Development and administration for Finance and Operations apps

2/18/2021 • 3 minutes to read • Edit Online

NOTE

Effective November 2020:

- Common Data Service has been renamed to Microsoft Dataverse. For more information, see Power Automate Blog.
- Some terminology in Microsoft Dataverse has been updated. For example, *entity* is now *table* and *field* is now *column*. For more information, see Terminology updates.

This topic will be updated soon to reflect the latest terminology.

Development and administration for Finance and Operations apps includes:

- Administrator experience and Lifecycle Services
- Developer experience
- Intelligence
- Mobile apps
- Data management and data entities
- Office integration

Developer experience

The developer experience is based on modern tooling using Visual Studio and .NET components.

- The development tools are decoupled from any running environment, which means that you develop against local, XML-based files, not the online database.
- Microsoft Visual Studio is the development environment. Finance and Operations customizes the Visual Studio environment to provide you with a smooth and familiar experience.
- The X++ compiler generates Common Intermediate Language (CIL) for all features. CIL is the same intermediate language used by other .NET-based (managed) languages, such as the C# programming language.
- You can leverage the browser-based client and design patterns for forms to provide an improved end-user experience.
- The Application Lifecycle Management (ALM) system supports build automation, test automation, and deployment of models to the cloud.

For more information, see Develop and customize home page.

Administrator experience and Lifecycle Services

Finance, Supply Chain Management, and Commerce are cloud-hosted. As an IT professional, you can use Dynamics Lifecycle Services (LCS) to monitor and tune your environments, deploy features, and stay up to date with recent hotfixes. Within your deployment, you can configure security, and manage when processes run. You can also use LCS when you are called on to support business intelligence and reporting, mobile apps, Office, and other integrations.

BI & reporting

Finance and Operations provides five distinct reporting experiences. Specialized tools are provided to meet the complex and diverse reporting needs of various functions throughout the organization.

- Operational views – Designed to address the specific needs of a given business persona.
- Business documents – Static documents used to capture and exchange processed business data.
- Analytical tools and visualizations – Personalized presentations of logical calculations that allow the user to explore their data.
- Electronic reporting – Tool used to configure formats for electronic documents.
- Financial reporting – Designed to provide in-depth accounting management tools based on standard views of financial activities across legal entities.

Mobile apps

The Finance and Operations mobile app empowers your organization to mobilize its business processes. After your IT admin enables the mobile workspaces feature for your organization, users can sign in to the app and immediately begin to run business processes from their mobile devices. The Dynamics 365 for Finance and Operations mobile app includes the following features that can help increase productivity:

- Users can view, edit, and act on business data, even if they have intermittent network connectivity or their mobile devices are offline. When a device reestablishes a network connection, offline data operations are automatically synchronized with Finance and Operations.
- IT admins or developers can build and publish mobile workspaces that have been tailored to their organization. The app uses your existing code assets, so you don't have to re-implement your validation procedures, business logic, or security configuration.
- IT admins or developers can easily design mobile workspaces by using the point-and-click workspace designer that is included with the Finance and Operations web client.
- IT admins or developers can optionally optimize the offline capabilities of workspaces by using the Business logic extensibility framework. Because data continues to be processed while a device is offline, your mobile scenarios remain rich and fluid, even if devices don't have constant network connectivity.

Data management and data entities

Data from Finance and Operations can easily be integrated with Microsoft and non-Microsoft data sources using Dataverse, Power Apps, and Power BI. For more information, see Data entities overview.

Office integration

The Microsoft Office integration capabilities provide users with a productive environment that helps them get the job done by using Office products. For more information, see Office integration overview.

eLearning courses

For online courses and training, check out Dynamics 365 Finance and Operations on Microsoft Learn.

What's new or changed in Finance and Operations apps home page

2/18/2021 • 2 minutes to read • Edit Online

Application releases

To see what's new or changed in each release of a Finance and Operations app, see the following topics:

Platform updates for version 10.0.17 of Finance and Operations apps (April 2021)

2/18/2021 • 2 minutes to read • Edit Online

IMPORTANT

Some or all of the functionality noted in this topic is available as part of a preview release. The content and the functionality are subject to change. For more information about preview releases, see Service update availability.

This topic lists the features that are included in the platform updates for version 10.0.17 of Finance and Operations apps. This version has a build number of 7.0.5934 and is available on the following schedule:

- **Preview of release:** February 2021
- **General availability of release (self-update):** March 2021
- **General availability of release (auto-update):** April 2021

Features included in this release

The following features are included in this release. Some of the listed features are still in preview, while others may already be generally available. See the release plan for official release dates for each feature.

- Visual Studio 2017 is now the primary supported version for X++ tools. Visual Studio 2015 is deprecated.
  - For more information, see Removed or deprecated platform features.
- (Preview) Translation support for organization views
  - For more information, see Saved views.
- Allow configuration of the publish batch size for the Excel add-in
  - For more information, see View and update entity data with Excel.
- Upgrade to React 17
- Freeze columns in grids
  - For more information, see Grid capabilities.
- Updates to client feature states
  - See the release plan for details about the client features that were turned on by default or made mandatory with this release.
- View independent software vendor (ISV) license status
  - It is now possible to view status and expiration dates for an ISV license. For more information, see View independent software vendor license status.
- executeQueryWithParameters method
  - This method runs SQL queries by using statement parameters that can help mitigate SQL injection attacks.

Most of these features must be enabled using Feature management before you can use them.

Dynamics 365: 2021 release wave 1 plan

Wondering about upcoming and recently released capabilities in any of our business apps or platform?

Check out the Dynamics 365: 2021 release wave 1 plan. We've captured all the details, end to end, top to bottom, in a single document that you can use for planning.

Removed and deprecated platform features

The Removed or deprecated platform features topic describes features that have been removed, or that are planned for removal in platform updates of Finance and Operations apps.

- A *removed* feature is no longer available in the product.
- A *deprecated* feature isn't in active development and might be removed in a future update.

A deprecation notice will be added in the Removed or deprecated platform features topic 12 months before the removal of any feature from the product.

For breaking changes that affect only compilation time, but that are binary-compatible with sandbox and production environments, the deprecation time will be less than 12 months. Typically, these changes are functional updates that must be made to the compiler.

Platform updates for version 10.0.16 of Finance and Operations apps (February 2021)

2/18/2021 • 3 minutes to read • Edit Online

This topic lists the features that are included in the platform updates for version 10.0.16 of Finance and Operations apps. This version has a build number of 7.0.5860 and is available on the following schedule:

- **Preview of release:** November 2020
- **General availability of release (self-update):** January 2021
- **General availability of release (auto-update):** February 2021

Features included in this release

The following features are included in this release. Some of the listed features are still in preview, while others may already be generally available. See the release plan for official release dates for each feature.

- User session management
  - Administrators have the ability to set a maximum session timeout for individual users. The range of the session can be from 1 hour to 2160 hours. When this session length expires, the user is required to sign in with their credentials. For more information, see User session management.

- Renamed 'Session idle timeout' to 'Session inactivity timeout'
  - To differentiate the types of session timeouts between maximum user session and inactivity user session, a change in the name was implemented. For more information, see Set the session inactivity timeout.

- Removing support for Visual Studio 2015
  - Version 10.0.16 is the last version to support Visual Studio 2015. For more information, see Removing support for Visual Studio 2015.

- Email throttling
  - This feature allows non-interactive email providers to adhere to a per-minute email sending limit, which prevents errors that are currently triggered when the system attempts to send more emails than the provider can handle. When email throttling is enabled, sending limits for Microsoft 365 email providers will be set automatically; manual configuration is required for all other email providers. For more information, see Configure and send email.

- Document (attachment) history
  - This document management feature creates a history mechanism for record attachments. This allows your organization to maintain an audit of actions related to individual attachments. For example, you can see when an attachment was created, marked for pending deletion, restored, deleted, or moved and who performed the action. The default history retention period is 180 days, however this is configurable on the **Document management parameters** page. For more information, see Configure document management.

- General availability of the Grouping with grids feature
  - For more information, see Grid capabilities.

- New HTML editor control

- Enhanced the Message::AddAction API
  - The Message::AddAction API now surfaces the action in notifications when messages are routed to the

Action center or Message details pane. For more information, see Messaging APIs.

- Mitigate a SQL injection attack
  - Use the new **Statement.executeQueryWithParameters** API to mitigate SQL injection attacks.

Most of these features must be enabled using Feature management before you can use them.

Dynamics 365: 2020 release wave 2 plan

Wondering about upcoming and recently released capabilities in any of our business apps or platform?

Check out the Dynamics 365: 2020 release wave 2 plan. We've captured all the details, end to end, top to bottom, in a single document that you can use for planning.

Removed and deprecated platform features

The Removed or deprecated platform features topic describes features that have been removed, or that are planned for removal in platform updates of Finance and Operations apps.

- A *removed* feature is no longer available in the product.
- A *deprecated* feature isn't in active development and might be removed in a future update.

A deprecation notice will be added in the Removed or deprecated platform features topic 12 months before the removal of any feature from the product.

For breaking changes that affect only compilation time, but that are binary-compatible with sandbox and production environments, the deprecation time will be less than 12 months. Typically, these changes are functional updates that must be made to the compiler.

Platform updates for version 10.0.15 of Finance and Operations apps (January 2021)

2/18/2021 • 2 minutes to read • Edit Online

This topic lists the features that are included in the platform updates for version 10.0.15 of Finance and Operations apps. This version has a build number of 7.0.5816 and is available on the following schedule:

- **Preview release:** October 2020
- **General availability (self-update):** November 2020
- **Auto-update:** January 2021

Features included in this release

- Azure Pipelines task for asset deployment now supports self-service environments
  - For more information to enable this support, see Deploy assets by using Azure Pipelines.
- Specific full user license information is now available when configuring security and assigning roles to users.
  - For more information, see Stay compliant with user licensing requirements.
- Regression suite automation tool (RSAT) 2.0
  - For RSAT users, version 10.0.15 requires the latest version of RSAT to address a known issue. RSAT 2.0.7031.98 or newer will be available for download at https://www.microsoft.com/en-us/download/details.aspx?id=57357 on Monday, October 12, 2020.

Removed or deprecated platform features

2/18/2021 • 10 minutes to read • Edit Online

This topic describes features that have been removed, or that are planned for removal in platform updates of Finance and Operations apps.

- A *removed* feature is no longer available in the product.
- A *deprecated* feature is not in active development and may be removed in a future update.

This list is intended to help you consider these removals and deprecations for your own planning.

Detailed information about objects in Finance and Operations apps can be found in the Technical reference reports. You can compare the different versions of these reports to learn about objects that have changed or been removed in each version of Finance and Operations apps.

Feature removed effective January 28, 2021

Batch job to handle SQL index defragmentation

Reason for deprecation/removal	In order to reduce the overhead of operating, monitoring, and maintaining the index management by customers, this feature has been removed.
Replaced by another feature?	Going forward, the index maintenance will be performed by Microsoft services. This will happen continuously without affecting the user workloads.
Product areas affected	Finance and Operations apps
Deployment option	Cloud deployment - affects Microsoft-managed production environments and Tier 2 through Tier 5 sandbox environments.
Status	This feature is removed.

Platform updates for version 10.0.17 of Finance and Operations apps

> **IMPORTANT**
> Version 10.0.17 is available as part of a preview release. The content and the functionality are subject to change. For more information about preview releases, see One version service updates FAQ.

Visual Studio 2015

Reason for deprecation/removal	To support the latest versions of Visual Studio, some changes have to be made to the X++ extensions for Visual Studio. These changes are incompatible with Visual Studio 2015.

Replaced by another feature?	Visual Studio 2017 will replace Visual Studio 2015 as the deployed and required version.
Product areas affected	Visual Studio development tools
Deployment option	All
Status	Deprecated. Upon updating, the previous X++ tools will be removed from Visual Studio 2015, and the updated tools will not install on Visual Studio 2015. There is no impact on hosted builds. For build virtual machines, the build pipeline (build definition) needs to be manually updated to change the dependency from MSBuild 14.0 (Visual Studio 2015) to MSBuild 15.0 (Visual Studio 2017) as described in Update a legacy pipeline in Azure Pipelines.

User avatar

Reason for deprecation/removal	The user avatar that displays on the right side of the navigation bar was retrieved using an API from the Dynamics 365 header control, which has been deprecated.
Replaced by another feature?	Users will see their initials in a circle in the navigation bar instead. This is the same visual currently used on development machines.
Product areas affected	Web client
Deployment option	All
Status	Removed as of version 10.0.17

Enterprise Portal (EP) deprecation

Reason for deprecation/removal	The metadata artifacts associated with Dynamics AX 2012 Enterprise Portal (EP) have been deprecated, as EP was never supported in the Finance and Operations apps.
Replaced by another feature?	No
Product areas affected	Web client
Deployment option	All
Status	Deprecated. All EP code is scheduled to be removed in the October 2021 release.

Platform updates for version 10.0.15 of Finance and Operations apps

Internet Explorer 11 support for Dynamics 365 is deprecated

Reason for deprecation/removal	Effective December 2020, Microsoft Internet Explorer 11 support for all Dynamics 365 products is deprecated, and Internet Explorer 11 won't be supported after August 2021. This will impact customers who use Dynamics 365 products that are designed to be used through an Internet Explorer 11 interface. After August 2021, Internet Explorer 11 won't be supported for such Dynamics 365 products.
Replaced by another feature?	We recommend that customers transition to Microsoft Edge.
Product areas affected	All Dynamics 365 products
Deployment option	All
Status	Deprecated. Internet Explorer 11 won't be supported after August 2021.

Visual Studio add-in to apply metadata hotfixes

Reason for deprecation/removal	Metadata hotfixes are no longer supported with the One Version service updates that were introduced in July 2018 with version 8.1.
Replaced by another feature?	Individual metadata hotfixes are not available for supported versions. Cumulative quality updates are applied instead.
Product areas affected	Visual Studio add-ins
Deployment option	Development virtual machines
Status	With version 10.0.15, the add-in is no longer included in the Visual Studio tools.

Platform updates for version 10.0.14 of Finance and Operations apps

Online users page

Reason for deprecation/removal	This is a legacy page that was built for previous client/server architecture. The information on this page is not always accurate, which can be confusing and misleading.
Replaced by another feature?	We will provide a new page in a future update.
Product areas affected	System Administration
Deployment option	All
Status	By October 2021 this form will be removed.

Platform updates for version 10.0.13 of Finance and Operations apps

Custom code defined in SSRS report properties

Reason for deprecation/removal	In general, custom code offers limited benefits while at the same time, requires significant resourcing and compute to support. Custom code is primarily used by report authors to call public methods from a custom code assembly. However, the cloud-hosted service does not support references to custom assemblies for SSRS reports.
Replaced by another feature?	Report authors may choose to continue referencing public .NET APIs for Math, Conversion, and Format operations from any textbox expression. For more information, see Add Code to a Report (SSRS).
Product areas affected	Subset of application report designs defined in RDL that contain custom code.
Deployment option	All
Status	With version 10.0.13, the compiler will begin issuing a warning for instances where custom code is detected in a SSRS report definition. To fix the issue, open the report design definition and remove all custom code artifacts. This warning will be replaced with a compiler error in a future update.

Upgrade of three jQuery component libraries

Reason for deprecation/removal	Three jQuery component libraries are being updated for security fixes and to maintain currency.
Replaced by another feature?	The following libraries are being affected: jQuery (to version 3.5.0 from version 2.1.4), jQuery UI (to version 1.12.1 from version 1.11.4), jQuery qTip (to version 3.0.3 from 2.2.1). Migration guidance has been provided online by jQuery.
Product areas affected	Extensible controls, specifically custom JavaScript code utilizing deprecated or removed APIs
Deployment option	All
Status	With version 10.0.13/Platform update 37, customers can optionally move to the latest libraries by enabling the "Upgrade three jQuery component libraries" feature. Moving to the new libraries will be mandatory with the April 2021 release to allow time for migration of affected APIs.

Existing grid control/forceLegacyGrid() API

Reason for deprecation/removal	The existing grid control is being replaced by the new grid control.

Replaced by another feature?	The new grid control
Product areas affected	Web client
Deployment option	All
Status	In version 10.0.13, the new grid control is generally available, and customers can optionally turn on this feature. The new grid control will become mandatory in the October 2021 release. When the new grid control becomes mandatory, the **forceLegacyGrid()** API will no longer be honored.

Personalization without saved views

Reason for deprecation/removal	The personalization subsystem has been overhauled with the saved views feature, so that it has better performance and offers additional capabilities.
Replaced by another feature?	Saved views
Product areas affected	Web client
Deployment option	All
Status	In version 10.0.13/Platform update 37, the saved views feature is generally available, and customers can optionally turn on this feature. The saved views feature will become mandatory in the October 2021 release.

Platform updates for version 10.0.12 of Finance and Operations apps

Grid or group control form extensions containing invalid field references

Reason for deprecation/removal	The data group property on grid or group controls is used to automatically show all the fields of a field group. A grid or group control added by extension could contain fields that are no longer defined on the field group, or it might be missing fields that are defined on the field group. This can cause inconsistent behavior at runtime. Platform updates for version 10.0.12 of Finance and Operations apps now categorize this issue as a compiler *warning*. To fix this issue, open the form extension and save it.
Replaced by another feature?	This compiler warning will be replaced with a compiler error in a future update.
Product areas affected	Visual Studio development tools
Deployment option	All
Status	A compiler warning is introduced in platform updates for version 10.0.12 of Finance and Operations apps.

Platform updates for version 10.0.11 of Finance and Operations apps

Explicit safe lists for self-service environments

Reason for deprecation/removal	The process for moving IP to safe lists has changed. Self-service no longer supports IP safe lists.
Replaced by another feature?	For more information, see Configuring Azure Active Directory Conditional Access.
Product areas affected	Security
Deployment option	Cloud
Status	**Deprecated:** This feature is fully-deprecated for self-service deployments.

Visual Studio 2015

Reason for deprecation/removal	To support the latest versions of Visual Studio, some changes have to be made to the X++ extensions for Visual Studio. These changes are incompatible with Visual Studio 2015.
Replaced by another feature?	Visual Studio 2017 will replace Visual Studio 2015 as the deployed and required version.
Product areas affected	Visual Studio development tools
Deployment option	All
Status	Virtual machines deployed on version 10.0.13 (Platform update 37) or later contain Visual Studio 2017. Version 10.0.16 (Platform update 40) is the final release with support for Visual Studio 2015. Virtual machines with only Visual Studio 2015 will not be able to update to version 10.0.17 (Platform update 41).

Field groups containing invalid field references

Reason for deprecation/removal	Field groups in table metadata definitions can contain field references that aren't valid. If these field groups are deployed, they can cause runtime failures in Financial Reporting and Microsoft SQL Server Reporting Services (SSRS). Platform update 23 introduced a compiler *warning* that enabled this metadata issue to be addressed. Platform updates for version 10.0.11 of Finance and Operations apps categorize this issue as a compiler *error*. To fix this issue, follow these steps. 1. Remove the invalid field reference from the table field group definition. 2. Recompile. 3. Make sure that any errors are addressed.
Replaced by another feature?	This compiler error permanently replaces the compiler warning.
Product areas affected	Visual Studio development tools
Deployment option	All
Status	**Deprecated:** The compiler warning is a compiler error in platform updates for version 10.0.11 of Finance and Operations apps.

ISV licenses created by using the SHA1 hashing algorithm

Reason for deprecation/removal	The process for creating independent software vendor (ISV) licenses has changed. For more information, see Independent software vendor (ISV) licensing.
Replaced by another feature?	Yes. Use Windows PowerShell to create licenses.
Product areas affected	Visual Studio development tools
Deployment option	All
Status	**Deprecated:** ISV licenses that were created by using the SHA1 hashing algorithm. This algorithm depended on certificates that were created by using the MakeCert utility, and this utility has been deprecated. **Deprecated:** The use of SHA1 for security or hashing purposes. SHA1 will cease to function in early 2021. Therefore, it should no longer be used. **Removed:** Support for Transport Layer Security (TLS) 1.0 and TLS 1.1 incoming or outgoing requests.

Platform update 32

Workflow request change dialog box no longer includes user selection drop-down list

Reason for deprecation/removal	This was a security issue because the request for change could be sent to an unintended user. This was also a usability issue because it forced the user to determine who the workflow originator was and manually select them.
Replaced by another feature?	No
Product areas affected	Workflow
Deployment option	All
Status	The user selection drop-down list was removed from the request change dialog box in Platform update 32. Request change requests will be automatically sent to the originator as intended. For more information about this functionality, see Actions in workflow approval processes.

Embedded drill-through links are no longer supported in paginated documents rendered by the cloud-hosted service

Reason for deprecation/removal	Navigation URLs embedded in documents rendered by the service may contain sensitive business data. We are removing support for embedded drill-through links in documents as a security precaution to further protect customer's data. Users will also benefit from improved performance while interactively producing documents as a result of this change.
Replaced by another feature?	No
Product areas affected	Reporting
Deployment option	All
Status	This feature is actively being removed from the service. The modern client offers numerous options for producing views that include auto-generated links to assist in navigating the application. Paginated documents rendered by the service are recommended for external communications that are emailed, archived, and printed for recipients. We have improved the experience for previewing documents directly in the browser, which offers direct access to local printers. For more information, see Preview PDF documents with an embedded viewer.

Previous announcements about removed or deprecated features

To learn more about features that have been removed or deprecated in previous releases, see Removed or deprecated features in previous releases.

NOTE

Can you tell us about your documentation language preferences? Take a short survey.

The survey will take about seven minutes. No personal data is collected (privacy statement).

Removed or deprecated features in previous releases

2/18/2021 • 51 minutes to read • Edit Online

NOTE

Effective November 2020:

- Common Data Service has been renamed to Microsoft Dataverse. For more information, see Power Automate Blog.
- Some terminology in Microsoft Dataverse has been updated. For example, *entity* is now *table* and *field* is now *column*. For more information, see Terminology updates.

This topic will be updated soon to reflect the latest terminology.

IMPORTANT

This topic is no longer updated. To see a current list of features that have been removed or deprecated from Finance and Operations apps, search for **"Removed or deprecated features"** content that relates to the app you're using.

This topic describes features that have been removed or deprecated from Dynamics 365 for Finance and Operations and previous releases of that product.

- A *removed* feature is no longer available in the product.
- A *deprecated* feature is not in active development and may be removed in a future update.

This list is intended to help you consider these removals and deprecations for your own planning.

Detailed information about objects in Finance and Operations apps can be found in the Technical reference reports. You can compare the different versions of these reports to learn about objects that have changed or been removed in each version of Finance and Operations apps.

Finance 10.0.7 with Platform update 31

Chinese voucher types without Account groups selection

Reason for deprecation/removal	Changed to the feature with account groups selection.
Replaced by another feature?	Yes
Product areas affected	Application
Deployment option	All
Status	Deprecated: By December 1, 2020, we plan to no longer support Chinese voucher types setup without Account groups selection. Find more details about new feature design in What's new in 10.0.7

Finance and Operations 10.0.6 with Platform update 30

DimensionHash.getHash(str _message)

Reason for deprecation/removal	Windows is deprecating the use of SHA1, as documented in Windows Enforcement of SHA1 Certificates.
Replaced by another feature?	Yes
Product areas affected	Application
Deployment option	All
Status	Deprecated: By April 1, 2020, developers must use the platform APIs found in the class **HasFunction**.

Hash.ComputeSHA1Hash(string message)

Reason for deprecation/removal	Windows is deprecating the use of SHA1, as documented in Windows Enforcement of SHA1 Certificates.
Replaced by another feature?	Yes
Product areas affected	Platform
Deployment option	All
Status	Deprecated: By April 1, 2020, developers must use the platform APIs found in the class **HasFunction**.

FormDateTimeControl.setUtcString()

Reason for deprecation/removal	We are retiring the **setUtcString()** method, because a better replacement method is available.
Replaced by another feature?	Yes
Product areas affected	Platform
Deployment option	All
Status	Deprecated: By October 1, 2020, we plan to no longer support the **setUtcString()** method. Developers should be using the **setUtcDateTime()** method instead.

Blacklist report (IT) – Feature reference IT-00001

Reason for deprecation/removal	Not legally required.
Replaced by another feature?	No
Product areas affected	Italian localization
Deployment option	All
Status	Deprecated: By October 1, 2020, we plan to no longer support the **Blacklist report (IT) – Feature reference IT-00001**.

Domestic tax report – Feature reference IT-00003

Reason for deprecation/removal	Not legally required.
Replaced by another feature?	No
Product areas affected	Italian localization
Deployment option	All
Status	Deprecated: By October 1, 2020, we plan to no longer support the **Domestic tax report – Feature reference IT-00003**.

Finance and Operations 10.0.5 with Platform update 29

US Payroll tax updates

Reason for deprecation/removal	We are retiring tax updates for the US Payroll functionality due to low usage and enhanced functionality that is now offered via strategic integrations.
Replaced by another feature?	Yes
Product areas affected	Payroll
Deployment option	All
Status	Deprecated: By July 31, 2024, we plan to no longer provide tax updates to US Payroll customers. The functionality will remain in the product, but enhancements will no longer keep the functionality up to date, and any product defects will be evaluated on a case-by-case basis.

> **NOTE**
>
> This represents a change from the original discontinuation date of October 1, 2021. For more information, see Tax updates being retired for US Payroll feature in Microsoft Dynamics 365 for Finance and Operations.

Data management staging clean up

Reason for deprecation/removal	Does not meet the core requirements that are needed for scheduling periodic cleanup.
Replaced by another feature?	Yes, the Job history cleanup feature is being added to meet the scenarios holistically.
Product areas affected	Data management
Deployment option	All
Status	Deprecated: Target timeframe for the functionality to be removed is December 2020.

Finance and Operations 10.0.4 with Platform update 28

France: FEC Accounting data export in XML

Reason for deprecation/removal	Replaced by TXT format, **French FEC audit file** is available through **General ledger** > **Periodic tasks** > **Data export**.
Replaced by another feature?	Yes
Product areas affected	General ledger
Deployment option	All
Status	Deprecated. Target timeframe for the functionality to be removed is July 2020.

Legacy navigation bar

Reason for deprecation/removal	Header alignment with other Dynamics and Office products. For more details, see Updated navigation bar that aligns with the Office header.
Replaced by another feature?	Starting in Platform update 24, a restyled navigation bar that features search was introduced.
Product areas affected	Web client

Deployment option	All
Status	Deprecated: Starting in April 2020, the legacy navigation bar will no longer be available. Until that point, customers can revert to the legacy navigation bar through the **Client performance options** page.

Finance and Operations 10.0.2 with Platform update 26

Legacy default action behavior

Reason for deprecation/removal	The legacy behavior for default actions in grids results in an unexpected column having the default action link after grid columns have been reordered via personalization. The new sticky default action feature corrects this. For more details, see Sticky default actions in grids.
Replaced by another feature?	Starting in Platform update 21, a feature for "sticky default actions" was introduced. This feature can be enabled on the **Client performance options** page.
Product areas affected	Grids in the web client
Deployment option	All
Status	Deprecated: Starting in April 2020, sticky default actions will be the default behavior, without a mechanism to revert to the legacy behavior.

Legacy "is one of" filtering experience

Reason for deprecation/removal	The "is one of" filtering experience went through a redesign in Platform update 22,with the plan for this to eventually be the only "is one of" filtering experience.
Replaced by another feature?	Starting in Platform update 22, an improved "is one of" filtering experience became available on the **Client performance options** page. For more information, see Optimized is one of filtering experience.
Product areas affected	Web client
Deployment option	All
Status	Deprecated: Starting in April 2020, the improved "is one of" experience will be the default behavior, without a mechanism to revert to the legacy behavior.

Parameter to enable sales orders with multiple project contract funding sources

Support for creating project-based sales orders where the project contract has multiple funding sources is

enabled with the **Project management parameters** setting **Allow sales orders for project with multiple funding sources**. By default, this parameter is not enabled.

Reason for deprecation/removal	The functionality will always be enabled after the parameter is removed.
Replaced by another feature?	No. The functionality to support project-based sales orders with multiple funding sources will always be enabled.
Product areas affected	The **Allow sales orders for projects with multiple funding sources** parameter will be removed. The following methods will be modified when the parameter is removed: **ctrlSalesOrderTable** method in **ProjStatusType** class, **validate** method for **ProjId** field, and **run** method in **SalescreateOrder** form. The following methods will be deprecated when the parameter is removed: **IsSalesOrderAllowedForMultipleFundingSources** in **ProjTable** table file, **IsAllowSalesOrdersForMultipleFundingSourcesParamEnabled** method in **ProjTable** table file, **AllowSalesOrdersForMultipleFundingSources** data field in **ProjParameters** form and **ProjParameterEntity** files, **IsAssociatedToMultipleFundingSourcesContract** private method in **ProjTable** table file.
Deployment option	All
Status	Deprecation is planned for the April 2020 release wave.

Legacy workflow reports for tracking and instance status

Reason for deprecation/removal	The legacy workflow reports for tracking and instance status are being deprecated because they are no longer referenced from the navigation. The report names are WorkflowWorkflowInstanceByStatusReport and WorkflowWorkflowTrackingReport.
Replaced by another feature?	The workflow history form can be used instead.
Product areas affected	Web client
Deployment option	All
Status	Deprecated: Target timeframe for the functionality to be removed is April 2020.

Finance and Operations 10.0.1 with Platform update 25

Deprecated APIs and potential breaking changes

Deriving from internal classes is deprecated

Reason for deprecation/removal	Before Platform update 25, it was possible to create a class or table that derives from an internal class/table that is defined in another package/module. This is not a safe coding practice. As of Platform update 25, the compiler will display a warning.
Replaced by another feature?	The compiler warning will be replaced by an error in Platform update 26. This change is backward compatible at runtime, which means that Platform update 25 or newer can be deployed on any sandbox or production environment without the need to modify custom code. This change only affects development and compile time.
Product areas affected	Visual Studio development tools
Deployment option	All
Status	Deprecated: The warning will become a compilation error in Platform update 26.

Overriding internal methods is deprecated

Reason for deprecation/removal	Before Platform update 25, it was possible to override an internal method in a derived class that is defined in another package/module. This is not a safe coding practice. As of Platform update 25, the compiler will display a warning.
Replaced by another feature?	This warning will be replaced by a compile error in Platform update 26. This change is backward compatible at runtime, which means that Platform update 25 or newer can be deployed on any sandbox or production environment without the need to modify custom code. This change only affects development and compile time.
Product areas affected	Visual Studio development tools
Deployment option	All
Status	Deprecated: The warning will become a compilation error in Platform update 26.

Finance and Operations 10.0.0 with Platform update 24

Renaming released products

Reason for deprecation/removal	When you use the **Rename primary key** function to change the ItemId of a released product, only direct foreign key references are updated. Any other references to the released product, such as from production orders, will retain the old ItemId. As a result, there could be inconsistent data that will eventually block business processes.

Replaced by another feature?	No.
Product areas affected	Product information management
Deployment option	All
Status	Removed as of Finance and Operations 10.0.0 with Platform update 24.

Finance and Operations 8.1.3 with Platform update 23

SQL Server Reporting Services ReportViewer Control

Customers can use the **Export** action provided by the embedded SQL Server Reporting Services (SSRS) ReportViewer control to download documents produced by Finance and Operations applications. This HTML-based presentation of the report offers users a non-paginated preview of the document.

Reason for deprecation/removal	The non-paginated nature of the HTML-based preview experience does **not** deliver fidelity with the physical documents ultimately produced by Finance and Operations. By fully embracing PDF as the standard format for business documents, users are able to take advantage of a modern viewing experience with improved performance when producing application reports.
Replaced by another feature?	Going forward, PDF documents will be the default format for reports rendered by Finance and Operations.
Product areas affected	This change does **not** impact customer scenarios where reports are distributed electronically or sent directly to printers.
Deployment option	All
Status	Deprecated: A removal date has not been set for this feature. The functionality to automatically preview application reports using an embedded PDF viewer is planned for the May 2019 Platform update.

Client KPI controls

Embedded key performance indicators (KPIs) could be modeled in Visual Studio by a developer and further customized by the end user.

Reason for deprecation/removal	The native client controls used to define KPIs have low customer uptake and rely on a developer to add trackable metrics.

Replaced by another feature?	PowerBI.com service delivers world-class tooling for defining and managing KPIs based on data from external sources. In an upcoming release, we plan to enable you to embed solutions hosted on PowerBI.com in application workspaces.
Product areas affected	This update will prevent developers from introducing new KPI controls in Visual Studio designer.
Deployment option	All
Status	Deprecated: A removal date has not been set for this feature.

Deprecated APIs and future breaking changes

Field groups containing invalid field references

Reason for deprecation/removal	It is possible for table metadata definitions to have field groups containing invalid field references. If deployed, this can cause runtime failures in Financial Reporting and SQL Server Reporting Services (SSRS). This issue is currently categorized as a *compiler warning* rather than an *error*, meaning that the deployable package creation and deployment can proceed without fixing the issue. To fix this issue: 1. Remove the invalid field reference from the table field group definition. 2. Recompile. 3. Ensure any warnings or errors are addressed.
Replaced by another feature?	This warning will be replaced by a compile error in the future.
Product areas affected	Visual Studio development tools
Deployment option	All
Status	Deprecated: The warning is a compile-time error with platform updates for version 10.0.11 of Finance and Operations apps.

Complete list

To access the full list of APIs that are being deprecated, see Deprecation of methods and metadata elements.

Finance and Operations 8.1 with Platform update 20

Batch transfer rules for subledger journal account entries

The Synchronous transfer mode is being deprecated in the General ledger parameters. This mode is replaced by Asynchronous and scheduled batch only, which already exist as options for transfer. For additional information, see the General Ledger Parameters – Batch transfer rules blog.

Reason for deprecation/removal	We are removing the synchronous option due to performance impact to the system.
Replaced by another feature?	Asynchronous and scheduled batch are options to use in place of Synchronous.
Product areas affected	General Ledger, Accounts payable, Accounts Receivable, Procurement, Expense
Deployment option	All
Status	Deprecated: Target timeframe for the functionality to be removed is the 10.0 version.

Electronic reporting for Russia

Feature for configuring .txt and .xml file formats of declarations.

Reason for deprecation/removal	Replaced with Electronic reporting.
Replaced by another feature?	Yes.
Product areas affected	General Ledger
Deployment option	All
Status	Removed as of Finance and Operations 8.1 with Platform update 20.

Financial reports generator for Russia

A tool for setting up data collection for accounting and tax reports, and to export data to XLS and DOC report templates. Functional parts: Export data to XLS and DOC report templates, queries, fixed requisites are removed.

Reason for deprecation/removal	Removed parts are replaced with Electronic reporting.
Replaced by another feature?	Yes. Financial reports setup user interface should be used for setting up data collection rules by GL accounts or tax registers. Export data to various file types, fixed requisites and query-like data collection rules should be configured in Electronic reporting.
Product areas affected	General ledger.
Deployment option	All
Status	Removed as of Finance and Operations 8.1 with Platform update 20.

Integration with external providers for sending electronic reporting through communication channels for

Russia

Feature exporting generated electronic files of declarations to folder for further sending to official providers of electronic reporting as well as importing state back.

Reason for deprecation/removal	Replaced with electronic messages configurable feature.
Replaced by another feature?	Yes.
Product areas affected	General Ledger, Tax
Deployment option	All
Status	Removed as of Finance and Operations 8.1 with Platform update 20.

Profit tax register wizard

Feature for creating templates for new profit tax registers. This feature creates X++ objects for new registers, which are then created as templates with the appropriate calculation logic added in.

Reason for deprecation/removal	Feature is not compatible with the Finance and Operations extensibility model.
Replaced by another feature?	No
Product areas affected	Tax
Deployment option	All
Status	Removed as of Finance and Operations 8.1 with Platform update 20.

Finance and Operations 8.0 with Platform update 15

No features have been removed or deprecated with this release. Platform update 15 is cumulative and contains new or changed features from Platform update 13, Platform update 14, and Platform update 15.

Finance and Operations, Enterprise edition 7.3 with Platform update 12

Personalized product recommendations

Starting February 15, 2018, retailers will no longer be able to display personalized product recommendations on a point of sale (POS) device. For more information, see Product recommendations overview.

Reason for deprecation/removal	We are removing the current version of the product recommendation service as we redesign this feature with a better algorithm and newer retail-oriented capabilities.

Replaced by another feature?	No. However, after Spring 2018, we plan to bring back this feature to leverage a new recommendation service.
Product areas affected	Personalized product recommendations in POS.
Deployment option	All
Status	Removed as of February 15, 2018. This affects customers running Dynamics 365 for Operations 1611 and later.

Extension of the list of Electronic reporting (ER) functions

The possibility to introduce custom functions to be used in the ER expression builder (for more information, see Extend the list of Electronic reporting (ER) functions) is not supported any more. Due to changes of the ER APIs, the API to call built-in functions from the ER expression builder became internal and can't be extended any longer.

Reason for deprecation/removal	Code sealing initiative
Replaced by another feature?	None. Whenever a new built-in function is needed, a new extension request must be addressed to the ER framework team. As a temporary work around while the requested function is under development by the ER team, the required logic can be programmed as a method of a custom application class. This method can be accessed in an ER expression as a property of the added ER data source of the **Application\Class** type that refers to that custom application class.
Product areas affected	Electronic reporting framework
Deployment option	All
Status	Removed as of Finance and Operations, Enterprise edition 7.3.

Inventory by item group and Inventory by inventory dimension aging reports

These two reports are no longer supported in Finance and Operations. Instead, the **Inventory aging** report can be used to improve the user experience.

Reason for deprecation	Duplicate functionality
Replaced by another feature?	Yes. The two reports have been replaced by the **Inventory aging** report.
Product areas affected	Inventory management, Cost management

Deployment option	All
Status	Deprecated: The menu items for the two reports have been removed in version 7.3. However, the code for the reports remains in the product. The plan is to remove the code in a future release.

Power BI content packs available on AppSource

The **Cost management**, **Financial performance**, and **Retail channel performance** content packs, available on the Microsoft AppSource site, are deprecated as a consequence of product updates in Microsoft Power BI. System administration forms used to deploy these content packs to PowerBI.com are also being deprecated in Finance and Operations.

Reason for deprecation/removal	Product updates in Microsoft Power BI.
Replaced by another feature?	The **Cost management**, **Financial performance**, and **Retail channel performance** content packs, available on the AppSource site, are being replaced by analytical applications which allow for solution integrations at the database level. For more information about analytical applications, see Embedded Power BI in workspaces.
Product areas affected	Cost management, Finance, and Retail
Deployment option	Cloud only (Integration with PowerBI.com is not supported in on-premises deployments.)
Status	Deprecated: Target timeframe for the functionality removal is Q2 2018.

Standard UI in data management workspace

The standard UI in data management is the legacy UI, which is the default UI presented to the users when they visit the data management workspace.

Reason for deprecation/removal	We are investing in providing new user experiences in the new UI.
Replaced by another feature?	The new UI called *Enhanced views* is replacing the old UI.
Product areas affected	Data management workspace
Deployment option	All
Status	Deprecated: Target timeframe for the functionality to be removed is Q2 2018.

Excise, Sales Tax, Service Tax for India

These taxes have been subsumed into Indian GST.

Reason for removal or deprecation	These taxes have been subsumed into Indian GST.
Replaced by another feature?	Indian GST
Product areas affected	Tax
Deployment option	All modules
Status	Deprecated: A removal date has not been set for this feature.

File Validation Utility (FVU) for India

Reason for removal or deprecation	Lack of customer usage
Replaced by another feature?	No
Product areas affected	Indian withholding tax
Deployment option	All modules
Status	Deprecated: A removal date has not been set for this feature.

TDS/TCS certificate for India

Users can download this from the government portal.

Reason for removal or deprecation	Lack of customer usage
Replaced by another feature?	No
Product areas affected	Indian withholding tax
Deployment option	All modules
Status	Deprecated: A removal date has not been set for this feature.

Export/import (EXIM) incentive scheme for India

Reason for removal or deprecation	Lack of customer usage
Replaced by another feature?	No
Product areas affected	Import and export

Deployment option	All modules
Status	Deprecated: A removal date has not been set for this feature.

Dynamics 365 for Retail 7.2

Personalized product recommendations

Starting February 15, 2018, retailers will no longer be able to display personalized product recommendations on a point of sale (POS) device. For more information, see Product recommendations overview.

Reason for deprecation/removal	We are removing the current version of the product recommendation service as we redesign this feature with a better algorithm and newer retail-oriented capabilities.
Replaced by another feature?	No. However, after Spring 2018, we plan to bring back this feature to leverage a new recommendation service.
Product areas affected	Personalized product recommendations in POS.
Deployment option	All
Status	Removed as of February 15, 2018. This affects customers running Dynamics 365 for Retail 7.2 and later.

Finance and Operations, Enterprise edition July 2017 with Platform update 8

Currency conversion for accounting and reporting currencies

Currency conversion for accounting and reporting currencies was introduced when the euro was introduced.

Reason for deprecation/removal	Limited usage and addition of the Copy legal entity functionality as a replacement.
Replaced by another feature?	No, but the Copy legal entity and Configurations features were added to make it easier to move to a company that has changing core requirements.
Product areas affected	Financial management
Status	Deprecated: A removal date has not been set for this feature.

Warehouse mobile devices portal

Warehouse mobile devices portal (WMDP) was a standalone component that was intended for on-premises self-deployment. This component is no longer supported in Finance and Operations. A native app that improves the user experience has replaced the functionality of WMDP.

Reason for deprecation/removal	Duplicate functionality.
Replaced by another feature?	Yes. This feature has been replaced by Finance and Operations - Warehousing. For more information about setup and prerequisites, see Install and configure the Warehousing app overview.
Product areas affected	Warehouse management, Transportation management
Deployment option	Warehouse mobile devices portal (WMDP) was a standalone component that was intended for on-premises self-deployment.
Status	Deprecated: Target timeframe for the functionality to be removed is Q4 2019.

Advanced bank reconciliation matching rule for manual matching

A matching rule was used to select and mark a bank document when documents were manually matched in the reconciliation worksheet.

Reason for deprecation/removal	Limited usage.
Replaced by another feature?	No. Column filtering capabilities should be used to find documents for reconciliation.
Product areas affected	Cash and bank management
Deployment option	All
Status	Removed as of July 2017.

Dynamics 365 for Operations 1611 with Platform update 3

AEB payment formats for Spain

The Consejo Superior Bancario payment formats were used to send remittance files to the bank for customer payments and vendor payments. The content of these formats was determined by the Asociación Española de Banca. It covers Cuaderno 19, 32, 58, 34.

Reason for deprecation/removal	The payment formats are no longer used.
Replaced by another feature?	Yes, ISO20022 Credit transfer and Direct debit payment formats for Spain
Product areas affected	Accounts payable, Accounts receivable

Status	Deprecated: A removal date has not been set for this feature.

Bank payments transfer for Lithuania

Bank payment transfers were generated and printed by using the Payment transfer (LT) export format for Lithuania. The Lithuanian market began to use LITAS, the unified electronic banking system, in 2005.

Reason for deprecation/removal	The payment formats are no longer used.
Replaced by another feature?	Yes, ISO20022 Credit transfer payment format for Lithuania
Product areas affected	Accounts payable
Status	Deprecated: A removal date has not been set for this feature.

BBS Direkte Remittering payment formats for Norway

BBS Direkte Remittering payment formats include customer payment collection export (direct debit) and return message import.

Reason for deprecation/removal	The payment formats are no longer used.
Replaced by another feature?	The AvtaleGiro customer payment format for Norway can be used to generate direct debit messages. Return message import will be implemented in future releases.
Product areas affected	Accounts payable, Accounts receivable
Status	Deprecated: A removal date has not been set for this feature.

Chart of Accounts tool for Spain

This tool is used when a chart of accounts in Spain requires major changes. Users can import a new chart of accounts in Microsoft Excel or text format, and can also import financial statements.

Reason for deprecation/removal	Limited usage
Replaced by another feature?	No
Product areas affected	General ledger
Status	Deprecated: A removal date has not been set for this feature.

Dom80 payment format for Belgium

Legacy Belgian payment format for payment collection (direct debit).

Reason for deprecation/removal	The payment format is no longer used.
Replaced by another feature?	Yes, ISO 20022 Direct debit payment format for Belgium
Product areas affected	Accounts receivable
Status	Deprecated: A removal date has not been set for this feature.

DTA/EZAG payment formats for Switzerland

DTA/EZAG formats are integrated into the ESR system, because they can carry on the reference number. Because the reference number isn't mandatory, these formats can be used to process any vendor payments. These formats are used by companies that have a bank account in a location other than "Postfinance."

Reason for deprecation/removal	The payment formats are no longer used.
Replaced by another feature?	Yes, ISO20022 Credit transfer payment format for Switzerland
Product areas affected	Accounts payable
Status	Deprecated: A removal date has not been set for this feature.

EDIFACT-DIRDEB payment format for Austria

EDIFACT-DIRDEB payment format for payment collection (direct debit).

Reason for deprecation/removal	The payment format is no longer used.
Replaced by another feature?	Yes, ISO 20022 Direct debit payment format for Austria
Product areas affected	Accounts receivable
Status	Deprecated: A removal date has not been set for this feature.

EDIVAT for Belgium

EDIVAT is an obsolete Belgian standard for electronic declaration via secure mail. Dynamics AX 2012 retains the read-only solution to enable access to the historical data.

Reason for deprecation/removal	The functionality is no longer used.
Replaced by another feature?	No

Product areas affected	General ledger
Status	Deprecated: A removal date has not been set for this feature.

eGiro EDIFACT CREMUL payment import format for Norway

eGiro is based on the international UN EDIFACT CREMUL (Multiple Credit Advice Message) standard that is used for automatic posting of customer payments. In Dynamics AX, eGiro is implemented as a customer payment import format.

Reason for deprecation/removal	The payment format is no longer used.
Replaced by another feature?	Yes, the ISO20022 Camt.054 notification import.
Product areas affected	Accounts receivable
Status	Deprecated: A removal date has not been set for this feature.

External inventory for Poland

Evidence of goods that are taken from a vendor for sales without purchase. Goods that are handled in external inventory don't affect standard inventory, and can be sold and then purchased automatically. This process creates real inventory movements.

Reason for deprecation/removal	Replaced by another feature
Replaced by another feature?	Yes, the core Inbound consignment functionality
Product areas affected	Accounts payable, Inventory management
Status	Deprecated: A removal date has not been set for this feature.

Financial reports generator for Eastern Europe

A tool is used to set up data collection for accounting and tax reports, and to export data to XLS and DOC report templates.

Reason for deprecation/removal	Limited usage
Replaced by another feature?	No. The tool will be replaced by Electronic reporting configurations in future releases.
Product areas affected	General Ledger

Status	Deprecated: A removal date has not been set for this feature.

Import of customer payment transactions for Finland

You can select an import format for Finnish payments to import customer payment transactions from an external file that the bank provides.

Reason for deprecation/removal	The payment format is no longer used.
Replaced by another feature?	Yes, the ISO20022 Camt.054 notification import.
Product areas affected	Accounts receivable
Status	Deprecated: A removal date has not been set for this feature.

Import of payment transactions into a general ledger journal for Finland

A format that is specific to Finland is used to import accounting transactions into the general ledger.

Reason for deprecation/removal	The payment format is no longer used.
Replaced by another feature?	Yes, the ISO20022 Camt.053 bank statement import using Advanced Bank Reconciliation.
Product areas affected	Accounts receivable
Status	Deprecated: A removal date has not been set for this feature.

Integration with Isabel synchronized (CIS) for Belgium

Isabel is the framework for electronic banking in Europe and is a de-facto standard in Belgium.

Reason for deprecation/removal	Integration with Isabel client has been discontinued.
Replaced by another feature?	No. The payment formats that are no longer used are replaced by ISO20022 Credit transfer payment format for Belgium.
Product areas affected	Accounts payable
Status	Deprecated: A removal date has not been set for this feature.

Modifications in the chart of accounts and accounting rules for Spain

This feature is used for changes in the chart of accounts and accounting rules in Spain. It maps accounts to help

transform the old chart of accounts into the new chart of accounts, and compares the previous fiscal year with the new fiscal year, even if they were posted to different account numbers.

Reason for deprecation/removal	Limited usage
Replaced by another feature?	No
Product areas affected	General ledger
Status	Deprecated: A removal date has not been set for this feature.

Pagamento Fornittori vendor payment format

Legacy Italian payment format for credit transfers.

Reason for deprecation/removal	The payment format is no longer used.
Replaced by another feature?	Yes, ISO20022 Credit transfer payment format for Italy
Product areas affected	Accounts payable
Status	Deprecated: A removal date has not been set for this feature.

Payment export formats for Estonia

The Telehansa and Teleservice formats are used for bank payment export.

Reason for deprecation/removal	The payment formats are no longer used.
Replaced by another feature?	Yes, ISO20022 Credit transfer payment format for Estonia
Product areas affected	Accounts payable
Status	Deprecated: A removal date has not been set for this feature.

Payment file archive for Norway

When payment files are generated, the file archive automatically archives all files that are created, even files that were previously written or read.

Reason for deprecation/removal	Replaced by another feature
Replaced by another feature?	Yes, Electronic reporting archived jobs

Product areas affected	Accounts payable, Accounts receivable, Organization administration
Status	Deprecated: A removal date has not been set for this feature.

Payment import formats for Estonia

The Telehansa and TeleTeenus formats are used for bank payment import.

Reason for deprecation/removal	The payment formats are no longer used.
Replaced by another feature?	Yes, the ISO20022 Camt.054 bank notification import.
Product areas affected	Accounts receivable
Status	Deprecated: A removal date has not been set for this feature.

Payroll information in Human Resources

Human Resources Payroll information

Reason for deprecation/removal	This functionality has been replaced by core Payroll and Human Resources pages.
Replaced by another feature?	**Benefits**, **Earnings**, and other related pages that were previously in US Payroll have been reconfigured, and are now part of the core Human Resources configuration to help support external payroll processing. This functionality is accessed by using the **Human Resources 1** > **Payroll** configuration key.
Product areas affected	Human Resources, Payroll
Status	Removed as of Dynamics 365 for Operations version 1611.

Performance management goal workflow

Performance management includes goal management and integration with performance reviews.

Reason for deprecation/removal	Performance management was redesigned, and the number of goal pages was reduced to simplify the process.
Replaced by another feature?	No. Goals are visible to managers through the Manager Self Service portal, and can be changed and viewed by the manager.
Product areas affected	Human capital management

Status	Removed as of Dynamics 365 for Operations version 1611.

Postgirot and Postgirot Utland payment formats for Sweden

Postgirot and Postgirot Utland payment formats for Sweden.

Reason for deprecation/removal	The payment formats are no longer used.
Replaced by another feature?	Yes, ISO20022 Credit transfer payment format for Sweden
Product areas affected	Accounts payable
Status	Deprecated: A removal date has not been set for this feature.

Radio frequency identifier

Radio Frequency Identification (RFID) is a data-collection technology that uses electronic tags to store identification data and a no-line-of-sight requirement reader to capture the identification data.

Reason for deprecation/removal	Low customer usage and a limited feature set.
Replaced by another feature?	No
Product areas affected	Inventory management
Status	Removed as of Dynamics 365 for Operations 1611.

Report about state invoices numbering for Latvia

Latvian legislation provides specific rules about the numbering of sales invoices. The functionality lets you assign specific numbers to sales invoices, based on the user or user group. You can then generate a report or an XML file. You can also print a report about invoice numbers that are used.

Reason for deprecation/removal	The state invoice numbering no longer has to be maintained. The report about used invoice numbers is no longer required.
Replaced by another feature?	No
Product areas affected	Accounts receivable
Status	Deprecated: A removal date has not been set for this feature.

Set up the names of the manager and general accountant of a company for Lithuania

The names of the manager and the general accountant of a company can be specified in the company

information and used in different local report printouts.

Reason for deprecation/removal	Replaced by another feature
Replaced by another feature?	Yes, the setup of officials can be used for the same purpose.
Product areas affected	Accounts payable, Accounts receivable, Cash and bank management
Status	Deprecated: A removal date has not been set for this feature.

Shipping carrier interface

Reason for deprecation/removal	Duplicate functionality
Replaced by another feature?	Partially replaced by Transportation management
Product areas affected	Sales and marketing, Inventory management
Status	Removed as of Dynamics 365 for Operations version 1611.

Telepay payment formats for Norway

Telepay payment formats include vendor payment export (credit transfer) and customer payment collection (direct debit).

Reason for deprecation/removal	The payment formats are no longer used.
Replaced by another feature?	Yes, ISO20022 Credit transfer payment format and AvtaleGiro customer payment format for Norway, as well as pain.002 and camt.054 bank notification return files import.
Product areas affected	Accounts payable, Accounts receivable
Status	Deprecated: A removal date has not been set for this feature.

Vendor payment export formats for Finland

Two formats for exporting payments are available for Finland. LM02 (FI) is used for domestic payments, and LUM2 (FI) is used for foreign payments.

Reason for deprecation/removal	The payment formats are no longer used.
Replaced by another feature?	Yes, ISO20022 Credit transfer payment format for Finland

Product areas affected	Accounts payable
Status	Deprecated: A removal date has not been set for this feature.

Warehouse management II

Reason for deprecation/removal	The Warehouse management II solution (WMS II) that was available in the **Inventory management** module duplicates functionality that is in the **Warehouse management** module that was released in Dynamics AX 2012 R3.
Replaced by another feature?	The **Warehouse management** module that was released in AX 2012 R3, Dynamics AX 2012 R3 CU8, and Dynamics AX 2012 R3 CU9 replaces the Warehouse management II features. The new module has more advanced features and more flexible warehouse management processes than Warehouse management II.
Product areas affected	Inventory management, Sales and marketing, Procurement and sourcing
Status	Removed as of Dynamics 365 for Operations version 1611.

Worker reminders in Human Resources

Human Resources Payroll information

Reason for deprecation/removal	Low usage
Replaced by another feature?	No
Product areas affected	Human resources
Status	Removed as of Dynamics 365 for Operations version 1611

Workflow for creating goals

A workflow for managing the creation of employee goals is one of several workflows that were available to help coordinate the performance management process.

Reason for deprecation/removal	Performance management has been completely redesigned in Finance and Operations.

Replaced by another feature?	The redesigned Performance management feature gives more control over the content of the goals, the measurements that are used to track progress, and the attachment of supporting documentation. Goals can be stored as templates and then reused. This feature can help you set up additional goals for your employees more quickly.
Product areas affected	Human capital management
Status	Removed as of Dynamics 365 for Operations version 1611.

Dynamics AX 7.0

Ability to cancel changes to a vendor invoice

Reason for deprecation/removal	Performance enhancement
Replaced by another feature?	No
Product areas affected	Accounts payable
Status	Removed as of Dynamics AX 7.0.

AIF, AxD, and AxBC integrations

In Application Integration Framework (AIF), data can be exchanged with external systems through business logic that is exposed as services. Dynamics AX includes services that are based on documents and .NET Business Connector (AxBC). A document is created by using XML. The XML includes header information that is added to create a *message* that can be transferred into or out of Dynamics AX. Examples of documents include sales orders and purchase orders. However, almost any entity, such as a customer, can be represented by a document. Services that are based on documents use the **Axd <Document>** classes.

Reason for deprecation/removal	The architecture of AIF and AxDs could not be scaled to a cloud service. There were performance issues around bulk import.
Replaced by another feature?	This feature is replaced by the Data Import/Export framework, which supports recurring bulk import/export. For AxBC, we recommend that you use the actual tables.
Product areas affected	AxDs, AxBCs, and AIF
Status	Removed as of Dynamics AX 7.0.

Billing code rate scripts

Billing scripts were used to calculate billing rates for billing codes. This scripts required custom development in the C Sharp or Visual Basic programming language. In the current version of Dynamics AX, the **billing code rate scripts** are not supported.

Reason for deprecation/removal	The support for the custom C Sharp or Visual Basic scripts was not added in Dynamics AX 7.0.
Replaced by another feature?	No
Product areas affected	Public sector, Accounts receivable
Status	Removed as of Dynamics AX 7.0.

BOMs without BOM versions

When the **BOM versions** configuration key was disabled, bill of materials (BOM) versions were hidden in all forms, and the system forced a 1:1 relationship between released products and BOMs. In the current version of Dynamics AX, the **BOM versions** configuration key can't be disabled.

Reason for deprecation/removal	Using a configuration key to control BOM versions doesn't scale in a cloud environment.
Replaced by another feature?	No
Product areas affected	Product information management, Inventory management
Status	Removed as of Dynamics AX 7.0.

Brazilian Bordero

Specific method of payment for Brazilian companies

Reason for deprecation/removal	Support for the Brazilian Bordero method of payment has been discontinued from Brazilian localization
Replaced by another feature?	No
Product areas affected	Accounts payable
Status	Deprecated: A removal date has not been set for this feature.

Brazilian Sintegra statement

Federal tax statement for ICMS tax

Reason for deprecation/removal	This statement is no longer applicable in some Brazilian states.
Replaced by another feature?	No. Users can use Generic Electronic reporting tool to configure the statement if required under specific situations.

Product areas affected	Fiscal books
Status	Deprecated: A removal date has not been set for this feature.

Brazilian SCAN contingency mode for NF-e

(SCAN) contingency environment is used to generate, export, and import the status of a Nota Fiscal eletrônica (NF-e) when the environment of Secretaria da Fazenda (SEFAZ) is not available.

Reason for deprecation/removal	This method of contingency is no longer applicable in all Brazilian states
Replaced by another feature?	No
Product areas affected	Accounts receivable
Status	Deprecated: A removal date has not been set for this feature.

Business Analyzer

This mobile application let users review key business metrics.

Reason for deprecation/removal	This functionality has been replaced by another feature.
Replaced by another feature?	The Monitor financial performance content pack for Microsoft Power BI will include key financial metrics that were previously available in Business Analyzer.
Product areas affected	General ledger
Status	Deprecated: The use of Business Analyzer has been deprecated.

Business statistics

The setup of business statistics inquiries that can help you analyze the performance of the organization

Reason for deprecation/removal	Legacy approach to business intelligence (BI), low customer usage, and a limited feature set
Replaced by another feature?	New BI solutions for the current version of Dynamics AX
Product areas affected	Procurement and sourcing, Accounts payable, Sales and marketing, Accounts receivable
Status	Removed as of Dynamics AX 7.0.

Change document date function in Invoice approval journal

Reason for deprecation/removal	Low usage
Replaced by another feature?	Yes. The document date on the posted vendor transaction can be changed.
Product areas affected	Accounts payable
Status	Removed as of Dynamics AX 7.0.

ClieOp03 payment format for the Netherlands

Reason for deprecation/removal	The format is no longer applicable in the Netherlands, because it has been replaced by SEPA functionality.
Replaced by another feature?	SEPA payments export
Product areas affected	All modules
Status	Deprecated: A removal date has not been set for this feature.

Compliance Center

The Compliance Center was an Enterprise Portal site for managing the documentation requirements for compliance initiatives that are related to the Sarbanes-Oxley law.

Reason for deprecation/removal	Lack of customer usage. Microsoft SharePoint includes the same capability that was available in the Compliance Center.
Replaced by another feature?	No
Product areas affected	Compliance and internal controls
Status	Removed as of Dynamics AX 7.0.

Connector for Microsoft Dynamics

This tool was used to integrate key data from Microsoft Dynamics CRM to Dynamics ERP applications.

Reason for deprecation/removal	This functionality has been replaced by another feature.
Replaced by another feature?	Dataverse
Product areas affected	Connector for Dynamics

Status	Removed as of Dynamics AX 7.0.

Container unit and multi dimension on-hand

Reason for deprecation/removal	Duplicate functionality
Replaced by another feature?	Yes. Since AX 2012, this functionality has been replaced by the consolidated batch orders feature set. This feature set includes the consolidated on-hand view.
Product areas affected	Product information management, Production control, Inventory management, Sales and marketing
Status	Removed as of Dynamics AX 7.0.

Cue group metadata

Reason for deprecation/removal	Cue groups were used to display one or more Cues in the FactBox area. There was limited uptake, and there were also performance concerns, because a record change in a parent form caused one query per Cue in the Cue group.
Replaced by another feature?	No
Product areas affected	All modules
Status	Removed as of Dynamics AX 7.0.

Cue metadata

Reason for deprecation/removal	Cue metadata was limited to count or sum information.
Replaced by another feature?	Tile metadata was introduced to provide more flexibility for modeling. For example, you can model current counts, navigation, and key performance indicators (KPIs). Count tile metadata is the direct replacement of the Cue metadata.
Product areas affected	All modules
Status	Removed as of Dynamics AX 7.0

Danish check format

Reason for deprecation/removal	Support for the Danish check format layout has been discontinued, and the report has been removed from DK localization.
Replaced by another feature?	No
Product areas affected	All modules
Status	Deprecated: A removal date has not been set for this feature.

Data partitions

Data partitions provide a logical separation of data in the Dynamics AX database.

Reason for deprecation/removal	Data partitions were introduced in Dynamics AX 2012 R2 to enable data isolation. In a common scenario, a company has subsidiaries, and the data from one subsidiary should not be visible to another subsidiary, even though both subsidiaries are managed by the same IT department. However, extra scripts and management overhead throughout the program were required in order to create new partitions and populate them with data, and to back up partition data. In the cloud, where we have access to platform as a service (PaaS) database services (Microsoft Azure SQL Database), it's much more efficient to use a database as the isolation container than to do isolation in the program. Regardless of whether data partitioning is required for subsidiaries, for multiple tenants, or just for scale, we believe that the scenarios can be handled better through multiple instances of Finance and Operations.
Replaced by another feature?	Customers using data partitions must use multiple instances of Finance and Operations if database level separation is a critical issue.
Product areas affected	All modules
Status	Removed as of Dynamics AX 7.0.

Database and file share storage for attachments

Dynamics AX 2012 allowed storage of attachments in the database and in file shares. Both of those options are no longer supported.

Reason for deprecation/removal	Files share storage is no longer supported because cloud-hosted environments cannot communicate with local file shares. Database storage has been deprecated in favor of Azure Blob storage. Azure Blob storage is equivalent to storage in the database, as documents can only be accessed through Finance and Operations client forms. This provides the added benefit of providing storage that doesn't negatively affect the performance of the database. Blob storage is the default storage mechanism for Document Management and works immediately.
Replaced by another feature?	Database storage has been deprecated in favor of Azure Blob storage.
Product areas affected	All modules
Status	Removed as of Dynamics AX 7.0.

Delimitation

Reason for deprecation/removal	No use of the functionality was found.
Replaced by another feature?	No
Product areas affected	Time and attendance
Status	Removed as of Dynamics AX 7.0.

Desktop client

Reason for deprecation/removal	The Dynamics AX client experience has been redesigned to improve usability across multiple platforms and devices.
Replaced by another feature?	The new web client is based on the desktop Form metadata and programming model that have been modified to provide a rich web platform.
Product areas affected	All modules
Status	Removed as of Dynamics AX 7.0.

Direct database connection

In Dynamics AX 2012 R3, Retail Modern POS could connect directly to the Channel DB in similar fashion to Enterprise POS. This was in addition to the standard communication method of Retail Modern POS communicating through Retail Server.

Reason for deprecation/removal	Direct database connectivity required lower security protocols and was primarily used to achieve the highest levels of performance. Due to the performance and security enhancements that have occurred in Finance and Operations, this functionality now causes more issues than it solves.
Replaced by another feature?	No. Only standard Retail Server communication is now supported.
Product areas affected	Channel DB/Retail Modern POS
Status	Removed as of Dynamics AX 7.0.

Dutch SWIFT MT940

Reason for deprecation/removal	Generic functionality is now used instead of localized functionality.
Replaced by another feature?	Yes, this functionality has been replaced by Advanced bank reconciliation functionality.
Product areas affected	All modules
Status	Deprecated: A removal date has not been set for this feature.

eBilanz (XBRL for Germany)

This functionality provided eXtensible Business Reporting Language (XBRL) output that is intended specifically for the German eBilanz taxonomy.

Reason for deprecation/removal	Lack of customer usage
Replaced by another feature?	This feature hasn't been replaced by another feature, but multiple specialized XBRL packages that provide rich XBRL functionality are available for the German market.
Product areas affected	Management Reporter
Status	Deprecated: A removal date has not been set for this feature.

Enterprise Portal client

Reason for deprecation/removal	A single client platform has been provided.

Replaced by another feature?	The new web client is based on the desktop form metadata and programming model that have been modified to provide a rich web platform.
Product areas affected	All modules
Status	Removed as of Dynamics AX 7.0.

Environmental sustainability

Reason for deprecation/removal	Low customer usage and a limited feature set
Replaced by another feature?	No
Product areas affected	Compliance and internal controls, Accounts payable
Status	Removed as of Dynamics AX 7.0.

Form ActiveX and Managed Host controls

Reason for deprecation/removal	The ActiveX and Managed Host controls are based on the deprecated desktop client.
Replaced by another feature?	The extensible control framework supports building new controls that are based on HTML, CSS, and JavaScript, and is a first-class control in the Microsoft Visual Studio Tooling environment.
Product areas affected	All modules
Status	Removed as of Dynamics AX 7.0.

Generate prenotes by using a batch

Prenote generation can't be done by using a batch, but it can still be done by a user.

Reason for deprecation/removal	No form exists to persist and display the resulting prenote file when it's generated by using a batch.
Replaced by another feature?	Prenotes can still be generated, and the user has control over the location where the file is saved.
Product areas affected	Accounts payable, Accounts receivable, Cash and bank management
Status	Removed as of AX 7.0.

German DTAUS payment export and account statement import (totals and transactions)

Reason for deprecation/removal	The format is no longer applicable in Germany, because it has been replaced by Single Euro Payments Area (SEPA) functionality.
Replaced by another feature?	Yes, this functionality has been replaced by SEPA payment export and advanced bank reconciliation functionality for importing account statements.
Product areas affected	All modules
Status	Deprecated: A removal date has not been set for this feature.

German DTAZV payment format in domestic Currency

Reason for deprecation/removal	The format is no longer applicable in Germany, because it has been replaced by SEPA functionality.
Replaced by another feature?	SEPA payments export
Product areas affected	Accounts payable
Status	Deprecated: A removal date has not been set for this feature.

German MT940 import

Reason for deprecation/removal	Generic functionality is now used instead of localized functionality.
Replaced by another feature?	Yes, this functionality has been replaced by Advanced bank reconciliation functionality.
Product areas affected	All modules
Status	Deprecated: A removal date has not been set for this feature.

German XML EU Sales list

Reason for deprecation/removal	The XML format for German EU Sales List reporting is no longer supported. Only the ELMA5 text file format can be used to submit the EU Sales List report to the German Tax Office.
Replaced by another feature?	No

Product areas affected	Tax
Status	Deprecated: A removal date has not been set for this feature.

GL SSRS reports

Reports that include the following menu items have been removed: **Summary trial balance**, **Detailed trial balance**, **Chart of accounts**, **Audit trail**, **Balances**, and **Balance list**.

Reason for deprecation/removal	Financial Microsoft SQL Server Reporting Services (SSRS) reports have been replaced by Management Reporter capabilities and default reports.
Replaced by another feature?	Management Reporter (labeled **Financial reporting** in the current version of Dynamics AX)
Product areas affected	General ledger
Status	Removed as of Dynamics AX 7.0.

InfoPart and FormPart metadata

Reason for deprecation/removal	InfoPart and FormPart metadata enabled the creation of FactBoxes for two different clients.
Replaced by another feature?	InfoPart metadata, which was a simplified form definition, is converted into a Form by upgrade tooling. FormPart metadata, which referenced a Form, is replaced by a more direct reference that is created by upgrade tooling.
Product areas affected	All modules
Status	Removed as of Dynamics AX 7.0.

Main account list page

A list of accounts for the legal entity and related balance information

Reason for deprecation/removal	Balance information is available on the **Trial balance** list page by account and dimension.
Replaced by another feature?	**Main accounts** contains the same list of accounts that the **Main account** list page contained. The grid view in **Main accounts** also shows an even smaller, grid-like view.
Product areas affected	General ledger

Status	Removed as of Dynamics AX 7.0.

Malaysia and Singapore bank cash flow report

This feature let the user print a cash flow report that shows transactions and details of the cash inflows and outflows for a specific date range for selected bank accounts.

Reason for deprecation/removal	The same information can be obtained from the Inquiry bank transaction.
Replaced by another feature?	The Inquiry bank transaction
Product areas affected	Cash and bank management
Status	Deprecated: A removal date has not been set for this feature.

Mexican CFD electronic invoice

This feature enabled the generation of Mexican electronic invoices by using the Comprobante Fiscal Digital (CFD) method, where the company signs the invoice by requesting the related authorization from the government. This feature also provides a monthly report that includes all electronics invoices that were issued in the period.

Reason for deprecation/removal	The method is no longer applicable. The generation of electronic invoices by using the CFD method was deprecated by the tax authorities and replaced by the Comprobante Fiscal Digital a través de Internet (CFDI) method, where the signing is delegated to the third-party provider (PAC). The monthly report has been removed, and an inquiry option lets users inquire about historical transactions.
Replaced by another feature?	No
Product areas affected	Account receivables, Project
Status	Deprecated: A removal date has not been set for this feature.

Mexico realized and unrealized VAT

Dynamics AX 2012 managed unrealized value-added tax (VAT) by using Mexico-specific functionality for unrealized tax.

Reason for deprecation/removal	Duplicate functionality
Replaced by another feature?	Yes, this functionality has been replaced by standard conditional sales tax functionality that is provided by Core.

Product areas affected	Tax
Status	Deprecated: A removal date has not been set for this feature.

Microsoft Outlook integration

Reason for deprecation/removal	This functionality has been replaced by Microsoft Exchange Server integration.
Replaced by another feature?	Yes
Product areas affected	Sales and marketing
Status	Removed as of Dynamics AX 7.0.

Private blocking of inventory and warehouse management journals

The inventory and warehouse journals no longer support the ability to mark a journal as private for a selected user. Only the process of blocking journals as private for user groups and blocking during editing is supported.

Reason for deprecation/removal	No use of the functionality was found.
Replaced by another feature?	No
Product areas affected	Inventory management
Status	Removed as of Dynamics AX 7.0.

Product builder

Product builder was used to dynamically configure items from a sales order, purchase order, production order, sales quotation, project quotation, or item requirement. Based on a product model that had modeling variables, the user could select values to meet the customer requirements and get a unique product variant that had a BOM and route.

Reason for deprecation/removal	Product builder exposed X++ code to end users and isn't supported in the current version of Dynamics AX. It has been removed to avoid duplicate maintenance efforts on overlapping, sizeable codebases.
Replaced by another feature?	Yes. The constraint-based configuration was introduced in Dynamics AX 2012 where the depreciation of Product builder in future versions was already announced. The constraint-based configuration technology is selected on the product masters to enable the configuration. To learn more, see Product configuration overview.

Product areas affected	Product information management, Sales and marketing
Status	Removed as of Dynamics AX 7.0.

Production Floor app

This is the app for tablet devices running Windows 8.1 RT and Windows 8.1 Pro.

Reason for deprecation/removal	With the change to a web-based client, it is possible to deliver similar functionality through the native Dynamics AX 7.0 client. The Job Card Device provides a production floor user interface that is optimized for touch and tablet form factors.
Replaced by another feature?	Yes. The Job Card Device, which is a native part of Dynamics AX 7.0.
Product areas affected	Production control
Status	Deprecated: A removal date from the Microsoft store has not yet been set for this feature.

Rename product dimension

This feature let you change the name of one of the three standard product dimensions (size, color, or style) to a name that better suited your business requirements. Renaming included all the labels where the product dimension name was used.

Reason for deprecation/removal	The current version of Dynamics AX doesn't support label changes at run time.
Replaced by another feature?	No
Product areas affected	Product information management
Status	Removed as of Dynamics AX 7.0.

Retail Server connectivity using HTTP

In Dynamics AX 2012 R3, the Retail Server could function using HTTP communication (non-secured). This was in addition to the standard communication using HTTPS.

Reason for deprecation/removal	Due to new security requirements, only secured communication using TLS 1.2 (or above, as available) is now supported. The self-service installer will automatically configure the computer for this communication.
Replaced by another feature?	No. Only standard HTTPS communication is now supported.

Product areas affected	Retail Server
Status	Removed as of Dynamics AX 7.0.

Role Center pages

Reason for deprecation/removal	Role Center pages were built on the deprecated Enterprise Portal platform, which has been replaced by the new web client platform in the current version of Dynamics AX.
Replaced by another feature?	The new Workspace form pattern provides users with a process-centered design that provides easy access to commonly used tasks within that process.
Product areas affected	All modules
Status	Removed as of Dynamics AX 7.0

Sales tax jurisdictions

Reason for deprecation/removal	Low customer usage and a limited feature set
Replaced by another feature?	No
Product areas affected	US sales tax
Status	Removed as of Dynamics AX 7.0.

Sites Services

Sites Services let you build websites that extend your business processes to the Internet without IT support.

Reason for deprecation/removal	The Microsoft Azure infrastructure that is used by Dynamics AX has new capabilities that can be used instead (for example, Azure sites).
Replaced by another feature?	No
Product areas affected	HR recruiting, Case management, Request for quotes, Vendor registration, Collaborative workspaces for opportunities and campaigns
Status	Removed as of Dynamics AX 7.0.

SSAS demand forecasting strategy

Reason for deprecation/removal	The design of the feature cannot be supported in the new cloud architecture.
Replaced by another feature?	Azure Machine Learning demand forecasting strategy
Product areas affected	Master planning
Status	Removed as of Dynamics AX 7.0.

Vendor invoice pool excluding posting details

Reason for deprecation/removal	Low usage. This functionality has been replaced by the Invoice journal that has workflow functionality.
Replaced by another feature?	Workflow capabilities of the Invoice journal.
Product areas affected	Accounts payable
Status	Removed as of Dynamics AX 7.0.

Virtual company accounts

The virtual companies feature is no longer supported in Dynamics AX. The virtual companies feature let users set up tables that could be shared by a set of companies. For a description of the feature, see Company accounts and Virtual company accounts. The feature works by grouping tables into collections that are assigned to virtual companies, which are groups of existing "real" companies. Queries are created so that all the companies in the virtual company can access the data in the tables of the associated table collections.

Reason for deprecation/removal	- Virtual companies must be set up before data is stored in the tables. Retrofitting virtual companies onto an existing implementation is very difficult. - Because there has been so much data normalization in the current version of Dynamics AX, it has become difficult to know what to add to the table collections. For example, it's difficult to know which tables to share. All the tables referenced from tables that are in a virtual company must also added. Because of table normalization, even simple master data that is spread across multiple tables must be part of the virtual company. Any mistake that is made here will cause functional issues. - When a table is part of a virtual company, it loses information about the origin of the data, and only the virtual company is recorded.
Replaced by another feature?	Global tables can be used to make tables accessible from all companies. Currently, there is no replacement.
Product areas affected	All modules

Status	Removed as of Dynamics AX 7.0.

Windows 8 tablet app

The Windows 8 tablet app provided functionality for expense entry and approval.

Reason for deprecation/removal	Finance and Operations is compatible with tablets. The tablet app is no longer required.
Replaced by another feature?	No.
Product areas affected	Expense management
Status	Removed: This functionality is only available for Dynamics AX 2012 R3.

Workplanner

Reason for deprecation/removal	Low usage
Replaced by another feature?	No, but the **Profile relation** page, which is opened from the **Profile groups** page, supports the same business scenario as the deprecated **Workplanner** page.
Product areas affected	Time and attendance
Status	The code has not been removed. However, the form, JmgWorkPlanner, was not migrated.

X++ financial statements

Reason for deprecation/removal	This functionality has been replaced by another feature.
Replaced by another feature?	Management Reporter (labeled **Financial reporting** in the current version of Dynamics AX)
Product areas affected	General ledger
Status	Removed as of Dynamics AX 2012

AX 2012 features that were postponed

2/18/2021 • 11 minutes to read • Edit Online

This topic lists features of Microsoft Dynamics AX 2012 that were postponed. These features weren't implemented in Microsoft Dynamics AX 7.0. In the following table, the **Current status** column indicates whether the feature has been implemented since the AX 7.0 release.

For a detailed list of the release date for each version, see Software lifecycle policy and cloud releases.

AX 2012 FEATURE THAT WAS POSTPONED	DESCRIPTION	CURRENT STATUS (AS OF FEBRUARY 2019)
Absence management in Human resources	Functionality for entering absence transactions isn't included. Additionally, functionality for approving absence transactions as a manager isn't included. Setup capabilities that are required for integration with other modules are available through the **Human Resources 2** configuration key.	Implemented in Dynamics 365 Human Resources
Alerts	Alerts help users keep track of data changes in the system.	Implemented in Platform update 15
Bank payment order for Latvia and Lithuania	You can print a payment order for Latvia and Lithuania. This feature will be available in a future update.	Not implemented
Bankgirot AP return format for Sweden	The Bankgirot return format is used to import bank return messages. This feature will be available in a future update.	Not implemented
Client drag-and-drop	The web client controls have application programming interfaces (APIs) for drag-and-drop operations, but these APIs are based on the deprecated desktop client technology and they require a redesign so that they work on the new web client platform. APIs that support drag-and-drop operations will be reviewed for inclusion in a future update.	Not implemented
Client right-to-left (RTL) layout	RTL layout is now supported.	Implemented in Platform update 2

AX 2012 FEATURE THAT WAS POSTPONED	DESCRIPTION	CURRENT STATUS (AS OF FEBRUARY 2019)
Cost accounting	The **Cost accounting** module is designed to meet the requirements of internal costs and profitability reports at multiple organizational levels. To define the cost object level, the module depends on a correct mapping of financial dimensions. The module lets you perform advanced allocations of cost origin from expenditures that are registered in the general ledger or budget. It also lets you compare realized costs and budgeted costs.	Implemented in version 1611
Customer self-service (CSS)	CSS lets you create approved customer records. It also allows users to view selected product catalogs, order items, and view the status of invoices. Additionally, CSS lets you create and follow return orders.	Not implemented
Customizable help topics	The ability to create customized help topics has not yet been implemented. Custom task guides and custom field help are available. This feature will be available in a future update.	Not implemented
Employee self-service (ESS)	ESS shows employees several tiles that have task-related and career-related information on a single page. Employees can view pending work items and click links that open pages where they can take action on their tasks. ESS pages also show employees the status of their certifications, when their next performance reviews are scheduled, skills, goals, and compensation information, and other information, such as balances for vacation and sick time. Employees can also access a company directory from their ESS page.	Implemented in version 1611
External questionnaire and recruiting functionality	Functionality for externally posting questionnaires and open jobs will be added to Human Resources in a future update.	External questionnaire functionality hasn't been implemented. Recruiting functionality is available in Microsoft Dynamics 365 Talent: Attract.
Fiscal printers for Poland	Integration with Polish fiscal printers enables the required information to be sent to the fiscal printer in the correct format during invoice posting. Examples of Polish fiscal printers include the Posnet Thermal and Elzab Omega printer types. This feature will be available in a future update.	Not implemented

AX 2012 FEATURE THAT WAS POSTPONED	DESCRIPTION	CURRENT STATUS (AS OF FEBRUARY 2019)
General budget reservations	The General budget reservations document is sometimes referred to as a commitment. Public sector entities often use this document to set aside or earmark budgeted funds so that they aren't available for other purposes.	Implemented in version 8.1
Graphics tab on the **Fixed asset value model** and **Depreciation book profile** pages	The chart shows the depreciation, accumulated depreciation, and net book value over time. Users can click the **Data** tab to view more detailed information than the chart shows. This chart will be redesigned in a future update.	Not implemented
Intelligent Data Management Framework (IDMF)	IDMF is an add-on tool that lets system administrators optimize performance. IDMF assesses the health of the application, analyzes current usage patterns, and helps reduce database size.	Not implemented
Microsoft Project client integration	The Microsoft Project client is integrated with projects.	Implemented in version 7.2 (July 2017 update)
Procurement site	In previous versions, the Employee self-service procurement site lets you enter requisitions for employees, view the status of an order (created, received, or receipt confirmed), and request onboarding of a new vendor. You could configure different procurement catalogs to show on the site depending on policy. You could also design procurement catalogs by adding new nodes. In the current version, procurement catalog capabilities are reduced and are used only to limit the products that can be ordered for an organization. The structure is always based on the Procurement categories hierarchy. Additionally, on the procurement site the employee could approve a vendor invoice and confirm receipts in relation to the requisitions and derived purchase orders.	Not implemented
Secure global address book	The ability to help secure the global address book by legal entity and address book is not available. This feature will be available in a future update.	Not implemented
Specifications for Electronic reporting (ER) payment formats	Currently, you must enter the payment format specifications manually. In a future update, you will be able to select payment format specifications in	Not implemented

AX 2012 FEATURE THAT WAS POSTPONED	DESCRIPTION	CURRENT STATUS (AS OF FEBRUARY 2019)
	a list. The following payment specifications are currently supported per payment format. [!NOTE] Values for these supported payment specifications are used as payment specification parameters on the **Payment specification** page for a selected method of payment. **BTL91 for the Netherlands** PAYMENT SPECIFICATION (USED IN ER) / EXPORT FORMAT DESCRIPTION ChqBen / Cheque, Begunstigde ChqOff / Cheque, Kantoor opdrachtgever ChqPri / Cheque, Opdrachtgever TrfBenBen / Overboeking Begunstigde/Begunstigde TrfBenBenUrg / Overboeking Begunstigde/Begunstigde Spoed TrfEurBen / Overboeking Euro/Begunstigde TrfEurBenUrg / Overboeking Euro/Begunstigde Spoed TrfEurEur / Overboeking Euro/Euro TrfEurEurUrg / Overboeking Euro/Euro Spoed TrfForBen / Overboeking VV-rekening/Begunstigde TrfForBenUrg / Overboeking VV-rekening/Begunstigde Spoed TrfForFor / Overboeking VV-rekening/VV-rekening

AX 2012 FEATURE THAT WAS POSTPONED	DESCRIPTION	CURRENT STATUS (AS OF FEBRUARY 2019)
Vendor collaboration (Vendor Portal)	Dynamics AX 2012 provided vendor portal capabilities via Enterprise Portal. Financial and Operations also provides these capabilities. In version 7.1 (also known as Dynamics 365 for Operations 1611), a vendor could view and respond to purchase orders. In version 7.3, the vendor can view and respond to RFQs. Vendors can also view and edit selected information from the vendor record such as addresses, contact information, and contact persons, and they can upload documents in relation to their certifications.	Implemented in version 7.3
Vendor requests - external request to become a new vendor	Dynamics AX 2012 provided the ability for an anonymous user to sign up to be a vendor in the system, which could lead to a vendor request for adding a new vendor to the vendor master. In version 7.3, the anonymous request from a prospective vendor can be imported via an entity (Data Management/OData), which can lead to inviting the vendor - or the vendor's contact person - to register more details about the prospective vendor. The information provided is included in a new vendor request that can be reviewed and approved via a workflow process. An approval of the vendor request leads to creation of a new vendor account.	Implemented in version 7.3
Vendor requests in general	Dynamics AX 2012 had a concept of vendor requests that served various purposes related to updating vendor-related information, such as requesting new procurement categories for the vendor, internal employees requesting new vendors, or requesting to add a vendor to another company. Only the vendor's request of being added as a vendor has been implemented in version 7.3.	Not implemented

AX 2012 FEATURE THAT WAS POSTPONED	DESCRIPTION	CURRENT STATUS (AS OF FEBRUARY 2019)
[Russia] Tax registers	Legal entities can use registers to disclose their revenues and expenses. The registers are used to track revenue and expense data from the time that primary documents, such as sales invoices and delivery notes, are first entered by using the calculation of cost prices for production. The data from the registers is used to confirm the declared profit of the legal entity. This functionality includes the following features: • Current period incomes • Tax expenses • Other expenses of current period • Unrealized expenses of current period • Other unrealized expenses • Accounts receivable debt – inventory • Bad debts reserve calculation • Bad debts reserve movement • Accounts receivable movement • Procedure for writing-off AR bad debts • Accounts payable debt - inventory • Accounts payable debt movement • Procedure for writing-off AP bad debts • Goods cost calculation • FA object information • IA object information • FA depreciation • IA depreciation • FA/IA sale • Depreciation bonus recovery	Implemented in version 8.1.3
[Russia] Electronic export/import format for Client-Bank interface and reconciliation procedure	Electronic formats for export of outgoing payments, and import of incoming payments.	Implemented in version 8.1.3
[Russia] VAT declaration	Electronic format of VAT declaration.	Implemented in version 10.0.1
[Russia] Cash Flow Management	The functionality which obtains a cash flow forecast and performs an analysis, manages payments on a daily basis using payment schedule journals, controls the company's cash position, and maintains the company's cash flows with centralized control,	Implemented in version 10.0.1

AX 2012 FEATURE THAT WAS POSTPONED	DESCRIPTION	CURRENT STATUS (AS OF FEBRUARY 2019)
[Russia] Accounting reporting format	Electronic format of the following accounting reports: BalanceSheet, IncomeStatement, CashFlow, EquityStatement, TargetUsageMoney	Implemented in version 10.0.1
[Russia] Assessed tax reporting	Assessed tax declaration.	Implemented in version 10.0.1
[Russia] Land tax reporting	Land tax declaration. Creation of Land tax declaration by separate divisions.	Implemented in version 10.0.1
[Russia] Transport tax reporting	Transport tax declaration.	Implemented in version 10.0.1
[Russia] Indirect tax return (VAT and Excise) on import of goods	Indirect (withholding) tax return (VAT and Excise) on import of goods from state members of Customs union.	Implemented in version 10.0.1
[Russia] Journal of Alcohol sales in Retail	Daily Alcohol journal.	Implemented in version 10.0.1
[Russia] Optional posting of transfer orders to General ledger	Option to post/not post transactions to General ledger when posting a transfer order.	Implemented in version 8.1.2
[Russia] Inventory owner	Inventory dimension used to track owner of inventory (consignment stock, bailment, tolling, etc.).	Implemented in version 10.0.1
[Russia] AP/AR - Third-party miscellaneous charges	Registration of third-party miscellaneous charges and allocation by the following regimes: Inclusion into cost of purchased goods (allocation to invoices lines from other vendors), and redrawing to other parties re-allocation to other expense accounts.	Implemented in version 8.1.1
[Russia] Goods in transit from vendor	Registering goods in transit from vendor by special posting profile with Item type "purchased items en route". Creating Act of inventory holdings en route. (INV-6)	Implemented in version 8.1.2
[Russia] Goods in transit - sales to customer with postponed passing of property	Post sales invoice with postponed property transfer: no customer debts posted, all outgoing taxes are posted, items are transferred to transit warehouse. Register passing of property with posting debts and items sale from transit warehouse.	Implemented in version 8.1.2
[Russia] Bailment - accounting at bailee side	Accounting of inventory receipt for bailment as required by the Law and generation of primary form MX-1. Accounting of inventory return from bailment and generation of primary form MX-3. Bailment costs calculation from bailee side.	Implemented in version 8.1.2

AX 2012 FEATURE THAT WAS POSTPONED	DESCRIPTION	CURRENT STATUS (AS OF FEBRUARY 2019)
[Russia] Bailment - accounting at owner side	Accounting of inventory transfer to bailment and inventory return from bailment on goods owner side under bailment service contract.	Implemented in version 8.1.2
[Russia] Localization of Process Industries solution	Basic localization in two areas: correspondence of accounts for all new general ledger postings, and functional coexistence of Process Industries features and Russian country context (no issues when both Process Industries and Russian country context are enabled).	Implemented in version 10.0.1
[Russia] Alcohol sales declarations: Application 6, 7, 8 for wholesale. Applications 11, 12 for retail	Keeping track of alcoholic beverages types including producers, unit of measures, licenses for retail and wholesale trade. Preparing data for alcoholic beverages activities, including printing declarations and exporting them in XML format through e-reporting.	Implemented in version 10.0.1

End of mainstream support for Microsoft Dynamics AX 2009, Dynamics AX 2012, and Dynamics AX 2012 R2

2/18/2021 • 4 minutes to read • Edit Online

Mainstream support for Dynamics AX 2009 Service Pack 1 (SP1), Dynamics AX 2012, and Dynamics AX 2012 R2 ends on October 9, 2018. After that date, only security hotfixes will continue to be provided for these three versions through the extended support period that continues until October 12, 2021. For more information, see support.microsoft.com.

Mainstream support for Dynamics AX 2012 R3 continues through October 12, 2021. Microsoft will continue making security hotfixes, non-security hotfixes, and regulatory updates for Dynamics AX 2012 R3 throughout that mainstream support period. The source code for these non-binary, non-security hotfixes and regulatory updates will continue to be available for customers, and their partners, active on the Enhancement Plan or Software Assurance.

Dynamics AX 2009 SP1, Dynamics AX 2012, and Dynamics AX 2012 R2 customers can selectively integrate those changes as required. Customers and partners can get the source code from packages attached to relevant Dynamics AX 2012 R3 KB articles published on Lifecycle Services (LCS) and discoverable through Issue Search.

Customers are advised to upgrade to the latest version of Finance and Operations apps, such as Dynamics 365 Finance, Supply Chain Management, Retail, and Human Resources:

- Dynamics AX 2009 Service Pack 1 customers should use the migration tool that is available.
- Dynamics AX 2012 and Dynamics AX 2012 R2 customers should upgrade to Finance and Operations apps through Dynamics AX 2012 R3 using the upgrade tool that is available. Additional upgrade information is available in the Upgrade from AX 2012 to Finance and Operations apps topic.

Frequently asked questions

When does the mainstream support for Dynamics AX 2009 Service Pack 1, Dynamics AX 2012, and Dynamics AX 2012 R2 end?

Mainstream support ends on October 9, 2018.

Was the information of the end date of the mainstream support for Dynamics AX 2009 Service Pack 1, Dynamics AX 2012, and Dynamics AX 2012 R2 available before?

Yes, it was always publicly available on the Microsoft Support Lifecycle site at support.microsoft.com.

Can customers on Premier Extended Hotfix Support or on Unified Support Advanced and Performance Levels get a non-security hotfix or regulatory update?

No. Neither non-security hotfixes nor regulatory updates will be available for the Dynamics AX products during the Extended Support phase of the product lifecycle (Dynamics AX 2009 SP1, Dynamics AX 2012, or Dynamics AX 2012 R2).

While the ability to request a non-security hotfix for select products is included with Unified Support Advanced and Performance Levels, Microsoft has determined that non-security hotfixes cannot be provided with a *commercially reasonable* effort for these products. As a result, no requests for non-security hotfixes or regulatory updates will be accepted. However, Microsoft will continue making security hotfixes, non-security hotfixes, and regulatory updates for Dynamics AX 2012 R3 throughout that mainstream support period. The source code for these non-binary, non-security hotfixes and regulatory updates will continue to be available for

customers, and their partners, active on the Enhancement Plan or Software Assurance. Dynamics AX 2009 SP1, Dynamics AX 2012, and Dynamics AX 2012 R2 customers can selectively integrate those changes as required. Customers and partners can get the source code from packages attached to relevant Dynamics AX 2012 R3 KB articles published on LCS and discoverable through LCS Issue Search.

I knew about the regulatory change before October 9, 2018, but it has the law enforcement date after October 9, 2018. Will I still get a regulatory update for Dynamics AX 2009 Service Pack 1, Dynamics AX 2012, and Dynamics AX 2012 R2?

No, we will only provide regulatory updates for Dynamics AX 2009 Service Pack 1, Dynamics AX 2012, and Dynamics AX 2012 R2 for regulatory changes with the law enforcement dates on or earlier than October 9, 2018.

A customer or partner can already download a fix through LCS and inspect the code by installing it into a test Dynamics AX 2012 R3 environment. Is there any difference with the approach that you have proposed?

No, there is no difference.

What happens if a new bug is found by a customer in Dynamics AX 2009 Service Pack 1, Dynamics AX 2012, or Dynamics AX 2012 R2?

The bug must be reproducible in Dynamics AX 2012 R3. If it is reproducible and accepted, then a hotfix will be provided for Dynamics AX 2012 R3 and the customers can elect to integrate this hotfix in their version themselves, or work with their partners to integrate the changes.

How are binary hotfixes handled for Dynamics AX 2009 Service Pack 1, Dynamics AX 2012, and Dynamics AX 2012 R2?

If a hotfix is needed for a part of the system where Microsoft does not provide the source code and it is not a security bug, the hotfix will not be provided.

Business events overview

2/18/2021 • 14 minutes to read • Edit Online

Business events provide a mechanism that lets external systems receive notifications from Finance and Operations applications. In this way, the systems can perform business actions in response to the business events.

Business events occur when a business process is run. During a business process, users who participate in it perform business actions to complete the tasks that make up the business process.

A business action that a user performs can be either a workflow action or a non-workflow action. Approval of a purchase requisition is an example of a workflow action, whereas confirmation of a purchase order is an example of a non-workflow action. Both types of actions can generate business events that external systems can use in integration and notification scenarios.

Prerequisites

Business events can be consumed using Microsoft Power Automate and Azure messaging services. Therefore, customers must bring their subscriptions to such assets to use business events

> **IMPORTANT**
>
> Business events must not be considered a mechanism for exporting data. By definition, business events are supposed to be lightweight and nimble. They aren't intended to carry large payloads to fulfill data export scenarios.

Business events that are implemented

Business events are implemented in some business processes out of the box. These business events include both workflow and non-workflow business events. For more information, see Application business events, Workflow business events, and Alerts as business events.

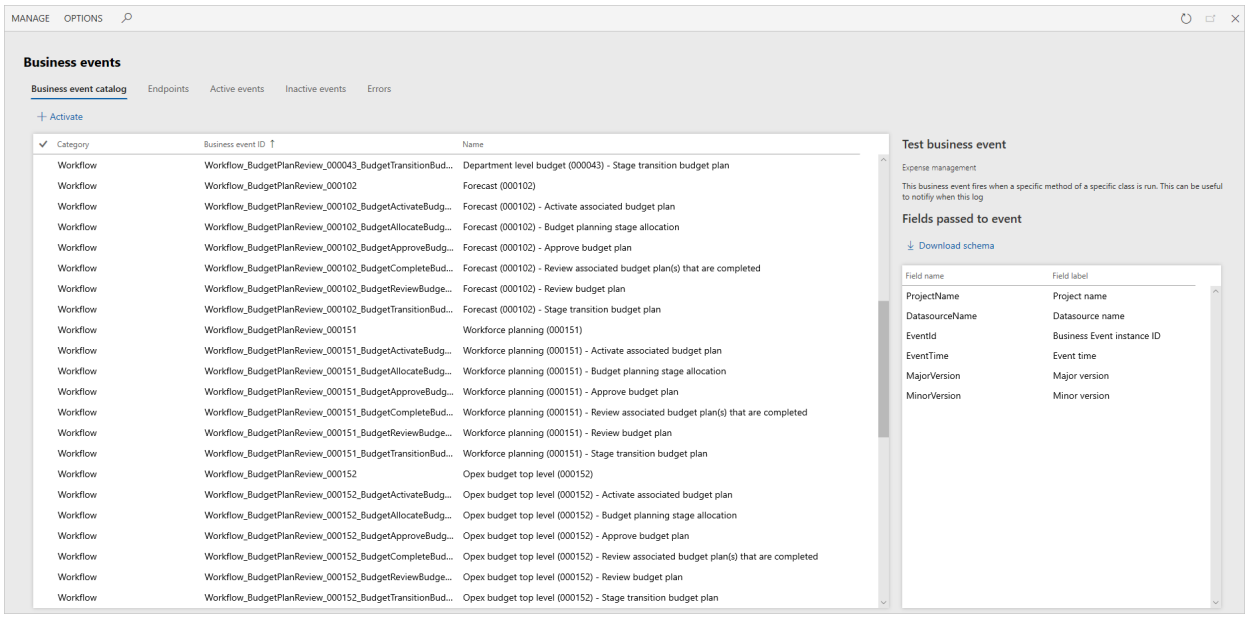
A developer must use extensions to implement new business events. For more information, see Business events developer documentation.

Business event catalog

The business events catalog can be accessed from **System administration > Set up > Business events**. The business event catalog lists the business events that are available in the instance that you're using. The catalog is useful because it shows which business events are available, and you can filter it by category, business event ID, and name.

The category of a business event identifies its source. Business events that originate from the workflow system are assigned to the **Workflow** category. For business events that originate from other modules, the module name is used as the category name.

The business event catalog is built during database synchronization at the time of deployment. Therefore, users should see the complete list of business events in the catalog. However, if an explicit update of the catalog is required, you can select **Manage > Rebuild business events catalog**.



For each business event, the business event catalog shows a description. This description can help you better understand the business event and its context in the business process. The catalog also shows the list of data fields that will be sent out in the event.

In scenarios where external integration systems require the schema of the payload for a business event during development, you can select **Download schema** to download the JavaScript Object Notation (JSON) schema.

In summary, the business event catalog helps identify the business events that are required for an implementation. It also helps identify the schema for each business event.

The next step is to manage the endpoints.

Business events parameters and processing

The application allocates dedicated batch threads to process business events in near real time. The maximum number of threads cannot exceed the total threads available in the system (**System administration > Server configuration**). Because threads are a shared resource for all batch processing, care must be taken when deciding to change the thread allocation for business events. The total threads allocated for business events is controlled using a parameter in the business events parameter table. This setting is not exposed from the user interface (UI), so a support case must be created to get this count changed in production environments as this will need database access.

> **IMPORTANT**
>
> There may be reliability issues with dedicated batch threads. Microsoft is working to resolve this issue and as a result, we recommend that you schedule the manual batch job to process business events, as explained below. We will update this topic when this issue is resolved.

The business events batch processing job is available as a workaround to mitigate issues with the dedicated processing, if needed. The batch job can be enabled and scheduled from the **Business events parameters** page.

In the event of an error while sending business events to its end point, the system retries to send the business events three times with an interval of one second per retry. This is the default setting that can be changed on the **Business events parameters** page.

The number of endpoints that can subscribe to the same business event in a legal entity is limited to ten by default. This can be changed on the **Business events parameters** page.

The out-of-the-box default settings for the above described parameters can be restored on the **Business events parameters** page.

Managing endpoints

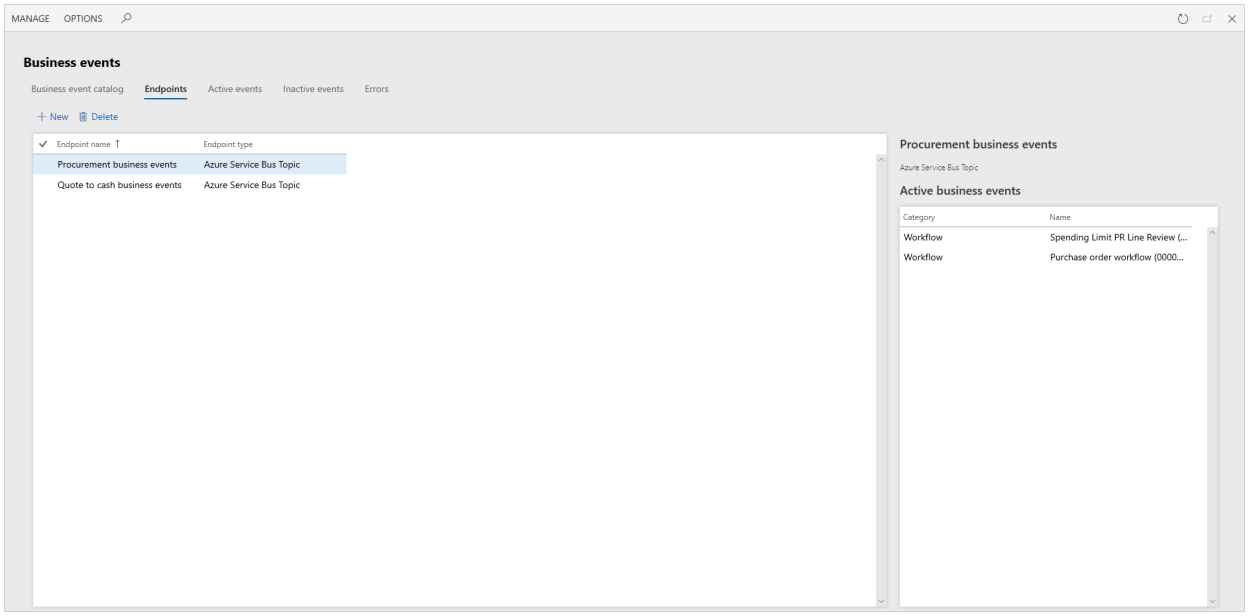
Endpoints let you manage the destinations for sending business events to. The following types of endpoints are currently supported. Endpoints can be created for these messaging and event brokers out of the box.

- Azure Service Bus Queue
- Azure Service Bus Topic
- Azure Event Grid
- Azure Event Hub
- HTTPS
- Microsoft Power Automate

Some scenarios might require multiple endpoints for organized distribution of business events to consumers. You can create multiple endpoints to support these scenarios.

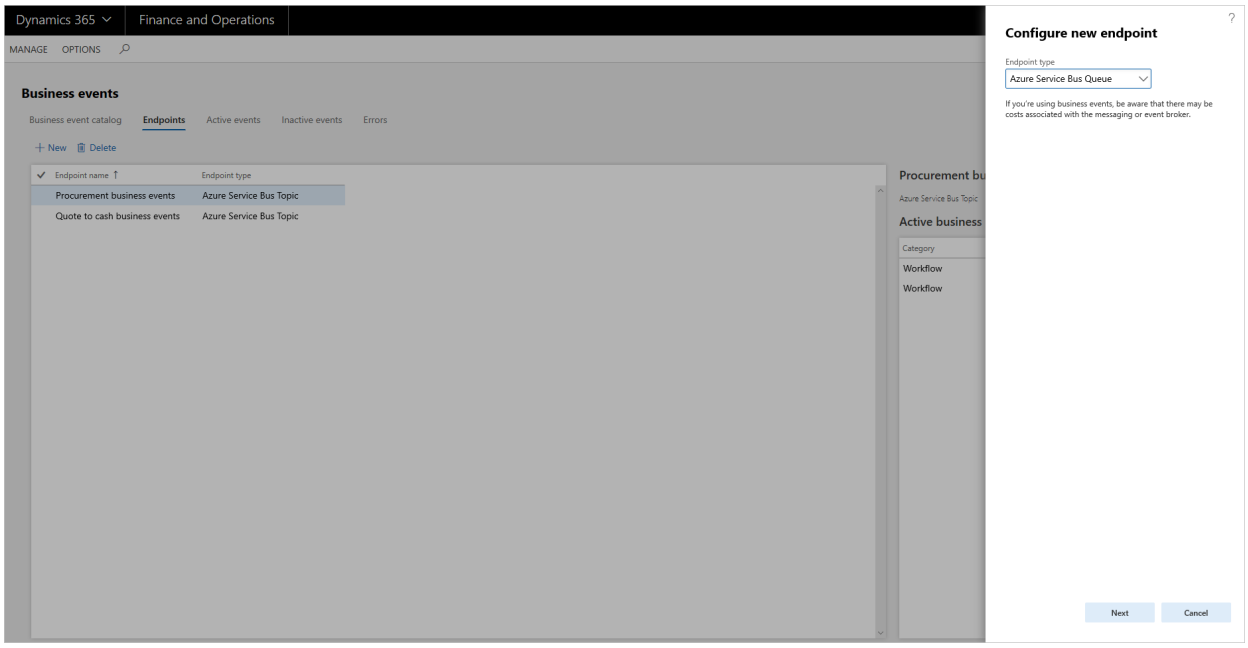
The Azure-based endpoints must be in the customer's Azure subscription. For example, if Event Grid is used as an endpoint, the endpoint must be in the customer's Azure subscription.

The application doesn't provision the endpoints. It just sends events to the endpoints that are provided. Customer might incur additional costs if they use these endpoints in their Azure subscription.

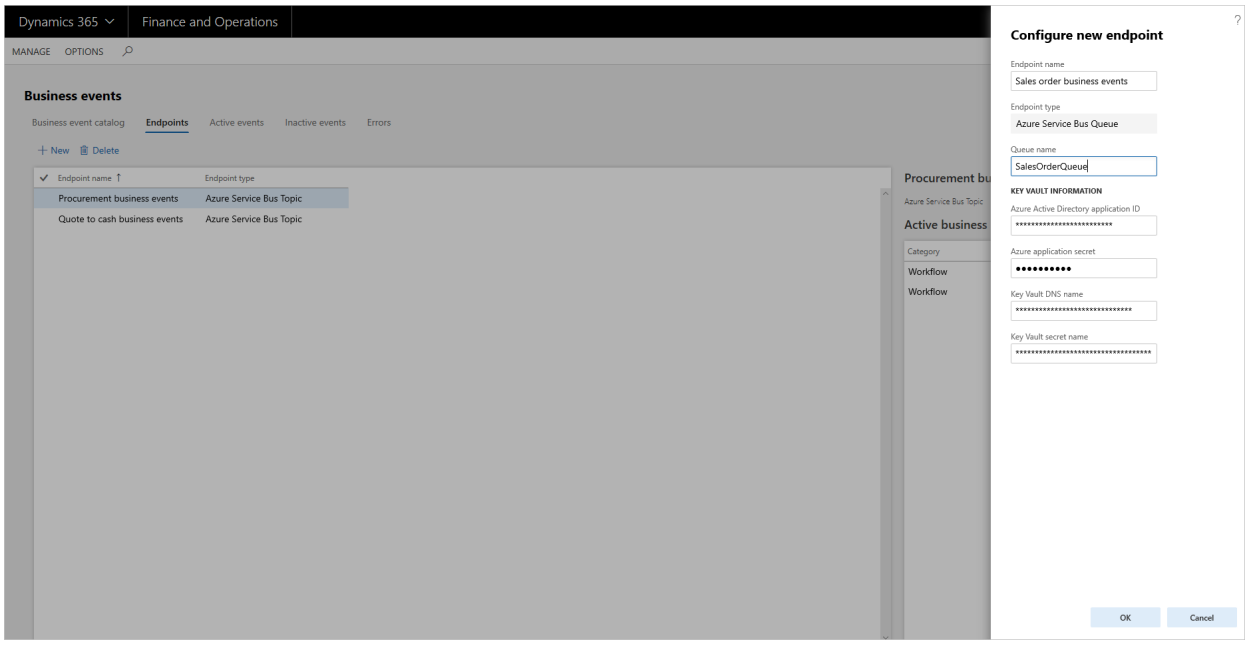


Create an Azure Service Bus Queue endpoint

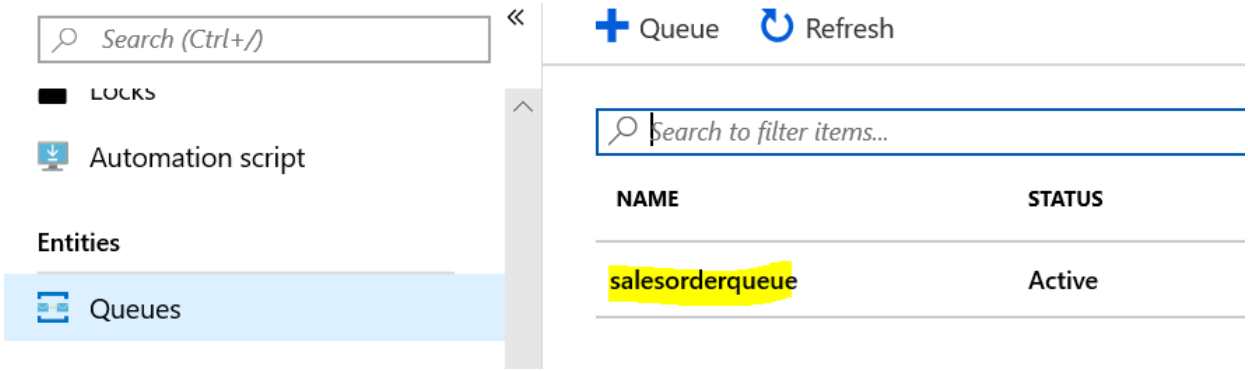
To create a new endpoint, select **New**. Then, in the **Endpoint type** field, select the appropriate endpoint type. To create an endpoint to a Service Bus queue, select **Azure Service Bus Queue**.



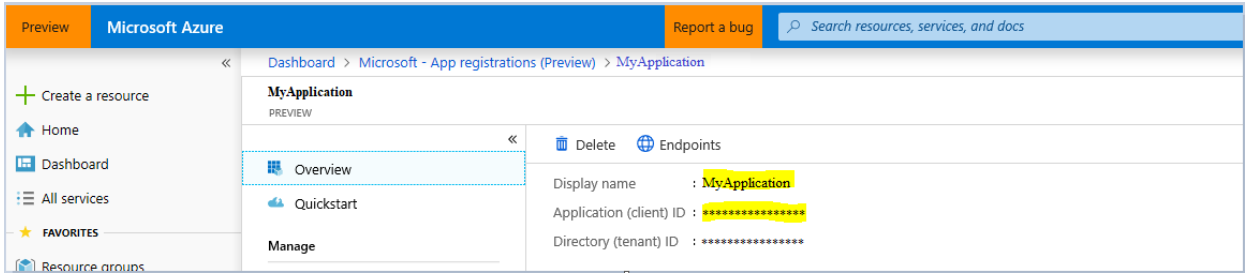
Select **Next**, and specify the name of the endpoint and the Service Bus queue. In addition, you must set up Azure Key Vault to provide the secret to the Azure messaging resource. You must also set up the Azure Active Directory (Azure AD) application ID and application secret.



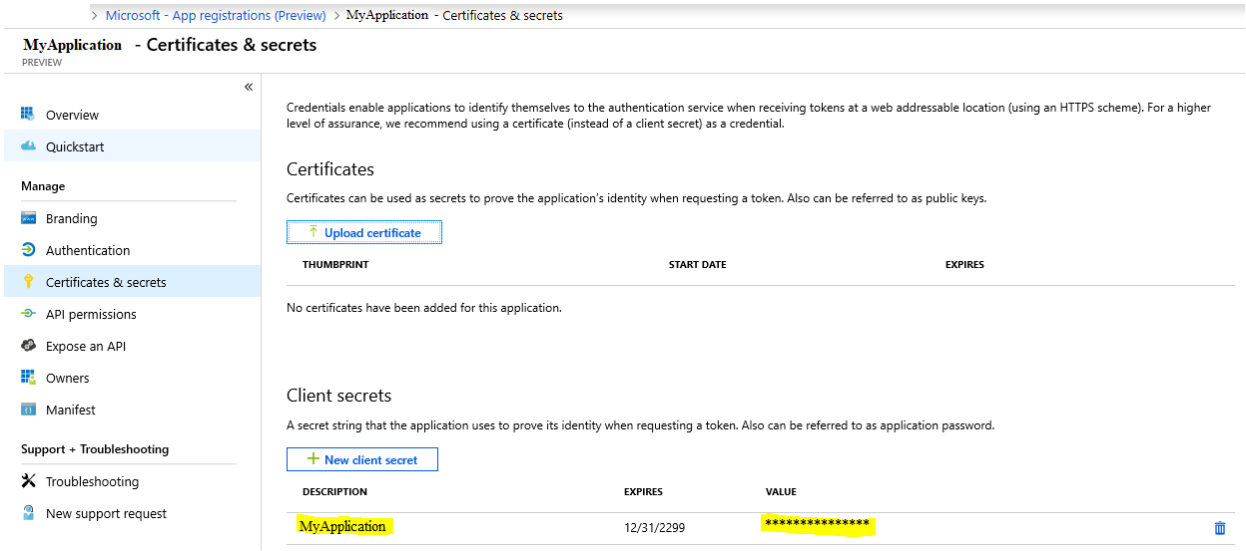
In the **Queue Name** field, enter the **Azure Service Bus Queue** name that you created in the Azure Service Bus Queue configuration in Azure.



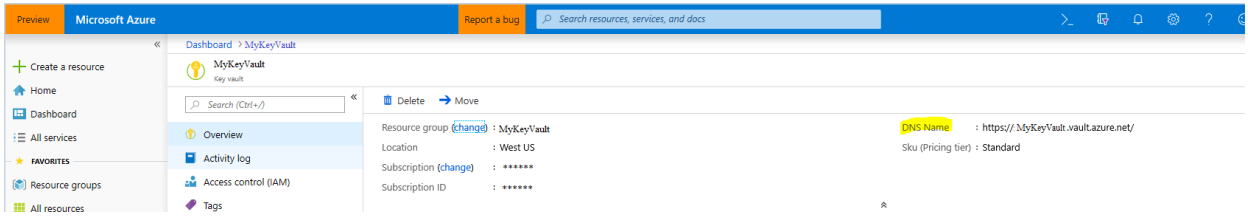
In the **Azure Active Directory application ID** field, enter the application ID that is created in Azure AD in the Azure portal.



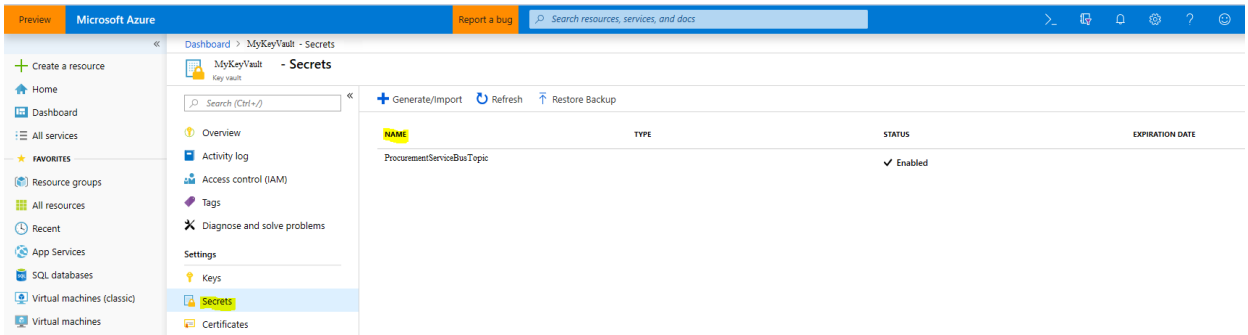
In the **Azure application secret** field, enter the secret value for the application.



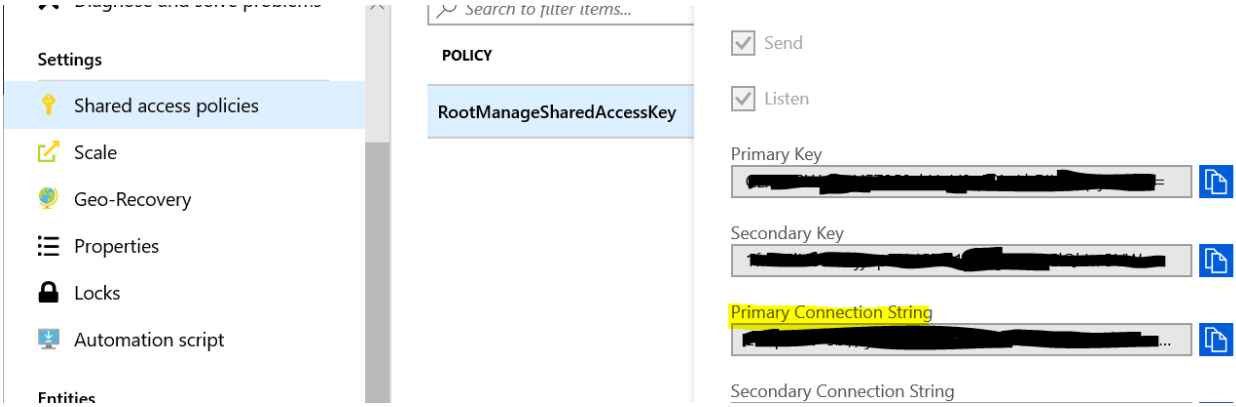
In the **Key vault DNS name** field, enter the name from your Key Vault setup.



In the **Key vault secret name** field, enter the secret name for the endpoint resource that must be created in Key Vault.



The **Key Vault Secret** value, in Azure, will be the Azure Service Bus **Primary Connection String** value. This value is found in the Azure Service Bus that you configured in **Shared Access Policies** > **RootManagedSharedAccessKey**.



IMPORTANT

The Azure application that was registered must be also added to the Key Vault set up under Access policies in the Key Vault. For this setup to be complete, select the **Key, Secret & Certificate Management** template and then select the application as the **principal**.

Create an Azure Service Bus Topic endpoint

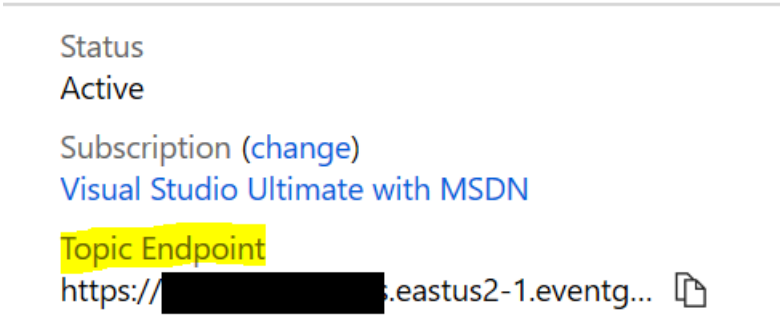
To create an endpoint to a Service Bus topic, select **New**, and then, in the **Endpoint type** field, select **Azure Service Bus Topic**. The **Topic name** field must be set to the name of the Service Bus topic. Key Vault information is set up in the same way that it is set up for an Azure Service Bus Queue endpoint.

Create an Azure Event Grid endpoint

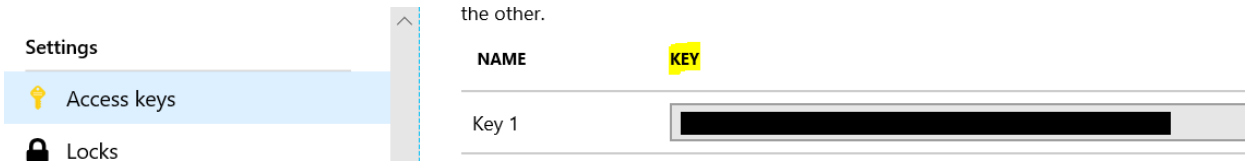
To create an endpoint, you need to create and configure an **Azure Event Grid Topic** in Azure Portal, and then create an endpoint to the Event Grid Topic in the **Business Events Workspace**. Go to the **Endpoints** tab, select **New**, and then select **Azure Event Grid** as the **Endpoint type**. In the **Endpoint URL** field, enter the URL from the **Azure Event Grid Topic**. This is the **Topic Endpoint** value in the **Overview** section of your Event Grid Topic.

IMPORTANT

The Azure application that was registered must be also added to the Key Vault set up under Access policies in the Key Vault. For this setup to be complete, select the **Key, Secret & Certificate Management** template and then select the application as the **principal**.



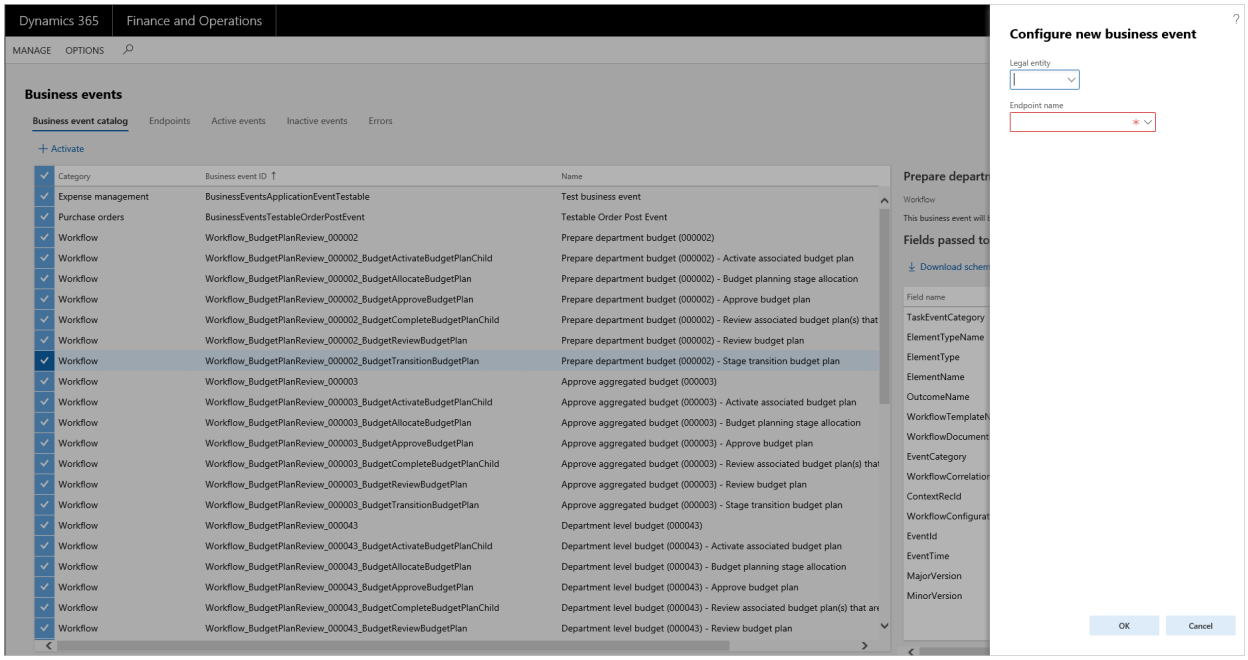
Key Vault information is set up in the same way that it is set up for an Azure Service Bus Queue endpoint, except the Key Vault secret should now point to the Event Grid credential, rather than the Service Bus connection string. The Event Grid Credential can be found under the Event Grid you created in the **Access Keys** section under Settings.



After you've created the endpoints that you require, the next step is to activate the business events.

Activating business events

Business events in the business event catalog aren't active by default. From the catalog, you can activate any business events that you require. Select one or more business events, and then select **Activate**.

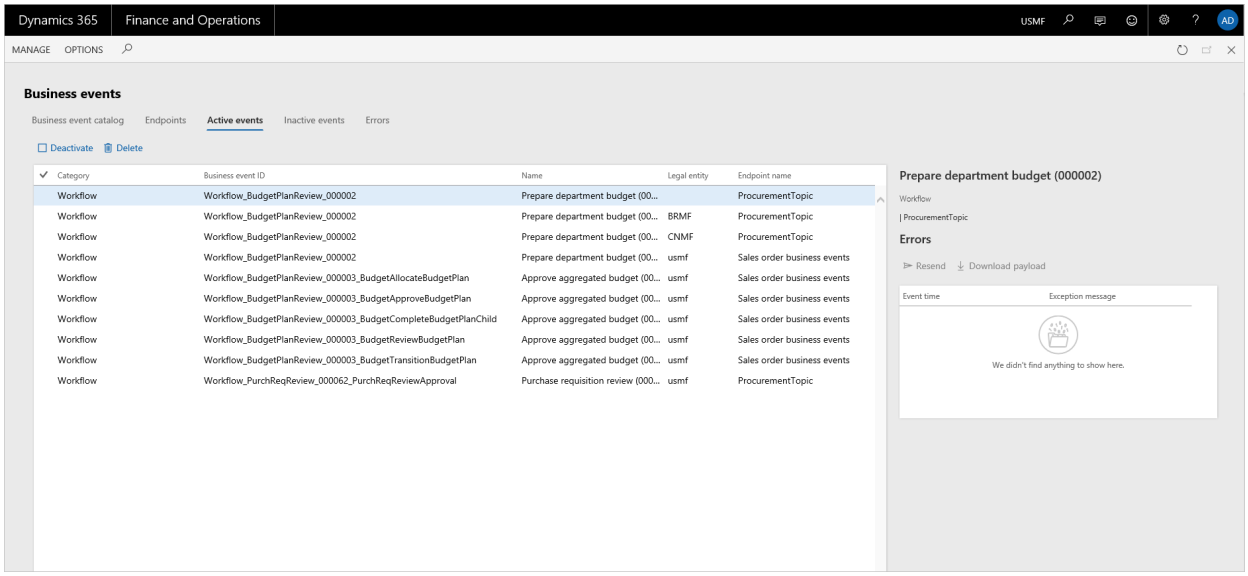


Business events can be activated either in all legal entities or in specific legal entities. If you leave the **Legal entity** field blank, the selected business events will be activated in *all* legal entities. If a business event is required only for specific legal entities, it must be configured separately for each legal entity.

Endpoints must be assigned to the business events that are activated.

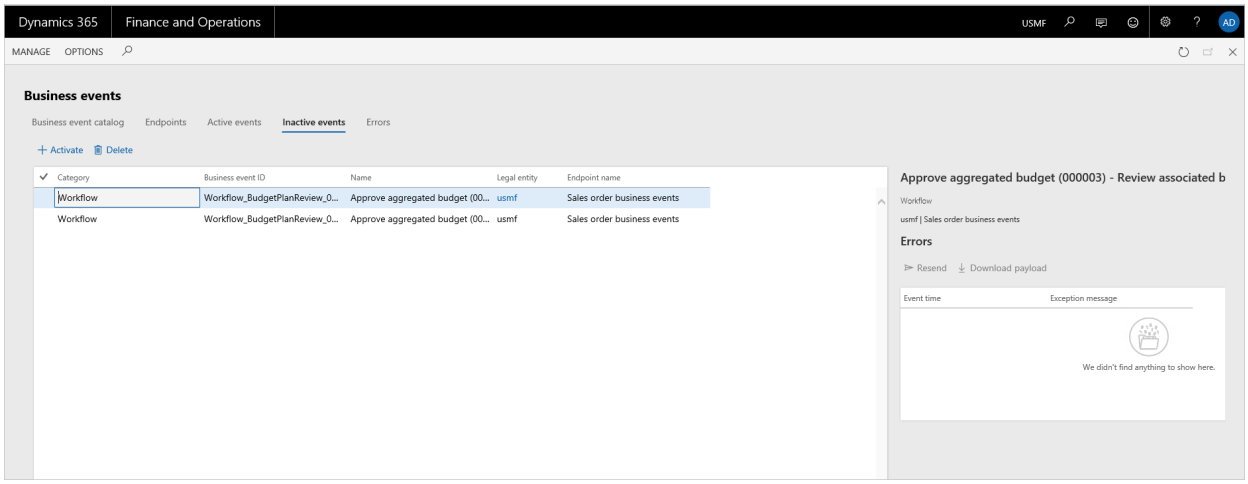
When business events occur as business processes are run, the system will do outbound processing only for business events that have been activated.

After business events are activated, they appear on the **Active events** tab.



From the **Active events** tab, you can inactivate business events. The system won't do outbound processing for inactivated events.

After business events are inactivated, they appear on the **Inactive events** tab.



Business events can be inactivated when processing of business events must be paused for a period because of specific system maintenance activities in the integration landscape.

When business requirements change, some business events might no longer be required. In this case, you can inactivate them instead of deleting them from the list of active events. This approach is useful if the history of errors for the business events must be preserved. Inactivated business events can be deleted later, when there is no longer a business need to keep them inactivated.

Errors

While the system does outbound processing of business events, errors can occur. These errors might prevent the system from successfully delivering a business event to the endpoint. If an error occurs, the system retries several times to successfully process the business event. However, if all attempts are unsuccessful, the business event is saved in an error log.

Error logs can be accessed from the **Active events**, **Inactive events**, and **Errors** tabs. The **Errors** tab shows all errors across all business events, whereas the other two tabs show errors in the context of a specific business event.

You can do on-demand outbound processing on each error by using the **Resend** action. This action invokes the outbound processing logic. This logic includes retries. If the outbound processing is still unsuccessful, the error is logged in the error log. In this case, the **Last process time** field on the **Errors** tab indicates when the last attempt to process the event occurred.

If an error can't be successfully processed, you can use the **Download payload** option to download the payload from the event for offline processing, as you require.

> **NOTE**
>
> If an endpoint is deleted and a new endpoint is associated with business events, all errors that are associated with the business events can still be resent. In this case, the system will do outbound processing to send to the new endpoint that is associated with the corresponding business event. This functionality allows for graceful recovery from misconfiguration or other error states.

Business event consumption models

The integration requirements and integration solution design for implementations vary. The integration

requirements play a role in identifying the consumption model for business events. In summary, you must consider the following points when you design integrations that use business events:

- Business events can be consumed using Power Automate, Service Bus, Event Grid, or other endpoint types.
- Customers must bring their own subscriptions to use Power Automate, Service Bus, Event Grid, or other endpoint types.
- A business event can be activated in all legal entities or in specific legal entities.
- A business event can be sent to a unique endpoint or the same endpoints.
- Power Automate can directly subscribe to business events.

Idempotency

Business events enable idempotent behavior on the consuming side by having a control number in the payload. The control number is an upwardly increasing number, which can be tracked by the consuming application to detect duplication and/or out of order delivery. The control number cannot be misread as the sequence number because the control number cannot be sequential. There can be gaps in the numbering space.

Filtering in Azure Event Grid and Azure Service Bus

Azure Service Bus and Azure Event Grid supports subscribing to topics by specifying criteria on the incoming message. For more information, see Topic filters and actions and Understand event filtering for Event Grid subscriptions.

A business event that is sent to an Azure Service Bus or Azure Event Grid has the following fields made available for this purpose. Subscribers can use this information to subscribe to more specific topics as required.

- **Category** – This is the business event category as displayed in the business event catalog. This is useful as a filter criterion when a common topic is used for receiving business events from multiple categories and subscribers want to only receive business events for the category that they are interested in.
- **Business event ID** – This is the class name of the business event implementation as displayed in the business event catalog. This uniquely identifies the business event (not the instance of the business event) and thus helps in validation of received business events on the consumer side to ensure the expected business event is what is being received and processed.
- **Legal entity** – This is the legal entity in which the business event happened. This is a useful information to base the consuming logic on if the processing and distribution of business events on the consumption side must be driven by a legal entity.

> **NOTE**
> The filterable fields that are sent in a business event can be modified to include custom fields. This is a developer experience.

Role-based security for business events

Starting in Platform update 29, role-based security can be applied to business events to meet the following requirements using the appropriate security artifact.

REQUIREMENT	PRIVILEGE	DUTY
Only certain users must have access to view the business events catalog.	**BusinessEventsCatalogView**	None

REQUIREMENT	PRIVILEGE	DUTY
Only certain users must have access to activate business events.	**BusinessEventsCatalogMaintain**	None
Only certain users must have access to create and manage endpoints.	**Business events security privilege**	**Business events security duty**
Users must only be able to subscribe to business events which they have been granted access to from external applications like Power Automate.	**Subscribe to business events from service**	None
Only certain users must be able to view the business events security setup.	**BusinessEventsCatalogSecuritySetupView**	None
Only certain users must be able to manage business events security.	**Maintain business events catalog security**	None

These privileges can be added to the required duties to grant corresponding roles appropriate access levels.

Enabling role-based security for business events

Role-based security for business events must be enabled via Feature management.

1. Go to **System administration > Feature management**.
2. Select the **Business events catalog security** feature.
3. Enable the feature.
4. Go to the business events catalog via **System administration > Set up > Business events > Business events catalog.**
5. The **Security** tab in the catalog is where a business event must be mapped to one or more roles. You must complete the configuration as required.
6. Enable security by selecting the **Enable** menu button on the **Security** menu on the top navigation pane. An informational message will confirm if security is enabled or disabled.
7. Modify the necessary security role to add the appropriate privilege or the duty based on security noted in the informational message.

Subscribe to business events from service

Users having access to the privilege **Subscribe to business events from service** via their roles will be able to only see and subscribe to business events that have been assigned to their roles, which is described below. The organizational assignments that are done, if any, as part of role-based security is honored in the context of business events by letting users to only subscribe to business events in the organizations to which they have access to via their roles. This behavior is effective using any service calls like from Power Automate or Logic Apps.

Backward compatibility

To ensure backward compatibility of business events with versions prior to Platform update 29, the following behavior must be understood.

- Role-based security for business events will be disabled by default.
- Even if the feature is enabled in Feature management, role-based security will not take effect.

- Role-based security must be explicitly enabled in the business events catalog via the **Security** menu.
- After role-based security is enabled completely, security will be enforced henceforth. This will mean that any user with administration role will not notice any change in behavior. However, any non-admin users will either only see business events to which their roles were assigned to in the business events catalog security configuration or they will not see any business events because their roles were not assigned to any business events.

> **NOTE**
>
> To ensure uninterrupted functionality, it is important to understand the backward-compatibility behavior described above before you enable security on business events.

> **NOTE**
>
> Can you tell us about your documentation language preferences? Take a short survey.
>
> The survey will take about seven minutes. No personal data is collected (privacy statement).

Application business events

2/18/2021 • 2 minutes to read • Edit Online

This topic lists application business events.

Procure to pay

BUSINESS EVENT	DESCRIPTION	MODULE	
Vendor invoice matched	This event is triggered when invoice matching validation is completed for a vendor invoice as part of the Procure to pay process.	Accounts payable	
Vendor invoice posted	This event business event is triggered when a user posts a vendor invoice as part of the Procure to Pay process.	Accounts payable	
Vendor payment posted	This event is triggered when a user posts a vendor payment as part of the Procure to pay process.	Accounts payable	
Invoice register journal posted	This event is triggered when a user posts an invoice register journal as part of the Procure to pay process.	Accounts payable	
Invoice journal posted	This event is triggered when a user posts an invoice journal as part of the Procure to pay process.	Accounts payable	
Invoice approval journal posted	This event is triggered when a user posts an invoice approval journal as part of the Procure to pay process.	Accounts payable	

BUSINESS EVENT	DESCRIPTION	MODULE	
Purchase order confirmed	This event is triggered when a purchase order is confirmed by a vendor. One of the following actions triggers the event: the user manually confirms a purchase order in the user interface for purchase orders, when the purchase order confirmation is executed in a batch, or when the confirmation is executed programmatically in intercompany scenarios. In scenarios where vendor collaboration is used, and the vendor collaboration policy is set to autoconfirm a purchase order, the trigger occurs when the **Accept** button is clicked on the **Purchase order confirmation** page in the **Vendor collaboration** portal.	Procurement and sourcing	
Purchase order received	This event is triggered when goods or services are registered as received against one or more purchase orders. One of the following actions triggers the event: a product receipt is generated for one or more purchase orders manually in the user interface for purchase orders and product receipts, when product receipts are generated in a batch, or when product receipts are generated programmatically in intercompany scenarios.	Procurement and sourcing	

Quote to cash

BUSINESS EVENT	DESCRIPTION	MODULE
Invoice is created from a sales order	This event is triggered when a user posts a sales order invoice as part of the Quote to Cash process.	Accounts receivable
Free text invoice posted	This event is triggered when a user posts a free text invoice as part of the Quote to Cash process.	Accounts receivable

BUSINESS EVENT	DESCRIPTION	MODULE
Payment posted	This event is triggered when a user posts a payment as part of the Quote to Cash process.	Accounts receivable
Transaction is written off	This event is triggered when a user writes off a customer transaction as part of the Quote to Cash process.	Accounts receivable
Collection status of a transaction changed	This event is triggered when a user updates the collection status of a transaction as part of the Quote to Cash process.	Accounts receivable
Interest note posted	This event is triggered when a user posts an interest note as part of the Quote to Cash process.	Accounts receivable
Collection letter created	This event is triggered when a user creates a collection letter for a customer as part of the Quote to Cash process.	Credit and collections

Workflow business events

2/18/2021 • 6 minutes to read • Edit Online

Workflow business events are generated at various points in the processing of a workflow.

Workflow construction

To construct a workflow, a developer can define workflows components in metadata and code in the Visual Studio tools.

An administrator can create workflows in the web client and then design them in the workflow designer. For more information, see Create workflows.

Workflow components

Workflow components are defined in metadata as:

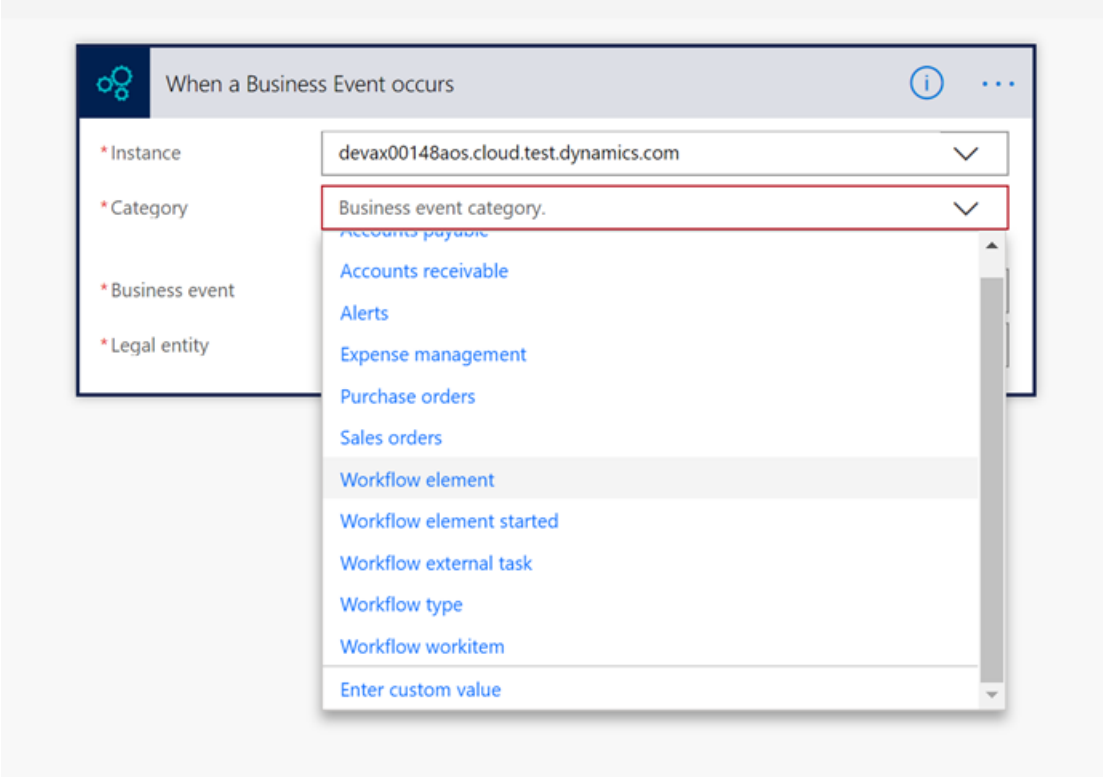
- **Workflow types** - Also known as templates, workflow types define the elements allowed in a workflow. The administrator decides which elements are actually used when they create the workflow design.
  - In the Application Explorer, go to **AOT > Business Process and Workflow > Workflow Types**.
- **Workflow elements** - Workflow elements are the executable pieces that make up a workflow. For details, see Workflow elements.
  - Tasks (aka manual tasks) - Go to **AOT > Business Process and Workflow > Workflow Tasks**.
  - Approvals - Go to **AOT > Business Process and Workflow > Workflow Approvals**.
  - Automated tasks - Go to **AOT > Business Process and Workflow > Workflow Automated Tasks**.

Workflow runtime

After a workflow is submitted by a user, it is added to a queue and run using the **Workflow message processing** batch job. As the workflow runs, it will progress through all the connected workflow elements until it reaches the end. When the workflow runtime encounters a manual task element, it will create a work item for the user assigned to the task. When the workflow runtime encounters an approval element, it will create a work item for each user assigned to each approval step.

Workflow business event categories

There are five different categories of workflow business events. The category will show up in Microsoft Power Automate to help with event selection.



- **Category: Workflow type**
  - These events will fire on workflow events like started and completed. All workflow instances will be represented in this category.
  - **ID format** - "Workflow_" + Workflow name + Workflow instance ID, for example "Workflow_BudgetPlanReview_000002"
  - **Name format** - Workflow label + " (" + Workflow instance ID ")", for example "Prepare department budget (000002)"
- **Category: Workflow element started**
  - These events will fire when a workflow element is started. All enabled workflow elements within a workflow instance will be represented in this category.
  - **ID format** - "Workflow_" + Workflow name + Workflow instance ID + "_" + Workflow element name + "_Started", for example "Workflow_BudgetPlanReview_000002_BudgetActivateBudgetPlanChild_Started"
  - **Name format** - Workflow label + " (" + Workflow instance ID ") - " + Workflow element label, for example "Prepare department budget (000002) - Activate associated budget plan"
- **Category: Workflow element**
  - These events will fire on workflow element events other than started, such as completed. All enabled workflow elements within a workflow instance will be represented in this category.
  - **ID format** - "Workflow_" + Workflow name + Workflow instance ID + "_" + Workflow element name, for example "Workflow_BudgetPlanReview_000002_BudgetActivateBudgetPlanChild"
  - **Name format** - Workflow label + " (" + Workflow instance ID ") - " + Workflow element label, for example "Prepare department budget (000002) - Activate associated budget plan"
- **Category: Workflow external task**
  - These events will fire when a workflow automated task element is started. All enabled workflow automated task elements within a workflow instance will be represented in this category.
  - **ID format** - "Workflow_" + Workflow name + Workflow instance ID + "_" + Workflow element name + "_ExternalTask", for example "Workflow_BudgetPlanReview_000002_BudgetActivateBudgetPlanChild_ExternalTask"
  - **Name format** - Workflow label + " (" + Workflow instance ID ") - " + Workflow element label, for example "Prepare department budget (000002) - Activate associated budget plan"

- **Category: Workflow workitem**
  - These events will fire when a workflow work item is created for a user. All enabled workflow tasks and workflow approvals within a workflow instance will be represented in this category.
  - **ID format** - "Workflow_" + Workflow name + Workflow instance ID + "_" + Workflow element name + "_WorkItem", for example "Workflow_BudgetPlanReview_000002_BudgetActivateBudgetPlanChild_WorkItem"
  - **Name format** - Workflow label + " (" + Workflow instance ID ") - " + Workflow element label, for example "Prepare department budget (000002) - Activate associated budget plan"

Completion of a work item in Power Automate

Workflow business events are a good target for triggering approval flows. The **workflow workitem** event can be used in conjunction with the validate and complete OData actions to facilitate completion of a work item in Power Automate.

An approval or task work item can be completed in Power Automate using the following steps:

- Trigger the Power Automate using the **when a business event occurs** trigger targeting the appropriate **workflow workitem** event.
- Validate that the **workflow workitem** contains a valid set of information so it is ready for completion by calling the **Validate** method on the **WorkflowWorkItems** entity.
- If the workitem is not ready for completion, then send a notification to the assigned user to let them know that there is a workitem that needs their attention.
- If the workitem is ready for completion, then request a response from the assigned user by sending the available response options to the user.
- After a response is provided, complete the workitem with that response by calling the **Complete** method on the **WorkflowWorkItems** entity.

To enable external completion of work items, the work item action manager class needs to implement the IValidateWorkflowWorkItemAction interface. The standard WorkflowWorkItemActionManager class has implemented this interface. In Platform update 32, the TrvWorkflowWorkItemActionManager class was updated to implement the IValidateWorkflowWorkItemAction interface. Use the existing IValidateWorkflowWorkItemAction implementations as examples to notify updates about other WorkflowWorkItemActionManager classes.

For a step-by-step guide to setting up work item completion in Microsoft Power Automate, see Consume workflow approval business events.

Templates for work item completion in Power Automate

The following templates for work item completion in Power Automate are available:

- Complete Dynamics 365 for Finance and Operations workflow work items (PU26)
- Complete Dynamics 365 for Finance and Operations workflow work items (PU29)

The Platform update 29 version gets completion options from the business event payload. These options were added in Platform update 29, and presented to the user via the approval action.

Troubleshooting workflow business events

Troubleshooting workflow issues

Ensure that the workflow is running correctly and creating work items as expected. If the workflow doesn't work inside the application so that state changes are occurring, then the events won't occur. Adjust the workflow configuration as needed. If needed, review the workflow details in the **Workflow History** form.

Troubleshooting Power Automate issues

Ensure that the Power Automate subscription is available in the **System administration > Setup > Business events > Business events catalog** on the **Active events** tab. If the Power Automate subscription isn't there, then check Power Automate and recreate it if needed.

Troubleshooting business events issues

Ensure that other business events are occurring by creating a Power Automate to trigger off another business event. For example, the Free Text Invoice Posted event can be triggered by simply creating a Free Text Invoice with a single line and posting it. For more information, see Troubleshoot business events.

Troubleshooting work item approval via Power Automate

If a flow is trying to handle approval for work items, but it isn't firing, then verify these steps:

- Are the work items being created so the applicable user can see them waiting for approval in the web client?
- Is the event subscription from Flow visible in the Business Events form?
- Are the workflow configuration and the event subscription from Flow for the correct legal entity (company)?

Alerts as business events

2/18/2021 • 2 minutes to read • Edit Online

There are two kinds of alerts that can be configured by users. These are change-based alerts and due date alerts. For more information about the alerts functionality, see Alerts.

The change-based alerts and due date alerts can be configured to send out a business event as a mechanism to notify or trigger external applications or systems. This allows alerts to participate in advanced user notification scenarios and also in business process integration across systems.

To generate a business event from an alert, in the **Create alert rule** dialog box, set **Alert me with** > **Send externally** to **Yes**.

In order for alerts to be processed, the batch processes for change-based and/or due-date alerts should be set for batch processing for due-date events. For more information, see Batch processing for due-date events.

The business event for the change-based alert and/or the due date alert must also be active for the alert to be sent out as a business event. To learn more about the activation process, see Activating business events.

Business events in Microsoft Power Automate

2/18/2021 • 2 minutes to read • Edit Online

Business events can be consumed in Microsoft Power Automate via the application connector. The connector has a trigger that is named **when a business event occurs**. This trigger can be used to subscribe to any of the business events that are available in the target instance of the application.

Prerequisite

It's important that you understand business events. For more information, see the Business events documentation.

> **IMPORTANT**
>
> The **when a business event happens** trigger works only with application instances that run Platform update 24 or later, because business events aren't available in earlier platform releases.

Subscribing to business events and unsubscribing from them

After the **when a business event happens** trigger is added to a flow, the following information must be provided:

- **Instance** – Specify the host name of the instance where business events occur. Environment instances should be available in the provided drop-down menu, but if an environment is not listed it can be entered as a custom value.
- **Category** – Select the category of business events. The **Business event** field then shows the business events in that category.
- **Business event** – The available business events in the selected category.
- **Legal entity** – Specify the legal entity where the business event is being subscribed to. The flow will be triggered when the business event occurs in that legal entity. By default, this field is blank and the business event is subscribed to in **all** legal entities.

When the flow is saved, a subscription to the selected business event is added into the environment instance. As part of the subscription process, the required endpoint is set up, and the corresponding business event is activated.

If the trigger is deleted or the flow is turned off, then the business event endpoint will be automatically deleted.

Multiple flows can subscribe to the same business event in different legal entities or in the same legal entity. Note that the default endpoint limit per event is ten. If needed, adjust the **Endpoints allowed per event** on the **Business event parameters** page.

> **NOTE**
>
> The Power Automate endpoint must not be configured manually. The endpoint will automatically get created from Power Automate as explained above.

For how-to information about using business events in Microsoft Flow, see Consume business events in Microsoft Flow.

Other ways to consume business events in Power Automate

The previous section explains how you can subscribe to business events directly from Power Automate by using the trigger in the connector. However, you can also consume business events in Microsoft Power Automate from Microsoft Azure Event Grid, by using the Event Grid connector for Microsoft Power Automate.

Event Grid might be a viable approach for consuming business events in Power Automate if it's already being used for other integrations in an implementation. If a business event in the same legal entity must trigger multiple flows, you should consider consuming the business event from Event Grid.

This approach is applicable to any messaging or event platform that is used as an endpoint for business events, provided that a connector is available for it in Power Automate.

Business events developer documentation

2/18/2021 • 19 minutes to read • Edit Online

This topic walks you through the development process and best practices for implementing business events.

What is a business event, and what isn't a business event?

This question comes up every time that we start to think about use cases where business events can help. Is the creation of a vendor a business event? Is confirmation of a purchase order a business event? Is it a business event if you capture the event at the table level? Or should business events be captured only at the business logic level in a business process? These questions aren't just valid, but they are also a key topic of discussion when a solution is planned and architected for integration. The following guidelines can help with this thought process and decision making.

Intent

The intent behind capturing a business event must be clearly understood. In other words, what is the reason for capturing the business event, and how it will be used by the recipient?

If your intent is to capture a business event so that you can take a business action outside Dynamics 365 Finance and Operations apps in response to a business event that occurs in Finance and Operations, you have a good use case for business events. The business action that is taken in response to the business event can be to notify users about the business event and/or to call into another business application to take a business action, such as creation of a sales order. It's important that you look at the business action generically and not base the need for a business event on the type of business action that will be taken.

If your intent is to transfer data to a recipient and, in effect, realize a data export scenario, you don't have a good use case for business events. In fact, the use of business events for data transfer scenarios is a misuse of the business events framework. Such scenarios must continue to use data export mechanisms that are already available in data management.

Fidelity

When the intent is clear, and a legitimate need for a business event is established, the next step is to evaluate the approach that must be used to capture the business event. This section summarizes the approach that must be evaluated.

Regardless of the approach that is used, the fidelity of business events is significant, because it helps guarantee that the following aspects are taken care of. Therefore, it must influence the design choice for implementing the business event. However, the design choice that you make to implement a business event must not influence the concept of business events. In other words, the chosen design must not be used as a decision-making tool, to determine whether an event is a business event. The intent must be used to make those decisions.

- **Durable business events** – No false business events should be sent to the recipient. If a purchase order confirmation business event is sent out, the recipient expects and must trust that the purchase order was really confirmed. The design choice must help guarantee this transactional nature. Therefore, you must not make a design choice that violates the recipient's expectations.
- **Targeted** – Business events must be designed to optimize the consumption story for the recipient. In other words, you should make it as easy as possible for the recipient to consume business events. Therefore, business events must be as specific as possible and must be targeted to specific use cases. They must not be generic, so that the consumer has to determine what the business event is for by trying to understand the

payload. The design choice must allow for preservation of targeted business events.

- **Noiseless** – The design should include very little effort to filter out noise. To make business events very specific, avoid writing filtering logic to filter out conditions that don't match the expected business event. The chosen approach must help guarantee that the business event is implemented in code at a sufficiently specific point so that no filtering of noise is required. Any attempt to filter noise by adding logic can affect performance and might also become complicated in specific use cases.

The following table compares capture at the business and table levels.

CAPTURE AT THE BUSINESS LOGIC LEVEL	CAPTURE AT THE TABLE LEVEL
Capture at this level helps guarantee durability because it occurs in the transaction.	Capture at this level helps guarantee durability because it occurs in the transaction.
Capture at this level allows for targeted business events.	Because events are captured at a lower level, it's difficult to provide targeted business events.
It's easy to remain noiseless.	It's difficult to remain noiseless unless additional effort is made to implement sound logic that filters out noise.
Capture at this level provides additional context for the business process, and can significantly improve the durability and quality of the payload.	Because events are captured at a lower level, business process context is probably lost.

> **NOTE**
> In general, if you implement business events at the table level, you might face other challenges, in addition to the challenges that are described in the preceding table. For example, if the business logic is run via a stored procedure that updates data in the underlying table, the business event might not even be generated, because it was implemented in the table insert method in X++. You might encounter additional challenges in specific use cases. Therefore, we don't recommend that you implement business events at the table level.

Implement a business event

The process for implementing a business event and sending it is fairly straightforward.

1. Build the contract.
2. Build the event.
3. Add code to send the event.

Two classes must be implemented:

- **Business event** – This class extends the **BusinessEventsBase** class. It supports constructing the business event, building the payload, and sending the business event.
- **Business event contract** – This class extends the **BusinessEventsContract** class. It defines the payload of the business event and allows for population of the contract at runtime.

BusinessEventsBase extension

Naming convention

The names of business events should follow the pattern <noun or noun phrase><past tense action>BusinessEvent. The <noun or noun phrase> part of the name should comply with existing definitions for application area prefixes.

Examples

- VendorInvoicePostedBusinessEvent
- CollectionLetterSentBusinessEvent

Implementation

The process of implementing an extension of the **BusinessEventsBase** class is straightforward. It involves extending the **BusinessEventsBase** class, and implementing a static constructor method, a private **new** method, methods to maintain internal state, and the **buildContract** method.

1. Implement a static **newFrom<my_buffer>** method. The <my_buffer> part of the method name is typically the table buffer that is used to initialize the business event contract.

```
static public SalesInvoicePostedBusinessEvent
newFromCustInvoiceJour(CustInvoiceJour _custInvoiceJour)
{
    SalesInvoicePostedBusinessEvent businessEvent = new
    SalesInvoicePostedBusinessEvent();
    businessEvent.parmCustInvoiceJour(_custInvoiceJour);
    return businessEvent;
}
```

2. Extend the **BusinessEventsBase** class.

```
[BusinessEvents(classStr(SalesInvoicePostedBusinessEventContract),
'AccountsReceivable:SalesOrderInvoicePostedBusinessEventName','AccountsReceivable:SalesOrderInvoicePo
stedBusinessEventDescription',ModuleAxapta::SalesOrder)]
public class SalesInvoicePostedBusinessEvent extends BusinessEventsBase
```

   Note the **BusinessEvents** attribute. This attribute provides the business events framework with information about the business event's contract, name, and description. It also provides the module that the business event is part of. Labels must be defined for the name and description arguments. However, these labels should be referenced without the at symbol (@) to avoid storing localized data.

3. Implement a private **new** method. This method is called only from the static constructor method.

```
private void new()
{
}
```

4. Implement private **parm** methods to maintain internal state.

```
private CustInvoiceJour parmCustInvoiceJour(CustInvoiceJour _custInvoiceJour = custInvoiceJour)
{
    custInvoiceJour = _custInvoiceJour;
    return custInvoiceJour;
}
```

5. Implement the **buildContract** method. Note that you need an **EventContract** stub for this step.

```
[Wrappable(true), Replaceable(true)]
public BusinessEventsContract buildContract()
{
    return
    SalesInvoicePostedBusinessEventContract::newFromCustInvoiceJour(custInvoiceJour);
}
```

   For extensibility, the **buildContract** method must have the **Wrappable(true)** and **Replaceable(true)**

attributes. The **buildContract** method is called only when a business event is enabled for a company.

Here is the complete implementation of the "Sales order invoice posted" business event.

```
/// <summary>
/// Sales order invoice posted business event.
/// </summary>
[BusinessEvents(classStr(SalesInvoicePostedBusinessEventContract),
'AccountsReceivable:SalesOrderInvoicePostedBusinessEventName',
'AccountsReceivable:SalesOrderInvoicePostedBusinessEventDescription',
ModuleAxapta::SalesOrder)]
public class SalesInvoicePostedBusinessEvent extends BusinessEventsBase
{
    private CustInvoiceJour custInvoiceJour;
    private CustInvoiceJour parmCustInvoiceJour(CustInvoiceJour _custInvoiceJour =
    custInvoiceJour)
    {
        custInvoiceJour = _custInvoiceJour;
        return custInvoiceJour;
    }
    /// <summary\>
    /// Creates a SalesInvoicePostedBusinessEvent from a CustInvoiceJour record.
    /// <summary>
    /// param name = "_custInvoiceJour"> CustInvoiceJour record <param>
    /// <returns>A SalesInvoicePostedBusinessEvent </returns>
    static public SalesInvoicePostedBusinessEvent
    newFromCustInvoiceJour(CustInvoiceJour _custInvoiceJour)
    {
        SalesInvoicePostedBusinessEvent businessEvent = new
        SalesInvoicePostedBusinessEvent();
        businessEvent.parmCustInvoiceJour(_custInvoiceJour);
        return businessEvent;
    }
    private void new()
    {
    }
    [Wrappable(true), Replaceable(true)]
    public BusinessEventsContract buildContract()
    {
        return SalesInvoicePostedBusinessEventContract::newFromCustInvoiceJour(custInvoiceJour);
    }
}
```

BusinessEventsContract extension

A business event contract class extends the **BusinessEventsContract** class. It defines and populates the payload of the business event. Although there is some variation across business events, the basic structure of the business event contract is consistent.

The process of implementing a business event contract involves extending the **BusinessEventContract** class, defining internal state, implementing an initialization method, implementing a static constructor method, and implementing **parm** methods to access the contract state.

1. Extend the **BusinessEventContract** class.

   ```
   [DataContract]
   public final class SalesInvoicePostedBusinessEventContract extends
   BusinessEventsContract
   ```

   The class must have the **DataContract** attribute.

2. Add private variables to hold the contract state.

```
private CustInvoiceAccount invoiceAccount;
private CustInvoiceId invoiceId;
private SalesIdBase salesId;
private TransDate invoiceDate;
private DueDate invoiceDueDate;
private AmountMST invoiceAmount;
private TaxAmount invoiceTaxAmount;
private LegalEntityDataAreaId legalEntity;
```

3. Implement a private initialization method.

```
private void initialize(CustInvoiceJour _custInvoiceJour)
{
    invoiceAccount = _custInvoiceJour.InvoiceAccount;
    invoiceId = _custInvoiceJour.InvoiceId;
    salesId = _custInvoiceJour.SalesId;
    invoiceDate = _custInvoiceJour.InvoiceDate;
    invoiceDueDate = _custInvoiceJour.DueDate;
    invoiceAmount = _custInvoiceJour.InvoiceAmountMST;
    invoiceTaxAmount = _custInvoiceJour.SumTaxMST;
    legalEntity = _custInvoiceJour.DataAreaId;
}
```

The **initialize** method is responsible for setting the private state of the business event contract class, based on data that is provided through the static constructor method.

4. Implement a static constructor method.

```
public static SalesInvoicePostedBusinessEventContract
newFromCustInvoiceJour(CustInvoiceJour _custInvoiceJour)
{
    var contract = new SalesInvoicePostedBusinessEventContract();
    contract.initialize(_custInvoiceJour);
    return contract;
}
```

The static constructor method calls a private **initialize** method to initialize the private class state.

5. Implement **parm** methods to access the contract state.

```
[DataMember('InvoiceAccount'), BusinessEventsDataMember("@AccountsReceivable:InvoiceAccount")]
public CustInvoiceAccount parmInvoiceAccount(CustInvoiceAccount _invoiceAccount = invoiceAccount)
{
    invoiceAccount = _invoiceAccount;
    return invoiceAccount;
}
```

The **parm** methods should have the **DataMember('<name>')** and **BusinessEventsDataMember('<description>')** attributes. The name that you provide on the **DataMember** attribute (for example, **'InvoiceAccount'**) will be visible to data contract consumers. The description that you provide in the **BusinessEventsDataMember** attribute will be visible in the Business Events catalog user interface (UI) and used to describe this contract's data members.

NOTE

- **RecId** values should not be part of a business event's payload. Use the alternate key (AK) instead.
- Enumeration (enum) values must be converted to their symbol value before they can be published. Use the **enum2Symbol** method to convert an enum's value to the symbol string. Here is an example:

```
status = enum2Symbol(enumNum(CustVendDisputeStatus), _custDispute.Status);
```

In some cases, population of the data contract's internal state requires that you implement additional retrieval methods. These retrieval methods should be implemented as private methods, and they should be called from the **initialize** method.

Here is the complete implementation of the "Sales order invoice posted" business event contract.

```
/// <summary>
/// The data contract for a SalesInvoicePostedBusinessEvent
/// </summary>
[DataContract]
public final class SalesInvoicePostedBusinessEventContract extends
BusinessEventsContract
{
    private CustInvoiceAccount invoiceAccount;
    private CustInvoiceId invoiceId;
    private SalesIdBase salesId;
    private TransDate invoiceDate;
    private DueDate invoiceDueDate;
    private AmountMST invoiceAmount;
    private TaxAmount invoiceTaxAmount;
    private LegalEntityDataAreaId legalEntity;
    /// <summary>
    /// Creates a SalesInvoicePostedBusinessEventContract from a CustInvoiceJour record.
    /// </summary>
    /// <param name = "_custInvoiceJour"> CustInvoiceJour record</param>
    /// <returns>A SalesInvoicePostedBusinessEventContract </returns>
    public static SalesInvoicePostedBusinessEventContract
    newFromCustInvoiceJour(CustInvoiceJour _custInvoiceJour)
    {
        var contract = new SalesInvoicePostedBusinessEventContract();
        contract.initialize(_custInvoiceJour);
        return contract;
    }
    private void initialize(CustInvoiceJour _custInvoiceJour)
    {
        invoiceAccount = _custInvoiceJour.InvoiceAccount;
        invoiceId = _custInvoiceJour.InvoiceId;
        salesId = _custInvoiceJour.SalesId;
        invoiceDate = _custInvoiceJour.InvoiceDate;
        invoiceDueDate = _custInvoiceJour.DueDate;
        invoiceAmount = _custInvoiceJour.InvoiceAmountMST;
        invoiceTaxAmount = _custInvoiceJour.SumTaxMST;
        legalEntity = _custInvoiceJour.DataAreaId;
    }
    private void new()

        return legalEntity;
    }
}
```

Sending a business event

You must modify application code so that it sends the business event at the appropriate point. Often, you can use a common point in a framework. Documents that extend **SourceDocument** have a common point for creating and sending a business event. For more information, see the Source document framework support section later in this topic.

Other frameworks also provide common points for sending business events. For example, the **CustVendVoucher** class hierarchy in the Application Object Tree (AOT) has a **post** method that is used to send business events that are related to posting customer or vendor vouchers. Overrides of the base class implementation provide specialization of the logic for sending business events. For an example, see **CustVoucher.createBusinessEvent** or **VendVoucher.createBusinessEvent** in the AOT.

The sending of a business event is linked to the commit of the underlying transaction. If the underlying transaction is aborted, the business event won't be sent. Therefore, applications can send the business event at the point where the payload information is available.

The business events framework determines whether a business event is published to a consumer. As a general rule, applications should always send a business event, regardless of whether the business event is enabled. If significant additional logic is required, or if the logic for sending a business event has a performance impact, an application can check whether a specific business event is enabled before it runs business logic that is associated with sending business events. This check is done through the **BusinessEventsConfigurationReader::isBusinessEventEnabled** method.

```
if
(BusinessEventsConfigurationReader::isBusinessEventEnabled(classStr(CollectionStatusUpdatedBusinessEvent)))
{
    while select dispute
    where dispute.Status == CustVendDisputeStatus::PromiseToPay
    && dispute.FollowUpDate _currentDate
    exists join custTrans
    where custTrans.RecId == dispute.CustTrans
    && !custTrans.Closed
    exists join _tmpCustAging
    where _tmpCustAging.AccountNum == custTrans.AccountNum
    {
        CollectionStatusUpdatedBusinessEvent::newFromCustDispute(dispute).send();
    }
}
```

Source document framework support

The source document framework supports sending business events automatically as part of the transition from an in-process state to a completed state for the document. To take advantage of this capability, documents that extend the source document framework must implement an extension of the **SourceDocumentStateInProcess.getBusinessEvent** method to create and return the correct **BusinessEventsBase** extension type.

Extending a business event payload

You might want to publish additional information as part of the payload of a business event. To send this additional information, you must extend the business event's standard payload.

Example scenario

This example shows how to extend the **CustFreeTextInvoicePostedBusinessEventContract** class so that it includes a customer classification. This customer classification is an industry-based custom classification.

Step 1: Create an extended business event contract

Create a contract that consists of the standard business event contract plus any additional information that must be included in the payload.

```
[DataContract]
public class CustFreeTextInvoicePostedBusinessEventExtendedContract
extends BusinessEventsContract
{
    // standard contract
    private CustFreeTextInvoicePostedBusinessEventContract
    custFreeTextInvoicePostedBusinessEventContract;
    // contract extensions
    private str customerClassification;
}
```

Step 2: Create an initialize method

Create an **initialize** method that initializes the value of the private contract.

```
private void initialize(CustFreeTextInvoicePostedBusinessEventContract
_custFreeTextInvoicePostedBusinessEventContract)
{
    custFreeTextInvoicePostedBusinessEventContract =
    _custFreeTextInvoicePostedBusinessEventContract;
}
```

Step 3: Create a static newFrom method

Create a static **newFrom** method that takes the standard contract as an argument and calls the **initialize** method.

```
public static CustFreeTextInvoicePostedBusinessEventExtendedContract
newFromCustFreeTextInvoicePostedBusinessEventContract(CustFreeTextInvoicePostedBusinessEventContract
_custFreeTextInvoicePostedBusinessEventContract)
{
    var contract = new CustFreeTextInvoicePostedBusinessEventExtendedContract();
    contract.initialize(_custFreeTextInvoicePostedBusinessEventContract);
    return contract;
}
```

Step 4: Map parm methods

Copy the **parm** methods from the standard data contract, and modify each method so that it gets and sets values in the class's standard contract instance.

```
[DataMember('InvoiceAccount')]
public CustInvoiceAccount parmInvoiceAccount(CustInvoiceAccount _invoiceAccount
= custFreeTextInvoicePostedBusinessEventContract.parmInvoiceAccount())
{
    return
    custFreeTextInvoicePostedBusinessEventContract.parmInvoiceAccount(_invoiceAccount);
}
[DataMember('InvoiceId')]
public CustInvoiceId parmInvoiceId(CustInvoiceId _invoiceId =
custFreeTextInvoicePostedBusinessEventContract.parmInvoiceId())
{
    return custFreeTextInvoicePostedBusinessEventContract.parmInvoiceId(_invoiceId);
}
```

Step 5: Add parm methods for additional payload data

```
[DataMember('CustomerClassification')]
public CustomerClassification parmCustomerClassification(CustomerClassification
_customerClassification = customerClassification)
{
    customerClassification = _customerClassification;
    return customerClassification;
}
```

Here is the complete implementation of the extended business contract.

```
[DataContract]
public class CustFreeTextInvoicePostedBusinessEventExtendedContract
extends BusinessEventsContract
{
    // standard contract
    private CustFreeTextInvoicePostedBusinessEventContract
    custFreeTextInvoicePostedBusinessEventContract;
    // contract extensions
    private str customerClassification;
    public static CustFreeTextInvoicePostedBusinessEventExtendedContract
```

```
newFromCustFreeTextInvoicePostedBusinessEventContract(CustFreeTextInvoicePostedBusinessEventContract
_custFreeTextInvoicePostedBusinessEventContract)
{
    var contract = new CustFreeTextInvoicePostedBusinessEventExtendedContract();
    contract.initialize(_custFreeTextInvoicePostedBusinessEventContract);
    return contract;
}
private void initialize(CustFreeTextInvoicePostedBusinessEventContract
_custFreeTextInvoicePostedBusinessEventContract)
{
    custFreeTextInvoicePostedBusinessEventContract =
    _custFreeTextInvoicePostedBusinessEventContract;
}
private void new()
{
}
[DataMember('InvoiceAccount')]
public CustInvoiceAccount parmInvoiceAccount(CustInvoiceAccount _invoiceAccount
= custFreeTextInvoicePostedBusinessEventContract.parmInvoiceAccount())
{
    return
    custFreeTextInvoicePostedBusinessEventContract.parmInvoiceAccount(_invoiceAccount);
}
[DataMember('InvoiceId')]
public CustInvoiceId parmInvoiceId(CustInvoiceId _invoiceId =
custFreeTextInvoicePostedBusinessEventContract.parmInvoiceId())
{
    return custFreeTextInvoicePostedBusinessEventContract.parmInvoiceId(_invoiceId);
}
[DataMember('InvoiceDate')]
public TransDate parmInvoiceDate(TransDate _invoiceDate =
custFreeTextInvoicePostedBusinessEventContract.parmInvoiceDate())
{
    return
    custFreeTextInvoicePostedBusinessEventContract.parmInvoiceDate(_invoiceDate);
}
[DataMember('InvoiceDueDate')]
public DueDate parmInvoiceDueDate(DueDate _invoiceDueDate =
custFreeTextInvoicePostedBusinessEventContract.parmInvoiceDueDate())
{
    return
    custFreeTextInvoicePostedBusinessEventContract.parmInvoiceDueDate(_invoiceDueDate);
}
[DataMember('InvoiceAmountInAccountingCurrency')]
public AmountMST parmInvoiceAmount(AmountMST _invoiceAmount =
custFreeTextInvoicePostedBusinessEventContract.parmInvoiceAmount())
{
    return
    custFreeTextInvoicePostedBusinessEventContract.parmInvoiceAmount(_invoiceAmount);
}
[DataMember('InvoiceTaxAmount')]
public TaxAmount parmInvoiceTaxAmount(TaxAmount _invoiceTaxAmount =
custFreeTextInvoicePostedBusinessEventContract.parmInvoiceTaxAmount())
{
    return
    custFreeTextInvoicePostedBusinessEventContract.parmInvoiceTaxAmount(_invoiceTaxAmount);
}
[DataMember('LegalEntity')]
public LegalEntityDataAreaId parmLegalEntity(LegalEntityDataAreaId _legalEntity
= custFreeTextInvoicePostedBusinessEventContract.parmLegalEntity())
{
    return
    custFreeTextInvoicePostedBusinessEventContract.parmLegalEntity(_legalEntity);
}
// contract extensions
[DataMember('CustomerClassification')]
public CustomerClassification parmCustomerClassification(CustomerClassification
_customerClassification = customerClassification)
{
```

```
        customerClassification = _customerClassification;
        return customerClassification;
    }
}
```

Step 6: Wrap the buildContract method

Provide a build contract implementation that calls **next** to load the standard business event contract and populates any payload extensions. Here is the complete class.

```
[ExtensionOf(classStr(CustFreeTextInvoicePostedBusinessEvent))]
public final class FreeTextInvoicePostedBusinessEventContract_Extension
{
    public BusinessEventsContract buildContract()
    {
        var businessEventContract =

CustFreeTextInvoicePostedBusinessEventExtendedContract::newFromCustFreeTextInvoicePostedBusinessEventContrac
t(next
        buildContract());

businessEventContract.parmCustomerClassification(CustomerClassifier::deriveCustomerClassification(businessEv
entContract.parmInvoiceAccount()));
        return businessEventContract;
    }
}
```

Extending filters so that they have custom fields (if the middleware supports this extension)

Some middleware systems allow for filtering of the events. For example, Microsoft Azure Service Bus has a property bag that can be populated with key-value pairs. These key-value pairs can be used to filter events when reading from the Service Bus Queue or Topic. Additionally, Azure Event Grid has filterable message properties such as **Subject**, **Event Type**, and **ID**. To support these various properties for the different systems, the business events framework uses a concept that is named *payload context*. This concept can be extended so that it includes custom fields that the different eventing systems can use for filtering.

Payload context

The business events framework supports the payload context concept. Payload context provides a way to decorate messages that the framework sends with context about the payload. In some scenarios, additional context might be required when messages are sent to endpoints. Therefore, the framework has hookpoints where the context can be overwritten and the adapters can be customized.

Step 1: Add a custom payload context

A custom payload context must be extended from the **BusinessEventsCommitLogPayloadContext** class.

```
class CustomCommitLogPayloadContext extends BusinessEventsCommitLogPayloadContext
{
    private utcdatetime eventTime;
    public utcdatetime parmEventTime(utcdatetime \_eventTime = eventTime)
    {
        eventTime = \_eventTime;
        return eventTime;
    }
}
```

Step 2: Construct the custom payload context

A Chain of Command (CoC) extension must be written for the **BusinessEventsSender.buildPayloadContext**

method, so that it can construct the new payload context type.

```
[ExtensionOf(classStr(BusinessEventsSender))]
public final class CustomPayloadContextBusinessEventsSender_Extension
{
    protected BusinessEventsCommitLogPayloadContext
    buildPayloadContext(BusinessEventsCommitLogEntry \_commitLogEntry)
    {
        BusinessEventsCommitLogPayloadContext payloadContext = next
        buildPayloadContext(_commitLogEntry);
        CustomCommitLogPayloadContext customPayloadContext = new
        CustomCommitLogPayloadContext();
        customPayloadContext.initFromBusinessEventsCommitLogEntry(_commitLogEntry);
        customPayloadContext.parmEventTime(_commitLogEntry.parmEventTime());
        return customPayloadContext;
    }
}
```

Step 3: Consume the custom payload context from an adapter

Adapters that consume payload context are written in such a way that they expose CoC methods that allow for the consumption of new payload contexts. The following example shows what this step looks like for the Service Bus adapter. This adapter has a generic property bag that Service Bus consumers can filter on.

The **BusinessEventsServiceBusAdapter** class has the CoC method that is named **addProperties**.

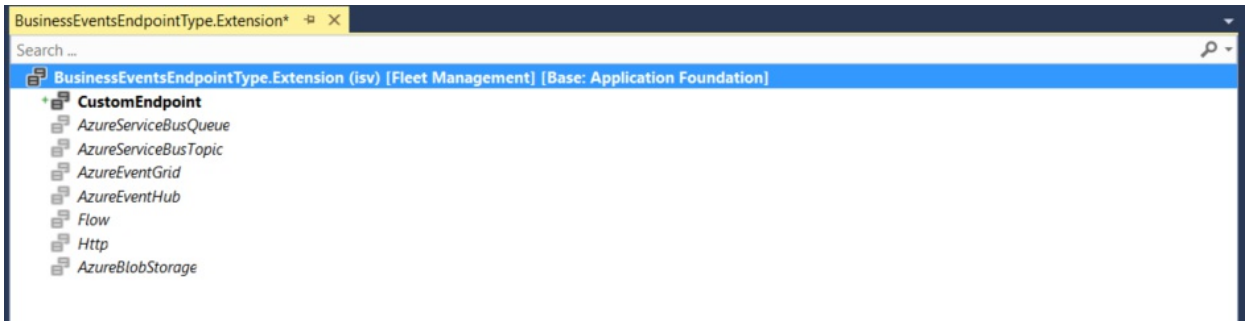
```
[ExtensionOf(classStr(BusinessEventsServiceBusAdapter))]
public final class CustomBusinessEventsServiceBusAdapter_Extension
{
    protected void addProperties(BrokeredMessage \_message,
    BusinessEventsEndpointPayloadContext \_context)
    {
        if (_context is CustomCommitLogPayloadContext)
        {
            CustomCommitLogPayloadContext customPayloadContext = \_context as
            CustomCommitLogPayloadContext;
            var propertyBag = \_message.Properties;
            propertyBag.Add('EventId', customPayloadContext.parmEventId());
            propertyBag.Add('BusinessEventId', customPayloadContext.parmBusinessEventId());
            // Convert the enum to string to be able to serialize the property.
            propertyBag.Add('BusinessEventCategory', enum2Symbol(enumNum(ModuleAxapta),
            customPayloadContext.parmBusinessEventCategory()));
            propertyBag.Add('LegalEntity', customPayloadContext.parmLegalEntity());
            propertyBag.Add('EventTime', customPayloadContext.parmEventTime());
        }
    }
}
```

Adding a custom endpoint type

The business events framework supports the addition of new endpoint types to the out-of-box endpoint types. This section provides an example that shows how to add new custom endpoint types.

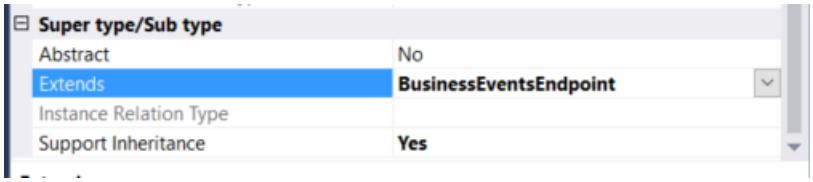
Step 1: Add a new endpoint type

Each endpoint type is represented by the **BusinessEventsEndpointType** enum. The first step in the process of adding a new endpoint is to extend this enum, as shown in the following illustration.

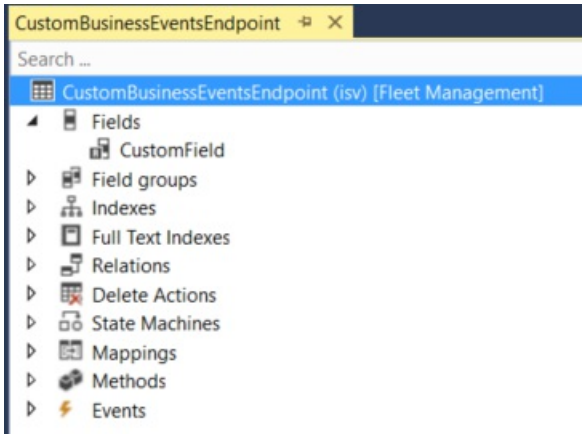


Step 2: Add a new endpoint table to the hierarchy

All endpoint data is stored in a hierarchy table. The root of this table is the BusinessEventsEndpoint table. A new endpoint table must extend this root table by setting the **Support Inheritance** property to **Yes** and the **Extends** property to **"BusinessEventsEndpoint"** (or any other endpoint in the BusinessEventsEndpoint hierarchy).



The new table then holds the definition of the custom fields that are required to initialize and communicate with the endpoint in code. To help avoid conflict, you should qualify field names to the specific endpoint where they belong. For example, two endpoints can have the concept of a **URL** field. To distinguish the fields, names should be specific to the custom endpoint. For example, name the field for the custom endpoint **CustomURL**.



Step 3: Add a new endpoint adapter class that implements the IBusinessEventsEndpoint interface

The new endpoint adapter class must implement the **IBusinessEventsEndpoint** interface. It must also be decorated with the **BusinessEventsEndpointAttribute** attribute.

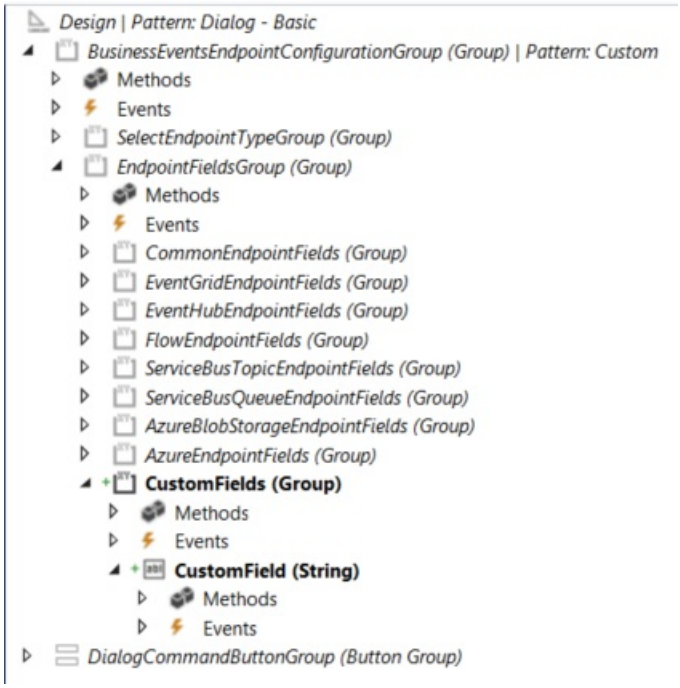
```
[BusinessEventsEndpoint(BusinessEventsEndpointType::CustomEndpoint)]
public class CustomEndpointAdapter implements IBusinessEventsEndpoint
{
```

The **initialize** method should be implemented to check the type of the **BusinessEventsEndpoint** buffer that is passed in, and then, if the buffer is of the correct type, initialize it, as shown in the following example.

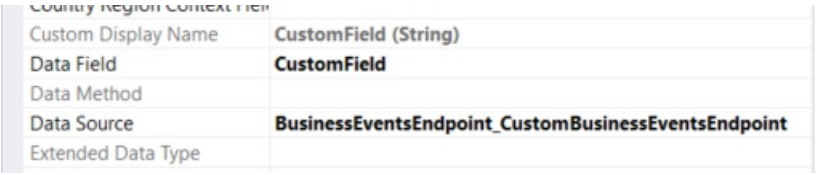
```
if (!(_endpoint is CustomBusinessEventsEndpoint))
{
    BusinessEventsEndpointManager::logUnknownEndpointRecord(tableStr(CustomBusinessEventsEndpoint),
    \_endpoint.RecId);
}
CustomBusinessEventsEndpoint customBusinessEventsEndpoint = \_endpoint as
CustomBusinessEventsEndpoint;
customField = customBusinessEventsEndpoint.CustomField;
if (!customField)
{
    throw warning(strFmt("\@BusinessEvents:MissingAdapterConstructorParameter",
    classStr(CustomEndpointAdapter), varStr(customField)));
}
```

Step 4: Extend the EndpointConfiguration form

Add a new group control under FormDesign/BusinessEventsEndpointConfigurationGroup/EndpointFieldsGroup/ to hold your custom field input.



The custom field input should be bound to the new table and field that you created in the previous step. Create a class extension to extend the **getConcreteType** and **showOtherFields** methods of **BusinessEventsEndpointConfiguration** form, as shown in the following example.



```
[ExtensionOf(formStr(BusinessEventsEndpointConfiguration))]
final public class CustomBusinessEventsEndpointConfiguration_Extension
{
    public TableName getConcreteTableType(BusinessEventsEndpointType \_endpointType)
    {
        TableName tableName = next getConcreteTableType(_endpointType);
        if (_endpointType == BusinessEventsEndpointType::CustomEndpoint)
        {
            tableName = tableStr(CustomBusinessEventsEndpoint);
        }
        return tableName;
    }
    public void showOtherFields()
    {
        next showOtherFields();
        BusinessEventsEndpointType selection =
        any2Enum(EndpointTypeSelection.selection());
        if (selection == BusinessEventsEndpointType::CustomEndpoint)
        {
            this.control(this.controlId(formControlStr(BusinessEventsEndpointConfiguration,
            CustomFields))).visible(true);
        }
    }
}
```

Adding human-readable data fields to the payload

This feature is available in Platform update 30 and later.

The serialization of business events uses FormJsonSerializer to serialize objects in the data contract. FormJsonSerializer can format **UtcDataTime** values in the ISO 8601 date and time format. This format is human-readable when the payload of a business event is viewed. For example, a **UtcDataTime** value can now be formatted as **"2007-12-05T14:30Z"** instead of **"/Date(1196865000000)/"**. In the "/Date(N)" format, N is the number of milliseconds that have passed since January 1, 1970, UTC+0. The ISO format is more often understood by tools that parse JavaScript Object Notation (JSON).

To get the human-readable format, use the extended data type (EDT) that is named **DateTimeIso8601** as the type of the value in the data contract. Alternatively, use an EDT that is derived from the **DateTimeIso8601** EDT.

```
[DataMember("TestIsoEdtUtcDateTime")]
public DateTimeIso8601 testIsoEdtUtcDateTime(DateTimeIso8601 _value = this._testIsoDateTime)
{
    if (!prmIsDefault(_value))
    {
        this._testIsoDateTime = _value;
    }
    return this._testIsoDateTime;
}
```

Troubleshoot business events

2/18/2021 • 4 minutes to read • Edit Online

This topic provides tips for troubleshooting issues that involve business events.

ISSUE	POSSIBLE RESOLUTION
Unable to find navigation to business events in the **System parameters** form	You can access business events by going to **System administration > Set up > Business events**. This change was made when business events was made generally available in Platform update 26.
Error: Unable to construct endpoint. Exception message: Error retrieving secret '[KeyValueSecretName]' from key vault 'https://[KeyVaultName].vault.azure.net/': AADSTS700016: Application with identifier '7e28cb03-dc28-43b5-b129-e13dcfb4b1fb' was not found in the directory 'ee3fe5c6-26af-42b1-9acf-5ee38e6ead6e'.	This can happen if the application has not been installed by the administrator of the tenant or consented to by any user in the tenant. It's likely that you may have sent your authentication request to the wrong tenant.
Error: Trace ID: 19dc9946-45b6-4335-9676-6a133dbf4000 Correlation ID: ecbc8a80-f9d0-41ec-9c8f-d334d050bd64 Timestamp: 2019-02-06 23:27:06Z	This error typically means that the value in the **Azure Active Directory Application ID** field is incorrect. Check the **Azure Active Directory Application ID** value in the customers Azure portal in **Azure Active Directory > App Registration**.
Error: Unable to construct endpoint. Exception message: Error retrieving secret '[KeyValueSecretName]' from key vault 'https://[KeyVaultName].vault.azure.net/': An error occurred while sending the request.	This error is likely due to an incorrect value in the **Key Vault DNS Name** field. To resolve this, go to the customer's Azure portal and open the key vault object. In the **Overview** section, check the **Key Vault DNS Name** value.
Error: Unable to send test event to endpoint. Exception message: 40103: Invalid authorization token signature, Resource:sb://[ServiceBusName].servicebus.windows.net/[QueueName]. TrackingId:cd0eccaa-1717-4f97-b837-4cd7eda99af4_G13, SystemTracker: [ServiceBusName].servicebus.windows.net:[QueueName], Timestamp:2019-02-06T23:36:54	The value in the customer's Key Vault Secret is likely incorrect. Check the **Key Vault Secret** value and make sure that it is correct for the endpoint type.
Error: Unable to construct endpoint. Exception message: Error retrieving secret '[KeyValueSecretName]' from key vault 'https://[KeyVaultName].vault.azure.net/': Access denied	This is likely due to the **Azure Active Directory Application ID** not having the appropriate permissions in the Key Vault. To resolve this, go to the Azure portal and open the **Key Vault** object. Go to **Access Policies** and add the AAD application with Key, Secret, and Certificate Management template.
Error: Unable to send test event to endpoint. Exception message: 40400: Endpoint not found., Resource:sb://[ServiceBusName].servicebus.windows.net/[QueueName].	This issue is likely a result of the queue/topic/hub name being incorrect. Check the **Name** field by going to service bus in the Azure portal and reviewing the **Topic** or **Queue** name. If it is an Event Hub, go to the **Event Hub** object in Azure and validate the **Hub** name.
Error: Unable to send test event to endpoint. Exception message: An error occurred while sending the request.	This is likely due to an incorrect endpoint value specified in the **Endpoint URL** field. Go to the **Event Grid** object in the Azure portal and open the **Event Grid**. In the **Overview** section, this value will be the **Topic Endpoint**.

ISSUE	POSSIBLE RESOLUTION
Business events do not show up in the catalog	The Business event catalog is built during full database sync. As a result, there are some use cases, as noted below, where a manual refresh of the catalog is needed in order to see the new business events. Manual refresh can be invoked from the catalog by going to **Manage > Rebuild business events catalog**. When you are implementing business events in Visual Studio you may not see the newly coded business event in the catalog. When new workflows are configured, such as the workflow elements or steps, might not show up in the business events catalog. In other situations, when you don't see certain business events, doing a manual refresh should resolve the issue.
- 0 is an invalid bundle size - Business events are not getting triggered - Microsoft Flow is not getting triggered by business events - Unable to configure business event because it has reached the limit of 0 configured endpoints	One of the reasons why this issue can occur is if certain parameters are not set as expected in the **BusinessEventsParameters** table. This is due to an update in which some of the business events parameters not being set correctly. In a non-production environment, you must update the parameters in **System administration > Setup** to set retry count = 3; End points allowed per event = 10 and wait time = 1000. After this update, restart the batch service and run IISReset to pick up the latest values. If business events still do not trigger, then the dedicated capacity is not working to process business events. A manual batch job must be scheduled to process business events, which can be enabled from the **Business events parameters** page in **System administration > Set up**.
Platform update 30 compiler warning when creating custom payload context fields by augmenting via Chain of Command (CoC) the addProperties method in the adapter class. **Class 'BusinessEventsServiceBusAdapter' is internal in model 'ApplicationFoundation' and cannot be extended**.	This is a change in the compiler that prevents an internal API from being extended. This is being tracked as a bug to provide alternate ways to add custom properties. For more information, see this Yammer discussion.
Error: Unable to load one or more of the requested types. Retrieve the LoaderExceptions property for more information	This error message on the error tab of active business events can typically be resolved by rebuilding the catalog.
Alert business events don't trigger	One of the reasons why an event is not triggering could be a potential issue with alerts email functionality. Try turning off the send email option in the alert to see if that resolves the issue.
Unable to send test event to endpoint. Exception message: The underlying connection was closed: Could not establish trust relationship for the SSL/TLS secure channel.	Make sure the middleware is using TLS 1.2

Use cases for business events

2/18/2021 • 9 minutes to read • Edit Online

NOTE

Effective November 2020:

- Common Data Service has been renamed to Microsoft Dataverse. For more information, see Power Automate Blog.
- Some terminology in Microsoft Dataverse has been updated. For example, *entity* is now *table* and *field* is now *column*. For more information, see Terminology updates.

This topic will be updated soon to reflect the latest terminology.

The following are potential uses cases for business events. These use cases aren't an exhaustive list of the potential use cases. Some of these use cases may not have been implemented yet either by Microsoft or other organizations. These use cases are meant to provide ideas and help with understanding business events.

BUSINESS PROCESS	USE CASE	VALUE
Procurement	The procurement process frequently relies on manual intervention, so automating this process should increase procurement manager productivity.	You can make the procurement process more efficient by alerting procurement managers when quotation requests are sent, allowing for prompt follow-up and faster engagement. The goal is to have procurement managers follow up within three days and possibly create a Microsoft Power Automate that automates this follow up.
Procurement	Many organizations use manual processes to communicate internally and externally about production orders. Some organizations have complex approval processes for production orders, and need quick and easy ways to review and approve orders.	By creating business events that are triggered when production orders are updated, you can help improve communications between the back office and the production floor. When integration is required with third-party systems for production, the business events can also be used to help simplify the integration process.
Reporting	Managers are not informed about newly created financial reports. As a result, managers might analyze and make decisions based on outdated data.	You can make the reporting process more efficient by alerting managers when financial reports are sent, allowing for prompt follow-up and faster engagement. The goal is to have managers follow up within three days and possibly create a Power Automate that automates this follow-up.

BUSINESS PROCESS	USE CASE	VALUE
Customer master	When a new customer is created, a credit limit check is needed. If something could automatically trigger an API that subscribes to a credit limit, and then check the website and import-specific credit limit check fields, such as limit amount and rating. At the same time, an approval Power Automate needs to start so that the customer account can be used after approval from management.	This check is required by many companies, especially in the retail area. This use case would be beneficial because partners develop customizations for this purpose.
Month end close	The month-end closing schedule is a simple list that does not allow automatic actions. If functionality could be created to inform a group of people about tasks that have been completed and verified as complete, then a different group of people could start working.	Use real-life scenarios to enhance the currently static and difficult to use month-end closing workspace. One such use case is explained in detail in Business events in Financial Period Close.
Month end close	If functionality could be created to trigger a Power Automate when the status of a period is changed – either opened or closed.	Users are not automatically informed when new periods are opened after the month-end close is completed and they are allowed to start recording transactions in the new period.
Vendor master	If you are using the supplier (vendor) collaboration workspace, there is no automated way to inform the supplier that a new record has been created or existing records have been updated. This is an issue with requests for quotation and purchase orders. This means that the supplier would need to review the supplier collaboration workspace in case there are issues.	Using business events, the supplier portal functionality will provide improved productivity and efficiency by removing the need for additional correspondence between the supplier and the application. This is a true collaboration and will lead to supply chain efficiency. Without this functionality, the organization must follow up on all new requests or updates with phone calls or emails to the suppliers. This improves the supplier collaboration workspace.
Vendor master	Many organizations use manual, offline, and paper-based processes to manage vendors. Additionally, in many organizations, there are "gate keepers" that manage the master data. When updates occur to vendor master data, communication throughout the organization is limited or complex.	By integrating with Power Automate and creating business events for actions and events that regularly occur with vendor master data, you can help improve the overall vendor onboarding process. You can also help improve internal communications within your organization and automate business processes with your trade partners.

BUSINESS PROCESS	USE CASE	VALUE
Sales quotation	A quotation is placed for a personalized product. After the quotation is won this needs to become a real product. Requests are sent to a Data team (using PowerApps or Office) to create the item. After the item has been manually created, the item on the line is updated and the quote triggers the creation of a sales order. Currently, when the item is created, the approach is to wait for the data integrator to copy it to Dataverse. Monitors are set to find new entries on Dataverse and compare the unique references to any open numbers. Ideally, an item created business event exists, which is extended so that it has the unique identifier. This event is then subscribed to (in Power Automate or PowerApps) and immediately updates the quote line.	Using business events, the business would be able to update the won quote with the new product when the new product is created. This removes possible delays, manual updates, and errors.
Sales orders	Shipment for sales orders starts in a different system to enable logistics balancing of third-party haulers, production of customs, and delivery documentation. This pushes the data to a major transport company. Upon picking or shipment of a sales order, the line details are the event that triggers the external system to analyze and determine the details of the utilized shipment. This pushing event depends on the ability for a business action to update the application. This could be that the order is picked and then the shipment information pushed to the application, or it is marked as shipped as it is pushed externally.	This allows businesses with third-party transport companies to send shipping information to their vendors. This approach puts the responsibility of dispatch utilization on the external vendors and simplifies the setup.
Sales orders	Picking for sales orders can be performed in different systems, whether it's a separate internal warehousing system or a third-party location that is not part of the application. Upon confirmation or picking of a sales order, the line details are the event that triggers the external system to analyze and determine the picking priority and utilization.	This allows businesses with third-party warehouses to send the picking information to the system. This can also be used if the warehouse has automated picking machines that determine what is required. This approach puts the responsibility of prioritizing picking and utilization on the external system and simplifies the setup in the application.

BUSINESS PROCESS	USE CASE	VALUE
Sales orders	Organizations are looking for ways to improve customer service, and to streamline and automate sales processes. These processes might involve several people, require many manual steps, or involve several third-party solutions. The email notification profile feature in Finance and Operations has limited email formatting capabilities.	By integrating with Power Automate and creating business events for actions that are taken on sales orders, you can help improve the overall sales process, help increase customer satisfaction, and automate collaboration between sales and operations.
Batch processing	Scheduling batch jobs to process polling logic can constrain resources. To realize near real-time processing, it is compelling to schedule the batch to run as fast as it can in Finance and Operations, which typically ends up being every few minutes. These batch jobs are typically data import/export jobs that look for data to be processed. However, if data is not available the batch job processes empty cycles, which can consume system resources.	Using business events, the polling use case can be redesigned to be asynchronous if it is triggered by the business event. Data will be processed only when it is available. The business logic that makes the data available triggers the business event, which can then be used to start the data processing job/logic. This can save thousands of batch executions from running empty cycles and wasting system resources.
Production orders	The production scheduling process often relies on external systems or optimization engines to finalize the schedule. Automation of the process and an ability to integrate with external systems when a production order is scheduled can help increase productivity and decrease integration costs.	You can improve the integration and automation capabilities by creating a business event when a production order is scheduled. The information can be communicated to downstream systems, such as Microsoft Dynamics 365 Field Service for Internet of Things (IoT) data exchange, third-party manufacturing execution systems (MESs), or a scheduling optimization engine.
Production orders	Many organizations use third-party MESs to control and manage their machinery on the production floor. Integration with these systems is often complex. Additionally, communication between the production floor and the back office can be difficult.	By creating business events that are triggered when production orders are updated, you can help improve communications between the back office and the production floor. When integration is required with third-party systems for production, the business events can also be used to help simplify the integration process.

BUSINESS PROCESS	USE CASE	VALUE
Case management	Case management is a platform feature that lets you track and manage various requests and issues that are internally or externally reported or requested. Typically, each type of case has a different process, and various contributors to the case might be involved throughout the case's lifecycle. The processes can be manual, and communication can often be delayed. Sometimes, contributors to the cases or stakeholders in them might not be users of the system.	By using Power Automate when cases are updated, you can streamline and automate the business processes that are related to various case types. You can also automate communication and implement approval processes when necessary, depending on your organizational requirements.
Transportation management	Many organizations have separate and disconnected systems for managing transportation. Additionally, the staff that is responsible for arranging transportation is typically not the same staff that creates and confirms orders, or the same staff that carries out the work to ship or receive orders. This situation can lead to a breakdown or lack of communication, and can require manual processes to notify various departments when an order is ready for the next step in the process. In many cases, third-party shipping software is used, and data is entered into many systems or tracked in paper logs.	By using business events together with Power Automate, you can streamline the overall transportation management process and help improve communications between departments.

Business events and Microsoft Power Automate

2/18/2021 • 3 minutes to read • Edit Online

This topic provides steps detailing how to configure and consume a business event from a Power Automate endpoint.

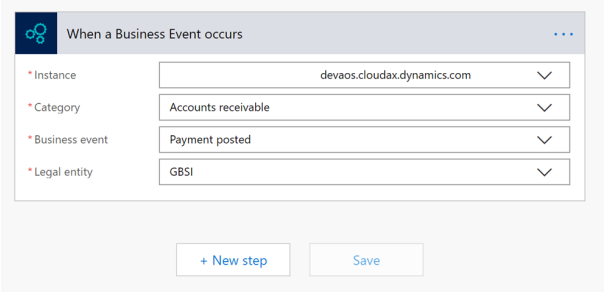
This topic shows how to perform the following tasks:

- Create a new flow in Power Automate.
- Trigger a business event.

Create a new flow in Power Automate

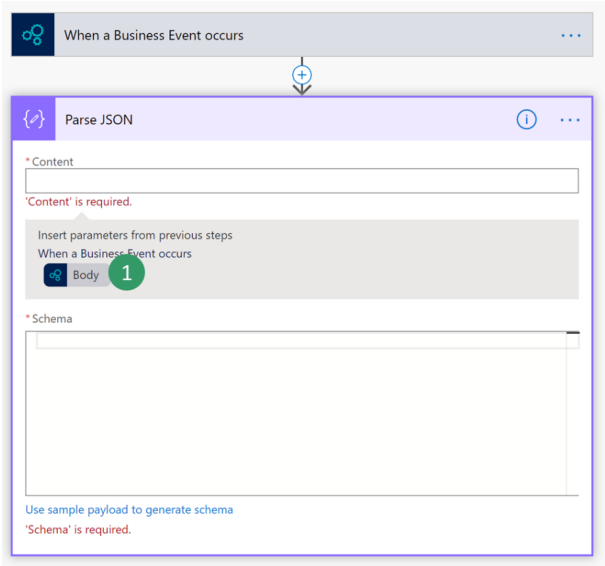
1. Sign in to Power Automate portal.
2. Select an existing environment where you have the permissions needed to create a Power Automate resource. The default environment is open to all companies.
3. Select **New > Create from blank**.
4. Search for **Dynamics 365 for Finance and Operations** and select the connector.
5. You will notice a trigger named **When a Business Event occurs**. Select this trigger.
6. Select your environment instance, category, event name, and legal entity.

> **TIP**
> Take advantage of the auto-complete that Power Automate provides by entering only part of the environment instance URL or part of the event name.

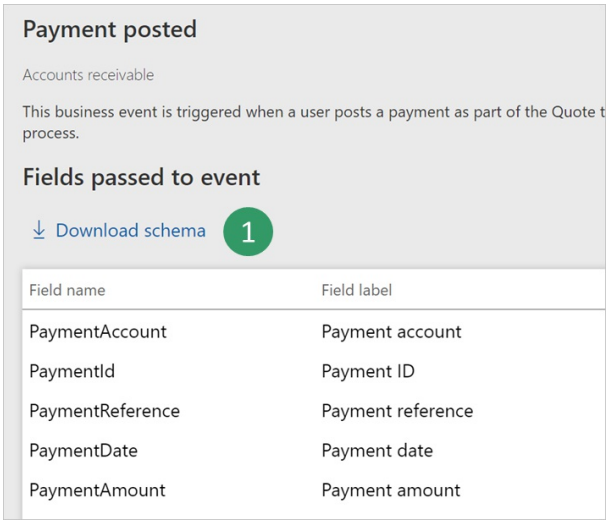


7. Select the **New Step** button to add a new action.
8. Search for the **Parse JSON** data operation. This step is needed to parse the message with the schema of the data contract.

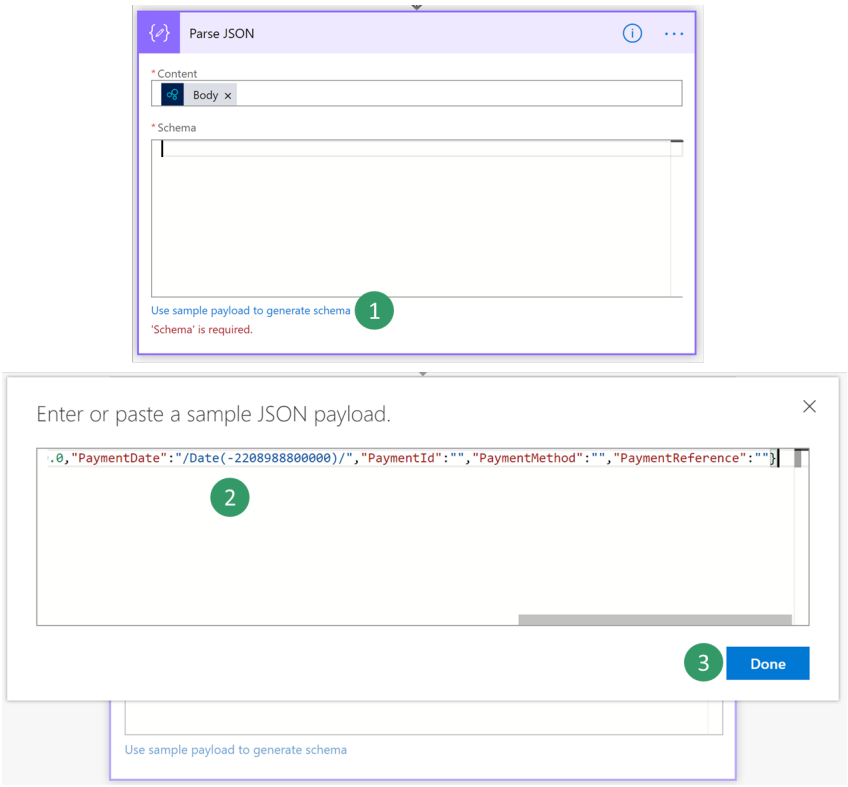
9. Select the content field of **Parse Json** action, then the **Body** output from the previous step should appear as an option. Select **Body**.



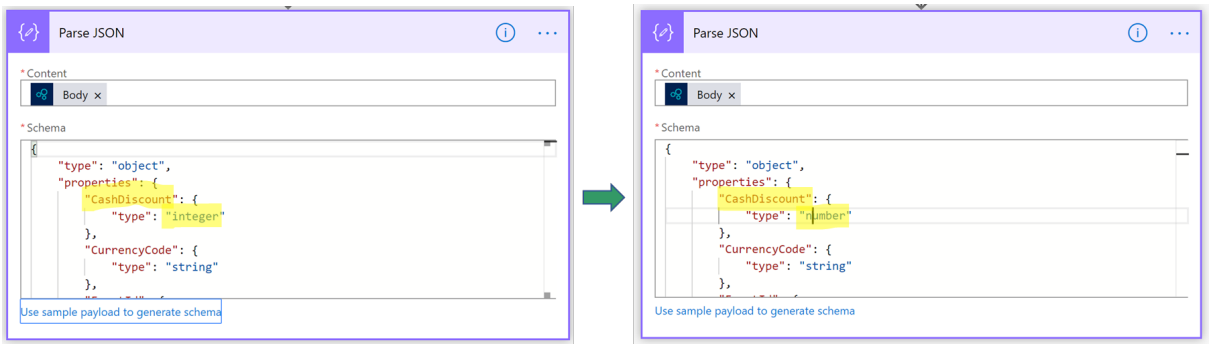
10. Enter the schema of the contract. Because the app provides only a sample payload you can use the Power Automate capability to generate a schema from a payload. Select an event in the catalog (for example, Customer Payment) and select the **Download schema** link. This will download a text file. Open the text file and copy the content.



11. Go Back to Power Automate and select the **Use sample payload to generate schema** link. Paste your text file content and select **Done**.

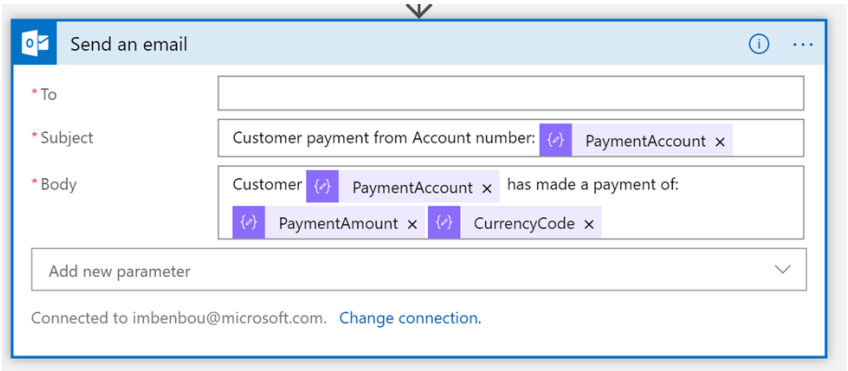


12. Depending on the quality of your sample payload, your generator will not be able to distinguish between an integer and a real number. This is true if the real number is provided as a whole number in the sample payload. Review your generated schema and check if you need to change an "integer" into "number". (In JSON, a "number" data type means real number).



13. Choose another final action to consume the business event content. For instance, you can send an email (or post a text message to Teams) to notify the customer about payment details. Search for the **Send email** action, then sign in to your Microsoft 365 account.

14. Fill in the message with the required fields.

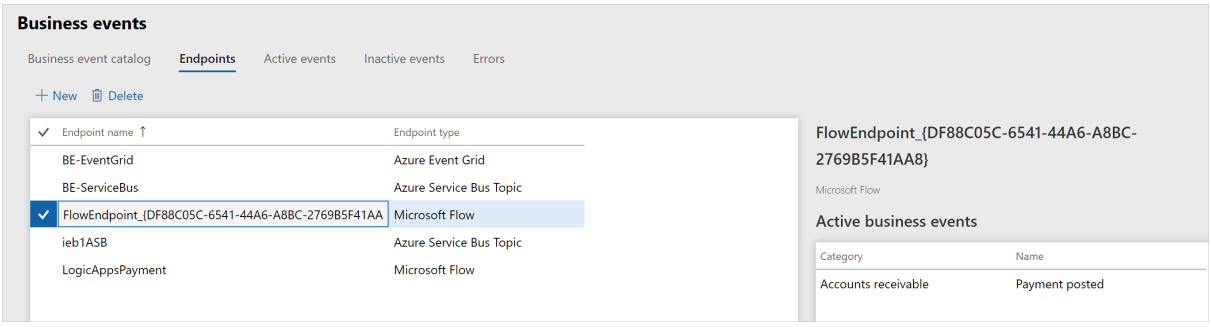


15. Save the flow.

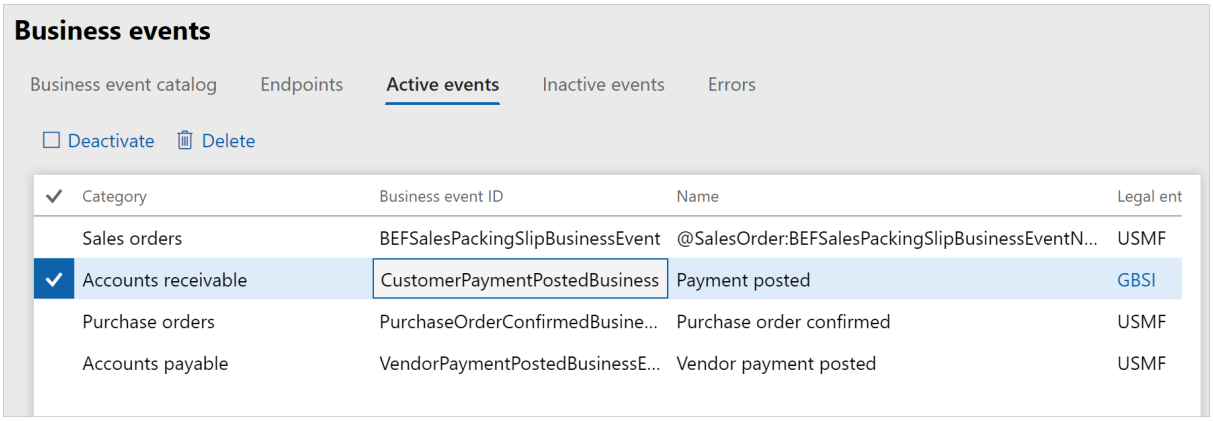
Trigger a Business Event

Power Automate can configure the application automatically for you. After you save your flow, it creates an endpoint, then it activates the business event for you. There is no remaining configuration step apart from verifying that the endpoint has been correctly configured before triggering an event.

1. Sign in to the client.
2. Go to **System Administration > Setup > Business Events**.
3. Select **Endpoints**.
4. Verify that a new endpoint has been created with a GUID appended in the name.



5. If you check the **Active events** tab you can also verify that "**Payment Posted**" is activated for legal entity GBSI.



6. The final step is to trigger the business event of a posted customer payment and check whether the flow runs and you receive an email with customer payment details.

Troubleshooting a flow

Here are some troubleshooting suggestions:

- Power Automate provides a full history of runs to help determine what might be wrong with a failing flow.
- When reviewing a failed run, carefully review the inputs and outputs of trigger and action blocks.
- After changes have been made to the flow, go to the latest run or a particular run, and **Resubmit** the inputs to run the flow again.

> **NOTE**
>
> Can you tell us about your documentation language preferences? Take a short survey.
>
> The survey will take about seven minutes. No personal data is collected (privacy statement).

Business events and Azure Event Grid

2/18/2021 • 6 minutes to read • Edit Online

This topic explains how to configure a Microsoft Azure Event Grid endpoint, and how to consume a business event from Event Grid.

Scenario overview

Security best practices recommend that you store connection strings outside applications, in an Azure Key Vault drive, and that you give applications the correct access to the key vault keys, secrets, or certificates.

Here are two of the many benefits of this approach:

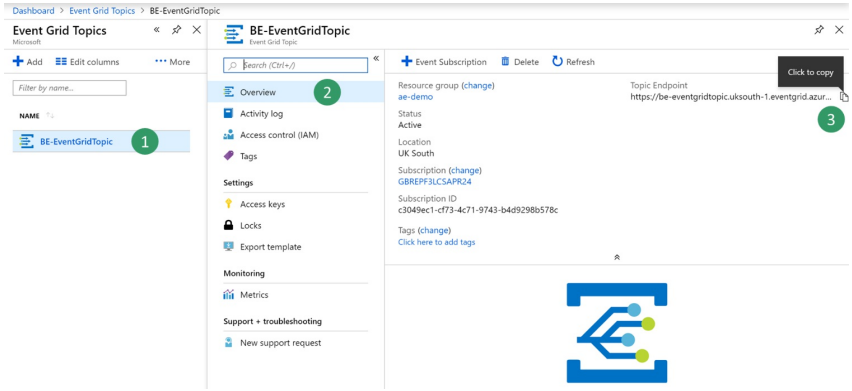
- Someone who gets access to the application database won't be able to get the third-party connection string.
- Maintenance is easier, especially when multiple applications access the same resources, because you must update connection strings in only one place.

Here is an overview of the procedures that you must complete:

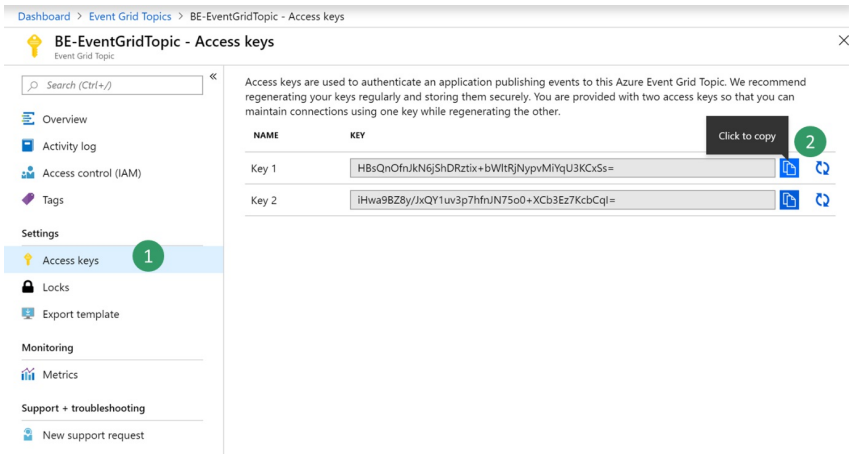
1. Create a new event grid topic.
2. Create a new key vault to store the key for the event grid topic.
3. Register an Azure app that has permission to access the key vault.
4. Configure the parameters of the endpoint.
5. Consume the business event.

Procedure 1: Create a new event grid topic

1. Sign in to the Azure portal.
2. Select **All services** > **Integration** > **Event Grid Topics**.
3. Select **Add** to create a new event grid topic. Set the parameters, and then select **Create**. You can create a new resource group as a container for your lab, or you can use an existing resource group.
4. After deployment is completed, select the new event grid. On the property blade, select **Overview**, and make a note of the **Topic Endpoint** value. You will need this value later.



5. Back on the property blade, select **Access keys**, and copy the **Key 1** value. You will need this value when you configure the key vault in the next procedure.

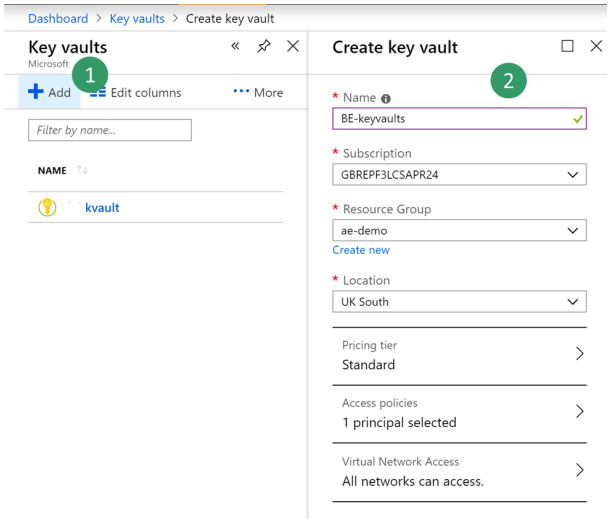


Procedure 2: Create a key vault

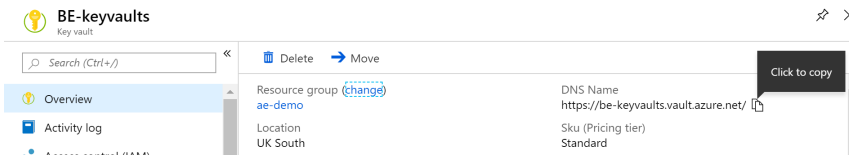
In this procedure, you will create a key vault to store the key that you copied in the previous procedure. A key vault is a secure drive that is used to store keys, secrets, and certificates. Instead of storing the connection string, a more typical and more secure approach is to store it in a key vault. You can then register a new application with Azure Active Directory (Azure AD) and grant it the right to retrieve the secret from the key vault.

1. In the Azure portal, select **All services > Security > Key vaults**.

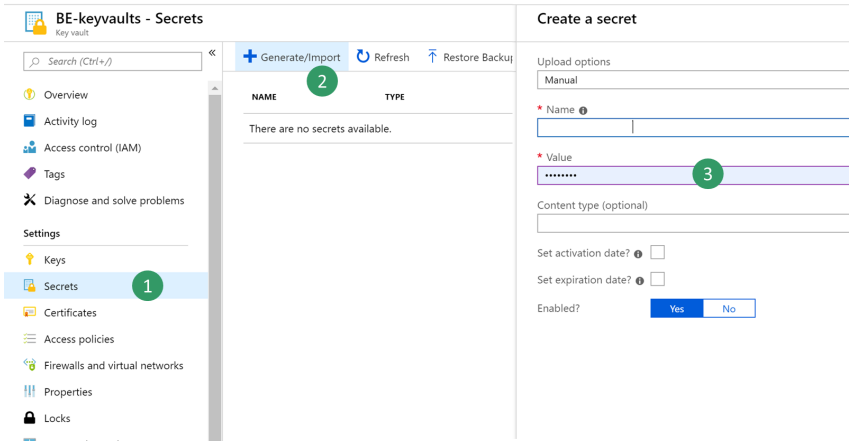
2. Create a new key vault in your resource group and set the default parameters.



3. Select **Overview**, then copy and save the **DNS Name** value for the key vault. You will use this value later.



4. Select **BE-key vault > Secrets > Generate/Import**. Enter a name for your secret, and paste the event grid connection string that you saved earlier.

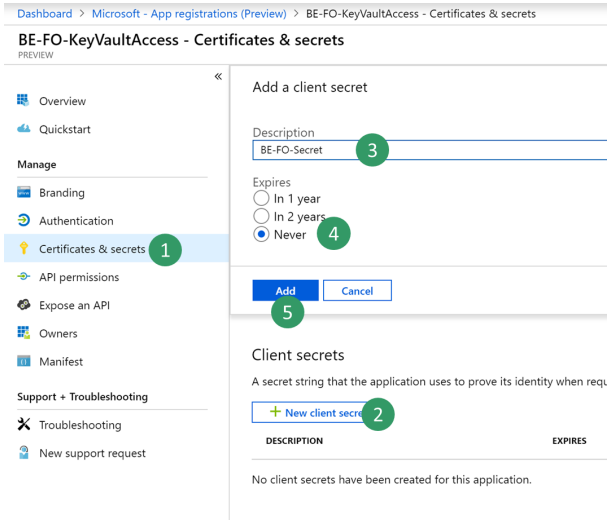


5. Select **Create**.

Procedure 3: Register a new application

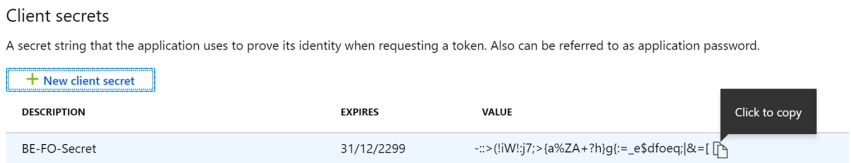
In this procedure, you will register a new application with Azure AD, and give it read and retrieve access to key vault secrets. The application will then use this application to retrieve event grid secrets.

1. In the Azure portal, select **All services > Security > Azure Active Directory**.
2. Select **App registrations (preview) > New registration**, and then enter a name for your application.
3. Select **Register**.
4. Select your new application, and then select **Certificates & secrets > New client secret**. Enter a name for your secret, and set the secret so that it never expires. Then select **Add**.

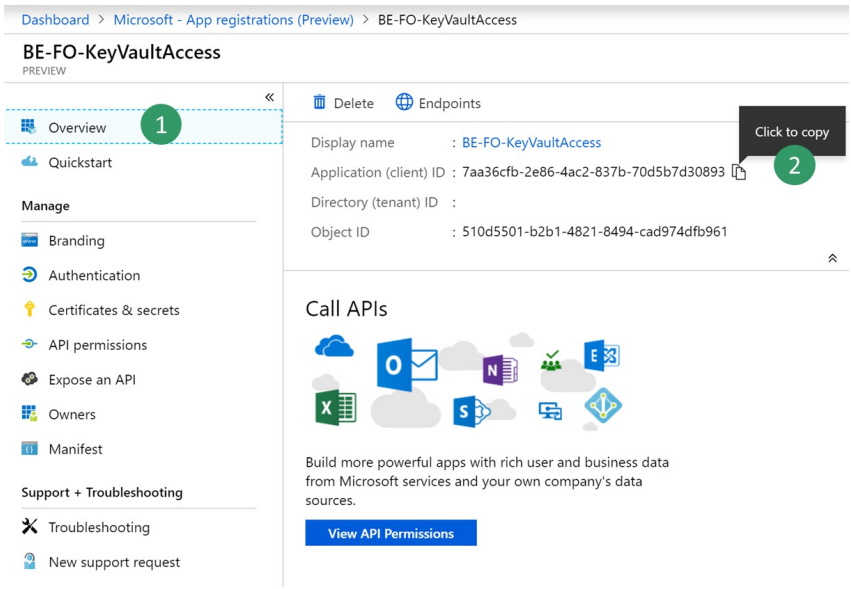


5. Copy and save your new secret. You will use it later.

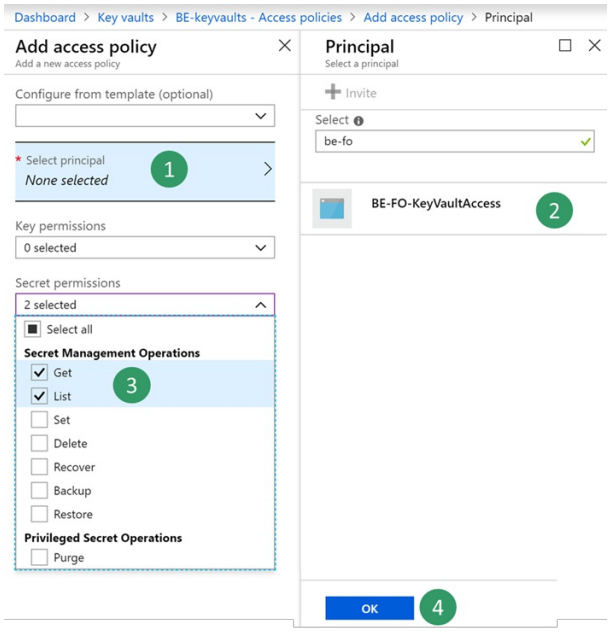
> **IMPORTANT**
>
> Secrets are visible only one time. If you forget to copy the secret, you will have to delete it and create a new secret.



6. Select **Overview**, and copy and save the application ID. You will use this value later.



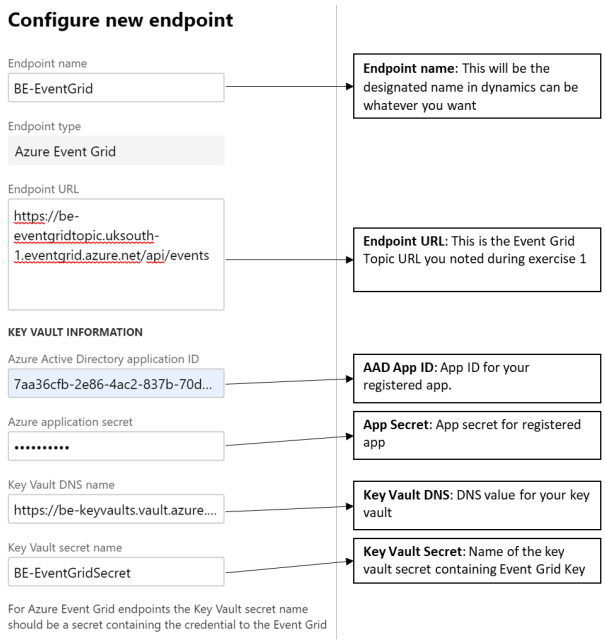
7. Select **All services** > **Security** > **Key vaults**.
8. Select the key vault that you created earlier, and then select **Access policies** > **Add new**.
9. On the **Principal** blade, select your new registered application. Select the check boxes for the **Get** and **List** secret permissions to retrieve key vault secrets.



10. Save your new access policy.

Procedure 4: Configure a Business Events endpoint

1. Sign in to the application and go to **System administration** > **Setup** > **Business events**.
2. Select **Endpoints**.
3. Select **New**.
4. Select **Azure Event Grid**.
5. Select **Next**.
6. Set the required parameter values.

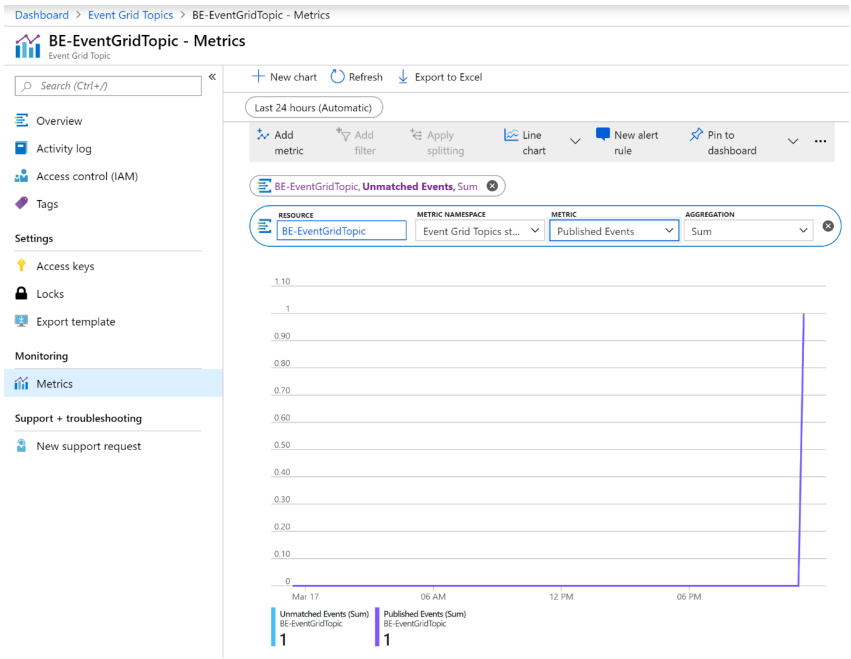


7. Select **OK**.

Procedure 5: Consume a business event

The business scenario involves sending an email message whenever a free text invoice is posted for the USMF company. The message must contain details such as the customer account number, the customer name, and the total amount of the invoice.

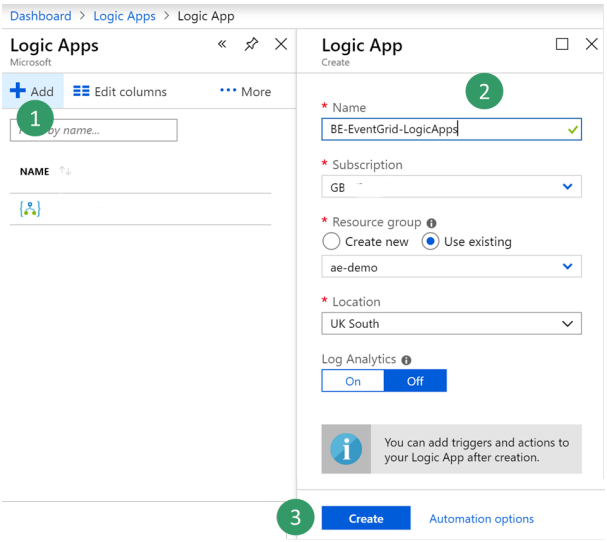
1. Select the business event catalog and look for **free text invoice posted** business event.
2. Then activate the business event for USMF company. Once activated, a test message is sent to validate the configuration and cache the connection.
3. To verify that the test message has been received, in the Azure portal, select your event grid topic, and then select **Metrics**. Verify that both the **Published Events** metric and the **Unmatched Events** metric show a value of at least **1**. If they don't, wait for the batch job to pick up your message.



When both metrics have a value of at least **1**, you will create a new logic app to subscribe to your event grid topic.

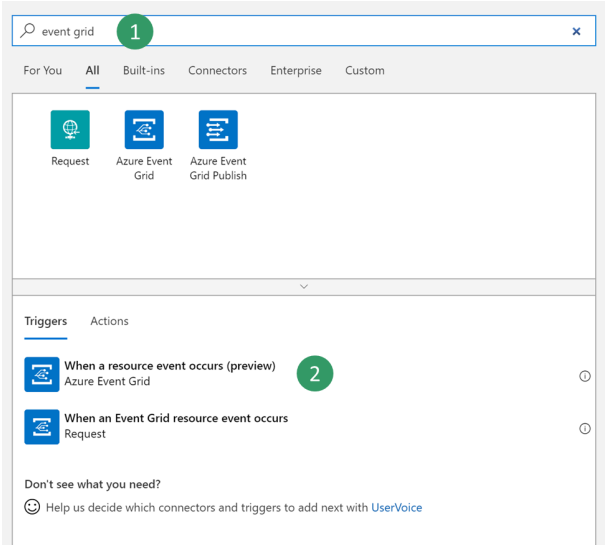
4. Select **All services** > **Integration** > **Logic Apps**.

5. Create a new logic app in your resource group.

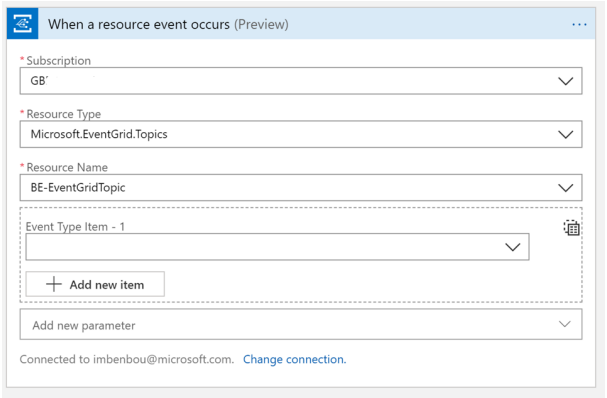


6. After your logic app resource has been created, select the option to create a blank logic app.

7. Search for **Event Grid**, and select the **When a resource event occurs (preview)** trigger.



8. Select your subscription, select **Microsoft.EventGrid.Topics** as the resource type, and select the name of the event grid topic that you created in procedure 1.

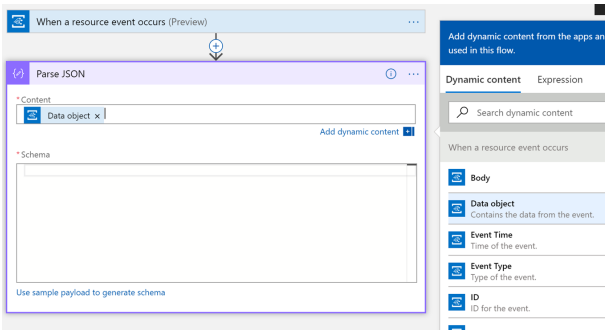


9. Select **New Step** to add a new action.

10. Search for the **Parse Json** data operation. This step is required so that the message can be parsed by using the provided schema for the data contract.

11. Click in the **Content** field of the **Parse Json** action. The pane that appears gives you the option form the previous trigger. You must select the **Data object** field of the event grid message that contains the

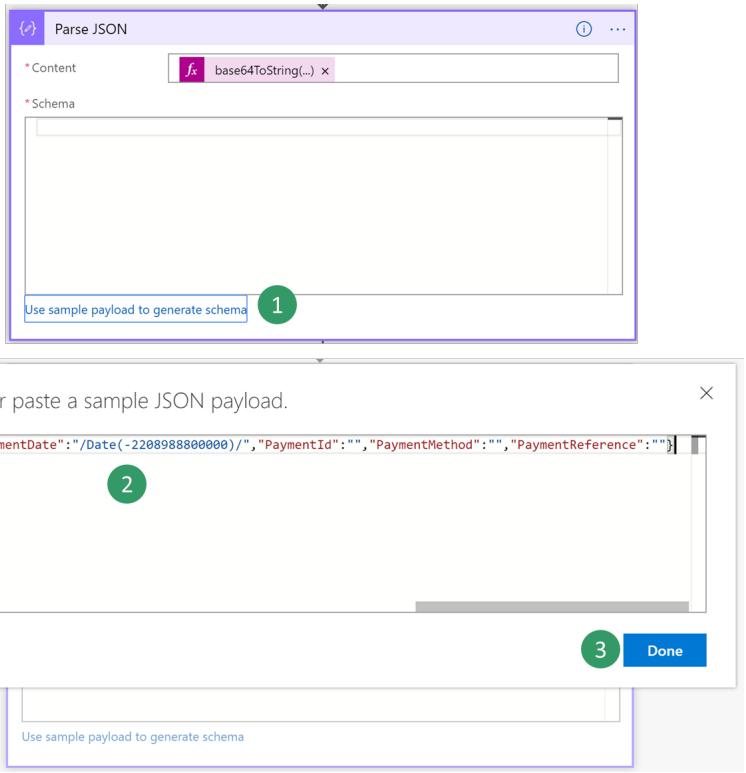
payload that is transmitted by Finance and Operations.



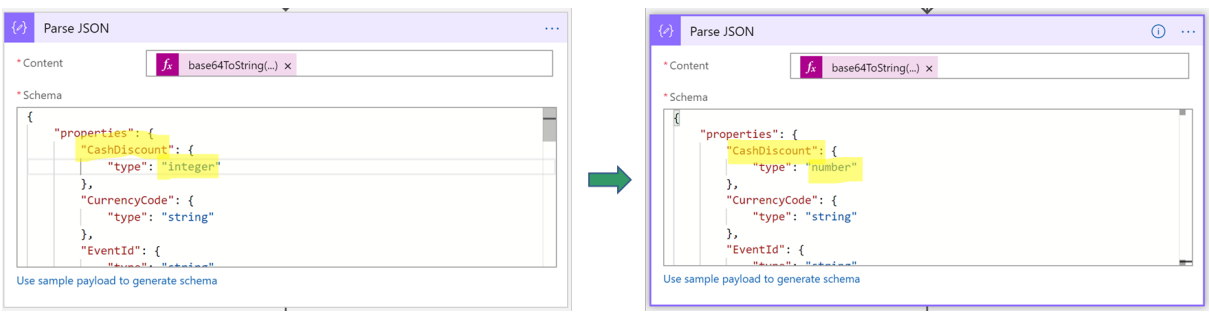
Next, you must enter the provided schema for the contract. This is only a sample payload. However, you can use a capability of Azure Logic Apps to generate a schema from a payload.

12. Select your event in the business event catalog, and then select the **Download schema** link. A text file is downloaded. Open the text file, and copy the contents.

13. Go back to Logic Apps, and select the **Use sample payload to generate schema** link. Paste the contents of the text file, and then select **Done**.



14. Depending on the quality of your sample payload, your generator won't be able to distinguish between an integer and a real value, especially if the real value is provided as a whole number in the sample payload. Review the schema that is generated, and determine whether you must change a field of the **integer** data type to the **number** data type. (In JavaScript Object Notation [JSON], the **number** data type represents real values.)



Next, you will select a final action, such as sending a notification email that includes customer payment

details.

15. Search for the **send email** action, and then sign in to your Microsoft 365 account.
16. Fill in the message with the required fields.
17. Save your logic app.
18. Trigger the business event by posting a customer payment. Then verify that the logic app runs, and that you receive an email that includes customer payment details.

Business events and Azure Service Bus

2/18/2021 • 8 minutes to read • Edit Online

This topic explains how to configure a Microsoft Azure Service Bus endpoint and how to consume a business event from Service Bus.

Scenario overview

Security best practices recommend that you store connection strings outside applications, in an Azure Key Vault drive, and that you give applications the correct access to the key vault keys, secrets, or certificates.

Here are two of the many benefits of this approach:

- Someone who gets access to the application database won't be able to get the third-party connection string.
- Maintenance is easier, especially when multiple applications access the same resources, because you must update connection strings in only one place.

Here is an overview of the procedures that you must complete:

1. Create a new Service Bus namespace.
2. Create a new Service Bus topic and subscription.
3. Create a new key vault to store the Service Bus key.
4. Register an Azure app that has permission to access the key vault.
5. Configure a Business Events endpoint.
6. Consume the business event.

Create a new Service Bus namespace

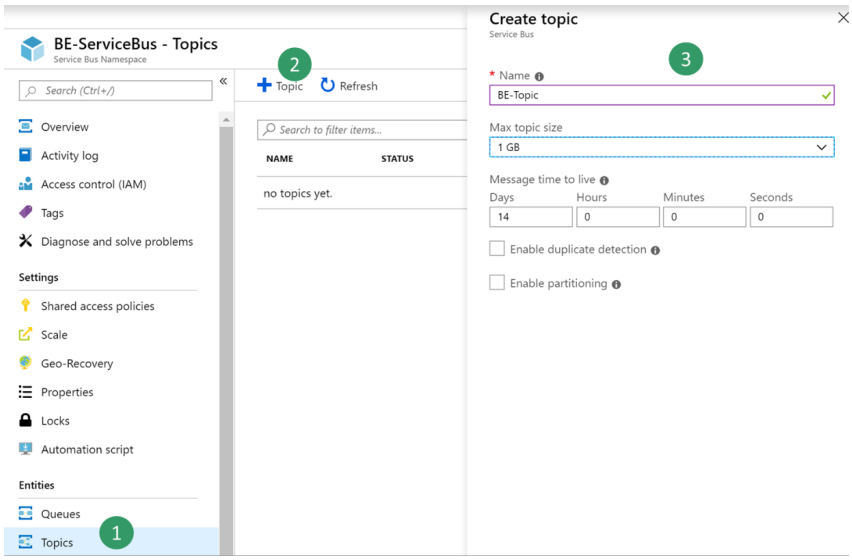
1. Sign in to the Azure portal.
2. Select **All services** > **Integration** > **Service Bus**.
3. Select **Add** to create a new Service Bus namespace, and set the parameters. Select the **Standard** pricing tier. You can create a new resource group as a container for your lab, or you can use an existing resource group.

   > **NOTE**
   >
   > If you select the **Basic** pricing tier, you can create only queues. To create topics, you must select the **Standard** pricing tier.

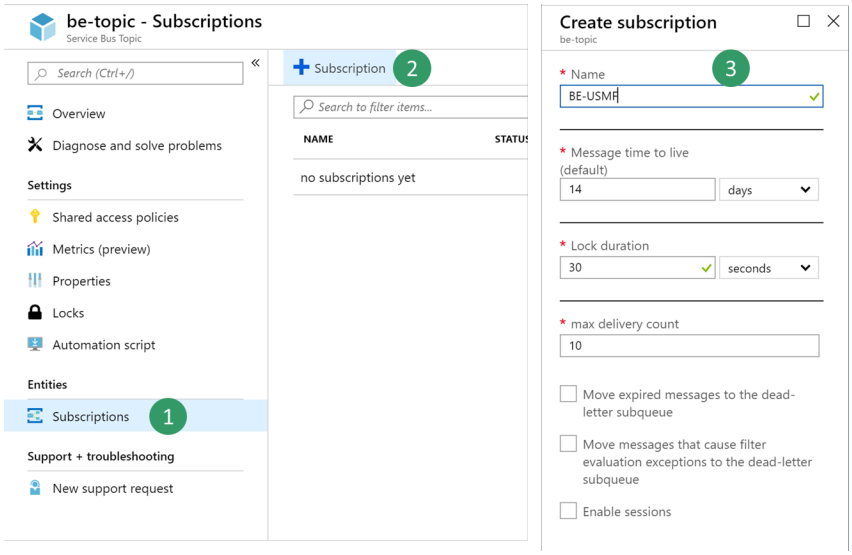
4. When you've finished setting all the parameters, select **Create**.

Create a new Service Bus topic and subscription

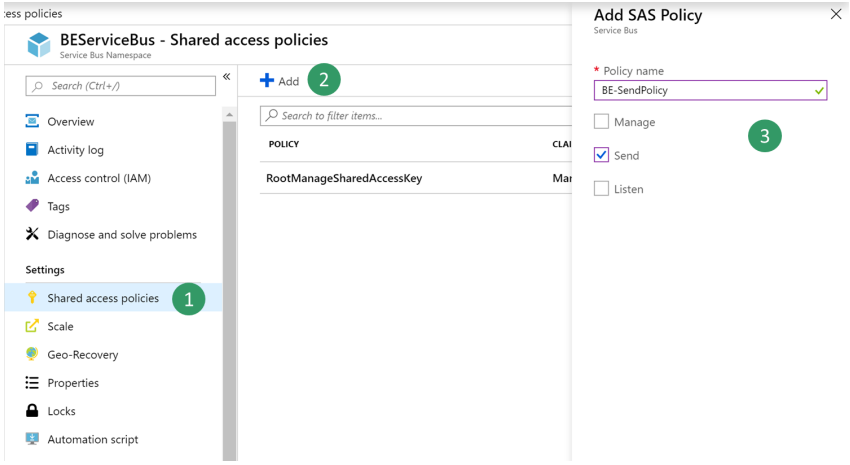
1. In the Azure portal, select the Service Bus that you just created, and then create a new topic.



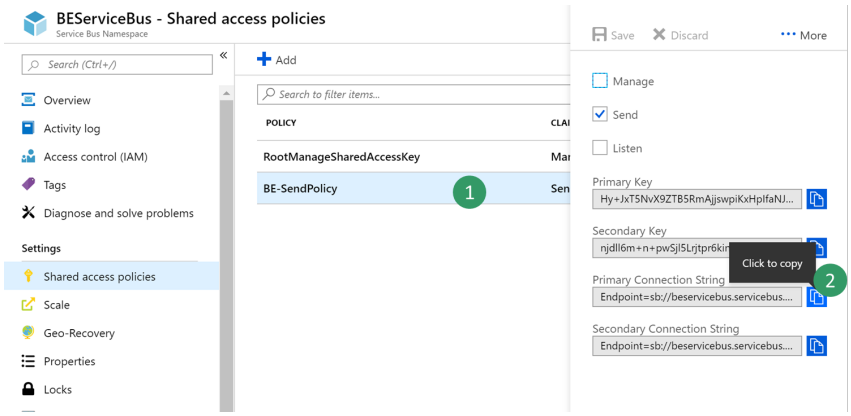
2. Select the new topic, and then create a new subscription that is named **BE-USMF**.



3. Go back to the blade for your Service Bus, and create a new shared access policy to send events. Only the **Send** policy is required to send events to the Service Bus topic.



4. Select the new **Send** policy, and then copy and save the **Primary Connection String** value. You will use this value later.



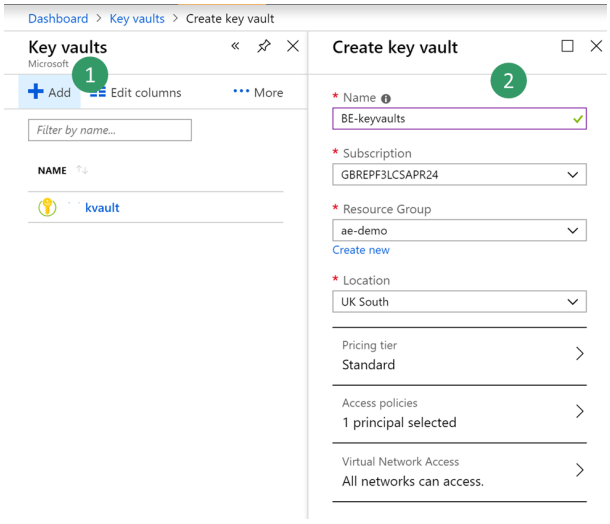
NOTE

The shared access policy must be at the name space level and not at the topic level. If the shared access policy from the topic level is used, the trailing string with semi colon EntityPath= must not be included when configuring the endpoint for business events.

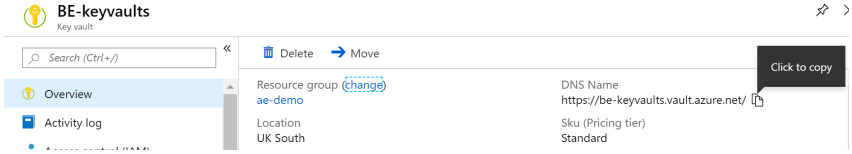
Create a new key vault

In this procedure, you will create a key vault to store the key that you copied in the previous procedure. A key vault is a secure drive that is used to store keys, secrets, and certificates. Instead of storing the connection string, a more typical and more secure approach is to store it in a key vault. You can then register a new application with Azure Active Directory (Azure AD) and grant it the right to retrieve the secret from the key vault.

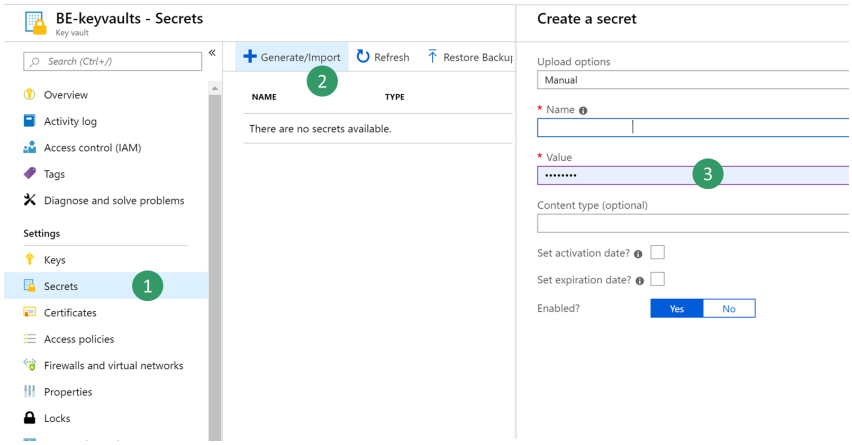
1. In the Azure portal, select **All services** > **Security** > **Key vaults**.
2. Create a new key vault in your resource group and set the default parameters.



3. Select **Overview**, then copy and save the **DNS Name** value for the key vault. You will use this value later.



4. Select **BE-key vault** > **Secrets** > **Generate/Import**. Enter a name for your secret, and paste the Service Bus connection string that you saved earlier.

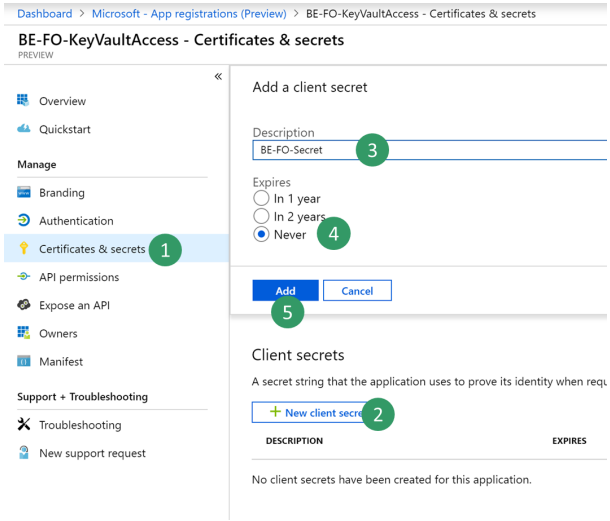


5. Select **Create**.

Register a new application

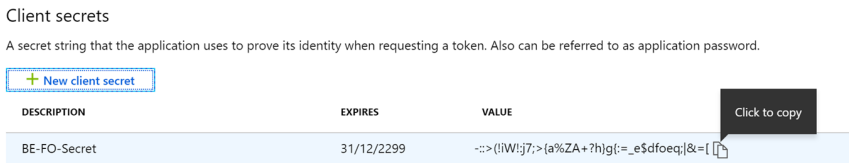
In this procedure, you will register a new application with Azure AD, and give it read and retrieve access to key vault secrets. Finance and Operations will then use this application to retrieve Service Bus secrets.

1. In the Azure portal, select **All services > Security > Azure Active Directory**.
2. Select **App registrations (preview) > New registration**, and enter a name for your application.
3. Select **Register**.
4. Select the new application, and then select **Certificates & secrets > New client secret**. Enter a name for your secret, and set the secret so that it never expires. Then select **Add**.

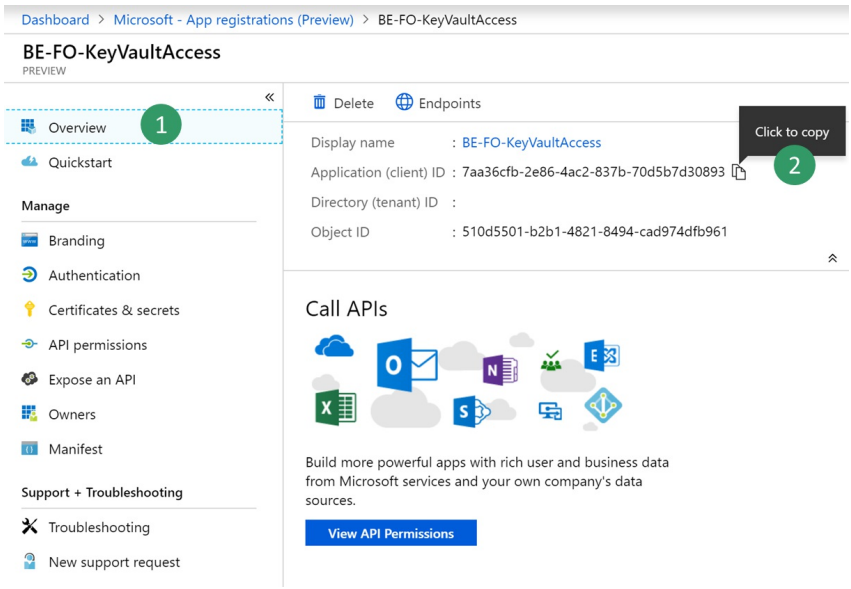


5. Copy and save your new secret. You will use it later.

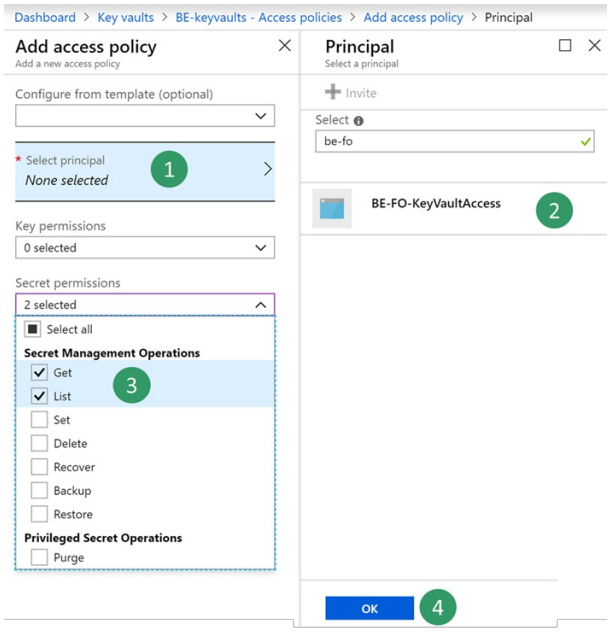
> **IMPORTANT**
>
> Secrets are visible only one time. If you forget to copy the secret, you will have to delete it and create a new secret.



6. Select **Overview**, and copy and save the application ID. You will use this value later.



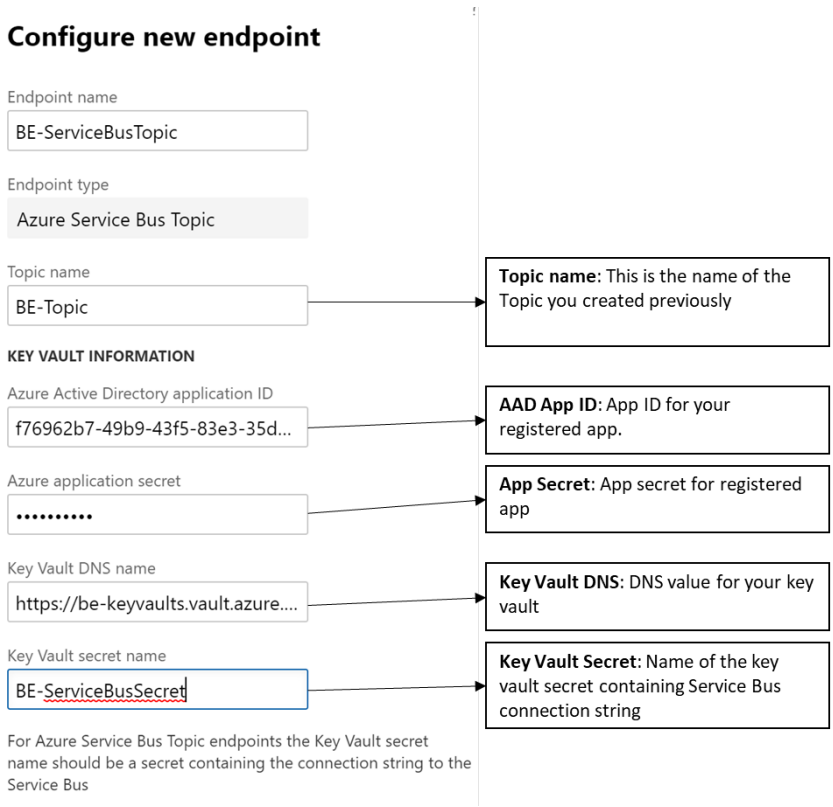
7. Select **All services** > **Security** > **Key vaults**.
8. Select the key vault that you created earlier, and then select **Access policies** > **Add new**.
9. On the **Principal** blade, select your new registered application. Select the check boxes for the **Get** and **List** secret permissions to retrieve key vault secrets.



10. Save your new access policy.

Configure a Business Events endpoint

1. Sign in to the application and go to **System administration** > **Setup** > **Business events**.
2. Select **Endpoints**.
3. Select **New**.
4. Select **Azure Service Bus Topic**.
5. Select **Next**.
6. Set the required parameter values.

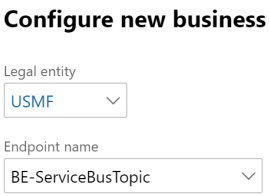


7. Select **OK**.

Consume a business event

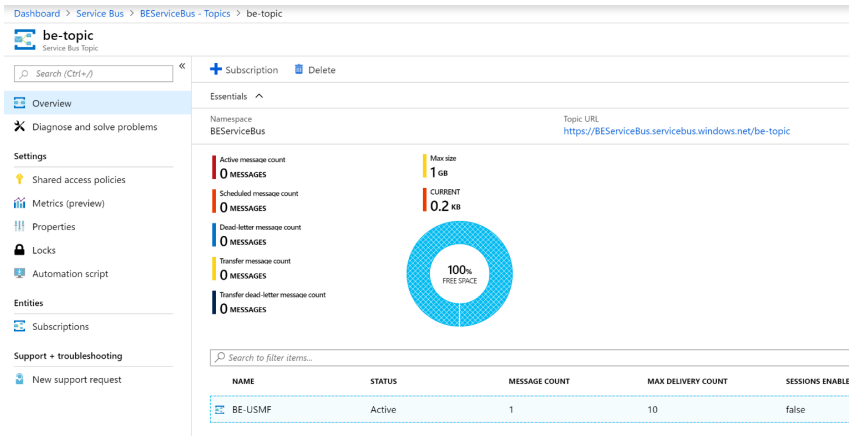
The business scenario involves sending an email or a message to a team channel whenever a customer payment is posted for the USMF company. The message must contain details such as the customer account number, the customer name, and the amount of the payment.

1. Select the business event catalog and look for **customer payment posted** business event
2. Activate the business event for USMF company.

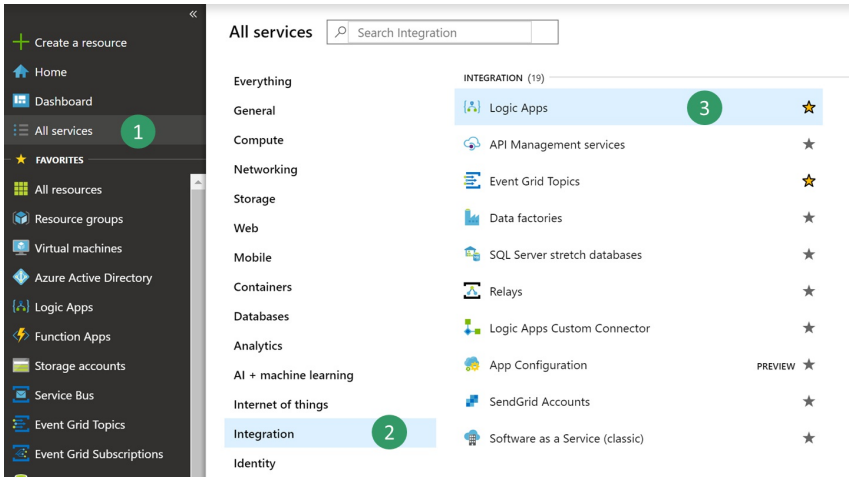


After you activate a business event that uses the new Service Bus endpoint, the application sends a test message to verify that the configuration is accurate and to cache the connection.

3. To verify that the test message has been received, in the Azure portal, select your **BE-Topic** Service Bus topic, and then go into the **BE-USMF** Service Bus subscription that you created earlier. Verify that the message count for the subscription shows a value of at least **1**. If it doesn't, wait for the batch job to pick up your message.



4. Select **All services** > **Integration** > **Logic Apps**.



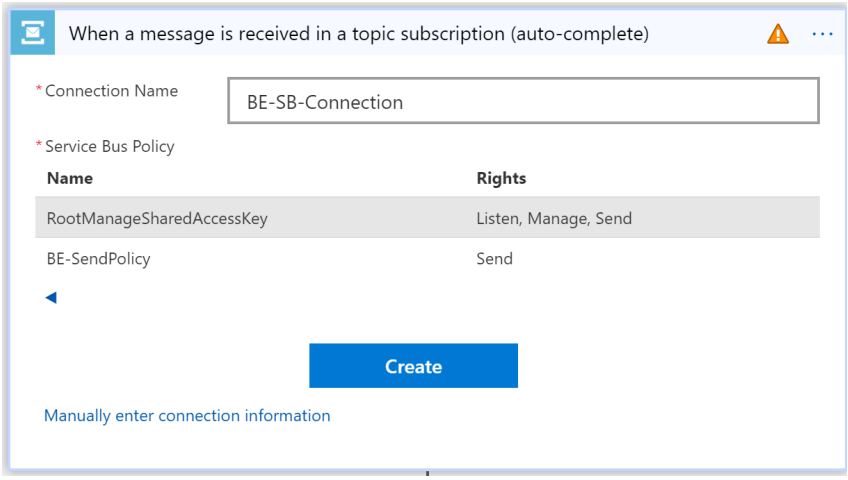
5. Create a new logic app in your resource group.
6. After your Logic Apps resource has been created, select the option to create a blank logic app.
7. Search for **Service Bus**, and select it.
8. Select the trigger that is named **When a message is received in a topic subscription (auto-complete)**.

> **NOTE**
>
> Auto-complete means that the message is deleted from the subscription queue after it's retrieved. Peek-lock authorizes concurrent consumers. It requires a call to the **complete** command of the Service Bus application programming interface (API) in order to delete the message.

Because Logic Apps is accessing your Service Bus for the first time, it asks for a new connection. This connection will cache connection details as a Service Bus namespace URL and credential.

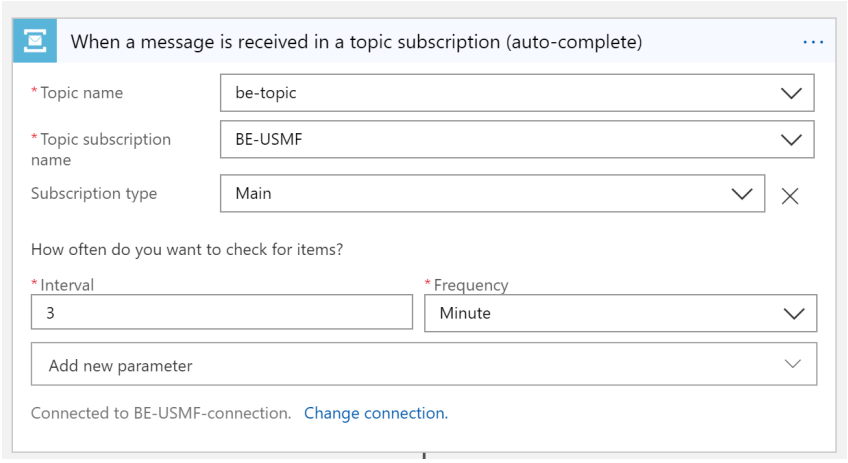
9. Select your Service Bus namespace, and enter a name for the new connection.
10. Select the **RootManageSharedAccessKey** policy for your logic app, and then select **Create**.

> **NOTE**
>
> The **Send** policy can't be used here, because you want to *retrieve* messages, not send them. As a best practice, you could have created a new policy for this use case and given it **Listen** permission only.



11. Select your trigger parameters. Be sure to use the correct names for the topic and subscription that you created.

    This API polls Service Bus for new messages at a configurable recurrence (by default, every three minutes). If the volume of messages is low, the API will have a cost impact for unnecessary triggers, because Logic Apps is priced per trigger call and action run. However, you can implement a push architecture that uses Azure Event Grid in the middle. Service Bus can then push events to Event Grid when there are messages in a queue or a subscription. For more information, see Azure Service Bus to Event Grid integration overview.

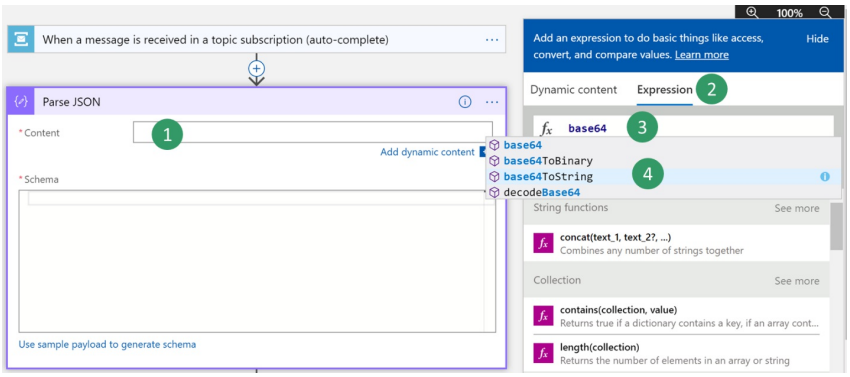


12. Select **New step** to add a new action.

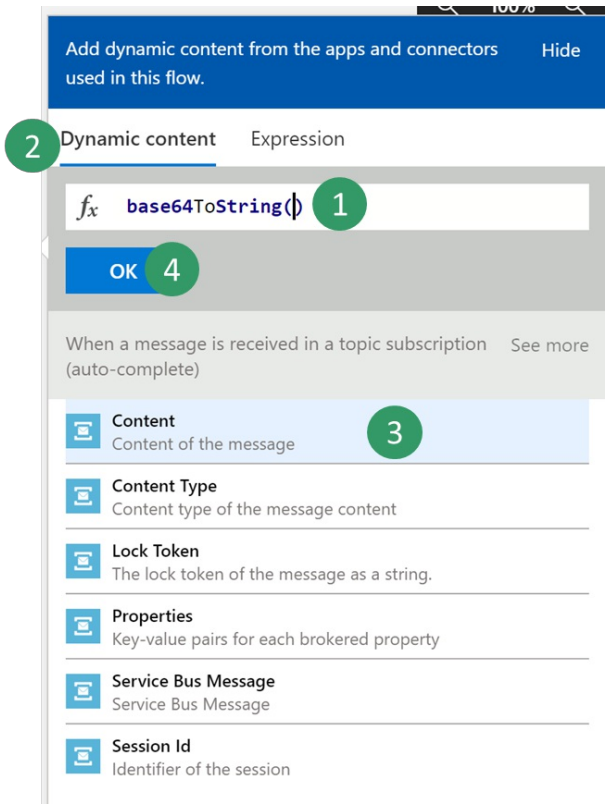
13. Search for the **Parse Json** data operation. This step is required so that the message can be parsed by using the schema of the data contract.

    The body content that is received from the Service Bus is encoded into base64 format. Therefore, you must transform it to string format before the JavaScript Object Notation (JSON) payload can be parsed.

14. Click in the **Content** field, and then, in the pane that appears, on the **Expression** tab, enter the following expression: **Base64ToString()**



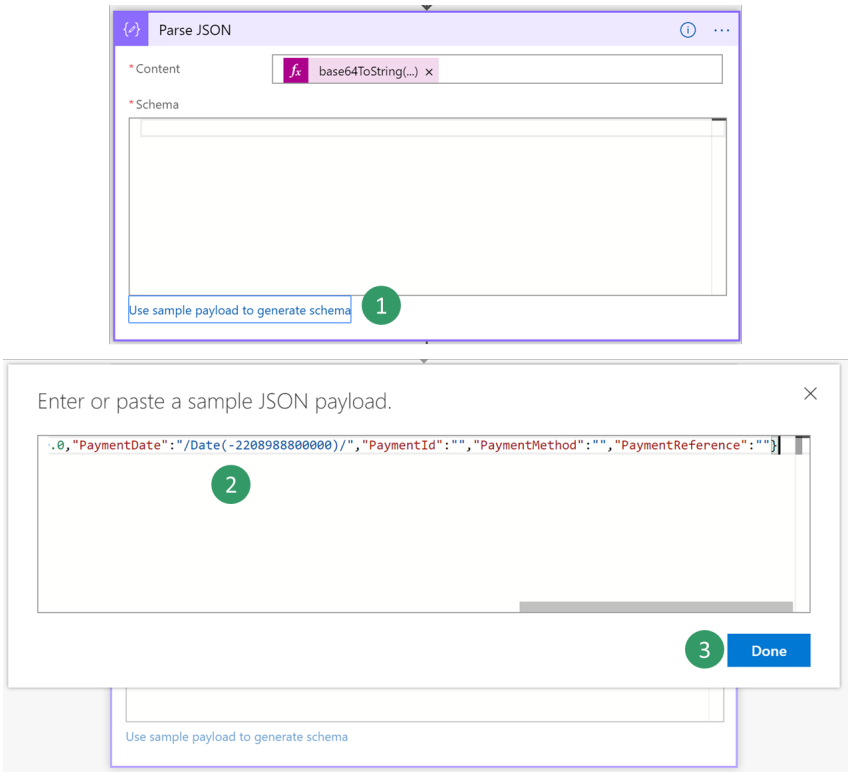
15. Put the cursor between the parentheses in the expression, and then, on the **Dynamic content** tab, find and select the **Content of the message** content from the previous Service Bus trigger. Then select **OK**.



Next, you must enter the schema of the contract that is received from the application. The application only provides a sample payload. However, you can use a capability of Azure Logic Apps to generate a schema from a payload.

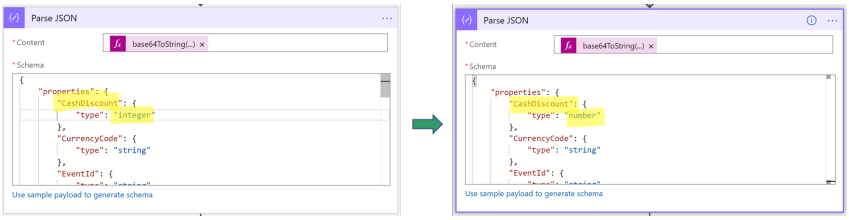
16. Select your event in the business event catalog, and then select the **Download schema** link. Open the text file that is downloaded, and copy the contents.

17. Go back to your Logic Apps, and select the **Use sample payload to generate schema** link. Paste the contents of the text file, and then select **Done**.



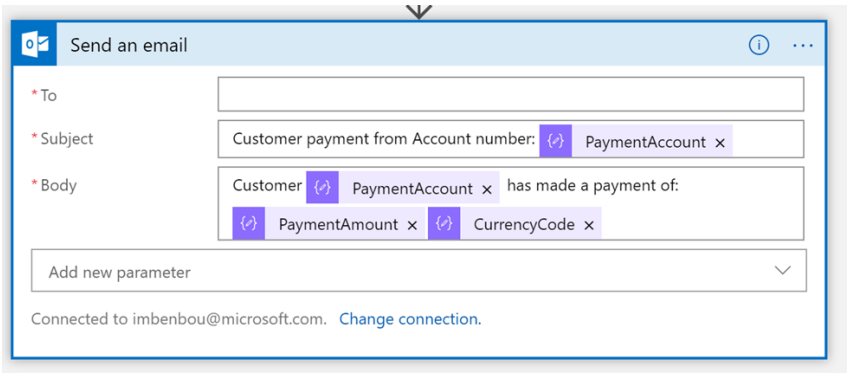
18. Depending on the quality of your sample payload, your generator won't be able to distinguish between

an integer and a real value, especially if the real value is provided as a whole number in the sample payload. Review the schema that is generated, and determine whether you must change a field of the **integer** data type to the **number** data type. (In JSON, the **number** data type represents real values.)



Next, you will select a final action, such as sending a notification email that includes customer payment details.

19. Search for the **send email** action, and then sign in to your Microsoft 365 account.
20. Fill in the message with the required fields.



21. Save your logic app.
22. Trigger the business event by posting a customer payment. Then verify that the logic app runs, and that you receive an email that includes customer payment details.

> **NOTE**
>
> Can you tell us about your documentation language preferences? Take a short survey.
>
> The survey will take about seven minutes. No personal data is collected (privacy statement).

Business events and workflow approvals

2/18/2021 • 5 minutes to read • Edit Online

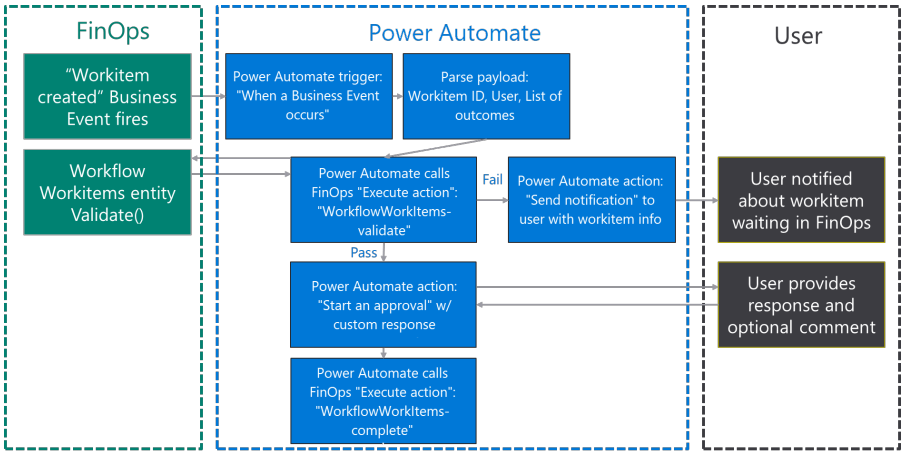
This topic explains how to use Microsoft Power Automate to configure and consume a workflow business event for purchase requisition approval.

To complete this topic, you must be running Microsoft Dynamics 365 for Finance and Operations version 10.0.2 (May 2019) with platform update 26 or later.

Scenario overview

The following illustration shows the high-level process that you must configure by using Power Automate. Note the following points:

1. The application fires a business event whenever a new approval starts.
2. Power Automate trigger starts.
3. After parsing business event payload from F&O, next step is to check wheter the workflow instance ID received from F&O is still alive. This is a security step in case approval has already taken place or workflow has been recalled.
4. If the check is unsuccessful, an email is sent to notify the user about a potential work item in their workspace.
5. If the check is successful, a new Power Automate approval is started.
6. Then workflow is completed by using the outcome of the approval. The outcome can be either **Approve** or **Reject**.



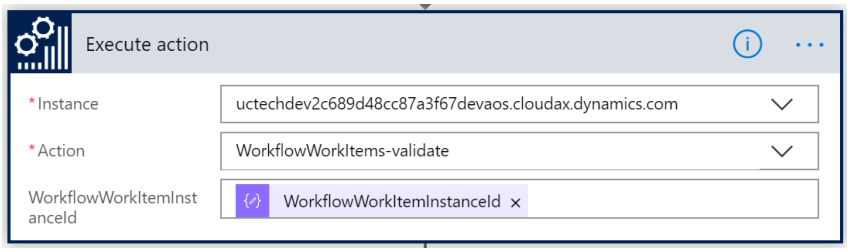
Exercise 1: Create a new flow

1. Sign in to the Power Automate portal.
2. Select an existing environment where you have the right to create a flow resource. The **(default)** environment is available to all companies.
3. Select **New > Create from blank**.
4. Search for **Dynamics 365 for Finance and Operations**, and select the connector.
5. A new trigger is created. This trigger is named **When a Business Event occurs**. Select it.
6. Select the environment instance that has these characteristics:
   - The category is **Workflow workitem**.

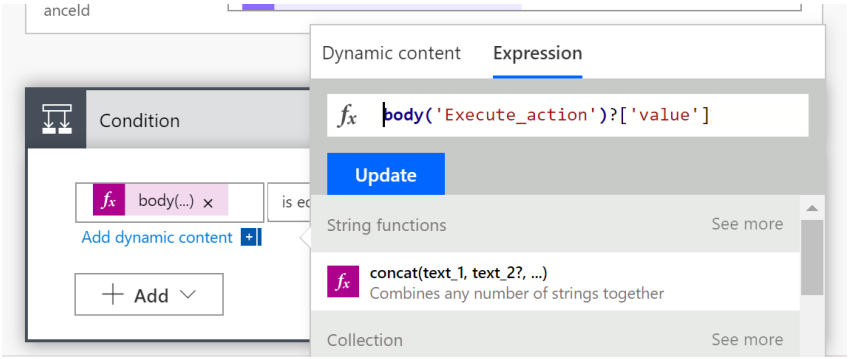
- The event name is **Purchase requisition review (000062) – Approve purchase requisitions**.
- Any legal entity is selected.

7. Select **New Step** to add a new action.
8. Search for the **Parse Json** data operation. This step is required so that the message can be parsed by using the schema of the data contract that the application provides.
9. Select the content field of the **Parse Json** action. The **Body** output from the previous step should appear as an option. Select **Body**.

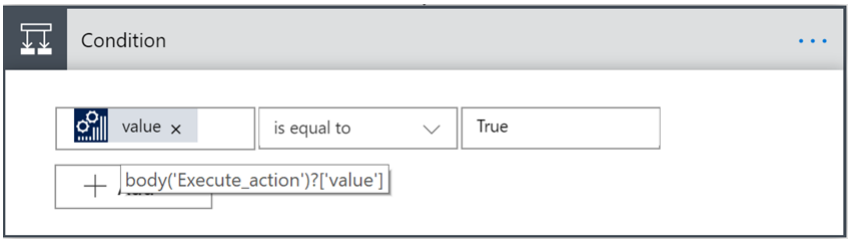
   Next, you must enter the schema of the contract. The application provides only a sample payload. However, you can use a capability of Microsoft Flow to generate a schema from a payload.
10. Select the **000062** workflow event in the catalog, and then select the **Download schema** link. Open the text file that is downloaded, and copy the contents.
11. Go back to Power Automate, and select the **Use sample payload to generate schema** link. Paste the contents of the text file, and then select **Done**.
12. Add a new step to call a workflow action that validates whether a workflow that has the correct instance ID is running and awaiting approval.



13. Add a new condition control step to check the result of the validate action. The dynamic field won't provide the required output. Therefore, you must manually enter the following expression instead: **Body('Execute_action')?['value']**. Then select **OK**.



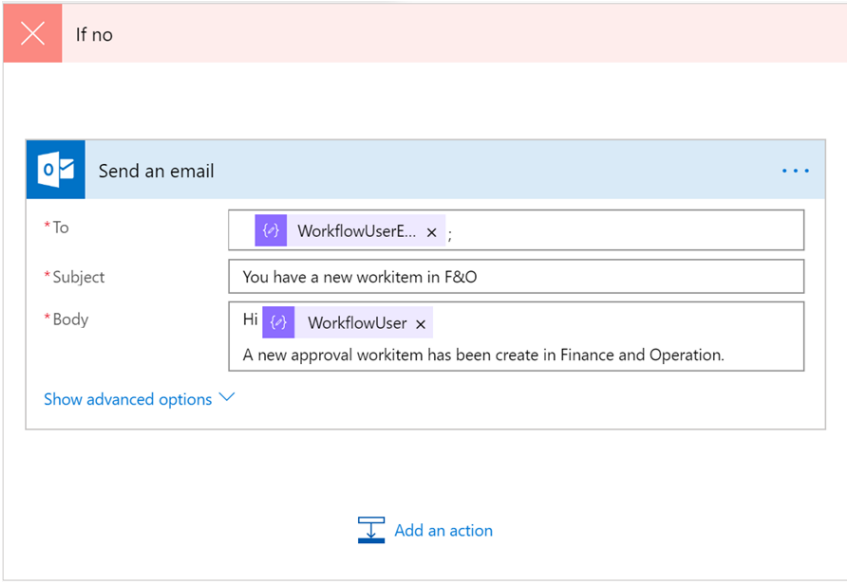
> **NOTE**
>
> The next time that you open the workflow, you will notice that the expression has been updated so that it shows the **value** field. As the following illustration shows, this field will have an application icon.



