

Parameters

JsonArray Type: JsonArray An instance of the JsonArray data type.

Return Value

Count Type: Integer The number of elements in the JsonArray.

See Also

JsonArray.Get Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Retrieves the value at the given index in the JsonArray.

Syntax

```
[Ok := ]  JsonArray.Get(Index: Integer, var Result: JsonToken)
```

Parameters

JsonArray Type: JsonArray An instance of the JsonArray data type.

Index
Type: Integer
The index of the element in the JsonArray that you want to retrieve.
Result
Type: JsonToken
A variable of type JsonToken that will contain the result if the operation is successful.

Return Value

Ok Type: Boolean **true** if the operation was successful; otherwise **false**. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

Remarks

The operation will fail if the Index is smaller than 0 or greater or equal than JsonArray.Count.

JsonArray.IndexOf Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Determines the index of a specific value in the JsonArray.

Syntax

```
Index :=   JsonArray.IndexOf(Value: JsonToken)
```

Parameters

JsonArray Type: JsonArray An instance of the JsonArray data type.

Value
Type: JsonToken

Return Value

Index Type: Integer The position of the value in the JsonArray. -1 will be returned if Value cannot be found in the array.

JsonArray.Path Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Retrieves the JSON path of the array relative to the root of its containing tree.

Syntax

```
Path :=   JsonArray.Path()
```

> **NOTE**
> This method can be invoked using property access syntax.

Parameters

JsonArray Type: JsonArray An instance of the JsonArray data type.

Return Value

Path Type: String The path of the array relative to its containing JSON tree. If the object is the root of the JSON tree, the path will be empty.

See Also

JsonArray Data Type
Getting Started with AL

JsonArray.ReadFrom Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Reads the JSON data from the string into a JsonArray variable.

Syntax

```
[Ok := ]  JsonArray.ReadFrom(String: String)
```

Parameters

JsonArray Type: JsonArray An instance of the JsonArray data type.

String
Type: String
The String object from which the JSON data will be read.

Return Value

Ok Type: Boolean **true** if the read was successful; otherwise, **false**. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

Remarks

This method can fail if the JSON data is malformed. If the operation succeeds, the JsonArray will be disconnected from its current JSON tree and the data contained by the JsonArray will be replaced with the new value. To delete the contents in a JsonArray variable use the Clear function.

```
Clear(JsonArray)
```

Example

This example shows how to read JSON data from a string into a JsonArray variable.

```
local procedure ReadJson(data : Text) result : JsonArray;
begin
    result.ReadFrom(data);
end;
```

JsonArray.ReadFrom Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Reads the JSON data from the stream into a JsonArray variable.

Syntax

```
[Ok := ]  JsonArray.ReadFrom(Data: InStream)
```

Parameters

JsonArray Type: JsonArray An instance of the JsonArray data type.

Data
Type: InStream
The InStream object from which the JSON data will be read.

Return Value

Ok Type: Boolean **true** if the read was successful; otherwise, **false**. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

Remarks

This method can fail if the stream is in an invalid state or if the JSON data is malformed. If the operation succeeds, the JsonArray will be disconnected from its current JSON tree and the data contained by the JsonArray will be replaced with the new value. To delete the contents in a JsonArray variable use the Clear function.

```
Clear(JsonArray)
```

Example

This example shows how to read JSON data from a stream into a JsonArray variable.

```
local procedure ReadJson(source : InStream) result : JsonArray;
begin
    result.ReadFrom(source);
end;
```

JsonArray.RemoveAt Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Removes the token at the given index.

Syntax

```
[Ok := ]  JsonArray.RemoveAt(Index: Integer)
```

Parameters

JsonArray Type: JsonArray An instance of the JsonArray data type.

Index
Type: Integer
The position of the element that will be removed.

Return Value

Ok Type: Boolean **true** if the read was successful; otherwise, **false**. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

Remarks

1. The operation will fail if the Index is smaller than 0 or (greater or equal) than JsonArray.Count.
2. Objects of type JsonArray represent a 0-based array.

JsonArray.SelectToken Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Selects a JsonToken using a JPath expression.

Syntax

```
[Ok := ]  JsonArray.SelectToken(Path: String, var Result: JsonToken)
```

Parameters

JsonArray Type: JsonArray An instance of the JsonArray data type.

Path
Type: String
A valid JPath expression.

Result
Type: JsonToken
A **JsonToken** variable that will contain the result if the operation is successful.

Return Value

Ok Type: Boolean **true** if the read was successful; otherwise, **false**. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

Remarks

The operation will fail if more or less than 1 tokens are the result of evaluating the JPath.

Example

The following example shows how to select a value from a complex JSON Object. We build up a select expression in the query variable, we select the token corresponding to the salary of the employee with the given employeeId, and finally, we convert the token to a Decimal value.

We assume that the company token contains JSON data similar to the one below.

```
{ "company": {
    "employees": [
      { "id": "Marcy",
        "salary": 8.95
      },
      { "id": "John",
        "salary": 7
      },
      { "id": "Diana",
        "salary": 10.95
      }
    ]
  }
}
```

```
local procedure SelectEmployeeSalary(companyData : JsonToken; employeeId : Text) salary : Decimal;
var
    query : Text;
    salaryToken : JsonToken;
begin
    query := '$.company.employees[?(@.id=='''+employeeId+''')].salary';
    companyData.SelectToken(query, salaryToken);

    salary := salaryToken.AsValue().AsDecimal();
end;
```

NOTE

Ensure that the selected expression contains ' (single quotation mark) and not " (double quotation mark) to decorate the string value.

JsonArray.Set Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Replaces the value at the given index with a new value.

Syntax

```
[Ok := ]  JsonArray.Set(Index: Integer, Result: JsonToken)
```

Parameters

JsonArray Type: JsonArray An instance of the JsonArray data type.

Index
Type: Integer

Result
Type: JsonToken

Return Value

Ok Type: Boolean **true** if the read was successful; otherwise, **false**. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

JsonObject Data Type

2/17/2021 • 3 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Is a container for any well-formed JSON object. A default JsonObject contains an empty JSON object.

The following methods are available on instances of the JsonObject data type.

METHOD NAME	DESCRIPTION
Add(String, JsonToken)	Adds a new property to a JsonObject.
Add(String, JsonObject)	Adds a new property to a JsonObject.
Add(String, JsonValue)	Adds a new property to a JsonObject.
Add(String, JsonArray)	Adds a new property to a JsonObject.
Add(String, Boolean)	Adds a new property to a JsonObject.
Add(String, Char)	Adds a new property to a JsonObject.
Add(String, Byte)	Adds a new property to a JsonObject.
Add(String, Option)	Adds a new property to a JsonObject.
Add(String, Integer)	Adds a new property to a JsonObject.
Add(String, BigInteger)	Adds a new property to a JsonObject.
Add(String, Decimal)	Adds a new property to a JsonObject.
Add(String, Duration)	Adds a new property to a JsonObject.
Add(String, String)	Adds a new property to a JsonObject.
Add(String, Date)	Adds a new property to a JsonObject.
Add(String, Time)	Adds a new property to a JsonObject.
Add(String, DateTime)	Adds a new property to a JsonObject.
AsToken()	Converts the value in a JsonObject to a JsonToken data type.
Clone()	Creates a deep-copy of the JsonToken value.
Contains(String)	Verifies if a JsonObject contains a property with a given key.
Get(String, var JsonToken)	Retrieves the value of a property with a given key from a JsonObject.

METHOD NAME	DESCRIPTION
Keys()	Gets a set of keys of the JsonObject.
Path()	Retrieves the JSON path of the object relative to the root of its containing tree.
ReadFrom(String)	Reads the JSON data from the string into a JsonObject variable.
ReadFrom(InStream)	Reads the JSON data from the stream into a JsonObject variable.
Remove(String)	Removes the property with the given key from the object.
Replace(String, JsonToken)	Replaces the value of the property with the given key with the new value.
Replace(String, JsonArray)	Replaces the value of the property with the given key with the new value.
Replace(String, JsonObject)	Replaces the value of the property with the given key with the new value.
Replace(String, JsonValue)	Replaces the value of the property with the given key with the new value.
Replace(String, Boolean)	Replaces the value of the property with the given key with the new value.
Replace(String, Char)	Replaces the value of the property with the given key with the new value.
Replace(String, Byte)	Replaces the value of the property with the given key with the new value.
Replace(String, Integer)	Replaces the value of the property with the given key with the new value.
Replace(String, Option)	Replaces the value of the property with the given key with the new value.
Replace(String, BigInteger)	Replaces the value of the property with the given key with the new value.
Replace(String, Decimal)	Replaces the value of the property with the given key with the new value.
Replace(String, Duration)	Replaces the value of the property with the given key with the new value.
Replace(String, Date)	Replaces the value of the property with the given key with the new value.
Replace(String, Time)	Replaces the value of the property with the given key with the new value.
Replace(String, DateTime)	Replaces the value of the property with the given key with the new value.

METHOD NAME	DESCRIPTION
Replace(String, String)	Replaces the value of the property with the given key with the new value.
SelectToken(String, var JsonToken)	Selects a JsonToken using a JPath expression.
Values()	Gets a set of values of the JsonObject.
WriteTo(var Text)	Serializes and writes the JSON data of the JsonObject to a given Text object.
WriteTo(OutStream)	Serializes and writes the JSON data of the JsonObject to a given OutStream object.

NOTE

For performance reasons all HTTP, JSON, TextBuilder, and XML types are reference types, not value types. Reference types holds a pointer to the data elsewhere in memory, whereas value types store its own data.

Remarks

An unitialized variable of JsonObject type represents an empty JSON object. Given a value of JsonObject type, you can check if it is empty by checking that the number of keys in the object is 0.

```
jsonObject.Keys.Count =  0
```

JsonObject.Add Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Adds a new property to a JsonObject.

Syntax

```
[Ok := ]  JsonObject.Add(Key: String, Value: JsonToken)
```

Parameters

JsonObject Type: JsonObject An instance of the JsonObject data type.

Key
Type: String

Value
Type: JsonToken

Return Value

Ok Type: Boolean **true** if the operation was successful; otherwise **false**. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

Remarks

The operation will fail if the object already contains a property with the given key.

JsonObject.AsToken Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Converts the value in a JsonObject to a JsonToken data type.

Syntax

```
Token :=   JsonObject.AsToken()
```

Parameters

JsonObject Type: JsonObject An instance of the JsonObject data type.

Return Value

Token Type: JsonToken The returned JsonToken contains the same data as the JsonObject, but allows for treating the data in a generic manner.

Version: *Available from runtime version 1.0.*

Retrieves the value of a property with a given key from a JsonObject.

Syntax

```
[Ok := ]  JsonObject.Get(Key: String, var Result: JsonToken)
```

Parameters

JsonObject Type: JsonObject An instance of the JsonObject data type.

Key
Type: String

Result
Type: JsonToken
A variable of type JsonToken that will contain the result if the operation is successful.

Return Value

Ok Type: Boolean **true** if the operation was successful; otherwise **false**. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

Remarks

The operation will fail if the object does not contain a property with the given Key.

JsonObject.Keys Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Gets a set of keys of the JsonObject.

Syntax

```
Keys :=   JsonObject.Keys()
```

NOTE

This method can be invoked using property access syntax.

Parameters

JsonObject Type: JsonObject An instance of the JsonObject data type.

Return Value

Keys Type: List of [Text]

See Also

JsonObject Data Type
Getting Started with AL
Developing Extensions

JsonObject.Path Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Retrieves the JSON path of the object relative to the root of its containing tree.

Syntax

```
Path :=   JsonObject.Path()
```

NOTE

This method can be invoked using property access syntax.

Parameters

JsonObject Type: JsonObject An instance of the JsonObject data type.

Return Value

Path Type: String The path of the object relative to its containing JSON tree. If the object is the root of the JSON tree, the path will be empty.

See Also

JsonObject Data Type
Getting Started with AL
Developing Extensions

JsonObject.ReadFrom Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Reads the JSON data from the string into a JsonObject variable.

Syntax

```
[Ok := ]  JsonObject.ReadFrom(String: String)
```

Parameters

JsonObject Type: JsonObject An instance of the JsonObject data type.

String
  Type: String
The String object from which the JSON data will be read.

Return Value

Ok Type: Boolean **true** if the read was successful; otherwise, **false**. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

Remarks

This method can fail if the JSON data is malformed. If the operation succeeds, the JsonObject will be disconnected from its current JSON tree and the data contained by the JsonObject will be replaced with the new value. To delete the contents in a JsonObject variable use the Clear function.

```
Clear(JsonObject)
```

Example

This example shows how to read JSON data from a string into a JsonObject variable.

```
local procedure ReadJson(data : Text) result : JsonObject;
begin
    result.ReadFrom(data);
end;
```

JsonObject.ReadFrom Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Reads the JSON data from the stream into a JsonObject variable.

Syntax

```
[Ok := ]  JsonObject.ReadFrom(InStream: InStream)
```

Parameters

JsonObject Type: JsonObject An instance of the JsonObject data type.

InStream
Type: InStream
The InStream object from which the JSON data will be read.

Return Value

Ok Type: Boolean **true** if the read was successful; otherwise, **false**. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

Remarks

This method can fail if the stream is in an invalid state or if the JSON data is malformed. If the operation succeeds, the JsonObject will be disconnected from its current JSON tree and the data contained by the JsonObject will be replaced with the new value. To delete the contents in a JsonObject variable use the Clear function.

```
Clear(JsonObject)
```

Example

This example shows how to read JSON data from a stream into a JsonObject variable.

```
local procedure ReadJson(source : InStream) result : JsonObject;
begin
    result.ReadFrom(source);
end;
```

JsonObject.Remove Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Removes the property with the given key from the object.

Syntax

```
[Ok := ]  JsonObject.Remove(Key: String)
```

Parameters

JsonObject Type: JsonObject An instance of the JsonObject data type.

Key
Type: String

Return Value

Ok Type: Boolean **true** if the operation was successful; otherwise **false**.

JsonObject.Replace Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Replaces the value of the property with the given key with the new value.

Syntax

```
[Ok := ]  JsonObject.Replace(Key: String, Value: JsonToken)
```

Parameters

JsonObject Type: JsonObject An instance of the JsonObject data type.

Key
Type: String

Value
Type: JsonToken

Return Value

Ok Type: Boolean **true** if the operation was successful; otherwise **false**. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

JsonObject.SelectToken Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Selects a JsonToken using a JPath expression.

Syntax

```
[Ok := ]  JsonObject.SelectToken(Path: String, var Result: JsonToken)
```

Parameters

JsonObject Type: JsonObject An instance of the JsonObject data type.

Path
Type: String
A valid JPath expression.

Result
Type: JsonToken
A JsonToken variable that will contain the result if the operation is successful.

Return Value

Ok Type: Boolean **true** if the read was successful; otherwise, **false**. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

Remarks

The operation will fail if more or less than 1 tokens are the result of evaluating the JPath.

Example

The following example shows how to select a value from a complex JSON Object. We build up a select expression in the query variable, we select the token corresponding to the salary of the employee with the given employeeId, and finally, we convert the token to a Decimal value.

We assume that the company token contains JSON data similar to the one below.

```
{ "company": {
    "employees": [
      { "id": "Marcy",
        "salary": 8.95
      },
      { "id": "John",
        "salary": 7
      },
      { "id": "Diana",
        "salary": 10.95
      }
    ]
  }
}
```

```
local procedure SelectEmployeeSalary(companyData : JsonToken; employeeId : Text) salary : Decimal;
var
    query : Text;
    salaryToken : JsonToken;
begin
    query := '$.company.employees[?(@.id=='''+employeeId+''')].salary';
    companyData.SelectToken(query, salaryToken);

    salary := salaryToken.AsValue().AsDecimal();
end;
```

NOTE

Ensure that the selected expression contains ' (single quotation mark) and not " (double quotation mark) to decorate the string value.

JsonObject.Values Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Gets a set of values of the JsonObject.

Syntax

```
Values :=   JsonObject.Values()
```

NOTE

This method can be invoked using property access syntax.

Parameters

JsonObject Type: JsonObject An instance of the JsonObject data type.

Return Value

Values Type: List of [JsonToken]

See Also

JsonObject.WriteTo Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Serializes and writes the JSON data of the JsonObject to a given Text object.

Syntax

```
[Ok := ]  JsonObject.WriteTo(var String: Text)
```

Parameters

JsonObject Type: JsonObject An instance of the JsonObject data type.

String
Type: Text
The Text object to which the JSON data will be written.

Return Value

Ok Type: Boolean **true** if the read was successful; otherwise, **false**. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

See Also

JsonObject Data Type

JsonObject.WriteTo Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Serializes and writes the JSON data of the JsonObject to a given OutStream object.

Syntax

```
[Ok := ]  JsonObject.WriteTo(OutStream: OutStream)
```

Parameters

JsonObject Type: JsonObject An instance of the JsonObject data type.

OutStream
Type: OutStream
The OutStream object to which the JSON data will be written.

Return Value

Ok Type: Boolean **true** if the read was successful; otherwise, **false**. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

See Also

JsonToken Data Type

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Is a container for any well-formed JSON data. A default JsonToken object contains the JSON value of NULL.

The following methods are available on instances of the JsonToken data type.

METHOD NAME	DESCRIPTION
AsArray()	Converts the value in a JsonToken to a JsonArray data type.
AsObject()	Converts the value in a JsonToken to a JsonObject data type.
AsValue()	Converts the value in a JsonToken to a JsonValue data type.
Clone()	Creates a deep-copy of the JsonToken value.
IsArray()	Indicates whether a JsonToken represents a JSON array.
IsObject()	Indicates whether a JsonToken contains a JSON object.
IsValue()	Indicates whether a JsonToken contains a JSON value.
Path()	Retrieves the JSON path of the token relative to the root of its containing tree.
ReadFrom(String)	Reads the JSON data from the string into a JsonToken variable.
ReadFrom(InStream)	Reads the JSON data from the stream into a JsonToken variable.
SelectToken(String, var JsonToken)	Selects a JsonToken using a JPath expression.
WriteTo(var Text)	Serializes and writes the JSON data of the JsonToken to a given Text object.
WriteTo(OutStream)	Serializes and writes the JSON data of the JsonToken to a given OutStream object.

NOTE

For performance reasons all HTTP, JSON, TextBuilder, and XML types are reference types, not value types. Reference types holds a pointer to the data elsewhere in memory, whereas value types store its own data.

JsonToken.AsArray Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Converts the value in a JsonToken to a JsonArray data type.

Syntax

```
Array :=   JsonToken.AsArray()
```

Parameters

JsonToken Type: JsonToken An instance of the JsonToken data type.

Return Value

Array Type: JsonArray The returned JsonArray contains the same data as the JsonToken, but allows array-specific operations to be performed on it.

See Also

JsonToken Data Type
Getting Started with AL
Developing Extensions

JsonToken.AsObject Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Converts the value in a JsonToken to a JsonObject data type.

Syntax

```
Object :=   JsonToken.AsObject()
```

Parameters

JsonToken Type: JsonToken An instance of the JsonToken data type.

Return Value

Object Type: JsonObject The returned JsonObject contains the same data as the JsonToken, but allows object-specific operations to be performed on it.

See Also

JsonToken Data Type

JsonToken.AsValue Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Converts the value in a JsonToken to a JsonValue data type.

Syntax

```
Value :=   JsonToken.AsValue()
```

Parameters

JsonToken Type: JsonToken An instance of the JsonToken data type.

Return Value

Value Type: JsonValue The returned JsonValue contains the same data as the JsonToken, but allows value-specific operations to be performed on the data.

See Also

JsonToken Data Type

JsonToken.Clone Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Creates a deep-copy of the JsonToken value.

Syntax

```
Clone :=   JsonToken.Clone()
```

Parameters

JsonToken Type: JsonToken An instance of the JsonToken data type.

Return Value

Clone Type: JsonToken The Result will be a full, deep-copy of the Value.

See Also

JsonToken Data Type

JsonToken.IsArray Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Indicates whether a JsonToken represents a JSON array.

Syntax

```
Ok :=   JsonToken.IsArray()
```

NOTE

This method can be invoked using property access syntax.

Parameters

JsonToken Type: JsonToken An instance of the JsonToken data type.

Return Value

Ok Type: Boolean **true** if the JsonToken represents a JSON array; otherwise, **false**.

See Also

JsonToken Data Type

JsonToken.ReadFrom Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Reads the JSON data from the string into a JsonToken variable.

Syntax

```
[Ok := ]  JsonToken.ReadFrom(String: String)
```

Parameters

JsonToken Type: JsonToken An instance of the JsonToken data type.

String
  Type: String
The String object from which the JSON data will be read.

Return Value

Ok Type: Boolean **true** if the read was successful; otherwise, **false**. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

Remarks

This method can fail if the JSON data is malformed. If the operation succeeds, the JsonToken will be disconnected from its current JSON tree and the data contained by the JsonToken will be replaced with the new value. To delete the contents in a JsonToken variable use the Clear function.

```
Clear(JsonToken)
```

Example

This example shows how to read JSON data from a string into a JsonToken variable.

```
local procedure ReadJson(data : Text) result : JsonToken;
begin
    result.ReadFrom(data);
end;
```

JsonToken.ReadFrom Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Reads the JSON data from the stream into a JsonToken variable.

Syntax

```
[Ok := ]  JsonToken.ReadFrom(InStream: InStream)
```

Parameters

JsonToken Type: JsonToken An instance of the JsonToken data type.

InStream
Type: InStream
The InStream object from which the JSON data will be read.

Return Value

Ok Type: Boolean **true** if the read was successful; otherwise, **false**. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

Remarks

This method can fail if the stream is in an invalid state or if the JSON data is malformed. If the operation succeeds, the JsonToken will be disconnected from its current JSON tree and the data contained by the JsonToken will be replaced with the new value. To delete the contents in a JsonToken variable use the Clear function.

```
Clear(JsonToken)
```

Example

This example shows how to read JSON data from a stream into a JsonToken variable.

```
local procedure ReadJson(source : InStream) result : JsonToken;
begin
    result.ReadFrom(source);
end;
```

JsonToken.SelectToken Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Selects a JsonToken using a JPath expression.

Syntax

```
[Ok := ]  JsonToken.SelectToken(Path: String, var Result: JsonToken)
```

Parameters

JsonToken Type: JsonToken An instance of the JsonToken data type.

Path
Type: String
A valid JPath expression.

Result
Type: JsonToken
A JsonToken variable that will contain the result if the operation is successful.

Return Value

Ok Type: Boolean **true** if the read was successful; otherwise, **false**. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

Remarks

The operation will fail if more or less than 1 tokens are the result of evaluating the JPath.

Example

The following example shows how to select a value from a complex JSON Object. We build up a select expression in the query variable, we select the token corresponding to the salary of the employee with the given employeeId, and finally, we convert the token to a Decimal value.

We assume that the company token contains JSON data similar to the one below.

```
{ "company": {
    "employees": [
      { "id": "Marcy",
        "salary": 8.95
      },
      { "id": "John",
        "salary": 7
      },
      { "id": "Diana",
        "salary": 10.95
      }
    ]
  }
}
```

```
local procedure SelectEmployeeSalary(companyData : JsonToken; employeeId : Text) salary : Decimal;
var
    query : Text;
    salaryToken : JsonToken;
begin
    query := '$.company.employees[?(@.id=='''+employeeId+''')].salary';
    companyData.SelectToken(query, salaryToken);

    salary := salaryToken.AsValue().AsDecimal();
end;
```

NOTE

Ensure that the selected expression contains ' (single quotation mark) and not " (double quotation mark) to decorate the string value.

JsonToken.WriteTo Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Serializes and writes the JSON data of the JsonToken to a given Text object.

Syntax

```
[Ok := ]  JsonToken.WriteTo(var String: Text)
```

Parameters

JsonToken Type: JsonToken An instance of the JsonToken data type.

String
Type: Text
The Text object to which the JSON data will be read.

Return Value

Ok Type: Boolean **true** if the read was successful; otherwise, **false**. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

JsonToken.WriteTo Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Serializes and writes the JSON data of the JsonToken to a given OutStream object.

Syntax

```
[Ok := ]  JsonToken.WriteTo(Data: OutStream)
```

Parameters

JsonToken Type: JsonToken An instance of the JsonToken data type.

Data
Type: OutStream
The OutStream object to which the JSON data will be read.

Return Value

Ok Type: Boolean **true** if the read was successful; otherwise, **false**. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

JsonValue Data Type

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Is a container for any well-formed fundamental JSON value. A default JsonValue is set to the JSON value of NULL.

The following methods are available on instances of the JsonValue data type.

METHOD NAME	DESCRIPTION
AsBigInteger()	Converts the value in a JsonValue to an BigInteger data type.
AsBoolean()	Converts the value in a JsonValue to a Boolean data type.
AsByte()	Converts the value in a JsonValue to a Byte data type.
AsChar()	Converts the value in a JsonValue to a Char data type.
AsCode()	Converts the value in a JsonValue to a Code data type.
AsDate()	Converts the value in a JsonValue to a Date data type.
AsDateTime()	Converts the value in a JsonValue to a DateTime data type.
AsDecimal()	Converts the value in a JsonValue to a Decimal data type.
AsDuration()	Converts the value in a JsonValue to a Duration data type.
AsInteger()	Converts the value in a JsonValue to an Integer data type.
AsOption()	Converts the value in a JsonValue to an Option data type.
AsText()	Converts the value in a JsonValue to a Text data type.
AsTime()	Converts the value in a JsonValue to a Time data type.
AsToken()	Converts the value in a JsonValue to a JsonToken data type.
Clone()	Creates a deep-copy of the JsonToken value.
IsNull()	Indicates whether the JsonValue contains the JSON value of NULL.
IsUndefined()	Indicates whether the JsonValue contains the JSON value of UNDEFINED.
Path()	Retrieves the JSON path of the value relative to its containing tree.

METHOD NAME	DESCRIPTION
ReadFrom(String)	Reads the JSON data into a JsonValue variable.
ReadFrom(InStream)	Reads the JSON data from the stream into a JsonValue variable.
SelectToken(String, var JsonToken)	Selects a JsonToken using a JPath expression.
SetValue(Boolean)	Set the contents of the JsonValue variable to the JSON representation of the given value.
SetValue(Char)	Set the contents of the JsonValue variable to the JSON representation of the given value.
SetValue(Byte)	Set the contents of the JsonValue variable to the JSON representation of the given value.
SetValue(Option)	Set the contents of the JsonValue variable to the JSON representation of the given value.
SetValue(Integer)	Set the contents of the JsonValue variable to the JSON representation of the given value.
SetValue(BigInteger)	Set the contents of the JsonValue variable to the JSON representation of the given value.
SetValue(Decimal)	Set the contents of the JsonValue variable to the JSON representation of the given value.
SetValue(Duration)	Set the contents of the JsonValue variable to the JSON representation of the given value.
SetValue(Date)	Set the contents of the JsonValue variable to the JSON representation of the given value.
SetValue(Time)	Set the contents of the JsonValue variable to the JSON representation of the given value.
SetValue(DateTime)	Set the contents of the JsonValue variable to the JSON representation of the given value.
SetValue(String)	Set the contents of the JsonValue variable to the JSON representation of the given value.
SetValueToNull()	Set the contents of the JsonValue variable to the JSON representation of NULL.
SetValueToUndefined()	Set the contents of the JsonValue variable to the JSON representation of UNDEFINED.
WriteTo(var Text)	Serializes and writes the JSON data of the JsonValue to a given object.
WriteTo(OutStream)	Serializes and writes the JSON data of the JsonValue to a given object.

> **NOTE**
>
> For performance reasons all HTTP, JSON, TextBuilder, and XML types are reference types, not value types. Reference types holds a pointer to the data elsewhere in memory, whereas value types store its own data.

JsonValue.AsBigInteger Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Converts the value in a JsonValue to an BigInteger data type.

Syntax

```
Result :=   JsonValue.AsBigInteger()
```

Parameters

JsonValue Type: JsonValue An instance of the JsonValue data type.

Return Value

Result Type: BigInteger If the JsonValue does not contain number or a string which can be converted without loss of precision to an BigInteger, the operation will fail with a run-time error.

See Also

JsonValue Data Type
Getting Started with AL
Developing Extensions

JsonValue.AsBoolean Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Converts the value in a JsonValue to a Boolean data type.

Syntax

```
Result :=   JsonValue.AsBoolean()
```

Parameters

JsonValue Type: JsonValue An instance of the JsonValue data type.

Return Value

Result Type: Boolean The operation will succeed if the value was created from a Boolean using SetValue or if the value was parsed from a string containing one of the values : **true** or **false**. The operation will fail with a run-time error otherwise.

See Also

JsonValue Data Type

JsonValue.AsByte Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Converts the value in a JsonValue to a Byte data type.

Syntax

```
Result :=   JsonValue.AsByte()
```

Parameters

JsonValue Type: JsonValue An instance of the JsonValue data type.

Return Value

Result Type: Byte If the JsonValue does not contain a number which can be converted without loss of precision to a Byte, the operation will fail with a run-time error.

See Also

JsonValue Data Type
Getting Started with AL
Developing Extensions

JsonValue.AsChar Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Converts the value in a JsonValue to a Char data type.

Syntax

```
Result :=   JsonValue.AsChar()
```

Parameters

JsonValue Type: JsonValue An instance of the JsonValue data type.

Return Value

Result Type: Char If the JsonValue does not contain a number which can be converted without loss of precision to a Char, the operation will fail with a run-time error.

See Also

JsonValue Data Type
Getting Started with AL
Developing Extensions

JsonValue.AsCode Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Converts the value in a JsonValue to a Code data type.

Syntax

```
Result :=   JsonValue.AsCode()
```

Parameters

JsonValue Type: JsonValue An instance of the JsonValue data type.

Return Value

Result Type: Code

Remarks

The operation will fail with a run-time error if the JsonValue contains NULL or UNDEFINED.

See Also

JsonValue Data Type
Getting Started with AL
Developing Extensions

JsonValue.AsDate Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Converts the value in a JsonValue to a Date data type.

Syntax

```
Result :=   JsonValue.AsDate()
```

Parameters

JsonValue Type: JsonValue An instance of the JsonValue data type.

Return Value

Result Type: Date If the JsonValue does not contain a string of the format "yyyy-MM-dd" e.g. "2017-01-17" (2017-January-17), the operation will fail with a run-time error.

See Also

JsonValue Data Type
Getting Started with AL
Developing Extensions

JsonValue.AsDateTime Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Converts the value in a JsonValue to a DateTime data type.

Syntax

```
Result :=   JsonValue.AsDateTime()
```

Parameters

JsonValue Type: JsonValue An instance of the JsonValue data type.

Return Value

Result Type: DateTime

Remarks

If the JsonValue does not contain a string of the format "o" as specified here the operation will fail with a run-time error.

If there is no timezone specifier, the value will be treated as a UTC DateTime. If the timezone specifier is local, it will be treated as local to the server's timezone and converted to UTC. We recommend using UTC time to prevent unexpected behavior.

JsonValue.AsDecimal Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Converts the value in a JsonValue to a Decimal data type.

Syntax

```
Result :=   JsonValue.AsDecimal()
```

Parameters

JsonValue Type: JsonValue An instance of the JsonValue data type.

Return Value

Result Type: Decimal If the JsonValue does not contain a number or a string which can be converted without loss of precision to a Decimal, the operation will fail with a run-time error.

See Also

JsonValue Data Type

Developing Extensions

JsonValue.AsDuration Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Converts the value in a JsonValue to a Duration data type.

Syntax

```
Result :=   JsonValue.AsDuration()
```

Parameters

JsonValue Type: JsonValue An instance of the JsonValue data type.

Return Value

Result Type: Duration If the JsonValue does not contain a number or a string which can be converted without loss of precision to a BigInteger, the operation will fail with a run-time error.

See Also

JsonValue Data Type
Getting Started with AL
Developing Extensions

JsonValue.AsInteger Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Converts the value in a JsonValue to an Integer data type.

Syntax

```
Result :=   JsonValue.AsInteger()
```

Parameters

JsonValue Type: JsonValue An instance of the JsonValue data type.

Return Value

Result Type: Integer If the JsonValue does not contain a number which can be converted without loss of precision to an Integer, the operation will fail with a run-time error.

See Also

JsonValue Data Type
Getting Started with AL
Developing Extensions

JsonValue.AsOption Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Converts the value in a JsonValue to an Option data type.

Syntax

```
Result :=   JsonValue.AsOption()
```

Parameters

JsonValue Type: JsonValue An instance of the JsonValue data type.

Return Value

Result Type: Option If the JsonValue does not contain a number which can be converted without loss of precision to an Option, the operation will fail with a run-time error.

See Also

JsonValue Data Type
Getting Started with AL
Developing Extensions

JsonValue.AsText Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Converts the value in a JsonValue to a Text data type.

Syntax

```
Result :=   JsonValue.AsText()
```

Parameters

JsonValue Type: JsonValue An instance of the JsonValue data type.

Return Value

Result Type: Text

Remarks

The operation will fail with a run-time error if the JsonValue contains NULL or UNDEFINED.

See Also

JsonValue Data Type
Getting Started with AL
Developing Extensions

JsonValue.AsTime Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Converts the value in a JsonValue to a Time data type.

Syntax

```
Result :=   JsonValue.AsTime()
```

Parameters

JsonValue Type: JsonValue An instance of the JsonValue data type.

Return Value

Result Type: Time If the JsonValue does not contain a string of the format "HH:mm:ss.FFFFFFF" (see Custom Date and Time Format Strings) the operation will fail with a run-time error.

JsonValue.AsToken Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Converts the value in a JsonValue to a JsonToken data type.

Syntax

```
Token :=   JsonValue.AsToken()
```

Parameters

JsonValue Type: JsonValue An instance of the JsonValue data type.

Return Value

Token Type: JsonToken The returned JsonToken contains the same data as the JsonValue, but allows for treating the data in a generic manner.

See Also

JsonValue Data Type
Getting Started with AL
Developing Extensions

JsonValue.Clone Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Creates a deep-copy of the JsonToken value.

Syntax

```
Clone :=   JsonValue.Clone()
```

Parameters

JsonValue Type: JsonValue An instance of the JsonValue data type.

Return Value

Clone Type: JsonToken The Result will be a full, deep-copy of the Value.

See Also

JsonValue Data Type
Getting Started with AL
Developing Extensions

JsonValue.IsNull Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Indicates whether the JsonValue contains the JSON value of NULL.

Syntax

```
Ok :=   JsonValue.IsNull()
```

NOTE

This method can be invoked using property access syntax.

Parameters

JsonValue Type: JsonValue An instance of the JsonValue data type.

Return Value

Ok Type: Boolean **true** if the JsonValue contains the JSON value of NULL; otherwise, **false**

See Also

JsonValue Data Type
Getting Started with AL
Developing Extensions

JsonValue.IsUndefined Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Indicates whether the JsonValue contains the JSON value of UNDEFINED.

Syntax

```
Ok :=   JsonValue.IsUndefined()
```

NOTE

This method can be invoked using property access syntax.

Parameters

JsonValue Type: JsonValue An instance of the JsonValue data type.

Return Value

Ok Type: Boolean **true** if the JsonValue contains the JSON value of UNDEFINED; otherwise, **false**

See Also

JsonValue Data Type
Getting Started with AL
Developing Extensions

JsonValue.Path Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Retrieves the JSON path of the value relative to its containing tree.

Syntax

```
Path :=   JsonValue.Path()
```

> **NOTE**
> This method can be invoked using property access syntax.

Parameters

JsonValue Type: JsonValue An instance of the JsonValue data type.

Return Value

Path Type: String The path of the value relative to its containing JSON tree. If the object is the root of the JSON tree, the path will be empty.

See Also

JsonValue Data Type
Getting Started with AL
Developing Extensions

JsonValue.ReadFrom Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Reads the JSON data into a JsonValue variable.

Syntax

```
[Ok := ]  JsonValue.ReadFrom(Data: String)
```

Parameters

JsonValue Type: JsonValue An instance of the JsonValue data type.

Data
Type: String
The String object from which the JSON data will be read.

Return Value

Ok Type: Boolean **true** if the read was successful; otherwise, **false**. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

Remarks

This method can fail if the JSON data is malformed. If the operation succeeds, the JsonValue will be disconnected from its current JSON tree and the data contained by the JsonValue will be replaced with the new value. To delete the contents in a JsonValue variable use the Clear function.

```
Clear(JsonValue)
```

Example

This example shows how to read JSON data from a string into a JsonValue variable.

```
local procedure ReadJson(data : Text) result : JsonValue;
begin
    result.ReadFrom(data);
end;
```

See Also

JsonValue Data Type
Getting Started with AL
Developing Extensions

JsonValue.ReadFrom Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Reads the JSON data from the stream into a JsonValue variable.

Syntax

```
[Ok := ]  JsonValue.ReadFrom(Data: InStream)
```

Parameters

JsonValue Type: JsonValue An instance of the JsonValue data type.

Data
Type: InStream
The InStream object from which the JSON data will be read.

Return Value

Ok Type: Boolean **true** if the read was successful; otherwise, **false**. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

Remarks

This method can fail if the stream is in an invalid state or if the JSON data is malformed. If the operation succeeds, the JsonValue will be disconnected from its current JSON tree and the data contained by the JsonValue will be replaced with the new value. To delete the contents in a JsonValue variable use the Clear function.

```
Clear(JsonValue)
```

Example

This example shows how to read JSON data from a stream into a JsonValue variable.

```
local procedure ReadJson(source : InStream) result : JsonValue;
begin
    result.ReadFrom(source);
end;
```

JsonValue.SelectToken Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Selects a JsonToken using a JPath expression.

Syntax

```
[Ok := ]  JsonValue.SelectToken(Path: String, var Result: JsonToken)
```

Parameters

JsonValue Type: JsonValue An instance of the JsonValue data type.

Path
Type: String

Result
Type: JsonToken

Return Value

Ok Type: Boolean **true** if the operation was successful; otherwise **false**. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

JsonValue.SetValue Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Set the contents of the JsonValue variable to the JSON representation of the given value.

Syntax

```
JsonValue.SetValue(Value: Boolean)
```

Parameters

JsonValue Type: JsonValue An instance of the JsonValue data type.

Value
Type: Boolean

Remarks

- When Value is a Boolean type, it will be stored and serialized as a JSON Boolean value.
- The JsonValue will be disconnected from its current JSON tree and the data contained by the JsonValue will be replaced with the new value.

Version: *Available from runtime version 1.0.*

Set the contents of the JsonValue variable to the JSON representation of the given value.

Syntax

```
JsonValue.SetValue(Value: Char)
```

Parameters

JsonValue Type: JsonValue An instance of the JsonValue data type.

Value
Type: Char

Remarks

- When Value is a Char, Byte, Option, Integer type, the integral value will be stored and serialized as a JSON Number.
- The JsonValue will be disconnected from its current JSON tree and the data contained by the JsonValue will be replaced with the new value.

JsonValue.WriteTo Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Serializes and writes the JSON data of the JsonValue to a given object.

Syntax

```
[Ok := ]  JsonValue.WriteTo(Data: OutStream)
```

Parameters

JsonValue Type: JsonValue An instance of the JsonValue data type.

Data
Type: OutStream
The OutStream object to which the JSON data will be written.

Return Value

Ok Type: Boolean **true** if the read was successful; otherwise, **false**. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

KeyRef Data Type

2/17/2021 • 2 minutes to read • Edit Online

> **Version**: *Available from runtime version 1.0.*

Identifies a key in a table and the fields in this key.

The following methods are available on instances of the KeyRef data type.

METHOD NAME	DESCRIPTION
Active()	Indicates whether the key is enabled.
FieldCount()	Gets the number of fields that have been defined in a key. Returns an error if no key is selected.
FieldIndex(Integer)	Gets the FieldRef of the field that has this index in the key referred to by the KeyRef variable. Returns an error if no key is selected.
Record()	Returns a RecordRef for the current record referred to by the key.

KeyRef.Active Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Indicates whether the key is enabled.

Syntax

```
Ok :=   KeyRef.Active()
```

> **NOTE**
> This method can be invoked using property access syntax.

Parameters

KeyRef Type: KeyRef An instance of the KeyRef data type.

Return Value

Ok Type: Boolean **true** if the key is enabled; otherwise, **false**.

Example

The following example uses the `KeyRef.Active` method to determine whether a key in a record is enabled. The table with ID 18 (the Customer table) is open with a reference to table 18. The KeyIndex Method (RecordRef) method retrieves the first key in the record and the `varKeyRef.Active` method returns a Boolean value that indicates whether the retrieved key is enabled. The Boolean value is displayed in a message box.

```
var
    RecRef: RecordRef;
    varKeyRef: KeyRef;
    IsActive: Boolean;
begin
    RecRef.Open(18);
    varKeyRef := RecRef.KeyIndex(1);
    IsActive := varKeyRef.Active;
    Message('Is the key active =  %1 ', IsActive);
end;
```

KeyRef.FieldCount Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Gets the number of fields that have been defined in a key. Returns an error if no key is selected.

Syntax

```
No :=   KeyRef.FieldCount()
```

NOTE

This method can be invoked using property access syntax.

Parameters

KeyRef Type: KeyRef An instance of the KeyRef data type.

Return Value

No Type: Integer The number of fields that have been defined in the key.

Example

The following example retrieves the number of fields that are defined in a key in record. The table with ID 18 (the Customer table) is open with a reference to table 18. The KeyIndex Method (RecordRef) method retrieves the second key in the record and store the *KeyRef* in the varKeyRef variable. The FieldCount Method (KeyREF) is then used to return the number of fields defined in the key and displayed in a message box.

```
var
    RecRef: RecordRef;
    varKeyRef: KeyRef;
    VarCount: Integer;
begin
    RecRef.Open(18);
    varKeyRef := RecRef.KeyIndex(2);
    VarCount := varKeyRef.FieldCount;
    Message('The number of fields defined in the key is: %1', VarCount);
end;
```

KeyRef.FieldIndex Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Gets the FieldRef of the field that has this index in the key referred to by the KeyRef variable. Returns an error if no key is selected.

Syntax

```
Field :=   KeyRef.FieldIndex(Index: Integer)
```

Parameters

KeyRef Type: KeyRef An instance of the KeyRef data type.

Index
Type: Integer
The input index.

Return Value

Field Type: FieldRef The FieldRef that refers to the field with this index in the key.

Remarks

The first field in the index must have index 1, the second index 2, and so on. The last field must have index = FieldCount. If the index is out of the range supplied or if no table is selected, the method returns an error.

Example

The following example displays the caption of a field in a record. The table with ID 18 (the Customer table) is open with a reference. The *Keyref* for the record is retrieved by using the KeyIndex Method (RecordRef). The method retrieves the second key in the record and stores the value in the varKeyRef variable. The varKeyRef variable is then used to return the *FieldRef*. The varFieldRef variable is used to display the caption of the field.

```
var
    RecRef: RecordRef;
    varKeyRef: KeyRef;
    varFieldRef: FieldRef;
begin
    RecRef.Open(18);
    varKeyRef := RecRef.KeyIndex(2);
    varFieldRef := varKeyRef.FieldIndex(1);
    Message('The Field name is: %1' ,varFieldRef.Caption);
end;
```

KeyRef Data Type

KeyRef.Record Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Returns a RecordRef for the current record referred to by the key.

Syntax

```
Record :=   KeyRef.Record()
```

Parameters

KeyRef Type: KeyRef An instance of the KeyRef data type.

Return Value

Record Type: RecordRef The RecordRef of the record that is currently selected referenced by the key. If a key is not selected, an error is returned.

The table with ID 18 (the Customer table) is open with a reference. The KeyRef Data Type for the record is retrieved by using the KeyIndex Method (RecordRef). The method retrieves the key that has an index of 1 in the record and stores the value in the varKeyRef variable. The varKeyRef variable is then used to return the RecordRef Data Type.

```
var
    RecRef: RecordRef;
    varKeyRef: KeyRef;
begin
    RecRef.Open(18);
    varKeyRef := RecRef.KeyIndex(1);
    RecRef := varKeyRef.Record;
end;
```

Label Data Type

2/17/2021 • 2 minutes to read • Edit Online

> **Version**: *Available from runtime version 1.0.*

Denotes a string constant that can be optionally translated into multiple languages.

Parameters

All of the parameters below are optional and the order is not enforced.

ATTRIBUTE	DESCRIPTION
Comment	It is used for general comments about the label, specifically about the placeholders in that label.
Locked	When Locked is set to **true**, the label should not be translated. Default value is **false**.
MaxLength	It determines how much of the label is used. ` If no maximum length is specified, the string can be any length.

Syntax example

```
var
a:Label'LabelText',Comment='Foo',MaxLength=999,Locked=true;
```

Remarks

The `Label` data type is used in .xlf files for translations. For more information, see Working with Translation Files.

For information about naming, see CodeCop Rule AA0074.

List Data Type

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Represents a strongly typed list of ordered objects that can be accessed by index. Contrary to the Array data type, a List is unbounded, such that its dimension does not need to be specified upon declaration.

The following methods are available on instances of the List data type.

METHOD NAME	DESCRIPTION
Add(T)	Adds a value to the end of the List.
AddRange(T [, T,...])	Adds the elements of the specified collection to the end of the list.
AddRange(List of [T])	Adds the elements of the specified collection to the end of the list.
Contains(T)	Determines whether an element is in the List.
Count()	Gets the number of elements contained in the List.
Get(Integer, var T)	Gets the element at the specified index.
Get(Integer)	Gets the element at the specified index. This method will raise an error if the index is outside the valid range.
GetRange(Integer, Integer)	Get a shallow copy of a range of elements in the source.
GetRange(Integer, Integer, var List of [T])	Get a shallow copy of a range of elements in the source.
IndexOf(T)	Searches for the specified value and returns the one-based index of the first occurrence within the entire List.
Insert(Integer, T)	Inserts an element into the List at the specified index.
LastIndexOf(T)	Searches for the specified value and returns the one-based index of the last occurrence within the entire List.
Remove(T)	Removes the first occurrence of a specified value from the List.
RemoveAt(Integer)	Removes the element at the specified index of the List.
RemoveRange(Integer, Integer)	Removes a range of elements from the List.
Reverse()	Reverses the order of the elements in the entire List.

METHOD NAME	DESCRIPTION
Set(Integer, T)	Sets the element at the specified index.
Set(Integer, T, var T)	Sets the element at the specified index.

Remarks

The List can only be used with simple types i.e. you can have a List of [Integer] but cannot have a List of [Blob]. Similarly, the List data type does not support holding instantiated records. For this purpose, use temporary tables.

Lists are 1-based indexed, that is, the indexing of a List begins with 1.

WARNING

Previously in C/AL, one would have typically used an in-memory temporary table to create an unbounded "array" data structure, as shown in the code below. In AL you use the List Data Type instead.

```
listRec.Value := ‘Some Value’;
listRec.Insert();
```

Example

In the following example, the variable `CustomerNames` is a list of Text values which represent customer names. The procedure `WorkWithListOfCustomers` displays how one would work with the List data type. The `Add` method is used to add the string `'John'` to the `CustomerNames` list. The `Contains` method is used to check whether the list contains the specified value, in this case, the string `'John'`. We continue by using the Message procedure to display a relevant message.

```
procedure WorkWithListOfCustomers();
var
    customerNames : List of [Text];
begin
    // Adding an element to the list
    customerNames.Add('John');

    // Checking if the list contains an element
    if customerNames.Contains('John') then
        Message('John is in the list')
    else
        Message('John is not in the list')
end;
```

List.Add Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Adds a value to the end of the List.

Syntax

```
List.Add(Value: T)
```

Parameters

List Type: List An instance of the List data type.

Value
Type: T
The value to be added to the end of the List.

List.AddRange Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Adds the elements of the specified collection to the end of the list.

Syntax

```
List.AddRange(Value: T [, Values: T,...])
```

Parameters

List Type: List An instance of the List data type.

Value
Type: T
The value to be added to the end of the List.

Values
Type: T
The collection whose elements should be added to the end of the List.

List.AddRange Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Adds the elements of the specified collection to the end of the list.

Syntax

```
List.AddRange(Values: List of [T])
```

Parameters

List Type: List An instance of the List data type.

Values

Type: List of [T]

The collection whose elements should be added to the end of the List.

List.Contains Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Determines whether an element is in the List.

Syntax

```
Result :=   List.Contains(Value: T)
```

Parameters

List Type: List An instance of the List data type.

Value
Type: T
The value to locate in the List.

Return Value

Result Type: Boolean **true** if the List contains the value, otherwise **false**.

List.Count Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Gets the number of elements contained in the List.

Syntax

```
Count :=   List.Count()
```

NOTE

This method can be invoked using property access syntax.

Parameters

List Type: List An instance of the List data type.

Return Value

Count Type: Integer The number of elements contained in the List.

List.Get Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Gets the element at the specified index.

Syntax

```
[Ok := ]  List.Get(Index: Integer, var Result: T)
```

Parameters

List Type: List An instance of the List data type.

Index
Type: Integer
The one-based index of the element to get.
Result
Type: T
The element at the specified index.

Return Value

Ok Type: Boolean **true** if an element exists at the given index, otherwise **false**. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

List.Get Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Gets the element at the specified index. This method will raise an error if the index is outside the valid range.

Syntax

```
Result :=   List.Get(Index: Integer)
```

Parameters

List Type: List An instance of the List data type.

Index

Type: Integer

The one-based index of the element to get.

Return Value

Result Type: T The element at the specified index.

List.GetRange Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Get a shallow copy of a range of elements in the source.

Syntax

```
Result :=   List.GetRange(Index: Integer, Count: Integer)
```

Parameters

List Type: List An instance of the List data type.

Index

Type: Integer

The one-based List index at which the range starts.

Count

Type: Integer

The number of elements in the range.

Return Value

Result Type: List of [T] A shallow copy of a range of elements in the source List.

See Also

List.GetRange Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Get a shallow copy of a range of elements in the source.

Syntax

```
[Ok := ]  List.GetRange(Index: Integer, Count: Integer, var Result: List of [T])
```

Parameters

List Type: List An instance of the List data type.

Index
Type: Integer
The one-based List index at which the range starts.

Count
Type: Integer
The number of elements in the range.

Result
Type: List of [T]
A shallow copy of a range of elements in the source List.

Return Value

Ok Type: Boolean **true** if the range is a valid range, otherwise **false**. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

List.IndexOf Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Searches for the specified value and returns the one-based index of the first occurrence within the entire List.

Syntax

```
Index :=   List.IndexOf(Value: T)
```

Parameters

List Type: List An instance of the List data type.

Value
Type: T
The value to locate in the List.

Return Value

Index Type: Integer The one-based index at which the value is found or 0 if the value does not exist in the List.

See Also

List.Insert Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Inserts an element into the List at the specified index.

Syntax

```
[Ok := ]  List.Insert(Index: Integer, Value: T)
```

Parameters

List Type: List An instance of the List data type.

Index
Type: Integer
The one-based index at which the value should be inserted.

Value
Type: T
The value to be inserted.

Return Value

Ok Type: Boolean **true** if the index was within the valid range, otherwise **false**. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

List.LastIndexOf Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Searches for the specified value and returns the one-based index of the last occurrence within the entire List.

Syntax

```
Index :=   List.LastIndexOf(Value: T)
```

Parameters

List Type: List An instance of the List data type.

Value
Type: T
The value to locate in the List.

Return Value

Index Type: Integer The one-based index at which the value is found or 0 if the value does not exist in the List.

List.Remove Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Removes the first occurrence of a specified value from the List.

Syntax

```
[Removed := ]  List.Remove(Value: T)
```

Parameters

List Type: List An instance of the List data type.

Value
Type: T
The value to remove from the List.

Return Value

Removed Type: Boolean **true** if item is successfully removed; otherwise, **false**. This method also returns **false** if item was not found in the List.

See Also

List.RemoveRange Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Removes a range of elements from the List.

Syntax

```
[Ok := ]  List.RemoveRange(Index: Integer, Count: Integer)
```

Parameters

List Type: List An instance of the List data type.

Index
Type: Integer
The one-based starting index of the range of elements to remove.

Count
Type: Integer
The number of elements to remove.

Return Value

Ok Type: Boolean **true** if the range is a valid range, otherwise **false**. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

List.Set Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Sets the element at the specified index.

Syntax

```
[Ok := ]  List.Set(Index: Integer, NewValue: T)
```

Parameters

List Type: List An instance of the List data type.

Index

Type: Integer

The one-based index of the element to set.

NewValue

Type: T

The new value associated with the specified index.

Return Value

Ok Type: Boolean **true** if the index was within the valid range, **false** otherwise. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

List.Set Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Sets the element at the specified index.

Syntax

```
[Ok := ]  List.Set(Index: Integer, NewValue: T, var OldValue: T)
```

Parameters

List Type: List An instance of the List data type.

Index
Type: Integer
The one-based index of the element to set.
NewValue
Type: T
The new value associated with the specified index.
OldValue
Type: T
The value previously associated with the specified index.

Return Value

Ok Type: Boolean **true** if the index was within the valid range, otherwise **false**. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

Media Data Type

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Encapsulates media files, such as image .jpg and .png files, in application database tables. The Media data type can be used as a table field data type, but cannot be used as a variable or parameter. The Media data type enables you to import a media file to the application database and reference the file from records, making it possible to display the media file in the client user interface. You can also export media from the database to files and streams.

The following methods are available on instances of the Media data type.

METHOD NAME	DESCRIPTION
ExportFile(String)	Exports the media object (such as an image) that is currently used on record to a file on your computer or network. On the record, the media object is referenced in a Media data type field.
ExportStream(OutStream)	Exports the current media object (such as a JPEG image) that is used on record to an OUTSTREAM object. The OUTSTREAM object can be created from a BLOB field, a File or from a .NET Framework interoperability object. In the record, the media is referenced in a Media data type field.
HasValue()	Checks whether a Media data type field in a record has been initialized with a media object and that the specified media object exists in the database.
ImportFile(Text, Text [, Text])	Adds a media type, such as a JPEG image, from a file to a Media data type field of a record for displaying the media with the record in the client. The media file is imported to the application database, and a reference to the media is included in the Media data type field.
ImportStream(InStream, Text [, Text])	Adds a media type (MIME), such as jpeg image, from an InStream object to a Media data type field of a record for displaying the media in the client. The media file is imported to the application database and a reference to the media is included in the Media data type field.
ImportStream(InStream, Text, Text, Text)	Adds a media type (MIME), such as jpeg image, from an InStream object to a Media data type field of a record for displaying the media in the client. The media file is imported to the application database and a reference to the media is included in the Media data type field.
MediaId()	Gets the unique identifier of a media object on a record.

Getting Started with AL

Media.ExportFile Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Exports the media object (such as an image) that is currently used on record to a file on your computer or network. On the record, the media object is referenced in a Media data type field.

> **NOTE**
> This method is supported only in Business Central on-premises.

Syntax

```
[Result := ]  Media.ExportFile(Filename: String)
```

Parameters

Media Type: Media An instance of the Media data type.

Filename
Type: String
Specifies the full path and name of the file to create for the exported media.

Return Value

Result Type: Boolean **true** if the media was successfully exported, otherwise **false**. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

Remarks

The exported media file will be of the same media type, such as JPEG (.jpg) or GIF (.gif), as it was when imported. For more information about the media types, see Supported Media Types.

If a file with the same name as the exported file already exists in the target folder and the current session has write access on the file, the existing file will be automatically replaced by the new file. If the export fails, the existing file will be erased.

Example

This example uses the ExportFile method to export media objects that are used on records in a sample table that is named **My Items**. Each media object is exported to a separate file in a folder on your computer.

The example assumes that the **My Items** table already exists. Also, the table contains a **Media** data type field that is named **Image**, and one or more records already include media. For information about importing media, see ImportFile Method (Media) or ImportStream Method (Media).

The code iterates over records in the **My Items** table. If a media object is referenced in the *Image* field, the media is exported to a file in the *C:\images* folder. The file is given a name in the format *ItemNN.jpg*, where *NN*

is the number assigned to item record in the table, as specified by the **No.** field.

```
 var
    myItemRec: Record "My Items";
    fileName: Text;
    count: Integer;
    Text000: Label '%1 media files were exported';
begin
    if myItemRec.FindFirst() then begin
        repeat begin
            fileName := 'C:\images\' + 'Item' + Format(myItemRec."No.") + '.jpg';
            if myItemRec.Image.ExportFile(fileName) then
                count := count + 1
        end until myItemRec.Next < 1;
        Message(Text000, count);
    end;
end;
```

Media.ExportStream Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Exports the current media object (such as a JPEG image) that is used on record to an OUTSTREAM object. The OUTSTREAM object can be created from a BLOB field, a File or from a .NET Framework interoperability object. In the record, the media is referenced in a Media data type field.

Syntax

```
[Result := ]  Media.ExportStream(Stream: OutStream)
```

Parameters

Media Type: Media An instance of the Media data type.

Stream

Type: OutStream

The OutStream object that is created by the object that will receive the media content.

Return Value

Result Type: Boolean **true** if the media was successfully exported, otherwise **false**. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

Example

This example uses the ExportStream to iterate over a sample table named **My Items** table and export any media that is used on records to an OutStream that is created on a file object.

This example assumes that the **My Item** table contains a **Media** data type field that is named **Image**, and that you have already imported some media on records. For information about importing media, see ImportFile Method (Media) or ImportStream Method (Media).

```
 var
    myItemRec: Record "My Items";
    fileName: Text;
    count: Integer;
    exportFile: File;
    dataOutStream: OutStream;
    Text000: Label '%1 media files were exported';
begin
    if myItemRec.FindFirst() then begin
        repeat begin
            if myItemRec.Image.HasValue then begin
              fileName := 'C:\images\export\' + 'ItemPictureFromStream' + Format(myItemRec."No.") + '.jpg';
              exportFile.Create(fileName);
              exportFile.CreateOutstream(dataOutStream);
              myItemRec.Image.ExportStream(dataOutStream);
              count := count + 1;
              exportFile.Close;
            end;
        end until myItemRec.Next < 1;
        Message(Text000, count);
    end;
end;
```

Media.HasValue Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Checks whether a Media data type field in a record has been initialized with a media object and that the specified media object exists in the database.

Syntax

```
HasValue :=   Media.HasValue()
```

NOTE

This method can be invoked using property access syntax.

Parameters

Media Type: Media An instance of the Media data type.

Return Value

HasValue Type: Boolean **true** if the Media data type field in a record has been initialized with a media object and the specified media object exists in the database, otherwise **false**.

Example

This example uses the HasValue method to iterate over the **My Items** table to determine whether media objects are available on records in the table.

The example assumes that **My Items** table exists and contains a **Media** data type field that is named **Image**. For information about importing media, see ImportFile Method (Media).

The code returns a message if a record does not include a media object.

```
 var
    myItemRec: Record "My Items";
begin
    if myItemRec.FindFirst() then begin
        repeat begin
            if not myItemRec.Image.HasValue then
                Error('Item %1 does not have a valid image', myItemRec."No.");
        end until myItemRec.Next < 1;
    end;
end;
```

Media Data Type

Media.ImportFile Method

2/17/2021 • 4 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Adds a media type, such as a JPEG image, from a file to a Media data type field of a record for displaying the media with the record in the client. The media file is imported to the application database, and a reference to the media is included in the Media data type field.

> **NOTE**
> This method is supported only in Business Central on-premises.

Syntax

```
[ID := ]  Media.ImportFile(Filename: Text, Description: Text [, MimeType: Text])
```

Parameters

Media Type: Media An instance of the Media data type.

Filename
Type: Text
Specifies the full path and name of the media file to be added.

Description
Type: Text
Specifies text that can be used in the client to describe the media.

MimeType
Type: Text
Specifies the media content type. MIME type is used by browsers, and is an Internet standard to describe the contents of a file. The MimeType value must be a two-part string that consists of a type and subtype, such as image/jpeg or image/gif. If this parameter is not specified, the function will deduct the MIME type from the file extension. For example the MIME type for a .jpg file is image/jpeg.

Return Value

ID Type: Guid The unique ID that is assigned to the media object in the database. You can also get the ID by using the MediaId method. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

Remarks

You use this method to upload a media, which you want to associate with a record, to the database. For example, you can upload an JPEG image for a record in a table. When a media file is imported, it is assigned a unique identifier (GUID) and stored in the system table **2000000183 Tenant Media** of the application database. The GUID is then included in the **Media** data type field as a reference to the media file.

If you import a media file into a record that already has a media object, and a modify operation is performed, the original media object will be permanently deleted from the database. However, if there are other rows in the same table that reference the original media object from the same field index, the original media object is not deleted from the database. This behavior allows a row to be copied.

Example

This example uses the ImportFile method to import a JPEG image from file to a record in a database table. After the image is imported, it can be displayed on a list page that uses the table, when the page is opened and viewed in a brick layout.

Preparation:

To support the example code that follows, create the following objects:

- A table that is named **My Items** and has the following characteristics (as a minimum):
  - An **Integer** data type field that has the name **No.**.

    This field is used to give an item a number.
  - A **Media** data type field that has the name **Image**.

    This is the field on which you will import the media file.
  - A field group that has the name **Brick** and includes the **No.** and **Image** fields.

    The field group is used to display the image on a page in the brick layout. For more information, see Define fields for a drop-down control.
- A page that is named **My Items** and has the following characteristics:
  - List type page that uses the **My Items** table as its source.
  - A repeater control that contains the fields of the **My Items** table.

    > **NOTE**
    > It is not necessary to include the **Media** data type field on the page.

  Use the page to add one or more items to the table, assigning each item a number like 1,2,3, and so on.
- JPEG image files for one or more items in the **My Items** table.
  - Give each file a name that corresponds to an item number in the table, such as 1.jpg, 2.jpg, 3.jpg, and so on.
  - Save the files in the *C:\images* folder on the computer that is running Dynamics 365 Business Central service.

Code:

With the objects in place, you can add and run the following AL code to import the images. For this code example, create a codeunit and add the code to the **OnRun** trigger of the codeunit.

The example code iterates over records in the **My Items** table. For each record, it looks in the *C:\images* folder for a file whose name matches the **No.** field of the record. If there is a match, the file is imported and a message appears; otherwise, nothing happens.

```
 var
    myItemRec: Record "My Items";
    fileName: Text;
    imageID: GUID;
    Text000: Label 'An image with the following ID has been imported on item %1: %2';
begin
    if myItemRec.FindFirst() then begin
        repeat begin
            fileName := 'C:\images\' + Format(myItemRec."No.") + '.jpg';
            if File.Exists(fileName) then begin
              imageID := myItemRec.Image.ImportFile(fileName, 'Demo image for item ' +
Format(myItemRec."No."));
              myItemRec.Modify;
              Message(Text000, myItemRec."No.", imageID)
            end;
        end until myItemRec.Next < 1;
    end;
end;
```

Media.ImportStream Method

2/17/2021 • 3 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Adds a media type (MIME), such as jpeg image, from an InStream object to a Media data type field of a record for displaying the media in the client. The media file is imported to the application database and a reference to the media is included in the Media data type field.

Syntax

```
[ID := ]  Media.ImportStream(Stream: InStream, Description: Text [, MimeType: Text])
```

Parameters

Media Type: Media An instance of the Media data type.

Stream
Type: InStream
The InStream object that contains the media that you want to use on the record.

Description
Type: Text
Specifies text that can be used in the client to describe the media file.

MimeType
Type: Text
Specifies the media content type. MIME type is used by browsers, and is an Internet standard to describe the contents of a file. The MimeType value must be a two-part string that consists of a type and subtype, such as image/jpeg or image/gif. If this parameter is not specified, the function will deduct the MIME type from the file extension. For example the MIME type for a .jpg file is image/jpeg.

Return Value

ID Type: Guid The unique ID that is assigned to the media object in the database. You can also get the ID by using the MediaId method. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

Remarks

You can use this method to import media into the database, and associate the media with a record. For example, you can upload an image of all items in table **27 Item**. When media is imported, the object is stored in the system table **2000000184 Tenant Media** of the application database.

If you import media on a record that already has a media object, and a modify operation is performed, the original media object will be permanently deleted from the database. However, if there are other rows in the same table that reference the original media object from the same field index, the original media object is not deleted from the database. This behavior allows a row to be copied.

Example

Preparation:
To support the example code that follows, create the following objects:

- A table that is named **My Items** and has the following characteristics (as a minimum):
  - An **Integer** data type field that has the name **No.**.

    This field is used to give an item a number.
  - A **Media** data type field that has the name **Image**.

    This is the field on which you will import the media file.
  - A field group that has the name **Brick** and includes the **No.** and **Image** fields.

    The field group is used to display the image on a page in the brick layout. For more information, see Define fields for a drop-down control.
- A page that is named **My Items** and has the following characteristics:
  - List type page that uses the **My Items** table as its source.
  - A repeater control that contains the fields of the **My Items** table.

    > **NOTE**
    > It is not necessary to include the **Media** data type field on the page.

  Use the page to add one or more items to the table, assigning each item a number like 1,2,3, and so on.
- JPEG image files for one or more items in the **My Items** table.
  - Give each file a name that corresponds to an item number in the table, such as 1.jpg, 2.jpg, 3.jpg, and so on.
  - Save the files in the *C:\images* folder on the computer that is running Dynamics 365 Business Central service.

Code
With the objects in place, you can add and run the following AL code to import the images. For this code example, create a codeunit and add the code to the **OnRun** trigger of the codeunit.

This code iterates over records in the **My Items** table. For each record, it looks in the *C:\images* folder for a file whose name matches the **No.** field of the record. If there is a match the file, an InStream object is created for the file, the media is imported into the record, and a confirmation message is returned.

```
 var
    myItemRec: Record "My Items";
    fileName: Text;
    importFile: File;
    imageInStream: InStream;
    imageID: GUID;
    Text000: Label 'An image with the following ID has been imported on item %1: %2';
begin
    if  myItemRec.FindFirst() then begin
        repeat begin
            fileName := 'C:\images\' + Format(myItemRec."No.") + '.jpg';

            if File.Exists(fileName) then begin
                importFile.Open(fileName);
                importFile.CreateInstream(imageInstream);
                imageID := myItemRec.Image.ImportStream(imageInstream, 'Demo image for item ' + Format(
myItemRec."No."));
                myItemRec.Modify;
                Message(Text000, myItemRec."No.", imageID);
                importFile.Close;
            end;
        end until myItemRec.Next < 1;
    end;
end;
```

Media.ImportStream Method

2/17/2021 • 3 minutes to read • Edit Online

Version: *Available from runtime version 3.0.*

Adds a media type (MIME), such as jpeg image, from an InStream object to a Media data type field of a record for displaying the media in the client. The media file is imported to the application database and a reference to the media is included in the Media data type field.

NOTE

This method is supported only in Business Central on-premises.

Syntax

```
[ID := ]  Media.ImportStream(Stream: InStream, Description: Text, MimeType: Text, FileName: Text)
```

Parameters

Media Type: Media An instance of the Media data type.

Stream

Type: InStream

The InStream object that contains the media that you want to use on the record.

Description

Type: Text

Specifies text that can be used in the client to describe the media file.

MimeType

Type: Text

Specifies the media content type. MIME type is used by browsers, and is an Internet standard to describe the contents of a file. The MimeType value must be a two-part string that consists of a type and subtype, such as image/jpeg or image/gif. If this parameter is not specified, the function will deduct the MIME type from the file extension. For example the MIME type for a .jpg file is image/jpeg.

FileName

Type: Text

Specifies the file name to associate with the Media object.

Return Value

ID Type: Guid The unique ID that is assigned to the media object in the database. You can also get the ID by using the MediaId method. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

Remarks

You can use this method to import media into the database, and associate the media with a record. For example,

you can upload an image of all items in table **27 Item**. When media is imported, the object is stored in the system table **2000000184 Tenant Media** of the application database.

If you import media on a record that already has a media object, and a modify operation is performed, the original media object will be permanently deleted from the database. However, if there are other rows in the same table that reference the original media object from the same field index, the original media object is not deleted from the database. This behavior allows a row to be copied.

Example

Preparation:
To support the example code that follows, create the following objects:

- A table that is named **My Items** and has the following characteristics (as a minimum):
  - An **Integer** data type field that has the name **No.**.

    This field is used to give an item a number.
  - A **Media** data type field that has the name **Image**.

    This is the field on which you will import the media file.
  - A field group that has the name **Brick** and includes the **No.** and **Image** fields.

    The field group is used to display the image on a page in the brick layout. For more information, see Define fields for a drop-down control.
- A page that is named **My Items** and has the following characteristics:
  - List type page that uses the **My Items** table as its source.
  - A repeater control that contains the fields of the **My Items** table.

    > **NOTE**
    > It is not necessary to include the **Media** data type field on the page.

  Use the page to add one or more items to the table, assigning each item a number like 1,2,3, and so on.
- JPEG image files for one or more items in the **My Items** table.
  - Give each file a name that corresponds to an item number in the table, such as 1.jpg, 2.jpg, 3.jpg, and so on.
  - Save the files in the *C:\images* folder on the computer that is running Dynamics 365 Business Central service.

Code
With the objects in place, you can add and run the following AL code to import the images. For this code example, create a codeunit and add the code to the **OnRun** trigger of the codeunit.

This code iterates over records in the **My Items** table. For each record, it looks in the *C:\images* folder for a file whose name matches the **No.** field of the record. If there is a match the file, an InStream object is created for the file, the media is imported into the record, and a confirmation message is returned.

```
 var
    myItemRec: Record "My Items";
    fileName: Text;
    importFile: File;
    imageInStream: InStream;
    imageID: GUID;
    Text000: Label 'An image with the following ID has been imported on item %1: %2';
begin
    if  myItemRec.FindFirst() then begin
        repeat begin
            fileName := 'C:\images\' + Format(myItemRec."No.") + '.jpg';

            if File.Exists(fileName) then begin
                importFile.Open(fileName);
                importFile.CreateInstream(imageInstream);
                imageID := myItemRec.Image.ImportStream(imageInstream, 'Demo image for item ' + Format(
myItemRec."No."));
                myItemRec.Modify;
                Message(Text000, myItemRec."No.", imageID);
                importFile.Close;
            end;
        end until myItemRec.Next < 1;
    end;
end;
```

Media.MediaId Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Gets the unique identifier of a media object on a record.

Syntax

```
MediaId :=   Media.MediaId()
```

> **NOTE**
> This method can be invoked using property access syntax.

Parameters

Media Type: Media An instance of the Media data type.

Return Value

MediaId Type: Guid The GUID of the Media object in the database.

Remarks

When a media is imported on the Media data type field of table record, the media is given a GUID and stored in the system table **2000000184 Tenant Media** of the application database. The GUID is then included in the **Media** data type field as a reference to the media in the database.

Example

This example uses the MediaId method to get the GUID of the media object that is used on item number **1** in the a the table named **My Items**.

The example assumes that the **My Items** table already exists and has a **Media** data type field named **Image**.

```
 var
    myItemRec: Record "My Items";
    imageID: GUID;
    Text000: Label 'Item %1 has a media object with the following ID: %2';
begin
    myItemRec.Get('1');
    mediaGuid := myItemRec.Image.MediaId;
    Message(Text000, myItemRec."No.", imageID);
end;
```

Media Data Type

MediaSet Data Type

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Encapsulates media, such as images, in application database tables.

The following methods are available on instances of the MediaSet data type.

METHOD NAME	DESCRIPTION
Count()	Gets the number of media objects that are included in the MediaSet of a record.
ExportFile(String)	Exports the media objects in the current media set of a record to individual files on your computer or network. In the record, the media set is referenced in a MediaSet data type field.
ImportFile(String, String [, String])	Adds a media, such as a JPEG image, to the MediaSet data type field of a record for displaying the media in the client. The media is imported to the database and included in a MediaSet for the record.
ImportStream(InStream, String [, String])	Adds a media file, such as a JPEG image, from an InStream object to the MediaSet of record for displaying in the client. The media is imported to the database and included in a MediaSet for the record.
Insert(Guid)	Adds a media object that already exists in the database to a MediaSet of a record.
Item(Integer)	Gets the unique identifier (GUID) of a media object that is assigned to a MediaSet on a record.
MediaId()	Gets the unique identifier that is assigned to a MediaSet of a record. The MediaSet is a collection of media objects that are used on the record that can be displayed in the client.
Remove(Guid)	Removes a media object from a MediaSet of a record.

Working With Media on Records

MediaSet.Count Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Gets the number of media objects that are included in the MediaSet of a record.

Syntax

```
Count :=   MediaSet.Count()
```

> **NOTE**
> This method can be invoked using property access syntax.

Parameters

MediaSet Type: MediaSet An instance of the MediaSet data type.

Return Value

Count Type: Integer The number of media objects that are included in the MediaSet of a record.

Example

This example counts the number of media objects that are available for item No. 1000 in table **27 Item** of the CRONUS demonstration database. In this example, the field in the **Item** table that is used for the MediaSet data type is **Picture**.

```
 var
    itemRec: Record Item;
    count: Integer;
    Text000: Label 'The number of media files: %1';
begin
    itemRec.Get('1000');
        count := (itemRec.Picture.Count);
        Message(Text000,count);
end;
```

MediaSet Data Type
Getting Started with AL
Developing Extensions

MediaSet.ExportFile Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Exports the media objects in the current media set of a record to individual files on your computer or network. In the record, the media set is referenced in a MediaSet data type field.

> **NOTE**
> This method is supported only in Business Central on-premises.

Syntax

```
[Count := ]  MediaSet.ExportFile(FilenamePrefix: String)
```

Parameters

MediaSet Type: MediaSet An instance of the MediaSet data type.

FilenamePrefix
Type: String
Specifies the location and name of the exported media files. Each exported media file is given a name that consists of a prefix that you specify, plus an index number that is automatically assigned. The file name has the format prefix-index.type, for example, Image-1.jpg, Image-2.jpg, and Image-3.jpg. To set the parameter value, use the format: path\prefix.type.

- path is the folder path where you want to store the files.
- prefix is the text that you want before the index number.
- type is the media type extension.

Return Value

Count Type: Integer The number of exported elements. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

Remarks

The exported media files will be of the same media file type as when they were imported. For more information about the media types, see Supported Media Types.

The method has the following behavior:

- If a file that has the same name as the exported file already is located in the target folder and the current session has write access on the file, the existing file will be automatically replaced by the new file.
- If the export fails, the existing file will be erased.
- If a media in the media set cannot be found in the database, no file will be generated for this object.

Example

This example first imports two media files (JPEG image files) from a local folder to the media set of a record in the table **27 Item** of the CRONUS demonstration database. Then, using the EXPORTFile method, the media objects are exported to files again in another local folder.

For using media sets on records, the **Item** table includes a **MediaSet** data type field that is named **Picture**.

The code imports the JPEG image files (.jpg) from the folder *C:\images* to record *1000* in the **Item** table, and then exports the media files to the folder *C:\images\export*.

```
var
    itemRec: Record Item;
    count: Boolean;
    Text000: Label '%1 media files were exported.';
begin
    // Import image files the C:\images folder.
    itemRec.Get('1000');
    itemRec.Picture.ImportFile('C:\images\1000-v1.jpg', 'Demo image for item ' + Format(itemRec."No."));
    itemRec.Picture.ImportFile('C:\images\1000-v2.jpg', 'Demo image for item ' + Format(itemRec."No."));
    itemRec.Modify;
    Commit;

    // Export the MediaSet to two separate image files in the c:\images\export folder.
    itemRec.Get('1000');
    count := itemRec.Picture.ExportFile('C:\images\export\' + 'Item1000Image.jpg');
    Message('%1 files exported.', count);
end;
```

MediaSet.ImportFile Method

2/17/2021 • 3 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Adds a media, such as a JPEG image, to the MediaSet data type field of a record for displaying the media in the client. The media is imported to the database and included in a MediaSet for the record.

> **NOTE**
> This method is supported only in Business Central on-premises.

Syntax

```
[ID := ]  MediaSet.ImportFile(Filename: String, Description: String [, MimeType: String])
```

Parameters

MediaSet Type: MediaSet An instance of the MediaSet data type.

Filename
Type: String
Specifies the full path and name of the media file to be imported.

Description
Type: String
Specifies text that can be used in the client to describe the media.

MimeType
Type: String
Specifies the media content type. MIME type is used by browsers, and is an Internet standard to describe the contents of a file. The MimeType value must be a two-part string that consists of a type and subtype, such as image/jpeg or image/gif. If this parameter is not specified, the function will deduct the MIME type from the file extension. For example the MIME type for a .jpg file is image/jpeg.

Return Value

ID Type: Guid The unique ID that is assigned to the MediaSet of the record. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

Remarks

You use this method to upload a media file as part of a collection of media objects that you want to associate with a record. The method is similar to the ImportFile Method (Media) except that this method enables you to import multiple media files for the same record. For example, you can add multiple images for an item in table **27 Item**.

When a media file is imported, a media object is created and stored in the system table **2000000181 Tenant Media** of the application database. The media object is assigned a unique identifier (GUID).

In addition, the media object is assigned to a MediaSet which also has a specific GUID. This GUID is included in the MediaSet data type field as a reference to the media objects. The MediaSet and its GUID are created with the first media that is imported, and the information is stored in table **2000000183 Tenant Media Set**. All additional media objects for the record are then associated with the same MediaSet GUID.

Example

This example uses the IMPORTFile method to add images to records in table **27 Item** of the CRONUS demonstration database.

In support of the example code, you alsmust complete these tasks:

- Create two sample image files that you want to use on item no. 1000 in table **27 Item**.

  Save the images as JPEG type, and give them the names 1000-v1.jpg and 1000-v2.jpg. Save the files in the *C:\images* folder on the computer that is running Dynamics 365 Business Central service instance.

- Verify that table **27 Item** has a field that is called **Picture** and has the data type **MediaSet**.

  This is field on which you will add the images. If the field is not present, then add it.

With these tasks in place, you can add the following AL code for importing the images. For this code example, create a codeunit, and add the code to the **OnRun** trigger.

```
 var
    itemRec: Record Item;
    count: Integer;
    mediasetId: GUID;
    Text000: Label 'The files have been imported. Item %1 has %2 pictures in MediaSet: %3';
begin
    itemRec.Get('1000');
    itemRec.Picture.ImportFile('C:\images\1000-v1.jpg', 'Demo image for item ' + Format(itemRec."No."));
    itemRec.Picture.ImportFile('C:\images\1000-v2.jpg', 'Demo image for item ' + Format(itemRec."No."));
    count := (itemRec.Picture.Count);
    mediasetId := itemRec.Picture.MediaId;
    Message(Text000,itemRec."No.", count, mediasetId);
end;
```

If you run system table **2000000181 Tenant Media**, you should see the new images in the list.

MediaSet.ImportStream Method

2/17/2021 • 3 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Adds a media file, such as a JPEG image, from an InStream object to the MediaSet of record for displaying in the client. The media is imported to the database and included in a MediaSet for the record.

Syntax

```
[ID := ]  MediaSet.ImportStream(Stream: InStream, Description: String [, MimeType: String])
```

Parameters

MediaSet Type: MediaSet An instance of the MediaSet data type.

Stream
Type: InStream
Specifies the InStream object that contains the media that you want to use on the record.

Description
Type: String
Specifies text that can be used in the client to describe the media files.

MimeType
Type: String
Specifies the media content type. MIME type is used by browsers, and is an Internet standard to describe the contents of a file. The MimeType value must be a two-part string that consists of a type and subtype, such as image/jpeg or image/gif. If this parameter is not specified, the function will deduct the MIME type from the file extension. For example the MIME type for a .jpg file is image/jpeg.

Return Value

ID Type: Guid The unique ID that is assigned to the MediaSet of the record. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

Remarks

You can use this method to upload media that you want to associate with a record to the database. For example, you can upload media to items in table **27 Item**. The method is similar to the ImportStream Method (Media) except that this method enables you to import multiple media objects on the same record.

When a media is imported, it is assigned a unique identifier (GUID) and stored in the system table **2000000181 Tenant Media** of the application database.

In addition, the media object is assigned to a MediaSet which also has a specific GUID. This GUID is included in the MediaSet data type field as a reference to the media objects. The MediaSet and its GUID are created with the first media that is imported, and the information is stored in table **2000000183 Tenant Media Set**. All additional media objects for the record are then associated with the same MediaSet GUID.

Example

This example uses the ImportStream method to add images to records in table **27 Item** of the CRONUS demonstration database.

To support the example code that follows, you also have to complete these tasks:

- Create two sample image files that you want to use on item no. 1000 in table **27 Item**.

  Save the images as JPEG type, and give them the names 1000-v1.jpg and 1000-v2.jpg. Save the files in the *C:\images* folder on the computer that is running Dynamics 365 Business Central service instance.

- Verify that table **27 Item** has a field that is called **Picture** and has the data type **MediaSet**.

  This is field on which you will add the images. If the field is not present, then add it.

With these tasks in place, you can add and run the following AL code to import the images. For this code example, create a codeunit and add the code to the OnRun trigger.

```
 var
    itemRec: Record Item;
    count: Integer;
    fileName: Text;
    inStreamObject: InStream;
    importFile: File;
    mediasetId: GUID;
    Text000: Label 'The files have been imported. Item %1 has %2 pictures in MediaSet: %3';
begin
    itemRec.Get('1000');

    fileName := 'C:\images\1000-v1.jpg';
    importFile.Open(fileName);
    importFile.CreateInStream(inStreamObject);
    itemRec.Picture.ImportStream(inStreamObject, 'Demo image for item ' + Format(itemRec."No."));
    itemRec.Modify;
    importFile.Close;

    fileName := 'C:\images\1000-v2.jpg';
    importFile.Open(fileName);
    importFile.CreateInStream(inStreamObject);
    itemRec.Picture.ImportStream(inStreamObject, 'Demo image for item ' + Format(itemRec."No."));
    itemRec.Modify;
    importFile.Close;

    count := (itemRec.Picture.Count);
    mediasetId := itemRec.Picture.MediaId;
    Message(Text000,itemRec."No.",count,mediasetId);
end;
```

If you run system table **2000000181 Tenant Media**, you should see the new images in the list.

MediaSet.Insert Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Adds a media object that already exists in the database to a MediaSet of a record.

Syntax

```
[Result := ]  MediaSet.Insert(MediaId: Guid)
```

Parameters

MediaSet Type: MediaSet An instance of the MediaSet data type.

MediaId
Type: Guid
Specifies the unique ID that is assigned to the media object that you want to insert. Existing media objects are stored in the system table 2000000184 Tenant Media of the application database. There are different ways of obtaining the GUID of a media object. You could identify the media object ID by looking in the table. Or programmatically, you can use either the Item function on a MediaSet data type field of a record or the MEDIAID function on Media data type field of a record.

