If those steps don't work, change the size of your remote desktop before you start the RDP session, so that the default zoom level in Internet Explorer is 100 percent.

Certificate thumbprint errors

Error example - Certificate thumbprint errors

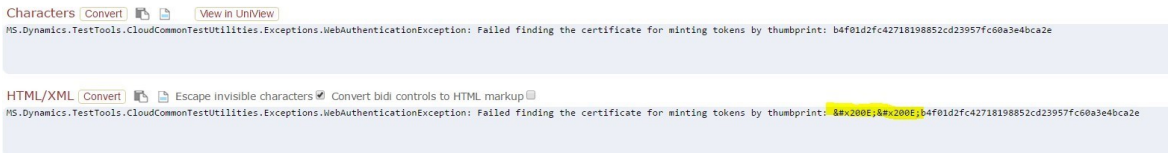
> Initialization method MS.Dynamics.Performance.Application.TaskRecorder.TestRecord1Base.TestSetup**

> threw an exception. System.TypeInitializationException: System.TypeInitializationException: The type initializer for 'MS.Dynamics.TestTools.CloudCommonTestUtilities.Authentication.UserManagement' threw an exception. --> MS.Dynamics.TestTools.CloudCommonTestUtilities.Exceptions.WebAuthenticationException: Failed finding the certificate for minting tokens by thumbprint: b4f01d2fc42718198852cd23957fc60a3e4bca2e.

Solution - Certificate thumbprint errors

You might receive the error message for one of the following reasons:

- The certificate thumbprint that you copied into the CloudEnvironment.Config and wif.config files includes invisible Unicode characters. To determine whether the thumbprint contains invisible Unicode characters, paste it into a Unicode code converter, and see whether extra characters appear in the **HTML/XML** field. For example, you can use the Unicode converter that is available at https://r12a.github.io/apps/conversion/.



- The certificate wasn't installed on the Application Object Server (AOS) machine. To verify that the certificate can be found on the AOS machine, run the following Microsoft Windows PowerShell script.

  ```
  cd Cert:\LocalMachine\My
  Get-ChildItem | Where-Object { $_.Subject -like "CN=<name of your certificate>" }
  ```

  If the thumbprint doesn't appear in the Windows PowerShell console after you run the script, the certificate isn't installed. To fix the issue, copy and install a .cer file on all AOS machines.

- If this issue occurs when you run load tests, the setup scripts might not have installed the corresponding .pfx file correctly. Verify that the password that is specified in the CloudCtuFakeACSInstall.cmd file matches the password that was set when the certificate was created.

No endpoint is listening

This issue can occur when you run single-user or multi-user tests, or when you create users by using MS.Dynamics.Performance.CreateUsers.exe.

Error example - No endpoint is listening

The tests fail, or the user creation process fails, and the following error message is shown:

> System.TypeInitializationException: The type initializer for 'MS.Dynamics.TestTools.CloudCommonTestUtilities.Authentication.UserManagement' threw an exception. ---> System.ServiceModel.EndpointNotFoundException: There was no endpoint listening at \<web address> that could accept the message. This is often caused by an incorrect address or SOAP action.

Solution - No endpoint is listening

This issue occurs when the host that is specified in the CloudEnvironment.Config file can't be accessed from the machine that is trying to run the tests or create users.

In the CloudEnvironment.Config file, review the values that are specified by the following keys:

- \<ExecutionConfigurations Key="HostName" Value="<web address of host>" />
- \<ExecutionConfigurations Key="SoapHostName" Value="<web address of SOAP>" />

The web addresses that are specified by these keys must be in the environment that you're testing. In a web browser on your developer machine, make sure that you can open the web address that is specified by the **HostName** key.

For online load tests, the environment that is specified by the **HostName** key in the CloudEnvironment.Config file must be publicly accessible from any machine. Therefore, if you must test a one-box environment, you won't be able to run the load test by using Microsoft Visual Studio Online, because the endpoint won't be accessible outside the one-box environment.

Users can't be enumerated

This issue can occur when you run multi-user tests, or when you create users by using MS.Dynamics.Performance.CreateUsers.exe.

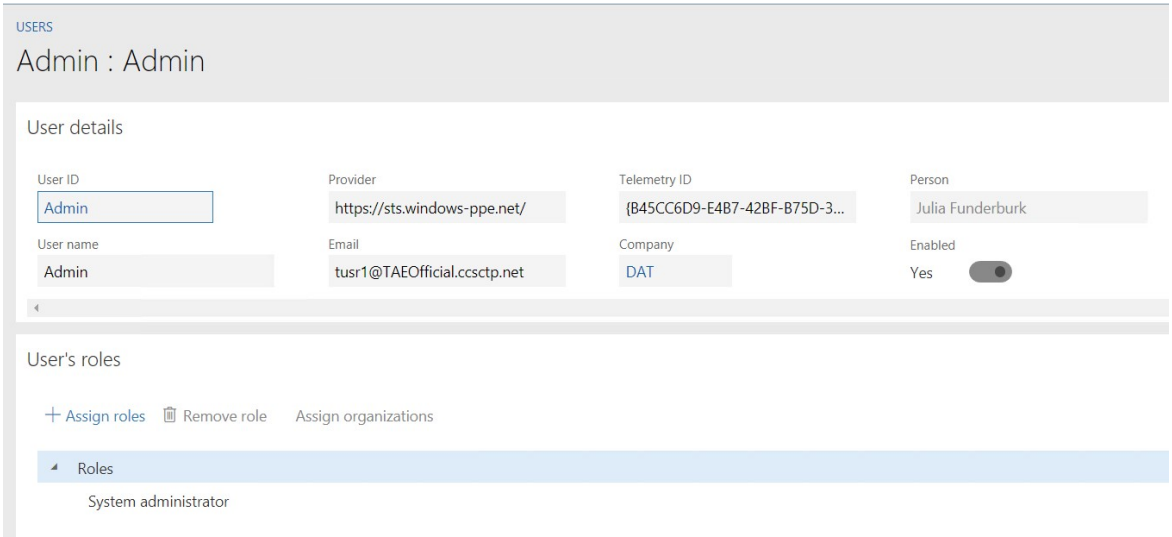
Error example - Users can't be enumerated

> System.TypeInitializationException: The type initializer for 'MS.Dynamics.TestTools.CloudCommonTestUtilities.Authentication.UserManagement' threw an exception. ---> System.InvalidOperationException: Could not enumerate AX users ---> System.ServiceModel.FaultException'1[System.ComponentModel.Win32Exception]: Forbidden

Solution - Users can't be enumerated

Three scenarios can cause this error:

- The System Administrator role isn't assigned to the user who is specified as **SelfMintingAdminUser** in the CloudEnvironment.config file. To verify that you've specified the correct user, sign in to the endpoint, and view the user's roles.



- The user who is specified as **SelfMintingAdminUser** in the CloudEnvironment.config file has a provider other than `https://sts.windows-ppe.net/` or `https://sts.windows.net/`. Sometimes, a company-specific domain is included in the **Provider** field for the admin user.
- If your Finance and Operations apps were deployed in 21Vianet, make sure that you have specified **NetworkDomain="https://sts.chinacloudapi.cn/"** in **SelfMintingSysUser** and **SelfMintingAdminUser**.

To work around this issue, create a user who has any name and email address. Assign the **System Administrator** role to the new user. You don't have to link the user to a real Microsoft Azure Active Directory (Azure AD) user. Specify this new admin user as **SelfMintingAdminUser** in the CloudEnvironment.config file.

The HTTP request was forbidden with client authentication scheme 'Anonymous'

Error example - The HTTP request was forbidden

> Initialization method <Test class name>.TestSetup threw exception. System.ServiceModel.Security.MessageSecurityException: System.ServiceModel.Security.MessageSecurityException: The HTTP request was forbidden with client authentication scheme 'Anonymous'. ---> System.Net.WebException: The remote server returned an error: (403) Forbidden.

Solution - The HTTP request was forbidden

Three known scenarios can cause this error:

- The test users are created by running MS.Dynamics.Performance.CreateUsers.exe without any arguments. For example, if the CreateUsers script is run without any arguments, the email addresses of test users that are created won't be correctly formatted. If these users are used to run the tests, the tests will generate the forbidden request error. You can verify that this scenario is causing the error by viewing the users. The incorrect email addresses of the test users will resemble the email addresses in the following illustration.

User ID	User name	Email	Company
$3D8C	$3D8C	TSTBadFormat_5@TAEOfficial.ccsctp.netAdmin (admin@ax7partner.ccsctp.net)	USMF
$4ED9	$4ED9	TSTBadFormat_10@TAEOfficial.ccsctp.netAdmin (admin@ax7partner.ccsctp.net)	USMF
$6CB7	$6CB7	TSTBadFormat_2@TAEOfficial.ccsctp.netAdmin (admin@ax7partner.ccsctp.net)	USMF
$8CE0	$8CE0	TSTBadFormat_9@TAEOfficial.ccsctp.netAdmin (admin@ax7partner.ccsctp.net)	USMF
$B07A	$B07A	TSTBadFormat_4@TAEOfficial.ccsctp.netAdmin (admin@ax7partner.ccsctp.net)	USMF
$C600	$C600	TSTBadFormat_8@TAEOfficial.ccsctp.netAdmin (admin@ax7partner.ccsctp.net)	USMF
$D14B	$D14B	TSTBadFormat_1@TAEOfficial.ccsctp.netAdmin (admin@ax7partner.ccsctp.net)	USMF
$E412	$E412	TSTBadFormat_3@TAEOfficial.ccsctp.netAdmin (admin@ax7partner.ccsctp.net)	USMF
$EDE4	$EDE4	TSTBadFormat_7@TAEOfficial.ccsctp.netAdmin (admin@ax7partner.ccsctp.net)	USMF
$FA4A	$FA4A	TSTBadFormat_6@TAEOfficial.ccsctp.netAdmin (admin@ax7partner.ccsctp.net)	USMF

  To resolve the issue, delete the test users who have incorrectly formatted email addresses. Rerun the CreateUsers script, and specify the user count and company.

- The number of users that you specify in the **UserCount** field in the CloudEnvironment.Config file exceeds the number of test users that you created by using MS.Dynamics.Performance.CreateUsers.exe. Make sure that you created at least as many test users as you request in the CloudEnvironment.Config file.

CloudEnvironment.Config

```
<?xml version="1.0" encoding="utf-8"?>
<EnvironmentalConfigSettings xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance" xmlns:xsd="http://www.w3.org/2001/XMLSchema">
  <EnvironmentalConfigSettingsCollection>
    <EnvironmentalConfigSetting ConfigName="DEVFABRIC">
      <!-- NOTE: the HostName value needs to be specified -->
      <ExecutionConfigurations Key="HostName" Value="usnconeboxaxlaos.cloud.onebox.dynamics.com" />
      <ExecutionConfigurations Key="SoapHostName" Value="usnconeboxaxlaos.cloud.onebox.dynamics.com" />
      <ExecutionConfigurations Key="SelfSigningCertificateThumbprint" Value="FDFDEFF031CA36B93B25378EAAAD6210825983F2" />
      <ExecutionConfigurations Key="AdminAuthenticatorConfigurationId" Value="SelfMintingAdminUser" />
      <ExecutionConfigurations Key="DefaultBrowser" Value="InternetExplorer" />
      <ExecutionConfigurations Key="FederationRealm" Value="spn:00000015-0000-0000-c000-000000000000" />
      <ExecutionConfigurations Key="DefaultDispatcher" Value="Microsoft.Dynamics.TestTools.Dispatcher.JsDispatcher, Microsoft.Dynamics.TestTools.Dispatcher.JsDispatcher" />
      <ExecutionConfigurationsNodes ConfigurationName="SVC">
        <ConfigurationSpecificDetails Key="AppConfig" Value="DEVFABRIC.Config" />
      </ExecutionConfigurationsNodes>
      <ExecutionConfigurationsNodes ConfigurationName="PRF">
        <ConfigurationSpecificDetails Key="UserCount" Value="10" />
        <ConfigurationSpecificDetails Key="UserFormat" Value="TST_{0}@TAEOfficial.ccsctp.net" />
        <ConfigurationSpecificDetails Key="UserRole" Value="-SYSADMIN-" />
        <ConfigurationSpecificDetails Key="ThinkTime" Value="0" />
        <ConfigurationSpecificDetails Key="Company" Value="USMF" />
      </ExecutionConfigurationsNodes>
    </EnvironmentalConfigSetting>
  </EnvironmentalConfigSettingsCollection>
  <AuthenticatorConfigurationCollection>
    <AuthenticatorConfiguration Id="SelfMintingRunnerUser" Class="MS.Dynamics.TestTools.CloudCommonTestUtilities.Authentication.SelfMintedTokenAuthenticator">
      <Credentials IsFromKeyVault="false" Username="daxrunneruser@daxmdsrunner.com" NetworkDomain="urn:Microsoft:Dynamics:Cloud:DaxRunner" />
    </AuthenticatorConfiguration>
    <AuthenticatorConfiguration Id="SelfMintingSysUser" Class="MS.Dynamics.TestTools.CloudCommonTestUtilities.Authentication.SelfMintedTokenAuthenticator">
      <Credentials IsFromKeyVault="false" Username="testuser@microsoft.com" />
    </AuthenticatorConfiguration>
    <AuthenticatorConfiguration Id="SelfMintingAdminUser" Class="MS.Dynamics.TestTools.CloudCommonTestUtilities.Authentication.SelfMintedTokenAuthenticator">
      <!-- NOTE: admin username needs to be specified -->
      <Credentials IsFromKeyVault="false" Username="Tusr1@TAEOfficial.ccsctp.net" />
    </AuthenticatorConfiguration>
  </AuthenticatorConfigurationCollection>
</EnvironmentalConfigSettings>
```

- If your Finance and Operations apps were deployed in 21Vianet, make sure that your development and performance testing environments are in Platform Update for 10.0.11 or above.

At least one security token in the message could not be validated

This issue can occur when you run multi-user tests, when you create users by using MS.Dynamics.Performance.CreateUsers.exe, when the AOS machine differs from the developer machine.

Error example - At least one security token in the message could not be validated

> System.TypeInitializationException: The type initializer for 'MS.Dynamics.TestTools.CloudCommonTestUtilities.Authentication.UserManagement' threw an exception. ---> System.ServiceModel.Security.MessageSecurityException: An unsecured or incorrectly secured fault was received from the other party. See the inner FaultException for the fault code and detail. ---> System.ServiceModel.FaultException: At least one security token in the message could not be validated.

Solution - At least one security token in the message could not be validated

This issue occurs when the AOS endpoint can't validate the thumbprint of the certificate that you created. There are two possible causes:

- The certificate wasn't installed on the AOS machine. To fix the issue, copy a .cer file to the AOS machine, and install it.
- The thumbprint of the certificate wasn't added to the wif.config file on the AOS machine. To fix the issue, add the certificate to the wif.config file. Be sure to restart Microsoft Internet Information Services (IIS) after you change the wif.config file.

MS.Dynamics.Test.Team.Foundation.WebClient.InteractionService.dll.config is missing from the deployment items

This issue usually occurs when you run load tests.

Error example - MS.Dynamics.Test.Team.Foundation.WebClient.InteractionService.dll.config is missing

> <Test class name>.TestSetup threw exception. System.InvalidOperationException: System.InvalidOperationException: Could not find endpoint element with name 'ClientCommunicationManager' and contract 'Microsoft.Dynamics.Client.InteractionService.Communication.Reliable.IReliableCommunicationManager' in the ServiceModel client configuration section. This might be because no configuration file was found for your application, or because no endpoint element matching this name could be found in the client element.. at System.ServiceModel.Description.ConfigLoader.LoadChannelBehaviors(ServiceEndpoint serviceEndpoint,

> String configurationName)

Solution - MS.Dynamics.Test.Team.Foundation.WebClient.InteractionService.dll.config is missing

This issue occurs when the system can't find the MS.Dynamics.Test.Team.Foundation.WebClient.InteractionService.dll.config file when the load tests are run, because the file wasn't added as a deployment item. Verify that the MS.Dynamics.Test.Team.Foundation.WebClient.InteractionService.dll.config file is in the Out folder for the test run:

<solution path>\TestResults\<your test run>\Out

If the file is missing, add it to the deployment items in the test settings.

There are two files that have very similar names. The name of one file ends in *.dll, and the name of the other file ends in *.dll.config. The *.dll.config file must be in the deployment items in the test settings.

CloudEnvironment.Config is missing from the deployment items

This issue usually occurs only when you run load tests.

Error example - CloudEnvironment.Config is missing

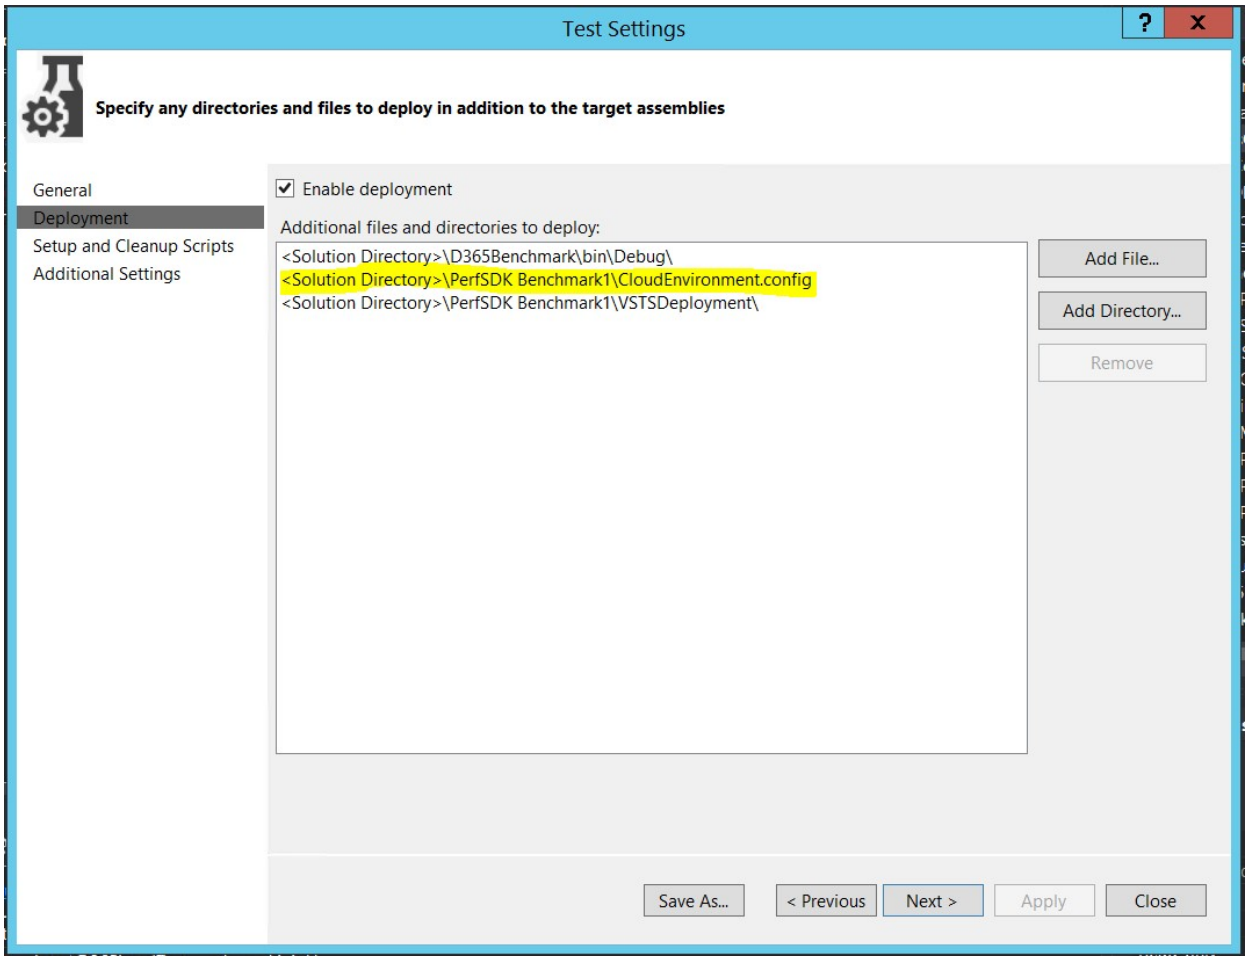
> Initialization method \<Test class name>.TestSetup threw exception. System.TypeInitializationException: System.TypeInitializationException: The type initializer for 'MS.Dynamics.TestTools.CloudCommonTestUtilities.Authentication.UserManagement' threw an exception. ---> MS.Dynamics.TestTools.TestLogging.EvaluateException: Assert.Fail failed. DateTime="10/13/2017 14:42:55" "The type initializer for 'MS.Dynamics.TestTools.CloudCommonTestUtilities.Authentication.SecretSettingsHelper' threw an exception.".

Solution - CloudEnvironment.Config is missing

This issue occurs when the CloudEnvironment.Config file isn't present when the tests are run. It typically occurs when you run load tests and the CloudEnvironment.Config file wasn't added as a deployment item. Verify that the CloudEnvironment.Config file is in the Out folder for the test run:

<solution path>\TestResults\<your test run>\Out

If the file is missing, add it to the deployment items in the test settings.



InteractiveClientId was not specified in the settings

Error example - InteractiveClientId was not specified in the settings

> The type initializer for 'MS.Dynamics.TestTools.CloudCommonTestUtilities.Authentication.SecretSettingsHelper' threw an exception. ---> Microsoft.CE.VaultSDK.SecretProviderException: InteractiveClientId was not specified in settings.

Solution - InteractiveClientId was not specified in the settings

This issue occurs when the **SelfSigningCertificateThumbprint** field is left blank in the CloudEnvironment.Config file. In the CloudEnvironment.Config file, find the following line, and paste in the thumbprint of the certificate that you created and installed.

```
\<ExecutionConfigurations Key="SelfSigningCertificateThumbprint" Value="" />
```

The remote host forcibly closed an existing connection

Error example - The remote host forcibly closed an existing connection

> System.TypeInitializationException: System.TypeInitializationException: The type initializer for 'MS.Dynamics.TestTools.CloudCommonTestUtilities.Authentication.UserManagement' threw an exception. ---> System.ServiceModel.CommunicationException: An error occurred while making the HTTP request to \<Host name>/Services/AxUserManagement/Service.svc/ws2007FedHttp. This could be due to the fact that the server certificate is not configured properly with HTTP.SYS in the HTTPS case. This could also be caused by a mismatch of the security binding between the client and the server. ---> System.Net.WebException: The underlying connection was closed: An unexpected error occurred on a send. ---> System.IO.IOException: Unable to read data from the transport connection: An existing connection was forcibly closed by the remote

> host. ---> System.Net.Sockets.SocketException: An existing connection was forcibly closed by the remote host.

Solution - The remote host forcibly closed an existing connection

Run the following Windows PowerShell script on the development machine.

```
Set-ItemProperty HKLM:\SOFTWARE\Microsoft\.NETFramework\v4.0.30319 -Name SchUseStrongCrypto -Value 1 -Type
dword -Force -Confirm:$false
if ((Test-Path HKLM:\SOFTWARE\Wow6432Node\Microsoft\.NETFramework\v4.0.30319))
{
    Set-ItemProperty HKLM:\SOFTWARE\Wow6432Node\Microsoft\.NETFramework\v4.0.30319 -Name SchUseStrongCrypto
-Value 1 -Type dword -Force -Confirm:$false
}
```

Service w3svc was not found on computer

This error occurs only when you run load tests by using Visual Studio Online.

Error example - Service w3svc was not found on computer

> Test method MS.Dynamics.Performance.Application.GFM.PDLTrend.ProcureToPayTrend.ProcureToPaymentTrend threw exception: System.TypeInitializationException: The type initializer for 'MS.Dynamics.TestTools.CloudCommonTestUtilities.Authentication.UserManagement' threw an exception. ---> System.InvalidOperationException: Service w3svc was not found on computer '.'. ---> System.ComponentModel.Win32Exception: The specified service does not exist as an installed service.

Solution - Service w3svc was not found on computer

A hotfix is available that resolves this issue. The Microsoft Knowledge Base (KB) number is 4095640.

The file IEDriverServer.exe does not exist

This issue affects only single-user tests.

Error example - The file IEDriverServer.exe does not exist

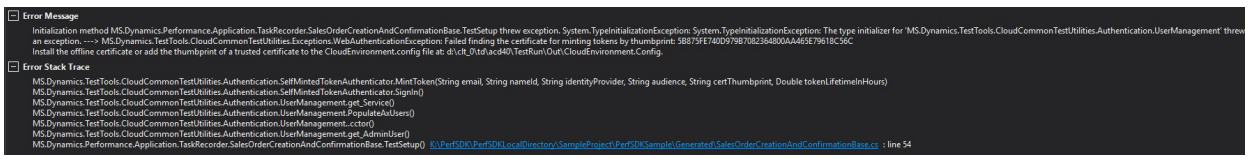
> The file K:\perfSDK\PerfSDKLocalDirectory\SampleProject\TestResults\Admin501201994c_devae648d1909-1 2018-06-25 03_40_51\Out\Common\External\Selenium\IEDriverServer.exe does not exist. The driver can be downloaded at `https://selenium-release.storage.googleapis.com/index.html`.

Solution - The file IEDriverServer.exe does not exist

Copy the **Common\External\Selenium** folder under **<Your_PerfSDK_Folder>** to the **<Your_PerfSDK_Folder>\SampleProject\ PerfSDKSample\bin\Debug** folder.

Failed finding the certificate for minting tokens by thumbprint: <your certificate thumbprint>

Error example - Failed finding the certificate for minting tokens by thumbprint



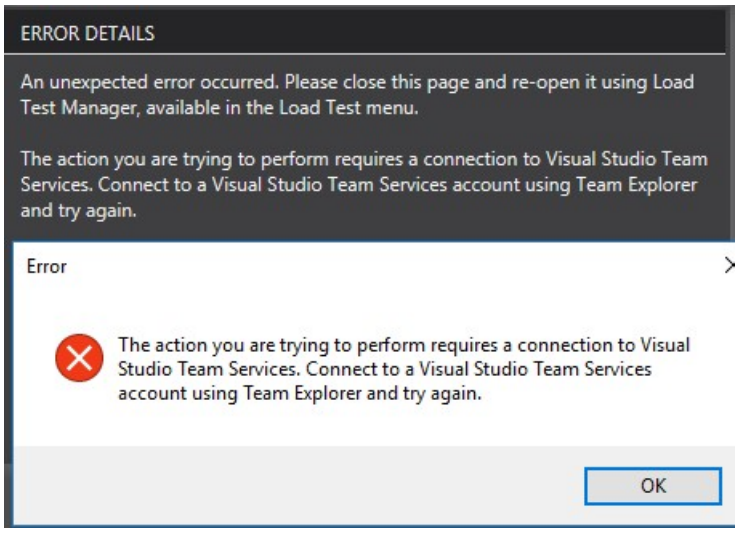
Solution - Failed finding the certificate for minting tokens by thumbprint

Make sure that you install the generated certificate on each AOS machine in your sandbox environment.

The action you are trying to perform requires a connection to Visual Studio Team Services

This issue affects only multi-user tests.

Error example - The action you are trying to perform requires a connection to Visual Studio Team Services



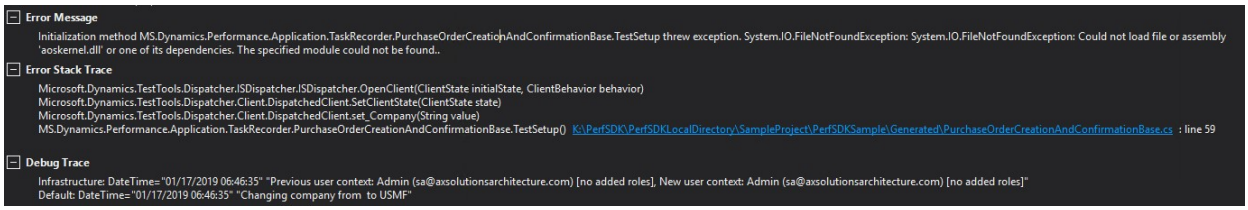
Solution - The action you are trying to perform requires a connection to Visual Studio Team Services

When you connect to Azure DevOps, use the old URI format (**<Azure_DevOps_Account>.visualstudio.com**) instead of **dev.azure.com/<Azure_DevOps_Account>**. Additionally, open Azure DevOps by using the old URI, and then select **Open in Visual Studio**.

Could not load file or assembly 'aoskernel.dll' or one of its dependencies

This error affects only multi-user tests.

Error example - Could not load file or assembly 'aoskernel.dll'



Solution - Could not load file or assembly 'aoskernel.dll'

Make sure that you're using Open Database Connectivity (ODBC) Driver 17 in an environment that has Platform update 20 or later.

AzureActiveDirectoryConfiguration node is missing in CloudEnvironment.config

Error example - AzureActiveDirectoryConfiguration node is missing

> Initialization method MS.Dynamics.Performance.Application.TaskRecorder.SalesOrderCreationAndConfirmationBase.TestSetup threw exception. System.TypeInitializationException: System.TypeInitializationException: The type initializer

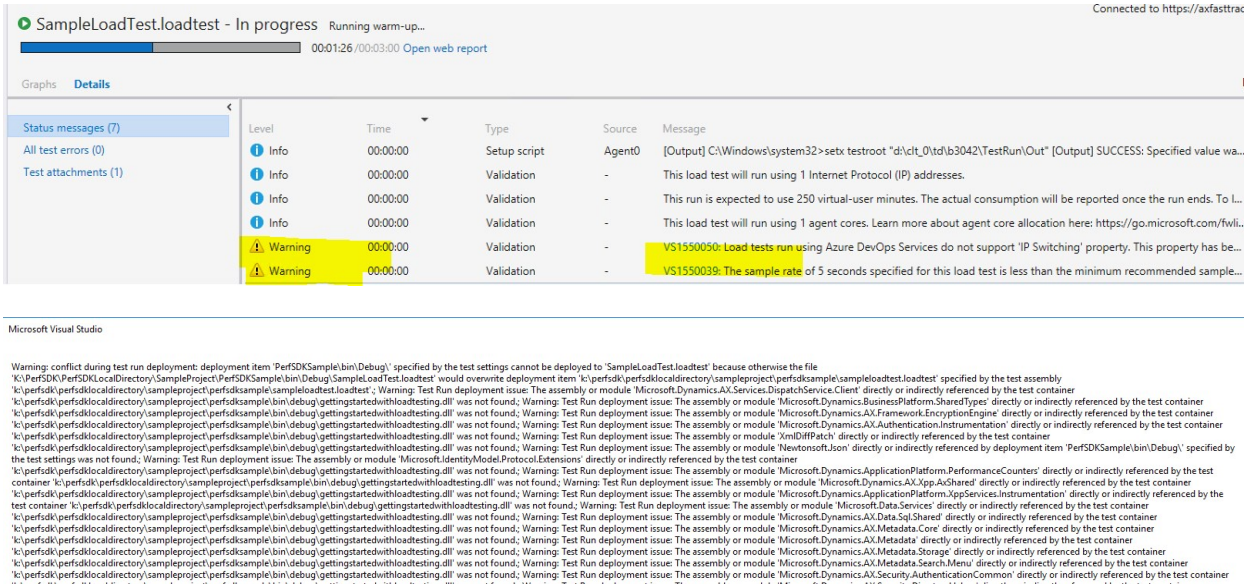
> for 'MS.Dynamics.TestTools.CloudCommonTestUtilities.Authentication.UserManagement' threw an exception. ---> System.Reflection.TargetInvocationException: Exception has been thrown by the target of an invocation. ---> System.MissingFieldException: AzureActiveDirectoryConfiguration node is missing in CloudEnvironment.config.

Solution - AzureActiveDirectoryConfiguration node is missing

Replace all instances of **"MS.Dynamics.TestTools.CloudCommonTestUtilities.Authentication.AadAuthenticator"** with **"MS.Dynamics.TestTools.CloudCommonTestUtilities.Authentication.SelfMintedTokenAuthenticator"** in the **AuthenticatorConfigurationCollection** section of the CloudEnvironment.config file.

Multiple warning messages before and after multi-user testing that uses Azure DevOps

Error example - Multiple warning messages before and after multi-user testing



]

Solution - Multiple warning messages before and after multi-user testing

There is no impact, and the messages can be ignored.

The type or namespace name 'xxxx' could not be found (are you missing a using directive or an assembly reference?)

Error example - The type or namespace name 'xxxx' could not be found

The type or namespace name 'InventTransferOrders' could not be found (are you missing a using directive or an assembly reference?)

Solution - The type or namespace name 'xxxx' could not be found

The sample solution shipped with the perfSDK was previously prepared and wasn't updated after the packages split. To resolve the issue, add the assembly **MS.Dynamics.TestTools.DirectoryProxyLibrary.dll** under <Service volume>:\PerfSDK\PerfSDKLocalDirectory as a reference.

Assembly was built against the ".NETFramework,Version=v4.6" framework

Error example - Assembly was built against the ".NETFramework,Version=v4.6" framework

The primary reference "MS.Dynamics.TestTools.ApplicationSuiteProxyLibrary" could not be resolved because it has an indirect dependency on the assembly "MS.Dynamics.TestTools.DirectoryProxyLibrary, Version=7.0.0.0, Culture=neutral, PublicKeyToken=a7cf325ee2c8a9ff" which was built against the ".NETFramework,Version=v4.6" framework. This is a higher version than the currently targeted framework ".NETFramework,Version=v4.5".

Solution- Assembly was built against the ".NETFramework,Version=v4.6" framework

Change the **Target framework** property in the properties window of PerfSDKSample to .Net Framework 4.6.

Performance SDK and multiuser testing in on-premises environments

2/18/2021 • 17 minutes to read • Edit Online

This topic explains how to use the Performance software development kit (SDK) to do multiuser load testing in an on-premises environment.

> **IMPORTANT**
>
> Visual Studio 2019 will be the last version of Visual Studio with web performance and load test features. In the future, we will be publishing some recommendations for alternative solutions.
>
> - If you are using the Visual Studio and Test Controller/Test Agent for on-premises load testing, Visual Studio 2019 will be the last version. You can continue using it until the end of support cycle.
> - If you are using the cloud-based load testing service, the cloud-based load testing service will continue to run through March 31, 2020. Until then, you can continue to use all of the experiences powered by this service without interruption. Alternatively, you can switch to on-premises load testing.
>
> For more information, see Cloud-based load testing service end of life.

Prerequisites

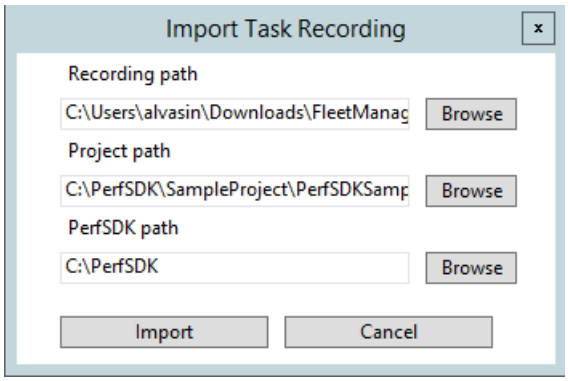
- An on-premises environment that has volume data
- A development environment that has the following characteristics:
  - Microsoft Visual Studio Enterprise or a later version is installed.
  - The Performance SDK is installed. (The SDK will likely be in K:\PerfSDK\PerfSDKLocalDirectory. However, depending on your environment, it might be in another location, such as C:\PerfSDK.)
  - The on-premises environment can be accessed in a web browser. (The development virtual machine [VM] might be in the same domain as the on-premises environment, or the on-premises environment might have a publicly registered domain name.)

Create a single-user C# test from an XML recording

1. Use Task recorder to create a recording of the scenario that you want to test.

   > **IMPORTANT**
   >
   > Your task recording must start on the default dashboard page. Otherwise, the test won't be able to run.

2. Start Microsoft Visual Studio as an administrator, and build the **PerfSDKSample** project. This project is in the **PerfSDK** folder. If you've already built the project, skip this step.
3. Select **Dynamics 365** > **Addins** > **Create C# perf test from recording**.
4. In the **Import Task Recording** dialog box, enter the required details, and then select **Import**.



A C# test is generated in the Generated folder for the project that you selected.

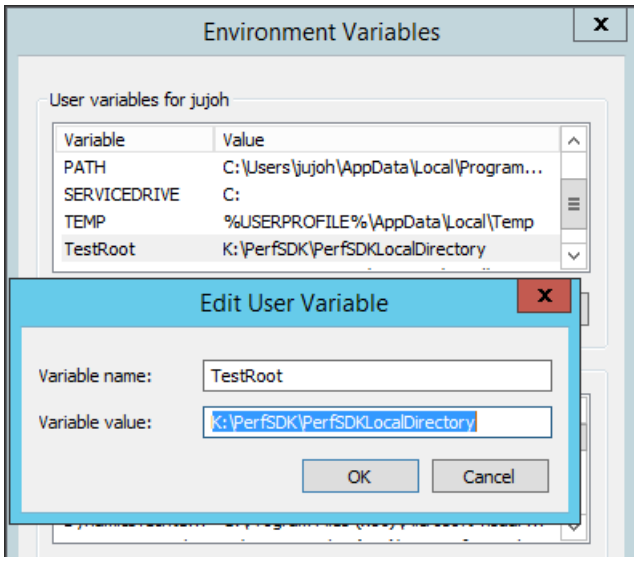
> **NOTE**
> The test that is generated might have to be edited to resolve any compilation issues.

Run a single-user test by using the Performance SDK

Prepare the development environment

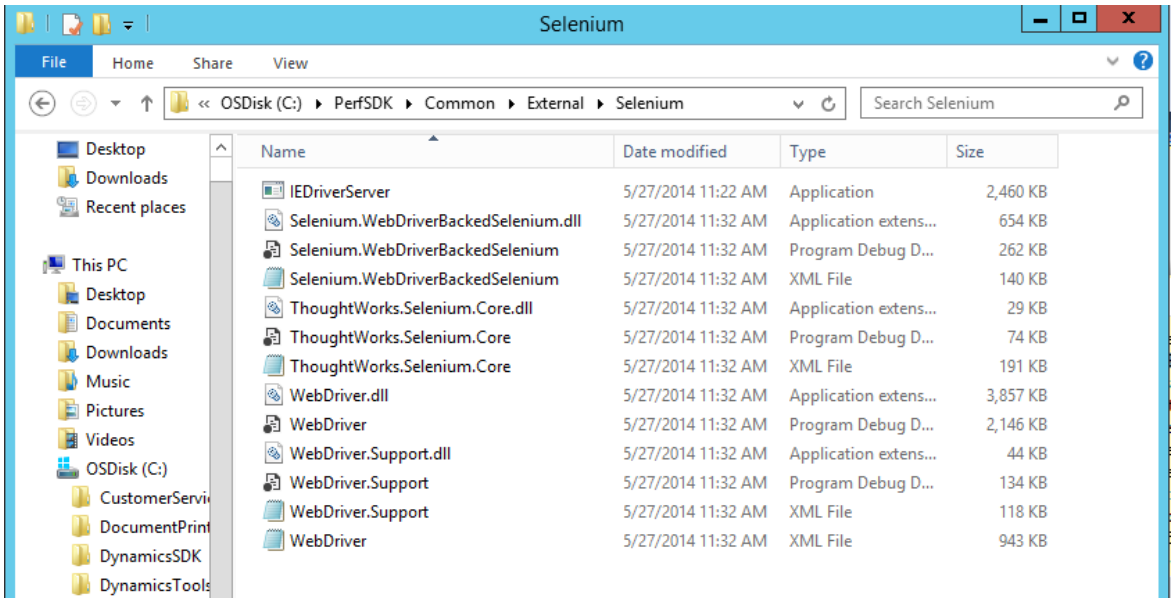
Follow these steps in the development environment.

1. In Control Panel in Microsoft Windows, select **System and Security** > **System** > **Advanced System Settings**. Verify that the **TestRoot** environment variable is set to the path of the PerfSDK folder.



2. Download the **selenium-dotnet-strongnamed-2.42.0.zip** and **IEDriverServer_Win32_2.42.0.zip** files from https://selenium-release.storage.googleapis.com/index.html?path=2.42/, and extract the files.

3. Copy the dynamic-link libraries (DLLs) from the **selenium-dotnet-strongnamed-2.42.0.zip\net40** folder to the **PerfSDK\Common\External\Selenium** folder. Also copy the **IEDriverServer.exe** from the **IEDriverServer_Win32_2.42.0.zip** to the **PerfSDK\Common\External\Selenium** folder.



4. Generate a certificate to use for authentication for the tests. To generate a certificate file, open a Command Prompt window as an administrator, and run the following commands. When you're prompted for a private key password, select **None**.

   ```
   "C:\Program Files (x86)\Windows Kits\8.1\bin\x64\makecert" -n "CN=127.0.0.1" -ss Root -sr
   LocalMachine -a sha256 -len 2048 -cy end -r -eku 1.3.6.1.5.5.7.3.1 -sv c:\temp\authcert.pvk
   c:\temp\authcert.cer

   "c:\Program Files (x86)\Windows Kits\8.1\bin\x64\pvk2pfx" -pvk c:\temp\authCert.pvk -spc
   c:\temp\authcert.cer -pfx c:\temp\authcert.pfx
   ```

   Note the following elements in these commands:

   - **-n "CN=127.0.0.1"** gives a human-readable name to the certificate. The name of this certificate must be **127.0.0.1**. Otherwise, the single-user tests won't be able to run.
   - **-eku 1.3.6.1.5.5.7.3.1** gives the purpose of the certificate. It indicates that the certificate can be used as a Secure Sockets Layer (SSL) server certificate.

   After the script has finished running, you should see the following files in **C:\Temp**:

   - authcert.pfx
   - authcert.cer
   - authcert.pvk
5. Install the **authcert.pfx** certificate file. When you install the file, make sure that you select **Local Machine**.
6. Copy the **authcert.pfx** file to the **PerfSDK** folder.
7. Open a Microsoft Windows PowerShell window as an administrator, and run the following commands to get the thumbprint of the installed certificate.

   ```
   cd Cert:\LocalMachine\My

   Get-ChildItem | Where-Object { $_.Subject -like "CN=127.0.0.1" }
   ```
8. In Visual Studio, open the **PerfSDKSample** project that is in the **PerfSDK** folder.
9. In the Visual Studio project, add a reference to the **WebDriver.dll** file in the **PerfSDK\Common\External\Selenium** folder.

10. Open the **CloudEnvironment.Config** file, and replace the contents with the following template.

```
<?xml version="1.0" encoding="utf-8"?>
<EnvironmentalConfigSettings xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
xmlns:xsd="http://www.w3.org/2001/XMLSchema">
    <EnvironmentalConfigSettingsCollection>
        <EnvironmentalConfigSetting ConfigName="DEVFABRIC">
            <!-- NOTE: the HostName value needs to be specified -->
            <ExecutionConfigurations Key="HostName" Value="[yourD365FOdomain]/namespaces/AXSF" />
            <ExecutionConfigurations Key="SoapHostName" Value="[yourD365FOdomain]/namespaces/AXSF" />
            <ExecutionConfigurations Key="SelfSigningCertificateThumbprint" Value="
[ThumbprintFromPowerShell]" />
            <ExecutionConfigurations Key="AdminAuthenticatorConfigurationId"
Value="SelfMintingAdminUser" />
            <ExecutionConfigurations Key="DefaultBrowser" Value="InternetExplorer" />
            <ExecutionConfigurations Key="FederationRealm" Value="spn:00000015-0000-0000-c000-
000000000000" />
            <ExecutionConfigurations Key="DefaultDispatcher"
Value="Microsoft.Dynamics.TestTools.Dispatcher.JsDispatcher,
Microsoft.Dynamics.TestTools.Dispatcher.JsDispatcher" />
            <ExecutionConfigurationsNodes ConfigurationName="SVC">
                <ConfigurationSpecificDetails Key="AppConfig" Value="DEVFABRIC.Config" />
            </ExecutionConfigurationsNodes>
            <ExecutionConfigurationsNodes ConfigurationName="PRF">
                <ConfigurationSpecificDetails Key="IsAdfs" Value="True" />
                <ConfigurationSpecificDetails Key="UserCount" Value="2" />
                <ConfigurationSpecificDetails Key="UserFormat" Value="[AdminUserEmail]" />
                <ConfigurationSpecificDetails Key="UserPassword" Value="[AdminUserPassword]" />
                <ConfigurationSpecificDetails Key="UserRole" Value="-SYSADMIN-" />
                <ConfigurationSpecificDetails Key="ThinkTime" Value="0" />
                <ConfigurationSpecificDetails Key="Company" Value="USMF" />
            </ExecutionConfigurationsNodes>
        </EnvironmentalConfigSetting>
    </EnvironmentalConfigSettingsCollection>
    <AuthenticatorConfigurationCollection>
        <AuthenticatorConfiguration Id="SelfMintingRunnerUser"
Class="MS.Dynamics.TestTools.CloudCommonTestUtilities.Authentication.SelfMintedTokenAuthenticator">
            <Credentials IsFromKeyVault="false" Username="daxrunneruser@daxmdsrunner.com"
NetworkDomain="urn:Microsoft:Dynamics:Cloud:DaxRunner" />
        </AuthenticatorConfiguration>
        <AuthenticatorConfiguration Id="SelfMintingSysUser"
Class="MS.Dynamics.TestTools.CloudCommonTestUtilities.Authentication.SelfMintedTokenAuthenticator">
            <Credentials IsFromKeyVault="false" Username="testuser@microsoft.com" />
        </AuthenticatorConfiguration>
        <AuthenticatorConfiguration Id="SelfMintingAdminUser"
Class="MS.Dynamics.TestTools.CloudCommonTestUtilities.Authentication.SelfMintedTokenAuthenticator">
            <!-- NOTE: admin username needs to be specified -->
            <Credentials IsFromKeyVault="false" Username="[AdminUserEmail]" NetworkDomain="[AdfsUrl]"
/>
        </AuthenticatorConfiguration>
    </AuthenticatorConfigurationCollection>
</EnvironmentalConfigSettings
```

11. In the **CloudEnvironment.Config** file, specify values for the following keys. These values replace the placeholder values in square brackets in the template.

    - **HostName** – Specify the URL that is used to access your on-premises environment. The URL should be **[yourD365FOdomain]/namespaces/AXSF**.
    - **SoapHostName** – Specify the same URL that you specified for **HostName**.
    - **SelfSigningCertificateThumbprint** – Specify the thumbprint that you retrieved from Windows PowerShell in step 7.
    - **UserFormat** – Specify the email address of a user who has the System Administrator role in your

on-premises environment. The user must be an Active Directory Federation Services (AD FS) user.

- **UserPassword** – Specify the password of the user whose email address you specified for **UserFormat**.
- **Username** – Specify the same email address that you specified for **UserFormat**.
- **NetworkDomain** – Specify the URL of the AD FS identity provider. You can find this value by running the following SQL query against the **AXDB** database of your on-premises deployment.

```
select NETWORKDOMAIN, NETWORKALIAS from USERINFO where NETWORKALIAS='[AdminUserEmail]'
```

Prepare the on-premises environment

Follow these steps on each Application Object Server (AOS) VM in the on-premises deployment.

1. Copy the **authcert.cer** file that you created in the Prepare the development environment section of this topic to the AOS VM.
2. Install the **authcert.cer** certificate file. When you install the certificate, make sure that you select **Local Machine**. Also make sure that you put the certificate in the **Trusted Root Certification Authorities** store.
3. Open the **wif.config** file in a text editor. The path of the file will resemble **C:\ProgramData\SF\AOS1\Fabric\work\Applications\AXSFType_App19\AXSF.Code.1.0.20180717001108**.

> **NOTE**
> In the file path, the AOS number (**AOS1** in this example) will vary, depending on the AOS node that you're on. Additionally, the **ProgramData** folder is a hidden folder. Therefore, to see the folder in File Explorer, you must enable hidden items.

4. In the **wif.config** file, find the authority that is named `https://fakeacs.accesscontrol.windows.net`. In the list of thumbprints for this authority, add the thumbprint of the certificate that you created in the Prepare the development environment section. In the following example, the fourth thumbprint has been added to the `https://fakeacs.accesscontrol.windows.net` authority.

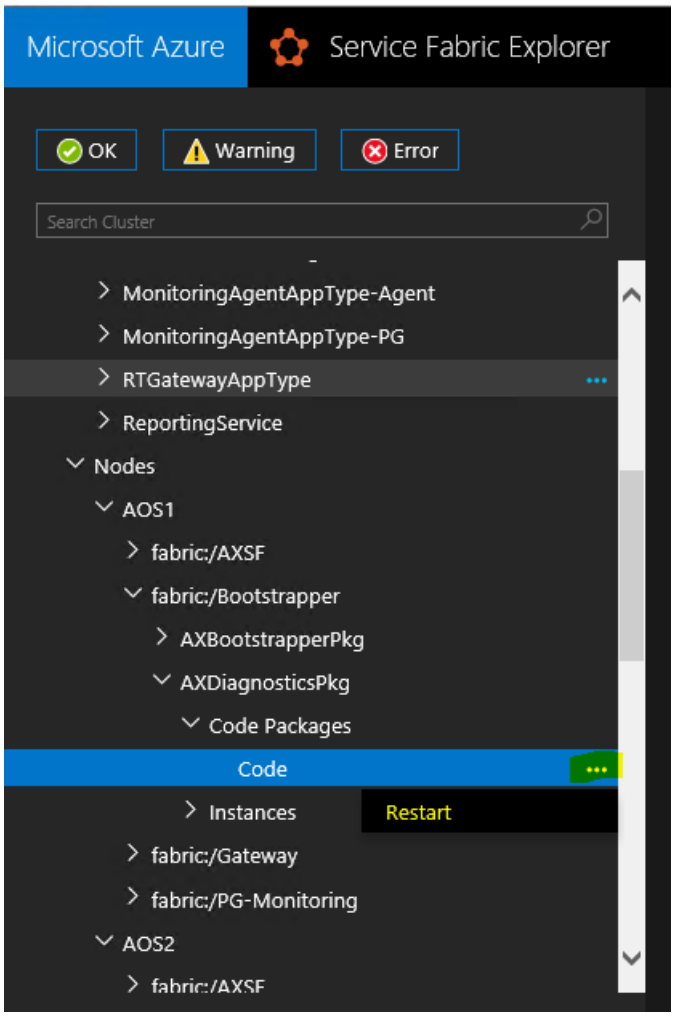
```
<authority name="https://fakeacs.accesscontrol.windows.net/">
    <keys>
        <add thumbprint="9567B0F32F4B312FEE44ACE88A9CAAA13B7FBB86" />
        <add thumbprint="B8F659E2FDD2A6811CD72BE753FF7ACB64351AC1" />
        <add thumbprint="B51C394E6EE9578D8C54AE0A9927D8B6DCEFF84B" />
        <add thumbprint="F9112DE3D4DE65CBE39601EBDC7FBB1F8F525DED" />
    </keys>
    <validIssuers>
        <add name="https://fakeacs.accesscontrol.windows.net/" />
    </validIssuers>
</authority>
```

5. Open the **AXService.exe.config** file in a text editor. You can find this file in the same directory as the **wif.config** file.
6. Search the **AXService.exe.config** file for **"Aos.AosRole"**. Replace the line that contains **"Aos.AosRole"** with the following line.

```
<add key="Aos.AosRole" value="AosRoleUnknown" />
```

> **NOTE**
>
> Setting the **AosRole** to **AosRoleUnknown** disables the limit on the number of web sessions per user. This is necessary to complete load testing with a large user load because the load test will create many sessions for a single user. Once you are finished with your load testing, reset this value to **"AosRoleWeb"**.

7. In Service Fabric Explorer, find the **Code** package for the AOS node, select the ellipse button (...), and then select **Restart** to restart the application.



Run the single-user test

1. In the **PerfSDKSample** project, find the **PurchaseReq.cs** file. This file is a sample single-user test. In the file, comment out the following lines.

```
if (this.TestContext !=null)
{
    timerProvider = new TimerProvider(this.TestContext);
}
```

```
private TimerProvider timerProvider;
[TestInitialize]
0 references
public void TestSetup()
{
    //if (this.TestContext != null)
    //{
    //    timerProvider = new TimerProvider(this.TestContext);
    //}
```

2. Select **Test** > **Test settings**, set the **Default processor architecture** field to **x64**, and then build the solution.
3. Select **Test** > **Windows** > **Test Explorer** to view the list of tests.

> **NOTE**
> Sometimes, Visual Studio might not update the list of tests after you create a test script from a task recording. In this case, restart Visual Studio, and then reopen Test Explorer.

4. Run the sample single-user test by right-clicking **CreatePurchReq**. Alternatively, you can run the test that you created from your task recording. When you run the test, Internet Explorer should be started, and it should replay the scenario that you recorded.

Run a multiuser load test by using the Performance SDK

Create a multiuser test from a single-user test

After you create a single-user test by using the information earlier in this topic, you can convert it to a multiuser test. Add **MS.Dynamics.TestTools.UIHelpers.Core;** to your test script, and find the following line in the **TestSetup** method.

```
Client = DispatchedClient.DefaultInstance;
```

Replace that line with the following lines.

```
DispatchedClientHelper helper = new DispatchedClientHelper();
Client = helper.GetClient();
```

The test script that was generated by the Task Importer might contain a line that resembles the following line.

```
UserContextRole _context = new UserContextRole(UserManagement.AdminUser);
```

Remove this line from any tests that will be run as load tests. This code is required only for single-user tests and has a negative effect on the performance of load tests.

Make sure that the values that you entered when you made the task recording are randomized.

Run the multiuser load test

1. In the Visual Studio editor, open the **ProcureToPay.cs** file, and append the following lines in the **TestSetup** method.

```
var testroot = System.Environment.GetEnvironmentVariable("DeploymentDir");
if (string.IsNullOrEmpty(testroot))
{
    testroot = System.IO.Directory.GetCurrentDirectory();
}
Environment.SetEnvironmentVariable("testroot", testroot);
```

2. Download the installer (.msi) file for Microsoft ODBC Driver 13 for SQL Server from https://www.microsoft.com/download/details.aspx?id=50420. (Select the 64-bit version of the .msi file.) Put the file in the **Visual Studio Online** folder in the **PerfSDK** directory.

3. Modify the contents of the **setup.cmd** file in the **Visual Studio Online** folder so that they match the following code.

```
setx testroot "%DeploymentDirectory%"
ECHO Installing D365 prerequisites
ECHO MSIEXEC /a %DeploymentDirectory%\msodbcsql /passive /norestart IACCEPTMSODBCSQLLICENSETERMS=YES
MSIEXEC /a %DeploymentDirectory%\msodbcsql /passive /norestart IACCEPTMSODBCSQLLICENSETERMS=YES
%windir%\sysnative\windowspowershell\v1.0\powershell.exe -File %DeploymentDirectory%\install-wif.ps1
Md %DeploymentDirectory%\Common\Team\Foundation\Performance\Framework
%DeploymentDirectory%\CloudCtuFakeACSInstall.cmd %DeploymentDirectory%\authcert.pfx
```

4. Modify the contents of the **CloudCtuFakeACSInstall.cmd** file so that the **Import** command has an empty string instead of '**password**'. The third line of the script should resemble the following line.

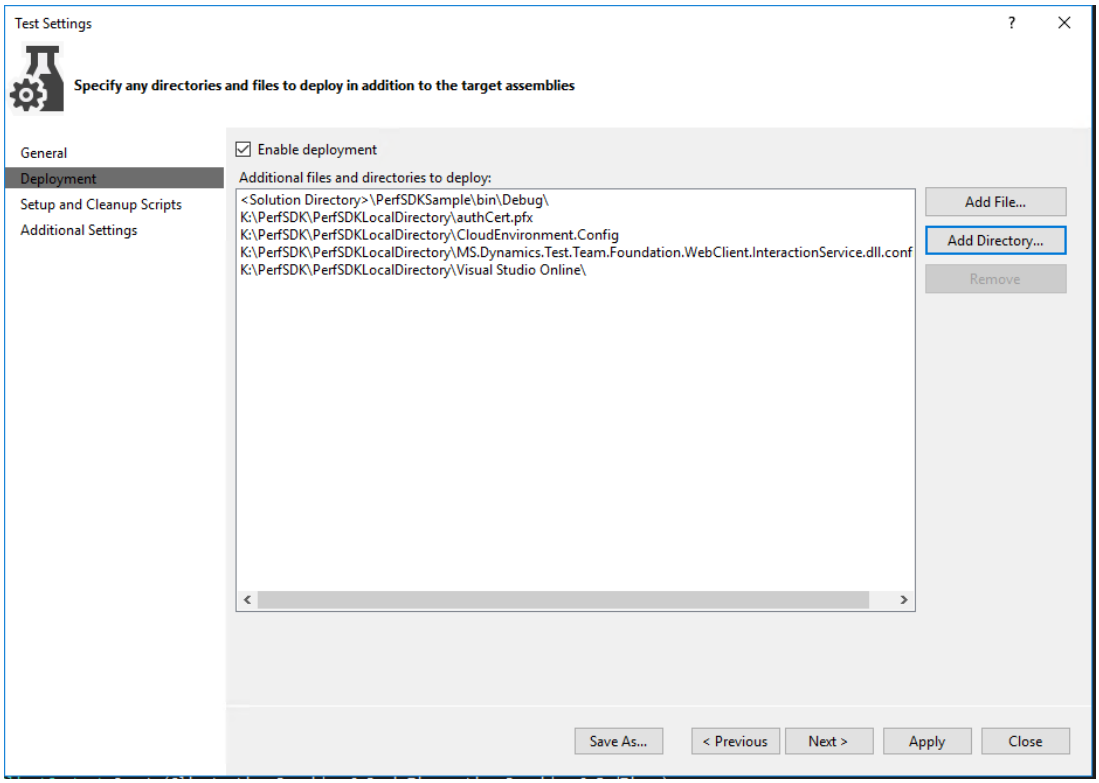
```
set MyStoreInstallCmd= .... $pfxcert.Import('%TestCertPath%', '', 'Exportable,PersistKeySet').... 
```

5. In your solution files, double-click the **vsonline.testsettings** file to modify the test settings.

6. In the **Test Settings** dialog box, on the **General** tab, set the **Test run location** field to **Run tests using local computer or a test controller**.

7. On the **Deployment** tab, use the following settings:

   - Select the **Enable deployment** check box.
   - In the **Additional files and directories to deploy** field, make sure that the following files and directories are listed:
     - <Solution Directory>\PerfSDKSample\bin\Debug\
     - C:\PerfSDK\CloudEnvironment.Config
     - C:\PerfSDK\authcert.pfx
     - C:\PerfSDK\MS.Dynamics.Test.Team.Foundation.WebClient.InteractionService.dll.config
     - C:\PerfSDK\Visual Studio Online\

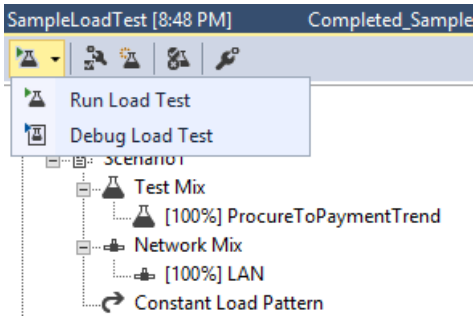


> **NOTE**
>
> Your PerfSDK folder might differ.

8. On the **Setup and Cleanup Scripts** tab, select the **setup.cmd** file that is in the **Visual Studio Online** folder in the **PerfSDK** directory.

9. On the **Hosts** tab, select **Run tests in 64 bit process on 64 bit machine**.

10. To run the test, open the **SampleLoadTest.loadtest** file, and select **Run Load Test**.



When the test has finished running, you should see a summary that shows transaction results. Here is an example.

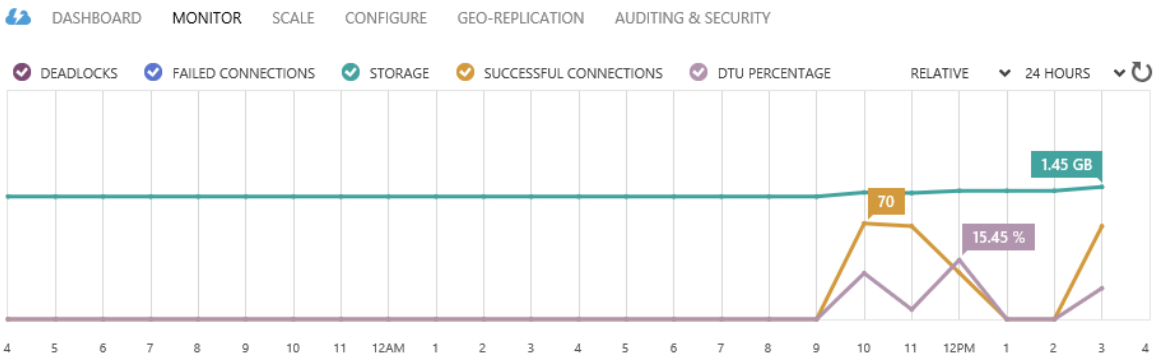
Test Results

Name	Scenario	Total Tests	Failed Tests (% of total)	Avg. Test
ProcureToPaymentTrend	Scenario1	10	10 (100)	56.6

Transaction Results

Name	Scenario	Test	Response Time (sec)
000_Navigate_purchtablelistpage	Scenario1	ProcureToPaymentTrend	1.56
002_PurchTable_SystemDefinedNewButton_Click	Scenario1	ProcureToPaymentTrend	0.44
004_PurchCreateOrder_VendorTab_Dispatcher_ActivateTab	Scenario1	ProcureToPaymentTrend	0.33
028_PurchTable_LineViewLines_Dispatcher_ActivateTab	Scenario1	ProcureToPaymentTrend	0.22
026_PurchTable_TabPageDetails_Dispatcher_ActivateTab	Scenario1	ProcureToPaymentTrend	0.22
014_PurchTable_TabPageDetails_Dispatcher_ActivateTab	Scenario1	ProcureToPaymentTrend	0.22
027_PurchTable_LineView_Dispatcher_ActivateTab	Scenario1	ProcureToPaymentTrend	0.11

11. To view various indicators for the test controller and test scenario, you can switch to the **Graphs** view.



> **NOTE**
>
> While tests are being run, information about your system isn't available in this view. To access this information, you must use Microsoft Dynamics Lifecycle Services (LCS) to monitor the CPU and memory usage of your AOS machine. Alternatively, you can set up perfmon directly on the AOS machine and set up the Microsoft Azure portal to monitor Microsoft SQL Server usage of Database Transaction Units (DTUs).

Troubleshooting

Zoom factor

This issue affects only single-user tests.

Error example

```
Initialization method <Test class name>.TestSetup threw exception. System.InvalidOperationException:
System.InvalidOperationException: Unexpected error launching Internet Explorer. Browser zoom level was set
to 200%. It should be set to 100% (NoSuchDriver).
```

Solution

In Internet Explorer, you can change the zoom factor to 100 percent by changing the following registry keys:

- Computer\HKEY_CURRENT_USER\SOFTWARE\Microsoft\Internet Explorer\Zoom\ResetZoomOnStartup = 0
- Computer\HKEY_CURRENT_USER\SOFTWARE\Microsoft\Internet Explorer\Zoom\ResetZoomOnStartup2 = 0
- Computer\HKEY_CURRENT_USER\SOFTWARE\Microsoft\Internet Explorer\Zoom\Zoomfactor = 80000

Depending on the version of the local machine that is used, before you start the Remote Desktop Protocol (RDP) session, you might have to select **Change the size of text, apps and other items**. This field is available in **Display settings** in Windows.

If those steps don't work, try to change the size of your remote desktop before you start the RDP session, so that the default zoom level in Internet Explorer is 100 percent.

Certificate thumbprint errors

Error example

```
Initialization method MS.Dynamics.Performance.Application.TaskRecorder.TestRecord1Base.TestSetup threw
exception.
System.TypeInitializationException: System.TypeInitializationException: The type initializer for
'MS.Dynamics.TestTools.CloudCommonTestUtilities.Authentication.UserManagement' threw an exception. -->
MS.Dynamics.TestTools.CloudCommonTestUtilities.Exceptions.WebAuthenticationException:
Failed finding the certificate for minting tokens by thumbprint: b4f01d2fc42718198852cd23957fc60a3e4bca2e
```

Solution

You might receive the error message for several reasons:

- The certificate thumbprint that you copied into the CloudEnvironment.Config and wif.config files includes invisible Unicode characters. To determine whether the thumbprint contains invisible Unicode characters, paste it into a Unicode code converter, and see whether extra characters appear in the **HTML/XML** field. For example, you can use the Unicode converter that is available at https://r12a.github.io/apps/conversion/.

- The certificate wasn't installed correctly on the AOS machine. To verify that the certificate can be found on the AOS machine, run the following Windows PowerShell script.

```
cd Cert:\LocalMachine\My
Get-ChildItem | Where-Object { $_.Subject -like "CN=127.0.0.1" }
```

  If the thumbprint doesn't appear in the Windows PowerShell console after you run the script, the certificate can't be found. To fix the issue, copy and install the .cer file that you created earlier in this topic to the AOS machine.

- If this issue occurs when you run load tests, the setup scripts might not have installed the corresponding .pfx file correctly. Verify that the password that is specified in the CloudCtuFakeACSInstall.cmd file matches the password that was set when the certificate was created.

No endpoint is listening

Error example

The tests process fails, and the following error message is shown.

```
System.TypeInitializationException: The type initializer for
'MS.Dynamics.TestTools.CloudCommonTestUtilities.Authentication.UserManagement' threw an exception. --->
System.ServiceModel.EndpointNotFoundException: There was no endpoint listening at <web address> that could
accept the message. This is often caused by an incorrect address or SOAP action.
```

Solution

This issue occurs when the host that is specified in the CloudEnvironment.Config file can't be accessed from the machine that is trying to run the tests or create users.

In the CloudEnvironment.Config file, review the values that are specified for the following keys:

- <ExecutionConfigurations Key="HostName" Value="<web address of host>" />
- <ExecutionConfigurations Key="SoapHostName" Value="<web address of SOAP>" />

The web addresses that are specified by these keys must be the environment that you're testing. In a web browser on your developer machine, make sure that you can open the web address that is specified for the **HostName** key.

Users can't be enumerated

This issue can occur when you run multiuser tests, or when you create users by using MS.Dynamics.Performance.CreateUsers.exe.

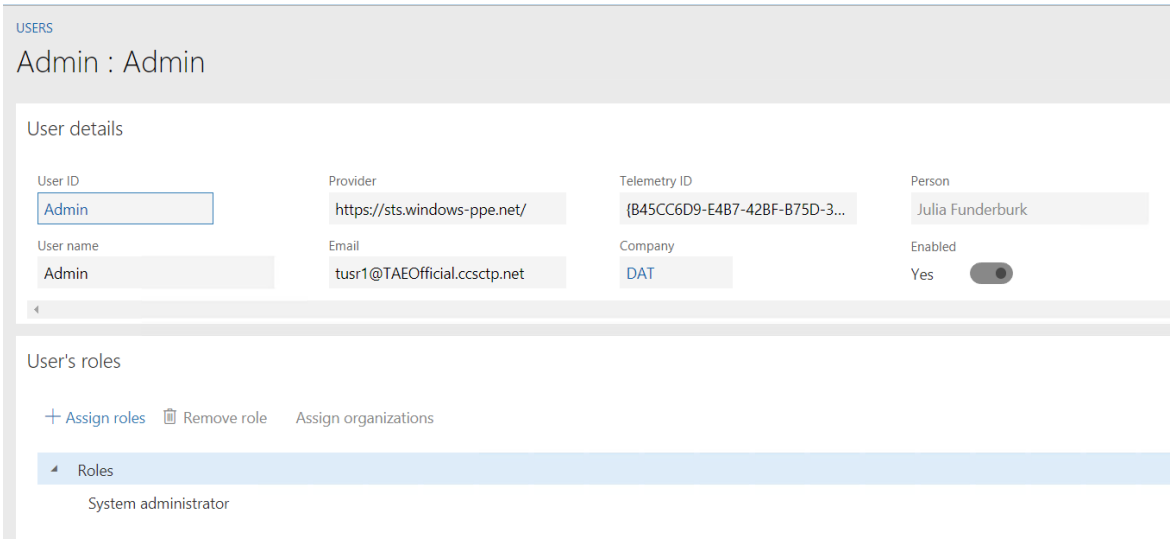
Error example

```
System.TypeInitializationException: The type initializer for
'MS.Dynamics.TestTools.CloudCommonTestUtilities.Authentication.UserManagement' threw an exception. --->
System.InvalidOperationException: Could not enumerate AX users --->
System.ServiceModel.FaultException'1[System.ComponentModel.Win32Exception]: Forbidden
```

Solution

Two scenarios can cause this error:

- The user who is specified as **SelfMintingAdminUser** in the CloudEnvironment.Config file must have the System Administrator role. This issue occurs when the System Administrator role isn't assigned to the user who is specified as **SelfMintingAdminUser**. To verify that you've specified the correct user, you can sign in to the endpoint and view the user's roles.



- An incorrect **NetworkDomain** value was specified for the user who is specified as **SelfMintingAdminUser** in the CloudEnvironment.Config file. You can find the correct value by running the following SQL query against the **AXDB** database of your on-premises deployment.

```
select NETWORKDOMAIN, NETWORKALIAS from USERINFO where NETWORKALIAS='[AdminUserEmail]'
```

At least one security token in the message could not be validated

This issue can occur when you run multiuser tests, or when you create users by using MS.Dynamics.Performance.CreateUsers.exe. It tends to occur when the AOS machine differs from the developer machine.

Error example

```
System.TypeInitializationException: The type initializer for
'MS.Dynamics.TestTools.CloudCommonTestUtilities.Authentication.UserManagement' threw an exception. --->
System.ServiceModel.Security.MessageSecurityException: An unsecured or incorrectly secured fault was
received from the other party. See the inner FaultException for the fault code and detail. --->
System.ServiceModel.FaultException: At least one security token in the message could not be validated.
```

Solution

This issue occurs when the AOS endpoint can't validate the thumbprint of the certificate that you created. There are three possible causes:

- In the CloudEnvironment.Config file, either a value isn't specified for the **IsAdfs** key, or the value is set to **False**. Make sure that the value for the **IsAdfs** key is set to **True**.
- The certificate wasn't installed on the AOS machine. To fix the issue, copy the .cer file that you created earlier

in this topic to the AOS machine, and install the certificate.

- The thumbprint of the certificate wasn't added to the wif.config file on the AOS machine. To fix the issue, see step 8 in the Run a single-user test by using the Performance SDK section for information about how to add the certificate to the wif.config file. After you modify the wif.config file, be sure to restart the application through Service Fabric Explorer.

MS.Dynamics.Test.Team.Foundation.WebClient.InteractionService.dll.config is missing from the deployment items

This issue usually occurs only when you run load tests.

Error example

```
<Test class name>.TestSetup threw exception. System.InvalidOperationException:
System.InvalidOperationException: Could not find endpoint element with name 'ClientCommunicationManager' and
contract 'Microsoft.Dynamics.Client.InteractionService.Communication.Reliable.IReliableCommunicationManager'
in the ServiceModel client configuration section. This might be because no configuration file was found for
your application, or because no endpoint element matching this name could be found in the client element..
at System.ServiceModel.Description.ConfigLoader.LoadChannelBehaviors(ServiceEndpoint serviceEndpoint, String
configurationName)
```

Solution

This issue occurs when the system can't find the MS.Dynamics.Test.Team.Foundation.WebClient.InteractionService.dll.config file when the load tests are run, because the file wasn't added as a deployment item. Verify that the MS.Dynamics.Test.Team.Foundation.WebClient.InteractionService.dll.config file is in the Out folder for the test run:

<solution path>\TestResults\<your test run>\Out

If the file is missing, add it to the deployment items in the test settings.

> **IMPORTANT**
> There are two files that have very similar names. The name of one file ends in ***.dll**, and the name of the other file ends in ***.dll.config**. The ***.dll.config** file must be in the deployment items in the test settings.

CloudEnvironment.Config is missing from the deployment items

This issue usually occurs only when you run load tests.

Error example

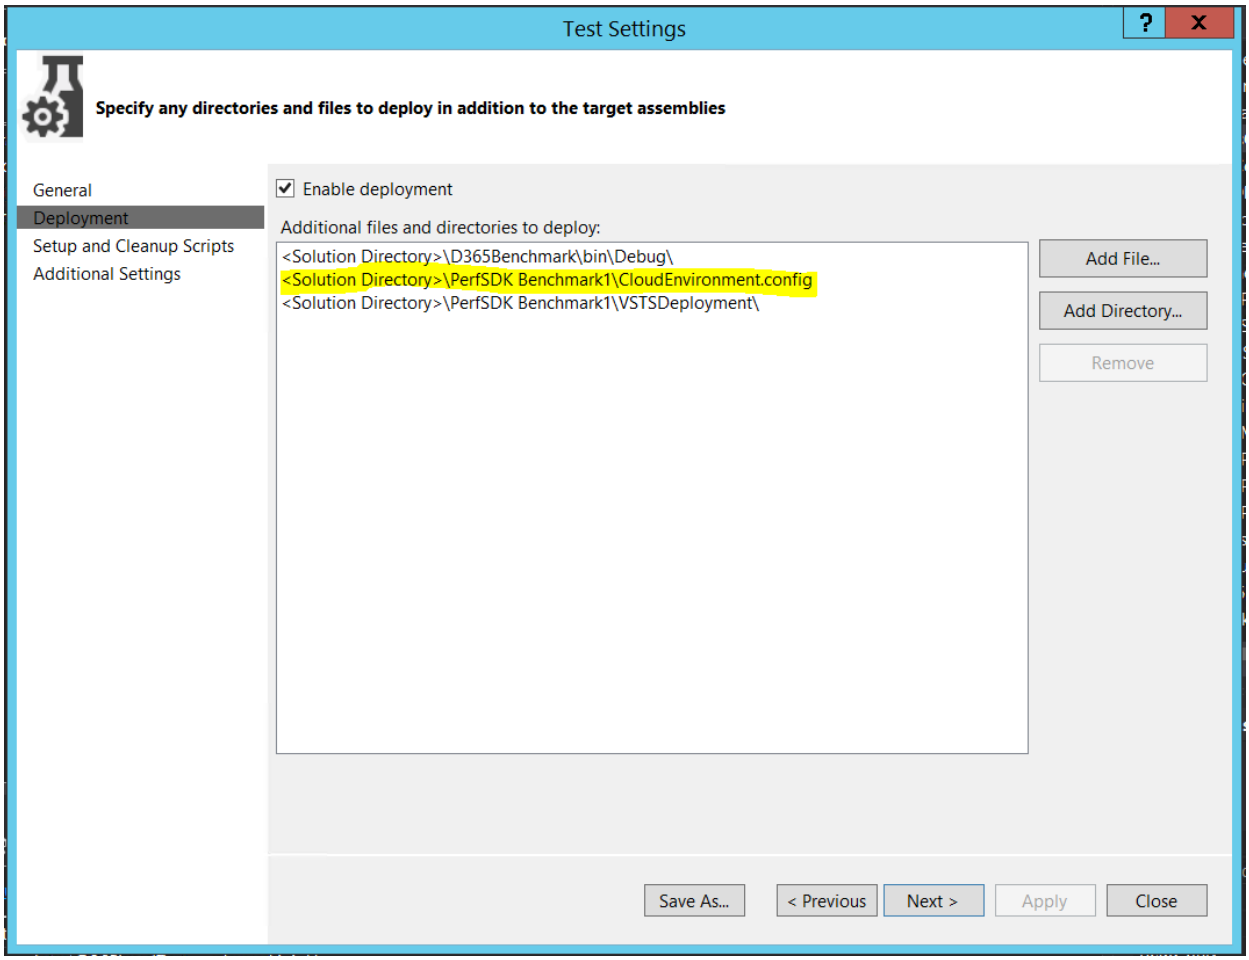
```
Initialization method <Test class name>.TestSetup threw exception.
System.TypeInitializationException: System.TypeInitializationException: The type initializer for
'MS.Dynamics.TestTools.CloudCommonTestUtilities.Authentication.UserManagement' threw an exception. --->
MS.Dynamics.TestTools.TestLogging.EvaluateException: Assert.Fail failed. DateTime="10/13/2017 14:42:55" "The
type initializer for 'MS.Dynamics.TestTools.CloudCommonTestUtilities.Authentication.SecretSettingsHelper'
threw an exception.".
```

Solution

This issue occurs when the CloudEnvironment.Config file isn't present when the tests are run. The issue typically occurs when you run load tests and the CloudEnvironment.Config file wasn't added as a deployment item. Verify that the CloudEnvironment.Config file is in the Out folder for the test run:

<solution path>\TestResults\<your test run>\Out

If the file is missing, add it to the deployment items in the test settings.



InteractiveClientId wasn't specified in the settings

Error example

```
The type initializer for
'MS.Dynamics.TestTools.CloudCommonTestUtilities.Authentication.SecretSettingsHelper' threw an exception. ---
>
Microsoft.CE.VaultSDK.SecretProviderException: InteractiveClientId was not specified in settings
```

Solution

This issue occurs when no value is specified for the **SelfSigningCertificateThumbprint** key in the CloudEnvironment.Config file. In the CloudEnvironment.Config file, find the following line, and paste in the thumbprint of the certificate that you created and installed.

```
<ExecutionConfigurations Key="SelfSigningCertificateThumbprint" Value="" />
```

The remote host forcibly closed an existing connection

Error example

```
System.TypeInitializationException: System.TypeInitializationException: The type initializer for
'MS.Dynamics.TestTools.CloudCommonTestUtilities.Authentication.UserManagement' threw an exception. --->
System.ServiceModel.CommunicationException: An error occurred while making the HTTP request to
<Host name>/Services/AxUserManagement/Service.svc/ws2007FedHttp. This could be due to the fact
that the server certificate is not configured properly with HTTP.SYS in the HTTPS case. This could also be
caused
by a mismatch of the security binding between the client and the server.** ---> System.Net.WebException:
The underlying connection was closed: An unexpected error occurred on a send. ---> System.IO.IOException:
Unable to read data from the transport connection: An existing connection was forcibly closed by the remote
host. --->
System.Net.Sockets.SocketException: An existing connection was forcibly closed by the remote host.
```

Solution

Run the following Windows PowerShell script on the development machine.

```
Set-ItemProperty HKLM:\SOFTWARE\Microsoft\.NETFramework\v4.0.30319 -Name SchUseStrongCrypto -Value 1 -Type
dword -Force -Confirm:$false
if ((Test-Path HKLM:\SOFTWARE\Wow6432Node\Microsoft\.NETFramework\v4.0.30319))
{
    Set-ItemProperty HKLM:\SOFTWARE\Wow6432Node\Microsoft\.NETFramework\v4.0.30319 -Name SchUseStrongCrypto
-Value 1 -Type dword -Force -Confirm:$false
}
```

The w3svc service wasn't found on the computer

This error only occurs when you run load tests by using Microsoft Visual Studio Online.

Error example

```
Test method MS.Dynamics.Performance.Application.GFM.PDLTrend.ProcureToPayTrend.ProcureToPaymentTrend threw
exception:
System.TypeInitializationException: The type initializer for
'MS.Dynamics.TestTools.CloudCommonTestUtilities.Authentication.UserManagement' threw an exception. --->
System.InvalidOperationException: Service w3svc was not found on computer '.'. --->
System.ComponentModel.Win32Exception: The specified service does not exist as an installed service
```

Solution

A hotfix is available that resolves this issue. The Microsoft Knowledge Base (KB) number is 4095640.