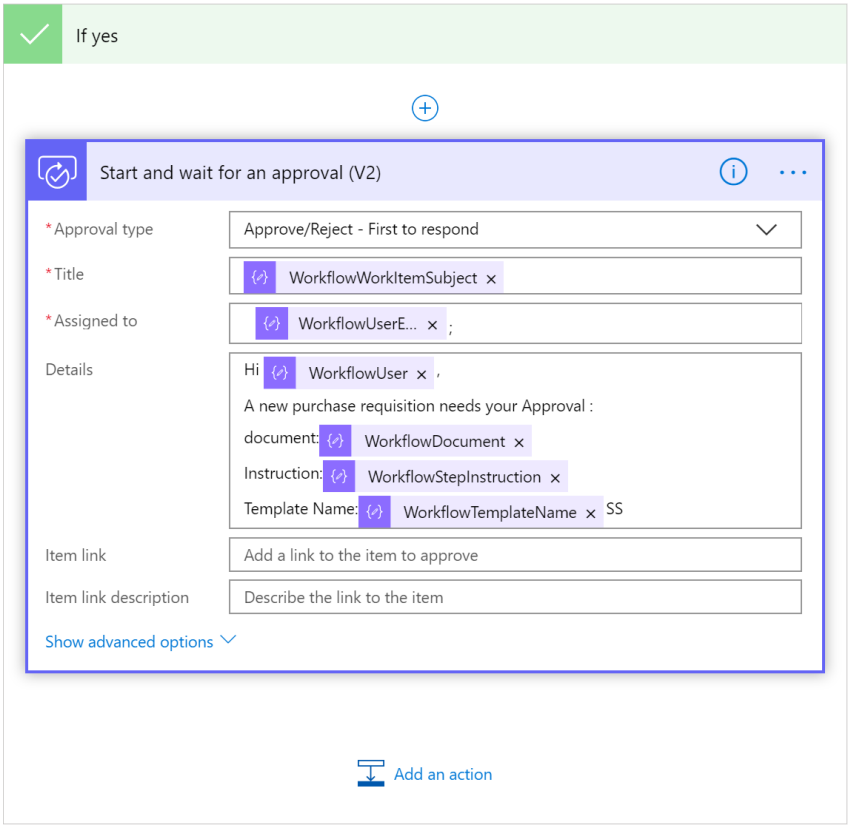
14. The condition control automatically creates two branches for **Yes/No** results. If the result of the validate step is **No**, an email must be sent to the user. This email notifies the user that a new task requires

attention, and that the user must sign in to the client. In order to complete this step create a new send email action within the **No** container and fill in the parameter with the email of the Approver from the previous step **workflowuseremail** and a subject and body of your choice.

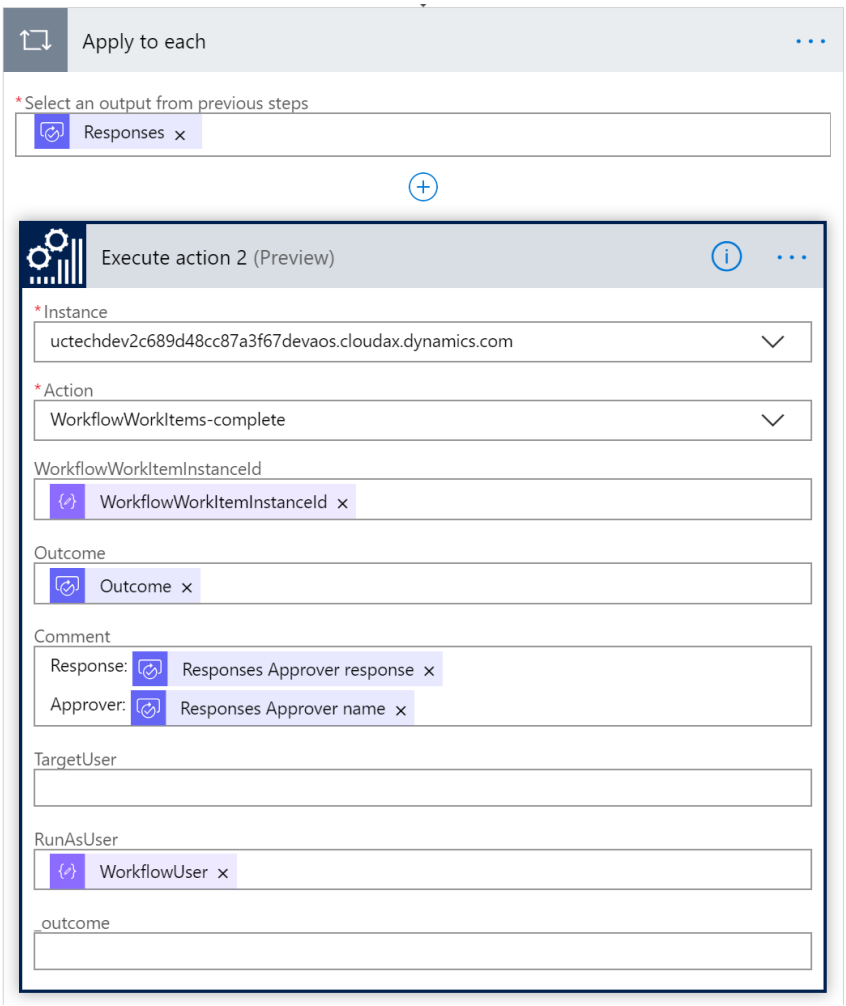
> **NOTE**
>
> The email address that the workflow business event returns is the email address of the workflow approver. If the workflow approver user hasn't been configured in yourdemo environment, you can use your own email address for demo purposes.



15. If the result of the validate step is **Yes**, you must start a new Power Automate approval step. In the **Yes** container, select a new action that is named **Start and wait for an approval (v2)**, and choose inputs as follows: Approval type: Approve/reject: first to respond title: **workflowworkitemsubject** output form Business event payload Assigned to: **workflowuseremail** output Then you can fill in the details section with as much information as needed from previous step such as **workflowdocument** or **workflowstepinstruction**. Again, you can use your own email address in the **Assigned to** field for demo purposes especially if the workflow approver user hasn't been configured in your demo environment.



16. Next, you must complete the workflow approval by using the outcome of the approval step. Still in the **Yes** container, add a new **Finance and Operations Execute Action** step, and choose the **WorkflowWorkitem-complete** action and the **WorkflowWorkitemInstanceID** parameter. Then fill in the rest of the parameters from the approval outputs. As a minimum the outcome section with Approval outcome and the comment section with the approver's responses. Because the approval step can support multiple approvers, the response output is an array. Therefore, as soon as you select the output **Reponses** as an input for the comment section, Power Automate automatically embeds your action in an **Apply to each** container as shown below.



17. Select **Save**.

Exercise 2: Trigger a business event

Power Automate can automatically configure the application for you. After you save your flow, Power Automate creates an endpoint and activates the business event. You don't have to complete any other configurations. You just have to verify that the endpoint has been correctly configured and then trigger an event.

1. Sign in to the client.
2. Go to **System administration** > **Setup** > **Business events**.
3. Select **Business events**.
4. Select **Endpoints**.
5. Verify that a new endpoint has been created, and that a globally unique identifier (GUID) has been appended to the name.
6. On the **Active events** tab, verify that **Workflow workitem** is activated for the USMF company.

Business events and Microsoft Forms Pro

2/18/2021 • 2 minutes to read • Edit Online

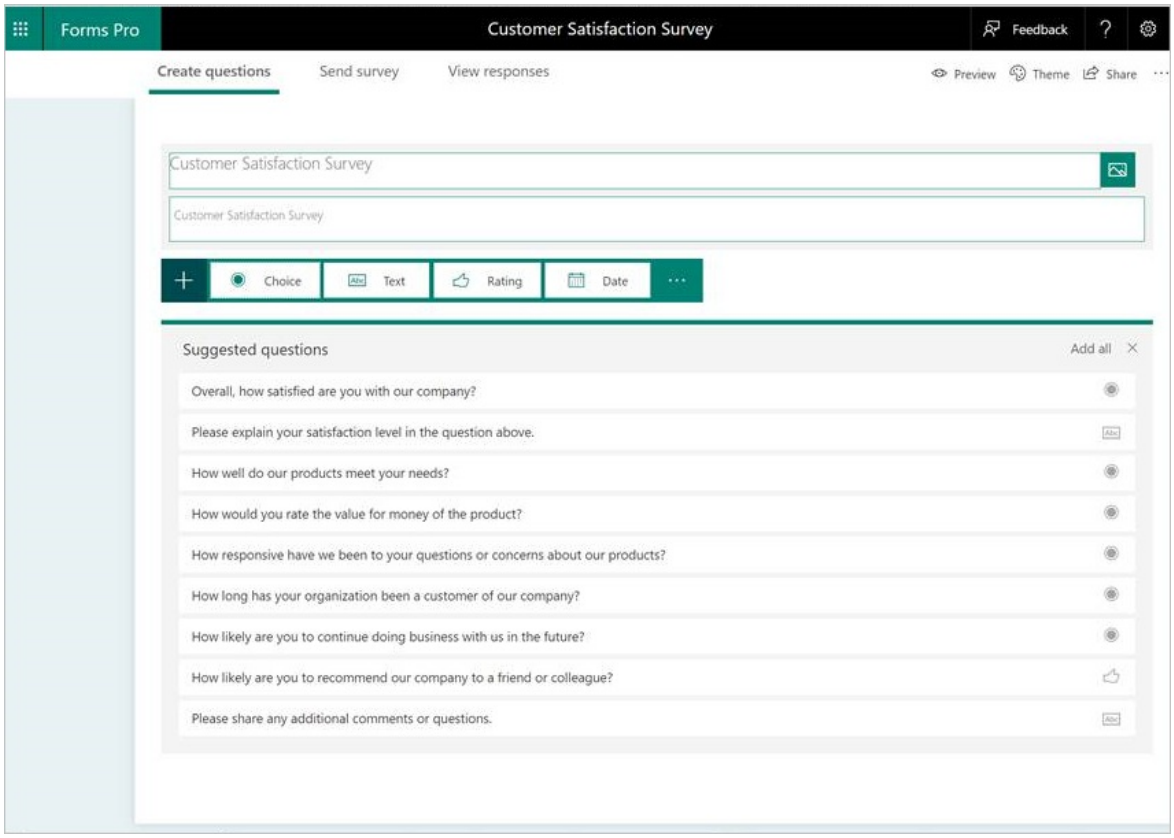
This topic goes through a scenario where Microsoft Forms Pro is used to create a survey that can be used with business events. Specifically, in the scenario that is described here, a survey is sent to customers when a product has been shipped. The survey information is gathered by using Forms Pro.

Prerequisites

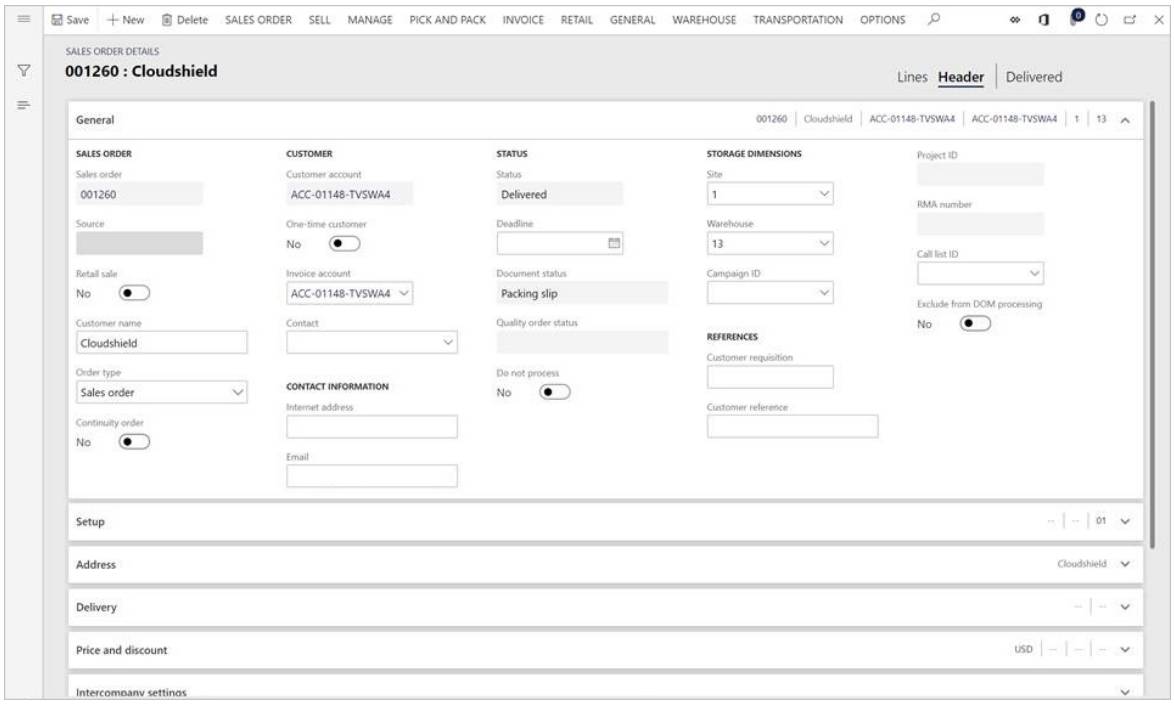
If you haven't used Forms Pro before, you should first read the Forms Pro documentation to learn how to use it.

Scenario

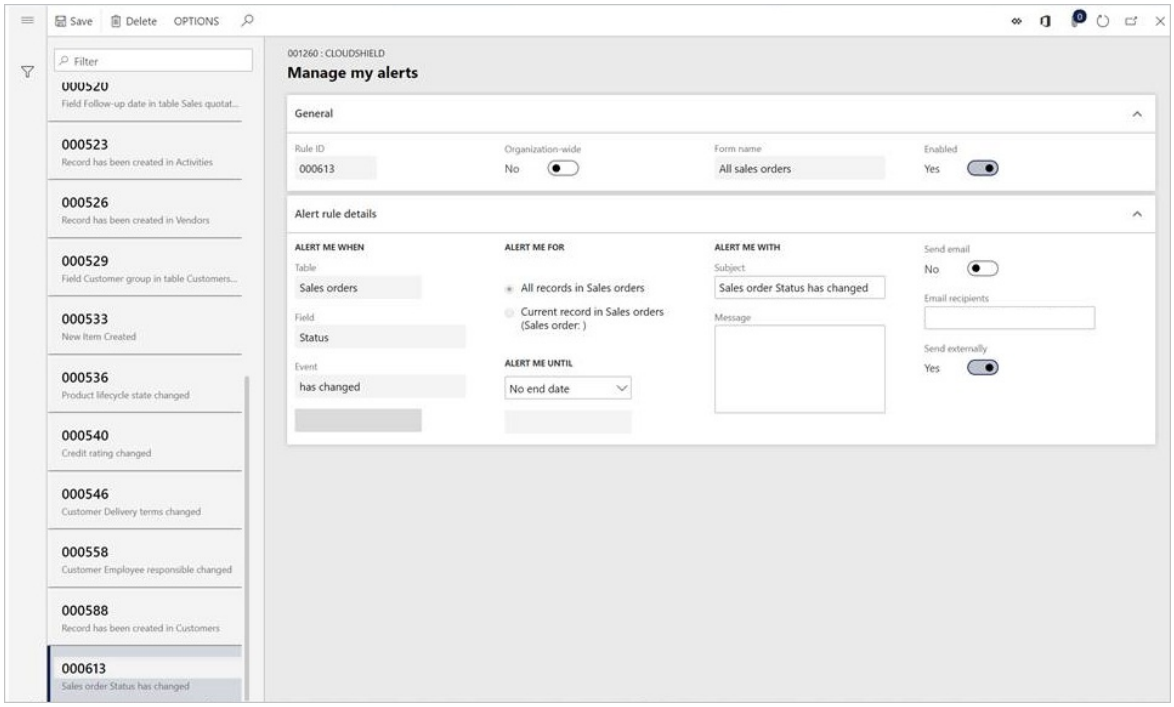
1. Create a survey. Based on the title that you enter for the survey, Forms Pro suggests survey questions.



2. The sales order tracks the shipment. When the product has been shipped, the status of the sales order is changed to **Delivered**.



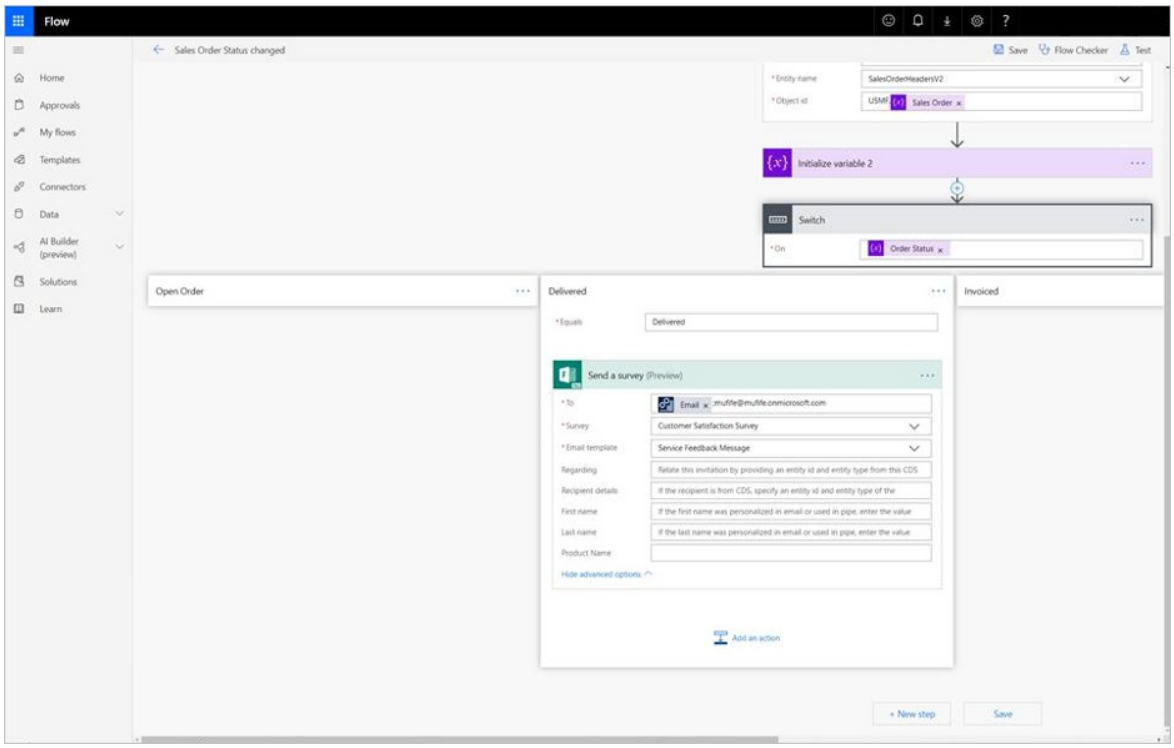
Therefore, configure an alert on the sales order, so that an alert is created whenever the value of the **Status** field is changed. Be sure to set the **Send externally** option to **Yes**, so that the alert will be sent out as a business event.



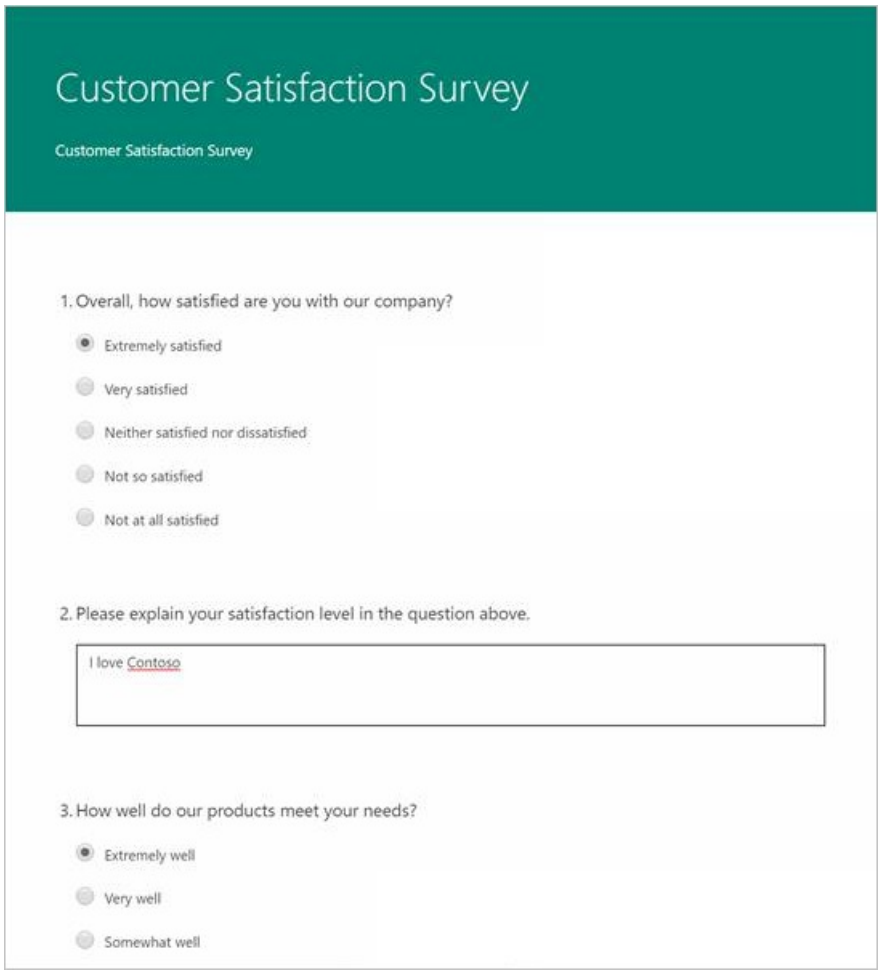
3. Set up the flow that will be triggered by the business event whenever the status of the sales order is updated (see the illustration in the next step). After it's triggered, the flow will use the Forms connector to send the survey to the customer email address that is registered on the sales order.

   The customer email address and other information that is required for the scenario must be in the payload of the business event. If the payload doesn't have this data, it can be extended so that it includes the appropriate fields. For more information, see the Business events developer documentation.

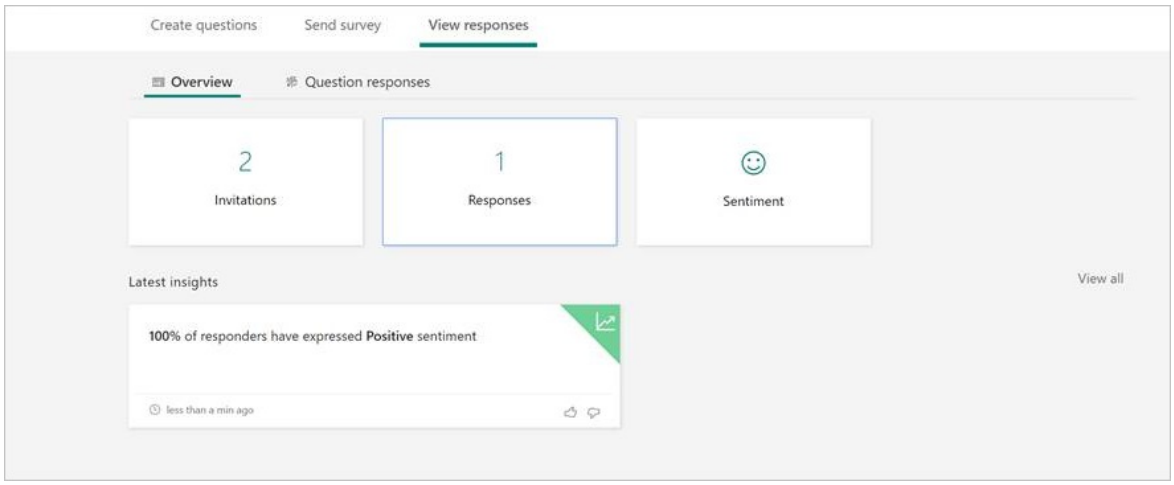
4. Because Microsoft Power Automate is used to orchestrate this scenario, don't activate the **When a change based alert occurs** business event in the application. Instead, set up Power Automate so that it subscribes directly to the business event.



5. After you've finished setting up the flow, it will be triggered and send out the survey whenever the sales order's status is updated.



As users fill in the survey and submit it, Forms Pro shows some analytics.



NOTE

Can you tell us about your documentation language preferences? Take a short survey.

The survey will take about seven minutes. No personal data is collected (privacy statement).

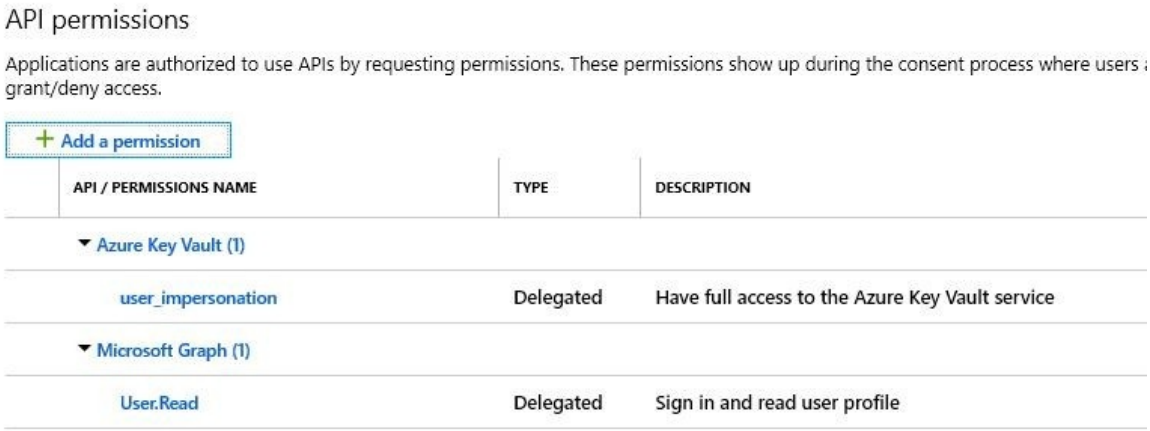
Business events and Azure Event Hubs

2/18/2021 • 2 minutes to read • Edit Online

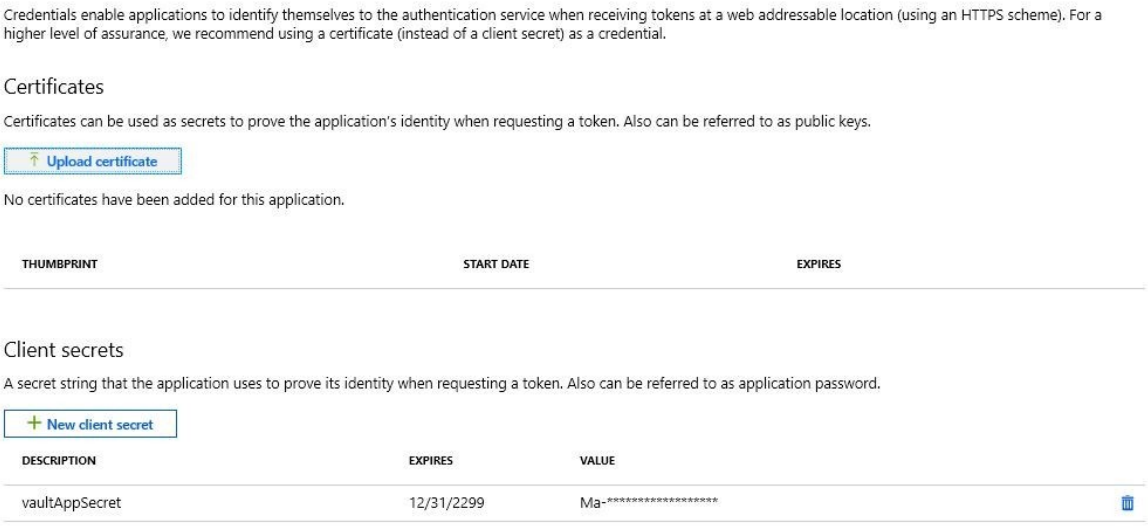
This tutorial describes the steps that you must follow to make business events work with Microsoft Azure Event Hubs.

1. In Azure portal, create an Active Directory application registration. Make a note of the application ID.

2. Give the app, permission to the Azure Key Vault application programming interface (API).

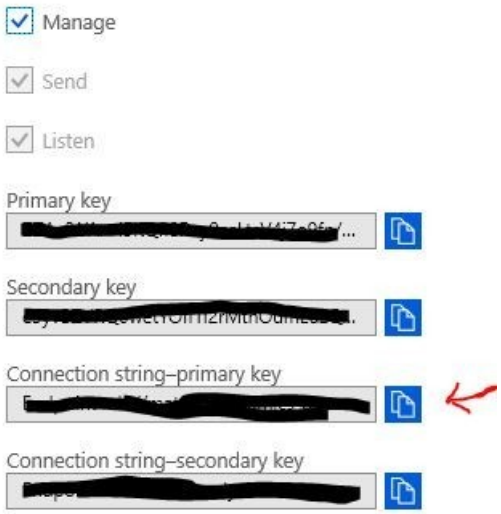


3. In the app registration, create an application secret. Make a note of the value.

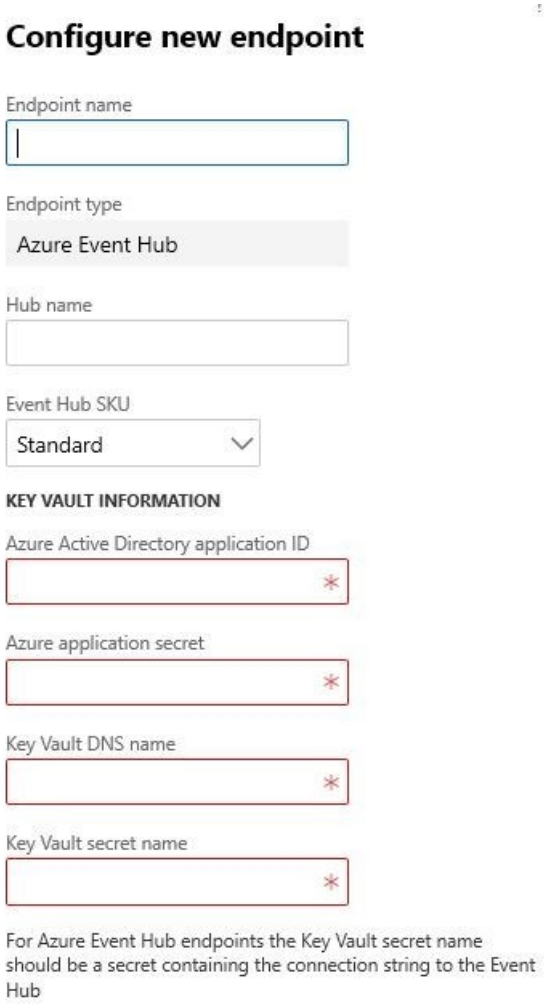


4. In the key vault, give permission to the new app registration.

5. In the key vault, create a new secret. The value of this secret must be the connection string to your event hub. Make a note of the value.



6. Create an endpoint configuration for the event hub. Go to **System administration** > **Setup** > **Business events** > **Business events catalog**, and then, on the **Endpoints** tab, select **New** to open the **Configure new endpoint** wizard.



7. In the **Endpoint type** field, select **Azure Event Hub**.
8. Select **Next**.
9. In the **Endpoint name** field, enter a name for the endpoint.
10. In the **Hub name** field, enter the name of your event hub.
11. In the **Azure Active Directory application ID** field, enter the application ID that was created earlier.
12. In the **Azure application secret** field, enter the value that was created earlier.
13. In the **Key Vault DNS name** field, enter the Domain Name System (DNS) name of your key vault. You can find this value on the **Overview** tab of the key vault configuration in the Azure portal.
14. In the **Key Vault secret name** field, enter the name from the secret that was created earlier.
15. Select **OK**.
16. You can now activate one or more business events that should be sent to this endpoint.

Business events in financial period close

2/18/2021 • 5 minutes to read • Edit Online

This topic explains how to use business events in the financial period close business process to gain insights and provide internal controls.

To complete this topic, you must be running version 10.0.2 (May 2019) with Platform update 26 or later.

Scenario overview

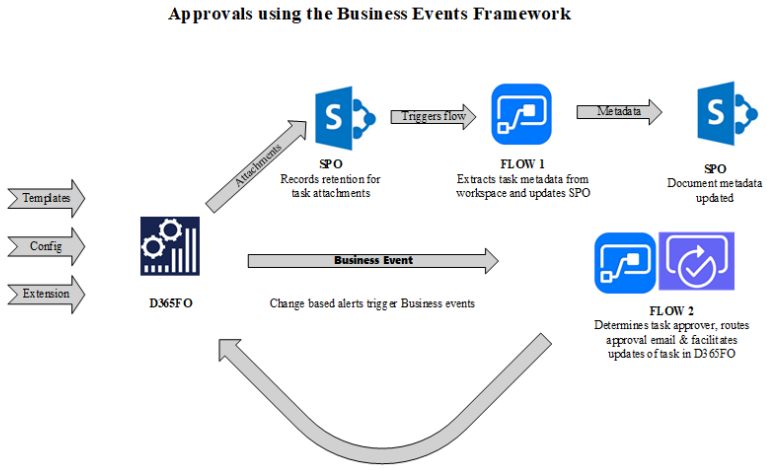
Task management is fundamental to managing business processes across industries. Out-of-box capabilities let users manage business process tasks in a structured manner. The **Financial period close** workspace illustrates these capabilities by offering a central location for managing tasks in a company's accounting period close process.

This topic looks at an organization that recently decided to explore how it can use the **Financial period close** workspace to track and report tasks that are associated with every period close. Performance management and traceability are some of the challenges that this organization faces in the current setup. Therefore, the organization undertook an exercise in business process transformation to identify the capabilities of the **Financial period close** workspace. This exercise revealed the following business requirements:

1. The ability to be notified when tasks must be started
2. The ability to attach documents
3. Record management and disposition capabilities for attachments
4. The ability for multiple approvers to approve tasks, based on predefined logic
5. Task questionnaires for audits
6. Reporting capabilities to track the current status of the period close process and do performance analysis for insights into efficiency

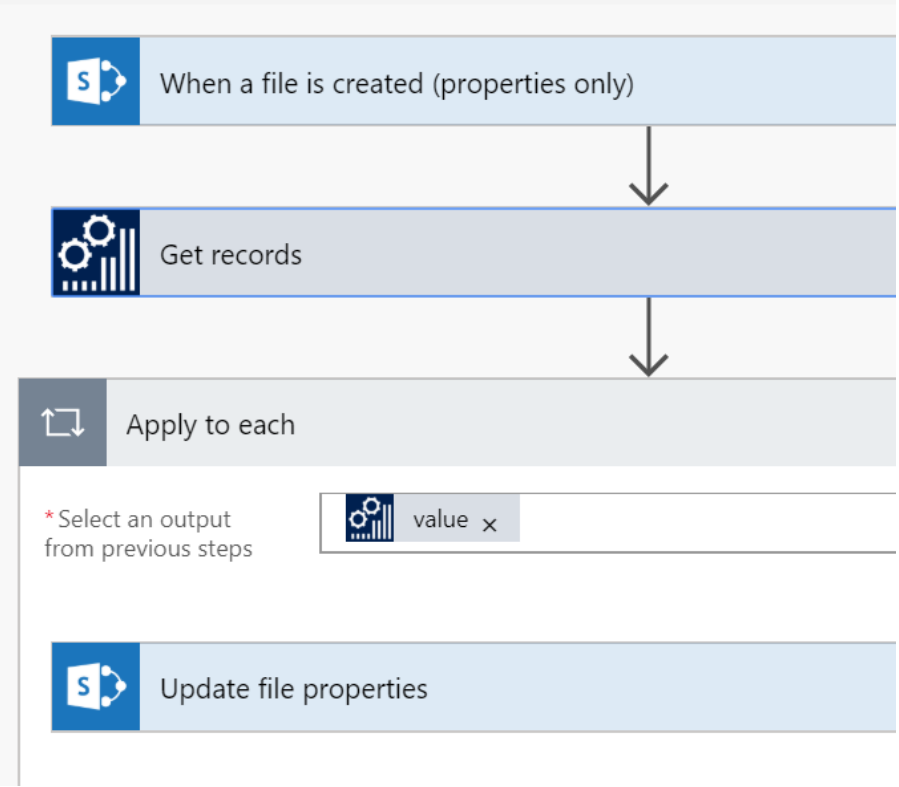
High-level design

To achieve the previously mentioned requirements, the organization used out-of-box capabilities of the **Financial period close** workspace. A gap analysis revealed that, by doing minor extensions to the workspace and the underlying data entities, the organization could achieve requirements 2, 5, and 6, and could partially achieve requirement 4. To achieve requirements 1 and 3, and parts of requirement 4, the organization chose to use Power Automate. The following illustration shows an architectural overview of the solution.



Managing attachments by using Microsoft Power Automate and SharePoint Online

Accountants view their tasks in the **Financial period close** workspace and start to work on them. Attachments are added to the task by using a SharePoint Online document type. SharePoint triggers in Microsoft Power Automate are used to trigger the Power Automate that is shown in the following illustration. This Power Automate updates the SharePoint metadata with metadata from the task in the **Financial period close** workspace. SharePoint columns were created for this purpose in the document library. A separate attachment data entity was created to hold the attachment metadata for every attachment that is added to the **Financial period close** workspace. Fields from the custom entity were mapped to the SharePoint Online columns in the Power Automate. When documents that use the specified document type are created in the predefined SharePoint Online library, Power Automate is triggered, obtains the metadata from the custom data entity, and updates the document's metadata columns in SharePoint Online.



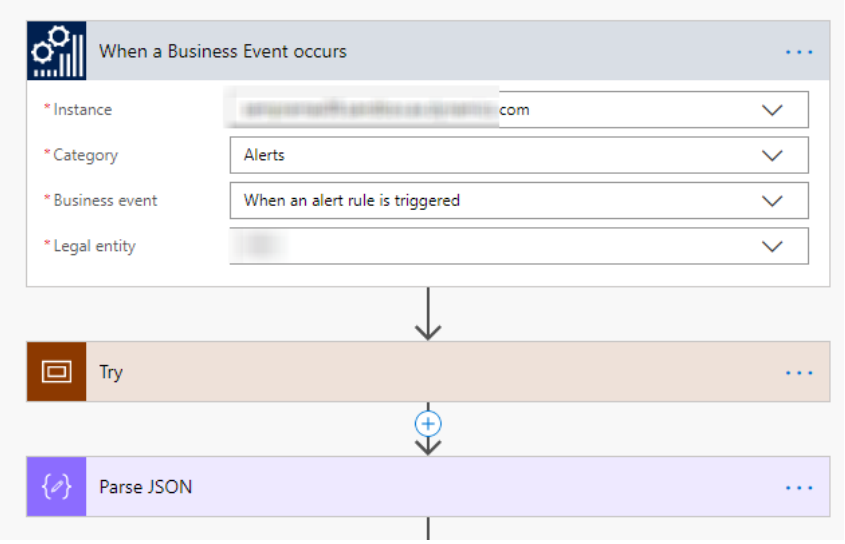
Enabling internal controls by using business events and Power Automate

As accountants complete their tasks, and the tasks become ready for review, the value of the **Review status** custom field is updated to **Ready for review**. The Power Automate gets triggered by the **When the change-based alert is triggered** business event when this update is made. The payload of this business event contains the task name and the area name. The Power Automate uses the combination of the task name and area name, together with the value of the **Review status** field, to route the task through an email-based workflow that is orchestrated by Power Automate. The Power Automate waits for approval, add new comments to the task log, and updates the task in the **Financial period close** workspace , based on both the outcome of the approval process and related metadata. Custom data entities were built in to query and update the **Financial period close** workspace by using Power Automate.

Subscribing to the business event

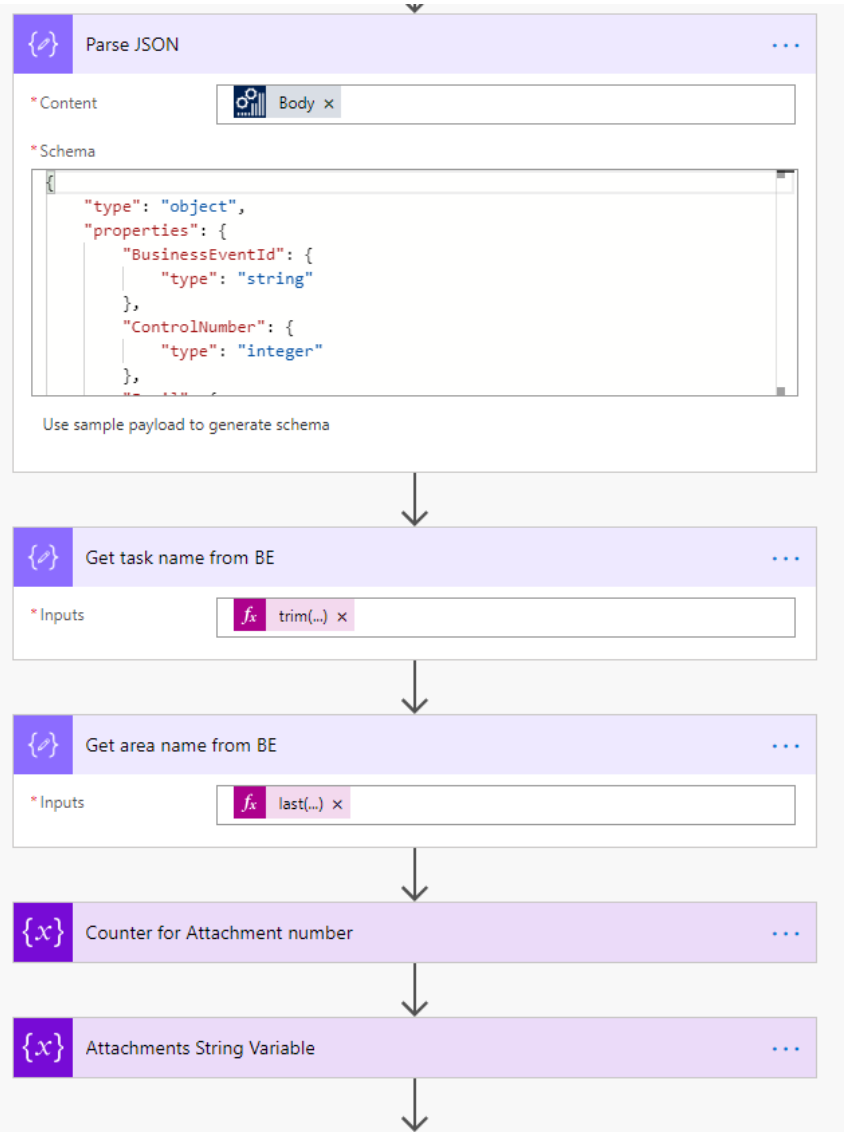
The following example describes the general steps for subscribing to a change-based alert business event.

1. Add the connector trigger to the Power Automate app, and subscribe to the change-based alert business event.



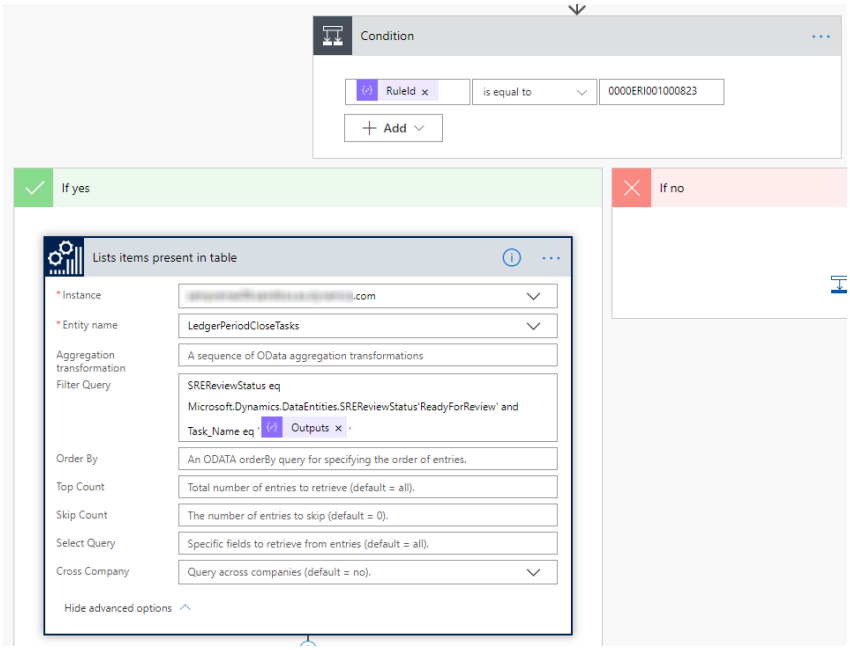
2. Parse the business event payload.

   When the business event is triggered, it triggers Power Automate. This business event contains a payload. In this step, the payload is parsed, and the required variables are initialized.



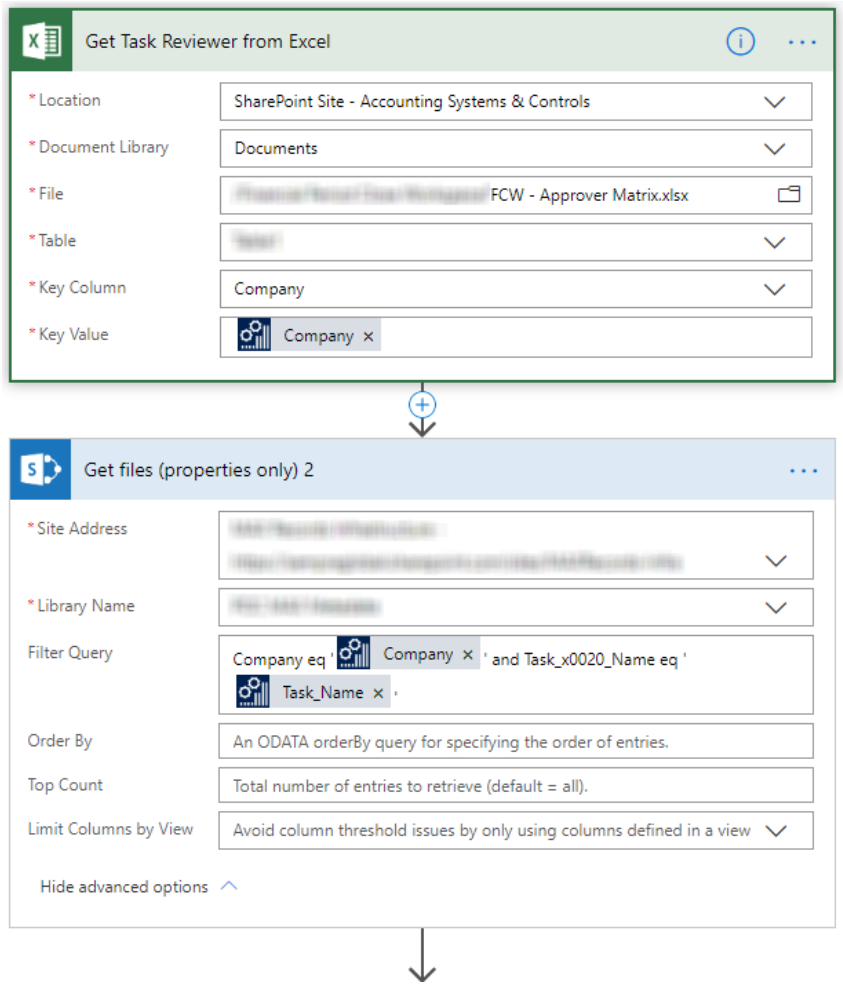
3. Retrieve the task, based on the values from the payload.

   When the task is updated, the business event triggers Power Automate. At that point, after the payload has been parsed, you will know basic information about the task. In this step, the custom data entity is used to retrieve more information about the task.



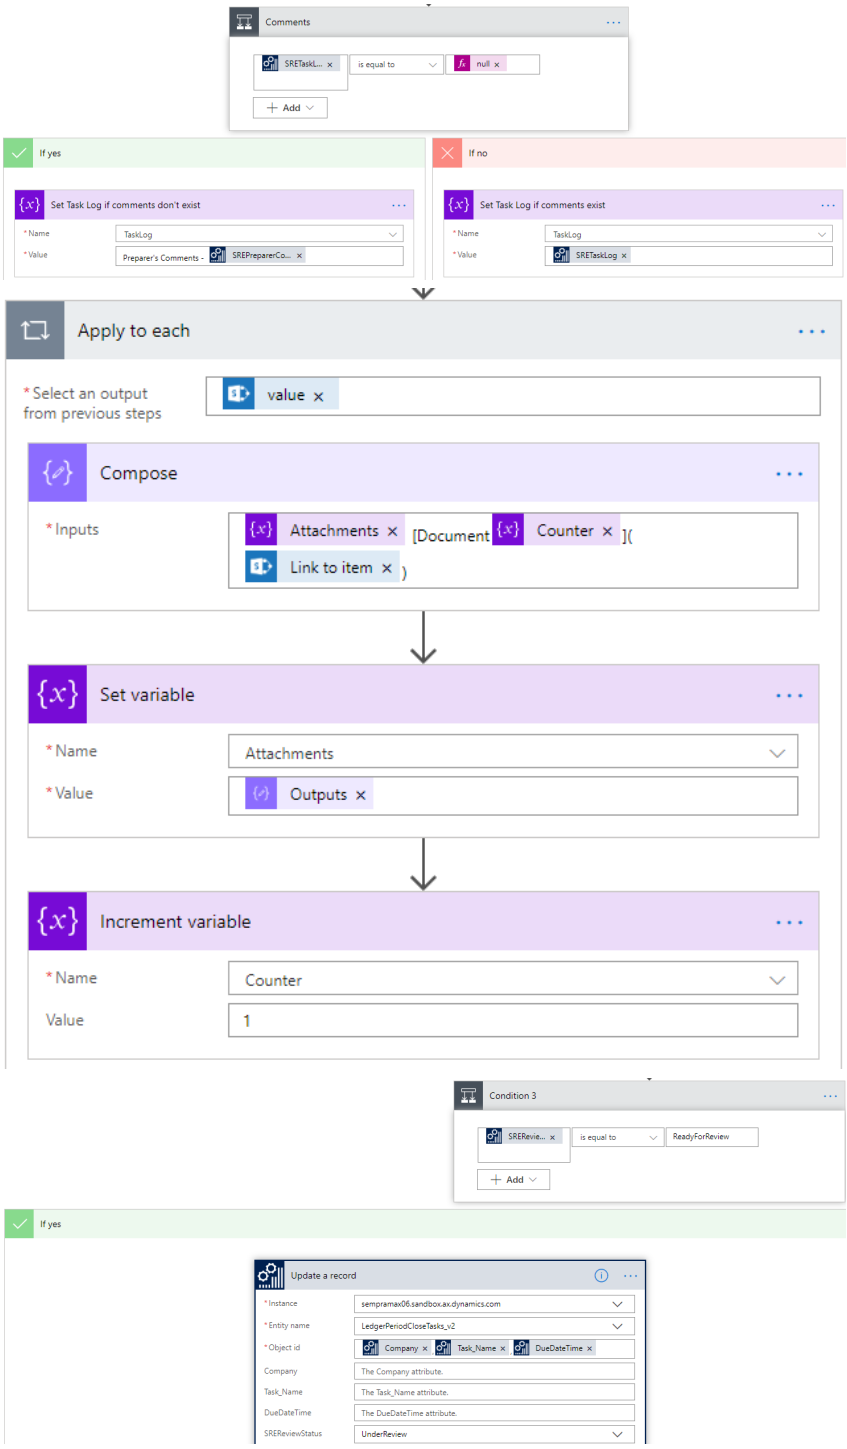
4. Retrieve approvers from the Microsoft Excel file, based on the criteria.

   Next, you must determine the list of approvers, so that you can send the approval request in the appropriate manner. This list is a custom Excel file in a SharePoint Online library. In this step, you query the Excel file to get the list of approvers. You also get the links to the attachments for each task, so that you can send the attachments to the approvers.



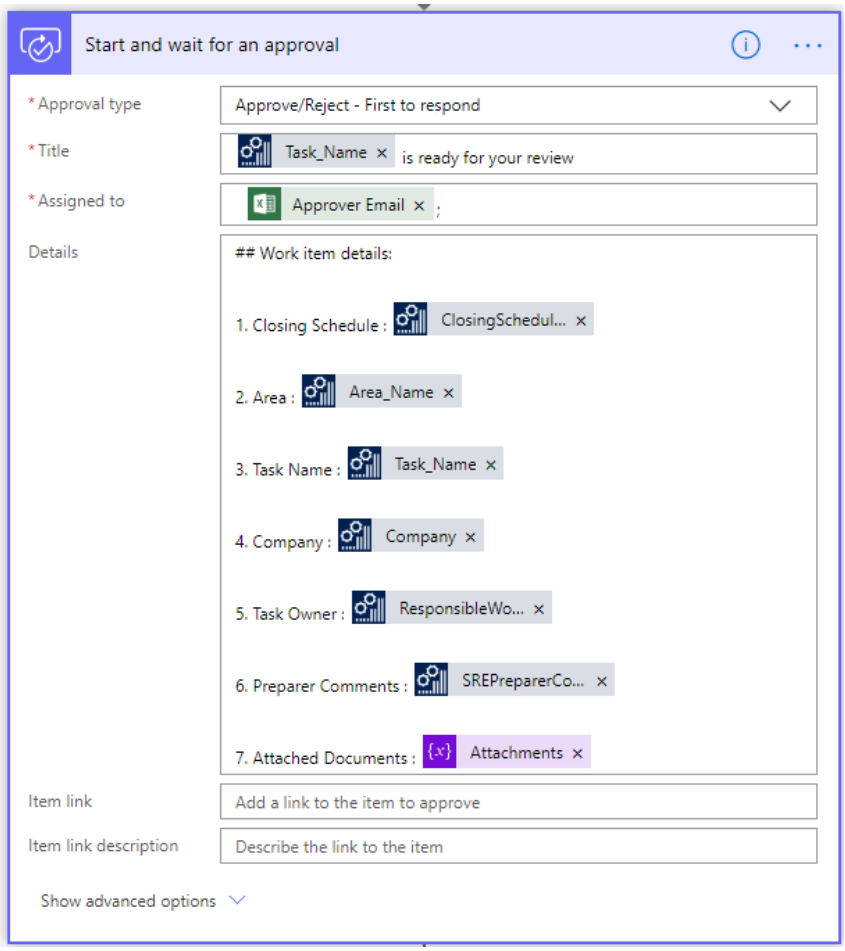
5. Prepare to send the request for approval.

   In this step, you prepare Power Automate to send the approval request by using all the information that was gathered and assembled in the previous step.



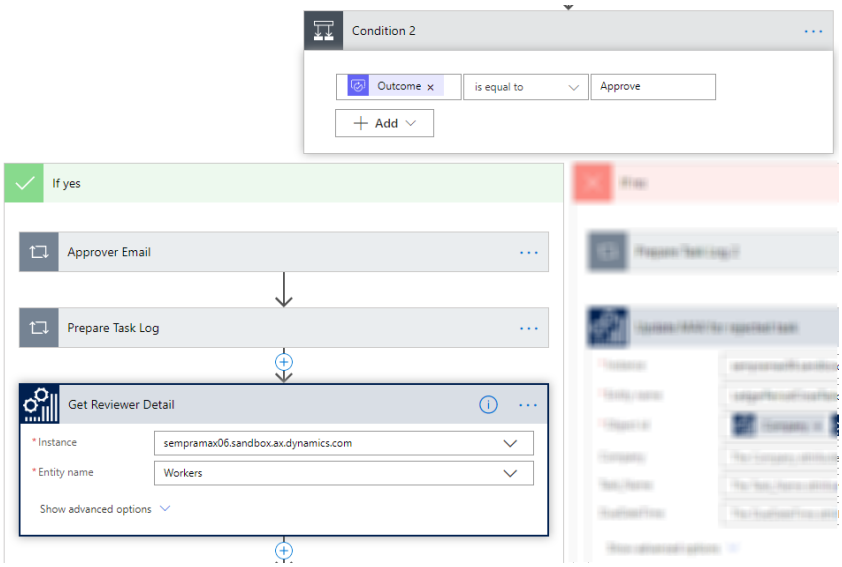
6. Start the approval process.

   In this step, the approval request is sent from Power Automate.



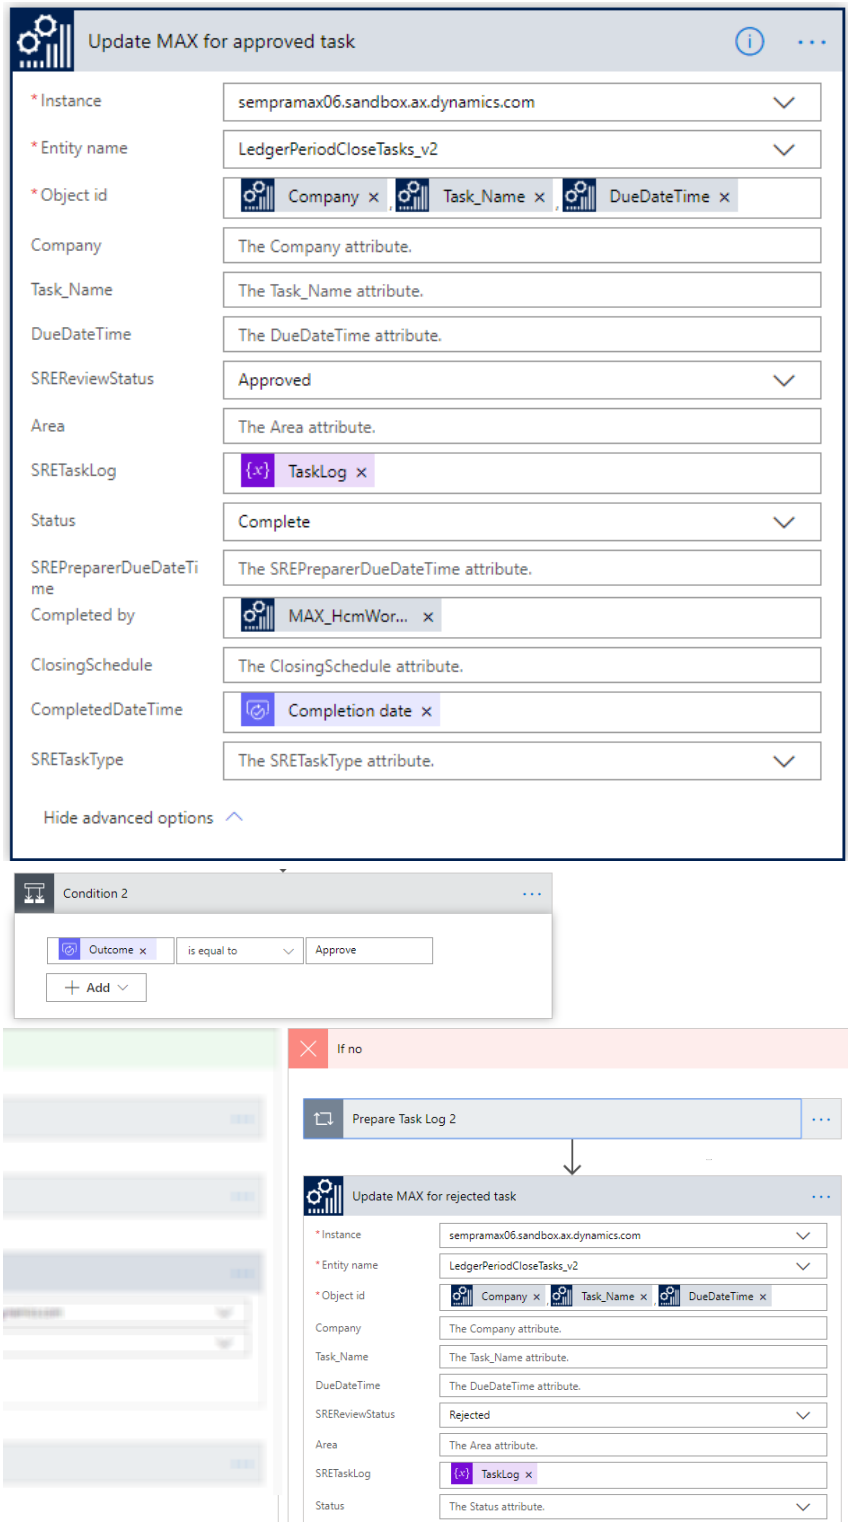
7. Process the approval action that is taken by approvers.

   After the approvers receive the approval request and take action, the Power Automate is notified, and additional processing is done.



8. Update the task with the approval outcome.

   Based on the outcome of the approval process, the task is updated with the result.



Conclusion

For the business requirements of the organization that is described in this topic, this solution involves minimal development and relies mostly on the **Financial period close** workspace, business events, SharePoint Online, and Power Automate to drive functionality. Development is restricted to the addition of fields to pages, the creation of custom data entities, and changes to page labels. Power Automate also provides greater flexibility in the approval process. Because the solution takes advantage of the various applications in the Microsoft 365 suite, internal users can use applications that they are already familiar with. Therefore, the amount of change management that is required is limited.

In conclusion, business events offer unique opportunities for extending functionality but also let you avoid extensive in-app customizations. Here are some things to consider before you start to use business events:

- Establish the security requirements of your solution. Business events honor role-based security. This behavior

can be beneficial in some use cases.

- Business events functionality continues to get enhanced. Be on the lookout for new capabilities.

Business events and Power Automate offer great opportunities for implementing low-code or no-code extensions. The important thing is that you identify opportunities where this framework can help, but that you also understand some of the limitations.

Continuous delivery home page

2/18/2021 • 2 minutes to read • Edit Online

These topics describe tools and guidelines related to continuous delivery of your solution.

FAQ and guidelines

- Development and continuous delivery FAQ

Build and test automation

- Deploy and use an environment that supports continuous build and test automation
- Build automation that uses Microsoft-hosted agents and Azure Pipelines
- Testing and validations
- Merge the build systems for Commerce and Finance
- SysTest filtering using class and method attributes
- Acceptance test library resources

Advanced topics in build automation

- Install metadata hotfixes in development environments
- Patch SQL Server Reporting Services (SSRS) in one-box environments
- Update the Visual Studio development tools

Development and continuous delivery FAQ

2/18/2021 • 9 minutes to read • Edit Online

This topic summarizes answers to questions that are frequently asked by ISVs and partners, especially regarding guidelines about development, testing, delivery, and lifecycle management.

Customization

Do I customize (overlayer) or use extensions?

Extensibility is the only customization framework in Finance, Supply Chain, and Commerce. Overlayering isn't supported.

Dynamics 365 Finance, Supply Chain, and Commerce are extensively customized by partners, value added resellers (VARs), and even some customers. The ability to customize the product is a strength that has historically been supported through overlayering of the application code. The move to the cloud, together with more agile servicing and frequent updates, requires a less intrusive customization model, so that updates are less likely to affect custom solutions. This new model is called *extensibility* and has replaced customization through overlayering.

For more information, see Extensibility home page and the Develop and customize home page.

How do I prevent my models from being customized by customers or other partners?

You can block customizations of your model as described in Turn off model customization and deprecate functionality, or you can distribute deployable packages to your customers instead of distributing model files. See the section titled "How do I distribute my application to customers" later in this topic.

How can I define the scope of my models? How many models or packages should I create?

Designing models and model elements is no different than designing other types of software libraries. You should apply SOLID (object-oriented design) design principles. In addition, we recommend the following tips that are specific to the platform:

- If there are components in your solution that you want to ship and service more frequent than the rest, they are good candidates to place in a separate model and package.
- It is common practice to start with two packages (each with one model) at the initial stage of an implementation, one foundation package that contains extensions to the Microsoft platform packages and one application package that contains extensions to the Microsoft application packages. More models can be introduced on an as-needed basis.
- Existing packages can be subdivided into smaller packages when necessary. If your implementation is already live using one of your packages, avoid renaming a package, to help simplify lifecycle management.

Continuous delivery

Do I need build environments?

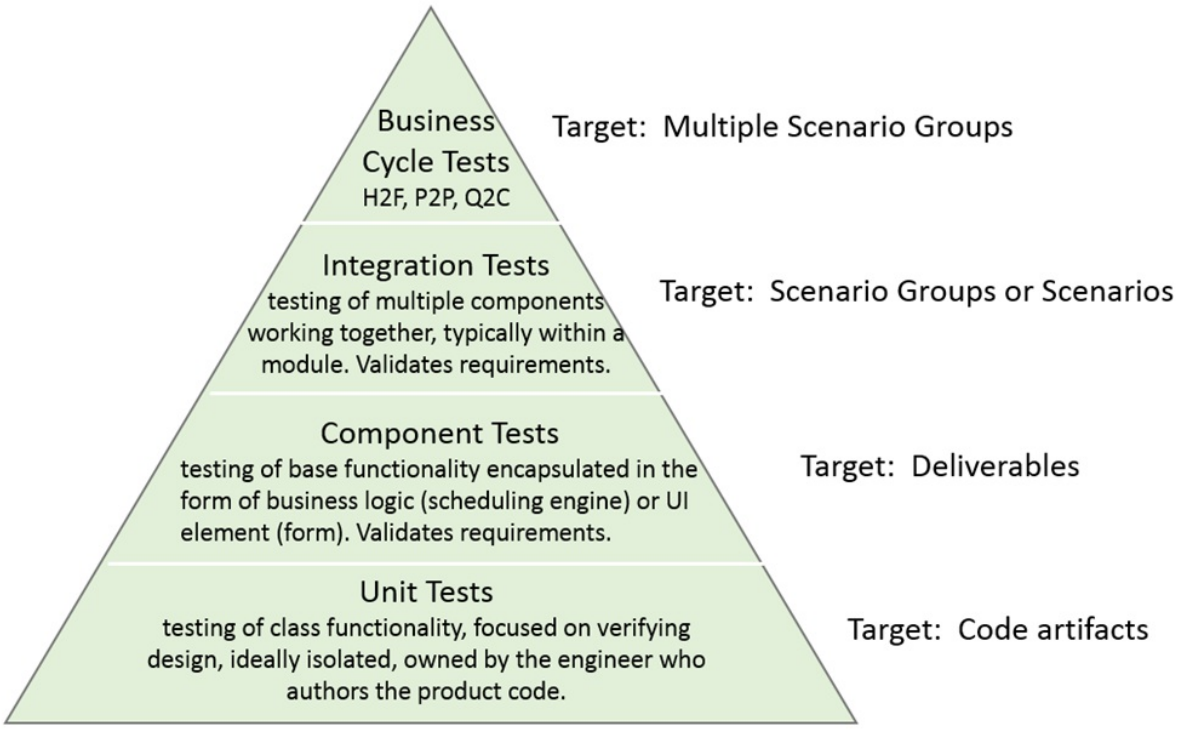
Yes, you should take advantage of the build and test automation tools provided in the build environments. You can deploy build environments from your Lifecycle Services (LCS) project. Creating daily builds and daily regression tests are key tools to enable the continuous delivery and maintain the quality of your application. Refer to Deploy and use an environment that supports continuous build and test automation for more details.

Do not use build environments for development activities. Do not keep a backup of your test database on these build VMs. Build VMs are designed to reset themselves to a known state with every build and whenever they are

updated with a Microsoft binary or platform updates from LCS. For example, if you apply a binary hotfix or platform update to a build VM, the VM prepares itself for the next build as part of the update. This will remove your customizations and also trigger a database synchronization.

What strategy do I use for test automation?

For test automation, concentrate on unit tests (use the SysTest framework) that are data independent or create their own data. Use a smaller number of functional scenario tests (based on Task Recorder) that rely on test data to execute. Scenario tests are more expensive to maintain. Unit tests can then be executed on any development environment easily and quickly. Review the Test Automation Pyramid blog article and refer to Automated testing guidance.



Some key concepts to keep in mind:

- Write tests that run independently and do not assume any kind of ordering.
- Task recorder tests should be limited to functional scenarios tests.
- Write scenario tests after scenarios are complete and after completing unit tests.
- Create test helper classes when possible, so others on your team can leverage that as well.
- SysTest framework supports role-based testing, leverage this feature.

How can I be more agile in my development?

Deliver incremental features every sprint (2 weeks, preferred) or cycle (1 month). Maintain shippable quality of your application at the end of each sprint. Use Azure DevOps for work item tracking and always prioritize bugs over new features. A large bug backlog will quickly become a burden on your efficient delivery of new features and on the quality of your application.

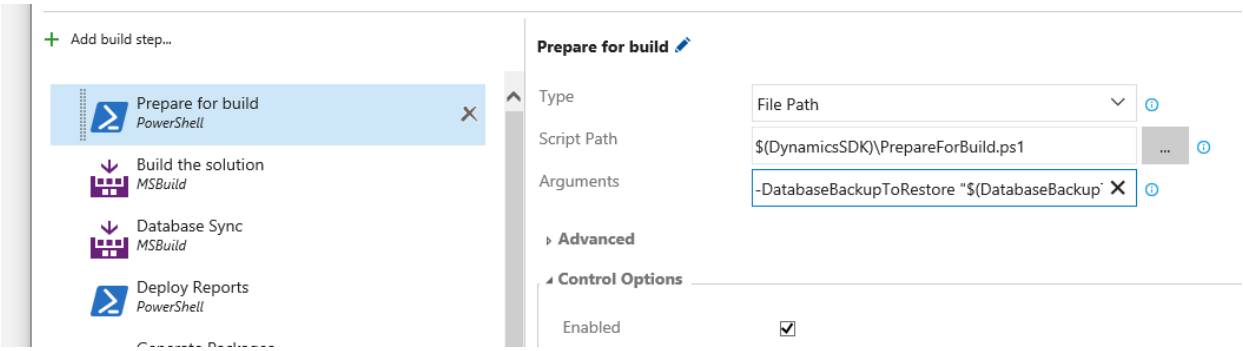
How do I manage test data?

Create and manage your test database as follows:

- Start on a clean environment.
- Create all base data as required. Base data will serve as the starting point for all the tests.
- Take a backup (.bak) of your AxDB database.
- Share this backup with developers.

On a build environment, copy this backup over to the I:\DynamicsBackupDatabases (on some environment it may be a different drive than i:). This database will be restored at the beginning of every build. This step is

executed as part of the first step of the build definition called **Prepare for build**.



How do I distribute my application to customers?

There are two artifacts you can use to distribute your application to your customers or partners: model files or deployable packages. Model files are design time artifacts that contain source code. Use model files if your customer is integrating your application with other third-party models or when you want to allow customization of your models. For more information, see Export and import models. Model files are the most common methods for ISVs to distribute solutions. Deployable packages are final applications. Use deployable packages with customers that will not be customizing or integrating your application with other third-party models. If you use deployable packages, your customer can only use or extend your application. They will not see or have access to your source code. To create a deployable package use the Visual Studio tools (**Dynamics 365** > **Deploy** > **Create Deployment package**) or use a build environment. Build environments generate a deployable package with every successful build.

Development topologies

Should I develop on premises or in the cloud?

There are two modes of development: Cloud VMs and on-premises VMs available via a downloadable VHD. Use a combination of on premise VMs and cloud VMs for development.

- On premise dev VMs are cost effective if you already have the hardware, IT infrastructure, and Windows server licenses to support it.
- Use cloud VMs to scale out when projects require additional resources for a limited period of time. It is more cost effective than planning for worst-case capacity on premise.
- Connect all VMs (on premise and cloud VMs) to Azure DevOps for version control.

Use cloud VMs for build, functional testing, and demos. If you are running on your own Microsoft Azure subscription, turn them off when not in use.

Should I use a customer's dev environment?

If you are a partner, use your own VMs for development of your own intellectual property (IP), this is code and configuration data packages that are reusable across different customer implementations. For customer-specific implementations, you can use the customer's dev VM. All customer subscriptions come with at least one development VM. Customers can pay for add-on dev VMs or run local dev VMs.

What are the benefits of MSDN subscriptions with respect to development?

The following is a summary of a Visual Studio (VS) with MSDN subscriptions benefits:

- Includes a Microsoft Azure subscription with a $50 monthly credit for Visual Studio Professional with MSDN and $150 for VS Enterprise with MSDN.
- Subscriptions come with lower dev/test rate, you will pay the Linux rates instead of the Windows rates.
- For more details, visit https://azure.microsoft.com/pricing/member-offers/msdn-benefits-details/

As a Microsoft partner, acquire Microsoft core competencies to earn free VS Enterprise with MSDN

subscriptions. For example, an application development competency for a gold partner will earn 25 free MSDN Enterprise licenses in addition to the 10 licenses that come with the core benefits. For more details, visit Monthly Azure credit for Visual Studio subscribers. These benefits make cloud development very economical, for example:

- D12v2 VM list price = $470/month (4 core, 28 Gigs)
- D12v2 VM price if running on MSDN Azure subscription or any other dev/test subscription = $276/month
- Turn off 12 hours per day: 276/2 => $138/month
- Monthly credit (VS Professional with MSDN) => 138 - 50 = **$88/month**
- Monthly credit (VS Enterprise with MSDN) => 138 – 150 = **Free**

Here is another example:

- D13v2 machine list price = $843/month (8 core, 56 Gigs)
- D13v2 machine price if running on MSDN Azure subscription = $551/month
- Turn off 12 hours per day: 551/2 = $275.5/month
- Monthly credit (VS Professional with MSDN): 275.5 - 50 = **$225.5/month**
- Monthly credit (VS Enterprise with MSDN) => 275.5 – 150 = **$125.5/month**

Add an average of $15 monthly for storage (non premium) per VM.

Can more than one developer develop concurrently on the same VM?

This is not supported. However, you can provision more than one developer account on the same VM, they just cannot develop concurrently. For details, see Create new users on development machines.

If you are a Microsoft partner developing code for more than one customer, we recommend having at least one development VM per customer. You will need one additional VM for every additional developer working on a customer project. Development VMs can be thought of as disposable assets as long as your source code is checked into version control (Azure DevOps) and you keep a backup of test databases.

Customer implementation LCS projects

How many sandbox environments do I need within an LCS customer implementation project?

A customer subscription comes with three environments by default: a dev or build environment, a tier-2 sandbox environment, and a production environment. You can use the tier-2 sandbox environment as a configuration and a UAT environment before the application goes live in production. After configuring the sandbox with the code and data that you need to go live (also known as your *gold configuration*), you can run your validation on the same environment. When your validation passes, restore your sandbox database to the point in time of its gold configuration. You can then deploy your code to production and copy the sandbox database to your production environment. You can also choose to have more than one sandbox environment that is tier-2 or higher, especially after your application is live. One sandbox can be used as a pre-production UAT environment, and the other sandboxes can be used for configuration, upgrade or other scenarios. You can purchase additional tier-2 or higher sandboxes.

The following servicing requests and tools are supported by LCS, which may help you decide whether one tier-2 sandbox is sufficient for your implementation.

1. Restore a sandbox database to a point in time.
2. Copy a sandbox database to a production environment (only allowed before the application is live in production).
3. Apply configuration data packages on a sandbox environment.
4. Apply configuration data packages on a production environment.
5. Refresh a sandbox database from production. Copy the production environment's database to a tier-2 sandbox environment. This is typical after the application is live and you want to debug an issue or validate

upcoming updates.

6. Apply updates (Hotfixes, customizations) to a sandbox environments for validation before applying them to a production environment.

For more information about planning an environment, see Environment planning.

> **NOTE**
>
> Can you tell us about your documentation language preferences? Take a short survey.
>
> The survey will take about seven minutes. No personal data is collected (privacy statement).

Exclude test packages from build output

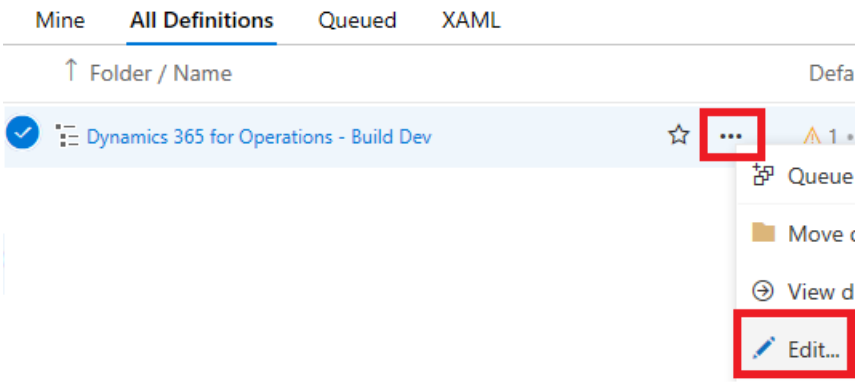
2/18/2021 • 2 minutes to read • Edit Online

In Platform update 4, the automated build process lets you prevent specific packages from being included in the deployable package in the build output. This capability can be important for customers that use automated testing. These customers might want to build and run their tests, but prevent them from being added to the deployable package that the build generates as output.

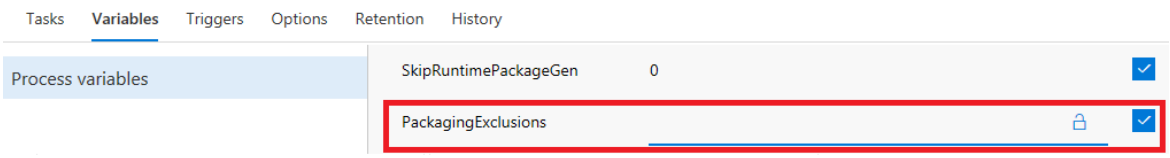
When customers that have an existing build definition from Platform update 3 or earlier upgrade, they won't see the build definition automatically updated. To use the new feature, these customers must make a few manual edits to the build definition (see below for details).

The new feature exposes a new optional parameter for the package creation step in the build process. Because this parameter is managed by a build variable, you can easily adjust it.

1. In Microsoft Azure DevOps, on the **Build & Release** page, under **Builds**, on the **All Definitions** tab, find your build definition. Click the ellipsis (...), and then click **Edit**.



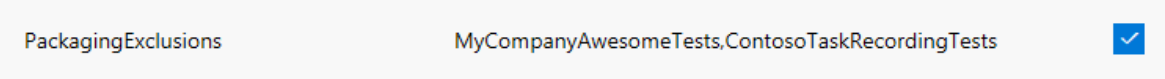
2. On the **Variables** tab, notice that the new build definition has a variable that is named **PackagingExclusions**.



3. In the **PackagingExclusions** variable, specify a comma-separated list of the names of packages that should not be packaged into the deployable package.

> **NOTE**
> The name of a package isn't necessarily the name of the model. Instead, the package name is typically the name of the folder where the model resides. Alternatively, you can copy and paste the package name from the descriptor file of one of the package's models. (In the XML, you can find the package name in the **ModelModule** field.)

   For example, you have one package that is named MyCompanysAwesomeTests and another package that is named ContosoTaskRecordingTests, and you want to exclude both these packages from the deployable package. In this case, the value for the **PackagingExclusions** variable will look like this.



After you complete this setup, the build process will still build the code and run any tests that the packages contain. However, the deployable package that the build creates won't include those packages.

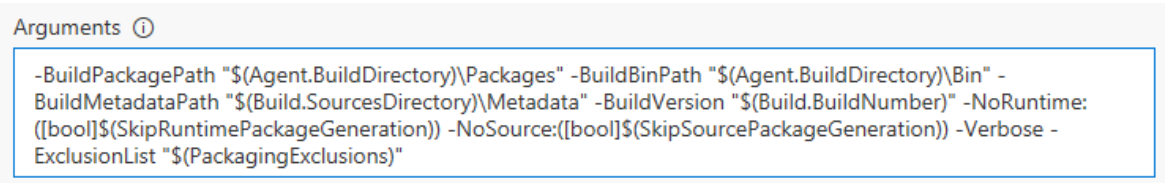
Update an existing build definition after upgrade to Platform update 4 or later

To use the new feature, you must manually update any existing build definitions that you deployed before Platform update 4.

> **NOTE**
> The feature can be added to a build definition only after you update the build virtual machine (VM) to Platform update 4 or later.

1. On the **Variables** tab, click **+ Add** at the bottom of the page.
2. In the **Name** column, enter **PackagingExclusions**. In the last column, select the **Settable at queue time** check box.
3. On the **Tasks** tab, find the **Generate Packages** task. Click to select it.
4. On the right side of the page, find the **Arguments** parameter. Click in the text box, and then press the End key or scroll to the end of the text box. The new build definition will have a new argument that passes the **PackagingExclusions** variable that you defined earlier. However, for an existing build definition, add a space and then the following text to the end of the parameter: **-ExclusionList "$(PackagingExclusions)"**

   The **Arguments** text box should now look like this.

5. Click **Save**.

You can now use the new feature as described.

> **NOTE**
> Can you tell us about your documentation language preferences? Take a short survey.
>
> The survey will take about seven minutes. No personal data is collected (privacy statement).

Manage third-party models and runtime packages by using source control

2/18/2021 • 4 minutes to read • Edit Online

Customers that work with solutions from third parties might receive different solution artifacts to use in their solution. Typically, these artifacts are distributed as code (in the form of models) or binaries (in the form of deployable packages). In some cases, third parties might provide some parts of their solution as code and other parts as a binary.

This topic outlines a recommended strategy for managing, distributing, and deploying these third-party solutions.

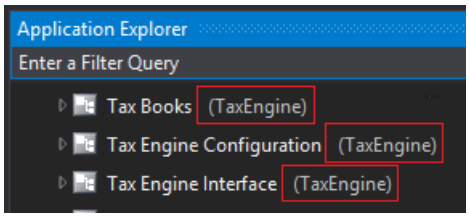
Models from third parties

Any source code that is received from third parties must be compiled into a binary and included in a deployable package. Models should be installed on a development virtual machine (VM) and added to source control. From there, the build VM can pick up the source code, build it, and include it in a deployable package. Other developers can just synchronize the model from Microsoft Azure DevOps to their development VMs. They don't have to manually install it.

For information about how to install a model on a development VM, see Export and import models.

After you install the model, follow these steps to add the new model to source control.

1. In Microsoft Visual Studio, on the **Dynamics 365** menu, click **Model Management** > **Refresh Models**.
2. Open Application Explorer by clicking **View** > **Application Explorer**.
3. Right-click the **AOT** root node, and then click **Model view**.
4. In the list of models, find the new model that you installed. Make a note of the name of the package that contains the model. The package name appears in parentheses after the model name. For example, in the following illustration, the **Tax Books**, **Tax Engine Configuration**, and **Tax Engine Interface** models all belong to the package that is named **TaxEngine**.



5. Open Source Control Explorer by clicking **View** > **Other Windows** > **Source Control Explorer**.
6. Navigate to the metadata folder that is mapped on this development VM, such as **MyProject/Trunk/Main/Metadata**.
7. In the metadata folder, find the folder for the package that contains the new model. Right-click the package folder, and then click **Add Items to Folder**.
8. In the **Add to Source Control** dialog box, select the **Descriptor** folder and the folder that has the name of the model. Some models may also contain referenced DLLs in the **bin** folder. If these exist you'll need to also include the approriate DLL files from the **bin** folder. Once all files have been selected, click **Next**.

9. Review the items that will be added, and then, when you're ready, click **Finish**.
10. Open the **Pending Changes** window from the **Team Explorer** pane or by clicking **View** > **Other Windows** > **Pending Changes**.
11. Review the changes, enter a check-in comment, and then click **Check In**.

Deployable packages from third parties

Deployable packages from third parties can be manually installed on a development VM, and the installed artifacts can then be added to source control. Then, by synchronizing their local workspace, other developers can receive the runtime package on their VMs without having to install the deployable package. The build process on the build VM will help guarantee that the runtime packages for any extensions or other dependencies are available on the build VM. In Platform update 6 and later, by default, these runtime packages will be included in the final deployable package that is created from the build VM. For more information, see the Deploying third-party code section later in this topic.

For information about how to install a deployable package on a development VM, see Install deployable packages from the command line.

> **NOTE**
> Don't install a software deployable package directly on the build VM. Use source control as described in this topic. Only binary updates should be installed on build VMs.

After you install the deployable package on a development VM, follow these steps to add the runtime package to source control.

1. Open Source Control Explorer by clicking **View** > **Other Windows** > **Source Control Explorer**.
2. Navigate to the metadata folder that is mapped on this development VM, such as **MyProject/Trunk/Main/Metadata**.
3. Right-click the **Metadata** folder, and then click **Add Items to Folder**.
4. In the **Add to Source Control** dialog box, double-click the folder that has the package name that you want to add to source control.
5. Select all the folders except **XppMetadata** and **Descriptor**, if they exist, and then click **Next**.
6. On the next page, on the **Excluded items** tab, select all files by clicking one of the files and then pressing Ctrl+A. At the bottom of the selection window, click **Include item(s)**. When you're ready, click **Finish**.
7. Open the **Pending Changes** window from the **Team Explorer** pane or by clicking **View** > **Other Windows** > **Pending Changes**.
8. Review the changes, enter a check-in comment, and then click **Check In**.

Deploying third-party code

Because the models and runtime packages are in source control, other developers who use other development environments can just synchronize the models and packages to their workspace by using the **Get latest** feature of source control.

As of Platform update 4, the automated build process will also pick up the runtime packages. Therefore, dependencies in packages that are built will be resolved correctly. This feature is also available for Platform update 3 and Platform update 2 through a hotfix.

In Platform update 6, the build process will include this runtime package in the final deployable package. This allows customers to take the deployable package from the build and have one package to deploy to their environments. The one package includes both custom solutions and all the third party solutions.

NOTE

Can you tell us about your documentation language preferences? Take a short survey.

The survey will take about seven minutes. No personal data is collected (privacy statement).

All-in-one deployable packages

2/18/2021 • 3 minutes to read • Edit Online

Customers can update the software in their environments by applying software deployable packages. These packages can originate from the customers themselves in the form of customizations. They can also be provided by partners and independent software vendors (ISVs). Microsoft recommends that customers combine all these various packages into a single package before they apply them to an environment. For customers who have self-service environments, this approach is a hard requirement.

This topic outlines the best practices for creating and managing an all-in-one deployable package.

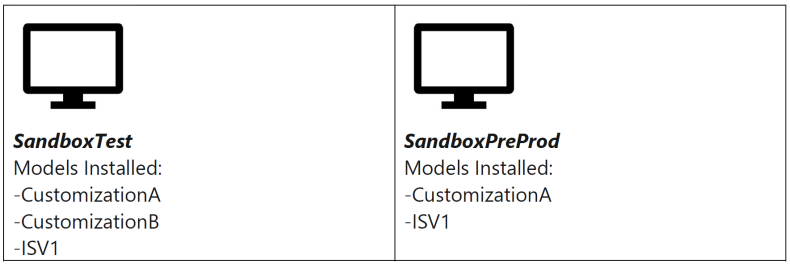
IMPORTANT

- The enforcement of all-in-one packages will be done in phases. Request to extend the support for deployable packages that are **not** all-in-one deployable packages will end October 31, 2020. The extension approval will be subject to valid justification.
- If a payment connector is currently deployed in your environment, you will have to create a payment connector package and include it in the all-in-one deployable package.
- If you currently use Microsoft Dynamics 365 Commerce functionality for the retail point of sale, you will also have to synchronize self-service installers.

What is an all-in-one deployable package?

An all-in-one deployable is a software deployable package that contains all the models and binaries that you currently have in an environment. Think of it as a single package that represents all the non-Microsoft software in an environment.

For example, you have two environments: **SandboxTest** and **SandboxPreProd**.



If your software deployable package contains CustomizationA, CustomizationB, and ISV1, it's a fully deployable package for the SandboxTest environment. This is because it exactly matches the model list. It's also a fully deployable package for the SandboxPreProd environment because it has all the models that are installed, plus CustomizationB.

However, if your software deployable package contains only CustomizationA, it isn't fully deployable for either environment. The package is missing some of the models that are already installed.

How do I create an all-in-one deployable package?

There are two primary methods for creating an all-in-one deployable package:

- If you're using the continuous integration/continuous deployment model, you're already creating all-in-one deployable packages.
- If you don't have a build environment, you can create a package in Microsoft Visual Studio. For more

information, see Create deployable packages of models.

What if my ISV packages don't contain source code?

ISVs can choose whether to share their source code with you. If they don't share it, they will provide a binary-only package. This package can easily be managed into an all-in-one deployable package. For instructions, see Manage third-party models and runtime packages by using source control.

How can I deploy ISV licenses?

ISVs can send license deployable packages to provide or update a license. However, for self-service environments licenses should also be included in an all-in-one deployable package. You can add a task to your build or release pipelines to add any licenses you have to a deployable package. For more information, see Add license files to a deployable package in Azure Pipelines.

Why are these packages important?

The best practice of using fully deployable packages helps reduce the complexity and number of packages that are applied to a given environment. In some circumstances, installation of different packages can change the behavior of your environment. For example, if you install ModelA and then ModelB instead of ModelB and then ModelA.

In addition, this approach is a hard requirement for self-service environments. This is because those environments use containerization technology and build a brand-new environment every time that you apply a package. If you apply ModelA today and then apply only ModelB tomorrow, you will effectively uninstall ModelA.

Update model versions in the automated build

2/18/2021 • 4 minutes to read • Edit Online

In Platform update 6, a new task in the automated build definition updates the models in the source package and deployable package of the build output with the version of the build that produced them.

Build definitions that were created before Platform update 6 must be manually updated to include this task. See the Updating an existing build definition section later in this topic.

Version numbers

Even though models are compiled into one package, the metadata information of all models is retained inside the binary package. This information can be reviewed from Microsoft Dynamics Lifecycle Services (LCS) or from the client.

In LCS, follow these steps to find the version numbers of models that are installed in an environment.

1. On the **Full details** page for the environment, under **Environment Version Information**, click the **View detailed version information** link.
2. On the **Installed updates** page, in the **Machine name** field, select an Application Object Server (AOS) computer.
3. In the table list, find the **Publisher name** field of the model, and expand the list by clicking the arrow icon. A full list of all models from that publisher is shown. The version number is shown in the **Version** column.

In the client, follow these steps to find the version numbers of models that are installed in an environment.

1. Open the URL for the environment, and sign in.
2. After the dashboard is loaded, click the gear symbol at the upper right of the page, and then click **About**.
3. In the dialog box that appears, expand **Loaded Packages and their Models**. Find the package where the model resides, and expand the list by clicking the arrow icon. The list of models for the package is shown, together with the version number.

All version numbers are in .NET assembly format. They consist of four numbers that are separated by a dot (.), such as **1.2.3.4**.

The purpose of model versioning

As code is updated, the build is used to produce new packages that can be deployed to environments. Microsoft Azure DevOps tracks the changes that have been included in each build since the previous build. When the version number of the build is included in the models that are produced, it provides end-to-end traceability of the code changes that are available in a specific environment. You can find the build number and then review the changes that are included in that build in Azure DevOps. For customers and partners that use builds on different branches, or that use different build definitions for nightly builds, gated check-in builds, or deployment builds, each build can have a different versioning scheme. This approach helps differentiate the model metadata in the deployable packages and tie them back to their originating build definition.

Setting up versioning

For build definitions that are created by Platform update 6 or newer deployments, the task to include build version in models is automatically added and active. The default build number of a new build definition in Azure DevOps consists of the year, month, and day, and the incremental number of the build for that day. For more

information about build numbers in Azure DevOps, and the options that are available, see Build definition options on the Microsoft Visual Studio docs site.

The automated build will apply the build version number to the models that are built.

Preventing models from being updated

By default, the build task assigns versions only to models that are in layers above the ISP layer. Therefore, customers can consume code models from third-party vendors without overwriting the version numbers that are supplied in their models. However, you can also prevent other models from having their version numbers overwritten during the build, regardless of layer. When you edit the build definition, on the **Variables** tab, in the **ModelVersionExclusions** variable, supply a comma-separated list of model names to exclude.

Updating models in lower layers

For third parties that develop solutions in the ISV or ISP layer, a manual change must be made to the build definition to automatically set model versions in those layers.

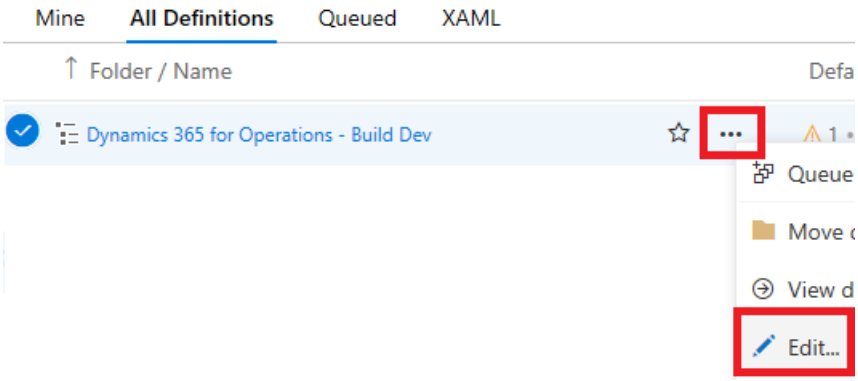
1. Edit the build definition. On the **Tasks** tab, click the **Set Model Versions** task.
2. In the **Arguments** field, add the following option at the end of the existing list of arguments: **-UpdateLayersAbove 7**

Updating an existing build definition

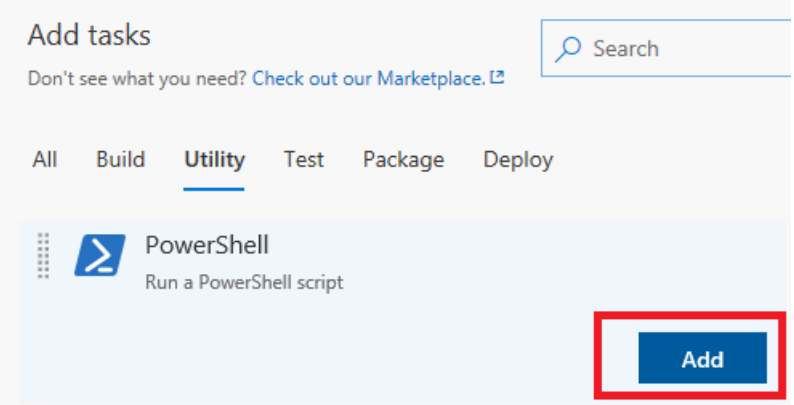
For build definitions that were created before Platform update 6, a new task must be manually added to the build definition.

> **NOTE**
> This feature can be added to a build definition only after the build virtual machine (VM) has been updated to Platform update 6 or later.

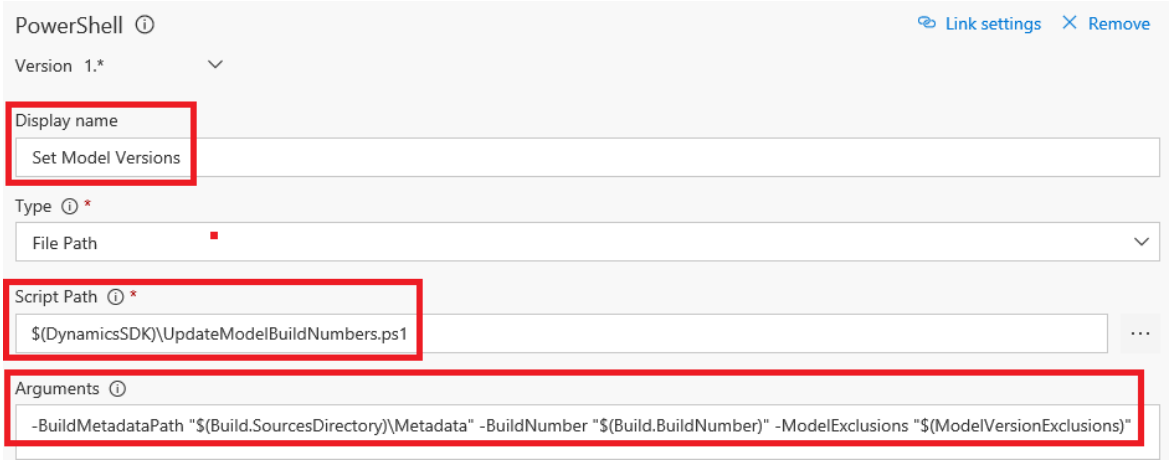
1. In Azure DevOps, on the **Build & Release** page, under **Builds**, on the **All Definitions** tab, find your build definition.
2. Click the ellipsis (...), and then click **Edit**.



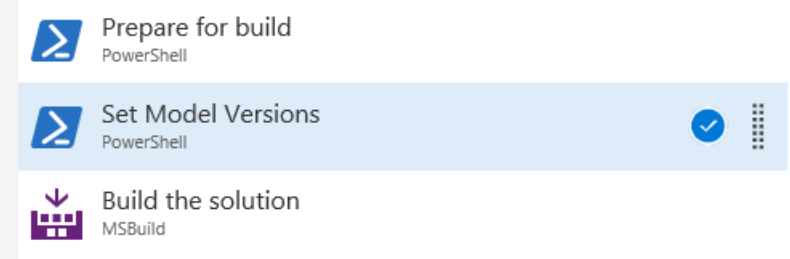
3. On the **Tasks** tab, click **+ Add Task** at the bottom of the page.
4. In the **Add tasks** pane on the right side of the page, on the **Utility** tab, scroll down to find the **PowerShell** task.
5. Hover the mouse pointer over the task, and click the **Add** button that appears.



6. In the list of tasks on the left side of the page, click to select the **PowerShell Script** task that is added.
7. On the right side of the page, change the **Display name**, **Script Path**, and **Arguments** properties to reflect the required settings.



8. In the list of tasks on the left side of the page, drag the **Set Model Versions** task so that it's between the **Prepare for build** and **Build the solution** tasks.



9. On the **Variables** tab, click **+ Add** at the bottom of the list of variables. In the first column, for the **Name** variable, enter **ModelVersionExclusions**.
10. Click **Save** to save the new task.

Choose a data integration strategy

2/18/2021 • 13 minutes to read • Edit Online

NOTE

Effective November 2020:

- Common Data Service has been renamed to Microsoft Dataverse. For more information, see Power Automate Blog.
- Some terminology in Microsoft Dataverse has been updated. For example, *entity* is now *table* and *field* is now *column*. For more information, see Terminology updates.

This topic will be updated soon to reflect the latest terminology.

This topic is intended to help architects and developers make sound design decisions when they implement integration scenarios.

The topic describes integration patterns, integration scenarios, and integration solutions and best practices. However, it doesn't include technical details about how to use or set up every integration pattern. It also doesn't include sample integration code.

NOTE

When providing guidance and discussing scenarios for choosing a pattern, data volume numbers are mentioned. These numbers must be used only to gauge the pattern and must not be considered as hard system limits. The absolute numbers will vary in real production environments due to various factors, configurations are only one aspect of this scenario.

The following table lists the integration patterns that are available.

PATTERN	DOCUMENTATION
Power Platform integration	Microsoft Power Platform integration with Finance and Operations apps
Dual-write	Dual-write overview
Classic data integration	Classic data integration overview
OData	Open Data Protocol (OData)
Batch data API	Recurring integrations Data management package REST API
Custom service	Custom service development
Consume external web services	Consume external web services
Excel integration	Office integration overview

NOTE

For on premise deployments, the only supported API is the Data management package REST API. This is currently available on 7.2, platform update 12 build 7.0.4709.41184.

Power platform integration

Finance and Operations is a virtual data source in Dataverse, and enables full create, read, update, delete (CRUD) operations from Dataverse and Microsoft Power Platform. By definition, the data for virtual entities doesn't reside in Dataverse. Instead, it continues to reside in Finance and Operations. To enable CRUD operations on Finance and Operations entities from Dataverse, entities must be made available as virtual entities in Dataverse. This allows CRUD operations to be performed, from Dataverse and Microsoft Power Platform, on data that resides in Finance and Operations apps. For detailed information, see Microsoft Power Platform integration.

Dual-write vs. classic data integration patterns vs. virtual entities

Dual-write provides synchronous, bi-directional, near-real time experience between model-driven applications in Dynamics 365 and Finance and Operations applications. Data synchronization happens with little or no intervention and is triggered by create, update and delete actions on an entity. Dual-write is suitable for interactive business scenarios that span across Dynamics 365 applications.

Classic data integration provides asynchronous and uni-directional data synchronization experience between customer engagement apps and Finance and Operations apps. It's an IT-administrator led experience and you must schedule the data sync jobs to run on a specific cadence. Classic data integration is suitable for business scenarios that involves bulk ingress/egress of data across Dynamics 365 applications.

PATTERN	TIMING	BATCH	TECHNOLOGY	FINANCE AND OPERATIONS APP	MODEL-DRIVEN APPS IN DYNAMICS 365
Dual-write	Synchronous Bi-directional	No	OData	Finance Supply Chain Commerce Service Industry CoreHR	Sales Marketing Customer Service Field Service Project Service Automation Talent
Classic data integration	Asynchronous, uni-directional	Yes	DIXF	Finance Supply Chain Commerce Service Industry CoreHR	Sales Marketing Customer Service Field Service Project Service Automation Talent

Virtual entities provide a mechanism to use Microsoft Power Platform with Finance and Operations without having to physically copy data to Dataverse. This guidance must be used to determine if the requirements will need dual-write or data integrator or virtual entities. Virtual entities and dual-write/data integrator are complementary technologies such that, they can be used together if required.

Synchronous vs. asynchronous integration patterns

Processing can be either synchronous or asynchronous. Often, the type of processing that you must use

determines the integration pattern that you choose.

A *synchronous* pattern is a blocking request and response pattern, where the caller is blocked until the callee has finished running and gives a response. An *asynchronous* pattern is a non-blocking pattern, where the caller submits the request and then continues without waiting for a response.

The following table lists the inbound integration patterns that are available.

PATTERN	TIMING	BATCH
OData	Synchronous	No
Batch data API	Asynchronous	Yes

Before you compare synchronous and asynchronous patterns, you should be aware that all the REST and SOAP integration application programming interfaces (APIs) can be invoked either synchronously or asynchronously.

The following examples illustrate this point. You can't assume that the caller will be blocked when the Open Data Protocol (OData) is used for integration. The caller might not be blocked, depending on how a call is made.

PATTERN	SYNCHRONOUS PROGRAMMING PARADIGM	ASYNCHRONOUS PROGRAMMING PARADIGM
OData	DbResourceContextSaveChanges	DbResourceContextSaveChangesAsync
Custom service	httpRequestGetResponse	httpRequestBeginGetResponse
SOAP	UserSessionServiceGetUserSessionInfo	UserSessionServiceGetUserSessionInfo Async
Batch data API	ImportFromPackage	BeginInvoke

Both OData and custom services are synchronous integration patterns, because when these APIs are called, business logic is immediately run. Here are some examples:

- If OData is used to insert product records, the records are immediately inserted as part of the OData call.
- If a custom service is used to look up on-hand inventory, business logic is immediately run as part of the JSON/SOAP call, and an inventory sum number is immediately returned.

Batch data APIs are considered asynchronous integration patterns, because when these APIs are called, data is imported or exported in batch mode. For example, calls to the ImportFromPackage API can be synchronous. However, the API schedules a batch job to import only a specific data package. The scheduling job is quickly returned, and the work is done later in a batch job. Therefore, batch data APIs are categorized as asynchronous.

Batch data APIs are designed to handle large-volume data imports and exports. It's difficult to define what exactly qualifies as a large volume. The answer depends on the entity, and on the amount of business logic that is run during import or export. However, here is a rule of thumb: If the volume is more than a few hundred thousand records, you should use the batch data API for integrations.

In general, when you're trying to choose an integration pattern, we recommend that you consider the following questions:

- Is there a business requirement that the integration should be in real time?
- What is the requirement for the peak data volume?
- What is the frequency?

Error handling

When you use a synchronous pattern, success or failure responses are returned to the caller. For example, when an OData call is used to insert sales orders, if a sales order line has a bad reference to a product that doesn't exist, the response that the caller receives contains an error message. The caller is responsible for handling any errors in the response.

When you use an asynchronous pattern, the caller receives an immediate response that indicates whether the scheduling call was successful. The caller is responsible for handling any errors in the response. After scheduling is done, the status of the data import or export isn't pushed to the caller. The caller must poll for the result of the corresponding import or export process, and must handle any errors accordingly.

Typical scenarios and patterns that use dual-write

Here are some typical scenarios that use dual-write.

Enable customer service representative to facilitate change of address for Finance and Operations customers

A customer relocates and wishes to change their billing and shipping address information. This customer contacts the customer support representative and requests a change of address. The customer support representative takes the call and changes the billing and shipping address information of the customer.

DECISION	INFORMATION
Is real-time data required?	Yes
Peak data volume	
Frequency	Ad hoc

Recommended solution

This scenario of near-real time data synchronization is best implemented by dual-write.

- The customer's information is sourced in a Finance and Operations app.
- A customer calls customer support and asks to change their billing and shipping address information.
- A customer support representative retrieves the customer’s record in Dynamics 365 Customer Service.
- The customer support representative updates the billing and shipping address and saves the data.
- The new billing and shipping address syncs back to the Finance and Operations app in real-time.

Sales representatives can change customer credit limits without logging into a Finance and Operations app

A customer has a credit limit of $2,000 and wants to increase it to $5,000. This customer calls the customer support and requests the increase. The ticket is assigned to the sales department. The head of sales reviews the request, checks the customer's payment history, and determines that the customer is eligible for an increased credit limit. The head of sales approves the request and responds to the ticket. The customer receives an email informing the approval of $5,000 credit limit.

DECISION	INFORMATION
Is real-time data required?	Yes
Peak data volume	
Frequency	Ad hoc

Recommended solution

This scenario is best implemented by dual-write.

- A customer calls customer support and wants to increase their credit limit from $2,000 to $5,000.
- A customer support representative creates a ticket in Dynamics 365 Customer Service.
- This ticket is assigned to the sales unit.
- A sales representative from the sales unit reviews and approves the request.
- This result is the increase of credit limit of the customer to $5,000 in Dynamics 365 Sales.
- The credit limit in the Finance and operations app is updated to $5,000.
- The sales representative responds to the ticket and resolves it.
- The customer receives an email about the increased credit limit.

Typical scenarios and patterns that use OData integrations

Here are some typical scenarios that use OData integrations.

> **NOTE**
> Use of OData for Power BI reports is discouraged. Using entity store for such scenarios is encouraged.

Create and update product information

A manufacturer defines and configures its product by using a third-party application that is hosted on-premises. This manufacturer wants to move its production information from the on-premises application to Finance and Operations. When a product is defined, or when it's changed in the on-premises application, the user should see the same change, in real time.

DECISION	INFORMATION
Is real-time data required?	Yes
Peak data volume	1,000 records per hour*
Frequency	Ad hoc

* Occasionally, many new or modified production configurations will occur in a short time.

Recommended solution

This scenario is best implemented by using the OData service endpoints to create and update product information in Finance and Operations.

In Finance and Operations:

- Determine all the entities that are required for the integration.
- Make sure that the OData service endpoints are available for the same set of entities.

In the third-party application:

- When product information is created or modified in the third-party application, an OData call is made to Finance and Operations to make the same change.

Read the status of customer orders

A company has a self-hosted customer portal where customers can check the status of their orders. Order status information is maintained in the application.

DECISION	INFORMATION
Is real-time data required?	Yes
Peak data volume	5,000 records per hour
Frequency	Ad hoc

Recommended solution

This scenario is best implemented by using the OData service endpoints to read order status information.

In Finance and Operations:

- Determine the entity that is required in order to read order status information.
- Make sure that the OData service endpoint is available for the entity.

On the customer portal site:

- When a customer checks the status of an order, make a real-time OData call to Finance and Operations to read the corresponding order and retrieve its status.

Approve BOMs

A company uses a product lifecycle management (PLM) system that is hosted on-premises. The PLM system has a workflow that sends the finished bill of materials (BOM) information to the application for approval.

DECISION	INFORMATION
Is real-time data required?	Yes
Peak data volume	1,000 records per hour
Frequency	Ad hoc

Recommended solution

This scenario can be implemented by using an OData action.

In Finance and Operations:

- Determine the entity that is required for the integration.
- Make sure that the OData service endpoints are available for the entity.
- On the entity, create an action to run the required business logic.

In the PLM solution:

- Make the PLM system invoke the OData action to approve the BOM.

> **NOTE**
> You can find an example of this type of OData action in **BOMBillOfMaterialsHeaderEntity::approve**.

Typical scenarios and patterns that use a custom service

Here are some typical scenarios that use a custom service.

Look up on-hand inventory

An energy company has field workers who schedule installation jobs for heaters. This company uses the application for the back office and third-party software as a service (SaaS) to schedule appointments. When field workers schedule appointments, they must look up inventory availability to make sure that installation parts are available for the job.

DECISION	INFORMATION
Is real-time data required?	Yes
Peak data volume	1,000 records per hour
Frequency	Ad hoc

Recommended solution

This scenario can be implemented by using a custom service.

In Finance and Operations:

- Create a custom service to calculate the physical on-hand inventory for a given item.

In the scheduling application:

- Make a real-time call to a custom service endpoint, through either SOAP or REST, to retrieve inventory information for the selected item.

> **NOTE**
> You can find an example of this type of custom service in the Retail Real Time Services implementation: **RetailTransactionServiceInventory::inventoryLookup**.

You can also use the inventorySiteOnHand entity to achieve the same result. Sometimes, you can use multiple methods to expose the same data and business logic, and all the methods are equally valid and effective. In this case, choose the method that works best for a given scenario and that a developer is most comfortable with.

Typical scenarios and patterns that use batch data integrations

Here are some typical scenarios that use batch data APIs.

Import large volumes of sales orders

A company receives a large volume of sales orders from a front-end system that runs on-premises. These orders must periodically be sent to the application for processing and management.

DECISION	INFORMATION
Is real-time data required?	No
Peak data volume	200,000 records per hour
Frequency	One time every five minutes

Recommended solution

This scenario is best implemented by using batch data APIs.

In Finance and Operations:

- Determine all the entities that are required for the integration.

- Make sure that data management is enabled for the entities.

In the on-premises system:

- Use the REST batch data API to import files.

Export large volumes of purchase orders

A company generates a large volume of purchase orders in Finance and Operations and uses an on-premises inventory management system to receive products. Purchase orders must be moved from Finance and Operations to the on-premises inventory system.

DECISION	INFORMATION
Is real-time data required?	No
Peak data volume	300,000 records per hour
Frequency	One time per hour

Recommended solution

This scenario is best implemented by using batch data APIs.

In Finance and Operations:

- Determine all the entities that are required for the integration.
- Make sure that data management is enabled for the entities.
- If incremental push is required, make sure that change tracking can be enabled on the entities.

In the on-premises inventory system:

- Use the REST batch data API to export the file from Finance and Operations and import it into the inventory system.

Typical scenarios and patterns that call external web services

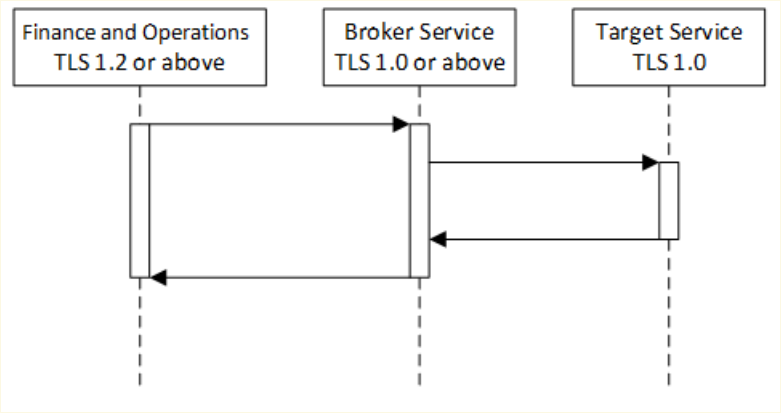
It's typical that the application calls out to an external web service that is hosted either on-premises or by another SaaS provider. In this case, the application acts as the integration client. When you write an integration client, you should follow the same set of best practices and guidelines that you follow when you write an integration client for any other application. For a simple example, see Consume external web services.

IMPORTANT

Because of security requirements, production and sandbox environments support only secured communication that uses Transport Layer Security (TLS) 1.2 or later. In other words, the target web service endpoint that the application calls out to must support TLS 1.2 or later. If the target service endpoint doesn't meet this requirement, calls fail. The exception error message resembles the following message:

Unable to read data from the transport connection: An existing connection was forcibly closed by the remote host.

If you can't modify the target service so that it uses TLS 1.2 or later, you can work around this issue by introducing a broker service and making a two-hop call, as shown in the following illustration.



NOTE

Can you tell us about your documentation language preferences? Take a short survey.

The survey will take about seven minutes. No personal data is collected (privacy statement).

Priority-based throttling

2/18/2021 • 3 minutes to read • Edit Online

NOTE

The functionality noted in this topic is available as part of a preview release. The content and the functionality are subject to change. To test this capability, configure integration priorities on the **Throttling priority mapping** page.

Priority-based throttling prevents the over-utilization of resources to preserve the system's responsiveness and ensure consistent availability and performance for environments running Dynamics 365 Finance and Operations apps.

- Integrations can be prioritized based on business-critical needs. Throttling honors these priorities.
- For OData and custom service requests, a429 error "Too many requests", will occur.
- You can query throttling events on the **Lifecycle Services Monitoring** page.

Priority-based throttling provides the ability to set priorities for OData and custom service-based integrations, depending on the business-critical need of integrations.

The **Integration priority** page is used to assign priorities for integrations so that priorities can be honored when requests are throttled.

Setting appropriate priorities ensures that low-priority integrations will be throttled before high-priority integrations, based on the integration. For more information about how to set up integration, see Enable connectivity with external services.

There are two kinds of applications are supported in Microsoft Azure Active Directory (Azure AD):

- User based - This flow uses a username and password for authentication and authorization.
- Azure AD app based - A confidential client is an application that can keep a client password confidential. The authorization server assigned this client password to the client application.

For more information, see Authentication.

Configure priorities for integrations

After you have registered your service in Azure AD and in your Finance and Operations apps, you can set up priorities for integrations.

NOTE

You must be assigned the System administrator or Integration priority manager role to complete the set up.

1. In Finance and Operations apps, go to**System administration** > **Setup** > **Throttling priority mapping**.
2. Select**New**.
3. In the**Authentication type**field, select **User** or **Azure AD application** based on your integration scenario.
4. If **Azure AD application type** is selected, in the**Client ID**field select the application that you registered in the Azure Active Directory application.
5. If **User type** is selected, in the**User ID**field select an appropriate service account user ID.
6. Assign the appropriate priority and then select **Save**.

Retry operations

When a request is throttled, the system provides a value indicating the duration before any new requests from the user can be processed. When a request is throttled and a 429 error occurs, the response header will include a**Retry-After** interval, which can be used to retry the request after a specific number of seconds. The following example shows this operation.

```
if (!response.IsSuccessStatusCode)
        {
            if ((int)response.StatusCode == 429)
            {
                int seconds = 30;
                //Try to use the Retry-After header value if it is returned.
                if (response.Headers.Contains("Retry-After"))
                {
                    seconds = int.Parse(response.Headers.GetValues("Retry-After").FirstOrDefault());
                }
                Thread.Sleep(TimeSpan.FromSeconds(seconds));

                // Retry sending the request.
            }
        }
```

Monitoring

To have a successful onboarding experience with the throttling capability, you must also be able to monitor your Odata and custom service integration patterns. Microsoft Dynamics Lifecycle Services (LCS), which is the administration center, contains a collection of monitoring and diagnostics tools that can help ensure that you have an accurate view of the environments you manage. For more details, see Monitoring and diagnostics tools in Lifecycle Services (LCS).

You can use a set of predefined queries to get raw logs for an issue. You can then export the logs for a more advanced analysis. The following types of queries are available:

- All throttling events
- Requests throttled

Access the Monitoring and diagnostics portal

1. In LCS, open the appropriate project.
2. In the **Environments** section, select the environment to view, and then select **Full details**.
3. On the **Environment details** page, select **Environment monitoring** to open the Monitoring and diagnostics portal.
4. On the **Environment monitoring** page, select the **Activity** tab to view the **Raw logs** page.
5. Select the **Query name**, and then select **All throttling events** for all Odata and custom services activities.
6. Select the **Query name**, and then select **Requests throttled** for all Odata and custom services requests that have been throttled.

Priority-based throttling FAQ

2/18/2021 • 2 minutes to read • Edit Online

IMPORTANT

Some or all of the functionality noted in this topic is available as part of a preview release. The content and the functionality are subject to change. For more information about preview releases, see Service update availability.

This topic provides answers to some frequently asked questions (FAQ) about priority-based throttling for Open Data Protocol (OData) and custom service-based integrations.

How do I access the Data management Yammer group?

Follow this link: Data management Yammer group.

Will a retry request receive preferential treatment over a new request?

No.

Is there a report that determines when throttling might occur?

Yes. A report will be provided and can be accessed through the **Raw logs** within environment monitoring page in Microsoft Dynamics Lifecycle Services (LCS).

Will throttling affect the Data Import/Export Framework (DIXF) and batch?

No. Throttling is only for OData and custom service integrations.

In Preview, will my requests be throttled if priorities aren't configured?

No, because only the telemetry is available. The actual throttling occurs if you configure priorities. We recommend that you use this approach in **non-production** environments during the Preview period.

What happens to requests if the user didn't retry a throttled request?

Currently, if a request isn't retried when a 429 error is received, the request won't be processed.

Will historic throttling information be used to advise me when I resize environments?

Yes. For one month, you can export the information to Excel for more analysis and archiving.

Is throttling functionality version-specific? If it is, which version is it available in?

Priority-based throttling will be available in Preview starting with the **Platform updates for version 10.0.13**

of Finance and Operations apps release.

Are there plans to provide an option for the Priority mapping grid entry?

Microsoft will consider this request in a future release.

Will the requests of my interactive users be throttled?

No. There will be no impact on the requests of interactive (online) users.

If I experience a performance issue in Dynamics 365 Finance while a page is being loaded or a business document is being processed, how does that performance issue differ from throttling?

Throttling helps maintain a healthy system when there is a resource constraint. It won't affect any page actions.

How can I determine the wait time before I retry a throttled request?

When a request is throttled, the response header includes a time that will be used in retry logic.

Do you recommend that I use a dedicated integration account instead of just the generic admin user account?

Yes, we recommend this approach. However, it isn't mandatory.

Does throttling depend on the tier that my environment is running on?

In the initial release, no. Throttling will calculate its threshold based on the resources that are available for each environment.

Is throttling functionality legal entity–specific?

No.

Does throttling affect bring your own database (BYOD) export?

No.

Will throttling monitoring be available in Application Insights?

Monitoring will be onboarded to any available tool in the future.

If a production environment regularly runs out of resources, will Microsoft have to resize it?

Yes. Sizing estimate will also have to be revalidated and uploaded.

After April 2021, will the system be able to override priority-based throttling?

The system will use default values if no priorities are configured after April 2021.

Can the throttling engine be configured (thresholds)?

No.

>
> The survey will take about seven minutes. No personal data is collected (privacy statement).

Data management package REST API

2/18/2021 • 10 minutes to read • Edit Online

This topic describes the Data management framework's package representational state transfer (REST) application programming interface (API). The package API lets you integrate by using data packages. The REST API can be used with both cloud deployments and on-premises deployments. For on-premises deployments, this functionality is currently available for Microsoft Dynamics 365 for Finance and Operations, Enterprise edition with platform update 12 (November 2017) (version 7.2), build 7.0.4709.41184, and later.

Although on-premises support has been added, API names haven't been changed. Therefore, Microsoft can keep a single API set for both cloud deployments and on-premises deployments.

Choosing an integration API

Two APIs support file-based integration scenarios: the Data management framework's package API and the recurring integrations API. Both APIs support both data import scenarios and data export scenarios. The following table describes the main decision points that you should consider when you're trying to decide which API to use.

DECISION POINT	RECURRING INTEGRATIONS API	DATA MANAGEMENT FRAMEWORK'S PACKAGE API
Scheduling	Scheduling in Finance and Operations apps	Scheduling outside Finance and Operations apps
Format	Files and data packages	Only data packages
Transformation	Support for Extensible Stylesheet Language Transformations (XSLT) if the data file is in XML format	Transformations that are external to the system
Supported protocols	SOAP and REST	REST
Service type	Custom service	Open Data Protocol (OData) action
Availability	Microsoft Dynamics Finance and Operations (February 2016) and later. Note: This is not supported with the on-premises version of Dynamics 365 Finance and Operations.	Microsoft Dynamics 365 for Finance and Operations with platform update 5 (March 2017) and later

If you decide that the recurring integrations API meets your requirement better than the Data management framework's package API, see Recurring integrations. The rest of this topic discusses the Data management framework's package API.

Authorization

The Data management framework's package API uses OAuth 2.0 to authorize access. The API must be called by using a valid OAuth access token. For more information about OAuth 2.0 and Microsoft Azure Active Directory (Azure AD), see Authorize access to web applications using OAuth 2.0 and Azure Active Directory. For on-premises deployments, Active Directory Federation Services (AD FS) is used for authorization.

NOTE

When you use the Client Credentials Grant flow, the application maintains an access control list. You can find the access control list at **System administration** > **Setup** > **Azure Active Directory applications**. The **Azure Active Directory applications** page shows the approved client IDs and the user security mapping that should be enforced when the API is called by using the Client Credentials Grant flow.

For on-premises deployments, this list must have a valid client ID from AD FS. Additionally, for on-premises use, **<baseurl>** in the following examples must append **/namespaces/AXSF** when a connection is made.

Import APIs

The following APIs are used to import files (data packages).

GetImportStagingErrorFileUrl

The GetImportStagingErrorFileUrl API is used to get the URL of the error file containing the input records that failed at the source to the staging step of import for a single entity. An empty string is returned if no error file is generated.

POST /data/DataManagementDefinitionGroups/Microsoft.Dynamics.DataEntities.GetImportStagingErrorFileUrl

```
Body
{
 "executionId":"<string>",
 "entityName":"<string>"
}

Successful Response:

HTTP/1.1 200 OK
{
 "@odata.context":"https://<baseurl>/data/$metadata#Edm.String",
 "value":"<errorfileurl>"
}
```

Input parameters

PARAMETER	DESCRIPTION
string executionId	Execution ID of import. This is called as Job ID in the UI.
string entityName	Name of the entity for which to get the error file.

Output parameters

PARAMETER	DESCRIPTION
string errorkeysfileurl	The URL of the error file. The return value is empty if an error file was not generated.

GenerateImportTargetErrorKeysFile

The GenerateImportTargetErrorKeysFile API is used to generate an error file containing the keys of the import records that failed at the staging to target step of import for a single entity.

If this API returns true, then use the GetImportTargetErrorKeysFileUrl API to get the URL of the generated error keys file.

POST
/data/DataManagementDefinitionGroups/Microsoft.Dynamics.DataEntities.GenerateImportTargetErrorKeysFile

```
Body

{
 "executionId":"<string>",
 "entityName":"<string>"
}

Successful Response:

HTTP/1.1 200 OK
{
 "@odata.context":"https://<baseurl>/data/$metadata#Edm.Boolean",
 "value": <errorsExist>
}
```

Input parameters

PARAMETER	DESCRIPTION
string executionId	Execution ID of import
string entityName	Name of the entity for which to get the error file

Output parameters

PARAMETER	DESCRIPTION
Boolean errorsExist	true if there are import errors; false if there are no errors

GetImportTargetErrorKeysFileUrl

The **GetImportTargetErrorKeysFileUrl** API is used to get the URL of the error file that contains the keys of the import records that failed at the staging-to-target step of import for a single entity.

If the error file is available, this API returns the URL. If the error file is still being generated, or if there is no error file, the API returns an empty string.

> **IMPORTANT**
> Before you call this API, call the **GenerateImportTargetErrorKeysFile** API to generate the error file. If the **GenerateImportTargetErrorKeysFile** API returns **true**, call this API in a loop until it returns a non-empty string. If the **GenerateImportTargetErrorKeysFile** API returns **false**, this API will always return an empty string, because there are no errors.

Pseudocode example

```
errorsExist = GenerateImportTargetErrorKeysFile(executionId, entityName)

if (errorsExist)
{
    errorFileUrl = null

    while (errorFileUrl is not a non-empty string)
    {
        errorFileUrl = GetImportTargetErrorKeysFileUrl(executionId, entityName)
        if (errorFileUrl is not a non-empty string)
        {
            wait for some time before retrying
        }
    }
}
```

```
POST
/data/DataManagementDefinitionGroups/Microsoft.Dynamics.DataEntities.GetImportTargetErrorKeysFileUrl

Body
{
    "executionId":"<string>",
    "entityName":"<string>"
}
```

Here is an example of a successful response.

```
HTTP/1.1 200 OK
{
    "@odata.context":"https://<baseurl>/data/$metadata#Edm.String",
    "value":"<errorkeysfileurl>"
}
```

Input parameters

PARAMETER	DESCRIPTION
string executionId	The execution ID of the import. This is called as Job ID in the UI.
string entityName	The name of the entity to get the error file for.

Output parameters

PARAMETER	DESCRIPTION
string errorkeysfileurl	The URL of the error keys file, if the file is available. If the error file is still being generated, or if no errors exist, the method returns an empty string.

GetAzureWritableUrl

The **GetAzureWritableUrl** API is used to get a writable blob URL. The method includes a shared access signature (SAS) token that is embedded in the URL. You can use this method to upload a data package to the Azure Blob storage container. For on-premises deployments, this API will still return the URL that has been abstracted to local storage.

NOTE

An SAS is valid only during an expiry time window. Any request that is issued after the window has passed returns an error. For more information, see Using shared access signatures (SAS).

```
POST /data/DataManagementDefinitionGroups/Microsoft.Dynamics.DataEntities.GetAzureWriteUrl
BODY
{
    "uniqueFileName":"<string>"
}
```

Here is an example of a successful response.

```
HTTP/1.1 200 OK
{
    "@odata.context":"https://<baseurl>/data/$metadata#Edm.String",
    "value": "{\"BlobId\":\"
{<GUID>}\",\"BlobUrl\":\"https://<baseurl_id>.blob.core.windows.net/dmf/<uniqueFileName>?<SAS Token>\"}"
    }
}
```

Input parameters

PARAMETER	DESCRIPTION
string uniqueFileName	A unique file name that is used to track blob IDs. You can include a globally unique identifier (GUID) to help guarantee a unique file name.

Output parameters

PARAMETER	DESCRIPTION
string BlobId	The blob ID of the allocated blob container.
string BlobUrl	A URL that has an embedded SAS token. The URL can be used to write to Blob storage.

ImportFromPackage

The **ImportFromPackage** API is used to initiate an import from the data package that is uploaded to the Blob storage that is associated with your implementation. For on-premises deployments, the import will be initiated from the local storage that the file was uploaded previously to.

NOTE

Starting in Platform update 12, the **ImportFromPackage** API supports composite entities. However, the limitation is that there can be only one composite entity in a package.

```
POST /data/DataManagementDefinitionGroups/Microsoft.Dynamics.DataEntities.ImportFromPackage
BODY
{
    "packageUrl":"<string>",
    "definitionGroupId":"<string>",
    "executionId":"<string>",
    "execute":<bool>,
    "overwrite":<bool>,
    "legalEntityId":"<string>"
}
```

Here is an example of a successful response.

```
HTTP/1.1 200 OK
{
    "@odata.context":"https://<baseurl>/data/$metadata#Edm.String",
    "value":"<executionId>"
}
```

Input parameters

PARAMETER	DESCRIPTION
string packageUrl	The URL of the data package in the Blob storage that is associated with a Finance and Operations app.
string definitionGroupId	The name of the data project for import.
string executionId	The ID to use for the job. This is called as Job ID in the UI. If an empty ID is assigned, a new execution ID will be created.
bool execute	Set this parameter to **True** to run the target step. Otherwise, set it to **False**.
bool overwrite	This parameter must always be set to **False** when a composite entity is used in a package. Otherwise, set it to **True**.
string legalEntityId	The legal entity for the data import.

Output parameters

PARAMETER	DESCRIPTION
string executionId	The execution ID of the data import. This is called as Job ID in the UI.

> **NOTE**
>
> **ImportFromPackage()** uses a batch to perform the import. Therefore, parallel processing rules must be used in Data management to perform parallel imports. **ImportFromPackage()** must not be called in parallel threads. Otherwise, it will fail.

Export APIs

The following APIs are used to export files (data packages).

ExportToPackage

The **ExportToPackage** API is used to initiate an export of a data package. This API is applicable to both cloud deployments and on-premises deployments.

- The export data project must be created before you call this API. If the project doesn't exist, a call to the API returns an error.
- If change tracking has been turned on, only records that have been created or updated since the last run are exported. (In other words, only the delta is returned.)

```
POST /data/DataManagementDefinitionGroups/Microsoft.Dynamics.DataEntities.ExportToPackage
BODY
{
    "definitionGroupId":"<Data project name>",
    "packageName":"<Name to use for downloaded file.>",
    "executionId":"<Execution Id if it is a rerun>",
    "reExecute":<bool>,
    "legalEntityId":"<Legal entity Id>"
}
```

Here is an example of a successful response.

```
HTTP/1.1 200 OK
{
    "@odata.context":"https://<baseurl>/data/$metadata#Edm.String",
    "value":{
        "value":"<executionId>"
    }
}
```

Input parameters

PARAMETER	DESCRIPTION
string definitionGroupId	The name of the data project for export.
string packageName	The name of the exported data package.
string executionId	The ID to use for the job. This is called as Job ID in the UI. If an empty ID is assigned, a new execution ID will be created.
bool reExecute	Set this parameter to **True** to run the target step. Otherwise, set it to **False**.
string legalEntityId	The legal entity for the data import.

Output parameters

PARAMETER	DESCRIPTION
string executionId	The execution ID of the data export. This is called as Job ID in the UI.

GetExportedPackageUrl

The **GetExportedPackageUrl** API is used to get the URL of the data package that was exported by a call to

ExportToPackage. This API is applicable to both cloud deployments and on-premises deployments.

```
POST /data/DataManagementDefinitionGroups/Microsoft.Dynamics.DataEntities.GetExportedPackageUrl
BODY
{"executionId":"<Execution Id>"}
```

Here is an example of a successful response.

```
HTTP/1.1 200 OK
{
    "@odata.context":"https://<baseurl>/data/$metadata#Edm.String",
    "value":{
        "value":"https://<baseurl_id>.blob.core.windows.net/dmf/<uniqueFileName>?<SAS Token>"
    }
}
```

Input parameters

PARAMETER	DESCRIPTION
string executionId	The execution ID of the data project run. This is called as Job ID in the UI.

Output parameters

PARAMETER	DESCRIPTION
string BlobUrl	A blob URL that has an embedded SAS token. The URL can be used to download the exported data package.

Status check API

The following APIs are used to check status. They are used during both import flows and export flows.

GetExecutionSummaryStatus

The **GetExecutionSummaryStatus** API is used for both import jobs and export jobs. It's used to check the status of a data project execution job. This API is applicable to both cloud deployments and on-premises deployments.

```
POST /data/DataManagementDefinitionGroups/Microsoft.Dynamics.DataEntities.GetExecutionSummaryStatus
BODY
{"executionId":"<executionId>"}
```

Here is an example of a successful response.

```
HTTP/1.1 200 OK
{
    "@odata.context":"https://<baseurl>/data/$metadata#Edm.String",
    "value":"<executionStatus>"
}
```

Input parameters

PARAMETER	DESCRIPTION
string executionId	The execution ID of the data project run. This is called as Job ID in the UI.

Output parameters

PARAMETER	DESCRIPTION
DMFExecutionSummaryStatus executionStatus	The execution status. Here are the possible values: • Unknown • NotRun • Executing • Succeeded • PartiallySucceeded • Failed • Canceled

> **NOTE**
> The file in Blob storage will remain there for seven days. It will then be automatically deleted.

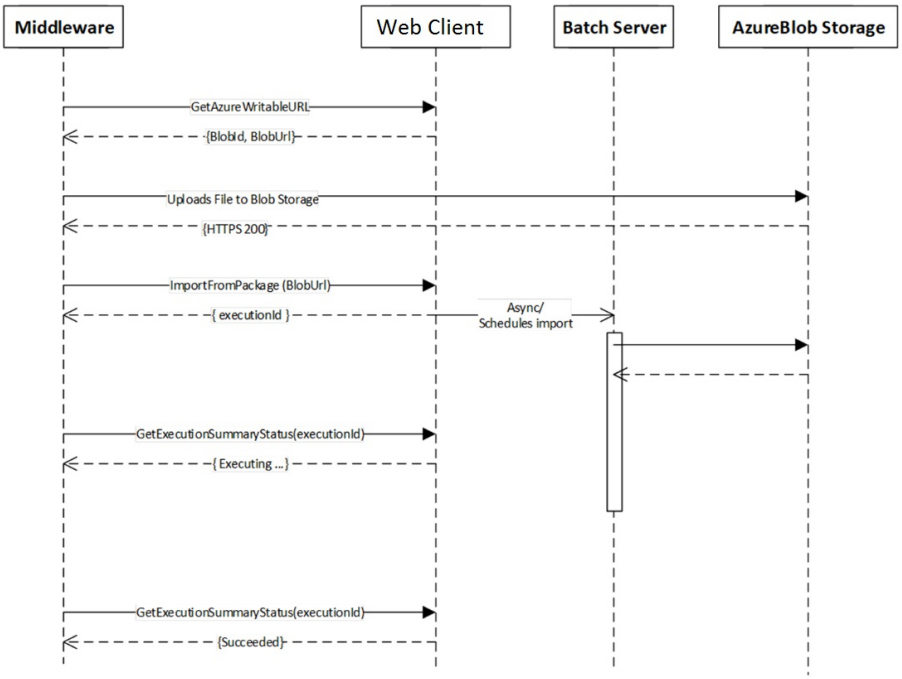
Getting the list of errors

GetExecutionErrors can be used to get the list of errors in a job execution. The API takes the Execution ID as the parameter, and returns a set of error messages in a JSON list.

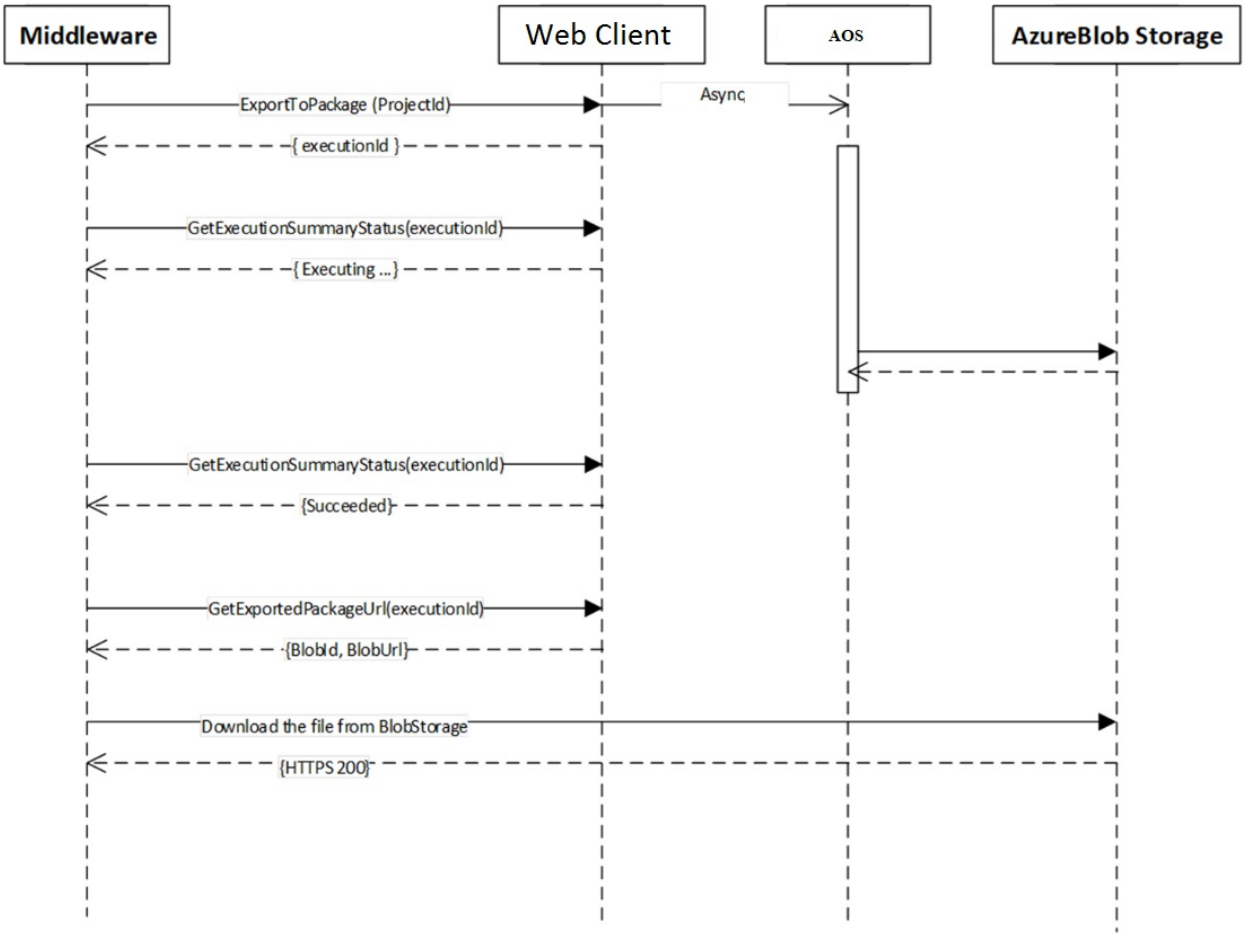
```
POST /data/DataManagementDefinitionGroups/Microsoft.Dynamics.DataEntities.GetExecutionErrors
BODY
{"executionId":"<executionId>"}
```

Import and export processes

The following illustration shows how the Data management package methods can be used to import data packages.



The following illustration shows how the Data management package methods can be used to export data packages.



A sample console application that showcases the data import and data export methods is available on GitHub. For more information, go to https://github.com/Microsoft/Dynamics-AX-Integration/tree/master/FileBasedIntegrationSamples/ConsoleAppSamples.

NOTE

Can you tell us about your documentation language preferences? Take a short survey.

The survey will take about seven minutes. No personal data is collected (privacy statement).

Service endpoints overview

2/18/2021 • 4 minutes to read • Edit Online

This topic describes the service endpoints that are available in Microsoft Dynamics 365 Finance. It also provides a comparison to the endpoints that are available in Microsoft Dynamics AX 2012.

List of services

The following table lists all the service endpoints, and compares the endpoints available for the application, and AX 2012.

SERVICE ENDPOINT	AX 2012	FINANCE AND OPERATIONS
Document services (AXDs)	Yes	No – Replaced by data entities
SOAP-based metadata service	Yes	No – Replaced by REST metadata
SOAP-based query service	Yes	No – Replaced by OData
OData query service	Yes	No – Replaced by OData
SOAP-based custom service	Yes	Yes
JSON-based custom service	No	Yes
OData Service	No	Yes
REST Metadata Service	No	Yes

This topic describes authentication for services, and the REST Metadata service. The following links provide detailed documentation for:

- Custom service development
- Open Data Protocol (OData)

Authentication

OData services, JSON-based custom services, and the REST metadata service support standard OAuth 2.0 authentication.

We currently support both Authorization Code Grant flow and Service to service calls using client credentials (shared secret or certificate).

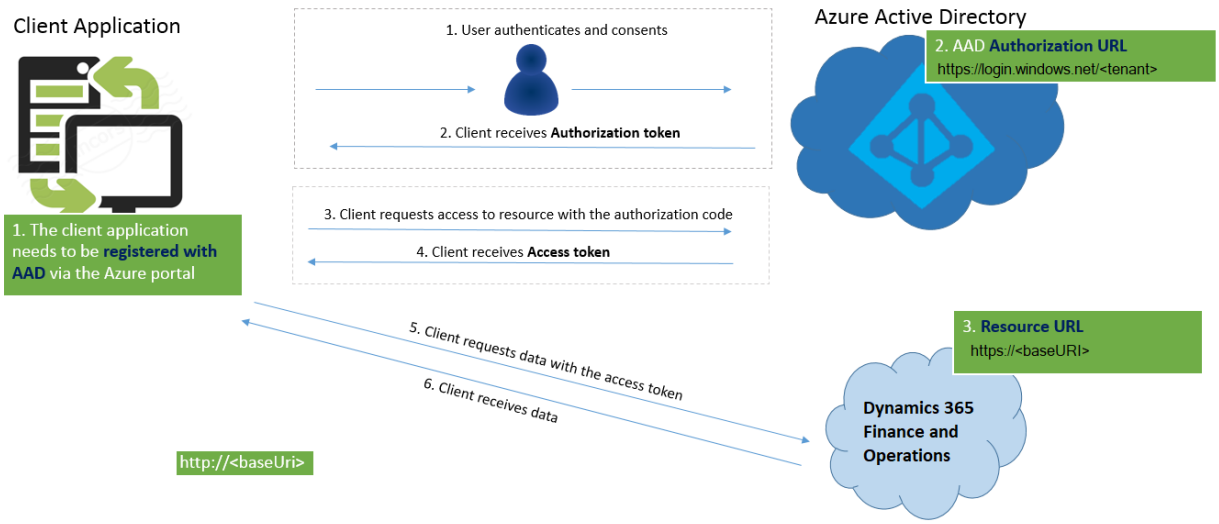
Two kinds of application are supported in Microsoft Azure Active Directory (AAD):

- **Native client application** – This flow uses a user name and password for authentication and authorization.
- **Web application (Confidential client)** – A confidential client is an application that can keep a client password confidential to the world. The authorization server assigned this client password to the client application.

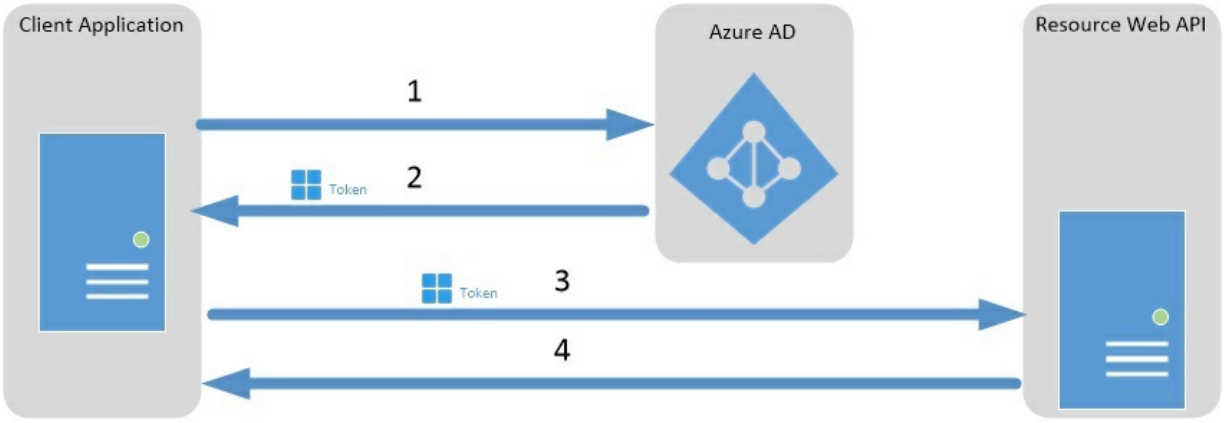
For more information, see:

- Authorize access to web applications using OAuth 2.0 and Azure Active Directory
- Troubleshoot service authentication issues

The following illustration describes how authorization must be configured for Authorization code grant flow.



And below is the illustration describes how authorization works for Service to service calls using client credentials (shared secret or certificate).



Register a web application with AAD

> **NOTE**
> These steps don't have to be completed by all the people in your organization. Only one Azure Service Administrator user can add the application and share the client ID with the developers.

Prerequisite: You must have an Azure subscription and admin access to Azure Active Directory (Azure AD).

Before any clients can communicate with the services, they must be registered in (Azure AD). These steps will help you register an application with (Azure AD). The steps are explained in the Azure app registration training guide. For specific configuration in this process, the following additional information must be used in context.

Select **Microsoft Dynamics ERP (Microsoft.ERP)**. If you search for **Microsoft Dynamics ERP** in the search field within **Select an API** it might appear to be unavailable. In that case, make sure that you search for the full name, as shown above. Under **Delegated permissions**, you must select, at a minimum, the following options:

- Access Dynamics AX Custom Service
- Access Dynamics AX data

- Access Dynamics AX online as organization users

> **IMPORTANT**
> Make sure that you copy the key, because you won't see it again. You will be required to know this secret key to complete your OAuth authentication and receive an Azure AD token.

Register your external application

1. In Finance and Operations apps, go to **System administration** > **Setup** > **Azure Active Directory applications**.
2. Select **New**.
3. Fill in the fields for the new record:
   - In the **Client Id** field, enter the application ID that you registered in Azure AD.
   - In the **Name** field, enter a name for the application.
   - In the **User ID** field, select an appropriate service account user ID. For this example, we have selected the **Admin** user. However, as a better practice, you should provision a dedicated service account that has the correct permissions for the operations that must be performed.

   When you've finished, select **Save**.

You've now finished setting up the prerequisites. After the external application retrieves an Azure AD authentication token, it should now be able to use the token in an authorization HTTP header to make subsequent service calls via OData or SOAP, for example.

Client sample code

The following is C# sample code for getting a token from AAD. In this flow, the user will be presented with a consent form (for cross-tenant application) and a sign-in form.

```
UriBuilder uri = new UriBuilder ("https://login.windows.net/contoso2ax.onmicrosoft.com");

AuthenticationContext authenticationContext = new AuthenticationContext(uri.ToString());

//request token for the resource - which is the URI for your organization. NOTE: Important do not add a
trailing slash at the end of the URI
AuthenticationResult authenticationResult =
authenticationContext.AcquireToken("https://axdynamics1001aos.cloud.dynamics.com", clientId, redirectURI);

//this gets the authorization token, which needs to be passed in the Header of the HTTP Requests
string authenticationHeader = authenticationResult.CreateAuthorizationHeader();
```

To pass the user name and password without showing a pop-up, you can use the following overload of **AcquireToken**.

```
UserCredential userCred = new UserCredential (username, password);
authenticationContext.AcquireToken("https://axdynamics1001aos.cloud.dynamics.com", clientId, userCred);
```

REST metadata service

The REST metadata service is a read-only service. In other words, users can make only GET requests. The main purpose of this endpoint is to provide metadata information for elements. It is an OData implementation.

This endpoint is hosted at `http://\[baseURI\]/Metadata`.

Currently, this endpoint provides metadata for the following elements:

- **Labels** – Returns labels from the system. Labels have a dual pair key of language and ID, so that you can retrieve the value of the label.

  Example: `https://[baseURI\]/metadata/Labels(Id='@SVC\_ODataLabelFile:Label1',Language='en-us')`

- **Data entities** – Returns a JSON-formatted list of all the data entities in the system.

  Example: `https://[baseURI\]/Metadata/DataEntities`

> **NOTE**
>
> Can you tell us about your documentation language preferences? Take a short survey.
>
> The survey will take about seven minutes. No personal data is collected (privacy statement).

Troubleshoot service authentication issues

2/18/2021 • 2 minutes to read • Edit Online

This topic provides some tips for troubleshooting issues that involve service authentication.

When you troubleshoot service authentication issues, there are a few basic and common procedures that can help resolve the issues that are most often encountered. These procedures also provide a hands-on demonstration of how the authentication mechanism works. This topic includes instructions and also lists a few common issues that users have encountered so far.

Inspect the JWT

Capture the JWT from an HTTP request

1. Download Fiddler from https://www.telerik.com/fiddler.
2. Set up HTTPS capture to watch the HTTPS traffic from the client.
3. Find the Open Authorization (OAuth) JSON Web Token (JWT). It's the value of the HTTP "Authorization" header without the "bearer" segment.

Use a deserializer tool to look at the token contents

1. Go to https://jwt.io, and paste the JWT into the input panel.
2. View the contents in the form of name-value pairs. See the example that follows.
3. Verify that the following information is correct:

   - **"aud"** – The value corresponds to the Microsoft Azure Active Directory (Azure AD) resource concept. Here are some typical issues that involve "aud":
     - The **"aud"** segment of the JWT contains a URI that has a trailing slash.
     - The **"aud"** segment of the JWT contains a URI that uses an incorrect capitalization style. The URI must be all lowercase.
   - **"appid"** – The value corresponds to the Azure AD Native Client App ID (or Service App ID).
   - **"upn"** – The value corresponds to the user who is being authenticated through a Native Client App.

The following illustration shows an example of the contents of the JWT.

```
{
  "aud":
"https://usnconeboxax1aos.cloud.onebox.dynamics.com",
  "iss": "https://sts.windows-ppe.net/4dbfcf74-c5a6-4727-
b638-d56e51d1f381/",
  "iat": 1464816034,
  "nbf": 1464816034,
  "exp": 1464819934,
  "acr": "1",
  "amr": [
    "pwd"
  ],
  "appid": "d8a9a121-b463-41f6-a86c-041272bdb340",
  "appidacr": "0",
  "family_name": "User 1",
  "given_name": "Test",
  "ipaddr": "131.107.174.200",
  "name": "Test User 1",
  "oid": "b45cc6d9-e4b7-42bf-b75d-3482ada55655",
  "puid": "100300008AC14B8D",
  "scp": "user_impersonation",
  "sub": "n6IT5RzrSP1_5kqlsYMZS4nXSZxitgh_UJOLdtc9Sd0",
  "tid": "4dbfcf74-c5a6-4727-b638-d56e51d1f381",
  "unique_name": "tusr1@taeofficial.ccsctp.net",
  "upn": "tusr1@taeofficial.ccsctp.net",
  "ver": "1.0"
}
```

Review the event logs

You can also look at the event logs of the instance machine, if you have access to the virtual machine (VM).

1. Start Event Viewer by running the **eventvwr** command from the **Run** window.
2. Go to the following channels:
   - Application and Services Logs > Microsoft > Dynamics > AX-IntegrationServices > Channel:Operational (Microsoft-Dynamics-AX-IntegrationServices/Operational)
   - Application and Services Logs > Microsoft > Dynamics > AX-SystemRuntime > Channel:Operational (Microsoft-Dynamics-AX-SystemRuntime/Operational)

Other approaches

- For more information about how OAuth is configured, see Service endpoints overview.
- You can also try to call the service in parallel by using your own client code. The sample code that we published is available at https://github.com/Microsoft/Dynamics-AX-Integration.
- If the second method works, you can compare the JWTs from each method.

Known issues

AADSTS65001: The user or administrator hasn't consented to use the application

- The **"aud"** segment of the JWT might contain a URI that has a trailing slash. The slash must be removed.
- The **"aud"** segment of the JWT might contain a URI that uses an incorrect capitalization style. The URI must be all lowercase.

NOTE

Can you tell us about your documentation language preferences? Take a short survey.

The survey will take about seven minutes. No personal data is collected (privacy statement).

Open Data Protocol (OData)

2/18/2021 • 8 minutes to read • Edit Online

This topic provides information about Open Data Protocol (OData) and explains how you can use OData V4 to expose updatable views.

What is OData?

OData is a standard protocol for creating and consuming data. The purpose of OData is to provide a protocol that is based on Representational State Transfer (REST) for create, read, update, and delete (CRUD) operations. OData applies web technologies such as HTTP and JavaScript Object Notation (JSON) to provide access to information from various programs. OData provides the following benefits:

- It lets developers interact with data by using RESTful web services.
- It provides a simple and uniform way to share data in a discoverable manner.
- It enables broad integration across products.
- It enables integration by using the HTTP protocol stack.

For more information about OData, see the following webpages.

TOPIC	WEBPAGE
OData standards	https://www.odata.org/documentation/
OData: Data access for the web, the cloud, mobile devices, and more	/aspnet/web-api/overview/odata-support-in-aspnet-web-api/

The public OData service endpoint enables access to data in a consistent manner across a broad range of clients. To see a list of all the entities that are exposed, open the OData service root URL. The URL for the service root on your system has the following format: **[Your organization's root URL]/data**

> **NOTE**
> OData actions added via extensions are currently not supported.

Addressing

The following table describes the resources and the corresponding URLs in the Fleet Management sample.

RESOURCE	URL	DESCRIPTION
Service endpoint	[Your organization's root URL]/data/	The root service endpoint for OData entities
Entity collection	[Your organization's root URL]/data/Customers	The collection of all customers
Entity	[Your organization's root URL]/data/Customers("[key]")	A single entity from the entity collection

RESOURCE	URL	DESCRIPTION
Navigation property	[Your organization's root URL]/data/Customers("[key]")/Reservations	The navigation from a customer to that customer's reservations
Property	[Your organization's root URL]/data/Customers("[key]")/FirstName	The customer's first name

OData services

We provide an OData REST endpoint. This endpoint exposes all the data entities that are marked as **IsPublic** in the Application Object Tree (AOT). It supports complete CRUD (create, retrieve, update, and delete) functionality that users can use to insert and retrieve data from the system. Detailed labs for this feature are on the LCS methodology.

> **NOTE**
> When working with data entities using OData, all fields in the entity key must be provided to make a successful OData call.

Code examples for consuming OData services are available in the Microsoft Dynamics AX Integration GitHub repository.

Supported features from the OData specification

The following are the high-level features that are enabled for the OData service, per the OData specification.

- CRUD support is handled through HTTP verb support for POST, PATCH, PUT, and DELETE.
- Available query options are:
  - $filter
  - $count
  - $orderby
  - $skip
  - $top
  - $expand (only first-level expansion is supported)
  - $select
- The OData service supports serving driven paging with a maximum page size of 10,000.

For more information, see: OData actions that are bound to entities.

Filter details

There are built-in operators for $filter:

- Equals (eq)
- Not equals (ne)
- Greater than (gt)
- Greater than or equal (ge)
- Less than (lt)
- Less than or equal (le)
- And

- Or
- Not
- Addition (add)
- Subtraction (sub)
- Multiplication (mul)
- Division (div)
- Decimal division (divby)
- Modulo (mod)
- Precedence grouping ({ })

You can also use the **Contains** option with $filter requests. It has been implemented as a wildcard character. For example: `http://host/service/EntitySet?$filter=StringField eq '\*retail\*'`

The operators 'has' and 'in' are not supported.

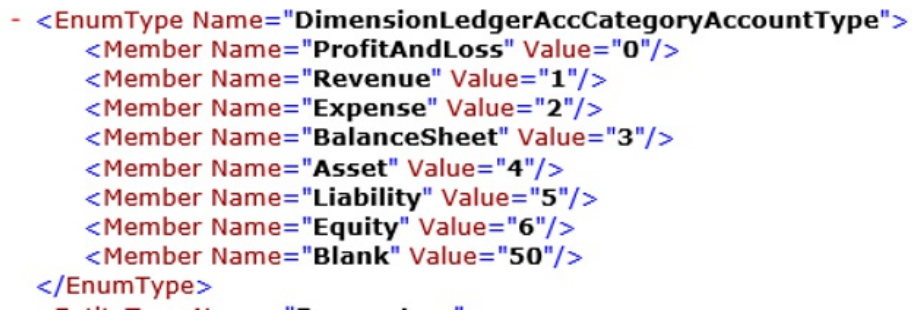
For more information, see OData operators.

Batch requests

Batch requests are supported in the OData service. For more information, see OData batch requests.

Metadata annotations

/data/$metadata provides annotations. EnumType is support in $metadata.



Cross-company behavior

By default, OData returns only data that belongs to the user's default company. To see data from outside the user's default company, specify the **?cross-company=true** query option. This option will return data from all companies that the user has access to.

Example: `http://[baseURI\]/data/FleetCustomers?cross-company=true`

To filter by a particular company that isn't your default company, use the following syntax:

```
http://[baseURI\]/data/FleetCustomers?$filter=dataAreaId eq 'usrt'&cross-company=true
```

Validate methods

The following table summarizes the validate methods that the OData stack calls implicitly on the corresponding data entity.

ODATA	METHODS (LISTED IN THE ORDER IN WHICH THEY ARE CALLED)

ODATA	METHODS (LISTED IN THE ORDER IN WHICH THEY ARE CALLED)
Create	1. **Clear()** 2. **Initvalue()** 3. **PropertyInfo.SetValue()** for all specified fields in the request 4. **Validatefield()** 5. **Defaultrow** 6. **Validatewrite()** 7. **Write()**
Update	1. **Forupdate()** 2. **Reread()** 3. **Clear()** 4. **Initvalue()** 5. **PropertyInfo.SetValue()** for all specified fields in the request 6. **Validatefield()** 7. **Defaultrow()** 8. **Validatewrite()** 9. **Write()**
Delete	1. **Forupdate()** 2. **Reread()** 3. **checkRestrictedDeleteActions()** 4. **Validatedelete()** 5. **Delete()**

Exposing OData entities

OData entities are based on the concept of an updatable view. When the **IsPublic** property for an updatable view is set to **TRUE**, that view is exposed as a top-level OData entity.

Setting navigation properties between OData entities

Links between OData entities are described by a navigation property. Navigation properties describe the navigation from one end of an association to the other end.

Adding actions on OData entities

Actions let you inject behaviors into the data model. To add actions, add a method to the updatable view, and decorate that method with specific attributes. Here is an example.

```
[SysODataActionAttribute("CalcMaintenanceDuration", true)]
public int CalculateMaintenanceDuration()
{
    //do something
    return 0;
}
```

In this example, the **SysODataActionAttribute** class decorates the **CalculateMaintenanceDuration** method that is exposed as an action. The first argument of the attribute is the publicly exposed name of the action, and the second argument indicates whether this action is always available. Methods that are exposed as actions can return any primitive type or another public updatable view. After this method is exposed, it appears in the OData

$metadata. Here is an example.

```
<Action Name="CalcMaintenanceDuration" IsBound="true">
    <Parameter Name="ViewMaintenance" Type="Microsoft.Dynamics.AX.Resources.ViewMaintenance"/>
    <ReturnType Type="Edm.String" />
</Action>
```

The following example of an OData action takes in a parameter and returns a list.

```
[SysODataActionAttribute("GetColors", true),
    SysODataCollectionAttribute("return", Types::Record, "CarColor")]
public List GetColorsByAvailability(boolean onlyAvailableVehicles)
{
    List returnList = new List(Types::Record);
    // do something
    return returnList;
}
```

In this example, the **SysODataCollectionAttribute** class enables OData to expose strongly typed collections from X++. This class takes in three parameters:

- The name of the parameter that is a list (Use **return** for the return value of the method.)
- The X++ type of the members of this list
- The public name of the OData resource that is contained in the collection

After these actions are exposed, they can be invoked from the service root URL.

You can find actions that are defined on data entities by searching for the **SysODataActionAttribute** attribute in the source code.

Querying or browsing an OData endpoint

OData enables an SQL-like language that lets you create rich queries against the database, so that the results include only the data items that you want. To create a query, append criteria to the resource path. For example, you can query the **Customers** entity collection by appending the following query options in your browser.

URL	DESCRIPTION
[Your organization's root URL]/data/Customers	List all the customers.
[Your organization's root URL]/data/Customers?$top=3	List the first three records.
[Your organization's root URL]/data/Customers?$select=FirstName,LastName	List all the customers, but show only the first name and last name properties.
[Your organization's root URL]/data/Customers?$format=json	List all the customers in a JSON format that can be used to interact with JavaScript clients.

The OData protocol supports many similar filtering and querying options on entities. For the full set of query options, see Windows Communication Foundation.

Using Enums

Enums are under namespace **Microsoft.Dynamics.DataEntities**. Enums can be included in an OData query is by using the following syntax.

`Microsoft.Dynamics.DataEntities.Gender'Unknown'`

`Microsoft.Dynamics.DataEntities.NoYes'Yes'`

An example query for using the above enum values is shown below.

```
https://environment.cloud.onebox.dynamics.com/data/CustomersV3?\$filter=PersonGender eq
Microsoft.Dynamics.DataEntities.Gender'Unknown'
```

```
https://environment.cloud.onebox.dynamics.com/data/Currencies?\$filter=ReferenceCurrencyForTriangulation eq
Microsoft.Dynamics.DataEntities.NoYes'No'
```

The operations supported for enums are **eq** and **ne**.

Authentication

OData sits on the same authentication stack as the server. For more information about the authentication, see Service endpoints overview.

Tips and tricks

Run multiple requests in a single transaction

The OData batch framework uses *changesets*. Each changeset contains a list of requests that should be treated as single atomic unit. In other words, either all the requests are run successfully or, if any request fails, none of the requests are run successfully. The following example shows how to send a batch request that has a list of requests in a single changeset.

The **SaveChangesOptions.BatchWithSingleChangeset** option in **SaveChanges()** helps guarantee that all requests are bundled into a single changeset.

```
public static void CreateProductColors(Resources context)
{
    var productColorsCollection = new DataServiceCollection<ProductColor>(context);

    var color1 = new ProductColor();
    productColorsCollection.Add(color);
    color1.ColorId = "New Color1"; // set any other properties needed

    var color2 = new ProductColor();
    productColorsCollection.Add(color1);
    color2.ColorId = "New Color2"; // set any other properties needed

    context.SaveChanges(SaveChangesOptions.BatchWithSingleChangeset);
}
```

Prevent unset records from being posted when you use an OData client

When you create a new record by using an OData client, as shown in example 1, properties that aren't set are included in the body of the request, and default values are assigned to them. To prevent this behavior and post only properties that are set explicitly, use the **SaveChangesOptions.PostOnlySetProperties** option in **SaveChanges()**, as shown in example 2.

Example 1

```
public static void CreateVendor(Resources context)
{
    var vendorCollection = new DataServiceCollection<Vendor>(context);
    var vendor = new Vendor();
    vendorCollection.Add(vendor);
    // set properties
    context.SaveChanges();
}
```

Example 2

```
public static void CreateVendor(Resources context)
{
    var vendorCollection = new DataServiceCollection<Vendor>(context);
    var vendor = new Vendor();
    vendorCollection.Add(vendor);
    // set properties

    // Save specifying PostOnlySetProperties flag
    context.SaveChanges(SaveChangesOptions.PostOnlySetProperties);
}
```

Handling duplicate names between enums and entities in metadata

There are instances where enums and entities share the same name. This name duplication results in OData client code generation errors. To recover from this error, the helper code in GitHub can be used to identify duplicate name instances that must be removed. The generated metadata document can be used for further processing of the OData logic on the client side.

Array fields

OData does not support array fields in entities. This must be taken into consideration when designing entities that will be used with OData.

After restarting AOS, the first OData call may take a long time to process

The first OData call processed by an AOS that was restarted may take a long time to process because the metadata is not being cached. This latency can be avoided by warming up OData on AOS startup. For more details, see Build OData metadata cache when the AOS starts.

Custom service development

2/18/2021 • 2 minutes to read • Edit Online

You can develop custom services for Finance and Operations. When a developer writes a custom service under a service group, the service group is always deployed on two endpoints:

- SOAP endpoint
- JSON endpoint

SOAP-based custom service

SOAP-based services remain the same as they were in Dynamics AX 2012.

Code examples for consuming custom services using SOAP are available in the Microsoft Dynamics AX Integration GitHub repository.

Key changes

- All the service groups under the **AOTService group** node are automatically deployed.
- All services that must be deployed must be part of a service group.

Example endpoint for a dev environment

```
https://usnconeboxax1aos.cloud.onebox.dynamics.com/soap/services/UserSessionService?wsdl
```

Example endpoint for a non-dev environment

```
https://<baseurl>/soap/services/UserSessionService?wsdl
```

For more information about custom services, see:

- Using Custom Services [AX 2012] (TechNet)
- Walkthrough: Exposing an X++ Class as a Data Contract (TechNet)

JSON-based custom service

This feature enables X++ classes to be consumed as JSON services. In other words, the return data set is in JSON format. JSON, which stands for JavaScript Object Notation, is a compact, lightweight format that is commonly used communicate data between the client and the server.

The JSON Endpoint is at `https://host_uri/api/services/service_group_name/service_group_service_name/operation_name`.

Example

```
https://usnconeboxax1aos.cloud.onebox.dynamics.com/en/api/services/UserSessionService/AifUserSessionService/GetUserSessionIr
```

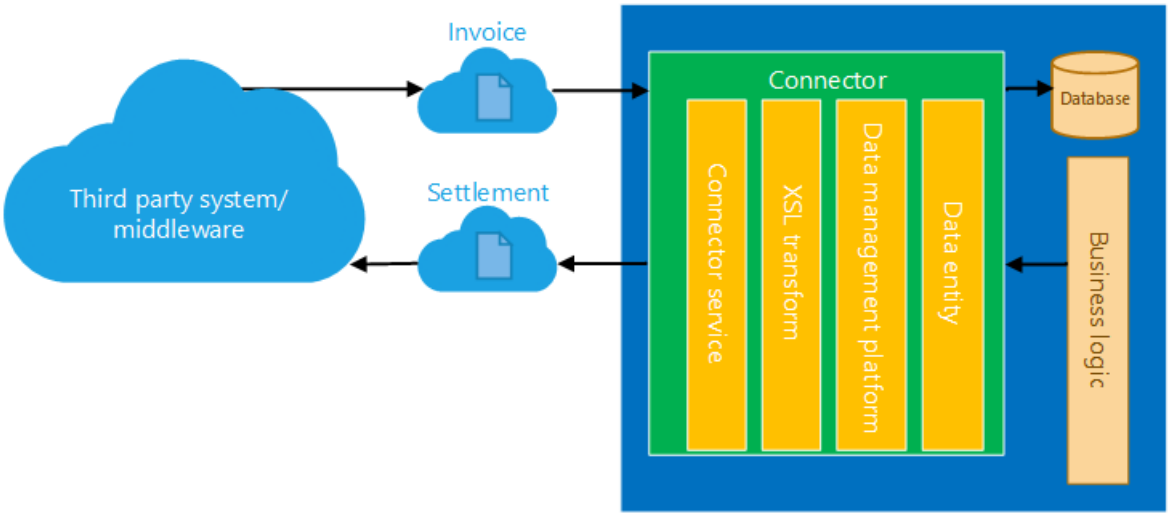
Code examples for consuming JSON services are available in the Microsoft Dynamics AX Integration GitHub repository.

Recurring integrations

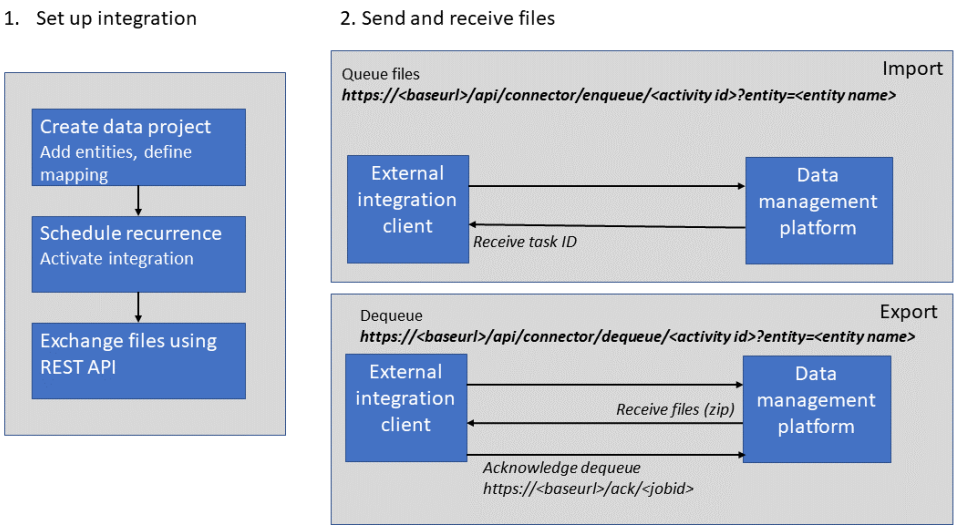
2/18/2021 • 8 minutes to read • Edit Online

Recurring integration does the following things:

- It builds on data entities and the Data management framework.
- It enables the exchange of documents or files between Finance and Operations and any third-party application or service.
- It supports several document formats, source mapping, Extensible Stylesheet Language Transformations (XSLT), and filters.



- It uses secure REST application programming interfaces (APIs) and authorization mechanisms to receive data from, and send data back to, integration systems.



Authorization for the integration REST API

The integration REST API uses the same OAuth 2.0 authentication model as the other service endpoints. Before the integrating client application can consume this endpoint, you must create an application ID in Microsoft

Azure Active Directory (Azure AD) and give it appropriate permission to the application. When you create and enable a recurring job, you're prompted to enter the Azure AD application ID that will interact with that recurring job. Therefore, be sure to make a note of the application ID.

> **NOTE**
> This feature is not supported with Dynamics 365 Finance + Operations (on-premises).

Set up a data project and recurring data jobs

Create a data project

1. On the main dashboard, select the **Data management** tile to open the **Data management** workspace.
2. Select the **Import** or **Export** tile to create a new data project.

   > **NOTE**
   > If you have an existing data project, select **Load project** on the card for any data project on the **Data projects** tab.

3. Enter a valid job name, data source, and entity name.
4. Upload a data file for one or more entities. Make sure that each entity is added, and that no errors occur.

   > **NOTE**
   > You can select each entity data card to set up, review, or modify field maps, and to set up XSLT-based transforms that must be applied to inbound data. For export data projects, the entity card also shows a filter link, so that you can set up filters to filter data. Currently, all recurring data jobs in a data project use the same filter.

5. Select **Save**.

Create a recurring data job

1. On the **Data project** page, select **Create recurring data job**.
2. Enter a valid name and a description for the recurring data job.
3. On the **Set up authorization policy** tab, enter the application ID that was generated for your application, and mark it as enabled.
4. Expand **Advanced options** tab, and specify either **File** or **Data package**.
   - **File** – Your external integration will push individual files so that they can be processed via this recurring data job. In this case, the format of the file that is expected is the same as the format that was specified when the entity was added to the data project.
   - **Data package** – You can push only data package files for processing. A data package is a new format that lets you submit multiple data files as a single unit that can be used in integration jobs.
   - **Process messages in order** – You can enable this option to force sequential processing of incoming files in an import scenario. This option is only applicable to files and not data packages.
5. Select **Set processing recurrence**, and then, in the **Define recurrence** dialog box, set up a valid recurrence for your data job.
6. Optional: Select **Set monitoring recurrence**, and set up a monitoring recurrence.

> **NOTE**
>
> Currently, monitoring recurrence enables load monitoring only on the queue for your recurring data job. No additional policies are supported via this service. You can use this feature to fine-tune the processing recurrence as the load demand requires.

7. Select **OK**, and then select **Yes** in the confirmation message box.

Manage recurring data jobs

1. In the **System administration** workspace (not the **System administration** module), select the **Data Management IT** workspace.
2. In the workspace, on the **Recurring data job** tab, select the recurring job to view the details. The **Manage scheduled data jobs** page contains a grid that lists any messages that are waiting in the queue. Therefore, you can monitor messages and the processing status.

Submitting data to recurring data jobs

You can use integration REST endpoints to integrate with the client, submit documents (import), or poll available documents for download (export). These endpoints support OAuth.

Integration REST APIs

The following set of APIs is used to exchange data between the integration client and the application.

API for import (enqueue)

Make an HTTP POST call against the following URL.

```
https://<base URL>/api/connector/enqueue/<activity ID>?entity=<entity name>
```

In the message body, you can the pass the data as a memory stream.

Example

```
POST https://usncax1aos.cloud.onebox.dynamics.com/en/api/connector/enqueue/%7B6D31E09F-0249-459F-94F0-
AAD9C2C47B64%7D?entity=Customer%20Groups
```

To get the activity ID, on the **Manage scheduled data jobs** page, in the **ID** field, copy the globally unique identifier (GUID).

API for export (dequeue)

To return a data package that contains all the data entities that were defined in the data project, and that the client application can unzip and consume, use the following structure.

```
https://<base URL>/api/connector/dequeue/<activity ID>
```

Example

```
GET https://usncax1aos.cloud.onebox.dynamics.com/en/api/connector/dequeue/%7BC03BB937-09ED-46DE-86EE-4520D7D7E373%7D
```

After the client downloads the data, an acknowledgment must be sent back to the application, so that you can mark the data as received.

In cases when there was no file uploaded to the blob, the dequeue API will return a response indicating as such.

API for acknowledgment

Use the following API.

> **NOTE**
> The body of the response of **/dequeue** must be sent in the body of the **/ack** POST request.

```
https://<base URL>/api/connector/ack/<activity ID>
```

Example

```
POST https://usncax1aos.cloud.onebox.dynamics.com/en/api/connector/ack/%7BC03BB937-09ED-46DE-86EE-4520D7D7E373%7D
```

> **NOTE**
> Until a message is successfully acknowledged, the same message will become available to dequeue every 30 minutes. In cases when a message is being dequeued more than one time, the dequeue response will send the last dequeued date time. This will be blank for the first dequeue of a message. It is important to ensure that a message is successfully acknowledged to prevent a repeated download of the same message. When an acknowledgement fails, having re-try logic to acknowledge the failure is recommended.

API for getting message status

The API to get the status of a message is available as of hotfix KB 4058074 for Platform update 12. This API is particularly useful in import scenarios to determine if a message has been successfully processed. A message is created when the enqueue process is completed. If the message returns a failed status, you can set your integration app to retry or take another action.

Example

```
POST /data/DataManagementDefinitionGroups/Microsoft.Dynamics.DataEntities.GetMessageStatus
BODY
{
    "messageId":"<string>"
}
```

The following table lists the possible status values.

VALUE	MEANING
Enqueued	The file has been successfully enqueued to blob storage
Dequeued	The file has been successfully dequeued from blob storage
Acked	The exported file has been acknowledged to be downloaded by the external application
Preprocessing	The import/export operation is pre-processing the request
Processing	The import/export operation is in process
Processed	The import/export operation completed successfully
PreProcessingError	The import/export operation failed in the pre-processing stage
ProcessedWithErrors	The import/export operation completed with errors
PostProcessingFailed	the import/export operation failed during post-processing

> **NOTE**
> The file in the blob storage will remain in the storage for seven days, after which it will be automatically deleted.

API to get the list of execution errors

GetExecutionErrors can be used to get the list of errors in a job execution. The API takes the Execution ID as the parameter, and returns a set of error messages in a JSON list.

```
POST /data/DataManagementDefinitionGroups/Microsoft.Dynamics.DataEntities.GetExecutionErrors
BODY
{"executionId":"<executionId>"}
```

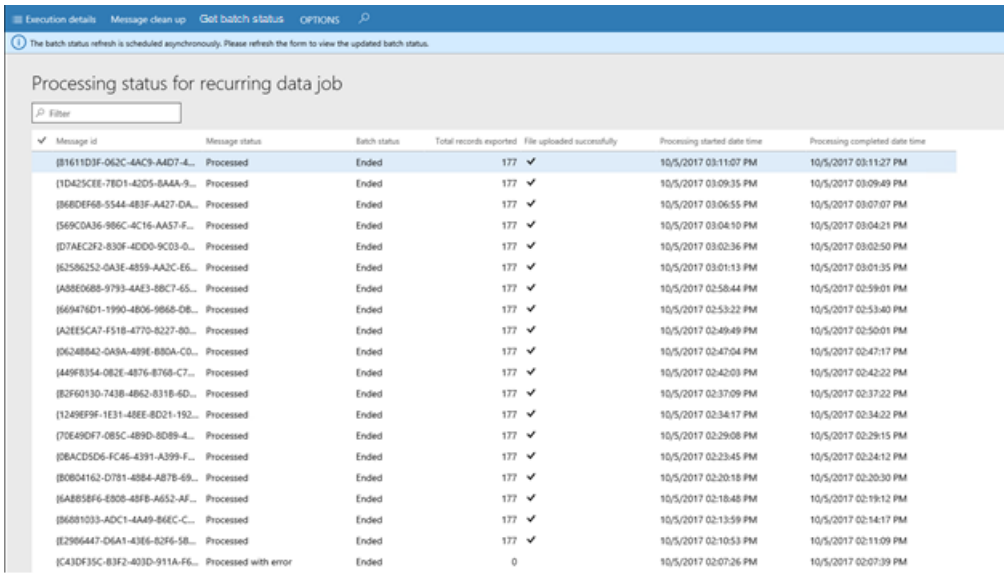
Tips and tricks

Viewing the batch job status for recurring integrations from the Data management workspace

Recurring integration data jobs run in batch mode. If a recurring job fails, you must investigate the instance of the batch job as part of the troubleshooting process. To make this investigation easier, click **Manage messages** to get to the **Process status for recurring data job** page, which now shows the status of the batch job.

The batch job status is retrieved asynchronously from the batch framework for the specified recurring data job. To see the most up-to-date batch job status, select **Get batch status**, and then refresh the page.

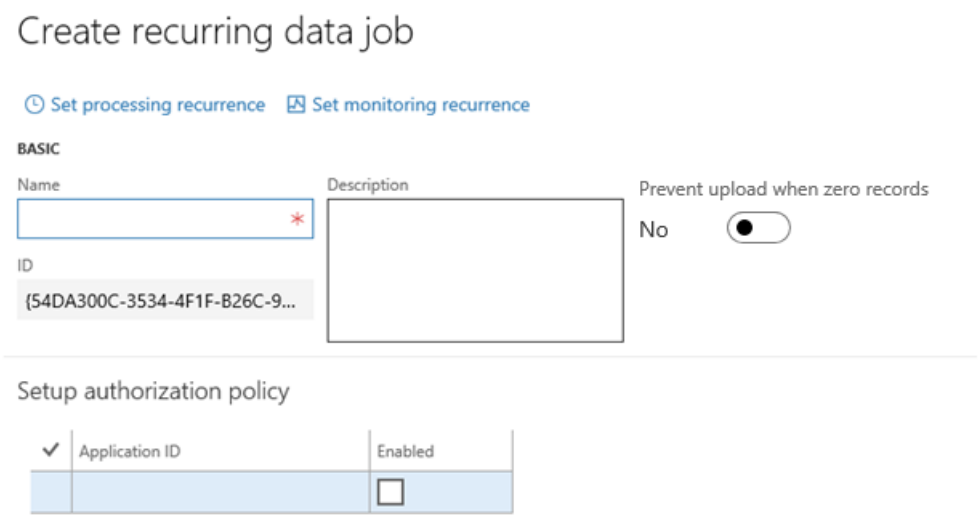
> **NOTE**
> If the record for the batch history is deleted, the status for the batch job on the **Processing status for recurring data job** page will be blank.



Preventing uploads when there are no records

When you use recurring exports you can choose not to upload a generated file or package if the total record count in that file or package is 0 (zero).

You can set the **Prevent upload when zero records** option either when you configure a recurring export job or after a job has been created. This option is available only when you use files or packages as data sources.



Your implementation might include runs of recurring jobs where files or packages were uploaded. Your implementation might also include runs where no files or packages were uploaded, because there was nothing to upload. If you suspect that a file that should have been uploaded wasn't uploaded, or that a file that should not have been uploaded was uploaded, you can use the **Manage messages** page for the recurring export job to help with the debugging process.

> **NOTE**
>
> These features were added in Microsoft Dynamics 365 for Finance and Operations, Enterprise edition platform update 12. Jobs that were run before you upgraded to Platform update 12 won't have values in the following columns.

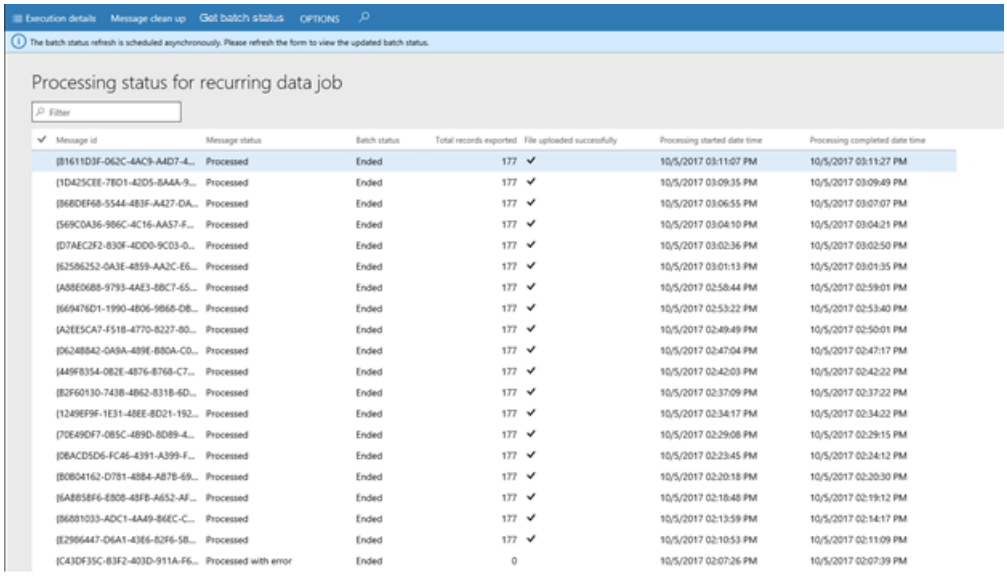
The **Total records exported** column shows the total count of records that were exported. A value of **0** (zero) indicates that no records were exported to the file or included in the package.

The **File uploaded successfully** column contains a check mark if the file or the package was uploaded

successfully. If the file wasn't uploaded because of an error, or because there were no records, the column will be blank.

Http vs Https

The dequeue API returns HTTP instead of HTTPS. This behavior can be seen in application environments that use a load balancer, such as production environments. (You cannot see the behavior in one box environments). We recommend that you change the URI scheme to HTTPS in the middleware application that is trying to dequeue from the application.



Test services by using third-party utilities

2/18/2021 • 7 minutes to read • Edit Online

At https://github.com/Microsoft/Dynamics-AX-Integration, Microsoft provides sample code for consuming services. However, there are many scenarios where the other endpoint in an integration might not use a Microsoft stack. Even when the other endpoint does use, for example, the Open Data Protocol (OData) client code that Microsoft makes available, you might find it useful to perform the following actions:

- Explore and analyze how an interaction's messages are constructed.
- Test the response of a service to a well-known request.
- Determine how exceptions will appear to the other endpoint.

Many frequently used tools that will help you perform these actions are available. This topic isn't an endorsement of any tool. Although it provides examples that use some frequently used software utilities, the principles should broadly apply to other, similar tools.

Prerequisites

Before you can test a service by using an external application, you must register the application in Microsoft Azure, and in Finance and Operations.

For details, see:

- Register an application with AAD
- Register your external application

Query OData by using Postman

Postman (https://www.getpostman.com/postman) is a tool that is often used to interact with RESTful services (such as OData) in scenarios that involve the development and testing of application programming interfaces (APIs). This procedure isn't an endorsement of Postman, and other similar tools are available. However, we are using Postman to illustrate the concepts and messages that are involved when you use OAuth to authenticate with Azure AD, and then make OData requests to and receive responses from the application.

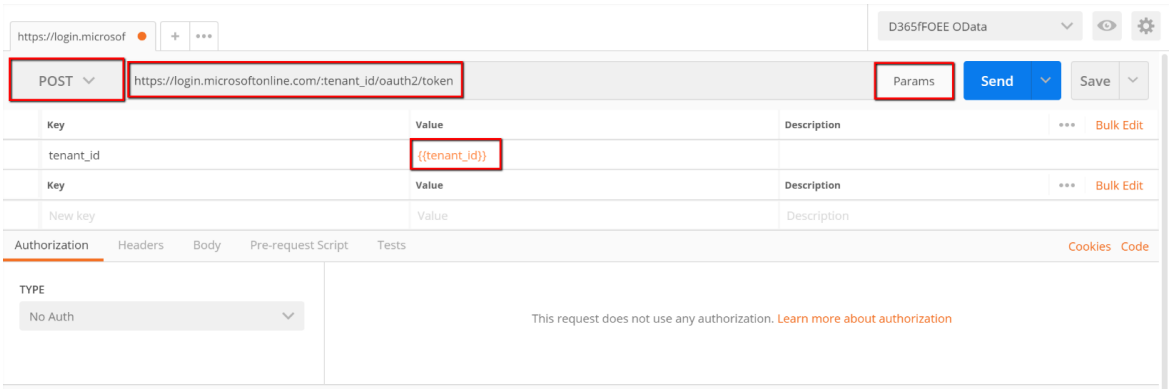
1. Start Postman.
2. In the upper-right corner, select the gear button, and then select **Manage environments** to create or update an environment.
3. Enter a name for the environment, and then select **Bulk Edit**.
4. Enter key-value pairs as shown in the following table. Enter one pair per line, and separate the key and value by using a colon (:).

KEY	VALUE
tenant_id	The Azure tenant ID that you looked up during the setup of prerequisites
client_id	The Azure AD application ID that you registered during the setup of prerequisites

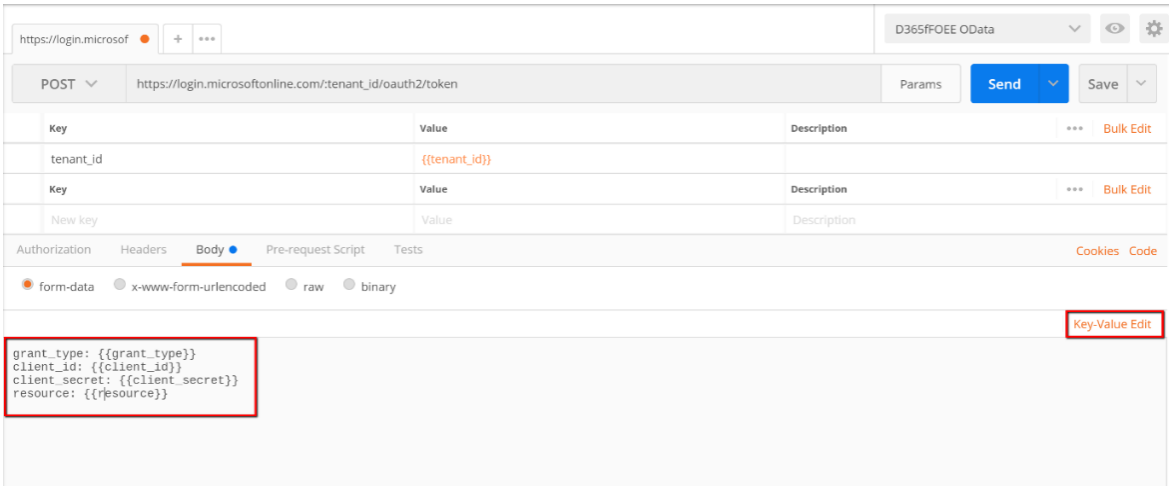
KEY	VALUE
client_secret	The secret key that you generated during application registration during the setup of prerequisites
grant_type	client_credentials
resource	The base URL of the instance without the trailing '/'

5. To verify that the key-value pairs can be parsed correctly, select **Key-Value Edit**, and review the results.
6. Close the environment page.
7. In the field to the left of the gear and eye buttons, select the new or updated environment.
8. To retrieve an Azure AD token, create a POST request that has a URL in the format `https://login.microsoftonline.com/[tenant ID]/oauth2/token`.

   You can use a URL parameter that refers to the **tenant_id** environment variable, such as `https://login.microsoftonline.com/:tenant_id/oauth2/token`.



9. On the **Body** tab, add body elements as request parameters that refer to the environment variables that you created earlier. Select **Bulk Edit**, enter the keys from the previous table, enter a colon (:), and then enter the key name again but enclose it in double braces ({{}}). Enter one request parameter per line. For example, enter **grant_type:{{grant_type}}**. Here is an example.

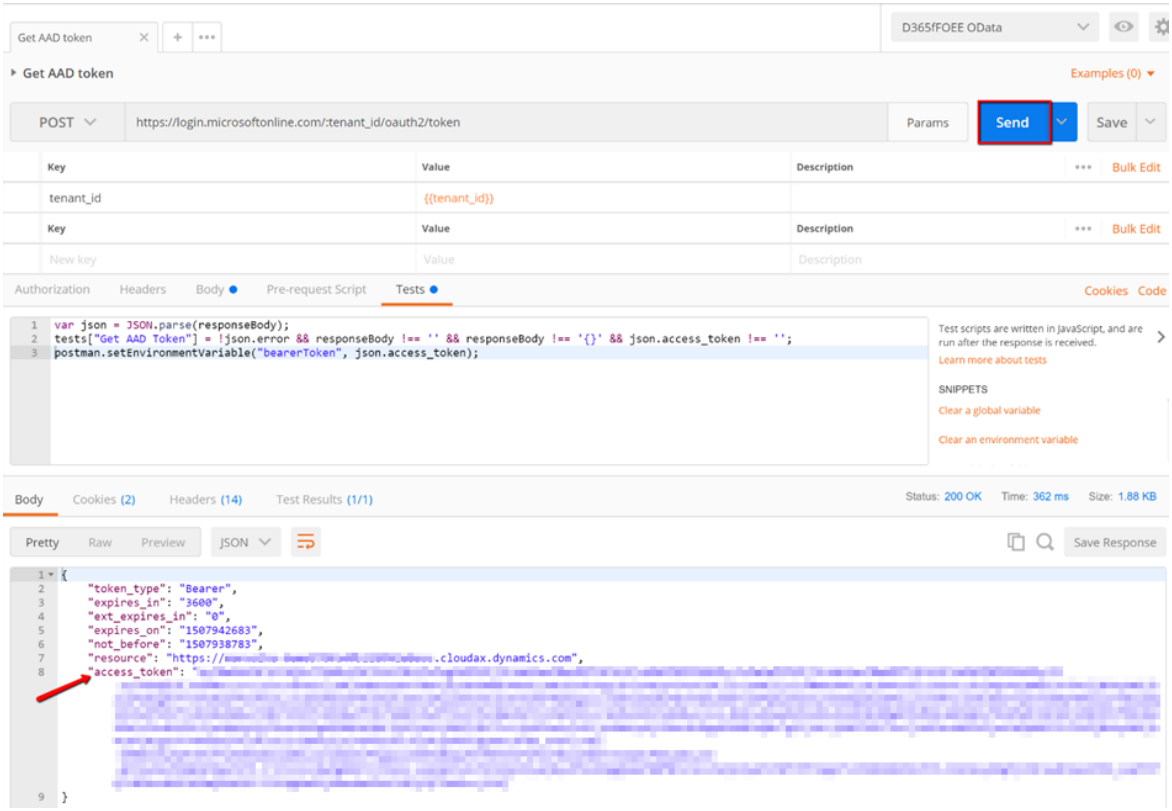


10. On the **Tests** tab, create a test that validates that the response is reasonable, and that stores the returned authorization token in an environment variable. Here is an example.

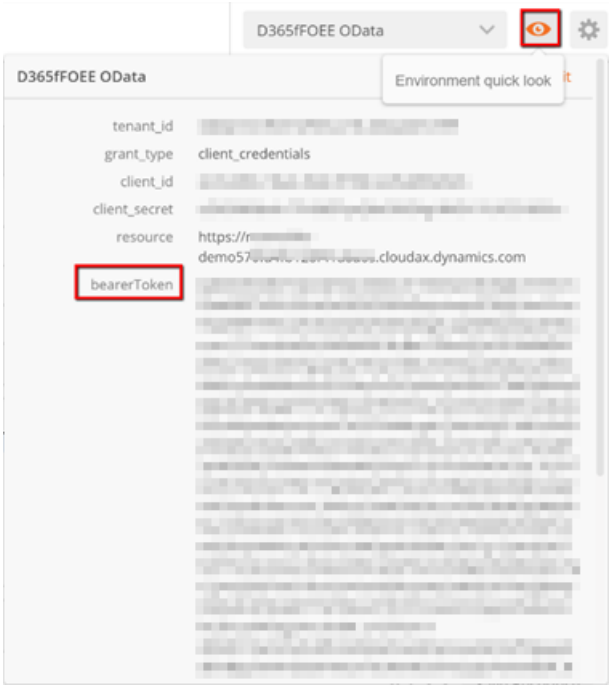
```
var json = JSON.parse(responseBody);
tests["Get Azure AD Token"] = !json.error && responseBody !== '' && responseBody !== '{}' &&
json.access_token !== '';
postman.setEnvironmentVariable("bearerToken", json.access_token);
```

11. Select **Save**, enter a name and collection for the request, and then select **Save** again.

12. Select **Send** to make the authorization request. The **Body** tab should now contain an Azure AD token together with other response details.



13. Because of the test code, the token is now in an environment variable. You can see that the token is an environment variable by selecting the **Environment quick look** button (the eye button).

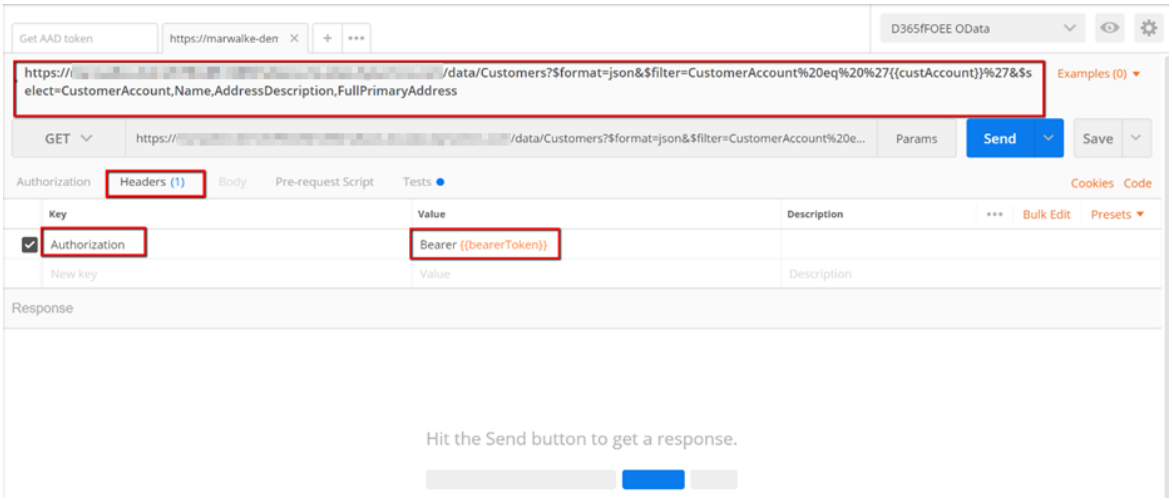


14. Create a request to perform create, read, update, or delete (CRUD) operations on the desired data entity

via the OData service. Create the URL according to your requirements. For more information, see Open Data Protocol (OData). You might find it useful to parameterize the request by using a variable that is stored in the environment, as shown earlier. The following example of a GET query uses a **Customer Account** parameter. The query returns name and address details for the customer account that is specified in the environment variable. Note that special characters must be correctly URL-encoded.

```
https://[Finance and Operations instance URL]/data/Customers?
$format=json&$filter=CustomerAccount%20eq%20%27{{custAccount}}%27&$select=CustomerAccount,Name,Addres
sDescription,FullPrimaryAddress
```

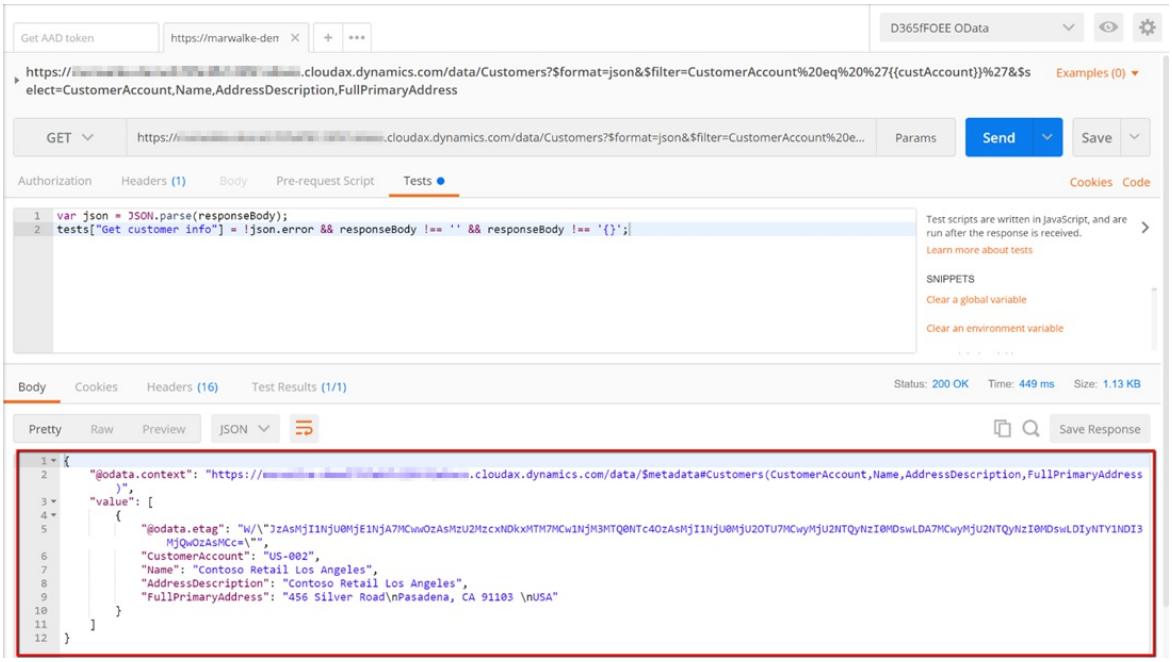
15. Add an Authorization header that refers to the authorization token that was retrieved earlier and stored in the **bearerToken** environment variable. The token must be prefixed by **Bearer** in the header.



16. Create a test to help validate the response. The following example tests that non-empty, JSON-formatted data is returned in the response body.

```
var json = JSON.parse(responseBody);
tests["Get customer info"] = !json.error && responseBody !== '' && responseBody !== '{}';
```

17. Save and send the request, and then verify the result. You must ensure that the user account being used is set to a default company that has data. Alternatively, you can also specify cross-company=true as the query parameter in the OData request.



In our example, we have now successfully authenticated and then used the OData service to read a customer record.

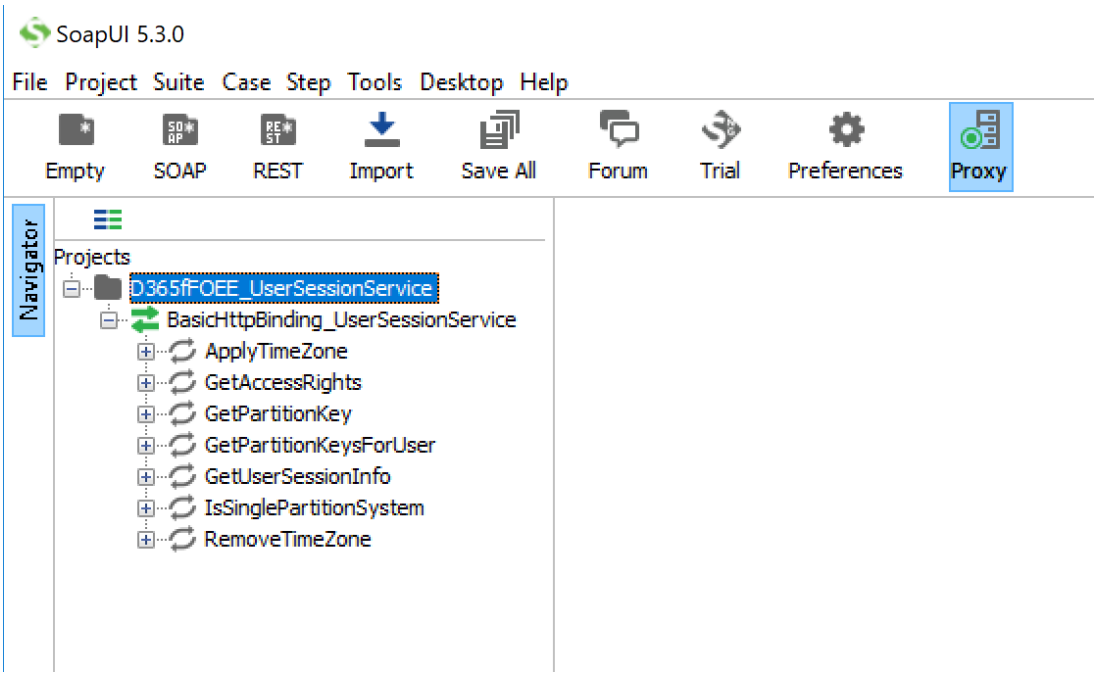
Query the SOAP custom service in your application by using SoapUI

SoapUI (https://www.soapui.org/) is a tool that is often used to interact with SOAP and REST web services in scenarios that involve API development and testing. This procedure isn't an endorsement of SoapUI, and other similar tools are available. However, we are using SoapUI to illustrate the concepts and messages that are involved when you use OAuth to authenticate with Azure AD, and then make SOAP requests to and receive responses.

1. Start SoapUI, and select the **SOAP** button to create a project.
2. Complete the information for the project:
   - In the **Project Name** field, enter a name for the project.
   - In the **Initial WSDL** field, enter the service address, and add the suffix **?wsdl**. (The service address should be in the format [Finance and Operations instance base URL]/soap/services/[service group name].) For more information, see the Services home page.

     For example, we are querying the user session service at the URL `https://[Finance and Operations base URL]/soap/services/UserSessionService?wsdl`.
   - Select the **Create sample requests for all operations?** check box.

     Because you selected to create sample requests, one sample request is created for each service operation that is available.



3. Right-click the new project, and then select **New TestSuite** to create a test suite. This test suite will generate a POST request for an Azure AD authorization token.
4. Right-click the test suite, and then select **New TestCase**.
5. Expand the test case, right-click **Test Steps**, select **Add Step**, and then select **HTTP Request**.
6. Enter a name for the request, and then select **OK**.
7. Enter a name for the test step. The endpoint that you should use for the POST request is

```
[https://login.microsoftonline.com/[tenant_id]/oauth2/token]
(https://login.microsoftonline.com/%5btenant_id%5d/oauth2/token)
```

.

8. Use the plus sign (**+**) button next to **Parameters** to add the following values.

PARAMETER	VALUE
grant_type	client_credentials
client_id	The application ID from the Azure AD application registration
client_secret	The secret key value from the Azure AD application registration
resource	The URL of the instance without the trailing '/'

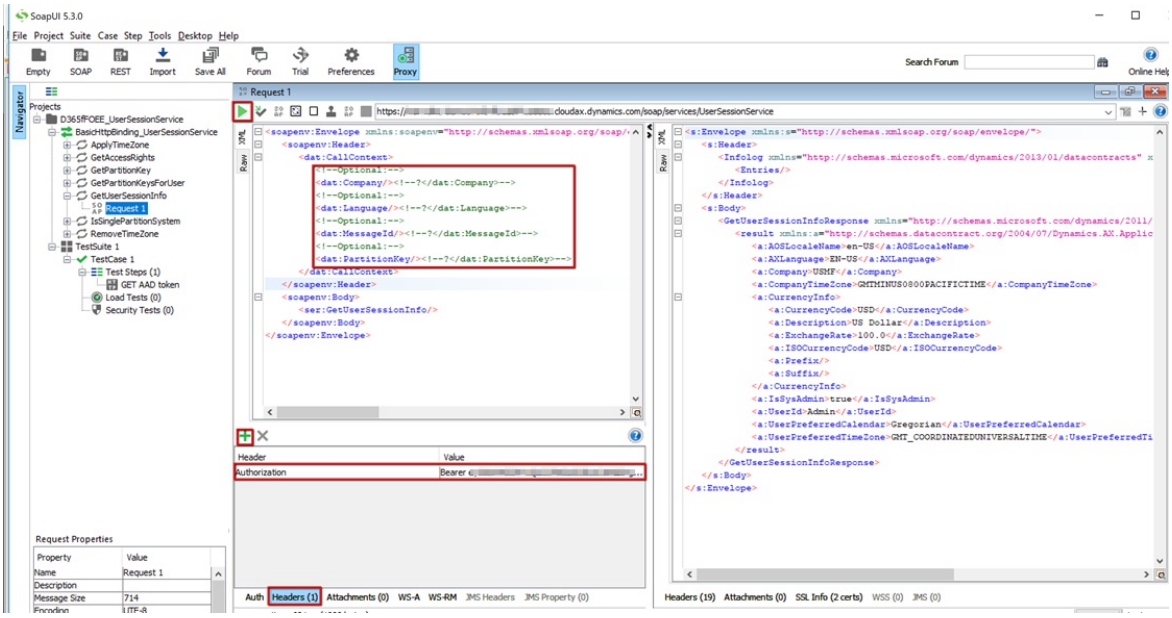
9. To make sure that the parameters are in the POST body, select **Post QueryString**, and then select **Play**. An access token should be returned in the response pane. The values will be most readable if you use the **JSON response** tab. Copy the access token so that you can use it in the authorization header of subsequent requests.

10. Go back to the first request node under the **GetUserSessionInfo** SOAP sample request. In the request pane on the left, select the plus sign (**+**) button to add a header that is named **Authorization**. Paste the access token into the **Value** field, and add the prefix **Bearer**.

11. The sample requests that SoapUI creates won't work unless you modify them. You must edit the call context and body so that they are consistent with the schema for what you're trying to do.

    For our simple scenario, you can edit the optional call context elements so that they are null-valued. Insert a forward slash (/) before the greater than sign (>) in the opening tags. Then comment out the question marks (?) and the closing tags by using the standard <!--...--> syntax to delimit the start and end of the comments. (Question marks aren't valid content for the XML schema.) Alternatively, you can just delete the question marks (?) so that the context elements are empty.

12. The SOAP request is now ready. Select **Play**, and validate the result on the right.



In our example, we have now successfully authenticated and then queried UserSessionService via SOAP.

NOTE

Can you tell us about your documentation language preferences? Take a short survey.

The survey will take about seven minutes. No personal data is collected (privacy statement).

Application Connector

2/18/2021 • 3 minutes to read • Edit Online

The application connector allows Microsoft Power Automate, Power Apps, Data Integrator, and Logic Apps to integrate with Finance and Operations. An external application can use the available trigger and actions to integrate with them.

> **IMPORTANT**
>
> The Application Connector cannot be used for integrations with Dynamics 365 Finance + Operations (on-premises) instances.

Prerequisites

We recommend that you read the following topics as a prerequisite to familiarize yourself with connectors before proceeding further

- Connectors
- Data management package REST API
- Open Data Protocol (OData)
- Recurring integrations

Triggers

Business events are exposed using the trigger *When a business event occurs*. For detailed information about business events, refer to Business events in Microsoft Power Automate and Business events.

Actions

This section describes the actions that are available in the connector.

Get a record

This action can be used to fetch a record for a specific data entity from the target instance.

Instance refers to the URL of the target instance of the application to which the connector must connect. The expected value is to enter the URL without the 'https://' prefix or choose one from the drop-down menu. This lists of all the environments that are deployed in the Azure Active Directory tenant for the user account that was used to sign in to the specific client like Power Automate, Power Apps, or Logic App.

Entity name refers to the data entity from which the record must be fetched. The drop-down menu shows the list of data entities from the target environment.

Object ID refers to the primary keys fields that must be specified to uniquely identify the record that must be fetched. The values must be specified as a comma-separated list of values in the order that is defined in the entity.

Create a record

This action can be used to create data records for a data entity.

Instance refers to the URL of the target instance to which the connector must connect. The syntax for this value

is to enter the URL without the 'https://' prefix or choose one from the drop- menu. This lists of all the environments that are deployed in the Azure Active Directory tenant for the user account that was used to sign in to the specific client like Power Automate, Power Apps, or Logic App.

Entity name refers to the data entity in which the record must be created. The dropdown menu shows the list of data entities from the target environment.

Based on the selected data entity, the list of fields displayed will be vary.

Update a record

This action can be used to update an existing data record for a data entity. The usage is the same as the create a record action.

Delete a record

This action can be used to delete an existing data record for a data entity. The usage is the same as the get a record action.

Execute action

This action can be used to invoke methods on a data entity to perform a business action.

Instance refers to the URL of the target instance to which the connector must connect. The syntax for this value is to enter the URL without the 'https://' prefix or choose one from the drop- menu. This lists of all the environments that are deployed in the Azure Active Directory tenant for the user account that was used to sign in to the specific client like Power Automate, Power Apps, or Logic App.

Action refers to the method on the data entity that must be executed. Based on the selected method, the list of fields displayed will be vary. These fields represent the parameters for the selected method.

Get list of entities

This action can be used to get the list of entities for further use in the app that is being developed.

Instance refers to the URL of the target instance to which the connector must connect. The syntax for this value is to enter the URL without the 'https://' prefix or choose one from the drop- menu. This lists of all the environments that are deployed in the Azure Active Directory tenant for the user account that was used to sign in to the specific client like Power Automate, Power Apps, or Logic App.

Data management and integration by using data entities overview

2/18/2021 • 2 minutes to read • Edit Online

This topic provides a brief overview of the mechanics of synchronous and asynchronous integration.

Synchronous services

Synchronous integrations are relatively straightforward. Any entity that has **Is public** enabled is automatically available as a service application programming interface (API) in the following URL: `https://[BaseURL]/Data/<<Data Entity Public Collection Name>>`.

Currently, OData protocol is used to expose endpoints where all public-enabled entities can be interacted with.

Supported protocol: OData V4.0

Data format: JSON

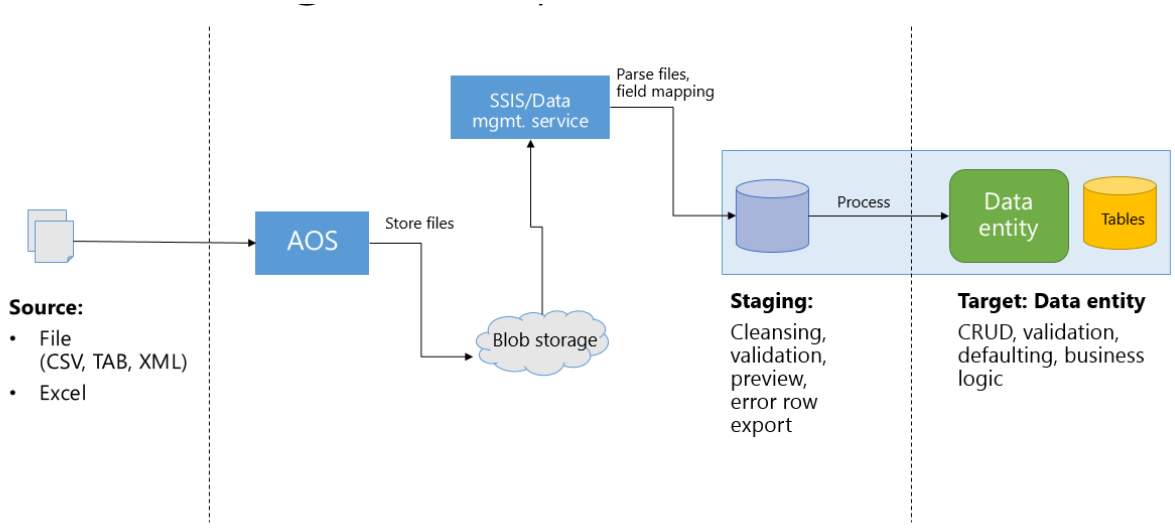
Metadata URL: `https://[BaseURL]/Data/$metadata`

Data import/export and recurring integration scenarios

Integration through the data management platform provides more capabilities and higher throughput for inserting/extracting data through entities. Typically, data goes through three phases in this integration scenario:

- **Source** – These are inbound data files or messages in the queue. Typical data formats include CSV, XML, and tab-delimited.
- **Staging** – These are automatically generated tables that map closely to the data entity. When **Data management enabled** is **true**, staging tables are generated to provide intermediary storage. This enables the framework to do high-volume file parsing, transformation, and some validations.
- **Target** – This is the data entity where data will be imported.

The following diagram shows an inbound flow.



Known limitations in data import/export

When you import text files, string sizes are limited to 32,768 characters. If there is a string larger than this, the imported string will be truncated. This is a limitation in the underlying implementation and is due to SQL Server Integration Services (SSIS).

If you need to import strings that are larger than 32,768 characters, we suggest that you use container entity fields.

For more information, watch the FastTrack Tech Talk video: Dynamics 365 for Operations – Tech Talk: Integration.

Develop entities for data migration

2/18/2021 • 7 minutes to read • Edit Online

This tutorial shows how to develop data entities in Microsoft Visual Studio and then use them for data migration.

This tutorial is broken out into two sections and four exercises. In the first section, you will build a **Project Category** entity in Visual Studio. You will then use this entity to export data. In the second section, you will use **Customer Groups** and **Customers** entities to import multiple sets of files by using the new Data Import/Export Framework.

> **NOTE**
>
> This tutorial is designed to be slightly more challenging than Build and consume data entities. Instead of providing a step-by-step guide, it has scenario exercises and describes the expected outcomes. The assumption is that you've already familiarized yourself with entities.

Prerequisites

This tutorial requires that you access the environment by using Remote Desktop. You must be provisioned as an administrator on the instance.

Base URL

Throughout this tutorial, "base URL" refers to the base URL of the instance.

- In the cloud environment, you obtain the base URL from Microsoft Dynamics Lifecycle Services (LCS).
- On a local virtual machine (VM), the base URL is `https://usnconeboxax1aos.cloud.onebox.dynamics.com`.

Developing an entity in Visual Studio and enabling it for data export

Business problem

You're developing a new solution for a Project module. As part of your implementation, you must represent the data from project categories, so that this data can be imported into the system or exported from it. To accomplish this goal, you will first build an entity for the project category and then use the export functionality to test data extraction.

Exercise 1: Build a Project Category entity

In this exercise, you will build an entity, **Project Category**, that uses the ProjCategory table as its primary data source. This entity has the following properties.

PROPERTY	VALUE
Entity AOT name	ProjectCategoryEntity
Label	Project Categories
Entity category	Reference

PROPERTY	VALUE
Public name	ProjectCategory
Collection name	ProjectCategories
Enable public API	Yes
Enable data management	Yes

The entity also has the following fields:

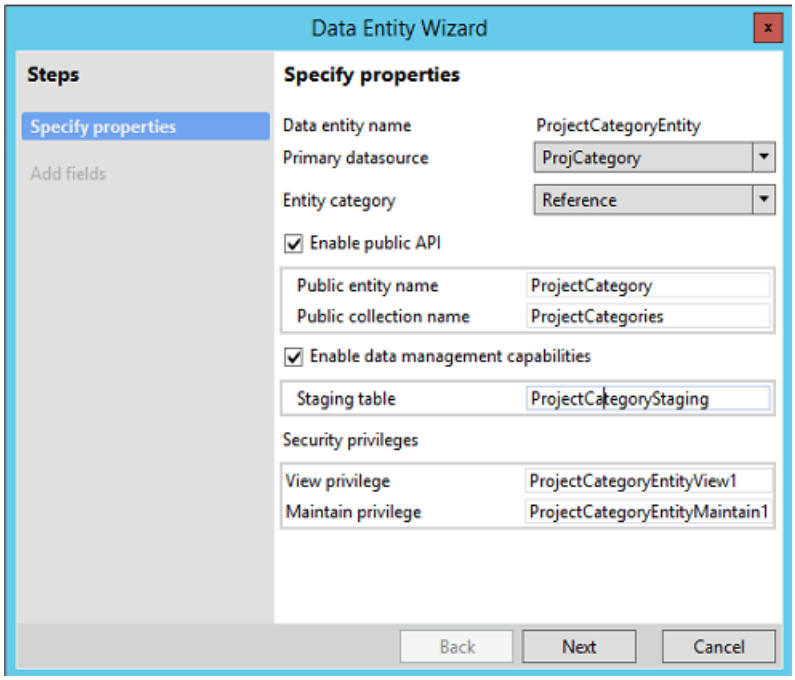
- ActiveInJournals
- CategoryGroup
- Category
- TransactionType
- CategoryName
- Worker
- CustomerPaymentRetention
- IndirectCostComponent
- ItemSalesTaxGroup
- ServiceCode
- Absence

Steps

1. In Visual Studio, create a new application project.
2. In Solution Explorer, select the project, and then right-click **Properties**.
3. Specify the following project properties, and then click **OK**.

PROPERTY	VALUE
Model	Application Suite
Company	USSI
Synchronize Database on build	True

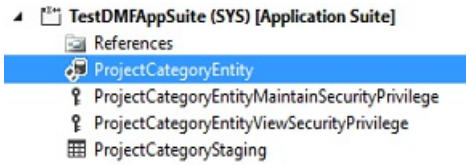
4. From the project, right-click **Add** > **New item**.
5. Select **Data Model** > **Data Entity** as your new item.
6. Enter a name, and then click **Add** to start the **Data Entity** wizard.
7. On the first page of the wizard, specify the set of properties for the entity by using the table earlier in this exercise. Then click **Next**.



8. On the next page, add fields from the primary data source. Make sure that each field name reflects the public contract (see the table earlier in this exercise). To use the field's label as the field name, select the **Convert label to field names** option. Clear the option for any fields that are not required for the entity.
9. Click **Finish** to complete the wizard, and to add the entity and its artifacts to the project.
10. Build your project, so that you can start to use the entity.

Expected outcome

- In Visual Studio, the following artifacts will appear in the project after you've completed the **Data Entity** wizard.



- Right-click the data entity, and then select **Open table browser**.

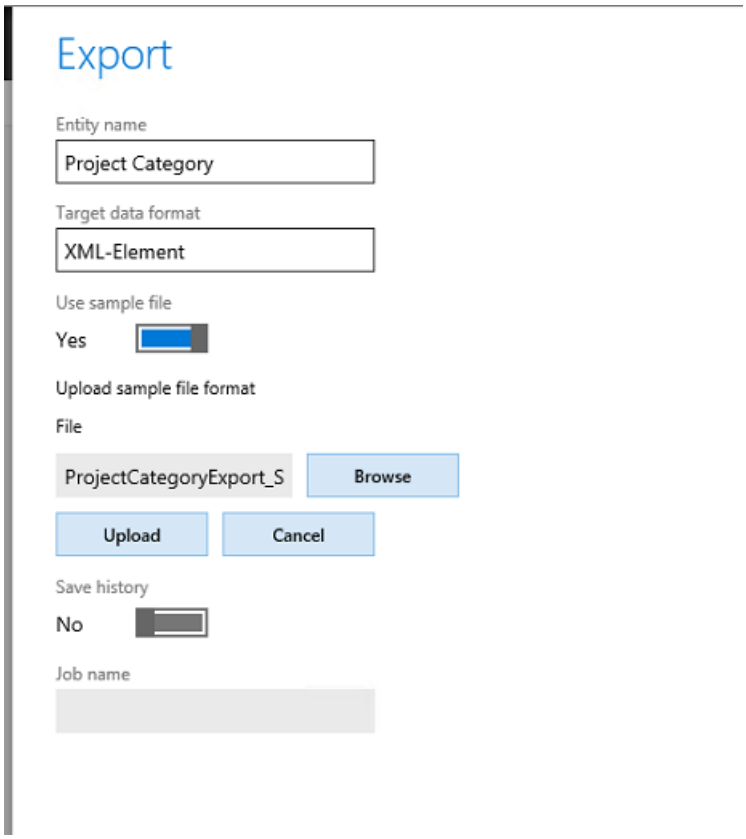
> **NOTE**
>
> Make sure that your company is set to **USSI**.

Exercise 2: Export a limited set of data by using a sample file mapping and filters

In this exercise, you will use the **Project Category** entity that you just built to export data. To export only a subset of the data, you will use a sample file mapping and filters. The exported data will be in XML format.

Steps

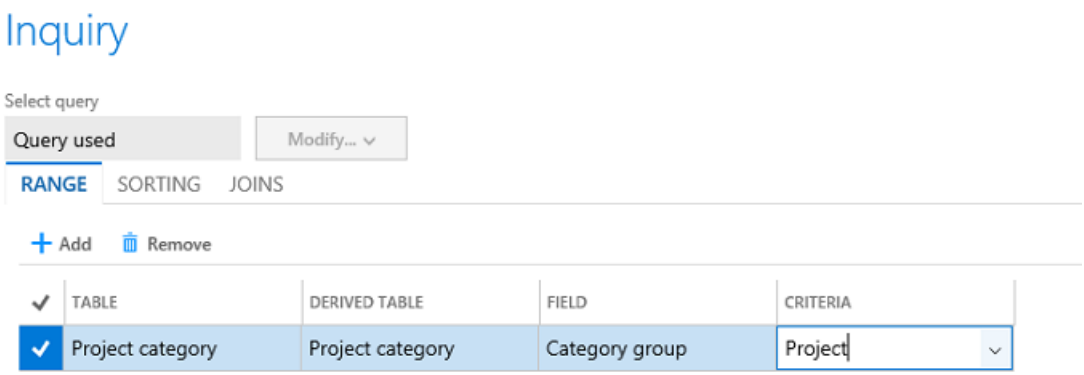
1. After you've finished building the **Project Category** entity, start the client.
2. Change the company to **USSI**.
3. In the **Data management** workspace, click **Export** to begin data extraction.
4. Enter the export details, such as entity name and target data format.



Use the following file as the sample file format for XML: ProjectCategoryExport_Sample.

Open this file in a text editor, and save it as an XML file. If the sample file mapping isn't valid, there is an incorrect field name in the entity. Fix either the entity or the sample file to continue.

5. Click **Filter**, and then specify **Project** as the filter criterion, so that only limited data is exported.



6. In the **Export** dialog box, click **OK**.

Expected outcome

- Fifteen records are successfully exported.
- The output is similar to the following file: ProjectCategoryExport_Output. (Open the file in a text editor to verify this outcome.)

Migrating data in multiple files by using the Data Import/Export Framework

Business problem

You're implementing a new environment. As part of this implementation, you want to migrate some legacy customer data. The data is contained in two sets of files, each of which has data for the **Customers** and **Customer Groups** entities. This migration is slightly complex, because some columns in the data files don't

map directly to the entities. Additionally, the files have validation errors that must be corrected during the import process.

Exercise 3: Create a data project and import multiple files

In this exercise, you will import two files into the **USRT** company by using the new Data Import/Export Framework. These files need to be imported in sequence by using a single data project. The **Customers** entity has a reference to the **Customer Groups** entity. Because the Customers1 file doesn't map correctly to the **Customers** entity, you will receive an error when you upload the file. Therefore, to complete the import process, you will have to provide the correct column mappings for the **Customers** entity.

Steps

1. Open the following files in Microsoft Excel, and save them as CSV files in your local directory:
   - Customers1
   - CustomerGroups1
2. In the client, change the company to **USRT**.
3. From the **User** dashboard, open the **Data Management** workspace.
4. Click **Import** to configure a new data project.
5. Enter the project details, such as the name and file format.
6. For each file, select an entity, and then upload the data file.
7. Because the Customer1.csv file doesn't map correctly to the **Customers** entity, you will receive an error when you upload the file. After the file is uploaded, click **View mappings** to fix the column mappings for the **Customers** entity.

   > **TIP**
   >
   > **CustomerAccount** is required in the entity during import. It is mapped from **AccountNum** in the source file. Address fields are optional for the import.

8. When you've finished, click the **Back** button in your browser to return to the data project.
9. On the **Data Project** page, click **Import now**.

Expected outcome

Four updates and 23 inserts are successfully imported and the **Execution summary** page shows the results.

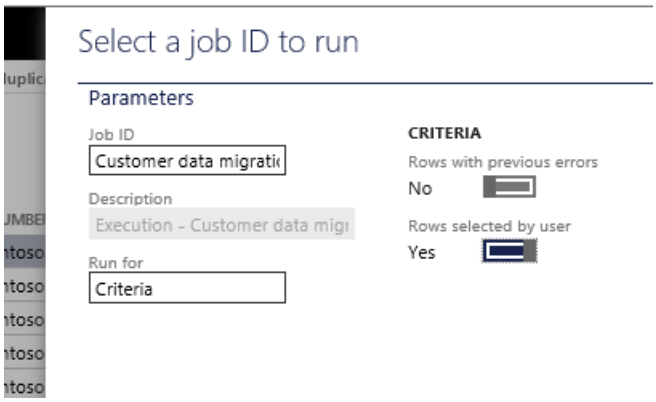
Exercise 4: Re-import by using an existing data project and manage data in staging

In this exercise, you will use a new set of files to import data through the existing data project. Customers2 contains new and updated data for the **Customers** entity. CustomerGroups2 contains updated data for the **Customer Groups** entity. Customers2 contains some error records. You will fix these errors in staging, validate the data, and then push it to the target to complete the import.

Steps

1. In the **Data management** workspace, select the existing data project, and the click **Re-import**. By using the re-import functionality, you can preserve your previous settings for the data project and use new files for the import. However, if you click **Reload data project** and upload new files instead, the previous mappings will be overridden.
2. Open the following files in Excel, and save them as CSV files in your local directory:
   - Customers2
   - CustomerGroups2

3. Upload the new files for each entity, and then click **Import now**.
4. On the **Status** page, click **View execution log** to investigate the errors.
5. On the **Status** page, click **View staging** to view the data in a staging table. This view will also show records that have errors.
6. Click **Edit** to fix records that have errors. (The **Customer Group** value for records DM10221 and DM1022 isn't valid.)
7. Select the records that you fixed, and then click **Validate**. Refresh the page to verify that the status of the records is **Validated**.
8. Click **Copy data to target**.
9. In the **Select a job ID to run** dialog box, in the **Run for** field, select **Criteria**, and set **Row selected by user** to **Yes**. Then click **OK**.



10. On the **Target data execution** page, click **Run**.
11. When the run is completed, refresh the page to see the latest staging status.

Expected outcome

- On the first try, the import succeeds for the **Customer Groups** entity and partially succeeds for the **Customers** entity.
- The **Execution summary** page shows that five records were created, three records were updated, and two records have errors.
- In the staging view, two records have errors.
- After you fix the records and run the import again, the staging view shows that all records are completed.

Develop composite data entities

2/18/2021 • 4 minutes to read • Edit Online

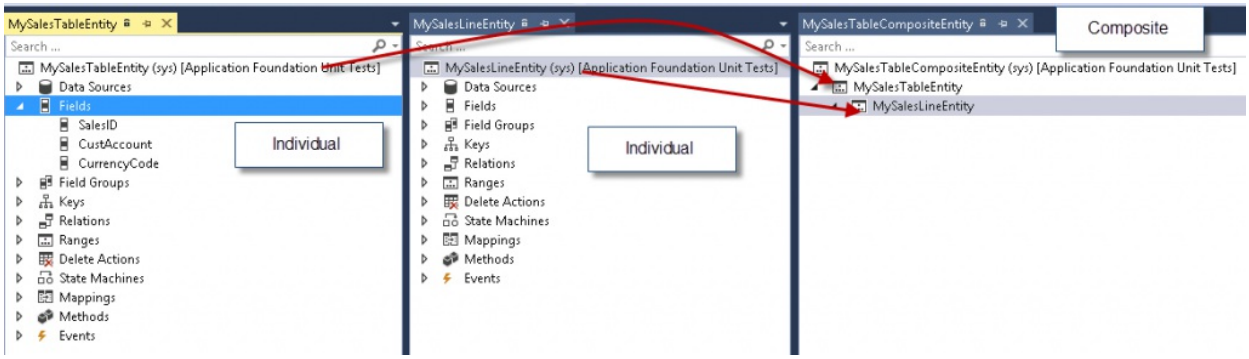
A composite entity is a concept that allows you to build a single entity by leveraging multiple entities that are related to each other.

What is a composite entity?

Composite entity is concept that allows you to build a single entity by leveraging multiple entities that are related to each other. The concept is heavily used in scenarios where an entity can be represented as a single document, like Sales header/line, Invoice header/line and Vendor Catalog. This concept is applicable in asynchronous integration scenarios rather than synchronous OData scenarios, and it will only be supported from a data management platform. There is no programmatic interface for composite entities in X++. It is only supported for a data management platform that is part of XML file-based imports/exports.

Example

Sales Header and Sales Line are two different entities in the system. In case the customer requirement suggests that header and lines are part of a single document, then these two entities can be merged as a composite entity. Sample sales order entity: The composite entity (MySalesTableCompositeEntity) represents a sales orders document which is comprised of Sales Order header entity (MySalesTableEntity) and Sales Order Line entity (MySalesTableLineEntity).



Based on the linked entities, these entities can be exposed as an XML document with embedded element tags for entities. XML is the only way to expose a composite entity in data management.

```
<?xml version="1.0" encoding="utf-8"?>
<Document>

<MySalesTableEntity SalesID="SO1" CurrencyCode="USD" CustAccount="Acc001">
<MySalesLineEntity SalesPrice="2.00" QtyOrdered="10.00" LineAmount="20.00" ItemId="1000" LineNum="1.00"
SalesID="SO1"/>
<MySalesLineEntity SalesPrice="2.00" QtyOrdered="10.00" LineAmount="20.00" ItemId="4401" LineNum="2.00"
SalesID="SO1"/>
</MySalesTableEntity>

<MySalesTableEntity SalesID="SO2" CurrencyCode="USD" CustAccount="Acc002">
<MySalesLineEntity SalesPrice="2.00" QtyOrdered="10.00" LineAmount="20.00" ItemId="4402" LineNum="1.00"
SalesID="SO2"/>
</MySalesTableEntity>

</Document>
```

Each node in the XML represents attributes from an individual entity. For example - <MySalesTableEntity SalesID="SO1" CurrencyCode="USD" CustAccount="Acc001"> SalesId, CurrencyCode and CustAccount are attributes from MySalesTableEntity.

Building the composite entity

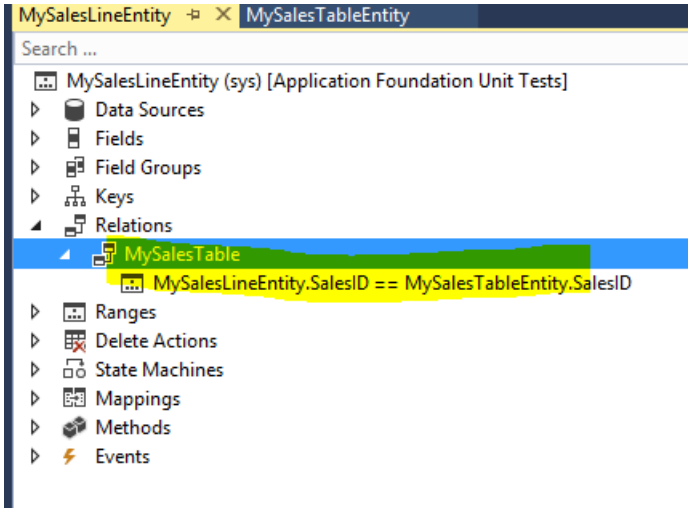
There is a node for composite data entities under Data model. Let's take the example of MySalesTableEntity.

Step 1: Identify and create the individual entities for the composite entity

Make sure that the entities are related to each other. In this example the individual entities are MySalesTableEntity and MySalesLineEntity.

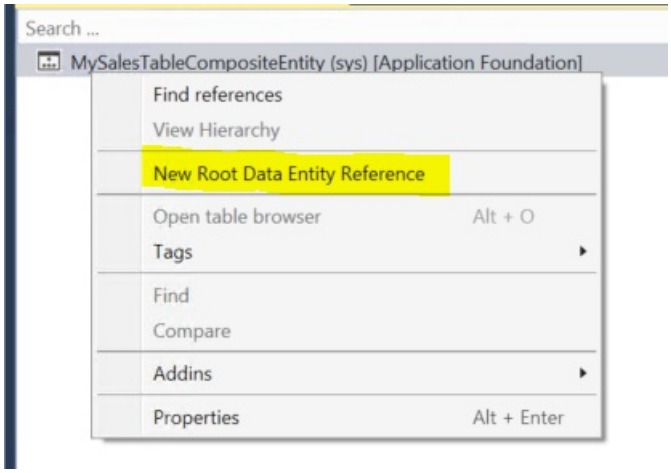
Step 2: Add relations between individual entities

Add a relation to parent entity in the relations node. Example – MySalesLineEntity has relationship to MySalesTableEntity.

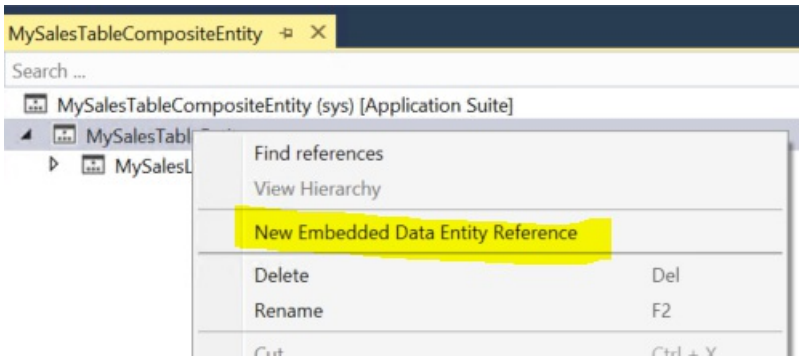


Step 3: Create a new composite entity

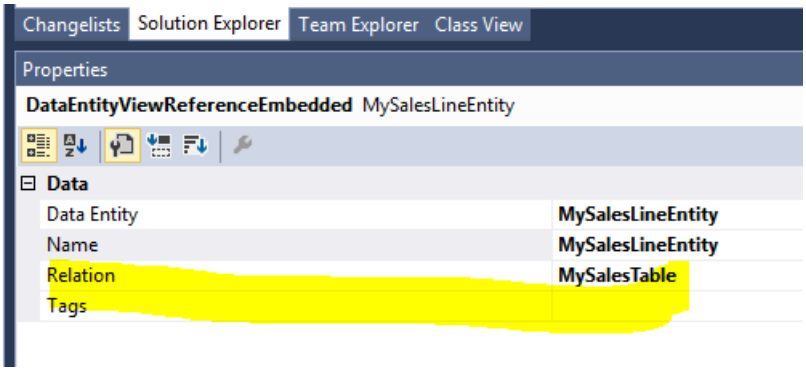
1. Add a new **Dynamics 365** artifact item of type **Composite entity** to the project.
2. In designer mode, right-click the entity and select **New Root Data Entity Reference**.



3. Set the data entity to parent data entity. In this case its MySalesTableEntity.
4. Right-click the parent entity node and select **New Embedded Data Entity Reference**.



5. Set the embedded data entity as the child entity. In this case it is MySalesLineEntity.
6. Set the **Relation** property from the drop-down list on the embedded data entity properties.

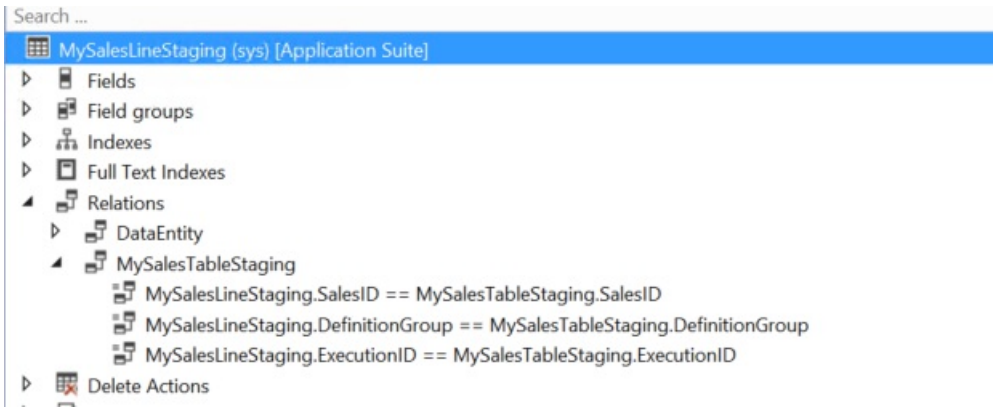


7. Composite entity supports multi-level child entities.

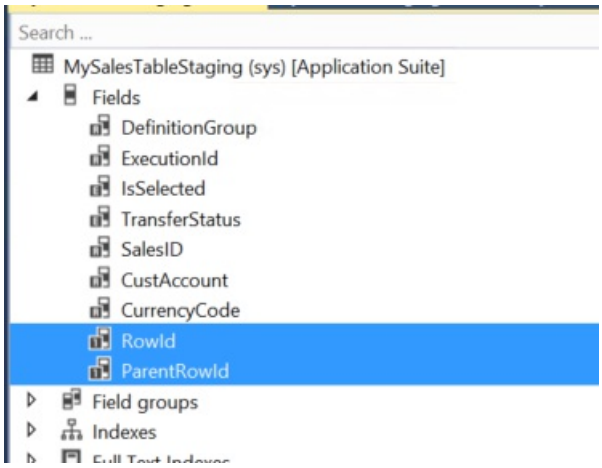
Step 4: Create relationships between staging tables

You need to create relationships between the parent and child entity staging tables based on the natural keys. For example, staging tables for MySalesTable and MySalesLine are linked by SalesID, DefinitionGroup, and ExecutionId.

1. Add a foreign key relation on MySalesLineStaging table.



2. Add two columns, RowId and ParentRowId (type int), on all the staging tables associated with the composite data entity. Refer to SysCompositeHeaderStaging table for the columns properties.



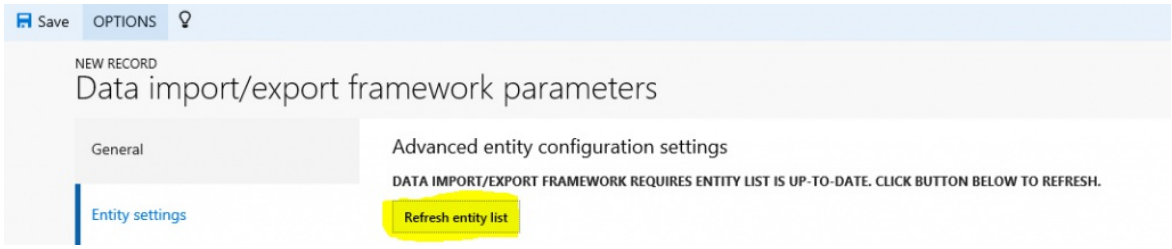
These columns are used to define runtime relationships during the target data movement.

- Create a cluster index on the staging tables which includes RowId, ParentRowid,DefinitionGroup, and ExecutionId. This is for performance reasons.
- Compile and synchronize the artifacts.

Step 5: Set up the metadata for DMFEntity

For local testing the composite entity metadata needs to be refreshed.

1. Go to **DIXF Parameters > Entity settings**. Click **Refresh entity list**.



2. Alternately, you can write the following job to refresh the composite entity list metadata.

```
DMFDataPopulation::refreshCompositeEntityList();
```

3. Execute the job. This refreshes the metadata required for the entity lookup.

> **NOTE**
> Currently this is a workaround. In the future a feature will be enabled to refresh the list at compile/sync time.

Step 6: Test the entity locally

We recommend that you import and export the data as a normal entity from DIXF standard process. Refer to the following the steps for importing and exporting entity.

> **NOTE**
> The source types of XML-Attribute or XML-Element are supported for composite entity. In entity execution parameters, composite entities cannot be imported in parallel using the parallel processing settings.

Import a composite entity

1. Click **Import**.

2. Enter **Name**, **Source data format**, and **Entity name**.
3. The **Source data format** is either xml-attribute or xml-element.
4. Click **Import now**.
5. The number of records created/updated/pending are shown.

Export a composite entity

1. Click **Export**.
2. Enter **Name**, **Source data format**, **and Entity name**.
3. Click **Add entity** and **Export now**.
4. Click **Download package**.

General troubleshooting guidelines

- Issue: The exported composite XML file is not imported. The scenario that produces this is:
  - Export a file for composite entity.
  - Import the same file.
  - Mapping fails and the file is not imported.
- Root cause:
  - Check if the exported file has lines or related child entity information.
  - If there no lines or related child entity information, then the lines will not be mapped during import.
- Resolution:
  - Create a sample file with all of the child entities.
  - Use this file for initial mapping only.
  - When the mapping is successful, import the actual file which does not have the line data into the entity. Use reimport or upload a new file.
  - This should import files with partial data (blank child records), depending on the validity of the records.

Configure financial cross-company data sharing

2/18/2021 • 2 minutes to read • Edit Online

This procedure shows how to configure, enable, validate, and resolve conflicts when sharing data between companies. It uses the USMF company and the Financial data sharing template.

This task guide requires Dynamics AX platform 7.1 or later.

1. Go to **Navigation pane > Modules > System administration > Workspaces > Data management**.
2. Click **Import**.
3. In the **Name** field, type a value.
4. In the **Source data format** field, select the 'Package' type. Click **Upload**. Navigate to the location of the Financial data sharing template package file and select that file.
5. Click **Save**.
6. In the list, mark the selected row. Select the data sharing policy that was just created.
7. Click **Import**.
8. Click **Close**.
9. Refresh the page.
10. Close the page.
11. Close the page.
12. Close the page.
13. Go to **Navigation pane > Modules > System administration > Setup > Configure cross-company data sharing**.
14. In the list, find and select **Payment days**.
15. Click **Add**.
16. In the list, mark the selected row.
17. In the **Company** field, type 'USSI'.
18. Click **Add**.
19. In the **Company** field, type 'USMF'.
20. Click **Save**.
21. Click **Enable**.
22. Click **Yes**.
23. Click **Find sharing issues**.
24. Click **Yes**.
25. Click **Update field value**.
26. Click **Use value from company 1**.
27. Refresh the page.
28. Close the page.

Create a record template to facilitate data entry

2/18/2021 • 2 minutes to read • Edit Online

This topic demonstrates how to create a record template so that field values that are used often do not have to be entered explicitly for each new record. In this procedure, you'll create a new record for new laptops that should be added to your fixed assets. This procedure uses the USMF sample company.

1. In the navigation pane, go to **Modules > Fixed assets > Fixed assets > Fixed assets**.
2. Select **New**.
3. In the **Fixed asset group** field, enter or select a value.
4. In the **Name** field, type a value. For example, enter **Corporate lead laptop**.
5. In the **Search name** field, type a value. For example, enter **laptop**.
6. Expand the **Technical information** section.
7. In the **Make**, **Model**, and **Model year** fields, type values.
8. On the Action Pane, select **Options**.
9. Select **Record info**.
10. Select **User template**.
11. In the **Name** field, type a value.
12. In the **Description** field, type a value.
13. Select **OK**.
14. Select **Close**.

Use record template to create a new record

2/18/2021 • 2 minutes to read • Edit Online

This procedure shows how to use a previously defined record template to create a new record. To complete this procedure, you must first complete the "Create a record template to facilitate data entry" procedure.

This procedure uses the USMF company.

1. In the **Navigation pane**, go to **Fixed assets > Fixed assets > Fixed assets**.
2. Click **New**. You will be prompted to select a template. Select the one that corresponds to your business need.
3. In the list, find and select the desired record.
4. Click **OK**.

Data integration using Dataverse overview

2/18/2021 • 2 minutes to read • Edit Online

NOTE

Effective November 2020:

- Common Data Service has been renamed to Microsoft Dataverse. For more information, see Power Automate Blog.
- Some terminology in Microsoft Dataverse has been updated. For example, *entity* is now *table* and *field* is now *column*. For more information, see Terminology updates.

This topic will be updated soon to reflect the latest terminology.

You can use Dataverse to enable the flow of data between Finance and Operations apps and Dynamics 365 Sales. For example, customer information in Sales can flow to Finance and Operations apps. You don't have to manually move the data or use a third-party data integration tool.

For more information about Dataverse data integration, see Integrate data into Dataverse for Apps in the Microsoft Power Apps documentation.

For an example of using Dataverse, see Prospect to cash.

NOTE

Can you tell us about your documentation language preferences? Take a short survey.

The survey will take about seven minutes. No personal data is collected (privacy statement).

Dual-write home page

2/18/2021 • 2 minutes to read • Edit Online

NOTE

Effective November 2020:

- Common Data Service has been renamed to Microsoft Dataverse. For more information, see Power Automate Blog.
- Some terminology in Microsoft Dataverse has been updated. For example, *entity* is now *table* and *field* is now *column*. For more information, see Terminology updates.

This topic will be updated soon to reflect the latest terminology.

These topics describe dual-write integration.

- What is dual-write?
  - Top reasons to use dual-write
  - What does dual-write mean for developers and architects of customer engagement app?
- What's new or changed in dual-write
- Frequently asked questions

Dual-write setup

- System requirements for dual-write
- Guidance for how to set up dual-write
- Considerations for initial synchronization
- Dual-write setup from Lifecycle Services
- Enable dual-write for existing Finance and Operations apps
  - Enable dual-write for existing Finance and Operations apps
  - System requirements and prerequisites
  - How to use the dual-write wizard to link your environments
  - Enable table map for dual-write
- Currency data-type migration for dual-write
- Set up the mapping for the sales order status columns
- Filter intercompany orders to avoid synchronizing Orders and OrderLines

Managing dual-write after setup

- Customize table and column mappings
- Handling multiple table maps
- Edit a legal table after dual-write setup
- Error management and alert notifications
- Application lifecycle management

Mapping concepts between apps

These topics describe mapping between concepts in Finance and Operations applications and concepts in model-driven apps in Microsoft Dynamics 365.

- Integrated customer master
- Integrated vendor master
  - Switch between vendor designs
- Customer loyalty cards and reward points
- Unified product experience
  - Integrated sites and warehouses
- Company concept in Dataverse
  - Initialize company data
- Organization hierarchy awareness
- Access to finance and tax reference data
  - Integrated ledger
  - Integrated tax master
- Integrate procurement in Supply Chain Management with Field Service
- Sync on-demand with the Supply Chain Management price engine
- Prospect to cash in dual-write
- In-house assets for servicing
- Integrated worker, job, and position
- Onhand inventory availability

Support

- Support for Field Service and Project Service Automation solutions
- Migrate Prospect to cash data from Data Integrator to dual-write

Troubleshooting

- Verify dual-write configuration in Finance and Operations apps and Dataverse
- Troubleshoot issues during initial setup
- Troubleshoot issues during initial synchronization
- Troubleshoot dual-write issues in Finance and Operations apps
- Troubleshoot live synchronization issues
- Troubleshoot issues related to solution awareness
- Troubleshoot issues from upgrades of Finance and Operations apps
- General troubleshooting

NOTE

Can you tell us about your documentation language preferences? Take a short survey.

The survey will take about seven minutes. No personal data is collected (privacy statement).

What's new or changed in dual-write

2/18/2021 • 7 minutes to read • Edit Online

NOTE

Effective November 2020:

- Common Data Service has been renamed to Microsoft Dataverse. For more information, see Power Automate Blog.
- Some terminology in Microsoft Dataverse has been updated. For example, *entity* is now *table* and *field* is now *column*. For more information, see Terminology updates.

This topic will be updated soon to reflect the latest terminology.

Dual-write is an out-of-box infrastructure that provides near-real-time interaction between customer engagement apps in Microsoft Dynamics 365 and Finance and Operations apps. To get started with dual-write, see the Dual-write home page.

Check out the latest information about dual-write features and changes in the release plans.

- Data in Dataverse – Phase 1
- Data in Dataverse – phase 1 & 2
- Finance and Operations data in Dataverse – Phase 3

January 2021 release

The January 2021 release of the Dual-write application orchestration solution version 2.2.1.30 is based on Dual-write core solution version 10.0.24 and version 10.0.14 of Finance and Operations apps.

This release contains the features and bug fixes listed in the following table.

FEATURE	DESCRIPTION	STATUS
Bug fix	French-localized strings in the user interface exceeded the maximum limit of 100 characters.	General availability
Bug fix	Error while starting the Dataverse released distinct products map.	General availability

The January 2021 release of the Dual-write application orchestration solution version 2.2.1.23 is based on Dual-write core solution version 10.0.24 and version 10.0.14 of Finance and Operations apps.

This release contains the features and bug fixes listed in the following table.

FEATURE	DESCRIPTION	STATUS
Purchase order integration	Integrates purchase order functionality between Dynamics 365 Field Service and Dynamics 365 Supply Chain Management.	General availability
Bug fix	Localization updates.	General availability

FEATURE	DESCRIPTION	STATUS
Bug fix	In customer engagement apps, on the **Contact** form, after you set **Is Sellable** to **Yes** and save the record, the contact is considered a customer who can transact. Because customers are associated with transactions, **Is Sellable** becomes read-only after saving. You can't change it back to **No**.	General availability

December 2020 release

The December 2020 release of the Dual-write core solution (10.0.24) contains the features and bug fixes listed in the following table.

FEATURE	DESCRIPTION	STATUS
Signal repeater service	Enables the dual-write runtime plugin to communicate with the Finance and Operations signal repeater service with authentication support.	General availability

November 2020 release

The November 2020 release of the Dual-write core solution (10.0.23) contains the features and bug fixes listed in the following table.

FEATURE	DESCRIPTION	STATUS
Authentication	Support for new authentication certificate to ensure security.	General availability

October 2020 release

The October 2020 release of the Dual-write application orchestration solution and the Dual-write core solution contains the features and bug fixes listed in the following table.

FEATURE	DESCRIPTION	STATUS
Camel-cased column mappings	Adds support for column mappings with camel-cased navigation properties.	General availability
Bug fix	Fixes the bug where an unrecognized tag configuration would cause dual-write execution to be skipped	General availability

September 2020 release

The September 2020 release of the Dual-write application orchestration solution version 2.0.777.493 is based on Dual-write core solution version 10.0.21.

The September 2020 release contains the features and bug fixes listed in the following table.

FEATURE	DESCRIPTION	STATUS
Lead qualification process in Sales is now company striped	Dynamics 365 Sales users can create a lead, qualify the lead to an opportunity, convert an opportunity into a quote, activate a quote, and create an order. This process was broken in dual-write due to lack of company striping on the **Lead** entity. We implemented company striping on the **Lead** entity, which cascades the company to the underlying **Account** and **Opportunity** tables. Thus the application behavior is restored to support the process. During the **Lead** qualification process, the **Contact** entity isn't company striped. This design supports the **Party** entity model that is due in October 2020. To learn about the **Party** and **GlobalAddressBook** model for dual-write, join the dual-write Yammer group.	General availability
Map state transitions from **Order** to **SalesOrder**	The **Order** form in Dynamics 365 Sales is always set to **Active**. To create state transitions from **Order** in Dynamics 365 Sales to **SalesOrder** in Dynamics 365 Supply Chain Management, we introduced the **ProcessingStatus** column.	General availability
Money to decimal data type conversion	Dataverse environments are limited to 4 decimal places for currency and 10 decimal places for exchange rates. Finance and Operations apps support more decimal places than Dataverse. You can now opt in to extend the decimal support in Dataverse to help ensure there's no loss of decimal place data when using dual-write.	General availability
Security role for company and currency exchange	Company and currency exchange tables are global in nature and all dual-write users require read access to these 2 tables. To simplify the experience, we've added a new security role named **dual-write app user**. Each dual-write user must be added to this security role.	General availability
Security role for setup	Adds the **Dual-write Runtime User** security role. This role allows non-administrator users to create rows that are set up for dual-write. This feature is part of Dual-write core solution 10.0.21.	General availability
Tracing	Internal column added for use in tracing. This feature is part of Dual-write core solution 10.0.21.	General availability

FEATURE	DESCRIPTION	STATUS
Bug fix	Fixes issues where dual-write fails because of a mismatch between the plugin and the destination environments. This fix is part of Dual-write core solution 10.0.21.	General availability
Bug fix	Support to ensure that unused plugins are deleted. This fix is part of Dual-write core solution 10.0.21.	General availability

August 2020 release

The August 2020 release of the dual-write orchestration package contains the features and bug fixes listed in the following table.

FEATURE	DESCRIPTION	STATUS
Manage multiple table maps	As part of day-to-day operations, you might need to bulk handle table maps. For example, you might want to simultaneously enable or pause a set of table maps. Instead of doing this one-by-one, which is cumbersome and time consuming, you can now enable, pause, resume, or stop more than one table map at the same time in the dual-write list page.	General availability
Bug fix	Fixes issues where rows would be skipped in certain cases during project execution. This fix is part of Dual-write core solution version 10.0.19.	General availability

June 2020 release

The June 2020 release of the dual-write orchestration package contains the features and bug fixes listed in the following table.

FEATURE	DESCRIPTION	STATUS
Edit legal entity after setup	The company or legal entity list isn't static and is constantly changing. You might need to add new companies, for example, during a phased rollout or acquisition. Previously, you couldn't add a company or legal entity without system downtime. During this downtime, you would have to unlink and relink your environment. That can be expensive, especially if you have pre-existing data. With this feature, you can add a company in a live environment without having to unlink and relink.	General availability

May 2020 release

The May 2020 release of the dual-write orchestration package (version 2.0.777.353) contains the features and bug fixes listed in the following table.

FEATURE	DESCRIPTION	STATUS
Look up on-hand inventory	Ability to look up on-hand inventory and available-to-promise dates on forms in customer engagement apps.	General availability
Unit conversions	When unit conversions occur in a Finance and Operations app at the quote line and order line, the customer engagement app honors the unit conversions and reflects the respective changes to unit and price in the customer engagement app quote detail and order detail.	General availability
Currency change restriction	When you try to change the currency in a Finance and Operations app for an existing quote or order, the change fails.	General availability
Parity in **Account** and **Contact** forms	Bring attribute parity in **Account** and **Contact** forms in customer engagement apps for B2B and B2C customers.	General availability
No address duplication	Don't duplicate an address in a Finance and Operations app when there's a create or update action on a customer engagement app quote or order.	General availability
SalesTaxGroup support	Support for **SalesTaxGroup** in **Account** and **Contact** forms for business-to-business (B2B) and business-to-consumer (B2C) customers.	General availability
Create sellable contacts	Allow creation of a sellable contact using the **Quick Create: Contact** form in customer engagement apps.	General availability
Quote and order creation	Enable quote and order creation for B2C customers.	General availability
Removal of tenant admin-level consent requirement	Until now, before you could enable dual-write, a tenant admin needed to explicitly give consent to the applications. This wasn't always practical and required additional approval, which can be time consuming. With this feature, we removed this prerequisite and the need for explicitly giving consent to the applications.	General availability

FEATURE	DESCRIPTION	STATUS
Force unlink dual-write environment	Previously, while testing dual-write, you had to disable all the table maps before unlinking a dual-write environment. This seemed cumbersome and sometimes not possible if one of the environments wasn't available. This new feature provides a quick way to unlink your test and trial environments.	General availability

The survey will take about seven minutes. No personal data is collected (privacy statement).

Dual-write overview

2/18/2021 • 4 minutes to read • Edit Online

NOTE

Effective November 2020:

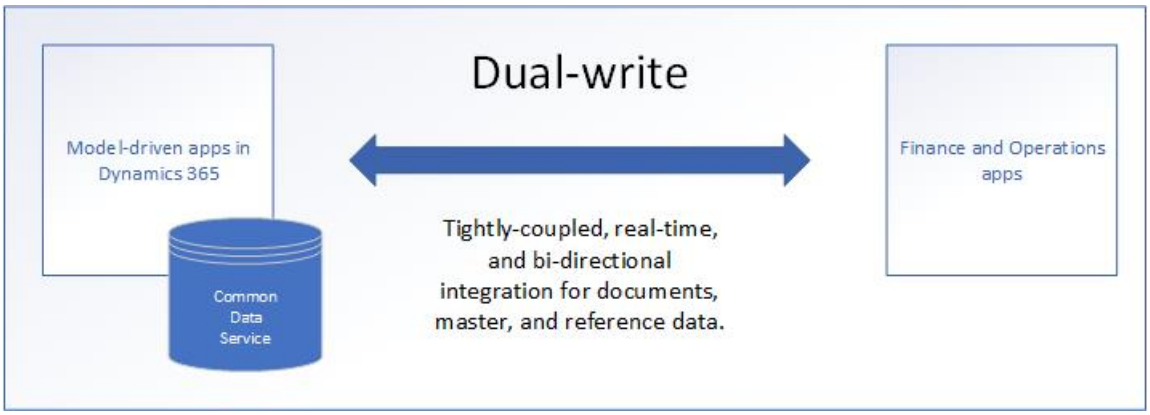
- Common Data Service has been renamed to Microsoft Dataverse. For more information, see Power Automate Blog.
- Some terminology in Microsoft Dataverse has been updated. For example, *entity* is now *table* and *field* is now *column*. For more information, see Terminology updates.

This topic will be updated soon to reflect the latest terminology.

What is dual-write?

Dual-write is an out-of-box infrastructure that provides near-real-time interaction between customer engagement apps and Finance and Operations apps. When data about customers, products, people, and operations flows beyond application boundaries, all departments in an organization are empowered.

Dual-write provides tightly coupled, bidirectional integration between Finance and Operations apps and Dataverse. Any data change in Finance and Operations apps causes writes to Dataverse, and any data change in Dataverse causes writes to Finance and Operations apps. This automated data flow provides an integrated user experience across the apps.



Dual-write has two aspects: an *infrastructure* aspect and an *application* aspect.

Infrastructure

The dual-write infrastructure is extensible and reliable, and includes the following key features:

- Synchronous and bidirectional data flow between applications
- Synchronization, together with play, pause, and catchup modes to support the system during online and offline/asynchronous modes.
- Ability to sync initial data between the applications
- Combined view of activity and error logs for data admins
- Ability to configure custom alerts and thresholds, and to subscribe to notifications
- Intuitive user interface (UI) for filtering and transformations
- Ability to set and view table dependencies and relationships
- Extensibility for both standard and custom tables and maps
- Reliable application lifecycle management

- Out-of-box setup experience for new customers

Application

Dual-write creates a mapping between concepts in Finance and Operations apps and concepts in customer engagement apps. This integration supports the following scenarios:

- Integrated customer master
- Access to customer loyalty cards and reward points
- Unified product mastering experience
- Awareness of organization hierarchy
- Integrated vendor master
- Access to finance and tax reference data
- On-demand price engine experience
- Integrated prospect-to-cash experience
- Ability to serve both in-house assets and customer assets through field agents
- Integrated procure-to-pay experience
- Integrated activities and notes for customer data and documents
- Ability to look up on-hand inventory availability and details
- Project-to-cash experience
- Ability to handle multiple addresses and roles through the party concept
- Single source management for users
- Integrated channels for retailing and marketing
- Visibility into promotions and discounts
- Request-for-service functions
- Streamlined service operations

Top reasons to use dual-write

Dual-write provides data integration across Microsoft Dynamics 365 applications. This robust framework links environments and enables different business applications to work together. Here are the top reasons why you should use dual-write:

- Dual-write provides tightly coupled, near-real-time, and bidirectional integration between Finance and Operations apps and model-driven apps in Dynamics 365. This integration makes Microsoft Dynamics 365 the one-stop shop for all your business solutions. Customers who use Dynamics 365 Finance and Dynamics 365 Supply Chain Management, but who use non-Microsoft solutions for customer relationship management (CRM), are moving toward Dynamics 365 for its dual-write support.
- Data from customers, products, operations, projects, and the Internet of Things (IoT) automatically flows to Dataverse through dual-write. This connection is useful for businesses that are interested in Power Platform expansions.
- The dual-write infrastructure follows the no-code/low-code principle. Minimal engineering effort is required to extend the standard table-to-table maps and to include custom maps.
- Dual-write supports both online mode and offline mode. Microsoft is the only company that offers support for online and offline modes.

What does dual-write mean for developers and architects of customer engagement apps?

Dual-write automates the data flow between Finance and Operations apps and customer engagement apps. Dual-write consists of two AppSource solutions that are installed on Dataverse. The solutions expand the table

schema, plugins, and workflows on Dataverse so that they can scale to ERP size. For a successful implementation, developers and architects of customer engagement apps must understand these changes and collaborate with their counterparts on Finance and Operations apps.

To create parity with Finance and Operations applications, dual-write makes some crucial changes in the Dataverse schema. If you understand the plan, you can avoid some design and development rework in the future.

- When the dual-write AppSource package is installed, Dataverse will have new concepts such as company and party. These concepts help applications built on Dataverse, including Dynamics 365 Sales, Dynamics 365 Marketing, Dynamics 365 Customer Service, and Dynamics 365 Field Service, to interact seamlessly with Finance and Operations apps.
- Activities and notes are unified and expanded to support both C1s (users of the system) and C2s (customers of the system).
- To prevent data loss during currency transmission between Finance and Operations apps and the Dataverse, you'll be able to extend the number of decimal places in the currency data type of customers engagement apps. The feature autotranslates existing rows to the new extended state at the metadata layer. During this process, the currency value is translated to decimal data rather than money data, and the currency value supports 10 decimal places. This feature is opt-in, and organizations that don't need more than 4 decimal places of precision do not need to opt in. For more information, see Currency data-type migration for dual-write.
- Date effectivity will be added to Dataverse. It will support past, present, and future data on the same table.
- Product unit conversions are supported for products, quotes, orders, and invoices.

For more information about upcoming changes, see What's new or changed in dual-write.

System requirements for dual-write

2/18/2021 • 2 minutes to read • Edit Online

The setup of a dual-write connection has the following requirements:

- Finance and Operations apps that have build version 10.0.9 (10.0.383.20013) (Quality update) and platform update 33 or later
- Customer engagement apps that have platform version 9.1.0000.11732 or later

Dual-write has these limitations:

- You can't run dual-write and the Prospect to cash solution for Data integrator side by side. If you're running the Prospect to cash solution for Data integrator, you must uninstall it.
- Dual-write setup is not supported on trial instances of Finance and Operations apps.
- Dual-write must be used to integrate a single Finance and Operations app instance and a single customer engagement app instance.
- Dual-write currently has a limit of 40 legal entities.
- Dual-write does not support cross-company data sharing.
- Dual-write requires that the Finance and Operations app and the customer engagement app must be in the same Microsoft Azure Active Directory (Azure AD) tenant.
- Dual-write requires that the Finance and Operations app and the customer engagement app must be deployed in the same Microsoft Azure datacenter.
- Dual-write is not triggered by the **doInsert**, **doUpdate**, and **doDelete** events of Finance and Operations apps. Use the **Insert**, **Update**, and **Delete** events in Finance and Operations apps when you want to trigger dual-write.
- Dual-write doesn't support distributed transactions. For example, if the product receipt posting process is cancelled, dual-write might create the product receipt in Dataverse but not create it in Supply Chain Management.

One Version

Future updates of the dual-write solution will be available through One Version.

Guidance for dual-write setup

2/18/2021 • 6 minutes to read • Edit Online

IMPORTANT

Some or all of the functionality noted in this topic is available as part of a preview release. The content and the functionality are subject to change. For more information about preview releases, see Service update availability.

NOTE

Effective November 2020:

- Common Data Service has been renamed to Microsoft Dataverse. For more information, see Power Automate Blog.
- Some terminology in Microsoft Dataverse has been updated. For example, *entity* is now *table* and *field* is now *column*. For more information, see Terminology updates.

This topic will be updated soon to reflect the latest terminology.

You can set up a dual-write connection between a Finance and Operations environment and a Dataverse environment.

- A **Finance and Operations environment** provides the underlying platform for **Finance and Operations apps** (for example, Microsoft Dynamics 365 Finance, Dynamics 365 Supply Chain Management, Dynamics 365 Commerce, and Dynamics 365 Human Resources).
- A **Dataverse environment** provides the underlying platform for **customer engagement apps** (Dynamics 365 Sales, Dynamics 365 Customer Service, Dynamics 365 column Service, Dynamics 365 Marketing, and Dynamics 365 Project Service Automation).

IMPORTANT

The Human Resources module in Dynamics 365 Finance supports dual-write connections, but the Dynamics 365 Human Resources app doesn't.

The setup mechanism varies, depending on your subscription and the environment:

- For new instances of Finance and Operations apps, the setup of a dual-write connection begins in Microsoft Dynamics Lifecycle Services (LCS). If you have a license for Microsoft Power Platform, you will get a new Dataverse environment if your tenant doesn't have one.
- For existing instances Finance and Operations apps, the setup of a dual-write connection begins in the Finance and Operations environment.

Before you start dual-write on an entity, you can run an initial synchronization to handle existing data on both sides: Finance and Operations apps and customer engagement apps. You can skip the initial synchronization if you don't have to sync data between the two environments.

An initial synchronization lets you copy existing data from one app to another bidirectionally. There are several setup scenarios, depending on the environments that you already have and the type of data in them.

The following setup scenarios are supported:

- A new Finance and Operations app instance and a new customer engagement app instance

- A new Finance and Operations app instance and an existing customer engagement app instance
- A new Finance and Operations app instance that has data and a new customer engagement app instance
- A new Finance and Operations app instance that has data and an existing customer engagement app instance
- An existing Finance and Operations app instance and a new customer engagement app instance
- An existing Finance and Operations app instance and an existing customer engagement app instance

A new Finance and Operations app instance and a new customer engagement app instance

To set up a dual-write connection between a new instance of a Finance and Operations app that has no data and a new instance of a customer engagement app, follow the steps in Dual-write setup from Lifecycle Services. When the connection setup is completed, the following actions automatically occur:

- A new, empty Finance and Operations environment is provisioned.
- A new, empty instance of a customer engagement app is provisioned, where the CRM prime solution is installed.
- A dual-write connection is established for DAT company data.
- Table maps are enabled for live synchronization.

Both environments are then ready for live data synchronization.

A new Finance and Operations app instance and an existing customer engagement app instance

To set up a dual-write connection between a new instance of a Finance and Operations app that has no data and an existing instance of a customer engagement app, follow the steps in Dual-write setup from Lifecycle Services. When the connection setup is completed, the following actions automatically occur:

- A new, empty Finance and Operations environment is provisioned.
- A dual-write connection is established for DAT company data.
- Table maps are enabled for live synchronization.

Both environments are then ready for live data synchronization.

To sync the existing Dataverse data to the Finance and Operations app, follow these steps.

1. Create a new company in the Finance and Operations app.
2. Add the company to the dual-write connection setup.
3. Bootstrap the Dataverse data by using a three-letter International Organization for Standardization (ISO) company code.
4. Run the **Initial sync** functionality for the tables that you want to sync data for.

For links to an example and an alternative approach, see the Example section later in this topic.

A new Finance and Operations app instance that has data and a new customer engagement app instance

To set up a dual-write connection between a new instance of a Finance and Operations app that has data and a new instance of a customer engagement app, follow the steps in the A new Finance and Operations app instance and a new customer engagement app instance section earlier in this topic. When the connection setup is completed, if you want to sync the data to the customer engagement app, follow these steps.

1. Open the Finance and Operations app from the LCS page, sign in, and then go to **Data Management** > **Dual-write**.
2. Run the **Initial sync** functionality for the tables that you want to sync data for.

For links to an example and an alternative approach, see the Example section.

A new Finance and Operations app instance that has data and an existing customer engagement app instance

To set up a dual-write connection between a new instance of a Finance and Operations app that has data and an existing instance of a customer engagement app, follow the steps in the A new Finance and Operations app instance and an existing customer engagement app instance section earlier in this topic. When the connection setup is completed, if you want to sync the data to the customer engagement app, follow these steps.

1. Open the Finance and Operations app from the LCS page, sign in, and then go to **Data Management** > **Dual-write**.
2. Run the **Initial sync** functionality for the tables that you want to sync data for.

To sync the existing Dataverse data to the Finance and Operations app, follow these steps.

1. Create a new company in the Finance and Operations app.
2. Add the company to the dual-write connection setup.
3. Bootstrap the Dataverse data by using a three-letter ISO company code.
4. Run the **Initial sync** functionality for the tables that you want to sync data for.

For links to an example and an alternative approach, see the Example section.

An existing Finance and Operations app instance and a new customer engagement app instance

The setup of a dual-write connection between an existing instance of a Finance and Operations app and a new instance of a customer engagement app occurs in the Finance and Operation environment.

1. Set up the connection from the Finance and Operations app.
2. Run the **Initial sync** functionality for the tables that you want to sync data for.

For links to an example and an alternative approach, see the Example section.

An existing Finance and Operations app instance and an existing customer engagement app instance

The setup of a dual-write connection between an existing instance of a Finance and Operations app and an existing instance of a customer engagement app occurs in the Finance and Operation environment.

1. Set up the connection from the Finance and Operations app.
2. To sync the existing Dataverse data to the Finance and Operations app, bootstrap the Dataverse data by using a three-letter ISO company code.
3. Run the **Initial sync** functionality for the tables that you want to sync data for.

For links to an example and an alternative approach, see the Example section.

Example

For an example, see Enabling the Customers V3—Contacts table map

For an alternative approach that is based on data volumes in each entity that must run an initial synchronization, see Considerations for initial synchronization.

> The survey will take about seven minutes. No personal data is collected (privacy statement).

Considerations for initial synchronization

2/18/2021 • 7 minutes to read • Edit Online

NOTE

Effective November 2020:

- Common Data Service has been renamed to Microsoft Dataverse. For more information, see Power Automate Blog.
- Some terminology in Microsoft Dataverse has been updated. For example, *entity* is now *table* and *field* is now *column*. For more information, see Terminology updates.

This topic will be updated soon to reflect the latest terminology.

Before you start dual-write on a table, you can run an initial synchronization to handle existing data on both sides: Finance and Operations apps and customer engagement apps. You can skip the initial synchronization if you don't have to sync data between the two environments.

The initial synchronization lets you copy existing data from one app to another bidirectionally, and there are several considerations when you run it. For example, you might have to migrate data before your go-live. In this case, data can be loaded into one side through data migration and then synced to the other side through the initial synchronization.

We recommend that you use the following approach for the initial synchronization:

- **Single-threaded tables**: First migrate data into the Finance and Operations app, and then trigger the initial synchronization to move the data over to Dataverse. Based on lab testing that Microsoft has done, this sequence has better performance than synchronization from Dataverse to Finance and Operations apps.
- **Multi-threaded tables**: First migrate data into Dataverse, and then trigger the initial synchronization to move the data over to the Finance and Operations app.

Constraints

Data migration slow-down with enabled dual-write

If you first activate the map in dual-write and then start to import data, migration performance will be poor. We recommend that you not activate running maps in dual-write until the data migration is completed.

Limit of 500,000 rows per run

The maximum number of rows that is allowed through initial synchronization is 500,000 per run. The limit of 500,000 rows applies to each legal table, because each legal entity runs separately. For more information, see Integrate data into Dataverse. In particular, pay attention to the note that states, "To optimize performance and not overload the apps, we currently limit project executions to 500k rows per execution per project."

If there must be more than 500,000 rows in a run when you the initial synchronization, we recommend that you migrate data into the Finance and Operations app and Dataverse separately, and skip the initial synchronization.

Twenty-four-hour limit

If you're running the initial synchronization from Dataverse to the Finance and Operations app, the import result must be received back from the Finance and Operations app within 24 hours. Otherwise, a time-out occurs. Therefore, if you're syncing lots of data, and the single run takes more than 24 hours, the initial synchronization might fail because of a time-out. For example, an initial synchronization from Dataverse to a Finance and Operations app for the **Customer/Account** table involves 70,000 rows. Therefore, the run might take more

than 24 hours and time out.

Don't run the initial synchronization from Dataverse to a Finance and Operations app for single-threaded tables if the data volume is more than 70,000 rows. Because these tables don't support multi-threading during import, a time-out might occur if the volume is more 70,000 rows. In this situation, you should migrate data into the Finance and Operations app and Dataverse separately, and skip the initial synchronization.

Limit of 40 legal entities while the environments are being linked

Currently, there is a limit of 40 legal entities while the environments are being linked. If you try to enable maps where more than 40 legal entities are linked between the environments, you will receive the following error message:

```
Dual-write failure - Plugin registration failed: [(Unable to get partition map for project DWM-1ae35e60-4bc2-4905-88ea-XXXXX. Error Exceeds the maximum partitions allowed for mapping DWM-1ae35e60-4bc2-4905-88ea-XXXXX)], One or more errors occurred.
```

Initial synchronization isn't currently supported for table maps that have 10 or more lookups

This limitation applies only to the initial synchronization from Dataverse for table maps that have 10 or more lookups. If you run the initial synchronization against a table map that has 10 or more lookups, you might receive the following error message:

```
5 Attempts to get data from https://XXXX.azure-apim.net/apim... Failed
```

As a workaround you can split the initial sync into these steps:

1. Remove some of the lookup columns that are not mandatory from the dual-write table map and bring the number of lookups to 10.
2. After the lookup columns are removed, save the map and do the initial sync.
3. After the initial sync for the first step is successful, add the remaining lookup columns and remove the lookup columns that were synced in first step. Once again make sure the number of lookup columns is 10. Save the map and run the initial sync. Repeat these steps to make sure all the lookup columns are synced.
4. Add all the lookup columns back to the map, save the map and run the map with skip initial sync. This will enable the map for live sync mode.

Five-minute limit for Finance and Operations data export

If you're running the initial synchronization from the Finance and Operations app to Dataverse and the Finance and Operations data export takes more than five minutes, then the initial sync might time out. The time-out can happen if the data table has virtual columns with the `postLoad` method, or the export query isn't optimized (for example, if it has missing indexes).

This type of synchronization is supported in Platform update 37 (PU37) and later. Therefore, you should update your Finance and Operations app to PU37 or later.

Error handling capabilities

Initial synchronization is always a full push

If an individual row fails to be synced, you can't resync only that individual row. The initial synchronization always pushes the whole data set. This behavior is known as a *full push*. If the initial synchronization only partially succeeds, a second synchronization runs for all the rows, not just the rows that failed to be synced during the initial synchronization.

Only the top five errors can be viewed

You can view only the top five errors from the initial synchronization error log.

Known issues

For information about known issues, see Troubleshoot issues during initial synchronization.

Guidance matrix

FINANCE AND OPERATIONS APP INSTANCE	DATAVERSE INSTANCE	HAS DATA TO RUN THE INITIAL SYNCHRONIZATION	DESCRIPTION	MAXIMUM VOLUME IN A TABLE	SINGLE-THREADED OR MULTI-THREADED	APPROACH

Single-threaded tables

- Sales tax codes (msdyn_taxcodes)
- Customers V3 (accounts)
- Vendors V2 (msdyn_vendors)
- Warehouses (msdyn_warehouses)
- Product categories (msdyn_productcategories)
- Employment (cdm_employments)
- Position worker assignments (cdm_positionworkerassignmentmaps)
- Warehouse locations (msdyn_inventorylocations)
- Modes of delivery (msdyn_shipvias)

Dual-write setup from Lifecycle Services

2/18/2021 • 2 minutes to read • Edit Online

NOTE

Effective November 2020:

- Common Data Service has been renamed to Microsoft Dataverse. For more information, see Power Automate Blog.
- Some terminology in Microsoft Dataverse has been updated. For example, *entity* is now *table* and *field* is now *column*. For more information, see Terminology updates.

This topic will be updated soon to reflect the latest terminology.

This topic explains how to set up a dual-write connection between a new Finance and Operations environment and a new Dataverse environment from Microsoft Dynamics Lifecycle Services (LCS).

Prerequisites

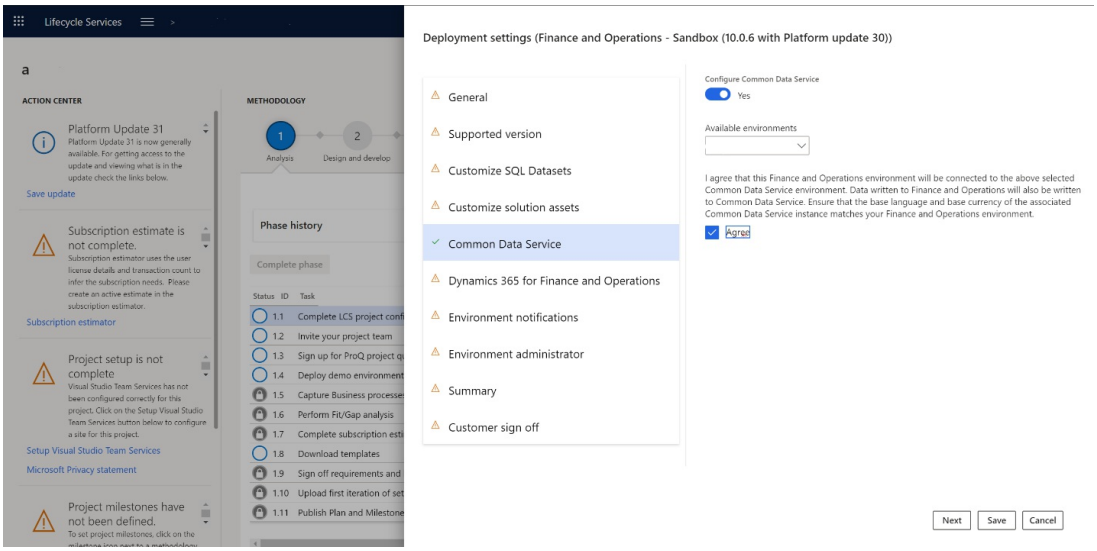
You must be an admin to set up a dual-write connection.

- You must have access to the tenant.
- You must be an admin in both Finance and Operations environments and Dataverse environments.

Set up a dual-write connection

Follow these steps to set up the dual-write connection.

1. In LCS, go to your project.
2. Select **Configure** to deploy a new environment.
3. Select the version.
4. Select the topology. If only one topology is available, it's automatically selected.
5. Complete the first steps in the **Deployment settings** wizard.
6. On the **Dataverse** tab, follow one of these steps:
   - If a Dataverse environment is already provisioned for your tenant, you can select it.
     a. Set the **Configure Dataverse** option to **Yes**.
     b. In the **Available environments** column, select the environment to integrate with your Finance and Operations data. The list includes all environments where you have admin privileges.
     c. Select the **Agree** check box to indicate that you agree to the terms and conditions.