Return Value

Result Type: Boolean **true** if the media is successfully added to the MediaSet, otherwise **false**. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

Remarks

When media object is inserted in a MediaSet, it is assigned in index number. For more information, see Indexing of media objects in a media set.

Example

This example uses the Insert method and Item Method (MediaSet) to take a media object that is already in the database and assigned to a record in a table (TableA), and add it to the MediaSet of a record in another table (TableB). This example assumes the following:

- TableA and TableB already exist
- Each table has a MediaSet data type field called **Images**
- Each table contains the record number '1000'.
- There is at least 1 media object in the MediaSet of record 1000 in TableA.

```
 var
    recA: Record TableA;
    recB: Record TableB;
    mediasetId: GUID;
    Text000: Label 'Media %1 was added to MediaSet %2.';
    Text000: Label 'The media was not added to MediaSet %1.';
begin
    // Retrieves the GUID of the first media object (index number 1) in the MediaSet of record 1000 in
TableA
    recA.Get('1000');
    MediaId := recA.Images.Item(1);

    // Adds media object to the MediaSet of record 1000 in TableB based on the media object GUID
    recB.Get('1000');
    if recB.Images.Insert(mediaId) then begin
        recB.Modify;
        Message(Text000, mediaId, recB.Images.MediaId);
    end else begin
       Message(Text001);
    end;
end;
```

MediaSet.Item Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Gets the unique identifier (GUID) of a media object that is assigned to a MediaSet on a record.

Syntax

```
MediaId :=   MediaSet.Item(Index: Integer)
```

Parameters

MediaSet Type: MediaSet An instance of the MediaSet data type.

Index

Type: Integer

Specifies the index number that is assigned to the media object in the MediaSet.

Return Value

MediaId Type: Guid The unique identifier (GUID) of the media object.

Example

For an example of using the Item method, see this example.

MediaSet.MediaId Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Gets the unique identifier that is assigned to a MediaSet of a record. The MediaSet is a collection of media objects that are used on the record that can be displayed in the client.

Syntax

```
MediaId :=   MediaSet.MediaId()
```

> **NOTE**
> This method can be invoked using property access syntax.

Parameters

MediaSet Type: MediaSet An instance of the MediaSet data type.

Return Value

MediaId Type: Guid The GUID of MediaSet on the record.

Remarks

When you import media on a table record by using either the ImportFile Method (MediaSet) or ImportStream Method (MediaSet), the media is assigned to a MediaSet GUID in the system table **2000000183 Tenant Media Set** of the application database. You can use the MediaId method to retrieve the MediaSet GUID. Note that the imported media object is also assigned a GUID. To get the media object's GUID, you can use the MediaId Method (Media).

Example

This example is gets the GUID of the MediaSet that is used on item No. 1000 in the **Item** table. The field in the **Item** table that is used for the MediaSet data type is **Picture**.

```
 var
    item: Record Item;
    mediasetId: GUID;
    Text000: Label 'The GUID of the MediaSet is: %1';
begin
    item.Get('1000');
    mediasetId := item.Picture.MediaId;
    Message(Text000, mediasetId);
end;
```

See Also

MediaSet.Remove Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Removes a media object from a MediaSet of a record.

Syntax

```
[Result := ]  MediaSet.Remove(MediaId: Guid)
```

Parameters

MediaSet Type: MediaSet An instance of the MediaSet data type.

MediaId
Type: Guid
Specifies the unique ID that is assigned to the media object that you want to remove from the MediaSet. Existing media objects are stored in the system table 2000000184 Tenant Media of the application database. There are different ways of obtaining the GUID of a media object. You could identify the media object ID by looking in the table. Or programmatically, you can use either the Item function on a MediaSet data type field of a record or the MEDIAID function on Media data type field of a record.

Return Value

Result Type: Boolean **true** if the object was removed or **false** if a media object with the given ID was not present in the set. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

Remarks

The Remove method disassociates the media object from the MediaSet. It does not delete the media object from the database.

Example

This example uses the REMOVE method and Item Method (MediaSet) to remove a media object from the MediaSet for record '1000' in the table called TableA. This example assumes the following about TableA:

- It has a MediaSet data type field called **Images**
- It contains the record number '1000'.
- Record '1000' has at least 1 media object in the MediaSet.

```
 var
    recA: Record TableA;
    mediasetId: GUID;
    Text000: Label 'Media %1 was removed from MediaSet %2.';
    Text001: Label 'The media was not removed from MediaSet %1.';
begin
    // Retrieves the GUID of the first media object (index number 1) in the MediaSet of record 1000 in
TableA
    recA.Get('1000');
    mediaId := recA.Images.Item(1);

    // Removes the media object from the MediaSet of record 1000
    if recA.Images.Remove(mediaId) then begin
        recA.Modify;
        Message(Text000, mediaId, recA.Images.MediaId);
    end else begin
        Message(Text001);
    end;
end;
```

ModuleDependencyInfo.Id Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Gets the app ID of the specified app.

Syntax

```
Id :=   ModuleDependencyInfo.Id()
```

> **NOTE**
> This method can be invoked using property access syntax.

Parameters

ModuleDependencyInfo Type: ModuleDependencyInfo An instance of the ModuleDependencyInfo data type.

Return Value

Id Type: Guid The application ID.

NavApp Data Type

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Provides information about a NavApp.

The following methods are available on the NavApp data type.

METHOD NAME	DESCRIPTION
DeleteArchiveData(Integer)	Deletes the archived data for a specified table of an extension during installation.
GetArchiveRecordRef(Integer, var RecordRef)	Returns a RecordRef for the specified table.
GetArchiveVersion()	Returns the version of the extension that the specified table is part of.
GetCallerModuleInfo(var ModuleInfo)	Gets information about the extension that contains the method that called the currently running method. For example, if method 1 (in extension A) calls method 2 (in extension B), which calls GetCallerModuleInfo, then GetCallerModuleInfo will return information about extension A.
GetCurrentModuleInfo(var ModuleInfo)	Gets information about the application that contains the AL object that is currently running.
GetModuleInfo(Guid, var ModuleInfo)	Gets information about the specified AL application.
IsInstalling()	Returns **true** if the application that contains the AL object that is currently running is being installed, otherwise it returns **false**.
LoadPackageData(Integer)	Loads default, or starting, table data into the specified table of an extension during installation.
RestoreArchiveData(Integer [, Boolean])	Restores archived data for a specified table of an extension during installation.

NavApp.DeleteArchiveData Method

2/17/2021 • 2 minutes to read • Edit Online

> **Version**: *Available from runtime version 1.0 until version 6.0 where it was deprecated for the following reason: "The features related to data migration from V1 to V2 extensions are being deprecated."*

Deletes the archived data for a specified table of an extension during installation.

Syntax

```
NavApp.DeleteArchiveData(TableNo: Integer)
```

Parameters

TableNo

Type: Integer

The ID of the table for which to delete archived data.

If you omit this optional return value and if archived data cannot be deleted for the specified table, then a run-time error occurs. If you include a return value, then it is assumed that you will handle any errors and no run-time error occurs, even though the archived data is not deleted.

Remarks

You use this method as part of the upgrade code for an extension, where it is called from the `OnNavAppUpgradePerDatabase()` or `OnNavAppUpgradePerCompany()` system methods. When an extension is uninstalled, the data in application tables of the extension is automatically stored into a set of special tables so that the data is still preserved. With the DeleteARCHIVEDATA method, you can delete the archived data from the application table of the new version of an extension when it is installed.

NavApp.GetArchiveRecordRef Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0 until version 6.0 where it was deprecated for the following reason: "The features related to data migration from V1 to V2 extensions are being deprecated."*

Returns a RecordRef for the specified table.

Syntax

```
[Ok := ]  NavApp.GetArchiveRecordRef(TableNo: Integer, var RecordRef: RecordRef)
```

Parameters

TableNo

Type: Integer

Specifies the table ID.

RecordRef

Type: RecordRef

Specifies the reference.

Return Value

Ok Type: Boolean **true**, if a record was found; other **false**

NavApp.GetCallerModuleInfo Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 6.0.*

Gets information about the extension that contains the method that called the currently running method. For example, if method 1 (in extension A) calls method 2 (in extension B), which calls GetCallerModuleInfo, then GetCallerModuleInfo will return information about extension A.

> **NOTE**
> This method is supported only in Business Central on-premises.

Syntax

```
[Ok := ]  NavApp.GetCallerModuleInfo(var Info: ModuleInfo)
```

Parameters

Info
Type: ModuleInfo
A value containing information about the calling application.

Return Value

Ok Type: Boolean **true** if the information could be retrieved, otherwise **false**. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

See Also

NavApp Data Type

NavApp.GetCurrentModuleInfo Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Gets information about the application that contains the AL object that is currently running.

Syntax

```
[Ok := ]  NavApp.GetCurrentModuleInfo(var Info: ModuleInfo)
```

Parameters

Info

Type: ModuleInfo

A value containing information about the currently running application.

Return Value

Ok Type: Boolean **true** if the information could be retrieved, otherwise **false**. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

See Also

NavApp Data Type

NavApp.GetModuleInfo Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Gets information about the specified AL application.

Syntax

```
[Ok := ]  NavApp.GetModuleInfo(AppId: Guid, var Info: ModuleInfo)
```

Parameters

AppId

Type: Guid

The ID of the application for which to retrieve information.

Info

Type: ModuleInfo

A value containing information about the application with the given ID.

Return Value

Ok Type: Boolean **true** if the information could be retrieved, otherwise **false**. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

See Also

NavApp Data Type

NavApp.IsInstalling Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Returns **true** if the application that contains the AL object that is currently running is being installed, otherwise it returns **false**.

Syntax

```
Result :=   NavApp.IsInstalling()
```

Return Value

Result Type: Boolean **true** if the application that contains the AL object that is currently running is being installed, otherwise **false**.

See Also

NavApp Data Type
Getting Started with AL
Developing Extensions

NavApp.LoadPackageData Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Loads default, or starting, table data into the specified table of an extension during installation.

Syntax

```
NavApp.LoadPackageData(TableNo: Integer)
```

Parameters

TableNo

Type: Integer

The ID of the table for which to load package data.

Remarks

You use this method as part of the upgrade code for an extension, where it is called from the `OnNavAppUpgradePerDatabase()` or `OnNavAppUpgradePerCompany()` system methods. With the LOADPACKAGEDATA method, you can populate a new table in your extension with data to help users get started using your extension.

NavApp.RestoreArchiveData Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0 until version 6.0 where it was deprecated for the following reason: "The features related to data migration from V1 to V2 extensions are being deprecated."*

Restores archived data for a specified table of an extension during installation.

Syntax

```
[Ok := ]  NavApp.RestoreArchiveData(TableNo: Integer [, RunTrigger: Boolean])
```

Parameters

TableNo
Type: Integer
The ID of the table for which to restore achived data.
RunTrigger
Type: Boolean
true if the table triggers should run, otherwise **false**.

Return Value

Ok Type: Boolean **true**, if the archived data was restored for the specified table; otherwise **false** If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

Remarks

You use this method as part of the upgrade code for an extension, where it is called from the `OnNavAppUpgradePerDatabase()` or `OnNavAppUpgradePerCompany()` system methods. When an extension is uninstalled, the data in application tables of the extension is automatically stored into a set of special tables so that the data is still preserved. With the RESTOREARCHIVEDATA method, you can restore the archived data to the application table of the new version of an extension when it is installed.

Notification Data Type

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Provides a programmatic way to send non-intrusive information to the user interface (UI) in the Business Central Web client.

The following methods are available on instances of the Notification data type.

METHOD NAME	DESCRIPTION
AddAction(String, Integer, String)	Specifies an action for the notification.
GetData(String)	Retrieves data that was passed to a notification instance as specified by a SetData method call.
HasData(String)	Checks if data was passed to a notification instance as specified by a SetData method call.
Id([Guid])	Specifies the identifier for a notification.
Message([String])	Specifies the content of the notification.
Recall()	Recall a sent notification.
Scope([NotificationScope])	Specifies the context in which the notification appears in the client.
Send()	Sends the notification to the client, where it will display in the UI.
SetData(String, String)	Specifies a data property value for the notification. The data is specified as text in a key-value pair.

See Also

Notifications
Getting Started with AL
Developing Extensions

Notification.AddAction Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Specifies an action for the notification.

Syntax

```
Notification.AddAction(Caption: String, CodeunitID: Integer, MethodName: String)
```

Parameters

Notification Type: Notification An instance of the Notification data type.

Caption

Type: String

The text string that appears as the caption of the action in the notification UI. The string can be a text constant that is enabled for multilanguage functionality.

CodeunitID

Type: Integer

The ID of the Codeunit to run when the action is initiated from the notification UI. The codeunit should contain at least one global method to be called by the notification action. The global method must have a Notification data type parameter for accepting the notification object.

MethodName

Type: String

The name of the method in the Codeunit, which is specified by the CodeunitID parameter, that you want to run for the action.

Remarks

An action provides a way for you to add an interactive notification that enables users to respond to or take action on the notification. The method that is called by the action contains logic that you want to run for the action.

For more information and a detailed example, see Notifications.

Example

The following code creates two actions for a notification. The actions call the **RunAction1** and **RunAction2** methods in the codeunit **Action Handler**.

```
MyNotification.Message := 'This is a notification';
MyNotification.Scope := NotificationScope::LocalScope;
MyNotification.AddAction('Action 1',CodeUnit::"Action Handler",'RunAction1');
MyNotification.AddAction('Action 2',CodeUnit::"Action Handler",'RunAction2');
MyNotification.Send;
```

To handle the actions, the **Action Handler** codeunit has two global methods that have a **Notification** data type parameter:

```
procedure RunAction1@1(MyNotification@1000 : Notification);
begin
    Message('This is RunAction1');
end;

procedure RunAction2@2(MyNotification@1000 : Notification);

Notification.GetData Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Retrieves data that was passed to a notification instance as specified by a SetData method call.

Syntax

```
Value :=   Notification.GetData(Name: String)
```

Parameters

Notification Type: Notification An instance of the Notification data type.

Name
Type: String
The name of the data item that is specified by the SetData method call.

Return Value

Value Type: String The data retrieved

Remarks

You use the SetData Method (Notification) and GetData methods for transferring data in a notification. The methods are typically needed for handling actions on the notification. The SetData Method (Notification) method is called from the source of the notification, while the GetData method is called from the action code.

For more information and a detailed example, see Notifications.

Example

The following code sets the data for a notification:

```
MyNotification.Message := 'This is a notification';
MyNotification.Scope := NotificationScope::LocalScope;
MyNotification.SetData('Created',Format(CurrentDateTime,0,9));
MyNotification.SetData('ID',Format(CreateGUID,0,9));
MyNotification.AddAction('Action 1',CodeUnit::"Action Handler",'RunAction1');
MyNotification.AddAction('Action 2',CodeUnit::"Action Handler",'RunAction2');
MyNotification.Send;
```

The following code gets the data for a notification:

```
MyNotification.GetData('Created');
MyNotification.GetData('ID');
```

Notification.HasData Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Checks if data was passed to a notification instance as specified by a SetData method call.

Syntax

```
Value :=   Notification.HasData(Name: String)
```

Parameters

Notification Type: Notification An instance of the Notification data type.

Name

Type: String

The name of the data item that is specified by the SetData method call.

Return Value

Value Type: Boolean **true**, if there is data; otherwise **false**.

See Also

Notification Data Type
Getting Started with AL
Developing Extensions

Notification.Id Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Specifies the identifier for a notification.

Syntax

```
[Id := ]  Notification.Id([Id: Guid])
```

> **NOTE**
> This method can be invoked using property access syntax.

Parameters

Notification Type: Notification An instance of the Notification data type.

Id
Type: Guid

Return Value

Id Type: Guid

Remarks

If left unassigned the notification will be assigned an ID when the Send method is called. For more information, see Send Method (Notification).

Example

The following code creates a notification and sends it if NewBalance is greater than the credit limit. If it is lower than the credit limit, it recalls the notification.

The example uses a pre-defined ID so that the notification can be recalled.

```
MyNotification.ID := '00000000-0000-0000-0000-000000000001';
IF NewBallance > Rec. "Credit Limit" THEN begin
  MyNotification.Message := 'The customer's current balance exceeds their credit limit.';
  MyNotification.Scope := NotificationScope::LocalScope;
  MyNotification.AddAction('Fix it.', 50001, 'FixCustomerCreditLimit');
  MyNotification.SetData('CustomerNo.', Rec."No.");
  MyNotification.Send;
END ELSE
  MyNotification.Recall;
```

See Also

Notification Data Type
Getting Started with AL
Developing Extensions

Notification.Message Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Specifies the content of the notification.

Syntax

```
[Message := ]  Notification.Message([Message: String])
```

NOTE

This method can be invoked using property access syntax.

Parameters

Notification Type: Notification An instance of the Notification data type.

Message

Type: String

Displays a text string in a message window.

Return Value

Message Type: String The message

Remarks

The Message method defines the notification. You use the Send Method (Notification) to send the notification to the client, where it will be displayed.

For more information and a detailed example, see Notifications.

Example

The following code creates a notification and sends it in the local scope.

```
MyNotification.Message := 'This is a notification';
MyNotification.Scope := NotificationScope::LocalScope;
MyNotification.Send;
```

See Also

Notification Data Type

Notification.Recall Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Recall a sent notification.

Syntax

```
[Ok := ]  Notification.Recall()
```

Parameters

Notification Type: Notification An instance of the Notification data type.

Return Value

Ok Type: Boolean **true** if it succeeds in sending a recall request to the client; otherwise **false**. The same notification can be recalled more than once, without failing. Also, a notification can be recalled successfully even if it hasn't been sent. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

Remarks

A typical reason that the RECALL method returns **false** is a failure in the communication with the client. Another reason could be that the code tries to recall a notification for which there is no instance.

Example

The following code creates a notification and sends it if NewBalance is greater than the credit limit. If it is lower than the credit limit, it recalls the notification.

```
MyNotification.ID := '00000000-0000-0000-0000-000000000001';
IF NewBalance > Rec. "Credit Limit" then begin
  MyNotification.Message := 'The customer's current balance exceeds their credit limit.';
  MyNotification.Scope := NotificationScope::LocalScope;
  MyNotification.AddAction('Fix it.', 50001, 'FixCustomerCreditLimit');
  MyNotification.SetData('CustomerNo.', Rec."No.");
  MyNotification.Send;
end else
  MyNotification.Recall;
```

Notification.Scope Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Specifies the context in which the notification appears in the client.

Syntax

```
[Scope := ]  Notification.Scope([Scope: NotificationScope])
```

NOTE

This method can be invoked using property access syntax.

Parameters

Notification Type: Notification An instance of the Notification data type.

Scope

Type: NotificationScope

The scope in which the notification appears in the client

Return Value

Scope Type: NotificationScope The scope of the current notification.

Remarks 1

For more information and a detailed example, see Notifications.

Example 1

The following code creates a notification and sends it in the local scope.

```
MyNotification.Message := 'This is a notification';
MyNotification.Scope := NotificationScope::LocalScope;
MyNotification.Send;
```

Remarks 2

The data that is specified by the SetData method can be retrieved by the GetData Method. The SetData and GetData methods are typically used for actions with actions on the notification. The SetData method is called from the source is the notification, while the GetData method is called from the action code.

You can use multiple SetData method calls to specify different data items. The data remains available for the life of the notification instance. The data is cleared once the notification instance has been dismissed or an action is taken.

For more information and a detailed example, see Notifications.

Example 2

The following code sets the data for a notification:

```
MyNotification.Message := 'This is a notification';
MyNotification.Scope := NotificationScope::LocalScope;
MyNotification.SetData('Created',Format(CurrentDateTime,0,9));
MyNotification.SetData('ID',Format(CreateGUID,0,9));
MyNotification.AddAction('Action 1',CodeUnit::"Action Handler",'RunAction1');
MyNotification.AddAction('Action 2',CodeUnit::"Action Handler",'RunAction2');
MyNotification.Send;
```

The following code gets the data for a notification:

```
MyNotification.GetData('Created');
MyNotification.GetData('ID');''
```

Notification.Send Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Sends the notification to the client, where it will display in the UI.

Syntax

```
[Ok := ]  Notification.Send()
```

Parameters

Notification Type: Notification An instance of the Notification data type.

Return Value

Ok Type: Boolean **true** if the notification was sent; otherwise **false** If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

Remarks

The Send method displays the content of the notification that is specified by the Message Method.

For more information and a detailed example, see Notifications.

Example

The following code creates a notification and sends it to the client in the local scope.

```
MyNotification.Message := 'This is a notification';
MyNotification.Scope := NotificationScope::LocalScope;
MyNotification.Send;
```

Notification.SetData Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Specifies a data property value for the notification. The data is specified as text in a key-value pair.

Syntax

```
Notification.SetData(Name: String, Value: String)
```

Parameters

Notification Type: Notification An instance of the Notification data type.

Name

Type: String

The text string to use as a unique identifier for the data item.

Value

Type: String

The text string that represents the data.

NumberSequence Data Type

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 4.0.*

Is a complex data type for creating and managing number sequences in the database.

The following methods are available on the NumberSequence data type.

METHOD NAME	DESCRIPTION
Current(String [, Boolean])	Gets the current value from the number sequence, without doing any increment. The value is retrieved out of transaction. The value will not be returned on transaction rollback.
Delete(String [, Boolean])	Deletes a specific number sequence.
Exists(String [, Boolean])	Checks whether a specific number sequence exists.
Insert(String [, BigInteger] [, BigInteger] [, Boolean])	Creates a number sequence in the database, with the given parameters.
Next(String [, Boolean])	Retrieves the next value from the number sequence.

NumberSequence.Current Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 4.0.*

Gets the current value from the number sequence, without doing any increment. The value is retrieved out of transaction. The value will not be returned on transaction rollback.

Syntax

```
Current :=   NumberSequence.Current(Name: String [, CompanySpecific: Boolean])
```

Parameters

Name
Type: String
Specifies the name of the number sequence.
CompanySpecific
Type: Boolean
Specifies if the number sequence is company-specific. Default is true.

Return Value

Current Type: BigInteger Returns the current value from number sequence.

Example

The following example gets the current value for the number sequence `MyNumberSequence`, which is not company specific.

```
number := NumberSequence.Current('MyNumberSequence', false);
```

See Also

NumberSequence.Delete Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 4.0.*

Deletes a specific number sequence.

Syntax

```
NumberSequence.Delete(Name: String [, CompanySpecific: Boolean])
```

Parameters

Name

Type: String

Specifies the name of the number sequence.

CompanySpecific

Type: Boolean

Specifies if the number sequence is company-specific. Default is true.

Example

The following example checks whether the number sequence `MyNumberSequence` exists, and if so, it deletes it.

```
if NumberSequence.Exists('MyNumberSequence', false) then
    NumberSequence.Delete('MyNumberSequence', false);
```

See Also

NumberSequence.Exists Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 4.0.*

Checks whether a specific number sequence exists.

Syntax

```
Exists :=   NumberSequence.Exists(Name: String [, CompanySpecific: Boolean])
```

Parameters

Name

Type: String

Specifies the name of the number sequence.

CompanySpecific

Type: Boolean

Specifies if the number sequence is company-specific. Default is true.

Return Value

Exists Type: Boolean Returns true if the number sequence exists.

Example

The following example checks whether the number sequence `MyNumberSequence` exists, and if so, it deletes it.

```
if NumberSequence.Exists('MyNumberSequence', false) then
    NumberSequence.Delete('MyNumberSequence', false);
```

See Also

NumberSequence.Insert Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 4.0.*

Creates a number sequence in the database, with the given parameters.

Syntax

```
 NumberSequence.Insert(Name: String [, Seed: BigInteger] [, Increment: BigInteger] [, CompanySpecific:
Boolean])
```

Parameters

Name

Type: String

Specifies the name of the number sequence.

Seed

Type: BigInteger

Specifies the first value coming from the number sequence. Default is 0.

Increment

Type: BigInteger

The increment value used for the number sequence. Default is 1.

CompanySpecific

Type: Boolean

Specifies if the number sequence is company-specific. Default is true.

Example

The following example creates the number sequence `MyNumberSequence` that starts at zero and increments by a value of ten. The number series is not company specific.

```
NumberSequence.Insert('MyNumberSequence', 0, 10, false);
```

NumberSequence.Next Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 4.0.*

Retrieves the next value from the number sequence.

Syntax

```
Next :=   NumberSequence.Next(Name: String [, CompanySpecific: Boolean])
```

Parameters

Name

Type: String

Specifies the name of the number sequence.

CompanySpecific

Type: Boolean

Specifies if the number sequence is company-specific. Default is true.

Return Value

Next Type: BigInteger Returns the next value from number sequence.

Example

The following example gets the next value in the number sequence `MyNumberSequence`. The number series is not company specific.

```
number := NumberSequence.Next('MyNumberSequence', false);
```

SessionInformation Data Type

2/17/2021 • 2 minutes to read • Edit Online

> **Version**: *Available from runtime version 4.0.*

Is a complex data type for exposing Session information into AL.

The following methods are available on the SessionInformation data type.

METHOD NAME	DESCRIPTION
SqlRowsRead()	Gets the amount of SQL rows read on the session, since the session started.
SqlStatementsExecuted()	Gets the amount of SQL statements executed on the session, since the session started.

SessionInformation.SqlRowsRead Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 4.0.*

Gets the amount of SQL rows read on the session, since the session started.

Syntax

```
SqlStatementsExecuted :=   SessionInformation.SqlRowsRead()
```

NOTE

This method can be invoked using property access syntax.

Return Value

SqlStatementsExecuted Type: BigInteger The amount of SQL rows read on the session, since the session started.

Remarks

AL debugger also lets you monitor the number of SQL rows read. For more information, see Debugging SQL behavior.

Example

The following code gets the number of SQL rows read for the session and displays the number in a message.

```
var
    SqlRowsRead := BigText;

begin

    SqlRowsRead := SessionInformation.SqlRowsRead();
    Message(Format(SqlRowsRead));
end;
```

SessionInformation.SqlStatementsExecuted Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 4.0.*

Gets the amount of SQL statements executed on the session, since the session started.

Syntax

```
SqlStatementsExecuted :=   SessionInformation.SqlStatementsExecuted()
```

> **NOTE**
> This method can be invoked using property access syntax.

Return Value

SqlStatementsExecuted Type: BigInteger The amount of SQL statements executed on the session, since the session started.

Remarks

AL debugger also lets you to monitor the number of SQL statements executed. For more information, see Debugging SQL behavior.

Example

The following code gets the number of SQL statements executed and displays the number in a message.

```
var
    SqlStatementsExecuted : BigText;

begin

    SqlStatementsExecuted := SessionInformation.SqlStatementsExecuted();
    Message(Format(SqlStatementsExecuted));
end;
```

Option Data Type

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Denotes an option value. In the code snippet below, you can see how the Option data type is declared.

Syntax example

```
procedure HelloWithOptions(OptionParameter : Option Alpha, "Bra-vo")
    var
        OptionVariable : Option C, "or D";
    begin
        Message('%1',OptionParameter::Alpha);
        Message('%1',OptionVariable::C);
    end;
```

NOTE

It is not possible to reference the members of the `OptionParameter` from outside the body of the procedure.

Remarks

In the OptionString Property of the field or variable, you can enter the option values as a comma-separated list. The Option type is a zero-based enumerator type, which means that the option values are assigned to sequential numbers, starting with 0. You can convert option data types to integers.

Example

This example shows how you can use the value of an option field as a constant in your AL code.

```
PurchHeaderRec."Document Type" := PurchHeaderRec."Document Type"::Invoice;
```

OutStream Data Type

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Is a generic stream object that you can use to write to files and BLOBs.

The following methods are available on instances of the OutStream data type.

METHOD NAME	DESCRIPTION
Write(Variant [, Integer])	Writes a specified number of bytes to the stream. Data is written in binary format.
Write(Boolean [, Integer])	Writes a specified number of bytes to the stream. Data is written in binary format.
Write(Byte [, Integer])	Writes a specified number of bytes to the stream. Data is written in binary format.
Write(Char [, Integer])	Writes a specified number of bytes to the stream. Data is written in binary format.
Write(Integer [, Integer])	Writes a specified number of bytes to the stream. Data is written in binary format.
Write(BigInteger [, Integer])	Writes a specified number of bytes to the stream. Data is written in binary format.
Write(Decimal [, Integer])	Writes a specified number of bytes to the stream. Data is written in binary format.
Write(Guid [, Integer])	Writes a specified number of bytes to the stream. Data is written in binary format.
Write(Text [, Integer])	Writes a specified number of bytes to the stream. Data is written in binary format.
Write(Code [, Integer])	Writes a specified number of bytes to the stream. Data is written in binary format.
Write(Label [, Integer])	Writes a specified number of bytes to the stream. Data is written in binary format.
Write(TextConst [, Integer])	Writes a specified number of bytes to the stream. Data is written in binary format.
Write(BigText [, Integer])	Writes a specified number of bytes to the stream. Data is written in binary format.
Write(Date [, Integer])	Writes a specified number of bytes to the stream. Data is written in binary format.

METHOD NAME	DESCRIPTION
Write(Time [, Integer])	Writes a specified number of bytes to the stream. Data is written in binary format.
Write(DateTime [, Integer])	Writes a specified number of bytes to the stream. Data is written in binary format.
Write(DateFormula [, Integer])	Writes a specified number of bytes to the stream. Data is written in binary format.
Write(Duration [, Integer])	Writes a specified number of bytes to the stream. Data is written in binary format.
Write(Option [, Integer])	Writes a specified number of bytes to the stream. Data is written in binary format.
Write(Record [, Integer])	Writes a specified number of bytes to the stream. Data is written in binary format.
Write(RecordId [, Integer])	Writes a specified number of bytes to the stream. Data is written in binary format.
Write(String [, Integer])	Writes a specified number of bytes to the stream. Data is written in binary format.
Write(Any [, Integer])	Writes a specified number of bytes to the stream. Data is written in binary format.
WriteText([String] [, Integer])	Writes text to an OutStream object.

OutStream.Write Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 2.0.*

Writes a specified number of bytes to the stream. Data is written in binary format.

Syntax

```
[Written := ]  OutStream.Write(Value: Variant [, Length: Integer])
```

Parameters

OutStream Type: OutStream An instance of the OutStream data type.

Value
Type: Variant
Contains the data to be written.

Length
Type: Integer
The number of bytes to be written. In the case of data types other than string, code, and binary, if you specify a length that differs from the size of the variable, an error message is displayed.

Return Value

Written Type: Integer The number of bytes that were written. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

Remarks

If the optional return value, *Written*, is not specified and it was not possible to write all the data, an error message is displayed.

If the return value is present, you must verify that all the data was streamed.

Example

```
 var
    recBinaries: Record "Company Information";
    OStream: OutStream;
    Var: Variant;
begin
    recBinaries.Find('-');
    recBinaries.Picture.CreateOutstream(OStream);
    OStream.Write(Var);
    recBinaries.Modify();
end;
```

Remarks

Write adds a zero byte at the end of the stream. This is differs from WriteText, which does not. For more information about how zero bytes and line endings are written and read, see Write, WriteText, Read, and ReadText Method Behavior Regarding Line Endings and Zero Terminators.

If the optional return value, *Written*, is not specified and it was not possible to write all the data, an error message is displayed.

If the return value is present, you must verify that all the data was streamed.

Example

```
recBinaries.Find('-');
recBinaries.Data.CreateOutstream(OutStream);
OutStream.Write('Secretary');
OutStream.Write('Alice');
OutStream.Write('Hart');
OutStream.Write(19960106D);
recBinaries.Modify();
```

OutStream.Write Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Writes a specified number of bytes to the stream. Data is written in binary format.

Syntax

```
[Written := ]  OutStream.Write(Value: Decimal [, Length: Integer])
```

Parameters

OutStream Type: OutStream An instance of the OutStream data type.

Value
Type: Decimal
Contains the data to be written.

Length
Type: Integer
The number of bytes to be written. In the case of data types other than string, code, and binary, if you specify a length that differs from the size of the variable, an error message is displayed.

Return Value

Written Type: Integer The number of bytes that were written. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

Remarks

Write adds a zero byte at the end of the stream. This is differs from WriteText, which does not. For more information about how zero bytes and line endings are written and read, see Write, WriteText, Read, and ReadText Method Behavior Regarding Line Endings and Zero Terminators.

If the optional return value, *Written*, is not specified and it was not possible to write all the data, an error message is displayed.

If the return value is present, you must verify that all the data was streamed.

Example

This example requires that you create the following variables.

```
 var
    recBinaries: Record "Company Information";
    OStream: OutStream;
begin
    recBinaries.Find('-');
    recBinaries.Picture.CreateOutstream(OStream);
    OStream.Write(0.33);
    recBinaries.Modify();
end;
```

OutStream Data Type

OutStream.WriteText Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Writes text to an OutStream object.

Syntax

```
[Written := ]  OutStream.WriteText([Text: String] [, Length: Integer])
```

Parameters

OutStream Type: OutStream An instance of the OutStream data type.

Text
Type: String
The text to write. If you do not specify this, a carriage return and a line feed are written.

Length
Type: Integer
The number of characters to be written.

Return Value

Written Type: Integer If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

Remarks

For more information about how zero bytes and line endings are written and read, see Write, WriteText, Read, and ReadText Method Behavior Regarding Line Endings and Zero Terminators.

Example

This example also requires that the c:\TestFiles folder exists.

```
var
    MyHTMLFile: File;
    TestOutStream: OutStream;
begin
    MyHTMLFile.Create('c:\TestFiles\main.html');
    MyHTMLFile.CreateOutstream(TestOutStream);
    TestOutStream.WriteText('<html>');
    TestOutStream.WriteText;
    TestOutStream.WriteText('<head>');
    TestOutStream.WriteText('<title>My Page</title>');
    TestOutStream.WriteText('</head>');
    TestOutStream.WriteText;
    TestOutStream.WriteText('<P>Hello world!</p>');
    TestOutStream.WriteText;
    TestOutStream.WriteText('</html>');
    FileMyHTML.Close;
end;
```

Page Data Type

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Contains a number of simpler elements called controls. Controls are used to display information to the user or receive information from the user.

The following methods are available on the Page data type.

METHOD NAME	DESCRIPTION
GetBackgroundParameters()	Gets the page background task input parameters.
Run(Integer [, Record] [, Any])	Creates and launches a page that you specify. You can use Clear method to remove the page.
Run(Integer, Record, Integer)	Creates and launches a page that you specify. You can use Clear method to remove the page.
RunModal(Integer [, Record] [, Any])	Creates, opens, and closes a page that you specify. When a page is run modally, no input, such as a keyboard or mouse click, can occur except for objects on the modal page.
RunModal(Integer, Record, Integer)	Creates, opens, and closes a page that you specify. When a page is run modally, no input, such as a keyboard or mouse click, can occur except for objects on the modal page.
RunModal(Integer, Record, FieldRef)	Creates, opens, and closes a page that you specify. When a page is run modally, no input, such as a keyboard or mouse click, can occur except for objects on the modal page.
SetBackgroundTaskResult(Dictionary of [Text, Text])	Sets the page background task result as a dictionary. When the task is completed, the OnPageBackgroundCompleted trigger will be invoked on the page with this result dictionary.

The following methods are available on instances of the Page data type.

METHOD NAME	DESCRIPTION
Activate([Boolean])	Activates the current page on the client if possible. The data on the page will not be refreshed.
CancelBackgroundTask(Integer)	Attempt to cancel a page background task.
Caption([String])	The caption shown in the title bar. For example, the default value in English (United States) is the same as the name of the page.
Close()	Closes the current page.

METHOD NAME	DESCRIPTION
Editable([Boolean])	Gets or sets the default editability of the page.
EnqueueBackgroundTask(var Integer, Integer [, var Dictionary of [Text, Text]] [, Integer] [, PageBackgroundTaskErrorLevel])	Creates and queues a background task that runs the specified codeunit (without a UI) in a read-only child session of the page session. If the task completes successfully, the **OnPageBackgroundTaskCompleted** trigger is invoked. If an error occurs, the **OnPageBackgroundTaskError** trigger is invoked. If the page is closed before the task completes, or the page record ID on the task changed, the task is cancelled.
GetRecord(var Record)	Gets the current record of the page.
LookupMode([Boolean])	Gets or sets the default lookup mode for the page.
ObjectId([Boolean])	Returns a string in the "Page xxx" format, where xxx is the caption or ID of the application object.
Run()	Creates and launches a page that you specify. You can use Clear method to remove the page.
RunModal()	Creates, opens, and closes a page that you specify. When a page is run modally, no input, such as a keyboard or mouse click, can occur except for objects on the modal page.
SaveRecord()	Saves the current record as if performed by the client. If the record does not exist it is inserted, otherwise it is modified.
SetRecord(var Record)	Sets the current record for the page.
SetSelectionFilter(var Record)	Notes the records that the user has selected on the page, marks those records in the table specified, and sets the filter to "marked only".
SetTableView(var Record)	Applies the table view on the current record as the table view for the page, report, or XmlPort.
Update([Boolean])	Saves the current record and then updates the controls on the page. If you set the SaveRecord parameter to false, this method will not save the record before the page is updated.

Page.GetBackgroundParameters Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 4.0.*

Gets the page background task input parameters.

Syntax

```
Parameters :=   Page.GetBackgroundParameters()
```

Return Value

Parameters Type: Dictionary of [Text, Text] The input parameters of the page background task.

Remarks

You use this method in a page background task codeunit, which is the codeunit that runs in a page background task. When a page background task is enqueued by the EnqueueBackgroundTask, it can include a set of parameters (a collection of key and value pairs) that can be used in the computations done in the background task codeunit. These parameters are passed as a dictionary of text to the codeunit's OnRun trigger when the page background task session is started. You use the GetBackgroundParameters method to retrieve these parameters.

Use the Evaluate method to convert parameter values to the data types required for calculations.

Example

The following code is an example of a page background task codeunit that uses the GetBackgroundParameters method to retrieve the value of the key named `Wait`, which is passed to the OnRun trigger from the calling page when the page background task is enqueued. For more details about this example, see Page Background Tasks.

```
codeunit 50100 PBTWaitCodeunit
{
    trigger OnRun()
    var
        Result: Dictionary of [Text, Text];
        StartTime: Time;
        WaitParam: Text;
        WaitTime: Integer;
        EndTime: Time;
    begin
        if not Evaluate(WaitTime, Page.GetBackgroundParameters().Get('Wait')) then
            Error('Could not parse parameter WaitParam');

        StartTime := System.Time();
        Sleep(WaitTime);
        EndTime := System.Time();

        Result.Add('started', Format(StartTime));
        Result.Add('waited', Format(WaitTime));
        Result.Add('finished', Format(EndTime));

        Page.SetBackgroundTaskResult(Result);
    end;
}
```

Page.Run Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Creates and launches a page that you specify. You can use Clear method to remove the page.

Syntax

```
Page.Run(Number: Integer [, Record: Record] [, Field: Any])
```

Parameters

Number

Type: Integer

The number of the page that you want to run. If you enter zero (0), the system displays the default lookup window for the current page. If the page you specify does not exist, a run-time error occurs.

Record

Type: Record

The record last displayed on the page. For each object, the system stores information about the most recently displayed record and the attached key and filters. Use this optional parameter to select a specific record to display on the page. The record must be of the same type as the table attached to the window. When the record is displayed, the key and filters attached to the record are used.

Field

Type: Any

Use this optional parameter to select a specific field on which focus will be placed.

Page.Run Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Creates and launches a page that you specify. You can use Clear method to remove the page.

Syntax

```
Page.Run(Number: Integer, Record: Record, FieldNo: Integer)
```

Parameters

Number

Type: Integer

The number of the page that you want to run. If you enter zero (0), the system displays the default lookup window for the current page. If the page you specify does not exist, a run-time error occurs.

Record

Type: Record

The record last displayed on the page. For each object, the system stores information about the most recently displayed record and the attached key and filters. Use this optional parameter to select a specific record to display on the page. The record must be of the same type as the table attached to the window. When the record is displayed, the key and filters attached to the record are used.

FieldNo

Type: Integer

Page.RunModal Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Creates, opens, and closes a page that you specify. When a page is run modally, no input, such as a keyboard or mouse click, can occur except for objects on the modal page.

Syntax

```
[Action := ]  Page.RunModal(Number: Integer [, Record: Record] [, Field: Any])
```

Parameters

Number

Type: Integer

The number of the page that you want to run.

Record

Type: Record

By default, this method shows the record that was last displayed on the page. For each object, information is stored about the most recently shown record and the attached key and filters. Use this optional parameter to select a specific record to display on the page. The record must be of the same type as the table that is attached to the page. When the record is displayed, the key and filters that are attached to the record are used.

Field

Type: Any

Use this optional parameter to select a specific field which will be in focus.

Return Value

Action Type: Action Specifies what action the user took on the page.

Page.RunModal Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Creates, opens, and closes a page that you specify. When a page is run modally, no input, such as a keyboard or mouse click, can occur except for objects on the modal page.

Syntax

```
[Action := ]  Page.RunModal(Number: Integer, Record: Record, FieldNo: Integer)
```

Parameters

Number

Type: Integer

The number of the page that you want to run.

Record

Type: Record

By default, this method shows the record that was last displayed on the page. For each object, information is stored about the most recently shown record and the attached key and filters. Use this optional parameter to select a specific record to display on the page. The record must be of the same type as the table that is attached to the page. When the record is displayed, the key and filters that are attached to the record are used.

FieldNo

Type: Integer

Use this optional parameter to select a specific field on which focus will be put.

Return Value

Action Type: Action Specifies what action the user took on the page.

Page.RunModal Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 3.0.*

Creates, opens, and closes a page that you specify. When a page is run modally, no input, such as a keyboard or mouse click, can occur except for objects on the modal page.

Syntax

```
[Action := ]  Page.RunModal(Number: Integer, Record: Record, FieldRef: FieldRef)
```

Parameters

Number

Type: Integer

The number of the page that you want to run.

Record

Type: Record

By default, this function shows the record that was last displayed on the page. For each object, information is stored about the most recently shown record and the attached key and filters. Use this optional parameter to select a specific record to display on the page. The record must be of the same type as the table that is attached to the page. When the record is displayed, the key and filters that are attached to the record are used.

FieldRef

Type: FieldRef

Use this parameter to select a specific field on which focus will be put.

Return Value

Action Type: Action Specifies what action the user took on the page.

Page.SetBackgroundTaskResult Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 4.0.*

Sets the page background task result as a dictionary. When the task is completed, the OnPageBackgroundCompleted trigger will be invoked on the page with this result dictionary.

Syntax

```
Page.SetBackgroundTaskResult(Results: Dictionary of [Text, Text])
```

Parameters

Results

Type: Dictionary of [Text, Text]

Specifies the dictionary of results for the page background task.

Remarks

You use this method in a page background task codeunit to pass the results of the page background task codeunit to the calling page. Before calling this method, use the Add method to populate the `Results` dictionary with the key-value pairs that you want to pass to calling page's OnPageBackgroundTaskCompleted trigger. The `OnPageBackgroundCompleted` trigger can then handle the results on the calling page, such as updating the record in the UI or database.

Example

The following code is an example of a page background task codeunit that uses the SetBackgroundTaskResult method to set a dictionary of results that will be passed to the calling page. For more details about this example, see Page Background Tasks.

```
codeunit 50100 PBTWaitCodeunit
{
    trigger OnRun()
    var
        Result: Dictionary of [Text, Text];
        StartTime: Time;
        WaitParam: Text;
        WaitTime: Integer;
        EndTime: Time;
    begin
        if not Evaluate(WaitTime, Page.GetBackgroundParameters().Get('Wait')) then
            Error('Could not parse parameter WaitParam');

        StartTime := System.Time();
        Sleep(WaitTime);
        EndTime := System.Time();

        Result.Add('started', Format(StartTime));
        Result.Add('waited', Format(WaitTime));
        Result.Add('finished', Format(EndTime));

        Page.SetBackgroundTaskResult(Result);
    end;
}
```

Page.Activate Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Activates the current page on the client if possible. The data on the page will not be refreshed.

Syntax

```
[Ok := ]  Page.Activate([Refresh: Boolean])
```

Parameters

Page Type: Page An instance of the Page data type.

Refresh

Type: Boolean

If set to **true**, the data on the page will be refreshed.

Return Value

Ok Type: Boolean

See Also

Page Data Type
Getting Started with AL
Developing Extensions

Page.CancelBackgroundTask Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 4.0.*

Attempt to cancel a page background task.

Syntax

```
[Ok := ]  Page.CancelBackgroundTask(TaskId: Integer)
```

Parameters

Page Type: Page An instance of the Page data type.

TaskId
Type: Integer
Specifies the ID of the page background task to cancel. The ID is assigned to the task when it is queued by the EnqueueBackgroundTask method.

Return Value

Ok Type: Boolean **true** if the page background task was marked for cancellation; otherwise **false**.

Example

The following example uses the CancelBackgroundTask method to cancel an existing page background task, based on its task ID.

```
var
  WaitTaskId: Integer;

trigger OnAfterGetRecord()
var
  TaskParameters: Dictionary of [Text, Text];
begin
  if (WaitTaskId > 0) then
    Currpage.CancelBackgroundTask(WaitTaskId);
    TaskParameters.Add('Wait', '1000');
    CurrPage.EnqueueBackgroundTask(WaitTaskId, 50100, TaskParameters, 1000,
PageBackgroundTaskErrorLevel::Warning);
end;
```

Page.Caption Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

The caption shown in the title bar. For example, the default value in English (United States) is the same as the name of the page.

Syntax

```
[Caption := ]  Page.Caption([NewCaption: String])
```

NOTE

This method can be invoked using property access syntax.

Parameters

Page Type: Page An instance of the Page data type.

NewCaption
Type: String
The new caption text.

Return Value

Caption Type: String The text used for the caption.

See Also

Page.Close Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Closes the current page.

Syntax

```
Page.Close()
```

Parameters

Page Type: Page An instance of the Page data type.

See Also

Page Data Type
Getting Started with AL
Developing Extensions

Page.Editable Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Gets or sets the default editability of the page.

Syntax

```
[Editable := ]  Page.Editable([NewEditable: Boolean])
```

NOTE

This method can be invoked using property access syntax.

Parameters

Page Type: Page An instance of the Page data type.

NewEditable

Type: Boolean

The new default editability of the page.

Return Value

Editable Type: Boolean Indicates the editability of the page.

See Also

Page Data Type
Getting Started with AL
Developing Extensions

Page.EnqueueBackgroundTask Method

2/17/2021 • 3 minutes to read • Edit Online

Version: *Available from runtime version 4.0.*

Creates and queues a background task that runs the specified codeunit (without a UI) in a read-only child session of the page session. If the task completes successfully, the **OnPageBackgroundTaskCompleted** trigger is invoked. If an error occurs, the **OnPageBackgroundTaskError** trigger is invoked. If the page is closed before the task completes, or the page record ID on the task changed, the task is cancelled.

Syntax

```
[Ok := ]  Page.EnqueueBackgroundTask(var TaskId: Integer, CodeunitId: Integer [, var Parameters: Dictionary
of [Text, Text]] [, Timeout: Integer] [, ErrorLevel: PageBackgroundTaskErrorLevel])
```

Parameters

Page Type: Page An instance of the Page data type.

TaskId

Type: Integer

Specifies the ID of the new page background task. The ID is assigned to the TaskId variable after the task is queued successfully. This parameter is passed by reference to the method.

CodeunitId

Type: Integer

Specifies the ID of the codeunit to run when the task is started.

Parameters

Type: Dictionary of [Text, Text]

Specifies a collection of keys and values that are passed to the OnRun trigger of the codeunit that runs when the page background task session is started.

Timeout

Type: Integer

Specifies the number of milliseconds that the page background task can run before it is automatically cancelled.

ErrorLevel

Type: PageBackgroundTaskErrorLevel

Specifies the level of error handling on page background task level.

Return Value

Ok Type: Boolean **true** if the page background task is successfully queued for execution; otherwise **false**. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

Remarks

The enqueued page background task stores the record ID of the current page. If the current record ID on the page changes, or the page is closed, the task is canceled. Typically, you call the EnqueueBackgroundTask method from a page trigger. The ID of the current record of the page must remain static after the call is made and while the background task is running. Otherwise, the task will be canceled. For this reason, we recommend that you

don't enqueue the background task from the `OnOpenPage` trigger. Instead, use the `OnAfterGetRecord` or `OnAfterGetCurrRecord` triggers.

The **Child Session Max Concurrency** setting of the Business Central Server controls how many page background tasks can be run simultaneously for a parent session. The setting has a default value of 5. If this number is exceeded, then they'll be queued and run when a slot becomes available as other tasks are finished. Enqueuing the task will fail if the total number of enqueued tasks exceed the **Child Sessions Max Queue Length** server configuration setting. For more information, see Configuring Business Central Server - Asynchronous Processing.

Timeout

When the value of the *Timeout* parameter is exceeded, the background task is canceled and an error with error code ChildSessionTaskTimeout occurs. On the page, the error will appear as a notification.

The Business Central Server instance includes two configuration settings related to the page back ground task timeout: PageBackgroundTaskDefaultTimeout and PageBackgroundTaskMaxTimeout.

- The PageBackgroundTaskDefaultTimeout (which has a default value of 00:02:00) determines the timeout if the *Timeout* parameter isn't given a value.
- The PageBackgroundTaskMaxTimeout specifies the maximum amount of time that a page background task can run. It doesn't matter what the *Timeout* parameter value is. If the *Timeout* value is greater than the PageBackgroundTaskMaxTimeout, which has a default value of 00:10:00, the PageBackgroundTaskMaxTimeout value determines the timeout.

For more information these settings, see Configuring Business Central Server.

It's possible to enqueue the task again in the completion trigger or error trigger, but this pattern isn't recommended as it can lead to an endless loop. For more information, see Page Background Tasks.

Example

The following code extends the **Customer Card** page with a page background task by using the EnqueueBackgroundTask method. For more information about this example, see Page Background Tasks.

```
pageextension 50100 CustomerCardExt extends "Customer Card"
{
    layout
    {
        addlast(General)
        {

            field(Before1; before1)
            {
                ApplicationArea = All;
                Caption = 'Before 1';
                Editable = false;
            }

            field(Duration1; duration1)
            {
                ApplicationArea = All;
                Caption = 'Duration 1';
                Editable = false;
            }

            field(After1; after1)
            {
                ApplicationArea = All;
                Caption = 'After 1';
                Editable = false;
            }
        }
    }

    var
        // Global variable used for the TaskID
        WaitTaskId: Integer;

        // Variables for the three fields on the page
        before1: Text;
        duration1: Text;
        after1: Text;

    trigger OnAfterGetRecord();
    var
        //Defines a variable for passing parameters to the background task
        TaskParameters: Dictionary of [Text, Text];
    begin
        // Adds a key-value pair to the parameters dictionary
        TaskParameters.Add('Wait', '1000');

        //Enqueues the page background task
        CurrPage.EnqueueBackgroundTask(WaitTaskId, 50100, TaskParameters, 10000,
PageBackgroundTaskErrorLevel::Warning);
    end;
```

Page.GetRecord Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Gets the current record of the page.

Syntax

```
Page.GetRecord(var Record: Record)
```

Parameters

Page Type: Page An instance of the Page data type.

Record

Type: Record

The Record variable that will contain the current record associated with the page.

See Also

Page Data Type
Getting Started with AL
Developing Extensions

Page.LookupMode Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Gets or sets the default lookup mode for the page.

Syntax

```
[LookupMode := ]  Page.LookupMode([NewLookupMode: Boolean])
```

> **NOTE**
> This method can be invoked using property access syntax.

Parameters

Page Type: Page An instance of the Page data type.

NewLookupMode
Type: Boolean
The new default lookup mode for the page.

Return Value

LookupMode Type: Boolean The current default lookup mode for the page

See Also

Page Data Type
Getting Started with AL
Developing Extensions

Page.ObjectId Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Returns a string in the "Page xxx" format, where xxx is the caption or ID of the application object.

Syntax

```
String :=   Page.ObjectId([UseNames: Boolean])
```

Parameters

Page Type: Page An instance of the Page data type.

UseNames
Type: Boolean
If **true**, the page caption is returned, else the page ID as text.

Return Value

String Type: String The text of the object

Example

If you add the following code to a page method or trigger, then the returned string is displayed in a message window.

```
Message(CurrPage.ObjectId(true));
```

Developing Extensions

Page.Run Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Creates and launches a page that you specify. You can use Clear method to remove the page.

Syntax

```
Page.Run()
```

Parameters

Page Type: Page An instance of the Page data type.

Remarks

If, at design time, you do not know the specific page you want to run, then use this method or the Page.RunModal Method and specify the page in the *Number* parameter.

If you do know which page you want to run, then you can create a Page variable, set the subtype of the variable to a specific page, and then use the Run Method (Page) or RunModal Method (Page) on the Page variable.

When you want to close the page, use CurrPage.Close. CurrPage is a predefined system variable.

Example

```
Page.Run(4711)
```

See Also

Page Data Type
Getting Started with AL
Developing Extensions

Page.RunModal Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Creates, opens, and closes a page that you specify. When a page is run modally, no input, such as a keyboard or mouse click, can occur except for objects on the modal page.

Syntax

```
[Action := ]  Page.RunModal()
```

Parameters

Page Type: Page An instance of the Page data type.

Return Value

Action Type: Action Specifies what action the user took on the page.

Specifies what action the user took on the page. The following table shows the possible return values for the different user actions.

RETURN VALUE	DESCRIPTION
OK	To close the page window, the user does one of the following: - Chooses the **Close** button. - Chooses the **X** button when there is no **Cancel** button on the window.
Cancel	To close the page window, the user does one of the following: - Chooses the **Cancel** button. - Chooses the **X** button when there is a **Cancel** button on the window.
LookupOK	To close a lookup window, the user chooses the **OK** button.
LookupCancel	To close a lookup window, the user chooses the **Cancel** button.
Yes	To close a confirmation window, the user selects **Yes**.
No	To close a confirmation window, the user does one of the following: - Chooses the **No** button. - Chooses the **X** button.

RETURN VALUE	DESCRIPTION
RunObject	The user selected an option that ran another object.
RunSystem	The user selected an option that ran an external program.

Remarks

If you know the specific page that you want to run when you are designing your application, then you can create a Page variable, set the Subtype of the variable to a specific page, and then use this method or the Run Method (Page).

If you do not know the specific page that you want to run, then use the Run Method (Page) or the **RunModal Method (Page)** and specify the page in the *Number* parameter.

After you define the page variable, you can use it before and after you run the page. If you use the Run Method (Page), then you can only use the variable before you run the page.

Example

This example shows how to use this method. Assume that the *SomePage* variable has been defined as `Page 1`.

```
Clear(SomePage);
SomePage.XXX; // Any user-defined method
SomePage.SetTableView(MyRecord);
SomePage.SetRecord(MyRecord);
if SomePage.RunModal = Action::LookupOK then
  SomePage.GetRecord(MyRecord)...
```

NOTE

This code example includes the Clear Method to make sure that the variable has been cleared.

Page.SaveRecord Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Saves the current record as if performed by the client. If the record does not exist it is inserted, otherwise it is modified.

Syntax

```
Page.SaveRecord()
```

Parameters

Page Type: Page An instance of the Page data type.

See Also

Page Data Type
Getting Started with AL
Developing Extensions

Page.SetRecord Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Sets the current record for the page.

Syntax

```
Page.SetRecord(var Record: Record)
```

Parameters

Page Type: Page An instance of the Page data type.

Record
Type: Record
The record to set as the current record. You cannot use a temporary record for the Record parameter.

Remarks

You can use this method to set the record to display when the user opens the page.

Example

The following example retrieves the record that has a primary key value of '30000' from the Customer table. If the record is found, it is stored in the MyRecord variable. The **SetRecord** method uses the retrieved record as the current record and sets record for MyPage, which is a Customer Card page. When the code unit is run, the record is displayed on the MyPage page. If the record is not found, a message box displays a message that indicates that the record was not found.

```
 var
    MyPage: Page "Customer Card";
    MyRecord: Record Customer;
    Text000: Label 'The record was not found';
begin
    if MyRecord.Get('30000') then begin
      MyPage.SetRecord(MyRecord);
      MyPage.Run;
    end else begin
      Message(Text000);
    end;
end;
```

Page.SetSelectionFilter Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Notes the records that the user has selected on the page, marks those records in the table specified, and sets the filter to "marked only".

Syntax

```
Page.SetSelectionFilter(var Record: Record)
```

Parameters

Page Type: Page An instance of the Page data type.

Record
Type: Record

Remarks

If all records are selected, marks will not be used.

If only the current record is selected on the page, then SetSelectionFilter does the following:

- Sets the current filter group to `0` on the destination record
- Adds filters on the primary key fields that point to the current record of the page

If more than one record is selected on the page, then SetSelectionFilter does the following:

- Copies the current key from the page source table to the destination record
- Copies the current sort order from the table to the destination record
- Copies the current filters that are set in all filter groups
- Copies the current filter group
- Marks the selected records and sets the "marked only" filter

Page.SetTableView Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Applies the table view on the current record as the table view for the page, report, or XmlPort.

Syntax

```
Page.SetTableView(var Record: Record)
```

Parameters

Page Type: Page An instance of the Page data type.

Record

Type: Record

The record that has a table view that you want to apply to the page or data item.

Remarks

The table view is the view of the table that you present to the user. You determine what records that the user can see by setting filters, determining the sorting order, and selecting the keys.

This method only narrows the view of the table that was set through the SourceTableView Property of the page or through the DataItemTableView Property of the data item.

> **IMPORTANT**
>
> SetTableView is not supported for setting views on subpages from code on table headers. For example, you cannot set a table view on the SalesOrder subpage from the SalesHeader.

Example

This example is based on the Sales Header table and shows how SetTableView is used for a page object.

```
 var
    SalesHeader: Record "Sales Header";
    SomePage: Page "Sales List";
begin
    SalesHeader.SetCurrentKey("Document Type");
    SalesHeader.SetRange("Document Type",SalesHeader."Document Type"::Order);
    SomePage.SetTableView(SalesHeader); // Only view sales orders.
    SomePage.Run;
end;
```

The page that is reference by the SomePage variable can be any page object that has Sales Header as the value of the SourceTable Property.

Page.Update Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Saves the current record and then updates the controls on the page. If you set the SaveRecord parameter to false, this method will not save the record before the page is updated.

Syntax

```
Page.Update([SaveRecord: Boolean])
```

Parameters

Page Type: Page An instance of the Page data type.

SaveRecord
Type: Boolean
Set this parameter to true if you want to save the current record. Set this parameter to false if you want to update without saving the current record.

Remarks

The `SaveRecord` default value is true. The default value of SaveRecord, however, depends on whether SourceTable is specified or not. If SourceTable is not defined (== null), then the default value is `false`. If SourceTable is specified then the default value is `true`.

ProductName Data Type

2/17/2021 • 2 minutes to read • Edit Online

> **Version**: *Available from runtime version 1.0.*

An application can have a full name, marketing name, and short name. The PRODUCTNAME functions enable you to retrieve these name variations.

The following methods are available on the ProductName data type.

METHOD NAME	DESCRIPTION
Full()	FULL returns a text string that contains the application's full name.
Marketing()	MARKETING returns a text string that contains the application's marketing name.
Short()	SHORT returns a text string that contains the application's short name.

Remarks

You define the different name variations for an application in the `navsettings.json` configuration file. For more information, see Configuring Business Central Web Server Instances.

See Also

Getting Started with AL
Developing Extensions

ProductName.Full Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

FULL returns a text string that contains the application's full name.

Syntax

```
ProductName :=   ProductName.Full()
```

Return Value

ProductName Type: String Text of the product's full name.

Remarks

This method is useful when you have to include the application name in UI text. Instead of using static text for the name, you use one of the PRODUCTNAME methods. This lets you reuse the same text string across different applications, and makes it easier if the application is ever renamed.

You define the different name variations for an application in the `navsettings.json` configuration file. For more information, see Configuring Business Central Web Server Instances.

ProductName.Marketing Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

MARKETING returns a text string that contains the application's marketing name.

Syntax

```
ProductNameMarketing :=   ProductName.Marketing()
```

Return Value

ProductNameMarketing Type: String Text of the product's marketing name.

Remarks

This method is useful when you have to include the application name in UI text. Instead of using static text for the name, you use one of the ProductName methods. This lets you reuse the same text string across different applications, and makes it easier if the application is ever renamed.

You define the different name variations for an application in the `navsettings.json` configuration file. For more information, see Configuring Business Central Web Server Instances.

ProductName.Short Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

SHORT returns a text string that contains the application's short name.

Syntax

```
ProductNameShort :=   ProductName.Short()
```

Return Value

ProductNameShort Type: String Text of the product's short name.

Remarks

This method is useful when you have to include the application name in UI text. Instead of using static text for the name, you use one of the ProductName methods. This lets you reuse the same text string across different applications, and makes it easier if the application is ever renamed.

You define the different name variations for an application in the `navsettings.json` configuration file. For more information, see Configuring Business Central Web Server Instances.

Query Data Type

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Enables you to retrieve data from multiple tables and combine the data in single dataset.

The following methods are available on the Query data type.

METHOD NAME	DESCRIPTION
SaveAsCsv(Integer, String [, Integer] [, String])	Saves the resulting data set of a query as a comma-separated values (CSV) file.
SaveAsCsv(Integer, OutStream [, Integer] [, String])	Saves the resulting data set of a query as a comma separated values (CSV) file.
SaveAsXml(Integer, String)	Saves the resulting data set of a query as an .xml file.
SaveAsXml(Integer, OutStream)	Saves the resulting data set of a query as an .xml file.

The following methods are available on instances of the Query data type.

METHOD NAME	DESCRIPTION
Close()	Closes a query data set and returns the query instance to the initialized state. The following code shows the syntax of the Close method. Query is a variable of the Query data type that specifies the query object.
ColumnCaption(Any)	Returns the current caption of a query column as a text string.
ColumnName(Any)	Returns the name of a query column as a text string.
ColumnNo(Any)	Returns the ID that is assigned to a query column in the query definition.
GetFilter(Any)	Returns the filters that are set on the field of a specified column in the query. The following code shows the syntax of the GetFilter method. Query is a variable of the Query data type that specifies the query object.
GetFilters()	Returns the filters that are applied to all columns in the query. The following code shows the syntax of the GetFilterS method. Query is a variable of the Query data type that specifies the query object.
Open()	Runs a query object and generates a data set that can be read. The following code shows the syntax of the Open method. Query is a variable of the Query data type that specifies the query object.

METHOD NAME	DESCRIPTION
Read()	Reads data from a row in the resulting data set of a query.
SaveAsCsv(String [, Integer] [, String])	Saves the resulting data set of a query as comma separated values (CSV)
SaveAsCsv(OutStream [, Integer] [, String])	Saves the resulting data set of a query as comma separated values (CSV)
SaveAsXml(String)	Saves the resulting data set of a query as XML
SaveAsXml(OutStream)	Saves the resulting data set of a query as XML
SecurityFiltering([SecurityFilter])	Gets or sets how security filters are applied to the query.
SetFilter(Any, String [, Any,...])	Sets a filter on a column of a query to limit the records in the resulting data set of a query.
SetRange(Any [, Any] [, Any])	Sets a filter on a range of values on a column of a query data set.
TopNumberOfRows([Integer])	Specifies the maximum number of rows to include in the resulting data set of a query.

Query.SaveAsCsv Method

2/17/2021 • 3 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Saves the resulting data set of a query as a comma-separated values (CSV) file.

> **NOTE**
> This method is supported only in Business Central on-premises.

Syntax

```
[Ok := ]  Query.SaveAsCsv(Number: Integer, FileName: String [, Format: Integer] [, FormatArgument: String])
```

Parameters

Number
Type: Integer
The ID of the query object. If the query that you specify does not exist, then a run-time error occurs.

FileName
Type: String
The path and name of the file that you want to save the query data set to.

Format
Type: Integer
Specifies whether the columns of the resulting data set are at fixed positions in the CSV file or separated only by a delimiter.

FormatArgument
Type: String
You set the FormatArgument parameter based on the setting of the Format parameter. If the Format parameter is set to 0, then the FormatArgument parameter specifies the starting position of each column in the data set. The value is a comma separated string of integers that includes an integer for every column. In a CSV file, each line is evenly divided into positions for holding characters. The first integer corresponds to the starting position of the first column, the second integer corresponds to the starting position of the second column, and so on.

Return Value

Ok Type: Boolean **true** if the operation was successful; otherwise **false**. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

Remarks

A CSV file stores data in a plain text format. When you save a query dataset as a CSV file, each row of the dataset is stored on a separate line in the file, and each column in a row is separated by a comma or another delimiter of your choice. The first line of the file will contain the column names of the query. A query column

name is specified by its Name Property.

When the **SaveAsCSV** method is called the query dataset is generated and then saved in CSV format to the file that is designated by the *FileName* parameter.

To apply filters with the **SetFilter** and **SetRange** methods, the SaveAsCSV method must be called after **SetFilter** and **SetRange** methods, as shown in the following example.

```
// Sets a filter on the Quantity column of the query
Query.SetFilter(Quantity, '>50');

// Opens a new query that is filtered by the SetFilter method and saves the dataset
Query.SaveAsCSV('c:\test.csv');
```

The **SaveAsCSV** method can be called at any place in the code and does not require that the **Close**, **Open** or **Read** methods are called before it. When the **SaveAsCSV** method is called, a new instance of the query is created. The query is implicitly opened, read, and closed. If there is currently a dataset in the opened state when the **SaveAsCSV** method is called, then that instance is closed. This means that the following code is illegal because the query is not open on the second **Read** call.

```
Query.Open;
Query.Read;
Query.SaveAsCSV('c:\test.csv');
Query.Read;
```

The correct code for this example is as follows.

```
Query.Open;
Query.Read;
Query.SaveAsCSV('c:\test.csv');
Query.Open;
Query.Read;
```

Example

The following example shows how to save the dataset of a query with the name **My Customers Query** as a CSV file. The file is given the name **mycustomers.csv** and is saved on the c: drive of the computer running Dynamics 365 Business Central service. The query consists of three columns: No., Name, and City. The file is set to place the columns at the following positions: 1, 10, and 40.

This example requires that you create a query called **My Customer Query** that is based on table **18 Customer** and contains the **No**, **Name**, and **City** columns.

```
var
  MyCustomerQuery: Query "My Customer Query";
  OK: Boolean;
  Text000: Label 'Query was not saved.';
begin
    OK := MyCustomerQuery.SaveAsCSV('c:\mycustomers.csv', 0, '1,10,40');
    if not OK then
      Error(Text000);
end;
```

The following code shows an example of the content of the saved file.

```
No       Name                          City
01121212 Spotsmeyer's Furnishings      Miami
01445544 Progressive Home Furnishings  Chicago
01454545 New Concepts Furniture        Atlanta
01905893 Candoxy Canada Inc.           Thunder Bay
01905899 Elkhorn Airport               Elkhorn
01905902 London Candoxy Storage Campus London
```

If for some reason the file cannot be saved, then the message **Query was not saved.** appears.

Query.SaveAsCsv Method

2/17/2021 • 3 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Saves the resulting data set of a query as a comma separated values (CSV) file.

Syntax

```
[Ok := ]  Query.SaveAsCsv(Number: Integer, OutStream: OutStream [, Format: Integer] [, FormatArgument:
String])
```

Parameters

Number

Type: Integer

The ID of the query object. If the query that you specify does not exist, then a run-time error occurs.

OutStream

Type: OutStream

The stream that you want to save the query as CSV to.

Format

Type: Integer

Specifies whether the columns of the resulting data set are at fixed positions in the CSV file or separated only by a delimiter.

FormatArgument

Type: String

You set the FormatArgument parameter based on the setting of the Format parameter. If the Format parameter is set to 0, then the FormatArgument parameter specifies the starting position of each column in the data set. The value is a comma separated string of integers that includes an integer for every column. In a CSV file, each line is evenly divided into positions for holding characters. The first integer corresponds to the starting position of the first column, the second integer corresponds to the starting position of the second column, and so on.

Return Value

Ok Type: Boolean **true** if the operation was successful; otherwise **false**. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

Remarks

A CSV file stores data in a plain text format. When you save a query dataset as a CSV file, each row of the dataset is stored on a separate line in the file, and each column in a row is separated by a comma or another delimiter of your choice. The first line of the file will contain the column names of the query. A query column name is specified by its Name Property.

When the **SaveAsCSV** method is called the query dataset is generated and then saved in CSV format to the file that is designated by the *FileName* parameter.

To apply filters with the **SetFilter** and **SetRange** methods, the SaveAsCSV method must be called after **SetFilter** and **SetRange** methods, as shown in the following example.

```
// Sets a filter on the Quantity column of the query
Query.SetFilter(Quantity, '>50');

// Opens a new query that is filtered by the SetFilter method and saves the dataset
Query.SaveAsCSV('c:\test.csv');
```

The **SaveAsCSV** method can be called at any place in the code and does not require that the **Close**, **Open** or **Read** methods are called before it. When the **SaveAsCSV** method is called, a new instance of the query is created. The query is implicitly opened, read, and closed. If there is currently a dataset in the opened state when the **SaveAsCSV** method is called, then that instance is closed. This means that the following code is illegal because the query is not open on the second **Read** call.

```
Query.Open;
Query.Read;
Query.SaveAsCSV('c:\test.csv');
Query.Read;
```

The correct code for this example is as follows.

```
Query.Open;
Query.Read;
Query.SaveAsCSV('c:\test.csv');
Query.Open;
Query.Read;
```

Example

The following example shows how to save the dataset of a query with the name **My Customers Query** as a CSV file. The file is given the name **mycustomers.csv** and is saved on the c: drive of the computer running Dynamics 365 Business Central service. The query consists of three columns: No., Name, and City. The file is set to place the columns at the following positions: 1, 10, and 40.

This example requires that you create a query called **My Customer Query** that is based on table **18 Customer** and contains the **No**, **Name**, and **City** columns.

```
  var
    MyCustomerQuery: Query "My Customer Query";
    OK: Boolean;
    Text000: Label 'Query was not saved.';
begin
    OK := MyCustomerQuery.SaveAsCSV('c:\mycustomers.csv', 0, '1,10,40');
    if not OK then
          Error(Text000);
end;
```

The following code shows an example of the content of the saved file.

```
No       Name                          City
01121212 Spotsmeyer's Furnishings      Miami
01445544 Progressive Home Furnishings  Chicago
01454545 New Concepts Furniture        Atlanta
01905893 Candoxy Canada Inc.           Thunder Bay
01905899 Elkhorn Airport               Elkhorn
01905902 London Candoxy Storage Campus London
```

If for some reason the file cannot be saved, then the message **Query was not saved.** appears.

Query.SaveAsXml Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Saves the resulting data set of a query as an .xml file.

> **NOTE**
> This method is supported only in Business Central on-premises.

Syntax

```
[Ok := ]  Query.SaveAsXml(Number: Integer, FileName: String)
```

Parameters

Number
Type: Integer
The ID of the query object that you want to save as an .xml file. If the query that you specify does not exist, then a run-time error occurs.

FileName
Type: String
The path and name of the file that you want to save the query to.

Return Value

Ok Type: Boolean **true** if the operation was successful; otherwise **false**. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

Remarks

When the **SaveAsXML** method is called, the dataset is generated and then saved in XML format in the file and location that is designated by the *FileName* parameter.

The **SaveAsXML** method can be called at any place in the code and does not require that the **Close**, **Open**, or **Read** methods are called before it. When the **SaveAsXML** method is called, a new instance of the query is created. The query is implicitly opened, read, and closed. If there is currently a dataset in the opened state when the **SaveAsXML** method is called, then that instance is closed. This means that the following code is unauthorized because the query is not open on the second **Read** call.

```
Query.Open;
Query.Read;
Query.SaveAsXML('c:\test.xml');
Query.Read;
```

The correct code for this example is as follows.

```
Query.Open;
Query.Read;
Query.SaveAsXML('c:\test.xml');
Query.Open;
Query.Read;
```

Example

The following example shows how to save a query with the name **My Customer Query** as an .xml file. The file is given the name **myquery.xml** and is saved on the c: drive of the computer running Dynamics 365 Business Central service.

```
var
    MyCustomerQuery: Query "My Customer Query";
    OK: Boolean;
    Text000: Label 'Query was not saved.';
begin
    OK := MyCustomerQuery.SaveAsXML('c:\myquery.xml');
    if not OK then
      Error(Text000);
end;
```

If the file cannot be saved, then the follow message appears:

Query not saved.

Query.SaveAsXml Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Saves the resulting data set of a query as an .xml file.

Syntax

```
[Ok := ]  Query.SaveAsXml(Number: Integer, OutStream: OutStream)
```

Parameters

Number

Type: Integer

The ID of the query object that you want to save as an .xml file. If the query that you specify does not exist, then a run-time error occurs.

OutStream

Type: OutStream

The stream that you want to save the query as XML to.

Return Value

Ok Type: Boolean **true** if the operation was successful; otherwise **false**. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

Remarks

When the **SaveAsXML** method is called, the dataset is generated and then saved in XML format in the file and location that is designated by the *FileName* parameter.

The **SaveAsXML** method can be called at any place in the code and does not require that the **Close**, **Open**, or **Read** methods are called before it. When the **SaveAsXML** method is called, a new instance of the query is created. The query is implicitly opened, read, and closed. If there is currently a dataset in the opened state when the **SaveAsXML** method is called, then that instance is closed. This means that the following code is unauthorized because the query is not open on the second **Read** call.

```
Query.Open;
Query.Read;
Query.SaveAsXML('c:\test.xml');
Query.Read;
```

The correct code for this example is as follows.

```
Query.Open;
Query.Read;
Query.SaveAsXML('c:\test.xml');
Query.Open;
Query.Read;
```

Example

The following example shows how to save a query with the name **My Customer Query** as an .xml file. The file is given the name **myquery.xml** and is saved on the c: drive of the computer running Dynamics 365 Business Central service.

```
var
    MyCustomerQuery: Query "My Customer Query";
    OK: Boolean;
    Text000: Label 'Query was not saved.';
begin
    OK := MyCustomerQuery.SaveAsXML('c:\myquery.xml');
    if not OK then
          Error(Text000);
end;
```

If the file cannot be saved, then the follow message appears:

Query not saved.

Query.Close Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Closes a query data set and returns the query instance to the initialized state. The following code shows the syntax of the Close method. Query is a variable of the Query data type that specifies the query object.

Syntax

```
Query.Close()
```

Parameters

Query Type: Query An instance of the Query data type.

Remarks

The **Close** method does not clear any filters that are set by the SetFilterS method. If you want to clear the filters, then you must call the Clear method.

In most cases, you do not have to call the **Close** method explicitly. The **Close** method is called implicitly when the following conditions are true:

- When the query variable goes out of scope.
- When the **Open** method is called on a dataset that is currently open.
- When the SetFilter Method (Query) or SetRange Method (Query) are called on a dataset that is currently open.

Example

The following example demonstrates how to use the **Close** method on a query. The example code sets filters on the query, opens the query, and then reads the dataset. For each row in the dataset, a message box is displayed that contains the values of the columns in the row.

This example requires that you create a query called **Customer_SalesQuantity** that is links table **18 Customer** with table **37 Sales Lines** from the CRONUS International Ltd. demonstration database. Include columns for the **Name** and **No.** fields from the Customer table and the **Quantity** field from Sales Lines table.

The following AL code opens the query, reads each row of the dataset, and then closes the query. You can add the code to a codeunit, and then run the codeunit to see the results.

```
var
  MyQuery: Query "Customer SalesQuantity";
  Text000: Label 'Customer name = %1, Quantity = %2';
begin
    // Sets a filter to display only sales quantities greater than 20.
    MyQuery.SetFilter(Quantity, '>20');
    // Runs the query.
    MyQuery.Open;
    // Reads each row in the dataset and displays a message with column values.
    // Stops reading when there are no more rows remaining in the dataset (Read is False).
    while MyQuery.Read do
    begin
      Message(Text000, MyQuery.Name, MyQuery.Quantity);
    end;
    MyQuery.Close;
end;
```

Query.ColumnCaption Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Returns the current caption of a query column as a text string.

Syntax

```
Caption :=   Query.ColumnCaption(Column: Any)
```

Parameters

Query Type: Query An instance of the Query data type.

Column
Type: Any
Refers to the name of the query column. The name of a query column is specified by the Name Property.

Return Value

Caption Type: String The query column caption.

See Also

Query Data Type

Query.ColumnName Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Returns the name of a query column as a text string.

Syntax

```
Name :=   Query.ColumnName(Column: Any)
```

Parameters

Query Type: Query An instance of the Query data type.

Column
Type: Any
Refers to the name of the query column. The name of a query column is specified by the Name Property.

Return Value

Name Type: String The query column name.

See Also

Query Data Type
Getting Started with AL
Developing Extensions

Query.ColumnNo Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Returns the ID that is assigned to a query column in the query definition.

Syntax

```
Number :=   Query.ColumnNo(Column: Any)
```

Parameters

Query Type: Query An instance of the Query data type.

Column
Type: Any
Refers to the name of the query column. The name of a query column is specified by the Name Property.

Return Value

Number Type: Integer The ID of the query column.

See Also

Query Data Type
Getting Started with AL
Developing Extensions

Query.GetFilter Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Returns the filters that are set on the field of a specified column in the query. The following code shows the syntax of the GetFilter method. Query is a variable of the Query data type that specifies the query object.

Syntax

```
Filter :=   Query.GetFilter(Column: Any)
```

Parameters

Query Type: Query An instance of the Query data type.

Column
Type: Any
The name of the column in the query. A column name is defined by the Name Property.

Return Value

Filter Type: String The filters of the column.

Remarks

The **GetFilter** method returns the filters that are currently set for a data column or filter row by the SetFilter Method (Query) method, SetRange Method (Query) method, and the column's ColumnFilter Property. The **GetFilter** method does not return filters that are set on a column's source field by the DataItemTableFilter Property or global filters that are set by the **FilterGroup** method.

You can call the **GetFilter** method multiple times and at any point in the code. If you call the **GetFilter** method before the **SetFilter** or **SetRange** method, then the **GetFilter** method returns only filters on the column that are set by the column's ColumnFilter property.

Filters that are set by the **SetFilter** method and **SetRange** method are applied to a query when the query is opened with a call to the **Open**, **SaveAsXML**, or **SaveAsCSV** methods. You must consider the location of the **GetFilterS** method with respect to these methods to obtain the desired results. For example, in the following two code examples, the **GetFilter** method will return the filter that is set by the **SetFilter** method. However, in the first example, the filter has been applied to the query dataset; in the second example, the filter has not been applied.

```
Query.SetFilter(Column, String);
Query.Open;
Query.GetFilter(Column);
Query.Read;
```

```
Query.Open;
Query.SetFilter(Column, String);
Query.GetFilter(Column);
Query.Read;
```

Example

The following AL code example demonstrates how to use the **GetFilter** method on a query. The example code sets a filter on a query column, and then displays a message when the query is run that indicates the filter on the column.

This example requires that you create a query called **Customer_SalesQuantity** that has the following characteristics:

- Links table **18 Customer** with table **37 Sales Lines** from the CRONUS International Ltd. demonstration database.
- Includes columns for the **Name** and **No.** fields from the **Customer** table and the **Quantity** field from **Sales Lines** table.
- The ColumnFilter property of the **Quantity** column is set to include values greater than 5.

The following AL code runs the query and displays a message that contains the filter that is set on a query column. You can add the code to a codeunit, and then run the codeunit to see the results.

```
var
    MyQuery: Query "Customer SalesQuantity";
    MyFilter: Text;
    Text000: Label 'The filter is: %1';
begin
    // Sets a filter to display only sales quantities greater than 10. This overwrites the ColumnFilter
property.
    MyQuery.SetFilter(Quantity, '>10');
    // Runs the query and applies the filter.
    MyQuery.Open;
    // Returns the filter on the Quantity column and displays the filter in a message.
    MyFilter := MyQuery.GetFilter(Quantity);
    Message(Text000, MyFilter);
end;
```

Running the code returns the following message:

The filter is: Quantity > 10

Query.GetFilters Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Returns the filters that are applied to all columns in the query. The following code shows the syntax of the GetFilterS method. Query is a variable of the Query data type that specifies the query object.

Syntax

```
Filter :=   Query.GetFilters()
```

NOTE

This method can be invoked using property access syntax.

Parameters

Query Type: Query An instance of the Query data type.

Return Value

Filter Type: String All filters of the query

Remarks

The **GetFilterS** method returns the filters that are currently set for all data columns and filter rows by the SetFilter Method (Query) method, SetRange Method (Query)method, and the ColumnFilter Property. The **GetFilter** method does not return filters that are set on a column's source field by the DataItemTableFilter Property or global filters that are set by the **FilterGroup** method.

You can call the **GetFilterS** method multiple times and at any point in the code. If you call the **GetFilterS** method before the first **SetFilter** or **SetRange** method call, then the **GetFilterS** method returns only filters that are set by the **ColumnFilter** property of the columns.

Filters that are set by the **SetFilter** method and **SetRange** method are applied to a query when the query is opened by using a call to the **Open**, the **SaveAsXML**, or **SaveAsCSV** methods. You must consider the location of the **GetFilterS** method with respect to these methods to obtain the results that you want. For example, in the following two code examples, the **GetFilterS** method will return the filter set by the **SetFilter** method call. However, in the first example, the filter has been applied to the query dataset; in the second example, the filter has not been applied.

```
Query.SetFilter(Column, String);
Query.Open;
Query.GetFilterS;
Query.Read;
```

```
Query.Open;
Query.SetFilter(Column, String);
Query.GetFilterS;
Query.Read;
```

Example

The following AL code example demonstrates how to use the **GetFilterS** method on a query. The example code sets filters on a query column, and then displays a message when the query is run that indicates the filter on the column.

This example requires that you create a query called **Customer_SalesQuantity** that has the following characteristics:

- Links table **18 Customer** with table **37 Sales Lines** from the CRONUS International Ltd. demonstration database.
- Includes columns for the **Name** and **No.** fields from the **Customer** table and the **Quantity** field from **Sales Lines** table.
- The **ColumnFilter** property of the **Quantity** column is set with a filter that includes values greater than 10.

The following AL code runs the query and displays a message that contains the filter that is set on a query column. You can add the code to the OnRun trigger of a codeunit, and then run the codeunit to see the results.