Diagnose issues and analyze performance by using Trace parser

2/18/2021 • 2 minutes to read • Edit Online

This topic explains how you can use the Trace parser to consume traces and analyze performance in your deployment. You can use the Trace Parser to find and diagnose various types of errors. You can also use the tool to visualize execution of X++ methods, as well as the execution call tree.

> **NOTE**
>
> There are many more features in the Trace parser are similar to Microsoft Dynamics AX 2012. See the Dynamics Ax Performance Team Blog for more information.

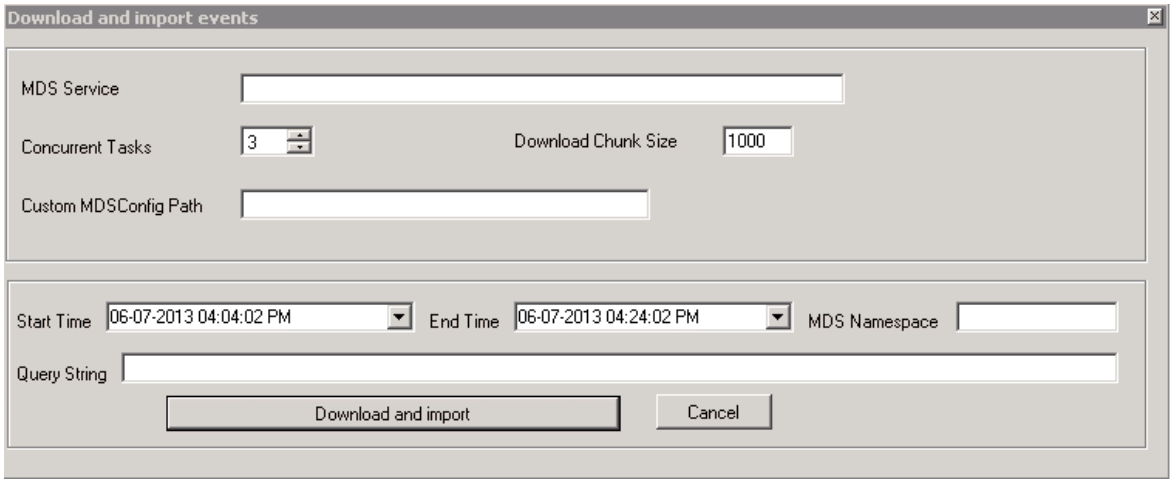
Finding the Trace parser

Trace parser should be preinstalled with your developer deployment or VHD. The install location is here: **C:\Program Files (x86)\Microsoft Dynamics Trace Parser**. If it's not installed, you can run the installer from **C:\PerfSDK\PerfTools\traceparser.msi**.

Capturing events

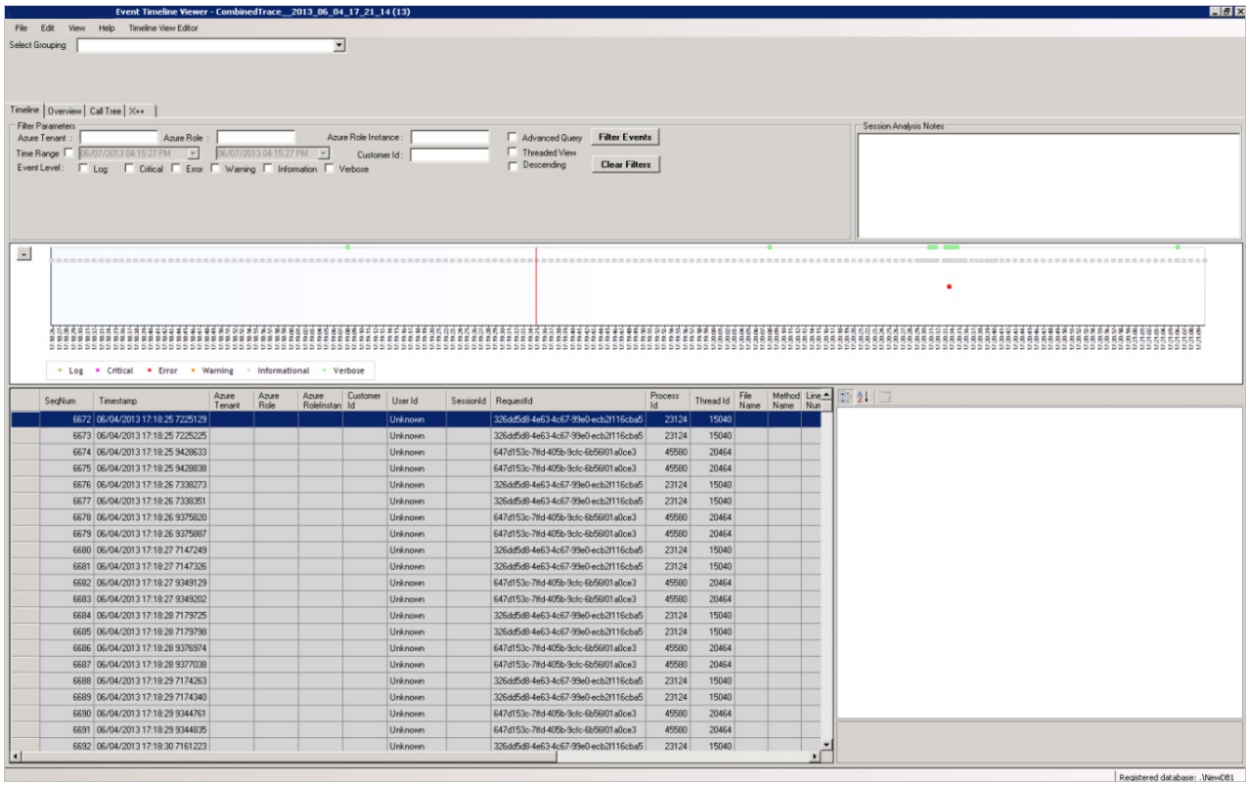
There are two ways that you can obtain the data that you will analyze in the Trace parser. They include:

- Capture events from the local installation.
    - If the **Select Trace** window isn't already open, go to the **File** menu and click **Open trace**. In the **Select Trace** window, click **Capture Events**. After selecting your providers, click **Start**. The Trace Parser tool will start listening to all the providers and capturing the events. Capturing stops when you click **Stop and Import**.
- Open an existing ETL (Windows Event) file that was captured using tools such as Logman.



Viewing traces

Timeline view The Timeline tab is the first tab that you see after you import a trace into the Trace Parser. This tab is shown in the following illustration.



The **Timeline** tab has the following major components:

- The **Select Grouping** drop-down allows you to group based on a variety of categories, such as Customer ID, Username, Session Name, etc. Groupings will display maximum and minimum timestamp of events, total number of events, and lowest event level within the grouping.
- List of all events in a threaded or unthreaded view.
- Property grid displayed for the selected event.
- Timeline chart for all the selected events.
- Filtering of events.
- Session analysis notes.

Call tree view By selecting the **Call Tree** tab, you can see the call tree for all X++ methods. The tab is shown below.

Example of information shown in the Call Tree tab](./media/3_desktop.png)

Similarly, you can display the **X++** tab to view a list of all the X++ methods. They will be sorted by fields such as Inclusive/Exclusive durations, RPC, or Database calls. Note that these are similar to the corresponding tabs in Trace Parser and have the same behavior.

Additional resources

Develop and customize home page

NOTE

Can you tell us about your documentation language preferences? Take a short survey.

The survey will take about seven minutes. No personal data is collected (privacy statement).

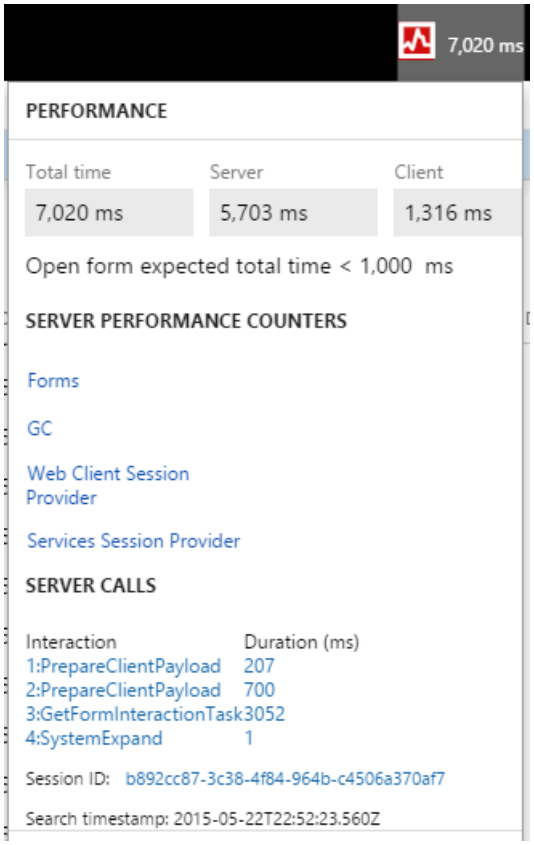
Performance timer

2/18/2021 • 2 minutes to read • Edit Online

This topic provides an overview of the Performance timer, which is a tool that helps you to determine why your system's performance might be slow.

To open the Performance timer, open your webpage with the added parameter debug=develop: https://*yoursite*.cloud.test.dynamics.com/en/?cmp=USMF&debug=develop Note: When you run in debug mode you will notice slower performance. You can quickly get an overview of most performance issues by pressing F12 and working with the debugging tools that are available in your browser. The timer will show up here.

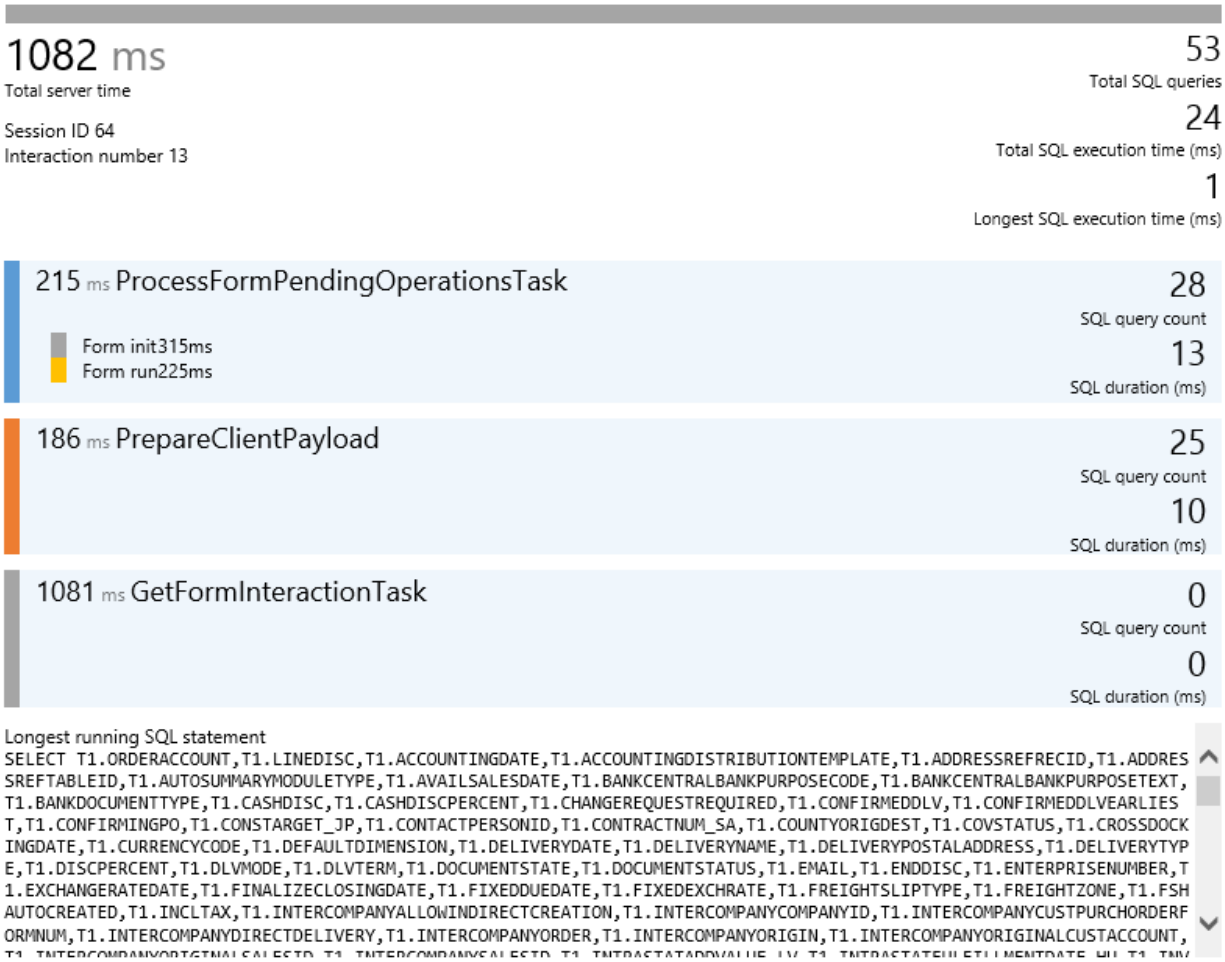
To open a list page, for example, such as the purchase order list page, click the Performance timer. The following screenshot shows the separation between client time and server time, and the total time. Additionally, you can see a set of performance counters and expensive server calls.



For more information about the server performance counters, click on any of the links.

- **Forms** - Forms will show how many forms are currently open, plus the rate at which they opened and closed (per second), and a set of counters, such as the total amount of created or closed forms.
- **GC** - This is information about the garbage collection processes on the server.
- **Web client session** - This shows how many web client sessions you currently have and how many are in use.
- **Services Session provider** - This is the total number of sessions created.

For more information, click a link. In the next screen, you can see how many SQL queries were triggered by this individual call and which SQL query was the most expensive.



This information can help you to understand what to trace and where to start troubleshooting.

> **NOTE**

Testing and validations

2/18/2021 • 6 minutes to read • Edit Online

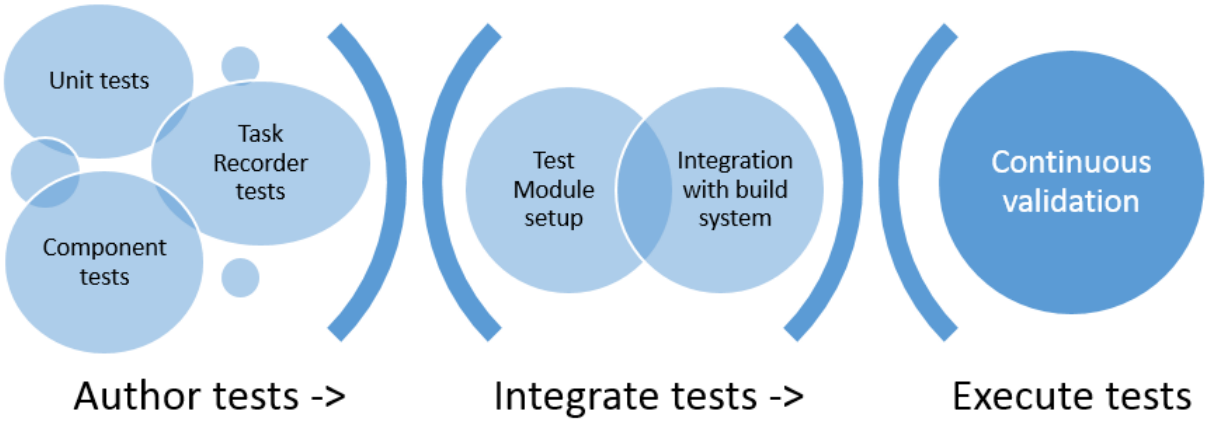
This tutorial shows you how to create and run test cases.

Prerequisites

You will need to deploy Developer Topology with Developer and Build VM.

Key concepts

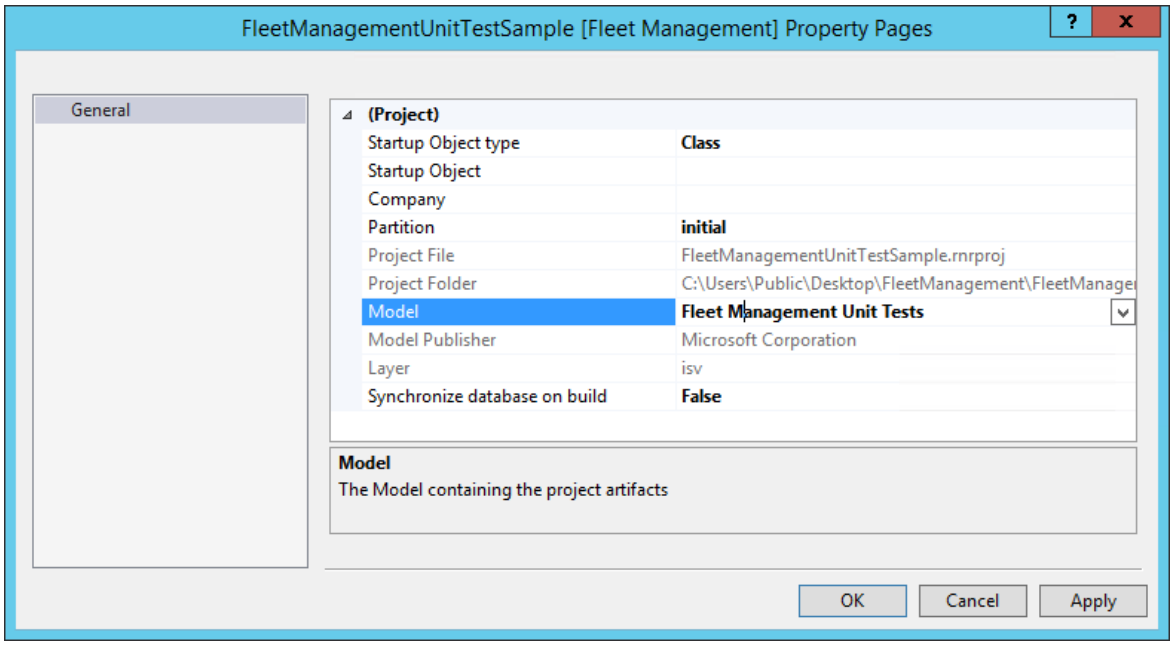
- Use SysTest Framework to author unit/component test code.
- Test isolation
- Test module creation to manage test code and FormAdaptors.
- Import Task Recorder recordings into Visual Studio to generate test code.
- Integrate a Test module with a build machine.



Use SysTest Framework to author unit/component test code

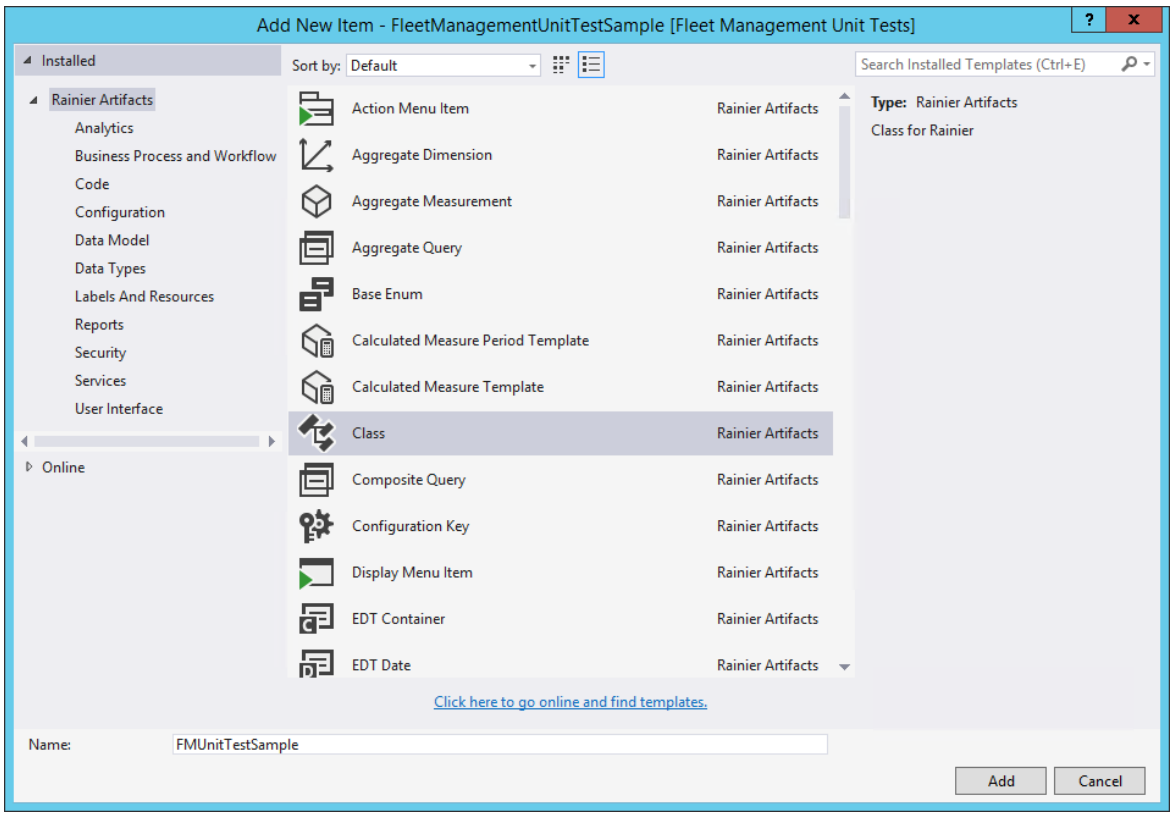
You can create new test cases to test the functionality in an application.

1. Open Visual Studio as an administrator.
2. On the **File** menu, click **Open** > **Project/Solution**, and then select **FleetManagement solution** from the desktop folder. If the solution file is not on your computer, the steps to create it are listed in Tutorial: Create a Fleet Management solution file out of the Fleet Management models in the AOT.
3. In **Solution Explorer**, right-click the **Fleet Management** solution, point to **Add**, and then click **New Project**.
4. Choose **Finance and Operations** as the project type to create.
5. Name this new project *FleetManagementUnitTestSample*, specify the FleetManagement folder on the desktop (C:\Users\Public\Desktop\FleetManagement) as the location, and then click **OK**.
6. In **Solution Explorer**, right-click the new project, and then click **Properties**.
7. Set the **Model** property to **FleetManagementUnitTests**, and then click **OK**.



8. Right-click the FleetManagementUnitTestSample project, point to **Add**, and then click **New Item**.

9. In the **Add New Item** window, select **Class** as the type of element to add. Name the new class FMUnitTestSample, and then click **Add**.



10. In the first line of the code for the new class, indicate that the class extends the SysTestCase class.

11. Add the following code to define the methods for the class. These methods define two additional tests.

```
class FMUnitTestSample extends SysTestCase
{
    public void setup()
    {
        // Reset the test data to be sure things are clean
        FMDataHelper::main(null);
    }

    [SysTestMethodAttribute]
    public void testFMTotalsEngine()
    {
        FMRental rental;
        FMTotalsEngine fmTotals;
        FMRentalTotal fmRentalTotal;
        FMRentalCharge rentalCharge;
        FMRentalTotal expectedtotal;
        str rentalID = '000022';

        // Find a known rental
        rental = FMRental::find(rentalID);

        // Get the rental charges associated with the rental
        // Data is seeded randomly, so this will change for each run
        select sum(ExtendedAmount) from rentalCharge
                where rentalCharge.RentalId == rental.RentalId;

        fmTotals = FMTotalsEngine::construct();
        fmTotals.calculateRentalVehicleRate(rental);

        // Get the totals from the engine
        fmRentalTotal = fmTotals.totals(rental);

        // Set the expected amount
        expectedTotal = rental.VehicleRateTotal + rentalCharge.ExtendedAmount;

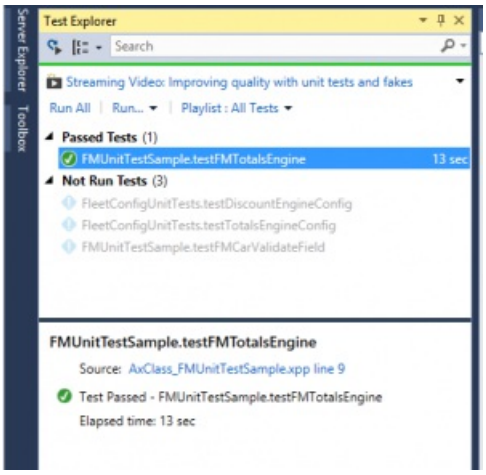
        this.assertEquals(expectedTotal,fmRentalTotal);
    }

    [SysTestMethodAttribute]
    public void testFMCarValidateField()
    {
        FMCarClass fmCar;

        fmCar.NumberOfDoors = -1;
        this.assertFalse(fmCar.validateField(Fieldnum("FMCarClass", "NumberOfDoors")));

        fmCar.NumberOfDoors = 4;
        this.assertTrue(fmCar.validateField(Fieldnum("FMCarClass", "NumberOfDoors")));
    }
}
```

12. Save the new class. After the save is complete, you will see the additional two test cases in **Test Explorer**. Right-click on the FleetManagementUnitTestSample project in **Solution Explorer**, and then click **Build.**
13. On the **View** menu, open **Test Explorer**.
14. Click **Run selected test** to execute specific test case.
15. Test Explorer will show the results of test after it is complete.



Test isolation

For a test to be of high value it must be reliable. A test will pass or fail consistently, independent of other factors such as other tests. One typical cause of unreliable tests is leaking state, such as data left behind in the data base that influences downstream tests. To prevent this type of issue, you can use the `SysTestTransaction` attribute.

TESTTRANSACTIONMODE	DESCRIPTION
AutoRollback	**Default**. This provides the best isolation. All transactions are rolled back using SQL save points, and all database statements are routed to the main connection, including user connections. No data will be persisted.
LegacyRollback	All insert statements are tracked and deleted during clean-up. All insert statements are downgraded to row-by-row. One typical use case is when testing user connections or concurrency scenarios. This isolation level will clean up setup data, and the recommendation is to wrap each test method in a ttsBegin and ttsAbort.
LegacyRollbackWithUpdateTracking	All update, delete, and insert statements are tracked and reverted during cleanup. All insert, update, and delete statements are tracked and downgraded to row-by-row. This is the slowest isolation level.
None	**Only use for debugging**. This provides no isolation. This setting can be useful to temporarily to debug a test, as it allows you to use the regular user interface to navigate the data that the test created.

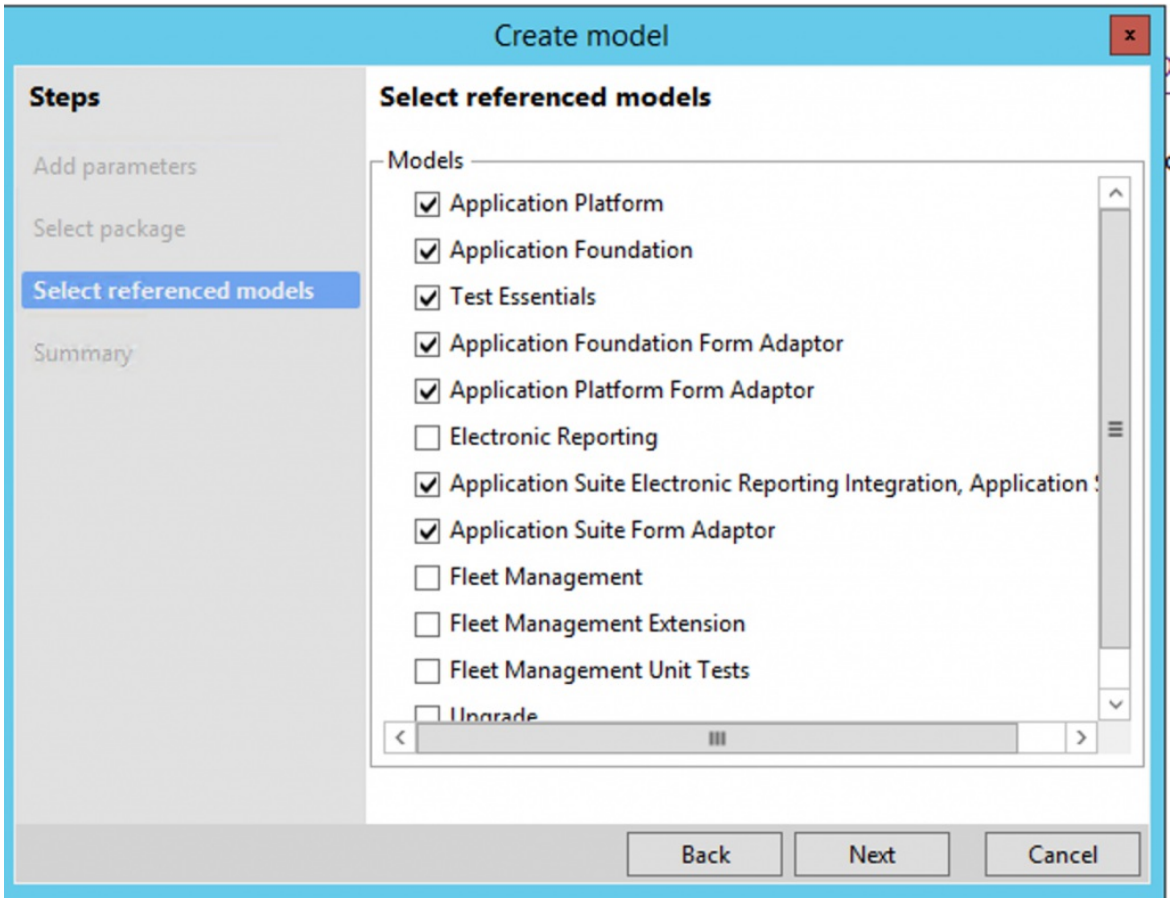
Example:

```
[SysTestTransaction(TestTransactionMode::LegacyRollback)]
class MyTestSample extends SysTestCase
```

Test module creation to manage test code and FormAdaptors

Creating a test specific module helps to keep test code together and manageable.

1. Open **Visual Studio** and go to **Finance and Operations** > **Model Management** > **Create model**.
2. Enter the model name, select the layer, and then enter any additional details. Note that it's a good idea to include the word **Test** in the name of the test module. The default build definition is configured to discover all test modules that contain the word **Test**.
3. Because this model holds forms from the Application Platform/Foundation, add references to models shown below.

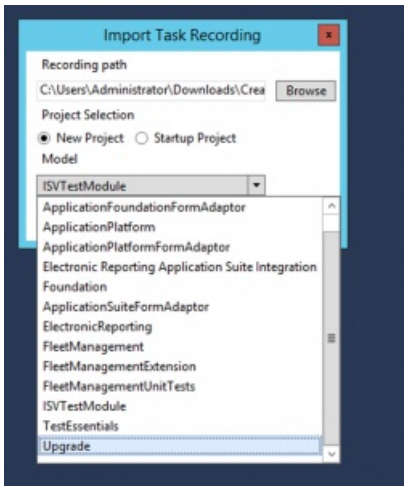


After the base test module is in place, you can import a Task Recorder recording to generate test code. When you import a Task Recorder recording XML, test code is generated using FormAdaptors. Form adaptors are wrapper classes over forms which provide strongly typed API that can be used to test form functionality. We have included pre-generated FormAdapters for each package for built-in forms. In the test module, add a reference to the corresponding Form Adaptor for packages and Test Essentials, which has helper methods to execute test code.

Import a Task Recorder recording into Visual Studio to generate test code

You can generate test code from Task Recorder recording to execute headless (non-UI) test.

1. Record a scenario in by using Task Recorder.
2. To import a Task Recording, in Visual Studio, click **Finance and Operations** > **Addins** > **Import Task Recording**.
3. In the **Import Task Recording** dialog, select the Test Module (ISVTestModule) under which you want to import task recording, and browse to recording xml file.

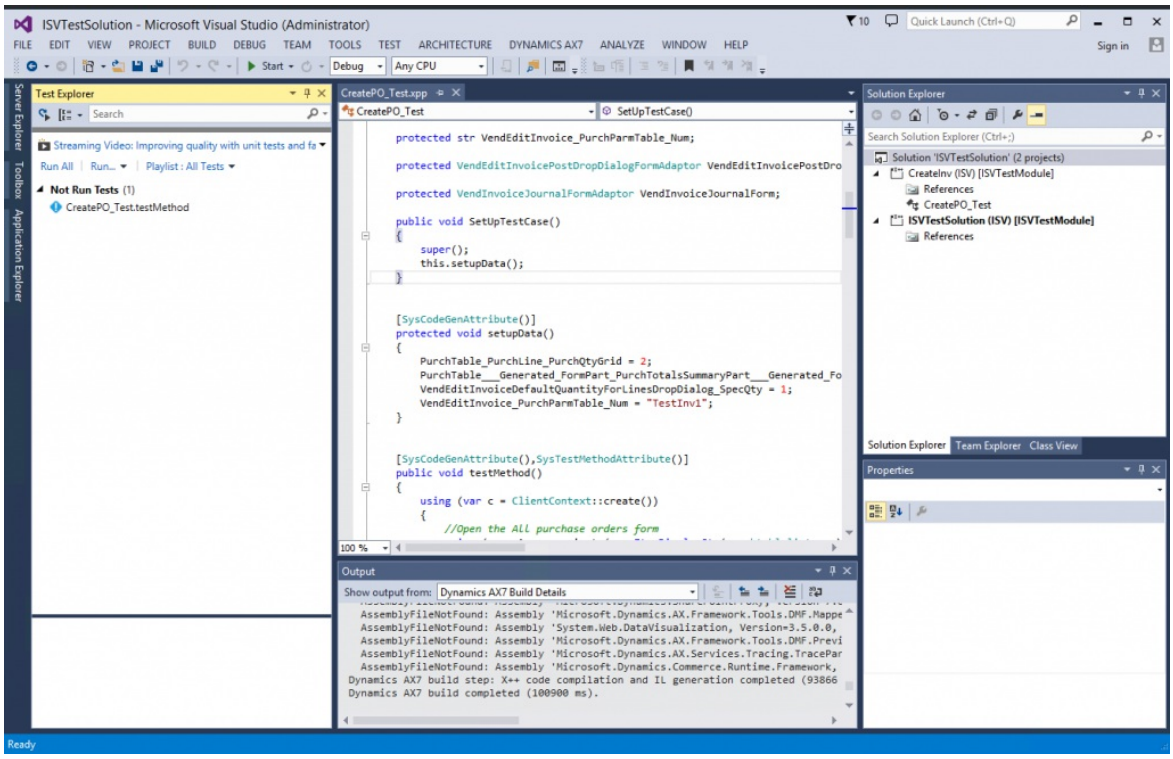


4. The task recording import process generates test code that is based on the SysTestAdapter and FormAdaptor which can be viewed in Visual Studio IDE. We do not expect you to change any test source code that is generated as part of this step.

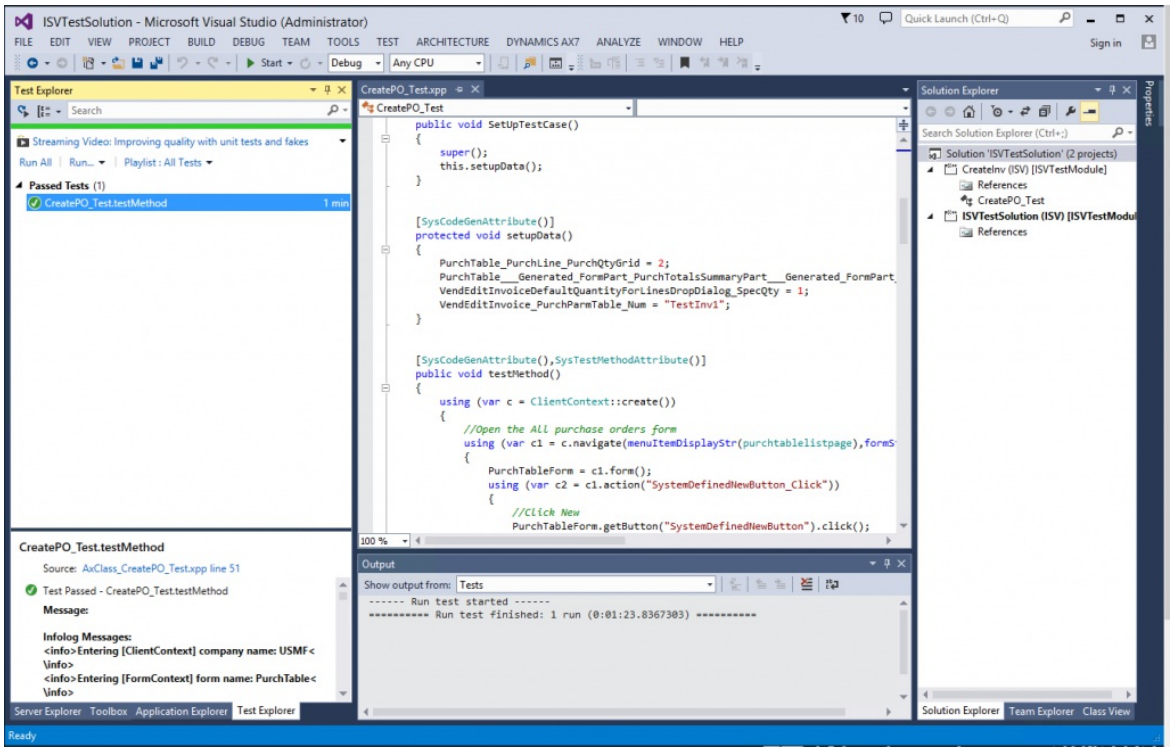
5. After the test code is generated, set up Visual Studio options for test discovery and execution:

   - If you have a 64-bit machine, you can run unit tests and capture code coverage information as a 64-bit process.
   - To configure this, select **Test** > **Test Settings** > **Default Processor Architecture**, and then select **X64**.
   - You might run into a situation in which the test execution engine opens and locks an assembly in your test project. When this happens, you can't for example, save changes to the assembly. To fix this, select **Test** > **Test Settings**, and then select **Keep Test Execution Engine Running**.
   - Now that you have test code generated in Visual Studio IDE, it's time to discover the test and try executing them locally.

6. From menu options, select **Test** > **Windows**, and then click **Test Explorer**. After the Test Explorer window is open, it will try to discover test from test code and list all the available tests as shown below.



7. Select the test and then click **Run** > **Execute selected**. This will execute test against the locally deployed environment.



Integration of the test module with build process

After the test module is a part of source control, the build process template will discover all test modules, which contain the word **Test** in the name. The following illustration shows build and test execution as part of Visual Studio Online.

CTP5[illegible]_03.18.15_18.11.18_20150318.1 - Build succeeded

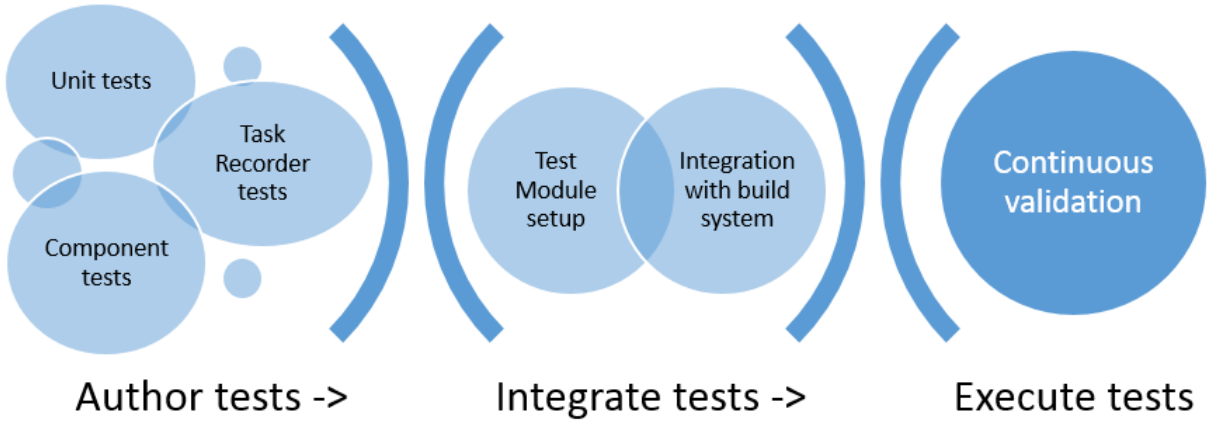
Test projects in Visual Studio

2/18/2021 • 2 minutes to read • Edit Online

This topic describes the options for testing in Visual Studio.

A custom unit test adapter is available in Visual Studio. This adapter lets test authors use the standard **Test Explorer** window in Visual Studio to schedule X++ tests and analyze test results. Developers can author tests by using **SysTestAdaptor**. They can also generate test code from Task Recorder recordings. These test cases can then be added to build systems for validations.

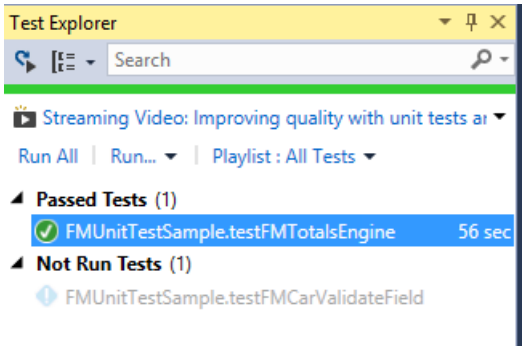


Author unit/component test code by using the SysTest Framework

When you create a project in Visual Studio, you can add an X++ unit test. You extend the class with **SysTestCase**, and then either add the **SysTestMethodAttribute** attribute or prefix the case with "test" in the method name.

```
class FMUnitTestSample extends SysTestCase
{
    [SysTestMethod]
    public void testTotalsEngineConfig()
    {
    }
}
```

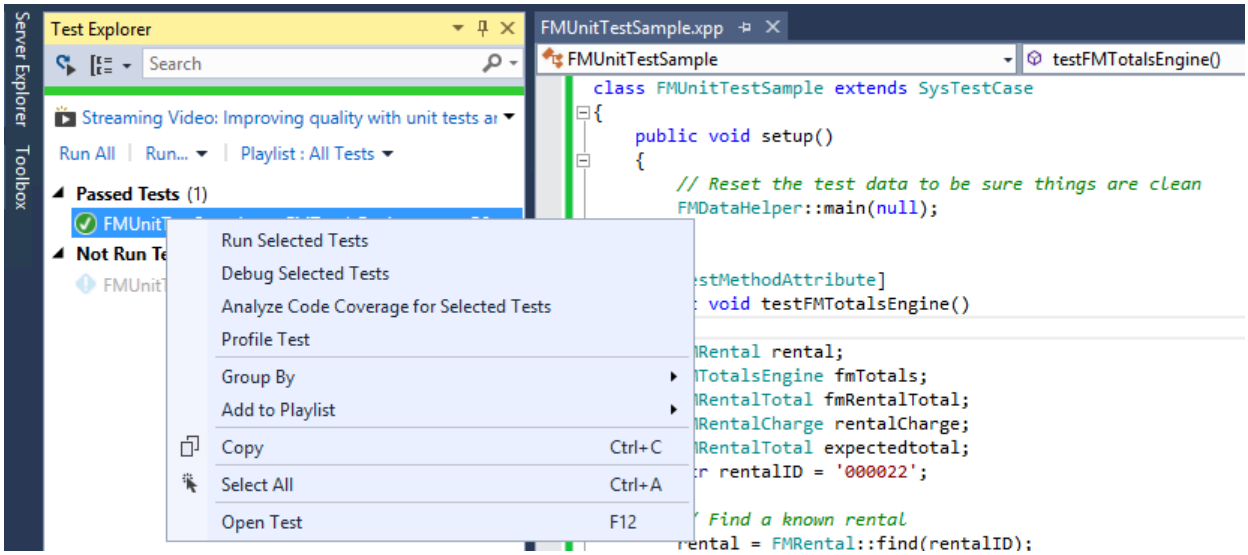
After you save the class, each test appears in Test Explorer, just as a C# test would appear.



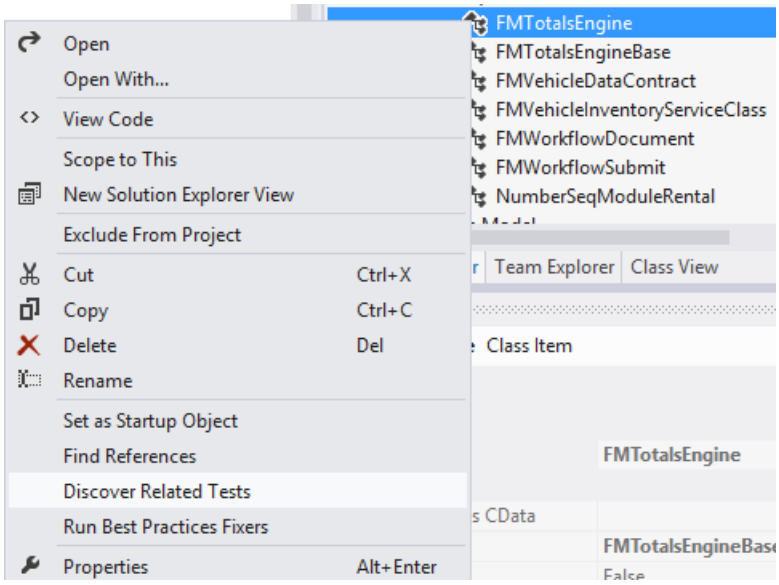
In Test Explorer, you can run the tests, or you can debug the test case by right-clicking and running or debugging the selected tests.

NOTE

Before you can run tests, you must build the project so that it includes tests.



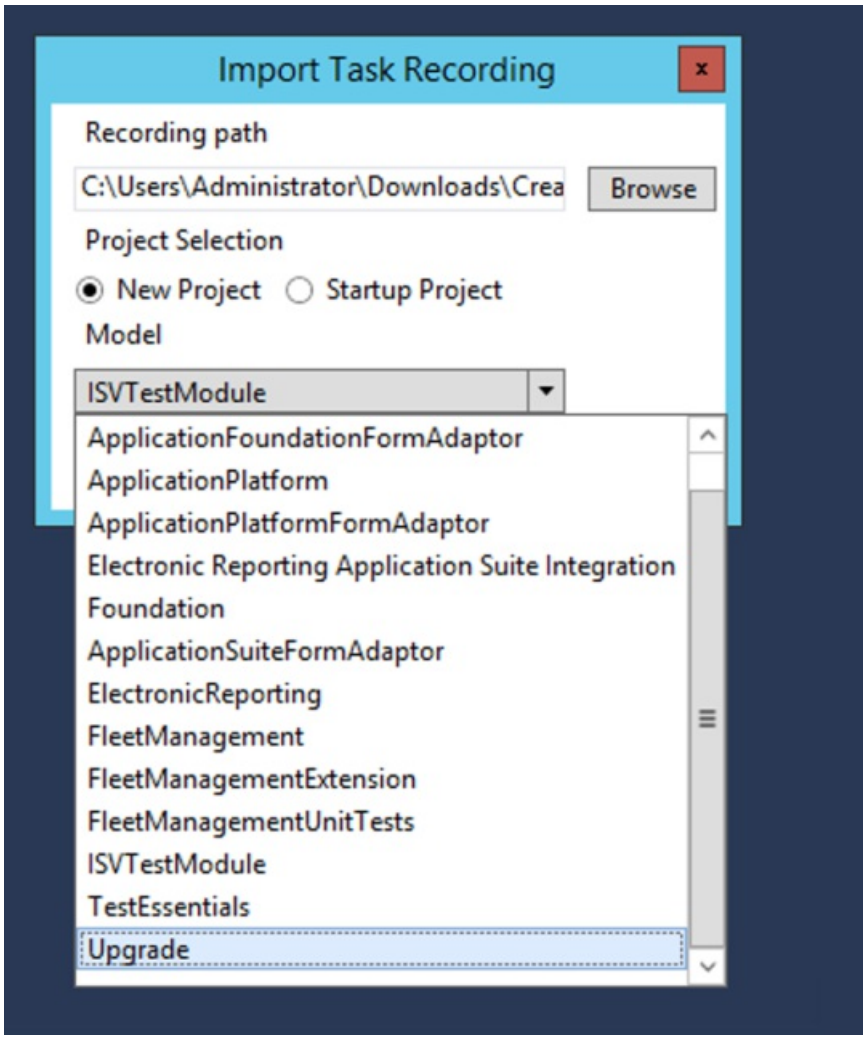
You can also discover existing tests for an object in your project. Discovery uses cross-reference data. Right-click an object in the project, and then select **Discover Related Tests**. This command queries the cross-reference data and returns any tests that reference the object. The list of test cases is displayed in Test Explorer.



By using this functionality, you can run all the relevant tests. Test Explorer contains all tests for the current project and all tests for the referenced objects.

Generate test code by importing Task Recorder recordings into Visual Studio

You can import the XML for Task Recorder recordings to generate test code that can be used to validate various business process scenarios.



Generated code is based on the SysTest Framework and FormAdaptors. FormAdaptors are wrapper classes over pages. They provide strongly typed application programming interfaces (APIs) that can be used to test page functionality. Pre-generated FormAdaptors are included for each package for built-in pages. In a test module, add a reference to a corresponding FormAdaptor for packages and "Test Essentials," which contain helper methods to run test code.

Advanced Options

For advanced options to categorize and filter tests for execution, see SysTest Filtering using class and method attributes.

NOTE

The survey will take about seven minutes. No personal data is collected (privacy statement).

Deploy and use a continuous build and test automation environment

2/18/2021 • 7 minutes to read • Edit Online

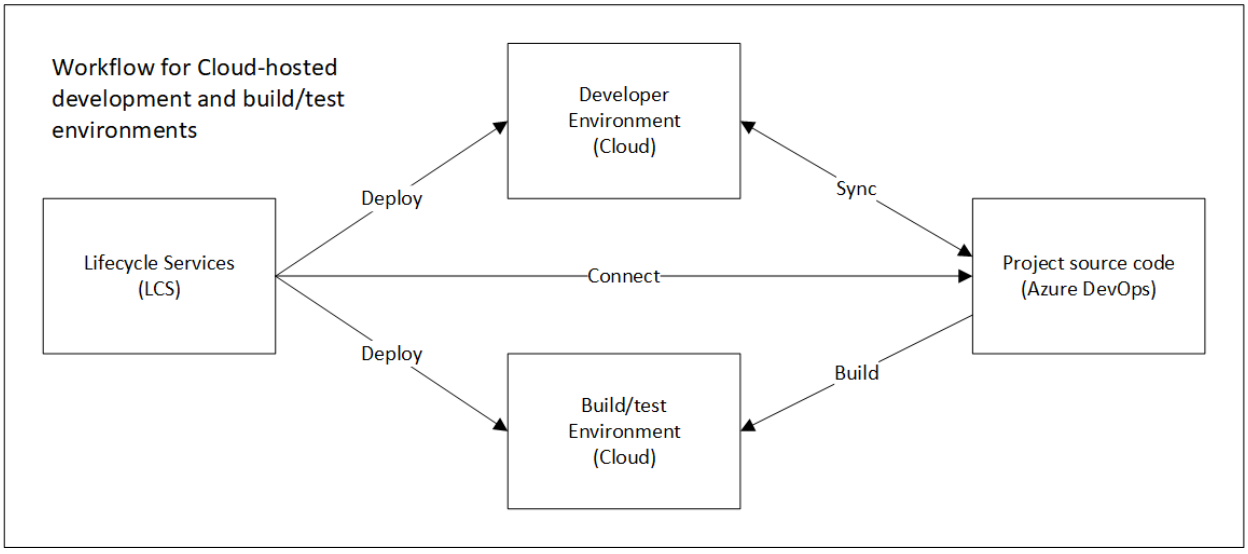
This topic describes how to deploy and use an environment that supports continuous build and test automation.

Prerequisites

Cloud deployment of virtual machines (VMs) requires a Microsoft Azure DevOps subscription.

Workflow

After you configure an Azure DevOps subscription in Microsoft Dynamics Lifecycle Services (LCS), you can use LCS to deploy developer VMs or build/test VMs. LCS configures a developer VM that can be mapped to an Azure DevOps project. LCS also configures a build VM that is automatically mapped to an Azure DevOps project and has a build agent/controller that builds modules from the Azure DevOps project and runs automated tests that have an external endpoint for validation. The following illustration shows a typical workflow.



This workflow includes an LCS deployment of a developer VM and a build/test VM in Azure.

- LCS creates developer and the build/test environments in Azure. To create a build/test environment, LCS must be able to determine where the source code for the Azure DevOps project is.
- The developer works on source code on the developer VM, and the work is synced to the Azure DevOps project.
- The build process synchronizes the code from Azure DevOps onto the build/test VM and produces deployable packages that you can apply to sandbox and production environments. The source code doesn't flow directly from the development VM to the build/test VM. They are synced through Azure DevOps.

For information about how to write custom test code or generate automated test code to integrate with the build infrastructure, see Testing and validations.

Set up Azure DevOps

Choose a plan

The first step is to choose an Azure DevOps plan for your organization.

> **NOTE**
>
> TFVC is the only source control repository that is supported. Git isn't supported.

Set up Azure DevOps

To set up Azure DevOps, follow these steps.

1. Create a personal access token. The token is used for all LCS background actions. These actions include upgrade and deployment. When users initiate actions from LCS, LCS expects that those users will be added to Azure DevOps. The users must authorize LCS access to Azure DevOps on their behalf.
2. Configure LCS.

Until you authorize LCS access to Azure DevOps, you will see a "setup is not complete" message in action center.

Suspend current builds

If you're deploying a build environment on an existing Azure DevOps project that already has a build definition, make sure that you don't have any active triggers to queue the build. Additionally, make sure that no builds are scheduled or queued against the build pool.

Deploy Developer and Build/Test environments from LCS

LCS provides an option to deploy Development and Build/Test environments. With this option, you can deploy developer and build VMs in the cloud that are connected to your Azure DevOps project.

Azure DevOps credential setup and linking to LCS project

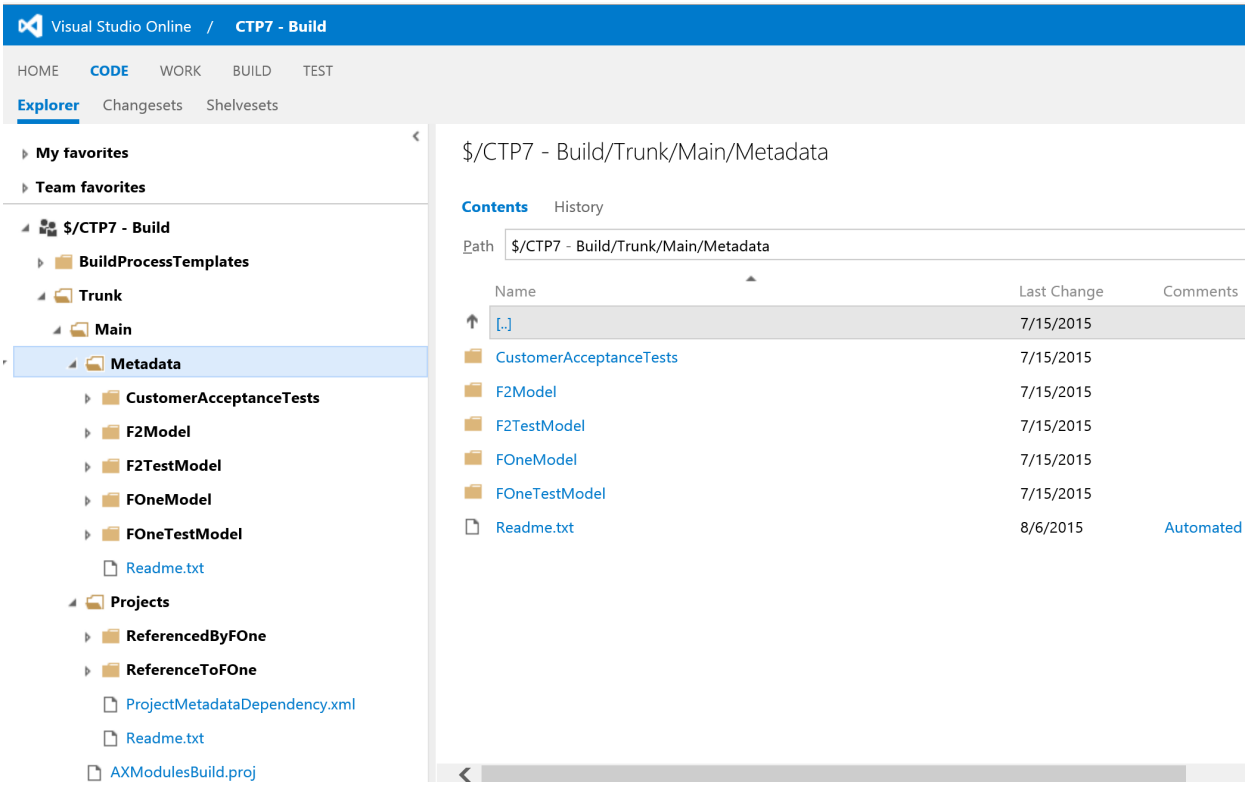
If you have not already done so, you need to first setup your LCS project to connect to your Azure DevOps project before you deploy a build environment.

1. Login to the LCS portal to connect to Azure DevOps and your LCS project at https://lcs.dynamics.com/.
2. Select a project that you are working on.
3. Click the **Project Settings** tile.
4. Select **Azure DevOps** and enter the Azure DevOps URL where the source code for your module project is located.
5. Specify the Azure DevOps link, authorize, and then click **Choose default project**.

   > **NOTE**
   >
   > We currently support VSTF as source control and do not support Git.

Check-in migrated or new module code into Azure DevOps

As part of code Migration process or development activities, we expect you to check-in your model source files and the associated test model source files into Azure DevOps. If you have migrated your code using the LCS migration service, this is automatically done for you. If you have not checked in any code into Azure DevOps and work on direct check-in, you must follow certain guidelines for the Azure DevOps folder structure. This will help with setting up correct build definition. All modules should be added to root folder **Metadata**. Under each module, there should be two folders. One folder contains all models. The other folder should contain descriptor XML for that module.



Deploy a Build environment

The topic Deploy and access development environments describes how to deploy developer environments. Use the same flow to deploy a build environment. As you are going through the deployment or configuration wizard, when prompted to **Select a Topology**, select **DevTest** then select a **Build and Test** topology.

As part of the deployment wizard, you can configure the build agent name and build agent pool.

Click **Advanced settings**, select **Azure DevOps**

1. Build Agent Name: Friendly name for build agent on Azure DevOps
2. Build Agent Pool: specify build agent pool name which should be used for build machine deployment. Make sure Azure DevOps contains at least one agent pool. By default, there will be the default pool. If you have deleted the default pool then build deployment will fail.
3. Branch Name: Specify your Azure DevOps source code branch which will be default source code sync location for the build VM. Default branch is "Main".

Test integration with the build

There are two ways to integrate test as part of build process for testing and validation:

- SysTest framework based unit and component level tests.
- Generate code from Task Recorder recording XML for automated test execution.

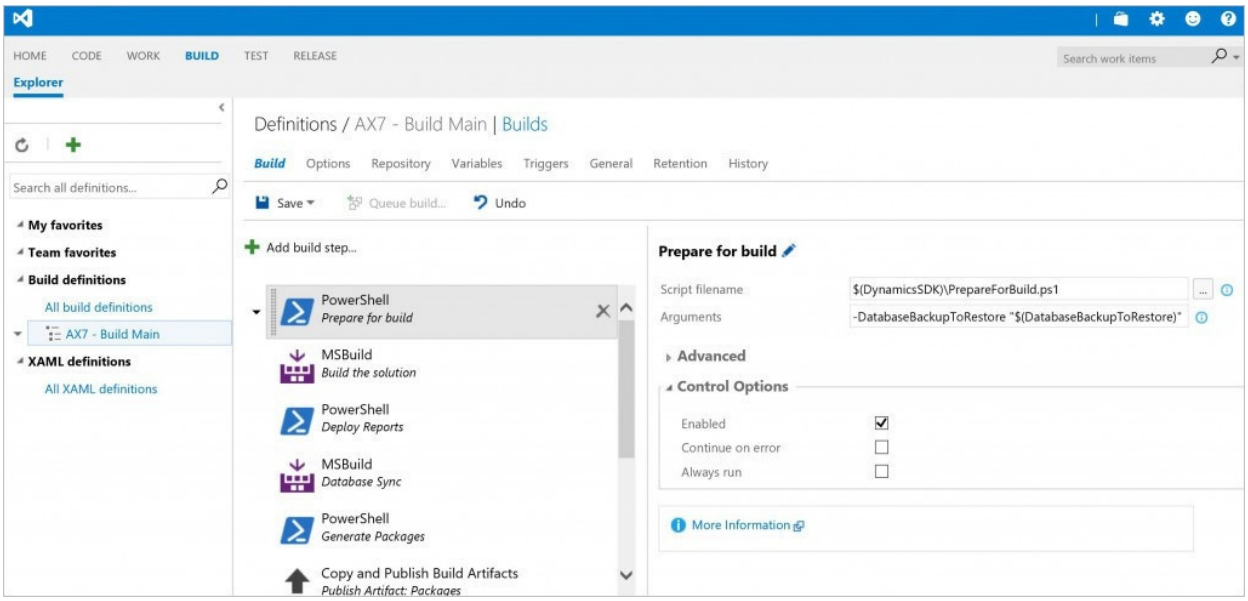
The details of these two approaches are mentioned in the Testing and validation article. Review this article for testing and validation strategy.

Use the Build VM environment

When a Build VM is deployed in Developer topology through LCS, it is pre-configured and ready to start a build. You can change the default configuration at any time from the Visual Studio IDE or the Azure DevOps interface. On a Build VM, the module source code is synchronized to the build machine for easy build setup. The build machine is also auto-configured with default settings for build agent, build controller, build process template, and build definition. Tests that are integrated with build definition are executed after the build is successful.

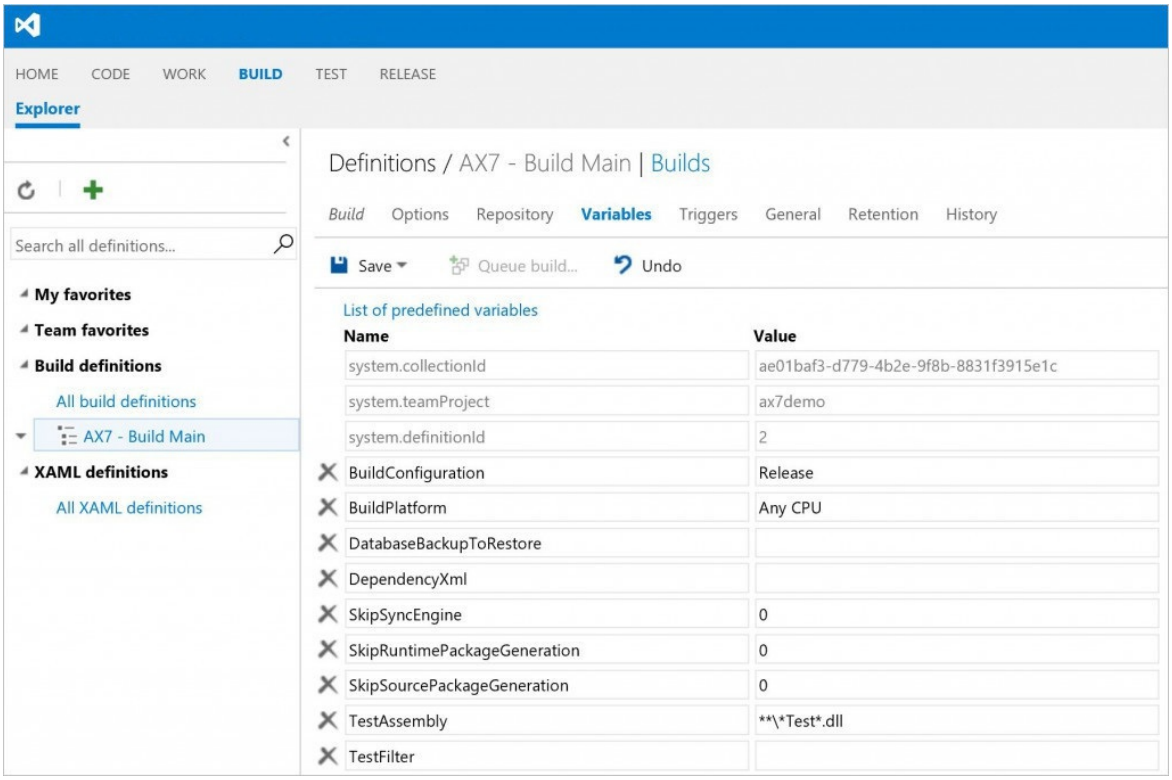
Review a pre-configured customizable build environment

The build VM contains the vNext build agent which was released as part of **Azure DevOps**. When you deploy the Build VM, the build agent is configured by default to connect and sync with the Azure DevOps project. As a part of the Build VM configuration, the default build definition is also created and configured, as shown below.

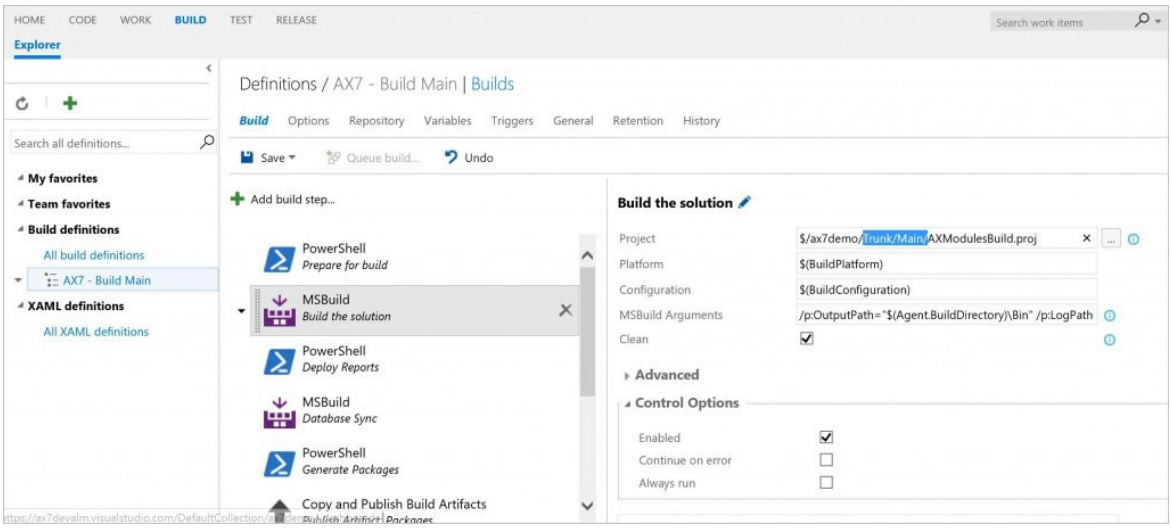


Default build definition contains multiple tasks to perform specific operation, as described below.

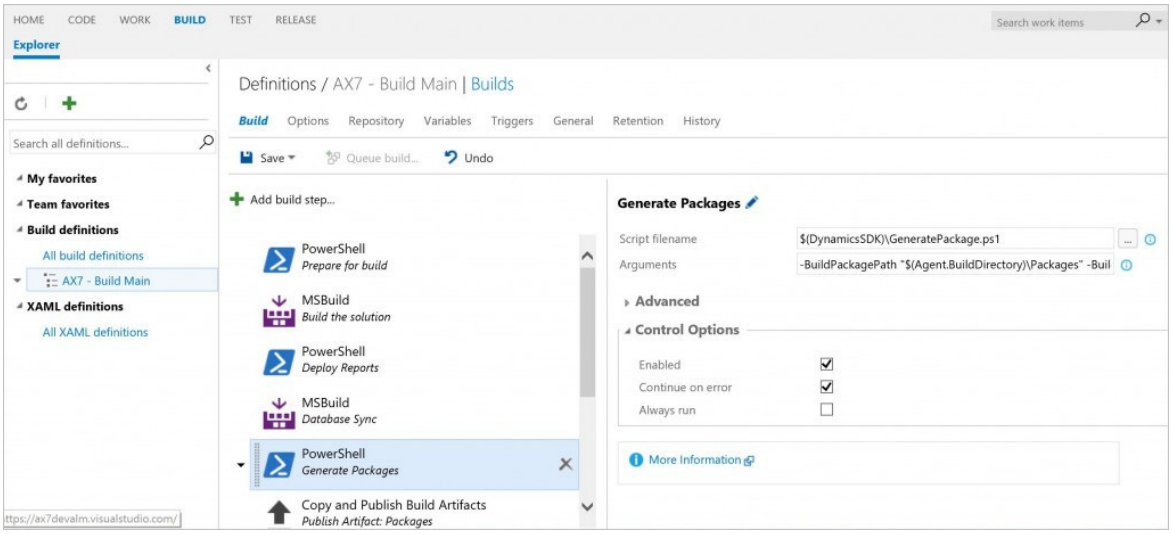
1. Configure the predefined variables parameters that will be passed to the build. To set up a clean database for every build execution, provide the name of the database backup file for the **DatabaseBackupToRestore** variable. The packages folder is restored at every build with a copy of a clean package folder.



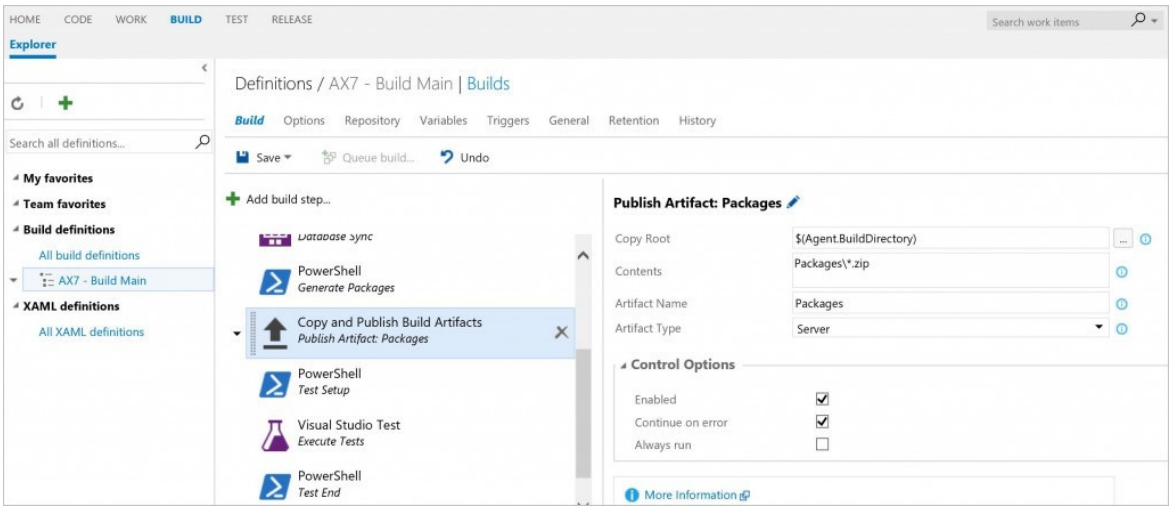
2. Build the solution to discover and build all modules under "Trunk/Main" branch as shown below.



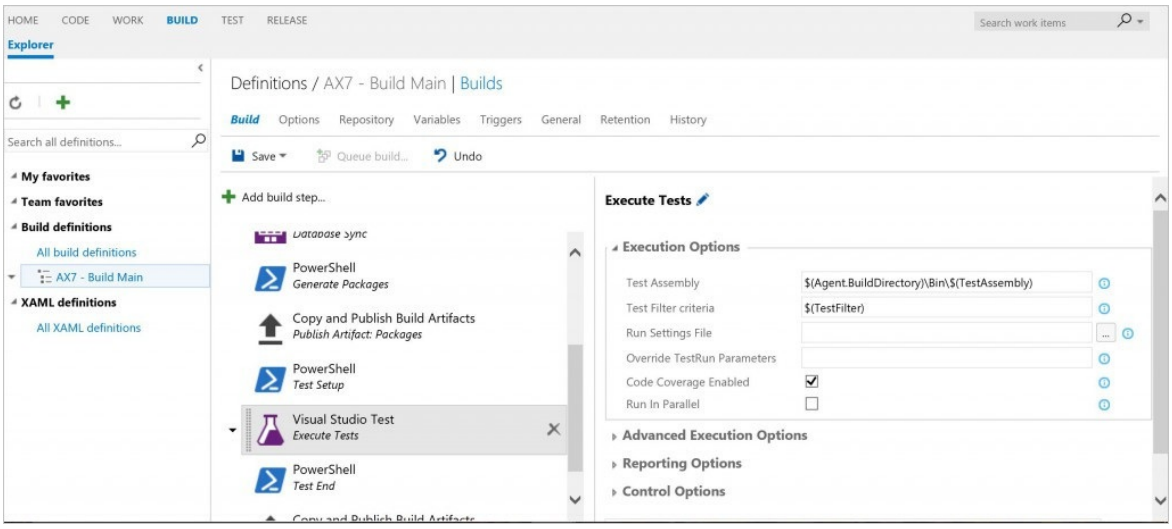
3. Use "Deploy Report" task to generate reports and deploy on build VM.
4. Use "Database Sync" task to synchronize the database to local SQL on build VM.
5. After the build is successful, create a deployable package that can be used to update sandbox/ staging environment.



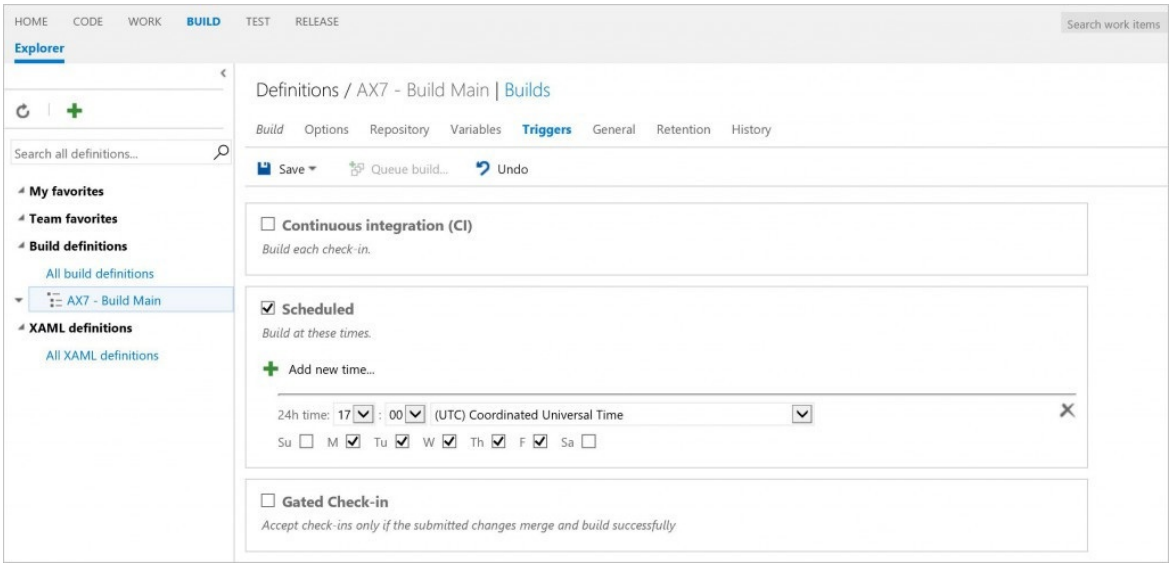
6. "Copy and publish build artifacts" uploads the deployable package to Azure DevOps artifacts location.



7. For test execution, there are three default tasks "Test Setup", "Execute Test" and "Test End".



8. The default build is scheduled to trigger start every day at 5 P.M. You can change trigger as per your team's need to "Continuous" for each check-in.



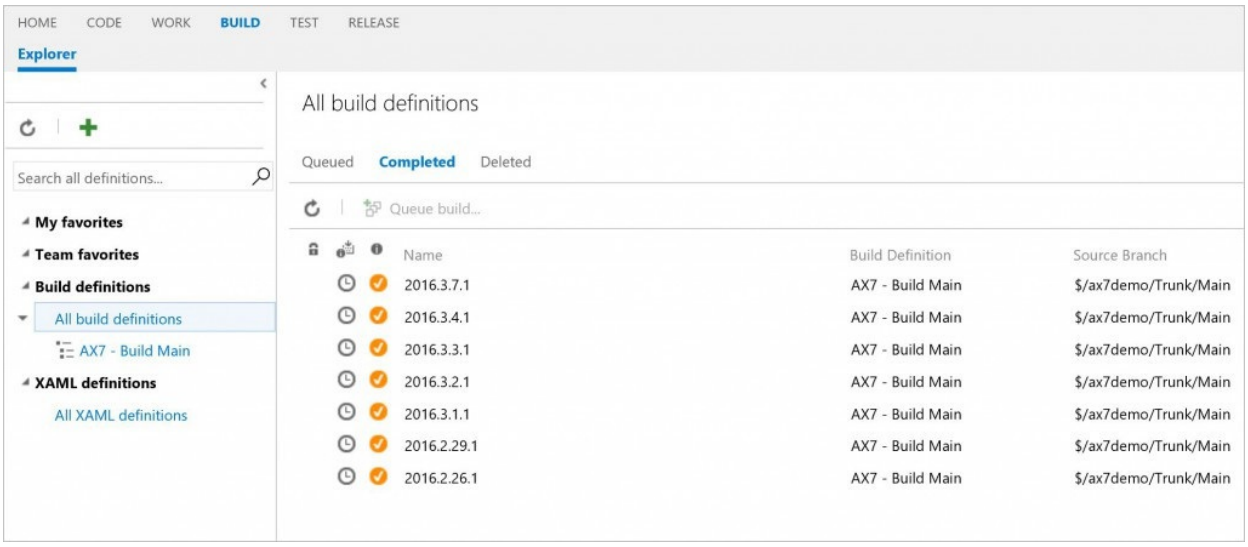
You can make changes to the default configuration, and the build VM will be ready to trigger a build.

Start a build and verify the build and test execution results

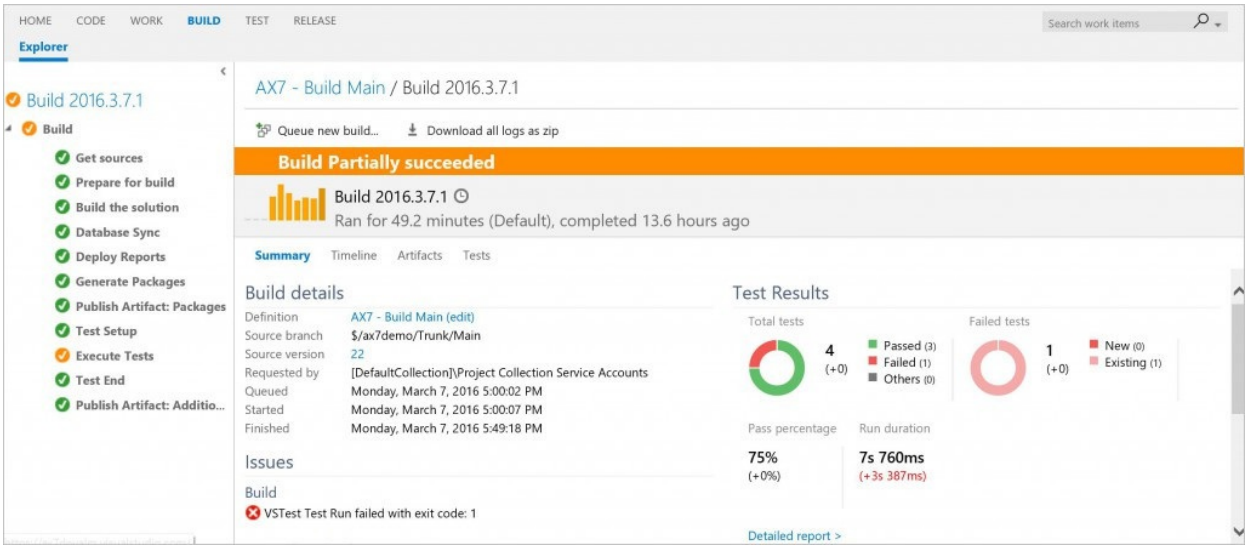
After you review the default build configuration, you can manually trigger a build from Visual Studio IDE or Azure DevOps web interface.