- If your tenant doesn't already have a Dataverse environment, a new environment will be provisioned.

  a. Set the **Configure Dataverse** option to **Yes**.

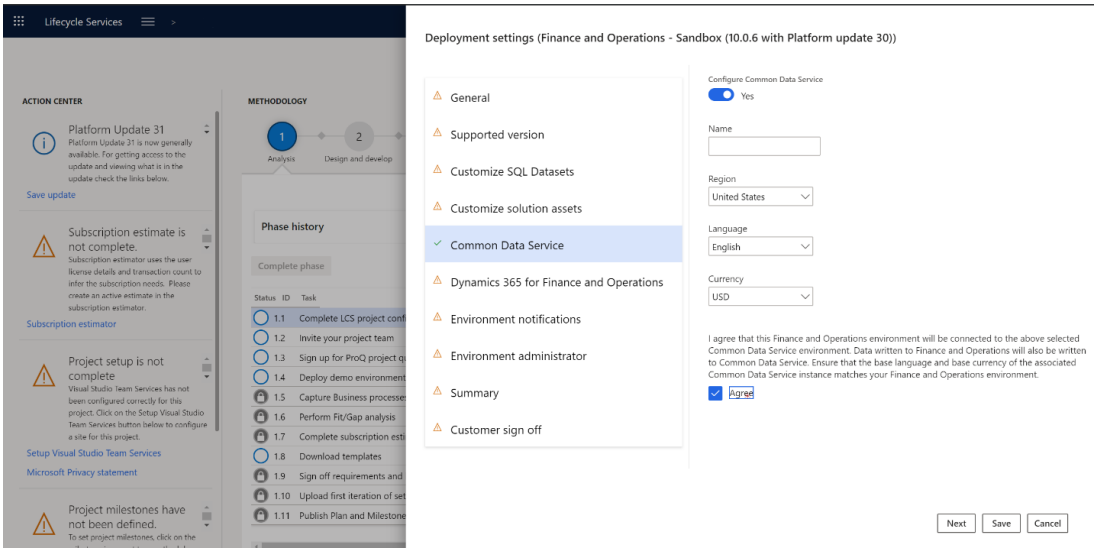
  b. Enter a name for the Dataverse environment.

  c. Select the region to deploy the environment in.

  d. Select the default language and currency for the environment.

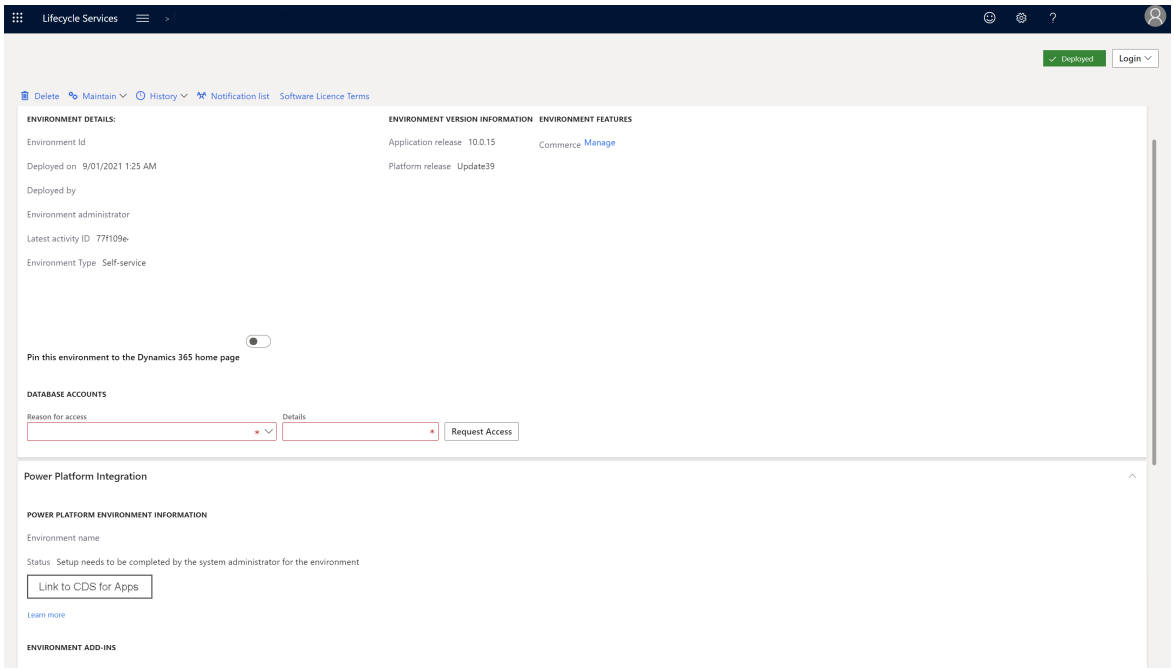
  > **NOTE**
  > You can't change the language and currency later.

  e. Select the **Agree** check box to indicate that you agree to the terms and conditions.



7. Complete the remaining steps in the **Deployment settings** wizard.

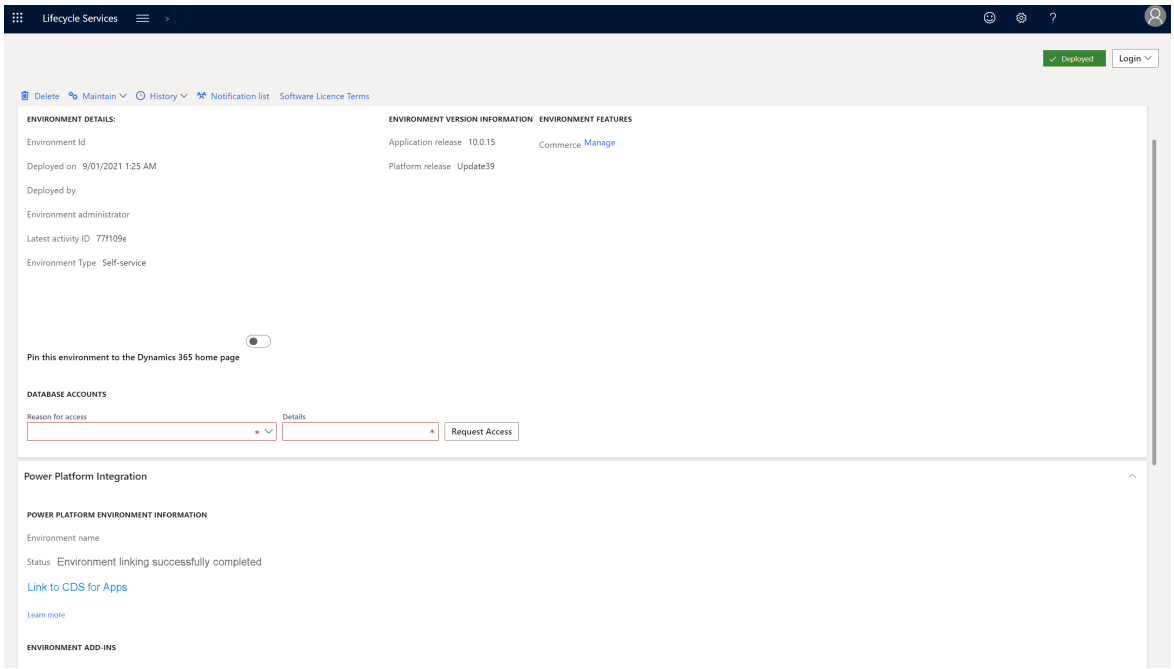
8. After the environment has a status of **Deployed**, open the environment details page. The **Power Platform Integration** section shows the names of the Finance and Operations environment and the Dataverse environment that are linked.



9. An admin of the Finance and Operations environment must sign in to LCS and select **Link to CDS for Apps** to complete the link. The environment details page shows the admin's contact information.

   After the link is completed, the status is updated to **Environment linking successfully completed**.

10. To open the **Data integration** workspace in the Finance and Operations environment and control the templates that are available, select **Link to CDS for Apps**.



NOTE

You can't unlink environments by using LCS. To unlink an environment, open the **Data integration** workspace in the Finance and Operations environment, and then select **Unlink**.

Enable dual-write for existing Finance and Operations apps

2/18/2021 • 2 minutes to read • Edit Online

NOTE

Effective November 2020:

- Common Data Service has been renamed to Microsoft Dataverse. For more information, see Power Automate Blog.
- Some terminology in Microsoft Dataverse has been updated. For example, *entity* is now *table* and *field* is now *column*. For more information, see Terminology updates.

This topic will be updated soon to reflect the latest terminology.

This set of topics provides step-by step instructions that explain how to enable dual-write for existing instances of Finance and Operations apps (Microsoft Dynamics 365 Finance and Dynamics 365 Supply Chain Management), and also for a new or existing Dataverse environment.

Step-by-step instructions to enable dual-write for existing instances of Finance and Operations apps and a new or existing Dataverse environment

The process of enabling dual-write has three parts:

1. Make sure that you meet all the system requirements and complete all the prerequisites.
2. Link your Finance and Operations app environment to Dataverse by using the dual-write wizard.
3. Enable the table maps.

Each part is described in a separate topic.

Next steps

System requirements and prerequisites

NOTE

Can you tell us about your documentation language preferences? Take a short survey.

The survey will take about seven minutes. No personal data is collected (privacy statement).

System requirements and prerequisites

2/18/2021 • 7 minutes to read • Edit Online

NOTE

Effective November 2020:

- Common Data Service has been renamed to Microsoft Dataverse. For more information, see Power Automate Blog.
- Some terminology in Microsoft Dataverse has been updated. For example, *entity* is now *table* and *field* is now *column*. For more information, see Terminology updates.

This topic will be updated soon to reflect the latest terminology.

What regions are available?

Currently, we support dual-write in the following regions:

- Asia
- Australia
- Canada
- Europe
- India
- Japan
- South America
- United Kingdom
- United States

Verify requirements and grant access

Before you enable dual-write, follow these steps to make sure that you meet the minimum system requirements and to grant access to the apps that must connect to each other. The dual-write health check validates the prerequisites as you complete the dual-write wizard to link a Finance and Operations app environment to a Dataverse environment.

You must set **Enable Dynamics 365 apps** to **Yes** when you set up the environment, as shown in the following image. Alternatively, you can choose a model-driven app for Dynamics 365 environment that comes with Dataverse and already has **Enable Dynamics 365 apps** set to **Yes**.

1. Validate the platform update and app version.

   Make sure that your Finance and Operations app environment is running Platform update 33 (app version 10.0.9) or later.

   Related health check result:

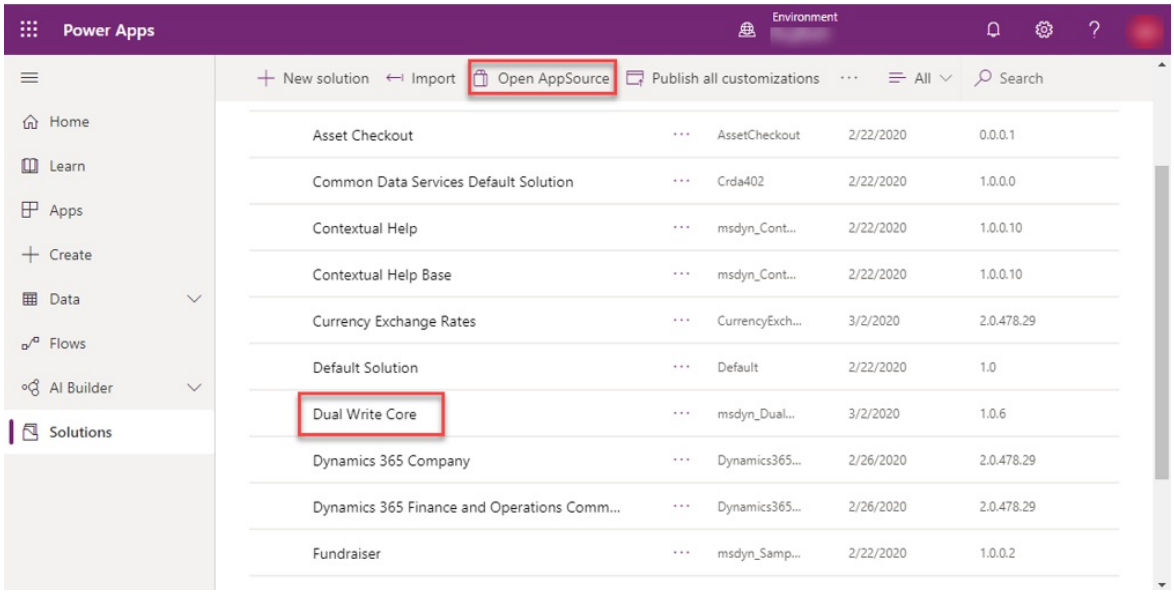
   App version is up to date

   Dual Write is supported on Finance and Operations app environments with Platform Update PU 33 (App version 10.0.9) or above

2. Install the dual-write core solution.

   The dual-write core solution contains metadata for your table maps and must be installed in your environments.

   a. In Power Apps, in the left pane, select **Solutions**.
   b. Select **Open AppSource**.
   c. Select the **Dual Write Core** solution.
   d. Follow the prompts to import the solution.



Related health check result:

The dual-write core solution was found

The dual-write core solution contains metadata for your table maps and must be installed in the environment

3. Grant Dataverse access so that it can connect to a Finance and Operations app.

   a. Open your instance of the Finance and Operations app, search and navigate to Azure Active Directory applications.

   b. Select **New** to add a new client ID row: **6f7d0213-62b1-43a8-b7f4-ff2bb8b7b452**. This row is the application ID for an app that will be used to connect from Dataverse to the Finance and Operations app.

   c. Repeat the previous two steps to add another client ID row: **2e49aa60-1bd3-43b6-8ab6-03ada3d9f08b**.

   When you've finished, follow these steps to refresh the list of tables:

   a. Go to **Workspaces** > **Data management**, select the **Data tables** tile, and make sure that the table list is filled in.

   b. Go to **Workspaces** > **Data management**, and select the **Framework parameters** tile. Then, on the **Entities** tab (

   ```
   https://<BaseFinanceandOperationsappsURL>/?
   cmp=USMF&mi=DM_DataManagementWorkspaceMenuItem&TableName=DMFDefinitionGroupEntity
   ```

   ), select **Refresh tables list**.

   Related health check result:

   The Dataverse can connect to the Finance and Operations app

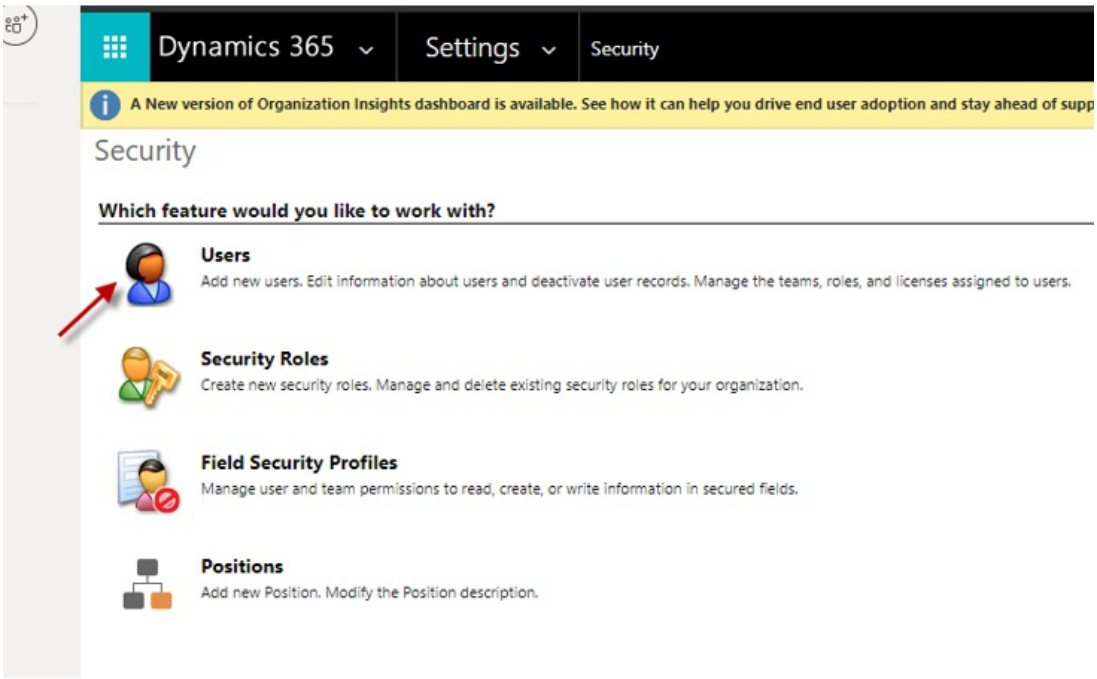
   Before you can enable dual-write, you must grant access to the apps to connect to each other

   App user with id 6f7d0213-62b1-43a8-b7f4-ff2bb8b7b452 exists

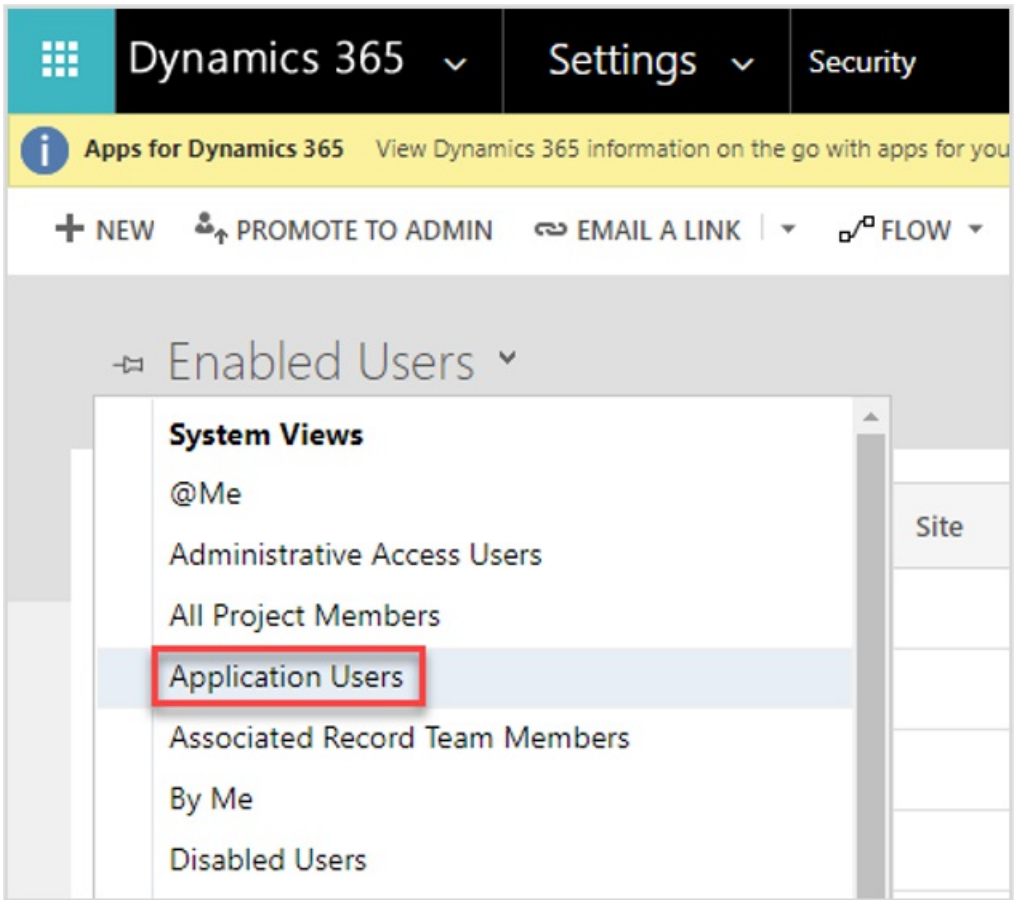
   App user with id 2e49aa60-1bd3-43b6-8ab6-03ada3d9f08b exists

4. Grant a Finance and Operations app access so that it can connect to Dataverse.

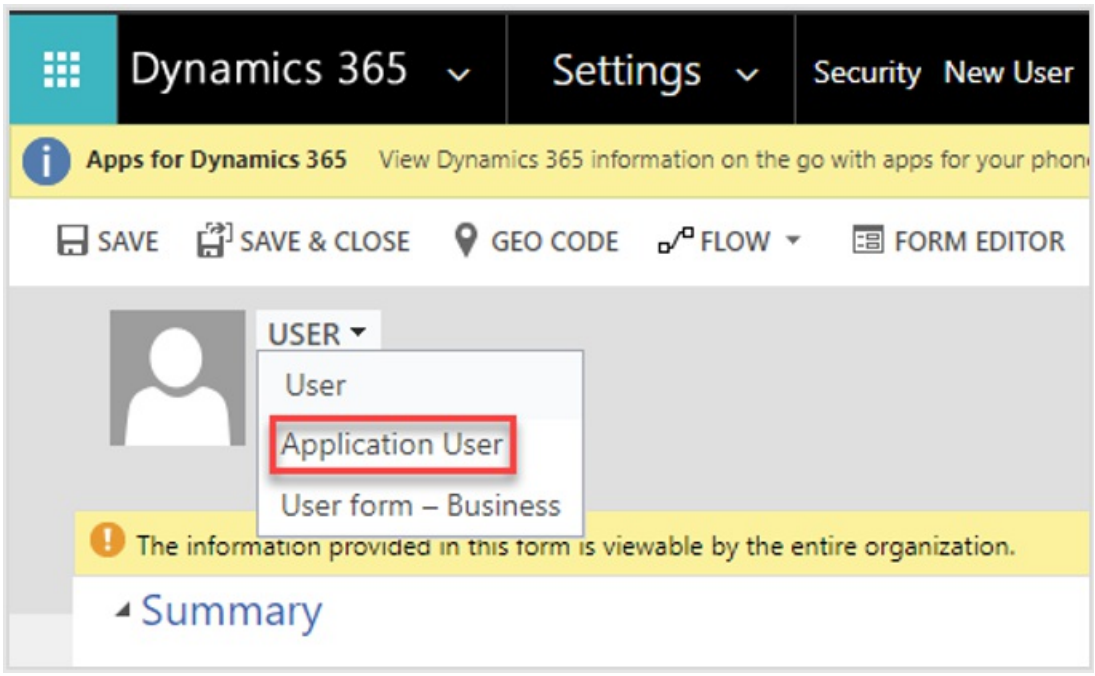
   a. In Power Apps, select the **Settings** button (gear symbol) in the upper-right corner, go to **Advanced settings** > **Security**, and then select **Users**.



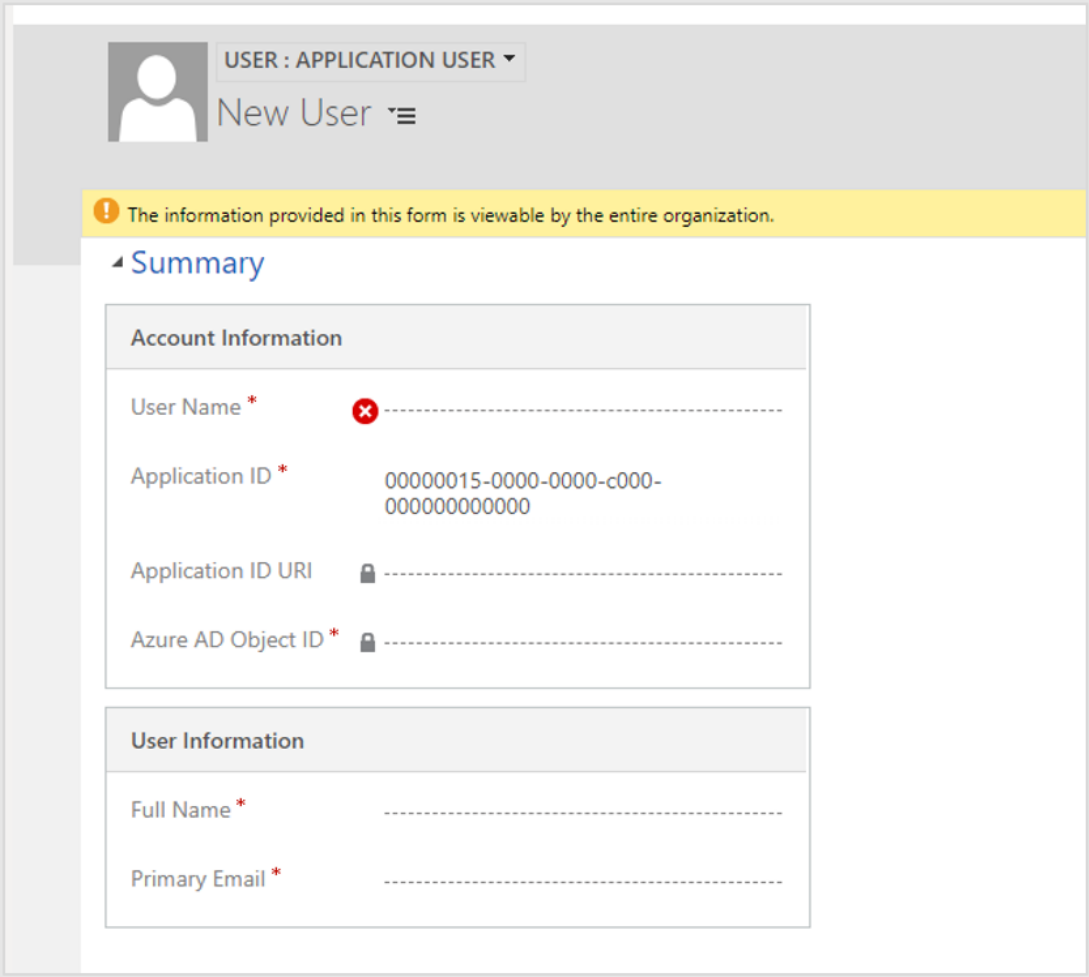
b. Use the drop-down menu to change the view from **Enabled Users** to **Application Users**.



c. Create a new user, and then, on the **User** menu, select **Application User**.

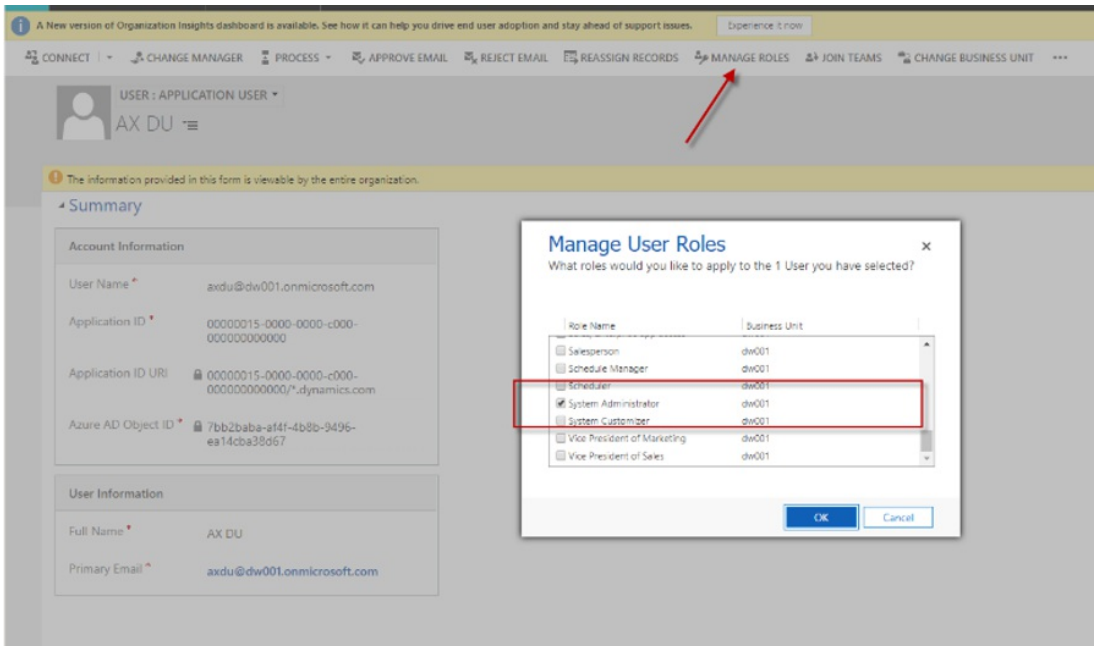


d. In the **Application ID** column, enter **00000015-0000-0000-c000-000000000000**. This application ID is for a Finance and Operations app and will enable the app to connect to Dataverse. When you've finished, follow the prompts to fill in the other columns, and then save the user account.



e. Provide a primary email address.

f. Select **Manage Roles**, and then, in the **Manage User Roles** dialog box, select the **System Administrator** check box to provide system admin rights to the selected application user.



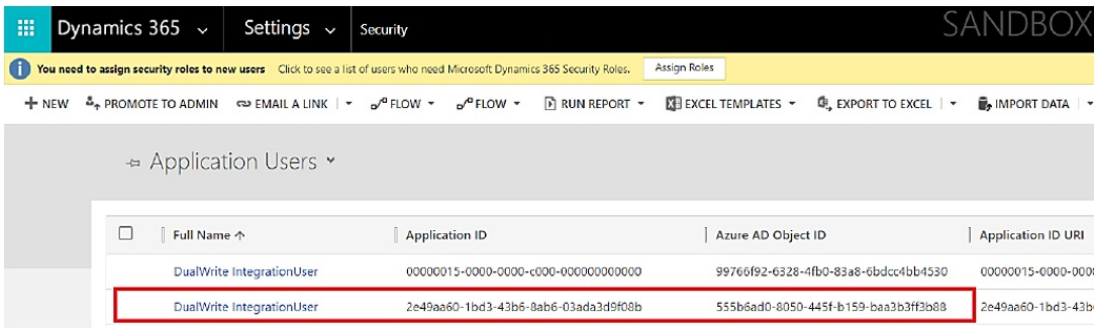
g. Go to **Dynamics 365 > Settings > Security**, select **Teams**, and then change the view to **All Owner Teams**.

h. Select **default team for the root Business Unit**, select **Manage Roles**, and then, in the **Manage Team Roles** dialog box, select a preconfigured **Security Role** to grant a **Read** privilege with a **User** scope for each table integrated through dual-write.

For instructions on how to create a Security Role, see Create or configure a custom security role.

> **NOTE**
>
> The root business unit's default team will become the default owner for all rows integrated through dual-write. Because that team must be assigned a security role, this means that all users in the root business unit will inherit the security role. This means that at the very least, **users from that business unit will have read access to all the rows that are owned by that team**. If this isn't the desired behavior, make sure that users are not a member of the root business unit.

i. Repeat the previous five steps for application ID **2e49aa60-1bd3-43b6-8ab6-03ada3d9f08b**.



Related health check result:
The Finance and Operations app can connect to the Dataverse
Before you can enable dual-write, you must grant access to the apps to connect to each other
App user with id 00000015-0000-0000-c000-000000000000 exists
App user with id 2e49aa60-1bd3-43b6-8ab6-03ada3d9f08b exists

5. Provide app consent in the tenant. For dual-write core solution version 1.0.16.0 or above, this step is no longer needed.

   Related health check result:
   Apps in tenant
   The required dual-write applications need to be installed in the tenant.
   App ID: 6f7d0213-62b1-43a8-b7f4-ff2bb8b7b452
   App ID: 2e49aa60-1bd3-43b6-8ab6-03ada3d9f08b

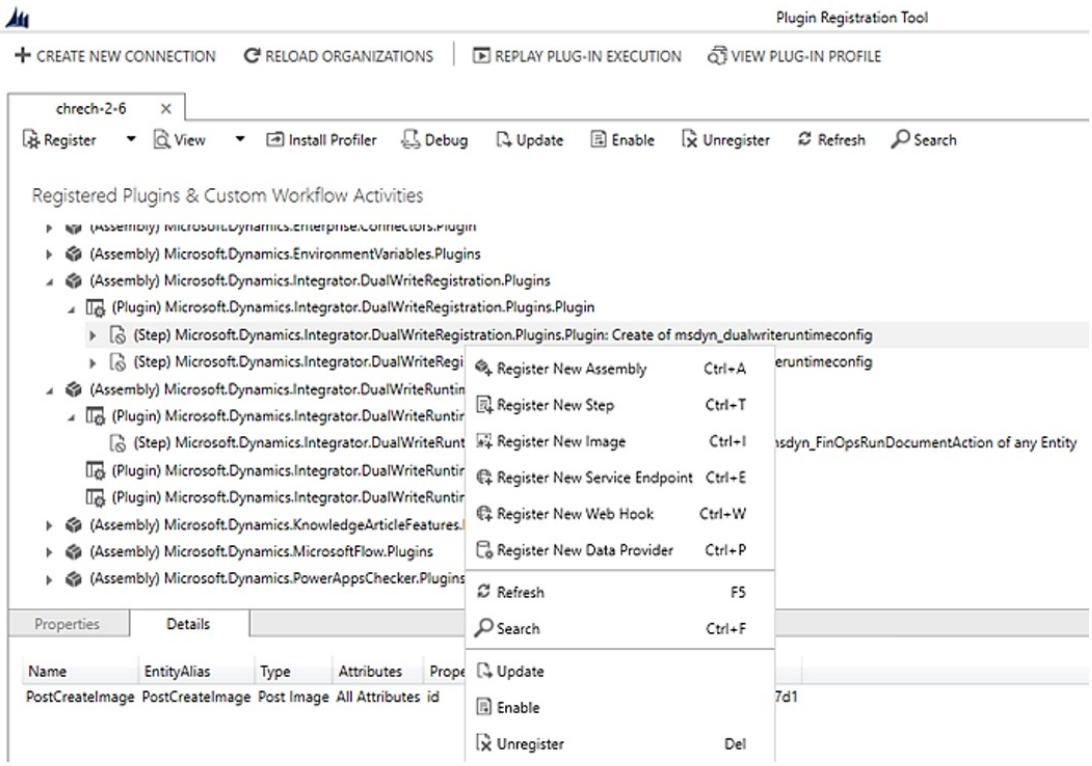
6. Make sure that the dual-write plug-ins are enabled.

   This step isn't usually required, because the plug-ins should be enabled as part of the process of installing the dual-write core solution. However, if the health check fails, follow these steps to manually enable the dual-write plug-ins:

   a. Download the Plug-in Registration Tool.

      In the Plugin Registration Tool, there should be two plug-in assemblies that are associated with dual-write: **DualWriteRegistration.Plugins** and **DualWriteRuntime.Plugins**. These assemblies have plug-in steps that must be enabled, in order, before dual-write can be used. To view the plug-in steps, expand a plug-in assembly and its plug-in types. All the steps that belong to the dual-write plug-in assemblies should be enabled.

   b. To enable a step, select and hold the step (or right-click it), and then select **Enable**. If no **Enable** option is available, only a **Disable** option, the step has already been enabled and doesn't have to be changed.



> **NOTE**
>
> If the dual-write plug-in assemblies can't be found, import the latest version of the dual-write core solution.

Related health check result:
The dual-write registration and runtime plugins are enabled
To ensure listening into CRUD operations on the Dataverse, the dual-write plugins need to be enabled

7. Install the **Dual-write application orchestration solution** maps solution.

   In Power Apps, in the left pane, select **Solutions**. Select **Open AppSource**, and search for the solution that is named **Dual-write application orchestration solution**. Select the solution, and follow the prompts to import it. After installation, you'll find several new solutions listed under **Solutions**. For more information, see Solutions overview.

   While the dual-write core solution contains metadata for your table maps, the dual-write application orchestration solution covers these additional master data scenarios:

   - Customers, products, and vendors.
   - End-to-end process flows like prospect to cash.
   - On-demand functions like pricing.
   - Reference data for ledger, tax, payment terms, and schedules.

   Dual-write will continue to expand in the future to support more scenarios including party, project, and hands-on inventory. The framework is extensible and accommodates customer-centric business data exchange through a few additional clicks.

   > **NOTE**
   >
   > You must select **Apply Solution** as part of the next steps, when you use the dual-write wizard to link your environments. It may take few minutes for the solution packages to be created in Power Apps solutions section. Wait for it to appear before moving to the next step.

8. Uninstall the Prospect to Cash (P2C) solution.

The P2C solution doesn't work concurrently with dual-write. Therefore, don't install the P2C solution. If it's already installed, you must uninstall it before you enable dual-write.

9. Provide the supported tenant configuration.

   Make sure that the Finance and Operations app and Dataverse are installed under the same tenant. Cross-tenant scenarios aren't currently supported.

   > **NOTE**
   > For dual-write core solution versions lower than 1.0.16.0, see the following section for modifications and additional steps.

For dual-write core solution lower than version 1.0.16.0 only

1. In step Step 3b above, create a new client ID row: **33976c19-1db5-4c02-810e-c243db79efde** (versus 6f7d0213-62b1-43a8-b7f4-ff2bb8b7b452).
2. Add app consent in the tenant:

   a. Open the following URL, and sign in by using your admin credentials. You should be prompted for consent.

      https://login.microsoftonline.com/common/oauth2/authorize?client_id=33976c19-1db5-4c02-810e-c243db79efde&response_type=code&prompt=admin_consent

   b. Select **Accept**.

      By selecting **Accept**, you indicate that you're providing consent to install the app that has application ID **33976c19-1db5-4c02-810e-c243db79efde** in your tenant. Dataverse requires this app to communicate with the Finance and Operations app.

Related health check result:
Apps in tenant
The required dual-write applications need to be installed in the tenant.
App ID: 33976c19-1db5-4c02-810e-c243db79efde
App ID: 2e49aa60-1bd3-43b6-8ab6-03ada3d9f08b

Use the dual-write wizard to link your environments

2/18/2021 • 2 minutes to read • Edit Online

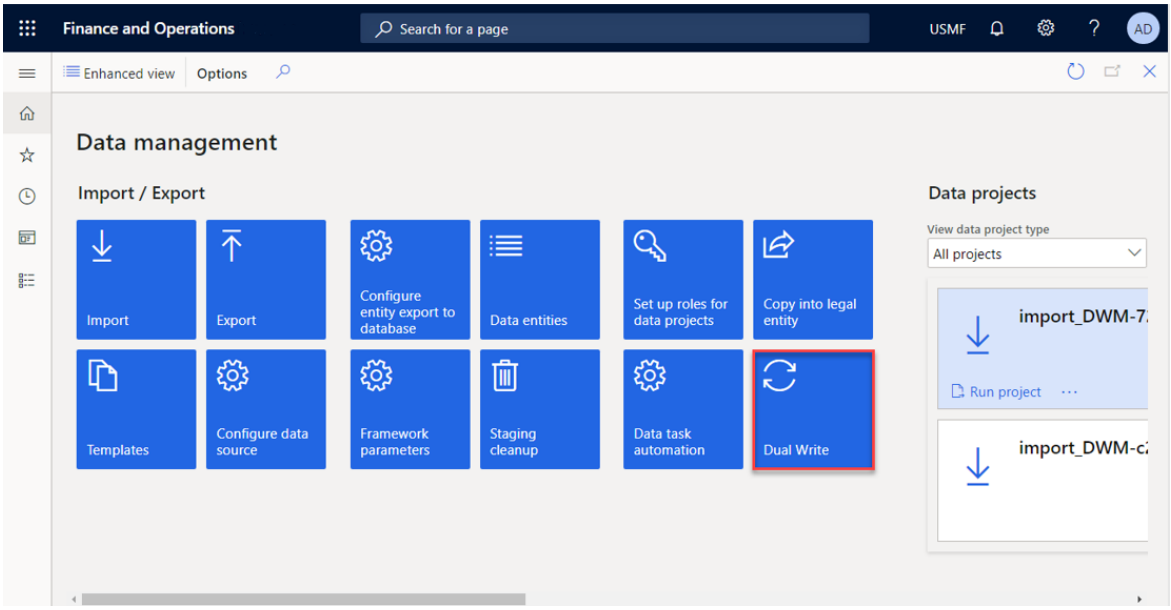
NOTE

Effective November 2020:

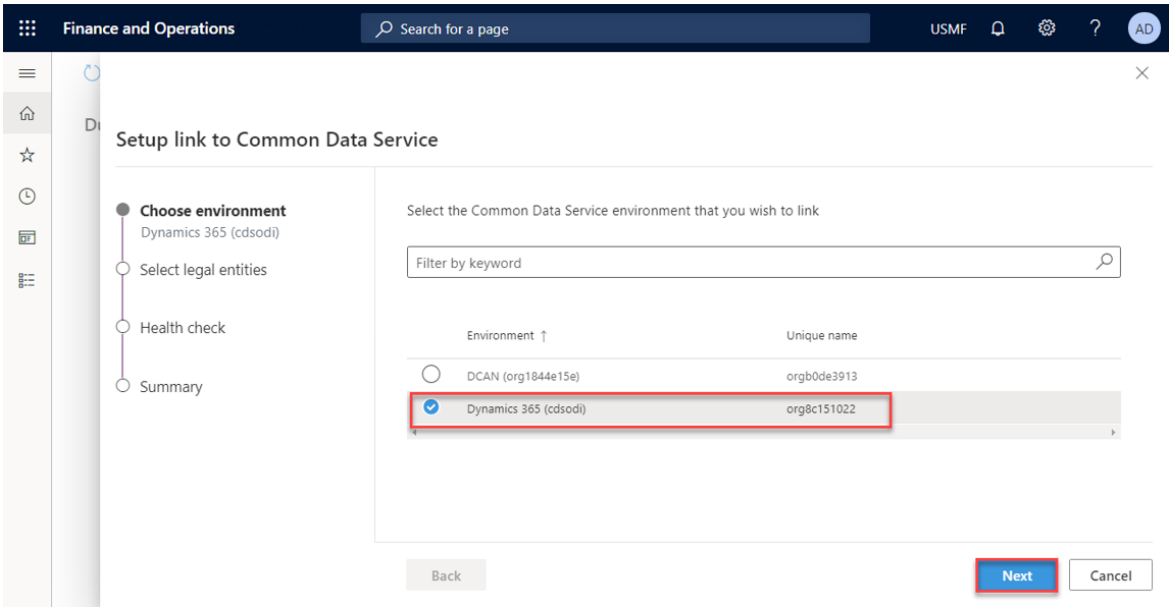
- Common Data Service has been renamed to Microsoft Dataverse. For more information, see Power Automate Blog.
- Some terminology in Microsoft Dataverse has been updated. For example, *entity* is now *table* and *field* is now *column*. For more information, see Terminology updates.

This topic will be updated soon to reflect the latest terminology.

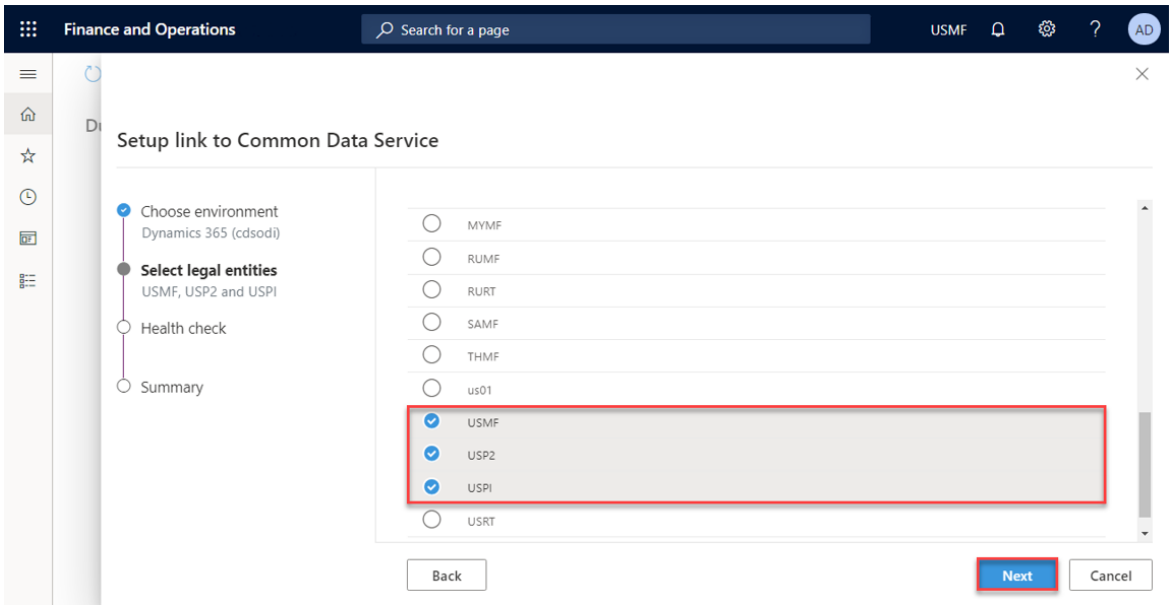
1. Sign in to the Finance and Operations app environment that you want to link to your Dataverse environment.
2. Go to **Workspaces** > **Data management**, and select the **Dual Write** tile.



3. Select **New link to environment** to open the **Setup link to Dataverse** wizard.
4. The **Choose environment** page lists all the Dataverse environments where the signed-in user is an environment admin. Select the Dataverse environment to link to, and then select **Next**.

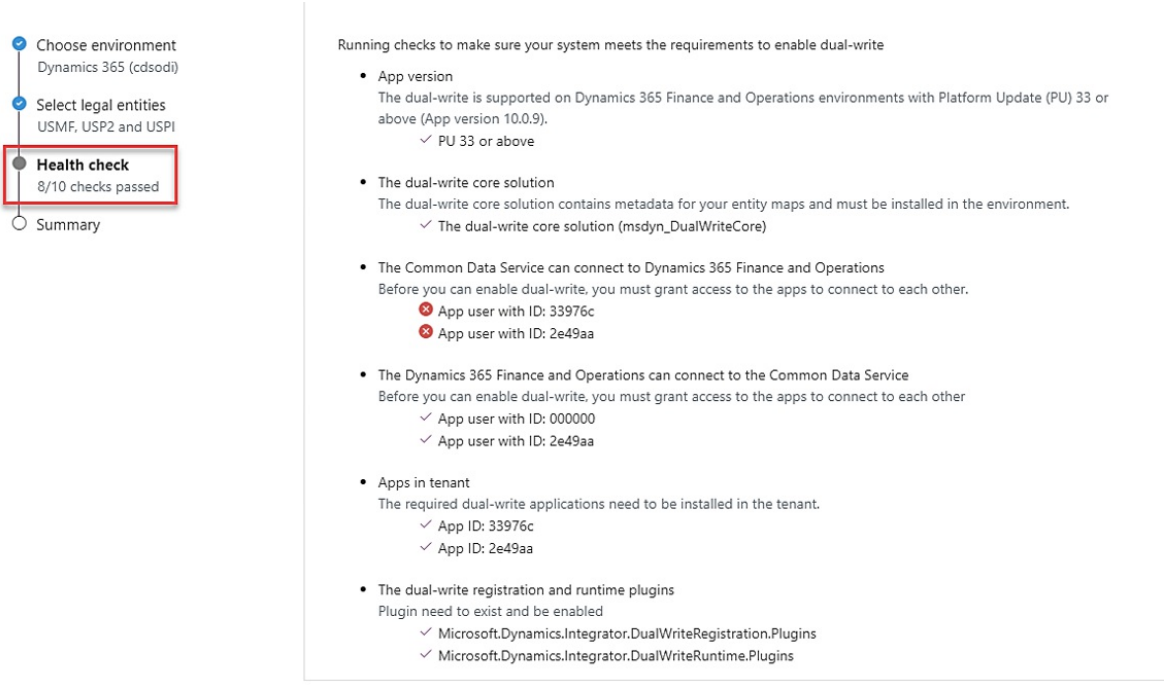


5. Select your legal entities, and then select **Next**.



A health check is run to verify that your system meets the requirements for enabling dual-write. The health check also verifies that all the prerequisites have been completed. If any health check test fails, make that you've completed all the prerequisites before you move on to the next step.

In the following example, the test about whether access was granted to connect the apps failed. In this case, you must first grant access to connect the apps by the creating the appropriate application IDs. You must then rerun the wizard.



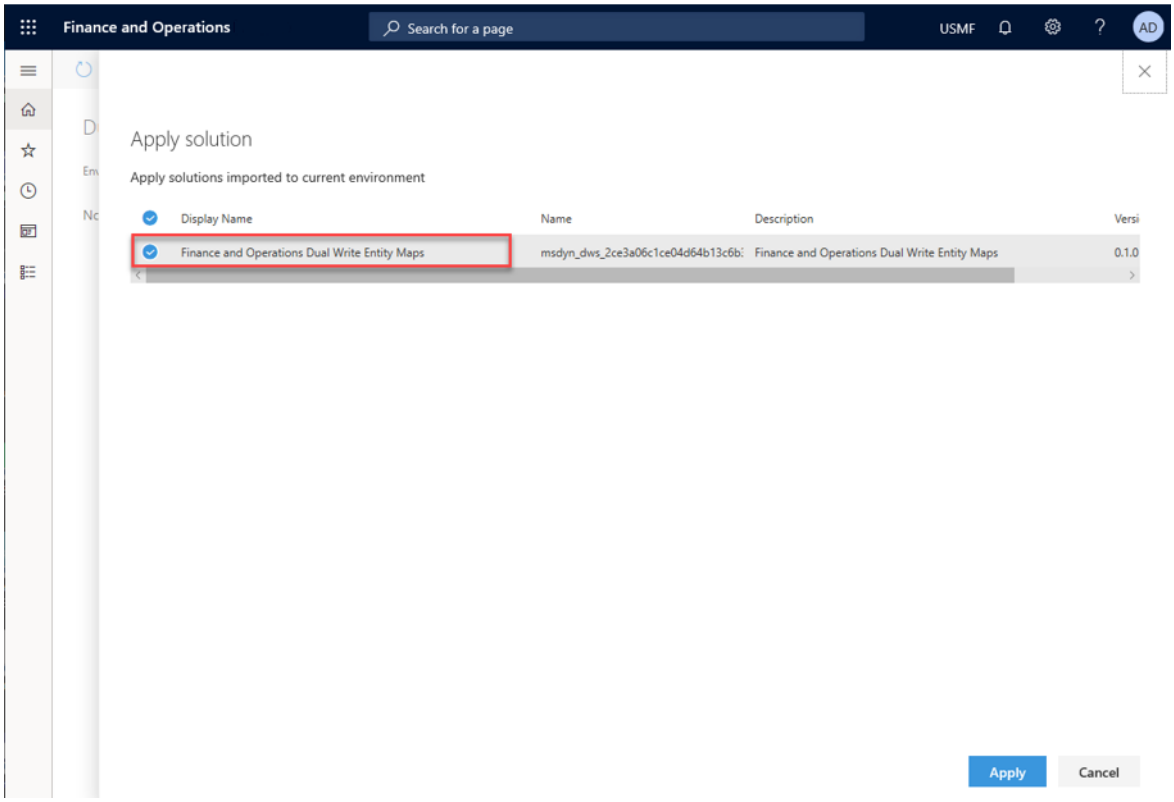
6. Review the summary, privacy notice, and consent, and then select **Create**.

You've now linked your Finance and Operations app to the Dataverse environment.

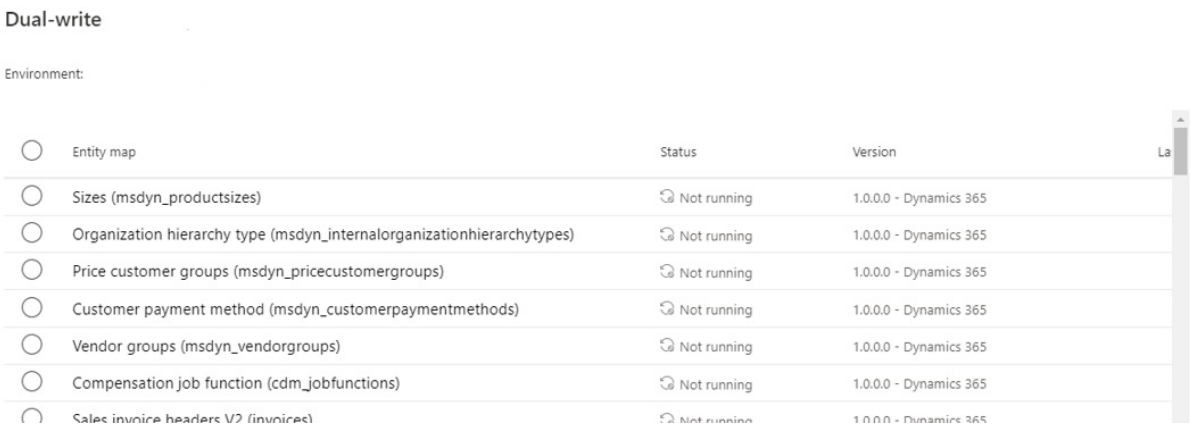
> **NOTE**
>
> If you don't see your table maps, or if you see a blank page, be sure to **Apply** the Dual-write application orchestration solution that you installed as part of the system requirements and prerequisities.

7. Apply the dual-write application orchestration solution.

   In the Finance and Operations app, on the **Dual-write** page, select **Apply Solution** to apply the table maps that you just downloaded and installed. After you apply the solution, you should see that the default table maps are published.



You've now successfully imported and applied a Microsoft-published dual-write table map solution to your environment.



Next steps

Enable table maps for dual-write

NOTE

Can you tell us about your documentation language preferences? Take a short survey.

The survey will take about seven minutes. No personal data is collected (privacy statement).

Enable table maps for dual-write

2/18/2021 • 3 minutes to read • Edit Online

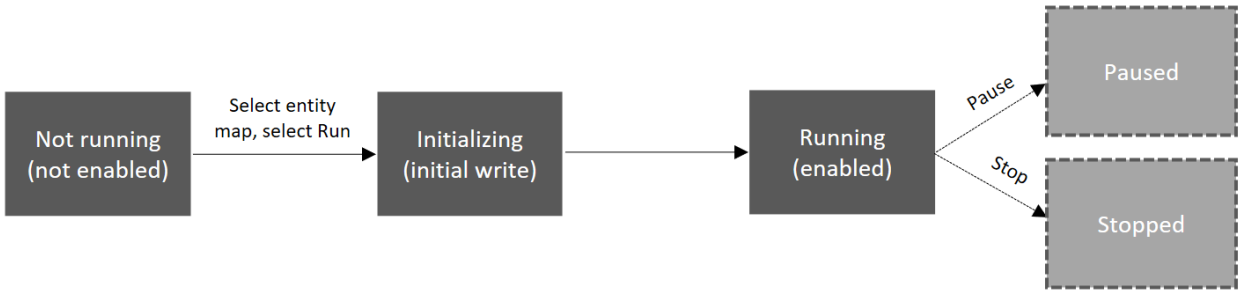
NOTE

Effective November 2020:

- Common Data Service has been renamed to Microsoft Dataverse. For more information, see Power Automate Blog.
- Some terminology in Microsoft Dataverse has been updated. For example, *entity* is now *table* and *field* is now *column*. For more information, see Terminology updates.

This topic will be updated soon to reflect the latest terminology.

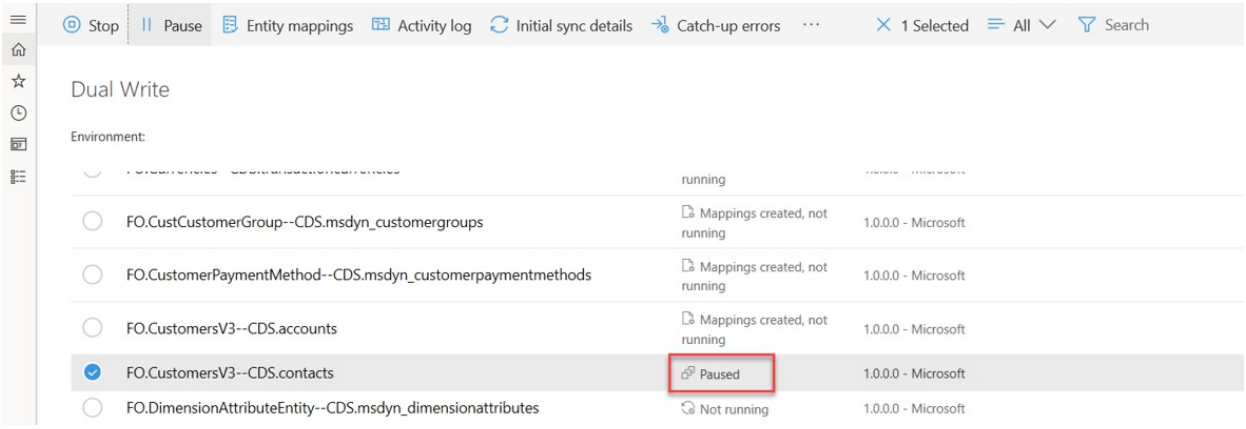
When you enable a table map for dual-write, it begins at the **Not running** status. The table map then goes through an initialization phase, where it does an initial write by copying pre-existing data on tables on both sides. Finally, when the table is completely enabled, the table map sets the status to **Running**.



Enabling entity map

While the status is **Running**, you can pause a table. All changes are then queued until you resume. When you resume, the table goes into "catch-up mode," where all the queued changes are played back.

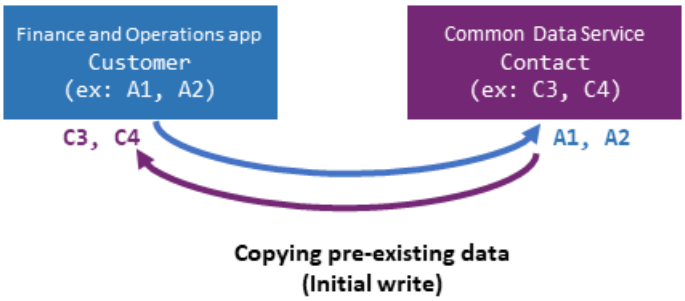
The following illustration show an example of a table that is paused.



STATUS	DESCRIPTION	AVAILABLE ACTIONS
Not running	The table has not yet been enabled for dual-write. Every table begins at the **Not running** status.	Run
Initializing	The initial write is occurring.	None

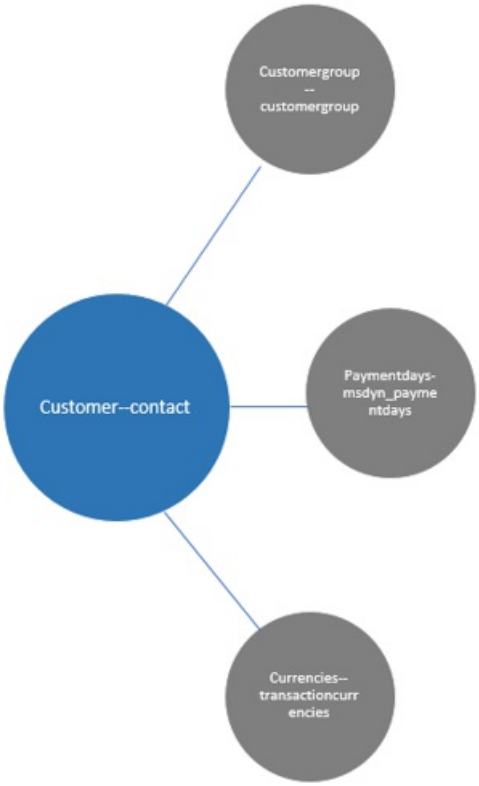
STATUS	DESCRIPTION	AVAILABLE ACTIONS
Running	The table has been enabled for dual-write.	Stop, Pause
Paused	The table is in a paused state, and all new requests are queued.	Run
Resuming	The table is catching up on rows that were queued while the table was paused.	None

During the initialization phase, any pre-existing data that you have is copied as part of the initial write phase.



Copying pre-existing data (Initial write)

Entities have several dependent tables. For example, Customer-Contact tables have customer groups and currencies as dependent tables.



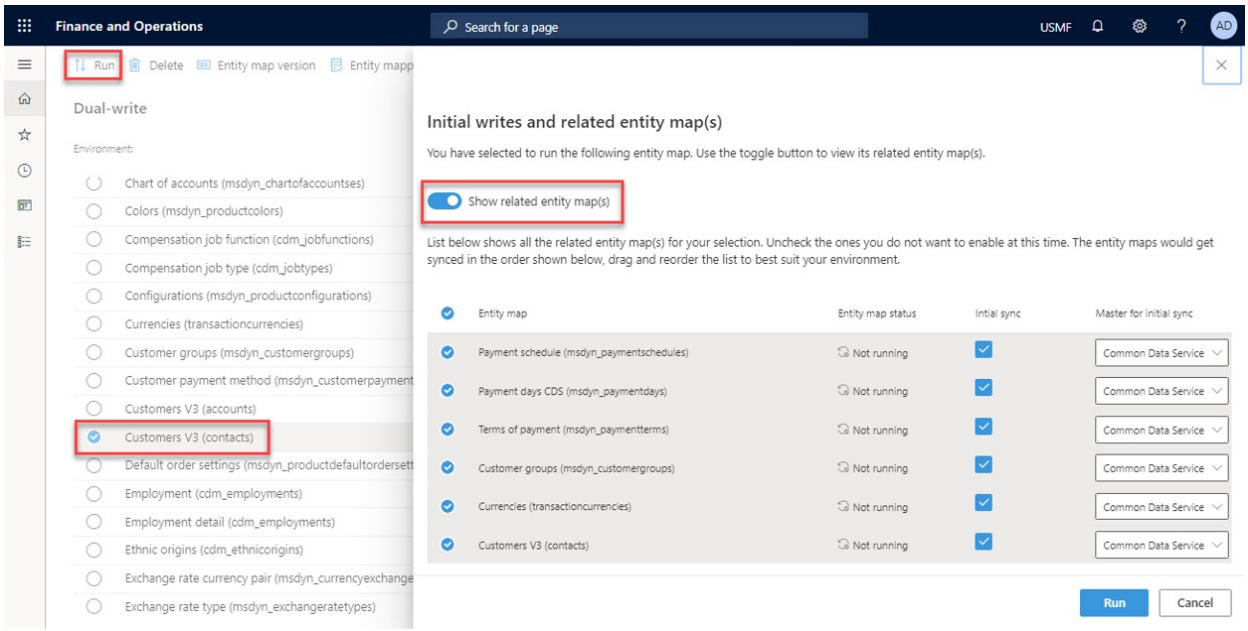
Dependent or Related Entities

Because these are relational apps that have relational data, if you don't enable the dependent tables, you might encounter errors later. To help prevent these errors, before you enable a table map, you're provided with a list of the related tables that we recommend that you enable.

Example: Enabling the Customers V3—Contacts table map

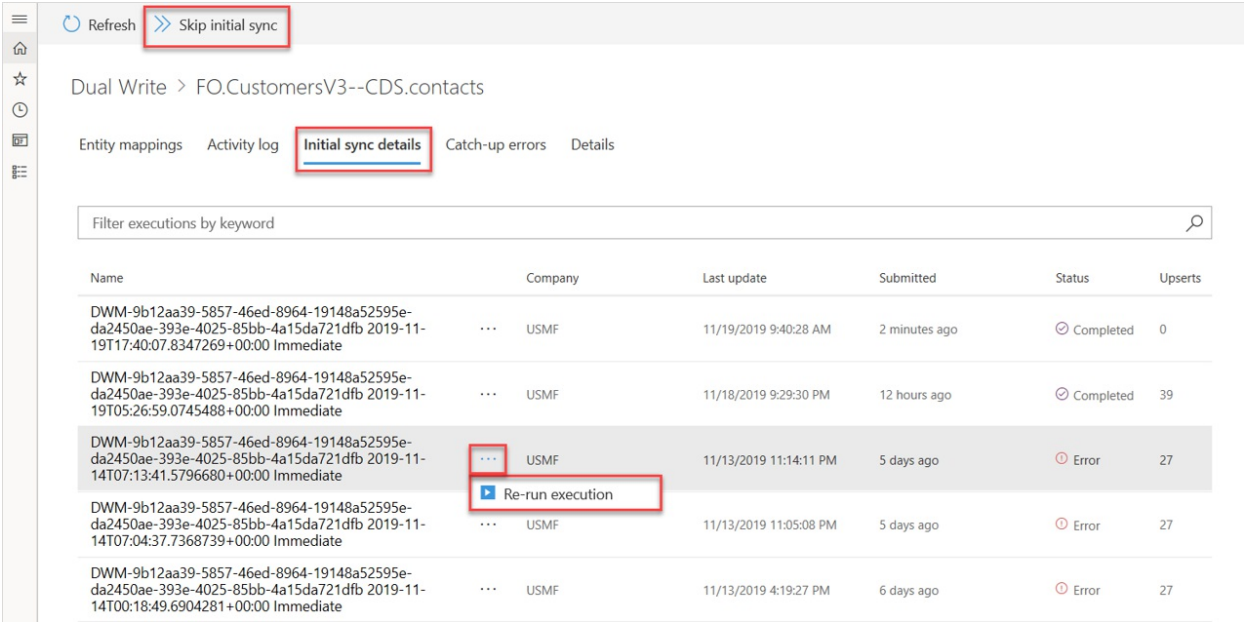
When you select a table map (for example, **Customers V3—Contacts**) and select **Run**, a dialog box appears before the table map is enabled. This dialog box lists all the dependent tables. You can select the **Show related table map(s)** option to show all the related table maps. To enable the selected table map and all its related tables, select **Run** in the dialog box.

> **NOTE**
>
> The behavior is similar when you pause a table. In that case, you have the option to pause all the related tables too.



You can further customize this by specifying a different master that should be used to resolve conflicts. (By default, Dataverse is used.) If you don't want to copy pre-existing data, skip the initial synchronization by clearing the **Initial Sync** check box. Alternatively, remove one or more of the related tables by canceling the selection of them. You can also drag the table maps to change the order that they will be synced in.

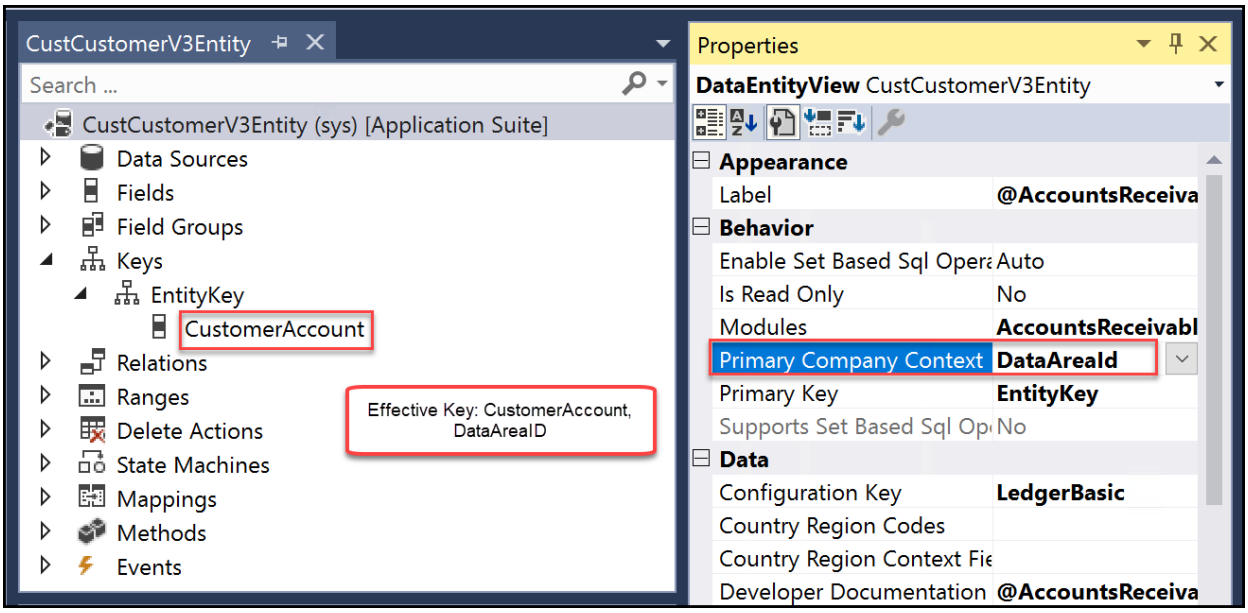
After you've finished making your selections in the dialog box, and you select **Run**, the table map and all its related tables go through the initial write phase. You're redirected to the table map list page. If any errors occur, you can view the details on the **Initial sync details** tab. This tab provides details about all the errors that occur while pre-existing data is being copied. After you fix the underlying errors, you can rerun the execution and monitor the outcome. Alternatively, if you no longer want to sync the pre-existing data, or if you experience recurring issues because of underlying data, you can skip the initial write phase. Instead, you can turn on live writes by selecting **Skip initial sync**.



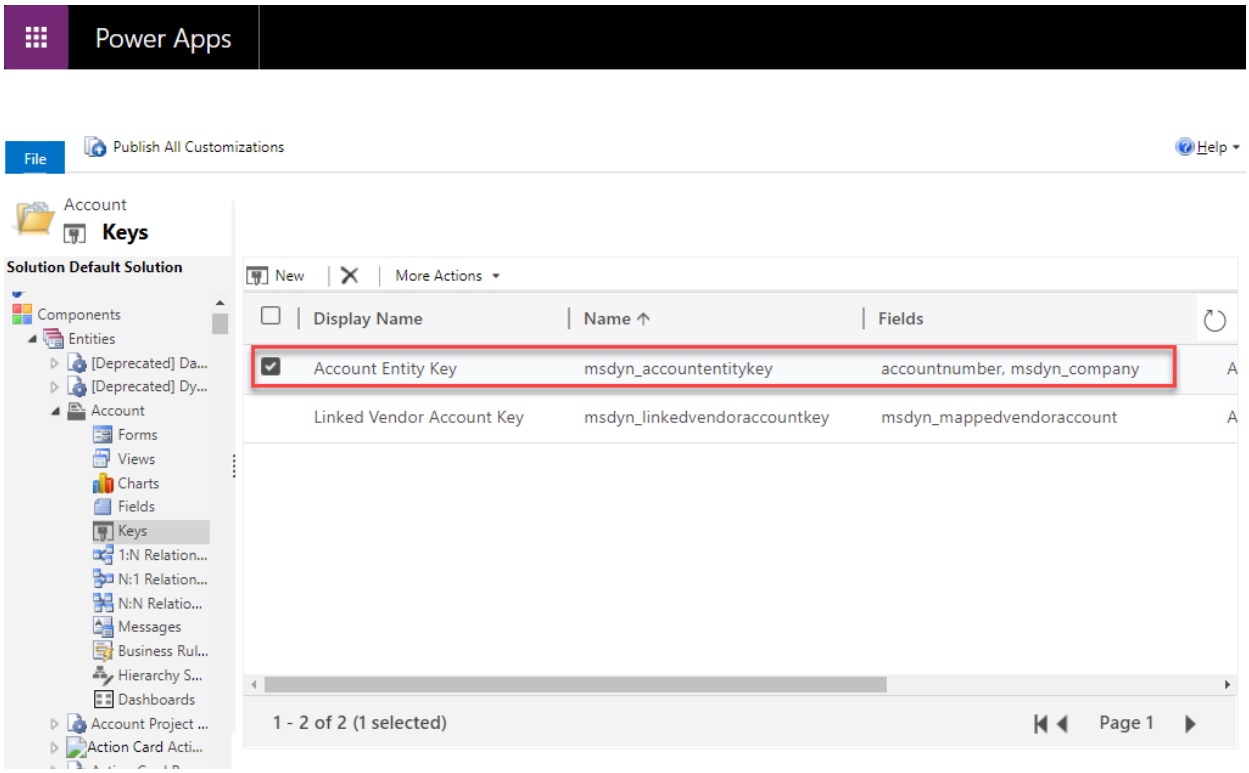
Criteria for linking tables

To enable table maps for dual-write, you must define an alternative key in Dataverse. The value of the alternative key in Dataverse must match the key that is defined in the Finance and Operations app.

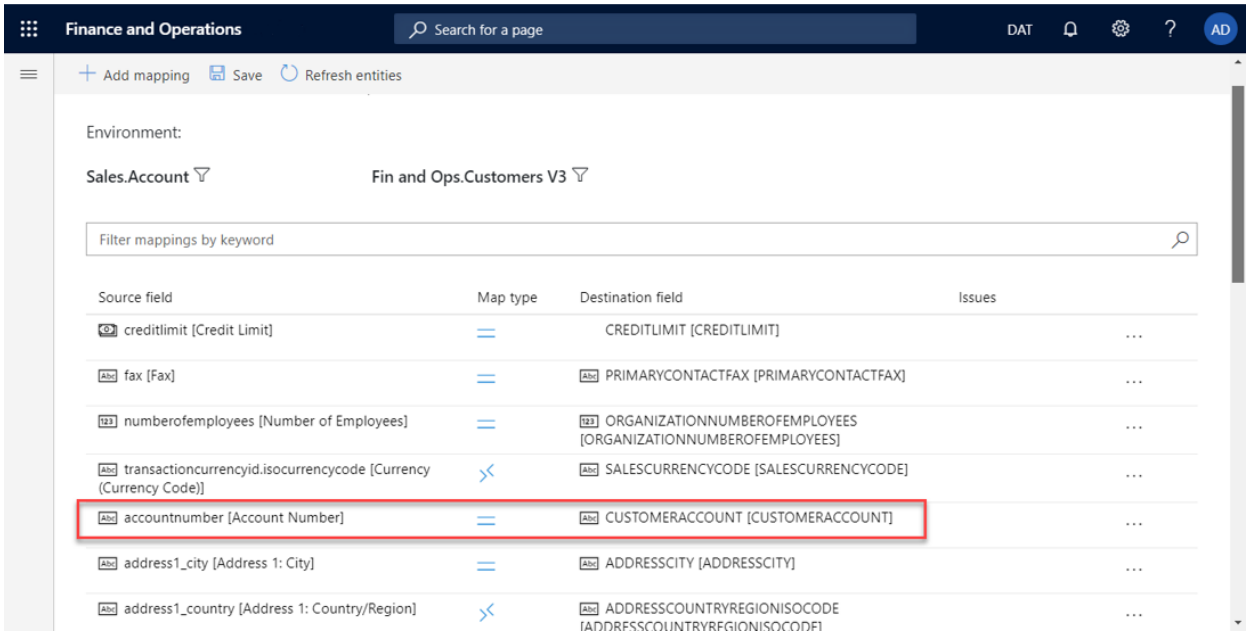
For example, in a Finance and Operations app, **CustomerAccount** is the key for the Account table.



In Dataverse, **accountnumber** is defined as the key for the Account table.



In the Customers V3 table map, you can see that **accountnumber** is mapped to **CustomerAccount**.



Next steps

Customize table and column mappings

NOTE

Can you tell us about your documentation language preferences? Take a short survey.

The survey will take about seven minutes. No personal data is collected (privacy statement).

Currency data-type migration for dual-write

2/18/2021 • 4 minutes to read • Edit Online

NOTE

Effective November 2020:

- Common Data Service has been renamed to Microsoft Dataverse. For more information, see Power Automate Blog.
- Some terminology in Microsoft Dataverse has been updated. For example, *entity* is now *table* and *field* is now *column*. For more information, see Terminology updates.

This topic will be updated soon to reflect the latest terminology.

You can increase the number of decimal places that are supported for currency values to a maximum of 10. The default limit is four decimal places. By increasing the number of decimal places, you help prevent data loss when you use dual-write to sync data. The increase in the number of decimal places is an opt-in change. To implement it, you must request assistance from Microsoft.

The process of changing the number of decimal places has two steps:

1. Request migration from Microsoft.
2. Change the number of decimal places in Dataverse.

The Finance and Operations app and Dataverse must support the same number of decimal places in currency values. Otherwise, data loss can occur when this information is synced between apps. The migration process reconfigures the way that currency and exchange rate values are stored, but it doesn't change any data. After the migration is completed, the number of decimal places for currency codes and pricing can be increased, and the data that users enter and view can have more decimal precision.

Migration is optional. If you might benefit from support for more decimal places, we recommend that you consider migration. Organizations that don't require values that have more than four decimal places don't have to migrate.

Requesting migration from Microsoft

Storage for existing currency columns in Dataverse can't support more than four decimal places. Therefore, during the migration process, currency values are copied to new internal columns in the database. This process occurs continuously until all data has been migrated. Internally, at the end of migration, the new storage types replace the old storage types, but the data values are unchanged. The currency columns can then support up to 10 decimal places. During the migration process, Dataverse can continue to be used without interruption.

At the same time, exchange rates are modified so that they support up to 12 decimal places instead of the current limit of 10. This change is required so that the number of decimal places is the same in both the Finance and Operations app and Dataverse.

Migration doesn't change any data. After the currency and exchange rate columns are converted, admins can configure the system to use up to 10 decimal places for currency columns by specifying the number of decimal places for each transaction currency and for pricing.

Request a migration

To make this feature available, email **CDSExpandDecimal@microsoft.com**, and include the following information:

- **Subject:** Request to enable expanded decimal support for <organizationID>
- **Body:** I would like to enable expanded decimal support for my org <organizationID>.

A Microsoft representative will contact you within two to three business days for the next steps.

When you request a migration, you should be aware of the following details and plan for them accordingly:

- The time that is required to migrate the data depends the amount of data in the system. Migration of large databases can take several days.
- The size of the database temporarily increases while the migration is running, because additional space is needed for indexes. Most of the additional space is freed when the migration is completed.
- During the migration process, if errors occur that prevent the migration from being completed, the system raise alerts to Microsoft Support, so that Support staff can intervene. However, even if errors occur during the migration, Dataverse remains fully available for regular use.
- The migration process isn't reversible.

Changing the number of decimal places

After the migration is completed, Dataverse can store numbers that have more decimal places. Admins can choose how many decimal places are used for specific currency codes and for pricing. Users of Microsoft Power Apps, Power BI, and Power Automate can then view and use numbers that have more decimal places.

To make this change, you must update the following settings in Power Apps:

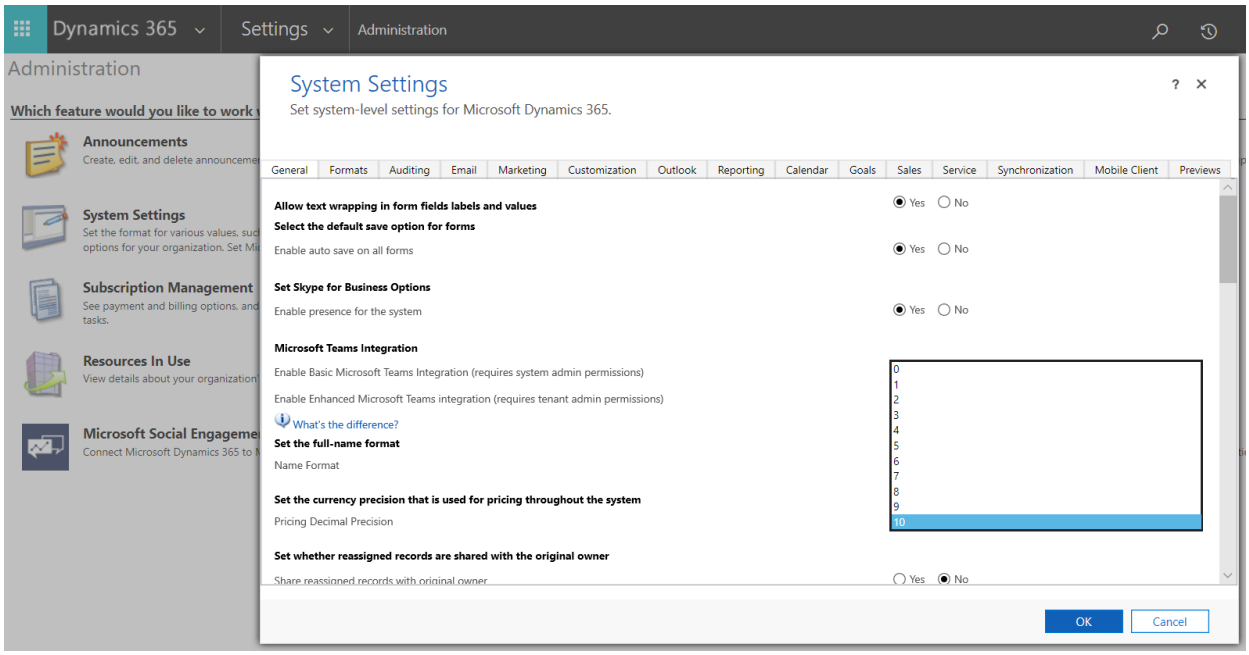
- **System Settings: Currency precision for pricing** – The **Set the currency precision that is used for pricing throughout the system** column defines how the currency will behave for the organization when **Pricing Precision** is selected.
- **Business Management: Currencies** – The **Currency Precision** column lets you specify a custom number of decimal places for a specific currency. There is a fallback to the organization-wide setting.

There are some limitations:

- You can't configure the currency column on a table.
- You can specify more than four decimal places only at the **Pricing** and **Transaction Currency** levels.

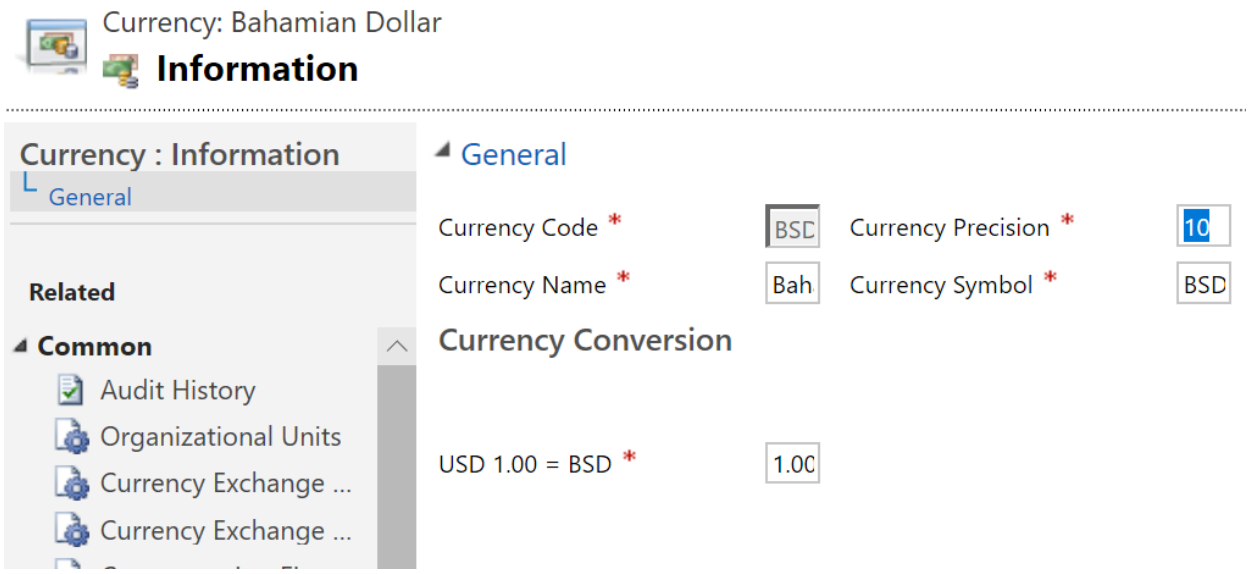
System Settings: Currency precision for pricing

After migration is completed, admins can set the currency precision. Go to **Settings > Administration**, and select **System Settings**. Then, on the **General** tab, change the value of the **Set the currency precision that is used for pricing throughout the system** column, as shown in the following illustration.



Business Management: Currencies

If you require that the currency precision for a specific currency differ from the currency precision that is used for pricing, you can change it. Go to **Settings > Business Management**, select **Currencies**, and select the currency to change. Then set the **Currency Precision** column to the number of decimal places that you want, as shown in the following illustration.



tables: Currency column

The number of decimal places that can be configured for specific currency columns is limited to four.

NOTE

Can you tell us about your documentation language preferences? Take a short survey.

The survey will take about seven minutes. No personal data is collected (privacy statement).

Set up the mapping for the sales order status columns

2/18/2021 • 2 minutes to read • Edit Online

The columns that indicate sales order status have different enumeration values in Microsoft Dynamics 365 Supply Chain Management and Dynamics 365 Sales. Additional setup is required to map these columns in dual-write.

columns in Supply Chain Management

In Supply Chain Management, two columns reflect the status of the sales order. The columns that you must map are **Status** and **Document Status**.

The **Status** enumeration specifies the overall status of the order. This status is shown on the order header.

The **Status** enumeration has the following values:

- Open Order
- Delivered
- Invoiced
- Cancelled

The **Document Status** enumeration specifies the most recent document that was generated for the order. For example, if the order is confirmed, this document is a sales order confirmation. If a sales order is partially invoiced, and then the remaining line is confirmed, the document status remains **Invoice**, because the invoice is generated later in the process.

The **Document Status** enumeration has the following values:

- Confirmation
- Picking List
- Packing Slip
- Invoice

columns in Sales

In Sales, two columns indicate the status of the order. The columns that you must map are **Status** and **Processing Status**.

The **Status** enumeration specifies the overall status of the order. It has the following values:

- Active
- Submitted
- Fulfilled
- Invoiced
- Cancelled

The **Processing Status** enumeration was introduced so that the status can be mapped more accurately with Supply Chain Management.

The following table shows the mapping of **Processing Status** in Supply Chain Management.

PROCESSING STATUS	STATUS IN SUPPLY CHAIN MANAGEMENT	DOCUMENT STATUS IN SUPPLY CHAIN MANAGEMENT
Active	Open Order	None
Confirmed	Open Order	Confirmation
Picked	Open Order	Picking List
Partially Delivered	Open Order	Packing Slip
Delivered	Delivered	Packing Slip
Partially Invoiced	Delivered	Invoice
Invoiced	Invoiced	Invoice
Cancelled	Cancelled	Not applicable

The following table shows the mapping of **Processing Status** between Sales and Supply Chain Management.

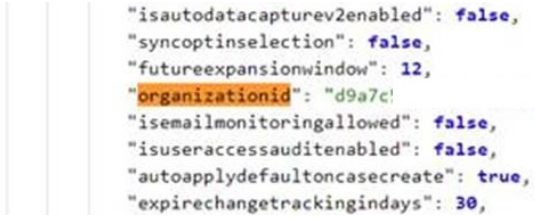
PROCESSING STATUS	STATUS IN SALES	STATUS IN SUPPLY CHAIN MANAGEMENT
Active	Active	Open Order
Confirmed	Submitted	Open Order
Picked	Submitted	Open Order
Partially Delivered	Active	Open Order
Partially Invoiced	Active	Open Order
Partially Invoiced	Fulfilled	Delivered
Invoiced	Invoiced	Invoiced
Cancelled	Cancelled	Cancelled

Setup

To set up the mapping for the sales order status columns, you must enable the **IsSOPIntegrationEnabled** and **isIntegrationUser** attributes.

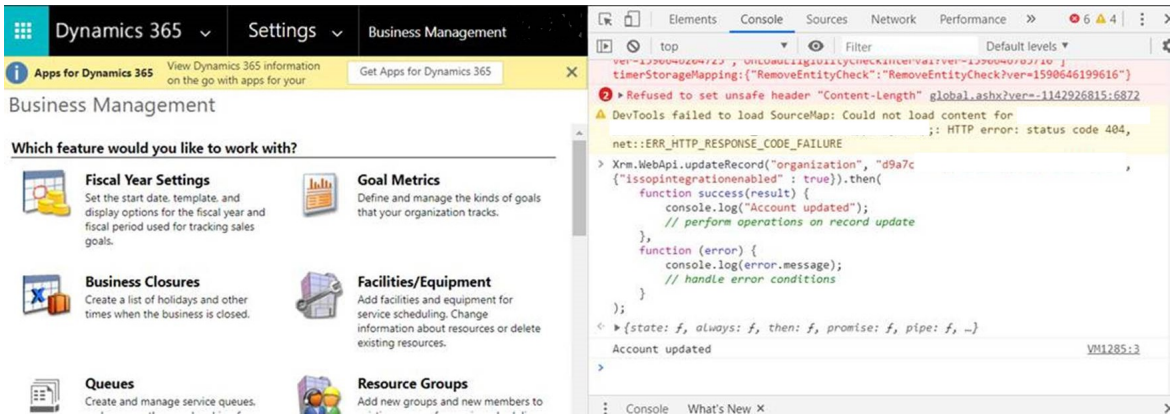
To enable the **IsSOPIntegrationEnabled** attribute, follow these steps.

1. In a browser, go to `https://<test-name>.crm.dynamics.com/api/data/v9.0/organizations`. Replace **<test-name>** with your company's link to Sales.
2. On the page that is opened, find **organizationid**, and make a note of the value.

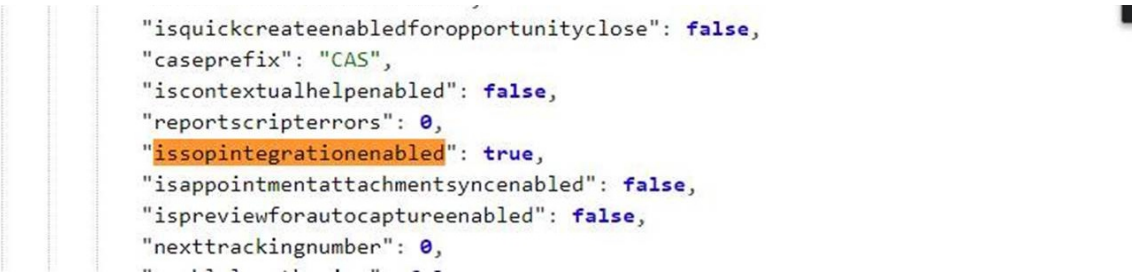


3. In Sales, open the browser console, and run following script. Use the **organizationid** value from step 2.

```
Xrm.WebApi.updateRecord("organization",
"d9a7c5f7-acbf-4aa9-86e8-a891c43f748c", {"issopintegrationenabled" :
true}).then(
    function success(result) {
        console.log("Account updated");
        // perform operations on row update
    },
    function (error) {
        console.log(error.message);
        // handle error conditions
    }
);
```

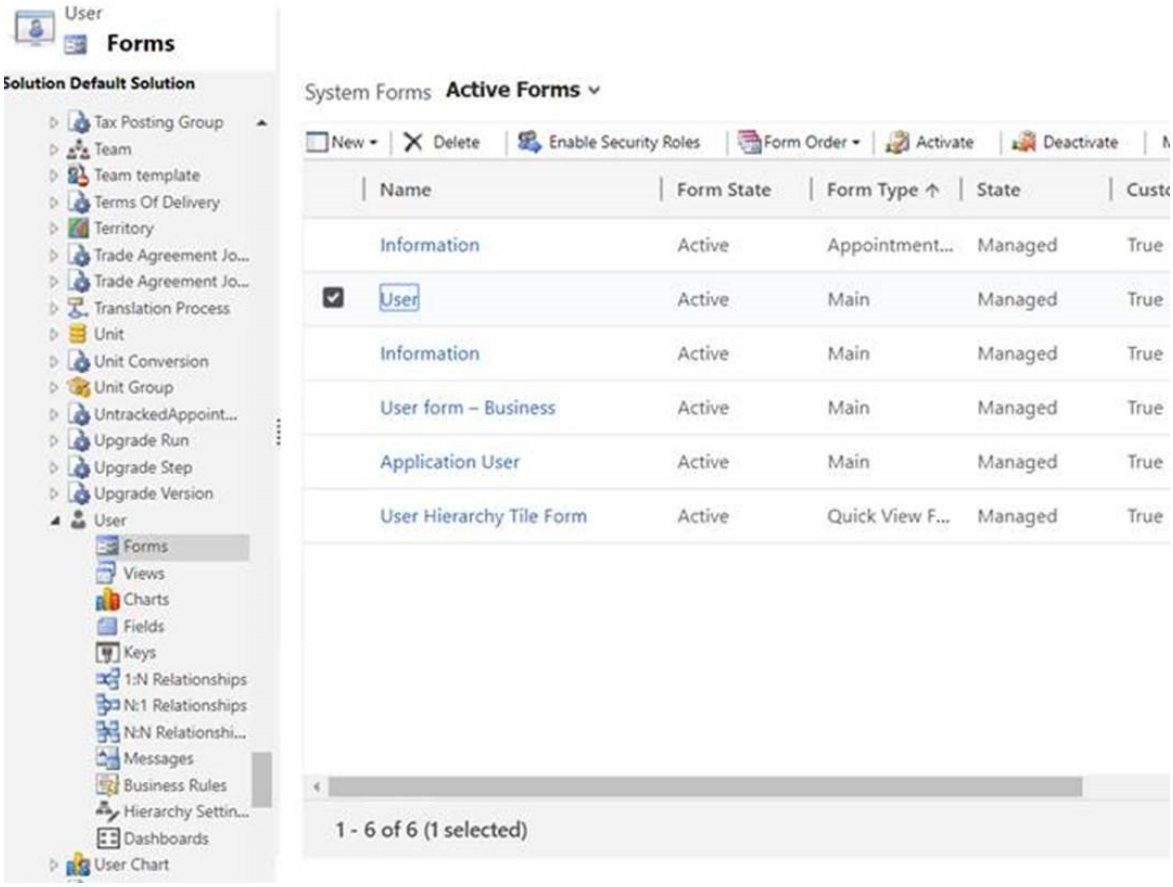


4. Verify that **IsSOPIntegrationEnabled** is set to **true**. Use the URL from step 1 to check the value.

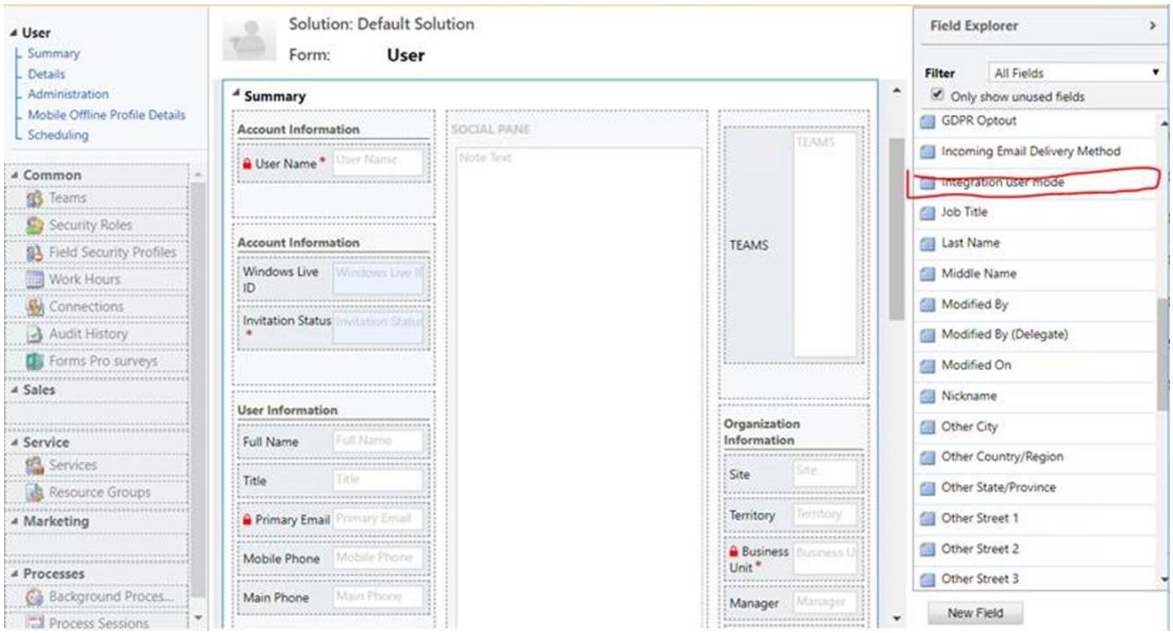


To enable the **isIntegrationUser** attribute, follow these steps.

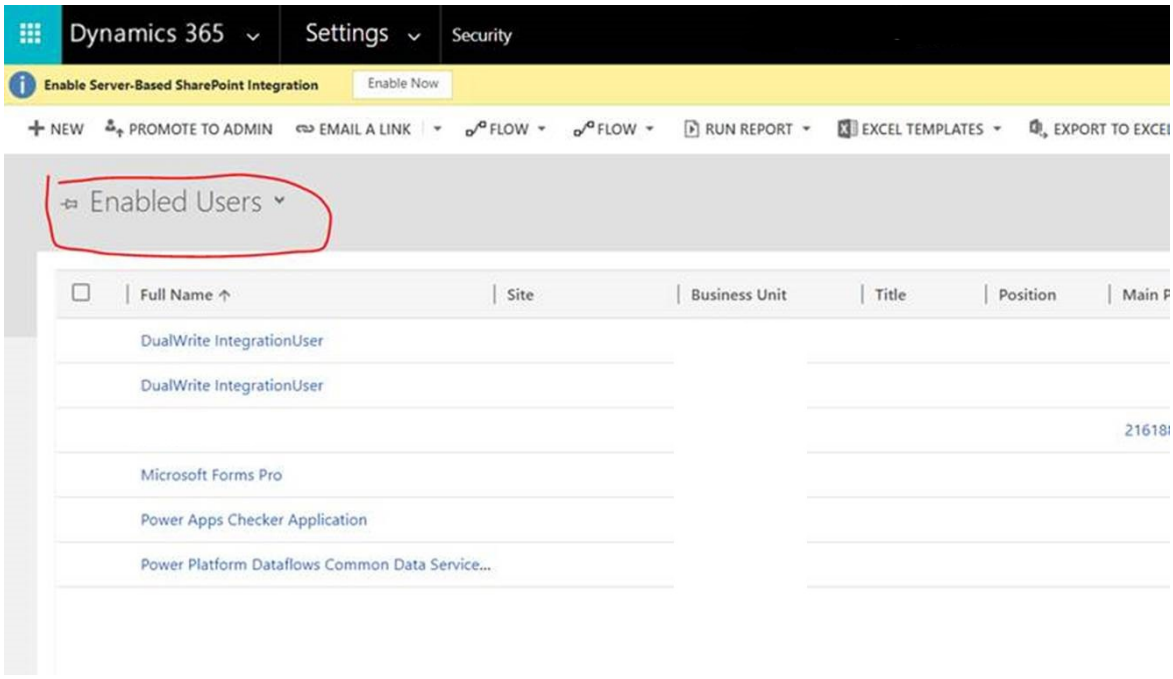
1. In Sales, go to **Setting > Customization > Customize the System**, select **User table**, and then open **Form > User**.



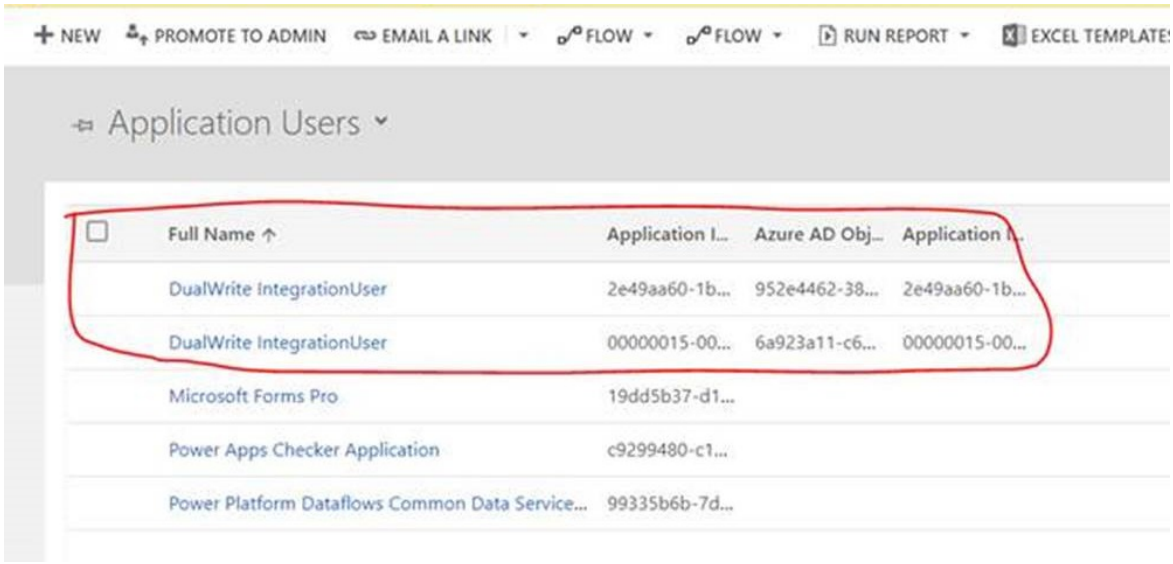
2. In Field Explorer, find **Integration user mode**, and double-click it to add it to the form. Save your change.



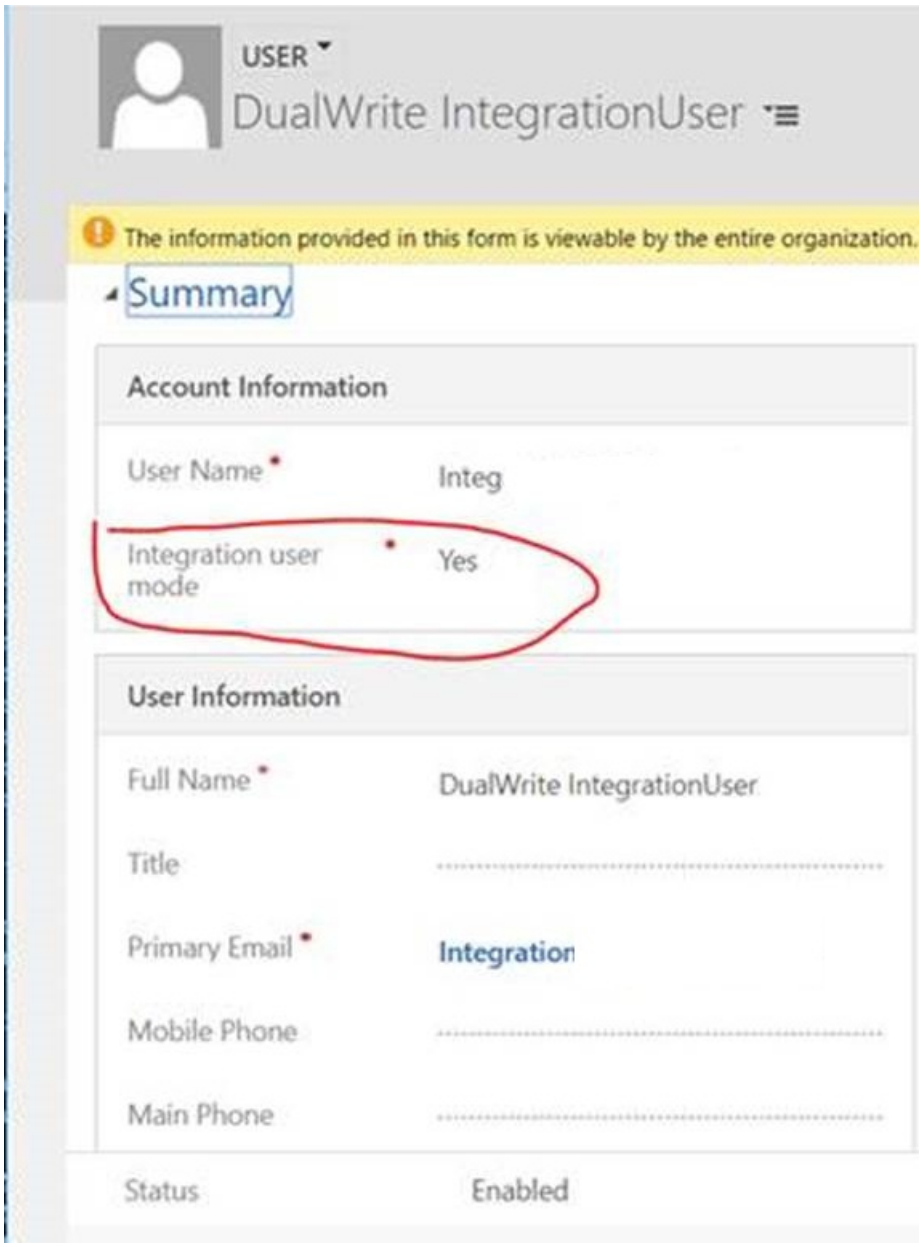
3. In Sales, go to **Setting > Security > Users**, and change the view from **Enabled Users** to **Application Users**.



4. Select the two entries for **DualWrite IntegrationUser**.



5. Change the value of the **Integration user mode** column to **Yes**.



Your sales orders are now mapped.

> **NOTE**

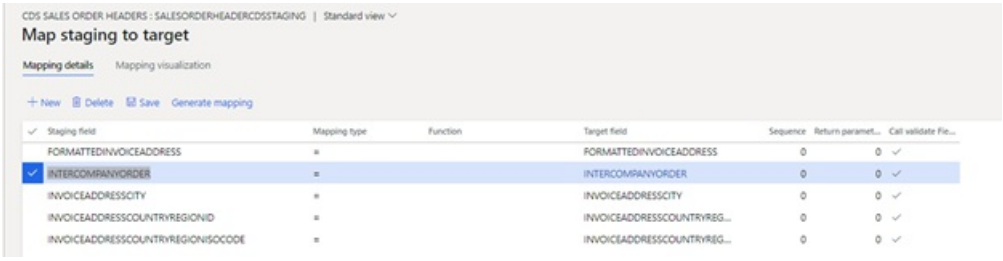
Filter intercompany orders to avoid syncing Orders and OrderLines

2/18/2021 • 2 minutes to read • Edit Online

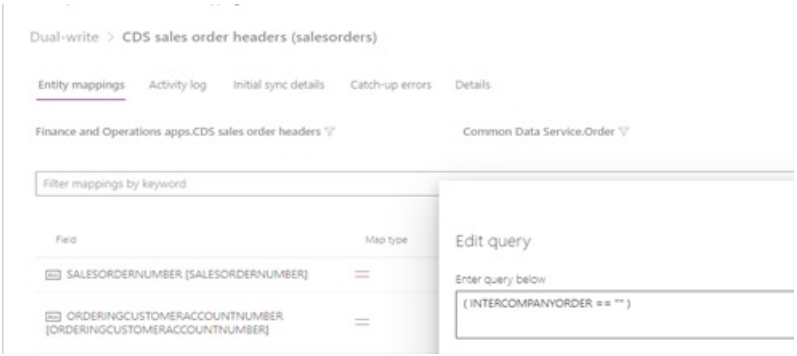
You can filter intercompany orders so that the **Orders** and **OrderLines** tables aren't synced. In some scenarios, the intercompany order details aren't required in a customer engagement app.

Each standard Dataverse table is extended through references to the **IntercompanyOrder** column, and the dual-write maps are modified so that they refer to the additional columns in the filters. Therefore, the intercompany orders are no longer synced. This process helps prevent unnecessary data in the customer engagement app.

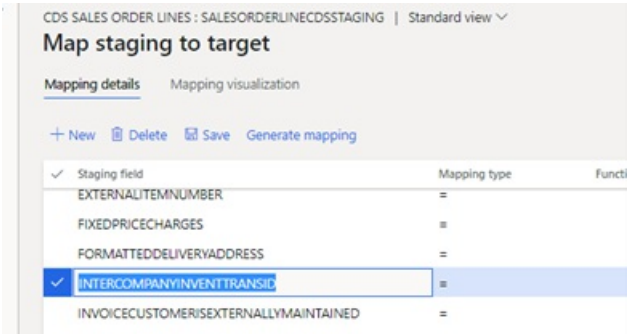
1. Extend the **CDS Sales Order Headers** table by adding a reference to the **IntercompanyOrder** column. This column is filled in only on intercompany orders. The **IntercompanyOrder** column is available in the **SalesTable** table.



2. After **CDS Sales Order Headers** is extended, the **IntercompanyOrder** column is available in the mapping. Apply a filter that has `INTERCOMPANYORDER == ""` as the query string.

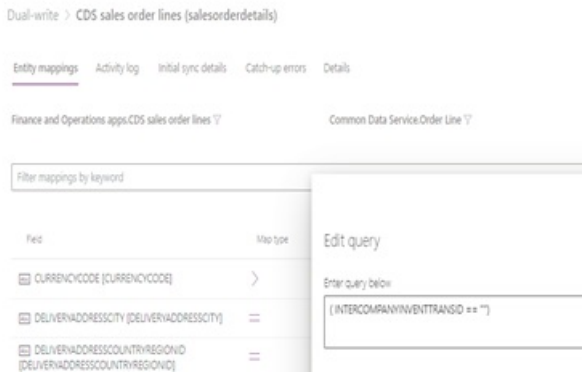


3. Extend the **CDS Sales Order Lines** table by adding a reference to the **IntercompanyInventTransId** column. This column is filled in only on intercompany orders. The **InterCompanyInventTransId** column is available in the **SalesLine** table.

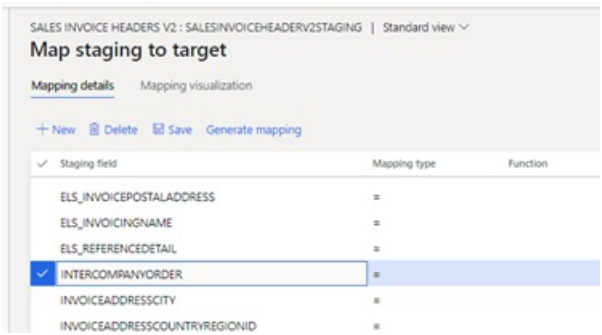


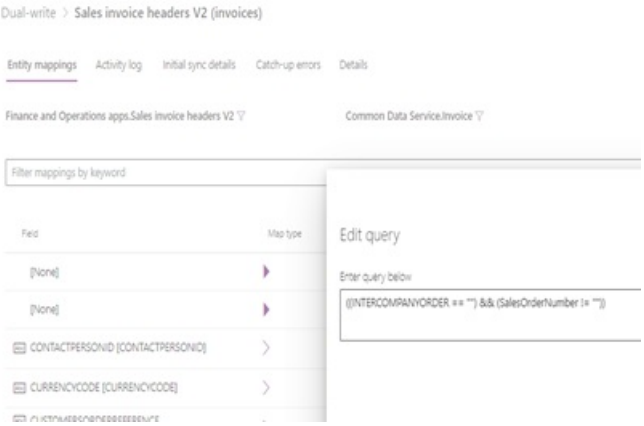
4. After **CDS Sales Order Lines** is extended, the **IntercompanyInventTransId** column is available in the

mapping. Apply a filter that has `INTERCOMPANYINVENTTRANSID == ""` as the query string.

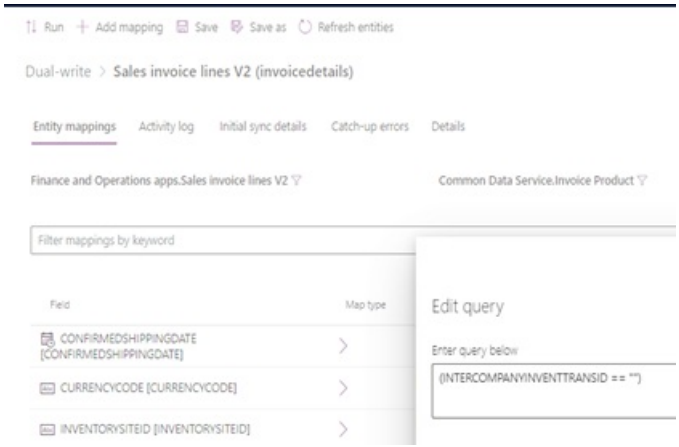


5. Repeat steps 1 and 2 to extend the **Sales Invoice Header V2** table and add a filter query. In this case, use `(INTERCOMPANYORDER == "") && (SALESORDERNUMBER != "")` as the query string for the filter.



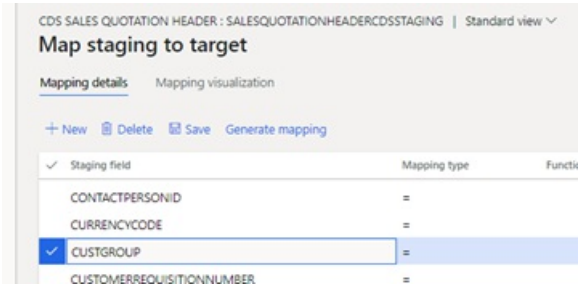


6. Repeat steps 3 and 4 to extend the **Sales Invoice Lines V2** table and add a filter query. In this case, use `INTERCOMPANYINVENTTRANSID == ""` as the query string for the filter.



7. The **Quotations** table doesn't have an intercompany relationship. If someone creates a quotation for one of your intercompany customers, you can use the **CustGroup** column to put all those customers into

one customer group. You can extend the header and lines by adding the **CustGroup** column, and then filter so that the group isn't included.



8. After **Quotations** is extended, apply a filter that has `CUSTGROUP != "<company>"` as the query string.

Customize table and column mappings

2/18/2021 • 3 minutes to read • Edit Online

NOTE

Effective November 2020:

- Common Data Service has been renamed to Microsoft Dataverse. For more information, see Power Automate Blog.
- Some terminology in Microsoft Dataverse has been updated. For example, *entity* is now *table* and *field* is now *column*. For more information, see Terminology updates.

This topic will be updated soon to reflect the latest terminology.

The out-of-box table maps have predefined table and column mappings that enable the flow of data between two apps. In this way, they serve as "blueprints." However, because every business is different, the default table maps might sometimes not be enough. Therefore, dual-write fully supports customization by providing ways to change table maps and column mappings.

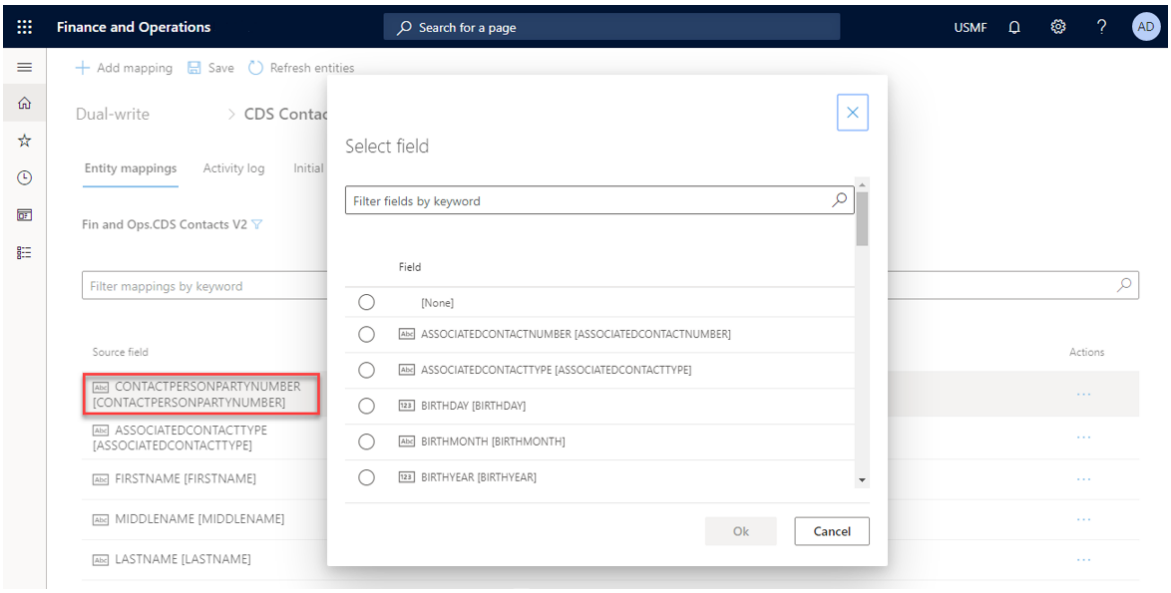
Customize column mappings, add transforms, and enable filtering

1. In your Finance and Operations app, on the **Dual-write** page, on the **Table mappings** tab, select the table map to customize.

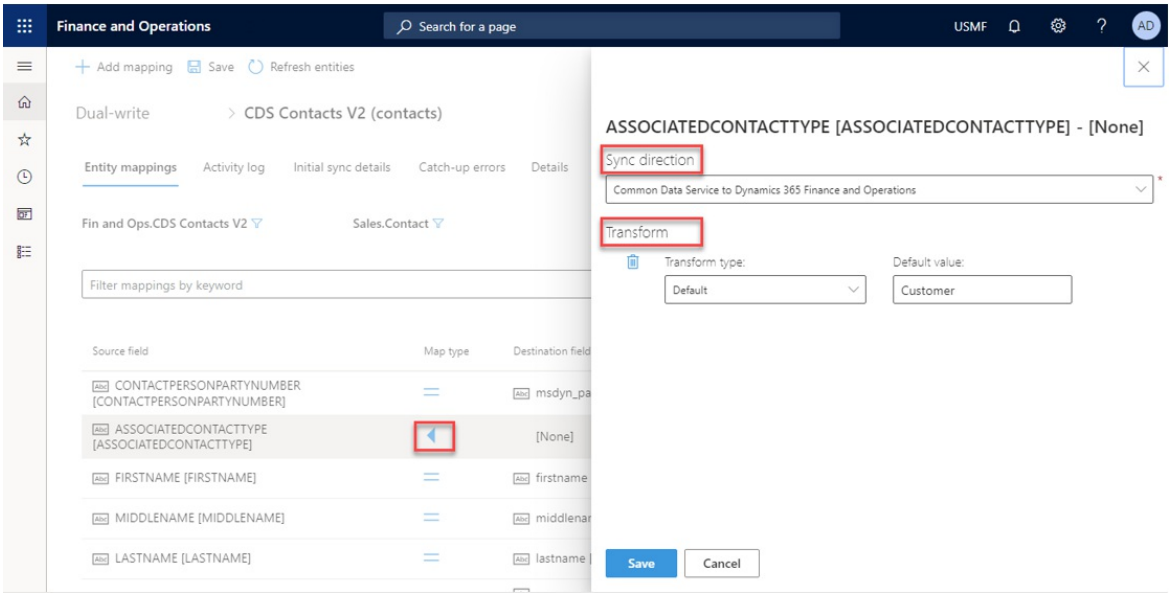
   NOTE

   Before you change table mappings, they must be stopped (not running). Otherwise, your changes won't be saved.

2. On the **Table mappings** tab, you can customize a column by selecting a new or custom column from either the Finance and Operations app or Dataverse.



3. You can customize the synchronization direction (unidirectional or bidirectional) and add transforms by selecting the map type.



The following table describes the available synchronization directions.

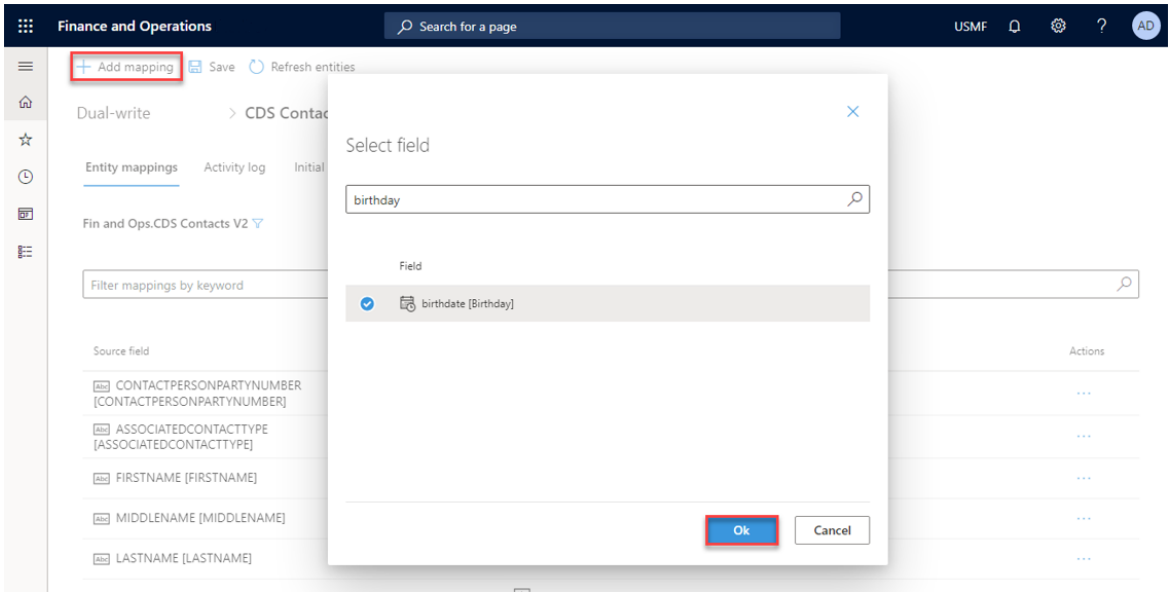
SYMBOL	DESCRIPTION
=	Bidirectional column assignment
><	Bidirectional column assignment that uses transforms
>	Unidirectional column assignment (left to right)
<	Unidirectional column assignment (right to left)
▶	Unidirectional column assignment that uses transforms (left to right)
◀	Unidirectional column assignment that uses transforms (right to left)

The following table describes the available transform types.

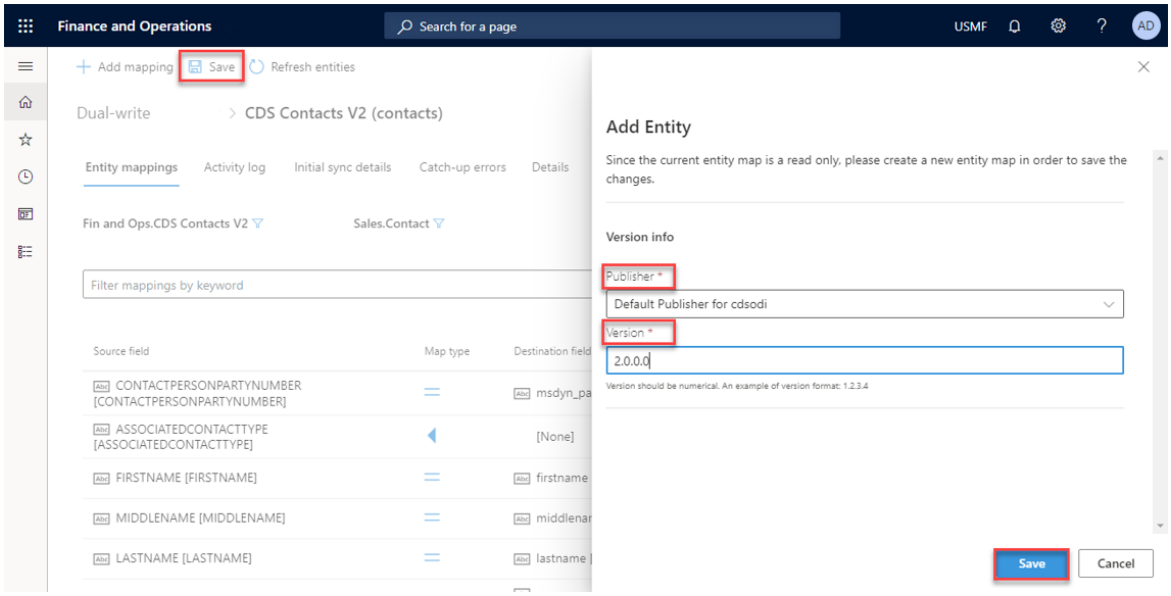
TRANSFORM TYPE	DESCRIPTION
Default	Default values are values that are applied to destination columns when no source column value is available. Use default values for columns that are required on the destination table when you have no corresponding source column.
Value map	Value maps define how values that are present in one table should be mapped to values in the other table.

4. You can add a new column by selecting **Add mapping** and then selecting an existing or custom column in the list.

   The following illustration shows an example where a new **birthdate** column is being added.



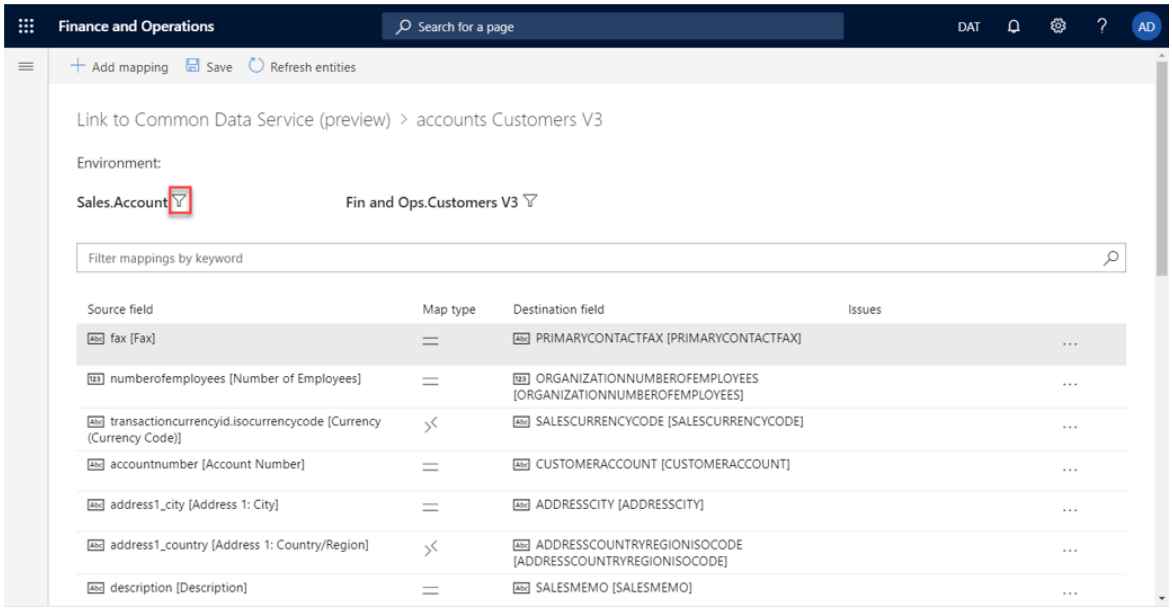
5. When you've finished customizing the column mappings, select **Save**. Then follow the prompts to specify a publisher and a version number.



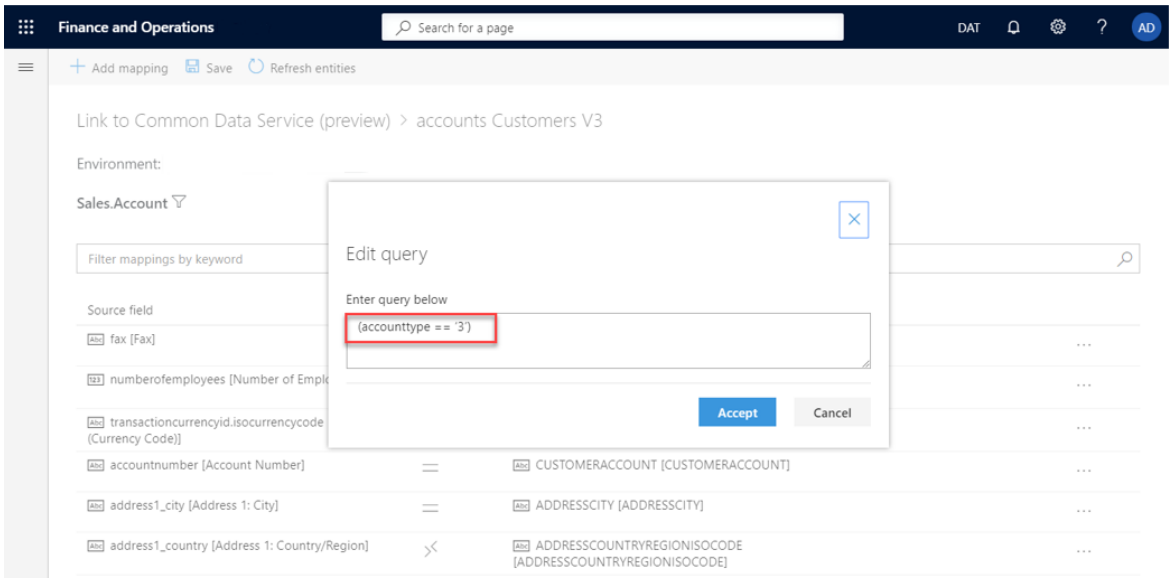
Filter your data

Dual-write lets you filter data by using Open Data Protocol (OData) filter expressions for Dataverse. For the Finance and Operations app, filtering resembles range expressions that are used in the query range.

1. On the table mapping page, select the filter button (funnel symbol).



2. In the **Edit query** dialog box, specify your filters. In this example, the filter that is specified will return only accounts where the account type equals **3**.



The following table shows some examples of filter expressions.

DATAVERSE	FINANCE AND OPERATIONS APPS
Accounttype eq '3'	(accounttype == '3')
numberofemployees gt 1000 and numberofemployees le 2000	((numberofemployees > 1000) && (numberofemployees <= 2000))

For more examples that show how to use expressions in query ranges, see Using Expressions in Query Ranges.

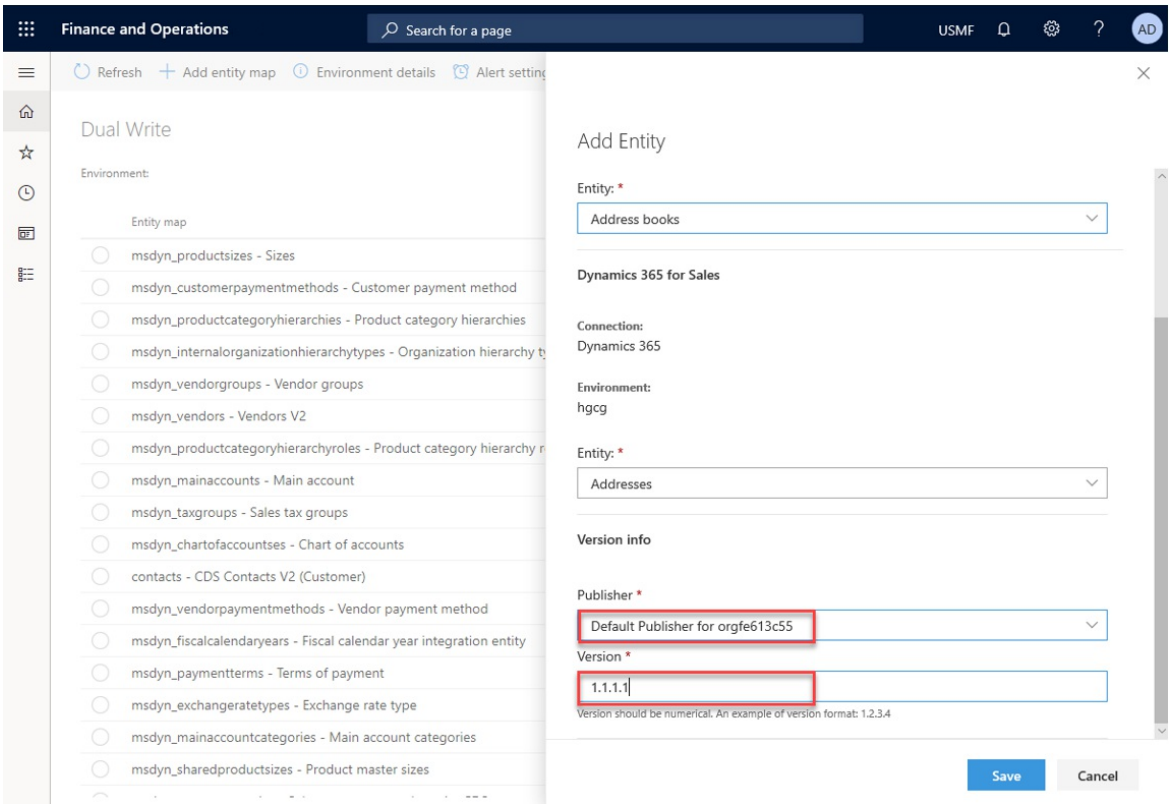
Currently, we do not support nested lookups in dual-write source filter. Only standard filter operators directly against table columns are supported. For more examples, see Standard filter operators.

Add new table maps

Although Microsoft is continuing to add new tables, you can also add standard or custom table maps.

The following example shows how to add a new table map that is named **Address books**.

1. In the Finance and Operations app, on the **Dual-write** page, select **Add table map**.



> **NOTE**
>
> When you create a new solution that uses these modified table maps, you must specify the same publisher.

2. Confirm the table maps that you just modified and added. Be sure to enable and test them, to ensure that they work as you expect.

NOTE

Can you tell us about your documentation language preferences? Take a short survey.

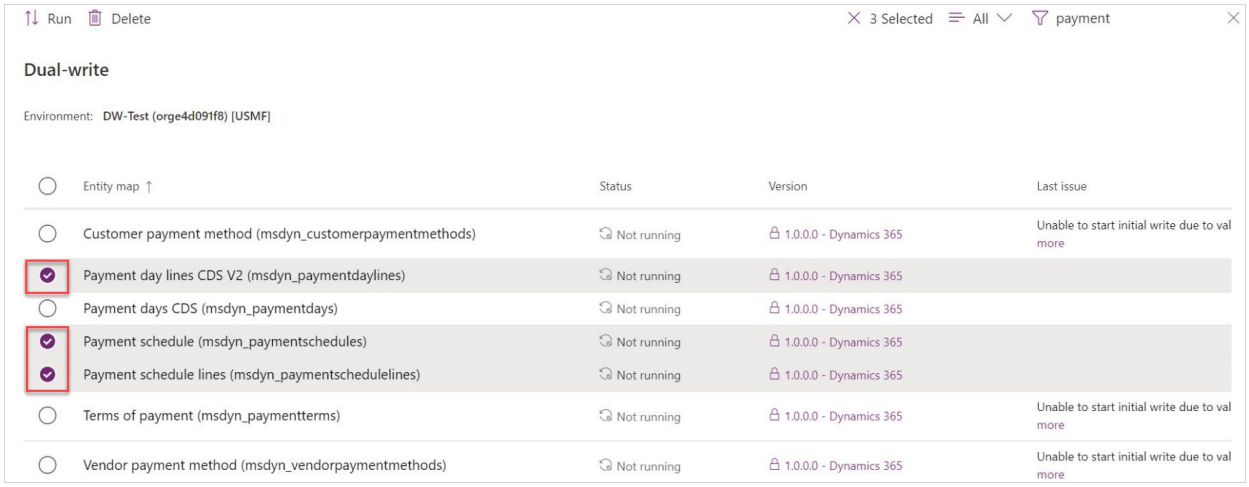
The survey will take about seven minutes. No personal data is collected (privacy statement).

Manage multiple table maps

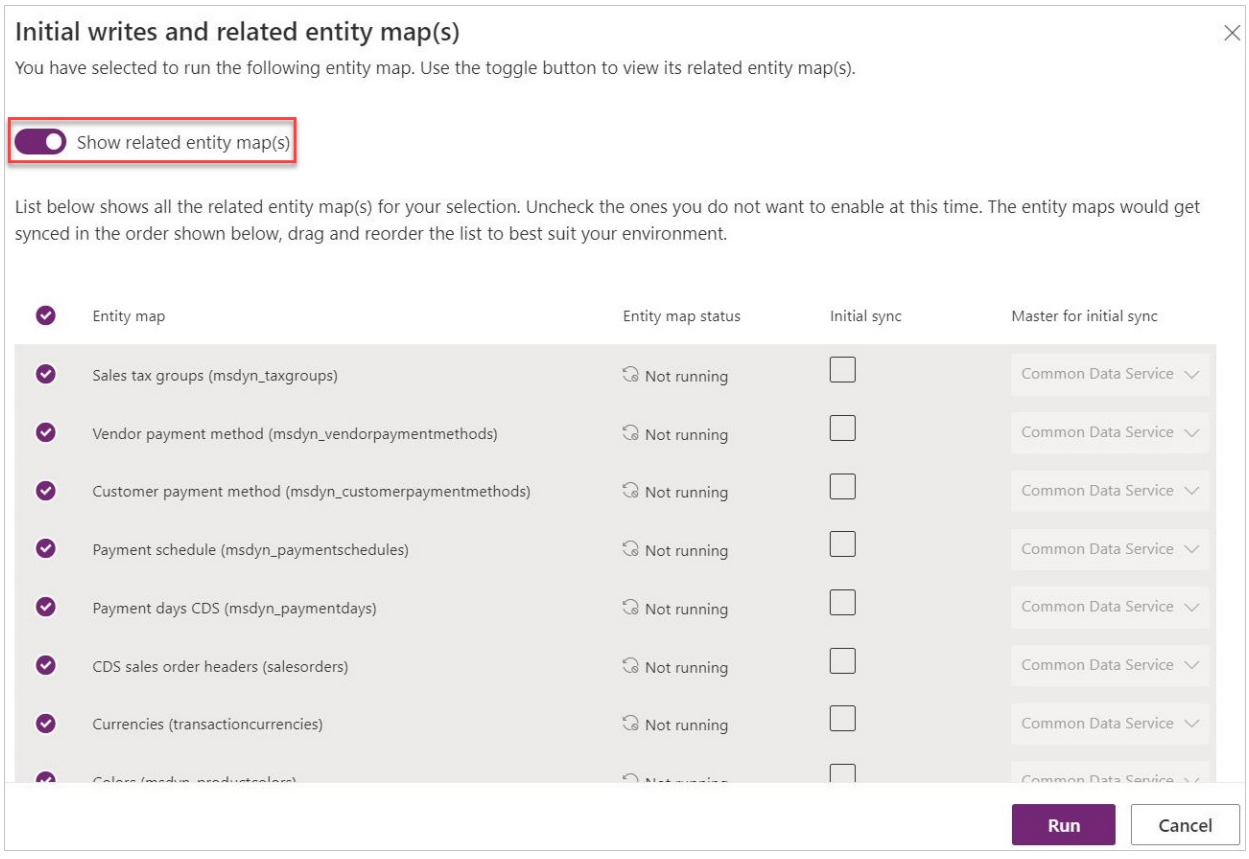
2/18/2021 • 2 minutes to read • Edit Online

This article describes how to select multiple table maps, view a list of dependent table maps, enable the table maps and all of its related tables, and copy pre-existing data.

As part of day to day operations, there may be a need to bulk handle table maps. For example, you may want to simultaneously enable or pause a set of table maps. Instead of doing this one by one, which is cumbersome and time consuming, you can now enable, pause, resume, or stop more than one table map at the same time in the dual-write list page.



As part of enabling multiple table maps, you also get to view the list of all the dependent table maps by selecting **Show related table map(s)**.



To enable the selected table map and all its related tables, select **Run**. If you want to copy the pre-existing data

for the selected table maps or its dependents, select the corresponding **Initial sync** check box. Alternatively, remove one or more of the related tables by clearing the corresponding check box. You can also drag and drop the table maps to change the order in which the maps will be synced.

Edit a legal entity after dual-write setup

2/18/2021 • 2 minutes to read • Edit Online

NOTE

Effective November 2020:

- Common Data Service has been renamed to Microsoft Dataverse. For more information, see Power Automate Blog.
- Some terminology in Microsoft Dataverse has been updated. For example, *entity* is now *table* and *field* is now *column*. For more information, see Terminology updates.

This topic will be updated soon to reflect the latest terminology.

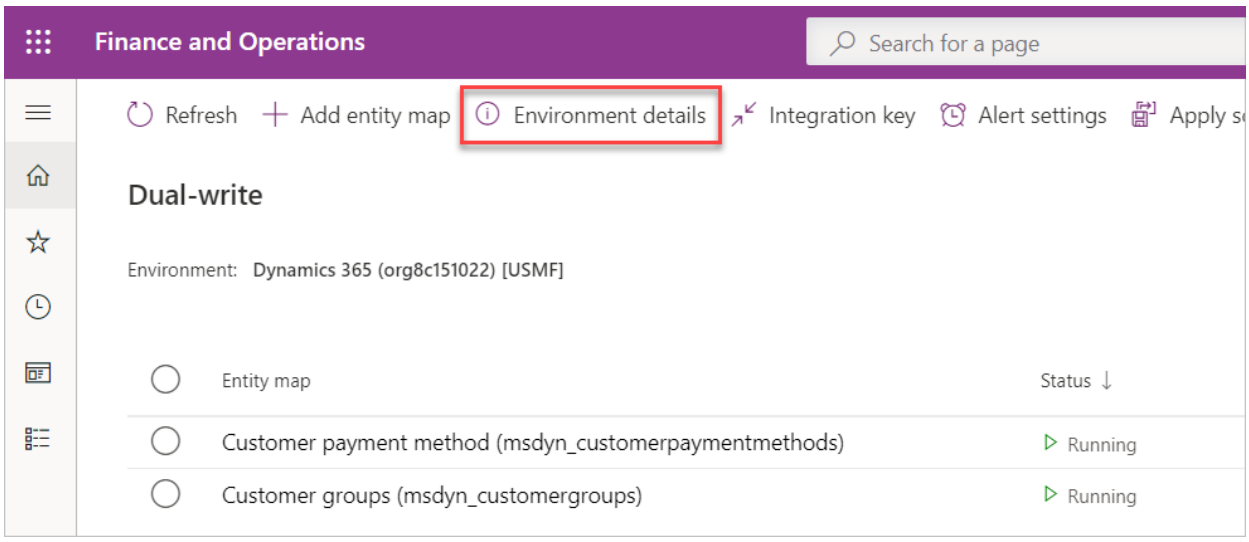
The dual-write wizard enables you to add or remove a company or legal entity after dual-write has been set up. You can do this without having to unlink and relink your dual-write environment.

The wizard enables you to link your Finance and Operations apps to Dataverse environments. As part of this wizard, you also can select one or more companies or legal entities. The company or legal entity list doesn't remain static and is constantly changing. This is because you may need to add new companies, especially as part of a phased rollout or acquisitions. Until now, you were unable to add a company or legal entity without system down-time, which required you to unlink and relink your environment. All of this can be expensive, especially because of pre-existing data. With this feature, you can add a company in a live environment without the need to unlink your existing dual-write environment.

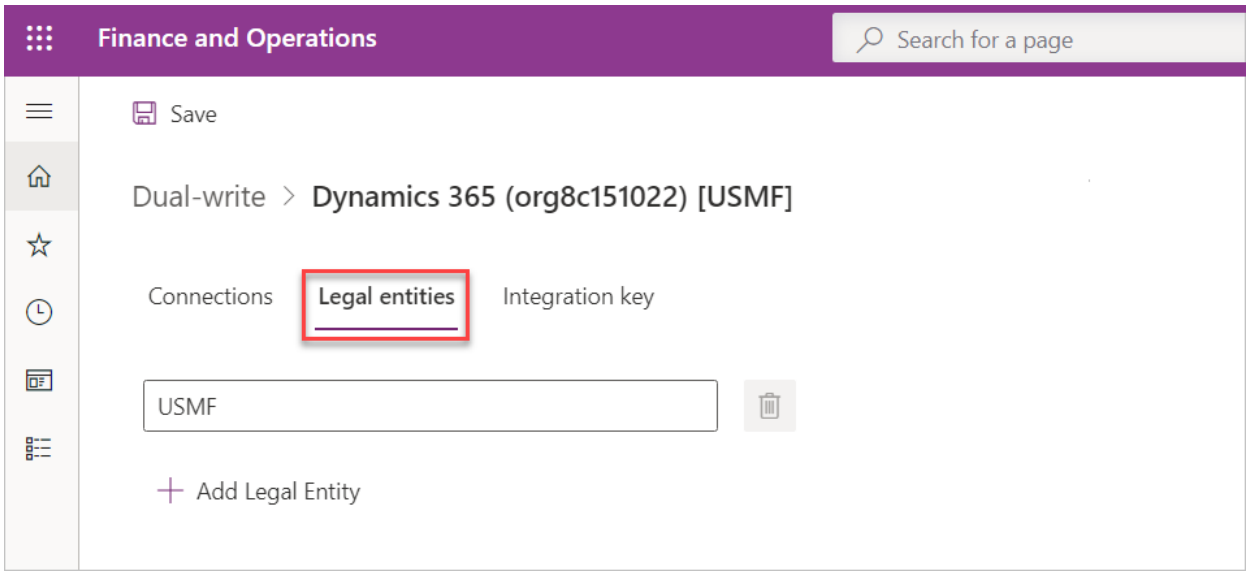
Add a company or legal entity after dual-write has been set up

Follow these steps to add a company or legal entity after dual-write has been set up.

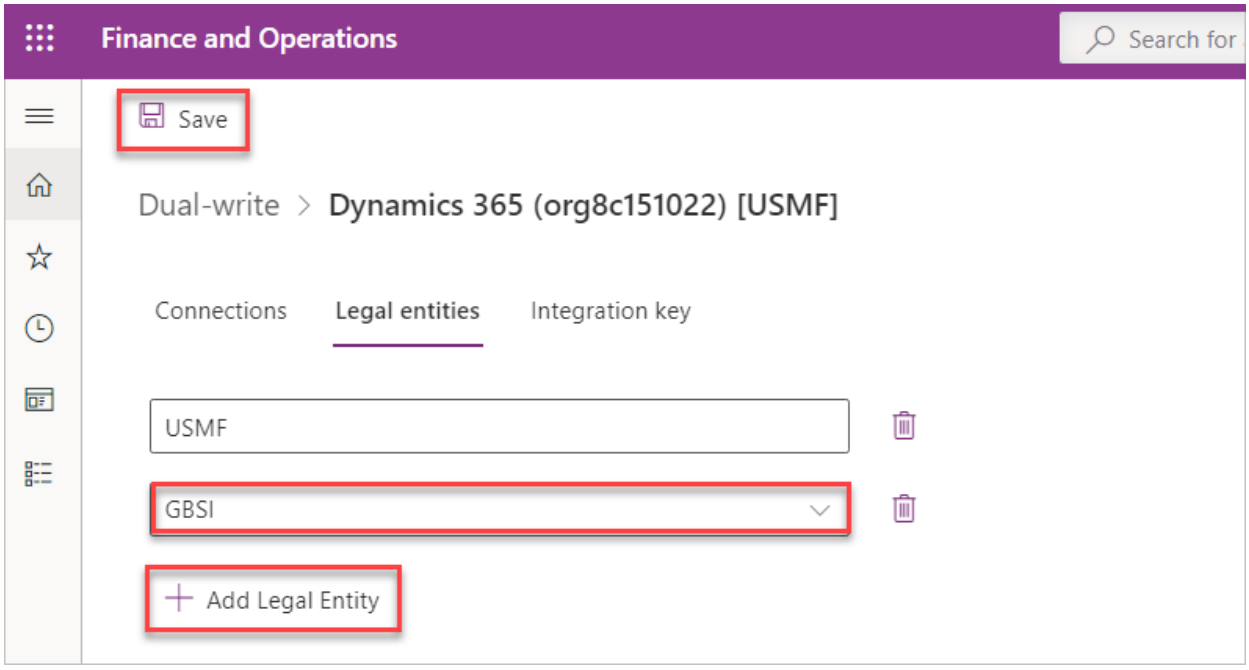
1. On the **Dual-write table map** list page, select the **Environment details** button.



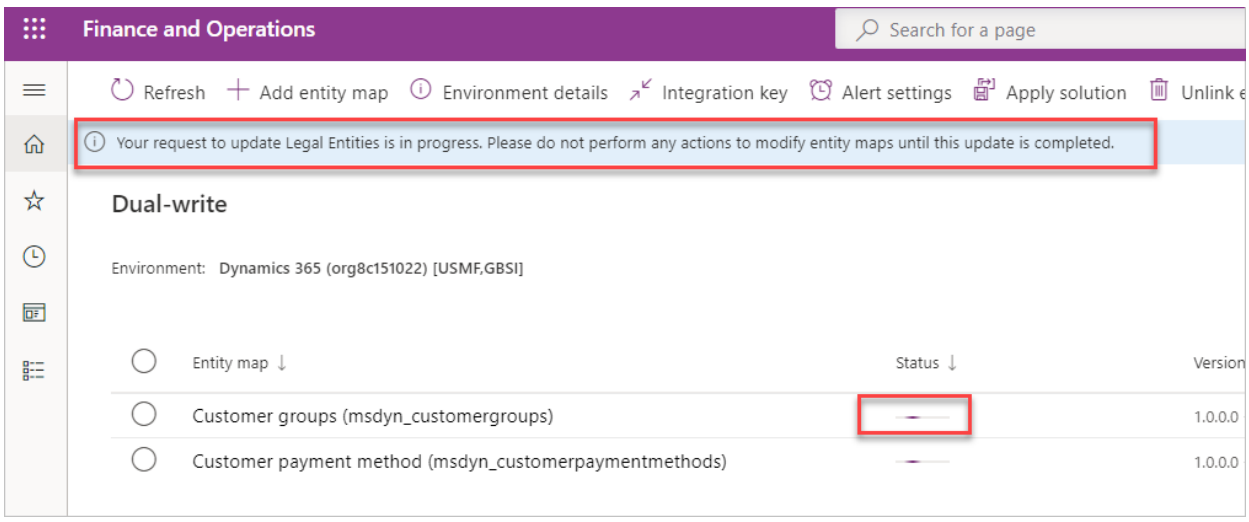
2. On the **Legal entities** tab, you see the company that you selected as part of the dual-write wizard to link environments. In this example, the company is USMF.



3. Select **Add legal entity** to add one or more companies to dual-write. In this example, GBSI. Select **Save**.



At this point, the legal entities start updating. The table maps that are currently running or paused go through the initial write process by copying pre-existing data. Until the process is completed, we recommend that you do not perform any actions to modify your table maps.

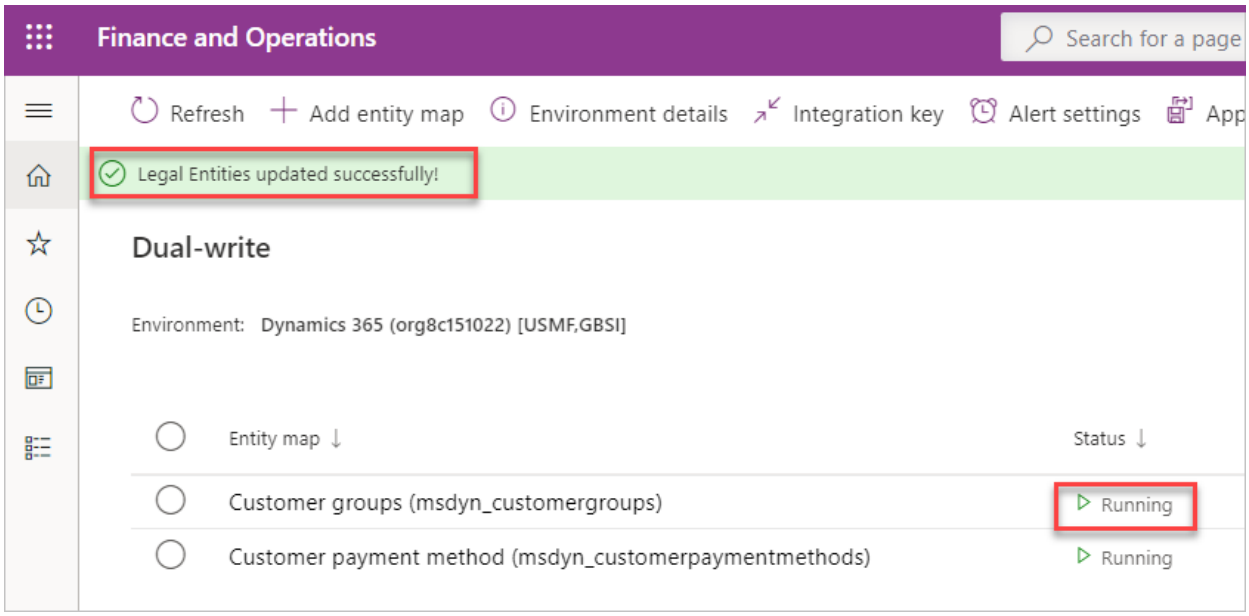


NOTE

This operation may fail if either of the following conditions are true:

- You add or remove a new company when one or more table maps is already in the Initial writes state. This the process where the system is copying pre-existing data.
- You remove a company when one or more table maps is in the Paused state.

4. After the process is complete, a banner displays informing you that the legal entities have been updated successfully. You can now resume updates to your table maps.



NOTE

Can you tell us about your documentation language preferences? Take a short survey.

The survey will take about seven minutes. No personal data is collected (privacy statement).

Error management and alert notifications

2/18/2021 • 2 minutes to read • Edit Online

NOTE

Effective November 2020:

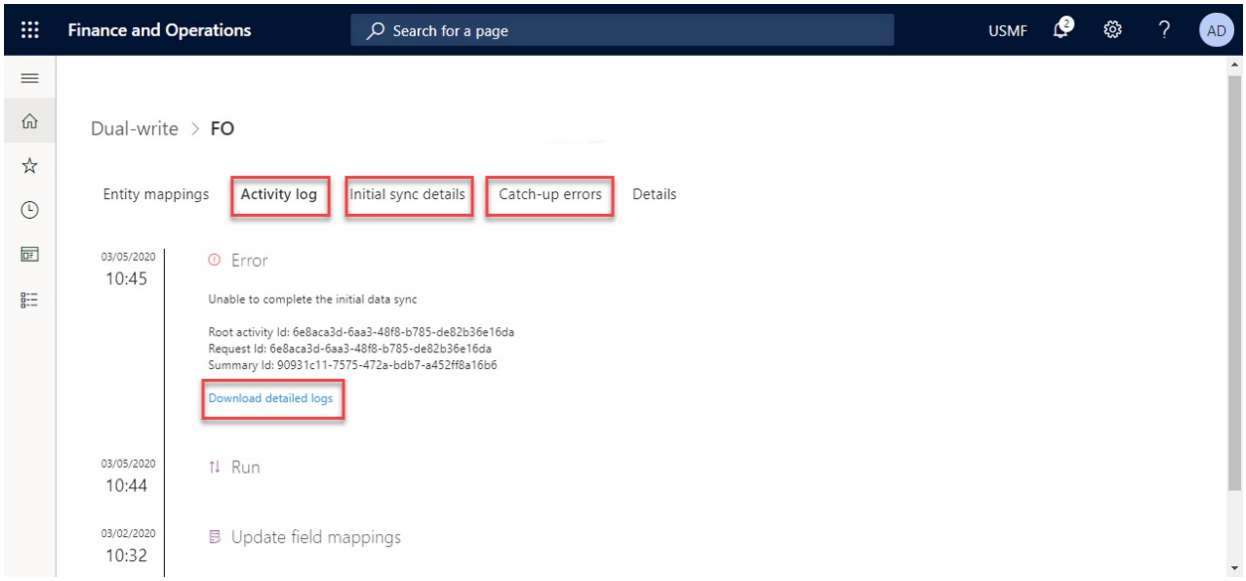
- Common Data Service has been renamed to Microsoft Dataverse. For more information, see Power Automate Blog.
- Some terminology in Microsoft Dataverse has been updated. For example, *entity* is now *table* and *field* is now *column*. For more information, see Terminology updates.

This topic will be updated soon to reflect the latest terminology.

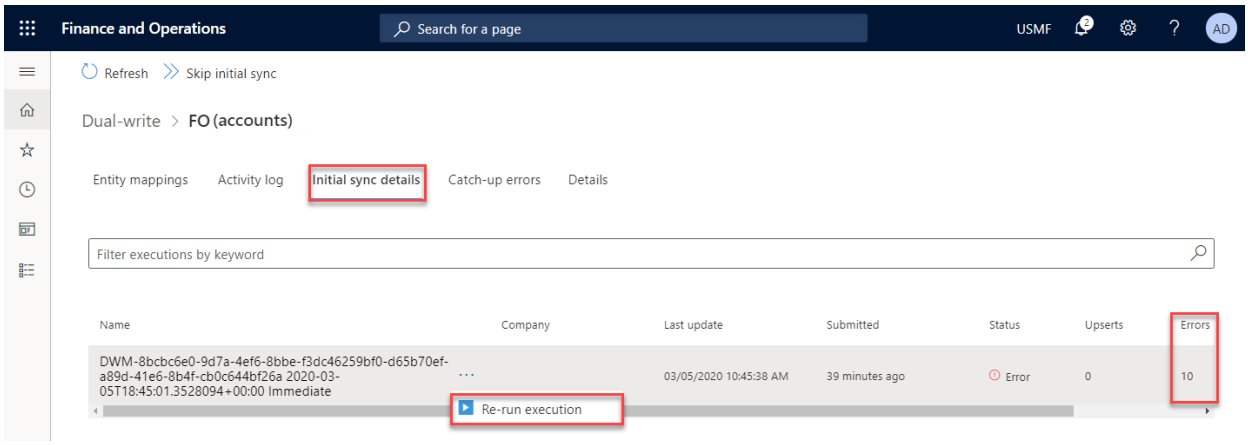
Microsoft has invested lots of time and effort into making dual-write resilient to errors. However, if you encounter an issue while or after you enable table maps for dual-write, you can select specific table maps to get a consolidated view of all the activities and errors for them. This consolidated view includes error logs. The goal is to help you during troubleshooting by providing a single view of the activities for a table map.

Consolidated error management

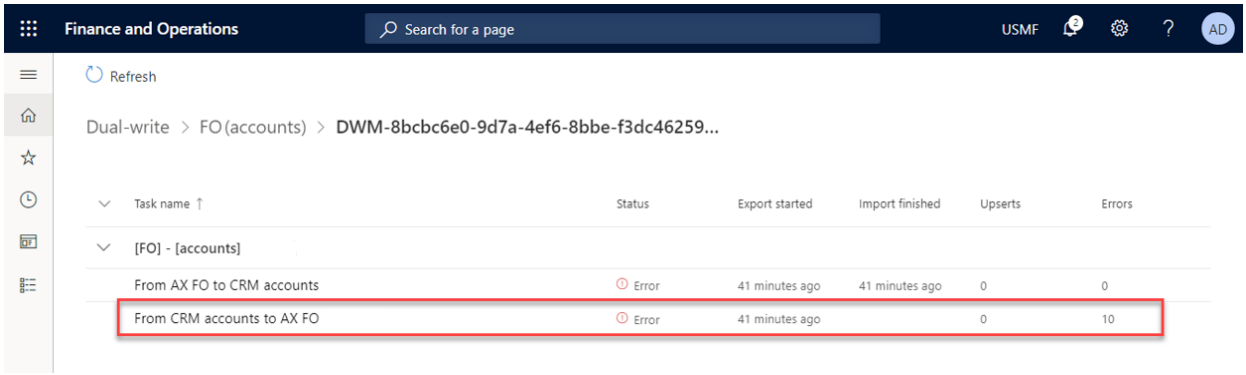
The activity log provides a chronological list of events that a specific table map goes through from the **Not Running** status to the **Running** status. For example, the list can include mappings that are created, updates of column mappings, and mappings that are run. Additionally, if errors occur, you can download the logs to get the next level of details.



If you encounter issues while you copy pre-existing data between Finance and Operations apps and Dataverse, the **Initial sync details** tab provides a count of the errors. It also lets you rerun the execution after you fix the underlying errors.



You can drill down further to view the synchronization direction where the error occurred. This information can help you narrow down the scope for troubleshooting.

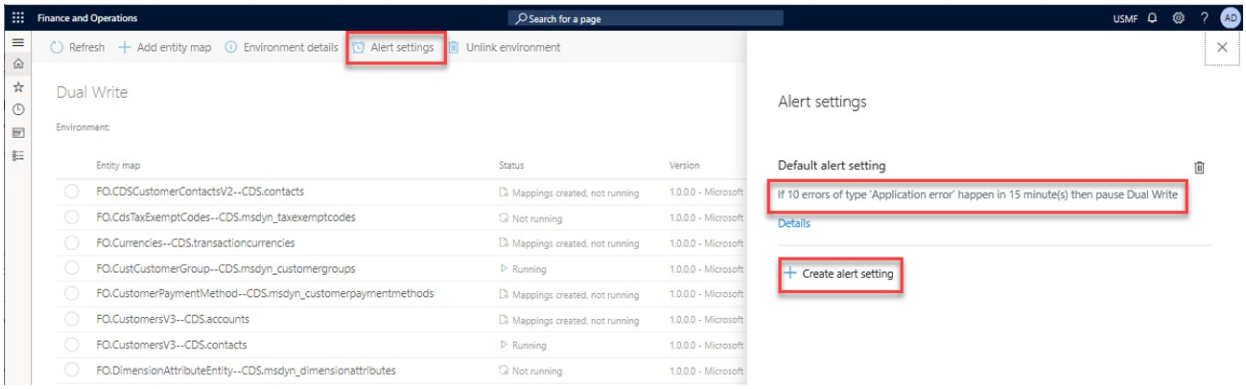


In a similar way, the **Catch-up errors** tab can help you troubleshoot issues when you resume from a paused state.

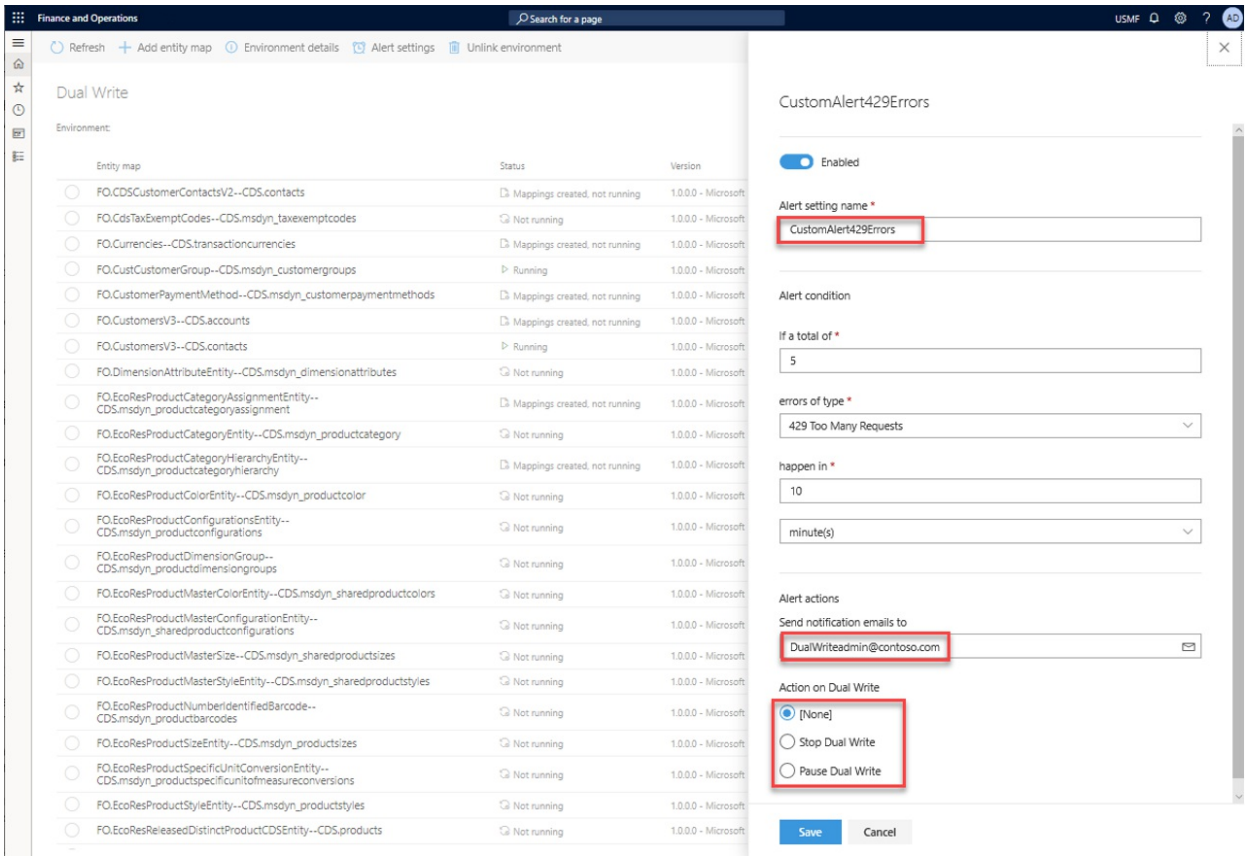
Alert notifications

As an admin, you can create one or more alert settings to handle cases of planned or unplanned maintenance. For example, you can set up the dual-write system to notify you by email if a specific error threshold is reached because of, for example, network errors. The dual-write system can also take action on your behalf. For example, it can pause or stop dual-write.

The following illustration shows an example where dual-write will be paused if 10 errors of the **Application error** type occur within 15 minutes.



By selecting **Create alert settings**, you can create more alerts. You can also select whether notifications should be sent to an individual or a group, and whether the dual-write system should take any action on your behalf.



This feature is especially useful if there is unplanned maintenance. For example, one of the apps becomes unavailable and, based on your defined thresholds, dual-write goes into a paused state where all new requests are queued (that is, they aren't lost). After you fix the underlying issue, and both apps are running smoothly, you can resume from the paused state. The updates will then be read back from the queue and written to the recovered app.

Next steps

Application lifecycle management

NOTE

The survey will take about seven minutes. No personal data is collected (privacy statement).

Application lifecycle management

2/18/2021 • 7 minutes to read • Edit Online

NOTE

Effective November 2020:

- Common Data Service has been renamed to Microsoft Dataverse. For more information, see Power Automate Blog.
- Some terminology in Microsoft Dataverse has been updated. For example, *entity* is now *table* and *field* is now *column*. For more information, see Terminology updates.

This topic will be updated soon to reflect the latest terminology.

By making dual-write solution-aware, you enable basic application lifecycle management (ALM) capabilities, such as transportation and backup/restore of dual-write table maps across environments. You also enable scenarios where you can get solutions that are published by Microsoft or an independent software vendor (ISV) from AppSource.

What is a dual-write solution?

A dual-write solution can contain one or more dual-write table maps. These maps can be imported into your environment (by selecting **Solutions** in Microsoft Power Apps). They can also be exported to other environments as a package. You can import Microsoft-published or ISV-published table maps from AppSource, modify them in your test environment, test them, and then, when they are ready, export them to your production environment. Additionally, you can publish your solution through AppSource, so that other people can use it.

There two types of solutions: managed and unmanaged.

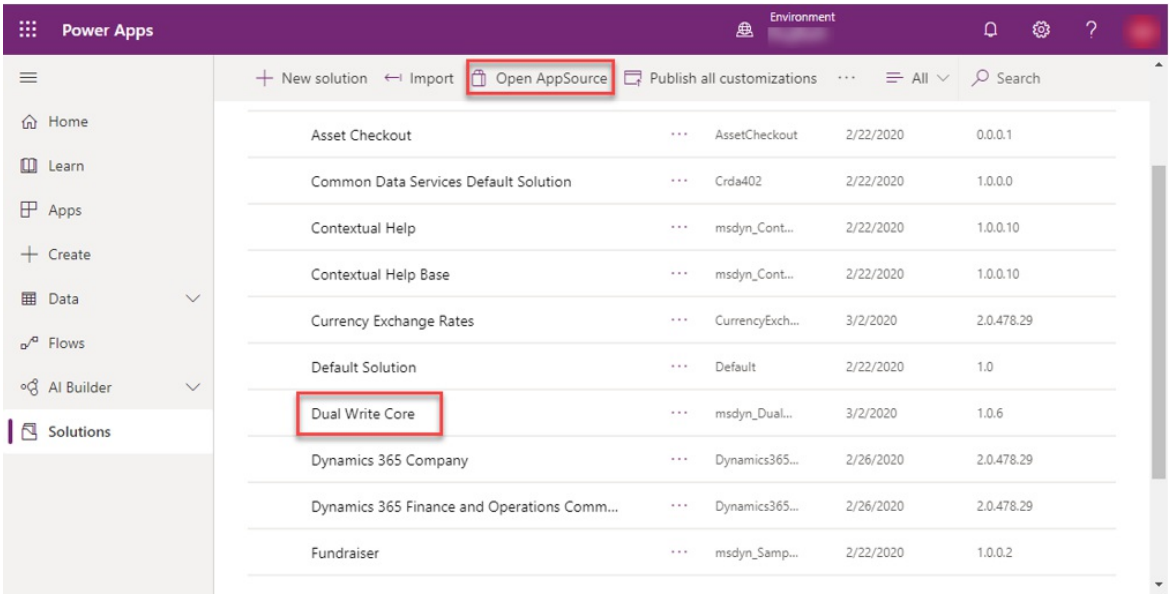
A managed solution can't be modified, and it can be uninstalled after it's imported. When you import an unmanaged solution, you add all the components of that solution into your environment. When you import an unmanaged solution that contains components that you've already customized, your customizations are overwritten by the customizations in the imported unmanaged solution.

For more information about solutions, see the solutions overview.

Install the dual-write core solution

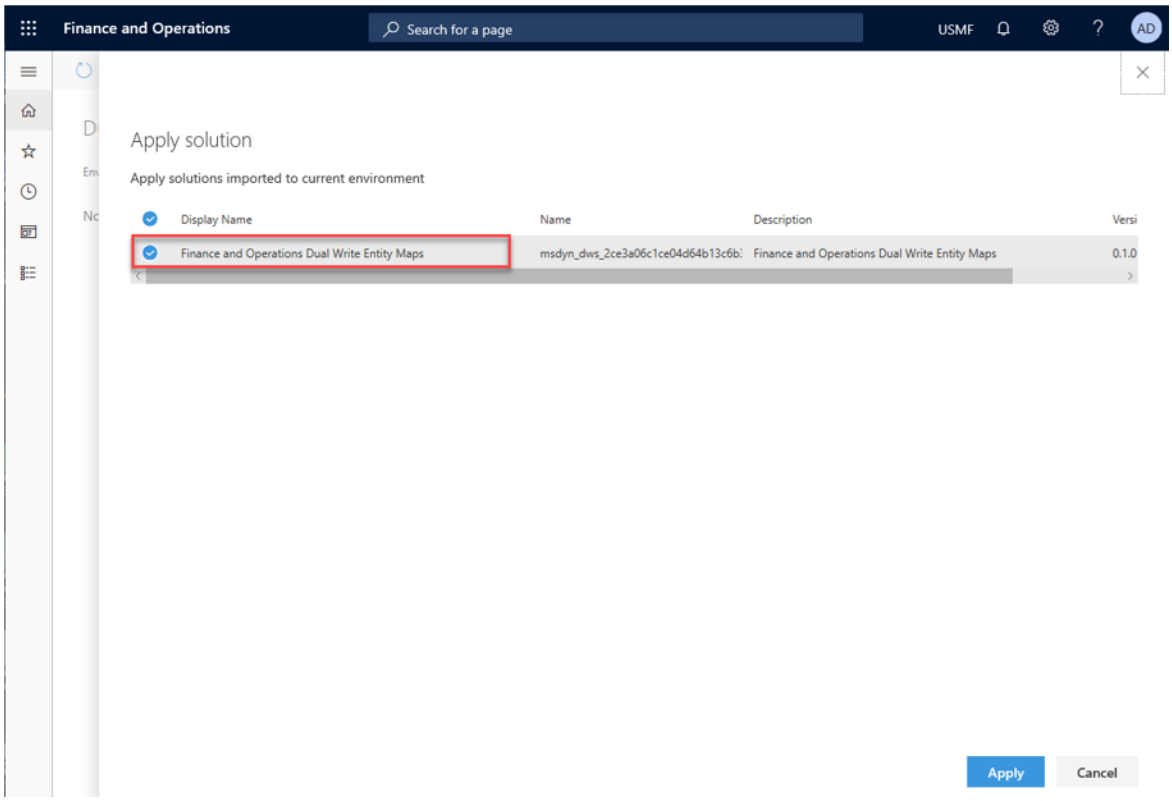
The dual-write core solution contains metadata for your table maps and must be installed in your environments.

1. In Power Apps, in the left pane, select **Solutions**.
2. Select **Open AppSource**, and search for the solution that is named **Dual Write Core**.
3. Follow the prompts to import the solution.



Install the dual-write table maps solution

1. In Power Apps, in the left pane, select **Solutions**.
2. Select **Open AppSource**, and search for the solution that is named **Dataverse Add-in for Finance and Operations package**.
3. Follow the prompts to import the solution.
4. In the Finance and Operations app, on the **Dual-write** page, select **Apply Solution** to apply the table maps that you downloaded and installed. After you apply the solution, you will see that the default table maps are published.

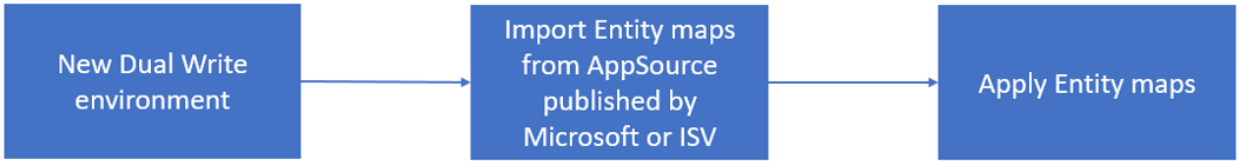


You've now successfully imported and applied a Microsoft-published dual-write table maps solution to your environment.

Import table maps through a dual-write solution and apply them to

your environment (New environments)

This section explains how to import table maps from AppSource and apply them to your environment.

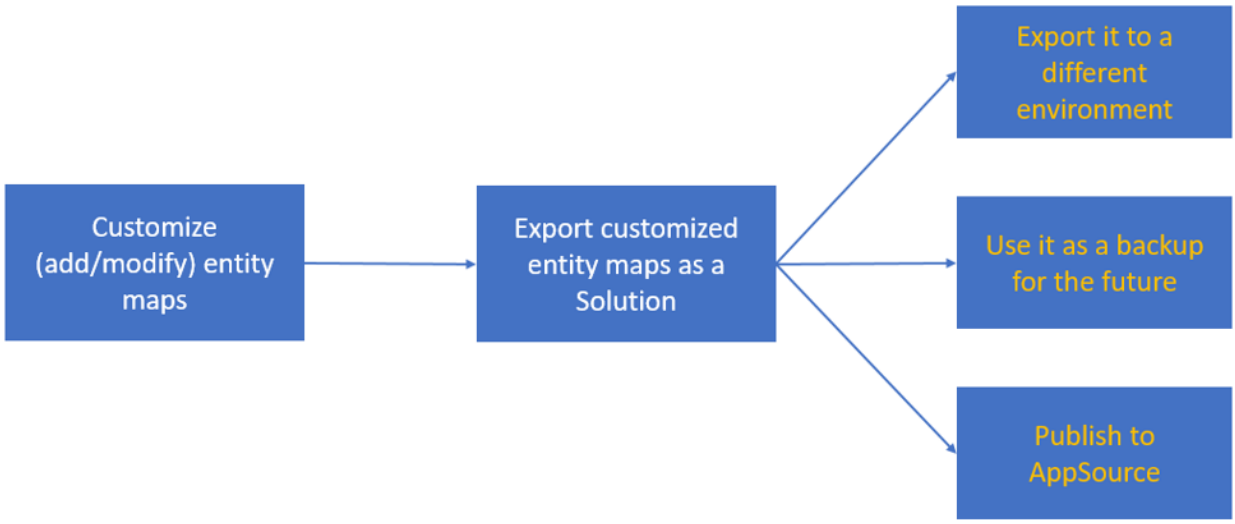


1. Import the dual-write core solution.
    a. Create a new dual-write environment (a Finance and Operations app environment and a Dataverse environment).
    b. Follow the instructions in the Install the dual-write core solution section earlier in this topic to install the dual-write core solution from AppSource in Power Apps.
    c. Verify that the dual-write core solution is listed under **Solutions** in Power Apps.
2. Import the Microsoft-published or ISV-published table maps solution.
    a. Follow the instructions in the Install the dual-write table maps solution section to download and install the Microsoft-published or ISV-published table maps from AppSource in Power Apps.
    b. Verify that the table maps solution is listed under **Solutions** in Power Apps.
3. Apply the dual-write table maps solution to your Finance and Operations app environment.

    Apply the solution that you downloaded by selecting **Apply Solutions** on the **Dual-write** page in the Finance and Operations app, as described in the Install the dual-write table maps solution section.

Update table maps and export them to other environments as a solution

This section explains how to export your customized table maps as a solution, use it as a backup, and move the artifacts across environments and/or publish them to AppSource.



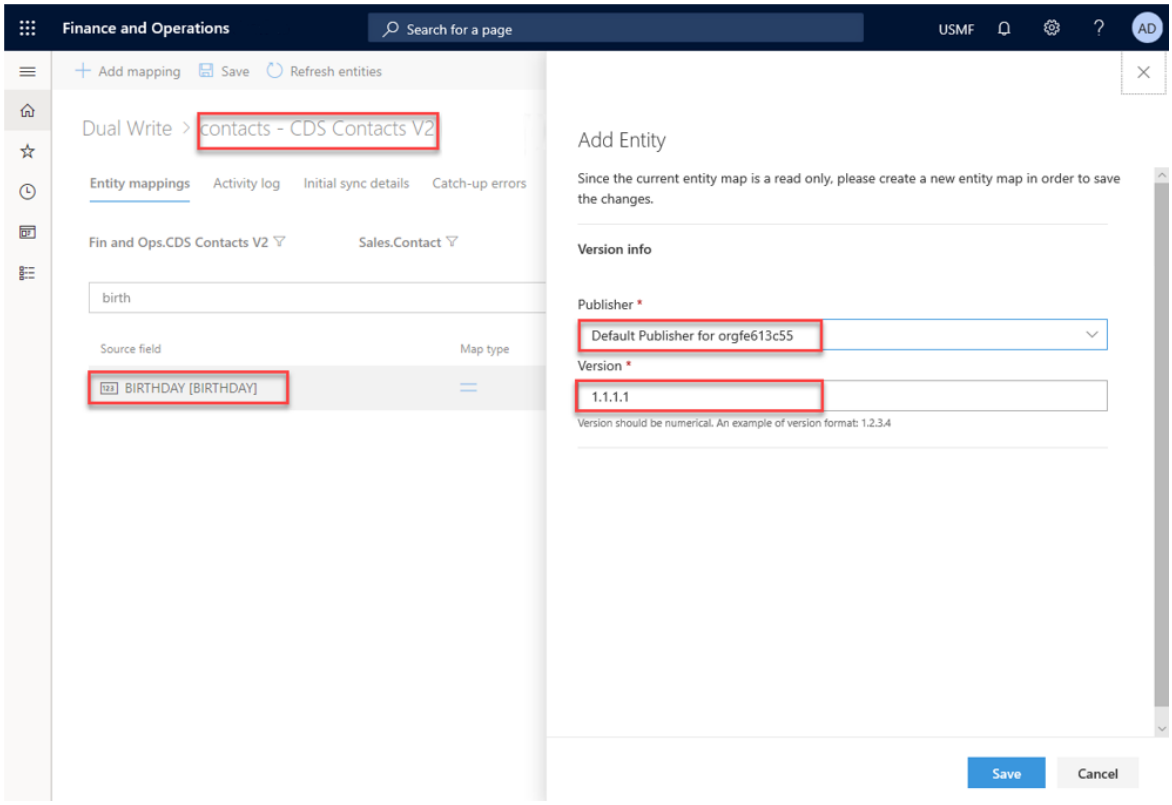
Customize your table maps

The first step is to customize your table maps by modifying existing table maps and adding a new table map.

1. In the Finance and Operations app, on the **Table mappings** tab, customize the mappings for the default table map that you just installed by using a solution. To add a new table map, select **Add Table**. In both cases, when you save the table map, you're prompted to specify the publisher and the version number.

    The following figure shows how to add a new column that is named **birthday** to the contacts - CDS

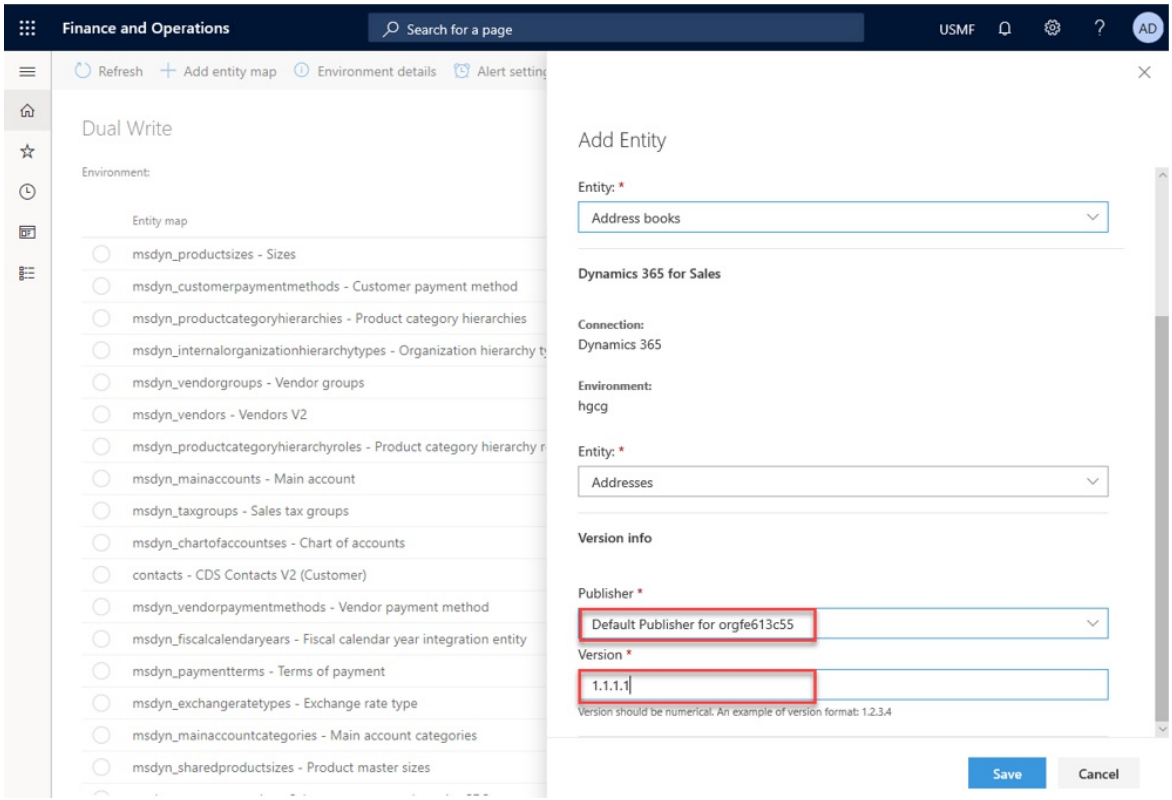
Contacts V2 table map and select the default publisher.



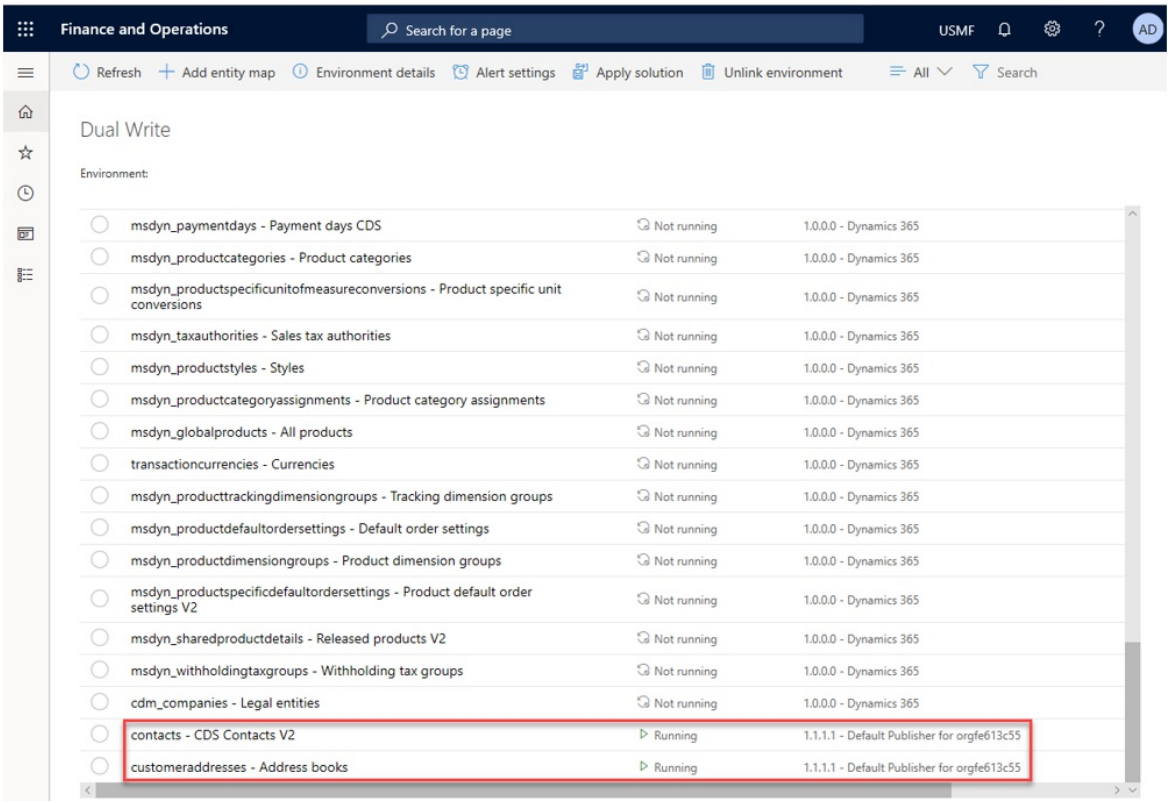
NOTE

When you create a new solution by using these modified table maps, you must specify the same publisher.

The following figure shows how to add a new table map that is named **Address books**.



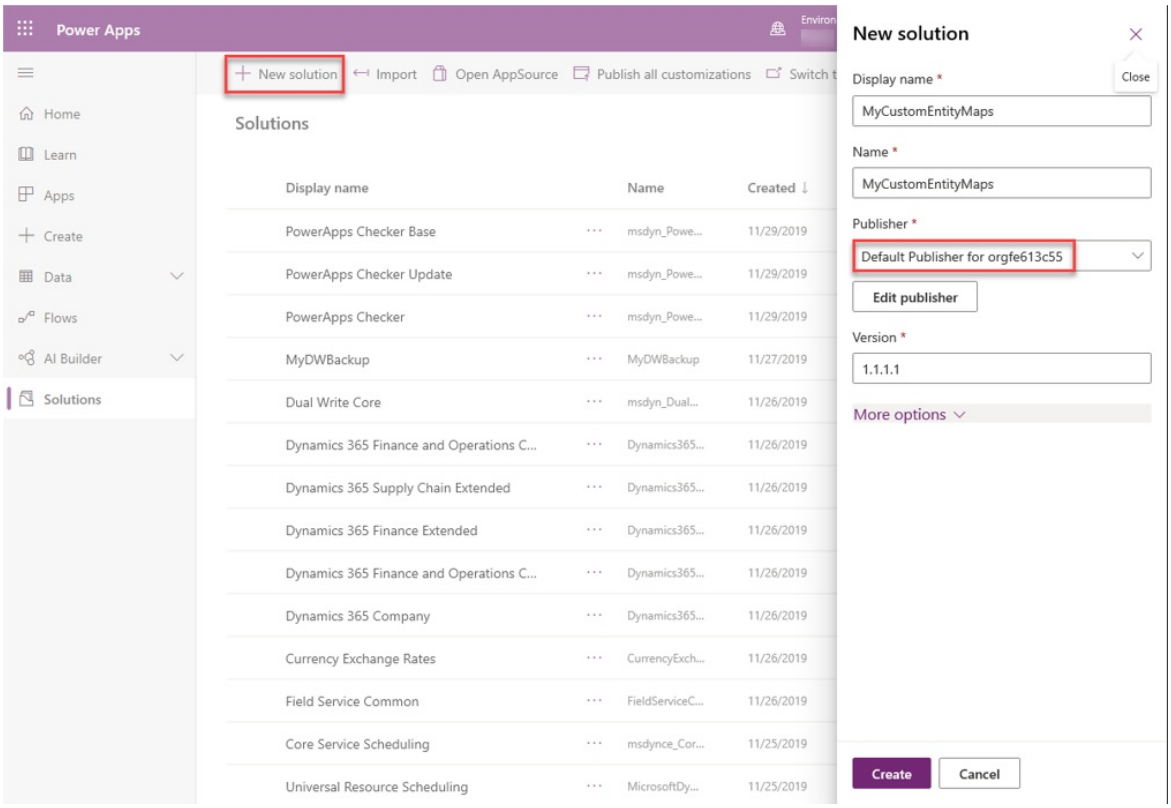
2. Confirm the table maps that you just modified and added. Be sure to enable and test them, to ensure that they work as you expect.



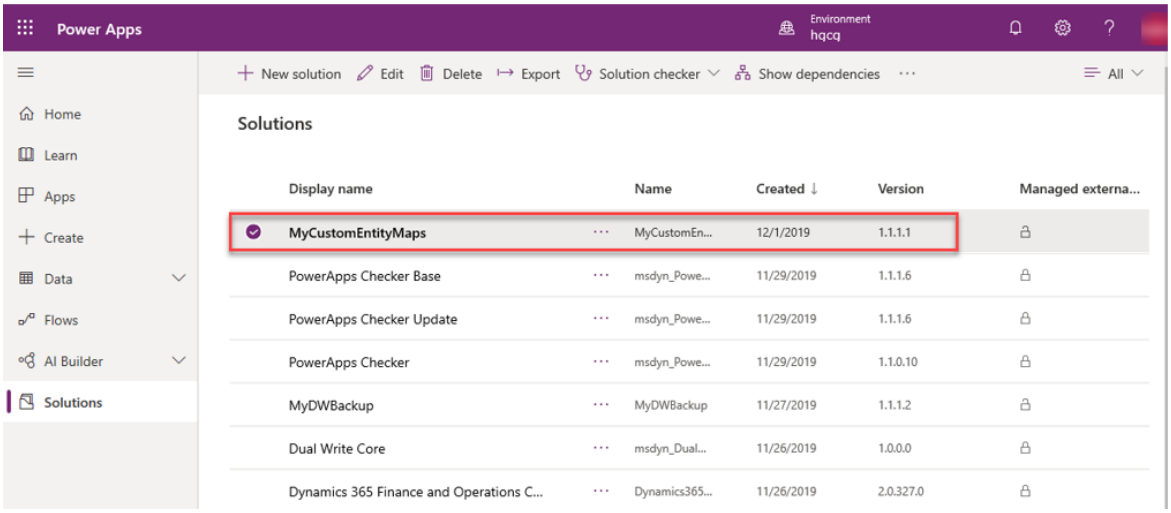
Create a new dual-write solution and add your components (Customized table maps)

Now that you've customized your mappings and added new mappings, the next step is to create a new dual-write solution and add the table maps to it.

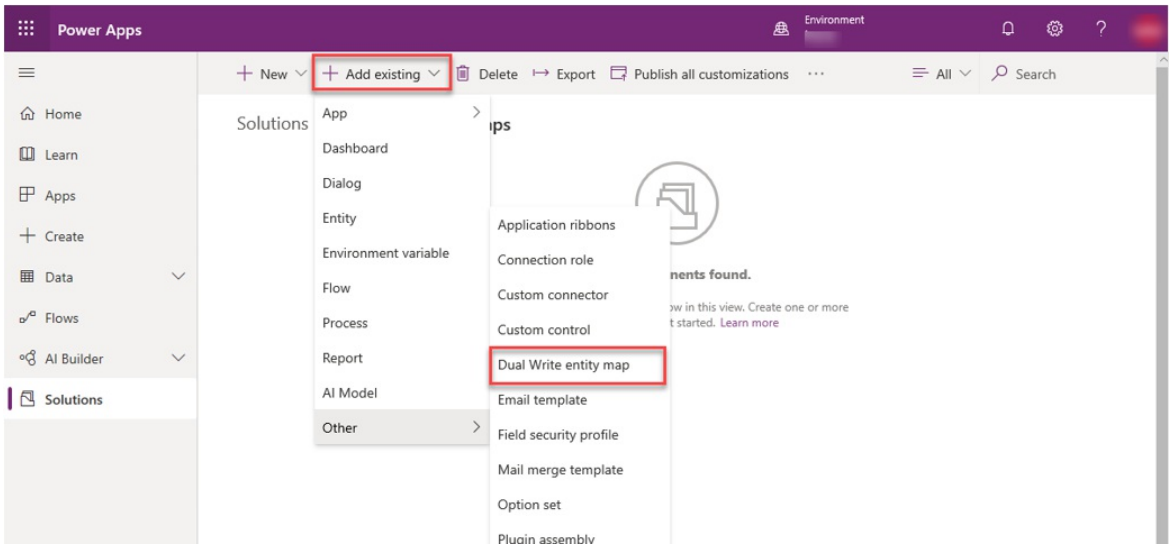
1. In Power Apps, in the left pane, select **Solutions**, and then select **New solution** to create a solution. For this example, the solution is named **MyCustomTableMaps**. Be sure to select the same publisher that you selected in previous steps.



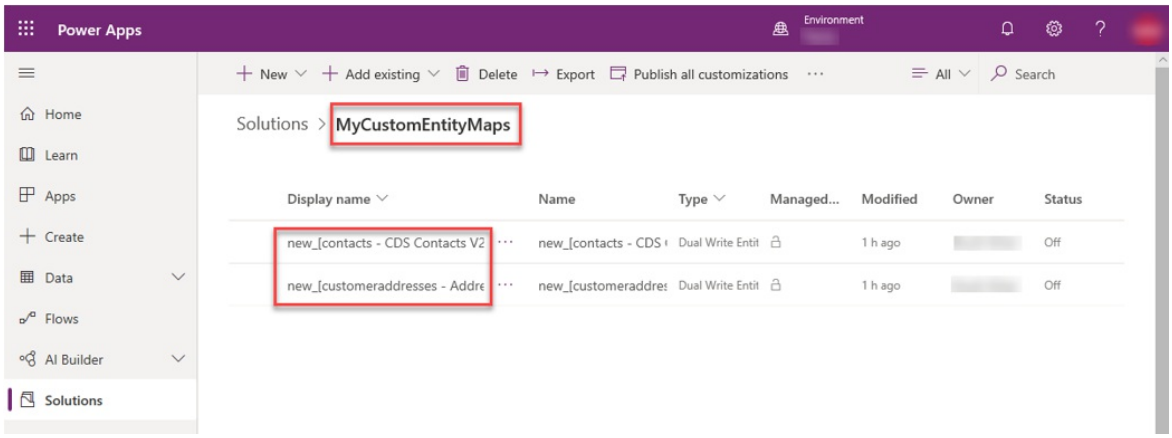
2. Select **Create**. The new solution appears on the **Solutions** list page.



3. Now that you've created your dual-write solution, you can add the customized table maps that you created in previous steps. Select the **MyCustomTableMaps** solution that you just created, select **Add existing**, point to **Other**, and then select **Dual Write table map**.



4. In the list, select the customized table maps, and add them to the solution. The solution should now contain your customized tables.



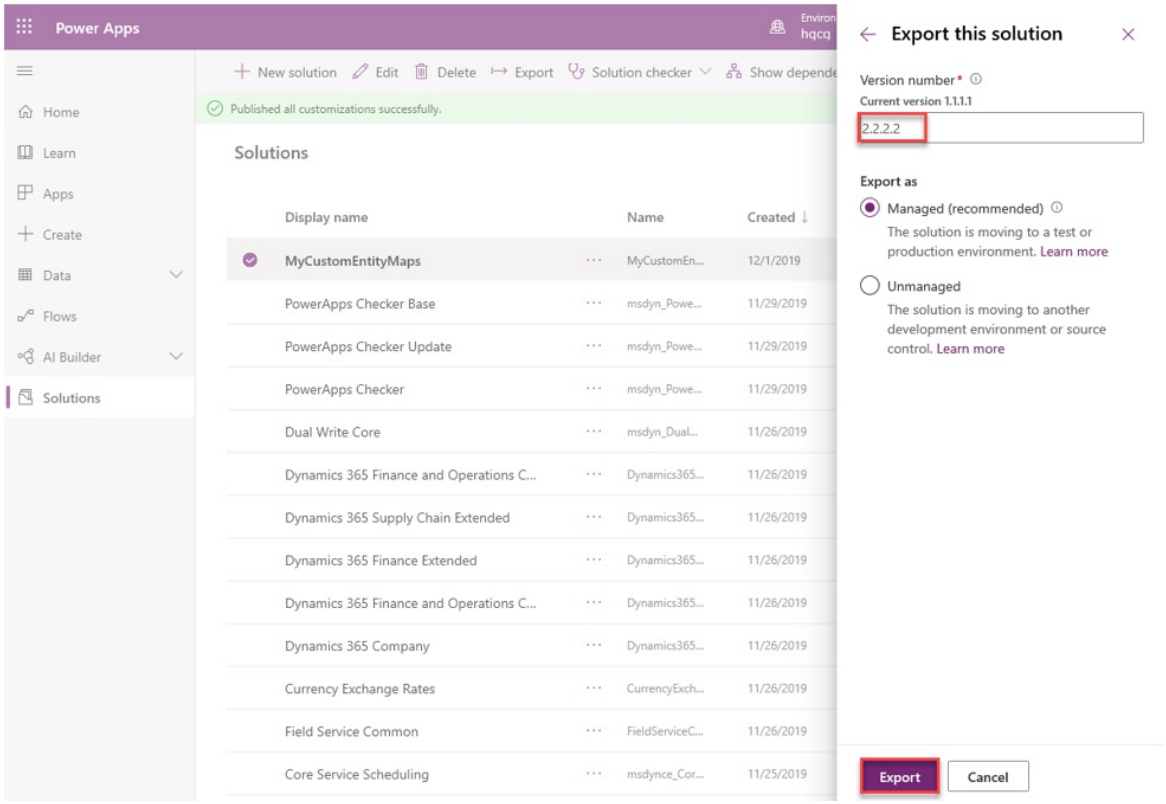
You've now customized your tables and put them into a solution.

Export and publish your solution

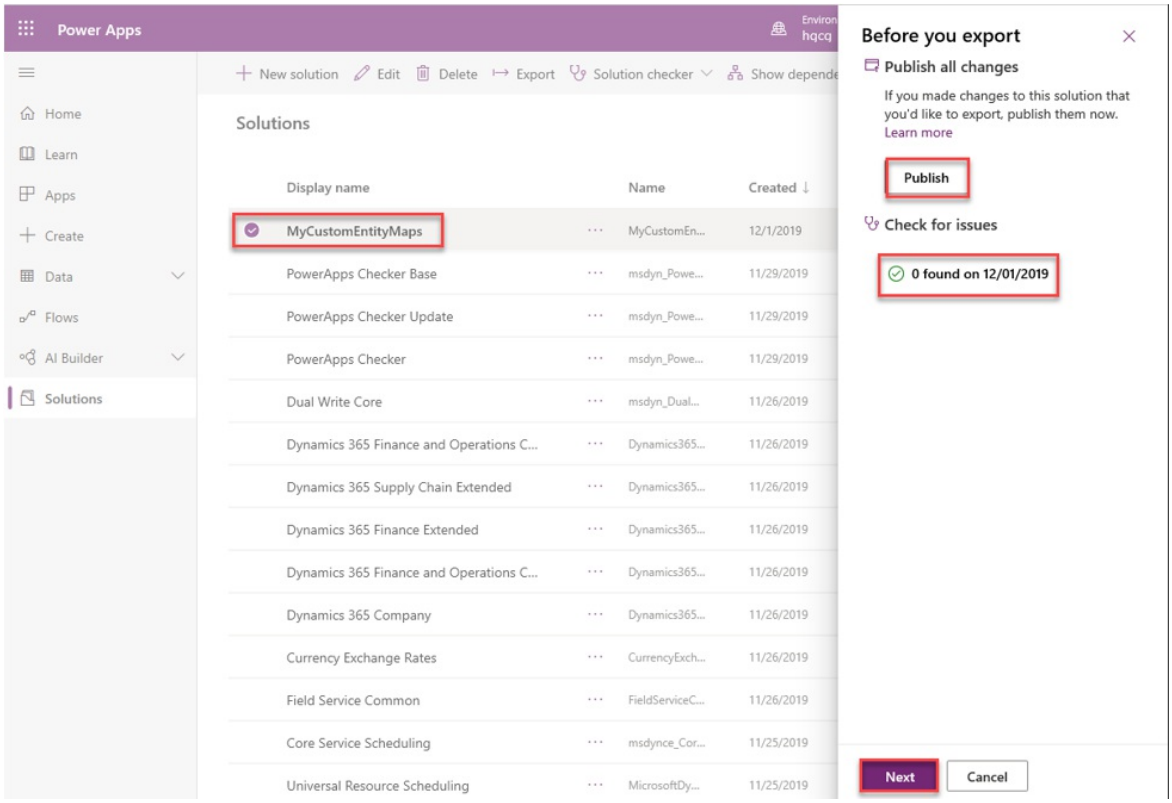
After you run the solution checker and make sure that there are no issues, you export the solution that you created and publish the changes.

1. In the list of solutions, select your solution, and then select **Export**.

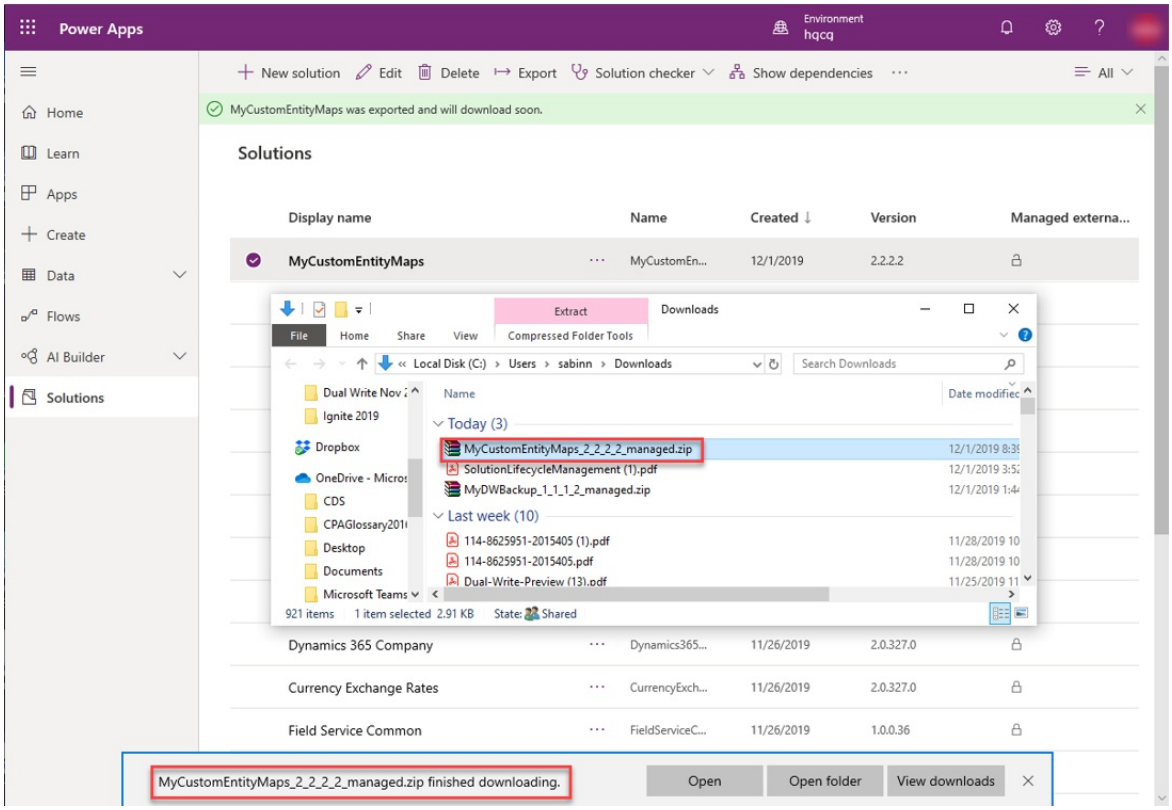
2. Update the version number, and select whether you want to export the solution as a managed or unmanaged solution. (We recommend that you export it as a managed solution.) Then select **Export**.



3. Before you export, select **Publish all changes**, and then select **Check for issues**. When you've finished, select **Next** to publish all your changes.



The solution, together with all its components, is exported to a zip file.



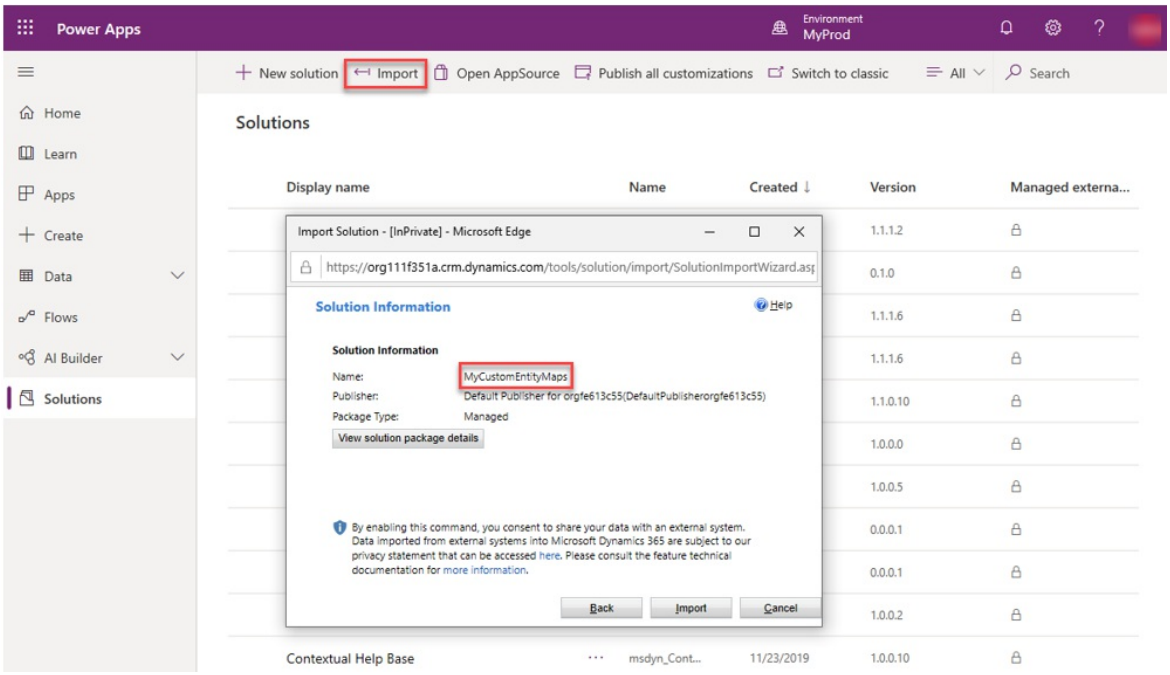
You've now customized your tables, added them to a new solution, and created a solution file that can be imported and applied to other environments. (This capability can be useful if you want to move table maps between test and production environments.) In a similar way, you can create a backup of all your table maps by adding them to a solution and exporting the solution as a package. That package can then be imported into to any environment to restore the table maps.

For information about how to publish the package to AppSource, see Publish your app on AppSource.

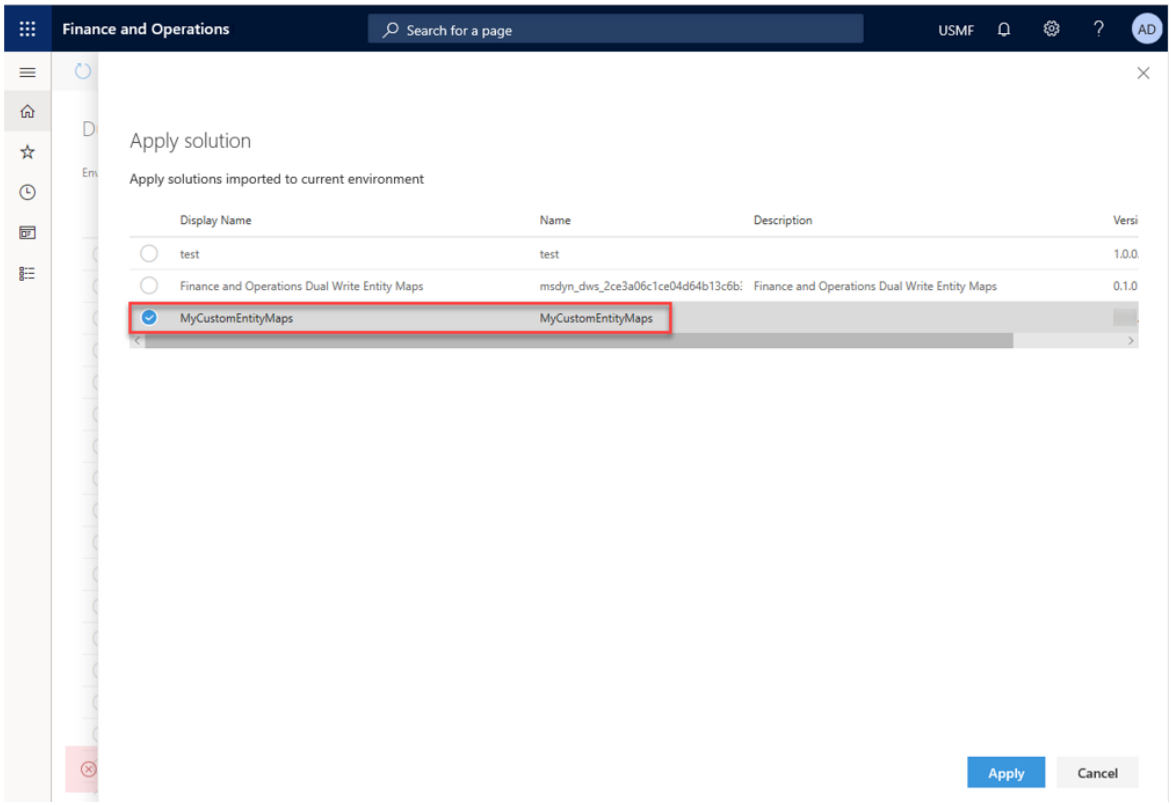
Test your exported solution package

You can test your exported solution package by importing and applying it to another environment.

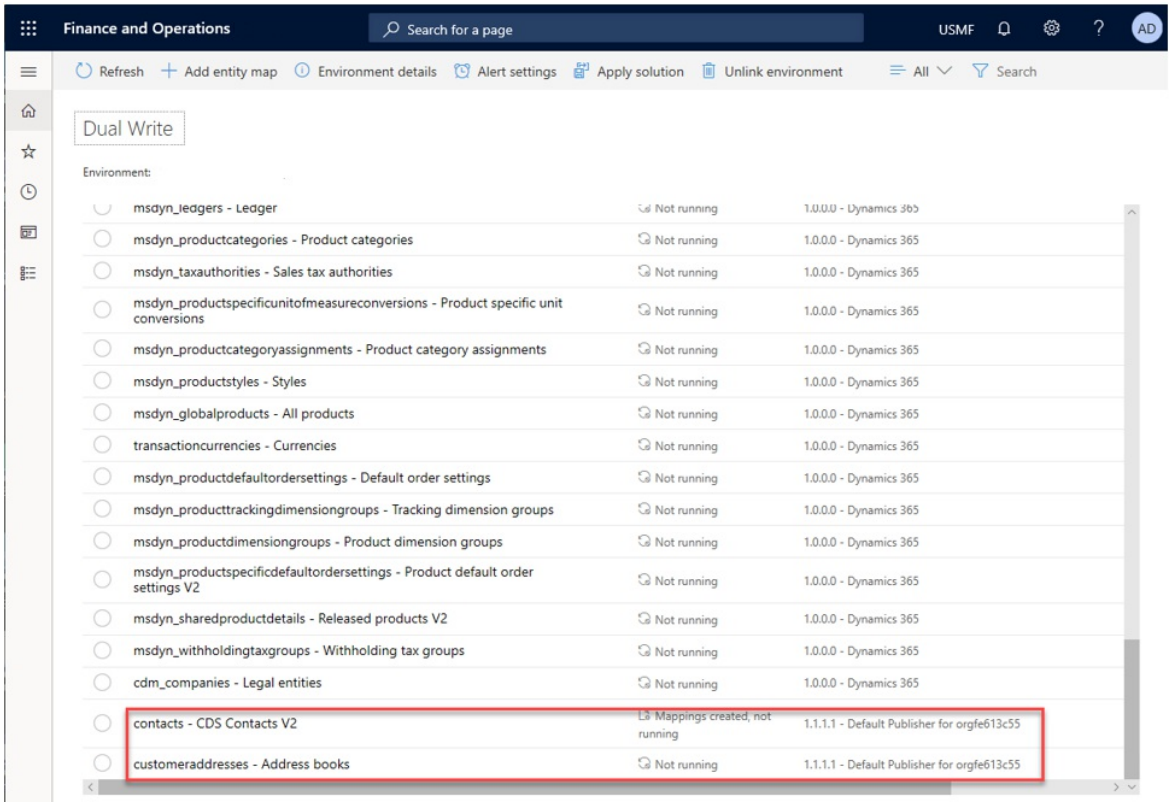
1. In Power Apps, select **Import** to import the package into a new environment.



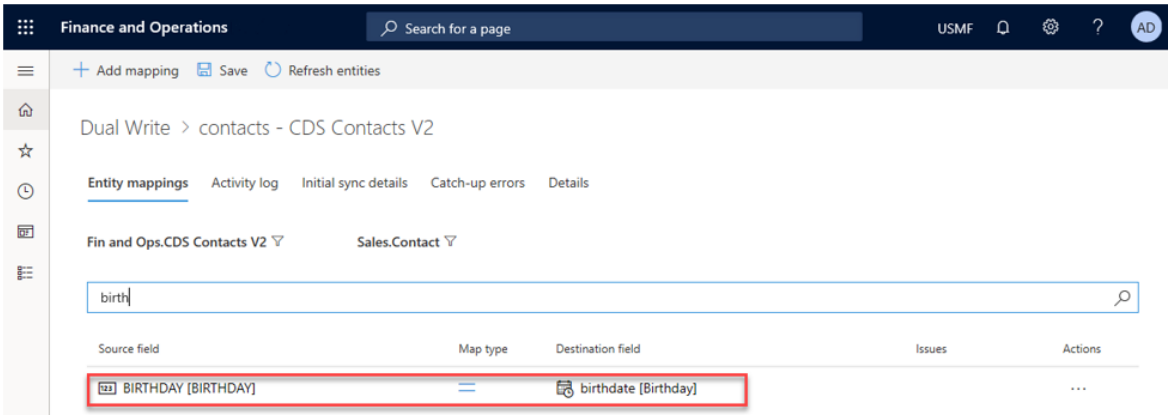
2. Apply the solution that you just imported to the environment.



3. Verify that the two customized table maps appear on the dual-write table maps list page.

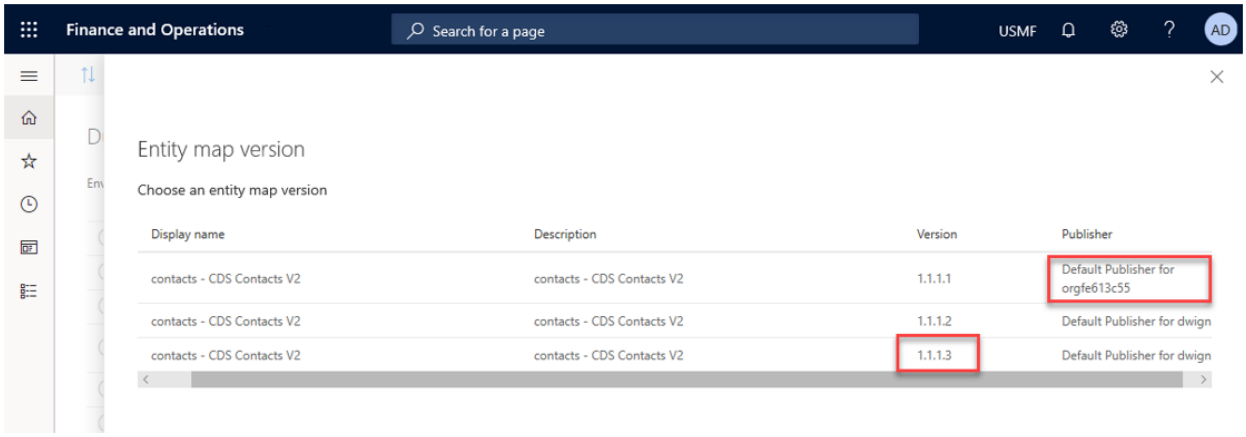


4. Make sure that the customizations from previous steps are preserved.



Use the table map version

Sometimes, a solution might contain different implementations of a table map. For example, the version of the contacts - CDS Contacts V2 table map might have a different publisher or a newer version number. In these cases, you can use the **Table Map version** button to select which table map you want to use in your environment.



Upgrade existing dual-write environments for solution awareness (Existing environments)

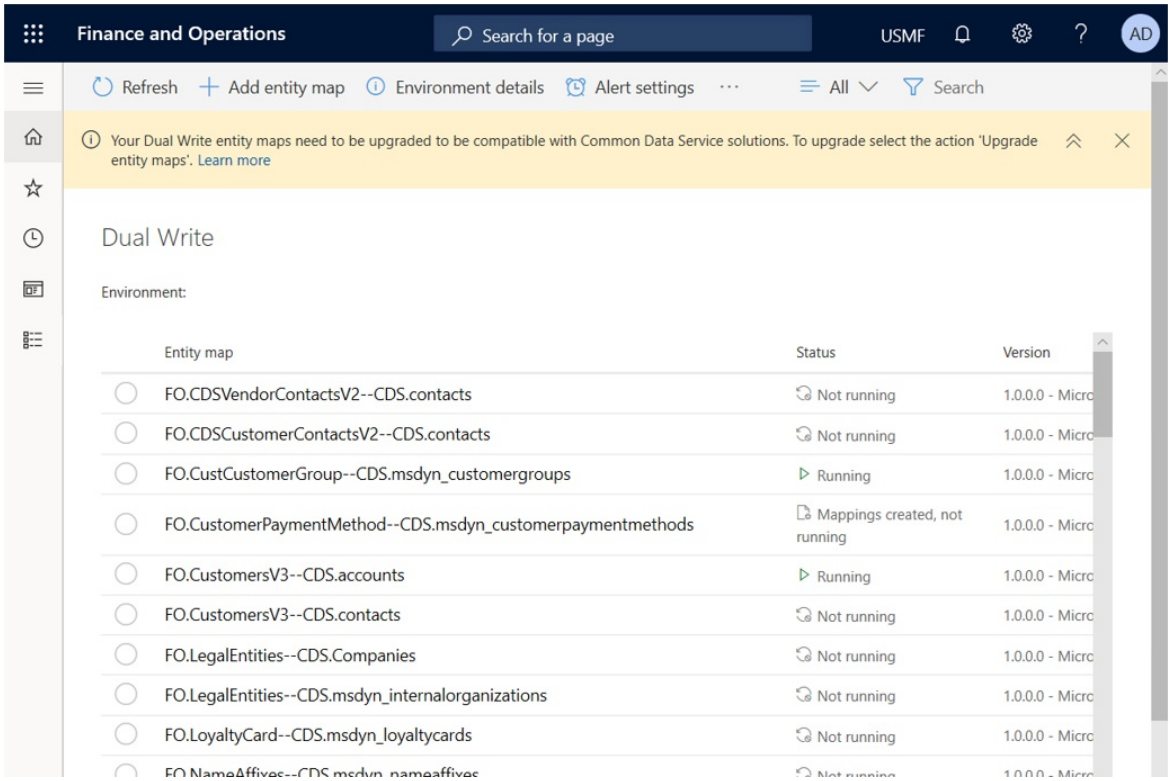
1. Import the dual-write core solution.

    a. Follow the instructions in the Install the dual-write core solution section earlier in this topic to import the dual-write core solution from AppSource into Power Apps.

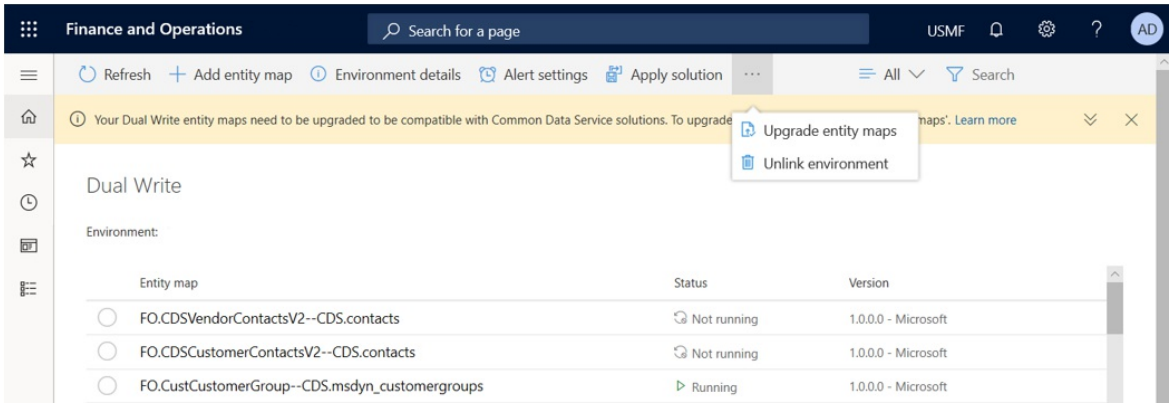
    b. Verify that the dual-write core solution is listed under **Solutions** in Power Apps.

2. Upgrade the table maps.

    You'll see a notification prompting you to upgrade.



Select **Upgrade table maps** at the top of the page.



The upgrade takes a few minutes. When it's completed, you receive a notification.

NOTE

Can you tell us about your documentation language preferences? Take a short survey.

The survey will take about seven minutes. No personal data is collected (privacy statement).

Integrated customer master

2/18/2021 • 8 minutes to read • Edit Online

NOTE

Effective November 2020:

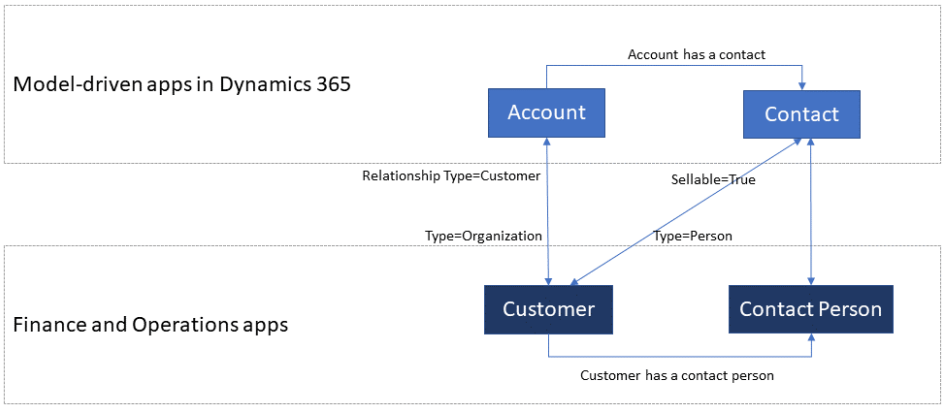
- Common Data Service has been renamed to Microsoft Dataverse. For more information, see Power Automate Blog.
- Some terminology in Microsoft Dataverse has been updated. For example, *entity* is now *table* and *field* is now *column*. For more information, see Terminology updates.

This topic will be updated soon to reflect the latest terminology.

Customer data can be mastered in more than one Dynamics 365 application. For example, a customer row can originate though sales activity in Dynamics 365 Sales (a model-driven app in Dynamics 365), or a row can originate through retail activity in Dynamics 365 Commerce (a Finance and Operations app). No matter where where the customer data originates, it is integrated behind the scenes. Integrated customer master gives you the flexibility to master customer data in any Dynamics 365 application and provides a comprehensive view of the customer across the Dynamics 365 application suite.

Customer data flow

Customer is a well-defined concept in applications. Therefore, the integration of customer data just involves harmonizing the customer concept between the two applications. The following illustration shows the customer data flow.



Customers can be broadly classified into two types: commercial/organizational customers and consumers/end users. These two types of customers are stored and handled differently in Finance and Operations and Dataverse.

In Finance and Operations, both commercial/organizational customers and consumers/end users are mastered in a single table that is named **CustTable** (CustCustomerV3Entity), and they are classified based on the **Type**

attribute. (If **Type** is set to **Organization**, the customer is a commercial/organizational customer, and if **Type** is set to **Person**, the customer is a consumer/end user.) The primary contact person information is handled through the SMMContactPersonEntity table.

In Dataverse, commercial/organizational customers are mastered in the Account table and are identified as customers when the **RelationshipType** attribute is set to **Customer**. Both consumers/end users and the contact person are represented by the Contact table. To provide a clear separation between a consumer/end user and a contact person, the **Contact** table has a Boolean flag that is named **Sellable**. When **Sellable** is **True**, the contact is a consumer/end user, and quotations and orders can be created for that contact. When **Sellable** is **False**, the contact is just a primary contact person of a customer.

When a non-sellable contact participates in a quotation or order process, **Sellable** is set to **True** to flag the contact as a sellable contact. A contact that has become a sellable contact remains a sellable contact.

Templates

Customer data includes all information about the customer, such as the customer group, addresses, contact information, payment profile, invoice profile, and loyalty status. A collection of table maps works together during customer data interaction, as shown in the following table.

FINANCE AND OPERATIONS APPS	OTHER DYNAMICS 365 APPS	DESCRIPTION
CDS Contacts V2	contacts	This template synchronizes all primary, secondary, and tertiary contact information, for both customers and vendors.
Customer groups	msdyn_customergroups	This template synchronizes customer group information.
Customer payment method	msdyn_customerpaymentmethods	This template synchronizes customer payment method information.
Customers V3	accounts	This template synchronizes customer master information for commercial and organizational customers.
Customers V3	contacts	This template synchronizes customer master data for consumers and end users.
Name affixes	msdyn_nameaffixes	This template synchronizes name affixes reference data, for both customers and vendors.
Payment day lines CDS V2	msdyn_paymentdaylines	This template synchronizes payment day lines reference data, for both customers and vendors.
Payment days CDS	msdyn_paymentdays	This template synchronizes payment days reference data, for both customers and vendors.
Payment schedule lines	msdyn_paymentschedulelines	Syncs payment schedule lines reference data, for both customers and vendors.

FINANCE AND OPERATIONS APPS	OTHER DYNAMICS 365 APPS	DESCRIPTION
Payment schedule	msdyn_paymentschedules	This template synchronizes payment schedule reference data, for both customers and vendors.
Terms of payment	msdyn_paymentterms	This template synchronizes payment terms (terms of payment) reference data, for both customers and vendors.

Mapping tables

Mapping types

There are several different mapping types. The following table explains the symbols used in the template tables.

SYMBOL	DESCRIPTION
>	One-way
>>	One-way, and data is transformed in the process.
=	Bidirectional
><	Bidirectional, and data is transformed in the process.
<<	One-way, and data is transformed in the process.

Filters

The source filter and reverse source filter determine which rows are synchronized.

Default values

If a synchronized field does not exist in either the Finance and Operations table or the other Dynamics 365 table, then a default value is assigned in the synchronized table. In some cases, the default value is an integer that is a lookup to an attribute value in the Common Data Model. For example, in the Contacts table of the Common Data Model, the default value of **address1_addresstypecode** is **3**. In the Common Data Model, for address1AddressTypeCode the value of **3** is **Primary address**.

Integrated vendor master

2/18/2021 • 5 minutes to read • Edit Online

NOTE

Effective November 2020:

- Common Data Service has been renamed to Microsoft Dataverse. For more information, see Power Automate Blog.
- Some terminology in Microsoft Dataverse has been updated. For example, *entity* is now *table* and *field* is now *column*. For more information, see Terminology updates.

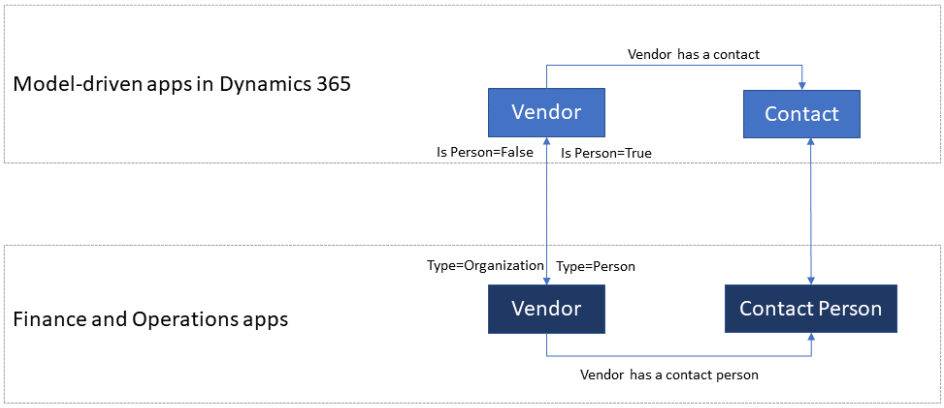
This topic will be updated soon to reflect the latest terminology.

The term *vendor* refers to a supplier organization, or a sole proprietor who supplies goods or services to a business. Although *vendor* is an established concept in Microsoft Dynamics 365 Supply Chain Management, no vendor concept exists in model-driven apps in Dynamics 365. However, you can overload the **Account/Contact** table to store vendor information. The integrated vendor master introduces an explicit vendor concept in model-driven apps in Dynamics 365. You can either use the new vendor design or store vendor data in the **Account/Contact** table. Dual-write supports both approaches.

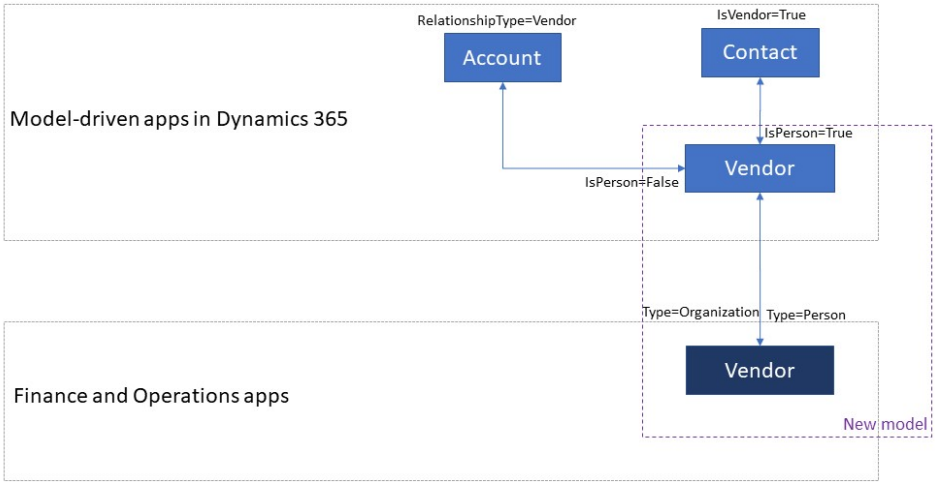
In both approaches, the vendor data is integrated between Dynamics 365 Supply Chain Management, Dynamics 365 Sales, Dynamics 365 Field Service, and Power Apps portals. In Supply Chain Management, the data is available for workflows such as purchase requisitions and purchase orders.

Vendor data flow

If you don't want to store vendor data in the **Account/Contact** table in Dataverse, you can use the new vendor design.



If you want to continue to store vendor data in the **Account/Contact** table, you can use the extended vendor design. To use the extended vendor design, you must configure the vendor workflows in the dual-write solution package. For more information, see Switch between vendor designs.



TIP

If you're using Power Apps portals for self-service vendors, the vendor information can flow directly to Finance and Operations apps.

Templates

Vendor data includes all information about the vendor, such as the vendor group, addresses, contact information, payment profile, and invoice profile. A collection of table maps work together during vendor data interaction, as shown in the following table.

FINANCE AND OPERATIONS APPS	OTHER DYNAMICS 365 APPS	DESCRIPTION
Vendor V2	Account	Businesses that use the Account table to store vendor information can continue to use it in the same way. They can also take advantage of the explicit vendor functionality that is coming because of Finance and Operations apps integration.
Vendor V2	Msdyn_vendors	Businesses that use a custom solution for vendors can take advantage of the out-of-box vendor concept that is being introduced in Dataverse because of Finance and Operations apps integration.
Vendor groups	msdyn_vendorgroups	This template synchronizes vendor group information.
Vendor payment method	msdyn_vendorpaymentmethods	This template synchronizes vendor payment method information.

FINANCE AND OPERATIONS APPS	OTHER DYNAMICS 365 APPS	DESCRIPTION
CDS Contacts V2	contacts	The contacts template synchronizes all primary, secondary, and tertiary contact information, for both customers and vendors.
Payment schedule lines	msdyn_paymentschedulelines	The payment schedule lines template synchronizes reference data for customers and vendors.
Payment schedule	msdyn_paymentschedules	The payment schedules template synchronizes payment schedule reference data, for both customers and vendors.
Payment day lines CDS V2	msdyn_paymentdaylines	The payment day lines template synchronizes payment day lines reference data for customers and vendors.
Payment days CDS	msdyn_paymentdays	The payment days template synchronizes payment days reference data, for both customers and vendors.
Terms of payment	msdyn_paymentterms	The terms of payment template synchronizes payment terms reference data, for both customers and vendors.
Name affixes	msdyn_nameaffixes	The name affixes template synchronizes name affixes reference data, for both customers and vendors.

Mapping tables

Mapping types

There are several different mapping types. The following table explains the symbols used in the template tables.

SYMBOL	DESCRIPTION
>	One-way
>>	One-way, and data is transformed in the process.
=	Bidirectional
><	Bidirectional, and data is transformed in the process.
<<	One-way, and data is transformed in the process.

Filters

The source filter and reverse source filter determine which rows are synchronized.

Default values

If a synchronized field does not exist in either the Finance and Operations table or the other Dynamics 365 table,

then a default value is assigned in the synchronized table. In some cases, the default value is an integer that is a lookup to an attribute value in the Common Data Model. For example, in the Contacts table of the Common Data Model, the default value of **address1_addresstypecode** is **3**. In the Common Data Model, for address1AddressTypeCode the value of **3** is **Primary address**.

Switch between vendor designs

2/18/2021 • 2 minutes to read • Edit Online

NOTE

Effective November 2020:

- Common Data Service has been renamed to Microsoft Dataverse. For more information, see Power Automate Blog.
- Some terminology in Microsoft Dataverse has been updated. For example, *entity* is now *table* and *field* is now *column*. For more information, see Terminology updates.

This topic will be updated soon to reflect the latest terminology.

Vendor data flow

If you choose to use the **Account** table to store vendors of the **Organization** type and the **Contact** table to store vendors of the **Person** type, configure the following workflows. Otherwise, this configuration isn't required.

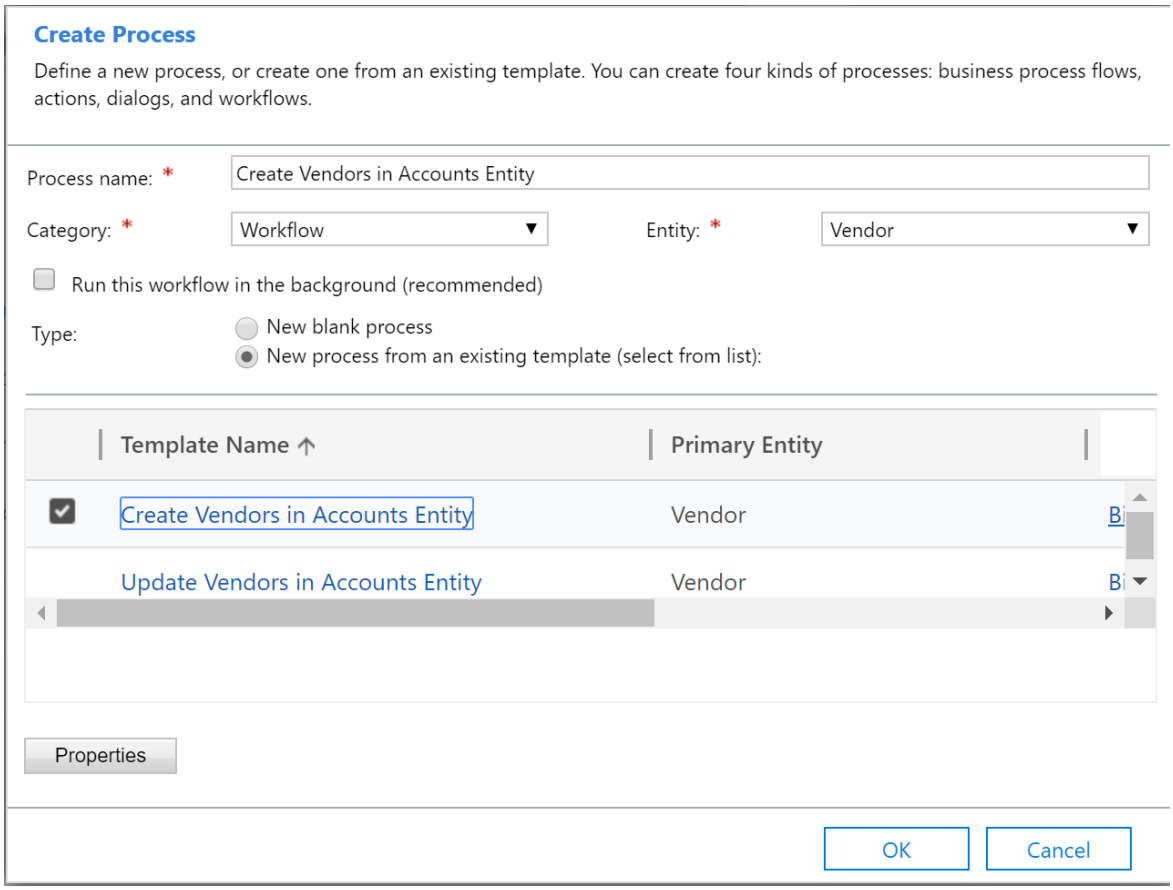
Use the extended vendor design for vendors of the Organization type

The **Dynamics365FinanceExtended** solution package contains the following workflow process templates. You will create a workflow for each template.

- Create Vendors in Accounts Table
- Create Vendors in Vendors Table
- Update Vendors in Accounts Table
- Update Vendors in Vendors Table

To create new workflow processes by using the workflow process templates, follow these steps.

1. Create a workflow process for the **Vendor** table, and select the **Create Vendors in Accounts Table** workflow process template. Then select **OK**. This workflow handles the vendor creation scenario for the **Account** table.

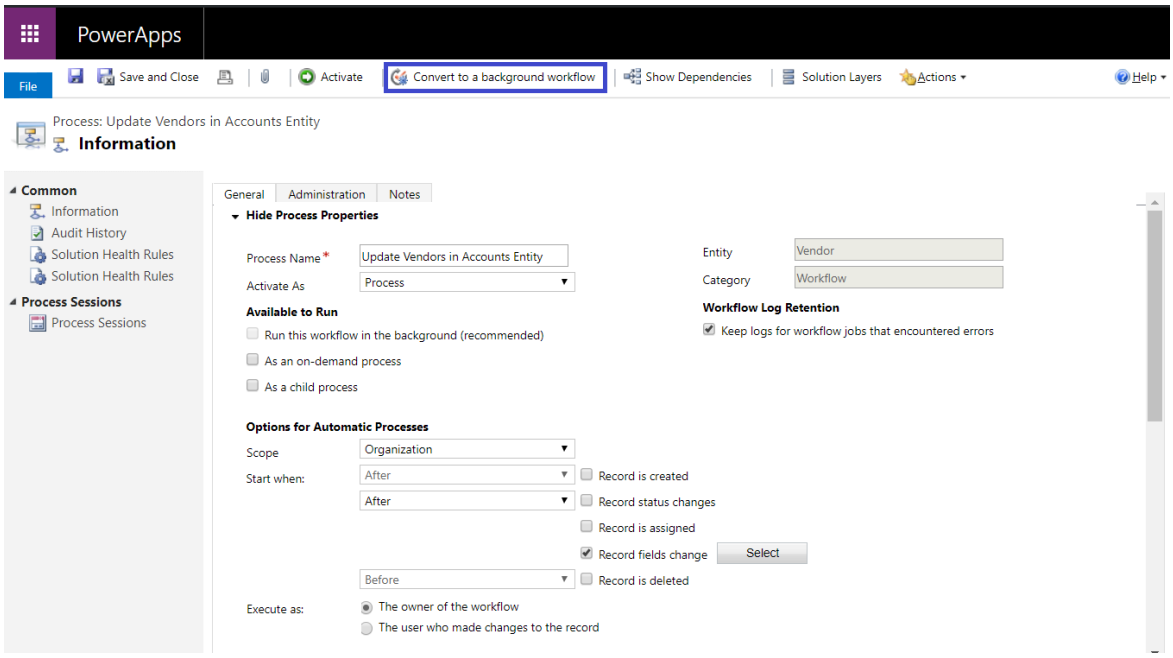


2. Create a workflow process for the **Vendor** table, and select the **Update Vendors in Accounts Table** workflow process template. Then select **OK**. This workflow handles the vendor update scenario for the **Account** table.

3. Create a workflow process for the **Account** table, and select the **Create Vendors in Vendors Table** workflow process template.

4. Create a workflow process for the **Account** table, and select the **Update Vendors in Vendors Table** workflow process template.

5. You can configure the workflows as either real-time workflows or background workflows, depending on your requirements. To configure a workflow as a background workflow, select **Convert to a background workflow**.



6. Activate the workflows that you created for the **Account** and **Vendor** tables to start to use the **Account** table to store information for vendors of the **Organization** type.

Use the extended vendor design for vendors of the Person type

The **Dynamics365FinanceExtended** solution package contains the following workflow process templates. You will create a workflow for each template.

- Create Vendors of type Person in Vendors Table
- Create Vendors of type Person in Contacts Table
- Update Vendors of type Person in Contacts Table
- Update Vendors of type Person in Vendors Table

To create new workflow processes by using the workflow process templates, follow these steps.

1. Create a workflow process for the **Vendor** table, and select the **Create Vendors of type Person in Contacts Table** workflow process template. Then select **OK**. This workflow handles the vendor creation scenario for the **Contact** table.
2. Create a workflow process for the **Vendor** table, and select the **Update Vendors of type Person in Contacts Table** workflow process template. Then select **OK**. This workflow handles the vendor update scenario for the **Contact** table.
3. Create a workflow process for the **Contact** table, and select the **Create Vendors of type Person in Vendors Table** template.
4. Create a workflow process for the **Contact** table, and select the **Update Vendors of type Person in Vendors Table** template.
5. You can configure the workflows as either real-time workflows or background workflows, depending on your requirements. To configure a workflow as a background workflow, select **Convert to a background workflow**.
6. Activate the workflows that you created on the **Contact** and **Vendor** tables to start to use the **Contact** table to store information for vendors of the **Person** type.

Customer loyalty cards and reward points

2/18/2021 • 2 minutes to read • Edit Online

NOTE

Effective November 2020:

- Common Data Service has been renamed to Microsoft Dataverse. For more information, see Power Automate Blog.
- Some terminology in Microsoft Dataverse has been updated. For example, *entity* is now *table* and *field* is now *column*. For more information, see Terminology updates.

This topic will be updated soon to reflect the latest terminology.

Businesses classify customers and provide sophisticated services, based on customer shopping and spending patterns. For example, Dynamics 365 Commerce has the infrastructure and functions to facilitate and handle customer loyalty cards, reward points, loyalty-based pricing, and rewards-based shopping experiences. When data about customer loyalty cards and reward points in Commerce is synced to Dataverse, customer engagement apps can use that data. For example, Dynamics 365 Customer Service users can use the data to provide the same sophisticated services through the help desk.

Templates

FINANCE AND OPERATIONS APPS	MODEL-DRIVEN APPS IN DYNAMICS 365	DESCRIPTION
Loyalty card	msdyn_loyaltycards	This template syncs information about customer loyalty cards.
Loyalty reward points	msdyn_loyaltyrewardpoints	This template syncs information about customer reward points.

Mapping tables

Mapping types

There are several different mapping types. The following table explains the symbols used in the template tables.

SYMBOL	DESCRIPTION
>	One-way
>>	One-way, and data is transformed in the process.
=	Bidirectional
><	Bidirectional, and data is transformed in the process.
<<	One-way, and data is transformed in the process.

Filters

The source filter and reverse source filter determine which rows are synchronized.

Default values

If a synchronized field does not exist in either the Finance and Operations table or the other Dynamics 365 table, then a default value is assigned in the synchronized table. In some cases, the default value is an integer that is a lookup to an attribute value in the Common Data Model. For example, in the Contacts table of the Common Data Model, the default value of **address1_addresstypecode** is **3**. In the Common Data Model, for address1AddressTypeCode the value of **3** is **Primary address**.

Unified product experience

2/18/2021 • 22 minutes to read • Edit Online

NOTE

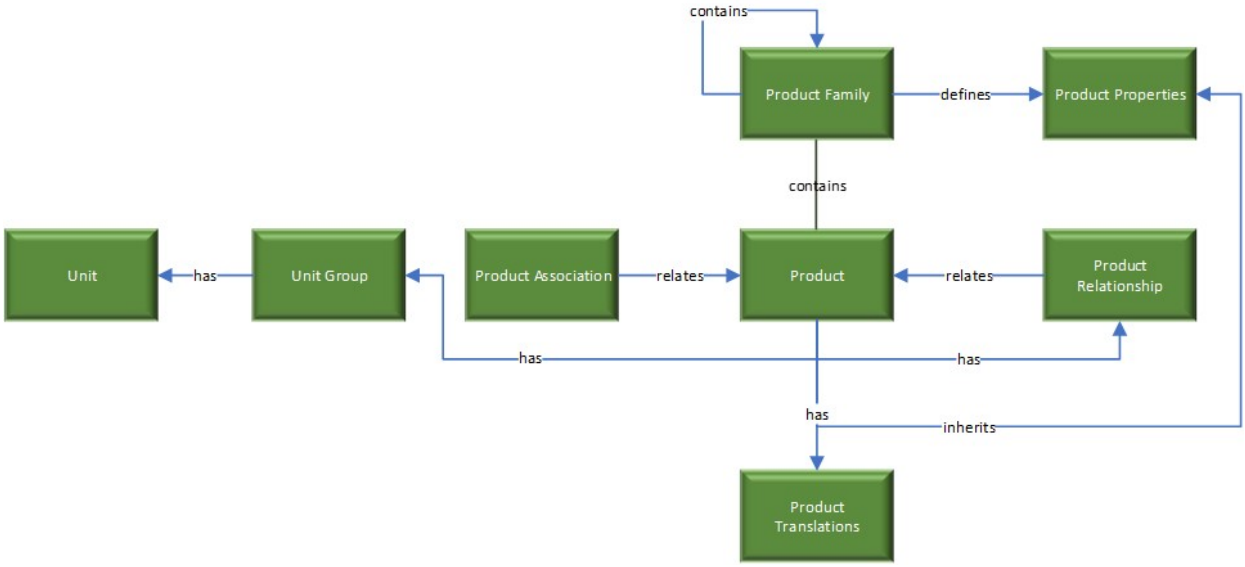
Effective November 2020:

- Common Data Service has been renamed to Microsoft Dataverse. For more information, see Power Automate Blog.
- Some terminology in Microsoft Dataverse has been updated. For example, *entity* is now *table* and *field* is now *column*. For more information, see Terminology updates.

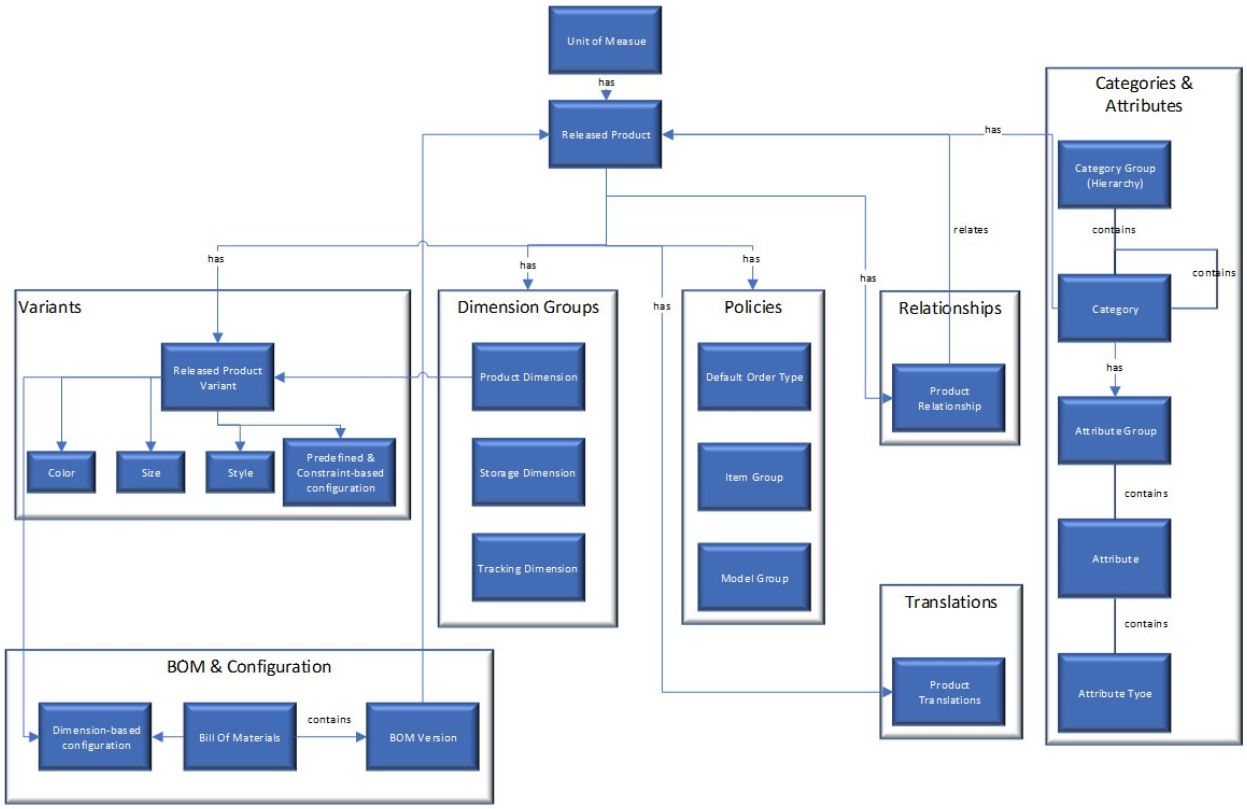
This topic will be updated soon to reflect the latest terminology.

When a business ecosystem is made up of Dynamics 365 applications, such as Finance, Supply Chain Management, and Sales, businesses often use these applications to source product data. This is because these apps provide a robust product infrastructure complemented with sophisticated pricing concepts and accurate on-hand inventory data. Businesses who use an external Product Lifecycle Management (PLM) system for sourcing the product data can channelize products from Finance and Operations apps to other Dynamics 365 apps. The unified product experience brings the integrated product data model in to Dataverse, so that all application users, including Power Platform users, can take advantage of the rich product data coming from Finance and Operations apps.

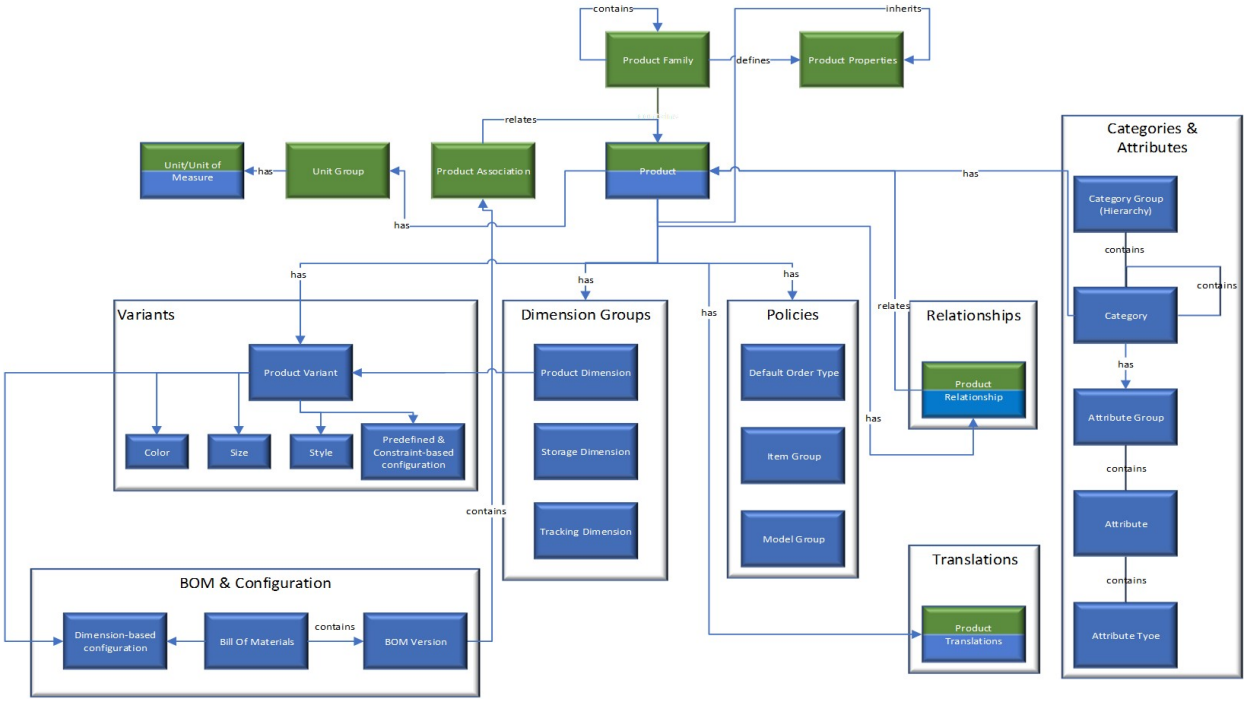
Here is the product data model from Sales.



Here is the product data model from Finance and Operations apps.



These two product data models have been integrated in Dataverse as shown below.



The dual-write table maps for products have been designed to flow data one-way only, in near-real time from Finance and Operations apps to Dataverse. However, the product infrastructure has been made open to make it bi-directional if required. Although you can customize it, it's at your own risk, as Microsoft does not recommend this approach.

Templates

Product information contains all the information related to the product and its definition, such as the product dimensions or the tracking and storage dimensions. As the following table shows, a collection of table maps is created to sync products and related information.

FINANCE AND OPERATIONS APPS	OTHER DYNAMICS 365 APPS	DESCRIPTION
Released products V2	msdyn_sharedproductdetails	The **msdyn_sharedproductdetails** table contains the columns from Finance and Operations apps that define the product, and that contain the product's financial and management information.
Dataverse released distinct products	Product	The **Product** table contains the columns that define the product. It includes individual products (products with subtype product) and the product variants. The following table shows the mappings.
Product number identified barcode	msdyn_productbarcodes	Product bar codes are used to uniquely identify products.
Default order settings	msdyn_productdefaultordersettings	
Product specific default order settings	msdyn_productdefaultordersettings	
Product dimension groups	msdyn_productdimensiongroups	The product dimension group defined which product dimensions define the product.
Storage dimension groups	msdyn_productstoragedimensiongroups	The product storage dimension group represents the method used to define the placement the product in the warehouse.
Tracking dimension groups	msdyn_producttrackingdimensiongroups	The product tracking dimension group represents the method used to track the product in inventory.
Colors	msdyn_productcolors	
Sizes	msdyn_productsizes	
Styles	msdyn_productsytles	
Configurations	msdyn_productconfigurations	
Product master colors	msdyn_sharedproductcolors	The **Shared product color** table indicates the colors that a specific product master can have. This concept is migrated to Dataverse to keep data consistent.
Product master sizes	msdyn_sharedproductsizes	The **Shared product size** table indicates the sizes that a specific product master can have. This concept is migrated to Dataverse to keep data consistent.

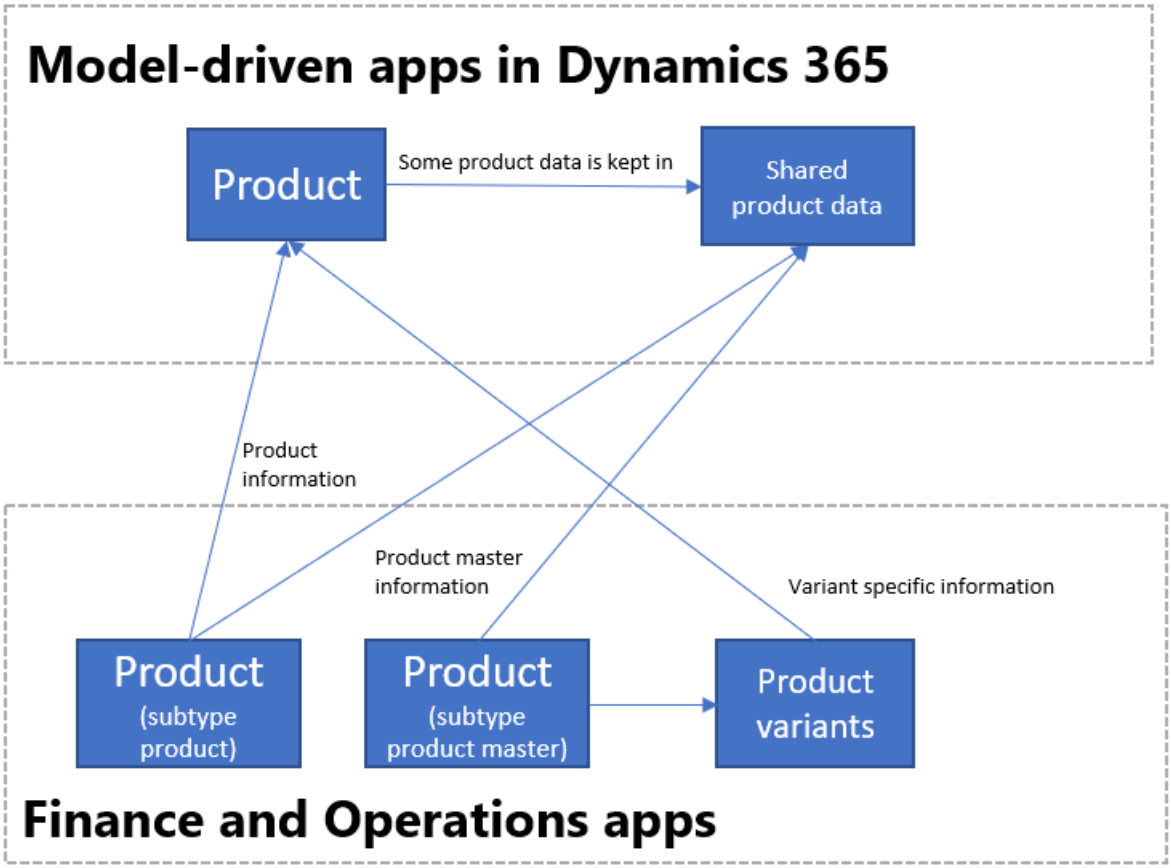
FINANCE AND OPERATIONS APPS	OTHER DYNAMICS 365 APPS	DESCRIPTION
Product master styles	msdyn_sharedproductstyles	The **Shared product style** table indicates the styles that a specific product master can have. This concept is migrated to Dataverse to keep data consistent.
Product master configurations	msdyn_sharedproductconfigurations	The **Shared product configuration** table indicates the configurations that a specific product master can have. This concept is migrated to Dataverse to keep data consistent.
All products	msdyn_globalproducts	The all products table contains all the products available in Finance and Operations apps, both the released products and the non-released products.
Unit	uoms	
Unit conversions	msdyn_ unitofmeasureconversions	
Product specific unit of measure conversion	msdyn_productspecificunitofmeasurec onversion	
Product categories	msdyn_productcategories	Each of the product categories and information about its structure and characteristics are contained in the product category table.
Product category hierarchies	msdyn_productcategoryhierarhies	You use product hierarchies to categorize or group products. The category hierarchies are available in Dataverse using the Product category hierarchy table.
Product category hierarchy roles	msdyn_productcategoryhierarchies	Product hierarchies can be used for different roles in D365 Finance and Operations. They specify which category is used in each role the product category role table is used.
Product category assignments	msdyn_productcategoryassignments	To assign a product to a category the product category assignments table can be used.

Integration of products

In this model, the product is represented by the combination of two tables in Dataverse: **Product** and **msdyn_sharedproductdetails**. Whereas the first table contains the definition of a product (the unique identifier for the product, the product name, and the description), the second table contains the columns stored at the product level. The combination of these two tables is used to define the product according to the concept of the stockkeeping unit (SKU). Each released product will have its information in the mentioned tables (Product and Shared Product Details). To keep track of all products (released and not released), the **Global products** table is used.

Because the product is represented as a SKU, the concepts of distinct products, product masters, and product variants can be captured in Dataverse in the following way:

- **Products with subtype product** are products that are defined by themselves. No dimensions have to be defined. An example is a specific book. For these products, one row is created in the **Product** table, and one row is created in the **msdyn_sharedproductdetails** table. No product family row is created.
- **Product masters** are used as generic products that hold the definition and rules that determine the behavior in business processes. Based on these definitions, distinct products that are known as product variants can be generated. For example, T-shirt is the product master, and it can have Color and Size as dimensions. Variants can be released that have different combinations of these dimensions, such a small blue T-shirt or a medium green T-shirt. In the integration, one row per variant is created in the product table. This row contains the variant-specific information, such as the different dimensions. The generic information for the product is stored in the **msdyn_sharedproductdetails** table. (This generic information is held in the product master.) The product master information is synced to Dataverse as soon as the released product master is created (but before variants are released).
- **Distinct products** refer to all the products subtype product and all the product variants.



With the dual-write functionality enabled, the products from Finance and Operations will be synchronized in other Dynamics 365 products in **Draft** state. They are added to the first price list with the same currency. In other words, they are added to the first price list in a Dynamics 365 app that matches the currency of your legal table where the product is released in a Finance and Operations app. If there is no price list for the given currency, a price list will automatically be created and the product will be assigned to it.

By default products from Finance and Operations apps are synchronized to other Dynamics 365 apps in **Draft** state. To synchronize the product with **Active** state so that you can directly use it in sales order quotations, for example, the following setting needs to be chosen: **System > Adminstration > System administration > System settings > Sales** tab and select **Create products in active state = yes**.

When products are synchronized, you must enter a value for the **Sales unit** field in the Finance and Operations app, because it is a mandatory field in Sales.

The synchronization of products happens from the Finance and Operations app to Dataverse. This means that the values of the product table columns can be changed in Dataverse, but when the synchronization is triggered (when a product column is modified in a Finance and Operations app), this will overwrite the values in Dataverse.

Mapping tables

Mapping types

There are several different mapping types. The following table explains the symbols used in the template tables.

SYMBOL	DESCRIPTION
>	One-way
>>	One-way, and data is transformed in the process.
=	Bidirectional
><	Bidirectional, and data is transformed in the process.
<<	One-way, and data is transformed in the process.

Filters

The source filter and reverse source filter determine which rows are synchronized.

Default values

If a synchronized field does not exist in either the Finance and Operations table or the other Dynamics 365 table, then a default value is assigned in the synchronized table. In some cases, the default value is an integer that is a lookup to an attribute value in the Common Data Model. For example, in the Contacts table of the Common Data Model, the default value of **address1_addresstypecode** is **3**. In the Common Data Model, for address1AddressTypeCode the value of **3** is **Primary address**.

Product dimensions

Product dimensions are characteristics that identify a product variant. The four product dimensions (Color, Size, Style, and Configuration) are also mapped to Dataverse to define the product variants. The following illustration shows the data model for the product dimension Color. The same model is applied to Sizes, Styles and Configurations.

CONFIGURATIONID	>>	msdyn_productconfiguration	

When a product has different product dimensions (for example, a product master has Size and Color as product dimensions), each distinct product (that is, each product variant) is defined as a combination of those product dimensions. For example, product number B0001 is an extra-small black T-shirt, and product number B0002 is a small black T-shirt. In this case, the existing combinations of product dimensions are defined. For example, the T-shirt from the preceding example can be extra-small and black, small and black, medium and black, or large and black, but it can't be extra-large and black. In other words, the product dimensions that a product master can take are specified, and variants can be released based on these values.

To keep track of the product dimensions that a product master can take, the following tables are created and mapped in Dataverse for each product dimension. For more information, see Product information overview.

Default order settings and product-specific default order settings

Default order settings define the site and warehouse where items will be sourced from or stored, the minimum, maximum, multiple and standard quantities that will be used for trading or inventory management, the lead times, the stop flag, and the order promising method. This information is available in Dataverse using the default order settings and product-specific default order settings entity. You can read more information about the functionality in the Default order settings topic.

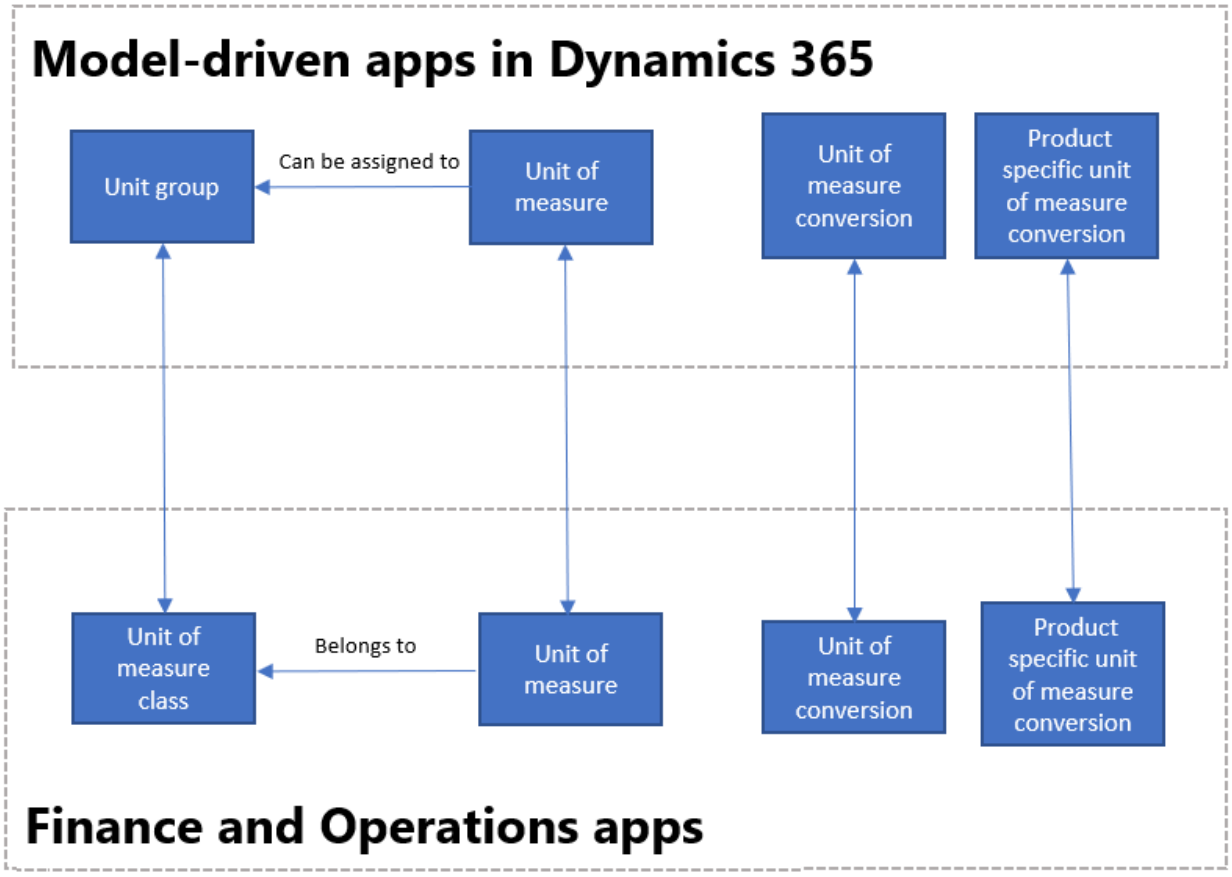
Unit of measure and unit of measure conversions

The units of measure and its respective conversion are available in the Dataverse following the data model shown in the diagram.



The unit of measure concept is integrated between Finance and Operations apps and other Dynamics 365 apps. For each unit class in a Finance and Operations app, a unit group is created in a Dynamics 365 app, which contains the units belonging to the unit class. A default base unit is also created for every unit group.

Initial synchronization of units data matching between Finance and

Operations and Dataverse

Initial synchronization of units

When dual write is enabled, units from Finance and Operations apps are synchronized to other Dynamics 365 apps. The unit groups synchronized from Finance and Operations apps in Dataverse have a flag set that indicates they are "Externally maintained".

Matching units and unit classes/groups data from Finance and Operations and other Dynamics 365 apps

First, it's important to note that the integration key for unit is msdyn_symbol. Therefore, this value must be unique in Dataverse or other Dynamics 365 apps. Because in other Dynamics 365 apps it is the pair "Unit group ID" and "Name" that define the uniqueness of a unit, you need to consider different scenarios for matching unit data between Finance and Operations apps and Dataverse.

For units matching/overlapping in Finance and Operations apps and other Dynamics 365 apps:

- **The unit belongs to a unit group in other Dynamics 365 apps that corresponds to the associated unit class in Finance and Operations apps**. In this case, the column msdyn_symbol in other Dynamics 365 apps must be filled in with the unit symbol from Finance and Operations apps. Therefore, when the data will be matched, and the unit group will be set as "Externally maintained" in other Dynamics 365 apps.
- **The unit belongs to a unit group in other Dynamics 365 apps that does not correspond to the associated unit class in Finance and Operations apps (no existing unit class in Finance and Operations apps for the unit class in other Dynamics 365 apps).** In this case, the msdyn_symbol must be filled in with a random string. Note that this value must be unique in other Dynamics 365 apps.

For units and unit classes in Finance and Operations not existing in other Dynamics 365 apps:

As part of dual-write the unit groups from Finance and Operations apps and its corresponding units are created and synchronized in other Dynamics 365 apps and Dataverse and the unit group will be set as "Externally maintained". No extra bootstrapping effort is required.

For units in other Dynamics 365 apps that do not exist in Finance and Operations apps:

The column msdyn_symbol must be filled in for all units. The units can always be created in Finance and Operations apps in the corresponding unit class (if it exists). If the unit class doesn't exist, first the unit class must be created (note that you cannot create a unit class in Finance and Operations apps except through extension if you are extending the enum) matching the other Dynamics 365 apps unit group. Then you can create the unit. Note that the unit symbol in Finance and Operations apps must be the msdyn_symbol previously specified in other Dynamics 365 apps for the unit.

Product policies: dimension, tracking and storage groups

The product policies are sets of policies used for defining products and its characteristics in inventory. The product dimension group, product tracking dimension group and storage dimension group can be found as product policies.

Integration key for products

To uniquely identify products between Dynamics 365 for Finance and Operations and products in Dataverse the integration keys are used. For products, the **(productnumber)** is the unique key that identifies a product in Dataverse. It's composed by the concatenation of: **(company, msdyn_productnumber)**. The **company** indicates the legal entity in Finance and Operations and **msdyn_productnumber** indicates the product number for the specific product in Finance and Operations.

For users of other Dynamics 365 apps, the product is identified in the UI with the **msdyn_productnumber** (note that the label of the column is **Product number**). In the product form both the company and the msydn_productnumber are shown. However, the (productnumber) column, the unique key for a product, is not shown.

If you build apps on Dataverse, you should pay attention to using the **productnumber** (the unique product ID) as the integration key. Do not use **msdyn_productnumber**, because it's not unique.

Initial synchronization of products and migration of data from Dataverse to Finance and Operations

Initial synchronization of products

When dual-write is enabled, products from Finance and Operations apps are synchronized to Dataverse and customer engagement apps. Products created in Dataverse and other Dynamics 365 apps before dual-write was released will not be updated or matched with product data from Finance and Operations apps.

Matching product data from Finance and Operations and other Dynamics 365 apps

If the same products are kept (overlapping/matching) in Finance and Operations and in Dataverse and other Dynamics 365 apps, when enabling dual-write the synchronization of products from Finance and Operations will take place, and duplicate rows will appear in Dataverse for the same product. To avoid the previous situation, if other Dynamics 365 apps have products that are overlapping/matching with Finance and Operations, then the administrator enabling dual write must bootstrap the columns **Company** (example: "USMF") and **msdyn_productnumber** (example: "1234:Black:S") before the synchronization of products takes place. In other words, these two columns in the product in Dataverse must be filled in with the respective company in Finance and Operations to which the product needs to be matched with and with its product number.

Then, when the synchronization is enabled and takes place, the products from Finance and Operations will be synchronized with the matched products in Dataverse and other Dynamics 365 apps. This is applicable for both distinct products and product variants.

Migration of product data from other Dynamics 365 apps to Finance and Operations

If other Dynamics 365 apps have products that aren't present in Finance and Operations, the administrator can first use the **EcoResReleasedProductCreationV2Entity** for importing those products in Finance and

Operations. And secondly, match the product data from Finance and Operations and other Dynamics 365 apps as described above.

Integrated sites and warehouses

2/18/2021 • 3 minutes to read • Edit Online

NOTE

Effective November 2020:

- Common Data Service has been renamed to Microsoft Dataverse. For more information, see Power Automate Blog.
- Some terminology in Microsoft Dataverse has been updated. For example, *entity* is now *table* and *field* is now *column*. For more information, see Terminology updates.

This topic will be updated soon to reflect the latest terminology.

This topic describes the integration of site and warehouse data between Finance and Operations and Dataverse. Operational sites and warehouses are common concepts in a Supply Chain Management application. They are used to model the supply chain of your company.

Templates

With the integration with Dataverse, these concepts and all their related information are available in Dataverse using the sites and warehouses data tables in the following table.

FINANCE AND OPERATIONS APPS	OTHER DYNAMICS 365 APPS	DESCRIPTION
Sites	msdyn_operationalsites	
Warehouses	msdyn_warehouses	

Mapping tables

Mapping types

There are several different mapping types. The following table explains the symbols used in the template tables.

SYMBOL	DESCRIPTION
>	One-way
>>	One-way, and data is transformed in the process.
=	Bidirectional
><	Bidirectional, and data is transformed in the process.
<<	One-way, and data is transformed in the process.

Filters

The source filter and reverse source filter determine which rows are synchronized.

Default values

If a synchronized field does not exist in either the Finance and Operations table or the other Dynamics 365 table, then a default value is assigned in the synchronized table. In some cases, the default value is an integer that is a lookup to an attribute value in the Common Data Model. For example, in the Contacts table of the Common Data Model, the default value of **address1_addresstypecode** is **3**. In the Common Data Model, for address1AddressTypeCode the value of **3** is **Primary address**.

Company concept in Dataverse

2/18/2021 • 5 minutes to read • Edit Online

NOTE

Effective November 2020:

- Common Data Service has been renamed to Microsoft Dataverse. For more information, see Power Automate Blog.
- Some terminology in Microsoft Dataverse has been updated. For example, *entity* is now *table* and *field* is now *column*. For more information, see Terminology updates.

This topic will be updated soon to reflect the latest terminology.

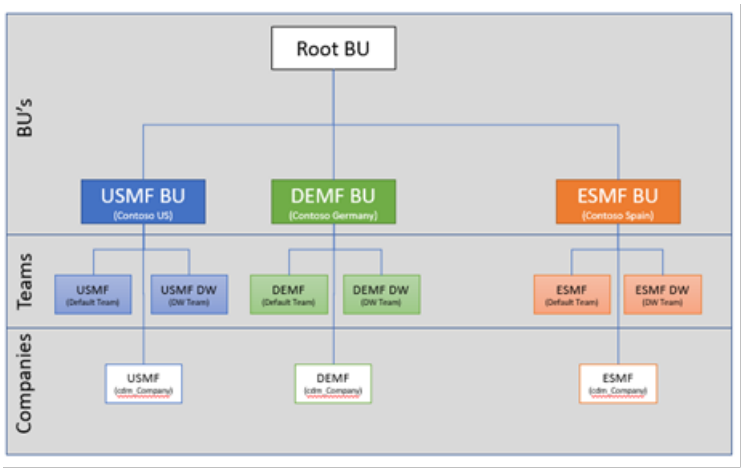
In Finance and Operations, the concept of a *company* is both a legal construct and a business construct. It's also a security and visibility boundary for data. Users always work in the context of a single company, and most of the data is striped by company.