```
var
    MyQuery: Query "Customer SalesQuantity";
    MyFilter: Text;
    Text000: Label 'The filters are as follows: %1';
begin
    // Sets a filter to display only sales quantities greater than 10. This overwrites the value of
ColumnFilter property.
    MyQuery.SetFilter(Quantity, '>10');
    // Sets a filter to display the columns with the value Selangorian Ltd. only.
    MyQuery.SetFilter(Name, 'Selangorian Ltd.');
    // Runs the query and applies the filter.
    MyQuery.Open;
    // Returns the filters that are on the Quantity column and displays the filters in a message.
    MyFilters := MyQuery.GetFilterS;
    Message(Text000, MyFilters);
end;
```

Running the code returns the following message:

The filters are as follows: Quantity > 10, Name = Selangorian Ltd.

Query.Open Method

2/17/2021 • 3 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Runs a query object and generates a data set that can be read. The following code shows the syntax of the Open method. Query is a variable of the Query data type that specifies the query object.

Syntax

```
[Ok := ]  Query.Open()
```

Parameters

Query Type: Query An instance of the Query data type.

Return Value

Ok Type: Boolean **true** if the operation was successful; otherwise **false**. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

Remarks

When the **Open** method is called, the query is executed and the *Query* variable is put in a state in which the resulting dataset can be read by the **Read** method. The **Open** method has the following behavior:

- To apply filters for the **SetFilterS** method or **SetRange** method, you call the **SetFilterS** method or **SetRange** method before the **Open** method.
- To read a row from the dataset, you must call the **Open** method before the **Read** method, as shown in the following code example.

  ```
  Query.SetFilter(Column1, String);
  Query.Open;
  Query.Read;
  ```

- To close an open query and return it to the initialized state, you can call the **Close** method. However, you can call the **Open** method multiple times without calling the **Close** method because the **Open** method implicitly calls the **Close** method if the query dataset is currently in an opened state.
- If the **Open** method is called on a query that is already in the opened or in the reading state, then the query dataset is closed, and then the query is executed again. To continue to loop through the dataset, the **Read** method must be called again. The next **Read** method call returns the first row in the dataset, as shown in the following code example.

```
// Opens the query and generates a dataset.
Query.Open;
Query.Read;
// Closes the query and reopens it.
Query.Open;
// Reads the first row in the new dataset.
Query.Read;
```

- **Open** method does not clear any filters that were set by the **SetFilter** or **SetRange** methods on a previous **Open** call. If you want to clear the filters, then you must call the **Clear** method on the query variable.

```
Query.SetFilter(Column1, String);
Query.Open;
Query.Read;
Clear(query);
Query.Open;
Query.Read;
```

- You are required to call the **Open** method before the SaveAsXML Method or SaveAsCSV Method. The **SaveAsXML** and **SaveAsCSV** methods automatically close the current query dataset and initialize a new instance of the query.

Example

The following example demonstrates how to use the **Open** method on a query. The example code sets filters on the query, opens the query, and then reads the dataset. For each row in the dataset, a message box is displayed that contains the values of the columns in the row.

This example requires that you create a query called **Customer_SalesQuantity** that links table **18 Customer** with table **37 Sales Lines** from the CRONUS International Ltd. demonstration database. Include columns for the **Name** and **No.** fields from the Customer table and the **Quantity** field from Sales Lines table.

The following AL code opens the query, reads each row of the dataset, and then displays a message that uses the content of the row. You can add the code to a codeunit, and then run the codeunit to see the results.

```
var
    MyQuery: Query "Customer SalesQuantity";
    Text000: Label 'Customer name = %1, Quantity = %2';
begin
    // Sets a filter to display only sales quantities greater than 20.
    MyQuery.SetFilter(Quantity, '>20');
    // Runs the query.
    MyQuery.Open;
    // Reads each row in the dataset and displays a message with column values.
    // Stops reading when there are no more rows remaining in the dataset (Read is False).
    while MyQuery.Read do
    begin
      Message(Text000, MyQuery.Name, MyQuery.Quantity);
    end;
    MyQuery.Close;
end;
```

When the code is run, a message that resembles the following appears for each row in the dataset:

Customer name = The Device Shop, Quantity = 30

Query.Read Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Reads data from a row in the resulting data set of a query.

Syntax

```
[Ok := ]  Query.Read()
```

Parameters

Query Type: Query An instance of the Query data type.

Return Value

Ok Type: Boolean **true** if the operation was successful; otherwise **false**. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

Remarks

When the **Read** method is called, the next row in the dataset query is retrieved. While in the reading state, values of columns in the row can be accessed by calling *Query.ColumnName*, where *Query* is the query type variable that specifies the query object and *ColumnName* is the column of the query.

To read a row in the dataset, you must call the **Open** method before the **Read** method. After the **Read** method call, columns can be accessed as shown in the following code example.

```
query.Open;
query.Read;
query.ColumnName
```

You can call the **Read** method multiple times after the **Open** method to read consecutive rows in the dataset. The first **Read** method call retrieves the first row from the resulting dataset and each subsequent **Read** method retrieves the next row from the dataset. For example, the second **Read** method call retrieves the second row, the third **Read** method call retrieves the third row, and so on.

```
Query.Open;
// Reads the first row in the dataset.
Query.Read;
// Accesses a column in the first row of the dataset.
Query.ColumnName
// Reads the second row in the dataset.
Query.Read;
// Accesses a column in the first row of the dataset.
Query.ColumnName
```

> **NOTE**
>
> If the **Read** method is called and there are no more rows in the dataset, then the **Read** method returns **false**.

Example

The following example demonstrates how to use the **Read** method on a query. The example code sets filters on the query, opens the query, and then reads the dataset. For each row in the dataset, a message box is displayed that contains the values of the columns in the row.

This example requires that you create a query called **Customer_SalesQuantity** that is links table **18 Customer** with table **37 Sales Lines** from the CRONUS International Ltd. demonstration database. Include columns for the **Name** and **No.** fields from the Customer table and the **Quantity** field from Sales Lines table.

The following AL code opens the query, reads each row of dataset, and then displays a message that has the content of the row. You can add the code to a codeunit, and then run the codeunit to see the results.

```
var
  MyQuery: Query "Customer SalesQuantity";
  Text000: Label 'Customer name = %1, Quantity = %2';
begin
    // Sets a filter to display only sales quantities greater than 20.
    MyQuery.SetFilter(Quantity, '>20');
    // Runs the query.
    MyQuery.Open;
    // Reads each row in the dataset and displays message with column values.
    // Stops reading when there are no more rows remaining in the dataset (Read is False).
    while MyQuery.Read do
    begin
      Message(Text000, MyQuery.Name, MyQuery.Quantity);
    end;
    // Closes the query.
    MyQuery.Close;
end;
```

Query.SaveAsCsv Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Saves the resulting data set of a query as comma separated values (CSV)

> **NOTE**
> This method is supported only in Business Central on-premises.

Syntax

```
[Ok := ]  Query.SaveAsCsv(FileName: String [, Format: Integer] [, FormatArgument: String])
```

Parameters

Query Type: Query An instance of the Query data type.

FileName
Type: String
The path and name of the file that you want to save the query to.

Format
Type: Integer
Specifies whether the columns of the resulting data set are at fixed positions in the CSV file or separated only by a delimiter.

FormatArgument
Type: String
You set the FormatArgument parameter based on the setting of the Format parameter. If the Format parameter is set to 0, then the FormatArgument parameter specifies the starting position of each column in the data set. The value is a comma separated string of integers that includes an integer for every column. In a CSV file, each line is evenly divided into positions for holding characters. The first integer corresponds to the starting position of the first column, the second integer corresponds to the starting position of the second column, and so on.

Return Value

Ok Type: Boolean **true** if the operation was successful; otherwise **false**. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

Query.SaveAsCsv Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Saves the resulting data set of a query as comma separated values (CSV)

Syntax

```
[Ok := ]  Query.SaveAsCsv(OutStream: OutStream [, Format: Integer] [, FormatArgument: String])
```

Parameters

Query Type: Query An instance of the Query data type.

OutStream
Type: OutStream
The stream that you want to save the query as CSV to.

Format
Type: Integer
Specifies whether the columns of the resulting data set are at fixed positions in the CSV file or separated only by a delimiter.

FormatArgument
Type: String
You set the FormatArgument parameter based on the setting of the Format parameter. If the Format parameter is set to 0, then the FormatArgument parameter specifies the starting position of each column in the data set. The value is a comma separated string of integers that includes an integer for every column. In a CSV file, each line is evenly divided into positions for holding characters. The first integer corresponds to the starting position of the first column, the second integer corresponds to the starting position of the second column, and so on.

Return Value

Ok Type: Boolean **true** if the operation was successful; otherwise **false**. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

Query.SaveAsXml Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Saves the resulting data set of a query as XML

> **NOTE**
> This method is supported only in Business Central on-premises.

Syntax

```
[Ok := ]  Query.SaveAsXml(FileName: String)
```

Parameters

Query Type: Query An instance of the Query data type.

FileName
Type: String
The path and name of the file that you want to save the query to.

Return Value

Ok Type: Boolean **true** if the operation was successful; otherwise **false**. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

Query.SecurityFiltering Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Gets or sets how security filters are applied to the query.

Syntax

```
[SecurityFiltering := ]  Query.SecurityFiltering([NewSecurityFiltering: SecurityFilter])
```

> **NOTE**
> This method can be invoked using property access syntax.

Parameters

Query Type: Query An instance of the Query data type.

NewSecurityFiltering
Type: SecurityFilter
The new security filter for the query

Return Value

SecurityFiltering Type: SecurityFilter The security filter applied to the query.

See Also

Query Data Type
Getting Started with AL

Query.SetFilter Method

2/17/2021 • 3 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Sets a filter on a column of a query to limit the records in the resulting data set of a query.

Syntax

```
Query.SetFilter(Column: Any, String: String [, Value: Any,...])
```

Parameters

Query Type: Query An instance of the Query data type.

Column
Type: Any
The name of the column in the query that you want to filter. The name is defined by the column's Name Property.

String
Type: String
The filter expression. A valid expression consists of alphanumeric characters and one or more of the following operators: <, >, \, &, |, and =. You can use replacement fields (%1, %2, and so on) to insert values at run-time.

Value
Type: Any
Replacement values to insert in replacement fields in the filter expression. The data type of Value must match the data type of field that is referred to by the ColumnName.

Remarks

To apply filters to a dataset, the **SetFilter** method must be called before the **Open**, **SaveAsXML**, and **SaveAsCSV** methods, as shown in the following example. To remove filters from query, you call the Clear Method.

```
Query.SetFilter(Column1, String);
Query.Open;
Query.Read;
Clear(Query);
```

A call to the **SetFilter** method automatically closes a query dataset that is currently open. Therefore, the following code is unauthorized and will fail because there is no open dataset for the **Read** method to read.

```
Query.Open;
Query.Read;
Query.SetFilter(Column2, String);
Query.Read;
```

You can have multiple calls to the **SetFilter** method. If **SetFilter** method calls set filters on different columns, then the filters are combined and applied to the dataset. If consecutive **SetFilter** method calls set filters on the same column, then the last **SetFilter** method call is applied to the column.

In addition to the **SetFilter** method, you can apply filters to a query using the SetRange Method (Query) method, the **FilterGroup** method, and the DataItemTableFilter Property and ColumnFilter Property.

IF THE SETFILTER METHOD...	THEN...
Sets a filter on the same field as the **DataItemTableFilter** property	The two filters are joined into a resulting filter.
Sets a filter on the same field as the **ColumnFilter** property	The **SetFilter** method overwrites the **ColumnFilter** property, so the filter that is set by the **SetFilter** method that is applied to the dataset.
Sets a filter on the same field as the **SetRange** method	The method that is called last is applied to the dataset.
Sets a filter on a field that has global filters that are applied by the **FilterGroup(1)** method	The filters of the **SetFilter** method are added to the global filters.

For example, a query has the following filters set on the **Quantity** column:

- **DataItemTableFilter** property: Quantity=Filter(<100)
- **ColumnFilter** property: Quantity=Filter(<>50)

`Query.SetFilter ("Quantity", '>1')` will result in a filter that is equivalent to: 1<Quantity <100.

Example

The following AL code example demonstrates how to use the **SetFilter** method on a query. The example code sets a filter on a query column, and then displays a message when the query is run that indicates the filter on the column.

This example requires that you create a query called **Customer_SalesQuantity** that has the following characteristics:

- Links table 18, Customer with table 37, Sales Lines from the CRONUS International Ltd. demonstration database.
- Includes columns for the **Name** and **No.** fields from the **Customer** table and the **Quantity** field from **Sales Lines** table.

```
var
  MyQuery: Query "Customer SalesQuantity";
  Text000: Label 'Customer name = %1, Quantity = %2';
begin
    // Sets a filter to display only sales quantities greater than 10.
    MyQuery.SetFilter(Quantity, '>10');
    // Sets a filter to display the columns with the value Selangorian Ltd. only.
    MyQuery.SetFilter(NAME, 'Selangorian Ltd.');
    // Runs the query.
    MyQuery.Open;
    // Reads each row in the dataset and displays message with column values.
    // Stops reading when there are no more rows remaining in the dataset (Read is False).
    while MyQuery.Read do
    begin
      Message(Text000, MyQuery.Name, MyQuery.Quantity);
    end;
    // Saves the resulting dataset as a CSV file.
    MyQuery.SaveAsCSV('c:\temp\CustomerSales.csv');
    // Closes the query.
    Myquery.Close;
end;
```

When the code is run, a message that resembles the following appears for each row in the dataset:

Customer name = Selangorian Ltd., Quantity = 30

See Also

Query Data Type

Developing Extensions

Query.SetRange Method

2/17/2021 • 3 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Sets a filter on a range of values on a column of a query data set.

Syntax

```
Query.SetRange(Column: Any [, FromValue: Any] [, ToValue: Any])
```

Parameters

Query Type: Query An instance of the Query data type.

Column
Type: Any
The name of the column in the query that you want to filter. The name is defined by the column's Name Property.

FromValue
Type: Any
The lower limit of the range. The data type of this parameter must match the data type of Column. If you set only the FromValue parameter, then the ToValue parameter is set to the same value as FromValue.

ToValue
Type: Any
The upper limit of the range. The data type of this parameter must match the data type of Column. If you omit the ToValue parameter, then the only the value that is specified for FromValue is used, which enables you to filter on a single column value instead of a range. If you omit both the FromValue and ToValue parameters, then the method removes all filters that are already set on the column.

Remarks

SetRange is a quick way to set a simple filter on a field. The SetRange method is functionally equivalent to calling *Query*.SetFilter(ColumnName, 'FromValue..ToValue').

To apply filters to a dataset, the **SetRange** method must be called before the **Open**, **SaveAsXML**, and **SaveAsCSV** methods, as shown in the following example. To remove filters, you call the Clear Method or **SetRange** without values for the *FromValue* and *ToValue* parameters.

```
Query.SetRange(Column1, FromValue, ToValue);
Query.Open;
Query.Read;
Clear(Query);
```

A call to the **SetRange** method automatically closes a query dataset that is currently open. Therefore, the following code is unauthorized and will fail because there is no open dataset for the **Read** method to read.

```
Query.Open;
Query.Read;
Query.SetRange(Column1, FromValue, ToValue);
Query.Read;
```

In addition to the **SetRange** method, you can apply filters to a query using the **SetFilter** method and the DataItemTableFilter Property and ColumnFilter Property.

IF THE SETRANGE METHOD...	THEN...
Sets a filter on the same field as the **DataItemTableFilter** property	The two filters are joined into a resulting filter.
Sets a filter on the same field as the **ColumnFilter** property	The **SetRange** method overwrites the **ColumnFilter** property, so the filter that is set by the **SetRange** method that is applied to the dataset.
Sets a filter on the same field as the **SetFilter** method	The method that is called last is applied to the dataset.
Sets a filter on a field that has global filters that are applied by the **FilterGroup(1)** method	The filters of the **SetRange** method are added to the global filters.

For example, a query has the following filters set on the **Quantity** column:

- **DataItemTableFilter** property: Quantity=Filter(<>10)
- **ColumnFilter** property: Quantity=Filter(<>5)

`Query.setRange(Quantity, 1, 15)` will result in a filter that is equivalent to: 1 < Quantity <15, except for 10.

Example

The following AL code example demonstrates how to use the **SetRange** method on a query. The example code sets a filter on a query column and saves the resulting dataset as a CSV file. A message also displays when the query is run that indicates the filter on the column.

This example requires that you do the following:

1. Create a query called **Customer_SalesQuantity** that has the following characteristics:
   - Links table **18 Customer** with table **37 Sales Lines** from the CRONUS International Ltd. demonstration database.
   - Includes columns for the **Name** and **No.** fields from the Customer table and the **Quantity** field from Sales Lines table.
2. Create the following AL variables and text constant in the object that will run the query, such as a codeunit.

   ```
   var
      MyQuery: Query "Customer SalesQuantity";
      Text000: Label 'Customer name = %1, Quantity = %2';
   ```

The following AL code uses the **SetRange** method to filter a query dataset over a range of values on the **Quantity** column. You can add the code to a codeunit, and then run the codeunit to see the results.

```
// Sets a filter to display only sales quantities greater than 10.
MyQuery.SetRange(Quantity, '10', '50');
// Sets a filter to display the columns with the value Selangorian Ltd. only.
MyQuery.SetFilter(Name, 'Selangorian Ltd.');
// Runs the query.
MyQuery.Open;
// Reads each row in the dataset and displays message with column values.
// Stops reading when there are no more rows remaining in the dataset (Read is False).
while MyQuery.Read do
begin
  Message(Text000, MyQuery.Name, MyQuery.Quantity);
end;
// Saves the resulting dataset as a CSV file.
MyQuery.SaveAsCSV('c:\temp\CustomerSales.csv');
MyQuery.Close;
```

When the code is run, a message that resembles the following appears for each row in the dataset:

Customer name = Selangorian Ltd., Quantity = 30

Query.TopNumberOfRows Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Specifies the maximum number of rows to include in the resulting data set of a query.

Syntax

```
[CurrentRows := ]  Query.TopNumberOfRows([NewRows: Integer])
```

> **NOTE**
> This method can be invoked using property access syntax.

Parameters

Query Type: Query An instance of the Query data type.

NewRows
Type: Integer
The number of rows to include in the resulting data set. If you do not set the NewRows parameter, then the resulting data set will include all rows. If you set the value to 0, then there is no limit and all rows of the data set are returned.

Return Value

CurrentRows Type: Integer Gets the current maximum number of rows included in the resulting data set

Remarks

You use the **TopNumberOfRows** method to limit the resulting dataset to the first set of rows that are generated for the query. For example, you can include only the first 10 or first 100 rows in the resulting dataset. The **TopNumberOfRows** method is useful for key performance indicators such as the top number of customers or sales.

You can also specify the number of rows to include in the dataset by setting the TopNumberOfRows Property. The **TopNumberOfRows** method will overwrite the **TopNumberOfRows** property setting.

Example

This code example demonstrates how to use the **TopNumberOfRows** method on a query to return the top 10 customer sales orders based on the quantity of items.

The following query object links table **18 Customer** and table **37 Sales Line** and uses the **TopNumberOfRows** property to get top 5 customer sales orders based on the quantity of items.

```
query 50123 "Customer_Sales_Quantity"
{
    QueryType = Normal;
    // Sets the resultS to include the top 5 the results in descending order
    TopNumberOfRows = 5;
    OrderBy = descending(Qty);

    elements
    {
        dataitem(C; Customer)
        {
            column(Customer_Number; "No.")
            {
            }

            column(Customer_Name; Name)
            {
            }

            dataitem(SL; "Sales Line")
            {
                DataItemLink = "Sell-to Customer No." = c."No.";
                SqlJoinType = InnerJoin;

                column(Qty; Quantity)
                {
                }
            }
        }
    }
}
```

The following codeunit runs the query, saves it as a CSV file, and displays a message that states the number of rows that are returned in the resulting dataset.

```
codeunit 50100 MyQueryTop10
{
    trigger OnRun()
    begin

        // Overwrites the TopNumberOfRows property and returns the first 10 rows in the dataset.
        //MyQuery.TopNumberOfRows(10);
        // Opens the query.
        MyQuery.Open;
        // Reads each row of the dataset and counts the number of rows.
        while MyQuery.Read do begin
            Counter += 1;
        end;
        // Saves the dataset as a CSV file.
        MyQuery.SaveAsCsv('c:\temp\CustomerSales.csv');
        // Displays a message that shows the number of rows.
        Message(Text000, counter);

    end;

    var
        MyQuery: Query "Customer_Sales_Quantity";
        Counter: Integer;
        Text000: Label 'count %1.';
}
```

RecordId Data Type

2/17/2021 • 2 minutes to read • Edit Online

> **Version**: *Available from runtime version 1.0.*

Contains the table number and the primary key of a table.

The following methods are available on instances of the RecordId data type.

METHOD NAME	DESCRIPTION
GetRecord()	Gets a RecordRef that refers to the record identified by the RecordID.
TableNo()	Gets the table number of the table that is identified by RecordID. This function returns an error if the record is blank.

Developing Extensions

RecordId.GetRecord Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Gets a RecordRef that refers to the record identified by the RecordID.

Syntax

```
RecordRef :=   RecordId.GetRecord()
```

Parameters

RecordId Type: RecordId An instance of the RecordId data type.

Return Value

RecordRef Type: RecordRef The RecordRef of the record.

Remarks

No data is read from the database when you run this method and therefore, no other fields in the record are set. Furthermore, no filters are set on the record.

Example

The following example opens table number 18 (Customer table) and sets a reference to the table. The FindLast Method (RecordRef) selects the last record in the table. The RecordId Method (RecordRef) retrieves the ID of the currently selected record. In this case, it is the last record in the table. The GetRecord Method (RecordId) uses the retrieved record ID to determine the RecordRef of the selected record (the last record). This example requires that you create the following global variables and text constant.

```
var
    RecRef: RecordRef;
    RecID: RecordID;
```

```
RecRef.Open(18);
RecRef.FindLast;
RecID := RecRef.RecordId;
RecRef := RecID.GetRecord;
```

RecordId.TableNo Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Gets the table number of the table that is identified by RecordID. This function returns an error if the record is blank.

Syntax

```
No :=   RecordId.TableNo()
```

NOTE

This method can be invoked using property access syntax.

Parameters

RecordId Type: RecordId An instance of the RecordId data type.

Return Value

No Type: Integer The ID of the table.

Remarks

In previous versions of Dynamics 365, if a RecordID referred to a temporary table, then the table number value of the RecordID was the run-time generated sequence ID, which is from the base value of 2000100000. You could use the table number to determine if a RecordID referred to a temporary table. In Dynamics 365, the table number value of a RecordID always contains the ID of the originating physical table and not the run-time generated sequence ID. If you previously used the TableNo Method (RecordID) to test for the sequence number and determine if the RecordID was temporary, then you use the IsTemporary Method (RecordRef) in Dynamics 365 Business Central instead.

Example

The following example opens the Customer table with the record reference variable named RecRef and finds the first record in the Customers table. If a record is found, the RecordId Method (RecordRef) gets the ID of the first record in the table. The TableNo method then uses the RecID variable to retrieve the number of the table that contains the record. The table number is then displayed in a message box.

```
var
    RecRef: RecordRef;
    RecID: RecordID;
    varTableNumber: Integer;
begin
    RecRef.Open(Database::Customer);
    if RecRef.Find('-') then begin
      RecID := RecRef.RecordId;
      varTableNumber := RecID.TableNo;
      Message('The Customer table is number: %1', varTableNumber);
    end else begin
    Message('No records found in the table');
    end;
end;
```

RecordRef Data Type

2/17/2021 • 8 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

References a record in a table.

The following methods are available on instances of the RecordRef data type.

METHOD NAME	DESCRIPTION
AddLink(String [, String])	Adds a link to a record in a table.
AddLoadFields([Integer,...])	Specifies additional fields to be initially loaded when the record is retrieved from its data source. Subsequent calls to AddLoadFields will not overwrite fields already selected for the initial load.
AreFieldsLoaded(Integer,...)	Checks whether the specified fields are all initially loaded.
Ascending([Boolean])	Changes or checks the order in which a search through the table that is referred to by RecordRef will be performed.
Caption()	Gets the caption of the table that is currently selected. Returns an error if no table is selected.
ChangeCompany([String])	Redirects references to table data from one company to another.
ClearMarks()	Removes all the marks from a record.
Close()	Closes the current page or table.
Copy(var Record [, Boolean])	Copies a specified record's filters, views, automatically calculated FlowFields, marks, fields, and keys that are associated with the record from a table or creates a reference to a record.
Copy(RecordRef [, Boolean])	Copies a specified record referece's filters, views, automatically calculated FlowFields, marks, fields, and keys that are associated with the record from a table or creates a reference to a record.
CopyLinks(Record)	Copies all the links from a particular record.
CopyLinks(RecordRef)	Copies all the links from a particular record.
CopyLinks(Variant)	Copies all the links from a particular record.
Count()	Counts the number of records that are in the filters that are currently applied to the table referred to by the RecordRef.
CountApprox()	Gets an approximate count of the number of records in the table
CurrentCompany()	Gets the current company of a database table referred to by a RecordRef.
CurrentKey()	Gets the current key of the table referred to by the RecordRef. The current key is returned as a string.

METHOD NAME	DESCRIPTION
CurrentKeyIndex([Integer])	Gets or sets the current key of the table referred to by the RecordRef. The current key is set or returned as a number. This first key = 1, and so on. If RecordRef does not have an active record, CurrentKeyIndex will return -1. If this value is then passed to KeyIndex, an index out of bounds error will occur. Therefore it is important to implement a check of the RecordRef parameter.
Delete([Boolean])	Deletes a record in a table.
DeleteAll([Boolean])	Deletes all records in a table that fall within a specified range.
DeleteLink(Integer)	Deletes a specified link from a record in a table.
DeleteLinks()	Deletes all of the links that have been added to a record.
Duplicate()	Duplicates the table that contains the RecordRef.
Field(Integer)	Gets a FieldRef for the field that has the number FieldNo in the table that is currently selected. If no field has this number, the method returns an error.
FieldCount()	Gets the number of fields in the table that are currently selected or returns the number of fields that have been defined in a key. Returns an error if no table or no key is selected.
FieldExist(Integer)	Determines if the field that has the number FieldNo exists in the table that is referred to by the RecordRef. Returns an error if no table is currently selected.
FieldIndex(Integer)	Gets the FieldRef of the field that has the specified index in the table that is referred to by the RecordRef.
FilterGroup([Integer])	Changes the filter group that is being applied to the table. You can also use this method to return the number of the current filtergroup. You cannot return the number of the filtergroup and set a new filtergroup at the same time.
Find([String])	Finds a record in a table based on the values stored in the key fields.
FindFirst()	Finds the first record in a table based on the current key and filter.
FindLast()	Finds the last record in a table based on the current key and filter.
FindSet([Boolean] [, Boolean])	Finds a set of records in a table based on the current key and filter. FindSet can only retrieve records in ascending order.
Get(RecordId)	Gets a record based on the ID of the record.
GetBySystemId(Guid)	Gets a record based on the ID of the record. The RecordRef must already be opened.
GetFilters()	Determines which filters have been applied to the table referred to by the RecordRef.
GetPosition([Boolean])	Gets a string that contains the primary key of the current record.
GetTable(Record)	Gets the table of a Record variable and causes the RecordRef to refer to the same table.

METHOD NAME	DESCRIPTION
GetView([Boolean])	Returns a string that describes the current sort order, key, and filters on a table.
HasFilter()	Determines whether a filter has been applied to the table that the RecordRef refers to.
HasLinks()	Determines whether a record contains any links.
Init()	Initializes a record in a table.
Insert()	Inserts a record into a table without executing the code in the OnInsert trigger.
Insert(Boolean)	Inserts a record into a table.
Insert(Boolean, Boolean)	Inserts a record into a table.
IsDirty()	Gets a boolean value that indicates whether the current in-memory instance of a record or filtered set of records has changed since being retrieved from the database.
IsEmpty()	Determines whether any records exist in a filtered set of records in a table.
IsTemporary()	Determines whether a RecordRef refers to a temporary table.
KeyCount()	Gets the number of keys that exist in the table that is referred to by the RecordRef. Returns an error if no table is selected.
KeyIndex(Integer)	Gets the KeyRef of the key that has the index specified in the table that is currently selected. The key can be composed of fields of any supported data type. Data types that are not supported include BLOBs, FlowFilters, variables, and functions. If the sorting key is set to a field that is not part of a key, then the KeyIndex is -1.
LoadFields(Integer,...)	Accesses the table's corresponding data source and loads the values of the specified fields on the record.
LockTable([Boolean] [, Boolean])	Locks a table to protect it from write transactions that conflict with each other.
Mark([Boolean])	Marks a record. You can also use this method to determine whether a record is marked.
MarkedOnly([Boolean])	Activates a special filter. After you use this function, your view of the table includes only records marked by this function.
Modify([Boolean])	Modifies a record in a table.
Name()	Identifies the name of the table
Next([Integer])	Steps through a specified number of records and retrieves a record.
Number()	Gets the table ID (number) of the table that contains the record that was referred to by the RecordRef.
Open(Integer [, Boolean] [, String])	Causes a RecordRef variable to refer to a table, which is identified by its number in a particular company.
ReadConsistency()	Gets a value indicating whether read consistency is enabled.

METHOD NAME	DESCRIPTION
ReadPermission()	Determines if you can read from a table.
RecordId()	Gets the RecordID of the record that is currently selected in the table. If no table is selected, an error is generated.
RecordLevelLocking()	Gets a value indicating whether record level locking is enabled.
Rename(Any [, Any,...])	Changes the value of a primary key in a table.
Reset()	Removes all filters, including any special filters set by the MarkedOnly method (Record), changes fields select for loading back to all, and changes the current key to the primary key. Also removes any marks on the record and clears any AL variables defined on its table definition.
SecurityFiltering([SecurityFilter])	Gets or sets how security filters are applied to the RecordRef.
SetLoadFields([Integer,...])	Sets the fields to be initially loaded when the record is retrieved from its data source. This will overwrite fields previously selected for initial load.
SetPermissionFilter()	Applies the user's security filter to the referenced record. The security filter is combined with any other filters that are placed on the record with SetFilter or SetRange. The combined filter will not include any records outside the range of the security filter and this will prevent a runtime permission error from occuring when the record is read. If the permission filter is not set, an error can occur if you attempt to read a record that is outside the range of the user's security filter.
SetPosition(String)	Sets the fields in a primary key on a record to the values specified in the String parameter. The remaining fields are not changed.
SetRecFilter()	Sets a filter on a record that is referred to by a RecordRef.
SetTable(Record)	Sets the table to which a Record variable refers as the same table as a RecordRef variable.
SetView(String)	Sets the current sort order, key, and filters on a table.
SystemCreatedAtNo()	Gets the field number that is used by the SystemCreatedAt field. The SystemCreatedAt field is a system field that the platform adds to all table objects.
SystemCreatedByNo()	Gets the field number that is used by the SystemCreatedBy field. The SystemCreatedBy field is a system field that the platform adds to all table objects.
SystemIdNo()	Gets the field number that is used by the SystemId field. The SystemId field is a system field that the platform adds to all table objects.
SystemModifiedAtNo()	Gets the field number that is used by the SystemModifiedAt field. The SystemModifiedAt field is a system field that the platform adds to all table objects.
SystemModifiedByNo()	Gets the field number that is used by the SystemModifiedBy field. The SystemModifiedBy field is a system field that the platform adds to all table objects.
WritePermission()	Determines if you can write to a table.

Remarks

The RecordRef object can refer to any table in the database. Use the Open method to use the table number to select the table that you want to access, or use the GetTable method to use another record variable to select the table that you want to access.

If one RecordRef variable is assigned to another RecordRef variable, then they both refer to the same table instance.

RecordRef.AddLink Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Adds a link to a record in a table.

Syntax

```
[ID := ]  RecordRef.AddLink(URL: String [, Description: String])
```

Parameters

RecordRef Type: RecordRef An instance of the RecordRef data type.

URL
Type: String
The link that you want to add to the record.
Description
Type: String
Optional description of the link.

Return Value

ID Type: Integer The ID of the URL that you want to add to the record. Every time that you add a link to a page or a table, an entry is created in the Record Link system table. Each entry is given an ID.

Remarks

The URL can be a link to a Web site, a file stored on the local or on a remote computer, or a link to a Dynamics 365 page. You can then view the link in the **Links** FactBox on pages that display the record.

Example

The following example adds a link to a record in the Customer table. The code starts by opening table 18 (Customer) as a RecordRef variable that is named CustomerRecref. The Field Method (RecordRef) creates a FieldRef variable that is named MyFieldRef for the first field (No.). Next, `MyFieldRef.Value` is set to record 01121212. The Find Method (RecordRef) method searches the records for record no. 01121212. If the record is found, then the AddLink method adds a link to the record. The link is assigned a link ID, which is stored in the LinkID variable. The link ID is displayed in a message box. You can view the link you added in the **Links** FactBox on the Customer List or Customer Card pages.

```
var
    CustomerNum: Code;
    varLink: Text;
    CustomerRecref: RecordRef;
    MyFieldRef: FieldRef;
    LinkID: Integer;
    Text000: Label 'The link with ID %1 has been added.';
    Text001: Label 'The customer cannot be found.';
begin
    CustomerNum := '01121212';
    CustomerRecref.Open(18);
    MyFieldRef := CustomerRecref.Field(1);
    MyFieldRef.Value := CustomerNum;
    if CustomerRecref.Find('=') then begin
      LinkID := CustomerRecref.AddLink(varLink);
      Message(Text000, LinkID);
    end else
      Message(Text001);
end;
```

RecordRef.AddLoadFields Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 6.0.*

Specifies additional fields to be initially loaded when the record is retrieved from its data source. Subsequent calls to AddLoadFields will not overwrite fields already selected for the initial load.

Syntax

```
[Ok := ]  RecordRef.AddLoadFields([Fields: Integer,...])
```

Parameters

RecordRef Type: RecordRef An instance of the RecordRef data type.

Fields
Type: Integer
The FieldNo's of the fields to be loaded.

Return Value

Ok Type: Boolean **true** if all fields are selected for subsequent loads; otherwise, **false**. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

Remarks

Calling SetLoadFields on a record without passing any fields will reset the fields selected to load to the default, where all readable normal fields are selected for load.

This method is part of the partial records capability for improving performance. For more information, see Using Partial Records.

Example

This code example uses the AddLoadFields method to make sure that if a record is a **Currency**, then the **Currency Factor** field is loaded. This code would have to be called before a database operation is executed on the RecordRef.

```
procedure AlwaysNeededFields(VAR MyRecordRef: RecordRef)
var
        Currency: Record Currency;
begin
if (MyecordRef.Number = Database::Currency) then
// We always want the Currency."Currency Factor"
MyRecordRef.AddLoadFields(Currency.FieldNo(Currency."Currency Factor"));
end;
```

See Also

RecordRef.AreFieldsLoaded Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 6.0.*

Checks whether the specified fields are all initially loaded.

Syntax

```
Ok :=   RecordRef.AreFieldsLoaded(Fields: Integer,...)
```

Parameters

RecordRef Type: RecordRef An instance of the RecordRef data type.

Fields

Type: Integer

The FieldNo's of the fields to check.

Return Value

Ok Type: Boolean **true** if all the fields specified by the Fields parameter are currently loaded; otherwise, **false**. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

Remarks

This method is part of the partial records capability for improving performance. For more information, see Using Partial Records.

Example

This code example shows how you could use the AreFieldsLoaded method to determines how many fields are currently loaded for a given recordRef. Note that, because the platform might require more fields be loaded than specified by calls to SetLoadFields and AddLoadFields, the result might be larger than expected.

```
procedure GetLoadedFieldCount(MyRecordRef: RecordRef): Integer
var
    MyFieldRef: FieldRef;
    LoadedFields: Integer;
    Idx: Integer;
begin
    for Idx := 0 to MyRecordRef.FieldCount do begin
        MyFieldRef := MyRecordRef.FieldIndex(idx);
        if (MyFieldRef.Active() AND MyRecordRef.AreFieldsLoaded(MyFieldRef.Number)) then
            LoadedFields += 1;
    end;

    exit(LoadedFields);
end;
```

RecordRef.Ascending Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Changes or checks the order in which a search through the table that is referred to by RecordRef will be performed.

Syntax

```
[IsAscending := ]  RecordRef.Ascending([SetAscending: Boolean])
```

NOTE

This method can be invoked using property access syntax.

Parameters

RecordRef Type: RecordRef An instance of the RecordRef data type.

SetAscending

Type: Boolean

If this parameter is true, it will search in ascending order. If this parameter is false, it will search in descending order. If you do not specify this parameter, it will check the search order.

Return Value

IsAscending Type: Boolean Specifies the order in which a search will be performed.

Remarks

This method works just like the Ascending Method (Record).

Example 1

The following example opens table 18 (Customer) as a RecordRef variable that is named CustomerRecref. The SetView Method (RecordRef) sets a filter that includes sorting the data in ascending order. The Ascending method then checks whether the sort order is ascending, stores the return value in the IsAscending variable and displays **True** in a message box.

```
var
    IsAscending: Boolean;
    CustomerRecref: RecordRef;
    Text000: Label 'Is the sort order ascending?  %1';
begin
    CustomerRecref.Open(18);
    CustomerRecref.SetView('Sorting(Name) Order(Ascending) Where(No.=Const(10000..20000))');
    IsAscending := CustomerRecref.Ascending;
    Message(Text000, IsAscending);
end;
```

Example 2

The following example opens table 18 (Customer) as a RecordRef variable that is named CustomerRecref. The SetView Method (RecordRef) sets a filter that includes sorting the data in descending order. The Ascending method then checks whether the sort order is ascending, stores the return value in the IsAscending variable and displays **False** in a message box because the sort order is descending. The Ascending method changes the sort order to ascending by setting the *SetAscending* parameter to **true**. The Ascending method checks the sort order again. This time **True** is displayed.

```
CustomerRecref.Open(18);
CustomerRecref.SetView('Sorting(Name) Order(Descending) Where(No.=Const(10000..20000))');
IsAscending := CustomerRecref.Ascending;
Message(Text000, IsAscending);
IsAscending := CustomerRecref.Ascending(True);
Message(Text000, IsAscending);
```

RecordRef.Caption Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Gets the caption of the table that is currently selected. Returns an error if no table is selected.

Syntax

```
Caption :=   RecordRef.Caption()
```

NOTE

This method can be invoked using property access syntax.

Parameters

RecordRef Type: RecordRef An instance of the RecordRef data type.

Return Value

Caption Type: String The caption of the table.

Remarks

This method works just like the TableCaption Method (Record).

Example

The following example selects tables 3 through 5 and opens each table as a RecordRef variable that is named MyRecordRef. The Caption method uses the RecorRef variable to retrieve the caption for each of the tables and displays the table number and the caption in a message box. The Close Method (RecordRef) closes the table.

```
var
    varCaption: Text;
    i: Integer;
    MyRecordRef: RecordRef;
    Text000: Label 'Table No: %1 Caption: %2';
begin
    for i := 3 to 6 do begin
        MyRecordRef.Open(i);
        varCaption := MyRecordRef.Caption;
        Message(Text000, i, varCaption);
        MyRecordRef.Close;
        end;
end;
```

This example displays the following:

Table No: 3 Caption: Payment terms

Table No: 4 Caption: Currency

Table No: 5 Caption: Finance Charge Terms

Developing Extensions

RecordRef.ChangeCompany Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Redirects references to table data from one company to another.

Syntax

```
[Ok := ]  RecordRef.ChangeCompany([CompanyName: String])
```

Parameters

RecordRef Type: RecordRef An instance of the RecordRef data type.

CompanyName
Type: String
The name of the company to which you want to change. If you omit this parameter, you change back to the current company.

Return Value

Ok Type: Boolean **true** if the operation was successful; otherwise **false**. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

Remarks

When executing this method, the user's access rights are respected. For example, a user cannot access data in *CompanyName* unless he already has the necessary access rights.

The **ChangeCompany** method is not affected by the Reset Method (RecordRef). You can deselect a company by making a new call to **ChangeCompany** or by using the Clear Method.

Global filters always belong to a specific company. If you use the following code to select the company named NewCompany, any filters assigned to *RecordRef* will be transferred to *RecordRef* in the new company.

```
RecordRef.ChangeCompany(NewCompany);
```

Even if you run the **ChangeCompany** method, triggers still run in the current company, not in the company that you specified in the **ChangeCompany** method.

Example

This example shows how to use the **ChangeCompany** method. The following code takes a RecordRef to table **18 Customer** in the current company and redirects it to the table in another company (in this case Company B). The last record in the Customer table of Company B is then deleted.

```
var
    RecID: RecordID;
    MyRecordRef: RecordRef;
    Text000: Label 'Record to be deleted: %1';
begin
    MyRecordRef.Open(18);
    MyRecordRef.ChangeCompany('Company B');
    MyRecordRef.FindLast;
    RecID := MyRecordRef.RecordId;
    Message(Text000, RecID);
    MyRecordRef.Delete;
end;
```

See Also

RecordRef.ClearMarks Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 5.3.*

Removes all the marks from a record.

Syntax

```
RecordRef.ClearMarks()
```

Parameters

RecordRef Type: RecordRef An instance of the RecordRef data type.

See Also

RecordRef Data Type
Getting Started with AL
Developing Extensions

RecordRef.Close Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Closes the current page or table.

Syntax

```
RecordRef.Close()
```

Parameters

RecordRef Type: RecordRef An instance of the RecordRef data type.

Remarks

You must use this method if you have several recordrefs defined as variables because these will be maintained until the variable gets out of scope.

Example

The following example opens tables 3 through 10 as a Recordref variable that is named MyRecordRef. For each table that is open, the Caption Method (RecordRef) retrieves the caption of the table and displays the table number and the caption in a messages box. After each caption is displayed, the Close method closes the table before the next table is open.

```
var
    varCaption: Text;
    MyRecordRef: RecordRef;
    i: Integer;
    Text000: Label 'Table No: %1 Caption: %2';
begin
    for i := 3 to 10 do begin
        MyRecordRef.Open(i);
        varCaption := MyRecordRef.Caption;
        Message(Text000, i, varCaption);
        MyRecordRef.Close;
    end;
end;
```

RecordRef.Copy Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 5.3.*

Copies a specified record's filters, views, automatically calculated FlowFields, marks, fields, and keys that are associated with the record from a table or creates a reference to a record.

Syntax

```
RecordRef.Copy(var FromRecord: Record [, ShareTable: Boolean])
```

Parameters

RecordRef Type: RecordRef An instance of the RecordRef data type.

FromRecord
Type: Record
The record to copy.

ShareTable
Type: Boolean
Specifies whether the method copies filters, views, automatically calculated FlowFields, marks, fields, and keys of the record or creates a reference to a temporary record. If FromRecord and Record are both temporary and ShareTable is true, then the COPY method causes Record to reference the same table as FromRecord. If ShareTable is true, then both Record and FromRecord must be temporary; otherwise an error will occur. The default value is false. If you specify false, only filters, marks, and keys are copied.

RecordRef.Copy Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 5.3.*

Copies a specified record referece's filters, views, automatically calculated FlowFields, marks, fields, and keys that are associated with the record from a table or creates a reference to a record.

Syntax

```
RecordRef.Copy(FromRecordRef: RecordRef [, ShareTable: Boolean])
```

Parameters

RecordRef Type: RecordRef An instance of the RecordRef data type.

FromRecordRef

Type: RecordRef

The record reference to copy.

ShareTable

Type: Boolean

Specifies whether the method copies filters, views, automatically calculated FlowFields, marks, fields, and keys of the record or creates a reference to a temporary record. If FromRecord and Record are both temporary and ShareTable is true, then the COPY method causes Record to reference the same table as FromRecord. If ShareTable is true, then both Record and FromRecord must be temporary; otherwise an error will occur. The default value is false. If you specify false, only filters, marks, and keys are copied.

RecordRef.CopyLinks Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Copies all the links from a particular record.

Syntax

```
RecordRef.CopyLinks(FromRecord: Record)
```

Parameters

RecordRef Type: RecordRef An instance of the RecordRef data type.

FromRecord
Type: Record
Specifies the record from which you want to copy links.

Remarks

Use this method to copy all the links from a specified record and paste the links to the current record.

The link can be a link to a Web site, a file stored on the local or on a remote computer, or a link to a page in your application.

Example

The following example copies all links from a source record that is named VendorRecord to the currently open record in the Customer table. The source record is record 10000 from the Vendor table. The code opens the Customer table as a RecordRef variable that is named CustomerRecref. The Field Method (RecordRef) creates a FieldRef variable that is named MyFieldRef for field 1 (No.) in the Customer table. The SetRange Method (FieldRef) selects records in the range 20000 to 40000 from the Customer table and record 10000 from the Vendor table. The Find Method (RecordRef) searches the Customer table for the records in the filtered range. If the record that meets the filter criteria is found, the links from the Vendor record No. 10000 are copied to the customer records in the range 30000 to 40000. The record id of the record to which the links were copied is displayed in a message box. The process is repeated until there is no more record in the range. The Close Method (RecordRef) closes the table.

```
var
    MyFieldRef: FieldRef;
    CustomerRecref: RecordRef;
    VendorRecord: Record Vendor;
    Count: Integer;
    Text000: Label 'The links have been copied to %1';
begin
    CustomerRecref.Open(Database::Customer);
    MyFieldRef := CustomerRecref.Field(1);
    MyFieldRef.SetRange('30000' , '40000');
    VendorRecord.SetRange("No.", '10000');
    Count := 0;
    if CustomerRecref.Find('-') then
      repeat
        Count := Count + 1;
        CustomerRecref.CopyLinks(VendorRecord);
        Message(Text000, CustomerRecref.RecordId);
      until CustomerRecref.Next = 0;
    CustomerRecref.Close;
end;
```

RecordRef.CopyLinks Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Copies all the links from a particular record.

Syntax

```
RecordRef.CopyLinks(FromRecord: RecordRef)
```

Parameters

RecordRef Type: RecordRef An instance of the RecordRef data type.

FromRecord
Type: RecordRef
Specifies the record from which you want to copy links.

Remarks

Use this method to copy all the links from a specified record and paste the links to the current record.

The link can be a link to a Web site, a file stored on the local or on a remote computer, or a link to a page in your application.

Example

The following example copies all links from a source record that is named VendorRecord to the currently open record in the Customer table. The source record is record 10000 from the Vendor table. The code opens the Customer table as a RecordRef variable that is named CustomerRecref. The Field Method (RecordRef) creates a FieldRef variable that is named MyFieldRef for field 1 (No.) in the Customer table. The SetRange Method (FieldRef) selects records in the range 20000 to 40000 from the Customer table and record 10000 from the Vendor table. The Find Method (RecordRef) searches the Customer table for the records in the filtered range. If the record that meets the filter criteria is found, the links from the Vendor record No. 10000 are copied to the customer records in the range 30000 to 40000. The record id of the record to which the links were copied is displayed in a message box. The process is repeated until there is no more record in the range. The Close Method (RecordRef) closes the table.

```
var
    MyFieldRef: FieldRef;
    CustomerRecref: RecordRef;
    VendorRecord: Record Vendor;
    Count: Integer;
    Text000: Label 'The links have been copied to %1';
begin
    CustomerRecref.Open(Database::Customer);
    MyFieldRef := CustomerRecref.Field(1);
    MyFieldRef.SetRange('30000' , '40000');
    VendorRecord.SetRange("No.", '10000');
    Count := 0;
    if CustomerRecref.Find('-') then
      repeat
        Count := Count + 1;
        CustomerRecref.CopyLinks(VendorRecord);
        Message(Text000, CustomerRecref.RecordId);
      until CustomerRecref.Next = 0;
    CustomerRecref.Close;
end;
```

RecordRef.CopyLinks Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 3.0.*

Copies all the links from a particular record.

Syntax

```
RecordRef.CopyLinks(FromRecordOrRecordRef: Variant)
```

Parameters

RecordRef Type: RecordRef An instance of the RecordRef data type.

FromRecordOrRecordRef
Type: Variant
Specifies the record from which you want to copy links.

Remarks

Use this method to copy all the links from a specified record and paste the links to the current record.

The link can be a link to a Web site, a file stored on the local or on a remote computer, or a link to a page in your application.

Example

The following example copies all links from a source record that is named VendorRecord to the currently open record in the Customer table. The source record is record 10000 from the Vendor table. The code opens the Customer table as a RecordRef variable that is named CustomerRecref. The Field Method (RecordRef) creates a FieldRef variable that is named MyFieldRef for field 1 (No.) in the Customer table. The SetRange Method (FieldRef) selects records in the range 20000 to 40000 from the Customer table and record 10000 from the Vendor table. The Find Method (RecordRef) searches the Customer table for the records in the filtered range. If the record that meets the filter criteria is found, the links from the Vendor record No. 10000 are copied to the customer records in the range 30000 to 40000. The record id of the record to which the links were copied is displayed in a message box. The process is repeated until there is no more record in the range. The Close Method (RecordRef) closes the table.

```
var
    MyFieldRef: FieldRef;
    CustomerRecref: RecordRef;
    VendorRecord: Record Vendor;
    Count: Integer;
    Text000: Label 'The links have been copied to %1';
begin
    CustomerRecref.Open(Database::Customer);
    MyFieldRef := CustomerRecref.Field(1);
    MyFieldRef.SetRange('30000' , '40000');
    VendorRecord.SetRange("No.", '10000');
    Count := 0;
    ifCustomerRecref.Find('-') then
      repeat
        Count := Count + 1;
        CustomerRecref.CopyLinks(VendorRecord);
        Message(Text000, CustomerRecref.RecordId);
      until CustomerRecref.Next = 0;
    CustomerRecref.Close;
end;
```

RecordRef.Count Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Counts the number of records that are in the filters that are currently applied to the table referred to by the RecordRef.

Syntax

```
Number :=   RecordRef.Count()
```

NOTE

This method can be invoked using property access syntax.

Parameters

RecordRef Type: RecordRef An instance of the RecordRef data type.

Return Value

Number Type: Integer The number of records in the table.

Remarks

This method returns the number of records that meet the conditions of any filters associated with the records. If no filters are set, the method shows the total number of records in the table.

NOTE

The Count method does not lock the table before it retrieves the number of records in the table. This means that the method reads both uncommitted and committed data, which could cause the number of records that is returned to be inaccurate. To make sure that the count is accurate, use the LockTable Method (RecordRef) before you use the Count method.

In previous versions of Dynamics 365, the Count method ignored security filters and always returned the total number of records unless you called the SetPermissionFilter method to get a filtered count. In Dynamics 365 Business Central, the Count method adheres to the SecurityFiltering Property. .

This method works just like the Count Method (Record).

Example

The following example opens table number 18 (Customer) as a RecordRef that is named MyRecordRef. The LockTable Method (RecordRef) locks the table. The Count method then retrieves the number of records in the table. The number of records is stored in the Count variable. The name of the table and the number of records in the table is displayed in a message box. The varTableNo variable can be used to open any table and get the

number of records in that table by changing the value of the varTableNo variable.

```
var
    MyRecordRef: RecordRef;
    varTableNo: Integer;
    Count: Integer;
    Text000: Label 'The number of records in the %1 table is: %2.';
begin
    varTableNo := 18;
    MyRecordRef.Open(varTableNo);
    MyRecordRef.LockTable;
    Count := MyRecordRef.Count;
    Message(Text000, MyRecordRef.Name, Count);
end;
```

RecordRef.CountApprox Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Gets an approximate count of the number of records in the table

Syntax

```
Number :=   RecordRef.CountApprox()
```

> **NOTE**
> This method can be invoked using property access syntax.

Parameters

RecordRef Type: RecordRef An instance of the RecordRef data type.

Return Value

Number Type: Integer Approximate number of records in the table.

See Also

RecordRef.CurrentCompany Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Gets the current company of a database table referred to by a RecordRef.

Syntax

```
Company :=   RecordRef.CurrentCompany()
```

> **NOTE**
> This method can be invoked using property access syntax.

Parameters

RecordRef Type: RecordRef An instance of the RecordRef data type.

Return Value

Company Type: String The name of the current company.

See Also

RecordRef Data Type
Getting Started with AL
Developing Extensions

RecordRef.CurrentKey Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Gets the current key of the table referred to by the RecordRef. The current key is returned as a string.

Syntax

```
CurrentKey :=   RecordRef.CurrentKey()
```

> **NOTE**
> This method can be invoked using property access syntax.

Parameters

RecordRef Type: RecordRef An instance of the RecordRef data type.

Return Value

CurrentKey Type: String The name of the current key of the record.

Example

```
var
    RecRef: RecordRef;
    Text000: Label 'The current key in the "%1" table is "%2".';
begin
    RecRef.Open(18);
    Message(Text000,RecRef.Caption,RecRef.CurrentKey);
end;
```

`RecRef.Open(18)` - Opens table 18 or causes a run-time error if table 18 does not exist.

`RecRef.Caption` - Returns the caption of the table.

`RecRef.CurrentKey` - Returns the caption of the current key in the table.

RecordRef.CurrentKeyIndex Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Gets or sets the current key of the table referred to by the RecordRef. The current key is set or returned as a number. This first key = 1, and so on. If RecordRef does not have an active record, CurrentKeyIndex will return -1. If this value is then passed to KeyIndex, an index out of bounds error will occur. Therefore it is important to implement a check of the RecordRef parameter.

Syntax

```
[CurrentKeyIndex := ]  RecordRef.CurrentKeyIndex([NewKeyIndex: Integer])
```

NOTE

This method can be invoked using property access syntax.

Parameters

RecordRef Type: RecordRef An instance of the RecordRef data type.

NewKeyIndex
Type: Integer
The number of the new key.

Return Value

CurrentKeyIndex Type: Integer The number of the current key.

Example

The following example loops through four tables (36-39) opens each table as a RecordRef variable that is named MyRecordRef. The CurrentKeyIndex method retrieves the current key index of the tables. The name of the table and the current key index of each table are displayed in a message box. Each table is close before the next one is opened.

```
var
    MyRecordRef: RecordRef;
    CurrentKeyIndex: Integer;
    i: Integer;
    varFromTable: Integer;
    varToTable: Integer;
    Text000: Label 'Table: %1  Current key index: %2';
begin
    varFromTable := 36;
    varToTable := 39;
    for i := varFromTable to varToTable do begin
      MyRecordRef.Open(i);
      CurrentKeyIndex := MyRecordRef.CurrentKeyIndex;
      Message(Text000, MyRecordRef.Name, CurrentKeyIndex);
      MyRecordRef.Close;
    end;
end;
```

RecordRef.Delete Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Deletes a record in a table.

Syntax

```
[Ok := ]  RecordRef.Delete([RunTrigger: Boolean])
```

Parameters

RecordRef Type: RecordRef An instance of the RecordRef data type.

RunTrigger
Type: Boolean
Specifies whether the code in the OnDelete trigger will be executed. If this parameter is true, the code will be executed. If this parameter is false, then the code in the OnDelete trigger is not executed. The default value is false. This parameter is optional.

Return Value

Ok Type: Boolean **true** if the operation was successful; otherwise **false**. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

Remarks

The current key and any filters on the record do not affect this operation. The record to delete is identified by the values in its primary key.

If an end-user modifies a record between the time that another end-user or another process reads the record and modifies it, then the second user must refresh the value of the record variable before editing the record. Otherwise, the end-user receives the following run-time error:

Another user has modified the record for this <Table Name> after you retrieved it from the database.

Enter your changes again in the updated window, or start the interrupted activity again.

In earlier versions of Dynamics 365, certain situations allowed code that an end-user runs to modify a record after a newer version of the record was written and committed to the database. This would overwrite the newer changes. However, in Dynamics 365 Business Central, we have restricted the Modify Method (RecordRef), Rename Method (RecordRef), and **Delete** Method (RecordRef) so that the end-user receives the following run-time error in these certain situations:

Unable to change an earlier version of the <Table Name> record. The record should be read from the database again. This is a programming error.

You must design your application so that you use the most up-to-date version of the record for modifications to the database. You use the Get Method (RecordRef) to refresh the record with the latest version.

Example

The following example deletes a record from the Customer table. The code starts by opening the **Customer** table (18) as a RecordRef variable that is named MyRecordRef. The Field Method (RecordRef) creates a FieldRef that is named MyFieldRef for field 1, which is the primary key of the **Customer** table. The Value Method (FieldRef, TestPage Field) assigns the value 10000 to the field that the MyFieldRef variable refers to. The Find Method (RecordRef) searches the table for a record with field 1 = 10000. If the record is found, then it is deleted, the table is modified, and a message is displayed.

```
var
    varRecordToDelete: Code;
    MyRecordRef: RecordRef;
    Text000: Label 'Customer %1 is deleted.;
begin
    varRecordToDelete := '10000';
    MyRecordRef.Open(18);
    MyFieldRef := MyRecordRef.Field(1);
    MyFieldRef.Value := varRecordToDelete;
    if MyRecordRef.Find('=') then begin
      ifMyRecordRef.Delete then begin
        MyRecordRef.Modify;
        Message(Text000, MyFieldRef.Value);
      end;
    end;
end;
```

RecordRef.DeleteAll Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Deletes all records in a table that fall within a specified range.

Syntax

```
RecordRef.DeleteAll([RunTrigger: Boolean])
```

Parameters

RecordRef Type: RecordRef An instance of the RecordRef data type.

RunTrigger
Type: Boolean
Specifies whether the code in the OnDelete trigger will be executed. If this parameter is true, the code will be executed. If this parameter is false (default), the code will not be executed. This parameter is optional.

Remarks

This method works the same way as the DeleteAll Method (Record).

Example

The following example opens table 18 (Customer) as a RecordRef variable that is named CustomerRecRef. The Field Method (RecordRef) creates a FieldRef variable that is named MyFieldRef for field 1 (No.). From the No. field, the SetRange Method (FieldRef) selects records in the range from 10000 to 20000. The number of records in the range is displayed in a message box. The DeleteALL method deletes all records in that range. The number of records is displayed again. This time, 0 is displayed because all the records in the range are deleted.

```
var
    MyFieldRef: FieldRef;
    CustomerRecRef: RecordRef;
    Text000: Label 'The number of records in the range is %1.;
begin
    CustomerRecRef.Open(18);
    MyFieldRef := CustomerRecRef.Field(1);
    MyFieldRef.SetRange('10000' , '20000');
    Message(Text000 ,CustomerRecRef.Count);
    CustomerRecRef.DeleteALL;
    Message(Text000 ,CustomerRecRef.Count);
end;
```

RecordRef.DeleteLink Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Deletes a specified link from a record in a table.

Syntax

```
RecordRef.DeleteLink(ID: Integer)
```

Parameters

RecordRef Type: RecordRef An instance of the RecordRef data type.

ID

Type: Integer

The ID of the link you want to delete.

Remarks

When you add a link to a page or a table, an entry is created in the Record Link system table. Each entry is given an ID. This ID is specified as a parameter in the DeleteLINK method.

Example

The following example deletes a link from a customer record in the Customer table. The code starts by opening table 18 (Customer) as a RecordRef variable that is named CustomerRecref. The Field Method (RecordRef) creates a FieldRef variable that is named MyFieldRef for the first field in the table (No.). `MyFieldRef.Value` selects record 01121212 from the No. field. This record is initialized in the CustomerNum variable. The Find Method (RecordRef) searches for record 01121212. If the record is found, the DeleteLINK method deletes the link that is specified in the varLinkid variable. A message that states that the link is deleted is displayed in a message box. You can verify that the link is deleted in the **Links** FactBox on the Customer List or Customer Card pages.

```
var
    MyFieldRef: FieldRef;
    CustomerRecRef: RecordRef;
    varLinkid: Integer;
    CustomerNUm: Integer;
    Text000: Label 'The link with id %1 is deleted.;
    Text001: Label 'The customer cannot be found.';
begin
    CustomerNum := '01121212';
    varLinkid := 21;
    CustomerRecref.Open(18);
    MyFieldRef := CustomerRecref.Field(1);
    MyFieldRef.Value := CustomerNum;
    if CustomerRecref.Find('=') then begin
      CustomerRecref.DeleteLink(varLinkid);
      Message(Text000, varLinkid);
    end else
      Message(Text001);
end;
```

RecordRef.DeleteLinks Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Deletes all of the links that have been added to a record.

Syntax

```
RecordRef.DeleteLinks()
```

Parameters

RecordRef Type: RecordRef An instance of the RecordRef data type.

Example

The following example deletes all links from a customer record in the Customer table. The code starts by opening table 18 (Customer) as a RecordRef variable that is named CustomerRecref. The Field Method (RecordRef) creates a FieldRef variable that is named MyFieldRef for the first field in the table (No.). `MyFieldRef.Value` selects record 01121212 from the No. field. This record is initialized in the CustomerNum variable. The Find Method (RecordRef) searches for record 01121212. If the record is found, the DeleteLINKS method deletes all the links in the record. A message that states that the links are deleted is displayed in a message box. You can verify that the links are deleted in the **Links** FactBox on the Customer List or Customer Card pages.

```
var
    MyFieldRef: FieldRef;
    CustomerRecRef: RecordRef;
    CustomerNUm: Integer;
    Text000: Label 'The link with id %1 is deleted.;
    Text001: Label 'The customer cannot be found.';
begin
    CustomerNum := '01121212';
    CustomerRecref.Open(18);
    MyFieldRef := CustomerRecref.Field(1);
    MyFieldRef.Value := CustomerNum;
    if CustomerRecref.Find('=') then begin
      CustomerRecref.DeleteLinks;
      Message(Text000, CustomerNum);
    end else
      Message(Text001);
end;
```

RecordRef.Duplicate Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Duplicates the table that contains the RecordRef.

Syntax

```
RecordRef :=   RecordRef.Duplicate()
```

Parameters

RecordRef Type: RecordRef An instance of the RecordRef data type.

Return Value

RecordRef Type: RecordRef A RecordRef that refers to a new record with the same filters, current keys, and marks as the original RecordRef.

Remarks

The RecordRef that is returned refers to a new record with the same filters, current keys, and marks as the original RecordRef. Any changes that you make to the filters, current keys, and marks of the new record are not observed in the original. This differs from assigning one RecordRef to another RecordRef. If you assign one RecordRef to another RecordRef, then both refer to the same record and changes that you make to one RecordRef are observed in the other RecordRef.

Example

The following example opens table 18 (Customer) as a RecordRef variable named RecordRef1 and uses the DUPLICATE method to copy the filters, current keys and marks from RecordRef1 into a new RecordRef variable named RecordRef2. After the DUPLICATE method is executed, the RecordRef1 and RecordRef2 variables are identical.

```
var
    RecordRef1: RecordRef;
    RecordRef2: RecordRef;
    Text000: Label 'RecordRef1 refers to the %1 table.\\ RecordRef2 refers to the %2 table.';
begin
    RecordRef1.Open(18);
    RecordRef2 := RecordRef1.Duplicate;
    Message(Text000, RecordRef1.Caption, RecordRef2.Caption);
end;
```

RecordRef.Field Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Gets a FieldRef for the field that has the number FieldNo in the table that is currently selected. If no field has this number, the method returns an error.

Syntax

```
Field :=   RecordRef.Field(FieldNo: Integer)
```

Parameters

RecordRef Type: RecordRef An instance of the RecordRef data type.

FieldNo

Type: Integer

The number that the field has in the table that is currently selected. This is the field for which you want the FieldRef.

Return Value

Field Type: FieldRef A new FieldRef of the record

Remarks

This method returns an error if the record is not opened and if the field is not found.

You might obtain better performance by using the FieldIndex Method (RecordRef).

Example

The following example opens table 18 (Customer) as a RecordRef variable that is named MyRecordRef. MyRecordRef uses the Field method to create a reference to the No. field (field 1). The value in the No. field is then set to a specified record No. In this example, the record is set to 30000. The Find Method (RecordRef) method.md records for record 30000. If record is found, the Field method retrieves the value in the Name field (field 2), stores it in the varOldName variable and displays it in a message box. The Value Method (FieldRef, TestPage Field) changes the value in the Name field to a new name. In this example, the new name is 'Contoso'. The table is then modified to reflect this change and the new value in the Name field is retrieved and displayed in a message box. You can specify any record in the table and change the value in the Name field.

```
var
    MyRecordRef: RecordRef;
    MyFieldRef: FieldRef;
    varOldName: FieldRef;
    varNewName: Text;
    MyRecord: Code;
begin
    MyRecord := '30000';
    varNewName := 'Contoso';
    MyRecordRef.Open(18);
    MyFieldRef := MyRecordRef.Field(1);
    MyFieldRef.Value := MyRecord;
    if MyRecordRef.Find('=') then begin
      varOldName := MyRecordRef.Field(2);
      Message('Old Name: %1', varOldName);
      varOldName.Value := varNewName;
      MyRecordRef.Modify;
      Message('New Name: %1', MyRecordRef.Field(2));
    end;
end;
```

RecordRef.FieldCount Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Gets the number of fields in the table that are currently selected or returns the number of fields that have been defined in a key. Returns an error if no table or no key is selected.

Syntax

```
Count :=   RecordRef.FieldCount()
```

NOTE

This method can be invoked using property access syntax.

Parameters

RecordRef Type: RecordRef An instance of the RecordRef data type.

Return Value

Count Type: Integer The number of fields in the table.

Example

The following example loops through tables 3 through 5 and displays the number of fields that are defined in each table. The code starts by opening table 3 (Payment Terms) as a RecordRef variable that is named MyRecordRef. MyRecordRef variable uses the FieldCount method to retrieve the number of fields that are defined in the table and stores it in the varFieldCount variable. The name of each table and the total number of fields in the table are displayed in a message box. The table that is open is closed before the next one is open.

```
var
    MyRecordRef: RecordRef;
    varFieldCount: Integer;
    Text000: Label 'The %1 table contains %2 field\(s\).\\';
begin
    for i := 3 to 5 do begin
      MyRecordRef.Open(i);
      varFieldCount := MyRecordRef.FieldCount;
      Message(Text000, MyRecordRef.Name, varFieldCount);
      MyRecordRef.Close;
     end;
end;
```

RecordRef.FieldExist Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Determines if the field that has the number FieldNo exists in the table that is referred to by the RecordRef. Returns an error if no table is currently selected.

Syntax

```
Exist :=   RecordRef.FieldExist(FieldNo: Integer)
```

Parameters

RecordRef Type: RecordRef An instance of the RecordRef data type.

FieldNo
Type: Integer
The FieldNo that you want to know whether exists in the table.

Return Value

Exist Type: Boolean **true** if the field exists; otherwise **false**.

Example

The following example opens table 18 (Customer) as a RecordRef variable that is named MyRecordRef. The code loops through fields 1 through 12 and uses the FieldEXIST method to determine whether the specified field exists. If the field exists, the name of the field and a message that indicates that the field exists is displayed. Otherwise, a message that indicates that the field does not exist is displayed.

```
var
    MyRecordRef: RecordRef;
    i: Integer;
    VarFieldName: FieldRef;
    Text000: Label 'The %1 table contains %2 field\(s\).\\';
begin
    MyRecordRef.Open(18);
    for i := 1 to 12 do begin
      if MyRecordRef.FieldExist(i) then begin
         VarFieldName := MyRecordRef.Field(i);
         Message(Text000, i, VarFieldName.Name);
        end else
        Message(Text001, i);
      end;
end;
```

RecordRef.FieldIndex Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Gets the FieldRef of the field that has the specified index in the table that is referred to by the RecordRef.

Syntax

```
Field :=   RecordRef.FieldIndex(Index: Integer)
```

Parameters

RecordRef Type: RecordRef An instance of the RecordRef data type.

Index
Type: Integer
The index of the field.

Return Value

Field Type: FieldRef The FieldRef of the field that has the specified index.

Remarks

The fields in the primary key are always listed first in the index. Therefore, the order of the fields in the index is not necessarily the same as the order of the fields in the table.

If the index is out of the range supplied or if no table is selected, then the method returns an error.

Example

```
var
    SalesInvHdr: RecordRef;
    FldRef: FieldRef;
    Str: Text[1024];
    Text001: Label 'Index 1: %1\\';
    Text002: Label 'Index 2: %2\\';
    Text003: Label 'Index 3: %3';
begin
    SalesInvHdr.Open(112);
    FldRef1 := SalesInvHdr.FieldIndex(1);
    FldRef2 := SalesInvHdr.FieldIndex(2);
    FldRef3 := SalesInvHdr.FieldIndex(3);
    Message(Text001 + Text002 + Text003, FldRef1.Caption, FldRef2.Caption, FldRef3.Caption);
end;
```

The message window displays the following:

- Index 1: No.
- Index 2: Sell-to Customer No.

- **Index 3: Bill-to Customer No.**

The following illustration shows the first fields in table 112, Sales Invoice Header, and shows the keys for table 112. The order of the fields in the index differs from the order of the fields in the table. The index lists the field in the primary key first.

RecordRef.FilterGroup Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Changes the filter group that is being applied to the table. You can also use this method to return the number of the current filtergroup. You cannot return the number of the filtergroup and set a new filtergroup at the same time.

Syntax

```
[Group := ]  RecordRef.FilterGroup([NewGroup: Integer])
```

NOTE

This method can be invoked using property access syntax.

Parameters

RecordRef Type: RecordRef An instance of the RecordRef data type.

NewGroup

Type: Integer

The ID of the new filter group.

Return Value

Group Type: Integer The ID of the filter group.

Remarks

A filtergroup can contain a filter for a RecordRef that has been set earlier with SetFilter or SetRange. The total filter applied is the combination of all the filters set in all the filtergroups.

Example

The following example determines the filtergroup that is set on the Customer table and then changes filtergroup to 1, which is the filtergroup that is applied globally to the entire application. The code starts by opening the Customer table with a RecordRef variable. The SetRecFilter Method (RecordRef) sets the values in the current key of the current record as a record filter. This filter is a standard filtergroup so it has a filtergroup number of 0. Then the FilterGroup method returns the number for the filtergroup. This filtergroup is a standard filter so the return value is 0. This value is stored in the varOrigGroup variable and displayed in a message box. The FilterGroup method changes the filtergroup to 1, which is the number for the global filtergroup. The new value is stored in the varCurrGroup variable and displayed in a message box.

```
var
    MyRecordRef: RecordRef;
    varOrigGroup: Integer;
    varCurrGroup: Integer;
    Text000: Label 'The original filtergroup is: %1';
    Text001: Label 'The current filtergroup is: %1';
begin
    MyRecordRef.Open(Database::Customer);
    MyRecordRef.SetRecFilter;
    varOrigGroup := MyRecordRef.FilterGroup;
    Message(Text000, varOrigGroup);
    varCurrGroup := MyRecordRef.FilterGroup(1);
    Message(Text001, varCurrGroup);
end;
```

RecordRef.Find Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Finds a record in a table based on the values stored in the key fields.

Syntax

```
[Ok := ]  RecordRef.Find([Which: String])
```

Parameters

RecordRef Type: RecordRef An instance of the RecordRef data type.

Which
Type: String
Specifies how to perform the search. The table will be searched until the record is found or there are no more records. Each character in the string can be present only one time. You can use the following characters:

- = search for a record that equals the key values (default)
- > search for a record that is larger than the key values
- < search for a record that is less than the key values
- + search for the last record in the table (+ can only be used alone)
- - search for the first record in the table (- can only be used alone) You can combine the '=', '>', and '<' characters. If this parameter contains '=', '>', or '<', then you must assign value to all fields of the current and primary keys before you call Find.

Return Value

Ok Type: Boolean **true** if the operation was successful; otherwise **false**. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

Remarks

Find retrieves the first record that meets the conditions set by the *Which* parameter and the filters associated with the record. The search path reflects the sort order defined by the current key. If the current key is not the primary key, there is a chance that several records might have the same values in current key fields. If this occurs, the sort order defined by the primary key is used as the search path.

Example

The following example opens table 18 (Customer) as a RecordRef variable named CustomerRecref. The value for the field 1 (No.) is set to a specified record. In this example, the field is set to record 40000. The code uses the Find method to find the record that matches. 40000 in the table. If the record is found, the number, name, address and city of the customer are displayed in message boxes. The values in the fields are retrieved by using the Field Method (RecordRef).

```
var
    CustomerRecref: RecordRef;
    MyFieldRef: FieldRef;
    varCustomerNo: Code;
    Text000: Label 'The customer was found.\\';
    Text001: Label 'Customer No. %1 is:\\%2';
    Text002: Label 'Sorry, that customer could not be found.';
begin
    varCustomerNo := '40000';
    CustomerRecref.Open(18);
    MyFieldRef := CustomerRecref.Field(1);
    MyFieldRef.Value := varCustomerNo;
    if CustomerRecref.Find('=') then begin
      Message(Text000 + Text001,  CustomerRecref.Field(1), CustomerRecref.Field(2));
      Message('Address: %1, %2',  CustomerRecref.Field(5),  CustomerRecref.Field(7));
    end else
      Message(Text002);
end;
```

RecordRef.FindFirst Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Finds the first record in a table based on the current key and filter.

Syntax

```
[Ok := ]  RecordRef.FindFirst()
```

Parameters

RecordRef Type: RecordRef An instance of the RecordRef data type.

Return Value

Ok Type: Boolean **true** if the operation was successful; otherwise **false**. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

Remarks

You should use this method instead of Find('-') when you need only the first record.

You should use this method only when you explicitly want to find the first record in a table or set. Do not use this method in combination with repeat..until.

Example

The following example opens the Item table (27) as a RecordRef variable that is named ItemRecref. The FindFirst method searches for the first record in the table. If the record is found, the description and unit price of the item in the record are displayed in a message box. Otherwise, a message that indicates that the first item was not found is displayed.

```
var
    ItemRecref: RecordRef;
    Text000: Label 'The first item is %1 and the unit price is %2.';
    Text001: Label 'The first item was not found.';
begin
    ItemRecref.Open(27);
    if ItemRecref.FindFirst then
      Message(Text000, ItemRecref.Field(3),  ItemRecref.Field(18))
    else
      Message(Text001);
end;
```

RecordRef Data Type

RecordRef.FindLast Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Finds the last record in a table based on the current key and filter.

Syntax

```
[Ok := ]  RecordRef.FindLast()
```

Parameters

RecordRef Type: RecordRef An instance of the RecordRef data type.

Return Value

Ok Type: Boolean **true** if the operation was successful; otherwise **false**. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

Remarks

You should use this method instead of Find('+') when you need only the last record.

You should use this method only when you explicitly want to find the last record in a table or set. Do not use this method in combination with repeat..until.

Example

The following example opens the Item table (27) as a RecordRef variable that is named ItemRecref. The FindLast method searches for the last record in the table. If the record is found, the description and unit price of the item in the record are displayed in a message box. Otherwise, a message that indicates that the last item was not found is displayed.

```
var
    ItemRecref: RecordRef;
    Text000: Label 'The last item is %1 and the unit price is %2.';
    Text001: Label 'The last item was not found.';
begin
    ItemRecref.Open(27);
    if ItemRecref.FindLast then
      Message(Text000, ItemRecref.Field(3),  ItemRecref.Field(18))
    else
      Message(Text001);
end;
```

RecordRef Data Type

RecordRef.FindSet Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Finds a set of records in a table based on the current key and filter. FindSet can only retrieve records in ascending order.

Syntax

```
[Ok := ]  RecordRef.FindSet([ForUpdate: Boolean] [, UpdateKey: Boolean])
```

Parameters

RecordRef Type: RecordRef An instance of the RecordRef data type.

ForUpdate
Type: Boolean
Set this parameter to false if you do not want to modify any records in the set. Set this parameter to true if you want to modify records in the set. If you set this parameter to true, the LockTable method (RecordRef) is immediately performed on the table before the records are read.
UpdateKey
Type: Boolean
This parameter only applies if ForUpdate is true. If you are going to modify any field value within the current key, set this parameter to true.

Return Value

Ok Type: Boolean **true** if the operation was successful; otherwise **false**. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

Remarks

You should use this method only when you explicitly want to loop through a recordset. You should only use this method in combination with repeat..until.

Furthermore, FindSet only allows you to loop through the recordset from the top down. If you want to loop from the bottom up, you should use Find('+').

The general rules for using FindSet are the following:

- FindSet(False,False) - Read-only. This uses no server cursors and the record set is read with a single server call.
- FindSet(True,False) - This is used to update non-key fields. This uses a cursor with a fetch buffer similar to Find('-').
- FindSet(True,True) - This is used to update key fields.

This method is designed to optimize finding and updating sets. If you set any or both of the parameters to **false**, you can still modify the records in the set but these updates will not be performed optimally.

This method works the same way as the FindSet Method (Record).

Example

The following example opens table 18 (Customer) as a RecordRef variable that is named MyRecordRef. The Field Method (RecordRef) creates a FieldRef variable that is named MyFieldRef with the first field (No.). The SetFilter Method (FieldRef) uses the MyFieldRef variable to set a filter that selects records from 30000 to 32000. `MyRecordRef.Field(2)` creates a FieldRef for the second field (Name). The FindSet method finds the set of records based on the key and the filters that have been set. The *ForUpdate* parameters and *UpdateKeys* are both set to **False**. This makes the records in the set read-only. The record ID and name of each customer in the record set is displayed in a message box until no records are left in the record set.

```
var
    MyRecordRef: RecordRef;
    MyFieldRef: FieldRef;
    Text000: Label '%1: "%2" is found in the set of records.';
begin
    MyRecordRef.Open(18);
    MyFieldRef := MyRecordRef.Field(1);
    MyFieldRef.SetFilter('30000..32000');
    MyFieldRef := MyRecordRef.Field(2);
    if MyRecordRef.FindSet(False, False) then begin
      repeat
        Message(Text000 , MyRecordRef.RecordId, MyFieldRef.Value);
      until MyRecordRef.Next = 0;
    end;
end;
```

RecordRef.Get Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Gets a record based on the ID of the record.

Syntax

```
[Ok := ]  RecordRef.Get(RecordID: RecordId)
```

Parameters

RecordRef Type: RecordRef An instance of the RecordRef data type.

RecordID
Type: RecordId
The RecordID that contains the table number and the primary key of the table and is used to identify the record that you want to get.

Return Value

Ok Type: Boolean **true** if the operation was successful; otherwise **false**. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

Remarks

This method always uses the primary key for the table. It ignores any filters that are set, except security filters. Security filters are applied or ignored based on the Security Filter Mode. The current key and filters are not changed after you call this method. .

Example

The following example opens the Customer table with the RecordRef variable, RecRef. The code assigns the first field in the table, which is the No. field, to MyFieldRef variable. The variable is assigned a value of 30000 by using the Field Method (RecordRef). The RecordId Method (RecordRef) retrieves the record ID of the record that has a value of 30000 in the No. field. The Get method then uses the RecID variable then to retrieves the record.

```
var
    RecRef: RecordRef;
    MyFieldRef: FieldRef;
    RecID: RecordId;
begin
    RecRef.Open(Database::Customer);
    MyFieldRef := RecRef.Field(1);
    MyFieldRef.Value := '30000';
    if RecRef.Find('=') then begin
      RecID := RecRef.RecordId;
      RecRef.Get(RecID);
    end;
end;
```

RecordRef.GetBySystemId Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 4.3.*

Gets a record based on the ID of the record. The RecordRef must already be opened.

Syntax

```
[Ok := ]  RecordRef.GetBySystemId(SystemId: Guid)
```

Parameters

RecordRef Type: RecordRef An instance of the RecordRef data type.

SystemId
Type: Guid
The systemid which uniquely identifies the record that you want to get.

Return Value

Ok Type: Boolean **true** if the operation was successful; otherwise **false**. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

RecordRef.GetFilters Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Determines which filters have been applied to the table referred to by the RecordRef.

Syntax

```
String :=   RecordRef.GetFilters()
```

NOTE

This method can be invoked using property access syntax.

Parameters

RecordRef Type: RecordRef An instance of the RecordRef data type.

Return Value

String Type: String Filters that have been applied to the table that is referred to by the RecordRef parameter.

Remarks

This method works just like the GetFilters Method (Record).

Property Value/Return Value

Filters that have been applied to the table that is referred to by the *RecordRef* parameter.

Example

The following example opens a table as a RecorRef variable. The variable, RecRef, is used with the GetFilters method to retrieve the filters that are applied in the Customer table. If filters are applied, they will be stored in the Filters1 variable. The Filters1 variable does not contain any filters because filters have not been set. Then the SetRecFilter Method (RecordRef) is used to set the value in the current key of the current record as a filter. The variable Filters2 will now contain No. as a filter.

```
var
    RecRef: RecordRef;
    Filters1: Text;
    Filters2: Text;
    Text000: TexConst ENU='Filters1 contains : %1  Filters2 contains: %2';
begin
    RecRef.Open(Database::Customer);
    Filters1 := RecRef.GetFilters;
    RecRef.SetRecFilter;
    Filters2 := RecRef.GetFilters;
    Message(Text000, Filters1, Filters2);
end;
```

RecordRef.GetPosition Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Gets a string that contains the primary key of the current record.

Syntax

```
String :=   RecordRef.GetPosition([UseNames: Boolean])
```

Parameters

RecordRef Type: RecordRef An instance of the RecordRef data type.

UseNames
Type: Boolean
Indicates whether a reference to the field caption or the field number should be returned. The UseCaptions parameter is optional. If it is set to true (default value) or if it is empty, then the returned string contains references to field captions in the table with which the record is associated. If the parameter is set to false, then field numbers are used instead.

Return Value

String Type: String The name or number of the field that contains the primary key.

Remarks

This method works just like the GetPosition Method (Record).

Example

The following example opens the Customer table as a RecordRef that is named RecRef. The RecordRef variable uses the GetPosition method to retrieve the position of the primary key. The *UseCaptions* parameter is set to **true** so the caption of the field that contains the primary key is returned. If you set *UseCaptions* to **false**, the number of the field is returned.