1. Open your browser and connect to the Azure DevOps URL.
2. Login using your credentials.
3. On the home page, under **Recent projects and solutions**, select a project.
4. From top links options, select **BUILD**.
5. On the left panel, select the default build definition instance.
6. Right-click and select **Queue Build** to trigger a build for your module and test module that is already checked into the Azure DevOps source control.

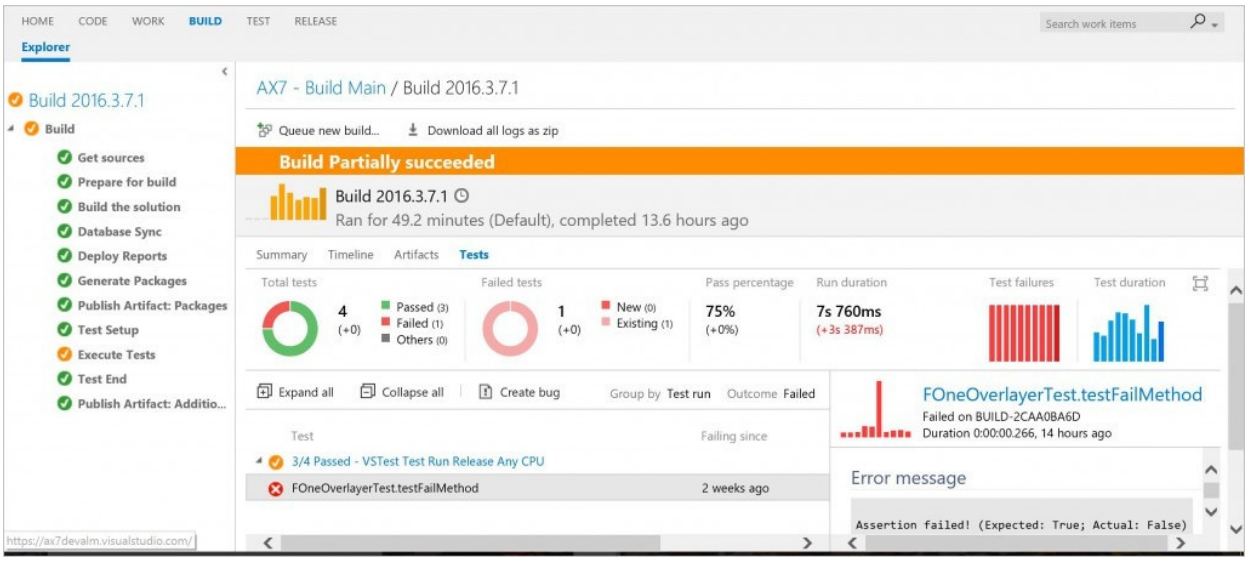
Success or failure for the build will display, as shown by the following examples. View all builds.



Select specific completed build and view success/ failure details.



Click on Test link to visualize test execution failure.



NOTE

Can you tell us about your documentation language preferences? Take a short survey.

The survey will take about seven minutes. No personal data is collected (privacy statement).

SysTest Filtering using class and method attributes

2/18/2021 • 2 minutes to read • Edit Online

Starting with Platform update 12, the SysTest framework contains improvements to the SysTest class and method attributes in X++. These improvements also change how these attributes work in the Visual Studio test window as well as the Visual Studio Test Console, which is the tool used in the automated build process. The SysTest framework now supports the major test attributes in the adaptor to be on par with the MSTest framework adaptor. This includes attributes like **Category**, **Owner**, **Priority**, and **Test Property**.

TestCategory

The **Category** attribute, **SysTestCategory**, was already available in previous platform updates using the **SysTestCategory** attribute. Starting with Platform update 12, you can specify multiple categories on both the class level and the individual method level. Additionally, **TestCategory** is enabled for filtering in the Visual Studio Test Console. This means that you can create build pipelines with test filters on specific categories. You can use the **TestFilter** variable in the build pipeline. For example, to run tests only with a category **Nightly**, set the variable to **TestCategory=Nightly**.

Priority

The **Priority** attribute **SysTestPriority**, which requires an integer value, is now available. A priority can only be specified once, but is supported on both the class and method level, with method level taking precedence over class level. The priority is also exposed as a test filter. This means that you can use the **TestFilter** variable in the build pipeline. For example, to only run tests with a priority of **1**, set the variable to **Priority=1**.

Owner

The **Owner** attribute, **SysTestOwner**, has also been added. This attribute was technically already supported for filtering in the **Test Toolbox** window, but the attribute itself was missing in X++. Similar to **Priority**, an owner can only be specified once and is supported on both the class and method level, with the method level taking precedence. **Owner** is not available as a test filter for the console, which aligns with the MSTest adaptor for Visual Studio Test Console. However, **Owner** will appear in the **Test Toolbox** window in Visual Studio.

Test Property

The **Test Property** attribute, **SysTestProperty**, has existed in previous releases of the platform, but wasn't fully functional. Unfortunately, the **SysTestProperty** attribute exists in the **Application Foundation** package as opposed to the other attributes which exist in the **Test Essentials** package. Because of our commitment to backward compatibility of the platform, we currently cannot move this attribute to its expected location, so your code will need a reference to the **Application Foundation** package to use it. **SysTestProperty** specifies a property and a value (two strings), and can now be used in the **Test Toolbox** window in Visual Studio. **Test Property** can be specified multiple times, and can exist on both the class and method level. **Test Property** is not available for test filtering in the Visual Studio Test Console, in line with the MSTest adaptor.

For advanced filtering syntax that can be used with the Visual Studio Test Console and to review the filtering example for the MSTest framework, see Running selective unit tests.

NOTE

For test filtering purposes, the SysTest framework allows you to filter on **FullyQualifiedName** and **Name**.

NOTE

The survey will take about seven minutes. No personal data is collected (privacy statement).

Acceptance test library resources

2/18/2021 • 2 minutes to read • Edit Online

The Acceptance test library (ATL) is an X++ test library that offers the following benefits:

- It lets you create consistent test data.
- It increases the readability of test code.
- It provides improved discoverability of the methods that are used to create test data.
- It hides the complexity of setting up prerequisites.
- It supports high performance of test cases.

Example of a test that is written in ATL

```
// Create the data root node
var data = AtlDataRootNode::construct();

// Get a reference to a well-known warehouse
var warehouse = data.invent().warehouses().default();

// Create a new item with the "default" setup using the item creator class. Adjust the default warehouse
before saving the item.
var item = items.defaultBuilder().setDefaultWarehouse(warehouse).create();

// Add on-hand (information about availability of the item in the warehouse) by using the on-hand adjustment
command.
onHand.adjust().forItem(item).forInventDims([warehouse]).setQty(100).execute();

// Create a sales order with one line using the sales order entity
var salesOrder = data.sales().salesOrders().createDefault();
var salesLine = salesOrder.addLine().setItem(item).setQuantity(10).save();

// Reserve 3 units of the item using the reserve() command that is exposed directly on the sales line entity
salesLine.reserve().setQty(3).execute();

// Verify inventory transactions that are associated with the sales line using the inventoryTransactions
query and specifications
salesLine.inventoryTransactions().assertExpectedLines(
    invent.trans().spec().withStatusIssue(StatusIssue::OnOrder).withInventDims([warehouse]).withQty(-7),
    invent.trans().spec().withStatusIssue(StatusIssue::ReservPhysical).withInventDims([warehouse]).withQty(-
3));
```

Concepts

The structure and naming of the classes and methods in ATL are quite rigid. This rigidity helps improve discoverability and also makes it easier to write tests, even in domains that you're unfamiliar with.

The classes are grouped into the following concepts:

- Navigation – Discover entities and test data methods in a familiar hierarchy.
- Test data methods – These methods are used to set up test data.
- Entities – Entities represent data and associated behavior that is perceived as a single unit.
- Creators – Creators let you create specific test data.
- Commands – Commands run business operations.
- Queries – Queries find entities.

- Specifications – Specifications describe expected entities at the end of the test.

Code generation

Queries and specifications help simplify the process of creating entities. For more information, see Acceptance test library Code generation wizard. The **Code generation** wizard can be used to create scenarios and update them.

Further reading

Microsoft has used ATL internally for several years, as the foundation for thousands of tests. For more information see, Best practices for the Acceptance test library and Acceptance test library FAQ.

Navigation concepts for test data

2/18/2021 • 2 minutes to read • Edit Online

To simplify the discoverability of generation methods for test data, a set of navigation objects is introduced. For more information about the generation methods, see Test data methods.

Navigation should start from the root object, the module must be specified, and then the entity must be specified together with the test data methods.

```
data.module().entity().testDataMethod();
```

Examples

```
modelGroup = data.invent().modelGroups().fifo();

itemBuilder = data.products().items().whsBuilder();

data.sales().salesOrders().ensureCanCreate();

data.invent().parameters().enableQualityManagement();
```

Advantages

- Discoverability of data creation application programming interfaces (APIs). IntelliSense helps you get to the helper methods that are relevant for the entity.
- Local references to frequently used nodes (for example, `items.whsBuilder()`). Therefore, long names aren't required.

Root navigation object

The root navigation object is the starting point for finding the test data methods that are required. The root navigation object exposes modules where test data methods are defined.

Variable naming

The suggested name for variables that reference the navigation root is `data`.

Class naming

The root class is named `AtlDataRootNode`.

Module navigation object

The module navigation objects let you group test data methods by relevant modules. Module navigation objects can expose entity navigation objects.

Navigation node naming

Module names should be based on the names of the modules on the main menu. However, a short version or an abbreviation should be used to support brevity of test code.

Examples

- **Sales and marketing** module: `data.sales()`
- **Inventory management** module: `data.invent()`

Class naming

`AtlData<ModuleName>`

Examples

- **Sales and marketing** module: `AtlDataSales`
- **Procurement and sourcing** module: `AtlDataPurch`
- **Inventory management** module: `AtlDataInvent`
- **Accounts receivable** module: `AtlDataCust`
- **Accounts payable** module: `AtlDataVend`

Entity navigation objects

Entity navigation objects let you group test data methods by relevant entities.

Navigation node naming

The plural of the entity name should be used as the name of the entity navigation node.

Examples

```
data.products().items();

data.whs().warehouses();
```

Class naming

`AtlData<ModuleName><EntityNamePlural>`

Examples

```
AtlDataProductsItems

AtlDataInventChargeGroups
```

Notes

The same entity navigation object can be exposed from multiple modules when this approach makes sense. For example, `AtlDataProductsItems` is exposed from both `data.product()` and `data.invent()`.

Helper navigation objects

Sometimes, a test data method isn't specific to any entity. In this case, a helpers node can be exposed at the module level.

Navigation node naming

The helpers navigation node should be named `helpers`.

Examples

```
data.helpers();

data.whs().helpers();
```

Class naming

`AtlData<ModuleName>Helpers`

Examples

```
AtlDataHelpers

AtlDataWHSHelpers
```

NOTE

Can you tell us about your documentation language preferences? Take a short survey.

The survey will take about seven minutes. No personal data is collected (privacy statement).

Test data methods

2/18/2021 • 4 minutes to read • Edit Online

Entity and helper navigation objects expose test methods that let you set up test data. This topic provides information about the most common types of test data methods.

Factory methods

Factory methods focus on creating data that doesn't yet exist in the database. There are two types of entity factory methods, `init` methods and `create` methods. An `init` method initializes the entity but doesn't save it to the database. A `create` method initializes the entity and saves it to the database.

Naming convention

`init<EntitySpecification>`

`create<EntitySpecification>`

In this naming convention, `<EntitySpecification>` is the description of the key characteristics of the object that must be created.

Examples

```
salesOrder = data.sales().salesOrders().initDefault();

purchaseOrder = data.purch().purchaseOrders().createDefault();
```

Best practices

The `create` method should always call the `init` method that has the same entity specification.

Example

```
public AtlEntitySalesOrder createDefault()
{
    AtlEntitySalesOrder salesOrder = this.initDefault();
    salesOrder.save();
    return salesOrder;
}
```

Prerequisite data

The `init` method should take care of setting up prerequisites.

Before some entities can be created, specific prerequisites must be set up. In these cases, the `ensure` method must be called before the entity is initialized. You must also subscribe to all the entity events that require automatic setup of prerequisites.

Example

```
public AtlEntitySalesOrder initDefault()
{
    AtlEntitySalesOrder salesOrder;

    this.ensureCanCreate();

    salesOrder = new AtlEntitySalesOrder();
    salesOrder.parmCustomer(data.cust().customers().default());

    _salesOrder.postingInvoice += eventhandler(this.ensureCanPostInvoice);
    _salesOrder.postingPackingSlip += eventhandler(this.ensureCanPostPackingSlip);
    _salesOrder.releasingToWarehouse += eventhandler(this.ensureCanReleaseToWarehouse);
}
```

Builder methods

Builder methods are responsible for initializing creator objects that will be used to create data that doesn't yet exist in the database.

Naming convention

`<EntitySpecification>Builder`

In this naming convention, `<EntitySpecification>` is the description of the key characteristics of the object that must be created.

Example

```
catchWeightItem = data.invent().items().cwBuilder();
```

Well-known data methods

Well-known data methods provide a way to reference an entity that is set up in a specific way. If the entity doesn't exist in the database, it's created.

Naming convention

`<EntitySpecification>`

In this naming convention, `<EntitySpecification>` is the description of the key characteristics of the object that must be retrieved.

Example

```
fifo = data.invent().modelGroup().fifo();
```

In this example, the contract of the method specifies that the model group should use first in, first out (FIFO) as the inventory model. The rest of the settings can be left at their default values.

Sometimes, a real-world name communicates the contract better.

```
pieces = data.common().units().pieces();
```

In this example, it's clear that **pieces** is a unit of measure of the "quantity" class, and that is has a decimal precision of 0 (zero).

Contract of well-known data methods

Here are a few things to remember about the common contract of the well-known data methods.

- Two calls to the same well-known data method should provide the caller with the reference to the same entity.

```
fifo1 = data.invent().modelGroups().fifo();
fifo2 = data.invent().modelGroups().fifo();
fifo1.InventModelGroupId == fifo2.InventModelGroupId;
```

- Creation of a test entity isn't always worth the effort. If a test entity isn't created, the corresponding record buffer should be returned from the well-known data method. For example, if you don't invest the time and effort to create the Site entity, the `site` well-known data method will return InventSite records.

```
InventSite site = data.invent().sites().default();
```

- Well-known data methods can take IDs as optional parameters when this approach makes sense.

```
item1 = data.products().items().default('Item1');
item2 = data.products().items().default('item2');
```

Implementation

If there is already a builder or a factory method that is named `<EntitySpecification>`, it should be used as the internal implementation to create the well-known entity.

Example

```
public InventTable whsBatchAbove(ItemId _itemId = this.whsBatchAboveItemId())
{
    InventTable whsItem = InventTable::find(_itemId, true);
    if (!whsItem)
    {
        whsItem = this.whsBatchAboveBuilder().setItemId(_itemId).create();
    }
    return whsItem;
}
```

Ensure methods

Ensure methods are responsible for setting up prerequisites that are required in order to create an entity or run a business operation.

Naming convention

`ensureCan<ExecuteBusinessOperation>`

In this naming convention, `<ExecuteBusinessOperation>` is a verb that describes the business operation.

Examples

```
data.sales().salesOrders().ensureCanCreate();

data.purch().purchaseOrders().ensureCanPostProductReceipt();
```

Implementation

Figuring out prerequisites for a complex business operation, such as invoice posting, can be complicated and requires lots of knowledge about the feature area.

Example

```
public void ensureCanCreate()
{
    data.helpers().setNumberSequenceReference(extendedTypeNum(InventDimId));
}
```

Automatic prerequisite setup

To enable automatic prerequisite setup, you must call the `ensure` methods in the appropriate `init` method. For more information, see the Factory methods section earlier in this topic.

Query methods

Query methods are responsible for initializing new queries for the entity type of the navigation node that they are defined on.

Naming convention

`query`

Examples

```
loadLinesQuery = data.whs().loadLines().query();

purchaseLinesQuery = data.invent().transferOrderLines().query();
```

Specification methods

Specification methods are responsible for initializing new specification objects for the entity type of the navigation node that they are defined on.

Naming convention

`spec`

Example

```
loadLinesSpec = data.whs().loadLines().spec();
```

Find methods

Find methods let you find an entity based on the primary key.

Naming convention

`find`

Example

```
salesOrder = data.sales().salesOrders().find(salesOrderId);
```

Automatic prerequisite setup

If the entity has query support, the implementation should use the query that has already set up prerequisite support. Otherwise, after you find the record buffer and initialize the new instance of the entity, you should subscribe `ensure` methods to the business operation events of the entity.

NOTE

Can you tell us about your documentation language preferences? Take a short survey.

The survey will take about seven minutes. No personal data is collected (privacy statement).

Entities in the Acceptance test library

2/18/2021 • 6 minutes to read • Edit Online

A test entity class represents data and behavior that are perceived as a single concept. Test entity classes are based on pages such as **Sales order**, **Transfer order**, and **Released product**. The test entity classes expose the properties that are most often used in test scenarios, and the behavior that is most important from the perspective of test data setup and scenario tests.

An entity in the Acceptance test library (ATL) **must** have the following methods:

- Property methods that are used to get and set entity properties.
- Fluent setter methods that enable entity properties to be set in a fluent manner.
- A method that saves the entity to the database.

An entity in ATL *can* have the following methods:

- Action methods that are used to expose business operations that are relevant to the entity.
- Query methods that are used to enable navigation to components and related entities.

Naming convention

`[AtlEntity]<ModuleName><EntityName>`

In this naming convention:

- `<ModuleName>` is based on the names of the modules in main menu. You should use a short version or an abbreviation to support brevity of test code.
- `<EntityName>` is based on the user interface (UI) names instead of the table names. For example, use `SalesOrder`, not `SalesTable`.

If an entity has two UI names, it's OK to use the shorter name. For example, you can use `Item` instead of `ReleasedProduct`, because these names are used interchangeably.

Examples

```
AtlEntitySalesOrder

AtlEntityTransferOrderLine
```

Property methods

One of the main purposes of a test entity is to expose data. The properties of the entity can be set or retrieved by using `parm` (property) methods.

Primitive type properties

Create a `parm` method to expose a primitive type property.

Example

```
public SalesQty parmQuantity(SalesQty _qty = 0)
{
    if (!prmisDefault(_qty))
    { // setter
        salesLine.SalesQty = _qty;
        this.onSalesQtyOrInventDimChange();
    }
    return salesLine.SalesQty;
}
```

Entity references

If there is a customer entity that is named `AtlEntityCustomer`, for example, a reference to `customer` should be exposed as a property method on the `AtlEntitySalesOrder` entity.

```
public AtlEntityCustomer parmCustomer(AtlEntityCustomer _custTable = null)
```

The property method can be used as either a setter or a getter.

```
salesOrder.parmCustomer(customer); // setter

customer = salesOrder.parmCustomer(); // getter
```

Entity reference methods naming conventions

The `parm` prefix should be used to identify property methods. When you expose an entity reference property, use the UI name of the field instead of the Application Object Tree (AOT) name. If the UI name includes the `Id`, `Code`, or `Number` suffix, omit the suffix. For example, use `parmItem` instead of `parmItemNumber`.

Record references

If the customer entity hasn't yet been created and won't be created in the near future, the reference property should expose the corresponding record buffer (`CustTable`).

```
public CustTable parmCustomer(CustTable _custTable = null)
```

Record reference naming conventions

Use the same naming conventions that are used for entity references.

Id references

In addition to having an entity or record reference, you can introduce the `Id` reference property.

```
public CustAccount customerId(CustAccount _custTable = null)
```

Don't introduce `Id` references unless you also introduce corresponding entity or buffer references. `Id` references are shortcuts to the entity or buffer reference methods. The implementation of `Id` references should delegate the call to the entity or buffer reference.

Id reference naming conventions

Use the UI name if it includes terms such as `Id`, `Number`, `Account`, `Code`, or `Name`. Otherwise, add an appropriate suffix to the name of the entity or record reference.

Id reference methods contract

The `Id` reference method always uses the provided `Id` to find the referenced entity, and it delegates the call to the entity or record reference method. If no entity or record is found based on the specified `Id` value, an error message is thrown.

Fluent setter methods

Create fluent setter methods to support the fluent initialization and modification of entities.

Declaration example

```
public AtlEntitySalesLine setQty(SalesQty _qty)
```

Code example

```
salesLine.setItem(batchItem).setInventDims([warehouse]).setQty(10).save();
```

Naming convention

`set<PropertyName>`

In this naming convention, `<PropertyName>` should match what is used in the name of the corresponding property method.

Action methods

Entities represent not only data but also relevant actions. Actions can be implemented either as a simple action method or as a command object initializer.

Simple action methods

Simple action methods represent a complete action. They should not be fluently chained. The exception is the `save` method, which should be fluent.

Naming convention

`<ExecuteBusinessOperation>`

In this naming convention, `<ExecuteBusinessOperation>` is a verb that represents the business operation. It should be the same term that is used on the menu item in the UI.

Examples

```
salesOrder.save();

salesOrder.postInvoice();
```

Command object initializers

Command object initializers return a command object that lets you specify parameters of the command and run it.

```
transferLine.pick().setQty(10).setWMSLocation(bulkLocation).execute();
```

Naming convention

`<ExecuteBusinessOperation>`

In this naming convention, `<ExecuteBusinessOperation>` is a verb that represents the business operation. It should be the same term that is used on the menu item in the UI.

Examples

```
salesOrder.pick().execute();

purchaseOrder.register().execute();
```

Action entities

Some actions that are available for an entity can be considered entities themselves. Vendor invoices are one example. Before you post an invoice, you might want to set up parameters of the invoice, edit lines, and save the invoice for later. For these commands, you can introduce a separate entity class.

Naming convention

`new<ActionName>`

In this naming convention, `<ActionName>` is a noun that represents the business operation. The name should be the UI name of the business operation.

Example

```
receipt = transfer.newReceipt().setEditLines(true).setExplodeLines(true);
receipt.lines().withBatch(batch1).single().setReceiptQty(6).setScrapQty(1).save();
receipt.lines().withBatch(batch2).single().setReceiptQty(4).setScrapQty(1).save();
receipt.post();
```

Class naming convention

`AtlEntity<ModuleName><EntityName><ActionName>`

Example

```
AtlEntityInventTransferOrderReceipt
```

Adding components

Composition is a relationship where the composite entity has sole responsibility for the disposition of the component parts. The relationship between the composite and the component is a strong "has a" relationship, because the composite object takes ownership of the component. Therefore, the composite is responsible for creating and destroying the component parts.

An object instance can be part of only one composite. If the composite object is destroyed, all the component parts must be destroyed. The component parts have no independent existence outside the composite object, and they can't be transferred to another object. Composition enforces encapsulation, because the component parts are usually members of the composite object.

An example of a composite object is a source document that is made up of source document lines.

Example

In the source document example, the document entity serves as the composition root and is responsible for creating any new instances of document lines. In this case, the source document entity will have an `addLine()` method that initializes and returns a new line for the document.

```
public AtlEntitySalesLine addLine()
```

The `addLine()` method adds the line object (`salesLine` in this example) to a collection of lines and returns the parent entity (`SalesOrder` in this example) to preserve the fluency of application programming interfaces (APIs). To create a new line, create a `newLine()` method.

Naming convention for adding components

Methods for adding components should use the UI names of the buttons.

Example

```
salesLine = salesOrder.addLine();
```

Component collections

You can search for components by using query methods.

Naming convention for component collections

Methods for accessing component collections should use the UI names of the grid on the hosting page.

Query methods

Query methods on an entity let you search for components and related entities.

Example

```
transferOrderLine = transferOrder.lines().withItem(item).single();
```

In this example, `lines()` is a query method that returns the `AtlQueryTransferOrderLines` query. This query is already filtered so that it returns only transfer order lines for the transfer order that the `lines()` method was called on.

Naming convention

Use the UI names whenever you can. Abbreviations are acceptable if the UI name is too long to be used in test automation.

Example

```
public AtlQueryWHSLoadLines lines()
{
    return new AtlQueryWHSLoadLines().forLoadId(this.parmLoadId());
}
```

Additional resources

Queries in the Acceptance test library

Acceptance test library commands

2/18/2021 • 2 minutes to read • Edit Online

Command classes are responsible for running business operations. They let you use fluent application programming interfaces (APIs) to set the parameters of these operations.

Naming convention

`AtlCommand<ModuleName><EntityName><ExecuteBusinessOperation>`

In this naming convention:

- `<ModuleName>` is based on the names of the modules on the main menu. You should use a short version or an abbreviation to support brevity of test code.
- `<EntityName>` is optional and is used when the command applies to different types of entities.
- `<ExecuteBusinessOperation>` is a verb that represents the name of the business operation.

Examples

```
AtlCommandInventMark

AtlCommandSalesReturnOrderLineRegister
```

Implementation

Command objects that are returned should implement the `AtlICommand` interface and should inherit from the `AtlCommand` class.

Command objects should provide fluent setter methods that are used to set the parameters of the command.

Example

```
salesLine.pick().setInventDims([locationOut]).setQty(pickedQty).execute();
```

Fluent setter methods

Commands allow for two types of fluent setter methods, `for` methods and `set` methods:

- **for** – These methods are used for command parameters that represent the entities that the command applies to.

  For example, the invoice command can apply to sales orders. Therefore, a `for` method is used to set the sales order that the invoice command applies to.

- **set** – These methods are used for all other parameters of the command.

  For example, when you reserve a sales line, you usually specify a quantity. The quantity isn't something that the command applies to but is instead a simple parameter of the command. Therefore, a `set` method is used to specify the quantity parameter of the reservation command.

Naming convention

`for<CommandParameterName>`

`set<CommandParameterName>`

In this naming convention, `<CommandParameterName>` is the name of the parameter that is being set for the command by using the fluent method.

Examples

```
onHandAdjustment.forItem(item).setQuantity(10).execute();

picking.forSalesLine(salesLine).setInventDims([warehouse, batch1]).setQuantity(10).execute();
```

Creators in the Acceptance test library

2/18/2021 • 2 minutes to read • Edit Online

Creator classes provide fluent application programming interfaces (APIs) that are used to create test data.

Naming convention

`AtlCreator<ModuleName><EntityName>`

In this naming convention:

- `<ModuleName>` is optional and is based on the names of the modules on the main menu. You should use a short version or an abbreviation to support brevity of test code.
- `<EntityName>` is optional and is used when the command applies to different types of entities.

Examples

```
AtlCreatorCostGroup

AtlCreatorCustomer
```

Fluent setter methods

Creator classes should provide fluent setter methods that are used to set the properties of the entity that is being constructed.

Naming convention

`set<EntityPropertyName>`

In this naming convention, `<EntityPropertyName>` is the name of the property that is being set for the entity by using the fluent method.

Example

```
item = new AtlCreatorProductsReleasedVariant()
    .setItemId('DemoItem')
    .setColor(ecoResColor)
    .setStyle(ecoResStyle)
    .setConfig(ecoResConfig)
    .setSize(ecoResSize)
    .create();
```

When should creators be used instead of entities?

For information that will help you choose between entities and creators, see Should I implement an entity or a creator class.

NOTE

Can you tell us about your documentation language preferences? Take a short survey.

The survey will take about seven minutes. No personal data is collected (privacy statement).

Queries in the Acceptance test library

2/18/2021 • 2 minutes to read • Edit Online

A query class provides fluent application programming interfaces (APIs) that are used to find an instance of the corresponding entity, based on various criteria. Query classes are often used in validation scenarios. They are usually used together with specifications.

Naming convention

`AtlQuery<ModuleName><EntityNamePlural>`

In this naming convention:

- `<ModuleName>` is optional and is based on the names of the modules on the main menu. However, a short version or an abbreviation should be used to support brevity of test code.
- `<EntityNamePlural>` is the plural version of the entity name.

Examples

```
AtlQueryWHSLoadLines

AtlQueryInventTransferOrderLines
```

Implementation

Query classes inherit from the `AtlQuery` class that is common to all queries.

Fluent setters

Query classes should provide fluent setter methods to specify ranges for the query.

Example

```
loadLine = data.whs().loadLines().query().forSalesOrder(salesOrder).single();
```

Queries allow for two types of fluent setter methods, `for` methods and `with` methods:

- **for** – These methods are used for filters of the query that act as parents of composition or aggregation relationships. For example, the sales lines query exposes a `for` method to filter sales lines for a specific sales order.
- **with** – These methods are used for all other ranges of the query.

Naming convention

`for<QueryRangeName>`

`with<QueryRangeName>`

In this naming convention, `<QueryRangeName>` is the name of the field that the range is applied on.

Examples

```
loadLine = data.whs().loadLines().query().forLoad(load).withInventQty(10).single();

transferLine =
data.invent().transferOrderLines().query().forTransferOrder(transferOrder).withInventDims([batch1]).single()
;
```

NOTE

Can you tell us about your documentation language preferences? Take a short survey.

The survey will take about seven minutes. No personal data is collected (privacy statement).

Specification classes

2/18/2021 • 2 minutes to read • Edit Online

A specification class provides fluent application programming interfaces (APIs) that are used to define the set of criteria that an entity should meet. Specifications are often used in validation scenarios. They are usually used together with query classes.

An advantage of specification classes is that the validation code becomes very concise and expressive. Basically, you can do multiple validations in a single line of code.

Naming convention

`AtlSpec<ModuleName><#EntityName>`

In this naming convention:

- `<ModuleName>` is optional and is based on the names of the modules on the main menu. However, a short version or an abbreviation should be used to support brevity of test code.
- `<#EntityName>` represents the name of the entity that is used throughout the Acceptance test library (ATL).

Examples

```
AtlSpecWHSLoadLine

AtlSpecWHSWorkLine
```

Implementation

Specification classes should provide fluent setter methods to specify various criteria of the specification.

Example

The following code verifies that the work contains six lines that meet the specified criteria. For example, the first line should have **1** as the line number of **1**, **Pick** as the work type, **1** as the quantity, **Closed** as the status, and **bulk** as the location.

```
work.lines().assertExpectedLines(
    workLines.spec().withLineNum(1).withWorkType(WHSWorkType::Pick).setQuantity(1)
        .setStatus(WHSWorkStatus::Closed).setLocation(locations.bulk()),
    workLines.spec().withLineNum(2).withWorkType(WHSWorkType::Pick).setQuantity(1)
        .setStatus(WHSWorkStatus::Closed).setLocation(locations.floor()),
    workLines.spec().withLineNum(3).withWorkType(WHSWorkType::Put)
        .setQuantity(2).setStatus(WHSWorkStatus::Closed).setLocation(locations.stage()),
    workLines.spec().withLineNum(4).withWorkType(WHSWorkType::Pick).setQuantity(2)
        .setStatus(WHSWorkStatus::Cancelled).setLocation(locations.stage()),

workLines.spec().withLineNum(5).withWorkType(WHSWorkType::Put).setQuantity(2).setStatus(WHSWorkStatus::Cance
lled)
);
```

NOTE

Can you tell us about your documentation language preferences? Take a short survey.

The survey will take about seven minutes. No personal data is collected (privacy statement).

Acceptance test library Code generation wizard

2/18/2021 • 2 minutes to read • Edit Online

The Acceptance test library (ATL) code generator quickly generates and updates new ATL entities, queries, and specifications, based on tables and data entities.

Create the AtlEntity class by using the wizard

Follow these steps to create the `AtlEntity` class by using the **Code generation** wizard.

1. In Microsoft Visual Studio, open the table in the designer window.
2. Right-click the name of the table, and then, on the **Add-ins** menu, select **Generate ATL Entity**.
3. Select the fields that should be included in the `AtlEntity` class, and then select **Add**.
4. Rename the entity and the fields as you require.
5. Select **Generate** to create the class.

Additional optional steps

When you create the `AtlEntity` class, you can also complete these tasks:

- Add required actions for the scenario.
- Add a `default` method to `AtlData` classes.
- Override the `setMainRecordField` method to call the `modifiedField(_fieldId)` method on the table.

```
protected void setMainRecordField(FieldId _fieldId, anytype _value)
{
    super(_fieldId, _value);
    common.modifiedField(_fieldId);
}
```

Create the AtlQuery class by using the wizard

Follow these steps to create the `AtlQuery` class by using the **Code generation** wizard.

1. In Visual Studio, open the table in the designer window.
2. Right-click the name of the table, and then, on the **Add-ins** menu, select **Generate ATL Query**.
3. Select the fields and relations that should be included in the `AtlQuery` class, and then select **Add**.
4. Rename the query, the fields, and the relations as you require.
5. Select **Generate** to create the class.

Additional optional steps

When you create the `AtlQuery` class, you can also add a `query` method to the `AtlData` class that returns an instance of the `AtlQuery` class that you created earlier in this topic.

Create the AtlSpec class by using the wizard

Follow these steps to create the `AtlSpec` class by using the **Code generation** wizard.

1. In Visual Studio, open the table in the designer window.
2. Right-click the name of the table, and then, on the **Add-ins** menu, select **Generate ATL Specification**.

3. Select the fields that should be included in the `AtlSpec` class, and then select **Add**.
4. Rename the specification and the fields as you require.
5. Select **Generate** to create the class.

Additional optional steps

Add a `spec` method to the data class that returns an instance of the `AtlSpec` class that you created earlier in this topic.

Best practices for the Acceptance test library

2/18/2021 • 2 minutes to read • Edit Online

Use var and declare variables inline

- Use the `var` keyword (type inference).
- Declare variables inline instead of in a separate statement.

Do this

```
var item = items.default();
var salesOrder = data.sales().salesOrders().createDefault();
var salesLine = salesOrder.addLine().setItem(item).setInventDims([warehouse]).setQuantity(10).save();
```

Don't do this

```
InventTable item;
AtlEntitySalesOrder salesOrder;
AtlEntitySaleOrderLine salesLine;
…
item = items.default();
salesOrder = data.sales().salesOrders().createDefault();
salesLine = salesOrder.addLine().setItem(item).setInventDims([warehouse]).setQuantity(10).save();
```

Justification

The advantages of using `var` are that you write less code, you don't have to remember exact type names, and the test logic isn't cluttered with unimportant information. Overall, the test code easier to read.

In the previous example, it doesn't matter whether `item` is of the `ItemId`, `InventlTable`, or `AtlEntityInventItem` type. The important detail is that you're creating a sales line that has a well-known default item. The exact types of the `salesOrder` and `salesLine` variables aren't important. The contracts of these types are clear from the naming and usage.

Considerations

- Don't use type inference if you want compilation to fail if the return type of a method changes.
- Don't use type inference if you can't invent meaningful variable or method names.

Use entities instead of IDs as method parameters

Well-known data methods, creator methods, and `init` methods usually return records or entities instead of IDs. We recommend that you use records or entities as method parameters.

Do this

```
var salesLine = salesOrder.addLine().setItem(item).save();
```

Don't do this

```
var salesLine = salesOrder.addLine().setItemId(item.ItemId).save();
```

Justification

The code is easier to read, because it isn't cluttered with unimportant technicalities.

Considerations

If you know only the ID, use the method that takes the ID as an argument.

Use navigation node shortcuts

When you automate a new domain area, introduce a base class that holds shortcuts to the most frequently used navigation objects in that area.

For example, for the warehouse management area, there is a base class that is named `AtlWHSTestCase`. It contains shortcuts to `data.whs()`, `data.invent()`, `data.invent().items()`, `data.invent().units()`, and other navigation objects. The shortcuts simplify your test code.

```
class AtlWHSTestCase extends SysTestCase
{
    AtlDataRootNote          data;
    AtlDataInvent            invent;
    AtlDataInventOnHand      onHand;
    AtlDataProductItems      items;
    AtlDataWHS               whs;

    protected void initDataSetupReferences()
    {
        data = new AtlDataRootNode();
        invent = data.invent();
        onHand = data.invent().onHand();
        items = data.invent().items();
        whs = data.whs();
```

It also makes sense to introduce shortcuts that are shared among many test methods in the same class.

Do this

```
class WHSMinMaxReplenishmentScenarioTest extends AtlWHSTestCase
…
    var item = items.default();
    var warehouse = invent.warehouses().default();
```

Don't do this

```
class WHSMinMaxReplenishmentScenarioTest extends SysTestCase
…
    var item = data.invent().items().default();
    var warehouse = data.invent().warehouses().default();
```

Considerations

You don't have to create a shortcut for every navigation node that you need. However, consider creating them for the navigation nodes that are frequently used.

Acceptance test library FAQ

2/18/2021 • 2 minutes to read • Edit Online

Which fluent prefix should I use: set, for, or with?

Depending on the class that you want to add a fluent method to, different rules might apply:

- Entities
- Creators
- Commands
- Queries
- Specifications

Should I implement an entity or a creator class?

For most entities, the effort of creating an entity class is the same as the effort of creating a creator class. Therefore, the entity class should be created. However, in some cases, the process of creating an entity might not be straightforward. A good example is the Item entity. Because more than ten different tables make up the Item entity, it's hard to create the entity class. Because you will almost never have to update existing items in your test cases, it's OK if you just have a creator class, which is much easier to implement.

Does the order of the chained fluent setters matter?

In most of the cases, the order of the chained fluent setters doesn't matter. However, be aware that defaulting occurs at the time of the call to the setter method. Therefore, a change in the order of the methods can produce different results. Here is an example for the sales line.

Option 1

```
salesLine.setQuantity(10).setUnitPrice(100).setAmount(2000).save()
```

This option produces a sales line where the amount == 2,000, because the amount is set last.

Option 2

```
salesLine.setAmount(2000).setQuantity(10).setUnitPrice(100).save()
```

This option produces a sales line where the amount == 1,000, because after you set the unit price, the amount is set to quantity × price by default.

Can I use ATL for tests that run on the empty data set?

The Acceptance test library (ATL) can be used on the empty data set without issues. The automatic setup of prerequisites is done on demand. For example, prerequisites for invoice posting will be set up only during the first call to `salesOrder.postInvoice()`. For more information, see Ensure.

`Ensure` methods can also be called in the `setUpTestCase` method to improve performance if more than one test in your test class must post invoices.

Can I use ATL for unit tests?

ATL should be used mostly for data setup and validation in integration and component tests. However, in some cases, it's also used for unit tests.

Why should I be cautious about using ATL in unit and component tests?

In some of the more complex entities, such as Sales order, all the business logic that is associated with the `modifiedField`, `insert`, and `update` events is called. Creation of invoice transactions, for example, is also done by running real invoice posting logic. Therefore, the performance of some operations will be slow. However, these issues don't occur for most of the entities that represent master data. Therefore, you should be able to use those entities in any type of test.

There should not be significant overhead if specifications and queries are used to do validation. These artifacts can also be used in unit tests.

Date effectivity

2/18/2021 • 8 minutes to read • Edit Online

This topic provides information about date-effective data entities and data sources, and shows how to create a date-effective entity. It also explains how date effectivity applies to read and write activities.

There are different design patterns for date-effective features that involve data entities. The patterns are classified into two main categories:

- **Date-effective entities** – The entity has at least one date-effective data source, and the entity itself is also date effective.
- **Non-date-effective entities** – The entity itself is not date effective, but it does contain date-effective data sources.

The next sections describe the small list of properties and methods that control the date-effective behavior of entities and their date-effective data sources.

Date-effective entities

The following table describes the properties that control the date-effective behavior of a data entity.

PROPERTY NAME OF THE ENTITY	NODE OF THE PROPERTY	VALUE	DESCRIPTION
ValidTimeStateEnabled	Data entity node in the designer	Yes (or No)	The value **Yes** makes the entity date effective. The entity must have **ValidFrom** and **ValidTo** fields. These fields are mapped to the **ValidFrom** and **ValidTo** fields of a date-effective data source. The value **No** does *not* disable the enforcement of date effectivity on any date-effective tables that are data sources of the entity.
ValidTimeStateKey	Under the data entity node, **Keys** > **EntityKey**	Yes (or No)	The value **Yes** identifies the key that is required to enforce the date-effective values on this particular entity.

Read activities

When date effectivity is set at the data entity level, reads from the entity behave the same way as reads from a table. The entity has **ValidFrom** and **ValidTo** fields that the system applies date filters to during reads.

Query modes and the validtimestate keyword of X++ SQL select

A date-effective entity supports the following three *query modes*, which vary in their use of the X++ **validtimestate** keyword:

- **Default mode** – Current records are returned using `select * from FMVehicleRateEntity; // X++ SQL.`

- **AsOfDate mode** – Records valid for the specified date are returned using `select validtimestate(d1) * from FMVehicleRateEntity;`
- **AsOfDateRange mode** – Records valid for the specified date range are returned using `select validtimestate(d1,d2) * from FMVehicleRateEntity;`

Important: For data entities that aren't themselves date effective, but that have a data-effective data source, only the default query mode is available. This concept is discussed later in this article.

Applying a date filter at the data source level

There are scenarios where date-effective filtering is required outside the data entity, at the data source level. For example, the customer entity (CustTableTestEntity) contains CustTable and LogisticsPostalAddress as data sources, where LogisticsPostalAddress is a date-effective table and CustTable is a regular table. The purpose of a customer entity is to have a list of customers and their active primary addresses, if they have primary addresses. Therefore, the customer entity itself isn't date effective, but it requires date filters on one of the data sources. In this case, the entity isn't marked **ValidTimeStateEnabled**. Instead, an **Apply Date Filter** property is added on the data source. If the value of **Apply Date Filter** is set to **Yes**, date filters are automatically applied to that data source. The following table describes the properties that control the date-effective behavior of a date-effective data source of a data entity.

PROPERTY NAME OF THE DATA SOURCE	NODE OF THE PROPERTY	VALUE	DESCRIPTION
Apply Date Filter	Node of any particular data source of the entity	Yes (or No)	For *reads*, this property controls whether date filters are applied on the entity data source. In this case, the data source should be marked **ValidTimeStateEnabled**. This property value has effect regardless of whether the entity itself is date effective. For *writes*, this property has no effect.

This article describes the use of these date-effective properties and the interactions between them.

State matrixes for reads

This section concerns only reads from the data entity. The following pair of reference matrixes describe the combinations of date-effective states that can exist between a data entity and its data source. Each table contains four cases, and each case discusses two distinct targets. Here are the primary points that you should understand:

- On any given read from the entity, the query mode is the same for both the entity and date-effective data sources.
- If the entity is not date effective, the query mode is limited to the default mode. Therefore, the date-effective data source is accessed only for the current date.
- On the date-effective data source, the **Apply Date Filter** property can be set to **No** to make the data source return all data – past, current, and future.
- For OData, date-effective filters are not applied to the data entity. However, filters on the data source are applied at all code paths.

A. Entity *is* date effective, because ValidTimeStateEnabled = Yes

Data source *is* date effective

Data source is *not* date effective

Apply Date Filter = Yes

- **Entity:** Date filters are applied. Any query mode is supported.
- **Data source:** Filters are applied. Any query mode is supported, but the mode is the same as is coded for the entity.

Non-date-effective data sources aren't affected.

Apply Date Filter = No

- **Entity:** Date filters are applied. Any query mode is supported.
- **Data source:** No date filters are applied.

Non-date-effective data sources aren't affected.

B. Entity is *not* date effective, because ValidTimeStateEnabled = No

Data source *is* date effective

Data source is *not* date effective

Apply Date Filter = Yes

- **Entity:** No date filters are applied.
- **Data source:** Date filters are applied. Only the default query mode is supported, where the X++ **validtimestate** keyword is omitted.

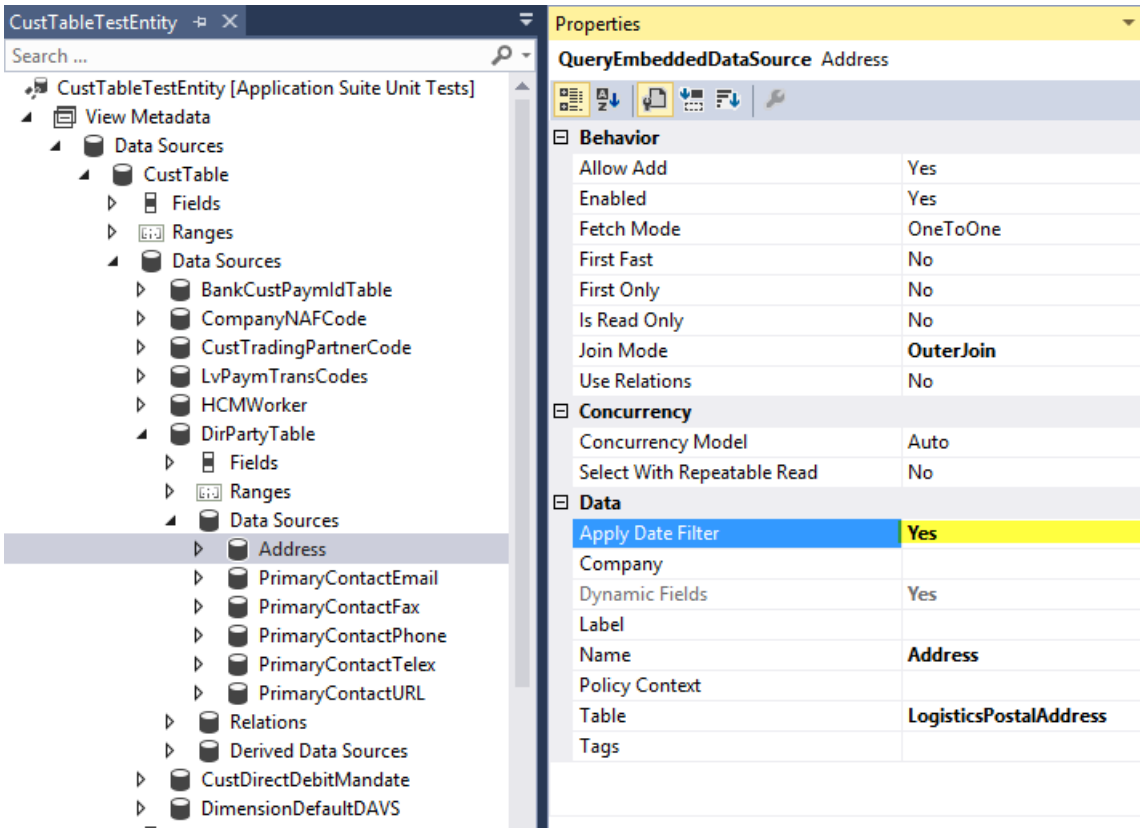
Non-date-effective data sources aren't affected.

Apply Date Filter = No

- **Entity:** No date filters are applied.
- **Data source:** No date filters are applied.

Non-date-effective data sources aren't affected.

The following screen shot shows the **Apply Date Filter** property set to **Yes**. Therefore, date filters will be applied to reads of the **Address** data source.



Write activities

This section describes your options for configuring the behavior of date-effective entities and their date-effective data sources. We will start by reviewing the concept of date-effective tables and contrasting them with date-effective entities. **Date-effective table:** When data is inserted or updated in a date-effective table, the process has the option of calling the **xRecord.validTimeStateUpdateMode** method on the table buffer. The method accepts an element of the **ValidTimeStateUpdate** enumeration. Here are the available element values:

- CreateNewTimePeriod
- Correction
- EffectiveBased

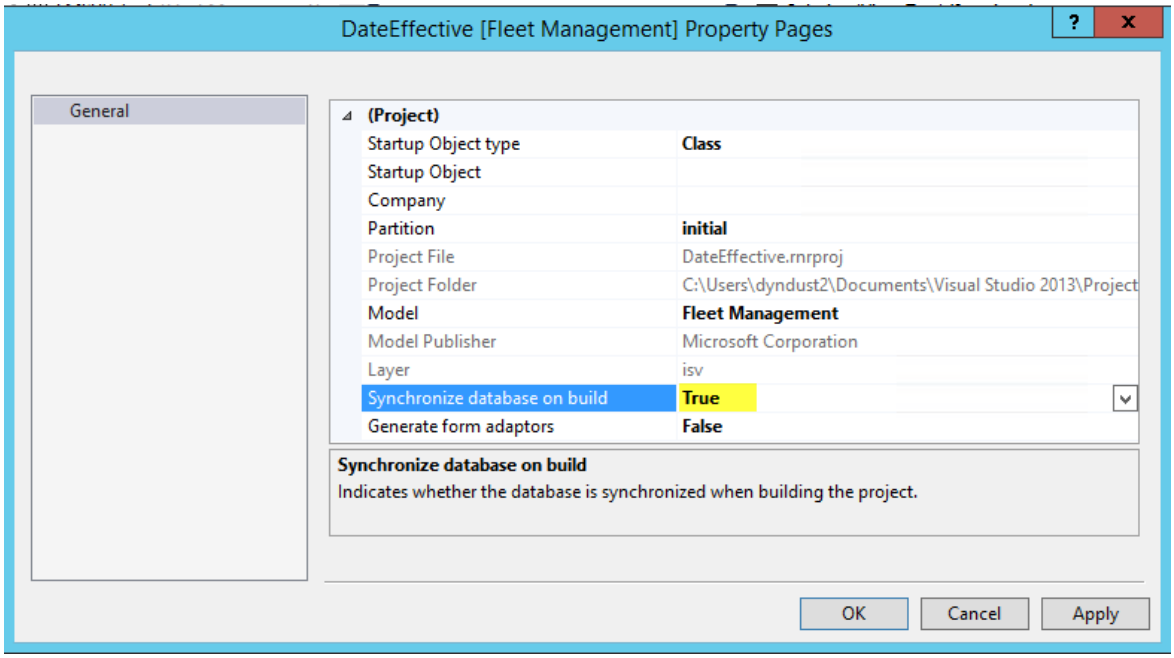
Date-effective entity: By contrast, when data is inserted or updated in a date-effective data entity, the **validTimeStateUpdateMode** method isn't used at the entity level. For writes, the data entity leaves the date-effective processing to the table level. You can use the **Valid Time State Update** property on the entity data source to specify the **validTimeStateUpdateMode** method to use for each data source of the data entity.

Creating a date-effective entity

This section shows how to create a date-effective entity.

Create a new project

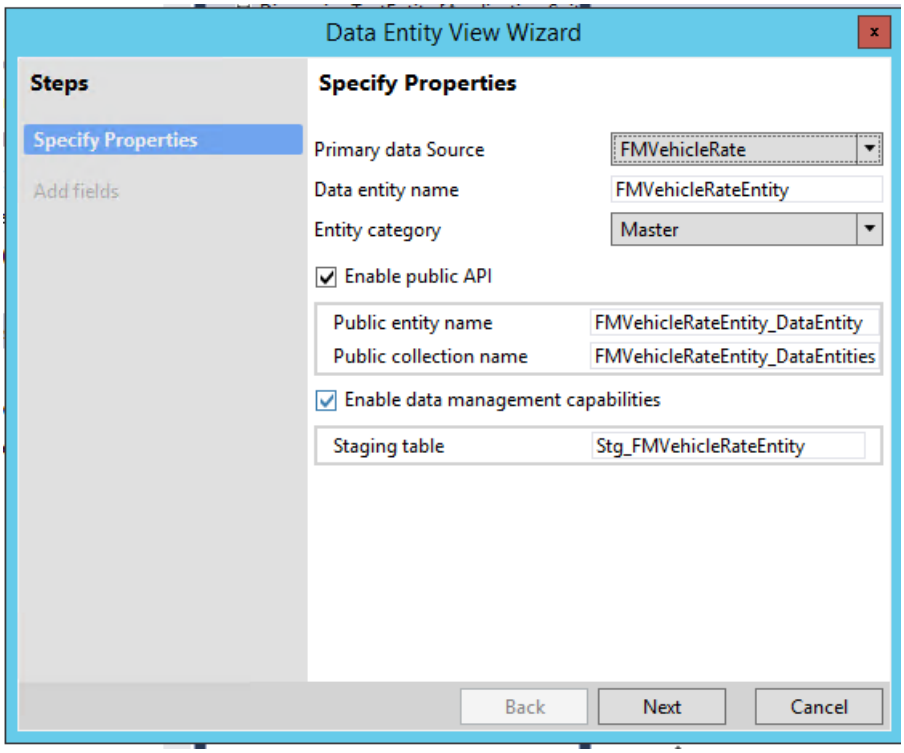
1. Click **File** > **New** > **Project** to create a new project.
2. In Solution Explorer, right-click your project, and then click **Properties**. The **Property Pages** dialog box for your project opens.
3. Change the value of the **Synchronize database on build** property to **True**, and then click **OK**. You must set this property only one time per project.



Add a new data entity to your project

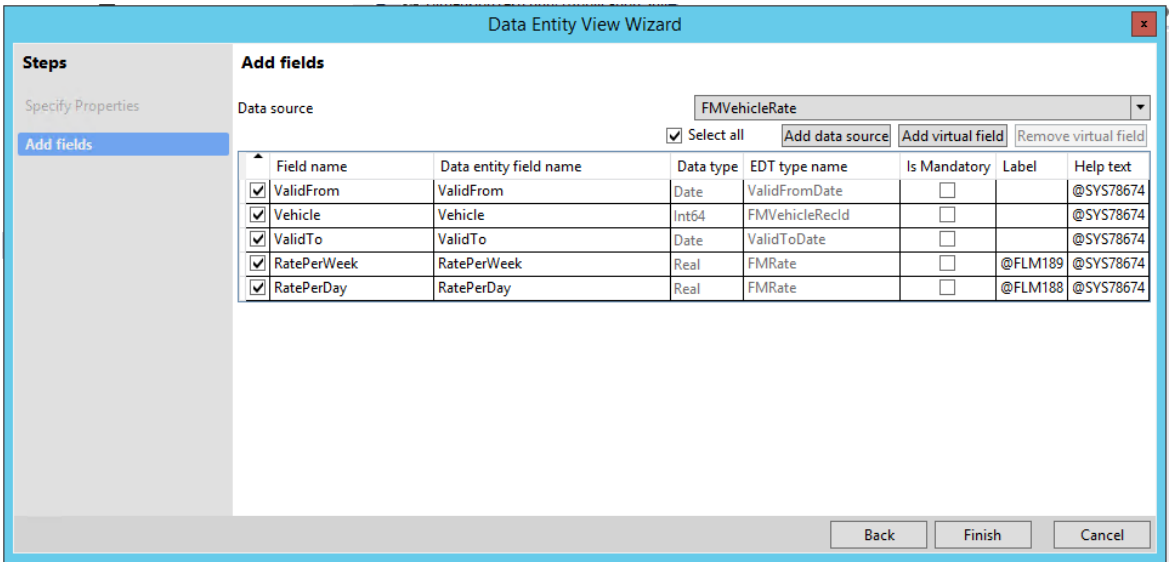
Create a new entity that is named **FMVehicleRateEntity**, and add it to the project.

1. In the left pane, select **Microsoft Dynamics 365 Artifacts**, and then click **Data Entity** in the left column of the main pane.
2. Click **Add**. The **Data Entity View** wizard starts.
3. Specify the property values for the data entity that you are creating, as shown in the following screen shot. The most important field is **Primary data source**, where you select **FMVehicleRate**.

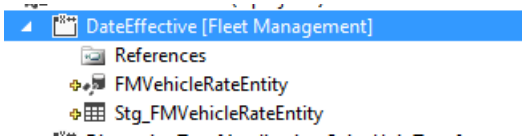


Click **Next**.

4. Add fields to the entity from the primary data source, **FMVehicleRate**.
5. Select all fields, and then click **Finish**.



The items are added to the project in Solution Explorer.

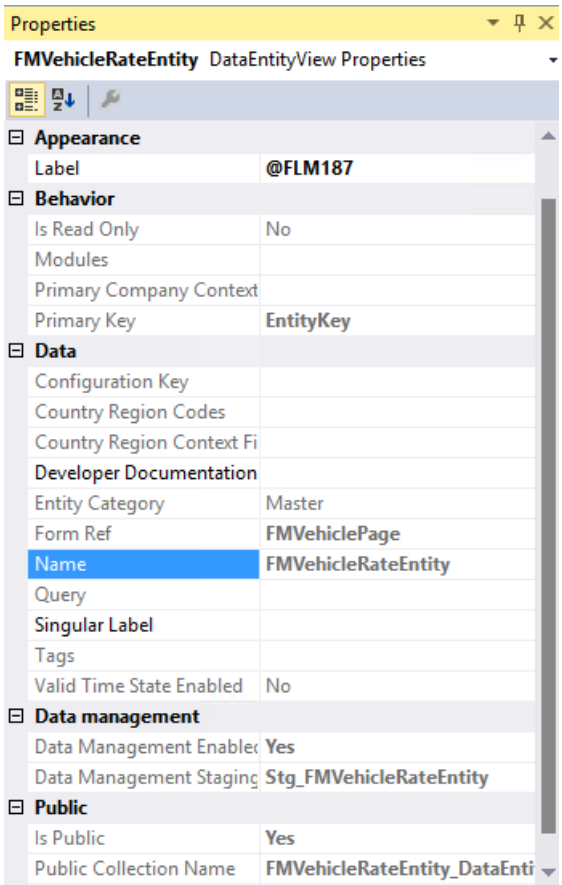


Build your project

1. Click **Build** > **Build Solution** to build your project.
2. Verify that the build has no errors. Warnings should be tolerated at this stage in the process.

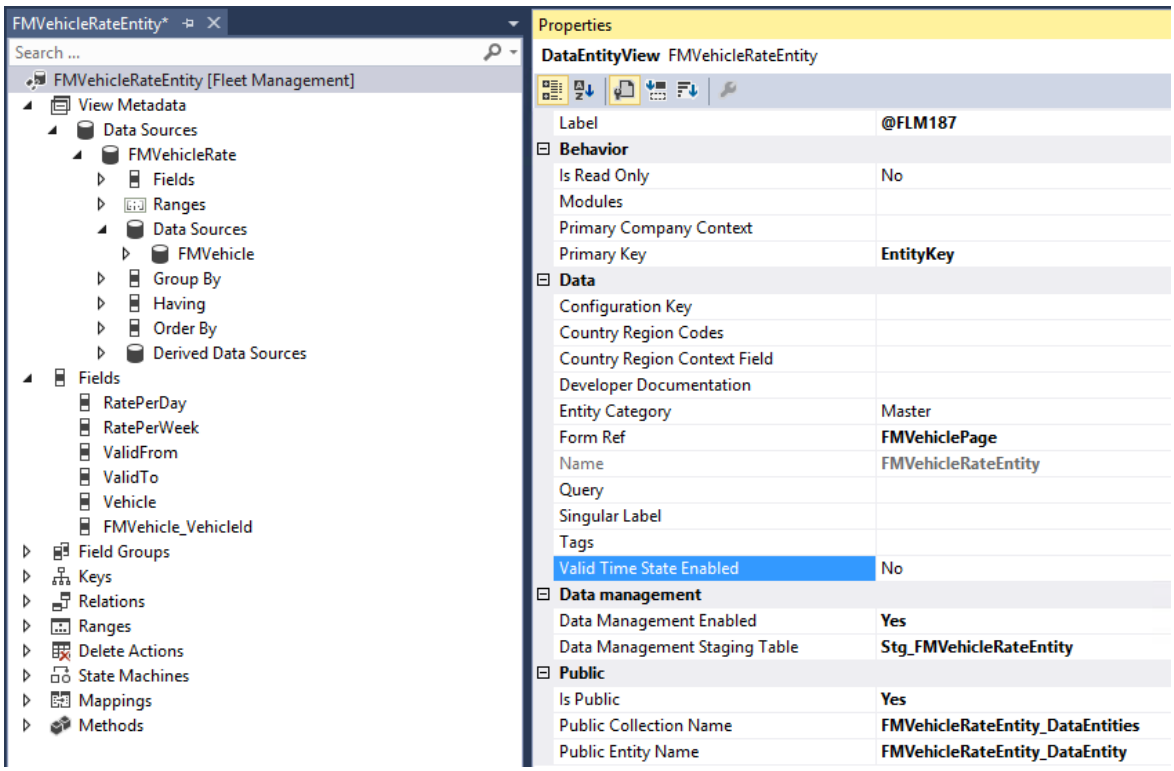
Validate the property values

- In Solution Explorer, select the **FMVehicleRateEntity** node, and validate the properties of the **FMVehicleRateEntity** entity by comparing them to the values in the **Properties** pane.

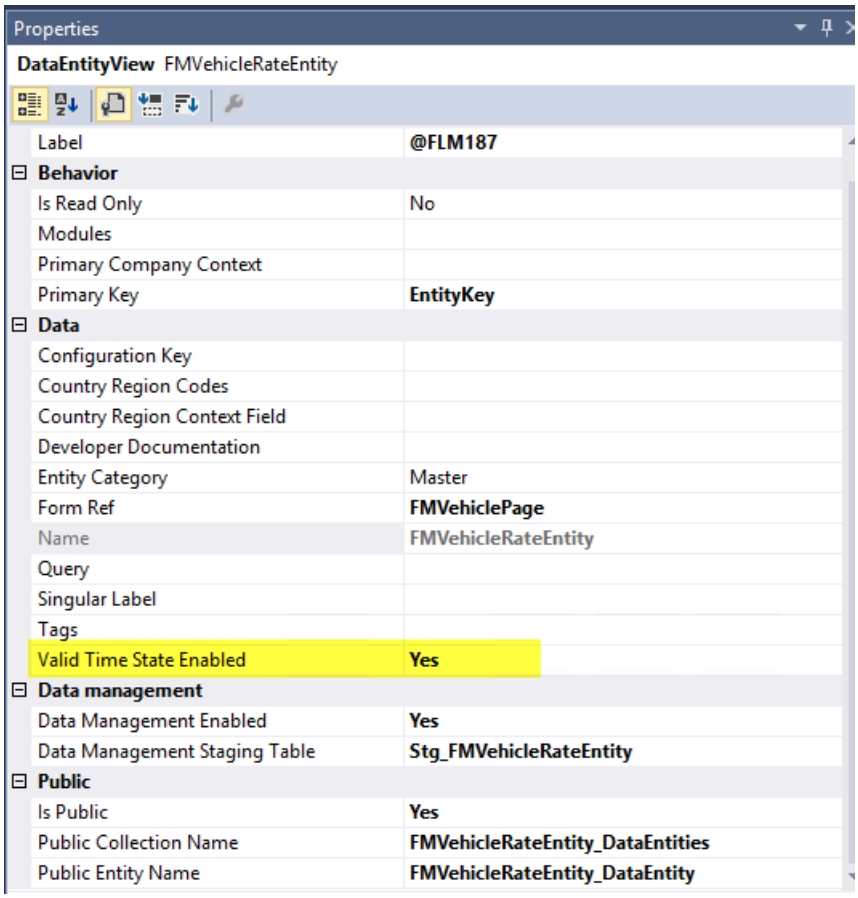


Make your entity date effective

1. In Solution Explorer, right-click the **FMVehicleRateEntity** node, and then click **Open**. The designer for the entity opens in the middle pane.

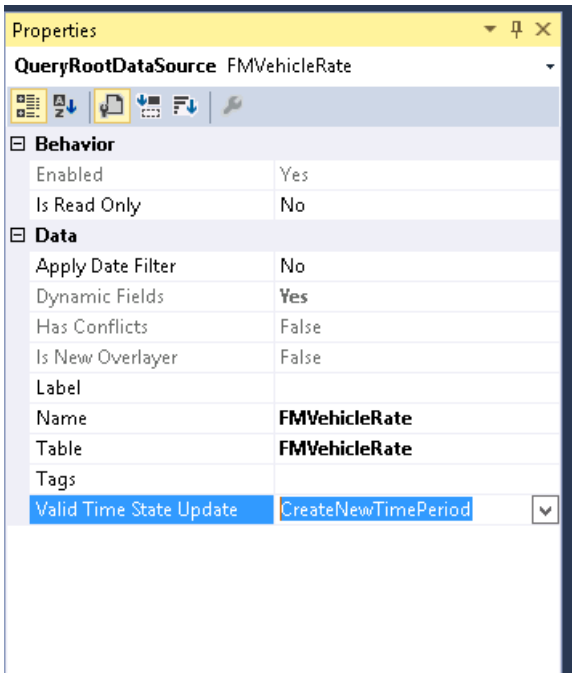


2. Change the value of the **Validate Time State Enabled** property to **Yes**.



Configure the Valid Time State Update property for the date-effective data source

- Select the **FMVehicleRate** data source, and then set the **Valid Time State Update** property to **CreateNewTimePeriod**.



Test your project

- Build your project again, and run the following X++ code to test your project.

```
/// <summary>
    /// Runs the class with the specified arguments.
    /// </summary>
    /// <param name = "_args">The specified arguments.</param>
    public static void main(Args _args)
    {
        FMVehicleRateEntity FMVehicleRateEntity;
        FMCarClass          vehicle;
        FMVehicleModel      model;
        FMVehicleRate       vehicleRateTable;
        TransDate           d1=1\1\1999,d2=31\12\2014;

        ttsbegin;

        select count(RecId) from FMVehicleRateEntity;
        info(strfmt("Entity - Valid today before insert %1",FMVehicleRateEntity.RecId));

        select count(RecId) from vehicleRateTable;
        info(strfmt("Table - Valid today before insert %1",vehicleRateTable.RecId));

        select firstonly model;

        vehicle.VehicleModel = model.RecId;
        vehicle.VehicleId = "TestV1001";
        vehicle.insert();

            if (vehicle)
            {
                FMVehicleRateEntity.clear();
                FMVehicleRateEntity.FMVehicle_VehicleId = vehicle.VehicleId;
                FMVehicleRateEntity.ValidFrom = d1;
                FMVehicleRateEntity.ValidTo = d2;
                FMVehicleRateEntity.RatePerDay = 100;
                FMVehicleRateEntity.RatePerWeek = 600;
                FMVehicleRateEntity.insert();

                // Should increase by one as compared to before insert numbers
                select count(RecId) from FMVehicleRateEntity;
                info(strfmt("Entity - Valid today after insert %1",FMVehicleRateEntity.RecId));

                // Should increase by one as compared to before insert numbers
```

```
            select count(RecId) from vehicleRateTable;
            info(strfmt("Table - Valid today after insert %1",vehicleRateTable.RecId));

            // New record should show in count
            select validtimestate(d1) count(RecId) from FMVehicleRateEntity;
            info(strfmt("Entity - Valid 1999 %1",FMVehicleRateEntity.RecId));

            // New record should show in count
            select validtimestate(d1) count(RecId) from vehicleRateTable;
            info(strfmt("Table - Valid 1999 %1",vehicleRateTable.RecId));

            // update newly created record
            // This should split record into two - 2009 to Today, today to 2014
            // Split happens because of mode in saveEntityDatasource
            select forupdate validtimestate(d1,d2) FMVehicleRateEntity
                 where FMVehicleRateEntity.FMVehicle_VehicleId == vehicle.VehicleId &&
                       FMVehicleRateEntity.ValidFrom == d1 &&
                       FMVehicleRateEntity.ValidTo == d2;
            FMVehicleRateEntity.RatePerDay = 200;
            FMVehicleRateEntity.update();

            // validate the split
            while select validtimestate(d1,d2) FMVehicleRateEntity
                 where FMVehicleRateEntity.FMVehicle_VehicleId == vehicle.VehicleId
            {
                info(strfmt("Entity - %1 to %2 , RatePerDay-%3, RatePerWeek-%4",
                       FMVehicleRateEntity.ValidFrom,
                       FMVehicleRateEntity.ValidTo,
                       FMVehicleRateEntity.RatePerDay,
                       FMVehicleRateEntity.RatePerWeek));
            }
            ttsabort;
        }
    }
```

Independent software vendor (ISV) licensing

2/18/2021 • 11 minutes to read • Edit Online

This topic describes the independent software vendor (ISV) licensing feature. It includes information about benefits and capabilities of the ISV licensing feature, and explains how to enable licensing for an ISV solution, create a package and generate a customer-specific license, and create self-signed certificates for test purposes.

The Microsoft Dynamics ecosystem provides tools and frameworks that let independent software vendors (ISVs) build, deploy, sell, and therefore monetize vertical industry solutions that can be repackaged. The ISV licensing feature provides the following benefits:

- It provides a safer licensing mechanism for ISV solutions for customers and partners. ISV solutions are enabled only if the customer has purchased a valid license key from the ISV.
- It aligns how customers handle licenses for ISV solutions from different ISVs, and therefore lowers the total cost of ownership (TCO).
- ISVs can independently generate, manage, and distribute ISV licenses by using industry standard frameworks.

This feature doesn't enable ISV competitor copycat protection (that is, source-based protection).

Capabilities

This section describes various capabilities of the ISV licensing feature.

ISVs can generate their own licenses

ISVs can independently generate their own licenses, apply them to solutions, and deliver those solutions to partners and customers. Each ISV license enables run-time features that help protect the ISV solution. Additionally, each ISV license is tied to an ISV Authenticode certificate, which ensures that the software was distributed by the ISV.

A run-time check makes sure that an ISV-generated license key exists in the customer's environment

Each ISV solution that is tied to a license runs only when a valid license key exists in the customer's environment. Therefore, if an ISV ties its solution to a license, but the customer doesn't have a valid license key, the solution doesn't run.

There are two types of license: Boolean and Number

ISVs can create two types of license: **Boolean** and **Number**. ISVs can associate an expiration date with either type of license. This expiration date is applied only to the ISV licenses and is independent of the system expiration date. A Boolean license is a simple activation license. The type of license (**Boolean** or **Number**) is set through a property in the license code node. ISVs can write their own custom logic to check the count that is provided in the ISV license, to make sure that their solutions are being used within the license terms. For more information, see Licensing Framework for ISVs.

License validation errors

When an ISV license becomes invalid after import, the ISV solution continues to run until the server is restarted. (After the server is restarted, the solution is disabled.) An error is thrown when the instance of the Application Object Server (AOS) starts. The error is written to the event log.

Implementing ISV licensing in a solution

ISVs must have a valid Authenticode certificate (X.509) from a certificate authority (CA). Microsoft doesn't

recommend any particular CA. However, many companies offer these certificates. Authenticode certificates come in various key sizes. The ISV licensing feature supports certificates of both 1024-bit and 2048-bit key sizes. By default, many providers use the 2048-bit key size, and we recommend that ISVs use this bit key size, because it provides stronger encryption. However, if an ISV already has an existing 1024-bit key size, that key size works with the ISV licensing feature.

> **NOTE**
>
> The ISV licensing feature doesn't support 4096-bit key sizes. Authenticode certificates can have various cryptographic service providers. The ISV licensing feature uses Enhanced Cryptographic Provider (which also covers Base Cryptographic Provider). There are many independent providers that you can purchase an Authenticode certificate from. Microsoft doesn't recommend any particular provider. Some providers that are often used are Symantec VeriSign, Thawte, and Go Daddy.

Certificate import and export

The certificate is used to sign your customer license files and validate the license files at the time of import. Authenticode certificates support four file formats. For the ISV licensing feature, you must have the certificate files in two formats:

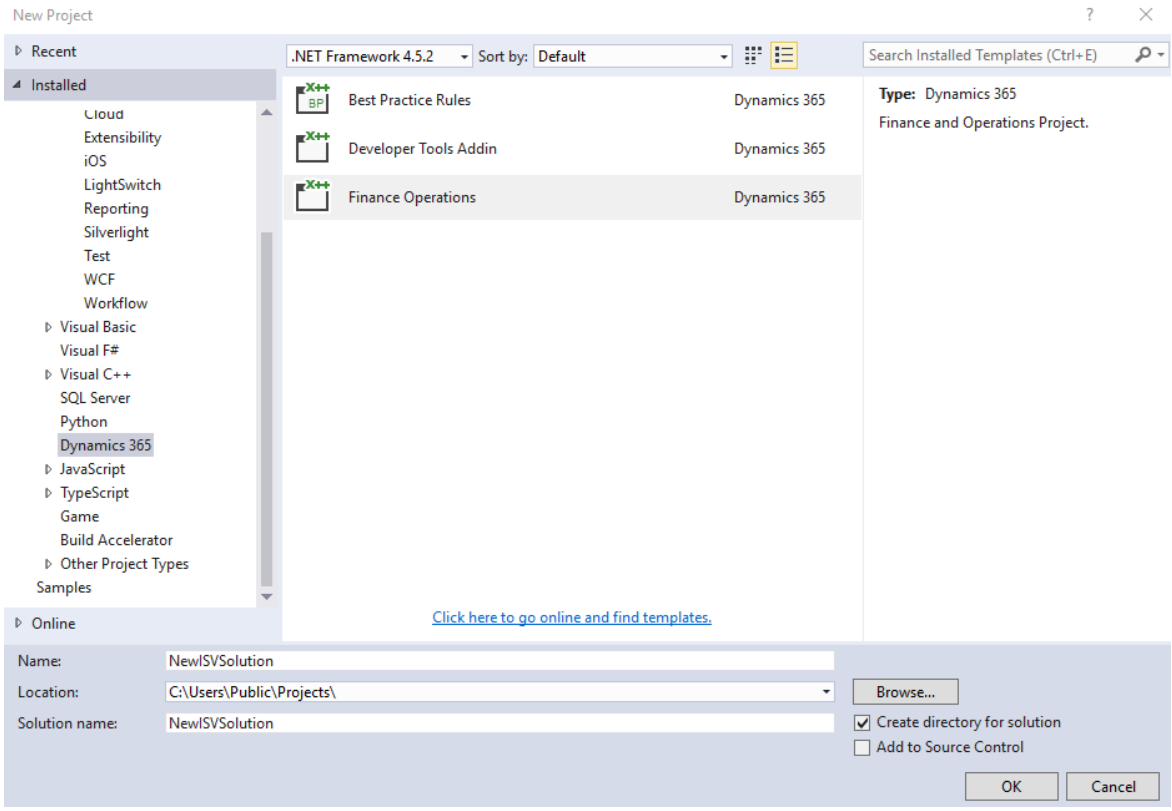
- **Personal Information Exchange (PFX, also known as PKCS #12)** – The PKCS #12 format, which uses the .pfx file name extension, supports secure storage of certificates, private keys, and all certificates in a certification path. The PKCS #12 format is the only file format that can be used to export a certificate and its private key.
- **Base64-encoded X.509** – The Base64 format supports storage of a single certificate. This format doesn't support storage of the private key or certification path.

There is a restriction on the format. The PFX (PKCS #12) format should be used only to export the certificate together with its private key for signing/generating purposes. It should never be shared outside the ISV organization. The DER-encoded binary X.509 format, which uses the .cer file name extension, should be used to export the public key of the certificate that must be embedded in the Application Object Tree (AOT) License. This public key is distributed to customers via the model. It's used when a license is imported, to make sure that the license is signed by the ISV license that owns the private key.

Enable licensing for your ISV solution

Follow these steps to enable licensing for your solution.

1. Create an ISV solution. In Visual Studio, click **File > New project**. In the **New Project** dialog, click **Installed > Templates > Dynamics 365**. Create a **Finance Operations** project. In this example, we named the project **NewISVSolution**.

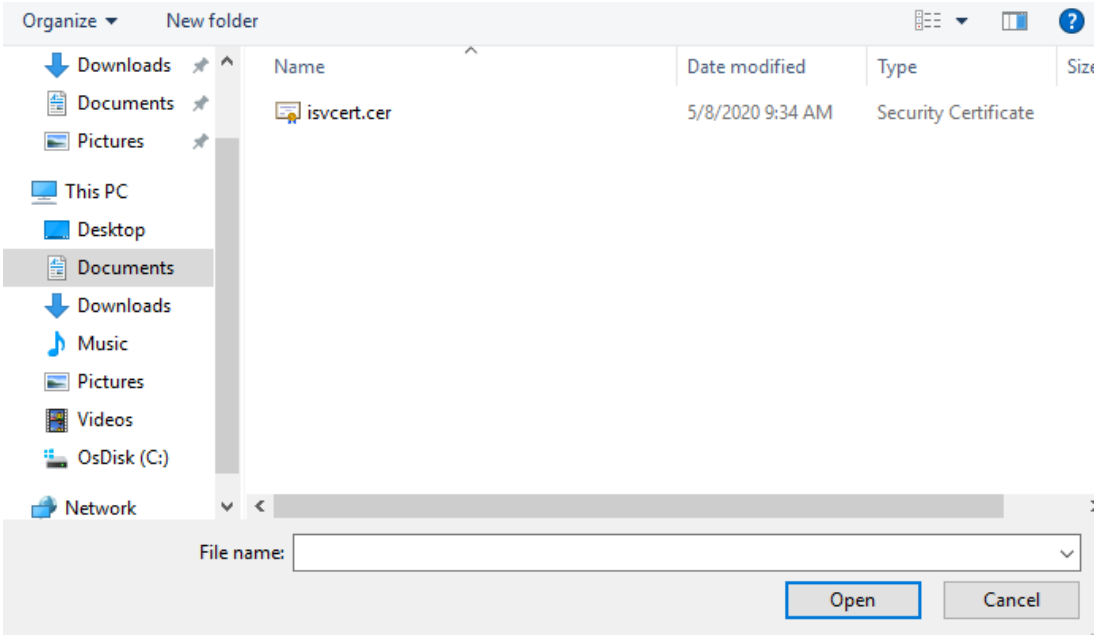


2. Add the certificate's public key (.cer file) to your project as a resource. To create a certificate for testing, see Appendix: Create self-signed certificates for test purposes.

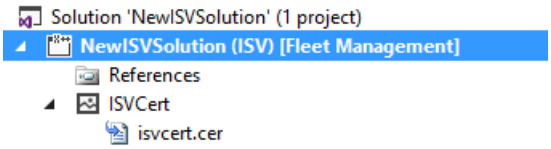
   a. Right-click the project in Solution Explorer, then click **Add > New item**.

   b. Under **Installed > Dynamics 365 Items**, click **Labels And Resources**, and then select **Resource**. Name the resource. In this example, we named the resource **ISVCert**.

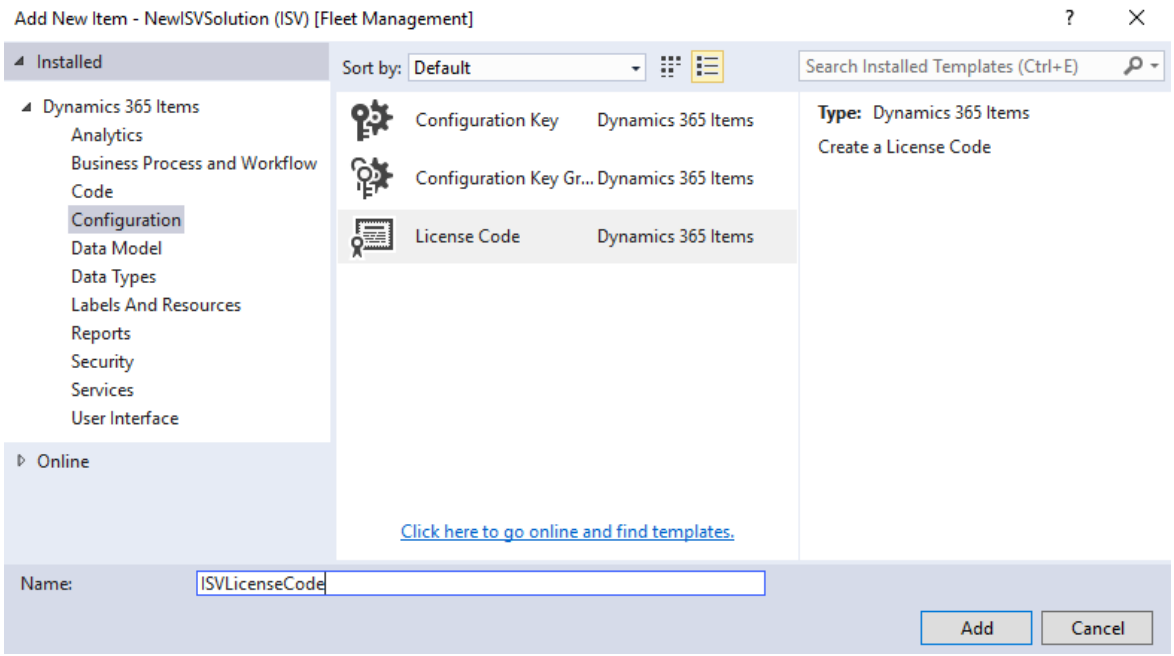
   c. Click **Add** and select the certificate's public key file (.cer file).