Dataverse doesn't have an equivalent concept. The closest concept is *business unit*, which is primarily a security and visibility boundary for user data. This concept doesn't have the same legal or business implications as the company concept.

Because business unit and company aren't equivalent concepts, it isn't possible to force a one-to-one (1:1) mapping between them for the purpose of Dataverse integration. However, because users must, by default, be able to see the same rows in the application and Dataverse, Microsoft has introduced a new table in Dataverse that is named cdm_Company. This table is equivalent to the Company table in the application. To help guarantee that visibility of rows is equivalent between the application and Dataverse out of the box, we recommend the following setup for data in Dataverse:

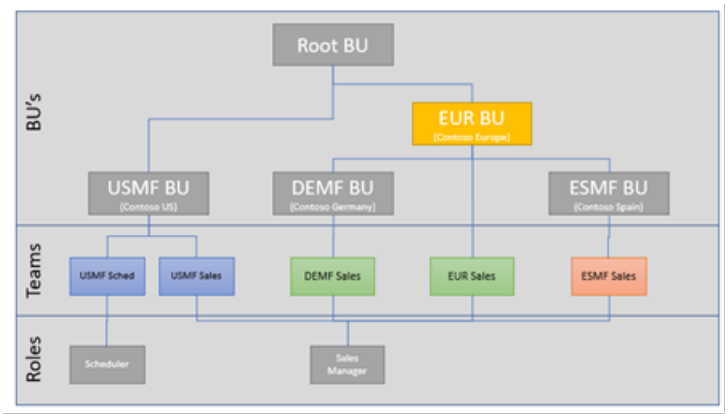
- For each Finance and Operations Company row that is enabled for dual-write, an associated cdm_Company row is created.
- When a cdm_Company row is created and enabled for dual-write, a default business unit is created that has the same name. Although a default team is automatically created for that business unit, the business unit isn't used.
- A separate owner team is created that has the same name. It's also associated with the business unit.
- By default, the owner of any row that is created and dual-written to Dataverse is set to the "DW Owner" team that is linked to the associated business unit.

The following illustration shows an example of this data setup in Dataverse.



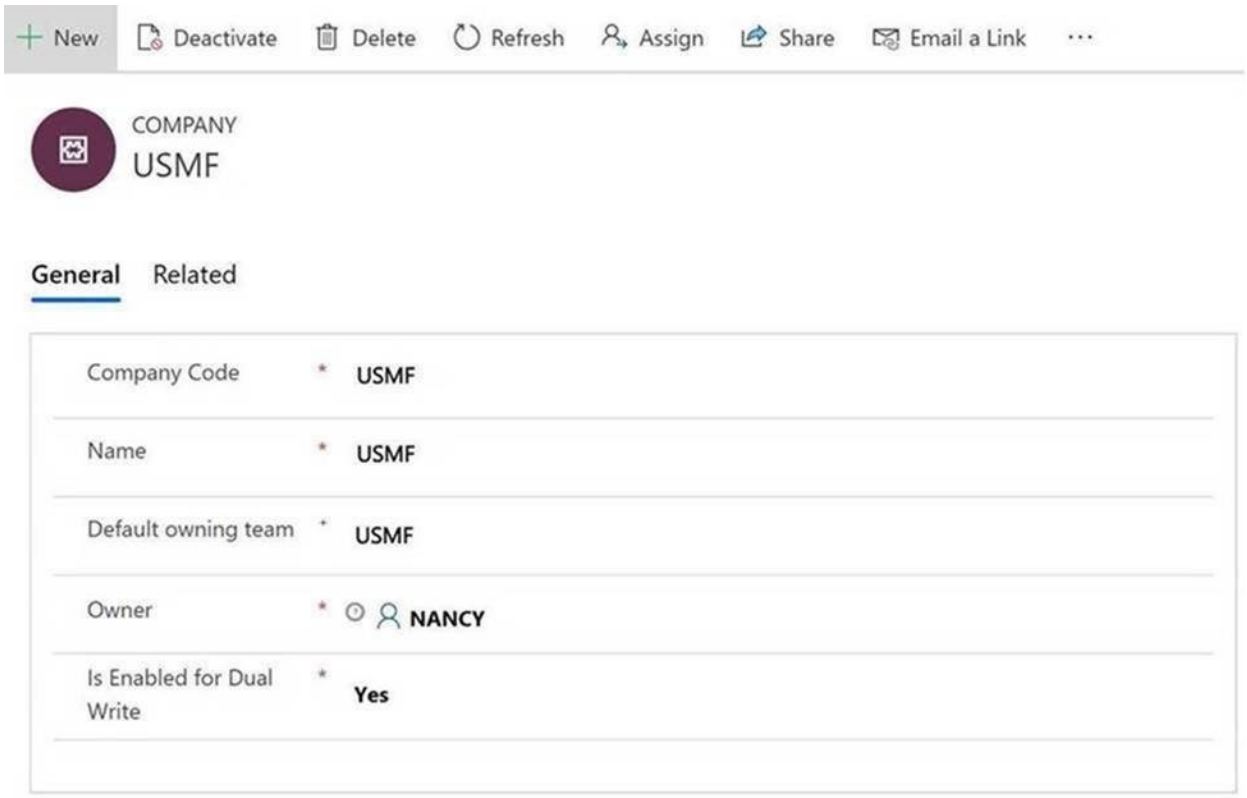
Because of this configuration, any row that is related to the USMF company will be owned by a team that is linked to the USMF business unit in Dataverse. Therefore, any user who has access to that business unit through a security role that is set to business unit–level visibility can now see those rows. The following example shows how teams can be used to provide the correct access to those rows.

- The "Sales Manager" role is assigned to members of the "USMF Sales" team.
- Users who have the "Sales Manager" role can access any account rows that are members of the same business unit that they are members of.
- The "USMF Sales" team is linked to the USMF business unit that was mentioned earlier.
- Therefore, members of the "USMF Sales" team can see any account that is owned by the "USMF DW" user, which would have come from the USMF Company table in Finance and Operations.



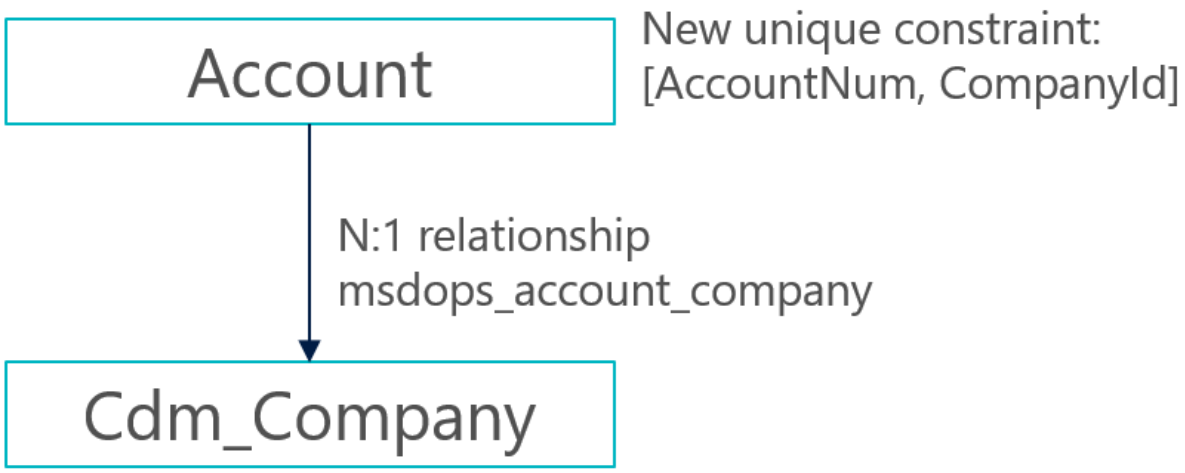
As the preceding illustration shows, this 1:1 mapping between business unit, company, and team is just a starting point. In this example, a new "Europe" business unit is manually created in Dataverse as the parent for both DEMF and ESMF. This new root business unit is unrelated to dual-write. However, it can be used to give members of the "EUR Sales" team access to account data in both DEMF and ESMF by setting the data visibility to **Parent/Child BU** in the associated security role.

A final topic to discuss is how dual-write determines which owner team it should assign rows to. This behavior is controlled by the **Default owning team** column on the cdm_Company row. When a cdm_Company row is enabled for dual-write, a plug-in automatically creates the associated business unit and owner team (if it doesn't already exist), and sets the **Default owning team** column. The admin can change this column to a different value. However, the admin can't clear the column as long as the table is enabled for dual-write.



Company striping and bootstrapping

Dataverse integration brings company parity by using a company identifier to stripe data. As the following illustration shows, all company-specific tables are extended so that they have a many-to-one (N:1) relationship with the cdm_Company table.

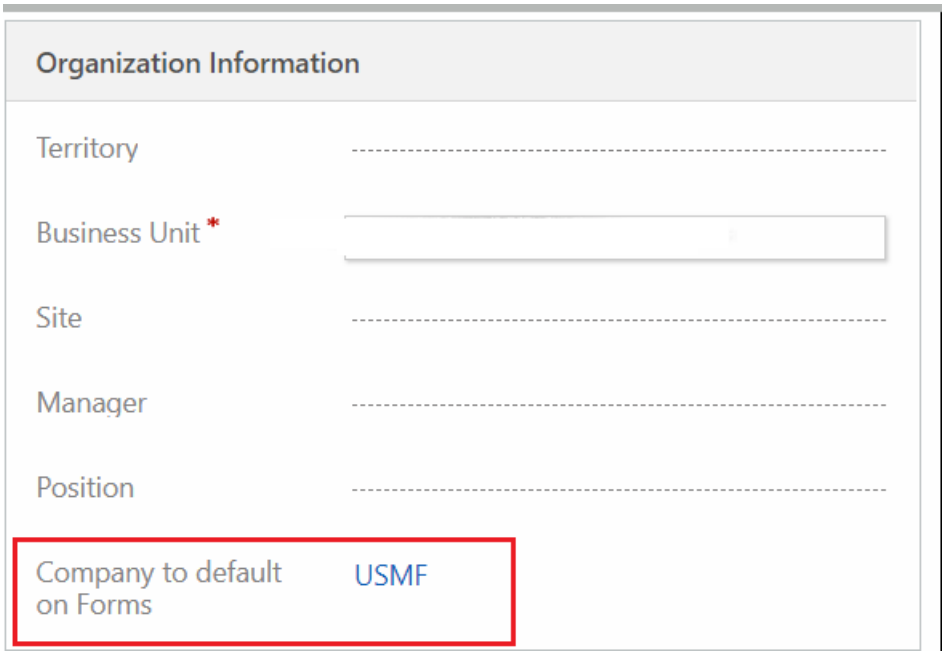


- For rows, after a company is added and saved, the value becomes read-only. Therefore, users should make sure that they select the correct company.
- Only rows that have company data are eligible for dual-write between the application and Dataverse.
- For existing Dataverse data, an admin-led bootstrapping experience will soon be available.

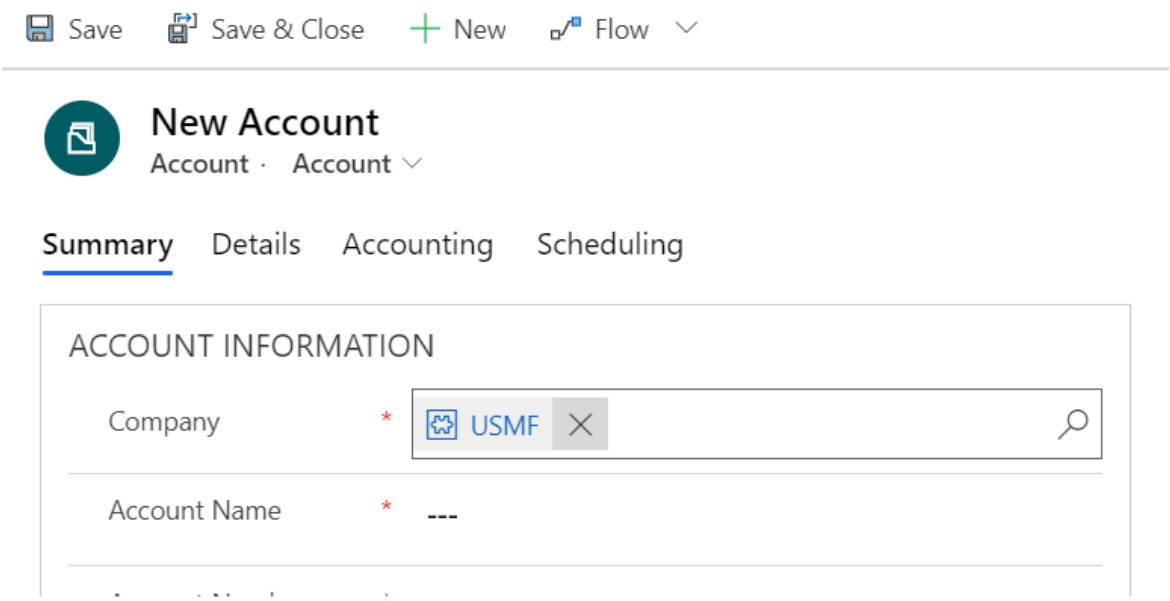
Autopopulate company name in customer engagement apps

There are several ways to auto-populate the company name in customer engagement apps.

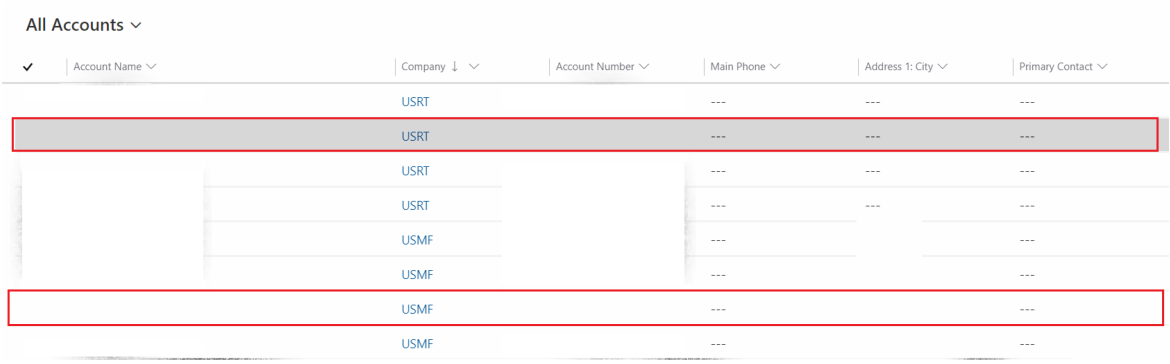
- If you are a system administrator, you can set the default company by navigating to **Advanced Settings** > **System** > **Security** > **Users**. Open the **User** form, and in the **Organization Information** section, set the **Company to default on Forms** value.



- If you have **Write** access to the **SystemUser** table for the **Business Unit** level, then you can change the default company on any form by selecting a company from the **Company** drop-down menu.



- If you have **Write** access to data in more than one company, then you can change the default company by choosing a row that belongs to different company.

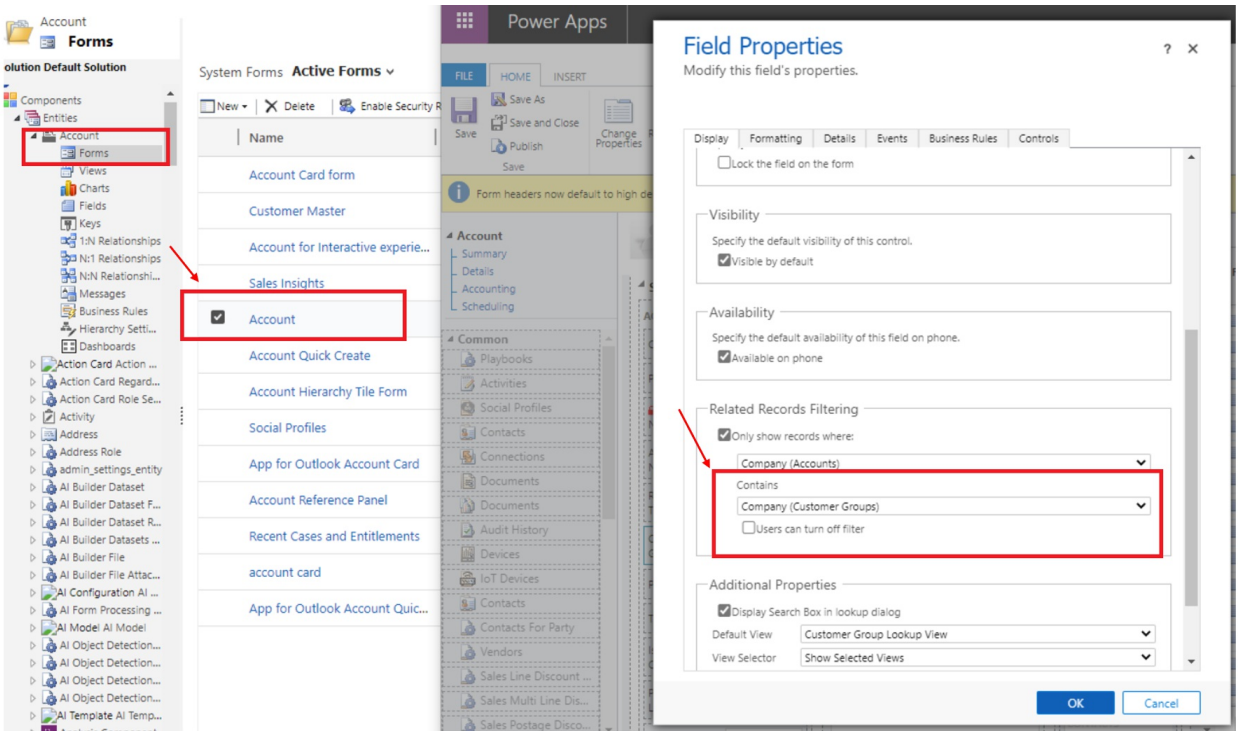


- If you are a system configurator or administrator, and you want to auto-populate company data on a custom form, then you can use form events. Add a JavaScript reference to **msdyn_/DefaultCompany.js** and use the following events. You can use any out-of-the-box form, for example, the **Account** form.
    - **OnLoad** event for the form: Set the **defaultCompany** column.

- **OnChange** event for the **Company** column: Set the **updateDefaultCompany** column.

Apply filtering based on the company context

To apply filtering based on the company context on your custom forms or on custom lookup columns added to the standard forms, open the form and use the **Related Records Filtering** section to apply the company filter. You must set this for each lookup column that requires filtering based on the underlying company on a given row. The setting is shown for **Account** in the following illustration.



NOTE

Can you tell us about your documentation language preferences? Take a short survey.

The survey will take about seven minutes. No personal data is collected (privacy statement).

Initialize company data

2/18/2021 • 4 minutes to read • Edit Online

IMPORTANT

Some or all of the functionality noted in this topic is available as part of a preview release. The content and the functionality are subject to change. For more information about preview releases, see Service update availability.

NOTE

Effective November 2020:

- Common Data Service has been renamed to Microsoft Dataverse. For more information, see Power Automate Blog.
- Some terminology in Microsoft Dataverse has been updated. For example, *entity* is now *table* and *field* is now *column*. For more information, see Terminology updates.

This topic will be updated soon to reflect the latest terminology.

If have an existing Microsoft Dataverse instance or Finance and Operations app instance that has business data, you might want to enable a dual-write connection against it. In this case, you must initialize the Dataverse data or Finance and Operations app data with company information before you enable dual-write. This initialization process is sometimes referred to as *bootstrapping*.

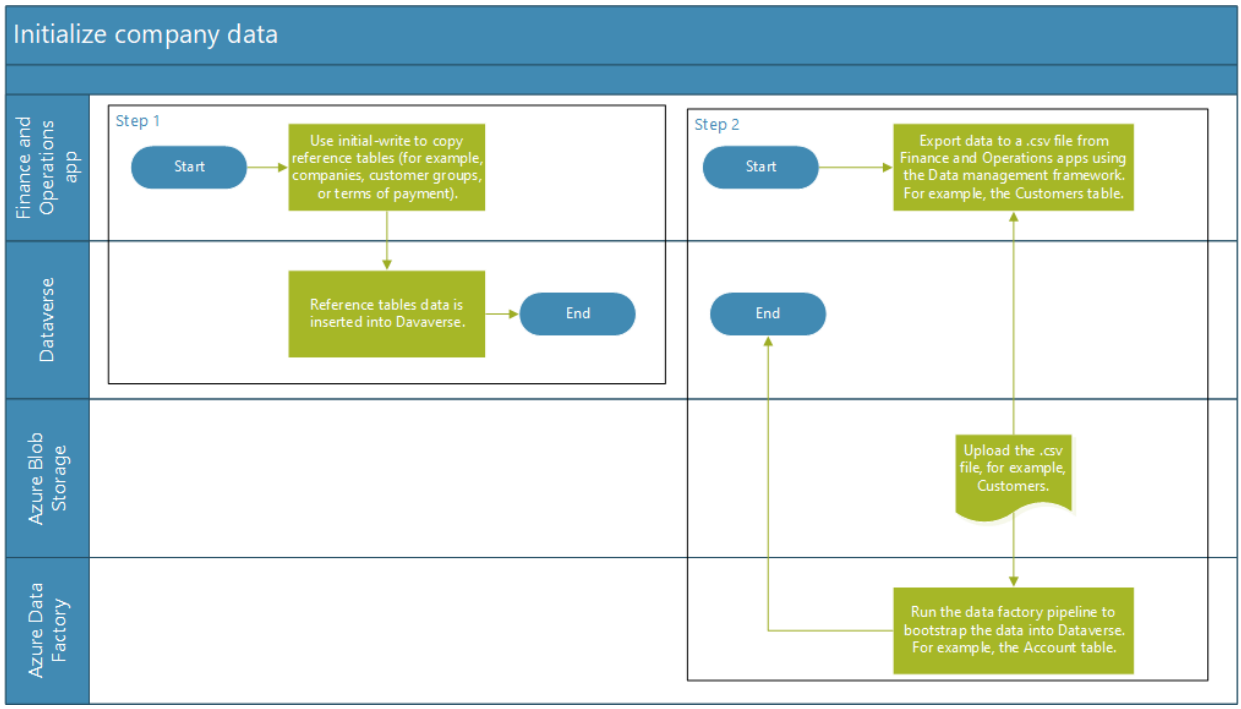
This topic includes sample scenarios that explain how to use Azure Data Factory to initialize data in Dataverse tables for dual-write. It doesn't cover all tables, error handling scenarios, or lookups. Use this topic and template as a reference to set up your own Azure Data Factory pipeline to import data into Dataverse or update data in Dataverse.

High-level scenario

Consider the **Customers** table in a Finance and Operations app, and the **Account** table in Dataverse.

- Use initial write to copy reference and dependent tables, such as **Company**, **Customer groups**, and **Terms of payment**, from the Finance and Operations app to Dataverse.
- Use the Data management framework to export data from the Finance and Operations app in comma-separated values (CSV) format. For example, set up an export project in Data management to export customers from each company by using the **DataAreaId** field in the Finance and Operations app. This process is a one-time manual process.
- Use Azure Blob Storage to store the CSV files for lookup and transformation. Upload the CSV file for your Finance and Operations customers into Azure Blob Storage.
- Use Azure Data Factory to initialize data in Dataverse.

The following illustration shows the workflow.



This scenario is based on the following assumptions:

- The source data is in the Finance and Operations app.
- If an account exists in Dataverse, but it doesn't exist in the Finance and Operations app, it won't be initialized as part of this flow.
- All account records in the customer engagement apps have a natural key (account number) that matches the Finance and Operations natural key (**CustomerAccount**).
- Rows have a one-to-one (1:1) mapping across the apps.

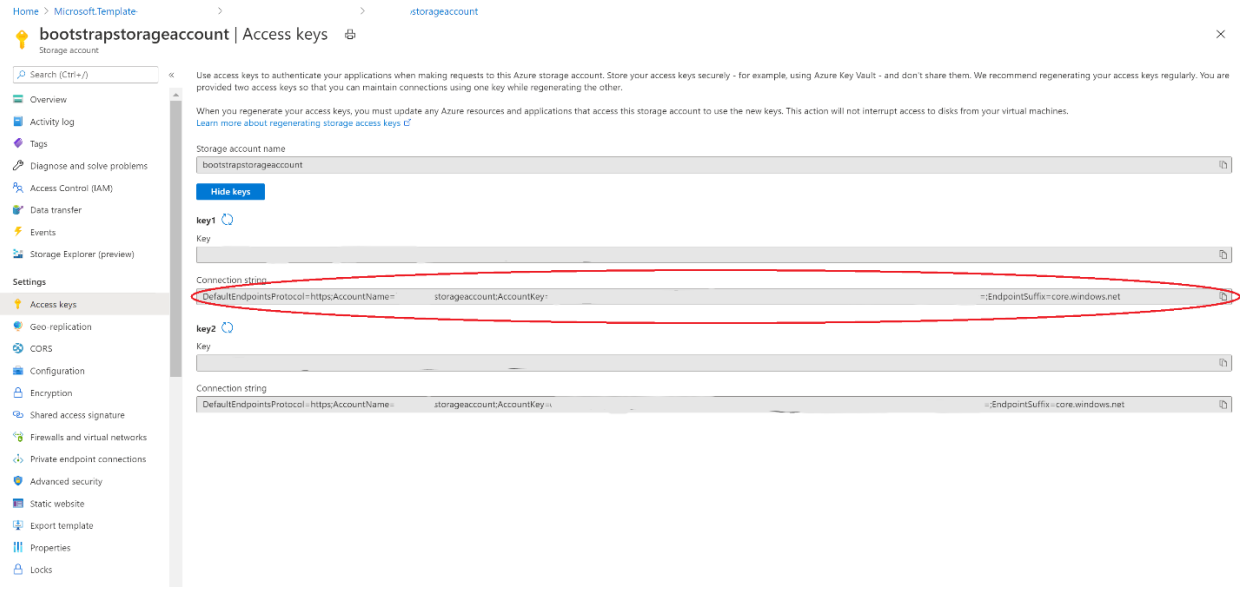
Prerequisites

- **Azure subscription** – You have **contributor access** to an existing Azure subscription. If you don't have an Azure subscription, create a free Azure account before you begin.
- **Azure storage account** – You have an Azure storage account. If you don't have a storage account, follow the steps in Create an Azure storage account to create one.
- **Azure data factory** – Create an Azure Data Factory resource by following the steps in Create a data factory.
- **Finance and Operations app** – Use the Data management framework to export the data in CSV format. For more information, see Data management overview. In this template, customers are exported by using the **CustCustomerV3Entity** table.
- **Dynamics 365 Dataverse** – Use the credentials for the Dataverse admin user to initialize the data.
- **Dual-write** – Dual-write solutions are installed, and reference data is copied by using initial write.

Deployment steps

Set up an Azure storage account

If you don't have an Azure storage account, follow these steps in Create an Azure storage account to create one. In your storage account, create one container that is named **ce-data**. This container will store all data files. You can change the container in your datasets and pipelines as you require. Go to **Access keys**, and copy the **Connection string** value, as shown in the following illustration. This value is required when you import the Azure Data Factory template.



Deploy an Azure Data Factory template

1. Make a note of the name of the Azure data factory that you created.
2. Make a note of the connection string for the Azure storage account.
3. Make a note of the service URI of the Dataverse instance, and the admin user name and password.

   The following table shows the parameters that are required.

PARAMETER NAME	DESCRIPTION	EXAMPLE VALUE
Factory name	The name of your data factory	*BootstrapDataverseDataADF*
Bootstrap blob storage account Linked Service_connection String	The connection string for blob storage	The value that you copied when you created the storage account
Bootstrap Dynamics 365 Linked Service_service Uri	The URI of the Dataverse instance	`https://contosod365.crm4.dynamics.com`
Bootstrap Dynamics 365 Linked Service_properties_type Properties_username	The Dynamics 365 admin user's user ID	`<adminservice@contoso.onmicrosoft.com>`
Bootstrap Dynamics 365 Linked Service_password	The Dynamics 365 admin user's password	********

4. Download the Azure Resource Manager (ARM) template file to your local directory.
5. In the Azure portal, go to Custom deployment.
6. Select **Build your own template in the editor**.
7. Select **Load file**, and find and select the ARM template file that you downloaded earlier. Then select **Save**.
8. Provide the required parameters, select **Review**, and then select **Create**.

Home >

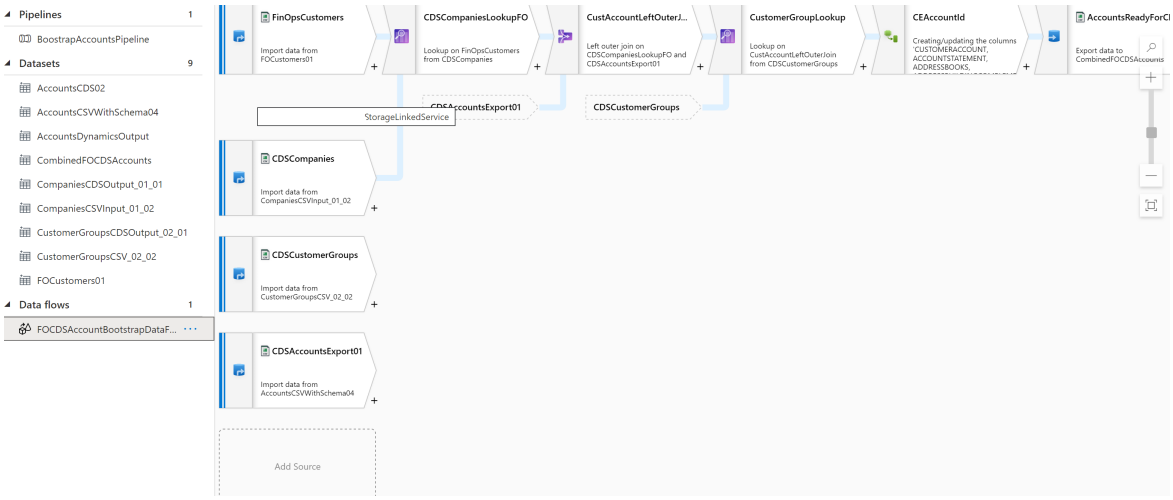
Bootstrap Dynamics 365 Linked Service_properties_type Properties_username

Bootstrap Dynamics 365 Linked Service_password *

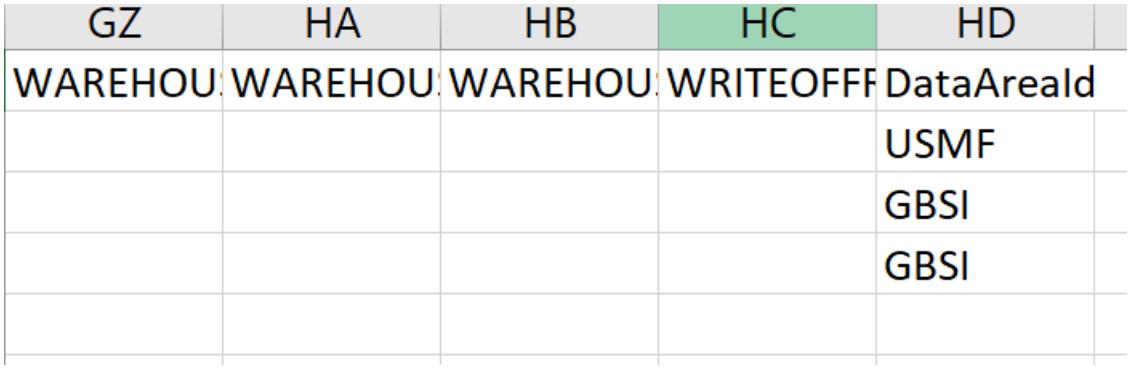
Review + create | < Previous | Next : Review + create >

9. After deployment, you will see **Pipelines**, **Datasets**, and **Data flows** sections in the list pane.



Run the process

1. In the Finance and Operations app, use the Data management framework to export data in CSV format. For more information, see Data management overview. In this template, customer data was exported from the **CustCustomerV3Entity** table. Set up **CustCustomerV3Entity**, and remove the **FullPrimaryAddress** field map from the mapping. Add the **DataAreaId** field to the CSV file. Rename the exported file **01-CustomersV3Export-Customers V3.csv**, and upload it to the Azure storage account that you named **ce-data**.



GZ	HA	HB	HC	HD
WAREHOU	WAREHOU	WAREHOU	WRITEOFFF	DataAreaId
				USMF
				GBSI
				GBSI

2. Download the sample customer file.

3. Run **BootstrapAccountsPipeline** from Azure Data Factory.

Organization hierarchy in Dataverse

2/18/2021 • 3 minutes to read • Edit Online

NOTE

Effective November 2020:

- Common Data Service has been renamed to Microsoft Dataverse. For more information, see Power Automate Blog.
- Some terminology in Microsoft Dataverse has been updated. For example, *entity* is now *table* and *field* is now *column*. For more information, see Terminology updates.

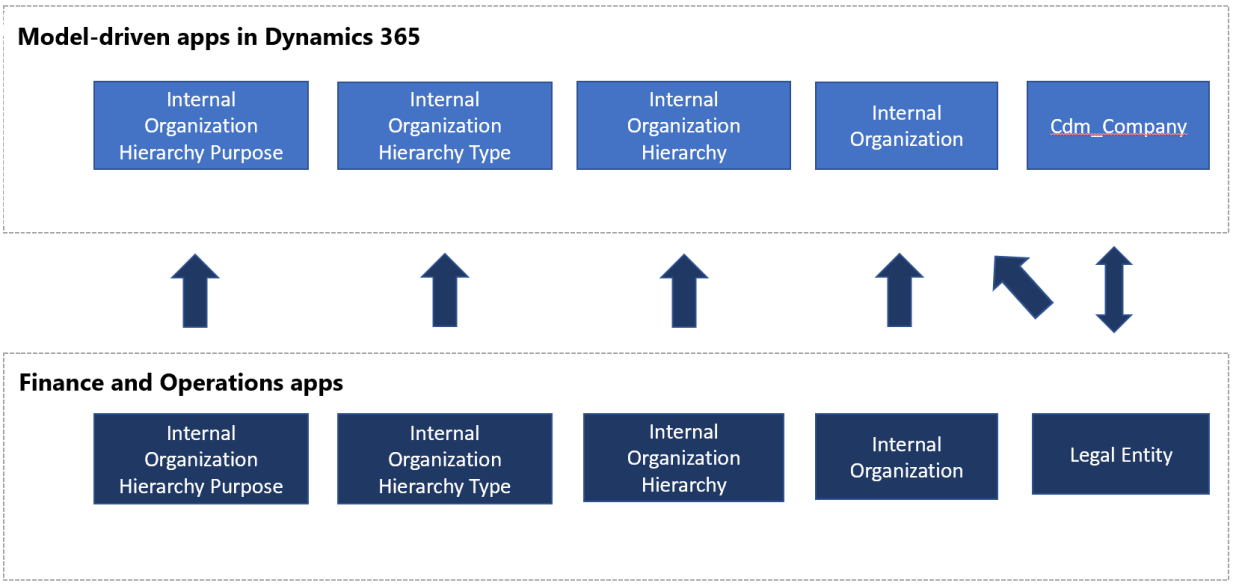
This topic will be updated soon to reflect the latest terminology.

Because Dynamics 365 Finance is a financial system, *organization* is a core concept, and system setup starts with the configuration of an organization hierarchy. Business financials can then be tracked at the organization level and also at any level in the organization hierarchy.

Although Dataverse doesn't have the concept of an organization hierarchy, it does have a few loose concepts, such as total sales revenue. As part of Dataverse integration, the organization hierarchy data structure is added to Dataverse.

Data flow

A business ecosystem that consists of Finance and Operations apps and Dataverse will continue to have an organization hierarchy. This organization hierarchy is built on Finance and Operations apps, but it's exposed in Dataverse for informational and extensibility purposes. The following illustration shows the organization hierarchy information that is exposed in Dataverse as a one-way data flow from Finance and Operations apps to Dataverse.



Organization hierarchy table maps are available for one-way synchronization of data from Finance and Operations apps to Dataverse.

Templates

Product information contains all the information related to the product and its definition, such as the product

dimensions or the tracking and storage dimensions. As the following table shows, a collection of table maps is created to sync products and related information.

FINANCE AND OPERATIONS APPS	OTHER DYNAMICS 365 APPS	DESCRIPTION
Organization hierarchy purposes	msdyn_internalorganizationhierarchypurposes	This template provides one-way synchronization of the Organization Hierarchy Purpose table.
Organization hierarchy type	msdyn_internalorganizationhierarchytypes	This template provides one-way synchronization of the Organization Hierarchy Type table.
Organization hierarchy - published	msdyn_internalorganizationhierarchies	This template provides one-way synchronization of the Organization Hierarchy Published table.
Operating unit	msdyn_internalorganizations	
Legal entities	msdyn_internalorganizations	
Legal entities	cdm_companies	Provides bidirectional synchronization of legal entity (company) information.

Mapping tables

Mapping types

There are several different mapping types. The following table explains the symbols used in the template tables.

SYMBOL	DESCRIPTION
>	One-way
>>	One-way, and data is transformed in the process.
=	Bidirectional
><	Bidirectional, and data is transformed in the process.
<<	One-way, and data is transformed in the process.

Filters

The source filter and reverse source filter determine which rows are synchronized.

Default values

If a synchronized field does not exist in either the Finance and Operations table or the other Dynamics 365 table, then a default value is assigned in the synchronized table. In some cases, the default value is an integer that is a lookup to an attribute value in the Common Data Model. For example, in the Contacts table of the Common Data Model, the default value of **address1_addresstypecode** is **3**. In the Common Data Model, for address1AddressTypeCode the value of **3** is **Primary address**.

Organization hierarchy purposes to msdyn_internalorganizationhierarchypurposes

Access to finance and tax reference data

2/18/2021 • 2 minutes to read • Edit Online

NOTE

Effective November 2020:

- Common Data Service has been renamed to Microsoft Dataverse. For more information, see Power Automate Blog.
- Some terminology in Microsoft Dataverse has been updated. For example, *entity* is now *table* and *field* is now *column*. For more information, see Terminology updates.

This topic will be updated soon to reflect the latest terminology.

Every business works with a basic set of financial data, such as the fiscal calendar year, the currency that business is transacted in, the accounts that the money to run the business comes in to or goes out of, tax rates, and remittance. This data resides in Finance and Operations apps. However, it's exposed to Dataverse so that model-driven apps in Microsoft Dynamics 365 can have a single source for finance and tax data. In this way, data is uniform across the business ecosystem.

Finance and tax data is integrated by using the following mappings:

- Integrated ledger
- Integrated tax master

NOTE

Integrated ledger

2/18/2021 • 4 minutes to read • Edit Online

NOTE

Effective November 2020:

- Common Data Service has been renamed to Microsoft Dataverse. For more information, see Power Automate Blog.
- Some terminology in Microsoft Dataverse has been updated. For example, *entity* is now *table* and *field* is now *column*. For more information, see Terminology updates.

This topic will be updated soon to reflect the latest terminology.

In a business application, ledger data defines the core set up for how a company does business. For example, ledger data describes the fiscal year the company follows, the currencies it transacts in, and the accounts it uses. This topic describes the integration of this core financial data.

Templates

Ledger data includes a collection of core financial table maps that work together during data interaction, as shown in the following table.

FINANCE AND OPERATIONS APPS	MODEL-DRIVEN APP IN DYNAMICS 365	DESCRIPTION
Currencies	transactioncurrencies	
FiscalCalendar	msdyn_fiscalcalendars

Integrate procurement between Supply Chain Management and Field Service

2/18/2021 • 15 minutes to read • Edit Online

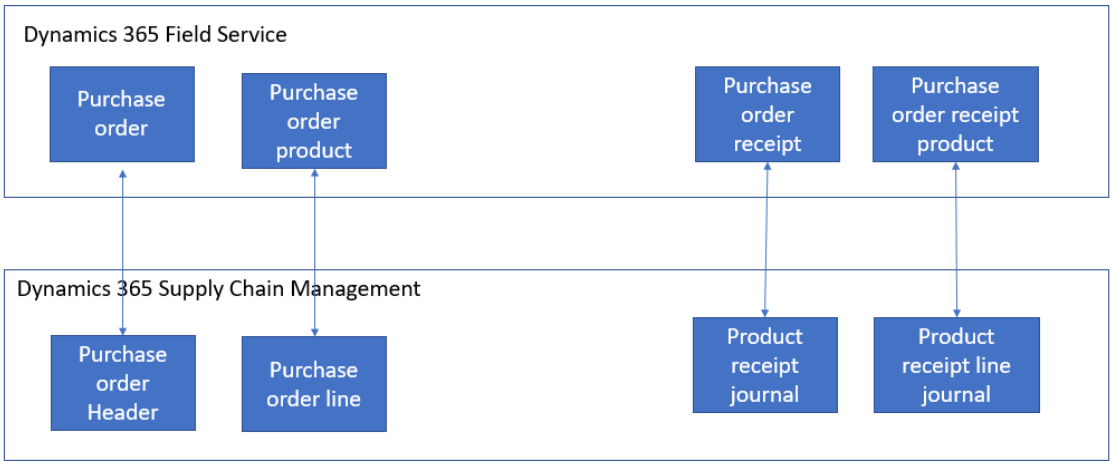
IMPORTANT

Some or all of the functionality noted in this topic is available as part of a preview release. The content and the functionality are subject to change. For more information about preview releases, see Service update availability.

Microsoft Dynamics 365 Supply Chain Management provides robust procurement functionality. Dynamics 365 Field Service offers similar functionality that supports the purchasing processes that are associated with the service process. The functionality in these two apps is integrated through dual-write, and the resulting cross-functional use cases are enabled through table mappings, solution logic, views, and forms.

This integration supports purchase order creation and, in most cases, updates from both apps. However, Supply Chain Management controls pricing, addresses, and product receipt. Several powerful cross-functional use cases are enabled for organizations that use both Field Service and Supply Chain Management. These use cases enable procurements to be initiated and tracked across both systems.

The following illustration shows the tables in both systems and how they are mapped to each other. Purchase orders in Field Service reference an *account* row, whereas purchase orders in Supply Chain Management reference a *vendor* row. To resolve the integration, dual-write uses a reference to link *vendor* rows with *account* rows. For more information, see Integrated vendor master.



Prerequisites

To integrate Supply Chain Management with Field Service, you must install the following components:

- Field Service version 8.8.31.60 or later, for comprehensive purchase order integration
- Supply Chain Management version 10.0.14 or later
- Dual-write, to run the OneFSSCM solution

Installation guidelines

Prerequisites

- **Dual-write** – For more information, see the Dual-write home page.
- **Dynamics 365 Field Service** – For more information, see How to install Dynamics 365 Field Service.

When they are enabled in Microsoft Dataverse, dual-write and Field Service introduce several solution layers that extend the environment with new metadata, forms, views, and logic. These solutions can be enabled in any

order, though you typically install in the order that is given here:

1. **Field Service Common** – Field Service Common is installed when Field Service is installed in the environment.
2. **Field Service (Anchor)** – Field Service (Anchor) is installed when Field Service is installed in the environment.
3. **Supply Chain Management Extended** – Supply Chain Management Extended is automatically installed when dual-write is enabled in an environment.
4. **OneFSSCM solution** – OneFSSCM is automatically installed by whichever solution (Field Service or Supply Chain Management) is installed last.
    - If Field Service is already installed in the environment, and you enable dual-write, which installs Supply Chain Management Extended, OneFSSCM is installed.
    - If Supply Chain Management Extended is already installed in the environment, and you install Field Service, OneFSSCM is installed.

Initial synchronization

To create new purchase orders and work with existing purchase orders, you must sync the reference data between Supply Chain Management and Dataverse. You use the initial write functionality to detect the table relationships and find the tables that you must enable for a given map.

You must sync the following tables:

- Product templates

  When you run the initial write, you get a full list of the tables that are required. Here are some examples of these templates:

  - All products
  - Released products V2
  - Dataverse released distinct products
- Sites
- Warehouses
- Procurement categories templates

  Here are some examples of these templates:

  - Procurement categories
  - Pro
  - Product category hierarchy
  - Product category assignments
- Vendor templates, such as Vendor V2
- Contact person templates, such as Dataverse Contacts V2
- Worker templates, such as Worker

Synchronization of the tables ensures that all documents (purchase orders and product receipts) in Supply Chain Management are available in Dataverse.

Account and Vendor tables

Purchase orders in Field Service rely on the Account table to track vendors. Therefore, the Dataverse tables for purchase orders use accounts to track vendors. To accommodate this key difference, the following four workflows must be activated to keep the accounts and vendors in sync:

- Create Vendors in Accounts table
- Create Vendors in Vendors table
- Update Vendors in Accounts table

- Update Vendors in Vendors table

If OneFSSCM is installed, because both Field Service and Supply Chain Management Extended are installed, these workflows are automatically activated. If Field Service isn't installed, but you want to integrate the purchase order tables with Dataverse, you must activate these workflows. In both cases, unless you start from scratch, you might have to ensure that all vendors are created as accounts in Dataverse before you create purchase orders. Otherwise, errors might occur.

Initial synchronization

After all the prerequisites are in place, if you want existing purchase orders and product receipts to be available in both systems, you must do an initial synchronization of the following templates:

- Purchase Order Header V2
- CDS Purchase Order Line
- CDS Purchase Order Line soft delete
- Purchase Order Receipt
- Purchase Order Receipt Product

Mappings with logic

The procurement integration extends the product mapping with the following logic to ensure that the **Field Service Product Type** column is correctly set in the products table in Dataverse:

- If **Product Type** is set to *Product*, and **Item model group, Stocked product** is set to *True*, **Field Service Product Type** is set to *Inventory*.
- If **Product Type** is set to *Product*, and **Item model group, Stocked product** is set to *False*, **Field Service Product Type** is set to *Non-Inventory*.
- If **Product Type** is set to *Service*, **Field Service Product Type** is set to *Service*.

In addition, Dataverse includes logic that maps vendors with their related accounts. This logic sets the default invoice vendor account. On create, server-side plug-in logic sets the default invoice vendor account from the vendor that is related to the account. The vendor has a reference to the invoice account that is used to set this value.

Supported scenarios

- Purchase orders can be created and updated by Dataverse users. However, the process and data are controlled by Supply Chain Management. The constraints on updates to purchase order columns in Supply Chain Management apply when updates come from Field Service. For example, you can't update a purchase order if it has been finalized.

- If the purchase order is controlled by change management in Supply Chain Management, a Field Service user can update the purchase order only when the Supply Chain Management approval status is *Draft*.

- Several columns are managed only by Supply Chain Management and can't be updated in Field Service. To learn which columns can't be updated, review the mapping tables in the product. For the sake of simplicity, most of these columns are set to read-only on Dataverse pages.

  For example, the columns for price information are managed by Supply Chain Management. Supply Chain Management has trade agreements that Field Service can benefit from. columns such as **Unit price**, **Discount**, and **Net amount** come only from Supply Chain Management. To ensure that the price is synced to Field Service, you should use the **Sync** feature on the **Purchase Order** and **Purchase Order Product** pages in Dataverse when purchase order data has been entered. For more information, see Sync with the Dynamics 365 Supply Chain Management procurement data on demand.

- The **Totals** column is available only in Field Service, because there are no up-to-date totals of the purchase order in Supply Chain Management. The totals in Supply Chain Management are calculated based on multiple parameters that aren't available in Field Service.

- Purchase order lines where only a procurement category is specified, or where the product that is specified is an item of the *Service* product type or Field Service product type, can be initiated only in

Supply Chain Management. The lines are then synced to Dataverse and are visible in Field Service.

- If only Field Service is installed, not Supply Chain Management, the **Warehouse** column is mandatory on the purchase order. However, if Supply Chain Management is installed, this requirement is relaxed, because Supply Chain Management allows for purchase order lines where no warehouse is specified in certain situations.
- Product receipts (purchase order receipts in Dataverse) are managed by Supply Chain Management and can't be created from Dataverse if Supply Chain Management is installed. The product receipts from Supply Chain Management are synced from Supply Chain Management to Dataverse.
- Under-delivery is allowed in Supply Chain Management. The OneFSSCM solution adds logic so that, when the product receipt line (or purchase order receipt product in Dataverse) is created or updated, an inventory journal row is created in Dataverse to adjust the remaining quantity that is on order for under-delivery scenarios.

Unsupported scenarios

- Field Service prevents lines from being added to a canceled purchase order in Supply Chain Management. As a workaround, you can change the system status of the purchase order in Field Service, and then add the new line in either Field Service or Supply Chain Management.
- Although procurement rows affect inventory levels in both systems, this integration doesn't ensure inventory alignment across Supply Chain Management and Field Service. Both Field Service and Supply Chain Management have other processes that update inventory levels. Those processes are outside the scope of procurement.

Status management

The statuses of purchase orders in Field Service differ from the statuses in Supply Chain Management.

Field Service purchase order and purchase order product statuses

HEADER – SYSTEM STATUS	HEADER - APPROVAL STATUS	ITEM STATUS
• Draft • Submitted • Cancelled • Product received • Billed	• Null • Approved • Rejected	• Pending • Received • Cancelled

Supply Chain Management purchase order and purchase order line statuses

Line approval statuses are active only when there is a line workflow.

HEADER – DOCUMENTS STATUS	HEADER - APPROVAL STATUS	LINE STATUS	LINE APPROVAL STATUS
• Open Order (Back order) • Received • Invoiced • Cancelled	• Draft • In Review • Approved • Rejected • In External Review • Confirmed • Finalized	• Open Order (back order) • Received • Invoiced • Cancelled	• Not Submitted • In Review • Approved • Rejected

The following rules are applied to the status columns:

- The status in Supply Chain Management can't be updated from Field Service. However, in some cases, the status in Field Service will be updated when the purchase order status in Supply Chain Management is changed.
- If a purchase order in Supply Chain Management is under change management, and a change is being processed, the approval status is *Draft* or *In Review*. In this case, the Field Service approval status will be set

to *Null*.

- If the purchase order approval status in Supply Chain Management is set to *Approved*, *In External review*, *Confirmed*, or *Finalized*, the Field Service purchase order approval status will be set to *Approved*.
- If the purchase order approval status in Supply Chain Management is set to *Rejected*, the Field Service purchase order approval status will be set to *Rejected*.
- If the document header status in Supply Chain Management is changed to *Open order (Back order)*, and the Field Service purchase order status is *Draft* or *Cancelled*, the Field Service purchase order status will be changed to *Submitted*.
- If the document header status in Supply Chain Management is changed to *Cancelled*, and no purchase order receipt products in Field Service are associated with the purchase order (via purchase order products), the Field Service system status is set to *Cancelled*.
- If purchase order line status in Supply Chain Management is *Cancelled*, the purchase order product status in Field Service is set to *Cancelled*. In addition, if the purchase order line status in Supply Chain Management is changed from *Cancelled* to *Back Order*, the purchase order product item status in Field Service is set to *Pending*.

Sync with the Supply Chain Management procurement data on demand

Supply Chain Management includes procurement data that handles trade agreements, discounts, and other scenarios that rely on secondary processes in Supply Chain Management. The procurement engine uses complex rules to determine the best price for a given purchase order. When you use dual-write, data isn't always kept synchronous across the two environments, especially in scenarios where the row was created or updated from Dataverse and might trigger follow-on processes in Supply Chain Management.

Sync the procurement data from Supply Chain Management

1. In Dataverse, go to **Inventory** > **Purchase Order**.
2. Select **New** to create a new purchase order, or select the row for an existing purchase order.
3. From the purchase order or purchase order line.
4. On the Action Pane, select **Sync**.

All columns from Dataverse and Field Service that are shared by Supply Chain Management are synced.

Here are the situations where you might use the **Sync** function:

- If you make multiple successive changes to the same row from Dataverse, run the **Sync** function.
- If you aren't sure whether a change might be the second successive change from Dataverse, it might make sense to run the **Sync** function.
- If you receive an error message about updating a value from Supply Chain Management, run the **Sync** function, and then retry the update in Dataverse.

Cancelling the posting process

If the product receipt posting process is cancelled during processing, then dual-write might create a product receipt row in Dataverse, but not create a product receipt row in Supply Chain Management. This situation happens because dual-write does not support distributed transactions.

Templates

The following templates are available for the integration of procurement-related documents.

SUPPLY CHAIN MANAGEMENT	FIELD SERVICE	DESCRIPTION
Purchase order header V2	msdyn_Purchaseorders	This table contains the columns that represent the purchase order header.

SUPPLY CHAIN MANAGEMENT	FIELD SERVICE	DESCRIPTION
Purchase order line entity	msdyn_PurchaseOrderProducts	This table contains the rows that represent lines on a purchase order. The product number is used for synchronization. This identifies the product as a stock keeping unit (SKU), including product dimensions. For more information about product integration with Dataverse, see Unified product experience.
Product receipt header	msdyn_purchaseorderreceipts	This table contains the product receipt headers that are created when a product receipt is posted in Supply Chain Management.
Product receipt line	msdyn_purchaseorderreceiptproducts	This table contains the product receipt lines that are created when a product receipt is posted in Supply Chain Management.
Purchase order line soft deleted entity	msdyn_purchaseorderproducts	This table contains information about purchase order lines that are soft-deleted. A purchase order line in Supply Chain Management can be soft-deleted only when the purchase order has been confirmed or approved, if change management is turned on. The row exists in the Supply Chain Management database and is marked as **IsDeleted**. Because Dataverse doesn't have a concept of soft-deletion, it's important that this information be synced to Dataverse. In this way, lines that are soft-deleted in Supply Chain Management can automatically be deleted from Dataverse. In this case, the logic for deleting a line in Dataverse is located in Supply Chain Management Extended.

Mapping tables

Mapping types

There are several different mapping types. The following table explains the symbols used in the template tables.

SYMBOL	DESCRIPTION
>	One-way
>>	One-way, and data is transformed in the process.
=	Bidirectional
><	Bidirectional, and data is transformed in the process.
<<	One-way, and data is transformed in the process.

Filters

The source filter and reverse source filter determine which rows are synchronized.

Default values

If a synchronized field does not exist in either the Finance and Operations table or the other Dynamics 365 table, then a default value is assigned in the synchronized table. In some cases, the default value is an integer that is a lookup to an attribute value in the Common Data Model. For example, in the Contacts table of the Common Data Model, the default value of **address1_addresstypecode** is **3**. In the Common Data Model, for address1AddressTypeCode the value of **3** is **Primary address**.

Sync on-demand with the Supply Chain Management pricing engine

2/18/2021 • 2 minutes to read • Edit Online

Microsoft Dynamics 365 Supply Chain Management includes a pricing engine that handles trade agreements, price lists, customer loyalty programs, promotions, and discounts. The pricing engine uses complex rules to determine the best price for a given quotation or order. When you use dual-write, you use either static pricing or the pricing engine from Dynamics 365 Supply Chain Management on the Quote and Order pages in Dynamics 365 Sales.

Use the pricing engine from Supply Chain Management in Sales

1. In Sales, go to **Sales > Orders**.
2. Select **New** to create a new order, or select an existing order in the **My Orders** list.
3. Add a new order line.
4. If you're creating a new order, select **Price Order** on the Action Pane. If you're updating an existing order, select **Recalculate** on the Action Pane.

   The following columns are automatically filled in:

   - Detail Amount
   - Discount %
   - Discount
   - Pre-Freight Amount
   - Freight Amount
   - Total Tax
   - Total Amount
5. To ensure that the system considers trade and sales agreements to calculate the price:

   a. Navigate to your Supply Chain Management environment.
   b. Navigate to **Accounts receivable > Setup > Accounts receivable parameters**.
   c. Select the **Prices** tab in the side navigation bar.
   d. Under the **Trade agreement evaluation** fastab, uncheck the **Manual entry** option.

How it works

When you select **Price Order** in Sales, the **Totals** function on the **Sales Order > View** tab in Supply Chain Management is called for the associated sales order. The values in the order total in Sales are used to fill in the corresponding columns in Supply Chain Management.

When the sales order total is calculated in Supply Chain Management, the calculation evaluates the existing trade agreements and sales agreements for the customer and the products that are listed in the sales order. This information is used to calculate the totals. When **Price Order** is selected, Sales automatically reflects all the setup that has been done in Supply Chain Management.

Limitations

When the columns in Sales are filled in, the following limitations apply:

- The setup of charges and charge allocations in Supply Chain Management isn't replicated in Sales.
- Pricing doesn't consider special retail pricing that is specified in the **Retail Channel** column on the sales order line page in Supply Chain Management.
- Discounts that are defined in the **Trade Allowance Management** section of Supply Chain Management aren't considered.

Prospect-to-cash in dual-write

2/18/2021 • 14 minutes to read • Edit Online

An important goal of most businesses is to convert prospects to customers and then maintain an ongoing business relationship with those customers. In Microsoft Dynamics 365 apps, the prospect-to-cash process occurs through quotations or order processing workflows, and the financials are reconciled and recognized. Integration of prospect-to-cash with dual-write creates a workflow that takes a quotation and an order that originate in either Dynamics 365 Sales or Dynamics 365 Supply Chain Management, and makes the quotation and order available in both apps.

In the app interfaces, you can access the processing statuses and invoice information in real time. Therefore, you can more easily manage functions such as product stocking, inventory handling, and fulfillment in Supply Chain Management, without having to re-create the quotations and orders.

For information about customer and contact integration, see Integrated customer master. For information about product integration, see Unified product experience.

> **NOTE**
> In Dynamics 365 Sales, both prospect and customer refer to a record in the **Account** table where the **RelationshipType** column is either **Prospect** or **Customer**. If your business logic includes an **Account** qualification process where the **Account** record is created and qualified as a prospect first and then as a customer, that record synchronizes to the Finance and Operations app only when it is a customer (`RelationshipType=Customer`). If you want the **Account** row to synchronize as a prospect, then you need a custom map to integrate the prospect data.

Prerequisites and mapping setup

Before you can sync sales quotations, you must update the following settings.

Setup in Sales

In Sales, go to **Settings** > **Administration** > **System settings** > **Sales**, and make sure that the following settings are used:

- The **Use system prizing calculation** system option is set to **Yes**.
- The **Discount calculation method** column is set to **Line item**.

Sites and warehouses

In Supply Chain Management, the **Site** and **warehouse** columns are required for quotation lines and order lines. If you set the site and warehouse in the default order settings, those columns will automatically be set when you add a product to a quotation line or an order line.

Number sequences for quotations and orders

The number sequences for Supply Chain Management and Sales aren't connected when quotations and orders are created and synced in Sales and Supply Chain Management. If a sales order that is created in Sales is synced to Supply Chain Management, it has the same sales order number in Supply Chain Management. To help ensure that the sales order number isn't duplicated, you must use different number sequence systems in the two apps.

For example, the number sequence in Supply Chain Management is **1, 2, 3, 4, 5, ...**, and the number sequence in Sales is **100, 99, 98, ...**. If you create 100 sales orders in Sales, an order number will eventually be generated

that already exists in Supply Chain Management. In other words, the two number sequences will eventually overlap as sales orders are created in Supply Chain Management and Sales. Instead, you might use a number sequence such as **F1, F2, F3, ...** in Supply Chain Management and a number sequence such as **C1, C2, C3, ...** in Sales. These number sequences will never produce duplicate sales order numbers.

Sales quotations

Sales quotations can be created in either Sales or Supply Chain Management. If you create a quotation in Sales, it's synced to Supply Chain Management in real time. Likewise, if you create a quotation in Supply Chain Management, it's synced to Sales in real time. Note the following points:

- You can add a discount to the product on the quotation. In this case, the discount will be synced to Supply Chain Management. The **Discount**, **Charges**, and **Tax** columns on the header are controlled by a setup in Supply Chain Management. This setup doesn't support integration mapping. Instead, the **Price**, **Discount**, **Charge**, and **Tax** columns are maintained and handled in Supply Chain Management.
- The **Discount %**, **Discount**, and **Freight Amount** columns on the sales quotation header are read-only columns.
- The **Freight terms**, **Delivery terms**, **Shipping method**, and **Delivery mode** columns aren't part of the default mappings. To map these columns, you must set up a value mapping that is specific to the data in the organizations that the table is synced between.

If you are also using the Field Service solution, make sure to re-enable the **Quote Line Quick Create** parameter. Re-enabling the parameter lets you continue creating quote lines using the quick create function.

1. Navigate to your Dynamics 365 Sales application.
2. Select the settings icon in the top navigation bar.
3. Select **Advanced Settings**.
4. Choose the **Customize the System** option.
5. Select the **Quote Line** menu item.
6. Go to the **Data Services** section and select the **Allow quick create** checkbox.

Sales orders

Sales orders can be created in either Sales or Supply Chain Management. If you create a sales order in Sales, it's synced to Supply Chain Management in real time. Likewise, if you create a sales order in Supply Chain Management, it's synced to Sales in real time. Note the following points:

- Write-in products on Dynamics 365 Sales will appear as product categories in Dynamics 365 Supply Chain Management.
- Discount calculation and rounding:
    - The discount calculation model in Sales differs from the discount calculation model in Supply Chain Management. In Supply Chain Management, the final discount amount on a sales line can be the result of a combination of discount amounts and discount percentages. If this final discount amount is divided by the quantity on the line, rounding can occur. However, this rounding isn't considered if a rounded per-unit discount amount is synced to Sales. To help ensure that the full discount amount from a sales line in Supply Chain Management is correctly synced to Sales, the full amount must be synced without being divided by the line quantity. Therefore, you must define the discount calculation method as **Line item** in Sales.
    - When a sales order line is synced from Sales to Supply Chain Management, the full line discount amount is used. Because Supply Chain Management has no column that can store the full discount amount for a line, the amount is divided by the quantity and stored in the **Line discount** column. Any rounding that occurs during this division is stored in the **Sales charges** column on the sales line.

Example: Synchronization from Sales to Supply Chain Management

You have the following sales order:

- **Sales:** Quantity = 3, per-line discount = $10.00
- **Supply Chain Management:** Quantity = 3, line discount amount = $3.33, sales charge = –$0.01

If you sync from Supply Chain Management to Sales, you get the following result:

- **Supply Chain Management:** Quantity = 3, line discount amount = $3.33, sales charge = –$0.01
- **Sales:** Quantity = 3, per-line discount = (3 × $3.33) + $0.01 = $10.00

Dual-write solution for Sales

New columns have been added to the **Order** table and appear on the page. Most of these columns appear on the **Integration** tab in Sales. To learn more about how the status columns are mapped, see Set up the mapping for sales order status columns.

- The **Create Invoice** and **Cancel Order** buttons on the **Sales order** page are hidden in Sales.
- The **Sales order status** value will remain **Active** to help ensure that changes from Supply Chain Management can flow to the sales order in Sales. To control this behavior, set the default **Statecode [Status]** value to **Active**.

Invoices

Sales invoices are created in Supply Chain Management and synced to Sales. Note the following points:

- An **Invoice number** column has been added to the **Invoice** table and appears on the page.
- The **Create invoice** button on the **Sales order** page is hidden, because invoices will be created in Supply Chain Management and synced to Sales. The **Invoice** page can't be edited, because invoices will be synced from Supply Chain Management.
- The **Sales order status** value is automatically changed to **Invoiced** when the related invoice from Supply Chain Management has been synced to Sales. Additionally, the owner of the sales order that the invoice was created from is assigned as the owner of the invoice. Therefore, the owner of the sales order can view the invoice.
- The **Freight terms**, **Delivery terms**, and **Delivery mode** columns aren't included in the default mappings. To map these columns, you must set up a value mapping that is specific to the data in the organizations that the table is synced between.

Templates

Prospect-to-cash includes a collection of core table maps that work together during data interaction, as shown in the following table.

FINANCE AND OPERATIONS APPS	CUSTOMER ENGAGEMENT APPS	DESCRIPTION
Sales invoice headers V2	invoices	The Sales invoice headers V2 table in the Finance and Operations app contains invoices for sales orders and free text invoices. A filter is applied in Dataverse for dual-write that will filter out any free text invoice documents.
Sales invoice lines V2	invoicedetails	
CDS sales order headers	salesorders	

FINANCE AND OPERATIONS APPS	CUSTOMER ENGAGEMENT APPS	DESCRIPTION
CDS sales order lines	salesorderdetails	
Sales order origin codes	msdyn_salesorderorigins	
CDS sales quotation header	quotes	
CDS sales quotation lines	quotedetails	

Here are the related core table maps for prospect-to-cash:

- Customers V3 to accounts
- CDS Contacts V2 to contacts
- Customers V3 to contacts
- Released products V2 to msdyn_sharedproductdetails
- All products to msdyn_globalproducts
- Pricelist

Limitations

- Return orders are not supported.
- Credit notes are not supported.
- Financial dimensions must be set for the master data, for example, customer and vendor. When a customer is added to a quotation or sales order, the financial dimensions associated with the customer record flow to the order automatically. Currently dual-write does not include financial dimensions data for master data.

Mapping tables

Mapping types

There are several different mapping types. The following table explains the symbols used in the template tables.

SYMBOL	DESCRIPTION
>	One-way
>>	One-way, and data is transformed in the process.
=	Bidirectional
><	Bidirectional, and data is transformed in the process.
<<	One-way, and data is transformed in the process.

Filters

The source filter and reverse source filter determine which rows are synchronized.

Default values

If a synchronized field does not exist in either the Finance and Operations table or the other Dynamics 365 table, then a default value is assigned in the synchronized table. In some cases, the default value is an integer that is a

lookup to an attribute value in the Common Data Model. For example, in the Contacts table of the Common Data Model, the default value of **address1_addresstypecode** is **3**. In the Common Data Model, for address1AddressTypeCode the value of **3** is **Primary address**.

Use the Dynamics 365 Commerce pricing engine with Dynamics 365 Sales

2/18/2021 • 2 minutes to read • Edit Online

This topic describes how to use the Microsoft Dynamics 365 Commerce pricing engine to create sales quotations in Dynamics 365 Sales.

The Dynamics 365 Commerce pricing engine supports most business-to-consumer (B2C) pricing scenarios, such as store-level pricing, affiliation-based and loyalty-based pricing, mix-and-match discounts, quantity discounts, and threshold discounts. The pricing engine uses complex rules to determine the best price for a given quotation or order.

When you use dual-write, you have three options for your pricing needs. You can use the static pricing that comes from the price list in Dynamics 365 Sales, the pricing engine in Dynamics 365 Supply Chain Management, or the pricing engine in Dynamics 365 Commerce. Among these options, the Commerce pricing engine is best suited to B2C scenarios.

Use the Commerce pricing engine in Sales

> **NOTE**
> Currently, the Commerce pricing engine can be used only for quotation creation in the Sales. Sales order integration with the Commerce pricing engine isn't yet available.

When users initiate a quotation in Sales, the dual-write framework copies the quotation details to Commerce. Any changes to existing quotation lines or any newly added quotation lines in Sales are copied to Commerce. When users want to use the Commerce pricing engine to price the quotation, they can select **Price quote** to update the prices of the quotation, based on the Commerce pricing engine. Prices are then automatically updated in both Sales and Commerce.

Prerequisites

- Before you can use the Commerce pricing engine in Sales, you must follow the steps in Prospect-to-cash in dual-write.
- You must turn off trade agreement evaluation for manual entry by following these steps:
  1. In your Commerce environment, go to **Accounts receivable** > **Setup** > **Accounts receivable parameters**.
  2. On the **Prices** tab, on the **Trade agreement evaluation** FastTab, clear the **Manual entry** check box.

Can you tell us about your documentation language preferences? Take a short survey.

The survey will take about seven minutes. No personal data is collected (privacy statement).

In-house assets for servicing

2/18/2021 • 4 minutes to read • Edit Online

Microsoft Dynamics 365 Field Service is designed to service customer assets. Asset management for Dynamics 365 Supply Chain Management is designed to maintain in-house assets. Integration of these two apps lets you use Field Service to service both customer assets and in-house assets. You can also classify the assets, based on functional location or hierarchy, and track the servicing at a detailed level.

For more information, see Integrate Dynamics 365 Field Service and Supply Chain Management.

Templates

In-house-assets include a collection of core table maps that work together during data interaction, as shown in the following table.

FINANCE AND OPERATIONS APPS	MODEL-DRIVEN APPS IN DYNAMICS 365	DESCRIPTION
Asset management asset lifecycle models	msdyn_assetlifecyclemodels	
Asset management asset lifecycle states	msdyn_assetlifecyclestates	
Asset management assets	msdyn_customerassets	
Asset management asset types	msdyn_customerassetcategories	
Asset management functional location lifecycle models	msdyn_functionallocationlifecyclemodels	
Asset management functional location lifecycle states	msdyn_functionallocationlifecyclestates	
Asset management functional locations	msdyn_functionallocations	
Asset management functional location types	msdyn_functionallocationtypes	
Asset management manufacturers	msdyn_manufacturers	
Asset management models	msdyn_models	
Asset management warranty	msdyn_warranties	

Mapping tables

Mapping types

There are several different mapping types. The following table explains the symbols used in the template tables.

SYMBOL	DESCRIPTION
>	One-way
> >	One-way, and data is transformed in the process.
=	Bidirectional
> <	Bidirectional, and data is transformed in the process.
< <	One-way, and data is transformed in the process.

Filters

The source filter and reverse source filter determine which rows are synchronized.

Default values

If a synchronized field does not exist in either the Finance and Operations table or the other Dynamics 365 table, then a default value is assigned in the synchronized table. In some cases, the default value is an integer that is a lookup to an attribute value in the Common Data Model. For example, in the Contacts table of the Common Data Model, the default value of **address1_addresstypecode** is **3**. In the Common Data Model, for address1AddressTypeCode the value of **3** is **Primary address**.

Asset management asset lifecycle models to msdyn_assetlifecyclemodels

Integrated worker, job, and position

2/18/2021 • 5 minutes to read • Edit Online

NOTE

Effective November 2020:

- Common Data Service has been renamed to Microsoft Dataverse. For more information, see Power Automate Blog.
- Some terminology in Microsoft Dataverse has been updated. For example, *entity* is now *table* and *field* is now *column*. For more information, see Terminology updates.

This topic will be updated soon to reflect the latest terminology.

Worker data can be mastered in more than one Microsoft Dynamics 365 app. For example, Human resources (HR) data can be managed in Dynamics 365 Human Resources, Dynamics 365 Commerce, and Dynamics 365 Supply Chain Management. Regardless of where the data originates, it's integrated behind the scenes. The ability to integrate data about workers gives you the flexibility to master worker data in any Dynamics 365 app. It also provides a comprehensive view of the information in Dynamics 365 apps.

Human resources

The integration of HR data involves just mapping the HR data between Finance and Operations apps and model-driven apps in Dynamics 365.

Templates

HR data includes information about employees and contractors, positions, and jobs. A collection of table maps works together during data interaction, as shown in the following table.

FINANCE AND OPERATIONS APPS	MODEL-DRIVEN APPS IN DYNAMICS 365	DESCRIPTION
Compensation job function	cdm_jobfunctions	
Compensation job type	cdm_jobtypes	
Employment	cdm_employments	
Employment detail	cdm_employments	
Jobs	cdm_jobs	
Job detail	cdm_jobs	
Position details	cdm_jobpositions	
Position durations	cdm_jobpositions	
Position hierarchies	cdm_jobpositions	

FINANCE AND OPERATIONS APPS	MODEL-DRIVEN APPS IN DYNAMICS 365	DESCRIPTION
Position type	cdm_positiontypes	
Position worker assignments	cdm_positionworkerassignmentmaps	
Worker	cdm_workers	In Dynamics 365 Finance and Supply Chain Management data, workers are classified as either employees or contractors. Dataverse can also classify workers as volunteers. Volunteers will become contractors when the data is transformed back into Finance and Supply Chain Management.

Mapping tables

Mapping types

There are several different mapping types. The following table explains the symbols used in the template tables.

SYMBOL	DESCRIPTION
>	One-way
>>	One-way, and data is transformed in the process.
=	Bidirectional
><	Bidirectional, and data is transformed in the process.
<<	One-way, and data is transformed in the process.

Filters

The source filter and reverse source filter determine which rows are synchronized.

Default values

If a synchronized field does not exist in either the Finance and Operations table or the other Dynamics 365 table, then a default value is assigned in the synchronized table. In some cases, the default value is an integer that is a lookup to an attribute value in the Common Data Model. For example, in the Contacts table of the Common Data Model, the default value of **address1_addresstypecode** is **3**. In the Common Data Model, for address1AddressTypeCode the value of **3** is **Primary address**.

Inventory availability in dual-write

2/18/2021 • 3 minutes to read • Edit Online

By using inventory availability, you can check your inventory before you add a product to the **Quotations**, **Orders**, or **Invoices** page in Microsoft Dynamics 365 Sales. For example, you check inventory and determine a fulfillment date as one key task in the prospect-to-cash process.

If you don't have enough inventory, you can estimate a delivery date, based on projected inventory receipts and issues. You can also check the product's available-to-promise (ATP) information, where you can find the ATP quantity in the predefined time fence.

On-hand inventory

In Dynamics 365 Sales, a new **On-hand Inventory** button has been added to the header of the **Quotes**, **Orders**, and **Invoices** pages. When you select this button, a dialog box appears, where you can specify the company and the product that you want to check the on-hand inventory for. This dialog box shows the same information as On-hand inventory.

The dialog box returns the inventory information from Dynamics 365 Supply Chain Management. This information includes the following quantities:

- On-hand quantity
- Reserved on-hand quantity
- Available on-hand quantity
- Ordered quantity
- On-order quantity
- Reserved ordered quantity
- Total available quantity

ATP information

In Sales, a new **ATP Information** button has been added to line items on the **Quotes**, **Orders**, and **Invoices** pages. When you select this button, a dialog box appears, where you can specify the company, product, inventory site, inventory warehouse, and order quantity. This dialog box has the same settings that are described in Order promising.

The dialog box returns the ATP information from Supply Chain Management. This information includes the following quantities:

- ATP quantity
- Receipt quantity
- Issue quantity
- On-hand quantity

How it works

When you select the **On-hand Inventory** button on the **Quotes**, **Orders**, or **Invoices** page, a live dual-write call is made to the **Onhand inventory** API. The API calculates the on-hand inventory for the given product. The result is stored in the **InventCDSInventoryOnHandRequestEntity** and **InventCDSInventoryOnHandEntryEntity** tables, and then is written to Dataverse by dual-write. To use this

functionality, you need to run the following dual-write maps. Skip initial synchronization when you run the maps.

- CDS inventory on-hand entries (msdyn_inventoryonhandentries)
- CDS inventory on-hand requests (msdyn_inventoryonhandrequests)

Templates

The following templates are available for the exposing the onhand inventory data.

FINANCE AND OPERATIONS APPS	CUSTOMER ENGAGEMENT APP	DESCRIPTION
CDS inventory on-hand entries	msdyn_inventoryonhandentries	
CDS inventory on-hand requests	msdyn_inventoryonhandrequests	

Mapping tables

Mapping types

There are several different mapping types. The following table explains the symbols used in the template tables.

SYMBOL	DESCRIPTION
>	One-way
>>	One-way, and data is transformed in the process.
=	Bidirectional
><	Bidirectional, and data is transformed in the process.
<<	One-way, and data is transformed in the process.

Filters

The source filter and reverse source filter determine which rows are synchronized.

Default values

If a synchronized field does not exist in either the Finance and Operations table or the other Dynamics 365 table, then a default value is assigned in the synchronized table. In some cases, the default value is an integer that is a lookup to an attribute value in the Common Data Model. For example, in the Contacts table of the Common Data Model, the default value of **address1_addresstypecode** is **3**. In the Common Data Model, for address1AddressTypeCode the value of **3** is **Primary address**.

The survey will take about seven minutes. No personal data is collected (privacy statement).

Support for Field Service and Project Service Automation solutions

2/18/2021 • 2 minutes to read • Edit Online

NOTE

Effective November 2020:

- Common Data Service has been renamed to Microsoft Dataverse. For more information, see Power Automate Blog.
- Some terminology in Microsoft Dataverse has been updated. For example, *entity* is now *table* and *field* is now *column*. For more information, see Terminology updates.

This topic will be updated soon to reflect the latest terminology.

NOTE

Effective November 2020:

- Common Data Service has been renamed to Microsoft Dataverse. For more information, see Power Automate Blog.
- Some terminology in Microsoft Dataverse has been updated. For example, *entity* is now *table* and *field* is now *column*. For more information, see Terminology updates.

This topic will be updated soon to reflect the latest terminology.

Support for Field Service solutions

Microsoft supports dual-write on top of existing Dataverse environments that are based on Field Service solutions.

For more information, see Integrate Dynamics 365 Field Service and Supply Chain Management.

Support for Project Service Automation solutions

Microsoft supports dual-write on top of existing Dataverse environments that are based on Project Service Automation solutions.

NOTE

Can you tell us about your documentation language preferences? Take a short survey.

The survey will take about seven minutes. No personal data is collected (privacy statement).

Migrate Prospect to cash data from Data Integrator to dual-write

2/18/2021 • 4 minutes to read • Edit Online

To migrate your Prospect to cash data from Data Integrator to dual-write, follow these steps.

1. Run the Prospect to cash Data Integrator jobs to do one final full synchronization. In this way, you ensure that both systems (Finance and Operations apps and customer engagement apps) have all the data.
2. To help prevent potential data loss, export the Prospect to cash data from Microsoft Dynamics 365 Sales to an Excel file or a comma-separated values (CSV) file. Export data from the following entities:
   - Account
   - Contact
   - Invoice
   - Invoice products
   - Order
   - Order products
   - Products
   - Quote
   - Quote products
3. Uninstall the Prospect to cash solution from the Sales environment. This step removes the columns and corresponding data that the Prospect to cash solution introduced.
4. Install the dual-write solution.
5. Create a dual-write connection between the Finance and Operations app and the customer engagement app for one or more legal entities.
6. Enable dual-write table maps, and run the initial synchronization for the required reference data. (For more information, see Considerations for initial synchronization.) Examples of required data include customer groups, payment terms, and payment schedules. Don't enable the dual-write maps for tables that require initialization, such as the account, quote, quote line, order, and order line tables.
7. In the customer engagement app, go to **Advanced Settings > System Settings > Data Management > Duplicate detection rules**, and disable all the rules.
8. Initialize the tables that are listed in step 2. For instructions, see the remaining sections of this topic.
9. Open the Finance and Operations app, and enable the table maps, such as the account, quote, quote line, order, and order line table maps. Then run the initial synchronization. (For more information, see Considerations for initial synchronization.) This process will sync additional information from the Finance and Operations app, such as processing status, shipping and billing addresses, sites, and warehouses.

Account table

1. In the **Company** column, enter the company name, such as **USMF**.
2. In the **Relationship Type** column, enter **Customer** as a static value. You might not want to classify every account record as a customer in your business logic.
3. In the **Customer Group ID** column, enter the customer group number from the Finance and Operations

app. The default value from the Prospect to cash solution is **10**.

4. If you're using the Prospect to cash solution without any customization of **Account Number**, enter an **Account Number** value in the **Party Number** column. If there are customizations, and you don't know the party number, pull this information from the Finance and Operations app.

Contact table

1. In the **Company** column, enter the company name, such as **USMF**.
2. Set the following columns, based on the **IsActiveCustomer** value in the CSV file:
   - If **IsActiveCustomer** is set to **Yes** in the CSV file, set the **Sellable** column to **Yes**. In the **Customer Group ID** column, enter the customer group number from the Finance and Operations app. The default value from the Prospect to cash solution is **10**.
   - If **IsActiveCustomer** is set to **No** in the CSV file, set the **Sellable** column to **No**, and set the **Contact For** column to **Customer**.
3. If you're using the Prospect to cash solution without any customization of **Contact Number**, set the following columns:
   - Migrate the contact number from the CSV file (**msdynce_contactnumber**) to the contact number in the **Contact** table (**msdyn_contactnumber**).
   - Use values from the **Contact Number** table in the **Party Number** column.
   - Use values from the **Contact Number** table in the **Account Number/Contact Person ID** column.

Invoice table

Because data from the **Invoice** table is designed to flow one way, from the Finance and Operations app to the customer engagement app, initialization isn't required. Run the initial synchronization to migrate all the required data from the Finance and Operations app to the customer engagement app. For more information, see Considerations for initial synchronization.

Order table

1. In the **Company** column, enter the company name, such as **USMF**.
2. Copy the value of the **Order ID** column in the CSV file to the **Sales Order Number** column.
3. Copy the value of the **Customer** column in the CSV file to the **Invoice customer number** column.
4. Copy the value of the **Ship To Country/Region** column in the CSV file to the **Ship To Country/Region** column. Examples of this value include **US** and **United States**.
5. Set the **Requested Receipt Date** column. If you aren't using a receipt date, use the **Requested Delivery Date**, **Date Fulfilled**, and **Date Submitted** columns in the CSV file. An example of this value is **2020-03-27T00:00:00Z**.
6. Set the **Language** column. An example of this value is **en-us**.
7. Set the **Order Type** column by using the **Item-based** column.

Order products table

- In the **Company** column, enter the company name, such as **USMF**.

Products table

Because data from the **Products** table is designed to flow one way, from the Finance and Operations app to the customer engagement app, initialization isn't required. Run the initial synchronization to migrate all the required data from the Finance and Operations app to the customer engagement app. For more information, see

Considerations for initial synchronization.

Quote and Quote product tables

For the **Quote** table, follow the instructions in the Order table section earlier in this topic. For the **Quote product** table, follow the instructions in the Order products table section.

Verify dual-write configuration in Finance and Operations apps and Dataverse

2/18/2021 • 2 minutes to read • Edit Online

NOTE

Effective November 2020:

- Common Data Service has been renamed to Microsoft Dataverse. For more information, see Power Automate Blog.
- Some terminology in Microsoft Dataverse has been updated. For example, *entity* is now *table* and *field* is now *column*. For more information, see Terminology updates.

This topic will be updated soon to reflect the latest terminology.

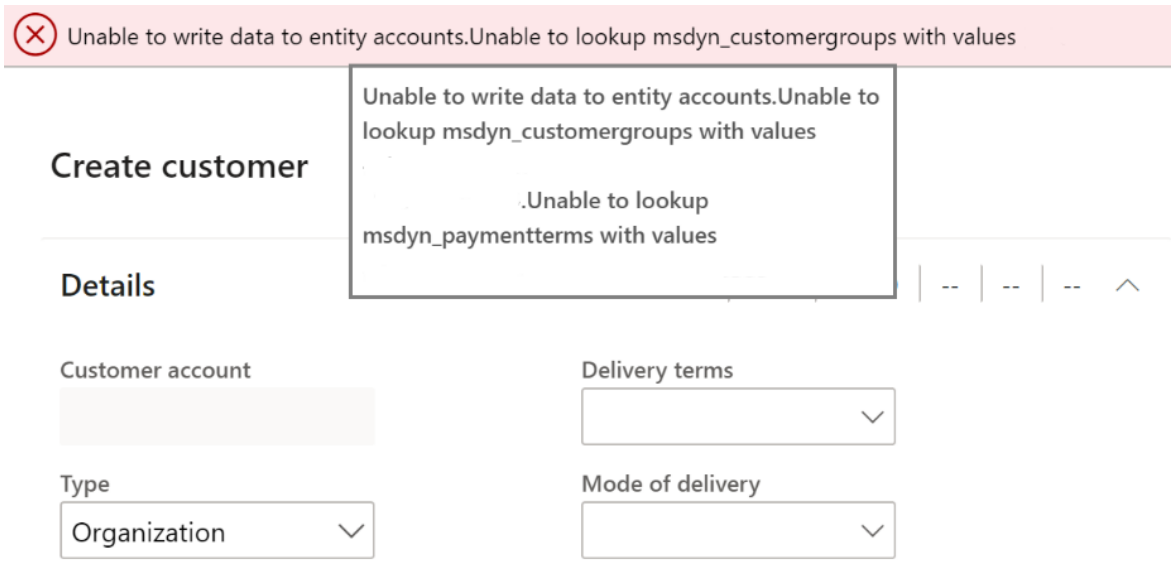
This topic provides troubleshooting information for dual-write integration between Finance and Operations apps and Dataverse. Specifically, it explains how you can determine whether dual-write is configured in Finance and Operations apps and in Dataverse.

Verify that dual-write is configured in a Finance and Operations app

To determine whether the errors that you see when you try to save rows for update come from dual-write, first verify that dual-write is configured.

- If you have admin privileges in the Finance and Operations app, go to **Workspaces** > **Data management**, and select the **Dual-write** tile. If the details of the linked environments and the list of table maps that are running are shown, dual-write is configured.

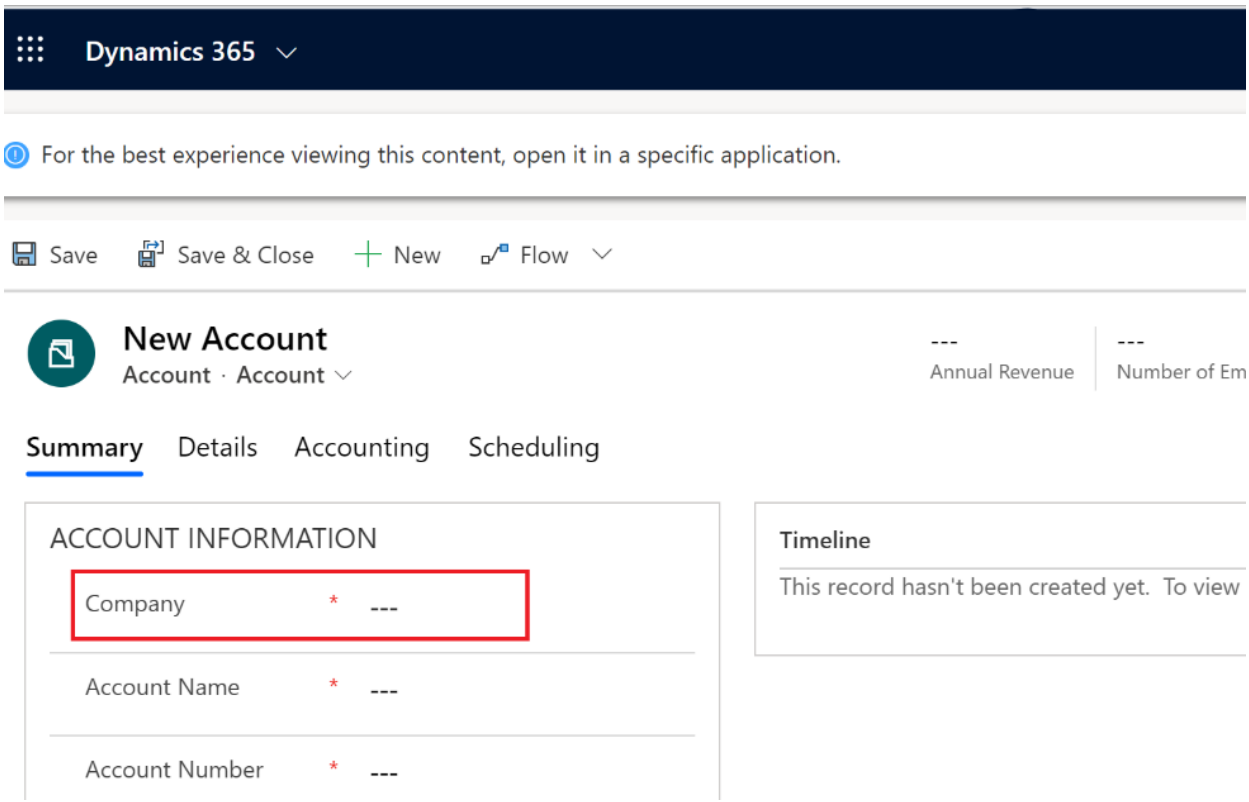
- If you don't have admin privileges, you will receive an error message, *Unable to write data to entity <entity name>*. In the example in the following illustration, you can't create a customer row in the Finance and Operations app, because dual-write is configured, but the customer group and payment terms reference data don't exist in Dataverse.



For information about how to fix issues when you create data in Finance and Operations apps, see Troubleshoot live synchronization issues.

Verify that dual-write is configured in Dataverse

When you create data, if you see the **Company** column on pages in Dataverse, dual-write is configured.



For information about how to fix issues when you create data in Dataverse, see Troubleshoot live synchronization issues.

For information about how to view error details if you encounter any errors while you create data in Dataverse, see Enable and view the plug-in trace log in Dataverse to view error details.

NOTE

Can you tell us about your documentation language preferences? Take a short survey.

The survey will take about seven minutes. No personal data is collected (privacy statement).

Troubleshoot issues during initial setup

2/18/2021 • 3 minutes to read • Edit Online

NOTE

Effective November 2020:

- Common Data Service has been renamed to Microsoft Dataverse. For more information, see Power Automate Blog.
- Some terminology in Microsoft Dataverse has been updated. For example, *entity* is now *table* and *field* is now *column*. For more information, see Terminology updates.

This topic will be updated soon to reflect the latest terminology.

This topic provides troubleshooting information for dual-write integration between Finance and Operations apps and Dataverse. Specifically, it provides information that can help you fix issues that might occur during the initial setup of dual-write integration.

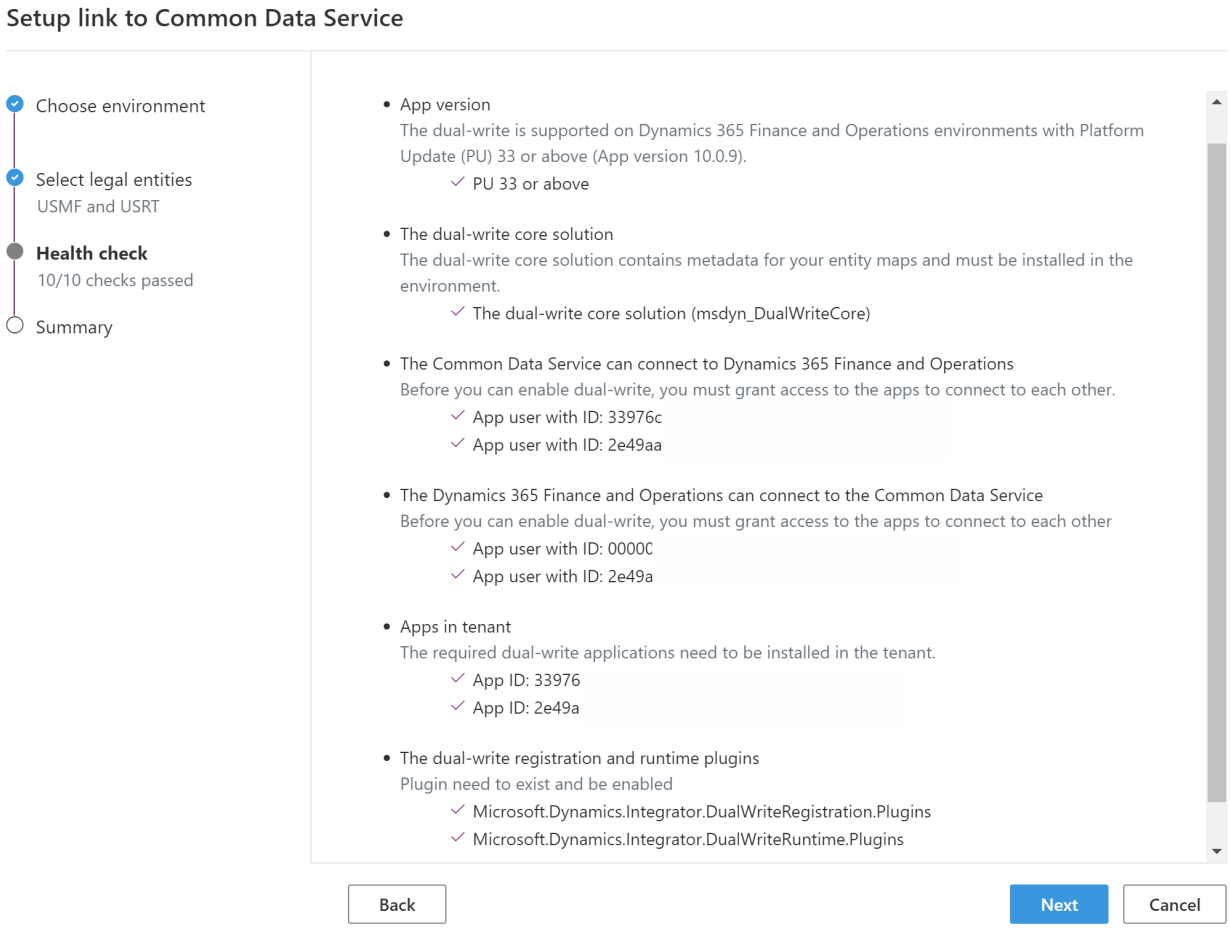
IMPORTANT

Some of the issues that this topic addresses might require either the system admin role or Microsoft Azure Active Directory (Azure AD) tenant admin credentials. The section for each issue explains whether a specific role or credentials are required.

You can't link a Finance and Operations app to Dataverse

Required role to set up dual-write: System administrator in Finance and Operations apps and Dataverse.

Errors on the **Setup link to Dataverse** page are usually caused by incomplete setup or permissions issues. Make sure that the whole health check passes on the **Setup link to Dataverse** page, as shown in the following illustration. You can't link dual-write unless the whole health check passes.



You must have Azure AD tenant admin credentials to link the Finance and Operations and Dataverse environments. After you link the environments, users can sign in by using their account credentials and update an existing table map.

Error when you open the Link to Dataverse page

Required credentials to fix the issue: Azure AD tenant admin

You might receive the following error message when you open the **Link to Dataverse** page in a Finance and Operations app:

Response status code does not indicate success: 404 (Not Found).

This error occurs when the consent step hasn't been completed. To validate whether the consent step has been completed, sign in to portal.Azure.com by using the Azure AD tenant admin account, and see whether the third-party app that has the ID **33976c19-1db5-4c02-810e-c243db79efde** appears in the Azure AD **Enterprise applications** list. If it doesn't, you must provide app consent.

To provide app consent, follow these steps.

1. Open the following URL by using your admin credentials. You should be prompted for consent.

   https://login.microsoftonline.com/common/oauth2/authorize?client_id=33976c19-1db5-4c02-810e-c243db79efde&response_type=code&prompt=admin_consent

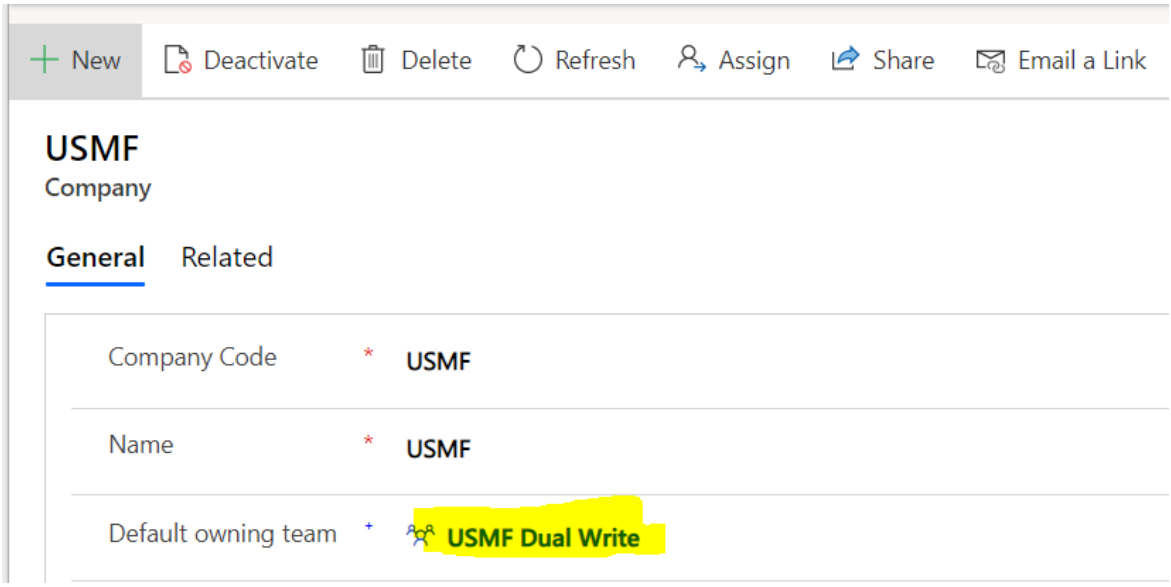
2. Select **Accept** to indicate that you're giving your consent to install the app that has the ID **33976c19-1db5-4c02-810e-c243db79efde** in your tenant.

> **TIP**
> This app is required to link Dataverse and Finance and Operations apps. If you have trouble with this step, open your browser in incognito mode (in Google Chrome) or InPrivate mode (in Microsoft Edge).

Verify that company data and dual-write teams are set up correctly during linking

To ensure that dual-write works correctly, the companies that you select during configuration are created in the Dataverse environment. By default, these companies are read-only, and the **IsDualWriteEnable** property is set to **True**. In addition, the default owning business unit owner and team are created and include the company name. Before you enable the maps, verify that the default team owner is specified. To find the **Companies (CDM_Company)** table, follow these steps.

1. In the model-driven app in Dynamics 365, select the filter in the upper-right corner.
2. In the drop-down list, select **Company**.
3. Select **Run** to see the results.
4. Select the company that was linked when you configured dual-write.
5. Verify that the **Default owning team** column has a value. In the following illustration, the **Default owning team** column is set to **USMF Dual Write**.



Find the limit on the number of legal tables or companies that can be linked for dual-write

You might receive the following error message when you try to enable maps:

Dual write failure - Plugin registration failed: [(Unable to get partition map for project DWM-1ae35e60-4bc2-4905-88ea-69efd3b29260-7f12cb89-1550-42e2-858e-4761fc1443ea. Error Exceeds the maximum partitions allowed for mapping DWM-1ae35e60-4bc2-4905-88ea-69efd3b29260-7f12cb89-1550-42e2-858e-4761fc1443ea)], One or more errors occurred.

The current limit when you link the environments is approximately 40 legal tables. This error occurs if you try to enable maps, and more than 40 legal tables are linked between the environments.

NOTE

The survey will take about seven minutes. No personal data is collected (privacy statement).

Troubleshoot issues during initial synchronization

2/18/2021 • 7 minutes to read • Edit Online

NOTE

Effective November 2020:

- Common Data Service has been renamed to Microsoft Dataverse. For more information, see Power Automate Blog.
- Some terminology in Microsoft Dataverse has been updated. For example, *entity* is now *table* and *field* is now *column*. For more information, see Terminology updates.

This topic will be updated soon to reflect the latest terminology.

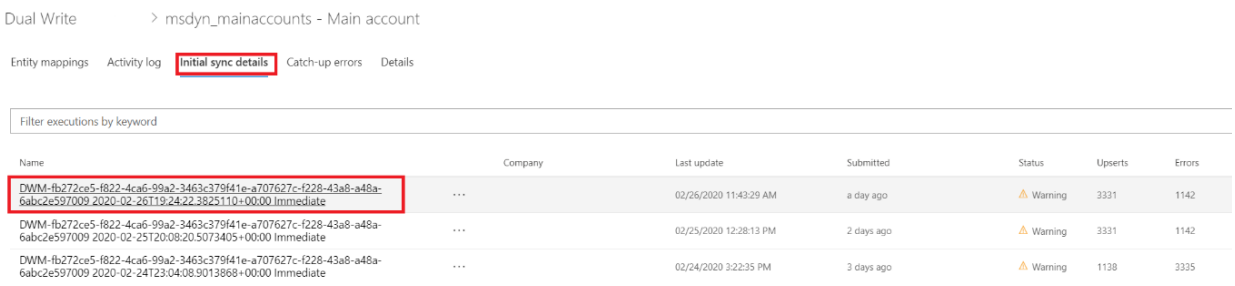
This topic provides troubleshooting information for dual-write integration between Finance and Operations apps and Dataverse. Specifically, it provides information that can help you fix issues that might occur during initial synchronization.

IMPORTANT

Some of the issues that this topic addresses might require either the system admin role or Microsoft Azure Active Directory (Azure AD) tenant admin credentials. The section for each issue explains whether a specific role or credentials are required.

Check for initial synchronization errors in a Finance and Operations app

After you enable the mapping templates, the status of the maps should be **Running**. If the status is **Not running**, errors occurred during initial synchronization. To view the errors, select the **Initial sync details** tab on the **Dual-write** page.



You can't complete initial synchronization: 400 Bad Request

Required role to fix the issue: System admin

You might receive the following error message when you try to run the mapping and initial synchronization:

([Bad Request], The remote server returned an error: (400) Bad Request.), AX export encountered an error

Here is an example of the full error message.

```
Dual write Initial Sync completed with status: Error. Following are the details:
Executed leg: From AX Financial dimensions to CRM msdyn_dimensionattributes
with exported records count: 0, ImportRecordsErrorCount: 0,
ImportRecordsInsertedCount: 0 and ImportRecordsUpdatedCount: 0
ErrorsDetails:
Dual write Initial sync failed
Message: ([Bad Request], The remote server returned an error: (400) Bad Request.), AX export encountered an
error
Stacktrace: at
Microsoft.Dynamics.Integrator.QueryGenerator.AxClient.\<ExportAxPackage\>d__16.MoveNext()
in X:\\bt\\1024532\\repo\\src\\Core\\QueryGenerator\\AxClient.cs:line 265
\--- End of stack trace from previous location where exception was thrown ---
at System.Runtime.ExceptionServices.ExceptionDispatchInfo.Throw()
at System.Runtime.CompilerServices.TaskAwaiter.HandleNonSuccessAndDebuggerNotification(Task task)
at Microsoft.D365.ServicePlatform.Context.ServiceContext.Activity.\<ExecuteAsync\>d__11\`2.MoveNext()
\--- End of stack trace from previous location where exception was thrown ---
```

If this error occurs consistently, and you can't complete the initial synchronization, follow these steps to fix the issue.

1. Sign in to the virtual machine (VM) for the Finance and Operations app.
2. Open Microsoft Management Console.
3. In the **Services** pane, make sure that the Microsoft Dynamics 365 Data import export framework service is running. Restart it if it has been stopped, because the initial synchronization requires it.

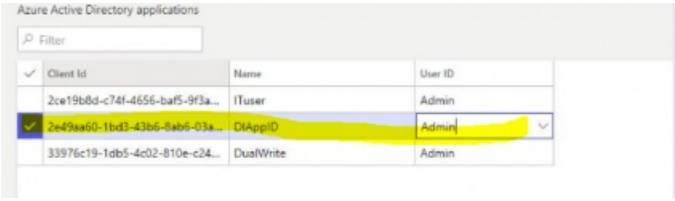
Initial synchronization error: 403 Forbidden

You might receive the following error message during initial synchronization:

([Forbidden], The remote server returned an error: (403) Forbidden.), AX export encountered an error

To fix the issue, follow these steps.

1. Sign in to the Finance and Operations app.
2. On the **Azure Active Directory applications** page, delete the **DtAppID** client, and then add it again.



Self-reference or circular reference failures during initial synchronization

You might receive an error messages if any of your mappings have self-references or circular references. The errors fall into these categories:

- Errors in the Vendors V2–to–msdyn_vendors table mapping
- Errors in the Customers V3–to–Accounts table mapping

Resolve errors in the Vendors V2–to–msdyn_vendors table mapping

You might encounter initial synchronization errors for the mapping of **Vendors V2** to **msdyn_vendors** if the tables have existing rows where there are values in the **PrimaryContactPersonId** and **InvoiceVendorAccountNumber** columns. These errors occur because **InvoiceVendorAccountNumber** is a self-referencing column, and **PrimaryContactPersonId** is a circular reference in the vendor mapping.

The error messages that you receive will have the following form.

Couldn't resolve the guid for the field: <field>. The lookup was not found: <value>. Try this URL(s) to check if the reference data exists:

```
https://focdsdevtest2.crm.dynamics.com/api/data/v9.0/<entity>?$select=<field>&$filter=<field> eq <value>
```

Here are some examples:

- *Couldn't resolve the guid for the field: msdyn_vendorprimarycontactperson.msdyn_contactpersonid. The lookup was not found: 000056. Try this URL(s) to check if the reference data exists:*

  ```
  https://focdsdevtest2.crm.dynamics.com/api/data/v9.0/contacts?
  $select=msdyn_contactpersonid.contactid&$filter=msdyn_contactpersonid eq '000056'
  ```

- *Couldn't resolve the guid for the field: msdyn_invoicevendoraccountnumber.msdyn_vendoraccountnumber. The lookup was not found: V24-1. Try this URL(s) to check if the reference data exists:*

  ```
  https://focdsdevtest2.crm.dynamics.com/api/data/v9.0/msdn_vendors?
  $select=msdyn_vendoraccountnumber,msdyn_vendorid&$filter=msdyn_vendoraccountnumber eq 'V24-1'
  ```

If any rows in the vendor table have values in the **PrimaryContactPersonId** and **InvoiceVendorAccountNumber** columns, follow these steps to complete the initial synchronization.

1. In the Finance and Operations app, delete the **PrimaryContactPersonId** and **InvoiceVendorAccountNumber** columns from the mapping, and then save the mapping.

   a. On the dual-write mapping page for **Vendors V2 (msdyn_vendors)**, on the **Table mappings** tab, in the left filter, select **Finance and Operations apps.Vendors V2**. In the right filter, select **Sales.Vendor**.

   b. Search for **primarycontactperson** to find the **PrimaryContactPersonId** source column.

   c. Select **Actions**, and then select **Delete**.

   
   d. Repeat these steps to delete the **InvoiceVendorAccountNumber** column.

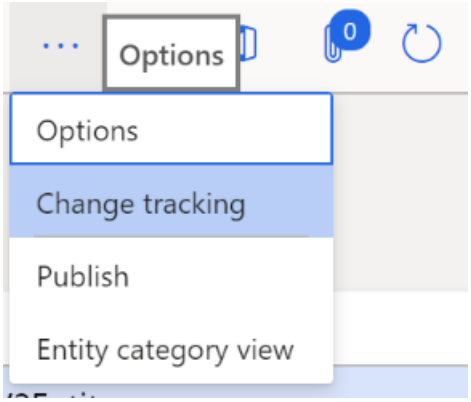
   
   e. Save your changes to the mapping.

2. Turn off change tracking for the **Vendors V2** table.

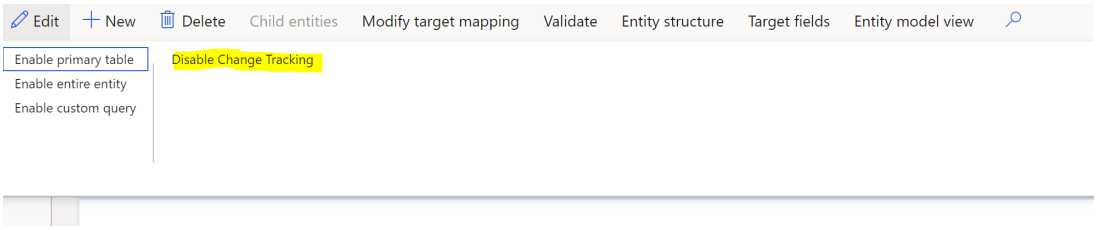
   a. In the **Data management** workspace, select the **Data tables** tile.

   b. Select the **Vendors V2** table.

   c. On the Action Pane, select **Options**, and then select **Change tracking**.



d. Select **Disable Change Tracking**.



3. Run initial synchronization for the **Vendors V2 (msdyn_vendors)** mapping. The initial synchronization should run successfully, without any errors.
4. Run initial synchronization for the **CDS Contacts V2 (contacts)** mapping. You must sync this mapping if you want to sync the primary contact column on the vendors table, because initial synchronization must also be done for the contact rows.
5. Add the **PrimaryContactPersonId** and **InvoiceVendorAccountNumber** columns back to the **Vendors V2 (msdyn_vendors)** mapping, and then save the mapping.
6. Run initial synchronization again for the **Vendors V2 (msdyn_vendors)** mapping. Because change tracking is turned off, all the rows will be synced.
7. Turn change tracking back on for the **Vendors V2** table.

Resolve errors in the Customers V3–to–Accounts table mapping

You might encounter initial synchronization errors for the mapping of **Customers V3** to **Accounts** if the tables have existing rows where there are values in the **ContactPersonID** and **InvoiceAccount** columns. These errors occur because **InvoiceAccount** is a self-referencing column, and **ContactPersonID** is a circular reference in the vendor mapping.

The error messages that you receive will have the following form.

Couldn't resolve the guid for the field: <field>. The lookup was not found: <value>. Try this URL(s) to check if the reference data exists:

```
https://focdsdevtest2.crm.dynamics.com/api/data/v9.0/<entity>?$select=<field>&$filter=<field> eq <value>
```

Here are some examples:

- *Couldn't resolve the guid for the field: primarycontactid.msdyn_contactpersonid. The lookup was not found: 000056. Try this URL(s) to check if the reference data exists:*

  ```
  https://focdsdevtest2.crm.dynamics.com/api/data/v9.0/contacts?
  $select=msdyn_contactpersonid.contactid&$filter=msdyn_contactpersonid eq '000056'
  ```

- *Couldn't resolve the guid for the field: msdyn_billingaccount.accountnumber. The lookup was not found: 1206-1. Try this URL(s) to check if the reference data exists:*

  ```
  https://focdsdevtest2.crm.dynamics.com/api/data/v9.0/accounts?
  $select=accountnumber.account&$filter=accountnumber eq '1206-1'
  ```

If any rows in the customer table have values in the **ContactPersonID** and **InvoiceAccount** columns, follow these steps to complete the initial synchronization. You can use this approach for any out-of-box tables, such **Accounts** and **Contacts**.

1. In the Finance and Operations app, delete the **ContactPersonID** and **InvoiceAccount** columns from the **Customers V3 (accounts)** mapping, and then save the mapping.

    a. On the dual-write mapping page for **Customers V3 (accounts)**, on the **Table mappings** tab, in the left filter, select **Finance and Operations app.Customers V3**. In the right filter, select **Dataverse.Account**.

    b. Search for **contactperson** to find the **ContactPersonID** source column.

    c. Select **Actions**, and then select **Delete**.

    d. Repeat these steps to delete the **InvoiceAccount** column.

    e. Save your changes to the mapping.

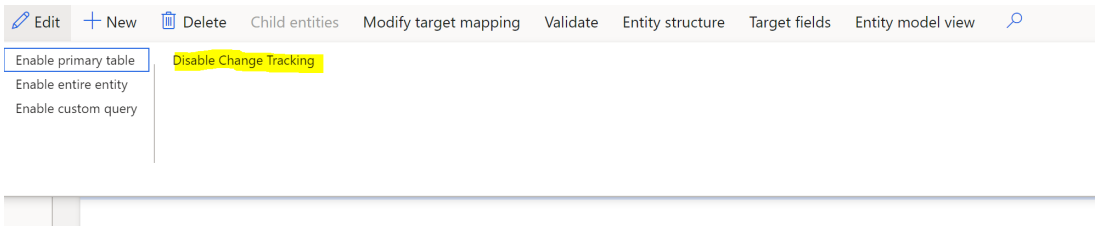
2. Turn off change tracking for the **Customers V3** table.

    a. In the **Data management** workspace, select the **Data tables** tile.

    b. Select the **Customers V3** table.

    c. On the Action Pane, select **Options**, and then select **Change tracking**.

    d. Select **Disable Change Tracking**.



3. Run initial synchronization for the **Customers V3 (Accounts)** mapping. The initial synchronization should run successfully, without any errors.

4. Run initial synchronization for the **CDS Contacts V2 (contacts)** mapping.

   > **NOTE**
   >
   > There are two maps that have the same name. Be sure to select the map that has the following description on the **Details** tab: **Dual-write template for sync between FO.CDS Vendor Contacts V2 to CDS.Contacts. Requires new package [Dynamics365SupplyChainExtended].**

5. Add the **InvoiceAccount** and **ContactPersonId** columns back to the **Customers V3 (Accounts)** mapping, and then save the mapping. Both the **InvoiceAccount** column and the **ContactPersonId** column are now part of live synchronization mode again. In the next step, you will do the initial synchronization for these columns.

6. Run initial synchronization again for the **Customers V3 (Accounts)** mapping. Because change tracking is turned off, the data for **InvoiceAccount** and **ContactPersonId** will be synced from the Finance and Operations app to Dataverse.

7. To sync the data for **InvoiceAccount** and **ContactPersonId** from Dataverse to the Finance and Operations app, you must use a data integration project.

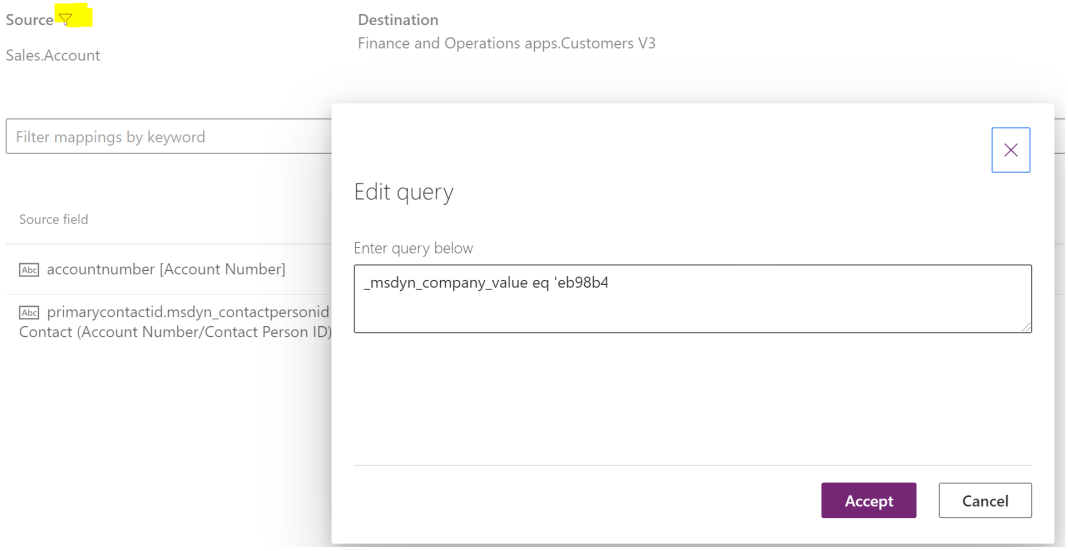
   a. In Power Apps, create a data integration project between the **Sales.Account** and **Finance and Operations apps.Customers V3** tables. The data direction must be from Dataverse to the Finance and Operations app. Because **InvoiceAccount** is a new attribute in dual-write, you might want to skip initial synchronization for it. For more information, see Integrate data into Dataverse.

   The following illustration shows a project that updates **CustomerAccount** and **ContactPersonId**.

   b. Add the company criteria in the filter on the Dataverse side, so that only rows that match the filter criteria will be updated in the Finance and Operations app. To add a filter, select the filter button. Then, in the **Edit query** dialog box, you can add a filter query such as **_msdyn_company_value eq '<guid>'**.

> [NOTE] If the filter button isn't present, create a support ticket to ask the data integration team to enable the filter capability on your tenant.

If you don't enter a filter query for **_msdyn_company_value**, all the rows will be synced.



The initial synchronization of the rows is now completed.

8. In the Finance and Operations app, turn change tracking back on for the **Customers V3** table.

Troubleshoot dual-write issues in Finance and Operations apps

2/18/2021 • 3 minutes to read • Edit Online

NOTE

Effective November 2020:

- Common Data Service has been renamed to Microsoft Dataverse. For more information, see Power Automate Blog.
- Some terminology in Microsoft Dataverse has been updated. For example, *entity* is now *table* and *field* is now *column*. For more information, see Terminology updates.

This topic will be updated soon to reflect the latest terminology.

This topic provides troubleshooting information for dual-write integration between Finance and Operations apps and Dataverse. Specifically, it provides information that can help you fix issues with the **Dual-write** module in Finance and Operations apps.

IMPORTANT

Some of the issues that this topic addresses might require either the system admin role or Microsoft Azure Active Directory (Azure AD) tenant admin credentials. The section for each issue explains whether a specific role or credentials are required.

You can't load the dual-write module in a Finance and Operations app

If you can't open the **Dual-write** page by selecting the **Dual Write** tile in the **Data management** workspace, the data integration service is probably down. Create a support ticket to request a restart of the data integration service.

Error when you try to create a new table map

Required credentials to fix the issue: The same user that setup dual-write.

You might receive the following error message when you try to configure a new table for dual-write. The only user that can create a map is the user who setup the dual-write connection.

Response status code does not indicate success: 401 (Unauthorized)

Error when you open the dual-write user interface

You might receive the following error message when you try to access dual-write from the **Data management** workspace:

login.microsoftonline.com refused to connect.

To fix the issue, sign in by using an InPrivate window in Microsoft Edge, an incognito window in Chromium, or an incognito window in Google Chrome. You must also unblock or clear third-party cookies.

Error when you link the environment for dual-write or add a new

table mapping

Required role to fix the issue: System administrator in both Finance and Operations apps and Dataverse.

You might encounter the following error when linking or creating maps:

Response status code does not indicate success: 403 (tokenexchange).
Session ID: <your session id>
Root activity ID: <your root activity id>

This error can occur if you don't have sufficient permissions to link dual-write or create maps. This error can also occur if the Dataverse environment was reset without unlinking dual-write. Any user with system administrator role in both Finance and Operations apps and Dataverse can link the environments. Only the user who setup the dual-write connection can add new table maps. After setup, any user with system administrator role can monitor the status and edit the mappings.

Error when you stop the table mapping

You might receive the following error message when you try to stop the table mappings:

[Forbidden], [{"status":403,"source":"","message":"Error from token exchange: User is not allowed to access connection dynamicscrmonline/xxxxxx-xxxx-xxxx-xxxxxxxx"}], The remote server returned an error: (403) Forbidden.

This error occurs when the linked Dataverse environment isn't available.

To fix the issue, create a ticket for the Data Integration team. Attach the network trace so that the Data Integration team can mark the maps as **Not running** in the back end.

Error while trying to start a table mapping

You might receive an error like the following when you try to set that state of a mapping to **Running**:

Unable to complete initial data sync. Error: dual-write failure - plugin registration failed: Unable to build dual-write lookup metadata. Error object reference not set to an instance of an object.

The fix for this error depends on the cause of the error:

- If the mapping has dependent mappings, then make sure to enable the dependent mappings of this table mapping.
- The mapping might be missing source or destination columns. If a column in the Finance and Operations app is missing, then follow the steps in the section Missing table columns issue on maps. If a column in Dataverse is missing, then click **Refresh tables** button on the mapping so that the columns are automatically populated back into the mapping.

Troubleshoot live synchronization issues

2/18/2021 • 4 minutes to read • Edit Online

NOTE

Effective November 2020:

- Common Data Service has been renamed to Microsoft Dataverse. For more information, see Power Automate Blog.
- Some terminology in Microsoft Dataverse has been updated. For example, *entity* is now *table* and *field* is now *column*. For more information, see Terminology updates.

This topic will be updated soon to reflect the latest terminology.

This topic provides troubleshooting information for dual-write integration between Finance and Operations apps and Dataverse. Specifically, it provides information that can help you fix issues with live synchronization.

IMPORTANT

Some of the issues that this topic addresses might require either the system admin role or Microsoft Azure Active Directory (Azure AD) tenant admin credentials. The section for each issue explains whether a specific role or credentials are required.

Live synchronization throws a 403 Forbidden error when you create a row in a Finance and Operations app

You might receive the following error message when you create a row in a Finance and Operations app:

[{\"error\":{\"code\":\"0x80072560\",\"message\":\"The user is not a member of the organization.\"}}], The remote server returned an error: (403) Forbidden."}}".

To fix the issue, follow the steps in System requirements and prerequisites. To complete those steps, the dual-write application users who are created in Dataverse must have the system admin role. The default owning team must also have the system admin role.

Live synchronization for any table consistently throws a similar error when you create a row in a Finance and Operations app

Required role to fix the issue: System admin

You might receive an error message like the following every time that you try to save table data in a Finance and Operations app:

Cannot save the changes to the database. Unit of Work can not commit transaction. Unable to write data to entity uoms. Writes to UnitOfMeasureEntity failed with error message Unable to sync with entity uoms.

To fix the issue, you must make sure that the prerequisite reference data exists in both the Finance and Operations app and Dataverse. For example, if the customer that you're in the Finance and Operations app belongs to a specific customer group, make sure that the customer group exists in Dataverse.

If data exists on both sides, and you've confirmed that the issue isn't data-related, follow these steps.

1. Stop the related table.

2. Sign in to the Finance and Operations app, and make sure that rows for the failing table exist in the DualWriteProjectConfiguration and DualWriteProjectFieldConfiguration tables. For example, here is what the query looks like if the **Customers** table is failing.

```
Select projectname, externalenvironmentURL ,\*
from DUALWRITEPROJECTCONFIGURATION
where INTERNALENTITYNAME = 'Customers V3' and
    EXTERNALENTITYNAME = 'accounts'
```

3. If there are rows for the failing table even after you stop the table mapping, delete the rows that are related to the failing table. Make a note of the **projectname** column in the DualWriteProjectConfiguration table, and fetch the row in the DualWriteProjectFieldConfiguration table by using the project name to delete the row.
4. Start the table mapping. Validate whether the data is synced without any issues.

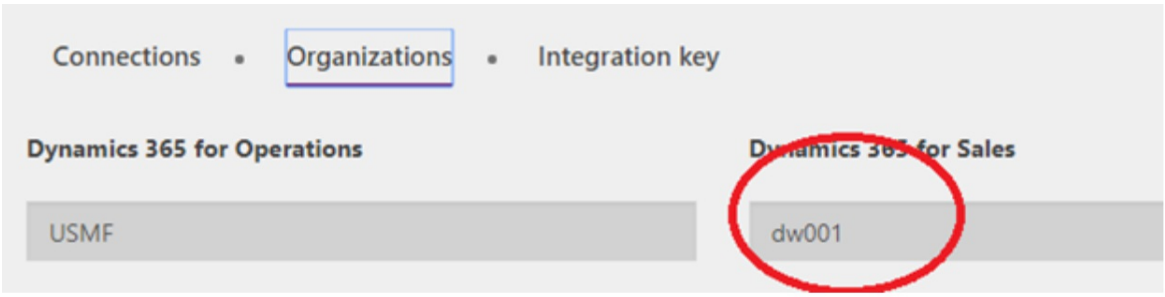
Handle read or write privilege errors when you create data in a Finance and Operations app

You might receive a "Bad Request" error message that resembles the following example when you create data in a Finance and Operations app.

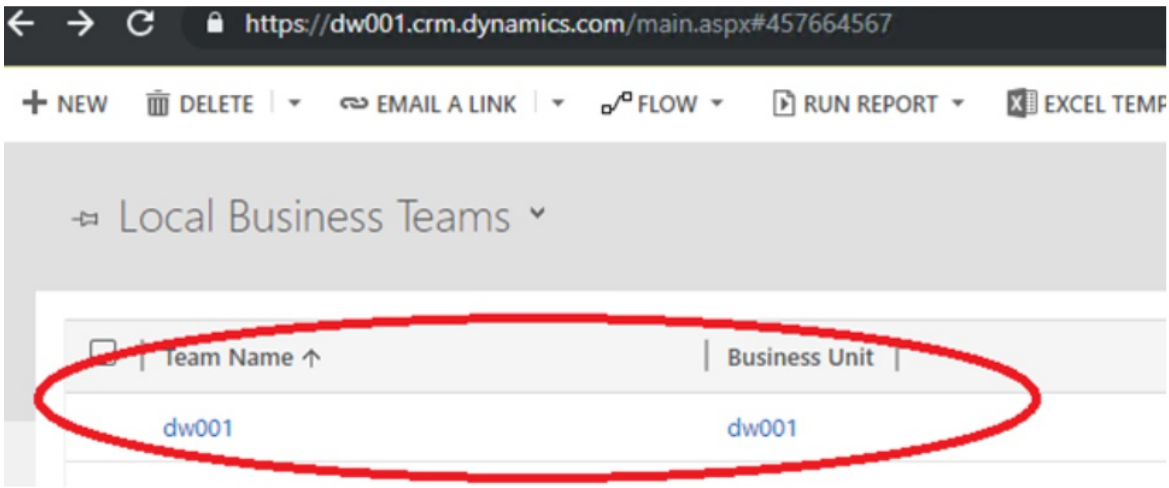
RECORD ID IN SOURCE	SOURCE FIELD WITH ISSUE	ERROR MESSAGE
	POST	Bad Request {"error":{"code":"0x80042f0a","message":"Principal team

To fix the issue, you must assign the correct security role to the team of the mapped Dynamics 365 Sales or Dynamics 365 Customer Service business unit to enable the missing privilege.

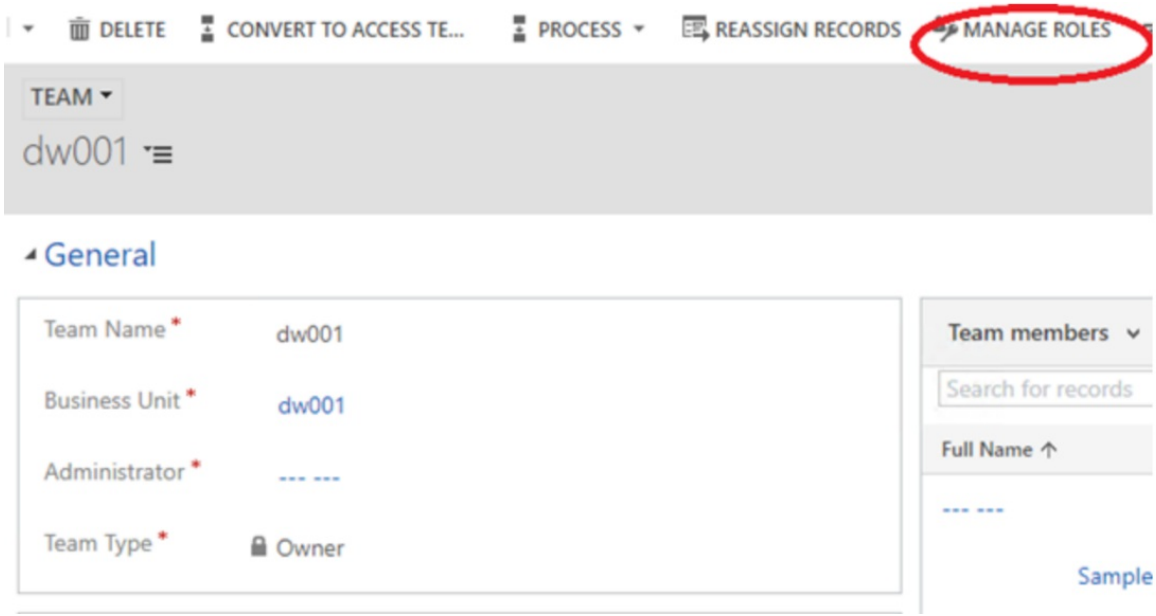
1. In the Finance and Operations app, find the business unit that is mapped in the Data Integration connection set.



2. Sign in to the environment in the model-driven app in Dynamics 365, navigate to **Setting > Security**, and find the team of the mapped business unit.



3. Open the page for the team for editing, and then select **Manage roles** to open the **Manage Team Roles** dialog box.



4. Assign the role that has the read/write privilege for the relevant tables, and then select **OK**.

Fix synchronization issues in an environment that has a recently changed Dataverse environment

Required role to fix the issue: System admin

You might receive the following error message when you create data in a Finance and Operations app:

*{"entityName":"CustCustomerV3Entity","executionStatus":2,"fieldResponses":[],"recordResponses":[{"errorMessage":"**Unable to generate payload for entity CustCustomerV3Entity**","logDateTime":"2019-08-27T18:51:52.5843124Z","verboseError":"Payload creation failed with error Invalid URI: The URI is empty."}],"isErrorCountUpdated":true}*

Here is what the error looks like in the model-driven app in Dynamics 365:

An unexpected error occurred from ISV code. (ErrorType = ClientError) Unexpected exception from plug-in (Execute): Microsoft.Dynamics.Integrator.DualWriteRuntime.Plugins.PostCommitPlugin: System.Exception: failed to process entity account - (A connection attempt failed because the connected party did not properly respond after a period of time, or established connection failed because connected host has failed to respond

This error occurs when the Dataverse environment is incorrectly reset at the same time that you try to create

data in the Finance and Operations app.

To fix the issue, follow these steps.

1. Sign in to the Finance and Operations virtual machine (VM), open SQL Server Management Studio (SSMS), and look for rows in the DUALWRITEPROJECTCONFIGURATIONENTITY table where **internalentityname** equals **Customers V3** and **externalentityname** equals **accounts**. Here is what the query looks like.

   ```
   select projectname, externalenvironmentURL ,\*
   from DUALWRITEPROJECTCONFIGURATION
   where INTERNALENTITYNAME = 'Customers V3' and EXTERNALENTITYNAME = 'accounts'
   ```

2. Use the project name from the results of the previous query to run the following query.

   ```
   select \*
   from DUALWRITEPROJECTFIELDCONFIGURATION
   where projectname = <project name from previous query>
   ```

3. Make sure that the **externalenvironmentURL** column has the correct Dataverse or app URL. Delete any duplicate rows that point to the wrong Dataverse URL. Delete the corresponding rows in the DUALWRITEPROJECTFIELDCONFIGURATION and DUALWRITEPROJECTCONFIGURATION tables.

4. Stop the table mapping, and then restart it

Troubleshoot issues related to solution awareness

2/18/2021 • 2 minutes to read • Edit Online

NOTE

Effective November 2020:

- Common Data Service has been renamed to Microsoft Dataverse. For more information, see Power Automate Blog.
- Some terminology in Microsoft Dataverse has been updated. For example, *entity* is now *table* and *field* is now *column*. For more information, see Terminology updates.

This topic will be updated soon to reflect the latest terminology.

This topic provides troubleshooting information for dual-write integration between Finance and Operations apps and Dataverse. Specifically, it provides information that can help you fix issues that are related to solution awareness.

IMPORTANT

Some of the issues that this topic addresses might require either the system admin role or Microsoft Azure Active Directory (Azure AD) tenant admin credentials. The section for each issue explains whether a specific role or credentials are required.

Error on the Dual-write page

On the **Dual-write** page, you might receive an error message that resembles the following example:

The entity with a name 'msdyn_dualwriteentitymap' with namemapping='Logical' was not found in the MetadataCache.

To fix the issue, make sure that the dual-write core solution is installed in Dataverse. The dual-write core solution is a prerequisite for solution awareness.

NOTE

Can you tell us about your documentation language preferences? Take a short survey.

The survey will take about seven minutes. No personal data is collected (privacy statement).

Troubleshoot issues from upgrades of Finance and Operations apps

2/18/2021 • 3 minutes to read • Edit Online

NOTE

Effective November 2020:

- Common Data Service has been renamed to Microsoft Dataverse. For more information, see Power Automate Blog.
- Some terminology in Microsoft Dataverse has been updated. For example, *entity* is now *table* and *field* is now *column*. For more information, see Terminology updates.

This topic will be updated soon to reflect the latest terminology.

This topic provides troubleshooting information for dual-write integration between Finance and Operations apps and Dataverse. Specifically, it provides information that can help you fix issues that are related to upgrades of Finance and Operations apps.

IMPORTANT

Some of the issues that this topic addresses might require either the system admin role or Microsoft Azure Active Directory (Azure AD) tenant admin credentials. The section for each issue explains whether a specific role or credentials are required.

Database synchronization errors

Required role to fix the issue: System admin

You might receive an error message that resembles the following example when you try to use the **DualWriteProjectConfiguration** table to update a Finance and Operations app to Platform update 30.

```
Infolog diagnostic message: 'Cannot select a row in Dual write project sync (DualWriteProjectConfiguration).
The SQL database has issued an error.' on category 'Error'. 10/28/2019 15:18:20: Infolog diagnostic message:
'Object Server Database Synchronizer: ' on category 'Error'. 10/28/2019 15:18:20: Infolog diagnostic
message: '[Microsoft][ODBC Driver 17 for SQL Server][SQL Server]Invalid column name 'ISDELETE'.' on category
'Error'. 10/28/2019 15:18:20: Infolog diagnostic message: 'SELECT
T1.PROJECTNAME,T1.EXTERNALENTITYNAME,T1.INTERNALENTITYNAME,T1.EXTERNALENVIRONMENTURL,T1.STATUS,T1.ENABLEBATC
HLOOKUP,T1.PARTITIONMAP,T1.QUERYFILTEREXPRESSION,T1.INTEGRATIONKEY,T1.ISDELETE,T1.ISDEBUGMODE,T1.RECVERSION,
T1.PARTITION,T1.RECID FROM DUALWRITEPROJECTCONFIGURATION T1 WHERE (PARTITION=5637144576)' on category
'Error'. 10/28/2019 15:18:20: Infolog diagnostic message: 'session 1043 (Admin)' on category 'Error'.
10/28/2019 15:18:20: Infolog diagnostic message: 'Stack trace: Call to TTSCOMMIT without first calling
TTSBEGIN.' on category 'Error'.
10/28/2019 15:18:20: Application configuration sync failed.
Microsoft.Dynamics.AX.Framework.Database.TableSyncException: Custom action threw exception(s), please
investigate before synchronizing again: 'InfoException:Stack trace: Call to TTSCOMMIT without first calling
TTSBEGIN."
```

To fix the issue, follow these steps.

1. Sign in to the virtual machine (VM) for the Finance and Operations app.
2. Open Visual Studio as an admin, and open the Application Object Tree (AOT).
3. Search for **DualWriteProjectConfiguration**.

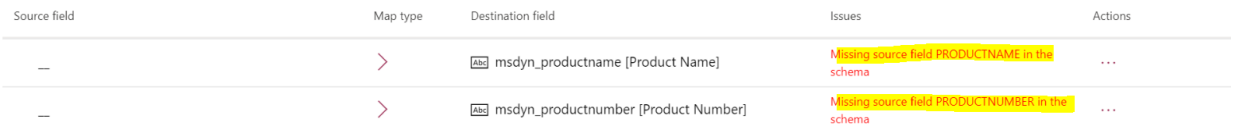
4. In the AOT, right-click **DualWriteProjectConfiguration**, and select **Add to new project**. Select **OK** to create the new project that uses default options.
5. In Solution Explorer, right-click **Project properties**, and set **Synchronize Database on Build** to **True**.
6. Build the project, and confirm that the build is successful.
7. On the **Dynamics 365** menu, select **Synchronize database**.
8. Select **Synchronize** to do a full database synchronization.
9. After the full database synchronization is successful, rerun the database synchronization step in Microsoft Dynamics Lifecycle Services (LCS) and use the manual upgrade scripts as applicable, so that you can proceed with the update.

Missing table columns issue on maps

Required role to fix the issue: System admin

On the **Dual-write** page, you might receive an error message that resembles the following example:

Missing source field <field name> in the schema.



To fix the issue, first follow these steps to make sure that the columns are in the table.

1. Sign in to the VM for the Finance and Operations app.
2. Go to **Workspaces > Data management**, select the **Framework parameters** tile, and then, on the **Table settings** tab, select **Refresh table list** to refresh the tables.
3. Go to **Workspaces > Data management**, select the **Data tables** tab, and make sure that the table is listed. If the table isn't listed, sign in to the VM for the Finance and Operations app, and make sure the table is available.
4. Open the **Table mapping** page from the **Dual-write** page in the Finance and Operations app.
5. Select **Refresh table list** to automatically fill the columns in the table mappings.

If the issue still isn't fixed, follow these steps.

> **IMPORTANT**
> These steps guide you through the process of deleting a table and then adding it again. To avoid issues, be sure to follow the steps exactly.

1. In the Finance and Operations app, go to **Workspaces > Data management**, and select the **Data tables** tile.
2. Find the table that is missing the attribute. Click **Modify target mapping** in the toolbar.
3. On the **Map staging to target** pane, click **Generate mapping**.
4. Open the **Table mapping** page from the **Dual-write** page in the Finance and Operations app.
5. If the attribute is not auto-populated on the map, add it manually by clicking **Add attribute** button and then clicking **Save**.
6. Select the map and click **Run**.

NOTE

Can you tell us about your documentation language preferences? Take a short survey.

The survey will take about seven minutes. No personal data is collected (privacy statement).

General troubleshooting

2/18/2021 • 4 minutes to read • Edit Online

NOTE

Effective November 2020:

- Common Data Service has been renamed to Microsoft Dataverse. For more information, see Power Automate Blog.
- Some terminology in Microsoft Dataverse has been updated. For example, *entity* is now *table* and *field* is now *column*. For more information, see Terminology updates.

This topic will be updated soon to reflect the latest terminology.

This topic provides general troubleshooting information for dual-write integration between Finance and Operations apps and Dataverse.

IMPORTANT

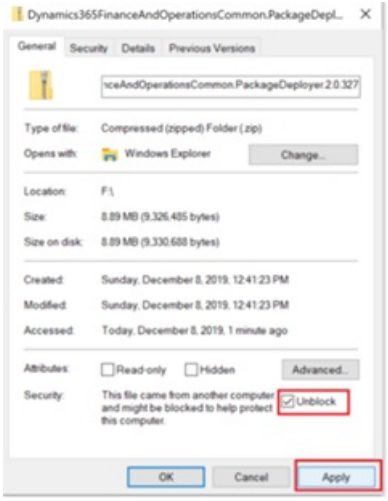
Some of the issues that this topic addresses might require either the system admin role or Microsoft Azure Active Directory (Azure AD) tenant admin credentials. The section for each issue explains whether a specific role or credentials are required.

When you try to install the dual-write package by using the package deployer tool, no available solutions are shown

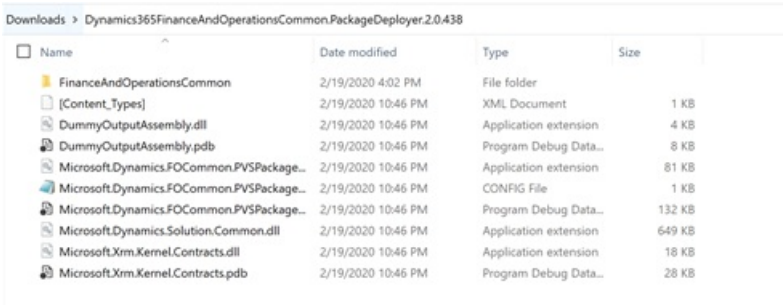
Some versions of the package deployer tool are incompatible with the dual-write solution package. To successfully install the package, be sure to use version 9.1.0.20 or later of the package deployer tool.

After you install the package deployer tool, install the solution package by following these steps.

1. Download the latest solution package file from Yammer.com. After the package zip file is downloaded, right-click it, and select **Properties**. Select the **Unblock** check box, and then select **Apply**. If you don't see the **Unblock** check box, the zip file is already unblocked, and you can skip this step.

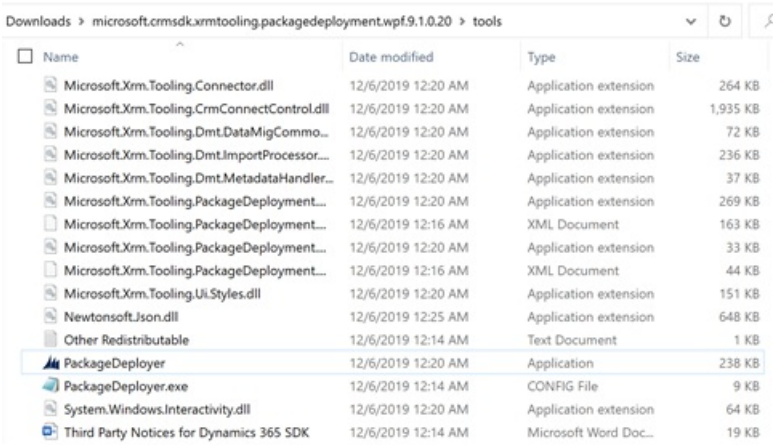


2. Extract the package zip file, and copy all the files in the **Dynamics365FinanceAndOperationsCommon.PackageDeployer.2.0.438** folder.



3. Paste all the copied files into the **Tools** folder of the package deployer tool.

4. Run **PackageDeployer.exe** to select the Dataverse environment and install the solutions.



Enable and view the plug-in trace log in Dataverse to view error details

Required role to turn on the trace log and view errors: System admin

To turn on the trace log, follow these steps.

1. Sign in to the model-driven app in Dynamics 365, open the **Settings** page, and then, under **System**, select **Administration**.
2. On the **Administration** page, select **System Settings**.
3. On the **Customization** tab, in the **Plug-in and custom workflow activity tracing** column, select **All** to enable the plug-in trace log. If you want to log trace logs only when exceptions occur, you can select **Exception** instead.

To view the trace log, follow these steps.

1. Sign in to the model-driven app in Dynamics 365, open the **Settings** page, and then, under **Customization**, select **Plug-in Trace Log**.
2. Find the trace logs where the **Type Name** column is set to **Microsoft.Dynamics.Integrator.DualWriteRuntime.Plugins.PreCommmitPlugin**.
3. Double-click an item to view the full log, and then, on the **Execution** FastTab, review the **Message Block** text.

Enable debug mode to troubleshoot live synchronization issues in Finance and Operations apps

Required role to view the errors: System admin Dual-write errors that originate in Dataverse can appear in the Finance and Operations app. In some cases, the full text of the error message isn't available because the message is too long or contains personally identifying information (PII). You can turn on verbose logging for

errors by following these steps.

1. All project configurations in Finance and Operations apps have an **IsDebugMode** property in the **DualWriteProjectConfiguration** table. Open the **DualWriteProjectConfiguration** table by using the Excel add-in.

   > **TIP**
   > An easy way to open the table is to turn on **Design** mode in the Excel add-in and then add **DualWriteProjectConfigurationEntity** to the worksheet. For more information, see Open table data in Excel and update it by using the Excel add-in.

2. Set the **IsDebugMode** property to **Yes** for the project.
3. Run the scenario that is generating errors.
4. The verbose logs are available in the DualWriteErrorLog table. To look up data in the table browser, use the following URL (replace **XXX** as appropriate):

   ```
   https://XXXaos.cloudax.dynamics.com/?mi=SysTableBrowser&tableName=DualWriteErrorLog
   ```

Check synchronization errors on the virtual machine for the Finance and Operations app

Required role to view the errors: System administrator

1. Sign in to Microsoft Dynamics Lifecycle Services (LCS).
2. Open the LCS project that you chose to do the dual-write testing for.
3. Select the **Cloud-hosted environments** tile.
4. Use Remote Desktop to sign in to the virtual machine (VM) for the Finance and Operations app. Use the local account that is shown in LCS.
5. Open Event viewer.
6. Select **Applications and Services Logs > Microsoft > Dynamics > AX-DualWriteSync > Operational**.
7. Review the list of recent errors.

Unlink and link another Dataverse environment from a Finance and Operations app

Required role to unlink the environment: System administrator for either Finance and Operations app or Dataverse.

1. Sign in to the Finance and Operations app.
2. Go to **Workspaces > Data management**, and select the **Dual Write** tile.
3. Select all running mappings, and then select **Stop**.
4. Select **Unlink environment**.
5. Select **Yes** to confirm the operation.

You can now link a new environment.

Unable to view the sales order line Information form

When you create a sales order in Dynamics 365 Sales, clicking on **+ Add products** might redirect you to the Dynamics 365 Project Operations order line form. There is no way from that form to view the sales order line

Information form. The option for **Information** does not appear in the dropdown below **New Order Line**. This happens because Project Operations has been installed in your environment.

To re-enable the **Information** form option, follow these steps:

1. Navigate to the **Order Line** table.
2. Find the **Information** form under the forms node.
3. Select the **Information** form and click **Enable security roles**.
4. Change the security setting to **Display to everyone**.

Dual-write FAQ

2/18/2021 • 9 minutes to read • Edit Online

NOTE

Effective November 2020:

- Common Data Service has been renamed to Microsoft Dataverse. For more information, see Power Automate Blog.
- Some terminology in Microsoft Dataverse has been updated. For example, *entity* is now *table* and *field* is now *column*. For more information, see Terminology updates.

This topic will be updated soon to reflect the latest terminology.

This topic lists frequently asked questions about dual-write and provides brief answers to help you quickly get the information that you require.

Dual-write setup

Do you plan to enable dual-write to use Dataverse as a hub between multiple Finance and Operations environments? If Dataverse is used as a hub, data can be synced between two or more Finance and Operations environments.

The current plan of row is to restrict dual-write to a one-to-one (1:1) mapping between a single Finance and Operations environment and a single Dataverse environment.

Can I control the sequencing of maps in dual-write, as I can in Data integrator?

Dual-write is transaction-based. For example, if a change in a Finance and Operations app triggers synchronization of multiple maps with Dataverse, by default, those changes will be sequenced in the order in which they are updated in the database. This pattern makes more sense in the context of initial synchronization. The system provides related table maps in a specified order, and you can reorder the list so that it best suits your environment.

Do application users require any special permissions to enable or configure dual-write?

You must have two Azure Active Directory (Azure AD) applications set up for the Finance and Operations environment and two application users set up in the Dataverse environment. These application users should contain the appropriate application IDs. For the connection to work properly, you must give the applications the relevant table permissions by using a security role. For more information, see Verify requirements and grant access.

Do end users require any special permissions to enable or configure dual-write?

End users who are configuring dual-write mappings should have System Administrator security roles assigned in both Dataverse and Finance and Operations environments.

Dual-write mappings can be accessed by multiple users, as long as all the users and environments belong to a single tenant, and the user has the required security and licenses assignment.

I have multiple legal entities. Some of my maps are legal table–specific or valid for only some of the legal entities. What is the best way to address this requirement? Can I apply a filter such as Company = USMF to address it?

Legal table mapping can be done when the Dataverse environment is linked. You can't map table maps to a specific legal entity.

If dual-write solutions are installed in Dataverse, can I uninstall them?

Dual-write solutions are managed solutions that can be uninstalled. However, when a managed solution is uninstalled, all components in the solution are deleted. Any data that is stored in the components is also deleted. For more information, see Maintain managed solutions.

I have data in both a customer engagement app and a Finance and Operations app, and I bootstrap my existing data in the customer engagement app. If my data isn't currently aligned, can I specify a master source for the initialization run, so that all differences are applied to the target?

After the bootstrapping is done, you can configure the initial synchronization to apply differences and select a master. For more information about bootstrapping, see Bootstrap with company data FAQ. For more information about the initial synchronization, see Enable table maps for dual-write.

Dual-write administration and management

What is the purpose of the integration key, and is it mandatory?

The integration key is the natural key that uniquely identifies rows. Integration keys are required only for Dataverse tables. You can manually create an integration key in dual-write. An integration key can also be automatically created from the table's alternate keys, if an alternate key is already provided for the table. Integration keys are used for the same purpose as alternate keys: they provide an efficient and accurate way to integrate data with external systems. Integration keys are essential in cases where an external system doesn't store the globally unique identifiers (GUIDs) that uniquely identify rows in Dataverse.

Dual-write uses integration keys to uniquely identify rows, by using one or more table column values that represent a unique combination. For example, to identify an account row by using an integration key, you can use the account number column. Alternatively, you can use the account number column together with other columns that have values that should not change. For more information, see Define alternate keys using Power Apps portal.

It's important that keys be matched between the Finance and Operations environment and the Dataverse environment. Otherwise, issues might occur during the initial synchronization phase.

How do I move table maps between environments? Is version control supported for table maps?

You can export maps and then import them into a different environment. You can automate the process by using Azure DevOps. You can have version control on your dual-write mappings, because the mappings are solution-aware components. For more information, see Update table maps and export them to other environments as a solution.

Where can I find examples and patterns for filtering dual-write maps?

For basic filtering examples, see Filter your data.

For more advanced examples for Dataverse, see Filter results. Nested lookup isn't supported in dual-write source filters. Only standard filter operators directly against table columns are supported.

For more advanced Finance and Operations filters, see Using Expressions in Query Ranges and Advanced filtering and query syntax.

Dual-write live synchronization introduces tight coupling across applications. What happens if one side fails? Will the other side fail too?

When the integration is in live sync mode, if the sync fails on one of the apps, then the other app will fail as well and users will receive an error. When the integration is paused, changes are staged. They are then written when the target system is up and running. For more information about how to automatically pause integrations, see Alert notifications

When live synchronization is paused and then resumed, does it follow the sequence of changes? For example, if the Name column in the Finance and Operations app is changed from NameA to NameB to NameC, is customer engagement data changed from NameA to NameB to NameC, or is it changed directly from NameA to NameC?

The integration follows the complete sequence of changes. In the example, the customer engagement app data is changed from **NameA** to **NameB** to **NameC**.

How do I handle a Finance and Operations database transfer from PROD to STAGE? What is the effect on dual-write? After the transfer, the systems are no longer in sync. Is the synchronization done automatically?

Each linked environment-pair (Finance and Operations apps environment and Dataverse environment) should be treated as a single unit and refreshed accordingly. For example, if you are refreshing a sandbox from production, then both Finance and Operations app sandbox environment and the Dataverse sandbox environment should be refreshed from their production counterparts. If dual-write is already used in target environments, those environments need to be unlinked. After the data refresh on target environments, these tables should be cleaned up:

- Finance and Operations apps tables: **DualWriteProjectConfiguration**, **DualWriteProjectFieldConfiguration**, and **BusinessEventsDefinition**.
- Dataverse tables: **DualwriteRuntimeConfiguration**.

The environments need to be relinked and maps reactivated manually.

I need real-time integration, and I want to move some tables or scenarios from Data integrator to dual-write. How do I migrate, and what are the implications of changing my integration pattern?

For information about how to migrate Prospect to cash to dual-write, see Migrating data from Data Integrator to Dual Write. In general, three things might change during migration:

- Manual migration of the maps from Data integrator to dual-write
- Table changes, because of the absence of advanced query capabilities
- Data migration, because of adaptation to new concepts such as company striping

On Finance and Operations data tables, can I develop unbounded columns that flow to Dataverse by using dual-write?

Yes. You can use both computed columns and virtual columns. However, you should monitor the performance overhead from the additional X++ logic that is required for reads and writes. Round-tripping within the same transaction isn't allowed. Therefore, you should avoid using virtual columns to transform or calculate additional values through X++ and expect that to go back to Dataverse within the same transaction.

When I use the Dataverse offline app, what happens if I can't sync the data after reconnection? Does this situation cause an inconsistent state between the Dataverse environment and the Finance and Operations environment?

You can interact with Dataverse data offline when using the Dynamics 365 for phones app or the Field Service Mobile app in offline mode. In both apps, data is stored offline and can be synced with the server at your discretion. If there are errors when the offline data is synced with the server, and updates can't be done because the other environment is failing, data sync will fail, and Dataverse will not be updated. When the integration is paused, you can re-run the sync and save your updates on the server. These changes will be staged and then synced with the Finance and Operations environment when the mapping is up and running again. For more information, see Run model-driven apps and canvas apps on Power Apps mobile.

Mapping concepts between apps

How are number sequences handled? For example, the customer account number is automatically generated in Finance and Operations apps, but it's added manually in customer engagement apps.

Number sequences for Finance and Operations apps and customer engagement apps aren't connected. In a scenario that involves a multi-mastered table, you must either plan for separate number sequence formats or create a range for each app. Here are some examples:

- In the Finance and Operations app, use **F0001, F0002, F0003**. In the customer engagement app, use **C0001, C0002, C0003**.

- In the Finance and Operations app, use **US0001 to US4999**. In the customer engagement app, use **US5000 to US9999**.

If a table is created in only one system, set up the number sequence in the source app only. For more information, see Autonumber columns.

Can I map a company-specific table in a customer engagement app with a global table in a Finance and Operations app, or a global table in a customer engagement app with a company-specific table in a Finance and Operations app?

Dual-write supports mappings only between cross-company tables or company-specific tables from both sides.

How do I make a company-specific table in Dataverse?

You can make Dataverse custom tables company-specific by adding a many-to-one (N:1) relationship between your custom tables and the out-of-box company table. You should also include the company foreign key as part of the table key. For more information, see Company concept in Dataverse.

To enable table maps for dual-write, you must define an alternate key in Dataverse. The value of the alternative key in Dataverse must match the key that is defined in the Finance and Operations app. For more information, see Criteria for linking tables.

Is there a document about best practices for table usage? Should I use Customers V2, Customers V3, or Customer Details? What is the difference between these tables, and what is the use case for each?

You should use the out-of-box scenarios if you can, because they cover common scenarios such as customer/vendor integration.

Prospect to cash

2/18/2021 • 2 minutes to read • Edit Online

The Prospect to cash solution provides direct synchronization across Dynamics 365 Supply Chain Management and Dynamics 365 Sales. The Prospect to cash templates that are available with the Data Integration feature enable the flow of data for accounts, contacts, products, sales quotations, sales orders, and sales invoices. While data is flowing, you can perform sales and marketing activities in Sales, and you can handle order fulfillment by using inventory management in Supply Chain Management.

For more information about the Prospect to cash integration, watch the short YouTube video Prospect to cash integration.

In the current version, the Prospect to cash solution provides the following types of direct synchronization:

- Synchronize accounts directly from Sales to customers in Supply Chain Management
- Synchronize products directly from Supply Chain Management to products in Sales
- Synchronize contacts directly from Sales to contacts or customers in Supply Chain Management
- Synchronize sales quotation headers and lines directly from Sales to Supply Chain Management
- Synchronization of sales orders directly between Sales and Supply Chain Management
- Synchronize sales invoice headers and lines directly from Supply Chain Management to Sales

System requirements for Supply Chain Management

Prospect to cash integration is supported on the following versions:

Microsoft Dynamics 365 for Finance and Operations, Enterprise edition 7.3 (December 2017)

- Dynamics 365 for Finance and Operations, Enterprise edition (December 2017) - Application build 7.3.11971.56116 with Platform Update 12 (7.0.4709.41129)

Dynamics 365 for Finance and Operations, Enterprise edition (July 2017)

- Dynamics 365 for Finance and Operations, Enterprise edition (July 2017) - with platform update 8 (application build 7.2.11792.56024 with platform build 7.0.4565.16212).
- The following hotfixes are required:
  - **KB4045570** – This hotfix enables sales order synchronization from Sales to Supply Chain Management via the Data Integration feature. It also provides several other enhancements.
  - **KB4036524** – This hotfix enables sales order line synchronization from Supply Chain Management to Sales via the Data Integration feature.
  - **KB4036461** – This hotfix enables sales order synchronization from Supply Chain Management to Sales via the Data Integration feature.

    > **NOTE**
    > You only have to install KB4045570 because the installation includes the changes from other hotfixes.

Dynamics 365 for Finance and Operations version 1611 (November 2016)

- Dynamics 365 for Finance and Operations version 1611 (November 2016) with platform update 8 or higher

- The following hotfixes are required:
  - KB4051266 - Enable sales order synchronization with Data integrator from Supply Chain Management to Sales.
  - KB4037542 - Enable sales order header and line synchronization with Data integrator from Supply Chain Management to Sales.
  - KB4033093 - Support for prospect to cash integration through data entities is required.

    NOTE

    After you install the hotfixes, you must trigger the following batch job from the **SalesPopulateProspectToCash** form. This form is hidden because you only need it once. To access the form, log in to the environment and add the following to the URL in your browser address: *&mi=action:SalesPopulateProspectToCash*, for example, `https://ax123456.cloud.test.dynamics.com/?cmp=USMF&mi=action:SalesPopulateProspectToCash`. When the form opens, click OK. This will populate a new **LineCreationSequnceNumber** field in the **SalesLine**, **SalesQuotationLine**, and **CustInvoiceTrans** tables with unique values, and the product list will be refreshed. This is required for the Prospect to cash integration to work.

System requirements for Sales

To use the Prospect to cash solution, you must install the following components:

- Dynamics 365 Sales version 1612 (8.2.1.207) (DB 8.2.1.207) online or a later version
- Prospect to cash solution for Dynamics 365 Sales, version 1.15.0.0 or a later version. The solution is available for download from AppSource. Download Dynamics 365, Prospect to Cash.

NOTE

Can you tell us about your documentation language preferences? Take a short survey.

The survey will take about seven minutes. No personal data is collected (privacy statement).

Synchronize accounts directly from Sales to customers in Supply Chain Management

2/18/2021 • 4 minutes to read • Edit Online

NOTE

Effective November 2020:

- Common Data Service has been renamed to Microsoft Dataverse. For more information, see Power Automate Blog.
- Some terminology in Microsoft Dataverse has been updated. For example, *entity* is now *table* and *field* is now *column*. For more information, see Terminology updates.

This topic will be updated soon to reflect the latest terminology.

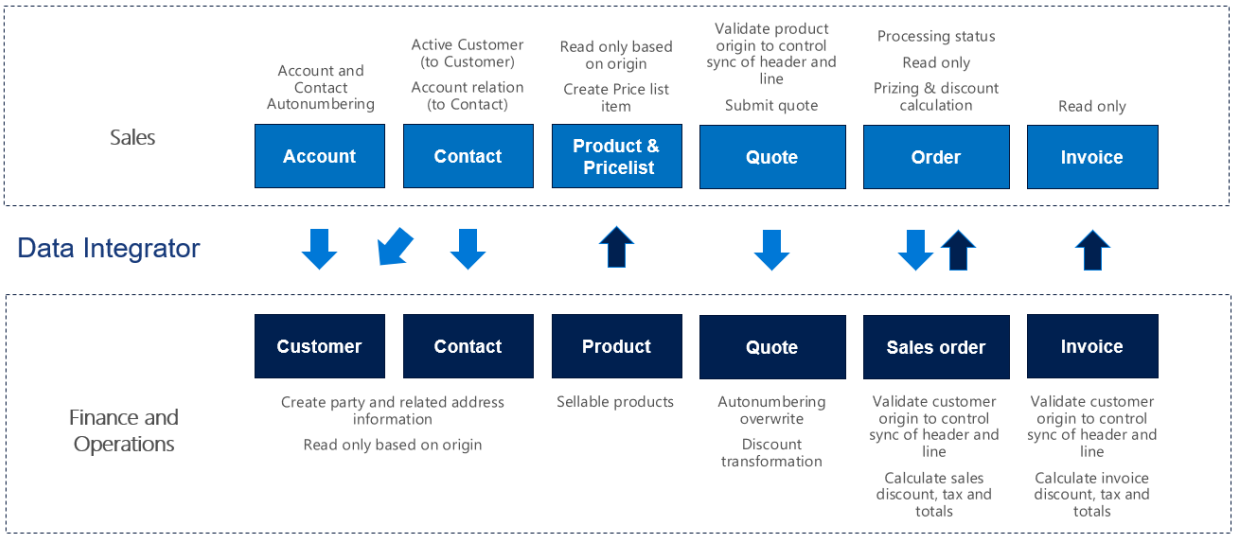
NOTE

Before you can use the Prospect to cash solution, you should be familiar with Integrate data into Microsoft Dataverse for Apps.

This topic discusses the templates and underlying tasks that are used to synchronize accounts directly from Dynamics 365 Sales to Dynamics 365 Supply Chain Management.

Data flow in Prospect to cash

The Prospect to cash solution uses the Data integration feature to synchronize data across instances of Supply Chain Management and Sales. The Prospect to cash templates that are available with the Data integration feature enable the flow of data about accounts, contacts, products, sales quotations, sales orders, and sales invoices between Supply Chain Management and Sales. The following illustration shows how the data is synchronized between Supply Chain Management and Sales.



Templates and tasks

To access the available templates, open Power Apps Admin Center. Select **Projects**, and then, in the upper-right corner, select **New project** to select public templates.

The following template and underlying task are used to synchronize accounts from Sales to Supply Chain Management:

- **Name of the template in Data integration:** Accounts (Sales to Fin and Ops) - Direct
- **Name of the task in the project:** Accounts - Customers

No synchronization tasks are required before Account/Customer synchronization can occur.

Entity set

SALES	SUPPLY CHAIN MANAGEMENT
Accounts	Customers V2

Entity flow

Accounts are managed in Sales and synchronized to Supply Chain Management as customers. The **Is Externally Maintained** property on these customers is set to **Yes** to track customers that originate from Sales. During invoicing, this information is used to filter invoices that are synchronized to Sales.

Prospect to cash solution for Sales

The **Account Number** column is available on the **Account** page. It has been made a natural and unique key in order to support the integration. The natural key feature of the Customer Relationship Management (CRM) solution might affect customers who already use the **Account Number** column, but who don't use unique **Account Number** values per account. Currently, the integration solution doesn't support this case.

When a new account is created, if an **Account Number** value doesn't already exist, it's automatically generated by using a number sequence. The value consists of **ACC**, followed by an increasing number sequence and then a suffix of six characters. Here is an example: **ACC-01000-BVRCPS**

When the integration solution for Sales is applied, an upgrade script sets the **Account Number** column for existing accounts in Sales. If there are no **Account Number** values, the number sequence that was mentioned earlier is used.

Preconditions and mapping setup

- The **CustomerGroupId** mapping must be updated to a valid value in Supply Chain Management. You can specify a default value, or you can set the value by using a value map.

  The default template value is **10**.

- By adding the following mappings, you can help reduce the number of manual updates that are required in Supply Chain Management. You can use a default value or a value map from, for example, **Country/Region** or **City**.

  - **SiteId** – A site is required in order to generate quotations and sales order lines in Supply Chain Management. A default site can be taken either from the product, or from the customer from the order header.

    The default template value is **1**.

  - **WarehouseId** – A warehouse is required in order to process quotations and sales order lines in Supply Chain Management. A default warehouse can be taken either from the product, or from the customer from the order header in Supply Chain Management.

The default template value is **13**.

- **LanguageId** – A language is required in order to generate quotations and sales orders in Supply Chain Management. By default, the language from the order header from the customer is used.

  The default template value is **en-us**.

Template mapping in Data integration

> **NOTE**
>
> The **Payment terms**, **Freight terms**, **Delivery terms**, **Shipping method**, and **Delivery mode** columns aren't included in the default mappings. To map these columns, you must set up a value mapping that is specific to the data in the organizations that the table is synchronized between.

The following illustrations show an example of a template mapping in Data integration.

> **NOTE**
>
> The mapping shows which column information will be synchronized from Sales to Supply Chain Management.

Synchronize products directly from Supply Chain Management to products in Sales

2/18/2021 • 4 minutes to read • Edit Online

NOTE

Effective November 2020:

- Common Data Service has been renamed to Microsoft Dataverse. For more information, see Power Automate Blog.
- Some terminology in Microsoft Dataverse has been updated. For example, *entity* is now *table* and *field* is now *column*. For more information, see Terminology updates.

This topic will be updated soon to reflect the latest terminology.

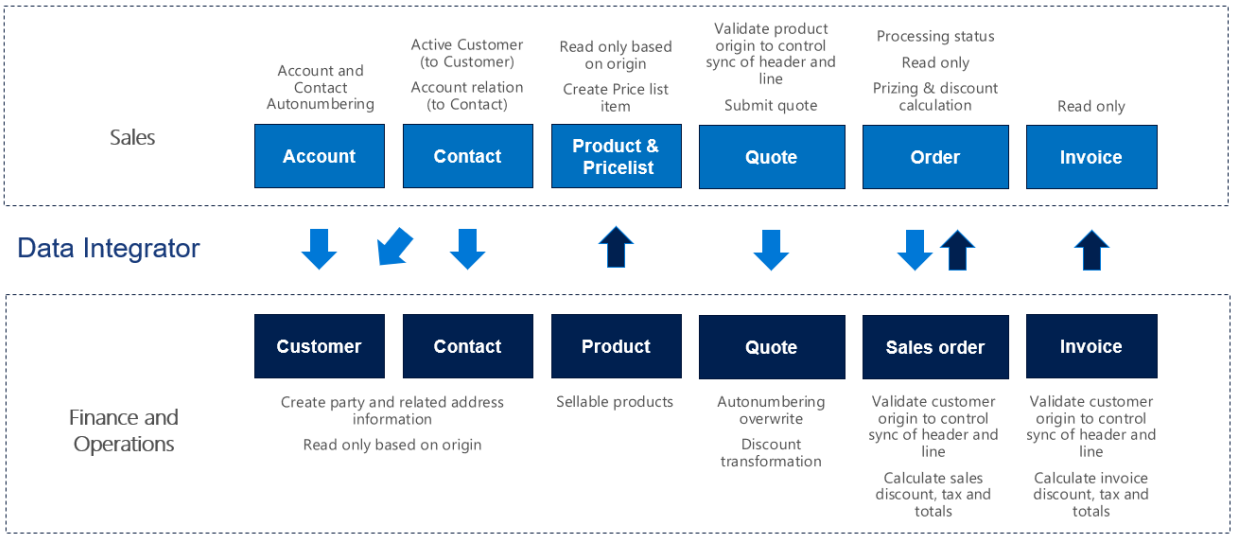
NOTE

Before you can use the Prospect to cash solution, you should be familiar with Integrate data into Microsoft Dataverse for Apps.

This topic discusses the templates and underlying tasks that are used to synchronize products directly from Dynamics 365 Supply Chain Management to Dynamics 365 Sales.

Data flow in Prospect to cash

The Prospect to cash solution uses the Data integration feature to synchronize data across instances of Supply Chain Management and Sales. The Prospect to cash templates that are available with the Data integration feature enable the flow of data about accounts, contacts, products, sales quotations, sales orders, and sales invoices between Supply Chain Management and Sales. The following illustration shows how the data is synchronized between Supply Chain Management and Sales.



Templates and tasks

To access the available templates, open Power Apps Admin Center. Select **Projects**, and then, in the upper-right corner, select **New project** to select public templates.

The following template and underlying tasks are used to synchronize products from Supply Chain Management to Sales.

- **Name of the template in Data integration:** Products (Supply Chain Management to Sales) - Direct
- **Name of the task in the Data integration project:** Products

No synchronization tasks are required before product synchronization can occur.

Entity set

SUPPLY CHAIN MANAGEMENT	SALES
Sellable released products	Products

Entity flow

Products are managed in Supply Chain Management and synchronized to Sales. The **Sellable released products** data entity in Supply Chain Management exports only products that are *sellable*. Sellable products are products that have the information that they require in order to be used on a sales order. The same rules apply when a product is validated by using the **Validate** function on the **Released product** page.

The product number is used as a key. Therefore, when product variants are synchronized to Sales, each product variant has an individual product ID.

Prospect to cash solution for Sales

In Sales, a new **Is Externally Maintained** field has been added on products to indicate that a given product is maintained externally. By default, the value is set to **Yes** during an import to Sales. The following values are available:

- **Yes** – The product originated from Supply Chain Management and won't be editable in Sales.
- **No** – The product was entered directly in Sales.
- **(Blank)** – The product existed in Sales before the Prospect to cash solution was enabled.

The **Is Externally Maintained** field helps ensure that only quotations and sales orders that have externally maintained products will be synchronized to Supply Chain Management.

Externally maintained products are automatically added to the first valid price list that has the same currency. Price lists are organized alphabetically by name. The product sales price from Supply Chain Management is used as the price on the price list. Therefore, there must be a price list in Sales for every product sales currency in Supply Chain Management. The currency on the released sellable products is set to the accounting currency in the legal entity that the product is exported from.

> **NOTE**
>
> - Product synchronization will not succeed unless there is a price list that has a matching currency.
> - You can control the used price list with the integration by mapping the pricelevelid.name [Default Price List (Name)] in the Data Integration project. The input has to be in all lowercase letters. For example, the default for a price list in Sales named 'Standard' would be: Destination field: pricelevelid.name [Default Price List (Name)] and Map type: [{ "transformType": "Default", "defaultValue": "standard" }].

Preconditions and mapping setup

- Before you run the synchronization for the first time, you must fill the Distinct product table for existing

products in Supply Chain Management. Existing products won't be synchronized until this job is completed.

1. In Supply Chain Management, use Search to search for **Populate distinct product table**.
2. Select **Populate distinct product table** to run the job. This job must be run only one time.

- Make sure that the required value map for the selling unit of measure (UOM) between Supply Chain Management and Sales exists in the mapping of **SalesUnitSymbol** to **DefaultUnit (Name)**.
- Update the value map for **Unit group** (**defaultuomscheduleid.name**) so that it matches **Unit groups** in Sales.

  The default template value is **Default unit**.
- Make sure that the selling UOMs for all products from Supply Chain Management exist in Sales.
- Make sure that price lists exist in Sales for every product sales currency in Supply Chain Management.
- When products are created in Sales, they can have a status of **Draft** or **Active**. The behavior is controlled at **Settings** > **Administration** > **System settings** > **Sales** in Sales.

  Products that have **Draft** status when they are created must be activated before they can be added to quotations or sales orders.

Template mapping in Data integration

The following illustration shows an example of a template mapping in Data integration.

> **NOTE**
> The mapping shows which field information will be synchronized from Sales to Supply Chain Management.

Synchronize contacts directly from Sales to contacts or customers in Supply Chain Management

2/18/2021 • 4 minutes to read • Edit Online

NOTE

Effective November 2020:

- Common Data Service has been renamed to Microsoft Dataverse. For more information, see Power Automate Blog.
- Some terminology in Microsoft Dataverse has been updated. For example, *entity* is now *table* and *field* is now *column*. For more information, see Terminology updates.

This topic will be updated soon to reflect the latest terminology.

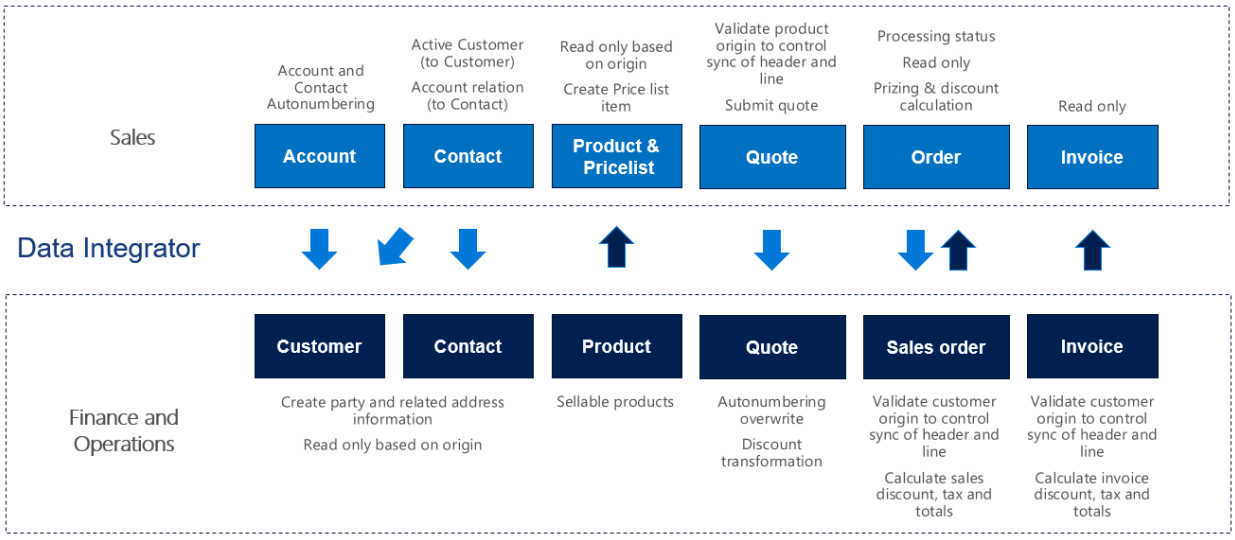
NOTE

Before you can use the Prospect to cash solution, you should be familiar with Integrate data into Microsoft Dataverse for Apps.

This topic discusses the templates and underlying tasks that are used to synchronize Contact (Contacts) and Contact (Customers) tables directly from Dynamics 365 Sales to Dynamics 365 Supply Chain Management.

Data flow in Prospect to cash

The Prospect to cash solution uses the Data integration feature to synchronize data across instances of Supply Chain Management and Sales. The Prospect to cash templates that are available with the Data integration feature enable the flow of data about accounts, contacts, products, sales quotations, sales orders, and sales invoices between Supply Chain Management and Sales. The following illustration shows how the data is synchronized between Supply Chain Management and Sales.



Templates and tasks

To access the available templates, open PowerApps Admin Center. Select **Projects**, and then, in the upper-right corner, select **New project** to select public templates.

The following templates and underlying tasks are used to synchronize Contact (Contacts) tables in Sales to Contact (Customers) tables in Supply Chain Management.

- **Names of the templates in Data integration**
  - Contacts (Sales to Supply Chain Management) - Direct
  - Contacts to Customer (Sales to Supply Chain Management) - Direct
- **Names of the tasks in the Data integration project**
  - Contacts
  - ContactToCustomer

The following synchronization task is required before contact synchronization can occur: Accounts (Sales to Supply Chain Management)

Entity sets

SALES	SUPPLY CHAIN MANAGEMENT
Contacts	Dataverse Contacts
Contacts	Customers V2

Entity flow

Contacts are managed in Sales and synchronized to Supply Chain Management.

A contact in Sales can become either a contact or a customer in Supply Chain Management. To determine whether a contact in Sales should be synchronized to Supply Chain Management as a contact or a customer, the system looks at the following properties on the contact in Sales:

- **Synchronization to a customer in Supply Chain Management**: Contacts where **Is Active Customer** is set to **Yes**
- **Synchronization to a contact in Supply Chain Management**: Contacts where **Is Active Customer** is set to **No** and **Company** (parent account/contact) points to an account (not a contact)

Prospect to cash solution for Sales

A new **Is Active Customer** column has been added to the contact. This column is used to differentiate contacts that have sales activity and contacts that don't have sales activity. **Is Active Customer** is set to **Yes** only for contacts that have related quotations, orders, or invoices. Only those contacts are synchronized to Supply Chain Management as customers.

A new **IsCompanyAnAccount** column has been added to the contact. This column indicates whether a contact is linked to a company (parent account/contact) of the **Account** type. This information is used to identify contacts that should be synchronized to Supply Chain Management as contacts.

A new **Contact Number** column has been added to the contact to help guarantee a natural and unique key for the integration. When a new contact is created, a **Contact Number** value is automatically generated by using a number sequence. The value consists of **CON**, followed by an increasing number sequence and then a suffix of six characters. Here is an example: **CON-01000-BVRCPS**

When the integration solution for Sales is applied, an upgrade script sets the **Contact Number** column for existing contacts by using the number sequence that was mentioned earlier. The upgrade script also sets the **Is Active Customer** column to **Yes** for any contacts that have sales activity.

In Supply Chain Management

Contacts are tagged by using the **IsContactPersonExternallyMaintained** property. This property indicates that a given contact is maintained externally. In this case, externally maintained contacts are maintained in Sales.

Preconditions and mapping setup

Contact to customer

- **CustomerGroup** is required in Supply Chain Management. To help prevent synchronization errors, you can specify a default value in the mapping. That default value is then used if the column is left blank in Sales.

  The default template value is **10**.

- By adding the following mappings, you can help reduce the number of manual updates that are required in Supply Chain Management. You can use a default value or a value map from, for example, **Country/Region** or **City**.

  - **SiteId** – A default site can also be defined on products in Supply Chain Management. A site is required in order to generate quotations and sales orders in Supply Chain Management.

    A template value for **SiteId** isn't defined.

  - **WarehouseId** – A default warehouse can also be defined on products in Supply Chain Management. A warehouse is required in order to generate quotations and sales orders in Supply Chain Management.

    A template value for **WarehouseId** isn't defined.

  - **LanguageId** – A language is required in order to generate quotations and sales orders in Supply Chain Management.

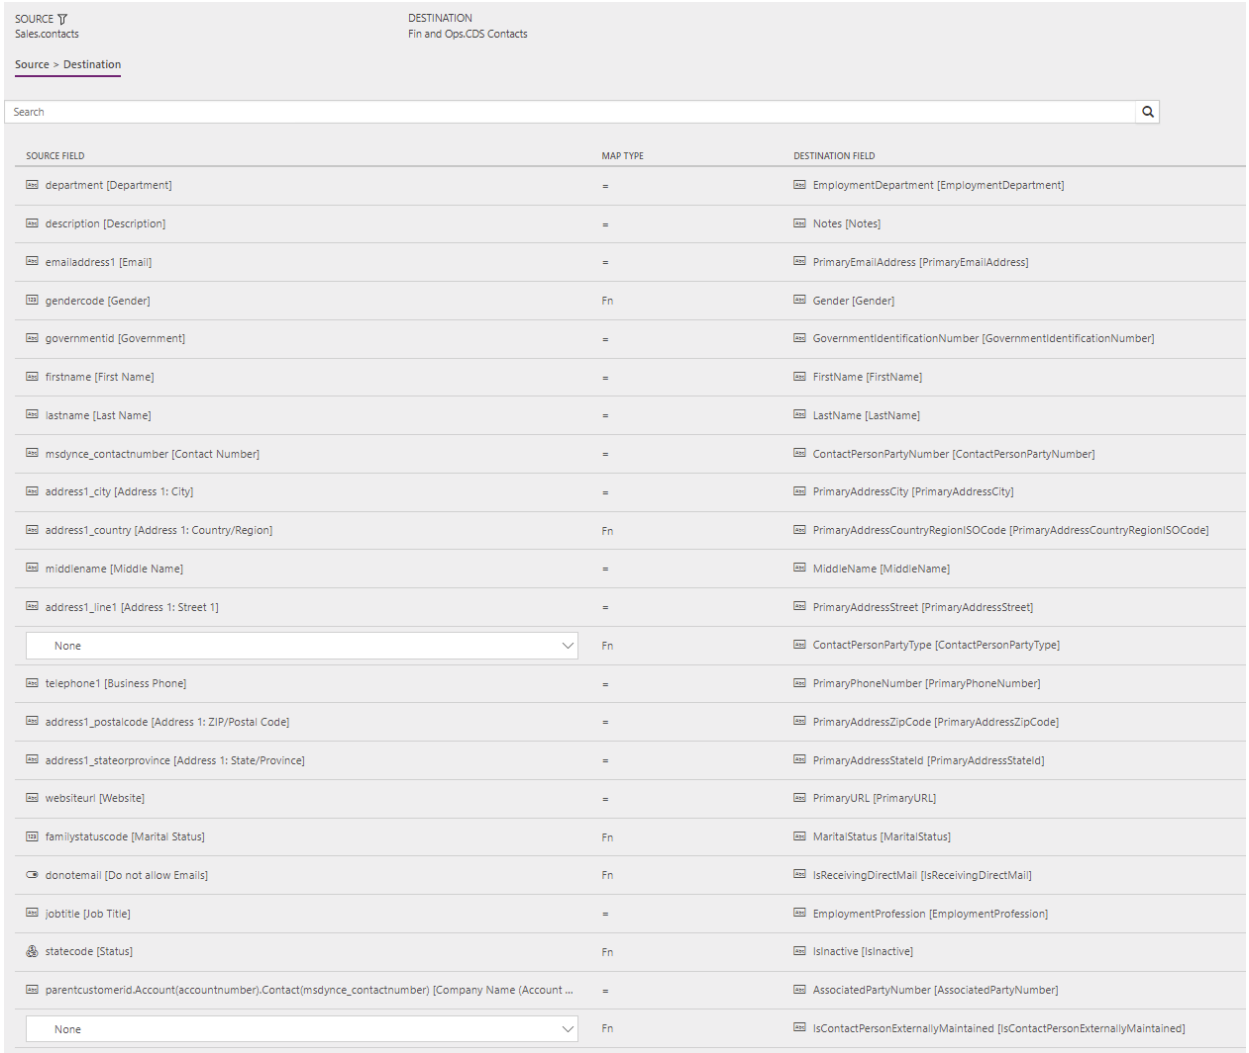
    The default template value for is **en-us**.

Template mapping in Data integration

The following illustrations show an example of a template mapping in Data integration.

> **NOTE**
> The mapping shows which column information will be synchronized from Sales to Supply Chain Management.

Contact to contact



Contact to customer

Synchronize sales quotation headers and lines directly from Sales to Supply Chain Management

2/18/2021 • 5 minutes to read • Edit Online

NOTE

Effective November 2020:

- Common Data Service has been renamed to Microsoft Dataverse. For more information, see Power Automate Blog.
- Some terminology in Microsoft Dataverse has been updated. For example, *entity* is now *table* and *field* is now *column*. For more information, see Terminology updates.

This topic will be updated soon to reflect the latest terminology.

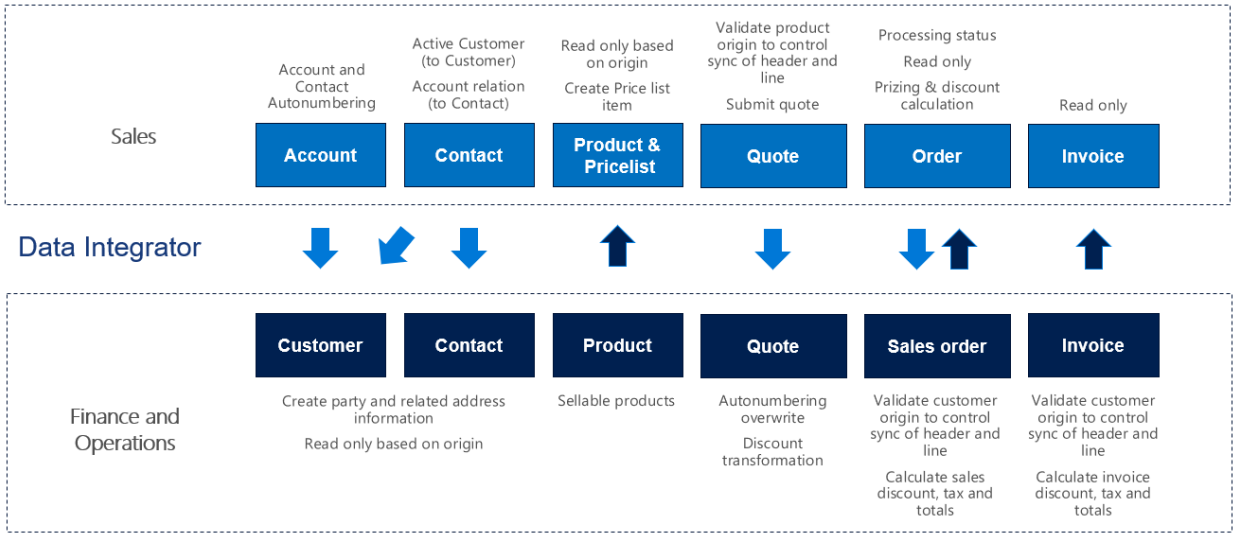
The topic discusses the templates and underlying tasks that are used to synchronize sales quotation headers and lines directly from Dynamics 365 Sales to Dynamics 365 Supply Chain Management.

NOTE

Before you can use the Prospect to cash solution, you should be familiar with Integrate data into Microsoft Dataverse for Apps.

Data flow in Prospect to cash

The Prospect to cash solution uses the Data integration feature to synchronize data across instances of Supply Chain Management and Sales. The Prospect to cash templates that are available with the Data integration feature enable the flow of data for accounts, contacts, products, sales quotations, sales orders, and sales invoices between Supply Chain Management and Sales. The following illustration shows how the data is synchronized between Supply Chain Management and Sales.



Template and tasks

The following template and underlying tasks are used to synchronize sales quotation headers and lines directly from Sales to Supply Chain Management:

- **Name of the template in Data integration:** Sales Quotes (Sales to Supply Chain Management) - Direct
- **Names of the tasks in the Data integration project:**
  - QuoteHeader
  - QuoteLine

The following synchronization tasks are required before synchronization of sales quotation headers and lines can occur:

- Products (Supply Chain Management to Sales) - Direct
- Accounts (Sales to Supply Chain Management) - Direct (if used)
- Contacts to Customers (Sales to Supply Chain Management) - Direct (if used)

Entity set

SALES	SUPPLY CHAIN MANAGEMENT
Quotes	Dataverse sales quotation header
QuoteDetails	Dataverse sales quotation lines

Entity flow

Sales quotations are created in Sales and synchronized to Supply Chain Management.

Sales quotations from Sales are synchronized only if the following conditions are met:

- All quote products on the sales quotation are externally maintained.
- After you click **Activate quote**, the sales quotation is active.

Prospect to cash solution for Sales

The **Has Externally Maintained Products Only** field has been added to the **Quote** entity to consistently track whether the sales quotation consists entirely of externally maintained products. If a sales quotation has only externally maintained products, the products are maintained in Supply Chain Management. This behavior helps guarantee that you don't try to synchronize sales quotation lines that have products that are unknown to Supply Chain Management.

All quote products on the sales quotation are updated with the **Has Externally Maintained Products Only** information from the sales quotation header. This information is found in the **Quote Has Externally Maintained Products Only** field on the **QuoteDetails** entity.

A discount can be added to the quote product and will be synchronized to Supply Chain Management. The **Discount**, **Charges**, and **Tax** fields on the header are controlled by a setup in Supply Chain Management. Currently, this setup doesn't support integration mapping. In the current design, the **Price**, **Discount**, **Charge**, and **Tax** fields are maintained and handled in FSupply Chain Management.

In Sales, the solution makes the following fields read-only, because the values aren't synchronized to Supply Chain Management:

- Read-only fields on the sales quotation header: **Discount %**, **Discount**, and **Freight Amount**
- Read-only fields on quote products: **Tax**

Preconditions and mapping setup

Before sales quotations are synchronized, it's important that you update the following settings.

Setup in Sales

- Make sure that permissions are set up for the team that the user from your connection set in Sales is assigned to. If you're using demo data, the user usually has admin access, but the team doesn't have admin access. If the team doesn't have admin access when you run the project from Data integration, you will receive an error message that states that the Principal team is missing.

  To set up permissions for the team, go to **Settings** > **Security** > **Teams**, and select the relevant team. Select **Manage Roles**, and then select a role that has the desired permissions, such as **System Administrator**.

- Go to **Settings** > **Administration** > **System settings** > **Sales**, and make sure that the following settings are used:

  - The **Use system prizing calculation system** option is set to **Yes**.
  - The **Discount calculation method** field is set to **Line item**.

Setup in the Data integration project

QuoteHeader

- Make sure that the required mapping exists for **Shipto_country** to **DeliveryAddressCountryRegionISOCode**. In the value map, you can define a default value that is used if the value is left blank. Just leave the left side blank, and set the right side to the desired country or region. In this way, you don't have to type the country or region for national orders.

  The template value is a value map where several countries or regions are mapped, and where a blank value equals a value of **US**.

QuoteLine

- Make sure that the required value map exists for **SalesUnitSymbol** in Supply Chain Management.
- Make sure that the required units are defined in Sales.

  A template value that has a value map is defined for **oumid.name** to **SalesUnitSymbol**.

- Optional: You can add the following mappings to help guarantee that sales quotation lines are imported into Supply Chain Management if there is no default information from either the customer or the product:

  - **SiteId** – A site is required in order to generate quotations and sales order lines in Supply Chain Management. There is no default template value for **SiteId**.
  - **WarehouseId** – A warehouse is required in order to process quotations and sales order lines in Supply Chain Management. There is no default template value for **WarehouseId**.

Template mapping in data integrator

> **NOTE**
>
> - The **Discount**, **Charges**, and **Tax** fields are controlled by a complex setup in Supply Chain Management. Currently, this setup doesn't support integration mapping. In the current design, the **Price**, **Discount**, **Charge**, and **Tax** fields are handled by Supply Chain Management.
> - The **Payment terms**, **Freight terms**, **Delivery terms**, **Shipping method**, and **Delivery mode** fields aren't part of the default mappings. To map these fields, you must set up a value mapping that is specific to the data in the organizations that the entity is synchronized between.

The following illustrations show an example of a template mapping in data integrator.

The survey will take about seven minutes. No personal data is collected (privacy statement).

Synchronization of sales orders directly between Sales and Supply Chain Management

2/18/2021 • 10 minutes to read • Edit Online

NOTE

Effective November 2020:

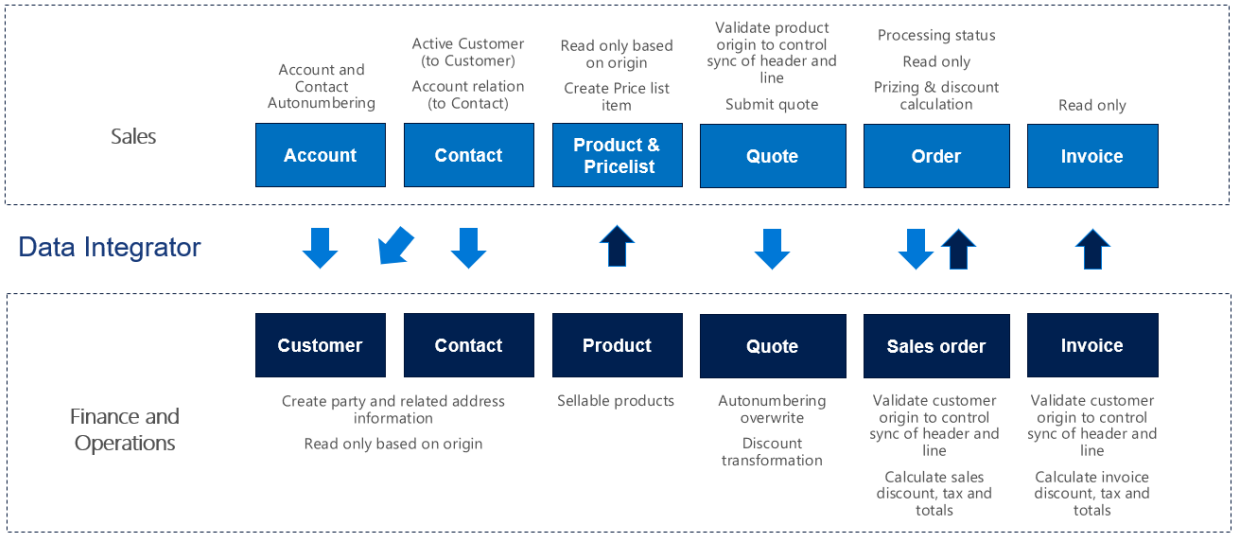
- Common Data Service has been renamed to Microsoft Dataverse. For more information, see Power Automate Blog.
- Some terminology in Microsoft Dataverse has been updated. For example, *entity* is now *table* and *field* is now *column*. For more information, see Terminology updates.

This topic will be updated soon to reflect the latest terminology.

The topic discusses the templates and underlying tasks that are used to run synchronization of sales orders directly between Dynamics 365 Sales and Dynamics 365 Supply Chain Management.

Data flow in Prospect to cash

The Prospect to cash solution uses the Data integration feature to synchronize data across instances of Supply Chain Management and Sales. The Prospect to cash templates that are available with the Data integration feature enable the flow of data for accounts, contacts, products, sales quotations, sales orders, and sales invoices between Supply Chain Management and Sales. The following illustration shows how the data is synchronized between Supply Chain Management and Sales.



Templates and tasks

To access the available templates, open Power Apps Admin Center. Select **Projects**, and then, in the upper-right corner, select **New project** to select public templates.

The following templates and underlying tasks are used to run synchronization of sales orders directly between Sales and Supply Chain Management.

- **Names of the templates in Data integration:**
  - Sales Orders (Sales to Supply Chain Management) - Direct

    - Sales Orders (Supply Chain Management to Sales) - Direct
- **Names of the tasks in the Data integration project:**
    - OrderHeader
    - OrderLine

The following synchronization tasks are required before synchronization of sales invoice headers and lines can occur:

- Products (Supply Chain Management to Sales) - Direct
- Accounts (Sales to Supply Chain Management) - Direct (if used)
- Contacts to Customers (Sales to Supply Chain Management) - Direct (if used)

Entity set

SUPPLY CHAIN MANAGEMENT	SALES
Dataverse sales order headers	SalesOrders
Dataverse sales order lines	SalesOrderDetails

Entity flow

Sales orders are created in Sales and synchronized to Supply Chain Management when **Run project** is triggered for a project based on the **Sales Orders (Sales to Supply Chain Management) - Direct** template. You can only activate and synchronize orders from Sales if all **Order Products** consist of products that are externally maintained. Therefore, there can be no write-in products. After the order is activated, the sales order becomes read-only in the user interface (UI). At that point, the updates are made from Supply Chain Management. After the sales order has a status of **Confirmed**, the a project based on the **Sales Orders (Supply Chain Management to Sales) - Direct** template can be used to synchronize updates or fulfillment status from Supply Chain Management to Sales.

You don't have to create orders in Sales. You can create new sales orders in Supply Chain Management instead. After a sales order has a status of **Confirmed**, it's synchronized to Sales as described in the previous paragraph.

In Supply Chain Management, filters in the template help guarantee that only the relevant sales orders are included in the synchronization:

- On the sales order, both the ordering customer and the invoicing customer have to originate from Sales to be included in the synchronization. In Supply Chain Management, the **OrderingCustomerIsExternallyMaintained** and **InvoiceCustomerIsExternallyMaintained** columns are used to filter sales orders from the data tables.
- The sales order in Supply Chain Management must be confirmed. Only confirmed sales orders or sales orders that have a higher processing status, such as **Shipped** or **Invoiced**, are synchronized to Sales.
- After a sales order is created or modified, the **Calculate sales totals** batch job in Supply Chain Management must be run. Only sales orders where sales totals are calculated will be synchronized to Sales.

Freight tax

Sales doesn't support tax at the header level, because tax is stored at the line level. To support tax at the header level from Supply Chain Management, such as tax on freight, the system synchronizes tax to Sales as a write-in product that is named **Freight Tax**, and that has the tax amount from Supply Chain Management. In this way, the standard price calculation in Sales can be used for totals, even when there is tax at the header level from

Supply Chain Management.

Discount calculation and rounding

The discount calculation model in Sales differs from the discount calculation model in Supply Chain Management. In Supply Chain Management, the final discount amount on a sales line can be the result of a combination of discount amounts and discount percentages. If this final discount amount is divided by the quantity on the line, rounding can occur. However, this rounding isn't considered if a rounded per-unit discount amount is synchronized to Sales. To help guarantee that the full discount amount from a sales line in Supply Chain Management is correctly synchronized to Sales, the full amount must be synchronized without being divided by the line quantity. Therefore, you must define the **Discount calculation method** as **Line item** in Sales.

When a sales order line is synchronized from Sales to Supply Chain Management, the full line discount amount is used. Because Supply Chain Management has no field that can store the full discount amount for a line, the amount is divided by the quantity and stored in the **Line discount** field. Any rounding that occurs in this division is stored in the **Sales charges** field on the sales line.

Example

Synchronization from Sales to Supply Chain Management

- **Sales:** Quantity = 3, per-line discount = $10.00
- **Supply Chain Management:** Quantity = 3, line discount amount = $3.33, sales charge = -$0.01

Synchronization from Supply Chain Management to Sales

- **Supply Chain Management:** Quantity = 3, line discount amount = $3.33, sales charge = -$0.01
- **Sales:** Quantity = 3, per-line discount = (3 × $3.33) + $0.01 = $10.00

Prospect to cash solution for Sales

New columns have been added to the **Order** table and appear on the page:

- **Is Maintained Externally** – Set this option to **Yes** when the order is coming from Supply Chain Management.
- **Processing status** – This column shows the processing status of the order in Supply Chain Management. The following values are available:
  - **Draft** – The initial status when an order is created in Sales. In Sales, only orders with this processing status can be edited.
  - **Active** – The status after the order is activated in Sales by using the **Activate** button.
  - **Confirmed**
  - **Packing Slip**
  - **Invoiced**
  - **Picked**
  - **Partially Picked**
  - **Partially Packed**
  - **Shipped**
  - **Partially Shipped**
  - **Partially Invoiced**
  - **Cancelled**

The **Has Externally Maintained Products Only** setting is used during order activation to consistently track

whether a sales order consists entirely of externally maintained products. If a sales order consists entirely of externally maintained products, the products are maintained in Supply Chain Management. This setting helps guarantee that you don't activate and try to synchronize sales order lines that have products that are unknown to Supply Chain Management.

The **Create Invoice**, **Cancel Order**, **Recalculate**, **Get Products**, and **Lookup Address** buttons on the **Sales order** page are hidden for externally maintained orders, because invoices will be created in Supply Chain Management and synchronized to Sales. These orders can't be edited, because sales order information will be synchronized from Supply Chain Management after activation.

The sales order status will remain **Active** to help guarantee that changes from Supply Chain Management can flow to the sales order in Sales. To control this behavior, set the default **Statecode [Status]** value to **Active** in the Data integration project.

Preconditions and mapping setup

Before you synchronize sales orders, it's important that you update the following settings in the systems.

Setup in Sales

- Make sure that permissions are set up for the team that the user from your Sales connection set is assigned to. If you're using demo data, the user usually has admin access, but the team doesn't have admin access. If the team doesn't have admin access, when you run the project from Data integration, you will receive an error message that states that the Principal team is missing.

  Go to **Settings** > **Security** > **Teams**, select the relevant team, select **Manage Roles**, and select a role that has the desired permissions, such as **System Administrator**.

- To ensure correct calculation of discounts in both Sales and Supply Chain Management **Discount calculation method** must be set to **Line item**.

- Go to **Settings** > **Administration** > **System settings** > **Sales**, and make sure that the following settings are used:

  - The **Use system prizing calculation system** option is set to **Yes**.
  - The **Discount calculation method** column is set to **Line item**.

Setup in Supply Chain Management

- Go to **Sales and marketing** > **Periodic tasks** > **Calculate sales totals**, and set the job to run as a batch job. Set the **Calculate totals for sales orders** option to **Yes**. This step is important, because only sales orders where sales totals are calculated will be synchronized to Sales. The frequency of the batch job should be aligned with the frequency of sales order synchronization.

If you also use work order integration, you need to set up the sales origin. The sales origin is used to distinguish sales orders in Supply Chain Management that were created from work orders in Field Service. When a sales order has a sales origin of the **Work order integration** type, the **External work order status** field appears on the sales order header. Additionally, the sales origin ensures that sales orders that were created from work orders in Field Service are filtered out during sales order synchronization from Supply Chain Management to Field Service.

1. Go to **Sales and marketing** > **Setup** > **Sales orders** > **Sales origin**.
2. Select **New** to create a new sales origin.
3. In the **Sales origin** column, enter a name for the sales origin, such as **SalesOrder**.
4. In the **Description** column, enter a description, such as **Sales Order from Sales**.
5. Select the **Origin type assignment** check box.
6. Set the **Sales origin type** column to **Sales order integration**.

7. Select **Save**.

Setup in the Sales Orders (Sales to Supply Chain Management) - Direct Data integration project

- Make sure that the required mapping exists for **Shipto_country** to **DeliveryAddressCountryRegionISOCode**. You can make blank a default value in the value map to avoid having to type country for national orders. Set the left side to 'Blank', and set the right side to the desired country or region.

  The template value is a value map where several countries or regions are mapped, and where 'Blank' = US.

Setup in the Sales Orders (Supply Chain Management to Sales) - Direct Data integration project

SalesHeader task

- A price list is required in order to create orders in Sales. Update the value map for **pricelevelid.name [Price List Name]** to the price list that is used in Sales per currency. You can use the default price list for a single currency. Alternatively, if you have price lists in multiple currencies, you can use a value map.

  The default template value for **pricelevelid.name [Price List Name]** is **CRM Service USA (sample)**.

SalesLine task

- Make sure that the required value map for **SalesUnitSymbol** in Supply Chain Management exists.
- Make sure that the required units are defined in Sales.

  A template value that has a value map is defined for **SalesUnitSymbol** to **oumid.name**.

Template mapping in Data integration

> **NOTE**
> The **Payment terms**, **Freight terms**, **Delivery terms**, **Shipping method**, and **Delivery mode** columns aren't part of the default mappings. To map these columns, you must set up a value mapping that is specific to the data in the organizations that the table is synchronized between.

The following illustrations show an example of a template mapping in Data integration.

> **NOTE**
> The mapping shows which column information will be synchronized from Sales to Supply Chain Management, or from Supply Chain Management to Sales.

The survey will take about seven minutes. No personal data is collected (privacy statement).

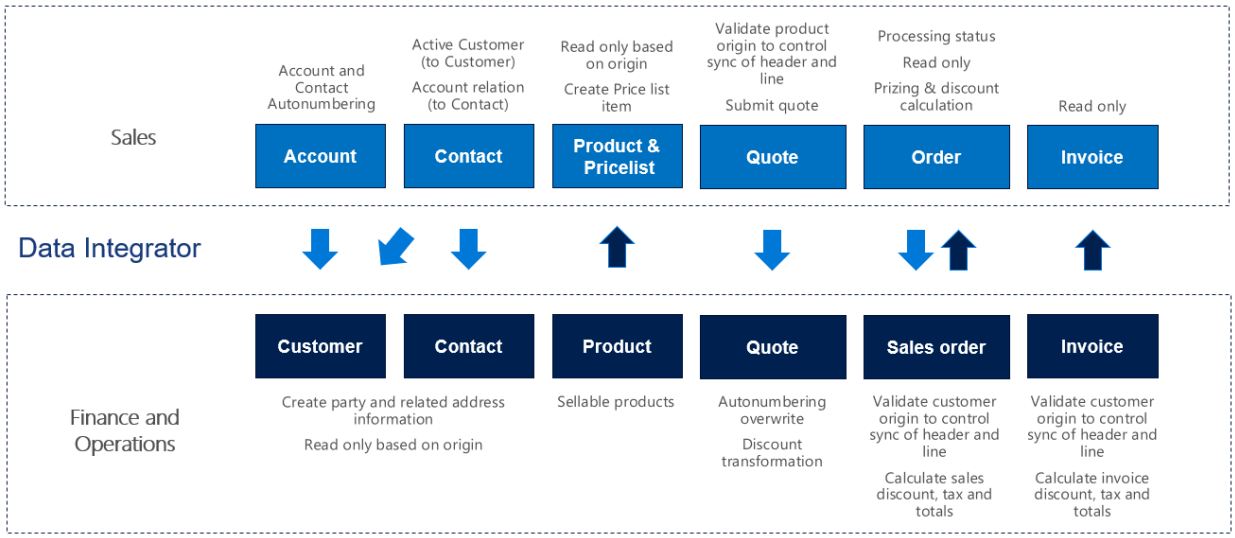
Synchronize sales invoice headers and lines directly from Finance and Operations to Sales

2/18/2021 • 4 minutes to read • Edit Online

This topic discusses the templates and underlying tasks that are used to synchronize sales invoice headers and lines directly from Dynamics 365 Supply Chain Management to Dynamics 365 Sales.

Data flow in Prospect to cash

The Prospect to cash solution uses the Data integration feature to synchronize data across instances of Supply Chain Management and Sales. The Prospect to cash templates that are available with the Data integration feature enable the flow of data about accounts, contacts, products, sales quotations, sales orders, and sales invoices between Supply Chain Management and Sales. The following illustration shows how the data is synchronized between Supply Chain Management and Sales.



Templates and tasks

To access the available templates, open Power Apps Admin Center. Select **Projects**, and then, in the upper-right corner, select **New project** to select public templates.

The following template and underlying tasks are used to synchronize sales invoice headers and lines from Supply Chain Management to Sales:

- **Name of the template in Data integration:** Sales Invoices (Fin and Ops to Sales) - Direct
- **Names of the tasks in the Data integration project:**
  - SalesInvoiceHeader
  - SalesInvoiceLine

The following synchronization tasks are required before synchronization of sales invoice headers and lines can occur:

- Products (Supply Chain Management to Sales) - Direct
- Accounts (Sales to Supply Chain Management) - Direct (if used)
- Contacts (Sales to Supply Chain Management) - Direct (if used)

- Sales order header and lines (Supply Chain Management to Sales) - Direct

Entity set

SUPPLY CHAIN MANAGEMENT	SALES
Externally maintained customer sales invoice headers	Invoices
Externally maintained customer sales invoice lines	InvoiceDetails

Entity flow

Sales invoices are created in Supply Chain Management and synchronized to Sales.

> **NOTE**
> Currently, tax that is related to charges on the sales invoice header isn't included in the synchronization from Supply Chain Managements to Sales. Sales doesn't support tax information at the header level. However, tax that is related to charges at the line level is included in the synchronization.

Prospect to cash solution for Sales

- An **Invoice number** field has been added to the **Invoice** entity and appears on the page.
- The **Create invoice** button on the **Sales order** page is hidden, because invoices will be created in Supply Chain Management and synchronized to Sales. The **Invoice** page can't be edited, because invoices will be synchronized from Supply Chain Management.
- The **Sales order status** value is automatically changed to **Invoiced** when the related invoice from Supply Chain Management has been synchronized to Sales. Additionally, the owner of the sales order that the invoice was created from is assigned as the owner of the invoice. Therefore, the owner of the sales order can view the invoice.

Preconditions and mapping setup

Before you synchronize sales invoices, it's important that you update the following settings in the systems.

Setup in Sales

Go to **Settings** > **Administration** > **System settings** > **Sales**, and make sure that the following settings are used:

- The **Use system prizing calculation system** option is set to **Yes**.
- The **Discount calculation method** field is set to **Line item**.

Setup in the Data integration project

SalesInvoiceHeader task

- Make sure that the required mapping exists for **InvoiceCountryRegionId** to **BillingAddress_Country**.

  The template value is a value map where several countries or regions are mapped.

- A price list is required in order to create invoices in Sales. Update the value map for **pricelevelid.name [Price list name]** to the price list that is used in Sales per currency. You can use the default price list for a single currency. Alternatively, if you have price lists in multiple currencies, you can use a value map.

  The template value for **pricelevelid.name [Price list name]** is a value map that is based on currency with USD = CRM Service USA (sample).

SalesInvoiceLine task

- Make sure that the required mapping exists for **Unit of measure**.
- Make sure that the required value map for **SalesUnitSymbol** in Supply Chain Management exists.

  A template value that has a value map is defined for **SalesUnitSymbol** to **Quantity_UOM**.

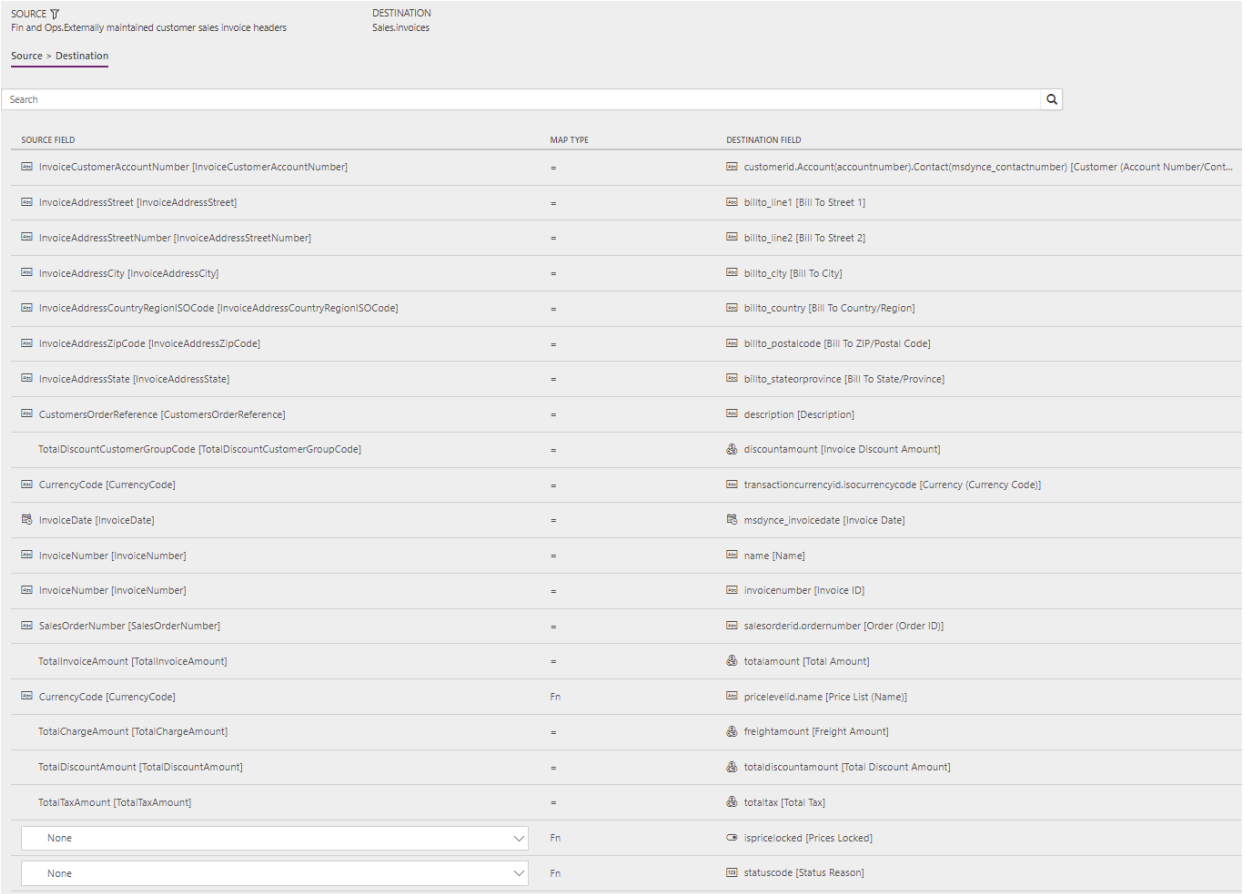
Template mapping in Data integration

> **NOTE**
>
> The **Payment terms**, **Freight terms**, **Delivery terms**, **Shipping method**, and **Delivery mode** fields aren't included in the default mappings. To map these fields, you must set up a value mapping that is specific to the data in the organizations that the entity is synchronized between.

The following illustrations show an example of a template mapping in Data integration.

> **NOTE**
>
> The mapping shows which field information will be synchronized from Sales to Supply Chain Management.

SalesInvoiceHeader



SalesInvoiceLine

Integration with Microsoft Dynamics 365 Field Service overview

2/18/2021 • 3 minutes to read • Edit Online

NOTE

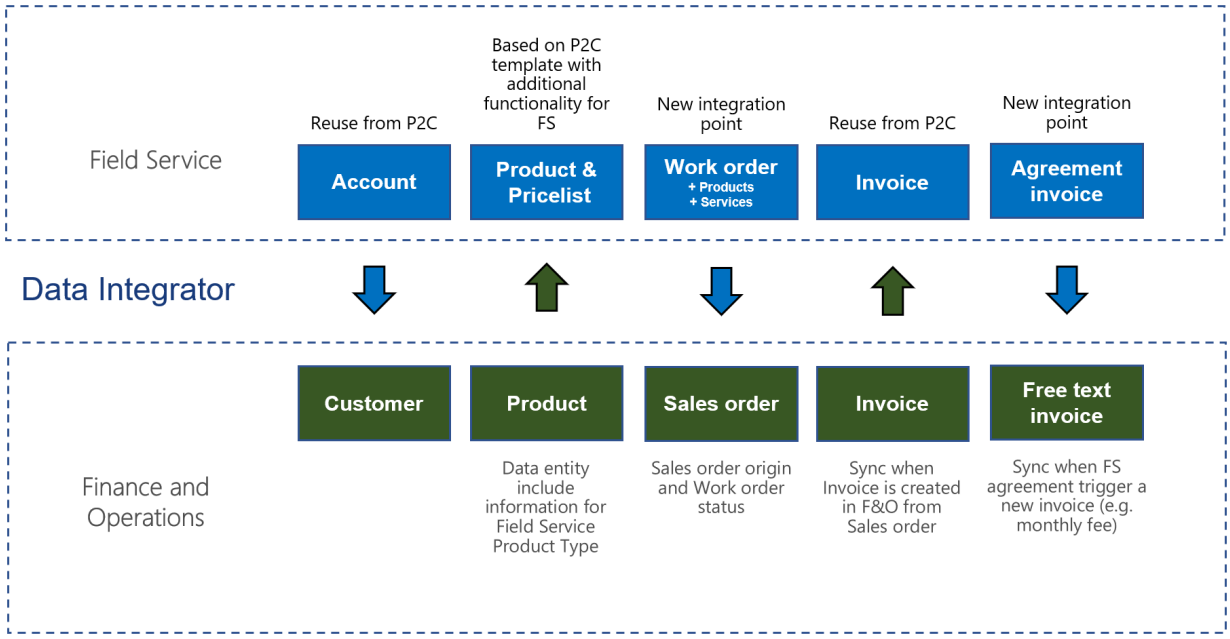
Effective November 2020:

- Common Data Service has been renamed to Microsoft Dataverse. For more information, see Power Automate Blog.
- Some terminology in Microsoft Dataverse has been updated. For example, *entity* is now *table* and *field* is now *column*. For more information, see Terminology updates.

This topic will be updated soon to reflect the latest terminology.

Supply Chain Management enables synchronization of business processes between Dynamics 365 Supply Chain Management and Dynamics 365 Field Service. The integration scenarios are configured by using extensible Data integrator templates and Microsoft Dataverse to enable the synchronization of business processes. Standard templates can be used to create custom integration projects, where additional standard and custom columns and tables can be mapped to adjust the integration and meet specific business needs.

The field service integration builds on top of the existing prospect-to-cash functionality.



The first phase of the integration between Field Service and Supply Chain Management is focused on enabling work orders and agreements in Field Service to be invoiced in Supply Chain Management. The supported flow starts in Field Service, where information from work orders is synchronized to Supply Chain Management as sales orders. In Supply Chain Management, the sales orders are invoiced to generate invoice documents. In addition, the information from Field Service agreement invoices is synchronized to Supply Chain Management. The Microsoft Dynamics 365 Data integrator synchronizes data by using customizable projects. Standard templates can be used to create custom integration projects where additional standard and custom columns, and also tables, can be mapped to adjust the integration and meet specific requirements.

The first phase of the integration between Field Service and Supply Chain Management enables synchronization of the following items:

- Synchronize products in Supply Chain Management to products in Field Service
- Synchronize work orders in Field Service to sales orders in Supply Chain Management
- Synchronize agreement invoices in Field Service to free text invoices in Supply Chain Management

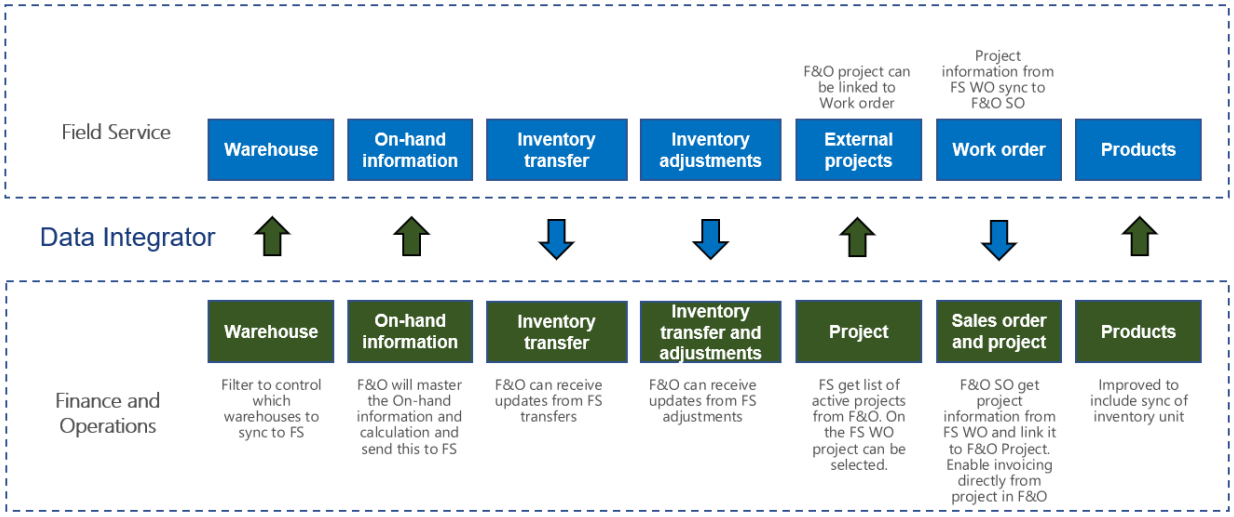
To see an example of how you can synchronize a work order between Field Service and Supply Chain Management, watch the short YouTube video How to synchronize a work order with Microsoft Dynamics 365 Integration.

Integration with Field Service, including inventory and project information

The additional functionality in this second phase focused on giving field technicians insight about the inventory information from Supply Chain Management, allowing them to update inventory levels and do material transfers. In addition, companies installing or servicing sold goods will benefit from better control and visibility to the full sales and service process with integration from projects.

Functionality includes integration of:

- Warehouse information
- On-hand inventory information
- Inventory transfers
- Inventory adjustments
- Supply Chain Management projects connected with Dynamics 365 Field Service work orders
- Dynamics 365 Field Service work orders with link to Supply Chain Management projects, apply this project number to the sales order to allow invoicing from the project.



The second phase of the integration between Field Service and Supply Chain Management enables synchronization with the following templates:

- Warehouses (Supply Chain Management to Field Service) - Warehouses from Supply Chain Management to Field Service [Advanced Query]
- Product Inventory (Supply Chain Management to Field Service) - Inventory level information from Supply Chain Management to Field Service [Advanced Query]
- Inventory Adjustment (Field Service to Supply Chain Management) - Inventory adjustments from Field Service to Supply Chain Management [Advanced Query]
- Inventory Transfers (Field Service to Supply Chain Management) - Inventory transfers from Field Service to Supply Chain Management [Advanced Query]
- Projects (Supply Chain Management to Field Service) - Project list from Supply Chain Management to Field Service

- Work Orders with Project (Field Service to Supply Chain Management) - Work orders in Field Service to Sales orders in Supply Chain Management, with support for Project [Advanced Query]
- Field Service Products with Inventory unit (Supply Chain Management to Sales) - Supply Chain Management 'Sellable released products' to Sales 'Products' for Field Service, including Inventory unit

System requirements

System requirements for Supply Chain Management

Field Service integration supports the following versions:

- Dynamics 365 for Finance and Operations version 8.1.2 (December 2018) was released in December 2018 and has an application build number 8.1.195 with Platform update 22 (7.0.5095).

System requirements for Field Service

To use the Field Service integration solution, you must install the following components:

- Field Service (version 8.2.0.286) or a later version on Dynamics 365 9.1.x - Released November 2018
- Prospect to Cash (P2C) solution for Dynamics 365, version 1.15.0.1 or a later version. The solution is available for download from AppSource.
- 'Field Service Integration, Project and Inventory' solution for Dynamics 365, version 2.0.0.0 or a later version. The solution is available for download from AppSource.

Synchronize products in Supply Chain Management to products in Field Service

2/18/2021 • 2 minutes to read • Edit Online

This topic discusses the templates and underlying task that are used to synchronize products from Dynamics 365 Supply Chain Management to Dynamics 365 Field Service.

The used **Field Service Products (Supply Chain Management to Field Service)** template is based on the **Products (Supply Chain Management to Sales) – Direct** template from Prospect to Cash. For more information, see Products (Supply Chain Management to Sales) – Direct.

This topic only describes the differences between the **Field Service Products (Supply Chain Management to Field Service)** and **Products (Supply Chain Management to Sales) – Direct** templates.

Templates and tasks

Name of the template in Data integration

- Field Service Products (Supply Chain Management to Field Service)

Name of the task in the Data integration project

- Products - Products

The **Field Service Products (Supply Chain Management to Field Service)** template includes one mapping that isn't included in the **Products (Supply Chain Management to Sales) – Direct** template. This mapping ensures that the required Field Service-specific field **Service Product Type** is set correctly.

```
FIELDSERVICEPRODUCTTYPE        Fn        msdyn_fieldserciveproducttype
```

The following value mapping is used.

```
inventory     :  690970000
nonInventory  :  690970001
service       :  690970002
```

In Supply Chain Management, the **Field Service product type** value on the **Sellable released products** data entity is calculated as follows:

- **Inventory:** Product type = Product and Item model group, Stocked product = True
- **NonInventory:** Product type = Product and Item model group, Stocked product = False
- **Service:** Product type = Service

Template mapping in Data integration

The following illustrations show the template mapping in Data integration.

Field Service Products (Supply Chain Management to Field Service): Products - Products

The survey will take about seven minutes. No personal data is collected (privacy statement).

Synchronize work orders in Field Service to sales orders in Supply Chain Management

2/18/2021 • 13 minutes to read • Edit Online

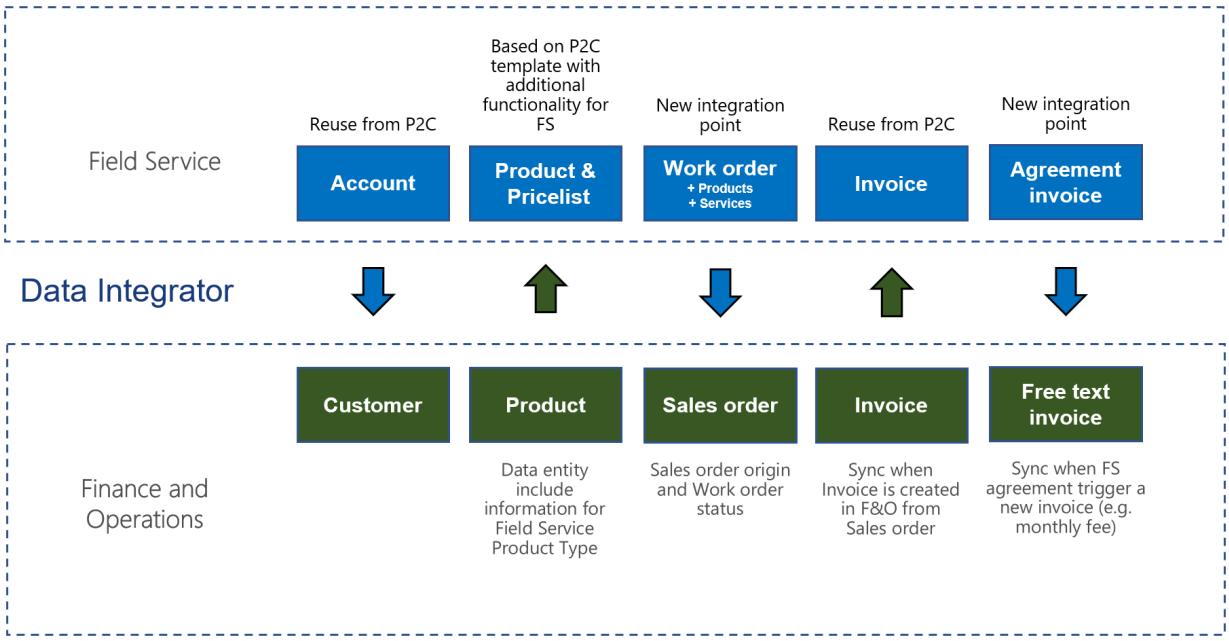
NOTE

Effective November 2020:

- Common Data Service has been renamed to Microsoft Dataverse. For more information, see Power Automate Blog.
- Some terminology in Microsoft Dataverse has been updated. For example, *entity* is now *table* and *field* is now *column*. For more information, see Terminology updates.

This topic will be updated soon to reflect the latest terminology.

This topic discusses the templates and underlying tasks that are used to synchronize work orders in Dynamics 365 Field Service to sales order in Dynamics 365 Supply Chain Management.



Templates and tasks

The following templates and underlying tasks are used to run the synchronization of work orders in Field Service to sales orders in Supply Chain Management.

Names of the templates in Data integration

The **Work orders to Sales orders (Field Service to Supply Chain Management)** template is used to run synchronization.

Names of the tasks in the Data integration project

- WorkOrderHeader
- WorkOrderServiceLineEstimate
- WorkOrderServiceLineUsed
- WorkOrderProductLineEstimate

- WorkOrderProductLineUsed

The following synchronization tasks are required before synchronization of sales order headers and lines can occur:

- Field Service Products (Supply Chain Management to Field Service)
- Accounts (Sales to Supply Chain Management) – Direct

Entity set

FIELD SERVICE	SUPPLY CHAIN MANAGEMENT
msdyn_workorders	Dataverse sales order headers
msdyn_workorderservices	Dataverse sales order lines
msdyn_workorderproducts	Dataverse sales order lines

Entity flow

Work orders are created in Field Service. If the work orders include only externally maintained products, and if the **Work order status** value differs from **Open-Unscheduled** and **Closed – Cancelled**, the work orders can be synchronized to Supply Chain Management via a Microsoft Dataverse Data integration project. Updates on the work orders will be synchronized as sales orders in Supply Chain Management. These updates include the information about the origin type and status.

Estimated versus Used

In Field Service, products and services on work orders have both **Estimated** values and **Used** values for quantities and amounts. However, in Supply Chain Management, sales orders don't have the same concept of **Estimated** and **Used** values. To support product allocation that uses the expected quantity on the sales order in Supply Chain Management, but to keep the used quantity that should be consumed and invoiced, two sets of tasks synchronize the products and services on the work order. One set of tasks is for **Estimated** values, and the other set of tasks is for **Used** values.

This behavior enables scenarios where estimated values are used for allocation or reservation in Supply Chain Management, whereas used values are used for consumption and invoicing.

Estimated

For synchronization of product lines, the **Estimated** values are used when the **Line Status** value is **Estimated**, the **Allocated** option is set to **Yes**, and **System Status** value isn't **Closed – Posted**.

For synchronization of service lines, the **Estimated** values are used when the **Line Status** value is **Estimated** and the **System Status** value isn't **Closed – Posted**.

Used

The **Used** values are used for consumption and invoicing. In these cases, the **Used** values are synchronized.

The following table provides an overview of the various combinations for product lines.

SYSTEM STATUS (FIELD SERVICE)	LINE STATUS (FIELD SERVICE)	ALLOCATED (FIELD SERVICE)	SYNCHRONIZED VALUE (SUPPLY CHAIN MANAGEMENT)
Open - Scheduled	Estimated	Yes	Estimated

SYSTEM STATUS (FIELD SERVICE)	LINE STATUS (FIELD SERVICE)	ALLOCATED (FIELD SERVICE)	SYNCHRONIZED VALUE (SUPPLY CHAIN MANAGEMENT)
Open - Scheduled	Estimated	No	Used
Open - Scheduled	Used	Yes	Used
Open - Scheduled	Used	No	Used
Open - In Progress	Estimated	Yes	Estimated
Open - In Progress	Estimated	No	Used
Open - In Progress	Used	Yes	Used
Open - In Progress	Used	No	Used
Open - Completed	Estimated	Yes	Estimated
Open - Completed	Estimated	No	Used
Open - Completed	Used	Yes	Used
Open - Completed	Used	No	Used
Closed - Posted	Estimated	Yes	Used
Closed - Posted	Estimated	No	Used
Closed - Posted	Used	Yes	Used
Closed - Posted	Used	No	Used

The following table provides an overview of the various combinations for service lines.

SYSTEM STATUS (FIELD SERVICE)	LINE STATUS (FIELD SERVICE)	SYNCHRONIZED VALUE (SUPPLY CHAIN MANAGEMENT)
Open - Scheduled	Estimated	Estimated
Open - Scheduled	Used	Used
Open - In Progress	Estimated	Estimated
Open - In Progress	Used	Used
Open - Completed	Estimated	Estimated
Open - Completed	Used	Used
Closed - Posted	Estimated	Used

SYSTEM STATUS (FIELD SERVICE)	LINE STATUS (FIELD SERVICE)	SYNCHRONIZED VALUE (SUPPLY CHAIN MANAGEMENT)
Closed - Posted	Used	Used

Synchronization of **Estimated** values versus **Used** values is managed through the two sets of tasks for product lines and service lines. Predefined filters trigger the correct task, and the underlying mapping helps guarantee that the correct values for **Expected** versus **Used** are synchronized.

Example

1. A work order is created and scheduled in Field Service.

   The **System Status** value is **Open – Scheduled**.

   - **Product line:** Estimated Qty = 5ea, Used Qty = 0ea, Line Status = Estimated, Allocated = No
   - **Service line:** Estimated Qty = 2h, Used Qty = 0h, Line Status = Estimated

   In this example, the product's **Used Qty** value of **0** (zero) and the service's **Estimated Qty** value of **2h** are synchronized to Supply Chain Management.

2. Products are allocated in Field Service.

   The **System Status** value is **Open – Scheduled**.

   - **Product line:** Estimated Qty = 5ea, Used Qty = 0ea, Line Status = Estimated, Allocated = Yes
   - **Service line:** Estimated Qty = 2h, Used Qty = 0h, Line Status = Estimated

   In this example, the product's **Estimated Qty** value of **5ea** and the service's **Estimated Qty** value of **2h** are synchronized to Supply Chain Management.

3. The service technician starts to work on the work order and registers material usage of 6.

   The **System Status** value is **Open – In Progress**.

   - **Product line:** Estimated Qty = 5ea, Used Qty = 6ea, Line Status = Used, Allocated = Yes
   - **Service line:** Estimated Qty = 2h, Used Qty = 0h, Line Status = Estimated

   In this example, the product's **Used Qty** value of **6** and the service's **Estimated Qty** value of **2h** are synchronized to Supply Chain Management.

4. The service technician completes the work order and registers used time of 1.5 hours.

   The **System Status** value is **Open – Completed**.

   - **Product line:** Estimated Qty = 5ea, Used Qty = 6ea, Line Status = Used, Allocated = Yes
   - **Service line:** Estimated Qty = 2h, Used Qty = 1.5h, Line Status = Used

   In this example, the product's **Used Qty** value of **6** and the service's **Used Qty** of **1.5h** are synchronized to Supply Chain Management.

Sales order origin and status

Sales origin

To keep track of sales orders that originate from work orders, you can create a sales origin where the **Origin type assignment** option is set to **Yes** and the **Sales origin type** field is set to **Work order integration**.

By default, the mapping selects the sales origin for the **Work order integration** sales origin type for all sales orders that are created from work orders. This behavior can be useful when you work with the sales order in Supply Chain Management. You must make sure that sales orders that originate from work orders aren't synchronized back to Field Service as work orders.

For details about how to create the correct sales origin setup in Supply Chain Management, see the "Preconditions and mapping setup" section of this topic.

Status

When the sales order originates from a work order, the **External work order status** field appears on the **Setup** tab on the sales order header. This field shows the system status from the work order in Field Service, to help track the synchronized work order status of sales orders in the Supply Chain Management. This field can also help the user determine when the sales order should be shipped or invoiced.

The **External work order status** field can have the following values:

- Open - Scheduled
- Open - In Progress
- Open - Completed
- Closed - Posted

Field Service CRM solution

To support the integration between Field Service and Supply Chain Management, additional functionality from the Field Service CRM solution is required. The solution includes the following changes.

Work Order entity

The **Has Externally Maintained Products Only** field has been added to the **Work Order** entity and appears on the page. It's used to consistently track whether a work order consists entirely of externally maintained products. A work order consists entirely of externally maintained products when all the related products are maintained in Supply Chain Management. This field helps guarantee that users don't synchronize work orders that have products that are unknown.

Work Order Product entity

- The **Order Has Externally Maintained Products Only** field has been added to the **Work Order Product** entity and appears on the page. It's used to consistently track whether the work order product is maintained in Supply Chain Management. This field helps guarantee that users don't synchronize work order products that are unknown to Supply Chain Management.
- The **Header System Status** field has been added to the **Work Order Product** entity and appears on the page. It's used to consistently track the system status of the work order and helps guarantee correct filtering when work order products are synchronized to Supply Chain Management. When filters are set on the integration tasks, **Header System Status** information is also used to determine whether the estimated or used values should be synchronized.
- The **Invoiced Unit Amount** field shows the amount that is invoiced per actual unit that is used. The value is calculated as the **Total Amount** value divided by the **Actual Quantity** value. The field is used for integration to systems that don't support different values for the used quantity and the billed quantity. This field doesn't appear in the user interface (UI).
- The **Invoiced Discount Amount** field is calculated as the **Discount Amount** value plus the rounding from the calculation of the **Invoiced Unit Amount** value. This field is used for integration and doesn't appear in the UI.
- The **Decimal Quantity** field stores the value from the **Quantity** field as a decimal number. This field is used for integration and doesn't appear in the UI.
- The value in **Used** fields is reset to **0** (zero) if the **Line Status** value of the work order product is changed from **Used** to **Estimated**. This change helps prevent situations where a used quantity that is mistakenly entered is used for synchronization when the **Line Status** value is **Estimated** and the **Allocated** option is set to **No**.

Work Order Service entity

- The **Order Has Externally Maintained Products Only** field has been added to the **Work Order Service** entity and appears on the page. It's used to consistently track whether the work order service is maintained in Supply Chain Management. This field helps guarantee that users don't synchronize work order services that are unknown to Supply Chain Management.
- The **Header System Status** field has been added to the **Work Order Service** entity and appears on the page. It's used to consistently track the system status of the work order and helps guarantee correct filtering when work order services are synchronized to Supply Chain Management. When filters are set on the integration tasks, **Header System Status** information is also used to determine whether the estimated or used values should be synchronized.
- The **Duration In Hours** field stores the value from the **Duration** field after that value is converted from minutes to hours. This field is used for integration and doesn't appear in the UI.
- The **Estimated Duration In Hours** field stores the value from the **Estimated Duration** field after that value is converted from minutes to hours. This field is used for integration and doesn't appear in the UI.
- The **Invoiced Unit Amount** field stores the amount that is invoiced per actual unit that is used. The value is calculated as the **Total Amount** value divided by the **Actual Quantity** value. This field is used for integration to systems that don't support different values for the used quantity and the billed quantity. The field doesn't appear in the UI.
- The **Invoiced Discount Amount** field is calculated as the **Discount Amount** value plus the rounding from the calculation of the **Invoiced Unit Amount** value. This field is used for integration and doesn't appear in the UI.
- The **External Line Order** field is a calculated negative line order number that can be used in external systems where work order product and service lines are combined. This field enables work order products that are inserted to have positive line numbers and work order services to have negative line numbers. The value of this this field is calculated as the **Line Order** value multiplied by -1. This field doesn't appear in the UI.
- The value in **Used** fields is reset to **0** (zero) if the **Line Status** value of the work order service is changed from **Used** to **Estimated** for some reason. This change helps prevent situations where a used quantity that is mistakenly entered is used for synchronization when the **Line Status** value is **Estimated** and the **Header System Status** value is **Closed – Posted**.

Preconditions and mapping setup

Before you synchronize work orders, it's important that you update the following settings in the systems.

Setup in Field Service

- Make sure that the number series that is used for work orders in Field Service doesn't overlap the number sequence that is used for sales orders in Supply Chain Management. Otherwise, existing sales orders can be incorrectly updated in Field Service or Supply Chain Management.
- The **Work Order Invoice Creation** field must be set to **Never**, because the invoicing will be done from Supply Chain Management. Go to **Field Service** > **Settings** > **Administration** > **Field Service Settings**, and make sure that the **Work Order Invoice Creation** field is set to **Never**.

Setup in Supply Chain Management

Work order integration requires that you set up the sales origin. The sales origin is used to distinguish sales orders in Supply Chain Management that were created from work orders in Field Service. When a sales order has a sales origin of the **Work order integration** type, the **External work order status** field appears on the sales order header. Additionally, the sales origin helps guarantee that sales orders that were created from work orders in Field Service are filtered out during sales order synchronization from Supply Chain Management to Field Service.

1. Go to **Sales and marketing** > **Setup** > **Sales orders** > **Sales origin**.
2. Select **New** to create a new sales origin.

3. In the **Sales origin** field, enter a name for the sales origin, such as **WorkOrder**.
4. In the **Description** field, enter a description, such as **Field Service Work Order**.
5. Select the **Origin type assignment** check box.
6. Set the **Sales origin type** field to **Work order integration**.
7. Select **Save**.

Setup in Data integration

Ensure the **Integration key** exist for **msdyn_workorders**

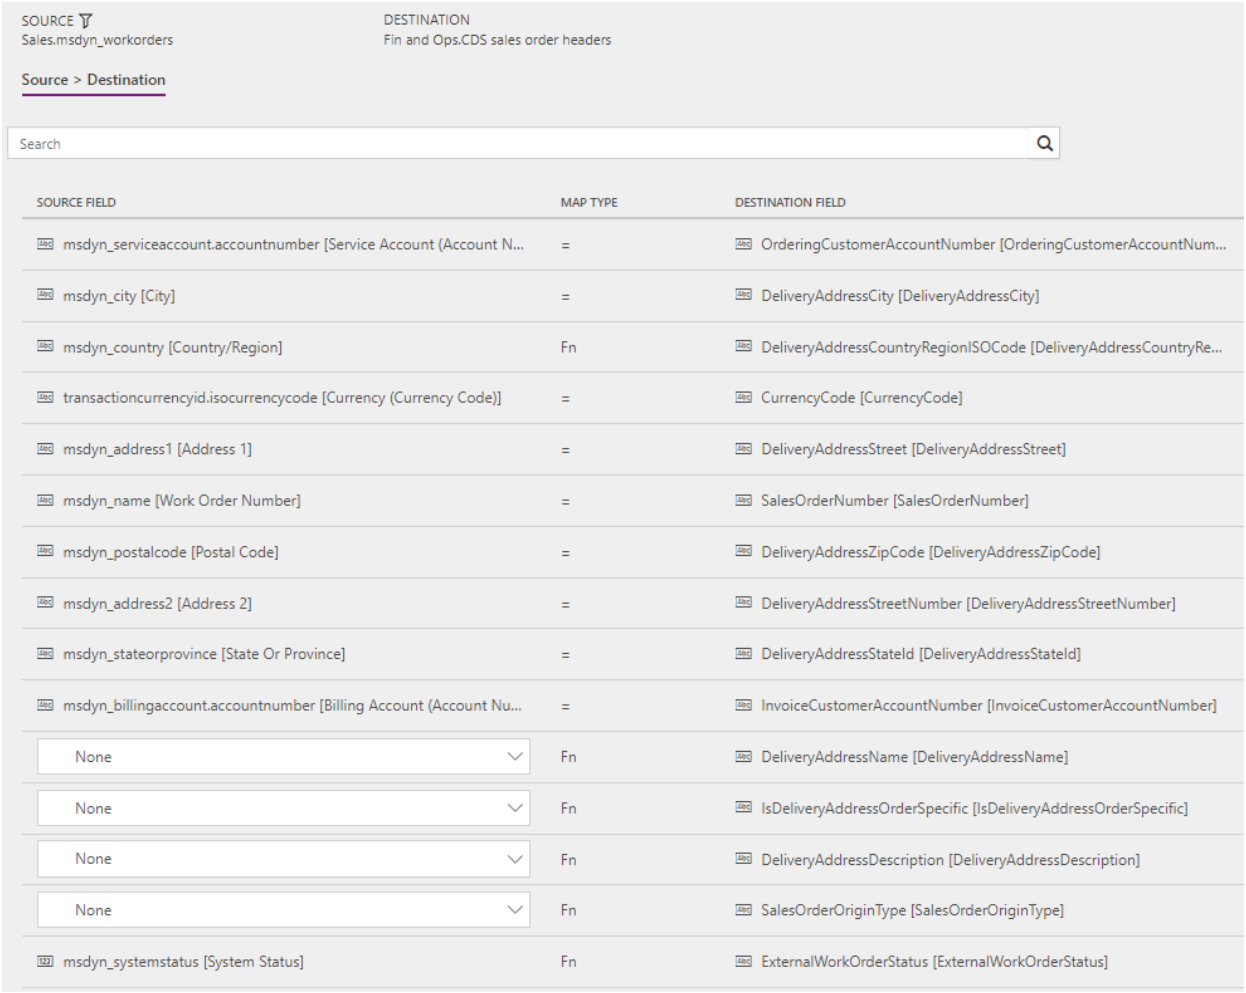
1. Go to Data Integration
2. Select **Connection Set** tab
3. Select the Connection set used for Work order synchronization
4. Select **Integration key** tab
5. Find msdyn_workorders and check that the key **msdyn_name (Work Order Number)** is added. If it is not shown, add it by click **Add key** and click **Save** in the top of the page

Template mapping in Data integration

The following illustrations show the template mapping in Data integration.

Work orders to Sales orders (Field Service to Supply Chain Management): WorkOrderHeader

Filter: (msdyn_systemstatus ne 690970005) and (msdyn_systemstatus ne 690970000) and (msdynce_hasexternallymaintainedproductsonly eq true)



Work orders to Sales orders (Field Service to Supply Chain Management): WorkOrderServiceLineEstimate

The survey will take about seven minutes. No personal data is collected (privacy statement).

Synchronize agreement invoices in Field Service to free text invoices in Supply Chain Management

2/18/2021 • 3 minutes to read • Edit Online

NOTE

Effective November 2020:

- Common Data Service has been renamed to Microsoft Dataverse. For more information, see Power Automate Blog.
- Some terminology in Microsoft Dataverse has been updated. For example, *entity* is now *table* and *field* is now *column*. For more information, see Terminology updates.

This topic will be updated soon to reflect the latest terminology.

This topic discusses the templates and underlying tasks that are used to synchronize agreement invoices in Dynamics 365 Field Service to free text invoices in Dynamics 365 Supply Chain Management.

Templates and tasks

The following template and underlying tasks are used to run synchronization of agreement invoices from Field Service to free text invoices in Supply Chain Management.

Name of the template in Data integration

- Agreement invoices (Field Service to Supply Chain Management)

Names of the tasks in the Data integration project

- Invoice headers
- Invoice lines

The following synchronization is required before synchronization of agreement invoices can occur:

- Accounts (Sales to Supply Chain Management) – Direct

Entity set

FIELD SERVICE	SUPPLY CHAIN MANAGEMENT
invoices	Dataverse customer free text invoice headers
invoicedetails	Dataverse customer free text invoice lines

Entity flow

Invoices that are created from an agreement in Field Service can be synchronized to Supply Chain Management via a Microsoft Dataverse Data integration project. Updates to these invoices will be synchronized to the free text invoices in Supply Chain Management if the accounting status of the free text invoices is **In process**. After the free text invoices are posted in Supply Chain Management, and the accounting status is updated to **Completed**, you can no longer synchronize updates from Field Service.

Field Service CRM solution

The **Has Lines With Agreement Origin** column has been added to the **Invoice** table. This column helps guarantee that only invoices that are created from an agreement are synchronized. The value is **true** if the invoice contains at least one invoice line that originates from an agreement.

The **Has Agreement Origin** column has been added to the **Invoice Line** table. This column helps guarantee that only invoice lines that are created from an agreement are synchronized. The value is **true** if the invoice line originates from an agreement.

Invoice date is a mandatory field in Supply Chain Management. Therefore, the column must have a value in Field Service before synchronization occurs. To meet this requirement, the following logic is added:

- If the **Invoice Date** column is blank on the **Invoice** table (that is, if it has no value), it's set to the current date when an invoice line that originates from an agreement is added.
- The user can change the **Invoice Date** column. However, when the user tries to save an invoice that originates from an agreement, he or she receives a business process error if the **Invoice Date** column is blank on the invoice.

Prerequisites and mapping setup

In Supply Chain Management

An invoice origin must be set up for the integration, to distinguish the free text invoices in Supply Chain Management that are created from agreement invoices in Field Service. When an invoice has an invoice origin of the **Agreement invoice integration** type, the **External invoice number** field is shown on the **Sales invoice** header.

Besides appearing on the invoice header, the **External invoice number** information can be used to help guarantee that invoices that are created from Field Service agreement invoices are filtered out during invoice synchronization from Supply Chain Management to Field Service.

1. Go to **Accounts receivable** > **Setup** > **Invoice origin codes**.
2. Select **New** to create a new invoice origin.
3. In the **Invoice origin** field, enter a name for the invoice origin, such as **FS**.
4. In the **Description** field, enter a description, such as **Field Service Agreement Invoice**.
5. Select the **Origin type assignment** check box.
6. Set the **Invoice origin type** field to **Agreement invoice integration**.
7. Select **Save**.

In the Data Integration project

Task: **Invoice lines**

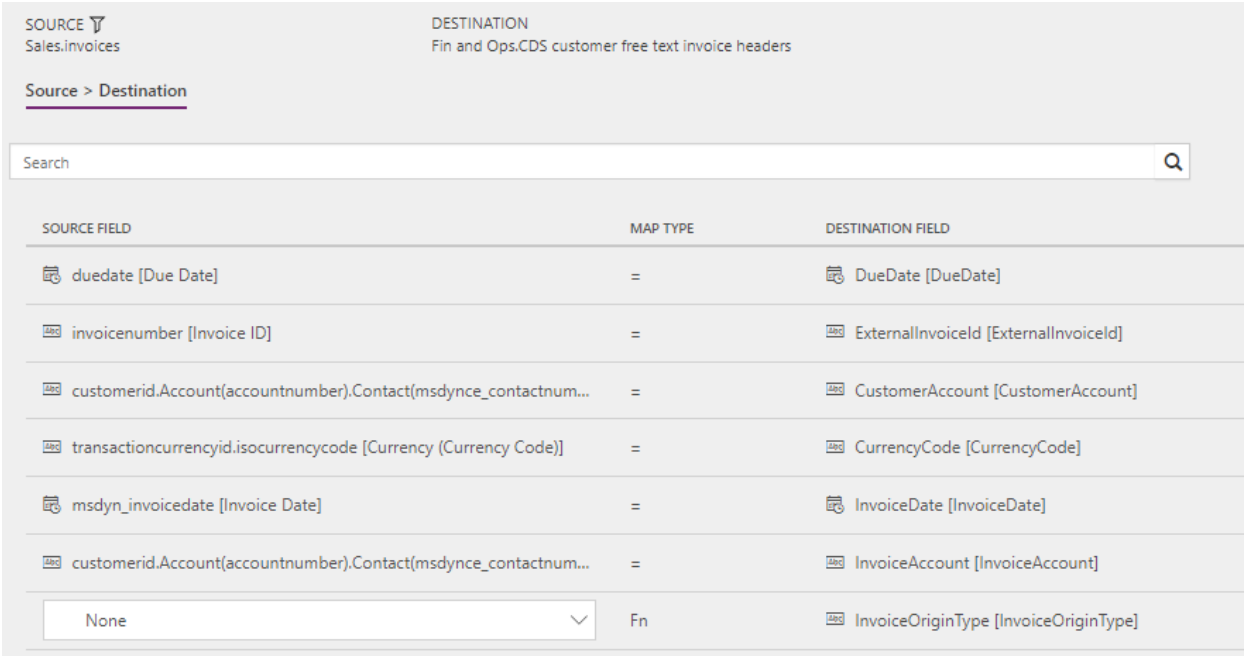
Make sure that the default value for the Supply Chain Management field **Main Account Display Value** is updated to match the desired value.

The default template value is **401100**.

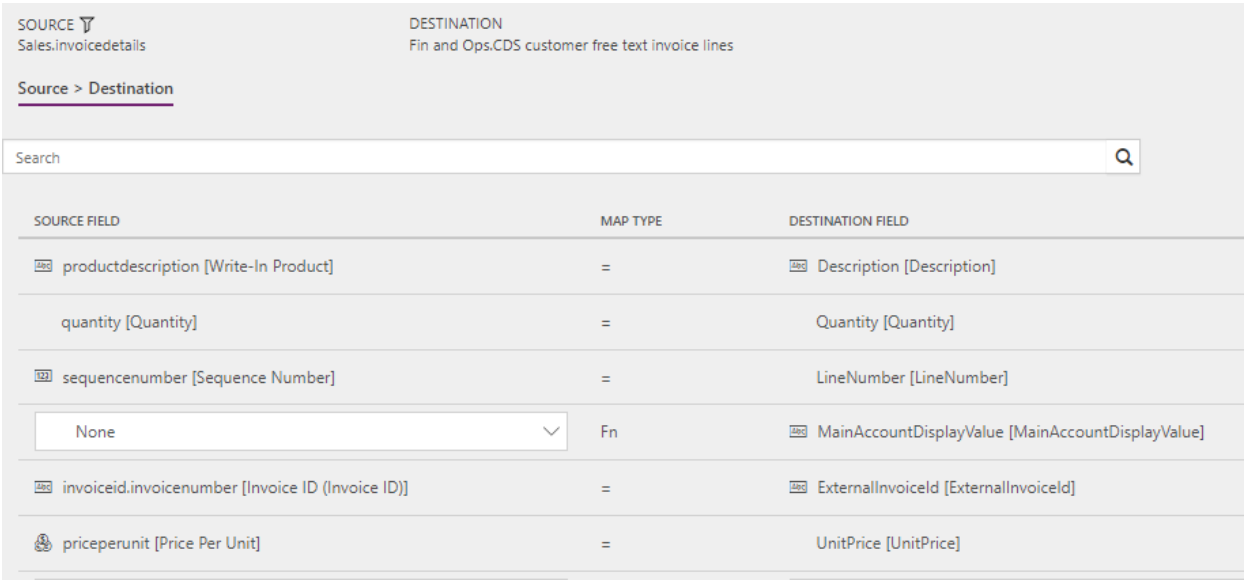
Template mapping in Data integration

The following illustrations show the template mapping in Data integration.

Agreement invoices (Field Service to Supply Chain Management): Invoice headers



Agreement invoices (Field Service to Supply Chain Management): Invoice lines



NOTE

The survey will take about seven minutes. No personal data is collected (privacy statement).

Synchronize inventory transfers and adjustments from Field Service to Supply Chain Management

2/18/2021 • 3 minutes to read • Edit Online

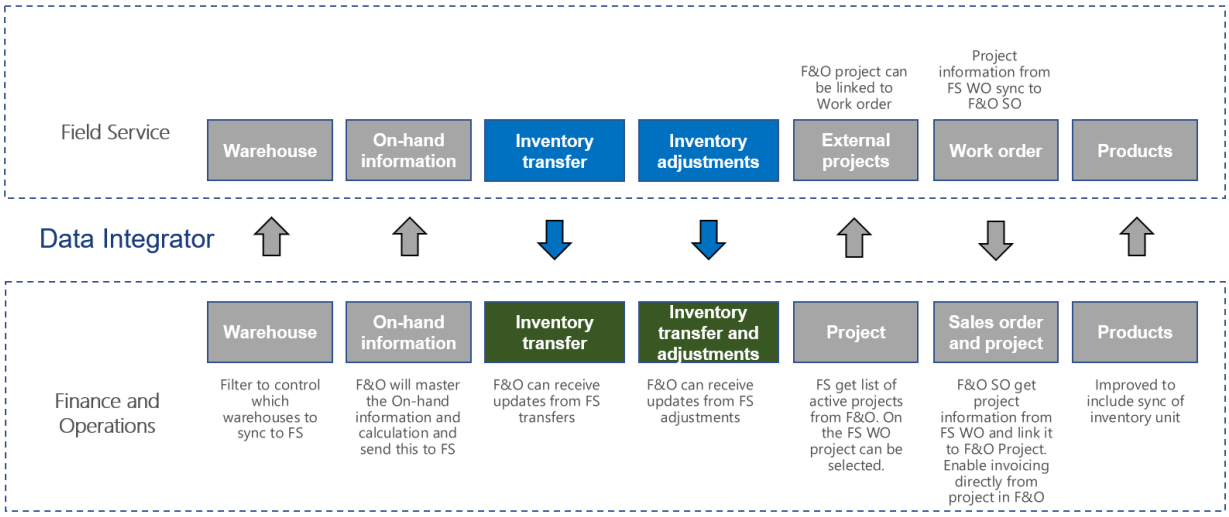
NOTE

Effective November 2020:

- Common Data Service has been renamed to Microsoft Dataverse. For more information, see Power Automate Blog.
- Some terminology in Microsoft Dataverse has been updated. For example, *entity* is now *table* and *field* is now *column*. For more information, see Terminology updates.

This topic will be updated soon to reflect the latest terminology.

This topic discusses the templates and underlying tasks that are used to synchronize inventory adjustments and transfers from Dynamics 365 Supply Chain Management to Dynamics 365 Field Service.



Templates and tasks

The following template and underlying tasks are used to synchronize inventory adjustments and transfers from Field Service to Supply Chain Management.

Templates in Data integration

- Inventory Adjustment (Field Service to Supply Chain Management)
- Inventory Transfers (Field Service to Supply Chain Management)

Tasks in the Data integration projects

- Inventory Adjustments
- Inventory Transfers

Table set

FIELD SERVICE	SUPPLY CHAIN MANAGEMENT
msdyn_inventoryadjustmentproducts	Dataverse Inventory adjustment journal headers and lines
msdyn_inventoryadjustmentproducts	Dataverse inventory transfer journal headers and lines

Table flow

Inventory adjustments and transfers made in Field Service will synchronize to Supply Chain Management after the **Post status** changes from **Created** to **Posted**. When this occurs, the adjustment or the transfer order will be locked and become read only. This means that adjustments and transfers can be posted in Supply Chain Management, but cannot be modified. In Supply Chain Management, you can set up a batch job to automatically post the adjustments and transfer inventory journals that have been generated during the integration. See the following prerequisites for details on how to enable the batch job.

Field Service CRM solution

The **Inventory unit** column has been added to the **Product** table. This column is needed because the Sales and Inventory unit is not always the same in Supply Chain Management, and the Inventory Unit is needed for the Warehouse Inventory in Supply Chain Management. When you set the product on an Inventory adjustment product for both Inventory adjustments and Inventory transfers, the unit will be fetched from the inventory product value. If a value is found, the **Unit** column will be locked on the Inventory adjustment product.

The **Post status** column has been added to both the **Inventory adjustment** table and the **Inventory transfer** table. This column is used as a filter when an adjustment or transfer is sent to Supply Chain Management. The default for this column is Created (1), however it is not sent to Supply Chain Management. When you update the value to Posted (2), it is sent to Supply Chain Management, but after that you will no longer be able to change the adjustment or transfer or add new lines.

The **Number sequence** column has been added to the **Inventory adjustment product** table. This column ensures that the integration has a unique number, so the integration can create and update the adjustment. When you create your first inventory adjustment product, it will create a new record in the **P2C AutoNumber** table to maintain the number series and the prefix that is used.

Prerequisites and mapping setup

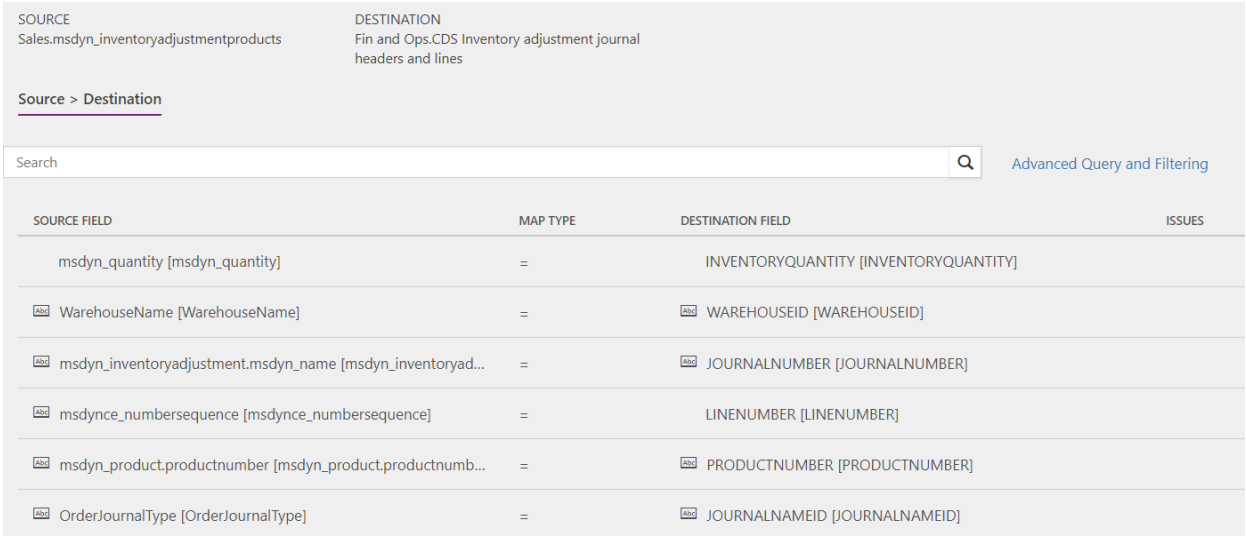
Supply Chain Management

The integration inventory journals generated by the integration can automatically be posted using a batch job. This is enabled from **Inventory management > Periodic tasks > Dataverse integration > Post integration inventory journals**.

Template mapping in Data integration

The following illustrations show the template mapping in Data integration.

Inventory adjustment (Field Service to Supply Chain Management): Inventory adjustment



Inventory transfer (Field Service to Supply Chain Management): Inventory transfer

Synchronize inventory level information from Supply Chain Management to Field Service

2/18/2021 • 3 minutes to read • Edit Online

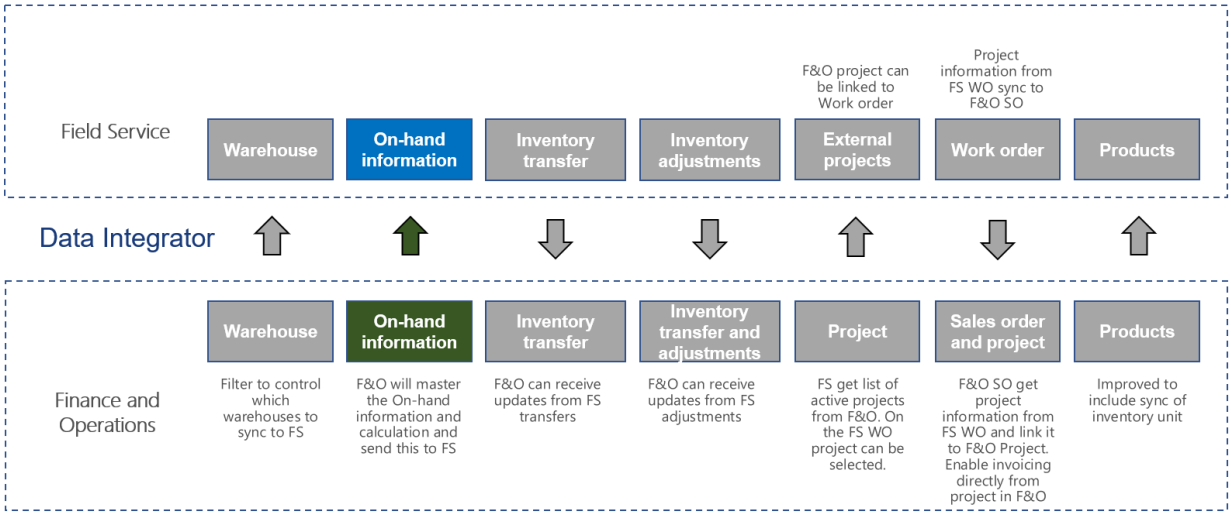
NOTE

Effective November 2020:

- Common Data Service has been renamed to Microsoft Dataverse. For more information, see Power Automate Blog.
- Some terminology in Microsoft Dataverse has been updated. For example, *entity* is now *table* and *field* is now *column*. For more information, see Terminology updates.

This topic will be updated soon to reflect the latest terminology.

This topic discusses the templates and underlying tasks that are used to synchronize inventory-level information from Dynamics 365 Supply Chain Management to Dynamics 365 Field Service.



Templates and tasks

The following template and underlying tasks are used to synchronize inventory on-hand levels from Supply Chain Management to Field Service.

Template in Data integration

- Product Inventory (Supply Chain Management to Field Service)

Task in the Data integration project

- Product inventory

The following synchronization tasks are required before synchronization of inventory levels can occur:

- Warehouses (Supply Chain Management to Field Service)
- Field Service products with Inventory unit (Supply Chain Management to Sales)

Entity set

FIELD SERVICE	SUPPLY CHAIN MANAGEMENT
msdynce_externalproductinventories	Dataverse inventory on-hand by warehouse

Entity flow

Inventory-level information from Finance and Operation is sent to Field Service for selected products. The inventory-level information includes:

- On hand quantity (current recorded physical quantity located in the warehouse)
- On order quantity (total recorded quantity on order, such as sales orders)
- Ordered quantity (total recorded ordered quantity, such as purchase orders)

This information is captured per released product for each warehouse and synchronized based on change tracking, when the inventory level changes.

In Field Service, the integration solution creates inventory journals for the delta, so that the levels in Field Service match the levels in Supply Chain Management.

Supply Chain Management will act as the master for inventory levels. Therefore it is important to set up integration for work orders, transfers, and adjustments from Field Service to Supply Chain Management if this functionality is used in Field Service, together with synchronization of inventory levels from Supply Chain Management.

The products and warehouses where inventory levels are mastered from Supply Chain Management can be controlled with the Advanced Query and Filtering (Power Query).

> **NOTE**
>
> It is possible to create multiple warehouses in Field Services (with **Is Externally Maintained = No**) and then map them to a single warehouse in Supply Chain Management, with the Advanced query and filtering functionality. This is used in situations where you want Field Service to master the detailed inventory level and only send updates to Supply Chain Management. In this case, Field Service will not receive inventory-level updates from Supply Chain Management. For additional information, see Synchronize inventory adjustments from Field Service to Supply Chain Management and Synchronize work orders in Field Service to sales orders linked to project in Supply Chain Management.

Field Service CRM solution

The **External product inventory** entity is only used for back end in to the integration. This entity receives the inventory level values from Supply Chain Management in the integration and then transforms those values to Manual inventory journals, which then changes the Inventory products in the Warehouse.

Prerequisites and mapping setup

Data integration

For the project to work, you need to ensure that the Integration key is updated for msdynce_externalproductinventories.

1. Go to **Data integration > Connection sets**.
2. Select the used Connection set.
3. On the **Integration key** tab, ensure that the following keys are added to msdynce_externalproductinventories:
   - msdynce_productnumber (Product Number)

- msdynce_warehouseid (Warehouse ID)

Data integration project

You can apply filters with Advanced Query and Filtering so that only certain products and warehouses send inventory-level information from Supply Chain Management to Field Service.

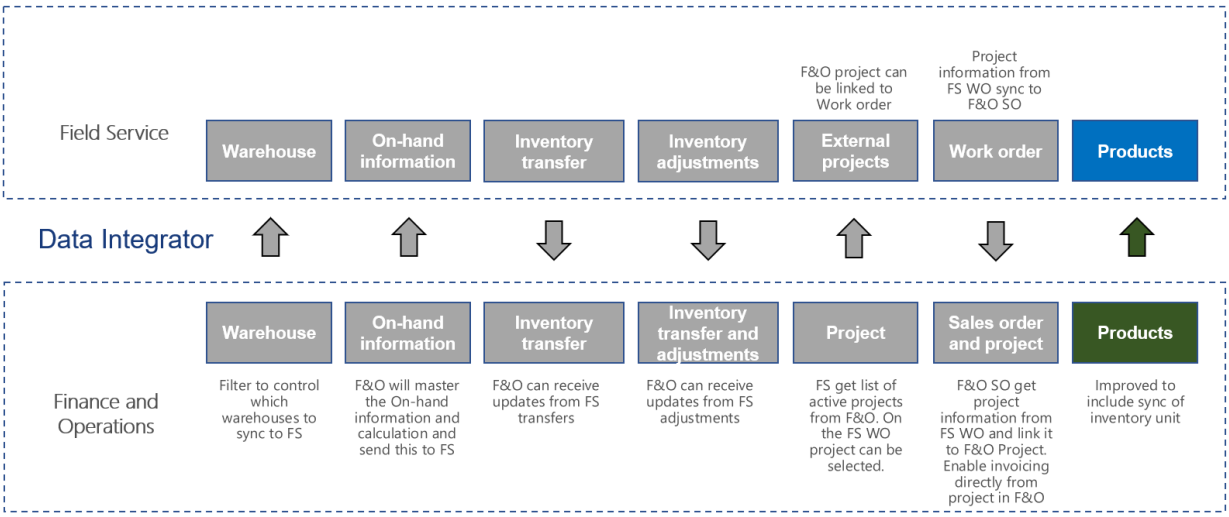
Synchronize products with inventory unit from Supply Chain Management to Field Service

2/18/2021 • 2 minutes to read • Edit Online

This topic discusses the templates and underlying task that are used to synchronize products with inventory unit from Dynamics 365 Supply Chain Management to Dynamics 365 Field Service.



The used **Field Service Products with Inventory unit (Supply Chain Management to Field Service)** template is based on the **Field Service Products (Supply Chain Management to Field Service)** template. For more information, see Synchronize products in Supply Chain Management to products in Field Service.

This topic only describes the differences between the two templates:

- **Field Service Products with Inventory unit (Supply Chain Management to Sales)**
- **Field Service Products (Supply Chain Management to Field Service)**

Templates and tasks

Name of the template in Data integration:

- Field Service Products with Inventory unit (Supply Chain Management to Sales)

Name of the task in the Data integration project:

- Products

The **Field Service Products with Inventory unit (Supply Chain Management to Field Service)** template includes one mapping that isn't included in the **Field Service Products (Supply Chain Management to Field Service)** template. This mapping ensures that the Inventory unit needed for inventory level synchronization is included.

```
INVENTORYUNITSYMBOL [INVENTORYUNITSYMBOL]        Fn        msdynce_inventoryunit.name [Inventory
Unit(Name)]
```

Template mapping in Data integration

The following illustrations show the template mapping in Data integration.

Field Service Products with Inventory unit (Supply Chain Management to Field Service): Products

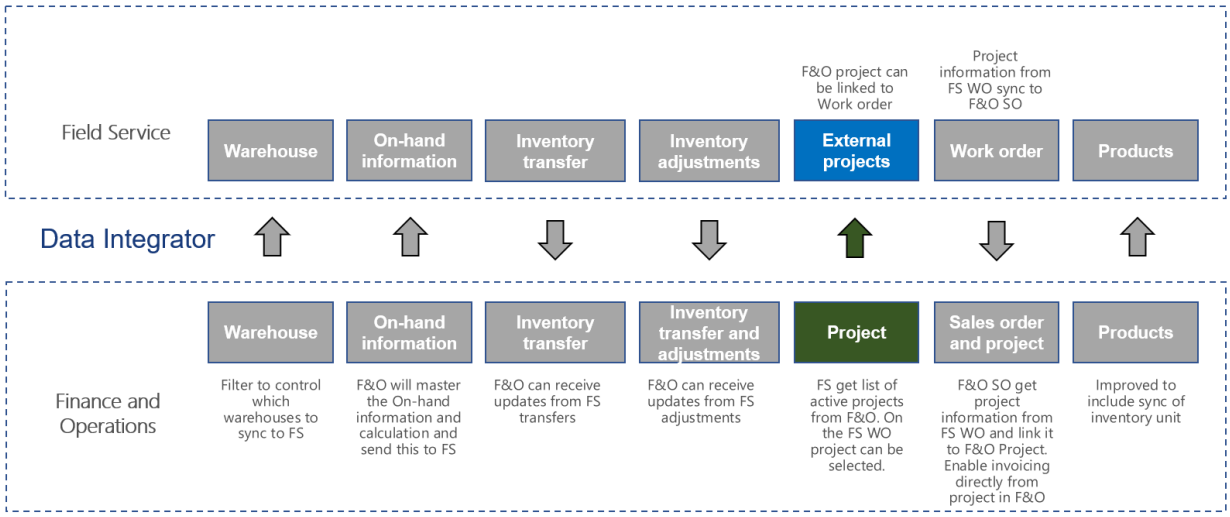
Synchronize project list from Supply Chain Management to Field Service

2/18/2021 • 2 minutes to read • Edit Online

This topic discusses the templates and underlying tasks that are used to synchronize projects from Dynamics 365 Supply Chain Management to Dynamics 365 Field Service.



Templates and tasks

The following template and underlying tasks are used to run synchronization of projects from Supply Chain Management to Field Service.

Template in Data integration

- Projects (Supply Chain Management to Field Service)

Task in the Data integration project

- Projects

The following synchronization tasks are required before synchronization of project list can occur:

- Accounts (Sales to Supply Chain Management)

Entity set

FIELD SERVICE	SUPPLY CHAIN MANAGEMENT
msdynce_externalprojects	Projects

Entity flow

Projects are created in Supply Chain Management. Projects with **Project type** set to **Time and material** and **Project stage** set to **In process** will synchronize to the **External Project** entity in Field Service, including Project number, Project name, Project stage, and Customer account information. The **External Project** list is used to pair Field service work orders with Supply Chain Management projects.

Field Service CRM solution

The **External Project** entity gets all the projects from Supply Chain Management. The **External Project** field has been added to the **Work Order** entity. This is a lookup field, so by tagging your work order with a project, the sales order will be connected to a project within Supply Chain Management. After the **System Status** changes **Open – In Progress(690,970,000)** to a higher status, the **External Project** field will be locked and you can no longer add, remove, or change the value.

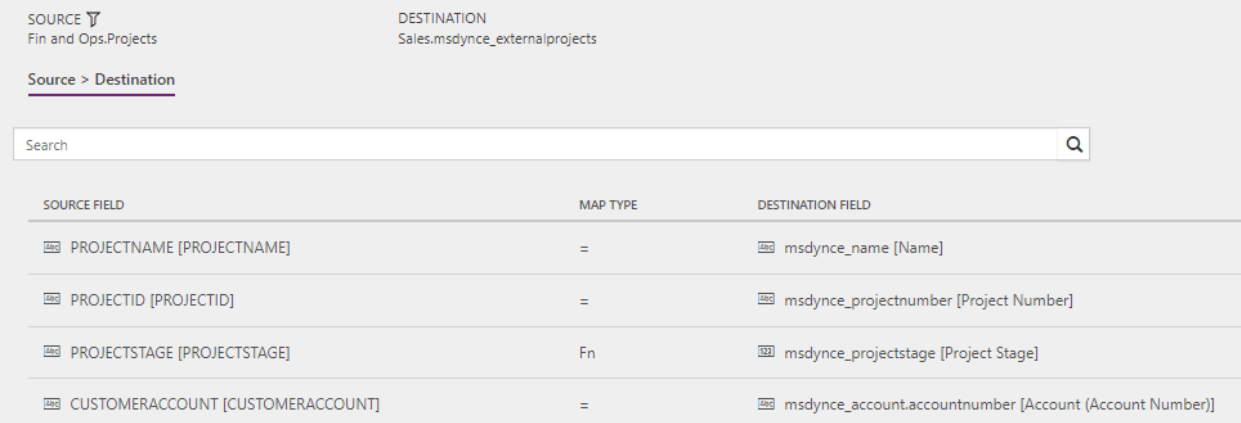
Prerequisites and mapping setup

Supply Chain Management

Enable change tracking for Data entity projects.

Template mapping in Data integration

Projects (Supply Chain Management to Field Service): Projects



NOTE

The survey will take about seven minutes. No personal data is collected (privacy statement).

Synchronize warehouses from Supply Chain Management to Field Service

2/18/2021 • 3 minutes to read • Edit Online

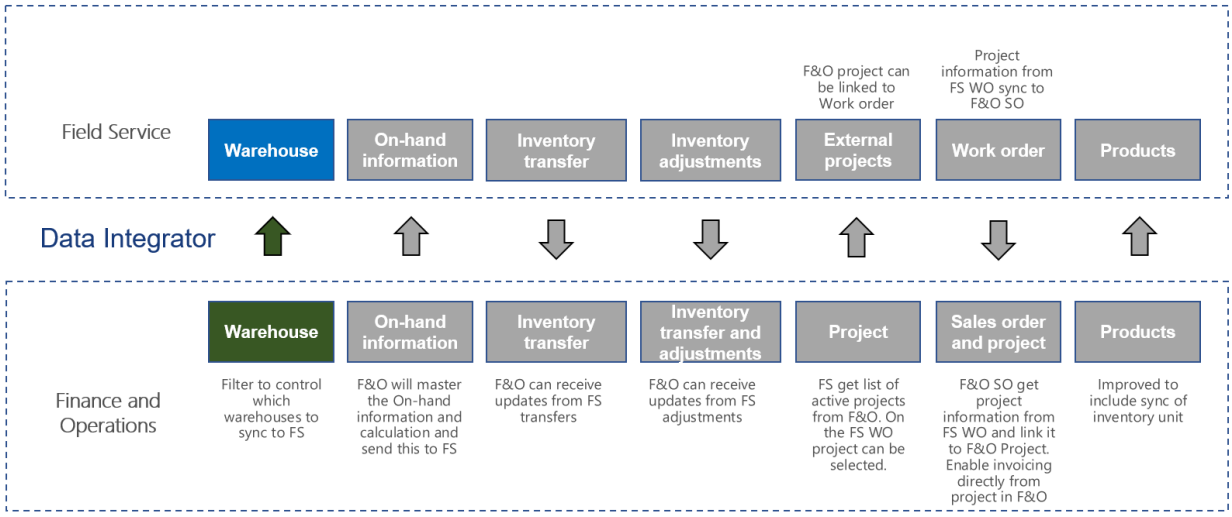
NOTE

Effective November 2020:

- Common Data Service has been renamed to Microsoft Dataverse. For more information, see Power Automate Blog.
- Some terminology in Microsoft Dataverse has been updated. For example, *entity* is now *table* and *field* is now *column*. For more information, see Terminology updates.

This topic will be updated soon to reflect the latest terminology.

This topic discusses the templates and underlying tasks that are used to synchronize warehouses from Dynamics 365 Supply Chain Management to Dynamics 365 Field Service.



Templates and tasks

The following template and underlying tasks are used to run synchronization of warehouses from Supply Chain Management to Field Service.

Template in Data integration

- Warehouses (Supply Chain Management to Field Service)

Task in the Data integration project

- Warehouse

Table set

FIELD SERVICE	SUPPLY CHAIN MANAGEMENT
msdyn_warehouses	Warehouses

Table flow

Warehouses that are created and maintained in Supply Chain Management can be synchronized to Field Service via a Microsoft Dataverse Data integration project. The warehouses that you want to synchronize to Field Service can be controlled with the Advanced query and filtering on the project. Warehouses that synchronize from Supply Chain Management are created in Field Service with the **Is maintained externally** column set to **Yes** and the record is read only.

Field Service CRM solution

To support the integration between Field Service and Supply Chain Management, additional functionality from the Field Service CRM solution is required. In the solution, the **Is Maintained Externally** column has been added to the **Warehouse (msdyn_warehouses)** table. This column helps to identify if the warehouse is handled from Supply Chain Management or if it only exists in Field Service. The settings for this column include:

- **Yes** – The warehouse originated from Supply Chain Management and won't be editable in Sales.
- **No** – The warehouse was entered directly in Field Service and is maintained here.

The **Is Externally Maintained** column helps control the synchronization of inventory levels, adjustments, transfers, and usage on work orders. Only warehouses with **Is Externally Maintained** set to **Yes** can be used to synchronize directly to the same warehouse in the other system.

> **NOTE**
>
> It is possible to create multiple warehouses in Field Service (with **Is Externally Maintained** = No) and then map them to a single warehouse, with the Advanced query and filtering functionality. This is used in situations where you want Field Service to master the detailed inventory level and just send updates to Supply Chain Management. In this case, Field Service will not receive inventory-level updates from Supply Chain Management. For additional information, see Synchronize inventory adjustments from Field Service to Finance and Operations and Synchronize work orders in Field Service to sales orders linked to project in Finance and Operations.

Prerequisites and mapping setup

Data Integration project

Before synchronizing the warehouses, make sure to update the Advanced query and filtering on the project to only include the warehouses that you want to bring from Supply Chain Management to Field Service. Note that you will need the warehouse in Field Service to apply it on work orders, adjustments, and transfers.

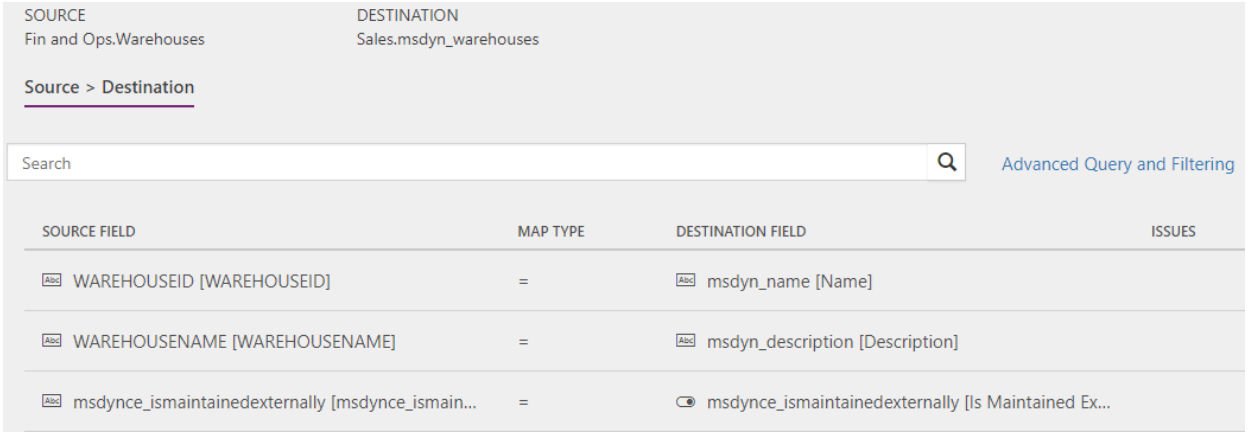
To ensure that the **Integration key** exists for **msdyn_warehouses**:

1. Go to Data Integration.
2. Select the **Connection Set** tab.
3. Select the connection set used for work order synchronization.
4. Select the **Integration key** tab.
5. Find msdyn_warehouses and confirm that the key **msdyn_name (name)** is added. If it is not shown, add it by clicking **Add key** and then click **Save** at the top of the page.