```
var
    RecRef: RecordRef;
    varPrimaryKey: Text;
    Text000: Label 'The primary key is: %1.';
begin
    RecRef.Open(Database::Customer);
    varPrimaryKey := RecRef.GetPosition(True);
    Message(Text000, varPrimaryKey);
end;
```

RecordRef.GetTable Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Gets the table of a Record variable and causes the RecordRef to refer to the same table.

Syntax

```
RecordRef.GetTable(Rec: Record)
```

Parameters

RecordRef Type: RecordRef An instance of the RecordRef data type.

Rec
Type: Record
Use this record variable to specify the table to which the RecordRefVar refers.

Remarks

Any filters that are applied to the *RecordVar* are also applied to the *RecordRefVar*.

Another way to select the table to which a RecordRef refers is to use the Open Method (RecordRef) and specify a table number in the parameters.

Example

The following example is an excerpt from codeunit 8, AccSchedManagement. It iterates through records in the G/L Account table. It sets some values on the fields of a new record in the Acc. Schedule Line table based on the current G/L Account record and inserts the new record into the Acc. Schedule Line table. It calls GetTable to cause a RecordRef variable to refer to the same table as the new Acc. Schedule Line record, and then calls the LogInsertion method from codeunit 423, Change Log Management to log the change. The LogInsertion method requires a RecordRef as a parameter.

This example assumes that the AccSchedLineNo variable has been assigned a value previously in the code.

```
var
    AccSchedLine: Record "Acc. Schedule Line";
    AccSchedLineNo: Integer;
    GLAcc: Record "G/L Account";
    RecRef: RecordRef;
    ChangeLogMgt: Codeunit "Change Log Management";
begin
    if GLAcc.Find('-') then
      repeat
        AccSchedLine.Init;
        AccSchedLine."Line No." := AccSchedLineNo;
        AccSchedLineNo := AccSchedLineNo + 10000;
        AccSchedLine.Description := GLAcc.Name;
        if GLAcc."Account Type" IN [GLAcc."Account Type"::Posting,GLAcc."Account Type"::Total,GLAcc."Account
Type"::"End-Total"] then begin
          AccSchedLine.Totaling := GLAcc."No.";
          AccSchedLine."Row No." := CopyStr(GLAcc."No.",1,MaxStrLen(AccSchedLine."Row No."));
        end;
        if GLAcc."Account Type" IN [GLAcc."Account Type"::Total,GLAcc."Account Type"::"End-Total"] then
          AccSchedLine."Totaling Type" := AccSchedLine."Totaling Type"::"Total Accounts"
        else
          AccSchedLine."Totaling Type" := AccSchedLine."Totaling Type"::"Posting Accounts";
        AccSchedLine.Insert;
        RecRef.GetTable(AccSchedLine);
        ChangeLogMgt.LogInsertion(RecRef);
      until GLAcc.Next = 0;
end;
```

RecordRef.GetView Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Returns a string that describes the current sort order, key, and filters on a table.

Syntax

```
String :=   RecordRef.GetView([UseNames: Boolean])
```

Parameters

RecordRef Type: RecordRef An instance of the RecordRef data type.

UseNames
Type: Boolean
If this parameter is true (default) or omitted, the returned string contains references to field captions in the table with which the record is associated. If this parameter is false, the returned string contains references to field numbers in the table with which the record is associated.

Return Value

String Type: String The string format is the same as the SourceTableView property on pages.

Remarks

If the SetView Method (RecordRef) has been executed, the *String* parameter will return the value set by SetView.

This method works the same way as the GetView Method (Record).

Example

The following example opens the Customer table as a RecordRef variable that is named RecRef. The RecRef variable uses the GetView method to retrieve the field that the table is sorted on and stores the value in the varView variable. The Customer table does not have any filters and keys set so no filters or keys are displayed. The *UseCaptions* parameter is set to **true** so the name of the field is displayed. If you set the *UseCaptions* to **false**, the field number will be displayed.

```
var
    RecRef: RecordRef;
    varView: Text;
    Text000: Label 'The current view of the table is: %1';
begin
    RecRef.Open(Database::Customer);
    varView := RecRef.GetView(True);
    Message(Text000, varView);
end;
```

RecordRef.HasFilter Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Determines whether a filter has been applied to the table that the RecordRef refers to.

Syntax

```
Ok :=   RecordRef.HasFilter()
```

> **NOTE**
> This method can be invoked using property access syntax.

Parameters

RecordRef Type: RecordRef An instance of the RecordRef data type.

Return Value

Ok Type: Boolean **true** if the table referred to by RecordRef has a filter; otherwise, **false**.

Remarks

This method works just like the HasFilter Method (Record).

Example

The following example opens the Customer table with a RecordRef variable that is named RecRef. The HasFilter method determines whether a filter has been applied in the Customer table. The method returns **false** because no filters are applied. The return value is stored in the varHasFilters variable. The SetRecFilter Method (RecordRef) is used to set a filter. The HasFilter method now returns **true**. This example requires that you create the following global variables and text constant.

```
var
    varHasFilters: Text;
    RecRef: RecordRef;
    Text000: Label 'Are there any filters? %1';
begin
    RecRef.Open(Database::Customer);
    VarHasFilters := RecRef.HasFilter;
    Message('Are there any filters? %1', VarHasFilters);
    RecRef.SetRecFilter;
    VarHasFilters := RecRef.HasFilter;
    Message(Text000, VarHasFilters);
end;
```

RecordRef.HasLinks Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Determines whether a record contains any links.

Syntax

```
Ok :=   RecordRef.HasLinks()
```

NOTE

This method can be invoked using property access syntax.

Parameters

RecordRef Type: RecordRef An instance of the RecordRef data type.

Return Value

Ok Type: Boolean **true** if the record contains any links, otherwise **false**.

Remarks

The link can be a link to a website, a file stored on the local computer or on a remote computer, or a link to a Dynamics 365 page.

Example

The following example opens table 18 (Customer) as a RecordRef variable that is named CustomerRecref. The Field Method (RecordRef) creates a FieldRef variable for field 1 (No.) and stores the value in the MyFieldRef variable. The Value Method (FieldRef, TestPage Field) selects record number 20000. The HasLinks method determines whether the selected record has any links. The method returns **No** because there are no links in the record.

```
var
    CustomerRecref: RecordRef;
    MyFieldRef: FieldRef;
    varHasLinks: Boolean;
    Text000: Label 'Does this record have one or more links? %1.';
begin
    CustomerRecref.Open(18);
    MyFieldRef := CustomerRecref.Field(1);
    MyFieldRef.Value := '20000';
    varHasLinks := CustomerRecref.HasLinks;
    Message(Text000, varHasLinks);
end;
```

RecordRef.Init Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Initializes a record in a table.

Syntax

```
RecordRef.Init()
```

Parameters

RecordRef Type: RecordRef An instance of the RecordRef data type.

Remarks

This method assigns default values to each field in the record, including the SystemId field. The values that are assigned in the record correspond to those defined when the table was created. If no value was assigned when the table was created, the values are assigned based on the data type, as shown in the following table.

DATA TYPE	DEFAULT VALUE
BigInteger	0
BigText	<Empty>
BLOB	<Empty>
Boolean	No
Code	'' (empty string)
Date	0d (Undefined date)
DateFormula	'' (empty string)
DateTime	0DT (Undefined datetime)
Decimal	0.0
Duration	0
GUID	00000000-0000-0000-0000-000000000000
Integer	0

DATA TYPE	DEFAULT VALUE
Option	0
RecordID	<Empty>
TableFilter	<Empty>
Text	'' (empty string)
Time	0T (Undefined time)

NOTE

Primary key and timestamp fields are not initialized.

After the method runs, you can change the values in any or all of the fields before you call the Insert Method (RecordRef) to enter the record in the table. Be sure that the fields that make up the primary key contain values that make the total primary key unique. If the primary key is not unique (such as the record already exists), then the record is rejected.

The method works in the same way as the Init Method (Record).

Example

The following example opens a table 18 (Customer) with a RecordRef variable that is named CustomerRecref. The Field Method (RecordRef) creates a FieldRef variable that is named MyFieldRef for the field. The Init method initializes the values in the fields by using default values and then uses the Insert Method (RecordRef) to insert a new record. The new record is 1120. This is the primary key for the new record.

NOTE

In this example, the Init method is called before the primary key is assigned a value. The Init method does not initialize primary key fields. Therefore calling the Init method before or after you assign values to the primary key field does not make any difference.

```
var
    CustomerRecref: RecordRef;
    MyFieldRef: FieldRef;
    Text000: Label 'The value of the field before initialization is %1.';
    Text001: Label 'The value of the field after you insert the record is %1.';
begin
    CustomerRecref.Open(18);
    MyFieldRef := CustomerRecref.Field(1);
    CustomerRecref.Init;
    Message('%1', MyFieldRef.Value);
    MyFieldRef.Value := '1120';
    CustomerRecref.Insert;
    Message('%1', MyFieldRef.Value);
end;
```

RecordRef.Insert Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Inserts a record into a table without executing the code in the OnInsert trigger.

Syntax

```
[Ok := ]  RecordRef.Insert()
```

Parameters

RecordRef Type: RecordRef An instance of the RecordRef data type.

Return Value

Ok Type: Boolean **true** if the operation was successful; otherwise **false**. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

RecordRef.Insert Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Inserts a record into a table.

Syntax

```
[Ok := ]  RecordRef.Insert(RunTrigger: Boolean)
```

Parameters

RecordRef Type: RecordRef An instance of the RecordRef data type.

RunTrigger
Type: Boolean
If this parameter is true, the code in the OnInsert Trigger is executed. If this parameter is false, the code in the OnInsert trigger is not executed. The default value is false.

Return Value

Ok Type: Boolean **true** if the operation was successful; otherwise **false**. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

RecordRef.Insert Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 4.1.*

Inserts a record into a table.

Syntax

```
[Ok := ]  RecordRef.Insert(RunTrigger: Boolean, InsertWithSystemId: Boolean)
```

Parameters

RecordRef Type: RecordRef An instance of the RecordRef data type.

RunTrigger
Type: Boolean
If this parameter is true, the code in the OnInsert Trigger is executed. If this parameter is false, the code in the OnInsert trigger is not executed. The default value is false.
InsertWithSystemId
Type: Boolean
If this parameter is true, the SystemId field of the record is given a value that you explicitly assign. If a value is not assigned, then the platform assigns one. If this parameter is false, the SystemId field is given a value that is auto-generated by the platform. The default value is false.

Return Value

Ok Type: Boolean **true** if the operation was successful; otherwise **false**. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

RecordRef.IsDirty Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 5.0.*

Gets a boolean value that indicates whether the current in-memory instance of a record or filtered set of records has changed since being retrieved from the database.

Syntax

```
Dirty :=   RecordRef.IsDirty()
```

NOTE

This method can be invoked using property access syntax.

Parameters

RecordRef Type: RecordRef An instance of the RecordRef data type.

Return Value

Dirty Type: Boolean **true** if the a table or filtered set of records has changed; otherwise, **false**.

See Also

RecordRef Data Type
Getting Started with AL
Developing Extensions

RecordRef.IsEmpty Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Determines whether any records exist in a filtered set of records in a table.

Syntax

```
Empty :=   RecordRef.IsEmpty()
```

NOTE

This method can be invoked using property access syntax.

Parameters

RecordRef Type: RecordRef An instance of the RecordRef data type.

Return Value

Empty Type: Boolean **true** if the record or table is empty; otherwise, **false**.

Remarks

If you have not applied filters to the record, this method determines whether the table is empty. If you have applied filters, the method determines whether the filtered set of records is empty.

The number of filters that you have applied to the records affects the speed of the IsEmpty method. The fewer the number of filters, the faster the operation is performed.

When you are using SQL Server, this method is faster than using the Count Method (Record) and then testing the result for zero.

This method works the same as the IsEmpty Method (Record).

Example

The following example opens table 18, the customer table as a RecordRef variable that is named. CustomerRecref. The IsEmpty Method (RecordRef) determines whether the table is empty. The message box displays **false** because the Customer table is not empty. **false** represents **false**.

```
var
    CustomerRecref: RecordRef;
    Text000: Label 'Is the table empty? %1.';
begin
    CustomerRecref.Open(18);
    IsEmpty := CustomerRecref.IsEmpty;
    Message(Text000, IsEmpty);
end;
```

If you open table 78 (Printer Selection), the message will display **true** because the table is empty.

RecordRef.IsTemporary Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Determines whether a RecordRef refers to a temporary table.

Syntax

```
Temporary :=   RecordRef.IsTemporary()
```

NOTE

This method can be invoked using property access syntax.

Parameters

RecordRef Type: RecordRef An instance of the RecordRef data type.

Return Value

Temporary Type: Boolean **true** if the RecordRef refers to a temporary table, otherwise **false**.

Remarks

In versions of Dynamics 365 earlier than Microsoft Dynamics NAV 2013, if a RecordID or a RecordRef referred to a temporary table, then the table number value of the RecordID or RecordRef was the run-time generated sequence ID, which is from the base value of 2000100000. You could use the table number to determine if a RecordID or a RecordRef referred to a temporary table. In Dynamics 365 Business Central, the table number value of a RecordID or a RecordRef always contains the ID of the originating physical table and not the run-time generated sequence ID. If you previously used the TableNo Method (RecordID) or the Number Method (RecordRef) to test for the sequence number and determine if the RecordID or RecordRef was temporary, then you must use the IsTemporary method in Dynamics 365 instead.

Example

This example shows that you can replace code that you used previously to determine if a RecordRef referred to a temporary table. This example requires that you create a RecordRef variable named RecordRefVar.

```
// Previous code
ifRecordRefVar.Number >= 2000100000 then begin
  // Code for temporary tables
end;

// New code
ifRecordRefVar.IsTemporary then begin
  // Code for temporary tables
end;
```

RecordRef.KeyCount Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Gets the number of keys that exist in the table that is referred to by the RecordRef. Returns an error if no table is selected.

Syntax

```
Count :=   RecordRef.KeyCount()
```

NOTE

This method can be invoked using property access syntax.

Parameters

RecordRef Type: RecordRef An instance of the RecordRef data type.

Return Value

Count Type: Integer The number of keys that have been identified in the table.

Example

The following example opens the Customer table (18) as a RecordRef variable that is named CustomerRecref. The KeyCount method retrieves the number of keys that are defined in the Customer table. The return value of the method is stored in the KeyCount variable and displayed in a message box. The KeyCount variable contains the number 13 because 13 keys are defined in the Customer table.

```
var
    CustomerRecref: RecordRef;
    KeyCount: Integer;
    Text000: Label 'The table has %1 keys.';
begin
    CustomerRecref.Open(18);
    KeyCount := CustomerRecref.KeyCount;
    Message(Text000, KeyCount);
end;
```

See Also

RecordRef Data Type

RecordRef.KeyIndex Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Gets the KeyRef of the key that has the index specified in the table that is currently selected. The key can be composed of fields of any supported data type. Data types that are not supported include BLOBs, FlowFilters, variables, and functions. If the sorting key is set to a field that is not part of a key, then the KeyIndex is -1.

Syntax

```
Key :=   RecordRef.KeyIndex(Index: Integer)
```

Parameters

RecordRef Type: RecordRef An instance of the RecordRef data type.

Index

Type: Integer

The number of the index in which you are interested.

Return Value

Key Type: KeyRef The KeyRef of the field that has the specified index.

Remarks

The first key in the index must have index 1, the second index 2, and so on. The last key must have index = KeyCount. If the specified index is out of the range or if no table is selected, the method returns an error.

Example

The following example opens table 18 (Customer) as a RecordRef variable that is named CustomerRecref. The loop starts from 1 and loops through the key indexes that are in the table. `CustomerRecref.KeyCount` returns the maximum number of keys that are defined in the table. The loop continues until the last key is reached. For each index that is specified, the KeyIndex method retrieves the KeyRef for the specified index. The key index and the KeyRef for the specified indexes are displayed in a message box.

```
var
    CustomerRecref: RecordRef;
    i: Integer;
    varKeyRef: KeyRef;
    Text000: Label 'KeyIndex: %1   KeyRef: %2';
begin
    CustomerRecref.Open(18);
      for i := 1 to CustomerRecref.KeyCount do begin
        varKeyRef := CustomerRecref.KeyIndex(i);
        Message(Text000, i, varKeyRef);
      end;
    CustomerRecref.Close;
end;
```

RecordRef.LoadFields Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 6.0.*

Accesses the table's corresponding data source and loads the values of the specified fields on the record.

Syntax

```
[Ok := ]  RecordRef.LoadFields(Fields: Integer,...)
```

Parameters

RecordRef Type: RecordRef An instance of the RecordRef data type.

Fields
Type: Integer
The FieldNo's of the fields to be loaded.

Return Value

Ok Type: Boolean **true** if all values were loaded on the record; otherwise, **false**. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

Remarks

This method will trigger a JIT load of the specified fields. The method allows for triggering the JIT load on multiple fields. If the fields are already loaded, another load won't be triggered. Using this method instead of of relying on implicit JIT loads lets you develop for more explicit error handling when a load fails.

The method is part of the partial records capability for improving performance. For more information, see Using Partial Records.

RecordRef.LockTable Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Locks a table to protect it from write transactions that conflict with each other.

Syntax

```
RecordRef.LockTable([Wait: Boolean] [, VersionCheck: Boolean])
```

Parameters

RecordRef Type: RecordRef An instance of the RecordRef data type.

Wait
Type: Boolean
Specifies what to do if the table is already locked. If this parameter is true and if another application has already locked the table, the system will wait until the table is unlocked. If this parameter is false and if another application has already locked the table, a run-time error occurs.

VersionCheck
Type: Boolean
If this parameter is true, the version of the RecordRef will be checked. If this parameter is false, blank, or not used, the version will not be checked.

Remarks

Because all write operations automatically lock the table that is being used, LockTable would appear unnecessary. However, you could have a transaction in which an application wants to inspect data before possibly changing it, with a guarantee that the data being changed has not been modified by other applications since the read operation. The solution is to explicitly lock the table before the read operation. This makes sure that no other application makes changes between the read operation and the possible write operation.

The table lock is released (unlocked) when the transaction is committed.

This method works the same as the LockTable Method (Record).

Example 1

The following example opens table number 18 (Customer) as a RecordRef that is named MyRecordRef. The LockTable method locks the table. This ensures that no records are inserted or deleted during the counting process. The Count Method (RecordRef) then retrieves the number of records in the table. The number of records is stored in the Count variable. The name of the table and the number of records in the table is displayed in a message box. The varTableNo variable can be used to open any table and get the number of records in that table by changing the value of the varTableNo variable.

```
var
    CustomerRecref: RecordRef;
    Count: Integer;
    varTableNo: Integer;
    Text000: Label 'The number of records in the %1 table is: %2.';
begin
    varTableNo := 18;
    MyRecordRef.Open(varTableNo);
    MyRecordRef.LockTable;
    Count := MyRecordRef.Count;
    Message(Text000, MyRecordRef.Name, Count);
end;
```

Example 2

This example uses pseudo-language to show the scope of write locks. Both an explicit lock and an automatic lock are illustrated. The first line (1) explicitly locks table A. If this explicit lock was not set on table A, the Database Management System (DBMS) would automatically lock this table when a record is inserted (3). Table B is not locked explicitly, but is locked automatically by the DBMS when a record is inserted (4). Both locks are active until the system exits the AL code module (5).

```
BeginWriteTransaction
TableA.LockTable // (1)
FindRec(TableA, ...) // (2)
.
.
InsertRec(TableA,...) // (3)
.
InsertRec(TableB) // (4)
.
.
EndWriteTransaction // (5)
```

If a data update depends on a prior read operation and there is a long time between the read operation and the write operation, you may not want to lock the table as you usually would during a transaction. This enables you to prevent other users from updating the table until your transaction is committed.

RecordRef.Mark Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 5.3.*

Marks a record. You can also use this method to determine whether a record is marked.

Syntax

```
[Marked := ]  RecordRef.Mark([Mark: Boolean])
```

Parameters

RecordRef Type: RecordRef An instance of the RecordRef data type.

Mark
Type: Boolean
Specifies if a record is marked.

Return Value

Marked Type: Boolean **true** if the record is marked; otherwise, **false**.

See Also

RecordRef Data Type
Getting Started with AL
Developing Extensions

RecordRef.MarkedOnly Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 5.3.*

Activates a special filter. After you use this function, your view of the table includes only records marked by this function.

Syntax

```
[MarkedOnly := ]  RecordRef.MarkedOnly([MarkedOnly: Boolean])
```

NOTE

This method can be invoked using property access syntax.

Parameters

RecordRef Type: RecordRef An instance of the RecordRef data type.

MarkedOnly

Type: Boolean

Activates a special filter.

Return Value

MarkedOnly Type: Boolean **true** if the special filter is being used; otherwise, **false**.

See Also

RecordRef Data Type
Getting Started with AL
Developing Extensions

RecordRef.Modify Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Modifies a record in a table.

Syntax

```
[Ok := ]  RecordRef.Modify([RunTrigger: Boolean])
```

Parameters

RecordRef Type: RecordRef An instance of the RecordRef data type.

RunTrigger
Type: Boolean
Specifies whether to run the AL code in the OnModify Trigger. If this parameter is true, then the code in the OnModify trigger is executed. If this parameter is false (default), then the code is not executed.

Return Value

Ok Type: Boolean **true** if the operation was successful; otherwise **false**. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

Remarks

Select the record that you want to modify by using the primary key fields. The record's current key and filters do not affect the operation.

If an end-user modifies a record between the time that another end-user or another process reads the record and modifies it, then the second user must refresh the value of the record variable before editing the record. Otherwise, the end-user receives the following run-time error:

Another user has modified the record for this <Table Name> after you retrieved it from the database.

Enter your changes again in the updated window, or start the interrupted activity again.

In earlier versions of Dynamics 365, certain situations allowed code that an end-user runs to modify a record after a newer version of the record was written and committed to the database. This would overwrite the newer changes. However, in Dynamics 365 Business Central, we have restricted the **Modify** Method (RecordRef), Rename Method (RecordRef), and Delete Method (RecordRef) so that the end-user receives the following run-time error in these certain situations:

Unable to change an earlier version of the <Table Name> record. The record should be read from the database again. This is a programming error.

You must design your application so that you use the most up-to-date version of the record for modifications to the database. You use the Get Method (RecordRef) to refresh the record with the latest version.

This method works the same as the Modify Method (Record).

RecordRef.Name Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Identifies the name of the table

Syntax

```
Name :=   RecordRef.Name()
```

NOTE

This method can be invoked using property access syntax.

Parameters

RecordRef Type: RecordRef An instance of the RecordRef data type.

Return Value

Name Type: String The name of the table.

Remarks

This method works the same as the TableName Method (Record).

Example

The following example opens a table as a RecordRef variable that is named MyRecordRef. You can specify any table number in the Open Method (RecordRef). In this example, the table 18 (Customer) is open. The Name method retrieves the name of table 18 and stores it in the varTableName variable. The table number and name are displayed in a message box.

```
var
    MyRecordRef: RecordRef;
    varTableName: Text;
    Text000: Label 'Table %1 is the %2 table.';
begin
    TableNo := 18;
    MyRecordRef.Open(TableNo);
    varTableName := MyRecordRef.Name;
    Message(Text000, TableNo, varTableName);
end;
```

See Also

RecordRef Data Type
Getting Started with AL

RecordRef.Next Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Steps through a specified number of records and retrieves a record.

Syntax

```
[Steps := ]  RecordRef.Next([Steps: Integer])
```

Parameters

RecordRef Type: RecordRef An instance of the RecordRef data type.

Steps
Type: Integer
Defines the direction of the search and how many records to step include. If this parameter is greater than zero, the method will search the number of records specified in Steps forward in the table. If this parameter is less than zero, the method will search the number of records specified in Steps backward in the table. If this parameter is 0, no records are stepped over. If you do not specify this parameter, the method finds the next record.

Return Value

Steps Type: Integer Defines the direction of the search and how many records to include.

Remarks

This method locates a record positioned a given number of steps forward or backward from the record specified by *RecordRef*. Movement through the table is governed by the filters and the current key associated with the records. The fields in the record which will be compared with the current key fields must contain appropriate values before the method is called.

This method works the same as the Next Method (Record).

Example

The following example opens the Customer table as a RecordRef object, creates a reference to the first (No.) field, and stores the reference in the MyFieldRef variable. The SetRange method sets a filter that selects all records from 10000 to 40000 in the No. field. The Find Method (RecordRef) searches and selects the first record in the filter and counts the number of records that are found. The number of records is stored in the Count variable. The process is repeated by looping through all the records in the filter until no more records are found. The Next method steps through the records and finds the next record because no value is specified for the *Steps* parameter. The number of records that are found in the range is stored in the Count variable and displayed in a message box.

```
var
    CustomerRecref: RecordRef;
    MyFieldRef: FieldRef;
    Count: Integer;
    Text000: Label '%1 records were retrieved.';
begin
    CustomerRecref.Open(Database::Customer);
    MyFieldRef := CustomerRecref.Field(1);
    MyFieldRef.SetRange('10000' , '40000');
    Count := 0;
    if CustomerRecref.Find('-') then
      repeat
        Count := Count + 1;
      until CustomerRecref.Next = 0;
    Message(Text000 , Count);
end;
```

RecordRef.Number Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Gets the table ID (number) of the table that contains the record that was referred to by the RecordRef.

Syntax

```
No :=   RecordRef.Number()
```

NOTE

This method can be invoked using property access syntax.

Parameters

RecordRef Type: RecordRef An instance of the RecordRef data type.

Return Value

No Type: Integer The table ID of the table that contains the record that was referred to by the RecordRef.

Remarks

In versions of Dynamics 365 earlier than Microsoft Dynamics NAV 2013, if a RecordRef referred to a temporary table, then the table number value of the RecordRef was the run-time generated sequence ID, which is from the base value of 2000100000. You could use the table number to determine whether a RecordRef referred to a temporary table. In Dynamics 365 Business Central, the table number value of a RecordRef always contains the ID of the originating physical table and not the run-time generated sequence ID. If you previously used the Number Method (RecordRef) to test for the sequence number and determine whether the RecordRef was temporary, then you must use the IsTemporary Method (RecordRef) in Dynamics 365 instead.

Example

The following example opens the Customer table (18) as a RecordRef object. The Open Method (RecordRef) accepts `Database::Customer` as an integer. The Number method retrieves the table number and displays the name and number of the table in a message box.

```
var
    MyRecordRef: RecordRef;
    varDatabaseName: Integer;
    varTableNumber: Integer;
    Text000: Label '%1 is table %2.';
begin
    varDatabaseName := Database::Customer;
    MyRecordRef.Open(varDatabaseName);
    varTableNumber := MyRecordRef.Number;
    Message(Text000, MyRecordRef.Caption, varTableNumber);
end;
```

RecordRef.Open Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Causes a RecordRef variable to refer to a table, which is identified by its number in a particular company.

Syntax

```
RecordRef.Open(No: Integer [, Temp: Boolean] [, CompanyName: String])
```

Parameters

RecordRef Type: RecordRef An instance of the RecordRef data type.

No
Type: Integer
The number of the table.

Temp
Type: Boolean

CompanyName
Type: String
The name of the company to which you want to change. If you omit this parameter, the current company is used.

Remarks

When you use the RecordRef.Open method a new object is created. This object contains references to the open table, filters, and the record itself and all the fields it contains. You can open a table by using the table number or the name of the table that represents the table number. For example, you open the Customer table by using following syntax: `RecordRef.Open(18)` or `RecordRef.Open(Database::Customer)`

If you use the *CompanyName* parameter, then this method works the same as the ChangeCompany Method (Record).

Example 1

The following example uses the Open method to create a RecordRef variable that is named MyRecordRef for the Customer table. The parameters are omitted in this example because there is only one company in this example and the table will not be open as temporary table. The caption and number of records in the table are displayed in a Message box. At the end of the display, the Close Method (RecordRef) closes the table.

```
var
    MyRecordRef: RecordRef;
    Text000: Label 'The %1 table contains %2 records.';
begin
    MyRecordRef.Open(Database::Customer);
    Message(Text000, MyRecordRef.Caption, MyRecordRef.Count);
    MyRecordRef.Close;
end;
```

Example 2

This example shows how to use the Open method. In this example, "MyRecordRef" opens table 27 and then "Find('-')" finds the first record in the table. "TempMyRecordRef" opens a temporary table which is empty and therefore the "Find('-')" returns false.

```
var
    MyRecordRef: RecordRef;
    TempMyRecordRef: RecordRef;
begin
    MyRecordRef.Open(27,false);
    TempMyRecordRef.Open(27,true);

    if MyRecordRef.Find('-') then // This is true and will find the first record in the table.
      Message('MyRecordRef finds')
    else
      Message('MyRecordRef does not find');

    if TempMyRecordRef.Find('-') then // This is false because there are no records in a temporary table.
      Message('TempMyRecordRef finds')
    else
      Message('TempMyRecordRef does not find');
end;
```

RecordRef.ReadConsistency Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Gets a value indicating whether read consistency is enabled.

Syntax

```
Ok :=   RecordRef.ReadConsistency()
```

NOTE

This method can be invoked using property access syntax.

Parameters

RecordRef Type: RecordRef An instance of the RecordRef data type.

Return Value

Ok Type: Boolean **true** if read consistency is enabled; otherwise, **false**.

See Also

RecordRef Data Type
Getting Started with AL
Developing Extensions

RecordRef.ReadPermission Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Determines if you can read from a table.

Syntax

```
Ok :=   RecordRef.ReadPermission()
```

NOTE

This method can be invoked using property access syntax.

Parameters

RecordRef Type: RecordRef An instance of the RecordRef data type.

Return Value

Ok Type: Boolean **true** if you can read from some or all of the table; otherwise, **false**.

Remarks

This method can test for both full read permission and a partial read permission that has been granted with a security filter.

This method uses the filter that is currently applied to the *RecordRef* to determine whether you have read permission. If no filter is applied, the method tests for full read permission. If a filter has been set, the method only tests for read permission in the range of the filter.

To determine whether the user has a partial read permission because a security filter has been applied, view the **Permissions** page.

If you do not have permission to read from a table and you attempt to read, a run-time error occurs. This method lets you determine in advance if you have read permission. When the permissions are checked, the combination of the permissions in the license file and the user's permissions in the Permission table is considered.

This method works the same as the ReadPermission Method (Record).

Example

The following example opens table 18 (Customer) and creates a RecordRef variable that is named MyRecordRef for the table. The ReadPermission method determines whether the table has read permission and stores the return value in the varHasReadPerm variable. The Customer table has read permission, so the message displays **Yes**. You can initialize the varTableNo variable with any table number.

```
var
    MyRecordRef: RecordRef;
    varHasReadPerm: Boolean;
    varTableNo: Integer;
    Text000: Label 'Does the %1 table have read permission? %2';
begin
    varTableNo := 18;
    MyRecordRef.Open(varTableNo);
    varHasReadPerm := MyRecordRef.ReadPermission;
    Message(Text000, MyRecordRef.Name, varHasReadPerm);
end;
```

RecordRef.RecordId Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Gets the RecordID of the record that is currently selected in the table. If no table is selected, an error is generated.

Syntax

```
RecordID :=   RecordRef.RecordId()
```

NOTE

This method can be invoked using property access syntax.

Parameters

RecordRef Type: RecordRef An instance of the RecordRef data type.

Return Value

RecordID Type: RecordId The ID of the table.

Example

The following example opens table 18 (Customer) as a RecordRef variable that is named MyRecordRef. The FindLast Method (RecordRef) finds the last record in the table. The record id of the last record is retrieved, stored in the RecID variable displayed in message box.

```
var
    MyRecordRef: RecordRef;
    RecID: RecordId;
    Text000: Label 'The record id for the last record is: %1';
begin
    MyRecordRef.Open(18);
    MyRecordRef.FindLast;
    RecID := MyRecordRef.RecordId;
    Message(Text000, RecID);
end;
```

RecordRef.RecordLevelLocking Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Gets a value indicating whether record level locking is enabled.

Syntax

```
Ok :=   RecordRef.RecordLevelLocking()
```

NOTE

This method can be invoked using property access syntax.

Parameters

RecordRef Type: RecordRef An instance of the RecordRef data type.

Return Value

Ok Type: Boolean **true** if record level locking is enabled, otherwise **false**.

See Also

RecordRef Data Type
Getting Started with AL
Developing Extensions

RecordRef.Rename Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Changes the value of a primary key in a table.

Syntax

```
[Ok := ]  RecordRef.Rename(Value1: Any [, Value2: Any,...])
```

Parameters

RecordRef Type: RecordRef An instance of the RecordRef data type.

Value1
Type: Any
The new values for the primary key.
Value2
Type: Any
The new values for the primary key.

Return Value

Ok Type: Boolean **true** if the operation was successful; otherwise **false**. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

Remarks

You cannot rename some tables. Examples of the types of tables that you cannot rename are:

- Tables in which the user is not allowed to rename the Document No. for legal or business reasons.
- Tables in which an Option data type field, such as Document Type, is part of the primary key.

Some examples of tables that you cannot rename are:

- Table 36, Sales Header
- Table 38, Purchase Header
- Table 5405, Production Order
- Table 5766, Warehouse Activity Header

If an end-user modifies a record between the time that another end-user or another process reads the record and modifies it, then the second user must refresh the value of the record variable before editing the record. Otherwise, the end-user receives the following run-time error:

Another user has modified the record for this <Table Name> after you retrieved it from the database.

Enter your changes again in the updated window, or start the interrupted activity again.

In earlier versions of Dynamics 365, certain situations allowed code that an end-user runs to modify a record after a newer version of the record was written and committed to the database. This would overwrite the newer changes. However, in Dynamics 365 Business Central, we have restricted the Modify Method (RecordRef), **Rename** Method (RecordRef), and Delete Method (RecordRef) so that the end-user receives the following run-time error in these certain situations:

Unable to change an earlier version of the <Table Name> record. The record should be read from the database again. This is a programming error.

You must design your application so that you use the most up-to-date version of the record for modifications to the database. You use the Get Method (RecordRef) to refresh the record with the latest version.

Example

This example shows how to change the value of the primary key of a Record variable, and how to change the value of the primary key of a RecordRef variable.

```
var
    CustomerRecRef: RecordRef;
    NewNo1: Code;
    NewNo2: Code;
    result: Boolean;
    CustomerRec: Record Customer;
begin
    CustomerRec.Get('0112121');
    NewNo1 := '9999999';
    NewNo2 := '8888888';
    Message('Customer name: %1; Customer number: %2',CustomerRec.Name, CustomerRec."No.");
    result := CustomerRec.Rename(NewNo1);
    if result then
      Message('After rename - Customer name: %1; Customer number: %2',CustomerRec.Name, CustomerRec."No.")
    else
      Message('No rename.');
    CustRecRef.GetTable(CustomerRec);
    result := CustRecRef.Rename(NewNo2);
    if result then begin
      CustomerRec.Get(NewNo2);
      Message('After rename 2 - Customer name: %1; Customer number: %2',CustomerRec.Name, CustomerRec."No.")
    end else
      Message('No rename.');
end;
```

If a record with No. 0112121 is found, and if the renames are successful, then the following messages are displayed:

Customer name: Spotsmeyer's Furnishings; Customer number: 0112121

After rename - Customer name: Spotsmeyer's Furnishings; Customer number: 9999999

After rename 2 - Customer name: Spotsmeyer's Furnishings; Customer number: 8888888

RecordRef.Reset Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Removes all filters, including any special filters set by the MarkedOnly method (Record), changes fields select for loading back to all, and changes the current key to the primary key. Also removes any marks on the record and clears any AL variables defined on its table definition.

Syntax

```
RecordRef.Reset()
```

Parameters

RecordRef Type: RecordRef An instance of the RecordRef data type.

Remarks

If no table is selected, this method returns an error.

This method works the same as the Reset Method (Record).

Example

The following example opens the Customer (18) table and creates a RecordRef variable that is named RecRef. The GetFilters Method (RecordRef) gets filters that have been applied to records in the table. The filters that are returned, if any, are stored in the Filters1 variable and displayed in message box. In this example, no filters are set so the message is blank. The SetRecFilter Method (RecordRef) sets a filter on the current key of the current record that is represented by the RecRef variable. The GetFilters Method (RecordRef) gets the filters that have been set and stores the value in the Filters2 variable. The message displays No. because the No. field is set as a filter. The Reset method removes the filter that was set. The value of the filter that is returned by the GetFilters Method (RecordRef) after the Reset Method (RecordRef) is executed is stored in the Filters3 variable. Filter3 is blank because the filter that was set by `RecRef.SetRecFilter;` is removed by the Reset method.

```
var
    RecRef: RecordRef;
    Filters1: Text;
    Filters2: Text;
    Filters3: Text;
    Text000: Label 'Filter before filter is set is: %1.';
    Text001: Label 'Filter after filter is set is: %1.';
    Text002: Label 'Filter before filter is reset is: %1.';
begin
    RecRef.Open(Database::Customer);
    Filters1 := RecRef.GetFilters;
    Message(Text000, Filters1);
    RecRef.SetRecFilter;
    Filters2 := RecRef.GetFilters;
    Message(Text001, Filters2);
    RecRef.Reset;
    Filters3 := RecRef.GetFilters;
    Message(Text002, Filters3);
end;
```

RecordRef.SecurityFiltering Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Gets or sets how security filters are applied to the RecordRef.

Syntax

```
[SecurityFiltering := ]  RecordRef.SecurityFiltering([NewSecurityFiltering: SecurityFilter])
```

NOTE

This method can be invoked using property access syntax.

Parameters

RecordRef Type: RecordRef An instance of the RecordRef data type.

NewSecurityFiltering

Type: SecurityFilter

The new security filter for the RecordRef.

Return Value

SecurityFiltering Type: SecurityFilter The security filter applied to the RecordRef.

See Also

RecordRef Data Type

Developing Extensions

RecordRef.SetLoadFields Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 6.0.*

Sets the fields to be initially loaded when the record is retrieved from its data source. This will overwrite fields previously selected for initial load.

Syntax

```
[Ok := ]  RecordRef.SetLoadFields([Fields: Integer,...])
```

Parameters

RecordRef Type: RecordRef An instance of the RecordRef data type.

Fields
Type: Integer
The FieldNo's of the fields to be loaded.

Return Value

Ok Type: Boolean **true** if all fields are selected for subsequent loads; otherwise, **false**. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

Remarks

Calling SetLoadFields on a recordref without passing any fields will reset the fields selected to load to the default, where all readable normal fields are selected for load.

It is not necessary to include the following fields, because they are always selected for loading: Primary key, SystemId, and data audit fields (SystemCreatedAt, SystemCreatedBy, SystemModifiedAt, SystemModifiedBy).

This method is part of the partial records capability for improving performance. For more information, see Using Partial Records.

Example

This code example uses the SetLoadFields method to speedup the calculation of the mean for values in a table field. The other fields aren't needed for the calculation, so they're not loaded.

```
procedure ComputeAritmeticMean(MyRecordRef: RecordRef; FieldNo: Integer): Decimal
var
    SumTotal: Decimal;
    Counter: Integer;
begin
    MyRecordRef.SetLoadFields(FieldNo);
    if MyRecordRef.FindSet() then begin
        repeat
            SumTotal := MyRecordRef.Field(FieldNo).Value;
            Counter += 1;
        until MyRecordRef.Next() = 0;
        exit(SumTotal / Counter);
    end;
end;
```

RecordRef.SetPermissionFilter Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Applies the user's security filter to the referenced record. The security filter is combined with any other filters that are placed on the record with SetFilter or SetRange. The combined filter will not include any records outside the range of the security filter and this will prevent a runtime permission error from occuring when the record is read. If the permission filter is not set, an error can occur if you attempt to read a record that is outside the range of the user's security filter.

Syntax

```
RecordRef.SetPermissionFilter()
```

Parameters

RecordRef Type: RecordRef An instance of the RecordRef data type.

See Also

RecordRef Data Type
Getting Started with AL
Developing Extensions

RecordRef.SetPosition Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Sets the fields in a primary key on a record to the values specified in the String parameter. The remaining fields are not changed.

Syntax

```
RecordRef.SetPosition(String: String)
```

Parameters

RecordRef Type: RecordRef An instance of the RecordRef data type.

String

Type: String

The string that is used to set the primary key. This string contains the primary key value to set.

Remarks

This method works the same as the SetPosition Method (Record).

Example

The following example changes the value in the primary key, the No. field, in table 23 (Vendor). Other fields are not changed. The code starts by opening table 23 (Vendor) as a RecordRef variable that is named MyRecordRef. The Field Method (RecordRef) selects the first field (No.) and stores the value in the MyFieldRef variable. The SetFilter Method (FieldRef) sets a filter that selects records from 10000 to 20000. The FindLast Method (RecordRef) finds and retrieves the last record in the record set. The SetPosition method changes the value in the No. field from 20000 to 20001. The record No. and the name of the record are displayed before and displayed again after the primary key value is changed. The string that contains the new primary key is initialized in the InputString variable.

```
var
    MyRecordRef: RecordRef;
    InputString: Text;
    MyFieldRef: FieldRef;
    Text000: Label 'The record No. before the primary key was changed is %1.\\ The vendor name before the
primary key was changed is %2.';
    Text001: Label 'The record No. after the primary key was changed is %1. \\ The vendor name after the
primary key was changed is %2';
begin
    InputString := 'No.=Const(20001)';
    MyRecordRef.Open(23);
    MyFieldRef := MyRecordRef.Field(1);
    MyFieldRef.SetFilter('10000..20000');
    MyRecordRef.FindLast;
    Message(Text000, MyRecordRef.RecordId, MyRecordRef.Field(2));
    MyRecordRef.SetPosition(InputString);
    Message(Text001, MyRecordRef.RecordId, MyRecordRef.Field(2));
end;
```

The following is displayed before the SetPosition method is called:

The record No. before the primary key was changed is Vendor: 20000.

The vendor name before the primary key was changed is AR Day property Management.

The following is displayed after the SetPosition method is called:

The record No. after the primary key was changed is Vendor: 20001.

The vendor name after the primary key was changed is AR Day property Management.

RecordRef.SetRecFilter Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Sets a filter on a record that is referred to by a RecordRef.

Syntax

```
RecordRef.SetRecFilter()
```

Parameters

RecordRef Type: RecordRef An instance of the RecordRef data type.

Remarks

This method works the same as the SetRecFilter Method (Record).

Example

The following example opens the Customer table as a RecordRef variable that is named MyRecordRef. The SetRecFilter method sets the values in the current key of the current record as a record filter. The GetFilters Method (RecordRef) retrieves the filters that have been set and displays them in a message box. No. is displayed because the filter is set on the No. field, which is the current key.

```
var
    MyRecordRef: RecordRef;
    varFilters: Text;
    Text000: Label 'The filter is set on the %1 field.';
begin
    MyRecordRef.Open(Database::Customer);
    MyRecordRef.SetRecFilter;
    varFilters := MyRecordRef.GetFilters;
    Message(Text000, varFilters);
end;
```

RecordRef.SetTable Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Sets the table to which a Record variable refers as the same table as a RecordRef variable.

Syntax

```
RecordRef.SetTable(Rec: Record)
```

Parameters

RecordRef Type: RecordRef An instance of the RecordRef data type.

Rec
Type: Record
Specifies the Record that you want to refer to the table.

Remarks

Any filters that are applied to the RecordRef are also applied to the Record. If you change the filter that is applied to the RecordRef, you must call SetTable again to apply the new filter to the Record.

Example

This example shows that if you have a RecordID data type, you can get a RecordRef for the table that the RecordID refers to. Then you can use the RecordRef to set the table to which a Record variable refers.

```
var
    RecRef: RecordRef;
    InvtEventBuf: Record "Inventory Event Buffer";
    RecID: RecordId;
    ProdOrderComp: Record "Prod. Order Component";
begin
    InvtEventBuf.Find('-');
    RecID := InvtEventBuf."Source Line ID";
    RecRef := RecID.GetRecord;
    RecRef.SetTable(ProdOrderComp);
end;
```

RecordRef.SetView Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Sets the current sort order, key, and filters on a table.

Syntax

```
RecordRef.SetView(String: String)
```

Parameters

RecordRef Type: RecordRef An instance of the RecordRef data type.

String
Type: String
The string format is the same as the SourceTableView property on pages.

Remarks

The value of the *String* parameter can be returned by the GetView Method (RecordRef).

If the SetView method is executed with an empty string, all the filters are removed and the primary key is used.

If no table is selected, the SetView method fails.

This method works the same as the SetView Method (Record).

Example

The following example opens the Customer (18) table as a RecordRef variable that is named CustomerRecRef. The SetView method sets the sort key to the Name field, sort order to Ascending and sets a filter that selects records between 1000 and 2000. The GetView Method (RecordRef) retrieves the sort order, key and filters that have been set and stores the value in the ViewString variable. The value in the ViewString variable is displayed in a message box.

```
var
    CustomerRecRef: RecordRef;
    ViewString: Text;
    Text000: Label 'The following is the current sort order, key, and filters that are set: %1';
begin
    CustomerRecRef.Open(18);
    CustomerRecRef.SetView('Sorting(Name) Order(Ascending) Where(No.=Const(10000..20000))');
    ViewString := CustomerRecRef.GetView;
    Message(Text000, ViewString);
end;
```

RecordRef.SystemCreatedAtNo Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 6.0.*

Gets the field number that is used by the SystemCreatedAt field. The SystemCreatedAt field is a system field that the platform adds to all table objects.

Syntax

```
SystemCreatedAtFieldNo :=   RecordRef.SystemCreatedAtNo()
```

NOTE

This method can be invoked using property access syntax.

Parameters

RecordRef Type: RecordRef An instance of the RecordRef data type.

Return Value

SystemCreatedAtFieldNo Type: Integer The field number of the SystemCreatedAt field.

RecordRef.SystemCreatedByNo Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 6.0.*

Gets the field number that is used by the SystemCreatedBy field. The SystemCreatedBy field is a system field that the platform adds to all table objects.

Syntax

```
SystemCreatedByFieldNo :=   RecordRef.SystemCreatedByNo()
```

NOTE

This method can be invoked using property access syntax.

Parameters

RecordRef Type: RecordRef An instance of the RecordRef data type.

Return Value

SystemCreatedByFieldNo Type: Integer The field number of the SystemCreatedBy field.

RecordRef.SystemIdNo Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 4.0.*

Gets the field number that is used by the SystemId field. The SystemId field is a system field that the platform adds to all table objects.

Syntax

```
SystemIdFieldNo :=   RecordRef.SystemIdNo()
```

NOTE

This method can be invoked using property access syntax.

Parameters

RecordRef Type: RecordRef An instance of the RecordRef data type.

Return Value

SystemIdFieldNo Type: Integer The field number of the SystemId field.

Example

This example shows how to use the SystemIdNo method to retrieve the field number that is used by the SystemId field of a table.

```
var
    CustomerRec: Record Customer;
    SystemIdFieldNo: Integer;
    Text000: Label 'The field number is: %1.';

begin
    CustomerRec.Open(Database::Customer);
    SystemIdFieldNo := CustomerRec.SystemIdNo();
    Message(Text000, Format(SystemIdFieldNo));
end;
```

RecordRef.WritePermission Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Determines if you can write to a table.

Syntax

```
Ok :=   RecordRef.WritePermission()
```

NOTE

This method can be invoked using property access syntax.

Parameters

RecordRef Type: RecordRef An instance of the RecordRef data type.

Return Value

Ok Type: Boolean Specifies if you have permission to write to the table

Remarks

This method can test for both full write permission and a partial write permission that has been granted with a security filter. A write permission consists of Insert, Delete, and Modify permissions.

This method uses the filter that is currently applied to the *RecordRef* to determine whether you have write permission. If no filter is applied, the method tests for full write permission. If a filter has been set, the method only tests for write permission in the range of the filter.

To determine whether the user has partial write permission, because a security filter has been applied, view the **Permissions** page.

If you do not have permission to write to a table and you attempt to write, a run-time error occurs. This method lets you determine in advance if you have write permission. When the permissions are checked, the combination of permissions in the license file and the user's permissions in the Permission table is considered.

This method works the same as the WritePermission Method (Record).

Example

The following example opens table 18 (Customer) and creates a RecordRef variable that is named MyRecordRef for the table. The WritePermission method determines whether the table has write permission and stores the return value in the varHasWritePerm variable. The Customer table has write permission, so the message displays **Yes**. You can initialize the varTableNo variable with any table number.

```
var
    MyRecordRef: RecordRef;
    varTableNo: Integer;
    varHasWritePerm: Boolean;
    Text000: Label 'Does the %1 table have write permission? %2';
begin
    varTableNo := 18;
    MyRecordRef.Open(varTableNo);
    varHasWritePerm := MyRecordRef.WritePermission;
    Message(Text000, MyRecordRef.Name, varHasWritePerm);
end;
```

Report Data Type

2/17/2021 • 7 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Is used to display, print, or process information from a database.

The following methods are available on the Report data type.

METHOD NAME	DESCRIPTION
DefaultLayout(Integer)	Gets the default built-in layout type that is used on a specified report.
Execute(Integer, String [, RecordRef])	Runs a report in preview or processing-only mode without showing the request page in the client. The method gets the request page parameter values as an input parameter string from a RunRequestPage method call. The OnOpen and OnClose triggers on the request page will run even though the request page is not shown.
GetSubstituteReportId(Integer)	Gets the ID of the report that will be run by the platform after considering any substitutions made by extensions.
Print(Integer, String [, String] [, RecordRef])	Prints a specified report without running the request page. Instead of using the request page to obtain parameters at runtime, the method gets the parameter values as an input parameter string, typically from a RunRequestPage method call.
RdlcLayout(Integer, InStream)	Gets the RDLC layout that is used on a report and returns it as a data stream. The method has an instance call and a static call. The following code shows the syntax of the RDLC function. The first line of code is the syntax for an instance method call. The second line of code is the syntax for a static method call.
Run(Integer [, Boolean] [, Boolean] [, var Record])	Loads and executes the report that you specify.
RunModal(Integer [, Boolean] [, Boolean] [, var Record])	Loads and executes the report that you specify.
RunRequestPage(Integer [, String])	Runs the request page for a report without running the report. Returns an XML string that contains the request page parameters that are entered on the request page.
SaveAs(Integer, String, ReportFormat, var OutStream [, RecordRef])	Runs a specific report without a request page and saves the report as a PDF, Excel, Word, HTML, or XML file. Instead of using the request page to obtain parameters at runtime, the method gets the parameter values as an input parameter string, typically from the return value of a RunRequestPage method call.
SaveAsExcel(Integer, String [, var Record])	Saves a report on the computer that is running the server as a Microsoft Excel (.xls) workbook.

METHOD NAME	DESCRIPTION
SaveAsHtml(Integer, String [, var Record])	Saves a report as an HTML file. The file is saved on the computer where the server instance is running, and then downloaded to the client when ready. > This method is only supported when a report uses a Word report layout when it is run.
SaveAsPdf(Integer, String [, var Record])	Saves a report as a .pdf file.
SaveAsWord(Integer, String [, var Record])	Saves a report on the computer that is running the server as a Microsoft Word (.doc) document.
SaveAsXml(Integer, String [, var Record])	Saves the resulting data set of a query as an .xml file. The following code shows the syntax of the SaveAsXML function. The first line of code is the syntax for an instance method call. The second line of code is the syntax for a static method call.
WordLayout(Integer, InStream)	Gets the Word report layout that is used on a report and returns it as a data stream. The method has an instance call and a static call. The following code shows the syntax of the WORDLAYOUT function. The first line of code is the syntax for an instance method call. The second line of code is the syntax for a static method call.
WordXmlPart(Integer [, Boolean])	Returns the report data structure as structured XML that is compatible with Microsoft Word custom XML parts. The method has an instance call and a static call. The following code shows the syntax of the WORDXMLPART function. The first line of code is the syntax for an instance method call. The second line of code is the syntax for a static method call.

The following methods are available on instances of the Report data type.

METHOD NAME	DESCRIPTION
Break()	Exits from a loop or a trigger in a data item trigger of a report or XmlPort.
CreateTotals(var Decimal [, var Decimal,...])	Maintains totals for a variable in AL.
CreateTotals(Array of [Decimal])	Maintains totals for a variable in AL.
DefaultLayout()	Gets the default built-in layout type that is used on a specified report.
Execute(String [, RecordRef])	Runs a report in preview or processing-only mode without showing the request page in the client. The method gets the request page parameter values as an input parameter string from a RunRequestPage method call. The OnOpen and OnClose triggers on the request page will run even though the request page is not shown.
IsReadOnly()	Gets if the current report's data access intent is readonly.
Language([Integer])	Gets or sets the current language setting for the report.
NewPage()	Forces a page break when printing a report.

METHOD NAME	DESCRIPTION
NewPagePerRecord([Boolean])	Gets or sets the current setting of the NewPagePerRecord property.
ObjectId([Boolean])	Gets or sets the name or number of the report.
PageNo([Integer])	Gets or sets the current page number of a report.
PaperSource(Integer [, Integer])	Gets or sets the paper source used for the current page or a specified page.
Preview()	Indicates whether a report is being printed in preview mode.
Print(String [, String] [, RecordRef])	Prints a specified report without running the request page. Instead of using the request page to obtain parameters at runtime, the method gets the parameter values as an input parameter string, typically from a RunRequestPage method call.
PrintOnlyIfDetail([Boolean])	Gets or sets the current settings of the PrintOnlyIfDetail property.
Quit()	Aborts the processing of a report or XmlPort.
RDLCLayout(var InStream)	Gets the RDLC layout that is used on a report and returns it as a data stream.The method has an instance call and a static call. The following code shows the syntax of the RDLC method. The first line of code is the syntax for an instance method call. The second line of code is the syntax for a static method call.
Run()	Loads and executes the report that you specify.
RunModal()	Loads and executes the report that you specify.
RunRequestPage([String])	Runs the request page for a report without running the report. Returns an XML string that contains the request page parameters that are entered on the request page.
SaveAs(String, ReportFormat, var OutStream [, RecordRef])	Runs a specific report without a request page and saves the report as a PDF, Excel, Word, or XML file. Instead of using the request page to obtain parameters at runtime, the method gets the parameter values as an input parameter string, typically from the return value of a RunRequestPage method call.
SaveAsExcel(String)	Saves a report on the computer that is running the server as a Microsoft Excel (.xls) workbook.
SaveAsHtml(String)	Saves a report as an HTML file. The file is saved on the computer where the server instance is running, and then downloaded to the client when ready. > This method is only supported when a report uses a Word report layout when it is run.
SaveAsPdf(String)	Saves a report as a .pdf file.

METHOD NAME	DESCRIPTION
SaveAsWord(String)	Saves a report on the computer that is running the server as a Microsoft Word (.doc) document.
SaveAsXml(String)	Saves the resulting data set of a query as an .xml file.The following code shows the syntax of the SaveAsXML method. The first line of code is the syntax for an instance method call. The second line of code is the syntax for a static method call.
SetTableView(var Record)	Applies the table view on the current record as the table view for the page, report, or XmlPort.
ShowOutput()	Returns the current setting of whether a section should be printed, and changes this setting.
ShowOutput(Boolean)	Returns the current setting of whether a section should be printed, and changes this setting.
Skip()	Skips the current iteration of the current report or XmlPort.
TotalsCausedBy()	Determines which field caused a group total to be calculated. This determines which field changed contents and thereby concluded a group.
UseRequestPage([Boolean])	Gets or sets whether a request page is presented to the user.
WordLayout(var InStream)	Gets the Word report layout that is used on a report and returns it as a data stream. The method has an instance call and a static call. The following code shows the syntax of the WORDLAYOUT method. The first line of code is the syntax for an instance method call. The second line of code is the syntax for a static method call.
WordXmlPart([Boolean])	Gets the report data structure as structured XML that is compatible with Microsoft Word custom XML parts.

Report.DefaultLayout Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Gets the default built-in layout type that is used on a specified report.

Syntax

```
DefaultLayout :=   Report.DefaultLayout(Number: Integer)
```

Parameters

Number

Type: Integer

The ID of the report that you want to save. If the report that you specify does not exist, then a run-time error occurs.

Return Value

DefaultLayout Type: DefaultLayout The default built-in layout type that is used on a specified report.

Remarks

The default layout for a report is specified by the report's DefaultLayout Property.

Developing Extensions

Report.Execute Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Runs a report in preview or processing-only mode without showing the request page in the client. The method gets the request page parameter values as an input parameter string from a RunRequestPage method call. The OnOpen and OnClose triggers on the request page will run even though the request page is not shown.

Syntax

```
Report.Execute(Number: Integer, Parameters: String [, RecordRef: RecordRef])
```

Parameters

Number

Type: Integer

The ID of the report that you want to run. If the report that you specify does not exist, then a run-time error occurs.

Parameters

Type: String

A string of request page parameters as XML to use to run the report. The parameter string is typically retrieved from the return value a RunRequestPage method call.

RecordRef

Type: RecordRef

The RecordRef that refers to a record in a table.

Remarks

You typically use this method together with the RunRequestPage Method method. The RunRequestPage Method) runs a report request page without actually running the report, but instead, returns the parameters that are set on the request page as a string. You can then call the Execute method to get the parameter string and run the report.

For RunRequestPage Method method topic.

Report.GetSubstituteReportId Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 2.0.*

Gets the ID of the report that will be run by the platform after considering any substitutions made by extensions.

Syntax

```
NewReportId :=   Report.GetSubstituteReportId(ReportId: Integer)
```

Parameters

ReportId

Type: Integer

The ID of the report for which you want to retrieve the ID of the possible report substitute.

Return Value

NewReportId Type: Integer The ID of the report that will be run by the platform after considering any substitutions made by extensions.

Report.Print Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Prints a specified report without running the request page. Instead of using the request page to obtain parameters at runtime, the method gets the parameter values as an input parameter string, typically from a RunRequestPage method call.

Syntax

```
Report.Print(Number: Integer, Parameters: String [, PrinterName: String] [, RecordRef: RecordRef])
```

Parameters

Number
Type: Integer
The ID of the report that you want to print. If the report that you specify does not exist, then a run-time error occurs.

Parameters
Type: String
A string of request page parameters as XML to use to run the report. The parameter string is typically retrieved from the return value a RunRequestPage method call.

PrinterName
Type: String
The name of the printer to use to print the report. The printer must be set up on the client computer. If you do not set this variable, the printer that is set as the default printer is used.

RecordRef
Type: RecordRef
The RecordRef that refers to the table in which you want to find a record.

Remarks

You typically use this method together with the RunRequestPage Method. The RunRequestPage method runs a report request page without actually running the report, but instead, returns the parameters that are set on the request page as a string. You can then call the Print method to get the parameter string and print the report.

For a simple example that illustrates how to use the Print method, see example in the RunRequestPage Method topic.

Report.RdlcLayout Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Gets the RDLC layout that is used on a report and returns it as a data stream. The method has an instance call and a static call. The following code shows the syntax of the RDLC function. The first line of code is the syntax for an instance method call. The second line of code is the syntax for a static method call.

Syntax

```
[Ok := ]  Report.RdlcLayout(Number: Integer, InStream: InStream)
```

Parameters

Number
Type: Integer
The ID of the report object for which you want to get the RDLC layout.

InStream
Type: InStream
The variable in which to return the RDLC layout.

Return Value

Ok Type: Boolean **true** if the operation was successful; otherwise **false**. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

Remarks

Using the return value is optional. When you use the return value, if the RDLC layout cannot be retrieved at run-time, then the system returns **false** and no error recorded. When you omit the return value, if the RDLC layout cannot be retrieved at run-time, then an error occurs, which states that the layout could not be retrieved.

Report.Run Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Loads and executes the report that you specify.

Syntax

```
Report.Run(Number: Integer [, RequestWindow: Boolean] [, SystemPrinter: Boolean] [, var Record: Record])
```

Parameters

Number

Type: Integer

The ID of the report that you want to run.

RequestWindow

Type: Boolean

Specifies whether the request window for the report will be displayed. The request window is part of the report object.

SystemPrinter

Type: Boolean

Specifies whether to use the default Windows printer or use table 78, Printer Selection, to find the correct printer for this report.

Record

Type: Record

Specifies which record to use in the report. Any filters that are attached to the record that you specify are used.

Remarks

Use this method, or the Report.RunModal Method, if you do not know the specific report that you want to run when you are designing your application. If you do know the specific report that you want to run, then you can use the Run Method or the RunModal Method.

If the report you specify does not exist, then a compile error occurs.

NOTE

Internet browsers can only handle one file per request. Therefore, with the Web client, if this method is called in a repetitive statement (or loop) that generates multiple files, only the last file will be sent to the browser. Alternatively, when designing for the Web client, bundle the files in an archive file (.zip), for example, by using the methods found in codeunit **419 File Management**. For more details about this design pattern, see Multi-File Download. Although this article is written for Dynamics NAV, it is still relevant for Business Central. The methods in codeunit 419 are not external, therefore cannot be used in extensions. Instead, when developing extensions in AL, use the external methods of codeunit **425 Data Compression**. The approach is similar.

Example 1

This example shows how to run a report. This example displays the request window and sends the report to the printer that is selected in the Printer Selection table.

```
Report.Run(1001);
```

Example 2

This example shows how to run a report. This example skips the request window, starts the report immediately, and sends the report to the printer that is selected in the Printer Selection table.

```
Report.Run(1001, False);
```

Example 3

This example shows how to run a report. This example skips the request window and starts the report immediately. It sends the report to the system printer instead of the printer that is selected in the Printer Selection table.

```
Report.Run(1001, False, True);
```

Example 4

This example shows how to run a report for which you specify a record. This example displays the request window and sends the report to the system printer.

```
var
    MyRec: Record Customer;
begin
    MyRec.FindLast;
    MyRec.SetRecFilter;
    Report.Run(101, True, True, MyRec);
end;
```

See Also

Report Data Type
Getting Started with AL
Developing Extensions

Report.RunModal Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Loads and executes the report that you specify.

Syntax

```
Report.RunModal(Number: Integer [, RequestWindow: Boolean] [, SystemPrinter: Boolean] [, var Record: Record])
```

Parameters

Number

Type: Integer

The ID of the report that you want to run.

RequestWindow

Type: Boolean

Specifies whether the request window for the report will be displayed. The request window is part of the report object.

SystemPrinter

Type: Boolean

Specifies whether to use the default Windows printer or use table 78, Printer Selection, to find the correct printer for this report.

Record

Type: Record

Specifies which record to use in the report. Any filters that are attached to the record that you specify are used.

Remarks

Use this method, or the Report.Run Method, if you do not know the specific report that you want to run when you are designing your application. If you do know the specific report that you want to run, then you can use the RunModal Method or the Run Method.

The request page is run modally when you use this method. However, when the user chooses **Preview** on the request page, the **Print Preview** page does not run modally.

NOTE

Internet browsers can only handle one file per request. Therefore, with the Web client, if this method is called in a repetitive statement (or loop) that generates multiple files, only the last file will be sent to the browser. Alternatively, when designing for the Web client, bundle the files in an archive file (.zip), for example, by using the methods found in codeunit **419 File Management**. For more details about this design pattern, see Multi-File Download. Although this article is written for Dynamics NAV, it is still relevant for Business Central. The methods in codeunit 419 are not external, therefore cannot be used in extensions. Instead, when developing extensions in AL, use the external methods of codeunit **425 Data Compression**. The approach is similar.

Example 1

This example shows how to run a report. This example displays the request window and sends the report to the printer selected through the Printer Selection table.

```
Report.RunModal(1001);
```

Example 2

This example shows how to run a report. This example skips the request window, starts the report immediately, and sends the report to the printer that is selected in the Printer Selection table.

```
Report.RunModal(1001, False);
```

Example 3

This example shows how to run a report. This example skips the request window and starts the report immediately. It sends the report to the system printer instead of the printer that is selected in the Printer Selection table.

```
Report.RunModal(1001, False, True);
```

Report.RunRequestPage Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Runs the request page for a report without running the report. Returns an XML string that contains the request page parameters that are entered on the request page.

Syntax

```
Parameters :=   Report.RunRequestPage(Number: Integer [, Parameters: String])
```

Parameters

Number

Type: Integer

The ID of the report for which you want to run the request page. If the report that you specify does not exist, then a run-time error occurs.

Parameters

Type: String

A string of request page parameters as XML to use to run the report.

Return Value

Parameters Type: String XML string that contains the request page parameters that are entered on the request page

Remarks

This method opens the request page for the specified report, where the user can provide parameters for the report. When the user closes the request page by choosing the **OK** button, a string that contains the parameter values that were set by the user is returned. When the user chooses the **Cancel** button, an empty string will be returned. The returned parameter string can be picked up by calling one of the following methods:

- Execute Method
- Print Method
- SaveAs Method

> **NOTE**
>
> You can use these methods to schedule reports in the job queue.

Because the request page runs in the context of where it was invoked from, users cannot bookmark a link to this page from the user interface.

Example

This example illustrates how to use the RunRequestPage method to run the request page for report ID 206 Sales Invoice. The request page parameters are saved to a table, and then uses the parameters with the Execute, SaveAs, and Print methods to preview the report, save it as a PDF file, and print it.

This example requires that you create a table for holding parameters that are entered on the report request page and a codeunit that runs the report methods.

Create a table called **Request Parameters** that has the following fields.

```
var
    ReportId: Integer;
    UserId: Code[100];
    Parameters: BLOB;
```

Create a codeunit and add the following code to the *OnRun* trigger of the codeunit.

```
var
    ReportParameters: Record "Report Parameters";
    XmlParameters: Text;
    OStream: OutStream;
    IStream: InStream;
    CurrentUser: Code[100];
    Content: File;
    TempFileName: Text;

begin
    // Use the Report.RunRequestPage method to run the request page to get report parameters
    XmlParameters := Report.RunRequestPage(206);
    CurrentUser := UserId;

    // Save the request page parameters to the database table
    with ReportParameters do begin
        // Cleanup
        if Get(206,CurrentUser) then
        Delete;

        SetAutoCalcFields(Parameters);
        ReportId := 206;
        UserId := CurrentUser;
        Parameters.CreateOutStream(OStream,TextEncoding::UTF8);
        Message(XmlParameters);
        OStream.WriteText(XmlParameters);

        Insert;
    end;

    Clear(ReportParameters);
    XmlParameters := '';

    // Read the request page parameters from the database table
    with ReportParameters do begin
        SetAutoCalcFields(Parameters);
        Get(206,CurrentUser);
        Parameters.CreateInStream(IStream,TextEncoding::UTF8);
        IStream.ReadText(XmlParameters);
    end;

    // Use the Report.SaveAs method to save the report as a PDF file
    Content.Create('TestFile.pdf');
    Content.CreateOutStream(OStream);
    Report.SaveAs(206,XmlParameters,ReportFormat::Pdf,OStream);
    Content.Close;

    // Use the Report.Execute method to preview the report
    Report.Execute(206,XmlParameters);

    // Use the Report.Print method to print the report
    Report.Print(206,XmlParameters);
```

Report.SaveAs Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Runs a specific report without a request page and saves the report as a PDF, Excel, Word, HTML, or XML file. Instead of using the request page to obtain parameters at runtime, the method gets the parameter values as an input parameter string, typically from the return value of a RunRequestPage method call.

Syntax

```
[Ok := ]  Report.SaveAs(Number: Integer, Parameters: String, Format: ReportFormat, var OutStream: OutStream
[, RecordRef: RecordRef])
```

Parameters

Number

Type: Integer

The ID of the report that you want to save. If the report that you specify does not exist, then a run-time error occurs.

Parameters

Type: String

A string of request page parameters as XML to use to run the report. The parameter string is retrieved from the return value a RunRequestPage method call.

Format

Type: ReportFormat

The type of file to save the report as. The following options are supported: Pdf, Excel, Word, and XML.

OutStream

Type: OutStream

The stream to which to write a report.

RecordRef

Type: RecordRef

The RecordRef that refers to the table in which you want to find a record.

Return Value

Ok Type: Boolean **true** if the operation was successful; otherwise **false**. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

Remarks

You typically use this method together with the RunRequestPage Method method. The RunRequestPage method runs a report request page without actually running the report, but instead, returns the parameters that are set on the request page as a string. You can then call the SaveAs method to get the parameter string and save the report to a file of the specified format.

For a simple example that illustrates how to use the SaveAs method, see example in the RunRequestPage Method method topic.

> **NOTE**
>
> By default, when a report uses an RDLC report layout at runtime, fonts are embedded in the generated PDF. You can specify whether fonts are embedded in the PDF for RDLC reports by changing the **Report PDF Font Embedding** setting in the Dynamics 365 Business Central service instance configuration or changing the **PDFFontEmbedding** property in report objects.

Report.SaveAsExcel Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Saves a report on the computer that is running the server as a Microsoft Excel (.xls) workbook.

> **NOTE**
> This method is supported only in Business Central on-premises.

Syntax

```
[Ok := ]  Report.SaveAsExcel(Number: Integer, FileName: String [, var Record: Record])
```

Parameters

Number
Type: Integer
The ID of the report that you want to run. If the report you specify does not exist, then a run-time error occurs.

FileName
Type: String
The path and the name of the file that you want to save the report as. The path must exist, the file must not be used, and the server process must have permission to write to the file. Otherwise, you will get errors.

Record
Type: Record
Specifies which record to use in the report. Any filters that have been applied to the record that you specify will be used.

Return Value

Ok Type: Boolean **true** if the operation was successful; otherwise **false**. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

Remarks

You can use the SaveAsExcel method on the global Report object and on Report variables. If, at design time, you do not know the specific report that you want to run, then use the global Report object and specify the report number in the *Number* parameter. If you do know which report you want to run, then create a Report variable, set the Subtype of the variable to a specific report, and use this variable when you call the SaveAsExcel method.

When you call the SaveAsExcel method, the report is generated and saved to "*FileName*." The request page is not shown.

If the destination folder that you specify in *FileName* does not exist, then you get the following error:

The specified path is invalid.

If the file that you specify in *FileName* is being used, then you get the following error:

An I/O exception occurred during the operation.

If the Dynamics 365 Business Central service process does not have permission to write to the file that you specify in *FileName*, then you get the following error:

Either the caller does not have the required permission or the specified path is read-only.

Example

This example shows how to use the SaveAsExcel method to save the Excel workbook to the Dynamics 365 Business Central service and then download the file to a computer that is running the Dynamics 365 application.

```
var
    TempFile: File;
    Name: Text[250];
    NewStream: InStream;
    ToFile: Text[250];
    ReturnValue: Boolean;
begin
    // Specify that TempFile is opened as a binary file.
    TempFile.TextMode(False);
    // Specify that you can write to TempFile.
    TempFile.WriteMode(True);
    Name := 'C:\Temp\TempReport.xls';
    // Create and open TempFile.
    TempFile.Create(Name);
    // Close TempFile so that the SaveAsExcel method can write to it.
    TempFile.Close;

    Report.SaveAsExcel(406,Name);

    TempFile.Open(Name);
    TempFile.CreateInStream(NewStream);
    ToFile := 'Report.xls';

    // Transfer the content from the temporary file on the
    // server to a file on the client.
    ReturnValue := DownloadFromStream(
      NewStream,
      'Save file to client',
      '',
      'Excel File *.xls| *.xls',
      ToFile);

    // Close the temporary file.
    TempFile.Close();
end;
```

You can create an action on a page and set the action to run this code. When you run the action, the **Export File** dialog box opens. Choose **Save** to save the file to the client.

Report.SaveAsHtml Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Saves a report as an HTML file. The file is saved on the computer where the server instance is running, and then downloaded to the client when ready. > This method is only supported when a report uses a Word report layout when it is run.

NOTE

This method is supported only in Business Central on-premises.

Syntax

```
[Ok := ]  Report.SaveAsHtml(Number: Integer, FileName: String [, var Record: Record])
```

Parameters

Number

Type: Integer

The ID of the report object that you want to run.

FileName

Type: String

The folder path and name of the file that you want to save the report as. The path must already exist and the service (login) account that is used by the server instance must have permission to write to the target folder. Otherwise, you will get errors.

Record

Type: Record

Specifies which record to use in the report. Any filters that have been applied to the record that you specify will be used.

Return Value

Ok Type: Boolean **true** if the operation was successful; otherwise **false**. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

Remarks

The SaveAsHTML method uses the logic in the codeunit **9651 Document Report Mgt.** code unit to handle the format transformation.

The SaveAsHTML method can be used on the Report data type and on Report variables. When you are programming the SaveAsHTML method, if you do not know the specific report that you want to run, then use the global Report object and specify the report number in the *Number* parameter. If you know which report you want to run, then create a Report variable, set the **Subtype** of the variable to a specific report, and then use this

variable when you call the SaveAsHTML method.

When you call the SaveAsXML method, the report is generated and saved to "FileName." The request page is not shown.

Reports that use an RDLC layout when run cannot be saved in the HTML format. A runtime error will occur if SaveAsHTML is used on an RDLC report.

Report.SaveAsPdf Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Saves a report as a .pdf file.

> **NOTE**
> This method is supported only in Business Central on-premises.

Syntax

```
[Ok := ]  Report.SaveAsPdf(Number: Integer, FileName: String [, var Record: Record])
```

Parameters

Number
Type: Integer
The ID of the report that you want to run.

FileName
Type: String
The path and name of the file that you want to save the report as.

Record
Type: Record
Specifies which record to use in the report. Any filters that have been applied to the record that you specify will be used.

Return Value

Ok Type: Boolean **true** if the operation was successful; otherwise **false**. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

Remarks

You can use the **SaveAsPDF** method on the global Report object or on Report variables. If, at design time, you do not know the specific report that you want to run, then use the global Report object and specify the report number in the *Number* parameter. If you do know which report you want to run, then create a Report variable, set the Subtype of the variable to a specific report, and use this variable when you call the **SaveAsPDF** method.

When you call **SaveAsPDF**, the report is generated and saved to "*FileName*." A **Saving to PDF** window shows the status of the process. Note that the request page will not be shown.

The *FileName* parameter specifies a location on the computer that is running Dynamics 365 Business Central service. If you call this method from a client, such as from an action on a page, then use the DOWNLOAD Method (File) to download the .pdf file from the computer that is running Dynamics 365 Business Central service to the computer that is running the client.

> **NOTE**
>
> By default, when a report uses an RDLC report layout at runtime, fonts are embedded in the generated PDF. You can specify whether fonts are embedded in the PDF for RDLC reports by changing the **Report PDF Font Embedding** setting in the Dynamics 365 Business Central service instance configuration or changing the **PDFFontEmbedding** property in report objects.

Example

This example shows how to use the **SaveAsPDF** method to save a specific report as a PDF file on the computer that is running Dynamics 365 Business Central service.

```
var
    Filename: Text;
    ReturnValue: Boolean;
    Report206: Report " Sales - Invoice";
begin
    Filename := 'C:\MyReports\report206.pdf';
    ReturnValue := Report206.SaveAsPDF(Filename);
end;
```

Report.SaveAsWord Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Saves a report on the computer that is running the server as a Microsoft Word (.doc) document.

> **NOTE**
> This method is supported only in Business Central on-premises.

Syntax

```
[Ok := ]  Report.SaveAsWord(Number: Integer, FileName: String [, var Record: Record])
```

Parameters

Number
Type: Integer
The ID of the report that you want to run. If the report you specify does not exist, then a run-time error occurs.

FileName
Type: String
The path and the name of the file that you want to save the report as. The path must exist, the file must not be being used, and the server process must have permission to write to the file. Otherwise, you will get errors.

Record
Type: Record
Specifies which record to use in the report. Any filters that have been applied to the record that you specify will be used.

Return Value

Ok Type: Boolean **true** if the operation was successful; otherwise **false**. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

Remarks

You can use the SaveAsWORD method on the global Report object or on Report variables. If, at design time, you do not know the specific report that you want to run, then use the global Report object and specify the report number in the *Number* parameter. If you do know which report you want to run, then create a Report variable, set the Subtype of the variable to a specific report, and use this variable when you call the SaveAsWORD method.

When you call the SaveAsWORD method, the report is generated and saved to "*FileName*." The request page is not shown.

If the destination folder that you specify in *FileName* does not exist, then you get the following error:

The specified path is invalid.

If the file that you specify in *FileName* is being used, then you get the following error:

An I/O exception occurred during the operation.

If the Dynamics 365 Business Central service process does not have permission to write to the file that you specify in *FileName*, then you get the following error:

Either the caller does not have the required permission or the specified path is read-only.

Example

This example shows how to use the SaveAsWORD method to save the Word document on the Dynamics 365 Business Central service, and then download the file to a different computer that is running the Dynamics 365 application.

```
var
    TempFile: File;
    Name: Text[250];
    NewStream: InStream;
    ToFile: Text[250];
    ReturnValue: Boolean;
begin
    // Specify that TempFile is opened as a binary file.
    TempFile.TextMode(False);
    // Specify that you can write to TempFile.
    TempFile.WriteMode(True);
    Name := 'C:\Temp\TempReport.doc';
    // Create and open TempFile.
    TempFile.Create(Name);
    // Close TempFile so that the SaveAsWORD method can write to it.
    TempFile.Close;

    Report.SaveAsWORD(406,Name);

    TempFile.Open(Name);
    TempFile.CreateInStream(NewStream);
    ToFile := 'Report.doc';

    // Transfer the content from the temporary file on the
    // server to a file on the client.
    ReturnValue := DownloadFromStream(
      NewStream,
      'Save file to client',
      '',
      'Word File *.doc| *.doc',
      ToFile);

    // Close the temporary file.
    TempFile.Close();
end;
```

You can create an action on a page and set the action to run this code. When you run the action, the **Export File** dialog box opens. Choose **Save** to save the file to the client.

Report.SaveAsXml Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Saves the resulting data set of a query as an .xml file. The following code shows the syntax of the SaveAsXML function. The first line of code is the syntax for an instance method call. The second line of code is the syntax for a static method call.

> **NOTE**
> This method is supported only in Business Central on-premises.

Syntax

```
[Ok := ]  Report.SaveAsXml(Number: Integer, FileName: String [, var Record: Record])
```

Parameters

Number
Type: Integer
The ID of the query object that you want to save as an .xml file. If the query that you specify does not exist, then a run-time error occurs.

FileName
Type: String
The path and name of the file that you want to save the query to.

Record
Type: Record
Specifies which record to use in the report. Any filters that have been applied to the record that you specify will be used.

Return Value

Ok Type: Boolean **true** if the operation was successful; otherwise **false**. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

Remarks

You can use the SaveAsXML method on the global Report object and on Report variables. If, at design time, you do not know the specific report that you want to run, then use the global Report object and specify the report number in the *Number* parameter. If you know which report you want to run, then create a Report variable, set the **Subtype** of the variable to a specific report, and then use this variable when you call the SaveAsXML method.

When you call the SaveAsXML method, the report is generated and saved to "*FileName*." The request page is not shown.

If the destination folder that you specify in *FileName* does not exist, then you get the following error:

The specified path is invalid.

If the file that you specify in *FileName* is being used, then you get the following error:

An I/O exception occurred during the operation.

If the Dynamics 365 Business Central service does not have permission to write to the file that you specify in *FileName*, then you get the following error:

Either the caller does not have the required permission or the specified path is read-only.

To resolve this issue, verify that the service account that is running the Dynamics 365 Business Central service instance has write permissions on the path.

Example

This example shows how to use the SaveAsXML method to save a report as an .xml file on the Dynamics 365 Business Central service, and then download the file to a computer that is running the Dynamics 365.

```
var
    TempFile: File;
    Name: Text[250];
    NewStream: InStream;
    ToFile: Text[250];
    ReturnValue: Boolean;
begin
    // Specify that TempFile is opened as a binary file.
    TempFile.TextMode(False);
    // Specify that you can write to TempFile.
    TempFile.WriteMode(True);
    Name := 'C:\Temp\TempReport.xml';
    // Create and open TempFile.
    TempFile.Create(Name);
    // Close TempFile so that the SaveAsXML method can write to it.
    TempFile.Close;

    Report.SaveAsXML(406,Name);

    TempFile.Open(Name);
    TempFile.CreateInStream(NewStream);
    ToFile := 'Report.xml';

    // Transfer the content from the temporary file on
    // server to a file on the client.
    ReturnValue := DownloadFromStream(
      NewStream,
      'Save file to client',
      '',
      'Excel File *.xml| *.xml',
      ToFile);

    // Close the temporary file.
    TempFile.Close();
end;
```

You can create an action on a page and set the action to run this code. When you run the action, the **Export File** dialog box opens. Choose **Save** to save the file to the client.

Report.WordLayout Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Gets the Word report layout that is used on a report and returns it as a data stream. The method has an instance call and a static call. The following code shows the syntax of the WORDLAYOUT function. The first line of code is the syntax for an instance method call. The second line of code is the syntax for a static method call.

Syntax

```
[Ok := ]  Report.WordLayout(Number: Integer, InStream: InStream)
```

Parameters

Number

Type: Integer

The ID of the report object for which you want to get the Word report layout.

InStream

Type: InStream

The variable in which to return the Word report layout.

Return Value

Ok Type: Boolean **true** if the operation was successful; otherwise **false**. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

Remarks

Using the return value is optional. When you use the return value, if the Word report layout cannot be retrieved at run-time, then the system returns **false** and no error recorded. When you omit the return value, if the Word report layout cannot be retrieved at run-time, then an error occurs, which states that the Word report could not be retrieved.

Report.WordXmlPart Method

2/17/2021 • 3 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Returns the report data structure as structured XML that is compatible with Microsoft Word custom XML parts. The method has an instance call and a static call. The following code shows the syntax of the WORDXMLPART function. The first line of code is the syntax for an instance method call. The second line of code is the syntax for a static method call.

Syntax

```
String :=   Report.WordXmlPart(Number: Integer [, ExtendedFormat: Boolean])
```

Parameters

Number

Type: Integer

The ID of the report that you want to run. If the report you specify does not exist, then a run-time error occurs.

ExtendedFormat

Type: Boolean

If you set this variable to true, then XML elements will include the following attributes:

- ElementType="Parameter|Column|DataItem". Specifies the element type as defined for the report in Report Designer. Parameter is typically used for elements, such as captions.
- ElementId="ID". Specifies the ID that is assigned to the element by its ID Property.
- DataType="Type". Specifies the data type of the element. If you omit this parameter or set it to false, then the element attributes are not included in the XML. This is the recommended setting when you will use the Word XML part in Word for modifying the report layout because the XML is simpler. The following example illustrates an XML element that has the ExtendedFormat set to true: <CompanyName ElementType="Column" ElementId="3" DataType="OemText"> The following example illustrates the same XML with the ExtendedFormat set to false:<CompanyName>

Return Value

String Type: String The report data structure as structured XML that is compatible with Microsoft Word custom XML parts.

Remarks

This method returns the data structure of the report as structured XML that complies with custom XML parts in Microsoft Word 2013. The following table provides a simplified overview of the XML that is returned by the method.

XML	DESCRIPTION
`<?xml version="1.0" encoding="utf-16"?>`	Header

XML	DESCRIPTION
`<NavWordReportXmlPart xmlns="urn:microsoft-../report/<reportname>/<id>/"`	XML namespace specification. `<reportname>` is the name assigned to the report object. `<id>` is the ID that is assigned to the report.

`..<Labels>`
 	
`....<ColumnNameCaption>ColumnNameCaption</ColumnNameCaption>`
 	
`....<LabelName>LabelCaption</LabelName>`
 	
`..</Labels>`
	Contains all the labels for the report. Labels are listed in alphabetical. The element includes labels that are related to columns that have the IncludeCaption Property set to **Yes** and labels that are defined in Report Label Designer.
	
	- Label elements that are related to columns have the format `<ColumnNameCaption>ColumnNameCaption</ColumnNameCaption>`, where `ColumnName` is determined by the column's Name Property.
	- Label elements from Report Label Designer have the format `<LabelName>LabelCaption</LableName`, where `LabelName` is determined by the label's Name Property and `LabelCaption` is determined by the label's Caption Property.

`..<DataItem1>`
 	
`....<DataItem1Column1>DataItem1Column1</DataItem1Column1>`
	Top-level data item and columns. Columns are listed in alphabetical order.
	
	The element names and values are determined by the Name property of the data item or column.

`....<DataItem2>`
 	
`......<DataItem2Column1>DataItem2Column1</DataItem2Column1>`
 	
`....</DataItem2>`
 	
`....<DataItem3>`
 	
`......<DataItem3Column1>DataItem3Column1</DataItem3Column1>`
 	
`....</DataItem3>`
	Data items and columns that are nested in the top-level data item. Columns are listed in alphabetical order under the respective data item.

`..</DataItem1>`
 	
`</NavWordReportXmlPart>`
	Closing elements.

Word custom XML parts enable you to integrate business data into Word documents. For example, the WORDXMLPART method is used internally by Dynamics 365 when you are creating report layouts in Word. You can use this method to create a custom XML part, and then, together with the SaveAsXML Method (Report) method and additional data merging tools, you can implement your own functionality for mapping and laying out report data in Word documents. To create a custom XML part, you can save the return value to an .xml file that is encoded in UTF-16 (16-bit Unicode Transformation Format). The resultant file can be added to Word documents as a custom XML part to map the report data set as XML data.

Example

The following example uses the WORDXMLPART method to save the data structure of Report 112 Sales Statistics in an XML file in a predefined folder *C:\Report Documents*. The resultant file can be used in Word as a custom

XML part.