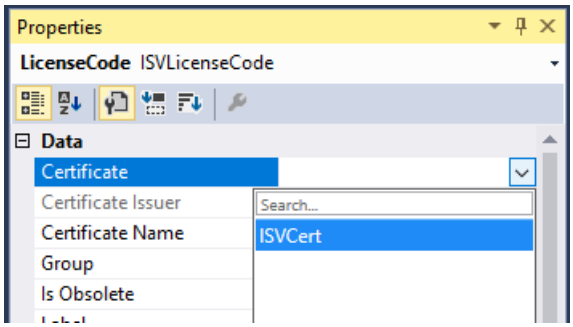
d. Click **Open** to add the certificate.



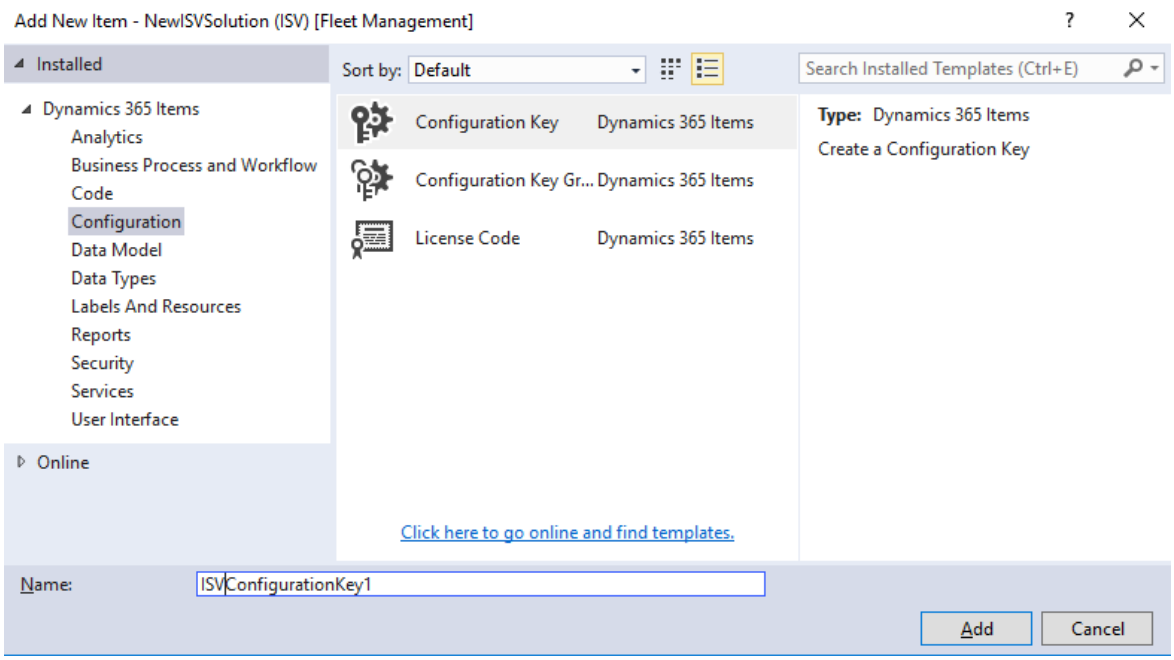
3. Create a license code. Right-click the project in Solution Explorer, then click **Add > New item**. Under **Installed > Dynamics 365 Items**, choose **Configuration**. In the list, choose **License Code** and name the license code. In this example, we named the license code **ISVLicenseCode**. Click **Add**.



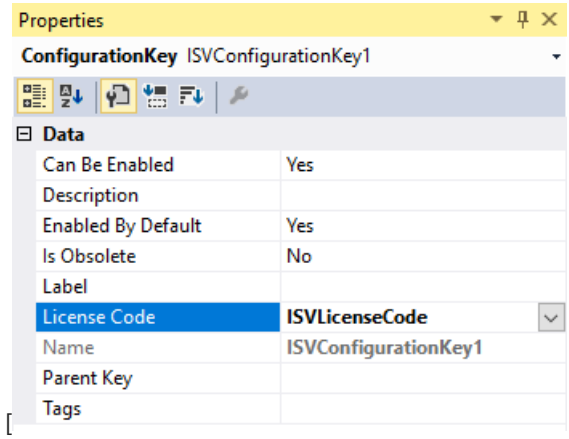
4. Map the certificate to the license code. In the Properties window for the license code, set the **Certificate** property to your certificate resource. In this example, we set **Certificate** to **ISVCert**.



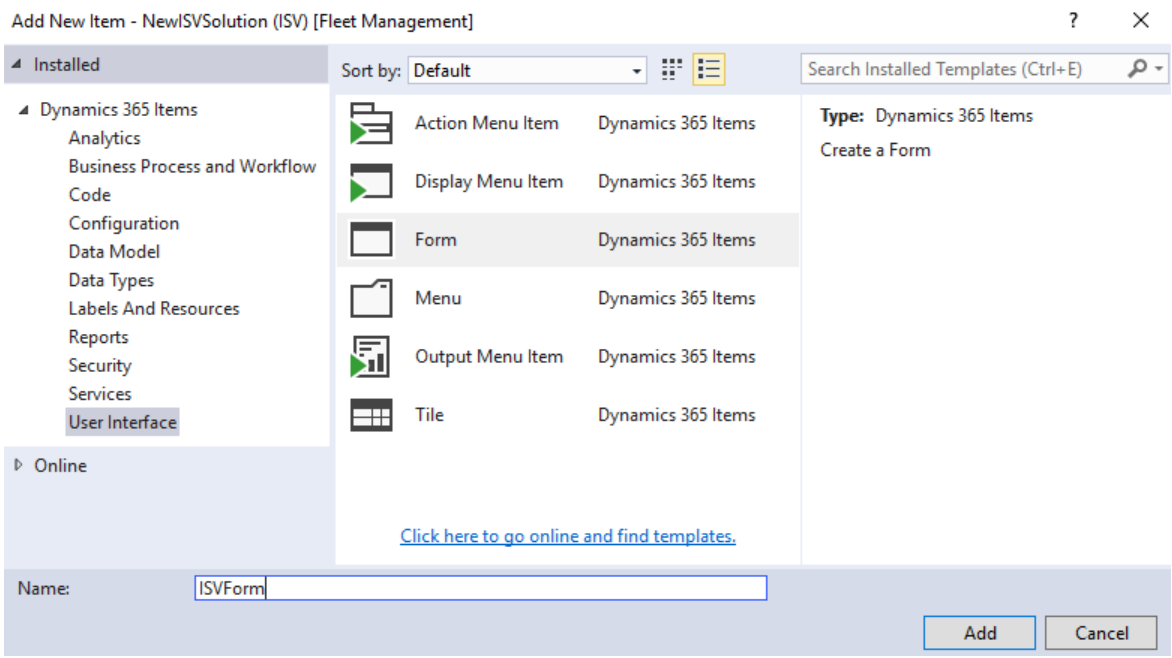
5. Create one or more configuration keys. Right-click the project in Solution Explorer, then click **Add > New item**. Under **Installed > Dynamics 365 Items**, choose **Configuration**. In the list, choose **Configuration Key**. Name the key and click **Add**. In this example, we named the configuration key **ISVConfigurationKey1**.



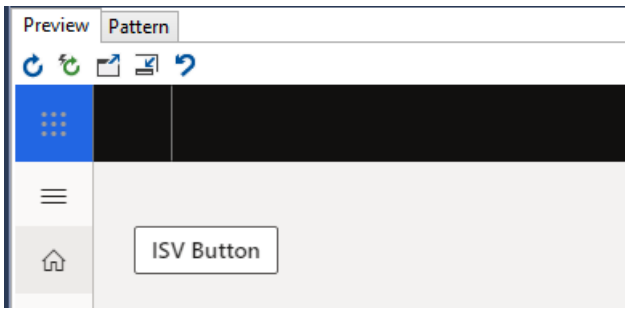
6. Associate the license code with the configuration key. In Solution Explorer, double-click the configuration key to open the Properties window. In the Properties window, set the **LicenseCode** property to your license code. In this example, we set the **LicenseCode** to **ISVLicenseCode**.



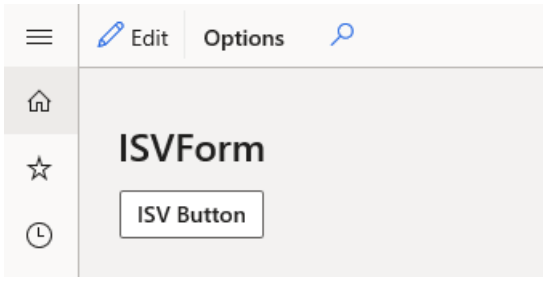
7. Associate a configuration key to an element in your solution. For example, create a new form. Right-click the project in Solution Explorer, then click **Add > New item**. Under **Installed > Dynamics 365 Items**, choose **User Interface**. In the list, choose **Form** and give it a name. In this example, we named the form **ISVForm**.



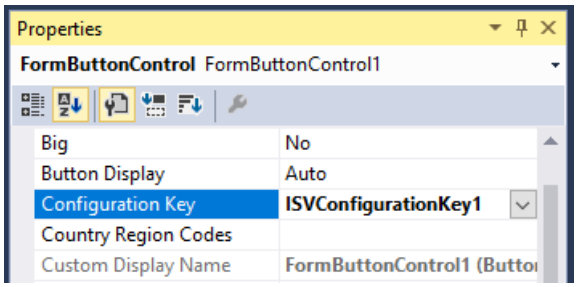
8. Add a button to the form. Double-click the form in the Solution Explorer. In the Design window, right-click and select **New**, and then **Button**. Set the **Text** property to **ISVButton**.



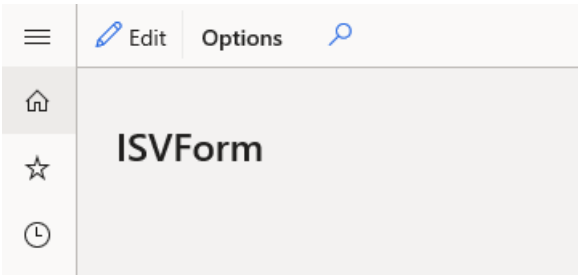
At runtime, the button is visible because it isn't controlled by a configuration key at first.



9. Associate a configuration key with the button. In the Properties window for the button, set the **Configuration Key** property to your configuration. In this example, we set the **Configuration Key** to **ISVConfigurationKey1**.

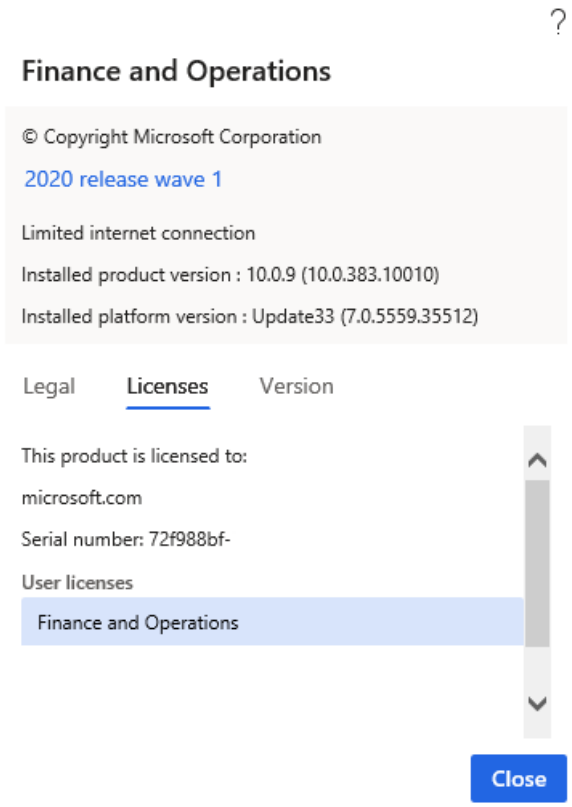


At runtime, the button is not visible because the configuration key must be available and enabled.



Create a package and generate a customer-specific license

1. Collect the tenant name and ID for the customer to issue the license to. You can find this information at **Settings > Help & Support > About** on the **Licenses** tab.



2. Generate a license for the customer (tenant ID and name), and sign the license by using the certificate's private key. You must pass the following parameters to the **axutil genlicense** command to create the license file.

PARAMETER NAME	DESCRIPTION
file	The name of your license file.
licensecode	The name of your license code (from Microsoft Visual Studio).
certificatepath	The path of your certificate's private key.
password	The password for your certificate's private key.
customer	The customer's tenant name (from the screenshot under step 1).

PARAMETER NAME	DESCRIPTION
serialnumber	The customer's tenant ID (labeled "Serial number" in the screenshot).
expirationdate	Optional: The expiration date for the license.
usercount	Optional: The number that custom validation logic can use as required. This could be users, but is not limited to users.

Here is an example.

```
C:\AOSService\PackagesLocalDirectory\Bin\axutil genlicense /file:c:\templicense.txt
/certificatepath:c:\tempisvcert.pfx /licensecode:ISVLicenseCode /customer:TAEOfficial.ccsctp.net
/serialnumber:4dbfcf74-c5a6-4727-b638-d56e51d1f381 /password:********
```

3. Import the license into the target environment.

> **NOTE**
> In production systems, you complete this step from Microsoft Dynamics Lifecycle Services (LCS), by using a deployable package. For more information, see the "Production environments" section later in this topic.

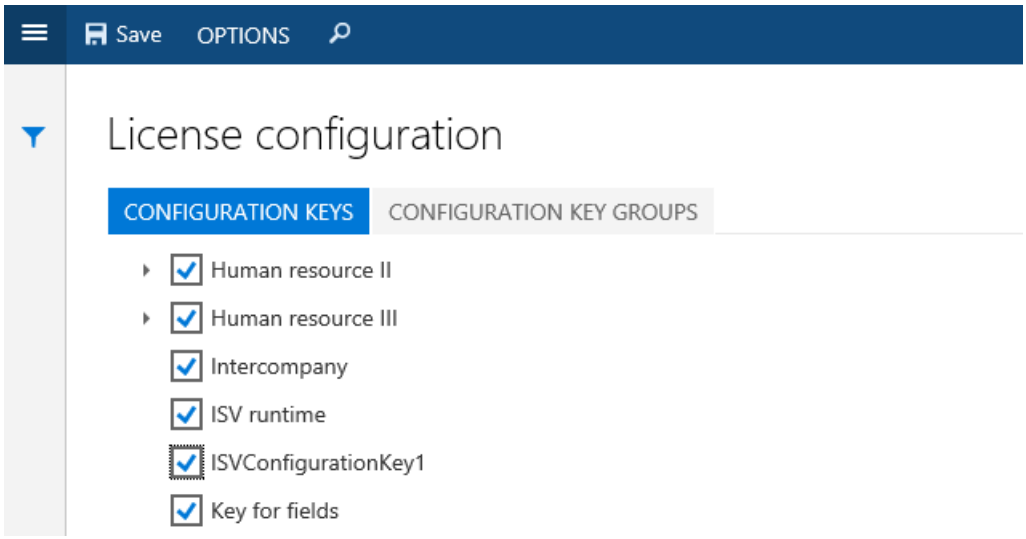
PARAMETER NAME	DESCRIPTION
--setupmode importlicensefile	Use this parameter to inform the setup tool that a license will be loaded.
--metadatadir	Use this parameter to specify the metadata directory. You should use the default packages directory.
--bindir	Use this parameter to specify the binaries directory. You should use the default packages directory.
--sqlserver	Use this parameter to specify the Microsoft SQL Server. For one-box environment, use a period (.).
--sqluser	Use this parameter to specify the SQL Server user. You should pass in **AOSUser**.
--sqlpwd	Use this parameter to specify the SQL Server password.
--licensefilename	Use this parameter to specify the license file that will be loaded.

Here is an example.

```
C:\AOSService\PackagesLocalDirectory\Bin\Microsoft.Dynamics.AX.Deployment.Setup.exe --setupmode
importlicensefile --metadatadir c:\packages --bindir c:\packages --sqlserver . --sqldatabase axdbrain
--sqluser AOSUser --sqlpwd ******** --licensefilename c:\templicense.txt
```

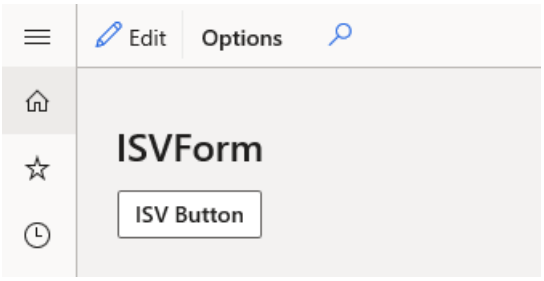
4. The corresponding configuration key will be available and enabled on the **License configuration** page. By default, the configuration is enabled. For example, see the **ISVConfigurationKey1** configuration key

in the following screenshot.



5. In non-production installations, you must start the database synchronization process from Visual Studio.

After the configuration key is enabled, the button becomes visible, as shown in the following screenshot.



Protection best practices

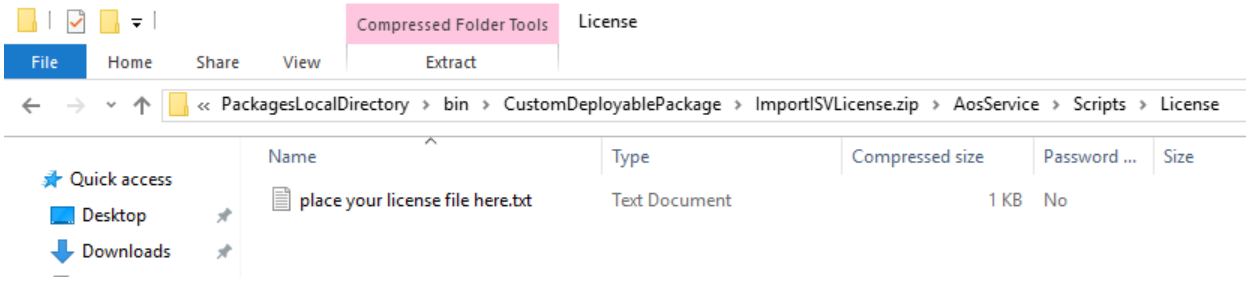
Solutions can be delivered in two forms:

- Model files (source code)
- Deployable packages (binary)

To protect your configuration keys and license codes, we recommend that you release them in binary form, by using a deployable package. Customers will then be able to install and interact with those elements in Visual Studio. Although customers will be able to refer to items in the deployable package, they won't be able to access source code or make modifications to the items. (However, they can create extensions.) More details about the capability to release solutions in binary form will be available soon. The deployable package (binary) can also include classes and other logic that your customer doesn't require access to and should not be able to customize.

Production environments

To install ISV licenses in production systems, you must use a deployable package through LCS. You can find a template package for configuration mode at the following location in all installations: <PackagesFolder>\bin\CustomDeployablePackage\ImportISVLicense.zip (Packages folder is typically under j:\AOSService\PackagesLocalDirectory or c:\AOSService\PackagesLocalDirectory\)



1. Make a copy of the package template.
2. Put the license file in the following folder within the package template: ImportISVLicense.zip\AosService\Scripts\License

More than one license can be installed at a time. If one of the licenses depends on another, make sure that it's named accordingly. (Licenses are installed in alphabetical order.)

Appendix: Create self-signed certificates for test purposes

> **NOTE**
> Self-signed certificates can be used only during development. They aren't supported in production environments.

For Platform update 34 and earlier: (Deprecated - uses SHA1 hash algorithm for license creation)

1. For test purposes, create a self-signed CA certificate. Use the Visual Studio tools prompt to run the following command.

   ```
   makecert -r -pe -n "CN=IsvCertTestAuthority O=IsvCertTestAuthority" -ss CA -sr LocalMachine -a sha256
   -len 2048 -cy authority -sky signature -b 01/01/2016 -sv c:\temp\CA.pvk c:\temp\CA.cer
   ```

   For more information, see the MakeCert documentation.

2. Create a certificate by using the CA.

   ```
   makecert -pe -n "CN=IsvCertTest O=IsvCertTest" -ss ISVStore -sr LocalMachine -a sha256 -len 2048 -cy
   end -sky signature -eku 1.3.6.1.5.5.7.3.3 -ic c:\temp\ca.cer -iv c:\temp\ca.pvk -b **/**/**** -sv
   c:\temp\isvcert.pvk c:\temp\isvcert.cer
   ```

3. Convert the ISV certificate to PFX format.

   ```
   pvk2pfx -pvk c:\temp\isvcert.pvk -spc c:\temp\isvcert.cer -pfx c:\temp\isvcert.pfx -po ********
   ```

4. For a test scenario, import the self-signed CA certificate manually on all the AOS instances.

   ```
   certutil -addstore root c:\temp\ca.cer
   ```

   However, if a self-signed ISV certificate was used, that certificate must be imported instead of the CA certificate.

   ```
   certutil -addstore root c:\temp\isvcert.cer
   ```

For Platform update 35 and later: (Uses SHA256 hash algorithm for license creation)

1. For test purposes, create a self-signed certificate using the PowerShell command `New-SelfSignedCertificate`:

   a. Create the certificate. (Note: adjust start and end dates accordingly.)

   ```
   $cert = New-SelfSignedCertificate -CertStoreLocation Cert:\LocalMachine\My -DnsName "IsvCert"
   -Type CodeSigningCert -KeyExportPolicy Exportable -HashAlgorithm sha256 -KeyLength 2048 -
   KeySpec Signature -Provider "Microsoft Enhanced RSA and AES Cryptographic Provider" -NotBefore
   (Get-Date -Year 2020 -Month 1 -Day 1) -NotAfter (Get-Date -Year 2022 -Month 12 -Day 31)
   ```

   b. Get a reference to the new certificate.

```
[String]$certPath = Join-Path -Path "cert:\LocalMachine\My\" -ChildPath "$($cert.Thumbprint)"
```

c. Create the secure string password that the certificate uses. (Replace "###############" with the certificate password)

```
[System.Security.SecureString]$certPassword = ConvertTo-SecureString -String "###############"
-Force -AsPlainText
```

d. Export the certificate private key as **.pfx** file using the password.

```
Export-PfxCertificate -Cert $certPath -FilePath "C:\Temp\IsvCert.pfx" -Password $certPassword
```

e. Export the certificate public key as a **.cer** file.

```
Export-Certificate -Cert $certPath -FilePath "C:\Temp\IsvCert.cer"
```

2. Add the certificate to the root store.

```
certutil -addstore root C:\Temp\IsvCert.cer
```

Independent software vendor (ISV) licensing (on-premises)

2/18/2021 • 4 minutes to read • Edit Online

This topic explains how to import independent software vendor (ISV) licenses into an on-premises deployment.

> **IMPORTANT**
> The process that is described in this topic is available only for customers who have on-premises environments that are deployed with Platform update 12 or later.

For general information about the benefits of ISV licensing, information about how to enable licensing for your solution, and other information that is related to self-signed certificates, see Independent software vendor (ISV) licensing.

Prerequisites

Before you import the ISV license file into your on-premises environment, verify that the following prerequisites are met:

- The most recent version of the local agent was used when the environment was deployed.
- The environment is deployed with Platform update 12, and all hotfixes for Platform update 12 are applied. This step is mandatory because Microsoft has released a fix for an ISV licensing scenario. To get the latest set of hotfixes, use the tiles on the **Environment details** page in Microsoft Dynamics Lifecycle Services (LCS).
- Before you import the ISV license, the environment must be deployed, and the Application Object Server (AOS) service must be running.
- Before you import the ISV license, the ISV solution must be applied to the on-premises environment. The ISV solution can be applied to an on-premises environment during the deployment flow. Alternatively, you can use the **Apply updates** flow in LCS to apply the ISV solution as a post-deployment step. If the ISV solution isn't applied before you import the license, the customizations won't be enabled.

Import licenses

The following procedure can be used for a sandbox environment or a production environment that is deployed in an on-premises project.

> **NOTE**
> Because import of an ISV license requires downtime, no business transactions can be performed in the environment during import. When you complete the import, make sure that no one is using the system, and that an official downtime notice has been communicated to all the users.

1. Collect the tenant name and ID for the customer to issue the license to:
    a. Connect to the instance of Service Fabric Explorer where the environment is hosted.
    b. Go to **Clusters** > **Applications** > **AXSFType** > **fabric:\AXSF**, and then, on the right page, select the **Details** tab.
    c. In the **Parameters** table, find the values for the **License_TenantDomainGuid** and

Licence_TenantId keys.

2. Generate a license for the customer (tenant ID and name), and sign the license by using the certificate's private key. The following parameters must be passed to theAXUtil **genlicense**command to create the license file. The command will generate an XML file.

PARAMETER NAME	DESCRIPTION
file	The name of the license file.
licensecode	The name of the license code from Microsoft Visual Studio.
certificatepath	The path of the certificate's private key.
password	The password of the certificate's private key.
customer	The customer's tenant name.
serialnumber	The customer's tenant ID.
expirationdate	Optional: The expiration date of the license.
usercount	Optional: The number that can be required for the custom validation logic. This number can be the number of users, but it isn't limited to users.

Here is an example of the command.

```
C:\AOSService\PackagesLocalDirectory\Bin\axutil genlicense /file:c:\templicense.txt
/certificatepath:c:\tempisvcert.pfx /licensecode:ISVLicenseCode /customer:TAEOfficial.ccsctp.net
/serialnumber:4dbfcf74-c5a6-4727-b638-d56e51d1f381 /password:********
```

3. Copy the licenses that are generated to a folder on one of the machines that is running fabric:/AXSF, and verify that fabric:/AXSF is healthy.

4. Run the **Import-LicensePackage.ps1** script from one of the AOS machines. You can find this script in the latest **Deployment scripts** folder on the **Model** tab in the Shared asset library in LCS. Here is a list of the parameters that you must pass to the script:

   - **LicenseFilesPath** – The path of a folder that contains the license files that must be imported.
   - **SqlUser** – The same user who is specified in the credentials.json file to run the AOS.
   - **SqlPassword** – The password that can be used to connect to SQL.
   - **EnvironmentConfigPath** – The configuration file for the environment. This file is named config.json and is located under the agent share in a folder that has the format wp\<environment-name>\StandaloneSetup.

     After the command is run, log files are generated for each license file that is processed. The names of the log files are in the format {license_file_name}.output.log and {license_file_name}.error.log. The logs that are generated during database synchronization are located in files that are structured like dbsync.output.log and dbsync.error.log.

5. When the script has been run successfully, validate that the configuration key has been imported and enabled. In the product, the corresponding configuration key will be available and enabled on the**License**

configuration page. By default, the configuration is enabled. For example, if you added a configuration key that is named ISVConfigurationKey1, it will appear in the list of configuration keys.

When the configuration key is enabled, the changes in the ISV solution will be visible in the product.

General Data Protection Regulation overview

2/18/2021 • 19 minutes to read • Edit Online

Overview of the GDPR

The European Union's General Data Protection Regulation (GDPR) sets a new global standard for privacy rights, security, and compliance for the citizens and residents of the European Union (EU). The GDPR governs the handling and use of personal data of EU citizens and residents. Enforcement of the GDPR begins May 25, 2018, and there are significant consequences for non-compliance. For more information about the regulation, see the European Union site.

> **NOTE**
>
> For information about the scope and coverage of this documentation, see Clarification of the scope of this content section at the end of this topic.
>
> Before utilizing any product features in support of your GDPR compliance efforts, please ensure that you have applied all of the related hotfixes.

The GDPR gives EU citizens specific data subject rights (DSRs) that let them perform the following actions:

- View their personal data.
- Correct errors in their personal data.
- Erase their personal data.
- Object to processing of their personal data.
- Export their personal data.

The GDPR defines personal data in the following way in article 4 of the regulation (organizations do not have personal data):

> (1) 'personal data' means any information relating to an identified or identifiable natural person ('data subject'); an identifiable natural person is one who can be identified, directly or indirectly, in particular by reference to an identifier such as a name, an identification number, location data, an online identifier or to one or more factors specific to the physical, physiological, genetic, mental, economic, cultural or social identity of that natural person;

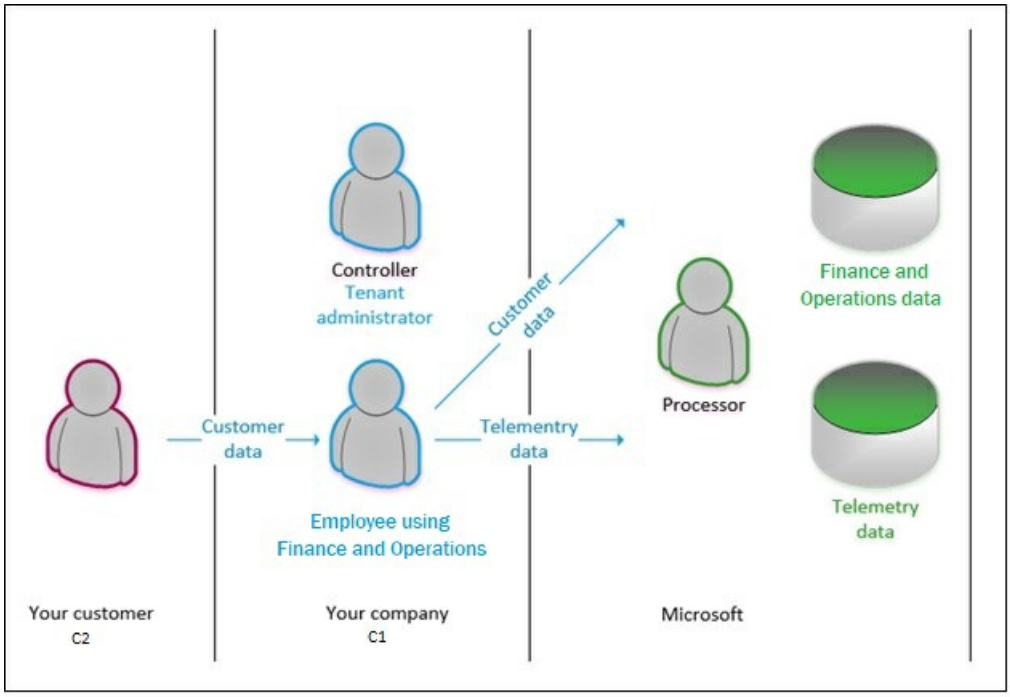
To determine responsibilities for compliance, the GDPR identifies the following roles:

- **Data controller** – The controller controls personal data and determines how it's used. The responsibilities of the controller include but are not limited to collecting, maintaining, directing actions, protecting, modifying and deleting personal data. The controller either adds users to the system, grants access to the system, and collects data from data subjects, or has employees who complete these tasks on the company's behalf. The burden of understanding the process for GDPR requests and carrying out a GDPR request rests with the controller.
- **Data processor** – The processor provides services to, and processes data on behalf of, the data controller. The processor performs actions on behalf of the controller. The processor makes it possible for the controller to be GDPR compliant, but has no ownership of the data and does not respond directly to DSR requests.
- **Data subject** – A data subject is a natural person whose personal information is being used.
- **C1** – C1 is a Microsoft direct customer (IT Admin in the Enterprise Cloud).

- **C2** – C2 is C1's customer.

For Finance and Operations apps, Microsoft acts as a processor. As a data processor, Finance and Operations provides processes and features that help you comply with your GDPR obligations as a data controller.

The following illustration shows the flow of data from your customer to the application database, and the roles that you and Microsoft play in that process. For each application, the controller is the tenant administrator, and Microsoft is the processor. In this scenario, the data is sent to the processor (Microsoft), who then processes the data by storing it, retrieving it, sorting it, and so on.



When a data subject chooses to submit a DSR, the data subject makes the request to the controller. Data subjects won't approach Microsoft to exercise their rights for data that your business has collected. As the processor, Microsoft assists the controller by providing features, or just by making sure that the actions are possible. In other words, the controller accepts and responds to a DSR request, and the processor assists with or enables the compliance request. The following table outlines some of the roles and responsibilities that are relevant.

Role	Scenarios	Implementation	Level of data access
Your customer (2)	• View personal data • Correct personal data • Erase personal data • Object to processing • Export personal data	You must provide a mechanism for your customer to exercise a DSR (process or service).	Your customer sees only their personal data.

Your employee – information worker	• View personal data • Correct personal data • Erase personal data • Object to processing • Export personal data	You must provide a mechanism for your worker to exercise a DSR (process or service). Some activity information may be obtained from Microsoft	Your information worker sees only their personal data.
Your employee – GDPR administrator	• Validates the user identity request • Locates the personal data across systems • Curates the data based on your policy • Creates a data package or executes an action	• Uses Finance and Operations to locate the data and fulfill the request. • Writes a customization. • Reaches out to third parties for shared-controller DSRs. • Reaches out to Microsoft for activity data.	Your GDRP administrator sees the data that has been obtained to fulfill the DSR request.

Responding to requests to view, correct, erase, object, or export personal data

Suppose that a customer decides that they want to understand what personal data of theirs is maintained by an organization. That customer approaches that organization and asks to exercise their DSR. When data subjects exercise their DSRs, controllers must address each of the following items specifically:

- Properly identify the person and role (is the person an employee, a customer, a vendor?) by using information that the data subject gave you as part of their request. This information might be a name, an employee ID or customer number, or another identifier.
- Record the date and time of the request. (You have 30 days to complete the request.)
- Affirm that the DSR request is proper and valid. You will need to work with your legal counsel to determine what is valid. For example, you must make sure that compliance with a DSR request doesn't conflict with any other legal obligations that you have.
- Verify that you have the information that is related to the request.

Reasons why certain personal data may not be modified or deleted

The following table lists several reasons why personal data modification or deletion is restricted in certain

scenarios.

REASON	COMMENT
Financial, tax, generally accepted accounting principles (GAAP)	A party can't be deleted, but the party's name can be updated.
Financial, tax, GAAP	A current worker's data can't be deleted, but the worker's name can be updated.
GAAP	Posted or completed transactions can't be modified.

Right to view

An organization might decide to take any of the following actions in response to a DSR request to view data:

- Use the Person search report to find and collect personal data. To access this report, from the navigation pane, select **Modules > System administration > Inquiries > Person search report**.
- Extend the Person search report by authoring a new entity or extending an existing entity.
- Use search and filter features to find specific personal data and export that data by using the Microsoft Office Export functionality or print that information to a .pdf using browser extensions.
- Use provided documentation to identify data tables that contain data that the controller has identified as personal data.
- Author a custom form that locates and exports personal data.
- Author an external portal or website that allows an authenticated customer to see their personal data.

The Person search report might help you discover personal data that is subject to a DSR request. If the report doesn't include the information that you're looking for, check the Microsoft Dynamics Lifecycle Services (LCS) site for possible hotfixes that include the information. You can also extend the report yourself by creating additional entities, or extending the provided entities.

If the Person search report doesn't contain all the information that the data subject is requesting, you can extend it by using tools that Microsoft has provided. For information about how to extend the Person search report, see Extend the Person search report.

**Right to correct* **

An organization might decide to take any of the following actions in response to a DSR request to correct data:

- Use the Person search report to find and collect personal data.
- Extend the Person search report by authoring a new entity or extending an existing entity.
- Use search and filter features to find specific personal data.
- Author a custom form that locates personal data.
- Author an external portal or website that allows an authenticated customer to correct their personal data.

When data is located, use in-product features to correct the data where the product offers the ability to do so.

*You might find that some data that qualifies as personal data can't be modified directly. Typically, this data is part of a financial transaction or other business data that is kept "as is" for compliance with financial laws (for example, tax laws), prevention of fraud (such as security audit trail), or compliance with industry certifications.

** GDPR is not a law exclusive of all other laws. As an enterprise resource planning system, Finance and Operations does not allow for modification of certain business or transactional data, and will not endorse nor provide functionality for the modification of business data that is necessary for compliance with other laws or certifications. Finance and Operations will not provide support for modifications/customizations or other actions that result in the corruption of referential or business data integrity.

Right to be forgotten*

An organization might decide to take any of the following actions in response to a DSR request to erase data:

- Delete or otherwise erase personal data where the product enables that action directly.
- Anonymize the personal data where the product enables that action directly.
- Author a customization to erase/modify the personal data.

* GDPR is not a law exclusive of all other laws. As an enterprise resource planning system, Finance and Operations does not allow for deletion of certain business or transactional data, and will not endorse nor provide functionality for the deletion of business data that is necessary for compliance with other laws or certifications. Finance and Operations will not provide support for modifications/customizations or other actions that result in the corruption of referential or business data integrity.

Right to port

An organization might decide to take any of the following actions in response to a DSR request to port data:

- Use the Microsoft Office Add-in to export personal data.
- Author a custom report that enables the export of personal data.
- Author a customization that exports personal data.
- Use or extend the Person search report to gather information in support of a request for a copy of the data subject's personal information.

The Person search report might help you discover personal data that is subject to a DSR request. If the report doesn't include the information that you're looking for, check the LCS site for possible hotfixes that include the information. You can also extend the report yourself by creating additional entities.

If the Person search report doesn't contain all the information that the data subject is requesting, you can extend it by using tools that Microsoft has provided. For information about how to extend the Person search report, see Extend the Person search report.

The controller may, at their sole discretion choose to redact certain types of information that may fall outside of the scope of data that must be returned to the data subject as defined within the GDPR.

Right to restrict

An organization might decide to take the following action in response to a DSR request to restrict optional data processing:

- Remove the customer from, for example, a marketing campaign.

* GDPR is not a law exclusive of all other laws. As an enterprise resource planning system, Finance and Operations does not allow for restricted processing of certain business or transactional data, and will not endorse nor provide functionality for the restriction of processing of business data that is necessary for compliance with other laws or certifications. Finance and Operations will not provide support for modifications/customizations or other actions that result in the corruption of referential or business data integrity.

Controller considerations

Controllers can use the following information to complete DSR requests.

System inventory

- **Data inventory and tagging** – Microsoft has enabled a tagging infrastructure that developers and customers can use. Each data field that is defined in metadata contains a classification property that has a suggested value that the controller can confirm or change to any value or term they choose in order to identify data that they deem fits within the definition of personal data.

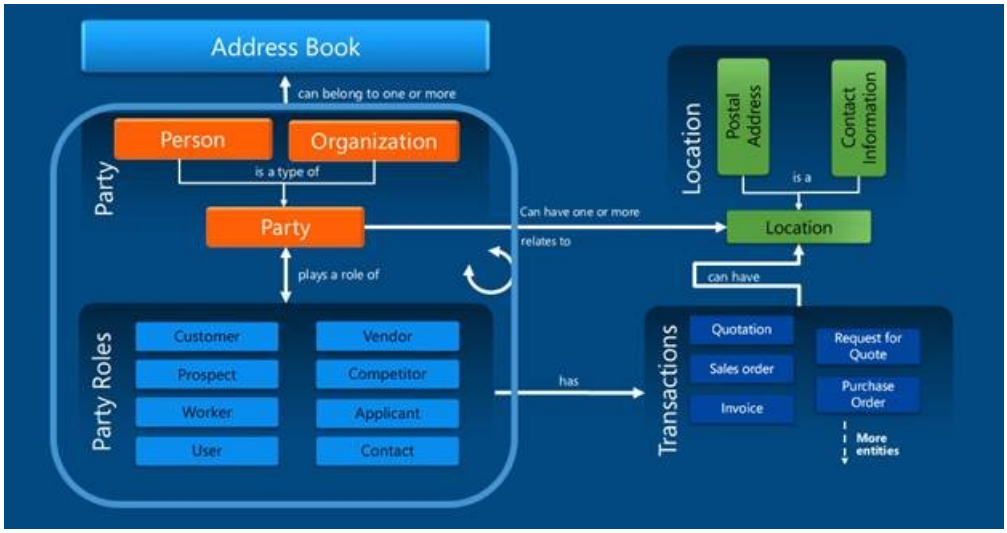
- **Data flow diagram** – Microsoft will publish a data flow diagram that identifies flows of data between systems in the customers production environments.
- **Person search report** – Finance and Operations includes the Person search report, which can be used to gather information in support of a request for a copy of the requestor's personal information.

Activity and diagnostic information

The controller can make DSR requests regarding telemetry data by using the Microsoft Enterprise Privacy Portal. Some telemetry data that we collect is in system generated logs. Without additional information or your assistance, the user's identity is anonymous.

Representation of a person in Finance and Operations

Finance and Operations has a common Global address book. Typically, every time that you add a contact, customer, user, worker, or other person in your system, you first create an address book entry for that person. Each person in the address book is referred to as a party and is assigned a PartyID. The person also takes on a role in the system, such as Customer, User, or Worker, and has a role ID: CustID, UserID, WorkerID, and so on.



Each person is a type of party

Roles that are associated with party records are referred to as party roles. There are several party roles, and they can be assigned to both party types (person and organization):

- **Customer** – An individual, company, or other entity that purchases goods and services that are produced by other individuals, companies, or entities.
- **Prospect** – A party that might be interested in goods or services an organization provides.
- **Worker** – A person who assumes the role of an employee or a contractor, or who is paid in exchange for services.
- **User** – A person who is a user of the system. The user isn't identified in the Global address book.
- **Vendor** – A party that supplies products to one or more legal entities in exchange for payment.
- **Competitor** – A person or organization that provides goods or services that are like the goods or services that your business provides. Out of the box, there is no particular identification for competitors.
- **Applicant** – A person who makes a formal written or electronic request to work for an organization or fill an open position in it.
- **Contact** – A person, either inside or outside your organization, that you've created an entry for. In this entry, you can save information such as the person's street and email addresses, telephone and fax numbers, and webpage URLs.

The right to view and port: It's all about the party

When a data subject approaches the controller to request a copy of their personal data, the controller might choose to use the Global address book information to locate the data that describes the person. As noted in the illustration earlier in this topic, a **person** is a type of **party** that plays a **role**.

Some organizations conduct their activities only through business-to-business relationships and will have modest DSR obligations. By contrast, other organizations conduct their activities through business-to-customer relationships. These organization might choose to use the Global address book and its associative data relationship to write custom reports, custom forms, custom queries, and custom data export features by using the extensibility and customization capabilities and Open in Excel experiences to serve the specific needs of the kinds of data that their business collects from their customers.

The Person search report

To support the controller, this report offers a refinement of the existing entity model reporting functionality that is available in the **Data management** workspace. The **Data management** workspace offers a collection of pre-packaged representations of most role types. These representations are known as entities.

> **NOTE**
> The Person search report is available for Finance, Supply Chain Managament, Commerce, and Human Resources. Currently the report does not support Microsoft Dynamics AX 2012.

An entity represents an instance of a specific role. The data management functionality lets the controller export entity data to several formats, such as colon-separated values, comma-separated values (CSV), semicolon-separated values, tab-separated values, Microsoft Excel, and XML.

The Person search report provides additional capabilities in the **Data management** workspace that export entity data by providing a party ID that is used to identify **all** roles (and corresponding entities) that are associated with the party. This capability lets you export all entity and transaction data in a single action, for either a single party or a collection of parties.

When a data subject approaches the controller to request a copy of their personal data, the controller might choose to use the Global address book information to locate the data that describes the person. As noted in the illustration earlier in this topic, a **person** is a type of **party** that plays a **role**.

Some organizations conduct their activities only through business-to-business relationships and will have modest DSR obligations. By contrast, other organizations conduct their activities through business-to-customer relationships. These organization might choose to use the Global address book and its associative data relationship to write custom reports, custom forms, custom queries, and custom data export features by using the extensibility and customization capabilities and Open in Excel experiences to serve the specific needs of the kinds of data that their business collects from their customers.

Additional notes that apply to requests for data

- Data in Management Reporter and in Microsoft Power BI presentations is generated from the information that is entered in various financial documents and then transferred to those applications for reporting purposes. Any request for data should be fulfilled from the financial documents by using tools such as reports, Export to Excel, and the Person search report. You should not need to do additional reporting from Management Reporter or Power BI to fulfill a GDPR request unless you have made customizations that have altered the base functionality.
- Personal data that is included in documents or attachments might also need to be returned to the data subject, independent of any reporting.
- If a master record has transactional data associated with it, it can't be deleted.
- Similarly, transactions that have been posted or completed can't be deleted.

Reasons why Finance and Operations might not support modifying or deleting data out of the box

The following table lists several reasons why data modifications might be restricted.

REASON	COMMENT
Audit	Data must be preserved for compliance and auditing.
Calculated	Data that has been calculated can be changed only by changing the data that is included in the calculation.
Financial, tax, generally accepted accounting principles (GAAP)	Posted transactions can't be modified or deleted.
Import log	Data must be preserved for compliance and auditing.

What types of personal data might exist in the product

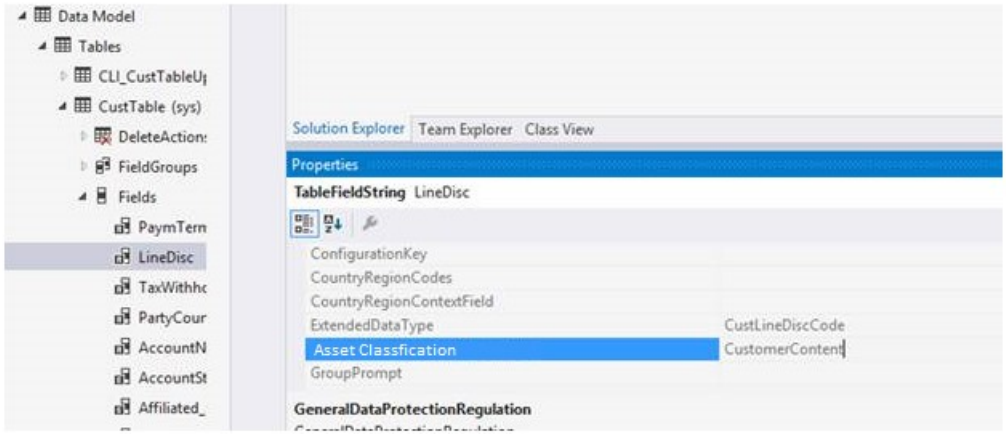
You should expect data requests to come to your company. You can categorize the people who request data into one or, in some cases, more than one relationship with your company:

- Customers
- Vendors
- Workers
- Users
- Warehouse workers
- Truck drivers
- Prospects
- Contacts
- Applicants
- Competitors

Personal data might also be contained in other roles that aren't listed here. Pages used to enter, view or edit personal data have been provided in worksheets for most roles in the preceding list. You can view or download the spreadsheets from the Reference documents for finding and managing personal data page on CustomerSource.

Detailed inventory

As you use Finance and Operations apps, you might find that you generate or collect large amounts of data that resides in multiple data stores. To help you make sense of where your data resides, we've introduced a data marker for each piece of data in our data stores. This marker is called "Asset Classification," and it can be used to identify or track personal data. Any data that you collect has been described as "customer content." Some customer content might contain personal data, and some customer content might contain business data. You can choose to treat all customer content as personal data, or you can change the classification yourself, so that you can identify and track any data that you feel is considered "Personal Data." Although Microsoft has a supplied a set of default classifications, you're free to use any classification or identifiers that you choose.



Age Gating: Preventing minors from using the service

Overview

Microsoft mandates that all users of Microsoft software where personal data is collected must use a Microsoft account (MSA) or Microsoft Azure Active Directory (Azure AD) account for authentication. Additionally, those accounts must be configured to enable minors who use the software or service to affirm parental consent for the service to use their personal data.

What is this feature?

As the tenant admin of the service, you will be required to set up Azure AD Age Gating and/or MSA age gating.

Any user who isn't configured by using Azure Age Gating will be restricted from using the service, even if the user isn't a minor. Age Gating must be configured.

We will restrict access to our software and systems by using a sign-in age gate.

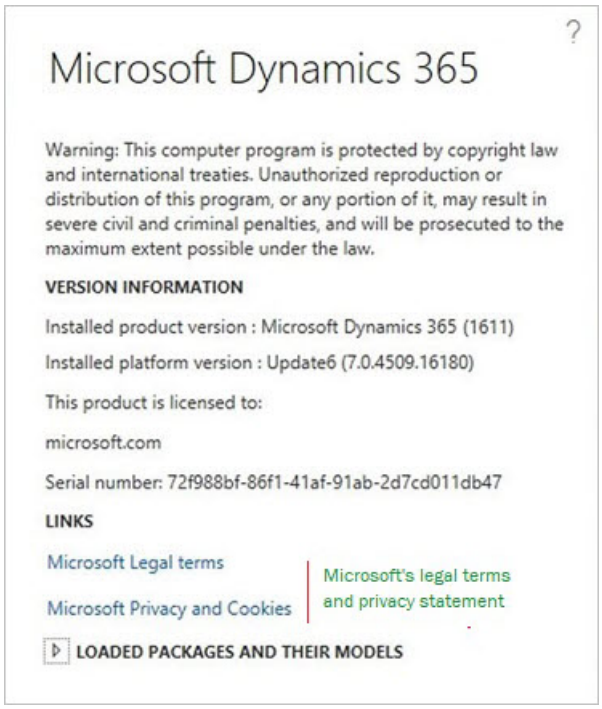
How will age gating work?

The GDPR specifies that systems must stop processing a minor's personal data if that minor doesn't have parental consent. Note that consent can be given and then withdrawn. Therefore, a user might have access to the system one day but not the next.

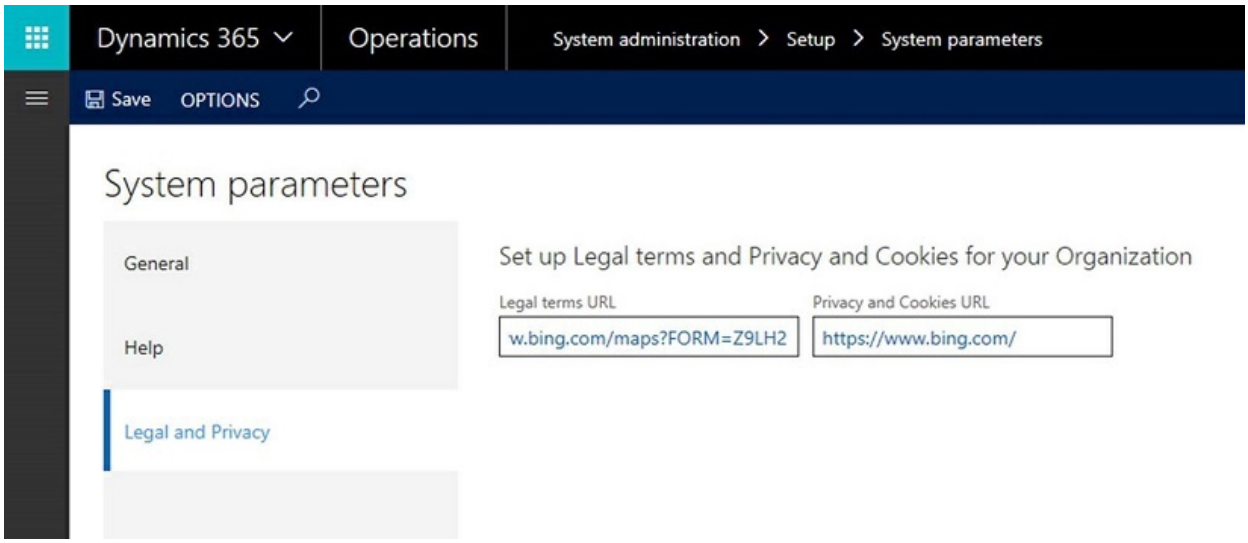
Privacy notices and user subject rights

Displaying your organizations user rights and privacy notice

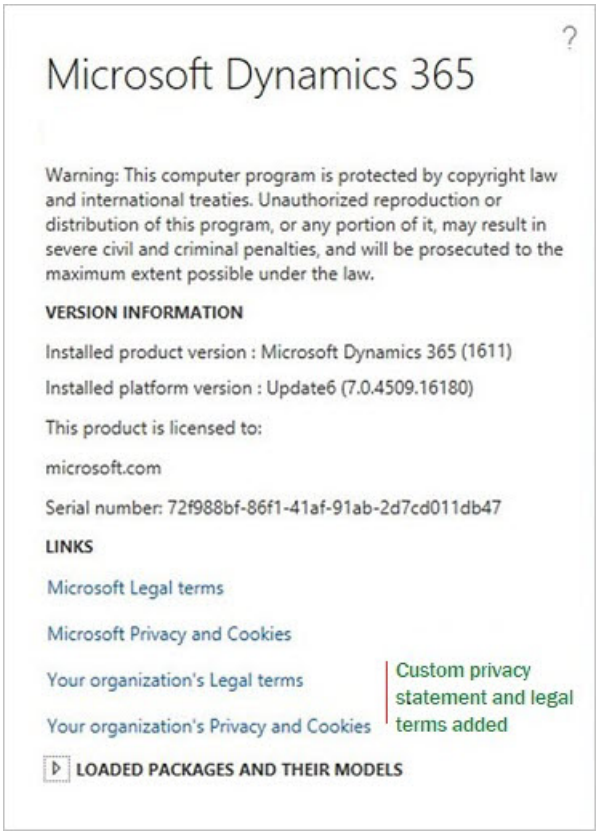
In the **About** box, you will find links to the Microsoft user rights documentation, and to the Microsoft privacy and cookies documentation. You can also add a link to your organization's privacy statement.



On the **System parameters** page, system administrator can add links to the organization's user rights and privacy notices. You can add a valid URL for one or both notice types.



When you've completed your entries in the system parameters, the link to your organization's privacy notice will appear in the **About** box, as show in the following illustration.



Clarification of the scope of this content

- This documentation is a commentary on the GDPR, as Microsoft interprets it, as of the publication date. We have spent a lot of time with the GDPR and believe that we have been thoughtful about its intent and meaning. But the application of the GDPR is highly fact-specific, and not all aspects and interpretations of the GDPR are well-settled.
- This documentation is provided for informational purposes only, and should not be relied upon as legal advice or to determine how the GDPR might apply to you and your organization. We encourage you to work with a legally qualified professional to discuss the GDPR, how it applies specifically to your organization, and how to best ensure compliance.
- MICROSOFT MAKES NO WARRANTIES, EXPRESS, IMPLIED, OR STATUTORY AS TO THE INFORMATION PROVIDED IN THIS PRESENTATION. This documentation is provided "as is." Information and views expressed in this documentation, including URL and other Internet website references, may change without notice.
- This documentation does not provide you with any legal rights to any intellectual property in any Microsoft product. You may copy and use this presentation for your internal, reference purposes only.

NOTE

Can you tell us about your documentation language preferences? Take a short survey.

The survey will take about seven minutes. No personal data is collected (privacy statement).

Respond to GDPR data requests resources

2/18/2021 • 2 minutes to read • Edit Online

This topic provides links to information that can help you respond to a request for information under the General Data Protection Regulation (GDPR) as a customer using Dynamics 365 Finance, Supply Chain Management, Commerce, Human Resources, and Microsoft Dynamics AX 2012.

Your first step in responding to a request for data will usually be to use the Person search report to locate the data that's requested. In some cases, you might need to use other reports, access specific pages in the product that you're using, or extend the Person search report. (The report is currently not available for Microsoft Dynamics AX 2012.) This topic points to content that will help you complete those tasks.

Overview

- General Data Protection Regulation overview
- Person search report
- Extend the Person search report
- Manage access to sensitive data

Product-specific considerations

- Respond to requests for personal data in AX 2012
- Respond to requests for personal data in Human Resources
- General Data Protection Regulation overview
- GDPR data requests for Lifecycle Services (LCS)

Compliance Manager

Compliance Manager is a cross–Microsoft Cloud services solution designed to help organizations meet complex compliance obligations like the GDPR. It performs a real-time risk assessment that reflects your compliance posture against data protection regulations when using Microsoft Cloud services, along with recommended actions and step-by-step guidance.

Compliance Manager

You can try Compliance Manager yourself by visiting https://aka.ms/compliancemanager.

Resources

There are a number of resources to help you learn more about Compliance Manager and what it can do you help you meet complex compliance obligations.

- Microsoft 365 - Compliance Manager preview (Office, November 2017)
- Compliance Manager preview is now available (Tech Community, November 2017)
- Get to know the new Service Trust Portal (TechNet, November 2017)
- Announcing Compliance Manager (Tech Community, September 2017)
- Advancing intelligence, management, and security to empower the modern workplace (Office, September 2017)
- New Microsoft 365 features to accelerate GDPR compliance (Microsoft Secure, September 2017)

Additional resources

For more information about the GDPR and the actions that your organization might need to take in response to a request for data, visit the Microsoft Service Trust Portal.

> **NOTE**
>
> Can you tell us about your documentation language preferences? Take a short survey.
>
> The survey will take about seven minutes. No personal data is collected (privacy statement).

Asset classifications

2/18/2021 • 2 minutes to read • Edit Online

Finance and Operations apps provide a default set of classifications for the kinds of data that are stored in each table. These classifications are subject to change depending on the need to identify different kinds of data. The actual classification for each field in each table can change at any time, depending on differing needs for identifying data.

Through customization, you can change the classification of the following data to meet your own classification and tracking needs.

- **Customer content** – Data collected and managed by the controller (some of which can be personal data).
- **End User Identifiable Information** (EUII) – A natural value used to identify a user of the service.
- **End User Pseudonymous Information** (EUPI) – A generated value used to identify the user of the service.
- **Organizational Identifiable Information** (OII) – A value used to identify the organization using the service.
- **System metadata** – A value that describes the software or used by the software, typically generated by the software.
- **Object metadata** – A value that describes the software or used by the software, but can be provided by the tenant or user of the software.
- **Account data** – A value provided by or used by the tenant to identify the billing information or identify the software used by the tenant.
- **Support data** – Information used to provide customer support.

Person search report

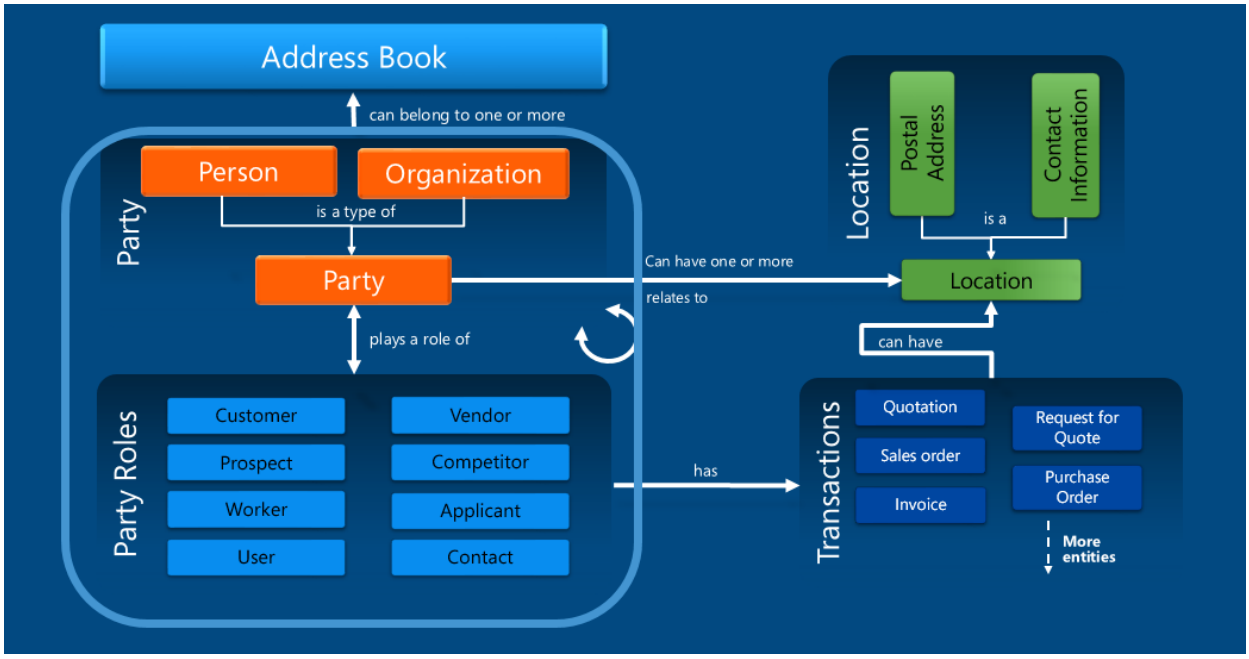
2/18/2021 • 4 minutes to read • Edit Online

The Person search report is a refinement of the existing Data management framework of Finance and Operations apps. The Data management framework offers a pre-packaged set of entities that Microsoft authored to identify personal data that is used to define a person and the roles that a person might be assigned to in Finance and Operations applications.

> **NOTE**
>
> You can use the report with Dynamics 365 Finance, Supply Chain Management, Commerce, and Human Resources. The report is not currently available for Microsoft Dynamics AX 2012. The Person search report is available in version 8.0. The report is also available in version 7.3 (delivered via monthly update 7.3.2), in version 7.2 (via KB 4132615), and in version 7.1 (via KB 4132441). The Person search report may be updated periodically. Before using this report, you need to ensure that you have obtained and applied all relevant hotfixes.

You can use the Global address book to create an instance of a person that is described in the data model as a party.

When you add a contact, customer, user, worker, or other person in Finance and Operations data, you typically start by creating an address book entry for that person. Each person in the address book is referred to as a party and is assigned a PartyID. The person also takes on a role in the system, such as customer, user, or worker, and has a role ID: CustID, UserID, WorkerID, and possibly others.



At times, you might want to verify that the information that is entered and used to describe or otherwise identify a person is correct. Situations might also arise where it's useful to share that information with the data subject who requested the data. The Person search report can help with both these tasks.

The Person search report is extensible. If you find that the existing entities do not contain all of the personal data you are looking for, they can be extended, or new entities can be written. In addition, you can change the data mappings for each entity and remove fields that you don't want to export.

The Person search report lets you specify different identifiers for a person, such as a CustomerID or VendorID. It

will then collect, filter, and populate the entity collection set with personal data that is related only to the person you specified.

On rare occasions, a single person might be entered in your system more than once. The Person search report lets you specify each person instance to be included on a single report. For example, someone named Fred Smith might be both "Fred Smith" and "F. D. Smith" in your address book.

An individual might exist as multiple parties in data. You can provide multiple identifiers for each party type, and each party type's personal data will be included on a single report.

Download the default template

The Person template contains a list of the entities that will be used to download information. The template must be loaded before the Person search report can be used. The template can be loaded from within the Templates form in Data management for versions 7.2 and later. To download templates fronm **Data management**, complete the following steps.

1. Open the **Data management** workspace.
2. If this is the first time that the workspace has been opened, it will load all of the data entities. You must load all the data entities before you load the template.
3. Click the **Templates** tile.
4. Select the **Load default templates** button.
5. Select **Person search**.
6. Click **Load selected**.

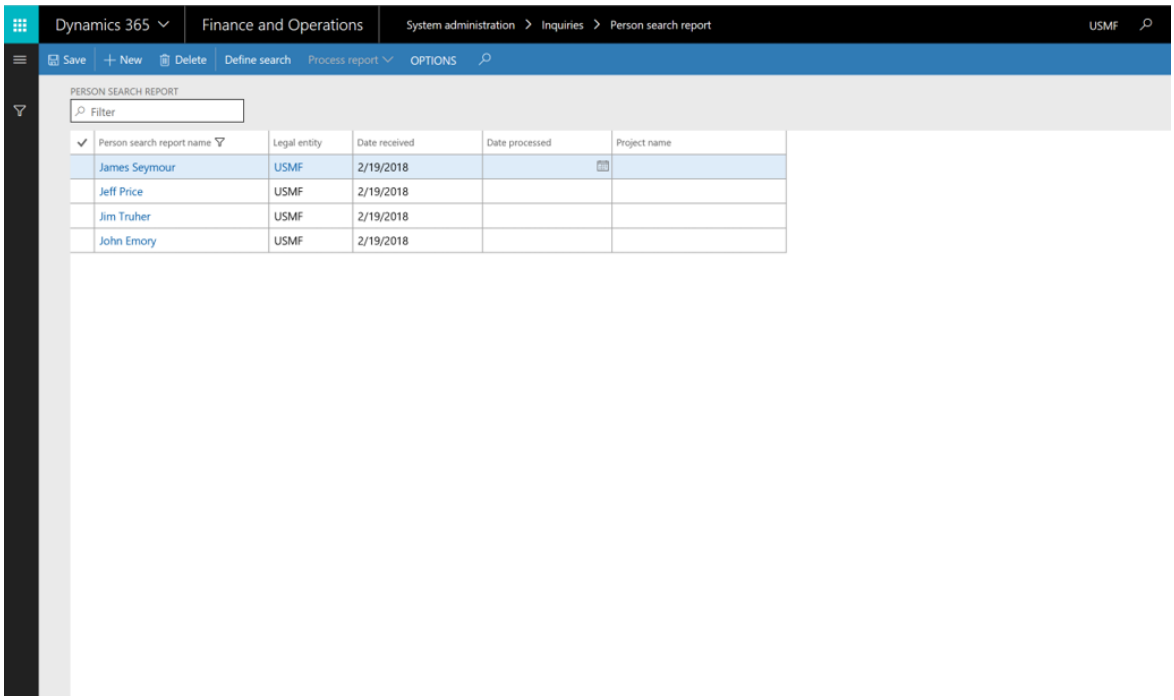
You can also download a template from LCS and import it for versions 7.1 or later. To do so, complete the following steps.

1. Log in to LCS.
2. Click the **Shared asset library** tile.
3. Select the **Data package asset** type.
4. Click the template named **Template-x.x-Person search**, where x.x is the application version that you're using, and download it.
5. Open the **Data Management** workspace.
6. If this is the first time that the workspace has been opened, the workspace will load all of the data entities. All entities loaded before you download the template.
7. Click on the **Templates** tile.
8. Create a new template called **Person search**.
9. Click **Import template**.
10. Browse to the template and click **Upload**.
11. Click **OK** to import the template.

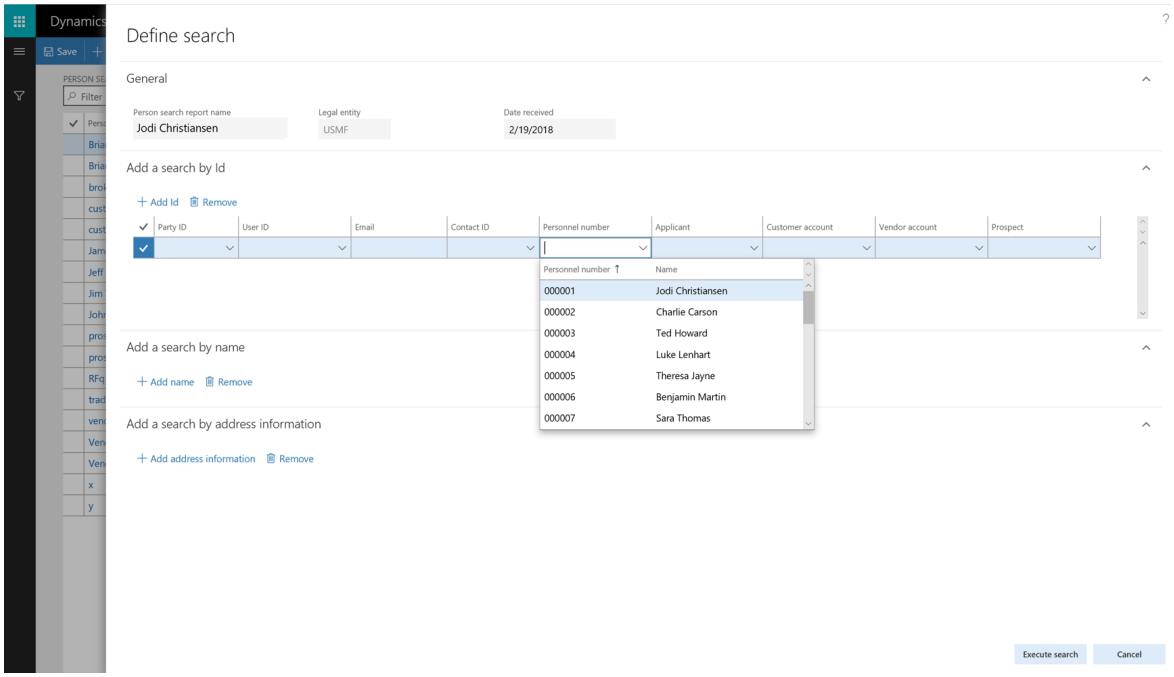
Generate a person search

To use the Person search report, you must complete these tasks.

1. From the System administration menu, open the Person search list page, and create a new search.

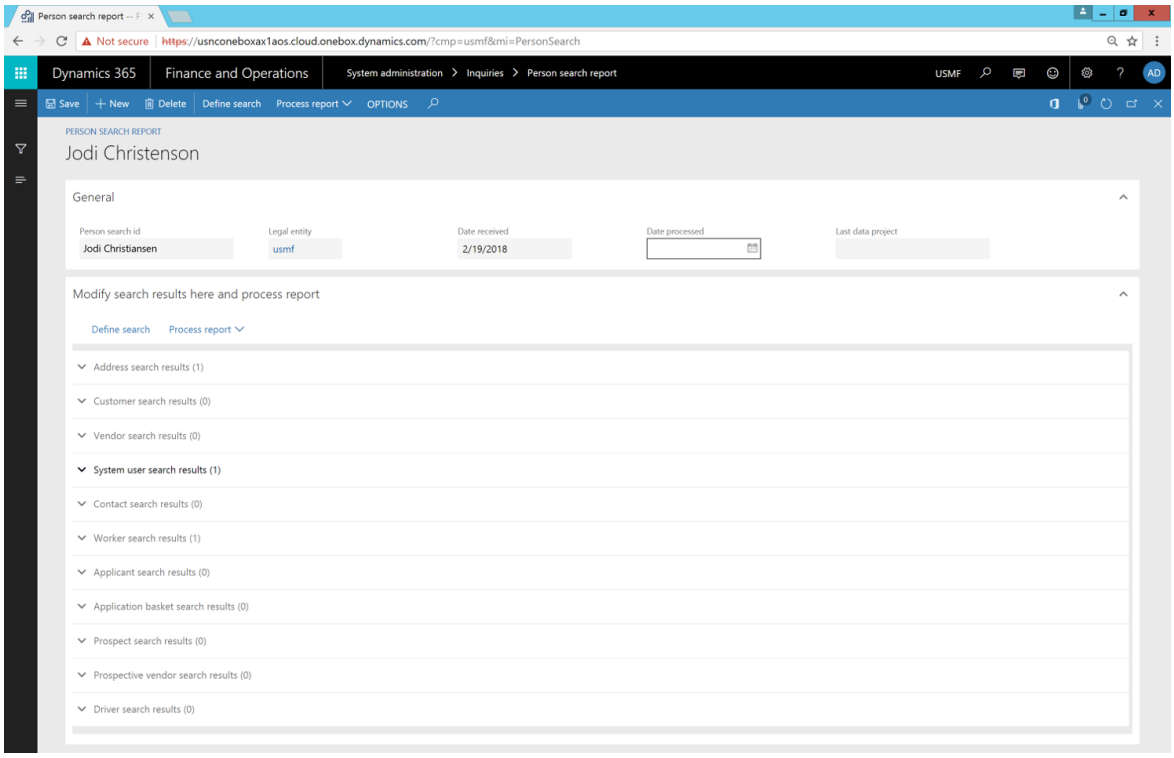


2. The search gives you three options: you can search by ID, by name, or by address. Add the type of search that you want.

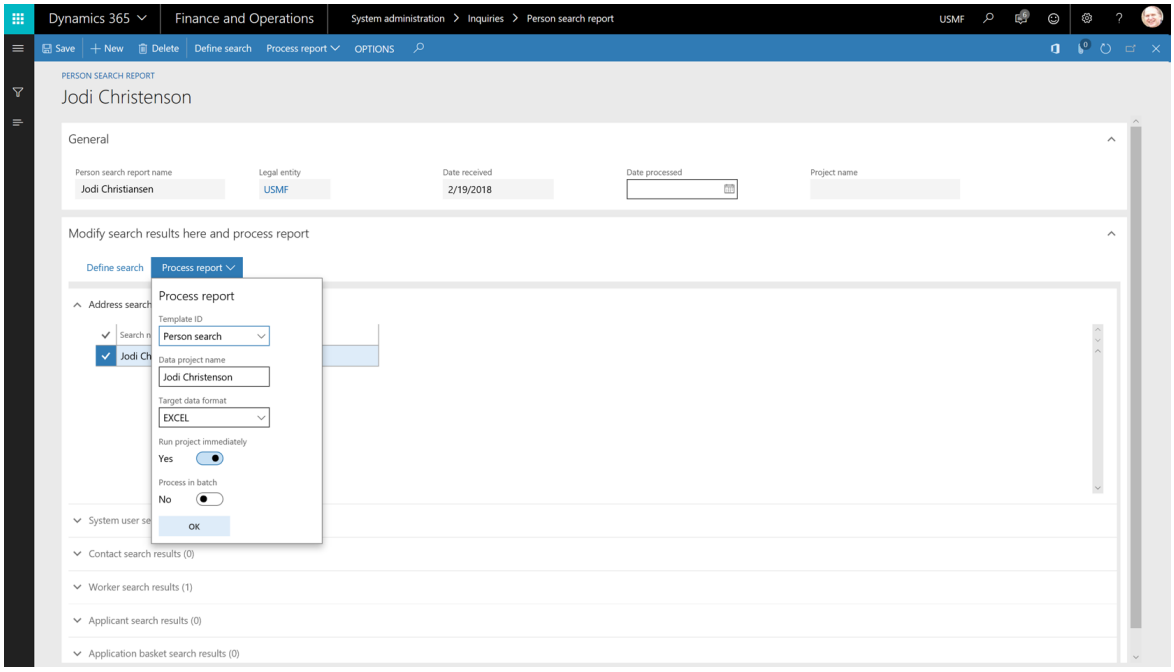


3. Run the search to show the results.

4. Verify that the results are valid. Clear any selections that return information that you don't want to include on the report.



5. Select **Process report**, and then select the Person search template.



6. Select **OK**. A data package is generated.

7. When the package has been generated, export it to your selected data format.

> **NOTE**
>
> Documents that are attached to records are not included in the data export. Attachments must be manually downloaded and shared with the individual who requested personal data.

Additional resources

You can learn more about the GDPR on the European Union's website, from information on the Microsoft Trust Center and in General Data Protection Regulation overview.

Disclaimer

NOTE

Can you tell us about your documentation language preferences? Take a short survey.

The survey will take about seven minutes. No personal data is collected (privacy statement).

Extend the Person search report

2/18/2021 • 4 minutes to read • Edit Online

The Person search report for Finance and Operations apps is backed by an intelligent search processor that is designed to manage a collection of entities for a single person. The Person search report searches Finance and Operations data and creates a set of resulting identifiers. Each result references a search category (for example, Customer) and a result record in a related table. For information about using the Person search report, refer the Person search report topic.

> **NOTE**
>
> The Person search is available for Dynamics 365 Finance, Supply Chain Management, Commerce, and Human Resources. The Person search report is not currently available for Microsoft Dynamics AX 2012.

Add another entity to the default template

You can add any entity to the default Person search report template. Open the **Data management** workspace, and select **Templates**. Add the entity to the template. The entity that you add must include at least one of the fields that are used to filter the Person search report.

Create a new search category

1. Use the **PersonSearchResultCategory** enumeration to distinguish different categories of results, such as workers versus applicants.
2. Extend the **PersonSearchResultCategory** enumeration as needed to create new result types.

Create search processing for the new search category

In this example, you will create a new processor class.

1. Extend the **PersonSearchModule** enumeration with a new search area.
2. Create a class that extends the **PersonSearchProcessor** class and includes the **PersonSearchProcessorFactoryAttribute** attribute, with the new person search module area as a parameter.
3. In the **PersonSearchProcessor** extended class, override the **doSearch** method with your desired search logic. As shown in the following example, extend the **PersonSearchResult** table to create new table relationships.

```
PersonSearchResultCategory::Customer needs a relation:PersonSearchResult.ResultRecId =
CustTable.RecId,PersonSearchResult.ResultTableId = CustTable.TableId
```

Integrate with the Global address book (Optional)

If you want to integrate with the Global address book, insert any discovered party numbers into the **PersonSearchPartyNumberTmp** table. The **findPartyLink** method of **PersonSearchProcessor** tries to link party numbers to other search artifacts, such as users, customers, or vendors.

This method has a delegate, **onFindPartyLink**, that lets you specify additional artifacts to search, based on the

party numbers.

The **PersonSearchCriteria** tables let end users specify the parameters by which to search the system for personal data.

Create new search criteria

If you need new search criteria, follow these steps.

1. Extend the **PersonSearchCriteriaName**, **PersonSearchCriteriaAddress**, and **PersonSearchCriteriaKnownId** tables, or create your own tables.
2. Extend the **PersonSearchDialog** form to show these new data fields.
3. Use the new criteria during search processing.

The **PersonSearch** form shows the set of results that was discovered by a person search.

Show the new search category in the PersonSearch form

1. Create a new view on the **PersonSearchResult** table. This view should restrict results to only your new **PersonSearchResultCategory**.
2. Join the view to your result record, and create the view fields that are needed (for example, **PersonSearchResultCustomerView**).
3. Extend the **PersonSearchResult** table to create a new relationship to the new view. This relationship should join on the person search ID.
4. Extend the **PersonSearch** form:
   a. Add the new view as a data source.
   b. Add a new tab to the results with the result grid and the **Include/Exclude** buttons.
   c. Create event handlers for the **Include/Exclude** buttons to update the **PersonSearchResult** records.

      The **PersonSearchEventHandler::updateMarkedOnButtonClicked()** method is provided for convenience.

> **NOTE**
> If you want to see the record count in the result caption, create an event handler on the **OnQueryExecuted** view data source event. Next, call the **setResultCountOnGridCaption()** method on the **PersonSearch** form to update the count.

Each **PersonSearchEntityFilterRelation** record specifies the conditions when a filter should apply, and the filter table and field to apply.

The set of filter relations is compared to the template metadata when the package is built.

For a filter to be created, a **PersonSearchResult** record with the matching filter category must exist. After it's found, the **PersonSearchResult** references the table field where the filter value resides.

Create new filters

1. Use the Chain of Command to extend the **PersonSearchEntityFilterRelation** table.
2. Decide on the type and source of the new filter:

a. If the filter is an extended data type (EDT) or enumeration, set the **MetadataTypeId** to the data type ID.
b. If the filter is a source table field, specify the source table and source field IDs.
c. If the filter is an entity field, specify the entity field ID.

3. Decide on the filter table and filter field.

   The filter table must be available as a **PersonSearchResult** with a matching category. Otherwise, no filters will be created.

4. Insert the new filter record.

   The person search framework will automatically manage initialization of all exclusions when the form is first opened. Exclusions let you suppress the filter building functionality for specific entity fields.

Create new exclusions

1. Use the Chain of Command (COC) to extend the **PersonSearchEntityExclusion** table.
2. In the **CoC method**, specify the entity, the entity field, and whether the exclusion is active.
3. Insert the new exclusion record.