Template mapping in Data integration

The following illustration shows the template mapping in Data integration.

Warehouses (Supply Chain Management to Field Service): Warehouse



NOTE

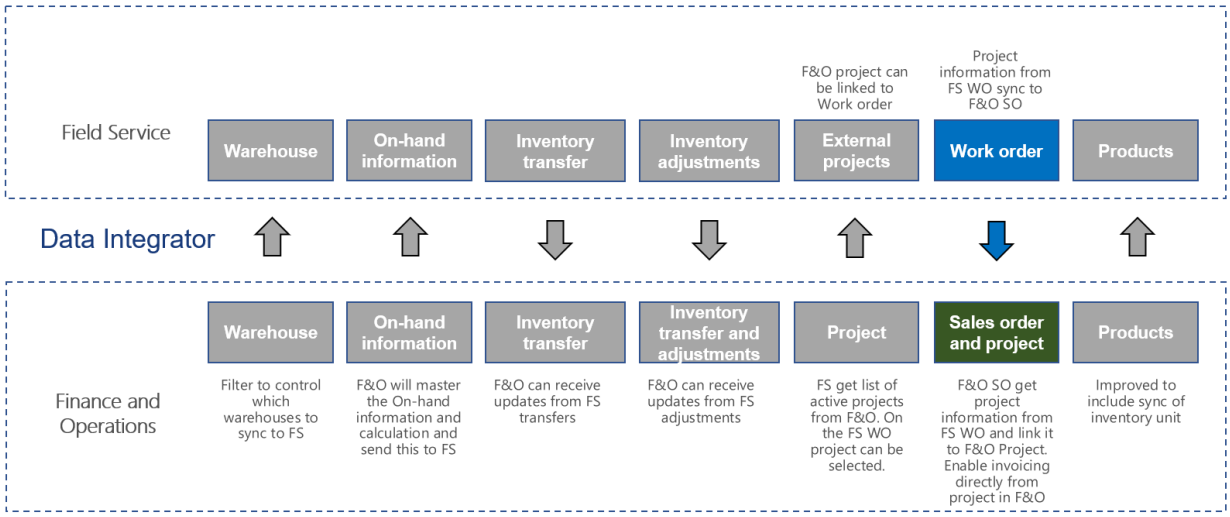
Can you tell us about your documentation language preferences? Take a short survey.

The survey will take about seven minutes. No personal data is collected (privacy statement).

Synchronize work orders with project from Field Service to Supply Chain Management

2/18/2021 • 2 minutes to read • Edit Online

This topic discusses the templates and underlying task that are used to synchronize work orders with a project number from Dynamics 365 Field Service to Dynamics 365 Supply Chain Management.



The used **Work Orders with Project (Field Service to Supply Chain Management)** template is based on the **Work Orders (Field Service to Supply Chain Management)** template. For more information, see Synchronize work orders in Field Service to sales orders in Supply Chain Management.

This topic only describes the differences between the two templates:

- **Work Orders with Project (Field Service to Supply Chain Management)**
- **Work Orders (Field Service to Supply Chain Management)**

The main difference is that this template includes mapping of the project number assigned to the Work order in Field Service, ensuring that the Sales order created in Supply Chain Management include the project number and that invoicing can happen on the related project. Besides this the template use Advanced Query and Filtering.

Templates and tasks

Name of the template in Data integration:

- Work Orders with Project (Field Service to Supply Chain Management)

Name of the task in the Data integration project:

- WorkOrderHeader
- WorkOrderHeaderProject
- WorkOrderProduct
- WorkOrderService

Field Service CRM solution

The **External Project** field has been added to the Work Order entity. This field is a lookup and buy tagging your Work Order with a project the Sales Order will then be connected to a Project within Supply Chain Management. When the **System Status** changes from Open – In Progress(690,970,000) to a higher status, the **External Project** field will be locked and you can't add, remove, or change the value.

Template mapping in Data integration

The following illustrations show the template mapping in Data integration.

The survey will take about seven minutes. No personal data is collected (privacy statement).

Consume external web services

2/18/2021 • 2 minutes to read • Edit Online

You can consume web services by adding new class libraries. In Microsoft Dynamics AX 2012, you could consume web services from X++ code by adding Microsoft Visual Studio projects as a reference and by using **Aif::CreateServiceClient**. This scenario is supported, but the steps have changed. Application Integration Framework (AIF) is no longer supported.

The following steps show how to consume an external StockQuote service from X++.

Note that the web service URL in this sample is fictional. There is no known web service at http://www.contoso.net/stockquote.asmx. To make this code work you will need to adapt it to your specific web service.

1. Create a new Class Library project in Visual Studio, and name it **ExternalServiceLibrary.csproj**.
2. In the Visual Studio project, add a service reference to the external web service: `http://www.contoso.net/stockquote.asmx`.
3. Create a new static class, and wrap the StockQuote service operation as shown in the following example.

```
public static string GetQuote(string s)
{
    var binding = new System.ServiceModel.BasicHttpBinding();
    var endpointAddress = new EndpointAddress("http://www.contoso.net/stockquote.asmx");
    ServiceLibrary.QuoteReference.StockQuoteSoapClient client = new
ServiceLibrary.QuoteReference.StockQuoteSoapClient(binding, endpointAddress);

    //GetQuote is the operation on the StockQuote service
    return client.GetQuote("MSFT");
}
```

4. Build the project. The binary ExternalServiceLibrary.dll is created.
5. Create a new Dynamics project in Visual Studio.
6. Add **ExternalServiceLibrary.dll** as a reference.
7. In the X++ class, you can use the external web services that were referenced in ExternalServiceLibrary.dll.

```
public static void main(Args _args)
{
    info(ServiceLibrary.StockQuoteClass::GetQuote("MSFT"));
}
```

Electronic messaging

2/18/2021 • 32 minutes to read • Edit Online

This topic provides overview and setup information for electronic messaging.

Recently, the governments and legislative authorities of various countries and regions around the world have implemented reporting requirements for companies that are registered in those countries or regions. The purpose of the requirements is to enable data to be obtained from those companies in electronic format, directly from the systems where it was accounted, stored, and processed.

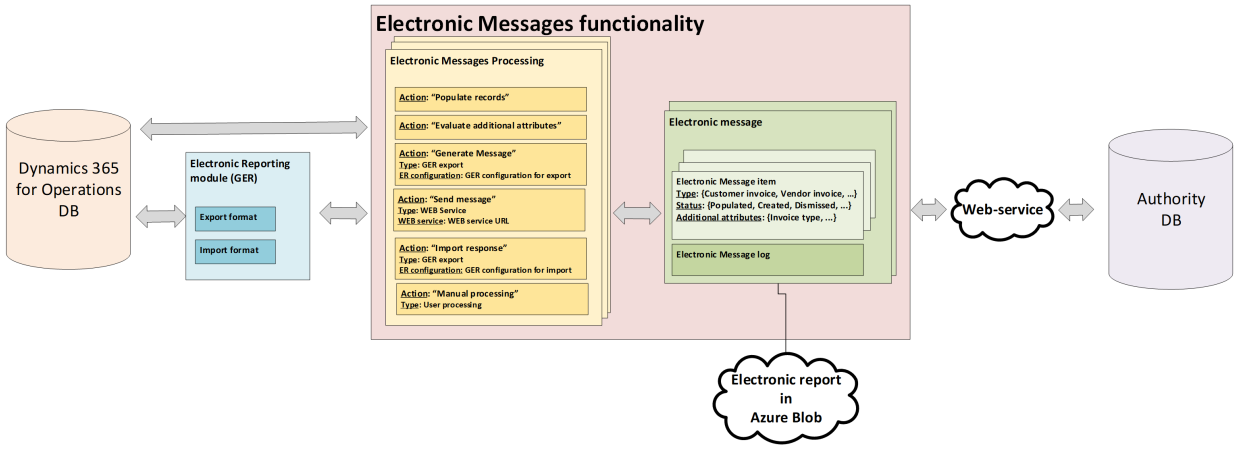
The Electronic messages functionality in Finance supports various processes for electronic interoperation between Finance and the systems that governments and legislative authorities offer for reporting, submitting, and receiving official information.

The Electronic messages functionality is integrated with the **Electronic Reporting** (ER) module. Therefore, you can set up ER formats for electronic messages. For more information, see Electronic reporting (ER).

Electronic messaging is based on the following entities:

- **Electronic message** – A report or declaration that should be reported and/or transmitted internally. An example is a report that is sent to a tax office.
- **Electronic message items** – Records that should be included in the message that is reported.
- **Electronic message processing** – A chain of actions that should be run to collect the required data, generate reports, store data in Microsoft Azure Blob storage, transmit reports outside the system, receive responses from outside the system, and, based on the information that is received, update the database. The actions in the chain can be either linked or unlinked

The following illustration shows the flow of data for electronic messaging.



The Electronic messages functionality supports the following scenarios:

- Manually create messages, and generate reports that are based on associated exporting ER formats of various types: Microsoft Excel, XML, JavaScript Object Notation (JSON), PDF, text, and Microsoft Word.
- Automatically create and process messages that are based on information that was requested and received from an authority via an associated importing ER format.
- Collect and process information from a data source as message items. The data source is a Finance table.
- Store additional information, and evaluate various values by calling specifically defined executable classes in relation to messages or message items.
- Aggregate information that is collected in message items, split that information by message, and generate

reports that are in associated exporting ER formats.

- Transmit the reports that are generated to a web service by using security information that is stored in Azure Key Vault.
- Receive a response from a web service, interpret the response, and update data in Finance as appropriate.
- Store and review all the reports that are generated.
- Store and review all the log information that is related to actions that are run for a message or message item.
- Control the processing through various message statuses and message item statuses.

Set up electronic messaging

Electronic messaging can help you maintain different electronic reporting processes for different document types. In some complex scenarios, electronic messaging is set up so that it has a combination of many message statuses, message items statuses, actions, additional fields, and executable classes. For these scenarios, packages of data entities are available for import. If you use these data entity packages, you should import them to a legal entity by using the Data management tool. For more information about how to use the Data management tool, see Data management.

If you don't import a data entity package, you can manually set up the Electronic messages functionality. In this case, you must set up the following elements:

- Number sequences
- Message item types and statuses
- Message statuses
- Additional fields
- Executable class settings
- Populate records actions
- Web applications
- Web service settings
- Message processing actions
- Electronic message processing

The following sections provide more information about each of these elements.

Number sequences

Set up number sequences for both messages and message items. The number sequences are used to automatically number the messages and the message items. The numbers that are assigned will be used as unique identifiers for the messages and message items in the system. You can set up number sequences for electronic messaging on the **General ledger parameters** page (**General ledger** > **Ledger setup** > **General ledger parameters**).

Message item types and statuses

Message item types identify the types of records that will be used in electronic messages. You can set up message item types on the **Message item types** page (**Tax** > **Setup** > **Electronic messages** > **Message item types**).

Message item statuses identify the statuses that will apply to message items in the processing that you're setting up. You can set up message item types on the **Message item statuses** page (**Tax** > **Setup** > **Electronic messages** > **Message item statuses**).

The **Allow delete** parameter of a message item status defines whether users can delete message items that have this status on the **Electronic messages** page or the **Electronic message items** page.

Message statuses

Set up the message statuses that should be available in message processing. You can set up message statuses on the **Message statuses** page (**Tax** > **Setup** > **Electronic messages** > **Message statuses**).

The following table describes the fields on the **Message statuses** page.

FIELD NAME	DESCRIPTION
Message status	Enter a unique name for the message status. Message statuses are used to characterize the state of an electronic message at every moment. The name that you enter is shown on the **Electronic messages** page and in a log that is related to electronic messages.
Description	Enter a description of the message status.
Response type	Select the type of response for the message status. Some actions in a processing can produce more than one response type. For example, actions of the **Web service** type can produce responses of either the **Successfully executed** type or the **Technical error** type, depending on the result of its execution. In this case, you must define message statuses for both response types. For more information about action types and the types of responses that are related to them, see Message processing action types.
Message item status	Sometimes, the status of an electronic message must influence the status of related message items. Select a message item status in this field to associate it with the message status.
Allow delete	Select this check box if users should be able to delete electronic messages that have this status on the **Electronic messages** page.

Additional fields

The Electronic messages functionality lets you fill in records from a transactional table. In this way, you can prepare the records for reporting and then report them. However, transactional tables sometimes don't have enough information to fill in records in a manner that meets the reporting requirements. To fill in all the information that must be reported for a record, you can set up additional fields. Additional fields can be associated with both messages and message items. You can set up additional fields on the **Additional fields** page (**Tax** > **Setup** > **Electronic messages** > **Additional fields**).

The following table describes the general fields on the **Additional fields** page.

FIELD	DESCRIPTION
Field name	Enter the name of an additional attribute of message items that are related to the process. This name is shown in the user interface (UI) while you work with the process. It can also be used in ER configurations that are related to the process.
Description	Enter a description of the additional field.
User edit	Set this option to **Yes** if users should be able to change the value of the additional field from the UI.

FIELD	DESCRIPTION
Counter	Set this option to **Yes** if the additional field should contain a number sequence in an electronic message. Value of the additional field will be filled in automatically when an action of the **Electronic reporting export** is run.
Hidden	Set this option to **Yes** if the additional field should be hidden in the UI.

Each additional field can have different values for the processing. You define these values on **Values** FastTab. The following table describes the fields.

FIELD	DESCRIPTION
Field value	Enter the field value to use for a message or message item during reporting.
Description	Enter a description of the field value.
Account type	Some field values might be limited to specific account types. Select one of the following values: **All**, **Customer**, or **Vendor**.
Account code	If you selected **Customer** or **Vendor** in the **Account type** field, you can further limit the use of the field value to a specific group or table.
Account/Group number	If you selected **Customer** or **Vendor** in the **Account type** field, and if you entered a group or table in the **Account code** field, you can enter a specific group or counteragent in this field.
Effective	Specify the date when the value should start to be considered.
Expiration	Specify the date when the value should stop being considered.

By default, combinations of criteria that are defined by the **Account/Group number**, **Account code**, **Effective**, and **Expiration** fields don't influence the selection of values for additional fields. However, these combinations can be used in an executable class to implement specific logic that calculates values for additional fields.

Executable class settings

An executable class is an X++ method or class that the electronic message processing can call in relation to an action if some evaluation is required for the process.

You can manually set up an executable class on the **Executable class settings** page (**Tax** > **Setup** > **Electronic messages** > **Executable class settings**). Create a line, and set the following fields.

FIELD	DESCRIPTION
Executable class	Enter the name that will be used during the setup of a message processing action that this class is called in relation to.

FIELD	DESCRIPTION
Description	Enter a description of the executable class.
Executable class name	Select an X++ executable class.
Execution level	This field is set automatically, because the value should be predefined for the selected executable class. This field limits the level that related evaluation is run on.
Class description	This field is set automatically, because the value should be predefined for the selected executable class.

Some executable classes might have mandatory parameters that must be defined before the executable class is run for the first time. To define these parameters, select **Parameters** on the Action Pane, set the fields in the dialog box that appears, and then select **OK**. It's important that you select **OK**. Otherwise, the parameters won't be saved to the database, and the executable class won't be called correctly.

Populate records actions

You use populate records actions to set up actions that add records to the Message items table so that they can be added to an electronic message. For example, if your electronic message must report customer invoices, you must set up a populate records action that is linked to the **Data source** field in the Customer invoice journal table. You can set up populate records actions on the **Populate records action** page (**Tax** > **Setup** > **Electronic messages** > **Populate records actions**). Create a new record for every action that should add records to the table, and set the following fields.

FIELD	DESCRIPTION
Name	Enter a name for the action that fills in records in your process.
Description	Enter a description of the populate records action.

On the **Datasources setup** FastTab, add a line for every data source that is used for the process, and set the following fields.

FIELD	DESCRIPTION
Name	Enter a name for the data source.
Message item type	Select the type of message item that should be used when records are created for the data source.
Account type	Select the type of account that should be associated with records from the data source.
Master table name	Select the table that should be a data source.
Document number field	Select the field that the document number should be taken from in the selected table.
Document date field	Select the field that the document date should be taken from in the selected table.

FIELD	DESCRIPTION
Document account field	Select the field that the document account should be taken from in the selected table.
User query	If this check box is selected, you can set up a query by selecting **Edit query** above the grid. Otherwise, all the records will be filled in from the selected data source.

Web applications

You use web application settings to set up a web application so that it supports Open Authorization (OAuth) 2.0. OAuth is the open standard that lets users grant "secure delegated access" to the application on their behalf, without sharing their access credentials. You can also go through the authorization process by getting an authorization code and access token. You can set up web application settings on the **Web applications** page (**Tax** > **Setup** > **Electronic messages** > **Web applications**).

The following table describes the fields on the **Web applications** page.

FIELD	DESCRIPTION
Application name	Enter a name for the web application.
Description	Enter a description of the web application.
Base URL	Enter the base internet address of the web application.
Authorization URL path	Specify the path that is used to compose the URL for authorization.
Token URL path	Specify the path that is used to compose the URL for the token.
Redirect URL	Enter the redirect URL.
Client ID	Enter the client ID of the web application.
Client secret	Enter the client secret of the web application.
Server token	Enter the server token of the web application.
Authorization format mapping	Select the ER format that is used to generate the request for authorization.
Import token model mapping	Select the ER importing model mapping that is used to store the access token.
Granted scope	The scope that is granted for requests to the application. This field is automatically updated.
Access token will expire in	The remaining time before the access token expires.
Accept	Specify the **Accept** property of the web request. For example, enter **application/vnd.hmrc.1.0+json**.

FIELD	DESCRIPTION
Content type	Specify the content type. For example, enter **application/json**.

In addition, the following buttons are available on the Action Pane of the **Web applications** page to support the authorization process:

- **Get authorization code** – Initialize authorization of the web application.
- **Obtain access token** – Initialize the process of getting an access token.
- **Refresh access token** – Refresh an access token.

When an access token to a web application is stored in the system's database in encrypted format, it can be used for requests to a web service. For security purposes, access to the access token must be limited to security roles that must be allowed to address those requests. If users outside the security group try to address a request, they receive an error that states that they aren't allowed to interoperate via the selected web application. To set up the security roles that must have access to the access token, use the **Security roles** FastTab on the **Web applications** page. If security roles aren't defined for a web application, only a system admin can interoperate via this web application.

Web service settings

You use web service settings to set up direct data transmission to a web service. You can set up web service settings on the **Web service settings** page (**Tax** > **Setup** > **Electronic messages** > **Web service settings**).

The following table describes the fields on the **Web service settings** page.

FIELD	DESCRIPTION
Web service	Enter a name for the web service.
Description	Enter a description of the web service.
Internet address	Enter the internet address of the web service. If a web application is specified for the web service, and if the internet address of the web service should be the same as the internet address that is defined for that web application, select **Copy base URL** to copy the base URL of the web application to this field.
Certificate	Select a Key Vault certificate that has previously been set up.
Web application	Select a Key Vault certificate that has previously been set up.
The response type – XML	Set this option to **Yes** if the response type is XML.
Request method	Specify the method of the request. HTTP defines a set of request methods that indicate the action that should be performed for a given resource. The request method can be **GET**, **POST**, or another HTTP method.
Request headers	Specify request headers. A request header is an HTTP header that can be used in an HTTP request, and that isn't related to the content of the message.
Accept	Specify the **Accept** property of the web request.

FIELD	DESCRIPTION
Accept encoding	Specify the **Accept-Encoding** value. The Accept-Encoding request HTTP header advertises the content encoding that the client can understand. This content encoding is usually a compression algorithm.
Content type	Specify the content type. The Content-Type entity HTTP header indicates the media type of the resource.
Successful response code	Specify the HTTP status code that indicates that the request was successful.
Request headers format mapping	Select the ER format that is used to generate web request headers.

Message processing actions

You use message processing actions to create actions for your processes and set up their parameters. You can set up message processing actions on the **Message processing actions** page (**Tax** > **Setup** > **Electronic messages** > **Message processing actions**).

The following tables describe the fields on the **Message processing actions** page.

General FastTab

FIELD	DESCRIPTION
Action type	Select the type of action. For information about the available options, see the Message processing action types section.
Format mapping	Select the ER format that should be called for the action. This field is available only for actions of the **Electronic reporting export**, **Electronic reporting import**, and **Electronic reporting export message** types.
Format mapping for URL path	Select the ER format that should be called for the action. This field is available only for actions of the **Web service** type. It's used to compose the path of the URL address that will be added to the base internet address that is specified for the selected web server.
Message item type	Select the type of records that the action should be evaluated for. This field is available for actions of the **Message item execution level**, **Electronic reporting export**, **Electronic reporting import**, and **Web service** types, and also some other types. If you leave this field blank, all the message item types that are defined for the message processing are evaluated.
Executable class	Select executable class settings that were previously created. This field is available only for actions of the **Message item execution level** and **Message item execution level** types.
Populate records action	Select a populate records action that was previously set up. This field is available only for actions of the **Populate records** type.

FIELD	DESCRIPTION
Web service	Select a web service that was previously set up. This field is available only for actions of the **Web service** type.
File name	Specify the name of the file that will be the result of the action. This file can be the response from the web server or the report that is generated. This field is available only for actions of the **Web service** and **Electronic reporting export message** types.
Show dialog	Set this option to **Yes** if a dialog box must be shown to users before report generation. This field is available only for actions of the **Electronic reporting export message** type.

Message processing action types

The following options are available in the **Action type** field:

- **Create message** – Use this action type to let users manually create messages on the **Electronic message** page. An initial status can't be set up for an action of this type.
- **Populate records** – An action of the **Populate records** type must previously be set up. Associate this action type with a populate records action to enable that action to be included in processing. It's assumed that this action type is used either for the first action in message processing (when no electronic message was created in advance) or for an action that adds message items to a message that was previously created by an action of **Create message** type. Therefore, for actions of this type, a result status can be set up only for message items. An initial status can be set up only for messages.
- **Message execution level** – Use this action type to set up an executable class that should be evaluated at the message level.
- **Message item execution level** – Use this action type to set up an executable class that should be evaluated at the message item level.
- **Electronic reporting export** – Use this action type for actions that should generate a report that is based on an exporting ER configuration at the message item level.
- **Electronic reporting export message** – Use this action type for actions that should generate a report that is based on an exporting ER configuration at the message level (for example, when a message doesn't have any message items).
- **Electronic reporting import** – Use this action type for actions that should generate a report that is based on an importing ER configuration.
- **Message level user processing** – Use this action type for actions that assume some manual action by the user at the message level. For example, the user might update the status of messages.
- **User processing** – Use this action type for actions that assume some manual action by the user at the message item level. For example, the user might update the status of messages items.
- **Web service** – Use this action type for actions that should transmit a generated report to a web service. This action type isn't used for Italian Purchase and Sales Invoices Communication reporting. For actions of **Web service** type, the **Message processing actions** page includes a **Miscellaneous details** FastTab, where you can specify a confirmation text. This confirmation text will be shown to users before requests to the selected web service are addressed.
- **Request verification** – Use this action type to request verification from a server.

Initial statuses FastTab

> **NOTE**
>
> The **Initial statuses** FastTab isn't available for actions that have an initial action type of **Create message**.

FIELD	DESCRIPTION
Message item status	Select the message item status that the selected message processing action should be evaluated for.
Description	A description of the selected message item status.

Result statuses FastTab

FIELD	DESCRIPTION
Message status	Select the message statuses that the selected message processing action should be evaluated for. This field is available only for message processing actions that are evaluated at the message level. For example, it's available for actions of the **Electronic reporting export** and **Electronic reporting import** types, but it isn't available for actions of the **User processing** and **Message item execution level** types.
Description	A description of the selected message status.
Response type	The response type of the selected message status.
Message item status	Select the resulting statuses that should be available after the selected message processing action is evaluated. This field is available only for message processing actions that are evaluated at the message item level. For example, it's available for actions of the **User processing** and **Message item execution level** types. For message processing actions that are evaluated at the message level, this field shows the message item status that was set up for the selected message status.

The following table shows the result statuses that must be set up for different action types and response types.

ELECTRONIC MESSAGE ACTION TYPE/RESPONSE TYPE	SUCCESSFULLY EXECUTED	BUSINESS ERROR	TECHNICAL ERROR	USER DEFINED	CANCEL
Create message	X				
Electronic reporting export	X				
Electronic reporting import					
Web service	X		X		
User processing					

ELECTRONIC MESSAGE ACTION TYPE/RESPONSE TYPE	SUCCESSFULLY EXECUTED	BUSINESS ERROR	TECHNICAL ERROR	USER DEFINED	CANCEL
Message execution level					
Populate records					
Message item execution level					
Request verification	X	X	X		
Electronic reporting export message	X				
Message level user processing					

Electronic message processing

Electronic message processing is a basic concept of the Electronic messages functionality. It aggregates actions that should be evaluated for the electronic message. The actions can be linked via an initial status and a result status. Alternatively, actions of the **User processing** type can be started independently. On the **Electronic message processing** page (**Tax** > **Setup** > **Electronic messages** > **Electronic message processing**), you can also select additional fields that should be supported for the processing on either the message level or the message items level.

The **Action** FastTab lets you add predefined actions to the processing. You can specify whether an action must be run separately, or whether it can be started by the processing. To specify that an action in the processing can be initialized only by a user, set the **Run separately** field to **Yes** for that action. If an action should be started by the processing for messages or message items that are in the status that is defined as the initial status for the action, set the **Run separately** field to **No**. Actions of the **User action** type must always be run separately.

Sometimes, several actions must be aggregated into a sequence, even though the first action is set up so that it runs separately. For example, a user must initialize report generation, but immediately after the report is generated, it must be sent to a web service, and the response from the web service must be reflected in the system. In this situation, you can create an inseparable sequence for the actions that must always run together. On the **Action** FastTab, select **Inseparable sequences** above the grid, and create a sequence. Then, for all the actions that must run together, select the sequence in the **Inseparable sequence** field. In this case, the **Run separately** field can be set to **Yes** for the first action in the sequence but **No** for all the other action.

The **Message item additional fields** FastTab lets you add predefined additional fields that are related to message items. You must add additional fields for each type of message item that the fields are related to.

The **Message additional fields** FastTab lets you add predefined additional fields that are related to messages.

The **Security roles** FastTab lets you set up the security roles that are predefined in the system for specific processing. Users who have a specific role will see only processing that is defined for that role.

The **Batch** FastTab lets you set up processing to work in a batch regime.

Work with the Electronic messages functionality

If you're working at the message level, the **Electronic messages** page (**Tax** > **Inquiries and reports** > **Electronic messages** > **Electronic messages**) is more useful. If you're operating at the data collection (message item) level, the **Electronic message items** page (**Tax** > **Inquires and reports** > **Electronic messages** > **Electronic message items**) is more useful.

Electronic messages

The **Electronic messages** page presents the processing that is available to you, based on your role. Security roles are associated with processing in the setup of that processing. For each processing that is available to you, the page shows electronic messages and information that is related to them.

The **Messages** FastTab shows electronic messages for the selected processing. Depending on the status of the selected message and predefined processing, you can run some actions by using the buttons above the grid:

- **New** – This button is associated with actions of the **Create message** type.
- **Delete** – This button is available if the **Allow delete** check box is selected for the current status of the selected message.
- **Collect data** – This button is associated with actions of the **Populate records** type.
- **Generate report** – This button is associated with actions of the **Electronic reporting export message** type.
- **Send report** – This button is associated with actions of the **Web service** type.
- **Import response** – This button is associated with actions of the **Electronic reporting import** type.
- **Update status** – This button is associated with actions of the **Message level user processing** type.
- **Message items** – Open the **Electronic message items** page.

The **Action log** FastTab shows information about all the actions that have been run for the selected message. If an action caused an error, information about the error is attached to the related line in the grid. To review the information about the error, select the line in the grid, and then select the **Attachment** button (the paper clip symbol) in the upper-right corner on the page.

The **Message additional fields** FastTab shows all the additional fields that are defined for messages in the processing setup. It also shows the values of those additional fields.

The **Message items** FastTab shows all the message items that are related to the selected message. Depending on the status of the selected message item, you can run some actions by using the buttons above the grid:

- **Delete** – This button is available if the **Allow delete** check box is selected for the current status of the selected message item.
- **Update status** – This button is associated with actions of the **User processing** type.
- **Original document** – Open a page that shows the original document for the selected message item.

All reports that have already been generated and received for a message are attached to that message. To review the attachments that are related to a message, select the message, and then select the **Attachment** button (the paper clip symbol) in the upper-right corner of the page.

The **Attachments** page shows all the attachments that are related to the selected message. To view a file, select it in the list on the left, and then select **Open** on the Action Pane.

You can also review attachments that are related to a specific action that was previously run for a message. On

the **Electronic messages** page, select the message on the **Messages** FastTab, select the action on **Action log** FastTab, and then select the **Attachment** button in the upper-right corner of the page.

You can also run either the whole processing or just a specific action by selecting **Run processing** on the Action Pane.

Electronic message items

The **Electronic message items** page presents all message items and a log of the actions that have been run for each message item. It also shows the additional fields that are defined for the message items, and the values of those additional fields.

The following table describes the fields on the **Message items** tab.

FIELD	DESCRIPTION
Processing	The name of the processing that was used to create the message item.
Message item	The ID of the message item. This ID is assigned automatically, based on the **Message item** number sequence that is defined on the **General ledger parameters** page.
Message item date	The date when the message item was created.
Message item type	The type of message item. Several types of messages items can be set up for the same processing (for example, **Incoming invoices** and **Outgoing invoices**). This field can be filled in automatically only when an invoice is added to the Message items table.
Message item status	The actual status of the message item. The available statuses vary, depending on the type of message item. Here are some examples: • **Populated** – A record was added to the Message items table. • **Evaluated** – Additional attributes were calculated for the message item. • **Reported** – The message item was successfully added to a report. • **Excluded** – This status can be useful if you must exclude some message items from a report before it's exported.
Transmission date	For processing that automatically transmits a generated report outside the system, the date when the message item was transmitted.
Document number	This field is filled in automatically, based on the setup of the populate records action. This field can be filled in automatically only when an invoice is added to the Message items table.
Account number	The account number of a customer or vendor (or another field value, depending on the field that is defined on the populate records action). This field can be filled in automatically only when an invoice is added to the Message items table.

FIELD	DESCRIPTION
Message	The number of the message. This number is assigned automatically, based on the **Message** number sequence that is defined on the **General ledger parameters** page.
Message status	The actual status of the electronic message.
Next action	The next actions that can be started for the current status of the message item.

The **Additional fields** tab shows the additional fields for the selected message item, and their values.

Run processing

Select **Run processing** on the Action Pane to run the processing for message items. To run a specific action, in the **Run processing** dialog box, set the **Choose action** option to **Yes**, and then select an action. To run the whole processing, leave the **Choose action** option set to **No**.

Generate report

Select **Generate report** on the Action Pane to generate a report. This button is associated with actions of the **Electronic reporting export** type.

Update status

Select **Update status** on the Action Pane to update the status of one or more message items. In the **Update status** dialog box, use the **Records to include** FastTab to select the message items to update. Make sure that you correctly define the selection criteria, because message item statuses will be updated according to these criteria, the initial status of the selected action, and the **New status** value that you specify. After a status update is completed, it will be difficult to determine which items were updated. Therefore, it will be difficult to roll back the status update.

Electronic messages

Select **Electronic messages** on the Action Pane to review an electronic message that is related to the selected message item.

You can also review all the files that are related to a specific message item. Select the **Message** field for the message item, or select **Electronic messages** on the Action Pane. Then, on the **Electronic message** page, select the message to review files for, and then select the **Attachment** button (the paper clip symbol) in the upper-right corner of the page.

The **Attachments** page shows all the attachments that are related to the message. To view a file, select it in the list on the left, and then select **Open** on the Action Pane.

Original document

Select **Original document** on the Action Pane to open the original document for the selected message item.

Example: Set up and run processing to call a simple ER exporting format to generate an Excel report

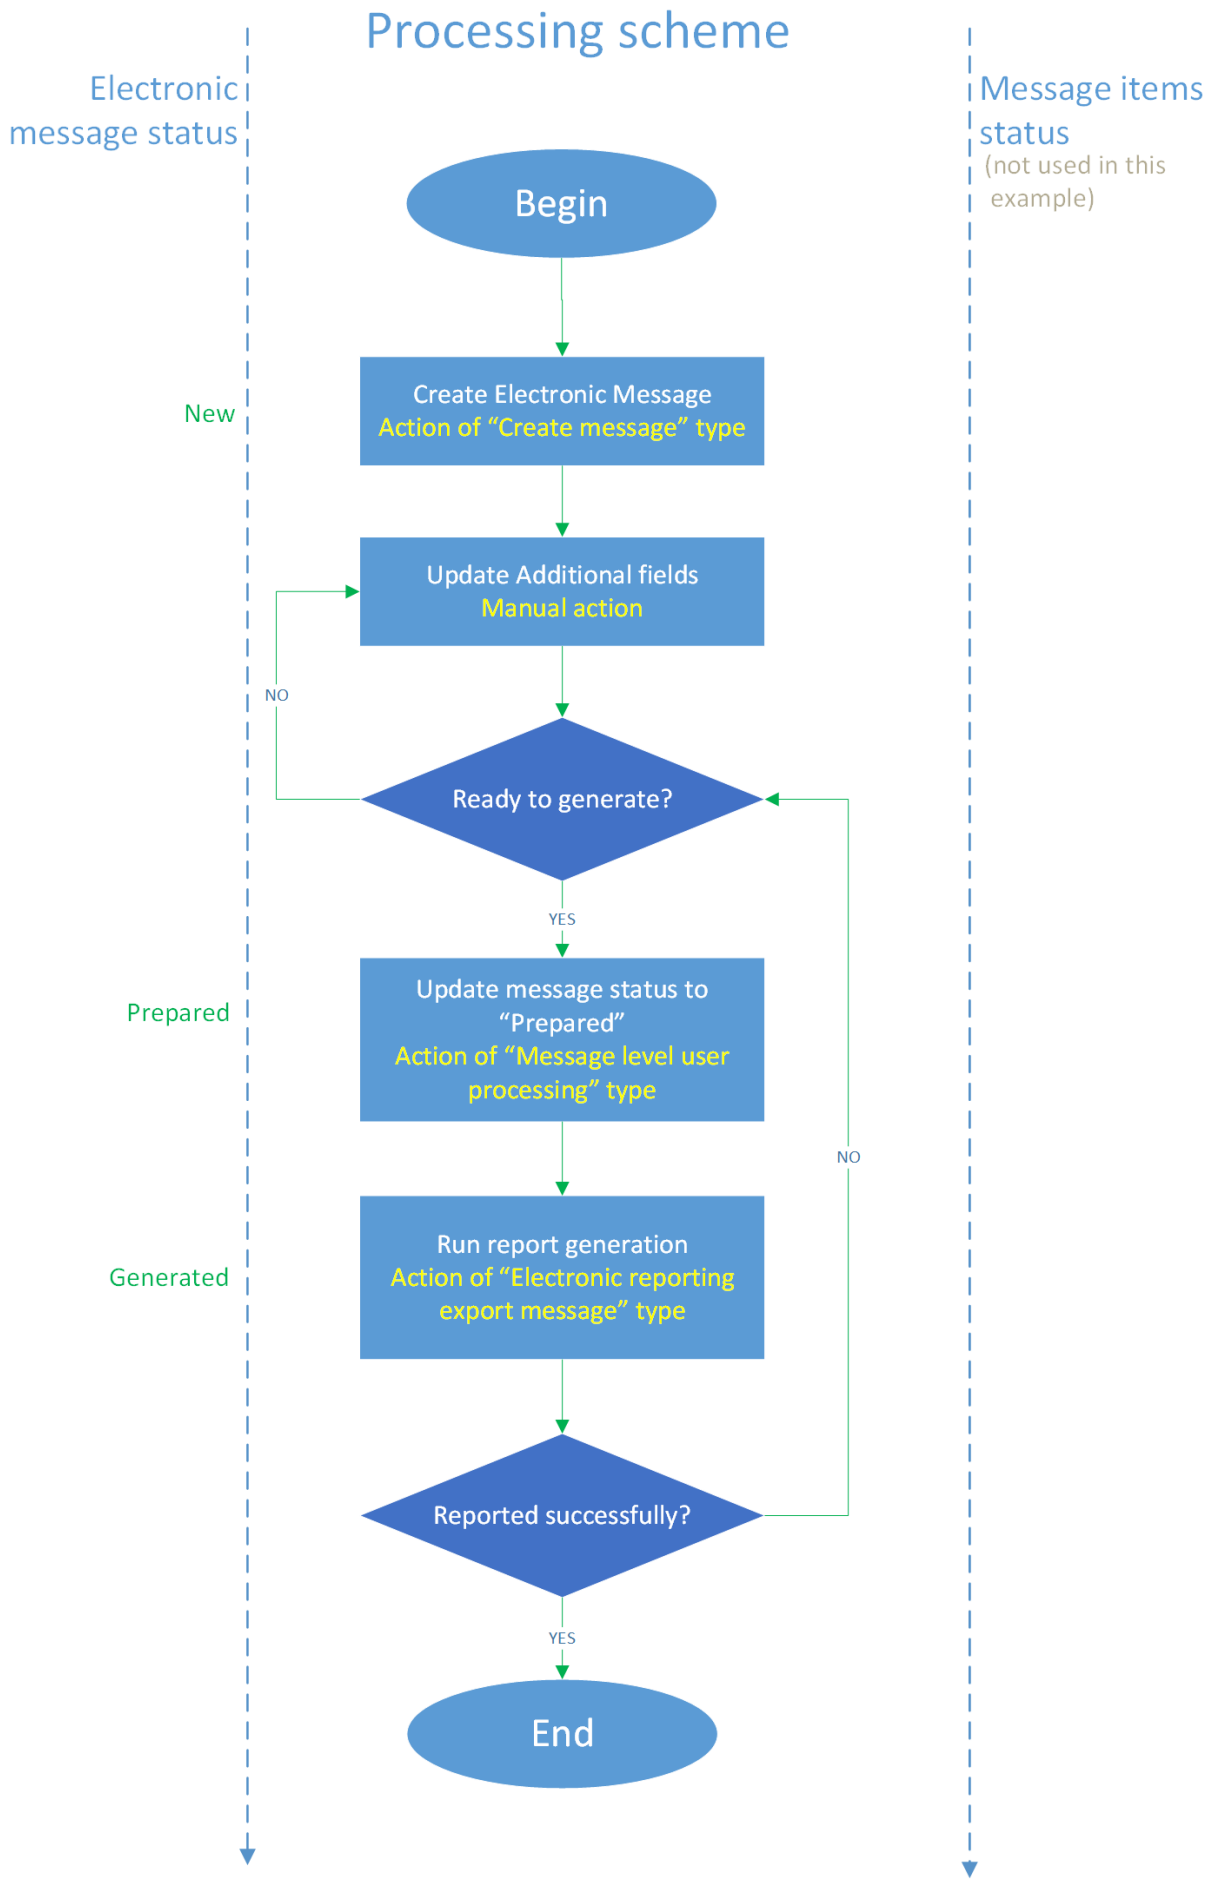
After you've created your ER format, mapped it to data sources, and completed it, you can run it by using the **Electronic reporting** workspace. A report is generated, and you can save it locally.

To control the following aspects of the reporting process, you must set up electronic messaging processing:

- Log information about who generated the report.
- Log information about when the report was generated.
- Save the reports that were generated for previous periods.

This section provides an example that shows how you can set up electronic messaging to generate a report that is based on an exporting ER format for Excel. If you want to follow this example, the ER Excel exporting format must already be created, mapped to data sources, and completed. Additionally, a number sequence must already be set up for electronic messages.

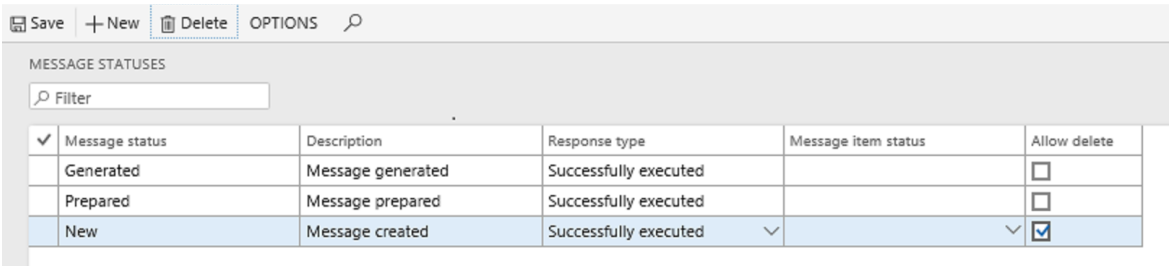
When you build processing, it's helpful if you first define the processing actions and statuses that will be set up. The following illustration shows what the processing looks like for this example.



Create message statuses

1. Go to **Tax** > **Setup** > **Electronic messages** > **Message statuses**.
2. Create the following message statuses:

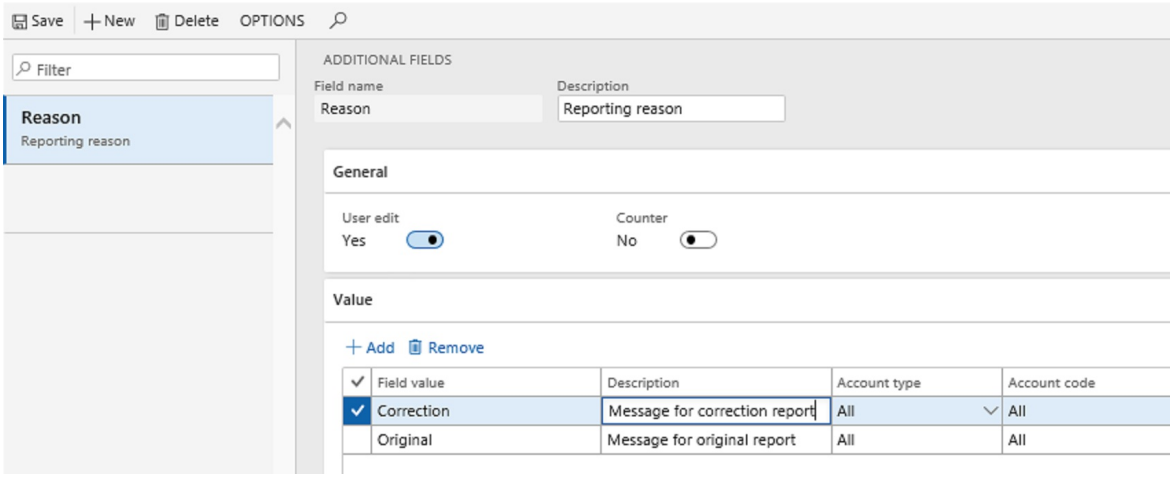
- New
- Prepared
- Generated



3. On the line for the **New** status, select the **Allow delete** check box to let users delete messages that have this status.

Create additional fields

1. Go to **Tax > Setup > Electronic messages > Additional fields**.
2. Add an additional field and its values. Here is an example.



3. Set the **User edit** option to **Yes** to let users edit the field.

Create message processing actions

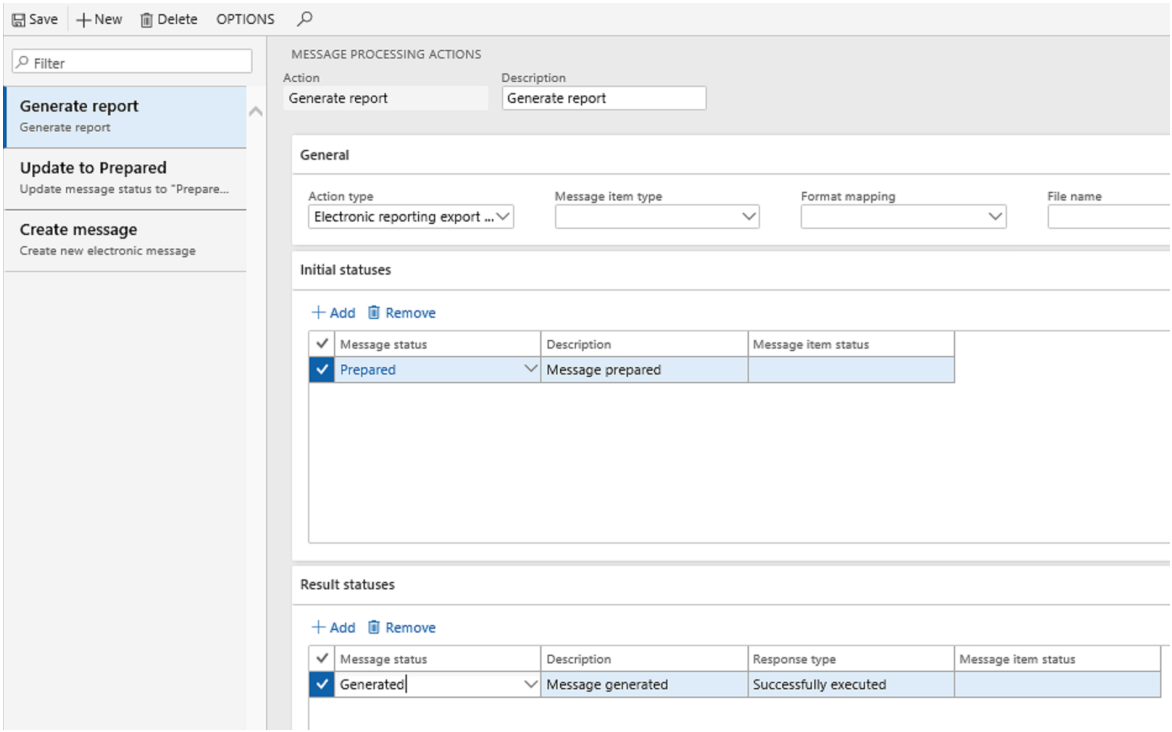
For this example, you will create the following actions:

- **Create message**
- **Update to Prepared**
- **Generate report**
- **Update to initial status** (optional)

1. Go to **Tax > Setup > Electronic messages > Message processing actions**.
2. Create an action that is named **Create message**. On the **General** FastTab, in the **Action type** field, select **Create message**.
3. Create an action that is named **Update to Prepared**, and set the following fields:
   - On the **General** FastTab, in the **Action type** field, select **Message level user processing**.
   - On the **Initial statuses** FastTab, in the **Message status** field, select **New**.
   - On the **Result statuses** FastTab, in the **Message status** field, select **Prepared**. In the **Response type** field, enter **Successfully executed**.
4. Create an action that is named **Generate report**, and set the following fields:
   - On the **General** FastTab, in the **Action type** field, select **Electronic reporting export**. In the

Format mapping field, select the exporting ER format. The options are **Excel**, **XML**, **JSON**, **Text**, and **Other**.

- On the **Initial statuses** FastTab, in the **Message status** field, select **Prepared**.
- On the **Result statuses** FastTab, in the **Message status** field, select **Generated**. In the **Response type** field, enter **Successfully executed**.



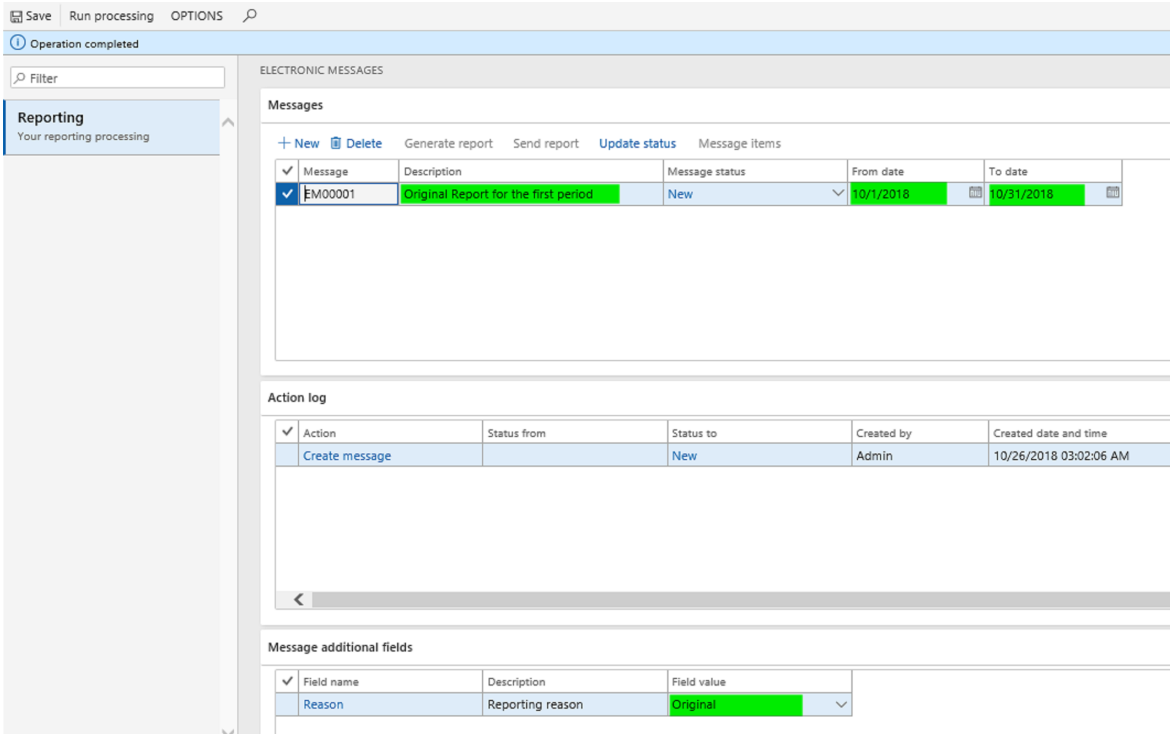
5. Optional: To let users regenerate a report several times, you can create an **Update to initial status** action and set the following fields:

   - On the **General** FastTab, in the **Action type** field, select **Message level user processing**.
   - On the **Initial statuses** FastTab, in the **Message status** field, select **Generated**.
   - On the **Result statuses** FastTab, add a separate line for each of the two message statuses (**Prepared** and **New**). For both lines, set the **Response type** field to **Successfully executed**.

Electronic message processing

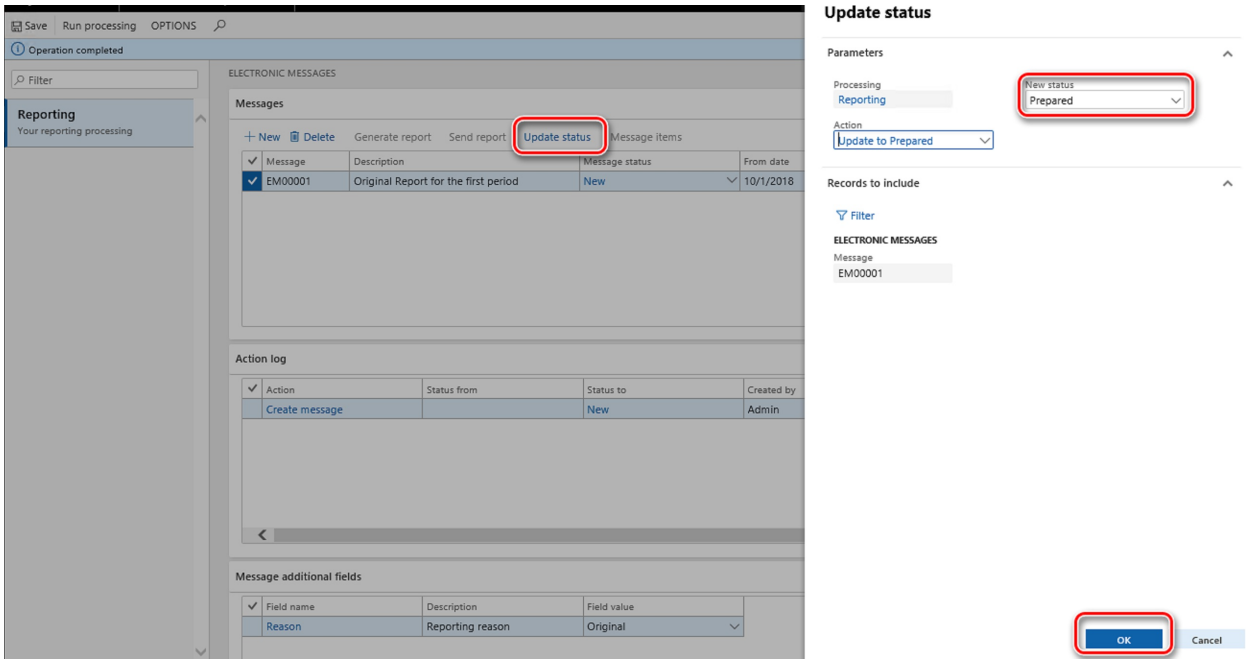
In this example, all the actions should be set up so that they run separately. The assumption is that the user will initialize every action.

1. Go to **Tax > Setup > Electronic messages > Electronic message processing**.
2. Add a record for your processing, and add all previously defined actions and an additional field.
3. Optional: On the **Security roles** FastTab, define security roles for your processing to limit access to specific reporting.
4. Go to **Tax > Inquires and reports > Electronic messages > Electronic messages**.
5. Select **New** to create a message. At this point, you can add dates and a description. You can also update the value of the additional field as you require.



The grid on the **Action log** FastTab is automatically filled in with a log of all actions that are performed on the message.

You can now either delete or update the message status. To update the message status, select **Update status**. In the **New status** field, select **Prepared**, and then select **OK**.



The message status is updated to **Prepared**, and you can now generate the report by selecting **Generate report**. The report is generated, and the message status and action log are updated. To view the generated report, select the **Attachment** button (the paper clip symbol) in the upper-right corner of the page.

The survey will take about seven minutes. No personal data is collected (privacy statement).

Data management overview

2/18/2021 • 19 minutes to read • Edit Online

This topic describes how you can use the data management framework to manage data entities and data entity packages in Finance and Operations.

The data management framework consists of the following concepts:

- **Data entities** - A data entity is a conceptual abstraction and encapsulation of one or more underlying tables. A data entity represents a common data concept or functionality, for example, Customers or Vendors. Data entities are intended to be easily understood by users familiar with business concepts. After data entities are created, you can reuse them through the Excel Add-in, use them to define import/export packages, or use them for integrations.
- **Data project** - A project that contains configured data entities, which include mapping and default processing options.
- **Data job** - A job that contains an execution instance of the data project, uploaded files, schedule (recurrence), and processing options.
- **Job history** - Histories of source to staging and staging to target jobs.
- **Data package** - A single compressed file that contains a data project manifest and data files. This is generated from a data job and used for import or export of multiple files with the manifest.

The data management framework supports using data entities in the following core data management scenarios:

- Data migration
- Set up and copy configurations
- Integration

Data entities

Data entities provide conceptual abstraction and encapsulation of underlying table schema that represent data concepts and functionalities. In Microsoft Dynamics AX 2012, most tables, like the Customer and Vendor tables, were de-normalized and split into multiple tables. This was beneficial from a database design point of view, but made it difficult for implementers and ISV's to use without a thorough understanding of the physical schema. Data entities were introduced as part of data management to be used as a layer of abstraction to easily understand by using business concepts. In previous versions there were multiple ways to manage data, such as Microsoft Excel Add-ins, AIF, and DIXF. The concept of data entities combines those different concepts into one. After data entities are created, you should be able to reuse them for an Excel Add-ins, import/export, or integration. The following table shows core data management scenarios.

Data Migration	• Migrate reference, master, and document data from legacy or external systems.
Setup and copy configuration	• Copy configuration between company/environments. • Configure processes or modules using the Lifecycle Services (LCS) environment.

Integration	• Real-time service based integration. • Asynchronous integration.

Data migration

Using the data management framework, you can quickly migrate reference, master, and document data from legacy or external systems. The framework is intended to help you quickly migrate data by using the following features:

- You can select only the entities you need to migrate.
- If an import error occurs, you can skip selected records and choose to proceed with the import using only the good data, opting to then fix and import the bad data later. You will be able to partially continue and use errors to quickly find bad data.
- You can move data entities straight from one system to another, without having to go through Excel, or XML.
- Data imports can be easily scheduled using a batch, which offers flexibility when it is required to run. For example, you can migrate customer groups, customers, vendors, and other data entities in the system at any time.

Set up and copy configuration

You can use the data management framework to copy configurations between companies or environments, and configure processes or modules using Microsoft Dynamics Lifecycle Services (LCS).

Copying configurations is intended to make it easier to start a new implementation, even if your team doesn't deeply understand the structure of data that needs to be entered, or data dependencies, or which sequence to add data to an implementation.

The data management framework allows you to:

- Move data between two similar systems
- Discover entities and dependencies between entities for a given business process or module
- Maintain a reusable library of data templates and datasets
- Use data packages to create incremental data entities. Data entities can be sequenced inside the packages. You can name data packages, which can be easily identifiable during import or export. When building data packages, data entities can be mapped to staging tables in grids or by using a visual mapping tool. You can also drag-and-drop columns manually.
- View data during imports, so you can compare data, and ensure that it is valid.

Working with data entities

The following sections provide quick snapshots of the different functionalities of data management using data entities. The goal is to help to you strategize and make effective decisions on how to best utilize the available tools during data migration. You will also find tips and tricks on how to effectively use each area during data migration. A list of available data entities for each area can also be found with the suggested data sequences, showing data dependencies. Microsoft provides data packages that can be found on Lifecycle Services (LCS) as an initial guide. The information in this document can be used as a guide for creating your own packages. The description of each data entity shows what the object contains and if it is needed during data migration.

Sequencing

There are two types of sequencing that should be considered when working with data entities.

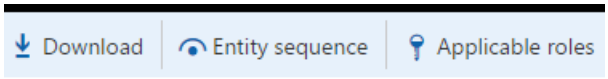
- Sequencing data entities within a data package
- Sequencing the order of data package imports

Sequence data entities within a data package

1. When a user adds data entities to a data project, by default, a sequence is set for the order in which the entities will load. The first entity added to the project will be set as the first entity to load, the next entity added will be second, the next entity will be third, and so on.

   For example, if a user added two entities in this order, **Sales tax codes** and **Sales Tax groups**, then **Sales tax codes** is assigned an entity sequence of **1.1.1**, and **Sales tax groups** is assigned an entity sequence of **1.1.2**. The sequence level indicates that the second entity will not start the import process until the first level is finished.

2. To view or edit a sequence, click the **Entity sequence** button on the Action Pane of the data project.



3. In the Definition group entity sequence, you can see the execution units and the sequence. You can change sequence by selecting the data entity in the list, setting a different Execution unit or Sequence in level, and then clicking **Update selected**. After clicking **Update selected**, the entity will move up or down in the entity list.

Example

The following screenshot shows the entity sequence that is set for the Sales Tax CodeGroups data package.

Definition group entity sequence

Entity	Execution unit	Level in execution unit	Sequence in level	Fail level on error	Fail execution u...
Sales tax codes	1	1	1	☐	☐
Sales tax code values	1	1	2	☐	☐
Sales tax code limits	1	1	3	☐	☐
Sales tax groups	1	1	4	☐	☐
Sales tax group details	1	1	5	☐	☐
Sales tax item groups	1	1	6	☐	☐
Sales tax exempt numbers	2	1	1	☐	☐
Sales tax exempt code	3	1	1	☐	☐
Sales tax reporting codes	4	1	1	☐	☐

In order to successfully import sales tax codes and groups, the sales tax codes and details have to be loaded first, before sales tax groups can be imported. Sales tax codes and groups are all in Execution unit = 1, but the sequences are in the order that they will be imported. Other related sales tax entities that are not dependent upon other data entities being loaded are included in the package. For example, sales tax exempt numbers is set in its own Execution unit = 2. This data entity will start loading immediately because there are no dependencies on other entities loading before it.

Sequence data package imports

In order to successfully load data, it's important to set the correct order for importing data packages, because of dependencies that exist within and across modules. The numbering format that has been created for the data packages within LCS are as follows:

- First segment: Module
- Second segment: Data type (setup, master, transaction)
- Third segment: Sequence number

The following tables provide more information about the default numbering format.

Module numbers

Module	Module Reference
System administration	01
General ledger	03
Public Sector	04
HRM	05
Accounts payable	10
Accounts receivable	11
Budgeting	12
Cash and bank management	13
Compliance and internal controls	14
Cost accounting	15
Fixed assets	16
Inventory management	19
Master planning	20
Organization administration	21
Payroll	22
Procurement and sourcing	23
Product information management	24
Production control	25
Project management and accounting	26
Retail	27
Sales and marketing	28
Service management	29
Trade allowance management	31
Transportation management	32
Travel and expense	33
Warehouse management	34

Data type numbers

Data Type	Data Type Reference
Setup	1
Master	4
Transaction	8

Sequence number

Numbering Format	
Module # . Data Type Reference . 001 (Sequence Number)	
01.1.001	System / Setup Data / Seq 001
01.1.002	System / Setup Data / Seq 002
01.4.001	System / Master Data / Seq 001
01.4.002	System / Master Data / Seq 002
03.1.001	General Ledger / Setup Data / Seq 001

Data packages follow the sequence number, followed by the module abbreviation, and then a description. The following example shows General ledger data packages.

Mapping

When working with data entities, mapping an entity to a source is automatic. The automatic mapping of fields

can be overridden if needed.

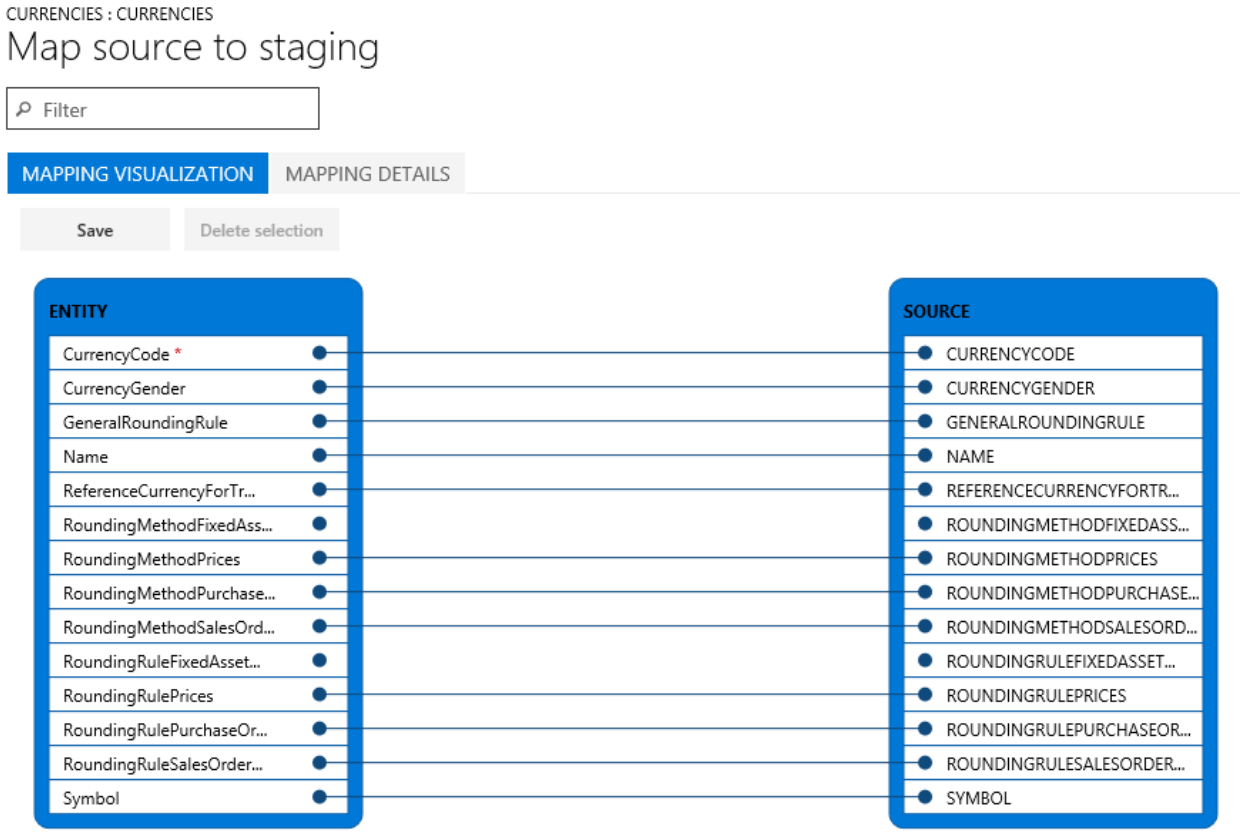
View mapping

To view how an entity is mapped, locate the tile for the entity in the project, and then click **View map**.

We provide mapping visualization view (default) and mapping details view. A red asterisk (*) identifies any required fields in an entity. These fields must be mapped in order to work with the entity. Other fields can be unmapped as required when working with the entity.

- To unmap a field, highlight the field in either column (**Entity** or **Source**), click **Delete selection**, and then click **Save**. After saving, close the form to return to the project.

The field mapping from source to staging can also be edited after import using the same process.



Regenerate a map

If you have extended an entity (added fields) or if the automatic mapping appears to be incorrect, the mapping of the entity can be regenerated in the **Mapping** form.

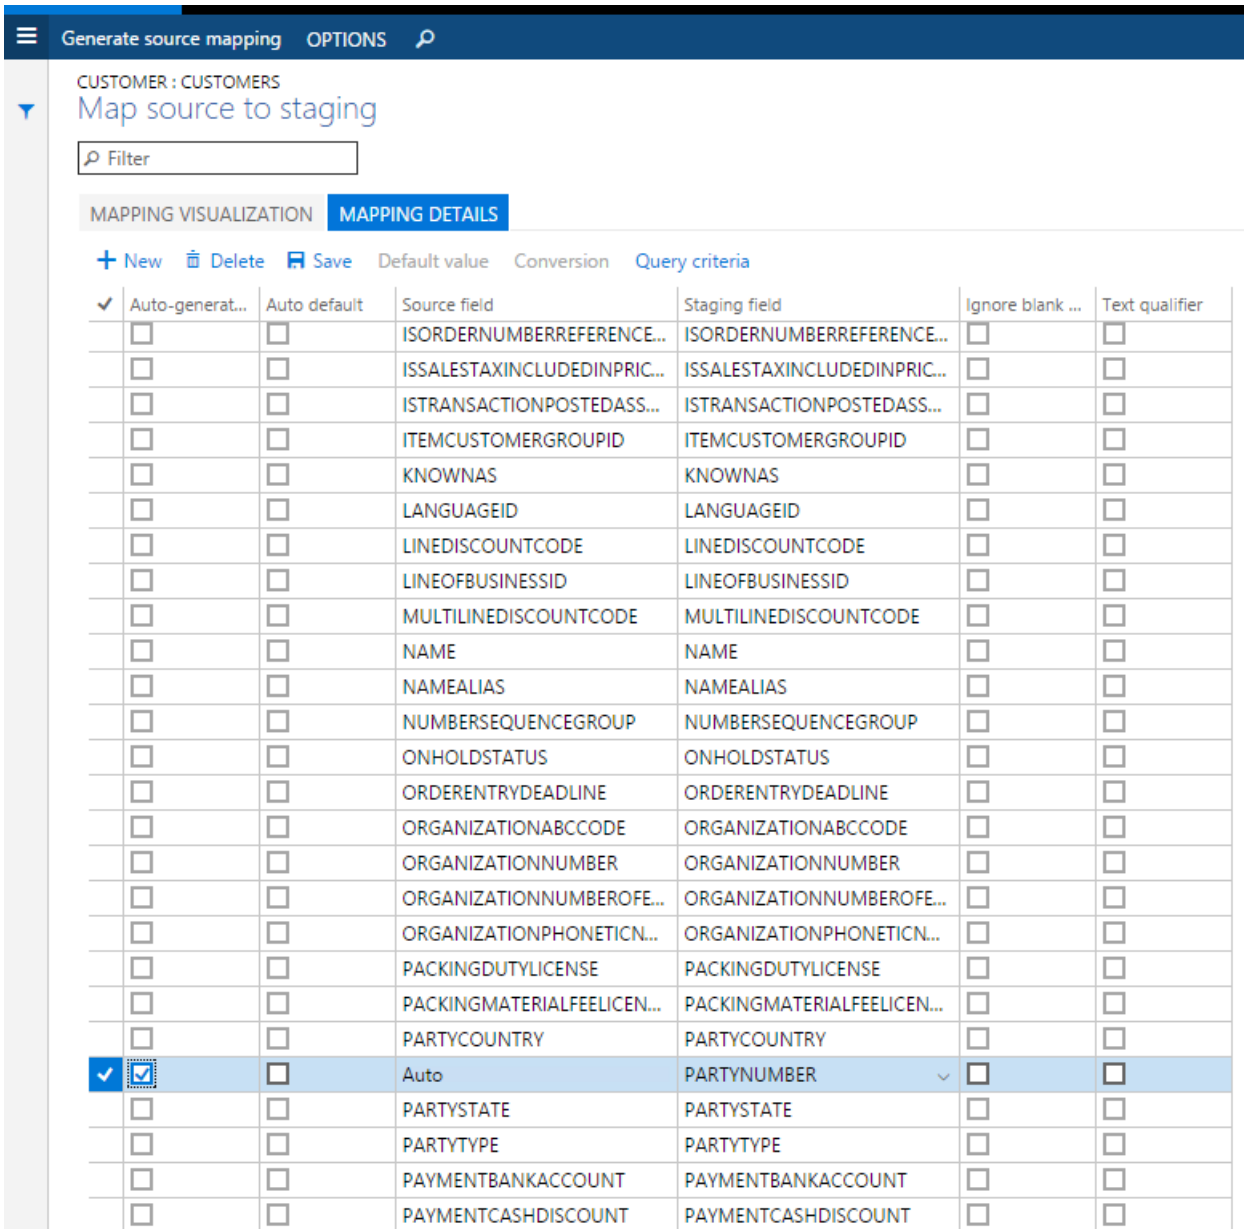
1. To do this, click **Generate source mapping**.

   A message will display asking, "Do you want to generate the mapping from scratch ?"

2. Click **Yes** to regenerate the mapping.

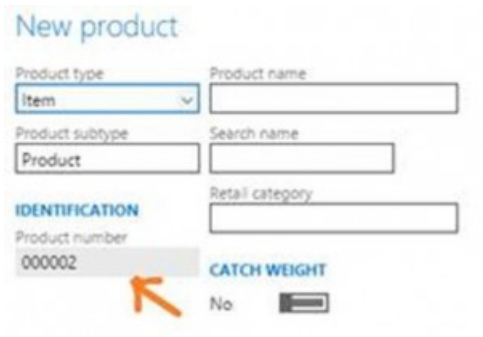
Generate data

If you have fields in entities that you want the system to generate data for on import, instead of providing the data in the source file, you can use the auto-generated functionality in the mapping details for the entity. For example, if you want to import customers and customer address information, but the address information was not previously imported with the Global Address Book entities, you can have the entity auto-generate the party number upon import and the GAB information will be created. To access this functionality, view the map of the entity and click the **Mapping details** tab. Select the fields that you want to auto-generate. This will change the source field to **Auto**.

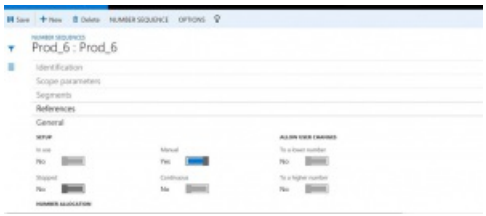


Turn off automatically generated number sequences

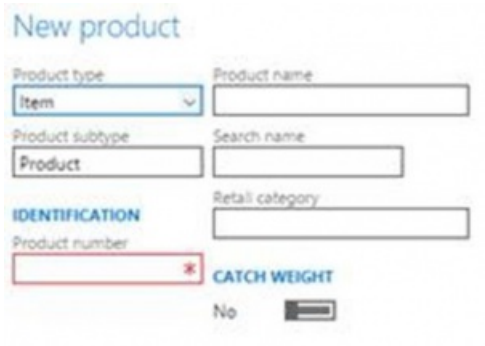
Many entities support automatic generation of identifiers based on number sequence setup. For example, when creating a product, the product number is automatically generated and the form does not allow you to edit values manually.



It is possible to enable manual assignment of number sequences for a specific entity.

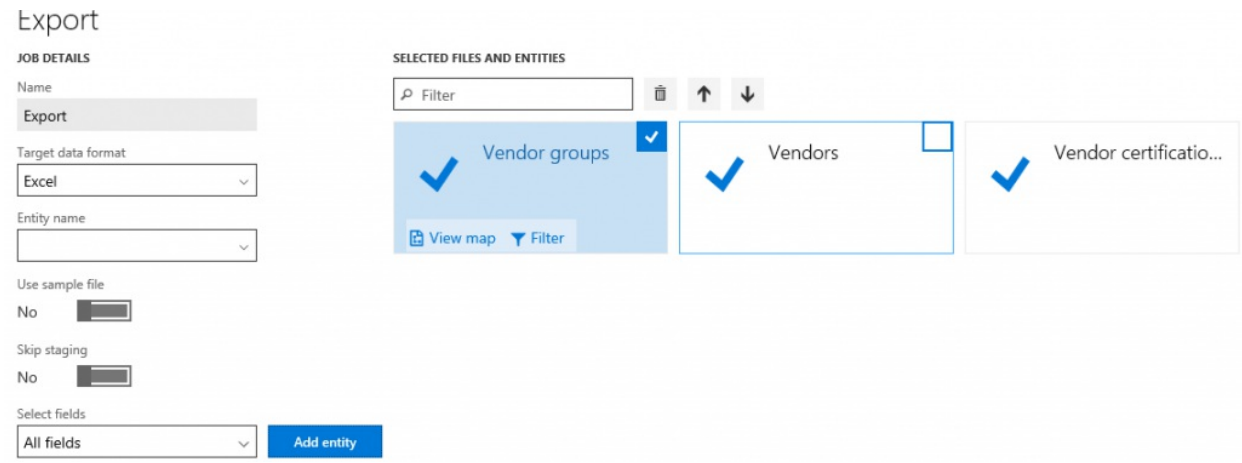


After you have enabled manual assignment, you can provide manually assigned numbers instead.

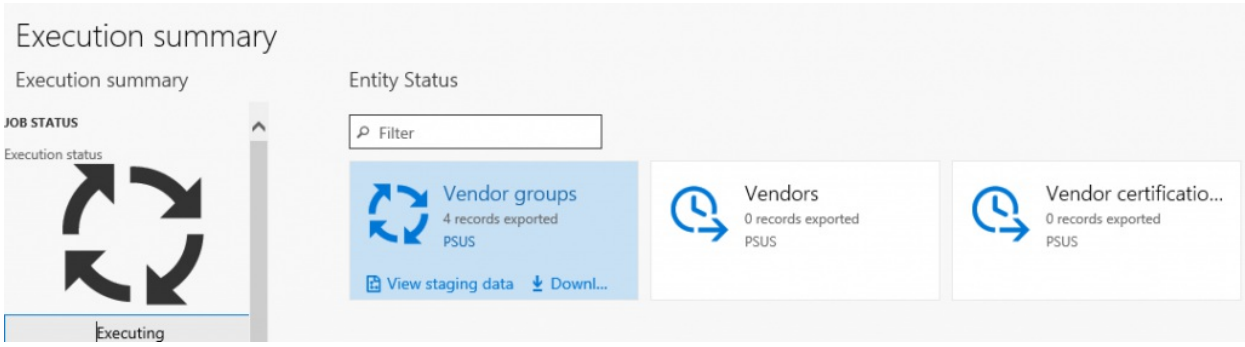


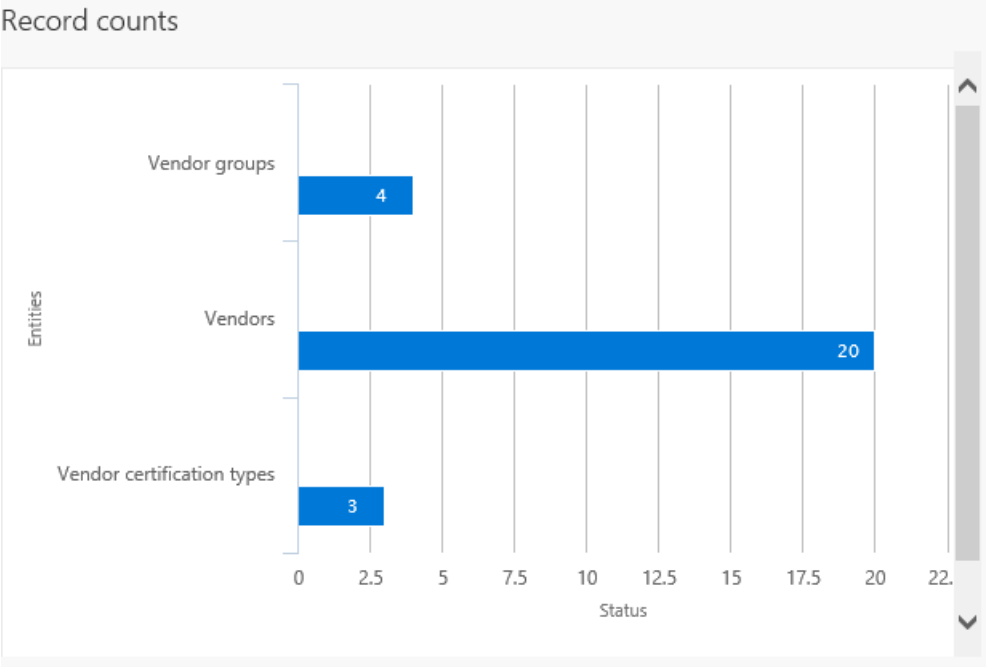
Export

Export is the process of retrieving data from a system using data entities. The export process is done through a project. When exporting, you have a lot of flexibility as to how the export project is defined. You can choose which data entities to export, but also the number of entities, the file format used (there are 14 different formats to choose for export), and apply a filter to each entity to limit what is exported. After the data entities have been pulled into the project, the sequencing and mapping described earlier can be performed for each export project.



After the project is created and saved you can export the project to create a job. During the export process, you can see a graphical view of the status of the job and the record count. This view shows multiple records so you can review the status of each record prior to downloading the actual files.





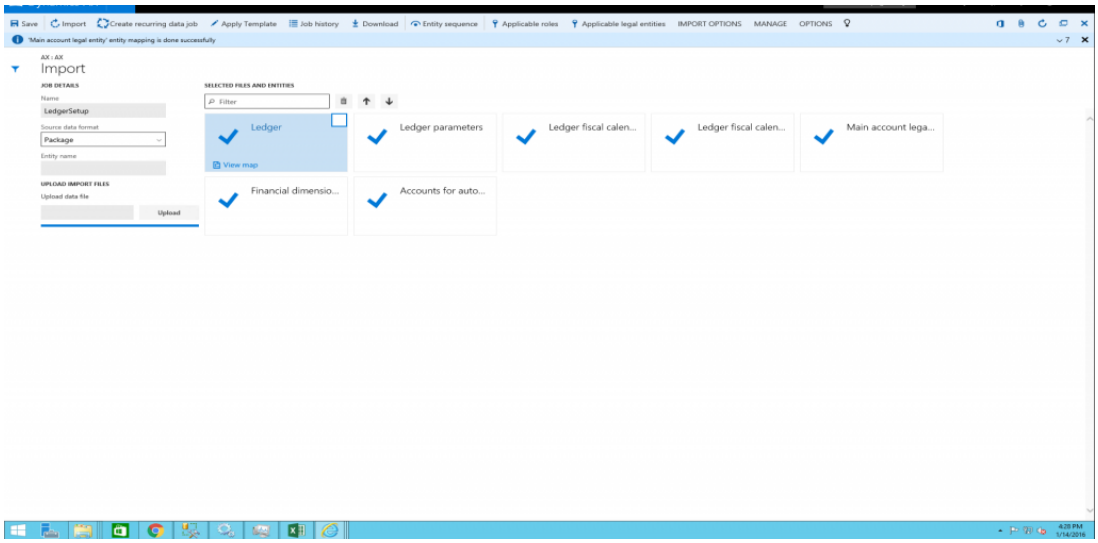
After the job is completed you can choose how to download the files: each data entity can be a separate file, or by combining the files into a package. If there are multiple data entities in the job, choosing the package option will speed up the upload process. The package is a zip file, containing a data file for each entity as well as a package header and manifest. These additional documents are used when importing in order to add the data files to the correct data entities and sequence the import process.

Import

Import is the process of pulling data into a system using data entities. The import process is done through the **Import** tile in the **Data Management** workspace. Data can be imported either for individual entities or for a group of logically related entities that are sequenced in the correct order. The file formats vary depending on the type of import. For an entity, it can be an Excel file that is comma-separated, tab-separated, or text. For a data package, it is a .zip file. In both cases, the files are exported using the above mentioned export process.

Import a data package

1. Log into the environment using a login with sufficient privileges (typically this is the Administrator role).
2. On the dashboard, click the **Data Management** workspace.
3. Click the **Import** tile.
4. On the next page, do the following:
    a. Provide a name.
    b. In the **Source Data Format** field, select **Package**.
    c. Click the **Upload** button and choose the appropriate package file from the location for the data being imported. This will import all the files from the package.

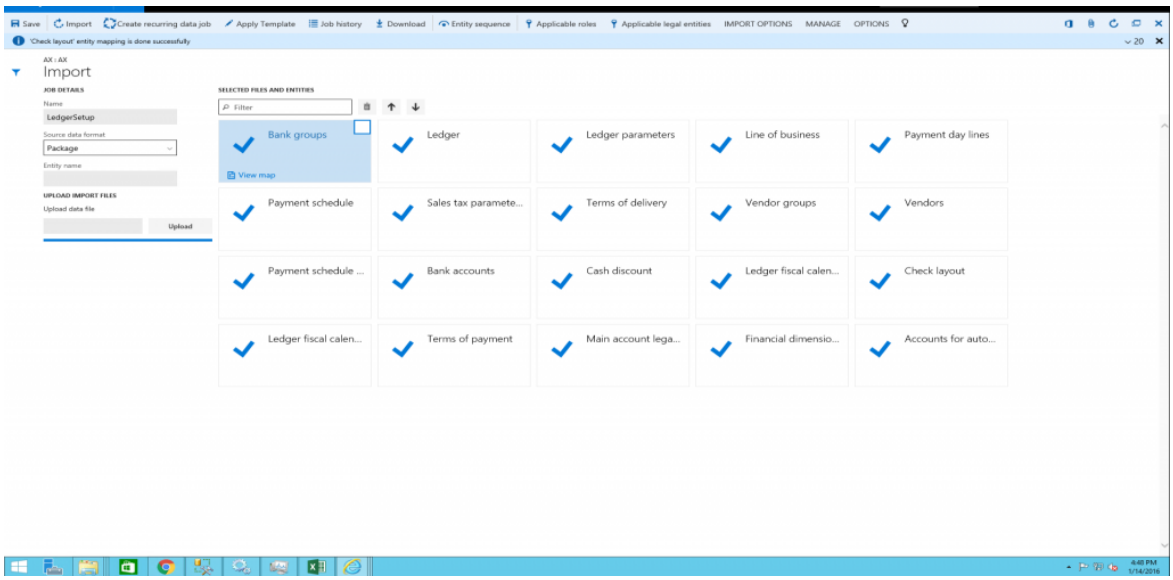


d. Click **Save**, and then click **Import**.

Import multiple data packages

Use one of the following methods to import multiple data packages.

- Create a new job for each package, and then repeat steps 4(a) through 4(d) above, for each package.
- Create one job to import multiple packages in a sequence. Repeat steps 4(a) through 4(c) above, and then repeat step 4(c) for all packages that need to be imported. After you select the packages, execute step 4(d) to import the data from the selected data packages through a single job.



After you click **Import**, the data will be imported through staging tables. The progress of the import can be tracked using the **Refresh** button in the upper-right corner of the screen.

Troubleshoot data package processing

This section provides troubleshooting information for the different stages of data package processing.

- Status and error details of a scheduled job can be found under the **Job history** section in the **Data management** form.
- Status and error details of previous runs for data entities can be displayed by selecting a data project and clicking **Job history**. In **the Execution history** form, select a job, and click **View staging data** and **View execution log**. The previous runs include data project runs that were executed as batch jobs or manually.

Export process troubleshooting

- If you get an error during the export process, click **View execution log** and review the log text, staging log details, and Infolog for more information.
- If you get an error during the export process with a note directing you to not skip staging, turn off the **Skip staging** option, and then add the entity. If you are exporting multiple data entities, you can use the **Skip staging** button for individual data entities.
- Prior to platform update 32, there was a 256 MB limit for the file size that can be handled via export. If there are a large number of records that will be exported, be sure that the resulting file size does not exceed this limit. An alternate way to handle such scenarios would be to use filters on the entity to export only a subset of data. If this is not feasible, then bring your own database must be considered for the overall solution. This limitation no longer exists starting in Platform update 32.

Import process troubleshooting

When uploading data entity files:

- If data entities do not display in **Selected files and entities** after you click **Upload** during the import process, wait a few minutes, and then check whether the OLEDB driver is still installed. If not, then reinstall the OLEDB driver. The driver is Microsoft Access Database Engine 2010 Redistributable – AccessDatabaseEngine_x64.exe.
- If data entities display in **Selected Files and Entities** with a warning after you click **Upload** during the import process, verify and fix the mapping of individual data entities by clicking **View map**. Update the mapping and click **Save** for each data entity.

During data entity import:

- If data entities fail (shown with a red X or yellow triangle icon on the data entity tile) after you click **Import**, click **View staging data** on each tile under the **Execution summary** page to review the errors. Sort and scroll through the records with Transfer status = Error to display the errors in the Message section. Download the staging table. Fix a record (or all records) directly in staging by clicking **Edit, Validate all, and Copy data to target**, or fix the import file (not staging file) and reimport the data.
- If data entities fail (shown with a red x or yellow triangle icon on the data entity tile) after you click **Import**, and **View staging data** shows no data, go back to the **Execution summary** page. Go to **View execution log**, select the data entity, and review the **Log text, Staging log details, and Infolog** for more information. **Staging log details** will display **Error column** (field) details and **Log description** will describe errors in detail.
- If data entities fail, you can check the import file to see if there's an extra line in the file with text which displays, "This is a string that is inserted into Excel as a dummy cell to make the column to support more than 255 characters. By default, an Excel destination component will not support more than 255 characters. The default type of Excel will be set based on the first few rows". This line is added during data export. If this line exists, delete this line, re-package the data entity, and try to import.

Features flighted in data management and enabling flighted features

The following features are enabled via flighting. *Flighting* is a concept that allows a feature to be ON or OFF by default.

FLIGHT NAME	DESCRIPTION
DMFEnableAllCompanyExport	Enables BYOD export from all companies in the same export job (supported for BYOD only and not files). By default, this is OFF. This flight is no longer needed after Platform update 27 because this feature can be turned ON using a parameter in data management framework parameters.

FLIGHT NAME	DESCRIPTION
DMFExportToPackageForceSync	Enables synchronous execution of data package API export. By default, it's asynchronous.
EntityNamesInPascalCaseInXMLFiles	Enables behavior where entity names are in Pascal Case in the XML files for entities. By default, the names are in upper case.
DMFByodMissingDelete	Enables the old behavior where under certain conditions, certain delete operations were not synced to BYOD using change tracking.
DMFDisableExportFieldsMappingCache	Disables caching logic when building target field mapping.
EnableAttachmentForPackageApi	Enables attachments functionality in the package API.
FailErrorOnBatchForExport	Enables fail on error at execution unit or level for export jobs.
IgnorePreventUploadWhenZeroRecord	Disables 'prevent upload when zero records' functionality.
DMFInsertStagingLogToContainer	By default this is ON. This improves performance and functional issues with error logs in the staging table.
ExportWhileDataEntityListIsBeingRefreshed	When enabled, additional validations are made on mappings when a job is scheduled while entity refresh is in progress. By default, this is OFF.
DMFDisableXSLTTransformationForCompositeEntity	This can disable the application of transformations on composite entities.
DMFDisableInputFileCheckInPackageImport	Additional validations are made to ensure if any entity file is missing from a data package, error message is shown. This is the default behavior. If required, this can be turned OFF by this flight.
FillEmptyXMLFileWhenExportingCompositeEntity	Prior to Platform update 15, when exporting composite entities that did not have any records to export, the XML file generated did not have any schema elements. This behavior can be changed to output empty schema by enabling this flight. By default, the behavior will still be to output empty schema.
EnableNewNamingForPackageAPIExport	A fix was made to ensure unique names are used for the execution ID when ExportToPackage is used for export scenarios. Duplicate execution ID's were being created when ExportToPackage was called in quick succession. To preserve compatibility, this behavior is OFF by default. Turning this flight ON will enable this new behavior where new naming convention for execution ID's will ensure unique names.
DMFDisableDoubleByteCharacterExport	A fix was made to ensure that data can be exported when the format is configured to use code page 932 setting. If an issue is encountered in relation to double byte exports, this fix can be turned off by disabling this flight to unblock, if applicable.

FLIGHT NAME	DESCRIPTION
DisablePendingRecordFromJobStatus	A fix was made to ensure that pending records are taken into consideration while evaluating the final status of an import job. If implementations have a dependency on the status evaluation logic and this change is considered a breaking change for an implementation, this new logic can be disabled using this flight.
DMFDisableEnumFieldDefaultValueMapping	A fix was made to ensure that default values set in advanced mapping for enum fields are successfully saved in the data package manifest file when generating the data package. This makes it possible for the data package to be used as a template for integrations when such advanced mappings are used. This fix is protected by this flight and can be disabled if the previous behavior is still needed (which is to always set the value to 0 in the data package manifest).
DMFXsltEnableScript	This flight only applies to Platform update 34 and non-production environments. A fix was made in Platform update 34 to prevent scripting in XSLT. However, this resulted in breaking some functionality that was dependent on scripting. As a result, this flight has been turned ON by Microsoft in all production environments as a preventive measure. In non-production environments, this must be added by customers if they encounter XSLT failures related to scripting. From Platform update 35 onward, a code change was made to revert the Platform update 34 change so this flight does not apply from Platform update 35 onward. Even if you enabled this flight in Platform update 34, upgrading to Platform update 35 will not cause any negative impact due to this flight being ON from Platform update 34.
DMFExecuteSSISInProc	This flight is OFF by default. This is related to a code fix that was made to run SQL Server Integration Services (SSIS) out of in-process to optimize memory utilization of SSIS when running DIXF jobs. However, this change has caused a regression in a scenario where if the DIXF data project name has an apostrophe (') in it, then the job will fail with an error. If you encounter this issue, removing the (') in the data project name will resolve the failure. However, if for some reason the name cannot be changed, then this flight can be enabled to overcome this error. Enabling this flight will make SSIS run in-process as before, which could lead to higher memory consumption when running DIXF jobs.

The following steps enable a flight in a non-production environment. Execute the following SQL command.

For enabling flights in a production environment, a support case must be logged with Microsoft.

- After running the SQL statement, ensure that the following is set in the web.config file on each of the AOS's. add key="DataAccess.FlightingServiceCatalogID" value="12719367"
- After making the above change, perform an IISReset on all AOS's.

```
INSERT INTO SYSFLIGHTING
([FLIGHTNAME]
,[ENABLED]
,[FLIGHTSERVICEID]
,[PARTITION]
,[RECID]
,[RECVERSION]
)
VALUES ('name', 1, 12719367, PARTITION, RECID, 1)
```

- Partition - Partition ID from the environment, which can be obtained by querying (select) for any record. Every record will have a partition ID that must be copied and used here.
- RecID - Same ID as partition. However, if multiple flights are enabled, then this can be partition ID + 'n' to ensure it has a unique value
- RecVersion = 1

The survey will take about seven minutes. No personal data is collected (privacy statement).

Data entities overview

2/18/2021 • 11 minutes to read • Edit Online

This topic defines and provides an overview of data entities. It includes information about the capabilities of data entities, the scenarios that they support, the categories that are used for them, and the methods for creating them.

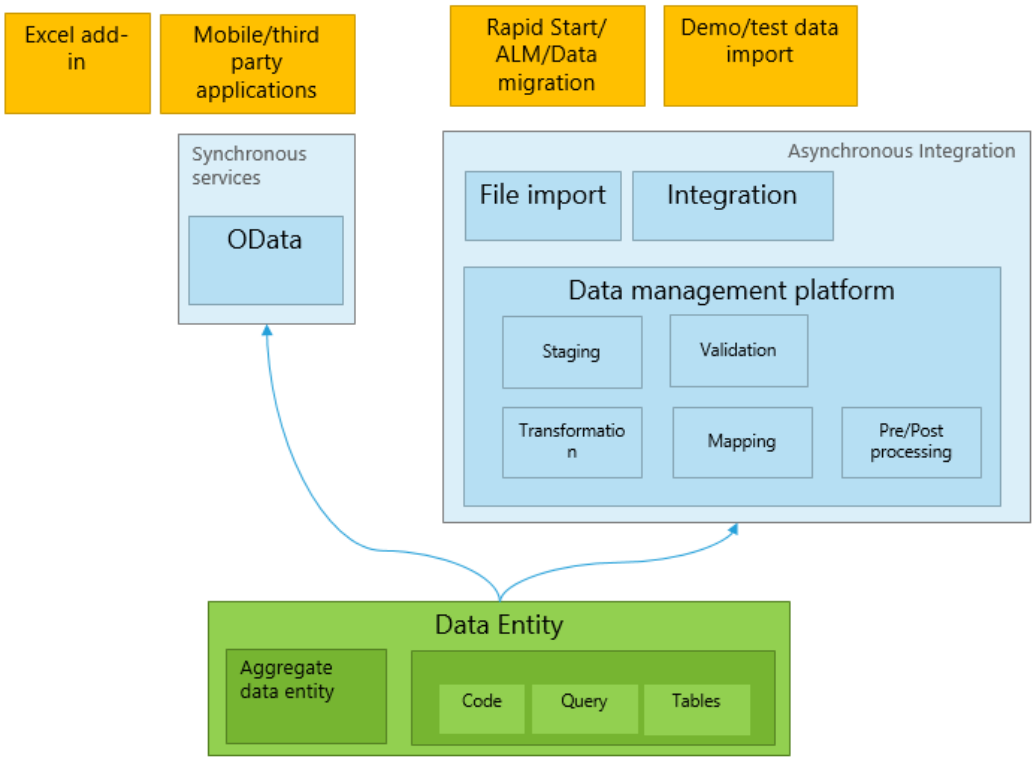
Overview

A *data entity* is an abstraction from the physical implementation of database tables. For example, in normalized tables, a lot of the data for each customer might be stored in a customer table, and then the rest might be spread across a small set of related tables. In this case, the data entity for the customer concept appears as one de-normalized view, in which each row contains all the data from the customer table and its related tables. A data entity encapsulates a business concept into a format that makes development and integration easier. The abstracted nature of a data entity can simplify application development and customization. Later, the abstraction also insulates application code from the inevitable churn of the physical tables between versions. **To summarize:** Data entity provides conceptual **abstraction** and **encapsulation** (de-normalized view) of underlying table schemas to represent key data concepts and functionalities.

Capabilities

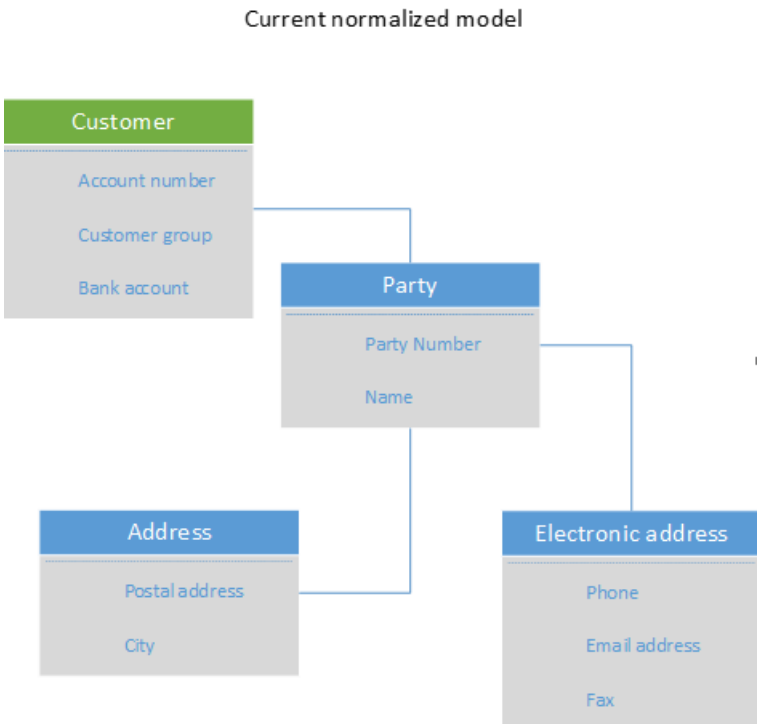
A data entity has the following capabilities:

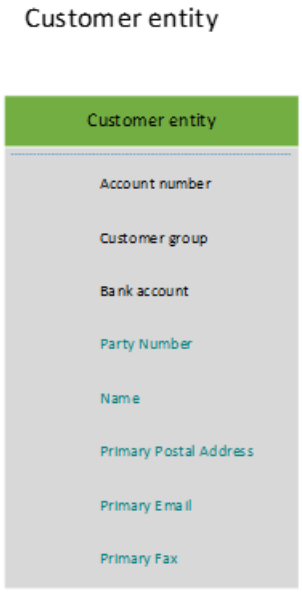
- It replaces diverging and fragmented concepts of AXD, Data Import/Export Framework (DIXF) entities, and aggregate queries with single concept.
- It provides a single stack to capture business logic, and to enable scenarios such as import/export, integration, and programmability.
- It becomes the primary mechanism for exporting and importing data packages for Application Lifecycle Management (ALM) and demo data scenarios.
- It can be exposed as OData services, and then used in tabular-style synchronous integration scenarios and Microsoft Office integrations.



Entity example

A consumer wants to access data that is related to a customer object, but this data is currently scattered across multiple normalized tables, such as DirParty, CustTable, LogisticPostalAddress, and LogisticElectronicAddress. Therefore, the process of reading and writing customer data is very tedious. Instead, the following customer entity can be designed to encapsulate the entire underlying physical schema into a single de-normalized view. This enables simpler read/write operations and also enables abstraction of any internal interaction between the tables.





Supported scenarios

Data entities support all the following scenarios.

Integration scenarios

Synchronous service (OData)

Data entities enable public application programming interfaces (APIs) on entities to be exposed, which enables synchronous services. Synchronous services are used for the following purposes:

- Office integration
- Third-party mobile apps

Asynchronous integration

Data entities also support asynchronous integration through a data management pipeline. This enables asynchronous and high-performing data insertion and extraction scenarios. Here are some examples:

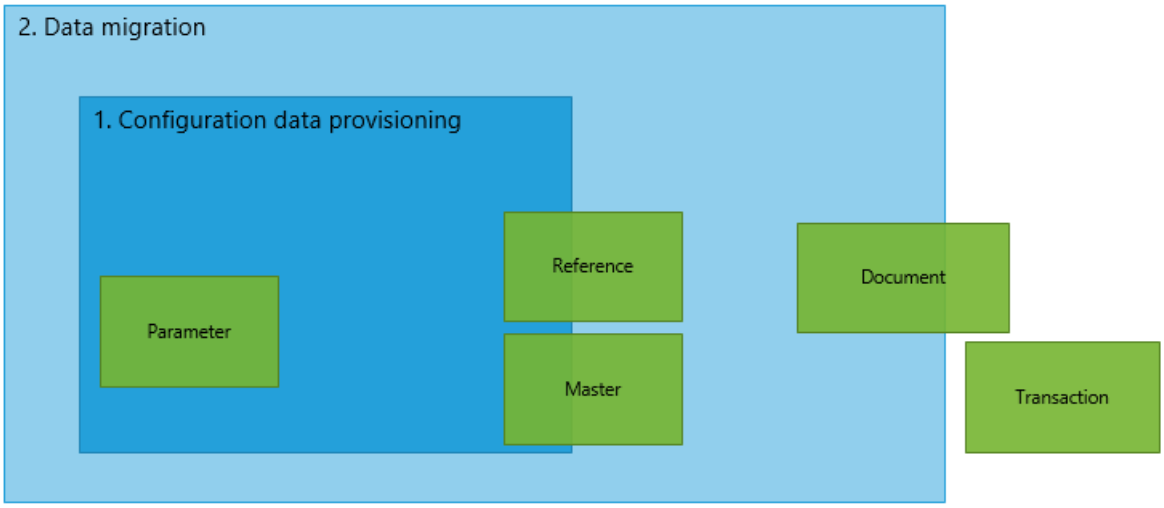
- Interactive file-based import/export
- Recurring integrations (file, queue, and so on)

Business intelligence

- Aggregate data
- Standardized key performance indicators (KPIs)

Application Lifecycle Management

Besides integration and business intelligence (BI) scenarios, data entities also initially support two critical ALM scenarios. The following two progressive levels of an ALM scenario show the scope of coverage by data entities.



Configuration data provisioning

A system implementer will use both a guided data collection wizard and bulk data input mechanisms to **bootstrap the initial deployment** (or module) with configuration data through Microsoft Dynamics Lifecycle Services (LCS). Configuration primarily targets to cover the following entity categories:

- All of Parameter
- Reference
- System parameter
- Number sequence
- Currency

Data migration from legacy or external systems

After the initial deployment is up and running, the system implementer will **migrate existing data assets of the customer** into the application, especially the following assets:

- Master data (for example, customers and vendors)
- Subsets of documents (for example, sales orders)

Categories of entities

Entities are categorized based on their functions and the type of data that they serve. The following are five categories for data entities.

Parameter

- Functional or behavioral parameters.
- Required to set up a deployment or a module for a specific build or customer.
- Can include data that is specific to an industry or business. The data can also apply to a broader set of customers.
- Tables that contain only one record, where the columns are values for settings. Examples of such tables exist for Account payable (AP), General ledger (GL), client performance options, workflows, and so on.

Reference

- Simple reference data, of small quantity, which is required to operate a business process.
- Data that is specific to an industry or a business process.
- Examples include units, dimensions, and tax codes.

Master

- Data assets of the business. Generally, these are the "nouns" of the business, which typically fall into categories such as people, places, and concepts.

- Complex reference data, of large quantity. Examples include customers, vendors, and projects.

Document

- Worksheet data that is converted into transactions later.
- Documents that have complex structures, such a several line items for each header record. Examples include sales orders, purchase orders, open balances,and journals.
- The operational data of the business.

Transaction

- The operational transaction data of the business.
- Posted transactions. These are non idempotent items such as posted invoiced and balances. Typically, these items are excluded during a full dataset copy to reduce the volume of data that is copied/migrated. Migrating completed transactions can also lead to further complexity in trying to preserve the referential integrity of related data in the new system. In general, transactions from a completed business process are not migrated in detail but in summary.
- Examples include pending invoices.

Building an entity

There are multiple ways to create an entity. For example, you can use a wizard, or you can build an entity from a table.

Building an entity by using a wizard

The simplest way to build an entity is to use a wizard. This wizard lets you select a root data source and expand to other related data sources, and then select fields for the entity. To start the wizard, add a new item of type **Data entity** to your project. For step-by-step instructions for using the wizard to build an entity, see Build and consume data entities. The following table provides information about the properties that you set for an entity in the wizard.

PROPERTY	DESCRIPTION
Primary data source	The root data source (table or view) that is used to construct the entity. You can add more related data sources, based on this root data source.
Data entity name	The name of the entity.
Entity category	The type of entity. Entity categories are similar to table groups for tables. The available categories include **Parameter**, **Reference**, **Master**, **Document**, and **Transaction**.
Public entity name	The public resource name for the entity.
Public collection name	The public resource set name.
Enable public API	Select this option to enable the entity for OData services.
Enable data management capabilities	Select this option to enable the entity for asynchronous integrations such as data import/export and connector integration.

PROPERTY	DESCRIPTION
Staging table	The name of the staging table that will be generated for the entity. The staging table is used in asynchronous integrations and high-volume scenarios.

Adding data sources

When you build an entity, you start with a root data source. However, you can add additional data sources. You can either manually add new data sources, or select a surrogate foreign key field in the root data source to automatically expand the required data sources.

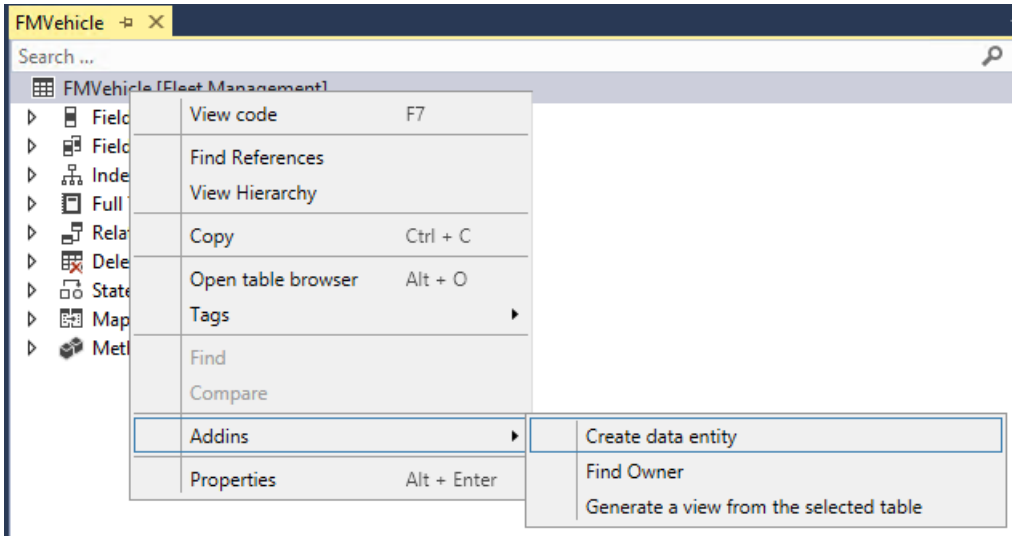
Output

When you complete the wizard, it produces the following items:

- Data entity
- Staging table (optional, if data management was enabled)

Building an entity from a table

You can quickly create an entity from a table, and then customize the properties, data sources, and fields later. Right-click the table, and then select **Addins** > **Create data entity**.



Entity list refresh

Entities in an environment must be refreshed using the following guidelines.

- When a new environment is deployed and the user navigates to the data management workspace, entity list refresh starts automatically.
- When code packages are deployed to an environment where data management has already been used, entity list refresh must be manually started from **Data management** > **Framework parameters** > **Entity settings** > **Refresh entity list**.
- When configuration keys are modified, entity list must be refreshed manually from **Data management** > **Framework parameters** > **Entity settings** > **Refresh entity list**.

Refreshing the entity list ensures all entities are available in the environment and that the entities have the latest metadata.

Configuration keys and data entities

Before you use data entities to import or export data, we recommended that you first determine the impact of configuration keys on the data entities that you are planning to use.

To learn more about configuration keys, see the License codes and configuration keys report.

Configuration key assignments

Configuration keys can be assigned to one or all of the following artifacts.

- Data entities
- Tables used as data sources
- Table fields
- Data entity fields

The following table summarizes how configuration key values, on the different artifacts that underlie an object, change the expected behavior of the object.

CONFIGURATION KEY SETTING ON DATA ENTITY	CONFIGURATION KEY SETTING ON TABLE	CONFIGURATION KEY SETTING ON TABLE FIELD	CONFIGURATION KEY ON DATA ENTITY FIELD	EXPECTED BEHAVIOR
Disabled	Not evaluated	Not evaluated	Not evaluated	If the configuration key for the data entity is disabled, the data entity will not be functional. It does not matter whether the configuration keys in the underlying tables and fields are enabled or disabled.
Enabled	Disabled	Not evaluated	Not evaluated	If the configuration key for a data entity is enabled, the data management framework checks the configuration key on each of the underlying tables. If the configuration key for a table is disabled, that table will not be available in the data entity for functional use. If a table's configuration key is disabled, the table and data entity configuration key settings are not evaluated. If the primary table in the entity has its configuration key disabled, then the system will act as though the entity's configuration key were disabled.

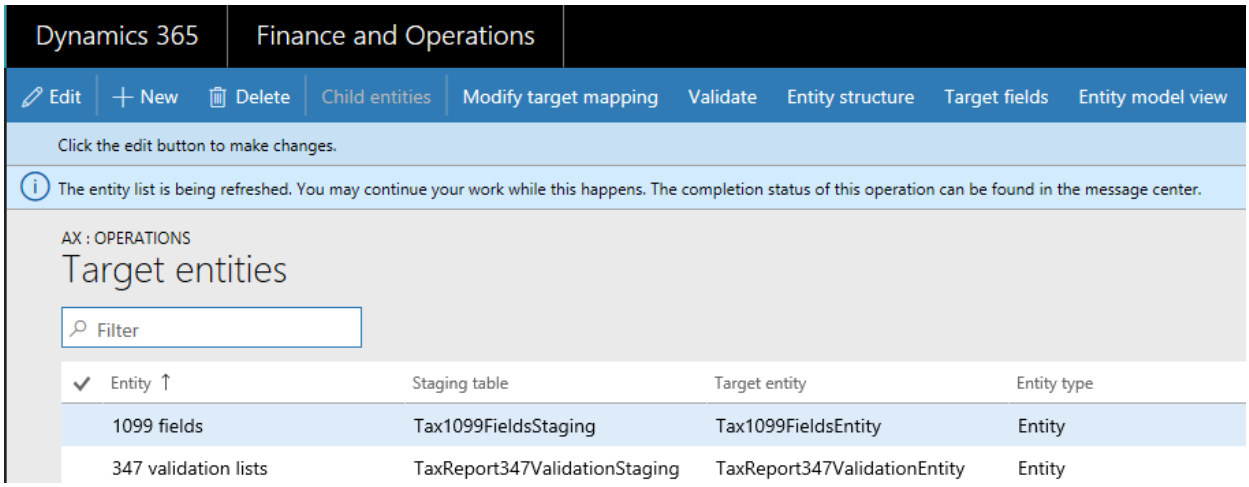
CONFIGURATION KEY SETTING ON DATA ENTITY	CONFIGURATION KEY SETTING ON TABLE	CONFIGURATION KEY SETTING ON TABLE FIELD	CONFIGURATION KEY ON DATA ENTITY FIELD	EXPECTED BEHAVIOR
Enabled	Enabled	Disabled	Not evaluated	If the configuration key for a data entity is enabled, and the underlying tables configuration keys are enabled, the data management framework will check the configuration key on the fields in the tables. If the configuration key for a field is disabled, that field will not be available in the data entity for functional use even if the corresponding data entity field has the configuration key enabled.
Enabled	Enabled	Enabled	Disabled	If the configuration key is enabled at all other levels, but the entity field configuration key is not enabled, then the field will not be available for use in the data entity.

NOTE

If an entity has another entity as a data source, then the above semantics are applied in a recursive manner.

Entity list refresh

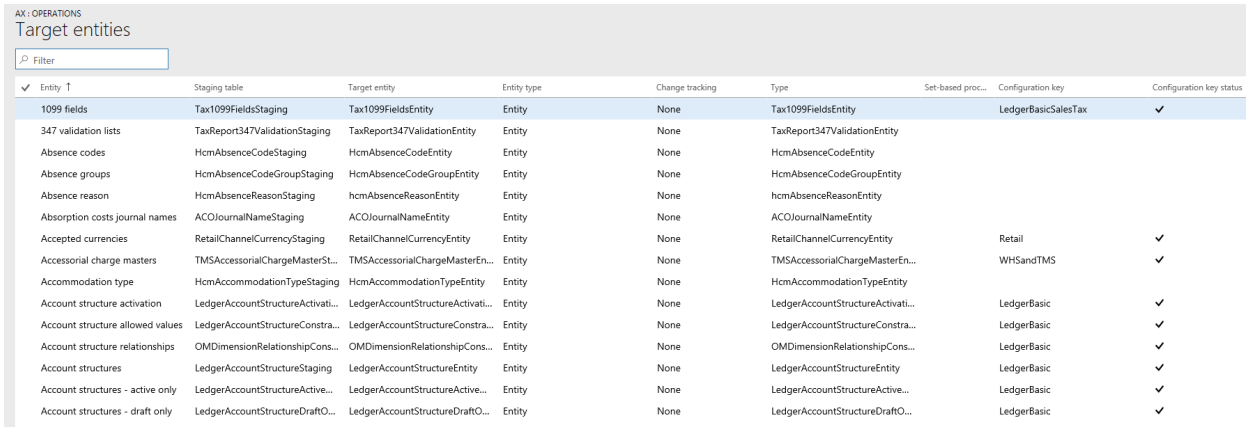
When the entity list is refreshed, the data management framework builds the configuration key metadata for runtime use. This metadata is built using the logic described above. We strongly recommend that you wait for the entity list refresh to complete before using jobs and entities in the data management framework. If you don't wait, the configuration key metadata may not be up to date and could result in unexpected outcomes. When the entity list is being refreshed, the following message is shown in the entity list page.



Data entity list page

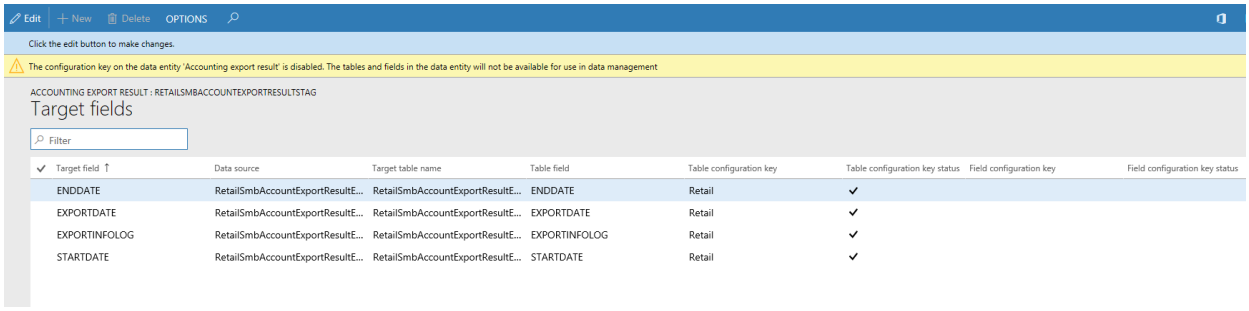
The data entity list page in the **Data management** workspace shows the configuration key settings for the entities. Start from this page to understand the impact of configuration keys on the data entity.

This information is shown using the metadata that is built during entity refresh. The configuration key column shows the name of the configuration key that is associated with the data entity. If this column is blank it means that there is no configuration key associated with the data entity. The configuration key status column shows the state of the configuration key. If it has a checkmark, it means the key is enabled. If it is blank, it means either the key is disabled or there is no key associated.



Target fields

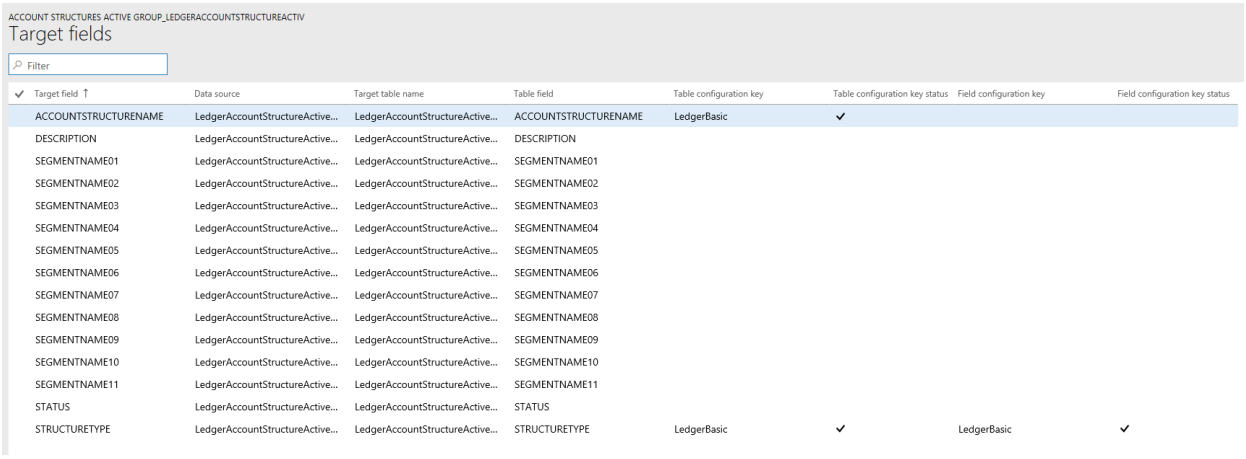
The next step is to drill into the data entity to view the impact of configuration keys on tables and fields. The target fields form for a data entity shows the configuration key and the key status information for the related tables and fields in the data entity. If the data entity itself has its configuration key disabled, a warning message is shown informing that the tables and fields in the target fields form for this entity will not be available, regardless of their configuration key status.



Child entities

Certain entities have other entities as data sources, or are composite data entities: configuration key information for these entities is shown in the **Child entities** form. Use this form in the similar way to the entities list page

described above. The target fields form for the child entity also behaves like what is described above.



Target field	Data source	Target table name	Table field	Table configuration key	Table configuration key status	Field configuration key	Field configuration key status
ACCOUNTSTRUCTURENAME	LedgerAccountStructureActive...	LedgerAccountStructureActive...	ACCOUNTSTRUCTURENAME	LedgerBasic	✓		
DESCRIPTION	LedgerAccountStructureActive...	LedgerAccountStructureActive...	DESCRIPTION				
SEGMENTNAME01	LedgerAccountStructureActive...	LedgerAccountStructureActive...	SEGMENTNAME01				
SEGMENTNAME02	LedgerAccountStructureActive...	LedgerAccountStructureActive...	SEGMENTNAME02				
SEGMENTNAME03	LedgerAccountStructureActive...	LedgerAccountStructureActive...	SEGMENTNAME03				
SEGMENTNAME04	LedgerAccountStructureActive...	LedgerAccountStructureActive...	SEGMENTNAME04				
SEGMENTNAME05	LedgerAccountStructureActive...	LedgerAccountStructureActive...	SEGMENTNAME05				
SEGMENTNAME06	LedgerAccountStructureActive...	LedgerAccountStructureActive...	SEGMENTNAME06				
SEGMENTNAME07	LedgerAccountStructureActive...	LedgerAccountStructureActive...	SEGMENTNAME07				
SEGMENTNAME08	LedgerAccountStructureActive...	LedgerAccountStructureActive...	SEGMENTNAME08				
SEGMENTNAME09	LedgerAccountStructureActive...	LedgerAccountStructureActive...	SEGMENTNAME09				
SEGMENTNAME10	LedgerAccountStructureActive...	LedgerAccountStructureActive...	SEGMENTNAME10				
SEGMENTNAME11	LedgerAccountStructureActive...	LedgerAccountStructureActive...	SEGMENTNAME11				
STATUS	LedgerAccountStructureActive...	LedgerAccountStructureActive...	STATUS				
STRUCTURETYPE	LedgerAccountStructureActive...	LedgerAccountStructureActive...	STRUCTURETYPE	LedgerBasic	✓	LedgerBasic	✓

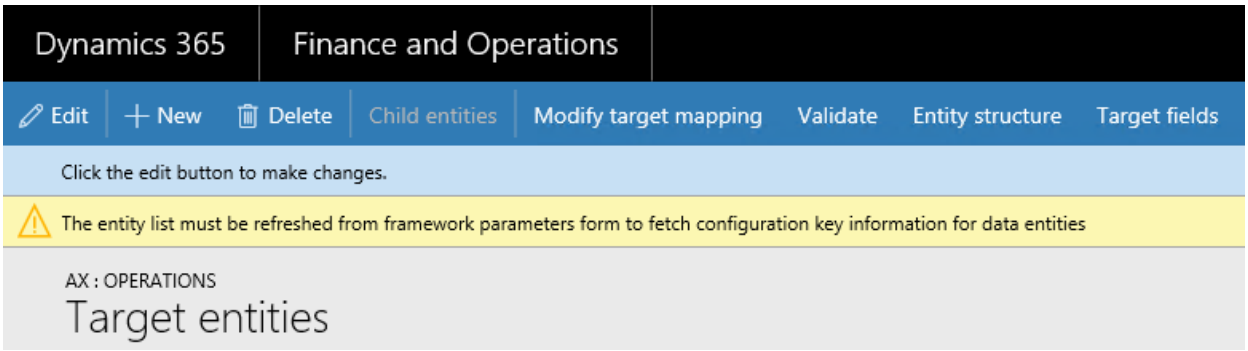
Run time validations for configuration keys

Using the configuration key metadata built during entity refresh list, run time validations are performed in the following use cases.

- When a data entity is added to a job.
- When user clicks **Validate** on the entity list.
- When the user loads a data package into a data project.
- When the user loads a template into a data project.
- When an existing data project is loaded.
- When a template is loaded into a data project.
- Before the export/import job is executed (batch, non-batch, recurring, OData).
- When the user generates mapping.
- When the user maps fields in the mapping UI.
- When the user adds only 'importable fields'.

Managing configuration key changes

Anytime that you update configuration keys at the entity, table, or field level, the entity list in the data management framework must be refreshed. This process ensures that the framework picks up the latest configuration key settings. Until the entity list is refreshed, the following warning will be shown in the entity list page. The updated configuration key changes will take effect immediately after the entity list is refreshed. We recommend that you validate existing data projects and jobs to make sure that they function as expected after the configuration keys changes are put in effect.



Configuration data projects

2/18/2021 • 4 minutes to read • Edit Online

Configuration data projects are used to manage the movement of company configuration data between instances of your application. They are intended to support the following scenarios:

- **Export of configurations** – Create configurations of entities, and use the data management framework to export the configurations to a package.
- **Import of configurations** – Upload a configuration package, and use the data management framework to import the package.

Configuration data packages are created by using data import and export projects in the **Data management** workspace. The **Data import** and **Data export** pages let you add and remove the entities that you require in order to manage the movement of company and shared data. After you create the list of entities in your configuration, you can export or import the configuration by using the data management framework to create a package. You can export packages locally and then move them to another instance for import.

Configuration data templates are predefined lists of entities for each module area that can be used in a data project. You can create, view, and modify these templates by using the **Template** page in the **Data management** workspace.

> **IMPORTANT**
> Default configuration templates were delivered in Microsoft Dynamics 365 for Finance and Operations, Enterprise edition July 2017 update. The Configuration data project feature is available in Microsoft Dynamics 365 for Operations platform update 7. You can create and use your own templates in the current product release.

Process for working with configuration data projects

We recommend that you follow this process when you start to use configuration data projects.

1. Set up your system by getting the new data configuration user interface (UI) and setting default file extensions.
2. Set up configuration templates for both export and import.
3. Create and run a configuration data project for export.
4. Create and run a configuration data project for import.

The rest of this topic describes the **Data management** workspace and explains how to set up your system for data configuration projects.

If you're ready to set up a configuration template, see Configuration data templates. If you're ready to create and run a configuration data project, see Copy configuration data between companies or legal entities overview.

Data management workspace overview

The **Data management** workspace provides access to important tasks for data management. It also provides information about projects and project execution tasks.

After you've created a configuration data project, it appears in the **Data projects** grid in the **Data management** workspace. For each project, the type of configuration (import or export) and the project category (**Project**, **Configuration**, **Integration**, or **Other**) are shown. Use the selections to the left of the grid

to filter by the appropriate project.

To open a project, select the project, and then select **Load project** to open the **Import or export** page. Use the **Delete** button to delete the selected projects. You can also download the project definitions by using the **Download** button.

Use **Job history** to find more details about the projects that you've run. Use the data range filters to filter by the dates when data projects were run. You can view execution details by selecting a job and then using the **Execution details** menu.

For export tasks, you can download the data from the workspace by using the **Download page** button.

Set up your system to manage configuration data projects

Before you begin, make sure that you have access to the new data configuration UI, and that you've set up the default data sources.

Get the new UI

We have updated the **Data management** workspace, and the **Template**, **Data export**, and **Data import** pages, so that they support configuration management. However, the updated pages are available only in Enhanced view. Standard view hasn't been updated from previous releases.

Change to the new UI for a single user

The system's default view settings can be changed to save settings for each user per each legal entity. To switch the view for a single user, the user must select the **Enhanced view** button on each page in the **Data management** workspace.

Change to the new UI for all users in all legal entities

1. In the **Data management** workspace, select the **Framework parameters** tile.
2. Change the **View default** setting from **Standard** to **Enhanced** for all users and legal entities.

Set file extensions for default data sources

The **Template** and **Import/export** pages let you add entities by selecting a file that was created by using the data management framework. We have added the following default file name extensions for the various types of data sources:

- .xlsx for Microsoft Excel data sources
- .zip for package data sources
- .xml for XML data sources
- .csv for comma-separated values (CSV) data sources
- .txt for delimited data sources

If you want to use other file name extensions, you must update your data sources so that they have a default file name extension that will be used as the target data format.

1. In the **Data management** workspace, select the **Configure data sources** tile, and then select **Data sources**.
2. Add a default file name extension to the appropriate data source.

Copy configuration data between companies or legal entities overview

2/18/2021 • 32 minutes to read • Edit Online

There are two options for copying configuration data in Finance and Operations:

- To move data between instances, you must first export it from one company and then import it to another company.
- To move data from one legal entity to another legal entity in the same instance, you can use the **Copy into legal entity** feature.

Export a configuration

The **Data management** workspace is your hub for managing configuration data projects and exporting data packages. To build a configuration, you must define a data project and export the information that is represented by entities.

To create an export configuration data project, follow these step.

1. Open the **Data management** workspace. If you're in Standard view, select **Enhanced view**.
2. Select the **Export** tile.
3. Select **New** to create an export configuration data project, and enter an ID and name for the configuration.
4. Set the operation type for the data project to **Export**, and set the project category to **Configuration**.
5. Add the entities that represent the information that you want to export. You can add entities by using several methods:
   - **Add one entity** – Enter the first part of the name of the entity until it appears in the lookup.
   - **Add multiple entities** – Enter any part of the entity name, use the lookup for the module, enter any part of the tag name, or use the lookup for the entity category to show a list of entities. Press Tab to move focus away from the **Lookup** field and activate the filter. In the grid, select the entities to add.
   - **Add a file** – Browse to a file that contains a name that matches the name of an entity and a file name extension that matches the file name extension that is in your data sources.
   - **Add a template** – Select from a list of templates that you've loaded in your instance.
6. Select a target data format. The system stores the last data format that you selected. Alternatively, if you select a file, the system automatically sets the data format to the data source that matches the file name extension.

   > **NOTE**
   > Composite entities require XML format.

7. Select **Add**. If you load a template, and the project already includes an entity that matches an entity in the template, the entity in the project will be replaced by the entity in the template. Some templates are very large, and they might take a few seconds to be loaded.
8. Select **Remove entity** to remove one or more selected entities.

9. When you've completed the configuration, select **Export** to start the export. You can monitor the results on the **Execution summary** page that appears.

Before you export a configuration, you might want to use some additional features that can help control the export process:

- To organize the list, use the **Sort by** button to reorder the entities by unit, level, and sequence.
- To change the execution sequence of any of the entities, you can manually edit the unit, level, or sequence. Alternatively, you can use the **Resequence** button to update any entities that you've selected. The **Resequence** button appears only if you select more than one entity. You can change the unit, level, and sequence individually. Alternatively, you can enable multiple changes and make them all at the same time. If you want the unit, level, or sequence to remain unchanged when you change multiple parts of the sequence, set the increment to **0** (zero).
- To add filters to the entity, use the **Filter** button. If you add a filter, the **Filter** button changes to an **Edit** button. The data will be filtered before it's exported. If you've added a template, and the template includes filters, those filters will be added to your project. However, you can modify or remove them as you require.
- If you must change the entity mappings, use the **View map** button. If you've added a template, and the template includes mapping changes, those changes will be applied to your project. However, you can modify them as you require.
- To temporarily prevent the entity from being used when you export a data project, use the check box in the **Disable** column.
- To open the contents of the grid in a Microsoft Excel workbook, use the **Open in Excel** button. Modify the entities as you require, and then use the **Publish** button to upload the changes back.

When the export is completed, complete the following tasks:

- Use the **Download** button on the **Export** page to download the configuration settings.
- Use the **Download package** button in the **Data management** workspace or on the **Execution summary** page to download the configuration settings and the data that was exported.

Setup considerations for some entities that are used to export configurations

Currently, several entities require additional steps when you build configurations. Follow these recommendations as you build your configurations.

> **IMPORTANT**
> This list will be updated as the Copy configuration feature is improved.

Using special-purpose entities

The following entities require special handling when they are used in configurations.

AREA	ENTITY	ACTION
System setup	Global address book	The entity no longer exports the records that are created automatically when a company is created. The import no longer accepts those records as well, starting in the platform 9 release.

AREA	ENTITY	ACTION
GL Shared	Account structures active group	This composite entity will export and import only the active account structures. If you use any other account structure entities, the status of the active account structures will be changed to **Draft**, and you must activate them before they can be used.
	Advanced rule structures active group	This composite entity is used in combination with the account structures active group entity. It will export and import only the active advanced rule structures. If you use any other advanced rule structure entities, the status of the advanced rule structures will be changed to **Draft**, and you must activate them before they can be used.
	Financial dimension values	All dimension values will be exported, even values that are based on system-defined entities such as projects or customers. Remove the system-defined values before you import them. If you leave the system-defined values in the package, they won't be imported. However, they will be filled as you import the data that backs the system-defined dimension.
Workflow	Workflow version	Change the owner for every record in the package data to **Admin**, unless the users in the workflow are already imported.
	Workflow expression	Some workflow expressions might be too long for an Excel cell. Use XML instead of Excel as the export format.
Tax	Sales tax parameters	The default value for the marginal base calculations method is **Total** for sales tax parameters. The Ledger Parameters entity doesn't set that value. However, the marginal base that some tax codes use, **Line**, will fail validation. A new entity that is named the Sales tax parameters preset entity was created so that you can import the marginal base calculation method first. You can then import tax codes.

AREA	ENTITY	ACTION
Accounts receivable	Customers	The Customers entity was designed to be used for OData scenarios. For configurations, use the Customer definitions entity and the Customer details entity. The Customer definitions entities let you import the basic information about a customer. In this way, you enable entities that require that a customer have that information earlier in the import process. The Customer details entity contains additional information about a customer that you can add after parameters and reference data have been set up.
Inventory management	Warehouse locations	Some warehouse locations require a location profile ID. Location profile IDs require a location format. Currently, the location format information must be manually added before the warehouse location. The entities for the location format and location profile were added in version 7.2.3, (App update 3 of the July 2017 release).
Product information management	Products	The Products and Released Products entities should be used for configurations. The Product master and Released product master entities should be used for OData scenarios.
	Product document attachments	For attachments to product documents released product documents, you must never skip staging, because additional steps are performed in the staging environment. You must use a data package for export and import, because the export file must be accompanied by a resources folder that contains the attachments. The entities support images, documents, notes, and links. When you export, you will see an image file that has a name that resembles a globally unique identifier (GUID). This file is a valid data package that is required in order to complete the import.
	Product attribute values	Product attribute values are assigned only when a user opens the **Attribute values** page from the **Products details** page. Currently, you can't import the values unless this step was performed in the golden build.

AREA	ENTITY	ACTION
Procurement	Vendor catalog	See the "Vendor catalogs import" section of Vendor catalogs in Dynamics AX on the Supply Chain Management blog.
Project	Shared category	The Shared category entity now exposes the following fields: **CATEGORYID**, **CATEGORYNAME**, **EXPENSETYPE**, **USINEXPENSE**, **USINPRODUCTION**, and **USEINPROJECT**. If you change the value of the **USEINEXPENSE** field to **yes**, the **EXPENSETYPE** should be set to one of the valid values that are available in the **Expense type** field on the **Shared category** page.

Remove the mapping and apply filters for specific entity fields

In a golden build, customer-specific fields might not be set up. To help guarantee that the import works, you should unmap those fields. For example, workers are stored in many tables, but they might not be set up in a golden build. Filters might also be required for some fields in an entity.

The following entities might have to be unmapped or filtered.

AREA	ENTITY	ACTION
System setup	Operating unit	Unmap Manager personnel number unless workers have been imported.
	User information	Apply a filter where **ID** isn't equal to **Admin**. Unmap Person name, and use the User to person relationship entity to map system users to directory users.
Accounts payable	Vendors	Unmap Purchase site (DefaultPurchaseSite) and Warehouse (DefaultProcurementWarehouseID) unless they are set up. Unmap the vendor bank account ID. The Vendor bank account entity will set up the link to the bank account when it's imported.
Accounts receivable	Customer details	Unmap Employee responsible number unless workers have been imported. Unmap Collections contact person (CollectionsContactPersonID) unless workers and their contact information have been imported. Unmap the site (SiteID) and warehouse (WarehouseID) unless they have already been imported.
Inventory management	Warehouse current postal address	Unmap Picking store area and Input store area unless Commerce information has been imported.

AREA	ENTITY	ACTION
Product information management	Products	Unmap NMFCCode and STCCCode unless you are adding the transportation management template to your data project.
	Released products	Unmap the project category, default product color, default configuration, default product size, and default product style. This entity is self-referencing and hasn't yet been updated to load these fields in a single pass.
	Period template	The Period template entity is a shared entity. Although it can be filtered by legal entity, the Period template lines entity doesn't have a **Legal entity** field. To import a single legal entity, you can filter the period template. However, you must currently remove the period template lines that aren't related to that legal entity.
	Item coverage group	Unmap Period template ID unless it has already been added manually.
Procurement	Vendors	Unmap Purchase site (DefaultPurchaseSite) and Warehouse (DefaultProcurementWarehouseID) unless they are set up. Unmap the vendor bank account ID. The Vendor bank account entity will set up the link to the bank account when it's imported.
Sales and marketing	Leads	Unmap LeadOpeningPersonnelNumber, LeadClosingPersonnelNumber, and LeadResponsiblePersonnelNumber unless workers have been imported.
	Sales type document entry policies	Unmap IsAtpGenrallyIncludingPlannedOrders. The default for Master planning was changed to be Yes for Disable all planning processes when a legal entity is created.
Project management	Projects	Unmap WorkerArchitectPersonelNumber, WorkerRespFinancialPersonelNumber, WorkerResponsiblePersonnelNumber, and WorkerRespSalesPersonelNumber unless workers have been imported.

AREA	ENTITY	ACTION
Retail	POS visual profiles	Unmap Pallet because no entity is available at this time. The POS visual profiles entity was added to the Retail template in version 7.2.3, (App update 3 of the July 2017 release).
	Retail channel	Unmap Channel profile name (ChannelProfileName) and Live database connection profile name (LiveDatabaseConnectionProfileName) because no entity is available at this time. The Retail channel entity was added to the Retail template in version 7.2.3, (App update 3 of the July 2017 release).

Golden builds that have multiple legal entities

The templates can be used to export data from any company in your golden build. When you export both shared data and company data, the templates first export the shared data for all legal entities. They then export the data for the legal entity that you're currently using. You can then switch companies and export the company data for additional legal entities by using projects that don't include the shared entities.

If you're exporting from a golden build that contains multiple legal entities, but you want to import the data from only one of those legal entities, you must apply a filter on the legal entity fields, so that only the data that you require for that legal entity is exported. This filter must remove all data for all legal entities except the legal entity that you want. In some cases, you must complete additional steps to clean up the exported data.

Most of the changes that are listed in the following table occur in the **System setup** and **General ledger** areas. If you export a golden build that uses a single legal entity, you should not require these filters.

The following entities require filters or special handling when you export the data.

AREA	ENTITY	ACTION
System setup	Legal entities	Apply a filter to Company.

AREA	ENTITY	ACTION
	Number sequence code	The number sequence codes can be shared, or they can be specific to a legal entity. To import all number sequences, you must have the legal entities setup for the number sequences that are stored for a specific legal entity. If you want only shared number sequences, apply a filter to remove the number sequences that are specific to a legal entity. If you want the number sequences only for a specific legal entity, apply a filter to Company. Number sequences can also have scope. You must delete number sequences when the following conditions are met: • The **SCOPETYPE** value is **DataArea**, and the **SCOPEVALUE** value either isn't equal to the legal entity or is blank. • The **SCOPETYPE** value is **LegalEntity**, and the **SCOPEVALUE** value isn't equal to the legal entity. • The **SCOPETYPE** value is **DataAreaFiscalCalendar**, and the **SCOPEVALUE** value isn't equal to the legal entity.
	Number sequence references	Number sequence references can also have scope. You must delete the number sequence references when the following conditions are met: • The **SCOPETYPE** value is equal to **DataArea**, **DataAreaFiscalCalendar**, or **LegalEntity**. • The **SCOPEVALUE** value either isn't equal to the legal entity that you want in the data or is blank.
	Organization hierarchies	There is no legal entity filter. Manually remove any references to the other legal entities that you aren't importing. For example, if you've set up centralized payments, but you're loading only one legal entity, you must not import the Centralized payments hierarchy.

AREA	ENTITY	ACTION
Global address book	Multiple entities	The global address book contains data for all legal entities. All legal entities will be created when you import the data, unless you remove the data for the legal entities that you don't want to load. To help guarantee that other legal entities aren't created, delete all records for those other legal entities. Alternatively, apply a filter to the Legal entity data area (<> blank). You must also remove global address book records that are used in the other legal entities.
	Party postal addresses	Address records for legal entities other than the legal entity that you're importing must be manually deleted before import.
	Party contacts	Contact records for legal entities other than the legal entity that you're importing must be manually deleted before import.
	Workflow	Apply a filter on DataAreaID. Many of the workflow entities can't be filtered for legal entity. Therefore, import failures might occur if you don't remove the data in all workflow entities that are related to legal entities that you don't want. We recommend that you manually set up workflows for this scenario.
General ledger	Ledger	Apply a filter to Company.
	Ledger fiscal calendar year	Apply a filter to Ledger name.
	Ledger fiscal calendar period	Apply a filter to Ledger name.
	Main account legal entity overrides	Apply a filter to Company.
	Financial dimension value legal entity	Apply a filter to Legal entity.
	Financial dimension values	Apply a filter to Legal entity. However, you can't filter out system-defined dimension values. Therefore, you must delete them. Those system-defined dimension values will be restored when you import data for the tables that back the system-defined dimensions.
	Journal names	Apply a filter to Voucher series company ID.
	Ledger allocation basis source	Apply a filter to Legal entity.

AREA	ENTITY	ACTION
	Ledger allocation rule destination	Apply a filter to Company.
Accounts receivable	Customer write-off reason code	Apply a filter to Company.
Budget	Budget control configuration	Apply a filter to Legal entity.
	Budget control configuration activation	Apply a filter to Legal entity.
	Budget control cycle model	Apply a filter to Legal entity.
	Budget control dimension attribute	Apply a filter to Legal entity.
	Budget control documents and journals	Apply a filter to Legal entity.
	Budget control group	Apply a filter to Legal entity.
	Budget control group criteria	Apply a filter to Legal entity.
	Budget control message level	Apply a filter to Legal entity.
	Budget control over budget permissions	Apply a filter to Legal entity.
	Budget control rule	Apply a filter to Legal entity.
	Budget control rule criteria	Apply a filter to Legal entity.
	Budget cost elements	Apply a filter to Cost element data area ID.
	Budget dimensions	Apply a filter to Legal entity.
	Budget plan allocation schedule	Apply a filter to Ledger.
	Budget plan process	Apply a filter to Ledger.
	Budget plan stage rule	If you applied a filter to Budget plan process, errors might occur when you import stage rules. Because the entity doesn't currently contain a ledger name that can be filtered, it will contain all companies.
	Budget plan priority constraint	You will experience the same issue that is described for the Budget plan stage rule entity.
	Budget plan process administration	You will experience the same issue that is described for the Budget plan stage rule entity.

AREA	ENTITY	ACTION
	Budget transfer rules	Apply a filter to Legal entity.
Inventory management	Warehouse current postal address	Apply a filter to Company.
	Site current postal address	Apply a filter to Company.
	Tracking number groups	The entity automatically filters the Number sequence scope data area by the legal entity. Therefore, you don't require a filter. However, if you must change the legal entity, the legal entity is stored in the table.
Retail	POS registers	Apply a filter to Legal entity. This entity was added to the Retail template version 7.2.3, (App update 3 of the July 2017 release).
	Retail store address book	There is no legal entity filter for this entity so the export will include records for all legal entities. This entity was added to the Retail template inversion 7.2.3, (App update 3 of the July 2017 release).
	Retail locator group member	There is no legal entity filter for this entity so the export will include records for all legal entities. This entity was added to the Retail template in version 7.2.3, (App update 3 of the July 2017 release).
	Retail locator group owner	There is no legal entity filter for this entity so the export will include records for all legal entities. This entity was added to the Retail template in version 7.2.3, (App update 3 of the July 2017 release).
	Retail devices	There is no legal entity filter for this entity so the export will include records for all legal entities. This entity was added to the Retail template in version 7.2.3, (App update 3 of the July 2017 release).

Changing the legal entity value before import

If you want to change the legal entity ID to another value, the value of all fields that resemble the fields that were listed earlier must be changed to the value of the new legal entity. For example, for Legal entities, change Company from the exported value to a new value in the exported file.

The legal entity ID is stored in many places. Therefore, it can be difficult to make this change, and you might cause errors if you try.

> **NOTE**
>
> When you set up a data project to copy into a legal entity, a legal entity filter for the source legal entity is automatically added to any entity field that is determined to be a legal entity field.

Selecting a single legal entity for export

To export a single legal entity, you can create a Copy into legal entity data project and specify the legal entity to copy as the source legal entity. When you add entities or load templates, that type of project will automatically add legal entity filters. You can then download the package or create a template from it on the **Templates** page. The package or template can then be added to an export project and used to export the legal entity.

Import a configuration

The **Data management** workspace is also your hub for importing configuration data projects. You can build a configuration project from an existing data project that you exported. Alternatively, you can build a configuration project from individual files that contain data that is formatted correctly for import.

To import a configuration, follow these steps.

1. Open the **Data management** workspace. If you're in Standard view, select **Enhanced view**.
2. Select the **Import** tile.
3. Select **New** to create a configuration data project, and enter an ID and name for the configuration.
4. Set the operation type for the data project to **Import**, and set the project category to **Configuration**.
5. Add the entities that represent the information that you want to copy. You can add entities by using several methods:
   - **Add one entity** – Enter the first part of the name of the entity until it appears in the lookup.
   - **Add multiple entities** – Enter any part of the entity name, use the lookup for the module, enter any part of the tag name, or use the lookup for the entity category to show a list of entities. Press Tab to move focus away from the **Lookup** field and activate the filter. In the grid, select the entities to add.
   - **Add a file** – Browse to a file that contains a name that matches the name of an entity and a file name extension that matches the file name extension that is in your data sources, and the source data format will be set automatically. If you haven't set up the default file name extensions, you must select a source data format before you select the file.
   - **Add a template** – Select from a list of templates that you've loaded in your instance.

   When you load a package, the **Import** page first reads the list of entities from the package. A progress indicator shows how much of the package has been read. After the list of entities is read, the **Import** page starts to load the data in the package. This process can take some time.
6. Select **Remove entity** to remove any selected entities, as required.
7. After you've completed the configuration, select **Import** to start the import. You can monitor the results on the **Execution details** page that appears.

Before you import a configuration, you might want to use some additional features that can help control the import process:

- To organize the list, use the **Sort by** button to reorder the entities by unit, level, or sequence.
- To change the execution sequence of any of the entities, you can manually edit the unit, level, or sequence. Alternatively, you can use the **Resequence** button to update any entities that you've selected.
- If you must change the entity mappings, use the **View map** button.

- To temporarily prevent the entity from being used when you export a data project, use the check box in the **Disable** column.

Copy into a legal entity

The **Data management** workspace is also your hub for copying configuration information from one legal entity to another. The process resembles an export and import that occur in one step. As in an import, if information that exists in the source legal entity doesn't exist in the destination legal entity, the copy process adds it. If information already exists in the destination legal entity, the copy process updates it.

To copy a configuration from one legal entity to another legal entity in the same instance, follow these steps.

1. Open the **Data management** workspace. If you're in Standard view, select **Enhanced view**.
2. Select the **Copy into legal entity** tile.
3. Select **New** to create a configuration data project, and enter an ID and name for the configuration.
4. Set the operation type for the data project to **Copy into legal entity**, and set the project category to **Configuration**.
5. Select the legal entity that should be the source of the data to copy. By default, the legal entity that you're currently using is selected.
6. On the **Legal entities** FastTab, you can select existing legal entities as a destination, or you can create new legal entities:
   - **Select** – Select one or more legal entities in the list, and then select **Add selected**. The legal entities are added to the list of destination legal entities.
   - **Create** – Enter the legal entity ID, the legal entity name, and the region that the legal entity belongs in. Then select **Create legal entity**. The legal entity is created and added to the list of destination legal entities.

   > **NOTE**
   > The functionality for creating destination legal entities is available in Finance and Operations 7.2.3.

7. After you've added the destination legal entities, select **Yes** if the number sequences should be copied. The entities that are required in order to copy the number sequence codes and number sequence references will be added to the project. The execution unit, level, and sequence number for these entities are set to the numbers in the default System and Shared templates. If you aren't using the default templates, adjust the entity sequences so that they are first in the list.
8. If you selected **Yes** for number sequences, select **Yes** or **No** to specify whether those number sequences should be reset to the smallest value.
9. Add the entities that represent the information that you want to copy. You can add entities by using several methods:
   - **Add one entity** – Enter the first part of the name of the entity until it appears in the lookup.
   - **Add multiple entities** – Enter any part of the entity name, use the lookup for the module, enter any part of the tag name, or use the lookup for the entity category to show a list of entities. Press Tab to move focus away from the **Lookup** field and activate the filter. In the grid, select the entities to add.
   - **Add a file** – Browse to a file that contains a name that matches the name of an entity and a file name extension that matches the file name extension that is in your data sources.
   - **Add a template** – Select from a list of templates that you've loaded in your instance.

To help guarantee that the correct order is maintained, we recommend that you use the default templates. Then add and remove entities to match the data that you want to copy. You can remove the entities that you don't want to copy.

> **NOTE**
>
> - If an entity has a field that represents the legal entity, a filter will be applied to that entity, so that only the data for the source legal entity is included. The value for that field will be changed to the destination legal entity.
> - Document, transaction, and composite entities aren't available when you copy to a legal entity.

10. Select **Remove entity** to remove any selected entities, as required.
11. After you've completed the configuration, select **Copy into legal entity** to start the import. The copy process will export the data from the source legal entity into the destination legal entity. Each destination legal entity will have its own import data project. You can monitor the results on the **Execution summary** page that appears. All import projects that are related to the Copy into legal entity project will appear in a list on the left of the page.

Any errors that occur are shown on the **Execution summary** page, just as they are for an import project. You can edit the errors in the staging tables and resubmit the values for each data project.

Special considerations when you copy into a legal entity

When you copy into a legal entity, you have the same validation that occurs when you import a file. It's important that you test your copy in a test environment, so that you can identify any dependencies that will cause failures. If dependent information isn't included in your list of entities to copy, the entity will show errors when it tries to copy into the legal entity. For example, if a customer has a default site or warehouse, you must use one of these approaches:

- Import the sites and warehouses as part of the copy.
- Manually load the sites and warehouses before you copy the legal entity.
- Unmap the site and warehouse fields before you copy the information.

You might also experience import errors if you copy from one region to another region. For example, you can have 1099 fields in a legal entity in the US region. However, if you try to import those values into a legal entity in a German region, you will see errors on the import. If a template that you load has entities that are incorrect for a region, you will receive an error message that states that the incorrect entity wasn't loaded. However, the rest of the template will continue to be loaded. You should copy only information that is appropriate for the destination region.

The following entities require special handling when they are used to copy into a legal entity.

AREA	ENTITY	ACTION

AREA	ENTITY	ACTION
System setup	Number sequences	If you use a number sequence for vendors and customers on the parameters forms and then you copy customers and vendors, you need to make sure that the "Allow user to change to a lower number" settings on the number sequences to Yes. The "No" settings will cause the import to reject vendor and customer numbers since they were created before using numbers lower than the next available number sequence. If you use the Reset to smallest feature, you need to change the "Allow user to change to a higher number" since the vendor and customer numbers are higher than the next available number sequence.
System setup	Workflow	Workflow requires additional changes before it can be copied. Workflow copies are not supported at this time.
Accounts payable	Vendors	Vendors have many settings that are dependent on the values that come from other entities. For example, if you update the matching settings to require three-way matching but you have vendors set for two-way matching, the vendor will fail validation. If you use auto sequencing for new vendor, you will need to unmap the vendor account before you do the copy into legal entity. In addition, if an auto-sequenced vendor has an invoice account, that vendor account is not transformed and may fail. You may see similar issues in other areas such as vendors in posting accounts and approved vendor list by products.
Accounts receivable	Customers	Customers have many settings that are dependent on the values that come from other entities. For example, if you have a default warehouse and site for a customer, you must add sites and warehouses first or the customer will fail validation. The collections contact will also fail if the contact is not available in the new company. If you use auto sequencing for new customers, you will need to unmap the customer account before you do the copy into legal entity. In addition, if an auto-sequenced customer has an invoice account, that invoice account is not transformed and may fail. You may see similar issues in other areas such as customers in posting accounts.

AREA	ENTITY	ACTION
Budget	Budget cost elements	There is an issue when importing budget cost elements when using an annual amount and there are budget cost elements in the Earnings basis tab. The issue will be addressed in a future release.
Fixed assets	Fixed assets depreciation profile manual schedule	The fixed asset depreciation profile must be processed first. Change the sequence on your data project for fixed asset depreciation profile to 15 (instead of 10). We will update the default templates in the monthly application release 4 to this value.
General ledger	Intercompany accounting	The copy into legal entity feature does not support intercompany accounting at this time. The issue will be addressed in a future release.
General ledger	Journal names	Only the journal names for the source legal entity will be copied to the destination companies. If you select the lookup in the journal names form, you will only see the number sequences that are available for that legal entity. However, if you choose to enter a number sequence manually that is not on that list, it will not be included in the copy process.
General ledger	Ledger allocation rules destination	If you are running a version earlier than version 7.3, if you have cross company allocation rules, you will not see the destination rules for legal entities that do not match the source legal entity. The copy into legal entity feature will only copy the destination records when the destination is equal to the source. The issue has been resolved in version 7.3.
General ledger	Ledger fiscal calendar year/period	The process is currently exporting all of the legal entities instead of just the source legal entity. The copy process works correctly. The issue has been resolved in version 7.3.

AREA	ENTITY	ACTION
General ledger	Ledger parameters	If you check for continuous number sequences but you have number sequences that are used on journal names and are not continuous, the imports will fail. You should temporarily turn off that setting in the ledger parameters. In addition, the ledger parameters must be processed first. Change the sequence on your data project for ledger parameters to 15 (instead of 40). We will update the default templates in the monthly application release 3 to this value.
Inventory management	Inventory dimension parameters	There is an issue where an error on import is shown but the correct number of parameters are imported. The issue will be addressed in a future release.
Inventory management	Warehouse locations	Some warehouse locations require a location profile ID. Location profile IDs require a location format. Currently, the location format information must be manually added before the warehouse location. The entities for the location format and location profile were added in version 7.2.3, (App update 3 of the July 2017 release).
Master planning	Intercompany master plan associations	The copy into legal entity feature does not support intercompany master plan associations at this time. The issue will be addressed in a future release.
Retail	POS registers	This entity is global and cannot be copied to another legal entity.
Retail	Retail channel	This entity is global and cannot be copied to another legal entity.
Retail	Retail store address book	This entity has a dependency on Retail channel so it cannot be used.
Sales and marketing	Intercompany trading partnerships	The copy into legal entity feature does not support intercompany trading partnerships at this time. The issue will be addressed in a future release.

Rules

The Copy into legal entity feature supports rules, which let you modify data before it's added to the import staging table. For example, rules are used to change the target legal entity to the destination legal entity and modify number sequences. You can extend rules.

Rule extensions require three changes:

1. Add the name of the rule to the extensible **DMFRulesType** enumeration (enum).

2. For each project definition group, insert the enum that you just created (for example, **DMFRulesType::NewRule**) into the DMFRules table. Use your source legal entity, your rule type, and the definition group name. If you require that more data be stored, such as various options for your rule, you can create your own table and extend the DMFRules table.
3. Create your own class to handle the data that the rule acts on. For the DMFRules framework to instantiate the rule, you must decorate the class with the **[DMFRulesBaseFactoryAttribute(DMFRulesType::NewRule)]** attribute.

The class must also extend the **DMFRulesBase** class. This extension will require an implementation of the **DMFRulesBase.runRule(Common_staging)** method. The _staging record will be the buffer of the staging record that the rule is applied to.

Additional information about entities

Obsolete entities

As the application is updated, the functionality of an entity might have to be updated. A new entity might be created that has a different name. In this case, the original entity will be marked as obsolete. You will no longer be able to add obsolete entities to a new data project or template.

If you load a data package that contains an obsolete entity, you will receive a warning about the existence of obsolete entities. However, you will still be able to import your data. You can find the obsolete entity by selecting the **Obsolete** column and filtering on **Yes**.

Self-referencing entities

Some entities represent tables that have references to themselves. For example, when you create a cash discount, you can refer to a related cash discount that creates a tiered discount calculation. To import data, you must sequence the data so that the cash discount that is referred to in the **Next cash discount** field is imported before the cash discount that uses that cash discount.

A new **DMFImportExportSequencer** class sequences the data in self-referencing entities and enables the data to be loaded in a single pass. In the Cash Discount entity (CashDiscountEntity), you can view the code that is required in order to update entities.

The class has been added to several self-referencing entities. It will be added to more entities as required. Here are some other examples of self-referencing entities:

- Customers
- Customer definitions
- Customer details
- Tax codes
- Budget control groups
- Projects
- Product categories
- Warehouses
- Budget plan workflow stage
- Sales units

Adding entities in the appropriate country/region context

When you add entities, the mappings are created in the context of the country or region of the company that is currently active. If there are any issues with the mappings, a red *X* appears in the **View map** column. Select the red *X*, and repair the mappings as required.

NOTE

By default, the DAT company doesn't have a country/region context. Some entities, such as the entities that are used for transaction codes and 1099 fields, won't be mapped correctly if they are added to a data project for the DAT company, because a country/region context is expected.

Configuration data packages

2/18/2021 • 7 minutes to read • Edit Online

IMPORTANT

This topic applies only to the July 2017 release of Microsoft Dynamics 365 for Finance and Operations. If you are running a later release, refer to the topic Copy configuration data between companies or legal entities overview.

Configuration data packages are available as process data packages from Microsoft Dynamics Lifecycle Services (LCS). These data packages can help improve the repeatability of implementations and accelerate the configuration.

Data packages contain configuration entity spreadsheets. These entity spreadsheets contain best practice data that you can use to create an initial golden build. The data entities in the data packages are also sequenced appropriately to help guarantee a successful single-click import of the data.

The entity spreadsheets include three types of data:

- **Business data** – The spreadsheet contains standard business data for a mid-sized trade or retail company. This data combines best practices and business standards that can be used as a starting point for your configuration.
- **Sample data** – The spreadsheet contains data that can be used as an example for business-specific data. This data can be imported and used as an example, but it must be changed for individual business practices.
- **No data** – The spreadsheet doesn't contain any data. Several areas of the product are unique to each business and its business practices. These areas must be configured specifically for the organization. These spreadsheets should be reviewed and updated for the organization as appropriate.

For more information about the type of data that is included in each entity spreadsheet in the data packages see the Data packages section of this topic. You can modify individual spreadsheets before you import the data packages, or you can import the data packages as they have been supplied and then update your data in the system.

Using configuration data packages

You can access configuration data packages from LCS. You can either apply them to an LCS environment, or download them so that you can manually import them.

1. Open your LCS project, and open the Asset library.
2. In the list of asset types, select **Process data package**.
3. Click **Import**.
4. Select the configuration data package.
5. Click **Pick**.

At this point, you can use the **Consume** function to apply the process data package to an LCS environment.

You can also download the individual data package files from the **Data package** area. Use the **Data management** workspace to import the data packages from LCS. For more information about how to import and export configurations, see Copy configuration data between companies or legal entities overview.

Special considerations

System setup

The System data package must be imported before any other data package. By default, the System data package creates a new legal entity that is named **ST01**. The data packages for the module areas depend on this legal entity.

General ledger

A generic chart of accounts is included in the configuration data packages. When this data is used as it's defined in the Main account entity spreadsheet, posting profiles across the system are filled with default posting data. If you change the main accounts that are used for the chart of accounts, you must also update the individual posting profiles and posting accounts for each area.

Configuration data packages

2/18/2021 • 7 minutes to read • Edit Online

IMPORTANT

This topic applies only to the July 2017 release of Microsoft Dynamics 365 for Finance and Operations. If you are running a later release, refer to the topic Copy configuration data between companies or legal entities overview.

Configuration data packages are available as process data packages from Microsoft Dynamics Lifecycle Services (LCS). These data packages can help improve the repeatability of implementations and accelerate the configuration.

Data packages contain configuration entity spreadsheets. These entity spreadsheets contain best practice data that you can use to create an initial golden build. The data entities in the data packages are also sequenced appropriately to help guarantee a successful single-click import of the data.

The entity spreadsheets include three types of data:

- **Business data** – The spreadsheet contains standard business data for a mid-sized trade or retail company. This data combines best practices and business standards that can be used as a starting point for your configuration.
- **Sample data** – The spreadsheet contains data that can be used as an example for business-specific data. This data can be imported and used as an example, but it must be changed for individual business practices.
- **No data** – The spreadsheet doesn't contain any data. Several areas of the product are unique to each business and its business practices. These areas must be configured specifically for the organization. These spreadsheets should be reviewed and updated for the organization as appropriate.

For more information about the type of data that is included in each entity spreadsheet in the data packages see the Data packages section of this topic. You can modify individual spreadsheets before you import the data packages, or you can import the data packages as they have been supplied and then update your data in the system.

Using configuration data packages

You can access configuration data packages from LCS. You can either apply them to an LCS environment, or download them so that you can manually import them.

1. Open your LCS project, and open the Asset library.
2. In the list of asset types, select **Process data package**.
3. Click **Import**.
4. Select the configuration data package.
5. Click **Pick**.

At this point, you can use the **Consume** function to apply the process data package to an LCS environment.

You can also download the individual data package files from the **Data package** area. Use the **Data management** workspace to import the data packages from LCS. For more information about how to import and export configurations, see Copy configuration data between companies or legal entities overview.

Special considerations

System setup

The System data package must be imported before any other data package. By default, the System data package creates a new legal entity that is named **ST01**. The data packages for the module areas depend on this legal entity.

General ledger

A generic chart of accounts is included in the configuration data packages. When this data is used as it's defined in the Main account entity spreadsheet, posting profiles across the system are filled with default posting data. If you change the main accounts that are used for the chart of accounts, you must also update the individual posting profiles and posting accounts for each area.

Configuration data templates

2/18/2021 • 9 minutes to read • Edit Online

Configuration data templates are predefined lists of entities for each module area that can be used in a data project. You can create, view, and modify these templates by using the **Template** page in the **Data management** workspace.

> **IMPORTANT**
>
> Default configuration templates available out-of-the- box will always have the latest version of an entity. Templates can be created from an existing data project as needed.

Create a new configuration data template

The **Template** page in the **Data management** workspace provides tools that let you create a template of entities. This page resembles the configurations page, and the two features work in a similar manner. You must use **Enhanced view** to take advantage of the new features.

To create a template, follow these steps.

1. Select **New** to create a template. Enter an ID and name for the template. Notice that the status is set to **Draft**.
2. Add or remove entities as you require.
3. Organize the list by using the **Sort by** button to reorder your entities by entity group, or by unit, level, and sequence.
4. To change the sequence of any of the entities, manually edit the unit, level, or sequence. Alternatively, use the **Resequence** button to update any entities that you've selected. The **Resequence** button appears only if you select more than one entity.
5. To add filters to an entity, use the **Filter** button. Then review the results of the filters by using the **Preview** button. If you add a filter, the **Filter** button is changed to an **Edit** button.
6. If you don't want all fields to be mapped, you can use the **View map** button to exclude fields from the mapping.
7. Select **Validate template** to change the status to **Validated**.

Your template can now be used in a project. However, you might want to use some additional features to control the export process.

- Use the **Open in Excel** button to open the contents of the grid in a Microsoft Excel workbook. Modify the entities as you require, and then select **Publish** to upload the changes back.
- If you exported a template and want to bring that template back, select **Import template**, browse to the template file, and then select **Create template** to load it.
- To replace the contents of an open template, select **Replace from template**, browse to the template file that has the entities to import, and then select **Create template** to load the template file. The values in the open template will be overwritten.
- To create a template from a project, select **New** to create a template. Enter an ID and name for the template, and then select **Replace template from project**. In the list of projects that appears, select a project, and then select **Create template** to bring the project entities from that project into the open template. The values in the open template will be overwritten.

Default data templates

In July 2017 update, we released predefined templates to help you create configuration data projects. The templates are sequenced, so that the data that the entities generate will be processed in the correct order. Our predefined templates are also designed to maintain the correct sequence when more than one template is added to the same data project. For more information, see the "Sequencing in the default templates" section.

Default templates are delivered together with each new release. Our long-term goal is to provide the templates in Microsoft Dynamics Lifecycle Services (LCS), so that you can push them to an instance. However, for the current releases, select the **Templates** tile in the **Data management** workspace, and then select **Load default templates** to load the templates. To see the **Load default templates** menu, you must use **Enhanced view**.

After the templates are loaded, you can change them to suit your business requirements. If you ever want to retrieve the original default templates, you can use the **Load default templates** button to add them back to your system. The templates will then be replaced with the latest versions. If you've made changes to the templates, you can make a copy of the old templates by exporting them.

Note that system administrator access is required in order to load default templates and import templates. This requirement helps guarantee that all entities are correctly loaded into the template.

How entities are sequenced for processing

Whether you're creating your own templates or using the default templates, it's important that you understand how templates are sequenced for processing during export and import.

Units, levels, and sequences

The unit, level, and sequence of an entity are used to control the order that the data is exported or imported in.

- Entities that have different units are processed in parallel.
- In the same unit, entities are processed in parallel if they have the same level.
- In the same level, entities are processed according to their sequence order in the level.
- After one level has been processed, the next level is processed.
- We use only unit 1 to help guarantee that all dependencies are handled in the correct order.

Entities are categorized by module name, entity category, and tag.

- The module represents the module that the entity is typically used for.
- The entity category represents the type of information in the category. For example, a category might include parameters or reference data.
- Tags provide additional details about the function of the entity in the feature area. For example, entities for the general ledger have **General ledger** as their module name. There are several tasks within the general ledger, and the tags represent those tasks. For example, **Setup** and **Journals** are tags that represent tasks that can be done for the general ledger.

Sequencing in the default templates

Our long-term goal for sequencing is to automatically sequence all the entities for every configuration. Until we reach that goal, for the entities in each of our default templates, we have created sequences that represent the dependency order between entities.

The following table shows how the templates were set up to handle dependencies. Note that the entities do **not** have to be processed in the order that we have sequenced them in. You can sequence them differently. However, you might inadvertently change the order that entities are processed in. If an entity requires data that hasn't been imported by another entity, you might receive errors because of missing dependent data.

MODULE	UNIT	LEVEL
System setup	1	10
Global address book	1	15
General ledger shared	1	20
Workflow	1	22
General ledger	1	25
Band 1 for dependencies	1	30

> The Retail template is scheduled to be released in Finance and Operations, App update 3.

We reserved levels 10 through 22 for shared system entities, so that those entities are processed first. Almost all systems also use the company-specific general ledger entities. Therefore, we reserved level 25 for those entities. These levels represent the minimum basic setup that is required for most shared data in a configuration.

After the basic setup is completed, many entities can be loaded in parallel across all the modules. These entities don't have to be loaded in silos by module. Instead, we set up bands of dependencies between the data for different entities. We added the entities that have no dependencies to band 30. We then added band 40 for entities that have a dependency on the entities in band 30. We continued the process for bands 50 through 90.

After we organized the basic entities so that they can be processed in parallel, we organized the remaining entities by module, in the order that the modules should be processed in. However, many entities have many dependencies, some of which are complex. For example, the Vendor posting profiles entity might require Vendors or Items entities. Although the Vendor posting profiles entity is in the **Accounts payable** module, it must be processed after the **Product management** module. In that case, if Vendors entities are 1.130.10 and Items entities are 1.300.10, the Vendor posting profiles entity must be moved so that it's after that sequence (for example, 1.310.20).

The sequences that we have implemented are a guideline, not a requirement. There is no required relationship between a level and a module. You can rearrange the entities if the sequence doesn't work for your implementation. To add your own templates to a configuration, you can follow the preceding guidelines to help guarantee that your template is correctly merged into a project that uses default templates.

Templates that have the same entity

Some entities are required in more than one template. For example, you must have payment terms in both the Accounts Payable and Accounts Receivable templates. However, you might require only the Accounts Receivable template. We added the entity to both templates for situations where you require only one of them.

A data project can include only one instance of an entity. If you add a template, and the template contains an entity that already exists in a data project, the entity in that template replaces the entity that is currently in the project.

You can use this capability to override the default templates without changing them. For example, the **worker** field hasn't been mapped in your data project, but you have your own template that adds workers. In this case, you can build a template that includes the entities that have the **worker** field. In that template, you can map the **worker** field. Any entities in the data project that don't have the field mapped will then be replaced.

Merged templates

We have created larger templates that cover multiple module areas. You can use the larger templates or any combination of smaller templates to build a data project. The following combined templates are available:

- System and Shared, which include system setup, global address book, shared general ledger, and workflow
- Financials, which includes general ledger, bank, accounts payable, tax, accounts receivable, fixed assets, and budgeting
- Supply Chain Management, which includes inventory management, product management, procurement, sales and marketing, limited warehouse management, production control, and costing

The Expense and Project Management templates aren't included in a larger template. However, they are designed so that they can easily be merged into a project that uses other templates.

The Workers template includes the entities needed to add workers and re-map entities where the worker mapping was removed.

Master data

Many default templates include entities for master data such as customers, vendors, and released products. These entities are included to indicate the correct sequence of entities that you will require after you've loaded parameters and reference data. Master entities are most often sequenced in the module bands that are numbered 100 and above. In the grid, the entity category for these entities will be **Master**.

If you don't want to include master data in your configuration, remove those entities from your project.

Enable change tracking for entities

2/18/2021 • 2 minutes to read • Edit Online

Change tracking enables incremental export of data from Finance and Operations by using Data management. In an incremental export, only records that have changed are exported. To enable incremental export, you must enable change tracking on entities. If you don't enable change tracking on an entity, you can only enable a full export each time. Although, change tracking can be enabled for BYOD and non-BYOD scenarios, it must be noted that only for bring your own database (BYOD) use cases, change tracking also tracks deletes if the entity supports this. Deletion is tracked only for the root data source in the entity.

Enable change tracking for BYOD

You can enable change tracking when you publish one or more entities to a data store (BYOD).

1. In the **Data management** workspace, select **Configure entity export to database**.
2. Select the database to export data to, and then select **Publish**.

   You can publish one or more entities to your database. Select **Show published only** to see a list of entities that have previously been published.
3. Select an entity that is published, and then select **Change tracking**.
4. Select the appropriate option for change tracking for your environment.

   An entity can be modeled by using more than one table. The options let you specify the granularity at which changes can be tracked in an entity.

OPTION	HOW CHANGES ARE TRACKED
Enable primary table	Changes that are made to any fields in the primary table trigger a change in entity. Changes that are made to fields in secondary tables don't trigger a change in entity.
Enable entire entity	Changes that are made to any fields in any table in the entity trigger a change in entity.
Enable Custom query	Uses a custom query that identifies the tables on which changes must be tracked. The custom query is defined in the entity.

> **NOTE**
> If a change is triggered, the change is tracked on the entire record and not at the field level. The entire entity record is exported to the destination. Regardless of the option that you select, the number of fields in the entity is the number that is exported to the destination.

Enable change tracking for non-BYOD scenarios

For non-BYOD scenarios, change tracking can be enabled from the data entities list page in data management by selecting the entities and clicking **Change tracking**.

Custom query for change tracking

The following example shows how to add a static method to an entity. You must make sure that the method returns a query, and that the root node is the same as the entity. For example, for the Customer entity, the root node is custTable, and the change tracking query for it is also custtable.

- You must enable change tracking on the tables that are part of the query.
- Create a join between the entity and the change tracking query (on the root table) to determine which records have changed in the entity.

```
public static Query defaultCTQuery()
{
 Query q = new Query();

 QueryBuildDataSource custDs = q.addDataSource(tableNum(CustTable));

 QueryBuildDataSource partyDs = custDs.addDataSource(tableNum(DirPartyTable));
 partyDs.relations(true);

 QueryBuildDataSource locationDs = partyDs.addDataSource(tableNum(DirPartyLocation));
 locationDs.addRange(fieldNum(DirPartyLocation, IsPrimary)).value(queryValue(NoYes::Yes));
 locationDs.addLink(fieldNum(DirPartyTable, RecId), fieldNum(DirPartyLocation, Party));

 QueryBuildDataSource addressDs = locationDs.addDataSource(tableStr(LogisticsPostalAddress));
 addressDs.addLink(fieldNum(DirPartyLocation, Location), fieldNum(LogisticsPostalAddress, Location));

 return q;
}
```

Find information about standard data entities

2/18/2021 • 2 minutes to read • Edit Online

The application ships with many default data entities. Data entities are frequently updated, so for documentation, we rely on the data entity templates to indicate which order data entities should be imported in, and on reports for a list of data entities that ship with each release.

Configuration data packages

Configuration data packages on Microsoft Dynamics Lifecycle Services (LCS) contain configuration entity spreadsheets. Configuration entity spreadsheets contain best practice data that you can use to create an initial golden build of an implementation. The data entities in the data packages are also sequenced appropriately using an XML file to help guarantee a successful single-click import of the data. We recommend that you download and review the configuration data packages to understand how we recommend that you order your data imports. For more information, see Configuration data templates and Copy configuration data between companies or legal entities overview.

Reports

Microsoft provides the following reports for data entities, which can be downloaded from Technical reference reports:

- Aggregate data entities: Lists the aggregate data entities, and the fields that each contains.
- Aggregate measures: Lists the aggregate measures.
- Config keys: Lists the configuration keys.
- Config key groups: Lists the configuration key groups.
- Data entities: Lists each data entity. The report indicates the data source of the entity and the fields included in the entity. The report also indicates whether the data entity is public.
- Data entities fields: Lists each field in a data entity, and the table that it originates from.
- KPIs: Lists the KPIs.
- License codes: Lists the license code associated with each configuration key.
- Menu items: Lists the menu items associated with each configuration key.
- SSRS reports: Lists each report. The report indicates the data set used for each report, as well as the filters and fields available on each report.
- Tables: Lists each table and its table group.
- Workflow type: Lists each type of workflow. The report also describes what each type of workflow is used for and indicates whether the workflows of each type are associated with a specific company in the organization or with the whole organization.

Scripts

You can download the scripts to run these reports from fin-ops-doc-scripts.

The survey will take about seven minutes. No personal data is collected (privacy statement).

Data templates with multiple worksheets

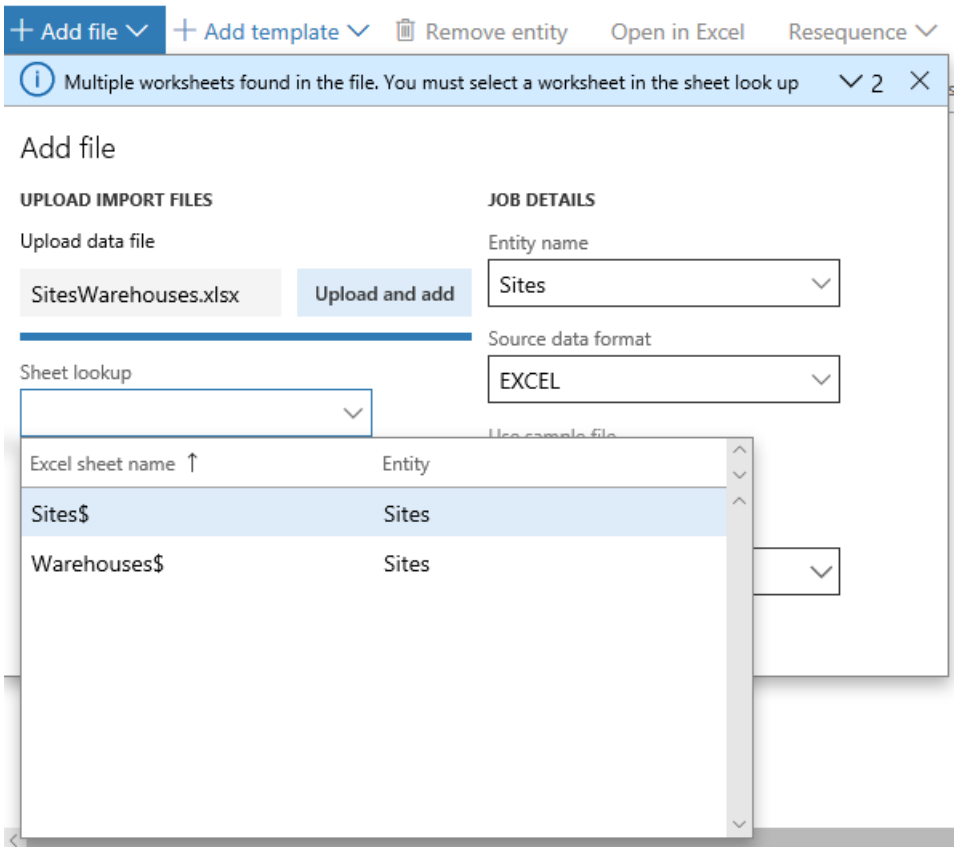
2/18/2021 • 2 minutes to read • Edit Online

Data management in the application supports Microsoft Excel-based templates for data entities. These templates can contain one or more worksheets. Templates with multiple worksheets are often used when it is convenient to manage data in a single file and import it to multiple data entities. An example would be sites and warehouses.

Upload a file once and map it to all entities

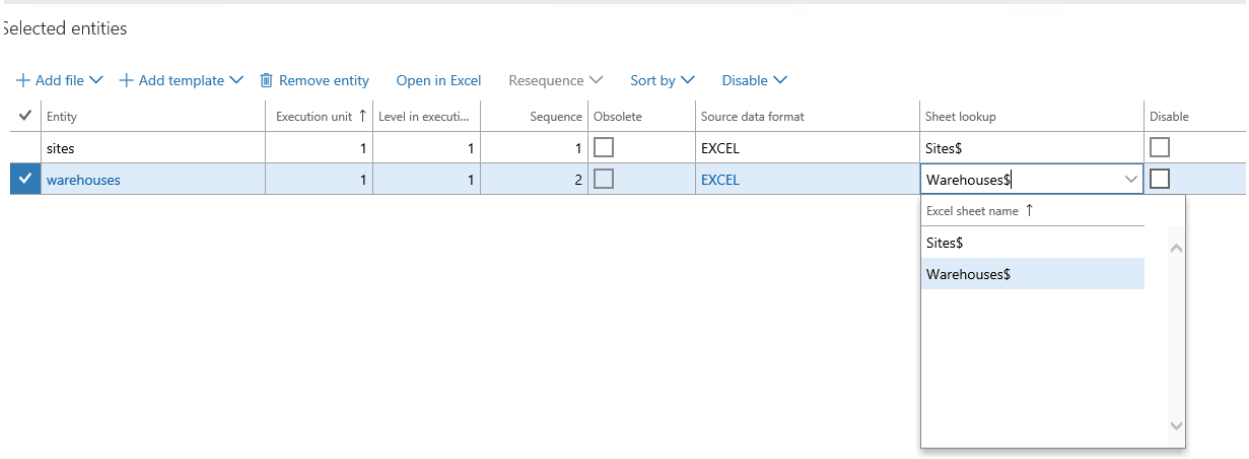
Let's take an example where there is one Excel file with worksheets called **Sites** and **Warehouses**. To set up the data import project, you would add the first data entity, **Sites** and then upload the file. You will be able to select **Sites** as the worksheet to be used for this entity.

If you add the second entity **Warehouses** without leaving the **Add file** form, the worksheet lookup will let you select the **Warehouses** worksheet without having to upload the file again. The only reason to upload a new file would be if the **Warehouses** data was in a different file.



Fix worksheet to entity mapping

The mapping of the worksheet to a data entity in the import job can be fixed from the grid. The **Worksheet** column in the grid shows the worksheets from the file that was mapped. You can choose a different worksheet from the drop-down menu. If the chosen worksheet is already mapped to an entity in the data project, the system asks you to confirm the change. We recommend that you fix all mappings in the grid.



Re-map to a new file

In cases where a new version of the same file or a completely new file must be uploaded for existing entities in a data project, you must use the **Add file** experience, and add the entities again as if they were being added for the first time. The system will confirm that you want to overwrite the existing entities in the data project before proceeding. Entities that are not added again (or overwritten) will continue to hold the previous mappings from the previous file.

Upload a file using Run project

You can upload an Excel file while using the **Run project** option to execute an import project. You must be careful to upload only files that have the same worksheets as the existing mappings on the data entities in the data project. If a worksheet is not found in the newly uploaded file, the system displays an error and will stop the import. If the mapping to the worksheet must be changed for an entity, then the mappings in the data project must be first updated from within the data project before using the file in the **Run project** experience.

Enable change tracking for entities

2/18/2021 • 2 minutes to read • Edit Online

Change tracking enables incremental export of data from Finance and Operations by using Data management. In an incremental export, only records that have changed are exported. To enable incremental export, you must enable change tracking on entities. If you don't enable change tracking on an entity, you can only enable a full export each time. Although, change tracking can be enabled for BYOD and non-BYOD scenarios, it must be noted that only for bring your own database (BYOD) use cases, change tracking also tracks deletes if the entity supports this. Deletion is tracked only for the root data source in the entity.

Enable change tracking for BYOD

You can enable change tracking when you publish one or more entities to a data store (BYOD).

1. In the **Data management** workspace, select **Configure entity export to database**.
2. Select the database to export data to, and then select **Publish**.

   You can publish one or more entities to your database. Select **Show published only** to see a list of entities that have previously been published.
3. Select an entity that is published, and then select **Change tracking**.
4. Select the appropriate option for change tracking for your environment.

   An entity can be modeled by using more than one table. The options let you specify the granularity at which changes can be tracked in an entity.

OPTION	HOW CHANGES ARE TRACKED
Enable primary table	Changes that are made to any fields in the primary table trigger a change in entity. Changes that are made to fields in secondary tables don't trigger a change in entity.
Enable entire entity	Changes that are made to any fields in any table in the entity trigger a change in entity.
Enable Custom query	Uses a custom query that identifies the tables on which changes must be tracked. The custom query is defined in the entity.

> **NOTE**
> If a change is triggered, the change is tracked on the entire record and not at the field level. The entire entity record is exported to the destination. Regardless of the option that you select, the number of fields in the entity is the number that is exported to the destination.

Enable change tracking for non-BYOD scenarios

For non-BYOD scenarios, change tracking can be enabled from the data entities list page in data management by selecting the entities and clicking **Change tracking**.

Custom query for change tracking

The following example shows how to add a static method to an entity. You must make sure that the method returns a query, and that the root node is the same as the entity. For example, for the Customer entity, the root node is custTable, and the change tracking query for it is also custtable.

- You must enable change tracking on the tables that are part of the query.
- Create a join between the entity and the change tracking query (on the root table) to determine which records have changed in the entity.

```
public static Query defaultCTQuery()
{
 Query q = new Query();

 QueryBuildDataSource custDs = q.addDataSource(tableNum(CustTable));

 QueryBuildDataSource partyDs = custDs.addDataSource(tableNum(DirPartyTable));
 partyDs.relations(true);

 QueryBuildDataSource locationDs = partyDs.addDataSource(tableNum(DirPartyLocation));
 locationDs.addRange(fieldNum(DirPartyLocation, IsPrimary)).value(queryValue(NoYes::Yes));
 locationDs.addLink(fieldNum(DirPartyTable, RecId), fieldNum(DirPartyLocation, Party));

 QueryBuildDataSource addressDs = locationDs.addDataSource(tableStr(LogisticsPostalAddress));
 addressDs.addLink(fieldNum(DirPartyLocation, Location), fieldNum(LogisticsPostalAddress, Location));

 return q;
}
```

Configuration keys and data entities

2/18/2021 • 5 minutes to read • Edit Online

Before you use data entities to import or export data, we recommended that you first determine the impact of configuration keys on the data entities that you are planning to use.

To learn more about configuration keys, see the License codes and configuration keys report.

Configuration key assignments

Configuration keys can be assigned to one or all of the following artifacts.

- Data entities
- Tables used as data sources
- Table fields
- Data entity fields

The following table summarizes how configuration key values on the different artifacts that underlie an object change the expected behavior of the object.

CONFIGURATION KEY SETTING ON DATA ENTITY	CONFIGURATION KEY SETTING ON TABLE	CONFIGURATION KEY SETTING ON TABLE FIELD	CONFIGURATION KEY ON DATA ENTITY FIELD	EXPECTED BEHAVIOR
Disabled	Not evaluated	Not evaluated	Not evaluated	If the configuration key for the data entity is disabled, the data entity will not be functional. It does not matter whether the configuration keys in the underlying tables and fields are enabled or disabled.

CONFIGURATION KEY SETTING ON DATA ENTITY	CONFIGURATION KEY SETTING ON TABLE	CONFIGURATION KEY SETTING ON TABLE FIELD	CONFIGURATION KEY ON DATA ENTITY FIELD	EXPECTED BEHAVIOR
Enabled	Disabled	Not evaluated	Not evaluated	If the configuration key for a data entity is enabled, the data management framework checks the configuration key on each of the underlying tables. If the configuration key for a table is disabled, that table will not be available in the data entity for functional use. If a table's configuration key is disabled, the table and data entity configuration key settings are not evaluated. If the primary table in the entity has its configuration key disabled, then the system will act as though the entity's configuration key were disabled.
Enabled	Enabled	Disabled	Not evaluated	If the configuration key for a data entity is enabled, and the underlying tables configuration keys are enabled, the data management framework will check the configuration key on of the fields in the tables. If the configuration key for a field is disabled, that field will not be available in the data entity for functional use even if the corresponding data entity field has the configuration key enabled.

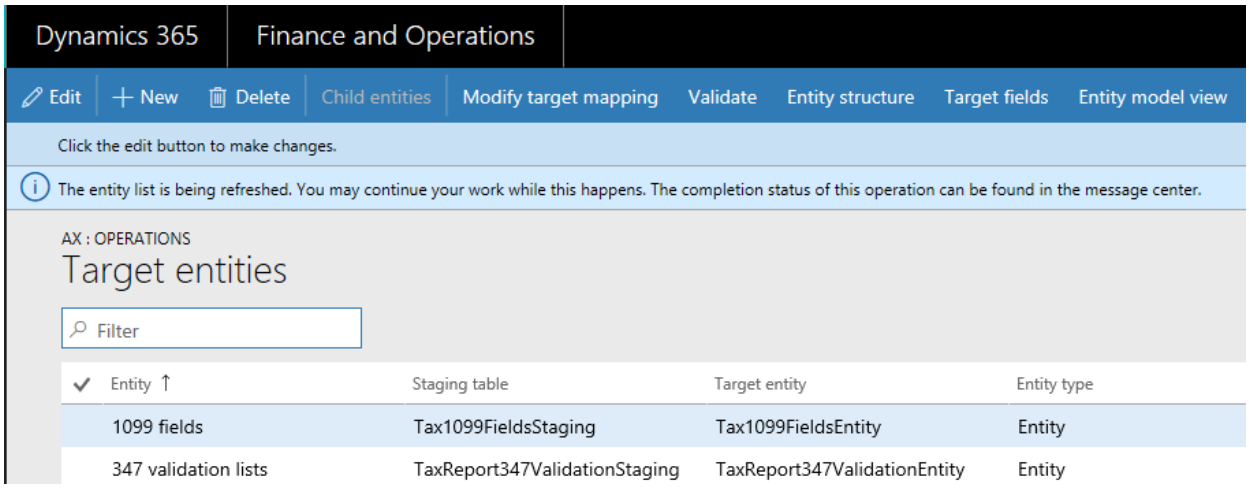
CONFIGURATION KEY SETTING ON DATA ENTITY	CONFIGURATION KEY SETTING ON TABLE	CONFIGURATION KEY SETTING ON TABLE FIELD	CONFIGURATION KEY ON DATA ENTITY FIELD	EXPECTED BEHAVIOR
Enabled	Enabled	Enabled	Disabled	If the configuration key is enabled at all other levels, but the entity field configuration key is not enabled, then the field will not be available for use in the data entity.

NOTE

If an entity has another entity as a data source then, the above semantics are applied in a recursive manner.

Entity list refresh

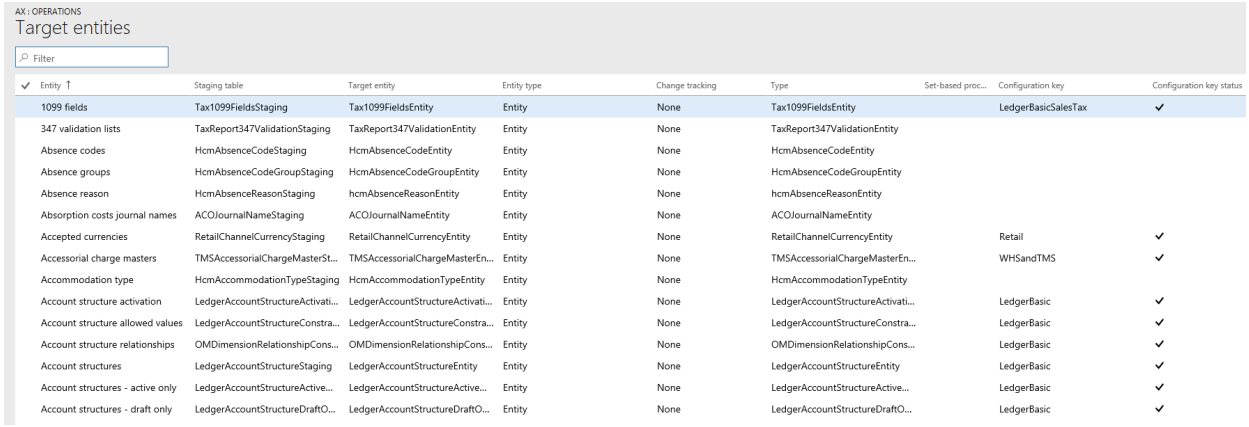
When the entity list is refreshed, the data management framework builds the configuration key metadata for runtime use. This metadata is built using the logic described above. We strongly recommend that you wait for the entity list refresh to complete before using jobs and entities in the data management framework. If you don't wait, the configuration key metadata may not be up to date and could result in unexpected outcomes. When the entity list is being refreshed, the following message is shown in the entity list page.



Data entity list page

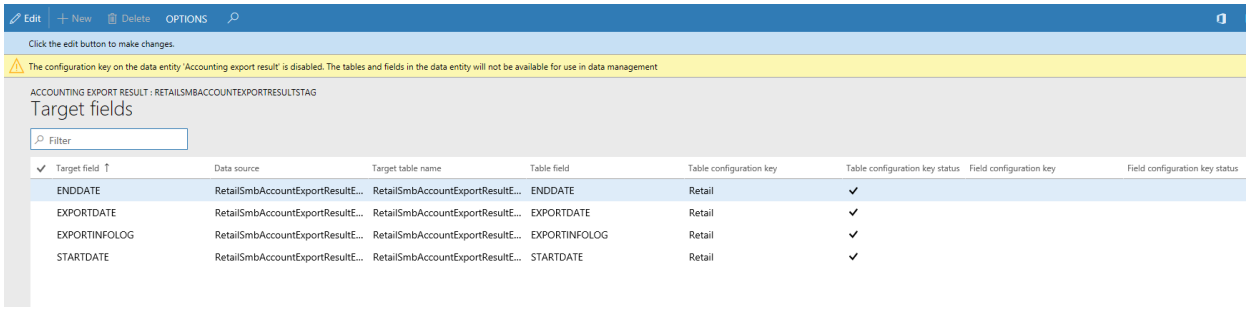
The data entity list page in the Data management workspace shows the configuration key settings for the entities. Start from this page to understand the impact from configuration keys on the data entity.

This information is shown using the metadata that is built during entity refresh. The configuration key column shows the name of the configuration key that is associated with the data entity. If this column is blank it means that there is no configuration key associated with the data entity. The configuration key status column shows the state of the configuration key. If it has a checkmark, it means the key is enabled. If it is blank, it means either the key is disabled or there is no key associated.



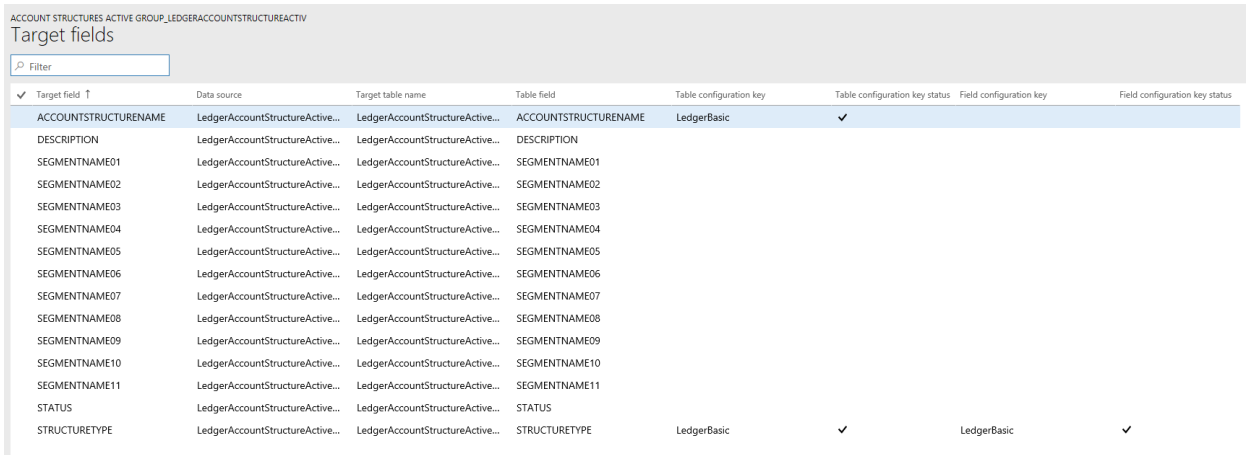
Target fields

The next step is to drill into the data entity to view the impact of configuration keys on tables and fields. The target fields form for a data entity shows configuration key and the key status information for the related tables and fields in the data entity. If the data entity itself has its configuration key disabled, a warning message is shown informing that the tables and fields in the target fields form for this entity will not be available at all regardless of their configuration key status.



Child entities

Certain entities have other entities as data sources, or are composite data entities: configuration key information for these entities is shown in the Child entities form. Use this form in the similar way to the entities list page described above. The target fields form for the child entity also behaves like what is described above.



Using data entities

After understanding the full impact, if any, of configuration keys on the data entities that you would like to use, you can now proceed to using the data entities by adding them to data projects.

Run time validations for configuration keys

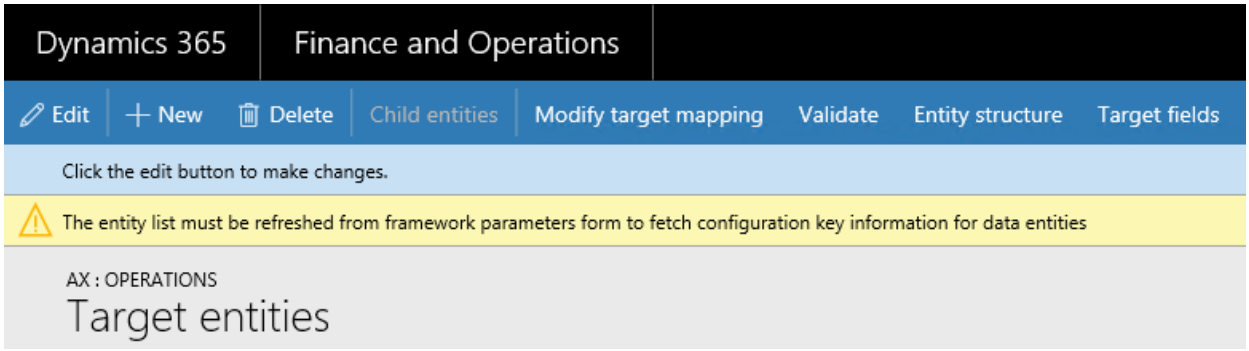
Using the configuration key metadata built during entity refresh list, run time validations are performed in the following use cases.

- When a data entity is added to a job

- When user clicks 'validate' on the entity list
- When the user loads a data package into a data project
- When the user loads a template into a data project
- When an existing data project is loaded
- When a template is loaded into a data project
- Before the export/import job is executed (batch, non-batch, recurring, OData)
- When the user generates mapping
- When the user maps fields in the mapping UI
- When the user adds only 'importable fields'

Managing configuration key changes

Anytime that you update configuration keys at the entity, table or field level, the entity list in the data management framework must be refreshed. This process ensures that the framework picks up the latest configuration key settings. Until the entity list is refreshed, the following warning will be shown in the entity list page. The updated configuration key changes will take effect immediately after the entity list is refreshed. We recommend that you validate existing data projects and jobs to make sure that they function as expected after the configuration keys changes are put in effect.



Configuration data packages

2/18/2021 • 7 minutes to read • Edit Online

IMPORTANT

This topic applies only to the July 2017 release of Microsoft Dynamics 365 for Finance and Operations. If you are running a later release, refer to the topic Copy configuration data between companies or legal entities overview.

Configuration data packages are available as process data packages from Microsoft Dynamics Lifecycle Services (LCS). These data packages can help improve the repeatability of implementations and accelerate the configuration.

Data packages contain configuration entity spreadsheets. These entity spreadsheets contain best practice data that you can use to create an initial golden build. The data entities in the data packages are also sequenced appropriately to help guarantee a successful single-click import of the data.

The entity spreadsheets include three types of data:

- **Business data** – The spreadsheet contains standard business data for a mid-sized trade or retail company. This data combines best practices and business standards that can be used as a starting point for your configuration.
- **Sample data** – The spreadsheet contains data that can be used as an example for business-specific data. This data can be imported and used as an example, but it must be changed for individual business practices.
- **No data** – The spreadsheet doesn't contain any data. Several areas of the product are unique to each business and its business practices. These areas must be configured specifically for the organization. These spreadsheets should be reviewed and updated for the organization as appropriate.

For more information about the type of data that is included in each entity spreadsheet in the data packages see the Data packages section of this topic. You can modify individual spreadsheets before you import the data packages, or you can import the data packages as they have been supplied and then update your data in the system.

Using configuration data packages

You can access configuration data packages from LCS. You can either apply them to an LCS environment, or download them so that you can manually import them.

1. Open your LCS project, and open the Asset library.
2. In the list of asset types, select **Process data package**.
3. Click **Import**.
4. Select the configuration data package.
5. Click **Pick**.

At this point, you can use the **Consume** function to apply the process data package to an LCS environment.

You can also download the individual data package files from the **Data package** area. Use the **Data management** workspace to import the data packages from LCS. For more information about how to import and export configurations, see Copy configuration data between companies or legal entities overview.

Special considerations

System setup

The System data package must be imported before any other data package. By default, the System data package creates a new legal entity that is named **ST01**. The data packages for the module areas depend on this legal entity.

General ledger

A generic chart of accounts is included in the configuration data packages. When this data is used as it's defined in the Main account entity spreadsheet, posting profiles across the system are filled with default posting data. If you change the main accounts that are used for the chart of accounts, you must also update the individual posting profiles and posting accounts for each area.

The survey will take about seven minutes. No personal data is collected (privacy statement).

Data import and export jobs overview

2/18/2021 • 16 minutes to read • Edit Online

To create and manage data import and export jobs, you use the **Data management** workspace. By default, the data import and export process creates a staging table for each entity in the target database. Staging tables let you verify, clean up, or convert data before you move it.

> **NOTE**
> This topic assumes that you are familiar with data entities.

Data import/export process

Here are the steps to import or export data.

1. Create an import or export job where you complete the following tasks:
   - Define the project category.
   - Identify the entities to import or export.
   - Set the data format for the job.
   - Sequence the entities, so that they are processed in logical groups and in an order that makes sense.
   - Determine whether to use staging tables.
2. Validate that the source data and target data are mapped correctly.
3. Verify the security for your import or export job.
4. Run the import or export job.
5. Validate that the job ran as expected by reviewing the job history.
6. Clean up the staging tables.

The remaining sections of this topic provide more details about each step of the process.

> **NOTE**
> In order to refresh the Data import/export form to see the latest progress, use the form refresh icon. Browser level refresh is not recommended because it will interrupt any import/export jobs that are not run in batch.

Create an import or export job

A data import or export job can be run one time or many times.

Define the project category

We recommend that you take the time to select an appropriate project category for your import or export job. Project categories can help you manage related jobs.

Identify the entities to import or export

You can add specific entities to an import or export job or select a template to apply. Templates fill a job with a list of entities. The **Apply template** option is available after you give the job a name and save the job.

Set the data format for the job

When you select an entity, you must select the format of the data that will be exported or imported. You define formats by using the **Data sources setup** tile. A source data format is a combination of **Type**, **File format**, **Row delimiter** and **Column delimiter**. There are also other attributes, but these are the key ones to understand. The following table lists the valid combinations.

FILE FORMAT	ROW/COLUMN DELIMITER	XML STYLE
Excel	Excel	-NA-
XML	-NA-	XML-Element XML-Attribute
Delimited, fixed width	Comma, semicolon, tab, vertical bar, colon	-NA-

Sequence the entities

Entities can be sequenced in a data template, or in import and export jobs. When you run a job that contains more than one data entity, you must make sure that the data entities are correctly sequenced. You sequence entities primarily so that you can address any functional dependencies among entities. If entities don't have any functional dependencies, they can be scheduled for parallel import or export.

Execution units, levels, and sequences

The execution unit, level in the execution unit, and sequence of an entity help control the order that the data is exported or imported in.

- Entities in different execution units are processed in parallel.
- In each execution unit, entities are processed in parallel if they have the same level.
- In each level, entities are processed according to their sequence number in that level.
- After one level has been processed, the next level is processed.

Resequencing

You might want to resequence your entities in the following situations:

- If only one data job is used for all your changes, you can use resequencing options to optimize the execution time for the full job. In these cases, you can use the execution unit to represent the module, the level to represent the feature area in the module, and the sequence to represent the entity. By using this approach, you can work across modules in parallel, but you can still work in sequence in a module. To help guarantee that parallel operations succeed, you must consider all dependencies.
- If multiple data jobs are used (for example, one job for each module), you can use sequencing to affect the level and sequence of entities for optimal execution.
- If there are no dependencies at all, you can sequence entities at different execution units for maximum optimization.

The **Resequencing** menu is available when multiple entities are selected. You can resequence based on execution unit, level, or sequence options. You can set an increment to resequence the entities that have been selected. The unit, level, and/or sequence number that is selected for each entity is updated by the specified increment.

Sorting

Use can use the **Sort by** option to view the entity list in sequential order.

Truncating

For import projects, you can choose to truncate records in the entities prior to import. This is useful if your records must be imported into a clean set of tables. This setting is off by default.

Validate that the source data and target data are mapped correctly

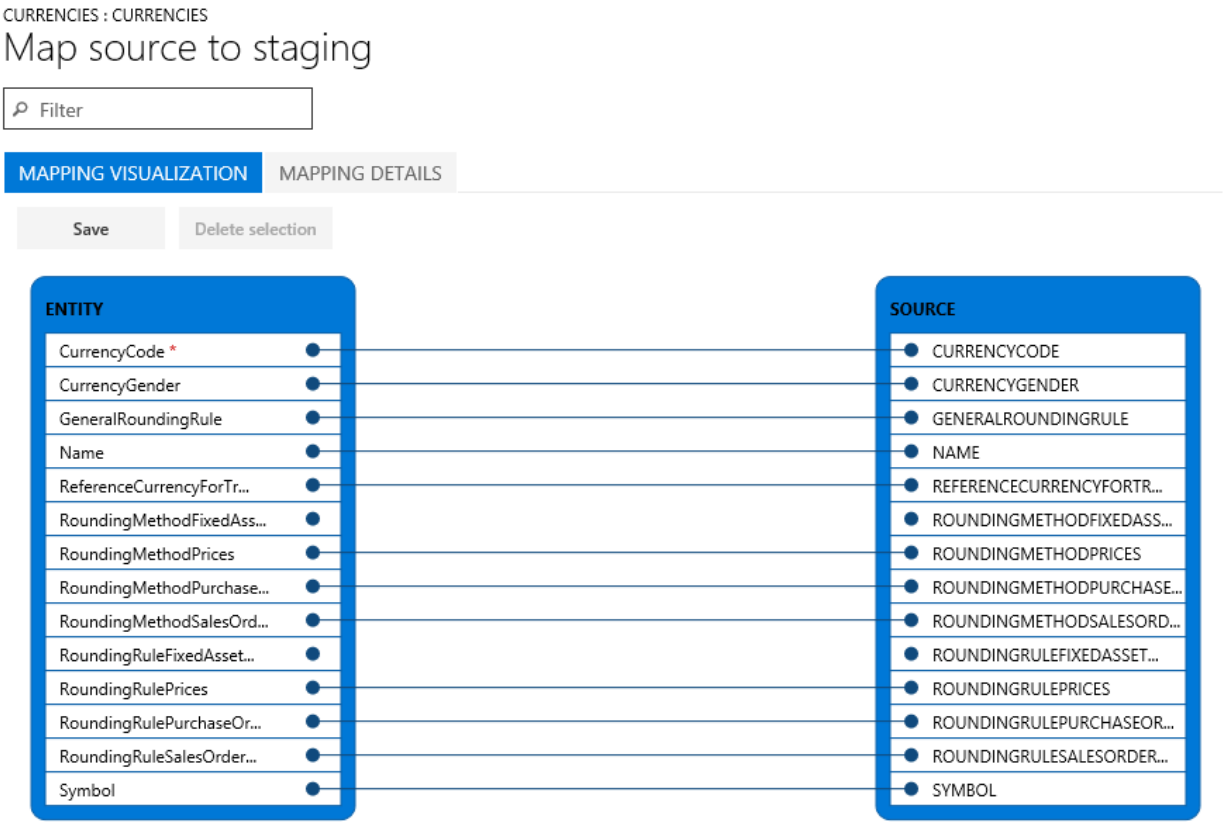
Mapping is a function that applies to both import and export jobs.

- In the context of an import job, mapping describes which columns in the source file become the columns in the staging table. Therefore, the system can determine which column data in the source file must be copied into which column of the staging table.
- In the context of an export job, mapping describes which columns of the staging table (that is, the source) become the columns in the target file.

If the column names in the staging table and the file match, the system automatically establishes the mapping, based on the names. However, if the names differ, columns aren't mapped automatically. In these cases, you must complete the mapping by selecting the **View map** option on the entity in the data job.

There are two mapping views: **Mapping visualization**, which is the default view, and **Mapping details**. A red asterisk (*) identifies any required fields in the entity. These fields must be mapped before you can work with the entity. You can unmap other fields as you require when you work with the entity. To unmap a field, select the field in either the **Entity** column or the **Source** column, and then select **Delete selection**. Select **Save** to save your changes, and then close the page to return to the project. You can use the same process to edit the field mapping from source to staging after you import.

You can generate a mapping on the page by selecting **Generate source mapping**. A generated mapping behaves like an automatic mapping. Therefore, you must manually map any unmapped fields.



Verify the security for your import or export job

Access to the **Data management** workspace can be restricted, so that non-administrator users can access only specific data jobs. Access to a data job implies full access to the execution history of that job and access to the staging tables. Therefore, you must make sure that appropriate access controls are in place when you create a data job.

Secure a job by roles and users

Use the **Applicable roles** menu to restrict the job to one or more security roles. Only users in those roles will have access to the job.

You can also restrict a job to specific users. When you secure a job by users instead of roles, there is more control if multiple users are assigned to a role.

Secure a job by legal entity

Data jobs are global in nature. Therefore, if a data job was created and used in a legal entity, the job will be visible in other legal entities in the system. This default behavior might be preferred in some application scenarios. For example, an organization that imports invoices by using data entities might provide a centralized invoice processing team that is responsible for managing invoice errors for all divisions in the organization. In this scenario, it's useful for the centralized invoice processing team to have access to invoice import jobs from all legal entities. Therefore, the default behavior meets the requirement from a legal entity perspective.

However, an organization might want to have invoice processing teams per legal entity. In this case, a team in a legal entity should have access only to the invoice import job in its own legal entity. To meet this requirement, you can configure legal entity–based access control on the data jobs by using the **Applicable legal entities** menu inside the data job. After the configuration is done, users can see only jobs that are available in the legal entity that they are currently signed in to. To see jobs from another legal entity, users must switch to that legal entity.

A job can be secured by roles, users, and legal entity at the same time.

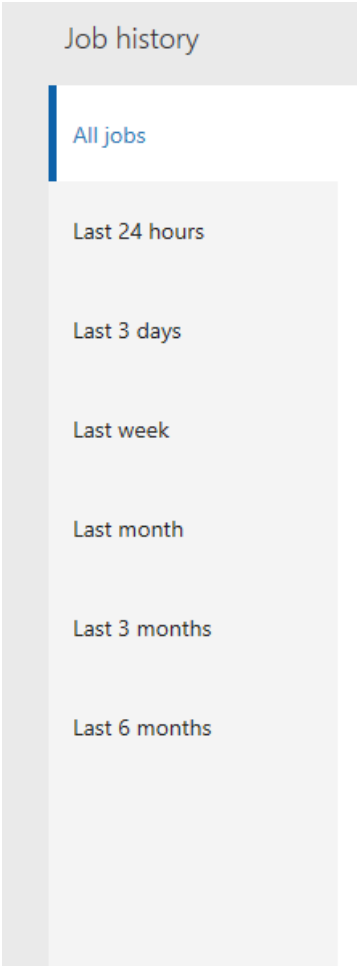
Run the import or export job

You can run a job one time by selecting the **Import** or **Export** button after you define the job. To set up a recurring job, select **Create recurring data job**.

> **NOTE**
>
> An import or an export job can be run by selecting the **Import** or **Export** button. This will schedule a batch job to run only once. The job may not execute immediately if batch service is throttling due to the load on the batch service. The jobs can also be run synchronously by selecting **Import now** or **Export now**. This starts the job immediately and is useful if the batch does not start due to throttling. The jobs can also be scheduled to execute at a later time. This can be done by choosing the **Run in batch** option. Batch resources are subject to throttling, so the batch job might not start immediately. Using a batch is the recommended option because it will also help with large volumes of data that need to be imported or exported. Batch jobs can be scheduled to run on a specific batch group, which allows more control from a load balancing perspective.

Validate that the job ran as expected

The job history is available for troubleshooting and investigation on both import and export jobs. Historical job runs are organized by time ranges.



Each job run provides the following details:

- Execution details
- Execution log

Execution details show the state of each data entity that the job processed. Therefore, you can quickly find the following information:

- Which entities were processed.
- For an entity, how many records were successfully processed, and how many failed.
- The staging records for each entity.

You can download the staging data in a file for export jobs, or you can download it as a package for import and export jobs.

From the execution details, you can also open the execution log.

Parallel imports

To speed up the import of data, parallel processing of importing a file can be enabled if the entity supports parallel imports. To configure the parallel import for an entity, the following steps must be followed.

1. Go to **System administration** > **Workspaces** > **Data management**.
2. In the **Import / Export** section, select the **Framework parameters** tile to open the **Data import/export framework parameters** page.
3. On the **Entity settings** tab, select **Configure entity execution parameters** to open the **Entity import execution parameters** page.
4. Set the following fields to configure parallel import for an entity:

- In the **Entity** field, select the entity.
- In the **Import threshold record count** field, enter the threshold record count for import. This determines the record count to be processed by a thread. If a file has 10K records, a record count of 2500 with a task count of 4 will mean, each thread will process 2500 records.
- In the **Import task count** field, enter the count of import tasks. This must not exceed the max batch threads allocated for batch processing in **System administration > Server configuration**.

Clean up the staging tables

Starting in Platform update 29, this functionality has been deprecated. This is replaced by a new version of job history clean-up functionality explained below.

You can clean up staging tables by using the **Staging clean up** feature in the **Data management** workspace. You can use the following options to select which records should be deleted from which staging table:

- **Entity** – If only an entity is provided, all records from that entity's staging table are deleted. Select this option to clean up all the data for the entity across all data projects and all jobs.
- **Job ID** – If only a job ID is provided, all records for all entities in the selected job are deleted from the appropriate staging tables.
- **Data projects** – If only a data project is selected, all records for all entities and across all jobs for the selected data project are deleted.

You can also combine the options to further restrict the record set that is deleted.

Job history clean up (available in Platform update 29 and later)

The job history clean-up functionality in data management must be used to schedule a periodic cleanup of the execution history. This functionality replaces the previous staging table clean-up functionality, which is now deprecated. The following tables will be cleaned up by the clean-up process.

- All staging tables
- DMFSTAGINGVALIDATIONLOG
- DMFSTAGINGEXECUTIONERRORS
- DMFSTAGINGLOGDETAIL
- DMFSTAGINGLOG
- DMFDEFINITIONGROUPEXECUTIONHISTORY
- DMFEXECUTION
- DMFDEFINITIONGROUPEXECUTION

The **Execution history cleanup** feature must be enabled in feature management and then can be accessed from **Data management > Job history cleanup**.

Scheduling parameters

When scheduling the clean-up process, the following parameters must be specified to define the clean-up criteria.

- **Number of days to retain history** – This setting is used to control the amount of execution history to be preserved. This is specified in number of days. When the clean-up job is scheduled as a recurring batch job, this setting will act like a continuously moving window thereby, always leaving the history for the specified number of days intact while deleting the rest. The default is 7 days.

- **Number of hours to execute the job** – Depending on the amount of history to be cleaned up, the total execution time for the clean-up job can vary from a few minutes to a few hours. This parameter must be set to the number of hours that the job will execute. After the clean-up job has executed for the specified number of hours, the job will exit and will resume the clean up the next time it is run based on the recurrence schedule.

  A maximum execution time can be specified by setting a max limit on the number of hours the job must run using this setting. The clean-up logic goes through one job execution ID at a time in a chronologically arranged sequence, with oldest being first for the cleanup of related execution history. It will stop picking up new execution ID's for cleanup when the remaining execution duration is within the last 10% of the specified duration. In some cases, it will be expected that the clean-up job will continue beyond the specified max time. This will largely depend on the number of records to be deleted for the current execution ID that was started before the 10% threshold was reached. The cleanup that was started must be completed to ensure data integrity, which means that cleanup will continue despite exceeding the specified limit. When this is complete, new execution ID's are not picked up and the clean-up job completes. The remaining execution history that was not cleaned up due to lack of enough execution time, will be picked up the next time the clean-up job is scheduled. The default and minimum value for this setting is set to 2 hours.

- **Recurring batch** – The clean-up job can be run as a one-time, manual execution, or it can be also scheduled for recurring execution in batch. The batch can be scheduled using the **Run in background** settings, which is the standard batch set up.

> **NOTE**
> If records in the staging tables are not cleaned up completely, ensure that the cleanup job is scheduled to run in recurrence. As explained above, in any clean up execution the job will only clean up as many execution ID's as is possible within the provided maximum hours. In order to continue cleanup of any remaining staging records, the job must be scheduled to run periodically.

Job history clean up and archival (available for preview in Platform update 39 or version 10.0.15)

The job history clean up and archival functionality replaces the previous versions of the clean up functionality. This section will explain these new capabilities.

One of the main changes to the clean up functionality is the use of system batch job for cleaning up the history. The use of system batch job allows Finance and Operations apps to have the clean up batch job automatically scheduled and running as soon as the system is ready. It is no longer required to schedule the batch job manually. In this default execution mode, the batch job will execute every hour starting at 12 midnight and will retain the execution history for the most recent 7 days. The purged history is archived for future retrieval.

> **NOTE**
> Because this functionality is in preview, the system batch job will not delete any execution history until it is enabled via the flight DMFEnableExecutionHistoryCleanupSystemJob. When the feature is generally available in a future release, this flight will not be required and the system batch job will start to purge and archive after the system is ready, based on the defined schedule as explained above.

> **NOTE**
> In a future release, the previous versions of the clean up functionality will be removed from Finance and Operations apps.

The second change in the clean up process is the archival of the purged execution history. The clean up job will archive the deleted records to the blob storage that DIXF uses for regular integrations. The archived file will be in the DIXF package format and will be available for 7 days in the blob during which time it can be downloaded. The default longevity of 7 days for the archived file can be changed to a maximum of 90 days in the parameters.

Changing the default settings

This functionality is currently in preview and must be explicitly turned on by enabling the flight DMFEnableExecutionHistoryCleanupSystemJob. The staging clean up feature must also be turned on in feature management.

To change the default setting for the longevity of the archived file, go to the data management workspace and select **Job history cleanup**. Set **Days to retain package in blob** to a value between 7 and 90 (inclusive). This will take effect on the archives that are created after this change was made.

Downloading the archived package

This functionality is currently in preview and must be explicitly turned on by enabling the flight DMFEnableExecutionHistoryCleanupSystemJob. The staging clean up feature must also be turned on in feature management.

To download the archived execution history, go to the data management workspace and select **Job history cleanup**. Select **Package backup history** to open the history form. This form shows the list of all archived packages. An archive can be selected and downloaded by selecting **Download package**. The downloaded package will be in the DIXF package format and contain the following files:

- The entity staging table file
- DMFDEFINITIONGROUPEXECUTION
- DMFDEFINITIONGROUPEXECUTIONHISTORY
- DMFEXECUTION
- DMFSTAGINGEXECUTIONERRORS
- DMFSTAGINGLOG
- DMFSTAGINGLOGDETAILS
- DMFSTAGINGVALIDATIONLOG

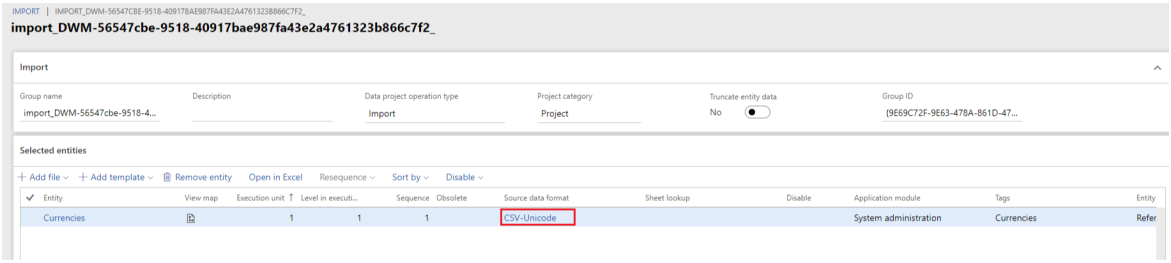
Synchronize date and time in import jobs

2/18/2021 • 2 minutes to read • Edit Online

It's important to set the time zone for your import job to Coordinated Universal Time (UTC). You might see unexpected dates and times in your imported data if you use a different setting. Without the correct setting, the import process converts the UTC date to the local format, and then system settings converts it again.

This dual conversion causes dates to change between applications. For example, the dual conversion could cause an employee's start date to be different between Dynamics 365 Human Resources and Dynamics 365 Finance due to differences in local time zones. Setting the import job to UTC resolves this problem.

1. In Dynamics 365 Finance and Operations, select **Data management**.
2. Select **Import projects**, and then select the project.
3. Under **Source date format**, select **CSV-Unicode**.



4. Change **Timezone** to **Coordinated Universal Timezone**, and change **Language** to **En-US**.

NOTE

Can you tell us about your documentation language preferences? Take a short survey.

The survey will take about seven minutes. No personal data is collected (privacy statement).

Importing vouchers by using the General journal entity

2/18/2021 • 5 minutes to read • Edit Online

This topic provides tips for importing data into the General journal by using the General journal entity.

You can use the General journal entity to import vouchers that have an account or offset account type of **Ledger**, **Customer**, **Vendor**, or **Bank**. The voucher can be entered as one line, using both the **Account** field and the **Offset account** field, or as a multi-line voucher, where only the **Account** field is used (and the **Offset account** is left blank on each line). The General journal entity doesn't support every account type. Instead, other entities exist for scenarios where different combinations of account types are required. For example, to import a project transaction, use the Project expense journal entity. Each entity is designed to support specific scenarios. This means additional fields may be available in entities for those scenarios. However, additional fields might not be available in entities for different scenarios.

Setup

Before you import by using the General journal entity, validate the following setup:

- **Number sequence setup for the journal batch number** – By default, when you import by using the General journal entity, the journal batch number uses the number sequence that is defined in the General ledger parameters. If you set the number sequence for the journal batch number to **Manual**, a default number isn't applied. This setup isn't supported.
- **Financial dimension configuration** – Every organization must define the order of financial dimensions when entities are used to import transactions. The order is defined for the **Ledger dimensions integration** format, at **General ledger** > **Chart of accounts** > **Dimensions** > **Financial dimension configuration for integrating applications** > **Select data entities**. The segments of the ledger account that is imported must have the same order. Otherwise, an error will occur during import.

General journal entity setup

Two settings in Data management affect how the default journal batch number or voucher number is applied:

- **Set-based processing** (on the data entity)
- **Auto-generated** (on the field mapping)

The following sections describe the effect of these settings. They also explain how the system generates batch numbers for journals and voucher numbers.

Journal batch number

- The **Set-based processing** setting on the General journal entity doesn't affect the way that journal batch numbers are generated.
- If the **Journal batch number** field is set to **Auto-generated**, a new journal batch number is created for every line that is imported. This behavior isn't recommended. The **Auto-generated** setting is found on the import project, under **View map**, on the **Mapping details** tab.
- If the **Journal batch number** field isn't set to **Auto-generated**, the journal batch number is created as follows:
    - If the journal batch number that is defined in the imported file matches an existing, unposted daily

journal, all lines that have a matching journal batch number are imported into the existing journal. Lines are never imported into a posted journal batch number. Instead, a new number is created.

- If the journal batch number that is defined in the imported file doesn't match an existing, unposted daily journal, all lines that have the same journal batch number are grouped under a new journal. For example, all lines that have a journal batch number of 1 are imported into a new journal, and all lines that have a journal batch number of 2 are imported into a second new journal. The journal batch number is created by using the number sequence that is defined in the General ledger parameters.

Voucher number

- When you use the **Set-based processing** setting on the General journal entity, the voucher number must be provided in the imported file. Every transaction in the General journal is assigned the voucher number that is provided in the imported file, even if the voucher isn't balanced. Note the following points if you want to use set-based processing, but you also want to use the number sequence that is defined for voucher numbers.
  - To enable this functionality, on the journal name that is used for imports, set **Number allocation at posting** to **Yes**.
  - A voucher number must still be defined in the imported file. However, this number is temporary and will be overwritten by the voucher number when the journal is posted. Be sure that the lines of the journal are grouped correctly by temporary voucher number. For example, during posting, three lines are found that have a temporary voucher number of 1. The temporary voucher number of all three lines is overwritten by the next number in the number sequence. If those three lines aren't a balanced entry, the voucher won't be posted. Next, if lines are found that have a temporary voucher number of 2, this number is overwritten by the next voucher number in the sequence, and so on.
- When you don't use the **Set-based processing** setting, you do not need to provide a voucher number in the imported file. The voucher numbers are created during import, based on the setup of the journal name (**One voucher only**, **In connection of balance**, and so on). For example, if the journal name is defined as **In connection of balance**, the first line receives a new default voucher number. The system then evaluates the line to determine whether the debits equal the credits. If an offset account exists on the line, the next line that is imported receives a new voucher number. If no offset account exists, the system evaluates whether the debits equal the credits as each new line is imported.
- If the **Voucher number** field is set to **Auto-generated**, the import won't succeed. The **Auto-generated** setting for the **Voucher number** field isn't supported.

By default, the General journal entity uses set-based processing. After you evaluate the business requirements for your organization, you can change the **Set-based processing** setting by clicking **Data entities** in the **Data management** workspace. Set-based processing is used to speed up the import process. If you don't use set-based processing, import of the General journal entity import will be slower.

Optimize data migration for Finance and Operations apps

2/18/2021 • 8 minutes to read • Edit Online

Data migration is a key success factor in almost every implementation. A primary concern of some customers is the speed that data can be migrated at, especially if there are vast amounts of data and a small cutover window. The Data migration framework is also used to move data as part of business requirements and operations.

The information in this topic represents a set of steps and actions that you can use to optimize the performance of data migration.

> **NOTE**
> Testing results in a Tier-1 environment should not be compared or extrapolated to performance in a Tier-2 or higher sandbox environment.

Not all standard entities have been optimized for data migration. Some entities have been optimized for integration with Open Data Protocol (OData), and if a required entity can't be optimized to meet the performance requirements, we recommend that you create a new optimized entity. A developer can accelerate this process by duplicating an existing entity.

Begin the optimization phase by using a subset of the data. For example, if you must import one million records, consider starting with 1,000 records, then increase the number to 10,000 records, and then increase it to 100,000 records.

After you've identified the entities that you will use, you should go through the following sections to explore opportunities for optimization.

Disable change tracking

You can enable and disable change tracking from the list of entities.

1. In the **Data management** workspace, select the **Data entities** tile.
2. On the **Target entities** page, select the entity in the grid, and then, on the Action Pane, on the **Change tracking** tab, select **Disable Change Tracking**.

Enable set-based processing

Follow these steps to verify that an entity supports set-based processing.

1. In the **Data management** workspace, select the **Data entities** tile.
2. On the **Target entities** page, find the entity in the grid, and review the value in the **Set-based processing** column.

For an example that shows how set-based processing can be enabled for the **General Journal** entity, see Best practices for importing vouchers by using the General journal entity. Not all entities support set-based processing. For example, if you try to enable support set-based processing for the **Customer definitions** (**CustCustomerBaseEntity**) entity and save your change, you will receive the following warning message:

```
Set operations not supported for 'Customer definitions' entity.
```

Here are some important considerations if you must create an entity that allows for set-based processing:

- The data sources can't be read-only.
- The **ValidTimeStateEnabled** property of the data entity view the must be set to **No**.
- All tables on the data sources must have **TableType** property set to **Regular**.
- The property **QueryType** on the used **Query** can't be set to **Union**.
- The main data source can't prevent data from being saved across companies. However, embedded data sources allow it.
- The main data source can't prevent data from being saved across partitions. However, embedded data sources allow it.

Create a data migration batch group

During cutover, run the data migration while there is little or no other activity. It can be helpful to configure and use a batch group where most or all compute nodes are assigned.

You can configure a batch group on the **Batch group** page (**System administration > Setup > Batch group**).

Enable priority-based batch scheduling

In Platform update 31, the new priority-based batch scheduling feature optimizes how batch jobs are run. If contention is identified in the batch framework, consider enabling priority-based batch scheduling.

Configure the maximum number of batch threads

To better use parallelism and multithreading, you can configure the maximum number of batch threads per instance of Application Object Server (AOS) by setting the **Maximum batch threads** field on the **Server configuration** page (**System administration > Setup > Server configuration**). Be careful about changing the value of this field. A value that is too high can have negative performance implications. Currently, the default value is **4**. You can change the value to **8** as you require. However, you should not set the field to a value that is more than 8 unless you do significant performance testing.

Import in batch mode

Whenever you run an import job, make sure that it's run in batch mode. Otherwise, a single thread will be used to run the job. In this case, the system won't be able to take full advantage of these optimization configurations.

Clean staging tables

We recommend that you clean up the staging tables. In Platform update 29 and later, you can achieve this optimization by scheduling the Job history cleanup job. To schedule this job, select the **Job history cleanup** tile in the **Data management** workspace.

> **NOTE**
> You must first turn on the **Execution history cleanup** feature in the **Feature management** workspace.

Update statistics

Before you run a data migration job that involves a large volume of data, consider updating the statistics across the associated tables. This optimization applies specifically to sandbox environments, because it's handled automatically in production environments. You can update statistics for a specific table from LCS. Alternatively, in

a sandbox environment, you can use the **sp_updatestats** stored procedure through direct SQL.

Clean the data

The time that is spent on validations and error reporting will increase the total time of the migration. Consider this fact when you import a high volume of invalid or inconsistent data. We recommend that you try to fix and reduce errors that are related to data quality. In this way, you help prevent unnecessary executions of validation and error handling.

Configurations to test during test runs of data migration

The following configurations can affect performance. Therefore, we recommend that you test changes by using different values that are suitable for your scenario.

Configure entity execution parameters

Follow these steps to change the execution parameters for all entities or specific entities.

1. In the **Data management** workspace, select the **Framework parameters** tile.
2. On the **Data import/export framework parameters** page, on the **Entity settings** tab, select **Configure entity execution parameters**.
3. On the **Entity import execution parameters** page, set the **Import threshold record count** and **Import task count** fields as appropriate for the desired entities.

Import threshold record count

This value determines the number of records to be processed per thread. By modifying the **Import threshold record count** you can control how you want to split the import into smaller tasks.

Import task count

This field defines the number of threads that will be used for the data migration job for a specific entity. For example, the **Maximum batch threads** field for each server is set to **8**, and four servers are assigned to the data migration batch group. In this case, the total maximum value of the **Import task count** field is **32** (= 8 × 4).

If a data entity doesn't support multithreading, you receive an error message when you try to configure the entity. Here is an example:

> Custom sequence is defined for the entity 'Customers V3', more than one task is not supported.

Validations

Validation logic for record insertions or updates might have been incorporated into the system, or there might be validation of individual fields. If the data migration is mature enough, the time that is spent on imports can be significantly reduced by disabling this validation, if it can be disabled.

Follow these steps to change the settings for each entity.

1. In the **Data management** workspace, select the **Data entities** tile.
2. On the **Target entities** page, select the entity in the grid, and then, on the Action Pane, select **Entity structure**.
3. On the **Entity structure** page, set the **Run business validations** and **Run business logic in insert or update method** fields as appropriate.

Run business validations

If this check box is selected, the system will run any logic that is written into the **validateWrite()** method on the table. It will also run any related event handlers.

Run business logic in insert or update method

If this check box is selected, the system will run any logic that is written into the **insert()** or **update()** method on the table. It will also run any related event handlers.

Call the validateField method on the target

Follow these steps to run field validation.

1. In the **Data management** workspace, select the **Data entities** tile.
2. On the **Target entities** page, select the entity in the grid, and then, on the Action Pane, select **Modify target mapping**.
3. On the **Map staging to target** page, select the **Call validate Field method** check box for the field that validation should be run for. The **validateField(FieldId p1)** method will then be called for that field.

Recommendations for optimizing data migration performance

Here are some general recommendations about the approach that you should use to optimize the performance of data migration:

- Break up large files into smaller chunks. This approach gives the SQL optimizer time to determine whether a new query plan will be optimal.
- Test performance in an appropriate Tier-2 or higher environment.
- Test performance in a mock cutover before go-live.

Testing of data migration performance is an iterative process. We recommend that you collect and compare information about each test to determine the optimal configuration for a specific entity. You should collect and verify some of the following settings:

- The batch group that is used
- The number of batch servers that are assigned to each batch group
- The maximum number of batch threads per batch server

Here is an example of the information that you might collect for each entity.

INFORMATION	DESCRIPTION
Entity	The name of the entity that is being tested
Number of records	The number of records that are being imported
Source format	The source format of the data that is being imported
Change tracking disabled	Yes/No
Set-based processing	Yes/No
Import threshold record count	The number of records
Import task count	The number of tasks
Run business validations	Yes/No
Run business logic in insert or update method	Yes/No
Call validate Field method	Yes/No (potential field list)

INFORMATION	DESCRIPTION
Required performance	The amount of time that the import must be completed within to achieve the cutover window
Actual performance	The actual amount of time that was required to import records

There are more areas where performance can be optimized. For example, you can analyze the specific queries and query plans. However, those processes are covered in other topics.

For more information about performance troubleshooting and optimization, see the following topics:

- Performance troubleshooting using tools in Lifecycle Services (LCS)
- Query cookbook

Design principles and best practices for data entities

2/18/2021 • 4 minutes to read • Edit Online

This article describes design principles for data entities. It also includes guidelines for the names of data entities, fields, relation roles, roles, and OData EntityTypes and EntitySets.

Entity design principles

A data entity should provide a holistic object that encapsulates the relevant business logic in a single consumable contract. The contract is then exposed through application interfaces (APIs), such as OData, import and export, integration, and the programming model. Each data entity should be designed to meet the following goals.

Encapsulation

- Each entity should provide an abstraction between the physical data model and the consumer of the entity. The entity should encapsulate the underlying tables that, together, can define an object that has a specific purpose in the business. Consumers of the entity might be form clients, services, and integration.
- Each entity should encapsulate multiple related tables to represent the domain object. In some situations, single table entities are acceptable.

A single public contract

- The public contract for an entity should be the same across all integration end points. For example, the customer entity must expose the same fields or API to both OData and import/export. This principle guarantees that the published schema for an entity is consistent, regardless of the mechanism for consumer interaction.
- When an entity is consumed, the business logic that is executed within the entity during CRUD operations must not vary based on the type of consumer.

Simplicity

- The consumer of an entity should be able to interact with the entity based on the accepted industry or domain definitions of the entity. The behavior details of the entity should be kept hidden and should be prevented from distorting the interaction.
- The consumer of an entity must be able to interact with the entity by using the natural key of the entity. The consumer must not be required to use any keys that are implementation-specific, such as any surrogate key that it generates.

Naming guidelines

Data entity names

DO	DON'T
Prefix the name with standard prefixes, because of the lack of namespaces.	Don't include underscores in names.
Add the postfix "Entity" to the name to prevent conflicts with tables and classes that have the same prefix.	Don't use abbreviations in conceptual names.

DO	DON'T
Give the entity a conceptual name that is aligned with the name in the en-us UI. For example, the conceptual name of the entity that exposes records from the InventTable table should be named **ReleasedProduct**, so that the full name of the entity will be **EcoResReleasedProductEntity**.	

Result: <prefix><ConceptualName>Entity

Data entity field names

DO	DON'T
Give the field name a conceptual name that is aligned with the name in the en-us UI. For example, use **ItemNumber** instead of **ItemID** as the field name to align with the UI, where the label is **Item number**.	Don't include prefixes in field names. For example, a field should not be named **InventLocationId**.
Add the postfix "ID," "Number," and so on, to the name of a field that is part of foreign keys to prevent collision with the navigation properties. For example, use **WarehouseID** instead of **Warehouse** as a field name, because **Warehouse** is the navigation method to the **Warehouse** entity.	Don't include country/region-specific postfixes in field names. For example, a field should not be named **InventoryProfileID_RU**.
	Don't include underscores in field names.
	Don't use abbreviations in field names.

Data entity relation role names

DO	DON'T
Use the plural form when you name roles that have a cardinality that is higher than 1. For example, the foreign key on Customer to Party should have the role name of Customers, because the cardinality from Party to Customer is 0...N.	Don't include prefixes in relation role names. For example, don't use the name **WMSWarehouseLocation**, even though the referenced entity includes the prefix "WMS."
Use the singular form when you name roles that have a cardinality of 0 (zero) or 1. For example, the foreign key on Worker to Person should have the role name of Worker, because the cardinality from Person to Worker is 0..1.	Don't add the postfix "Entity" to relation role names. For example, don't use the role name **WarehouseEntity** in a relationship, even though the referenced entity includes the name "Entity." Instead, use the name **Warehouse**.
Consider adding the role of the relationship as a prefix. For example, to clearly describe the role of the relationship, name a relationship **BuyingLegalEntity** instead of **LegalEntity**.	Don't add country/region-specific postfixes to relation role names. For example, don't use the role name **InventoryProfile_RU**, even though the relationship applies only in an RU country/region format.
	Don't include underscores in relation role names.

Data entity relation names

Do

- Give the relation name the same name as the related role name, in singular form. For example, the relation that describes the foreign key from Customer to Party should be named **Party**.

OData EntityType names

Do

- Give the EntityType a conceptual name. The name should be the same as the conceptual name of the data entity, but without the prefix and without the "Entity" postfix. For example, **EcoResReleasedProductEntity** becomes **ReleasedProduct**.
- Name the EntityType in singular form.

OData EntitySet (Entity Collection) names

Do

- Name the EntitySet in plural form. For example, the EntitySet for the **ReleasedProduct** EntityType is **ReleasedProducts**.

Number of columns in a data entity

Note that Microsoft Excel based import/export supports a maximum of 255 columns. If it is expected for an entity to be able to export/import more than 255 columns, then a non-Excel format must be planned or the entity should have less than or equal to 255 columns.

Build and consume data entities

2/18/2021 • 15 minutes to read • Edit Online

This tutorial shows how to build an entity and how to consume some out-of-band (OOB) entities in an integration scenario. You will also preview how these data entities will be consumed in various integrations scenarios, such as data import and export, integration, and OData services.

When you are ready to build your first entity for production, you will need to:

- Create your own package and model. For more information, see Models and packages.
- Create a new project and set the model property to the one that you just created.

Prerequisites

This tutorial requires that you access an environment by using Remote Desktop, and that you be provisioned as an administrator on the instance.

Throughout this tutorial, baseUrl refers to the base URL of the instance.

- In the cloud environment, the base URL is obtained from Microsoft Dynamics Lifecycle Services (LCS).
- On a local virtual machine (VM), the base URL is `https://usnconeboxax1aos.cloud.onebox.dynamics.com`.
- Download FMLab sample code to C:. For details, see FMLab sample code.

Key concepts

- Developing a data entity in Microsoft Visual Studio
- Enabling a data entity for data management and OData services
- Consuming a data entity in integration scenarios

Business problem

Fleet Management stores customer data in the FMCustomer table and address data in the FMAddressTable table. To access or update customer information, users must access multiple tables. Instead, you can create a business object that functionally represents customer information, and that you can use to build integration solutions.

Building the FMLabCustomer entity

In this section, you must create a data entity for FMLabCustomer in the Fleet Management model. This entity will be used to manage master data through import/export and integration services. The primary data source is FMCustomer, and the secondary data source is FMAddressTable.

Data entity

FMLabCustomerEntity

Data entity fields

NAME	MAPPING
CellPhone	FMCustomer.CellPhone

NAME	MAPPING
DriverLicense	FMCustomer.DriverLicense
Email	FMCustomer.Email
FirstName	FMCustomer.FirstName
LastName	FMCustomer.LastName
CustomerGroup	FMCustomer.CustGroup
AddressLine1	FMAddressTable.AddressLine1
AddressLine2	FMAddressTable.AddressLine2
City	FMAddressTable.City
State	FMAddressTable.State
ZipCode	FMAddressTable.ZipCode
Country	FMAddressTable.Country

Corresponding staging table

Staging tables are used in import/export scenarios to provide intermediary storage during file parsing and transformation. These tables are also used in connector integration scenarios. In many cases, staging table are mapped 1:1 to an entity. The staging table that corresponds to the **FMLabCustomerEntity** entity is named FMLabCustomerStaging.

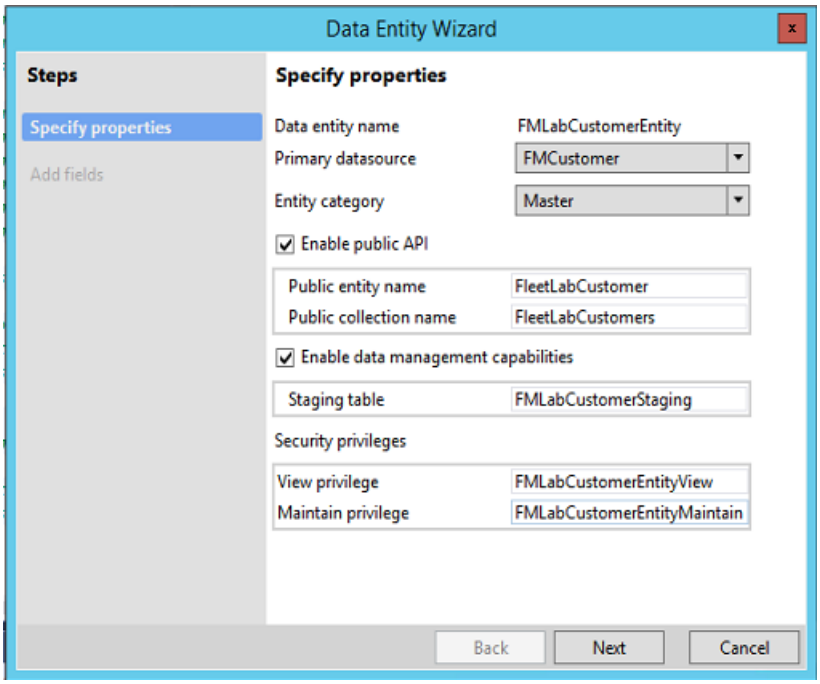
Create a new project

1. In Visual Studio click **File** > **New** > **Project**, and then select **Finance and Operations Project**.
2. Right-click the project, click **Properties**, and verify that the project is in the Fleet Management model. If it isn't, set the **Model** property to **Fleet Management**.

Add a new data entity to your project

1. Create a new entity that is named **FMLabCustomerEntity**. Right-click you project, and then click **Add** > **New item**. The **Add New Item** dialog box opens.
2. Select **Data Entity**, and then set the **Name** property to **FMLabCustomerEntity**.
3. Click **Add**.
4. In the **Data entity** wizard, specify the properties for the data entity that you're creating. Use the values that are shown in the following image.

> **NOTE**
>
> The name of an entity must not have '_' or any numeric digits (0...9). Using these characters may result in mapping errors later.

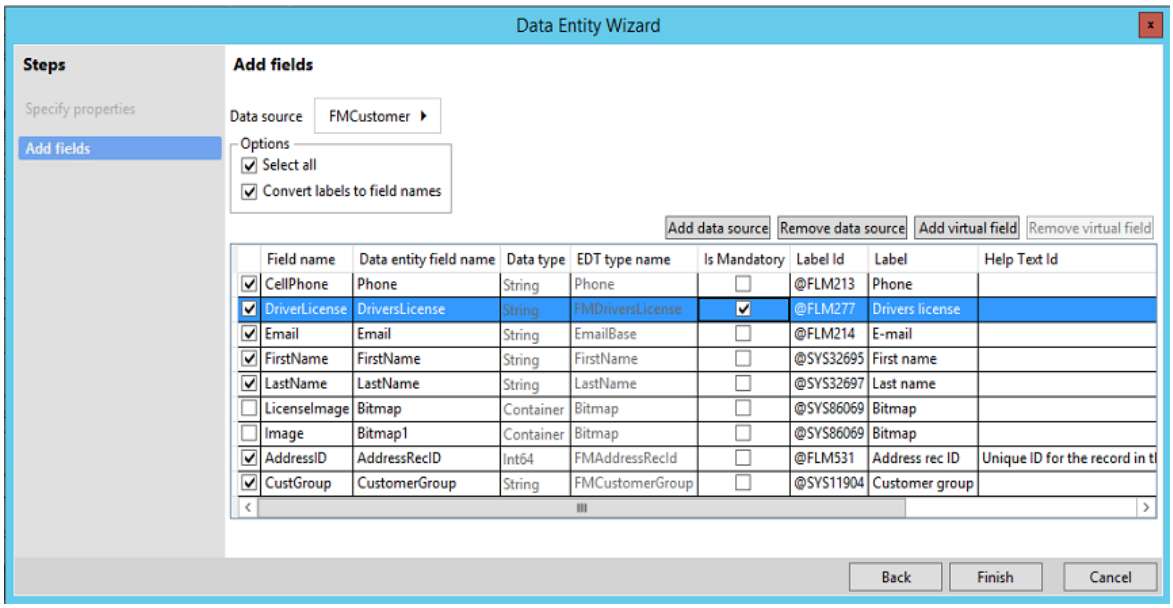


5. Click **Next**. For more information about the function of each property, see "Categories of entities" and "Building an entity" in Data entities overview.

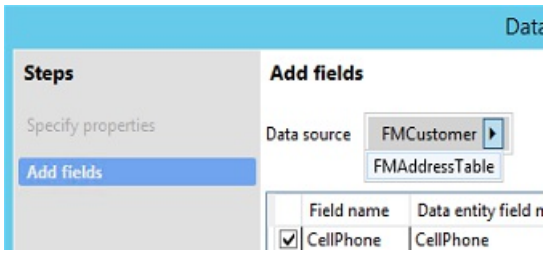
6. Add fields to the new entity from your data source, as shown in the following image. You can add fields from the primary data source, **FMCustomer**. For this entity, clear the check box for the **Image** and **LicenseImage** container types to simplify testing.

7. Rename the data entity fields to reflect public data contract standards, or click **Convert labels to field names** to generate names from the existing labels.

8. On the line for the **DriverLicense** field, select the **Is mandatory** check box. This field will be used as the natural key for the entity.

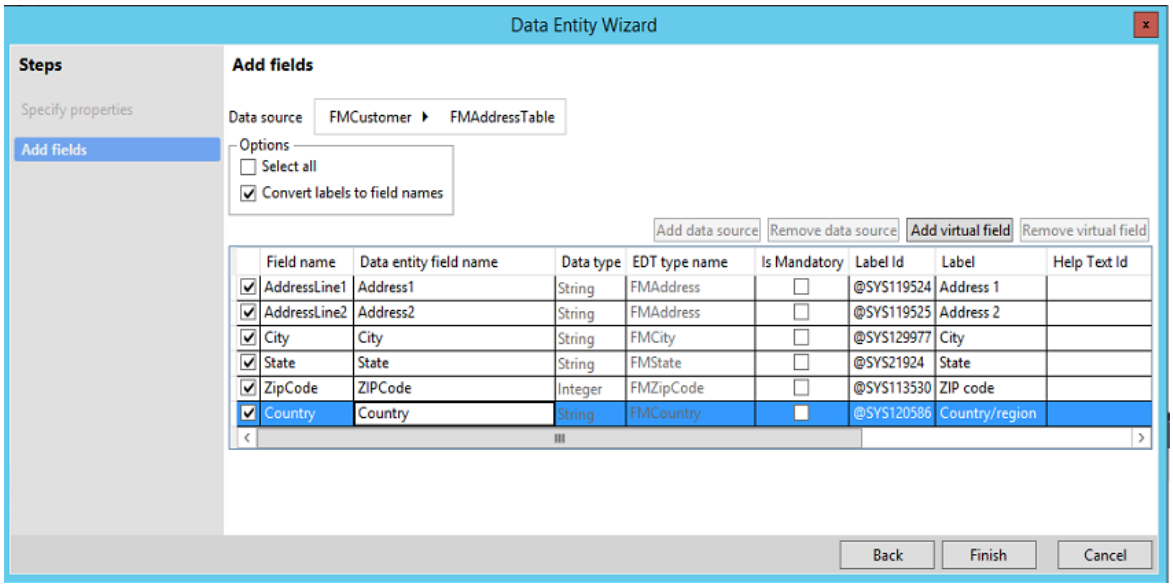


9. In the **Data source** field, select **PrimaryAddress**. Notice that the **PrimaryAddress** data source is automatically added because of automatic expansion or the surrogate foreign key replacement of **AddressID**.

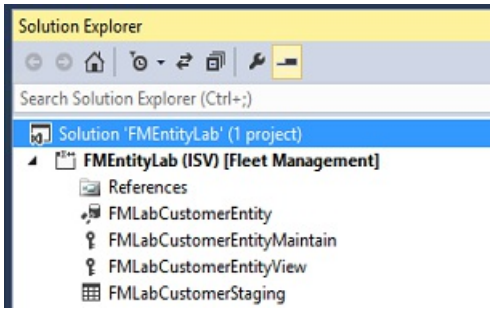


10. Select the fields from the **PrimaryAddress** data source that you want to be part of your entity. Additionally, rename the following fields to reflect proper public data contract naming:

    - PrimaryAddress _AddressLine1 > AddressLine1
    - PrimaryAddress _AddressLine2 > AddressLine2
    - PrimaryAddress _City > City
    - PrimaryAddress _State > State
    - PrimaryAddress _ZipCode > ZipCode
    - PrimaryAddress _Country > Country



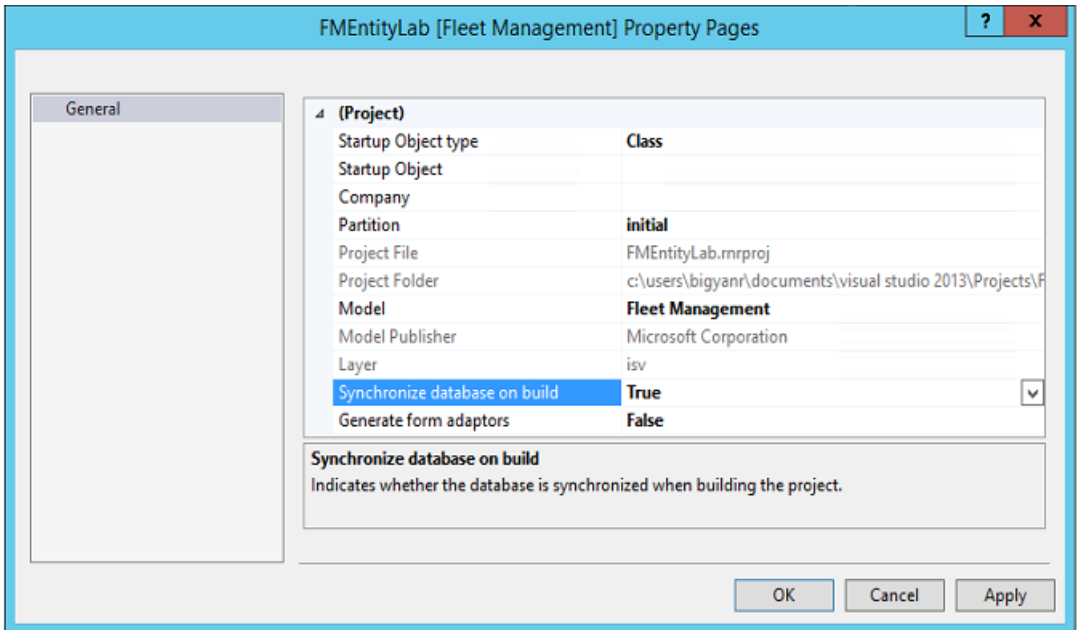
11. Click **Finish**. A data entity item and staging table are added to the project.



Build your project

1. In Solution Explorer, right-click your project, and then click **Properties**.
2. Change the value of the **Synchronize database on build** property to **True**, and then click **OK**. This property must be set only one time per project.

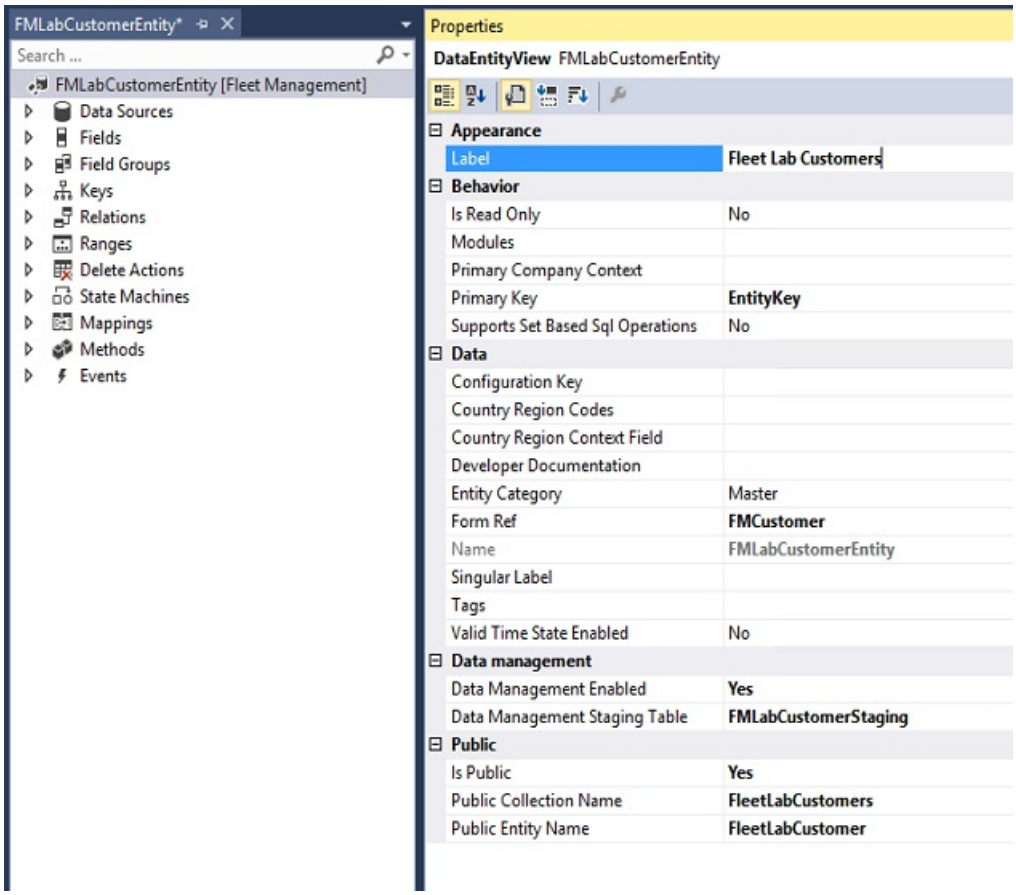
> **NOTE**
>
> Entities are created as views in Microsoft SQL Server, and staging tables are also added. Therefore, you must sync a database when you build entities.



3. On the Visual Studio toolbar, click **Build** > **Build Solution** to build the project.
4. Verify that the build doesn't contain any errors. At this point in the tutorial, warnings are allowed.

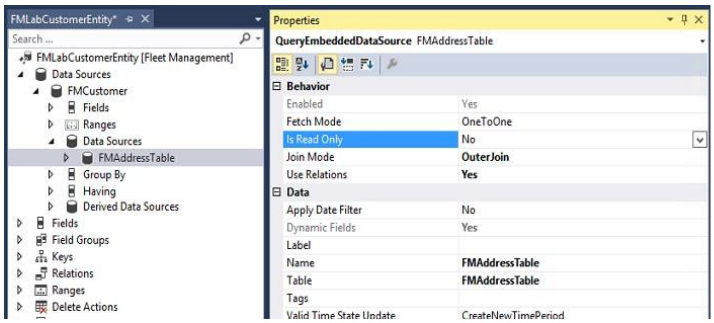
Visually validate and customize an entity

1. In Solution Explorer, right-click the **FMLabCustomerEntity** node, and then click **Open**. The designer for the entity opens in the middle pane.
2. Validate the properties of the **FMLabCustomerEntity** entity. Select the entity in Solution Explorer, and compare the **Properties** pane values to the following image.
3. Set the **Label** property to **Fleet Lab Customers**.

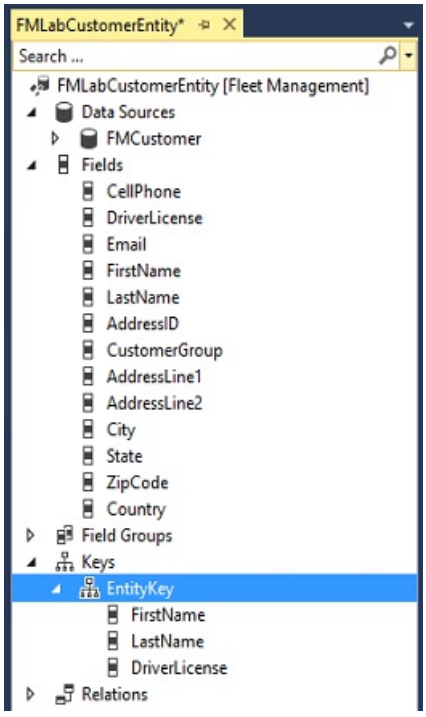


4. In the left pane, click **Data Sources** > **FMCustomer** > **Data Sources** > **FMAddressTable**.

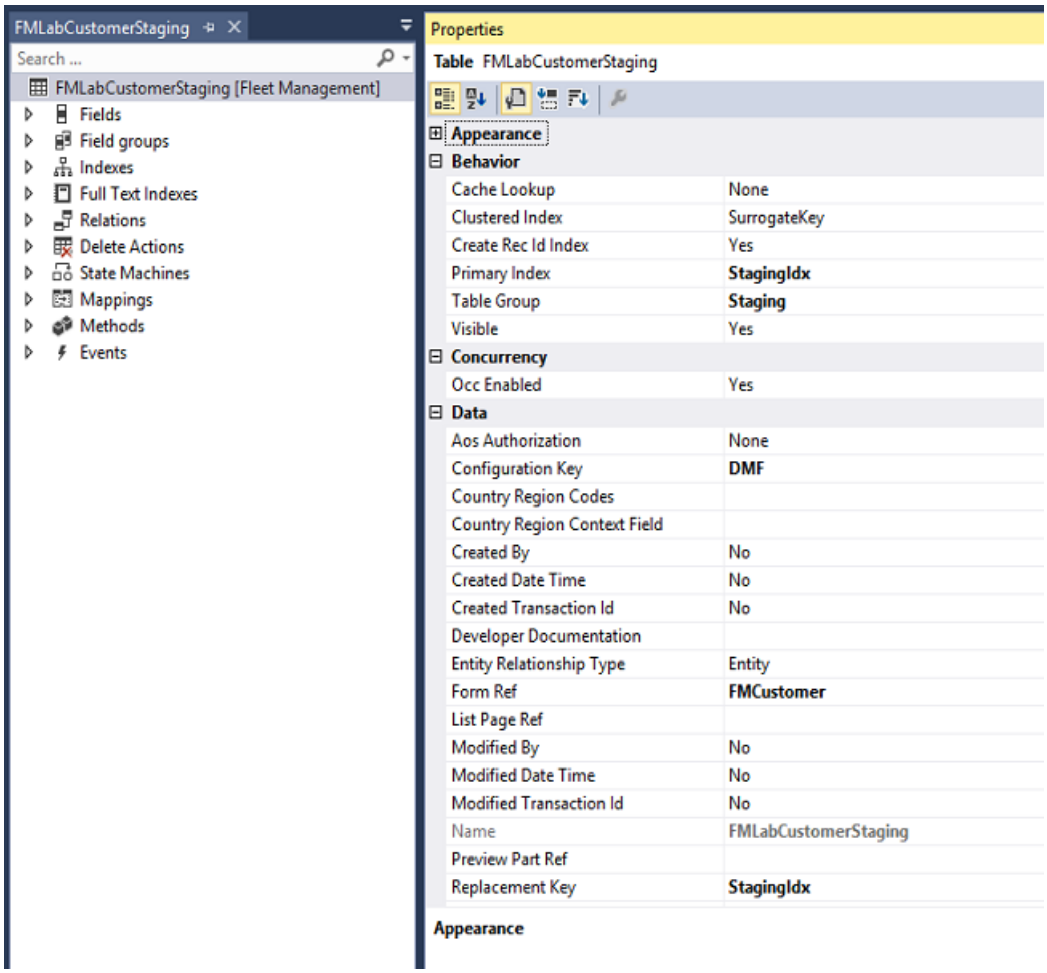
5. Change the **Is Read Only** property to **No**. This is a known issue. Eventually, the value will be set to **Yes** or **No** automatically, based on the type of join. The value should be **Yes** for composition scenarios, and **No** for associations (surrogate foreign key expansions). This property enables the data source to be read/write.



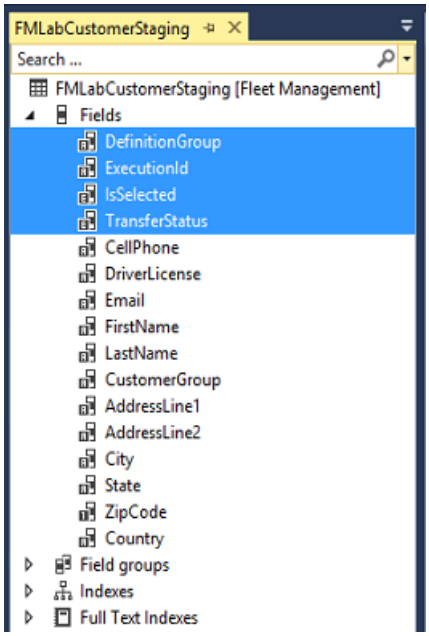
6. In the **FMLabCustomerEntity** designer, click **Keys** > **EntityKey**, and then expand the **Fields** node. Verify that the list of fields matches the following image.



7. To visually validate the staging table that will be used for import/export, open the **FMLabCustomerStaging** table in the designer, and then select the **FMLabCustomerStaging** node.



8. Click **FMLabCustomerStaging** > **Fields**. In the following image, the standard fields of the staging tables are selected. All entity staging tables have these standard fields. The image also shows the data fields that belong on this data entity.



9. In Solution Explorer, right-click your project, and then select **Rebuild** to rebuild and synchronize the project.

Testing data entities

Entities can be tested by using various methods in X++, through data import/export, or through integrations. In this section, we'll explore scenarios for validating entities.

Test the entity by using X++ code

One of the most common ways of interacting with data entities is through X++, by using a unit test or a runnable job to validate that the entities have been built. In this example, we will use a runnable job.

1. In Solution Explorer, click **Add** > **New item** > **Runnable class** to add a runnable class to your project.
2. Copy and paste the following code into the class to test your data entity.

```
public static void main(Args _args)
{
    FMLabCustomerEntity customer;
    str license = "License";
    Random r = new Random();
    int rand = r.nextInt();
    license = license + int2str(rand);

    //Create a new record in FM lab customer entity
    customer.clear();
    customer.FirstName = "Bob";
    customer.LastName = "Smith";
    customer.DriverLicense = license;
    customer.insert();

    info(strfmt("Tried to insert customer '%1 %2' with license %3",
        customer.FirstName, customer.LastName, customer.DriverLicense));

    //Display newly created record
    select forupdate customer where customer.DriverLicense==license;
    info(strfmt("Found newly created customer '%1 %2' with license %3",
        customer.FirstName, customer.LastName, customer.DriverLicense));

    //Now delete the record from the entity
    customer.delete();
    select customer where customer.DriverLicense==license ;
    info(strfmt("Deleted customer does not exist: license- %1", customer.DriverLicense));
}
```

3. Run the code in debugger to set it as a startup object.
4. To validate the entity, view the Infolog in the debugger window or in notifications on the website. You will see that three successful messages are logged. You will also see the actions that were taken.

Importing data by using entities

Data entities that have the **Data Management Enabled** property can be used to import and export data in various file formats. In this section, you will import data in a CSV file format for the **FMLabCustomer** entity.

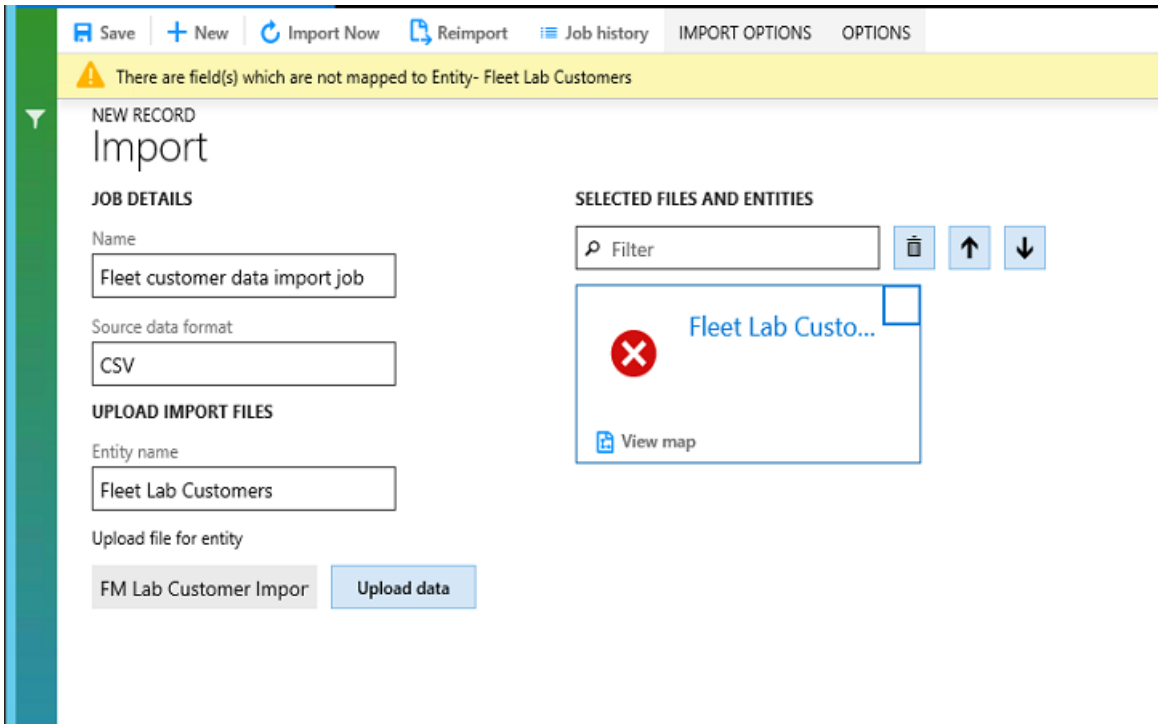
File import

After you create your data entity, you can validate import/export.

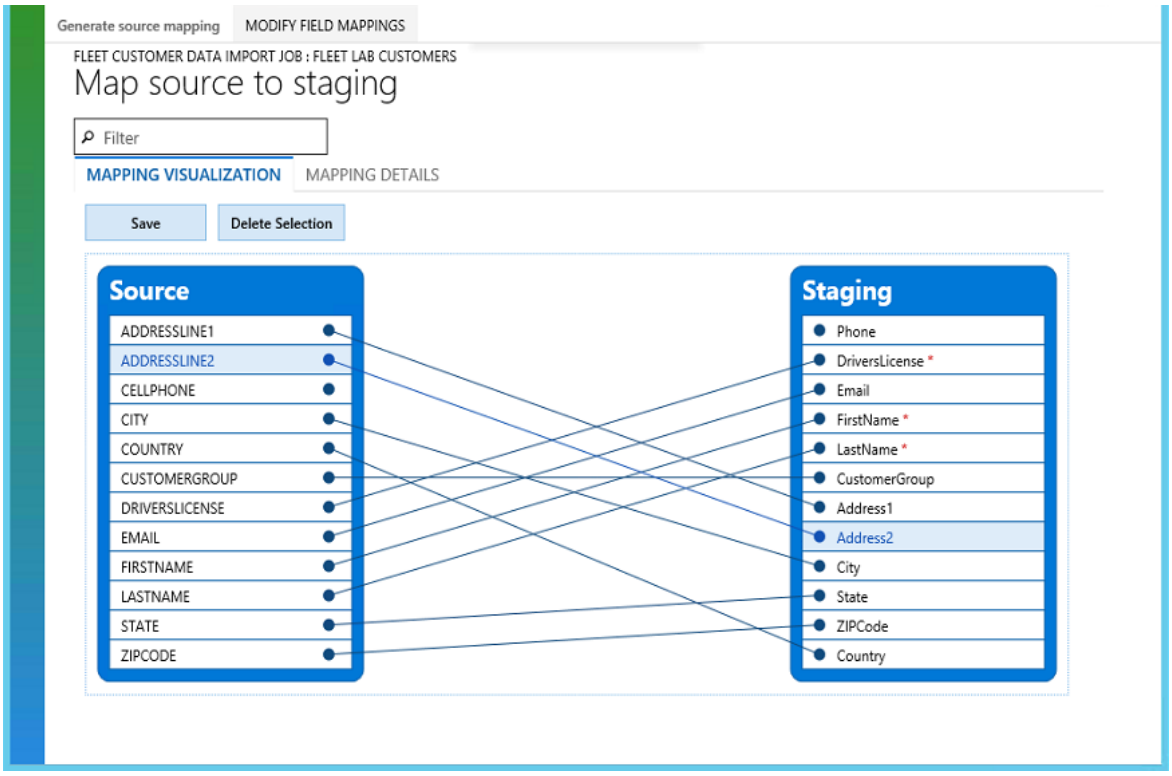
1. Create a sample CSV file that you can import. Copy the following text, and save it as **FM Lab Customer Import.csv**.

```
CELLPHONE,DRIVERSLICENSE,EMAIL,FIRSTNAME,LASTNAME,CUSTOMERGROUP,ADDRESSLINE1,ADDRESSLINE2,CITY,STATE,
ZIPCODE,COUNTRY(999) 555-0100,S615-3939-2349,chris.spencer@adatum.com,Chris,Spencer,adv\_mem\_1,444
Main Street,,Orlando,FL,77899,US(188) 555-0101,S615-3939-
2350,Ichiro.lannin@blueyonderairlines.com,Ichiro,Lannin,non\_mem\_1,12 Long Street,,New York
City,NY,99087,US(777) 555-0102,S615-3939-2351,josh.smith@fourthcoffee.com,Josh,Smith,adv\_mem\_1,9606
122th Avenue,,Sydney,TX,99874,US(456) 555-0103,S615-3939-
2352,Vince@fabrikam.us,Vince,Ahmed,non\_mem\_1,123 Microsoft Way,Unit 87,Seattle,WA,90001,US(345)
555-0104,S615-3939-2353,tony.parker@lucernepublishing.com,Tony,Parker,non\_mem\_1,12012 11th PLNE,Apt
160,San Francisco,CA,75645,US(312) 555-0105,S615-3939-
2354,Julia@fineartschool.net,Julia,Natarajan,exec\_mem\_1,449 Long Street,Apt
160,Bruxelles,ID,34213,US
```

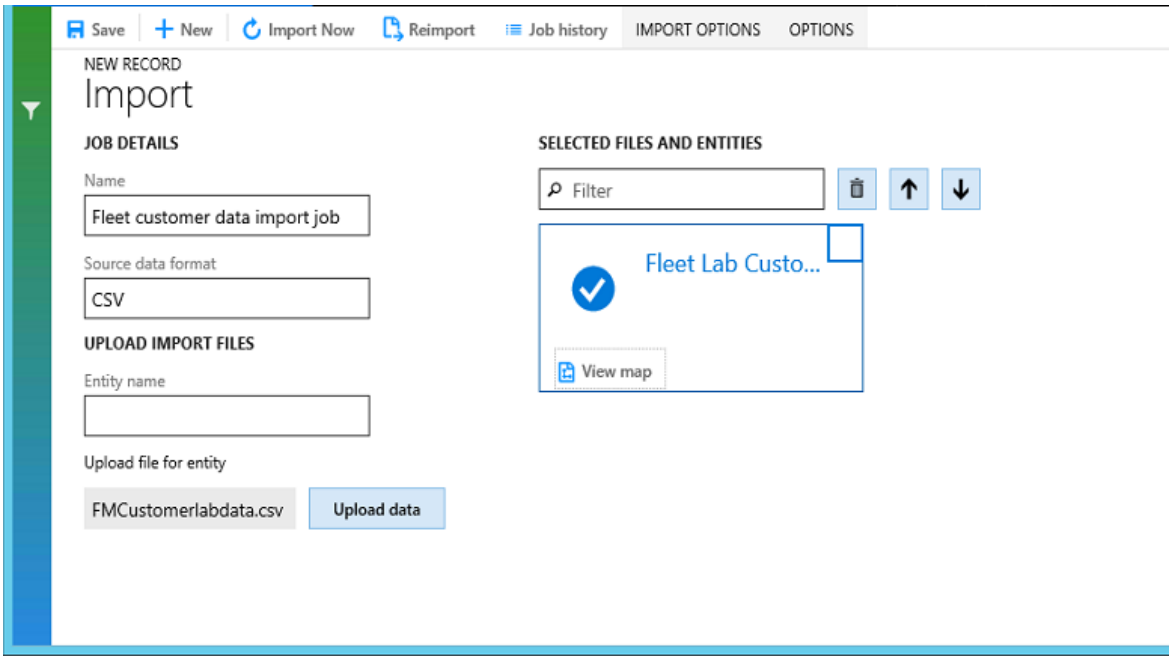
2. Click **User Dashboard** > **Data management**.
3. In the **Data Management** workspace, click the **Import** tile.
4. On the **Import** page, enter the import details, as shown in the following image.



5. Click the **Upload data** button next to the **Upload file for entity** field, and select the CSV file that you created.
6. After the file is uploaded, you will notice that the entity is added to the middle section. You will also receive an error that states that the mapping isn't valid. A few fields aren't mapped correctly between the source file and the target entity.
7. In the entities list, click **View map**.
8. **AddressLine1** and **AddressLine2** are two fields in the source that aren't mapped to target fields. In the visual mapper, or details view, map these fields as follows, and then click **Save**:
   - AddressLine1 – Address1
   - AddressLine2 – Address2



9. Click the **Back** button in your browser to go back to the **Import job** page. The check mark in the entities list indicates that the entity is now ready for import.



10. Click **Import Now**. After the import is completed, the job status page opens.

Consuming entities by using OData

In this section, you will learn how to expose and consume an entity for OData. Before you begin, verify that the Fleet demo data is loaded from the client: [baseURL]/?f=FMSetup

Review the FleetRental entity and add a navigation property for OData

You will review the existing **FleetRental** entity and then create a relationship from one data entity to another. This relationship will be used as a navigation property for OData entities.

1. In Solution Explorer, verify that you're in the **FMEntityLab** project.
2. In Application Explorer, search for **FMRentalEntity**, right-click it, and then select **Add to Project**.

3. In Application Explorer, search for **FMCustomerEntity**, right-click it, and then select **Add to project**.
4. In Solution Explorer, right-click **FMRentalEntity**, and then select **Open**.
5. In the view designer, select the root node, **FMRentalEntity**, and review the following properties.

PROPERTY	VALUE	DESCRIPTION
IsPublic	Yes	When this property is set to **Yes**, the entity is visible by using the OData application programming interface (API).
Public Entity Name	FleetRental	The name that will be used in the OData APIs for **EntityType**.
Public Collection Name	FleetRentals	The name that will be used for the OData collection entity.

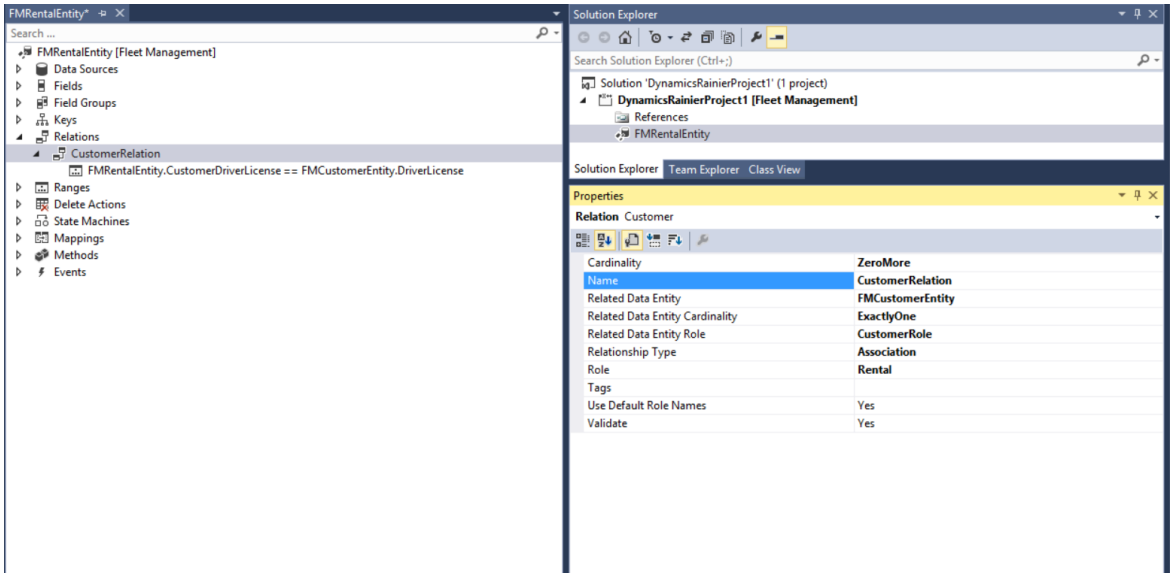
6. In the view designer, expand the **Relations** node.
7. Select **Customer Relation**, and then click **Delete**.
8. Right-click **Relations**, and then select **New** > **Relation**.
9. Select **Relation1**, and set the following properties.

PROPERTY	VALUE
Cardinality	ZeroMore
Name	CustomerRelation
Related Data Entity	FMCustomerEntity
Related Data Entity Cardinality	ExactlyOne
Related Data Entity Role	CustomerRole
Relationship Type	Association
Role	Rental

10. In the view designer, right-click the **CustomerRelation** node, and then select **New** > **Normal**.
11. Right-click the new node under **CustomerRelation**, and then select **Properties**.
12. Set the following properties.

PROPERTY	VALUE
Field	**CustomerDriverLicense**This is the foreign key field on **FMRentalEntity**.
Related Field	**DriverLicense**This is the unique key on **FMCustomerEntity**.

The following image shows the relation in Visual Studio.



13. On the **BUILD** menu, click **Build Solution** to save your changes and build the project. You can view the build progress in the **Output** window.

14. To update the OData endpoint with the changes, you must run an **iisreset** command. Open a **Command Prompt** window as an administrator, and enter **iisreset**.

You've now created a navigation property between **FMRentalEntity** and **FMCustomerEntity**.

Use standard OData syntax to retrieve data

In this section, you will use some of the standard OData syntax to navigate and query the OData entities that are exposed in the Fleet Management model. First, follow these steps to enable Internet Explorer to view JSON formatted data.

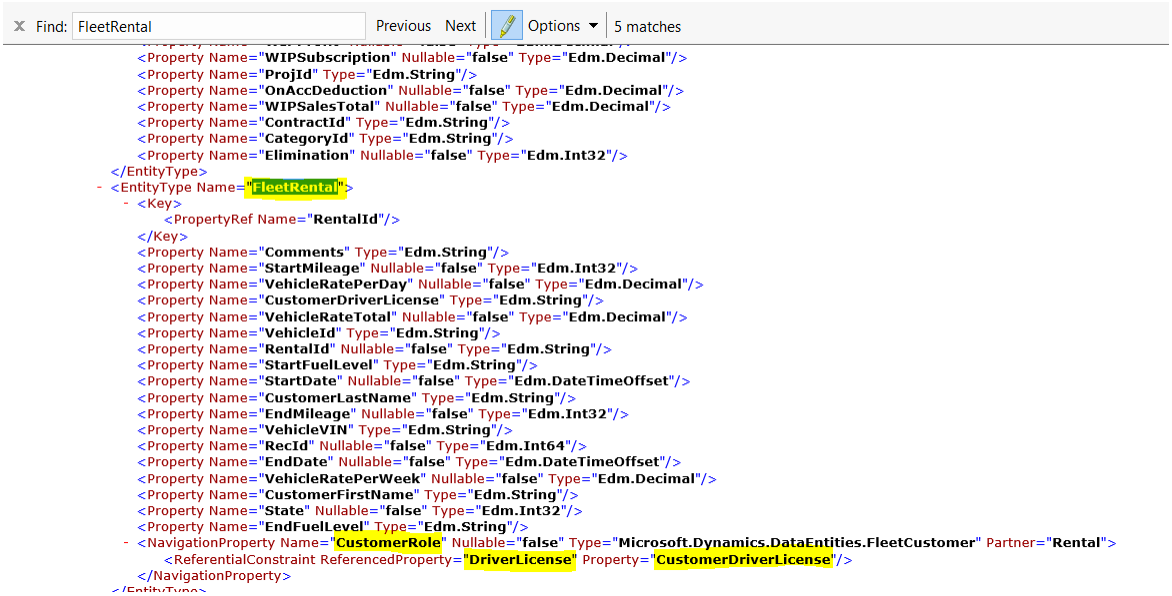
1. Close all Internet Explorer windows.
2. Go to C:\FMLab, and select and double-click the json-ie.reg file.
3. In the **Registry Editor** dialog box, click **Yes**.
4. Click **OK**.