```
var
    ReportAsString Text;
    SalesStatsReport: File;
begin
    ReportAsString := Report.WORDXMLPART(112);
    SalesStatsReport.TextMode(True);
    SalesStatsReport.WriteMode(True);
    SalesStatsReport.Create('C:\Report Documents\SalesStatsReport.xml', TextEncoding::UTF16);
    SalesStatsReport.WRITE(ReportAsString);
    SalesStatsReport.Close;
end;
```

The code generates the report structure as XML, and then writes the XML to the file *C:\Report Documents\SalesStatsReport.xml*.

Report.Break Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Exits from a loop or a trigger in a data item trigger of a report or XmlPort.

Syntax

```
Report.Break()
```

Parameters

Report Type: Report An instance of the Report data type.

Remarks

BREAK causes the current trigger to end. When used inside a loop, such as a WHILE-DO or REPEAT-UNTIL construction, BREAK interrupts the loop and causes the current trigger to end.

Compare this with the QUIT Method (Report, XMLport).

> **TIP**
> You can also use the AL BREAK Statement to exit an iteration or loop. The difference is that the BREAK statement does not terminate the trigger. It just exits the loop.

Example

```
var
    MyVar: Integer;
    Text000: Label "The variable is now %1.";
begin
    MyVar := 0;
    repeat
      MyVar := MyVar + 1;
      if MyVar = 5 then
        CurrReport.BREAK;
      Message(Text000,MyVar);
    until Myvar = 10;
    Message('After REPEAT-UNTIL loop'); //This statement is never called.
end;
```

When you run the previous code, the loop will end when MyVar is 5 and the execution of the current trigger ends. Statements after the loop are not executed.

Report.CreateTotals Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0 until version 1.0 where it was deprecated.*

Maintains totals for a variable in AL.

Syntax

```
Report.CreateTotals(var Var1: Decimal [, var Var2: Decimal,...])
```

Parameters

Report Type: Report An instance of the Report data type.

Var1
Type: Decimal
Variable for which the system will maintain the total.

Var2
Type: Decimal
Variable for which the system will maintain the total.

Remarks

IMPORTANT

This method will be deprecated in a future update and we recommend that you do not use it.

CreateTOTALS maintains group and grand totals. The totals can be printed by placing controls that have the variable or variables that are the arguments of CreateTOTALS as their source expressions in the appropriate sections. The group totals are printed in GroupFooter sections, and the grand totals are printed in Footer sections.

This method is not supported on client report definition (RDLC) report layouts. In most cases, when you create a layout suggestion for a Classic report layout that uses the CreateTOTALS method, a SUM expression is created instead and no action is required.

Example

This example shows how to use the CreateTOTALS method to maintain totals for the two variables Amount and Quantity.

```
CurrReport.CreateTOTALS(Amount, Quantity);
```

See Also

Report.CreateTotals Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0 until version 1.0 where it was deprecated.*

Maintains totals for a variable in AL.

Syntax

```
Report.CreateTotals(Vars: Array of [Decimal])
```

Parameters

Report Type: Report An instance of the Report data type.

Vars
Type: Decimal
Array of variables for which the system will maintain individual totals.

Remarks

IMPORTANT

This method will be deprecated in a future update and we recommend that you do not use it.

CreateTOTALS maintains group and grand totals. The totals can be printed by placing controls that have the variable or variables that are the arguments of CreateTOTALS as their source expressions in the appropriate sections. The group totals are printed in GroupFooter sections, and the grand totals are printed in Footer sections.

This method is not supported on client report definition (RDLC) report layouts. In most cases, when you create a layout suggestion for a Classic report layout that uses the CreateTOTALS method, a SUM expression is created instead and no action is required.

Example

This example shows how to use the CreateTOTALS method to maintain totals for the two variables Amount and Quantity.

```
CurrReport.CreateTOTALS(Amount, Quantity);
```

Report.DefaultLayout Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Gets the default built-in layout type that is used on a specified report.

Syntax

```
DefaultLayout :=   Report.DefaultLayout()
```

Parameters

Report Type: Report An instance of the Report data type.

Return Value

DefaultLayout Type: DefaultLayout The default built-in layout type that is used on a specified report.

Remarks

The default layout for a report is specified by the report's DefaultLayout Property.

See Also

Report Data Type
Getting Started with AL
Developing Extensions

Report.Execute Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Runs a report in preview or processing-only mode without showing the request page in the client. The method gets the request page parameter values as an input parameter string from a RunRequestPage method call. The OnOpen and OnClose triggers on the request page will run even though the request page is not shown.

Syntax

```
Report.Execute(Parameters: String [, RecordRef: RecordRef])
```

Parameters

Report Type: Report An instance of the Report data type.

Parameters

Type: String

A string of request page parameters as XML to use to run the report. The parameter string is typically retrieved from the return value a RunRequestPage method call.

RecordRef

Type: RecordRef

The RecordRef that refers to a record in a table.

Remarks

After the Execute method is executed, the system does not automatically clear the *Report* variable. You must handle clearing the variable.

You typically use this method together with the RunRequestPage Method. The RunRequestPage method runs a report request page without actually running the report, but instead, returns the parameters that are set on the request page as a string. You can then call the Execute method to get the parameter string and run the report.

For a simple example that illustrates how to use the Execute method, see example in the RunRequestPage Method topic.

Report.IsReadOnly Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 7.0.*

Gets if the current report's data access intent is readonly.

Syntax

```
DataAccessIntent :=   Report.IsReadOnly()
```

NOTE

This method can be invoked using property access syntax.

Parameters

Report Type: Report An instance of the Report data type.

Return Value

DataAccessIntent Type: Boolean A value specifying the readonly data access intent.

See Also

Report Data Type Getting Started with AL Developing Extensions

Report.Language Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Gets or sets the current language setting for the report.

Syntax

```
[CurrentLanguage := ]  Report.Language([Language: Integer])
```

> **NOTE**
> This method can be invoked using property access syntax.

Parameters

Report Type: Report An instance of the Report data type.

Language
Type: Integer
The new language setting for the report.

Return Value

CurrentLanguage Type: Integer The current language setting for the report.

Example

If you have documents that you want to print in the language of the recipient rather than in your own working language, you can add a single line of code in the document to handle this. This functionality is already enabled for most reports in the standard Business Central database. The document is printed in the language that is specified in the **Language Code** field on the **Customer Card** page.

In reports that need the multiple document languages functionality, you must insert the following AL code as the first line in the `OnAfterGet Record()` trigger:

```
Report.LANGUAGE := Language.GetLanguageID("Language Code")
```

For each of these reports, you must create a new variable, `Language`, with the data type `Record` pointing to the `Language` table. When you have compiled the object, it will no longer print in the user's working application language if another language has been specified on the **Customer Card** page.

Report.NewPagePerRecord Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0 until version 1.0 where it was deprecated.*

Gets or sets the current setting of the NewPagePerRecord property.

Syntax

```
[IsNewPagePerRecord := ]  Report.NewPagePerRecord([SetNewPagePerRecord: Boolean])
```

NOTE

This method can be invoked using property access syntax.

Parameters

Report Type: Report An instance of the Report data type.

SetNewPagePerRecord

Type: Boolean

The new setting of the NewPagePerRecord property.

Return Value

IsNewPagePerRecord Type: Boolean The setting of the NewPagePerRecord property.

Report.ObjectId Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Gets or sets the name or number of the report.

Syntax

```
String :=   Report.ObjectId([UseNames: Boolean])
```

Parameters

Report Type: Report An instance of the Report data type.

UseNames
Type: Boolean
true (default value) if the returned string contains the name of the report, **false** if the returned string contains the number of the report.

Return Value

String Type: String The name or number of the report.

Report.PageNo Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0 until version 1.0 where it was deprecated.*

Gets or sets the current page number of a report.

Syntax

```
[CurrPageNo := ]  Report.PageNo([NewPageNo: Integer])
```

Parameters

Report Type: Report An instance of the Report data type.

NewPageNo
Type: Integer
The new page number of a report.

Return Value

CurrPageNo Type: Integer The current page number of a report.

Report.PaperSource Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0 until version 1.0 where it was deprecated.*

Gets or sets the paper source used for the current page or a specified page.

Syntax

```
Report.PaperSource(PaperBinNo: Integer [, PhysicalPage: Integer])
```

Parameters

Report Type: Report An instance of the Report data type.

PaperBinNo
Type: Integer
The tray number.

PhysicalPage
Type: Integer
The page number.

Report.Preview Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Indicates whether a report is being printed in preview mode.

Syntax

```
IsPreview :=   Report.Preview()
```

NOTE

This method can be invoked using property access syntax.

Parameters

Report Type: Report An instance of the Report data type.

Return Value

IsPreview Type: Boolean **true** if the report is being printed in preview mode, otherwise **false**.

Remarks

You must use the return value. A compile error is generated if this value is not used.

If you run a client report definition (RDLC) report layout in preview mode and then call the CurrReport.PREView method, then the Print icon, Print Layout icon, Page Setup icon, and Save As icon are not displayed.

If you run a client report definition (RDLC) report layout in preview mode and do not call the CurrReport.PREView method, then you can print from the **Print Preview** window.

Example

This example shows how to use the PREView method. You can use this method in an application that stores a count of how many times a document has been printed in the database. This number must be updated from inside the report that is used to print the document. To avoid updating the number when the report is run in preview mode, add a construct to the OnPreDataItem trigger that resembles the one that is shown in this example when you add the code that updates the count.

```
if CurrReport.PREView then
... // Preview-specific processing.
else
... // Processing that is not preview specific:
... // Update the print count.
```

Report.Print Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Prints a specified report without running the request page. Instead of using the request page to obtain parameters at runtime, the method gets the parameter values as an input parameter string, typically from a RunRequestPage method call.

> **NOTE**
> This method is supported only in Business Central on-premises.

Syntax

```
Report.Print(Parameters: String [, PrinterName: String] [, RecordRef: RecordRef])
```

Parameters

Report Type: Report An instance of the Report data type.

Parameters
Type: String
A string of request page parameters as XML to use to run the report. The parameter string is typically retrieved from the return value a RunRequestPage method call.

PrinterName
Type: String
The name of the printer to use to print the report. The printer must be set up on the client computer. If you do not set this variable, the printer that is set as the default printer is used.

RecordRef
Type: RecordRef
The RecordRef that refers to the table in which you want to find a record.

Remarks

You typically use this method together with the RunRequestPage Method method. The RunRequestPage method runs a report request page without actually running the report, but instead, returns the parameters that are set on the request page as a string. You can then call the Print method to get the parameter string and print the report.

For a simple example that illustrates how to use the Print method, see example in the RunRequestPage Method method topic.

Report.PrintOnlyIfDetail Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Gets or sets the current settings of the PrintOnlyIfDetail property.

> **NOTE**
> This method is supported only in Business Central on-premises.

Syntax

```
[IsPrintOnlyIfDetail := ]  Report.PrintOnlyIfDetail([SetPrintOnlyIfDetail: Boolean])
```

> **NOTE**
> This method can be invoked using property access syntax.

Parameters

Report Type: Report An instance of the Report data type.

SetPrintOnlyIfDetail
Type: Boolean
The new setting of PrintOnlyIfDetail property.

Return Value

IsPrintOnlyIfDetail Type: Boolean The current settings of the PrintOnlyIfDetail property.

Example 1

The following example is from the OnAfterGetRecord trigger of a report. If the PrintOnlyIfDetail property is true and if a GLEntryPage record exists, given the current filters, then the PageGroupNo is incremented.

```
var
    GLEntryPage: Record "G/L Entry";
    PageGroupNo: Integer;
begin
    if CurrReport.PrintONLYifDETAIL and GLEntryPage.Find('-') then
      PageGroupNo := PageGroupNo + 1;
end;
```

Example 2

The following example sets the value of the PrintOnlyIfDetail Property to true. It requires that you create a Report variable named Report111. The Subtype of the variable is report 111, Customer - Top 10 List.

```
IsPrintOnlyIfDetail := Report111.PrintONLYifDETAIL(true);
```

Report.Quit Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Aborts the processing of a report or XmlPort.

Syntax

```
Report.Quit()
```

Parameters

Report Type: Report An instance of the Report data type.

Remarks

When you use the QUIT method, the report or XMLport is exited without committing any changes that were made to the database during the execution. The OnPostReport Trigger or OnPostXMLport Trigger trigger will not be called.

Example

The following example shows how to use the QUIT method to abort an execution without committing any changes that were made during the processing.

```
// Do some database processing.
CurrReport.QUIT;
```

Report.RDLCLayout Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Gets the RDLC layout that is used on a report and returns it as a data stream.The method has an instance call and a static call. The following code shows the syntax of the RDLC method. The first line of code is the syntax for an instance method call. The second line of code is the syntax for a static method call.

Syntax

```
[Ok := ]  Report.RDLCLayout(var InStream: InStream)
```

Parameters

Report Type: Report An instance of the Report data type.

InStream
Type: InStream
The variable in which to return the RDLC layout.

Return Value

Ok Type: Boolean **true** if the operation was successful; otherwise **false**. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

Remarks

Using the return value is optional. When you use the return value, if the RDLC layout cannot be retrieved at run-time, then the system returns **false** and no error recorded. When you omit the return value, if the RDLC layout cannot be retrieved at run-time, then an error occurs, which states that the layout could not be retrieved.

Report.Run Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Loads and executes the report that you specify.

Syntax

```
Report.Run()
```

Parameters

Report Type: Report An instance of the Report data type.

Remarks

After you define the *Report* variable, you can run this method or the RunModal Method (Report) on the variable. With the Run method, the variable is automatically cleared after the method is executed. With the RunModal method, the variable is not automatically cleared.

Use Run method or the RunModal method if you know at design time the exact report that you want to run. Otherwise, use the Report.Run Method or Report.RunModal Method.

If the report you specify does not exist, then a compile error occurs.

> **NOTE**
> Internet browsers can only handle one file per request. Therefore, with the Web client, if this method is called in a repetitive statement (or loop) that generates multiple files, only the last file will be sent to the browser. Alternatively, when designing for the Web client, bundle the files in an archive file (.zip), for example, by using the methods found in codeunit **419 File Management**. For more details about this design pattern, see Multi-File Download. Although this article is written for Dynamics NAV, it is still relevant for Business Central. The methods in codeunit 419 are not external, therefore cannot be used in extensions. Instead, when developing extensions in AL, use the external methods of codeunit **425 Data Compression**. The approach is similar.

Example

```
var
    CustomerRec: Record Customer;
    SomeReport: Report "Salesperson - Sales Statistics";
begin
    CustomerRec.SetCurrentKey("No.");
    CustomerRec.SetFilter("Salesperson Code", 'JR|PS');
    SomeReport.SetTableView(CustomerRec);
    SomeReport.Run;
end;
```

See Also

Report Data Type
Getting Started with AL
Developing Extensions

Report.RunModal Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Loads and executes the report that you specify.

Syntax

```
Report.RunModal()
```

Parameters

Report Type: Report An instance of the Report data type.

Remarks

After you define the *Report* variable, you can run this method or the Run Method (Report) on the variable. As opposed to the Run method, with the RunModal method, the variable is not cleared after it executes this function. You must handle clearing the variable.

Use the RunModal method or the Run method if you know at design time the exact report you want to run. Otherwise, use the Report.RunModal Method or Report.Run Method.

If the report you specify does not exist, then a compile error occurs.

The request page is run modally when you use this method.

> **NOTE**
> Internet browsers can only handle one file per request. Therefore, with the Web client, if this method is called in a repetitive statement (or loop) that generates multiple files, only the last file will be sent to the browser. Alternatively, when designing for the Web client, bundle the files in an archive file (.zip), for example, by using the methods found in codeunit **419 File Management**. For more details about this design pattern, see Multi-File Download. Although this article is written for Dynamics NAV, it is still relevant for Business Central. The methods in codeunit 419 are not external, therefore cannot be used in extensions. Instead, when developing extensions in AL, use the external methods of codeunit **425 Data Compression**. The approach is similar.

Example

```
var
    CustomerRec: Record Customer;
    SomeReport: Report "Chart of Accounts";
begin
    …
    Clear(CustomerRec);
    CustomerRec.SetRecFilter;
    SomeReport.XXX; // Any user-defined method.
    SomeReport.SetTableView(CustomerRec);
    SomeReport.RunModal();
end;
```

Report.RunRequestPage Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Runs the request page for a report without running the report. Returns an XML string that contains the request page parameters that are entered on the request page.

Syntax

```
ReportParameters :=   Report.RunRequestPage([PageParameters: String])
```

Parameters

Report Type: Report An instance of the Report data type.

PageParameters
Type: String
A string of request page parameters as XML to use to run the report.

Return Value

ReportParameters Type: String XML string that contains the request page parameters that are entered on the request page

Remarks

This method opens the request page for the specified report, where the user can provide parameters for the report. When the user closes the request page by choosing the **OK** button, a string that contains the parameter values that were set by the user is returned. When the user chooses the **Cancel** button, an empty string will be returned. The returned parameter string can be picked up by calling one of the following methods:

- Execute Method
- Print Method
- SaveAs Method

> **NOTE**
> You can use these methods to schedule reports in the job queue.

Because the request page runs in the context of where it was invoked from, users cannot bookmark a link to this page from the user interface.

Example

This example illustrates how to use the RunRequestPage method to run the request page for report ID 206 Sales Invoice. The request page parameters are saved to a table, and then uses the parameters with the Execute,

SaveAs, and Print methods to preview the report, save it as a PDF file, and print it.

This example requires that you create a table for holding parameters that are entered on the report request page and a codeunit that runs the report methods.

Create a table called **Request Parameters** that has the following fields.

```
var
    ReportId: Integer;
    UserId: Code[100];
    Parameters: BLOB;
```

Create a codeunit and add the following code to the *OnRun* trigger of the codeunit.

```
var
    ReportParameters: Record "Report Parameters";
    XmlParameters: Text;
    OStream: OutStream;
    IStream: InStream;
    CurrentUser: Code[100];
    Content: File;
    TempFileName: Text;
begin
    // Use the Report.RunRequestPage method to run the request page to get report parameters
    XmlParameters := Report.RunRequestPage(206);
    CurrentUser := UserId;

    // Save the request page parameters to the database table
    with ReportParameters do begin
        // Cleanup
        if Get(206,CurrentUser) then
        Delete;

        SetAutoCalcFields(Parameters);
        ReportId := 206;
        UserId := CurrentUser;
        Parameters.CreateOutStream(OStream,TextEncoding::UTF8);
        Message(XmlParameters);
        OStream.WriteText(XmlParameters);

        Insert;
    end;

    Clear(ReportParameters);
    XmlParameters := '';

    // Read the request page parameters from the database table
    with ReportParameters do begin
        SetAutoCalcFields(Parameters);
        Get(206,CurrentUser);
        Parameters.CreateInStream(IStream,TextEncoding::UTF8);
        IStream.ReadText(XmlParameters);
    end;

    // Use the Report.SaveAs method to save the report as a PDF file
    Content.Create('TestFile.pdf');  // only supported in Business Central on-premises
    Content.CreateOutStream(OStream);  // only supported in Business Central on-premises
    Report.SaveAs(206,XmlParameters,ReportFormat::Pdf,OStream);
    Content.Close;  // only supported in Business Central on-premises

    // Use the Report.Execute method to preview the report
    Report.Execute(206,XmlParameters);

    // Use the Report.Print method to print the report
    Report.Print(206,XmlParameters);
end;
```

Report.SaveAs Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Runs a specific report without a request page and saves the report as a PDF, Excel, Word, or XML file. Instead of using the request page to obtain parameters at runtime, the method gets the parameter values as an input parameter string, typically from the return value of a RunRequestPage method call.

Syntax

```
[Ok := ]  Report.SaveAs(Parameters: String, Format: ReportFormat, var OutStream: OutStream [, RecordRef:
RecordRef])
```

Parameters

Report Type: Report An instance of the Report data type.

Parameters
Type: String
A string of request page parameters as XML to use to run the report. The parameter string is retrieved from the return value a RunRequestPage method call.

Format
Type: ReportFormat
The type of file to save the report as. The following options are supported: Pdf, Excel, Word, and XML.

OutStream
Type: OutStream
The stream to which to write a report.

RecordRef
Type: RecordRef
The RecordRef that refers to the table in which you want to find a record.

Return Value

Ok Type: Boolean **true** if the operation was successful; otherwise **false**. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

Remarks

You typically use this method together with the RunRequestPage Method method. The RunRequestPage method runs a report request page without actually running the report, but instead, returns the parameters that are set on the request page as a string. You can then call the SaveAs method to get the parameter string and save the report to a file of the specified format.

For a simple example that illustrates how to use the SaveAs method, see example in the RunRequestPage Method method topic.

NOTE

By default, when a report uses an RDLC report layout at runtime, fonts are embedded in the generated PDF. You can specify whether fonts are embedded in the PDF for RDLC reports by changing the **Report PDF Font Embedding** setting in the Dynamics 365 Business Central service instance configuration or changing the **PDFFontEmbedding** property in report objects.

Report.SaveAsExcel Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Saves a report on the computer that is running the server as a Microsoft Excel (.xls) workbook.

> **NOTE**
> This method is supported only in Business Central on-premises.

Syntax

```
[Ok := ]  Report.SaveAsExcel(FileName: String)
```

Parameters

Report Type: Report An instance of the Report data type.

FileName
Type: String
The path and the name of the file that you want to save the report as. The path must exist, the file must not be being used, and the server process must have permission to write to the file. Otherwise, you will get errors.

Return Value

Ok Type: Boolean **true** if the operation was successful; otherwise **false**. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

Remarks

You can use the SaveAsExcel method on the global Report object and on Report variables. If, at design time, you do not know the specific report that you want to run, then use the global Report object and specify the report number in the *Number* parameter. If you do know which report you want to run, then create a Report variable, set the Subtype of the variable to a specific report, and use this variable when you call the SaveAsExcel method.

When you call the SaveAsExcel method, the report is generated and saved to "*FileName*." The request page is not shown.

If the destination folder that you specify in *FileName* does not exist, then you get the following error:

The specified path is invalid.

If the file that you specify in *FileName* is being used, then you get the following error:

An I/O exception occurred during the operation.

If the Dynamics 365 Business Central service process does not have permission to write to the file that you specify in *FileName*, then you get the following error:

Either the caller does not have the required permission or the specified path is read-only.

Example

This example shows how to use the SaveAsExcel method to save the Excel workbook to the Dynamics 365 Business Central service and then download the file to a computer that is running the Dynamics 365 application.

```
var
    TempFile: File;
    Name: Text[250];
    NewStream: InStream;
    ToFile: Text[250];
    ReturnValue: Boolean;
begin
    // Specify that TempFile is opened as a binary file.
    TempFile.TextMode(False);
    // Specify that you can write to TempFile.
    TempFile.WriteMode(True);
    Name := 'C:\Temp\TempReport.xls';
    // Create and open TempFile.
    TempFile.Create(Name);
    // Close TempFile so that the SaveAsExcel method can write to it.
    TempFile.Close;

    Report.SaveAsExcel(406,Name);

    TempFile.Open(Name);
    TempFile.CreateInStream(NewStream);
    ToFile := 'Report.xls';

    // Transfer the content from the temporary file on the
    // server to a file on the client.
    ReturnValue := DownloadFromStream(
      NewStream,
      'Save file to client',
      '',
      'Excel File *.xls| *.xls',
      ToFile);

    // Close the temporary file.
    TempFile.Close();
end;
```

You can create an action on a page and set the action to run this code. When you run the action, the **Export File** dialog box opens. Choose **Save** to save the file to the client.

Report.SaveAsHtml Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Saves a report as an HTML file. The file is saved on the computer where the server instance is running, and then downloaded to the client when ready. > This method is only supported when a report uses a Word report layout when it is run.

NOTE

This method is supported only in Business Central on-premises.

Syntax

```
[Ok := ]  Report.SaveAsHtml(FileName: String)
```

Parameters

Report Type: Report An instance of the Report data type.

FileName

Type: String

The folder path and name of the file that you want to save the report as. The path must already exist and the service (login) account that is used by the server instance must have permission to write to the target folder. Otherwise, you will get errors.

Return Value

Ok Type: Boolean **true** if the operation was successful; otherwise **false**. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

Remarks

The SaveAsHTML method uses the logic in the codeunit **9651 Document Report Mgt.** code unit to handle the format transformation.

The SaveAsHTML method can be used on the Report data type and on Report variables. When you are programming the SaveAsHTML method, if you do not know the specific report that you want to run, then use the global Report object and specify the report number in the *Number* parameter. If you know which report you want to run, then create a Report variable, set the **Subtype** of the variable to a specific report, and then use this variable when you call the SaveAsHTML method.

When you call the SaveAsXML method, the report is generated and saved to "FileName." The request page is not shown.

Reports that use an RDLC layout when run cannot be saved in the HTML format. A runtime error will occur if SaveAsHTML is used on an RDLC report.

Report.SaveAsPdf Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Saves a report as a .pdf file.

> **NOTE**
> This method is supported only in Business Central on-premises.

Syntax

```
[Ok := ]  Report.SaveAsPdf(FileName: String)
```

Parameters

Report Type: Report An instance of the Report data type.

FileName
Type: String
The path and name of the file that you want to save the report as.

Return Value

Ok Type: Boolean **true** if the operation was successful; otherwise **false**. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

Remarks

You can use the **SaveAsPDF** method on the global Report object or on Report variables. If, at design time, you do not know the specific report that you want to run, then use the global Report object and specify the report number in the *Number* parameter. If you do know which report you want to run, then create a Report variable, set the Subtype of the variable to a specific report, and use this variable when you call the **SaveAsPDF** method.

When you call **SaveAsPDF**, the report is generated and saved to "*FileName*." A **Saving to PDF** window shows the status of the process. Note that the request page will not be shown.

The *FileName* parameter specifies a location on the computer that is running Dynamics 365 Business Central service. If you call this method from a client, such as from an action on a page, then use the DOWNLOAD Method (File) to download the .pdf file from the computer that is running Dynamics 365 Business Central service to the computer that is running the client.

NOTE

By default, when a report uses an RDLC report layout at runtime, fonts are embedded in the generated PDF. You can specify whether fonts are embedded in the PDF for RDLC reports by changing the **Report PDF Font Embedding** setting in the Dynamics 365 Business Central service instance configuration or changing the **PDFFontEmbedding** property in report objects.

Example

This example shows how to use the **SaveAsPDF** method to save a specific report as a PDF file on the computer that is running Dynamics 365 Business Central service.

```
var
    Filename: Text;
    ReturnValue: Boolean;
    Report206: Report "Sales - Invoice';
begin
    Filename := 'C:\MyReports\report206.pdf';
    ReturnValue := Report206.SaveAsPDF(Filename);
end;
```

Report.SaveAsWord Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Saves a report on the computer that is running the server as a Microsoft Word (.doc) document.

> **NOTE**
> This method is supported only in Business Central on-premises.

Syntax

```
[Ok := ]  Report.SaveAsWord(FileName: String)
```

Parameters

Report Type: Report An instance of the Report data type.

FileName
Type: String
The path and the name of the file that you want to save the report as. The path must exist, the file must not be being used, and the server process must have permission to write to the file. Otherwise, you will get errors.

Return Value

Ok Type: Boolean **true** if the operation was successful; otherwise **false**. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

Remarks

You can use the SaveAsWORD method on the global Report object or on Report variables. If, at design time, you do not know the specific report that you want to run, then use the global Report object and specify the report number in the *Number* parameter. If you do know which report you want to run, then create a Report variable, set the Subtype of the variable to a specific report, and use this variable when you call the SaveAsWORD method.

When you call the SaveAsWORD method, the report is generated and saved to "*FileName*." The request page is not shown.

If the destination folder that you specify in *FileName* does not exist, then you get the following error:

The specified path is invalid.

If the file that you specify in *FileName* is being used, then you get the following error:

An I/O exception occurred during the operation.

If the Dynamics 365 Business Central service process does not have permission to write to the file that you specify in *FileName*, then you get the following error:

Either the caller does not have the required permission or the specified path is read-only.

Example

This example shows how to use the SaveAsWORD method to save the Word document on the Dynamics 365 Business Central service, and then download the file to a different computer that is running the Dynamics 365 application.

```
var
    TempFile: File;
    Name: Text[250];
    NewStream: InStream;
    ToFile: Text[250];
    ReturnValue: Boolean;
begin
    // Specify that TempFile is opened as a binary file.
    TempFile.TextMode(False);
    // Specify that you can write to TempFile.
    TempFile.WriteMode(True);
    Name := 'C:\Temp\TempReport.doc';
    // Create and open TempFile.
    TempFile.Create(Name);
    // Close TempFile so that the SaveAsWORD method can write to it.
    TempFile.Close;

    Report.SaveAsWORD(406,Name);

    TempFile.Open(Name);
    TempFile.CreateInStream(NewStream);
    ToFile := 'Report.doc';

    // Transfer the content from the temporary file on the
    // server to a file on the client.
    ReturnValue := DownloadFromStream(
      NewStream,
      'Save file to client',
      '',
      'Word File *.doc| *.doc',
      ToFile);

    // Close the temporary file.
    TempFile.Close();
end;
```

You can create an action on a page and set the action to run this code. When you run the action, the **Export File** dialog box opens. Choose **Save** to save the file to the client.

Report.SaveAsXml Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Saves the resulting data set of a query as an .xml file.The following code shows the syntax of the SaveAsXML method. The first line of code is the syntax for an instance method call. The second line of code is the syntax for a static method call.

> **NOTE**
> This method is supported only in Business Central on-premises.

Syntax

```
[Ok := ]  Report.SaveAsXml(FileName: String)
```

Parameters

Report Type: Report An instance of the Report data type.

FileName
Type: String
The path and name of the file that you want to save the query to.

Return Value

Ok Type: Boolean **true** if the operation was successful; otherwise **false**. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

Remarks

You can use the SaveAsXML method on the global Report object and on Report variables. If, at design time, you do not know the specific report that you want to run, then use the global Report object and specify the report number in the *Number* parameter. If you know which report you want to run, then create a Report variable, set the **Subtype** of the variable to a specific report, and then use this variable when you call the SaveAsXML method.

When you call the SaveAsXML method, the report is generated and saved to "*FileName*." The request page is not shown.

If the destination folder that you specify in *FileName* does not exist, then you get the following error:

The specified path is invalid.

If the file that you specify in *FileName* is being used, then you get the following error:

An I/O exception occurred during the operation.

If the Dynamics 365 Business Central service does not have permission to write to the file that you specify in

FileName, then you get the following error:

Either the caller does not have the required permission or the specified path is read-only.

To resolve this issue, verify that the service account that is running the Dynamics 365 Business Central service instance has write permissions on the path.

Example

This example shows how to use the SaveAsXML method to save a report as an .xml file on the Dynamics 365 Business Central service, and then download the file to a computer that is running the Dynamics 365.

```
var
    TempFile: File;
    Name: Text[250];
    NewStream: InStream;
    ToFile: Text[250];
    ReturnValue: Boolean;
begin
    // Specify that TempFile is opened as a binary file.
    TempFile.TextMode(False);
    // Specify that you can write to TempFile.
    TempFile.WriteMode(True);
    Name := 'C:\Temp\TempReport.xml';
    // Create and open TempFile.
    TempFile.Create(Name);
    // Close TempFile so that the SaveAsXML method can write to it.
    TempFile.Close;

    Report.SaveAsXML(406,Name);

    TempFile.Open(Name);
    TempFile.CreateInStream(NewStream);
    ToFile := 'Report.xml';

    // Transfer the content from the temporary file on
    // server to a file on the client.
    ReturnValue := DownloadFromStream(
      NewStream,
      'Save file to client',
      '',
      'Excel File *.xml| *.xml',
      ToFile);

    // Close the temporary file.
    TempFile.Close();
end;
```

You can create an action on a page and set the action to run this code. When you run the action, the **Export File** dialog box opens. Choose **Save** to save the file to the client.

Report.SetTableView Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Applies the table view on the current record as the table view for the page, report, or XmlPort.

Syntax

```
Report.SetTableView(var Record: Record)
```

Parameters

Report Type: Report An instance of the Report data type.

Record
Type: Record
The record that has a table view that you want to apply to the page or data item.

Remarks

The table view is the view of the table that you present to the user. You determine what records that the user can see by setting filters, determining the sorting order, and selecting the keys.

This method only narrows the view of the table that was set through the SourceTableView Property of the page or through the DataItemTableView Property of the data item.

> **IMPORTANT**
> SETTableView is not supported for setting views on subpages from code on table headers. For example, you cannot set a table view on the SalesOrder subpage from the SalesHeader.

Example

This example is based on the Sales Header table and shows how SETTableView is used for a page object.

```
var
    SalesHeader: Record "Sales Header";
    SomePage: Page "Sales List";
begin
    SalesHeader.SETCURRENTKey("Document Type");
    SalesHeader.SETRANGE("Document Type",SalesHeader."Document Type"::Order);
    SomePage.SETTableView(SalesHeader); // Only view sales orders.
    SomePage.Run;
end;
```

The page that is reference by the SomePage variable can be any page object that has Sales Header as the value of the SourceTable Property.

Report.ShowOutput Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0 until version 1.0 where it was deprecated.*

Returns the current setting of whether a section should be printed, and changes this setting.

Syntax

```
Show :=   Report.ShowOutput()
```

Parameters

Report Type: Report An instance of the Report data type.

Return Value

Show Type: Boolean **true** if the section is printed, otherwise **false**.

See Also

Report Data Type
Getting Started with AL
Developing Extensions

Report.ShowOutput Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 2.3 until version 2.3 where it was deprecated.*

Returns the current setting of whether a section should be printed, and changes this setting.

Syntax

```
[Show := ]  Report.ShowOutput(Value: Boolean)
```

NOTE

This method can be invoked using property access syntax.

Parameters

Report Type: Report An instance of the Report data type.

Value

Type: Boolean

true if the section is printed, otherwise **false**.

Return Value

Show Type: Boolean **true** if the section is printed, otherwise **false**.

Developing Extensions

Report.Skip Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Skips the current iteration of the current report or XmlPort.

Syntax

```
Report.Skip()
```

Parameters

Report Type: Report An instance of the Report data type.

Remarks

The SKIP Method (Report, XMLport) allows you to conditionally skip processing of the current report or XMLport. If the processing occurs inside a loop, the processing continues with the next record after the SKIP Method (Report, XMLport) is called.

A typical situation in which you will use SKIP is when you want to retrieve records from a related table by using values in the current record for forming a filter. If the values in the current record already indicate that no records from the related table will be retrieved, there is no need to perform this processing and you can use SKIP to avoid the processing.

Example

The following example shows how to use the SKIP Method (Report, XMLport) to skip processing the current record if the balance field of the record is zero. Processing of records will continue until a record that has a balance of 0 is encountered.

```
var
    Balance: Decimal;
begin
    if Balance = 0 then
      CurrReport.SKIP
    else
      ... // Do some processing.
end;
```

Report.TotalsCausedBy Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0 until version 1.0 where it was deprecated.*

Determines which field caused a group total to be calculated. This determines which field changed contents and thereby concluded a group.

Syntax

```
FieldNo :=   Report.TotalsCausedBy()
```

Parameters

Report Type: Report An instance of the Report data type.

Return Value

FieldNo Type: Integer The number of the field that caused the group to end and a group total to be calculated.

Report.UseRequestPage Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Gets or sets whether a request page is presented to the user.

Syntax

```
[IsUseRequestPage := ]  Report.UseRequestPage([SetUseRequestPage: Boolean])
```

NOTE

This method can be invoked using property access syntax.

Parameters

Report Type: Report An instance of the Report data type.

SetUseRequestPage

Type: Boolean

true if a request page will be presented to the user, otherwise **false**.

Return Value

IsUseRequestPage Type: Boolean **true** if a request page is presented to the user, otherwise **false**.

See Also

Report Data Type

Report.WordLayout Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Gets the Word report layout that is used on a report and returns it as a data stream. The method has an instance call and a static call. The following code shows the syntax of the WORDLAYOUT method. The first line of code is the syntax for an instance method call. The second line of code is the syntax for a static method call.

Syntax

```
[Ok := ]  Report.WordLayout(var InStream: InStream)
```

Parameters

Report Type: Report An instance of the Report data type.

InStream
Type: InStream
The variable in which to return the Word report layout.

Return Value

Ok Type: Boolean **true** if the operation was successful; otherwise **false**. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

Remarks

Using the return value is optional. When you use the return value, if the Word report layout cannot be retrieved at run-time, then the system returns **false** and no error recorded. When you omit the return value, if the Word report layout cannot be retrieved at run-time, then an error occurs, which states that the Word report could not be retrieved.

Report.WordXmlPart Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Gets the report data structure as structured XML that is compatible with Microsoft Word custom XML parts.

Syntax

```
String :=   Report.WordXmlPart([ExtendedFormat: Boolean])
```

Parameters

Report Type: Report An instance of the Report data type.

ExtendedFormat
Type: Boolean
If you set this variable to true, then XML elements will include the following attributes:

- ElementType="Parameter|Column|DataItem". Specifies the element type as defined for the report in Report Designer. Parameter is typically used for elements, such as captions.
- ElementId="ID". Specifies the ID that is assigned to the element by its ID Property.
- DataType="Type". Specifies the data type of the element. If you omit this parameter or set it to false, then the element attributes are not included in the XML.

Return Value

String Type: String A string representation of the report data structure as structured XML that is compatible with Microsoft Word custom XML parts.

Remarks

This method returns the data structure of the report as structured XML that complies with custom XML parts in Microsoft Word 2013. The following table provides a simplified overview of the XML that is returned by the method.

XML	DESCRIPTION
`<?xml version="1.0" encoding="utf-16"?>`	Header
`<NavWordReportXmlPart xmlns="urn:microsoft-../report/<reportname>/<id>/"`	XML namespace specification. `<reportname>` is the name assigned to the report object. `<id>` is the ID that is assigned to the report.

XML	DESCRIPTION

`..<Labels>`
 	
`....`
`<ColumnNameCaption>ColumnNameCaption</ColumnNameCaption>`
 	
`....<LabelName>LabelCaption</LabelName>`
 	
`..</Labels>`
	Contains all the labels for the report. Labels are listed in alphabetical. The element includes labels that are related to columns that have the IncludeCaption Property set to **Yes** and labels that are defined in Report Label Designer.
	
	- Label elements that are related to columns have the format `<ColumnNameCaption>ColumnNameCaption</ColumnNameCaption>`, where `ColumnName` is determined by the column's Name Property.
	- Label elements from Report Label Designer have the format `<LabelName>LabelCaption</LableName`, where `LabelName` is determined by the label's Name Property and `LabelCaption` is determined by the label's Caption Property.

`..<DataItem1>`
 	
`....`
`<DataItem1Column1>DataItem1Column1</DataItem1Column1>`
	Top-level data item and columns. Columns are listed in alphabetical order.
	
	The element names and values are determined by the Name property of the data item or column.

`....<DataItem2>`
 	
`......`
`<DataItem2Column1>DataItem2Column1</DataItem2Column1>`
 	
`....</DataItem2>`
 	
`....<DataItem3>`
 	
`......`
`<DataItem3Column1>DataItem3Column1</DataItem3Column1>`
 	
`....</DataItem3>`
	Data items and columns that are nested in the top-level data item. Columns are listed in alphabetical order under the respective data item.

`..</DataItem1>`
 	
`</NavWordReportXmlPart>`
	Closing elements.

Word custom XML parts enable you to integrate business data into Word documents. For example, the WORDXMLPART method is used internally by Dynamics 365 when you are creating report layouts in Word. You can use this method to create a custom XML part, and then, together with the SaveAsXML Method (Reports) method and additional data merging tools, you can implement your own functionality for mapping and laying out report data in Word documents. To create a custom XML part, you can save the return value to an .xml file that is encoded in UTF-16 (16-bit Unicode Transformation Format). The resultant file can be added to Word documents as a custom XML part to map the report data set as XML data.

Example

The following example uses the WORDXMLPART method to save the data structure of Report 112 Sales Statistics in an XML file in a predefined folder *C:\Report Documents*. The resultant file can be used in Word as a custom XML part.

```
var
    SalesStatsReport: File;
    ReportAsString: Text;
begin
    ReportAsString := Report.WORDXMLPART(112);
    SalesStatsReport.TextMode(True);
    SalesStatsReport.WriteMode(True);
    SalesStatsReport.Create('C:\Report Documents\SalesStatsReport.xml', TextEncoding::UTF16);
    SalesStatsReport.WRITE(ReportAsString);
    SalesStatsReport.Close;
end;
```

The code generates the report structure as XML, and then writes the XML to the file *C:\Report Documents\SalesStatsReport.xml*.

RequestPage Data Type

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Is a page that is run before the report starts to execute. Request pages enable end-users to specify options and filters for a report.

The following methods are available on instances of the RequestPage data type.

METHOD NAME	DESCRIPTION
Activate([Boolean])	Activates the current page on the client if possible. The data on the page will not be refreshed.
Caption([String])	Shows the caption in the title bar. For example, the default value in English (United States) is the same as the name of the page.
Close()	Closes the current page.
Editable([Boolean])	Gets or sets the default editability of the page.
LookupMode([Boolean])	Gets or sets the default lookup mode for the page.
ObjectId([Boolean])	Returns a string in the "Page xxx" format, where xxx is the caption or ID of the application object.
SaveRecord()	Saves the current record as if performed by the client. If the record does not exist, it is inserted, otherwise it is modified.
SetSelectionFilter(var Record)	
Update([Boolean])	Saves the current record and then updates the controls on the page. If you set the SaveRecord parameter to false, this method will not save the record before the page is updated.

RequestPage.Activate Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Activates the current page on the client if possible. The data on the page will not be refreshed.

Syntax

```
[Ok := ]  RequestPage.Activate([Refresh: Boolean])
```

Parameters

RequestPage Type: RequestPage An instance of the RequestPage data type.

Refresh

Type: Boolean

If set to **true**, the data on the page will be refreshed.

Return Value

Ok Type: Boolean

See Also

RequestPage Data Type

Developing Extensions

RequestPage.Caption Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Shows the caption in the title bar. For example, the default value in English (United States) is the same as the name of the page.

Syntax

```
[Caption := ]  RequestPage.Caption([NewCaption: String])
```

NOTE

This method can be invoked using property access syntax.

Parameters

RequestPage Type: RequestPage An instance of the RequestPage data type.

NewCaption
Type: String

Return Value

Caption Type: String

See Also

RequestPage Data Type
Getting Started with AL
Developing Extensions

RequestPage.Close Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Closes the current page.

Syntax

```
RequestPage.Close()
```

Parameters

RequestPage Type: RequestPage An instance of the RequestPage data type.

See Also

RequestPage Data Type
Getting Started with AL
Developing Extensions

RequestPage.Editable Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Gets or sets the default editability of the page.

Syntax

```
[Editable := ]  RequestPage.Editable([NewEditable: Boolean])
```

NOTE

This method can be invoked using property access syntax.

Parameters

RequestPage Type: RequestPage An instance of the RequestPage data type.

NewEditable

Type: Boolean

Return Value

Editable Type: Boolean

See Also

RequestPage Data Type
Getting Started with AL
Developing Extensions

RequestPage.LookupMode Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Gets or sets the default lookup mode for the page.

Syntax

```
[LookupMode := ]  RequestPage.LookupMode([NewLookupMode: Boolean])
```

NOTE

This method can be invoked using property access syntax.

Parameters

RequestPage Type: RequestPage An instance of the RequestPage data type.

NewLookupMode
Type: Boolean

Return Value

LookupMode Type: Boolean

See Also

RequestPage Data Type
Getting Started with AL
Developing Extensions

RequestPage.ObjectId Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Returns a string in the "Page xxx" format, where xxx is the caption or ID of the application object.

Syntax

```
String :=   RequestPage.ObjectId([UseNames: Boolean])
```

Parameters

RequestPage Type: RequestPage An instance of the RequestPage data type.

UseNames
Type: Boolean

Return Value

String Type: String

See Also

RequestPage Data Type
Getting Started with AL
Developing Extensions

RequestPage.SaveRecord Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Saves the current record as if performed by the client. If the record does not exist, it is inserted, otherwise it is modified.

Syntax

```
RequestPage.SaveRecord()
```

Parameters

RequestPage Type: RequestPage An instance of the RequestPage data type.

See Also

RequestPage Data Type
Getting Started with AL
Developing Extensions

RequestPage.SetSelectionFilter Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Syntax

```
RequestPage.SetSelectionFilter(var Record: Record)
```

Parameters

RequestPage Type: RequestPage An instance of the RequestPage data type.

Record
Type: Record

Remarks

If all records are selected, marks will not be used.

If only the current record is selected on the page, then SetSelectionFilter does the following:

- Sets the current filter group to 0 on the destination record
- Adds filters on the primary key fields that point to the current record of the page

If more than one record is selected on the page, then SetSelectionFilter does the following:

- Copies the current key from the page source table to the destination record
- Copies the current sort order from the table to the destination record
- Copies the current filters that are set in all filter groups
- Copies the current filter group
- Marks the selected records and sets the "marked only" filter

RequestPage.Update Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Saves the current record and then updates the controls on the page. If you set the SaveRecord parameter to false, this method will not save the record before the page is updated.

Syntax

```
RequestPage.Update([SaveRecord: Boolean])
```

Parameters

RequestPage Type: RequestPage An instance of the RequestPage data type.

SaveRecord

Type: Boolean

Indicates if the current record is saved. To save the current record, set the value to true. If the value is set to false, the page is updated without saving the record.

Developing Extensions

Session Data Type

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Represents a Microsoft Dynamics Business Central session.

The following methods are available on the Session data type.

METHOD NAME	DESCRIPTION
ApplicationArea([String])	Gets or sets the application areas for the current session.
ApplicationIdentifier()	Gets the application ID associated with the current thread.
BindSubscription(Codeunit)	Binds the event subscriber methods in the codeunit to the current codeunit instance for handling the events that they subscribe to. This essentially activates the subscriber functions for the codeunit instance.
CurrentClientType()	Gets the client type that is running in current session.
CurrentExecutionMode()	Specifies the mode in which the session is running.
DefaultClientType()	Gets the default client that is configured for the server instance that is used by the current session.
EnableVerboseTelemetry(Boolean, Duration)	Temporarily enable verbose telemetry on the current session.
GetCurrentModuleExecutionContext()	Gets the current session's execution context for the currently executing module.
GetExecutionContext()	Gets the current session's execution context.
GetModuleExecutionContext([Guid])	Gets the current session's execution context scoped to a specific module.
IsSessionActive(Integer)	Tests if the specified SessionID is active on the server instance where it was started.
LogMessage(String, String, Verbosity, DataClassification, TelemetryScope, String, String [, String] [, String])	Logs a trace message to a telemetry account.
LogMessage(String, String, Verbosity, DataClassification, TelemetryScope, Dictionary of [Text, Text])	Logs a trace message to a telemetry account.
SendTraceTag(String, String, Verbosity, String [, DataClassification])	Send a trace tag to the telemetry service.
SetDocumentServiceToken(String)	Sets the document service token in the current session.

METHOD NAME	DESCRIPTION
StartSession(var Integer, Integer [, String] [, var Record])	Starts a session without a UI and runs the specified codeunit.
StopSession(Integer [, String])	Stops a session.
UnbindSubscription(Codeunit)	Unbinds the event subscriber methods from in the codeunit instance. This essentially deactivates the subscriber methods for the codeunit instance.

Session.ApplicationArea Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Gets or sets the application areas for the current session.

Syntax

```
[ApplicationArea := ]  Session.ApplicationArea([ApplicationArea: String])
```

> **NOTE**
> This method can be invoked without specifying the data type name.

Parameters

ApplicationArea
Type: String
The new application areas for the current session.

Return Value

ApplicationArea Type: String The application areas for the current session.

Remarks

This method lets you hide certain user interface elements (including page fields and actions, and report request page options) based on the application area to which they belong. Controls that define these items can be tagged with one or more application areas by setting the ApplicationArea property. When the ApplicationArea method is called in a client session, only those controls that are tagged with the application areas set by the method will be appear in the user interface.

> **NOTE**
> Currently, this functionality is intended for the application areas that are defined in **table 9178 Application Area Setup**. You can define your own application areas but be aware that the implementation might change in future release.

Session.ApplicationIdentifier Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Gets the application ID associated with the current thread.

Syntax

```
AppId :=   Session.ApplicationIdentifier()
```

NOTE

This method can be invoked without specifying the data type name.

Return Value

AppId Type: String The application ID associated with the current thread.

See Also

Session Data Type
Getting Started with AL
Developing Extensions

Session.BindSubscription Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Binds the event subscriber methods in the codeunit to the current codeunit instance for handling the events that they subscribe to. This essentially activates the subscriber functions for the codeunit instance.

Syntax

```
[Ok := ]  Session.BindSubscription(Codeunit: Codeunit)
```

> **NOTE**
> This method can be invoked without specifying the data type name.

Parameters

Codeunit
Type: Codeunit
The codeunit that contains the event subscribers.

Return Value

Ok Type: Boolean **true** if the event subscriber methods bind successfully to the codeunit instance and no errors occurred, otherwise **false**. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

Remarks

You can only call this method on codeunits that have the EventSubscriberInstance Property set to **Manual**.

The codeunit instance that event subscribers are bound to will be this exact instance. Events will be raised on this instance. You can't bind the same instance more than once, but you can bind multiple instances of the same codeunit. This condition will result in an event subscriber call on each bound instance when a given event is raised.

Example

The following sample code illustrates a typical use of the BindSubscription method.

```
Method MyFunction(….)
LocalVar
  SubScriberCodeunit5000;
begin
  // Set global information on the subscriber codeunit if required
  // You can rely on the instance being the same as the one receiving the event subscriber call

  SubScriberCodeunit5000.MySetGlobalInfo(<info you can later test in the subscriber event method>)
  BindSubscription(SubscriberCodeunit5000);
  DoSomething(…);  // After binding, all subscriptions on SubscriberCodeunit5000 are "active".

end; // Notice, that when SubScriberCodeunit5000 goes out of scope, all bindings are removed.
```

Session.CurrentClientType Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Gets the client type that is running in current session.

Syntax

```
ClientType :=   Session.CurrentClientType()
```

NOTE

This method can be invoked using property access syntax.

NOTE

This method can be invoked without specifying the data type name.

Return Value

ClientType Type: ClientType The client type that is running in current session.

Remarks

You can use CurrentClientType as a parameter in the GetURL Method to get the URL of the current client.

Example 1

In the following example, CurrentClientType is used to get the client type for the session and return a message if the session uses the Tablet client.

```
if CurrentClientType = ClientType::Tablet then
  Message('The session is running the Tablet client');
```

Example 2

In the following example, CurrentClientType is used as a parameter of the GetURL Method to return the URL of the client that invokes the code.

```
url := GetURL(CurrentClientType);
Message('The URL is %1.', url);
```

Session Data Type

Session.CurrentExecutionMode Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Specifies the mode in which the session is running.

Syntax

```
ExecutionMode :=   Session.CurrentExecutionMode()
```

NOTE

This method can be invoked using property access syntax.

NOTE

This method can be invoked without specifying the data type name.

Return Value

ExecutionMode Type: ExecutionMode The mode in which the session is running.

Example

This example requires that you create a variable named Mode that has a DataType of ExecutionMode.

```
Mode := CurrentExecutionMode;
Message('Current execution mode is %1.', Mode);
```

Session.DefaultClientType Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Gets the default client that is configured for the server instance that is used by the current session.

Syntax

```
ClientType :=   Session.DefaultClientType()
```

NOTE

This method can be invoked using property access syntax.

NOTE

This method can be invoked without specifying the data type name.

Return Value

ClientType Type: ClientType The default client that is configured for the server instance that is used by the current session.

Remarks

You can use DefaultClientType in a GetURL Method call to get the URL of the default client.

Example 1

In the following example, DefaultClientType is used to return the default client type that is configured for the Dynamics 365 Business Central service instance that is used by the current session.

```
if DefaultClientType = ClientType::Web then
  Message('The default client is Web client');
```

Example 2

In the following example, DefaultClientType is used as a parameter in the GetURL method to return the URL of the default client that is configured for the Dynamics 365 Business Central service instance.

```
url := GetURL(DefaultClientType);
Message('The URL is %1.', url);
```

Session.EnableVerboseTelemetry Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 3.2.*

Temporarily enable verbose telemetry on the current session.

> **NOTE**
> This method is supported only in Business Central on-premises.

Syntax

```
Session.EnableVerboseTelemetry(EnableFullALFunctionTracing: Boolean, Duration: Duration)
```

> **NOTE**
> This method can be invoked without specifying the data type name.

Parameters

EnableFullALFunctionTracing
Type: Boolean
Specifies whether to enable method tracing.
Duration
Type: Duration
Specifies the amount of time, in milliseconds, that verbose telemetry is enabled on the session. When the time is exceeded, system specified telemetry level is used again. The maximum value is 3600000, one hour.

Session.GetExecutionContext Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Gets the current session's execution context.

Syntax

```
ExecutionContext :=   Session.GetExecutionContext()
```

NOTE

This method can be invoked using property access syntax.

NOTE

This method can be invoked without specifying the data type name.

Return Value

ExecutionContext Type: ExecutionContext The current session's execution context.

Remarks

For an example of when and how to run the `GetExecutionContext` method, see Protecting sensitive code from running during upgrade.

Session.GetModuleExecutionContext Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Gets the current session's execution context scoped to a specific module.

Syntax

```
ExecutionContext :=   Session.GetModuleExecutionContext([AppId: Guid])
```

> **NOTE**
> This method can be invoked without specifying the data type name.

Parameters

AppId
Type: Guid
The application ID.

Return Value

ExecutionContext Type: ExecutionContext The current session's execution context scoped to a specific module.

See Also

Developing Extensions

Session.IsSessionActive Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Tests if the specified SessionID is active on the server instance where it was started.

Syntax

```
Ok :=   Session.IsSessionActive(SessionID: Integer)
```

> **NOTE**
> This method can be invoked without specifying the data type name.

Parameters

SessionID
Type: Integer
The ID of the session that you want to test if it is still active.

Return Value

Ok Type: Boolean **true** if the specified SessionID is active on the server instance where it was started, otherwise **false**.

Remarks

Use this method to test if a session has completed or is still active, for example if you want to check that a session started with StartSession is still running.

> **NOTE**
> The method looks for sessions on the local machine.

Session.LogMessage Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 5.4.*

Logs a trace message to a telemetry account.

Syntax

```
Session.LogMessage(EventId: String, Message: String, Verbosity: Verbosity, DataClassification:
DataClassification, TelemetryScope: TelemetryScope, Dimension1: String, Value1: String [, Dimension2:
String] [, Value2: String])
```

NOTE

This method can be invoked without specifying the data type name.

Parameters

EventId

Type: String

The event ID of trace message.

Message

Type: String

The message logged into telemetry.

Verbosity

Type: Verbosity

The verbosity of the log.

DataClassification

Type: DataClassification

Classification of data in message.

TelemetryScope

Type: TelemetryScope

Specifies the scope of this trace message:

- ExtensionPublisher: Will emit this trace message to the Extension Publisher's telemetry account.
- All: Will emit this trace message additionally to the Partner's telemetry account.

  Dimension1

  Type: String

  Additional dimension that will be emitted to the telemetry account and that can be used to specify filters in the query.

  Value1

  Type: String

  The value of Dimension1.

  Dimension2

  Type: String

  Additional dimension that will be emitted to the telemetry account and that can be used to specify filters in the query.

Value2

Type: String

The value of Dimension2.

Remarks

For more information about using this method, see Creating Custom Telemetry Events for Application Insights.

Example

```
trigger OnRun();
begin
    LogMessage('MyExt-0001', 'This is a critical error message', Verbosity::Critical,
DataClassification::CustomerContent, TelemetryScope::ExtensionPublisher, 'result', 'failed', 'reason',
'critical error in code');
end;
```

Session.LogMessage Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 5.4.*

Logs a trace message to a telemetry account.

Syntax

```
Session.LogMessage(EventId: String, Message: String, Verbosity: Verbosity, DataClassification:
DataClassification, TelemetryScope: TelemetryScope, CustomDimensions: Dictionary of [Text, Text])
```

> **NOTE**
> This method can be invoked without specifying the data type name.

Parameters

EventId
Type: String
The event ID of trace message.
Message
Type: String
The message logged into telemetry.
Verbosity
Type: Verbosity
The verbosity of the log.
DataClassification
Type: DataClassification
Classification of data in message.
TelemetryScope
Type: TelemetryScope
Specifies the scope of this trace message:

- ExtensionPublisher: Will emit this trace message to the Extension Publisher's telemetry account.
- All: Will emit this trace message additionally to the Partner's telemetry account.

CustomDimensions
Type: Dictionary of [Text, Text]
Set of additional dimensions, specified as a dictionary, that will be emitted to the telemetry account and that can be used to specify filters in the query.

Remarks

For more information about using this method, see Creating Custom Telemetry Events for Application Insights.

Example

```
trigger OnRun();
var
    CustDimension: Dictionary of [Text, Text];
begin
    CustDimension.Add('result', 'failed');
    CustDimension.Add('reason', 'critical error in code');
    LogMessage('MyExt-0001', 'This is a critical error message', Verbosity::Normal,
DataClassification::OrganizationIdentifiableInformation, TelemetryScope::ExtensionPublisher, CustDimension);
end;
```

Session.SendTraceTag Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0 until version 6.0 where it was deprecated for the following reason: "Use LogMessage instead."*

Send a trace tag to the telemetry service.

NOTE

This method is supported only in Business Central on-premises.

Syntax

```
Session.SendTraceTag(Tag: String, Category: String, Verbosity: Verbosity, Message: String [,
DataClassification: DataClassification])
```

NOTE

This method can be invoked without specifying the data type name.

Parameters

Tag

Type: String

The tag.

Category

Type: String

The category.

Verbosity

Type: Verbosity

The verbosity.

Message

Type: String

The message.

DataClassification

Type: DataClassification

Classification of data in message.

Remarks

You use the SendTraceTag method for instrumenting the application for telemetry. When the SendTraceTag method called, a telemetry trace event is emitted. The event can then be recorded in the Windows event log or collected by other event trace collection tools, like PerfView, Logman, and Performance Monitor.

A telemetry event is given one of the following event IDs, depending on the `DataClassification` and `Verbosity`:

DATACLASSIFICATION	VERBOSITY	ID
All except `CustomerContent` and `EndUserIdentifiableInformation`	Critical	700
	Error	701
	Informational	702
	Verbose	704
	Warning	705
`CustomerContent` or `EndUserIdentifiableInformation`	Critical	707
	Error	708
	Informational	709
	Verbose	711
	Warning	712

NOTE

The SendTraceTag method is marked as obsolete in Business Central 2020 release wave 2 (v17). You can still use it, but we recommend that you send traces to Application Insights using the LOGMessage method instead. For more information, see Creating Custom Telemetry Traces for Application Insights Monitoring.

Example

The following code defines simple telemetry events for the five different severity levels.

```
SendTraceTag('Cronus-0001', 'Action', Verbosity::Critical, 'This is a critical message.',
DataClassification::CustomerContent);
SendTraceTag('Cronus-0002', 'Action', Verbosity::Error, 'This is an error message.',
DataClassification::EndUserIdentifiableInformation);
SendTraceTag('Cronus-0003', 'Action', Verbosity::Warning, 'This is a warning message.',
DataClassification::AccountData);
SendTraceTag('Cronus-0004', 'Action', Verbosity::Normal, 'This is an informational message.',
DataClassification::OrganizationIdentifiableInformation);
SendTraceTag('Cronus-0005', 'Action', Verbosity::Verbose, 'This is a verbose message.',
DataClassification::SystemMetadata);
```

The events emitted by this code will have the events IDs (listed in the order that the are called): 707, 708, 705, 702, and 704.

Session.SetDocumentServiceToken Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 6.0.*

Sets the document service token in the current session.

Syntax

```
Session.SetDocumentServiceToken(Token: String)
```

> **NOTE**
> This method can be invoked without specifying the data type name.

Parameters

Token

Type: String

The access token.

See Also

Session Data Type
Getting Started with AL
Developing Extensions

Session.StartSession Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Starts a session without a UI and runs the specified codeunit.

Syntax

```
[Ok := ]  Session.StartSession(var SessionId: Integer, CodeunitId: Integer [, Company: String] [, var
Record: Record])
```

NOTE

This method can be invoked without specifying the data type name.

Parameters

SessionId

Type: Integer

The ID of the new session that is started. The ID is assigned to the SessionID variable after the session is started successfully. This parameter is passed by reference to the method.

CodeunitId

Type: Integer

The ID of the codeunit to run when the session is started.

Company

Type: String

The company in which to start the session. By default, the session is started in the same company as the calling session.

Record

Type: Record

A record that is passed to the OnRun trigger of the codeunit that runs when the session is started. This parameter is optional.

Return Value

Ok Type: Boolean **true** if the operation was successful; otherwise **false**. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

Remarks

The session is started on the same Dynamics 365 Business Central service instance from which the method is called. The session that is started is a background session and therefore has no UI. The session executes using the same user credentials as the calling AL code.

The following table describes how dialog boxes are handled in a background session, which has no UI.

METHOD THAT CREATES THE DIALOG BOX	BEHAVIOR
Confirm Method (Dialog)	- Dialog box is suppressed. - The following error occurs on the Dynamics 365 Business Central service instance: **Dynamics 365 Business Central service attempted to issue a client callback to show a confirmation dialog box.**
Error Method (Dialog)	- Dialog box is suppressed. - AL code execution ends. - The error is logged to the event log of the Dynamics 365 Business Central service instance. - The error is added to the **Comments** field of the **Session Event** table.
Message Method (Dialog)	- Dialog box is suppressed. - The message is recorded in the event log of the computer that is running Dynamics 365 Business Central service instance. The log entry has type Information and includes the context of the message.
Open Method (Dialog)	- Dialog box is suppressed. - Dialog box text is not displayed or logged.

Each background session has the same impact on resources as a regular user session. In addition, it takes time and resources to start each background session. Therefore, we recommend that you consider when and how you use background sessions. For example, do not use background sessions for small tasks that occur often because the cost of starting the session for each tasks is high.

Example

In this example, the Cache Stress Test codeunit is a custom codeunit.

```
var
    CacheStressTestRec: Record Customer;
    SessionID: Integer;
    OK: Boolean;
begin
    OK := StartSession(SessionId, CodeUnit::"Cache Stress Test", CompanyName, CacheStressTestRec);
    if OK then
      StopSession(SessionId, 'Logoff cache stress test session')
    else
      Error('The session was not started successfully.');
end;
```

See Also

Session Data Type

Developing Extensions

Session.StopSession Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Stops a session.

Syntax

```
[Ok := ]  Session.StopSession(SessionId: Integer [, Comment: String])
```

NOTE

This method can be invoked without specifying the data type name.

Parameters

SessionId

Type: Integer

The ID of the session that you want to stop.The session can be any of the following:

- Windows client session
- Web client session
- NAS services session
- SOAP web services client session
- OData web services client session
- Background session

Comment

Type: String

An optional comment about the session event. The comment is stored in Table 2000000111, the Session Event table.

Return Value

Ok Type: Boolean **true** if the operation was successful; otherwise **false**. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

Remarks

The session that you want to stop and the session that calls StopSession must be running on the same instance of Dynamics 365 Business Central service. The session is stopped before the next AL statement executes. Open transactions are rolled back.

NOTE

If the current executing statement is the **Sleep** method, then the session is stopped immediately.

When a session is executing AL that does not interact with the server connection or the access lock used by the connection, StopSession cannot terminate the connection. StopSession can terminate connections that are inactive, idle, or using the database but not blocked.

You cannot stop the current, active session in which you are executing the **StopSession** call.

Example

This example assumes that you have a table named CacheStressTest that you use for testing.

```
var
    CacheStressTestRec: Record Customer;
    SessionID: Integer;
begin
    StartSession(SessionId, CodeUnit::"Cache Stress Test", CompanyName, CacheStressTestRec);
    StopSession(SessionId, 'Logoff cache stress test session');
end;
```

Session.UnbindSubscription Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Unbinds the event subscriber methods from in the codeunit instance. This essentially deactivates the subscriber methods for the codeunit instance.

Syntax

```
[Ok := ]  Session.UnbindSubscription(Codeunit: Codeunit)
```

> **NOTE**
> This method can be invoked without specifying the data type name.

Parameters

Codeunit
Type: Codeunit
The codeunit that contains the event subscribers.

Return Value

Ok Type: Boolean **true** if the event subscriber methods unbind successfully to the codeunit instance and no errors occurred, otherwise **false**. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

Remarks

You can only call this method on codeunits that have the EventSubscriberInstance Property set to **Manual**.

Calling this method on a codeunit that hasn't been bound (by the BindSubscription Method) will result in an error. If the call to this method is successful, all bindings are removed.

The codeunit instance that is unbound will be the same instance that previously was bound.

Example

The following sample code illustrates a typical use of the BindSubscription method.

```
Method MyFunction(….)
LocalVar
  SubScriberCodeunit5000;
begin
  // Set global information on the subscriber codeunit if required
  // You can rely on the instance being the same as the one receiving the event subscriber call

  SubScriberCodeunit5000.MySetGlobalInfo(<info you can later test in the subscriber event method>)
  BindSubscription(SubscriberCodeunit5000);
  DoSomething(…);  // After binding, all subscriptions on SubscriberCodeunit5000 are "active".
  UNBindSubscription(SubscriberCodeunit888);  // Now deactivating again
  DoStuff(…);  // This time no events are raised inside SubscriberCodeunit888;

end;
```

SessionSettings Data Type

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Is a complex data type for passing user personalization settings for a client session as an object. The object contains properties that correspond to the fields in the system table **2000000073 User Personalization**, including: App ID, Company, Language ID, Locale ID, Profile ID, Scope, and Time Zone. You can use the AL methods of the SessionSettings data type to get, set, and send the user personalization settings for the current client session.

The following methods are available on instances of the SessionSettings data type.

METHOD NAME	DESCRIPTION
Company([String])	Gets or sets the company property in a SessionSettings object.
Init()	Populates the instance of a SessionsSettings with the current client user's personalization properties (such as Profile ID and Company) that are stored in the database.
LanguageId([Integer])	Gets or sets the language ID property in a SessionSettings object.
LocaleId([Integer])	Gets or sets the locale ID property in a SessionSettings object.
ProfileAppId([Guid])	Gets or sets the ID of an extension, which provides a profile, in a SessionSettings object.
ProfileId([String])	Gets or sets the profile ID property in a SessionSettings object.
ProfileSystemScope([Boolean])	Gets or sets the profile scope property in a SessionSettings object.
RequestSessionUpdate(Boolean)	Passes a SessionSettings object to the client to request a new session that uses the user personalization properties that are set in the object. The current client session is abandoned and a new session is started.
TimeZone([String])	Gets or sets the time zone property in a SessionSettings object.

SessionSettings.Company Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Gets or sets the company property in a SessionSettings object.

Syntax

```
[Company := ]  SessionSettings.Company([NewCompanyName: String])
```

> **NOTE**
> This method can be invoked using property access syntax.

Parameters

SessionSettings Type: SessionSettings An instance of the SessionSettings data type.

NewCompanyName
Type: String
Specifies the name of the company in the SessionSettings object. The company must already exist in the database, otherwise you will get an error at runtime.

Return Value

Company Type: String The name of the company that is set in the SessionSettings object.

Remarks

The company property in the SessionSettings object corresponds to the **Company** field in the in the system table **2000000073 User Personalization**.

Example

This example creates a SessionSettings object that is populated with the current client user's personalization data, and then calls the Company method to change the company to 'MyCompany'. Finally, the RequestSessionUpdate method sends a request to the client to abandon the current session and start a new session that uses the new company. This example requires a SessionSettings data type variable.

```
var
  MySessionSettings : SessionSettings;
begin
  MySessionSettings.Init;
  MySessionSettings.Company('MyCompany');
  MySessionSettings.RequestSessionUpdate(false);
end;
```

SessionSettings.Init Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Populates the instance of a SessionsSettings with the current client user's personalization properties (such as Profile ID and Company) that are stored in the database.

Syntax

```
SessionSettings.Init()
```

Parameters

SessionSettings Type: SessionSettings An instance of the SessionSettings data type.

Remarks

The method gets the data from the following fields in system table **2000000073 User Personalization**: App ID, Company, Language ID, Locale ID, Profile ID, Scope, and Time Zone. In the SessionSettings object, the data is stored in properties that correspond to the fields of the system table.

After you call the Init method, you can change the values in the object by calling the following methods:

- Company
- LanguageId
- LocalId method
- ProfileAppId
- ProfileId
- ProfileSystemScope
- TimeZone

The Init method is useful before calling the RequestSessionUpdate method to ensure that all properties are initialized before sending the request to the server instance to start a new client session.

Example

This example uses the Init method to create a SessionSettings object that includes the current client user's personalization settings from the database, and uses the Company method to set the company to 'MyCompany'. Then, the RequestSessionUpdate method sends a request to the client to abandon the current client session and start a new session that uses the personalization settings in the SessionSettings object.

```
var
  MySessionSettings : SessionSettings;
begin
  MySessionSettings.Init
  MySessionSettings.Company('MyCompany');
  MySessionSettings.RequestSessionUpdate(false);
end;
```

SessionSettings.LanguageId Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Gets or sets the language ID property in a SessionSettings object.

Syntax

```
[LanguageId := ]  SessionSettings.LanguageId([NewLanguageId: Integer])
```

> **NOTE**
> This method can be invoked using property access syntax.

Parameters

SessionSettings Type: SessionSettings An instance of the SessionSettings data type.

NewLanguageId
Type: Integer
Specifies the language ID to set in the SessionSettings object. The value must be a valid Windows language ID, which is typically a 4-digit value such as 1033 for English or 1030 for Danish. The default value is 1033.

Return Value

LanguageId Type: Integer The language ID that is set in the SessionSettings object.

Remarks

The langauge ID in the SessionSettings object corresponds to the **Language ID** field in the system table **2000000073 User Personalization**.

Example

This example creates a SessionSettings object that is populated with the current client user's personalization data, and then uses the LanguageId method to change the language ID to '1030'. Finally, the RequestSessionUpdate method sends a request to the client to abandon the current client session and start a new session that uses the new language. This example requires a SessionSettings data type variable.

```
var
  MySessionSettings : SessionSettings;
begin
  MySessionSettings.Init;
  MySessionSettings.LanguageId(1030);
  MySessionSettings.RequestSessionUpdate(false);
end;
```

SessionSettings.LocaleId Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Gets or sets the locale ID property in a SessionSettings object.

Syntax

```
[LocaleId := ]  SessionSettings.LocaleId([NewLocaleId: Integer])
```

> **NOTE**
> This method can be invoked using property access syntax.

Parameters

SessionSettings Type: SessionSettings An instance of the SessionSettings data type.

NewLocaleId
Type: Integer
Specifies the locale ID to set in the SessionSettings object. The value must be a valid Windows locale ID.

Return Value

LocaleId Type: Integer The locale ID that is set in the SessionSettings object.

Remarks

The locale ID in the SessionSettings object corresponds to the **Locale ID** field in the system table **2000000073 User Personalization** for the client session user.

Example

This example creates a SessionSettings object that is populated with the current client user's personalization data, and then uses the LocaleId method to set the locale ID to '1033'. Finally, the RequestSessionUpdate method sends a request to the client to abandon the current client session and start a new session that uses the new locale ID. This example requires a SessionSettings data type variable.

```
var
  MySessionSettings : SessionSettings;
begin
  MySessionSettings.Init;
  MySessionSettings.LocaleId(1033);
  MySessionSettings.RequestSessionUpdate(false);
end;
```

Developing Extensions

SessionSettings.ProfileAppId Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Gets or sets the ID of an extension, which provides a profile, in a SessionSettings object.

Syntax

```
[ProfileAppId := ]  SessionSettings.ProfileAppId([NewProfileAppId: Guid])
```

NOTE

This method can be invoked using property access syntax.

Parameters

SessionSettings Type: SessionSettings An instance of the SessionSettings data type.

NewProfileAppId

Type: Guid

Sets the GUID of the extension that provides the profile. The value must be a valid GUID for an extension in the system table **2000000072 Profile**.

Return Value

ProfileAppId Type: Guid The ID of the extension that is set in the SessionSettings object.

Remarks

A profile can be included as part of an extension, instead of being defined as part of the base application. In order to properly identify a profile from an extension in the SessionSettings object, you must specify the extension ID, by using the ProfileAppId method, and the profile ID, by using ProfileId method.

The ProfileAppId property in a SessionSettings object corresponds to the **App ID** field in the in the system table **2000000073 User Personalization**

Example

This example creates a SessionSettings object that is populated with the current client user's personalization data, and then uses the ProfileAppId method and ProfileId method to set the object to use the profile that has the ID 'MyExtensionProfile', which is provided in the extension that has the ID '12345678-1234-1234-1234-1234567890AB'. Finally, the RequestSessionUpdate method sends a request to the client to abandon the current client session and start a new session that uses the new profile. This example requires a SessionSettings data type variable.

```
var
  MySessionSettings : SessionSettings;
begin
  MySessionSettings.Init;
  MySessionSettings.ProfileId('MyExtensionProfile');
  MySessionSettings.ProfileAppId('12345678-1234-1234-1234-1234567890AB');
  MySessionSettings.RequestSessionUpdate(false);
end;
```

SessionSettings.ProfileId Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Gets or sets the profile ID property in a SessionSettings object.

Syntax

```
[ProfileId := ]  SessionSettings.ProfileId([NewProfileId: String])
```

> **NOTE**
> This method can be invoked using property access syntax.

Parameters

SessionSettings Type: SessionSettings An instance of the SessionSettings data type.

NewProfileId
Type: String
Specifies the ID of the profile to set in the SessionSettings object. The value must be a valid profile ID in the system table **2000000072 Profile**.

Return Value

ProfileId Type: String The profile ID that is set in the SessionSettings object.

Remarks

The profile ID determines the Role Center that is used in the client session. The ProfileId property in a SessionSettings object corresponds to the **Profile ID** field in the in the system table **2000000073 User Personalization**.

Example

This example creates a SessionSettings object that is populated with the current client user's personalization data, and uses the changes the Profile method to set the profile to 'Business Manager'. Finally, the RequestSessionUpdate method sends a request to the client to abandon the current session and start a new session that uses the new profile ID. This example requires a SessionSettings data type variable.

```
var
  MySessionSettings : SessionSettings;
begin
  MySessionSettings.Init;
  MySessionSettings.ProfileId('Business Manager');
  MySessionSettings.RequestSessionUpdate(false);
end;
```

SessionSettings.ProfileSystemScope Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Gets or sets the profile scope property in a SessionSettings object.

Syntax

```
[ProfileSystemScope := ]  SessionSettings.ProfileSystemScope([NewProfileScope: Boolean])
```

> **NOTE**
> This method can be invoked using property access syntax.

Parameters

SessionSettings Type: SessionSettings An instance of the SessionSettings data type.

NewProfileScope
Type: Boolean
Specifies whether the profile applies to the system or to a tenant only. **true** sets the profile to apply to the system; **false** sets the profile to apply to a tenant only.

Return Value

ProfileSystemScope Type: Boolean **true** if the profile applies to the system; **false** if the profile applies to a tenant.

Remarks

The ProfileSystemScope property in a SessionSettings object corresponds to the **Scope** field in the in the system table **2000000073 User Personalization**.

Example

This example creates a SessionSettings object, and then uses the ProfileSystemScope method to set the profile scope to apply to the system. This example requires a SessionSettings data type variable.

```
var
  MySessionSettings : SessionSettings;
begin
  MySessionSettings.ProfileSystemScope(true);
end;
```

See Also

SessionSettings Data Type

SessionSettings.RequestSessionUpdate Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Passes a SessionSettings object to the client to request a new session that uses the user personalization properties that are set in the object. The current client session is abandoned and a new session is started.

Syntax

```
SessionSettings.RequestSessionUpdate(saveSettings: Boolean)
```

Parameters

SessionSettings Type: SessionSettings An instance of the SessionSettings data type.

saveSettings
Type: Boolean

Specifies whether to save the personalization properties in the SessionSettings object to the table **2000000073 User Personalization** in the database for the current client user. **true** saves the settings; **false** does not. If you set this parameter to **true**, before sending the request to the client, the server instance will store the property values of the SessionSettings object to the corresponding fields in the table **2000000073 User Personalization**. If you set this to **false**, when the new client session is closed, the next time the user signs in, the session will return to the previous personalization settings. This enables you to use the SessionSettings object to temporarily change the personalization settings for the current session.

Remarks

Within the scope of the RequestSessionUpdate method, it is not recommended to run code after the RequestSessionUpdate method call that requires client communication because the current client session will be abandoned.

Before the RequestSessionUpdate method is called, be sure that all user personalization properties in the SessionSettings object have values; otherwise the system default values will be used for empty properties. To help, you can use the Init method to populate the object with the values in the database.

Example

This example uses the Init method to create a SessionSettings object that includes the current client user's personalization settings from the database, and then uses the Company method to set the company to 'MyCompany'. Finally, the RequestSessionUpdate method sends a request that saves the SessionSettings object property values to the database and starts a new client session that uses the new company.

```
var
  MySessionSettings : SessionSettings;
begin
  MySessionSettings.Init
  MySessionSettings.Company('MyCompany');
  MySessionSettings.RequestSessionUpdate(true);
end;
```

SessionSettings.TimeZone Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Gets or sets the time zone property in a SessionSettings object.

Syntax

```
[TimeZone := ]  SessionSettings.TimeZone([NewTimeZone: String])
```

> **NOTE**
> This method can be invoked using property access syntax.

Parameters

SessionSettings Type: SessionSettings An instance of the SessionSettings data type.

NewTimeZone
Type: String
Specifies the time zone property in the SessionsSettings object. The value must be a valid Windows time zone name, such as **UTC** or **Pacific Standard Time**.

Return Value

TimeZone Type: String The time zone set in the SessionSettings object.

Remarks

The default time zone is **UTC**. This method can also be used with web service sessions.

Example

This example creates a SessionSettings object that is populated with the current client user's personalization data, and then uses the TimeZone method to set the time zone to 'UTC' (Coordinated Universal Time). Finally, the RequestSessionUpdate method sends a request to the client to abandon the current session and start a new session that uses the new profile ID. This example requires a SessionSettings data type variable.