   The person search framework will automatically manage initialization of all exclusions when the form is first opened.

Additional resources

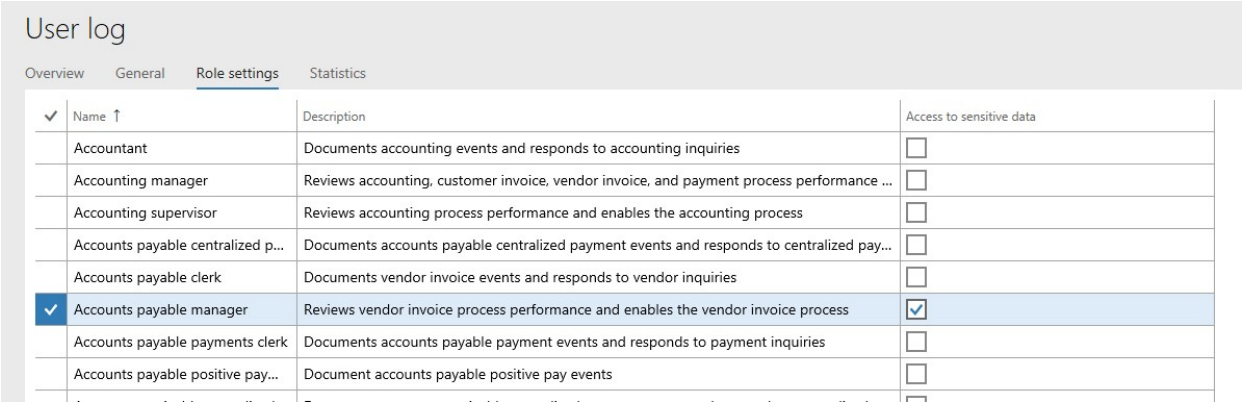
If you're extending the Person search report as part of a response to a request for data under the General Data Protection Regulation (GDPR) in the European Union, more information about that regulation is available in the General Data Protection Regulation overview.

You can learn more about the GDPR on the European Union's website and on the Microsoft Trust Center.

Manage access to sensitive data

2/18/2021 • 2 minutes to read • Edit Online

System administrators can use the **User log** page to keep an audit log of users who have logged on to the system. Knowing who has logged in can help protect your organization's data. We've enhanced the user logging capability to let the administrator identify roles that provide access to sensitive data.



Name	Description	Access to sensitive data
Accountant	Documents accounting events and responds to accounting inquiries	☐
Accounting manager	Reviews accounting, customer invoice, vendor invoice, and payment process performance ...	☐
Accounting supervisor	Reviews accounting process performance and enables the accounting process	☐
Accounts payable centralized p...	Documents accounts payable centralized payment events and responds to centralized pay...	☐
Accounts payable clerk	Documents vendor invoice events and responds to vendor inquiries	☐
Accounts payable manager	Reviews vendor invoice process performance and enables the vendor invoice process	☑
Accounts payable payments clerk	Documents accounts payable payment events and responds to payment inquiries	☐
Accounts payable positive pay...	Document accounts payable positive pay events	☐

What is sensitive data?

An organization can define what constitutes *sensitive data* in whatever way serves its needs. For some organizations, sensitive data might be any data that is related to financial or human resource data, or just data that is personal data. Some industries or some countries or regions might have a more specific definition of sensitive data that an organization can adopt for itself. It's up to each organization to decide whether and how to use the sensitive data identifier.

The sensitive data identifier enhances the user logging experience by letting your organization produce audit logs that show who in your system has access to sensitive data. This capability is helpful for organizations that might have multiple roles that have varying degrees of access to certain data. It can also be helpful for organizations that want a detailed level of auditing to track users who have had access to data that's been identified as sensitive data.

ID	Name	Type	Time ↓	Online time	RolesWithAccessToSensitiveData
Admin	Admin	Logon	11/16/2017 03:10:08 PM	0:00:00	[Auditor][System administrator]
Admin	Admin	Logon	11/16/2017 02:43:14 PM	0:23:40	[System administrator]
Admin	Admin	Logon	11/16/2017 01:59:17 PM	0:43:56	
Admin	Admin	Logon	11/16/2017 01:49:21 PM	0:00:09	

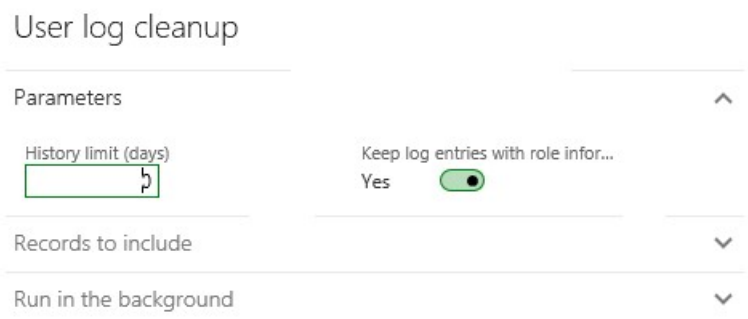
Language-specific information

The role information in the user log is language-specific and matches the current user language.

Tidspunkt ↓	Onlinetid	Roles with access to sensitive data
11/16/2017 05:29:31 PM	0:00:00	[Revisor],[Systemadministrator]
11/16/2017 05:10:15 PM	0:17:44	[Revisor],[Systemadministrator]
11/16/2017 03:47:25 PM	0:52:03	[Revisor],[Systemadministrator]
11/16/2017 03:21:56 PM	0:24:22	

Log retention

The log entries of users who have access to data that's been declared to be sensitive data can be retained separately from all other data in the log. The administrator can enable this functionality by setting an option on the **User log cleanup** page.



> **NOTE**
>
> This feature is available in version 8.0. This feature is available for Dynamics AX 2012 R3 (via KB 4074643)

Additional resources

You can learn more about the GDPR on the European Union's website and on the Microsoft Trust Center.

Respond to requests for personal data in Human Resources

2/18/2021 • 5 minutes to read • Edit Online

This topic can help both businesses that use Microsoft Dynamics 365 Human Resources, and also partners and independent software vendors (ISVs), when they comply with data subject rights (DSR) requests. For more information about the European Union's General Data Protection Regulation (GDPR) and the related resources that Microsoft provides, see General Data Protection Regulation overview.

For Human Resources, Microsoft acts as a processor. As a data processor, Human Resources provides processes and features that let you comply with your GDPR obligations as a data controller.

Rights

Data subjects have the following rights under the GDPR, and a data controller might take any of the actions that are listed under each right in response to a DSR request.

Right to view

- Use the Person search report to find and collect personal data that is subject to a DSR request. For information about using this report, see the Person search report topic.
- Use advanced search and filters to find specific personal data and export that data by using the Microsoft Office Export functionality.
- Extend the Person search report by adding an existing entity. For information that can help you extend the report, see Extend the Person search report.

Right to modify*

- Use advanced search and filters to find the data that should be corrected, and correct the data directly in Human Resources.

* You might find that some data that qualifies as personal data can't be modified directly in the product or feature. Typically, this data is part of a financial transaction or other business data that is kept "as is" for compliance with financial laws (for example, tax laws), prevention of fraud (such as security audit trail), or compliance with industry certifications. As the controller, it's your responsibility to correct inaccurate or incomplete personal data.

Right to be forgotten*

- You can delete or erase personal data where the product enables that action directly. As the controller, you should ensure any personal data that a data subject requests be erased does not conflict with other compliance obligations your organization may have around data retention, for example proof of payment or proof of tax.

* You might find that some data that qualifies as personal data can't be modified directly in the product or feature. Typically, this data is part of a financial transaction or other business data that is kept "as is" for compliance with financial laws (for example, tax laws), prevention of fraud (such as security audit trail), or compliance with industry certifications. As the controller, it's your responsibility to correct inaccurate or incomplete personal data.

Right to port

The following options are available to help you port personal data in response to a data rights request.

- Use the Microsoft Office Add-in to export personal data.
- Author a custom report that enables the export of personal data.
- Use or extend the Person search report to gather information in support of a request for a copy of the data subject's personal data.

Right to restrict processing

- Remove the employee from, for example, a course.
- Following guidance from an organization's legal counsel, the company might refuse the right to restrict processing where data is needed by the company for compliance with other legal or industry mandates.

Additional notes that apply to requests for personal data

- Personal data that is found in Microsoft Power BI is generated from the information that is entered in Human Resources and then transferred to that application for reporting purposes. Any request for personal data should be fulfilled from the information in Human Resources, by using tools such as reports, Export to Excel, and the Person search report. You should not need to do additional reporting from Power BI to fulfill a DSR request.
- Human Resources doesn't export documents that are attached to records. These attachments must be manually downloaded and shared with the individual who has made the DSR.
- If transactional data is associated with a master record, that record can't be deleted.
- Similarly, transactions that have been posted or completed can't be deleted.

Reasons why certain personal data may not be modified or deleted in Human Resources

The following table lists several reasons why personal data modification or deletion is restricted in certain scenarios.

REASON	COMMENT
Financial, tax, generally accepted accounting principles (GAAP)	A party can't be deleted, but the party's name can be updated.
Financial, tax, GAAP	A current worker's data can't be deleted, but the worker's name can be updated.
GAAP	Posted or completed transactions can't be modified.

Additional information

Only terminated workers can be deleted from Human Resources. Follow these steps to delete terminated workers.

- Delete position assignments.

  To delete a position assignment, select **Position assignments** on the **Worker** page. Select **As of date** and select **Display all records**. Drill into the position number, select **Changes timeline** > **Manage changes** > **Position worker assignments**, and remove the position assignment record that is associated with the worker that you're deleting.

- Delete fixed compensation.

  To delete fixed compensation, select **Employment history** on the **Worker** page. Select **Employment history** > **Employment** > **Fixed compensation**, and delete the fixed compensation plans for the worker.

- Delete variable compensation enrollments.

  To delete variable compensation, select **Employment history** on the **Worker** page. Select **Employment history** > **Employment** > **Variable compensation plan enrollment** and delete the variable compensation plan enrollments for the worker.

- Delete any associated checklists.

  To delete the checklists, select the **Checklists** option on the **Worker** page.

Compensation isn't assigned to contractors. Therefore, those steps can be skipped in the preceding process.

An admin can search and export personal data in Microsoft Dynamics 365 Talent: Attract and Microsoft Dynamics 365 Talent: Onboard via https://attract.talent.dynamics.com/personreport.

Additional resources

You can learn more about the GDPR on the European Union's website and on the Microsoft Trust Center.

The survey will take about seven minutes. No personal data is collected (privacy statement).

Respond to requests for personal data in AX 2012

2/18/2021 • 2 minutes to read • Edit Online

This topic can help businesses that use Microsoft Dynamics AX 2012, implementation partners, and independent software vendors (ISVs) comply with requests from a data subject concerning their personal data under the European Union's General Data Protection Regulation (GDPR). For more information about the GDPR and the related resources that Microsoft provides, see the General Data Protection Regulation overview. Although the "Guide to the GDPR for Finance and Operations" was written for Finance and Operations apps, the rights that a data subject has under the GDPR apply to organizations using Dynamics AX 2012. The steps listed in the "Guide to the GDPR for Finance and Operations" can be used by an organization responding to a request for personal data and are also appropriate for organizations using Dynamics AX 2012, with the exception of the **Person search** report, which is not available for Dynamics AX 2012. This topic lists additional points that are specific to Dynamics AX 2012.

Applicable product updates for Dynamics AX 2012

Additional product updates and information related to GDPR that's specific to AX 2012 are available from Microsoft Dynamics Lifecycle Services (LCS). Sign-in is required for access to LCS.

Here are some example inquiries and reports that are available in AX 2012 that might help you find and report personal data:

- **Home** > **Common** > **Global address book**

  In the inquiry window, enter a person's name in the search box.

- **Accounts payable** > **Common** > **Vendor** > **All vendors**
- **Accounts receivable** > **Common** > **Customer** > **All Customers**
- **Human resources** > **Common** > **Workers**
- **Sales and marketing** > **Common** > **Customers**, **Prospects**, **Leads**, or **Contacts**

Additional resources

You can learn more about the GDPR on the European Union's website and on the Microsoft Trust Center.

GDPR data requests for Lifecycle Services (LCS)

2/18/2021 • 2 minutes to read • Edit Online

Overview

This topic offers information for complying with requests for data under the General Data Protection Regulation (GDPR) if the request requires accessing data in Microsoft Lifecycle services (LCS). For general information about this regulation and the resources Microsoft is providing to support compliance with it, see General Data Protection Regulation overview.

User management

A tenant administrator can view and manage users on the **Organization users** tile on the home page in LCS.

An administrator can view and manage all organization users on the **Organization user** page in LCS.

To export a user, the administrator can use filtering to find a specific user, select that user, and copy the name and email address of the user.

Additional resources

- Official GDPR site
- Microsoft Service Trust Portal

Lifecycle Services resources

2/18/2021 • 2 minutes to read • Edit Online

Lifecycle Services (LCS) for Microsoft Dynamics is a collaboration portal that provides an environment and a set of regularly updated services that can help you manage the application lifecycle of your implementations of the Dynamics 365 Finance and Operations apps.

- What's new in Lifecycle Services (LCS)
- Lifecycle Services (LCS) user guide
- Projects in Lifecycle Services (LCS)
- Project onboarding
- Methodologies in Lifecycle Services (LCS)
- Business process modeler (BPM) in Lifecycle Services (LCS)
- Cloud-hosted environments in Lifecycle Services (LCS)
- Manage the support experiences for Finance and Operations apps
- Configuration in Lifecycle Services overview
- Customization analysis in Lifecycle Services (LCS)
- Infrastructure estimator in Lifecycle Services (LCS)
- Issue search in Lifecycle Services (LCS)
- License sizing estimator in Lifecycle Services (LCS)
- Request for proposals (RFP) responses
- System diagnostics in Lifecycle Services (LCS)
- Upgrade analysis in Lifecycle Services (LCS)
- Usage profiler in Lifecycle Services (LCS)
- Downloadable tools in Lifecycle Services (LCS)

Additional resources

- For information about how to contact Microsoft if you have technical questions about Dynamics 365 Finance and Operations apps, or if you need help accessing Microsoft Dynamics Lifecycle Services (LCS), see Get support for Finance and Operations apps or Lifecycle Services (LCS).
- For information about how to contact Microsoft if you have technical questions about Microsoft Dynamics AX 2012 or need support, see Manage the support experiences for Finance and Operations apps.

Lifecycle Services (LCS) for Finance and Operations apps customers

2/18/2021 • 4 minutes to read • Edit Online

This topic is intended for customers who have signed up for the current versions of Finance and Operations apps. Partners who are working with customers to help them move through the lifecycle of their Lifecycle Services (LCS) project will also find this information useful.

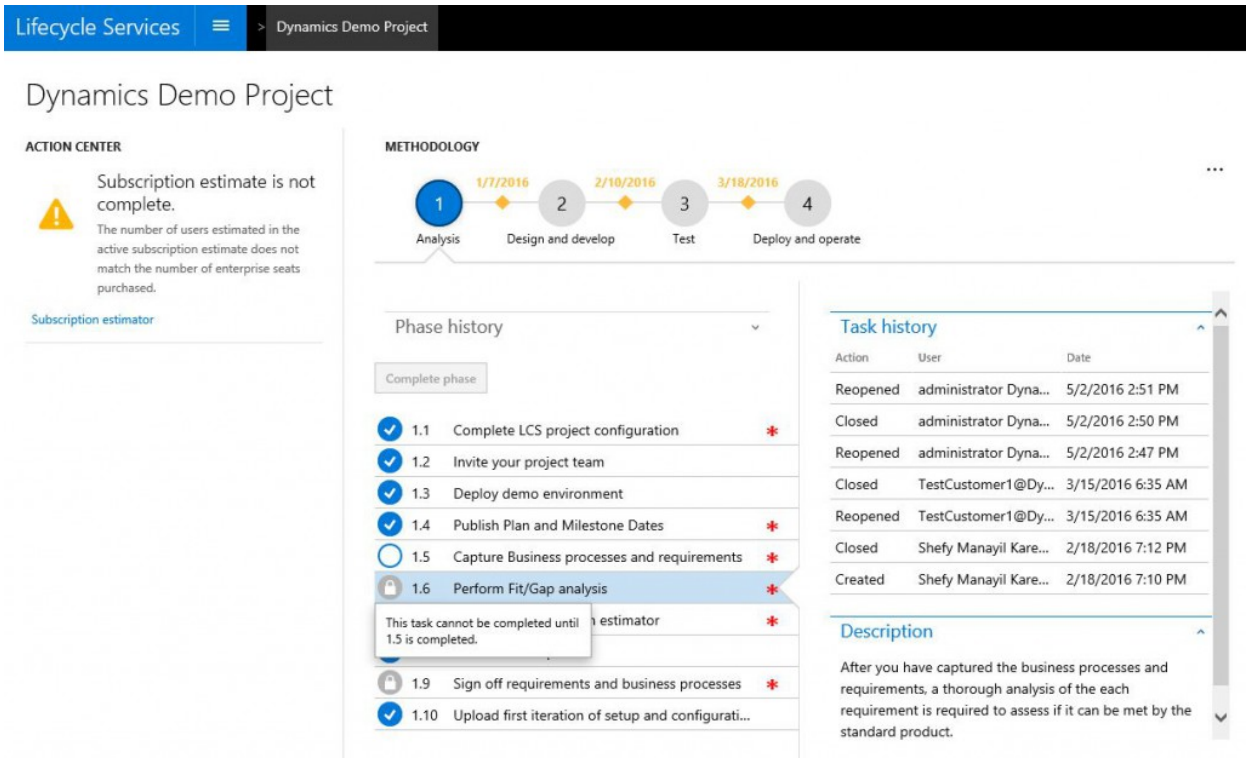
LCS workspace for the current versions of the Finance and Operations apps

When you sign up for the current versions of Finance and Operations apps, your subscription includes an Implementation project workspace. After you activate the service, the tenant administrator must sign in at https://lcs.dynamics.com by using the tenant account. The project workspace is automatically created for your organization. The workspace includes the following elements:

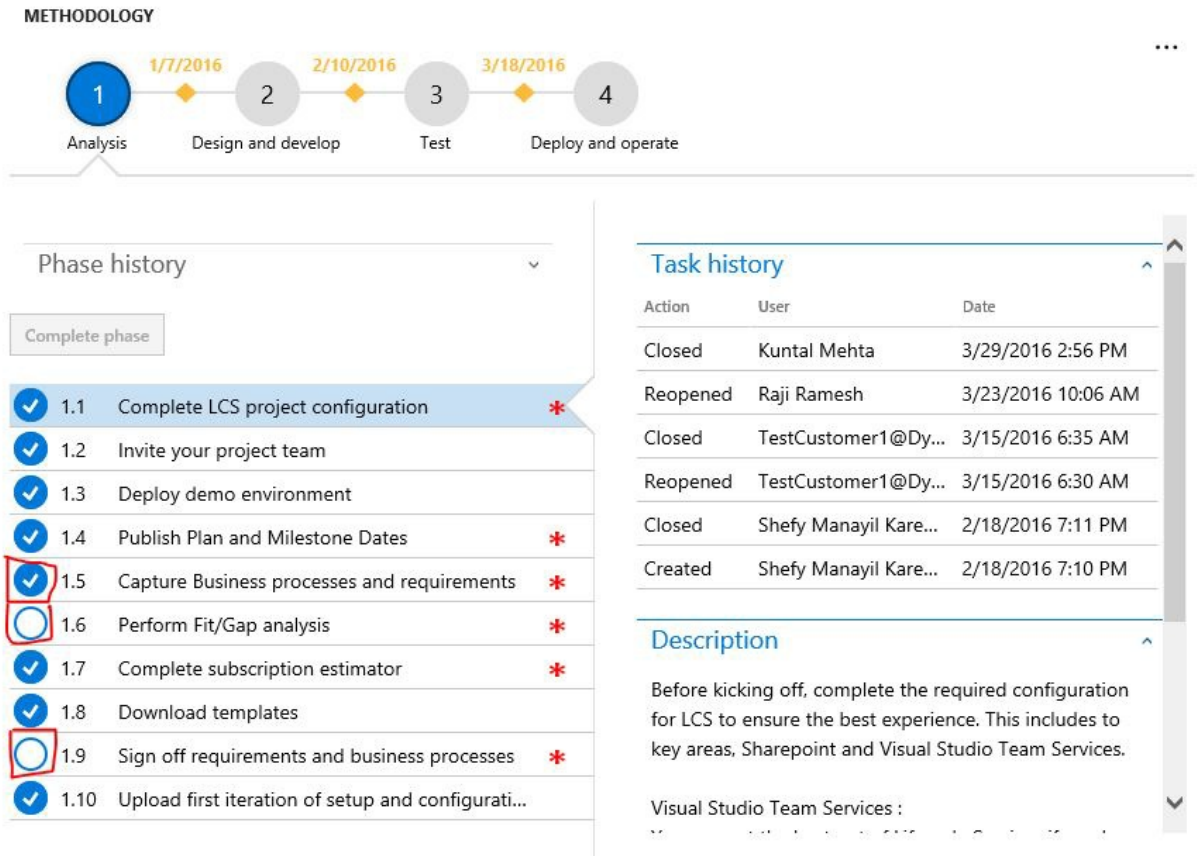
- Enabled features, based on the offer that you selected
- Environments that are deployed and managed by Microsoft
- Guidance that is provided through the Action center to help you complete required actions
- A new methodology experience that includes tasks that lock as you move through the implementation
- A more complete history that specifies who completed each methodology phase and task
- Milestones that you can use to track critical project dates
- Various services to help you with your implementation

Methodologies

As a customer, you must complete the steps that are outlined in the methodology to gain access to the production environment. Before a phase can be marked as completed, you must complete the specified mandatory tasks. Locked tasks, such as tasks 1.6 and 1.9 in the following screenshot, are unlocked after you've completed the required actions. To learn which actions must be completed before a specific task can be unlocked, click the lock icon for that task.

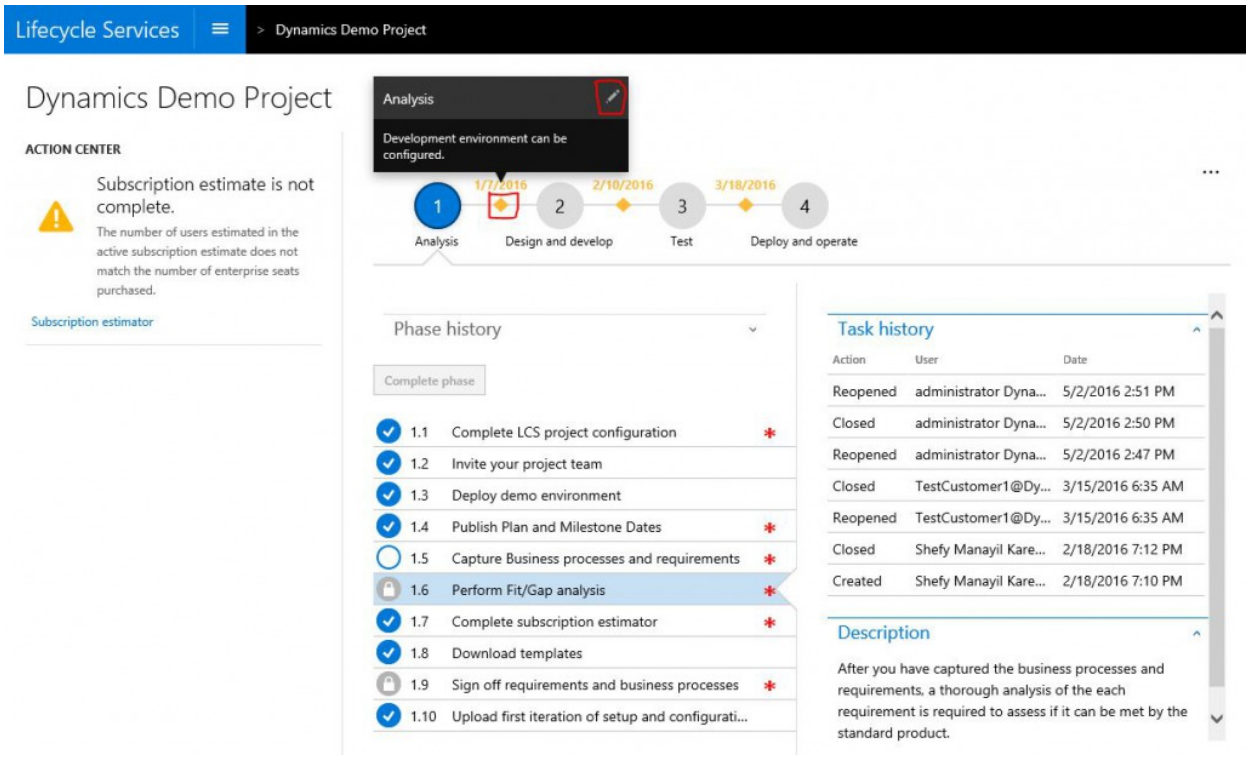


In the case of prerequisites, after you complete the required tasks, you can mark the dependent tasks as completed. For example, in the following screenshot, tasks 1.6 and 1.9 depend on task 1.5. Because task 1.5 has now been completed, the two dependent tasks can be marked as completed.

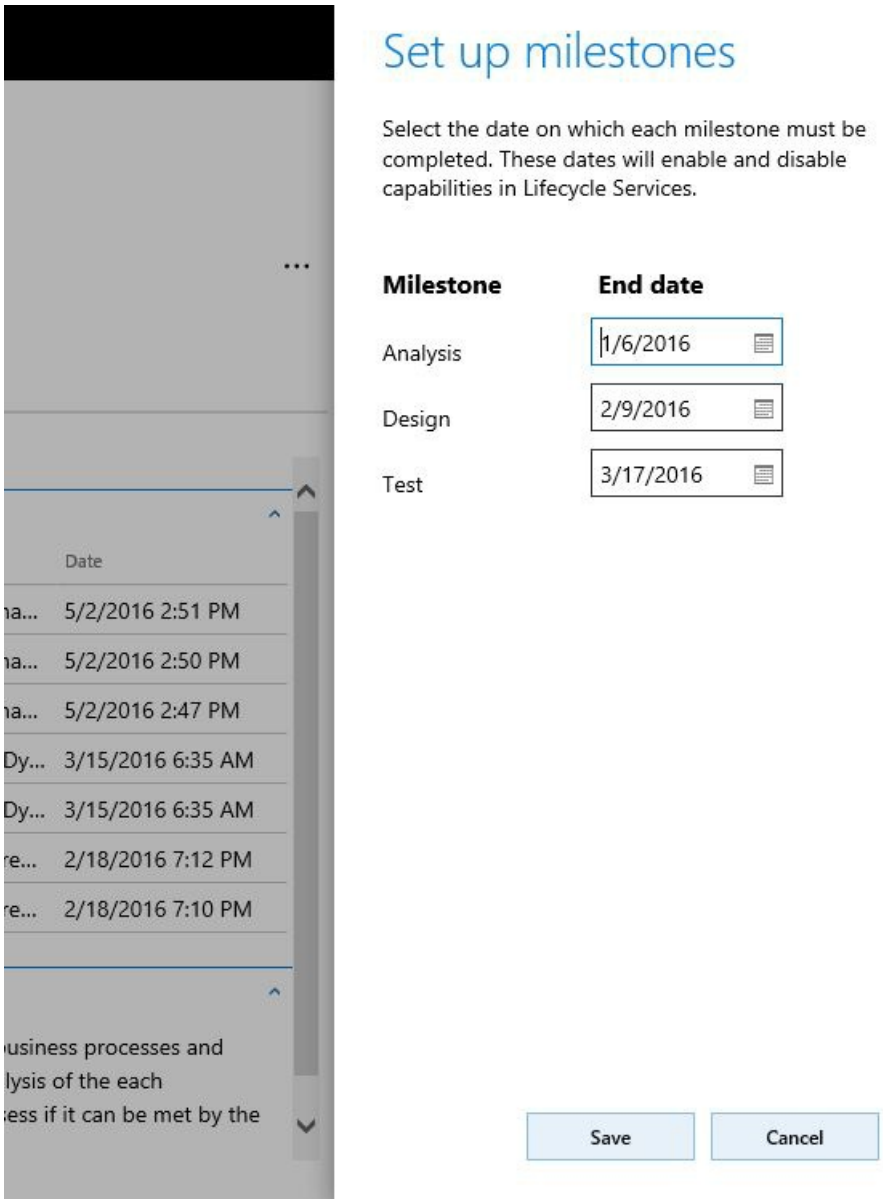


Milestones

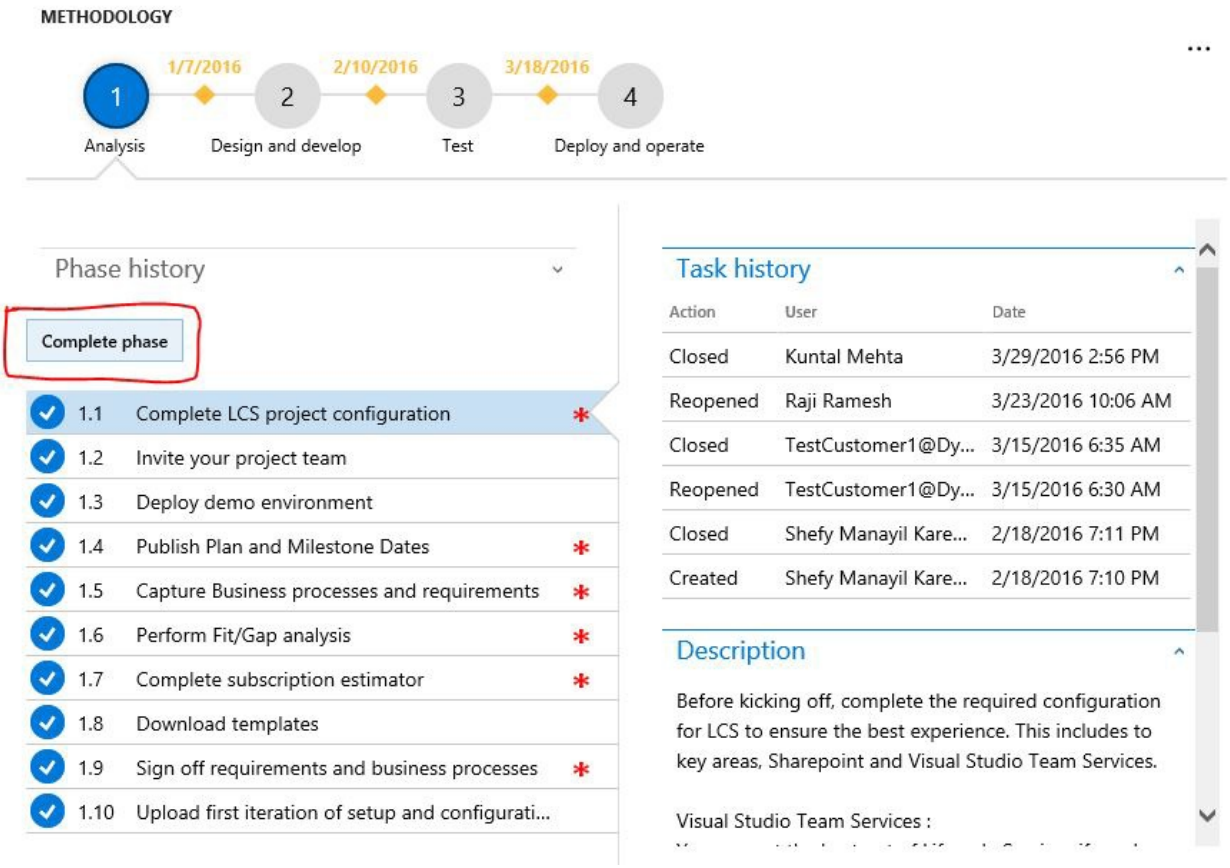
High-level milestones must be defined for a project. Milestones can help you track the deliverables that must be completed and your progress toward the milestone goals. Color indicators help you quickly learn whether you're behind schedule. For example, in the following screenshot, the milestones are yellow. To enter or update the milestone dates, click the diamond shape in the methodology, and then click the **Edit** button (pencil icon). You can change milestone dates at any time.



When you've finished entering milestones, the **Publish plan and milestone** task opens, and you can mark it as completed.

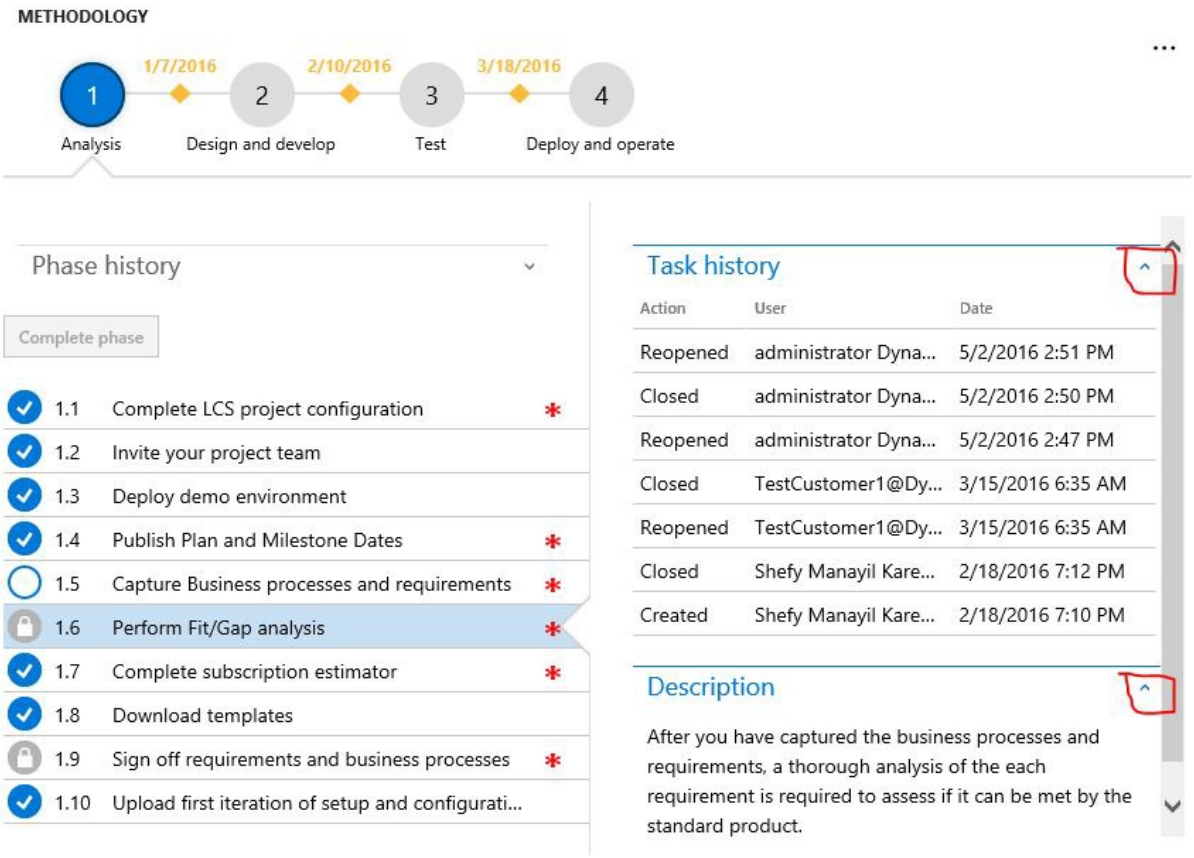


When you've completed all the required tasks in a phase, you can click **Complete phase** to mark the phase as completed. After you mark a phase as completed, next steps become available in Microsoft Dynamics Lifecycle Services (LCS).



Methodology description and history

Descriptions can help you understand what is expected of you for a specific methodology task or phase. You can expand the methodology description to learn more about each task, and then collapse the description when you've finished. The task and phase history can tell you when a task or phase was completed or reopened. If you're a project manager, this information can help you stay on top of the high-level tasks that are required for your implementations.



Subscription estimator

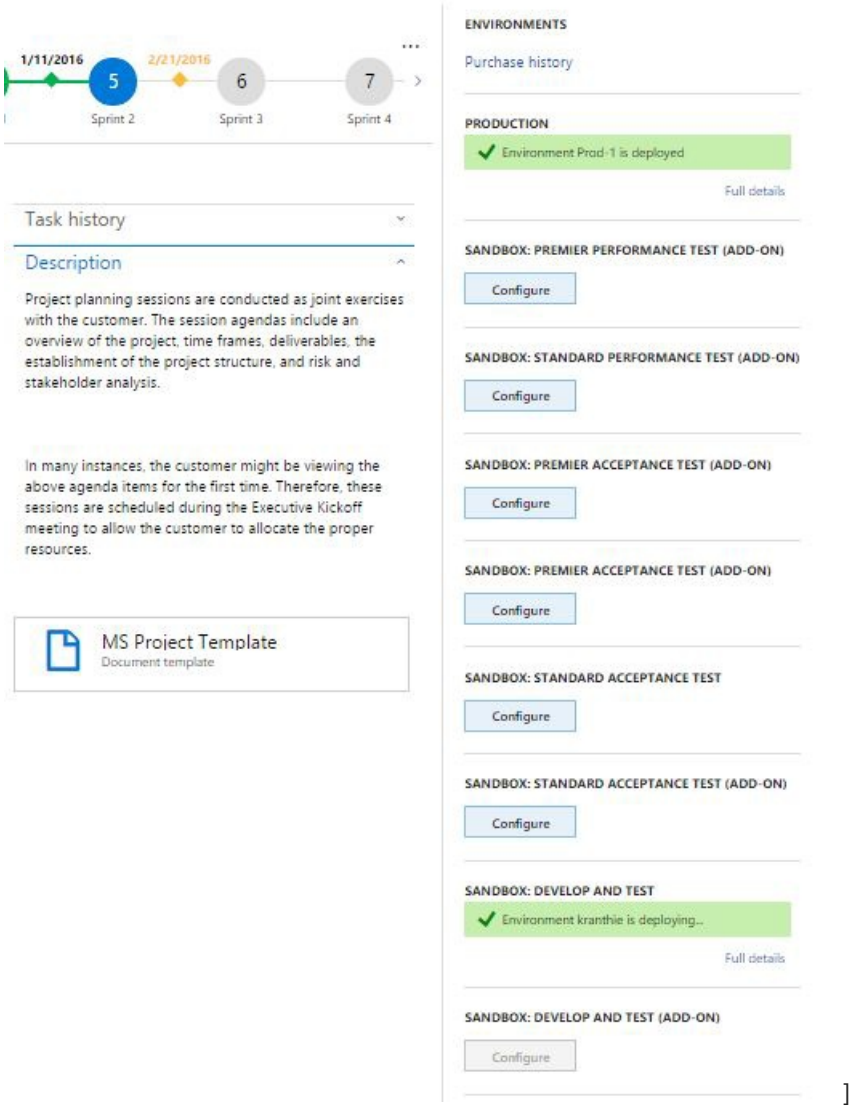
You can use the Subscription estimator tool to evaluate your subscription requirements for the current versions of the Finance and Operations apps. To use Subscription estimator, download the usage profile, which is a Microsoft Excel workbook. Then, in the workbook, complete the following worksheets:

- Deployment details
- Instance Characteristics
- Retail & Commerce

After you've completed the worksheets, enter the data from the summary sheet into Subscription estimator by clicking **+ New estimate**. You must make one estimate the active estimate. Make sure that the estimate that you mark as active is same as the offer that you bought through the VL or CSP channel.

New deployment experience

To provision your environment, you must to complete a configuration checklist. As you make progress through the methodology, environments become available to you. Click **Configure** to add deployment information.



]

Because the information that you enter determines your experience, carefully review your input. After you've entered all the required information, sign-off is required for the deployment request. The user who completes the sign-off becomes the system administrator on the instance. Verify that the correct user completes the sign-off for the deployment. After the sign-off is completed, the Microsoft site reliability engagement team reviews the request. After the team has reviewed the information that you entered, it initiates the provisioning. If the information isn't correct, the team will contact you. After the provisioning is completed, the status is updated to indicate that the environment has been deployed, as shown in the following screenshot. If the provisioning takes longer than expected, the Microsoft site reliability engagement team reviews the status and takes appropriate actions. These actions might include contacting you. After the environment is provisioned, click **Full details** to open the **Detailed environment** page, where you can sign in to the system, view the monitoring status, or view relevant updates.

NOTE

Can you tell us about your documentation language preferences? Take a short survey.

The survey will take about seven minutes. No personal data is collected (privacy statement).

Lifecycle Services (LCS) for Finance and Operations apps partners

2/18/2021 • 2 minutes to read • Edit Online

This article explains how partners can get started with Microsoft Dynamics Lifecycle Services (LCS).

As a Finance and Operations partner, you can access the current version by following the steps in Sign up for preview subscriptions.

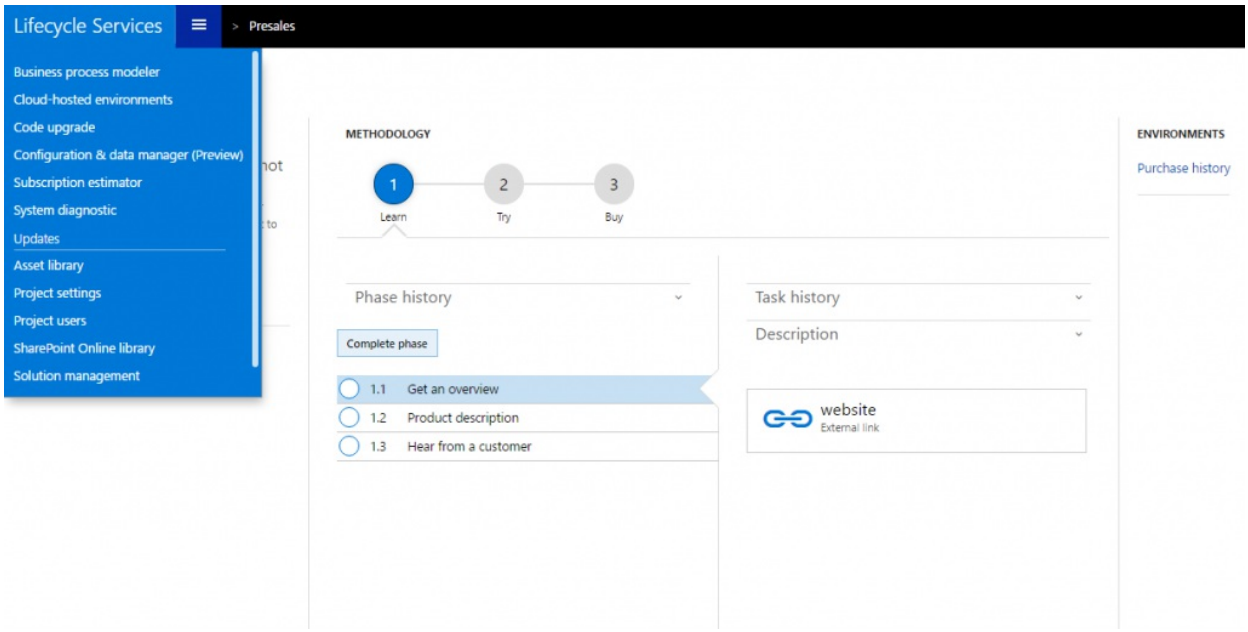
Projects for partners in LCS

After you sign up as a partner for the current version, you can create two types of projects:

- Prospective presales
- Migrate, create solutions, and learn the Dynamics 365 Finance and Operations apps

Prospective presales project

Work with new prospects to help them understand the business processes that are available, and to help them evaluate their subscription needs. Note that only partners can provision a new cloud environment.



Migrate, create solutions, and learn the project for Finance and Operations apps

Create a Microsoft Dynamics AX 2012 project workspace. You can use the project to support the upgrade from Dynamics AX 2012 to the current version. You can also use the project to learn how to use the current version or create solutions in Microsoft Dynamics AX Lifecycle Services (LCS).

Projects for customers in LCS

For every customer who signs up for LCS, an Implementation project workspace is automatically created during the sign-up process. As a partner, you can't create an Implementation project. For more information about the Implementation project workspace, see Lifecycle Services (LCS) for Finance and Operations apps customers. Services within project workspaces behave in the same manner. However, an important difference between an Implementation project and other project types is the ability to configure the current version of Finance and Operations, which is managed by Microsoft.

NOTE

Can you tell us about your documentation language preferences? Take a short survey.

The survey will take about seven minutes. No personal data is collected (privacy statement).

What's new or changed in Lifecycle Services (LCS)

2/18/2021 • 2 minutes to read • Edit Online

Microsoft Dynamics Lifecycle Services (LCS) provides a cloud-based collaborative workspace that customers and their partners can use to manage projects from pre-sales through implementation and operations. LCS provides checklists and tools to help you manage your project, based on the phase of the project and the industry that you're working in. It also provides a dashboard, so that you have a single location where you can obtain up-to-date project information.

To get started with LCS, see the Lifecycle Services (LCS) user guide.

> **IMPORTANT**
> LCS features and service changes will no longer be announced via blog posts. Descriptions of LCS features are provided in the release plans.

The following sections list the features that are included in LCS releases.

June 2020 - wave 1

AREA	FEATURE	STATUS
Business process modeler (BPM)	Download task recording (AXTR)	General availability
Service updates	View canceled updates	General availability

May 2020 - wave 2

This release contains general performance improvements and minor bug fixes.

May 2020 - wave 1

AREA	FEATURE	STATUS
Issue Search improvements	Lifecycle Services Issue search improvements	General availability

April 2020 - wave 2

AREA	FEATURE	STATUS
Environment actions	Lifecycle Services support for dual-write capabilities	Preview
Environment actions	Removing Remote Desktop access to Tier 2-5 Standard Acceptance Test (or sandbox) environments	Preview

April 2020 - wave 1

This release contains general performance improvements and minor bug fixes.

March 2020 - wave 2

AREA	FEATURE	STATUS
Admin APIs	RESTful APIs for database export	Preview
Environment actions	Apply data upgrade packages for AX2012 customers on sandbox environments	General availability
Environment actions	Platform update 20 required for database movement operations	General availability

March 2020 - wave 1

This release contains general performance improvements and minor bug fixes.

February 2020 - wave 2

AREA	FEATURE	STATUS
Environment actions	Platform update 20 required for database movement operations	General availability

February 2020 - wave 1

AREA	FEATURE	STATUS
Admin APIs	Database movement RESTful APIs	General availability

LCS releases before November 2019

For information about LCS releases that occurred before November 2019, see the blog posts that the Lifecycle Services team published on the Dynamics 365 blog.

NOTE

Can you tell us about your documentation language preferences? Take a short survey.

The survey will take about seven minutes. No personal data is collected (privacy statement).

Known issues

2/18/2021 • 3 minutes to read • Edit Online

This topic explains how to view the known issues that you might experience when you use Finance and Operations.

You can find known issues in Finance and Operations by using the Issue search tool in Microsoft Dynamics Lifecycle Services (LCS). You can sign in to LCS by using your CustomerSource or PartnerSource account. Then, in the **Issue search** field, enter the search text that is shown in the following table.

> **NOTE**
> Be sure to enter the text exactly as it appears in the table. Otherwise, you might get different search results.

Dynamics 365 for Operations	Platform update 5	7.0.4475.16165	March 2017	Known issue in Dynamics 365 for Operations platform update 5 (March 2017)
Dynamics 365 for Operations	Platform update 4	7.0.4425.16161	February 2017	Known issue in Dynamics 365 for Operations platform update 4 (February 2017)
Dynamics 365 for Operations	Platform update 3	7.0.4307.16141	November 2016	Known issue in Dynamics 365 for Operations version 1611 with platform update 3
Microsoft Dynamics AX	Platform update 2	7.0.4230.16130	August 2016	Known issue in Dynamics AX platform version 7.2 (August 2016)
Microsoft Dynamics AX	Platform update 1	7.0.4127.16103	May 2016	Known issue in May 2016 release
Microsoft Dynamics AX	7.0	7.0.4030.16079	February 2016	Known issue in February 2016 release

Removed or deprecated features in Lifecycle Services (LCS)

2/18/2021 • 2 minutes to read • Edit Online

This topic describes features that have been removed or deprecated for Microsoft Dynamics Lifecycle Services (LCS).

- A *removed* feature is no longer available in the service.
- A *deprecated* feature isn't in active development and might be removed in a future update.

This list is provided so that you can consider these removals and deprecations as you do your own planning.

October 2019 announcements

Flowchart diagrams in Business process modeler

Reason for deprecation/removal	We are deprecating the flowchart diagrams component in Business process modeler (BPM), because the legacy design caused low usage.
Replaced by another feature?	No
Areas affected	Business process modeler
Status	Deprecated: The flowchart diagrams component in BPM is expected to be removed in 2020. The following functionality will be unavailable: • All flowcharts will be read-only and unavailable for editing. The shape properties that are associated with flowchart activities will also be unavailable. These flowcharts include both the default flowcharts that are automatically generated and customized flowcharts that are modified based on those default flowcharts. • The process steps will be read-only and unavailable for editing. • The legacy fit/gap analysis feature will be unavailable. Therefore, no gap list will be automatically created or available for export. **Note:** This feature had previously been deprecated and replaced by Microsoft Azure DevOps integrations. • The version history of the flowchart will be unavailable.

Lifecycle Services (LCS) user guide

2/18/2021 • 4 minutes to read • Edit Online

Microsoft Dynamics Lifecycle Services (LCS) provides regularly updated services. The goal of LCS is to deliver the right information, at the right time, to the right people, and to help ensure repeatable, predictable success with each roll-out of an implementation, update, or upgrade. LCS is available to customers and partners as part of their support plans. If you're a Microsoft Dynamics AX 2012 customer, you can sign in by using your CustomerSource or PartnerSource credentials. If you're a customer of the newest version of the Dynamics 365 Finance and Operations apps, you can sign in by using your Microsoft Azure Active Directory (Azure AD) credentials. Go to LCS.

Tools that are provided in LCS

The following table lists the tools that are provided in LCS and describes the phases that each tool applies to.

TOOL	DESCRIPTION
Projects	Projects are the key organizer for your experience in LCS. Projects let you invite your partners to collaborate with you, and they also let you track progress.
Methodologies	Methodologies provide a tool that you can use to ensure more repeatable, predictable implementation projects. You can use one of our methodologies or create your own. By using a methodology, you can easily track and report on your progress.
Business process modeler	Business process modeler lets you create, view, and modify standard process flows. By using Business process modeler, you can achieve the following goals: standardize process flows; align your business processes with industry-standard processes, as described by the American Productivity & Quality Center (APQC); identify fit and gaps between user requirements and the default functionality that Microsoft Dynamics products provides.
Cloud-hosted environments	Cloud-hosted environments is a tool that you can use to deploy Microsoft Dynamics environments on Azure. When you use Cloud-hosted environments, you must select the type of environment to deploy, such as a demo, developer/test, or production environment. Based on your selection, the Cloud-hosted environments tool provisions the appropriate number of virtual machines (VMs) in Azure. These VMs have Microsoft Dynamics components (and all their prerequisites) already installed on them.
Cloud-powered support	Cloud-powered support helps you manage support incidents. It lets you create a VM in Azure that has the same hotfixes installed as your local environment. You can reproduce and record an incident on the VM, and then submit the incident to our support team. Support follows up by investigating and, if possible, testing a fix on the VM, and then sends the fix back to you for verification.

TOOL	DESCRIPTION
Configuration and data manager (preview)	Configuration and data manager (preview) lets you copy a configuration from one instance to another. You can copy from and to environments that meet the following criteria: they are managed as part of an LCS project; they run the Data Import/Export Framework.
Customization analysis	Customization analysis validates model files against best practices and provides a report of potential areas for improvement.
Issue search	Issue search helps you find existing solutions and workarounds for known issues in Microsoft Dynamics products. You can see which issues have been fixed, which issues remain open, and which issues have been resolved as "won't fix."
Asset library	The Asset library is a storage location for the various assets that are associated with a tenant in LCS.
Get updates	Get updates is a tool that customers to access the updates that are available for their environments.
Environment monitoring	Environment monitoring is a set of tools that helps you monitor, diagnose, and analyze the health of the environments that you manage.
Translation service	The Microsoft Dynamics 365 Translation Service (DTS) is hosted in LCS. It's designed to enhance the experience for partners and independent software vendors (ISVs) when they translate their solutions or add a new language for the supported Dynamics products.
Regulatory updates	Regulatory updates is a tool that lets customers, partners, and ISV solution providers stay up to date about regulatory updates by setting up alerts through LCS.
System diagnostics	System diagnostics is a tool that helps administrators monitor AX 2012 environments.
Updates	The **Updates** page hosts the details of updates that are available for an AX 2012 environment. It also provides access to groups of updates that can be used for slipstream installations.
Upgrade analysis	Upgrade analysis helps you plan your upgrade to the latest version by analyzing code artifacts from Microsoft Dynamics AX 4.0, Microsoft Dynamics AX 2009, or AX 2012.
Usage profiler	Usage profiler is a data-gathering tool that helps you describe your projected or current usage of an. The usage profile that is generated can be used for various purposes, such as hardware sizing and support.
Downloadable tools	The **Downloadable tools** page provides a set of tools that were previously hosted on Microsoft Dynamics InformationSource.

TOOL	DESCRIPTION
License sizing estimator	License sizing estimator helps you estimate the number of licenses that are required. It provides a shared workspace that lets you model default and customized roles, and then automatically calculate the required client access licenses (CALs).

Access Lifecycle Services

NOTE

Can you tell us about your documentation language preferences? Take a short survey.

The survey will take about seven minutes. No personal data is collected (privacy statement).

Project onboarding

2/18/2021 • 5 minutes to read • Edit Online

Project onboarding is a self-paced, wizard-driven onboarding experience that guides project users in Microsoft Dynamics Lifecycle Services (LCS) through the process of setting up the key configuration components for a new implementation project for Dynamic 365 Finance, Dynamics 365 Supply Chain Management, or Dynamic 365 Retail. This wizard can also be accessed during and after the implementation, and can be used to update the information as required.

Microsoft relies on the information that you provide. You must provide the most current and accurate data as you complete Project onboarding. After you complete Project onboarding, you can deploy environments and continue with the project implementation.

To access Project onboarding, sign in to LCS, and then, on the main menu, select **Project onboarding**.

> **NOTE**
> Project onboarding is available for implementation projects and must be completed before any of the Microsoft-managed environments are deployed. For more information about implementation projects, see Lifecycle Services (LCS) for Finance and Operations apps customers.

For more information about the onboarding process, see Onboard an implementation project, and watch the Finance and Operations: Onboarding to Dynamics 365 TechTalk.

Onboarding steps

Each step in Project onboarding is designed to give you guidance about the project implementation or to gather information about the project context, so that the FastTrack team can better serve you. By providing accurate information in the wizard, you help Microsoft understand your implementation plan, so that it can provide appropriate guidance.

You can move through the wizard either by using the **Next** and **Back** buttons, or by selecting each step directly. For some steps, the right column of the page shows additional contextual information that will help you complete the step.

Welcome

The **Welcome** page provides general guidance and information that you will need to complete Project onboarding.

Project overview

- Provide the overview information for the implementation project.
- Describe the vision and goals for the project in a few sentences. This information will help Microsoft understand the goals that you want to achieve and how you define success for the project.
- Provide the Partner MPN ID, which you can get from the implementation partner team. If a partner is not involved or not yet identified, choose the appropriate option in the implementation partner drop-down list. Note that providing accurate partner data is a pre-requisite for FastTrack Program assignment. You could miss the opportunity for valuable services if you do not provide the correct partner information. Once partner identified, you need to update the MPN ID.

- Specify the estimated number of user licenses after full roll-out including current licenses. This number can differ from the current license purchase. If no change is planned, provide the current user license count. If a license type isn't applicable, enter **0** (zero).
- If your implementation project is a demo project, or if you're moving from another tenant, provide the details.

Project scope

- Provide information about how you plan to scope the implementation in terms of features and products. This information will help Microsoft understand your implementation and provide any guidance that is required.
- After you set the option for specific features to **Yes** in this step, you must provide additional data that is related to those features. This data will help Microsoft have a better engagement with you during the implementation. The additional data fields are mandatory.

Define your team

- Verify that all project team members are invited and configured.
- Set the **Primary contact for FastTrack** option to **Yes** for at least two users who have an active email address in the user list. If this option isn't set to **Yes** for any team member, FastTrack will reach out to all team members for implementation guidance during your implementation. If necessary, you should nominate at least one customer and one partner team member to be contacted by FastTrack.
- Each team member will be assigned a project security role and an implementation role. The project security role is relevant to access to the LCS project workspace, and the implementation role is relevant to the individual team member's role on the implementation team. We highly recommend that you include representatives from the customer among the project team members who have a monitored email address.

For more information, see Configuring project security and Roles in a Dynamics 365 implementation.

Define milestone dates

- Define all mandatory milestone steps. Milestones are associated with the methodology of the project. If the milestone dates haven't yet been decided, use tentative dates.
- Update the milestone dates as plans change. Microsoft uses the milestone dates to provide appropriate guidance for each milestone. To edit milestone dates, select the pencil symbol.

Associate LCS with Azure DevOps

- Connect LCS and Azure DevOps to maintain the application lifecycle.
- Enter the root URL of your Azure DevOps account and the personal access token that you obtained from Azure DevOps. The Azure DevOps account should belong to the customer.

Configure Azure DevOps

- Map work items between LCS and Business process modeler (BPM).
- Acknowledge the setup.
- If you choose to use a custom process template, follow these best practices:
    - Don't remove any existing work item types.
    - Don't remove any existing state for a work item type.
    - Don't add any required fields to a work item type.

FastTrack

- The **FastTrack** page introduces the FastTrack program. It explains what the program consists of and how your implementation can benefit from it.
- We strongly recommend that you watch the existing TechTalks and subscribe to upcoming TechTalks as Microsoft continues to share best practice guidance and information about the changes that are occurring in the product and platform.

Next steps

The **Next Steps** page provides additional resources about the most critical aspects of the implementation. You can access this page at any time during the implementation.

Complete onboarding

- Complete Project onboarding so that you can move on to the next steps in your implementation.
- You can complete Project onboarding only after all previous steps have been completed. If any previous steps haven't been completed, the **Complete onboarding** button won't be available.
- Any skipped steps are marked with an asterisk (*). You can also view any missing steps.
- After you complete Project onboarding, you can continue to update information, such as project scope values.

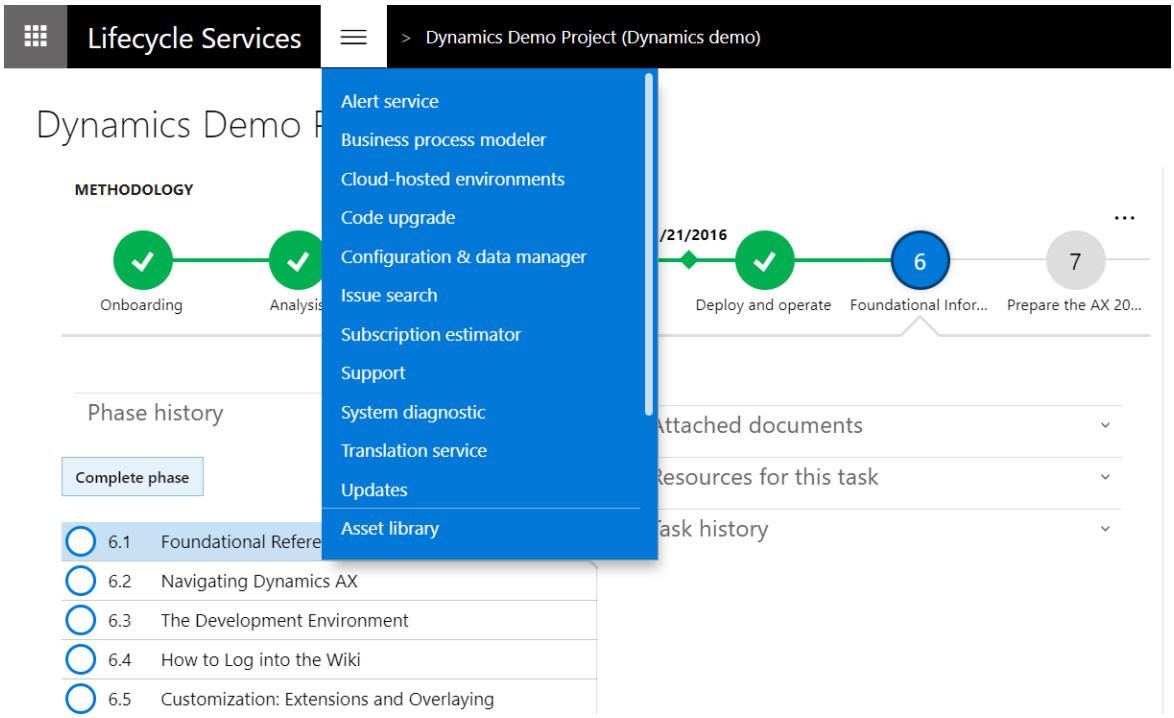
Subscription estimator in Lifecycle Services (LCS)

2/18/2021 • 2 minutes to read • Edit Online

Subscription estimator is a tool that is available in Microsoft Dynamics Lifecycle Services (LCS). Microsoft uses this tool to estimate the initial size of the production environment that must be provisioned for a customer. Before customers can request deployment of a production environment, they must estimate their peak workloads in terms of transaction counts and then upload that information to LCS. By using the details of user licenses and transaction counts to infer subscription requirements, the Subscription estimator tool helps ensure that the provisioned environment meets the customer's business requirements.

Follow these steps to use the Subscription estimator tool.

1. In LCS, open the project that is associated with the implementation project.
2. At the top of the page, select the hamburger icon, and then select **Subscription estimator**.



3. Download the sample usage profile.
4. Answer the required questions on each tab. If you're a Commerce customer, be sure to answer the questions on the **Retail and Commerce** tab.
5. Save the usage profile locally.
6. To upload the usage profile, select **New estimate**, name the estimate, and then upload the usage profile.
7. After the upload is completed, select **Mark as Active** to activate an estimate. An active estimate is required in order to configure a production deployment.

When there is a valid active estimate, the **Configure** button becomes available. You can use this button to request a production environment deployment.

NOTE

Although you can have multiple estimates, one estimate must be marked as **Active**. After the production environment has been deployed, or deployment of the environment has received sign-off, the active estimate is locked. To mark a different estimate as the active estimate, create a support request by using the Support portal in LCS.

Frequently asked questions

Question: Why isn't the **Configure** button for deploying a production environment available, even though there is an active estimate? And why does a warning message appear in the Action center on the project dashboard?

Answer: If you have multiple implementation projects, the **Configure** button might not be enabled and a warning message will appear in the Action center regarding an insufficient number of licenses. Log a support request, and the support team can help resolve this issue.

Question: Why does an error occur when I mark an estimate as **Active**?

Answer: When you mark an estimate as **Active**, you might receive the following error message:

- **Estimate created but does not meet requirements** – This error occurs if transaction lines that are entered aren't within the limits of the Subscription estimation tool. To resolve this error, create a support request, and attach the usage profile. Your instance can then be manually sized.

If you receive any other error message or encounter any other issue, create a support request, and attach your active estimate so that the support team can address the issue.

NOTE

Can you tell us about your documentation language preferences? Take a short survey.

The survey will take about seven minutes. No personal data is collected (privacy statement).

Configure Lifecycle Services (LCS) security

2/18/2021 • 3 minutes to read • Edit Online

Security in Microsoft Dynamics Lifecycle Services (LCS) is controlled at both the organization level and the project level. Not all members of an organization have access to all projects. Additionally, the members of a project might not all be members of the same organization.

Currently, users can sign in by using the Microsoft Azure Active Directory (Azure AD) credentials that they created in the Microsoft 365 portal when they signed up. Users who are administrators for their organization in Azure AD will be administrators in Lifecycle Services (LCS).

For Microsoft Dynamics AX 2012, organization-level access to LCS is controlled by the association of a person's Microsoft ID with an organization in CustomerSource or PartnerSource. Therefore, users of CustomerSource or PartnerSource automatically have access to their organization's workspace in LCS, and can view all projects that they have been invited to participate in. Users who are administrators for their organization in CustomerSource and PartnerSource will be administrators in LCS.

Although an administrator can invite users who don't have CustomerSource or PartnerSource credentials to be members of an organization in LCS, we don't recommend this approach. Users who are invited to be members of an LCS organization aren't provided with credentials in CustomerSource or PartnerSource.

Project-level access to LCS is by invitation. You can invite members of your organization to be project owners and team members. Additionally, you can invite users who aren't part of your organization, and who don't have accounts in Azure AD or CustomerSource or PartnerSource, to be team members.

> **IMPORTANT**
> We strongly recommend that you manage all users within your company at the organization level. In that way, you help ensure that their relationship with your organization is correct in CustomerSource, PartnerSource, and Azure AD. Additionally, you help ensure that users can access the benefits that are available to your organization.

Manage LCS organization users

Only an administrator can manage users. Follow these steps.

1. In CustomerSource, PartnerSource, or Azure AD, associate all the users in your organization who require access to LCS with your organization. Users might have to wait up to two business days before they can sign in to LCS.
2. Add your users to the appropriate projects in LCS.

Invite a user to an LCS project

1. Sign in to LCS.
2. Select the project to add the user to.
3. Select the **Project users** tile, and then, on the **Project users** page, select the plus sign (+).
4. Enter the user's email address, select the correct security role, and then select **Invite**.

NOTE

For implementation projects, you can select the implementation role for the invited user. If you set **Allow FastTrack to contact** to **Yes**, then Microsoft FastTrack team may reach out to you based on your implementation role and the stages of the implementation project.

Configuring project security

You can invite users from inside or outside your organization to join your project as users. The following table describes the roles that are available for users.

ROLE	DESCRIPTION
Project owner	Members of this role have access to all tools in LCS, can add other users in any role, and can delete the project.
Environment manager	Members of this role have access to all tools in LCS and can manage cloud-hosted environments.
Project team member	Members of this role have access to all tools in LCS but can't manage cloud-hosted environments.
Project team member (prospect)	Members of this role have limited access to all tools in an LCS project. Prospects are users who have been added to a project, but who don't have an account in VOICE or an Azure AD account. You can identify that a user is a prospect, because **prospect** is listed as the organization.
Operations user	Members of this role have access to the following tools in LCS: • System diagnostics • Issue search • Cloud-powered support • Updates • Cloud-hosted environments

After you've configured security for one project, you can import the users to another project.

Configure implementation roles

If you have an implementation project, you will have the option to specify project user's implementation roles. For more information, see Roles in a Dynamics 365 implementation.

NOTE

Can you tell us about your documentation language preferences? Take a short survey.

The survey will take about seven minutes. No personal data is collected (privacy statement).

Issue search in Lifecycle Services (LCS)

2/18/2021 • 3 minutes to read • Edit Online

This article provides information about the Issue search tool on Microsoft Dynamics Lifecycle Services (LCS). It explains how to search for product issues and regulatory features, and describes the information that is provided for each status.

Prerequisites

None

Search for product issues and regulatory features

You can use Issue search to search for product issues, and determine whether an issue has been resolved, is open, or has a workaround. You can also search for regulatory features, and determine whether a feature is available or is planned in a future release. Finally, you can find regulatory white papers, certifications, and registrations.

1. Go to Microsoft Dynamics Lifecycle Services (LCS).
2. Select a project to work in.
3. Click the **Issue search** tile.
4. Enter search terms. You can enter a keyword or group of keywords, or a Microsoft Knowledge Base (KB) number. You can also use a dollar sign ($) to indicate an Application Object Tree (AOT) object path in the format $*ObjectType**Object* or $\\*ObjectType*\\*Object*#*Method* (for example, **$\Classes\Tax#Save**). Standard search operators such as **AND** and **OR** are supported.

You can filter the results list for resolved or open issues, workarounds, and issues that won't be fixed or are postponed. You can also filter by the application version. By default, the results are sorted by relevance. However, you can sort by date ascending, date descending, version ascending, or version descending instead. By default, all status and product version filters are selected. **Note:** Results for Microsoft Dynamics AX 2009 are included in Microsoft Dynamics AX 2012 projects only when you search for regulatory features. The following table describes the information that is provided for each status when you search by product issue.

STATUS	COLOR	DESCRIPTION OF RESULTS

STATUS	COLOR	DESCRIPTION OF RESULTS
Resolved	Green	The KB number, title, version, description of the problem and change, and hotfix are provided. A list of objects that are affected by the hotfix is also provided whenever possible. • To download the hotfix, click **Download hotfix**. • To determine what code was changed in a hotfix, click **View changes**. Added code is indicated by a green highlight, and deleted code is indicated by a red highlight. **Important:** The list of code changes is provided for reference only. Code changes should not be manually inserted into a higher development layer. Otherwise, they become unsupported customized objects that the partner or customer assumes full responsibility for.
Open	Red	A bug number, title, version, and description of the problem are provided.
Workarounds	Brown	The issue number, title, version, problem description, and mitigation are provided.
Postponed	Gray	A bug number, title, version, and description of the problem are provided. If a workaround is available, it's described. A bug that has this status has been evaluated and won't be fixed at this time.
By design	Gray	A bug number, title, version, and description of the problem are provided. An explanation of the design is provided whenever possible. A bug that has this status has been evaluated, and it has been determined that this functionality is working as designed.
Not reproducible	Gray	A bug number, title, version, and description of the problem are provided. An explanation of the problem is provided whenever possible. A bug that has this status has been evaluated, and a fix won't be issued at this time.

STATUS	COLOR	DESCRIPTION OF RESULTS
Will not be fixed	Gray	A bug number, title, version, and description of the problem are provided. If a workaround is available, it's described. A bug that has this status has been evaluated and won't be fixed.

The following table describes the information that is provided for each status when you search by regulatory feature.

STATUS	COLOR	DESCRIPTION OF RESULTS
Resolved	Green	For feature updates: The KB number, title, version, description of the problem, and hotfix are provided. A list of objects that are affected by the hotfix is also provided whenever possible. • To download the hotfix, click **Download hotfix**. • To read the KB article for the hotfix, click **Read KB article**. For white papers, certifications, registrations, and reports: The title, product version, and description of the white paper, certification, registration, or report are provided. • To read the documentation, click **Read documentation**.
Open	Red	A bug number, title, version, planned release date, and description of the problem are provided.

Issue details

The code changes are provided for reference only and should not be manually inserted into a higher development layer. Otherwise, they become unsupported customized objects that the partner or customer assumes full responsibility for.

Configuration in Lifecycle Services overview

2/18/2021 • 2 minutes to read • Edit Online

You can use the Configuration manager to copy from and to Dynamics AX 2012 R3 environments that meet the following criteria:

- Managed as part of a Lifecycle Services project
- Running System diagnostics
- Running the Data Import/Export Framework

> **IMPORTANT**
>
> This feature is **not** supported for production use. Configuration manager (beta) relies on entities from the Data Import/Export Framework in your environment. Because these entities do not currently include all the functionality in AX 2012 R3, some configuration data is not copied between environments.

For more information, see:

- Set up Configuration manager
- Copy configurations by using Configuration manager

> **NOTE**
>
> Can you tell us about your documentation language preferences? Take a short survey.
>
> The survey will take about seven minutes. No personal data is collected (privacy statement).

Set up Configuration manager

2/18/2021 • 3 minutes to read • Edit Online

> **IMPORTANT**
>
> This feature is **not** supported for production use. Configuration manager (beta) relies on entities from the Data Import/Export Framework in your environment. Because these entities do not currently include all the functionality in AX 2012 R3, some configuration data is not copied between environments.

Before you begin

Before you begin, your environment must include the following components:

- A running version of AX 2012 R3 that has been configured for your business. For more information about how to install AX 2012 R3, see Install Microsoft Dynamics AX 2012.
- A running instance of the Data Import/Export Framework. For more information about how to install the Data Import/Export Framework, see Install the Data import/export framework (AX 2012 R#).

  > **IMPORTANT**
  >
  > You must deploy the DMFEntityExecutionStatusService and DMFService service groups to enable to Configuration manager (beta) to connect to Data Import/Export Framework.

- An AX 2012 R3 project in Lifecycle Services.

  > **WARNING**
  >
  > Copying configurations between environments can be a destructive operation. All project owners have the right to configure and perform these operations. Make sure that only trusted individuals are set as project owners.

Create Data Import/Export Framework source data formats in AX 2012 R3

You must create both a Dynamics AX and a CSV source data format to manage configurations in all environments where you intend to export and import configurations.

Create an AX source data format

Complete the following procedure in the environment that you intend to export a configuration from.

1. Click **Data import export framework** > **Setup** > **Source data formats**.
2. Click **New**, and name the source AX.
3. Verify that the type is **AX**.
4. Repeat this procedure in the environment that you intend to import the configuration to.

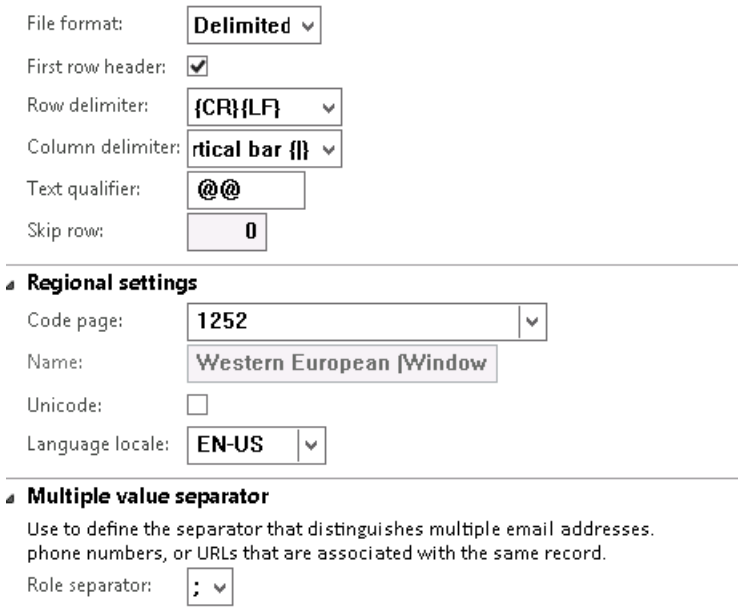
Create a CSV source data format

Complete the following procedure in the environment that you intend to export a configuration from.

1. Click **Data import export framework** > **Setup** > **Source data formats**.

2. Click **New**, and name the source CSV.
3. Verify that the type is **File**.
4. On the **General** tab, set the following values.

SETTING	VALUE
File format	Delimited
First row header	Selected
Row delimiter	{CR}{LF}
Column delimiter	Vertical bar {
Text qualifier	@@
Skip row	0
Code page	1252
Language locale	EN-US
Multiple value separator	;



5. Repeat this procedure in the environment that you intend to import the configuration to.

Install and configure the local component of the System diagnostics (Lifecycle Services)

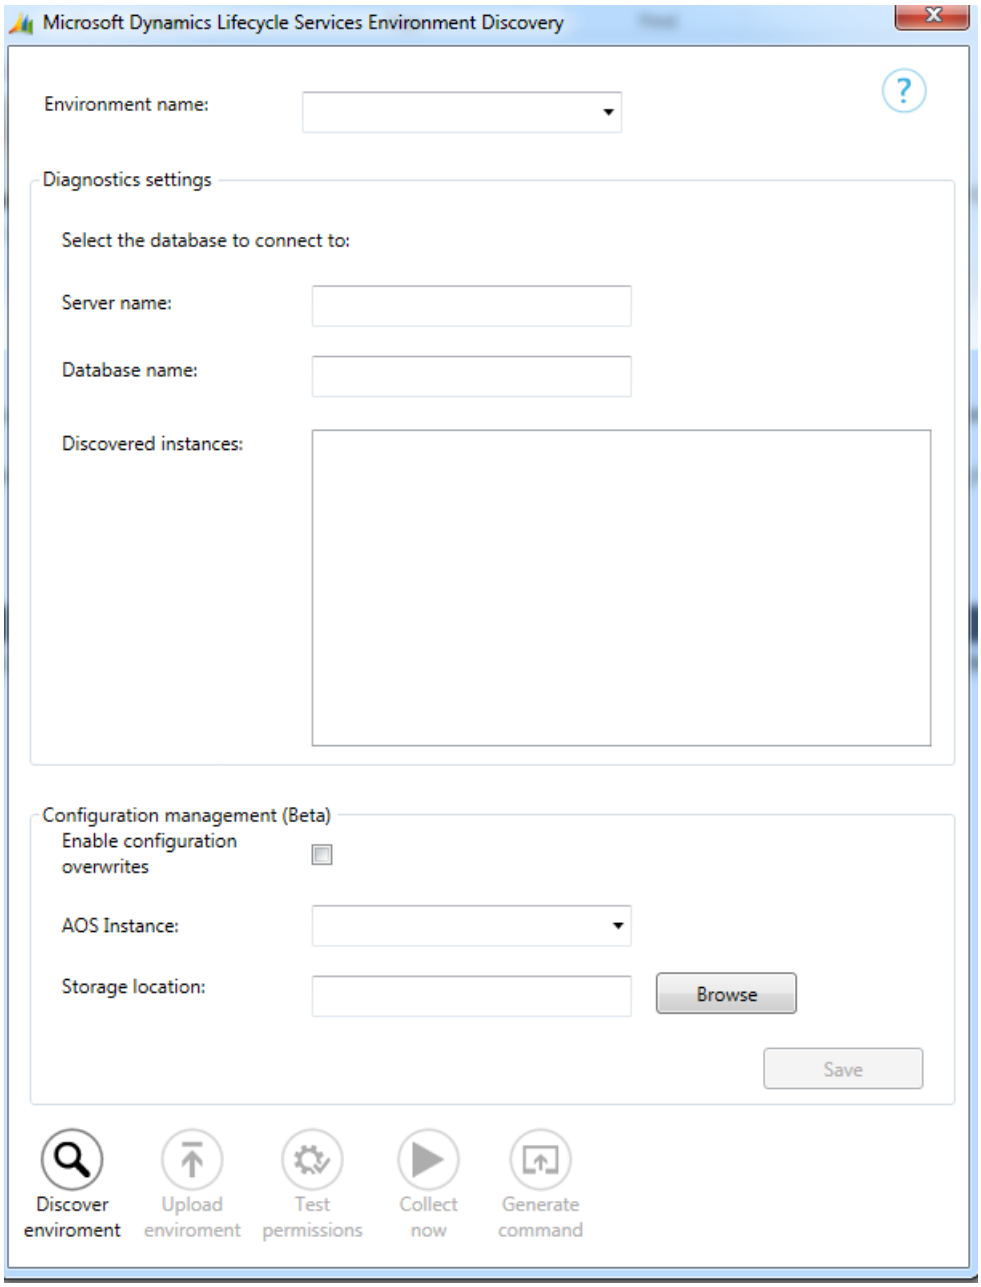
Complete the following procedure in the environment that you intend to export a configuration from.

IMPORTANT

If you have already installed the local component of the System diagnostics for your project and environment, you must uninstall it by using **Add/Remove programs**. Only one instance of Microsoft Dynamics AX Application Object Server (AOS) per environment can be used with Configuration management, regardless of the number of instances that are discovered.

1. Install the local component of the System diagnostics. For details, see Install and run System diagnostics. Important: For this beta release, we require that you add the service account for the System diagnostics to the sysadmin role in AX 2012 R3.
2. Click **Start** > **Microsoft Dynamics AX Lifecycle Services Diagnostic Service Discovery**.
3. In the **Environment Discovery** window, enter a name for the environment, and the fully-qualified name of the Microsoft SQL Server instance and database. Then click Discover environment.
4. After discovery is completed, enter the values in the **Configuration management (Beta)** section, click **Save**, and then click **Upload environment**.