You can now use Internet Explorer to explore some OData URIs.

1. Start Internet Explorer, and enter the following URL in the address bar: [baseURL]/data/$metadata You will see all the metadata that is associated with OData entities.

> **NOTE**
>
> The metadata might take a few minutes to appear the first time that you access it. In the XML, you can see all of the properties and navigation properties associated with the OData entities.

2. In the browser, find **FleetRental**. The following image shows the metadata of the **FleetRental** entity, together with the new relationship, **NavigationProperty**.



3. To view all the customers in the Fleet Management application in JSON format, enter the following URL into the address bar of your browser: [baseURL]/data/FleetCustomer

> **NOTE**
>
> Entity names are case-sensitive.

4. If you don't want to retrieve all properties for the customers, you can retrieve just selected properties. For example, to retrieve only **FirstName** and **LastName**, enter the following URL: [baseURL]/data/FleetCustomers?$filter=FirstName.LastName

5. You can also apply filters. For example, to filter on all customers where **FirstName**=**Phil**, enter the following URL: [baseUrl]/data/FleetCustomers?$filter=FirstName%20eq%20'Phil'

> **NOTE**
>
> These URLs won't work if you copy and paste them. You must manually enter them in the address bar.

6. To retrieve all the **Rental** records, together with all details of the customers, enter the following URL: [baseURL]/data/FleetRentals?$expand=CustomerRole The following example shows a **Rental** record, together with details of the linked customer, in JSON format.

```
"@odata.context":"https://testax32aos.cloud.test.dynamics.com/en/data/$metadata#FleetRentals","value"
:
{
    {
        "@odata.etag":"W/"JzEsNTYzNzE0NDU3NjsxLDU2MzcxNDQ1NzY7MTc4NjA2OTg1Niw1NjM3MTQ0NjA1Jw==",
        "Comments":"","StartMileage":0,"VehicleRatePerDay":40,"CustomerDriverLicense":
        "S468-3184-6541","VehicleRateTotal":280,"VehicleId":"Litware_LitwareFour_1",
        "RentalId":"000001",
        "StartFuelLevel":"Full","StartDate":"2010-04-09T00:00:00Z","CustomerLastName":"Spencer",
        "EndMileage":0,"VehicleVIN":"2J4FY19P0NJ710529",
        "RecId":5637144576,"EndDate":"2010-04-16T00:00:00Z",
        "VehicleRatePerWeek":270,"CustomerFirstName":"Phil","State":3,
        "EndFuelLevel":"","CustomerRole":

        {"@odata.etag":"W/"JzEsNTYzNzE0NDU3NjsxLDU2MzcxNDQ1NzYn"",
        "CellPhone":"(999) 555-0100",
        "DriverLicense":"S468-3184-6541","AddressLine2":"",
        "State":"FL","Country":"US","FirstName":"Phil",
        "Email":"phil.spencer@adatum.com","CustomerGroup":
        "adv_mem_1","AddressLine1":"167 BBN Way","City":"Orlando",
        "ZipCode":77899,"RecId":5637144576,"LastName":"Spencer"
    }
}
```

Add an action to OData entity

Actions provide a way to inject behaviors into the data model. In Dynamics 'AX 7,' you add actions by adding a method to the data entity and then decorating the method with specific attributes. In this section, we'll walk through the steps for adding an action.

1. In Solution Explorer, right-click **FMRentalEntity**, and then select **View code**.
2. Copy the following code lines, and paste them into the **Code** window.

```
public class FMRentalEntity extends common
{
    [SysODataActionAttribute("ReturnRental", true)]
    public str ReturnRental()
    {
        //do something
        return "Rental was successfully returned. Thanks for your business";
    }
}
```

3. On the **BUILD** menu, click **Rebuild Solution** to save your changes and build the project. You can view the build progress in the **Output** window.
4. To update the OData endpoint with the changes, you must run an **iisreset** command. Open a **Command Prompt** window as an administrator, and enter **iisreset**.

   The action that you just added can be invoked through code, as you will see in the next section.

Consume the OData API from an external console application

In this section, you will use a console application to consume the OData endpoints that are exposed in the Fleet Management application. The console application first creates a new customer and then creates a new reservation for that customer. This tutorial shows how easy it is to use OData together with standard .NET Windows Communication Foundation (WCF) data service libraries to integrate with Dynamics AX.

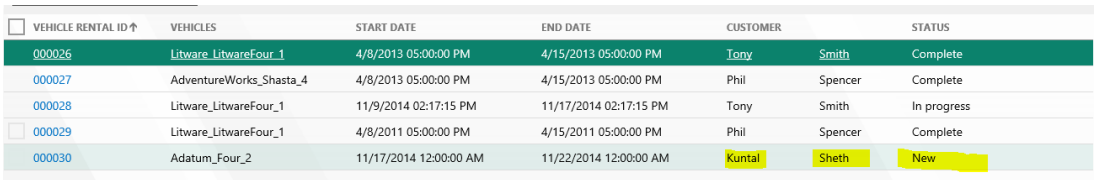
1. Start a new instance of Visual Studio.
2. On the **File** menu, click **Open** > **Project/Solution**.

3. In the **Open Project** dialog box, browse to **C:\FMLab\Odata4ConsoleApplication**, and then select **Odata4ConsoleApplication.csproj**.
4. Click **Open**. The **Odata4ConsoleApplication** project appears in Solution Explorer.
5. In Solution Explorer, double-click **OdataProxyGenerator.tt**.
6. In the code editor, replace the following string with your organization's URL.

```
<baseURL> public const string MetadataDocumentUri = "<baseURL>/data/"
```

7. Save the OdataProxyGenerator.tt file.
8. In the **Save of Read-only file** dialog box, click **Overwrite**. The proxy class for the OData metadata endpoint is generated. This operation might take a few minutes.
9. In Solution Explorer, double-click **Program.cs**.
10. Replace the value of the **dynamicsBaseUri** variable with your organization's URL.
11. Verify that there is a final closing slash (/) in the URL, and then click **Save**.
12. In the **Save of Read-only file** dialog box, click **Overwrite**.
13. Press F5 to run the application, and then follow the instructions in the output console window. The application might prompt you for your Dynamics AX credentials. After the application has run, the new customer and the corresponding reservation are created.
14. Follow these steps to verify that the new reservation appears on the **Rental** page:
    a. Start Internet Explorer, and enter the following URL in the address bar: [baseURL]/?mi=FMRental The **FMRental** page shows the list of rentals.

    b. At the bottom of the list, click **Next** to view the next page. On this page, you can see that the reservation was created for the new customer that you added.



This completes the walkthrough, where you've seen an external client interacting with the Fleet Management model by using OData endpoint.

Casing rules in data entities

XML format

During an export, the entity name and the field names are exported in uppercase. If there is a need to apply a transformation, the transformation must use uppercase in all references.

During an import, data management accepts input file in any casing. However, care must be taken to have the same format for a given attribute/element in the file. When applying a transformation, ensure that the transformation is using the same casing rules in all references as in the incoming file.

Excel format

During an export, column names will be exported in uppercase. Imports are not case sensitive.

CSV format

During an export, column names will be exported in uppercase. Imports are not case sensitive.

Tips and tricks

Max join limits

During entity development, ensure that the overall structure of the entity does not exceed the max join limit of 26. This is the default limit. Increasing the join limit is not recommended because it can have unintended consequences. If this limit is exceeded, the entity will most likely fail to process records and will result in the following SQL error. We also recommend managing the total number of columns in the entity to avoid this error.

```
Cannot create a row of size xxx which is greater than the allowable maximum row size of 8060
```

Exporting container fields

If an entity has container fields and these fields need to be exported, the entity must implement **getFieldsToBeConvertedToFile** to allow each container field to export its data value to a separate file. This allows for container fields to be exportable and at the same time, prevents making the entity export file (core entity data without the container fields) unreadable. If **getFieldsToBeConvertedToFile** is not implemented, then these fields will not be exported but the rest of the entity data will export as usual.

Develop entities for data migration

Behavioral properties on data entities

2/18/2021 • 3 minutes to read • Edit Online

Every data entity has properties that let you override the same property values on the tables or views that are the data sources of that entity. Your choices affect the behavior of the entity. In the following table, the first column lists the properties that are discussed in this topic. The top row lists the levels where the property is found in the entity designer. The levels are listed in order of increasing granularity: the data source level is more granular than the entity level but less granular than the field level.

	ENTITY LEVEL	DATA SOURCE LEVEL	FIELD LEVEL
ReadOnly	Applies	Applies	.
AllowEdit	.	.	Applies
AllowEditOnCreate	.	.	Applies
Mandatory	.	.	Applies

Entity level

In the designer for your data entity, when you click the name at the root node, the **Properties** pane includes the **Is Read Only** property. The following table describes the behavioral differences between the **Yes** and **No** values of this property.

GROUP	PROPERTY NAME	DISPLAY NAME	VALUES	DEFAULT	DESCRIPTION

GROUP	PROPERTY NAME	DISPLAY NAME	VALUES	DEFAULT	DESCRIPTION
Behavior	IsReadOnly	Is Read Only	No, Yes	No	• **No:** Data modification operations (CUD) *are* allowed, *unless* an individual data source node in the entity's designer is set to **IsReadOnly** = **Yes**. • **Yes:** Only read operations are allowed, regardless of the **IsReadOnly** settings on the individual data source nodes in the entity's designer.

You would set **IsReadOnly** to **Yes** for entities that are consumed mainly for export.

Data source level

If a data entity has three data sources, you might want to allow processes to use the entity to modify the data in one of the data sources but not in the other two. A read-only data source can be used for lookup purposes. You can use the entity designer to achieve this extra degree of granular control. Under the entity's **Metadata** > **Data Sources** node, you can select an entity node and then set the **IsReadOnly** property value for that one data source. The following table describes the interaction between the **IsReadOnly** settings at the data source level and the entity level.

GROUP	PROPERTY NAME	DISPLAY NAME	VALUES	DEFAULT	DESCRIPTION

GROUP	PROPERTY NAME	DISPLAY NAME	VALUES	DEFAULT	DESCRIPTION
Behavior	IsReadOnly	Is Read Only	No, Yes	No	• **No:** Data modification operations (CUD) *are* allowed on the data source, *unless* **IsReadOnly** is set to **Yes** at the entity level. • **Yes:** Only operations are allowed, regardless of the **IsReadOnly** setting on the entity.

Field level

At the field level, the **AllowEdit** and **AllowEditOnCreate** properties are available instead of an **IsReadOnly** property. The two **Allow** properties include **Auto** as a third available value. The **Auto** value inherits the value that is on the field in the underlying table.

> **NOTE**
> The **Auto** value isn't available for unmapped fields, such as computed or virtual fields.

GROUP	PROPERTY NAME	DISPLAY NAME	VALUE	DEFAULT	DESCRIPTION
Behavior	AllowEditOnCreate	Allow edit on create	Auto, No, Yes	Auto	• **Auto:** The property is inherited from the underlying table field. > [!NOTE] The **Auto** value

GROUP	PROPERTY NAME	DISPLAY NAME	VALUE	DEFAULT	DESCRIPTION
					isn't available for unmapped fields, such as computed or virtual fields. - **No**: Users aren't allowed to modify the data for this field in a new record. - **Yes**: Users are allowed to modify the data for this field for a new record. This behavior is enforced for all consumers – X++, OData, and so on. [!IMPORTANT] The **No** and **Yes** values do *not* override the setting on the field in the underlying table.

GROUP	PROPERTY NAME	DISPLAY NAME	VALUE	DEFAULT	DESCRIPTION
Behavior	AllowEdit	Allow edit	Auto, No, Yes	Auto	The behavior is the same as the behavior for **AllowEditOnCreate**, but it applies to updates to *existing* records instead of new records that are being created. This behavior is enforced for all consumers – X++, OData, and so on.
Behavior	Mandatory	Mandatory	Auto, No, Yes	Auto	**Auto:** The property is inherited from the underlying table field. This behavior is enforced for all consumers – X++, OData, and so on. [!IMPORTANT] The **No** and **Yes** values do *not* override the setting on the field in the underlying table.

Computed columns and virtual fields in data entities

2/18/2021 • 6 minutes to read • Edit Online

This article provides information about computed and virtual fields, which are the two types of unmapped fields that a data entity can have. The article includes information about the properties of unmapped fields, and examples that show how to create, use, and test them.

The sample code is targeted towards creating or modifying an entity that is a part of solution that you own. Extending an existing entity requires slight modifications.

Overview

A data entity can have additional *unmapped* fields beyond those that are directly mapped to fields of the data sources. There are mechanisms for generating values for unmapped fields:

- Custom X++ code
- SQL executed by Microsoft SQL Server

The two types of unmapped fields are computed and virtual. Unmapped fields always support read actions, but the feature specification might not require any development effort to support write actions.

Computed field

- Value is generated by an SQL view computed column.
- During read, data is computed by SQL and is fetched directly from the view.
- For writes, custom X++ code must parse the input value and then write the parsed values to the regular fields of the data entity. The values are stored in the regular fields of the data sources of the entity.
- Computed fields are used mostly for reads.
- If possible, it's a good idea to use computed columns instead of virtual fields, because they are computed at the SQL Server level, whereas, virtual fields are computed row by row in X++.

Virtual field

- Is a non-persisted field.
- Is controlled by custom X++ code.
- Read and write happens through custom X++ code.
- Virtual fields are typically used for intake values that are calculated by using X++ code and can't be replaced by computed columns.

Properties of unmapped fields

CATEGORY	NAME	TYPE	DEFAULT VALUE	BEHAVIOR

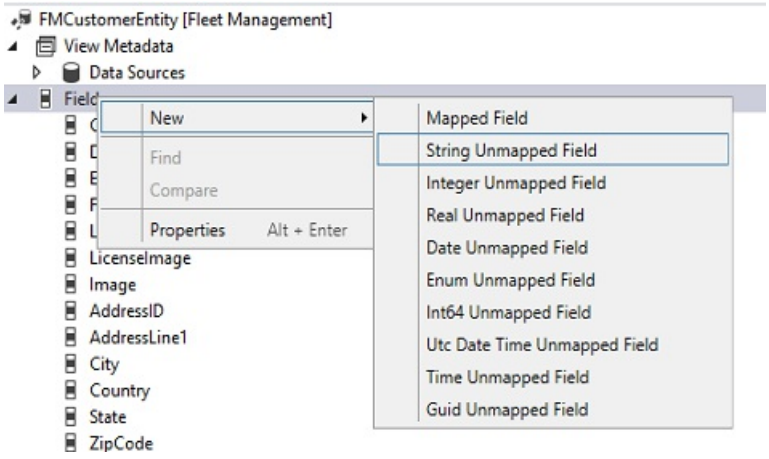
CATEGORY	NAME	TYPE	DEFAULT VALUE	BEHAVIOR
Data	IsComputedField	NoYes	Yes	• **Yes** – The field is synchronized as a SQL view computed column. Requires an X++ method to compute the SQL definition string for the column. The virtual column definition is static and is used when the entity is synchronized. After that, the X++ method is not called at run time. • **No** – The field is a true virtual field, where inbound and outbound values are fully controlled through custom code.
Data	ComputedFieldMethod	String		A static **DataEntity** method in X++ to build the SQL expression that will generate the field definition. This property is disabled and irrelevant if the property **IsComputedField** is set to **No**. The method is required if the property **IsComputedField** is set to **Yes**.
Data	ExtendedDataType	String		

Example: Create a computed field

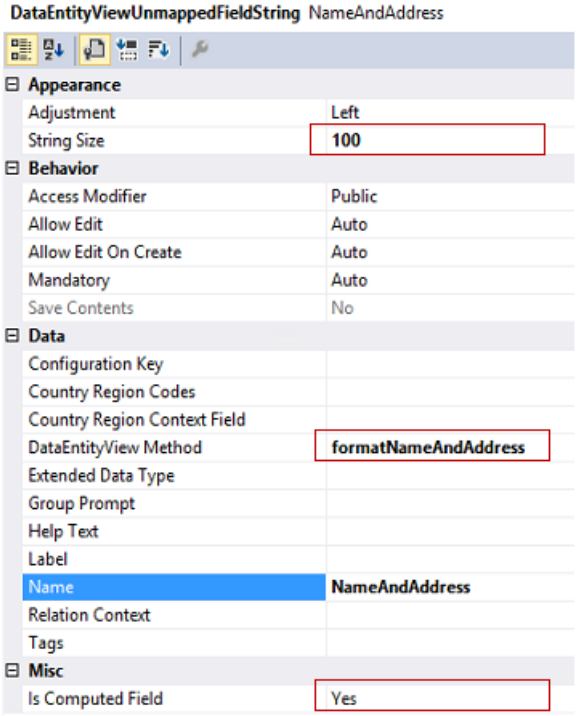
In this example, you add a computed field to the **FMCustomerEntity** entity. For reads, the field combines the name and address of the customer into a nice format. For writes, your X++ code parses the combined value into

its separate name and address values, and then the code updates the regular name and address fields.

1. In Microsoft Visual Studio, right-click your project, and add the existing **FMCustomerEntity**.
2. In Solution Explorer, right-click the **FMCustomerEntity** node, and then click **Open**.
3. In the designer for **FMCustomerEntity**, right-click the **Fields** node, and then click **New** > **String Unmapped Field**.



4. Rename the new field **NameAndAddress**.
5. Update properties of the **NameAndAddress** unmapped field, as shown in the following screenshot.



6. Go to **FMCustomerEntity** > **Methods**. Right-click the **Methods** node, and then click **New**. Ensure that the method name matches the **DataEntityView Method** property value of the unmapped computed field.
7. Paste the following X++ code into the method. The method returns the combined and formatted **NameAndAddress** value.

> **NOTE**
>
> The **server** keyword is required.

```
private static server str formatNameAndAddress()   // X++
{
    DataEntityName      dataEntityName= tablestr(FMCustomerEntity);
    List                fieldList = new List(types::String);
    ////Format name and address to look like following
    ////John Smith, 123 Main St, Redmond, WA 98052
    fieldList.addEnd(SysComputedColumn::returnField(DataEntityName, identifierstr(FMCustomer),
fieldstr(FMCustomer, FirstName)));
    fieldList.addEnd(SysComputedColumn::returnLiteral(" "));
    fieldList.addEnd(SysComputedColumn::returnField(DataEntityName, identifierstr(FMCustomer),
fieldstr(FMCustomer, LastName)));
    fieldList.addEnd(SysComputedColumn::returnLiteral("; "));
    fieldList.addEnd(SysComputedColumn::returnField(DataEntityName, identifierstr(FMAddressTable),
fieldstr(FMAddressTable, AddressLine1)));
    fieldList.addEnd(SysComputedColumn::returnLiteral(", "));
    fieldList.addEnd(SysComputedColumn::returnField(DataEntityName, identifierstr(FMAddressTable),
fieldstr(FMAddressTable, City)));
    fieldList.addEnd(SysComputedColumn::returnLiteral(", "));
    fieldList.addEnd(SysComputedColumn::returnField(DataEntityName, identifierstr(FMAddressTable),
fieldstr(FMAddressTable, State)));
    fieldList.addEnd(SysComputedColumn::returnLiteral(", "));
    fieldList.addEnd(SysComputedColumn::cast(
        SysComputedColumn::returnField(DataEntityName, identifierstr(FMAddressTable),
fieldstr(FMAddressTable, ZipCode)), "NVARCHAR"));
    return SysComputedColumn::addList(fieldList);
}

T-SQL for the computed column.

( Cast (( ( T1.firstname ) + ( N' ' ) + ( T1.lastname ) + ( N'; ' ) +
    ( T5.addressline1 )
    + ( N', ' ) + ( T5.city ) + ( N', ' ) + ( T5.state ) + (
    N', '
    ) +
    ( Cast(T5.zipcode AS NVARCHAR) ) ) AS NVARCHAR(100))
)
AS
NAMEANDADDRESS
```

TIP

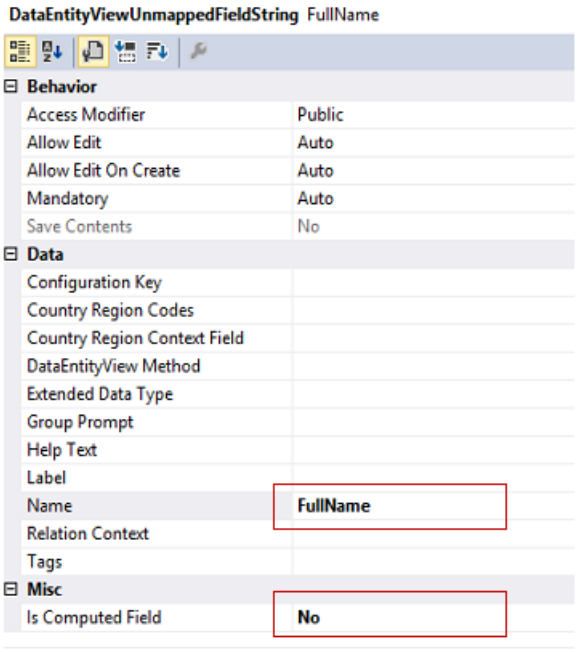
If you receive error in data entity synchronization because of computed columns, it's easier to come up with the SQL definition in Microsoft SQL Server Management Studio (SSMS) before using it in X++.

8. Rebuild the project.
9. Synchronize the database. Don't forget this step. You can do this by going to **Dynamics 365 > Synchronize database > Synchronize**.

Example: Create a virtual field

In this example, you add a virtual field to the **FMCustomerEntity** entity. This field displays the full name as a combination of the last name and first name. X++ code generates the combined value.

1. In the designer for the **FMCustomerEntity** entity, right-click the **Fields** node, and then click **New > String Unmapped Field**.
2. In the properties pane for the unmapped field, set the **Name** property to **FullName**.
3. Set the **Is Computed Field** property to **No**. Notice that you leave the **DataEntityView Method** empty.



4. In the **FMCustomerEntity** designer, right-click the **Methods** node, and then click **Override > postLoad**. Your X++ code in this method will generate the values for the virtual field.

5. Paste the following X++ code in for the **postLoad** override. Notice that the **postLoad** method returns **void**.

```
public void postLoad()
{
    super();
    //Populate virtual field once entity has been loaded from database
    //Format full name - "Doe, John"
    this.FullName = this.LastName + ", " + this.FirstName;
}
```

6. Compile your project.

Example: Use a virtual field to receive and parse an inbound field

Imagine that an external system sends the name of a person as a compound value that combines the last and first names in one field that comes into our system. However, our system stores the last and first names separately. For this scenario, you can use the **FullName** virtual field that you created. In this example, the major addition is an override of the **mapEntityToDataSource** method. When **update** is called, **mapEntityToDataSource** methods are invoked for each data source.

1. In the designer for the **FMCustomerEntity**, right-click the **Methods** node, and then click **Override > mapEntityToDataSource**.

2. Paste the following X++ code in for the **mapEntityToDataSource** method.

```
public void mapEntityToDataSource(DataEntityRuntimeContext entityCtx,
DataEntityDataSourceRuntimeContext dataSourceCtx)
{
    super(entityCtx, dataSourceCtx);
    //Check if desired data source context is available
    if (dataSourceCtx.name() == "FMCustomer")
    {
        FMCustomer dsCustomer = dataSourceCtx.getBuffer();
        //Find position of "," to parse full name format "Doe, John"
        int commaPosition = strfind(this.FullName, ",",0,strlen(this.FullName));
        //Update FirstName and LastName in the data source buffer to update
        dsCustomer.LastName = substr(this.FullName,0,commaPosition-1);
        dsCustomer.FirstName = substr(this.FullName, commaPosition+1, strlen(this.FullName));
    }
}
```

Test the computed and virtual fields

The following **main** method tests your computed and virtual fields. Both fields are tested in a read action, and the virtual field is tested in an update action.

1. For this example, ensure that you have the data set named **Fleet Management (migrated)**. The data set is available from the dashboard in the browser. Click the menu icon in the upper-right corner, click the **APP LINKS** menu, and then scroll to find the data set named **Fleet Management (migrated)**.
2. Paste the following X++ code into the startup object of your project. Run your project.

```
public static void main(Args _args)   // X++
{
    FMCustomerEntity customer;
    //Using transactions to avoid committing updates to database
    ttsbegin;
    //SELECT single customer entity record from the database
    select customer
        where customer.Email == "phil.spencer@adatum.com";
    //Read full name (Virtual Field)
    info(customer.FullName);
    //Read formatted NameAndAddress(computed Field)
    info(customer.NameAndAddress);
    //UPDATE full name (virtual field)
    customer.FullName = "Doe, John";
    customer.update();
    //Reselect data from database to get updated information
    select customer
        where customer.Email == "phil.spencer@adatum.com";
    //Read full name (virtual field)
    info(customer.FullName);
    ttsabort;
}
```

Note on computed column generation failures

If the X++ method that generates the SQL for a computed column throws an exception, DbSync catches the exception, **sets the value of that column to** `NULL`, and logs a *warning*.

Developers are advised to check configuration keys manually in computed column methods to avoid hitting a `NULL` value, if the generation failed.

Can you tell us about your documentation language preferences? Take a short survey.

The survey will take about seven minutes. No personal data is collected (privacy statement).

Cross-company behavior of data entities

2/18/2021 • 7 minutes to read • Edit Online

This topic provides information about how data entities interact with the cross-company concept. To understand this aspect of data entities, you must understand how tables and views apply the cross-company concept. Therefore, this topic begins with a brief review of tables and views, and then explains how data entities are related.

Review of tables and views for cross-company

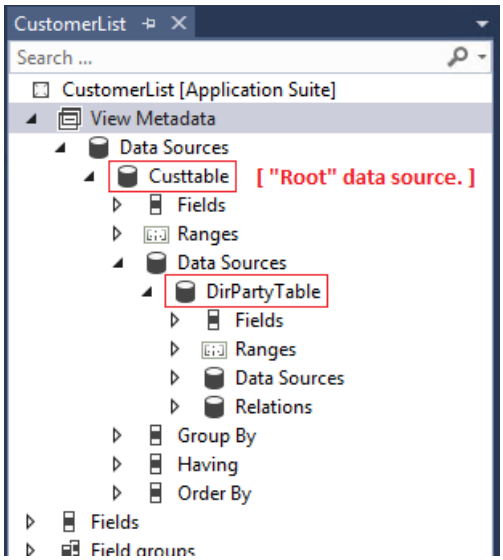
Each table has a **SaveDataPerCompany** property, and each view has a **AllowCrossCompany** property. The following table describes these two properties.

	TABLE	VIEW
Property name	SaveDataPerCompany	AllowCrossCompany
Relevant CRUD mode	CUD	R
Timing of effect	Run time, Design time	Run time, mostly. At design time, this setting causes the view to have **dataAreaId** in its list of selected fields. However, the filter for a specific **dataAreaId** value is added later, at run time.
Meaning of value = Yes	At design time, the system automatically *adds* a **dataAreaId** field to the table, even though the field isn't displayed in the Application Object Tree (AOT). Every record in the table is tagged with the company (or legal entity) that it belongs to. The system automatically *adds* a filter to the SQL **Where** clause to limit the returned set of rows to one **dataAreaId** value.	At run time, the system does *not* automatically add a filter for **dataAreaId** on the **Where** clause of the SQL **Select** statement that it sends to the underlying Microsoft SQL Server system. Therefore, SQL **Select** statements from the view can return a set of records that contains records for *multiple* companies.
Meaning of value = No	The system does *not* add a **dataAreaId** field to the table. The table is said to be a shared table, because none of its records contain any formal company-specific data.	The system automatically *adds* a filter to the SQL **Where** clause to limit the returned set of rows to one **dataAreaId** value. However, the **AllowCrossCompany** property is ignored if the *root* data source of the view is a shared table.

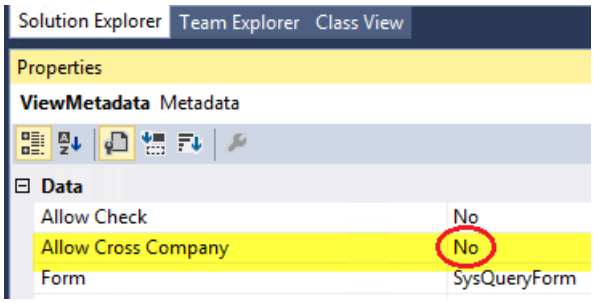
Comparisons within AllowCrossCompany = No

In the following screenshot, the **CustomerList** view has two data sources:

- **Root** – CustTable, which has its **SaveDataPerCompany** property set to **Yes**.
- **Non-root** – DirPartyTable, which has its **SaveDataPerCompany** property set to **No**.



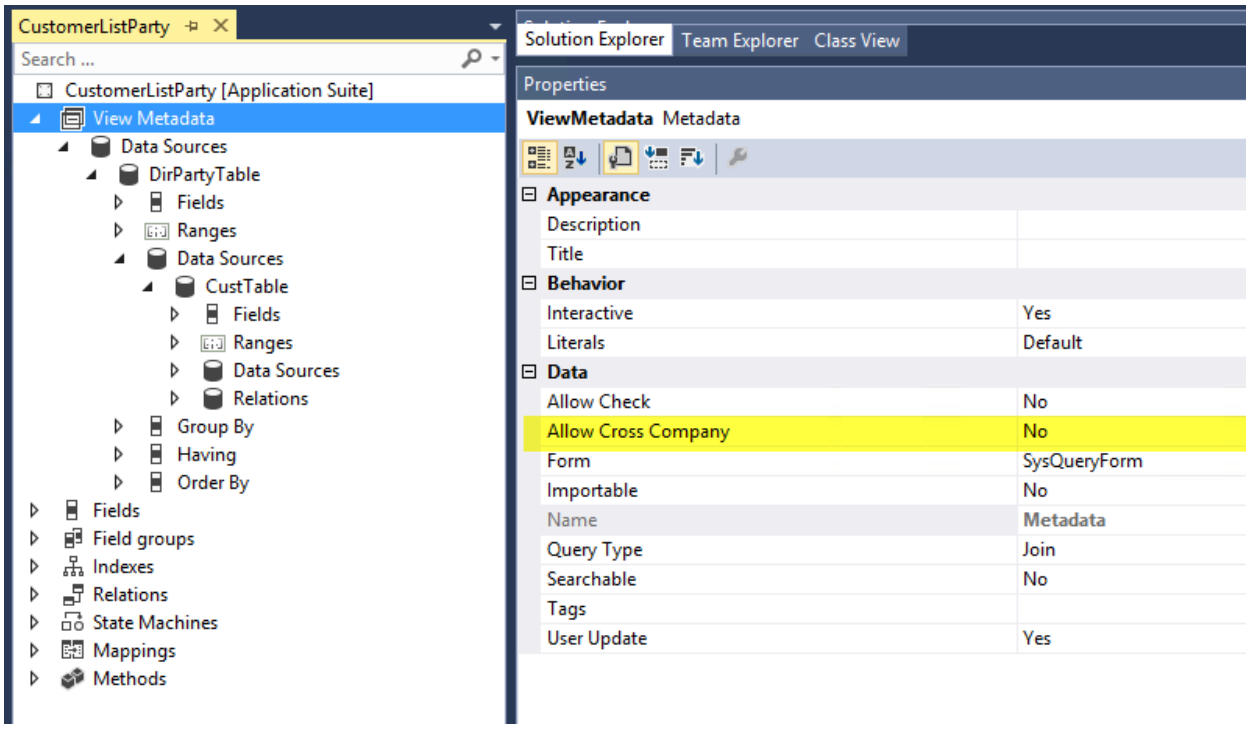
The **CustomerList** view has its **AllowCrossCompany** property set to **No**, as shown in the following screenshot.



Given the preceding information about the **CustomerList** view, the system creates the view in the underlying SQL Server system by generating and then running the following SQL **Create View** statement.

```
CREATE VIEW [dbo].[CUSTOMERLIST]
AS
       SELECT T1.accountnum AS ACCOUNTNUM,
              T1.dataareaid AS DATAAREAID,  -- AllowCrossCompany =No caused this line.
              T1.partition  AS PARTITION,
              T1.recid      AS RECID,
              T2.partition  AS PARTITION#2,
              T2.name       AS NAME
       FROM   custtable T1
              CROSS JOIN dirpartytable T2
       WHERE ( T1.party = T2.recid
              AND ( T1.partition = T2.partition ) )
```

Making DirPartyTable the root data source



By swapping the positions of the two data source tables in the **CustomerList** view, you make the DirPartyTable table the root data source.

```
CREATE VIEW [dbo].[CUSTOMERLISTPARTY]
AS
       SELECT T1.name       AS NAME,
              T1.partition  AS PARTITION,
              T1.recid      AS RECID,
              T2.partition  AS PARTITION#2,
              T2.accountnum AS ACCOUNTNUM
       FROM   dirpartytable T1
              CROSS JOIN custtable T2
       WHERE  ( T2.party = T1.recid
              AND ( T2.partition = T1.partition ) )
go
```

In this case, the SQL **Create View** statement is the same, except for the following two differences:

- The **FROM** clause mentions DirPartyTable first and CustTable second.
- The **SELECT** column list does *not* include the line for **dataAreaId** (because DirPartyTable has its **SaveDataPerCompany** property set to **No**.)

Limitations of tables and views

In some cases, the cross-company control features of tables and views aren't as granular control as you might require. Here are the limitations:

- Company or legal entity fields other than the system **dataAreaId** field can’t be recognized or treated automatically in the that way **dataAreaId** can.
- The cross-company behavior for views is too restricted to the properties of the root data source, even when non-root data sources have a **dataAreaId** field.

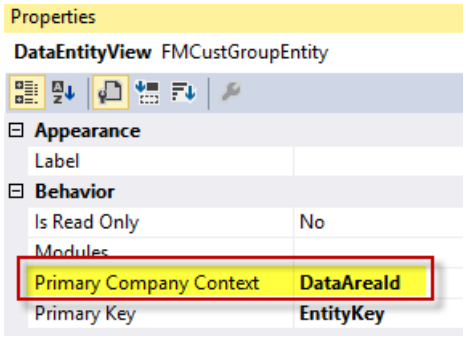
For example, this might happen if the legal entity information is in **LegalEntityRecId**, or if shared tables don't have a **dataAreaId** column.

Design time: Setting the PrimaryCompanyContext property

Data entities help you overcome the limitations of tables and view where cross-company functionality is concerned. Data entities have a **PrimaryCompanyContext** property, where you can specify the entity field to use for company identification. This property provides flexibility and granular control in the following ways:

- The field can be from any data source of the entity and isn't limited to fields of the root data source.
- The field can be any field that is extended from the **DataAreaId** extended data type (EDT), and isn't limited to an underlying system **dataAreaId** field.
- You can use the **PrimaryCompanyContext** property even when the entity has only shared tables as its data sources, if this makes sense for your specific situation.

The following screenshot shows the value set for the **PrimaryCompanyContext** property on the **FMCustGroupEntity** entity.



When the **PrimaryCompanyContext** value is set to a non-empty value, the entity can't behave as a shared entity. The **dataAreaId** field is added to the SQL **Create View** statement.

```
CREATE VIEW [dbo].[FMCUSTGROUPENTITY]
AS
       SELECT T1.custgroup   AS GROUPNAME,
              T1.description AS DESCRIPTION,
              T1.dataareaid  AS DATAAREAID,   -- dataAreaId is added.
              T1.recversion  AS RECVERSION,
              T1.partition   AS PARTITION,
              T1.recid       AS RECID
       FROM   fmcustgroup T1
```

Run time: The behavior of data entities for cross company

In the context of X++ code, the cross-company behavior of data entities resembles the behavior of tables. If the **PrimaryCompanyContext** property for an entity has no value and is empty, the entity behaves like a shared table.

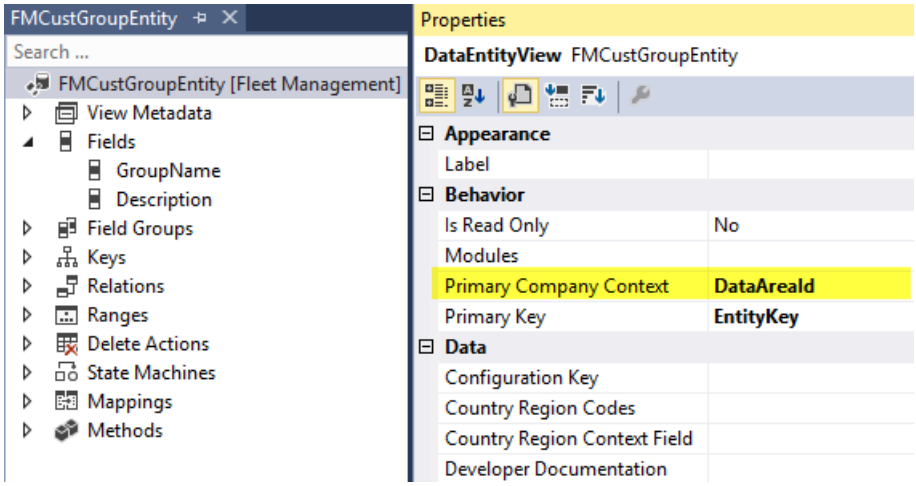
X++ when PrimaryCompanyContext is set

The following table describes the behavior of a data entity under CRUD access when the **PrimaryCompanyContext** property is set to a field value. Both X++ and OData accesses are described.

	X++	ODATA
Read (R)	By default, results are *always* filtered by **dataAreaId** = current company, and cross-company data can be fetched by using the **cross company** option.	Results are *not* filtered by **dataAreaId**. The consumer must filter explicitly.

	X++	OData
Write (CUD)	CUD access to the data entity always occurs in the context of the current company. If cross-company CUD access to the entity is required, use the **changeCompany** keyword.	CUD access to the entity can be accomplished by the consumer for any company by setting the value of the **PrimaryCompanyContext(myDataAreaId)** field. The framework handles the necessary **ChangeCompany** action.

The following X++ code example accesses **FMCustGroupEntity**, which has its **PrimaryCompanyContext** property set to **dataAreaId**.



```
class CrossCompanyXPlusPlusTest   // X++
{
    /// <summary>
    /// Runs the class with the specified arguments.
    /// </summary>
    /// <param name = "_args">The specified arguments.</param>
    public static void main(Args _args)
    {
        FMCustGroupEntity customerGroup;

        // Reads
        // Returns record(s) from current company
        while select GroupName from customerGroup
        {
            info(strfmt("%1-%2",customerGroup.GroupName,customerGroup.DataAreaId));
        }

        // Returns record(s) from crosscompany
        while select crosscompany GroupName from customerGroup
        {
            info(strfmt("%1-%2",customerGroup.GroupName,customerGroup.DataAreaId));
        }

        // Writes
        // create record in current company
        customerGroup.clear();
        customerGroup.GroupName = "CG test";
        customerGroup.insert();

        select firstonly GroupName from customerGroup where customerGroup.GroupName == "CG test";
        info(strfmt("%1-%2",customerGroup.GroupName,customerGroup.DataAreaId));

        // update record in current company
        ttsbegin;

        select firstonly forupdate customerGroup where customerGroup.GroupName == "CG test";
        if (customerGroup)
        {
            customerGroup.Description = "CG test";
            customerGroup.update();
        }
        ttscommit;

        select firstonly GroupName,Description from customerGroup
               where customerGroup.GroupName == "CG test";
        info(strfmt("%1-%2",customerGroup.Description,customerGroup.DataAreaId));

        // Writes
        // create record in CEE company
        changecompany('cee')
        {
            customerGroup = null;
            customerGroup.GroupName = "Cee test";
            customerGroup.insert();

            select firstonly GroupName from customerGroup
                   where customerGroup.GroupName == "Cee test";
            info(strfmt("%1-%2",customerGroup.GroupName,customerGroup.DataAreaId));

            // update record in CEE company
            ttsbegin;

            select firstonly forupdate customerGroup
                   where customerGroup.GroupName == "Cee test";
            if (customerGroup)
            {
                customerGroup.Description = "Cee test";
                customerGroup.update();
            }
            ttscommit;

            select firstonly GroupName,Description from customerGroup
                   where customerGroup.GroupName == "Cee test";
            info(strfmt("%1-%2",customerGroup.Description,customerGroup.DataAreaId));

        }
    }
}
```

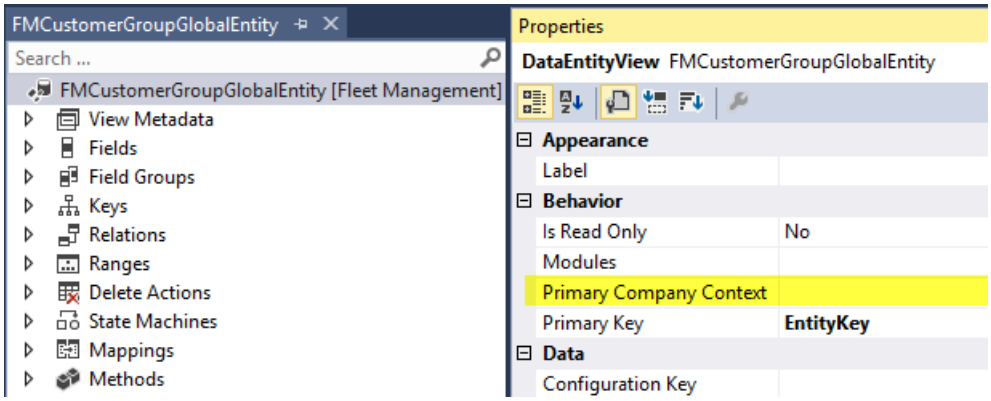
X++ when PrimaryCompanyContext is empty

When the **PrimaryCompanyContext** property is set on the data entity, a **dataAreaId** field is created in the view schema and mapped to the **PrimaryCompanyContext** field. The following table describes the behavior of a data entity under CRUD access when the **PrimaryCompanyContext** property is empty. Both X++ and OData accesses are described.

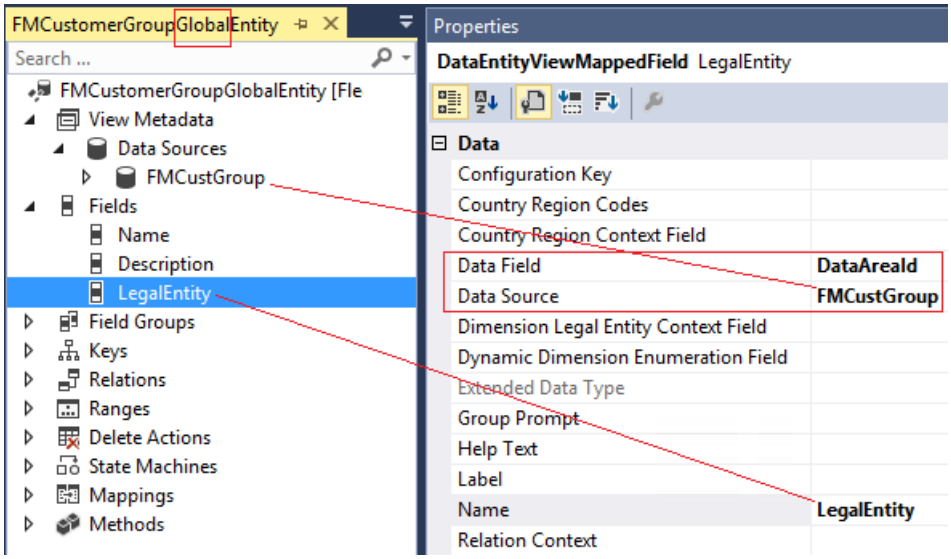
	X++	ODATA

	X++	ODATA
Read (R)	Results aren't filtered, because no system **dataAreaId** field is created on the view schema.	(The same as for R with X++)
Write (CUD)	There is no primary company context to set. Therefore, CUD access to the entity is always in the context of the current company.	(The same as for CUD with X++)

In the current example, the **FMCustomerGroupGlobalEntity** entity has no value assigned to its **PrimaryCompanyContext** property.



However, a **dataAreaId** field from the FMCustGroup table is mapped to the **FMCustomerGroupGlobalEntity** entity as a regular field that is named **LegalEntity**. In this example, the FMCustGroup table is the root data source for **FMCustomerGroupGlobalEntity**. However, we are using this **dataAreaId** field in an informal way that bypasses the automatic mechanisms of the system. All these details are shown in the following screenshot of the **LegalEntity** field.



NOTE

Although the terms *legal entity* and *data entity* both use the word *entity*, don't confuse them. Legal entities and data entities are two entirely different concepts. When the **PrimaryCompanyContext** property is empty, the SQL **Create View** statement usually contains no mention of a system **dataAreaId** column. However, in the current example, **dataAreaId** is "half-mentioned" because of the **LegalEntity** regular field on the data entity. This field is shown in the following SQL statement.

```
CREATE VIEW [dbo].[FMCUSTOMERGROUPGLOBALENTITY]
AS
       SELECT T1.custgroup   AS NAME,
              T1.description AS DESCRIPTION,
              T1.dataareaid  AS LEGALENTITY,   -- dataAreadId is named LegalEntity.
              T1.recversion  AS RECVERSION,
              T1.partition   AS PARTITION,
              T1.recid       AS RECID
       FROM   fmcustgroup T1
```

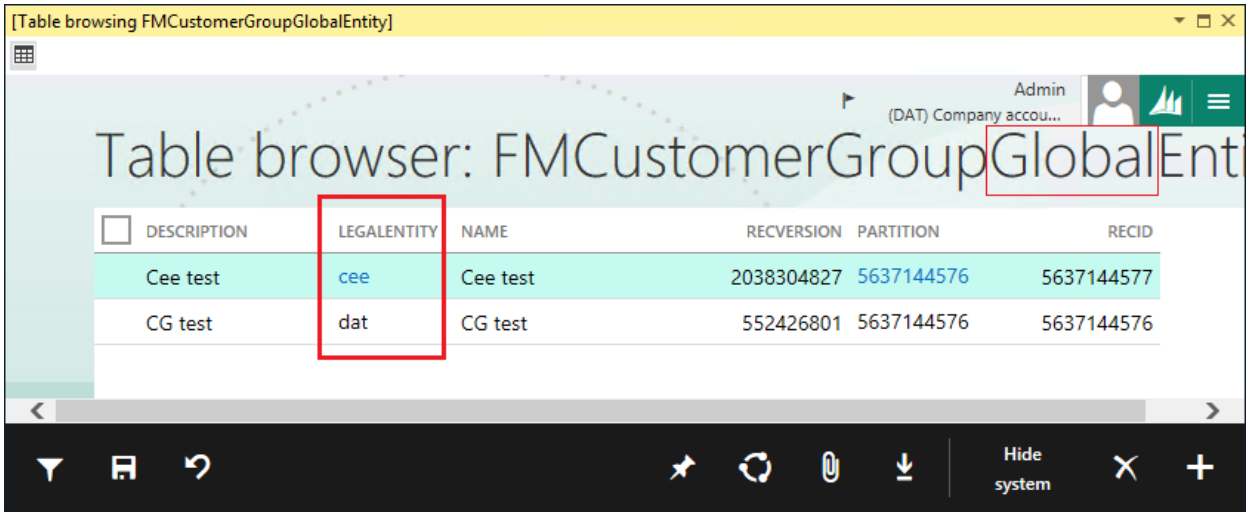
Purpose of this example

This example has two purposes:

- Show shared data by default, even though the backing table might be company-specific.
- Enable the consumer of the data entity to filter on or apply **dataAreaId** if this is required, by using the regular field that is named **LegalEntity**.

Test data

The following screenshot of the **Table browser** page shows the test data that is in the **FMCustomerGroupGlobalEntity** entity before the X++ test code is run.



X++ code

Here's how the X++ test code works with the shared entity:

- It accesses the data entity in shared mode for reads.
- It accesses the data entity with one specific company when a new record is created.

```
class GlobalCrossCompanyXPlusPlusTest
{
    /// <summary>
    /// Runs the class with the specified arguments.
    /// </summary>
    /// <param name = "_args">The specified arguments.</param>
    public static void main(Args _args)
    {
        FMCustomerGroupGlobalEntity customerGroup;

        // Reads
        // Returns record(s) for global entity from all legal entities
        while select Name,LegalEntity from customerGroup
        {
            info(strfmt("%1-%2",customerGroup.Name,customerGroup.LegalEntity));
        }

        // Writes
        // create record in company based on Legal entity
        // In this case, even without ChangeCompany, data source insert would happen
        // in company identified by Legal entity automatically. However, there is a
        // known bug around this area.
        changecompany('ceu')
        {
            customerGroup.clear();
            customerGroup.Name = "CEU test-1";
            customerGroup.LegalEntity = 'CEU';
            customerGroup.insert();
        }

        select firstonly Name,LegalEntity from customerGroup
                where customerGroup.Name == "CEU test-1";
        info(strfmt("%1-%2",customerGroup.Name,customerGroup.LegalEntity));
    }
}
```

Country/region codes and configuration keys

2/18/2021 • 2 minutes to read • Edit Online

This article provides scenarios that are applicable from an implementation perspective for both configuration keys and country/region.

Customer table schema

FIELD NAME	FIELD LABEL	COUNTRY CONTEXT
CustNum	Customer number	
CustName	Customer name	
EinvoiceEANNum	EAN	DK
FiscalCode	Fiscal code	IT

Sample data

CUSTNUM	CUSTNAME	EINVOICEEANNUM{DK}	FISCALCODE{IT}	DATAAREAID
1	Contoso Denmark	AA	{Empty}	DK
2	Contoso Italy	{Empty}	DD	IT

Sample entity

FIELD NAME	COUNTRY CONTEXT
CustomerNumber	
CustomerName	
EAN	DK
FiscalCode	IT

Scenario – Field level only

Isaac, a developer, builds a customer entity that has fields that contain regional settings. The entity is consumed through OData.

For read operations: The consumer of the entity uses this information to complete an effective regional mapping. The consumer ignores the fields that aren't required for that region. For example, consumers in Denmark (DK) are concerned with reading the values of the **EAN** field and core fields only.

For write operations: The consumer of the entity uses this information to identify only the fields that are required to populate data. The consumer expects validation to occur for regional fields and associated core fields.

Behaviors – Fields only

SCENARIO	DESCRIPTION
Design	Entities automatically inherit localization properties from underlying fields.
Design	Developers can't override or set localization properties on entity fields. These properties should be inherited only from tables. Only override on unmapped fields.
Read behavior (OData metadata)	The consumer of an entity from OData will have metadata or annotations to specify which fields are localized.
Read behavior (Data management)	In import/export fields, metadata displays country/region values, so that this information is obvious to the end user.
Read behavior	During cross-company read operations, data from localized fields is displayed only if the context matches. Note that this should already be implemented through the table/view.
Read behavior (Performance)	During company-specific read operations, localized fields are dropped from the query when the context doesn't match.
Write	During write operations to localized fields, hard errors occur if the fields don't match the context.
(Shared table)	If the data source or fields contain a country/region that is a shared (global) table, all operations are ignored, just as if no keys are applied.

Behavior – Data source

The behavior of configuration keys and a country/region that are applied at the data source resembles the behavior of fields. These values are inferred from the data source, just as if they are applied to the field level. Here's an example.

```
Entity E1

    |_ Data Source 1 (DS1)

        Field1

        Field2

    |_Data Source 2 (DS2) UK

        Field3

            Field4
```

Evaluation at the entity E1 level

```
Entity E1

|_F1

|_F2

|_F3 (UK inferred)

|_F4 (UK inferred)
```

Super types and sub types

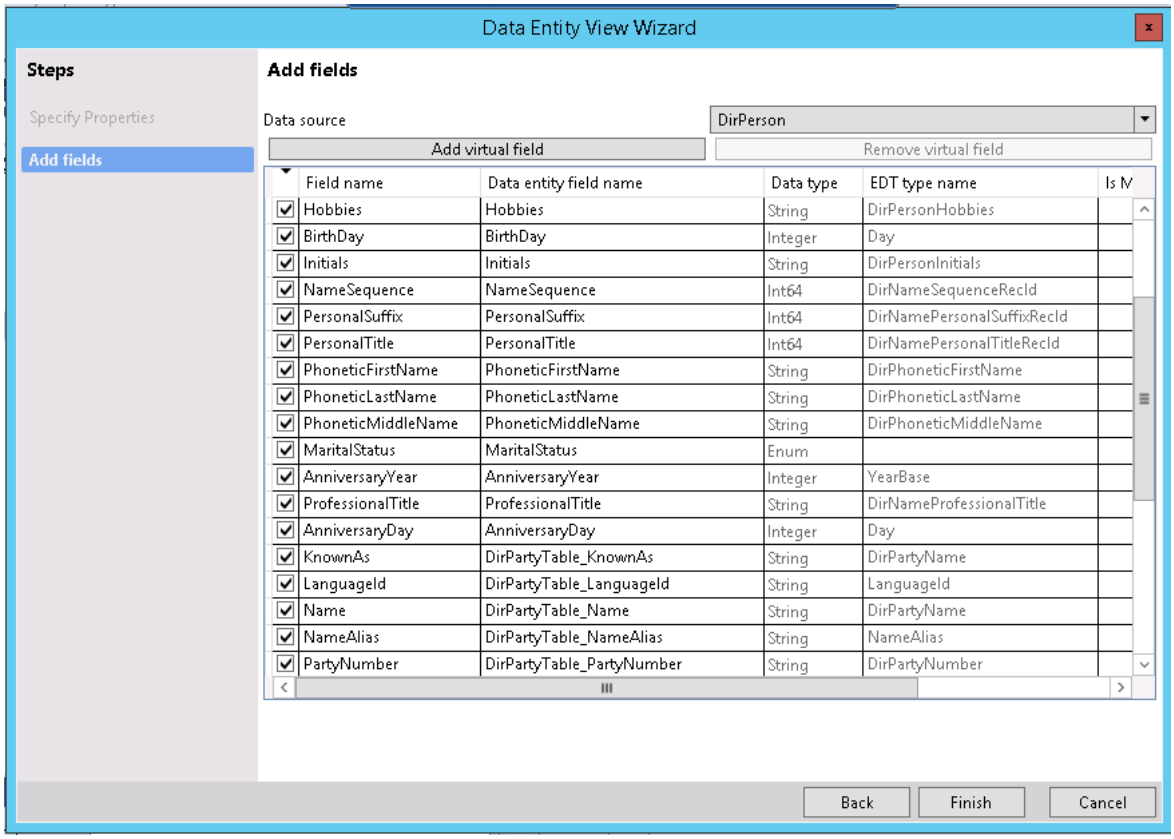
2/18/2021 • 2 minutes to read • Edit Online

Describes support for inheritance patterns in data entities.

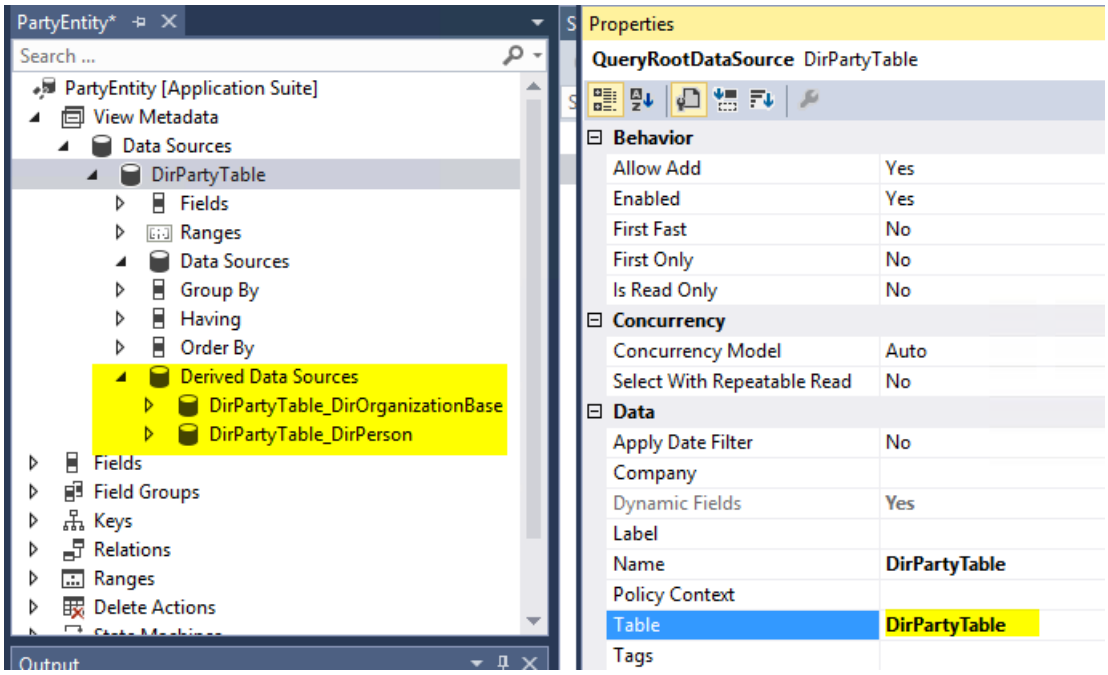
Patterns

There are several ways to create entities for tables that involve inheritance:

- **Leaf/concrete type as data source:** If a concrete type is used as a data source, fields are displayed for both the base type and the current type. For example, in the following screen shots, if DirPerson is the data source, data source fields from both DirPerson and DirPartytable appear.



- **Abstract type/non-leaf as data source:** If a non-leaf type is used as a data source, fields are displayed for both the base type and the current type, but fields from any derived types aren't displayed. Fields from derived types must be added from derived data sources, as shown in the following screen shot.

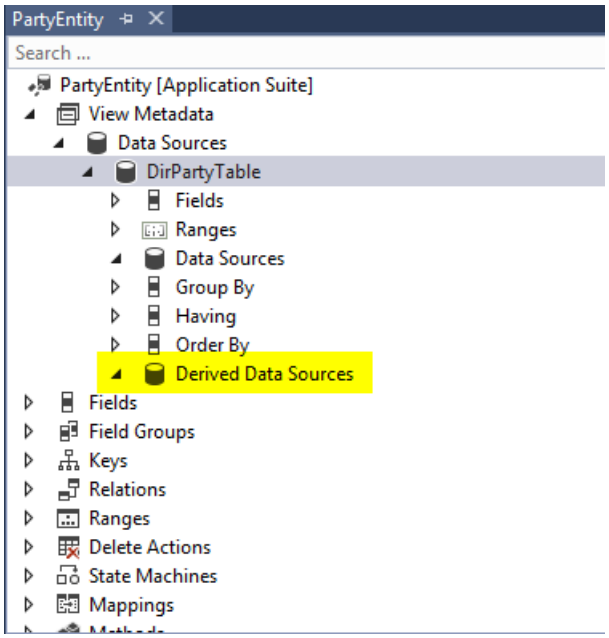


Data Entity View wizard

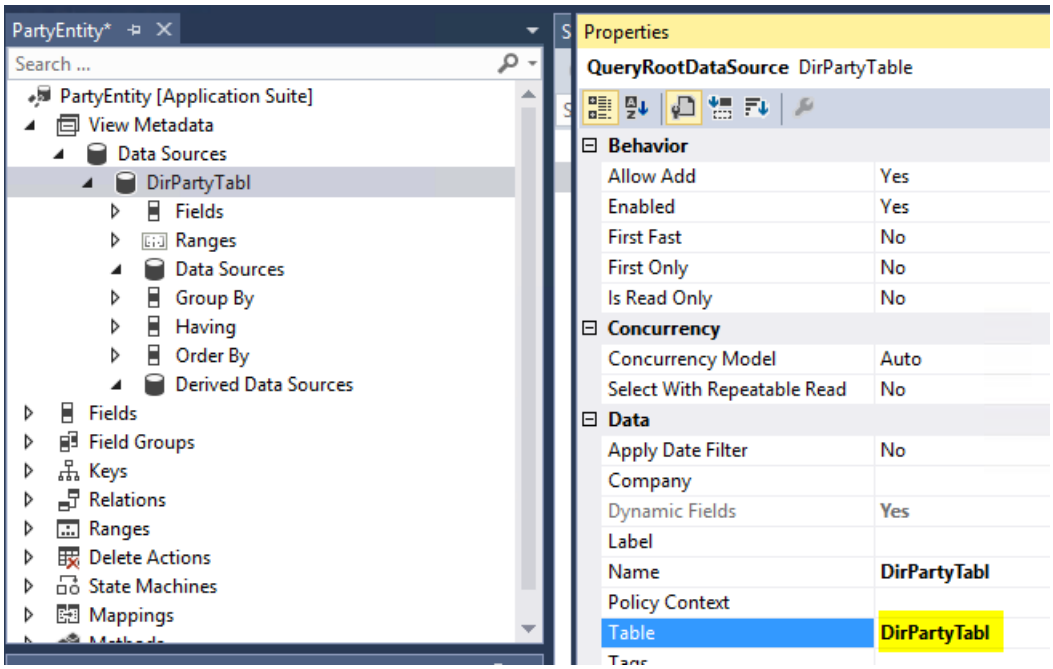
You can use the **Data Entity View** wizard to create data entities where the primary data source (and additional data sources) can be tables that are involved in inheritance.

> **NOTE**
>
> Currently, the wizard doesn't support derived data sources. It shows only fields from the current type or the base type. After you create an entity, you can manually modify it to display derived data sources.

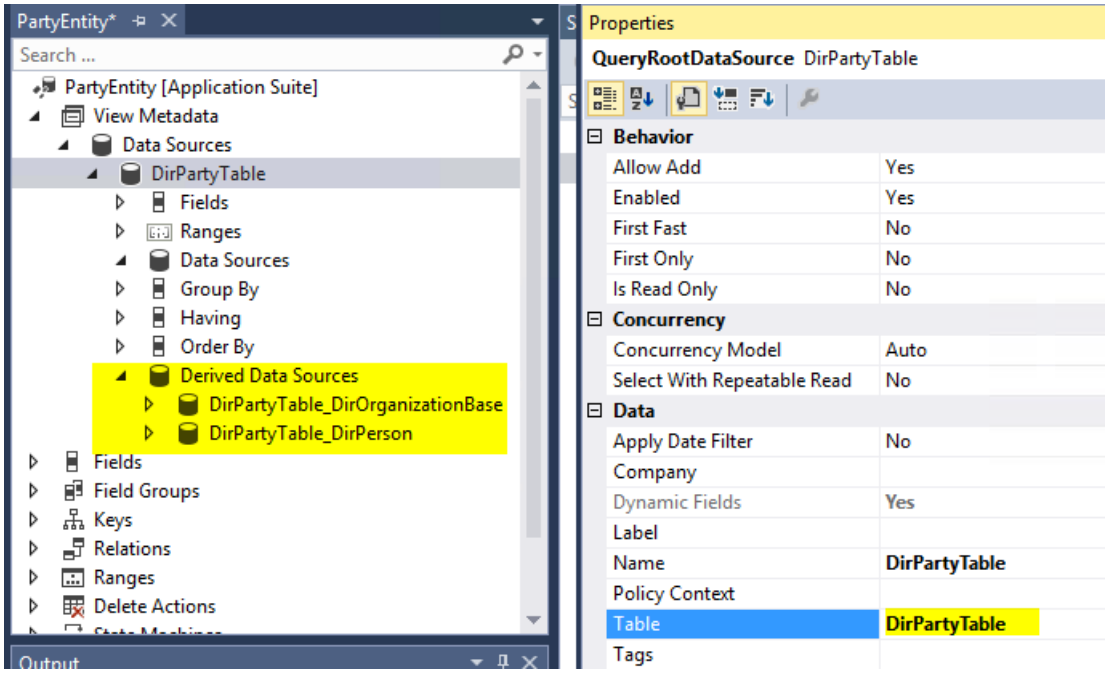
The following screen shots show a data entity that was created by using the wizard, where DirPartyTable is the primary data source.



1. Update the data source table to **DirPartyTabl**.



2. Update the data source table to **DirPartyTable**.



Run time

There is run-time behavior for entities that related to inheritance.

Creating entities for specified types

In this example, we create separate **Person** and **Organization** entities. The primary data source for the **Person** entity is DirPerson, and the primary data source for the **Organization** entity is DirOrganization. This approach, which is reflected in the following screen shots, doesn't require that you write any special run-time code.

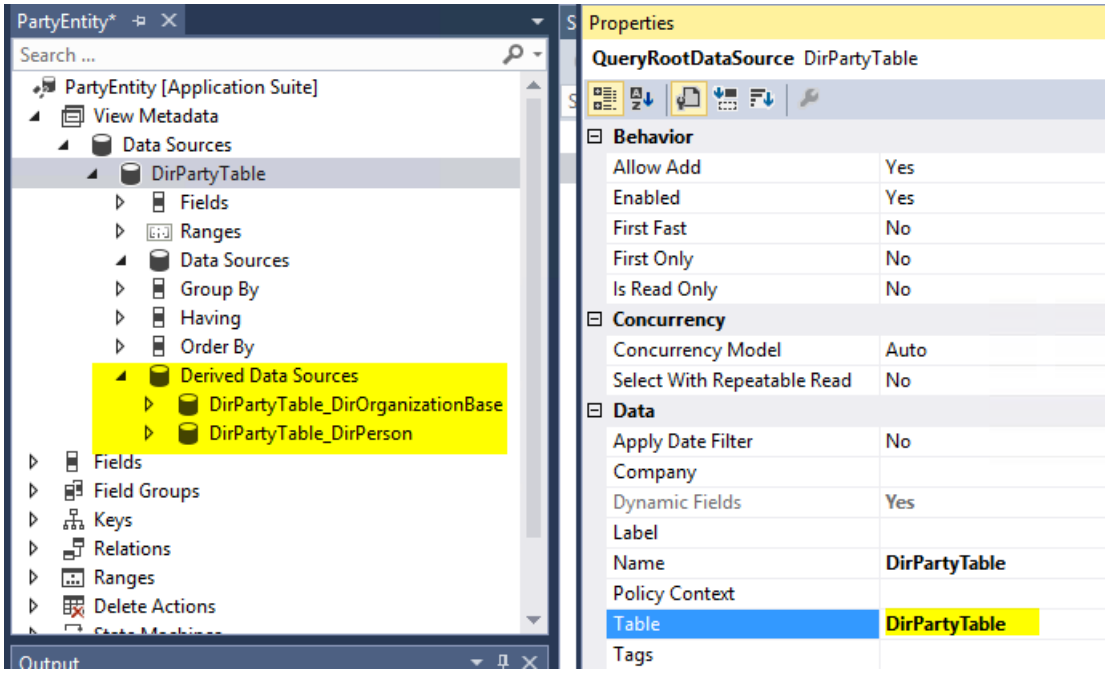
Creating entities for generalized types

In this example, we create a single entity, **Party**, that can be used for both **Person** and **Organization**. The primary data source is DirPartyTable, and derived data sources are DirPerson and DirOrganization. The new entity contains the following kinds of fields:

- **Common attributes** – Attributes that aren't specific to **Person** or **Organization**, such as **Name**. These fields are mapped to DirPartyTable.
- **Person-specific attributes** – **Gender**, **Marital Status**, and so on. These fields are mapped to derived data source DirPartyTable_DirPerson.
- **Organization-specific attributes** – **OrgNumber**, **ABC**, and so on. These fields are mapped to derived

data source DirPartyTable_DirOrganization.



Mapping fields from base and multiple derived types in a single data entity is a design-time task. However, at run time, we must specify when each derived type should be created. This can be based on fields such as **InstanceRelationType**, or a computed column can be created to use **String** to represent different types. In the **Party** entity example, a **PartyType** computed column can be created to represent the **Person** and **Organization** derived types. The following code snippet illustrates this approach.

```
    private static server str PartyType()
    {
        str type = ' CASE '+ SysComputedColumn::returnField(tablestr(PartyEntity),
            tablestr(DirPartyTable),fieldstr(DirPartyTable,instancerelationtype))  +
         ' WHEN ' + int2str(tablenum(DirOrganization)) +" THEN 'Organization' "+
        ' WHEN ' + int2str(tablenum(DirPerson)) +" THEN 'Person' "+
        " ELSE 'Party' " +
        ' END ';
        return type;
    }
```

In this example, the **Party** type is computed by using the **InstanceRelationType** column on DirPartyTable. This approach works for reading data. However, to do **Create** or **Update** operations, you must write code where you override the **initializeEntityDataSource** method on the data entity, based on type, and set a correct instance of the derived type for the data source run-time context buffer.

```
    /// <summary>
    ///
    /// </summary>
    /// <param name = "entityCtx"></param>
    /// <param name = "dataSourceCtx"></param>
    public void initializeEntityDataSource(DataEntityRuntimeContext entityCtx,
DataEntityDataSourceRuntimeContext dataSourceCtx)
    {
        DirPerson           person;
        DirOrganization     org;
        DirPartyTable       party;

        if (dataSourceCtx.name() == tablestr(DirPartyTable) &&
            (dataSourceCtx.getDatabaseOperation() == DataEntityDatabaseOperation::Insert ||
             dataSourceCtx.getDatabaseOperation() == DataEntityDatabaseOperation::Update)
           )
        {
if ( dataSourceCtx.getDatabaseOperation() == DataEntityDatabaseOperation::Update)
            {
                party = dataSourceCtx.getBuffer();
                if (this.PartyType == 'Person')
                {
                    person = party as DirPerson;
                    dataSourceCtx.setBuffer(person);
                }
                else
                {
                    org = party as DirOrganization;
                    dataSourceCtx.setBuffer(org);
                }

            }
            else
            {
                if (this.PartyType == 'Person')
                {
dataSourceCtx.setBuffer(new DictTable(tablenum(DirPerson)).makeRecord());
                }
                else
                {
dataSourceCtx.setBuffer(new DictTable(tablenum(DirOrganization)).makeRecord());
                }
            }

        }
        super(entityCtx, dataSourceCtx);
    }
```

Data entity wizard rules

2/18/2021 • 3 minutes to read • Edit Online

This topic provides information about the natural key expansion of surrogate foreign key fields and the expansion of child/parent relations.

Natural key expansion of surrogate foreign keys

A surrogate foreign key field's extended data type must be **RefRecId** or a derivative. The natural key expansion of a surrogate foreign key field uses the rules in the following list. These rules are listed in the order of evaluation.

1. **Replacement key** – The replacement key fields
2. **Primary key** – The primary index key fields
3. **Alternate key** – The first unique alternate key
4. **Auto-identification key** – The auto-identification fields

Surrogate foreign key fields that are nested in the natural key are recursively expanded. Recurring nested surrogates are limited to the first occurrence. If you select the `is mapped` property of a surrogate foreign key (that is, if you set the property to **true**), the related data source is automatically added to the entity, and the `is mapped` property of each field in the related data source's natural key is selected. In addition, any nested surrogate foreign key data sources are recursively added to the entity. If you clear the `is mapped` property of a surrogate foreign key (that is, if you set the property to **false**), the related data source are automatically removed and unmapped from the entity and any nested surrogate foreign key data sources. The effect of selecting and clearing the **is mapped** property of a surrogate foreign key field differs from the effect of using the **Add data source** and **Remove data source** buttons. If you add a surrogate foreign key data source, the **is mapped** property of the parent data source surrogate foreign key field isn't automatically set to **true**. If you are removing a surrogate foreign key data source, the **is mapped** property of the parent data source surrogate foreign key field isn't automatically set to **false**. By default, the **is mapped** property of the root data source's surrogate foreign key field is set to **true**. Therefore, by default, surrogate foreign key relations are expanded to one level.

Expansion of parent/child relations

Parent/child relations are composition/extension relations that are stored as a relation on the child table. The parent table doesn't detect the relation. A parent/child relation can be either a surrogate foreign key relation or a natural foreign key. Parent/child relations use the following rules:

- The collection of child tables is obtained by querying the cross-reference database for "type reference" relations to the parent table.
- The child table must belong to the same table group as the parent table.
- The relation between the child and parent **relationship type** property must be **association**, **composition**, **link**, or **aggregation**.
- The relation between the child and parent **cardinality** property must be **exactly one** or **zero or one**.
- The relation between the child and parent **related table cardinality** property must be **exactly one** or **zero or one**.

By default, parent/child relations aren't expanded. You must add them by using the **Add data source** button. To change the default behavior for a project in Microsoft Visual Studio, set the **Expand parent/child** option to

true.

Using label text as field names

The following rules enable label text to be used as the field name when the option is selected (**true**):

- All whitespace is removed from the label text.
- The label text is truncated to 77 characters, and then a unique three-digit numeric identifier (000 through 999) is added.
- The label text is passed to the **NamedElement.IsValid** method. If the name is valid, it can be used as the field name. Otherwise, the label text isn't used, and the field name remains unchanged.

The Is mandatory field

The default value of data entity fields is **auto**. This value is used unless it's explicitly changed. For relations, the related field's **Is mandatory** property is set based on the value of the field's **Is mandatory** value.

- If the field's **Is mandatory** property and the related field's **Is mandatory** are both **true**, both fields are explicitly set to **true**.
- If the field's **Is mandatory** property and the related field's **Is mandatory** are both **false**, both fields are explicitly set to **false**.

If the field's **Is mandatory** property and the related field's **Is mandatory** property differ in value, both fields remain unchanged. In this case, the default value of **auto** is used.

Behavioral properties on data entities

2/18/2021 • 3 minutes to read • Edit Online

Every data entity has properties that let you override the same property values on the tables or views that are the data sources of that entity. Your choices affect the behavior of the entity. In the following table, the first column lists the properties that are discussed in this topic. The top row lists the levels where the property is found in the entity designer. The levels are listed in order of increasing granularity: the data source level is more granular than the entity level but less granular than the field level.

	ENTITY LEVEL	DATA SOURCE LEVEL	FIELD LEVEL
ReadOnly	Applies	Applies	.
AllowEdit	.	.	Applies
AllowEditOnCreate	.	.	Applies
Mandatory	.	.	Applies

Entity level

In the designer for your data entity, when you click the name at the root node, the **Properties** pane includes the **Is Read Only** property. The following table describes the behavioral differences between the **Yes** and **No** values of this property.

GROUP	PROPERTY NAME	DISPLAY NAME	VALUES	DEFAULT	DESCRIPTION

GROUP	PROPERTY NAME	DISPLAY NAME	VALUES	DEFAULT	DESCRIPTION
Behavior	IsReadOnly	Is Read Only	No, Yes	No	• **No:** Data modification operations (CUD) *are* allowed, *unless* an individual data source node in the entity's designer is set to **IsReadOnly** = **Yes**. • **Yes:** Only read operations are allowed, regardless of the **IsReadOnly** settings on the individual data source nodes in the entity's designer.

You would set **IsReadOnly** to **Yes** for entities that are consumed mainly for export.

Data source level

If a data entity has three data sources, you might want to allow processes to use the entity to modify the data in one of the data sources but not in the other two. A read-only data source can be used for lookup purposes. You can use the entity designer to achieve this extra degree of granular control. Under the entity's **Metadata** > **Data Sources** node, you can select an entity node and then set the **IsReadOnly** property value for that one data source. The following table describes the interaction between the **IsReadOnly** settings at the data source level and the entity level.

GROUP	PROPERTY NAME	DISPLAY NAME	VALUES	DEFAULT	DESCRIPTION

GROUP	PROPERTY NAME	DISPLAY NAME	VALUES	DEFAULT	DESCRIPTION
Behavior	IsReadOnly	Is Read Only	No, Yes	No	• **No:** Data modification operations (CUD) *are* allowed on the data source, *unless* **IsReadOnly** is set to **Yes** at the entity level. • **Yes:** Only operations are allowed, regardless of the **IsReadOnly** setting on the entity.

Field level

At the field level, the **AllowEdit** and **AllowEditOnCreate** properties are available instead of an **IsReadOnly** property. The two **Allow** properties include **Auto** as a third available value. The **Auto** value inherits the value that is on the field in the underlying table.

> **NOTE**
> The **Auto** value isn't available for unmapped fields, such as computed or virtual fields.

GROUP	PROPERTY NAME	DISPLAY NAME	VALUE	DEFAULT	DESCRIPTION
Behavior	AllowEditOnCreate	Allow edit on create	Auto, No, Yes	Auto	• **Auto:** The property is inherited from the underlying table field. > [!NOTE] The **Auto** value

GROUP	PROPERTY NAME	DISPLAY NAME	VALUE	DEFAULT	DESCRIPTION
					isn't available for unmapped fields, such as computed or virtual fields. - **No:** Users aren't allowed to modify the data for this field in a new record. - **Yes:** Users are allowed to modify the data for this field for a new record. This behavior is enforced for all consumers – X++, OData, and so on. [!IMPORTANT] The **No** and **Yes** values do *not* override the setting on the field in the underlying table.

GROUP	PROPERTY NAME	DISPLAY NAME	VALUE	DEFAULT	DESCRIPTION
Behavior	AllowEdit	Allow edit	Auto, No, Yes	Auto	The behavior is the same as the behavior for **AllowEditOnCreate**, but it applies to updates to *existing* records instead of new records that are being created. This behavior is enforced for all consumers – X++, OData, and so on.
Behavior	Mandatory	Mandatory	Auto, No, Yes	Auto	**Auto:** The property is inherited from the underlying table field. This behavior is enforced for all consumers – X++, OData, and so on. [!IMPORTANT] The **No** and **Yes** values do *not* override the setting on the field in the underlying table.

Validations, default values, and unmapped fields

2/18/2021 • 7 minutes to read • Edit Online

This topic describes how data entity values are validated, how default values can be provided, and how to use fields that are not mapped to data source values, but instead contain virtual or computed data (unmapped fields).

Validations

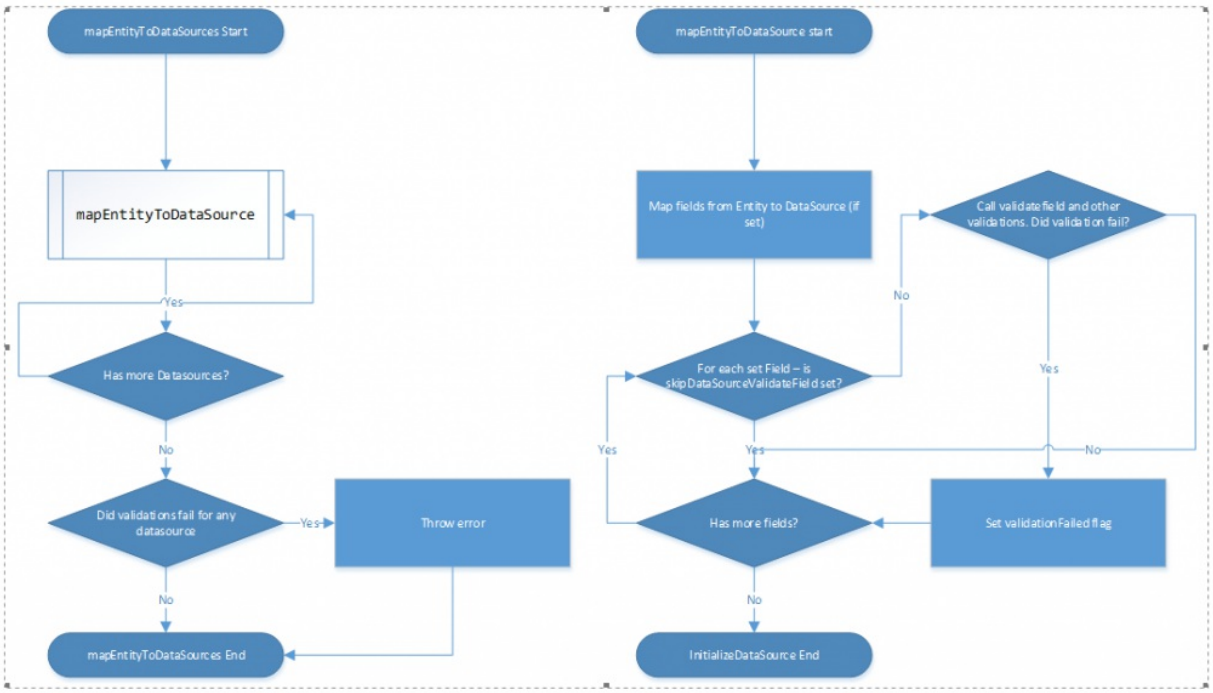
Validations can be defined on the tables that back up entities, at both the field level and the record level. Validations can also be defined at the data entity level.

Table (data source) vs. entity validation

Entities are backed by tables (data sources), and validations are defined for these tables at both the field level (**Table.validateField()**) and the record level (**Table.validateWrite()**). The validations are respected by data entities that are built by using those tables. Although these validations are intrinsic to the tables that back a data entity, validations can also be defined at the data entity level. Like table-based validations, entity-based validations can be written at the field level (**DataEntity.validateField()**) or the record level (**DataEntity.validateWrite()**).

Table-based validation behavior

Table validations are fired automatically as a part of the CUD operations. **Table.ValidateField, AllowEdit, AllowEditOnCreate** Field-level validations are fired automatically when you perform inserts or updates on the data entity. This is true for all paths (X++, OData, and so on). These validations occur during the mapping process, when fields are mapped from an entity to individual data sources.

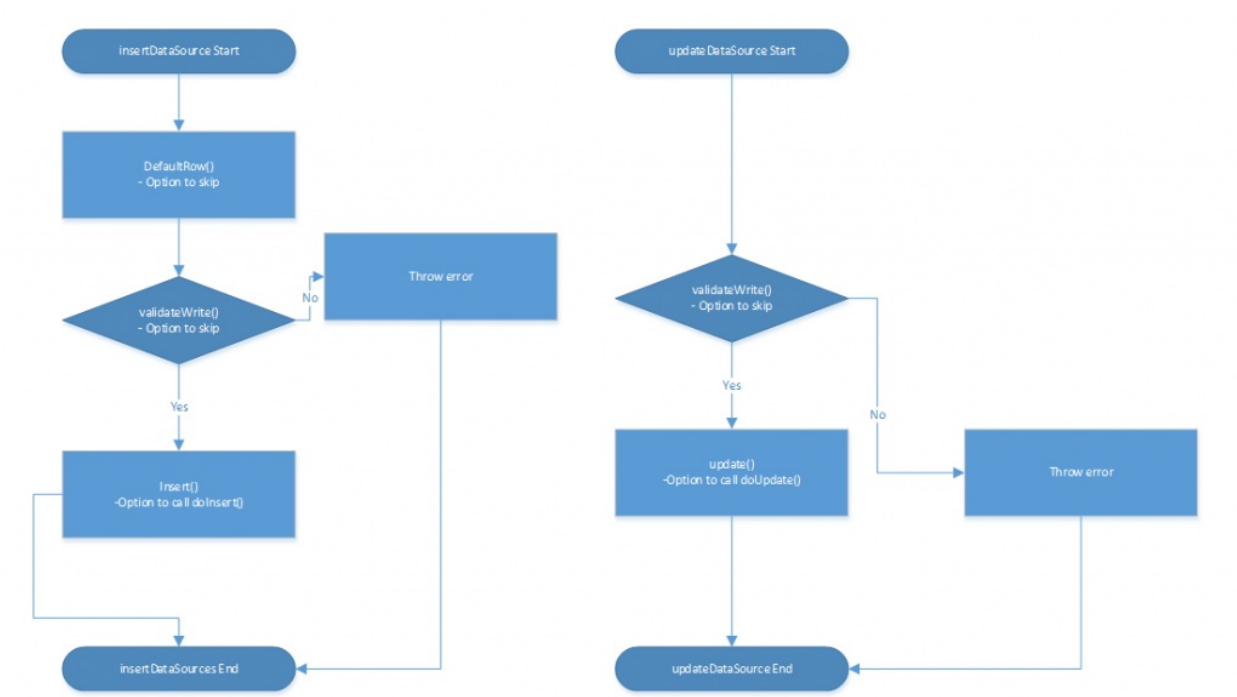


After the field values from the data entity are copied to mapped data source fields, field validations are run on the set fields. Validations include table-level **validateField**, which validates **AllowEdit** and **AllowEditOnCreate**. If a validation fails because of an error, validation for the remaining fields continues. Finally, validation checks whether any error occurred during the validation process for any of the data sources. If there was an error, the process errors out at this point, and table-level **validateWrite()** isn't called. To skip

validateField for a back-end table, a consumer can call **DataEntity.skipDataSourceValidateField(Int _DataEntityFieldId, Boolean _skip)**. Note that the field ID for this method is the field ID of the data-entity mapped field, not the back-end table field. By using the following API, you can skip validation for a particular field, regardless of the consumer.

```
/// <summary>
///
/// </summary>
/// <param name = "entityCtx"></param>
public void persistEntity(DataEntityRuntimeContext entityCtx)
{
    this.skipDataSourceValidateField(<FieldId>,true)
    super(entityCtx);
}
```

Table.ValidateWrite Record-level **ValidateWrite** validations that are defined in back-end tables are fired automatically when you perform data-entity inserts and updates. This is true for all paths (X++, OData, and so on). These validations occur just before the actual insert or update is applied to the data source. If the validation fails, an error is thrown, and the process stops for other data sources.



To skip **validateWrite** for all back-end tables for a data entity, a consumer can call **DataEntity.skipDataSourceValidateWrite(Boolean _skip)**. This method turns **validateWrite** on or off for all data sources. By using the following API, you can skip validation for a particular field, regardless of the consumer.

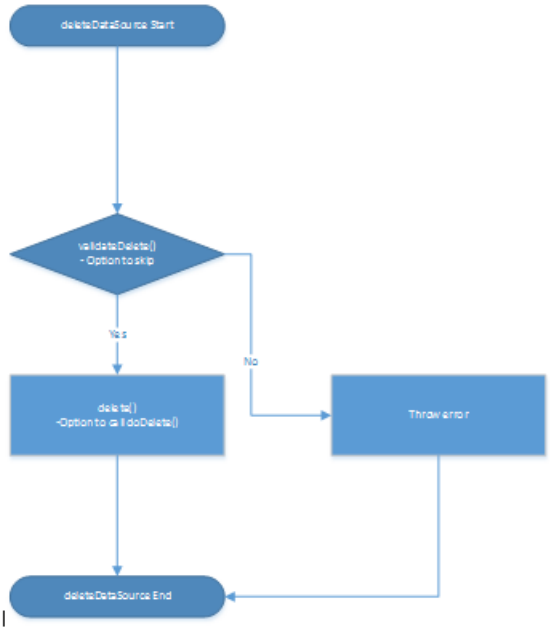
```
    /// <summary>
    ///
    /// </summary>
    /// <param name = "entityCtx"></param>
    /// <param name = "dataSourceCtx"></param>
    /// <returns></returns>
    public boolean saveEntityDataSource(DataEntityRuntimeContext entityCtx,
DataEntityDataSourceRuntimeContext dataSourceCtx)
    {
        boolean ret;

        if (entityCtx.getDatabaseOperation() == DataEntityDatabaseOperation::Insert && dataSourceCtx.name()
== tablestr(DirPartyTable))
        {

        dataSourceCtx.skipValidateWrite(true);
}
        ret = super(entityCtx, dataSourceCtx);

        return ret;
    }
```

Table.ValidateDelete Record-level **ValidateDelete** validations that are defined in back-end tables are fired automatically when you perform data entity deletes. This is true for all paths (X++, OData, and so on). These validations occur just before the delete is applied to the data source. If the validation fails, an error is thrown, and the process stops for other data sources.



To skip **validateDelete** for all back-end tables for a data entity, a consumer can call **DataEntity.skipDataSourceValidateDelete(Boolean _skip)**. This method turns **validateDelete** on or off for all data sources. By using the following API, you can skip validation for a particular data source, regardless of the consumer.

```
    /// <summary>
    ///
    /// </summary>
    /// <param name = "entityCtx"></param>
    /// <param name = "dataSourceCtx"></param>
    /// <returns></returns>
public boolean saveEntityDataSource(DataEntityRuntimeContext entityCtx,
DataEntityDataSourceRuntimeContext dataSourceCtx)
       {
        boolean ret;

        if (entityCtx.getDatabaseOperation() == DataEntityDatabaseOperation::Delete && dataSourceCtx.name()
== tablestr(DirPartyTable))
        {
            dataSourceCtx.skipValidateDelete(true);
        }
        ret = super(entityCtx, dataSourceCtx);

        return ret;
       }
```

Entity-based validation behavior

VALIDATION	TARGET	CALLER
DataEntity.ValidateField	• Data types • Mandatory relationships (both tables and extended data types [EDTs]) • Any custom validation • Doesn't call **validateField** for underlying mapped table fields	• Is called automatically from OData • Is called by the form engine when a field is modified • Isn't called automatically if an insert/update is fired from X++ code
DataEntity.ValidateWrite	• Mandatory columns • Relationships (both tables and EDTs) • Any custom validation • Doesn't call table-level **validateWrite** for underlying tables	• Is called automatically from OData • Is called by the form engine when a record is saved. • Isn't called automatically if an insert/update is fired from X++ code
DataEntity.ValidateDelete	• DeleteActions • Any custom validation • Doesn't call table-level **validateDelete** for underlying tables	• Is called automatically from OData. • Is called by the form engine when a record is deleted • Isn't called automatically if a delete is fired from X++ code

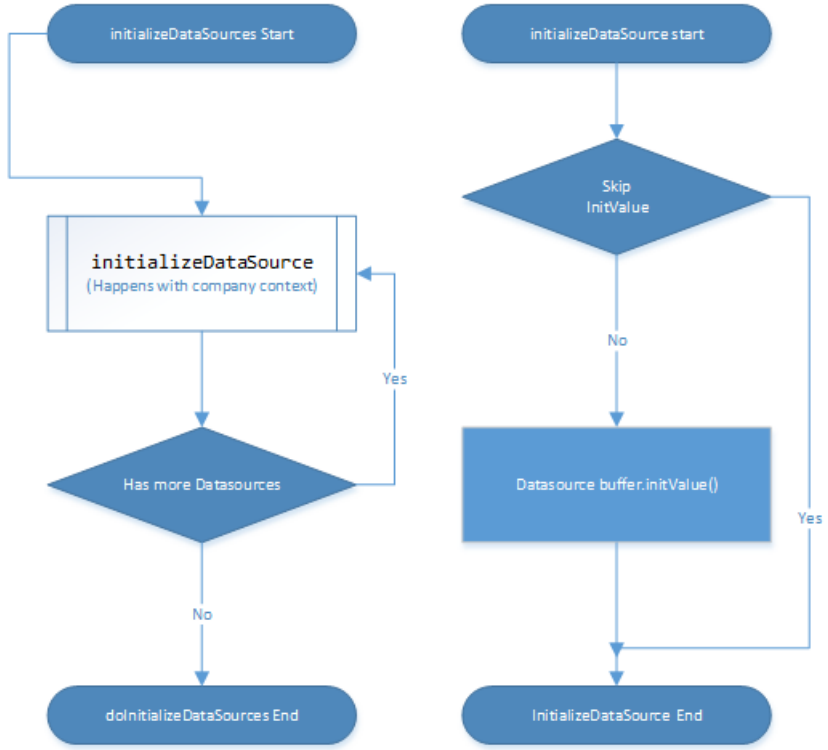
Defaults

Default values can be provided for initializations and rows.

Initializations

DataEntity.initValue: A data entity is initialized with default values and by using any custom logic that is present in entity-level **initValue**. This method isn't called automatically when an insert or update is performed on a data entity from X++. It must be called explicitly if it's required. The method is called automatically by the form engine when a new record is created. **DataEntity.initValue** doesn't call the **initValue** method for back-end tables that are used in the data entity. **Table.initValue:** Table-level **initValue**, as defined for back-end tables, is fired when you perform a data entity insert. This is true for all paths (X++, OData, and so on). **Table.initValue**

is run just before the entity is mapped to data source fields.



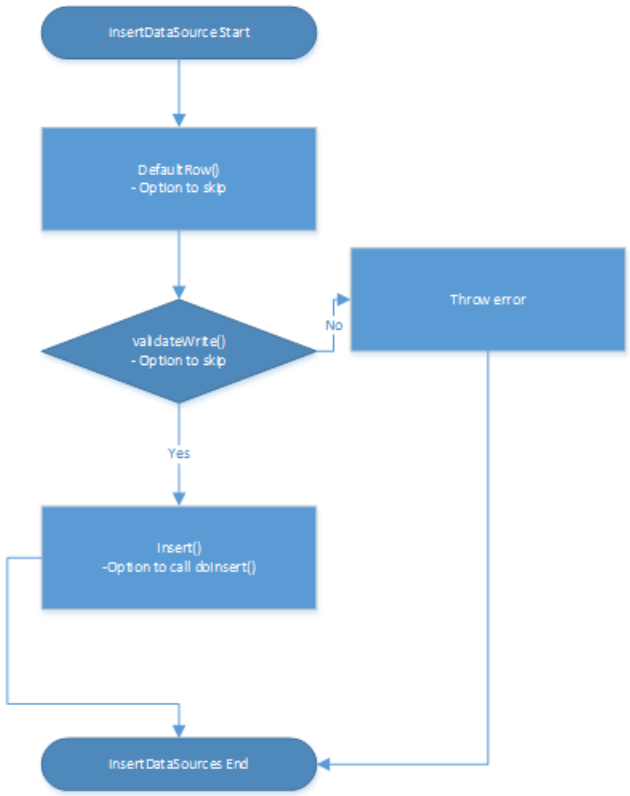
To skip entity-level **initValue** for all back-end tables for a data entity, a consumer can call **DataEntity.skipDataSourceInitValue(Boolean _skip)**. This method turns **initValue** on or off for all data sources. By using the following API, you can skip **initValue** for a particular field, regardless of the consumer.

```
    /// <summary>
    ///
    /// </summary>
    /// <param name = "uvCtx"></param>
    /// <param name = "uvdsCtx"></param>
public void initializeEntityDataSource(DataEntityRuntimeContext uvCtx, DataEntityDataSourceRuntimeContext
uvdsCtx)
    {

        if (uvdsCtx.name() == tablestr(DirPartyTable)
&& uvdsCtx.getDatabaseOperation() == DataEntityDatabaseOperation::Insert)
        {
            uvdsCtx.skipInitValue(true);
        }
        super(uvCtx, uvdsCtx);
    }
```

DefaultRow

DataEntity.DefaultRow: DataEntity.DefaultRow is used in conjunction with **defaultField** and **getDefaultingDependencies** to provide defaults. It isn't called automatically by X++ or the form engine. **Table.DefaultRow: Table.DefaultRow** is called automatically for each data source after mapping is completed, and before the insert and validation on the data source.



Unmapped fields

A data entity can have *unmapped* fields in addition those fields that are directly mapped to fields of the data sources. There are two mechanisms for generating values for unmapped fields:

- Custom X++ code
- SQL that is run by Microsoft SQL Server

The two types of unmapped fields are *virtual* and *computed*. Unmapped fields always support read actions, but the feature specification might not require any development effort to support write actions.

Virtual field

- A non-persisted field.
- Controlled by custom X++ code.
- Read and writes occur through custom X++ code.
- Typically used for intake values that are calculated by using X++ code and can't be replaced by computed columns.

Computed field

- The value is generated by an SQL view computed column.
- During reads, data is computed by SQL and fetched directly from the view.
- For writes, custom X++ code must parse the input value and then write the parsed values to the regular fields of the data entity. The values are stored in the regular fields of the data sources of the entity.
- Used mostly for reads.
- It's a good idea to use computed columns instead of virtual fields whenever you can, because computed columns are computed at the SQL Server level, whereas virtual fields are computed row by row in X++.

Properties of unmapped fields

CATEGORY	NAME	TYPE	DEFAULT VALUE	BEHAVIOR
Data	IsComputedField	NoYes	Yes	• **Yes:** The field is synchronized as a SQL view computed column. An X++ method is required to compute the SQL definition string for the column. The virtual column definition is static and is used when the entity is synchronized. After that, the X++ method isn't called at run time. • **No:** The field is a true virtual field, where inbound and outbound values are fully controlled through custom code.
Data	ComputedFieldMethod	String		A static **DataEntity** method in X++ is used to build the SQL expression that generates the field definition. This property is disabled and irrelevant if the **IsComputedField** property is set to **No**. The method is required if the **IsComputedField** property is set to **Yes**.
Data	ExtendedDataType	String		

Unmapped field comparison

	VIRTUAL FIELD	COMPUTED FIELD

	VIRTUAL FIELD	COMPUTED FIELD
Metadata properties	Is computed = No	• Is Computed = Yes • Computed Field Method = static method
Read	• X++ (override **postLoad**) • Row by row	• SQL computed column • Set-based read possible
Write	X++ (override **mapEntityToDataSource**)	X++ (override **mapEntityToDataSource**)
Advantages	• Unbound to the schema, keeps the public contract the same, but the implementation can change • Call X++ methods	Faster reads, large export can occur directly from the view

Examples

The following table provides a computed example if a **UnitOfMeasure** relationship exists, and displays that in an unmapped field.

VIRTUAL FIELD	COMPUTED FIELD
On postLoad()*//Check to see if record exists in UnitOfMeasureInternalCode.UnitOfMeasure//Set hasFixedInternalCode value based on the field*if(this.UnitOfMeasure)this.HasFixedInternalCodeVirtual = NoYes::Yes; else this.HasFixedInternalCodeVirtual = NoYes::No;	On computedFieldMethod()*//Desired SQL computed column statement(CASE WHEN T2.RECID IS NULL THEN 0 ELSE 1 END) AS INT)*

Security and data entities

2/18/2021 • 7 minutes to read • Edit Online

> **NOTE**
> Data entities do not support the Extensible Data Security (XDS) concepts.

Entry points

Data entities support entry point security. This support resembles the support that menu items and pages have. To give you flexibility when you define a security model, data entities allow for a separate security configuration for each integration mode. Currently, two entry points/integration modes are identified for a data entity.

ENTRY POINT	DESCRIPTION
Data services	The ability to use OData services (API) for the entity.
Data management	The ability to use asynchronous integration options for the entity, such as import/export and connector integration.

Target scenarios

Data entities can support multiple categories of scenarios. Each category might have to be secured separately.

- **Data management (file-based import/export, and so on)** – Typically, a data manager performs these scenarios. These scenarios might provide access to data that isn't usually accessible through the UI for the client. Therefore, you will often want to secure data management scenarios independently of access to the related page, so that a data manager can perform only import/export operations.
- **General integration via OData** – Many integration scenarios require that data entities be exposed as services, so that data can be accessed via OData (for example, from an online storefront or a Process Lifetime Management [PLM] system). Often, you will want to control access to data entities that are built for this purpose independently of page access. In other words, you will want to grant access to the service interface without granting access through the client UI.
- **Microsoft Office integration (Edit in Excel, and so on)** – Office integration scenarios also require that data entities be accessed via OData. However, from an end-user perspective, these scenarios can be viewed as a natural extension of the client, where, for example, Microsoft Excel is used to simplify some editing tasks. Therefore, there is usually no reason to secure the Microsoft Office integration independently of page access.

Privilege/duty mapping

Depending on the target scenarios for a data entity, you should create one or more new privileges, and extend existing duties. Alternatively, you can map the new privileges to duties that are created specifically for the target scenario. This approach helps guarantee that no user is granted more access than the user requires for the scenario.

The following table shows the privileges that you should create. It also explains how you should map these privileges to duties. If your data entity is intended to support more than one scenario, you should create the combined set of privileges and duty mappings.

TARGET SCENARIO	PRIVILEGES	DUTY MAPPING

The data entity is intended for data management.	Create the following new privileges:
	• *<DataEntity>***Import**
	  ○ Grant=Create
	  ○ IntegrationMode=Data Management
	• *<DataEntity>***Export**
	  ○ Grant=Read
	  ○ IntegrationMode=Data Management
		Extend the relevant data management duties with the new privileges. For more information, see the "Data administrator role" section later in this topic.

The data entity is intended for general integration via OData.	Create the following new privileges:
	• *<DataEntity>***View**
	  ○ Grant=Read
	  ○ IntegrationMode=Data Services
	• *<DataEntity>***Maintain**
	  ○ Grant=Delete
	  ○ IntegrationMode=Data Services
		Create new duties for the integration scenario, and map the relevant new privileges to these duties. For more information, see the "Duty naming guidelines" section later in this topic.

The data entity is intended for Microsoft Office integration.	Create the following new privileges:
	• *<DataEntity>***View**
	  ○ Grant=Read
	  ○ IntegrationMode=Data Services
	• *<DataEntity>***Maintain**
	  ○ Grant=Delete
	  ○ IntegrationMode=Data Services
		Extend the relevant existing duties that provide access to the related pages with the new privileges.

Because the approach that is described in the preceding table complies with the principle of least privilege, we recommend that you use it. Nevertheless, in some situations, you can use the following simpler approach. However, be aware that this approach might be less secure. It might also be slightly harder to maintain and extend.

TARGET SCENARIO	PRIVILEGES	DUTY MAPPING	POTENTIAL ISSUES

The data entity is intended for data management, general integration via OData, and Microsoft Office integration.	Create the following new privileges:
	• *<DataEntity>***View**
	  ○ Grant=Read
	  ○ IntegrationMode=All
	• *<DataEntity>***Maintain**
	  ○ Grant=Delete
	  ○ IntegrationMode=All
		1. Extend the relevant data management duties with the new privileges.
		2. Create new duties for the integration scenario, and map the relevant new privileges to these duties.
		3. Extend the relevant existing duties that provide access to the related page with the new privileges.
			When you use this approach, a data manager who is granted access to import/export data can also access the system from a web service. Likewise, a user who is granted access to the page that is associated with a data entity can also access the system from a web service. This user will be prevented from data import/export only if the user hasn't been granted the related data management duty.

Duty naming guidelines

When you create data entities for specific integration scenarios, you should also create separate duties. These duties grant the external application or service the required access to the data entities. The duties that you create should follow the same naming guidelines as the corresponding duties that provide access through the client UI. However, you should add a "using services" suffix.

DUTY TYPE	DUTY OBJECT NAME SUFFIX	DUTY NAME TEMPLATE
Enable	...IntegrationEnable	Enable ... using services
Record	...IntegrationMaintain	Maintain ... using services
Authorize	...IntegrationApprove (Release, Confirm, Journalize)	Approve (Release, Confirm, Journalize) ... using services
Inquire	...IntegrationInquire	Inquire into ... using services

Here are some examples of duty names that follow these guidelines:

- Maintain route master using service
- Inquire into case progress using services

Data administrator role

The **DataManagementApplicationAdministrator** security role enables an associated user to have full import/export capabilities in the **Data management** workspace. This security role has two security duties for each of the five data entity categories that are assigned to it. One duty is for importing data via data entities of the associated category, and one for exporting data via data entities of the associated category. Therefore, a total of 10 security duties are assigned to this security role:

- DataManagementApplicationDocumentEntitiesMaintain
- DataManagementApplicationDocumentEntitiesView
- DataManagementApplicationMasterEntitiesMaintain
- DataManagementApplicationMasterEntitiesView
- DataManagementApplicationParametersEntitiesMaintain
- DataManagementApplicationParametersEntitiesView
- DataManagementApplicationReferenceEntitiesMaintain
- DataManagementApplicationReferenceEntitiesView
- DataManagementApplicationTransactionEntitiesMaintain
- DataManagementApplicationTransactionEntitiesView

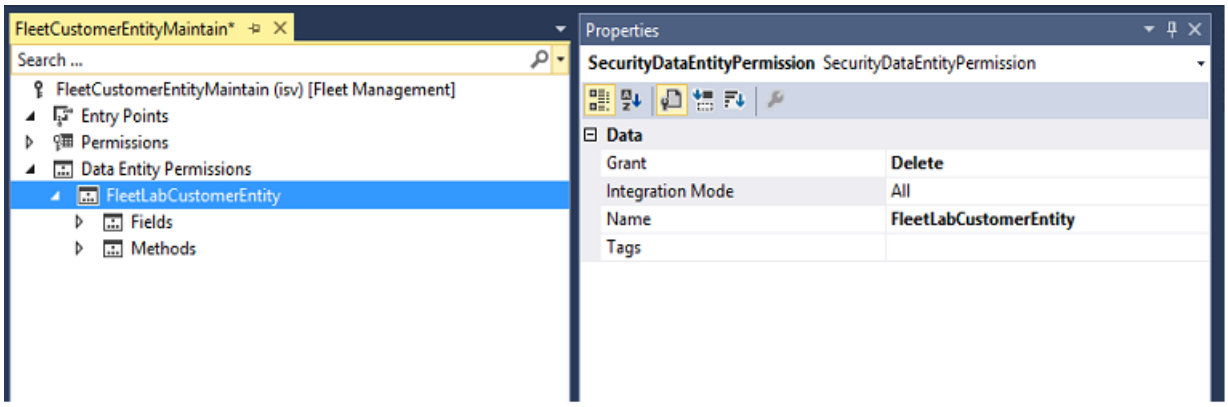
When you create data entities that can be used in the **Data management** workspace, you must extend these duties with the new security privileges, based on the **Entity Category** property that is specified on the data entity. (For information about how to extend duties with the new security privileges, see the "Privilege/duty mapping" section earlier in this topic.) You can also use the duties to create new roles for specific data management scenarios.

Modeling new entry point security in the Application Explorer

The pattern for modeling security resembles the pattern for modeling security with privileges on an entry point. To model security, follow these steps.

1. Create a new privilege.

2. Create new data entity permissions.
3. Set the **Name** to **Data Entity**.
4. Select the **Access Level**.
5. Select **Integration Mode** (All > Data Services > Data Management). This is specific to Object Type: Data Entity.
    - **All** – Applies same security settings to be applied to both OData and data import/export.
    - **Data Management** – Applies only to data import/export and connector integration.
    - **Data Services** – Only applies to OData Services.



Sensitive data

The Table Protection Framework (TPF) enables strict access control to data that is stored in Finance and Operations. This feature is exposed through the AOSAuthorization property on tables and table fields. If you mark a table or field by using AOSAuthorization, the security framework now requires that a user be granted explicit access to that resource. This requirement also applies when the table or field is accessed through data entities. This section describes the guidelines for granting TPF permissions for data entities.

Data management

For data entities that are targeted at data migration, you should assign TPF permissions to the corresponding import/export privileges. In this way, you help guarantee that all data can be imported and exported.

Integration by using OData

For data entities that are targeted at integration scenarios, the TPF permissions that you should assign depend on whether the TPF-protected field is essential for the data entity as a whole to work:

- **If the TPF-protected field is essential**: An essential field is a field that will always be read/written. In this case, TPF permissions should be granted to the same privileges that grant access to the data entity.
- **If the TPF-protected field isn't essential**: Examples of nonessential fields include the field for a worker's Social Security number and the field for a vendor's bank account number. In this case, TPF permissions for accessing the field should be granted through a separate privilege, and that privilege should be assigned directly to the roles that require access to the TPF-protected field. However, if the field is a mapped field on the entity, that access has probably already been granted to the role, if that role also has access to the field through pages in the client UI.

There are several advantages to granting explicit access to TPF-protected fields that aren't considered essential for the entity:

- You can more easily discover who has access to sensitive data.
- You help reduce the risk that someone will gain access to sensitive data by accident, because a role gains

access only if you assign both a duty and a privilege to it.

NOTE

Can you tell us about your documentation language preferences? Take a short survey.

The survey will take about seven minutes. No personal data is collected (privacy statement).

Test services by using third-party utilities

2/18/2021 • 7 minutes to read • Edit Online

At https://github.com/Microsoft/Dynamics-AX-Integration, Microsoft provides sample code for consuming services. However, there are many scenarios where the other endpoint in an integration might not use a Microsoft stack. Even when the other endpoint does use, for example, the Open Data Protocol (OData) client code that Microsoft makes available, you might find it useful to perform the following actions:

- Explore and analyze how an interaction's messages are constructed.
- Test the response of a service to a well-known request.
- Determine how exceptions will appear to the other endpoint.

Many frequently used tools that will help you perform these actions are available. This topic isn't an endorsement of any tool. Although it provides examples that use some frequently used software utilities, the principles should broadly apply to other, similar tools.

Prerequisites

Before you can test a service by using an external application, you must register the application in Microsoft Azure, and in Finance and Operations.

For details, see:

- Register an application with AAD
- Register your external application

Query OData by using Postman

Postman (https://www.getpostman.com/postman) is a tool that is often used to interact with RESTful services (such as OData) in scenarios that involve the development and testing of application programming interfaces (APIs). This procedure isn't an endorsement of Postman, and other similar tools are available. However, we are using Postman to illustrate the concepts and messages that are involved when you use OAuth to authenticate with Azure AD, and then make OData requests to and receive responses from the application.

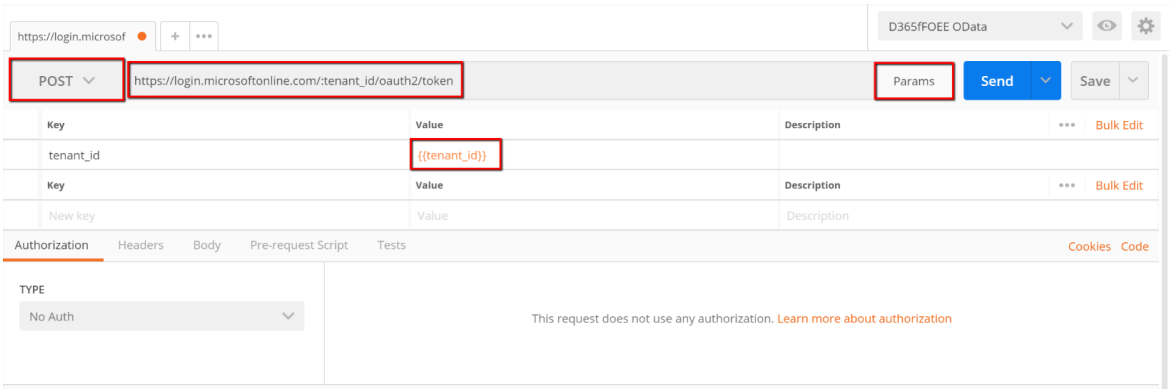
1. Start Postman.
2. In the upper-right corner, select the gear button, and then select **Manage environments** to create or update an environment.
3. Enter a name for the environment, and then select **Bulk Edit**.
4. Enter key-value pairs as shown in the following table. Enter one pair per line, and separate the key and value by using a colon (:).

KEY	VALUE
tenant_id	The Azure tenant ID that you looked up during the setup of prerequisites
client_id	The Azure AD application ID that you registered during the setup of prerequisites

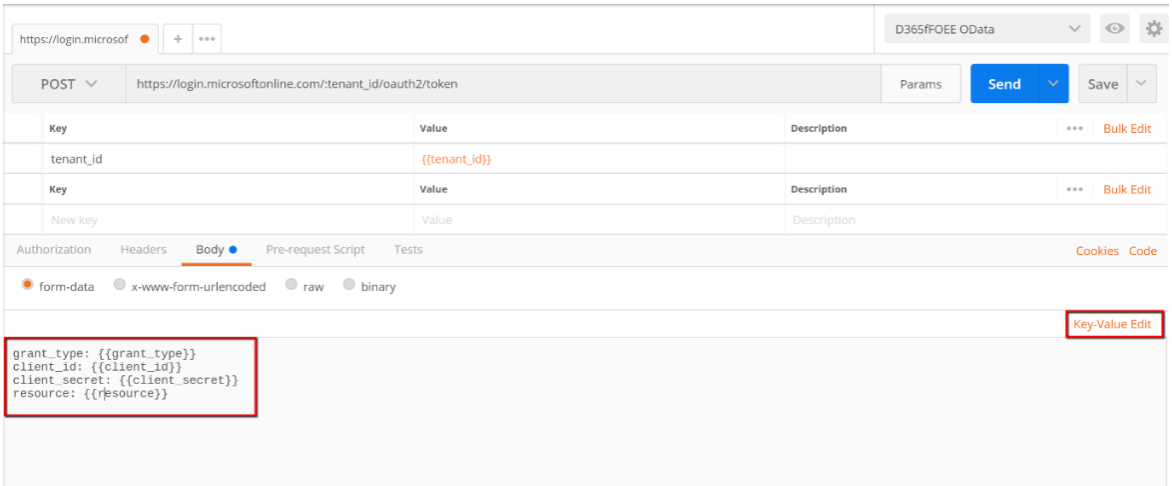
KEY	VALUE
client_secret	The secret key that you generated during application registration during the setup of prerequisites
grant_type	client_credentials
resource	The base URL of the instance without the trailing '/'

5. To verify that the key-value pairs can be parsed correctly, select **Key-Value Edit**, and review the results.
6. Close the environment page.
7. In the field to the left of the gear and eye buttons, select the new or updated environment.
8. To retrieve an Azure AD token, create a POST request that has a URL in the format `https://login.microsoftonline.com/[tenant ID]/oauth2/token`.

   You can use a URL parameter that refers to the **tenant_id** environment variable, such as `https://login.microsoftonline.com/:tenant_id/oauth2/token`.



9. On the **Body** tab, add body elements as request parameters that refer to the environment variables that you created earlier. Select **Bulk Edit**, enter the keys from the previous table, enter a colon (:), and then enter the key name again but enclose it in double braces ({{}}). Enter one request parameter per line. For example, enter **grant_type:{{grant_type}}**. Here is an example.

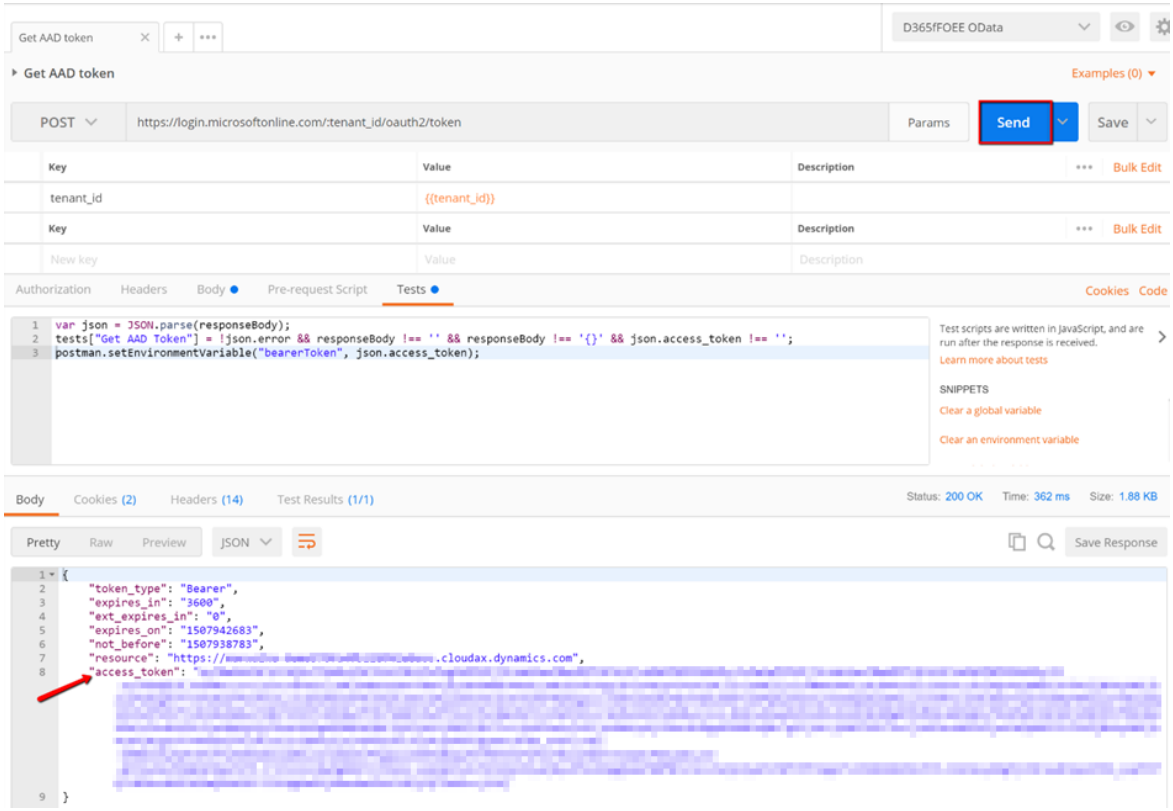


10. On the **Tests** tab, create a test that validates that the response is reasonable, and that stores the returned authorization token in an environment variable. Here is an example.

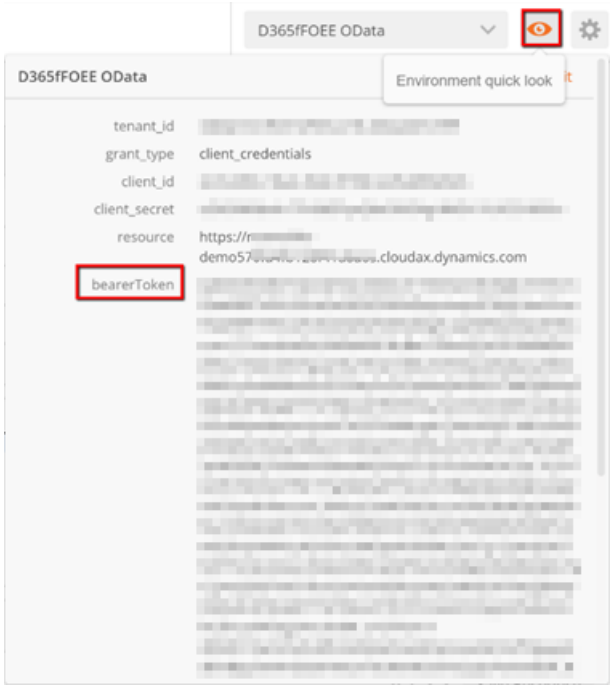
```
var json = JSON.parse(responseBody);
tests["Get Azure AD Token"] = !json.error && responseBody !== '' && responseBody !== '{}' &&
json.access_token !== '';
postman.setEnvironmentVariable("bearerToken", json.access_token);
```

11. Select **Save**, enter a name and collection for the request, and then select **Save** again.

12. Select **Send** to make the authorization request. The **Body** tab should now contain an Azure AD token together with other response details.



13. Because of the test code, the token is now in an environment variable. You can see that the token is an environment variable by selecting the **Environment quick look** button (the eye button).

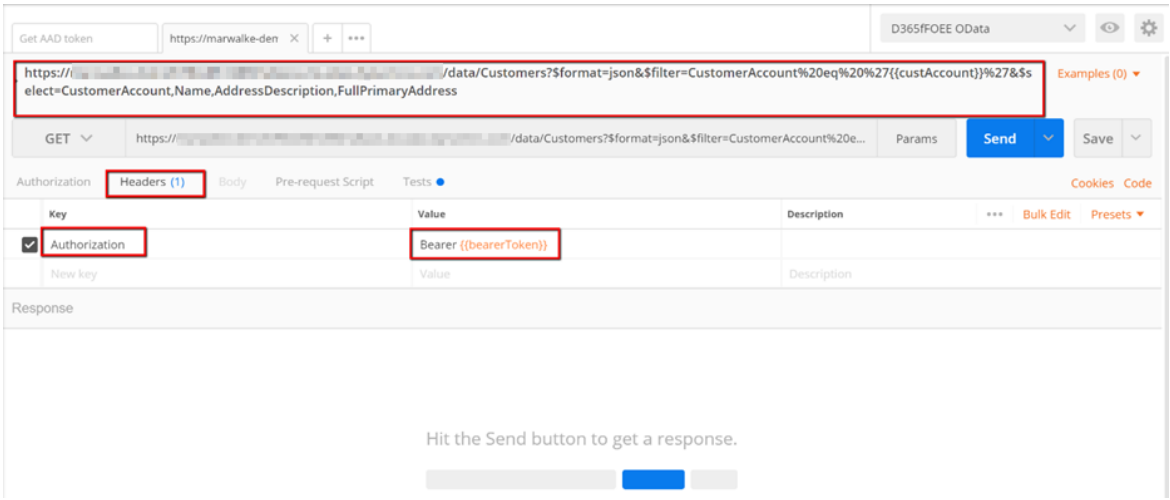


14. Create a request to perform create, read, update, or delete (CRUD) operations on the desired data entity

via the OData service. Create the URL according to your requirements. For more information, see Open Data Protocol (OData). You might find it useful to parameterize the request by using a variable that is stored in the environment, as shown earlier. The following example of a GET query uses a **Customer Account** parameter. The query returns name and address details for the customer account that is specified in the environment variable. Note that special characters must be correctly URL-encoded.

```
https://[Finance and Operations instance URL]/data/Customers?
$format=json&$filter=CustomerAccount%20eq%20%27{{custAccount}}%27&$select=CustomerAccount,Name,Addres
sDescription,FullPrimaryAddress
```

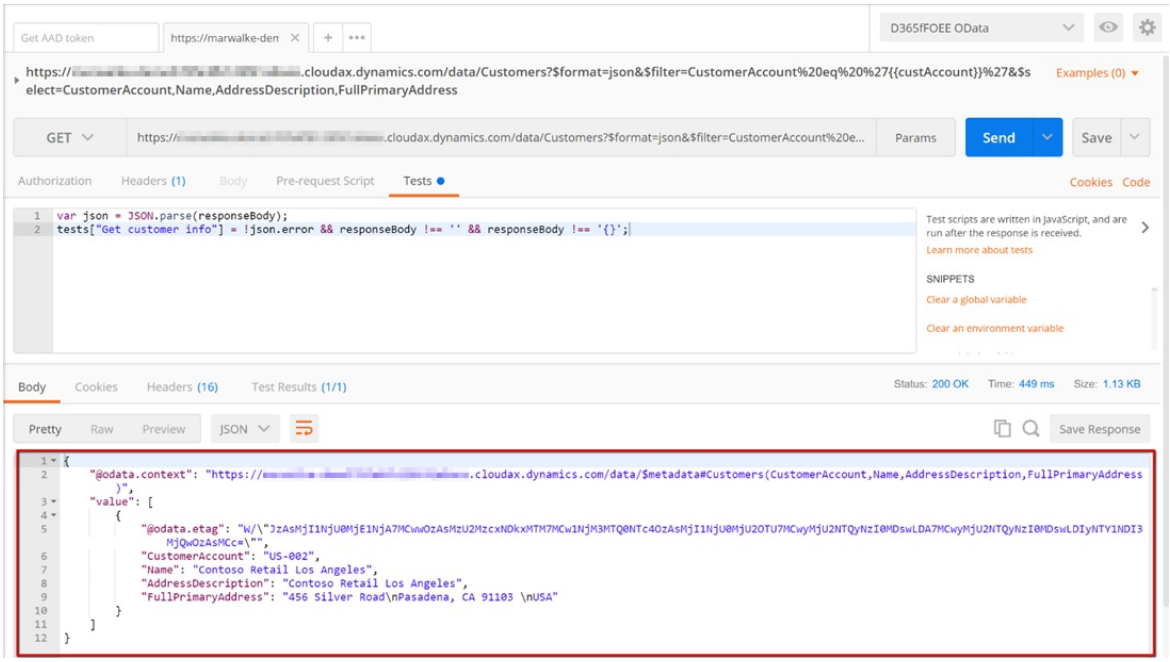
15. Add an Authorization header that refers to the authorization token that was retrieved earlier and stored in the **bearerToken** environment variable. The token must be prefixed by **Bearer** in the header.



16. Create a test to help validate the response. The following example tests that non-empty, JSON-formatted data is returned in the response body.

```
var json = JSON.parse(responseBody);
tests["Get customer info"] = !json.error && responseBody !== '' && responseBody !== '{}';
```

17. Save and send the request, and then verify the result. You must ensure that the user account being used is set to a default company that has data. Alternatively, you can also specify cross-company=true as the query parameter in the OData request.



In our example, we have now successfully authenticated and then used the OData service to read a customer record.

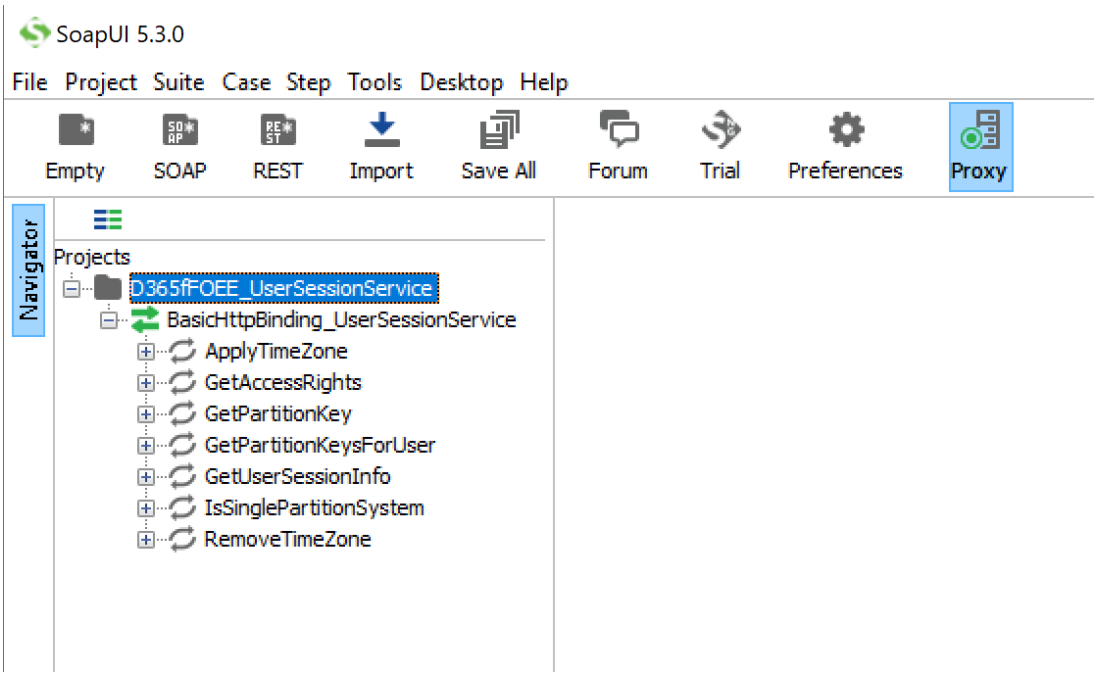
Query the SOAP custom service in your application by using SoapUI

SoapUI (https://www.soapui.org/) is a tool that is often used to interact with SOAP and REST web services in scenarios that involve API development and testing. This procedure isn't an endorsement of SoapUI, and other similar tools are available. However, we are using SoapUI to illustrate the concepts and messages that are involved when you use OAuth to authenticate with Azure AD, and then make SOAP requests to and receive responses.

1. Start SoapUI, and select the **SOAP** button to create a project.
2. Complete the information for the project:
   - In the **Project Name** field, enter a name for the project.
   - In the **Initial WSDL** field, enter the service address, and add the suffix **?wsdl**. (The service address should be in the format [Finance and Operations instance base URL]/soap/services/[service group name].) For more information, see the Services home page.

     For example, we are querying the user session service at the URL `https://[Finance and Operations base URL]/soap/services/UserSessionService?wsdl`.
   - Select the **Create sample requests for all operations?** check box.

     Because you selected to create sample requests, one sample request is created for each service operation that is available.



3. Right-click the new project, and then select **New TestSuite** to create a test suite. This test suite will generate a POST request for an Azure AD authorization token.
4. Right-click the test suite, and then select **New TestCase**.
5. Expand the test case, right-click **Test Steps**, select **Add Step**, and then select **HTTP Request**.
6. Enter a name for the request, and then select **OK**.
7. Enter a name for the test step. The endpoint that you should use for the POST request is

```
[https://login.microsoftonline.com/[tenant_id]/oauth2/token]
(https://login.microsoftonline.com/%5btenant_id%5d/oauth2/token)
```

.

8. Use the plus sign (+) button next to **Parameters** to add the following values.

PARAMETER	VALUE
grant_type	client_credentials
client_id	The application ID from the Azure AD application registration
client_secret	The secret key value from the Azure AD application registration
resource	The URL of the instance without the trailing '/'

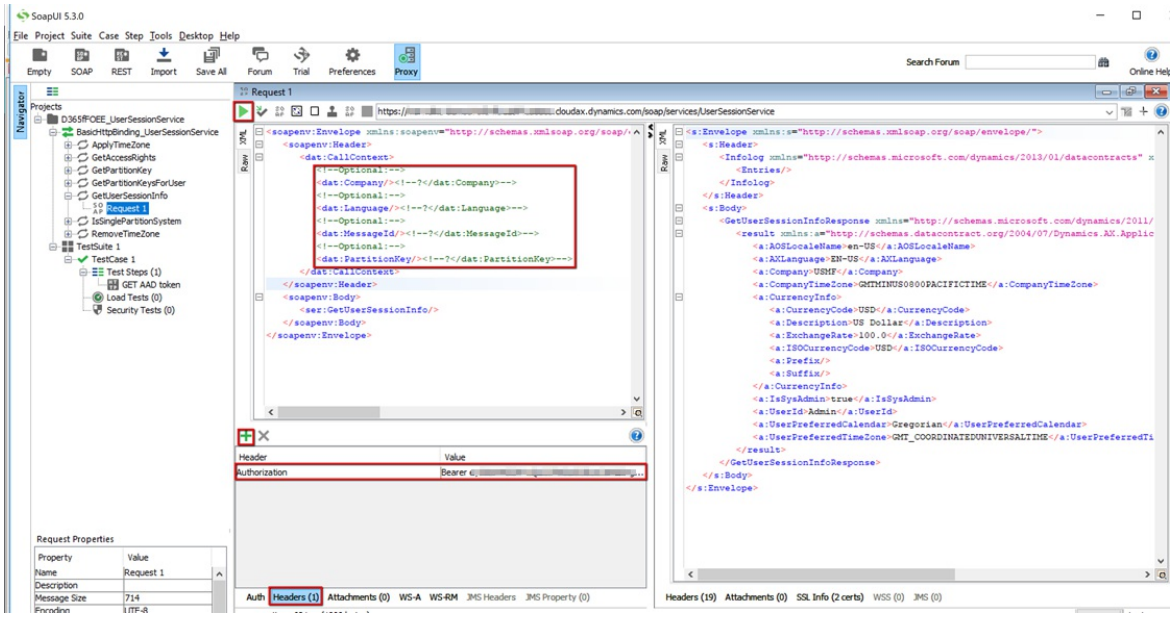
9. To make sure that the parameters are in the POST body, select **Post QueryString**, and then select **Play**. An access token should be returned in the response pane. The values will be most readable if you use the **JSON response** tab. Copy the access token so that you can use it in the authorization header of subsequent requests.

10. Go back to the first request node under the **GetUserSessionInfo** SOAP sample request. In the request pane on the left, select the plus sign (+) button to add a header that is named **Authorization**. Paste the access token into the **Value** field, and add the prefix **Bearer**.

11. The sample requests that SoapUI creates won't work unless you modify them. You must edit the call context and body so that they are consistent with the schema for what you're trying to do.

    For our simple scenario, you can edit the optional call context elements so that they are null-valued. Insert a forward slash (/) before the greater than sign (>) in the opening tags. Then comment out the question marks (?) and the closing tags by using the standard <!--...--> syntax to delimit the start and end of the comments. (Question marks aren't valid content for the XML schema.) Alternatively, you can just delete the question marks (?) so that the context elements are empty.

12. The SOAP request is now ready. Select **Play**, and validate the result on the right.



In our example, we have now successfully authenticated and then queried UserSessionService via SOAP.

NOTE

Can you tell us about your documentation language preferences? Take a short survey.

The survey will take about seven minutes. No personal data is collected (privacy statement).

Create read-only entities that expose financial dimensions

2/18/2021 • 5 minutes to read • Edit Online

In this topic, we describe how to build an entity for registered transactions that are registered.

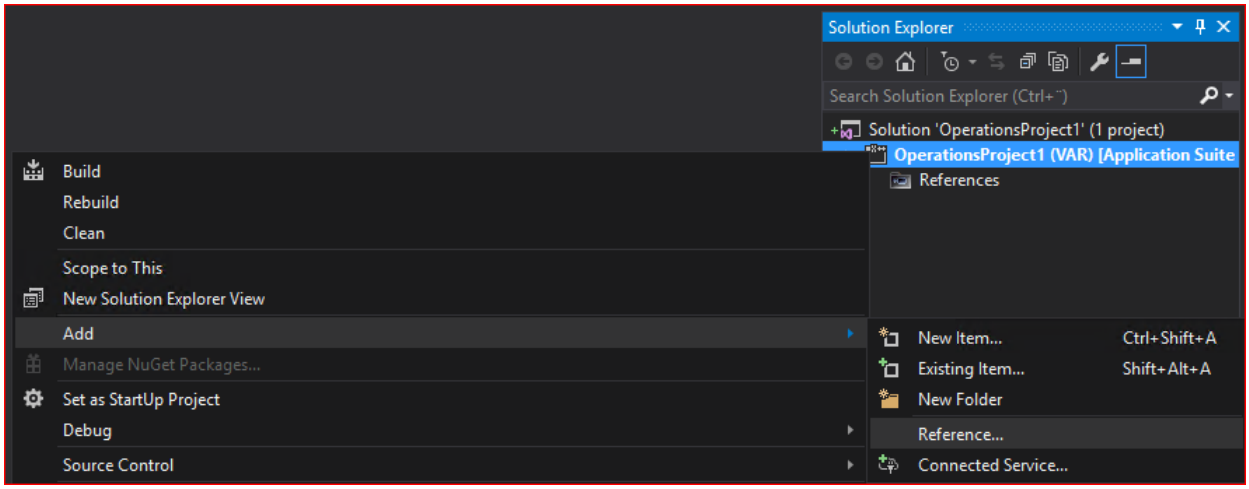
> **NOTE**
>
> This topic comes from Per Baarsoe Jorgensen of the Solutions Architecture team. It describes a real-world scenario that we have encountered as we work with customers.

Imagine a scenario where we must expose all vendor invoice line transactions together with the financial dimensions that were applied through the distributions. Because easy consumption by a third-party tool is essential, we will create an entity for this scenario. As a result, the entity should not have to be joined with other related entities but should be able to provide value on its own.

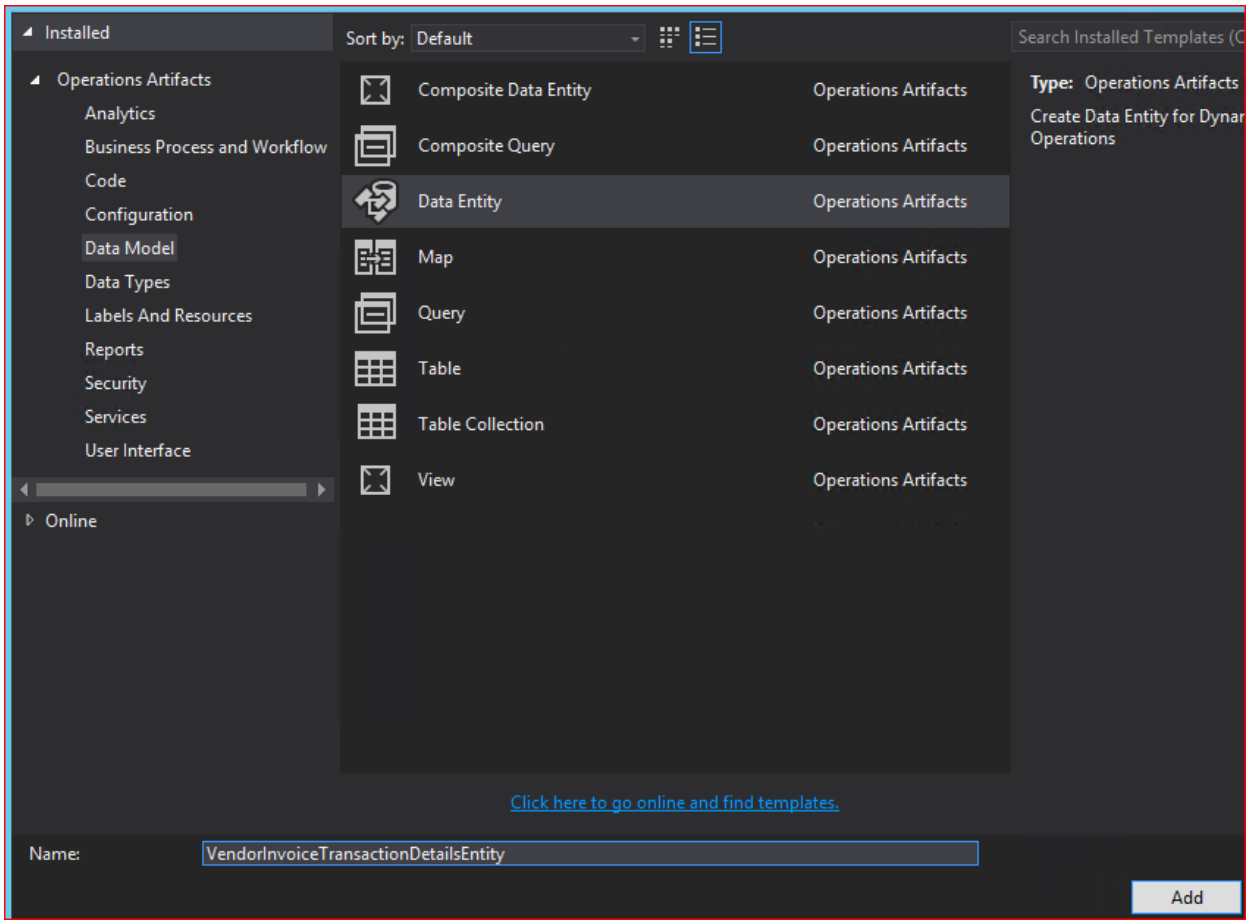
We will walk through the process of creating a sample entity to meet these requirements. (We will leave out instructions for integrating with Microsoft Azure DevOps, because those steps are already well documented.)

Create a basic entity

The first step is to create a new element in a project by selecting **New Item**.



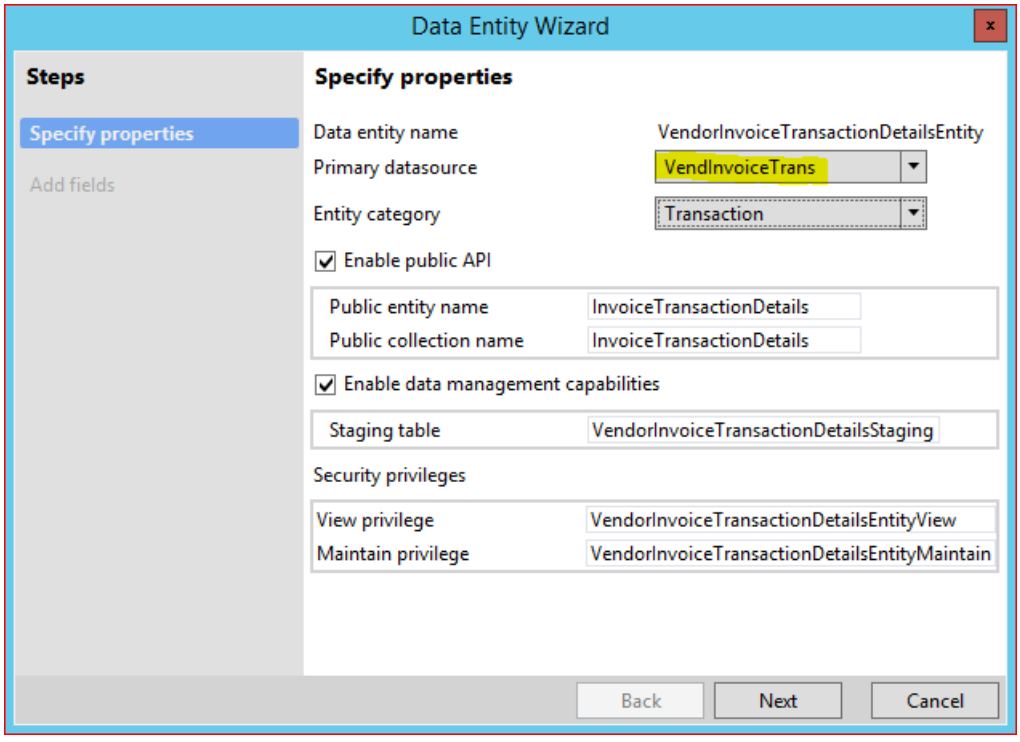
In the form that opens, under Data Model, we select the **Data Entity** element type.



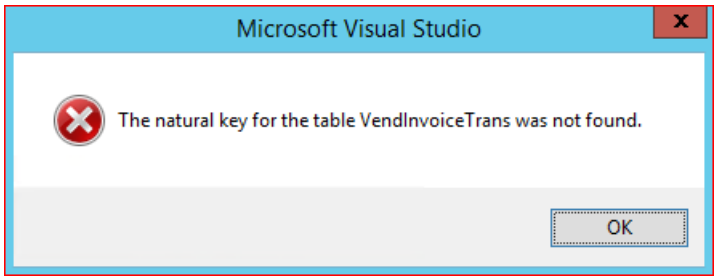
NOTE

Be careful when you name the entity, because you can't rename it later.

Next, in the Data Entity wizard, we select the appropriate primary data source. For our scenario, this data source is VendInvoiceTrans.

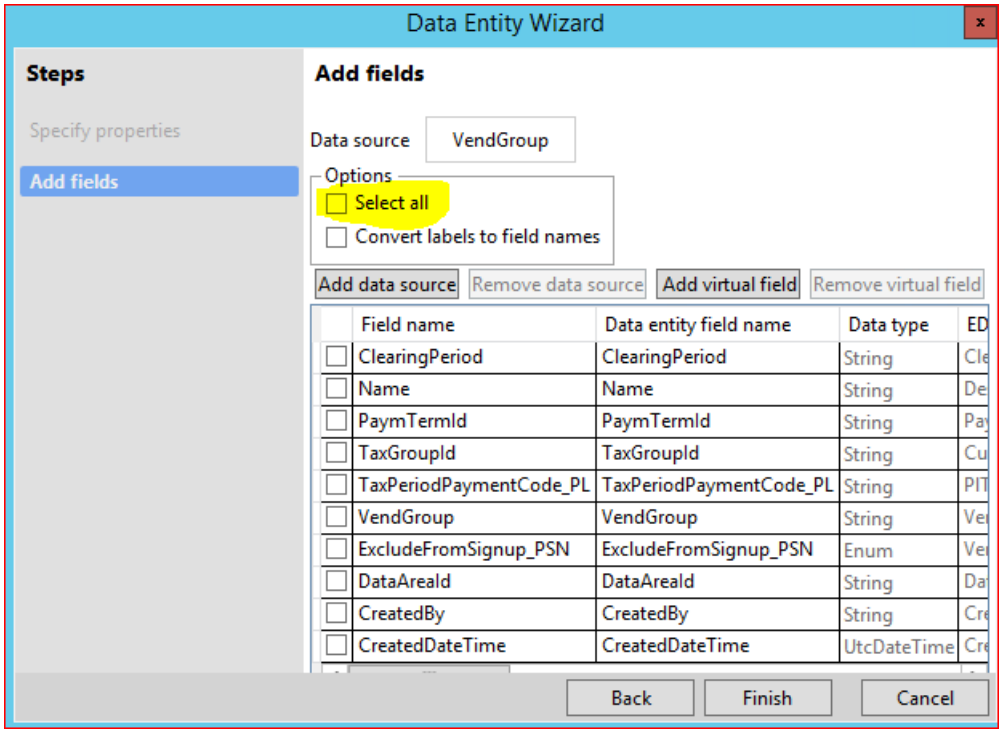


The wizard doesn't accept tables that don't have a natural key, as is the case with VendInvoiceTrans. Therefore, we receive the following error message.



The workaround is to select any other primary data source that has a natural key associated, such as VendGroup.

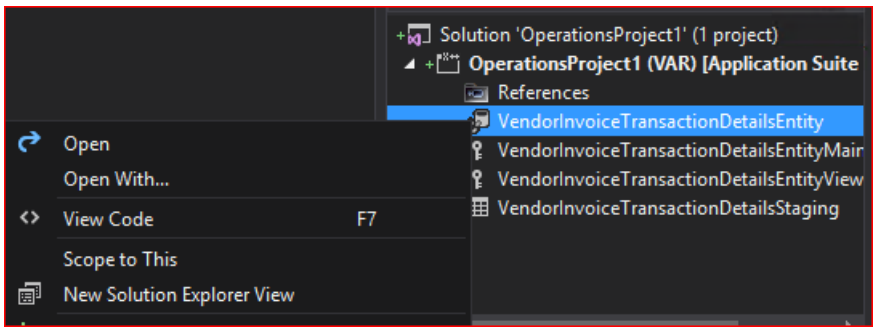
Because we don't really need this data source, we also don't need any fields for it. Therefore, we clear the **Select all** check box.



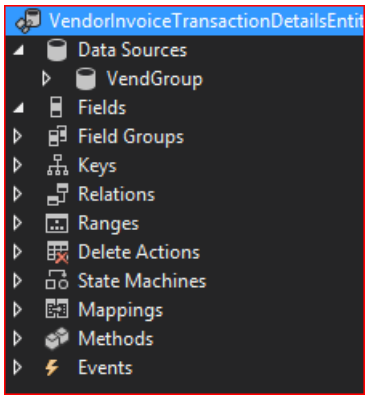
Finally, we create the template for our entity by clicking **Finish**.

Customize the basic entity

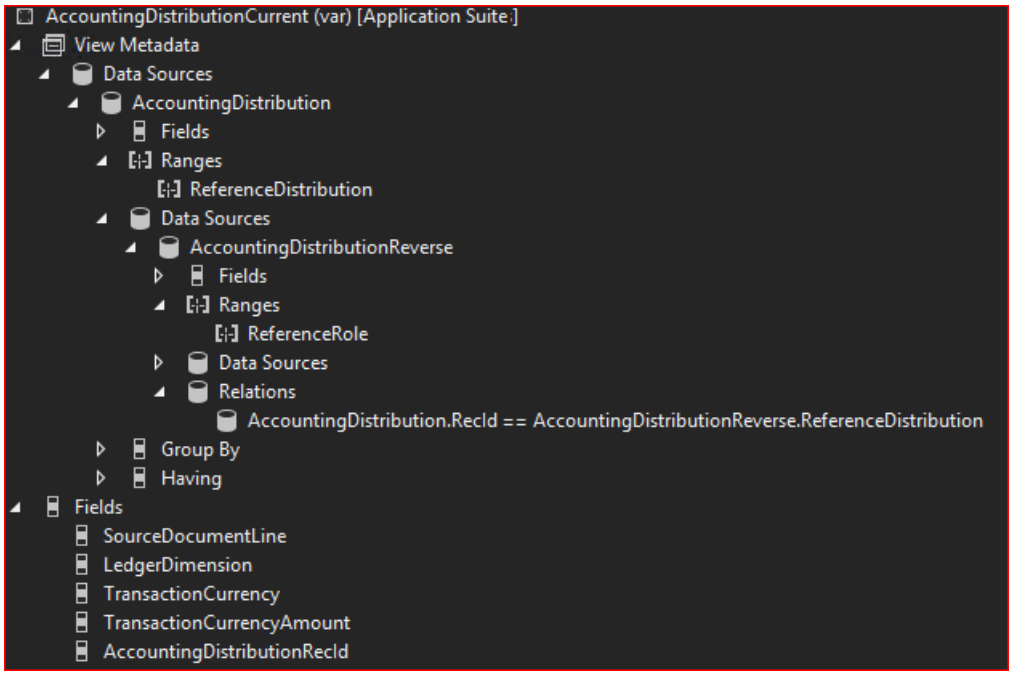
The entity, staging table, and security assets have been created, and we can now produce our custom entity. In the project, we open the VendorInvoiceTransactionDetailsEntity entity in the designer.



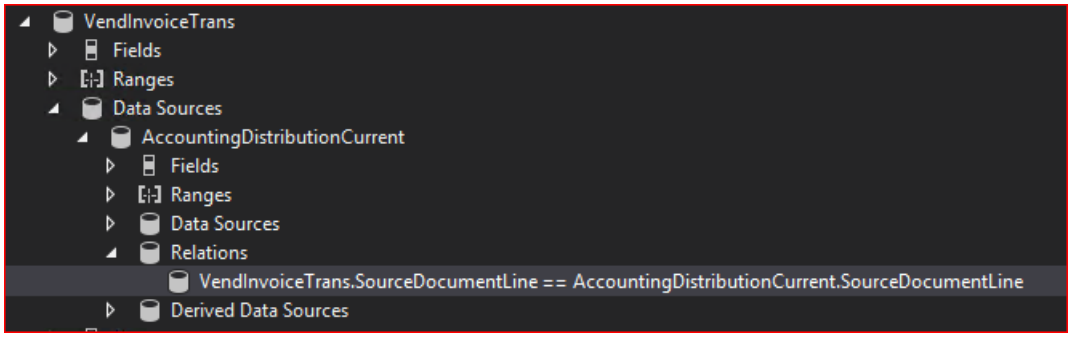
In the designer, we replace the dummy table (VendGroup) that we applied in the wizard with the transaction table VendInvoiceTrans. Because we didn't choose to add the fields, we don't have to remove fields in the entity.



> **NOTE**
>
> Because we are exposing transactional data by using this entity, it's important that we mark the entity as read-only. Therefore, we set the **Is read only** property to **Yes** on the top node. Because accounting distributions are versioned, it's important that only the current version be returned when we query. Therefore, we create a view that makes this part easily reusable across multiple entities.



In the properties, we assign **ReferenceDistribution** a range filter value of **0** and **ReferenceRole** a range filter value of **1**. The join mode property for the AccountDistributionReverse data source must be **NoExistsJoin**. After the new view is in place, we can add it to the VendorInvoiceTransactionDetailsEntity entity that we are currently building.



Expose financial dimensions as fields

The next important step is to expose the financial dimensions as separate fields on the entity. Because our

scenario builds on top of a posted transaction, we must add the fields to the DimensionCombinationentity entity. We want to make the adjustments in a resilient manner by using the extension approach, so that minimal maintenance will be required when we upgrade the code base to newer versions in the future.

Microsoft Dynamics 365 for Finance and Operations, Enterprise edition version 1611

For version 1611 or later, you should use the wizard that is available in Microsoft Visual Studio (at **Dynamics 365** > **Addins** > **Add financial dimensions for Odata**). For instructions, see Add dimensions to Excel templates.

Earlier versions

If you're working with earlier versions, you must complete the steps that are outlined here. First, we add the entity extension itself. Select **Create extension** on the context menu (shortcut menu). Next, we create the code that retrieves the data. Because the entity extension is already in place, we must create a new class. The following example adds code for an arbitrary dimension that is named **ProductLine**.

```
[ExtensionOf(dataentityviewstr(DimensionCombinationentity))]
  public final class DimensionCombinationentity_Extension
  {
    private static server str getEmptyOrDimensionValueSqlString(str _attributeName)
    {
        str sqlStatement;

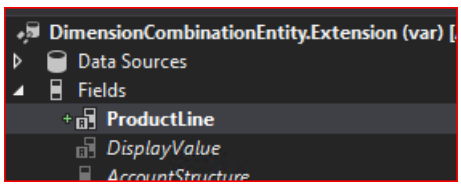
        DimensionAttribute dimensionAttribute = DimensionAttribute::findByName(_attributeName);

        if (!dimensionAttribute)
        {
            sqlStatement = SysComputedColumn::returnLiteral('');
        }
        else
        {
            sqlStatement = strFmt('SELECT TOP 1 T1.%1 ', dimensionAttribute.DimensionValueColumnName);
        }

        return sqlStatement;
    }

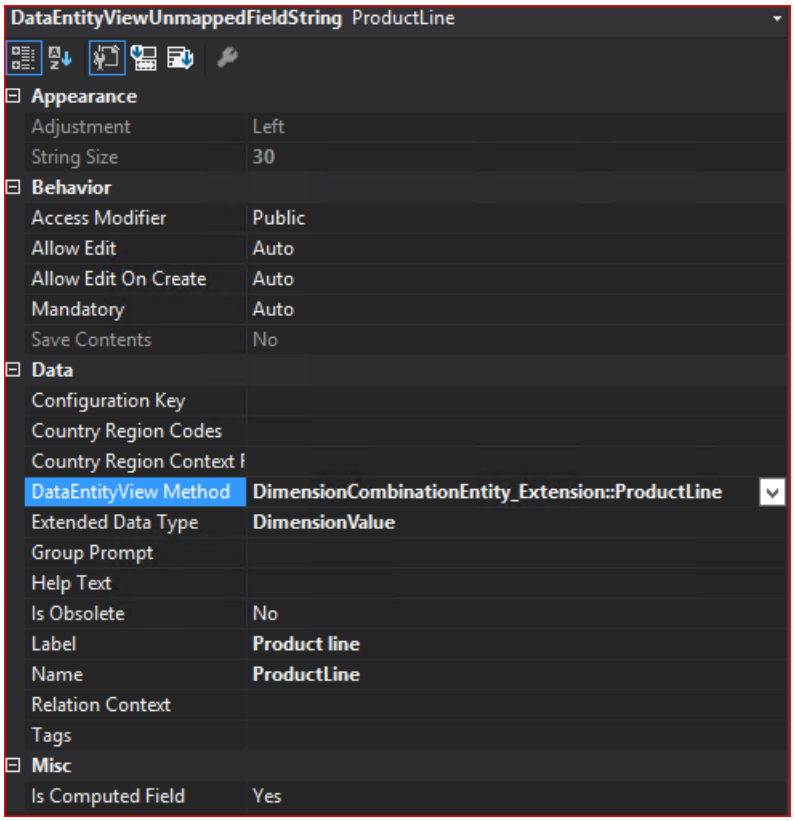
    /// Generates the sql to populate the FOTA view field.
    public static server str ProductLineValue()
    {
        return DimensionCombinationentity::getEmptyOrDimensionValueSqlString('ProductLine');
    }
  }
```

We now add fields to the newly created entity extension by using custom fields that reference these methods.



Next, we set the property values to reflect the fact that the field is unmapped and should be retrieved through the code that we made for the extension class. When you create the relation, also set the following values:

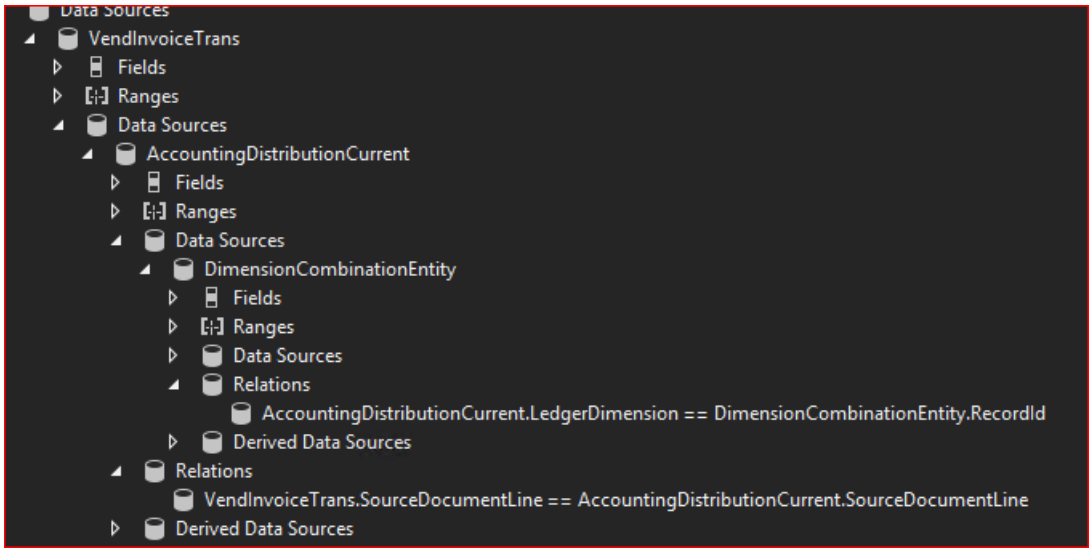
- Cardinality: **ZeroMore**
- Related data entity: **DimensionCombinationentity**
- Related data entity cardinality: **ZeroOne**
- Relationship type: **Association**



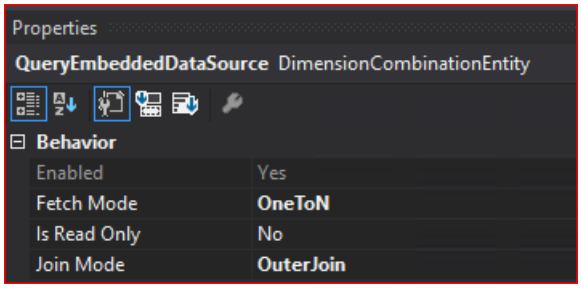
NOTE

We must fully qualify the data method with the class name.

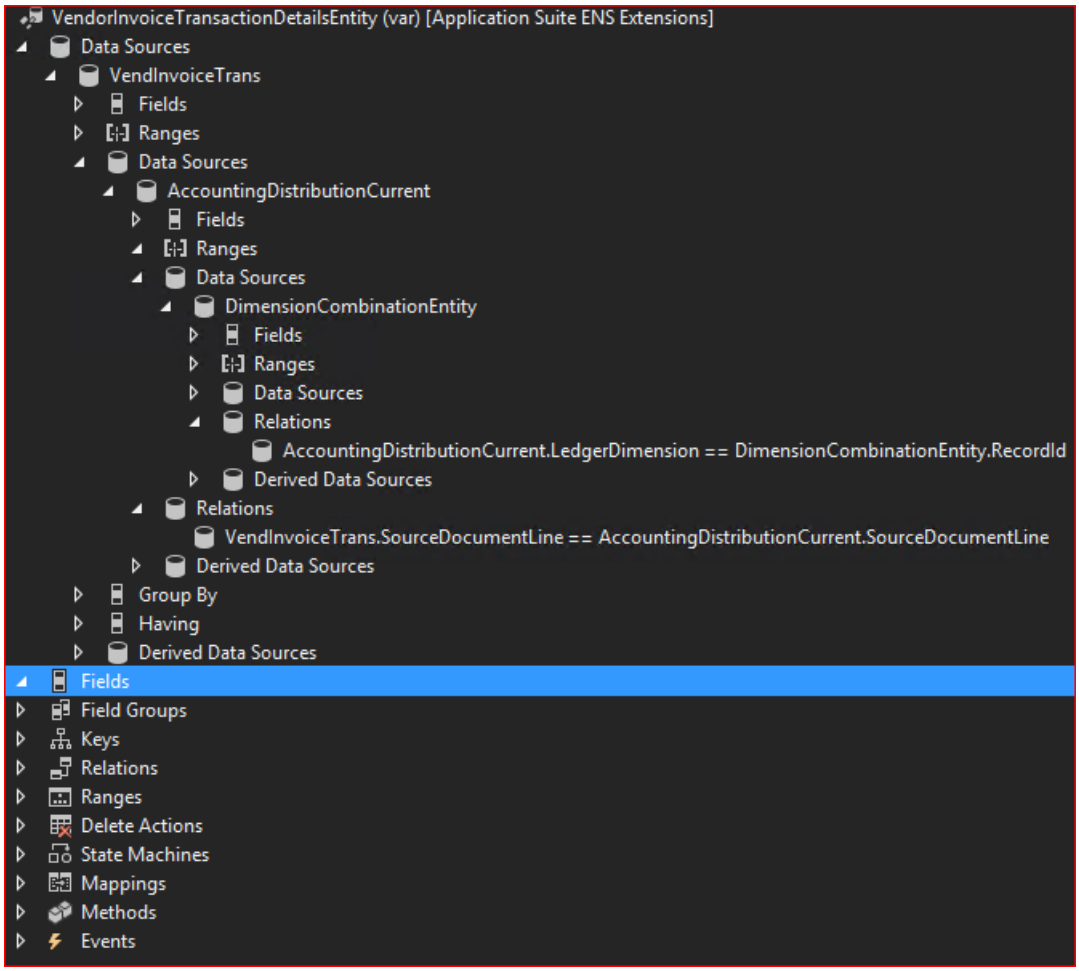
We are now ready to add the DimensionCombinationentity entity to our new VendInvoiceTransactionentity entity.



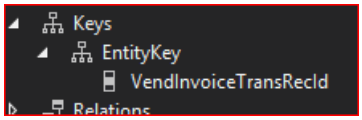
Notice that both the AccountingDistributionCurrent and the DimensionCombinationentity entity should be outer-joined.



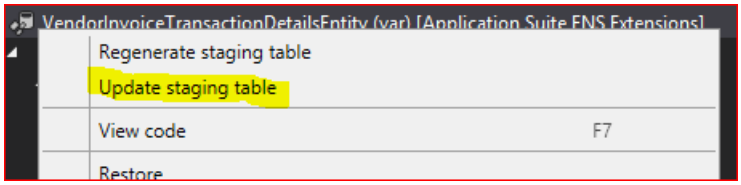
Now, we just have to drag the required fields from the various data sources to the **Fields** node on the new entity (that is, to our newly created ProductLine).



We should add a key to the entity to enable the incremental update functionality during the export configuration. Therefore, we must make sure that RecId from the VendInvoiceTrans data source is part of the fields named e.g. VendInvoiceTransRecId. After the field is in the field list, we can drag it to the **EntityKey** node.



To make sure that the staging table is associated with the fully configured entity, we must update it. On the context menu for the entity, we select **Update staging table**.



The entity work is now complete, and we can build it.

> **NOTE**
>
> In this scenario, a LedgerDimension was associated with the DimensionCombinationentity entity. In scenarios where there is a DefaultDimension, we must associate it with the DimensionSetentity entity. The improvements and extensions that are required are identical to the improvements and extensions that we made to the DimensionCombinationentity entity.

Export Dynamics AX 7 Entities to your own Azure SQL Database

Bring your own database (BYOD)

2/18/2021 • 13 minutes to read • Edit Online

This topic explains how administrators can export data entities from the application into their own Microsoft Azure SQL database. This feature is also known as *bring your own database* (BYOD). The BYOD feature was released in Microsoft Dynamics AX with platform update 2 (August 2016). Minor improvements and bug fixes have been included in subsequent platform updates.

The BYOD feature lets administrators configure their own database, and then export one or more data entities that are available in the application into the database. (Currently, more than 1,700 data entities are available.) Specifically, this feature lets you complete these tasks:

- Define one or more SQL databases that you can export entity data into.
- Export either all the records (*full push*) or only the records that have changed or been deleted (*incremental push*).
- Use the rich scheduling capabilities of the batch framework to enable periodic exports.
- Access the entity database by using Transact-SQL (T-SQL), and even extend the database by adding more tables.

Entity store or BYOD?

If you followed the series of blog posts about Microsoft Power BI integration, you will be familiar with Entity store. Entity store is the operational data warehouse. Entity store provides built-in integration of operational reports with Power BI. Ready-made reports and analytical workspaces use Entity store. If you write Power BI reports by using data in your application environment, you should use Entity store.

However, the BYOD feature is recommended for the following scenarios:

- You must export data into your own data warehouse.
- You use analytical tools other than Power BI, and those tools require T-SQL access to data.
- You must perform batch integration with other systems.

> **NOTE**
>
> The application doesn't allow T-SQL connections to the production database. If you're upgrading from a previous version of Finance and Operations, and you have integration solutions that require direct T-SQL access to the database, BYOD is the recommended upgrade path.

You can use either Entity store or BYOD. The default operational reports that are available take advantage of embedded Power BI and Entity store. We recommend that you use our default operational reports as your first choice. You can also extend the ready-made operational reports to meet your requirements. You should consider BYOD a complementary option that you use as you require.

Creating a SQL database

Before you can configure the entity export option and use the BYOD feature, you must create a SQL database by using Azure portal.

For one-box development environments, you can create a database in the local Microsoft SQL Server database. However, this database should be used only for development and testing purposes. For production

environments, you must create an Azure SQL database.

You should also create a SQL user account for sign-in to the database. Write down the server name, database name, and the SQL user ID and password. You will use this information when you configure the entity export option in the next section.

If you're using the BYOD feature for integration with a business intelligence (BI) tool, you should consider using clustered columnstore indexes (CCIs). CCIs are in-memory indexes that improve the performance of read queries that are typical in analytical and reporting workloads.

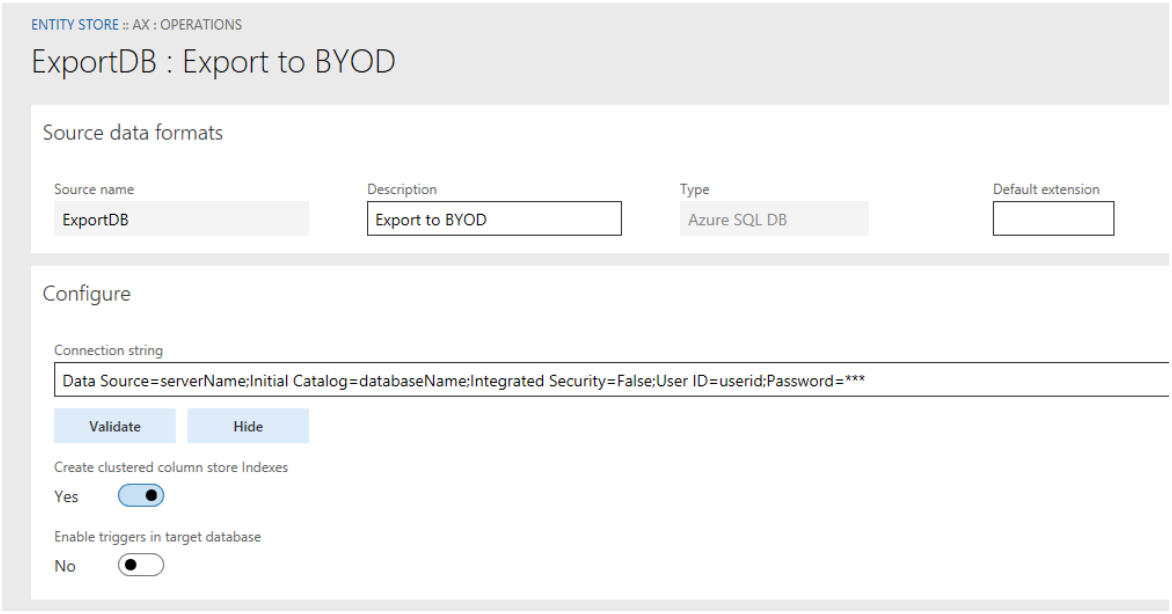
> **NOTE**
>
> Your BYOD database must be accessible to Finance and Operations apps. If you encounter issues where you are unable access to access BYOD, you must ensure firewall rules in your BYOD are configured appropriately.

Configuring the entity export option

1. Start the client, and then, in the **Data management** workspace, select the **Configure Entity export to database** tile.
2. If you've configured any databases, a list is shown. Otherwise, you must configure a new database. In this case, select **New**, and then enter a unique name and a description for the new database. Note that you can export entities into multiple databases.
3. Enter the connection string in the following format:

   Data Source=<logical server name>,1433; Initial Catalog=<your DB name>; Integrated Security=False; User ID=<SQL user ID>; Password=<password>

   In this connection string, the logical server name should resemble **nnnn.database.windows.net**. You should be able to find the logical server name in Azure portal. The following illustration shows an example of a connection string.



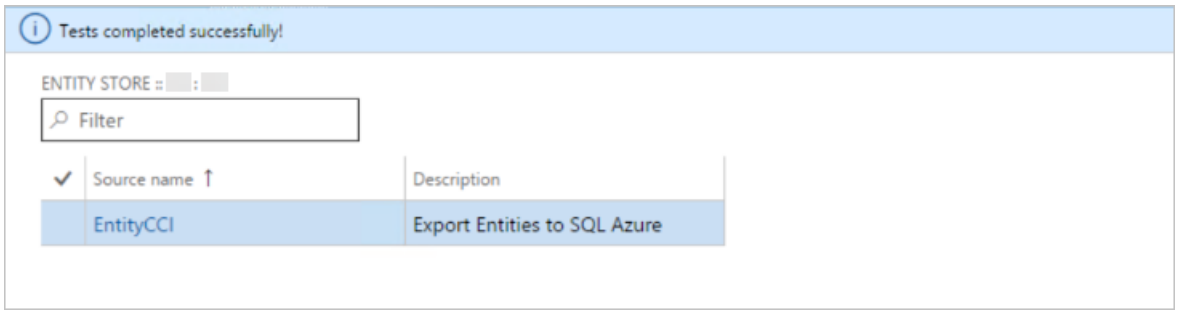
> **NOTE**
>
> The default extension field shown in the image above does not apply to BYOD.

4. Select **Validate**, and make sure that the connection is successful.

- The **Create clustered column store indexes** option optimizes the destination database for selected queries by defining CCIs for entities that are copied. However, CCIs are currently supported only on SQL premium databases. Therefore, to enable this option, you must create a SQL premium database.
- The **Enable triggers in target database** option sets export jobs to enable SQL triggers in the target database. This option lets you hook downstream processes into the trigger to orchestrate actions that must be started after records have been inserted. One trigger is supported per bulk insert operation. The size of the bulk insert is determined by the **Maximum insert commit size** parameter in the Data management framework.

For scenarios in which reporting systems read data from BYOD, there is always the challenge of ensuring that the reporting systems get consistent data from BYOD while the sync is in progress. You can achieve this result by not having the reporting systems read directly from the staging tables created by the BYOD process. The staging tables hold the data while data is being synced from the instance and hence will be constantly changing. Use the SQL trigger feature to determine when the data sync has been completed, and then hydrate the downstream reporting systems.

When the validation is passed, the database that you configured for entity export appears in lists of databases, as shown in the following illustration.



You can now publish one or more entities to the new database by selecting the **Publish** option on the menu.

Publishing the entity schema to the database

The **Publish** page enables several scenarios:

- Publish new entities to the database.
- Delete previously published entities from the database. (For example, you might want to re-create the schema.)
- Compare published entities with the entity schema. (For example, if new fields are added later, you can compare the fields with your database schema.)
- Configure change tracking functionality that enables incremental updates of your data.

The following sections discuss each option.

Publish

The **Publish** option defines the entity database schema on the destination database. When you select one or more entities, and then select the **Publish** option, a batch job is started. This job creates the entities in the destination database. When the database definition job is completed, you receive a message, which you can access by using the bell symbol in the upper right.

The actual data update occurs when you export data. At this point, you're just creating the schema.

Drop entity

The **Drop entity** option deletes the data and the entity definition from the destination database.

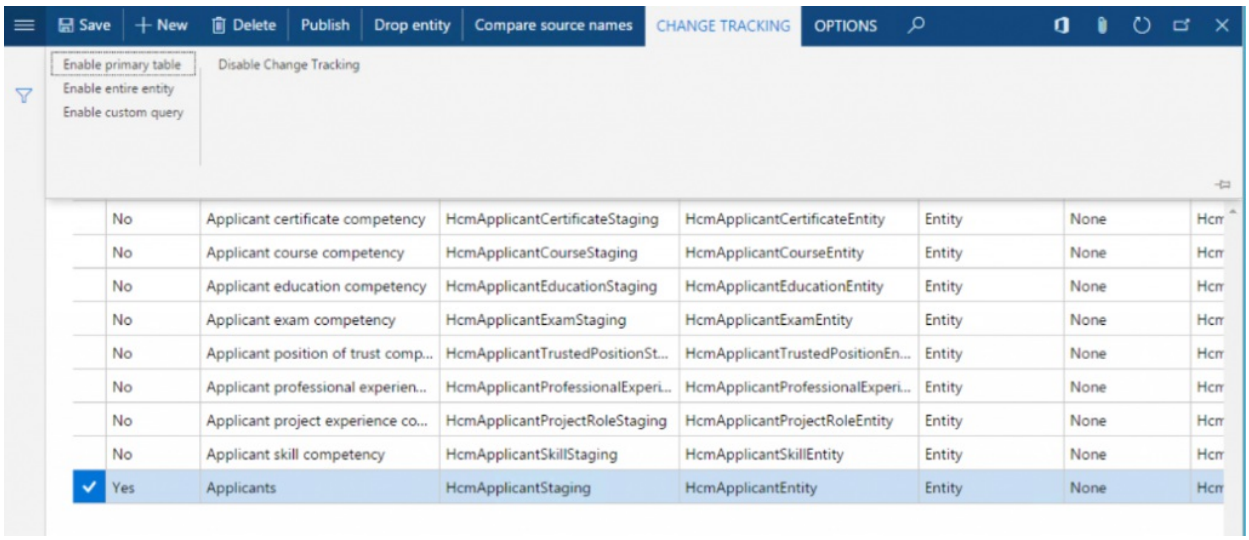
Compare source names

The **Compare source names** option lets you compare the entity schema in the destination with the entity schema in the application. This option is used for version management. You can also use this option to remove any unwanted columns from the destination table.

Configure change tracking

Change tracking is a feature that is provided in SQL Server and SQL Database. Change tracking enables the database to track changes including deletes that are made on tables. The system uses change tracking to identify changes that are made to tables as transactions. However, because the application must track changes at the data entity level, there is additional logic on top of SQL change tracking to make this functionality work. The steps to enable change tracking are explained later in this section.

The **Change tracking** option on the **Publish** page lets you configure how changes are tracked on the underlying entity.



The following table describes the change tracking options that are available.

OPTION	DESCRIPTION
Enable primary table	An entity consists of several tables. Select this option to track all changes that are made to the primary table of the entity. When changes are made to the primary table, the corresponding record is inserted into or updated in the destination database. Although data from the whole entity is written to the destination table, the system triggers the insert or update option only when the primary table is modified.
Enable entire entity	Select this option to track all changes to the entity. (These changes include changes to all the tables that make up the entity.) When changes are made to the entity, corresponding updates are made to the destination.
Enable custom query	This option lets a developer provide a custom query that the system runs to evaluate changes. This option is useful when you have a complex requirement to track changes from only a selected set of fields. You can also select this option when the entities that will be exported were built by using a hierarchy of nested views. For more information, see Enable change tracking for entities.

To use change tracking, you must enable the **Change tracking** option as shown above in data management. This action is available on the **Data entities** list page, by going to **Data management > Data entities**. You need to select an entity and select from one of the options listed above to enable change tracking on the data entity.

If you republish an entity that exists in the destination database, the system warns you that existing data will be

deleted because of the new operation.

When you confirm the publish operation, the system publishes the schema to the database, and you're notified when the operation is completed.

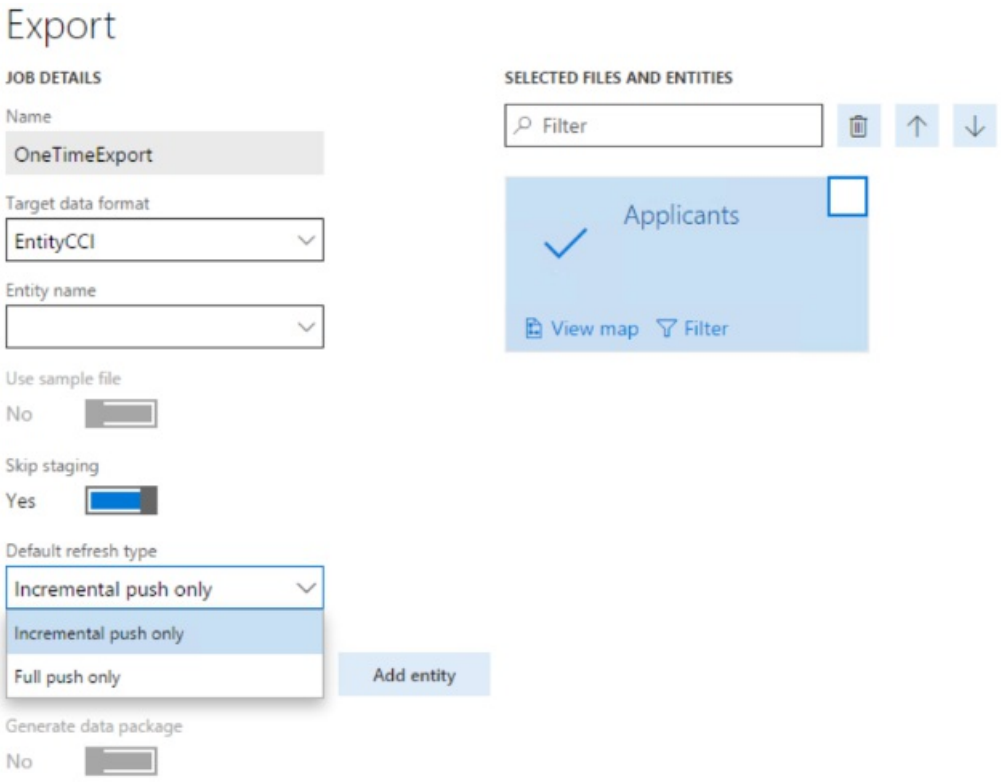
By selecting the **Show published only** option on the **Publish** page, you can show only the entities that were published to a given destination database. The Publish function creates the entity schema in the database. You can navigate to the database and see the table schemas that were created, together with corresponding indexes.

> **NOTE**
> Currently, you can't use BYOD to export composite entities into a database. You must export each entity in the composite entity.

Exporting data into your database

After entities are published to the destination database, you can use the Export function in the **Data management** workspace to move data. The Export function lets you define a Data movement job that contains one or more entities.

You can use the **Export** page to export data into many target data formats, such as a comma-separated values (CSV) file. This page also supports SQL databases as another destination.



You can create a data project that has multiple entities. You can schedule this data project to run by using the batch framework. You also schedule the data export job to run on a periodic basis by selecting the **Export in batch** option.

The same job can also be used to export data from all companies. In prior to Platform update 27, this feature can be enabled by enabling the flight DMFEnableAllCompanyExport as explained in Data management overview. Starting in Platform update 27, this feature can be enabled in data management framework parameters. After the feature is enabled, a new option will appear when adding an entity to a data project. This option can be enabled to export data from all companies for the specific entity.

> **NOTE**
>
> Adding multiple entities to an export project for BYOD must be done carefully to ensure the overall reliability of the BYOD export is not compromised. Different parameters must be taken into consideration when deciding the number of entities that are added to the same project. Some of these parameters should be the degree of complexity of the entities, data volume per entity that is expected, and the overall time for export to complete at the job level. Adding hundreds of entities must be avoided, therefore creating multiple jobs with smaller number of entities is recommended.
>
> Use of recurring exports in **Manage > Manage recurring data jobs** for BYOD is discouraged. You must use the **Export in batch** option.

Incremental export

When you add an entity for data export, you can select to do an incremental export (which is also known as incremental push) or a full push. For incremental push to work, you must enable the **Change tracking** option in the database and specify an appropriate change tracking option, as described earlier in this topic.

> **NOTE**
>
> A full push deletes all existing records from an entity and then inserts the current set of records from the selected entity.

If you select an incremental push, the first push is always going to be a full push. This is because SQL needs to know which records have been 'tracked' in order to be able to track subsequent changes. Whenever a new record is inserted, or a record is added or deleted, the corresponding change will be reflected in the destination entity.

Because the first push is always a full push, we do not recommend that you do an explicit full push before you enable change tracking.

We recommend that you first enable change tracking and schedule a export job with incremental push. This will take care of the first full push and the subsequent incremental exports.

Timeouts

The default timeouts for BYOD exports are set to ten minutes for truncation operations and one hour for actual bulk insert operations. When volumes are high, these timeout settings may not be sufficient and must be updated. Starting with the release of Platform update 18, you can update the timeout settings by navigating to **Data management > Framework parameters > Bring your own database**. These timeouts are company specific and must be set separately for each company.

Known limitations

The BYOD feature has the following limitations.

There should be no active locks on your database during synchronization

Because BYOD is your own database, you must ensure that there are no active locks on your Azure SQL database when data is being synced. Having active locks on your database during synchronization can result in slow writes or even failure to export to your Azure SQL database.

You can't export composite entities into your own database

Currently, composite entities aren't supported. You must export individual entities that make up the composite entity. However, you can export both the entities in the same data project.

Entities that don't have unique keys can't be exported by using incremental push

You might face this limitation especially when you try to incrementally export records from a few ready-made entities. Because these entities were designed to enable the import of data, they don't have a unique key. However, you can enable change tracking only for entities that have a unique key. Therefore, there is a limitation on incremental push. One workaround is to extend the required entity and define a unique key.

Troubleshooting

Incremental push not working correctly

Issue - When a full push occurs for some entity then a large set of records can be seen in BYOD using a select statement. However, an incremental push results in only a few records in BYOD. It seems as if the incremental push deleted all the records and added only the changed records in BYOD.

Solution - In cases like this it is recommended to disable and re-enable change tracking for the entity in question. The state of the SQL change tracking tables might not be in the expected state. Also verify that there are no other incremental exports that cover the same tables (DMF, MR, Retail).

SSIS Error Code DTS_E_OLEDBERROR. An OLE DB error has occurred. Error code: 0x80004005

Issue - Export to BYOD fails with an SSIS exception shown below.

```
An OLE DB error has occurred. Error code: 0x80004005.

An OLE DB record is available. Source: "Microsoft SQL Server Native Client 11.0"  Hresult: 0x80004005
Description: "Communication link failure".

An OLE DB record is available. Source: "Microsoft SQL Server Native Client 11.0"  Hresult: 0x80004005
Description: "TCP Provider: An existing connection was forcibly closed by the remote host.

Failed to open a fastload rowset for <entityStaging>. Check that the object exists in the database.

OLE DB Destination failed the pre-execute phase and returned error code 0xC0202040.
```

Solution - This can occur if the connection policy on the Azure SQL BYOD server is set to Proxy. This must be changed to 'Redirect' as explained in SQL DB Connectivity Architecture

Automated Entity store refresh

2/18/2021 • 2 minutes to read • Edit Online

Overview

Entity store refresh is automated and managed by the system. Administrators do not need to schedule or monitor the Entity store refresh with the system batch schedules. The refresh operation is based on anticipated latency. This functionality is enabled in Platform update 23. As an administrator you do need to opt-in to use this feature.

Enable automated refresh

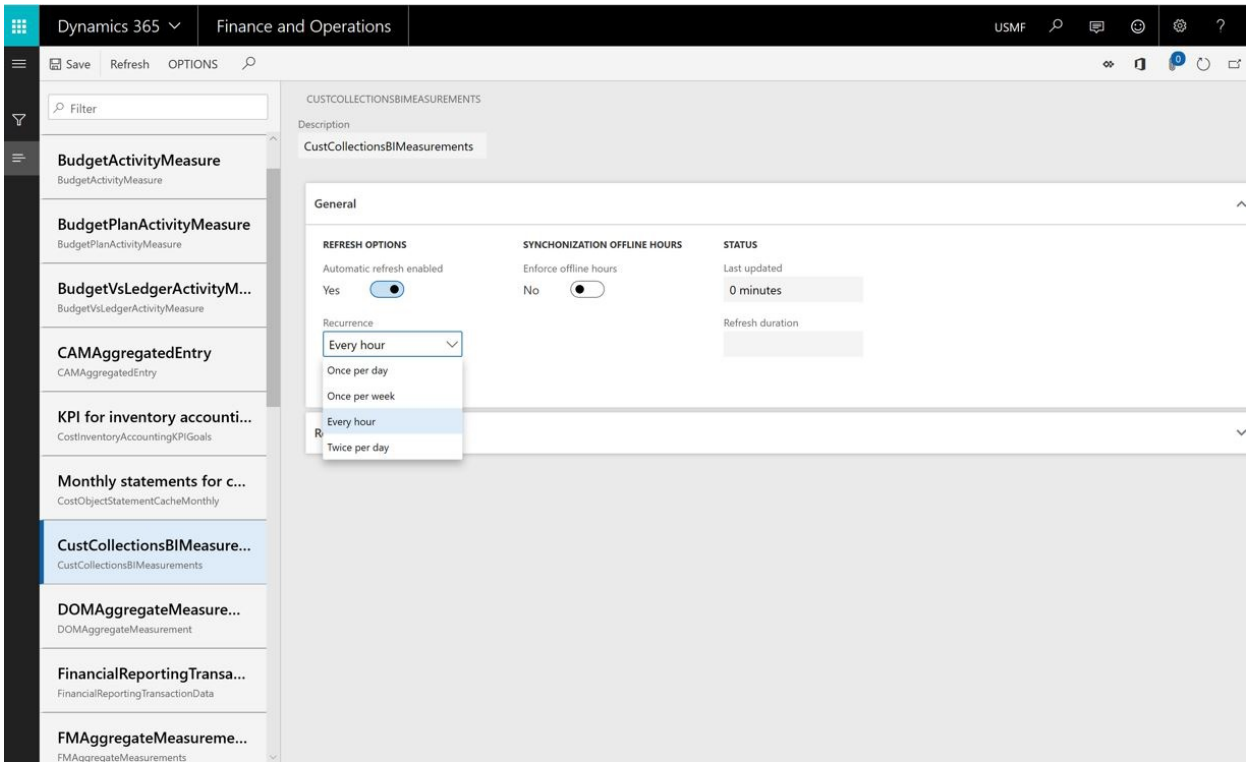
Complete the following steps to enable automated Entity store refresh.

1. Go to **System administration** > **Set up** > **Entity store**. On the **Entity store** page, a message indicates that you can switch to the **Automated Entity store refresh** option. This option is managed by the system. An admin does not have to schedule or monitor the Entity store refresh.
2. Select **Switch now**.

> **IMPORTANT**
> This action isn't reversible. After you switch to the **Automated Entity store refresh** option, you can't revert to the old user interface (UI) experience.

3. Select **Yes** to continue.

You will now see the new experience.



After the new experience is turned on, you can define the refresh for each aggregate measurement. The following refresh options are available:

- Every hour
- Twice a day
- Once a day
- Once a week

An admin can also refresh any aggregate measurement on demand by clicking the **Refresh** button. Additional options will be added in future platform updates. These options will include options for real-time refresh.

> **IMPORTANT**
>
> When automated refresh is enabled, the system can disable the refresh of aggregate measurements. You must revisit aggregate measurements and validate that appropriate refresh intervals have been applied.

> **NOTE**
>
> Can you tell us about your documentation language preferences? Take a short survey.
>
> The survey will take about seven minutes. No personal data is collected (privacy statement).

Data task automation

2/18/2021 • 17 minutes to read • Edit Online

Data task automation lets you easily repeat many types of data tasks and validate the outcome of each task. Data task automation is very useful for projects that are in the implementation phase. For example, you can automate the creation and configuration of data projects. You can also configure and trigger the execution of import/export operations, such as the setup of demo data and golden configuration data, and other tasks that are related to data migration. You can also create automated testing of data entities by using task outcome validation.

> **IMPORTANT**
>
> Data task automation isn't currently supported for on-premises environments. The user who executes data task automation must be in the same tenant as the application environment and LCS project.

We recommend the following approach for data task automation.

1. Identify the data-related tasks that will benefit from automation.

   We recommend that implementation teams review their configuration management plan and data migration plan to identify potential data tasks for automation, and also to identify data entity test cases.

2. Define tasks.

   Tasks are defined in an XML manifest. You can keep your manifest under source control as part of configuration management in your application lifecycle management (ALM) strategy.

3. Put the data packages that are related to data task automation in the Shared asset library of Microsoft Dynamics Lifecycle Services (LCS). You can also use a specific LCS project as you require.

   Data task automation manager can consume packages from any sandbox and/or production environment that is related to the LCS project.

   > **IMPORTANT**
   >
   > - The user account that runs Data task automation manager must have access to LCS and to the LCS project that is referenced in the manifest for data packages.
   > - Although data task automation can be run in any environment in the cloud, we strongly recommend that you not run any import/export tasks that use integration application programming interfaces (APIs) in a production environment. Data task automation that involves integration APIs should be used only for automated testing.

4. Run the data tasks, and then review the outcomes.

   Data task automation manager provides the success or failure outcome for each task. It also provides insights into the reason why a task failed.

> **IMPORTANT**
>
> Although data task automation can be run in any environments in the cloud, we recommend that you not run any import/export tasks that use integration APIs in a production environment. Data task automation that involves integration APIs should be used only for automated testing.

The following video is a 55-minute TechTalk that walks you through an early release of Data task automation manager: Task automation framework.

Task manifest

A task must be defined in an XML manifest. This section describes the manifest. For guidance about how to name and design the manifest, see the "Best practices for manifest design" section later in this topic.

Manifest root

The **<TestManifest>** element is the root of the manifest. All other elements are children of this element.

```
<?xml version='1.0' encoding='utf-8'?>
<TestManifest name='Data management demo data set up'>
    <SharedSetup />
        <JobDefinition ID='ImportJobDefinition_1' />
        <EntitySetup ID='Generic' />
    </SharedSetup>
    <TestGroup />
</TestManifest>
```

ELEMENT	ELEMENT CARDINALITY	ATTRIBUTES	ATTRIBUTE DESCRIPTION
<TestManifest>	1..1	name	The *name* helps to identify the purpose of the manifest.

Shared setup

The **Shared setup** section defines general task parameters and behaviors for all tasks in the manifest.

PARENT ELEMENT	ELEMENT	ELEMENT CARDINALITY	ATTRIBUTES	ATTRIBUTE DESCRIPTION
<TestManifest>	<SharedSetup>	1..1	-	This element takes no attributes.

Data files

<DataFile> elements define the data packages and data files that the tasks in the manifest will use. The data files must be either in the LCS asset library of your LCS project or in the Shared asset library.

```
<DataFile ID='SharedSetup' name='Demo data-7.3-100-System and Shared'  assetType='Data package'
lcsProjectId=''/>
<DataFile ID='FinancialsHQUS' name='Demo data-7.3-200-Financials-HQUS' assetType='Data package'
lcsProjectId=''/>
<DataFile ID='FinancialsPICH' name='Demo data-7.3-200-Financials-PICH' assetType='Data package'
lcsProjectId=''/>
<DataFile ID='FinancialsPIFB' name='Demo data-7.3-200-Financials-PIFB' assetType='Data package'
lcsProjectId=''/>
```

PARENT ELEMENT	ELEMENT	ELEMENT CARDINALITY	ATTRIBUTES	ATTRIBUTE DESCRIPTION
<SharedSetup>	<DataFile>	1..n	-	-
	<DataFile>	-	ID	
	<DataFile>	-	name	Name of the asset that represents the data file.
	<DataFile>	-	assetType	The asset type in LCS asset library that stores the data file. This is the asset type name as shown in LCS asset library.
	<DataFile>	-	lcsProjectId	The LCS project that has the data file in its asset library. If the project ID is specified as '' then, it indicates the Shared asset library.

Data project definition

The **<JobDefinition>** element defines the data project definition. There can be more than one job definition in a manifest.

```
<JobDefinition ID='ImportJobDefinition_1'>
    <Operation>Import</Operation>
    <ConfigurationOnly>No</ConfigurationOnly>
    <Truncate></Truncate>
    <Mode>Import async</Mode>
    <BatchFrequencyInMinutes>1</BatchFrequencyInMinutes>
    <NumberOfTimesToRunBatch >2</NumberOfTimesToRunBatch>
    <UploadFrequencyInSeconds>1</UploadFrequencyInSeconds>
    <TotalNumberOfTimesToUploadFile>1</TotalNumberOfTimesToUploadFile>
    <SupportedDataSourceType>Package</SupportedDataSourceType>
    <ProcessMessagesInOrder>No</ProcessMessagesInOrder>
    <PreventUploadWhenZeroRecords>No</PreventUploadWhenZeroRecords>
    <UseCompanyFromMessage>Yes</UseCompanyFromMessage>
    <LegalEntity>DAT</LegalEntity>
    <PackageAPIExecute>true</PackageAPIExecute>
    <PackageAPIOverwrite>false</PackageAPIOverwrite>
    <PackageAPIReexecute>false</PackageAPIReexecute>
    <DefinitionGroupID>TestExport</DefinitionGroupID>
    <PackageName>TestExportPackage</PackageName>
</JobDefinition>
```

PARENT ELEMENT	ELEMENT	ELEMENT CARDINALITY	ATTRIBUTE	DESCRIPTION
<SharedSetup>	<JobDefinition>	1..n	ID	The job definition ID is used in the tasks to reference the definition to be used for the data project.

PARENT ELEMENT	ELEMENT	ELEMENT CARDINALITY	ATTRIBUTE	DESCRIPTION
<JobDefinition>	<Operation>	1..1	-	The operation to be performed is specified by the following values: - Import - Export
	<Truncate>	1..1	-	This is a Boolean field with possible values of Yes or No. This is applicable only when operation is set to *Import*.
	<Mode>	1..1	-	The mode specifies the method using which the operation must be performed. The possible values are: - Import async - Export async - Recurring batch: This uses the enqueue API. Dequeue API is not supported yet. Package API supports both export and import.
	<ConfigurationOnly>	0..1	-	This is a Boolean field with possible values of Yes or No. This must be set to Yes if the task is only to configure the data project but not to perform the specified operation.
	<BatchFrequencyInMinutes>	1..1	-	This specifies the frequency in which the batch must be scheduled. This is applicable only when mode is set to *recurring batch*.
	<NumberOfTimesToRunBatch>	1..1	-	This is used to set a limit to how many times the scheduled batch should run. This is applicable only when mode is set to *recurring batch*.

PARENT ELEMENT	ELEMENT	ELEMENT CARDINALITY	ATTRIBUTE	DESCRIPTION
	<UploadFrequencyInSeconds>	1..1	-	This is used to control the rate at which a file is uploaded to the recurring batch job for import. This must be used only for automated testing of recurring integrations in non-production environments. This is applicable only when mode is set to *recurring batch* and operation is set to *Import*.
	<TotalNumberOfTimesToUpload>	1..1		This controls the total number of times the file should be uploaded to the recurring batch. This must be used only for automated testing of recurring integrations in non-production environments. This is applicable only when mode is set to *recurring batch* and operation is set to *Import*.
	<SupportedDataSourceType>	1..1		This must be used to specify if a file is being sent to the recurring batch or a package. This is only applicable when mode is set to 'recurring batch'.
	<ProcessMessagesInOrder>	1..1		This is a Boolean field with possible values of Yes or No. This is applicable only when mode is set to *recurring batch* and operation is *Import*.
	<PreventUploadWhenZeroRecords>	1..1		This is a Boolean field with possible values of Yes or No. This is applicable only when mode is set to *recurring batch* and operation is *Export*.

PARENT ELEMENT	ELEMENT	ELEMENT CARDINALITY	ATTRIBUTE	DESCRIPTION
	<UseCompanyFrom Message>	1..1		This is a Boolean field which can be set to Yes or No. This is applicable only when mode is set to *recurring batch* and operation is *Import*.
	<LegalEntity>	1..1		This is used to specify the legal entity in which the import/export job must be executed.
	<PackageAPIExecute >	1..1		Refer to package API documentation to understand this parameter. This is a Boolean field which takes 'true' or 'false'.
	<PackageAPIOverwri te>	1..1		Refer to package API documentation to understand this parameter. This is a Boolean field which takes 'true' or 'false'.
	<PackageAPIReexecu te>	1..1		Refer to package API documentation to understand this parameter. This is a Boolean field which takes 'true' or 'false'.
	<DefinitionGroupID>	1..1		Refer to package API documentation to understand this parameter. This is a string field.
	<PackageName>	1..1		Refer to package API documentation to understand this parameter. This is a string field.

Entity setup

The **Entity setup** section defines the characteristics of an entity that a task in the manifest will use. There can be more than one definition, one for each entity that is used by the tasks in the manifest.

```
<EntitySetup ID='Generic'>
    <Entity name='*'>
        <SourceDataFormatName>Package</SourceDataFormatName>
        <ChangeTracking></ChangeTracking>
        <PublishToBYOD></PublishToBYOD>
        <DefaultRefreshType>Full push only</DefaultRefreshType>
        <ExcelWorkSheetName></ExcelWorkSheetName>
        <SelectFields>All fields</SelectFields>
        <SetBasedProcessing></SetBasedProcessing>
        <FailBatchOnErrorForExecutionUnit>No</FailBatchOnErrorForExecutionUnit>
        <FailBatchOnErrorForLevel>No</FailBatchOnErrorForLevel>
        <DisableEntity>No</DisableEntity>
        <SkipStaging>Yes</SkipStaging>
        <ParallelProcessing>
            <Threshold></Threshold>
            <TaskCount></TaskCount>
        </ParallelProcessing>
        <MappingDetail StagingFieldName='RoundingRulePrices' AutoGenerate='Yes' AutoDefault='No'
DefaultValue='' IgnoreBlankValues='No' TextQualifier='No' UseEnumLabel='No'/>
        </Entity>
</EntitySetup>
```

PARENT ELEMENT	ELEMENT	ELEMENT CARDINALITY	ATTRIBUTE	DESCRIPTION
<SharedSetup>	<EntitySetup>	1..n	ID	An identification that will be used by tasks to reference an entity definition to be used.
<EntitySetup>	<Entity>	1..1	name	The entity element is identified by the entity's name. However, to facilitate easy manifest definition, this element also supports * as a wild card which will mean all entities being used in a task. This comes in very handy when using data packages with hundreds of entities in a task.
<Entity>	<SourceDataFormat Name>	1..1	-	This is the file format to be used for the entity.
	<ChangeTracking>	1..1	-	This is a Boolean field with possible values of Yes or No. It enables or disables change tracking on the entire entity.
	<PublishToBYOD>	1..1	-	This is a Boolean field with possible values of Yes or No.

PARENT ELEMENT	ELEMENT	ELEMENT CARDINALITY	ATTRIBUTE	DESCRIPTION
	<DefaultRefreshType>	1..1	-	This sets the default refresh rate on the entity. The possible values are *Incremental push only* or *Full push*.
	<ExcelWorkSheetName>	1..1	-	This is used to specify the worksheet to be used for the entity.
	<SelectFields>	1..1	-	This can be used to specify the fields to be included in the template for an export operation.
	<SetBasedProcessing>	1..1	-	This is a Boolean field with possible values of Yes or No. It is used to enable or disable set based processing on an entity.
	<FailBatchOnErrorForExecutionUnit>	1..1	-	This is a Boolean field with possible values of Yes or No. It is used to enable or disable failure at execution unit level on an entity.
	<FailBatchOnErrorForLevel>	1..1	-	This is a Boolean field with possible values of Yes or No. It is used to enable or disable failure at execution level on an entity.
	<DisableEntity>	1..1	-	This is a Boolean field with possible values of Yes or No. It is used to enable or disable an entity in a data project.
	<SkipStaging>	1..1	-	This is a Boolean field with possible values of Yes or No. It is used to skip staging table for an entity during exports.

PARENT ELEMENT	ELEMENT	ELEMENT CARDINALITY	ATTRIBUTE	DESCRIPTION
	<ParallelProcessing>	1..1	-	This is used to define the parallel processing set up for an entity. The task will delete these settings if already exits at the beginning of the task and it will delete the created settings at the end of its execution.
<ParallelProcessing>	<Threshold>	1..1	-	This specifies the threshold for the parallel processing rule.
	<TaskCount>	1..1	-	This is used to specify the number of parallel tasks to be used for parallel processing.
<Entity>	<MappingDetail>	0..n	-	Allows to configure the *auto generate*, *auto default* and other settings on the mapping for an entity.
	<MappingDetail>	-	StagingFieldName	This attribute is used to identify the entity column for which the settings are to be specified.
	<MappingDetail>	-	AutoGenerate	This is a Boolean field with possible values of Yes or No for enabling/disabling auto generate option.
	<MappingDetail>	-	AutoDefault	This is a Boolean field with possible values of Yes or No for enabling/disabling auto default option.
	<MappingDetail>	-	DefaultValue	This is the default value to be used if auto defaulting is enabled.

PARENT ELEMENT	ELEMENT	ELEMENT CARDINALITY	ATTRIBUTE	DESCRIPTION
	<MappingDetail>	-	IgnoreBlankValues	This is a Boolean field with possible values of Yes or No for enabling/disabling this option.
	<MappingDetail>	-	TextQualifier	This is a Boolean field with possible values of Yes or No for enabling/disabling this option.
	<MappingDetail>	-	UseEnumLabel	This is a Boolean field with possible values of Yes or No for enabling/disabling this option.

Test groups

Test groups can be used to organize related tasks in a manifest. There can be more than one test group in a manifest.

```
<TestGroup name='Set up Financials'>
    <TestCase Title='Import shared set up data package' ID='3933885' RepeatCount='1' TraceParser='off'
TimeOut='20'>
        <DataFile RefID='SharedSetup' />
        <JobDefinition RefID='ImportJobDefinition_1' />
        <EntitySetup RefID='Generic' />
    </TestCase>

    <TestCase Title='Import financials for HQUS' ID='3933886' RepeatCount='1' TraceParser='off'
TimeOut='20'>
        <DataFile RefID='FinancialsHQUS' />
        <JobDefinition RefID='ImportJobDefinition_1'>
            <LegalEntity>HQUS</LegalEntity>
        </JobDefinition>
        <EntitySetup RefID='Generic' />
    </TestCase>

    <TestCase Title='Import financials for PICH' ID='3933887' RepeatCount='1' TraceParser='off'
TimeOut='20'>
        <DataFile RefID='FinancialsPICH' />
        <JobDefinition RefID='ImportJobDefinition_1'>
            <LegalEntity>PICH</LegalEntity>
        </JobDefinition>
        <EntitySetup RefID='Generic' />
    </TestCase>

    <TestCase Title='Import financials for PIFB' ID='3933888' RepeatCount='1' TraceParser='off'
TimeOut='20'>
        <DataFile RefID='FinancialsPIFB' />
        <JobDefinition RefID='ImportJobDefinition_1'>
            <LegalEntity>PIFB</LegalEntity>
        </JobDefinition>
        <EntitySetup RefID='Generic' />
    </TestCase>
</TestGroup>
```

PARENT ELEMENT	ELEMENT	ELEMENT CARDINALITY	ATTRIBUTES	DESCRIPTION
<TestManifest>	<TestGroup>	1..n	-	-
	<TestGroup>	1..1	Name	This is the name for the group to identify its functional reason.
<TestGroup>	<TestCase>	1..n	-	The task is defined in this element. The task can refer to the shared set up to inherit task parameters and task behavior. The task can also override parameters and behavior at its level thus making the management of the manifest simple.
	<TestCase>	-	Title	This is the title for the task.
	<TestCase>	-	ID	This is the ID for the task. This can be alphanumeric with a max character limit of 10.
	<TestCase>	-	RepeatCount	This is a placeholder for a future functionality. However, this must be specified with a value of *1*.
	<TestCase>	-	TraceParser	This is a placeholder for a future functionality. However, this must be specified with a value *off*.
	<TestCase>	-	Timeout	This is the maximum duration a task will be monitored by the task automation manager. If the task is still active beyond the timeout specified, the manager will proceed to the next task in the manifest.

PARENT ELEMENT	ELEMENT	ELEMENT CARDINALITY	ATTRIBUTES	DESCRIPTION
<TestCase>	<DataFile>	1..n	-	This element is used to define the file or data package to be used by the task. This can reference to an already declared file or a data package in the shared section of the manifest. A task can have more than one data file specified for recurring batch import scenarios only. For other scenarios, even if more than one files are specified, the first file is what will be used by the task.
	<JobDefinition>	1..1	-	This element is used to define the data project to be used by the task. This can reference to an already declared job definition in the shared section of the manifest. The task can override elements of job definition to a new value than what is defined in the shared set up.
	<EntitySetup>	1..1	-	This element is used to define the entity set up for entities used by the task. This can reference to an already declared entity set up in the shared section of the manifest. The task can override elements of entity setup to a new value than what is defined in the shared set up.

Best practices for manifest design

You can define a manifest in many ways. Here are a few pointers that you should consider when you design a manifest.

Granularity

We recommend that you determine the granularity of your manifest as a functional decision. Your team must

decide whether it wants to manage many manifests or manage changes in a single manifest.

- Start with as many manifests as your team thinks you logically need. Later, when the team actually starts to run the manifests, it might find that it uses fewer manifests than it expected, and it might want to merge them. In this case, you can merge manifests.
- Consider separation of duties. For example, you might have one manifest for the setup of demo data and another manifest for the setup of the golden configuration for your environment. In this way, you can make sure that team members use only the manifests that they are supposed to use.
- Consider user access to LCS. For example, larger and globally distributed implementation teams might have multiple instances of the application or multiple LCS projects.

Inheritance

The manifest schema supports inheritance of common elements that will apply to all tasks in the manifest. A task can override a common element to define a unique behavior. The purpose of the **Shared setup** section is to minimize repetition of configuration elements, so that elements are reused as much as possible. The goal is to keep the manifest concise and clean, to improve maintenance and readability.

Source control

Manifests that must be used by all the members of an implementation team should be stored in source control in the Application Object Tree (AOT). This approach not only provides the benefits of source control, but also enables a process to distribute or make manifests available to all users in a consistent manner. This approach also enables configuration management for data projects that are related to data management, if manifests are used for configuration.

Number of job definitions and entity definitions

For most of the use cases, one job definition in a manifest should be enough, because inheritance can be used to change the behavior at the task level. This principle also applies to entity definitions.

Validations

Data task automation manager performs validations, based on the setup of a task. If a task fails, you can quickly determine the reason for the failure by viewing the validations after the task is completed. The level of information that Data task automation manager provides is optimized to facilitate initial discovery. For detailed investigation, you must look at the corresponding data project and its execution details.

The following data validations are currently supported:

- **Job status** – This validation checks whether the job was successful.
- **Batch status** – This validation checks whether the batch was successful.
- **Message status** – If the test is about integrations, the message status is validated.
- **Truncation** – If truncation is enabled, this validation checks whether truncation occurred.
- **Skip staging** – If **Skip staging** is enabled on a test, this validation checks whether staging was skipped.

Example 1: Configuration management for data projects

The **<ConfigurationOnly>** element can be used to create configuration tasks for data projects. When ConfigurationOnly is set to Yes, the data projects are only created but not executed. This allows for managing data projects across environments in an automated manner.

```
<?xml version='1.0' encoding='utf-8'?>
<TestManifest name='Data management demo data set up'>
    <SharedSetup>
        <DataFile ID='SharedSetup' name='Demo data-7.3-100-System and Shared'  assetType='Data package'
lcsProjectId=''/>
        <DataFile ID='FinancialsHQUS' name='Demo data-7.3-200-Financials-HQUS' assetType='Data package'
```

```
lcsProjectId=''/>
        <DataFile ID='FinancialsPICH' name='Demo data-7.3-200-Financials-PICH' assetType='Data package'
lcsProjectId=''/>
        <DataFile ID='FinancialsPIFB' name='Demo data-7.3-200-Financials-PIFB' assetType='Data package'
lcsProjectId=''/>

        <JobDefinition ID='ImportJobDefinition_1'>
            <ConfigurationOnly>Yes</ConfigurationOnly>
            <Operation>Import</Operation>
            <Truncate>No</Truncate>
            <Mode>Import async</Mode>
            <BatchFrequencyInMinutes>1</BatchFrequencyInMinutes>
            <NumberOfTimesToRunBatch >2</NumberOfTimesToRunBatch>
            <UploadFrequencyInSeconds>1</UploadFrequencyInSeconds>
            <TotalNumberOfTimesToUploadFile>1</TotalNumberOfTimesToUploadFile>
            <SupportedDataSourceType>Package</SupportedDataSourceType>
            <ProcessMessagesInOrder>No</ProcessMessagesInOrder>
            <PreventUploadWhenZeroRecords>No</PreventUploadWhenZeroRecords>
            <UseCompanyFromMessage>Yes</UseCompanyFromMessage>
            <LegalEntity>DAT</LegalEntity>
        </JobDefinition>

        <EntitySetup ID='Generic'>
            <Entity name='*'>
                <SourceDataFormatName>Package</SourceDataFormatName>
                <ChangeTracking>No</ChangeTracking>
                <PublishToBYOD>No</PublishToBYOD>
                <DefaultRefreshType>Full push only</DefaultRefreshType>
                <ExcelWorkSheetName></ExcelWorkSheetName>
                <SelectFields>All fields</SelectFields>

                <FailBatchOnErrorForExecutionUnit>No</FailBatchOnErrorForExecutionUnit>
                <FailBatchOnErrorForLevel>No</FailBatchOnErrorForLevel>
                <FailBatchOnErrorForSequence>No</FailBatchOnErrorForSequence>
                <ParallelProcessing>
                    <Threshold></Threshold>
                    <TaskCount></TaskCount>
                </ParallelProcessing>
            </Entity>
        </EntitySetup>
    </SharedSetup>

    <TestGroup name='Set up import jobs for Financials'>
        <TestCase Title='Set up import job for shared set up data package' ID='3933885' RepeatCount='1'
TraceParser='off' TimeOut='20'>
            <DataFile RefID='SharedSetup' />
            <JobDefinition RefID='ImportJobDefinition_1' />
            <EntitySetup RefID='Generic' />
        </TestCase>

        <TestCase Title='Set up import job for financials HQUS' ID='3933886' RepeatCount='1'
TraceParser='off' TimeOut='20'>
            <DataFile RefID='FinancialsHQUS' />
                <JobDefinition RefID='ImportJobDefinition_1'>
                    <LegalEntity>HQUS</LegalEntity>
                </JobDefinition>
                <EntitySetup RefID='Generic' />
        </TestCase>

        <TestCase Title='Set up import job for financials PICH' ID='3933887' RepeatCount='1'
TraceParser='off' TimeOut='20'>
            <DataFile RefID='FinancialsPICH' />
                <JobDefinition RefID='ImportJobDefinition_1'>
                    <LegalEntity>PICH</LegalEntity>
                </JobDefinition>
                <EntitySetup RefID='Generic' />
        </TestCase>

        <TestCase Title='Set up import job for financials PIFB' ID='3933888' RepeatCount='1'
```

```
TraceParser='off' TimeOut='20'>
            <DataFile RefID='FinancialsPIFB' />
                <JobDefinition RefID='ImportJobDefinition_1'>
                    <LegalEntity>PIFB</LegalEntity>
                </JobDefinition>
                <EntitySetup RefID='Generic' />
        </TestCase>
    </TestGroup>
</TestManifest>
```

Example 2: Automated setup of demo data

The following manifest shows the setup of demo data for three legal entities when the demo data packages are stored in the Shared asset library. The difference in this example from the previous example is the actual execution of the data projects to set up the demo data. This is accomplished by not using the ConfigurationOnly option or setting it to No to use it for consistency of the manifest.

```
<?xml version='1.0' encoding='utf-8'?>
<TestManifest name='Data management demo data set up'>
    <SharedSetup>
        <DataFile ID='SharedSetup' name='Demo data-7.3-100-System and Shared'  assetType='Data package'
lcsProjectId=''/>
        <DataFile ID='FinancialsHQUS' name='Demo data-7.3-200-Financials-HQUS' assetType='Data package'
lcsProjectId=''/>
        <DataFile ID='FinancialsPICH' name='Demo data-7.3-200-Financials-PICH' assetType='Data package'
lcsProjectId=''/>
        <DataFile ID='FinancialsPIFB' name='Demo data-7.3-200-Financials-PIFB' assetType='Data package'
lcsProjectId=''/>

        <JobDefinition ID='ImportJobDefinition_1'>
                <Operation>Import</Operation>
                <Truncate></Truncate>
                <Mode>Import async</Mode>
                <BatchFrequencyInMinutes>1</BatchFrequencyInMinutes>
                <NumberOfTimesToRunBatch >2</NumberOfTimesToRunBatch>
                <UploadFrequencyInSeconds>1</UploadFrequencyInSeconds>
                <TotalNumberOfTimesToUploadFile>1</TotalNumberOfTimesToUploadFile>
                <SupportedDataSourceType>Package</SupportedDataSourceType>

Data validation checklist workspace

2/18/2021 • 2 minutes to read • Edit Online

This topic provides an overview of the **Data validation checklist workspace** and the associated configuration.

The **Data validation checklist** workspace lets you track data validation processes across companies, areas, and people. The checklist can be used during a new implementation, after an upgrade, or after a migration. Depending on your view of the **Data validation checklist** workspace, you'll see either all tasks and statuses for a data validation project, or just the tasks that are assigned to you.

You must first select a data validation project at the top of the workspace. All data that is shown in the workspace is then filtered by the selected data validation project.

Summary tiles

The **Summary** tiles provide an overview of the process, and indicators help you keep the data validation process on track. You can see all remaining tasks, completed tasks, in progress tasks, and not started tasks for the process. This information is for all companies that are included in the selected data validation project.

Tasks and status section

In the **Tasks and status** section, the status of the overall data validation project is displayed in various ways: status by legal entity, by area, and by task list. You can select the filter to view the status for a specific company. Each status tab provides a breakdown by both the percentage that has been completed and the number of tasks that remain.

The last tab is for the detailed task list. This list shows the full task list. You can filter the task list in several ways. Click **Edit task** to change the status of a task or assign a task. Click **Attachments** to view attachments for a task.

The task name is a hyperlink to the page where the user must go to complete the work. You can set this hyperlink by using the **Menu item name** field when you edit or create a task from the **Configure data validation project** form.

You can attach files, notes, images, and URLs to a task by using the **Attachments** action. For example, you can attach a report file that was printed for a task. An icon appears in the **Attachment** column for the task if an attachment is present.

The **Completed by** option will be automatically filled after the task is completed with the name of the worker who completed the task. When a task is marked as completed, the **Completed date** field is automatically updated to the current date and time.

Configure data validation project page

Before you can use the **Data validation checklist** workspace, you must configure the process by using the **Configure data validation project** page. (Click **Workspaces** > **Data validation checklist** > **Configure data validation project**.)

Task areas

You use task areas to group data validation tasks into logical areas of ownership within your organization. For

example, Accounts payable, Accounts receivable, or General ledger might be used as task areas.

The **Menu item name** is associated with the task work effort and can be used to go directly to the associated page from the task link in the workspace. For example, a data validation task to run the **Accounts payable aging** report for Accounts payable can be linked to the **Accounts payable aging report** page.

Data management error descriptions

2/18/2021 • 3 minutes to read • Edit Online

This topic documents the scenarios when a specific error will be seen. These scenarios aren't a complete list of errors and scenarios, however this list will be continuously updated so keep checking back for updates. Any feedback on this page with regards to specific errors that should be covered are welcome.

This topic describes the error messages that you might encounter in data management.

Import to target failed due to an update conflict as more than one process is trying to update the same record at the same time

When you use recurring imports (enqueue API), if the files are sent to the end point at high frequency and the sequential processing of messages isn't enabled, data management will try to process the files in parallel. When files are processed in parallel, and multiple files have the same record, multiple threads will try to update the same record at the same time. If this is a data issue, you must update the data so that the same records don't repeat across files. If this is not a data issue and the entity is expected to handle such cases, this might be a bug. For bugs, to mitigate the issue, you can choose to sequentially process the files. If this is not a data issue and the entity is not expected to process in parallel, then this entity must not be subjected to parallel processing. You should enable sequential processing of messages in the recurring job.

There are field(s) which are not mapped to Entity <EntityName>

It is a common practice to use the export functionality to generate the entity template file that can be later used for imports. However, while exporting the template, in fixed width format with 'First row header' set to 'No' (in source data formats set up), the exported template will not have the column names. When this file is imported, it will result in this error.

Data package download - Error downloading data package for job ''. Record for ID - {GUID} not found

One of the scenarios where this error can happen is when the environment, such as the dev environment, points to the database in another environment, such as UAT, and the export job is run from the source environment. which is dev in this example. The exported file gets uploaded to the blob storage that is associated with the source environment (dev, in this example). However, this job will also show up in the target environment (UAT) since the database is shared. If you try to download the exported file using the **Download file** option, this error will display because the file does not exist in the blob storage of the target environment (UAT) from where you are trying to download.

XML is not in correct format-Exception from HRESULT: 0xC0010009

This message covers all XML formatting issues in the file. For example, the data project has mappings for columns that do not exist in the file that is being used for the operation. This error can happen if certain columns were removed from the file and this file is now used. Either fix the mapping in the data project or fix the file to have all the columns as expected.

Error while uploading a file during export

When running an export on a development environment, an error could occur relating to not being able to

upload the export file. This could occur if Azure Storage Emulator is not available or an older version of the emulator is installed. To resolve this issue, install the latest emulator, restart the virtual machine (VM), and rerun the export job. The storage emulator can be installed from Azure Storage Emulator.

Azure Data Lake overview

2/18/2021 • 13 minutes to read • Edit Online

NOTE

Effective November 2020:

- Common Data Service has been renamed to Microsoft Dataverse. For more information, see Power Automate Blog.
- Some terminology in Microsoft Dataverse has been updated. For example, *entity* is now *table* and *field* is now *column*. For more information, see Terminology updates.

This topic will be updated soon to reflect the latest terminology.

What is Azure Data Lake?

Microsoft Azure Data Lake is a technology in Azure cloud that enables big data analytics and artificial intelligence (AI). When this topic mentions "Data Lake," it's referring specifically to storage technology that is based on Azure Data Lake Storage Gen2.

Data lakes provide cloud storage that is less expensive than the cloud storage that relational databases provide. Therefore, large amounts of data can be stored in the cloud. This data includes both business data that is traditionally stored in business systems and data warehouses, device and sensor data, such as signals from devices. In addition, Data Lake supports a range of tools and programming languages that enable large amounts of data to be reported on, queried, and transformed.

For an overview of Data Lake Storage Gen2, see Introduction to Azure Data Lake Storage Gen2.

Dynamics 365 products, such as Finance and Operations apps, use Data Lake for AI and analytics scenarios. Therefore, customers can take advantage of the strengths and cost advances that this technology offers. The following sections provide an overview of the scenarios.

Analytical workspaces

Analytical workspaces provide contextual and actionable insights in Finance and Operations apps. They give users a bird's-eye view of a business process, so that they can immediately get relevant information and take appropriate action.

Analytical workspaces are based on Entity store and use embedded Power BI technology to provide rich, interactive visuals of data from Finance and Operations apps. Analytical workspaces are fun and exciting to use: they invite your users to explore data.

Analytical workspaces can be used for operational analytics scenarios in two ways:

- Use and extend the ready-made analytical workspaces, so that you don't have to build workspaces from scratch.
- Build your own Power BI–based analytical reports.

For more information, see Embedded Power BI in workspaces.

BYOD

Bring your own database (BYOD) is a service that lets customers extract data from Finance and Operations apps

into their own data warehouses. We recommend that you use BYOD when you must combine data from Finance and Operations apps with other systems or with reporting that uses earlier data.

For more information, see Bring your own database (BYOD).

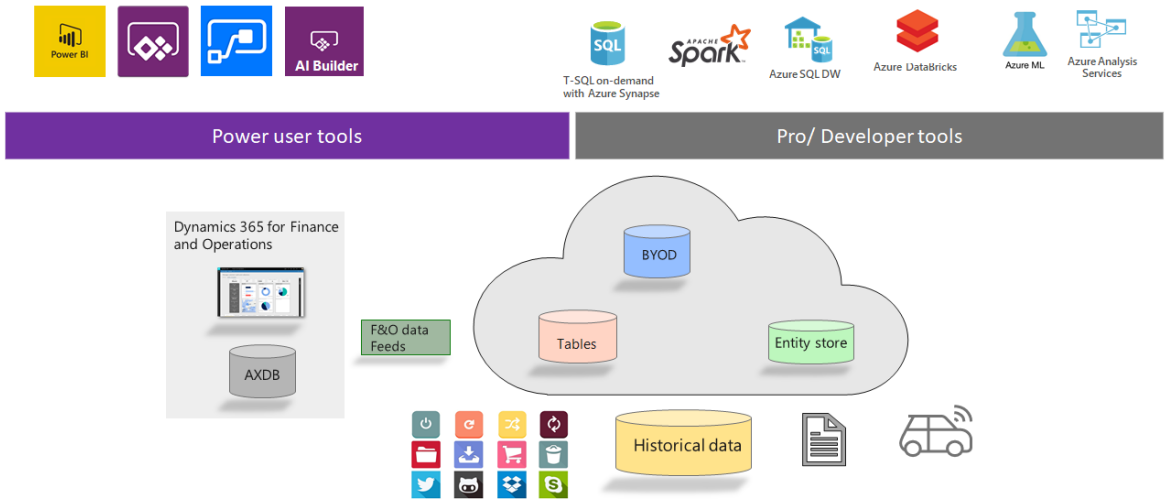
Data Lake combines BYOD and Entity store

Customers use a combination of analytical workspaces (which are based on Entity store) and BYOD for different scenarios. Following table compares the scenarios and capabilities

ANALYTICAL WORKSPACES BUILT-ON ENTITY STORE	DATA WAREHOUSE WITH BRING YOUR OWN DB (BYOD)
Near real-time Operational Analytics (with embedded Power BI)	Data warehouse with PowerBI.com or other tools
Reporting on data from F&O	Mash-up F&O data with other data sources
Ready-made reports shipped with F&O or ISV solution	Reports extended or authored by partner

Reports authored with both these sources can be pinned into Analytical workspaces in F&O with contextual security and drill thru actions Data Lake combines both these services into a single service that offers the "best of both worlds":

- Because Data Lake is included in customer subscriptions, you can bring your own data lake and integrate it with Finance and Operations apps. Finance and Operations apps will use your data lake to store Entity store data and operate analytical workspaces. Analytical workspaces continue to work as they worked before.
- Entity store is staged in your data lake and provides a set of simplified (denormalized) data structures to make reporting easier. Your users can now be given direct access to the data that is most relevant to them, and they can create their own reports by using a tool of their choice.
- Instead of exporting data by using BYOD, customers can select the data that is staged in the data lake. Data feed service, which is part of Finance and Operations services, keeps the data in the data lake fresh.
- You can bring your own data into the data lake to supplement the data that Finance and Operations apps provide. This capability allows for easy data mash-up scenarios in the data lake.
    - Data from external sources can easily be ingested into the data lake via hundreds of ready-made connectors that are available in tools such as Power BI dataflows and Azure Data Factory.
    - Historical data and earlier data that is often inherited as a part of the transition to Finance and Operations apps can be ingested directly into the data lake.
    - Data lakes provide options for ingesting non-business data. For example, device data can easily be ingested into the data lake.
- Cloud-based services let both power users and developers consume this data.

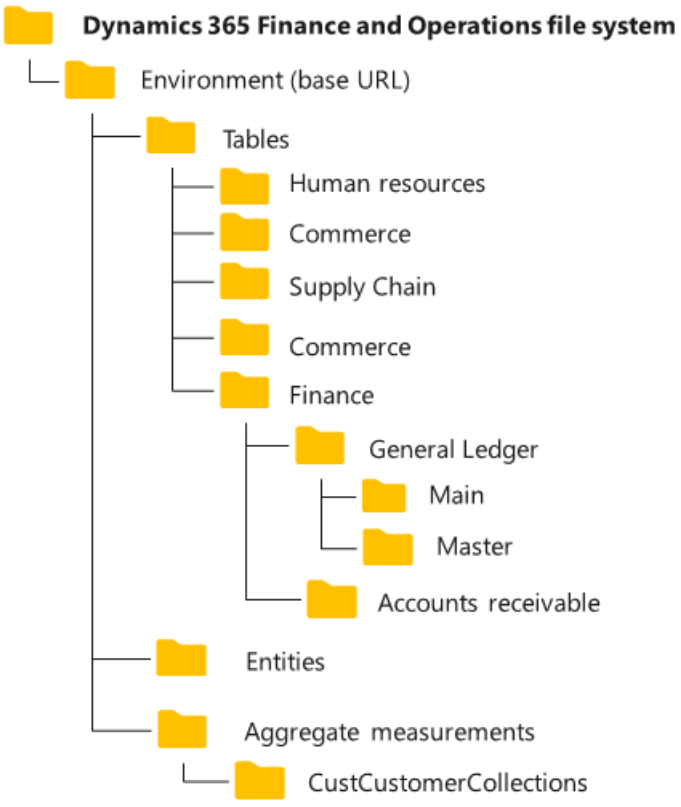


Common Data Model folders

Data is stored in Data Lake to comply with the Common Data Model folder standard. Here are some results:

- Data that Finance and Operations apps stage in Data Lake is organized into a set of folders.
- Common Data Model folders contain metadata definitions in addition to data files. Metadata definitions are kept in model files, according to the standard that is specified by the Common Data Model language.
- Because metadata is present and data storage complies with the Common Data Model folder standard, Azure and other services can read and transform the data.

The following illustration shows the Common Data Model folder structure from Finance and Operations apps.



For more information about Common Data Model in Data Lake, see Use the Common Data Model to optimize Azure Data Lake Storage Gen2.

Here is an example:

- You can attach a Common Data Model folder to Power BI dataflows as a reference dataflow. You can work

with Power BI dataflows and further reshape the data, or you can create Power BI datasets and reports.
- You can use Data Factory or other data transformation tools to further shape the data.

Like Finance and Operations apps, other services (including Dataverse), Azure IoT, and many third-party tools and service can understand and work with data in Common Data Model folders. The list of services is growing. Here are some examples:

- Dataverse lets you export data to your own data lake. For more information, see Exporting Dataverse data to Azure Data Lake is Generally Available.
- Power users can transform data in Data Lake by using Dataverse dataflows. For more information, see Use the Common Data Model to optimize Azure Data Lake Storage Gen2.

How you can use Data Lake later if you're currently using BYOD

In most cases, customers use BYOD to extract data from Finance and Operations apps so that they can use that data for reporting or analytics. BYOD requires that customers provision and maintain an Azure SQL database to store data that is exported from Finance and Operations apps.

Some customers use the exported data in BYOD for reporting. These customers can just point reporting tools to the SQL database and create reports.

Some customers use BYOD as a staging area, where a "snapshot" of the Finance and Operations data is retained. These customers have an enterprise data warehouse, and they use additional data pipelines that copy the data from the BYOD "staging area" to their data warehouse. They might also have other downstream processing and transformation pipelines.

If you're currently using BYOD for these scenarios, you will gain several benefits by onboarding to Data Lake.

Because data is already present, export isn't required

Data Lake integration lets users select tables and entities, just as they can in the BYOD experience. After tables and entities are selected, the system updates the data in Data Lake. The system also continuously exports data as it changes in Finance and Operations apps. The data lake reflects the updated Finance and Operations data within a few minutes after the changes occur.

> **NOTE**
> Table data is updated within minutes after a change occurs in Finance and Operations apps. According to the current service-level agreement (SLA) that the services offer, data is updated within **10 minutes**.

Because of Data Lake integration, customers don't have to monitor and manage complex data export and orchestration schedules. No user intervention is required to update data in the data lake.

Reduced cost of data storage

Data is stored in a data lake (Gen2) instead of the SQL database that BYOD requires. Therefore, customer can use a storage medium that is much less expensive than Azure SQL Database.

> **NOTE**
>
> Because Data Lake Storage Gen2 is included in a customer's subscription, the customer must pay for data storage and input/output (I/O) costs that are incurred when data is read and written to the data lake. The customer might also incur I/O costs because Finance and Operations apps write data to the data lake or update the data in it. To help reduce intra-region I/O costs, Finance and Operations apps require that data lakes be provisioned in the same country or region as the Finance and Operations environment.

For more information about cost, see the Azure Data Lake Storage Gen2 pricing page.

Existing downstream/consumption pipelines can be preserved

As was discussed earlier, BYOD is mostly used in two scenarios:

- Reporting tools and other tools access BYOD directly.
- BYOD is used as a temporary staging area to store data while it's being exported to other downstream systems, such as data warehouses.

For the first scenario, you can point reporting tools to the SQL database. Many reporting tools work with SQL databases, because they can use Transact-SQL (T-SQL) to read data.

For the second scenario, you can use data integration/transformation tools such as Data Factory. Many data integration tools can consume data directly from the data lake.

For both scenarios, if you're using T-SQL to read the database, you can create a SQL Server endpoint by using Azure Synapse Analytics. Azure Synapse include SQL-on-demand capability that enables Data Lake to be queried by using the T-SQL language. Downstream tools don't have to be modified, because you can preserve the data shape, as you can when you use BYOD.

Simplified data pipeline for near-real-time reporting

In a traditional data warehouse, data is stored in a staging area before it can be aggregated and simplified for reporting. You might also have reporting tools that aggregate data for better user experiences. If you have multiple data stops (for staging, denormalization, and aggregation), data staleness increases (that is, after activity occurs, more time passes before reports reflect the results).

Traditional data warehouses that have multiple data stops are ideal for reporting on data that changes every day or even several times a day. However, if you must report on near-real-time data (for example, if you must report on retail sales data within minutes after the sales occur), you might have to design a data pipeline that has minimal data stops. This pattern is known as *hot-path, cold-path reporting* (or *lambda architecture*). Multiple data stops and multiple data pipelines increase complexity and management efforts.

Data Lake integration makes *warm-path reporting* available as the default reporting option. Because data in a data lake is updated within minutes, this approach might be acceptable for most reporting scenarios, even scenarios that involve near-real-time reporting.

For near-real time reporting, you can minimize the data staging and preparation steps by using on-demand query (for example, Azure Synapse) and Power BI direct query mode, which queries semi-prepared data in the data lake. For analytical reporting, you can denormalize and aggregate the data in the data lake.

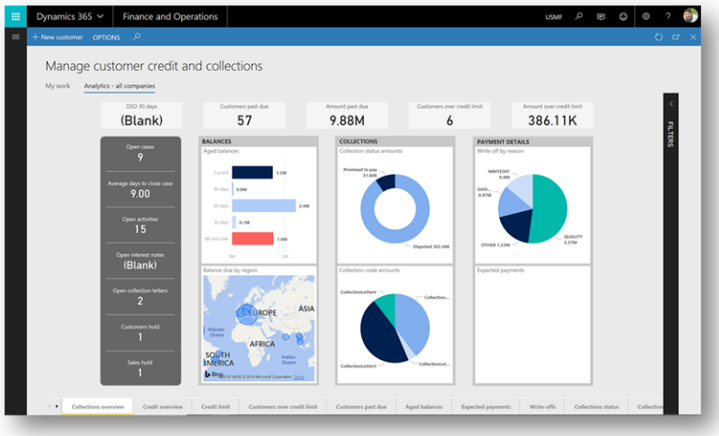
How you can use Data Lake later if you're currently using analytical workspaces

Analytical workspaces make in-context operational analytics available in Finance and Operations apps. Analytical workspaces are built as an extension to Finance and Operations workspaces. They are a type of a "cockpit" that

provides a bird's-eye view of business processes. There are more than 25 ready-made analytical workspaces that provide interactive, near-real-time data exploration.

You can drive action by adding contextual gestures to analytical workspaces. Therefore, users can act on results without having to leave the report that they are viewing. An extensive programming model that is built into Finance and Operations apps enables enterprise resource planning (ERP) actions and business logic to be driven from analytical workspaces.

You can use the ready-made analytical workspaces from Microsoft, partners, and independent software vendors (ISVs) as starting points. Alternatively, if you've built your own Power BI–based analytical reports by using BYOD or your own data warehouse, you can pin them to analytical workspaces. In both cases, you can enrich business processes through in-context reporting that drives action.



- **Real-time insights** into business processes
- **Interactive visuals** - explore lots of data in a fun and exciting way
- jump into details right here and **take action**
- **In context, embedded** - you don't need to go anywhere else
- Power users can modify or create new pages with **Web edit**
- **Pin your own** reports into Analytical workspaces

The ready-made analytical workspaces that are part of core Finance and Operations apps (or part of ISV extensions) include reports that are built by using Entity store. Entity store contains *aggregate measurements* (that is, simplified data structures, such as fact tables and dimensions).

Aggregate measurements will be available in the data lake instead of Entity store. If you're using ready-made analytical workspaces that were built by using Entity store, they will be pointed to Data Lake in an upcoming monthly service update. The Microsoft service team will notify you when your Entity store is ready for the transition to Data Lake. You won't have to modify the reports themselves. Therefore, no development work will be required.

If you've pinned your own Power BI reports to analytical workspaces, you can transition them to Data Lake on your own schedule.

How you can modernize your existing data warehouse by using Data Lake

Although you can use Data Lake integration to transition from BYOD and gain immediate benefits, Data Lake also lets you do much more.

Data Lake is designed to store large amounts of data: hundreds of terabytes (TB) or more. It takes advantage of Azure Blob storage, which is inexpensive storage technology that many underlying services of Azure use.

Data lakes are designed for big data analytics. You can bring your historical data and earlier data from your own systems into Data Lake. This data can consist of scanned documents in addition to business data. You can then apply machine learning models to the documents to make sense of the content and the opinions that the document authors expressed. You can also collect signals from devices and vehicles or machines on the shop floor, and store the data in data lakes. You can then apply machine learning models to detect anomalies and patterns in the signals, and you can join the results with business data to take proactive action.

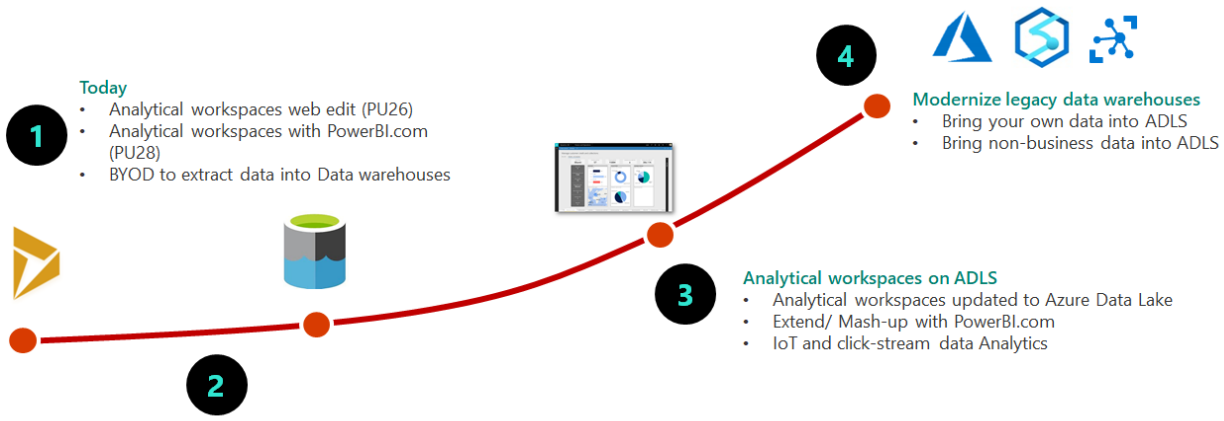
Data Lake has many associated services that enable analytics, data transformation, and the application of AI and

machine learning. Azure services from Microsoft, partners, and open-source tools can be used to reason over the data.

Instead of downloading Finance and Operations data from a data lake into your on-premises data warehouses, you can bring your on-premises data into a data lake. Microsoft refers to this transformation as *modernization of data warehouses*.

Planning the transition

You can plan your transition to Data Lake in multiple stages, as shown in the following illustration. Each stage offers business benefits that can be justified on their own. You can use the stages that are shown here as a planning guideline.



1. **Your current situation:** You might already be using BYOD and analytical workspaces that are based on Entity store.
2. **Getting easy access to data:** As you gain access to tables, entities, and aggregate measurements in Data Lake, you will be able to retire BYOD and use the data that is readily available. Therefore, management effort and costs can be reduced, as was discussed earlier. You can keep your existing downstream data warehouses and pipelines to manage project scope and budget.
3. **Empowering power users:** Analytical workspaces will be transitioned to Data Lake as a service update. Therefore, ready-made analytical workspaces are based on the same data that is available in the data lake. Power users can easily extend analytical workspaces. When the service update occurs, you will be able to make the full capabilities of PowerBI.com available to your power users. By using capabilities such as Power BI dataflows, power users can easily combine data from online services and data is already available in the data lake. The same reports that are available in analytical workspaces can be consumed directly on PowerBI.com.
4. **Modernizing your previous data warehouse:** Modernization will probably be the investment that brings the most benefits. You can move data that currently exists in your on-premises data warehouse to the cloud. You can rely on cloud-based computing services and apply the same transformations on a pay-per-use basis. You can also combine your business data with sensor and device data.

Configure export to Azure Data Lake

2/18/2021 • 10 minutes to read • Edit Online

NOTE

The **Export to Azure Data Lake** feature is in limited preview and may not be available in all regions and environments supported by Finance and Operations apps. If you are unable to find the **Export to Azure Data Lake** functionality in Lifecycle Services (LCS) or your Finance and Operations apps, this feature is not currently available in your environment.

Currently, previews are closed. In the coming months we will enable additional environments in several regions. We are accepting requests from customers who would like to join the preview. If you would like to join a future preview, complete the survey. We will contact you when we are ready to include you. You can also join a Yammer group by completing the survey. You can use the Yammer group to stay in contact and ask questions that will help you understand the feature.

Until the feature is enabled in your environment, you have the option to prototype/plan the feature implementation using GitHub tools. The tools will enable you to export data from your sandbox environment into a storage account in the same format as exported by the feature.

At this time, **Export to Azure Data Lake** feature is not available in Tier-1 (developer) environments. You need a cloud-based Tier-2 or higher environment to enable this feature.

To make aggregate measurements available in a data lake, continue to use the feature in the manner that is described in Make entity store available as a Data Lake.

Create Service Principle for Microsoft Dynamics ERP Microservices

The **Export to Azure Data Lake** feature is built using a microservice that exports Finance and Operations app data to Azure Data Lake and keeps the data fresh. Microservice uses the Azure service principle, **Microsoft Dynamics ERP Microservices**, to securely connect to your Azure resources. Before you configure the Export to Data Lake feature, add the **Microsoft Dynamics ERP Microservices** service principle to your Azure Active Directory (Azure AD). This step enables Azure AD to authenticate the microservice.

NOTE

You will need **Azure Active Directory tenant administrator** rights to perform these steps.

To add the service principle, complete the following steps.

1. Launch the Azure portal and go to the Azure Active Directory.
2. On the left menu, select **Manage** > **Enterprise Applications**, and search for the following applications.

APPLICATION	APP ID
Microsoft Dynamics ERP Microservices	0cdb527f-a8d1-4bf8-9436-b352c68682b2

If you are unable to find the above applications, complete following steps.

3. On your local machine, open the **Start** menu, and search for **PowerShell**.
4. Right-click **Windows PowerShell**, and then select **Run as administrator**.
5. Run the following command to install **AzureAD** module:

```
Install-Module -Name AzureAD
```

- If NuGet provider is required to continue, select **Y** to install it.
- If an **Untrusted repository** message appears, select **Y** to continue.

6. Run the following commands to add the application to the Azure Active Directory.

```
Connect-AzureAD
```

```
New-AzureADServicePrincipal –AppId '0cdb527f-a8d1-4bf8-9436-b352c68682b2'
```

7. Sign in as the Azure Active Directory administrator when prompted.

Configure Azure Resources

To configure the export to Data Lake, create a storage account in your own Azure subscription. This storage account is used to store data. Next, create an Azure AD application ID that grants access to the root of your storage account. Your Finance or Operations app will use the Azure AD application to gain access to storage, create the folder structure, and write data. Create a key vault in your subscription and store the name of the storage account, application ID, and the application secrets. If you don't have permission to create resources in Azure portal, you will need assistance from someone in your organization with the required permissions.

The steps, which take place in the Azure portal, are as follows:

> **NOTE**
> When you are working in the Azure portal, you will be instructed to save several values for subsequent steps. You will also provide some of these values to your Finance and Operations apps by using Lifecycle Services (LCS). You will need Administrator access to LCS in order to do this.

1. Create an application in Azure Active Directory
2. Grant access control roles to applications
3. Create a Data Lake Storage (Gen2 account) in your subscription
4. Create a key vault
5. Add secrets to the key vault
6. Authorize the application to read secrets in the key vault
7. Install the Export to Data Lake add-in in LCS

Create an application in Azure Active Directory

1. In the Azure portal, select **Azure Active Directory**, and then select **App registrations**.
2. Select **New registration**, and enter the following information:
   - **Name:** Enter a name for the app.
   - **Supported Account types**: Choose the appropriate option.
3. After the application is created, select it and then copy and save the Application (client) ID at the top of the page. You will need this later.
4. On the left navigation pane, select **API permissions**.
5. Select **Add a permission**, and in the **Request API permissions** dialog box, select **Azure Key vault**.
6. Select **Delegated permissions**, select **user_impersonation**, and then select **Add permissions**.

7. On the left navigation pane, select **Certificates & secrets**, and then select **New client secret**.
8. In the **Description** field, enter a name.
9. In the **Expires** field, select an option, and then select **Add**. The system will generate a secret and display it under the grid.
10. Copy the secret **Value** to the clipboard. This is the value you will need to provide when you set up the key vault later.

Create a Data Lake Storage (Gen2) account in your subscription

The Data Lake Storage account will be used to store data from your Finance and Operations apps. To manually create a storage account, you must have administrative rights to your organization's Azure subscription. To create a storage account, complete the following steps.

1. In the Azure portal, select **Create new resource**, and then search for and select **Storage account – blob, file, table, queue**.
2. In the **Create storage account** dialog box, provide values for the following parameter fields:
   - **Location:** Select the data center where your environment is located. If the data center that you select is in a different Azure region, you may incur additional data movement costs. If your Microsoft Power BI or your data warehouse is in a different region, you can use replication to move storage between regions.
   - **Performance**: We recommend you select **Standard**.
   - **Account kind**: You must select **StorageV2**. In the **Advanced options** dialog box, you will see the option, **Data Lake storage Gen2**.
3. On the **Advanced tab**, select **Data Lake storage Gen2** > **Hierarchical namespaces**, and then select **Enabled**. If you disable this option, you may not be able to consume data that is written by Finance and Operations apps with services such as Power BI data flows and AI builder.
4. Select **Review and create**. When the deployment is complete, the new resource will be shown in the Azure portal.
5. In the Azure portal, select the storage account you created. Copy and save the storage account name.

Grant access control roles to applications

You need to grant your application permissions to read and write to the storage account. These permissions are granted by using Roles in Azure AD.

1. In **Azure portal**, open the storage account that you created earlier.
2. Select **Access Control (IAM)** in the left navigation.
3. On the **Access control** page, select the **Role assignments** tab.
4. Select **Add** at the top of the page, and then select **Add role assignment**.
5. In the **Add role assignment** dialog, select the **Role** field, and then select **Owner**.

> **NOTE**
> Don't make any changes to the fields, **Assign access to** and **Azure AD user, group, or service principal**.

6. In the **Select** field, select the application that you registered earlier.
7. Select **Save**.
8. Add the remaining roles shown in the following table by repeating steps 4-7.

APPLICATION TO BE SELECTED	ROLE TO BE ASSIGNED
The application you created earlier	Storage blob data contributor
The application you created earlier	Storage blob data reader

Create a key vault

A key vault is a secure way to share details such as storage account name to your Finance and Operations apps. Complete the following steps to create a key vault and a secret.

1. In the Azure portal, select **Create a new resource** and then search for and select, **Key Vault**.
2. In the **Create key vault** dialog box, in the **Location** field, select the datacenter where your environment is located.
3. After the key vault is created, select it from the list, and on the left navigation pane, select **Overview**.
4. Save the value in the **DNS name** field. You will need this value later.

Add secrets to the key vault

You are going to create three secrets in the Key vault and then add the values saved from previous steps. For each of the secrets, you will need to provide a secret name and provide the value you saved from earlier steps.

SUGGESTED SECRET NAME	SECRET VALUE THAT YOU SAVED EARLIER	EXAMPLE
app-id	The ID of the application created earlier.	8936e905-197b-xxx-xxxx-xxxxxxxxx
app-secret	The client secret specified earlier.	NaeIxxxxxxx---xxxx7eixxx~1g-
storage-account-name	The name of the storage account created earlier.	contosod365datalake

You will need to complete the following steps three times, once for each secret.

1. In the Azure portal, go to the key vault you created earlier and on the left navigation pane, select **Secrets**.
2. Select **Generate/Import**, and in the **Create a secret** dialog box, in the **Upload options** field, select **Manual**.
3. Enter a name for the secret. See the table in the introduction of this section for suggested names.
4. Copy and paste the corresponding secret value in the **Value** field.
5. Select **Enabled**, and then select **Create**.

You will notice the secret created in the list of secrets.

Authorize the application to read secrets in the key vault

1. In **Azure portal**, open the key vault that you created earlier.
2. In the **Add access policy** dialog box, select **Add**.
3. On the left navigation pane, select **Access policies > Add Access Policy** to create a new policy.
4. In the **Add access policy** dialog box, in the **Select principal** field, locate and select the application, **Microsoft Dynamics ERP Microservices**, and then click **Select**.

> **NOTE**
>
> If you can't find **Microsoft Dynamics ERP Microservices**, see the Create Service Principle section in this document.

5. In the **Secret permissions** fields, select **Get** and **List**.
6. In the **Access policy** dialog, select **Add**.

You should see application with access to your key vault as shown below.

APPLICATION	SECRET PERMISSIONS
Microsoft Dynamics ERP Microservices	Get, List

7. Select **Save**.

Install the Export to Data Lake add-in in LCS

Before you can export data to your Data lake from your Finance and Operations apps, you must install the **Export to Data Lake** add-in in LCS. To complete this task, you must be an environment administrator in LCS for the environment that you want to use.

You need the following information before you start. Keep the information handy before you begin.

INFORMATION YOU NEED FOR EXPORT TO DATA LAKE ADD-IN	WHERE CAN YOU FIND IT	EXAMPLE
Your environment Azure AD Tenant ID	Your Azure AD tenant ID in the Azure portal. Sign in to the **Azure portal** and open the **Azure Active Directory** service. Open the **Properties** page and copy the value in the **Directory ID** field.	72f988bf-0000-0000-00000-2d7cd011db47
DNS name of your key vault	This name should have been previously saved. Enter the DNS name of your key vault	https://contosod365datafeedpoc.vault.azure.net/
The secret that contains the name of your storage account	If you used the suggested name, enter **storage-account-name**. If not, enter the secret name you defined.	storage-account-name
Secret that contains the Application ID	If you used the suggested name, enter **app-id**. If not, enter the secret name you defined.	app-id
Secret that contains the Application secret	If you used the suggested name, enter **app-secret**. If not, enter the secret name you defined.	app-secret

1. Sign in to LCS and navigate to your environment.
2. On the **Environment** page, select the **Environment add-ins** tab. If **Export Data Lake** appears in the list, the Data Lake add-in is already installed, and you can skip the rest of this procedure. Otherwise, complete the remaining steps.
3. Select **Install a new add-in**, and in the dialog box, select **Export to Data lake** in the list. If **Export to data lake** isn't listed, the feature might not be available for your environment at this time.

4. In the **Setup add-in** dialog box, provide the required information. To answer the questions, you must already have a storage account. If you don't already have a storage account, create one, or ask your admin to create one on your behalf.
5. Accept the terms of the offer by selecting the check box, and then select **Install**.

The system installs and configures the data lake for the environment. After installation and configuration are complete, you should see **Azure Data Lake** listed on the **Environment** page.

Finance and Operations apps data in Azure Data Lake

2/18/2021 • 9 minutes to read • Edit Online

NOTE

The **Export to Azure Data Lake** feature is in limited preview and may not be available in all regions and environments supported by Finance and Operations apps. If you are unable to find the **Export to Azure Data Lake** functionality in Lifecycle Services (LCS) or your Finance and Operations apps, this feature is not currently available in your environment.

Currently, previews are closed. In the coming months we will enable additional environments in several regions. We are accepting requests from customers who would like to join the preview. If you would like to join a future preview, complete the survey. We will contact you when we are ready to include you. You can also join a Yammer group by completing the survey. You can use the Yammer group to stay in contact and ask questions that will help you understand the feature.

Until the feature is enabled in your environment, you have the option to prototype/plan the feature implementation using GitHub tools. The tools will enable you to export data from your sandbox environment into a storage account in the same format as exported by the feature.

At this time, **Export to Azure Data Lake** feature is not available in Tier-1 (developer) environments. You need a cloud-based Tier-2 or higher environment to enable this feature.

To make aggregate measurements available in a data lake, continue to use the feature in the manner that is described in Make entity store available as a Data Lake.

The **Export to Azure Data Lake** feature lets you copy data from your Finance and Operations apps into your own Azure Data Lake (Gen 2). The system let's you choose the tables and entities to include. After you select the data that you want, the system will make an initial copy. The system then keeps the selected data up to date by applying changes, deletions, and additions. There may be a delay of a few minutes between data changes in your Finance and Operations apps instances and the time when the data is available in your data lake.

Before you can use this feature, you must configure the **Export to Data Lake**. For more information, see Configure export to Azure Data Lake.

Turn on the Export Data to Azure Data Lake feature

An administrator must turn on the **Export to Azure Data Lake** feature before it can be activated. To do this, go to the **Feature management** workspace, locate and select the **Export Data to Azure Data Lake** feature, and then select **Enable**.

After the feature is enabled, you should see the **Export to Azure Data Lake** option under **System administration**.

Select data

NOTE

If the feature, **Export to Azure Data Lake** isn't available in the **Feature management** module in your environment, sign in to the environment and add the following to the URL in your browser address: &mi=DataFeedsDefinitionWorkspace. For example, https://ax123456.cloud.test.dynamics.com/?cmp=USMF&mi=DataFeedsDefinitionWorkspace.

You can select the tables and entities that should be staged in Data Lake.

1. In your environment, go to **System Administration** > **Export to Azure Data Lake**.
2. Select **Configure Data feeds for export to Lake**.
3. On the **Configure data feeds to Data Lake** page, on the **Choose Tables** tab, select the data tables that should be staged in Data Lake. You can search for tables by display name or system name. You can also see whether a table is being synced.
4. When you've finished, select **Add Tables** to add the selected tables to Data Lake.

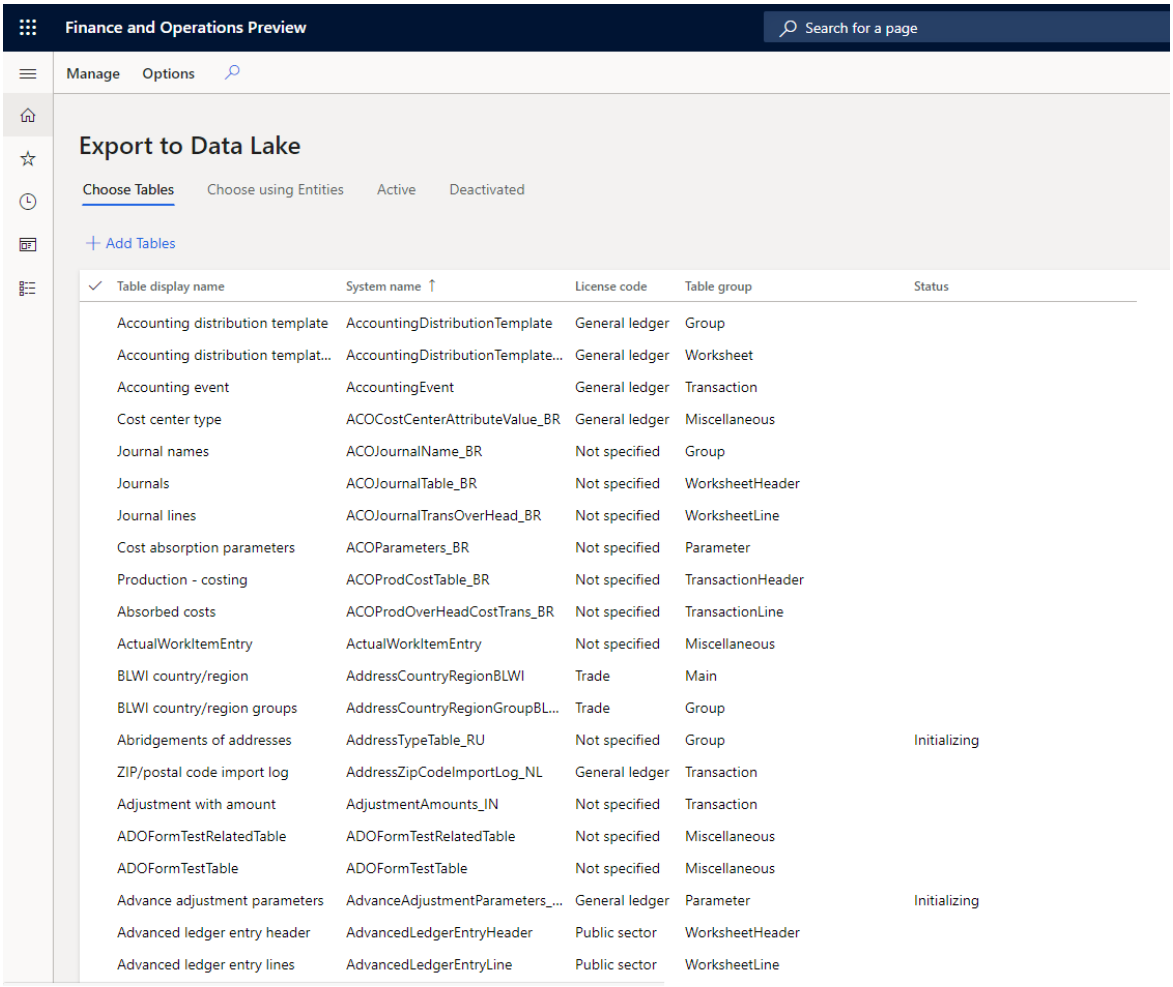


Table display name	System name	License code	Table group	Status
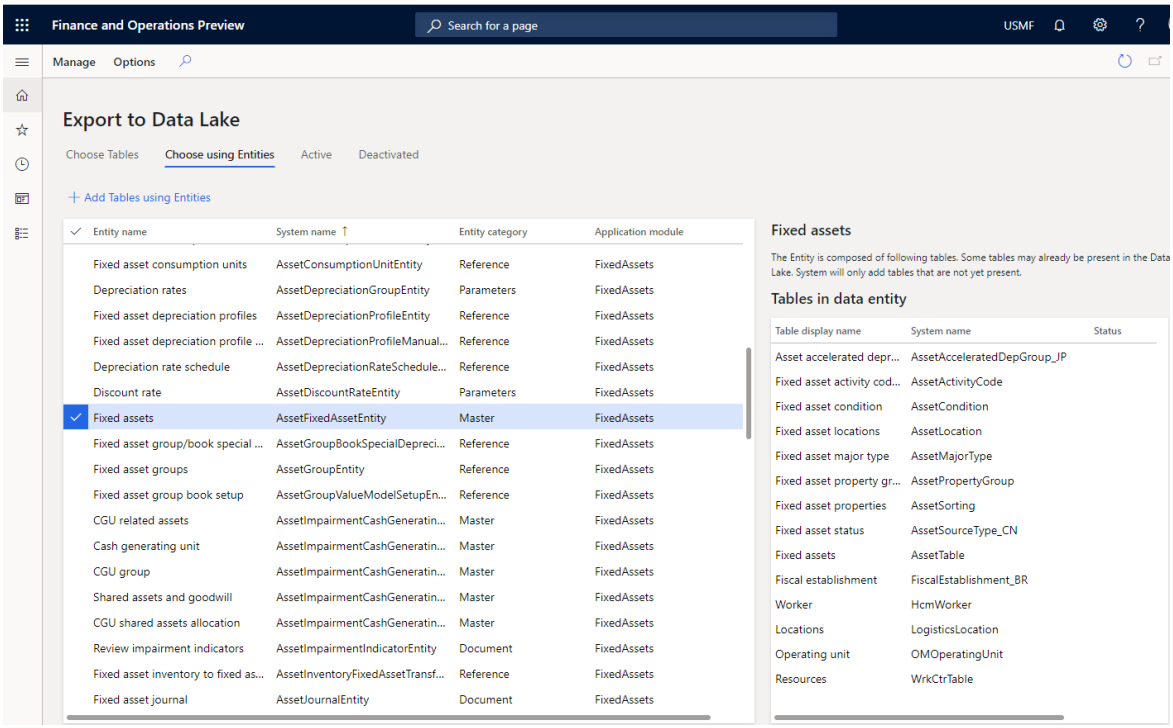
Accounting distribution template	AccountingDistributionTemplate	General ledger	Group	
Accounting distribution templat...	AccountingDistributionTemplate...	General ledger	Worksheet	
Accounting event	AccountingEvent	General ledger	Transaction	
Cost center type	ACOCostCenterAttributeValue_BR	General ledger	Miscellaneous	
Journal names	ACOJournalName_BR	Not specified	Group	
Journals	ACOJournalTable_BR	Not specified	WorksheetHeader	
Journal lines	ACOJournalTransOverHead_BR	Not specified	WorksheetLine	
Cost absorption parameters	ACOParameters_BR	Not specified	Parameter	
Production - costing	ACOProdCostTable_BR	Not specified	TransactionHeader	
Absorbed costs	ACOProdOverHeadCostTrans_BR	Not specified	TransactionLine	
ActualWorkItemEntry	ActualWorkItemEntry	Not specified	Miscellaneous	
BLWI country/region	AddressCountryRegionBLWI	Trade	Main	
BLWI country/region groups	AddressCountryRegionGroupBL...	Trade	Group	
Abridgements of addresses	AddressTypeTable_RU	Not specified	Group	Initializing
ZIP/postal code import log	AddressZipCodeImportLog_NL	General ledger	Transaction	
Adjustment with amount	AdjustmentAmounts_IN	Not specified	Transaction	
ADOFormTestRelatedTable	ADOFormTestRelatedTable	Not specified	Miscellaneous	
ADOFormTestTable	ADOFormTestTable	Not specified	Miscellaneous	
Advance adjustment parameters	AdvanceAdjustmentParameters_...	General ledger	Parameter	Initializing
Advanced ledger entry header	AdvancedLedgerEntryHeader	Public sector	WorksheetHeader	
Advanced ledger entry lines	AdvancedLedgerEntryLine	Public sector	WorksheetLine	

5. Select **Activate data feed**, and then select **OK**. The system may show the status of this table as **Initializing** when you add the table. This means, the system is making an initial copy of data. When the initial copy is complete, the system changes the status to **Running**

In case of an error, the system shows the status **Deactivated**. You can consume data in the lake when you see the **Running** state. If you consume data in the lake while **Initializing** or **Deactivated** status, you may not see all the data.

If you aren't familiar with the specific tables that you require, you can select tables by using entities. Entities are a higher-level abstraction of data and might include multiple tables. By selecting entities, you're also selecting the tables that include them.

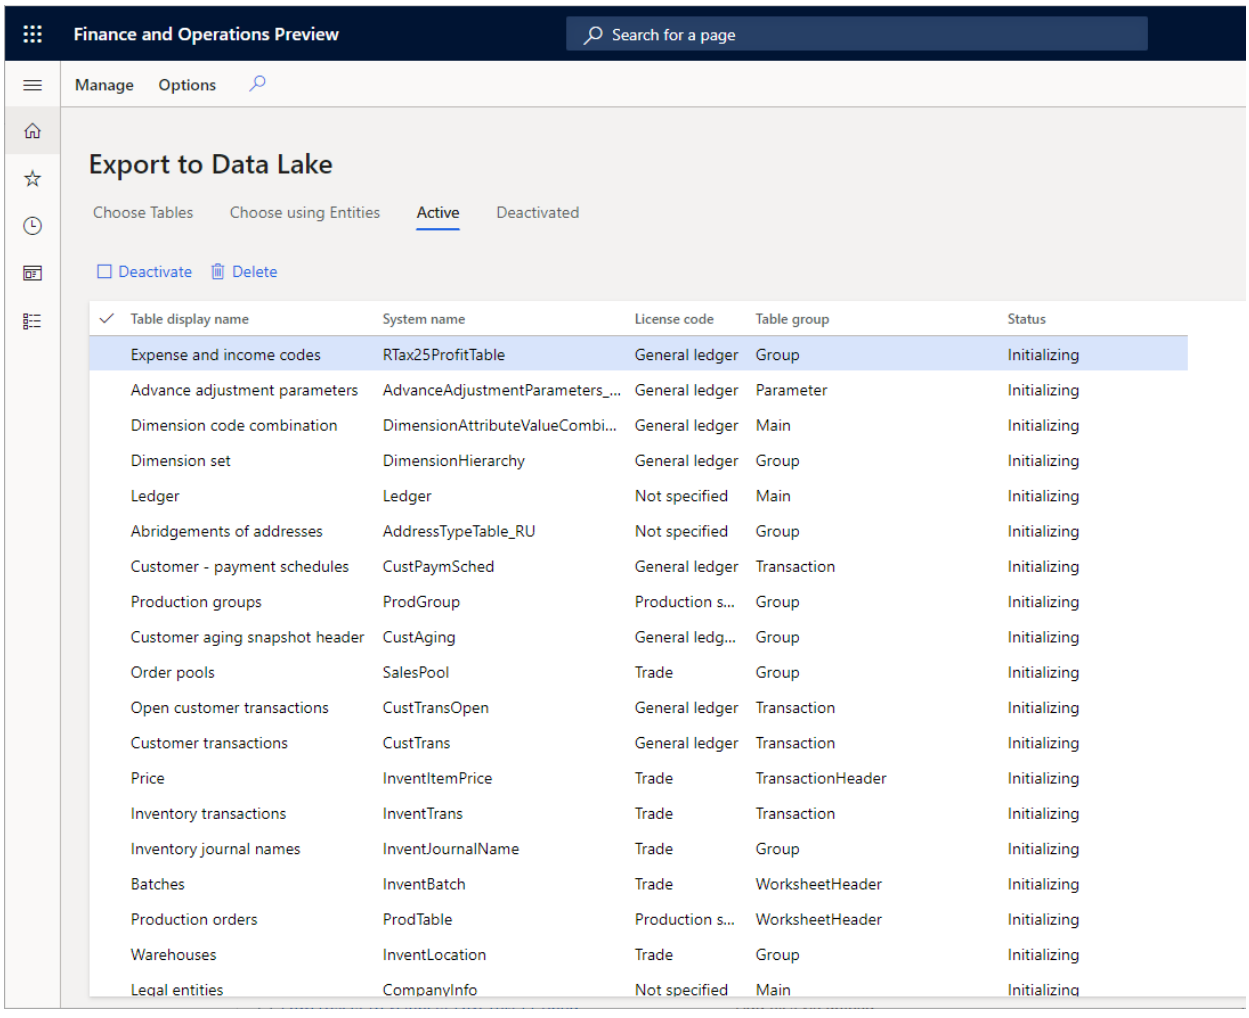
7. On the **Choose using Entities** tab, select the entities, and then select **Add Tables using Entities**.



Regardless of the method that you use to select tables, the tables will be staged in Data Lake.

Monitor the tables in Data Lake

You don't have to monitor or schedule data exports because the system keeps the data updated in Data Lake. However, you can view the status of ongoing data exports on the **Active** tab on the **Configure data feeds to Data lake** page.



Troubleshooting common issues and errors

Export to Data Lake feature is not available in your region and/or your environment at this time

This feature is not available in Tier-1 (developer) environments. You need a sandbox environment (Tier 2 or higher) with Platform updates for version 10.0.13 or higher.

This feature is in limited preview and may not be available in all Azure regions where Finance and Operations apps are available, or this feature may not be available for your environment. If you would like to join a future preview, complete the survey. We will contact you when we are ready to include you. You can also join a Yammer group by completing the survey. You can use the Yammer group to stay in contact and ask questions that will help you understand the feature. We are working hard to make this feature available soon.

Export to Data Lake feature is currently being installed for your environment. Please check back later.

Before you can use this feature, you need to configure the export to Data Lake. For more information, see Configure export to Azure Data Lake.

Export to Data Lake add-in is not installed.

Ask your administrator to install this add-in using Dynamics Lifecycle Services (LCS). Before you can use this feature, you need to configure the export to Data Lake. For more information, see Configure export to Azure Data Lake.

Export to Data Lake feature failed to install in Dynamics Life Cycle Services (LCS).

Ask your administrator to re-install the Export to Data Lake add-in. If this issue persists, contact Support. When you configure the Export to Data Lake feature, the system may report an error. Or, there may be an error when you access the data lake after configuration due to a change in your environments. For more information, see Configure export to Azure Data Lake.

Export to Data Lake feature is temporarily unavailable. Please check back later.

If you see this error for a prolonged period of time, contact Support.

Status codes with extended errors

When an error occurs in a table that you added to Export to Data Lake, you may see an error code in the status column. The following error codes provide the cause of the error and how to correct the issue.

Error status codes 4xx indicate an issue with the table

ERROR CODE	ISSUE	NEXT STEPS
400	The table you added doesn't contain a RecID field.	RecID fields are used by the system to index table data. Tables that don't contain a RecID field can't be added to the Data Lake. If this issue is from a table in a Finance and Operations app, contact Microsoft support. If this table was developed by your partner or ISV, contact the developer to include a RecID field.
401	The table you added is missing in the database.	The table you added is no longer available in the database and the system can't continue updating data in the lake. The table may have been removed because of a software or database update. Contact your database administrator or a developer. If this table was developed by your partner or ISV, contact the developer.

ERROR CODE	ISSUE	NEXT STEPS
402	The RecID field isn't indexed.	The system has detected that the RecID field contained in the table isn't part of an index. This may lead to poor performance in updating the data lake and updates may take longer to reflect in the data lake. If this issue is from a table in a Finance and Operations app, contact Microsoft support. If this table was developed by your partner or ISV, contact the developer.

Error status codes 5xx indicate a system error encountered while exporting data Due to the error, the system has paused data export – data that exists in the lake won't be updated until the error is resolved. Try to deactivate and activate the table to see if this resolves the issue. Note that deactivating and activating the table may cause the system to re-initialize the data in the lake by taking a full copy. If the issue persists, contact Microsoft support with the table name and the error code.

Error status codes 8xx and 9xx indicate a change to the table or database structure since it was added

ERROR CODE	ISSUE	NEXT STEPS
800	There is a change in the data table schema.	The system found a change in the table structure when adding changed data to the lake. This change is typically the result of a software update or a database modification. For example, when a new field is added to a table, or a field is modified or removed, the data updated in the lake may not be in the same format as the existing data. Because of the error, the system has paused data export. The data that exists in the lake won't be updated until the error is resolved. Deactivate and activate the table to see if the issue is resolved.
801	There is an issue with the Change data capture feature.	The Export to Data Lake feature uses the Change data capture feature. Change data can't be exported because the Change data capture feature is disabled in the Finance and Operations apps database. This may be the result of a database maintenance operation. Deactivate and activate the table to see if the issue is resolved. If the issue persists, contact Microsoft support.

ERROR CODE	ISSUE	NEXT STEPS
802	There is an issue with the Change data capture feature for the table.	The Export to Data lake feature uses the Change data capture feature. Change data can't be exported because the Change data capture feature isn't enabled for this table in your Finance and Operations apps database. This may be the result of a database maintenance operation. Deactivate and activate the table to see if the issue is resolved.
900	There is an issue with the Change data capture feature in this environment.	The Export to Data lake feature uses the Change data capture feature. Change data can't be exported because the Change data capture feature isn't enabled for this table in the Finance and Operations apps database. This may be the result of a database maintenance operation. Deactivate and activate the table to see if the issue is resolved. If the issue persists, contact Microsoft support.

NOTE

Deactivating and activating the table may cause the system to re-initialize the data in the lake by creating a full copy. If this is a large table, the initialize process may take some time. In the future, the system may automatically update data in the lake to reflect the table structure changes.

Make Entity store available as a Data Lake

2/18/2021 • 6 minutes to read • Edit Online

IMPORTANT

This feature is currently in public preview. This feature is comprised of the following components:

- **Automated Entity store refresh** - Available in Platform update 23.
- **Entity store data in Microsoft Azure Data Lake (full push)** - Available in Platform update 26.
- **DataFlows for Entity store schemas on PowerBI.com** - Available in a future platform update.
- **Entity store data in Azure Data Lake (trickle feed)** - Available in Platform update 28.
- **Extend analytical workspaces by using PowerBI.com** - Available in a future platform update.

Automated Entity store refresh

You need to enable automated Entity store refresh before enabling Data Lake integration.

1. Go to **System administration** > **Set up** > **Entity store**.

   On the **Entity store** page, a message indicates that you can switch to the **Automated Entity store refresh** option. This option is managed by the system. An admin doesn't have to schedule or monitor the Entity store refresh.

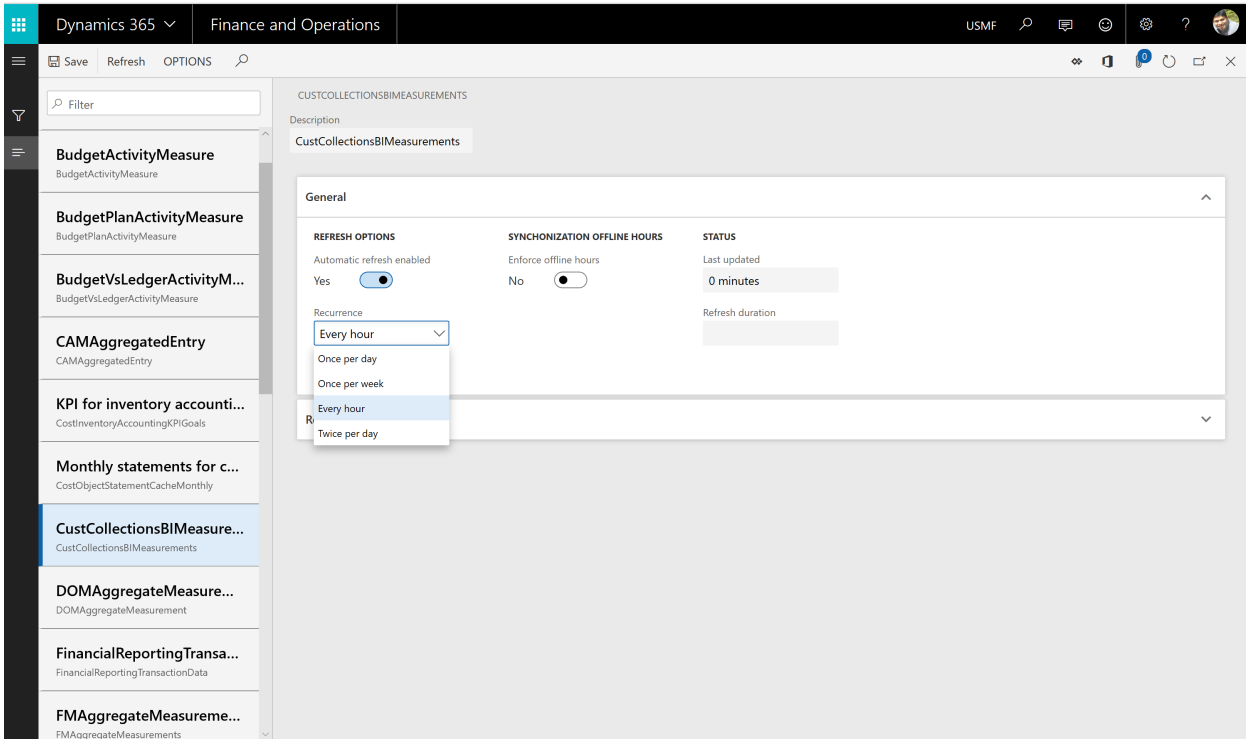
2. Select **Switch now**.

   IMPORTANT

   This action isn't reversible. After you switch to the **Automated Entity store refresh** option, you can't revert to the old user interface (UI) experience.

3. Select **Yes** to continue.

You will now see the new experience.



After the new experience is turned on, you can define the refresh for each aggregate measurement. The following refresh options are available:

- Every hour
- Twice a day
- Once a day
- Once a week

In addition, an admin can refresh any aggregate measurement on demand by selecting the **Refresh** button. Additional options will be added in future platform updates. These options will include options for real-time refresh.

> **IMPORTANT**
>
> When the automated refresh is enabled, in some cases the system may disable refresh of Aggregate measurements. You must revisit aggregate measurements and validate that appropriate refresh intervals have been applied by the system.

Entity store data in Azure Data Lake (full push and trickle feed)

> **IMPORTANT**
>
> This feature is currently in public preview. Do not enable this feature in production environments.

When this feature is turned on, Entity store data isn't populated in the relational Entity store database in the Microsoft subscription. Instead, it's populated in an Azure Data Lake Storage Gen2 account in your own subscription. You can use the full capabilities of PowerBI.com and other Azure tools to work with Entity store.

Before you start, you must complete these tasks in the Azure portal.

1. **Create storage accounts.** Provision a storage account in the same data center where your environment is provisioned. Make a note of the connection string for the storage account, because you will have to provide it later.
2. **Create a Key Vault and a secret.** Provision Azure Key Vault in your own subscription. You will need the

Domain Name System (DNS) name of the Key Vault entry that you created. Also add a secret to Key Vault. As the value, specify the connection string that you made a note of in the previous task. Make a note of the name of the secret, because you will have to provide it later.

3. **Register the app.** Create an Azure Active Directory (Azure AD) application, and grant application programming interface (API) access to Key vault. Make a note of the application ID and its application key (secret), because you will have to provide them later.
4. **Add a service principal to Key Vault.** In Key Vault, use the **Access policies** option to grant the Azure AD application **Get** and **List** permissions. In this way, the application will have access to the secrets in Key Vault.

The following sections describe each task in more detail.

Create storage accounts

1. In the Azure portal, create a new storage account.
2. In the **Create storage account** dialog box, provide values for the following parameter fields:
   - **Location:** Select the data center where your environment is located. If the data center that you select is in a different Azure region, you will incur additional data movement costs. If your Microsoft Power BI and/or your data warehouse is in a different region, you can use replication to move storage between regions.
   - **Performance:** We recommend that you select **Standard**.
   - **Account kind:** You must select **StorageV2**.
3. In the **Advanced options** dialog box, you will see the **Data Lake storage Gen2** option. Select **Enable** under the Hierarchical namespaces feature. If you disable this option, you can't consume data written by Finance and Operations apps with services such as Power BI data flows.
4. Select **Review and create**. When the deployment is completed, the new resource will be shown in the Azure portal.
5. Select the resource, and then select **Settings** > **Access keys**.
6. Make a note of the connection string value, because you will have to provide it later.

Create a Key Vault and a secret

1. In the Azure portal, create a new Key Vault.
2. In the **Create key vault** dialog box, in the **Location** field, select the data center where your environment is located.
3. After Key Vault is created, select it in the list, and then select **Secrets**.
4. Select **Generate/Import**.
5. In the **Create a secret** dialog box, in the **Upload options** field, select **Manual**.
6. Enter a name for the secret. Make a note of the name, because you will have to provide it later.
7. In the value field, enter the connection string that you obtained from the storage account in the previous procedure.
8. Select **Enabled**, and then select **Create**. The secret is created and added to Key Vault.

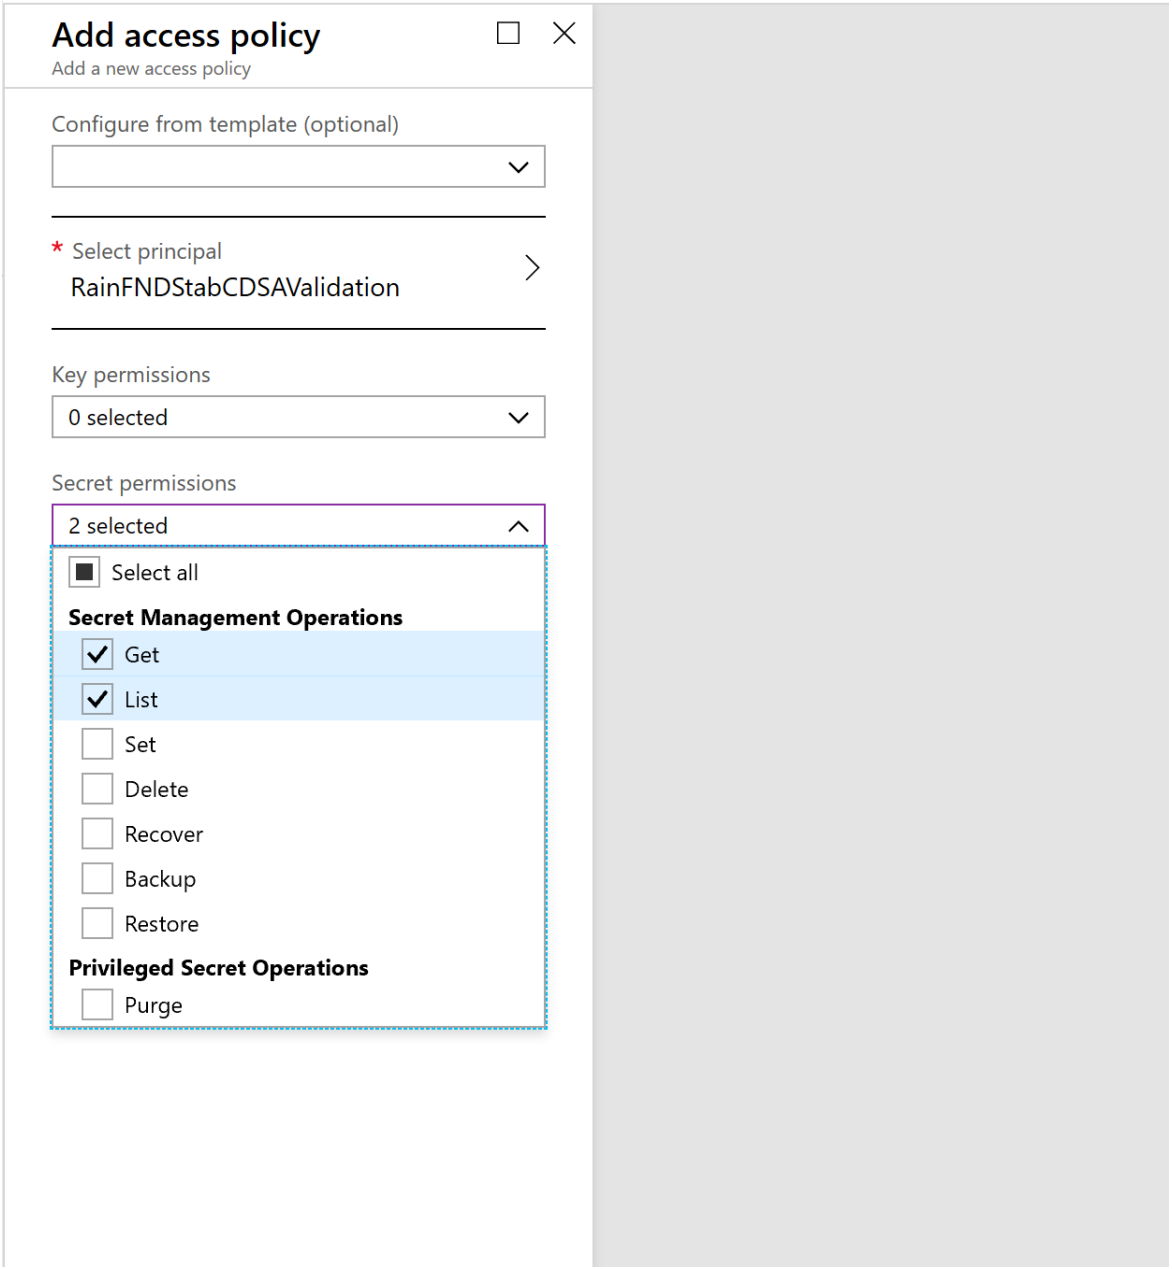
Register the app

1. In the Azure portal, select **Azure Active Directory**, and then select **App registrations**.
2. Select **New registration** at the top of the menu, and enter the following information:
   - **Name** - Enter a friendly name for the app.
   - Select **Accounts in this Organizational directory only** unless your storage account and your Dynamics environment are in different Azure Active Directory domains.
3. After the application is created, select **API permissions**.

4. In the dialog box that appears, select **Add a permission**.
5. You will see a dialog box with a list of APIs. In the list, select **Azure Key Vault**.
6. Select the **Delegated permissions** box, select **user_impersonation**, and then select **Add permissions** to save your changes.
7. Select the **Certificates & secrets** menu on the left navigation pane, and then select **New client secret**.
8. In the **Description** field, enter a name and choose an expiry period. Select **Add**.
9. A secret is generated and shown in the **Value** field.
10. Immediately copy the secret to the clipboard, because it will disappear within one or two minutes. You will have to provide this key to the application later.

Add a service principal to Key Vault

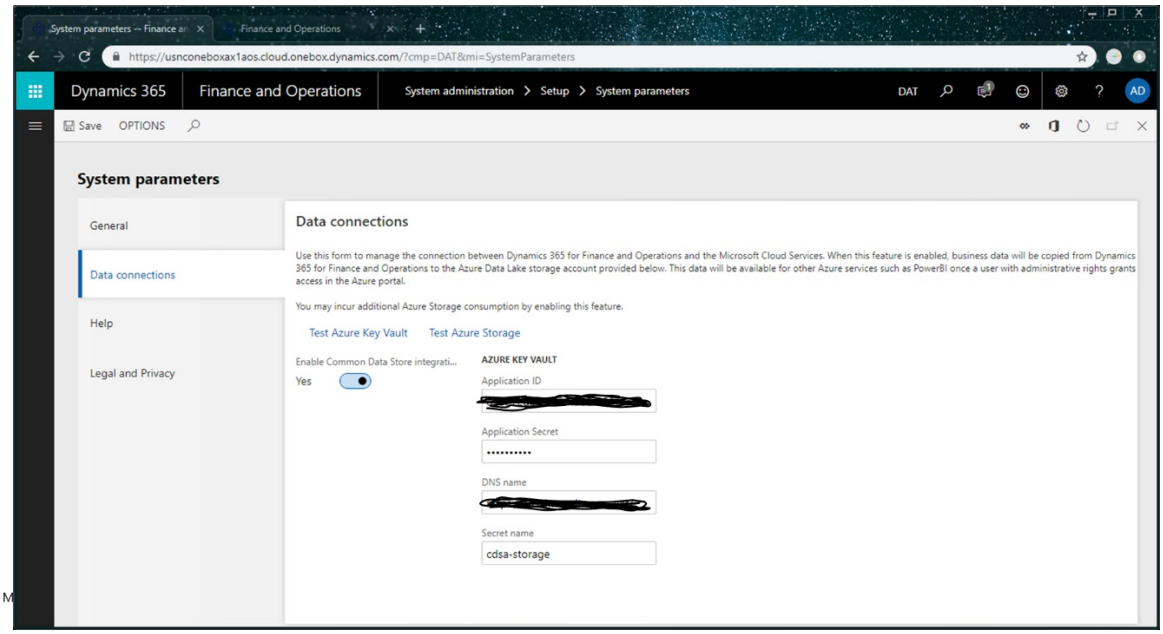
1. In the Azure portal, open Key Vault that you created earlier.
2. Select **Access policies**, and then select **Add** to create a new access policy.
3. In the **Select principal** field, select the name of the application that you previously registered.
4. In the **Key permissions** field, select **Get** and **List** permissions.
5. In the **Secret permissions** field, select **Get** and **List** permissions.



6. Select **Save**.

Work in Entity store in a Data Lake

1. Go to **System administration** > **Set up** > **System parameters**.
2. On the **Data connections** tab, enter the following information that you made a note of earlier in this topic:
    - **Application ID:** Enter the application ID of the Azure AD application that you registered earlier.
    - **Application Secret:** Enter the application key (secret) for the Azure AD application.
    - **DNS name:** Enter the DNS name of Key Vault.
    - **Secret name:** Enter the name of the secret that you added to Key Vault together with connection string information.



3. Select the **Test Azure Key Vault** and **Test Azure Storage** links to validate that system can access the configuration information that you provided.

4. Select the **Enable data connection** check box.

Entity store data should now be populated in the storage location that you provided, not in the relational Entity store database.

The aggregate measurements and refresh options that you select in the Entity store UI should now apply to data that is copied to Data Lake.

Database movement operations home page

2/18/2021 • 2 minutes to read • Edit Online

Database movement operations are a suite of self-service actions that can be used as part of Data Application Lifecycle Management (also referred to as *DataALM*). These actions provide structured processes for common implementation scenarios such as golden configuration promotion, debugging/diagnostics, destructive testing, and general refresh for training purposes.

In this topic, you will learn how to use database movement operations to perform refresh, export, import, and various flavors of point-in-time restore.

Database movement quick start guides

Learn how to perform the individual operations on your Standard or Premier Acceptance Test environments:

- Refresh database
- Export a database
- Import a database
- Point-in-time restore (PITR)
- Point-in-time restore of the production database to a sandbox environment
- Enable just-in-time database access

Step-by-step tutorials

Learn how to achieve common implementation scenarios using DataALM to your advantage:

- Refresh for training purposes
- Debug a copy of the production database
- Export a copy of the standard user acceptance testing (UAT) database
- Golden configuration promotion
- Destructive testing

Database Movement API

The Database Movement application programming interface (API) lets you integrate several of the previously mentioned database movement operations into your overall ALM process. In addition, by using the API together with your preferred scheduling engine, you can build recurrence into the process, so that it runs daily or on demand.

- Overview
- Versioning and support
- Authentication
- Throttling

Database movement toolkit

2/18/2021 • 2 minutes to read • Edit Online

The Database movement toolkit is a ZIP file hosted in Microsoft Dynamics Lifecycle Services (LCS). This toolkit is available for download. It contains a series of scripts that enhance the customer experience for movement of data between developer environments and sandbox environments. This topic explains the components of the toolkit, how to download it, and any recent changes.

Download the latest version

The toolkit is available in the LCS Shared Asset Library under the **Models** section. Search for the entry titled **Database Movement Toolkit** and then download it to your Tier1 DevTest environment.

Toolkit components

The toolkit contains the following primary components:

- **Sqlpackage.exe** - This tool is used to perform extract and publish actions against Microsoft Azure SQL databases, as well as SQL Server databases hosted on Tier1 DevTest environments.
- **PowerShell 7.0** - This is a self-contained version of PowerShell that includes capabilities for parallelism, which increases the performance of transferring data between environments.
- **PowerShell script** - There are several scripts included to provide an enhanced and more automated experience for scenarios such as AX 2012 data upgrade.

Supported scenarios

The toolkit currently supports the following scenarios. More will be added over time.

- Upgrade from AX 2012 - Data upgrade in sandbox environments

Versions

Version 5

FEATURE	DETAILS
Schema publish	Added CleanupSource and CleanupTarget scripts.
Data transfer	Added timer to capture transfer time.

Version 4

FEATURE	DETAILS
Schema publish	Minor improvements.

Version 3

FEATURE	DETAILS
Schema publish	Fixed the scripts to output errors in PublishDiag.log.

Version 2

FEATURE	DETAILS
Schema publish	Fixed the scripts to use current directory reference to Sqlpackage directory.
Schema publish	Fixed the scripts to delete local users from the source database, and tidy up environment-specific tables.
Data transfer	Fixed the scripts to install missing PowerShell modules.

Version 1

FEATURE	DETAILS
Initial	Toolkit uploaded to LCS Shared Asset Library.

Refresh database

2/18/2021 • 9 minutes to read • Edit Online

You can use Microsoft Dynamics Lifecycle Services (LCS) to perform a refresh of the database to a sandbox user acceptance testing (UAT) environment. A database refresh lets you copy the transactional and financial reporting databases of your production environment into the target, sandbox UAT environment. If you have another sandbox environment, you can also copy the databases from that environment to your target, sandbox UAT environment.

> **IMPORTANT**
> Copying production data to your sandbox environment for the purpose of production reporting is not supported.

Self-service database refresh

With the goal of providing Data Application Lifecycle Management (also referred to as *DataALM*) capabilities to our customers without relying on human or manual processes, the Lifecycle Services team has introduced an automated **Refresh database** action. This process is outlined below:

1. Visit your target sandbox on the **Environment Details** page, and click the **Maintain** > **Move database** menu option.
2. Select the **Refresh database** option and choose your source environment.
3. Note the warnings and review the list of data elements that are not copied from the source environment.
4. The refresh operation will begin immediately.

Refresh operation failed

In case of failure, the option to perform a rollback is available. By clicking the **Rollback** option after the operation has initially failed, your target sandbox environment will be restored to the state it was before the refresh began. This is made possible by the Azure SQL point-in-time restore capability to restore the database. This is often required if a customization, that is present in the target sandbox, cannot complete a database synchronization with the newly refreshed data.

To determine the root cause of the failure, use the available buttons to download the runbook logs before you start the rollback operation.

Data elements that aren't copied during refresh

The information in this section lists certain elements of the database that are not copied over to the target environment during a database refresh operation.

When refreshing a production environment to a sandbox environment or a sandbox to another sandbox environment

- Email addresses in the LogisticsElectronicAddress table.
- SMTP Relay server in the SysEmailParameters table.
- Print Management settings in the PrintMgmtSettings and PrintMgmtDocInstance tables.
- All users except the admin will be set to **Disabled** status.

When refreshing from sandbox environment to production environment

This is also referred to as Golden configuration promotion.

- Batch job history is stored in the BatchJobHistory, BatchHistory, and BatchConstraintHistory tables.

These elements are removed for all database refresh operations

- Environment-specific records in the SysServerConfig, SysServerSessions, SysCorpNetPrinters, SysClientSessions, BatchServerConfig, and BatchServerGroup tables.
- Document attachments in the DocuValue table. These attachments include any Microsoft Office templates that were overwritten in the source environment.
- All batch jobs are set to **Withhold** status.
- All users will have their partition value reset to the "initial" partition record ID.
- All Microsoft-encrypted fields will be cleared, because they can't be decrypted on a different database server. An example is the **Password** field in the SysEmailSMTPPassword table.
- Maintenance mode settings will be disabled even if it was enabled in source.

Some of these elements aren't copied because they are environment-specific. Examples include BatchServerConfig and SysCorpNetPrinters records. Other elements aren't copied because of the volume of support tickets. For example, duplicate emails might be sent because Simple Mail Transfer Protocol (SMTP) is still enabled in the UAT environment, invalid integration messages might be sent because batch jobs are still enabled, and users might be enabled before admins can perform post-refresh cleanup activities.

Environment administrator

The System Administrator account in the target environment (UserId of 'Admin') is reset to the value found in the web.config file on the target. This should be the same value as that of the Administrator from Lifecycle Services. To preview which account this will be, visit your target sandbox **Environment Details** page in LCS. The value of the **Environment Administrator** field that was selected when the environment was first deployed is updated to be the System Administrator in the transactional database. This also means that the tenant of the environment will be that of the Environment Administrator.

If you have used the Admin User Provisioning Tool on your environment to change the web.config file to a different value, it may not match what is in Lifecycle Services. If you require a different account to be used, you will need to deallocate and delete the target sandbox, and redeploy selecting another account. After this, you can perform another refresh database action to restore the data.

An environment can't be refreshed from one tenant to another. This restriction applies even to .onmicrosoft.com tenants. You should make sure that the admin accounts in the source and target environments are from the same tenant domain.

Conditions of a database refresh

Here is the list of requirements and conditions of operation for a database refresh:

- A refresh performs a delete operation on the original target database.
- The target environment will be available until the database copy has reached the target server. After that point, the environment will be offline until the refresh process is completed.
- The refresh will affect only the application and Financial Reporting databases.
- Documents in Azure blob storage are not copied from one environment to another. This means that attached document handling documents and templates won't be changed and will remain in their current state.
- All users except the Admin user and other internal service user accounts will be unavailable. This process allows the Admin user to delete or obfuscate data before allowing other users back into the system.
- The Admin user must make required configuration changes, such as reconnecting integration endpoints to specific services or URLs.
- All data management framework with recurring import and export jobs must be fully processed and stopped in the target system prior to initiating the restore. In addition, we recommend that you select the database from the source after all recurring import and export jobs have been fully processed. This will ensure there are no orphaned files in Azure storage from either system. This is important because orphaned files cannot be processed after the database is restored in the target environment. After the restore, the integration jobs can be resumed.
- Any user with a role of Project owner or Environment manager in LCS will have access to the SQL and

machine credentials for all non-production environments.

- The databases must be hosted in the same Azure geographic region, unless the databases are Spartan-managed. Databases are Spartan-managed when you see 'spartan' as part of the fully qualified SQL server address.
- The allocated database capacity of the source environment must be less than the maximum database capacity of the target environment.

Steps to complete after a database refresh for environments that use Commerce functionality

> **IMPORTANT**
>
> Some environment-specific records are not included in automated database movement operations and require additional steps. These include the following:
>
> - Commerce self-service installer references
> - Commerce Scale Unit channel database configuration records

If you copy a database between environments, Commerce capabilities in the destination environment will not be fully functional until you perform the following additional steps.

Initialize Commerce Scale Units

If you are moving a database to a sandbox UAT or production environment, you must Initialize Commerce Scale Unit after the database movement operation is complete. The Commerce Scale Unit's association from the source environment will not copy over to the destination environment.

Synchronize Commerce self-service installers

To be able to access Commerce self-service installers in HQ, you must Synchronize self-service installers after the database movement operation is complete.

> **IMPORTANT**
>
> The Environment re-provisioning step has now been fully automated as part of database movement operations, and no longer needs to be run manually. The Environment re-provisioning tool is still available in the Asset Library and may be used in certain situations to mitigate error conditions.

To run the Environment re-provisioning tool on the destination environment, run the following steps:

1. In your project's **Asset Library**, in the **Software deployable packages** section, select **Import**.
2. From the list of shared assets, select the **Environment Reprovisioning Tool**.
3. On the **Environment details** page for your destination environment, select **Maintain** > **Apply updates**.
4. Select the **Environment Reprovisioning** tool that you uploaded earlier, and then select **Apply** to apply the package.
5. Monitor the progress of the package deployment.

For more information about how to apply a deployable package, see Create deployable packages of models. For more information about how to manually apply a deployable package, see Install deployable packages from the command line.

Re-activate POS devices

If you use point of sale (POS) devices, after you import a database you must activate the POS devices again. Previously activated devices in the destination environment will no longer function. For more information, see Point of sale device activation.

Known issues

Refresh is denied for environments that run Platform update 20 or earlier

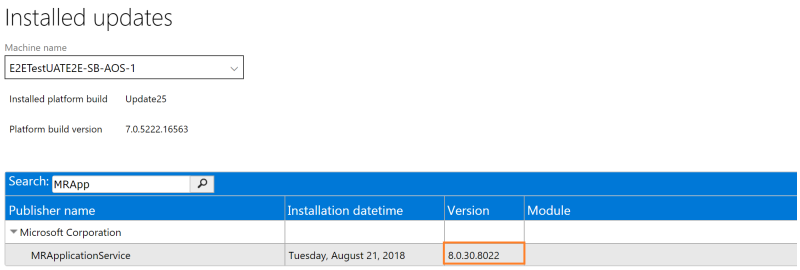
The database refresh process can't currently be completed if the environment is running Platform update 20 or earlier. For more information, see the list of currently supported platform updates.

Incompatible version of Financial Reporting between source and target environments

The database refresh process (self-service or via a service request) can't be completed successfully if the version of Financial Reporting in the target environment is earlier than the version in the source environment. To resolve this issue, update both environments so that they have the latest version of Financial Reporting.

To determine the version you have installed in your source and target environments, visit the **View detailed version information** link on the **Environment Details** page.

Search for **MRApplicationService** and ensure that the target environment is greater than or equal to the source environment.



For customers that are using version 8.1 or later:

1. Go to the **Update** tiles for your UAT environment. Save the updates to your Project asset library.
2. Apply this package to your UAT environment.
3. Verify that the error has been resolved.

For customers that are using version 8.0 or earlier:

1. Review the Environment history of your source environment. Specifically, look for any "Platform and application binary package" that might have been deployed to the source environment and not the target environment.
2. Apply this binary package to your target environment.
3. Verify that the error has been resolved.

Incompatible application versions between source and target environments

The database refresh process (self-service or via service request) cannot be completed if the Application release of your source and target environment are not the same. This is because the data upgrade process is not executed by database movement operations such as refresh, and data loss can occur.

If upgrading your sandbox UAT environment to a newer Application version (for example, 7.3 to 8.1), be sure to perform the database refresh action prior to starting the upgrade. After your sandbox is upgraded to the newer version, you cannot restore an older production environment database in to the sandbox UAT environment.

Conversely, if your production environment is newer than your target sandbox, you will need to either upgrade the target sandbox prior to the refresh or simply deallocate, delete, and redeploy prior to performing the refresh.

NOTE

Can you tell us about your documentation language preferences? Take a short survey.

The survey will take about seven minutes. No personal data is collected (privacy statement).

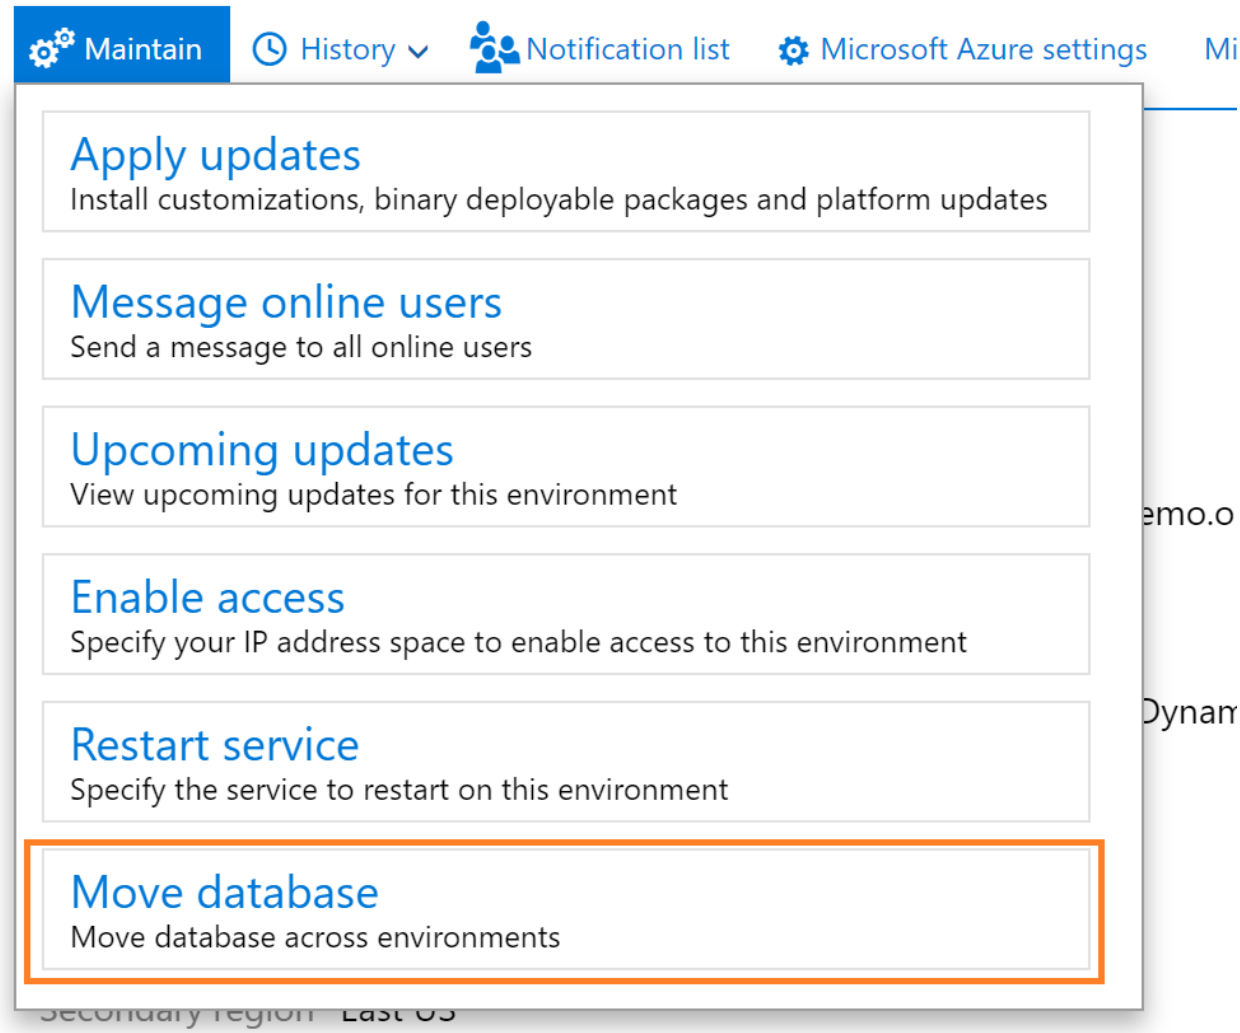
Export a database

2/18/2021 • 4 minutes to read • Edit Online

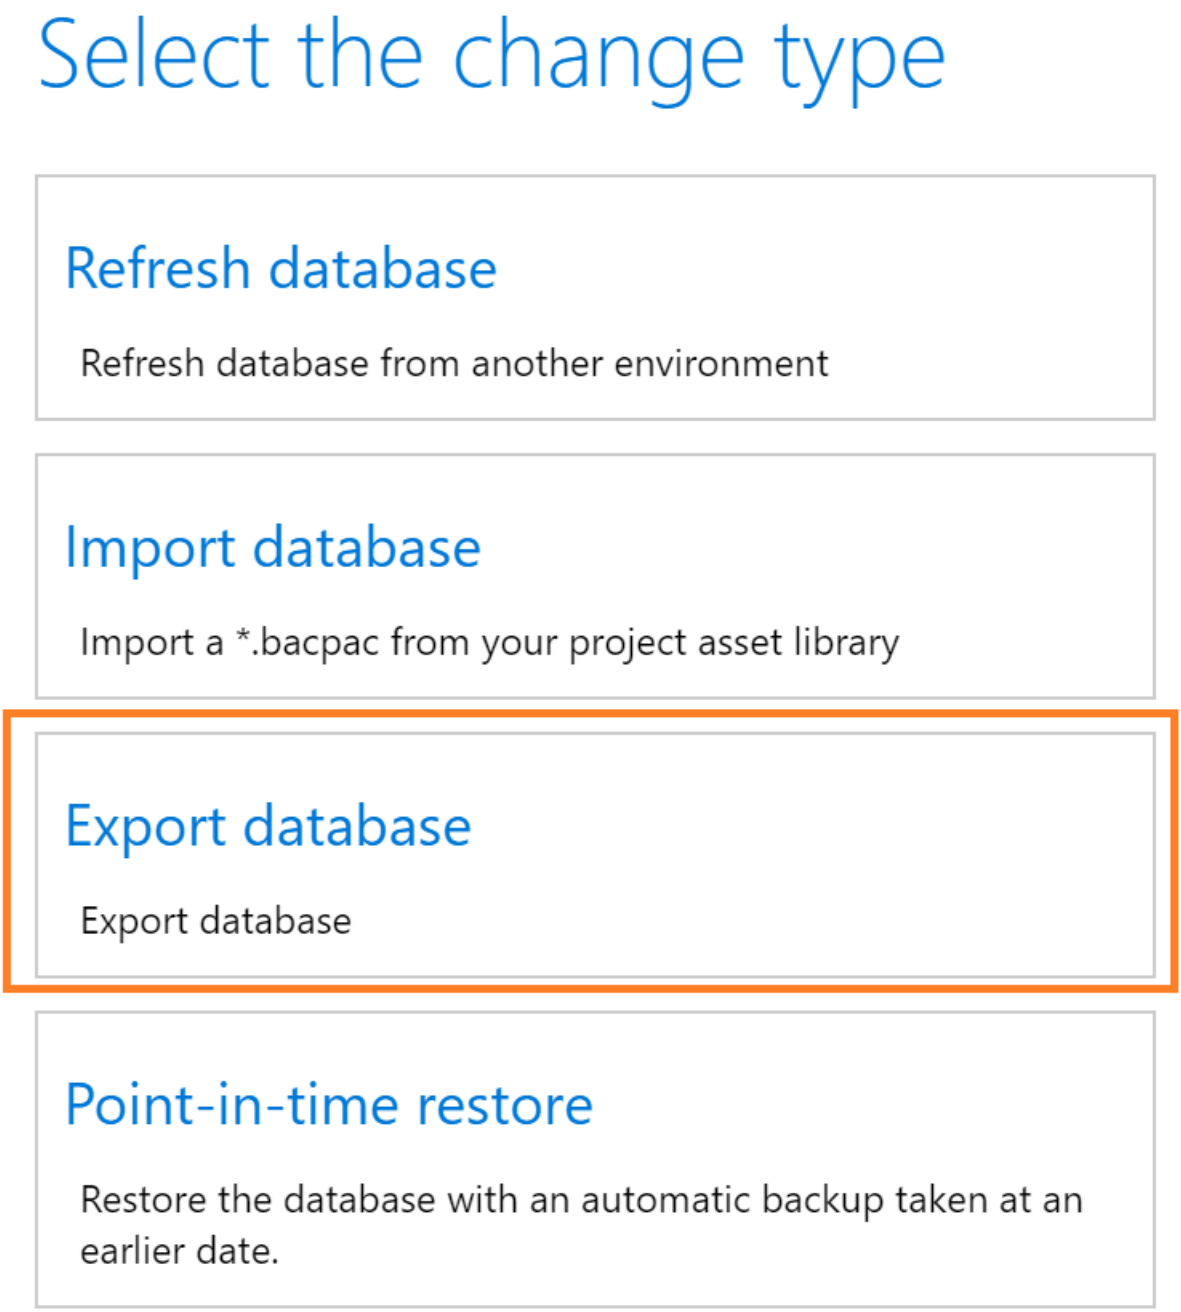
You can use Microsoft Dynamics Lifecycle Services (LCS) to export a database from a sandbox user acceptance testing (UAT) environment to the Asset library.

Self-service export database

From your sandbox **Environment Details** page, click the **Maintain** menu, and then select **Move database**.

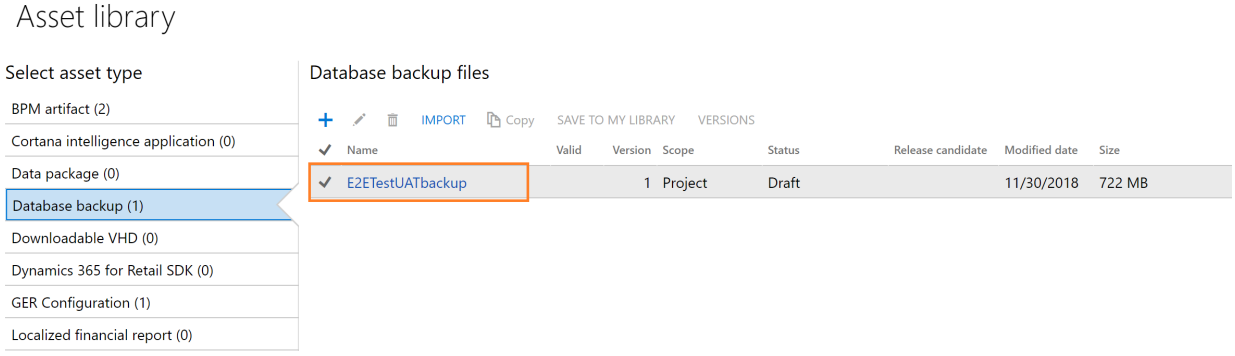


A slider pane will open on the page where you can use the **Export database** action.



The environment will be unavailable for other servicing operations, such as Sandbox refresh or package deployment during this time. The source environment will be usable from a Dynamics user perspective.

After the export operation completes successfully, sign out of the servicing operation on your **Environment details** page. You can then see the asset in your **Asset Library** in the **Database backups** section.



The **.bacpac** files are stored here and can be manually downloaded to your Tier 1 developer environments for import. In the future, Microsoft will provide APIs to trigger the export action, as well as list the available backup files in your asset library. This includes the secured URL for automatically downloading a backup asset file or copying it directly to your secure blob storage using Microsoft Azure Storage SDKs.

Maximum limit 50 GB on exported bacpacs

To maintain the system that performs database export from LCS, a limit on the maximum bacpac size is being imposed. This limit is set at 50 GB for each bacpac exported. The reasons for this limit include:

- A centralized system is performing the exports for multiple customers in the same geographic region, and this system has constraints on disk space.
- Azure SQL neatly compresses the data in the bacpac format and in many cases, where customers exceed 50 GB, customizations or binary data drastically oversize the backup file.

If you experience an export failure because the resulting bacpac is over 50 GB in size, try running the following SQL script against your sandbox database to identify the top 15 tables by size in megabytes. Any tables that are for data entity staging (they will have "staging" at the end of the table name) can be truncated. Any tables that are storing binary or blob data (JSON/XML/binary) should either be truncated or the contents of that field should be deleted to free up space. Binary data cannot be compressed, so storing large volumes of data in the database itself will cause you to quickly reach the 50 GB limit.