```
var
  MySessionSettings : SessionSettings;
begin
  MySessionSettings.Init;
  MySessionSettings.TimeZone('UTC');
  MySessionSettings.RequestSessionUpdate(false);
end;
```

System Data Type

2/17/2021 • 6 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Is a complex data type.

The following methods are available on the System data type.

METHOD NAME	DESCRIPTION
Abs(Decimal)	Calculates the absolute value of a number (Decimal, Integer or BigInteger). ABS always returns a positive numeric value or zero.
ApplicationPath()	Returns the path of the directory where the executable file for the product is installed.
ArrayLen(Array of [Any] [, Integer])	Returns the total number of elements in an array or the number of elements in a specific dimension.
CalcDate(String [, Date])	Calculates a new date that is based on a date expression and a reference date.
CalcDate(DateFormula [, Date])	Calculates a new date that is based on a date expression and a reference date.
CanLoadType(DotNet)	Tests if the specified .NET Framework type can be loaded.
CaptionClassTranslate(String)	Returns a translated version of the caption string. The string is translated to the current local language.
Clear(var Array of [Any])	Clears the value of a single variable. Also, it clears all the filters that were set if the variable is a record and resets the key to the primary key and the company on a record variable.
Clear(var Any)	Clears the value of a single variable. Also, it clears all the filters that were set if the variable is a record and resets the key to the primary key and the company on a record variable.
ClearAll()	Clears all internal variables (except REC variables), keys, and filters in the object and in any associated objects, such as reports, pages, codeunits, and so on that contain AL code.
ClearLastError()	Removes the last error message from memory.
ClosingDate(Date)	Gets the closing date for a Date Data Type.
CodeCoverageInclude(var Record)	Includes the code that has been logged.

METHOD NAME	DESCRIPTION
CodeCoverageLoad()	Loads the code that has been logged.
CodeCoverageLog([Boolean] [, Boolean])	Starts and stops the logging of code. You can also use this method to retrieve the current logging status.
CodeCoverageRefresh()	Refreshes the code that has been logged.
CompressArray(Array of [String])	Moves all non-empty strings (text) in an array to the beginning of the array. The resulting StringArray has the same number of elements as the input array, but empty entries appear at the end of the array.
CopyArray(Array of [Any], Array of [Any], Integer [, Integer])	Copies one or more elements in an array to a new array.
CopyStream(OutStream, InStream [, Integer])	Copies the information that is contained in an InStream to an OutStream.
CreateDateTime(Date, Time)	Creates a DateTime object from a date and a time.
CreateEncryptionKey()	Creates an encryption key for the current tenant.
CreateGuid()	Creates a new unique GUID. The value can then be assigned to a GUID data type or a text data type. Use the text data type if you want to compare the GUID to another text string.
CurrentDateTime()	Gets the current DateTime.
Date2DMY(Date, Integer)	Gets the day, month, or year of a Date Data Type.
Date2DWY(Date, Integer)	Gets the day of the week, week number, or year of a Date Data Type.
DaTi2Variant(Date, Time)	Creates a variant that contains an encapsulation of a COM VT_DATE.
Decrypt(String)	Takes a string as input and returns the decrypted value of the string.
DeleteEncryptionKey()	Deletes an encryption key for the current tenant.
DMY2Date(Integer [, Integer] [, Integer])	Gets a Date object based on a day, month, and year.
DT2Date(DateTime)	Gets the date part of a DateTime object.
DT2Time(DateTime)	Gets the time part of a DateTime object.
DWY2Date(Integer [, Integer] [, Integer])	Gets a Date that is based on a week day, a week, and a year.
Encrypt(String)	Takes a string as input and returns the encrypted value of the string.

METHOD NAME	DESCRIPTION
EncryptionEnabled()	Checks if the tenant is configured to allow encryption.
EncryptionKeyExists()	Checks whether an encryption key for the current tenant is present on the server tenant.
Evaluate(var Any, String [, Integer])	Evaluates a string representation of a value into its typical representation. The result is assigned to a variable.
ExportEncryptionKey(String)	Returns a password protected temporary filepath containing the encryption key. When encrypting or decrypting data in Dynamics 365 Business Central, an encryption key is used. A single key is used per tenant and every tenant will have a different key. Keys can be exported to a file which may be necessary in the case of upgrading or migrating a system from one set of hardware to another. The EXPORTEncryptIONKey method allows an administrator to specify a destination file for the key and specify a password protection for the file.
ExportObjects(String, var Record [, Integer])	Exports application objects to a file.
Format(Any [, Integer] [, Integer])	Formats a value into a string.
Format(Any, Integer, String)	Formats a value into a string.
GetDocumentUrl(Guid)	Gets the URL for the specified temporary media object ID.
GetDotNetType(Any)	Gets the System.Type that corresponds to the given value.
GetLastErrorCallStack()	Gets the call stack from where the last error occurred.
GetLastErrorCode()	Gets the classification of the last error that occurred.
GetLastErrorObject()	Gets the last System.Exception object that occurred.
GetLastErrorText()	Gets the last error that occurred in the debugger.
GetUrl(ClientType [, String] [, ObjectType] [, Integer] [, Record] [, Boolean])	Generates a URL for the specified client target that is based on the configuration of the server instance. If the code runs in a multitenant deployment architecture, the generated URL will automatically apply to the tenant ID of the current user.
GetUrl(ClientType, String, ObjectType, Integer, RecordRef [, Boolean])	Generates a URL for the specified client target that is based on the configuration of the server instance. If the code runs in a multitenant deployment architecture, the generated URL will automatically apply to the tenant ID of the current user.
GlobalLanguage([Integer])	Gets and sets the current global language setting.
GuiAllowed()	Checks whether the AL code can show any information on the screen.
Hyperlink(String)	Passes a URL as an argument to an Internet browser, such as Windows Internet Explorer.

METHOD NAME	DESCRIPTION
ImportEncryptionKey(String, String)	Points to a password protected file that contains the key on the current server. When encrypting or decrypting data in Dynamics 365 Business Central, an encryption key is used. A single key is used per tenant, and every tenant will have a different key. Keys can be created or imported if one exists already, as may be the case if upgrading or migrating a system from one set of hardware to another. The IMPORTEncryptIONKey method allows an administrator to specify a file (password protected) which contains a key and imports it to the current Dynamics 365 Business Central service.
ImportObjects(String [, Integer])	Imports application objects from a file.
ImportStreamWithUrlAccess(InStream, String [, Integer])	Imports an object into a media container to be used in a temporary URL with a default expiration time.
IsNull(DotNet)	Gets a value indicating whether a DotNet object has been created or not.
IsNullGuid(Guid)	Indicates whether a value has been assigned to a GUID. A null GUID that consists only of zeros is valid but must never be used for references.
IsServiceTier()	Gets a value indicating whether the runtime is a service tier.
NormalDate(Date)	Gets the regular date (instead of the closing date) for the argument Date.
Power(Decimal, Decimal)	Raises a number to a power. For example, you can use this method to square the number 2 to get the result of 4.
Random(Integer)	Returns a pseudo-random number.
Randomize([Integer])	Generates a set of random numbers from which the RANDOM method (Integer) will select a random number.
Round(Decimal [, Decimal] [, String])	Rounds the value of a numeric variable.
RoundDateTime(DateTime [, BigInteger] [, String])	Rounds a DateTime.
Sleep(Integer)	Returns control to the operating system for a specified time.
TemporaryPath()	Gets the path of the directory where the temporary file is stored.
Time()	Gets the current time from the operating system.
Today()	Gets the current date set in the operating system.
Variant2Date(Variant)	Gets a date from a variant.
Variant2Time(Variant)	Gets a time from a variant.

METHOD NAME	DESCRIPTION
WindowsLanguage()	Gets the current Windows language setting.
WorkDate([Date])	Gets and sets the work date for the current session.

System.Abs Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Calculates the absolute value of a number (Decimal, Integer or BigInteger). ABS always returns a positive numeric value or zero.

Syntax

```
NewNumber :=   System.Abs(Number: Decimal)
```

NOTE

This method can be invoked without specifying the data type name.

Parameters

Number

Type: Decimal

The input value.

Return Value

NewNumber Type: Decimal

Remarks

The system automatically converts all of the numeric data types for you.

Example

This example shows how to remove the sign from a negative numeric value.

```
var
    x: Decimal;
    y: Decimal;
    Text000: Label "x = %1, y = %2";
begin
    x := -10.235; // x is assigned a negative value
    y := ABS(x); // y is assigned the value of x without sign
    Message(Text000, x, y);
end;
```

The message window displays the following:

x = -10.235, y = 10.235

See Also

System.ApplicationPath Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Returns the path of the directory where the executable file for the product is installed.

NOTE

This method is supported only in Business Central on-premises.

Syntax

```
String :=   System.ApplicationPath()
```

NOTE

This method can be invoked using property access syntax.

NOTE

This method can be invoked without specifying the data type name.

Return Value

String Type: String

Remarks

This method returns a string that contains the path of the directory where the executable file for Dynamics 365 Business Central is installed. This string ends with a backslash ('\') and does not contain the name of the executable file.

The string cannot contain more than 255 characters.

If this method is called from an application that is running on a Dynamics 365 Business Central Application Server, it returns the path of the directory where the Dynamics 365 Business Central Application Server is installed.

System.ArrayLen Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Returns the total number of elements in an array or the number of elements in a specific dimension.

Syntax

```
Length :=   System.ArrayLen(Array: Array of [Any] [, Dimension: Integer])
```

> **NOTE**
> This method can be invoked without specifying the data type name.

Parameters

Array

Type: Any

The array that you want to investigate.

Dimension

Type: Integer

If you omit this optional argument, the method returns the total number of elements in the array. To get the number of elements in a specific dimension, use Dimension with a valid value. The valid values are determined by the number of dimensions of the input array. For example, the valid values for a three-dimensional array would be 1, 2, and 3.

Return Value

Length Type: Integer

Remarks

If you use ArrayLen with an input parameter that is not an array, a run-time error occurs.

Example

This example shows how to use the ArrayLen method.

```
var
    Array1: array[2] of Integer;
    Array2: array[3,4] of Integer;
begin
    Message('Array1, Total number of elements: %1', ArrayLen(Array1));
    Message('Array2, Dimension 1 size: %1', ArrayLen(Array2,1));
    Message('Array2, Dimension 2 size: %1', ArrayLen(Array2,2));
    Message('Array2, Total number of elements: %1', ArrayLen(Array2));
end;
```

The following messages are displayed.

Array1, Total number of elements: 2

Array2, Dimension 1 size: 3

Array2, Dimension 2 size: 4

Array2, Total number of elements: 12

System.CalcDate Method

2/17/2021 • 3 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Calculates a new date that is based on a date expression and a reference date.

Syntax

```
NewDate :=   System.CalcDate(DateExpression: String [, Date: Date])
```

NOTE

This method can be invoked without specifying the data type name.

Parameters

DateExpression

Type: String

The date expression can be any length. The string is interpreted from left to right with one subexpression at a time. The following rules describe the valid syntax of date expressions:

- DateExpression = [<Subexpression>][<Subexpression>][<Subexpression>]
- <Subexpression> = [<Sign>] <Term>- <Sign> = + | -
- <Term> = <Number><Unit> | <Unit><Number> | <Prefix><Unit>
- <Number> = Positive integer
- <Unit> = D | WD | W | M | Q | Y (D=day, WD=weekday, W=week, M=month, Q=quarter, Y=year)
- <Prefix> = C (C=current) These production rules show that date expressions consist of zero, one, two, or three subexpressions. Each subexpression consists of an optional sign and a term. The following are some typical examples of terms:
- 30D (30 days; corresponds to <Number><Unit>)
- WD2 (weekday number 2; corresponds to <Unit><Number>)
- CW (current week; corresponds to <Prefix><Unit>) The internal calendar starts on Monday and ends on Sunday. This means that Monday is weekday 1 and Sunday is weekday 7. A run-time error occurs if the syntax of DateExpression is incorrect.

Date

Type: Date

Use this optional parameter to define a reference date. The default is the current system date. If you omit this optional value, the current system date is used.

Return Value

NewDate Type: Date

Remarks

DateExpression can be a field or variable of type Text or Code, and it can be a field or variable of type DateFormula. The benefit of using a DateFormula field or variable is that the date formula becomes language independent.

The user can enter formulas in the currently selected language. The formula is stored in a generic format in a field or variable. When the formula must be displayed, the actual string that is displayed is converted to the currently selected language.

For example, if a user who has language set to ENG (English) enters the date formula "1W+1D" for one week and one day, then a user who has the language set to FRA (French) sees "1S+1J," and a user who has the language set to ESP (Spanish) sees "1S+1D".

If a date formula is entered with < > delimiters surrounding it, then the date formula is stored in a generic, nonlanguage-dependent format. This makes it possible to develop date formulas that are not dependent on the currently selected language.

For more information about how to calculate the duration between two DateTimes, see Duration Data Type.

Example 1

This code example shows how to use the production rules that were previously described.

```
<CQ+1M-10D>
```

This should be interpreted as the following: current quarter + 1 month - 10 days.

The DateExpression is composed of the following:

<Prefix><Unit><Sign><Number><Unit><Sign><Number><Unit>

> **NOTE**
> The angle brackets (< >) specify that the expression is not translated, regardless of the application language.

Example 2

This example shows how to use the CalcDate method.

```
var
    Expr1: Text[30];
    Expr2: Text[30];
    Expr3: Text[30];
    RefDate: Date;
    Date1: Date;
    Date2: Date;
    Date3: Date;
    RefDateTxt: Label 'The reference date is: %1 \\';
    Expr1Txt: Label 'The expression: %2 returns %3\\';
    Expr2Txt: Label 'The expression: %4 returns %5\\';
    Expr3Txt: Label 'The expression: %6 returns %7';
begin
    Expr1 := '<CQ+1M-10D>'; // Current quarter + 1 month - 10 days
    Expr2 := '<-WD2>'; // The last weekday no.2, (last Tuesday)
    Expr3 := '<CM+30D>'; // Current month + 30 days
    RefDate := 19960521D;
    Date1 := CalcDate(Expr1, RefDate);
    Date2 := CalcDate(Expr2, RefDate);
    Date3 := CalcDate(Expr3, RefDate);
    Message(RefDateTxt + Expr1Txt + Expr2Txt + Expr3Txt,
      RefDate, Expr1, Date1, Expr2, Date2, Expr3, Date3);
end;
```

The message window displays the following text:

The reference date is: 05/21/96

The expression: CQ+1M-10D returns 07/20/96

The expression: -WD2 returns 05/14/96

The expression: CM+30D returns 06/30/96

System.CalcDate Method

2/17/2021 • 3 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Calculates a new date that is based on a date expression and a reference date.

Syntax

```
NewDate :=   System.CalcDate(DateExpression: DateFormula [, Date: Date])
```

NOTE

This method can be invoked without specifying the data type name.

Parameters

DateExpression

Type: DateFormula

The date expression can be any length. The string is interpreted from left to right with one subexpression at a time. The following rules describe the valid syntax of date expressions:

- DateExpression = [<Subexpression>][<Subexpression>][<Subexpression>]
- <Subexpression> = [<Sign>] <Term>
- <Sign> = + | -
- <Term> = <Number><Unit> | <Unit><Number> | <Prefix><Unit>
- <Number> = Positive integer
- <Unit> = D | WD | W | M | Q | Y (D=day, WD=weekday, W=week, M=month, Q=quarter, Y=year)
- <Prefix> = C (C=current) These production rules show that date expressions consist of zero, one, two, or three subexpressions. Each subexpression consists of an optional sign and a term. The following are some typical examples of terms:
- 30D (30 days; corresponds to <Number><Unit>)
- WD2 (weekday number 2; corresponds to <Unit><Number>)
- CW (current week; corresponds to <Prefix><Unit>) The internal calendar starts on Monday and ends on Sunday. This means that Monday is weekday 1 and Sunday is weekday 7. A run-time error occurs if the syntax of DateExpression is incorrect.

Date

Type: Date

Use this optional parameter to define a reference date. The default is the current system date. If you omit this optional value, the current system date is used.

Return Value

NewDate Type: Date

Remarks

DateExpression can be a field or variable of type Text or Code, and it can be a field or variable of type DateFormula. The benefit of using a DateFormula field or variable is that the date formula becomes language independent.

The user can enter formulas in the currently selected language. The formula is stored in a generic format in a field or variable. When the formula must be displayed, the actual string that is displayed is converted to the currently selected language.

For example, if a user who has language set to ENG (English) enters the date formula "1W+1D" for one week and one day, then a user who has the language set to FRA (French) sees "1S+1J," and a user who has the language set to ESP (Spanish) sees "1S+1D".

If a date formula is entered with < > delimiters surrounding it, then the date formula is stored in a generic, nonlanguage-dependent format. This makes it possible to develop date formulas that are not dependent on the currently selected language.

For more information about how to calculate the duration between two DateTimes, see Duration Data Type.

Example 1

This code example shows how to use the production rules that were previously described.

```
<CQ+1M-10D>
```

This should be interpreted as the following: current quarter + 1 month - 10 days.

The DateExpression is composed of the following:

<Prefix><Unit><Sign><Number><Unit><Sign><Number><Unit>

> **NOTE**
> The angle brackets (< >) specify that the expression is not translated, regardless of the application language.

Example 2

This example shows how to use the CalcDate method.

```
var
    Expr1: Text[30];
    Expr2: Text[30];
    Expr3: Text[30];
    RefDate: Date;
    Date1: Date;
    Date2: Date;
    Date3: Date;
    Text000: Label 'The reference date is: %1 \\';
    Text001: Label 'The expression: %2 returns %3\\';
    Text002: Label 'The expression: %4 returns %5\\';
    Text003: Label 'The expression: %6 returns %7';
begin
    Expr1 := '<CQ+1M-10D>'; // Current quarter + 1 month - 10 days
    Expr2 := '<-WD2>'; // The last weekday no.2, (last Tuesday)
    Expr3 := '<CM+30D>'; // Current month + 30 days
    RefDate := 19960521D;
    Date1 := CalcDate(Expr1, RefDate);
    Date2 := CalcDate(Expr2, RefDate);
    Date3 := CalcDate(Expr3, RefDate);
    Message(Text000 + Text001 + Text002 + Text003,
      RefDate, Expr1, Date1, Expr2, Date2, Expr3, Date3);
end;
```

The message window displays the following text:

The reference date is: 05/21/96

The expression: CQ+1M-10D returns 07/20/96

The expression: -WD2 returns 05/14/96

The expression: CM+30D returns 06/30/96

System.CanLoadType Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 2.0.*

Tests if the specified .NET Framework type can be loaded.

> **NOTE**
> This method is supported only in Business Central on-premises.

Syntax

```
Ok :=   System.CanLoadType(DotNet: DotNet)
```

> **NOTE**
> This method can be invoked without specifying the data type name.

Parameters

DotNet
Type: DotNet
A variable of the DotNet data type to represent the .NET Framework type.

Return Value

Ok Type: Boolean

Example

The following code example is based on codeunit 5300 in the CRONUS International Ltd. demonstration database.

```
var
    OObjLibrary: DotNet
"Microsoft.Dynamics.NAV.OLSync.OLSyncSupplier.OutlookObjectLibrary.'Microsoft.Dynamics.NAV.OLSync.OLSyncSupp
lier, Version=7.1.0.0, Culture=neutral, PublicKeyToken=31bf3856ad364e35'";
    MyError: Label 'Cannot access the specified type.';
if not CanLoadType(OObjLibrary) then
   Error(MyError);
```

System.CaptionClassTranslate Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Returns a translated version of the caption string. The string is translated to the current local language.

Syntax

```
String :=   System.CaptionClassTranslate(CaptionClassText: String)
```

> **NOTE**
> This method can be invoked without specifying the data type name.

Parameters

CaptionClassText
Type: String
A literal string that defines the caption.

Return Value

String Type: String

Remarks

You can use the SelectLatestVersion Method (Database) to clear the current session's cache for the CaptionClassTranslate strings. The strings will then be reevaluated by the **CaptionClassTranslate** method trigger in codeunit 42.

Developing Extensions

System.Clear Method

2/17/2021 • 3 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Clears the value of a single variable. Also, it clears all the filters that were set if the variable is a record and resets the key to the primary key and the company on a record variable.

Syntax

```
System.Clear(var Variable: Any)
```

NOTE

This method can be invoked without specifying the data type name.

Parameters

Variable

Type: Any

The identifier (variable) of any AL data type, including simple and composite data types. The following rules apply when you run the Clear method:

- A number variable is set to 0 (zero)
- A string variable is set to empty string
- A date variable is set to 0D (undefined date)
- A time variable is set to 0T (undefined time)
- A Boolean variable is set to False

Remarks

Use the ClearAll Method to clear all internal variables, keys, and filters in the object and in any associated objects such as reports, pages, and codeunits that contain AL code. Note, however, that ClearAll Method does not affect or change values for variables in single instance codeunits.

For a composite data type, such as a record or an array, all elements are cleared. Furthermore, all fields in a record will be initialized with the InitValue Property of the field.

Clear can also be used on the Guid Data Type. It converts the GUID to zeros. Use the CreateGuid Method (Guid) to create a new unique GUID.

Clear can also be used to deselect a company. For more information, see ChangeCompany Method (Record).

If you use **Clear** on a codeunit, only the reference to the codeunit is deleted and not the codeunit itself, as with Automation objects. This means that the content of the codeunit stays intact.

If you have an array of controls, the whole array is destroyed when the array variable goes out of scope.

If you have an array of automation servers, you may clear the whole array at once, or clear each element individually.

Example 1

This example shows how to use the **Clear** method.

```
var
    Text000: Label 'Joe Raybon';
    Text001: Label 'Initially the variable "Name" contains: >;%1\>';
    Text002: Label 'After using Clear, the variable "Name" contains: >;%1\>';
begin
    Name := Text000;
    Message(Text001, Name);
    Clear(Name);
    Message(Text002, Name);
end;
```

The first message window displays the following:

Initially the variable "Name" contains: >;Joe Raybon>

The second message window displays the following:

After using Clear, the variable "Name" contains: >;>

Example 2

In the following example you will declare two variables:

```
var
    MyTextVar: Text;
    GuidVar: Guid;
```

These variables will be declared and cleared, first by using **Clear** and then by using ClearAll Method.

```
var
    Text000: Label 'My Text';
    Text001: Label 'Initially the variable "MyTextVar" contains >;%1> and "GuidVar" is defined as >;%2>';
    Text002: Label 'After using Clear(MyTextVar), the variable "MyTextVar" contains >;%1> and "GuidVar" is
still defined as >;%2>';
    Text003: Label 'After using Clear(GuidVar) the variable "GuidVar" becomes undefined';
    Text004: Label 'Giving the "MyTextVar" variable the initial value again and creating a new "GuidVar"
results in >;%1> and >;%2>';
    Text005: Label 'Using ClearAll results in an empty "MyTextVar" >;%1> and an undefined "GuidVar"';
begin
    MyTextVar : Text000;
    GuidVar := CreateGuid();
    Message(Text001,MyTextVar,GuidVar);
    Clear(MyTextVar);
    Message(Text002,MyTextVar,GuidVar);
    Clear(GuidVar);
    Message(Text003,GuidVar);
    MyTextVar := Text000;
    GuidVar := CreateGuid();
    Message(Text004,MyTextVar,GuidVar);
    ClearAll;
    Message(Text005,MyTextVar,GuidVar);
end;
```

The first message window displays the following:

Initially the variable "MyTextVar" contains: >;My Text> and "GuidVar" is defined as >;12345678-

1234-1234-1234-1234567890AB>

The second message window displays the following:

After using Clear(MyTextVar), the variable "MyTextVar" contains: >;> and GuidVar is still defined as >;12345678-1234-1234-1234-1234567890AB>

The third message window displays the following:

After using Clear(GuidVar) the variable "GuidVar" becomes undefined

The fourth message window displays the following:

Giving the "MyTextVar" variable the initial value again and creating a new "GuidVar" results in >;My Text> and >;87654321-4321-4321-4321-BA0987654321>

The fifth message window displays the following:

Using ClearAll results in an empty "MyTextVar" >;> and an undefined "GuidVar"

System.Clear Method

2/17/2021 • 3 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Clears the value of a single variable. Also, it clears all the filters that were set if the variable is a record and resets the key to the primary key and the company on a record variable.

Syntax

```
System.Clear(var Variable: Any)
```

> **NOTE**
> This method can be invoked without specifying the data type name.

Parameters

Variable

Type: Any

The identifier (variable) of any AL data type, including simple and composite data types. The following rules apply when you run the Clear method:

- A number variable is set to 0 (zero)
- A string variable is set to empty string
- A date variable is set to 0D (undefined date)
- A time variable is set to 0T (undefined time)
- A Boolean variable is set to False

Remarks

Use the ClearAll Method to clear all internal variables, keys, and filters in the object and in any associated objects such as reports, pages, and codeunits that contain AL code. Note, however, that ClearAll Method does not affect or change values for variables in single instance codeunits.

For a composite data type, such as a record or an array, all elements are cleared. Furthermore, all fields in a record will be initialized with the InitValue Property of the field.

Clear can also be used on the Guid Data Type. It converts the GUID to zeros. Use the CreateGuid Method (Guid) to create a new unique GUID.

Clear can also be used to deselect a company. For more information, see ChangeCompany Method (Record).

If you use **Clear** on a codeunit, only the reference to the codeunit is deleted and not the codeunit itself, as with Automation objects. This means that the content of the codeunit stays intact.

If you have an array of controls, the whole array is destroyed when the array variable goes out of scope.

If you have an array of automation servers, you may clear the whole array at once, or clear each element individually.

Example 1

This example shows how to use the **Clear** method.

```
var
    Text000: Label 'Joe Raybon';
    Text001: Label 'Initially the variable "Name" contains: >;%1\>';
    Text002: Label 'After using Clear, the variable "Name" contains: >;%1\>';
begin
    Name := Text000;
    Message(Text001, Name);
    Clear(Name);
    Message(Text002, Name);
end;
```

The first message window displays the following:

Initially the variable "Name" contains: >;Joe Raybon>

The second message window displays the following:

After using Clear, the variable "Name" contains: >;>

Example 2

In the following example you will declare two variables:

```
var
    MyTextVar: Text;
    GuidVar: Guid;
```

These variables will be declared and cleared, first by using **Clear** and then by using ClearAll Method.

```
var
    Text000: Label 'My Text';
    Text001: Label 'Initially the variable "MyTextVar" contains >;%1> and "GuidVar" is defined as >;%2>';
    Text002: Label 'After using Clear(MyTextVar), the variable "MyTextVar" contains >;%1> and "GuidVar" is
still defined as >;%2>';
    Text003: Label 'After using Clear(GuidVar) the variable "GuidVar" becomes undefined';
    Text004: Label 'Giving the "MyTextVar" variable the initial value again and creating a new "GuidVar"
results in >;%1> and >;%2>';
    Text005: Label 'Using ClearAll results in an empty "MyTextVar" >;%1> and an undefined "GuidVar"';
begin
    MyTextVar : Text000;
    GuidVar := CreateGuid();
    Message(Text001,MyTextVar,GuidVar);
    Clear(MyTextVar);
    Message(Text002,MyTextVar,GuidVar);
    Clear(GuidVar);
    Message(Text003,GuidVar);
    MyTextVar := Text000;
    GuidVar := CreateGuid();
    Message(Text004,MyTextVar,GuidVar);
    ClearAll;
    Message(Text005,MyTextVar,GuidVar);
end;
```

The first message window displays the following:

Initially the variable "MyTextVar" contains: >;My Text> and "GuidVar" is defined as >;12345678-

1234-1234-1234-1234567890AB>

The second message window displays the following:

After using Clear(MyTextVar), the variable "MyTextVar" contains: >;> and GuidVar is still defined as >;12345678-1234-1234-1234-1234567890AB>

The third message window displays the following:

After using Clear(GuidVar) the variable "GuidVar" becomes undefined

The fourth message window displays the following:

Giving the "MyTextVar" variable the initial value again and creating a new "GuidVar" results in >;My Text> and >;87654321-4321-4321-4321-BA0987654321>

The fifth message window displays the following:

Using ClearAll results in an empty "MyTextVar" >;> and an undefined "GuidVar"

System.ClearAll Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Clears all internal variables (except REC variables), keys, and filters in the object and in any associated objects, such as reports, pages, codeunits, and so on that contain AL code.

Syntax

```
System.ClearAll()
```

NOTE

This method can be invoked without specifying the data type name.

Remarks

ClearAll works by calling the Clear Method repeatedly on each variable. However, this is not the case with codeunits, where the ClearAll method works by calling ClearAll inside the codeunit. It deletes the contents of the codeunit, whereas Clear only deletes the reference to the codeunit.

ClearAll does not affect or change values for variables in single instance codeunits.

When a method is called repeatedly in the same transaction, the system retains all values for variables and filters in memory between calls. For example, this is used to assign numbers to entry numbers when posting. When you do not want to retain the values in memory, use the ClearAll method to clear them.

For information about the initial values of cleared variables, see the Clear Method. Take into consideration that fields in a record will be initialized with the InitValue Property of the field.

System.ClearLastError Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Removes the last error message from memory.

Syntax

```
System.ClearLastError()
```

NOTE

This method can be invoked without specifying the data type name.

Remarks

You can use the GetLastErrorText Method to determine whether an error has occurred and to see the text in the last error message that was generated. You can then use the ClearLastError method to remove the last error message from memory. If you subsequently call the GetLastErrorText Method, an empty string is returned.

System.ClosingDate Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Gets the closing date for a Date Data Type.

Syntax

```
ClosingDate :=   System.ClosingDate(Date: Date)
```

> **NOTE**
> This method can be invoked without specifying the data type name.

Parameters

Date
Type: Date
The input date.

Return Value

ClosingDate Type: Date

Remarks

All dates have a corresponding closing date. A closing date is a period in time following the given date but before the next regular date. Closing dates are sorted immediately after the corresponding regular date but before the next regular date.

xxxxxxD: Regular date

xxxxxxC: Closing date

The compiler cannot convert the expression xxxxxxC to a Date data type. Therefore, you must use the ClosingDate method to create a closing date.

Example 1

The first example shows how to use the ClosingDate method. A regular date is given as input.

```
var
    Date1: Date;
    CloDate: Date;
    Text000: Label 'The closing date for %1 is %2.';
begin
    Date1 := 20140404D;
    CloDate := ClosingDate(Date1);
    Message(Text000, Date1, CloDate);
end;
```

The following message is displayed:

The closing date for 04/04/14 is C04/04/14.

Example 2

The second example shows some statements that do not work and explains why they do not work.

```
var
    Date1: Date;
    CloDate1: Date;
    CloDate2: Date;
    Text000: Label 'The closing date for %1 is %2.';
begin
    // Date1 := 20140404C;
    // The previous statement does not compile because the compiler
    // cannot convert '20140404C' to a Date data type.
    Date1 := 20140404D;
    // The previous statement compiles.
    // The compiler converts '20140404D' to a Date data type.
    // CloDate1 := ClosingDate(20140505C);
    // The previous statement does not compile because the compiler
    // cannot convert '20140505C' to a Date data type and the ClosingDate
    // method requires a Date data type for its parameter.
    CloDate1 := ClosingDate(Date1);
    // The previous statement compiles.
    // Date1 is a Date data type.
    CloDate2 := ClosingDate(CloDate1);
    // The previous statement compiles.
    // CloDate1 is a Date data type.
    Message(Text001, CloDate1, CloDate2);
end;
```

The following message is displayed:

The closing date for C04/04/14 is C04/04/14.

System.CodeCoverageLog Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Starts and stops the logging of code. You can also use this method to retrieve the current logging status.

Syntax

```
[IsActive := ]  System.CodeCoverageLog([NewIsActive: Boolean] [, MultiSession: Boolean])
```

NOTE

This method can be invoked without specifying the data type name.

Parameters

NewIsActive

Type: Boolean

true starts code logging;**false** stops code logging.

MultiSession

Type: Boolean

Return Value

IsActive Type: Boolean **true** is code logging is active;**false** otherwise.

System.CompressArray Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Moves all non-empty strings (text) in an array to the beginning of the array. The resulting StringArray has the same number of elements as the input array, but empty entries appear at the end of the array.

Syntax

```
[Count := ]  System.CompressArray(StringArray: Array of [String])
```

> **NOTE**
> This method can be invoked without specifying the data type name.

Parameters

StringArray
Type: String
The string array that you want to compress.

Return Value

Count Type: Integer

Remarks

When compressing an array of strings, the non-empty strings in the resulting array are sorted just like in the original array.

The **CompressArray** method is useful for printing names and addresses. For instance, you can use this method to remove blank lines in account statements.

This method compresses an array of Text or Code, but not BigText. The compression is performed by moving empty strings to the end of the array.

For example, "Redmond", "Copenhagen", "", "Fargo", "Paris" is changed to "Redmond", "Copenhagen", "Fargo", "Paris", "".

In Dynamics 365 Business Central, it is not supported to use the **CompressArray** method on multidimensional arrays. In earlier versions, **CompressArray** works for arrays of arrays.

Example

This example shows how to use the **CompressArray** method. The input array has the following values: Joe Raybon, One Meca Way, Atlanta.

The output StringArray has the following values: Joe Raybon, One Meca Way, Atlanta.

All non-empty entries have been moved to the beginning of the array.

```
var
    CustomerData: array[6] of Text;
begin
    CustomerData[1] := 'Joe Raybon';
    CustomerData[2] := ''; // Empty string.
    CustomerData[3] :='One Meca Way';
    CustomerData[4] := '  '; // A non-empty string that contains blanks.
    CustomerData[5] := 'Atlanta';
    CustomerData[6] := ''; // Empty string.
    Message('Before compression the address is: \%1\%2\%3\%4\%5\%6', CustomerData[1], CustomerData[2],
CustomerData[3], CustomerData[4], CustomerData[5], CustomerData[6]);
    CompressArray(CustomerData); // The empty lines (strings) are removed.
    Message('After compression the address is: \%1\%2\%3\%4\%5\%6', CustomerData[1], CustomerData[2],
CustomerData[3], CustomerData[4], CustomerData[5], CustomerData[6]);
end;
```

The first message window displays the following:

Before compression, the address is:

Joe Raybon

One Meca Way

Atlanta

The second message window displays the following:

After compression, the address is:

Joe Raybon

One Meca Way

Atlanta

All empty strings, which cause blank lines, are moved to the end of the array.

> **NOTE**
> Empty lines are not printed if they occur on the first or last line in a message window.

System.CopyArray Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Copies one or more elements in an array to a new array.

Syntax

```
System.CopyArray(NewArray: Array of [Any], Array: Array of [Any], Position: Integer [, Length: Integer])
```

> **NOTE**
> This method can be invoked without specifying the data type name.

Parameters

NewArray
Type: Any
The array to copy to; the destination array.

Array
Type: Any

Position
Type: Integer
The position of the first array element to copy.

Length
Type: Integer
The number of array elements to copy. If you do not specify Length, all array elements are copied from Position to the last element. Use the following equation to determine valid values. 1 =< LENGTH =< MAXLEN(ARRAY) - POSITION + 1

Remarks

You can only copy from one-dimensional arrays. Repeat the CopyArray method to copy two-dimensional and three-dimensional arrays.

You cannot copy an array if the data type of the array is a complex data type. For more information about complex data types, see AL Data Types.

Example 1

The following example assigns values to Array1 and copies values from Array1 to Array2. Array1 is an integer array with the Dimensions Property set to 10. It contains integers from 1 to 10. The example code copies the numbers 6, 7, 8, 9, and 10 to Array2, an integer array with the **Dimensions** property set to 5.

```
var
    Array1: array[10] of Integer;
    Array2: array[5] of Integer;
begin
    Array1[1] := 1;
    Array1[2] := 2;
    Array1[3] := 3;
    Array1[4] := 4;
    Array1[5] := 5;
    Array1[6] := 6;
    Array1[7] := 7;
    Array1[8] := 8;
    Array1[9] := 9;
    Array1[10] := 10;
    COPYARRAY(Array2,Array1,6,5);
end;
```

Example 2

If Array1 is an integer array with dimension 10, and it contains the numbers from 1 to 10, and Array2 is an integer array with dimension 5, then the following command causes a run-time error.

```
CopyArray(Array2,Array1,3);
```

The error occurs because the code attempts to copy eight elements from Array1 to Array2, and Array2 has room for only five elements.

Developing Extensions

System.CopyStream Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Copies the information that is contained in an InStream to an OutStream.

Syntax

```
[Ok := ]  System.CopyStream(OutStream: OutStream, InStream: InStream [, BytesToRead: Integer])
```

NOTE

This method can be invoked without specifying the data type name.

Parameters

OutStream

Type: OutStream

The OutStream object to which you will copy the information; the destination stream.

InStream

Type: InStream

The InStream object from which you want to copy; the source stream.

BytesToRead

Type: Integer

Return Value

Ok Type: Boolean **true** if the operation was successful; otherwise **false**. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

Example

```
var
    F1: File;
    F2: File;
    InS: InStream;
    OutS: OutStream;
begin
    F1.Open('c:\Test.txt');
    F1.CreateInStream(InS);
    F2.Create('c:\CopyTest.txt');
    F2.CreateOutStream(OutS);
    CopyStream(OutS,InS);
    F1.Close();
    F2.Close();
end;
```

System.CreateDateTime Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Creates a DateTime object from a date and a time.

Syntax

```
Datetime :=   System.CreateDateTime(Date: Date, Time: Time)
```

> **NOTE**
> This method can be invoked without specifying the data type name.

Parameters

Date

Type: Date

The date that you want to use to create a DateTime. You cannot use an undefined date to create a DateTime.

Time

Type: Time

The time that you want to use to create a DateTime. You cannot use an undefined time to create a DateTime.

Return Value

Datetime Type: DateTime

Example

```
var
    TestDate: Date;
    TestTime: Time;
    TestDateTime: DateTime;
begin
    TestDate := Today;
    TestTime := Time;
    TestDateTime := CreateDateTime(TestDate,TestTime);
    …
    TestDateTime := CreateDateTime(081111D,020000T);
    …
    TestDateTime := CreateDateTime(010101D,0T);
end;
```

System.CreateEncryptionKey Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Creates an encryption key for the current tenant.

Syntax

```
[Ok := ]  System.CreateEncryptionKey()
```

> **NOTE**
> This method can be invoked without specifying the data type name.

Return Value

Ok Type: Boolean **true** if the operation was successful; otherwise **false**. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

Remarks

If a key already exists, the following error will be displayed: **Unable to create a new encryption key. An encryption key already exists**.

Example

This code example creates an encryption key for the current tenant. It uses the EncryptionEnabled method to perform a check.

```
if not EncryptionEnabled then
        CreateEncryptionKey();
```

System.CreateGuid Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Creates a new unique GUID. The value can then be assigned to a GUID data type or a text data type. Use the text data type if you want to compare the GUID to another text string.

Syntax

```
Guid :=   System.CreateGuid()
```

NOTE

This method can be invoked without specifying the data type name.

Return Value

Guid Type: Guid

See Also

System Data Type
Getting Started with AL
Developing Extensions

System.CurrentDateTime Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Gets the current DateTime.

Syntax

```
Datetime :=   System.CurrentDateTime()
```

NOTE

This method can be invoked using property access syntax.

NOTE

This method can be invoked without specifying the data type name.

Return Value

Datetime Type: DateTime

Example

This example requires that you create a DateTime variable named TestDateTime.

```
TestDateTime := CurrentDateTime;
Message(Format(TestDateTime));
```

The message window displays the current date and time.

System.Date2DMY Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Gets the day, month, or year of a Date Data Type.

Syntax

```
Number :=   System.Date2DMY(Date: Date, Value: Integer)
```

> **NOTE**
> This method can be invoked without specifying the data type name.

Parameters

Date

Type: Date

The input date.

Value

Type: Integer

Return Value

Number Type: Integer

Example

This example shows how to use the **Date2DMY** method.

```
var
    InputDate: Date;
    Day: Integer;
    Month: Integer;
    Year: Integer;
    Text000: Label 'Today is day %1 of month %2 of the year %3.';
begin
    InputDate := Today;
    Day := Date2DMY(InputDate,1);
    Month := Date2DMY(InputDate,2);
    Year := Date2DMY(InputDate,3);
    Message(Text000,Day,Month,Year);
end;
```

The message window displays the following:

Today is day 16 of month 2 of the year 2014.

See Also

System.Date2DWY Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Gets the day of the week, week number, or year of a Date Data Type.

Syntax

```
Number :=   System.Date2DWY(Date: Date, Value: Integer)
```

> **NOTE**
> This method can be invoked without specifying the data type name.

Parameters

Date

Type: Date

The input date.

Value

Type: Integer

Specifies what the function returns. The valid options are 1, 2, and 3.

- The value 1 corresponds to day of the week (1-7, Monday = 1).
- The value 2 corresponds to week number (1-53).
- The value 3 corresponds to year.

Return Value

Number Type: Integer The resulting day of the week, week number, or year.

Remarks

When the input date to the **Date2DWY** method is in a week that spans two years, the **Date2DWY** method computes the output year as the year that has the most days. For example, the input date is 010114. This date is in a week that starts on Monday, December 29, 2013, and ends Sunday, January 4, 2014. The week has three days in 2008 and four days in 2014. So the output year is 2014.

> **IMPORTANT**
> Date2DWY always uses the **ISO week-numbering year** scheme for the week, regardless of the server or device configuration. This means that week 01 of a year is the week that includes the first Thursday of the Gregorian year. Or in other words, the week that includes 4 January.

Example

This example shows a special case that occurs when you use the **Date2DWY** method in a week that spans two years.

```
var
    InputDate: Date;
    DayOfWeek: Integer;
    WeekNumber: Integer;
    Year: Integer;
    Text000: Label 'The date %1 corresponds to:\\';
    Text001: Label 'The day of the week: %2\\';
    Text002: Label 'The week number: %3\\';
    Text003: Label 'The year: %4';
begin
    InputDate := 20140101D;
    DayOfWeek := Date2DWY(InputDate, 1);
    WeekNumber := Date2DWY(InputDate, 2);
    Year := Date2DWY(InputDate, 3);
    Message(Text000 + Text001 + Text002 + Text003, InputDate, DayOfWeek, WeekNumber, Year);
end;
```

The message window displays the following information:

The date 01/01/14 corresponds to:

The day of the week: 4

The week number: 1

The year: 2014

This example shows that the date 01/01/14 is regarded as day number 4 (Thursday) in week number 1 in the year 2014.

System.Decrypt Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Takes a string as input and returns the decrypted value of the string.

Syntax

```
PlainTextString :=   System.Decrypt(EncryptedString: String)
```

> **NOTE**
> This method can be invoked without specifying the data type name.

Parameters

EncryptedString
Type: String
The input string that will be decrypted.

Return Value

PlainTextString Type: String The output string that is decrypted.

Remarks

If encryption is not enabled or the encryption key does not exist, the following error will be displayed: **An encryption key is required to complete the request**. If decryption failed because input data could not be decrypted, the following error will be displayed: **Unable to decrypt data. The data was encrypted using a different key**.

Example

This code example checks whether the tenant is configured to allow encryption using the EncryptionEnabled method, and then it decrypts an encrypted text string.

This example requires that you create the following text constants: EncryptedText and PlainText.

```
if not EncryptionEnabled then
        Error('Encryption has not been enabled.');
      PlainText := Decrypt(EncryptedText);
```

System.DeleteEncryptionKey Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Deletes an encryption key for the current tenant.

Syntax

```
System.DeleteEncryptionKey()
```

> **NOTE**
> This method can be invoked without specifying the data type name.

Example

This code example checks if encryption is configured for the tenant using the EncryptionEnabled method and if so, it performs the deletion of the encryption key.

```
if not EncryptionEnabled then
  Error('Encryption has not been enabled.');
  DeleteEncryptionKey();
```

System.DMY2Date Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Gets a Date object based on a day, month, and year.

Syntax

```
Date :=   System.DMY2Date(Day: Integer [, Month: Integer] [, Year: Integer])
```

> **NOTE**
> This method can be invoked without specifying the data type name.

Parameters

Day
Type: Integer
The number of the day in the month (1-31)

Month
Type: Integer
The number of the month in the year (1-12). If you omit this optional parameter, the current month will be used as the default.

Year
Type: Integer
The four-digit number of the year. If you omit this optional parameter, the current year is used as the default.

Return Value

Date Type: Date

Example

```
var
    Day: Integer;
    Month: Integer;
    Year: Integer;
    OutputDate: Date;
    Text000: Label "Day number %1, month number %2, and year number %3 corresponds to the date %4.";
begin
    Day := 17;
    Month := 2;
    Year := 2014;
    OutputDate := DMY2Date(Day, Month, Year);
    Message(Text000, Day, Month, Year, OutputDate);
end;
```

On a computer that has the regional format set to English (United States), the message window displays the following:

Day number 17, month number 2, and year number 2014 corresponds to the date 02/17/14.

System.DT2Date Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Gets the date part of a DateTime object.

Syntax

```
Date :=   System.DT2Date(Datetime: DateTime)
```

> **NOTE**
> This method can be invoked without specifying the data type name.

Parameters

Datetime
Type: DateTime
The DateTime of which to return the date part.

Return Value

Date Type: Date

Remarks

If *Datetime* is undefined, then this method returns an undefined date.

See Also

System Data Type

Developing Extensions

System.DT2Time Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Gets the time part of a DateTime object.

Syntax

```
Time :=   System.DT2Time(Datetime: DateTime)
```

> **NOTE**
> This method can be invoked without specifying the data type name.

Parameters

Datetime
Type: DateTime
The DateTime of which to return the time part.

Return Value

Time Type: Time

Remarks

If *Datetime* is undefined, then this method returns an undefined time.

System.DWY2Date Method

2/17/2021 • 3 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Gets a Date that is based on a week day, a week, and a year.

Syntax

```
Date :=   System.DWY2Date(WeekDay: Integer [, Week: Integer] [, Year: Integer])
```

> **NOTE**
> This method can be invoked without specifying the data type name.

Parameters

WeekDay
Type: Integer
The number of the day in the week (1-7). Monday is day number 1.

Week
Type: Integer
The number of the week. Week 1 is the first week of the year that has four or more days in the year. If you omit this optional parameter, the current week is used as the default.

Year
Type: Integer
The four-digit number of the year. If you omit this optional parameter, the year of the current week is used as the default.

Return Value

Date Type: Date

Remarks

A special situation occurs if the week (*Week*) that is input into DWY2Date spans two years. Depending on *Weekday*, the year of the output *Date* can differ from the input year. This scenario is shown in the following code example.

Example 1

The input week in this example spans two years.

```
var
    DayOfWeek: Integer;
    Week: Integer;
    Year: Integer;
    OutputDate: Date;
    Text000: Label"Day %1 of week %2 in the year %3 is the date %4.";
begin
    DayOfWeek := 1;
    Week := 1;
    Year := 2014;
    OutputDate := DWY2Date(DayOfWeek, Week, Year);
    Message(Text000, DayOfWeek, Week, Year, OutputDate);
end;
```

On a computer that has the regional format set to English (United States), the message window displays the following:

Day 1 of week 1 in the year 2014 is the date: 12/30/13.

The example shows that the first day of the week in the first week of the year 2014 is regarded as the date December 30, 2013. The first week of the year 2014 is the first week that has four or more days in the year 2014. That week starts on Monday, December 30, 2013, and ends on Sunday, January 5, 2014.

Example 2

The input week in this example spans two years.

```
var
    DayOfWeek: Integer;
    Week: Integer;
    Year: Integer;
    OutputDate: Date;
    Text000: Label"Day %1 of week %2 in the year %3 is the date %4.";
begin
    DayOfWeek := 1;
    Week := 1;
    Year := 2016;
    OutputDate := DWY2Date(DayOfWeek, Week, Year);
    Message(Text000, DayOfWeek, Week, Year, OutputDate);
end;
```

On a computer that has the regional format set to English (United States), the message window displays the following:

Day 1 of week 1 in the year 2016 is the date: 01/04/16.

The example shows that the first day of the week in the first week of the year 2016 is regarded as the date January 4, 2016. The first week of the year 2016 is the first week that has four or more days in the year 2016. That week starts on Monday, January 4, 2016, and ends on Sunday, January 11, 2015.

Example 3

This example shows how to use the DWY2Date method without specifying the optional *Year* parameter. The output in this example depends on the day on which you run the code.

```
var
    DayOfWeek: Integer;
    Week: Integer;
    OutputDate: Date;
    Text000: Label"Day %1 of week %2 is the date %3.";
begin
    DayOfWeek := 1;
    Week := 1;
    OutputDate := DWY2Date(DayOfWeek, Week);
    Message(Text000, DayOfWeek, Week, OutputDate);
end;
```

On a computer that has the regional format set to English (United States), if you ran the code on January 1, 2014, then the message window displays the following:

Day 1 of week 1 is the date: 12/30/13.

If you do not specify the year, then the year of the current week is used. On January 1, 2014, the current week is the week that starts on December 30, 2013 and ends on January 5, 2014. This week has four days in 2014 so the year of the current week is 2014. The first day of the first week of 2014 is 12/30/13.

On a computer that has the regional format set to English (United States), if you ran the code on January 1, 2016, then the message window displays the following:

Day 1 of week 1 is the date: 12/29/14.

On January 1, 2016, the current week is the week that starts on December 28, 2015 and ends on January 3, 2016. This week has four days in 2015 so the year of the current week is 2015. The first day of the first week of 2015 is 12/29/14.

System.Encrypt Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Takes a string as input and returns the encrypted value of the string.

Syntax

```
EncryptedString :=   System.Encrypt(PlainTextString: String)
```

> **NOTE**
> This method can be invoked without specifying the data type name.

Parameters

PlainTextString
Type: String
The input string that will be encrypted. The input string cannot exceed a length of 215 plain characters. If the input string includes special characters the length is even more reduced.

Return Value

EncryptedString Type: String The output string that is encrypted.

Remarks

If encryption is not enabled or the encryption key is not found, the following error will be displayed: **An encryption key is required to complete the request**.

Example

```
var
    Text000: Text;
begin
    Text000 := 'ABC123';
    Message('Value: ' + Text000);
    Text000 := Encrypt(Text000);
    Message('Value: ' + Text000);
end;
```

This code example takes the string value **ABC123** and outputs the encrypted value of the string. The encrypted value will vary from system to system due to differences in the encryption key.

System Data Type

System.EncryptionEnabled Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Checks if the tenant is configured to allow encryption.

Syntax

```
Ok :=   System.EncryptionEnabled()
```

> **NOTE**
> This method can be invoked without specifying the data type name.

Return Value

Ok Type: Boolean

Example

This code example checks if the tenant is configured for encryption.

```
if EncryptionEnabled then
        Message('Encryption has been enabled')
else
  Message('Encryption has not been enabled')
```

System.EncryptionKeyExists Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Checks whether an encryption key for the current tenant is present on the server tenant.

Syntax

```
Ok :=   System.EncryptionKeyExists()
```

> **NOTE**
> This method can be invoked without specifying the data type name.

Return Value

Ok Type: Boolean

Example

This code example performs checks to determine if an encryption key already exists.

```
if EncryptionEnabled then
        if EncryptionKeyExists then
          Message('Encryption has been enabled and the encryption key is present in this server instance')
        else
          Message('Encryption has been enabled but the encryption key is not present on this server
instance')
else
  Message('Encryption has not been enabled');
```

System.Evaluate Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Evaluates a string representation of a value into its typical representation. The result is assigned to a variable.

Syntax

```
[Ok := ]  System.Evaluate(var Variable: Any, String: String [, Number: Integer])
```

> **NOTE**
> This method can be invoked without specifying the data type name.

Parameters

Variable
Type: Any
The value of the string is assigned to the variable.

String
Type: String
A string that contains a value of any simple AL data type.

Number
Type: Integer
This optional value can be used when exporting data with an XmlPort. The only valid value is 9, which indicates that the data must be converted from XML format to C/SIDE format.

Return Value

Ok Type: Boolean **true** if the operation was successful; otherwise **false**. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

Example

This example shows how to use the **Evaluate** method when it is called with four different types of variables.

```
var
    VarInteger: Integer;
    VarDate: Date;
    VarYesNo: Boolean;
    VarDuration: Duration;
    Value: Text;
    Ok1: Boolean;
    Ok2: Boolean;
    Ok3: Boolean;
    Ok4: Boolean;
    Text000: Label 'VarInteger = \#1\#\#\#\#\#. The return code is: %2.\\';
    Text001: Label 'VarDate = \#3\#\#\#\#\#. The return code is: %4.\\';
    Text002: Label 'VarYesNo = \#5\#\#\#\#\#. The return code is: %6.\\';
    Text003: Label 'VarDuration = %7. The return code is: %8.';
begin
    Value := '19960101';
    Ok1 := Evaluate(VarInteger, Value);
    Ok2 := Evaluate(VarDate, Value);
    Ok3 := Evaluate(VarYesNo, Value);
    Value := '2days 4hours 3.7 seconds 17 milliseconds';
    Ok4 := Evaluate(VarDuration, Value);
    Message(Text000 + Text001 + Text002 + Text003, VarInteger, Ok1, VarDate, Ok2, VarYesNo, Ok3,
VarDuration, Ok4);
end;
```

The message window displays the following:

VarInteger = 10196 . The return code is: Yes.

VarDate = 01/01/96. The return code is: Yes.

VarYesNo = No . The return code is: No.

VarDuration = 2 days 4 hours 3 seconds 717 milliseconds. The return code is: Yes.

This example shows that although Value ('010196') can be interpreted as both an integer and a date expression, it cannot be interpreted as a Boolean expression. This causes an error, shown in the return code Ok3 (=False).

This example also shows that when you evaluate a string as a duration data type, you can use certain words in the string to describe the duration. The following words or abbreviations are supported:

- day, days, d
- hour, hours, h
- minute, minutes, min, m
- second, seconds, sec, s
- millisecond, milliseconds, milli, millis

You can include decimal values in the string that you evaluate as a duration, except for milliseconds, which must be a whole number.

System.ExportEncryptionKey Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Returns a password protected temporary filepath containing the encryption key. When encrypting or decrypting data in Dynamics 365 Business Central, an encryption key is used. A single key is used per tenant and every tenant will have a different key. Keys can be exported to a file which may be necessary in the case of upgrading or migrating a system from one set of hardware to another. The EXPORTEncryptIONKey method allows an administrator to specify a destination file for the key and specify a password protection for the file.

> **NOTE**
> This method is supported only in Business Central on-premises.

Syntax

```
Path :=   System.ExportEncryptionKey(Password: String)
```

> **NOTE**
> This method can be invoked without specifying the data type name.

Parameters

Password
Type: String
Specifies the password for the encryption key file.

Return Value

Path Type: String A temporary filepath to where the key is exported.

Remarks

> **NOTE**
> This applies only to on-premises versions of Business Central. For online versions, encryption is always enabled and you cannot turn it off.

If encryption is not enabled or the encryption key is not found, the following error will be displayed: **An encryption key is required to complete the request**.

Example

This code example uses the ExportEncryptionKey method to return a password protected file that contains an

encryption key. With the Download method the file is sent from the Dynamics 365 Business Central service computer to the client computer.

This example requires that you create the following text constants: ExportFileName and ClientFileName.

```
if not EncryptionEnabled then
    Error('Encryption has not been enabled.');
    ExportFileName := ExportEncryptionKey('This is my personal secret');

    ClientFileName := 'ExportedKey.ekey';
    Download(ExportFileName,'Save the encrypted key file','','Encrypted Key File
(*.ekey)|*.ekey',ClientFileName);

    Erase(ExportFileName);
```

System.ExportObjects Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0 until version 1.0 where it was deprecated.*

Exports application objects to a file.

> **NOTE**
> This method is supported only in Business Central on-premises.

Syntax

```
System.ExportObjects(FileName: String, var ObjectRecord: Record [, Format: Integer])
```

> **NOTE**
> This method can be invoked without specifying the data type name.

Parameters

FileName
Type: String
The path of the file to export to.

ObjectRecord
Type: Record
A record to the Object table.

Format
Type: Integer
The format to use when exporting.

See Also

System Data Type

Developing Extensions

System.Format Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Formats a value into a string.

Syntax

```
String :=   System.Format(Value: Any [, Length: Integer] [, FormatNumber: Integer])
```

NOTE

This method can be invoked without specifying the data type name.

Parameters

Value

Type: Any

This is an AL variable (expression) of any simple data type, such as Option, Integer, BigInteger, Decimal, Char, Text, Code, Date, Time, DateTime, Boolean, or GUID. If, when the system formats Value, the result is a value larger than the maximum length MaxStrLen method (Code, Text) of String, a run-time error occurs.

Length

Type: Integer

This optional parameter specifies the length of String.

FormatNumber

Type: Integer

This optional parameter specifies the format that you want to use.

Return Value

String Type: String

See Also

System Data Type
Getting Started with AL
Developing Extensions

System.Format Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Formats a value into a string.

Syntax

```
String :=   System.Format(Value: Any, Length: Integer, FormatString: String)
```

NOTE

This method can be invoked without specifying the data type name.

Parameters

Value

Type: Any

This is an AL variable (expression) of any simple data type, such as Option, Integer, BigInteger, Decimal, Char, Text, Code, Date, Time, DateTime, Boolean, or GUID. If, when the system formats Value, the result is a value larger than the maximum length MaxStrLen method (Code, Text) of String, a run-time error occurs.

Length

Type: Integer

This optional parameter specifies the length of String.

FormatString

Type: String

A literal string that defines a format as in the Format Property.

Return Value

String Type: String

Remarks

For the *Length* parameter, the following rules apply:

- If *Length* = 0 then the entire value is returned (default).
- If *Length* > 0 then the returned string will be exactly *Length* characters.

  If *Value* is less than *Length* characters, then either leading or trailing spaces are inserted, depending on the format that you select.

  If *Value* exceeds *Length* characters, then *String* is truncated to *Length* characters.
- If *Length* < 0 then the returned string will not have leading or trailing spaces.

  If *Value* is less than *Length* characters, the length of *String* will equal the length of *Value*.

If *Value* exceeds *Length* characters, then *String* is truncated to *Length* characters.

For the *Format* parameter, see Format Property for more information.

The *FormatNumber* parameter specifies the format that you want to use. The basic options for the Decimal data type are as follows:

- <*Sign*><*Integer Thousand*><*Decimals*> is Format 0
- <*Sign*><*Integer*><*Decimals*> is Format 1
- <*Sign*><*Integer*><*Decimals*><*Comma,.*> is Format 2
- <*Integer Thousand*><*Decimals*><*Sign,1*> is Format 3
- <*Integer*><*Decimals*><*Sign,1*> is Format 4

> **NOTE**
> You cannot use both *FormatNumber* and *FormatStr* at the same time.

Example 1

```
var
    Text000: Label 'The formatted value >%1<';
begin
    Message(Text000, Format(-123456.78, 12, 3));
    Message(Text000, Format(-123456.78, 12, '<Standard Format,3>'));
    Message(Text000, Format(-123456.78, 12, '<Integer Thousand><Decimals><Sign,1>'));
end;
```

The Regional and Language settings on the computer on which you run the code affect how the string is displayed. For example, on a computer that has the regional format set to English (United States), the message window displays the following:

The formatted value: > 123,456.78-<

The formatted value: > 123,456.78-<

The formatted value: > 123,456.78-<

On a computer that has the regional format set to Danish (Denmark), the message window displays the following:

The formatted value: > 123.456,78-<

The formatted value: > 123.456,78-<

The formatted value: > 123.456,78-<

Example 2

This example shows how to use a string to build a format.

```
var
    Text000: Label 'Today is %1';
begin
    Message(Text000, Format(Today,0,'<Month Text> <Day>'));
end;
```

The message window displays the following:

Today is April 15.

System.GetDocumentUrl Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Gets the URL for the specified temporary media object ID.

> **NOTE**
> This method is supported only in Business Central on-premises.

Syntax

```
Url :=   System.GetDocumentUrl(ID: Guid)
```

> **NOTE**
> This method can be invoked without specifying the data type name.

Parameters

ID

Type: Guid

The temporary media object ID.

Return Value

Url Type: String The URL for the specified temporary media object ID.

System.GetDotNetType Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 2.0.*

Gets the System.Type that corresponds to the given value.

> **NOTE**
> This method is supported only in Business Central on-premises.

Syntax

```
Type :=   System.GetDotNetType(Expression: Any)
```

> **NOTE**
> This method can be invoked without specifying the data type name.

Parameters

Expression
Type: Any
The value for which to retrieve the System.Type.

Return Value

Type Type: DotNet

See Also

System Data Type
Getting Started with AL
Developing Extensions

System.GetLastErrorCallStack Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Gets the call stack from where the last error occurred.

Syntax

```
String :=   System.GetLastErrorCallStack()
```

NOTE

This method can be invoked using property access syntax.

NOTE

This method can be invoked without specifying the data type name.

Return Value

String Type: String

Remarks

For some errors, such as divide by zero errors and overflow errors, **GetLastErrorCallStack** does not return every call in the stack. To get the complete call stack for these types of errors, use the debugger and specify that you want to break on errors. On the **Debugger** page, in the **Call Stack** FactBox, you can view all the method calls that led to the error.

Example

In this example, an error occurs in codeunit 50003. The text of the Message includes a call to the GetLastErrorCallStack method.

```
// Codeunit 50001, TestErrors1
// OnRun trigger
Error('Some error message')

// Codeunit 50002, TestErrors2
// OnRun trigger
ClearLastError;
if not Codeunit.Run(50001) then
  Message('The call stack for the last error is:\' + GetLastErrorCallStack);
```

When you run codeunit 50002, the message window displays the following:

The call stack for the last error is:

TestErrors1(CodeUnit 50001).OnRun(Trigger) line 1

TestErrors2(CodeUnit 50002).OnRun(Trigger) line 2

See Also

System.GetLastErrorCode Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Gets the classification of the last error that occurred.

Syntax

```
String :=   System.GetLastErrorCode()
```

NOTE

This method can be invoked using property access syntax.

NOTE

This method can be invoked without specifying the data type name.

Return Value

String Type: String

Remarks

You use the GetLastErrorCode method to identify the type of the last error that occurred. You use the GetLastErrorText Method to get the details of the last error.

The result of the GetLastErrorCode method is not translated into the local language. The result of the GetLastErrorText Method is translated into the local language.

Example

This example opens a file and then causes an error to occur by trying to open the file again. If the code for the error that occurred is not the expected error code, then an error message is displayed.

```
var
    ErrorCode: Text[1024];
    ExpectedErrorCode: Text[1024];
    FileObj1: File;
    FileObj2: File;
    Text0001: Label 'The error code is not valid. Expected: %1. Actual: %2. Error message: %3';
begin
    ExpectedErrorCode := 'StreamIO';
    FileObj1.CreateTempFile;
    AssertError FileObj2.Create(FileObj1.Name);
    ErrorCode := GetLastErrorCode;
    if ErrorCode <> ExpectedErrorCode then
      Error(Text001, ExpectedErrorCode, ErrorCode, GetLastErrorText);
end;
```

System.GetLastErrorObject Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 2.0.*

Gets the last System.Exception object that occurred.

> **NOTE**
> This method is supported only in Business Central on-premises.

Syntax

```
DotNet :=   System.GetLastErrorObject()
```

> **NOTE**
> This method can be invoked without specifying the data type name.

Return Value

DotNet Type: DotNet

Remarks

You use this method to retrieve and handle the last exception that occurred in the application. The System.Exception object exposes several members that enable you to get detailed information about the exception, such Exception.InnerException and Exception.Message.

Example

This example uses the GetLastErrorObject method to get an exception object that occurs. In this example, the Microsoft .NET Framework objects are executed by MyCodeunit. The AL code uses the InnerException property of the System.Exception object to identify whether the inner exception has the type WebException and returns an exception message accordingly.

```
var
    MyCodeunit: Codeunit MyCodeunit;
    Exception: DotNet "'System, Version=4.0.0.0, Culture=neutral,
PublicKeyToken=b77a5c561934e089'.System.Net.WebException";
    WebException: DotNet "'mscorlib, Version=4.0.0.0, Culture=neutral,
PublicKeyToken=b77a5c561934e089'.System.Exception";
begin
    if not MyCodeunit.Run then begin
        Exception := GetLastErrorObject;

        if not Exception.InnerException.GetType.Equals(WebException.GetType) then
            Error(Exception.Message);

        WebException := Exception.InnerException;
        Error(WebException.Message);
    end;
end;
```

System.GetLastErrorText Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Gets the last error that occurred in the debugger.

Syntax

```
String :=   System.GetLastErrorText()
```

NOTE

This method can be invoked using property access syntax.

NOTE

This method can be invoked without specifying the data type name.

Return Value

String Type: String

Remarks

If you call the GetLastErrorText method immediately after you call the ClearLastError method, then an empty string is returned.

The result of the GetLastErrorCode Method is not translated into the local language. The result of the GetLastErrorText method is translated into the local language.

Example

If you call the Codeunit.Run method to run a codeunit and an error occurs in the codeunit, then the error is displayed. However, if you also use the return value of the Codeunit.Run method, then the error is not displayed. In this case, you can use the GetLastErrorText method to determine whether an error has occurred and to see the text of the last error message that was generated. This example shows how to use the GetLastErrorText method. This example requires that you create two codeunits. Codeunit 50001 generates an error. Codeunit 50002 runs codeunit 50001 and if an error occurs, then it displays the text of the error.

```
// Codeunit 50001
// OnRun trigger
Error('Some error message.');

// Codeunit 50002
// OnRun trigger
ClearLastError();
if not Codeunit.Run(50001) then
  Message('The last error was: ' + GetLastErrorText);
```

In this example, because the if statement uses the return value of the Codeunit.Run method, the error from codeunit 50001 is not displayed. Instead, you use the GetLastErrorText method to display the error.

When you run codeunit 50002, the message window displays the following:

The last error was: Some error message.

System.GetUrl Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Generates a URL for the specified client target that is based on the configuration of the server instance. If the code runs in a multitenant deployment architecture, the generated URL will automatically apply to the tenant ID of the current user.

Syntax

```
String :=   System.GetUrl(ClientType: ClientType [, Company: String] [, ObjectType: ObjectType] [, ObjectId:
Integer] [, Record: Record] [, UseFilters: Boolean])
```

NOTE

This method can be invoked without specifying the data type name.

Parameters

ClientType

Type: ClientType

Specifies the client that you want to generate the URL for. If you want to generate a URL that depends on the client that the user is accessing the URL from, choose Current. A runtime error occurs if the ClientType is set to SOAP or OData but the specified object type and ID has not been published as a web service.

Company

Type: String

Specifies the company that the URL must contain. If you do not specify a company, the URL will run in the user's current company.

ObjectType

Type: ObjectType

Value: Table, Page, Report, Codeunit, Query, or XmlPort. Specifies the object type that the URL must open. If you specify an object type, you must also specify an object ID in the ObjectId parameter. Otherwise, the user will see a runtime error. If you set the ObjectType parameter to Page, you can also specify a record variable in the Record parameter.

ObjectId

Type: Integer

Specifies the ID of the specified object type that the URL must open.

Record

Type: Record

Specifies the Record variable that specifies which record to open.

UseFilters

Type: Boolean

Specifies whether to include filters that are defined on the object as a text string in the URL.

Return Value

String Type: String

System.GetUrl Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Generates a URL for the specified client target that is based on the configuration of the server instance. If the code runs in a multitenant deployment architecture, the generated URL will automatically apply to the tenant ID of the current user.

Syntax

```
String :=   System.GetUrl(ClientType: ClientType, Company: String, ObjectType: ObjectType, ObjectId:
Integer, RecordRef: RecordRef [, UseFilters: Boolean])
```

NOTE

This method can be invoked without specifying the data type name.

Parameters

ClientType

Type: ClientType

Specifies the client that you want to generate the URL for. This parameter is required. If you want to generate a URL that depends on the client that the user is accessing the URL from, choose Current. The following table describes the options.> A runtime error occurs if the ClientType is set to SOAP or OData but the specified object type and ID has not been published as a web service.

Company

Type: String

Specifies the company that the URL must contain. If you do not specify a company, the URL will run in the user's current company.

ObjectType

Type: ObjectType

Value: Table, Page, Report, Codeunit, Query, or XmlPort. Specifies the object type that the URL must open. If you specify an object type, you must also specify an object ID in the ObjectId parameter. Otherwise, the user will see a runtime error. If you set the ObjectType parameter to Page, you can also specify a record variable in the Record parameter.

ObjectId

Type: Integer

Specifies the ID of the specified object type that the URL must open.

RecordRef

Type: RecordRef

Specifies the RecordRef variable that specifies which record to open.

UseFilters

Type: Boolean

Specifies whether to include filters that are defined on the object as a text string in the URL.

Return Value

String Type: String

System.GlobalLanguage Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Gets and sets the current global language setting.

Syntax

```
[LanguageID := ]  System.GlobalLanguage([NewLanguageID: Integer])
```

NOTE

This method can be invoked using property access syntax.

NOTE

This method can be invoked without specifying the data type name.

Parameters

NewLanguageID

Type: Integer

The Microsoft language ID (LCID), such as 1033 for English (US).

Return Value

LanguageID Type: Integer The Microsoft language ID (LCID).

Remarks

The LanguageID is a standard Windows language ID. The Windows Language virtual table contains a list of these IDs and the corresponding names and short names.

For more information, see Multilanguage Development.

System.GuiAllowed Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Checks whether the AL code can show any information on the screen.

Syntax

```
Ok :=   System.GuiAllowed()
```

NOTE

This method can be invoked using property access syntax.

NOTE

This method can be invoked without specifying the data type name.

Return Value

Ok Type: Boolean

Remarks

User Portal Application Server accepts GuiAllowed.

Example

This example shows how to use the GuiAllowed method.

```
var
    Text000: Label 'Code is running on a client.';
begin
    if GuiAllowed then
     Message(Text000);
end;
```

If the code runs on a client, which means that the user interface is available, a message box will appear with the following message.

Code is running on a client

If the code runs on Microsoft Dynamics NAV Application Server, then the message will not be displayed.

NOTE

If the Message Method (Dialog) or the Error Method (Dialog) is called when the code is running on Microsoft Dynamics NAV Application Server, then the message is written to the event log of the operating system.

System.Hyperlink Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Passes a URL as an argument to an Internet browser, such as Windows Internet Explorer.

Syntax

```
System.Hyperlink(URL: String)
```

> **NOTE**
> This method can be invoked without specifying the data type name.

Parameters

URL
Type: String
A URL that is passed to the Internet browser as an argument.

Remarks

The syntax must be a valid URL, such as *https://www.microsoft.com*, or path to a file on file share, such as *file://d$/myfiles/myfile.txt*. If you want the URL to be configurable, you can get the URL from a field or a variable instead. If you pass an empty string, then no browser window is opened.

At runtime, a new tab is opened in the same browser window where Dynamics 365 Business Central is running.

The `HyperLink` method works with different protocols and file types as along as the syntax is valid.

> **NOTE**
> When using the *file://* protocol to open a file, the file should be stored on a network file share, not locally; otherwise the file will not open. Browsers block hyperlinks to files from a web page for security reasons and the hyperlink must be manually copied and pasted into a manually opened tab page.

The HyperLink method does not work on NAS services.

Example

The following example shows two uses of the HyperLink method to open the specified URL in the default browser. In the first line of code, the URL is specified in code. The second line of code illustrates how you can get a URL that is stored in a field on the current table.

```
HyperLink('https://www.microsoft.com');
...
HyperLink(Rec.UrlField);
```

System.ImportEncryptionKey Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Points to a password protected file that contains the key on the current server. When encrypting or decrypting data in Dynamics 365 Business Central, an encryption key is used. A single key is used per tenant, and every tenant will have a different key. Keys can be created or imported if one exists already, as may be the case if upgrading or migrating a system from one set of hardware to another. The IMPORTEncryptIONKey method allows an administrator to specify a file (password protected) which contains a key and imports it to the current Dynamics 365 Business Central service.

> **NOTE**
> This method is supported only in Business Central on-premises.

Syntax

```
[Ok := ]  System.ImportEncryptionKey(Path: String, Password: String)
```

> **NOTE**
> This method can be invoked without specifying the data type name.

Parameters

Path
Type: String
Specifies the file that contains the encryption key.
Password
Type: String
Specifies the password the protects the file.

Return Value

Ok Type: Boolean **true** if the operation was successful; otherwise **false**. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

Remarks

If the import key file cannot be imported, the following error will be displayed: **Import Failed. The provided encryption key file contains invalid data and could not be imported**.

Example

This code example uses the EncryptionEnabled and EncryptionExists methods to do a check before importing the encryption key.

This example requires that you create a text constant ServerFileName.

```
if EncryptionEnabled then
        if EncryptionExists then
          if not Confirm('Encryption has been enabled and the server already contains an encryption key.\'
          + 'Importing a key will overwrite any existing key and may result in lost data.\\'
          + 'Do you wish to continue?') then
            exit
       else
          if not Confirm('Importing a key different from the already configured key will result in data
corruption.\\'
          + 'Do you wish to continue?') then
            exit

      if not Upload('Upload encrypted key','','Encrypted Key File
(*.ekey)|*.ekey','ExportedKey.ekey',ServerFileName) then
        Exit;

      ImportEncryptionKey(ServerFileName,'This is my personal secret');
      Erase(ServerFileName);
```

System.ImportObjects Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0 until version 1.0 where it was deprecated.*

Imports application objects from a file.

> **NOTE**
> This method is supported only in Business Central on-premises.

Syntax

```
System.ImportObjects(FileName: String [, Format: Integer])
```

> **NOTE**
> This method can be invoked without specifying the data type name.

Parameters

FileName

Type: String

The path of the file from which the objects will be imported.

Format

Type: Integer

The format in which the objects are represented in the file.

System.ImportStreamWithUrlAccess Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Imports an object into a media container to be used in a temporary URL with a default expiration time.

> **NOTE**
> This method is supported only in Business Central on-premises.

Syntax

```
ID :=   System.ImportStreamWithUrlAccess(InStream: InStream, Filename: String [, MinutesToExpire: Integer])
```

> **NOTE**
> This method can be invoked without specifying the data type name.

Parameters

InStream
Type: InStream
Input stream that contains the object to store as a media object.

Filename
Type: String
File name to associate with the created media object.

MinutesToExpire
Type: Integer
Number of minutes after which the object will expire.

Return Value

ID Type: Guid The ID of the media container, if the import is successful.

System.IsNull Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 2.0.*

Gets a value indicating whether a DotNet object has been created or not.

> **NOTE**
> This method is supported only in Business Central on-premises.

Syntax

```
Ok :=   System.IsNull(DotNet: DotNet)
```

> **NOTE**
> This method can be invoked without specifying the data type name.

Parameters

DotNet
Type: DotNet
A DotNet expression.

Return Value

Ok Type: Boolean **True** if the DotNet object is NULL, otherwise **false**.

Getting Started with AL
Developing Extensions

System.IsNullGuid Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Indicates whether a value has been assigned to a GUID. A null GUID that consists only of zeros is valid but must never be used for references.

Syntax

```
Ok :=   System.IsNullGuid(Guid: Guid)
```

NOTE

This method can be invoked without specifying the data type name.

Parameters

Guid

Type: Guid

The GUID that you want to check whether it is null.

Return Value

Ok Type: Boolean

Remarks

The Guid data type is useful when you want to uniquely identify data so that it can be exchanged with external applications. For example, if you want to transfer an item catalog to an external application, you add a Guid field to the record in the table and use it as the primary reference when you communicate with the external application. A Guid is a 16-byte binary data type that can be logically grouped into the following subgroups: 4byte-2byte-2byte-2byte-6byte.

Example

The following example initializes two variables named validGuid and nullGuid. The validGuid variable is assigned a valid Guid value, and the nullGuid variable is assigned a null GUID that consists of only zeros. The IsNullGuid method determines whether the Guid that is contained in the *validGuid* parameter is null. In this case, the Guid is not null so a message that states that the Guid is not null is displayed and the value is displayed. The method then checks the *nullGuid* parameter. This time, a message that states that the Guid is null is displayed because the Guid is a null Guid that consists of only zeros.

```
var
    validGuid: Guid;
    nullGuid: Guid;
    Text000: Label 'The Guid is null';
    Text0001: Label 'The Guid is not null.\\';
    Text0002: Label 'The value is %1.';
begin
    validGuid := '{FC841BE6-0ADA-46C4-A6A9-142AEC211613}';
    nullGuid  := '{00000000-0000-0000-0000-000000000000}';
    if IsNullGuid(validGuid) then
      Message(Text000)
    else
      Message(Text001 + Text002, validGuid);
    if IsNullGuid(nullGuid) then
      Message(Text000);
end;
```

System.IsServiceTier Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0 until version 1.0 where it was deprecated.*

Gets a value indicating whether the runtime is a service tier.

Syntax

```
Ok :=   System.IsServiceTier()
```

NOTE

This method can be invoked using property access syntax.

NOTE

This method can be invoked without specifying the data type name.

Return Value

Ok Type: Boolean **True** if the runtime is a service tier, otherwise **false**.

See Also

System Data Type

Developing Extensions

System.NormalDate Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Gets the regular date (instead of the closing date) for the argument Date.

Syntax

```
NormalDate :=   System.NormalDate(Date: Date)
```

> **NOTE**
> This method can be invoked without specifying the data type name.

Parameters

Date

Type: Date

The input date. You can enter a closing date or a normal date. A run-time error occurs if the value of Date is set to the undefined date (0D).

Return Value

NormalDate Type: Date

Example 1

The input date is a regular date.

```
var
    InputDate: Date;
    OutputDate: Date;
    Text000: Label 'The normal date for %1 is %2.';
begin
    InputDate := 20140404D;
    OutputDate := NormalDate(InputDate);
    Message(Text000, InputDate, OutputDate);
end;
```

On a computer that has the regional format set to English (United States), the message window displays the following:

The normal date for 04/04/14 is 04/04/14.

Example 2

The input date is a closing date.

```
var
    InputDate: Date;
    OutputDate: Date;
    Text000: Label 'The normal date for %1 is %2.';
begin
    InputDate := ClosingDate(20140404C);
    OutputDate := NormalDate(InputDate);
    Message(Text001, InputDate, OutputDate);
end;
```

On a computer that has the regional format set to English (United States), the message window displays the following:

The normal date for C04/04/14 is 04/04/14.

System.Power Method

2/17/2021 • 3 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Raises a number to a power. For example, you can use this method to square the number 2 to get the result of 4.

Syntax

```
NewNumber :=   System.Power(Number: Decimal, Power: Decimal)
```

NOTE

This method can be invoked without specifying the data type name.

Parameters

Number

Type: Decimal

The number you want to raise exponentially. This number is the base in the exponential method.

Power

Type: Decimal

The exponent in the exponential method.

Return Value

NewNumber Type: Decimal

Example 1

```
var
    Number1: Decimal;
    Power1: Decimal;
    Result1: Decimal;
    Text000: Label '%1 raised to the power of %2 = %3';
begin
    Number1 := 64;
    Power1 := 0.5;
    Result1 := Power(Number1, Power1);
    Message(Text000, Number1, Power1, Result1);
end;
```

On a computer that has the regional format set to English (United States), the first message window displays the following:

64 raised to the power of 0.5 = 8

This example shows that raising a number to the power of 0.5 corresponds to the square root of the number.

Example 2

This example shows a typical use for the POWER method.

If a principal amount P is deposited at interest rate R and compounded annually, then at the end of N years, the accumulated amount (A) is:

$A = P(1 + R)^N$

For example, you put LCY 2800 into a bank account that pays 5 percent, which is compounded quarterly. To determine what the amount will be in eight years, you must consider:

N = 32 payment periods (8 years times 4 quarterly periods)

R = 0.0125 per period (5 percent divided by 4 quarterly periods)

The accumulated amount A is:

$A = LCY\ 2800(1 + 0.0125)^{32} = LCY\ 2800(1.4881) = LCY\ 4166.77$

If a principal amount P is deposited at the end of each year at interest rate R (in decimal notation) compounded annually, then at the end of N years, the accumulated amount is:

$A = P[((1 + R)^N - 1)/R]$

This is typically called an *annuity*.

For example, you have an annuity in which a payment of LCY 500 is made at the end of each year. The interest on this annuity is 4 percent, which is compounded annually. To determine what the annuity will be worth in 20 years, you must consider:

R = 0.04

N = 20

The amount of the annuity A will be:

$A = LCY\ 500[((1 + 0.04)^{20} - 1)/0.04 = LCY\ 14,889.04$

```
var
    P: Decimal;
    R: Decimal;
    N: Decimal;
    A: Decimal;
    FormatString: Text;
    Text000: Label 'Principal $%1 at a 5 percent interest rate is compounded quarterly.\\';
    Text001: Label '(Rate = %2)\\';
    Text002: Label 'The amount after %3 years = $%4.';
    Text003: Label 'Principal $%1 is deposited at the end of each year at a 4 percent interest rate,
compounded annually.\\';
    Text004: Label '(Rate = %2)\\';
    Text005: Label 'The amount after %3 years = $%4.';
begin
    FormatString := '<Precision,2><Standard Format,1>';
    // Example 1
    P := 2800;
    R := 0.0125;
    N := 32;
    A = P * (Power(1 + R, N));
    Message(Text000 + Text001 + Text002, P, R, N, Format(A,0,FormatString);
    // Example 2
    P = 500;
    R = 0.04;
    N = 20;
    A = P * ((Power(1 + R, N) - 1)/R);
    Message(Text001, P, R, N, Format(A,0,FormatString));
end;
```

On a computer that has the regional format set to English (United States), the first message window displays the following:

Principal $2,800 at a 5 percent interest rate is compounded quarterly.

(Rate = 0.0125)

The amount after 32 years = $4166.77.

The second message window displays the following:

Principal $500 is deposited at the end of each year at a 4 percent interest rate, compounded annually.

(Rate = 0.04)

The amount after 20 years = $14889.04.

System.Random Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Returns a pseudo-random number.

Syntax

```
Number :=   System.Random(MaxNumber: Integer)
```

NOTE

This method can be invoked without specifying the data type name.

Parameters

MaxNumber

Type: Integer

The largest acceptable number. In effect, you are setting a range from one (1) to the number that you specify with the MaxNumber parameter.

Return Value

Number Type: Integer

Remarks

If *MaxNumber* is negative it acts as a positive.

If *MaxNumber* is zero, this method always returns 1.

A number is always chosen from the same set of numbers. Use Randomize Method (Integer) to generate a new set of numbers.

Example

This example shows how to generate a pseudo-random number. The value of the variable Number2 is positive though the value of *MaxNumber* is negative and the value of the variable Number3 is always 1 because *MaxNumber* is 0.

```
var
    x: Integer;
    y: Integer;
    z: Integer;
    Number1: Integer;
    Number2: Integer;
    Number3: Integer;
    Text000: Label 'Number1 = %1, Number2 = %2, Number3 = %3';
begin
    x := 100; // x is assigned a positive value.
    y := -100; // y is assigned a negative value.
    z := 0; // z is assigned zero.
    Number1 := Random(x);
    Number2 := Random(y);
    Number3 := Random(z);
    Message(Text000, Number1, Number2, Number3);
end;
```

System.Randomize Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Generates a set of random numbers from which the RANDOM method (Integer) will select a random number.

Syntax

```
System.Randomize([Seed: Integer])
```

> **NOTE**
> This method can be invoked without specifying the data type name.

Parameters

Seed

Type: Integer

A number used to create a unique set of numbers.

Remarks

If you use the same number as *Seed*, the same set of numbers is generated. If you omit this optional parameter, **Randomize** uses the current system time (total number of milliseconds since midnight). Calling the **Randomize** method before the Random Method makes the random numbers more unpredictable.

Furthermore, the random generator is specific to each connection so the sequence of numbers that is returned when you call the Random Method will be the same after each call to **Randomize** with a specific seed.

Example

The following example generates random numbers between 1 and 5 by using the *Seed* from the **Randomize** method to initialize the random number generator in the Random Method. The **Randomize** method uses the data from system clock as the *Seed* value.