OPTION	VALUE
Enable configuration overwrites	Select this option to enable configurations to be copied and overwritten for the specified AOS instance. **Important:** We strongly recommend that you disable configuration overwrites when you have fully configured an environment.
AOS instance	Specify the AOS instance that can be copied from or overwritten.
Storage location	Specify the location where configurations are stored locally. The AOS service account and the Data Import/Export Framework service account must have read and write access to this location. **Important:** We strongly recommend that you use the same directory that is used for the Data Import/Export Framework.Be aware that the shared directory might contain sensitive data, depending on what you are importing and exporting. Make sure that as few users as possible, in addition to the AOS service account and the Data Import/Export Framework service account, have access to the location.



5. Repeat this procedure in the environment that you intend to import a configuration to.

Next steps

The environment is now ready for you to copy and manage configurations. For more information, see Copy configurations by using Configuration manager.

> **NOTE**
>
> Can you tell us about your documentation language preferences? Take a short survey.
>
> The survey will take about seven minutes. No personal data is collected (privacy statement).

Configure the code upgrade service in Lifecycle Services (LCS)

2/18/2021 • 5 minutes to read • Edit Online

This topic explains how to configure the **Code upgrade** tile in Lifecycle Services (LCS) to migrate your solution to the latest version of the Dynamics 365 Finance and Operations apps.

Overview

The code upgrade tool operates by connecting to your Azure DevOps project, locating your Trunk\Main branch, branching to a new branch that will be named as Releases\<version number>, and then performing the code upgrade there. After this process is complete, you can synchronize your developer environment to this new branch under Releases\<version number> and resolve conflicts. When you have compiled and tested your upgraded code you can merge the new branch back into Trunk\Main, using source control explorer in Visual Studio and the process is complete.

Dynamics 365 for Finance and Operations version 8.0 and newer, does not allow customization via overlayering of Microsoft models. Before you upgrade, you must have a plan to refactor your customizations into extensions. For more information, see the Extensibility home page and Relax model restrictions to refactor overlayering into extensions.

Process

Create the Trunk\Main folder structure

For the code upgrade service to recognize your source code, your Azure DevOps project must contain a Team Foundation Version Control (TFVC) code repository. In addition, the code repository folder structure must conform to the following strict pattern.

- For code and metadata: //Trunk/Main/Metadata
- For Visual Studio project and solution files: //Trunk/Main/Projects

You can create new folders directly in the Azure DevOps web interface under **Repos**.

> **NOTE**
>
> - Folder names are case sensitive, that is, you must use Main and not MAIN, or the code upgrade service will not recognize the folder.
> - Azure DevOps projects use Git version control by default. You will need to add a TFVC repository.
>   1. Go to Project settings, then Repositories.
>   2. Select New repository.
>   3. In the Type field, select TFVC, and then click Create.

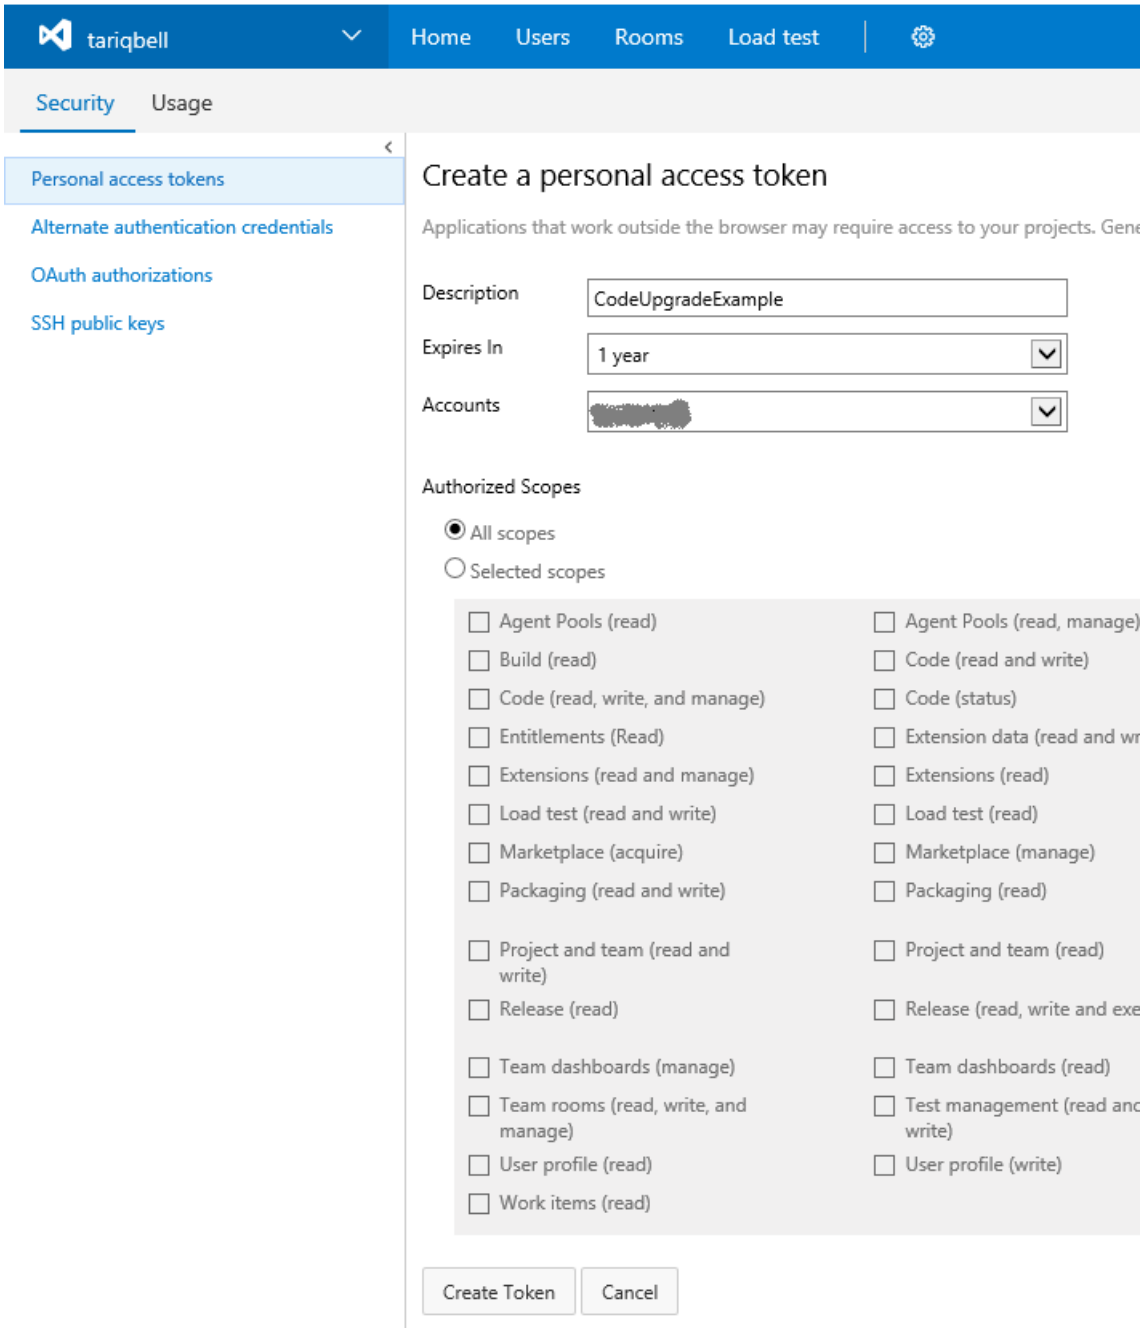
Create a personal access token

To connect to an Azure DevOps project, LCS is authenticated using a personal access token. Use the following steps to create a personal access token in Azure DevOps. If you have already configured your LCS project to connect to your Azure DevOps project, you can skip this section.

1. Sign in to visualstudio.com and locate your Azure DevOps project.

2. In the top-right corner, hover over your name, a menu appears, select **Security**.

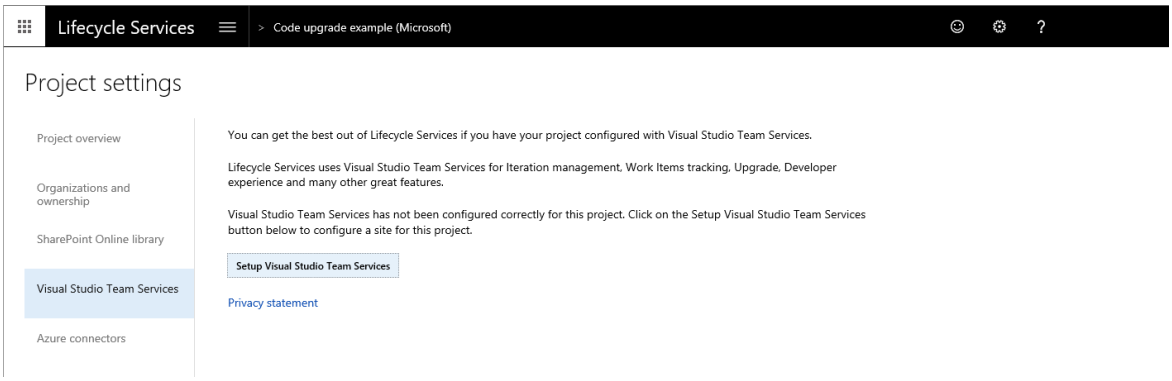
3. Select **Add** to create a new personal access token, give it a name, and then enter the amount of time that you want the token to last for. Select **Create Token**.



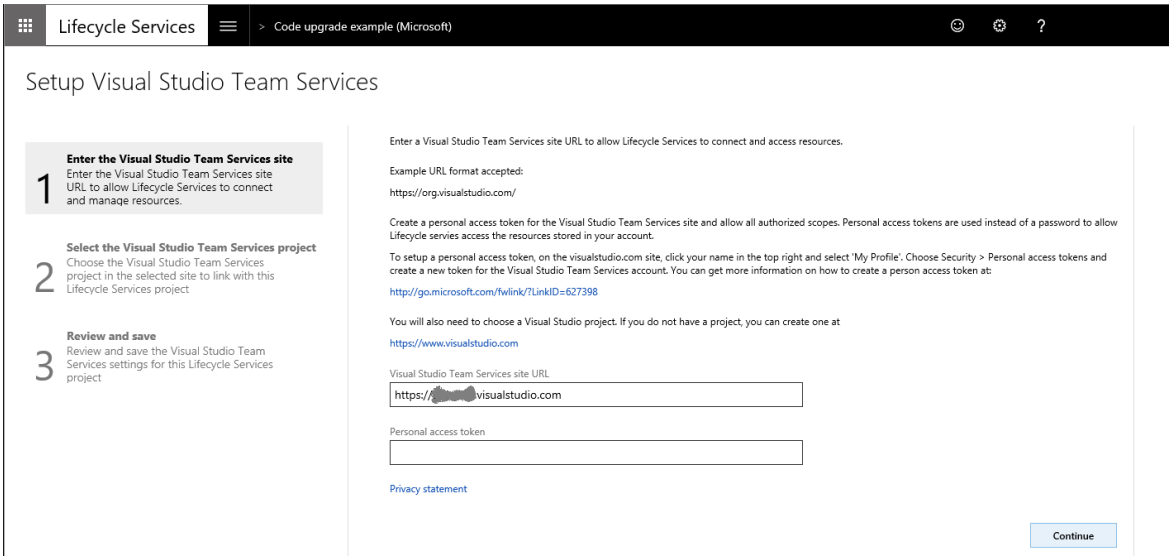
4. Copy the token to your clipboard. You will not be able to find the token details after this step is completed, so be sure that you have copied the token before navigating away from this page.

Configure your Lifecycle Services project to connect to Azure DevOps

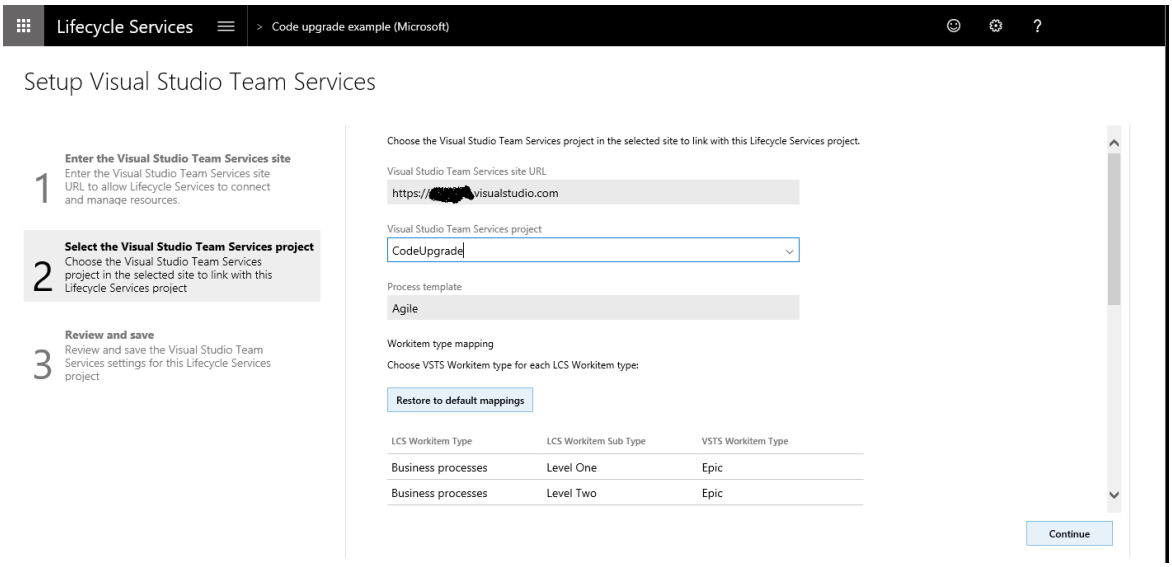
1. In your LCS project, go to the **Project settings** tile, select **Visual Studio Team Services**, and then select the **Setup Visual Studio Team Services** button. This configuration is needed by many LCS tools, if you have already configured LCS to connect to your Azure DevOps project, you can skip this section.



2. Enter the root URL for your Azure DevOps organization and the access token created earlier, and then select **Continue**.



3. Select the project within your Azure DevOps organization that you want to connect to, and select **Continue**.

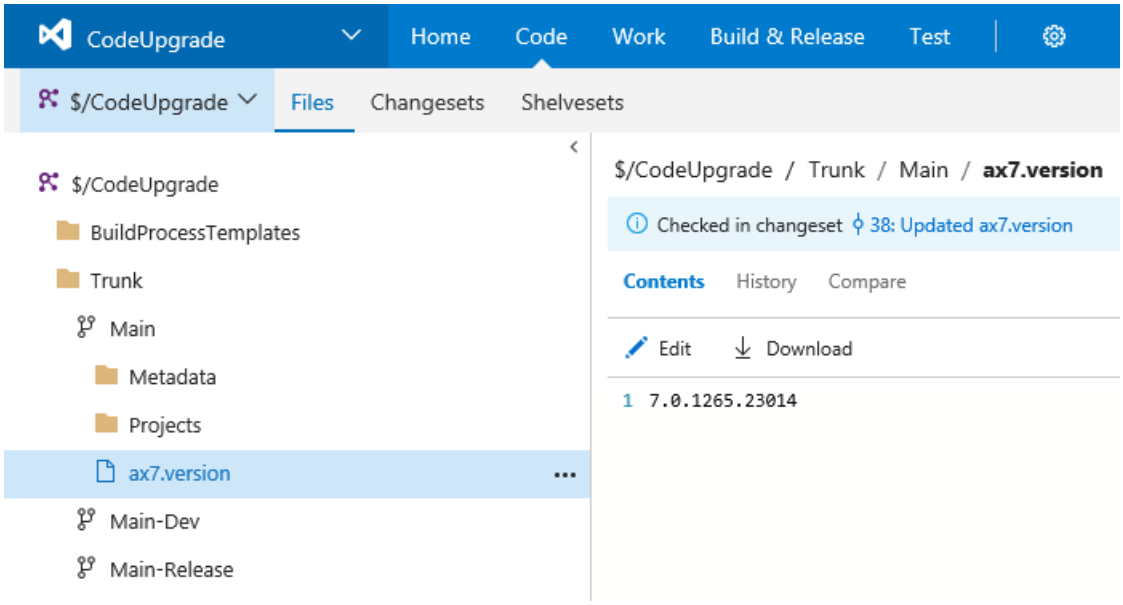


4. On the **Review and save** page, select **Save**.

Create an ax7.version file

> **NOTE**
>
> If you are migrating from AX 2012, you can skip this step.

The code upgrade tile in LCS automatically finds the version that you are migrating from, by reading the ax7.version file under the Main folder in your source control. You must create this file manually, either in Visual Studio or through the Azure DevOps web portal, as shown below. This file is not needed if you are migrating your code from Dynamics AX 2012 R3 or an earlier version. The version number entered here must be the application version (not the platform version). Take care to enter the correct version number here as entering an incorrect version number in this file may cause your code upgrade run to fail.



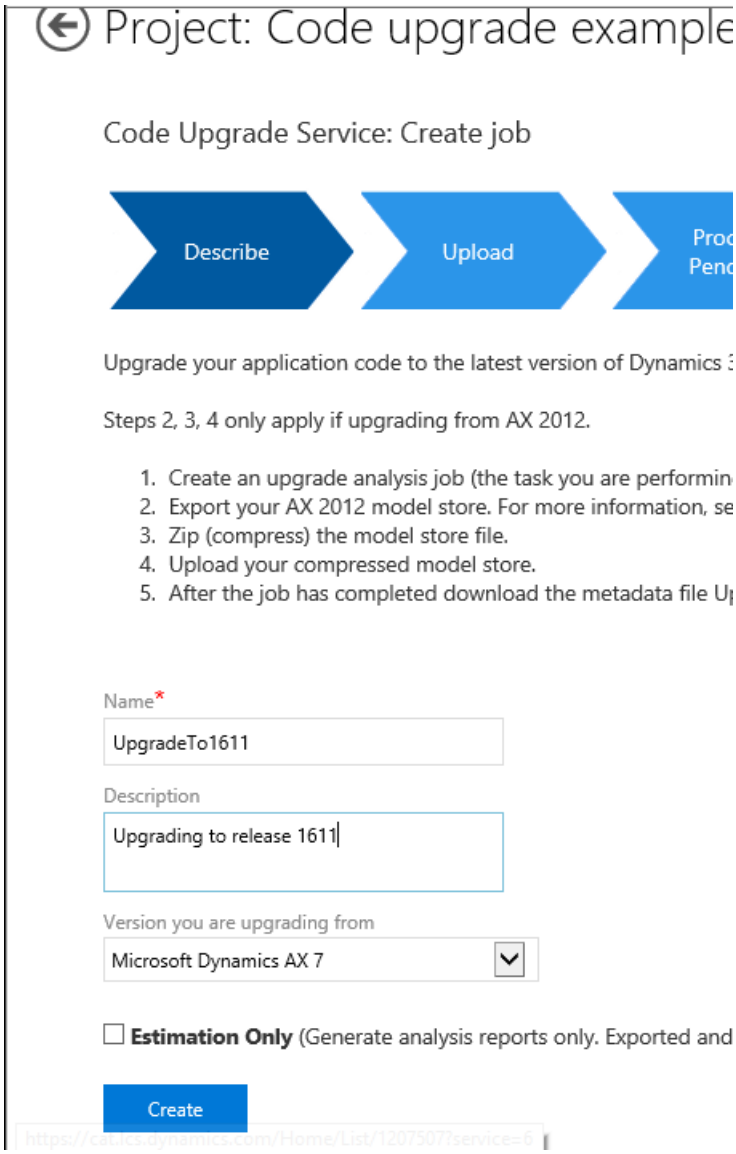
For more information about how to identify which application version you have, see Overview of Microsoft Dynamics AX build numbers.

Execute the code upgrade tile

1. In your LCS project, select the **Code upgrade** tile.

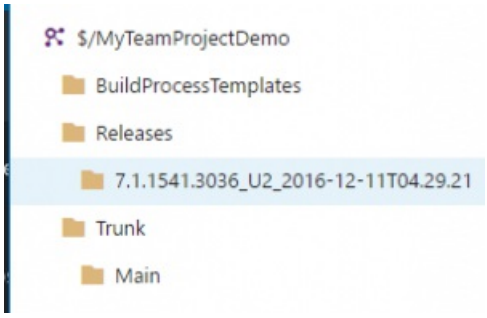
2. In the bottom-left corner of the screen, select **Add**, and then enter a name and description. Select the version you are upgrading from as Microsoft Dynamics AX 7, and then select **Create**.

   - If you are upgrading your code from Dynamics AX 2012 R3, select the version you are upgrading from. You will be prompted to upload a zipped version of your Dynamics AX 2012 R3 model store file.
   - If the **Estimation Only** check box is selected, the tool only generates a report and does not check in or create a new code branch in Azure DevOps for you. You should use this option if you want to evaluate the potential size of the work involved in upgrading before you commit to the actual upgrade.



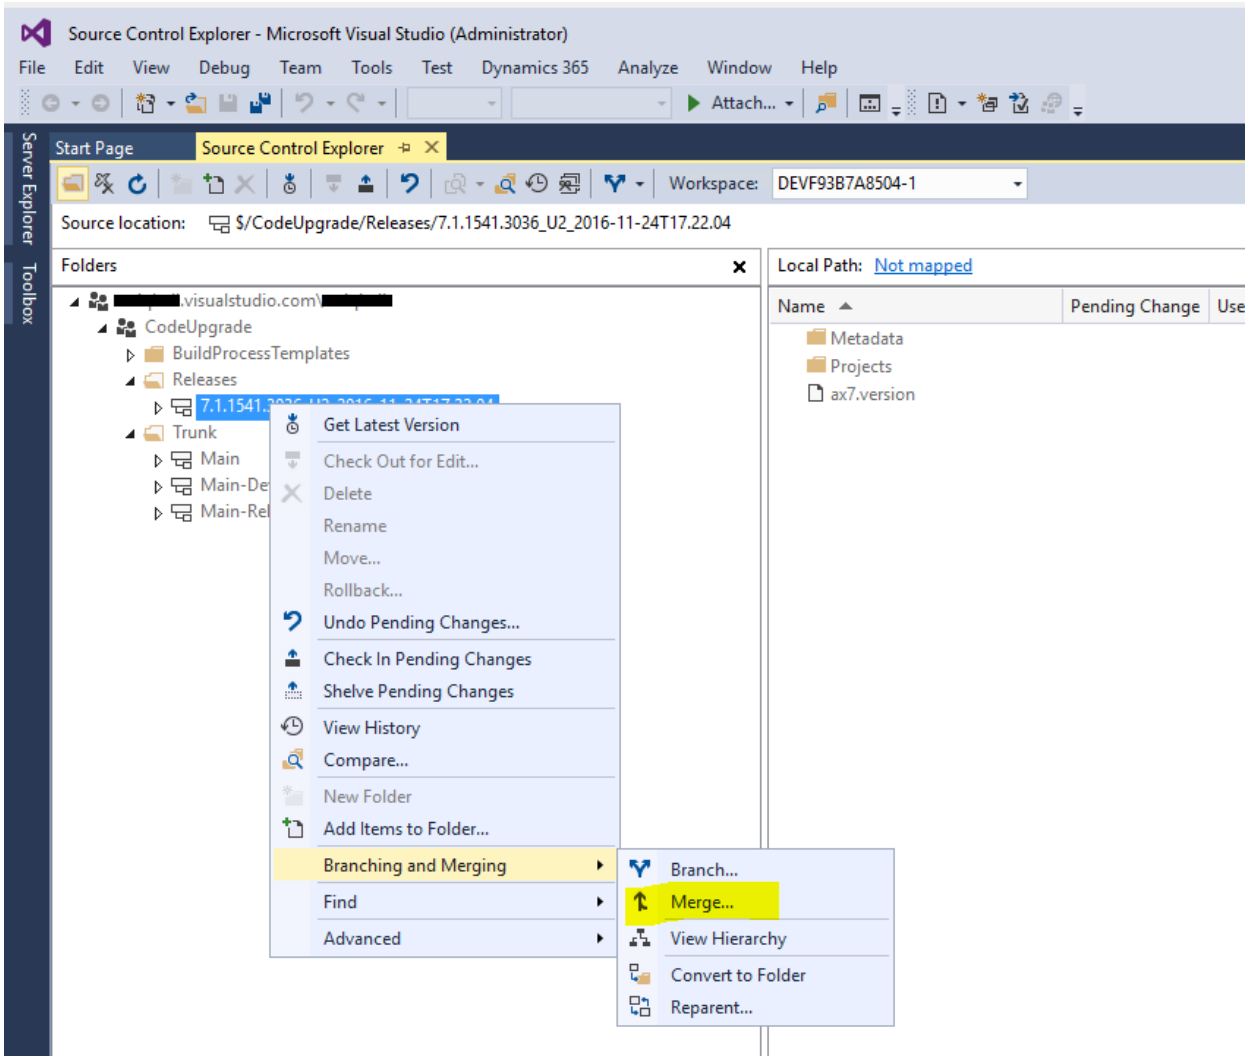
3. Select **Analyze code** in the bottom-right corner. The code upgrade process will start. This process typically takes 40 minutes for a large solution to complete. When complete, return to the **Code upgrade** tile in LCS to view the results.

4. The code upgrade service creates a new branch and checks in the upgraded code to your Azure DevOps project. After the upgrade process is complete, your code will exist in a new branch under the **Releases** folder. The branch name is suffixed with the date and time of the upgrade.



Merge Releases back into Trunk\Main

Once the upgraded code in Releases\<version number> compiles successfully and you have completed your code migration and testing, you are ready to merge this branch back into Trunk\Main. To merge, on your development environment in Visual Studio, open the Source control explorer pane then right-click on the **Releases\<version number>** branch, and in the context menu go to **Branching and Merging**, and then on the submenu select **Merge**.



The Source Control Merge Wizard opens, which guides you through merging the Releases\<version number> branch back into Trunk\Main.

NOTE

Can you tell us about your documentation language preferences? Take a short survey.

The survey will take about seven minutes. No personal data is collected (privacy statement).

Create or update methodologies

2/18/2021 • 2 minutes to read • Edit Online

Lifecycle Services (LCS) for Microsoft Dynamics provides methodologies that you can use to ensure a more repeatable and predictable implementation project experience. You can use one of the provided methodologies or create your own. With a methodology, you can easily track and report on your progress.

A methodology consists of phases, tasks, and milestones. Each phase can have any number of tasks, some of which are mandatory. When all of the tasks in a phase are completed, the phase can be marked as complete. You can also create a milestone for when you anticipate a phase to be completed. The following methodologies are included in an LCS project:

- Implementation
- Sure Step
- Learn development
- Migrate and create solutions
- Consume solutions

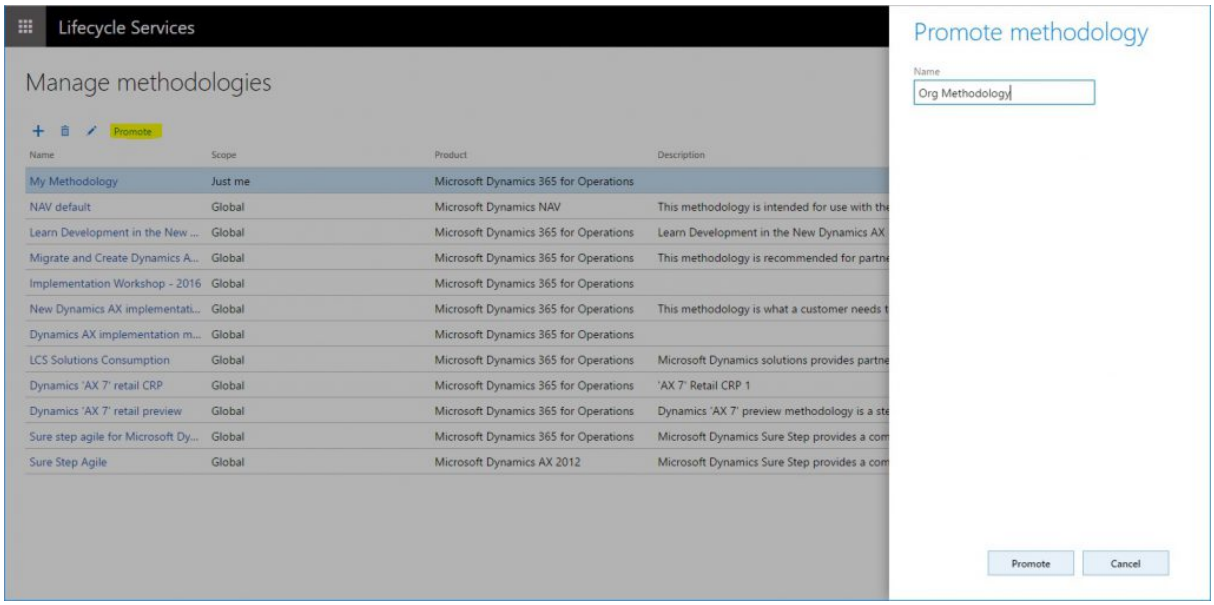
Note: There is a known limitation where new changes that are published to the Microsoft Methodology are not pushed to existing projects. Only new projects get these changes.

Add or update methodologies

A partner or a project administrator can create new methodologies or make changes to an existing methodology for their organization or within the scope of a specific project. These additions and changes can be made at the project level or at the organization level. Use the following procedures to create and save a new methodology, update existing methodologies, and when appropriate, promote a new methodology or methodology changes to the organization level.

Create a new methodology

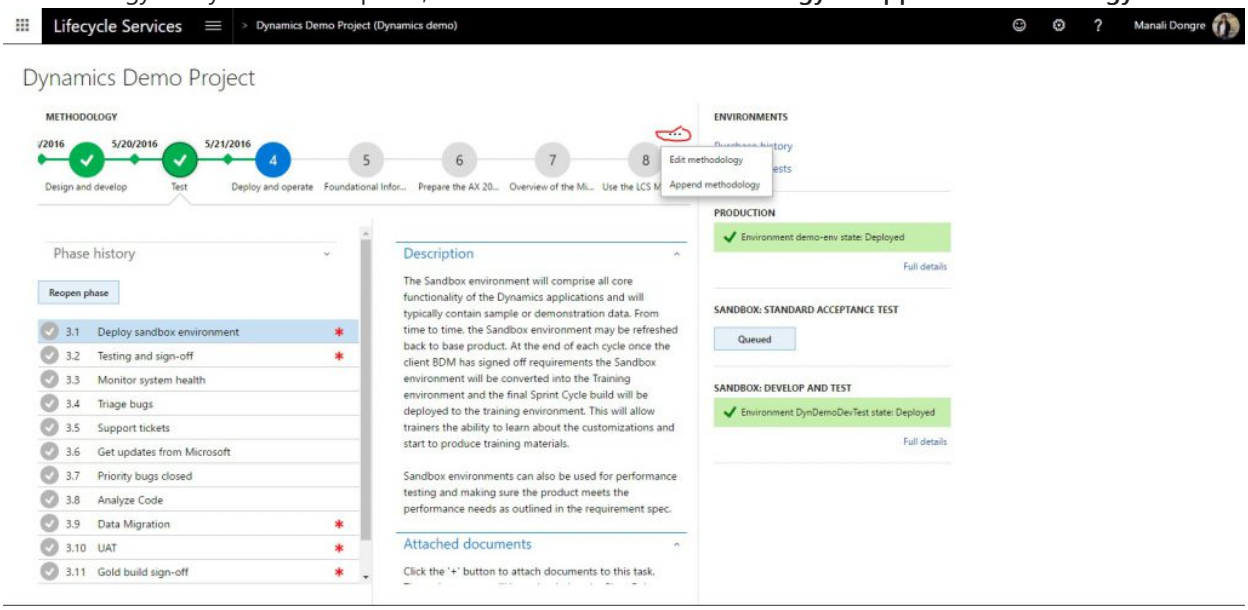
1. On the Lifecycle Services dashboard, on the right side of the screen, click **Manage methodologies**.
2. On the **Manage methodologies **page, click the plus sign (+).
3. In the **New methodology** pane, enter a name and description for the new methodology. Click **Confirm**.
4. **Optional:** After you have confirmed the methodology, you can promote it to the organization level by selecting the methodology in the grid, and then selecting **Promote**.



Note: You must be an admin in your organization to promote a methodology to the organization level.

Change or update a methodology

There are two ways to make changes to a methodology. You can append an existing methodology or you can make changes to a methodology in the scope of a project. From the LCS project dashboard, select the methodology that you want to update, and then select **Edit methodology** or **Append methodology**.



If you select to edit the methodology, you can make the following changes:

- Add a new phase.
- Add a new task.
- Edit a phase or task. (Some phases and tasks can be edited, but others are enforced by Microsoft and are therefore locked and can't be edited.)
- Copy a phase or task.
- Reorder phases and tasks.
- Delete a phase or task.

Business process modeler (BPM) in Lifecycle Services (LCS)

2/18/2021 • 2 minutes to read • Edit Online

Business process modeler (BPM) in Microsoft Dynamics Lifecycle Services (LCS) is a tool that you can use to create, view, and modify repeatable implementations that are based on business process libraries. BPM helps you align your business processes with industry-standard processes that are described by the American Productivity & Quality Center (APQC). You can perform fit-gap analysis between your business requirements and the default processes in Finance and Operations apps. Additionally, you can add new business processes that aren't already defined.

BPM is compatible with the following products:

- **Microsoft Word** – You can generate documentation for business processes.
- **Microsoft Visio** – You can export business process maps to Visio files.

> **NOTE**
>
> The information in this topic is specific only to Finance and Operations apps. For information about Business process modeler and Microsoft Dynamics AX 2012, see Business process modeler (BPM) in Lifecycle Services (LCS).

Prerequisites

To effectively use BPM, you must have Microsoft Office 2010 and a Microsoft Azure DevOps project.

Getting started

Follow these steps to access BPM.

1. Go to LCS.
2. Sign in, open a project, and then select the **Business process modeler** from the drop-down menu. The **Business process libraries** page has three sections:
   - **Project libraries** – This section contains business processes that a user has created or added.
   - **Corporate libraries** – This section contains custom business processes that someone in your organization has published.
   - **Global libraries** – This section contains cross-industry standard business processes, typically published by Microsoft.
3. To copy a standard business process library from the **Global libraries** section to the **Project libraries** section, select the upper-right corner of the tile in the **Global libraries** section, and then select **Copy**.
4. After the business process library has been added to the **Project libraries** section, select the tile to view the business process library.

Additional resources

- Create, edit, and browse Business process modeler (BPM) libraries
- Synchronize BPM libraries with Azure DevOps
- Complete tasks in Business process modeler (BPM)

- Work with activity diagrams in Business process modeler libraries
- Business process libraries in Business process modeler (BPM)
- Flowcharts in Business process modeler (BPM)

NOTE

Can you tell us about your documentation language preferences? Take a short survey.

The survey will take about seven minutes. No personal data is collected (privacy statement).

Business process libraries in Business process modeler (BPM)

2/18/2021 • 2 minutes to read • Edit Online

This article explains how to view a standard business process library in Business process modeler, how to copy and modify a business process library, and how to export information about the business process library to Microsoft Word.

This topic explains how to view a standard business process library, how to copy a business process library, modify it, and how to export information for the business process library to Microsoft Word.

View and copy a standard business process library

You can select a standard business process library on the Business process library page. To open this page, sign in to Lifecycle Services, open a project, and then click the Business process modeler tile.

> **IMPORTANT**
> The business process libraries that are available depend on the industry that was selected when the Lifecycle Services project was created.

To select a standard business process library to start with, follow these steps:

1. Sign in to Lifecycle Services, open a project, and then click the **Business process modeler** tile.
2. In the **Global libraries** or **Corporate libraries** section, right-click a library.
3. On the app bar, click **Copy**. The library is added to the **My libraries** section.
4. In the **My libraries** section, click the library to display the business process library.

Search for a process within a library

You can search for a relevant business process within a business process library.

1. Sign in to Lifecycle Services, open a project, and then click the **Business process modeler** tile.
2. Open a business process library.
3. In the search field, enter a search term or phrase, or a $ followed by the AOT name of an object. For example, $LedgerJournalTransDaily.

Modify a business process library

You can modify a business process library if it is associated with a project as described in the previous procedure. To modify a business process library, follow these steps:

1. Sign in to Lifecycle Services, open a project, and then click the **Business process modeler** tile.
2. Open a business process library.
3. Make changes to the business process library.
   - To change an existing library node, right-click the node to display the app bar, and then click **Edit**. Make changes, and then click **Save**.
   - To add a library node, drag a node from the **Activities** list to the library. Right-click the new node and then click **Edit** to change the name and other information for the node. Make changes, and then click

Save.

- To delete a library node, right-click the node, and then click **Delete**.

Export a business process library to Word

You can export information about a business process library, and all the flowcharts that are associated with it, to a Word document. To export a business process library to Word, follow these steps:

1. Sign in to Lifecycle Services, open a project, and then click the **Business process modeler** tile.
2. Open a business process library.
3. In the **Core Business Processes** list, right-click a top-level node in the library.
4. On the app bar, click **Doc**, and save the document.

Create, edit, and browse Business process modeler (BPM) libraries

2/18/2021 • 4 minutes to read • Edit Online

This topic provides information about how to create, edit, and browse Business process modeler (BPM) libraries. It's important to note You can browse a BPM library that is a global library or a corporate library. However, before you can edit and work with a BPM library, it must be part of your project in Microsoft Dynamics Lifecycle Services (LCS). Libraries that are distributed by Microsoft appear under **Global libraries**, whereas libraries that are published by your organization appear under **Corporate libraries**.

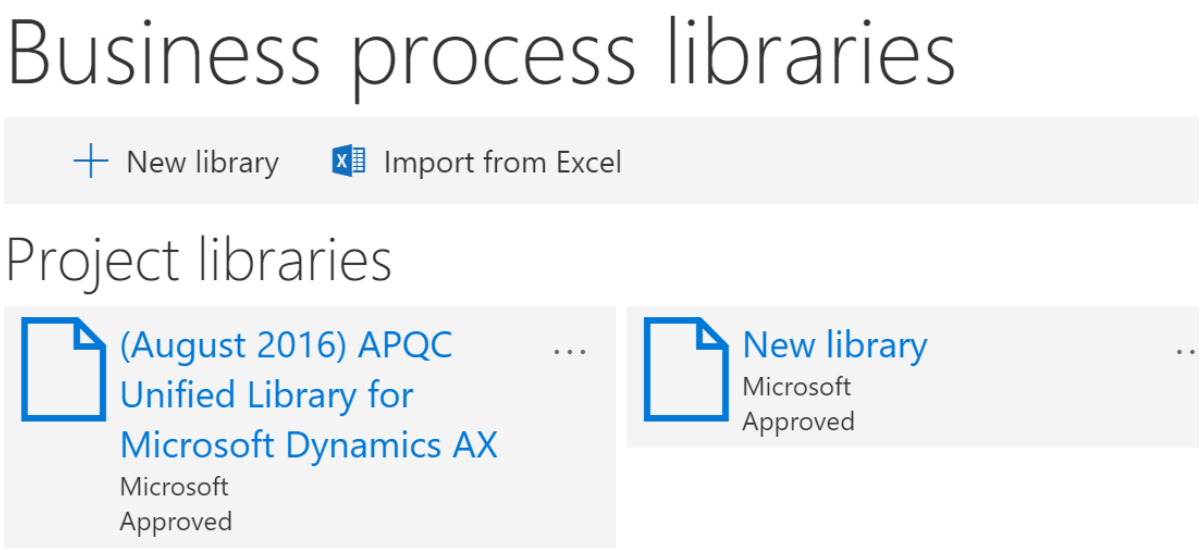
> **NOTE**
>
> BPM localization is not supported. If you edit in the new BPM client in any language other than EN-US, your changes will only display when you view the BPM in the language in which the changes were made. To view any changes made in EN-US, you must synchronize with Visual Studio Team Server before the changes will display.

Create a BPM library

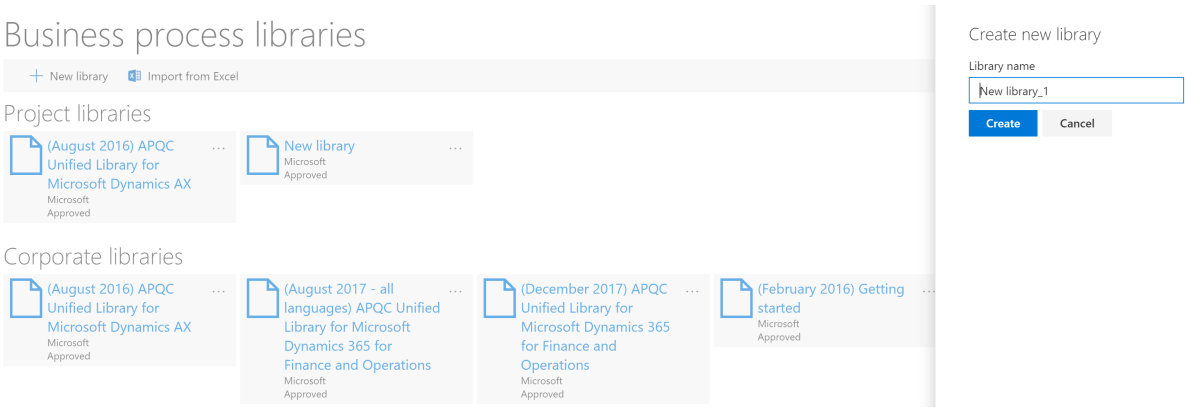
There are several ways to author a BPM library. You can do so from scratch either building directly in the client or by importing an Excel template. Additionally, you can copy an existing library. This section walks through each of these methods.

Use the BPM client

1. On the **Business process libraries** page, select **New library**.

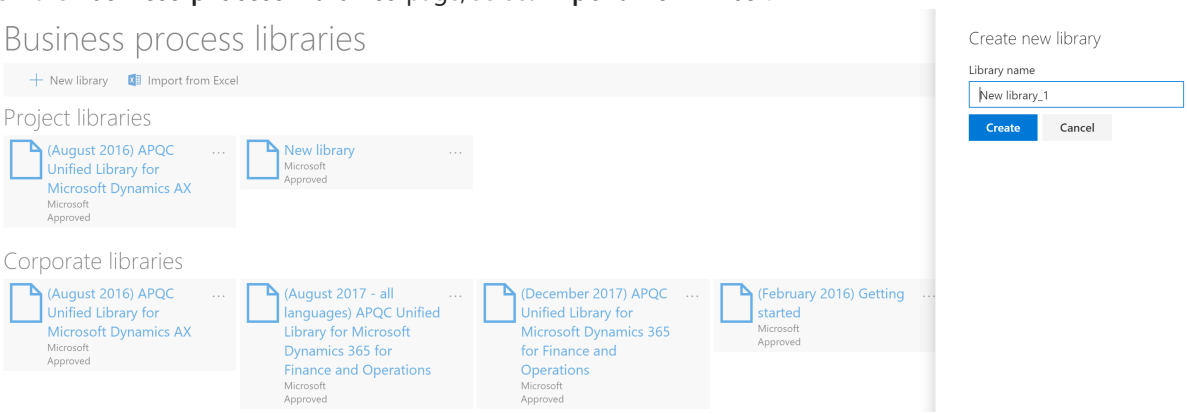


2. Enter a name for the new library, and then select **Create**.

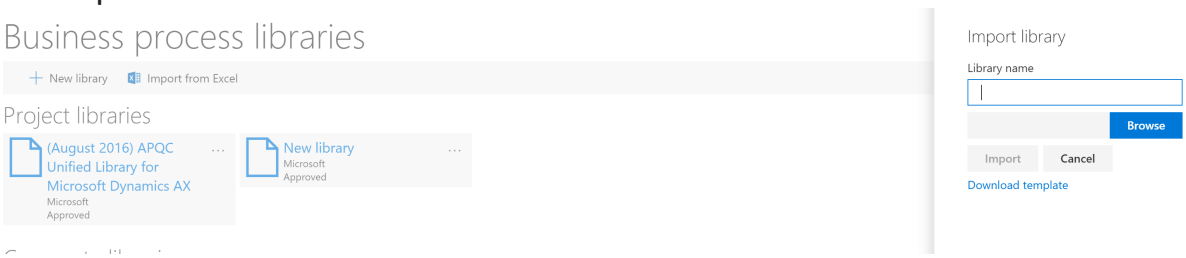


Use Excel Import

1. On the **Business process libraries** page, select **Import from Excel**.

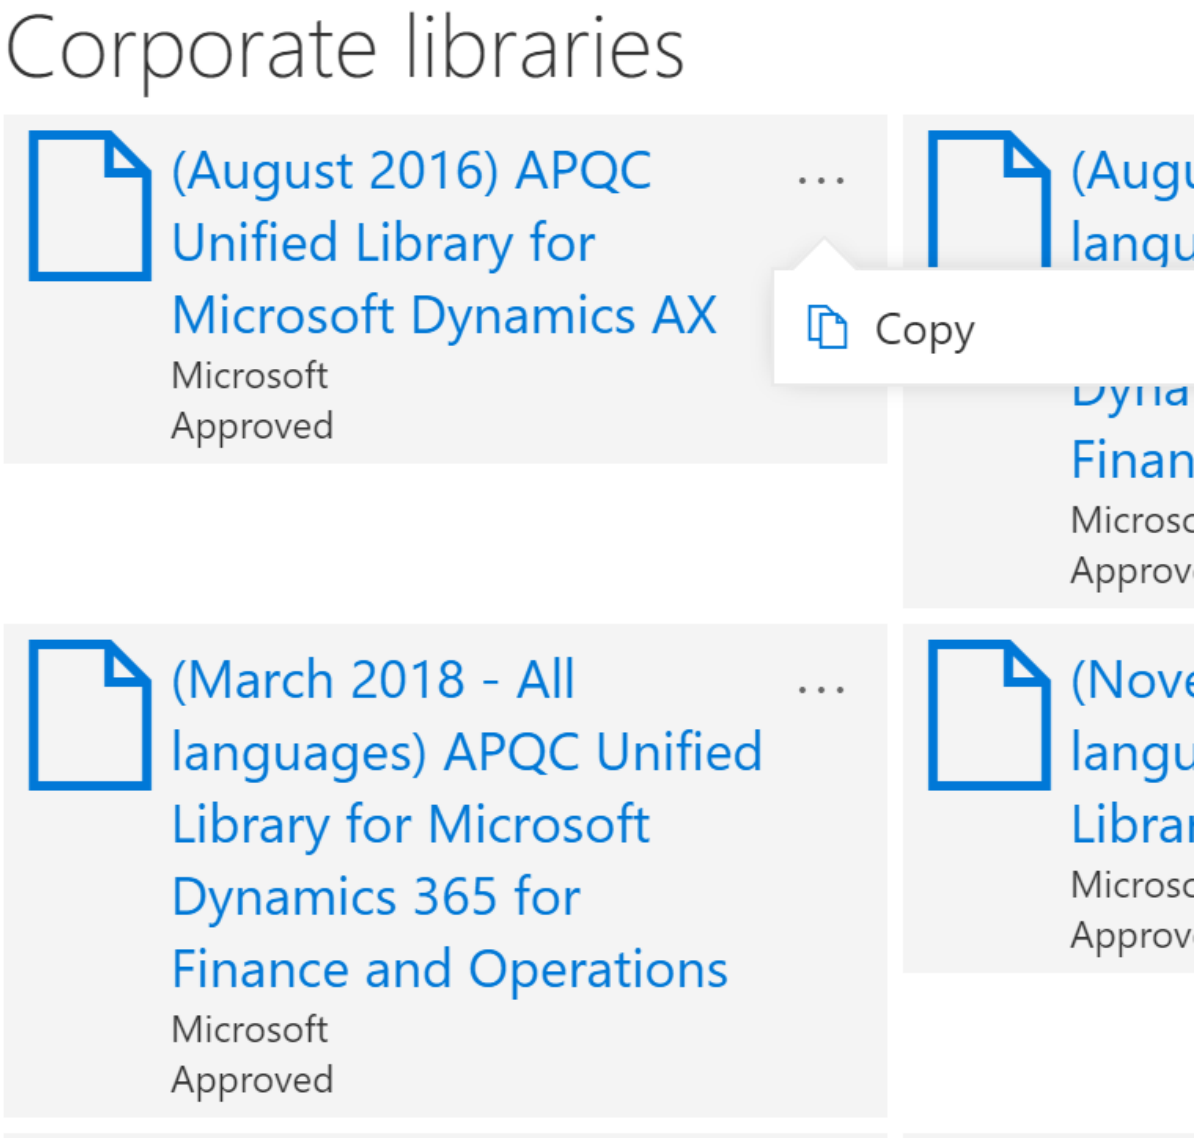


2. Select **Download template** from the pane. Once downloaded, open the file.
3. The template has several columns, most importantly **Id** and **Parent Id**. Associate each line with a new Id number, if you'd like to make a line a child item, add the Id of the line you'd like it to fall under in the parent Id column. the
4. Once complete, save the template and return to BPM.
5. Using the import pane, select **Browse** to upload the updated template, enter a name for the new library, and select **Import**.

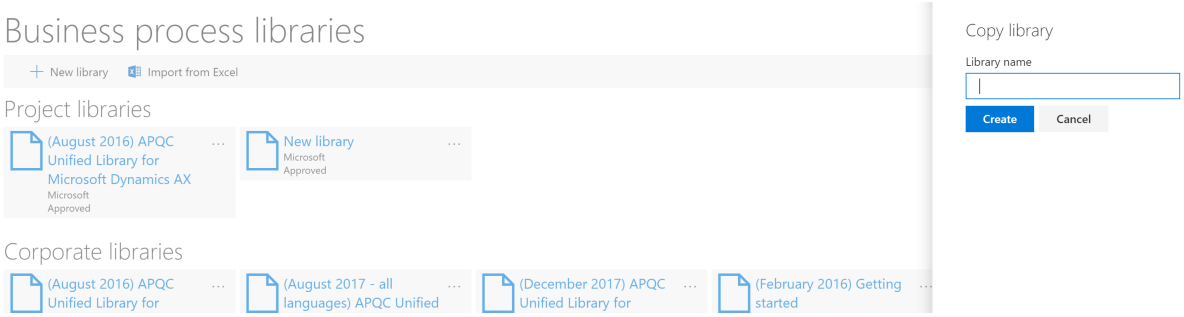


Copy a library

1. Open the **Business process libraries** page.
2. On the tile for the library that you want to copy, select the ellipsis button (...), and then select **Copy**.

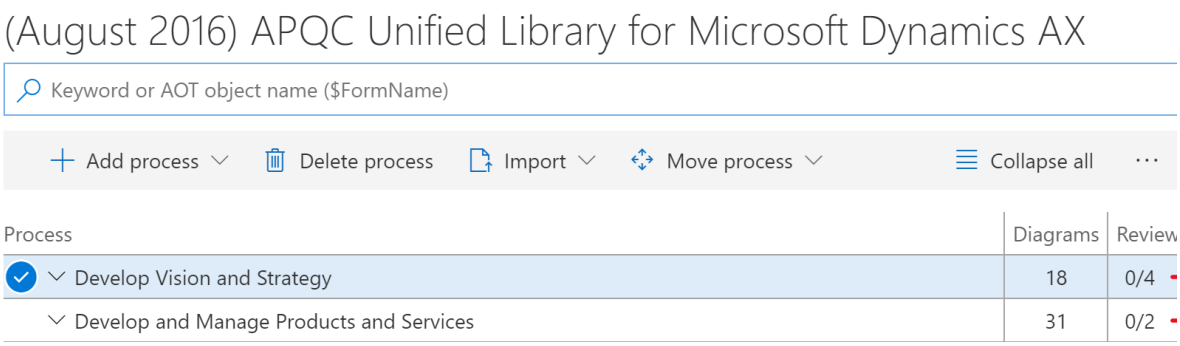


3. Enter a name for the library, and then click **Create**.

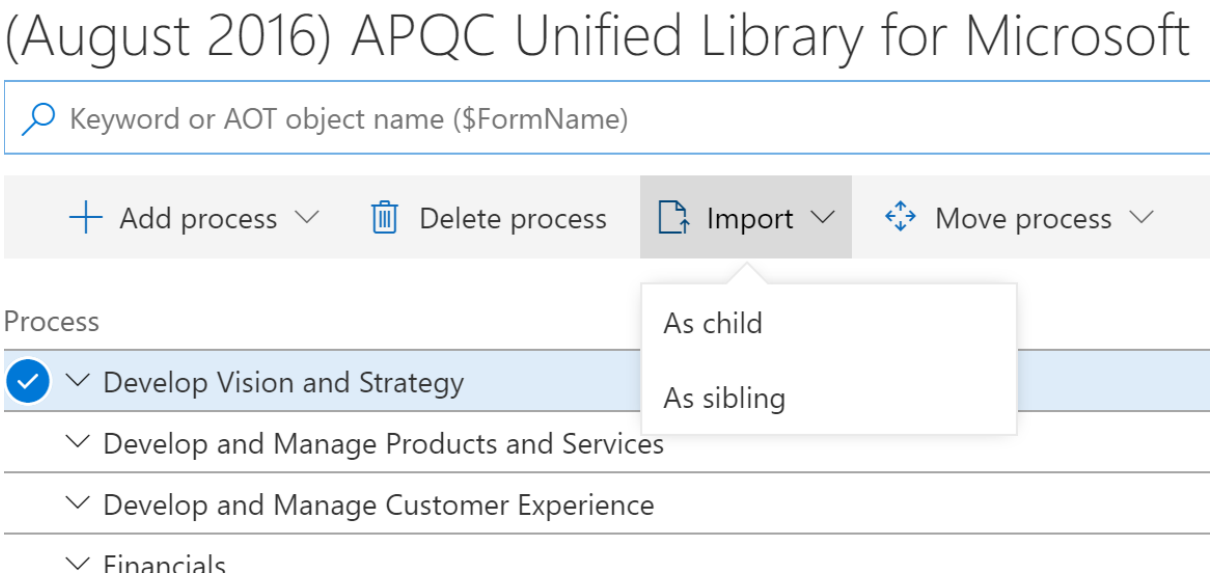


Import a sections of another library

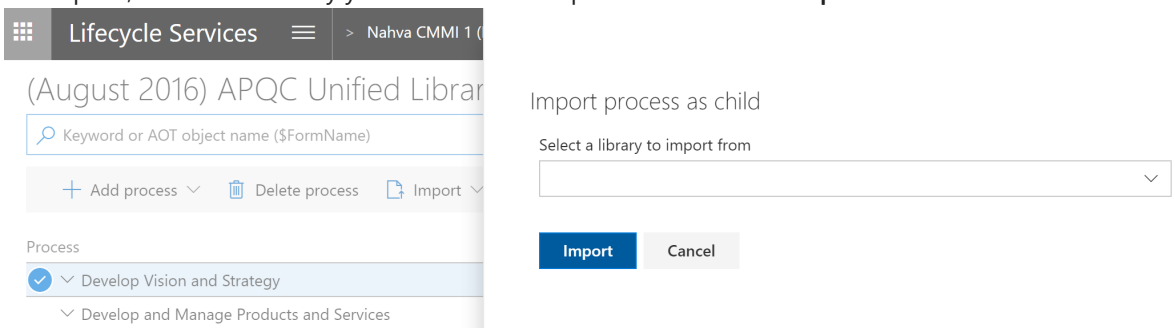
1. Openn the **Business process libraries** page, and then open the library you want to edit.
2. Navigate to the line you would like to import to and select **Import**.



3. Select **As child** or **As sibling**.

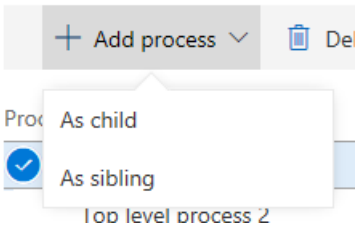


4. In the pane, choose the library you would like to import from and click **Import**.



Add a new process

1. In the BPM library, select an existing process.
2. Select **Add process**. You can select to add the process as a child or a sibling of the selected process node. In this way, you can create a semantic hierarchy of business processes.



Edit the properties of a process

1. In the BPM library, select the process node to edit.
2. In the right pane, on the **Overview** tab, click **Edit mode**.

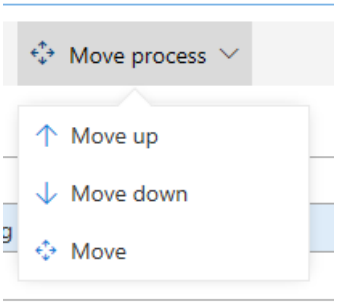
3. Enter a name and description for the process node.
4. Select the industries and the countries or regions that the process applies to. You can also add keywords and links. Keywords let you define categories, work streams, or other metadata. Links (URLs) let you reference external sites or documentation.

5. When you've finished editing the properties, click **Save**.

Move a process

You can move a process node or assign it to another parent node in the BPM hierarchy.

1. Select the process node to move, and then click **Move process**. You can select to move the process up or down, or you can select **Move** to see more options.



2. If you selected **Move**, you can browse the hierarchy, select a node to move the process to, and then select **Move as child** or **Move as sibling**. To cancel the move operation, click **Cancel**.

Delete a process

To delete a business process, select the process to delete, and then select **Delete**.

Copy a global or corporate library to your project

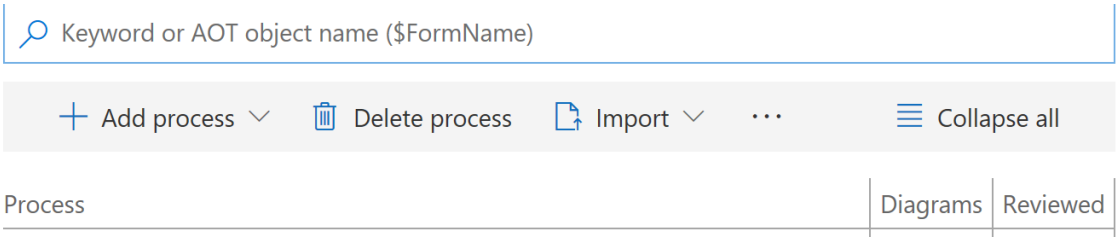
You can browse a BPM library that is a global library or a corporate library. However, before you can edit and work with a BPM library, it must be part of your project in Microsoft Dynamics Lifecycle Services (LCS). Libraries that are distributed by Microsoft appear under **Global libraries**, whereas libraries that are published by your organization appear under **Corporate libraries**.

Browse a BPM library

1. On the **Business process libraries** page, double-click the tile for the library that you want to browse.
2. In the BPM library, select a process to view its substeps.

Process	Diagrams	Reviewed
Develop vision and strategy	22	0/3
Develop and Manage Products and Services	37	0/2
Manage product and service portfolio	28	0/7
Evaluate performance of existing products/services against market opportunities		0/1
Define product/service development requirements		0/2
Perform discovery research		0/3
Confirm alignment of product/service concepts with business strategy		0/4
Manage product and service life cycle		0/3
Manage product and service master data	11	0/18
Manage product configuration models	17	0/2
Develop products and services	9	0/5

3. Use the buttons on the toolbar to add, delete, or import processes as a child or a sibling. You can also select **Collapse all** to view only parent processes.

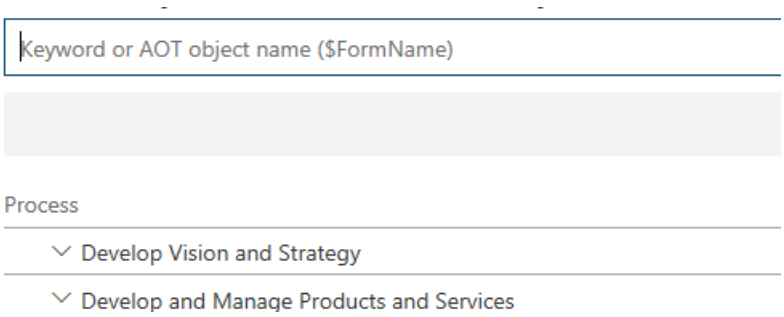


Search a BPM library

You can search for words or phrases in your BPM library. The search functionality searches the names and descriptions of business processes.

- To search for a *word*, enter the search word in the search box, and then press Enter.
- To search for a *phrase*, put double quotation marks around the search phrase.

  For example, enter **technology** (word) or **"information technology"** (phrase) in the search box.
- You can also search for Application Object Tree (AOT) elements that are part of the task recordings that are in your library. Typically, these AOT elements are the names of pages or menu items. When you search for an AOT element, prefix it with a dollar sign ($). For example, enter **$CustTable** in the search box.



NOTE

Can you tell us about your documentation language preferences? Take a short survey.

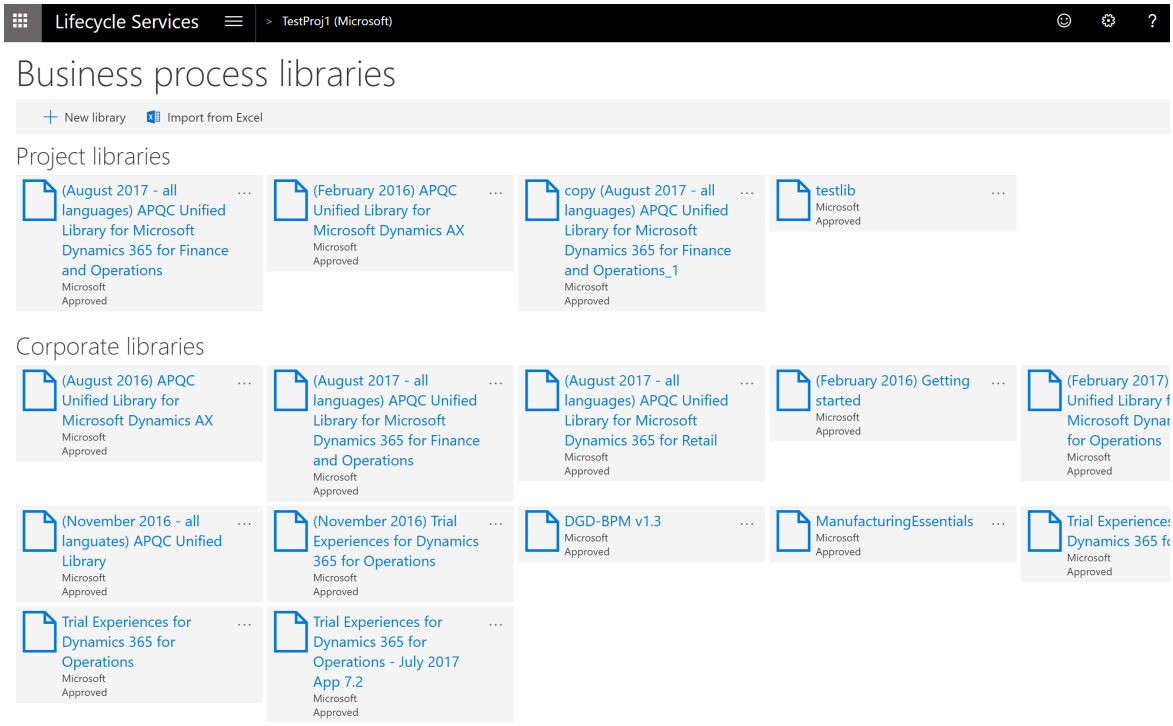
The survey will take about seven minutes. No personal data is collected (privacy statement).

Complete tasks in Business process modeler (BPM)

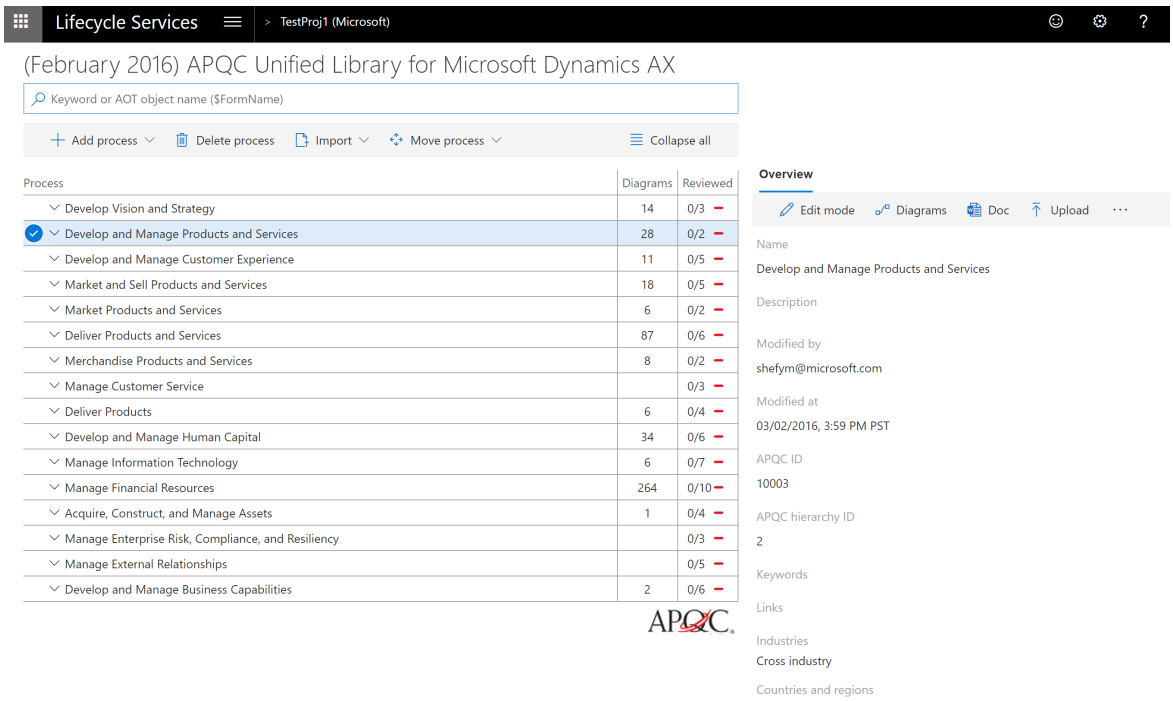
2/18/2021 • 2 minutes to read • Edit Online

Upload a task recording

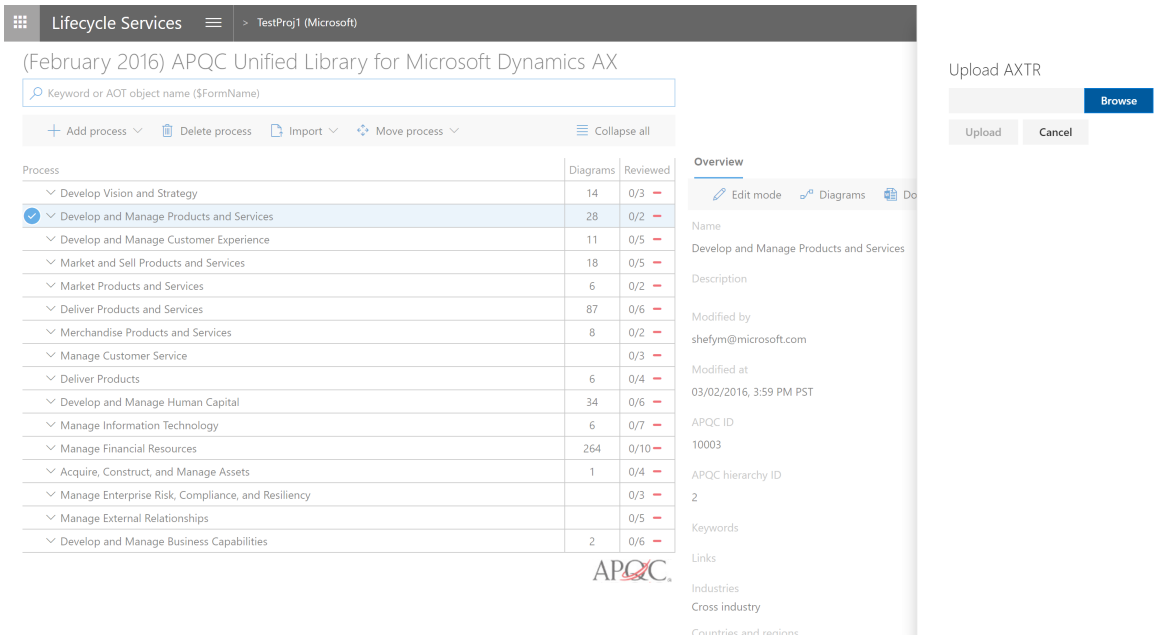
1. In Microsoft Dynamics Lifecycle Services (LCS), in your project, on the **Business process libraries** page, select the library to upload the task recording to.



2. Select the process to upload the task recording to.



3. On the **Overview** pane, select **Upload**. Select **Browse** to find and select the file to upload, and then select **Upload**.



Download a task recording

You can download a task recording (AXTR file) that has been uploaded to a BPM process.

1. In your LCS project, on the **Business process libraries** page, select the library to download the task recording.
2. Select a process that has task recording uploaded.
3. On the **Overview** pane, select **Download** to save the task recording (AXTR).

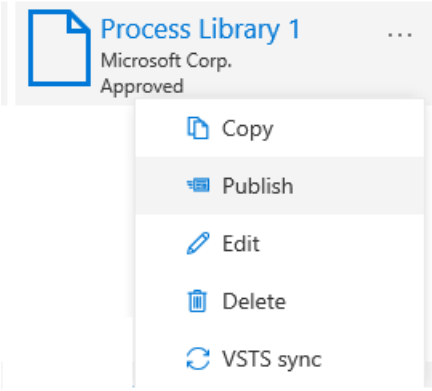
Export a methodology to Word

1. In your LCS project, on the **Business process libraries** page, select the library to export.
2. Select the process to export, and then, in the right pane, select **Doc** to begin the download.

> **NOTE**
>
> The methodology will begin from the process step that you selected.

Publish a BPM library

- In your LCS project, on the **Business process libraries** page, on the tile for the library that you want to copy, select the ellipsis button (...), and then select **Publish**.



Distribute a BPM library

When you distribute a BPM library, the library will be available to all users who are a part of your organization. In other words, it will be available to all users who sign in to LCS by using your organization's domain (for example, all users who have an @contoso.com account).

1. Ask the customer to invite you to their project.
2. Sign in to the customer's LCS project by using your organization's account.
3. On the **Business process libraries** page, copy the library from the **Corporate libraries** pane to the customer's project.

NOTE

Can you tell us about your documentation language preferences? Take a short survey.

The survey will take about seven minutes. No personal data is collected (privacy statement).

Work with activity diagrams in Business process modeler libraries

2/18/2021 • 2 minutes to read • Edit Online

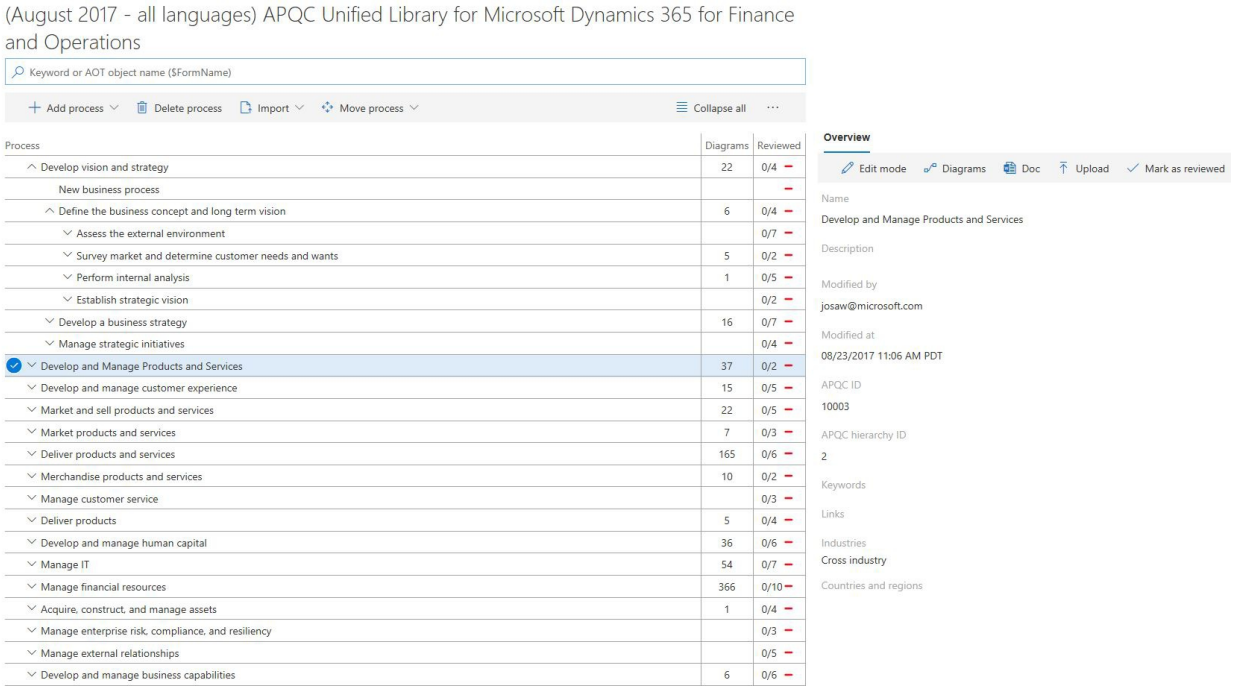
You can associate an activity diagram with a business process. Activity diagrams are used to describe how a business process or task is completed in a proposed software solution.

There are two types of activity diagrams:

- **Task recordings** – Business processes that are associated with task recordings for Finance and Operations, include activity diagrams and process steps that are automatically generated.
- **Microsoft Visio** – You can associate a business process with a Visio diagram by manually uploading a Visio file.

Browse activity diagrams

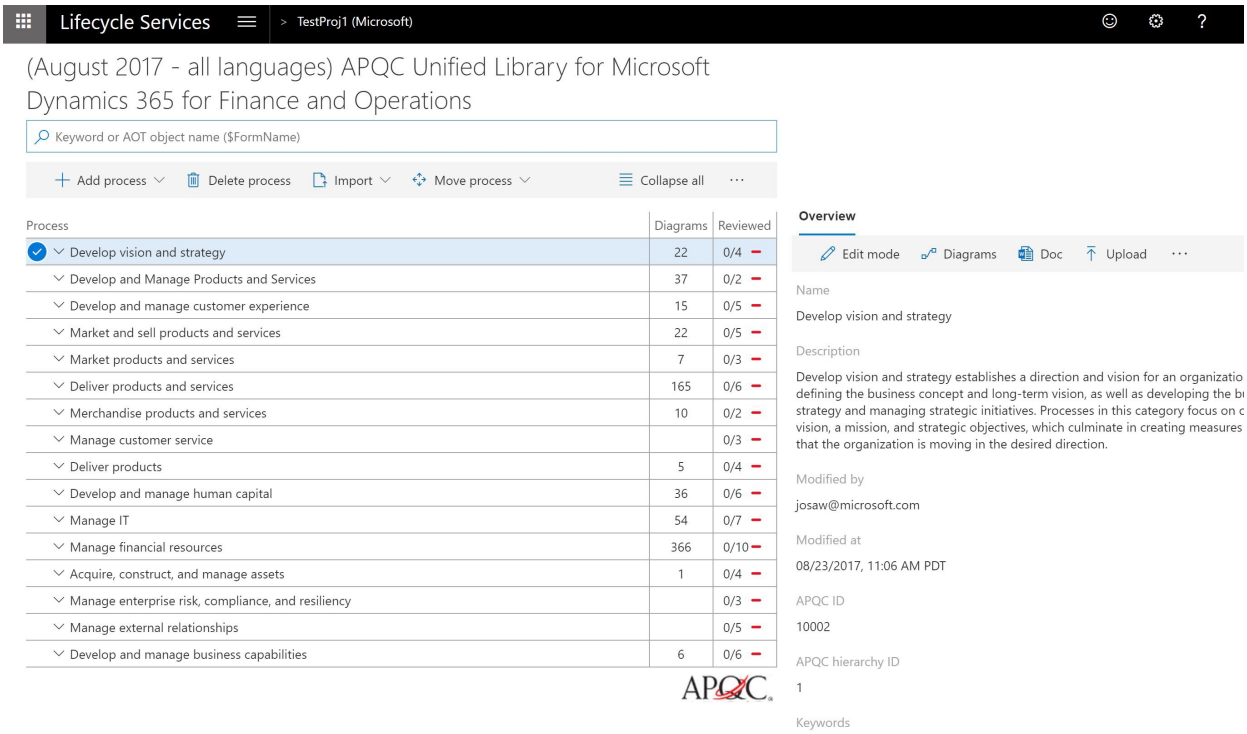
The **Diagrams** column in your BPM library indicates whether a particular business process is associated with an activity diagram. The number in the column indicates the number of child processes that include diagrams. The symbol next to the number indicates whether the current node or process is associated with a diagram. These indicators don't apply to Visio diagrams.



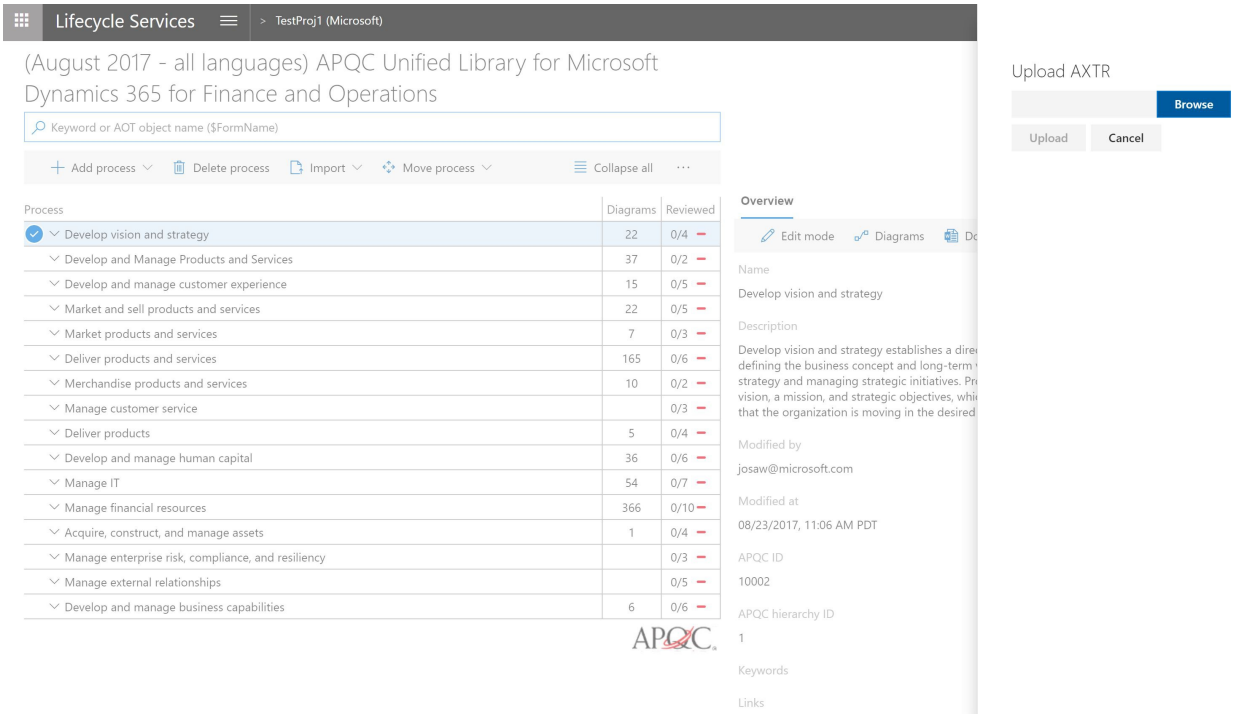
To view an activity diagram, select the business process, and then, in the right pane, on the **Overview** tab, select **Diagrams**. The **Flowchart** page appears.