```
USE [YourDBName] -- replace your dbname
GO
SELECT top 15
s.Name AS SchemaName,
t.Name AS TableName,
p.rows AS RowCounts,
CAST(ROUND((SUM(a.used_pages) / 128.00), 2) AS NUMERIC(36, 2)) AS Used_MB,
CAST(ROUND((SUM(a.total_pages) - SUM(a.used_pages)) / 128.00, 2) AS NUMERIC(36, 2)) AS Unused_MB,
CAST(ROUND((SUM(a.total_pages) / 128.00), 2) AS NUMERIC(36, 2)) AS Total_MB
FROM sys.tables t
INNER JOIN sys.indexes i ON t.OBJECT_ID = i.object_id
INNER JOIN sys.partitions p ON i.object_id = p.OBJECT_ID AND i.index_id = p.index_id
INNER JOIN sys.allocation_units a ON p.partition_id = a.container_id
INNER JOIN sys.schemas s ON t.schema_id = s.schema_id
GROUP BY t.Name, s.Name, p.Rows
ORDER BY Total_MB DESC
GO
```

Export operation failure

Most often, export operations fail because the process in LCS times out while it's waiting for a response from Microsoft Azure SQL Database. You can use the **Resume** button to reconnect LCS to the ongoing export process and see it through to completion. If more than 24 hours have passed since you began the export, the pending asset in the LCS Project asset library will be expired. In this case, you must roll back the export operation and restart it.

To cancel an export operation that has failed, you can use the **Rollback** button.

Data elements that aren't exported

When you export a database backup from an environment, some elements of the database aren't exported in the backup file. Here are some examples:

- Email addresses in the **LogisticsElectronicAddress** table.
- Batch job history in the **BatchJobHistory**, **BatchHistory**, and **BatchConstraintsHistory** tables.
- SMTP Relay server in the **SysEmailParameters** table.
- Print Management settings in the **PrintMgmtSettings** and **PrintMgmtDocInstance** tables.
- Environment-specific records in the **SysServerConfig**, **SysServerSessions**, **SysCorpNetPrinters**,

SysClientSessions, **BatchServerConfig**, and **BatchServerGroup** tables.

- Document attachments in the **DocuValue** table. These attachments include any Microsoft Office templates that were overwritten in the source environment.
- All users except the admin will be set to **Disabled** status.
- All batch jobs are set to **Withhold** status.
- All users will have their partition value reset to the "initial" partition record ID.
- All Microsoft-encrypted fields will be cleared, because they can't be decrypted on a different database server. An example is the **Password** field in the **SysEmailSMTPPassword** table.

Known issues

Export ran for some time and then reached a "Preparation failed" state

The export process can time out on Azure SQL Database when large databases are involved. In some cases, the export process can be recovered by using the **Resume** action from LCS. The Lifecycle Services team is working to identify known error codes, so these can be added to the logs for the export database operation to help guide users toward a resolution. These known error codes will be added in a future release of LCS.

Export doesn't show any progress in LCS

The export process differs from other database movement operations, and the general package deployment doesn't use a runbook. Therefore, the progress indicator in LCS doesn't show any output, even though it typically shows output in other scenarios. The LCS team is working to identify known error codes so that they can be added to the logs for the export database operation to help guide users toward a resolution. These known error codes will be added in a future release of LCS.

Import a database

2/18/2021 • 5 minutes to read • Edit Online

You can use Microsoft Dynamics Lifecycle Services (LCS) to import a golden configuration database into a sandbox user acceptance testing (UAT) environment.

Self-service import database

To import a database that is prepared from a developer environment to a standard user acceptance test (UAT), or a database previously exported from a UAT environment, follow the steps outlined below:

1. Go to your target sandbox **Environment Details** page, and select the **Maintain** > **Move database** menu option.
2. Select **Import database** and choose your source database backup (.bacpac format) file from the Asset Library.
3. Note the warnings. Review the list of data elements that are cleaned up from the backup file.
4. The import operation will begin immediately.

To import a database to a developer environment after you've downloaded a database backup (.bacpac) file, you can begin the manual import operation on your Tier 1 environment. When you import the database, we recommend that you follow these guidelines:

- Keep a copy of the existing AxDB database, so that you can revert to it later if needed.
- Import the new database under a new name, such as **AxDB_fromProd**.

To ensure the best performance, copy the *.bacpac file to the local computer that you're importing from. Download sqlpackage .NET Core for Windows from Get sqlpackage .NET Core for Windows. Open a **Command Prompt** window, and run the following commands from the sqlpackage .NET Core folder.

```
SqlPackage.exe /a:import /sf:D:\Exportedbacpac\my.bacpac /tsn:localhost /tdn:<target database name>
/p:CommandTimeout=1200
```

Here is an explanation of the parameters:

- **tsn (target server name)** – The name of the Microsoft SQL Server instance to import into.
- **tdn (target database name)** – The name of the database to import into. The database should **not** already exist.
- **sf (source file)** – The path and name of the file to import from.

> **NOTE**
> During import, the user name and password aren't required. By default, SQL Server uses Microsoft Windows authentication for the user who is currently signed in.

For information about how to complete the manual import operations into a Tier 1 environment, see Import the database.

Import operation failure

If the import operation isn't successful, you can do a *rollback*. If you select the **Rollback** option after the initial

failure of the operation, your target sandbox environment is restored to the state that it was in before the import began. The rollback operation is made available by the Microsoft Azure SQL Database point-in-time restore capability for restoring the database. Rollback is often required if a customization that is present in the target sandbox can't complete a database synchronization with the newly imported data.

Data elements that require attention after import

Specific activities must be completed when you import a database backup into a sandbox UAT environment. Here are some examples:

- Make sure that the source database contains only a single record in the Partitions table.
- Make sure that email capabilities are correctly reconfigured or turned off, according to your requirements.
- Make sure that integration settings are turned on or off, according to your requirements.
- Make sure that Application Object Server (AOS) servers are added back to required batch groups.
- Make sure that system Help and task guides are reconnected.
- Make sure that batch jobs are set to a status of **Waiting**.
- Make sure that users are re-enabled.

Environment admin

The system admin account in the target environment (**Admin** user ID) is reset to the value that is found in the web.config file in that environment. This account should be the same as the admin account from LCS. To preview which account this account will be, visit the **Environment details** page for your target sandbox in LCS. The value that was selected in the **Environment Administrator** field when the environment was first deployed is updated to the system admin in the transactional database. Therefore, the tenant of the environment will be the tenant of the environment admin.

If you've used the Admin User Provisioning Tool on your environment to change the web.config file, the value might not match the value in LCS. If you require that a different account be used, you must deallocate and delete the target sandbox, redeploy, and select another account. You can then do another database refresh action to restore the data.

Steps to complete after a database import for environments that use Commerce functionality

> **IMPORTANT**
>
> Some environment-specific records are not included in automated database movement operations and require additional steps. These include the following:
>
> - Commerce self-service installer references
> - Commerce Scale Unit channel database configuration records

If you copy a database between environments, Commerce capabilities in the destination environment will not be fully functional until you perform the following additional steps.

Initialize Commerce Scale Units

If you are moving a database to a sandbox UAT or production environment, you must Initialize Commerce Scale Unit after the database movement operation is complete. The Commerce Scale Unit's association from the source environment will not copy over to the destination environment.

Synchronize Commerce self-service installers

To be able to access Commerce self-service installers in HQ, you must Synchronize self-service installers after the database movement operation is complete.

IMPORTANT

The Environment re-provisioning step has now been fully automated as part of database movement operations, and no longer needs to be run manually. The Environment re-provisioning tool is still available in the Asset Library and may be used in certain situations to mitigate error conditions.

To run the Environment re-provisioning tool on the destination environment, run the following steps:

1. In your project's **Asset Library**, in the **Software deployable packages** section, select **Import**.
2. From the list of shared assets, select the **Environment Reprovisioning Tool**.
3. On the **Environment details** page for your destination environment, select **Maintain** > **Apply updates**.
4. Select the **Environment Reprovisioning** tool that you uploaded earlier, and then select **Apply** to apply the package.
5. Monitor the progress of the package deployment.

For more information about how to apply a deployable package, see Create deployable packages of models. For more information about how to manually apply a deployable package, see Install deployable packages from the command line.

Re-activate POS devices

If you use point of sale (POS) devices, after you import a database you must activate the POS devices again. Previously activated devices in the destination environment will no longer function. For more information, see Point of sale device activation.

NOTE

Can you tell us about your documentation language preferences? Take a short survey.

The survey will take about seven minutes. No personal data is collected (privacy statement).

Database point-in-time restore (PITR)

2/18/2021 • 4 minutes to read • Edit Online

You can use Microsoft Dynamics Lifecycle Services (LCS) to perform the point-in-time restore (PITR) for a sandbox user acceptance testing (UAT) environment. Microsoft maintains automated backups of the business and financial reporting databases for 28 days for Production environments and 14 days for Sandbox environments.

Self-service point-in-time restore

To restore the database of a standard user acceptance test (UAT) environment to a previous point-in-time, follow the steps outlined below:

1. Go to your target sandbox **Environment Details** page, and select the **Maintain** > **Move database** menu option.
2. Select the **Point-in-time restore** option and choose a point-in-time.
3. Note the warnings. Review the list of data elements that are not copied over from the previous point-in-time.
4. The restore operation will begin immediately.

Restore operation failed

In the event of failure, the option to do a **rollback** is available. If you select the rollback option after the operation originally fails, your target sandbox environment is restored to the state that it was in before the restore began. A rollback is often required if a customization that is present in the target sandbox environment can't complete a database synchronization with the newly restored data.

To determine the root cause of the failure, download the runbook logs using the available buttons before starting the rollback operation.

Data elements that need attention after restore

When you restore a database from a previous point in time, keep in mind that the database is provided "as was." For example, batch jobs and other data elements in the system can be in an in-progress state. These elements will require manual review.

Environment administrator

The system administrator account in the target environment (that is, the account that has a **UserId** value of **Admin**) is reset to the value that is found in the web.config file in the target environment. This value should match the value of the administrator account in LCS. To preview which account will be used, go to the **Environment Details** page for your target sandbox environment in LCS. The value that was selected in the **Environment Administrator** field when the environment was first deployed is updated to the system administrator in the transactional database. The tenant of the environment will be the tenant of the environment administrator.

If you've used the Admin User Provisioning Tool in your environment to change the value in the web.config file, the value might not match the value in LCS. If you require a different account, you must deallocate and delete the target sandbox environment, and then redeploy it by selecting another account. You can then do another refresh database action to restore the data.

Steps to complete after a database restore for environments that use Commerce functionality

IMPORTANT

Some environment-specific records are not included in automated database movement operations and require additional steps. These include the following:

- Commerce self-service installer references
- Commerce Scale Unit channel database configuration records

If you copy a database between environments, Commerce capabilities in the destination environment will not be fully functional until you perform the following additional steps.

Initialize Commerce Scale Units

If you are moving a database to a sandbox UAT or production environment, you must Initialize Commerce Scale Unit after the database movement operation is complete. The Commerce Scale Unit's association from the source environment will not copy over to the destination environment.

Synchronize Commerce self-service installers

To be able to access Commerce self-service installers in HQ, you must Synchronize self-service installers after the database movement operation is complete.

IMPORTANT

The Environment re-provisioning step has now been fully automated as part of database movement operations, and no longer needs to be run manually. The Environment re-provisioning tool is still available in the Asset Library and may be used in certain situations to mitigate error conditions.

To run the Environment re-provisioning tool on the destination environment, run the following steps:

1. In your project's **Asset Library**, in the **Software deployable packages** section, select **Import**.
2. From the list of shared assets, select the **Environment Reprovisioning Tool**.
3. On the **Environment details** page for your destination environment, select **Maintain** > **Apply updates**.
4. Select the **Environment Reprovisioning** tool that you uploaded earlier, and then select **Apply** to apply the package.
5. Monitor the progress of the package deployment.

For more information about how to apply a deployable package, see Create deployable packages of models. For more information about how to manually apply a deployable package, see Install deployable packages from the command line.

Re-activate POS devices

If you use point of sale (POS) devices, after you import a database you must activate the POS devices again. Previously activated devices in the destination environment will no longer function. For more information, see Point of sale device activation.

Known issues

Breaking the chain of available restore points

Several frequently used actions create a new database that won't have the same restore point history as the previously used database. These actions include point-in-time restores, database refreshes, database imports, and point-in-time restores from the production environment to the sandbox environment. In addition, if a software deployable package that you apply to your environment fails during update of the database, and you use the rollback functionality in LCS, the rollback functionality does a point-in-time restore of the database, and that restore also creates a new database.

Although the new database doesn't have any restore point history, it does begin to accrue new restore points from that time onward. After you perform any of the previously mentioned actions, you can't perform it again by using the same restore date and time.

Restore is denied for environments that run Platform update 20 or earlier

The restore database process cannot be completed if the environment is running Platform update 20 or earlier. For more information, see the list of currently supported Platform updates in the Software lifecycle policy and cloud releases.

Point-in-time restore of the production database to a sandbox environment

2/18/2021 • 10 minutes to read • Edit Online

You can use Microsoft Dynamics Lifecycle Services (LCS) to do a point-in-time restore (PITR) of the production database to a user acceptance testing (UAT) sandbox environment. Microsoft maintains automated backups of the business and financial reporting databases for 28 days for Production environments and 7 days for Sandbox environments.

> **IMPORTANT**
> Microsoft doesn't support copying production data to a sandbox environment for the purpose of production reporting.

Self-service point-in-time restore Production to Sandbox

To provide customers with data application lifecycle management (DataALM) capabilities that don't rely on human or manual processes, the Lifecycle Services team has introduced an automated refresh database action. Here is an overview of the process for doing a self-service database refresh.

1. Go to the **Environment Details** page for your target Sandbox, and select **Maintain** > **Move database** button.
2. Select the **Point-in-time restore Prod to Sandbox** option, and then select the desired point in time.
3. Make a note of the warnings, and review the list of data elements that aren't copied from the source environment's previous point in time.
4. The restore operation begins immediately.

> **IMPORTANT**
> Self-service point in time restore (PITR) is not supported between environments that are on different regions. For more details, refer to the "Known issues" section later in this topic.

Restore operation failure

If the restore operation isn't successful, you can do a rollback. If you select the **Rollback** option after the operation originally fails, your target sandbox environment is restored to the state that it was in before the refresh began. Rollbacks are made available by the PITR capability of Azure SQL Database. They are typically required if a customization that is present in the target sandbox environment can't complete a database synchronization with the newly refreshed data.

To determine the root cause of the failure, use the available buttons to download the runbook logs before you start the rollback operation.

Data elements that aren't copied during restore copy

When you refresh a production environment to a sandbox environment, or a sandbox environment to another sandbox environment, some elements of the database aren't copied over to the target environment. Here are some examples:

- Email addresses in the LogisticsElectronicAddress table.
- Batch job history in the BatchJobHistory, BatchHistory, and BatchConstraintHistory tables.

- Simple Mail Transfer Protocol (SMTP) Relay server in the SysEmailParameters table.
- Print Management settings in the PrintMgmtSettings and PrintMgmtDocInstance tables.
- Environment-specific records in the SysServerConfig, SysServerSessions, SysCorpNetPrinters, SysClientSessions, BatchServerConfig, and BatchServerGroup tables.
- Document attachments in the DocuValue table. These attachments include any Microsoft Office templates that were overwritten in the source environment.
- All users except the admin will be set to **Disabled** status.
- All batch jobs will be set to **Withhold** status.
- All users will have their partition value reset to the "initial" partition record ID.
- All Microsoft-encrypted fields will be cleared, because they can't be decrypted on a different database server. An example is the **Password** field in the SysEmailSMTPPassword table.

Some of these elements aren't copied because they are environment-specific. Examples include BatchServerConfig and SysCorpNetPrinters records. Other elements aren't copied because of the volume of support tickets. For example, duplicate emails might be sent because SMTP is still turned on in the UAT environment, invalid integration messages might be sent because batch jobs are still enabled, and users might be enabled before admins can perform post-refresh cleanup activities.

Environment administrator

The system administrator account in the target environment (that is, the account that has a **UserId** value of **Admin**) is reset to the value that is found in the web.config file in the target environment. This value should match the value of the administrator account in LCS. To preview this account, go to the **Environment Details** page for your target sandbox environment in LCS. The value that was selected in the **Environment Administrator** field when the environment was first deployed is updated so that it matches the system administrator account in the transactional database. Therefore, the tenant of the environment will also be the tenant of the environment administrator.

If you've used the Admin User Provisioning Tool on your environment to change the value in the web.config file, that value might not match the value in LCS. If you require that a different account be used, you must deallocate and delete the target sandbox environment, and then redeploy it and select another account. You can then perform another refresh database action to restore the data.

An environment can't be refreshed from one tenant to another. This restriction applies even to .onmicrosoft.com tenants. You should make sure that the admin accounts in the source and target environments are from the same tenant domain.

Conditions for doing a PITR copy of a production environment to a sandbox environment

Here is the list of requirements and conditions of operation for a database refresh:

- A refresh performs a delete operation on the original target database.
- The target environment will be available until the database copy has reached the target server. After that point, the environment will be offline until the refresh process is completed.
- The refresh will affect only the application and Financial Reporting databases.
- Documents in Azure Blob storage aren't copied from one environment to another. Therefore, attached document handling documents and templates won't be changed and will remain in their current state.
- All users except the Admin user and other internal service user accounts will be unavailable. Therefore, the Admin user can delete or obfuscate data before other users are allowed back into the system.
- The Admin user must make required configuration changes, such as reconnecting integration endpoints to specific services or URLs.
- All data management integration jobs that have recurring import and export enabled must be fully processed and stopped in the target system before the restore is started. In addition, we recommend that you select the database from the source after all recurring import and export jobs have been fully processed. In this way, you ensure that there are no orphaned files from either system in Azure storage. This step is

important because orphaned files can't be processed after the database is restored in the target environment. After the restore, the integration jobs can be resumed.

- Business events end points must be deleted and reconfigured in the environment where the database is restored to ensure the same end points are not used. This will also require the business events to be deactivated and re-activated to the new end points that were configured in the environment.
- Any user who has the Project owner or Environment manager role in LCS will have access to the SQL and machine credentials for all non-production environments.
- The databases must be hosted in the same Azure geographic region, unless the databases are Spartan-managed. Databases are Spartan-managed when you see 'spartan' as part of the fully qualified SQL server address.
- The allocated database capacity of the source environment must be less than the maximum database capacity of the target environment.

Steps to complete after a restore is done for environments that use Commerce functionality

> **IMPORTANT**
>
> Some environment-specific records are not included in automated database movement operations and require additional steps. These include the following:
>
> - Commerce self-service installer references
> - Commerce Scale Unit channel database configuration records

If you copy a database between environments, Commerce capabilities in the destination environment will not be fully functional until you perform the following additional steps.

Initialize Commerce Scale Units

If you are moving a database to a sandbox UAT or production environment, you must Initialize Commerce Scale Unit after the database movement operation is complete. The Commerce Scale Unit's association from the source environment will not copy over to the destination environment.

Synchronize Commerce self-service installers

To be able to access Commerce self-service installers in HQ, you must Synchronize self-service installers after the database movement operation is complete.

> **IMPORTANT**
>
> The Environment re-provisioning step has now been fully automated as part of database movement operations, and no longer needs to be run manually. The Environment re-provisioning tool is still available in the Asset Library and may be used in certain situations to mitigate error conditions.

To run the Environment re-provisioning tool on the destination environment, run the following steps:

1. In your project's **Asset Library**, in the **Software deployable packages** section, select **Import**.
2. From the list of shared assets, select the **Environment Reprovisioning Tool**.
3. On the **Environment details** page for your destination environment, select **Maintain** > **Apply updates**.
4. Select the **Environment Reprovisioning** tool that you uploaded earlier, and then select **Apply** to apply the package.
5. Monitor the progress of the package deployment.

For more information about how to apply a deployable package, see Create deployable packages of models. For

more information about how to manually apply a deployable package, see Install deployable packages from the command line.

Re-activate POS devices

If you use point of sale (POS) devices, after you import a database you must activate the POS devices again. Previously activated devices in the destination environment will no longer function. For more information, see Point of sale device activation.

Known issues

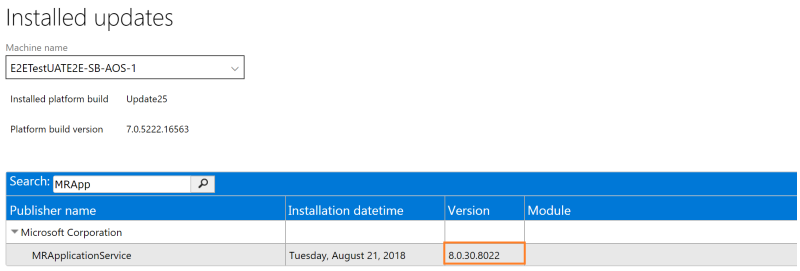
Restore is denied for environments that run Platform update 20 or earlier

The database refresh process can't currently be completed if the environment is running Platform update 20 or earlier. For more information, see the list of currently supported platform updates.

The source and target environments have incompatible versions of Financial Reporting

The database refresh process (self-service or via a service request) can't be successfully completed if the version of Financial Reporting in your target environment is earlier than the version in your source environment. To resolve this issue, update both environments so that they have the latest version of Financial Reporting.

To determine the version that is installed in your source and target environments, select **View detailed version information** on the **Environment Details** page. Then search for **MRApplicationService**, and make sure that the version in the target environment is later than or the same as the version in the source environment.



Customers that are using version 8.1 or later should follow these steps.

1. Go to the **Update** tiles for your UAT environment. Save the updates to your Project asset library.
2. Apply the package to your UAT environment.
3. Verify that the error has been resolved.

Customers that are using version 8.0 or earlier should follow these steps.

1. Review the environment history of your source environment. Specifically, look for any "Platform and application binary package" package that has been deployed to the source environment but not to the target environment.
2. Apply the binary package to your target environment.
3. Verify that the error has been resolved.

The source and target environments have incompatible application versions

The database refresh process (self-service or via service request) can't be completed if the application release of your source environment and the application release of your target environment aren't the same. Because the data upgrade process isn't run by using database movement operations such as refresh, data loss can occur.

If you're upgrading your sandbox UAT environment to a newer application version (for example, from 7.3 to 8.1), be sure to perform the database refresh action before you start the upgrade. After your sandbox environment is upgraded to the newer version, you can't restore an older production environment database to the sandbox UAT environment.

Conversely, if your production environment is newer than your target sandbox environment, you must either upgrade the target sandbox environment before the refresh, or just deallocate, delete, and redeploy the environment before you do the refresh.

The source and target are on different infrastructure (Microsoft-managed vs. self-Service)

The PITR process is not supported between Microsoft-managed and self-service environments across different regions. For example, if the production environment is Microsoft-managed and in East US2 and a PITR is needed to the sandbox environment, which is self-service and in East US, PITR is not supported. The alternative is to move the production environment to self-service or opt for a regular database refresh instead.

Point in time restore between source and target that are both on self-Service, in different regions

The PITR process is not supported between self-service environments across different regions. For example, if the production environment is in East US and a PITR is needed for the sandbox environment, which is self-service and in West Europe, PITR is not supported. The alternative is to get both the environments in the same region or opt for a regular database refresh instead.

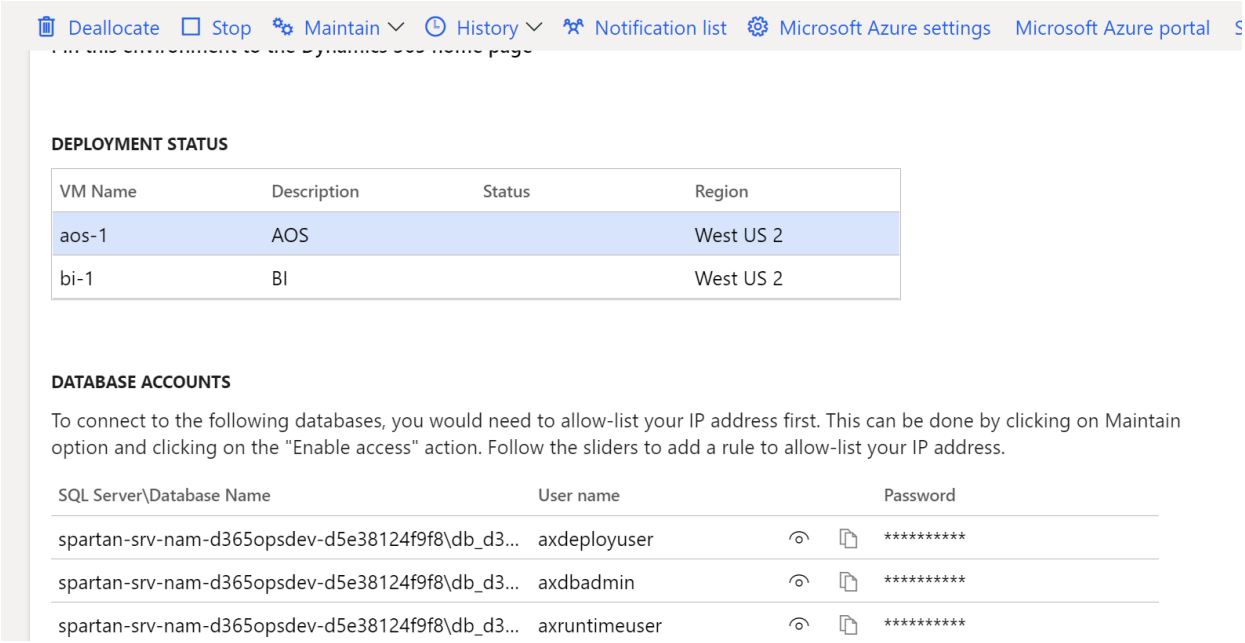
Enable just-in-time database access

2/18/2021 • 2 minutes to read • Edit Online

This topic provides the steps necessary to enable database access using a just-in-time (JIT) fashion. This is useful if access to the database is required for various troubleshooting efforts, running unplanned queries, or data upgrade problem solving. This process is available for both self-service as well as Microsoft-managed sandbox acceptance test environments. For more information about the available environment types, see Deployment overview.

Microsoft-managed environments without RDP access

If you no longer have Remote Desktop Protocol (RDP) access to your sandbox, you can add your IP address to the allow-list in a self-service manner from Lifecycle Services (LCS). When RDP is removed from an environment, the machine credentials section of the environment details page is removed. This leaves just the database accounts section, as shown in the following screenshot.



From the environment details page for your sandbox environment, select **Maintain** > **Enable access**, and then in the dialog box, add the IP address of your source environment. This entry will expire, with the expire date shown alongside the IP address you entered. It also will be lost after the database is replaced by a database movement operation, such as database refresh or database import.

You can now use tools like SQL Server Management Studio (SSMS) to connect to the database, using the accounts from LCS and the IP address that you enabled. Note that LCS shows the server and database in the following format: **serverName\databaseName**. To connect in SSMS, you will need to append the domain name suffix, such as **serverName.database.windows.net** if you are in Azure public cloud. On the **Options** tab in the SSMS connection window, you will also need to explicitly enter the databaseName value in the **Database** field to successfully connect.

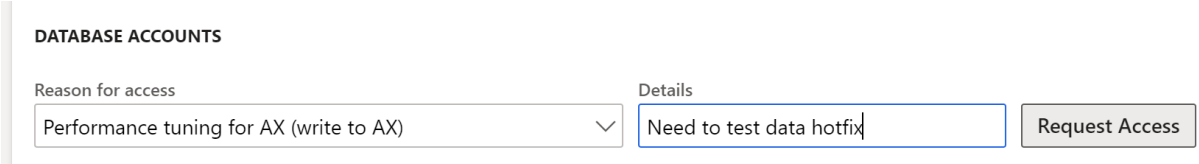
Self-service environments

The self-service environment type has never had Remote Desktop Protocol (RDP) access or static database accounts. However, it is still possible to access the database.

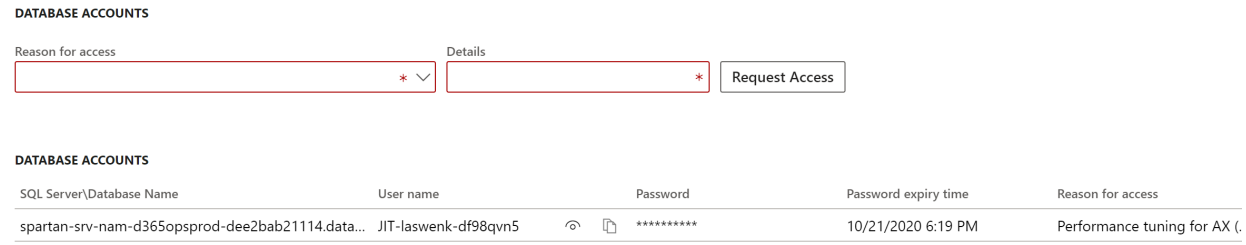
From the environment details page for your sandbox environment, select **Maintain** > **Enable access**, and then

in the dialog box, add the IP address of your source environment. This entry will not expire, however it will be lost after the database is replaced by a database movement operation, such as database refresh or database import.

You also need to enter which type of access you require in the **Database Accounts** section. The available options include read or read-write access. Enter a short reason description and then select **Request access**.



When the page is refreshed, the database account will be shown with its expiry time.



You can now use tools like SQL Server Management Studio (SSMS) to connect to the database, using the accounts from LCS and the IP address you enabled.

> **NOTE**
>
> Can you tell us about your documentation language preferences? Take a short survey.
>
> The survey will take about seven minutes. No personal data is collected (privacy statement).

Refresh for training purposes

2/18/2021 • 4 minutes to read • Edit Online

Database movement operations are a suite of self-service actions that can be used as part of data application lifecycle management (DataALM). This tutorial shows how to use the refresh database operation in a training scenario.

In this tutorial, you will learn how to:

- Prepare the target environment.
- Run the refresh.
- Reconfigure the target environment.
- Enable selected users.

As an example of this scenario, a customer who has already gone live with the application wants to load a recent copy of production transactions into the user acceptance testing (UAT) environment. In this way, the customer can support training of new employees and evaluate configuration changes without affecting the live environment.

Prerequisites

To do a refresh database operation, your production environment must be deployed, or you must have a minimum of two standard UAT environments.

Notify users about the pending downtime

Before you start the bulk of the work, notify users of the target environment that the environment will be offline for a period. You can notify users either manually via Microsoft Dynamics Lifecycle Services (LCS) or programmatically by using RESTful application programming interface (API) calls.

Manually send a broadcast message

To notify users manually via LCS, follow these steps.

1. In LCS, open the **Environment details** page for the target environment.
2. Select **Maintain** > **Message online users**.
3. Select **Broadcast a new message for downtime**.
4. Select the valid from/valid to times in your local time zone.
5. Select **Post**.

Programmatically send a broadcast message

The following sample code can be used as shown in a console application, or it can be modified to make it work with other services that can be called on demand, such as Microsoft Azure Functions. Before this sample code will work, you must set up your application registration as described in Service endpoints overview.

```
[Serializable]
public class SysAddBroadcastMessageDataContract
{
    public SysAddBroadcastMessageRequest request { get; set; }
}
[Serializable]
public class SysAddBroadcastMessageRequest
{
    public DateTime FromDateTime { get; set; }
    public DateTime ToDateTime { get; set; }
}
public class Program
{
    public static AuthenticationResult getResult(AuthenticationContext ctx, string url)
    {
        return ctx.AcquireTokenAsync(url, "YOUR_APP_REGISTRATION_ID", new Uri("YOUR_REPLY_URL"), new
PlatformParameters(PromptBehavior.Always)).Result;
    }
    static void Main(string[] args)
    {
        SysAddBroadcastMessageRequest request = new SysAddBroadcastMessageRequest();
        request.FromDateTime = DateTime.UtcNow;
        request.ToDateTime = DateTime.UtcNow.AddHours(12);

        SysAddBroadcastMessageDataContract dc = new SysAddBroadcastMessageDataContract();
        dc.request = request;

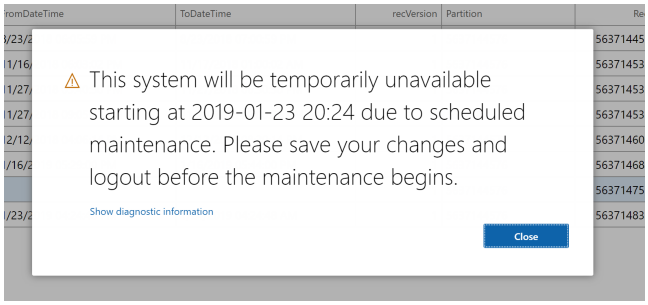
        AuthenticationContext ctx = new
AuthenticationContext("https://login.microsoftonline.com/YOUR_TENANT.COM");
        AuthenticationResult res = getResult(ctx,
"https://YOUR_SANDBOX_UAT.sandbox.operations.dynamics.com");

        HttpClient restfulCli = new HttpClient();
        restfulCli.DefaultRequestHeaders.Clear();
        restfulCli.BaseAddress = new Uri("https://YOUR_SANDBOX_UAT.sandbox.operations.dynamics.com/");
        restfulCli.DefaultRequestHeaders.Add("Authorization", res.CreateAuthorizationHeader());
        restfulCli.DefaultRequestHeaders.Accept.Add(new
MediaTypeWithQualityHeaderValue("application/json"));

        HttpRequestMessage requestMsg = new HttpRequestMessage(HttpMethod.Post,
string.Format("api/services/SysBroadcastMessageServices/SysBroadcastMessageService/AddMessage"));
        requestMsg.Content = new StringContent(JsonConvert.SerializeObject(dc));

        HttpResponseMessage responseMsg = restfulCli.SendAsync(requestMsg).Result;
        if(responseMsg.IsSuccessStatusCode)
        {
            Console.WriteLine("Wow I just notified the users programmatically!");
        }
    }
```

Both approaches, manual via LCS and programmatic via RESTful API calls, will show users that a period of downtime is pending.



Begin the refresh

Depending on the size of your source environment, it might make sense to begin the refresh process immediately. The larger the source database, the longer it will take to copy to your target Azure SQL Database instance. While the copy is in progress, the target environment will still be online. The downtime will start after the copy is completed.

This process can be done manually via LCS. For the latest steps, see Refresh database. In a future release of LCS, you will also be able to trigger this process via a RESTful API.

Reconfigure environment specific settings

After the refresh is completed, use the **Sign off** button in LCS to close out of the operation. You can then start to configure the environment-specific settings.

First, sign in to the environment by using the admin account that can be found on the **Environment details** page in LCS. Here are typical areas of reconfiguration. You might require additional reconfiguration, based on your setup and the independent software vendor (ISV) solutions that are installed.

- **System administration** > **Setup** > **Batch groups:** Add the various Application Object Server (AOS) instances to the batch server groups that you require.
- **System administration** > **Setup** > **Entity Store:** Refresh the various entities that you require for Microsoft Power BI reporting.
- **System administration** > **Setup** > **System parameters:** Reconnect the environment to the LCS Help configuration for task guides.
- **System administration** > **Setup** > **Email** > **Email parameters:** Enter the Simple Mail Transfer Protocol (SMTP) settings if you use email in your UAT environment.
- **System administration** > **Inquiries** > **Batch jobs:** Select the jobs that you want to run in your UAT environment, and update the status to **Waiting**.

To complete this reconfiguration more quickly, we recommend that you build a custom web service endpoint that can be called on demand after the refresh is completed. An example of this type of web service will be added in a future update of this topic.

Open the environment to users

When the system is configured as you require, you can enable selected users to let them access the environment. By default, all users except the admin and Microsoft service accounts are disabled.

Go to **System administration** > **Users** > **Users**, and enable the users that should have access to the UAT environment. If many users must be enabled, you can complete this task more quickly by using the Microsoft Excel Add-In.

Debug a copy of the production database

2/18/2021 • 4 minutes to read • Edit Online

Database movement operations are a suite of self-service actions that can be used as part of data application lifecycle management (DataALM). This tutorial shows how to debug specific data and transactions from a recent copy of production data.

In this tutorial, you will learn how to:

- Refresh the user acceptance testing (UAT) environment.
- Add the IP address of your developer environment to an approved list ("safe list").
- Update your developer environment so that it connects to the UAT database.
- Set a breakpoint, and start to debug the data.

As an example of this scenario, a customer who has already gone live wants to debug a recent copy of production transactions from the development environment. In this way, the customer will be able to debug specific transactions that are stuck, or develop new features and reports by using realistic datasets.

Prerequisites

To do a refresh operation, you must have your production environment deployed, or you must have a minimum of two standard UAT environments. To complete this tutorial, you must have a developer environment deployed.

> **IMPORTANT**
>
> For debugging, we highly recommend that you use a DevTest environment that runs the same code and business logic that are available in your UAT environment. If you use multiple branches in version control, we recommend that the DevTest environment that is used to debug recent UAT or production transactions be connected to the same branch that you use to build packages for UAT and, later, for production. In this way, you don't have to run a database synchronization between your DevTest environment and UAT database, because the schema will be compatible. Historically, this environment is known as a Hotfix/Support environment, because it's outside your usual code promotion path.

Refresh the UAT environment

This refresh operation overwrites the UAT environment with the latest copy of the production database. To complete this step, follow the instructions in Refresh for training purposes.

Enable database access

By default, all Sandbox Standard Acceptance Test environments use Microsoft Azure SQL Database as their database platform. The databases for these environments are protected by firewalls that restrict access to the Application Object Server (AOS) with which it was originally deployed.

To connect to the database, follow the instructions in Enable just-in-time access.

> **NOTE**
>
> Every time that a refresh is done, the firewall safe list is reset. You must add your DevTest environments back to this database when they are required in the future.

Update a OneBox DevTest environment to connect to the UAT database

In your developer environment, you must now update the web.config file to change the database connection. This step will let you run your local code and binaries that are configured against the database from UAT.

On your Services drive, go to the **AoSService\WebRoot** directory. (Typically, the Services drive is drive J or K.) Find the file that is named web.config, and *make a backup of it*. Then open the **web.config** file in Notepad or another editor, and find the following configurations:

- DataAccess.Database
- DataAccess.DBServer
- DataAccess.SqlPwd
- DataAccess.SqlUser

Update these configurations so that they use the values from the environment details page for the UAT environment in LCS.

```
<add key="DataAccess.Database" value="<example_axdb_fromAzure>" />
<add key="DataAccess.DbServer" value="<example_axdb_server.database.windows.net>" />
<add key="DataAccess.SqlPwd" value="<axdbadmin_password_from_LCS>" />
<add key="DataAccess.SqlUser" value="axdbadmin" />
```

Save the file. If you're operating in a cloud-hosted environment, run IISRESET. If you're on a Microsoft-managed developer machine and have limited permissions, make sure that Microsoft Visual Studio is closed.

Finally, open a web browser, go to the URL of your DevTest environment, and verify that you're pulling data from the UAT database.

Debug transactions in the DevTest environment

Now that your environment is correctly reconfigured, you can open Visual Studio and set a breakpoint in the application code that best meets your needs. Note that users in the UAT environment aren't affected while you debug in the DevTest environment.

Debugging batch

For scenarios where you need to debug batch jobs, on the debugging DevTest machine, you may need to restart the batch service before it will show up as an option to attach the debugger from Visual Studio. In addition, it may also be helpful to isolate this DevTest machine in to its own batch group to ensure that any jobs that you want to debug will run on the DevTest machine.

Best practices

Here are some common best practices that will help guarantee that your debugging experience is quick, reliable, and doesn't disrupt other users in your organization:

- Make sure that the version of the code and binaries in the DevTest environment exactly match the version in the UAT environment. Connect the DevTest environment to the same branch that you build packages for deployment from. Alternatively, connect it to a "HotfixSupport" branch that is kept up to date with the latest customizations that are released.
- Don't run a database synchronization from Visual Studio. Otherwise, you will affect the availability of the schema in the UAT database and might affect users in the UAT environment.
- For the best experience, use a developer environment that was deployed in the same datacenter as the UAT environment.

NOTE

Can you tell us about your documentation language preferences? Take a short survey.

The survey will take about seven minutes. No personal data is collected (privacy statement).

Export a copy of the standard user acceptance testing (UAT) database

2/18/2021 • 12 minutes to read • Edit Online

Database movement operations are a suite of self-service actions that can be used as part of data application lifecycle management (DataALM). This tutorial shows how to export all the data and transactions from a sandbox standard user acceptance testing (UAT) environment.

In this tutorial, you will learn how to:

- Refresh the UAT environment.
- Run the export to the Asset library in Microsoft Dynamics Lifecycle Services (LCS).
- Download the database backup.
- Import the database, and prepare it so that it can be used in a developer environment.

As an example of this scenario, a customer who has already gone live wants to load a recent copy of production transactions into the development environment. In this way, the customer will be able to debug specific transactions, or develop new features and reports by using realistic datasets.

> **IMPORTANT**
>
> Database copy to a build environment is not supported. Learn more about build environments.

Known limitations

Because of recent restrictions by the Microsoft Azure SQL Database platform, we don't recommend that you export your database if it's larger than 200 gigabytes (GB). If you must export a larger database, we recommend that you use the legacy documentation until SQL Database can support larger exports. Note that this recommendation applies to export operations, not refresh operations. Refresh operations can support databases that are up to 4 terabytes (TB) in size.

Prerequisites

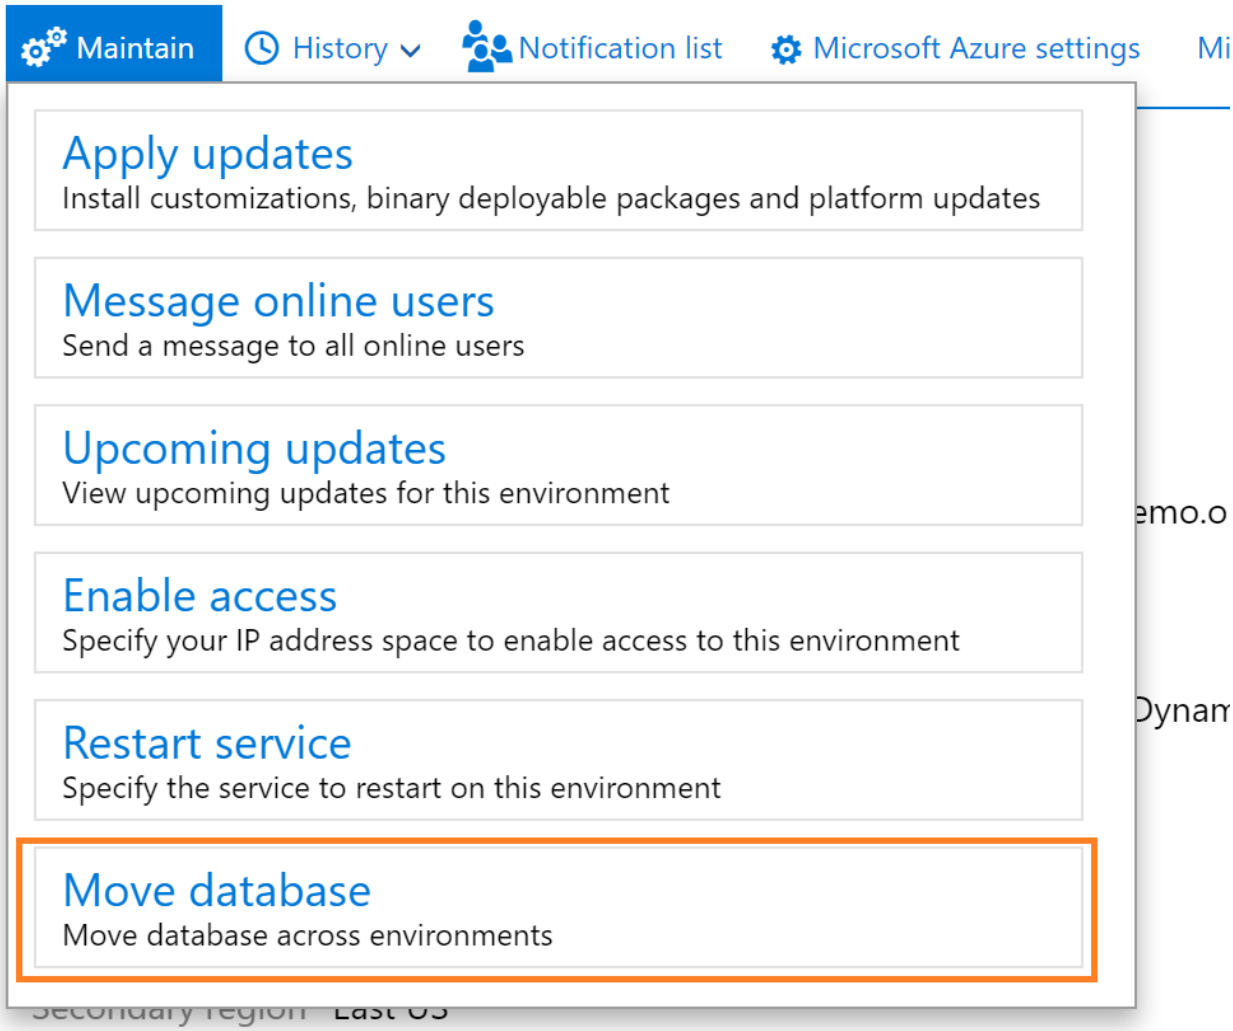
To do a refresh operation, you must have your production environment deployed, or you must have a minimum of two standard UAT environments. To complete this tutorial, you must have a developer environment deployed.

Refresh the UAT environment

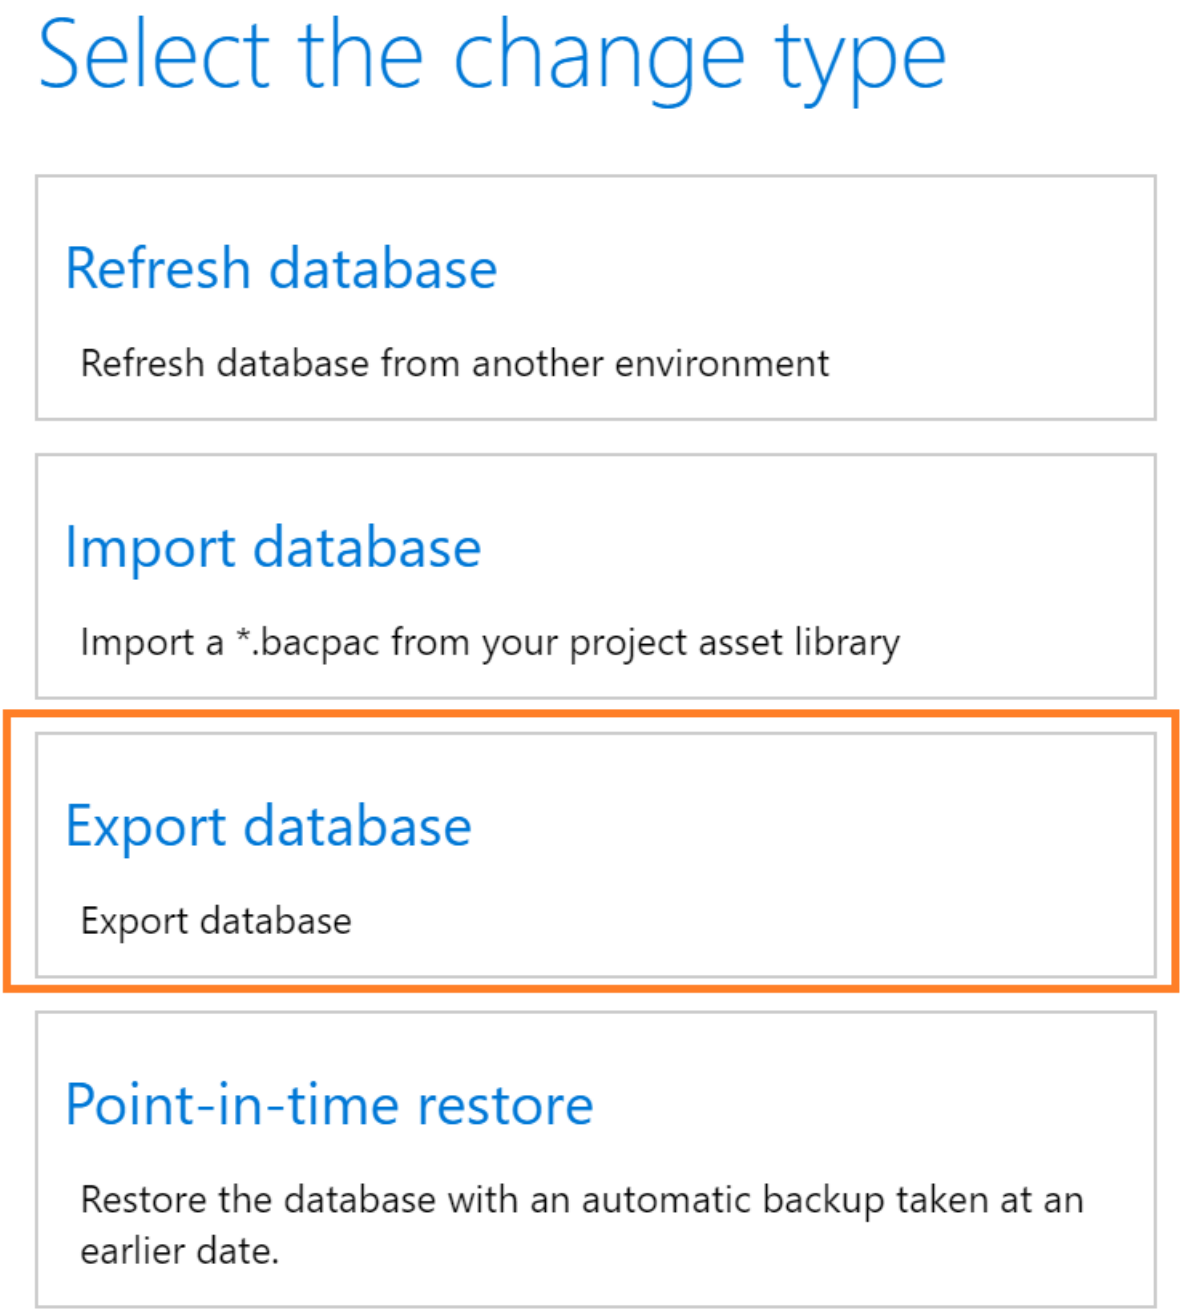
This refresh operation overwrites the UAT environment with the latest copy of the production database. To complete this step, follow the instructions in Refresh for training purposes.

Back up to the Asset Library

From your sandbox **Environment Details** page, click the **Maintain** menu, and then select **Move database**.

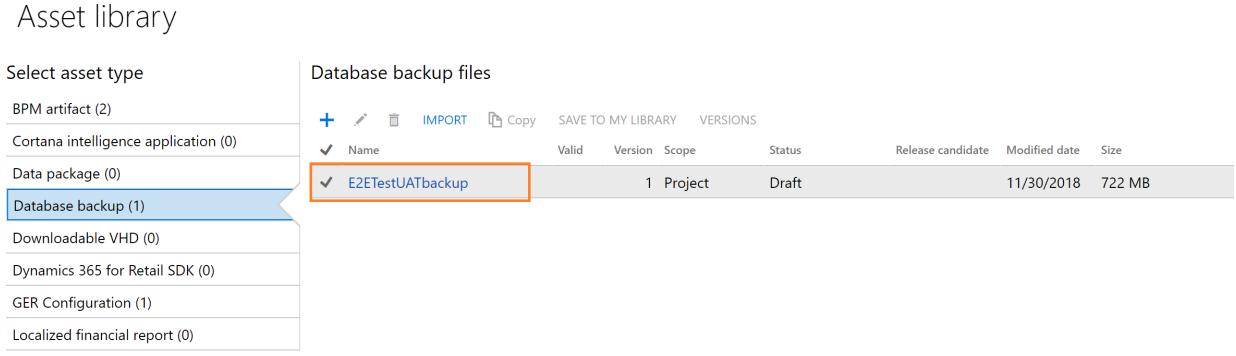


A slider pane will open on the page where you can use the **Export database** action.



The environment will be unavailable for other servicing operations, such as Sandbox refresh or package deployment during this time. The source environment will be usable from a Dynamics user perspective.

After the export operation completes successfully, sign out of the servicing operation on your **Environment details** page. You can then see the asset in your **Asset Library** in the **Database backups** section.



The **.bacpac** files are stored here and can be manually downloaded to your Tier 1 developer environments for import. In the future, Microsoft will provide APIs to trigger the export action, as well as list the available backup files in your asset library. This includes the secured URL for automatically downloading a backup asset file or copying it directly to your secure blob storage using Microsoft Azure Storage SDKs.

Import the database

After you've downloaded a database backup (.bacpac) file, you can begin the manual import operation on your Tier 1 environment. When you import the database, we recommend that you follow these guidelines:

- Keep a copy of the existing AxDB database, so that you can revert to it later if you must.
- Import the new database under a new name, such as **AxDB_fromProd**.

To ensure the best performance, copy the *.bacpac file to the local computer that you're importing from. Download sqlpackage .NET Core for Windows from Get sqlpackage .NET Core for Windows. Open a **Command Prompt** window, and run the following commands from the sqlpackage .NET Core folder.

```
SqlPackage.exe /a:import /sf:D:\Exportedbacpac\my.bacpac /tsn:localhost /tdn:<target database name>
/p:CommandTimeout=1200
```

Here is an explanation of the parameters:

- **tsn (target server name)** – The name of the Microsoft SQL Server instance to import into.
- **tdn (target database name)** – The name of the database to import into. The database should **not** already exist.
- **sf (source file)** – The path and name of the file to import from.

> **NOTE**
> During import, the user name and password aren't required. By default, SQL Server uses Microsoft Windows authentication for the user who is currently signed in.

Update the database

Run the following SQL script against the imported database. This script adds back the users that you deleted from the source database and correctly links them to the SQL logins for this SQL Server instance. The script also turns change tracking back on. Remember to edit the final **ALTER DATABASE** statement so that it uses the name of your database.

```
CREATE USER axdeployuser FROM LOGIN axdeployuser
EXEC sp_addrolemember 'db_owner', 'axdeployuser'

CREATE USER axdbadmin FROM LOGIN axdbadmin
EXEC sp_addrolemember 'db_owner', 'axdbadmin'

CREATE USER axmrruntimeuser FROM LOGIN axmrruntimeuser
EXEC sp_addrolemember 'db_datareader', 'axmrruntimeuser'
EXEC sp_addrolemember 'db_datawriter', 'axmrruntimeuser'

CREATE USER axretaildatasyncuser FROM LOGIN axretaildatasyncuser
EXEC sp_addrolemember 'DataSyncUsersRole', 'axretaildatasyncuser'

CREATE USER axretailruntimeuser FROM LOGIN axretailruntimeuser
EXEC sp_addrolemember 'UsersRole', 'axretailruntimeuser'
EXEC sp_addrolemember 'ReportUsersRole', 'axretailruntimeuser'

CREATE USER axdeployextuser FROM LOGIN axdeployextuser
EXEC sp_addrolemember 'DeployExtensibilityRole', 'axdeployextuser'

CREATE USER [NT AUTHORITY\NETWORK SERVICE] FROM LOGIN [NT AUTHORITY\NETWORK SERVICE]
EXEC sp_addrolemember 'db_owner', 'NT AUTHORITY\NETWORK SERVICE'

UPDATE T1
SET T1.storageproviderid = 0
    , T1.accessinformation = ''
    , T1.modifiedby = 'Admin'
    , T1.modifieddatetime = getdate()
FROM docuvalue T1
WHERE T1.storageproviderid = 1 --Azure storage

DROP PROCEDURE IF EXISTS SP_ConfigureTablesForChangeTracking
DROP PROCEDURE IF EXISTS SP_ConfigureTablesForChangeTracking_V2
GO
-- Begin Refresh Retail FullText Catalogs
DECLARE @RFTXNAME NVARCHAR(MAX);
DECLARE @RFTXSQL NVARCHAR(MAX);
DECLARE retail_ftx CURSOR FOR
SELECT OBJECT_SCHEMA_NAME(object_id) + '.' + OBJECT_NAME(object_id) fullname FROM SYS.FULLTEXT_INDEXES
    WHERE FULLTEXT_CATALOG_ID = (SELECT TOP 1 FULLTEXT_CATALOG_ID FROM SYS.FULLTEXT_CATALOGS WHERE NAME =
'COMMERCEFULLTEXTCATALOG');
OPEN retail_ftx;
FETCH NEXT FROM retail_ftx INTO @RFTXNAME;

BEGIN TRY
    WHILE @@FETCH_STATUS = 0
    BEGIN
        PRINT 'Refreshing Full Text Index ' + @RFTXNAME;
        EXEC SP_FULLTEXT_TABLE @RFTXNAME, 'activate';
        SET @RFTXSQL = 'ALTER FULLTEXT INDEX ON ' + @RFTXNAME + ' START FULL POPULATION';
        EXEC SP_EXECUTESQL @RFTXSQL;
        FETCH NEXT FROM retail_ftx INTO @RFTXNAME;
    END
END TRY
BEGIN CATCH
    PRINT error_message()
END CATCH

CLOSE retail_ftx;
DEALLOCATE retail_ftx;
-- End Refresh Retail FullText Catalogs
```

Turn on change tracking

If change tracking was turned on in the source database, be sure to turn it on in the newly provisioned database in the target environment. To turn on change tracking, use the **ALTER DATABASE** command.

```
ALTER DATABASE [your database name] SET CHANGE_TRACKING = ON (CHANGE_RETENTION = 6 DAYS, AUTO_CLEANUP = ON);
```

To help guarantee that the current version of the store procedure that is related to change tracking is used in the new database, you must turn change tracking on or off for a data entity in Data management. You can choose any entity. This step is required in order to trigger a refresh of the store procedure.

Start to use the new database

To switch environments and use the new database, first stop the following services:

- World Wide Web Publishing Service
- Microsoft Dynamics 365 Unified Operations: Batch Management Service
- Management Reporter 2012 Process Service

After these services have been stopped, rename the AxDB database **AxDB_orig**, rename your newly imported database **AxDB**, and then restart the three services.

To switch back to the original database, reverse this process. In other words, stop the services, rename the databases, and then restart the services.

Post steps for Commerce environments

If you are using Commerce channels, when importing a database to a developer environment, which was originally exported from a self-service sandbox, the following additional steps must be performed on the destination developer environment. Without completing these steps, Commerce channels will not function.

1. To restore Commerce channels functionality, apply the latest Microsoft service update or quality update, which will create the channel database.
2. To restore any previously deployed channel database extensions, re-apply the corresponding Retail self-service deployable package.

Reprovision the target environment

> **IMPORTANT**
>
> Some environment-specific records are not included in automated database movement operations and require additional steps. These include the following:
>
> - Commerce self-service installer references
> - Commerce Scale Unit channel database configuration records

If you copy a database between environments, Commerce capabilities in the destination environment will not be fully functional until you perform the following additional steps.

Initialize Commerce Scale Units

If you are moving a database to a sandbox UAT or production environment, you must Initialize Commerce Scale Unit after the database movement operation is complete. The Commerce Scale Unit's association from the source environment will not copy over to the destination environment.

Synchronize Commerce self-service installers

To be able to access Commerce self-service installers in HQ, you must Synchronize self-service installers after the database movement operation is complete.

IMPORTANT

The Environment re-provisioning step has now been fully automated as part of database movement operations, and no longer needs to be run manually. The Environment re-provisioning tool is still available in the Asset Library and may be used in certain situations to mitigate error conditions.

To run the Environment re-provisioning tool on the destination environment, run the following steps:

1. In your project's **Asset Library**, in the **Software deployable packages** section, select **Import**.
2. From the list of shared assets, select the **Environment Reprovisioning Tool**.
3. On the **Environment details** page for your destination environment, select **Maintain** > **Apply updates**.
4. Select the **Environment Reprovisioning** tool that you uploaded earlier, and then select **Apply** to apply the package.
5. Monitor the progress of the package deployment.

For more information about how to apply a deployable package, see Create deployable packages of models. For more information about how to manually apply a deployable package, see Install deployable packages from the command line.

Re-activate POS devices

If you use point of sale (POS) devices, after you import a database you must activate the POS devices again. Previously activated devices in the destination environment will no longer function. For more information, see Point of sale device activation.

Reset the Financial Reporting database

If you're using Financial Reporting, you must reset the Financial Reporting database by following the steps in Reset the Financial reporting data mart. (Financial Reporting was previously named Management Reporter.)

Reenter data from encrypted and environment-specific fields in the target database

In the client, enter the values that you documented for the encrypted and environment-specific fields. The following fields are affected. The field names are given in *Table.Field* format.

FIELD NAME	WHERE TO SET THE VALUE
CreditCardAccountSetup.SecureMerchantProperties	Select **Accounts receivable** > **Payments setup** > **Payment services**.
ExchangeRateProviderConfigurationDetails.Value	Select **General ledger** > **Currencies** > **Configure exchange rate providers**.
FiscalEstablishment_BR.ConsumerEFDocCsc	Select **Organization administration** > **Fiscal establishments** > **Fiscal establishments**.
FiscalEstablishmentStaging.CSC	This field is used by the Data Import/Export Framework (DIXF).
HcmPersonIdentificationNumber.PersonIdentificationNumber	Select **Human resources** > **Workers** > **Workers**. On the **Worker** tab, in the **Personal information** group, select **Identification numbers**.

FIELD NAME	WHERE TO SET THE VALUE
HcmWorkerActionHire.PersonIdentificationNumber	This field has been obsolete since Microsoft Dynamics AX 7.0 (February 2016). It was previously in the **All worker actions** form (**Human resources** > **Workers** > **Actions** > **All worker actions**).
SysEmailSMTPPassword.Password	Select **System administration** > **Email** > **Email parameters**.
SysOAuthUserTokens.EncryptedAccessToken	This field is used internally by Application Object Server (AOS). It can be ignored.
SysOAuthUserTokens.EncryptedRefreshToken	This field is used internally by AOS. It can be ignored.

Community tools

Are you looking for more tools to help you import backup files into your developer environments? Here are some other sources of information:

- D365fo.Tools provides many valuable tools that have been created by the community.
- Community-provided open source projects on GitHub.

Known issues

The export database is in a "Preparation failed" state

If the automation from LCS times out, the state of the export database is changed to **Preparation failed**. The export operation to export to the Asset library is still running in SQL Database. To resolve this issue, you can use the **Resume** button to reconnect the process with SQL Database. The process should then be successfully completed.

The export database takes a very long time

The Azure SQL team recently announced that the Import/Export application programming interface (API) that LCS uses has variable execution times for any database that is over 200 GB in size. If you encounter this issue, you can either connect your DevTest environment directly to the UAT database or follow the legacy documentation. We don't recommend that you export databases for backup purposes, because the point-in-time restore functionality is available and included with your environment.

The Lifecycle Services team is working directly with the Azure SQL team to increase the performance of the Import/Export API and will make improvements in upcoming releases of LCS.

I can't download Management Studio installation files

When you try to download the Microsoft SQL Server Management Studio installer, you might receive the following error message:

> Your current security settings do not allow this file to be downloaded.

To work around this issue, follow these steps to enable file downloads.

1. In your web browser, open **Internet options**.
2. On the **Security** tab, select the **Internet** zone, and then select **Custom level**.
3. Scroll to **Downloads**, and then, under **File download**, select the **Enable** option.

Database synchronization fails

When you sync the database against the newly imported database from Microsoft Visual Studio, the synchronization might fail, and you might receive the following error message:

> Failed to open SQL connection syncengine.exe exited with code -1.

In this case, the following message is also logged under event ID 140 in the Windows application log:

> Object Server Database Synchronizer: The internal system table version number stored in the database is higher than the version supported by the kernel (141/138). Use a newer Microsoft Dynamics kernel, or start Microsoft Dynamics using the -REPAIR command line parameter to enforce synchronization.

This issue can occur when the platform build number of the current environment is lower than the platform build number of the source environment. To resolve the issue, follow one of these steps, depending on your circumstances:

- Use the **Updates** tiles on the environment page in LCS to upgrade the platform in the current environment so that it matches the platform in the source environment.
- Run the following query to adjust the expected version in the database.

```
UPDATE SQLSYSTEMVARIABLES

SET VALUE = 138

WHERE PARM = 'SYSTABVERSION'
```

> **NOTE**
>
> The value **138** in this query is taken from the event log message, where version 138 was expected in this particular environment.

Performance

The following guidelines can help you achieve optimal performance:

- Always import the .bacpac file locally on the computer that runs the SQL Server instance. Don't import it from Management Studio on a remote machine.
- In a one-box environment that is hosted in Azure, put the .bacpac file on drive D when you import it. (A one-box environment is also known as a Tier 1 environment.) For more information about the temporary drive on Azure virtual machines (VMs), see the Understanding the temporary drive on Windows Azure Virtual Machines blog post.
- Grant the account that runs the SQL Server Windows service Instance File Initialization rights. In this way, you can help improve the speed of the import process and the speed of a restore from a *.bak file. For a developer environment, you can easily make sure that the account that runs the SQL Server service has these rights by setting SQL Server to run as the axlocaladmin account.

Golden configuration promotion

2/18/2021 • 11 minutes to read • Edit Online

Database movement operations are a suite of self-service actions that can be used as part of data application lifecycle management (DataALM). "Golden configuration" refers to a common practice among customers and partners in the Microsoft Dynamics ecosystem, where a developer environment is used as a configuration store. In this way, implementation projects can store finalized global and company-specific settings in a database that can later become a baseline for Conference Room Pilots, mock go-lives, and go-lives. This tutorial shows how to prepare a golden configuration database and hydrate a target user acceptance testing (UAT) environment.

In this tutorial, you will learn how to:

- Prepare the golden configuration database for Microsoft Azure SQL Database.
- Run the import to the target UAT environment.
- Copy the UAT environment into a production environment.

As an example of this scenario, a customer who hasn't gone live is instead preparing for a Conference Room Pilot, mock go-live, or go-live. This scenario supports promoting a baseline golden database from a developer environment to a UAT environment and eventually to production.

Prerequisites

To complete this tutorial, you must have a developer environment that is deployed with a database that is curated as a golden configuration database. You must also have at least one standard UAT environment deployed and, optionally, a production environment.

The developer environment must run the same *application version* as the target UAT environment. In addition, the *platform version* of the developer environment must be earlier than or the same as the platform version in the target UAT environment.

Before you begin

Supported SQL Server collation

The only supported collation databases in the cloud is **SQL_Latin1_General_CP1_CI_AS**. Make sure that your Microsoft SQL Server and database collations in development environments are set to this value. Also make sure that any configuration environments that are published to sandbox have this collation.

Document the values of encrypted fields

Encrypted and environment-specific values can't be imported into a new environment. After you've completed the import, you must reenter some data from your source environment in your target environment.

Because of a technical limitation that is related to the certificate that is used for data encryption, values that are stored in encrypted fields in a database will be unreadable after that database is imported into a new environment. Therefore, after an import, you must manually delete and reenter values that are stored in encrypted fields. New values that are entered in encrypted fields after an import will be readable. The following fields are affected. The field names are given in *Table.Field* format.

FIELD NAME	WHERE TO SET THE VALUE

FIELD NAME	WHERE TO SET THE VALUE
CreditCardAccountSetup.SecureMerchantProperties	Select **Accounts receivable** > **Payments setup** > **Payment services**.
ExchangeRateProviderConfigurationDetails.Value	Select **General ledger** > **Currencies** > **Configure exchange rate providers**.
FiscalEstablishment_BR.ConsumerEFDocCsc	Select **Organization administration** > **Fiscal establishments** > **Fiscal establishments**.
FiscalEstablishmentStaging.CSC	This field is used by the Data Import/Export Framework (DIXF).
HcmPersonIdentificationNumber.PersonIdentificationNumber	Select **Human resources** > **Workers** > **Workers**. On the **Worker** tab, in the **Personal information** group, select **Identification numbers**.
HcmWorkerActionHire.PersonIdentificationNumber	This field has been obsolete since Microsoft Dynamics AX 7.0 (February 2016). It previously appeared on the **All worker actions** page (**Human resources** > **Workers** > **Actions** > **All worker actions**).
SysEmailSMPTPassword.Password	Select **System administration** > **Email** > **Email parameters**.
SysOAuthUserTokens.EncryptedAccessToken	This field is used internally by Application Object Server (AOS). It can be ignored.
SysOAuthUserTokens.EncryptedRefreshToken	This field is used internally by AOS. It can be ignored.

If you're running Commerce components, document encrypted and environment-specific values

The values on the following pages are either environment-specific or encrypted in the database. Therefore, all the imported values will be incorrect.

- Payments services (**Accounts receivable** > **Payments setup** > **Payments services**)
- Hardware profiles (**Retail and commerce** > **Channel setup** > **POS setup** > **POS profiles** > **Hardware profiles**)

Create a copy of the source database

Back up the source database using SSMS. Right-click the source database, and select **Tasks** > **Backup option**. After this is completed, right-click the **Databases** folder in the SSMS navigation window, and select **Restore database**. Choose the backup that you just made, but give the target database a new name such as AXDB_CopyForExport.

Prepare the database

Run the following script against the AxDB_CopyForExport database that you created in the previous section. This script makes the following changes:

- Set the **SysGlobalConfiguration** flag to inform the application that the database is Azure-based.
- Remove a reference to tempDB in the XU_DisableEnableNonClusteredIndexes procedure. References to tempDB aren't allowed in an Azure SQL database. The database synchronization process will re-create the reference later.

- Drop users, because Microsoft Windows users are forbidden in Azure SQL databases. Other users must be re-created later, so that they're correctly linked to the appropriate sign-in on the target server.
- Clear encrypted hardware profile merchant properties.

A successful export and import of the database requires all these changes.

```
update sysglobalconfiguration
set value = 'SQLAZURE'
where name = 'BACKENDDB'

update sysglobalconfiguration
set value = 1
where name = 'TEMPTABLEINAXDB'

drop procedure if exists XU_DisableEnableNonClusteredIndexes
drop procedure if exists SP_ConfigureTablesForChangeTracking
drop procedure if exists SP_ConfigureTablesForChangeTracking_V2
drop schema [NT AUTHORITY\NETWORK SERVICE]
drop user [NT AUTHORITY\NETWORK SERVICE]
drop user axdbadmin
drop user axdeployuser
drop user axmrruntimeuser
drop user axretaildatasyncuser
drop user axretailruntimeuser
drop user axdeployextuser

--Tidy up the batch server config from the previous environment
DELETE FROM SYSSERVERCONFIG

--Tidy up server sessions from the previous environment
DELETE FROM SYSSERVERSESSIONS

--Tidy up printers from the previous environment
DELETE FROM SYSCORPNETPRINTERS

--Tidy up client sessions from the previous environment
DELETE FROM SYSCLIENTSESSIONS

--Tidy up batch sessions from the previous environment
DELETE FROM BATCHSERVERCONFIG

--Tidy up batch server to batch group relation table
DELETE FROM BATCHSERVERGROUP

-- Clear encrypted hardware profile merchant properties
update dbo.RETAILHARDWAREPROFILE set SECUREMERCHANTPROPERTIES = null where SECUREMERCHANTPROPERTIES is not
null
```

Export the database from SQL Server

Open a **Command Prompt** window, and run the following commands.

> **IMPORTANT**
>
> The 140 folder reflects the current version. You must use the version that is available in your sandbox environment. Therefore, you might have to install the latest version of Microsoft SQL Server Management Studio in your development environment.

```
cd C:\Program Files (x86)\Microsoft SQL Server\140\DAC\bin\
SqlPackage.exe /a:export /ssn:localhost /sdn:<database to export> /tf:D:\Exportedbacpac\my.bacpac
/p:CommandTimeout=1200 /p:VerifyFullTextDocumentTypesSupported=false
```

Here is an explanation of the parameters:

- **ssn (source server name)** – The name of the SQL Server to export from. For the purposes of this topic, the name should always be **localhost**.
- **sdn (source database name)** – The name of the database to export.
- **tf (target file)** – The path and name of the file to export to. The folder should already exist, but the export process will create the file.

Import the database

Upload the .bacpac file that was created in the previous step to the **Database backup** section in your LCS project's Asset Library. Then begin the import. The target UAT environment's databases will be overwritten by the golden configuration database.

> **NOTE**
> Certain elements are not copied as part of the import database step. In the golden configuration scenario, this would impact things such as Email Addresses and Print Management setup. These settings ideally should be populated as part of the master data migration in the steps below, and should not be part of the golden configuration database.

To import a database that is prepared from a developer environment to a standard user acceptance test (UAT), or a database previously exported from a UAT environment, follow the steps outlined below:

1. Go to your target sandbox **Environment Details** page, and select the **Maintain** > **Move database** menu option.
2. Select **Import database** and choose your source database backup (.bacpac format) file from the Asset Library.
3. Note the warnings. Review the list of data elements that are cleaned up from the backup file.
4. The import operation will begin immediately.

To import a database to a developer environment after you've downloaded a database backup (.bacpac) file, you can begin the manual import operation on your Tier 1 environment. When you import the database, we recommend that you follow these guidelines:

- Keep a copy of the existing AxDB database, so that you can revert to it later if needed.
- Import the new database under a new name, such as **AxDB_fromProd**.

To ensure the best performance, copy the *.bacpac file to the local computer that you're importing from. Download sqlpackage .NET Core for Windows from Get sqlpackage .NET Core for Windows. Open a **Command Prompt** window, and run the following commands from the sqlpackage .NET Core folder.

```
SqlPackage.exe /a:import /sf:D:\Exportedbacpac\my.bacpac /tsn:localhost /tdn:<target database name>
/p:CommandTimeout=1200
```

Here is an explanation of the parameters:

- **tsn (target server name)** – The name of the Microsoft SQL Server instance to import into.
- **tdn (target database name)** – The name of the database to import into. The database should **not** already

exist.

- **sf (source file)** – The path and name of the file to import from.

> **NOTE**
> During import, the user name and password aren't required. By default, SQL Server uses Microsoft Windows authentication for the user who is currently signed in.

For information about how to complete the manual import operations into a Tier 1 environment, see Import the database.

Perform master data migration

Now that the UAT environment is hydrated with the golden configuration, you can begin to migrate master data. You can do this data migration by using data entities. We recommend that you complete your data migration activities before you copy the UAT environment to production, because you will have access to the database in the UAT environment for troubleshooting.

> **IMPORTANT**
> Document attachments are not copied from UAT to Production in the next step. If your go live requires attachments, you will want to import those in the Production environment directly.

Copy the sandbox database to production

When you're ready to do a mock go-live or actual go-live, you can copy the UAT environment to production. This process is often referred to as *cutover*. We recommend that you do a cutover more than one time before your actual go-live. In this way, you can get detailed time estimates for each step of the process.

Determine the **Environment type** of your production environment and follow the relevant steps accordingly.

Microsoft-managed

1. In LCS, on the project home page, select **Service requests**.
2. On the **Service requests** page, select **Add**, and then select **Sandbox to Production**.
3. In the **Sandbox to Production** dialog box, follow these steps:
    a. In the **Source environment name** field, select the sandbox environment to copy the database from.
    b. Set the **Preferred downtime start date** and **Preferred downtime end date** fields. The end date must be at least four hours after the start date. To help ensure that resources are available to run the request, it's recommended that you submit your request at least 24 hours before your preferred downtime window.
    c. Select the check boxes at the bottom to agree to the terms.

Self-service

1. In LCS, open the **Full details** for the production environment to load the **Environment page**.
2. In the **Maintain** menu, select **Move database**.
3. In the options of operations select **Refresh database**.
4. In the **Source environment** chose the sandbox where your golden configuration is. Note the important instructions found on the Refresh database page for this kind of operation.
5. Select the check box to confirm that you understand this operation will overwrite the production database. The operation starts immediately after submitting the request.

> **IMPORTANT**
> Every database refresh will create a new database that will reset the **Point-in-time-restore** chain of restore points.

Reconfigure environment specific settings

After the refresh is completed, use the **Sign off** button in LCS to close out of the operation. You then can start to configure the environment-specific settings.

First, sign in to the environment by using the admin account that can be found on the **Environment details** page in LCS. Here are some typical areas of reconfiguration. You might require additional reconfiguration, based on your setup and the independent software vendor (ISV) solutions that are installed:

- **System administration** > **Setup** > **Batch groups:** Add the various AOS instances to the batch server groups that you require.
- **System administration** > **Setup** > **Entity Store:** Update the various entities that you require for Microsoft Power BI reporting.
- **System administration** > **Setup** > **System parameters:** Reconnect the environment to the LCS Help configuration for task guides.
- **System administration** > **Setup** > **Email** > **Email parameters:** Enter the Simple Mail Transfer Protocol (SMTP) settings if you use email in your UAT environment.
- **System administration** > **Setup** > **Integration configuration** > **Azure storage account connection string:** Enter the storage account string.
- **System administration** > **Setup** > **System Parameters:** On the **Document connections** tab enter the Azure Key and Application Secret.
- **System administration** > **Inquiries** > **Batch jobs:** Select the jobs that you want to run in your UAT environment, and update the status to **Waiting**.

> **NOTE**
> As a best practice, all mission-critical batch jobs that will run with recurrence should be created and run by the admin account. The admin should be a generic user such as `erp@customer.com`. It should not be linked to a specific employee's Azure Active Directory (Azure AD) account, because that account might be disabled later if the employee leaves the company.

Open the environment to users

When the system is configured as you require, you can enable selected users to access the environment. By default, all users except the admin and Microsoft service accounts are disabled.

Go to **System administration** > **Users** > **Users**, and enable the users that should have access to the Production environment. If many users must be enabled, you can complete this task more quickly by using the Microsoft Excel Add-In.

Community tools

Are you looking for more tools to help you prepare backup files from your developer environments? Here are some other sources of information:

- D365fo.Tools provides many valuable tools that are created by the community.
- Community-provided open source projects on GitHub.

NOTE

Can you tell us about your documentation language preferences? Take a short survey.

The survey will take about seven minutes. No personal data is collected (privacy statement).

Destructive testing

2/18/2021 • 4 minutes to read • Edit Online

Database movement operations are a suite of self-service actions that can be used as part of data application lifecycle management (DataALM). In some situations, destructive testing must be done on an environment. In this context, destructive testing means that the environment is rendered no longer useful for continued testing. Destructive testing is typical in an implementation lifecycle during Conference Room Pilots. This tutorial shows how to use database movement operations to facilitate destructive testing.

In this tutorial, you will learn two approaches:

- Use a database backup asset.
- Use point-in-time restore.

As an example of this scenario, a customer wants to do a Conference Room Pilot and wants to start with an environment that has no transactions (that is, no sales orders or purchase orders). The customer will be traveling from physical warehouse to physical warehouse throughout the geographic region to do the same pilot, and wants the environment to be "reset" before each pilot is done.

Prerequisites

To complete this tutorial, you must have a standard user acceptance testing (UAT) environment deployed in your project.

Using a database backup

If you've prepared a database backup (.bacpac) file that is already at the starting point for the test, the easiest approach is to upload the backup file to the **Database backup** section in your LCS project's Asset Library. It can then be imported to your target environment as described here.

To import a database that is prepared from a developer environment to a standard user acceptance test (UAT), or a database previously exported from a UAT environment, follow the steps outlined below:

1. Go to your target sandbox **Environment Details** page, and select the **Maintain** > **Move database** menu option.
2. Select **Import database** and choose your source database backup (.bacpac format) file from the Asset Library.
3. Note the warnings. Review the list of data elements that are cleaned up from the backup file.
4. The import operation will begin immediately.

To import a database to a developer environment after you've downloaded a database backup (.bacpac) file, you can begin the manual import operation on your Tier 1 environment. When you import the database, we recommend that you follow these guidelines:

- Keep a copy of the existing AxDB database, so that you can revert to it later if needed.
- Import the new database under a new name, such as **AxDB_fromProd**.

To ensure the best performance, copy the *.bacpac file to the local computer that you're importing from. Download sqlpackage .NET Core for Windows from Get sqlpackage .NET Core for Windows. Open a **Command Prompt** window, and run the following commands from the sqlpackage .NET Core folder.

```
SqlPackage.exe /a:import /sf:D:\Exportedbacpac\my.bacpac /tsn:localhost /tdn:<target database name>
/p:CommandTimeout=1200
```

Here is an explanation of the parameters:

- **tsn (target server name)** – The name of the Microsoft SQL Server instance to import into.
- **tdn (target database name)** – The name of the database to import into. The database should **not** already exist.
- **sf (source file)** – The path and name of the file to import from.

> **NOTE**
> During import, the user name and password aren't required. By default, SQL Server uses Microsoft Windows authentication for the user who is currently signed in.

For information about how to complete the manual import operations into a Tier 1 environment, see Import the database.

Database backup pros and cons

The advantage of using backup file assets is that you can keep importing the same file to get back to the starting point for the test.

The disadvantage is that if many configurations (for example, batch jobs) must be set after the import is completed but before users can begin, more effort will be required before each destructive testing session.

Using point-in-time restore

If you didn't start with a database backup (.bacpac) file but instead have the UAT environment in a known good state, you can just record the date and time in your time zone. You can then begin the destructive testing. Then, when the testing is completed, you can restore the environment to the previous time by using the following steps.

To restore the database of a standard user acceptance test (UAT) environment to a previous point-in-time, follow the steps outlined below:

1. Go to your target sandbox **Environment Details** page, and select the **Maintain** > **Move database** menu option.
2. Select the **Point-in-time restore** option and choose a point-in-time.
3. Note the warnings. Review the list of data elements that are not copied over from the previous point-in-time.
4. The restore operation will begin immediately.

Point-in-time restore pros and cons

The advantage of using point-in-time-restore is that you can avoid dealing with database backup (.bacpac) files and can reduce the time between destructive testing sessions.

The disadvantage is that, because of current limitations of point-in-time restore, you must record a new restore date and time in your time zone after the restore is completed. Because point-in-time restore always creates a new database, the original date and time that were used won't be available as a restore point on the new database.

NOTE

Can you tell us about your documentation language preferences? Take a short survey.

The survey will take about seven minutes. No personal data is collected (privacy statement).

Database Movement API

2/18/2021 • 2 minutes to read • Edit Online

The Database Movement application programming interface (API) is a RESTful endpoint that is used to manage the data lifecycle of Microsoft Dynamics 365 environments. It provides a versioned set of capabilities that you can currently use to copy databases between environments, and to list and download database backups. More supported actions will be added in later releases.

What is supported by the Database Movement API?

The Database Movement API exposes RESTful endpoints for the following Dynamics 365 services:

- Dynamics 365 Finance
- Dynamics 365 Supply Chain Management
- Dynamics 365 Commerce

Next steps

- Learn how to set up authentication.
- Review the API reference.

Versioning and support

2/18/2021 • 2 minutes to read • Edit Online

This topic provides an overview of the versioning and breaking change policies for the Database Movement application programming interface (API).

Support and deprecation information

As new versions of the REST APIs are released, earlier versions will be retired. Microsoft will declare a version deprecated at least six months before it retires an API endpoint.

By incrementing the version number of the API (for example, from v1 to v2), Microsoft announces that the lowest version (in this example, v1) is immediately deprecated and will no longer be supported six months after the announcement. However, Microsoft might make exceptions to this policy for service health and security issues.

When an API is marked as deprecated, a date value will be entered in the **VersionEOL** (Version end of life) field. Therefore, you can proactively monitor this field and plan for upcoming changes.

Compatible and breaking changes

Microsoft will provide details of API changes in the private preview group. If the changes are non-breaking in nature, the API version number will remain the same. If the changes are breaking in nature, Microsoft will increment the API version number.

Here are some examples of breaking changes:

- The URL or fundamental request/response is changed.
- A declared property is removed or renamed, or its type is changed.
- The API or API parameters are removed or renamed.
- A required request parameter is added.

Here are some examples of non-breaking changes:

- Properties are added that are nullable or have a default value.
- A member is added to an enumeration.
- Paging is introduced to existing collections.
- Error codes are changed.
- The order of properties in requests or responses is changed.

Example of VersionEOL in a response contract

The following example shows a response contract in JavaScript Object Notation (JSON) format. All response contracts contain the **VersionEOL** property of which has a default value of DateMax() from the Microsoft .NET Framework. Your applications can monitor the value of this field on responses from Microsoft to get an immediate alert when Microsoft has deprecated a specific endpoint or a whole API version.

```
{
    "IsSuccess": true,
    "OperationActivityId": "55eb4327-9346-4c7b-82bd-fe8ef15112c6",
    "ErrorMessage": null,
    "VersionEOL": "9999-12-31T23:59:59.9999999"
}
```

NOTE

Can you tell us about your documentation language preferences? Take a short survey.

The survey will take about seven minutes. No personal data is collected (privacy statement).

Database movement API - Authentication

2/18/2021 • 3 minutes to read • Edit Online

This topic provides overview information about how to authenticate with the Database Movement application programming interface (API).

Fundamentals

To call the Database Movement API, your application must acquire an access token from the Microsoft identity platform. The access token contains information about your application and the permission that it has to call resources in Microsoft Dynamics Lifecycle Services (LCS).

Access token

Access tokens that are issued by the Microsoft identity platform are base64–encoded JavaScript Object Notation (JSON) Web Tokens (JWTs). They contain information (claims) that the Database Movement API and other web APIs that are secured by the Microsoft identity platform use to validate the caller and make sure that the caller has the correct permissions to perform the operation that they are requesting. During calls, you can treat access tokens as opaque. You should always transmit access tokens over a secure channel, such as Transport Layer Security (TLS) and Hypertext Transfer Protocol Secure (HTTPS).

Here is an example of an access token that is issued by the Microsoft identity platform.

```
EwAoA8l6BAAU7p9QDpi/D7xJLwsTgCg3TskyTaQAAXu71AU9f4aS4rOK5xoO/SU5HZKSXtCsDe0Pj7uSc5Ug008qTI+a9M1tBeKoTs7tHzhJ
NSKgk7pm5e8d3oGWXX5shyOG3cKSqgfwuNDnmmPDNDivwmi9kmKqWIC9OQRf8InpYXH7NdUYNwN+jljffvNTewdZz42VPrvqoMH7hSxiG7A1
h8leOv4F3Ek/oeJX6U8nnL9nJ5pHLVuPWD0aNnTPTJD8Y4oQTp5zLhDIIfaJCaGcQperULVF7K6yX8MhHxIBwek418rKIp11om0SWBXOYSGO
M0rNNN59qNiKwLNK+MPUf7ObcRBN5I5vg8jB7IMoz66jrNmT2uiWCyI8MmYDZgAACPoaZ9REyqke+AE1/x1ZX0w7OamUexKF8YGZiw+cDpT/
BP1GsONnwI4a8M7HsBtDgZPRd6/Hfqlq3HE2xLuhYX8bAc1MUr0gP9KuH6HDQNlIV4KaRZWxyRo1wmKHOF5G5wTHrtxg8tnXylMc1PKOtaXI
U4JJZ1l4x/7FwhPmg9M86PBPWr5zwUj2CVXC7wWlL/6M89Mlh8yXESMO3AIuAmEMKjqauPrgi9hAdI2oqnLZWCRL9gcHBida1y0DTXQhcwMv
1ORrk65VFHtVgYAegrxu3NDoJiDyVaPZxDwTYRGjPII3va8GALAMVy5xou2ikzRvJjW7Gm3XoaqJCTCExN4m5i/Dqc81Gr4uT7OaeypYTUjn
wCh7aMhsOTDJehefzjXhlkn//2eik+NivKx/BTJBEdT6MR97Wh/ns/VcK7QTmbjwbU2cwLngT7Ylq+uzhx54R9JMaSLhnw+/nIrcVkG77Hi3
neShKeZmnl5DC9PuwIbtNvVge3Q+V0ws2zsL3z7ndz4tTMYFdvR/XbrnbEErTDLWrV6Lc3JHQMs0bYUyTBg5dThwCiuZ1evaT6BlMMLuSCVx

```

To call the Database Movement API, you attach the access token as a bearer token to the authorization header in your HTTP request. Here is an example.

```
HTTP/1.1
Authorization: Bearer EwAoA8l6BAAU ... 7PqHGsykYj7A0XqHCjbKKgWSkcAg==
Host: lcsapi.lcs.dynamics.com
GET https://lcsapi.lcs.dynamics.com/databasemovement/v1/databases
```

Register a new application by using the Azure portal

1. Sign in to the Microsoft Azure portal by using a work or school account, or a personal Microsoft account.
2. If your account gives you access to more than one tenant, select your account in the upper-right corner, and set your portal session to the Azure Active Directory (Azure AD) tenant that you want.
3. In the left pane, select the **Azure Active Directory** service, and then select **App registrations > New registration**.
4. When the **Register an application** page appears, enter your application's registration information:

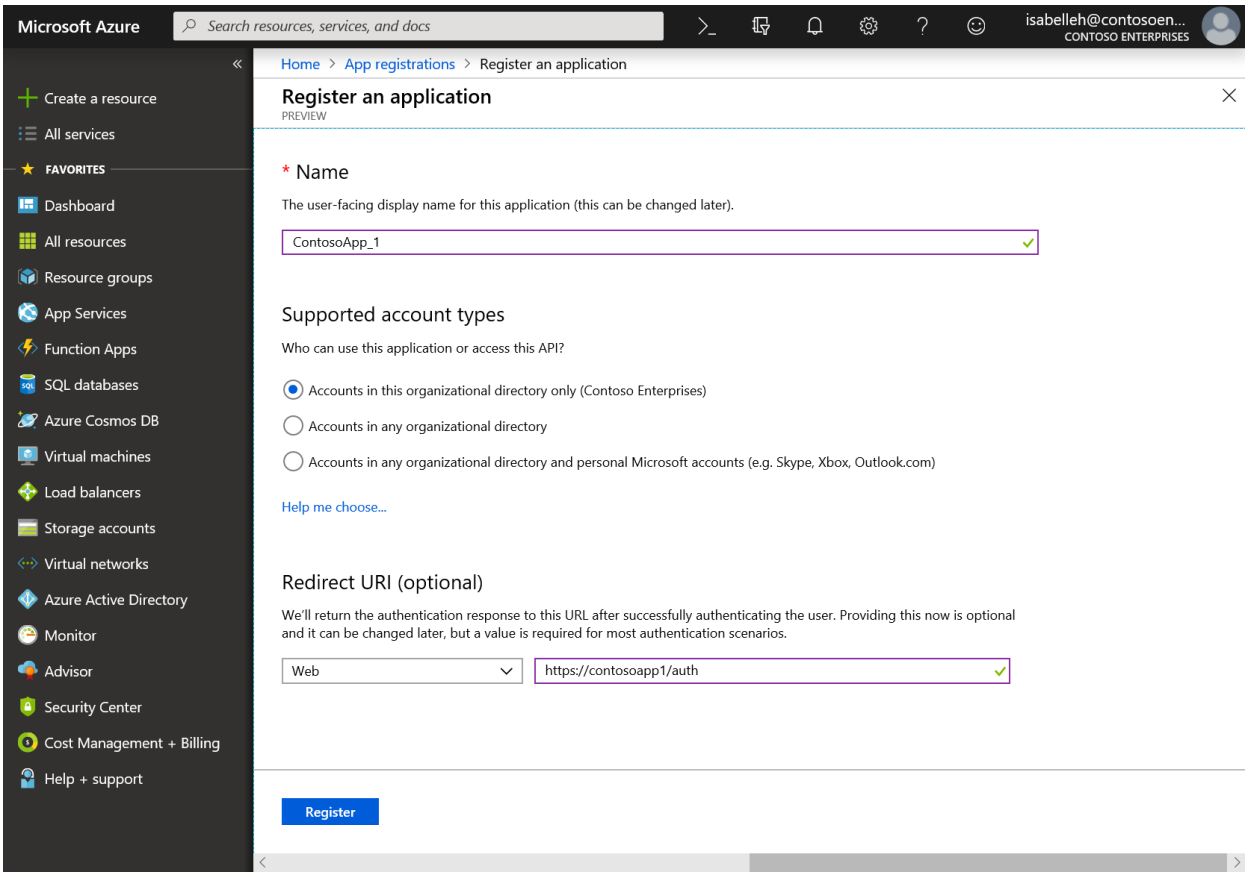
- **Name** – Enter a meaningful application name that will be shown to users of the app.
- **Supported account types** – Select the types of accounts that your app should support.

SUPPORTED ACCOUNT TYPES	DESCRIPTION
Accounts in this organizational directory only	Select this option if you're building a line-of-business app. This option isn't available unless you're registering the app in a directory. This option is mapped to **Azure AD only single-tenant**. This option is the default option unless you're registering the app outside a directory. In that case, the default option is **Azure AD multi-tenant and personal Microsoft accounts**.
Accounts in any organizational directory	Select this option to target all business and educational customers. This option is mapped to **Azure AD only multi-tenant**. If you registered the app as **Azure AD only single-tenant**, you can use the **Authentication** blade to update it to **Azure AD only multi-tenant** and then back to **Azure AD only single-tenant**.
Accounts in any organizational directory and personal Microsoft accounts	Select this option to target the widest set of customers. This option is mapped to **Azure AD multi-tenant and personal Microsoft accounts**. If you registered the app as **Azure AD multi-tenant and personal Microsoft accounts**, you can't change this setting in the user interface (UI). Instead, you must use the application manifest editor to change the supported account types.

- **Redirect URI (optional)** – Select the type of app that you're building: **Web** or **Public client (mobile & desktop)**. Then enter the redirect URI (or reply URL) for the app.
  - For web apps, provide the base URL of the app. For example, `http://localhost:31544` might be the URL for a web app that runs on your local machine. Users then use this URL to sign in to a web client app.
  - For public client apps, provide the URI that Azure AD uses to return token responses. Enter a value that is specific to your app, such as `myapp://auth`.

  To see specific examples for web apps or native apps, see the quick start guides from Azure AD.

5. Under **API permissions**, select **Add a permission**. Then, on the **APIs my organization uses** tab, search for **Dynamics Lifecycle services**, and add the **user_impersonation** permission to your app.
6. Select **Register**.



Azure AD assigns a unique application ID (client ID) to your app, and you're taken to the **Overview** page for your app. To add more capabilities to your app, you can select other configuration options, such as options for branding, and for certificates and secrets.

Throttling

2/18/2021 • 2 minutes to read • Edit Online

This topic provides an overview of throttling for the Database Movement application programming interface (API).

Rate limits

To help maintain the reliability of the service and reduce costs, throttling will be turned on for the Database Movement API. Throttling helps protect against malicious and excessive use of the RESTful endpoints. Database movement operations are some of the most time-consuming and CPU-intensive tasks that can be run from Microsoft Dynamics Lifecycle Services (LCS), and Microsoft might change the current call limits later.

Current limits

Currently, the Database Movement API has a global call limit of **three executions per 24-hour timeframe** for all actions that trigger a new operation in LCS. These operations include database refresh operations.

If you exceed the limit, you won't be able to start a new operation and will receive an error that resembles the following example.

```
{
    "IsSuccess": false,
    "OperationActivityId": "55eb4327-9346-4c7b-82bd-fe8ef15112c6",
    "ErrorMessage": "Maximum allowed API operations are 3 from 2019-09-30T04:01:01.9999999",
    "VersionEOL": "9999-12-31T23:59:59.9999999"
}
```

NOTE

Can you tell us about your documentation language preferences? Take a short survey.

The survey will take about seven minutes. No personal data is collected (privacy statement).

API v1 reference overview

2/18/2021 • 2 minutes to read • Edit Online

Welcome to the Database Movement application programming interfaces (API) reference for the version 1 (v1) endpoint. Use the table of contents to the left to view details of each endpoint that is available.

NOTE

Can you tell us about your documentation language preferences? Take a short survey.

The survey will take about seven minutes. No personal data is collected (privacy statement).

List database backups

2/18/2021 • 2 minutes to read • Edit Online

You can retrieve a list of database backups from the Project asset library.

Permissions

One of the following permissions is required to call this application programming interface (API). For more information about permissions and how to select them, see Authentication.

PERMISSION TYPE	PERMISSIONS (FROM LEAST PRIVILEGED TO MOST PRIVILEGED)
Delegated (work or school account)	user_impersonation

HTTP request

```
GET /databasemovement/v1/databases/project/{projectId}
```

Request headers

HEADER	VALUE
Authorization	Bearer {token} (required)
'x-ms-version'	'2017-09-15' (required)
Content-Type	application/json

Request body

Don't supply a request body for this method.

Response

The response is always a **200 OK** response, unless you aren't correctly authenticated. Be sure to use the **IsSuccess** property to evaluate the success or failure of the action.

Example

```
GET /databasemovement/v1/databases/project/12345
```

```
{

    "DatabaseAssets": [
        {
            "Id": "4a2c52d4-49ca-4606-94a9-92b3a6b42985",
            "ProjectId": 12345,
            "OrganizationId": 1,
            "Name": "LanesBackupRecord",
            "FileName": "RandomFile.bacpac",
            "FileDescription": "",
            "FileLocation": "https://scrubbed.blob.core.windows.net/product-ax7productname/e6244b15-5112-
4d1d-a422-49c63496ab6d/AX7ProductName-12-17-83c6e642-676a-4048-b413-6e284f5d1f55-e6244b15-5112-4d1d-a422-
49c63496ab6d?sv=2015-12-11&sr=b&sig=rO3zmAZ3zM6s%2FV%2BeihBA2LMVvqMsxbtsnbauvd8keYo%3D&se=2019-09-
28T15%3A18%3A05Z&sp=r",
            "ModifiedDateTime": "2019-09-27T15:17:35.867",
            "CreatedDateTime": "2019-09-27T15:17:35.867",
            "CreatedByName": null,
            "ModifiedByName": null
        }
    ],
    "IsSuccess": true,
    "OperationActivityId": "55eb4327-9346-4c7b-82bd-fe8ef15112c6",
    "ErrorMessage": null,
    "VersionEOL": "9999-12-31T23:59:59.9999999"
}
```

Create a database refresh

2/18/2021 • 2 minutes to read • Edit Online

You can create a database refresh between two environments. Note that the same validation rules from the details page in Microsoft Dynamics Lifecycle Services (LCS) apply to the application programming interface (API).

Permissions

One of the following permissions is required to call this API. For more information about permissions and how to select them, see Authentication.

PERMISSION TYPE	PERMISSIONS (FROM LEAST PRIVILEGED TO MOST PRIVILEGED)
Delegated (work or school account)	user_impersonation

HTTP request

```
POST
/databasemovement/v1/refresh/project/{projectId}/source/{sourceEnvironmentId}/target/{targetEnvironmentId}
```

Request headers

HEADER	VALUE
Authorization	Bearer {token} (required)
'x-ms-version'	'2017-09-15' (required)
Content-Type	application/json

Request body

Don't supply a request body for this method.

Response

The response is always a **200 OK** response, unless you aren't correctly authenticated. Be sure to use the **IsSuccess** property to evaluate the success or failure of the action.

Example

```
POST /databasemovement/v1/refresh/project/12345/source/5362377c-bc37-4f92-b30e-fe0c1e664cc0/target/6a90b45f-1764-4077-b924-3f4671540237
```

```
{
    "IsSuccess": true,
    "OperationActivityId": "55eb4327-9346-4c7b-82bd-fe8ef15112c6",
    "ErrorMessage": null,
    "VersionEOL": "9999-12-31T23:59:59.9999999"
}
```

Create a database export

2/18/2021 • 2 minutes to read • Edit Online

You can create a database export from a sandbox environment to the project's asset library. Note that the same validation rules from the details page in Microsoft Dynamics Lifecycle Services (LCS) apply to the application programming interface (API).

Permissions

One of the following permissions is required to call this API. For more information about permissions and how to select them, see Authentication.

PERMISSION TYPE	PERMISSIONS (FROM LEAST PRIVILEGED TO MOST PRIVILEGED)
Delegated (work or school account)	user_impersonation

HTTP request

```
POST /databasemovement/v1/export/project/{projectId}/environment/{environmentId}/backupName/{backupName}
```

Request headers

HEADER	VALUE
Authorization	Bearer {token} (required)
Content-Type	application/json

Request body

Don't supply a request body for this method.

Response

The response is always a **200 OK** response, unless you aren't correctly authenticated. Be sure to use the **IsSuccess** property to evaluate the success or failure of the action.

Example

```
POST /databasemovement/v1/export/project/12345/environment/5362377c-bc37-4f92-b30e-
fe0c1e664cc0/backupName/TestBackupViaAPI
```

```
{
    "IsSuccess": true,
    "OperationActivityId": "55eb4327-9346-4c7b-82bd-fe8ef15112c6",
    "ErrorMessage": null,
    "VersionEOL": "9999-12-31T23:59:59.9999999"
}
```

Get status

2/18/2021 • 2 minutes to read • Edit Online

You can get the status of an ongoing operation.

Permissions

One of the following permissions is required to call this application programming interface (API). For more information about permissions and how to select them, see Authentication.

PERMISSION TYPE	PERMISSIONS (FROM LEAST PRIVILEGED TO MOST PRIVILEGED)
Delegated (work or school account)	user_impersonation

HTTP request

```
GET
/databasemovement/v1/fetchstatus/project/{projectId}/environment/{environmentId}/operationactivity/{operationactivityId}
```

Request headers

HEADER	VALUE
Authorization	Bearer {token} (required)
'x-ms-version'	'2017-09-15' (required)
Content-Type	application/json

Request body

Don't supply a request body for this method.

Response

The response is always a **200 OK** response, unless you aren't correctly authenticated. Be sure to use the **IsSuccess** property to evaluate the success or failure of the action.

Example

```
GET /databasemovement/v1/fetchstatus/project/12345/environment/5362377c-bc37-4f92-b30e-fe0c1e664cc0/operationactivity/55eb4327-9346-4c7b-82bd-fe8ef15112c6
```

```
{
    "IsSuccess": true,
    "OperationActivityId": "6a90b45f-1764-4077-b924-3f4671540237",
    "ErrorMessage": null,
    "VersionEOL": "9999-12-31T23:59:59.9999999",
    "ProjectId": 12345,
    "EnvironmentId": "5362377c-bc37-4f92-b30e-fe0c1e664cc0",
    "ActivityId": "55eb4327-9346-4c7b-82bd-fe8ef15112c6",
    "CompletionDate": null,
    "OperationStatus": "InProgress"
}
```

OperationStatus property

STATUS	DESCRIPTION
NotStarted	The action hasn't yet been started.
InProgress	The action is in progress.
Completed	The action was successfully completed.
Failed	The action was halted.
SignedOff	The action was successfully completed and signed off.
Aborted	The action was canceled without automated cleanup.
RollbackInProgress	Reversal of the action is in progress.
RollbackFailed	Reversal of the action was halted.
RollbackCompleted	Reversal of the action was successfully completed.

Start and stop environments

2/18/2021 • 2 minutes to read • Edit Online

You can start and stop environments through Microsoft Dynamics Lifecycle Services (LCS) via the Database Movement API. Using these APIs will ensure the LCS environment status is synced with the actual environment.

Note that the same validation rules from the details page in LCS apply to the API.

NOTE

- Only **Customer-managed** environments are supported. Self-service environments do not have the same concept of stop and start and are not supported by this API. Microsoft-managed environments are not supported.
- These APIs will trigger/invoke the operation. A successful response only indicates that the trigger was successful.
- For **stop**, non-success will be returned if the environment is already undergoing another operation or if the environment is already stopped.
- For **start**, non-success will be returned if the environment is already undergoing another operation but will return success if the environment is already started.

Permissions

One of the following permissions is required to call this API. For more information about permissions and how to select them, see Authentication.

PERMISSION TYPE	PERMISSIONS (FROM LEAST PRIVILEGED TO MOST PRIVILEGED)
Delegated (work or school account)	user_impersonation

HTTP request

Use the following POST method to send an HTTP request to stop or start an environment.

Stop an environment

```
POST /environment/v1/stop/project/{projectId}/environment/{environmentId}
```

Start an environment

```
POST /environment/v1/start/project/{projectId}/environment/{environmentId}
```

Request headers

Use the following header value in the HTTP request header.

HEADER	VALUE
Authorization	Bearer {token} (required)

HEADER	VALUE
'x-ms-version'	'2017-09-15' (required)
Content-Type	application/json

Request body

Don't supply a request body for this method.

Response

The response is always a **200 OK** response, unless you aren't correctly authenticated. Be sure to use the **IsSuccess** property to evaluate the success or failure of the action.

Example

Request to stop an environment

```
POST /environment/v1/stop/project/{projectId}/environment/{environmentId}
```

Successful response

```
{
    "IsSuccess": true,
    "OperationActivityId": "55eb4327-9346-4c7b-82bd-fe8ef15112c6",
    "ErrorMessage": null,
    "VersionEOL": "9999-12-31T23:59:59.9999999"
}
```

Demo data overview

2/18/2021 • 5 minutes to read • Edit Online

This topic provides an overview of the demo data that is available.

Demo data is the base data set that is released for implementation support and demonstration purposes. The current demo data set supports the following verticals:

- Commerce
- Distribution
- Service Industries
- Public Sector
- Discrete & Process Manufacturing

The demo data set supports 40 languages across 16 countries or regions. It also supports various implementation scenarios. The following table lists the legal entities that are included in the demo data set.

LEGAL ENTITY	DESCRIPTION
BRMF	Contoso Entertainment System Brazil
CNMF	Contoso Entertainment China
DAT	Default Company
DEMF	Contoso Entertainment System Germany
FRRT	Contoso Retail FR
FRSI	Contoso Consulting FR
GBSI	Contoso Consulting GB
GLCO	Contoso Group
GLMF	Contoso Entertainment System
GLRT	Contoso Retail
GLSI	Contoso Consulting
INMF	Contoso India
ITCO	Contoso Italy
JPMF	Contoso Entertainment Japan
MXMF	Contoso Entertainment System Mexico

LEGAL ENTITY	DESCRIPTION
MYMF	Contoso Entertainment System MYMF
RUMF	Contoso Entertainment System Russia
RURT	Contoso Retail RUS
US01	Contoso US01
USMF	Contoso Entertainment System USA
USP2	Contoso Orange Juice
USPI	Contoso Process Industry
USRT	Contoso Retail USA
USSI	Contoso Consulting USA

Embedded analytics

Demo data has been updated in five companies to provide better reports on the new embedded analytics within workspace. Filter the embedded analytics to the following legal entities for the improved report data:

LEGAL ENTITY	DESCRIPTION
DEMF	Contoso Entertainment System Germany
GLMF	Contoso Entertainment
USMF	Contoso Entertainment System USA
USRT	Contoso Retail USA
USSI	Contoso Consulting USA

Reports from the Cash overview Power BI content are displayed in the **Cash overview** and **Bank management** workspaces.

To view the Cash flow forecasting reports with data, you must first run the forecast calculation process using the **Calculate cash flow forecasts** function from the **Cash and bank management area**. This needs to be completed for each company included in the forecast. You then need to refresh the LedgerCovLiquidityMeasurement aggregate measure on the **Entity Store** page.

For demonstration purposes, you can add cash flow forecasting demo data using the **Generate data** page from the **Demo data** module. This script will insert data into the cash flow forecasting tables to quickly populate information necessary for reports.

The credit and collections analytics can be viewed on the **Manage customer credit and collections** workspace. To view the analytics you need to refresh the CustCollectionsBIMeasurements aggregate measure on the **Entity Store** page.

The vendor payments analytics can be viewed on the **Vendor payments** workspace. To view the analytics, you

need to refresh the VendPaymentBIMeasure aggregate measure on the **Entity Store** page.

The Purchase performance analytics can be viewed on the **Purchase spend analysis** page from the Procurement and sourcing module. To view the analytics, you need to refresh the Purchase cube aggregate measure on the **Entity Store** page.

The Sales and profitability analytics can be viewed on the **Sales and profitability performance** page from the Sales and marketing module. To view the analytics, you need to refresh the Sales cube aggregate measure on the **Entity Store** page.

The production performance analytics can be viewed on the **Production performance** page from the Production control module. To view the analytics, you need to refresh the Production cube aggregate measure on the **Entity Store** page.

For demonstration purposes, you can add production performance demo data using the **Generate data** page from the Demo data module. This script will generate production orders and with associated feedback journals to populate the production performance reports with data.

The warehouse performance analytics can be viewed on the **Warehouse performance** page from the Warehouse management module. To view the analytics, you need to refresh the Warehouse aggregate measure on the **Entity Store** page.

For demonstration purposes, you can add warehouse performance demo data using the **Generate data** page from the Demo data module. This script will generate sales orders and warehouse work to populate the warehouse performance reports with data.

The demo data module is only available if you have the Demo data suite model deployed on the environment.

Vendor collaboration

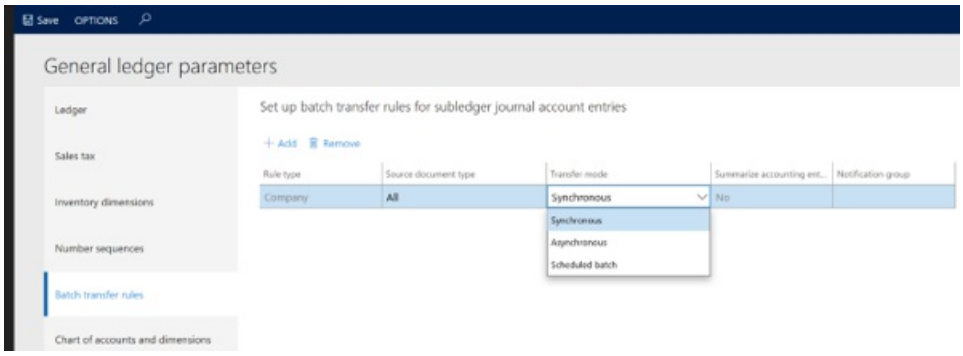
In the USMF demo company, there are three purchase orders for vendor US-104 to use for demonstration purposes. You can log in as user ErinH, who is a contact person who has access to vendor collaboration for US-104.

Purchase order approval

In the USMF demo company, there are two purchase orders for INGA to approve. You can log in as user INGA to see the purchase orders awaiting approval.

Batch transfer rules for subledger journals

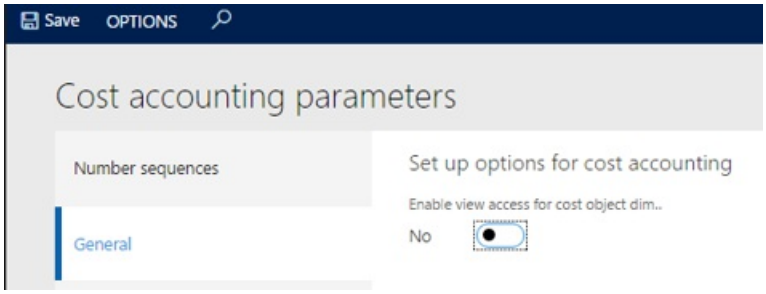
The batch transfer rules for subledger journal account entries have been changed to **Scheduled batch** to reflect a best practice. The batches are configured to run every 10 minutes. It is important to understand that accounting entries for all source documents will not be reflected in General ledger until the batch process has run. If you have requirements to see the immediate effect in General ledger, set the **Transfer mode** to **Synchronous** on the **Batch transfer rules** page within **General ledger** parameters. While Synchronous works well for product demos and environments with low transaction volumes, it can cause performance issues in larger transaction volume environments.



Cost accounting

Three Cost accounting ledgers are created in demo data. The Cost accounting ledger USP2 provides an E2E demo experience based on data from legal entity USP2. The Cost control unit consists of 2 Cost object dimensions (Cost centers and Product groups). Actual cost, Budget cost and Statistical measures are transferred for all 12 fiscal periods of year 2017. Overhead calculation has also been performed for all fiscal periods of year 2017.

Access level security is configured but not enabled. This is enabled in the **Cost accounting parameters** page.



After Access level security has been enabled, you can assign an employee to the role Cost object controller. You can log in as the employee and access the **Cost control** workspace. The employee can now see their Cost center performance and drill into details of how these were calculated.

> **NOTE**
>
> Can you tell us about your documentation language preferences? Take a short survey.
>
> The survey will take about seven minutes. No personal data is collected (privacy statement).

Generate demo data by using data packages

2/18/2021 • 16 minutes to read • Edit Online

In previous releases, demo data was delivered as a database. In Microsoft Dynamics 365 for Finance and Operations, Enterprise edition 7.3, a subset of demo data has been released as data packages. These packages are available in the Shared asset library in Microsoft Dynamics Lifecycle Services (LCS). The packages are designed so that they can be loaded into an empty environment.

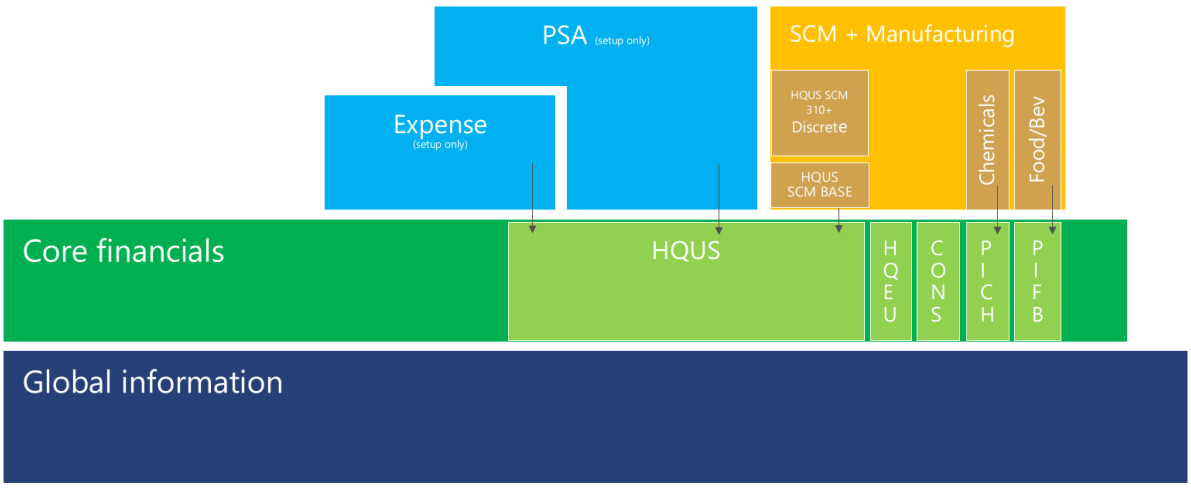
Here are some of the benefits of using data packages instead of a database to deliver demo data:

- The download times are significantly faster.
- You can import just the data packages that you require.
- You can edit the spreadsheets to customize the data for your customers.
- Updated demo data can be provided very quickly through LCS.

> **NOTE**
> The demo data packages aren't yet a full replacement for the demo database that is currently provided.

How the packages are organized

The demo data packages are designed to be layered on top of each other, as shown in the following illustration.



However, the global information for one demo scenario might have completely different requirements than the global information for another demo scenario. For example, the dimensions for one scenario will interfere with the dimensions for another scenario. In this case, a separate global information package will be created, and only packages that are related to that global information can be layered on top of the package.

For example, there is currently a commercial system and shared package as well as a separate public sector system and shared package that can't be used together.

System and Shared package

The base package, System and Shared, is the foundation for all other packages. This package creates legal entities, loads the global address book, and adds other shared information. It must be loaded first to support all the remaining packages. The package is named **100-System and Shared.zip**.

After the System and Shared package is loaded, you will see one or more of the following legal entities.

LEGAL ENTITY	DESCRIPTION
HQUS	The US-based headquarters for your demo company. This company is based on the original USMF data, but it has been changed to remove the manufacturing focus in the name. It includes setup information that is intended for US companies.
HQEU	The non-US-based headquarters for your demo company. This company is based on the original DEMF data, but it has been changed to remove the manufacturing focus in the name. It includes setup information that is intended for non-US companies.
CONS	A small consolidations company.
PICH	A process industries company that is focused on chemicals.
PIFB	A process industries company that is focused on food and beverages.

Financials

The Financials data packages contain data for the general ledger, bank, accounts payable, tax, accounts receivable, fixed assets, and budgeting for a single company. The names of these data packages consist of **200-Financials** followed by the legal entity that the packages are intended for. For example, the Financials data package for the HQUS legal entity is named **200-Financials-HQUS.zip**.

At least two financial companies are required for cross-company tasks such as centralized payments. To facilitate cross-company tasks, all customers and vendors have been added to each legal entity. The CONS legal entity is required if you want to do consolidations.

The Financials data packages also have five inventory products to support the creation of invoices that can move through the accounts receivable and accounts payable processes. These items use a minimum of inventory and product functionality to support those processes. However, you no longer have to set up products when you want to demonstrate only Financials functionality. More complete products will be added when you import the Supply chain data packages.

Expense management

The expense management data packages contain data for expense management and aren't specific to project management. The names of these data packages consist of **225-Expense** followed by the legal entity that the packages are intended for. For example, the Expense management data package for the HQUS legal entity is named **225-Expense management HQUS.zip**.

Project management and accounting

The Project management and accounting data packages contain data for project accounting and expense management. The names of these data packages consist of **250-Project management and accounting** followed by the legal entity that the packages are intended for. For example, the Project management and accounting data package for the HQUS legal entity is named **250-Project management and accounting-HQUS.zip**.

Supply chain

The Supply chain data packages contain data for inventory management, product information, procurement and sourcing, sales and marketing, quality management, warehouse management, transportation management,

production control, process manufacturing, costing, and master planning for a single company. Because of the large number of entities, the Supply chain packages for some companies have been split into two packages. You must load both packages to complete the supply chain scenarios. However, you can load these packages as two separate projects.

These names of these data packages consist of **300-Supply chain** followed by the legal entity that the packages are intended for. For example, the Supply chain data package for the PICH legal entity is named **300-Supply chain-PICH.zip**. The supply chain package for the HQUS legal entity is split into packages that are named **300-Supply chain 1 of 2-HQUS.zip** and **300-Supply chain 2 of 2-HQUS.zip**.

Demo data package releases

The demo data packages will be released through LCS and will be specific to a release. Note that the contents of a given package are subject to change as we add more demo scenarios and tune the packages. Additional packages will also be released as we add more module areas and industry-specific scenarios.

Package names will include a release identifier. For example, for Finance and Operations 7.3, **Demo data-7.3-** will precede the package name that uses the previously described naming conventions. For example, the full name of the Financials package for the HQUS legal entity for Finance and Operations 7.3 will be **Demo data-7.3-200-Financials-HQUS.zip**.

Before you load the packages

Before you load the data packages, you must manually follow these steps.

1. If you want to sign in as a specific user, change the user's email address to the sign-in address that you want to use. You can make this change in the **User information** data entity spreadsheet or, after you load data, on the **Users** page (**System administration** > **Users**).
2. Start the **Ready to post** batch scheduler. This batch job automatically posts transactions. You must start the scheduler in every legal entity where data should be processed. Follow the steps in the "The Ready to post process" section later in this topic.
3. If you aren't using the en-us locale, you may need to alter the source data format to match the format the packages were built on. Once you've loaded a data entity, click into the source data format column which should be specified as value = Excel. From the next page, again select Excel. From within the source data formats page, the bottom fast-tab will be regional settings. Change the language locale to en-us if it isn't specified as en-us. After loading packages, you can change it back to its original non en-us value.

Load the packages

The data packages must be loaded into a specific legal entity in a specific order. The number before the name of the package gives you guidance about the order that the data must be loaded in. For example, you must import **100-System and Shared.zip** before you can load the Financials package for the HQUS legal entity, **200-Financials-HQUS.zip**. Then, to add Supply chain data to the HQUS legal entity, you can load **300-Supply chain 1 of 2-HQUS.zip** and **300-Supply chain 2 of 2-HQUS.zip**.

Follow these steps to load the packages.

1. Start with an empty instance where no data is loaded.
2. Open the **Data management** workspace.
3. Select the **Import** tile to create an import job.
4. Enter a name for the job. For example, enter **Import shared information**.
5. Select **Add file**.
6. Select **Upload and add**, and browse to the data package that you want to import. You must start with the System and Shared data package.

7. Select the data package, and wait for the data to be loaded.
8. After the data is loaded, close the dialog box, and then select **Import**.
9. Repeat steps 5 through 8 for every additional package that you want to load. Be sure to switch to the legal entity that the data package is intended for.

Loading package combinations

The following packages can be loaded. When you import any package except the System and Shared package, you must be in the legal entity that is listed in the package name. The System and Shared package can be loaded from any legal entity. However, it's typically loaded from the default company, DAT.

Commercial Data

DESCRIPTION	NOTES
100 - System and Shared	Load this package before you any other package.
200 - Financials - HQUS	You can load this package alone or together with another Financials package.
200 - Financials - HQEU	You can load this package alone or together with another Financials package.
200 - Financials - CONS	You can load this package alone or together with another Financials package.
200 - Financials - PICH	You can load this package alone or together with another Financials package.
200 - Financials - PIFB	You can load this package alone or together with another Financials package.
225 - Expense Management - HQUS	Follow the prerequisite step before starting the import. Load this package after the HQUS Financials package.
250 - Project management - HQUS	Load this package after the HQUS Financials or Expense package. If you want to also use Supply chain, you must import this package first.
300 - Supply chain 1 of 2 (base) - HQUS	Load this package after the HQUS Financials package. If you want to also use Project management, you must import the Project management package first before you import this package.
310 - Supply chain 2 of 2 (Discrete) - HQUS	Load this package after the HQUS Supply chain base package.
300 - Supply chain - PIFB	Load this package after the PICH Supply chain package.
300 - Supply chain - PICH	Load this package after the PIFB Supply chain package.
900 - Financial transactions - HQUS	Load this package after the HQUS Financials package.
900 - Financial transactions - HQEU	You can load this package alone or together with another Financials package.

Public Sector data

DESCRIPTION	NOTES
100 - Public Sector System and Shared	Load this package before you any other package.
200 - PSUS Financials	You can load this package alone.
900 - PSUS Financial transactions	Load this package after the PSUS Financials package.

To load the data correctly, you need to load one package at a time, import it, and then load the next one once the import is complete. We are considering additional methods for loading the demo data to improve the process.

Troubleshooting and known issues

> **NOTE**
>
> We discovered an issue with the Number sequence references entity that causes a random failure during import although the data in the packages is correct. If you see an error during the import of number sequence references, follow these steps to process the failed records.
>
> 1. Click on the name of the entity (**number sequence references**) to display a form that lists all of the records in the data package.
> 2. Click on **Copy data to target**.
> 3. Change the **Run for** value to **Criteria** and **Change Rows with previous errors** to **Yes**.
> 4. Click **Ok** and then click **Run** on the form that appears.
> 5. Repeat these steps until all records import without error.

> **NOTE**
>
> There is currently an issue that some data entities have the same name, which can cause an import failure for **document types** and **date intervals** in the **200 - Financials** packages. If you see an error during the import of these entities extract them from the .zip file provided and manually import, making sure to use the **document types** pointing to **DocuTypeEntity** and **date intervals** pointing to **LedgerDateIntervalEntity**. Once these are imported you can retry the failed records from the **200 - Financials** packages.

After you load the packages

Check **Ready to post** if anything needs to be posted. In some cases individual demo scripts may recommend some setup be done prior to loading this data.

In some cases, there might be data that you want to add because of a special scenario or a missing entity. Add that data after you've finished loading the data packages. You might also want to manually post additional transactions or add your own data packages to enhance the demo experience.

After you load the data packages, you must also manually follow these steps.

1. Start the workflow jobs. Select **System administration** > **Workflow infrastructure configuration**, and then select **OK**.
2. Set up policy precedence rules. Select **Procurement and sourcing** > **Setup** > **Policies** > **Purchasing policies**, and then select **Parameters**. Then select **Companies**, and move it to the right column.
3. Setup policy precedence prior to importing Expense packages. Select **Expense management** > **Setup** > **Policies** > **Expense report**, and then select **Parameters**. then select **Companies**, and move it to the right column.
4. After you load the Project management and accounting packages, you must run the **Resource capacity roll-up** batch job. You can run this job from the **Synchronize resource capacity roll-ups** page (**Project management and accounting** > **Periodic** > **Capacity synchronization** > **Synchronize resource**

capacity roll-ups). Specify an end date that lets you schedule resources a long time in the future. After the batch job is run, automatic generation of team functionality will be enabled in the project's work breakdown structure (WBS).

5. Add Print management settings for each module.

Scenario scripts

Scripts have been provided for many of the scenarios that the demo data supports. You can find these scripts in Demo data scripts.

Transactions and automatic posting

Many scenarios for demo data require that transactions be processed after they are imported. You can process transactions by using the Ready to post feature. This feature includes both a page that lets you define the transactions that should be posted, and an entity that lets you import the definitions and automatically run them.

The following transaction types are supported when demo data is posted.

DOCUMENT	ENTITY DOCUMENT ID	DATE FILTER	ID FILTERS	OTHER FILTERS
Budget registry update	BudgetRegistryUpdate	Default date	Budget entry number	Not in use, Status = Draft
Costing version	CostingVersion	Not applicable	Version ID	Version Activation blocked = No
Customer payment journal	CustomerPaymentJournal	Transaction date	Journal number	Not posted, not workflow, not system blocked
Daily journal	GeneralJournal	Transaction date	Journal number	Not posted, not workflow, not system blocked
Fixed assets journal	FixedAssetsJournal	Transaction date	Journal number	Not posted, not workflow, not system blocked
Free text invoice	FreeTextInvoice	Invoice date	Not applicable	
Inventory adjustment journal	InventoryAdjustmentJournal	Transaction date	Journal number	Not posted
Invoice journal	InvoiceJournal	Transaction date	Journal number	Not posted, not workflow, not system blocked
Price calculation	PriceCalculation	Not applicable	Version ID	Version Activation blocked = No
Purchase order	PurchaseOrder	Delivery date	Purchase order ID	Able to confirm/PR/Vendor confirm/invoice

DOCUMENT	ENTITY DOCUMENT ID	DATE FILTER	ID FILTERS	OTHER FILTERS
Sales order	SalesOrder	Delivery date	Sales order ID	Able to confirm/packing slip/invoice
Trade agreement	TradeAgreement	Not applicable	Price/discount journal number	
Vendor invoice	VendorInvoice	Posting date	Invoice number	Approved, not in use, not yet
Vendor payment journal	VendorPaymentJournal	Transaction date	Journal number	Not posted, not workflow, not system blocked

For journals that support date ranges, the Ready to post process examines all the journal lines for a date that falls in the specified range. If any line in the journal falls in the date range, the search is stopped, and the whole batch is posted.

The Ready to post process

The Ready to post feature uses a batch to monitor the list of transaction types that you want to post. When the monitor detects a transaction of the type that you want to post, it uses the transaction type to generate a batch that posts those transactions. The batch that is created is the same type of batch that is created when you use the user interface for that transaction type. When the transaction batch is completed, the Ready to post monitor updates the list with the results of the processing. It also adds links to the batch and the original transaction.

Use the Ready to post page to process transactions

1. Select **System administration** > **Periodic tasks** > **Batch job ready to post** to open the **Ready to post** page.
2. Select **Create posting monitor**, and set up the batch parameters so that a recurring batch is running. You must complete this step only one time for each legal entity to start the batch process for posting.
3. Select **New**, and enter a name for the demo data job. The job name must be unique across all companies.
4. Select **Add line** to add a transaction type.
5. Select the transaction target. For journals, the target is **Post**. For other transactions, the target depends on the transaction type.
6. Specify a start date and an end date (that is, a date range) to limit the transactions that will be processed (when available).
7. Specify a "from" document and a "to" document (that is, a document range) to limit the transactions that will be processed (when available).
8. Select **Add line** to add additional transaction types. You can use the same type on multiple lines.
9. Select **Mark ready to post**. The batch status is changed from **Open** to **Ready**, and the posting monitor starts to process each line.
10. If you want to process a document immediately, select **Process documents**. The batch status is changed to **Scheduled**, and a batch is started without using the posting monitor.

When the batch is running, the status is changed to **In Progress**.

When the batch is completed, the status is changed to **Successful** or **Error**, depending on the results. The posting results are shown at the bottom of the page.

Use the Ready to post entity to process transactions

An entity that is named **Demo data posting** lets you import a list of document types that you want to post. The

entity will create a demo data job on the **Ready to post** page. If you've started the posting monitor, the transactions are automatically posted after you import the data by using the entity.

The following columns appear in the **Ready to post** entity.

COLUMN	PURPOSE
DemoDataJob	The unique ID of the demo data job to run. Use the same ID for every line that belongs to a single job.
LineNum	The order that the tasks will be run in.
DataProjectId	A link to the data project that contains the **Ready to post** entity. This information is for export only.
DemoDataJobStatus	The status of your demo data project. This information is for export only.
Document	The document type to process.
DocumentTarget	The process to run. For journals, the target must be **Post**. For transactions such as sales orders, the target will match the options that appear on the page when you add the task.
EndDate	An optional end date that limits the transactions that are processed.
FromDocument	An optional "from" document that limits the transactions that are processed.
ProcessOnImport	If you change the value to **Yes**, the demo data job will be set to **Ready**, and the process monitor will pick it up automatically. No action is required.
StartDate	An optional start date that limits the transactions that are processed.
ToDocument	An optional "to" document that limits the transactions that are processed.

Insert the **Ready to post** entity at the end of your data project, after all the transaction entities. In the data project, specify a sequence number that is larger than the sequence numbers that are used for the transactions entities.

If you have a mixture of transactions, some of which should be processed whereas others should not be processed, you must use date and document ranges to limit the transactions that are processed. If you can't use the ranges, you must use a separate data package for the unposted transactions.

Deploy a demo environment

2/18/2021 • 2 minutes to read • Edit Online

This topic explains how to deploy a demo environment on Microsoft Azure using Microsoft Dynamics Lifecycle Services (LCS). This topic applies to deploying a demo environment for:

- Dynamics 365 Finance
- Dynamics 365 Supply Chain Management
- Dynamics 365 Commerce

Prerequisites

Before you begin your deployment, the following prerequisites must be in place:

- Verify that you have an Azure subscription, and that you are a co-administrator on it.
- Verify that you have access to an LCS project and permissions to deploy an environment.
- Verify that you've connected your Azure subscription to your LCS project by using the information in the Complete the Azure Resource Manager (ARM) onboarding process topic.

Deploy a demo environment

Use this procedure to deploy a demo environment on Azure using LCS.

1. In LCS, open your project, and then, in the **Environments** section, click the plus sign (**+**).
2. Select the Azure environment topology, and then select **Demo**.
3. Select a topology.
   - For Finance and Operations, select the most recent Azure Resource Manager (ARM) topology for Finance and Operations.
   - For Commerce, select **Dynamics 365 for Commerce - Demo**.
4. In the **Deploy environment** dialog box, enter the name of the environment. This name should be unique in the Azure subscription. To make environments easy to identify, consider forming an acronym using the user's name and the topology.
5. Select the size of the virtual machine (VM). You must use **Ev3-series sizes** for Finance and Operations workloads. We recommend **Ev3**. If you experience allocation failures, see the Azure troubleshooting guide.
6. Set the **Instances** field to 1.

   > **NOTE**
   > The size of the VM and the number of instances affect the cost of your subscription. For more information, see Azure pricing.

7. Click **Advanced settings** to add customizations to your deployment. For the demo environment, we recommend that you keep the default settings.
8. Agree to the licensing and pricing terms, and then click **Next**.

9. In the **Confirm** message box, click **Deploy**.
10. Open the **Cloud hosted environments** page to view the status of the deployment. After the deployment is successfully completed, the environment will be ready.

Log on to your demo environment

To log on to your demo environment, do the following.

1. In LCS, open the **Cloud-hosted environments** page, and select the demo environment that you just deployed.
2. Scroll to the right and in the **Environment details** pane, under **Cloud services**, click the appropriate link:
   - **Log on to Finance and Operations**
   - **Log on to Commerce**

Cloud deployment overview

2/18/2021 • 15 minutes to read • Edit Online

Working with Microsoft to deploy Finance and Operations apps in the cloud requires that you understand the environment and subscription that you are deploying to, who can perform which tasks, and the data and customizations that you need to manage. We recommend that you sign up for the Full Microsoft FastTrack for Dynamics 365 to help speed your deployment and implementation - it's a program that provides training and consulting to help you realize business value faster. For more information, see Microsoft FastTrack. If you choose to use the Essentials FastTrack program instead, you will be using the Implementation Project Methodology in Lifecycle Services (LCS) to help you manage your implementation project.

Customer lifecycle, subscriptions, and environment types

Microsoft assumes that all customers will follow a lifecycle similar to the following for all cloud deployments, and therefore need different environment topologies at each phase.

- Evaluate
- Develop customizations, if needed.
- Curate a "golden configuration" environment that contains only module configurations without master or transactional data. This is to be the baseline for your data migration testing and eventual go live.
- Install and test customizations and partner solutions on a tier-1 sandbox (Development or test environment).
- Test customizations, partner solutions and data configuration on a tier-2 sandbox environment.
- Deploy customizations and data configurations to a production environment with high availability.

At some phases of a project, you may have all of the environments live at once. For more information, about the default licenses and tiers that are available, see the Dynamics 365 Licensing Guide.

You may notice the terms cloud hosted or Microsoft subscriptions. A *cloud hosted subscription* means that the customer or partner brings their own Azure subscription and deploys Finance and Operations apps to it, for evaluation and development purposes only. The customer or partner pays for the resources deployed to their Azure subscription based on the Azure price list. A *Microsoft subscription* means that the customer purchases Finance and Operations licenses, which will then allow them to deploy environments to an Azure subscription which is managed by Microsoft, therefore, the customer has no separate Azure billing.

With each Enterprise offer, two environments are included by default:

- One Tier 2 sandbox (multi-box environment) for user acceptance testing (UAT).
- One production environment with high availability (HA).

Additional environments may be purchased as add-ons. For information about licensing and what is included in Microsoft Dynamics 365, see the Dynamics 365 Licensing Guide.

Here's how the lifecycle maps to the available environments. If you already have environments deployed in your Lifecycle Services project, you can find the Environment Type and Environment Sub type on each environment's details page.

LIFECYCLE PHASE	ENVIRONMENT TIER	SUBSCRIPTION	ENVIRONMENT TYPES	ENVIRONMENT SUB-TYPE
Evaluation and analysis	Tier 1 Sandbox	Cloud hosted	Customer Managed	Demo

LIFECYCLE PHASE	ENVIRONMENT TIER	SUBSCRIPTION	ENVIRONMENT TYPES	ENVIRONMENT SUB-TYPE
Customize	Tier 1 Sandbox	Cloud hosted or VHD	Customer Managed	Develop
Golden configuration	Tier 1 Sandbox	Cloud hosted	Customer Managed	Develop
User acceptance testing (UAT)	Tiers 2-5 Sandbox	Microsoft	Microsoft Managed or Self-service	Not applicable
Go live	Production	Microsoft	Microsoft Managed or Self-service	Not applicable

Tiers 2-5 can be purchased to increase performance of the environment. The higher the tier, the more compute and database capacity is reserved for your use. For more information about Self-service environment types, check out the Self-service deployment overview.

Environment lifecycle operations

Users with the Environment Administrator or Project Owner roles in Lifecycle Services can perform various lifecycle operations on their environments. These operations often involve downtime on the environment until the task is finished. Each of these operations are located under or next to the **Maintain** button on each environment details page.

LIFECYCLE OPERATION	DESCRIPTION	LEARN MORE
Apply software	Install Microsoft updates, ISV solutions, or your own customization packages.	Apply updates to cloud environments
Enable access	Allow list your IP for Remote Desktop or database access	See the Remote Desktop section later in this topic
Restart services	Ability to restart components of your environment	Restart environment services
Move database	Full data lifecycle management	Database movement operations
Maintenance mode	Ability to change configuration with only admin access	Maintenance mode
Upgrade	Upgrade code and data from 7.x to the latest version	Process for moving to the latest update
Deallocate	Ability to turn off an environment not being used, or to troubleshoot a failed action	Not applicable
Start	Ability to turn on an environment for use	Not applicable
Delete	Ability to delete an environment previously deallocated	Not applicable

Security and compliance

Finance and Operations is PA-DSS 3.1 certified which means that all communications between components are secured out-of-the-box.

All Finance and Operations front-end virtual machines in Microsoft Azure are configured during deployment to only accept TLS 1.2.

IMPORTANT

Customers who have administrator access to Microsoft-managed sandboxes, including any add-on sandboxes purchased, must follow these guidelines:

- By default, automatic Windows update is enabled for all Tier 1 - 5 sandboxes and should NOT be disabled. This ensures that any time that Microsoft pushes security or critical infrastructure updates to your environment, your environment receives the latest set of updates and is updated each month with the operating system fixes that Microsoft releases.
- Admin passwords on these environments should NOT be changed. Environments that have admin passwords changed will be flagged by Microsoft. Microsoft reserves the right to, and will reset the admin password.
- Adding new user accounts to any Microsoft managed VM is NOT permitted. Microsoft reserves the right to, and will remove the newly added user accounts without providing notice.

> Finance and Operations is not covered by a FedRAMP ATO at this time. If Finance and Operations is provisioned in the United States, all customer data at rest is stored in data centers located in the United States, as described in International availability of Dynamics 365. Finance and Operations does not support any other Dynamics 365 US Government or Microsoft 365 GCC compliance attributes (for example, access by US screened personnel, and support for CJIS and IRS 1075).

Remote Desktop

Microsoft-managed environments

WARNING

Microsoft will be removing the use of Remote Desktop by customers and partners. Each environment will first have administrator access removed, but still allow non-administrator access to the virtual machines. After this, all access will be removed. For each step of this phased removal, an email notification will be sent to the Notification list setup for each environment. All Remote Desktop access will be removed by November 2020.

Customers are required to complete additional setup to connect to virtual machines (VMs) through Microsoft Remote Desktop (RDP). This additional setup applies to all Microsoft-managed environments, including Tier 1 through Tier 5 sandboxes and add-ons. In order to connect to Tier 1 through Tier 5 sandbox environments, you must explicitly enable access (safe list) from your organization's IP address space. This can be done by a Lifecycle Services (LCS) user who has access to the **Environment** page (**Maintain** > **Enable Access**) where they can enter the IP address space that will be used to connect to the virtual machines through Remote Desktop. Access rules are either a single IP address (example: 10.10.10.10) or an IP address range (example: 192.168.1.0/24). You may add multiple entries at once as a semi-colon(;) separated list (example: 10.10.10.10;20.20.20.20;192.168.1.0/24). These entries are used to configure the Azure Network Security Group that is associated with your environment's virtual network. For more information, see Security rules.

IMPORTANT

Customers need to ensure that RDP endpoints are secured through explicit IP safe list rules as mentioned above. The IP safe list rules must adhere to the following conditions.

- IP safe list rules must NOT use asterisk/zero.
- Wide IP address ranges must NOT be used.
- IP address ranges must restrict to the customer's CORPNET.
- If computers outside the customer's CORPNET (such as a home office) are used to connect to sandbox environments, only the specific IP addresses of the computers used to connect to the sandbox environments must be added.
- Azure Datacenter IP address ranges must NOT be added.
- Public IP addresses, such as a coffee shop location, must NOT be added.
- IP safe list rules should be removed when not in use. Periodic review of environment IP safe list rules is recommended.

> Microsoft will run periodic tests on the Microsoft Managed environments validating that the environments are sufficiently restricted. Microsoft reserves the right to and will remove any IP Address safe list rules that violate the above guidelines, immediately without providing notice.

Partner/Customer managed environments

By default, Remote Desktop is enabled for all non-Microsoft managed environments. We recommend that customers restrict access to any environments that belong to their subscriptions. This can be done by configuring Network Security Group rules on the environments directly in Azure Portal.

Windows Remoting (WinRM)

Windows Remoting (WinRM) is disabled on all environments. Although you can enable WinRM on environments that belong to your subscriptions through Azure Portal, we strongly recommend that you do not do this.

WARNING

Exceptions to enable WinRM will not be granted for any Microsoft-managed environments.

Availability

The guaranteed uptime for Finance and Operations apps is 99.9%. Planned downtime occurs once a month and lasts no longer than eight hours. Because the work completed during the downtime doesn't always take eight hours, we will always communicate the estimated amount of time that your environments will be down. For more information, see Get support for Finance and Operations apps or Lifecycle Services (LCS).

High-availability features

To ensure service availability, all production environments are protected by using default Azure high availability (HA) features. HA functionality provides ways to avoid downtime caused by the failure of a single node within a datacenter, and DR features protect against outages broadly impacting an entire datacenter. Azure availability sets are used to prevent single-point-of-failure events. For more information about Azure availability sets, see Use availability zones to protect from datacenter level failures. High availability for databases is supported through Azure SQL. For more information, see Overview of business continuity with Azure SQL Database.

Disaster recovery features

Production environments are configured with Azure disaster recovery support that includes the following:

- Azure SQL active-geo replication is configured for the Finance and Operations database of the production

environment. For more information about SQL replication, see Compare geo-replication with failover groups.

- Geo-redundant copies of Azure blob storage (containing document attachments) in other Azure regions. For more information, see Azure Storage redundancy.
- Same secondary region for the Azure SQL and Azure blog storage replication.

Only primary data stores are supported by replication. The Financial reporting services and Entity store database use transformed data from the primary database and must be generated after the recovery site has been set up and the Finance and Operations service has started.

Service availability in Azure Regions

Finance and Operations apps can be deployed into a subset of Microsoft Azure datacenters using Dynamics Lifecycle Services (LCS). Azure is generally available in datacenters and geographical locations around the world. With Finance and Operations apps, customers can specify the region or datacenter where their customer data will be stored. Microsoft may replicate data to other regions for data durability, but we will not replicate or move customer data outside the geographical location. For more details, see the Service description white paper.

> **IMPORTANT**
>
> Regardless of where customer data is stored, Microsoft does not control or limit the locations from which customers or their end-users may access it. For more information, see International availability of Dynamics 365.

Upcoming changes to region availability

Dynamics 365 solutions consist of a collection of multiple services. Looking across Dynamics 365 applications, the Power Platform and the Azure services that they both depend on, the required matrix of services is quite large and growing. We have locked on a strategy of selecting a subset of data center regions across the globe to simplify ensuring that we have availability of the full portfolio of required services. Our plan is to optimize to have minimal latency between the component services of a solution and as a result, we are focused on having the full portfolio of services available in each of the designated data centers.

Additionally, the Finance and Operations architecture is being enhanced to build on self-service for greater elasticity, stronger reliability, and more seamless maintenance. Customers gain material efficiency by having deeper self-service deployments in fewer data centers. This transition also benefits from selecting a subset of Azure regions. To that effect, the regional availability of Finance and Operations apps will now be **limited to East US, West US, and Central US in North America** for all new projects. For a list of the latest supported regions, see International availability of Dynamics 365.

Support for East US2, West US2, West Central US, North Central US, and South Central US will continue to be available for projects and environments that currently have their data stored in those regions on Microsoft-managed environments.

> **NOTE**
>
> Microsoft will work with customers to move them to an appropriate data center beginning October 19, 2020. This will happen in a phased approach. Select customers will receive advance notification before we migrate them to a supported region.

If there are other customer workloads that are not part of the Dynamics 365 or Power Platform family that also require proximity to the Dynamics 365 and Power Platform services, Microsoft will work with customers to coordinate a plan for the overall migration. For more information, see Cloud deployment overview: Frequently asked questions.

Frequently asked questions

Why does the status display 'Maintenance' on my environment in LCS?

To provide the best experience and performance, Microsoft performs maintenance operations on your environment. During some of these maintenance operations, your environment status may display one of the following statuses:

- Preparing for maintenance
- Prepared for maintenance
- Maintenance in progress

While your environment is in this state and until the status returns to 'Deployed', you will not be able to perform any lifecycle operations, such as package applications. There will be no impact to Finance and Operations apps. Users can continue with normal operations without any service interruption. You will receive an email notification before any maintenance operation puts your environment in this state.

How do I connect to the SQL database on my Sandbox environment?

To connect to the SQL database in your Sandbox environment, follow the steps in Enable just-in-time access.

How do I access a development instance?

For information about how to access development instances, configure on-premises development VMs, and find configurations settings for developers and administrators, see Deploy and access development environments.

How do I deploy a demo environment?

A demo environment includes only Microsoft demo data. You can use a demo environment to explore default features and functionality. For more information, see Deploy a demo environment.

How do I move my customizations between environments?

To move customizations from a development to a sandbox or production environment, see Create deployable packages of models

Can I bring my own domain name?

You can bring your own domain name if it is running Azure Active Directory (AAD), and the administrator of your AAD instance has enabled the Finance and Operations apps within their AAD. This is usually done through the office email, after you buy a license. When you click the link to accept the offer, AAD is set up for you.

Can I add guest AAD accounts as users?

You can add guest AAD accounts if you have correctly configured them within Azure Active Directory, and enabled the Finance and Operations apps within your AAD.

Why am I no longer able to see the Private AOS machines in one or more of my Tier 2 through Tier 5 Sandbox environments?

The Private AOS VMs were part of your environment configuration as they were needed to secure communication between the AOS and BI machines in the past. With recent updates, all communication between AOS and BI machines are secure directly and no longer need the intermediary Private AOS machines. Therefore, we are in the process of rolling out removing the Private AOS machines. As we are removing the machines in batches, you may notice that only some of your environments have the Private AOS machines removed. This change will not impact functionality or security in any way and will be transparent to you.

Why am I no longer able to Remote Desktop into one or more of my Tier 1 through Tier 5 Microsoft managed Sandbox environments?

Microsoft managed Tier 1 through Tier 5 sandbox environments require Remote Desktop management endpoints to be restricted to specific IP Address sets (safe list). Microsoft regularly validates that the environments are sufficiently restricted. Microsoft reserves the right to immediately remove any IP Address safe list rules that violate the above guidelines without notice. You may not be able to Remote Desktop into your

environment for one of these reasons:

- Your current IP address is not in the safe list.
- Your IP has changed from the IP address listed in the safe list.
- Microsoft deleted the rule containing your IP address from the safe list because it violated a guideline.

To regain access to the environment, you will need to add the IP address of the computer from which you are connecting to. To do this, complete the steps Remote Desktop section earlier in this topic.

When will the availability of reduced regions go into effect for new onboarding?

Beginning August 1, 2020, new projects for Finance and Operations will be onboarded to the following regions:

- East US
- West US
- Central US

My environments are currently in the regions that will be deprecated. How will this change affect me?

We will deprecate support for the following regions only for new projects that will be onboarded on or after August 1, 2020:

- East US2
- West US2
- West Central US
- North Central US
- South Central US

This will not affect any environments that have their data stored in the deprecated regions before August 2020. In the near future there is a transition plan to move customers in the deprecated regions into the reduced regions.

I'm unable to redeploy an environment after deleting it, the environment slot is missing.

This is due to the license expiring, which means that you no longer have the minimum required licenses to obtain an environment slot. Please review your subscription status and then reactivate the expired license to enable the redeployment.

> **NOTE**
>
> Can you tell us about your documentation language preferences? Take a short survey.
>
> The survey will take about seven minutes. No personal data is collected (privacy statement).

Self-service deployment overview

2/18/2021 • 3 minutes to read • Edit Online

> **IMPORTANT**
>
> Functionality noted in this topic will be made available to users based on the geographic location recognized by Microsoft Azure.

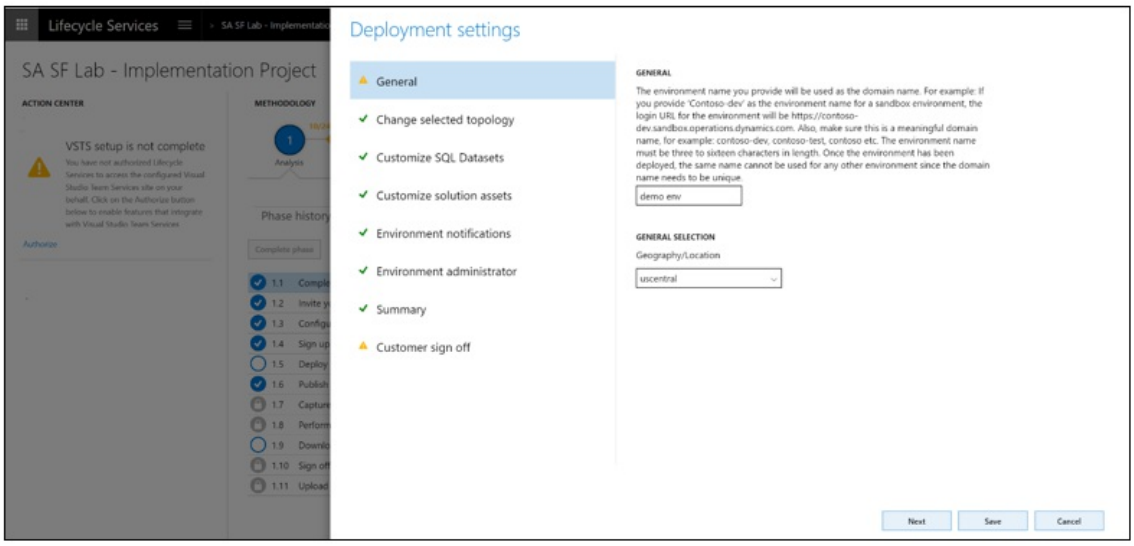
Self-service deployment is available for cloud environments. Self-service deployment enables easier deployment and significantly reduced deployment times.

> **IMPORTANT**
>
> The functionality for this feature will be released incrementally, based on your Microsoft Azure country/region. However, this functionality is currently available only for **new customers** who are in the process of signing up for Finance and Operations apps. There is no change in existing environments for current customers.
>
> Note that not all new customers will see this functionality. However, the number of new customers who have access to it will gradually increase.

What's new or changed

Customers using the self-service capabilities will see the following changes in their Lifecycle Services (LCS) experience.

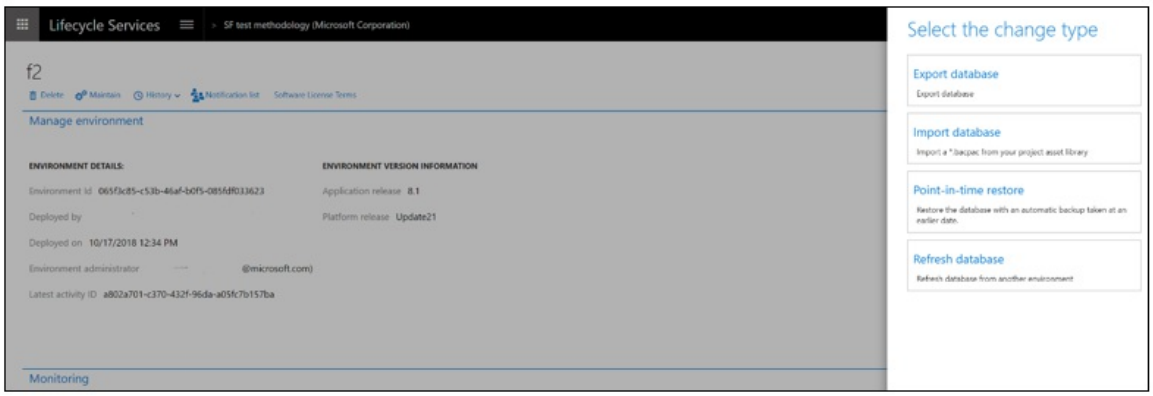
- Deployment is self-service and can be completed within an average time of 30 minutes. There are no longer lead times and wait times for deployment. You can control when you deploy, and verify that the environment is deployed. This experience is the same as the current experience. For more information, see Self-service deployment FAQ.



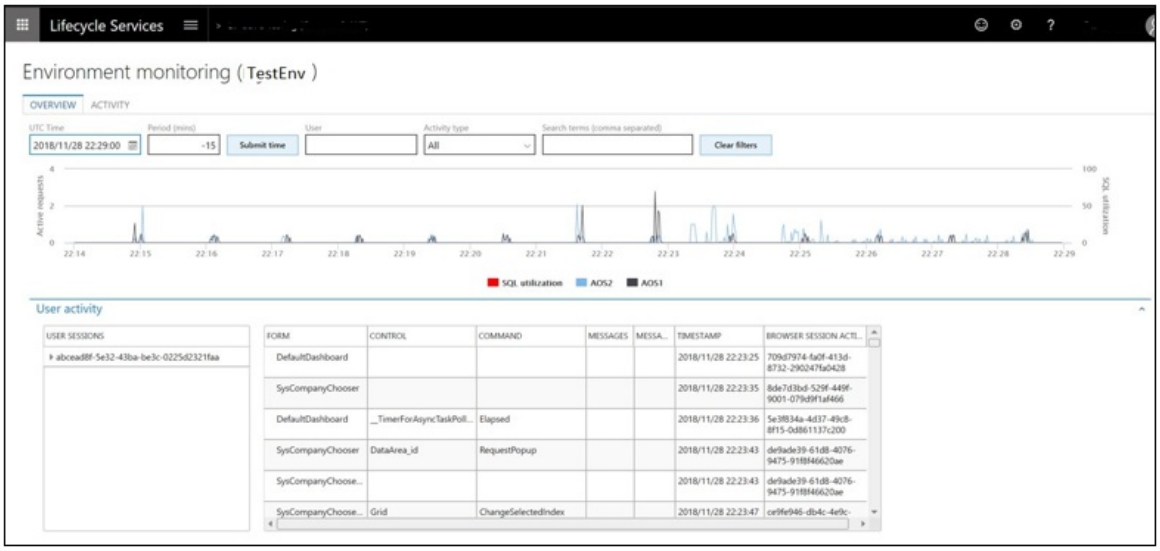
- You will no longer have remote desktop access to the Tier 2+ sandbox environments. All operations that need remote desktop access are now available as self-service actions. The following image shows some of the operations in the environment's **Maintain** > **Move database menu** option. For more information, see Maintenance operations for deployments.

IMPORTANT

Remote desktop access will be restricted only to environments deployed using the self-service deployment. There is no change to existing environments or existing customers.



- The diagnostics capabilities will remain the same, which enables troubleshooting without remote desktop access. For more information, see Troubleshoot environments deployed through self-service deployment.



- You will not have SQL Server access on Tier 2+. You will continue to have SQL database access using just-in-time access.
- You will need to provide a combined deployable package for customizations. That is, all custom extension packages, including ISV packages, must be deployed as a single software deployable package. You will not be able to deploy one module at a time. This was always a recommended best practice and is now enforced.
- The document preview experience has been improved to deliver greater fidelity with the printed output. Before this change, documents viewed on screen were displayed using an HTML viewer. Although the HTML format supported interactive functions like embedded drill-thru links and collapsible sections, this was not a true representation of the document rendered by the service. With the new embedded PDF Viewer, customers have access to a preview that's consistent with the printed documents. For more information, see Preview PDF documents with an embedded viewer.
- Custom fonts are no longer supported for document reports rendered using the built-in SSRS framework. Finance and Operations apps include access to hundreds of standard, business-ready fonts available for documents rendered by the cloud-hosted service. This portfolio will continue to grow as the service expands into new regions and industries. However, the service no longer supports the installation of custom fonts in customer environments. Requests to expand the collection of fonts supported by the

service will be considered on a case-by-case basis.

- The service no longer supports business logic defined using Visual Basic script embedded in SQL Server Reporting Services (SSRS) reports. Visual Basic expressions defined in Tablix controls used to format and evaluate data at runtime will continue to be fully supported. However, the service will ignore instructions defined in Visual Basic script functions. This change was necessary to improve the security and reliability of the service.
- Sub reports are no longer supported in document reports defined using the SSRS development tools. Application solutions that include sub reports will need to be recreated or replaced with solutions that take advantage of other reporting options supported by the service.

  > **IMPORTANT**
  > Support for sub report items has been re-introduced with the Platform update 36 release. Customers dependent on solutions that include properly formatted sub report items can transition to self-service deployments running on Platform update 36 or later.

> **NOTE**
> Can you tell us about your documentation language preferences? Take a short survey.
>
> The survey will take about seven minutes. No personal data is collected (privacy statement).

Deploy a new environment

2/18/2021 • 2 minutes to read • Edit Online

IMPORTANT

Functionality noted in this topic will be made available to users based on the geographic location recognized by Microsoft Azure.

This topic walks through the process of deploying sandbox (Tier 2 and above) and production environments with the self-service deployment experience. Refer to the following procedure to deploy these environments.

1. Select **Configure** on the project dashboard page.
2. Select the **Application** and **Platform** version for the environment that you want to deploy.
3. Provide a **unique name** for the environment.
4. Select the **region** where you want this environment to be deployed.
5. Choose whether you want to load **demo data** in your environment or if you want an **empty database**.
6. Select the **BPM library** that will be set as the Getting started library in the product.
7. Select from a list of available **AOT packages** (customization packages) on the Software Deployable tabs in the Asset Library if you want to apply customizations. Only packages generated from a build environment on version 8.1 and above should be selected. Applying a package from an incompatible version will have an adverse effect on the environment.
8. Specify **two user email addresses** that will receive **notifications** related to this environment. These users are in addition to the users who are already on the project team (such as an ISV or a partner).
9. Select the **email address** of the **user** that will be set as the **system administrator** in the product.
10. After you validate the configurations, click **Submit** to trigger the deployment.
11. If you plan to use channels, you must also Initialize Retail Cloud Scale Unit.

The environment deployment starts immediately and could take anywhere between **1-2 hours** to complete.

To closely monitor the deployment progress, you can view the **Environment details** page. The environment state should change to either **Deploying** or **Deployed/Failed**.

If the deployment **succeeds**, the environment state will be **Deployed**, and the user set as the environment administrator will be able to sign in to the environment.

If the deployment **fails**, then create a Microsoft support ticket and provide the **Last Activity ID** (available under **Manage environment** on the **Environment details** page) in the support ticket.

Delete an environment

You can delete an environment that is in the deployed state directly through the environment details page. To delete an environment, go to the environment details page and click the **Delete** button on the action bar. A confirmation dialog box will display asking you to enter the name of the environment that you want to delete. After you enter the environment name and select **Yes**, the deletion operation will start. When the deletion operation is complete, the **Configure** button for this environment will be enabled on the project dashboard if you want to redeploy the environment.

NOTE

To redeploy an environment, you will need to delete the environment and then deploy it again using the steps listed above.

IMPORTANT

For existing customers using channel functionality in the cloud, to ensure continued and uninterrupted support for your business, we require that you Initialize Retail Cloud Scale Unit no later than January 31, 2020. There is no action required for customers who exclusively use Store Scale Unit. Contact your Microsoft FastTrack Solution Architect if you require an extension.

NOTE

Can you tell us about your documentation language preferences? Take a short survey.

The survey will take about seven minutes. No personal data is collected (privacy statement).

Self-service deployment FAQ

2/18/2021 • 5 minutes to read • Edit Online

IMPORTANT

Functionality noted in this topic will be made available to users based on the geographic location recognized by Microsoft Azure.

This topic provides answers to some frequently asked questions about self-service deployment. Refer to the known issues list if your scenario is not listed here.

Why do I see only application version 8.1.1 and Platform update 21 and above when I try to deploy my sandbox environment using self-service deployment?

Currently, self-service deployment supports only application version 8.1.1 with Platform update 21 and above.

My development environment is on application version 8.1. Am I still able to move my customization to the sandbox environment?

Yes. Application version 8.1.1 is fully backward compatible with application 8.1.

What is the minimum supported application and platform version when trying to use the self-service deployment?

Application version 8.1 with Platform update 20 is the minimum supported version.

What do I do if deployment fails?

1. Delete the deployment.
2. If you want to reuse the same environment name, wait 5 minutes and try again. Otherwise, retry deploying with a new name.
3. If deployment fails again, log a Support ticket.

NOTE

Microsoft will add automatic retry logic in an upcoming release and make logs available.

What if my deployment fails with an “environment already exists” error?

You may be trying to reuse the environment name of a deployment that you just deleted. Wait 5–10 minutes before retrying the deployment.

I don't have Remote Desktop access to my sandbox environment. How do I perform critical actions that require Remote Desktop access

today?

Although you will no longer have Microsoft Remote Desktop access, you can continue to operate your Tier 2+ sandbox environments, because Microsoft is providing self-service capabilities and tools that you can use to perform the common critical actions that are described here.

Access the Azure SQL database

You can access the Microsoft Azure SQL database by following these steps.

1. From LCS, add a safe list of the IP address of the machine that you will use to connect to the Azure SQL database using SQL Management Studio.
2. Use LCS to request access to see the database credentials. You must provide a reason for requesting access.

As soon as you submit the request, it's automatically approved. Within a minute or two, you will be able to see the database access credentials on the LCS environment details page. You can use the credentials to connect to the SQL database.

> **NOTE**
>
> The credentials are valid for eight hours, and then they will expire. After the credentials expire, you will have to request access again.

Access log files

You can view and download all log files from the **Activity** tab on the LCS environment monitoring page.

Use perfmon tools

Although you can no longer use Remote Desktop and then use perfmon.exe to diagnose performance issues, you can monitor critical health metrics for CPU and memory consumption through LCS. In addition, you can run predefined queries on demand, and you can run predefined actions to mitigate performance issues on your Tier 2+ environments.

Access self-service logs

All logs that are related to self-service operations that are performed on the environment through LCS are available for download from LCS. These self-service operations include deployment, servicing, and database movement. You can download the log folders from the LCS environment history page.

Turn Maintenance mode on/off

Starting in the January 2019 release, you will be able to turn Maintenance mode in your environment on and off through a self-service action in LCS.

Restart services

Starting in the January 2019 release, you will able to restart services through a self-service action in LCS.

Configure the Regression suite automation tool

Microsoft is working on tooling that will let you update certificate thumbprints in the wif.config file without having to use Remote Desktop. This tooling is scheduled for release in February 2019. If you must use the Regression suite automation tool before then, log a support request.

I must perform one of the critical actions that are listed earlier in this topic, but the self-service feature isn't yet available. How do I get help?

Log a support ticket, and Microsoft will help you perform the action on your environment.

I don't have Remote Desktop access to my sandbox environment, and the critical action that I must perform isn't listed in this topic. How do I get help?

If your critical action isn't listed earlier in this topic, add a comment to this topic or log a documentation bug, and Microsoft will address your requirement.

For my Microsoft-managed environments, I have external components that have dependencies on an explicit outbound IP safe list. How can I ensure my service is not impacted after the move to self-service deployment?

With self-service migrations, we are changing the outbound IP addresses in regions where your environments are hosted. New outbound IP addresses are available so you can add them in preparation for the upcoming self-service migrations or post migrations.

- If none of your external components have dependencies on an explicit inclusion list of IPs or special handling of outbound IP addresses for routing or firewall, no action is required.
- If any of your external components have special handling for the outbound IP addresses to communicate to the AOS, add the new outbound IP addresses where the existing ones appear. Don't replace the existing IP addresses. You can find the new outbound IP addresses in the following list. For example, an outbound IP address may be explicitly included in a firewall outside your AOS, or an external service may have an allowed list that contains the outbound IP address for your AOS.

The inbound IP address to the AOS is dynamic. This can, and will, change over time as infrastructure changes occur.

> **NOTE**
> The outbound IP address from the AOS will remain static for the duration of an individual AOS session, which is currently listed to end in June 2021.

REGION	IP PREFIX
West US	52.250.195.128/26
East US	52.255.218.64/26
Central US	13.86.98.128/26
West EUR	51.105.159.192/26
West EUR-2	20.61.88.128/26
North EUR	52.155.160.192/26
UK West	51.137.139.0/26
UK South	51.11.26.192/26
Australia East	20.40.190.0/26

REGION	IP PREFIX
Australia SouthEast	20.40.165.192/26
Canada Central	20.151.60.0/26
Canada East	52.155.27.128/26
Brazil South	191.234.130.0/26
East Asia	52.229.231.64/26
South East Asia	20.44.247.0/26
Japan East	20.48.77.192/26
Japan West	20.39.179.192/26

Is there a potential impact on the environment's certificates?

Yes, if you are migrating from the previous non self-service deployment, your environment's certificate may be renewed due to infrastructure differences. Determine if there is any dependence on the certificates in your solution/integration and perform the needed actions after the migration.

Known issues with self-service deployment

2/18/2021 • 3 minutes to read • Edit Online

> **IMPORTANT**
> Functionality noted in this topic will be made available to users based on the geographic location recognized by Microsoft Azure.

This topic describes the known issues with self-service deployment.

Lifecycle Services (LCS)

Features not intended to be implemented

The following LCS features will not be implemented in self-service deployment.

- **System diagnostics** - All data and functionality provided by system diagnostics today will be available through other features in the product and LCS.
- **Service requests** - Service requests are being replaced with self-service actions.

Known issues in this release

Know issues are bugs that will be addressed in upcoming releases. Every 2 weeks there is a new release of LCS.

Finance and Operations apps

> **NOTE**
> Dynamics 365 Commerce is implemented in the modern deployment experience with the 10.0.10 release. For more information, see Create payment packaging for Application Explorer for self-service deployment.

Features not intended to be implemented

The following feature will not be implemented in self-service deployment.

- **Custom fonts** - Custom fonts are not supported. For more information, see Document Reporting Service in Dynamics 365 applications.
- **Customizations related to UI components on self service** - Customizations that do not use the standard Financial Reporting or SQL Server Reporting Services (SSRS) in Finance and Operations apps often take a dependency on UI components of the operating system where the AOS runs. Example dependencies include Windows fonts, web browsers such as Internet Explorer, or custom PDF rendering. We do not ensure the host operating system will include any support for font infrastructure, web browsers, or any general UI components. The host operating system will change when migrating to self-service infrastructure. If you have such dependencies and have additional questions, please contact Microsoft support.

Features no longer supported

The following feature is no longer supported with self-service deployment.

FTP

Customizations relying on FTP are not supported with self-service deployment and should consider the following actions.

- **Add retries** - This should be viewed as a short to medium term option. The current infrastructure design allows control and data calls to occasionally have matching IP. This design is subject to change.
- **Disabling the FTP requirement for control and data that is from the same IP** - Carefully evaluate the security implications for your situation in this case.
- **Remove the use of FTP** - For example, use Power Apps to pull the files in and make API calls into Finance and Operations apps to import the files using the Data Integration framework. For more information, see Choose a data integration strategy.
- **Use SFTP** - We do not recommend using static outbound IP addresses. For more information, see the Finance and Operations Static IP Addresses blog post.

Our general recommendation is to remove the use of FTP. Do not use a direct connection from Dynamics 365 to an SFTP. Instead, use a Logic App in between the two. With the Logic App you have two options:

- Use the native SFTP connector (as described in Monitor, create, and manage SFTP files in Azure Logic Apps), which still requires some port opening on the firewall to call the on-premises service. Consider that for Logic Apps, the list of IPs is much shorter than the entire region allow list and the limits and configuration in Power Automate.

- Use the "Local Filesystem" connector, as described in Outbound IP addresses, in combination with the on-premises data gateway. For more information, see Install on-premises data gateway for Azure Logic Apps. This solution completely removes the need for the IP allow list, which is deprecated in self-service deployment, while keeping a very high-level of security.

> **NOTE**
>
> For more information about deprecated features, see Removed or deprecated platform features and Removed or deprecated features from previous releases and Removed or deprecated features in previous releases.

Maintenance operations for deployments

2/18/2021 • 2 minutes to read • Edit Online

IMPORTANT

Functionality noted in this topic will be made available to users based on the geographic location recognized by Microsoft Azure.

This topic explains how to perform maintenance operations for an environment that was deployed by using the self-service deployment experience.

Restart services

You can use the restart services functionality to restart individual services that are associated with a Tier 2, Tier 3, Tier 4, or Tier 5 standard acceptance test (sandbox) environment that is deployed in a Microsoft subscription. The services that you can restart are **AOS service**, **DIXF (Data import export framework service)**, and **MR (Management Reporter service)**.

To restart a service, follow these steps.

1. In Microsoft Dynamics Lifecycle Services (LCS), on the environment details page, select **Maintain** > **Restart service**.
2. Select the service to restart, and then select **Confirm**.

   During the restart, the environment's status is updated to **Restarting service**, and you can't start any other maintenance operations. After the service has been restarted, the environment's status is returned to **Deployed**.

Maintenance mode

Finance and Operations apps includes a system-wide setting that is named maintenance mode. Maintenance mode gives system admins a safe way to make system changes that might affect system functionality. For example, configuration keys can be turned on or off. While maintenance mode is on, only the system admin and users who are assigned to the **Maintenance mode** user role can sign in to the system. By default, maintenance mode is turned off.

To turn maintenance mode on or off, follow these steps.

1. In LCS, on the environment details page, select **Maintain** > **Enable Maintenance mode**.

   The environment's status is changed from **Deployed** to **Servicing**. After maintenance mode has been turned on, the environment's status is updated to **In Maintenance**, and only the system admin can sign in.

2. After the system admin has finished making configuration changes, on the environment details page, select **Maintain** > **Disable Maintenance mode**.

   The environment's status is changed from **In Maintenance** to **Servicing**. After maintenance mode has been turned off, the environment's status is returned to **Deployed**. The environment history is updated to reflect the fact that the environment was put into maintenance mode.

Access database

Remote access is turned off for environments that were deployed by using the self-service deployment experience. During implementation, if you must connect to the database on your Tier 2, Tier 3, Tier 4 or Tier 5 standard acceptance test environments for troubleshooting purposes, access will be granted as it's required. The access won't be persistent.

To connect to a database, follow the instructions in Enable just-in-time access.

Update an environment

2/18/2021 • 6 minutes to read • Edit Online

IMPORTANT

Functionality noted in this topic will be made available to users based on the geographic location recognized by Microsoft Azure.

This topic walks through the process of applying updates to an environment that was deployed by using the self-service deployment experience.

IMPORTANT

In the next-generation infrastructure, updates are applied differently than they are applied in the current flow. *Whatever is provided in the package is applied to the environment, and it **overwrites** whatever is already present in that environment.* Therefore, you **must** create a single deployable package that contains all customizations and independent software vendor (ISV) solutions from your build environment. If the list of models in the environment differs from the list of models in in the package, you receive a warning before the update is applied. For information about how to create a single package, see Manage third-party models and runtime packages by using source control.

Supported package types

Because environments that are deployed by using the self-service deployment experience will be running on version 8.1 (October 2018) or a later version, the following package types are supported:

- **AOT deployable package** – A deployable package that is generated from application metadata and source code. This type of deployable package is created in a **build** environment.
- **Binary update package** – A deployable package that contains dynamic-link libraries (DLLs), and other binaries and metadata that the platform and application depend on. This type of package is released by Microsoft.

Development Application Lifecycle Management (ALM) flow

To apply code customizations to your sandbox and production environments, you must create a deployable code package from your build environment. For more information, see Create deployable packages of models.

Microsoft updates

To access Microsoft updates, go to the environment details page for your environment in Microsoft Dynamics Lifecycle Services (LCS). You will see a **single tile** that shows a cumulative binary update of all the application and platform fixes. To apply this update, select the package, and then select **Save Package** to save the Microsoft update to the project asset library.

Apply updates

Tier 1 sandbox/develop and test/demo/build environments

To apply updates to a Tier 1 sandbox/develop and test/demo/build environment that was deployed through LCS, follow the steps in Apply updates to cloud environments.

Tier 2 and above Standard Acceptance Test/sandbox environments

> **IMPORTANT**
> Package application causes system downtime. All relevant services will be stopped, and you won't be able to use your environments while the package is being applied.

Before you begin, verify that the deployable package has been uploaded to the project asset library in LCS, and that validations have succeeded.

After the package is in the project asset library, follow these steps to update your environment.

1. Open the environment details page for the environment where you want to apply the package.
2. Select **Maintain** > **Apply updates** to apply an update.
3. Enter a **unique name** for the update. You will use this name to identify the update that you want to move to the production environment.
4. Select the package to apply. Use the filter at the top to find your package. The list will include application and platform binary packages and application deployable packages that have passed validation from the asset library.
5. Select **Apply**.

   The status in the upper-right corner of the environment details page changes from **Queued** to **Servicing**. Then, when package application is completed, the status changes to **Deployed**.
6. After package application is completed, the environment history is updated. To view the environment history, select **History** > **Environment changes** on the environment details page.
7. You can also download the logs from the environment history page.
8. After the validations are completed, you can sign-off on the update from the environment history page by selecting either **Sign off** or **Sign off with issues**.

Production environment

To improve the reliability of updates that are applied to a production environment, a specific update that is done in the sandbox environment is designated ("marked") as a **release candidate** and moved to the production environment. This update contains both the base product and the customization. Therefore, both will be moved over when the selected update is applied to the production environment. This behavior differs from the current servicing behavior. Currently, you can move only the customization, but the base product **will not** change. In the case of a self-service deployment environment, the base product version **might change**, depending on the update that is marked as a release candidate in the sandbox environment.

> **IMPORTANT**
> Package application causes system downtime. All relevant services will be stopped, and you won't be able to use your environments while the package is being applied.

After you've successfully applied the update in the sandbox environment and are ready to move the update over to the production environment, follow these steps to mark an update as a release candidate.

1. Open the environment history page by selecting **History** > **Environment changes** on the environment details page.
2. Select the update to move over to the production environment.

3. In the details for the update, select **Mark as release candidate**.

   The **Is Release Candidate** option is set to **Yes**.

After you've marked an update as a release candidate, follow these steps to update your environment.

1. Open the environment details page for the production environment.
2. Select **Maintain > Update environment** to apply an update.
3. In the **Available sandboxes** list, select the source sandbox environment where the update was applied, validated, and marked as a release candidate.
4. In the grid, select the update to apply to the production environment. This grid shows only updates that have been marked as release candidates.
5. In the **Downtime start** field, select a date and time. The environment will be taken down for servicing at the specified time on the specified date. The **Downtime end** field is set to through hours from the start of the downtime.

   No lead time is required for this update.
6. Select **Schedule**. LCS runs validations to make sure that the selected update is applicable to the environment. To prevent downgrade of the environment, the update isn't allowed if its application version is lower than the current environment version. Additionally, customers are asked to confirm that they want the update to proceed.

   If the update is **successfully** scheduled, an email notification is sent to all project stakeholders.

   The status in the upper-right corner of the environment details page changes from **Queued** to **Servicing**. Then, when the update is completed, the status changes to **Deployed**.

   All stakeholders are notified of the progress of the operation.
7. After the update is completed, the environment history is updated. To view the environment history, select **History > Environment changes** on the environment details page.
8. You can also download the logs from the environment history page.
9. After the validations are completed, you can sign-off on the update from the environment history page by selecting either **Sign off** or **Sign off with issues**.

> **NOTE**
>
> If there is an on-going operation in the environment, or if the environment is already running on the same version or a later version, the scheduled update is canceled. When a scheduled update is canceled, an email notification is sent to all project stakeholders. Customers can also cancel an update by selecting **Cancel** on the environment details page. If customers want to reschedule or change an update, they can cancel the current operation and schedule a new one.

> **IMPORTANT**
>
> For environments that are deployed in the modern infrastructure stack, if servicing is unsuccessful, the environment is automatically rolled back. To learn why the operation was unsuccessful, you can download the logs from the environment history page.

NOTE

Can you tell us about your documentation language preferences? Take a short survey.

The survey will take about seven minutes. No personal data is collected (privacy statement).

Troubleshoot environments deployed through self-service deployment

2/18/2021 • 2 minutes to read • Edit Online

IMPORTANT

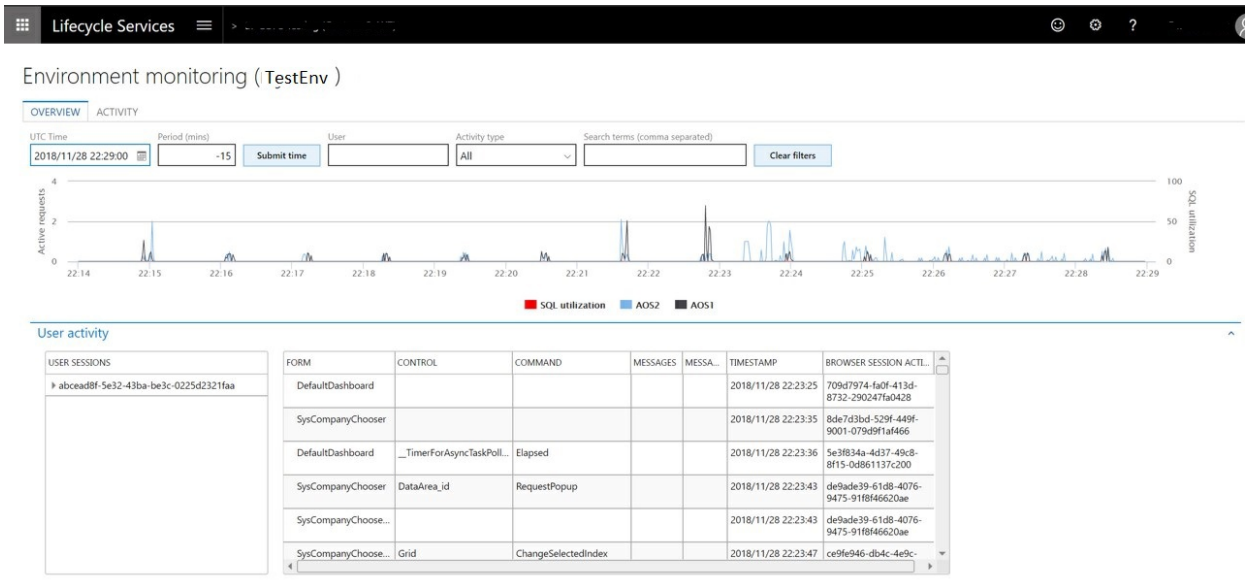
Functionality noted in this topic will be made available to users based on the geographic location recognized by Microsoft Azure.

This topic explains how you can troubleshoot issues on an environment that was deployed using the self-service deployment experience. When a user reports an issue, you can use various tools in Lifecycle Services (LCS) for troubleshooting. The rich set of telemetry data helps you build a storyboard view that shows what that user and other users were doing when the issue was reported.

To open the **Environment Monitoring** dashboard, follow the steps listed below:

1. Open LCS and navigate to the appropriate project.
2. In the **Environments** section, select the environment that you want to view, and then click **Full details**.
3. On the **Environment details** page, click **Environment monitoring** to open the Monitoring and diagnostics portal.

On the Environment Monitoring dashboard, you will see two tabs: **Overview** and **Activity**.



Overview tab

The **Overview** tab provides a storyboard view that shows how the environment was being used during a specific period. You can use the filters on this page to narrow the information logs. Here are some of the filters that are available:

- **Time duration**: Go back 60 minutes from the selected date and time.
- **User**: View a specific user's activities.
- **Search terms**: Create a search that is based on the issue that is being investigated.

In addition, you will also see two sections:

- The **User interaction** chart shows a user's activities on various machines in the environment and the SQL utilization trend.
- The **User activity** grid shows the various activities that users performed, based on their session timestamp. The active sessions display on the left side of the grid. For each session, the Form:Control:Command and the corresponding timestamp show when the action was taken. You can trace the exact steps that the user was taking in the information presented in this grid.

> **IMPORTANT**
> The Overview tab will also include the CPU and memory health metrics to help with diagnostics. This feature is currently not available but will be added soon.

Activity tab

The **Activity** tab shows a predefined set of queries for advanced troubleshooting. This gives you access to the raw information logs. You can then export the logs to do more advanced analysis. The following types of queries are available:

- User-related errors
- Slow queries
- Deadlocks
- Crashes

> **NOTE**
> The data shown on the **Overview** and **Activity** tabs is only retained for 30 days.

> **IMPORTANT**
> The Environment monitoring will also include advanced SQL troubleshooting tools to diagnose and mitigate performance issues. This feature is currently not available but will be added soon.

> **NOTE**
> Can you tell us about your documentation language preferences? Take a short survey.
>
> The survey will take about seven minutes. No personal data is collected (privacy statement).

Complete the Azure Resource Manager (ARM) onboarding process

2/18/2021 • 4 minutes to read • Edit Online

This topic explains how to complete the Azure Resource Manager (ARM) onboarding process for your connectors.

To deploy Microsoft Azure Resource Manager (ARM) topologies, you must complete the ARM onboarding process for your connectors. To start the onboarding process, you must have the following items:

- The Azure subscription ID that you're deploying to
- Ownership of the Azure subscription, or access to the subscription owner, so that you can add contributor workflows, and the Upload Management certificate
- The tenant administrator, to work through the admin consent workflow

ARM onboarding process

You can consider ARM onboarding a two-step procedure, where each step has its own sub-procedures. You must complete all these procedures for every subscription that you add to the Microsoft Dynamics Lifecycle Services (LCS) project.

1. Authorize the LCS Deployment Service (DSU) to work on the Azure subscription.
    a. Authorize the workflow.
    b. Set the contributor workflow.
2. Enable the Azure subscription to deploy ARM resources.
    a. Enable the Azure connector, and add an LCS user.
    b. Optional: Upload the Management certificate.
    c. Configure deployment settings.

Authorize the LCS DSU to work on the Azure subscription

Complete the following procedures to authorize the LCS DSU to work on the Azure subscription.

Authorize the workflow

The administrator of the tenant must complete the following procedure.

1. In LCS, on the **Project** page, in the **Environments** section, click **Microsoft Azure settings**.
2. On the **Project settings** page, on the **Azure connectors** tab, in the **Organization list** group, click **Authorize** to start the ARM Contributor workflow. This workflow sets up permissions for the DSU, so that it can deploy to your subscription on your behalf.
3. On the **Grant admin consent** page, click **Authorize**. Then sign in by using the administrator account of the Azure subscription that you must connect to, and click **Accept**. The authorization is now shown as completed.

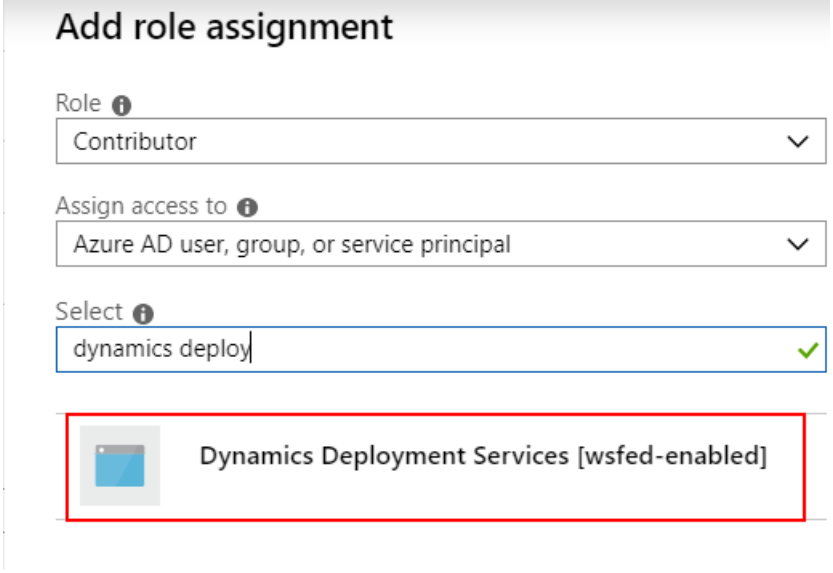
Set the contributor workflow

Follow these steps to assign the **Contributor** role to the **Dynamics Deployment Services [wsfed-enabled]** application.

1. In the Azure portal, on the **Subscription** tab, select the Azure subscription, and then click the **Access Control (IAM)** line item.

2. Click **Add**, select **Add role assignment**. In the dialog box, set **Role** to **Contributor** and set **Assign access to** to **Azure AD user, group, or service principal**. In the **Select** field, search for and select **Dynamics Deployment Services [wsfed-enabled]**. Select **Save**.

> **NOTE**
>
> Some Azure subscriptions have a **Users** section instead of an **Access control (IAM)** section. In this case, in the **Add users** dialog box, in the **Select** field, enter **Dynamics Deployment Services [wsfed-enabled]**, and then select **Select**.



3. On the **Role assignments** tab, the App is assigned as a **Contributor**.

> **NOTE**
>
> If Dynamics Deployment Services [wsfed-enabled] doesn't appear, the authorize process hasn't been completed, or it was completed on another Azure subscription.

Enable the Azure subscription to deploy ARM resources

Complete the following procedures to enable the Azure subscription to deploy ARM resources.

Enable the Azure connector and add an LCS user

Follow these steps to enable the Azure Connector and, as required, add an LCS user.

1. In LCS, on the **Project** page, in the **Environments** section, click **Microsoft Azure settings**.
2. On the **Project settings** page, on the **Azure connectors** tab, under **Azure connectors**, click **Add**.

> **NOTE**
>
> If you're enabling ARM for an existing connector, click **Edit**.

3. Enter the connector name, enter the Azure subscription ID to deploy to, and set the **Configure to use Azure Resource manager** option to **Yes**.
4. In the **Azure subscription AAD Tenant domain** field, enter the domain name of the Azure subscription account admin, and then click **Next**.
5. Authorize access to the subscription, either by adding the LCS user to the Azure subscription or by using the Management certificate. **Important:** If you're adding an LCS user, continue with step 6. If you must upload a Management certificate, don't complete steps 6 through 8 of this procedure. Instead, complete the next procedure, "Upload the Management certificate."

6. In the Azure portal, on the **Subscription** tab, select the Azure subscription, and then click the **Access Control (IAM)** line item.
7. In the **Access Control (IAM)** dialog box, click **Add**, select **Contributor**, and then click **OK**.
8. In the **Add users** dialog box, in the **Select** field, enter the LCS user, and then press Enter.

> **NOTE**
>
> You must specifically enter a user. You can't just add a group that the user is a member of. When the **Users** page opens, you can see that the user is assigned as a **Contributor**.

Upload the Management certificate

Complete this procedure only if you didn't complete steps 6 through 8 of the previous procedure, "Enable the Azure Connector and add an LCS user."

1. In LCS, on the **Microsoft Azure setup** page, click **Download**. Make a note of the location of the certificate file that is downloaded. You will use this information to upload the certificate to the Azure subscription.
2. In the Azure classic portal, in the left pane, click **Settings**.
3. Filter to the Azure subscription that is used, and then, on the **Management certificates** tab, click **Upload**.
4. Select the Management certificate that you downloaded in step 1, and then click **OK**.

Configure deployment settings

1. In LCS, on the **Project** page, in the **Environments** section, click **Microsoft Azure settings**.
2. On the **Microsoft Azure setup** page, select the region to deploy to, and then click **Connect**. The ARM onboarding flow is now completed. You should now see that the subscription has been added to the **Azure connectors** list. Additionally, a check mark should appear under **ARM Enabled**.

Azure ExpressRoute and Finance and Operations apps

2/18/2021 • 2 minutes to read • Edit Online

Customers can use Microsoft Azure ExpressRoute with Finance and Operations apps to connect to their on-premises infrastructure. This topic provides the information that you need to get started with ExpressRoute.

Microsoft Azure ExpressRoute lets you create dedicated, readily available, highly reliable, low latency connections between Azure datacenters and your on-premises locations. An ExpressRoute circuit is a logical connection between a customer's on-premises network and Microsoft cloud services through a connectivity provider. ExpressRoute is configured separately from Finance and Operations apps. To get an ExpressRoute circuit for your implementation, you must contact a network service provider directly. After ExpressRoute is configured, in addition to connecting to Finance and Operations apps, customers can connect to apps such as Microsoft 365 and supported Azure services, such as connecting to virtual machines and cloud services deployed in virtual networks. To learn more about other supported services, see ExpressRoute FAQ. Before purchasing an ExpressRoute circuit, you will need to know the following information:

- The datacenter that your Finance and Operations apps are located in.
- The region where you will be connecting from.

This information is necessary to determine whether a standard or premium offering of ExpressRoute is required.

Resources for getting started

- ExpressRoute service page
- ExpressRoute technical overview
- ExpressRoute partners and peering locations
- ExpressRoute pricing

NOTE

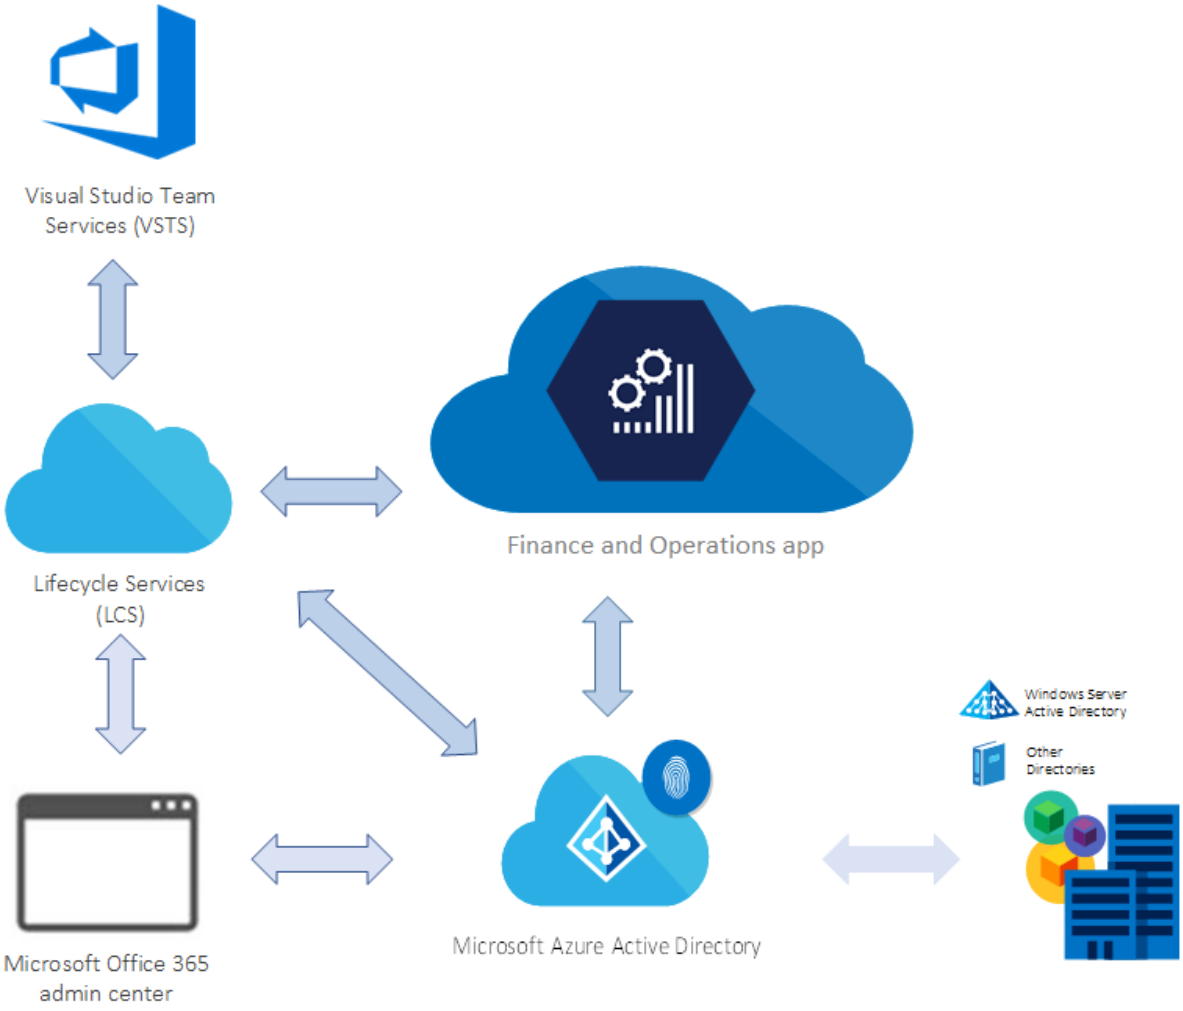
Can you tell us about your documentation language preferences? Take a short survey.

The survey will take about seven minutes. No personal data is collected (privacy statement).

Finance and Operations application architecture

2/18/2021 • 4 minutes to read • Edit Online

The Finance and Operations application cloud architecture contains all the elements that are common to all Microsoft cloud offerings, as described in Subscriptions, licenses, accounts, and tenants for Microsoft's cloud offerings. Beyond this, it also includes services that automate software deployment and provisioning, operational monitoring and reporting, and seamless application lifecycle management.



The cloud architecture consists of these conceptual areas:

- **Subscription** – A subscription to Finance and Operations apps gives you an online cloud environment (or multiple environments) and experience.
- **Licenses** – Customers must purchase subscription licenses (SLs) for their organization, or for their affiliates' employees and on-site agents, vendors, or contractors who directly or indirectly access Finance and Operations apps. These apps are licensed through Microsoft Volume Licensing and the Microsoft Cloud Solution Provider (CSP) program. For more information, download the latest Microsoft Dynamics 365 Licensing Guide from Dynamics 365 pricing.
- **Tenant** – In Microsoft Azure Active Directory (AAD), a tenant represents an organization. It's a dedicated instance of the AAD service that an organization receives and owns when it creates a relationship with Microsoft (for example, by signing up for a Microsoft cloud service, such as Azure, Microsoft Intune, or Microsoft 365). Every AAD tenant is distinct and separate from other AAD tenants. For more information

about AAD tenants, see How to get an Azure Active Directory Tenant.

A tenant houses the company's user information. This information includes passwords, user profile data, permissions, and related information. The tenant also contains groups, applications, and other information that pertains to an organization and its security.

The tenant is created when customers sign up for their first subscription to any Microsoft online service, such as Microsoft 365, Microsoft Dynamics 365, or Azure. Any later subscriptions to the same online services or other online services can be grouped within the same tenant.

An organization can have multiple AAD tenants. If there are multiple tenants, make sure that any subscriptions for Finance and Operations apps are associated with the correct tenant.

- **Azure Active Directory (AAD)** – AAD is the multi-tenant, cloud-based directory and identity management service from Microsoft that combines core directory services, application access management, and identity protection in a single solution. For more information, see Azure Active Directory. Finance and Operations apps use AAD as the store for identity. Access to AAD is provided as part of a subscription to Finance and Operations apps.
- **Microsoft 365 admin center** – Microsoft 365 admin center is the subscription management portal that Microsoft 365 provides for administrators. It's used to provide management functions for users (AAD) and subscriptions. As part of these management functions, it provides information about service health. For more information, see About the Microsoft 365 admin center.

  > **NOTE**
  > You don't have to have an Microsoft 365 license to deploy Finance and Operations apps. However, you might require a license for specific Office integration scenarios. For more information, see Office integration overview.

- **Microsoft Dynamics Lifecycle Services (LCS)** – LCS is a collaboration portal that provides an environment and a set of regularly updated services that can help you manage the application lifecycle of your implementations. For more information, see Lifecycle Services resources. After you purchase and activate a subscription for a Finance and Operations app, an **Implementation project** workspace is provisioned in LCS when the tenant administrator signs in for the first time.

  > **NOTE**
  > An implementation project is an LCS project for the cloud service. As a Microsoft partner, you can also provision non-implementation LCS projects for your own purposes. For more information, see Lifecycle Services (LCS) for Finance and Operations apps partners.

- **Finance and Operations apps** – Finance and Operations apps are deployed through LCS. Various topologies are available: development/test/build, acceptance test, performance test, and high-availability production. For more information about the various topologies, download the latest Microsoft Dynamics 365 Licensing Guide from Dynamics 365 pricing.
- **Microsoft Azure DevOps** – Azure DevOps is used primarily for code version control, development, and to deploy a build environment. Azure DevOps is also used to track support incidents, such as work items in Azure DevOps that are submitted to Microsoft through Cloud-powered support, and to integrate the Business process modeler (BPM) library hierarchy into your Azure DevOps project as a hierarchy of work items. Azure DevOps is also used during code upgrade.

"Under the hood," Finance and Operations apps use many features of the Azure platform, such as Azure Storage, networking, monitoring, and Azure SQL Database, to name just a few. Shared services put into operation and orchestrate the application lifecycle of the environments for participants. Together, Azure functionality and LCS

offer a robust cloud service.

> **NOTE**
>
> Although many features of the Azure platform are used, you don't have to have an Azure subscription to deploy Finance and Operations apps in the Microsoft-managed cloud. You must have an Azure subscription only if you want to deploy Finance and Operations apps cloud-hosted environments in your own Azure subscription.

> **NOTE**
>
> Can you tell us about your documentation language preferences? Take a short survey.
>
> The survey will take about seven minutes. No personal data is collected (privacy statement).

Apply updates to cloud environments

2/18/2021 • 9 minutes to read • Edit Online

This topic describes how you can use Microsoft Dynamics Lifecycle Services (LCS) to automatically apply updates to cloud environments.

> **IMPORTANT**
> Updates are applied using deployable packages. Applying updates causes system downtime. All relevant services will be stopped, and you won't be able to use your environments while the package is being applied. You should plan accordingly.

Supported environments

All environments deployed through Lifecycle Services are supported.

> **NOTE**
> If you have a build environment, you can only use LCS to apply Binary updates and Data upgrade packages. You can't use LCS to apply an Application Deployable package.

For other environments (listed below), you must use Remote Desktop Protocol (RDP) to connect to the environment and install from the command line. For information about manual package deployment, see Install deployable packages from the command line.

- Local development environments (Downloadable virtual hard disk [VHD])
- Multi-box dev/test environments in Microsoft Azure (Partner and trial projects)

Key concepts

Before you begin, you should understand *deployable packages*, *runbooks*, and the *AXInstaller*. A deployable package is a unit of deployment that can be applied in any environment. A deployable package can be a binary update to the platform or other runtime components, an updated application (AOT) package, or a new application (AOT) package. The AXInstaller creates a runbook that enables installing a package. For more details, see Packages, runbooks, and the AXUpdateInstaller in depth at the end of this topic.

Supported package types

- **AOT deployable package** – A deployable package that is generated from application metadata and source code. This deployable package is created in a development or build environment.
- **Application and Platform Binary update package** – A deployable package that contains dynamic-link libraries (DLLs) and other binaries and metadata that the platform and application depend on. This is a package released by Microsoft. This is available from the **All binary updates** tile from LCS.
- **Platform update package** – A deployable package that contains dynamic-link libraries (DLLs) and other binaries and metadata that the platform depend on. This is a package released by Microsoft. This is available from the **Platform binary updates** tile from LCS.
- **Commerce deployable package** – A combination of various packages that are generated after the Commerce code is combined.
- **Merged package** – A package that is created by combining one package of each type. For example, you can

merge one binary update package and one AOT package, or one AOT package and one Commerce deployable package. The packages are merged in the Asset library for the project in LCS.

> **NOTE**
>
> A binary package and a Commerce deployable package can't be included in the same merged package.
>
> For information about how to download an update from LCS and what you see in the tiles based on your environment version, see Download updates from Lifecycle Services (LCS).
>
> If your environment is on an application version 8.1 and later, then the **Platform Update package** does not apply to your environment. Starting with 8.1 and later releases, **Application and Platform Binary update package** is the one that applies since application and platform will be combined into a single cumulative package and will be released by Microsoft. Also note that you will no longer be applying granular X++ hotfixes and will get all application and platform updates together. This means that on the environment details page, clicking on **View detailed version information** will not have details on the granular hotfixes or KBs applied as there is no way to apply them.

Prerequisite steps

- **Make sure that the package that should be applied is valid.** When a package is uploaded to the Asset library, it isn't analyzed. If you select the package, the package status appears in the right pane as **Not Validated**. A package must pass validation before it can be applied in an environment by using the following procedures. The status of the package will be updated in the Asset library to indicate whether the package is valid. We require validation to help ensure that production environments aren't affected by packages that don't meet the guidelines.

  There are three types of validations:

  - Basic package format validations
  - Platform version checks
  - Types of packages
- **Make sure that the package is applied in a sandbox environment before it's applied in the production environment.** To help ensure that the production environment is always in a good state, we want to make sure that the package is tested in a sandbox environment before it's applied in the production environment. Therefore, before you request that the package be applied in your production environment, make sure that it has been applied in your sandbox environment by using the automated flows.
- **If you want to apply multiple packages, create a merged package that can be applied first in a sandbox environment and then in the production environment.** Application of a single package in an average environment requires about 5 hours of downtime. To avoid additional hours of downtime when you must apply multiple packages, you can create a single combined package that contains one package of each type. If you select a binary package and an application deployable package in the Asset library, a **Merge** button becomes available on the toolbar. By clicking this button, you can merge the two packages into a single package and therefore reduce the total downtime by half.
- **Make sure that the Application binary update package is applied to your dev/build environment before it is applied to your sandbox and production environment** - If the application binary package is applied directly to your Tier 2+ sandbox environment but is not applied on your dev/build environment, the next time you move an AOT package from dev/build box (which does not have the same application binaries as your sandbox environment) to sandbox, some of the application binaries will be overwritten with what is in your dev/build environment. This could result in a regression of the version of your sandbox environment.

Apply a package to a non-production environment by using LCS

Before you begin, verify that the deployable package has been uploaded to the Asset library in LCS.

1. For a binary update, upload the package directly to the Asset library. For information about how to download an update from LCS, see Download updates from Lifecycle Services (LCS). For an application (AOT) deployable package that results from an X++ hotfix, or from application customizations and extensions, create the deployable package in your development or build environment, and then upload it to the Asset library.
2. Open the **Environment details** view for the environment where you want to apply the update.
3. Click **Maintain** > **Apply updates** to apply an update.
4. Select the package to apply. Use the filter at the top to find your package.
5. Click **Apply**. Notice that the status in the upper-right corner of the **Environment details** view changes from **Queued** to **In Progress**, and an **Environment updates** section now shows the progress of the package. You can refresh the page to check the status.
6. Continue to refresh the page to see the status updates for the package application request. When the package has been applied, the environment status changes to **Deployed**, and the servicing status changes to **Completed**.

Apply a package to a production environment by using LCS

In a production environment, customers can schedule a downtime for when they want the update to be applied.

> **IMPORTANT**
> An important prerequisite for applying a package to a production environment is that the package must be successfully applied to at least one sandbox environment in the same project.

1. After the update is successfully applied in a sandbox environment, go to the project's asset library. On the **Asset library** page, select the **Software deployable package** tab, select the package that you want to move to production, and click **Release candidate**. This indicates that this package is ready for production deployment.
2. Open the **Environment details** view for the production environment where you want to apply the package.
3. Select **Maintain** > **Apply updates** to apply the package.
4. Select the package to apply in your production environment, and then click **Schedule** to submit a request to apply it.

   > **NOTE**
   > The list of packages includes only the packages that have been successfully signed off in the sandbox environment, and that have been marked as release candidates.

5. Specify the date and time to schedule the package application. Click **Submit**, and then click **OK** to confirm. Note that your environments will be unavailable to perform business while the package is being applied.
6. At the scheduled downtime, package deployment will start.
7. After the environment is serviced, you can monitor the status. The **Servicing status** field indicates the status of package application. Additionally, a progress indicator shows the number of steps that have

been run, out of the total number of steps that are available.

8. After the deployment is successfully completed, the **Servicing status** field is set to **Completed**.
9. If package application isn't successfully completed, Microsoft will investigate the issue. The **Servicing status** field will indicate that package application has failed. The environment will be rolled back to a good state.

Troubleshoot package deployment failures

If package deployment fails, see the Troubleshoot package application issues topic.

Applying updates and extensions

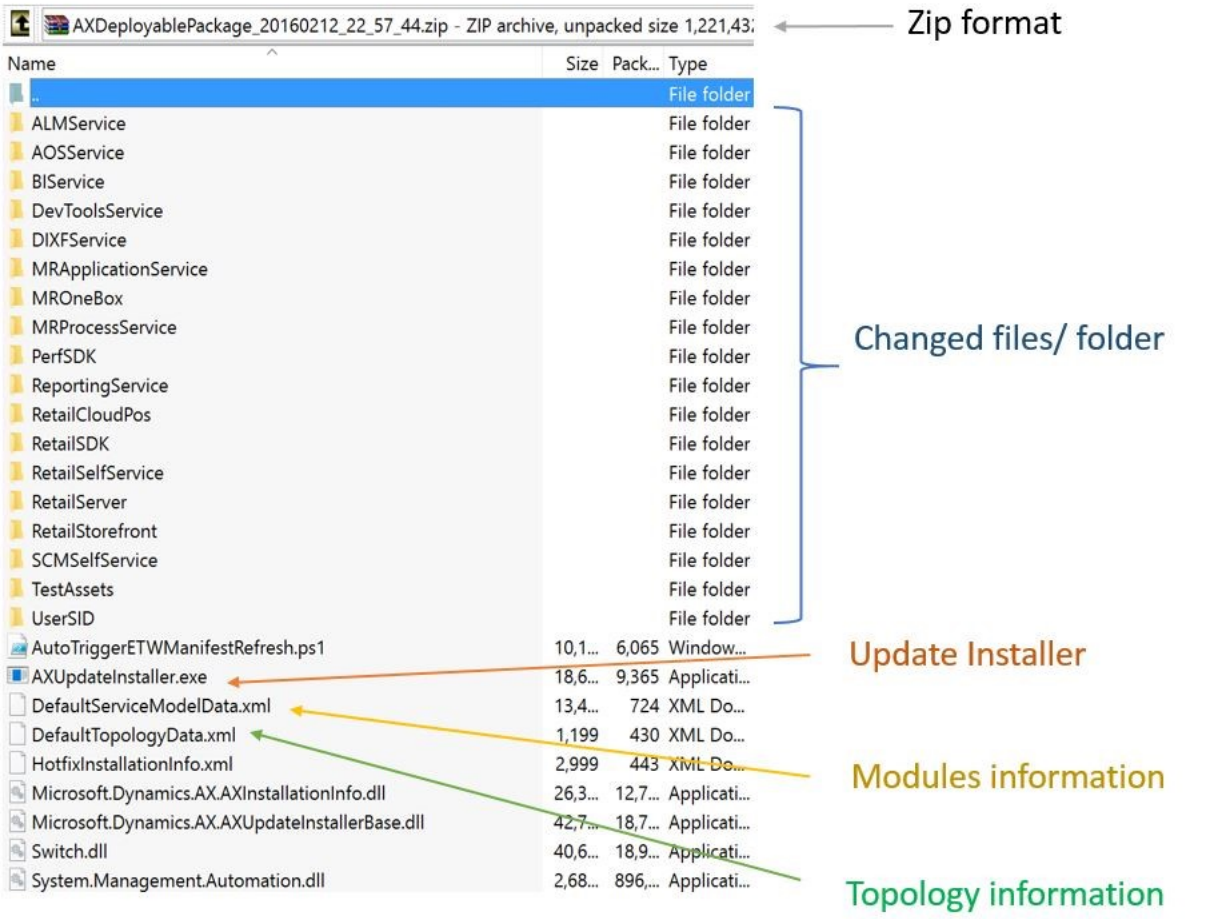
If you are updating a Tier-2 Sandbox or Production environment on application version 8.1.2.x or newer and have initialized Cloud Scale Unit, you will also need to update Commerce channel components. For more information, see Update Retail Cloud Scale Unit.

If you're using components (such as Modern POS), after you've applied updates and extensions in your environment, you must also update your in-store components. For more information, see Configure, install, and activate Modern POS (MPOS).

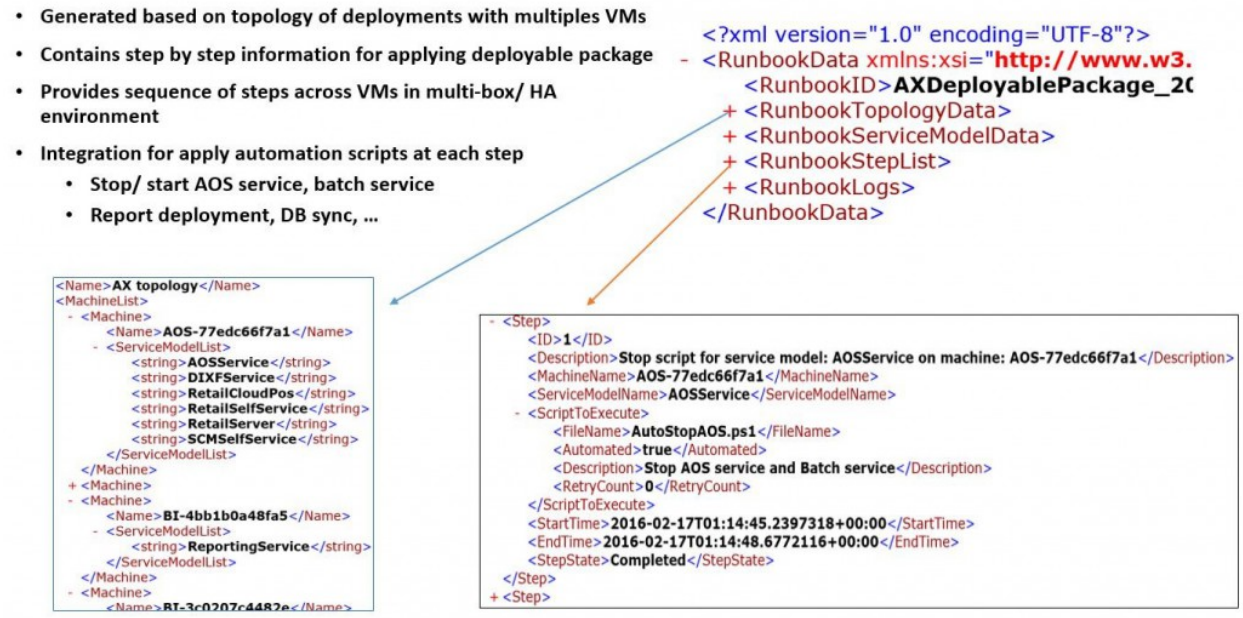
Packages, runbooks, and the AXUpdateInstaller in depth

Deployable packages, runbooks, and the AXUpdateInstaller are the tools you use to apply updates.

Deployable package – A deployable package is a unit of deployment that can be applied in an environment. A deployable package can be a binary update to the platform or other runtime components, an updated application (AOT) package, or a new application (AOT) package. Deployable packages downloaded from LCS or created in a development environment cannot be applied across product types. For example, a Finance deployable package cannot be applied in a Commerce app environment, and vice versa. If you have an existing customization for a Finance and Operations app that is compatible with the Commerce app, and you would like to apply it to a Commerce environment, you will need to re-package your source code in a Commerce development environment, and conversely if moving in the other direction.



Runbook – The deployment runbook is a series of steps that are generated in order to apply the deployable package to the target environment. Some steps are automated, and some steps are manual. AXUpdateInstaller lets you run these steps one at a time and in the correct order.



AXUpdateInstaller – When you create a customization package from Microsoft Visual Studio or a Microsoft binary update, the installer executable is bundled together with the deployable package. The installer generates the runbook for the specified topology. The installer can also run steps in order, according to the runbook for a specific topology.

Additional resources

Install deployable packages from the command line

NOTE

Can you tell us about your documentation language preferences? Take a short survey.

The survey will take about seven minutes. No personal data is collected (privacy statement).

Apply updates and extensions to Commerce Scale Unit (cloud)

2/18/2021 • 2 minutes to read • Edit Online

If you are updating a Tier-2 sandbox or production environment on application version 8.1.2 or newer and have initialized Commerce Scale Unit (CSU), you will also need to update channel components. This topic shows how to apply updates and extensions to CSU.

Updates to CSU are cumulative. This means that any update that you apply will include all previously released changes. Applying a Dynamics 365 Commerce deployable package for extensions is also a cumulative process and will replace the previously deployed version of the extension.

Prerequisites

Before you proceed, you must first apply updates and extensions (if applicable) to the environment. For more information, see Apply updates to cloud environments.

To update CSU, complete the following steps for each:

1. On the **Environment details** page, go to **Environment features > Retail and Commerce**.
2. On the **Commerce deployment setup** page, select **Update**.
3. In the selection panel, select the version to update to.
4. You can choose to update to the newest service update to access the latest features, or you can update to the latest quality update to apply quality improvements for the currently deployed service update. For more information, see Download updates from Lifecycle Services (LCS).
5. You can choose to apply an extension at the same time.

To apply an extension to a CSU, complete the following steps:

1. On the **Commerce deployment setup** page, select **Apply Extension**.
2. In the selection panel, select the extension to apply.

> **NOTE**
> You must first upload the Commerce deployable package to the project asset library in Microsoft Dynamics Lifecycle Services (LCS) before you can select to deploy it on the **Commerce deployment setup page** in LCS.

Both **Apply updates** and **Apply extension** operations will involve a period of downtime that may last up to 1 hour, or in some cases up to 2 hours or more. For example, when updating non-US locations of CSU, large data volumes, or complex schema updates. For a realistic estimate of the downtime duration, note the downtime duration in Sandbox UAT for an equivalent update and dataset that you plan to use in your production environment. During this time, the following will occur:

- Cloud-hosted Commerce channels will not function (unless POS offline capability is enabled).
- POS devices that have the offline capability feature enabled will have reduced functionality.
- Any e-commerce clients that are dependent on CCSU will be disrupted.
- Channels hosted on CSUs will remain unaffected.
- Head office functionality will remain unaffected.

NOTE

Applying an extension and an update at the same time requires a single downtime, and can be an effective way of averting multiple downtimes.

View history

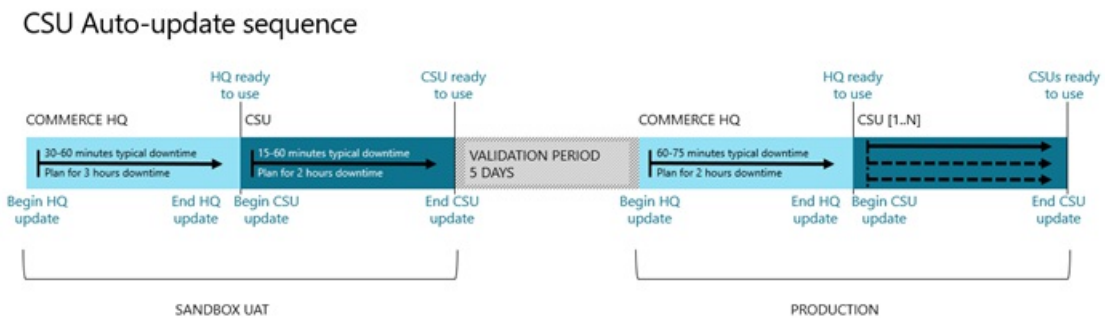
To view the history of recent operations on a Scale Unit, select **History** on the **Action** tab to open the **Scale Unit History** page. On this page, you can view recent operations such as initialize, service update, quality update, version, extension details, and other relevant information.

CSU auto-update sequence

NOTE

Auto-update for CSU is being gradually rolled out to all Commerce customers. If you are a LCS project owner or environment administrator, you'll recieve an email notification when CSU auto-update is rolled out to your LCS project.

When CSU is auto-updated by Microsoft, it takes place in the following sequence.



NOTE

Can you tell us about your documentation language preferences? Take a short survey.

The survey will take about seven minutes. No personal data is collected (privacy statement).

Initialize Commerce Scale Unit (cloud)

2/18/2021 • 8 minutes to read • Edit Online

If you're using a Tier-2 sandbox or production environment that has application version 8.1.2.x or later, you must initialize Commerce Scale Unit (cloud) before you can use retail channel functionality either for point of sale (POS) operations or for e-Commerce operations that use Retail Server in the cloud. Initialization will deploy a Commerce Scale Unit (cloud).

This topic describes the steps for initializing Commerce Scale Unit (cloud).

> **IMPORTANT**
>
> For existing customers using retail channel functionality in the cloud, to ensure continued and uninterrupted support for your business, we require that you update your retail channels to use Commerce Scale Unit. New environments deployed without Commerce Scale Unit will no longer receive quality and service updates for cloud-hosted retail channel components. There is no action required for customers who exclusively use Commerce Scale Unit (self-hosted). Contact your Microsoft FastTrack solution architect if you require an extension.

Prerequisites

1. Deploy a Tier-2 sandbox or production environment that has application version 8.1.2.x or later.
2. If you require more than 1 RCSU per environment, in Microsoft Dynamics Lifecycle Services (LCS), create a support request, and enter **Access request for multiple Commerce Cloud Scale Units** and indicate the environment ID, number of CSUs, and corresponding datacenter regions. The request will be completed within five business days. If you do not require multiple CSUs per environment, you do not need to create a support request.
3. Ensure that Retail license configuration keys are enabled in your environment. For more information, see License codes and configuration keys report. You must have the following keys turned on to use Commerce Scale Unit.

- RetailBasic
- RetaileCommerce - If you plan to use E-Commerce for Dynamics 365 Commerce.
- RetailGiftCard - If you plan to use gift cards.
- RetailInvent - If you plan to use inventory.
- RetailModernPos - If you plan to use point of sale (POS).
- RetailReplenishment - If you plan to use replenishments.
- RetailScheduler
- RetailStores - If you plan to use POS.

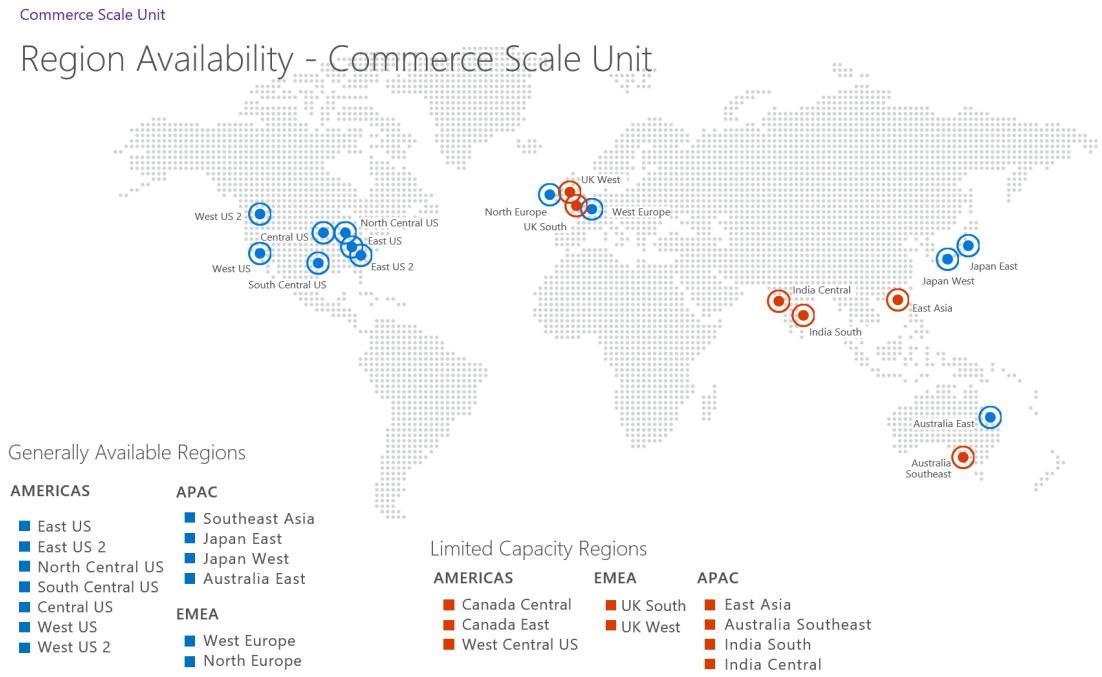
Region availability

Commerce Scale Unit is available for deployment in the following regions.

GLOBAL LOCATION	REGION	AVAILABILITY
AMERICAS	East US	Generally available
AMERICAS	East US 2	Generally available

GLOBAL LOCATION	REGION	AVAILABILITY
AMERICAS	North Central US	Generally available
AMERICAS	South Central US	Generally available
AMERICAS	Central US	Generally available
AMERICAS	West US	Generally available
AMERICAS	West US 2	Generally available
AMERICAS	Canada Central	Limited capacity
AMERICAS	Canada East	Limited capacity
AMERICAS	West Central US	Limited capacity
APAC	Australia East	Generally available
APAC	Southeast Asia	Generally available
APAC	Japan East	Generally available
APAC	Japan West	Generally available
APAC	Australia Southeast	Limited capacity
APAC	East Asia	Limited capacity
APAC	India South	Limited capacity
APAC	India Central	Limited capacity
EMEA	West Europe	Generally available
EMEA	North Europe	Generally available
EMEA	UK South	Limited capacity
EMEA	UK West	Limited capacity

Deployment capacity in Limited capacity regions are extremely constrained. Requests for deployment are evaluated on a case-by-case basis. If you have a compelling business need for deployment in Limited capacity regions, you can file a support request to be added to the waitlist.



Initialize Commerce Scale Unit as part of a new environment deployment

Please make sure the headquarters is available. This is required to register the scale unit with the headquarters during the initialization process. It is not recommended to initialize a scale unit when the headquarters is under servicing, as it may become unavailable during its servicing process.

1. Make sure the headquarters environment is available and not in Maintenance mode.
2. In LCS, on the environment details page, select **Environment features > Retail**.
3. On the Retail setup deployment page, select **Initialize**.
4. Select the version of the Commerce Scale Unit to initialize.
5. Select a region to initialize Commerce Scale Unit in.

Configure retail channels to use Commerce Scale Unit

1. After Commerce Scale Unit has been deployed, in the head office client go to **Retail and commerce > Retail Headquarters > Retail Scheduler setup > Channel database** to ensure that your retail channels are configured to use the database for this Commerce Scale Unit.
2. Go to each retail channel and select the Channel Profile for the corresponding Commerce Scale Unit.

Database refresh and Commerce Scale Units

Before you begin, make sure you are familiar with Steps to complete after a database refresh for environments that use Commerce functionality.

The scale unit channel database records (in the Channel Database form) cannot be moved across environments as part of database refresh. This is because the records represent environment specific configuration.

After database refresh, you can regenerate the scale unit's channel database record by issuing a re-deployment of your scale unit in LCS. Any deployment or servicing operation in the scale unit will attempt to register the scale unit with the headquarters, if the registration is detected as missing.

You can issue a re-deployment of the scale unit, without changing any components, by selecting to deploy the same version your scale unit is at already. This can be done in LCS by the following steps:

1. In LCS, on the environment details page, select **Environment features > Retail**.

2. On the setup deployment page, select the scale unit you would like to redeploy.
3. On the scale unit's operation menu, select **Update**.
4. On the slider, on the drop-down for **Select version**, pick the option **Specify a version**.
5. On the text box under **Specify a version**, type in the version shown for your scale unit, shown besides the **Current version** label.
6. Click on **Update** button.

You do not need to select **Update extensions**, even if you have applied extensions previously, since the last extension package applied to the scale unit is automatically picked when updating a scale unit.

If you have multiple scale units, you need to perform the operation above for each scale unit. You may perform these operations in parallel, if desired.

Deploy additional Commerce Scale Units (optional)

After you have initialized the first Commerce Scale Unit (CSU), if you require additional cloud scale units, enter a support request. In the support request, state the number of RCSUs needed, environment name, and desired regions.

For each additional RCSU that you deploy, it is also recommended that you create a separate channel database group for each RCSU. To do this, follow these steps:

1. In Commerce head office, go to **Retail and commerce > Retail Headquarters > Retail Scheduler setup > Channel database group**.
2. Create a new channel database group.
3. Go to the **Retail and commerce > Retail Headquarters > Retail Scheduler setup > Channel database** form and select the channel database that corresponds to the newly created RCSU.
4. Select **Edit** and select the new channel database group.
5. Select **Save**.
6. Select **Run Full data sync** for the selected channel database.

Additional considerations if you initialize cloud-hosted Commerce channel components in an existing environment

If you're already using cloud-hosted Commerce channel components in an environment, initialization of Commerce Scale Unit will help reduce the downtime when those components are updated. Additional planning is required before initialization of Commerce Scale Unit.

When you initialize your first Commerce Scale Unit in an environment that uses cloud-hosted Commerce channel components, the initialization process will migrate your channels associated to the cloud-hosted channel components to the first scale unit. Channels associated with Store Scale units are unaffected.

The migration process is transparent to the channels. After the scale unit initialization starts, the following operations are automatically performed:

1. A new Commerce Scale Unit will be created and associated with the environment.
2. The Commerce Scale Unit will be registered as an available Channel Database in the headquarters.
3. All channels mapped to the **Default** channel database in the headquarters will be updated to map to the new Commerce Scale Unit.
4. A Commerce Data Exchange (CDX) full data sync will be performed to bring the channel data to the new scale unit.

Planning and testing for Commerce Scale Unit initialization As a general rule, when initializing Commerce Scale Unit, you must plan for a five-hour downtime window for store operations as well as any e-

commerce channel operations that use Retail Server or Cloud Point of Sale.

1. Perform a database refresh from your production environment to a sandbox UAT environment.
2. Initialize Commerce Scale Unit in the sandbox UAT environment.
3. Note the initialization time to complete for Commerce Scale Unit. This will be comparable to the time this operation takes in your production environment, during which store operations and e-commerce operations will be unavailable.

You must perform the following additional steps before initializing Commerce Scale Unit.

- **Close all POS shifts** - After migration, POS users will be unable to close any shifts that were active during the migration process.
- **Validate that all P-jobs have been successfully completed** - It is recommended that P-jobs to synchronize pending transactions have completed before CSU is initialized.
- **Sign out of all POS device** - POS operations are not supported during migration.
- **Recall and void all suspended transactions at POS** - Suspended transactions are not preserved as part of the initialization.

> **IMPORTANT**
>
> As part of Commerce Scale Unit initialization, prior suspended transactions will be lost and cannot be recalled.

Here is what occurs during the initialization period:

- Cloud-hosted Commerce channels won't work, unless you turn on POS offline capability.
- POS devices with offline capability turned on will have reduced functionality.
- Any e-Commerce clients that depend on Retail Server will be disrupted.
- Channels that are hosted on Commerce Scale Units (self-hosted) won't be affected.
- Head office functionality is not affected.

Here is what occurs after initialization is completed:

- The device activation state of all activated POS devices is preserved, which means that the devices won't have to be reactivated.
- Stand-alone hardware station instances will continue to work.
- POS channel–side reports will be reset and won't show data from before the initialization.
- Show journal operation will also be reset and won't show data from before the initialization.

> **NOTE**
>
> Can you tell us about your documentation language preferences? Take a short survey.
>
> The survey will take about seven minutes. No personal data is collected (privacy statement).

Migrate channels to a different Commerce Scale Unit

2/18/2021 • 3 minutes to read • Edit Online

This topic explains how to migrate Microsoft Dynamics 365 Commerce store channels from the Commerce Scale Unit (CSU) that they are currently working with to a different CSU. You might want to migrate channels to a different CSU for better load isolation and resource governance between channels, to reduce latency to your stores, or to manage different update/extension deployment schedules for staged roll-out and pilots. Migration to a different CSU involves downtime for the channels.

This topic describes best practices that will help you minimize business disruption and downtime while you migrate channels. It applies to the migration of channels between cloud-hosted CSUs, between self-hosted CSUs, from cloud-hosted CSUs to self-hosted CSUs, and from self-hosted CSUs to cloud-hosted CSUs.

> **NOTE**
> If you migrate channels between CSUs, temporary sales data that was used for journal records and point of sale (POS) reports before the migration will no longer be available at the POS after migration. After the migration is completed, journals and channel reports will be started afresh by using new data.

In the following procedures, the terms *origin* and *destination* are used to distinguish the CSUs and corresponding channel databases that are involved in the migration.

Planning for downtime

When you follow the procedures that are described in this topic, all long-running system processes that are involved are run before the actual migration, while the stores are still operational. These processes including synchronization of master data for products, prices, and customers. Then, during the migration, the critical period when you must take planned downtime in your environment involves data synchronization of a very small payload of channel configuration data to the new CSU. In most cases, this synchronization can be completed in under 10 minutes. However, from an operational perspective, you must plan for a longer downtime window to ensure that all prerequisite steps have enough time to be completed. These steps include closing all shifts, syncing transactions to Commerce headquarters, and posting statements. The amount of time that is required will vary by organization.

Prerequisites

First, complete all the following procedures in a sandbox user acceptance testing (UAT) environment. Then repeat them in your production environment. In this way, you can measure and estimate the downtime that you should expect in the production environment.

Migration

Configure data synchronization

The following steps can be completed while the stores are still operational. They synchronize master data to the destination CSU.

1. In Commerce headquarters, on the **Channel database** page, select the record for the channel database for the destination CSU.

2. Add the desired channels to the destination channel database.
3. Select **Full data sync**, and specify that job **9999** (**All jobs**) should be used.

> **NOTE**
> If your destination CSU is self-hosted, consider creating separate channel database groups to reduce the volume of unnecessary master data synchronization.

Prepare for migration

This procedure and the next procedure must be completed during the planned downtime for your channels.

1. On all POS devices, make sure that all shifts are closed.
2. Sign out of all POS devices.
3. Confirm that all POS offline transactions are synced to Commerce headquarters. Run P-jobs for all existing channel databases that will be migrated. If you start the migration before P-jobs are completed, and if you use Cloud POS, you might lose transactions because of duplicate transaction numbers.
4. Confirm that all statements are posted.

Migrate channels to a new CSU

1. On the **Store details** page, set the **Live channel database** field to the destination CSU database.
2. Set the **Channel profile** field to the channel profile that is associated with the destination CSU.
3. On the **Distribution schedule** page, run job **1070** (**Channel configuration job**) and job **1110** (**Global configuration job**). Select **Run now** for each job. (For asynchronous processing, select **Create batch job** instead of **Run now**.) After the jobs are completed, your channels have been migrated to the new CSU.
4. If you're using Cloud POS, you must use the URL of Cloud POS for the new CSU and reactivate the POS device. If you reactivate the POS device before all P-jobs on the origin channel database are completed, you might lose transactions because of duplicate transaction numbers.

   If you're using Modern POS, close each POS device, reopen it, and sign in.

Post-migration

You can continue to use the origin CSU to serve other channels.

> **NOTE**
> Do not delete the origin CSU. Doing so may make the store unoperable.

After you've completed all the procedures in a sandbox UAT environment, repeat them in your production environment.

Commerce data residency

2/18/2021 • 2 minutes to read • Edit Online

Choose a region

When you initialize a Commerce Scale Unit (cloud), you need to select a data center location to host. To minimize network latency and improve performance, you should choose a datacenter location that is in proximity to the channels that you plan to serve using the RCSU. To reference approximate locations of each datacenter, see Azure regions. You can also reference a web-based utility, such as Azure speed reference, and measure latency to Azure datacenters from each store location. This can help you to make the right choice of datacenter when you initialize the RCSU.

Data between regions

If you initialize RCSU in a data center that is different than where your head office is located, the data will travel between these data centers with periodic synchronization. The system is pre-configured to transfer specific types of data. You can modify this configuration to synchronize different data.

To view the data synchronization configuration, go to **Retail and Commerce** > **Headquarters setup** > **Commerce scheduler** > **Scheduler jobs** to view the data synchronization jobs and sub-jobs. To view the fields being synchronized, click through a sub-job.

Synchronize specific segments of records

You can configure Commerce Data Exchange (CDX) so that only specific segments of records are synchronized to specific RCSUs.

Prerequisites

Before you configure the record segments that will be synchronized, you need to configure Channel database groups. These database groups must be configured for each CSU where you want to synchronize segmented data. All CSUs in the same Channel database group receive the data that is needed to serve all the channels in that CSU. You will need to create a separate database group for each CSU channel database where you plan to synchronize segmented data. To do this, perform the following steps:

1. Go to **Retail and Commerce** > **Headquarters setup** > **Commerce scheduler** > **Channel database group**.
2. Create a new database group for each CSU where you want to synchronize segmented data.
3. Go to **Retail and Commerce** > **Retail and Commerce IT** > **Distribution schedule**.
4. Add the newly created Channel database group to each scheduler job.
5. Go to **Retail and Commerce** > **Headquarters setup** > **Commerce scheduler** > **Channel database**.
6. Select the Channel database for the corresponding Commerce Scale Unit (cloud).
7. Select **Edit** and choose the channel database group that you created in step 2.
8. Select **Save**.
9. Select **Full data sync for all jobs** for the selected channel database.

Available controls for synchronizing segments of data to different RCSUs

Channel configuration data will only be synchronized for channels that are served by specific RCSUs. For example, only the channel configuration data for channels that are configured to be served by the West Europe channel will be synchronized to that RCSU.

Using assortments, product and pricing related data can be segmented by specific channels. For example, if your stores in North America only sell women's shoes and your stores in West Europe only sell sporting goods, you can use Assortments to segment this data. When data is synchronized to RCSU, women's shoes data will only be synchronized to the North America RCSU and sporting goods data will only be synchronized to the West Europe RCSU.

Customer and employee records are configured using the Global Address Book, which can be configured for specific channels. For example, you can configure separate address books for customers and employees for channels served by the West Europe RCSU and those for North America RCSU.

On-premises deployment home page

2/18/2021 • 2 minutes to read • Edit Online

You can deploy Dynamics 365 Finance + Operations (on-premises). When you choose an on-premises deployment type, the system requirements, hardware sizing, and functionality differ from a cloud deployment. This topic provides links to content that contains information specific to on-premises deployments.

Get started

- On-premises deployment overview
- Plan and prepare for on-premises deployments
- System requirements for on-premises deployments
- Hardware sizing requirements for on-premises environments
- Buy Finance + Operations (on-premises)
- Comparison of cloud and on-premises features

Onboard

- Set up on-premises projects in Lifecycle Services (LCS)
- Set up and deploy on-premises environments (Platform update 12 and later)
- Install network printer devices in on-premises environments
- Configure SQL Server Reporting Services for on-premises deployments
- Develop and deploy custom models to on-premises environments

Work in your on-premises deployment

- Configure document management
- Import Electronic reporting (ER) configurations
- Document generation, publishing, and printing in on-premises deployments
- Configure proxies for on-premises environments
- Set up technical support for Finance and Operations apps
- Client internet connectivity
- Apply updates to on-premises deployments
- Redeploy on-premises environments
- Reuse the same AD FS instance for multiple environments

Commerce

- Commerce capabilities that are available in on-premises deployments
- Installation steps for Retail channel components in an on-premises environment
- Configure, install, and activate Modern POS (MPOS)
- Configure and install Commerce Scale Unit

Upgrade

- In-place upgrade process for on-premises environments

Other resources

- Troubleshoot on-premises deployments
- Scripts for resolving issues in on-premises environments
- Certificate rotation
- On-premises diagnostics
- Removed or deprecated features for Finance and Operations
- Software lifecycle policy and on-premises releases

On-premises deployment overview

2/18/2021 • 2 minutes to read • Edit Online

Microsoft Dynamics 365 Finance + Operations (on-premises) supports running business processes in customer data centers. With this deployment option, application servers and the Microsoft SQL Server database will run in the customer's data center. Customers and partners will utilize Microsoft Dynamics Lifecycle Services (LCS) to manage their on-premises deployments. LCS is an application management portal that provides tools and services for managing the application lifecycle of your implementations in the cloud and on-premises. LCS features, such as business process modeling, software deployment and patching, and monitoring and diagnostics, are used to help support on-premises deployments.

> **IMPORTANT**
>
> Dynamics 365 Finance + Operations (on-premises) is not supported on any public cloud infrastructure, including Azure.

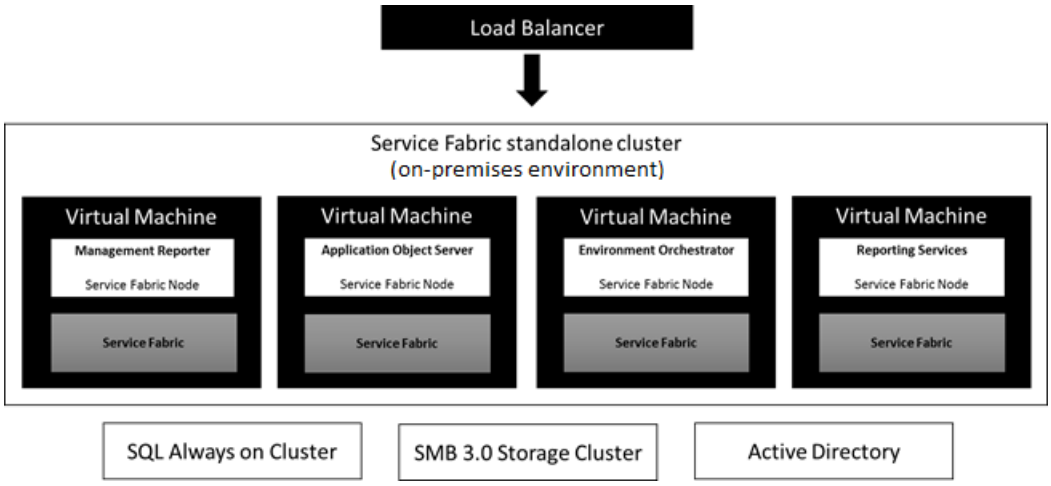
Architecture

The on-premises deployment option uses cloud components running on-premises using Microsoft Azure Server Service Fabric standalone clusters. Service Fabric is the next-generation Microsoft middleware platform for building and managing enterprise-class high-scale applications. Service Fabric standalone clusters can be deployed on any computer that is running Windows Server.

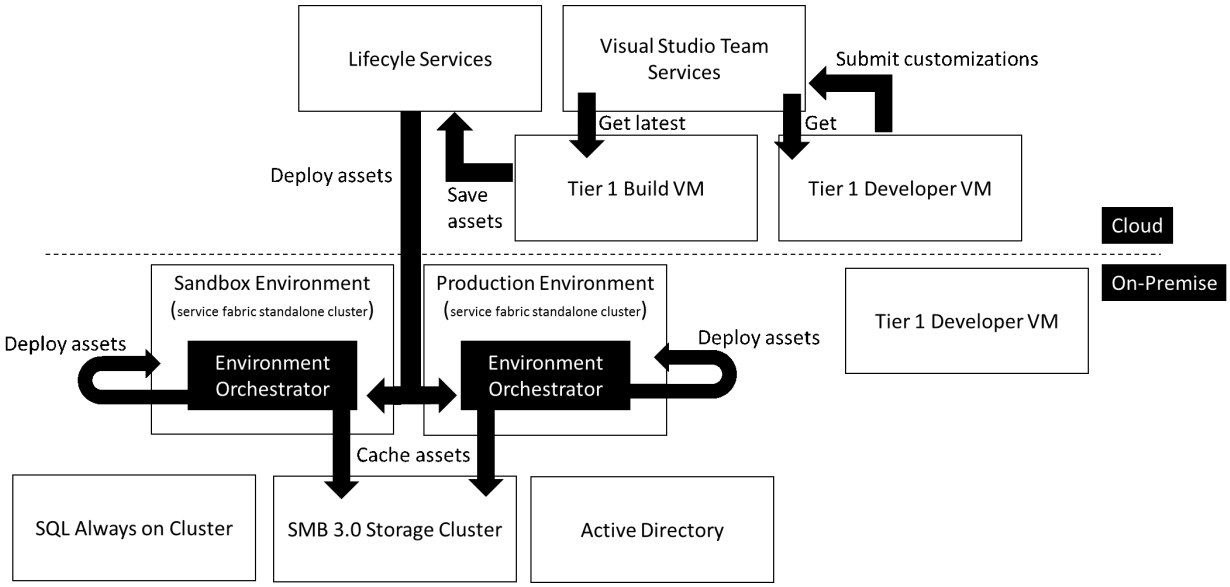
On-premises deployment defines two types of Service Fabric standalone clusters: clusters for production environments and clusters for sandbox environments. The following roles or node types are deployed into both types of clusters:

- Application Object Servers (AOS) – Provides the ability to run the application functionality in client, batch, and import/export scenarios.
- Management Reporter (MR) – Provides financial reporting functionality.
- SQL Server Reporting Services (SSRS) – Provides document reporting functionality.
- Environment Orchestrator – Enables on-premises environment management from LCS.

Figure 1 shows a logical diagram of the node types deployed in a Service Fabric standalone cluster.



Application lifecycle management for on-premises deployments is orchestrated through LCS. Customers can use the proven tools and methodologies in LCS to help manage their on-premises deployments (Figure 2). The development experience continues to be the same as in cloud deployments through 1-box VHDs.



Data storage

The on-premises deployment option stores core customer data on-premises. Core customer data is a subset of the customer data definition provided in the Microsoft Trust Center. Table 1 outlines the categories of customer data that are stored in Microsoft Azure data centers located in the United States by services such as LCS, Azure Active Directory, and Microsoft Office signup portal. All other customer data, referred to as core customer data, is stored on-premises.

Table 1: Customer data stored in Microsoft Azure data centers located in the United States by services supporting on-premises environments. These services enable initial onboarding, initiation, and tracking of support incidents, and service updates and upgrades.

SUPPORTING SERVICES	CUSTOMER DATA DEFINITION
Microsoft Dynamics Lifecycle Services	Project content and files are stored in a project. This includes application configuration data, code, metadata, and data assets that comprise the application and business process models. Also included is anonymized user activity logs and information that is collected during the onboarding process.
Microsoft Office signup portal	Customer information that is collected during the onboarding process.
Microsoft Azure Active Directory	Authentication for LCS and Azure DevOps.

Additional services or components can be configured to extend an on-premises deployment as needed; however, configuration choices may cause core customer data to be transferred outside of the customer's data center. For example, configuring data management features that are used to integrate external services with an on-premises deployment may result in the transfer of core customer data outside the on-premises deployment.

Plan and prepare for on-premises deployments

2/18/2021 • 12 minutes to read • Edit Online

Dynamics 365 Finance + Operations (on-premises) supports running business processes in customer data centers. With this deployment option, application servers and the Microsoft SQL Server database will run in the customer's data center.

This topic will help you plan and prepare for your on-premises deployment.

> **IMPORTANT**
> Dynamics 365 Finance + Operations (on-premises) is not supported on any public cloud infrastructure, including Azure.

Differences between cloud deployments and on-premises deployments

The features in cloud deployments and on-premises deployments differ. These differences will affect your planning. The differences are described in the following topics:

- Deployment options
- Comparison of cloud and on-premises features
- Removed or deprecated features for Finance and Operations

How LCS is used with on-premises deployments

Microsoft Dynamics Lifecycle Services (LCS) is an application management portal that provides tools and services for managing the application lifecycle. Customers and partners use LCS to manage both cloud and on-premises deployments. You can use LCS for the following tasks:

- Deploy cloud and on-premises environments.
- Service your environments.
- Monitor, diagnose, and analyze the health of the environments that you manage (cloud only).
- Search for product issues and regulatory features.
- Obtain support.

For more information about LCS, see Lifecycle Services resources.

Environments

There are four types of environments that you need to plan for. This section describes the four environments and how to access and deploy them.

Demo environment

You can sign up for a demo environment to learn about the system. The demo environment is applicable to both cloud and on-premises deployments. For more information, see Sign up for preview subscriptions.

Developer environment

The development experience is the same for cloud and on-premises deployments. To access a developer environment, see Deploy and access development environments.

Sandbox environment

Business users and functional team members validate application functionality by using a sandbox environment. This functionality includes customizations and data that was brought forward from Microsoft Dynamics AX 2012 environments. To deploy an on-premises sandbox environment, see Set up and deploy on-premises environments home page.

At a minimum, an on-premises sandbox environment requires:

- 3 machines running Environment Orchestrator
- 2 machines running Application Object Servers (AOS)
- 1 machine running Management Reporter (MR)
- 1 machine running SQL Server Reporting Services (SSRS)
- 1 machine running Active Directory
- 1 machine running SQL Server

Production environment

The production environment is the live deployment that your users and customers have access to. To deploy a production environment, see Set up and deploy on-premises environments home page.

At a minimum, an on-premises production environment requires:

- 3 machines running Environment Orchestrator
- 3 machines running Application Object Servers (AOS)
- 1 machine running Management Reporter (MR)
- 1 machine running SQL Server Reporting Services (SSRS)
- 2 or more machines running SQL Server
- 2 or more machines running Active Directory

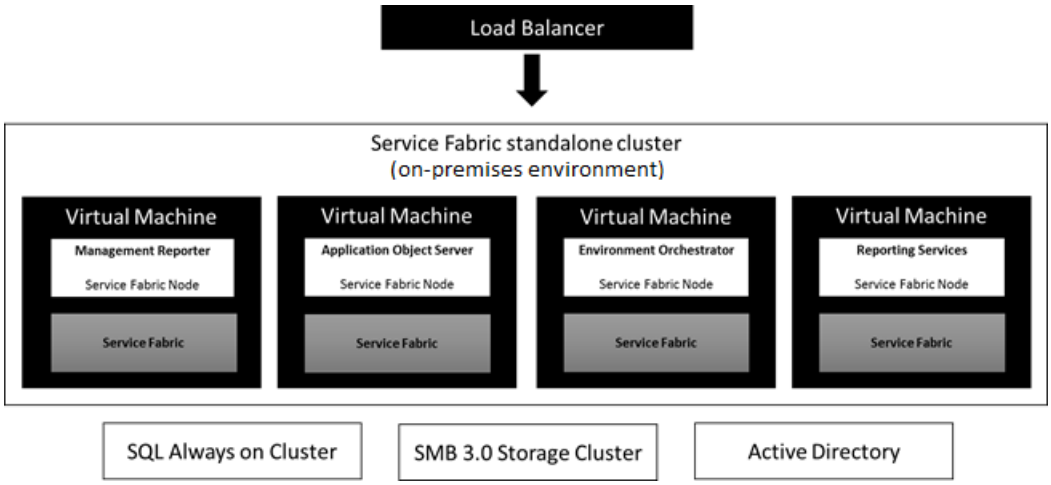
Service Fabric

An on-premises deployment uses Azure Service Fabric standalone clusters. Service Fabric is the next-generation Microsoft middleware platform for building and managing enterprise-class, high-scale applications. Service Fabric standalone clusters can be deployed on any computer that is running Windows Server.

An on-premises deployment has a standalone cluster for each sandbox environment and a standalone cluster for each production environment. The following roles or node types are deployed into both types of clusters:

- Application Object Servers (AOS) – Provides the ability to run the application functionality in client, batch, and import/export scenarios.
- Management Reporter (MR) – Provides financial reporting functionality.
- SQL Server Reporting Services (SSRS) – Provides document reporting functionality.
- Environment Orchestrator – Enables on-premises environment management from LCS.

The following diagram shows the node types deployed in a Service Fabric standalone cluster.



Service Fabric resources

To learn more about Service Fabric, see the following topics:

- Azure Service Fabric documentation - To learn more about Service Fabric.
- Service Fabric application upgrade - An Azure Service Fabric application is a collection of services that requires periodic upgrades.
- Plan and prepare your Service Fabric standalone cluster deployment - Additional information about Service Fabric clusters and antivirus exclusions.

System requirements

Review the system requirements in System requirements for on-premises deployments and be aware of the number of machines that are required for on-premises deployments.

Hardware sizing

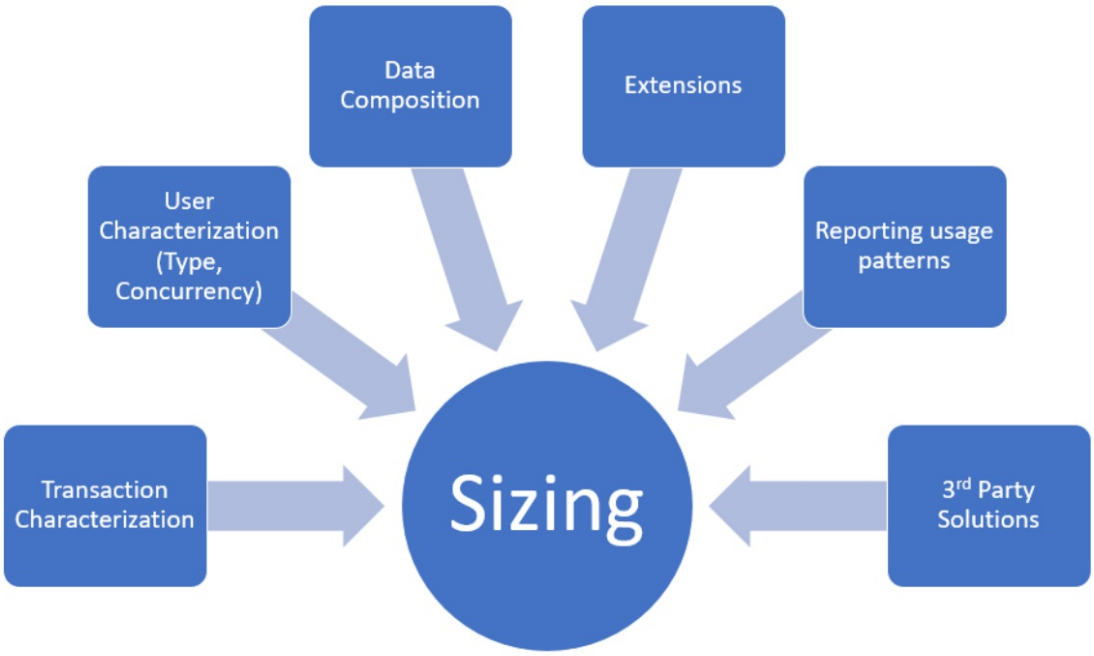
Before you begin the hardware and infrastructure sizing process for an on-premises environment, familiarize yourself with the System requirements for on-premises deployments and Set up and deploy on-premises environments home page to gain a solid understanding of the underlying infrastructure. Pay close attention to the system setup best practices for optimum performance. After you have reviewed the documentation, you can start the process of estimating your transactional and concurrent user volume and sizing your environment based on the average core throughput.

Factors that affect sizing

The core factors that affect sizing are:

- Transaction characterization
- User characterization - Type and concurrency
- Data composition
- Extensions
- Reporting usage patterns
- Third-party solutions

The more detailed data that you collect, the more precisely you can estimate sizing. Hardware sizing, without supporting data, is likely to be inaccurate. The minimum data that you need to collect is the peak transaction line load per hour. The factors that affect sizing are shown in the following diagram.



From left to right, the first and most important factor needed to accurately estimate sizing is a transaction profile or a transaction characterization. It's important to find the peak transactional volume per hour. If there are multiple peak periods, then these periods need to be accurately defined.

As you understand the load that impacts your infrastructure, you also need to understand more detail about these factors:

- **Transactions** – Transactions typically have certain peaks throughout the day or week. The peaks might depend on the transaction type. For example, time and expense entries usually show peaks once per week, while sales orders might arrive in bulk via integration or trickle in during the day.
- **Number of concurrent users** – The number of concurrent users is the second most important sizing factor. You cannot get reliable sizing estimates based only on the number of concurrent users. If concurrent users is the only data that you have available, then estimate an approximate number for transactions, and revisit this when you have more data. An accurate concurrent user definition means that:
  - Named users are not concurrent users.
  - Concurrent users are always a subset of named users.
  - Peak workload defines the maximum concurrency for sizing. For concurrent users, the user must meet all the following criteria:
    - The user is logged on.
    - There are working transactions or inquiries at the time of counting.
    - The session is not idle.
- **Data composition** – Data composition is how your system will be set up and configured. For example, this can include the number of legal entities, the number items, the number of BOM levels, and how complex the security setup will be. Each of these factors might have an impact on performance, however the impact can be offset by using smart choices when it comes to infrastructure.
- **Extensions** – Customizations can be simple or complex. The number of customizations and the nature of complexity and usage has a varied impact on the size of the infrastructure needed. For complex customizations, you should conduct performance evaluations to ensure that they are not only tested for efficiency but also help understand the infrastructure needs. This is even more critical when the extensions are not coded according to best practices for performance and scalability.
- **Reporting and analytics** – Reporting and analytics typically include running heavy queries against the database systems. Reducing the frequency of when data intensive reports run will help reduce their impact. It's also important to understand how the design of your queries impacts their performance.

- **Third-party solutions** – These solutions, like ISVs, have the same implications and recommendations as extensions.

Sizing your environment

To determine your sizing requirements, you must know the peak volume of transactions that you need to process. Most auxiliary systems, like Management Reporter or SSRS, are less mission critical. As a result, this topic focuses primarily on AOS and SQL Server.

In general, the compute tiers scale out and should be set up in an N+1 fashion, meaning if you estimate three AOS, add a fourth AOS. The database tier should be set up in an Always On highly-available setup.

SQL Server (OLTP)

Sizing

- 3K to 15K transaction lines per hour per core on DB server.
- Typical AOS-to-SQL core ratio 3:1 for the primary SQL Server. Additional cores are required based on the high-availability configuration.
  - Processing database-heavy operations may regress this to 2:1.
- The following factors influence variations:
  - Parameter settings in use.
  - Levels of extensions.
  - Additional functionality usage, such as database logs and alerts. Extreme database logging will further reduce throughput per hour per core below 3K lines.
  - Complexity of data composition. For example, a simple chart of accounts versus a detailed fine-grained chart of accounts has implications on throughput.
  - Transaction characterization.
  - 2 GB to 4 GB memory for each core.
  - Auxiliary databases on DB server such as Management reporter and SSRS databases.
  - Temp DB = 15% of DB size, with as many files as physical processors.
  - SAN size and throughput based on total concurrent transaction volume/usage.

High availability

You should always utilize SQL Server in either a cluster or mirroring setup. The second SQL node should have the same number of cores as the primary node.

Active Directory Federation Services (AD FS)

For AD FS sizing, see the AD FS Server Capacity documentation. A sizing spreadsheet is available for planning the number of instances in your deployment.

AOS (Online and batch)

Sizing

- Sizing by transaction volume/usage
  - 2K to 6K lines per core
  - 16 GB per instance
  - Standard box – 4 to 24 cores
  - 10 to 15 Enterprise users per core
  - 15 to 25 Activity users per core
  - 25 to 50 Team members per core
- Batch
  - 1 to 4 batch threads per core
  - Size based on batch window characterization
- Note that AOS, Data Management, and Batch are the same role in the Service Fabric. You need to size for

these three workloads combined, and not separately as you did with Microsoft Dynamics AX 2012.

- The same variability factors for SQL Server apply here.

High availability

- Ensure that you have at least 1 to 2 more AOS available than you estimate.
- Ensure that you have at least 3 to 4 virtual hosts available.

Management reporter

In most cases, unless used extensively, the recommended minimum requirements using two nodes should work well. Only in cases where there is heavy use will you need more than two nodes, after which you can scale as needed.

SQL Server Reporting Services

For the current release of Finance + Operations, only one SSRS node can be deployed. Monitor your SSRS node while testing and increase the number of cores available for SSRS as needed. Make sure that you have a preconfigured secondary node available on a virtual host that is different than the SSRS VM. This is important if there is an issue with the virtual machine that hosts SSRS or the virtual host. If this the case, the node would need to be replaced.

Environment Orchestrator

The Orchestrator service is the service that manages your deployment and the related communication with LCS. This service is deployed as the primary Service Fabric service and requires at least three VMs. This service is co-located with the Service Fabric orchestration services. This should be sized to the peak load of the cluster. For more information, see Plan and prepare your Service Fabric Standalone cluster deployment.

Virtualization and oversubscription

Mission critical services like the AOS should be hosted on Virtual hosts that have dedicated resources – core, memory, and disk.

Authentication methods

The following authentication methods are used with on-premises deployments:

- **Azure Active Directory (Azure AD)** - Azure AD is the authentication method used to log in to LCS. Azure AD is used configure the LCS Local Agent. For more information, see What is Azure Active Directory?
- **Active Directory Domain Services (AD DS)** - The machines that host Finance + Operations components must belong to an Active Directory domain. You must configure Active Directory Domain Services (AD DS) in native mode. For more information, see Active Directory Domain Services.
- **Active Directory Federation Services (AD FS)** - AD FS is the authentication method used in an on-premises deployment. AD FS provides access control and single sign on across a wide variety of applications including Microsoft 365, cloud-based SaaS applications, and applications on the corporate network.
  - For the IT organization, it enables you to provide sign on and access control to both modern and legacy applications, on-premises and in the cloud, based on the same set of credentials and policies.
  - For the user, it provides seamless sign on using the same, familiar account credentials.
  - For the developer, it provides an easy way to authenticate users whose identities live in the organizational directory. This means you can focus your efforts on your application, not authentication or identity.

    For more information, see Active Directory Federation Services.

Data stored in Azure data centers

The on-premises deployment option for Finance + Operations stores core customer data on-premises. Core customer data is a subset of the customer data definition provided in the Microsoft Trust Center.

The following table outlines the services that are used to store customer data in Azure data centers located in the United States. Services include Lifecycle Services (LCS), Microsoft Office signup portal, and Azure Active Directory. These services enable initial onboarding, initiation, tracking of support incidents, and service updates and upgrades. All other customer data, referred to as core customer data, is stored on-premises.

SUPPORTING SERVICES	CUSTOMER DATA DEFINITION
Microsoft Dynamics Lifecycle Services	Project content and files are stored in a project. This includes application configuration data, code, metadata, and data assets that include the application and business process models.
Microsoft Office signup portal	Customer information that is collected during the onboarding process.
Microsoft Azure Active Directory	Authentication for LCS and Azure DevOps.

Additional services or components can be configured to extend an on-premises deployment as needed; however, configuration choices may cause core customer data to be transferred outside of the customer's data center. For example, configuring data management features that are used to integrate external services with an on-premises deployment may result in the transfer of core customer data outside the on-premises deployment.

Next steps

After you've completed the planning activities mentioned in this topic, you can begin the procedures listed in the Onboard section of the On-premises deployment home page.

Be sure to refer to the On-premises deployment home page throughout your implementation for more information about planning, deployment, maintenance, and troubleshooting.

Hardware sizing requirements for on-premises environments

2/18/2021 • 6 minutes to read • Edit Online

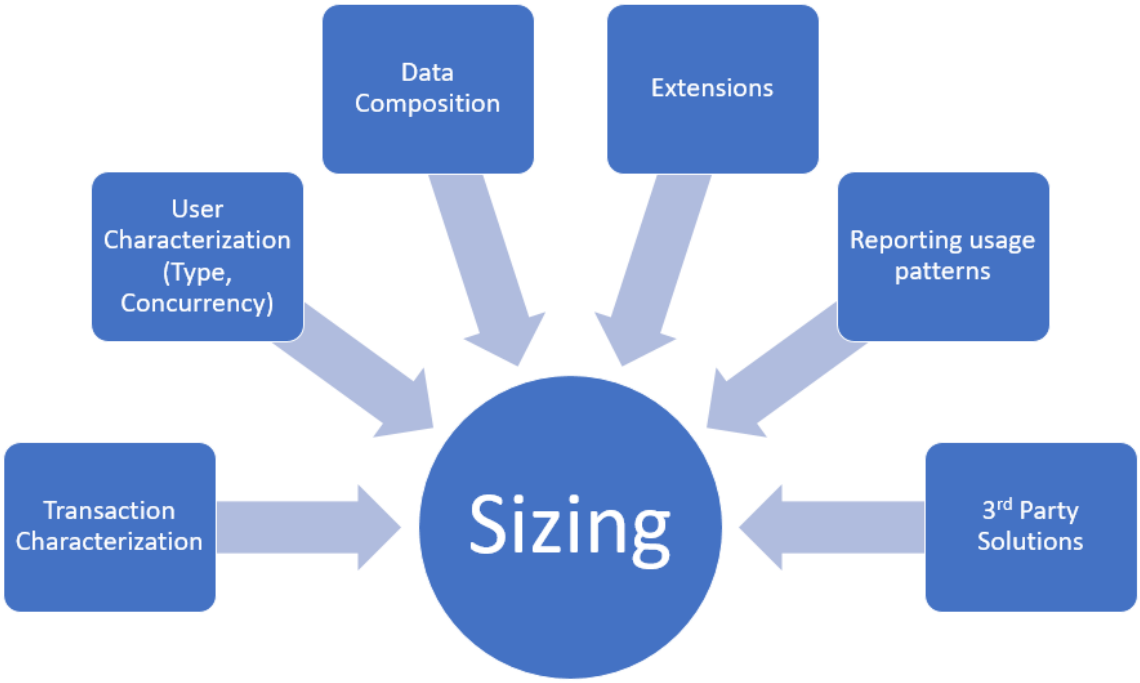
Before you begin the hardware and infrastructure sizing process for an on-premises environment, familiarize yourself with the System requirements for cloud deployments and Setup and deployment instructions to gain a solid understanding off the underlying infrastructure.

> **NOTE**
> Pay close attention to the system setup best practices for optimum performance.

After you have reviewed the documentation, you can start the process of estimating your transactional and concurrent user volume and sizing your environment based on the average core throughput.

Factors that affect sizing

All the factors shown in the following illustration contribute to sizing. The more detailed information that is collected, the more precisely you can determine sizing. Hardware sizing, without supporting data, is likely to be inaccurate. The absolute minimum requirement for necessary data is the peak transaction line load per hour.



Viewed from left to right, the first and most important factor needed to accurately estimate sizing is a transaction profile or a transaction characterization. It's important to always find the peak transactional volume per hour. If there are multiple peak periods, then these periods need to be accurately defined.

As you understand the load that impacts your infrastructure, you also need to understand more detail about these factors:

- **Transactions** – Typically transactions have certain peaks throughout the day/week. This mostly depends

on the transaction type. Time and expense entries usually show peaks once per week, whereas Sales order entries often come in bulk via integration or trickle in during the day.

- **Number of concurrent users** – The number of concurrent users is the second most important sizing factor. You cannot reliably get sizing estimates based on the number of concurrent users, so if this is the only data you have available, estimate an approximate number, and then revisit this when you have more data. An accurate concurrent user definition means that:
  - Named users are not concurrent users.
  - Concurrent users are always a subset of named users.
  - Peak workload defines the maximum concurrency for sizing.

  Criteria for concurrent users is that the user meets all the following criteria:
  - Logged on.
  - Working transactions/inquiries at the time of counting.
  - Not an idle session.
- **Data composition** – This is mostly about how your system will be set up and configured. For example, how many legal entities you will have, how many items, how many BOM levels, and how complex your security setup will be. Each of those factors may have a small impact on performance, so these factors can be offset by using smart choices when it comes to infrastructure.
- **Extensions** – Customizations can be simple or complex. The number of customizations and the nature of complexity and usage has a varied impact on the size of the infrastructure needed. For complex customizations, it's advised to conduct performance evaluations to ensure that they are not only tested for efficiency but also help understand the infrastructure needs. This is even more critical when the extensions are not coded according to best practices for performance and scalability.
- **Reporting and analytics** – These factors typically include running heavy queries against the various databases in the system. Understanding and reducing the frequency when expensive reports run will help you understand the impact of them.
- **Third-party solutions** – These solutions, like ISVs, have the same implications and recommendations as extensions.

Sizing your environment

To understand your sizing requirements, you need to know the peak volume of transactions that you need to process. Most auxiliary systems, like Management Reporter or SSRS, are less mission critical. As a result, this document focuses mostly on AOS and SQL Server.

> **NOTE**
>
> In general, the compute tiers scale out and should be set up in an N+1 fashion, meaning if you estimate three AOS, add a fourth AOS. The database tier should be set up in an Always On highly-available setup.

SQL Server (OLTP)

Sizing

- 3K to 15K transaction lines per hour per core on DB server.
- Typical AOS-to-SQL core ratio 3:1 for the primary SQL Server. Additional cores are required based on the chosen high availability configuration.
  - Processing database-heavy operations may regress this to 2:1.

- The following factors influence variations:
    - Parameter settings in use.
    - Levels of extensions.
    - Usage of additional functionality, such as database log and alerts. Extreme database logging will further reduce throughput per hour per core below 3K lines.
    - Complexity of data composition – A simple chart of accounts versus a detailed fine-grained chart of accounts has implications on throughput (as an example).
    - Transaction characterization.
    - 2 GB to 16 GB memory for each core.
    - Auxiliary databases on DB server such as Management reporter and SSRS databases.
    - Temp DB = 15% of DB size, with as many files as physical processors.
    - SAN size and throughput based on total concurrent transaction volume/usage.

High availability

We recommend always utilizing SQL Server in either a cluster or mirroring setup. The second SQL node should have the same number of cores as the primary node.

Active Directory Federation Services (AD FS)

For AD FS sizing, see the AD FS Server Capacity documentation.

A sizing spreadsheet is available for planning the number of instances in your deployment.

AOS (Online and batch)

Sizing

- Sizing by transaction volume/usage
    - 2K to 6K lines per core
    - 16 GB per instance
    - Standard box – 4 to 24 cores
    - 10 to 15 Enterprise users per core
    - 15 to 25 Activity users per core
    - 25 to 50 Team members per core
- Batch
    - 1 to 4 batch threads per core
    - Size based on batch window characterization
- Note that the AOS, Data Management, and Batch are on the same role in the Service Fabric. You need to size for these three workloads combined, and not separate these like in Microsoft Dynamics AX 2012.
- The same variability factors for SQL Server apply here.

High availability

- Ensure that you have at least 1 to 2 more AOS available than you estimate.
- Ensure that you have at least 3 to 4 virtual hosts available.

Management reporter

In most cases, unless used extensively, the recommended minimum requirements using two nodes should work well. Only in cases where there is heavy use will you need more than two nodes. Please scale as needed.

SQL Server Reporting Services

For the general availability release, only one SSRS node can be deployed. Monitor your SSRS node while testing and increase the number of cores available for SSRS on a need basis. Make sure that you have a preconfigured secondary node available on a virtual host that is different than the SSRS VM. This is important if there is an issue with the virtual machine that hosts SSRS or the virtual host. If this the case, they would need to be replaced.

Environment Orchestrator

The Orchestrator service is the service that manages your deployment and the related communication with LCS. This service is deployed as the primary Service Fabric service and requires at least three VMs. This service is co-located with the Service Fabric orchestration services. This and should be sized to the peak load of the cluster. For more information, see Plan and prepare your Service Fabric Standalone cluster deployment.

Virtualization and oversubscription

Mission critical services like the AOS should be hosted on Virtual hosts that have dedicated resources – cores, memory, and disk.

Authentication in Dynamics 365 Finance + Operations (on-premises)

2/18/2021 • 4 minutes to read • Edit Online

This topic explains authentication in Dynamics 365 Finance + Operations (on-premises). This topic also provides background information about how the process works so that if you encounter issues with authentication you can work to resolve them.

The URL for Active Directory Federation Services (AD FS)

The first part of the authentication process is to provide the URL for Active Directory Federation Services (AD FS). This URL will be similar to: `https://adfs.contoso.com/adfs/.well-known/openid-configuration`

You'll find this URL in the deployment instructions found in Configure AD FS. During deployment, the URL is used to set various options in the AOS startup variables of each AOS instance. These startup variables reside in an .XML config file located in a Service Fabric directory. This directory will vary from machine to machine, but the path should look similar to:

C:\ProgramData\SF\AOS_10\Fabric\work\Applications\AXSFType_App218\AXSF.Package.1.0.xml

XML configuration file

There is a file called AXSF.Package.Current.xml. This file will be a copy of the AXSF.Package.1.0.xml in Finance and Operations deployments. The AXSF.Package.Current.xml file represents the variable that have been used to initialize the currently running AOS instance (AxService.exe).

Within this configuration file (which is on each AOS machine), you'll find some sections that are set from the Lifecycle Services (LCS) deployment setting for AD FS.