```
var
    x: Integer;
    Text000: Label 'X=%1';
begin
    Randomize();
    x := Random(5);
    Message(Text000, x);
end;
```

System.Round Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Rounds the value of a numeric variable.

Syntax

```
NewNumber :=   System.Round(Number: Decimal [, Precision: Decimal] [, Direction: String])
```

NOTE

This method can be invoked without specifying the data type name.

Parameters

Number

Type: Decimal

The number that you want to round.

Precision

Type: Decimal

This optional parameter determines the precision used when rounding. If you do not specify a Precision parameter, then the following steps are used to specify the precision:

1. The method ReadRounding in Codeunit 45, ReadRounding, is called. ReadRounding returns a decimal value that is the precision. By default, the ReadRounding method returns the Amount Rounding Precision field from the GLSetup table.
2. If you have customized Codeunit 45 and it does not implement the ReadRounding method, then the precision is specified as 2 digits after the decimal.

Direction

Type: String

This optional parameter specifies how to round the Number parameter. The default rounding method is '='. The following are the options for rounding:

- '=' rounds up or down to the nearest value (default). Values of 5 or greater are rounded up. Values less than 5 are rounded down.
- '>' rounds up
- '<' rounds down

Return Value

NewNumber Type: Decimal

Example

This example shows how to use the **Round** method.

```
var
    DecimalToRound: Decimal;
    Direction: Text;
    Precision: Decimal;
    Result: Decimal;
    Text00: Label 'Round(%1, %2, %3) returns %4.';
begin
    DecimalToRound := 1234.56789;
    Direction := '>';
    Precision := 0.001;
    Result := Round(DecimalToRound, Precision, Direction);
    Message(Text000, Format(DecimalToRound,0,1), Precision, Direction, Result);
end;
```

On a computer that has the regional format set to English (United States), the message window displays the following:

Round(1234.56789, 0.001, '>') returns 1,234.568

The following table displays some additional Round examples.

NUMBER	PRECISION	DIRECTION	ROUNDED NUMBER
1234.56789	100	=	1200
1234.56789	0.1	=	1234.6
1234.56789	0.001	=	1234.568
1234.56789	0.001	<	1234.567
1234.56789	0.001	>	1234.568
-1234.56789	100	=	-1200
-1234.56789	0.1	=	-1234.6
-1234.56789	0.001	=	-1234.568
-1234.56789	0.001	<	-1234.567
-1234.56789	0.001	>	-1234.568

When you round down ('<') a negative number, such as -1234.56789, it is rounded down to -1234.567. However, -1234.567 is a mathematically greater value than -1234.56789.

When you round up ('>') a negative number, such as -1234.56789, it is rounded up to -1234.568. However, -1234.568 is a mathematically smaller value than -1234.56789.

System.RoundDateTime Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Rounds a DateTime.

Syntax

```
NewDatetime :=   System.RoundDateTime(Datetime: DateTime [, Precision: BigInteger] [, Direction: String])
```

NOTE

This method can be invoked without specifying the data type name.

Parameters

Datetime

Type: DateTime

The DateTime that you want to round.

Precision

Type: BigInteger

This optional parameter determines the precision used when rounding. The default value is 1000, which rounds to the nearest second. You can only use positive BigIntegers.

Direction

Type: String

This optional parameter specifies how to round the DateTime. The default rounding method is '='. You can change the method by using the following options:

- '=' rounds up or down to the nearest value (default). Values of 5 or greater are rounded up. Values less than 5 are rounded down.
- '>' rounds up
- '<' rounds down

Return Value

NewDatetime Type: DateTime The rounded result.

Remarks

A variable of type DateTime is stored as a 64 bit integer. The integer value is the number of milliseconds since year 0. When you call RoundDateTime, the DateTime integer value is rounded as a numeric variable.

If you use 1 for the *Precision* parameter, then the resulting DateTime is rounded to the nearest millisecond. If you use 1000 for the *Precision* parameter, which is the default value, then the resulting DateTime will be rounded to the nearest second.

We recommend that you do not use a value greater than 60*60*1000, which is the number of milliseconds in an

hour, for the *Precision* parameter. The Regional and Language Options in Windows affect how the hour and date parts of a DateTime are rounded. To display a DateTime in a specific format, we recommend that you use the Format Method (Code, Text) instead of the RoundDateTime method.

Example

This example shows how to use the RoundDateTime method to round to the nearest second.

```
var
    Text000: Label 'RoundDateTime(%1, %2) returns %3.';
begin
    DateToRound := 20081127D;
    TimeToRound := 093524.567T;
    DateTimeToRound := CreateDateTime(DateToRound, TimeToRound);
    Precision := 1000L;
    FormatString := '<Month,2>/<Day,2>/<Year> <Hours24,2>:<Minutes,2>:<Seconds,2>.<Thousands,3>';
    Result := RoundDateTime(DateTimeToRound, Precision);
    Message(TEXT000, Format(DateTimeToRound,0,FormatString), Precision, Format(Result,0,FormatString));
end;
```

The message window displays the following:

RoundDateTime(11/27/08 09:35:24.567, 1000) returns 11/27/08 09:35:25.000.

System.Sleep Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Returns control to the operating system for a specified time.

Syntax

```
System.Sleep(Duration: Integer)
```

> **NOTE**
> This method can be invoked without specifying the data type name.

Parameters

Duration

Type: Integer

The number of milliseconds to return control to the operating system.

Remarks

When you use the Sleep method, control is guaranteed to return to the operating system for at least *Duration* milliseconds.

> **NOTE**
> The period may be longer than *Duration* milliseconds, depending on what the operating system is doing at the time that control is to return to the caller.

System.TemporaryPath Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Gets the path of the directory where the temporary file is stored.

> **NOTE**
> This method is supported only in Business Central on-premises.

Syntax

```
String :=   System.TemporaryPath()
```

> **NOTE**
> This method can be invoked using property access syntax.

> **NOTE**
> This method can be invoked without specifying the data type name.

Return Value

String Type: String

Remarks

This method returns a string that contains the path of the directory where the temporary file for Dynamics 365 is stored. This string ends with a backslash ('\') and does not contain the name of the temp file.

The string cannot contain more than 255 characters.

If this method is called from an application that is running on a Dynamics 365 Application Server, it returns the path of the directory where the Dynamics 365 Application Server is installed.

System.Time Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Gets the current time from the operating system.

Syntax

```
Time :=   System.Time()
```

NOTE

This method can be invoked using property access syntax.

NOTE

This method can be invoked without specifying the data type name.

Return Value

Time Type: Time

Remarks

The time that is returned is different for the Business Central Web client and Dynamics NAV Client connected to Business Central. For the Web client, the time is determined by the Regional Setting that is set under **MySetting** in the client. The very first time a user signs in, the system automatically determines the Regional Setting based on the user's browser/computer. For the Windows client, Time returns the current day of the computer that is running the client, as determined by the date and time settings of the operating system.

You can only use the Time method to retrieve the time from the operating system. You cannot use it to set the time in the operating system.

Example

```
var
    Text000: Label 'The current system time is %1.";
begin
    Message(Text000, Time);
end;
```

On a computer that has the regional format set to English (United States), the message window could display the following:

The current system time is 11:15:46 AM.

System.Today Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Gets the current date set in the operating system.

Syntax

```
Date :=   System.Today()
```

NOTE

This method can be invoked using property access syntax.

NOTE

This method can be invoked without specifying the data type name.

Return Value

Date Type: Date

Remarks

The date that is returned is different for the Business Central Web client and Dynamics NAV Client connected to Business Central. For the Web client, the day is determined by the Regional Setting that is set under **MySetting** in the client. The very first time a user signs in, the system automatically determines the Regional Setting based on the user's browser/computer. For the Windows client, Today returns the current day of the computer that is running the client, as determined by the date and time settings of the operating system.

You can only use the **Today** method to retrieve the current date from the operating system. You cannot use it to set the date in the operating system.

Example

This example shows how to use the **Today** method.

```
var
    Text000: Label 'The current date is: %1';
begin
    Message(Text000, Today);
end;
```

The message window could display the following:

The current date is: 05/27/08

System.Variant2Date Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Gets a date from a variant.

Syntax

```
Date :=   System.Variant2Date(Variant: Variant)
```

> **NOTE**
> This method can be invoked without specifying the data type name.

Parameters

Variant
Type: Variant
The input variant.

Return Value

Date Type: Date

Example

```
var
    TextDate: Date;
    variant1: Variant;
begin
    variant1 := Today;
    TestDate := Variant2Date(variant1);
end;
```

System.Variant2Time Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Gets a time from a variant.

Syntax

```
Time :=   System.Variant2Time(Variant: Variant)
```

> **NOTE**
> This method can be invoked without specifying the data type name.

Parameters

Variant
Type: Variant
The input variant.

Return Value

Time Type: Time

Example

```
var
    TextTime: Time;
    variant1: Variant;
begin
    variant1 := Time;
    TestTime := Variant2Time(variant1);
end;
```

System.WindowsLanguage Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Gets the current Windows language setting.

Syntax

```
LanguageID :=   System.WindowsLanguage()
```

NOTE

This method can be invoked using property access syntax.

NOTE

This method can be invoked without specifying the data type name.

Return Value

LanguageID Type: Integer

Remarks

The *LanguageID* is a standard Windows language ID. The Windows Language virtual table contains a list of these IDs and the corresponding names and short names.

For more information, see Multilanguage Development.

System.WorkDate Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Gets and sets the work date for the current session.

Syntax

```
[WorkDate := ]  System.WorkDate([NewDate: Date])
```

> **NOTE**
> This method can be invoked without specifying the data type name.

Parameters

NewDate

Type: Date

The new work date you want to set.

Return Value

WorkDate Type: Date

Remarks

To set the work date to follow the calendar day so that the work date is always the current date, set *NewDate* to `Today` or `0D`. If you explicitly set *NewDate* to the current date, then the work date will also follow the calendar day.

Example

This example shows how to use the WorkDate method.

```
var
    NewDate: Date;
    Text000: Label 'The new work date is: %1';
begin
    NewDate := WorkDate(20180101D);
    Message(Text000, NewDate);
end;
```

The code sets the work date to January 1, 2018, and returns the new date in a message. On a computer that has the regional format set to English (United States), the message window displays the following:

The work date is: 01/01/18

Record Data Type

2/17/2021 • 7 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Is a complex data type.

The following methods are available on instances of the Record data type.

METHOD NAME	DESCRIPTION
AddLink(String [, String])	Adds a link to a record.
AddLoadFields([Any,...])	Specifies fields to be initially loaded when the record is retrieved from its data source. Subsequent calls to AddLoadFields will not overwrite fields already selected for the initial load.
AreFieldsLoaded(Any,...)	Checks whether the specified fields are all initially loaded.
Ascending([Boolean])	Gets or sets the order in which the system searches through a table.
CalcFields(Any [, Any,...])	Calculates the FlowFields in a record. You specify which fields to calculate by using parameters.
CalcSums(Any [, Any,...])	Calculates the total of a column in a table. You specify which fields to calculate by using parameters.
ChangeCompany([String])	Redirects references to table data from one company to another.
ClearMarks()	Removes all the marks from a record.
Consistent(Boolean)	Marks a table as being consistent or inconsistent.
Copy(var Record [, Boolean])	Copies a specified record's filters, views, automatically calculated FlowFields, marks, fields, and keys that are associated with the record from a table or creates a reference to a record.
CopyFilter(Any, Any)	Copies the filter that has been set for one field and applies it to another field.
CopyFilters(var Record)	Copies all the filters set by the SetFilter method (Record) or the SETRANGE method (Record) from one record to another.
CopyLinks(var Record)	Copies all the links from a specified record.
CopyLinks(RecordRef)	Copies all the links from a specified record.
Count()	Counts the number of records in a table.
CountApprox()	Returns an approximate count of the number of records in the table, for example, for updating progress bars or displaying informational messages.
CurrentCompany()	Gets the current company of a database table record.
CurrentKey()	Gets the current key of a database table.
Delete([Boolean])	Deletes a record in a table.
DeleteAll([Boolean])	Deletes all records in a table that fall within a specified range.
DeleteLink(Integer)	Deletes a specified link from a record in a table.
DeleteLinks()	Deletes all of the links that have been added to a record.

METHOD NAME	DESCRIPTION
FieldActive(Any)	Checks whether a field is enabled.
FieldCaption(Any)	Gets the current caption of the specified field as a string.
FieldError(Any [, String])	Stops the execution of the code causing a run-time error, and creates an error message for a field.
FieldName(Any)	Gets the name of a field as a string.
FieldNo(Any)	Gets the number assigned to a field in the table description.
FilterGroup([Integer])	Gets or sets the filter group that is applied to a table.
Find([String])	Finds a record in a table that is based on the values stored in keys.
FindFirst()	Finds the first record in a table based on the current key and filter.
FindLast()	Finds the last record in a table based on the current key and filter.
FindSet([Boolean] [, Boolean])	Finds a set of records in a table based on the current key and filter.
Get([Any,...])	Gets a record based on values stored in primary key fields.
GetAscending(Any)	Gets the sort order for the records returned. You can use GetASCENDING to identify the sort order of the specified field because fields can be sorted in ascending or descending order. For example, you can read data from an ODATA web service where the data is sorted in ascending order on the Name field but in descending order on the City field.
GetBySystemId(Guid)	Gets a record by its SystemId.
GetFilter(Any)	Gets a list of the filters within the current filter group that are applied to a field.
GetFilters()	Gets a string that contains a list of the filters within the current filter group for all fields in a record. In addition, this method also returns the state of the MARKEDONLY method (Record).
GetPosition([Boolean])	Gets a string that contains the primary key of the current record.
GetRangeMax(Any)	Gets the maximum value in a range for a field.
GetRangeMin(Any)	Gets the minimum value in a range for a field.
GetView([Boolean])	Gets a string that describes the current sort order, key, and filters on a table.
HasFilter()	Determines whether a filter is attached to a record within the current filter group.
HasLinks()	Determines whether a record contains any links.
Init()	Initializes a record in a table.
Insert()	Inserts a record into a table without executing the code in the OnInsert trigger.
Insert(Boolean)	Inserts a record into a table.
Insert(Boolean, Boolean)	Inserts a record into a table.
IsEmpty()	Determines whether a table or a filtered set of records is empty.

METHOD NAME	DESCRIPTION
IsTemporary()	Determines whether a record refers to a temporary table.
LoadFields(Any,...)	Accesses the table's corresponding data source and loads the values of the specified fields on the record.
LockTable([Boolean] [, Boolean])	Locks a table to protect it from write transactions that conflict with each other.
Mark([Boolean])	Marks a record. You can also use this method to determine whether a record is marked.
MarkedOnly([Boolean])	Activates a special filter. After you use this function, your view of the table includes only records marked by this function.
Modify([Boolean])	Modifies a record in a table.
ModifyAll(Any, Any [, Boolean])	Modifies a field in all records within a range that you specify.
Next([Integer])	Steps through a specified number of records and retrieves a record.
ReadConsistency()	Determines if the table supports read consistency.
ReadPermission()	Determines whether a user is granted read permission to the table that contains a record. This method can test for both full read permission and partial read permission that has been granted with a security filter.
RecordId()	
RecordLevelLocking()	Determines whether the table supports record-level locking.
Relation(Any)	Determines the table relationship of a given field.
Rename(Any [, Any,...])	Changes the value of a primary key in a table.
Reset()	Removes all filters, including any special filters set by MarkedOnly, changes fields select for loading back to all, and changes the current key to the primary key. Also removes any marks on the record and clears any AL variables defined on its table definition.
SecurityFiltering([SecurityFilter])	
SetAscending(Any, Boolean)	Sets the sort order for the records returned. Use this method after you have set the keys to sort after, using SetCurrentKey. The default sort order is ascending. You can use SetAscending to change the sort order to descending for a specific field, while the other fields in the specified key are sorted in ascending order.
SetAutoCalcFields([Any,...])	Sets the FlowFields that you specify to be automatically calculated when the record is retrieved from the database.
SetCurrentKey(Any [, Any,...])	Selects a key for a table.
SetFilter(Any, String [, Any,...])	Assigns a filter to a field that you specify.
SetLoadFields([Any,...])	Sets the fields to be initially loaded when the record is retrieved from its data source. This will overwrite fields previously selected for initial load.
SetPermissionFilter()	Applies the user's security filter.
SetPosition(String)	Sets the fields in a primary key on a record to the values specified in the supplied string. The remaining fields are not changed.
SetRange(Any [, Any] [, Any])	Sets a simple filter, such as a single range or a single value, on a field.

METHOD NAME	DESCRIPTION
SetRecFilter()	Sets the values in the current key of the current record as a record filter.
SetView(String)	Sets the current sort order, key, and filters on a table.
TableCaption()	Gets the current caption of a table as a string.
TableName()	Gets the name of a table.
TestField(Any)	Tests whether the contents of a field match a given value.
TestField(Any, Boolean)	Tests whether the contents of a field match a given value.
TestField(Any, Integer)	Tests whether the contents of a field match a given value.
TestField(Any, BigInteger)	Tests whether the contents of a field match a given value.
TestField(Any, Decimal)	Tests whether the contents of a field match a given value.
TestField(Any, Guid)	Tests whether the contents of a field match a given value.
TestField(Any, Text)	Tests whether the contents of a field match a given value.
TestField(Any, Label)	Tests whether the contents of a field match a given value.
TestField(Any, TextConst)	Tests whether the contents of a field match a given value.
TestField(Any, Code)	Tests whether the contents of a field match a given value.
TestField(Any, String)	Tests whether the contents of a field match a given value.
TestField(Any, Enum)	Tests whether the contents of a field match a given value.
TestField(Any, Any)	Tests whether the contents of a field match a given value.
TransferFields(var Record [, Boolean])	Copies all matching fields in one record to another record.
TransferFields(var Record, Boolean, Boolean)	Copies all matching fields in one record to another record.
Validate(Any [, Any])	Calls the OnValidate trigger for the field that you specify.
WritePermission()	Determines whether a user can write to a table. This method can test for both full write permission and partial write permission that has been granted with a security filter. A write permission consists of Insert, Delete, and Modify permissions.

Record.AddLink Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Adds a link to a record.

Syntax

```
[ID := ]  Record.AddLink(URL: String [, Description: String])
```

Parameters

Record Type: Record An instance of the Record data type.

URL
Type: String

Description
Type: String

Return Value

ID Type: Integer

See Also

Record Data Type
Getting Started with AL
Developing Extensions

Record.AddLoadFields Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 6.0.*

Specifies fields to be initially loaded when the record is retrieved from its data source. Subsequent calls to AddLoadFields will not overwrite fields already selected for the initial load.

Syntax

```
[Ok := ]  Record.AddLoadFields([Fields: Any,...])
```

Parameters

Record Type: Record An instance of the Record data type.

Fields

Type: Any

The FieldNo's of the fields to be loaded.

Return Value

Ok Type: Boolean **true** if all fields are selected for subsequent loads; otherwise, **false**. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

Remarks

It is not necessary to include the following fields, because they are always selected for loading: Primary key, SystemId, and data audit fields (SystemCreatedAt, SystemCreatedBy, SystemModifiedAt, SystemModifiedBy).

This method is part of the partial records capability for improving performance. For more information, see Using Partial Records.

Example

The following example code shows how to use the AddLoadFields method to add a field for loading on a report. The example loads a field that is outside of the default fields selected by DataColumns of the report. The field is added by using the AddLoadFields on the OnPreDataItem trigger.

```
trigger OnPreDataItem()
begin
    CurrencyDataItem.AddLoadFields(CurrencyDataItem."ISO Numeric Code");
end;

trigger OnAfterGetRecord()
begin
    if (CurrencyDataItem."ISO Numeric Code" <> 'DKK') then begin
        CurrReport.Skip();
    end;
end;
```

Using Partial Records
Record Data Type
Getting Started with AL
Developing Extensions

Record.AreFieldsLoaded Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 6.0.*

Checks whether the specified fields are all initially loaded.

Syntax

```
Ok :=   Record.AreFieldsLoaded(Fields: Any,...)
```

Parameters

Record Type: Record An instance of the Record data type.

Fields
Type: Any
The FieldNo's of the fields to check.

Return Value

Ok Type: Boolean **true** if all the fields specified by the Fields parameter are currently loaded; otherwise, **false**. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

Remarks

This method is part of the partial records capability for improving performance. For more information, see Using Partial Records.

Example

This example shows how to use the AreFieldsLoaded method when you only need to load either the **Name** or the **Name 2** field on the **Customer** table. The procedure selects which ever field is actually loaded. If neither is loaded, this causes a JIT load.

```
procedureGetLoadedName(Cust:RecordCustomer):Text
begin
ifCust.AreFieldsLoaded(Cust.Name)then
exit(Cust.Name)
else
ifCust.AreFieldsLoaded(Cust."Name 2")then
exit(Cust."Name 2")
else
exit(Cust.Name);
end;
```

Record Data Type

Record.Ascending Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Gets or sets the order in which the system searches through a table.

Syntax

```
[Ascending := ]  Record.Ascending([Ascending: Boolean])
```

> **NOTE**
> This method can be invoked using property access syntax.

Parameters

Record Type: Record An instance of the Record data type.

Ascending
Type: Boolean

Return Value

Ascending Type: Boolean

See Also

Record Data Type
Getting Started with AL
Developing Extensions

Record.CalcFields Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Calculates the FlowFields in a record. You specify which fields to calculate by using parameters.

Syntax

```
[Ok := ]  Record.CalcFields(Field1: Any [, Field2: Any,...])
```

Parameters

Record Type: Record An instance of the Record data type.

Field1
Type: Any

Field2
Type: Any

Return Value

Ok Type: Boolean **true** if the operation was successful; otherwise **false**. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

Remarks

FlowFields are virtual fields. The values in these fields are not saved in the table. This means that you must use either the **CalcFields** method or the SetAutoCalcFields Method (Record) to update them. For example, if you retrieve a record using the Find Method (Record) and Next Method (Record), the FlowFields in those records are set to zero (0). Then, when you call **CalcFields**, their values are updated.

When a FlowField is a direct source expression on a page or a report, the calculation is performed automatically.

You can also use the **CalcFields** method to retrieve binary large objects (BLOBs). For more information, see BLOB Data Type.

Dynamics 365 Business Central automatically maintains a count for all SIFT indexes. Therefore, SumIndexField Technology (SIFT) is used by default when the calculation method for a FlowField is **Count** or **Average**.

You can prevent the SIFT indexes from being updated by setting the MaintainSIFTIndex Property of the index in the base table to **False**. Then Business Central will traverse all records in the base table to perform the calculation instead of using SIFT. This can reduce the number of required SIFT indexes, which can improve performance. For more information, see SIFT and Performance.

In Dynamics 365 Business Central, an index is not required to support a certain sorting, but sorting without an index could lead to bad performance if a search returns a large result set, which would then have to be sorted before the first row is returned.

Example

This example shows how to use the **CalcFields** method to find the balance on December 31, 2008 and the net change for a customer in 2008.

```
var
    CustomerRec: Record Customer;
begin
    CustomerRec.SetRange("Date Filter",20080101D,20081231D);
    CustomerRec.CalcFields(Balance, "Net Change");
end;
```

The first line sets up a filter for the Date Filter field in the Customer record. This field is a FlowFilter field which is used in the filter definition for several FlowFields in the Customer record. In the second line, the FlowFields are calculated.

Record.CalcSums Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Calculates the total of a column in a table. You specify which fields to calculate by using parameters.

Syntax

```
[Ok := ]  Record.CalcSums(Field1: Any [, Field2: Any,...])
```

Parameters

Record Type: Record An instance of the Record data type.

Field1
Type: Any

Field2
Type: Any

Return Value

Ok Type: Boolean **true** if the operation was successful; otherwise **false**. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

AL Database Methods and Performance on SQL Server

Record.ChangeCompany Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Redirects references to table data from one company to another.

Syntax

```
[Ok := ]  Record.ChangeCompany([CompanyName: String])
```

Parameters

Record Type: Record An instance of the Record data type.

CompanyName
Type: String
The name of the company to which you want to change. If you omit this parameter, you change back to the current company.

Return Value

Ok Type: Boolean **true** if the operation was successful; otherwise **false**. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

Record.ClearMarks Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Removes all the marks from a record.

Syntax

```
Record.ClearMarks()
```

Parameters

Record Type: Record An instance of the Record data type.

See Also

Record Data Type
Getting Started with AL
Developing Extensions

Record.Consistent Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Marks a table as being consistent or inconsistent.

Syntax

```
Record.Consistent(Consistent: Boolean)
```

Parameters

Record Type: Record An instance of the Record data type.

Consistent

Type: Boolean

The mark to be set on the table. If this parameter is true, the table is marked as consistent. If this parameter is false, the table is marked as inconsistent.

See Also

Record Data Type
Getting Started with AL
Developing Extensions

Record.Copy Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Copies a specified record's filters, views, automatically calculated FlowFields, marks, fields, and keys that are associated with the record from a table or creates a reference to a record.

Syntax

```
Record.Copy(var FromRecord: Record [, ShareTable: Boolean])
```

Parameters

Record Type: Record An instance of the Record data type.

FromRecord

Type: Record

The record to copy.

ShareTable

Type: Boolean

Specifies whether the method copies filters, views, automatically calculated FlowFields, marks, fields, and keys of the record or creates a reference to a temporary record. If FromRecord and Record are both temporary and ShareTable is true, then the COPY method causes Record to reference the same table as FromRecord. If ShareTable is true, then both Record and FromRecord must be temporary; otherwise an error will occur. The default value is false. If you specify false, only filters, marks, and keys are copied.

See Also

Record Data Type

Developing Extensions

Record.CopyFilter Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Copies the filter that has been set for one field and applies it to another field.

Syntax

```
Record.CopyFilter(FromField: Any, Record.ToField: Any)
```

Parameters

Record Type: Record An instance of the Record data type.

FromField
Type: Any
The field from which the filter will be copied.

Record.ToField
Type: Any

Remarks

The filter is copied and remains in the assigned group number. For example: `Rec.CopyFilter(FromRec);` disregards the current filter group on both `Rec` and `FromRec`, and copies the filter in `FromRec` (regardless of group number) into the same filter group assignment on `Rec`.

See Also

Record Data Type
Getting Started with AL
Developing Extensions

Record.CopyFilters Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Copies all the filters set by the SetFilter method (Record) or the SETRANGE method (Record) from one record to another.

Syntax

```
Record.CopyFilters(var FromRecord: Record)
```

Parameters

Record Type: Record An instance of the Record data type.

FromRecord
Type: Record
The record from which you want to copy filters.

Remarks

All filters are copied and remain in their assigned group numbers. For example: `Rec.CopyFilters(FromRec);` disregards the current filter group on both `Rec` and `FromRec`, and copies all filters in `FromRec` (regardless of group number) into the same filter group assignments on `Rec`.

Record.CopyLinks Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Copies all the links from a specified record.

Syntax

```
Record.CopyLinks(var FromRecord: Record)
```

Parameters

Record Type: Record An instance of the Record data type.

FromRecord

Type: Record

Specifies the record from which you want to copy links.

See Also

Record.CopyLinks Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 4.0.*

Copies all the links from a specified record.

Syntax

```
Record.CopyLinks(FromRecordRef: RecordRef)
```

Parameters

Record Type: Record An instance of the Record data type.

FromRecordRef
Type: RecordRef
Specifies the record from which you want to copy links.

Record.Count Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Counts the number of records in a table.

Syntax

```
Number :=   Record.Count()
```

NOTE

This method can be invoked using property access syntax.

Parameters

Record Type: Record An instance of the Record data type.

Return Value

Number Type: Integer

See Also

Record Data Type
Getting Started with AL
Developing Extensions

Record.CountApprox Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Returns an approximate count of the number of records in the table, for example, for updating progress bars or displaying informational messages.

Syntax

```
Number :=   Record.CountApprox()
```

NOTE

This method can be invoked using property access syntax.

Parameters

Record Type: Record An instance of the Record data type.

Return Value

Number Type: Integer

See Also

Record Data Type

Record.CurrentCompany Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Gets the current company of a database table record.

Syntax

```
Company :=   Record.CurrentCompany()
```

NOTE

This method can be invoked using property access syntax.

Parameters

Record Type: Record An instance of the Record data type.

Return Value

Company Type: String

See Also

Record.CurrentKey Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Gets the current key of a database table.

Syntax

```
CurrentKey :=   Record.CurrentKey()
```

NOTE

This method can be invoked using property access syntax.

Parameters

Record Type: Record An instance of the Record data type.

Return Value

CurrentKey Type: String

See Also

Record.Delete Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Deletes a record in a table.

Syntax

```
[Ok := ]  Record.Delete([RunTrigger: Boolean])
```

Parameters

Record Type: Record An instance of the Record data type.

RunTrigger
Type: Boolean
Specifies whether to run the AL code in the OnDelete Trigger. If this parameter is true, then the code in the OnDelete trigger is executed. If this parameter is false, then the code in the OnDelete trigger is not executed. The default value is false. This parameter is optional.

Return Value

Ok Type: Boolean **true** if the operation was successful; otherwise **false**. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

Record.DeleteAll Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Deletes all records in a table that fall within a specified range.

Syntax

```
Record.DeleteAll([RunTrigger: Boolean])
```

Parameters

Record Type: Record An instance of the Record data type.

RunTrigger
Type: Boolean
Specifies whether to run the AL code in the OnDelete Trigger. If this parameter is true, then the code in the OnDelete trigger will be executed. If this parameter is false, then the code in the OnDelete trigger will not be executed. The default value is false.

Record.DeleteLink Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Deletes a specified link from a record in a table.

Syntax

```
Record.DeleteLink(ID: Integer)
```

Parameters

Record Type: Record An instance of the Record data type.

ID

Type: Integer

The ID of the link to delete.

Record.FieldActive Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Checks whether a field is enabled.

Syntax

```
Ok :=   Record.FieldActive(Field: Any)
```

Parameters

Record Type: Record An instance of the Record data type.

Field

Type: Any

The field that you want to check.

Return Value

Ok Type: Boolean

See Also

Record Data Type
Getting Started with AL
Developing Extensions

Record.FieldCaption Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Gets the current caption of the specified field as a string.

Syntax

```
Caption :=   Record.FieldCaption(Field: Any)
```

Parameters

Record Type: Record An instance of the Record data type.

Field
Type: Any
The field for which you want to retrieve the caption.

Return Value

Caption Type: String

See Also

Record Data Type
Getting Started with AL
Developing Extensions

Record.FieldError Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Stops the execution of the code causing a run-time error, and creates an error message for a field.

Syntax

```
Record.FieldError(Field: Any [, Text: String])
```

Parameters

Record Type: Record An instance of the Record data type.

Field

Type: Any

The field for which you want to create an error message.

Text

Type: String

Use this optional parameter to include the text of the error message. If you do not use this parameter, then default text is used as shown in the following examples. You can use backslashes (\) to break lines.

Remarks

Like a run-time error, this method causes the system to automatically end any transaction.

Programming guidelines

The following guidelines for error messages are recommended:

- Describe what is wrong and how to solve the problem.
- Write a short descriptive message. Do not use more words than necessary.
- Note that a period is automatically inserted at the end of a FieldError.
- Use a label data type for the *Text* parameter.

For more information, see Progress Windows, Message, Error, and Confirm Methods.

Example 1

In the first example, there is no *Text* parameter and the field does not have a value.

```
var
    CustomerRec: Record Customer;

...
CustomerRec."No." := '';
CustomerRec.FieldError("No.");
```

The following message is displayed:

You must specify No. in Customer No.=''.

Example 2

In the next example, there is no *Text* parameter and the field has a value.

```
var
    CustomerRec: Record Customer;

...
CustomerRec."No." := 'NEW 3500';
CustomerRec.FieldError("No.");
```

The following message is displayed:

No. must not be NEW 3500 in Customer No.='NEW 3500'.

Example 3

The third example uses a non-empty string as the *Text* parameter.

```
var
    CustomerRec: Record Customer;
    Text001: Label 'is not valid';

...
CustomerRec."No." := 'NEW 3500';
CustomerRec.FieldError("No.", Text001);
```

The following message is displayed:

No. is not valid in Customer No.='NEW 3500'.

Record.FieldName Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Gets the name of a field as a string.

Syntax

```
Name :=   Record.FieldName(Field: Any)
```

Parameters

Record Type: Record An instance of the Record data type.

Field
Type: Any
The name of the field in the record.

Return Value

Name Type: String

Remarks

The advantage of using the FieldName method call instead of a static assignment, like NameOfField := 'MyField', is that using the FieldName method dynamically adapts to any change to the field name made in the development environment.

Example

The following example gets the name of the **No.** field in the **Customer** table, and stores it in a string.

```
var
    NameOfField: Text;
    CustomerRec: Record Customer;

begin
    NameOfField := CustomerRec.FieldName("No.");
end;
```

Record.FieldNo Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Gets the number assigned to a field in the table description.

Syntax

```
Number :=   Record.FieldNo(Field: Any)
```

Parameters

Record Type: Record An instance of the Record data type.

Field

Type: Any

The name of the field in the record.

Return Value

Number Type: Integer

See Also

Record Data Type
Getting Started with AL
Developing Extensions

Record.FilterGroup Method

2/17/2021 • 3 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Gets or sets the filter group that is applied to a table.

Syntax

```
[Group := ]  Record.FilterGroup([Group: Integer])
```

NOTE

This method can be invoked using property access syntax.

Parameters

Record Type: Record An instance of the Record data type.

Group

Type: Integer

Return Value

Group Type: Integer

Remarks

A filter group can contain a filter for a Record that has been set earlier with the SetFilter Method (Record) or the SetRange Method (Record). The total filter applied is the combination of all the filters set in all the filtergroups.

When you select a filter group, subsequent filter settings by the SetFilter Method (Record) or the SetRange Method (Record) apply to that group.

All groups are active at all times. The only way to turn off a group is to remove the filters set in that group.

Filters in different groups are all effective simultaneously. For example, if in one group, a filter is set on customer numbers 1000 to 2000, while in another group, a filter is set on customer numbers 1800 to 3000, then only numbers in the range 1800 to 2000 are visible.

Dynamics 365 Business Central uses the following filter groups internally.

NUMBER	NAME	DESCRIPTION
-1	Cross-column	Used to support the cross-column search.

NUMBER	NAME	DESCRIPTION
0	Std	The default group where filters are placed when no other group has been selected explicitly. This group is used for filters that can be set from the filter dialogs by the end user.
1	Global	Used for filters that apply globally to the entire application.
2	Form	Used for the filtering actions that result from the following: - SetTableView Method (XMLport), SetTableView Method (Page) - SourceTableView Property - DataItemTableView Property.
3	Exec	Used for the filtering actions that result from the following: - SubPageView Property - RunPageView Property
4	Link	Used for the filtering actions that result from the following: - DataItemLink Property (Reports) - SubPageLink Property
5	Temp	Not currently used.
6	Security	Used for applying security filters for user permissions.
7	Factboxes	Used for clearing the state of factboxes.

A filter set in a group different from filter group 0 cannot be changed by a user that uses a filter dialog to set a filter. If, for example, a filter has been set on customer numbers 1000 to 2000 in group 4, then the user can set a filter that delimits this selection further, but cannot widen it to include customer numbers outside the range 1000 to 2000.

> **NOTE**
> It is possible to use one of the internally used groups. If you do this, you replace the filter that Dynamics 365 Business Central assumes is in this group. If, for example, you use filter group 4 in a page, you will replace the filtering that is actually the result of applying the SubPageLink Property. This could seriously alter the way pages and subpages interact.

> **IMPORTANT**
> Using filter group 7 may cause factboxes to not work as intended.

Reset filter

To reset the filters in filter group 1, you add an empty filter to the group. To add an empty filter, to filter group 1, you must first set the filter group.

```
Rec.FilterGroup(1);
```

Then, for each field in the table that to which the Rec variable refers, set an empty filter.

```
Rec.SetFilter(<field>,'');
```

Example 1

The following example uses the SetFilter Method (Record) to set a filter that selects records with No. field between 10000 and 20000. Then the **FilterGroup** method returns the number for the filter group. No filter group was selected explicitly so the filter is set in filter group 0. This value is stored in the `varOrigGroup` variable and displayed in a message box. Next, the **FilterGroup** method changes the filter group to 100. The new value is stored in the `varCurrGroup` variable and displayed in a message box.

```
var
        Customer: Record Customer;
        varOrigGroup: Integer;
        varCurrGroup: Integer;
        Text000: Label 'The original filtergroup is: %1';
        Text001: Label 'The current filtergroup is: %1';
begin
    Customer.SetFilter("No.", '10000..20000');
    varOrigGroup := Customer.FilterGroup;
    Message(Text000, varOrigGroup);
    varCurrGroup := Customer.FilterGroup(1);
    Message(Text001, varCurrGroup);
end;
```

Example 2

The following example finds all customers where the Customer Name or Contact Name contains the string **John**.

```
var
    SearchString: Text;
begin
    Customer.FilterGroup := -1;
    SearchString := '@*John*';
    Customer.SetFilter(Customer.Name, SearchString);
    Customer.SetFilter(Customer.Contact, SearchString);
end;
```

Record.Find Method

2/17/2021 • 3 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Finds a record in a table that is based on the values stored in keys.

Syntax

```
[Ok := ]  Record.Find([Which: String])
```

Parameters

Record Type: Record An instance of the Record data type.

Which
Type: String
Specifies how to perform the search. The table is searched until either a record is found or there are no more records. Each character in this string can be present only one time. You can combine the '=', '<', and '>' characters. You can use the following characters:

- = to search for a record that equals the key values (default)
- > to search for a record that is larger than the key values
- < to search for a record that is less than the key values
- + to search for the last record in the table (+ can only be used alone)
- - to search for the first record in the table (- can only be used alone) If this parameter contains '=', '>' or '<', then you must assign value to all fields of the current and primary keys before you call Find.

Return Value

Ok Type: Boolean **true** if the operation was successful; otherwise **false**. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

Remarks

Find retrieves the first record that meets the conditions set by *Which* and the filters associated with *Record*. The search path reflects the sort order defined by the current key. If the current key is not the primary key, several records might have the same values in current key fields. If this occurs, the sort order defined by the primary key as the search path is used.

Calling Find on an empty table from the OnNewRecord trigger causes the Business Central Server to throw an exception, and the AL execution stops. However, the client suppresses this error and does not show any error message to the user. Therefore, when using Find inside this trigger, you should add code that conditionally verifies whether a record was found, and if not, notify the user with a message. For example:

```
if not MyRecord.Find then
    Error('error message');
```

Example 1

The following example shows how use the **Find** method to find a record in a table. The code sets the number of the record to find to 1100, which is the primary key of the record to find. The **Find** method uses the '=' parameter to find the record that has a primary value that equals the specified primary key. If the record is found, then the item number, description, and unit price of the item are displayed in a message box. Otherwise, a message that specifies that the item is not found is displayed.

```
begin
    ItemRec."No." := '1100';
    if ItemRec.Find('=') then
        Message(Text000, ItemRec."No.", ItemRec.Description, ItemRec."Unit Price")
    else
        Message(Text001);
end;

var
    ItemRec: Record Item;
    Text000: Label 'Item No. %1.\Description: %2. Price: $%3.';
    Text001: Label 'The item was not found.';
```

Example 2

The following example defines a record variable that is named ItemRec. The **Find** method uses the '+' parameter to find the last record in the table. If the record is found, then the item number, description, and unit price of the item are displayed in a message box. Otherwise, the message that specifies that the item was not found is displayed.

```
begin
    if ItemRec.Find('+') then
        Message(Text000, ItemRec."No.", ItemRec.Description, ItemRec."Unit Price")
    else
        Message(Text001);
end;

var
    ItemRec: Record Item;
    Text000: Label 'Item No. %1.\Description: %2. Price: $%3.';
    Text001: Label 'The item was not found.';
```

Record.FindFirst Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Finds the first record in a table based on the current key and filter.

Syntax

```
[Ok := ]  Record.FindFirst()
```

Parameters

Record Type: Record An instance of the Record data type.

Return Value

Ok Type: Boolean **true** if the operation was successful; otherwise **false**. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

Remarks

This method should be used instead of **Find**('-') when you only need the first record.

You should only use this method when you explicitly want to find the first record in a table or set. Do not use this method in combination with **Repeat**.. **Until**.

Calling FindFirst on an empty table from the OnNewRecord trigger causes the Business Central Server to throw an exception, and the AL execution stops. However, the client suppresses this error and does not show any error message to the user. Therefore, when using FindFirst inside this trigger, you should add code that conditionally verifies whether a record was found, and if not, notify the user with a message. For example:

```
if not MyRecord.FindFirst then
    Error('error message');
```

Example

This example also assumes that you have a **ConfigurePost** method.

```
var
    SalesSetupRec: Record "Sales & Receivables Setup";
begin
    // Read the first record only.
    if SalesSetupRec.FindFirst then
        begin
           ConfigurePost(SalesSetupRec);
        end;
end;
```

Record.FindLast Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Finds the last record in a table based on the current key and filter.

Syntax

```
[Ok := ]  Record.FindLast()
```

Parameters

Record Type: Record An instance of the Record data type.

Return Value

Ok Type: Boolean **true** if the operation was successful; otherwise **false**. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

Remarks

This method should be used instead of Find('+') when you only need the last record.

You should only use this method when you explicitly want to find the last record in a table/set. Do not use this method in combination with Repeat...Until.

Calling FindLast on an empty table from the OnNewRecord trigger causes the Business Central Server to throw an exception, and the AL execution stops. However, the client suppresses this error and does not show any error message to the user. Therefore, when using FindLast inside this trigger, you should add code that conditionally verifies whether a record was found, and if not, notify the user with a message. For example:

```
if not MyRecord.FindLast then
    Error('error message');
```

Example

This example requires that you create a Record variable named GLEntryRec for the G/L Entry table.

```
// Read the last record only.
if GLEntryRec.FindLast then
  ...
```

Record.FindSet Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Finds a set of records in a table based on the current key and filter.

Syntax

```
[Ok := ]  Record.FindSet([ForUpdate: Boolean] [, UpdateKey: Boolean])
```

Parameters

Record Type: Record An instance of the Record data type.

ForUpdate
Type: Boolean
Set this parameter to true if you want to modify any records in the set; otherwise, set the parameter to false.If you set this parameter to true, then the LOCKTable method (Record) is immediately run on the table before the records are read. If you set this parameter to false, then you can still modify the records in the set, but these updates will not be performed optimally. The default value is false.

UpdateKey
Type: Boolean
Set this parameter to true if you want to modify any field value within the current key. This parameter only applies if the ForUpdate parameter is true. If you set this parameter to false, then you can still modify the records in the set, but these updates will not be performed optimally. The default value is false.

Return Value

Ok Type: Boolean **true** if the operation was successful; otherwise **false**. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

Getting Started with AL
Developing Extensions
AL Database Methods and Performance on SQL Server

Record.Get Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Gets a record based on values stored in primary key fields.

Syntax

```
[Ok := ]  Record.Get([Value: Any,...])
```

Parameters

Record Type: Record An instance of the Record data type.

Value
Type: Any

Return Value

Ok Type: Boolean **true** if the operation was successful; otherwise **false**. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

Remarks

This method always uses the primary key for the table. It ignores any filters that are set, except security filters. Security filters are applied or ignored based on the Security Filter Mode. The current key and filters are not changed after you call this method.

> **NOTE**
> `Get` does not require specifying all fields of the key in the call; any omitted field is treated as default value (for example, '' for text/code, false for boolean). You can only omit from the end of the key, not a field in the middle of a key. If a record with a blank/default value exists that is the one being returned, otherwise it will fail with a record does not exist error.

This method ignores any call to the SetAutoCalcFields Method. Therefore, a Get call on a record after a `SetAutoCalcFields` call does not automatically calculate FlowFields in the record.

> **NOTE**
> You cannot use the Get method to retrieve a record in a table by its primary key value if the primary key field in the table has the data type RecordID. In this case, you can retrieve the record by using the SetRange Method.

Record.GetAscending Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Gets the sort order for the records returned. You can use GetASCENDING to identify the sort order of the specified field because fields can be sorted in ascending or descending order. For example, you can read data from an ODATA web service where the data is sorted in ascending order on the Name field but in descending order on the City field.

Syntax

```
IsAscending :=   Record.GetAscending(Field: Any)
```

Parameters

Record Type: Record An instance of the Record data type.

Field

Type: Any

The field that you want to get the sort order for.

Return Value

IsAscending Type: Boolean

Record.GetBySystemId Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 4.0.*

Gets a record by its SystemId.

Syntax

```
[RecordExists := ]  Record.GetBySystemId(SystemId: Guid)
```

Parameters

Record Type: Record An instance of the Record data type.

SystemId
Type: Guid
The SystemId of the record to retrieve.

Return Value

RecordExists Type: Boolean **true** if the record exists; otherwise **false**. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

Remarks

Every record has a SystemId, which is stored in the SystemId field of the table. The SystemId cannot be changed.

Example

This example shows how to use the GetBySystemId method to retrieve a record.

```
var
    CustomerRec: Record Customer;
    Text000: Label 'Customer was found.';
begin
    If CustomerRec.GetBySystemId('{5286305A-08A3-E911-8180-001DD8B7338E}') then
    Message(Text000);
end;
```

Record.GetFilter Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Gets a list of the filters within the current filter group that are applied to a field.

Syntax

```
String :=   Record.GetFilter(Field: Any)
```

Parameters

Record Type: Record An instance of the Record data type.

Field
Type: Any
The input field.

Return Value

String Type: String

See Also

Record Data Type
Getting Started with AL
Developing Extensions

Record.GetFilters Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Gets a string that contains a list of the filters within the current filter group for all fields in a record. In addition, this method also returns the state of the MARKEDONLY method (Record).

Syntax

```
String :=   Record.GetFilters()
```

NOTE

This method can be invoked using property access syntax.

Parameters

Record Type: Record An instance of the Record data type.

Return Value

String Type: String

See Also

Record Data Type
Getting Started with AL
Developing Extensions

Record.GetPosition Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Gets a string that contains the primary key of the current record.

Syntax

```
String :=   Record.GetPosition([UseNames: Boolean])
```

Parameters

Record Type: Record An instance of the Record data type.

UseNames
Type: Boolean

Return Value

String Type: String

See Also

Record Data Type
Getting Started with AL
Developing Extensions

Record.GetRangeMax Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Gets the maximum value in a range for a field.

Syntax

```
Value :=   Record.GetRangeMax(Field: Any)
```

Parameters

Record Type: Record An instance of the Record data type.

Field

Type: Any

The field for which you want to find the maximum value. The current filter on Field must be a single range filter; otherwise, a run-time error occurs.

Return Value

Value Type: Any

See Also

Record Data Type
Getting Started with AL
Developing Extensions

Record.GetRangeMin Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Gets the minimum value in a range for a field.

Syntax

```
Value :=   Record.GetRangeMin(Field: Any)
```

Parameters

Record Type: Record An instance of the Record data type.

Field

Type: Any

The field for which you want to find the minimum value.

Return Value

Value Type: Any

See Also

Record Data Type
Getting Started with AL
Developing Extensions

Record.GetView Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Gets a string that describes the current sort order, key, and filters on a table.

Syntax

```
String :=   Record.GetView([UseNames: Boolean])
```

Parameters

Record Type: Record An instance of the Record data type.

UseNames
Type: Boolean

Return Value

String Type: String

See Also

Record Data Type
Getting Started with AL
Developing Extensions

Record.HasFilter Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Determines whether a filter is attached to a record within the current filter group.

Syntax

```
Ok :=   Record.HasFilter()
```

NOTE

This method can be invoked using property access syntax.

Parameters

Record Type: Record An instance of the Record data type.

Return Value

Ok Type: Boolean

See Also

Record Data Type
Getting Started with AL
Developing Extensions

Record.HasLinks Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Determines whether a record contains any links.

Syntax

```
Ok :=   Record.HasLinks()
```

NOTE

This method can be invoked using property access syntax.

Parameters

Record Type: Record An instance of the Record data type.

Return Value

Ok Type: Boolean

See Also

Record Data Type
Getting Started with AL
Developing Extensions

Record.Init Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Initializes a record in a table.

Syntax

```
Record.Init()
```

Parameters

Record Type: Record An instance of the Record data type.

Remarks

This method assigns default values to each field in the record, including the SystemId field. The values that are assigned in the record correspond to those defined when the table was created. If no value was assigned when the table was created, the values are assigned based on the data type, as shown in the following table.

DATA TYPE	DEFAULT VALUE
BigInteger	0
BigText	<Empty>
BLOB	<Empty>
Boolean	No
Code	'' (empty string)
Date	0d (Undefined date)
DateFormula	'' (empty string)
DateTime	0DT (Undefined datetime)
Decimal	0.0
Duration	0
GUID	00000000-0000-0000-0000-000000000000
Integer	0

DATA TYPE	DEFAULT VALUE
Option	0
RecordID	<Empty>
TableFilter	<Empty>
Text	'' (empty string)
Time	0T (Undefined time)

> **NOTE**
> Primary key and timestamp fields are not initialized.

After the method runs, you can change the values in any or all of the fields before you call the Insert Method (RecordRef) to enter the record in the table. Be sure that the fields that make up the primary key contain values that make the total primary key unique. If the primary key is not unique (such as the record already exists), then the record is rejected.

The method works in the same way as the Init Method (RecordRef).

Record.Insert Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Inserts a record into a table without executing the code in the OnInsert trigger.

Syntax

```
[Ok := ]  Record.Insert()
```

Parameters

Record Type: Record An instance of the Record data type.

Return Value

Ok Type: Boolean **true** if the operation was successful; otherwise **false**. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

Remarks

The inserted record will automatically get assigned a SystemId by the platform. To assign a specific SystemId instead of the one assigned by the platform, use Insert(Boolean, Boolean) instead.

Example 1

This example shows how to use the Insert method without a return value.

```
Customer.Init;
Customer."No." := '1120';
Customer.Insert();
```

If customer 1120 already exists, then a run-time error occurs.

Example 2

This example shows how to use the Insert method with a return value.

```
var
    CustomerRec: Record Customer;
    Text000: Label 'Customer no: %1 inserted.';
    Text001: Label 'Customer no: %1 already exists.';
begin
    CustomerRec.Init();
    CustomerRec."No." := '1120';
    if CustomerRec.Insert() then
      Message(Text000, CustomerRec."No.")
    else
      Message(Text001, CustomerRec."No.");
end;
```

No run-time error occurs if customer 1120 already exists.

Record.Insert Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Inserts a record into a table.

Syntax

```
[Ok := ]  Record.Insert(RunTrigger: Boolean)
```

Parameters

Record Type: Record An instance of the Record data type.

RunTrigger
Type: Boolean
If this parameter is true, the code in the OnInsert Trigger is executed. If this parameter is false, the code in the OnInsert trigger is not executed. The default value is false.

Return Value

Ok Type: Boolean **true** if the operation was successful; otherwise **false**. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

See Also

Record Data Type

Developing Extensions

Record.Insert Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 4.0.*

Inserts a record into a table.

Syntax

```
[Ok := ]  Record.Insert(RunTrigger: Boolean, InsertWithSystemId: Boolean)
```

Parameters

Record Type: Record An instance of the Record data type.

RunTrigger
Type: Boolean
If this parameter is true, the code in the OnInsert Trigger is executed. If this parameter is false, the code in the OnInsert trigger is not executed. The default value is false.

InsertWithSystemId
Type: Boolean
If this parameter is true, the SystemId field of the record is given a value that you explicitly assign. If a value is not assigned, then the platform assigns one. If this parameter is false, the SystemId field is given a value that is auto-generated by the platform. The default value is false.

Return Value

Ok Type: Boolean **true** if the operation was successful; otherwise **false**. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

Remarks

The inserted record will automatically get assigned a SystemId by the platform. To assign a specific SystemId instead of the one assigned by the platform, use Insert(Boolean, Boolean) instead.

Example

This example shows how to use the Insert method to insert a record with a specified SystemId.

```
var
    CustomerRec: Record Customer;
    Text000: Label 'Customer no: %1 inserted.';
    Text001: Label 'Customer no: %1 already exists.';
begin
    CustomerRec.Init();
    CustomerRec."No." := '1120';
    CustomerRec.SystemId := '{B6666666-F5A2-E911-8180-001DD8B7338E}';
    if CustomerRec.Insert(true, true) then
      Message(Text000, CustomerRec."No.")
    else
      Message(Text001, CustomerRec."No.");
end;
```

No run-time error occurs if customer 1120 already exists.

Record.IsEmpty Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Determines whether a table or a filtered set of records is empty.

Syntax

```
Empty :=   Record.IsEmpty()
```

NOTE

This method can be invoked using property access syntax.

Parameters

Record Type: Record An instance of the Record data type.

Return Value

Empty Type: Boolean

See Also

Record Data Type
Getting Started with AL
Developing Extensions

Record.IsTemporary Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Determines whether a record refers to a temporary table.

Syntax

```
Temporary :=   Record.IsTemporary()
```

NOTE

This method can be invoked using property access syntax.

Parameters

Record Type: Record An instance of the Record data type.

Return Value

Temporary Type: Boolean

See Also

Record Data Type
Getting Started with AL
Developing Extensions

Record.LoadFields Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 6.0.*

Accesses the table's corresponding data source and loads the values of the specified fields on the record.

Syntax

```
[Ok := ]  Record.LoadFields(Fields: Any,...)
```

Parameters

Record Type: Record An instance of the Record data type.

Fields
Type: Any
The FieldNo's of the fields to be loaded.

Return Value

Ok Type: Boolean **true** if all values were loaded on the record; otherwise, **false**. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

Remarks

This method will trigger a JIT load of the specified fields. The method allows for triggering the JIT load on multiple fields. If the fields are already loaded, another load will not be triggered. Using this method instead of relying on implicit JIT loads lets you develop for more explicit error handling when a load fails.

This method is part of the partial records capability for improving performance. For more information, see Using Partial Records.

Record.LockTable Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Locks a table to protect it from write transactions that conflict with each other.

Syntax

```
Record.LockTable([Wait: Boolean] [, VersionCheck: Boolean])
```

Parameters

Record Type: Record An instance of the Record data type.

Wait

Type: Boolean

Specifies what to do if the table is already locked. If this parameter is true and if another application has already locked the table, the system will wait until the table is unlocked. If this parameter is false and if another application has already locked the table, a run-time error occurs.

VersionCheck

Type: Boolean

If this parameter is true, the version of the Record will be checked. If this parameter is false, blank, or not used, the version will not be checked.

Record.Mark Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Marks a record. You can also use this method to determine whether a record is marked.

Syntax

```
[Marked := ]  Record.Mark([Mark: Boolean])
```

Parameters

Record Type: Record An instance of the Record data type.

Mark
Type: Boolean
Specifies if a record is marked.

Return Value

Marked Type: Boolean **true** if the record is marked; otherwise, **false**.

See Also

Record Data Type
Getting Started with AL
Developing Extensions

Record.MarkedOnly Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Activates a special filter. After you use this function, your view of the table includes only records marked by this function.

Syntax

```
[MarkedOnly := ]  Record.MarkedOnly([MarkedOnly: Boolean])
```

NOTE

This method can be invoked using property access syntax.

Parameters

Record Type: Record An instance of the Record data type.

MarkedOnly

Type: Boolean

Activates a special filter.

Return Value

MarkedOnly Type: Boolean **true** if the special filter is being used; otherwise, **false**.

See Also

Record Data Type
Getting Started with AL
Developing Extensions

Record.Modify Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Modifies a record in a table.

Syntax

```
[Ok := ]  Record.Modify([RunTrigger: Boolean])
```

Parameters

Record Type: Record An instance of the Record data type.

RunTrigger
Type: Boolean
Specifies whether to run the AL code in the OnModify Trigger. If this parameter is true, then the code in the OnModify trigger is executed. If this parameter is false (default), then the code in the OnModify trigger is not executed.

Return Value

Ok Type: Boolean **true** if the operation was successful; otherwise **false**. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

See Also

Record Data Type
Getting Started with AL
Developing Extensions
AL Database Methods and Performance on SQL Server

Record.ModifyAll Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Modifies a field in all records within a range that you specify.

Syntax

```
Record.ModifyAll(Field: Any, NewValue: Any [, RunTrigger: Boolean])
```

Parameters

Record Type: Record An instance of the Record data type.

Field
Type: Any
The field that you want to modify.

NewValue
Type: Any
The value that you want to assign to Field in all records. The data type of NewValue must match the data type of Field.

RunTrigger
Type: Boolean
If this parameter is true, the code in the OnModify Trigger is executed. If this parameter is false (default), the code in the OnModify trigger is not executed.

Remarks

If no filter is set, the field is modified in all records in the table. If a filter is set, the fields are modified only in the records which fall within the range specified by the filter. Records where the field is already equal to the new value are also updated.

The `OnValidate` field trigger is never run when `ModifyAll` is used. Using ModifyAll() is recommended if field validation is not wanted or needed. Otherwise, Record.Modify Method can be used.

Example

```
var
    customerRec: record Customer;

begin
    // The result of this statement:
    customerRec.ModifyAll("Statistics Group", 2);
    // is equivalent to:
    if customerRec.Find('-') then
        repeat
            customerRec."Statistics Group" := 2;
            customerRec.Modify;
        until customerRec.Next = 0;
end;
```

Record.Next Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Steps through a specified number of records and retrieves a record.

Syntax

```
[Steps := ]  Record.Next([Steps: Integer])
```

Parameters

Record Type: Record An instance of the Record data type.

Steps
Type: Integer
Specifies the direction of the search and how many records to step over. This parameter follows the following rules:

- > 0 Search Steps records forward in the table.
- < 0 Search Steps records backward in the table.
- = 0 Stay on the same record in the table. If you do not specify this parameter, then the next record is found.

Return Value

Steps Type: Integer

Record.ReadConsistency Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Determines if the table supports read consistency.

Syntax

```
Ok :=   Record.ReadConsistency()
```

NOTE

This method can be invoked using property access syntax.

Parameters

Record Type: Record An instance of the Record data type.

Return Value

Ok Type: Boolean

See Also

Record Data Type
Getting Started with AL
Developing Extensions

Record.ReadPermission Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Determines whether a user is granted read permission to the table that contains a record. This method can test for both full read permission and partial read permission that has been granted with a security filter.

Syntax

```
Ok :=   Record.ReadPermission()
```

NOTE

This method can be invoked using property access syntax.

Parameters

Record Type: Record An instance of the Record data type.

Return Value

Ok Type: Boolean

See Also

Record Data Type
Getting Started with AL
Developing Extensions

Record.RecordId Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Syntax

```
RecordID :=   Record.RecordId()
```

NOTE

This method can be invoked using property access syntax.

Parameters

Record Type: Record An instance of the Record data type.

Return Value

RecordID Type: RecordId

Record.RecordLevelLocking Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Determines whether the table supports record-level locking.

Syntax

```
Ok :=   Record.RecordLevelLocking()
```

NOTE

This method can be invoked using property access syntax.

Parameters

Record Type: Record An instance of the Record data type.

Return Value

Ok Type: Boolean

See Also

Record Data Type
Getting Started with AL
Developing Extensions

Record.Relation Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Determines the table relationship of a given field.

Syntax

```
TableNumber :=   Record.Relation(Field: Any)
```

Parameters

Record Type: Record An instance of the Record data type.

Field

Type: Any

The field for which you want to find the table relationship.

Return Value

TableNumber Type: Integer

See Also

Record Data Type
Getting Started with AL

Record.Rename Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Changes the value of a primary key in a table.

Syntax

```
[Ok := ]  Record.Rename(Value1: Any [, Value2: Any,...])
```

Parameters

Record Type: Record An instance of the Record data type.

Value1
Type: Any

Value2
Type: Any

Return Value

Ok Type: Boolean **true** if the operation was successful; otherwise **false**. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

Record.SetAscending Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Sets the sort order for the records returned. Use this method after you have set the keys to sort after, using SetCurrentKey. The default sort order is ascending. You can use SetAscending to change the sort order to descending for a specific field, while the other fields in the specified key are sorted in ascending order.

Syntax

```
Record.SetAscending(Field: Any, Ascending: Boolean)
```

Parameters

Record Type: Record An instance of the Record data type.

Field

Type: Any

The field that you want to set the sort order for.

Ascending

Type: Boolean

The sort order. Specify false if data must be sorted in descending order; otherwise true.

Remarks

SetAscending is applicable to records that aren't displayed in a page in the client. For example, you can read data from an ODATA web service where data is sorted in ascending order on one field and descending on another. When the records are shown in a page, the method has no effect.

Example

The following code example shows how to use SetCurrentKey and SetAscending to sort data in two different directions based on two fields. It uses SetCurrentKey to specify the sort based on City and Name. Data will be sorted in ascending order based on those two fields, first by City, then by Name. Next, you use SetAscending to sort City in descending order instead.

```
page 50100 MyCustomerList
{
    PageType = List;
    ApplicationArea = All;
    UsageCategory = Lists;
    SourceTable = Customer;

    layout
    {
        area(Content)
        {
            repeater(GroupName)
            {
                field("City"; City)
                {
                    ApplicationArea = All;
                }
                field(Name; Name)
                {
                    ApplicationArea = All;
                }
            }
        }

    }

    trigger OnOpenPage()
    begin
        SetCurrentKey(City, Name);
        SetAscending(Name, false);
    end;

}
```

If you publish the page as a web service, and read the OData feed, you'll see the records sorted in ascending alphabetical order by city and descending alphabetical order by name. However, if you open the page in the client the city and name are both sorted in ascending order.

Record.SetAutoCalcFields Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Sets the FlowFields that you specify to be automatically calculated when the record is retrieved from the database.

Syntax

```
[Ok := ]  Record.SetAutoCalcFields([Field1: Any,...])
```

Parameters

Record Type: Record An instance of the Record data type.

Field1

Type: Any

Return Value

Ok Type: Boolean **true** if the operation was successful; otherwise **false**. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

Example

See AL Database Methods and Performance on SQL Server - SetAutoCalcFields.

See Also

Record Data Type
Getting Started with AL
Developing Extensions
AL Database Methods and Performance on SQL Server

Record.SetCurrentKey Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Selects a key for a table.

Syntax

```
[Ok := ]  Record.SetCurrentKey(Field1: Any [, Field2: Any,...])
```

Parameters

Record Type: Record An instance of the Record data type.

Field1
Type: Any

Field2
Type: Any

Return Value

Ok Type: Boolean **true** if the operation was successful; otherwise **false**. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

Remarks

You can use SetCurrentKey for selecting a key and sorting When you use SetCurrentKey the following rules apply:

- Inactive fields are ignored. Only active keys are scanned.
- When searching for a key, the first occurrence of the specified fields is selected. This means the following:
  - If you specify only one field as a parameter when you call SetCurrentKey, the key that is actually selected may consist of more than one field.
  - If the field that you specify is the first component of several keys, the key that is selected may not be the key that you expect.
  - If no keys can be found that include the fields that you specify, the return value is **false**. If you do not test the return value, a run-time error occurs. If you do test the return value, the program will continue to run even though no key was found.

SetCurrentKey, SetRange, SetFilter, GetRangeMin, and GetRangeMax Methods

Record.SetFilter Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Assigns a filter to a field that you specify.

Syntax

```
Record.SetFilter(Field: Any, String: String [, Value: Any,...])
```

Parameters

Record Type: Record An instance of the Record data type.

Field

Type: Any

The field that you want to filter.

String

Type: String

The filter expression. A valid expression consists of alphanumeric characters and one or more of the following operators: <, >, \, &, |, and =. You can use replacement fields (%1, %2, and so on) to insert values at run-time.

Value

Type: Any

Replacement values to insert in replacement fields in the filter expression. The data type of Value must match the data type of Field.

Remarks

`SetFilter` does not filter for empty values. For example, if you set `MyRecord.SetFilter(MyTextField, '');` no filter is applied.

Record.SetLoadFields Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 6.0.*

Sets the fields to be initially loaded when the record is retrieved from its data source. This will overwrite fields previously selected for initial load.

Syntax

```
[Ok := ]  Record.SetLoadFields([Fields: Any,...])
```

Parameters

Record Type: Record An instance of the Record data type.

Fields

Type: Any

The FieldNo's of the fields to be loaded.

Return Value

Ok Type: Boolean **true** if all fields are selected for subsequent loads; otherwise, **false**. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

Remarks

Calling SetLoadFields on a record without passing any fields will reset the fields selected to load to the default, where all readable normal fields are selected for load.

It is not necessary to include the following fields, because they are always selected for loading: Primary key, SystemId, and data audit fields (SystemCreatedAt, SystemCreatedBy, SystemModifiedAt, SystemModifiedBy).

This method is part of the partial records capability for improving performance. For more information, see Using Partial Records.

Example

This example uses the SetLoadFields method to speedup the calculation of the mean for values of the **Standard Cost** field in the **Item** table. Instead of loading all fields, only the **Standard Cost** is loaded. The other fields aren't needed for the calculation, so they're not loaded.

```
procedure ComputeArithmeticMean(): Decimal;
var
    Item: Record Item;
    SumTotal: Decimal;
    Counter: Integer;
begin
    Item.SetLoadFields(Item."Standard Cost");
    if Item.FindSet() then begin
        repeat
            SumTotal += Item."Standard Cost";
            Counter += 1;
        until Item.Next() = 0;
        exit(SumTotal / Counter);
    end;
end;
```

Record.SetPermissionFilter Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Applies the user's security filter.

Syntax

```
Record.SetPermissionFilter()
```

Parameters

Record Type: Record An instance of the Record data type.

See Also

Record.SetPosition Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Sets the fields in a primary key on a record to the values specified in the supplied string. The remaining fields are not changed.

Syntax

```
Record.SetPosition(String: String)
```

Parameters

Record Type: Record An instance of the Record data type.

String

Type: String

The string that is used to set the primary key. This string contains the primary key value to set.

See Also

Record Data Type
Getting Started with AL
Developing Extensions

Record.SetRange Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Sets a simple filter, such as a single range or a single value, on a field.

Syntax

```
Record.SetRange(Field: Any [, FromValue: Any] [, ToValue: Any])
```

Parameters

Record Type: Record An instance of the Record data type.

Field

Type: Any

The field that you want to filter.

FromValue

Type: Any

The lower limit of the range. The data type of this parameter must match the data type of Field.

ToValue

Type: Any

The upper limit of the range. If you omit this parameter, then the value that you specified for FromValue is used. The data type of this parameter must match the data type of Field.

Record.SetRecFilter Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Sets the values in the current key of the current record as a record filter.

Syntax

```
Record.SetRecFilter()
```

Parameters

Record Type: Record An instance of the Record data type.

Record.SetView Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Sets the current sort order, key, and filters on a table.

Syntax

```
Record.SetView(String: String)
```

Parameters

Record Type: Record An instance of the Record data type.

String
Type: String
A string that contains the sort order, key, and filter to set. The string format is the same as the SourceTableView Property on pages.

Record.TableCaption Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Gets the current caption of a table as a string.

Syntax

```
Caption :=   Record.TableCaption()
```

NOTE

This method can be invoked using property access syntax.

Parameters

Record Type: Record An instance of the Record data type.

Return Value

Caption Type: String

Record.TestField Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Tests whether the contents of a field match a given value.

Syntax

```
Record.TestField(Field: Any, Value: Boolean)
```

Parameters

Record Type: Record An instance of the Record data type.

Field

Type: Any

The field that you want to test.

Value

Type: Boolean

The value that you want to compare to Field. The data type of this parameter must match the data type of Field. If you include this optional parameter and the contents of Field do not match, then an error message is displayed. If you omit this parameter and the contents of Field is zero or blank (empty string), then an error message is displayed.

Record.TransferFields Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Copies all matching fields in one record to another record.

Syntax

```
Record.TransferFields(var FromRecord: Record [, InitPrimaryKeyFields: Boolean])
```

Parameters

Record Type: Record An instance of the Record data type.

FromRecord
Type: Record
The record from which to copy.

InitPrimaryKeyFields
Type: Boolean
Default: true If this parameter is true and the records are in the same table, both the timestamp and the Primary Key fields of the destination record will be changed. If this parameter is true and the records are not in the same table, then the Primary Key fields of the destination record will be changed but the timestamp of the destination record will not be changed. If this parameter is false, then neither the timestamp nor the Primary Key fields of the destination record are changed.

Record.TransferFields Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 4.2.*

Copies all matching fields in one record to another record.

Syntax

```
Record.TransferFields(var FromRecord: Record, InitPrimaryKeyFields: Boolean, SkipFieldsNotMatchingType:
Boolean)
```

Parameters

Record Type: Record An instance of the Record data type.

FromRecord
Type: Record
The record from which to copy.

InitPrimaryKeyFields
Type: Boolean
Default: true If this parameter is true and the records are in the same table, both the timestamp and the Primary Key fields of the destination record will be changed. If this parameter is true and the records are not in the same table, then the Primary Key fields of the destination record will be changed but the timestamp of the destination record will not be changed. If this parameter is false, then neither the timestamp nor the Primary Key fields of the destination record are changed.

SkipFieldsNotMatchingType
Type: Boolean
Specifies whether fields where the field type on the source record do not match the field type on the target record should be ignored.

Record.Validate Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Calls the OnValidate trigger for the field that you specify.

Syntax

```
Record.Validate(Field: Any [, NewValue: Any])
```

Parameters

Record Type: Record An instance of the Record data type.

Field

Type: Any

A field together with associated triggers.

NewValue

Type: Any

The value to insert into Field.

Record.WritePermission Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Determines whether a user can write to a table. This method can test for both full write permission and partial write permission that has been granted with a security filter. A write permission consists of Insert, Delete, and Modify permissions.

Syntax

```
Ok :=   Record.WritePermission()
```

NOTE

This method can be invoked using property access syntax.

Parameters

Record Type: Record An instance of the Record data type.

Return Value

Ok Type: Boolean

TaskScheduler Data Type

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Is a complex data type for creating and managing tasks in the task scheduler, which runs codeunits at scheduled times.

The following methods are available on the TaskScheduler data type.

METHOD NAME	DESCRIPTION
CancelTask(Guid)	Cancels and deletes a scheduled task that runs a specific codeunit.
CanCreateTask()	Checks whether it is possible to schedule tasks in this session.
CreateTask(Integer, Integer [, Boolean] [, String] [, DateTime] [, RecordId])	Adds a task to ensure that a codeunit is not run before the specified time.
SetTaskReady(Guid [, DateTime])	Sets a task that runs a codeunit to the ready state. The task will not run unless it is in the ready state.
TaskExists(Guid)	Checks whether a specific task exists.

See Also

Getting Started with AL
Developing Extensions

TaskScheduler.CancelTask Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Cancels and deletes a scheduled task that runs a specific codeunit.

Syntax

```
[Ok := ]  TaskScheduler.CancelTask(Task: Guid)
```

Parameters

Task

Type: Guid

Specifies the unique identifier of the task. The unique identifier is returned by the CreateTASK method.

Return Value

Ok Type: Boolean

Remarks

Scheduled tasks are recorded in table **2000000175 Scheduled Task**. CancelTask removes the task entry from the table.

CancelTask can only cancel pending tasks. It cannot cancel a task that is in process. To see an example of CancelTask in use, refer to AL code of table **472 Job Queue Entry**.

For more information about tasks and TaskScheduler data type methods, see managing tasks Task Scheduler.

TaskScheduler.CanCreateTask Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Checks whether it is possible to schedule tasks in this session.

Syntax

```
Ok :=   TaskScheduler.CanCreateTask()
```

Return Value

Ok Type: Boolean

See Also

TaskScheduler Data Type
Getting Started with AL
Developing Extensions

TaskScheduler.CreateTask Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Adds a task to ensure that a codeunit is not run before the specified time.

Syntax

```
[Task := ]  TaskScheduler.CreateTask(CodeunitId: Integer, FailureCodeunitId: Integer [, IsReady: Boolean] [,
Company: String] [, NotBefore: DateTime] [, RecordID: RecordId])
```

Parameters

CodeunitId

Type: Integer

Specifies the ID of the codeunit to run.

FailureCodeunitId

Type: Integer

Specifies the ID of the codeunit to run if the task fails. If you do not want to provide a failure codeunit, then use 0.

IsReady

Type: Boolean

Sets the task to the ready state. A task cannot run unless it is ready.

Company

Type: String

Specifies the company to run the task for. If you do not specify a company, the task will run in the user's current company.

NotBefore

Type: DateTime

Specifies the date and time that you want to run the task. When the task actually runs will depend on whether other tasks are running at the same time. The task will run the first opportunity on or after the date and time that you specify.

RecordID

Type: RecordId

Specifies the recordID of the record that you want to run the task on.

Return Value

Task Type: Guid

Remarks

Scheduled tasks are recorded in table **2000000175 Scheduled Task**. For more information about tasks and task scheduler, see managing tasks Task Scheduler.

Example

The following example schedules a task to run the **Job Queue Dispatcher** and uses codeunit **Job Queue Error Handler** as the failure codeunit.

```
var
    JobQueueEntry: Record "Job Queue Entry";
begin
    TaskScheduler.CreateTASK(CodeUnit::"Job Queue Dispatcher", CodeUnit::"Job Queue Error Handler", True,
CompanyName, CurrentDateTime + 1000 + Random(3000), JobQueueEntry.RecordID);
end;
```

TaskScheduler.SetTaskReady Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Sets a task that runs a codeunit to the ready state. The task will not run unless it is in the ready state.

Syntax

```
[Ok := ]  TaskScheduler.SetTaskReady(Task: Guid [, NotBefore: DateTime])
```

Parameters

Task
Type: Guid

NotBefore
Type: DateTime

Return Value

Ok Type: Boolean

Remarks

For more information about tasks and **TaskScheduler** data type methods, see managing tasks Task Scheduler.

Example

The following example creates a task, and then uses the SetTaskReady method to set the task to ready.

```
var
    TaskID: GUID;
begin
    TaskID := TaskScheduler.CreateTASK(CodeUnit::"Job Queue Dispatcher", CodeUnit::"Job Queue Error
Handler");
    TaskScheduler.SetTaskReady(taskID);
end;
```

TaskScheduler.TaskExists Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Checks whether a specific task exists.

Syntax

```
Exists :=   TaskScheduler.TaskExists(Task: Guid)
```

Parameters

Task

Type: Guid

The unique identifier of the task. The unique identifier is returned by the CreateTASK method.

Return Value

Exists Type: Boolean

Remarks

Scheduled tasks are recorded in table **2000000175 Scheduled Task**. To see an example of TaskExists in use, refer to AL code of table **472 Job Queue Entry**.

For more information about tasks and TaskScheduler data type methods, see managing tasks Task Scheduler.

TestField Data Type

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Represents a testable field on a page.

The following methods are available on instances of the TestField data type.

METHOD NAME	DESCRIPTION
Activate()	Activates a field on a test page.
AsBoolean()	Converts the value in a field on a test page to a Boolean data type.
AsDate()	Converts the value in a field on a test page to a Date data type.
AsDateTime()	Converts the value in a field on a test page to a DateTime data type.
AsDecimal()	Converts the value in a field on a test page to a Date data type.
AsInteger()	Converts the value of the field on a test page to an Integer data type.
AssertEquals(Any)	Asserts that the value in a field on a test page equals a specified value.
AssistEdit()	Provides assist-edit functionality to a field on a test page.
AsTime()	Converts the value in a field on a test page to a Time data type.
Caption()	Gets the current caption of the field as a String.
Drilldown()	Applies drill-down capability for a field on a test page.
Editable()	Gets the editable state for the field.
Enabled()	Gets the enabled state for the field.
GetOption([Integer])	Gets the options for a field on a test page.
GetValidationError([Integer])	Gets the validation error that occurred on a test page.
HideValue()	Gets the hide value state for the field.

METHOD NAME	DESCRIPTION
Invoke()	Invokes the default action on the field.
Lookup()	Provides a lookup window for a text box on a test page.
Lookup(RecordRef)	Calls the OnAfterLook trigger with the selected record
OptionCount()	Gets the number of options in a field on a test page.
SetValue(Any)	Sets a value for a field on a test page.
ShowMandatory()	Gets the ShowMandatory state for the field.
ValidationErrorCount()	Gets the number of validation errors that occurred on the test page.
Value([String])	Gets or sets the value of this field.
Visible()	Gets the visible state for the field.

TestField.Activate Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Activates a field on a test page.

Syntax

```
TestField.Activate()
```

Parameters

TestField Type: TestField An instance of the TestField data type.

See Also

TestField Data Type
Getting Started with AL
Developing Extensions

TestField.AsBoolean Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Converts the value in a field on a test page to a Boolean data type.

Syntax

```
Result :=   TestField.AsBoolean()
```

Parameters

TestField Type: TestField An instance of the TestField data type.

Return Value

Result Type: Boolean The value of the field as a Boolean.

TestField.AsDate Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Converts the value in a field on a test page to a Date data type.

Syntax

```
Result :=   TestField.AsDate()
```

Parameters

TestField Type: TestField An instance of the TestField data type.

Return Value

Result Type: Date The value of the field as a Date.

TestField.AsDateTime Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Converts the value in a field on a test page to a DateTime data type.

Syntax

```
Result :=   TestField.AsDateTime()
```

Parameters

TestField Type: TestField An instance of the TestField data type.

Return Value

Result Type: DateTime The value of the field as a DateTime.

See Also

TestField Data Type

TestField.AsDecimal Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Converts the value in a field on a test page to a Date data type.

Syntax

```
Result :=   TestField.AsDecimal()
```

Parameters

TestField Type: TestField An instance of the TestField data type.

Return Value

Result Type: Decimal The value of the field as a Decimal.

See Also

TestField.AsInteger Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Converts the value of the field on a test page to an Integer data type.

Syntax

```
Result :=   TestField.AsInteger()
```

Parameters

TestField Type: TestField An instance of the TestField data type.

Return Value

Result Type: Integer The value of the field as an Integer.

TestField.AssertEquals Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Asserts that the value in a field on a test page equals a specified value.

Syntax

```
TestField.AssertEquals(Value: Any)
```

Parameters

TestField Type: TestField An instance of the TestField data type.

Value
Type: Any
Specifies the value that the field should equal.

See Also

TestField Data Type

TestField.AssistEdit Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Provides assist-edit functionality to a field on a test page.

Syntax

```
TestField.AssistEdit()
```

Parameters

TestField Type: TestField An instance of the TestField data type.

See Also

TestField Data Type

TestField.AsTime Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Converts the value in a field on a test page to a Time data type.

Syntax

```
Result :=   TestField.AsTime()
```

Parameters

TestField Type: TestField An instance of the TestField data type.

Return Value

Result Type: Time The value of the field as a Time.

See Also

TestField Data Type
Getting Started with AL
Developing Extensions

TestField.Caption Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Gets the current caption of the field as a String.

Syntax

```
Result :=   TestField.Caption()
```

NOTE

This method can be invoked using property access syntax.

Parameters

TestField Type: TestField An instance of the TestField data type.

Return Value

Result Type: String The current caption of the field as a String.

Remarks

Caption returns the caption of a field. Caption first looks for a CaptionML Property.

If it does not find one, it will use the Name Property. This means that Caption is enabled for multilanguage functionality.

This method is similar to the FieldCaption Method (Record) method.

Example

The following example opens table 18 (Customer) as a RecordRef variable that is named CustomerRecref. The code uses the Field Method (RecordRef) to loop through field 1 through 9 and creates a FieldRef variable that is named MyFieldRef. For each field, the Caption method retrieves the caption of the field, stores it in the varCaption variable and displays it in a message box.

```
var
    CustomerRecRef: RecordRef;
    MyFieldRef: FieldRef;
    varCaption: Text;
    i: Integer;
    Text000: Label 'The caption for field %1 is "%2".';
begin
    CustomerRecref.Open(18);
    for i := 1 to 9 do begin
      MyFieldRef := CustomerRecref.Field(i);
      varCaption := MyFieldRef.Caption;
      Message(Text000, i, varCaption);
    end;
    CustomerRecref.Close;
end;
```

TestField.Editable Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Gets the editable state for the field.

Syntax

```
Result :=   TestField.Editable()
```

Parameters

TestField Type: TestField An instance of the TestField data type.

Return Value

Result Type: Boolean The editable state for the field.

TestField.Enabled Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Gets the enabled state for the field.

Syntax

```
Result :=   TestField.Enabled()
```

Parameters

TestField Type: TestField An instance of the TestField data type.

Return Value

Result Type: Boolean The enabled state for the field.

TestField.GetOption Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Gets the options for a field on a test page.

Syntax

```
Result :=   TestField.GetOption([Index: Integer])
```

Parameters

TestField Type: TestField An instance of the TestField data type.

Index
Type: Integer
The index of the field that you want to get the options from. This parameter is optional.

Return Value

Result Type: String The options for a field on a test page.

TestField.GetValidationError Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Gets the validation error that occurred on a test page.

Syntax

```
Result :=   TestField.GetValidationError([Index: Integer])
```

Parameters

TestField Type: TestField An instance of the TestField data type.

Index
Type: Integer
The index of the validation error that occurred on the test page.

Return Value

Result Type: String The validation error that occurred on a test page.

TestField.Lookup Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Provides a lookup window for a text box on a test page.

Syntax

```
TestField.Lookup()
```

Parameters

TestField Type: TestField An instance of the TestField data type.

See Also

TestField Data Type Getting Started with AL Developing Extensions

TestField.Lookup Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 7.0.*

Calls the OnAfterLook trigger with the selected record

Syntax

```
TestField.Lookup(Selected: RecordRef)
```

Parameters

TestField Type: TestField An instance of the TestField data type.

Selected

Type: RecordRef

Specifies the record that is selected during lookup.

TestField.ValidationErrorCount Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Gets the number of validation errors that occurred on the test page.

Syntax

```
Result :=   TestField.ValidationErrorCount()
```

Parameters

TestField Type: TestField An instance of the TestField data type.

Return Value

Result Type: Integer The number of validation errors that occurred on the test page.

See Also

TestField Data Type
Getting Started with AL
Developing Extensions

TestField.Value Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Gets or sets the value of this field.

Syntax

```
[Value := ]  TestField.Value([Value: String])
```

NOTE

This method can be invoked using property access syntax.

Parameters

TestField Type: TestField An instance of the TestField data type.

Value

Type: String

The new value to set for this field.

Return Value

Value Type: String The value of this field.

Remarks

If you omit NewValue, the method returns the current value of the field.

If you want to format the value of a FieldRef you must use `Format(FieldRef)` instead of `Format(FieldRef.Value)`.

Example

The following example opens table 18, the **Customer** table, a RecordRef variable that is named CustomerRecref. The Field Method (RecordRef) creates a FieldRef for the first field (No.). The reference to the field is stored in the MyFieldRef variable. The Active Method (FieldRef) method determines whether the field is enabled. If the field is enabled, then the record that is identified by the number in the CustomerNo variable is selected. The MyFieldRef variable is updated to refer to the second field (Name). Then the value in the second field is changed to Contoso. The Modify Method (RecordRef) modifies the record in the table to reflect the change. `MyFieldRef.Value` retrieves the new name and displays it in message box.