Upload Task Recording

To upload a task recording, open the business process library that you want to upload to. Select the process step that you want to upload the task recording to, and then click **Upload**.



In the right pane, click **Browse** to choose a file, and then click **Upload**.



Activity diagrams that are created from task recordings

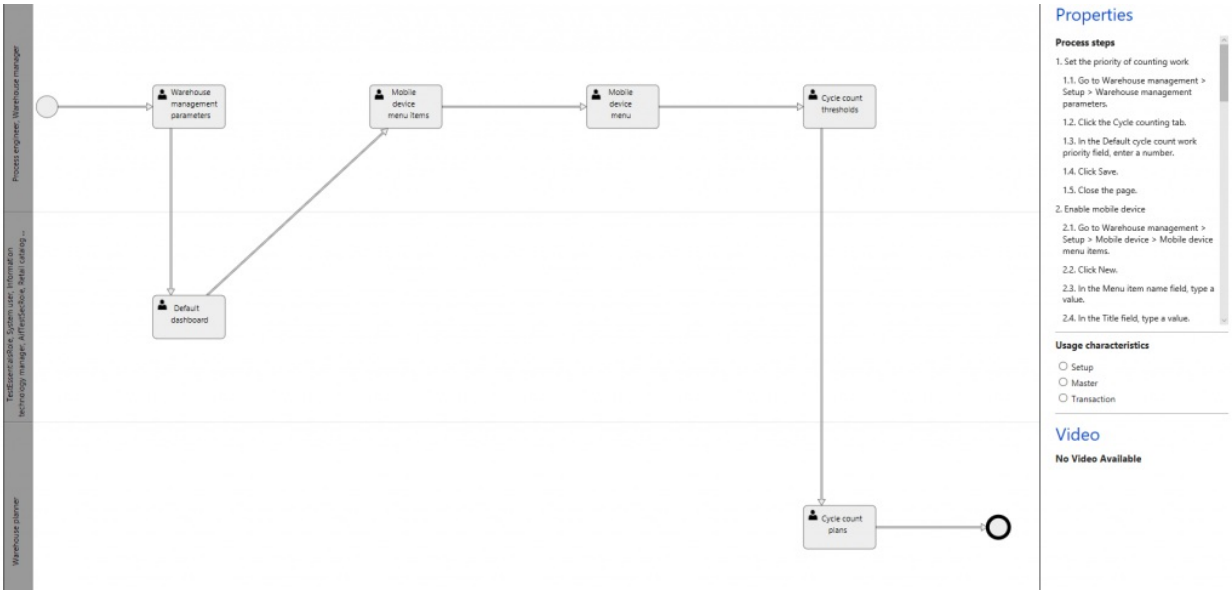
> [!IMPORTAMT] Flowchart diagrams in Business process modeler have been deprecated. To learn more about the deprecation, see Flowchart diagrams in Business process modeler.

You can create a task recording in your environment and save it directly to Microsoft Dynamics Lifecycle Services (LCS). In this way, you can associate the task recording with a business process in a BPM library. For more information, see Connecting the help system and Create documentation or training with Task Recorder.

The Task recorder tool lets you create a distributable recording file. Recording files have the .axtr file name extension. You can associate a business process in BPM with a task recording by manually uploading the recording file.

To upload a recording file, select the business process, and then, in the right pane, on the **Overview** tab, select **Upload**.

BPM automatically generates an activity diagram and detailed process steps for all task recordings that are created. The following illustration shows an example.



Visio files

You can associate a business process with a Visio diagram. Typically, this functionality is used for high-level processes that can't be represented by a task recording.

> **NOTE**
>
> BPM supports .vsd and .vsdx files. However, it doesn't support .vsdm files (macro-enabled Visio drawing files). If a .vsd file contain macros, BPM disables the execution of the macros.

To view or upload a Visio file, follow these steps.

1. Select the business process, and then, in the right pane, on the **Overview** tab, select **Diagrams**.
2. On the **Flowchart** page, select the **Visio** tab. For more information, see the "Unconnected flowcharts" section in Flowcharts in Business process modeler (BPM).

> **NOTE**
>
> Can you tell us about your documentation language preferences? Take a short survey.
>
> The survey will take about seven minutes. No personal data is collected (privacy statement).

Synchronize BPM libraries with Azure DevOps

2/18/2021 • 6 minutes to read • Edit Online

You start the implementation stage of a project by synchronizing a Business process modeler (BPM) library with your project in Microsoft Azure DevOps. In this way, you can review processes and associate requirements with business processes. By synchronizing a BPM library with a Azure DevOps project, you can also track the progress of your implementation project in Azure DevOps, and can associate various work items with requirements and business processes. These work items include bugs, tasks, backlog items, tests, and documents.

Currently, BPM-Azure DevOps synchronization doesn't support custom work item types or synchronizing business processes with custom work item types. If you try either of these, you will receive a warning. If you choose to ignore the warning and attempt a Azure DevOps sync with a custom template, you can avoid synchronization issues by verifying the following for the template:

- Does not delete any work item type
- Does not delete any state of a work item type
- Does not add any required fields to a work item type

To learn more about Azure DevOps, go to www.visualstudio.com/team-services.

LCS project settings: Set up Azure DevOps

If you've already set up Azure DevOps from Microsoft Dynamics Lifecycle Services (LCS), you can skip the procedures in this section.

Create a personal access token

To connect to a Azure DevOps project, LCS is authenticated by using a personal access token. Follow these steps to create a personal access token in Azure DevOps.

1. Go to https://www.visualstudio.com, sign in, and find your Azure DevOps project.
2. In the upper-right corner, hold the pointer over your name, and then, on the menu that appears, select **Security**.
3. Select **Add** to create a new personal access token.
4. Enter a name for the token, and then specify how long the token should last.
5. Select **Create Token**.
6. Copy the token to your clipboard.

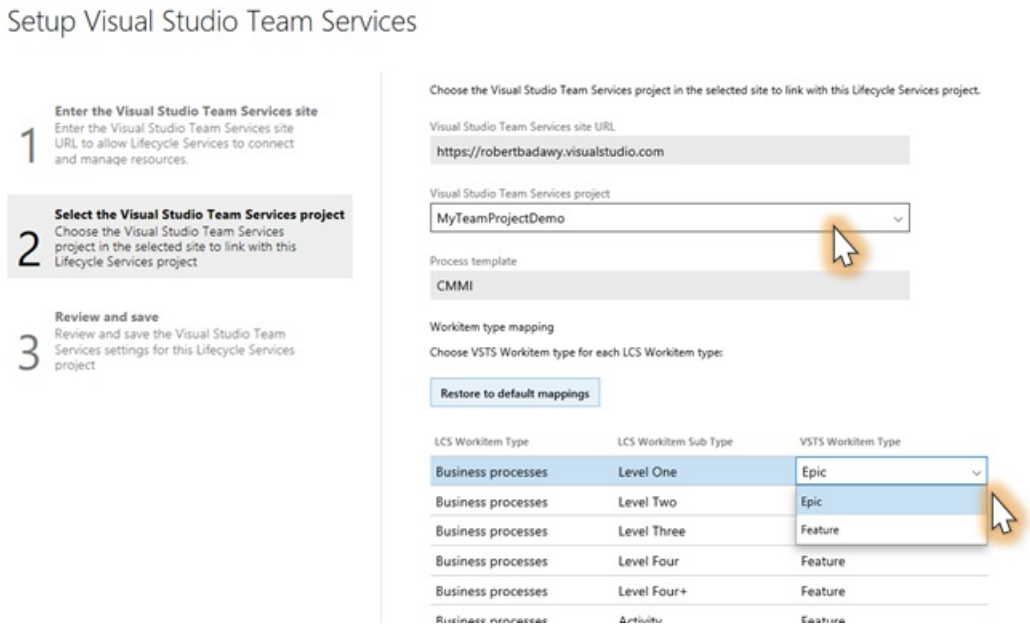
> **NOTE**
> You won't be able to find the token details again after you complete this step and move away from the page. Therefore, make sure that you've copied the token before you move away from the page.

Configure your LCS project to connect to Azure DevOps

1. In your LCS project, select the **Project settings** tile.
2. Select **Azure DevOps**, and then select **Setup Azure DevOps**. This configuration is required by many LCS tools. If you've already configured LCS to connect to your Azure DevOps project, you can either skip

this procedure or select **Change** to change the existing configuration.

3. Enter the root URL for your Azure DevOps account, and the personal access token that you created earlier, and then select **Continue**.
4. Select your Azure DevOps project.
5. Specify the mapping between LCS/BPM items and the associated Azure DevOps work item types.



6. Select **Continue**, review your changes, and then select **Save**.

Synchronize a BPM library with a Azure DevOps project

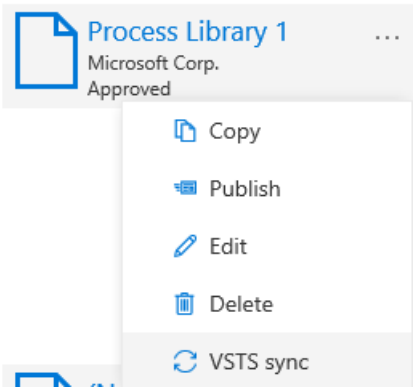
After you've set up the connection between the LCS project and a Azure DevOps project, you can synchronize a BPM library with the Azure DevOps project. When you synchronize a BPM library with a Azure DevOps project, a Azure DevOps work item is created for each business process line in the BPM library. In addition, the hierarchy of business processes in BPM is reflected in the hierarchy of work items in Azure DevOps. The type of work items that are created in Azure DevOps depends on the settings of your LCS project.

This synchronization is a one-way synchronization. Changes in LCS are reflected in Azure DevOps, but changes in Azure DevOps aren't reflected in LCS.

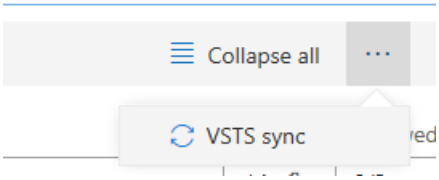
The following information is synchronized:

- Business process names
- Business process descriptions
- Keywords (as tags)
- Countries or regions (as tags)
- Industries (as tags)

To synchronize a BPM library with a Azure DevOps project, on the **Business process libraries** page, on the tile for the library that you want to synchronize, select the ellipsis button (...), and then select **Azure DevOps sync**.



You can also start Azure DevOps synchronization from the toolbar in a BPM library. Select the ellipsis button (...), and then select **Azure DevOps sync**.



> **NOTE**
> BPM localization is not supported. If you edit in the new BPM client in any language other than EN-US, your changes will only display when you view the BPM in the language in which the changes were made. To view any changes made in EN-US, you must synchronize with Visual Studio Team Server before the changes will display.

Turn off synchronization of BPM with Azure DevOps

To turn off synchronization, on the **Business process libraries** page, select the library that you want to stop synchronizing, select the ellipsis button (...), and then unselect **Azure DevOps sync**.

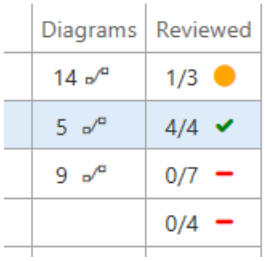
Review processes and add requirements

During the project phase where you're gathering requirements, you can use the BPM library to review business processes and tasks, and to identify requirements. In BPM, you can mark business processes as reviewed to track the review process.

To mark a process or one of its child processes as reviewed, select the process in BPM, and then, in the right pane, on the **Overview** tab, select **Mark as reviewed**.

When a business process is marked as reviewed, the **Reviewed** column is updated. This column shows the following information:

- A fraction indicates how many direct child processes have been reviewed.
- A symbol indicates how completely the process and its child processes have been reviewed:
  - **Green check mark** – The process and all its child processes have been fully reviewed.
  - **Yellow circle** – The process and its child processes have been partially reviewed.
  - **Red dash** – The process and its child processes haven't been reviewed.



While you're reviewing a business process that is connected to Azure DevOps, you can add a requirement directly to your Azure DevOps project.

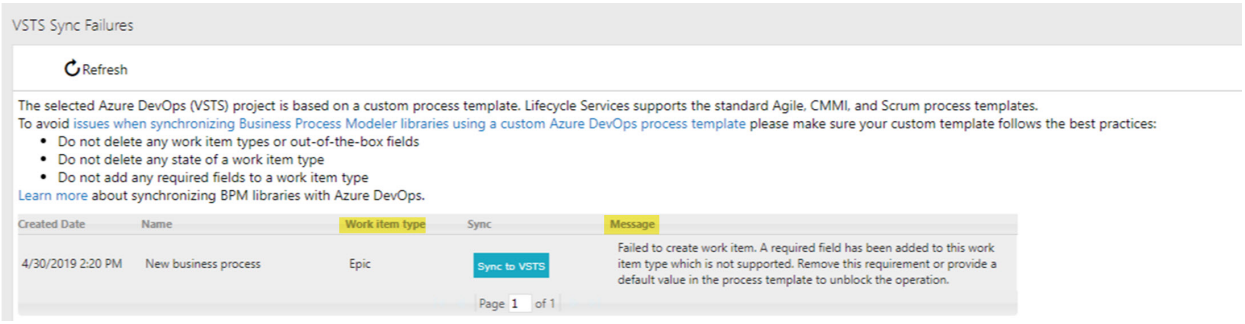
1. Select a business process.
2. In the right pane, on the **Requirements** tab, select **Add requirement**.
3. Enter a name, description, and type, and then select **Create**.

   In Azure DevOps, a requirement work item is created that is associated with the current business process.

To go to the Azure DevOps work items that are associated with the current business process, on the **Requirements** tab, select the appropriate links.

Common syncing errors

If the BPM to Azure DevOps synchronization fails, you will see the failed process name, work item type, and an error message.



Here are some common causes and suggested actions to resolve the error.

POSSIBLE CAUSE	ERROR MESSAGE	SUGGESTED SOLUTION
Required field added	Failed to create work item. A required field has been added to this work item type, which is not supported. Remove this requirement or provide a default value in the process template to unblock the operation.	Remove the required field or provide a default value.
Work item type disabled	Failed to create work item. The work item type has been disabled in the process template. Enable the work item type to unblock the operation.	Enable the work item type in the process template

POSSIBLE CAUSE	ERROR MESSAGE	SUGGESTED SOLUTION
Couldn't find work item to update	Failed to update work item. The work item does not exist, or you do not have permissions to read it. Check the PAT configuration in the project settings or restore the work item if it has been deleted directly from the DevOps project.	Restore the work item from the recycle bin if it was deleted, or create a new Personal Access Token (PAT) and make sure that it has full permissions.
Personal Access Token is expired	Failed to sync with Visual Studio Team Services. The request response is: Unauthorized. Please check that the PAT is setup correctly and still valid, try again and contact support if the error persists.	Create a new Personal Access Token (PAT) from Azure DevOps and update the PAT value in your LCS Project settings.
Generic error	Failed to sync with Visual Studio Team Services. The request response is: {0}. Please check that the PAT is setup correctly and still valid, try again and contact support if the error persists.	Contact customer support with the request response that caused the syncing error.

Create and automate user acceptance tests

2/18/2021 • 8 minutes to read • Edit Online

You can use Task recorder and Business process modeler (BPM) to create user acceptance test libraries. Task recorder is a powerful tool to record test cases and organize them by business process using BPM. As a Microsoft partner you can use BPM to distribute test libraries to your customers via LCS and LCS solutions. If you are a customer, use BPM to author and distribute test libraries across different projects and team.

Because BPM can be synchronized with Azure DevOps (formerly known as Visual Studio Team Services), you can automatically create test cases (including test steps) in your Azure DevOps project. Azure DevOps can then serve as your test configuration and test management tool where you can create targeted test plans and test suites, manage the execution of tests and investigate results. For more information about testing with Azure DevOps, see What are test plans, test suites, and test cases?

This topic walks through the process of creating and executing acceptance test suites to be used for manual or automated testing.

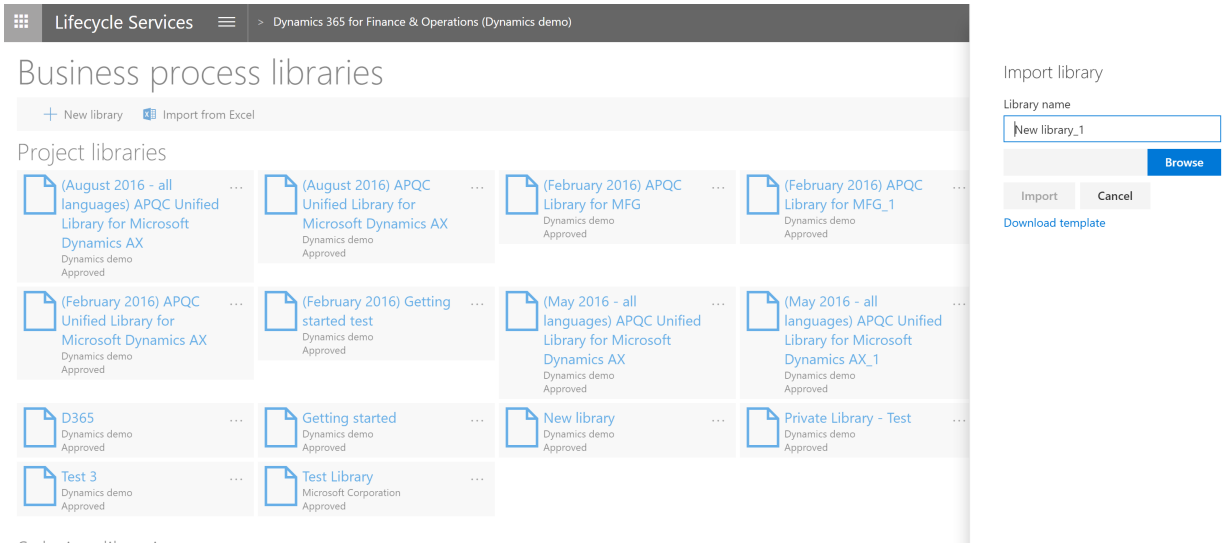
Create a Scenario Acceptance Testing BPM library

BPM is a great LCS tool to describe a hierarchy of business processes and user tasks. LCS also allows Microsoft partners and customers to author and distribute BPM libraries across LCS projects via the Asset library. This section describes how to take advantage of BPM to define your acceptance test library.

Create a BPM library

There are several ways to create a Business process modeler (BPM) library. For more information about how to create libraries in BPM, see Create, edit, and browse Business process modeler (BPM) libraries.

For illustration purposes, this topic uses a library that contains common business processes, such as create an expense report and approve order requests. The library was created by using the Excel import functionality.



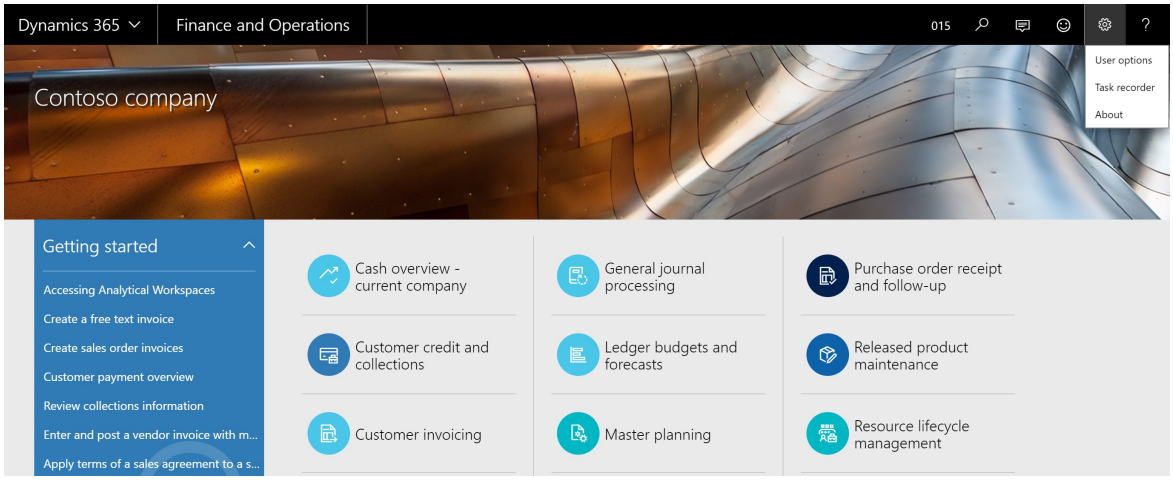
Record test cases and save to BPM

After you have created a BPM library, you'll need to use Task recorder to create your test cases and then upload the cases to BPM. There are several ways to do this.

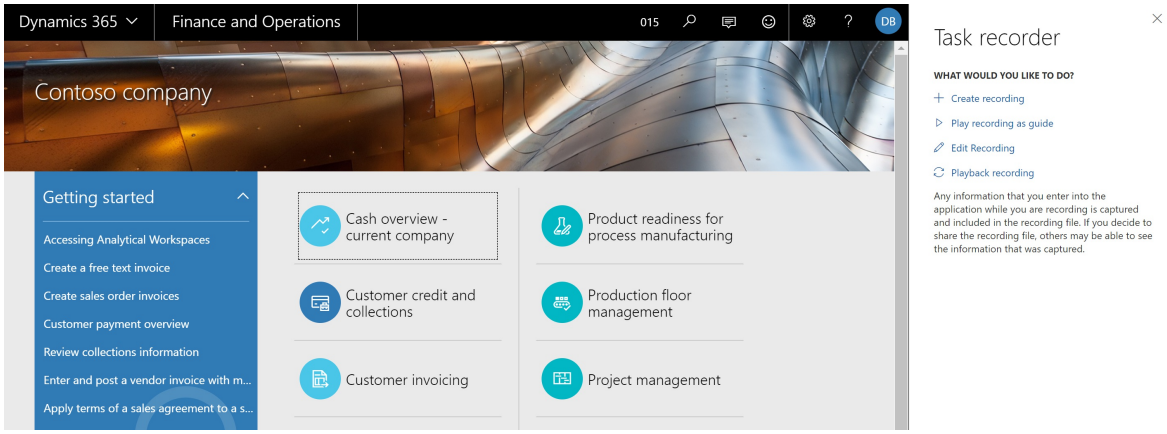
If you're using a BPM library that already has all of the necessary task recordings (test cases) attached, you can skip this step. Otherwise, follow the instructions below to create new task recordings.

Create and save a new task recording

1. Open the client and sign in.
2. Select the company that you want to use while recording.
3. Go to **Settings** > **Task recorder**.



4. Click **Create a new recording**.
5. Enter a name for the recording, and then click **Start**. Recording begins the moment that you click **Start**.
6. When the recording is complete, in the Task recorder pane, click **Stop**.
7. To save the task recording to an attached BPM, click **Save to Lifecycle Services**.



8. Select the library that you want to save the recording to, and then click **Save**. Otherwise, select **Save to Disk** and follow the steps in the next section, "Upload an AXTR file to BPM."

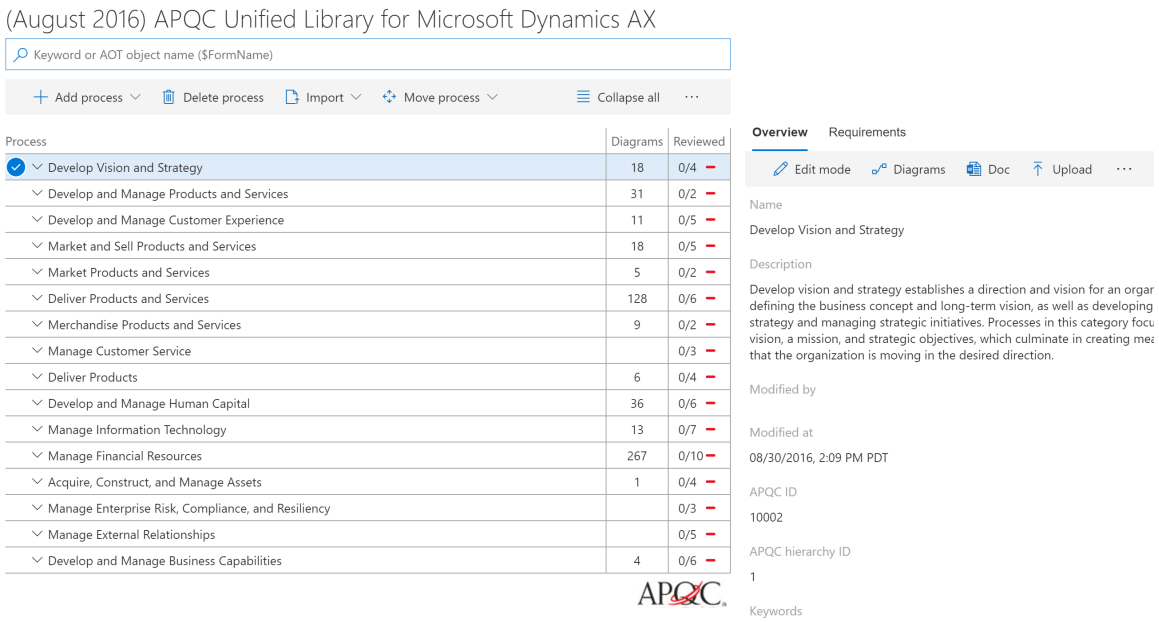
> **NOTE**
>
> To enable the effective execution of your tests using automation tools, make sure all of your task recordings start on the main dashboard of your application. For end-to-end processes that are performed by more than one user, we recommend that you divide your task recordings into user-specific tasks. This simplifies the maintenance of test cases and allows you to execute test cases in the context of security roles, which is a best a practice.

Upload an AXTR file to BPM

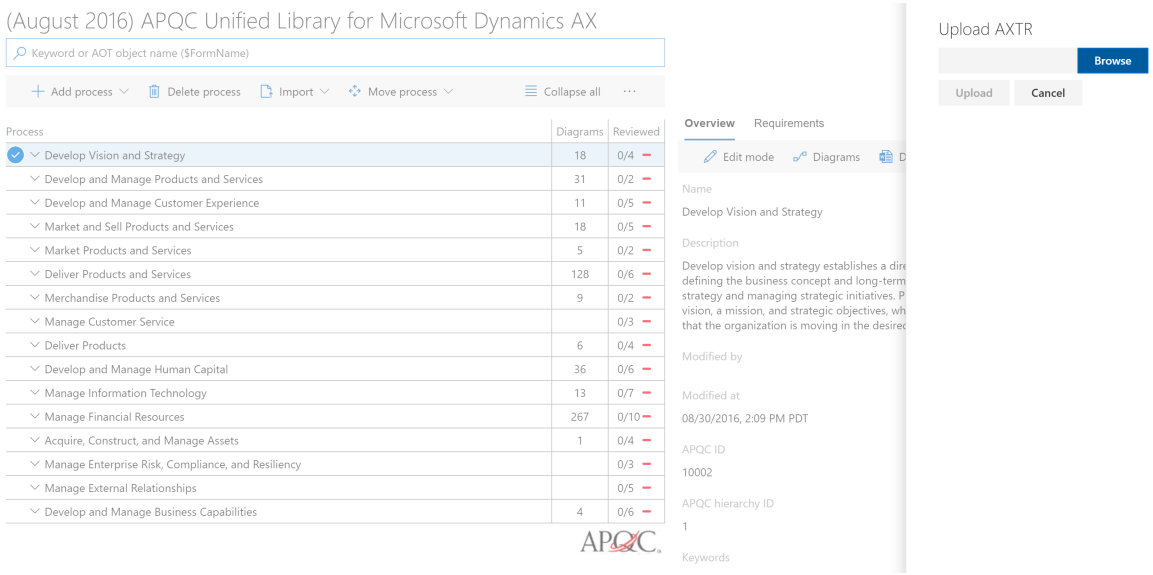
If you have saved your recordings (AXTR files) to disk, follow these steps to upload them to BPM.

1. In Lifecycle Services (LCS), in your project, on the **Business process libraries** page, select the library to upload the task recording to.
2. Click **Author and edit** and in the lines, locate and select the process to upload the task recording to.

3. In the right pane, click **Upload**.



4. Click **Browse** to find and select the file to upload, and then click **Upload**.



Save an existing task recording to BPM

1. To attach an existing task recording, sign in to the client.
2. Go to **Settings** > **Task recorder**.
3. Select **Edit Task Recording** and attach the file by either saving directly to LCS or downloading the AXTR and then uploading to BPM.

Guidelines for recording test cases

Follow these guidelines when authoring and recording your test cases, especially if you are planning to automate test execution. The process and tools described in this article apply to business process acceptance tests. They are not meant to replace component and unit testing that is typically owned by developers.

- Author a limited number of test cases that, when combined, cover complete end-to-end processes.
- Focus on business processes that have been customized.
- An individual test case (recording) should cover one or two business tasks only, typically executed by one person. This simplifies task recording maintenance. Do not combine a complete end-to-end business process such as "Procure to Pay" or "Order to Cash" into one large task recording. For example, instead of having RFQ > Purchase Order > Product Receipt > Vendor Invoice > Vendor Payment as one test case, divide the process into three or four test cases. You will have the opportunity to combine these tests into an ordered

test suite later.

- A test case should have at least one validation. Try to validate critical fields that cover the impact of other fields. For example: Validation of totals on sales or purchase orders cover the unit price/quantity/discount/tax ...etc.
- Avoid printing a report in a test case. If a test case needs to print a report, it should be selected on screen.
- 80+% of test cases should be of transactions or source documents. Master data should be limited to up to 20% of test cases only.

Synchronize and configure your test plan in Azure DevOps

An acceptance test library is your starting point. It typically contains all test cases (task recordings) of a particular application organized by business process. During a particular test pass, you usually do not need to execute all test cases. What test cases you select depends on the phase of your implementation or the nature of the update you are planning to apply to your production environment. Azure DevOps enables you to organize your test cases in test plans and test suites. A test plan contains one or more test suites (A subset of your test library); test cases can belong to more than one test suite.

Once you have selected your acceptance testing BPM library, synchronize it with Azure DevOps and create your test plan and test suites.

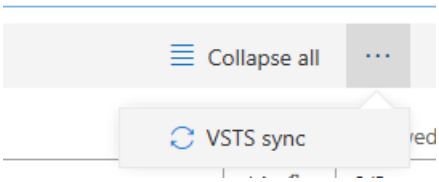
Sync with Azure DevOps

Synchronize your BPM library with your Azure DevOps project. For more information, see Synchronize BPM libraries with Azure DevOps.

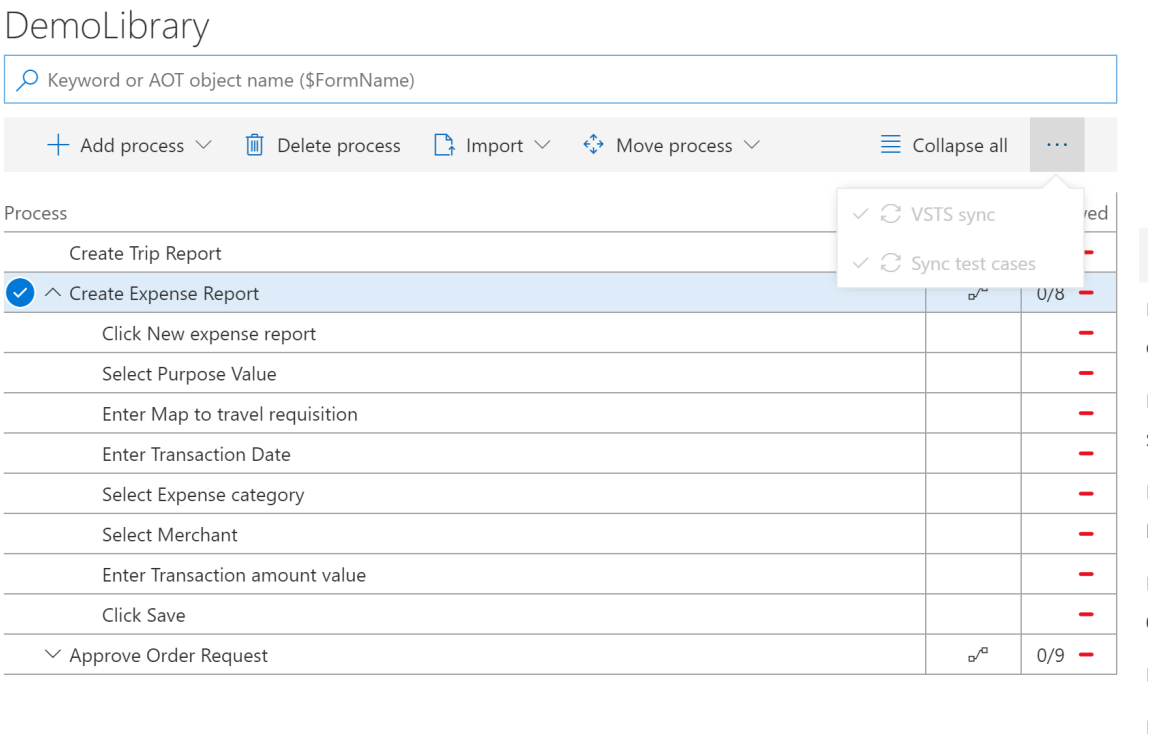
After configuration is complete, synchronize the BPM library with a Azure DevOps project.

1. On the **Business process libraries** page, on the tile for the library that you want to synchronize, select the ellipsis button (...), and then select **Azure DevOps sync**.

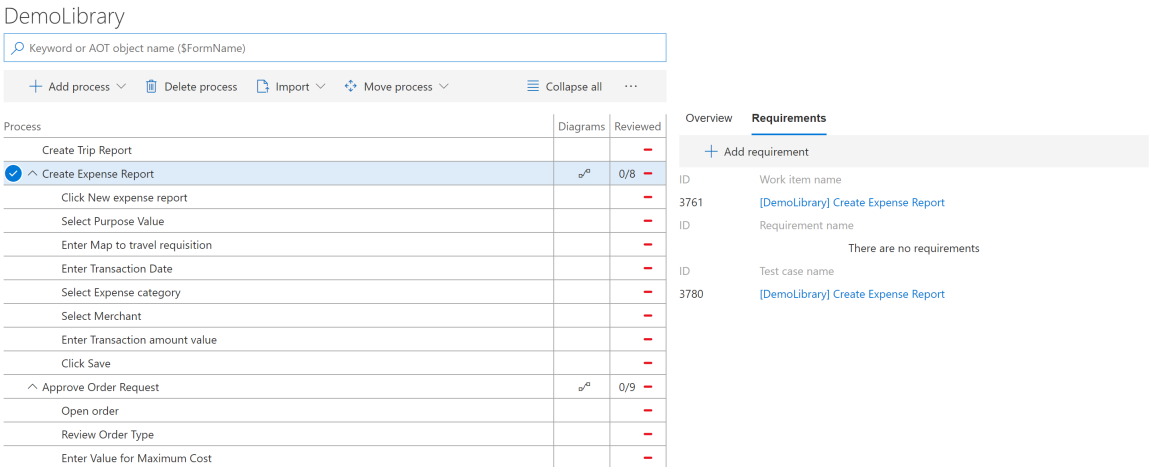
   You can also start Azure DevOps synchronization from the toolbar in a BPM library. Select the ellipsis button (...), and then select **Azure DevOps sync**.



2. After Azure DevOps synchronization is complete, select the ellipsis button (...), and then select **Sync test cases**.



3. When this step is complete, your task recordings will become test cases in Azure DevOps and a link will appear under the **Requirements** tab.

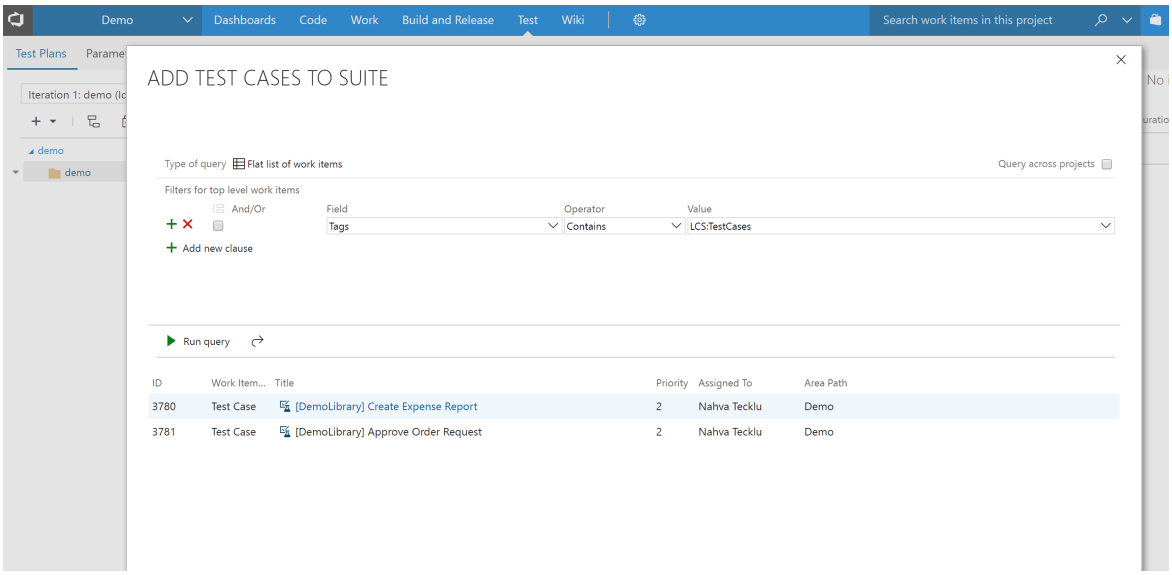


In addition to the test steps, the task recording XML file is attached to the Azure DevOps test case. This file will be needed if you want to automate test execution.

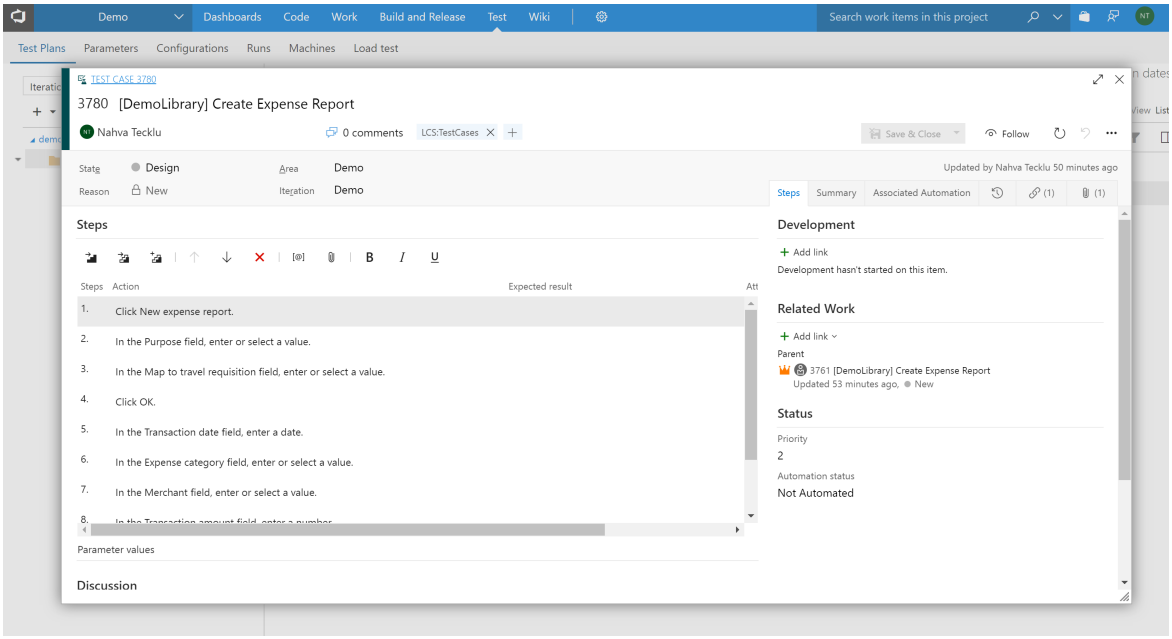
Create a test suite in Azure DevOps

Next, you will need to create a test plan and test suite in Azure DevOps. This will allow you to execute an ordered suite of test cases and easily manage, investigate, and track the results.

1. Sign in to Azure DevOps and select the project and test plan that you want to test in.
2. On the toolbar, select **Test** > **Test Plans**.
3. In the left pane, select **+**, and then select **Static suite**.
4. Enter a name for the suite.
5. Click **Add existing** and query the tag **LCS:Test Cases**.
6. Click **Run** > **Add test cases**.



7. Select the test case to view details and the attached XML file.

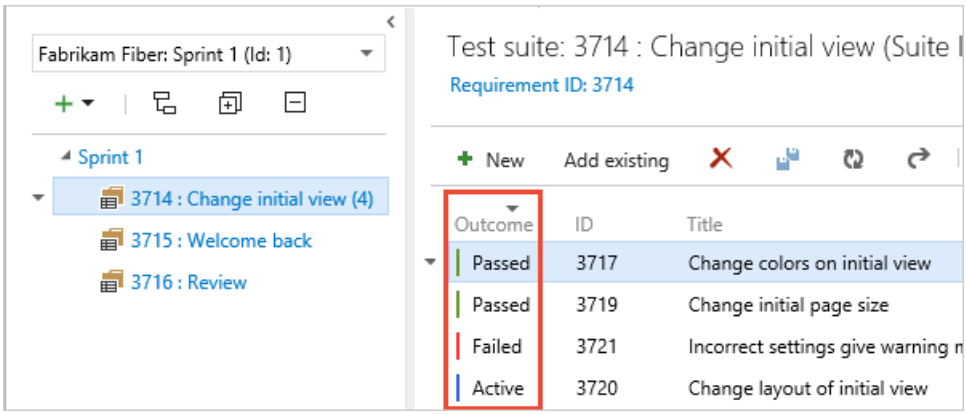


> **NOTE**
>
> This example shows how to create one comprehensive acceptance test suite with all test cases added. Instead, you should create various test suites under the same test plan and then use custom queries to add specific test cases to a test suite. A test case can belong to more than one test suite.

Execute your tests

Run manual test cases

After you have a test suite, you are ready to use it for regression testing after updates have been made to your application in a sandbox or test environment. You can run the test cases in your test suite manually or play the task recordings that are part of the test suite and use Azure DevOps to mark the test cases as passed or failed.



Azure DevOps also provides a tool, **Test Runner**, to manage manual test case execution. For more information about using Test Runner, see Run manual tests.

We recommend that you take advantage of Azure DevOps as it provides a rich set of management features not only for testing, but result management and mitigation.

Run automated test cases

The platform for Finance and Operations provides developers with tools to author test cases based on task recordings and use Azure DevOps to manage the automated execution of these test cases.

Developers can use the build and test automation capabilities of **build and test** environments. For details, see the Continuous delivery home page.

Functional power users can automate the execution of their test cases using the **Regression suite automation tool**. For more information, download the tool and read the Regression suite automation tool.

Investigate test runs

Once an automated run is complete, on the Azure DevOps toolbar, select **Test > Runs** (or **Test Plans > Runs**) to investigate your test run. Select the desired test run to investigate test case failures and errors. You can also go to your test suite in Azure DevOps to see the latest results associated with your test cases. For more information on testing and test management in Azure DevOps, see the Azure DevOps documentation.

> **NOTE**
>
> Can you tell us about your documentation language preferences? Take a short survey.
>
> The survey will take about seven minutes. No personal data is collected (privacy statement).

Flowcharts in Business process modeler (BPM)

2/18/2021 • 2 minutes to read • Edit Online

IMPORTANT

Flowchart diagrams in Business process modeler have been deprecated. To learn more about the deprecation, see Flowchart diagrams in Business process modeler.

You can use Business process modeler in Microsoft Dynamics Lifecycle Services (LCS) to define and store business process flowcharts for an organization. This topic explains how you can view the default connected flowcharts, export a connected flowchart as a Visio file, and upload and view unconnected flowcharts.

- Connected flowcharts are the automatically generated flowcharts based on data recorded in Task recorder and uploaded to Business process modeler, this also includes the process steps from the task recording.
- Unconnected flowcharts are uploaded directly from Visio.

View a connected flowchart

Default connected flowcharts are available for many nodes in the industry-standard libraries. You can view a connected flowchart to determine whether it meets your needs.

To view a connected flowchart, follow these steps:

1. Sign in to Lifecycle Services, open a project, and then click **Business process modeler**.
2. In the **Project libraries** section, select a library to display it.
3. Expand the business process library and then click a library node that has a flowchart icon associated with it: 

   The flowchart is displayed. Each activity in the process is represented by a shape in the diagram. Process steps are displayed in the right pane.

Export a flowchart as a Visio file

You can export a business process model flowchart to a Visio file.

1. Sign in to Lifecycle Services, open a project, and then click **Business process modeler**.
2. In the **Project libraries** section, select a library to display it.
3. Expand the library and then select any library node that has a flowchart icon associated with it.
4. From the **Overview** pane, select **Diagram** to view the flowchart.
5. From the flowchart tab, click **Export** to save as a Visio file.

Unconnected flowcharts

Unconnected flowcharts, such as a Visio diagram, can be very helpful for describing high-level business processes that are performed outside of the Finance and Operations apps.

Upload an unconnected flowchart

1. In the **Project libraries** section, select a library to display it.
2. Expand the library and then click any library node that has a flowchart icon associated with it.
3. From the **Overview** pane, select **Diagram**.

4. From the **Visio** tab, click **Upload** to upload a Visio file.

> **NOTE**
>
> If you have uploaded the wrong file, you can delete the existing one, and upload a new one to replace it.

> **NOTE**
>
> Can you tell us about your documentation language preferences? Take a short survey.
>
> The survey will take about seven minutes. No personal data is collected (privacy statement).

Upload custom business processes to Business process modeler (BPM)

2/18/2021 • 2 minutes to read • Edit Online

In Microsoft Dynamics Lifecycle Services, you can record information about custom business processes by using an updated version of Task recorder. You can then upload the files that you record to Business process modeler.

This topic explains where to find the updated version of Task recorder and how to upload the custom business process files that you record. The updated version of Task recorder is available as a hotfix. You can download the hotfix from the following sites:

- Microsoft Dynamics AX 2012 and Microsoft Dynamics AX 2012 Feature Pack – Knowledgebase article 2863182
- Microsoft Dynamics AX 2012 R2 – Knowledgebase article 2863182

For more information about how to work with the updated Task recorder, see Task recorder update for Microsoft Dynamics AX 2012.

Upload custom recorded business processes

You can upload business process artifacts (*.axbpm files) to the business process library. These files are generated from Task recorder. After they are uploaded, you can view and modify the recorded processes in Business process modeler. To upload custom business processes that you recorded, follow these steps:

1. On the **Project** home page, click the **Business process modeler** tile.
2. On the **Business process library** page, click **Upload** in the **My libraries** section or the **Corporate libraries** section.
3. On the **Upload** page, select the industry and enter a name and description for the file that you are uploading. Click **Upload**, select the .axbpm file, and then click **OK**. The upload process can take some time. You can view the status of the upload on the **Administration** page.
4. After the business process file has been uploaded, you can view the business process framework from the **Business process library** page.

Cloud operations and servicing

2/18/2021 • 5 minutes to read • Edit Online

For customers, partners, and Microsoft to be successful in this endeavor, we must ensure that most of the actions are self-serve with the Microsoft Dynamics Service Engineering (DSE) team managing by exception. To attain this self-serve mode, the Microsoft Product team continues to add more automation around the various features needed to operate an environment.

The Finance and Operations apps are managed services. This means that Microsoft is responsible for managing and operating the production environments. Microsoft's Dynamics Service Engineering team is available 24 hours a day, 7 days a week, and 365 days a year to operate and manage our customers' production systems.

Monitor and troubleshoot the health of your environment

A key tenant for a successful onboarding experience to the cloud service is knowing the health of your environments at all times and being able to troubleshoot health issues when necessary. Lifecycle Services (LCS), which is the admin center for Finance and Operations, contains a collection of monitoring and diagnostics tools which can help ensure that you have an accurate view of the environments that you manage. For more information, see Monitoring and diagnostics tools in Lifecycle Services (LCS).

Update your environment

After go-live, the Production environment must be updated at regular intervals. Lifecycle Services (LCS) provides a self-serve experience to continuously update your environments.

Update types

For customers who are on **Dynamics 365 for Finance and Operations version 8.0 (April 2018) and earlier**, the following updates are available:

- **Platform updates** – A single cumulative binary update of all the platform fixes.
- **Application hotfixes** – Application hotfixes that are released as granular X++ updates.
- **Application release** – A new major release of the application. This type of update typically requires an upgrade.
- **Application customizations** – Customizations that are built on top of the application. The best practice is to apply a single deployable package that consists of all your independent software vendor (ISV) solutions and customizations.

For customers who are on **Dynamics 365 for Finance and Operations version 8.1 (October 2018) and later**, the following updates are available:

- **Application updates** – A single cumulative binary update of the application and the platform fixes. You can update for yourself by using the regular update flows. Otherwise, you will be automatically updated by Microsoft.
- **Application customizations** – Customizations that are built on top of the application. The best practice is to apply a single deployable package that consists of all your ISV solutions and customizations.

Cloud infrastructure

Microsoft is responsible for managing the infrastructure for your environments. Therefore, some updates, such as operating system updates, must be done on a monthly basis in a planned maintenance window. Other kinds of updates might include changes to the infrastructure components.

Update policy

Currently, service updates require production tenant downtime and are applied in two kinds of maintenance windows.

- **Microsoft planned maintenance window** - Microsoft will provide customers with no less than five business days' notice regarding upcoming planned maintenance downtime. The default downtime window is defined per region and is scheduled to occur over a weekend to minimize impact to the business. Cloud infrastructure updates can be done in this window. For more information about planned maintenance, see the Planned maintenance window FAQ.
- **Customer initiated maintenance window** - A customer selects the maintenance window through LCS as a part of the package application flow. Updates are done in this maintenance window.

Search for and apply an update in Lifecycle Services

Updates are applied as deployable package on an environment. A deployable package is a format that is used to apply updates to all the environments in a project. When you encounter an issue in the production environment, you can quickly find and apply a hotfix on all of the environments (Dev/Sandbox and Prod).

- **Search for and download an update** In LCS, you can search for an update using Issue search in Lifecycle Services (LCS) or the Download updates from Lifecycle Services (LCS). Because the steps to prepare an update differ based on the update type, after the update is downloaded, use the following list to determine how to proceed with preparation.
  - Platform update: Platform updates are cumulative and binary. This means that they can be applied directly to an environment. After the update is downloaded, it can be automatically applied to an environment by uploading it to the Asset Library.
  - Application hotfixes: Application hotfixes are code changes. After the application hotfix is downloaded, it must be applied on a dev environment to generate a deployable package. For more information, see Create deployable packages of models and Install metadata hotfixes in development environments.
  - Application customizations: These are customizations that ISV or partners create. These are deployable packages that are uploaded to the Asset Library and can be applied from there.
- **Apply an update** Use the information in the topic, Apply updates to cloud environments, to walk through the steps for applying a deployable package. The update package can be a binary hotfix for Application Object Server (AOS) or a deployable package that was created in your development environment.
- **Validate an update** After an update is applied, you should validate the application to:
  - Ensure that the update addressed the issue that it was applied for.
  - Verify that no regressions occurred from applying the update.
  - Verify that the build information was updated to reflect an update to the binaries.
    - For Platform updates, verify that the version of the AOS Service Model under Microsoft is updated.
    - For Application updates, check the version of the model that included the fix. For example, if the fix was in Application suite, then the version of the Application suite is updated.

Upgrade your environment

For information about how to upgrade to the latest version, see Process for moving to the latest update of Finance and Operations and What's new or changed in Finance and Operations home page.

Environment data management

These are the options for managing databases, including the ability to copy a database from one environment to another or restore a database to a previous state. For more information, see Database movement operations home page.

Sign up for cloud operations notifications

When the status of the package application is changed, LCS sends a notification to all of the users in a project. Any additional stakeholders who should be notified must be specified in the notification list.

1. To add additional stakeholders, in LCS, in the Environment details view, click Notification list.
2. Add the email address of each user who must be notified, and then click Save.

Submit service requests to the Dynamics Service Engineering team

2/18/2021 • 7 minutes to read • Edit Online

A service request is a ticket that you use to request that the Dynamics Service Engineering (DSE) team perform a predefined set of tasks on your environments.

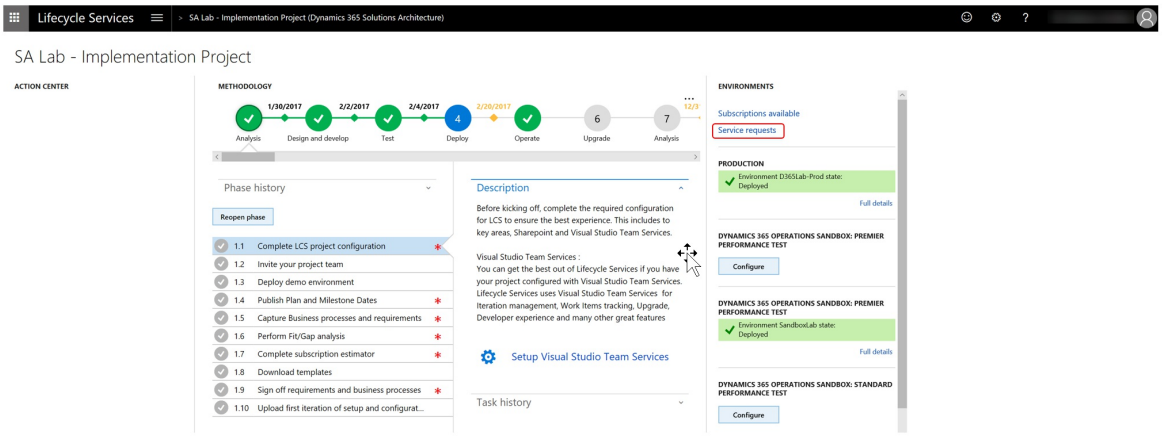
> **NOTE**
>
> Don't use service requests for product issues. If you encounter a situation that doesn't fit into any of the tasks that are described in this topic, submit a support ticket instead. For more information about support tickets, see Get support for Finance and Operations apps or Lifecycle Services (LCS).

You can use Microsoft Dynamics Lifecycle Services (LCS) to submit service requests directly to the DSE team. You can also view which requests have been submitted, executed, and canceled for your environments.

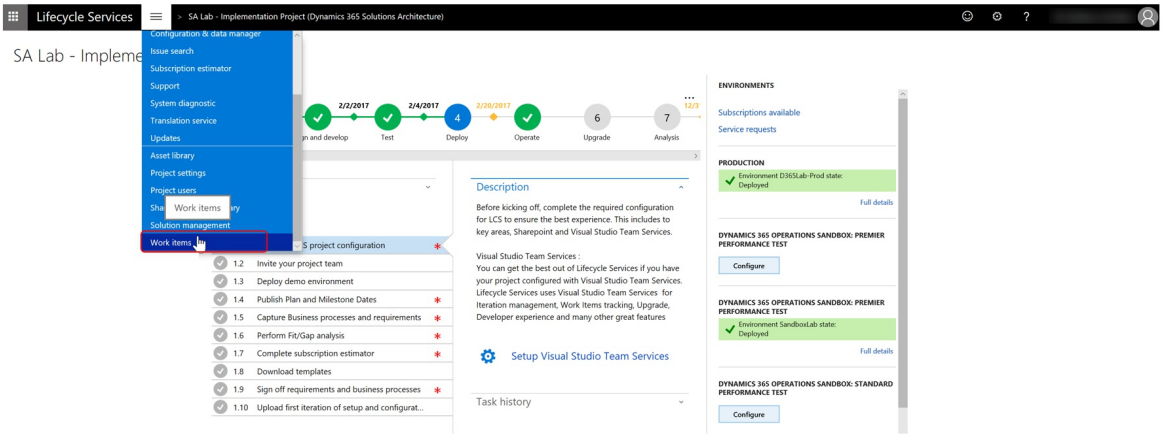
View service requests

There are two ways to view service requests:

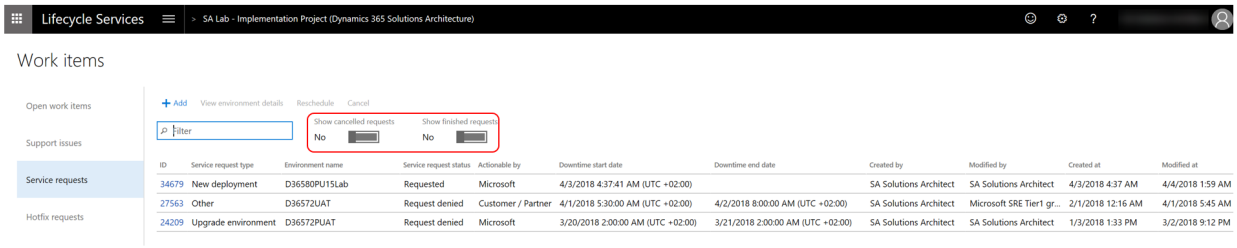
- On the project dashboard, in the **Environments** section, select **Service requests**.



- Select the **Menu** button and select **Work items**. On the **Work items** page select the **Service requests** tab.



By default, the **Service requests** tab on the **Work items** page lists all requests that are currently active and requests that have been denied. However, you can use the filter options to show canceled and finished requests too.



After you submit a request, it has a status of **Requested**. Before the DSE team acts on the request, it might ask for clarification by entering a comment in the **Comment** field. For example, you might receive a comment from the DSE team if you request deployment of a production environment, but the data center differs from the data center where your sandbox environments are deployed. Carefully review the comments, and provide any required clarification in your own comment. To view the details of a specific request, or to submit comments for a service request, select the request ID.

If you signed up for LCS notifications, you receive an email when the status of a service request changes or a comment is entered.

If you submit a service request to the DSE team, and the action is outside the team's scope, the service request will be denied. In this case, the reason for the denial and suggestions for further action are provided. For some typical examples of service requests that the DSE team will deny, see the "Denied service requests" section later in this topic.

Create service requests

There are two ways to create a service request: automatically and on demand.

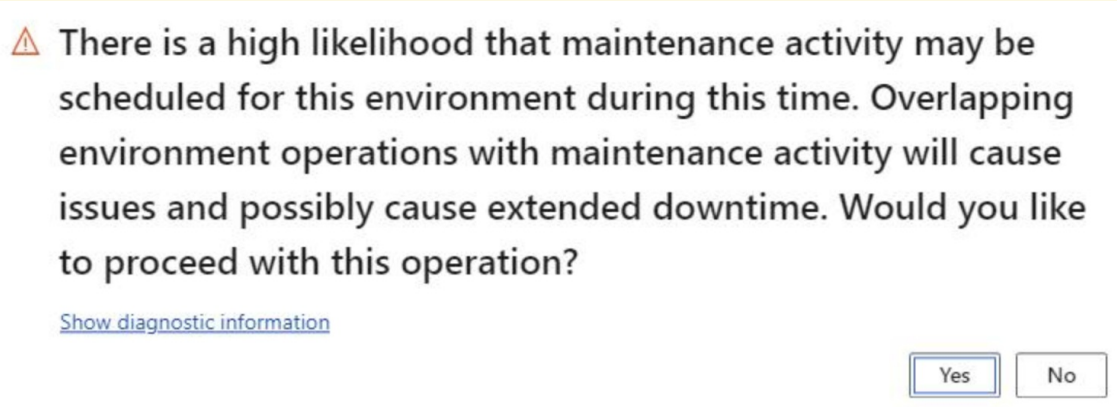
- **Automatically** – A service request is automatically created when you request deployment of an environment, or an application of a package.
- **On demand** – A service request is manually created when you enter a request for a database point-in-time restore, and some other services.

Automatically create a service request

- **Environment deployment** – To set up deployment options and submit a request to the DSE team to deploy a new environment, in the **Environments** section, select **Configure**.
- **Package application** – To apply a package to the production environment, on the **Environment details** page, select **Maintain**, select the package to apply, and then select **Schedule**. For more information, see Apply updates to cloud environments.

IMPORTANT

If your scheduled time overlaps with a planned maintenance window, you will receive the following warning message.



If you choose to continue deploying the package, the package deployment operation will be rolled-back in the event of conflict, as planned maintenance takes priority.

This restriction is appliable to **Microsoft-managed IAAS environments** only.

Create a service request on demand

Service requests that are created on demand aren't explicitly accepted by the DSE team. They will be addressed during the specified downtime window unless the DSE team has entered a comment in the request or has had to deny the request. For details, review the comments in the service request.

Microsoft frequently reviews all incoming service requests. By selecting the correct type of service request for your scenario, you help the DSE team handle the request in a timely manner.

1. On the **Work items** page, on the **Service requests** tab, select **Add**.
2. In the **Create request** dialog box, select the type of service request to create. The options on the page then reflect the specific type of request that you selected.

   - **Sandbox point-in-time restore request** – Select this request type to restore a *non-production* database to a specific point in time. For more information, see Database movement operations home page.

     NOTE

     If you need to restore a *production* database to a previous point-in-time during the cutover phase, select the **Production point-in-time restore request** type. If you need to restore a production database when you're already live in operations, submit a support ticket through LCS.

   - **Database refresh request** – Select this request type to refresh a database from a production environment to a sandbox environment, or from one sandbox environment to another. For more information, see Refresh database. *This request type is being retired on January 31, 2019*.

     NOTE

     If you need to refresh a database from a sandbox environment to a production environment during the cutover phase, select the **Sandbox to Production** type.

   - **Sandbox to Production** - Perform a database refresh of your configuration data to a production

environment during the cutover phase. For more information, see Database movement operations home page.

- **Other request** – You need to use the **Other request** type exactly as described here. If you word a request in a way that isn't clear to the DSE team, the team will enter a comment to ask for clarification, and your request will be delayed. If you use the **Other request** type for any request that isn't listed below, the request will be denied. Select this request type to request that the DSE team perform one of the following actions:
  - Turn on maintenance mode in a production environment. For more information, see Maintenance mode.
  - Tenant move of a live Production environment. Request the Microsoft Service Engineering team to move the Production database and Azure Blob Storage from the old tenant to the new tenant if you are moving tenant on a live Production environment. Make sure that you only request this service when you are ready with all prerequisites. For more details, see Move LCS implementation projects to different Azure AD tenants.
  - Define explicit Internet Protocol (IP) safe list rules in a production environment.

    > **NOTE**
    > Support for explicit safe list rules is deprecated for self-service environments. For more information, see Removed or deprecated platform features.

  - Request that Microsoft Power BI Embedded be activated in a sandbox environment, Standard Acceptance Test environment, or production environment if you receive the following message: "Power BI embedded isn't enabled. Please contact your system administrator."

Commonly denied service requests

Here are some typical examples of service requests that will be denied:

- You submit a request of the **Other request** type for one of the following actions, but you should have submitted a support ticket instead:
  - You want to activate a new subscription estimate after you're live in production or after you've requested a production environment.
  - You want to reset the Financial reporting data mart in a release that is earlier than Microsoft Dynamics 365 for Finance and Operations Financial reporting release 7.2.6.0.
  - You want to restore a production database after go-live.
  - You encountered an issue after the DSE team did an application upgrade.
- You submit a request of the **Other request** type for an action that you should have requested through a different request type. Examples include a database refresh in a non-production environment.
- You submit a request of the **Other request** type for an action that you should perform yourself. Examples include a database upgrade in a development environment.

Service request types and SLAs

SERVICE REQUEST TYPE	APPLICABLE ENVIRONMENTS	REQUESTED SERVICE	LEAD TIME	DOWNTIME

SERVICE REQUEST TYPE	APPLICABLE ENVIRONMENTS	REQUESTED SERVICE	LEAD TIME	DOWNTIME
Environment deployment	Any	Environment deployment	Service level agreement (SLA): within two business days	
Package application	Production	Deployable package application	Five hours	Five hours
Sandbox point-in-time restore	Any Tier 2 or higher sandbox	Database point-in-time restore	Five hours	Four hours
Production point-in-time restore	Production	Database point-in-time restore	Based on data volume	Based on data volume
Sandbox to Production	Tier 2 or higher sandbox to Production	Sandbox to Production	Five hours	Four hours
Other	Production	Maintenance mode	Five hours	Not applicable, because the customer indicates in the service request when the environment should be taken out of maintenance mode again
	Production	IP safe list rules	Five hours	Two hours
	Production	Power BI Embedded	Five hours	Two hours

Planned maintenance window FAQ

2/18/2021 • 5 minutes to read • Edit Online

What is a planned maintenance window?

A planned maintenance window is the timeframe that Microsoft has scheduled to apply infrastructure or service updates to your cloud service.

How does a planned maintenance window work?

For planned maintenance scheduled on your Tier 2 through Tier 5 sandbox environments and production environments, Microsoft will send a notification to all stakeholders **five business days** before the start of the patching window. The patching window is the period when the environment is patched. It's defined by geographic region. Details about the maintenance activity will be included in the notification that is sent to stakeholders. For Microsoft-managed Tier 1 environments, we will not send any notifications before the update.

When is this planned maintenance window taken?

To limit the impact on users, the maintenance window is planned according to the region where environments are deployed. The following list shows the maintenance window for each region. All environments fall into one of these three regions. The times are shown in Coordinated Universal Time (UTC, which is also known as Greenwich Mean Time).

- **NAM:** 2 AM to 10 AM
- **EMEA:** 10 PM to 6 AM
- **APAC:** 12 PM to 9 PM

Will the maintenance from Microsoft require any uptake?

Most of the maintenance operations require no action on your end. If there is a critical security update that requires uptake, you will be notified.

Who will be notified about the upcoming planned maintenance?

The following stakeholders will be notified about the upcoming maintenance:

- Project owners
- Organization admins
- Environment admins
- Other people who are specified in the list during deployment or through the **Notify** button on the environment details page in Microsoft Dynamics Lifecycle Services (LCS)

How do I sign up to be notified about the maintenance window?

Any partner, independent software vendor (ISV), and other interested party who wants to be notified about upcoming updates can request to be added to the LCS project as a relevant stakeholder (project owner, environment admin, or additional stakeholder).

Why can't these updates be applied in zero downtime?

Microsoft is continually working to reduce the necessity of downtime for the service, and many regular maintenance tasks don't incur downtime. However, to help guarantee the most predictability, Microsoft can't yet do all patching in zero downtime.

Microsoft service updates

A separate set of frequently asked questions (FAQ) provides details about service updates that are done by

Microsoft. See One Version service updates FAQ.

Infrastructure updates

How long is the maintenance window?

Most operating system–level updates are completed in approximately one hour. However, Microsoft asks for a three-hour window, so that there is time to handle any failures and to bring the system back to a healthy state.

The exact downtime for all updates will be included in the maintenance window notification email that is sent to you before the start of the update.

How frequent are the updates?

Operating system–level updates are applied monthly to your Microsoft-managed Tier 2 through Tier 5 sandbox environments and to the production environments. However, Microsoft-managed Tier 1 environments are updated weekly in the maintenance windows defined per region.

Where can I learn more about what is applied?

For more information about the updates that will be applied, see Microsoft Security Bulletins.

Where can I track progress of the update?

During operating system–level updates, LCS doesn't currently indicate that any patching is in progress. However, Microsoft plans to add this functionality at some point.

What environments are updated?

Operating system–level updates are applied to all Microsoft-managed environments that are included as part of the Microsoft base offer. This includes your Tier 1, Tier 2 through Tier 5, and Production environments. They are also applied to add-ons that have been purchased. However, other environments, such as environments hosted in your subscription (known as Cloud hosted environments), are the responsibility of the customer or partner.

What notifications will I receive about upcoming planned maintenance?

You will receive a notification email for the scheduled update on your Tier 2 to Tier 5 sandbox environment and production environment, five days before the update is scheduled to occur. This email will include information about the environments that will be updated, the update type, the estimated amount of time that the update will take, and any action that you might have to take. We do not send notifications for Microsoft-managed Tier 1 environments.

Will I be notified when the update is completed?

If your update is completed within the defined maintenance window, you won't receive any notification when the update is completed.

How do I report an issue that is identified during validation of the updates that were applied to the environment?

To report an issue that is identified during update validation, file a support ticket with Microsoft and append the title with 'Planned Maintenance Window'.

What happens if the patching fails?

If the patching fails during an operating system–level update, the specific patch is skipped and will be applied in the next update cycle.

Will I be compensated if the update takes longer than the scheduled maintenance window?

If the update takes longer than the scheduled maintenance window, the extra time is considered unplanned downtime and is subject to the general service level agreement (SLA).

How do I reschedule security maintenance activities?

Security maintenance helps ensure a secure environment, and not doing the maintenance could potentially

introduce an avoidable security risk.

If there is an absolute business need and you are unable to move forward with this maintenance during the timeframe listed above, you can request to reschedule the current maintenance activity for Tier 2 through Tier 5 sandbox environments and production environments by filing a support ticket with Microsoft. The deadline for filing the support ticket to request a reschedule will be included in your notification email. Any request submitted after that deadline will not be honored.

We do not offer rescheduling of security maintenance activities on Microsoft-managed Tier 1 environments.

Monitoring and diagnostics tools in Lifecycle Services (LCS)

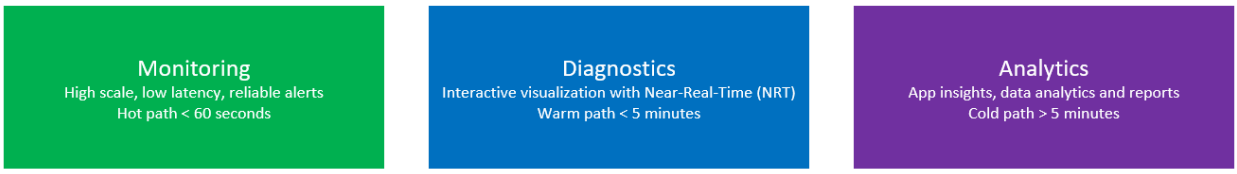
2/18/2021 • 5 minutes to read • Edit Online

This topic describes the various tools that Microsoft Dynamics Lifecycle Services (LCS) provides to help you monitor, diagnose, and analyze the health of the Finance and Operations environments that you manage.

To have a successful onboarding experience to the cloud service, you must know the health of your environments at all times. You must also be able to troubleshoot any health issues that occur. Microsoft Dynamics Lifecycle Services (LCS), which is the administration center, contains a collection of monitoring and diagnostics tools that can help to ensure that you have an accurate view of the environments that you manage.

Telemetry data

The telemetry data that is the basis of the Monitoring and diagnostics portal in LCS has three primary use cases: monitoring, diagnostics, and analytics.



Monitoring

In business operations software, you should always know whether your environment is up and running, so that it can perform business operations. You should also be able to easily view the health of the environment through LCS. Microsoft supports two types of monitoring capabilities:

- **Availability monitoring** – This type of monitoring performs a check against the environment to make sure that it's available at all times. If the check fails, the Microsoft Service Engineering team is immediately notified.
- **Health monitoring** – In addition to availability checks, some basic health checks must be performed. These health checks span various components, such as Application Object Server (AOS), Batch Framework, Data Management Framework, Microsoft Azure SQL, and Management Reporter. These checks are done based on multiple data sources, such as the telemetry that is collected from the environments, checks that are done by a watchdog service that continuously monitors the environment, and CPU counters and other system-level counters that the environment emits. Some health checks are self-healing and are mitigated immediately. However, other health checks are reported to the Microsoft Service Engineering team for investigation.

Diagnostics

When a user reports an issue, you can use various tools in LCS for troubleshooting. The rich set of telemetry data helps you build a storyboard view that shows what that user and other users were doing when the issue was reported. In addition to user activity tracking, a rich set of SQL data is available for performance troubleshooting.

Analytics

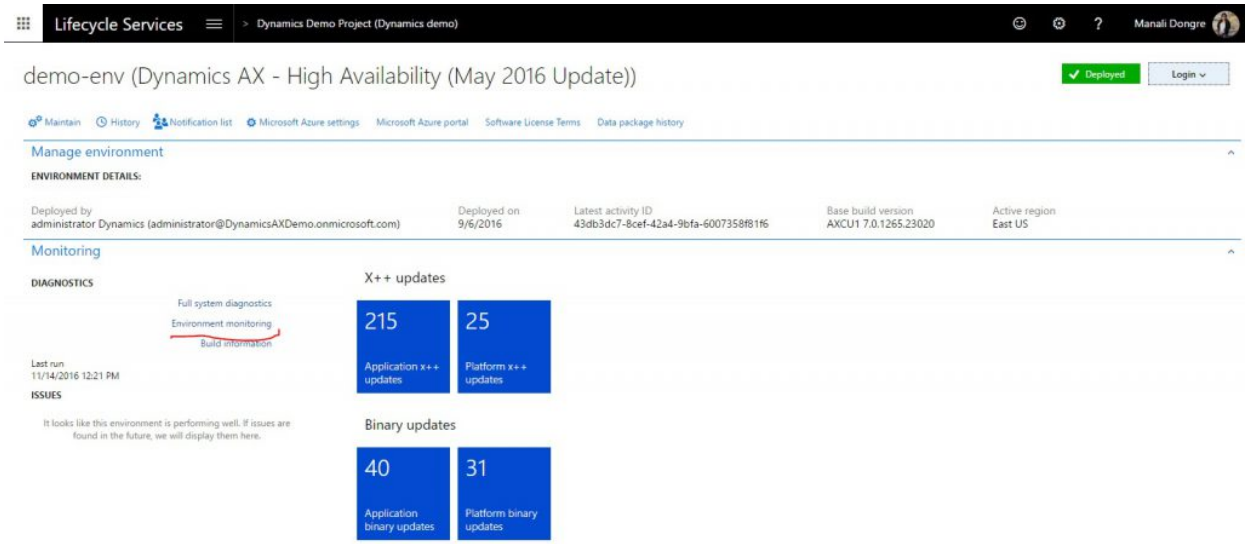
Analytics is another critical use case for the telemetry data that is collected. Currently, only Microsoft can perform analytics, so that it can gauge and understand feature usage and performance through Microsoft Power BI.

Responsibilities

For a managed cloud service such as Finance and Operations, Microsoft is responsible for actively monitoring the health of production environments at all times. If a customer's environment is affected by an issue, the Microsoft Service Engineering team is immediately alerted. The team will start to investigate the issue and will work with you to find a resolution. However, you're responsible for proactively or reactively monitoring and troubleshooting the health of non-production environments.

Access the Monitoring and diagnostics portal

1. Open LCS, and navigate to the appropriate project.
2. In the **Environments** section, select the environment to view, and then select **Full details**.
3. On the environment details page, select **Environment monitoring** to open the Monitoring and diagnostics portal.



Tools

Several tools and resources are available in the Monitoring and diagnostics portal.

> **NOTE**
> Not all environments contain all the tools. The following table shows the tools that are available for each type of environment.

ENVIRONMENT TYPE	TOOLS
Production systems	• Activity monitoring • Environment monitoring • SQL insights • System diagnostics
User acceptance testing (UAT)/sandbox	• Activity monitoring • SQL insights • System diagnostics

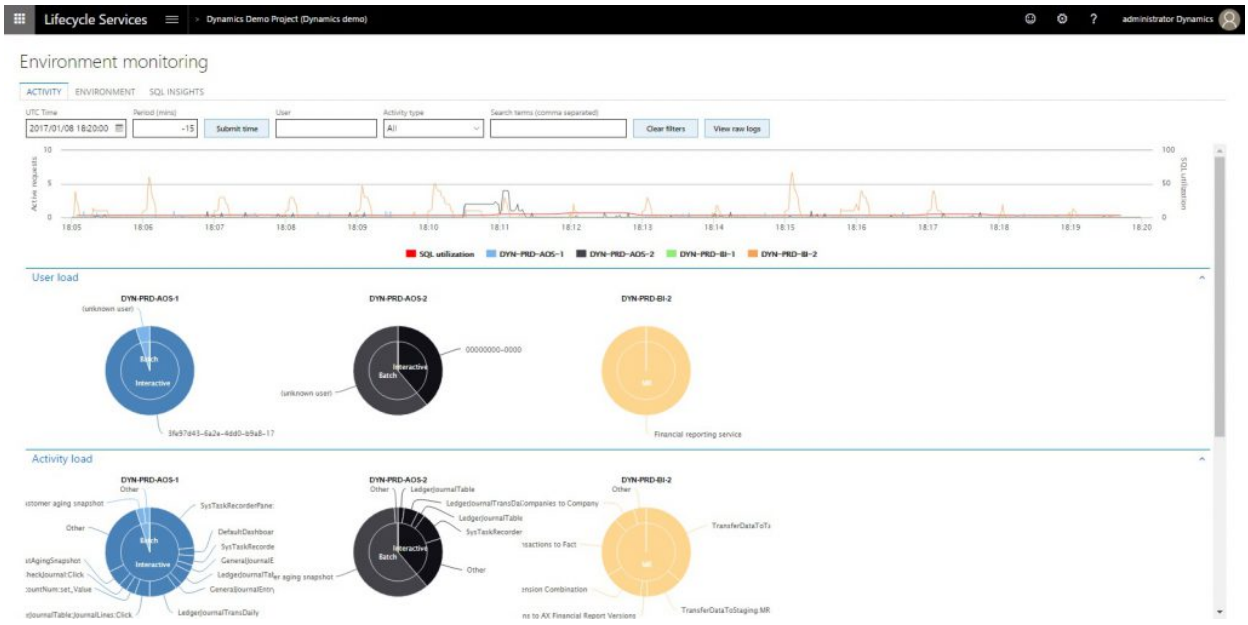
ENVIRONMENT TYPE	TOOLS
Demo/build	• Activity monitoring • System diagnostics
Environments deployed in customer/partner subscriptions	• System diagnostics

Monitoring dashboard

On the **Environment monitoring** page, select the **Health metrics** tab to view the **Monitoring** dashboard. Health metrics are collected for every machine and component. These health metrics include CPU usage, available memory, errors logged per second, and batch heartbeat. You're alerted about any abnormalities in the metrics. Although some alerts are self-healing, the Microsoft Service Engineering team will investigate the cause of other alerts and then take action to mitigate them. You can view the health monitors for a specific area to see what is occurring.

Activity monitoring

On the **Environment monitoring** page, select the **Activity** tab to use the Activity monitoring tool. This tool provides a storyboard view that shows what you or another user was doing during a specific period.



- The **User interaction** chart shows a user's activities on various machines in the environment and the SQL utilization trend.
- The **User load** section shows all the system users. Each chart shows the time that the user spent on a specific machine.
- The **Activity load** section shows the activities that were performed on each machine. If you hover over an activity, you see the Form:Control:Action as a tuple. For example, if you look at LedgerJournal:New:Click in this section, you can see that user A opened the **LedgerJournals** page and selected the **New** button to create a new journal entry.
- The **User activity** grid shows the various activities that users performed, based on their session timestamp.

You can use the filters on this page to narrow the information logs. Here are some of the filters that are available:

- **Time duration** – Go back 60 minutes from the selected date and time.
- **User** – View a specific user's activities.
- **Search terms** – Create a search that is based on the issue that is being investigated.

NOTE

The page doesn't load data by default. To load the data that is required in order to show the page, you must select the time duration and then select **Submit time**.

IMPORTANT

The Activity monitoring tool retains data for only 30 days.

Raw information logs

For advanced troubleshooting, you can view raw information logs. You can use a set of predefined queries to get raw logs for an issue. You can then export the logs to do more advanced analysis. The following types of queries are available:

- Slow queries
- Deadlocks
- Crashes
- Financial reporting issues

SQL insights

The Monitoring and diagnostics portal also includes advanced SQL troubleshooting tools to enable performance analysis. Some of these tools are similar to the DynPerf tool that was used for SQL troubleshooting in Microsoft Dynamics AX 2012. For more details, see Performance troubleshooting using tools in Lifecycle Services (LCS).