```
<Section Name="Aad">
    <Parameter Name="AADIssuerNameFormat" Value="http://ADFS.contoso.com/{0}/services/trust" />
    <Parameter Name="AADLoginWsfedEndpointFormat" Value="https://ADFS.contoso.com/{0}/wsfed" />
    <Parameter Name="AADMetadataLocationFormat" Value="https://ADFS.contoso.com/FederationMetadata/2007-
06/FederationMetadata.xml" />
    <Parameter Name="AADTenantId" Value="adfs" />
    <Parameter Name="AADValidAudience" Value="https://ax.contoso.com/" />
    <Parameter Name="ACSServiceEndpoint" Value="https://accounts.accesscontrol.windows-
ppe.net/tokens/OAuth/2" />
    <Parameter Name="ACSServicePrincipal" Value="00000001-0001-0000-c000-000000000000" />
    <Parameter Name="ADFSEndpoint" Value="https://ADFS.contoso.com/adfs" />
    <Parameter Name="ADFSIdentifier" Value="http://ADFS.contoso.com/adfs/services/trust" />
    <Parameter Name="FederationMetadataLocation" Value="https://ADFS.contoso.com/FederationMetadata/2007-
06/FederationMetadata.xml" />
    <Parameter Name="Realm" Value="spn:00000015-0000-0000-c000-000000000000" />
    <Parameter Name="TenantDomainGUID" Value="adfs" />
    <Parameter Name="TrustedServiceAppIds" Value="913c6de4-2a4a-4a61-a9ce-945d2b2ce2e0" />
</Section>
```

You will also find the following sections.

```
<Section Name="OfficeApps">
    <Parameter Name="AppInsightsKey" Value="" />
    <Parameter Name="AuthClientId" Value="d8230a86-015d-4c14-bcd6-c7fb65176b16" />
</Section>
<Section Name="OpenIDConnect">
    <Parameter Name="ClientID" Value="d8230a86-015d-4c14-bcd6-c7fb65176b16" />
    <Parameter Name="Metadata" Value="https://ADFS.contoso.com/adfs/.well-known/openid-configuration" />
</Section>
<Section Name="Provisioning">
    <Parameter Name="AdminIdentityProvider" Value="http://ADFS.contoso.com/adfs/services/trust" />
    <Parameter Name="AdminPrincipalName" Value="axserviceuser@contoso.com" />
</Section>
```

NOTE

The settings shown above represent a deployment configured with Microsoft 365 compatibility. For more information, see AD FS Microsoft 365 compatibility.

Configuration values used by the AOS

The AOS uses the configuration values above to determine where to redirect an unauthenticated request when a user sends a request to the application URL.

1. Request is sent by the browser to the application URL (`https://ax.contoso.com/namespaces/AXSF/`).
2. The request is processed by the Gateway and gets forwarded to an AOS node that accepts interactive sessions.
3. The request reaches the AOS server and checks for the authentication cookies.
4. No authentication is present so the AOS server returns a redirect request for the user to authenticate with AD FS. At this point, the AOS also sets an affinity cookie to bind the user session to that AOS.
5. The Gateway receives the response and forwards it back to the browser.
6. The browser receives the redirect request and displays the AD FS authentication page so the user signs in.
7. When successfully authenticated against AD FS, the AD FS then redirects the user back to the application URL and provides the authentication cookies.
8. The Gateway receives this response and forwards the affinitized request to the appropriate AOS node.
9. The AOS checks the authentication information provided and checks against the **UserInfo** table to determine whether the user is allowed to access the application and which permissions are available.

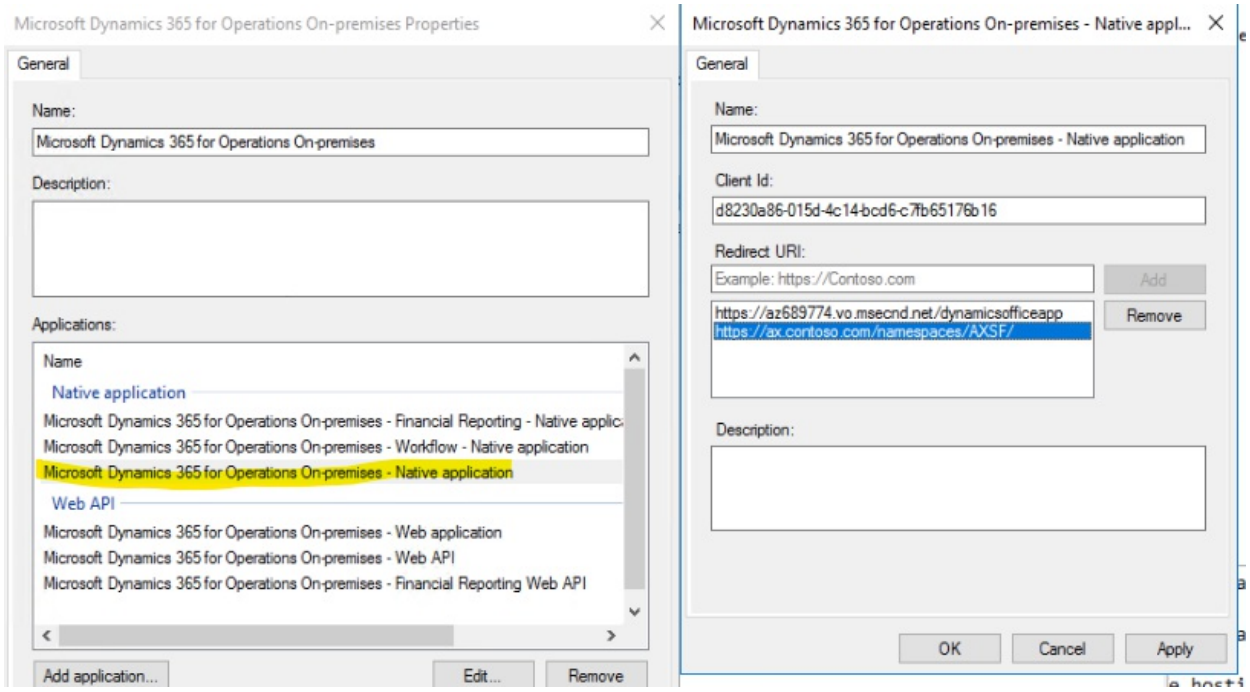
If values in the AOS config file are incorrect, then that typically means the value provided for the AD FS endpoint when deploying the environment was incorrect. The easiest thing is to delete and redeploy the environment from LCS with the correct value. It is possible to manually edit the configuration files, but to be safe, do a redeploy. Otherwise you will need to manually change the values after each servicing operation on each AOS node. If you do edit the config files, then you need to restart the AOS service (AxService.exe) for it to take effect. You can do that from the Service Fabric explorer (right-click the AOS node under **Nodes**, choose **Restart**, and then wait at least a minute for the status to change to green). You can also reboot the machine.

Receiving a 500 error when accessing the application URL is an indication that there may be an invalid URL for AD FS. This is because on startup the AOS will use that URL to obtain information from the AD FS server. If the URL is incorrect or inaccessible, the AOS will be unable to start.

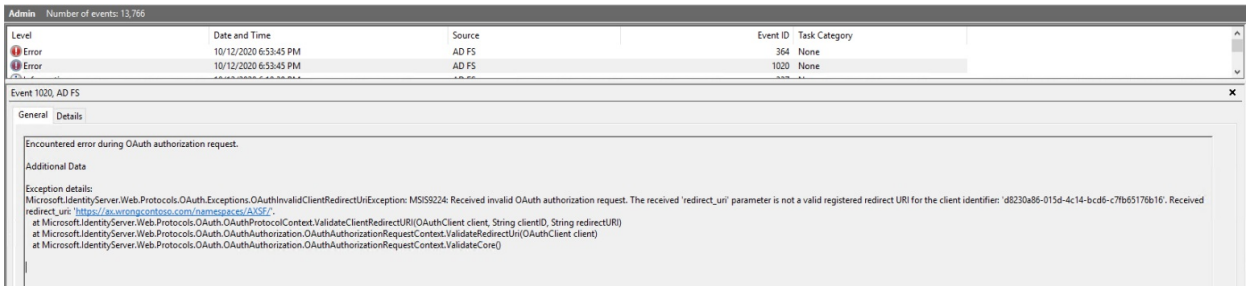
AD FS

The second part of the authentication process is AD FS itself. On the AD FS server if you open AD FS Management ((from **Control Panel > System and Security > Administrative Tools**), and go to **Application groups**, you'll find a group called **Microsoft Dynamics 365 for Operations On-premises**.

Within this group, the settings for AD FS for your Dynamics 365 application are stored.



AD FS uses the client ID and the URLs to determine whether the request for access should be honored. You will notice that the client ID from the screenshot above matches the IDs specified in the OfficeApps and OpenIDConnect sections from earlier. If both the client ID and the redirect URL don't match what the AOS is requesting, then AD FS will deny the request to authenticate. If that happens, you'll find an error in the event log on the AD FS server. There's a special event log for AD FS under **Application and Services logs > AD FS > Admin**.



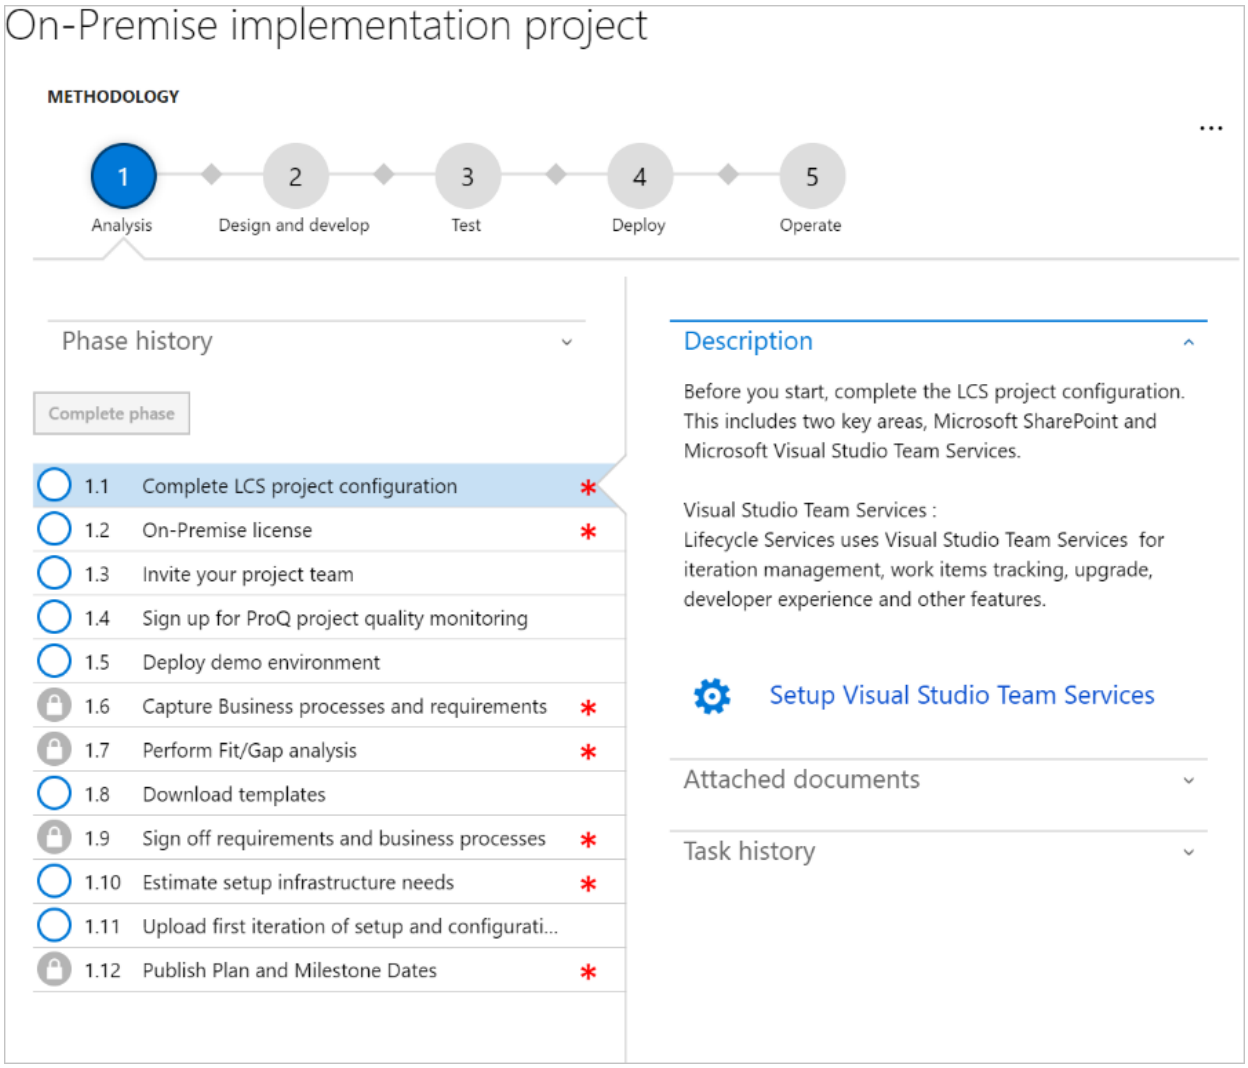
If any of the AD FS application group setup is incorrect, you're likely see an error in the event log that explains the value it was looking for, so you can determine what is set incorrectly.

> **NOTE**
>
> Can you tell us about your documentation language preferences? Take a short survey.
>
> The survey will take about seven minutes. No personal data is collected (privacy statement).

Set up on-premises projects in Lifecycle Services (LCS)

2/18/2021 • 2 minutes to read • Edit Online

You must use Microsoft Dynamics Lifecycle Services (LCS) to deploy and update an instance of Dynamics 365 Finance + Operations (on-premises). After you purchase a server and user license through the Volume Licensing flow or the Dynamics Price List flow, see the topic, Buy Finance + Operations (on-premises), to create an Azure AD account or use an existing Azure AD account, and then complete all the sign-up steps. You will be redirected to LCS, where an on-premises implementation project will be provisioned for you.



The on-premises project has all the tools that you require in order to implement, maintain, and operate an on-premises solution. Here are some of the tools that are available in the on-premises project:

- **Methodology** – The on-premises methodology provides best practices that will help customers implement and manage on-premises projects.
- **Business process modeler** – Business process modeler (BPM) is used to capture requirements and do fit gap analysis.
- **Cloud-hosted environments** – Cloud-hosted environments are used to deploy developer and build topologies, and to complete Dev Application Lifecycle Management (ALM) for on-premises solutions.
- **Code upgrade** – These tools will help you upgrade code to a newer release.
- **Issue search** – Search for published KBs that are related to application and platform issues.

- **Localization and translation** – Localize and translate assets.
- **Support** – File and track support incidents.
- **Project users** – Assign users to a project.
- **Project settings** – Edit project-level settings, such as connectors, the project name, organization users, and the license number.
- **Asset library** – The Asset library is a library for various assets, such as packages.
- **SharePoint online library** – Connect to an online Microsoft SharePoint library.

To start your on-premises implementation, you must follow the steps in the methodology to correctly set up the project, deploy the developer and build environments, and then deploy sandbox and production environments. To help you with deployments, two environment slots are pre-allocated to the on-premises project. One slot is for a sandbox environment, and the other slot is for a production environment. These slots will be used during the Servicing flow to help guarantee that packages are tested in the sandbox environment before they are applied in the production environment.

Set up and deploy on-premises environments (Platform update 12 and later)

2/18/2021 • 42 minutes to read • Edit Online

This topic provides information about how to plan, set up, and deploy Dynamics 365 Finance + Operations (on-premises) with Platform update 12 and later.

The Local Business Data Yammer group is available. You can post questions or feedback you may have about the on-premises deployment there.

If you have questions or feedback about the content in this topic, please post them in the **Comments** section at the bottom of this page.

Finance + Operations components

The Finance + Operations application consists of three main components:

- Application Object Server (AOS)
- Business Intelligence (BI)
- Financial Reporting/Management Reporter

These components depend on the following system software:

- Microsoft Windows Server 2016 (only English OS installations are supported)
- Microsoft SQL Server 2016 SP1 and SP2 (from Platform update 33), which has the following features:
  - Full-text index search is enabled.
  - SQL Server Reporting Services (SSRS) - This is deployed on BI virtual machines.
  - SQL Server Integration Services (SSIS) - This is deployed on AOS virtual machines.

    WARNING

    Full Text Search must be enabled.
- SQL Server Management Studio
- Standalone Microsoft Azure Service Fabric
- Microsoft Windows PowerShell 5.0 or later
- Active Directory Federation Services (AD FS) on Windows Server 2016
- Domain controller

WARNING

The domain controller must be Microsoft Windows Server 2012 R2 or later and must have a domain functional level of 2012 R2 or more. For more information about domain functional levels, see the following topics:

- What Are Active Directory Functional Levels
- Understanding Active Directory Domain Services Functional Levels
- Full 2-way trust

Lifecycle Services

Finance + Operations bits are distributed through Microsoft Dynamics Lifecycle Services (LCS). Before you can deploy, you must purchase license keys through the Enterprise Agreements channel and set up an on-premises project in LCS. Deployments can be initiated only through LCS. For more information about how to set up on-premises projects in LCS, see Set up on-premises projects in Lifecycle Services (LCS).

Authentication

The on-premises application works with AD FS. To interact with LCS, you must also configure Azure Active Directory (AAD). To complete the deployment and configure the LCS Local agent, you will need AAD. If you do not already have an AAD tenant, you can get one for free by using one of the options provided by AAD. For more information, see How to get an Azure Active Directory tenant.

Standalone Service Fabric

Finance + Operations uses standalone Service Fabric. For more information, see the Service Fabric documentation.

Setup of Finance + Operations will deploy a set of applications inside Service Fabric (SF). During deployment, each node in the cluster will be defined via configuration to have one of the following node types:

- **AOSNodeType** - Hosts the application object server (business logic).
- **OrchestratorType** - Functions as Service Fabric primary nodes, and hosts deployment- and servicing logic.
- **ReportServerType** - Hosts SSRS and reporting logic.
- **MRType** - Hosts management reporting logic.

Infrastructure

Finance + Operations falls under the standard Microsoft support policy about operation on non-Microsoft virtualization platforms, specifically VMware. For more information, see Support policy for Microsoft software. In short, we support our products in this environment. However, if we are asked to investigate an issue, we might first ask the customer to reproduce the issue without the virtualization platform or on the Microsoft virtualization platform.

If you are using VMWare, you must implement the fixes that are documented on the following web pages:

- After upgrading a virtual machine to hardware version 11, network dependent workloads experience performance degradation (2129176)
- Several issues with vmxnet3 virtual adapter

WARNING

Dynamics 365 Finance + Operations (on-premises) is not supported on any public cloud infrastructure, including Azure.

The hardware configuration includes the following components:

- Standalone Service Fabric cluster that is based on Windows Server 2016 virtual machines (VMs)
- Microsoft SQL Server (both Clustered SQL and Always-On are supported)
- AD FS for authentication
- Server Message Block (SMB) version 3 file share for storage
- Optional: Microsoft Office Server 2017

For more information, see System requirements for on-premises deployments.

Hardware layout

Plan your infrastructure and Service Fabric cluster based on the recommended sizing in Hardware sizing requirements for on-premises environments. For more information about how to plan the Service Fabric cluster, see Plan and prepare your Service Fabric standalone cluster deployment.

The following table shows an example of a hardware layout. This example is used throughout this topic to illustrate the setup. You will need to replace the machine names and IP addresses given in the following instructions with the names and IP addresses for the machines in your environment.

> **NOTE**
> The Primary node of the Service Fabric cluster must have at least three nodes. In this example, **OrchestratorType** is designated as the Primary node type.

MACHINE PURPOSE	SF NODE TYPE	MACHINE NAME	IP ADDRESS
Domain controller		DAX7SQLAODC1	10.179.108.2
AD FS		DAX7SQLAOADFS1	10.179.108.3
File server		DAX7SQLAOFILE1	10.179.108.4
SQL Always-On cluster		DAX7SQLAOSQLA01	10.179.108.5
		DAX7SQLAOSQLA02	10.179.108.6
		DAX7SQLAOSQLA	10.179.108.9
Client		SQLAOCLIENT1	10.179.108.11
AOS 1	AOSNodeType	SQLAOSF1AOS1	10.179.108.12
AOS 2	AOSNodeType	SQLAOSF1AOS2	10.179.108.13
AOS 3	AOSNodeType	SQLAOSF1AOS3	10.179.108.14
Orchestrator 1	OrchestratorType	SQLAOSF1ORCH1	10.179.108.15
Orchestrator 2	OrchestratorType	SQLAOSF1ORCH2	10.179.108.16
Orchestrator 3	OrchestratorType	SQLAOSF1ORCH3	10.179.108.17

MACHINE PURPOSE	SF NODE TYPE	MACHINE NAME	IP ADDRESS
Management Reporter node	MRType	SQLAOSMR1	10.179.108.18
SSRS node	ReportServerType	SQLAOSFBIN1	10.179.108.10

Setup

Prerequisites

Before you start the setup, the following prerequisites must be in place. The setup of these prerequisites is out of scope for this document.

- Active Directory Domain Services (AD DS) must be installed and configured in your network.
- AD FS must be deployed.
- SQL Server 2016 SP2 must be installed on the SSRS machines.
- SQL Server Reporting Services 2016 must be installed in **Native** mode on the SSRS machines.

The following prerequisite software is installed on the VMs by the infrastructure setup scripts downloaded from LCS.

NODE TYPE	COMPONENT	DETAILS
AOS	SNAC – ODBC driver 13	/sql/connect/odbc/windows/release-notes-odbc-sql-server-windows#131

Overview

The following steps must be completed to set up the infrastructure for Finance + Operations. Reading all the steps before you begin will make it easier to plan your setup.

1. Plan your domain name and DNS zones
2. Plan and acquire your certificates
3. Plan your users and service accounts
4. Create DNS zones, and add A records

5. Join VMs to the domain
6. Download setup scripts from LCS
7. Describe your configuration
8. Configure certificates
9. Setup VMs
10. Set up a standalone Service Fabric cluster
11. Configure LCS connectivity for the tenant
12. Set up file storage
13. Set up SQL Server
14. Configure the databases
15. Encrypt credentials
16. Set up SSIS
17. Set up SSRS
18. Configure AD FS
19. Configure a connector and install an on-premises local agent
20. Tear down CredSSP, if remoting was used
21. Deploy your Finance + Operations environment from LCS
22. Connect to your Finance + Operations environment

1. Plan your domain name and DNS zones

We recommend that you use a publicly registered domain name for your production installation of AOS. In that way, the installation can be accessed outside the network, if outside access is required.

For example, if your company's domain is contoso.com, your zone for Finance + Operations might be d365ffo.onprem.contoso.com, and the host names might be as follows:

- ax.d365ffo.onprem.contoso.com for AOS machines
- sf.d365ffo.onprem.contoso.com for the Service Fabric cluster

2. Plan and acquire your certificates

Secure Sockets Layer (SSL) certificates are required in order to secure a Service Fabric cluster and all the applications that are deployed. For your production and sandbox workloads, we recommend that you acquire certificates from a certificate authority (CA) such as DigiCert, Comodo, Symantec, GoDaddy, or GlobalSign. If your domain is set up with Active Directory Certificate Services (AD CS), you can create the certificates through AD CS. Each certificate must contain a private key that was created for key exchange, and it must be exportable to a Personal Information Exchange (.pfx) file.

Self-signed certificates can be used only for testing purposes. For convenience, the setup scripts provided in LCS include scripts that generate and export self-signed certificates. If you are using self-signed scripts, you will be instructed to run the creation scripts in later steps. As we've mentioned, these certificates can be used for testing purposes only.

Recommended settings for certificates are:

- Signature algorithm: sha256RSA
- Signature hash algorithm: sha256
- Public key: RSA (2048 bits)
- Thumbprint algorithm: sha1

PURPOSE	EXPLANATION	ADDITIONAL REQUIREMENTS

PURPOSE	EXPLANATION	ADDITIONAL REQUIREMENTS
SQL Server SSL certificate	This certificate is used to encrypt data that is transmitted across a network between an instance of SQL Server and a client application.	The domain name of the certificate should match the fully qualified domain name (FQDN) of the SQL Server instance or listener. For example, if the SQL listener is hosted on the machine DAX7SQLAOSQLA, the certificate's DNS name is DAX7SQLAOSQLA.contoso.com. CN: DAX7SQLAOSQLA.contoso.com DNS Name: DAX7SQLAOSQLA.contoso.com
Service Fabric Server certificate	This certificate is used to help secure the node-to-node communication between the Service Fabric nodes. This certificate is also used as the Server certificate that is presented to the client that connects to the cluster.	For this certificate you can also use SSL wild card certificate of your domain. For example, *.contoso.com. This is explained in more details below the table. Otherwise, use the following values: CN: sf.d365ffo.onprem.contoso.com DNS Name: sf.d365ffo.onprem.contoso.com
Service Fabric Client certificate	This certificate is used by clients to view and manage the Service Fabric cluster.	CN: client.d365ffo.onprem.contoso.com DNS Name: client.d365ffo.onprem.contoso.com
Encipherment Certificate	This certificate is used to encrypt sensitive information such as the SQL Server password and user account passwords.	The certificate must be created by using the provider **Microsoft Enhanced Cryptographic Provider v1.0**. The certificate key usage must include Data Encipherment (10) and should not include Server authentication or Client authentication. For more information, see Managing secrets in Service Fabric applications. CN: axdataenciphermentcert DNS Name: axdataenciphermentcert

PURPOSE	EXPLANATION	ADDITIONAL REQUIREMENTS
AOS SSL Certificate	This certificate is used as the Server certificate that is presented to the client for the AOS website. It's also used to enable Windows Communication Foundation (WCF)/Simple Object Access Protocol (SOAP) certificates.	You can use the same wild card certificate that you used as the Service Fabric Server certificate. Otherwise, use the following values: CN: ax.d365ffo.onprem.contoso.com DNS Name: ax.d365ffo.onprem.contoso.com
Session Authentication certificate	This certificate is used by AOS to help secure a user's session information.	This certificate is also the File Share certificate that will be used at the time of deployment from LCS. CN: SessionAuthentication DNS Name: SessionAuthentication
Data Encryption certificate	This certificate is used by the AOS to encrypt sensitive information.	This must be created using the provider **Microsoft Enhanced RSA and AES Cryptographic Provider**. CN: DataEncryption DNS Name: DataEncryption
Data Signing certificate	This certificate is used by the AOS to encrypt sensitive information.	This is separate from the Data Encryption certificate and must be created using the provider **Microsoft Enhanced RSA and AES Cryptographic Provider**. CN: DataSigning DNS Name: DataSigning
Financial Reporting client certificate	This certificate is used to help secure the communication between the Financial Reporting services and the AOS.	CN: FinancialReporting DNS Name: FinancialReporting
Reporting certificate	This certificate is used to help secure the communication between SSRS and the AOS.	**Do not reuse the Financial Reporting Client certificate.** CN: ReportingService DNS Name: ReportingService

PURPOSE	EXPLANATION	ADDITIONAL REQUIREMENTS
On-Premises local agent certificate	This certificate is used to help secure the communication between a local agent that is hosted on-premises and on LCS. This certificate enables the local agent to act on behalf of your Azure AD tenant, and to communicate with LCS to orchestrate and monitor deployments. **Note:** Only 1 on-premises local agent certificate is needed for a tenant.	CN: OnPremLocalAgent DNS Name: OnPremLocalAgent

SSL wild card certificate of your domain can be used to combine Service Fabric Server certificate and AOS SSL certificate.

The following is an example of a Service Fabric Server certificate combined with an AOS SSL certificate.

Subject name

```
CN = *.d365ffo.onprem.contoso.com
```

Subject alternative names

```
DNS Name=ax.d365ffo.onprem.contoso.com
DNS Name=sf.d365ffo.onprem.contoso.com
DNS Name=*.d365ffo.onprem.contoso.com
```

> **NOTE**
>
> The wild card certificate allows you to secure only the first-level subdomain of the domain to which it is issued.

3. Plan your users and service accounts

You must create several user or service accounts for Finance + Operations to work. You must create a combination of group managed service accounts (gMSAs), domain accounts, and SQL accounts. The following table shows the user accounts, their purpose, and example names that will be used in this topic.

USER ACCOUNT	TYPE	PURPOSE	USER NAME
Financial Reporting Application Service Account	gMSA		Contoso\svc-FRAS$
Financial Reporting Process Service Account	gMSA		Contoso\svc-FRPS$
Financial Reporting Click Once Designer Service Account	gMSA		Contoso\svc-FRCO$

USER ACCOUNT	TYPE	PURPOSE	USER NAME
AOS Service Account	gMSA	This user should be created for future proofing. We plan to enable AOS to work with the gMSA in upcoming releases. By creating this user at the time of setup, you will help to ensure a seamless transition to the gMSA.	Contoso\svc-AXSF$
AOS Service Account	Domain account	AOS uses this user in the general availability (GA) release.	Contoso\AXServiceUser
AOS SQL DB Admin user	SQL user	Finance + Operations uses this user to authenticate with SQL*. This user will also be replaced by the gMSA user in upcoming releases**.	AXDBAdmin
Local Deployment Agent Service Account	gMSA	This account is used by the local agent to orchestrate the deployment on various nodes.	Contoso\Svc-LocalAgent$

* If the password of the SQL user contains special characters, this could cause problems during deployment.

** The SQL user name and password for SQL authentication are secured because they are encrypted and stored in the file share.

4. Create DNS zones and add A records

DNS is integrated with AD DS, and lets you organize, manage, and find resources in a network. The following instructions provide steps to create a DNS forward lookup zone and A records for the AOS host name and Service Fabric cluster. In this example setup, the DNS zone name is d365ffo.onprem.contoso.com, and the A records/host names are as follows:

- **ax**.d365ffo.onprem.contoso.com for AOS machines
- **sf**.d365ffo.onprem.contoso.com for the Service Fabric cluster

Add a DNS zone

Use the following procedure to add a DNS zone.

1. Sign in to the domain controller machine, select **Start**, and start DNS Manager by typing **dnsmgmt.msc** and selecting the **dnsmgmt (DNS)** application.
2. Right-click the domain controller name in the console tree, and then select **New Zone** > **Next**.
3. Select **Primary Zone**.
4. Leave the **Store the zone in Active Directory (available only if the DNS Server is a writeable domain controller** check box selected, and then select **Next**.
5. Select **To all DNS Servers running on Domain Controllers in this domain: Contoso.com**, and then select **Next**.
6. Select **Forward Lookup Zone**, and then select **Next**.
7. Enter the zone name for your setup, and then select **Next**. For example, enter **d365ffo.onprem.contoso.com**.
8. Select **Do not allow dynamic updates**, and then select **Next**.

9. Select **Finish**.

Set up an A record for AOS

In the new DNS zone, create one A record that is named **ax.d365ffo.onprem.contoso.com** for **each** Service Fabric cluster node of the **AOSNodeType** type. Don't create A records for the other node types.

1. Find the newly created zone under the **Forward Lookup Zones** folder in DNS Manager.
2. Right-click the new zone, and then select **New Host**.
3. Enter the name and IP address of the Service Fabric node. (For example, enter **ax** as the name and enter **10.179.108.12** as the IP address.) Select **Add Host**.
4. Do not select either check box.
5. Repeat steps 1-4 for each AOS node.

Set up an A record for the orchestrator

In the new DNS zone, create an A record that is named **sf.d365ffo.onprem.contoso.com** for **each** Service Fabric cluster node of the **OrchestratorType** type. Don't create A records for the other node types.

1. Right-click the new zone, and then select **New Host**.
2. Enter the name and IP address of the Service Fabric node. (For example, enter **sf** as the name and enter **10.179.108.15** as the IP address.) Select **Add Host**.
3. Do not select either check box.
4. Repeat for each Orchestrator node.

5. Join VMs to the domain

Join each VM to the domain by completing the steps in the Join a Computer to a Domain document. Alternatively, use the following Windows PowerShell script.

```
$domainName = Read-Host -Prompt 'Specify domain name (ex: contoso.com)'
Add-Computer -DomainName $domainName -Credential (Get-Credential -Message 'Enter domain credential')
```

> **IMPORTANT**
>
> You must restart the VMs after you join them to the domain.

6. Download setup scripts from LCS

We have provided several scripts to help improve the setup experience. Follow these steps to download the setup scripts from LCS.

> **IMPORTANT**
>
> The scripts must be executed from a computer in the same domain that the on-premises infrastructure is in.

1. Sign in to LCS.
2. On the dashboard, select the **Shared asset library** tile.
3. On the **Model** tab, in the grid, select the **Dynamics 365 for Operations on-premises - Deployment scripts** row.
4. Select **Versions**, and then download the latest version of the zip file for the scripts.

> **NOTE**
>
> If you need the older version for Platform update 8 or Platform update 11, download version 1.

5. Right-click the zip file, and then select **Properties**. In the dialog box, select the **Unblock** check box.
6. Copy the zip file to the machine that will be used to execute the scripts.
7. Unzip the files into a folder that is named **infrastructure**.

> **IMPORTANT**
> Ensure all edits are made to the ConfigTemplate.xml file in this folder.

7. Describe your configuration

The infrastructure setup scripts use the following configuration files to drive the setup.

- infrastructure\ConfigTemplate.xml
- infrastructure\D365FO-OP\NodeTopologyDefinition.xml
- infrastructure\D365FO-OP\DatabaseTopologyDefinition.xml

> **NOTE**
> Configuration files must be updated based on your environment for the setup scripts to work correctly. Be sure to update these files with the proper computer names, IP addresses, service accounts, and domain based on your setup.

infrastructure\ConfigTemplate.xml describes:

- Service Accounts that are needed for the application to operate
- Certificates necessary for securing communications
- Database configuration
- Service Fabric cluster configuration

> **IMPORTANT**
> Make sure that there are three fault domains for OrchestratorType when you configure Service Fabric cluster.
> Make sure that no more than one type of node is deployed in a single machine when you configure Service Fabric cluster.

For each Service Fabric node type, **infrastructure\D365FO-OP\NodeTopologyDefinition.xml** describes:

- The mapping between each node type and the application, domain and service accounts, and certificates.
- Whether to enable the UAC.
- Prerequisites for Windows features and system software.
- Whether strong name validation should be enabled.
- List of firewall ports to be opened.

For each database, **infrastructure\D365FO-OP\DatabaseTopologyDefinition.xml** describes:

- The database settings.
- The mappings between users and roles.

Create gMSA and domain user accounts

1. Navigate to the machine that has the unzipped infrastructure scripts in the **infrastructure** folder.
2. Copy the **infrastructure** folder to the domain controller machine.
3. Start Windows PowerShell in elevated mode, change the directory to the **infrastructure** folder, and run

the following commands.

> **IMPORTANT**
> The following script doesn't create a domain user AxServiceUser for you. You must create it yourself.

```
Import-Module .\D365FO-OP\D365FO-OP.psd1
New-D365FOGMSAAccounts -ConfigurationFilePath .\ConfigTemplate.xml
```

4. Add the AOS Service Accounts, **Contoso\svc-AXSF$** and **Contoso\AXServiceUser** to the local administrators group for all AOS machines. For more information, see Add a member to local group.

5. If you must make changes to accounts or machines, update the ConfigTemplate.xml file in the original **infrastructure** folder, copy it to this machine and then run the following script.

```
Update-D365FOGMSAAccounts -ConfigurationFilePath .\ConfigTemplate.xml
```

8. Configure certificates

1. Navigate to the machine that has the **infrastructure** folder.

2. Generate certificates:

   a. If you must generate self-signed certificates:

      a. Set the **generateSelfSignedCert** attribute to **true**. Only set this for the certificates that you need to generate.
      b. Run the following command. The script will create the certificates. Put the certificates in the CurrentUser\My certificate store on the machine, and update the thumbprints in the XML file.

```
# Create self-signed certs
.\New-SelfSignedCertificates.ps1 -ConfigurationFilePath .\ConfigTemplate.xml
```

   b. If you want to generate Active Directory Certificate Services (AD CS) certificates:

      a. Set the **generateADCSCert** attribute to **false** for the certificates that you don't want generated.
      b. Run the following commands. The script will create the certificate templates in AD CS. Generate the certificates from the templates, place the certificates in the CurrentUser\My certificate store on the machine, and update the thumbprints in the XML file.

```
.\New-ADCSCertificates.ps1 -ConfigurationFilePath .\ConfigTemplate.xml -CreateTemplates
.\New-ADCSCertificates.ps1 -ConfigurationFilePath .\ConfigTemplate.xml
```

> **NOTE**
> The AD CS scripts need to run on a Domain Controller, or a Windows Server with Remote Server Admin Tools installed.

3. If you're using SSL certificates that were already generated, skip the certificate generation and update the thumbprints in the configTemplate.xml file. The certificates need to be installed in the CurrentUser\My store and their private keys must be exportable.

WARNING

Because of a leading not-printable special character, which is difficult to determine when present, the cert manager should not be used to copy thumbprints. If the not-printable special character is present, you will get the error, **X509 certificate not valid**. To retrieve the thumbprints, see results from PowerShell commands or run the following commands in PowerShell.

```
dir cert:\CurrentUser\My
dir cert:\LocalMachine\My
dir cert:\LocalMachine\Root
```

4. Specify a semi-colon separated list of users or groups in the **ProtectTo** tag for each certificate. Only Active directory users and groups specified in the **ProtectTo** tag will have permissions to import the certificates that are exported using the scripts. Passwords are not supported by the script to protect the exported certificates

5. Export the certificates into .pfx files. As part of the export, this script will check that your certificates have the correct cryptographic provider set.

```
# Exports Pfx files into a directory VMs\<VMName>, all the certs will be written to
infrastructure\Certs folder.
.\Export-PfxFiles.ps1 -ConfigurationFilePath .\ConfigTemplate.xml
```

9. Setup VMs

1. Export the scripts that must be run on each VM.

```
# Exports the script files to be execute on each VM into a directory VMs\<VMName>.
.\Export-Scripts.ps1 -ConfigurationFilePath .\ConfigTemplate.xml
```

2. Download the following Microsoft Windows Installers (MSIs) into a file share that is accessible by all VMs.

COMPONENT	DOWNLOAD LINK	EXPECTED FILE NAME
SNAC – ODBC driver 13	/sql/connect/odbc/windows/release-notes-odbc-sql-server-windows#131	msodbcsql.msi
SNAC – ODBC driver 17	https://aka.ms/downloadmsodbcsql	msodbcsql_17.msi
Microsoft SQL Server Management Studio 17.5	/sql/ssms/download-sql-server-management-studio-ssms	SSMS-Setup-*.exe
Microsoft Visual C++ Redistributable Packages for Microsoft Visual Studio 2013	https://support.microsoft.com/help/3179560	vcredist_x64.exe
Microsoft Visual C++ Redistributable Packages for Microsoft Visual Studio 2017	Go to https://lcs.dynamics.com/V2/SharedAssetLibrary, select **Model** as the asset type, and then select **VC++ 17 Redistributables**.	vc_redist.x64_14_16_27024.exe
Microsoft Access Database Engine 2010 Redistributable	https://www.microsoft.com/download/details.aspx?id=13255	AccessDatabaseEngine_x64.exe

COMPONENT	DOWNLOAD LINK	EXPECTED FILE NAME
The Microsoft .NET Framework version 4.8 (CLR 4.0)	https://dotnet.microsoft.com/download/thank-you/net48-offline	ndp48-x86-x64-allos-enu.exe
The Microsoft .NET Framework version 4.7.2 (CLR 4.0)	https://dotnet.microsoft.com/download/thank-you/net472-offline	ndp472-x86-x64-allos-enu.exe

IMPORTANT

- Make sure the Microsoft SQL Server Management Studio setup is in the same language as the operating system of the target machine.
- Make sure that the installer files have the names that are specified in the **"Expected file name"** column of the preceding table.
- You may need to rename some of the downloads if the **"Expected file name"** is different. Failure to do so will result in errors when running the "Configure-PreReqs.ps1" script.
- When you download **VC++ 17 Redistributables**, the executable file is inside the zip file.

Follow these steps for each VM, or use remoting from a single machine

NOTE

The following section requires execution on multiple VMs. This process can be eased by using the supplied remoting scripts, which provide the option of running the necessary scripts from a single machine, such as the same machine used to execute `.\Export-Scripts.ps1`. The remoting scripts, when available, are declared after a "`# If Remoting`" comment in the PowerShell sections. When the remoting scripts are used, you may not need to execute the remaining scripts in a section, please see the section text for cases such as that. Remoting uses WinRM and requires CredSSP to be enabled in certain cases. The enabling and disabling of CredSSP is handled by the remoting module on a per-execution basis. Keeping CredSSP enabled when it is not in use is not advised, as it introduces security risks in the shape of credential theft. See the Tear down CredSSP section when you are finished setting up.

1. Copy the contents of each infrastructure\VMs<VMName> folder into the corresponding VM (if remoting scripts are used, they will automatically copy the content to the target VMs), and then run the following scripts as an Administrator.

```
# Install pre-req software on the VMs.

# If Remoting, execute
# .\Configure-PreReqs-AllVMs.ps1 -MSIFilePath <share folder path of the MSIs> -ConfigurationFilePath
.\ConfigTemplate.xml

.\Configure-PreReqs.ps1 -MSIFilePath <path of the MSIs>
```

IMPORTANT

1. Each time you are prompted, restart the machine. Make sure that you rerun the `.\Configure-PreReqs.ps1` script after each restart until all of the prerequisites are installed. In the case of remoting, rerun the AllVMs script when all of the machines are back online.
2. When you use the remoting script, ensure that the current user has access to the share folder of MSIs.
3. When you use the remoting script, ensure no user is accessing the AOSNoteType, MRType, and ReportServerType type machines. Otherwise, the remoting script will fail to restart the computer because of the users being logged on to the computer.

2. Run the following scripts, if they exist, to complete the VM setup.

```
# If Remoting, only execute
# .\Complete-PreReqs-AllVMs.ps1 -ConfigurationFilePath .\ConfigTemplate.xml

# Note: Script "Add-GMSAOnVM.ps1" is not present on BI node
.\Add-GMSAOnVM.ps1
.\Import-PfxFiles.ps1
.\Set-CertificateAcls.ps1
```

3. Run the following script to validate the VM setup.

```
# If Remoting, execute
# .\Test-D365FOConfiguration-AllVMs.ps1 -ConfigurationFilePath .\ConfigTemplate.xml

.\Test-D365FOConfiguration.ps1
```

> **IMPORTANT**
> If remoting was used, be sure to execute the clean up steps when the setup is complete. See the 20. Tear down CredSSP section.

10. Set up a standalone Service Fabric cluster

1. Download the Service Fabric standalone installation package onto one of your Service Fabric nodes. After the zip file is downloaded, unblock it by right-clicking the zip file and then selecting **Properties**. In the dialog box, select the **Unblock** check box in the lower right.
2. Copy the zip file to one of the nodes in the Service Fabric cluster, and unzip it. Ensure the **infrastructure** folder has access to this folder.
3. Navigate to the **infrastructure** folder and execute the following command to generate the Service Fabric ClusterConfig.json file.

```
.\New-SFClusterConfig.ps1 -ConfigurationFilePath .\ConfigTemplate.xml -TemplateConfig
<ServiceFabricStandaloneInstallerPath>\ClusterConfig.X509.MultiMachine.json
```

4. Additional modifications to your cluster configuration may be necessary based on your environment. For more information, see, Step 1B: Create a multi-machine cluster, Secure a standalone cluster on Windows using X.509 certificates, and Create a standalone cluster running on Windows Server.
5. Copy the generated ClusterConfig.json file to the <ServiceFabricStandaloneInstallerPath>.
6. Navigate to the <ServiceFabricStandaloneInstallerPath> in Windows PowerShell by using elevated privileges. Run the following command to test ClusterConfig.

```
.\TestConfiguration.ps1 -ClusterConfigFilePath .\clusterConfig.json
```

7. If the test is successful, run the following command to deploy the cluster.

```
# If using offline (internet-disconnected) install
# .\CreateServiceFabricCluster.ps1 -ClusterConfigFilePath .\ClusterConfig.json -
FabricRuntimePackagePath <Path to MicrosoftAzureServiceFabric.cab download>

.\CreateServiceFabricCluster.ps1 -ClusterConfigFilePath .\ClusterConfig.json
```

8. After the cluster is created, open the Service Fabric explorer on any client machine to validate the

installation.

a. Install the Service Fabric client certificate in CurrentUser\My if it isn't already installed.
b. Go to **IE settings** > **Compatibility Mode**, and clear the **Display Intranet sites in compatibility mode** check box.
c. Go to `https://sf.d365ffo.onprem.contoso.com:19080`, where sf.d365ffo.onprem.contoso.com is the host name of the Service Fabric cluster that is specified in the zone. If DNS name resolution isn't configured, use the IP address of the machine.
d. Select the client certificate. The **Service Fabric explorer** page appears.
e. Verify that all nodes are appear as green.

> **IMPORTANT**
> If your client machine is a server machine like Windows Server 2016, you must turn off the IE Enhanced Security Configuration when you access the **Service Fabric explorer** page. If any antivirus software is installed, ensure you set exclusion following the guidance in the Service Fabric documentation.

11. Configure LCS connectivity for the tenant

Deployment and servicing of Finance + Operations is orchestrated through LCS by using an on-premises local agent. To establish connectivity from LCS to the Finance + Operations tenant, you must configure a certificate that enables the local agent to act on behalf on your Azure AD tenant (for example, Contoso.onmicrosoft.com).

Use the on-premises agent certificate that you acquired from a certificate authority or the self-signed certificate that you generated by using scripts.

The on-premises agent certificate can be reused across multiple sandbox and production environments per tenant.

Only user accounts that have the Global Administrator directory role can add certificates to authorize LCS. By default, the person who signs up for Microsoft 365 for your organization is the global administrator for the directory.

> **IMPORTANT**
> - You must configure the certificate exactly **one** time per tenant. All on-premises environments under the same tenant must use the same certificate to connect with LCS.
> - If you run this in a server machine like Windows Server 2016, you must turn off the IE Enhanced Security Configuration temporarily. If you don't, the Azure login window content will be blocked.

1. Sign in to the customer's Azure portal to verify that you have the Global Administrator directory role.
2. Determine whether the certificate is already registered by running the following script from the **Infrastructure** folder.

```
# If you have issues downloading the Azure PowerShell Az module, run the following:
# [Net.ServicePointManager]::SecurityProtocol = [Net.SecurityProtocolType]::Tls12

Install-Module Az
Import-Module Az
.\Add-CertToServicePrincipal.ps1 -CertificateThumbprint 'OnPremLocalAgent Certificate Thumbprint' -
Test
```

> **IMPORTANT**
> If you previously installed AzureRM, please remove it as it may not be compatible with any existing AzureRM installs in PowerShell 5.1 for Windows. For more information, Migrate Azure PowerShell from AzureRM to Az.

3. If the script indicates that the certificate isn't registered, run the following command.

```
.\Add-CertToServicePrincipal.ps1 -CertificateThumbprint 'OnPremLocalAgent Certificate Thumbprint'
```

> **NOTE**
> If you have multiple tenants associated with the login account, you can pass the tenant ID as a parameter to ensure that the context is set to the correct tenant.

```
.\Add-CertToServicePrincipal.ps1 -CertificateThumbprint 'OnPremLocalAgent Certificate Thumbprint' -
TenantId 'xxxx-xxxx-xxxx-xxxx'
```

12. Set up file storage

You must set up the following SMB 3.0 file shares:

- A file share that stores user documents that are uploaded to AOS (for example, \\DAX7SQLAOFILE1\aos-storage).
- A file share that stores the latest build and configuration files to orchestrate the deployment (for example, \\DAX7SQLAOFILE1\agent).

> **WARNING**
> Keep this file share path as short as possible to avoid exceeding the maximum path length on the files that will be put in the share.

For information about how to enable SMB 3.0, see SMB Security Enhancements.

> **IMPORTANT**
> - Secure dialect negotiation can't detect or prevent downgrades from SMB 2.0 or 3.0 to SMB 1.0. Therefore, we strongly recommend that you disable the SMB 1.0 server. By disabling the SMB 1.0 server, you can take advantage of the full capabilities of SMB encryption.
> - To help ensure that your data is protected while it's at rest in your environment, BitLocker Drive Encryption must be enabled on every machine. For information about how to enable BitLocker, see BitLocker: How to deploy on Windows Server 2012 and later.

1. On the file share machine, run the following command.

```
Install-WindowsFeature -Name FS-FileServer -IncludeAllSubFeature -IncludeManagementTools
```

2. Follow these steps to set up the \\DAX7SQLAOFILE1\aos-storage file share:

   a. In Server Manager, select **File and Storage Services** > **Shares**.

b. Select **Tasks** > **New Share** to create a new share. Name the share **aos-storage**.

c. Leave **Allow caching of share** selected.

d. Check **Encrypt data access**.

e. Grant **Modify** permissions for every machine in the Service Fabric cluster except OrchestratorType.

f. Grant **Modify** permissions for the user AOS domain user (contoso\AXServiceUser) and the gMSA user (contoso\svc-AXSF$).

> **NOTE**
> You may need to enable **Computers** under **Object Types** to add machines or enable **Service Accounts** under **Object Types** to add service accounts.

3. Follow these steps to set up the \\DAX7SQLAOFILE1\agent file share:

a. In Server Manager, select **File and Storage Services** > **Shares**.

b. Select **Tasks** > **New Share** to create a new share. Name the share **agent**.

c. Grant **Full-Control** permissions to the gMSA user for the local deployment agent (contoso\svc-LocalAgent$).

```
# Specify user names
$AOSDomainUser = 'Contoso\AXServiceUser';
$LocalDeploymentAgent = 'contoso\svc-LocalAgent$';

# Specify the path
$AosStorageFolderPath = 'D:\aos-storage';
$AgentFolderPath = 'D:\agent';

# Create new directory
$AosStorageFolder = New-Item -type directory -path $AosStorageFolderPath;
$AgentFolder = New-Item -type directory -path $AgentFolderPath;

# Create new SMB share
New-SmbShare –Name aos-storage -Path $AosStorageFolderPath -EncryptData $True
New-SmbShare –Name agent -Path $AgentFolderPath

# Set ACL for AOS storage folder
$Acl = Get-Acl $AosStorageFolder.FullName;
$Ar = New-Object system.security.accesscontrol.filesystemaccessrule($AOSDomainUser,'Modify','Allow');
$Acl.SetAccessRule($Ar);
Set-Acl $AosStorageFolder.FullName $Acl;

# Set ACL for AgentFolder
$Acl = Get-Acl $AgentFolder.FullName;
$Ar = New-Object
system.security.accesscontrol.filesystemaccessrule($LocalDeploymentAgent,'FullControl','Allow');
$Acl.SetAccessRule($Ar);
Set-Acl $AgentFolder.FullName $Acl;
```

13. Set up SQL Server

1. Install SQL Server 2016 SP2 with high availability. (Unless you're deploying in a sandbox environment, where one instance of SQL Server is sufficient. You may want to install SQL Server with high availability in sandbox environments to test high-availability scenarios.)

> **IMPORTANT**
>
> You must enable the SQL Server and Windows Authentication mode.

You can install SQL Server with high availability either as SQL clusters that include a Storage Area Network (SAN) or in an Always-On configuration. Verify that the Database Engine, SSRS, Full-Text Search, and Management Tools are already installed.

> **NOTE**
>
> Make sure that Always-On is set up as described in Select Initial Data Synchronization Page (Always On Availability Group Wizards), and follow the instructions in To Prepare Secondary Databases Manually.

2. Run the SQL service as a domain user or a group-managed service account.
3. Get an SSL certificate from a certificate authority to configure SQL Server for Finance + Operations. For testing purposes, you can create and use a self-signed certificate or an AD CS certificate. You will need to replace the computer name and domain name in the following examples.

   #### Self-signed certificate for an Always-On SQL instance

   If you are setting up testing certificates for Always-On, use the following **remoting** script. This will perform the same as the following **manual** script and steps **a-e**.

   a. Self-signed certificate

   ```
   .\New-SelfSigned-SQLCert-AllVMs.ps1 -SqlMachineNames SQL1,SQL2 -SqlListenerName SQL-LS -
   ProtectTo CONTOSO\dynuser
   ```

   b. AD CS certificate

   ```
   .\New-ADCS-SQLCert-AllVMs.ps1 -SqlMachineNames SQL1,SQL2 -SqlListenerName SQL-LS -ProtectTo
   CONTOSO\dynuser
   ```

   #### Manual self-signed steps for an Always-On SQL instance or Windows Server Failover Clustering with SQL Server

   For each node of the SQL cluster, follow these steps.

   a. Run the following PowerShell script on each of the SQL Server Always-On replicas.

   ```
   # Manually create certificate for each SQL Node (i.e. 2 nodes = 2 certificates)
   # Run script on each node
   $computerName = $env:COMPUTERNAME.ToLower()
   $domain = $env:USERDNSDOMAIN.ToLower()
   $listenerName = 'dax7sqlaosqla'
   $cert = New-SelfSignedCertificate -Subject "$computerName.$domain" -DnsName "$listenerName.$domain",
   $listenerName, $computerName -Provider 'Microsoft Enhanced RSA and AES Cryptographic Provider' -
   CertStoreLocation "cert:\LocalMachine\My" -KeyAlgorithm "RSA" -HashAlgorithm "sha256" -KeyLength 2048
   ```

   b. Grant certificate permissions to the account that is used to run the SQL service.
      a. Open Manage Computer Certificates (**certlm.msc**).
      b. Right-click the certificate created, and then select **Tasks** > **Manage Private Keys**.
      c. Add in the SQL Server service account and grant Read access.

c. Enable **ForceEncryption** and the new **Certificate** in Microsoft SQL Server Configuration Manager.
   a. In **SQL Server Configuration Manager**, expand **SQL Server Network Configuration**, right-click **Protocols for [server instance]**, and then select **Properties**.
   b. In the **Properties** dialog box, on the **Certificate** tab, select the desired certificate from the drop-down menu for the **Certificate** box.
   c. In the **Properties** dialog box, on the **Flags** tab, in the **ForceEncryption** box, select **Yes**.
   d. Select **OK** to save.
d. Export the certificate (.cer file) from each SQL cluster node, and install it in the trusted root of each Service Fabric node. You will have a minimum of 2 certificates for the Always-On cluster, but there may be more if you have additional replicas.
e. Restart the SQL Server service.

> **NOTE**
> For more information, see How to enable SSL encryption for an instance of SQL Server by using Microsoft Management Console.

> **IMPORTANT**
> If remoting was used, be sure to execute the clean up steps when the setup is complete. See the 20. Tear down CredSSP section for more information.

14. Configure the databases

1. Sign in to LCS.
2. On the dashboard, select the **Shared asset library** tile.
3. On the **Model** tab, select the demo data for the release that you want and download the zip file.

RELEASE	DEMO DATA
On-premises General Availability (GA) release	Dynamics 365 for Operations on-premises - Demo data
On-premises Platform Update 11 Nov 2017 release	Dynamics 365 for Operations on-premises, Enterprise edition - Update 11 Demo data
On-premises Platform Update 12 Mar 2018 release	Dynamics 365 for Operations on-premises, Enterprise edition - Update 12 Demo data

4. The zip file contains empty and demo data .bak files. Select the .bak file, based on your requirements. For example, if you require demo data, download the AxBootstrapDB_Demodata.bak file.
5. Ensure the database section in the infrastructure\ConfigTempate.xml is configured correctly with the following:
   a. The database name.
   b. The db file and log settings. The db settings should not be lower than the defaults specified.
   c. The path to the backup file downloaded from LCS Shared Asset library. The default name for the Finance + Operations database is AXDB.

> **WARNING**
>
> - The user running the SQL service and the user running the scripts should have READ access on the folder or share where the backup file is located.
> - If a database with the same name exists, the database will be reused.

6. Copy the **infrastructure** folder to the SQL Server machine and navigate to it in a PowerShell window with elevate privileges.

Configure the OrchestratorData database

1. Execute the following script.

```
.\Initialize-Database.ps1 -ConfigurationFilePath .\ConfigTemplate.xml -ComponentName Orchestrator
```

The script will do the following:

- Create an empty database named **OrchestratorData**. This database is used by the on-premises local agent to orchestrate deployments.
- Grant the local agent gMSA (svc-LocalAgent$) **db_owner** permissions on the database.

Configure the Finance + Operations database

1. Execute the following scripts.

```
.\Initialize-Database.ps1 -ConfigurationFilePath .\ConfigTemplate.xml -ComponentName AOS
.\Configure-Database.ps1 -ConfigurationFilePath .\ConfigTemplate.xml -ComponentName AOS
```

The **Initialize-Database.ps1** script will do the following:

a. Restore the database from the specified backup file.

b. Create a new user that has SQL authentication enabled (axdbadmin).

c. Map users to database roles based on the following table for AXDB.

USER	TYPE	DATABASE ROLE
svc-AXSF$	gMSA	db_owner
svc-LocalAgent$	gMSA	db_owner
svc-FRPS$	gMSA	db_owner
svc-FRAS$	gMSA	db_owner
axdbadmin	SqlUser	db_owner

d. Map users to database roles based on the following table for TempDB.

USER	TYPE	DATABASE ROLE
svc-AXSF$	gMSA	db_datareader, db_datawriter, db_ddladmin

USER	TYPE	DATABASE ROLE
axdbadmin	SqlUser	db_datareader, db_datawriter, db_ddladmin

The **Configure-Database.ps1** script will do the following:

a. Set READ_COMMITTED_SNAPSHOT ON
b. Set ALLOW_SNAPSHOT_ISOLATION ON
c. Set the specified database file and log settings
d. GRANT VIEW SERVER STATE TO axdbadmin
e. GRANT ALTER ANY EVENT SESSION TO axdbadmin
f. GRANT VIEW SERVER STATE TO [contoso\svc-AXSF$]
g. GRANT ALTER ANY EVENT SESSION TO [contoso\svc-AXSF$]

2. Run the following command to reset the database users.

```
.\Reset-DatabaseUsers.ps1 -DatabaseServer '<FQDN of the SQL server>' -DatabaseName '<AX database name>'
```

Configure the Financial Reporting database

1. Execute the following script.

```
.\Initialize-Database.ps1 -ConfigurationFilePath .\ConfigTemplate.xml -ComponentName MR
```

The script will do the following:

a. Create an empty database named **FinancialReporting**.

b. Map the users to database roles based on the following table.

USER	TYPE	DATABASE ROLE
svc-LocalAgent$	gMSA	db_owner
svc-FRPS$	gMSA	db_owner
svc-FRAS$	gMSA	db_owner

15. Encrypt credentials

1. On any client machine, install the encipherment certificate in the LocalMachine\My certificate store.
2. Grant the current user read access to the private key of this certificate.
3. Create the Credentials.json file, as shown here.

```
{
    "AosPrincipal": {
        "AccountPassword": "<encryptedDomainUserPassword>"
    },
    "AosSqlAuth": {
        "SqlUser": "<encryptedSqlUser>",
        "SqlPwd": "<encryptedSqlPassword>"
    }
}
```

- **AccountPassword** is the encrypted domain user password for the AOS domain user (contoso\axserviceuser).
- **SqlUser** is the encrypted SQL user (axdbadmin) that has access to the Finance + Operations database (AXDB), and **SqlPassword** is the encrypted SQL password.

4. Copy the .json file to the SMB file share, \\AX7SQLAOFILE1\agent\Credentials\Credentials.json.
5. Update the Credentials.json file with encrypted values.

```
# Service fabric API to encrypt text and copy it to the clipboard.
Invoke-ServiceFabricEncryptText -Text '<textToEncrypt>' -CertThumbprint '<DataEncipherment
Thumbprint>' -CertStore -StoreLocation LocalMachine -StoreName My | Set-Clipboard
```

> **IMPORTANT**
> Before you can invoke *Invoke-ServiceFabricEncryptText*, you need to install Microsoft Azure Service Fabric SDK. If you encounter the following error, "Invoke-ServiceFabricEncryptText is not recognized command" after you install the Azure Service Fabric SDK, restart the computer and retry.

> **WARNING**
> After you've finished invoking all **Invoke-ServiceFabricEncryptText** commands, remember to delete the Windows PowerShell history. Otherwise, your non-encrypted credentials will be visible.

16. Set up SSIS

To enable Data management and Integration workloads, SSIS must be installed on each of the AOS virtual machines. Complete the following steps on each AOS virtual machine.

1. Verify that the machine has access to the SSIS installation and open the SSIS Setup Wizard.
2. In the **Feature Selection** window, in the **Features** pane, select the **Integration Services** and **SQL Client Connectivity SDK** check boxes.
3. Complete the setup and verify that the installation was successful.

For more information, see Install integration services.

17. Set up SSRS

1. Before you begin, make sure that the prerequisites that are listed at the beginning of this topic are installed.
2. Follow the steps in Configure SQL Server Reporting Services for on-premises deployments.

> **IMPORTANT**
> You must install then database engine when you install SSRS.

18. Configure AD FS

Before you can complete this procedure, AD FS must be deployed on Windows Server 2016. For information about how to deploy AD FS, see Deployment Guide Windows Server 2016 and 2012 R2 AD FS Deployment Guide.

Finance + Operations requires additional configuration beyond the default out-of-box configuration of AD FS. The following Windows PowerShell commands must be run on the machine where the AD FS role service is installed. The user account must have enough permissions to administer AD FS. For example, the user must have a domain administrator account. For complex AD FS scenarios, consult your domain administrator.

1. Configure the AD FS identifier so that it matches the AD FS token issuer.

This command is related to adding new users using the **Import users** option on the **Users** page (**System administration** > **Users** > **Users**) in the Finance + Operations client.

```
$adfsProperties = Get-AdfsProperties
Set-AdfsProperties -Identifier $adfsProperties.IdTokenIssuer
```

2. You should disable Windows Integrated Authentication (WIA) for intranet authentication connections, unless you've configured AD FS for mixed environments. For more information about how to configure WIA so that it can be used with AD FS, see Configure browsers to use Windows Integrated Authentication (WIA) with AD FS.

   This command is related to using forms authentication upon signing into the Finance + Operations client. Other options, such as single sign-on, may be available which require additional setup.

   ```
   Set-AdfsGlobalAuthenticationPolicy -PrimaryIntranetAuthenticationProvider FormsAuthentication,
   MicrosoftPassportAuthentication
   ```

3. For sign-in, the user's email address must be an acceptable authentication input.

   This command is related to setting up email claims. Other options, such as transformation rules, may be available which require additional setup.

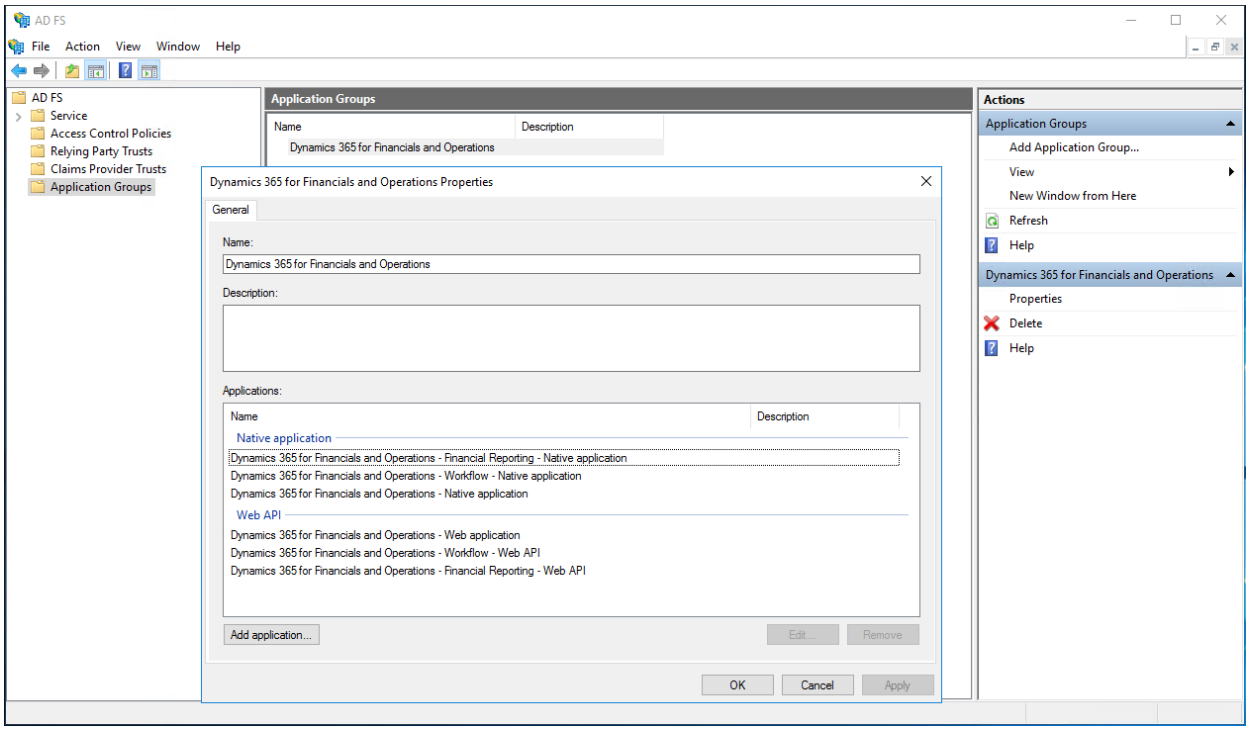
   ```
   Add-Type -AssemblyName System.Net
   $fqdn = ([System.Net.Dns]::GetHostEntry('localhost').HostName).ToLower()
   $domainName = $fqdn.Substring($fqdn.IndexOf('.')+1)
   Set-AdfsClaimsProviderTrust -TargetIdentifier 'AD AUTHORITY' -AlternateLoginID mail -LookupForests
   $domainName
   ```

In order for AD FS to trust Finance + Operations for the exchange of authentication, various application entries must be registered in AD FS under an AD FS application group. To speed up the setup process and help reduce errors, you can use the following script for registration. Copy the Publish-ADFSApplicationGroup.ps1 script and D365FO-OP directory to a machine where the AD FS role service is installed. Then run the script by using a user account that has enough permissions to administer AD FS. (For example, use an administrator account.)

For more information about how to use the script, see the documentation that is listed in the script. Make a note of the client IDs that are specified in the output, because you will need this information in LCS in a later step. Should you lose the client IDs, log in to the machine which has AD FS installed, open **Server Manager** > **Tools** > **AD FS Management** > **Application Groups** > **Microsoft Dynamics 365 for Operations On-premises** and find the client IDs under the native applications.

> **NOTE**
>
> If you want to reuse your previously configured AD FS server for additional environments, see Reuse the same AD FS instance for multiple environments.

```
# Host URL is your DNS record\host name for accessing the AOS
.\Publish-ADFSApplicationGroup.ps1 -HostUrl 'https://ax.d365ffo.onprem.contoso.com'
```



Finally, make sure that you can access the AD FS OpenID Configuration URL on a Service Fabric node of the **AOSNodeType** type. To perform this check, try to open `https://<adfs-dns-name>/adfs/.well-known/openid-configuration` in a web browser. If you receive a message that states that the site isn't secure, you haven't added your AD FS SSL certificate to the Trusted Root Certification Authorities store. This step is described in the AD FS deployment guide, and if you are using remoting, you can use the following script to install the certificate on all nodes in the Service Fabric cluster:

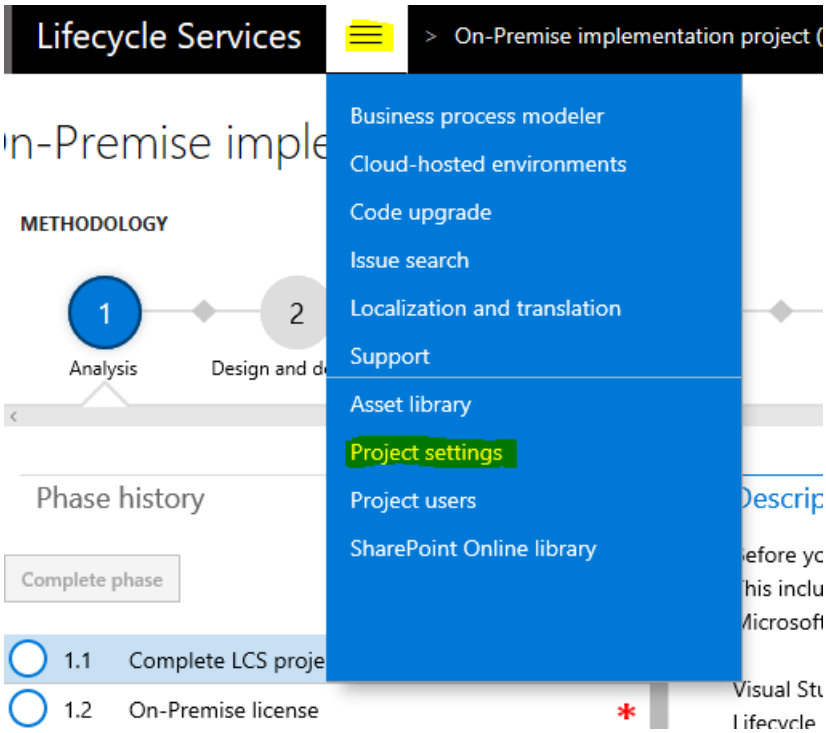
```
# If remoting, execute
.\Install-ADFSCert-AllVMs.ps1 -ConfigurationFilePath .\ConfigTemplate.xml
```

If you successfully access the URL, a JavaScript Object Notation (JSON) file is returned that contains your AD FS configuration, and you will see that your AD FS URL is trusted.

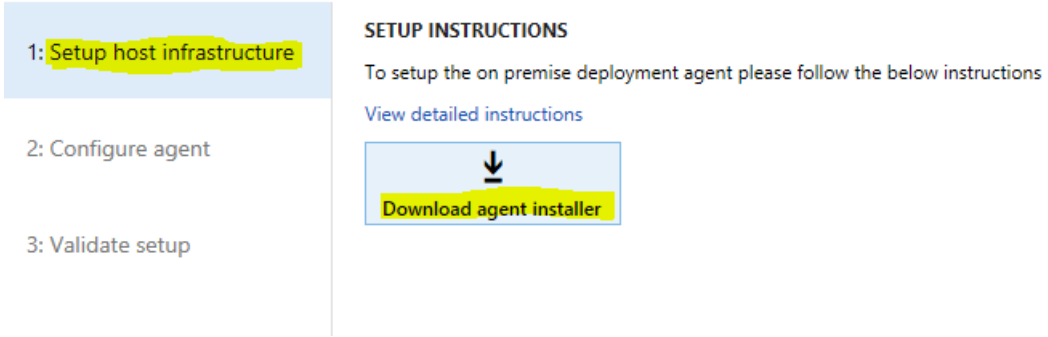
You've now completed the setup of the infrastructure. The following sections describe how to navigate to LCS to set up your connector and deploy your Finance + Operations environment.

19. Configure a connector and install an on-premises local agent

1. Sign in to LCS, and open the on-premises implementation project.
2. On the hamburger menu, select **Project settings**.



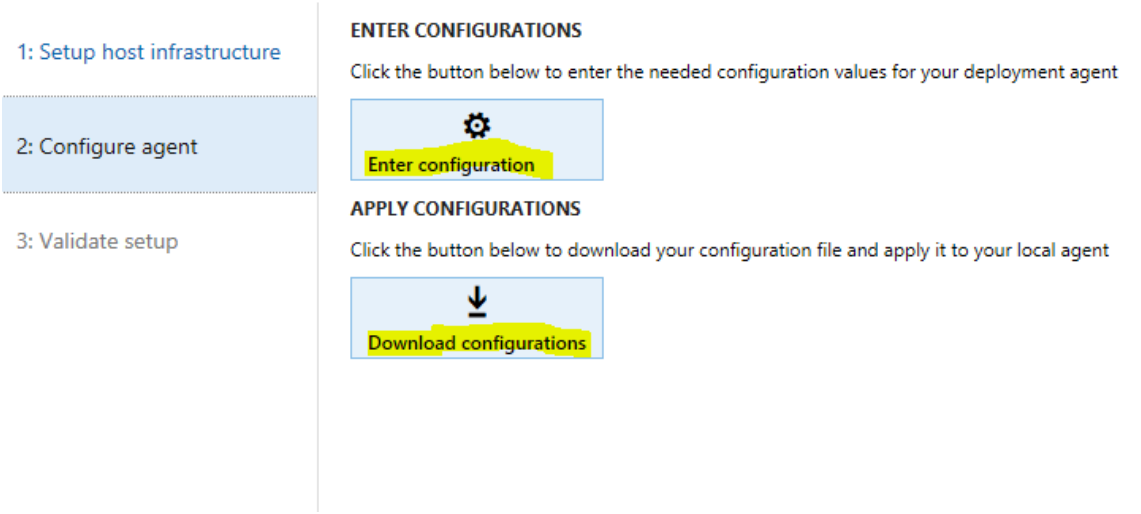
3. Select **On-premises connectors**.
4. Select **Add** to create a new connector.
5. On the **Setup host infrastructure** tab, download the agent installer.



6. Verify that the zip file is unblocked. Right-click the file, and then select **Properties**. In the dialog box, select **Unblock**.
7. Unzip the agent installer on one of the Service Fabric nodes of the **OrchestratorType** type.
8. On the **Configure agent** tab, enter the configuration settings. Execute the following script on any machine with access to it and the configuration file, to get the needed values.

```
.\Get-AgentConfiguration.ps1 -ConfigurationFilePath .\ConfigTemplate.xml
```

9. Save the configuration, and then select **Download configurations** to download the localagent-config.json configuration file.

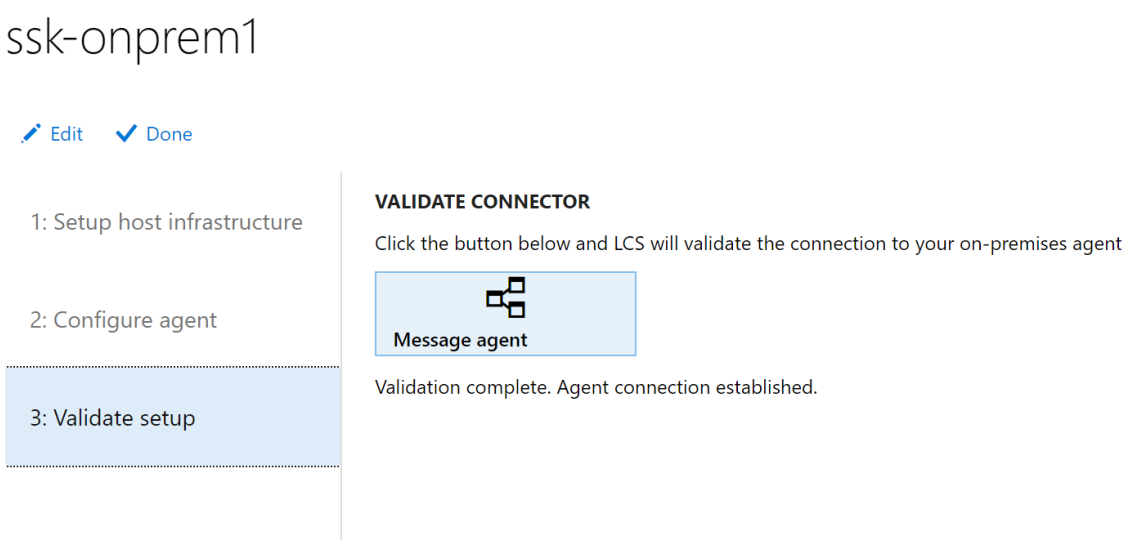


10. Copy the localagent-config.json file to the machine where the agent installer package is located.
11. In a **Command Prompt** window, run the following command by navigating to the folder that contains the agent installer.

```
LocalAgentCLI.exe Install <path of config.json>
```

> **NOTE**
> The user who runs this command must have **db_owner** permissions on the OrchestratorData database.

12. After the local agent is successfully installed, navigate back to your on-premises connector in LCS.
13. On the **Validate setup** tab, select **Message agent** to test for LCS connectivity to your local agent. When a connection is successfully established, the page will resemble the following illustration.



20. Tear down CredSSP, if remoting was used

If any of the remoting scripts were used during setup, be sure to execute the following script when there are breaks in the setup process, or the setup has finished.

```
.\Disable-CredSSP-AllVMs.ps1 -ConfigurationFilePath .\ConfigTemplate.xml
```

If the previous remoting PowerShell window was accidentally closed and CredSSP was left enabled, the script

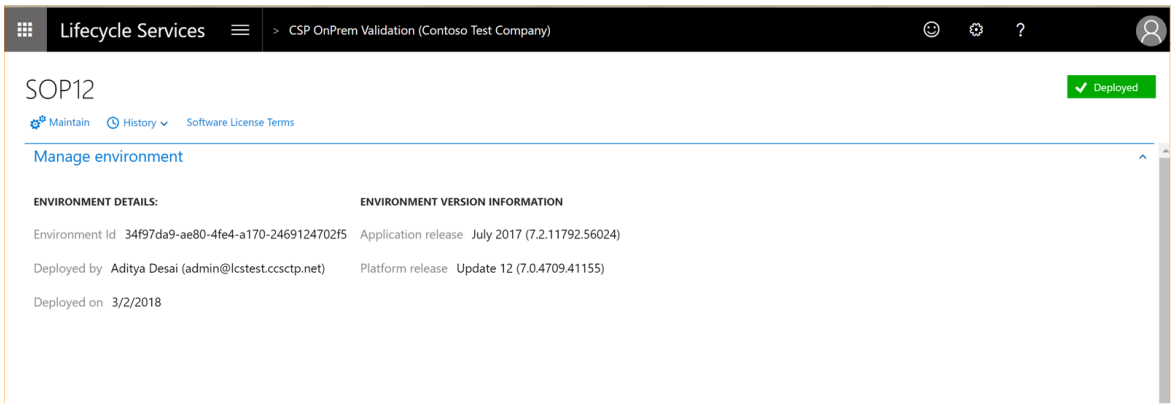
will disable it on all the machines specified in the configuration file.

21. Deploy your Finance + Operations environment from LCS

1. In LCS, navigate to your on-premises project, go to **Environment** > **Sandbox**, and then select **Configure**. Execute the following script on the primary domain controller VM, which must have access to ADFS and the DNS server settings, to get the needed values.

```
.\Get-DeploymentSettings.ps1 -ConfigurationFilePath .\ConfigTemplate.xml
```

2. For new deployments, select your environment topology, and then complete the wizard to start your deployment.

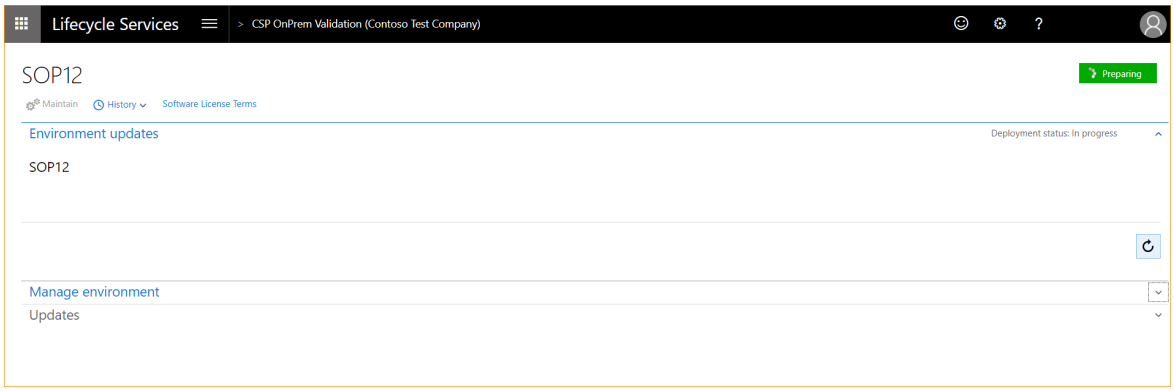


3. If you have an existing Platform update 8 or Platform update 11 deployment:

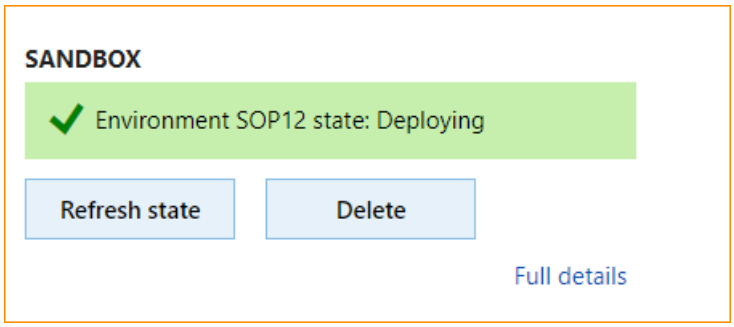
   - Update the local agent. See Update the local agent for more details.
   - Validate the local agent from LCS.
   - Deploy Platform update 12 while going through the steps in Reconfigure environments to take a new platform or topology.

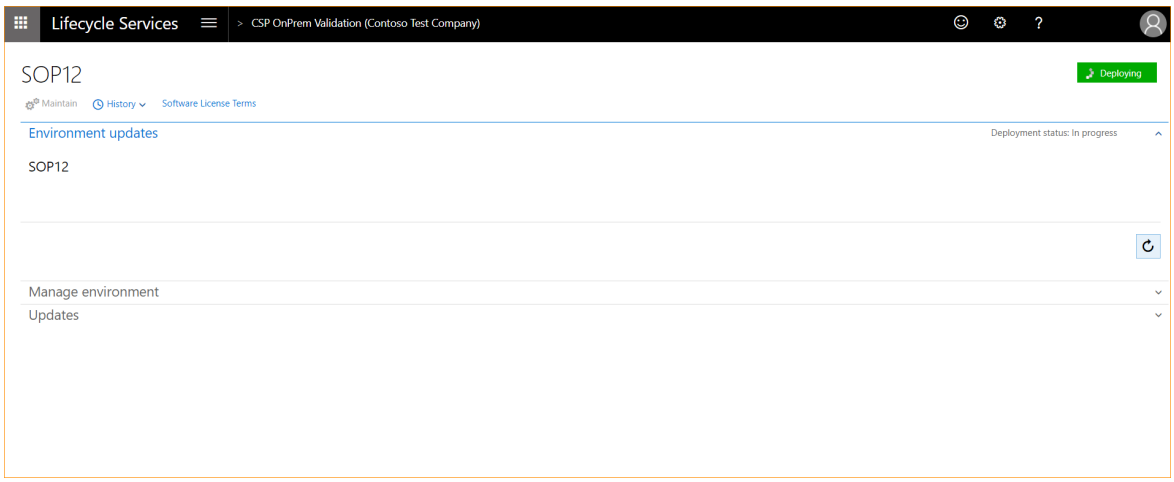
4. LCS will assemble the Service Fabric application packages for your environment during the preparation phase. It then sends a message to the local agent to start deployment. You will notice the **Preparing** status as below.

   Click **Full details** to take you to the environment details page, as shown below.

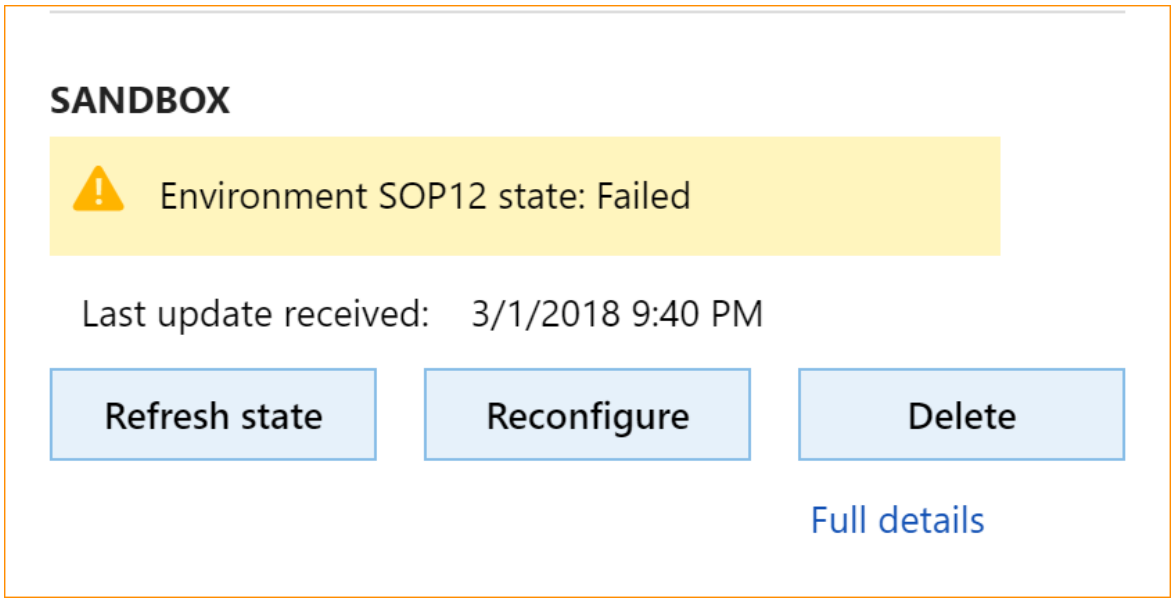


5. The local agent will now pick up the deployment request, start the deployment, and communicate back to LCS when the environment is ready. When deployment starts, the status will change to **Deploying**, as shown.

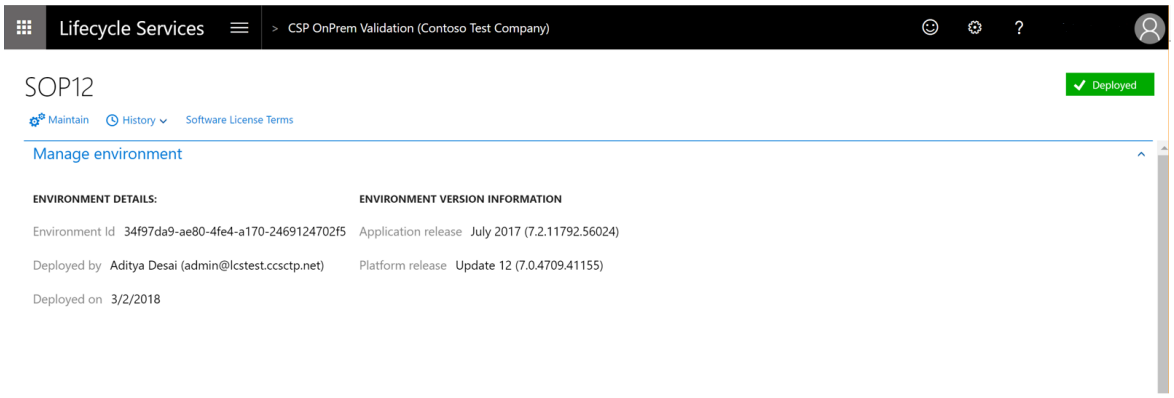




If the deployment fails, the **Reconfigure** button will become available for your environment in LCS, as shown below. Fix the underlying issue, click **Reconfigure**, update any configuration changes, and click **Deploy** to retry the deployment.



See the Reconfigure environments to take a new platform or topology topic for details about how to reconfigure. The following graphic shows a successful deployment.



22. Connect to your Finance + Operations environment

In your browser, navigate to https://[yourD365FOdomain]/namespaces/AXSF, where yourD365FOdomain is the domain name that you defined in the Plan your domain name and DNS zones section of this topic.

- Client internet connectivity

Known issues

Error "Key does not exist" when running the New-D365FOGMSAAccounts cmdlet

If this is your first time creating and generating group Managed Service Account passwords in your domain, you need to first create the **Key Distribution Services KDS Root Key**. For more information, see Create the Key Distribution Services KDS Root Key.

Error "The WinRM client cannot process the request" when running the remoting script Configure-Prereqs-AllVms cmdlet

You need to follow the instructions in the error message to enable the computer policy **Allow delegation fresh credentials** in all machines of Service Fabric cluster.

Error "Not process argument transformation on parameter 'Test'. Cannot convert value "System.String" to type "System.Management.Automation.SwitchParameter" when running the Config-Prereqs-AllVms cmdlet

To work around this error, remove "-Test:$Test" in line 56 of Config-Prereqs-AllVms.ps1, which is found under the **Infrastructure** folder.

Error "Not process argument transformation on parameter 'Test'. Cannot convert value "System.String" to type "System.Management.Automation.SwitchParameter" when running the Complete-Prereqs-AllVms cmdlet

To work around this error, remove "-Test:$Test" in line 56, 61 and 66 of Complete-Prereqs-AllVms.ps1 which is found under the **Infrastructure** folder.

Error "Install-WindowsFeature: The request to add or remove features on the specified server failed" when running Configure-Prereqs on MRType and ReportServerTyoe servers

.NET Framework 3.5 is required in MRType and ReportServerType servers. By default, however, .NET Framework 3.5 source files aren't included in your Windows Server 2016 installation. To work around this error, install it and specify the source files using the **source** option when you manually add new features by server manager.

Error "MSIS7628: Scope names should be a valid Scope description name in AD FS configuration" when running the Publish-ADFSApplicationGroup cmdlet

This error occurs because of an OpenID scope **allatclaims** that is required by the D365FO-OP-ADFSApplicationGroup, but it might be missing in some Windows Server 2016 installation. To work around this error, add the scope description **allatclaims** through AD FS Management\Service\Scope Descriptions.

Error "ADMIN0077: Access control policy does not exist: Permit everyone" when running the Publish-ADFSApplicationGroup cmdlet

When your AD FS is installed with a non-English version of Windows Server 2016, the permit everyone access control policy is created with your local language. Invoke the cmdlet by specifying AccessControlPolicyName parameter as: .\Publish-ADFSApplicationGroup.ps1 -HostUrl 'https://ax.d365ffo.onprem.contoso.com' -AccessControlPolicyName ''.

Installation steps for Retail channel components in an on-premises environment

2/18/2021 • 5 minutes to read • Edit Online

This topic covers the installation steps for Commerce channel components in an on-premises environment.

Overview

Channel functionality, in an on-premises environment, is enabled exclusively via use of Commerce Scale Unit (self-hosted). For an overview, see Commerce Scale Unit (self-hosted).

Unlike a cloud deployment, an on-premises environment does not enable seamless, high-availability deployment of channel components via Lifecycle Services (LCS). The only way to use channel components is by installing Commerce Scale Unit (self-hosted).

Prerequisites

Before you can start installation of channel components, you must first complete all prior installation steps for an on-premises environment. These steps are listed in Set up and deploy on-premises environments (Platform update 12 and later). In addition, version 8.1.1 must be installed in order for Commerce have full functionality. We recommend that you update to version 8.1.2.

> **NOTE**
> It is critical to ensure that a secure network, that is not publicly accessible, is used to connect Commerce Scale Unit to Headquarters. You must also restrict network access to Headquarters, so access is only allowed to known Commerce Scale Unit devices via network filtering or other means. This means that a firewall must exist and using a safe list is highly recommended.

Installation steps

1. On the previously created Application share, (not the **LocalAgent** share folder), create a new folder called **selfservicepackages** in the root directory of the share location.
2. On each AOS computer, create an easily accessible directory, such as **C:/selfservicepackages**.
3. On one AOS computer (which one does not matter), run the following PowerShell script.

```
.\RetailUpdateDatabase.ps1 -envName '<Environment name>' -AosUrl 'https://<My Environment
Name>.com/namespaces/AXSF/' -SendProductSupportTelemetryToMicrosoft
```

IMPORTANT

The above steps apply to version 10.0 and later. For the original 8.1.3 release of Retail on-premises functionality, the original version of the script delimiters must be used.

```
.\RetailUpdateDatabase.ps1 -DatabaseServer '<Database server name for AOS database>' -
DatabaseName '<Database name for AOS database>' -envName '<Environment name>' -
RetailSelfServicePackages '<Local path of Retail self-service packages, such as
**C:/selfservicepackages**>' -SendProductSupportTelemetryToMicrosoft
```

- The parameter **-envName** should be known based on creation when the environment is generated.
- The legacy parameters **-DatabaseServer** and **-DatabaseName** should be known based on the environment setup.
- The parameter **-SendProductSupportTelemetryToMicrosoft** is a required value to enable telemetry to Microsoft. This is critical to maximize support from Microsoft.
- This script will perform a variety of actions, including updating the Service user and role and updating registry keys.

4. On each AOS computer, run the following PowerShell script.

```
.\RetailUpdateDatabase.ps1 -RetailSelfServicePackages 'C:\RetailSelfService\Packages'
```

NOTE

The parameter **-RetailSelfServicePackages** is the full path location created in the beginning of this step (**C:/selfservicepackages**).

5. Download the appropriate binary update from LCS to have the Commerce installers. For instructions, see Download updates from Lifecycle Services (LCS).

6. Extract the zip file and copy all self-service installers into the folder **C:/selfservicepackages** defined and created in step 2 in each of the AOS machines. The six self-service installers include:

   - AsyncServerConnectorServiceSetup.exe
   - RealtimeServiceAX63Setup.exe
   - HardwareStationSetup.exe
   - ModernPosSetup.exe
   - ModernPosSetupOffline.exe
   - StoreSystemSetup.exe

NOTE

Cloud environments can synchronize self-service installers through Headquarters from what is available in LCS (Synchronize self-service installers in Dynamics 365 Commerce). On-premises environments cannot utilize this functionality, however, these environments can still download from LCS. The SDK is available in the deployable package zip file. The self-service installers are available from the LCS **Asset library**. You can utilize the upload and download mechanism from within LCS, but the Headquarters synchronization functionality will not work.

7. Navigate to the AD FS machine, then go to the InfrastructureScripts folder. This is the same file directory where the previously run PowerShell script was located (**RetailUpdateDatabase.ps1**). Find the PowerShell script **Create-ADFSServerApplicationForRetail.ps1**.

8. On the AD FS machine that you're currently using, run this script in a new PowerShell window using the

command **.\Create-ADFSServerApplicationForRetail -HostUrl 'https://ax.d365ffo.onprem.contoso.com'**, where the **HostUrl** value can be found in Service Fabric. To find the **HostUrl** value, go to **Service Fabric** > **Application fabric:/AXSF** > **Details** > **Aad_AADValidAudience**.

9. Access the newly generated Server application from the **Application Groups** in AD FS Management.
10. Edit the newly generated Server application and select **Reset the Secret**.

> **NOTE**
>
> It is an important security measure to run this script for each Commerce Scale Unit. This maximizes security and minimizes the workload in case of a security breach.
>
> It is critical to keep this secret safe. This secret should only be copied once and never stored on the system. The Client ID and Secret generated will be used during the Commerce Scale Unit installer, so it is required to be used at a later time. You can always reset the secret again, but it must then be updated on any Commerce Scale Unit that used the previous secret.

11. Go to **Retail and Commerce** > **Headquarters setup** > **Commerce scheduler** > **Connector for Microsoft Dynamics AX**.
12. Select **Edit** on the Action pane.
13. In the **Profile** field, enter the value **Default**. If needed, enter a description in the **Description** field.

> **NOTE**
>
> It is possible for the following fields in steps 12 through 14 to already have values. If this occurs, skip those steps and continue from there. What is important is to have a selectable profile title (default in this case).

14. In the **Web application name** field, enter **RetailCDXRealTimeService**.
15. In the **Protocol** field, select **https**.
16. In the **Common name** field, enter **AXServiceUser@contoso.com**.
17. Select **Save** on the Action Pane.
18. In Headquarters, go to **Retail and Commerce** > **Headquarters setup** > **Parameters** > **Commerce shared parameters**.
19. Select the **Security** tab.
20. Under the sub-heading **Transaction service legacy properties**, select the **Real-time Service profile** field, and then select the newly created **Default** value.
21. Select the **Identity providers** tab.
22. On the **Identity providers** FastTab, select **Add**.
23. In the new **Issuer** row, enter the new Identity provider value **https://sts.windows.net/** in the field.
24. Select **Save** on the Action Pane.
25. Go to **Retail and Commerce** > **Headquarters setup** > **Parameters** > **Commerce parameters**.
26. On the **General** tab, select the **Initialize** link to configure seed data for Commerce functionality.

NOTE

The installers will not download from their relevant pages the first time a download is attempted. This is because the installers have only just been placed into the download location and the associated database values do not yet exist. In Headquarters, when the **Download** functionality is attempted (for example, Commerce Scale Unit or Modern POS), an error will display and then an automated upload functionality will be initiated to allow the installers to be downloaded the second time that the download is attempted. (Wait one minute before attempting to download the installer again).

The Peripheral Simulator (downloaded on the Hardware profile page in headquarters) will not be available until at least one Hardware profile has been created and is functional. After that point has been achieved, the following script can be run.

```
.\RetailUpdateDatabase.ps1 -envName 'LBDenv1' -UpdateRetailHardwareProfileSelfServicePackage
```

27. Follow the installation steps for installing the Commerce Scale Unit. For instructions, see Configure and install Commerce Scale Unit (self-hosted). At multiple locations in this document there will be notes referencing changes to the instructions for an on-premises deployment. It is important to note each of these changes.

NOTE

Can you tell us about your documentation language preferences? Take a short survey.

The survey will take about seven minutes. No personal data is collected (privacy statement).

Develop and deploy custom models to on-premises environments

2/18/2021 • 3 minutes to read • Edit Online

This topic describes how to develop customizations and extensions, and deploy them to an on-premises environment. On-premises environments are also referred to as local business data (LBD) environments. This topic focuses on the ways that this process differs from the process in a run-time cloud environment.

The process has the following main steps:

1. Deploy your development and build environments.
2. Create a deployable package of your code and customizations.
3. Upload the deployable package to your project in Microsoft Dynamics Lifecycle Services (LCS).
4. Configure and deploy an on-premises runtime environment that includes your deployable package. This environment can be either a sandbox environment or a production environment.

The following sections provide more information about this process.

Development tools and platform

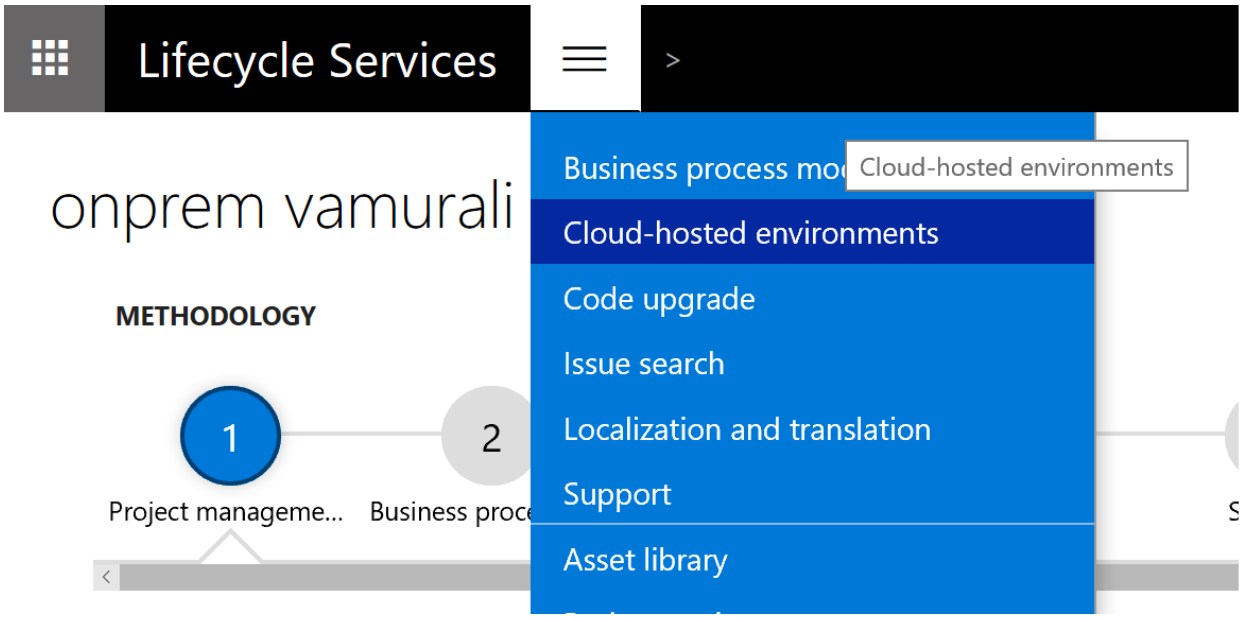
Whether you're developing, extending, or customizing cloud applications or on-premises applications, the development platform, tools, and environments (virtual machines [VMs]) are the same. Your custom code is developed on the same development VMs, regardless of whether your target runtime environments are in a cloud environment or an on-premises environment.

For detailed information about development, see the Develop and customize home page. For information about extensibility and customization, see the Extensibility home page. For information about building, testing, and continuous delivery, see the Continuous delivery home page.

Deploy development and build environments

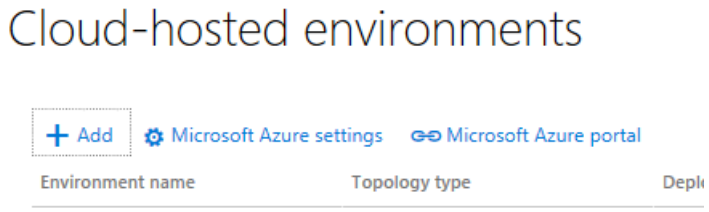
You can use an on-premises LCS project to deploy build and development environments on Microsoft Azure by using your own Azure subscription. Alternatively, you can download a virtual hard disk (VHD) for local development.

To deploy a development or build environment in your Azure subscription, or to download a development VHD, open the **Cloud-hosted environments** page in LCS.



Then follow these steps.

1. Click **Add**.

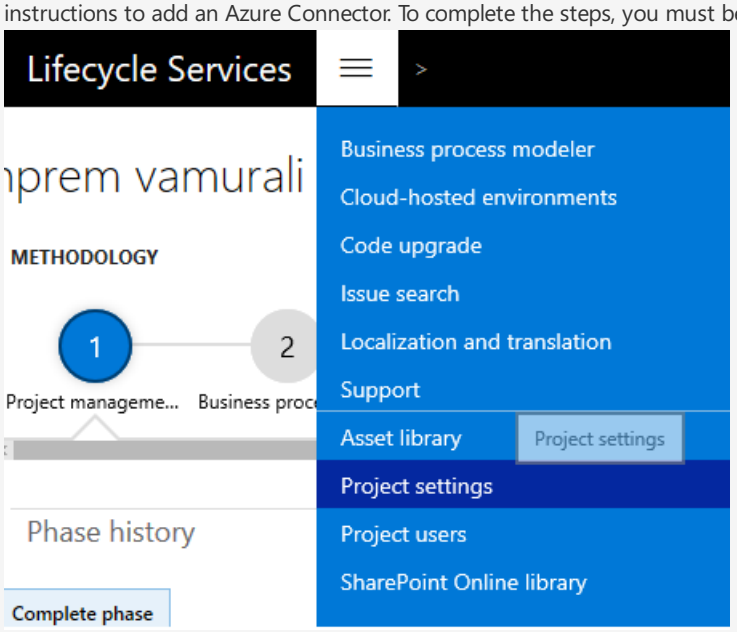


2. Select **Azure** or **Locally**. If you select **Locally**, find and download a development VHD. If you select **Azure**, you're prompted to select one of three topologies: **Build and Test**, **Demo**, or **Development**.
3. Complete the deployment steps, and deploy a VM in your Azure subscription.

For more information about how to configure a local development VHD, see Deploy and access development environments.

NOTE

To deploy environments in your own Azure subscription, you must set up at least one Azure Connector. To set up an Azure Connector, in LCS, open the **Project settings** page, and then click the **Azure connectors** tab. Then follow the instructions to add an Azure Connector. To complete the steps, you must be the tenant administrator of the organization.



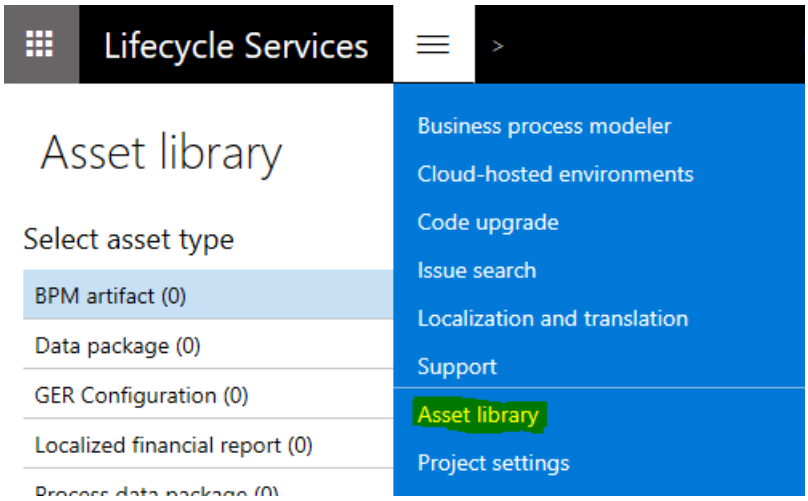
Create and upload a deployable package to the LCS Asset library

When you complete a phase of development, and are ready to deploy your code to a sandbox or production on-premises environment, you must create an application deployable package from your models. This process doesn't differ from the process for cloud environments.

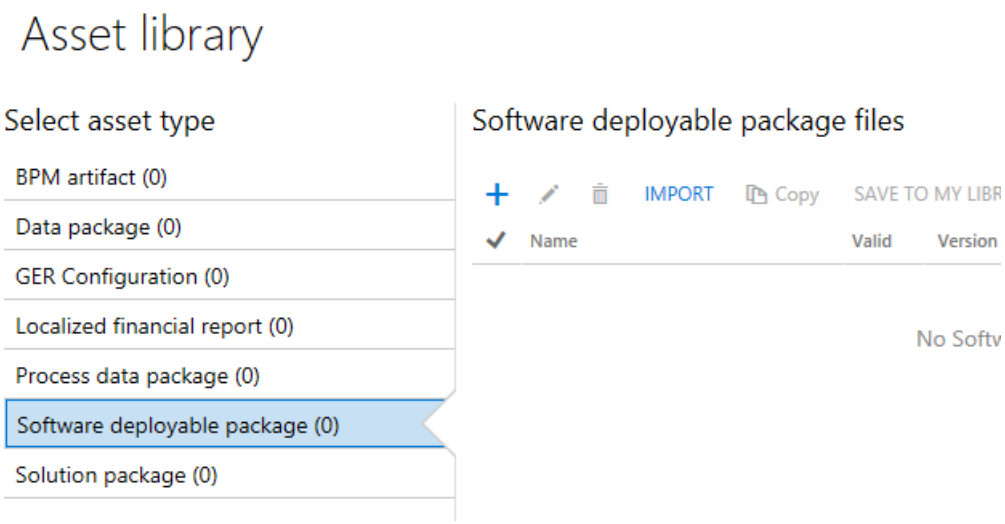
If you're using automated builds (a build environment), the build process creates an application deployable package for you. You can also create an application deployable package from Microsoft Visual Studio in your development environment. For more information on how to create an application deployable package in your development environment, see Create deployable packages of models.

When your deployable package is ready, follow these steps to upload it to your LCS project's Asset library.

1. Open the **Asset library** page.



2. Click the **Software deployable package** tab.

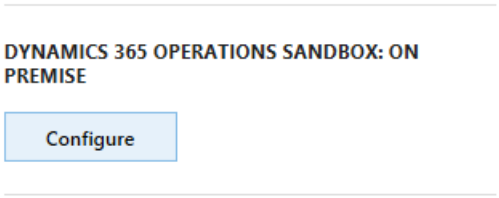


3. Click the plus sign (+) to upload the deployable package.

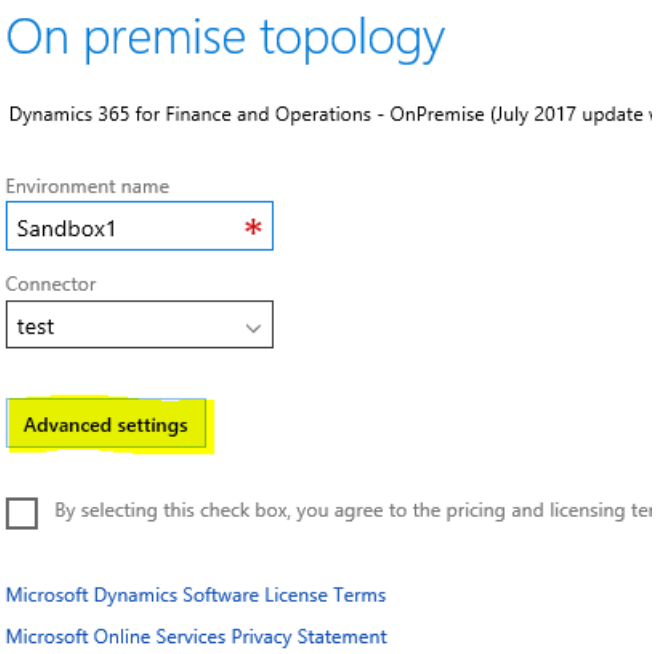
Configure an on-premises runtime environment that uses your code

As of the July 2017 release of Microsoft Dynamics 365 for Finance and Operations (on-premises), you can apply your customizations and extensions only during the deployment of a sandbox or production environment.

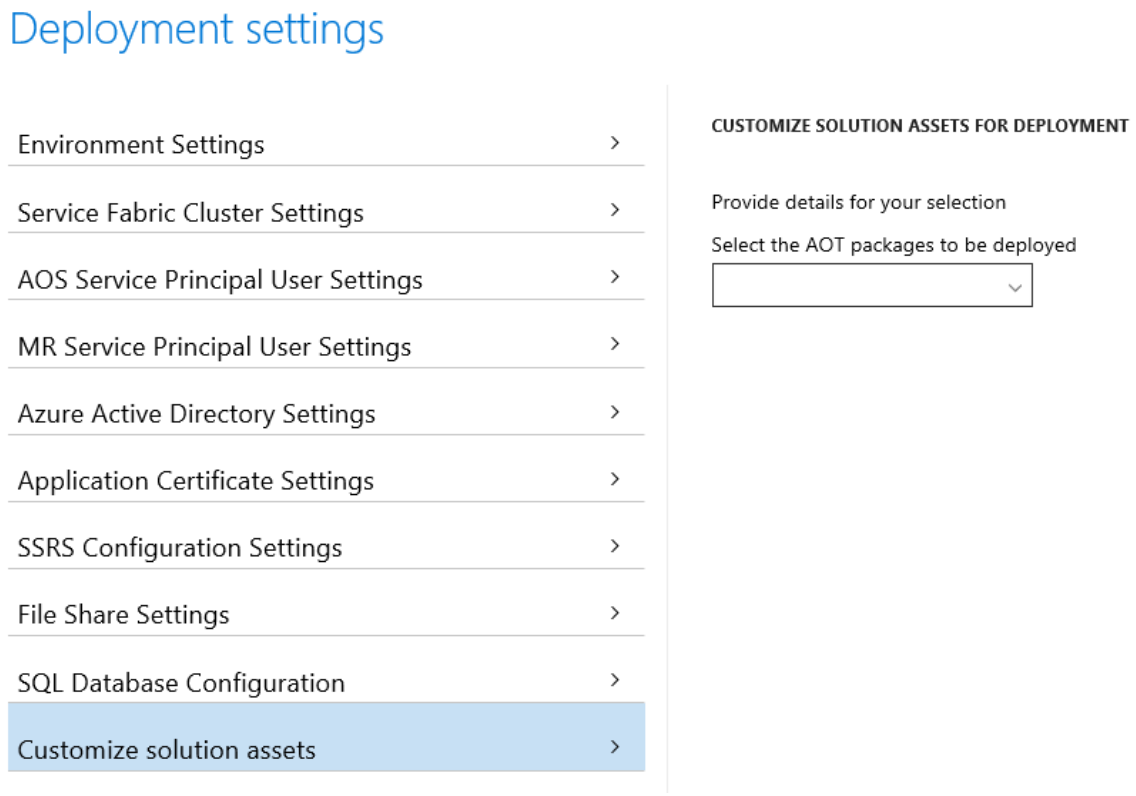
1. In your LCS project, click **Configure** to deploy your environment.



2. In the deployment tool, when you must enter the environment name, click **Advanced settings**.



3. Click the **Customize solution assets** tab.



4. In the **Select the AOT packages to be deployed** field, select the application (AOT) deployable package that contains your customizations. This field lists all the AOT packages in your Asset library.
5. Click **Done** to close the **Deployment settings** page, and then continue with the environment deployment process.

> **NOTE**

> The survey will take about seven minutes. No personal data is collected (privacy statement).

Apply updates to on-premises deployments

2/18/2021 • 8 minutes to read • Edit Online

This topic explains how to apply supported updates to Dynamics 365 Finance + Operations (on-premises). All updates to on-premises environments are done through Microsoft Dynamics Lifecycle Services (LCS).

Search for and download updates

For more information about how to find the updates that you can apply to your on-premises environment, see Issue search in Lifecycle Services (LCS). For information about how to download updates from the tiles in the **Updates** section of the **Environment details** page in LCS, see Download updates from Lifecycle Services (LCS).

> **NOTE**
>
> When you are updating an on-premises environment, always select updates from the update tiles on the **Environment** details page. If you select updates from another location, the updates might not work.

Update an on-premises deployment

You can apply updates to an on-premises environment either during deployment or after the deployment is completed.

While an on-premises environment is being deployed, you can select to deploy a custom package in the **Advanced** settings. For more information about how to apply customizations or application X++ updates, see Develop and deploy custom models to on-premises environments.

To apply updates to an on-premises environment after it has been deployed, in LCS, on the **Environment details** page for the environment, under **Maintain**, select **Apply updates**.

> **NOTE**
>
> You can apply updates after deployment only on environments that have Platform update 12 for Finance and Operations or later. The environment must also have the latest version of the local agent available in LCS. For more information, see Update the local agent. If you're on a platform version that is older than Platform update 12, you can reconfigure an environment that is already deployed to update the customizations or update to the latest platform release. For more information about how to redeploy an environment, seeRedeploy on-premises environments.

Apply application or binary updates through LCS

The following steps can be used to apply X++, All Binary, or Platform binary updates.

> **IMPORTANT**
>
> The application of updates requires downtime for your environment. Therefore, no business transactions can be performed in the environment during the update. When you complete the following steps, verify that the system isn't being used, and that an official downtime notice has been communicated to all system users.

> **IMPORTANT**
> To move to the latest platform, always select the platform update from the **Platform Binary Updates** tile on the **Environment** details page. If you select updates from another location, the updates might not work.

Prerequisites

- Before you begin, complete a full backup of the Management Reporter (MR), Microsoft Dynamics AX, and Microsoft SQL Server Reporting Services (SSRS databases). Although the code is restored through LCS, the database must be manually restored to help guarantee that there is no data loss.
- Update your environment to the latest build of Platform update 12.
- Update the local agent to the latest version. For more information, see Update the local agent.
- Depending on the type of update, complete the following steps to generate a deployable package:
  - **Platform binary updates** – Download or save the update directly to the Asset library in LCS by following the steps in Download updates from Lifecycle Services (LCS).
  - **Application binary updates** – Download or save the update directly to the Asset library in LCS by following the steps in Download updates from Lifecycle Services (LCS).
  - **Application X++ updates** – Download the required hotfix to your development environment, and then follow the steps in Create deployable packages of models.
  - **Customizations** – Follow the steps in Develop and deploy custom models to on-premises environments.

Update a sandbox environment

1. In the LCS Asset library, upload the deployable package that was generated in the "Prerequisites" section of this topic to the**Software deployable packages**tab.
2. In LCS, open the on-premises implementation project, and then open the **Environment details** page of the environment to update.
3. Under **Maintain**, select **Apply updates**. A slider shows the updates that were uploaded to the Asset library. Note that only packages that are marked as **Valid** in the Asset library appear.

If you are on local agent version 2.1.0 and higher, complete the following steps.

1. Select the update, and then click **Prepare**. Clicking on **Prepare** will prepare your on-premises environment for servicing.

   > **NOTE**
   > During preparation, the environment state will be **Deployed** but the Deployment status field will show the progress of Preparation. Steps such formatting the package and downloading the package are executed during preparation. The environment is not directly touched during preparation and hence there is no downtime during the preparation phase. Users can continue to use the system during preparation.

2. After the preparation is complete, you will see **Abort** and **Update Environment** buttons. To start applying the update, click **Update Environment**. If preparation fails, see the "Resolve a failed update application" section later in this topic.
3. In the confirmation message, select **Yes**. The servicing operation has started on this environment. This is the start of the downtime on your environment.
4. The environment state is changed from **Deployed** to **Deploying**.
5. After the update is completed, the environment state is changed back to **Deployed**. If application of the

update fails, the environment state is changed to **Failed**. For information about what to do if package application fails, see the "Resolve a failed update application" section later in this topic.

6. Open the **History** and **Environment details** pages to view the operations that were performed on the environment. You can also view a record of major actions that were performed on the environment, such as deployments, servicing, and rollbacks.

If you are on local agent version lower than 2.1.0, complete the following steps.

1. Select the update, and then click **Apply**.
2. In the confirmation message, select **Yes**. The servicing operation has started on this environment. This is the start of the downtime on your environment.
3. Environment state changes from **Deployed** to **Preparing**.

> **NOTE**
> During preparation, steps such formatting the package and downloading the package are executed during preparation. The environment is not directly touched during preparation and hence there is no downtime during the preparation phase. Users can continue to use the system during preparation. However, we recommend that the downtime starts when the environment enters the Preparing state.

4. After preparation is complete, the environment state is changed from **Preparing** to **Deploying**.
5. After the update is completed, the environment state is changed back to **Deployed**. If application of the update fails, the environment state is changed to **Failed**. For information about what to do if package application fails, see the "Resolve a failed update application" section later in this topic.
6. Open the **History** and **Environment details** pages to view the operations that were performed on the environment. You can also view a record of major actions that were performed on the environment, such as deployments, servicing, and rollbacks.

Update a production environment

Before you update a production environment, you must successfully complete the package application update on a sandbox environment.

1. In the project for the sandbox environment that you applied the package to, open the Asset library, and then, on the **Software deployable packages** tab, select the package, and mark it as a **Release candidate**.
2. On the **Environment details** page, under **Maintain**, select **Apply updates**. In the dialog box, only packages that are marked as a **Release candidate** are shown.
3. Select the Release candidate package to be applied to the Production environment.
4. The rest of the Update flow is the same as that of a sandbox environment. Your update experience will differ based on the version of the local agent running on your environment. We recommend that you always run with the latest version.

Resolve a failed update application

When preparation fails, the environment state is **Deployed**. When the application of an update fails, the environment state is **Failed**. The first step is to determine why there is a failure. The location of the logs varies, depending on the stage where the failure occurred:

- **Preparation stage:** If the operation fails during the **Preparation** stage, the logs are uploaded to LCS. In the log files, select **Download logs** to download the log files. If the package has any merge issues, the error is included in the log file.
- **Deploying stage:** If the operation fails during the **Deploying** stage, the logs are located in the on-premises

environment. You must sign in to the environment, and then access the logs and event viewer.

For more information about how to use the troubleshooting logs, see Troubleshoot on-premises deployments.

After you review the logs and determine the cause of the failure, complete one of the following operations to restore the environment to a healthy state. No actions can be performed on an environment that is in a **Failed** state. The environment must first be restored to a healthy state.

- **Retry failed operation** – If update application fails, select **Retry** to recover from the failed operation.
- **Abort failed operation** – Because there is no change made to the on-premises environment, if the preparation fails, you have the option to cancel the operation. Select **Abort** to cancel the preparation.
- **Roll back the update** – To roll back the update that failed, select **Rollback**. Before you start the rollback, you must restore the database to the last known good state. When you select **Rollback**, the environment is restored to the last known good state. The environment state is then changed to **Preparation**, then to **Deploying**, and then to either **Deployed** or **Failed**.

  > **NOTE**
  >
  > The **Rollback** button doesn't roll back the database. You're responsible for restoring the database to the last known backup that was made before update application. This step is critical to help guarantee that there is no data loss.

- **Refresh the state** – If update application fails during the **Preparation** stage, the failure is on the LCS side, and update application hasn't yet started. Therefore, the on-premises environment is in a good state. To restore the LCS environment state to **Deployed**, on the project dashboard page, select **Refresh**.
- **Delete and redeploy an environment** – If the retry and rollback options don't work, you must delete and redeploy the environment. To delete the environment, on the project dashboard page, select **Delete**. You then see the option to configure the environment.

  > **IMPORTANT**
  >
  > This option should **not** be used on a production environment. However, it can be used on a sandbox deployment to restore the environment to a healthy state.

  > Because this option requires that you do a fresh deployment of the environment, you lose any updates that were previously applied. Any customizations and binary updates must be reapplied to the environment.

> **NOTE**
>
> Can you tell us about your documentation language preferences? Take a short survey.
>
> The survey will take about seven minutes. No personal data is collected (privacy statement).

Certificate rotation

2/18/2021 • 9 minutes to read • Edit Online

You may need to rotate the certificates used by your Dynamics 365 Finance + Operations (on-premises) environment as they approach their expiration date. In this topic, you will learn how to replace the existing certificates and update the references within the environment to use the new certificates.

WARNING

The certificate rotation process should be initiated well before the certificates expire. This is very important for the Data Encryption certificate, which could cause data loss for encrypted fields. For more information, see After certificate rotation.

Old certificates must remain in place until the certificate rotation process is complete, removing them in advance will cause the rotation process to fail.

Caution

The certificate rotation process should not be carried out on Service Fabric clusters running 7.0.x and 7.1.x.

Upgrade your Service Fabric cluster to 7.2.x or later before attempting certificate rotation.

Preparation steps

1. Rename the original **Infrastructure** folder that you created during the process to Download setup scripts from LCS. Rename the folder to **InfrastructureOld**.
2. Download the latest setup scripts from Download setup scripts from LCS. Unzip the files into a folder that is named **Infrastructure**.
3. Copy **ConfigTemplate.xml** and **ClusterConfig.json** from **InfrastructureOld** to **Infrastructure**.
4. Configure certificates as needed in **ConfigTemplate.xml**. Follow the steps in Configure certificates, specifically these steps.

```
# Create self-signed certs
.\New-SelfSignedCertificates.ps1 -ConfigurationFilePath .\ConfigTemplate.xml
```

Alternatively, if you have or would like to switch to Active Directory Certificate Services (AD CS) certificates, use this information.

```
# Only run the first command if you have not generated the templates yet.
.\New-ADCSCertificates.ps1 -ConfigurationFilePath .\ConfigTemplate.xml -CreateTemplates
.\New-ADCSCertificates.ps1 -ConfigurationFilePath .\ConfigTemplate.xml
```

NOTE

The AD CS scripts need to run on a domain controller, or a Windows Server computer with Remote Server Admin Tools installed. The AD CS functionality is only available with Infrastructure scripts release 2.7.0 and later.

> Self-signed certificates should never be used in production environments. If you're using publicly trusted certificates, manually update the values of those certificates in the ConfigTemplate.xml file.

```
# Export Pfx files into a directory VMs\<VMName>, all the certs will be written to
infrastructure\Certs folder
.\Export-PfxFiles.ps1 -ConfigurationFilePath .\ConfigTemplate.xml
```

5. Continue to Setup VMs. The specific steps that are needed for this process include:

   a. Export the scripts that must be run on each VM.

   ```
   # Export the script files to be executed on each VM into a directory VMs\<VMName>
   .\Export-Scripts.ps1 -ConfigurationFilePath .\ConfigTemplate.xml
   ```

   b. Copy the contents of each infrastructure\VMs folder into the corresponding VM (if remoting scripts are used, they will automatically copy the content to the target VMs), and then run the following scripts, if they exist. Perform these steps as an Administrator.

   ```
   # If remoting, only execute
   # .\Complete-PreReqs-AllVMs.ps1 -ConfigurationFilePath .\ConfigTemplate.xml -
   ForcePushLBDScripts

   .\Import-PfxFiles.ps1
   .\Set-CertificateAcls.ps1
   ```

   c. Run the following script to validate the VM setup.

   ```
   # If remoting, only execute
   # .\Test-D365FOConfiguration-AllVMs.ps1 -ConfigurationFilePath .\ConfigTemplate.xml
   .\Test-D365FOConfiguration.ps1
   ```

6. If axdataenciphermentcert certificates are rotated, you need to regenerate the credentials.json file. For more information, see Encrypt credentials.

7. Run the following PowerShell command to have values that can be used in LCS later. For more information, see Deploy your on-premises environment from LCS.

```
.\Get-DeploymentSettings.ps1 -ConfigurationFilePath .\ConfigTemplate.xml
```

Activate new certificates within Service Fabric cluster

Service Fabric with certificates that aren't expired

1. Open the **Clusterconfig.json** file for editing, and find the following section. If a secondary thumbprint is defined, go to Clean up old Service Fabric certificates before you go any further.

```
"security": {
    "metadata":  "The Credential type X509 indicates this cluster is secured using X509 Certificates.
    The thumbprint format is - d5 ec 42 3b 79 cb e5 07 fd 83 59 3c 56 b9 d5 31 24 25 42 64.",
    "ClusterCredentialType":  "X509",
    "ServerCredentialType":  "X509",
    "CertificateInformation":  {
        "ClusterCertificate":  {
                                "X509StoreName":  "My",
                                 "Thumbprint": "*Old server thumbprint(Star/SF)*"
                            },
        "ServerCertificate":   {
                                 "X509StoreName":  "My",
          "Thumbprint": "*Old server thumbprint(Star/SF)*"
                            },
        "ClientCertificateThumbprints":  [
                                {
                                     "CertificateThumbprint": "*Old client thumbprint*",
                                     "IsAdmin":  true
                                }
                                      ]
                            }
           },
```

2. Replace that section in the file with following section.

```
"security":  {
    "metadata":  "The Credential type X509 indicates this cluster is secured using X509 Certificates.
    The thumbprint format is - d5 ec 42 3b 79 cb e5 07 fd 83 59 3c 56 b9 d5 31 24 25 42 64.",
    "ClusterCredentialType":  "X509",
    "ServerCredentialType":  "X509",
    "CertificateInformation":  {
        "ClusterCertificate":  {
                                "X509StoreName":  "My",
                                 "Thumbprint": "*New server thumbprint(Star/SF)*",
                                 "ThumbprintSecondary": "Old server thumbprint(Star/SF)"
                            },
        "ServerCertificate":   {
                                 "X509StoreName":  "My",
          "Thumbprint": "*New server thumbprint(Star/SF)*",
                                 "ThumbprintSecondary": "Old server thumbprint(Star/SF)"
                            },
        "ClientCertificateThumbprints":  [
                                {
                                     "CertificateThumbprint": "*Old client thumbprint*",
                                     "IsAdmin":  false
                                },
                                {
                                     "CertificateThumbprint": "*New client thumbprint*",
                                     "IsAdmin":  true
                                }
                                      ]
                            }
           },
```

3. Edit the new and old thumbprint values.

4. Change clusterConfigurationVersion to the new version, for example 2.0.0.

```
{
"name": "Dynamics365Operations",
"clusterConfigurationVersion": "2.0.0",
"apiVersion": "10-2017",
```

5. Save the new ClusterConfig.json file.

6. Run the following PowerShell command.

```
# Connect to the Service Fabric cluster
Connect-ServiceFabricCluster

# Get path of ClusterConfig.json for following command
# Note that after running the following command, you need to manually cancel using the red button
(Stop Operation) in Windows PowerShell ISE or Ctrl+C in Windows PowerShell, otherwise you will
receive the following notification, "Start-ServiceFabricClusterConfigurationUpgrade : Operation timed
out.". Be aware that the upgrade will proceed.
Start-ServiceFabricClusterConfigurationUpgrade -ClusterConfigPath ClusterConfig.json

# If you are using a single Microsoft SQL Server Reporting Services node, use
UpgradeReplicaSetCheckTimeout to skip PreUpgradeSafetyCheck check, otherwise it will timeout
Update-ServiceFabricClusterUpgrade -UpgradeReplicaSetCheckTimeoutSec 30

# To monitor the status of the upgrade, run the following and note UpgradeState and
UpgradeReplicaSetCheckTimeout
Get-ServiceFabricClusterUpgrade

# While monitoring the status of the upgrade, if UpgradeReplicaSetCheckTimeout was reset to the
default (example 49710.06:28:15), run the following command again
Update-ServiceFabricClusterUpgrade -UpgradeReplicaSetCheckTimeoutSec 30

# When UpgradeState shows RollingForwardCompleted, the upgrade is finished
```

Service Fabric with or without expired certificates (cluster not accessible)

Continue this process following Troubleshoot on-premises deployments.

Update the LocalAgent certificate

You must reinstall the LocalAgent if:

- You changed the service fabric cluster/server certificate.
- You changed the service fabric client certificate.
- You changed the LocalAgent certificate.

1. Update your current localagent-config.json by replacing the **serverCertThumprint** and **clientCertThumbprint** values with the new thumbprints.

```
{
"serviceFabric": {
    "connectionEndpoint": "192.168.8.22:19000",
    "clusterId": "Orch",
    "certificateSettings": {
        "serverCertThumbprint": "New server thumbprint(Star/SF)",
        "clientCertThumbprint": "New client thumbprint"
    }
},
```

2. Run the following PowerShell command on one of the Orchestrator nodes.

```
.\LocalAgentCLI.exe Cleanup <path of localagent-config.json>
```

3. Run the following PowerShell command and note the new LocalAgent thumbprint.

```
.\Get-AgentConfiguration.ps1 -ConfigurationFilePath .\ConfigTemplate.xml
```

4. Follow the steps in Configure LCS connectivity for the tenant.

> **NOTE**
> If you receive the error **Update to existing credential with KeyId '<key>' is not allowed**, follow the instructions in Error: "Updates to existing credential with KeyId '' is not allowed".

5. Continue with Configure a connector and install an on-premises local agent, specifically the following changes:

   - Client certificate thumbprint
   - Server certificate thumbprint
   - Tenant service principle certificate thumbprint

Update your current deployment configuration

Because you've updated your certificates, the configuration file that is present in your environment is outdated and must be manually updated. Otherwise, the cleanup job will probably fail. (This manual update must be done just this one time.)

1. Open your configuration file. You can find the location of this file by running the following command.

```
select Location from DeploymentInstanceArtifact where AssetId='config.json' and DeploymentInstanceId
= 'LCSENVIRONMENTID'
```

> **NOTE**
> Replace **LCSENVIRONMENTID** with the ID of your environment. You can obtain this ID from the page for your environment in LCS.

   The beginning of the file should resemble the following example.

```
{
"serviceFabric": {
    "connectionEndpoint": "192.168.8.22:19000",
    "clusterId": "Orch",
    "certificateSettings": {
        "serverCertThumbprint": "Old server thumbprint(Star/SF)",
        "clientCertThumbprint": "Old client thumbprint"
    }
},
```

2. Replace the **serverCertThumprint** and **clientCertThumbprint** values with the new thumbprints.

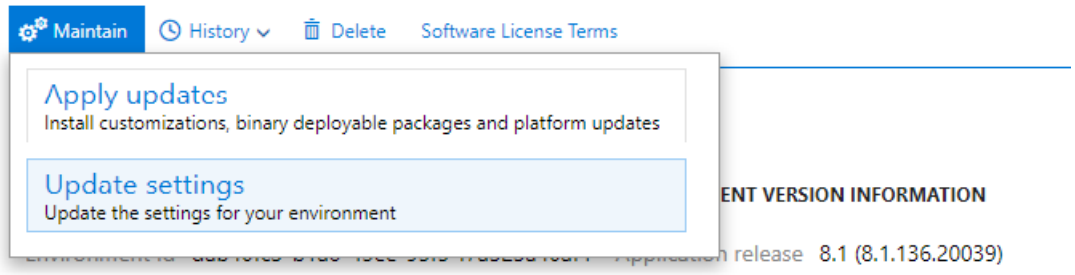
```
{
"serviceFabric": {
    "connectionEndpoint": "192.168.8.22:19000",
    "clusterId": "Orch",
    "certificateSettings": {
        "serverCertThumbprint": "New server thumbprint(Star/SF)",
        "clientCertThumbprint": "New client thumbprint"
    }
},
```

3. Save and close the file. Remember to close any programs that are accessing this network location. Otherwise, the cleanup process might fail.

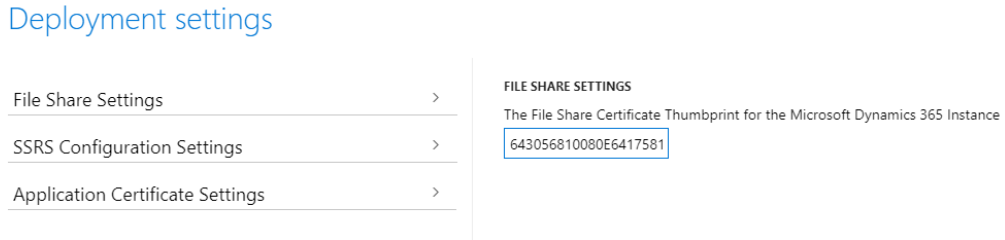
Update deployment settings in LCS

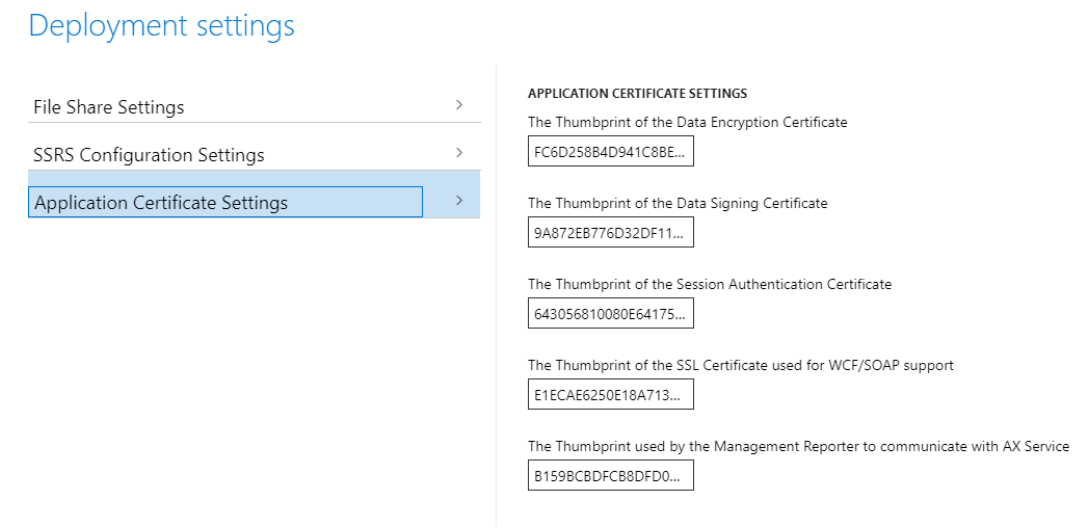
> **NOTE**
>
> Note that the Client, Data Signing, and Encipherment certificates will only be replaced. You will also need to recreate the Credentials.json file, as described in Encrypt credentials.
>
> Before you continue, you need to make a backup of the local Dynamics database.

1. In LCS, select the "Full Details" link for the environment where you want to change the certificates.
2. Select **Maintain** and then select **Update Settings**.

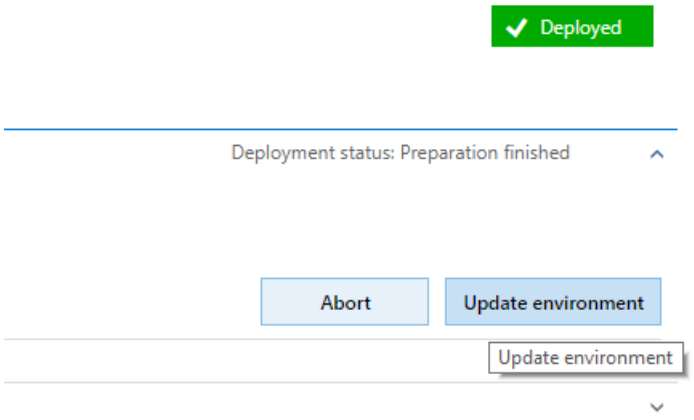


3. Change the thumbprints to the new thumbprints that you previously configured. You can find them in the ConfigTemplate.xml file in the InfrastructureScripts folder.



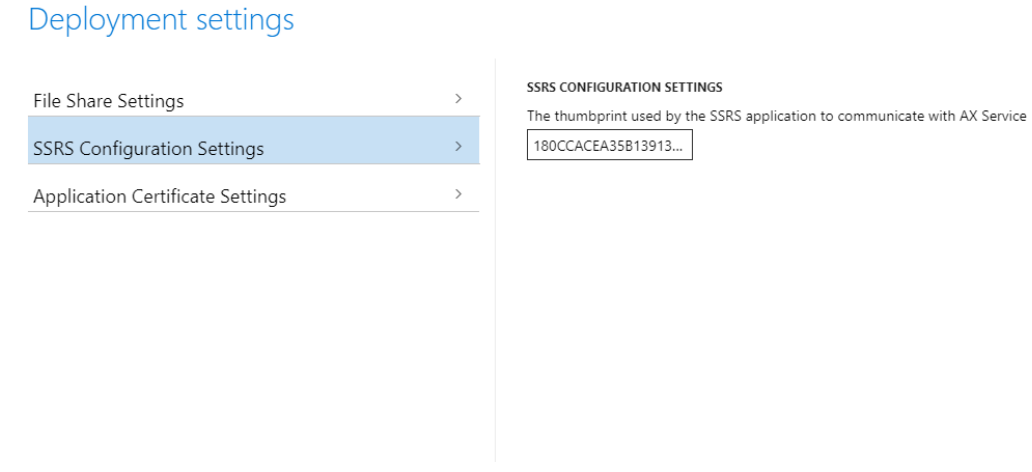


4. Select **Prepare**.
5. After downloading and preparation is complete, the **Update environment** button will display.



6. Select **Update environment** to start updating your environment.
7. During the update, the environment will be unavailable.
8. After the environment is successfully updated with the new certificates, you can view the new thumbprints in Service Fabric Cluster Explorer. The names of the thumbprints in Service Fabric Explorer might differ from the names in LCS. However, the values should be the same.

   Here is an example of how the name of the same thumbprint might differ.



Update other certificates as needed

1. Always check if the SQL server certificate has expired. For more information, see Set up SQL Server.
2. Check to be sure that the Active Directory Federation Service (ADFS) certificate has not expired.

Clean up old Service Fabric certificates

This procedure should be completed either after a successful certificate rotation or before the next certificate rotation.

1. Remove the old/secondary thumbprints from the cluster configuration. After you've removed them, the appropriate section should resemble the following example.

```
"security": {
    "metadata":  "The Credential type X509 indicates this is cluster is secured using X509
Certificates.
    The thumbprint format is - d5 ec 42 3b 79 cb e5 07 fd 83 59 3c 56 b9 d5 31 24 25 42 64.",
    "ClusterCredentialType":  "X509",
    "ServerCredentialType":  "X509",
    "CertificateInformation":  {
        "ClusterCertificate":  {
                                    "X509StoreName":  "My",
                                     "Thumbprint": "server thumbprint(Star/SF)"
                                },
        "ServerCertificate":   {
                                     "X509StoreName":  "My",
          "Thumbprint": "server thumbprint(Star/SF)"
                                },
        "ClientCertificateThumbprints":  [
                                    {
                                         "CertificateThumbprint": "client thumbprint",
                                         "IsAdmin":  true
                                    }
                                          ]
                                }
            },
```

2. Follow steps 4 through 6 in the Service Fabric with certificates that are not expired section earlier in this topic.

After certificate rotation

Data encryption certificate

This certificate is used to encrypt data stored in the database. By default there are certain fields that are encrypted with this certificate, you can check those fields in Document the values of encrypted fields. However, our API can be used to encrypt other fields that customers deem should be encrypted.

In Platform update 33 and later, the batch job that is named "Encrypted data rotation system job" will use the newly rotated certificate to re-encrypt data. This batch job crawls through your data to re-encrypt all the encrypted data by using the new certificate. It will run for two hours per day until all of the data has been re-encrypted. In order to enable the batch job, a flight and a configuration key need to be enabled. Execute the following commands against your business database (for example, AXDB).

```
IF (EXISTS(SELECT * FROM SYSFLIGHTING WHERE [FLIGHTNAME] = 'EnableEncryptedDataCrawlerRotationTask'))
  UPDATE SYSFLIGHTING SET [ENABLED] = 1 WHERE [FLIGHTNAME] = 'EnableEncryptedDataCrawlerRotationTask'
ELSE
  INSERT INTO SYSFLIGHTING ([FLIGHTNAME],[ENABLED],[FLIGHTSERVICEID]) VALUES
('EnableEncryptedDataCrawlerRotationTask', 1, 0)

IF (EXISTS(SELECT * FROM SECURITYCONFIG WHERE [KEY_] = 'EnableEncryptedDataRotation'))
  UPDATE SECURITYCONFIG SET [VALUE] = 'True' WHERE [KEY_] = 'EnableEncryptedDataRotation'
ELSE
  INSERT INTO SECURITYCONFIG ([KEY_], [VALUE]) VALUES ('EnableEncryptedDataRotation', 'True')
```

After the above commands have been executed, restart your AOS nodes from Service Fabric Explorer. The AOS will detect the new configuration and will schedule the batch job to run during off hours. After the batch job has been created, the schedule can be modified from the user interface.

WARNING

Make sure that the old Data Encryption certificate is not removed before all encrypted data has been re-encrypted and it has not expired. Otherwise, this could lead to data loss.

Client internet connectivity

2/18/2021 • 2 minutes to read • Edit Online

The configuration of the local network for a deployment of Dynamics 365 Finance + Operations (on-premises) can affect the features that are available in the web client. In particular, if the network configuration does not allow a client machine to access the internet, several degradations in the web client will occur. These include:

- The Office app launcher and Dynamics 365 areas in the navigation bar will no longer be clickable.
- The Help pane will not be accessible.
- The Ideas portal will not be accessible from the web client.
- Users will see their initials instead of a user image.
- Skype integration will not be available.
- The favorite icon shown in the browser tab will be the browser's default favorite icon instead of the application icon.
- The Open in Excel options are hidden because the Excel Add-in will not run.

In addition to platform features that may not be accessible when the client can't access the internet, there may also be application features that rely on an internet connection that developers will need to hide or turn off. To facilitate this, developers can use the **clientHasRestrictedInternet()** method that has been added to the **Session** class. This method will return true if the client does not have access to the internet.

Client internet connectivity options

Client internet connectivity options allow an administrator to manually turn off the external connections that the client makes even when internet connectivity is available. These can be used for troubleshooting issues or to see what the client will look like when internet connectivity is not available. These client internet connectivity options are available out-of-the-box starting in Platform update 16 but are also available in Platform update 15 (via KB 4091764) and Platform update 12 (via KB 4091763).

The client internet connectivity options can be found on the **System administration** > **Setup** > **Client performance options** page.

- **Internet connectivity enabled** - Allows an administrator to turn off all external connections that the web client would otherwise make.
- **Skype presence enabled** - Allows an administrator to turn off external connections to Skype that the web client would otherwise make.

Why does the client connect to the Skype for Business API when it first loads?

When the client loads, it performs a quick call (ping) to the Skype for Business API to check if an internet connection is available. If it isn't available then the client functions in a disconnected fashion. An environment doesn't need to have Skype for Business visible/enabled for this check to be made.

Configure Batch-only and Interactive-only AOS nodes in on-premises deployments

2/18/2021 • 3 minutes to read • Edit Online

IMPORTANT

This feature is supported starting in application update 10.0.12, Platform update 36.

This topic explains how to configure your environment so that you can deploy batch-only and interactive-only Application Object Server (AOS) nodes.

To make this feature available, Microsoft has introduced two new Microsoft Azure Service Fabric node types. For batch-only AOS nodes, the new node type is **BatchOnlyAOSNodeType**. For interactive-only AOS nodes, the new node type is **InteractiveOnlyAOSNodeType**.

NOTE

The traditional deployment option, where an AOS node is interactive and is running batch jobs, is still supported and isn't affected by these changes.

Sizing

For sandbox environments, we recommend that you have at least two nodes of each type.

For production environments, there should be at least three nodes of each type.

New deployments

1. When you're describing your configuration as explained in Set up and deploy on-premises environments, edit the **configtemplate.xml** file to add the new node types. When you've finished, the new **NodeType** sections should resemble the following example.

```
<NodeType name="InteractiveOnlyAOSNodeType" primary="false" namePrefix="AOS" purpose="AOS">
    <VMList>
        <VM name="LBDE05FS1AOS01" ipAddress="192.168.5.51" faultDomain="fd:/fd0" updateDomain="ud0"
/>
        <VM name="LBDE05FS1AOS02" ipAddress="192.168.5.52" faultDomain="fd:/fd1" updateDomain="ud1"
/>
        <VM name="LBDE05FS1AOS03" ipAddress="192.168.5.53" faultDomain="fd:/fd0" updateDomain="ud2"
/>
    </VMList>
</NodeType>
<NodeType name="BatchOnlyAOSNodeType" primary="false" namePrefix="AOS" purpose="AOS">
    <VMList>
        <VM name="LBDE05FS1AOS04" ipAddress="192.168.5.54" faultDomain="fd:/fd0" updateDomain="ud0"
/>
        <VM name="LBDE05FS1AOS05" ipAddress="192.168.5.55" faultDomain="fd:/fd1" updateDomain="ud1"
/>
        <VM name="LBDE05FS1AOS06" ipAddress="192.168.5.56" faultDomain="fd:/fd0" updateDomain="ud2"
/>
    </VMList>
</NodeType>
```

2. Follow the remaining instructions in Set up and deploy on-premises environments in the usual way.

Existing deployments

1. Follow the instructions in Remove an AOS node up through the point where you save the configuration file.

> **IMPORTANT**
>
> You must use option 1, "Use a configuration file (preferred option)." Do **not** use option 2.

2. Continue to edit the **ClusterConfig.json** file to add the new node types to the **NodeTypes** section. When you've finished, the **NodeTypes** section should resemble the following example.

```
"NodeTypes": [
    {
        "Name": "AOSNodeType",
        "PlacementProperties": {
            "IsAosEnabled": "True"
        },
        "ClientConnectionEndpointPort": 19000,
        "HttpGatewayEndpointPort": 19080,
        "ReverseProxyEndpointPort": 19081,
        "LeaseDriverEndpointPort": 19002,
        "ClusterConnectionEndpointPort": 19001,
        "ServiceConnectionEndpointPort": 19003,
        "ApplicationPorts": {
            "StartPort": 20001,
            "EndPort": 20031
        },
        "IsPrimary": false
    },
    {
        "Name": "BatchOnlyAOSNodeType",
        "PlacementProperties": {
            "IsAosEnabled": "True"
        },
        "ClientConnectionEndpointPort": 19000,
        "HttpGatewayEndpointPort": 19080,
        "ReverseProxyEndpointPort": 19081,
        "LeaseDriverEndpointPort": 19002,
        "ClusterConnectionEndpointPort": 19001,
        "ServiceConnectionEndpointPort": 19003,
        "ApplicationPorts": {
            "StartPort": 20001,
            "EndPort": 20031
        },
        "IsPrimary": false
    },
    {
        "Name": "InteractiveOnlyAOSNodeType",
        "PlacementProperties": {
            "IsAosEnabled": "True"
        },
        "ClientConnectionEndpointPort": 19000,
        "HttpGatewayEndpointPort": 19080,
        "ReverseProxyEndpointPort": 19081,
        "LeaseDriverEndpointPort": 19002,
        "ClusterConnectionEndpointPort": 19001,
        "ServiceConnectionEndpointPort": 19003,
        "ApplicationPorts": {
            "StartPort": 20001,
            "EndPort": 20031
        },
        "IsPrimary": false
    },
    ...
]
```

3. Continue to follow the instructions in Remove an AOS node from the point where you stopped until you've finished removing the nodes from your cluster.

4. On the machines that you've removed from the Service Fabric cluster, follow these steps:

    a. Delete the contents of your Service Fabric data root (**C:\ProgramData\SF**) and your Service Fabric log root (**C:\ProgramData\SF\Log**).

    b. Copy or download the standalone package for Service Fabric for Windows Server to the virtual machine (VM) or machine.

c. Unzip the package (**C:\Temp\ServiceFabricStandalone**).

d. Open Windows PowerShell as an admin.

e. Run the following commands.

> **IMPORTANT**
> Replace parameters as appropriate for your machine configuration.

```
cd C:\Temp\ServiceFabricStandalone
.\AddNode.ps1 -NodeName AOS_12 -NodeType BatchOnlyAOSNodeType -NodeIpAddressOrFQDN
192.168.5.12 -ExistingClientConnectionEndpoint 192.168.5.21:19000 -UpgradeDomain ud0 -
FaultDomain fd:/fd0 -X509Credential -ServerCertThumbprint
1A1A1A1A1A1A1A1A1A1A1A1A1A1A1A1A1A1A1A1A -AcceptEULA -StoreLocation LocalMachine -StoreName MY
-FindValueThumbprint 1A1A1A1A1A1A1A1A1A1A1A1A1A1A1A1A1A1A1A1A
```

> **NOTE**
> When the node first reappears in Service Fabric Explorer, it might show the old node type. However, it should show the updated node type after a few minutes.

5. Query the Service Fabric cluster again for the **ClusterConfig.json** file.

```
Get-ServiceFabricClusterConfiguration -UseApiVersion -ApiVersion 10-2017 > C:\Temp\ClusterConfig.json
```

6. In the **fabricSettings** section, remove the **NodesToBeRemoved** parameter. When you've finished, the **fabricSettings** section should resemble the following example.

```
"fabricSettings": [
    {
        "name": "Setup",
        "parameters": [
            {
                "name": "FabricDataRoot",
                "value": "C:\\\\ProgramData\\\\SF"
            },
            {
                "name": "FabricLogRoot",
                "value": "C:\\\\ProgramData\\\\SF\\\\Log"
            }
        ]
    }
]
```

7. Remove the following lines from the **Security** section.

```
"WindowsIdentities": {
    "\$id": "3"
},
```

> **NOTE**
>
> If you don't remove these lines, you will receive the following error message later:
>
> *ValidationException: Authentication type can't be changed from unsecured to Windows.*

8. Increment the version number of the configuration file. Make this change at the lowest increment. In the following example, the version number went from **1.0.1** to **1.0.2**.

```
"ClusterConfigurationVersion": "1.0.2"
```

9. Save the configuration file.
10. Open Windows PowerShell as an admin, and run the following commands.

```
Connect-ServiceFabricCluster
Start-ServiceFabricClusterConfigurationUpgrade -ClusterConfigPath C:\Temp\ClusterConfig.json
Update-ServiceFabricClusterUpgrade -UpgradeReplicaSetCheckTimeoutSec 30
```

11. To monitor the upgrade, you can run the following command.

```
Get-ServiceFabricClusterUpgrade
```

12. Once the upgrade is finished from LCS use the Update Settings button without changing any settings to trigger an environment refresh. Alternatively you could also apply the latest hotfix.

> **IMPORTANT**
>
> This step causes downtime so be sure that your environment can be unavailable for some time.

> **NOTE**
>
> Can you tell us about your documentation language preferences? Take a short survey.
>
> The survey will take about seven minutes. No personal data is collected (privacy statement).

Configure proxies for on-premises environments

2/18/2021 • 2 minutes to read • Edit Online

You may want to secure the Dynamics 365 Finance + Operations (on-premises) environment behind a proxy. Proxy is a server that hides the actual servers that are serving traffic from the clients. The proxy server accepts requests from the clients on behalf of the environment and forwards the traffic to it. The clients are not aware of the actual servers that compose the environment. This adds another measure of security and enables load balancing.

Configure the proxy

Perform the following steps in **each** node of type **OrchestratorType** in the Microsoft Azure Service Fabric cluster.

1. Use remote access to connect to the Orchestrator virtual machine (VM).
2. Execute the following PowerShell script to retrieve the path of the `machine.config` file.

```
[System.Runtime.InteropServices.RuntimeEnvironment]::SystemConfigurationFile
```

3. Edit the `machine.config` file to add the following code example.

```
<system.net>
 <defaultProxy enabled="true" >
  <proxy <<<SET YOUR PROXY SETTINGS>> />
    </defaultProxy>
</system.net>
```

4. Save the file.
5. Restart the virtual machine.

The above procedure must be performed for all Orchestrator node VMs.

Safe list URLs

The LocalAgent needs to communicate with Azure resources. As a result, the following URLs should be added to a safe list on the proxy or firewalls so that all **OrchestratorType** nodes can access them:

```
- lcsapi.lcs.dynamics.com
- login.windows.net
- uswelcs1lcm.queue.core.windows.net
- www.office.com
- login.microsoftonline.com
- dc.services.visualstudio.com
- uswelcs1lcm.blob.core.windows.net
```

NOTE

Can you tell us about your documentation language preferences? Take a short survey.

The survey will take about seven minutes. No personal data is collected (privacy statement).

On-premises diagnostics

2/18/2021 • 12 minutes to read • Edit Online

The Microsoft Dynamics 365 team monitors the health and performance of the Azure Services that provide functionality for our cloud-based customers by using state-of-the-art Azure diagnostic tools. For customers who have implemented Finance + Operations (on-premises) and would like to have the ability to monitor the health and performance of their on-premises solution, there are several third-party offerings available.

This topic describes the setup and configuration of Elastic Stack, a third-party product, and one of many choices that can provide diagnostic monitoring of your on-premises solution.

When you consider a diagnostic solution, consider the following fundamentals of your implementation:

- Your diagnostic system should be able to collect and store 30 days' worth of diagnostic information.
- Your diagnostic repository should be set up in a central location that is sharable among many client computers.
- Create structured diagnostics events, including event type, classification, and data.
- Events stored in raw text (deserialized) can be easily queried and searched.
- Avoid storing sensitive or personal data in events.

> **NOTE**
>
> By default, communication in an Elastic Stack cluster is not sent over HTTPS. Don't set up the Elastic Stack unless you've considered the risks, and prepared or implemented mitigations for those risks. The paid version of X-Pack can be used to encrypt communication in the Elastic Stack. For setup information, see Setting up TLS on a cluster. There is also an open source Elasticsearch plug-in. Although Microsoft hasn't tested this plug-in, according to the documentation, it can enable HTTPS. Microsoft recommends that you always utilize encrypted communication using HTTPs, VPN, or another secure, encrypted protocol. Many industry certifications and laws require the use of encrypted transmission if your content includes end user, customer, personal, or sensitive data.

Diagnostic data guidelines

To diagnose the deployment and execution of Finance + Operations (on-premises), you must have access to diagnostic data. For a cloud deployment, Microsoft stores and monitors the diagnostic data from services to help keep the environment healthy. For an on-premises deployment, the customer is responsible for this task.

You can select the diagnostic data store and query tool that you prefer to use. However, at a minimum, the tool should perform the following tasks:

- The store should be able to store 30 days' worth of diagnostic data.
- The events should be stored in a centralized location, so that support engineers don't have to switch between multiple machines to find events that are relevant to an issue.
- The events should be discoverable based on event type and event data.
- The event data (in XML format) should be deserialized so that the event data can be queried on and traversed.

Elastic Stack example

To meet the diagnostic data guidelines that are listed in the previous section, Microsoft tested the Elastic Stack setup. This setup includes the following components:

- **Elasticsearch** – For storage, event indexing, and event querying. For more information about Elasticsearch, see the Elastic website.
- **Logstash** – For load distribution and event data transformation.
- **Winlogbeat** – For diagnostic data collection.
- **Kibana** – An interface for querying the data that is stored in Elasticsearch.

> **NOTE**
>
> By default, communication in an Elastic Stack cluster is **not** sent over HTTPS. Don't set up the Elastic Stack unless you've considered the risks, and prepared or implemented mitigations for those risks. The paid version of X-Pack can be used to encrypt communication in the Elastic Stack. For setup information, see Setting up TLS on a cluster. There is also an open source Elasticsearch plug-in. Although Microsoft hasn't tested this plug-in, according to the documentation, it can enable HTTPS.

If you deploy the Elastic Stack, your experience might vary if you follow the steps that are described in this topic. For its tests, Microsoft used version 6.2.3 of the Elastic Stack components and Microsoft Dynamics 365 for Finance and Operations 7.3 with platform update 12.

This topic describes how Microsoft handled the setup and configuration steps that are required for the Elastic Stack to work for an on-premises deployment. For guidance that isn't related to Finance + Operations (on-premises), see the documentation on Elastic.co.

Install and configure the Elastic Stack

All hosted components of the Elastic Stack, except Winlogbeat, run on Java. For the test scenario, Microsoft first downloaded and installed the latest version of Java Runtime Environment (JRE) 8 (64-bit) on each node that will run Elasticsearch, Logstash, or Kibana (that is, all the Orchestrator nodes). You can get Java 8 from https://www.oracle.com/technetwork/java/javase/downloads/index.html.

As of June 2018, the Elastic Stack runs on Java 8. Any attempt to run it on a newer version of Java might not work.

> **NOTE**
>
> The whole Elastic Stack, except Winlogbeat, can be hosted on Linux. For its tests, Microsoft hosted the stack on Microsoft Windows Server 2016 virtual machines (VMs).

Remember to open ports in the firewall for the various components on each node.

If you get stuck during setup, Elastic.co has extensive and well-written documentation about the installation and configuration of the Elastic Stack. For help with specific types of errors, web searches yield reliable results from both the Elastic.co forum and StackOverflow.

Component matrix

For its tests, Microsoft used the following setup for a small to medium-sized deployment.

NODE	ELASTICSEARCH	LOGSTASH	KIBANA	WINLOGBEAT
Orchestrator #1	X			X
Orchestrator #2	X	X		X
Orchestrator #3		X	X	X

NODE	ELASTICSEARCH	LOGSTASH	KIBANA	WINLOGBEAT
AOS #1...*n*				X

> **IMPORTANT**
> For testing purposes, Microsoft used the Orchestrator machines for the ELK installation. Because it can take up critical resources from the Orchestration services, don't use the Orchestrator machines for ELK installations on production environments or critical Sandbox Environments. Instead, use separate machines to host the ELK services.

Elasticsearch

The installation of Elasticsearch is fairly straightforward. For its tests, Microsoft downloaded the Microsoft Windows Installer (MSI) file onto the Orchestrator #1 and Orchestrator #2 nodes. Most of the default settings in the installer can be left as is. This section describes the settings that Microsoft changed.

To facilitate Elasticsearch to start running again if the operating system (OS) is restarted, Microsoft installed it as a service on Windows. The installer can be used to set up the service.

On the **Configuration** page of the installer, Microsoft used the same cluster name when it installed each Elasticsearch node in the cluster.

Microsoft set every Elasticsearch node to perform all three roles: Data, Master, and Ingest.

Depending on the amount that you expect Kibana and Elasticsearch to be used, consider increasing the memory usage. You can change this setting later by modifying the -Xm options in the C:\ProgramData\Elastic\Elasticsearch\config\jvm.options file and restarting Elasticsearch.

Depending on the number of Elasticsearch nodes that you set up, you can set the Discovery minimum master nodes appropriately. If you aren't sure, you can keep the master nodes empty. For more information about discovery and nodes, see Node.

For discoverability, in **Network settings**, Microsoft set the **Network host** value of each node to that node's IP address and added the IP addresses of all Elasticsearch nodes to the **Unicast Hosts** list for each node. For example, for Orchestrator #1, which has the IP address 10.0.0.12, Microsoft set the **Network host** value to **10.0.0.12** and added the following IP addresses to the **Unicast Hosts** list: 10.0.0.12 and 10.0.0.13, where 10.0.0.13 is Orchestrator #2.

If you're installing Elasticsearch version 6.3 or higher, you can disregard this paragraph. You can install X-Pack either now or later. For more information about setup and whether you should install X-Pack, see the "X-Pack" section of this topic. For now, unless you know what X-Pack is for, don't install it.

> **IMPORTANT**
> Open the HTTP port (by default, port 9200) and the node communication port (by default, port 9300) in your firewall.

To verify that the installation was successful, start a browser, and open the application address. You should see some JavaScript Object Notation (JSON) output.

Logstash

In its test setup, Microsoft found that some events from Winlogbeat required adjustments. Logstash provides that functionality.

Microsoft downloaded Logstash to C:\ELK\Logstash on the Orchestrator #2 and Orchestrator #3 nodes.

To help ensure that Logstash runs on startup, we used the Non-Sucking Service Manager (NSSM) to set up a

service for the Logstash batch script.

1. Copy nssm.exe to the Logstash bin folder (for example, C:\ELK\Logstash\6.2.4\bin\).
2. Open Windows PowerShell from the bin folder, and run the following command.

   ```
   .\nssm.exe install Logstash
   ```

3. On the **Application** tab, set the following fields, and then click **Save**:

   - **Path:** C:\ELK\Logstash\6.2.4\bin\logstash.bat
   - **Startup directory:** C:\ELK\Logstash\6.2.4
   - **Arguments:** -f C:\ELK\Logstash\config\logstash-dyn365finops.conf

   (There are more settings that you can set. However, these settings suffice for now.)

4. Run the following command.

   ```
   .\nssm.exe start Logstash
   ```

In the tests that Microsoft performed, NSSM had trouble restarting the installed services. Because NSSM wasn't 100-percent reliable for Logstash and Kibana, the service was treated as an OS startup service and little else.

Microsoft created a configuration file for Logstash and put it in C:\ELK\Logstash\6.2.4\config. This file performs useful transformations on diagnostics.

To make the configuration work for your setup, you must change the **hosts** fields in the **output** section so that they point to the Elasticsearch nodes in your cluster. For example, change **hosts** to **["ORCH1:9200", "ORCH2:9200"]**.

The configuration was tested by using the Winlogbeat configuration from the next section.

Remember to open the Winlogbeat port (by default, port 5044) in your firewall on the machine that is hosting Logstash, so that Beats can send data to Logstash.

Winlogbeat

Microsoft downloaded Winlogbeat to each Application Object Server (AOS) and Orchestrator node at C:\ELK\Winlogbeat, and configured the winlogbeat.yml file.

To make the configuration work for your set up, you must change the **output.logstash.hosts** fields so that they point to all your Logstash nodes. Winlogbeat handles the load balancing.

When Winlogbeat runs on an Orchestrator node, the **Tags** field can be changed from **AOS** to **ORCH** or a similar value. Microsoft also used the **fields.env** field to set the environment of the deployment (sandbox, sandbox-n, or production). In this way, there is a cleaner separation when data from multiple environments and node types is queried.

Winlogbeat includes a service installer. Microsoft used this installer to set up Winlogbeat as a service on each node. Press the Windows logo key+R to start the Run tool, and then run the following command.

```
powershell.exe -ExecutionPolicy Bypass -File C:\ELK\Winlogbeat\install-service-winlogbeat.ps1
```

Kibana

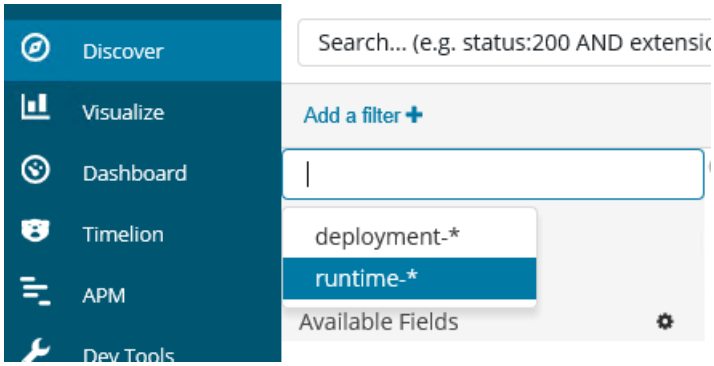
Kibana provides the interface to query the diagnostic data in Elasticsearch.

Microsoft downloaded Kibana to C:\ELK\Kibana and configured the kibana.yml file in the following manner.

```
server.host: "10.0.0.14"
server.name: "Dyn365FinOps On-Premises Diagnostics"
elasticsearch.url: "http://ORCH1:9200"
```

From Kibana, Microsoft had to define index patterns on the **Management** tab. Because index patterns group indexes by name, an index pattern was required for the two indexes that were made: deployment-* and runtime-*. The index names are case-sensitive.

Microsoft set the runtime-* index pattern as the default pattern. When you're looking at the index patterns on the **Management** tab, click the asterisk (*). The index pattern will then appear on the **Discover** tab.



Microsoft ran Kibana as a service in the same manner as Logstash, so that Kibana is started at OS startup. Unlike Logstash, kibana.bat doesn't need the path of the configuration files. Therefore, you can just install an NSSM service that points to C:\ELK\Kibana\6.2.4\bin\kibana.bat.

If you want users to browse Kibana on your network, remember to open the port for Kibana. The default port is 5601.

Example queries on the Discover tab in Kibana

The following sample queries can help you start probing the diagnostic data. If you require something more than the examples show, you can try one of the following queries:

- **Find slow database queries:** Enter **slow** in the search field to find events that have the word "slow" somewhere in the event data. If you want to be more precise, you can find events that have a task name of **AosDatabaseSlowQuery** and then enter **TaskName:AosDatabaseSlowQuery** in the search field.
- **Find recent exceptions:** Enter **exception** in the search field to find events that have either thrown an exception, or handled an exception and logged it. In the upper-right corner of Kibana, you can select the time frame that the search should be limited to. The time frame that you set there is persisted between tabs. Therefore, the data on the **Visualize** tab will reflect the selected time frame.

- **Find events from an AOS node:** Enter **host:AOS1** in the search field to find all events from that node.
- **Find events with proximity, in time, to another:** When you've found an event that you're interested in, click **View surrounding documents** next to the header of that event to find events that occurred at the same time. If you see events that occurred at around the same time but from different AOS nodes, you can add additional filtering to view only events from the node that you want.

Thirty-day data retention

To keep its hard disks free from stale data, Microsoft used Curator v5.5 to clean up indexes that were older than 30 days.

Microsoft downloaded Curator to one of the Orchestrator nodes at C:\ELK\Curator. Microsoft then used the configuration file that was put in C:\ELK\Curator to connect Curator to its Elasticsearch cluster.

Curator runs actions, and Microsoft created an action to clean up 30-day-old indexes that were put in C:\ELK\Curator.

Microsoft created a basic task in Windows Task Scheduler. This task has a weekly trigger on Saturday and Sunday, and the trigger has the following settings to start a program:

- **Program/script:** C:\ELK\Curator\curator.exe
- **Add arguments:** --config curator.yml .\30day_data_retention_actions.yml
- **Start in:** C:\ELK\Curator

X-Pack

> **IMPORTANT**
> As of June 2018, Elastic Stack components have been released that start with version 6.3. This updated version handles X-Pack in a more graceful manner, by enabling the free features of X-Pack by default, without requiring that you update the license every year, and by letting you opt in to the paid features afterward. If you install an Elastic Stack version that is earlier than 6.3, the content in this section only partially applies to the setup.

You can select to install X-Pack when you install Elasticsearch. Alternatively, you can install it later.

X-Pack has a free basic license that must be updated every year.

Microsoft installed the free version to enable query data to be exported from Kibana in comma-separated value (CSV) format. There are other useful features in X-Pack, but some are available only in a paid subscription.

To enable only the free features and avoid using other X-Pack trial features, Microsoft added the following settings to our elasticsearch.yml and kibana.yml configuration files:

```
xpack.graph.enabled: false
xpack.ml.enabled: false
xpack.security.enabled: false
xpack.watcher.enabled: false
```

These settings also stop Kibana and Elasticsearch from asking for credentials because the security module is no longer enabled.

For X-Pack to work, the logstash.yml configuration file must also be configured in the following manner.

```
xpack.monitoring.elasticsearch.url: "http://orch1:9200"
```

The paid version of X-Pack includes HTTPS encryption for connections throughout the cluster, password-protected data access, and more. For more information about X-Pack, see the Elastic website.

Export a query to a CSV file

In Kibana, on the **Discover** tab, write a query, and save it. After you save the query, on the **Reporting** tab at the top of the **Discover** page, click **Generate CSV**.

Troubleshooting

You don't receive any data in Kibana

If you don't receive any data in Kibana, review the logs from Winlogbeat to Logstash, Elasticsearch, and Kibana. Note that the Winlogbeat installation puts its logs in C:\ProgramData\winlogbeat\Logs, whereas the other Elastic Stack components put their logs close to the installation path (for example, in C:\ELK\Elasticsearch\logs).

On-premises disaster recovery configuration

2/18/2021 • 8 minutes to read • Edit Online

Disaster recovery is an important consideration for on-premises deployments of Dynamics 365 Finance + Operations (on-premises) to protect from events that could put your organization's operations at risk. Examples of such events include equipment failures, datacenter break downs due to cyberattacks, electrical, physical, or other disasters.

The core concept of disaster recovery involves the use of a second datacenter including a data recover environment. We recommend that you plan, document, and test disaster recovery as carefully as your production setup.

Limitations of this content

This topic does not cover specific configuration details for disaster recovery of the following components:

- Active Directory Federation Services (AD FS)
- File storage
- SQL Server

> **NOTE**
> High availability configuration isn't covered in this topic. For more information about the minimum setup required for high availability, see System requirements for on-premises deployments.

Recommendations

Remember to keep your disaster recovery environment updated with the latest Windows Updates. Your environment should have the latest security updates and not require updates during a disaster event.

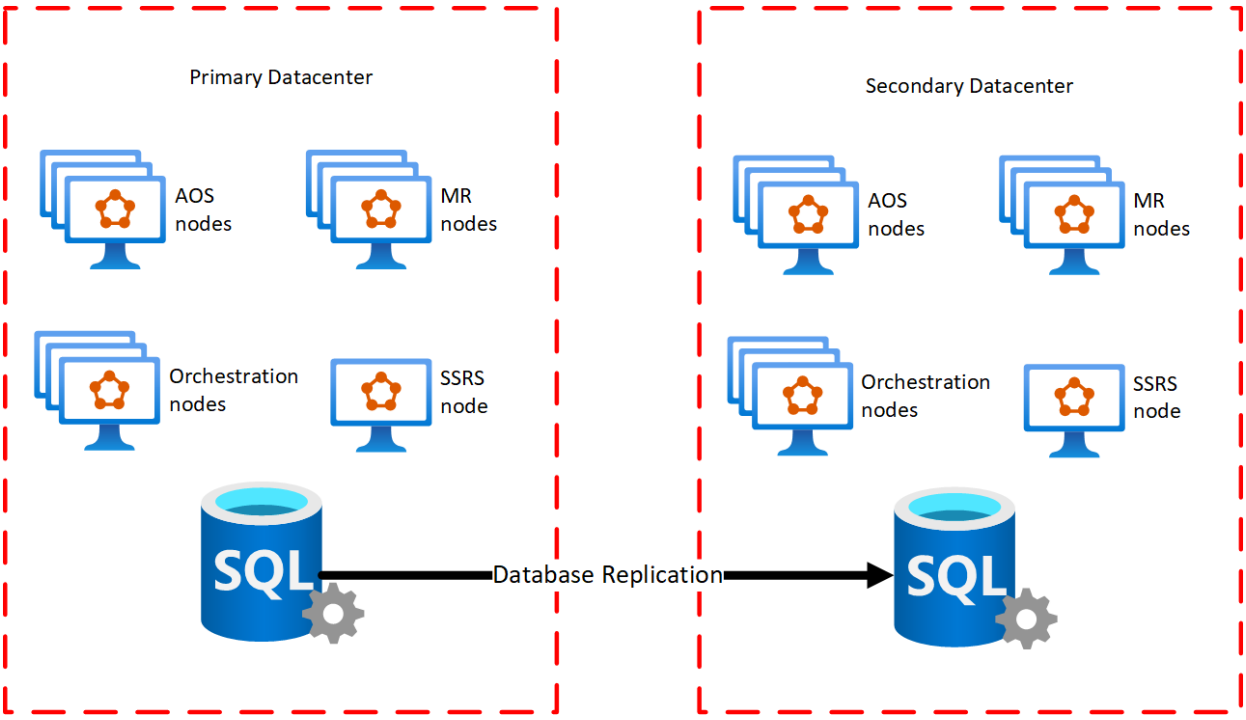
Ensure that you're applying new prerequisites that are specified by Microsoft. Also, keep your Service Fabric cluster updated and perform certificate rotations as required.

After you've read through this topic, document the steps that need to be taken by your team. After you've done that, go through the steps multiple times to ensure that you don't encounter unexpected problems and you minimize the potential downtime.

Overview

The basic configuration for disaster recovery involves deploying a duplicate of the production environment within another datacenter (the secondary datacenter) and replicating databases to that datacenter. If a disaster event takes place, a few manual steps can be taken to bring the environment that is within the secondary datacenter online.

The following diagram illustrates the required setup, at a high level.



Environment configuration

In Lifecycle Services (LCS), the production environment should be deployed using the environment slot named **Production**. Your disaster recovery environment will not use an additional environment slot in LCS. It will instead reuse the slot for your production environment.

Finance and Operations AOS nodes and SQL Server must be co-located within the same datacenter. For more information, see System requirements for on-premises deployments.

Deploying code packages to production

When code packages are deployed to the production environment, they don't need to be deployed to the disaster recovery environment. That environment should be unused and no Service Fabric services should be deployed.

Environment deployment settings

The disaster recovery environment should have a similar configuration as the production environment. The following table illustrates the shared and specific settings for disaster recovery.

ENVIRONMENT SETTINGS	DISASTER RECOVERY ENVIRONMENT
Active Directory settings	
Administrator user	Same as production
AD FS URL	Same as production
AD FS OpenId Connect client ID for AOS	Same as production
AD FS OpenId Connect client ID for Financial Reporting	Same as production
SQL Database configuration	

ENVIRONMENT SETTINGS	DISASTER RECOVERY ENVIRONMENT
SQL Server name	Same as production
AX database name	Same as production
Financial Reporting database name	Same as production
File share settings	
File share for document store	Same as production
File share certificate thumbprint	Same as production
SSRS configuration settings	
IP address of SSRS instance	Can be different [1]
SSRS certificate thumbprint	Same as production
Configure service settings	
DNS host name of Dynamics 365 instance	Can be different [2]
AOS service user	Same as production
MR application service user	Same as production
MR process service user	Same as production
MR click-once service user	Same as production
Application certificate settings	
Data encryption certificate thumbprint	Same as production
Data signing certificate thumbprint	Same as production
Session authentication certificate thumbprint	Same as production
SSL certificate thumbprint	Same as production
Management reporter certificate thumbprint	Same as production

[1] SSRS is referenced by IP. If the exact machine IP can't be configured in the disaster recovery environment, the IP can be different.

[2] This depends on your network configuration. If you have a load balancer that can handle diverting traffic to the other environment, then the host name can be the same. If you're unable to do that, then use a different host name.

SQL Server Always-On Availability configuration

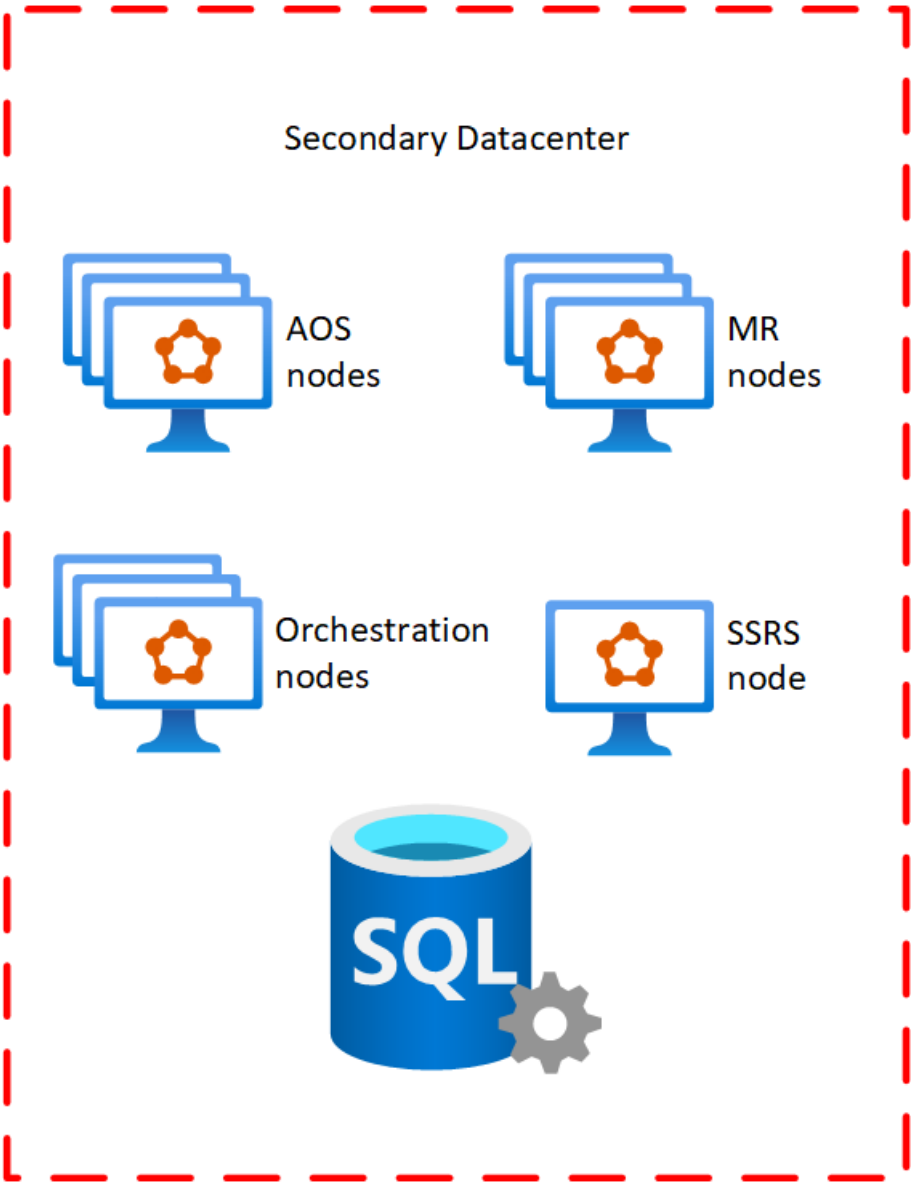
The business data database (AXDB) should be replicated to the secondary datacenter, typically using SQL Server Always-On availability groups feature. For more information, see Always On availability groups.

DATABASE	REPLICATED
Business data (AXDB)	Yes
Financial Reporting	Yes
BYODB	Yes
OrchestratorData	Yes

Failing over to disaster recovery

Overview

When a disaster event occurs, the primary datacenter may be unavailable but within the secondary datacenter, the following components will be available.



At the initial moment of the disaster event, the disaster recovery environment will be empty. The only thing present will be a configured Service Fabric cluster and SQL Server, which contain all of the replicated production data.

To bring the disaster recovery environment online, you'll need to have LCS deploy what is currently available in your Production environment into the disaster recovery environment.

> **IMPORTANT**
>
> Before you continue, ensure that no Dynamics Service Fabric services are running in your production environment (in case you're only failing due to a partial disaster event).

Deploy the LocalAgent

Download the LocalAgent installer and configuration file from LCS to your disaster recovery environment. After you have the configuration file, open it. Ensure that the connectionEndpoint under the serviceFabric section points to the IP or FQDN of a server in the disaster recovery environment. After modifying the file, save it locally and deploy the LocalAgent as you typically would.

> **IMPORTANT**
>
> Do not make changes to your connector settings in LCS.

Until your main production environment comes back online, this LocalAgent will process all requests that LCS puts into the message queue. That's why it's important that you ensure no services are running in your production environment. Eventually, when your orchestrator nodes come back up in your primary datacenter, unprovision the LocalAgent from the cluster.

Caution

The LocalAgent must only be running in one datacenter at a time. At this point it should only be running in your secondary datacenter.

Prepare your pre-deployment scripts (optional)

Pre-deployment scripts are necessary when changes to the deployment configuration are required. This script will have to modify the config.json file with the values you specify. It will be the customers' responsibility to create this script.

You can find the location of the config.json file by running the following command.

```
  select Location from DeploymentInstanceArtifact where AssetId='config.json' and DeploymentInstanceId =
'LCSENVIRONMENTID'
```

> **NOTE**
>
> Replace **LCSENVIRONMENTID** with the ID of your environment. You can obtain this ID from the full details page for your environment in LCS.

If the SSRS node IP is different, you'll have to modify the following values.

```
        "biReporting": {
          "persistentVirtualMachineIPAddressSSRS": {
            "value": "192.168.5.31"
          },
          "reportingServers": {
            "value": "192.168.5.31"
          },
```

If you are changing the host name, the following modifications are required.

```
    "name": "AOS",
      "parameters": {
        "activeDirectory": {
          ...
          "aadValidAudience": {
            "value": "https://ax.contosoen05.com/"
          },
          ...
        "infrastructure": {
          "hostName": {
            "value": "ax.contosoen05.com"
          },
          ...
        }
    ...
    "name": "FinancialReporting",
      "parameters": {
        ...
        "aad": {
         ...
         "cookieDomain": {
            "value": "ax.contosoen05.com"
          },
          "validAudiences": {
            "value": "https://ax.contosoen05.com/"
          },
          ...
```

IMPORTANT

If you are changing the hostname URL for your deployment, ensure that your AD FS server is configured to accept the new URL. For more information, see Reuse the same AD FS instance for multiple environments.

If the file share is shared between the production and disaster recovery environments, this pre-deployment script should be disabled. Only enable it when deploying to your disaster recovery environment.

Ensure reports get deployed

Because the database has previously been synchronized successfully, synchronization typically would be skipped. However, to synchronize the reports because the SSRS node is empty, perform the following actions.

Version 10.0.13 or later

Run the following command against your business data database (AXDB):

```
 UPDATE SF.synclog SET STATE=5, SyncStepName = 'ReportSyncstarted' WHERE CODEPACKAGEVERSION in (SELECT
TOP(1) CODEPACKAGEVERSION from SF.SYNCLOG ORDER BY CREATIONDATE DESC)
```

Version 10.0.12 or earlier

Run the following command against your business data database (AXDB):

```
    DELETE FROM SF.synclog WHERE CODEPACKAGEVERSION in (SELECT TOP(1) CODEPACKAGEVERSION from SF.SYNCLOG
ORDER BY CODEPACKAGEVERSION DESC)
```

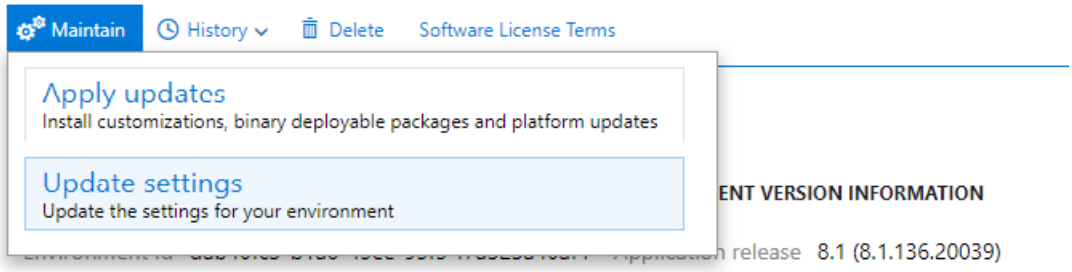
NOTE

If you are using version 10.0.12 or earlier, a full database synchronization will be executed.

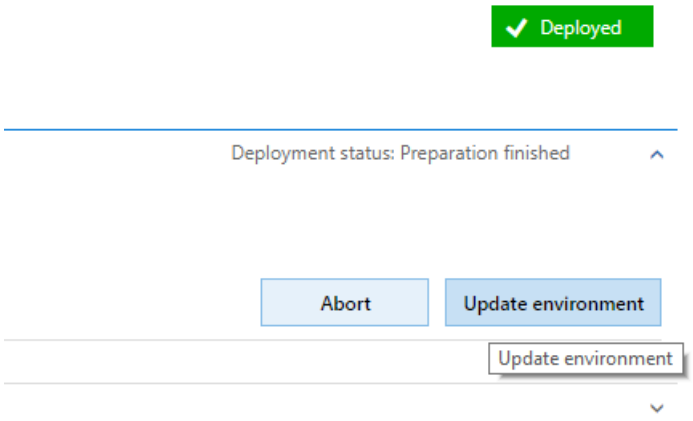
Deploy your environment

To deploy your environment, follow these instructions.

1. In LCS, go to the environment page for your production environment.
2. Select **Maintain** and then select **Update Settings**.



3. Don't change any values. Select **Prepare**.
4. After downloading is finished and preparation is completed, the **Update environment** button will be displayed. Select this button to start updating your environment



5. After the environment is deployed, the disaster recovery environment is ready for use.

Using your disaster recovery environment

You can use your disaster recovery environment as you typically would, except that updates or hotfixes shouldn't be applied to the environment. If you must apply updates to your environment, your failback process will differ from the one described below. Failing back under this condition is not covered in this topic.

Failing back to your production environment

> **IMPORTANT**
> At this point, no Dynamics Service Fabric services should be running in your production environment.

Secure a downtime window in which you can switch operation from the disaster recovery environment to the Production environment. In the downtime window, disable all non-Orchestrator nodes in the disaster recovery environment through Service Fabric Explorer. Once all nodes are disabled, failover your SQL Server to the production datacenter.

After the failover has occurred, start the AOS, SSRS, and MR nodes in your primary datacenter. Carry out validation tests to ensure that your environment is functioning as expected. When you determine that your environment is working as expected, remove the LocalAgent from your disaster recovery environment and

reinstall it on your Production environment.

Clean up your DR environment by manually unprovisioning all Dynamics Service Fabric services.

Caution

Do not use the Cleanup functionality in LCS to perform the clean up of your disaster recovery environment.

Failback checklist

- Non-orchestrator nodes are disabled in disaster recovery datacenter.
- SQL Server is failed back to primary datacenter.
- LocalAgent is uninstalled in your disaster recovery datacenter.
- All Dynamics Service Fabric services (including LocalAgent) are running in your primary datacenter.
- No Dynamics Service Fabric services are deployed in your disaster recovery datacenter.

IMPORTANT

Your primary environment will be functioning as usual and can be serviced after you ensure that all items in the checklist are verified.

PowerBI.com integration with on-premises environments

2/18/2021 • 5 minutes to read • Edit Online

The cloud version provides several features that allow for deeper integration with Microsoft Power BI. Some of these features haven't yet been implemented for on-premises deployments. However, the availability of Entity Store in on-premises deployments lets customers use PowerBI.com to report on and analyze data.

This topic outlines the analytical capabilities that are available in on-premises deployments that run Microsoft Dynamics 365 for Finance and Operations platform update 26 (May 2019) and later.

FEATURE/CAPABILITY	CLOUD	ON-PREMISES (PLATFORM UPDATE 26 OR LATER)
Analytical workspaces	Available	**Not yet implemented** Customers can use the reports that are built on Entity Store together with PowerBI.com.
Pin reports, tiles, and dashboards from PowerBI.com into the client.	Available	**Not yet implemented**
Author and distribute Power BI reports that use application data.	Available	**Available** Customers can modify ready-made reports and create new reports by using Entity Store on-premises.
Extract application data into data warehouses.	Available	**Available**

Enable Entity Store on-premises

This topic supplements the Set up and deploy on-premises environments (Platform update 12 and later) topic. The section numbers that follow correspond to the section numbers in that topic.

3. Plan your users and service accounts

USER ACCOUNT	TYPE	PURPOSE	USER NAME
AOS SQL AXDW DB Admin user	SQL user	The application uses this user to enter information in the AXDW database. This user is optional and must be created only if you want Entity Store support.	axdwadmin

USER ACCOUNT	TYPE	PURPOSE	USER NAME
AOS SQL AXDW FB Admin user	SQL user	The application uses this user to enter information in the AXDW database. This user is optional and must be created only if you want Entity Store support.	axdwruntimeuser

14. Configure the databases

The steps in this section are optional.

If you want to create a database that can be used for Entity Store, you must first modify the ConfigTemplate.xml file.

1. Under **DbServer – Security**, set the **generateUser** flags for **axdwadmin** and **axdwruntimeuser** to **True**. The scripts that you run in the next step will then create those two users. You will be prompted to set passwords for the users.

2. Run the following scripts.

   ```
   .\Initialize-Database.ps1 -ConfigurationFilePath .\ConfigTemplate.xml -ComponentName EntityStore
   .\Configure-Database.ps1 -ConfigurationFilePath .\ConfigTemplate.xml -ComponentName EntityStore
   ```

   The Initialize-Database.ps1 script performs the following actions:

   - Create an empty database that is named **AXDW**. This database is used for Entity Store.
   - Create a new user that is named **axdwadmin** and that has SQL authentication enabled, and prompt you for the user's password.
   - Create a new user that is named **axdwruntimeuser** and that has SQL authentication enabled, and prompt you for the user's password.
   - Grant the axdwadmin and axdwruntimeuser users **db_owner** permissions on the database.

   The Configure-Database.ps1 script performs the following actions:

   - Set the specified database file and log settings.
   - GRANT VIEW SERVER STATE TO axdwadmin.
   - GRANT VIEW SERVER STATE TO axdwruntimeuser.

15. Encrypt credentials

Create a Credentials.json file as shown here. The **AosDWAuth** category is optional and is used only if Entity Store is enabled.

```
{
    "AosPrincipal": {
        "AccountPassword": "<encryptedDomainUserPassword>"
    },
    "AosSqlAuth": {
        "SqlUser": "<encryptedSqlUser>",
        "SqlPwd": "<encryptedSqlPassword>"
    },
    "AosDWAuth": {
        "DWUser": "<encryptedDWUser>",
        "DWPwd": "<encryptedDWPassword>",
        "DWRuntimeUser": "<encryptedDWRuntimeUser>",
        "DWRuntimePwd": "<encryptedDWRuntimePassword>"
    }
}
```

Here is an explanation of the preceding code lines:

- **AccountPassword** is the encrypted domain user password for the Application Object Server (AOS) domain user (contoso\axserviceuser).
- **SqlUser** is the encrypted SQL user (axdbadmin) that has access to the application database (AXDB). **SqlPwd** is the encrypted SQL password.
- **DWUser** is the encrypted SQL user (axdwadmin) that has access to the Entity Store database (AXDW). **DWPwd** is the encrypted SQL password that is entered when the Initialize-Database.ps1 script is run.
- **DWRuntimeUser** is the encrypted SQL user (axdwruntimeuser) that has access to the Entity Store database (AXDW). **DWRuntimePwd** is the encrypted SQL password that is entered when the Initialize-Database.ps1 script is run.

More information

Entity Store was enabled in Platform update 26.

Creation of the Entity Store database and users is optional. When you configure a deployment in Microsoft Dynamics Lifecycle Services (LCS), you can leave the Entity Store customizations blank.

If Entity Store should be enabled in an environment, the following tasks must be completed:

- Create an **AXDW** database by using the scripts that are described in step 14.
- Create **axdwadmin** and **axdwruntimeuser** users that have appropriate privileges, by using the scripts in that are described step 14. Users are defined in the following files: ConfigTemplate.xml and DatabaseTopologyDefinition.xml.
- Create a **Credentials.json** file as described in step 15. User names and passwords should be defined for axdwadmin and axdwruntimeuser as described in step 14, and they should be encrypted.
- The Entity Store SQL Server name and Entity Store database name must be filled in during deployment in LCS.
    - The database name is created in step 14 and is defined in the DatabaseTopologyDefinition.xml file. The default name is **AXDW**.
    - The SQL Server name is the fully qualified domain name (FQDN) of the Microsoft SQL Server or Always on listener. An example of this FQDN is **sqlinstance.onprem.contoso.com**. It's the server that the AXDW database is created on.

Currently, you can enable Entity Store only during initial deployment. If it must be enabled in an existing environment, that environment must be deleted and then deployed again by using a platform update that supports Entity Store.

Authoring and distributing reports by using Entity Store on-premises

Entity Store is an operational data warehouse that is included. It lets power users and business analysts author reports that use simplified and enriched data. Entity Store contains aggregate measurements, which are simplified star schemas. For more information about how to author reports by using Entity Store, see Create analytical reports by using Power BI Desktop.

Note the following additional steps that are specific to on-premises deployments:

- For on-premises environments, you don't have to use LCS to deploy Power BI reports to production or sandbox environments. Because admins can point PowerBI.com datasets to specific Entity Store databases in on-premises environments, you don't have to use the functionality that LCS offers. However, you might have to configure the on-premises gateway to enable PowerBI.com to access data on-premises. For more information about the gateway, see Power BI gateway documentation.
- Although cloud-based application environments support only reports that are authored by using the DirectQuery option, on-premises Entity Store supports both DirectQuery reports and Import mode reports.
- Analytical workspaces aren't yet implemented in on-premises deployments. Instead of viewing reports in analytical workspaces, you can deploy them to PowerBI.com environments. The reports can then be used by users who have access to PowerBI.com. Your users might require appropriate licenses to access reports on PowerBI.com.

Reconfigure environments to take a new platform or topology

2/18/2021 • 2 minutes to read • Edit Online

This topic provides information about how to reconfigure your environment with a new platform or topology and how to update the configuration of your existing environment.

Prerequisites

Before you complete the steps in this topic, you must update your local agent. For more information, see the topic, Update the local agent. The procedure in this topic will only work with local agents that are on or above version 1.1.0.

Reconfigure your environment

1. In Lifecycle Services (LCS), navigate to your on-premises project and open the **Environments** blade.
2. Do one of the following based on whether you are going to reconfigure or take a new deployment.

- If you need to reconfigure your environment, click **Reconfigure**.
- If you need to take a new deployment or topology, select the new topology for your platform and enter the environment name. You can use the same name or enter a new one.

3. Click **Advanced Settings** to update your configuration. The configuration from your previous deployment will be saved.

Redeploy on-premises environments

2/18/2021 • 3 minutes to read • Edit Online

At some point, you might have to redeploy your on-premises environment. This could be to apply a new platform update or because of changes or issues in your implementation. Before you delete the environment you are currently working with, you should save your configuration setting information to use when you redeploy. This topic describes how to save configuration settings and how to redeploy your environment.

Save your configuration

Before you delete the environment you plan to update, use the following steps to save your configuration.

1. In LCS, navigate to **Project Settings** > **On-prem Connectors**.
2. Select the connector to your environment, and then click **Edit**.
3. On the **Edit connector** tab, navigate to **Configure Agent** > **Enter Configuration**.
4. Copy the value of the Download Fileshare location in the **Configuration Settings** section. You will need this later.
5. Log in to the on-premises environment file share machine and copy the **\agent\wp\StandaloneSetup\config.json**. You can use the configuration settings in this json file to redeploy your environment.

Configuration settings

The following tables provide information about configuration settings. Use the **Configuration setting** value from the .json file that you saved in the previous procedure.

Active Directory Federation Services settings

FIELD	CONFIGURATION SETTING
The email address of the user who will be the initial administrator (such as, `adminuser@yourdomain.com`)	components.(AOS).parameters.provisioning.adminPrincipleName.value
ADFS OpenID metadata endpoint for the Dynamics 365 Application group. (such as, https://[federation-service-name]/adfs/.well-known/openid-configuration)	components.(AOS).parameters.activeDirectory.adfsMetadata.value
ADFS OpenID Connect client ID for the AOS application group	components.(AOS).parameters.activeDirectory.adfsClientId.value
ADFS OpenID Connect client ID for the Financial Reporting application group	components.(FinancialReporting).parameters.aad.nativeClientAuthentication.clientId.value

SQL database configuration

FIELD	CONFIGURATION SETTING
SQL SERVER	components.(AOS).parameters.database.dbServer.value
AX DATABASE	components.(AOS).parameters.database.dbName.value

FIELD	CONFIGURATION SETTING
FINANCIAL REPORTING DATABASE	components.(FinancialReporting).parameters.mrdb.dbName.value

File share settings

FIELD	CONFIGURATION SETTING
The file share path for the Microsoft Dynamics 365 instance. This share is used as the document store for files uploaded by users.	components.(AOS).parameters.storage.fileSharePath.value
The File share certificate thumbprint for the Microsoft Dynamics 365 instance.	components.(AOS).parameters.storage.sharedAccessThumbprint.value

> **NOTE**
>
> When you copy the file path configuration value from .json file to LCS UI, make sure to remove the extra backslashes. For example, configuration value **\\DC1\D365FFOStorage** from the .json file should be **\DC1\D365FFOStorage** in the LCS UI.

SSRS configuration settings

FIELD	CONFIGURATION SETTING
The IP Address of the SSRS instance.	components.(AOS).parameters.biReporting.persistentVirtualMachineIPAddressSSRS.value
The thumbprint used by the SSRS application to communicate with AX Service.	components.(ReportingServices).parameters.reportingClientCertificateThumbprint.value

Configure service settings

FIELD	CONFIGURATION SETTING
DYNAMICS 365 DNS INFORMATION - The DNS host name of the Microsoft Dynamics 365 instance, such as ax.d365ffo.onprem.contoso.com.	components.(AOS).parameters.infrastructure.hostName
AOS SERVICE PRINCIPAL USER SETTINGS - The domain user account to run the AX service, such as yourdomain\axserviceuser.	components.(AOS).parameters.infrastructure.principalUserAccountName *
MR SERVICE PRINCIPAL USER SETTINGS - The group managed service account (gMSA) to run the MR application service, such as yourdomain\Svc-FRAS$.	components.(FinancialReporting).parameters.ApplicationServicePrincipalUser.accountName.value *
The group managed service account (gMSA) to run the MR process service, such as yourdomain\Svc-FRPS$.	components.(FinancialReporting).parameters.ProcessServicePrincipalUser.accountName.value *

FIELD	CONFIGURATION SETTING
The group managed service account (gMSA) to run the MR click-once service, such as yourdomain\Svc-FRCO$.	components.(FinancialReporting).parameters.ClickOnceServicePrincipalUser.accountName.value *

> **NOTE**
> Remove the extra backslash from the Principal username cofiguration value in the .json file before entering in the LCS UI. For example, contoso\\AXServiceUser should be entered as contoso\AXServiceUser in LCS.

Application certificate settings

FIELD	CONFIGURATION SETTING
The thumbprint of the Data Encryption certificate.	components.(AOS).parameters.database.dataEncryptionCertificateThumbprint.value
The thumbprint of the Data Signing certificate.	components.(AOS).parameters.database.dataSigningCertificateThumbprint.value
The thumbprint of the Session Authentication certificate.	components.(FinancialReporting).parameters.sessionAuthenticationCertificateThumbprint.value
The thumbprint of the SSL certificate used for WCF/SOAP support.	components.(AOS).parameters.infrastructure.sslCertificateThumbprint.value
The thumbprint used by the Management Reporter to communicate with AX service.	components.(FinancialReporting).parameters.tokenSpec.certThumbprint.value

Redeploy your environment

The following instructions provide information about how to update or redeploy your environment with a new platform or topology.

1. In LCS, navigate to the **Environments** blade in your on-premises project.
2. Click **Delete** to delete your environment.

   > **NOTE**
   > Deleting the environment will not delete the database, infrastructure or Local agent. Only the Service Fabric applications are deleted.

3. Wait for a few minutes and verify that the deployment is deleted. To confirm the deployment is deleted, log in to the on-premises environment and navigate to the Service Fabric Explorer.

   The following applications should be deleted:

   - AXBootstapperAppType

- AXSFType
- FinancialReportingType
- RTGatewayAppType
- ReportingService

  The following on-premises service fabric agent applications should not be deleted:

- LocalAgentType
- MonitoringAgentAppType

4. After all of the applications in step 3 are deleted, go back to LCS and click **Configure**.
5. Select the new topology for your platform.
6. Enter the environment name. You can use the same name or enter a new one.
7. Click **Advanced Settings**. You can now use the relevant configurations from the .json file that you saved to configure your environment.

Remove and reinstall, or add an AOS node

2/18/2021 • 9 minutes to read • Edit Online

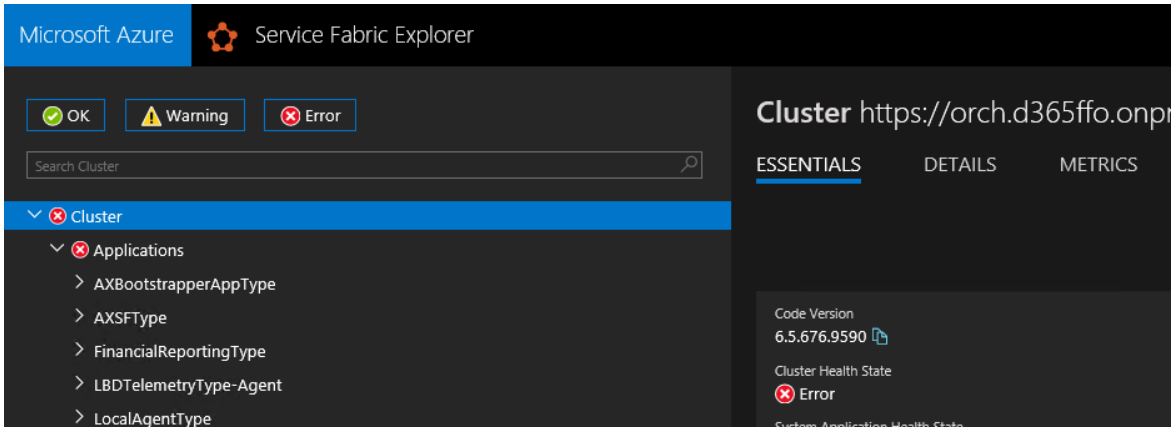
This topic explains how to remove an Application Object Server (AOS) node in your on-premises environment to reduce or replace a failed node. It also explains how to add a new AOS node for scale-out performance.

Remove a node

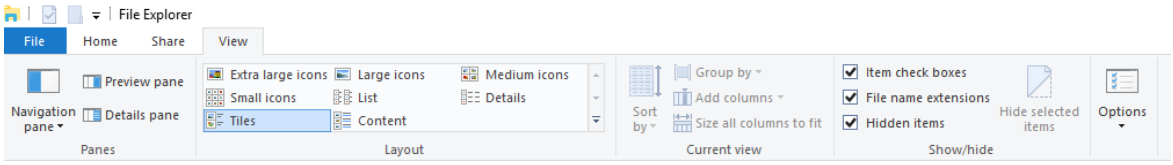
Option 1: Use a configuration file (preferred option)

Reference document: Add or remove nodes to a standalone Service Fabric cluster running on Windows Server

1. In Service Fabric Explorer, select **Cluster**, and make a note of the Microsoft Service Fabric cluster version. For this example, the cluster version is **6.5.676.9590**.



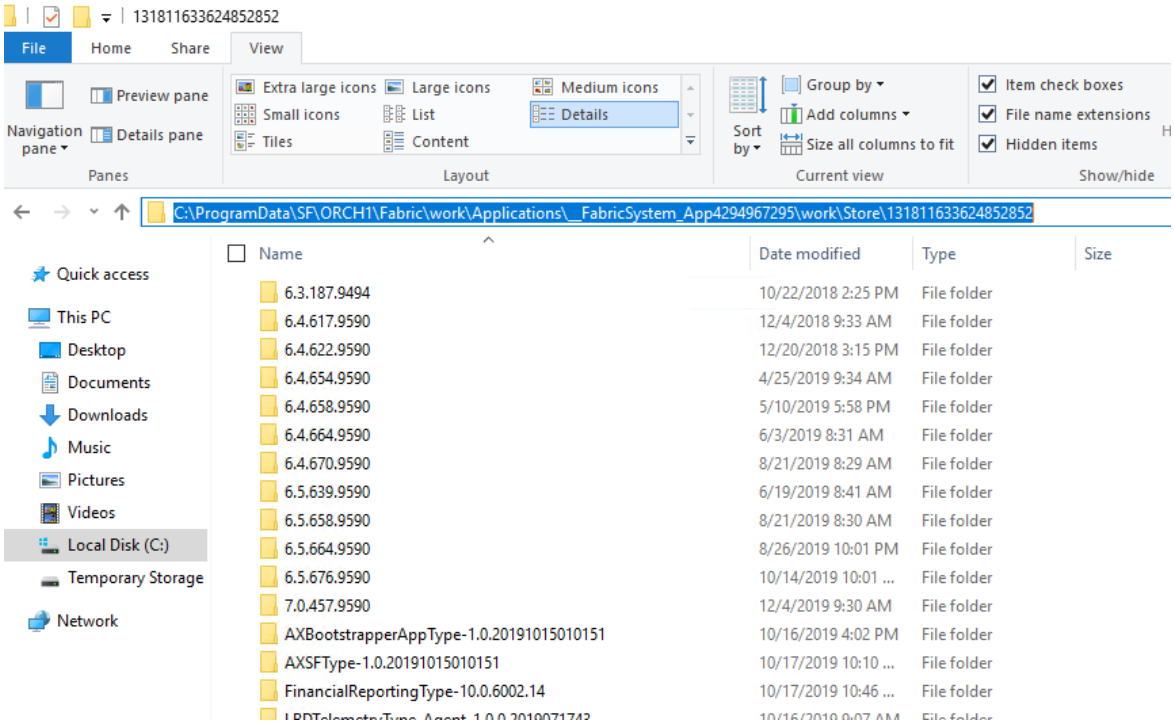
2. On one of the orchestrator nodes, open File Explorer. On the **View** tab, in the **Show/hide** group, make sure that the **File name extensions** and **Hidden items** check boxes are selected.



3. Expand drive C, and then drill down into the following folder. (Note that the bold parts of the path will vary, depending on the node name and setup.)

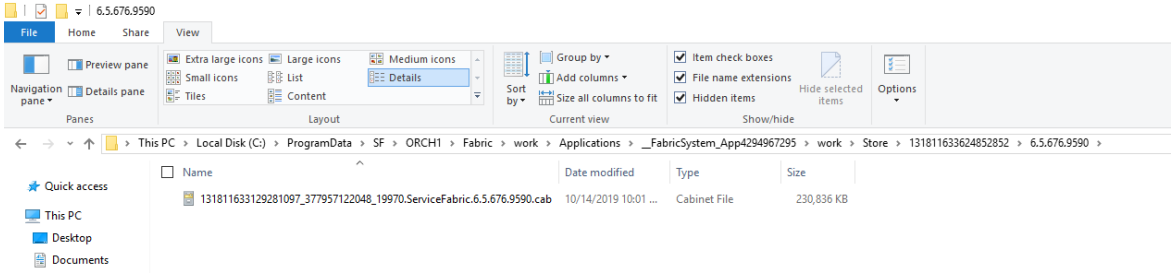
   C:\ProgramData\SF**ORCH1**\Fabric\work\Applications__FabricSystem_**App4294967295**\work\Store**131811633624852852**

   In the folder, you should see a list of folders for various versions of Microsoft Service Fabric. Here is an example.

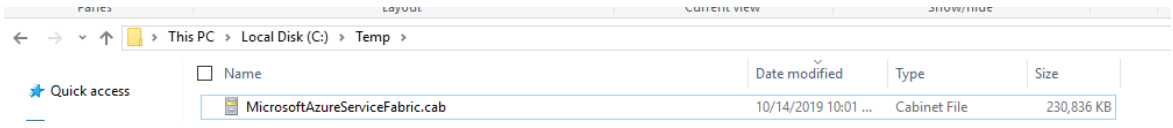


4. Open the folder with the name the same as the version of Microsoft Service Fabric cluster you that you made a note of earlier. For this example, the folder is named **6.5.676.9590**.

5. In the folder, you should see a .cab file.



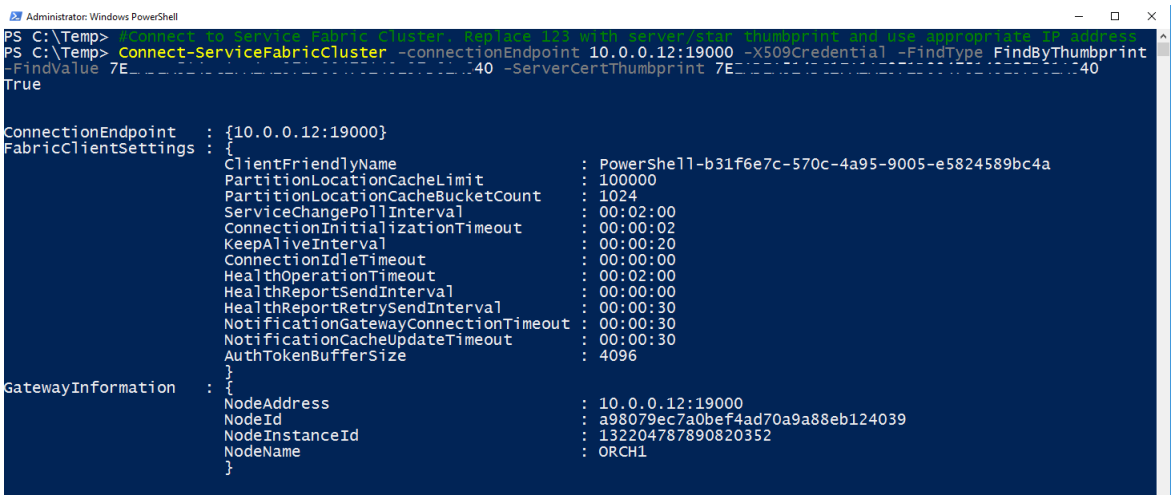
6. Copy the .cab file to C:\Temp, and rename the copied file **MicrosoftAzureServiceFabric.cab**. (If you don't have a Temp folder, create it.)



7. Open a Windows PowerShell Command Prompt window as an admin.

8. Run the following command to connect to the Service Fabric cluster.

```
#Connect to Service Fabric Cluster. Replace 123 with server/star thumbprint and use appropriate IP
address
Connect-ServiceFabricCluster -connectionEndpoint 10.0.0.12:19000 -X509Credential -FindType
FindByThumbprint -FindValue 123 -ServerCertThumbprint 123
```



9. Run the following command to save the configuration file to C:\Temp\ClusterConfig.json. (Make sure that the C:\Temp path exists.)

```
Get-ServiceFabricClusterConfiguration -UseApiVersion -ApiVersion 10-2017 >C:\Temp\ClusterConfig.json
```

10. In the configuration file that you saved in the previous step, in the **fabricSettings** section, in the **Setup** section, add a section for the **NodesToBeRemoved** parameter. The parameter value should be a comma-separated list of names of the nodes that must be removed.

> **NOTE**
>
> Be sure to add a comma to the end of the line that precedes the new section.

```
"fabricSettings": [
    {
        "name": "Setup",
        "parameters": [
            {
                "name": "FabricDataRoot",
                "value": "C:\\\\ProgramData\\\\SF"
            },
            {
                "name": "FabricLogRoot",
                "value": "C:\\\\ProgramData\\\\SF\\\\Log"
            },
            {
                "name": "NodesToBeRemoved",
                "value": "AOS1"
            }
        ]
    }
]
```

11. Remove the node from the **Nodes** section. In the following example, the **AOS1** node was removed.

```
"Nodes": [
    {
        "NodeName": "AOS2",
        "NodeTypeRef": "AOSNodeType",
        "IPAddress": "10.0.0.10",
        "FaultDomain": "fd:/fd1",
        "UpgradeDomain": "ud1"
    },
    {
    "NodeName": "AOS3",
    "NodeTypeRef": "AOSNo…
```

12. Remove the following lines from the **Security** section.

```
"WindowsIdentities": {
    "\$id": "3"
},
```

> **NOTE**
>
> If you don't remove these lines, you will receive the following error message later:
>
> ValidationException: Authentication type can't be changed from unsecured to Windows.

13. Increment the version number of the configuration file. Make this change at the lowest increment. In the following example, the version number went from **1.0.0** to **1.0.1**.

```
"ClusterConfigurationVersion": "1.0.1"
```

14. Save the configuration file.

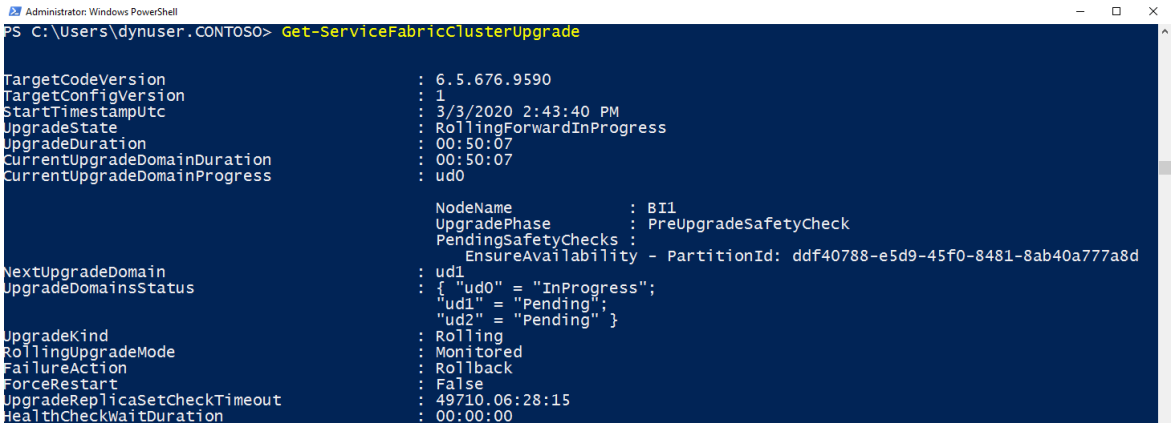
15. Run the following command to remove the node.

```
Start-ServiceFabricClusterConfigurationUpgrade -ClusterConfigPath C:\Temp\ClusterConfig.json
```

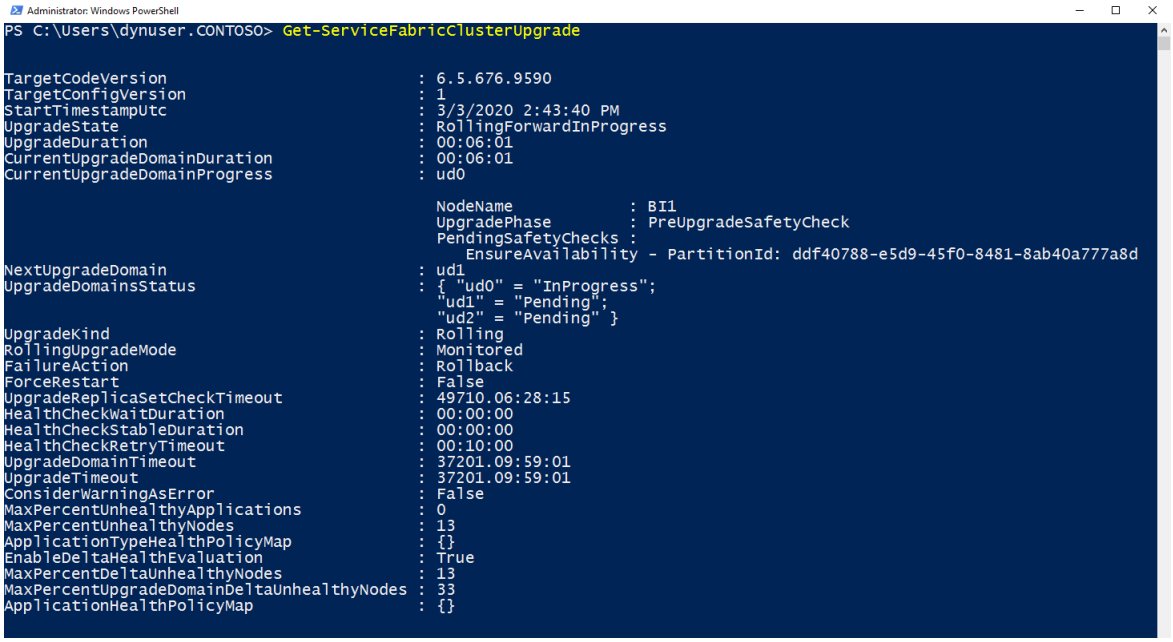
16. Run the following command to monitor the progress.

```
Get-ServiceFabricClusterUpgrade
```

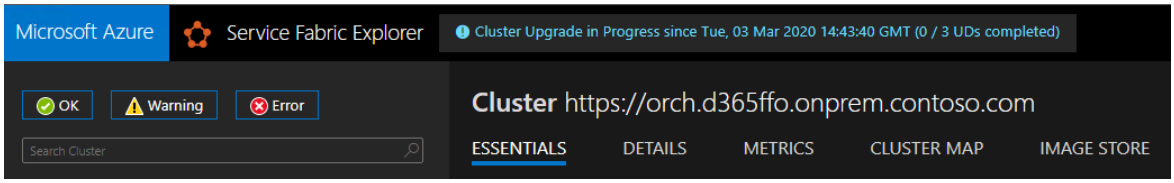
    If the upgrade stops responding at "UpgradePhase: PreUpgradeSafetyCheck," make a note of the **NodeName** value, and restart that node from Service Fabric Explorer. In the following illustration, the upgrade has stopped responding. It was running for 50 minutes at the same status on node BI1.



During upgrade of the cluster configuration, if you receive an error message that states that you previously added a node through the **Add-ServiceFabricNode** command, you will need to run a configuration upgrade without making any changes to the configuration file except for the version number. You can use the **Get-ServiceFabricClusterConfiguration** and **Start-ServiceFabricClusterConfigurationUpgrade** commands for this purpose.

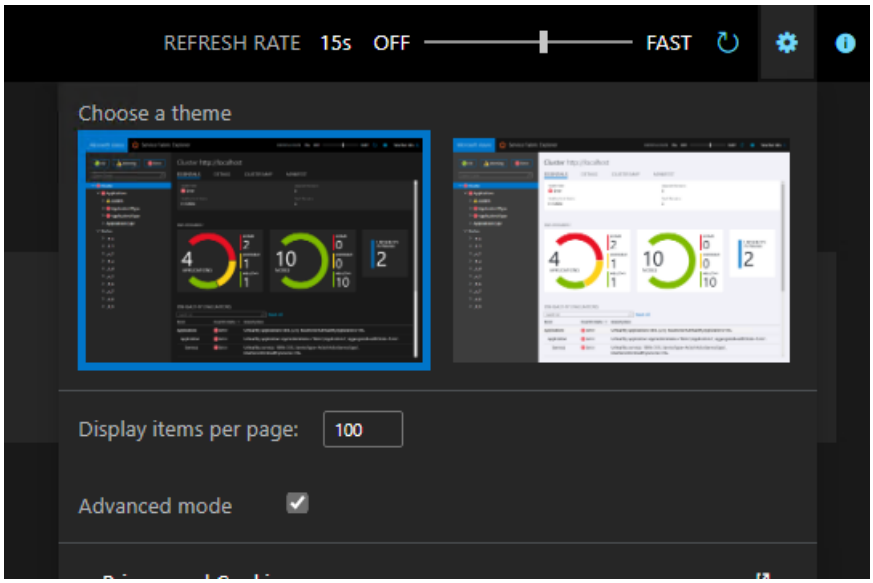


You can also view the progress in Service Fabric Explorer.

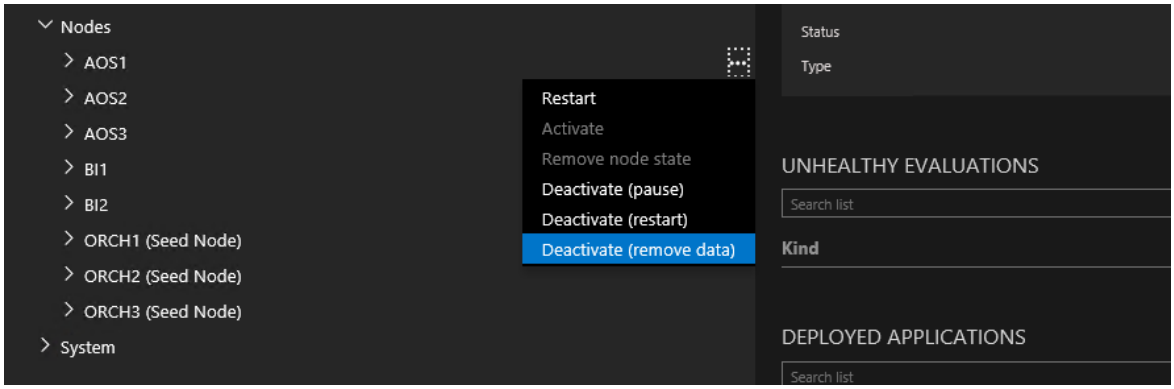


Option 2: Use Service Fabric Explorer

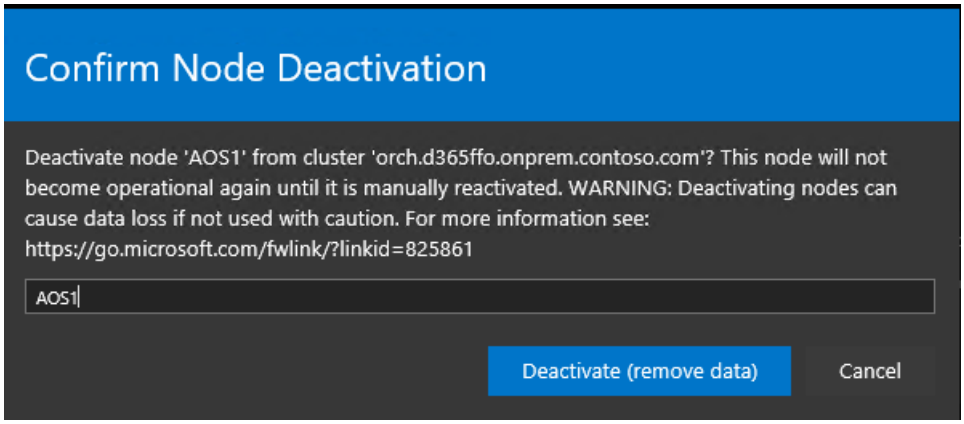
1. Sign in to Service Fabric Explorer.
2. Select the **Settings** button (gear symbol), and make sure that **Advanced** mode is turned on.



3. Expand **Nodes**, select the ellipsis (...) button next to the node that you want to remove, and then select **Deactivate (remove data)**. Note that this option might not be available if the node is already down (for example, if the node server can't be started).



4. When you're prompted to confirm deactivation, enter the name of the node, and then select **Deactivate (remove data)**.

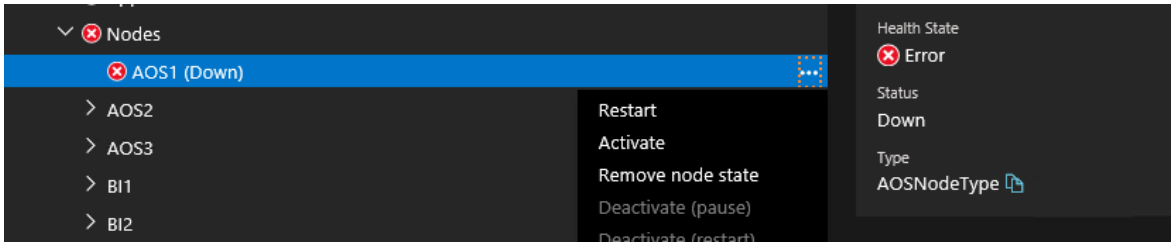


After the node has been deactivated, its status is shown as **Disabled**.

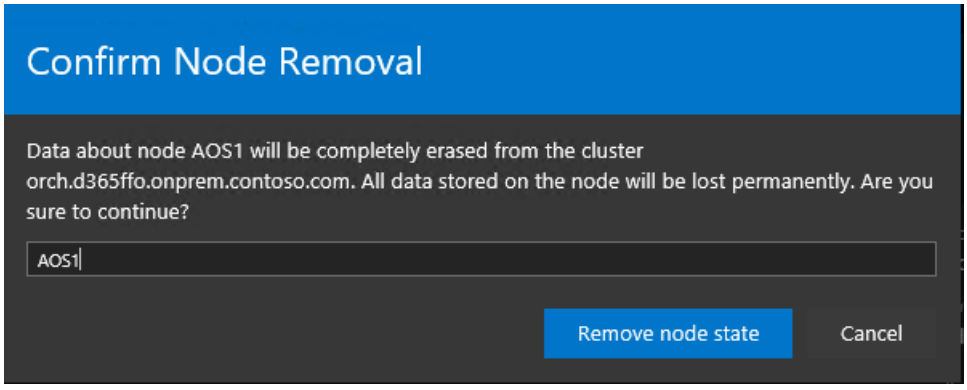
5. If the server is still active and connected to the domain, you might have to follow these steps if you will be replacing the deactivated node with a new server:

   a. Sign in to the server.
   b. Remove the server from the domain.
   c. Rename the server.
   d. Make a note of the IP address, and then change the IP address to a free address that you have in your range.
   e. Shut down the server.

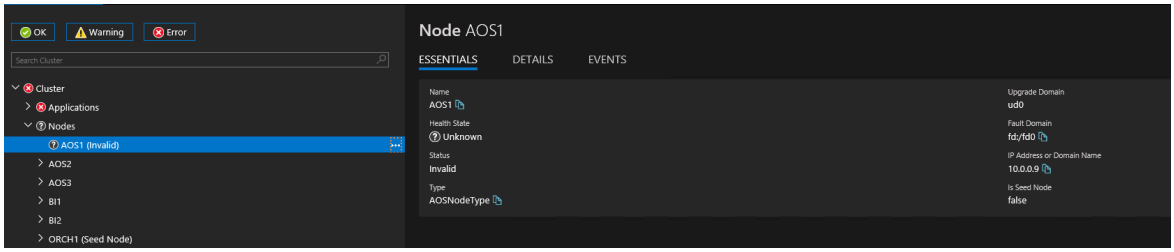
6. After the server has been shut down, or if it was already down, Service Fabric Explorer reflects its status. Select the ellipsis (...) button again next to the node, and then select **Remove node state**.



7. Confirm removal of the node.



After the node has been removed, its status is shown as **Invalid**.



8. Make a note of the node name and type. For this example, the node name is **AOS1**, and the type is **AOSNodeType**. Remember that the node name might not match the network name. Also make a note of the **Upgrade Domain** and **Fault Domain** settings, and the IP address. The previous illustration shows all these values.

Add a node

The next step is to start a new AOS server.

1. Follow these steps if you're replacing an existing server that was removed:

   a. Give the server the network name of the previous AOS server.
   b. Assign the original IP address. For this example, that IP address is **10.0.0.9**.
   c. Join the server to the domain.

2. If you're adding a new server to an existing cluster, update the ConfigTemplate.xml file so that it contains the additional information. This information will be used when you push out the prerequisites and apply settings through Windows PowerShell scripts.

3. Make sure that you've added the **AXServiceUser** and **svc-AXSF$** group Managed Service Accounts (gMSAs) to the local admin group on the AOS server.

   After the server is connected to the domain, you must follow the prerequisite steps for on-premises environments in Set up and deploy on-premises environments (Platform update 12 and later). The following steps summarize those prerequisite steps.

4. Copy the contents of each infrastructure\VMs<VMName> folder into the corresponding virtual machine (VM). (If you use remoting scripts, they will automatically copy the contents to the target VMs.) Then run the following Windows PowerShell scripts as an admin.

   > **NOTE**
   > If you're running remotely and repairing an existing server, you must delete the lbdscripts_remote_status.json file from the infrastructure folder to ensure the file copy process is run against all servers again.

   ```
   # Install pre-req software on the VMs.
   # If Remoting, execute
   # .\Configure-PreReqs-AllVMs.ps1 -MSIFilePath <share folder path of the MSIs> -ConfigurationFilePath
   .\ConfigTemplate.xml
   .\Configure-PreReqs.ps1 -MSIFilePath <share folder path of the MSIs>
   ```

5. Restart the computer every time that you're prompted. Make sure that you rerun the **.\Configure-PreReqs.ps1** script after every restart, until all the prerequisites are installed. In the case of remoting, rerun the **AllVMs** script when all the computers are back online.

6. If you use the remoting script, make sure that the current user has access to the share folder of Microsoft Windows Installer package files (.msi files).

7. If you use the remoting script, make sure that no user is accessing computers of the **AOSNodeType**, **MRType**, and **ReportServerType** types. Otherwise, the remoting script won't be able to restart the computer because users are signed in to it.

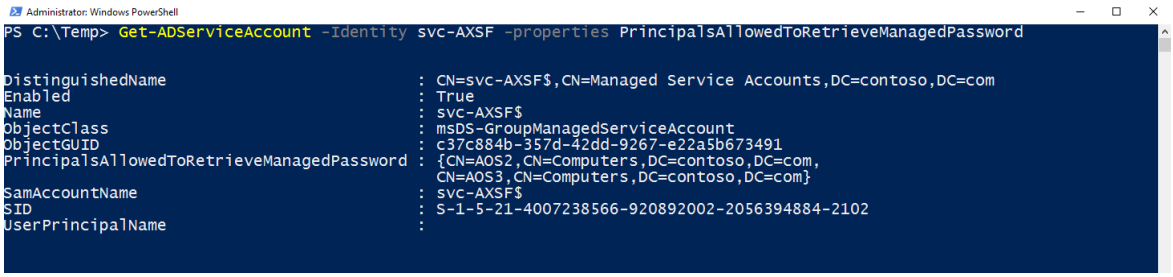
8. Run the following scripts, if they exist, to complete the VM setup.

   ```
   # If Remoting, only execute
   # .\Complete-PreReqs-AllVMs.ps1 -ConfigurationFilePath .\ConfigTemplate.xml
   .\Add-GMSAOnVM.ps1
   .\Import-PfxFiles.ps1
   .\Set-CertificateAcls.ps1
   ```

9. If errors occur while you run **Add-GMSAonVM.ps1**, you must run the following command. (Edit the command if your service account differs. Note that you remove the dollar sign [$] from the service

account name.)

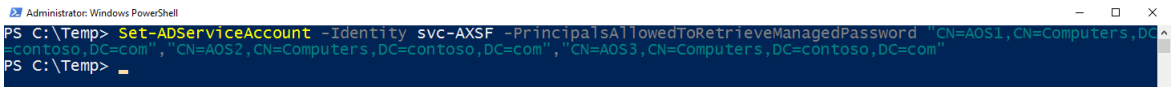
```
Get-ADServiceAccount -Identity svc-AXSF -properties PrincipalsAllowedToRetrieveManagedPassword
```



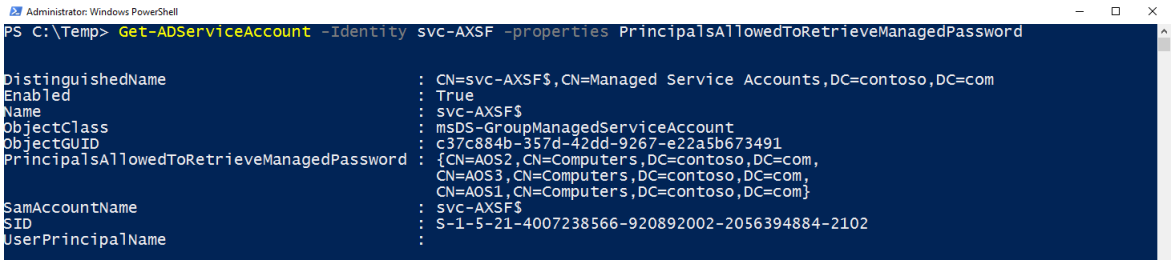
You see a list of the servers that have permission to retrieve the password for the **svc-AXFS$** gMSA. If you see a globally unique identifier (GUID) value for the server that was removed, ignore it.

10. Copy the list of principals from the result, and use them to edit or amend the following command. (Note that, because the **Set** command isn't additive, you must add all references back in.)

```
Set-ADServiceAccount -Identity svc-AXSF -PrincipalsAllowedToRetrieveManagedPassword
"CN=AOS1,CN=Computers,DC=contoso,DC=com","CN=AOS2,CN=Computers,DC=contoso,DC=com","CN=AOS3,CN=Compute
rs,DC=contoso,DC=com"
```



11. Run the original **Get** command to verify that the new AOS node was added back in. (Note in the example screenshot below you can see that AOS1 was added to the list of PrincipalsAllowedToRetrieveManagedPassword.)

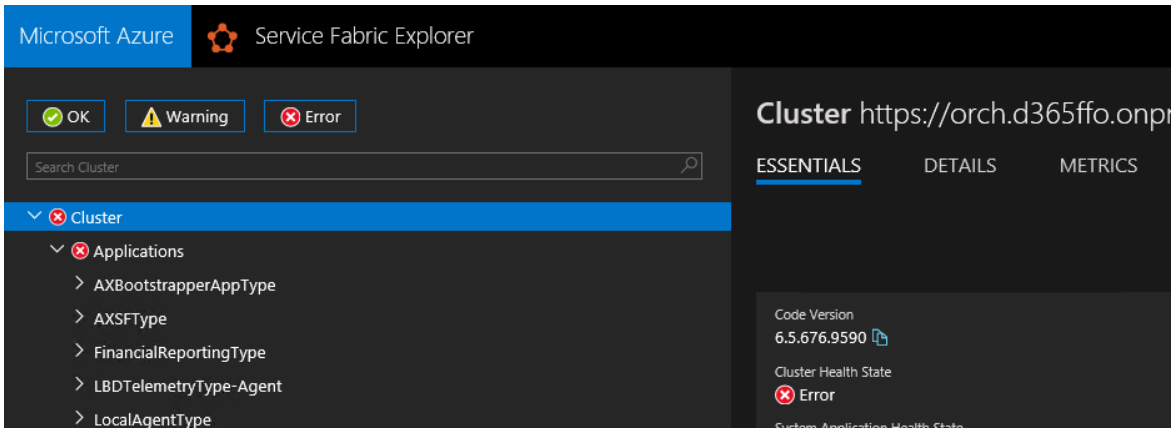


12. Run the following script to validate the VM setup.

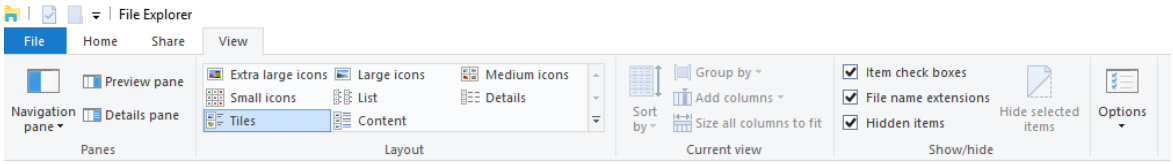
```
# If Remoting, execute
# .\Test-D365FOConfiguration-AllVMs.ps1 -ConfigurationFilePath .\ConfigTemplate.xml
.\Test-D365FOConfiguration.ps1
```

13. Before you continue, fix anything that fails as part of the validation script.

14. In Service Fabric Explorer, select **Cluster**, and make a note of the Microsoft Service Fabric cluster version. For this example, the cluster version is **6.5.676.9590**.



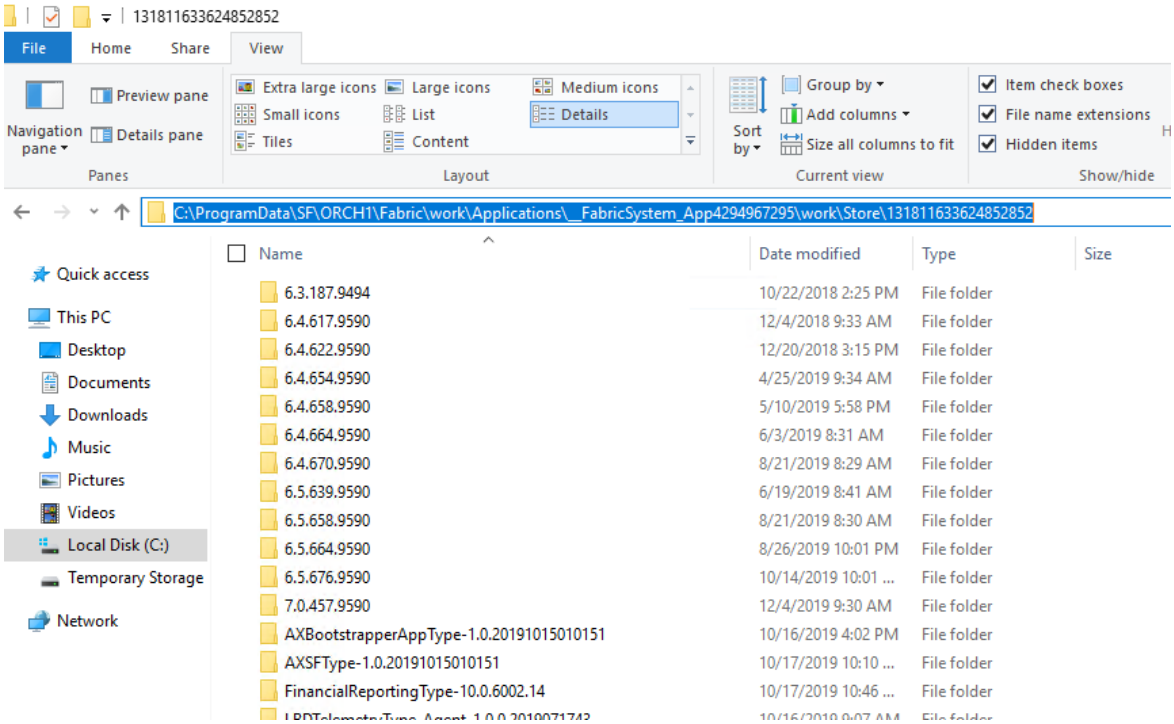
15. On one of the orchestrator nodes, open File Explorer. On the **View** tab, in the **Show/hide** group, make sure that the **File name extensions** and **Hidden items** check boxes are selected.



16. Expand drive C, and then drill down into the following folder. (Note that the bold parts of the path will vary, depending on the node name and setup.)

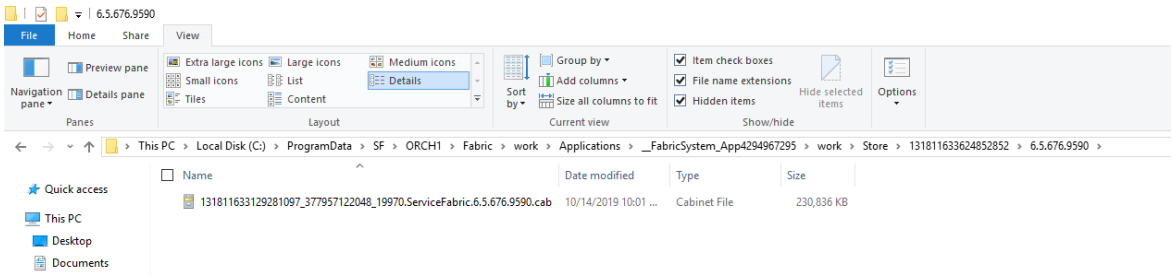
    C:\ProgramData\SF**ORCH1**\Fabric\work\Applications__FabricSystem_**App4294967295**\work\Store**131811633624852852**

    In the folder, you should see a list of folders for various versions of Service Fabric. Here is an example.

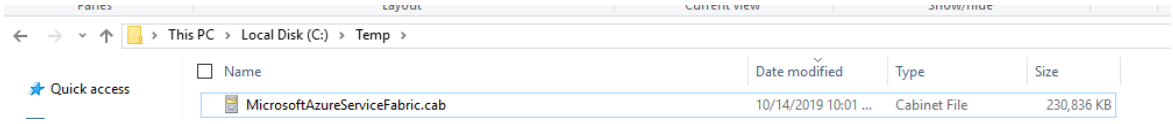


17. Open the folder that has the same name as the version of Microsoft Service Fabric cluster that you made a note of earlier. For this example, the folder is named **6.5.676.9590**.

18. In the folder, you should see a .cab file.



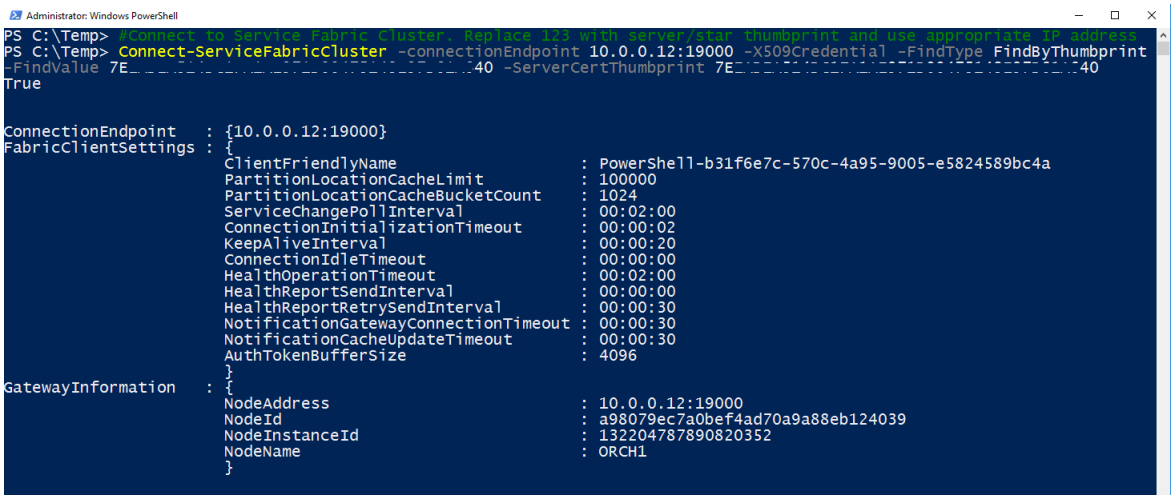
19. Copy the .cab file to C:\Temp, and rename the copied file **MicrosoftAzureServiceFabric.cab**. (If you don't have a Temp folder, create it.)



20. Open a Windows PowerShell Command Prompt windows as an admin.

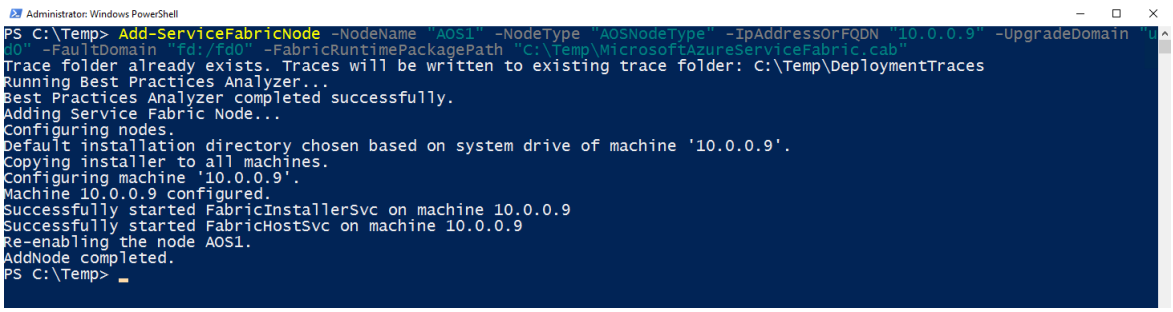
21. Run the following command to connect to your Service Fabric cluster. (Edit the command as you require.)

```
#Connect to Service Fabric Cluster. Replace 123 with server/star thumbprint and use appropriate IP
address
Connect-ServiceFabricCluster -connectionEndpoint 10.0.0.12:19000 -X509Credential -FindType
FindByThumbprint -FindValue 123 -ServerCertThumbprint 123
```



22. Run the following command to add the node back in. Before you run it, make the required edits to the **NodeName**, **IPAddress**, **UpgradeDomain**, and **FaultDomain** parameters. (If you're replacing an existing server, you should have made a note of the values earlier.)

```
Add-ServiceFabricNode -NodeName "AOS1" -NodeType "AOSNodeType" -IpAddressOrFQDN "10.0.0.9" -
UpgradeDomain "ud0" -FaultDomain "fd:/fd0" -FabricRuntimePackagePath
"C:\Temp\MicrosoftAzureServiceFabric.cab"
```



23. After the node has been added back in, return to Service Fabric Explorer, and view the application

deployment status. Several minutes will be required before all the AOS applications are restored (**AXBootstrapperAppType**, **AXSFType**, **RTGatewayAppType**, and **LBDTelemetryType-<envname>** or **MonitoringAgentAppType**) are pushed out again and installed on the node.

NOTE

Can you tell us about your documentation language preferences? Take a short survey.

The survey will take about seven minutes. No personal data is collected (privacy statement).

Reuse the same AD FS instance for multiple environments

2/18/2021 • 2 minutes to read • Edit Online

This topic explains how to use the same instance of Active Directory Federation Services (AD FS) in multiple Microsoft Dynamics 365 Finance + Operations (on-premises) environments.

Setup

> **IMPORTANT**
>
> This procedure assumes that you've previously configured AD FS for one environment by following the instructions in the Set up and deploy on-premises environments content. It also assumes that that environment is running without any issues.

1. In AD FS Manager, go to **AD FS** > **Application groups**, and open **Microsoft Dynamics 365 for Operations On-premises**.
2. In the **Native application** section, follow these steps:
   a. Open **Microsoft Dynamics 365 for Operations On-premises - Native application**, and add the redirect URI of the new environment (`https://ax.contoso.com/namespaces/AXSF`).
   b. Open **Microsoft Dynamics 365 for Operations On-premises - Financial Reporting - Native application**, and add the redirect URI of the new environment (`https://ax.contoso.com/FinancialReporting/ApplicationService/soap/`).
3. In the **Web API** section, follow these steps:
   a. Open **Microsoft Dynamics 365 for Operations On-premises - Web API**, and add two entries for the redirect URI of the new environment (`https://ax.contoso.com/namespaces/AXSF` and `https://ax.contoso.com`).
   b. Open **Microsoft Dynamics 365 for Operations On-premises - Financial Reporting Web API**, and add the redirect URI of the new environment (`https://ax.contoso.com/FinancialReporting`).
4. Optional: In the **Server** section, open **Microsoft Dynamics 365 for Operations On-premises - Retail**, and add the redirect URI of the new environment (`https://ax.contoso.com/namespaces/AXSF/`).
5. Optional: Configure the warehouse mobile app for the new environment by following the instructions in Configure the Warehousing app for on-premises deployments again. Remember to use the URI of the new environment (`https://ax.contoso.com`) as the **Resource URL** value.

   > **NOTE**
   >
   > No additional configuration is required for the workflow and retail designer applications.

6. Verify that you can reach the OpenID metadata endpoint (`https://<adfs-dns-name>/adfs/.well-known/openid-configuration`) from the **AOS** and **MR** nodes in your new environment. If you're using self-signed certificates, you might have to import the AD FS Secure Sockets Layer (SSL) certificate into the Trusted Root Certification Authorities store of each node.
7. When you deploy the new environment from Microsoft Dynamics Lifecycle Services (LCS) and are

specifying the deployment configuration, make sure that you use the same AD FS OpenID metadata endpoint and AD FS OpenID connect client IDs that you specified for the previous environment.

AD FS Microsoft 365 compatibility

2/18/2021 • 2 minutes to read • Edit Online

IMPORTANT

This feature is only fully supported starting with application update 10.0.8, Platform update 32, and LocalAgent 2.2.0. For details, see Partial support.

This topic explains how to use the same instance of Active Directory Federation Services (AD FS) for a Dynamics 365 Finance + Operations (on-premises) environment and for Microsoft 365.

Existing deployments

1. Download the new local agent version from Microsoft Dynamics Lifecycle Services (LCS). It should be version 2.2.0 or later.
2. Download the new version of the local agent configuration file, because it has additional configuration that is required for this functionality.
3. Modify the new local agent configuration file, and set the **office365AdfsCompatibility** value to **True**.
4. Run the following command to uninstall the old local agent version from your cluster.

```
.\LocalAgentCLI.exe Cleanup '<path of localagent-config.json>'
```

5. Run the following command to install the new local agent version.

```
.\LocalAgentCLI.exe Install '<path of localagent-config.json>'
```

6. Perform any servicing operation with Platform update 28 or later to make the new configuration available.
7. After servicing is completed, run the following script.

```
.\Reset-DatabaseUsers.ps1 -DatabaseServer '<FQDN of the SQL server>' -DatabaseName '<AX database
name>'
```

IMPORTANT

If you skip this step, the primary admin user won't be able to sign in.

8. Use Service Fabric Explorer to Restart applications (such as AOS).
9. Verify that you are able to sign in to the product with the system administrator user that was specified during deployment.
10. Download the newest version of the infrastructure scripts from the LCS Shared asset library.
11. Copy the Reset-SID.ps1 script from the downloaded infrastructure scripts folder into one of your AOS machines.

12. Execute the Reset-Sid.ps1 script.

```
.\Reset-SID.ps1 -AxsfCodePath
'C:\ProgramData\SF\AOS_13\Fabric\work\Applications\AXSFType_App184\AXSF.Code.1.0.20190902'
```

New deployments

1. Follow the instructions for installing the local agent in the "Configure a connector and install an on-premises local agent" section of Set up and deploy on-premises environments. However, before you actually install the local agent, complete step 2 of this procedure.
2. Modify the local agent configuration file, and set the **office365AdfsCompatibility** value to **True**.
3. Continue to follow the instructions in the "Configure a connector and install an on-premises local agent" section of Set up and deploy on-premises environments, and deploy a base version that runs Platform update 28 or later. If there is no base version that runs Platform update 28 or later, deploy the latest base version that is available. Then service it so that Platform update 28 is deployed on top.

Partial support

For partial support, it is necessary to have Local Agent 2.2.0 or later installed and to update the service with Platform update 28 or later.

With partial support, authentication against the Financial Reporting service is not supported.

Local agent pre-deployment and post-deployment scripts

2/18/2021 • 2 minutes to read • Edit Online

Local agent 2.3.0 supports the execution of pre-deployment and post-deployment scripts. Therefore, customers can now set up Microsoft Windows PowerShell scripts that are run before and after the environment is deployed. This feature applies to deployments and redeployments, and also to servicing operations.

To make this feature available, you must create a Scripts folder in the agent file share. To run a pre-deployment script, create a **PreDeployment.ps1** file in the Scripts folder. To run a post-deployment script, create a **PostDeployment.ps1** file. The following examples show the folder structure:

- \\\fileserver\agent\scripts\PreDeployment.ps1
- \\\fileserver\agent\scripts\PostDeployment.ps1

If these files don't exist, the deployment continues as usual. The following examples show the new deployment flow.

Deployment or redeployment:

1. Get unhealthy modules. In this step, the health of existing services is obtained to find which are unhealthy. This step applies only to redeployment scenarios.
2. Clean up modules. In this step, the services are removed and the contents of the **wp** folder are deleted. This step applies only to redeployment scenarios.
3. Link download artifacts. In this step, download, extraction, and processing of artifacts from Microsoft Dynamics Lifecycle Services (LCS) takes place.
4. Pre-deployment script. In this step the **PreDeployment.ps1** script is executed (if it exists).
5. Set up modules. In this step, the new services are deployed.
6. Post-Deployment script. In this step the **PostDeployment.ps1** script is executed (if it exists).

Servicing:

1. Prepare for servicing. In this step, the package is prepared in LCS and gets downloaded to the environment.
2. Clean up modules. In this step, the services are removed and the contents of the **wp** folder are deleted.
3. Link download artifacts. In this step, extraction and processing of previously downloaded artifacts from LCS takes place.
4. Pre-deployment script. In this step the **PreDeployment.ps1** script is executed (if it exists).
5. Set up modules. In this step, the new services are deployed.
6. Post-Deployment script. In this step the **PostDeployment.ps1** script is executed (if it exists).

> **NOTE**
> The pre-deployment and post-deployment scripts can contain anything. The code that the scripts run is solely the customer's responsibility. The local agent just invokes the scripts.

Customizations

The default time-out for script execution is 30 minutes. To change this value, modify the localagent-config.json file, and then reinstall the local agent by using the modified file. The following attribute defines time-out value

and must be set as shown here. (The code that is shown here is part of the **LocalAgent** component in the file.)

```
"powershellScriptRunner": {
    "timeoutMinutes": {
        "value": "30"
        }
    }
```

Logging

The outputs and error messages from the scripts are written, as .log and .err files, into the Logs folder in the Scripts folder. If a script times out, only an error message is logged. This error message has a time-out message. No other outputs are logged in this situation.

Execution of the scripts is also logged as Event Tracing for Windows (ETW) events. You can view these events in Event Viewer. If a script produces any errors, an error event is logged, but deployment continues as usual.

Update the local agent

2/18/2021 • 5 minutes to read • Edit Online

This topic explains how to update the local agent. The latest version of the local agent is version 2.6.0, which was released in October 2020.

LOCAL AGENT VERSION	CAPABILITY
Null	This initial version deploys Platform update 8.
1.0.0	This version enables the Reconfigure feature for failed deployments.
1.1.0	This version enables the Reconfigure feature for successful deployments, enables multi-model package deployments, and deploys Platform update 8 and 11.
2.0.0	This version enables servicing flows and deploys Platform update 12.
2.1.0	This version enables two-phased servicing where **Preparation** and **Update** are two separate steps.
2.1.1	This version fixes an issue that occurs when the download fails and the LCS Maintain button is not available. Additional changes include updates to Azure storage libraries to improve communication with Azure storage and enable TLS 1.2.
2.1.2	This version contains updated Azure dependencies for improved download stability and logic to correctly evaluate if files are downloaded. This fixes an issue where files are fully downloaded, but the logic would still consider them as missing a few bytes and therefore fail the download.
2.2.0	This version fixes locked dlls during cleanup and enables prerequisites for supporting Active Directory Federation Services (AD FS) that also is used for Microsoft 365.
2.3.0	This version adds support for pre- and post-deployment scripts.
2.3.1	This version fixes orchestration service crashes that may occur during clean up on some environments. Deploying version 10.0.5 with Platform update 29 or earlier requires the use of pre-deployment scripts for automatic updating of FinancialReportingDeployer.exe.config. For more information, see Troubleshoot on-premises deployments.
2.4.0	This version fixes a deployment issue and upgrades the runtime of the local agent.

LOCAL AGENT VERSION	CAPABILITY
2.5.0	This version updates dependencies and fixes a cleanup bug.
2.6.0	This version upgrades the Service Fabric SDK, fixes a bug with refresh state, and increases the application provisioning timeout.

What's new in local agent 2.6.0

- Local agent 2.6.0 uptakes a new Service Fabric SDK and runtime.
- This release fixes a bug where, if refresh state is triggered when the environment is stuck in the Downloading phase, the environment would automatically move to a deployed state without updating the environment. In this situation, the refresh state will mark the Downloading phase as failed.
- The timeout for provisioning an application has been increased.

> **IMPORTANT**
> This release is only compatible with 7.x Service Fabric clusters.

What's new in local agent 2.5.0

- Local agent 2.5.0 uptakes new versions of various dependencies. The main changes are Service Fabric and Entity Framework.
- This release also fixes a bug where, if cleanup fails without cleaning up any services, subsequent reattempts always fail during cleanup.

What's new in local agent 2.4.0

- Local agent 2.4.0 now requires .NET Framework 4.8 to uptake the newest changes from Lifecycle Services (LCS). Be sure to run the latest Infrastructure Scripts available in LCS to meet the newest requirements.