```
var
    CustomerRecRef: RecordRef;
    MyFieldRef: FieldRef;
    CustomerNo: Code;
    Text000: Label 'Customer name has changed to %1.';
begin
    CustomerNo := '50000';
    CustomerRecref.Open(18);
    MyFieldRef := CustomerRecref.Field(1);
    if MyFieldRef.Active then begin
      MyFieldRef.Value(CustomerNo);
      MyFieldRef := CustomerRecref.Field(2);
      MyFieldRef.Value('Contoso');
      CustomerRecref.Modify;
      Message(Text000, MyFieldRef.Value);
    end;
end;
```

TestFilter Data Type

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Represents a test filter on a page.

The following methods are available on instances of the TestFilter data type.

METHOD NAME	DESCRIPTION
Ascending([Boolean])	Gets or sets the order in which to search through a data set on a test page.
CurrentKey()	Gets the current key of a data set that is displayed on a test page.
GetFilter(TestFilterField)	Gets the filter that is applied to the specified field in a data set that is displayed on a test page.
SetCurrentKey(TestFilterField [, TestFilterField,...])	Sets the specified fields in a data set on a test page as the current key.
SetFilter(TestFilterField, String)	Applies a filter to the specified field on a test page.

TestFilter.Ascending Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Gets or sets the order in which to search through a data set on a test page.

Syntax

```
[Ascending := ]  TestFilter.Ascending([Value: Boolean])
```

> **NOTE**
> This method can be invoked using property access syntax.

Parameters

TestFilter Type: TestFilter An instance of the TestFilter data type.

Value
Type: Boolean
Sets the order in which to search through a data set on a test page.

Return Value

Ascending Type: Boolean

See Also

TestFilter.CurrentKey Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Gets the current key of a data set that is displayed on a test page.

Syntax

```
CurrentKey :=   TestFilter.CurrentKey()
```

NOTE

This method can be invoked using property access syntax.

Parameters

TestFilter Type: TestFilter An instance of the TestFilter data type.

Return Value

CurrentKey Type: String

See Also

TestFilter.GetFilter Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Gets the filter that is applied to the specified field in a data set that is displayed on a test page.

Syntax

```
String :=   TestFilter.GetFilter(Field: TestFilterField)
```

Parameters

TestFilter Type: TestFilter An instance of the TestFilter data type.

Field
Type: TestFilterField
The field that you want to get the filter from.

Return Value

String Type: String

See Also

TestFilter.SetCurrentKey Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Sets the specified fields in a data set on a test page as the current key.

Syntax

```
[Ok := ]  TestFilter.SetCurrentKey(Field1: TestFilterField [, Field2: TestFilterField,...])
```

Parameters

TestFilter Type: TestFilter An instance of the TestFilter data type.

Field1
Type: TestFilterField
The field that you want to set as the current key.

Field2
Type: TestFilterField
Additional field that you want to set as the current key. This parameter is optional.

Return Value

Ok Type: Boolean **true** if the operation was successful; otherwise **false**. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

TestFilter.SetFilter Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Applies a filter to the specified field on a test page.

Syntax

```
TestFilter.SetFilter(Field: TestFilterField, String: String)
```

Parameters

TestFilter Type: TestFilter An instance of the TestFilter data type.

Field

Type: TestFilterField

The field that you want to apply the filter to.

String

Type: String

The filter to apply to the specified field.

TestPage Data Type

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Represents a variable type that can be used to test Page Application Objects.

The following methods are available on instances of the TestPage data type.

METHOD NAME	DESCRIPTION
Cancel()	Gets the Cancel system action.
Caption()	Gets the caption of the test page.
Close()	Closes an open test page.
Edit()	Gets the Edit system action.
Editable()	Gets the runtime value of the Editable property on a test page.
Expand(Boolean)	Expands rows on a test page.
FindFirstField(TestField, Any)	Finds the first field in the data set that is displayed on a test page.
FindNextField(TestField, Any)	Finds the next field in the data set that is displayed on a test page.
FindPreviousField(TestField, Any)	Finds the previous field in the data set that is displayed on a test page.
First()	Sets the current row of the test page as the first row in the data set.
GetField(Integer)	Gets a field on a test page.
GetValidationError([Integer])	Gets the list of all validation error that occurred on a test page as a string.
GoToKey([Any,...])	Finds the row in a data set on the test page that is identified by the specified values.
GoToRecord(Record)	Finds the specified record in a data set on a test page.
IsExpanded()	Specifies if rows on a test page are expanded.
Last()	Sets the current row of the test page as the last row in the data set.

METHOD NAME	DESCRIPTION
New()	Sets the current row of the test page to an empty row in a data set.
Next()	Sets the current row of the test page as the next row in the data set.
No()	Gets the No system action.
OK()	Gets the OK system action.
OpenEdit()	Opens a test page in edit mode.
OpenNew()	Opens a blank test page in edit mode.
OpenView()	Opens a test page in view mode.
Prev()	Sets the current row of the test page as the previous row in the data set.
Previous()	Sets the current row of the test page as the previous row in the data set.
RunPageBackgroundTask(Integer [, var Dictionary of [Text, Text]] [, Boolean])	Runs the page background task codeunit in the current session. Note that by default, no triggers are invoked at this point.
Trap()	Traps the next test page that is invoked and assigns it to the test page variable.
ValidationErrorCount()	Gets the number of validation errors that occurred on the test page.
View()	Gets the View system action.
Yes()	Gets the Yes system action.

TestPage.Cancel Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Gets the Cancel system action.

Syntax

```
Action :=   TestPage.Cancel()
```

Parameters

TestPage Type: TestPage An instance of the TestPage data type.

Return Value

Action Type: TestAction The Cancel system action.

See Also

TestPage Data Type
Getting Started with AL
Developing Extensions

TestPage.Caption Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Gets the caption of the test page.

Syntax

```
String :=   TestPage.Caption()
```

> **NOTE**
> This method can be invoked using property access syntax.

Parameters

TestPage Type: TestPage An instance of the TestPage data type.

Return Value

String Type: String The caption of the test page.

See Also

TestPage Data Type
Getting Started with AL
Developing Extensions

TestPage.Close Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Closes an open test page.

Syntax

```
TestPage.Close()
```

Parameters

TestPage Type: TestPage An instance of the TestPage data type.

Remarks

If *TestPage* has never been opened or is already closed, then a run-time error occurs, and the outcome of the test method is FAILURE.

Example

This example requires that you create a TestPage variable named CustTestPage with a Subtype of Customer List and that the codeunit in which you write the code is a test codeunit.

```
// Open the test page.
CustPage.OpenEdit;
// Add code to test the Customer List page.
// …
// Close the Customer Card
CustPage.Close;
```

TestPage.Edit Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Gets the Edit system action.

Syntax

```
Action :=   TestPage.Edit()
```

Parameters

TestPage Type: TestPage An instance of the TestPage data type.

Return Value

Action Type: TestAction The Edit system action.

See Also

TestPage Data Type

TestPage.Editable Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Gets the runtime value of the Editable property on a test page.

Syntax

```
Editable :=   TestPage.Editable()
```

NOTE

This method can be invoked using property access syntax.

Parameters

TestPage Type: TestPage An instance of the TestPage data type.

Return Value

Editable Type: Boolean The runtime value of the Editable property on the test page.

See Also

TestPage Data Type

TestPage.Expand Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Expands rows on a test page.

Syntax

```
TestPage.Expand(Expand: Boolean)
```

Parameters

TestPage Type: TestPage An instance of the TestPage data type.

Expand
Type: Boolean
The rows that you want to expand on the test page.

See Also

TestPage.FindFirstField Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Finds the first field in the data set that is displayed on a test page.

Syntax

```
[Ok := ]  TestPage.FindFirstField(Field: TestField, Value: Any)
```

Parameters

TestPage Type: TestPage An instance of the TestPage data type.

Field
Type: TestField
The field to find.

Value
Type: Any
The value of the field.

Return Value

Ok Type: Boolean **true** if the operation was successful; otherwise **false**. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

TestPage.FindNextField Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Finds the next field in the data set that is displayed on a test page.

Syntax

```
[Ok := ]  TestPage.FindNextField(Field: TestField, Value: Any)
```

Parameters

TestPage Type: TestPage An instance of the TestPage data type.

Field
Type: TestField
The field to find.

Value
Type: Any
The value of the field.

Return Value

Ok Type: Boolean **true** if the operation was successful; otherwise **false**. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

See Also

TestPage Data Type

TestPage.FindPreviousField Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Finds the previous field in the data set that is displayed on a test page.

Syntax

```
[Ok := ]  TestPage.FindPreviousField(Field: TestField, Value: Any)
```

Parameters

TestPage Type: TestPage An instance of the TestPage data type.

Field
Type: TestField
The field to find.

Value
Type: Any
The value of the field.

Return Value

Ok Type: Boolean **true** if the operation was successful; otherwise **false**. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

TestPage.First Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Sets the current row of the test page as the first row in the data set.

Syntax

```
[Ok := ]  TestPage.First()
```

Parameters

TestPage Type: TestPage An instance of the TestPage data type.

Return Value

Ok Type: Boolean **true** if the current row has changed, otherwise **false**.

Remarks

If *TestPage* is closed or has never been opened, then the method call fails.

Example

This example sets the current row to the first customer in the dataset. It requires that you create a TestPage variable named CustomerList with a Subtype of Customer List.

```
CustomerList.OpenView;
CustomerList.First;
Message(CustomerList.Name.Value);
```

TestPage.GetField Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 3.0 until version 3.0 where it was deprecated.*

Gets a field on a test page.

Syntax

```
TestField :=   TestPage.GetField(Id: Integer)
```

Parameters

TestPage Type: TestPage An instance of the TestPage data type.

Id

Type: Integer

The ID of the field that you want to get.

Return Value

TestField Type: TestField The field on the test page.

See Also

TestPage Data Type

TestPage.GetValidationError Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Gets the list of all validation error that occurred on a test page as a string.

Syntax

```
Error :=   TestPage.GetValidationError([Index: Integer])
```

Parameters

TestPage Type: TestPage An instance of the TestPage data type.

Index
Type: Integer
The index of the validation error that occurred on the test page.

Return Value

Error Type: String A string where each line represents a validation error that occured on the test page.

See Also

TestPage Data Type
Getting Started with AL
Developing Extensions

TestPage.GoToKey Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Finds the row in a data set on the test page that is identified by the specified values.

Syntax

```
[Ok := ]  TestPage.GoToKey([Value: Any,...])
```

Parameters

TestPage Type: TestPage An instance of the TestPage data type.

Value
Type: Any
The value or list of values to use to find the row. If this parameter is omitted, the value of the primary key that is defined for the underlying table is used.

Return Value

Ok Type: Boolean **true** if the operation was successful; otherwise **false**. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

Remarks

The GoToKey method loops over all records until it finds the identifies row. For each record, the OnAfterGetCurrentRecord Trigger is executed.

TestPage.GoToRecord Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Finds the specified record in a data set on a test page.

Syntax

```
[Ok := ]  TestPage.GoToRecord(Rec: Record)
```

Parameters

TestPage Type: TestPage An instance of the TestPage data type.

Rec
Type: Record
The record to find.

Return Value

Ok Type: Boolean **true** if the operation was successful; otherwise **false**. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

Remarks

The GoToRecord method loops over all records until it finds the identifies record. For each record, the OnAfterGetCurrentRecord Trigger is executed.

TestPage.IsExpanded Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Specifies if rows on a test page are expanded.

Syntax

```
Expanded :=   TestPage.IsExpanded()
```

NOTE

This method can be invoked using property access syntax.

Parameters

TestPage Type: TestPage An instance of the TestPage data type.

Return Value

Expanded Type: Boolean **true** if the rows on the test page are expanded, otherwise **false**.

See Also

TestPage Data Type
Getting Started with AL
Developing Extensions

TestPage.Last Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Sets the current row of the test page as the last row in the data set.

Syntax

```
[Ok := ]  TestPage.Last()
```

Parameters

TestPage Type: TestPage An instance of the TestPage data type.

Return Value

Ok Type: Boolean **true** if the current row has changed, otherwise **false**.

Remarks

If *TestPage* is closed or has never been opened, then the method call fails.

The Last method loops over all records until it sets the identifies the current record. For each record, the OnAfterGetCurrentRecord Trigger is executed.

Example

This example sets the current row to the last customer in the dataset. It requires that you create a TestPage variable named CustomerList with a Subtype of Customer List.

```
CustomerList.OpenView;
CustomerList.Last;
Message(CustomerList.Name.Value);
```

TestPage.New Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Sets the current row of the test page to an empty row in a data set.

Syntax

```
TestPage.New()
```

Parameters

TestPage Type: TestPage An instance of the TestPage data type.

See Also

TestPage Data Type
Getting Started with AL
Developing Extensions

TestPage.Next Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Sets the current row of the test page as the next row in the data set.

Syntax

```
[Ok := ]  TestPage.Next()
```

Parameters

TestPage Type: TestPage An instance of the TestPage data type.

Return Value

Ok Type: Boolean **true** if the current row has changed, otherwise **false**.

Remarks

If *TestPage* is closed or has never been opened, then the method call fails.

Example

This example requires that you create a TestPage variable named CustomerList with a Subtype of Customer List.

```
CustomerList.OpenView;
// Loops through all customers and displays the customer name.
if CustomerList.First then
  repeat
    Message('%1';CustomerList.Name);
until not CustomerList.NEXT;
```

TestPage.No Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Gets the No system action.

Syntax

```
Action :=   TestPage.No()
```

Parameters

TestPage Type: TestPage An instance of the TestPage data type.

Return Value

Action Type: TestAction The No system action.

See Also

TestPage.OK Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Gets the OK system action.

Syntax

```
Action :=   TestPage.OK()
```

Parameters

TestPage Type: TestPage An instance of the TestPage data type.

Return Value

Action Type: TestAction The OK system action.

See Also

TestPage.OpenEdit Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Opens a test page in edit mode.

Syntax

```
TestPage.OpenEdit()
```

Parameters

TestPage Type: TestPage An instance of the TestPage data type.

Remarks

If *TestPage* is already open, then a run-time error occurs, and the outcome of the test method is FAILURE.

If the page to which *TestPage* refers is a card page, then the data that is loaded on the page is from the first row in the dataset.

Example

This example requires that you create a TestPage variable named CustTestPage with a Subtype of Customer List and that the codeunit in which you write the code is a test codeunit.

```
// Opens the TestPage in edit mode.
CustTestPage.OpenEdit()
```

TestPage.OpenNew Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Opens a blank test page in edit mode.

Syntax

```
TestPage.OpenNew()
```

Parameters

TestPage Type: TestPage An instance of the TestPage data type.

Remarks

If *TestPage* is already open, then a run-time error occurs, and the outcome of the test method is FAILURE.

Example

This example requires that you create a TestPage variable named CustTestPage with a Subtype of Customer List and that the codeunit in which you write the code is a test codeunit.

```
// Opens a blank Customer Card test page.
CustTestPage.OpenNEW;
```

TestPage.OpenView Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Opens a test page in view mode.

Syntax

```
TestPage.OpenView()
```

Parameters

TestPage Type: TestPage An instance of the TestPage data type.

Remarks

If *TestPage* is already open, then a run-time error occurs, and the outcome of the test method is FAILURE.

If the page to which *TestPage* refers is a card page, then the data that is loaded on the page is from the first row in the dataset.

Example

This example requires that you create a variable named CustTestPage with a Subtype of Customer List and that the codeunit in which you write the code is a test codeunit.

```
// Opens the Customer Card on the first Customer in the dataset.
CustTestPage.OpenView;
```

TestPage.Prev Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 3.0 until version 3.0 where it was deprecated.*

Sets the current row of the test page as the previous row in the data set.

Syntax

```
[Ok := ]  TestPage.Prev()
```

Parameters

TestPage Type: TestPage An instance of the TestPage data type.

Return Value

Ok Type: Boolean **true** if the current row has changed, otherwise **false**.

See Also

TestPage.Previous Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Sets the current row of the test page as the previous row in the data set.

Syntax

```
[Ok := ]  TestPage.Previous()
```

Parameters

TestPage Type: TestPage An instance of the TestPage data type.

Return Value

Ok Type: Boolean **true** if the current row has changed, otherwise **false**.

Remarks

If *TestPage* is closed or has never been opened, then the method call fails.

Example

This example requires that you create a TestPage variable named CustomerList with a Subtype of Customer List.

```
CustomerList.OpenView;
…
if CustomerList.Last then repeat
  Message(CustomerList.Name);
until not CustomerList.Previous;
```

TestPage.RunPageBackgroundTask Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 4.0.*

Runs the page background task codeunit in the current session. Note that by default, no triggers are invoked at this point.

Syntax

```
Results :=   TestPage.RunPageBackgroundTask(CodeunitId: Integer [, var Parameters: Dictionary of [Text, Text]] [, RunCompletionTriggers: Boolean])
```

Parameters

TestPage Type: TestPage An instance of the TestPage data type.

CodeunitId
Type: Integer
Specifies the ID of the codeunit to run.
Parameters
Type: Dictionary of [Text, Text]
Specifies a collection of keys and values that are passed to the OnRun trigger of the codeunit that runs when the page background task session is started.
RunCompletionTriggers
Type: Boolean
Runs the completion triggers after the completion of the code unit. Default value is **false**.

Return Value

Results Type: Dictionary of [Text, Text] The dictionary of results for the page background task.

TestPage.Trap Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Traps the next test page that is invoked and assigns it to the test page variable.

Syntax

```
TestPage.Trap()
```

Parameters

TestPage Type: TestPage An instance of the TestPage data type.

Remarks

Only non-modal pages can be trapped.

TestPart Data Type

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Represents a variable type that can be used to test Page Application Objects of type Part.

The following methods are available on instances of the TestPart data type.

METHOD NAME	DESCRIPTION
Caption()	Gets the caption of the test page.
Editable()	Gets the runtime value of the Editable property on a test page.
Expand(Boolean)	Expands rows on a test page.
FindFirstField(TestField, Any)	Finds the first field in the data set that is displayed on a test page.
FindNextField(TestField, Any)	Finds the next field in the data set that is displayed on a test page.
FindPreviousField(TestField, Any)	Finds the previous field in the data set that is displayed on a test page.
First()	Sets the current row of the test page as the first row in the data set.
GetField(Integer)	Gets a field on a test page.
GetValidationError([Integer])	Gets the list of all validation error that occurred on a test page as a string.
GoToKey([Any,...])	Finds the row in a data set on the test page that is identified by the specified values.
GoToRecord(Record)	Finds the specified record in a data set on a test page.
IsExpanded()	Specifies if the current row on the test page is expanded.
Last()	Sets the current row of the test page as the last row in the data set.
New()	Sets the current row of the test page to an empty row in a data set.
Next()	Sets the current row of the test page as the next row in the data set.

METHOD NAME	DESCRIPTION
Prev()	Sets the current row of the test page as the previous row in the data set.
Previous()	Sets the current row of the test page as the previous row in the data set.
ValidationErrorCount()	Gets the number of validation errors that occurred on the test page.

TestPart.FindFirstField Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Finds the first field in the data set that is displayed on a test page.

Syntax

```
[Ok := ]  TestPart.FindFirstField(Field: TestField, Value: Any)
```

Parameters

TestPart Type: TestPart An instance of the TestPart data type.

Field
Type: TestField
The field to find.
Value
Type: Any
The value of the field.

Return Value

Ok Type: Boolean **true** if the operation was successful; otherwise **false**. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

TestPart.FindNextField Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Finds the next field in the data set that is displayed on a test page.

Syntax

```
[Ok := ]  TestPart.FindNextField(Field: TestField, Value: Any)
```

Parameters

TestPart Type: TestPart An instance of the TestPart data type.

Field
Type: TestField
The field to find.
Value
Type: Any
The value of the field.

Return Value

Ok Type: Boolean **true** if the operation was successful; otherwise **false**. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

TestPart.FindPreviousField Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Finds the previous field in the data set that is displayed on a test page.

Syntax

```
[Ok := ]  TestPart.FindPreviousField(Field: TestField, Value: Any)
```

Parameters

TestPart Type: TestPart An instance of the TestPart data type.

Field
Type: TestField
The field to find.
Value
Type: Any
The value of the field.

Return Value

Ok Type: Boolean **true** if the operation was successful; otherwise **false**. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

TestPart.GetField Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 3.0 until version 3.0 where it was deprecated.*

Gets a field on a test page.

Syntax

```
TestField :=   TestPart.GetField(Id: Integer)
```

Parameters

TestPart Type: TestPart An instance of the TestPart data type.

Id

Type: Integer

The ID of the field that you want to get.

Return Value

TestField Type: TestField The field on the test page.

See Also

TestPart.GetValidationError Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Gets the list of all validation error that occurred on a test page as a string.

Syntax

```
Error :=   TestPart.GetValidationError([Index: Integer])
```

Parameters

TestPart Type: TestPart An instance of the TestPart data type.

Index
Type: Integer
The index of the validation error that occurred on the test page.

Return Value

Error Type: String A string where each line represents a validation error that occured on the test page.

See Also

TestPart.GoToKey Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Finds the row in a data set on the test page that is identified by the specified values.

Syntax

```
[Ok := ]  TestPart.GoToKey([Value: Any,...])
```

Parameters

TestPart Type: TestPart An instance of the TestPart data type.

Value
Type: Any
The value or list of values to use to find the row. If this parameter is omitted, the value of the primary key that is defined for the underlying table is used.

Return Value

Ok Type: Boolean **true** if the operation was successful; otherwise **false**. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

TestRequestPage Data Type

2/17/2021 • 3 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Stores test request pages. A test request page part is a logical representation of a request page on a report. A test request page does not display a user interface (UI). The subtype of a test request page is the report whose request page you want to test.

The following methods are available on instances of the TestRequestPage data type.

METHOD NAME	DESCRIPTION
Cancel()	Gets a TestAction representing an action on the Page under Test.
Caption()	Gets the caption of the test page.
Editable()	Gets the runtime value of the Editable property on a test page.
Expand(Boolean)	Expands rows on a test page.
FindFirstField(TestField, Any)	Finds the first field in the data set that is displayed on a test page. The row is searched from the beginning of the dataset defined by the current filter. The search is performed by iterating across the rows, comparing the primary key with the primary key fields of the record. For large dataset, use SetFilter to limit the dataset.
FindNextField(TestField, Any)	Finds the next field in the data set that is displayed on a test page.The row is searched from the beginning of the dataset defined by the current filter. The search is performed by iterating across the rows, comparing the primary key with the primary key fields of the record. For large dataset, use SetFilter to limit the dataset.
FindPreviousField(TestField, Any)	Finds the previous field in the data set that is displayed on a test page. The row is searched from the beginning of the dataset defined by the current filter. The search is performed by iterating across the rows, comparing the primary key with the primary key fields of the record. For large dataset, use SetFilter to limit the dataset.
First()	Sets the current row of the test page as the first row in the data set.
GetValidationError([Integer])	Gets the validation error that occurred on a test page.

METHOD NAME	DESCRIPTION
GoToKey([Any,...])	Finds the row in a data set on the test page that is identified by the specified values. The key is searched from the beginning of the dataset defined by the current filter. The search is performed by iterating across the rows, comparing the primary key with the primary key fields of the record. For large dataset, use SetFilter to limit the dataset.
GoToRecord(Record)	Finds the specified record in a data set on a test page. The record is searched from the beginning of the dataset defined by the current filter. The search is performed by iterating across the rows, comparing the primary key with the primary key fields of the record. For large dataset, use SetFilter to limit the dataset.
IsExpanded()	Specifies if rows on a test page are expanded.
Last()	Sets the current row of the test page as the last row in the data set.
New()	Sets the current row of the test page to an empty row in a data set.
Next()	Sets the current row of the test page as the next row in the data set.
OK()	Gets a TestAction representing an action on the Page under Test.
Preview()	Gets a TestAction representing an action on the Page under Test.
Previous()	Sets the current row of the test page as the previous row in the data set.
Print()	Gets a the Print representing an action on the Page under Test.
SaveAsExcel(String)	Saves a report as a Microsoft Excel (.xls) file.
SaveAsPdf(String)	Saves a report as an Adobe Acrobat (.pdf) file.
SaveAsWord(String)	Saves a report as a Microsoft Word (.doc) file.
SaveAsXml(String, String)	Saves a report data set and the labels on a report as two XML (.xml) files.
Schedule()	Gets a TestAction representing an action on the Page under Test.
ValidationErrorCount()	Gets the number of validation errors that occurred on the test page.

TestRequestPage.Expand Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Expands rows on a test page.

Syntax

```
TestRequestPage.Expand(Expand: Boolean)
```

Parameters

TestRequestPage Type: TestRequestPage An instance of the TestRequestPage data type.

Expand
Type: Boolean
The rows that you want to expand on the test page.

TestRequestPage.FindFirstField Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Finds the first field in the data set that is displayed on a test page. The row is searched from the beginning of the dataset defined by the current filter. The search is performed by iterating across the rows, comparing the primary key with the primary key fields of the record. For large dataset, use SetFilter to limit the dataset.

Syntax

```
[Ok := ]  TestRequestPage.FindFirstField(Field: TestField, Value: Any)
```

Parameters

TestRequestPage Type: TestRequestPage An instance of the TestRequestPage data type.

Field
Type: TestField
The field to find.

Value
Type: Any
The value of the field.

Return Value

Ok Type: Boolean **true** if the row is found, otherwise **false**. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

TestRequestPage.FindNextField Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Finds the next field in the data set that is displayed on a test page.The row is searched from the beginning of the dataset defined by the current filter. The search is performed by iterating across the rows, comparing the primary key with the primary key fields of the record. For large dataset, use SetFilter to limit the dataset.

Syntax

```
[Ok := ]  TestRequestPage.FindNextField(Field: TestField, Value: Any)
```

Parameters

TestRequestPage Type: TestRequestPage An instance of the TestRequestPage data type.

Field
Type: TestField
The field to find.
Value
Type: Any
The value of the field.

Return Value

Ok Type: Boolean **true** if the row is found, otherwise **false**. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

TestRequestPage.FindPreviousField Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Finds the previous field in the data set that is displayed on a test page. The row is searched from the beginning of the dataset defined by the current filter. The search is performed by iterating across the rows, comparing the primary key with the primary key fields of the record. For large dataset, use SetFilter to limit the dataset.

Syntax

```
[Ok := ]  TestRequestPage.FindPreviousField(Field: TestField, Value: Any)
```

Parameters

TestRequestPage Type: TestRequestPage An instance of the TestRequestPage data type.

Field
Type: TestField
The field to find.

Value
Type: Any
The value of the field.

Return Value

Ok Type: Boolean **true** if the row is found, otherwise **false**. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

TestRequestPage.First Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Sets the current row of the test page as the first row in the data set.

Syntax

```
[Ok := ]  TestRequestPage.First()
```

Parameters

TestRequestPage Type: TestRequestPage An instance of the TestRequestPage data type.

Return Value

Ok Type: Boolean **true** if a first row is present, otherwise **false**.Throws a NavTestPageNotOpenedException if the page is not opened.

TestRequestPage.GetValidationError Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Gets the validation error that occurred on a test page.

Syntax

```
Error :=   TestRequestPage.GetValidationError([Index: Integer])
```

Parameters

TestRequestPage Type: TestRequestPage An instance of the TestRequestPage data type.

Index

Type: Integer

The index of the validation error that occurred on the test page.

Return Value

Error Type: String The validation error that occured at the specified index.

TestRequestPage.GoToKey Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Finds the row in a data set on the test page that is identified by the specified values. The key is searched from the beginning of the dataset defined by the current filter. The search is performed by iterating across the rows, comparing the primary key with the primary key fields of the record. For large dataset, use SetFilter to limit the dataset.

Syntax

```
[Ok := ]  TestRequestPage.GoToKey([Value: Any,...])
```

Parameters

TestRequestPage Type: TestRequestPage An instance of the TestRequestPage data type.

Value
Type: Any
The value or list of values to use to find the row. If this parameter is omitted, the value of the primary key that is defined for the underlying table is used.

Return Value

Ok Type: Boolean **true** if the key is found, otherwise **false**. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

TestRequestPage.GoToRecord Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Finds the specified record in a data set on a test page. The record is searched from the beginning of the dataset defined by the current filter. The search is performed by iterating across the rows, comparing the primary key with the primary key fields of the record. For large dataset, use SetFilter to limit the dataset.

Syntax

```
[Ok := ]  TestRequestPage.GoToRecord(Rec: Record)
```

Parameters

TestRequestPage Type: TestRequestPage An instance of the TestRequestPage data type.

Rec
Type: Record
The record to find.

Return Value

Ok Type: Boolean **true** if the record is found, otherwise **false**. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

TestRequestPage.IsExpanded Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Specifies if rows on a test page are expanded.

Syntax

```
Expanded :=   TestRequestPage.IsExpanded()
```

NOTE

This method can be invoked using property access syntax.

Parameters

TestRequestPage Type: TestRequestPage An instance of the TestRequestPage data type.

Return Value

Expanded Type: Boolean **true** if the rows on the test page are expanded, otherwise **false**.

TestRequestPage.Last Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Sets the current row of the test page as the last row in the data set.

Syntax

```
[Ok := ]  TestRequestPage.Last()
```

Parameters

TestRequestPage Type: TestRequestPage An instance of the TestRequestPage data type.

Return Value

Ok Type: Boolean **true** if a last row is present, otherwise **false**. Throws a NavTestPageNotOpenedException if the page is not opened.

TestRequestPage.SaveAsExcel Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Saves a report as a Microsoft Excel (.xls) file.

> **NOTE**
> This method is supported only in Business Central on-premises.

Syntax

```
TestRequestPage.SaveAsExcel(FileName: String)
```

Parameters

TestRequestPage Type: TestRequestPage An instance of the TestRequestPage data type.

FileName
Type: String
The path and file name to which the report is saved. The file name extension should be .xls.

Remarks

All filters and options that have been set on the TestRequestPage are respected in the saved report.

After you run this method, you cannot continue to interact with the *TestRequestPage*. If you want to continue to use the *TestRequestPage* variable, you must run a report again.

Example

The following example shows the code for a test method to run a report and a request page handler method to test the request page. This example requires that you create the following:

- A test codeunit called SaveAsExcel.
- A test method in the test codeunit called TestSaveAsExcel.
- A handler method of type RequestPageHandler called ReqPageHandler. This handler method has one parameter called RequestPage of Type TestRequestPage and Subtype Customer – Top 10 List. The RequestPage parameter is specified as VAR and is passed by reference to the handler method.

```
var
    Filename: Text;
begin
    //Test method: TestSaveAsExcel
    Filename := TemporaryPath + 'MyRep.xls';
    Message(Filename);
    if not File.Erase(Filename) then
      Error('Cannot erase %1',Filename);
    Report.Run(111);
    if not File.Exists(Filename) then
      Error('File should exist!');

    //Request Page Handler method
    RequestPage.Customer.SetFilter("No.", '20000');
    RequestPage.ChartType.Value('Pie chart');
    RequestPage.SaveAsExcel(Filename);
end;
```

TestRequestPage.SaveAsPdf Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Saves a report as an Adobe Acrobat (.pdf) file.

> **NOTE**
> This method is supported only in Business Central on-premises.

Syntax

```
TestRequestPage.SaveAsPdf(FileName: String)
```

Parameters

TestRequestPage Type: TestRequestPage An instance of the TestRequestPage data type.

FileName
Type: String
The path and file name to which the report is saved. The file name extension should be .pdf.

Remarks

All filters and options that have been set on the TestRequestPage are respected in the saved report.

After you run this method, you cannot continue to interact with the *TestRequestPage*. If you want to continue to use the *TestRequestPage* variable, you must run a report again.

Example

The following example shows the code for a test method to run a report and a request page handler method to test the request page. This example requires that you create the following:

- A test codeunit called SaveAsPDF.
- A test method in the test codeunit called TestSaveAsPDF.
- A handler method of type RequestPageHandler called ReqPageHandler. This handler method has one parameter called RequestPage of Type TestRequestPage and Subtype Customer – Top 10 List. The RequestPage parameter is specified as VAR and is passed by reference to the handler method.

```
var
    Filename: Text;
begin
    //Test method: TestSaveAsPDF
    Filename := TemporaryPath + 'MyRep.pdf';
    Message(Filename);
    if not File.Erase(Filename) then
      Error('Cannot erase %1',Filename);
    Report.Run(111);
    if not File.Exists(Filename) then
      Error('File should exist!');

    //Request Page Handler method
    RequestPage.Customer.SetFilter("No.", '20000');
    RequestPage.ChartType.Value('Pie chart');
    RequestPage.SaveAsPDF(Filename);
end;
```

TestRequestPage.SaveAsWord Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Saves a report as a Microsoft Word (.doc) file.

> **NOTE**
> This method is supported only in Business Central on-premises.

Syntax

```
TestRequestPage.SaveAsWord(FileName: String)
```

Parameters

TestRequestPage Type: TestRequestPage An instance of the TestRequestPage data type.

FileName
Type: String
The path and file name to which the report is saved. The file name extension should be .doc.

Remarks

All filters and options that have been set on the TestRequestPage are respected in the saved report.

After you run this method, you cannot continue to interact with the *TestRequestPage*. If you want to continue to use the *TestRequestPage* variable, you must run a report again.

Example

The following example shows the code for a test method to run a report and a request page handler method to test the request page. This example requires that you create the following:

- A test codeunit called SaveAsWord.
- A test method in the test codeunit called TestSaveAsWord.
- A handler method of type RequestPageHandler called ReqPageHandler. This handler method has one parameter called RequestPage of Type TestRequestPage and Subtype Customer – Top 10 List. The RequestPage parameter is specified as VAR and is passed by reference to the handler method.

```
var
    Filename: Text;
begin
    //Test method: TestSaveAsWord
    Filename := TemporaryPath + 'MyRep.doc';
    Message(Filename);
    if not File.Erase(Filename) then
      Error('Cannot erase %1',Filename);
    Report.Run(111);
    if not File.Exists(Filename) then
      Error('File should exist!');

    //Request Page Handler method
    RequestPage.Customer.SetFilter("No.", '20000');
    RequestPage.ChartType.Value('Pie chart');
    RequestPage.SaveAsExcel(Filename);
end;
```

TestRequestPage.SaveAsXml Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Saves a report data set and the labels on a report as two XML (.xml) files.

> **NOTE**
> This method is supported only in Business Central on-premises.

Syntax

```
TestRequestPage.SaveAsXml(ParameterFileName: String, DataSetFileName: String)
```

Parameters

TestRequestPage Type: TestRequestPage An instance of the TestRequestPage data type.

ParameterFileName
Type: String
The path and file name to which the paramater file is saved.

DataSetFileName
Type: String
The path and file name to which the data set file is saved.

Remarks

All filters and options that have been set on the TestRequestPage are respected in the saved report.

After you run this method, you cannot continue to interact with the *TestRequestPage*. If you want to continue to use the *TestRequestPage* variable, you must run a report again.

Example

The following example shows the code for a test method to run a report and a request page handler method to test the request page. This example requires that you create the following:

- A test codeunit called SaveAsXML.
- A test method in the test codeunit called TestSaveAsXML.
- A handler method of type RequestPageHandler called ReqPageHandler. This handler method has one parameter called RequestPage of Type TestRequestPage and Subtype Customer – Top 10 List. The RequestPage parameter is specified as VAR and is passed by reference to the handler method.

```
var
    LabelsFilename: Text;
    DatasetFilename: Text;
begin
    // Add the following code to the TestSaveAsXML test method.
    LabelsFilename := TemporaryPath + 'MyLabels.xml';
    DatasetFilename := TemporaryPath + 'MyDataset.xml';
    Report.Run(111);
    if not File.Exists(LabelsFilename) then
      Error('Labels file should exist!');
    if not File.Exists(DatasetFilename) then
      Error('Dataset file should exist!');

    // Add the following code to the ReqPageHandler method.
    RequestPage.Customer.SetFilter("No.", '20000');
    RequestPage.ChartType.Value('Pie chart');
    RequestPage.SaveAsXML(LabelsFilename,DatasetFilename);
end;
```

Text Data Type

2/17/2021 • 5 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Denotes a text string.

The following methods are available on the Text data type.

METHOD NAME	DESCRIPTION
ConvertStr(String, String, String)	Replaces all chars in source found in FromCharacters with the corresponding char in ToCharacters and returns the converted string. If the length of the FromCharacters parameter and the ToChars parameter are different, an exception is thrown. If the parameter FromCharacters or the parameter ToChars is empty, the source is returned unmodified. Each element in source is only converted ONCE a double-replacement cannot happen.
CopyStr(String, Integer [, Integer])	Copies a substring of any length from a specific position in a string (text or code) to a new string.
DelChr(String [, String] [, String])	Deletes chars contained in the which parameter in a string based on the contents on the where parameter. If the where parameter contains an equal-sign, then all occurrences of characters in which is deleted from the current value. If the where parameter contains a less-than, then the characters are only deleted when they are first in the string. If the where parameter contains a greater-than, then the characters are only deleted when they are the last in the string. If the where parameter contains any other char, an exception is thrown. If the where parameter or the which parameter is empty, the source is returned unmodified. The which parameter is to be considered as an array of chars to delete where the order does not matter.
DelStr(String, Integer [, Integer])	Deletes a substring inside a string (text or code).
IncStr(String)	Increases a positive number or decrease a negative number inside a string by one (1).
InsStr(String, String, Integer)	Inserts a substring into a string.
LowerCase(String)	Converts all letters in a string to lowercase.
MaxStrLen(String)	Gets the maximum defined length of a string variable.
MaxStrLen(Variant)	Gets the maximum defined length of a variant variable.
PadStr(String, Integer [, String])	Changes the length of a string to a specified length. If the string is shorter than the specified length, length spaces are added at the end of the string to match the length. If the string is longer than the specified length, the string is truncated. If the specified length is less than 0, an exception is thrown.
SelectStr(Integer, String)	Retrieves a substring from a comma-separated string.

METHOD NAME	DESCRIPTION
StrCheckSum(String [, String] [, Integer])	Calculates a checksum for a string that contains a number. If the source is empty, 0 is returned. Each char in the source and in the weight must be a numeric character 0-9, otherwise an exception is thrown. If the WeightString parameter is shorter then the source, it is padded with '1' up until the length of source. If the WeightString parameter is longer than the source, an exception is thrown.
StrLen(String)	Gets the length of a string you define.
StrPos(String, String)	Searches for the first occurrence of substring inside a string.
StrSubstNo(String [, Any,...])	Replaces %1, %2, %3... and #1, #2, #3... fields in a string with the values you provide as optional parameters.
UpperCase(String)	Converts all letters in a string to uppercase.

The following methods are available on instances of the Text data type.

METHOD NAME	DESCRIPTION
Contains(Text)	Returns a value indicating whether a specified substring occurs within this string.
EndsWith(Text)	Determines whether the end of this string instance matches the specified string.
IndexOf(Text [, Integer])	Reports the one-based index of the first occurrence of the specified string in this instance.
IndexOfAny(Text [, Integer])	Reports the one-based index of the first occurrence of the specified string in this instance. The search starts at a specified character position.
IndexOfAny(List of [Char] [, Integer])	Reports the one-based index of the first occurrence in this instance of any character in a specified array of Unicode characters. The search starts at a specified character position.
LastIndexOf(Text [, Integer])	Reports the one-based index position of the last occurrence of a specified string in this instance.
PadLeft(Integer [, Char])	Returns a new Text that right-aligns the characters in this instance by padding them on the left, for a specified total length.
PadRight(Integer [, Char])	Returns a new string that left-aligns the characters in this string by padding them with spaces on the right, for a specified total length.
Remove(Integer [, Integer])	Returns a new Text in which a specified number of characters from the current string are deleted.
Replace(Text, Text)	Returns a new Text in which all occurrences of a specified string in the current instance are replaced with another specified string.
Split([Text,...])	Splits a string into a maximum number of substrings based on a collection of separators.
Split(List of [Text])	Splits a string into a maximum number of substrings based on a collection of separators.

METHOD NAME	DESCRIPTION
Split(List of [Char])	Splits a string into a maximum number of substrings based on a collection of separators.
StartsWith(Text)	Determines whether the beginning of this instance matches a specified string.
Substring(Integer [, Integer])	Retrieves a substring from this instance.
ToLower()	Returns a copy of this string converted to lowercase.
ToUpper()	Returns a copy of this string converted to uppercase.
Trim()	Returns a new Text in which all leading and trailing white-space characters from the current Text object are removed.
TrimEnd([Text])	Removes all trailing occurrences of a set of characters specified in an array from the current Text object.
TrimStart([Text])	Removes all leading occurrences of a set of characters specified in an array from the current Text object.

Remarks

The **Text** data type is a value type, such that every time you use a method on it, you create a new string object in memory. This requires a new allocation of space. In situations where you need to perform repeated modifications to a string, the overhead associated with creating a **Text** data type can be costly.

The TextBuilder Data Type is a reference type, which holds a pointer elsewhere in memory. For performance reasons, we recommend you to use it when you want to modify a string without creating a new object. For example, using TextBuilder Data Type can boost performance when concatenating many strings together in a loop.

TextBuilder Data Type

Text.ConvertStr Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Replaces all chars in source found in FromCharacters with the corresponding char in ToCharacters and returns the converted string. If the length of the FromCharacters parameter and the ToChars parameter are different, an exception is thrown. If the parameter FromCharacters or the parameter ToChars is empty, the source is returned unmodified. Each element in source is only converted ONCE a double-replacement cannot happen.

Syntax

```
NewString :=   Text.ConvertStr(String: String, FromCharacters: String, ToCharacters: String)
```

NOTE

This method can be invoked without specifying the data type name.

Parameters

String

Type: String

The string that you want to convert.

FromCharacters

Type: String

The characters that you want to replace. This function is case-sensitive.

ToCharacters

Type: String

The new characters with which you want to replace the FromCharacters. This function is case-sensitive.

Return Value

NewString Type: String The input string with the converted characters.

Remarks

The characters in the *FromCharacters* parameter are replaced by the characters in the *ToCharacters* parameter.

If the lengths of the *FromCharacters* and *ToCharacters* strings are not equal, then a run-time error occurs.

If either the *FromCharacters* or the *ToCharacters* strings are empty, then the source is returned unchanged.

Example

```
var
    OriginalString: Text[30];
    FromChars: Text[30];
    ToChars: Text[30];
    NewString: Text[30];
    Text000: Label 'Do you want to leave without saving?';
    Text001: Label 'lws';
    Text002: Label 'LWS';
    Text003: Label 'The original sentence is \\: %1';
    Text004: Label 'The sentence is converted to:\\ %1';
begin
    OriginalString := Text000;
    FromChars := Text001;
    ToChars := Text002;
    NewString := ConvertStr(OriginalString, FromChars, ToChars);
    Message(Text003, OriginalString);
    Message(Text004, NewString);
end;
```

The first message window shows:

The original sentence is:

Do you want to leave without saving?

The second message window shows:

The sentence is converted to:

Do you Want to Leave Without Saving?

Text.CopyStr Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Copies a substring of any length from a specific position in a string (text or code) to a new string.

Syntax

```
NewString :=   Text.CopyStr(String: String, Position: Integer [, Length: Integer])
```

NOTE

This method can be invoked without specifying the data type name.

Parameters

String

Type: String

The string that you want to copy from.

Position

Type: Integer

The position of the first character to copy. If the value of Position is less than 1, then the CopyStr function returns an error. If Position is greater than the length of the string, then the CopyStr function returns an empty string.

Length

Type: Integer

The number of characters to copy. If the value of Length is less than 0, then the CopyStr function returns an error. If the value of Length causes Position + Length to be > (total length of the string), then the result includes all the characters from Position to the end of the string. If you omit Length, then the resulting string includes all the characters from Position to the end of the string.

Return Value

NewString Type: String The copied string.

Remarks

If *Position* combined with *Length* exceeds the length of the string, all the characters from *Position* to the end of the string are returned.

Example

```
var
    Str: Text[30];
    Position: Integer;
    Length: Integer;
    NewStr: Text[30];
    Text000: Label 'Using the CopyStr method';
    Text001: Label 'The original string is:>%1<';
    Text002: Label 'The copied string is:>%1<';
begin
    Str := Text000;
    Position := 7;
    Length := 8;
    Message(Text001, Str);
    NewStr := CopyStr(Str, Position, Length);
    Message(Text002, NewStr);
end;
```

The first message window shows the original string:

The original string is:

>Using the CopyStr method<

The second message window shows the copied string:

The copied string is:

>the COPY<

Text.DelChr Method

2/17/2021 • 4 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Deletes chars contained in the which parameter in a string based on the contents on the where parameter. If the where parameter contains an equal-sign, then all occurrences of characters in which is deleted from the current value. If the where parameter contains a less-than, then the characters are only deleted when they are first in the string. If the where parameter contains a greater-than, then the characters are only deleted when they are the last in the string. If the where parameter contains any other char, an exception is thrown. If the where parameter or the which parameter is empty, the source is returned unmodified. The which parameter is to be considered as an array of chars to delete where the order does not matter.

Syntax

```
NewString :=   Text.DelChr(String: String [, Where: String] [, Which: String])
```

NOTE

This method can be invoked without specifying the data type name.

Parameters

String

Type: String

The input string.

Where

Type: String

Specifies where to delete characters.

Which

Type: String

Specifies the characters that you want to delete.

Return Value

NewString Type: String The end result String.

Remarks

The DelChr method is case-sensitive.

If you omit the *Which* parameter, then the method deletes spaces from *String* based on the contents of the *Where* parameter as follows:

- If *Where* contains =, then all the spaces are deleted from *String*.
- If *Where* contains <, then all the spaces at the start of *String* are deleted.
- If *Where* contains >, then all the spaces at the end of *String* are deleted.

- If *Where* contains any other character, then an error is returned.
- If *Where* is empty, then *String* is returned unchanged.

If you use the *Where* and the *Which* parameters, then the method deletes from *String* the characters that are contained in the *Which* parameter based on the contents of the *Where* parameter as follows:

- If *Where* contains =, then every occurrence of the characters in *Which* are deleted from *String*.
- If *Where* contains <, then the characters in *Which* are only deleted if they occur at the start of *String*.
- If *Where* contains >, then the characters in *Which* are deleted only if they occur at the end of *String*.
- If *Where* contains any other character, then an error is returned.
- If *Where* is empty, then *String* is returned unchanged.
- If *Which* is empty, then *String* is returned unchanged.

The *Which* parameter contains an array of the characters that you want to delete. The order of the characters is of no significance. If *String* contains a character that is specified in *Which*, it is deleted from *String*.

Example 1

```
var
    String: Text;
    Where: Text;
    Which: Text;
    NewString: Text;
    Text000: TexConst ENU='Windy West Solutions';
    Text001: TexConst ENU='>%1< is transformed to >%2<';
begin
    String := Text000;
    Where := '<>';
    Which := 'Ws';
    NewString := DelChr(String, Where, Which);
    Message(Text001, String,NewString);
end;
```

The message window displays the following:

>Windy West Solutions< is transformed to >indy West Solution<

The method deletes every W and s that is either the first or last character in *String*.

Example 2

```
var
    String: Text;
    Where: Text;
    Which: Text;
    NewString: Text;
    Text000: TexConst ENU='This is an example';
    Text001: TexConst ENU='>%1< is transformed to >%2<';
begin
    String := Text000;
    Where := '=';
    Which := 'sx';
    NewString := DelChr(String, Where, Which);
    Message(Text001, String,NewString);
end;
```

The message window displays the following:

>This is an example< is transformed to >Thi i an eample<

The method deletes every s and x from *String*.

Example 3

```
var
    String: Text;
    Where: Text;
    Which: Text;
    NewString: Text;
    Text000: TexConst ENU='This is an example';
    Text001: TexConst ENU='>%1< is transformed to >%2<';
begin
    String := Text000;
    Where := '>';
    Which := 'Tely';
    NewString := DelChr(String, Where, Which);
    Message(Text001, String,NewString);
end;
```

The message window displays the following:

>This is an example< is transformed to >This is an examp<

If T, e, l, or y is the last character in *String*, the method deletes them.

Example 4

```
var
    String: Text;
    Where: Text;
    Which: Text;
    NewString: Text;
    Text000: TexConst ENU='This is an example';
    Text001: TexConst ENU='>%1< is transformed to >%2<';
begin
    String := Text000;
    Where := '<';
    Which := 'This ';
    NewString := DelChr(String, Where, Which);
    Message(Text001, String,NewString);
end;
```

The message window displays the following:

>This is an example< is transformed to >an example<

If T, h, s, i, or space is the first character in *String*, the method deletes them.

Example 5

```
var
    String: Text;
    Where: Text;
    Which: Text;
    NewString: Text;
    Text000: TexConst ENU='This is an example';
    Text001: TexConst ENU='>%1< is transformed to >%2<';
begin
    String := Text000;
    Where := '<';
    NewString := DelChr(String, Where);
    Message(Text001, String,NewString);
end;
```

The message window displays the following:

> This is an example< is transformed to >This is an example<

The method removes any spaces from the start of *String*.

Example 6

```
var
    String: Text;
    NewString: Text;
    Text000: Label ' Windy West Solutions '; // note that there can be multiple leading and trailing spaces
    Text001: Label '>%1< is transformed to >%2<';
begin
    String := Text000;
    NewString := DelChr(String);
    Message(Text001, String, NewString);
end;
```

The message window displays the following:

> Windy West Solutions < is transformed to >WindyWestSolutions<

Text.DelStr Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Deletes a substring inside a string (text or code).

Syntax

```
NewString :=   Text.DelStr(String: String, Position: Integer [, Length: Integer])
```

> **NOTE**
> This method can be invoked without specifying the data type name.

Parameters

String
Type: String
The input string.

Position
Type: Integer
The position of the first character that you want to delete. Position must be greater than zero (0). If Position exceeds the length of String, DelStr returns the original string, unchanged.

Length
Type: Integer
Specifies how many characters to delete. Length must be greater than zero (0).

Return Value

NewString Type: String The input string without the specified substring.

Remarks

If you omit *Length*, all the characters starting with *Position* are deleted until the end of the string.

If you omit *Length* and *Position* is less than 1, then an error is returned.

If you omit *Length* and *Position* is greater than the length of *String*, then *String* is returned unchanged.

Example

```
var
    Str: Text[40];
    NewStr: Text[40];
    Position: Integer;
    Length: Integer;
    Text000: TexConst ENU='Adjusting prices - Please wait.';
    Text001: TexConst ENU='The original string:>%1<';
    Text002: TexConst ENU='The original modified:>%2<';
begin
    Str := Text000;
    Position := 11; // Remove the word 'prices' and a blank.
    Length := 7;
    NewStr := DelStr(Str, Position, Length);
    Message(Text001, Str);
    Message(Text002, NewStr);
end;
```

The first message window displays the following:

The original string:

>Adjusting prices - Please wait.<

The second message window displays the following:

The modified string:

>Adjusting - Please wait.<

Text.IncStr Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Increases a positive number or decrease a negative number inside a string by one (1).

Syntax

```
NewString :=   Text.IncStr(String: String)
```

NOTE

This method can be invoked without specifying the data type name.

Parameters

String

Type: String

The string that you want to increase or decrease.

Return Value

NewString Type: String The incremented string.

Remarks

If *String* contains more than one number, then only the number closest to the end of the string is changed. For example, 'A10B20' is changed to 'A10B21' and 'a12b12c' to 'a12b13c'.

If *String* contains a negative number, then it is decreased by one. For example, '-55' is changed to '-56'.

Zero (0) is considered a positive number. Therefore, it is increased it by one. For example, 'A0' is changed to 'A1'.

When *String* contains a number such as 99, it is increased to 100 and the length of the output string is: LEN(String) + 1. For example, 'a12b99c' is changed to 'a12b100c'.

If *String* does not contain any number, the output string is an empty string. For example, 'aaa' is changed to ''.

IncStr only increments integer numbers within strings, not decimals. For example, if you call IncStr on the string **a99.99b** then the result is **a99.100b**.

Example

```
var
    Account: Text[60];
    NegAccount: Text[60];
    EmptyAccount: Text[60];
    MyAccount: Text[60];
    ResultAccount: Text[60];
    ResultNegAccount: Text[60];
    ResultEmptyAccount: Text[60];
    ResultMyAccount: Text[60];
    Text000: TexConst ENU='Account no. 99 does not balance.';
    Text001: TexConst ENU='Account no. 2342 shows a total of $-452.';
    Text002: TexConst ENU='My bank account is empty.';
    Text003: TexConst ENU='My bank account shows a total of $0.';
    Text004: TexConst ENU='The text strings before IncStr is called:\\%1\\%2\\%3\\%4';
    Text005: TexConst ENU='The text strings after IncStr is called:\\%1\\%2\\%3\\%5';
begin
    Account := Text000;
    NegAccount := Text001;
    EmptyAccount := Text002;
    MyAccount := Text003;
    Message(Text004, Account, NegAccount, EmptyAccount, MyAccount);
    ResultAccount := IncStr(Account);
    ResultNegAccount := IncStr(NegAccount);
    ResultEmptyAccount := IncStr(EmptyAccount);
    ResultMyAccount := IncStr(MyAccount);
    Message(Text005, ResultAccount, ResultNegAccount, ResultEmptyAccount, ResultMyAccount);
end;
```

The first message displays the following:

The text strings before IncStr is called:

Account no. 99 does not balance.

Account no. 2342 shows a total of $ -452.

My bank account is empty.

My bank account shows a total of $ 0.

The second message displays the following:

The text strings after IncStr has been called:

Account no. 100 does not balance.

Account no. 2342 shows a total of $ -453.

My bank account shows a total of $ 1.

The example shows that if the string contains more than one number, only the last number is changed. Furthermore, positive numbers and zero are increased and negative numbers are decreased. Finally, if there are no numbers in the string, then an empty string is returned.

Text.InsStr Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Inserts a substring into a string.

Syntax

```
NewString :=   Text.InsStr(String: String, SubString: String, Position: Integer)
```

NOTE

This method can be invoked without specifying the data type name.

Parameters

String

Type: String

The string into which you want to insert a substring.

SubString

Type: String

The substring that you want to insert into String.

Position

Type: Integer

Specifies where to insert SubString. Position must be greater than or equal to 1. If Position is greater than the length of String, then the result is concatenated and copied to NewString.

Return Value

NewString Type: String The input string including the specified substring

Remarks

If *SubString* is empty, then *String* is returned unchanged.

If *Position* is less than 1, an error is returned.

If *Position* is greater than the length of *String*, *SubString* is added at the end of *String*. For example, `InsStr("Thomas","AAA",999)` returns 'ThomasAAA'.

Example

```
var
    Str: Text[60];
    SubString: Text[60];
    NewString: Text[60];
    Text000: Label 'Press ENTER to continue.';
    Text001: Label 'or ESC';
    Text002: Label ' The test string before InsStr is called:>%1<';
    Text003: Label ' The resulting string after InsStr is called:>%1<';
begin
    Str := Text000;
    SubString := Text001;
    Message(Text002, Str);
    NewString := InsStr(Str, SubString, 13);
    Message(Text003, NewString);
end;
```

The first message window displays the following:

The test string before InsStr is called:

>Press ENTER to continue.<

The second message window displays the following:

The resulting string after InsStr is called:

>Press ENTER or ESC to continue.<

Text.LowerCase Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Converts all letters in a string to lowercase.

Syntax

```
NewString :=   Text.LowerCase(String: String)
```

NOTE

This method can be invoked without specifying the data type name.

Parameters

String

Type: String

The string that you want to convert to lowercase. Only letters in the range A to Z and, if applicable, special language characters are converted.

Return Value

NewString Type: String The string converted to lowercase.

Example

```
var
    Str: Text[60];
    Lower: Text[60];
    Text000: Label 'The Entries are Sorted by Name.';
    Text001: Label 'The string before LowerCase is:>%1<';
    Text002: Label 'The string after LowerCase is:>%1<';
begin
    Str := Text000;
    Message(Text001, Str);
    Lower := LowerCase(Str);
    Message(Text002, Lower);
end;
```

The first message window displays the following:

The string before LowerCase is:

>The Entries are Sorted by Name.<

The second message window displays the following:

The string after LowerCase is:

>the entries are sorted by name.<

Text.MaxStrLen Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Gets the maximum defined length of a string variable.

Syntax

```
MaxLength :=   Text.MaxStrLen(String: String)
```

NOTE

This method can be invoked without specifying the data type name.

Parameters

String

Type: String

The string variable for which you want to find the maximum length.

Return Value

MaxLength Type: Integer The maximum length of the string variable.

Remarks

If you call this method on a Variant, it returns an error.

Example

```
var
    City: Text[30];
    MaxLength: Integer;
    Length: Integer;
    Text000: Label 'Vedbaek';
    Text001: Label 'The MaxStrLen method returns %1,\\';
    Text002: Label 'whereas the StrLen method returns %2';
begin
    City := Text000;
    MaxLength := MaxStrLen(City);
    Length := StrLen(City);
    Message(Text001 + Text002, MaxLength, Length);
end;
```

The message window displays the following:

The MaxStrLen method returns 30,

whereas the StrLen method returns 7.

See Also

Text.MaxStrLen Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0 until version 1.0 where it was deprecated.*

Gets the maximum defined length of a variant variable.

Syntax

```
MaxLength :=   Text.MaxStrLen(Variant: Variant)
```

> **NOTE**
> This method can be invoked without specifying the data type name.

Parameters

Variant

Type: Variant

The source variant for which you want to find the maximum length.

Return Value

MaxLength Type: Integer The maximum length of the string variable.

Remarks

If you call this method on a Variant, it returns an error.

Example

```
var
    City: Text[30];
    MaxLength: Integer;
    Length: Integer;
    Text000: Label 'Vedbaek';
    Text001: Label 'The MaxStrLen method returns %1,\\';
    Text002: Label 'whereas the StrLen method returns %2';
begin
    City := Text000;
    MaxLength := MaxStrLen(City);
    Length := StrLen(City);
    Message(Text001 + Text002, MaxLength, Length);
end;
```

The message window displays the following:

The MaxStrLen method returns 30,

whereas the StrLen method returns 7.

Text.PadStr Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Changes the length of a string to a specified length. If the string is shorter than the specified length, length spaces are added at the end of the string to match the length. If the string is longer than the specified length, the string is truncated. If the specified length is less than 0, an exception is thrown.

Syntax

```
NewString :=   Text.PadStr(String: String, Length: Integer [, FillCharacter: String])
```

> **NOTE**
> This method can be invoked without specifying the data type name.

Parameters

String
Type: String
The string that you want to increase or decrease.

Length
Type: Integer
The new length of the output string. If Length is less than the length of String, then String is truncated. Otherwise String is expanded with filler characters. If Length is less than 0, then an error is returned.

FillCharacter
Type: String
This is a string of length 1. This character is used to fill empty spaces at the end of the output string. If not specified, spaces are used as default. If the length of FillCharacter is not 1, an error is returned.

Return Value

NewString Type: String A copy of the string with the expected length.

Remarks

If you omit *FillCharacter* and *String* is shorter than *Length*, then spaces are added at the end of *String* to match *Length*.

If you omit *FillCharacter* and *String* is longer than *Length*, then *String* is truncated.

Example

```
var
    Str1: Text[30];
    Str2: Text[30];
    Len1: Integer;
    Len2: Integer;
    Text000: Label '13 characters';
    Text001: Label 'Four';
    Text002: Label 'Before PadStr is called:\\';
    Text003: Label '>%1< has the length %2\\';
    Text004: Label '>%3< has the length %4\\';
    Text005: Label 'After PadStr is called:\\';
begin
    Str1 := Text000;
    Str2 := Text001;
    Len1 := StrLen(Str1);
    Len2 := StrLen(Str2);
    Message(Text002 + Text003 + Text004, Str1, Len1, Str2, Len2);
    Str1 := PadStr(Str1, 5); // Truncate the length to 5
    Str2 := PadStr(Str2, 15, 'w'); // Concatenate w until length = 15
    Len1 := StrLen(Str1);
    Len2 := StrLen(Str2);
    Message(Text005 + Text003 + Text004, Str1, Len1, Str2, Len2);
end;
```

The first message window displays the following:

Before PadStr is called:

>13 characters< has the length 13

>Four< has the length 4

The second message window displays the following:

After PadStr is called:

>13 ch< has the length 5

>Fourwwwwwwwwwww< has the length 15

Text.SelectStr Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Retrieves a substring from a comma-separated string.

Syntax

```
NewString :=   Text.SelectStr(Number: Integer, CommaString: String)
```

NOTE

This method can be invoked without specifying the data type name.

Parameters

Number

Type: Integer

Specifies which substring to retrieve. The substrings in the comma-separated string are numbered 1, 2, 3, and so on. If Number is greater than the actual number of substrings, then a run-time error occurs.

CommaString

Type: String

A string that contains substrings separated by commas. The maximum length of this string is 391 characters.

Return Value

NewString Type: String The substring from the comma-separated string at the index specified.

Remarks

SelectStr treats string values as OPTIONS. This means that identical values in different strings are not allowed.

Any trailing commas are removed before the operation starts.

If *Number* is less than 1 or greater than the number of real values (excluding trailing commas) in the string, then an error is returned.

Quotes are not supported. For example, a,b,"c,d",e is treated as a five-element substring where substring 4 is d".

Example 1

```
var
    CommaStr: Text[60];
    CommaStr2: Text[60];
    SubStr1: Text[60];
    SubStr2: Text[60];
    SubStr3: Text[60];
    SubStr4: Text[60];
    Text000: Label 'This,is a comma,separated,string';
    Text001: Label 'The calls to SelectStr return:\\';
    Text002: Label '11,22,33,,55,,,';
begin
    CommaStr := Text000;
    CommaStr2 := Text002;
    SubStr1 := SelectStr(2, CommaStr); // Pick out the 2nd substring.
    SubStr2 := SelectStr(4, CommaStr); // Pick out the 4th substring.
    SubStr3 := SelectStr(1, CommaStr2);
    SubStr4 := SelectStr(3, CommaStr2);
    Message(Text001 + '>%1<\' + '>%2<\' + '>%3<\' + '>%4<\', SubStr1, SubStr2, SubStr3, SubStr4);
end;
```

The message window displays the following text:

The calls to SelectStr return:

>is a comma<

>string<

>11<

>33<

Example 2

```
var
    CommaStr2: Text[60];
    SubStr5: Text[60];
    Text002: Label '11,22,33,,55,,,';
begin
    CommaStr2 := Text002;
    SubStr5 := SelectStr(6,CommaStr2);
    Message('>%1<\', SubStr5);
end;
```

This example returns an error.

Text.StrCheckSum Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Calculates a checksum for a string that contains a number. If the source is empty, 0 is returned. Each char in the source and in the weight must be a numeric character 0-9, otherwise an exception is thrown. If the WeightString parameter is shorter then the source, it is padded with '1' up until the length of source. If the WeightString parameter is longer than the source, an exception is thrown.

Syntax

```
CheckNumber :=   Text.StrCheckSum(String: String [, WeightString: String] [, Modulus: Integer])
```

NOTE

This method can be invoked without specifying the data type name.

Parameters

String

Type: String

This string contains the number for which you want to calculate a checksum. You can only enter the numeric characters 0-9 in this string. If you enter anything else, a run-time error will occur. If String is empty, 0 is returned.

WeightString

Type: String

This string contains numbers that you want to use as weights when calculating the checksum. The default value is a string that contains StrLen(String) '1'-characters.

Modulus

Type: Integer

The number that you want to use in the checksum formula. The default value is 10.

Return Value

CheckNumber Type: Integer The resulting checksum value.

Example 1

This example shows how to use the StrCheckSum method to calculate a checksum.

```
var
    StrNumber: Text[30];
    Weight: Text[30];
    Modulus: Integer;
    Text000: Label 'The number: %1\\';
    Text001: Label 'has the checksum: %2';
begin
    StrNumber := '4378';
    Weight := '1234';
    Modulus := 7;
    CheckSum := StrCheckSum(StrNumber, Weight, Modulus);
    Message(Text000 + Text001, StrNumber, CheckSum);
end;
```

The formula is:

(7 - (4x1 + 3x2 + 7x3 + 8x4) MOD 7) MOD 7=0

The message window displays the following:

The number: 4378

has the checksum: 0

Example 2

This example shows how to use the StrCheckSum method to calculate a modulus 10 checksum for a bar code.

The StrCheckSum method can be used to calculate checksums for 13- and 8-digit European Article Number (EAN) and EAN-compatible bar codes such as a Universal Product Code (UPC) or Japanese Article Number (JAN).

A 13-digit EAN code has the following format:

1. The 12 digits in positions 13 to 2 are used to calculate the checksum at position 1.
2. Starting with position 2, all even values are totaled. The result is then multiplied by three. This value is called Even.
3. Starting with position 3, all odd values are totaled. The result is called Odd.
4. Total=Even + Odd.
5. The modulus 10 checksum is then (10 - Total MOD 10) MOD 10.

```
var
    StrNumber: Text[30];
    Weight: Text[30];
    Modulus: Integer;
    Text000: Label 'The EAN code: %1\\';
    Text001: Label 'has the checksum: %2';
begin
    StrNumber := '577622135746';
    Weight := '131313131313';
    CheckSum := StrCheckSum(StrNumber, Weight);
    Message(Text000 + Text001, StrNumber, CheckSum);
end;
```

The message window displays the following:

The EAN code: 577622135746

has the checksum: 3

Text.StrLen Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Gets the length of a string you define.

Syntax

```
Length :=   Text.StrLen(String: String)
```

> **NOTE**
> This method can be invoked without specifying the data type name.

Parameters

String
Type: String
The string for which you want to determine the length.

Return Value

Length Type: Integer The length of the string.

Remarks

The difference between the StrLen method and the MaxStrLen Method (Code, Text) is that the StrLen returns the actual number of characters in the input string, whereas MaxStrLen returns the maximum defined length of the input string.

In Dynamics 365 Business Central, if you call StrLen on a Variant, then you get an error that the contents of the parameter are not valid. In earlier versions of Dynamics 365, if you call StrLen on a Variant, then 0 is returned.

Example

This example shows the difference between the StrLen and the MaxStrLen methods.

```
var
    City: Text[30];
    MaxLength: Integer;
    Length: Integer;
    Text000: Label 'Atlanta';
    Text001: Label 'The MaxStrLen method returns: %1,\\';
    Text002: Label 'whereas the StrLen method returns: %2';
begin
    City := Text000;
    MaxLength := MaxStrLen(City);
    Length := StrLen(City);
    Message(Text001 + Text002, MaxLength, Length);
end;
```

The message window displays the following:

The MaxStrLen method returns: 30

whereas the StrLen method returns: 7

This shows that the MaxLength method returns the maximum possible length according to the definition of the string variable, whereas StrLen returns the actual length of the text.

Text.StrPos Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Searches for the first occurrence of substring inside a string.

Syntax

```
Position :=   Text.StrPos(String: String, SubString: String)
```

> **NOTE**
> This method can be invoked without specifying the data type name.

Parameters

String
Type: String
The string in which you want to search.

SubString
Type: String
The substring for which you want to search.

Return Value

Position Type: Integer The one-based index of the first occurrence of the substring inside the string.

Remarks

The StrPos method returns the position of the first occurrence of the substring.

If *SubString* cannot be found, then the method returns zero.

If *String* or *SubString* is empty, then the method returns zero.

Example 1

This example shows how to use the StrPos method.

```
var
    Text000: Label 'ABC abc abc xy';
    Text001: Label 'abc';
    Text002: Label 'The search for the substring: >%1<\\';
    Text003: Label 'in the string: >%2<,\\';
    Text004: Label 'returns the position: %3';
begin
    String := Text000;
    SubStr := Text001
    Pos := StrPos(String, SubStr);
    Message(Text002 + Text003 + Text004, SubStr, String, Pos);
    // The StrPos method is case-sensitive. Furthermore, it only
    // returns the position of the 1st occurrence of the substring.
end;
```

The message window displays the following:

The search for the substring: >abc<

in the string: >ABC abc abc xy<

returns the position: 5

Example 2

```
Pos1 := StrPos("abc",""); // Returns 0.
Pos2 := StrPos("abc","c"); // Returns 3.
Pos3 := StrPos("abc","bc"); // Returns 2.
Pos4 := StrPos("abc","x"); // Returns 0.
```

Text.StrSubstNo Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Replaces %1, %2, %3... and #1, #2, #3... fields in a string with the values you provide as optional parameters.

Syntax

```
NewString :=   Text.StrSubstNo(String: String [, Value1: Any,...])
```

NOTE

This method can be invoked without specifying the data type name.

Parameters

String

Type: String

A string containing '#' and/or '%' fields.

Value1

Type: Any

One or more values (expressions) that you want to insert into String. You can specify up to 10 values.

Return Value

NewString Type: String Returns a new string with the provided values inserted into the specified string.

Remarks

This method replaces the numbered specifiers in a string with a string representation of the equivalent numbered value.

The specifiers in the string can be either %*n* or #######*n*, where *n* represents a 1-based number. When you use the # specifier, the number can be anywhere in the specifier. For example, ###2#### is allowed.

The %*n* specifier is replaced with the string representation of the value with their full lengths.

The ##*n* specifier is replaced with the same number of characters as the length of the specifier (including the number). The values are truncated to the length of the # field.

If the string representation is shorter than the length of the specifier, then it is left aligned.

For example, `StrSubstNo('Test %1 >#2##< >#3<', 1,2,3)` returns "Test 1 >2 < >3 <".

In this example, the following substitutions are made:

- %1 is replaced by '1' because a % field is replaced by the specified value in its full length.
- '#2##' is replaced by '2 space space space' because the value is shorter than the field and therefore, the 2

is left aligned and the field is four characters long.

- #3 is replaced by '3 space' because the 3 is left aligned and the field is two characters long

If the string is longer, then asterisks are inserted to indicate overflow.

For example, `StrSubstNo('Test %1 >###2< >#3<', 'Thomas','Thomas',0)` returns "Test Thomas >****< >0 <".

In this example the following substitutions are made:

- %1 is replaced by 'Thomas' because a %1 field is replaced by the specified value in its full length.
- '###2' is replaced by '****' because the string 'Thomas' is longer than the ###2 field. Each character in the field is replaced by an asterisk.
- #3 is replaced by '0 space' because the 0 is left aligned and the field is two characters long.

You can have several references to the same value.

For example, `StrSubstNo('Test %1 %3 %1', 555, 666, 777)` returns "Test 555 777 555".

If one of the values is null, then it is treated as an empty string.

Example

The following example shows how to use the StrSubstNo method.

```
var
    Str: Text[1024];
    AccountNo: Integer;
    Balance: Decimal;
    Text000: Label 'The balance of account %1 is $ %2';
    Text001: Label 'The test string before StrSubstNo is called:\\%1';
    Text002: Label 'The string after StrSubstNo is called:\\%1';
begin
    Str := Text000;
    AccountNo := 3452;
    Balance := 2345 + 5462;
    Message(Text001, Str);
    Str := StrSubstNo(Str, AccountNo, Balance);
    Message(Text002, Str);
end;
```

The first message window displays the following text:

The string before StrSubstNo has been called:

The balance of account %1 is $ %2

The second message window displays the following text:

The string after StrSubstNo has been called:

The balance of account 3452 is $ 7,807

> **NOTE**
> This example is run on a computer that has the regional format set to English (United States).

Text.UpperCase Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Converts all letters in a string to uppercase.

Syntax

```
NewString :=   Text.UpperCase(String: String)
```

NOTE

This method can be invoked without specifying the data type name.

Parameters

String

Type: String

The string that you want to convert to uppercase.

Return Value

NewString Type: String The string converted to uppercase.

Example

The following example shows how to use the **UpperCase** method.

```
var
    Text000: Label 'Outstanding Order Status';
    Text001: Label 'The test string before UpperCase is called:\\%1';
    Text002: Label 'The string after UpperCase is called:\\%1';
begin
    Lower := Text000;
    Message(Text001, Lower);
    Upper := UpperCase(Lower);
    Message(Text002, Upper);
end;
```

The first message window displays the following:

The test-string before UpperCase is called:

Outstanding Order Status

The second message window displays the following:

The string after UpperCase is called:

OUTSTANDING ORDER STATUS

Text.Contains Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Returns a value indicating whether a specified substring occurs within this string.

Syntax

```
Ok :=   Text.Contains(Value: Text)
```

> **NOTE**
> This method can be invoked without specifying the data type name.

Parameters

Text Type: Text An instance of the Text data type.

Value
Type: Text
The string to seek.

Return Value

Ok Type: Boolean **true** if the specified substring occurs in the specified string, otherwise **false**.

See Also

Text Data Type

Text.EndsWith Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Determines whether the end of this string instance matches the specified string.

Syntax

```
Ok :=   Text.EndsWith(Value: Text)
```

> **NOTE**
> This method can be invoked without specifying the data type name.

Parameters

Text Type: Text An instance of the Text data type.

Value
Type: Text
The string to compare to the substring at the end of this instance.

Return Value

Ok Type: Boolean **true** if the end of this string instance matches the specified string, otherwise **false**.

See Also

Text.IndexOf Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Reports the one-based index of the first occurrence of the specified string in this instance.

Syntax

```
Index :=   Text.IndexOf(Value: Text [, StartIndex: Integer])
```

> **NOTE**
> This method can be invoked without specifying the data type name.

Parameters

Text Type: Text An instance of the Text data type.

Value
Type: Text
The string to seek.

StartIndex
Type: Integer
The one-based search starting position.

Return Value

Index Type: Integer The one-based index of the first occurrence of the specified string in this instance. If the index returned is 0, the value is not present in the string.

See Also

Text.IndexOfAny Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Reports the one-based index of the first occurrence of the specified string in this instance. The search starts at a specified character position.

Syntax

```
Index :=   Text.IndexOfAny(Values: Text [, StartIndex: Integer])
```

> **NOTE**
> This method can be invoked without specifying the data type name.

Parameters

Text Type: Text An instance of the Text data type.

Values
Type: Text
The collection of characters to seek.

StartIndex
Type: Integer
The one-based search starting position.

Return Value

Index Type: Integer The one-based index of the first occurrence of the specified string in this instance. If the index returned is 0, the value is not present in the string.

See Also

Text Data Type

Text.IndexOfAny Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Reports the one-based index of the first occurrence in this instance of any character in a specified array of Unicode characters. The search starts at a specified character position.

Syntax

```
Index :=   Text.IndexOfAny(Values: List of [Char] [, StartIndex: Integer])
```

NOTE

This method can be invoked without specifying the data type name.

Parameters

Text Type: Text An instance of the Text data type.

Values

Type: List of [Char]

The collection of characters to seek.

StartIndex

Type: Integer

The one-based search starting position.

Return Value

Index Type: Integer The one-based index of the first occurrence of the specified string in this instance. If the index returned is 0, the value is not present in the string.

See Also

Text Data Type

Developing Extensions

Text.LastIndexOf Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Reports the one-based index position of the last occurrence of a specified string in this instance.

Syntax

```
Index :=   Text.LastIndexOf(Value: Text [, StartIndex: Integer])
```

NOTE

This method can be invoked without specifying the data type name.

Parameters

Text Type: Text An instance of the Text data type.

Value

Type: Text

The string to seek.

StartIndex

Type: Integer

The search starting position. The search proceeds from startIndex toward the beginning of this instance.

Return Value

Index Type: Integer The one-based index of the last occurrence of the specified string in this instance. If the index returned is 0, the value is not present in the string.

Text.PadLeft Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Returns a new Text that right-aligns the characters in this instance by padding them on the left, for a specified total length.

Syntax

```
Result :=   Text.PadLeft(Count: Integer [, Char: Char])
```

> **NOTE**
> This method can be invoked without specifying the data type name.

Parameters

Text Type: Text An instance of the Text data type.

Count
Type: Integer
The number of characters in the resulting string, equal to the number of original characters plus any additional padding characters.

Char
Type: Char
A padding character.

Return Value

Result Type: Text The end result Text.

See Also

Text Data Type

Text.PadRight Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Returns a new string that left-aligns the characters in this string by padding them with spaces on the right, for a specified total length.

Syntax

```
Result :=   Text.PadRight(Count: Integer [, Char: Char])
```

NOTE

This method can be invoked without specifying the data type name.

Parameters

Text Type: Text An instance of the Text data type.

Count

Type: Integer

The number of characters in the resulting string, equal to the number of original characters plus any additional padding characters.

Char

Type: Char

A padding character.

Return Value

Result Type: Text The end result Text.

Text.Remove Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Returns a new Text in which a specified number of characters from the current string are deleted.

Syntax

```
Result :=   Text.Remove(StartIndex: Integer [, Count: Integer])
```

> **NOTE**
> This method can be invoked without specifying the data type name.

Parameters

Text Type: Text An instance of the Text data type.

StartIndex
Type: Integer
The one-based position to begin deleting characters.

Count
Type: Integer
The number of characters to delete.

Return Value

Result Type: Text The end result Text.

See Also

Text.Replace Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Returns a new Text in which all occurrences of a specified string in the current instance are replaced with another specified string.

Syntax

```
Result :=   Text.Replace(OldValue: Text, NewValue: Text)
```

> **NOTE**
> This method can be invoked without specifying the data type name.

Parameters

Text Type: Text An instance of the Text data type.

OldValue
Type: Text
The string to replace all occurrences of OldValue.

NewValue
Type: Text
The string to be replaced.

Return Value

Result Type: Text The end result Text.

See Also

Text.Split Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Splits a string into a maximum number of substrings based on a collection of separators.

Syntax

```
Result :=   Text.Split([Separators: Text,...])
```

> **NOTE**
> This method can be invoked without specifying the data type name.

Parameters

Text Type: Text An instance of the Text data type.

Separators
Type: Text
A collection of separators that delimit the substrings in this string.

Return Value

Result Type: List of [Text] The collection of substrings from the original string based on the collection of separators.

See Also

Text Data Type

Text.TrimEnd Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Removes all trailing occurrences of a set of characters specified in an array from the current Text object.

Syntax

```
Result :=   Text.TrimEnd([Chars: Text])
```

NOTE

This method can be invoked without specifying the data type name.

Parameters

Text Type: Text An instance of the Text data type.

Chars

Type: Text

A string containing the characters to remove.

Return Value

Result Type: Text A copy of this string without all trailing white-space characters.

TextConst Data Type

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Denotes a multi-language string constant.

Remarks

The `TextConst` data type is typically used for UI messages; process or error messages. Keeping the `TextConst` data type in global scope, makes it easier to reuse the same message for several situations. For information about naming, see CodeCop Rule AA0074.

> **IMPORTANT**
>
> The `TextConst` data type is not included in the .xlf files for translation. Make sure to use the Label Data Type instead.

Example

The data type can be declared with the syntax as shown in the example below.

```
codeunit 50100 MyCodeunit
{
    procedure MyProcedure()
    var
        localTextConst: TextConst ENU = 'My text', DAN = 'Min tekst';
    begin
        Message(localTextConst);
    end;

    var
        globalTextConst: TextConst ENU = 'My text', DAN = 'Min tekst';
}
```

Developing Extensions

TextBuilder Data Type

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Represents a lighweight wrapper for the .Net implementation of StringBuilder.

The following methods are available on instances of the TextBuilder data type.

METHOD NAME	DESCRIPTION
Append(Text)	Appends a copy of the specified string to this TextBuilder instance.
AppendLine([Text])	Appends a copy of the specified string followed by the default line terminator to the end of the current TextBuilder object. If this parameter is omitted, only the line terminator will be appended.
Capacity([Integer])	Gets or sets the maximum number of characters that can be contained in the memory allocated by the current instance.
Clear()	Removes all characters from the current TextBuilder instance.
EnsureCapacity(Integer)	Ensures that the capacity of this TextBuilder instance is at least the specified value.
Insert(Integer, Text)	Inserts a string into this TextBuilder instance at the specified character position.
Length([Integer])	Gets or sets the length of this TextBuilder instance.
MaxCapacity()	Gets the maximum capacity of this TextBuilder instance.
Remove(Integer, Integer)	Removes the specified range of characters from this TextBuilder instance.
Replace(Text, Text)	Replaces all occurrences of a specified string in this TextBuilder instance with another specified string.
Replace(Text, Text, Integer, Integer)	Replaces, within a substring of this instance, all occurrences of a specified string in this TextBuilder instance with another specified string.
ToText()	Converts the value of this TextBuilder instance to a Text.
ToText(Integer, Integer)	Converts the value of a substring of this TextBuilder instance to a Text.

Remarks

The **TextBuilder** data type is one-based indexed, that is, the indexing begins with 1.

The Text Data Type is a value type, such that every time you use a method on it, you create a new string object in memory. This requires a new allocation of space. In situations where you need to perform repeated modifications to a string, the overhead associated with creating a Text Data Type can be costly.

The **TextBuilder** data type is a reference type, which holds a pointer elsewhere in memory. For performance reasons, we recommend you to use it when you want to modify a string without creating a new object. For example, using **TextBuilder** data type can boost performance when concatenating many strings together in a loop.

TextBuilder.Append Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Appends a copy of the specified string to this TextBuilder instance.

Syntax

```
[Ok := ]  TextBuilder.Append(Text: Text)
```

Parameters

TextBuilder Type: TextBuilder An instance of the TextBuilder data type.

Text
Type: Text
The text to append.

Return Value

Ok Type: Boolean **true** if the copy of the specified string succeeded, otherwise **false**. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.

TextBuilder.AppendLine Method

2/17/2021 • 2 minutes to read • Edit Online

Version: *Available from runtime version 1.0.*

Appends a copy of the specified string followed by the default line terminator to the end of the current TextBuilder object. If this parameter is omitted, only the line terminator will be appended.

Syntax

```
[Ok := ]  TextBuilder.AppendLine([Text: Text])
```

Parameters

TextBuilder Type: TextBuilder An instance of the TextBuilder data type.

Text
Type: Text
The string to append.

Return Value

Ok Type: Boolean **true** if the copy of the specified string with the default line terminator succeeded, otherwise **false**. If you omit this optional return value and the operation does not execute successfully, a runtime error will occur.