Impact analysis report in Lifecycle Services (LCS)

2/18/2021 • 3 minutes to read • Edit Online

IMPORTANT

Functionality noted in this topic is available to targeted users as part of a private preview release. The content and the functionality are subject to change.

The **Impact analysis** report can help you focus your testing efforts for a new release. It provides insight into the Microsoft code that was changed in the release, together with usage information for the production environments that are associated with the project in Microsoft Dynamics Lifecycle Services (LCS). This content provides an overview of the capabilities and also some important considerations. However, the report doesn't provide comprehensive information. Therefore, you should use it in combination with other tools when you're planning test activities for a release.

After accessing a project, the report can be accessed via the hamburger in Lifecycle Services (LCS).

Code churn

One key measure in the report is the amount of code change, or churn, that Microsoft made for selected models in recent releases. Code change measures the number of lines of code that were changed, added, or deleted. The report has a code change measure for each file check-in that contributed to a release.

Code changes can be aggregated to the level of a specific module by using a standardized naming convention that is part of the Microsoft engineering system. In this way, you can determine the relative amount of change in different parts of the product for one or more releases.

In addition to filtering code changes by the release and module, you can filter them by the phase of the engineering cycle. The Engineering branch is where changes are made before the release is made available as a preview. This branch has most of the changes. The Stabilization branch includes changes that are made between the preview and general availability of the release. The ability to filter for changes that were made during stabilization can be useful for organizations that start their release review and testing when the release is made available as a preview.

Usage

The second key measure in the report is the form-based usage of the product in the production environments that are associated with the active LCS project. This usage is measured by summing the user interactions for forms. A user interaction is an event that is logged whenever interaction is triggered between the web client and the service. The most frequent type of user interaction is mouse or keyboard input by a user. However, system-generated interactions can also be counted.

By using the same naming convention that is used for code churn, you can have the usage information summed to the module level. The **Custom** module represents forms that weren't provided by Microsoft.

The usage information isn't tied to the release filters. Instead, it's time-based and has two levels of detail. For module-based visualizations, the data is from the last 95 days of usage in the production environments that are associated with the active LCS project. For form-based visualizations, the data is from the last 35 days of usage in the production environments that are associated with the active LCS project. These time frames were chosen because they offer a compromise between volume of data and sufficient history to help guarantee coverage of

activities that occur only monthly or quarterly.

Important considerations

There are a few important considerations when you use the report:

- The tool uses the number of lines of code that were changed (added, updated, or deleted) as an approximation of change impact for the release. Although there is reasonable correlation between the number of lines of code that were changed and the impact, be aware that any single line of code change can cause impact.
- Not all Microsoft models are included in the code change analysis. Platform changes aren't considered. Additionally, changes in other lower-level models, such as Ledger, CaseManagement, and ApplicationCommon, aren't considered. The models that are included are identified in the code change details in the report.
- Use the report together with the documentation for the release to gain a functional view of the changes.
- The report shows all code changes, regardless of whether the related features are enabled. If a feature is disabled through feature control capabilities, the code changes should have limited impact.
- The production usage is based on user interactions with the web client. Other uses of the system, such as batch processing or integration scenarios, are excluded.
- Code changes from solutions from independent software vendors (ISVs), and code changes from implementation-specific extensions, are excluded.

In summary, the report provides an approximation of code change and usage. In combination with other activities and tools, it can be useful for assessing risk in a release.

>
> The survey will take about seven minutes. No personal data is collected (privacy statement).

Restart environment services

2/18/2021 • 2 minutes to read • Edit Online

You can use the Restart services functionality in Microsoft Dynamics Lifecycle Services (LCS) to restart individual services that are associated with a Tier 2, Tier 3, Tier 4, or Tier 5 standard acceptance test (sandbox) environment that is deployed in a Microsoft subscription. You can use this functionality to restart the following services:

- IIS
- DIXF
- LCS Diagnostics
- Batch
- Reporting Server

Any user who has been added as a project owner, organization admin, or environment manager in an LCS project has permissions to use this functionality.

Restart a specific service

To restart a specific service in a deployed environment, follow these steps.

1. In LCS, open the appropriate project, and select the environment to restart the service for.
2. On the **Environment details** page, select **Maintain** > **Restart services**.
3. In the **Restart a service** dialog box, select the service to restart, and then select **OK**.

   The **Environment state** value is updated when the service is restarted.
4. To view the updated status, refresh the page.

> **NOTE**
>
> Because restart of a service might require only a few seconds, the **Environment state** value might already have been reset to **Deployed**. When the restart is completed, an entry is added to the **History** page.

Stop and start all services

To stop and start **all** services, use the **Stop** menu option followed by the **Start** option on the environment details page.

> **NOTE**
>
> This functionality is only available in Tier-2+ Sandbox environments and not in the production environment.

Report a production outage

2/18/2021 • 2 minutes to read • Edit Online

Lifecycle Services (LCS) has a feature called **Report production outage**. This feature is available to all customers who have purchased one or more Dynamics 365 Finance and Operations apps and have implementation projects with a production environment deployed in LCS. This feature provides a quick and effective channel to escalate issues to Microsoft Support in the event that the services in a production environment are degraded or become unavailable.

Following mutually inclusive conditions, a production outage can be defined as one or more system-wide issues on a live production environment that impact multiple users and prevent your business from performing daily operations.

Reporting flow

The following list shows the order in which an issue should be handled:

1. In a live production environment, a customer experiences an outage or other situation with prevents business from continuing.
2. The customer reports a production outage issue by using the LCS Support portal.
3. The customer selects a production outage issue and provides additional information.
4. A Microsoft support engineer acknowledges the production outage ticket within 30 minutes of submission and begins to immediately collaborate with stakeholders to investigate and resolve the issue.
5. A support engineer contacts the customer to provide a status update.

Access and availability

All users who have been added to a customer's implementation project have access to this feature. This includes project owners, organization admins, team members, and environment managers.

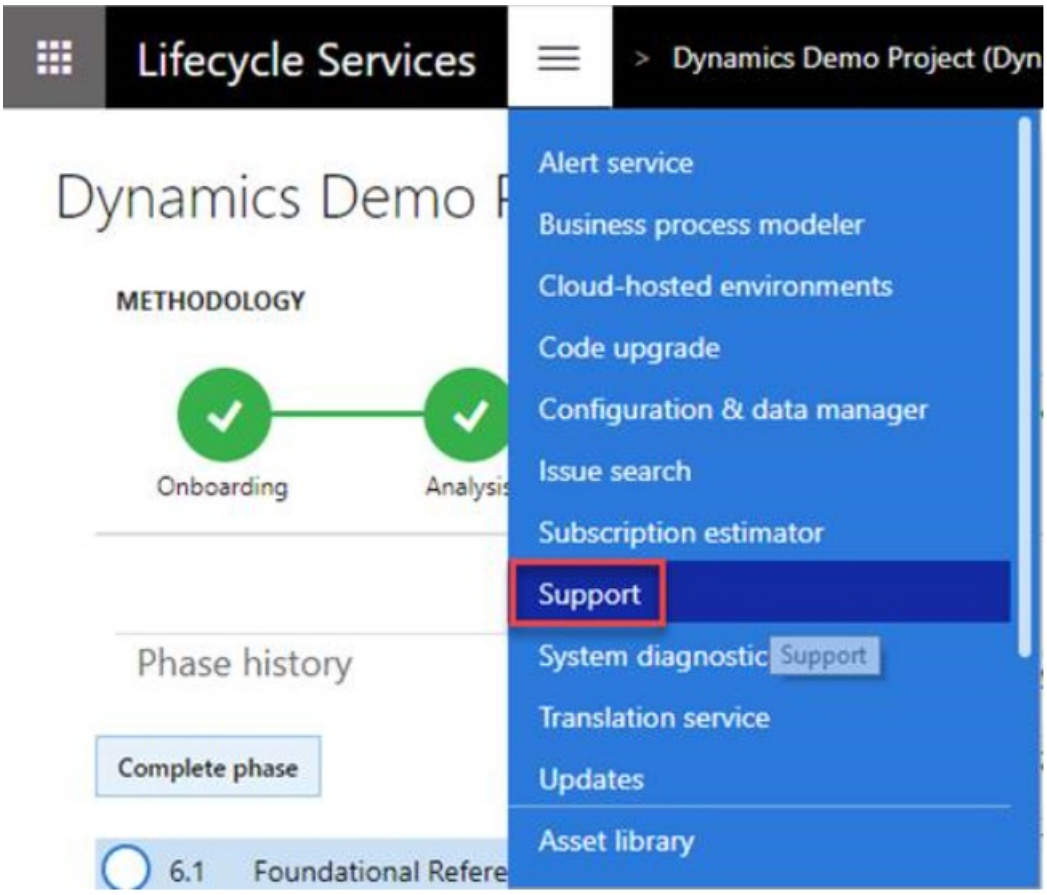
This feature is available for:

- Dynamics 365 Finance
- Dynamics 365 Supply Chain Management
- Environments that are managed by Microsoft
- A production environment in the LCS project
- All support plans

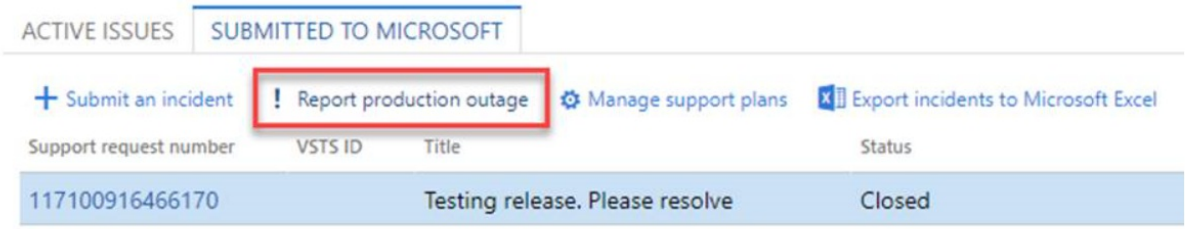
Report a production outage

To report a production outage, follow these steps:

1. Log in to your LCS project.
2. From the hamburger menu, click **Support**.



3. On the **Submitted To Microsoft** tab, click **Report production outage**.



4. Confirm the production outage, select the outage scenario from the drop-down list, and then click **Continue**.
5. Add a title and details about the outage, and then click **Next**.
6. Provide contact information, and then click **Next**.
7. Click **Done**.

If you're unable to report a production outage in LCS, phone support is available.

> **NOTE**
>
> If you don't see your situation listed in the outage scenarios, enter a support incident through LCS. During the initial investigation by a Microsoft support engineer, if it is found that the situation does not meet the current list of production outage scenarios, the support incident will be transferred to the correct support team and service-level agreement (SLA) based on your current support plan.

> **NOTE**
>
> Can you tell us about your documentation language preferences? Take a short survey.
>
> The survey will take about seven minutes. No personal data is collected (privacy statement).

Track user sign-ins

2/18/2021 • 2 minutes to read • Edit Online

Many organizations are required to maintain an audit trail of users who have used the system. This requirement can be in place for compliance reasons, or to enable trackbacks in the event of incorrect use.

In Microsoft Dynamics AX 2012, the **Audit log** form recorded which users accessed the Microsoft Dynamics AX environment. In Microsoft Dynamics 365 Finance and Operations apps, this information is captured in telemetry. IT administrators can download this information by using Microsoft Dynamics Lifecycle Services (LCS) and then move it to offline storage to maintain the audit trail of users who have signed in.

To generate an audit log of users who have used the system, follow these steps.

1. Sign in to LCS, and open the project that is associated with your implementation.
2. Navigate to the production environment, and open the **Environment details** page.
3. On the **Monitoring** tab, select the **Environment monitoring** link to open the monitoring dashboard.
4. On the **Activity** tab, select **View raw logs**.
5. In the **Query** field, select **User Login Events**. You see a time duration that has a start date that is set to **End date - 7 days**.
6. Set the end date, and then select **Search**. The search results that are returned include all users who signed in to the system during the seven days before the selected end date.
7. The search results show the **AADUserID** value and the sign-in start and end times of the user's session. To map the **AADUserID** value to the user's user name and email address, use the **Users** page (**System administration** > **Users**).
8. To export the records and keep them for a longer period, select **Export grid**.

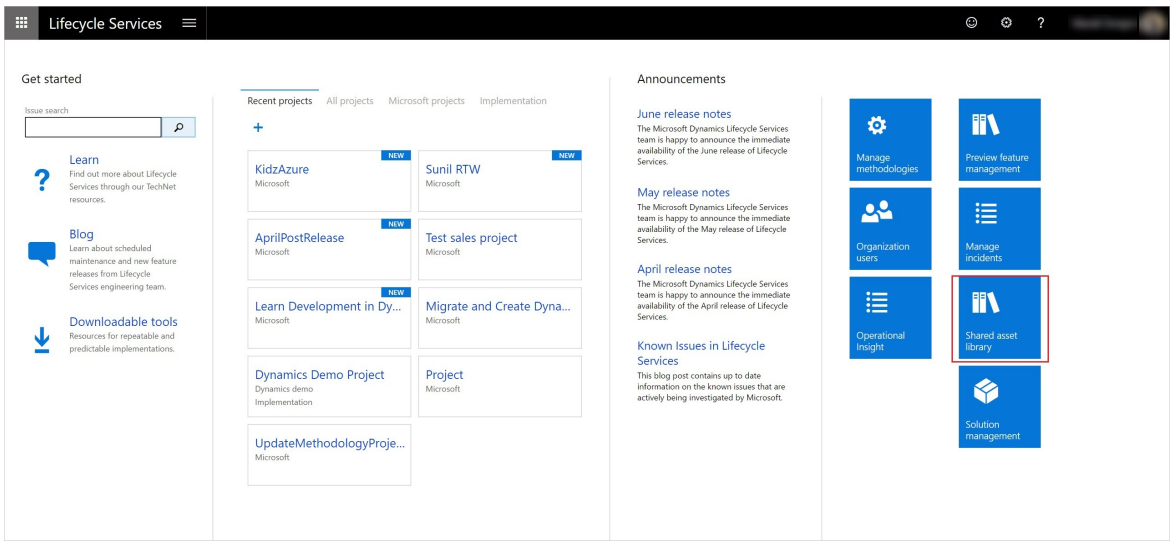
To help guarantee a complete audit trail, an IT administrator must complete this procedure every seven days.

Asset library in Lifecycle Services (LCS)

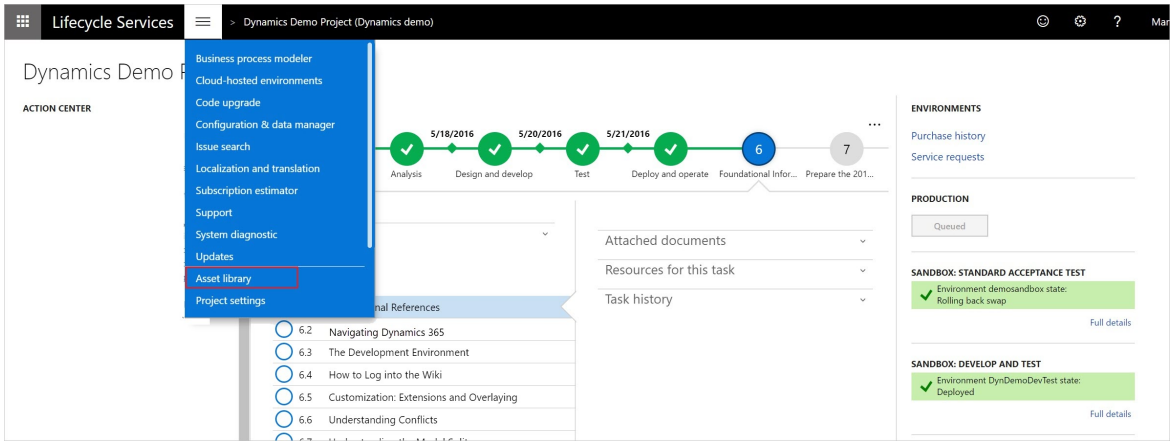
2/18/2021 • 4 minutes to read • Edit Online

The Asset library is a storage location for the various assets that are associated with a tenant in Microsoft Dynamics Lifecycle Services (LCS). Two types of Asset library are available in LCS: the Shared asset library and the project-level Asset library.

- **Shared asset library** – The Shared asset library is used by Microsoft and Partners to share assets across multiple tenants, projects, and environments in LCS. This library can be accessed by any user who signs in to LCS. To access the Shared asset library, sign in to LCS, and then click the **Shared asset library** tile.



- **Project-level Asset library** – The project-level Asset library is used to share assets across environments within a project in LCS. This library can be accessed by all users within a project. To access the project-level Asset library, sign in to LCS, and open a project. Then, on the hamburger menu, click **Asset library**.



> **NOTE**
>
> Uploading versions for the same asset in the project asset library is not supported.

Asset library support

The Asset library supports multiple types of assets. Here are some asset types that are frequently used:

- **Software deployable package** – This asset type represents all the packages that are used to update an environment with the latest set of updates.
- **Data package** – This asset type stores assets that are used for configuration and data management.
- **GER Configuration** – This asset type stores all localization and translation assets that are applied to the client.
- **Retail SDK** – This asset type stores all the latest scripts for the Retail software development kit (SDK).
- **Database backups** - This asset type is used for import and export of databases from Sandbox Tiers 2 - 5 environments.

Asset scopes

Every asset that the Asset library supports has multiple scopes. Here are some of the supported asset scopes:

- **Me** – When an asset is uploaded, it's set to the **Me** scope. An asset that has the **Me** scope is visible only to the person who uploaded the asset.
- **Project** – When an asset is imported from the **Global** scope to another project, it's set to the **Project** scope.
- **Organization** – When an asset must be shared with multiple users within a tenant, the tenant admin can promote the asset to the **Organization** scope.
- **Global** – Only Microsoft can upload assets to the **Global** scope. These assets are assets that Microsoft wants to be made publicly available to all LCS projects and users.

Asset status

Every asset has one of two statuses: **Draft** or **Published**.

- **Draft** – The asset can still be edited.
- **Published** – The asset is published at an **Organization** or **Global** scope, and edits are completed.

Actions in the Asset library

You can perform various actions in the Asset library as you require.

Upload an asset to the Asset library

1. Select the tab to upload the asset to.
2. Click the plus sign (**+**).
3. Enter a name and description for the asset.
4. Upload the file for the asset, and then click **Confirm**.

Upload a new version for a specific asset (Shared asset library only)

1. Select the asset in the Asset library.
2. On the toolbar, click the **Upload new version** button.
3. Repeat the steps in the previous procedure, "Upload an asset to the asset library."
4. On the toolbar, click **Versions** to view multiple versions for a single asset.
5. Individual versions can then be imported in to a specific project asset library as required.

Move assets from the Shared asset library to the project-level Asset library

There are two ways to move an asset from the Shared asset library to the project-level asset library: you can import the asset or copy it.

Import from the Shared asset library

Follow these steps to import an asset from the Shared asset library to the project-level Asset library so that it can be applied across environments.

1. In the project-level Asset library, select the tab for the asset type to import.

2. Click **Import**.
3. In the list of assets in the Shared asset library, select the asset to import, and then click **Pick**.

The selected asset is imported and put into the project-level Asset library. The status of the asset in the project-level Asset library is set to **Published**. This method is for packages that you don't plan to edit. If you want to edit an imported package, create a copy by using the following procedure. The status of the package will then be **Draft**.

Copy from the Shared asset library

Follow these steps to create a copy of an asset so that it can be edited.

1. In the project-level Asset library, select the tab for the asset type to copy.
2. Select the asset to copy, and then, on the toolbar, click **Copy**.

A copy of the published asset is created, and the status is set to **Draft**.

Save to my library

After you've edited an asset, follow these steps to move the edited asset back to the Shared asset library so that it can be promoted to the **Organization** scope and shared with multiple customers.

1. In the project-level Asset library, select the tab for the asset type to import.
2. Select the asset to save, and then click **Save to my library**.

The asset is saved from the project-level Asset library back to the Shared asset library, and the scope is set to **Me**.

Performance troubleshooting using tools in Lifecycle Services (LCS)

2/18/2021 • 5 minutes to read • Edit Online

This topic describes how you can troubleshoot and mitigate performance issues using the tools available in Microsoft Dynamics Lifecycle Services (LCS).

Overview

Common feedback from customers and partners has been that they are unable to successfully diagnose performance issues using the tools in LCS. We have addressed this feedback by creating a more reliable way to collect performance metrics on demand. This enables customers and partners to execute a predefined set of actions that can be used to mitigate issues in a sandbox or production environment. This feature queries SQL Server directly, so you get query store metrics in near real-time. We have also added an audit trail on the action performed so that you can easily determine who performed the action and when it was performed.

Details

All SQL performance tools in LCS are available under the **SQL Insights** tab on the **Environment Monitoring** page for a specific environment. The following tabs are available:

- **Live View** – Shows current DTU, executing statements, and blocking statements. The current **SQL Now** page that shows performance issues will be replaced with **Live View**.
- **Queries** – Shows a list of predefined queries that can be used to retrieve metrics on demand. Examples of queries include a current blocking tree, a list of active plan guides, and a list of most expensive queries.

  > **IMPORTANT**
  > To help guarantee that the query results are returned instantaneously, most of the queries are run synchronously. However, if there is an ongoing performance issue, synchronous query execution might cause a time-out error. To address this issue, a new **Use Fast Query** option has been added. By default, this option is turned on for most queries. If you receive a time-out error after you run a query, turn the **Use Fast Query** option off, and then try to run the query again. The query will now run asynchronously.

- **Actions** – Shows a list of predefined actions that should be taken to mitigate issues in the sandbox and production environments. Examples of actions include adding/dropping an index, updating stats on a table, rebuilding indexes, and terminating a blocking statement. Any time that an action is performed, the environment history for an environment will show a record for the action performed. A history record is created only for actions and not when queries are executed.
- **Performance Metrics** – Shows the most expensive queries that were run in the system during the selected period, based on logical I/O, execution count, duration, CPU time, and wait count. This data is queried from the SQL query store. The data is retained for 30 days, and the tool runs its data collection every day at a random time between midnight and 4 AM in the time zone in which your environment is hosted. The last run date and time is visible from your environment details page in Lifecycle Services, under the **Monitoring** tab in the **Last run** field. To use the tool, select a period during the last 30 days. When the query results appear, select the bar in the duration chart to highlight where the query falls based on other metrics. On the **Statement** tab, you can either view the query or download the query

execution plan.

- **Index Analysis** – Shows aggregated index and table information, based on user scans, user seeks, user updates, and row count. Like performance metrics, this tool shows the trend for the selected index along with additional table metrics.
- **Queries** tab and **Actions** tab – For details about the queries that are shown on the **Queries** and **Actions** tabs, see the Query cookbook.

How do I use this feature?

1. Go to your project in LCS and open the environment details page. Select the **Environment Monitoring** link in the **Monitoring** section. Select the **SQL Insights** tab to access this feature.
2. You can navigate to each of the tabs (**Live View**, **Queries**, **Actions**, **Performance Metrics**, **Index Analysis**) to view or query for more information.
3. You have the option to search or export to Excel any of results from the query execution.
4. After you have narrowed down the reason for the performance issue, you can use a predefined action to mitigate the issue.
5. After an action is performed, an entry is made on the **Environment History** page, which shows the details of the action, the parameters that were passed in, a timestamp, and who triggered the action.

Sample flow

Scenario: Users report slow performance when using the system. One issue could be a blocking statement. Blocking by itself is typical in a healthy system and is only a problem when it becomes excessive or starts degrading business activities.

1. Go to the **Live View** tab and check if there are any blocking statements. If there is a blocking statement, copy the blocking query ID.
2. Open the **Queries** tab and select the **Current Blocking Tree** query. This will return the root blocker that is blocking the SQL operation.
3. To resolve the issue, you can either let it run and clear naturally, or end the process for the lead blocker, which will roll work back. Typically, you should only end the lead blocker process if you think that it will not clear naturally (such as a bad query plan), or in situations where a critical process is unable to run and needs to complete immediately.
4. Confirm that it's okay to terminate the statements that are currently being executed.
5. Open the **Actions** tab and select the **End SQL Process** action and pass in the root blocker query ID. This will execute a query against the SQL database to terminate the blocking statement.
6. Go to the **Queries** tab and run **Current blocking query** to verify if the blocking statement was terminated.
7. You can also check the **Environment History** page to see details on what process was terminated.
8. To avoid this issue in the future, you should use indexes or plan guides, or turn off lock escalation, or use page locks if processes are blocking each other while operating on different records. If processes are operating on the same records, the only way to avoid blocking is by refactoring or rescheduling the processes to not operate on the same records at the same time.

Query cookbook

2/18/2021 • 22 minutes to read • Edit Online

This topic provides details on each query under the **SQL Insights** tab on the **Environment Monitoring** page in Lifecycle Services (LCS) and how they should be used when troubleshooting performance issues. For details about this feature, see Performance troubleshooting using tools in Lifecycle Services (LCS).

Current blocking

Description

Lists any currently blocked queries, and also the SPID that is blocking them, how long they have been blocked, and what resource they are waiting on. This can be used in conjunction with the query to see the blocking tree, which provides a graphical overview of some of the same information. Blocking by itself is normal in a healthy system and is only a problem when it becomes excessive or starts degrading business activities.

Next steps

- Determine which process is blocked, and which process is blocking it and why.
- To resolve blocking, the only two options are to let it run and clear naturally, or to end the lead blocker process, which will roll back work. Generally, the lead blocker should only end in situations where it is not believed that it will clear naturally (such as a bad query plan), or in situations where a critical process is unable to run and needs to be completed immediately.
- To avoid the same blocking in the future, you can use indexes or plan guides, or disable lock escalation and page locks if processes are blocking each other while operating on different records. If processes are operating on the same records, the only way to avoid blocking is by refactoring or rescheduling the processes so that they do not operate on the same records at the same time.

Current blocking tree

Description

Provides a graphical view of the SPIDs and statements that are currently causing blocking or being blocked. This can be used in conjunction with the current blocking query to see more detailed information. Blocking by itself is normal in a healthy system and is only a problem when it becomes excessive or starts degrading business activities.

Next steps

- Determine which process is blocked, and which process is blocking it and why.
- To resolve blocking, the only two options are to let it run and clear naturally, or to end the lead blocker process, which will roll back work. Generally, the lead blocker should only end in situations where it is believed that it will not clear naturally (such as a bad query plan), or in situations where a critical process is unable to run and needs to be completed immediately.
- To avoid the same blocking in the future, you can use indexes or plan guides, or disable lock escalation and page locks, if processes processes are blocking each other while operating on different records. If processes are operating on the same records, the only way to avoid blocking is by refactoring or rescheduling the processes so that they do not operate on the same records at the same time.

Current DTU

Description

Provides a detailed breakdown of the current DTU by component. DTU is a percentage measure of total SQL load and is reported as the maximum value of any of the subcomponents. Use this query to determine which subcomponent is causing high DTU. High CPU is often related to bad query plans. High Data I/O is often related to large imports or exports. A high Log Write percentage is often related to bulk processes, such as reporting, which make changes to large numbers of intermediate records.

Next steps

- If high CPU is the cause of high DTU, view the currently running queries or most expensive queries for the last hour. To address the issue, get better query plans by adding indexes, changing the query, or, as a last resort, adding plan guides.
- If high Data I/O is the cause of high DTU, look at currently running queries and also current batch jobs, and try to determine what might be writing large volumes of data. Consider scheduling those processes to run outside of business hours.
- If high Log I/O is the cause of high DTU, look at currently running queries and also current batch jobs to determine what might be doing large amounts of intermediate processing. Often, high Log I/O is caused by the use of real fully logged tables as pseudo-temp tables during processing, such as in reporting. Address this by running those processes outside of business hours or by changing the processes.

Currently running queries

Description

Provides a list of all queries that are currently in a state of being executed or blocked on this database, and also the total execution and wait times of each query. Queries that have high execution time and low wait time are often indicative of bad query plans. Queries with high wait time and low execution time are indicative of blocking. If relatively fast operations are being run many times, sometimes they can be found by running this query multiple times in a row and looking for commonly occurring queries with fast execution time.

Next steps

- If high CPU time is seen, get the query plan for the query, and also see whether other query plans that have been used for this query are more efficient. Consider addressing the issues with a new index, with a change to the query, or, as a last resort, by adding a plan guide.
- If high wait time is seen, view the current blocking and current blocking tree to determine why the query is blocked. This is occasionally addressed by disabling lock escalation or page locks if that is the cause of the blocking. More often, it is addressed by segmenting the work that is being performed to ensure that the same record is not processed by two queries at the same time.

Get fragmentation details

Description

Fragmentation is when the records are not stored contiguously inside of the page. When there is unused space between records on a page, which occurs through data modification that is made against the table and to the indexes defined on the table, this is SQL index fragmentation. Dynamics 365 Finance and Operations apps use SQL Azure DB premium SKUs which are backed by SSDs. This means that the fragmentation does not cause the same level of issues as on a database that is backed by a SCSI drive, but it still it could cause slower performance. With higher fragmentation, there is a higher chance that it could affect the performance of queries that use this fragmented table/index.

Next steps

- This query shows the list of tables, indexes with their fragmentation percentage, and a recommendation to either REBUILD the index or REORG the index. When you rebuild or reorg an index it will pack the records next to each other and avoid gaps in between, thus reducing the fragmentation.

Get index details

Description

Provides details about all indexes on a given table. This query is usually used before adding new indexes, to ensure there are no existing indexes that should be altered instead.

Next steps

- If you are adding a new index, verify that there is not an existing index that should just be adjusted instead. Each new index adds overhead on all write operations. Therefore, new indexes should be added sparingly.
- Existing indexes can occasionally cause blocking if they support page locks, and large processes running at the same time are locking pages that contain records for each process. Disabling page locks should also be done sparingly, because it will degrade write operations that would have benefitted from page locks.

Get lock details

Description

Provides a list of all locks held by a given SPID. This is useful when a blocking tree shows that a SPID is part of a blocking chain. Sometimes, this query will reveal that page locks or lock escalation are the cause of the blocking. Other times this query is useful for seeing how many keylocks in given tables are being held.

Next steps

- If page locks or lock escalation are causing issues, they can be disabled. However, this should be done cautiously, because there are valid cases where lock escalation and page locks are needed for good performance.
- If a SPID is just holding large numbers of locks, reducing the amount of data processed within one transactional scope can reduce the number of locks and therefore the chances of experiencing blocking and deadlocks.

Parameters

The SPID can be obtained either from the list of currently running queries or through the list of current blocking queries. No historical information about SPIDs is available because the SPID ID is only valid while the SPID is currently being executed.

List of current plan guides

Description

Provides a list of all plan guides currently installed in the database.

Next steps

- You can determine whether a query plan was created based on a plan guide by looking in the query plan XML. If the plan was generated based on a plan guide, the plan guide name will be specified in the XML.
- If a plan guide is installed but is not being used, verify that the SQL statement text and parameter list for the plan guide are identical to the actual query. Any differences, even in whitespace, will stop a plan guide from being used.

Get list of query ID's

Description

If query text is known to be causing a problem, this query can be used to find the query ID for that query. This can occur if the SQL statement is showing up in an error message, in tracing, or in telemetry. After the query ID for the statement is found, it can be used for other operations, such as finding query plans or applying plan guides.

Next steps

- After the query ID for a given statement is found, it can be used to find previous plans for that query so that it can be optimized.

Parameters

- Provide a substring of the query statement, such as "%FROM GENERALJOURNALENTRY T1%".

Get XML for a given plan ID

Description

This provides the SQL plan in XML format for a given plan ID.

Next steps

- Save the XML as a .sqlplan file, and open it in SQL Server Management Studio or other plan reading tools. From the query plan, you can often find optimizations, such as index additions, that will be beneficial.
- The plan might have an index recommendation listed, but be cautious when applying those indexes. SQL will often recommend creating indexes with excessive numbers of columns to optimize a single query, which can have a negative impact on other queries or the system as a whole. View these recommended indexes as hints to begin analysis, not as something to be directly applied.

Parameters

- The plan ID can be obtained from a variety of sources, such as currently running queries. If you only have a query ID, you can use "get a list of query plans for a query" to figure out which plan IDs have been used for a query.

Get query plan and execution stats

Description

Provides a list of plans and execution statistics for a given query. This is useful for determining whether a query is obtaining multiple query plans with different performance characteristics over time.

Next steps

- If a query is getting multiple query plans with vastly different performance characteristics, start by retrieving and analyzing the plans to determine what is different and why one is far better than others.
- In order for SQL to use a better query plan, the best solution is to make index changes or add query hints directly in code.
- If indexes and query hints are not enough, as a last resort, a plan guide can be added to force the better plans always to be used. Be careful when using a plan guide, because sometimes a query plan is fast for some parameter values but overly slow for other parameter values.

Parameters

- The **query ID** can be obtained from multiple other operations, such as currently running queries, current blocking queries, most expensive queries, and query by statement text.
- The **time interval** in terms of hours will often be specified as "168" to show all plans for the last week or "24" to show all plans for the last day. Often, plans will change multiple times per week but might be stable for a few days. Therefore, selecting larger intervals here is often advantageous.

Get wait stats

Description

Provides information about what a given query plan has waited on in a given time range. This is useful when a query regularly takes longer than it should, and you have been unable to determine whether it is CPU time or

blocking. Similarly, if you see blocking but need to know what kind it is, this will provide that information.

Next steps

- If a plan is primarily waiting on CPU, the plan is just inefficient and needs to be fixed through the addition of indexes or hints, or by restructuring the query.
- If it is waiting on lock, the query is experiencing blocking. This is more difficult to determine unless you can see the blocking happening actively through the blocking tree query. In this case, the next step is to evaluate the records that are being edited and try to determine what other processes could be editing the same records at the same time. Often, the same query running in multiple threads at the same time will block itself.
- If it is waiting on I/O or latch, there are likely either large volumes of data being transferred or large numbers of small transactions. If possible, perform writes in small batches instead of just one record per transaction.

Parameters

- The plan ID can be obtained from a variety of sources, including currently running queries and the most expensive queries. If you have a query ID, you can get plan IDs by using the query to get a list of plans for that query.
- Ideally, the time range should target a specific time when an issue was occurring. For instance, if DTU was high for an hour, you should target just that hour of execution.

List most expensive queries

Description

Provides a list of the most expensive queries during the specified period. The decision about which attribute should be considered when computing most expensive queries can also be provided. This is often used when high DTU is seen for a period, to determine which query is causing the high DTU. In order to use this query effectively, it is important to determine which DTU component is being addressed.

Next steps

- View the most expensive queries by total CPU to find queries that are causing high DTU utilization. These queries are usually fixed through indexes, query changes, or, as a last resort, plan guides.
- View the most expensive queries by total duration to find queries that might be slowing down the user experience. If these queries also have high total CPU, fix the query plans. If they have low CPU, it is likely the result of blocking.

Parameters

- For the number of hours, specify "0" if you are looking at currently occurring issues, such as currently high DTU. This will provide results for the current hour. If you are looking for generally high DTU over time, specify either "24" for the last day or "168" for the last week.
- For the ordering, select "total cpu" to find high DTU impact for recurring queries. Select "average duration" to find queries that are not run often but that might be slow. Select "total duration" to find recurring queries that might be slowing down users.

Create non-unique index on table

Background

Indexes should generally be created through the standard metadata package and database synchronization. This ensures that Sandbox and PROD, and any other environments, always share a common definition. Occasionally, it is necessary to install a new non-unique index at runtime to mitigate an ongoing outage or issue where a regular deployment would take too long. This action can be used to install that non-unique index.

Next steps

- After specifying the index to create, the next step should be to migrate that same index definition to the next

available official metadata release.

- Duplicate indexes generally do not cause any noticeable issues. Therefore, leave the manually created index in the system until after the official index has been completely rolled out.

Parameters

- The index name is any unique string not currently in use by an existing index on this table. For easy identification, it is recommended but not required that the index name follow the format PERF_IDX_<tablename>_<number>. For instance, an index might be named PERF_IDX_LEDGERJOURNALTRANS_1.
- The columns parameter is a comma-separated list of physical column names in the order that they should appear in.
- The included columns parameter is a comma-separated list of physical column names in the order that they should appear in. If no included columns must be specified, leave this parameter blank.

Create a plan guide to force Plan ID

Description

SQL will recompute a new plan each time the plan cache is flushed, such as when an update of statistics runs. The plan that is chosen is based on "sniffing" the parameters of the first execution of that query. After that, the same plan will be used, regardless of parameters. For this reason, the same query might sometimes get multiple plans, some of which are far worse than others for given data distributions. This action can be used to force SQL to use a specific plan, regardless of which parameters are sniffed. Note that this action applies only to the database that it is executed on. Therefore, it should be used as a last resort, after the addition of indexes, hints, or code changes that will flow between development and production environments.

Next steps

- After the list of plan IDs and execution statistics for a specific query ID are found, the SQL plan for each ID should be downloaded and analyzed. After the best plan is determined, this script can be used to force that plan to be used, regardless of parameters.

Parameters

- The force_plan_id parameter is the ID of the plan that should be used going forward. This can be found from the query to get all plan IDs for a given query. Be sure to validate that the XML of the plan is a good plan before forcing, because forcing a bad plan can have negative effects.
- The name parameter is any unique string not currently used by an existing plan guide.
- The statement parameter is the SQL statement that should be forced. This can be obtained from many other queries, including currently running queries and most expensive queries. Ensure that this is copied precisely, including whitespace, because differences in whitespace will cause the plan guide not to work. Also, do not include the parameters for the query in this text, because they are specified separately. For instance, on a select query, the first characters of the statement should always be "SELECT".
- The params parameter is the set of @P1, @P2, and so on, parameters for the query. These can be obtained from other queries, including currently running queries and most expensive queries. When pasting in the parameters, remove the outer parenthesis. For instance, paste in "@P1 int,@P2 nvarchar(21)". If there are no parameters for the query, leave this value blank.

Create a plan guide to add table hints

Description

SQL will recompute a new plan each time the plan cache is flushed, such as when an update of statistics runs. The plan that is chosen is based on "sniffing" the parameters of the first execution of that query. After that, the same plan will be used, regardless of parameters. For this reason, the same query might sometimes get multiple plans, some of which are far worse than others for given data distributions. This action can be used to add

specific hints to the query. This is different than forcing a plan guide, because SQL will still perform parameter sniffing and occasionally select different plans. However, the query hints will be applied in those plan computations. Note that this action applies only to the database that it is executed on. Therefore, it should be used as a last resort, after the addition of indexes, hints, or code changes that will flow between development and production environments.

Next steps

- Usually, query hints are determined after looking through multiple different query plans for a given query. For example, if an index seek on a table always outperforms a scan, it might be beneficial to add a FORCESEEK hint.
- After hints have been determined and tested locally, use this action to install a plan guide that will add those query hints to future executions of the query.

Parameters

- The name parameter is any unique string not currently used by an existing plan guide.
- The statement parameter is the SQL statement that should be forced. This can be obtained from many other queries, including currently running queries and most expensive queries. Ensure that this is copied precisely, including whitespace, because differences in whitespace will cause the plan guide not to work. Also, do not include the parameters for the query in this text, because they are specified separately. For instance, on a select query the first characters of the statement should always be "SELECT".
- The params parameter is the set of @P1, @P2, and so on, parameters for the query. These can be obtained from other queries, including currently running queries and most expensive queries. When pasting in the parameters, remove the outer parenthesis. For instance, paste in "@P1 int,@P2 nvarchar(21)". If there are no parameters for the query, leave this value blank.
- The hints to apply can be tested locally by just manually adding them to the end of a query. If table aliases are used, they should match the table aliases in the statement text.

Drop index

Background

Usually, extra indexes on a table only add minor incremental costs. But in some situations, such as high-throughput tables, the existence of an extra index can cause large performance degradation. The correct way to remove indexes is to remove them from metadata. But if they need to be removed more aggressively to mitigate an ongoing issue, this action can be used.

Next steps

- From the query to list all indexes for a table, determine the index name to drop.
- Verify that no other workloads will be negatively affected by removing this index. This is a dangerous operation to perform and might cause other workloads to regress.
- Provide the table and the index name to drop.
- Apply the same change in other environments, such as DEV and Sandbox, ideally by removing the index in metadata to keep all environments in sync.

End SQL process

Background

If a SPID is consuming too many resources and degrading the operation of other processes, it might be beneficial to end the SPID process. This will cause the open transaction to roll back, meaning that data should not be lost, but the process might need to be manually restarted. Note that rollback can also take a long time and consume a lot of resources if the transaction has already performed a lot of work. Therefore, this action should be used with caution.

Next steps

- From the blocking tree and other queries, determine which SPID should end.
- Verify that the processing that is being performed by the SPID can end without causing harm to ongoing business operations.
- Provide the SPID number to end, and roll back that operation.

Disable/enable page locks and lock escalation

Background

In many situations, SQL will either take page locks (locking a full page at a time) or escalate to entire table locks (locking the whole table). This enables SQL to perform actions that edit a high volume of rows more efficiently. However, this can cause problems and unnecessary contention in certain workloads. Consider two large posting jobs, each running for 10 minutes and editing different rows of data that happen to reside on the same physical data page. This might cause the two postings to serialize and to take 20 minutes because of the contention. This query can be used to disable lock escalation and page locks for a given table. It should be used cautiously, however, because there are valid reasons for SQL to use page locks and lock escalation.

Next steps

- After determining that unnecessary contention is being experienced on a given table because of lock escalation or page locks, use this query to disable those options.

Parameters

- The table name is the physical name of the table.
- The value of the lock escalation and page locks is either "ON" or "OFF".

Rebuild index

Background

Over time, as processes edit existing records and write new records into tables, indexes might become fragmented. This increases the amount of I/O necessary to process the same number of records, and might cause performance degradation. This operation will rebuild indexes to reduce page fragmentation. This is an expensive operation and has been known to cause contention while running. Therefore, the environment should be monitored while this operation is running.

Next steps

- Monitor blocking and DTU in the system while this operation is running. If the system degrades unacceptably, consider ending this operation.

Remove plan guide

Background

If plan guides have been installed and are having a negative impact, or if they just are not working, it might be necessary to remove a plan guide. This query enables removal of an existing plan guide. Note that removing a plan guide will not affect any currently running queries until the next time they are executed.

Next steps

- After determining which plan guide should be removed, specify the name of the plan.

Parameters

- The list of existing plan guides and associated names can be found from the list of current plan guides query.

Update statistics on table

Background

Updates statistics on the specified table. Occasionally, statistics can be found to be out of date and to be causing query plan issues, such as after an import process that has skewed the statistics of the table. Note that this action will have a significant performance overhead while running and has also been known to cause blocking on queries that use the same table. Therefore, it should be used sparingly and monitored while running to ensure that the system does not degrade.

Next steps

- While running this query, monitor both current blocking and current DTU to ensure that system performance does not degrade unacceptably. If it does, consider ending the update statistics command.

Parameters

- The table name parameter is the physical name of the table to update statistics for.

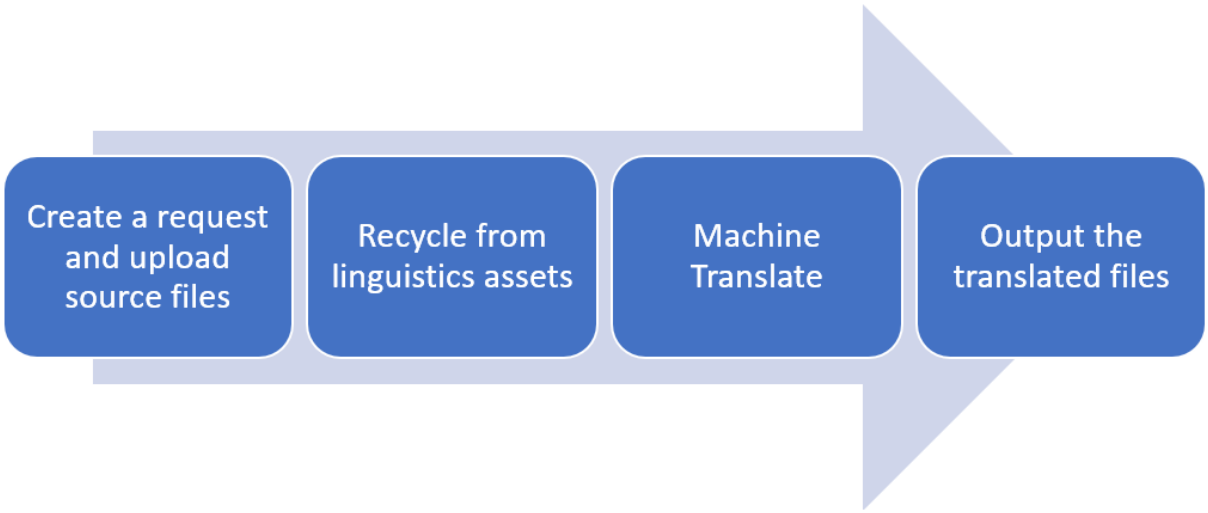
Dynamics 365 Translation Service overview

2/18/2021 • 4 minutes to read • Edit Online

The Microsoft Dynamics 365 Translation Service (DTS) is hosted in Microsoft Dynamics Lifecycle Services (LCS). It's designed to enhance the experience for partners and independent software vendors (ISVs) when they translate their solutions or add a new language for supported Dynamics products.

DTS uses a machine translation (MT) system that is custom-trained for Microsoft General Availability (GA) languages to maximize the quality of the translation output. DTS also supports translation recycling from the linguistic assets of Microsoft Dynamics and partners/ISVs. Therefore, identical strings are translated one time and then consistently reused.

The following illustration shows, at a high level, how the service works.



Recycling existing translations

Existing linguistic assets can be recycled only when the assets are uploaded in a zip file that contains translation memory (TM) files that use Localization Interchange File Format (XLIFF). For more information, see Translation memory files.

Custom-trained MT system

DTS uses a Microsoft Translator service and a custom translator to customize Microsoft Translator's advanced neural machine translation for Microsoft Dynamics products. The custom-trained MT system can only be used for GA languages, unless partners upload XLIFF TM files that contain more than 10,000 translation units (TUs). (A TU typically contains a source string, translation, state, state qualifier, and note.) In those cases, DTS creates a custom-trained MT system that is specific to the translation request that the XLIFF TM files are submitted for.

> **NOTE**
>
> Microsoft Translator supports the text translation through the Microsoft Translator Text API. DTS uses V3 Translator API because V2 will be discontinued on April 30, 2019 with the retirement ofMicrosoft Translator Hub. For information about the supported languages for V3, see Language and region support for the Translator Text API.

Supported products

DTS currently supports the following product versions.

PRODUCT NAME	VERSIONS	SUPPORTED FORMAT FOR USER INTERFACE FILES	SUPPORTED FORMAT FOR DOCUMENTATION FILES	NOTES
Microsoft Dynamics AX 2012	All versions	.ktd, .ald	.docx	
Dynamics 365 Finance and Operations apps	All versions	.label.txt	.docx, .html	.txt is the specific label format and .html is the custom help solution format.
Microsoft Dynamics 365 Commerce	All versions	.label.txt	.docx	
Microsoft Dynamics CRM	All versions	.resx	.docx	
Microsoft Dynamics NAV	All versions	.etx, .stx, .resx, .txt, .xml, .xlf	.docx	.txt and .xml are the NAV specific format, and .xlf is the Business Central extension resource format.

Accessing DTS

You can access DTS in two places in LCS:

- From the LCS home page
- From within an LCS project

Accessing DTS from the LCS home page

Sign in to LCS, and scroll to the right side of the page. Expand the tiles waffle, and then select the **Translation service** tile to open the dashboard view for DTS.

Accessing DTS from within an LCS project

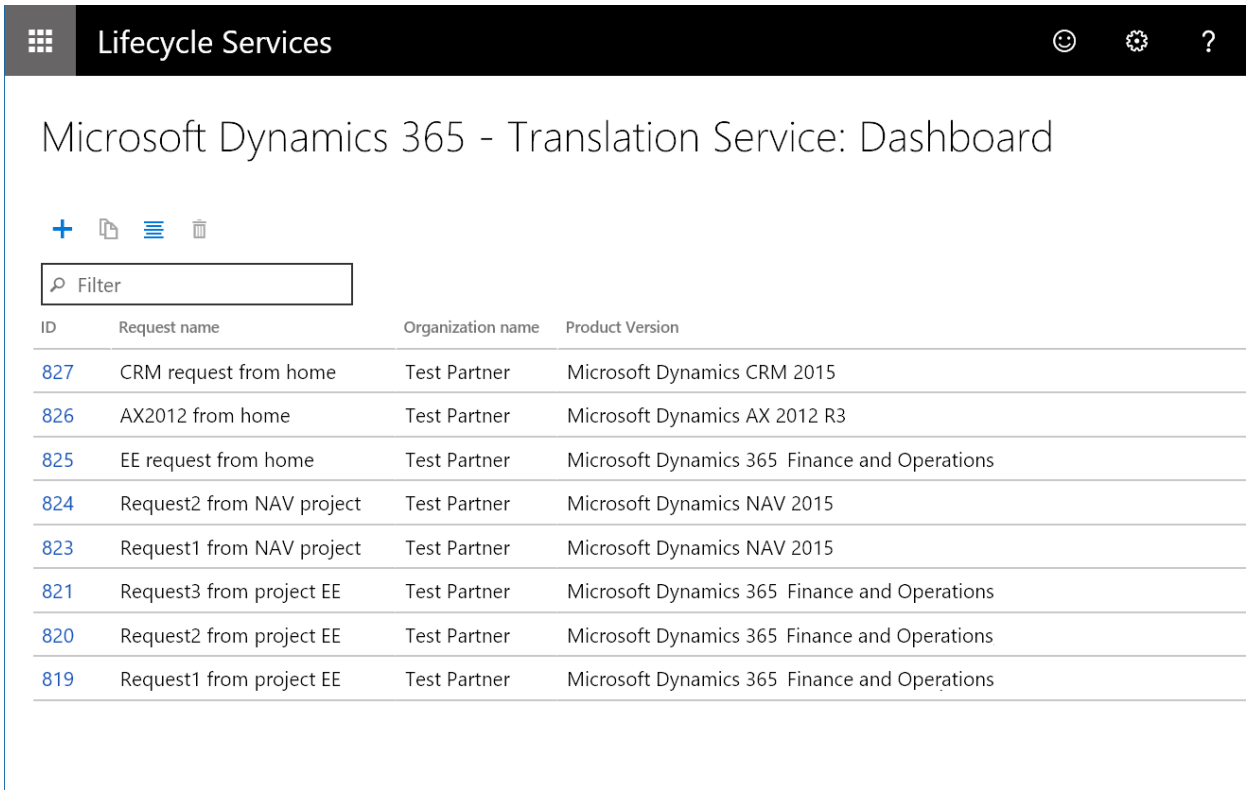
Create a new project, or open an existing project. On the project dashboard, in the **More tools** section, select the **Translation service** tile. Alternatively, on the project dashboard, select the **Menu** button, and then select **Translation service**.

Accessing DTS from the LCS home page vs. accessing it from within an LCS project

When you access DTS from the LCS home page and create a translation request, you can select the product that is used for the request. To add more requests that use different products, you can just change the product selection. You don't have to close the service and open a different translation project.

This option is convenient when you work on multiple product translation projects. However, because you access the service outside an LCS project, no other users can view your requests on the DTS dashboard. Instead, this option gives you your own DTS dashboard that shows all the translation requests that you've made from within all LCS projects and from the LCS home page.

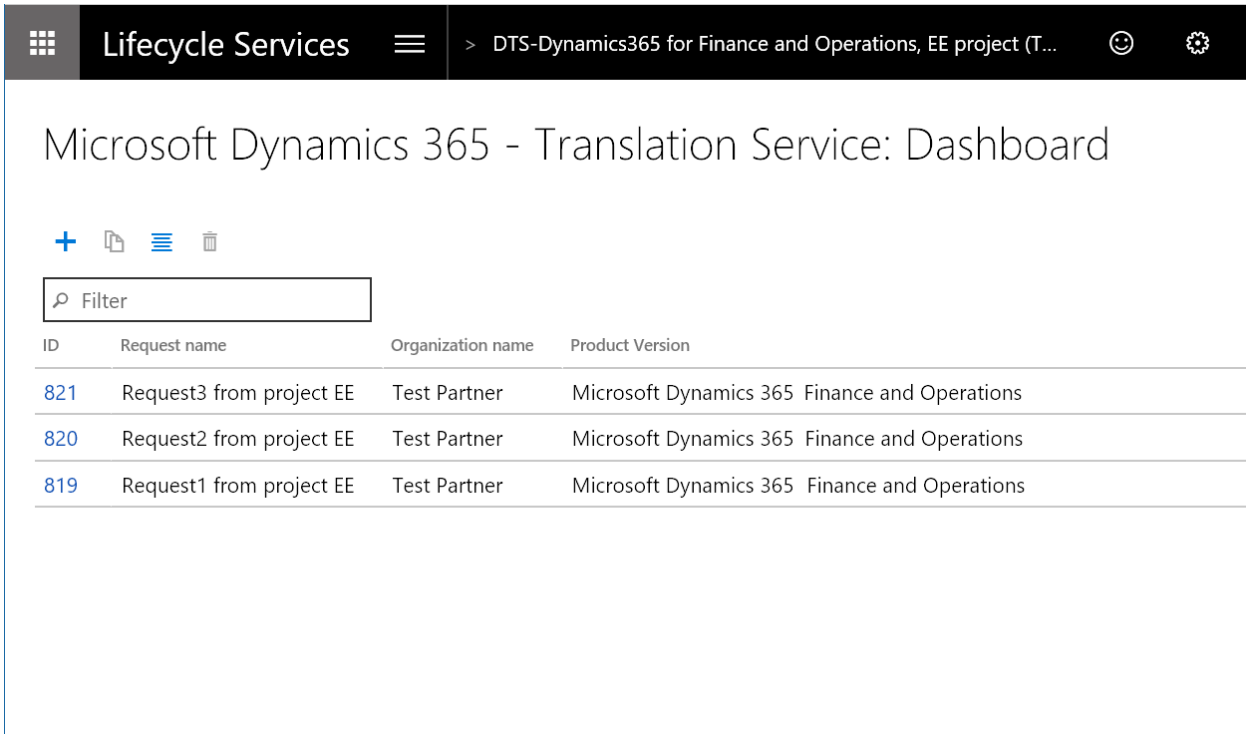
The following illustration shows an example of the DTS dashboard that you open from the LCS home page.



Because an LCS project is always tied to a product, any translation request that you submit from a project automatically carries the product type and version information from the project. You can't select a different product for the request.

In an LCS project, the project owner and the users will have permission to access the DTS dashboard and the translation requests that are submitted from within that project. Therefore, this option is useful when you work with a group of people on one product translation project in LCS.

The following illustration shows an example of the DTS dashboard that you open from within an LCS project.



Accessing LCS preview features

LCS offers some services or features only as preview features for various reasons. To view the list of preview features that are available, on the LCS home page, select the **Preview feature management** tile. To turn on a

feature, select the feature, and then set the **Preview feature enabled** option to **Yes**.

Two preview features are available for DTS:

- **Dynamics 365 Translation Service - Documentation Translation Support** – You must turn on this feature if you want to translate a product or solution document (for example, a Microsoft Word document).
- **NAV product availability** – You must turn on this feature if you want to create an LCS project for NAV products and access DTS from within the project.

Glossary

TERM	DESCRIPTION
XLIFF	XML Localization Interchange File Format. XLIFF is an XML-based format. It was created to standardize the way that localizable data is passed between tools during a localization process, and to serve as a common format for files that are used by computer-aided translation (CAT) tools.
Microsoft GA languages	General availability of the Microsoft-produced languages. The list varies, depending on the product.
TU	Translation unit. A TU typically contains a source string, translation, state, state qualifier, and note.

For more information about how to use DTS, see Translate user interface files and Translate documentation files.

> **NOTE**
>
> Can you tell us about your documentation language preferences? Take a short survey.
>
> The survey will take about seven minutes. No personal data is collected (privacy statement).

Translate user interface files

2/18/2021 • 6 minutes to read • Edit Online

This topic provides information about how to translate a user interface (UI) file for Microsoft Dynamics products or solutions.

For more information about the Microsoft Dynamics 365 Translation Service, see Dynamics 365 Translation Service overview. For information about how to translate a documentation file, see Translate documentation files.

Create a translation request

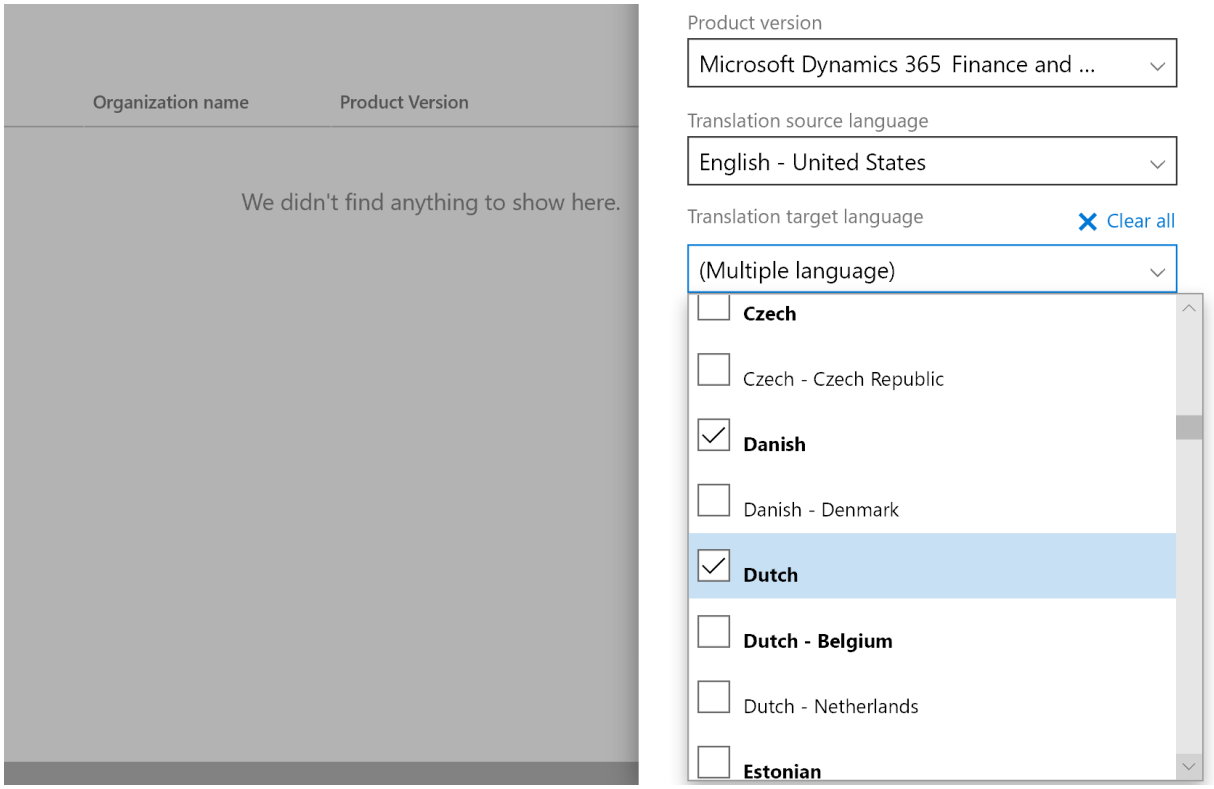
1. In Microsoft Dynamics Lifecycle Services (LCS), on the DTS dashboard, select **Add** to create a new translation request.

   You can open the DTS dashboard either from the LCS home page or from within a project. For more information, see Accessing DTS.

2. Enter the required information for the request.

FIELD	DESCRIPTION
Request name	Enter a name for the request.
File type	Select **User Interface**.
Product name	Select a product name. If you accessed DTS from within an LCS project, this field is automatically filled in and is read-only.
Product version	Select a product version. If you accessed DTS from within a LCS project, this field shows the default product version information from the project. However, you can select a different version.

FIELD	DESCRIPTION
Translation source language, Translation target language	Select the set of source and target languages to translate from and to. If your business requires that multiple target languages be translated for the same source language, you can select all of the target languages in one request. Select the target languages using the check box next to the language name. This saves time and allows you to track the status of all the target language translations in one request. The fields list all the languages that are supported for the selected product name and version. Language names that are shown in **bold** type are General Availability (GA) languages for Microsoft Dynamics products. This means that Microsoft-trained machine translation (MT) systems are available in those languages and the MT system is trained on the terminology for Microsoft Dynamics. For non-GA languages, the MT system uses the general domain training.



3. Select **Create**. Verify the request details were selected correctly and then click **Yes** to continue.

NOTE

To take advantage of the Microsoft-trained MT system for Microsoft Dynamics linguistic assets, you must select **English – United States** as either the source language or the target language. Here is an example.

TRANSLATION SOURCE LANGUAGE	TRANSLATION TARGET LANGUAGE	MT SYSTEM THAT IS USED
English – United States	Japanese	Microsoft-trained MT system
Japanese	English – United States	Microsoft-trained MT system
German	Japanese	Generic MT system, unless the user provides a translation memory (TM) that uses XML Localization Interchange File Format (XLIFF) and has more than 10,000 translation units (TUs)

Upload files

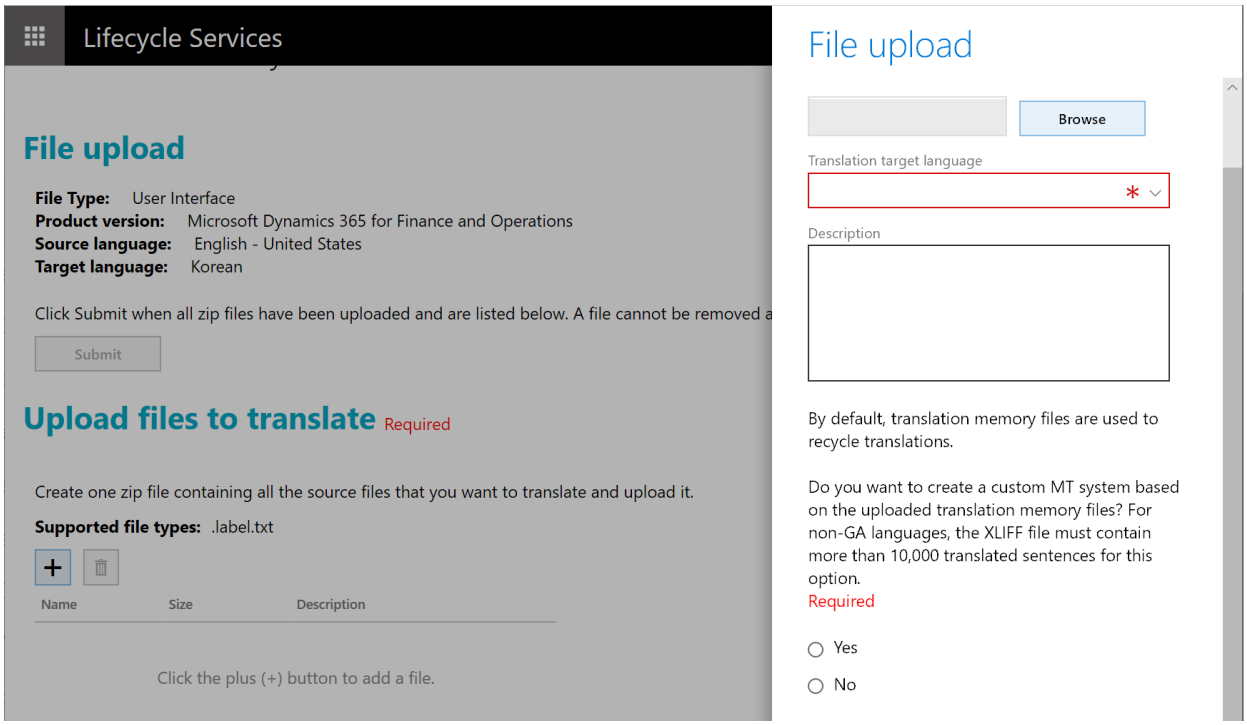
Select the plus sign (+) in each section to open the **File upload** page.

Upload the files to translate (Required)

Create one zip file that contains all the UI files in the source language that you want to translate from. The zip file can include different file types, provided that the file types are supported for the product. For more information about supported file types, see Supported products. Note that DTS doesn't change the source files that you upload. The source files are only used to create files in the corresponding target languages you requested.

Upload XLIFF translation memory files (Optional)

If you have XLIFF TM files from a previous UI translation request, or if you used the Align tool to create an XLIFF TM, create a zip file that contains all TM files before you upload them. Strings that match are then recycled to help guarantee consistency between product versions. For more information about XLIFF TMs, see Translation memory files.



If you created the translation request for multiple target languages, you must select which target language the TM file is for.

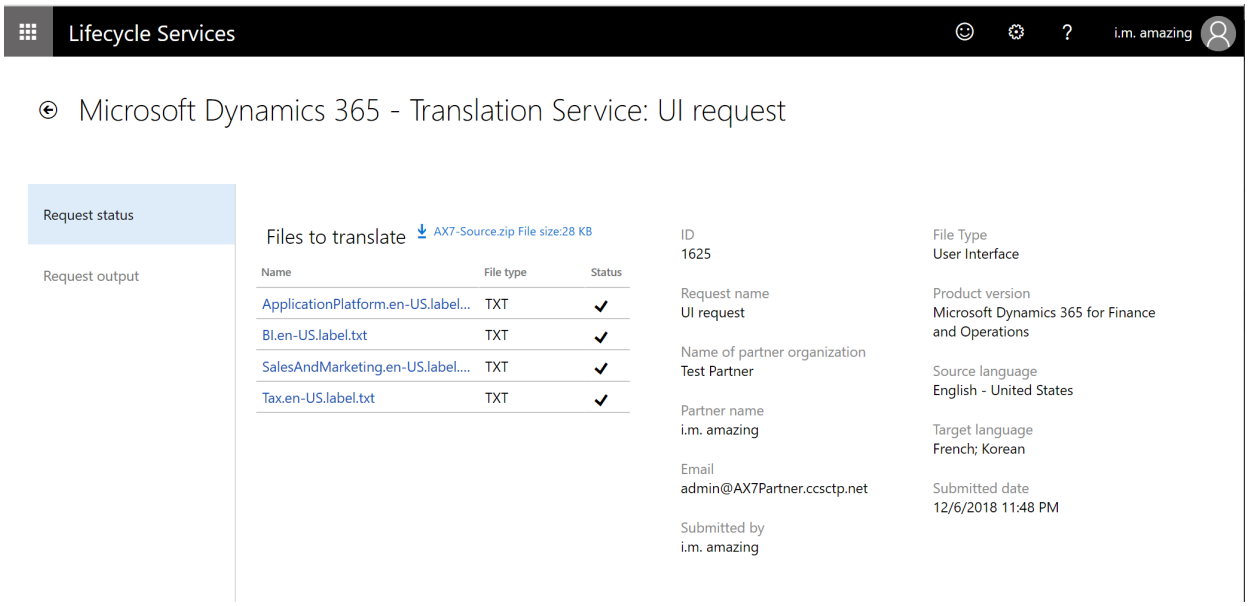
With the translation memory file you are providing, you have an option to decide whether you want to create a custom MT system trained with it. This option may take longer time to complete the request. You must choose Yes or No to be able to continue with the TM file upload.

However, if neither the source language nor the target language is a Microsoft GA language, and if the XLIFF TM contains fewer than 10,000 TUs, DTS uses a general domain MT system after recycling is completed. This behavior occurs because of requirements that are set by Microsoft Translator Hub (MT Hub).

After you've finished uploading files, select **Submit** to start the translation process.

After you submit the request, a new request ID is created on the DTS dashboard. If you submitted the request with multiple target languages, you will see each target language status displayed n a separate line with the same request ID. Selecting a line on the dashboard will extend the dashboard window to the right to show the request summary information.

To see the request status, click a request ID link on the dashboard. The **Request status** tab shows the source files list you uploaded with the summary of the request information.

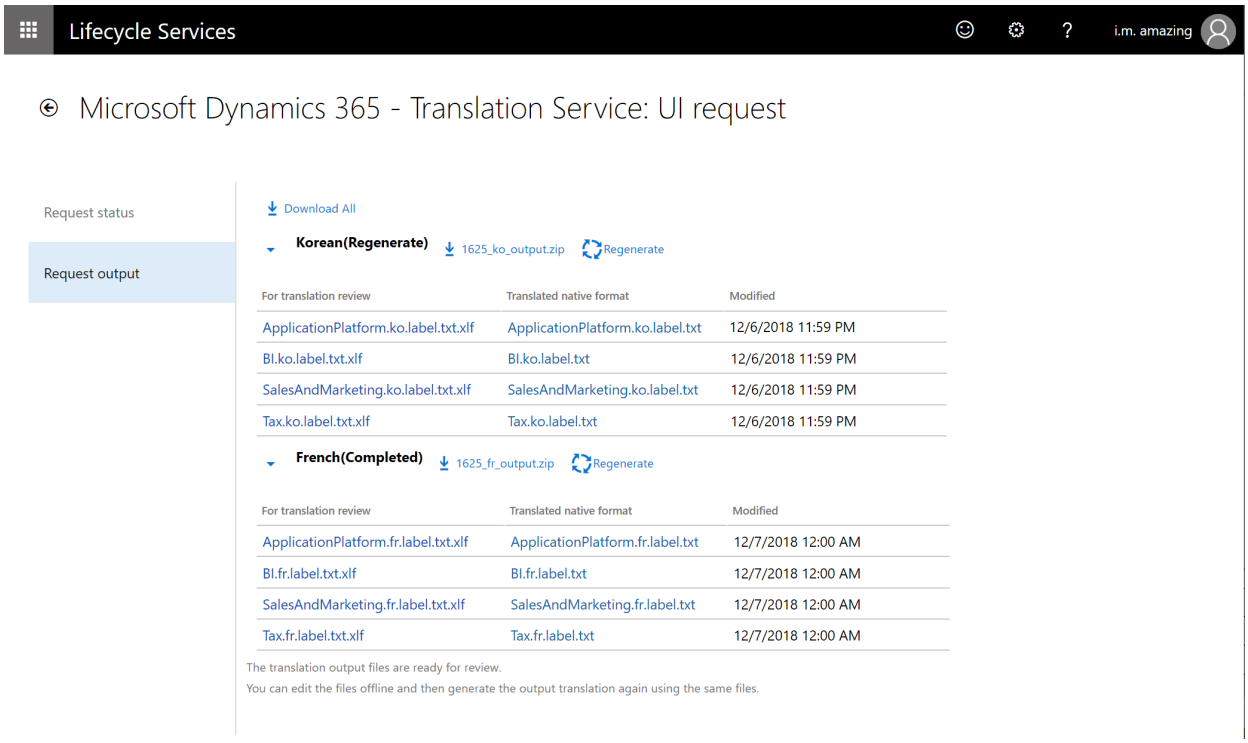


Note that the processing time depends on the number of requests that are in the DTS queue and the word count in the source files that you submit.

- UI translation requests that don't have an XLIFF TM can be completed in a few minutes, depending on the file size.
- If a UI translation request does have an XLIFF TM, the time that is required depends on the type of MT system:
  - Creation of a custom MT system requires two to three days.
  - If you're using a generic MT system, requests can be completed in a few minutes, depending on the file size.

After translation is completed

When processing of your translation request is completed, you receive an email notification from DTS. You can then view the result on the **Request output** tab of the request details page.



For UI translation requests, two types of output file are available after the translation process is completed.

- **For translation review** – Download the XLIFF file to review and, as required, edit the translations. The file shows the source and target languages side by side.
- **Translated native format** – Download this file if you don't intend to review or edit the translations. *Native format* means that the file is in the same format as the source file that you submitted.

Click an individual file link or the download links to download a single file, all files for one target language, or all files for all target languages in one zip for convenience.

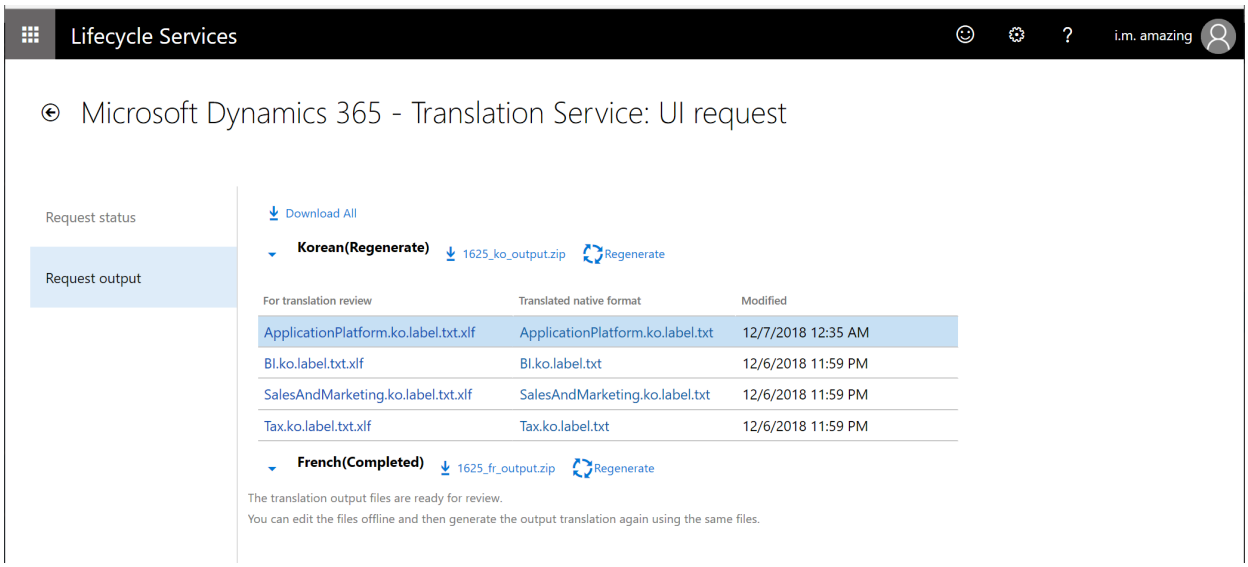
Review and edit the translations in the XLIFF file

We recommend that you review and edit the translations in the XLIFF file that DTS provides, to verify that the translation output meets your product's quality standards. For more information about how to edit the XLIFF file, see Translation memory files.

Regenerate output files

When you've finished reviewing and editing the translation files in XLIFF, you must regenerate the translated native format files next. You can then apply the latest translations (that is, your edited versions of the translations) to the UI files in the target language. You can regenerate any number of files from the output files set per target language.

1. Click the **Regenerate** icon next to the target language section. The **File upload** slider will open.
2. Zip the edited XLIFF files, and then click **Upload**. Don't change the XLIFF file name that DTS originally provided.
3. In the prompt, confirm the upload.
4. The **Request output** tab promptly refreshes the content. Expand the target language node you just regenerated to verify the **Modified** timestamp and then download the updated output files.



You can repeat the regeneration process as many times as you require.

NOTE

Can you tell us about your documentation language preferences? Take a short survey.

The survey will take about seven minutes. No personal data is collected (privacy statement).

Translate documentation files

2/18/2021 • 6 minutes to read • Edit Online

This topic explains how to translate a documentation file for Microsoft Dynamics products and solutions.

Create a translation request

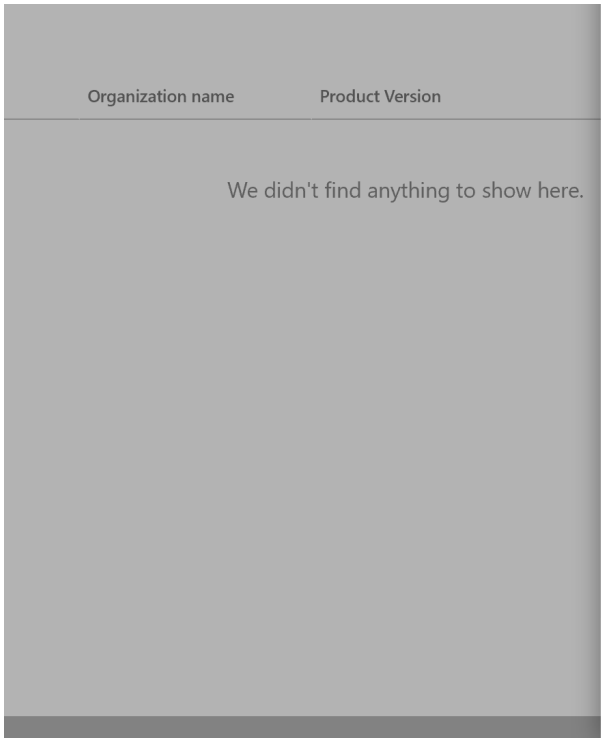
1. In Microsoft Dynamics Lifecycle Services (LCS), on the DTS dashboard, select **Add** to create a new translation request.

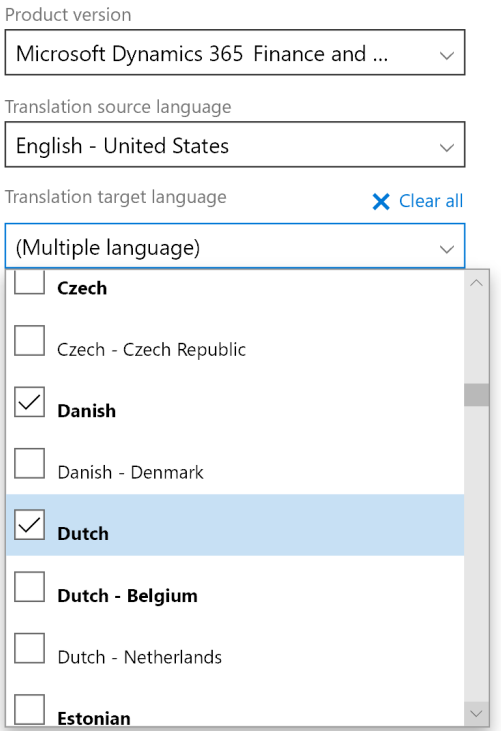
   You can open the DTS dashboard either from the LCS home page or from within a project. For more information, see Accessing DTS.

2. Enter the required information for the request.

FIELD	DESCRIPTION
Request name	Enter a name for the request.
File type	Select **Documentation**. This option is only available if you've turned on the **Dynamics 365 Translation Service - Documentation Translation Support** preview feature in LCS. For more information, see Accessing LCS preview features.
Product name	Select a product name. If you accessed DTS from within an LCS project, this field is automatically filled in and is read-only.
Product version	Select a product version. If you accessed DTS from within a LCS project, this field shows the default product version information from the project. However, you can select a different version.

FIELD	DESCRIPTION
Translation source language, Translation target language	Select the set of source and target languages to translate from and to. If your business needs multiple target languages translated for the same source language, you can select all target languages in one request. Make sure you actually select the target languages using the checkbox next to the language name. This saves your time to submit multiple translation requests individually and you can also track all the target languages translation status in one request. Language names that are shown in **bold** type are General Availability (GA) languages for Microsoft Dynamics products. Therefore, Microsoft-trained machine translation (MT) systems are available in those languages. In other words, the MT system is trained on the terminology for Microsoft Dynamics. For non-GA languages, the MT system uses the general domain training.





3. Select **Create**.

NOTE

To take advantage of the Microsoft-trained MT system for Microsoft Dynamics linguistic assets, you must select **English – United States** as either the source language or the target language. Here is an example.

TRANSLATION SOURCE LANGUAGE	TRANSLATION TARGET LANGUAGE	MT SYSTEM THAT IS USED
English – United States	Japanese	Microsoft-trained MT system
Japanese	English – United States	Microsoft-trained MT system
German	Japanese	Generic MT system, unless the user provides a translation memory (TM) that uses XML Localization Interchange File Format (XLIFF) and has more than 10,000 translation units (TUs)

Upload files

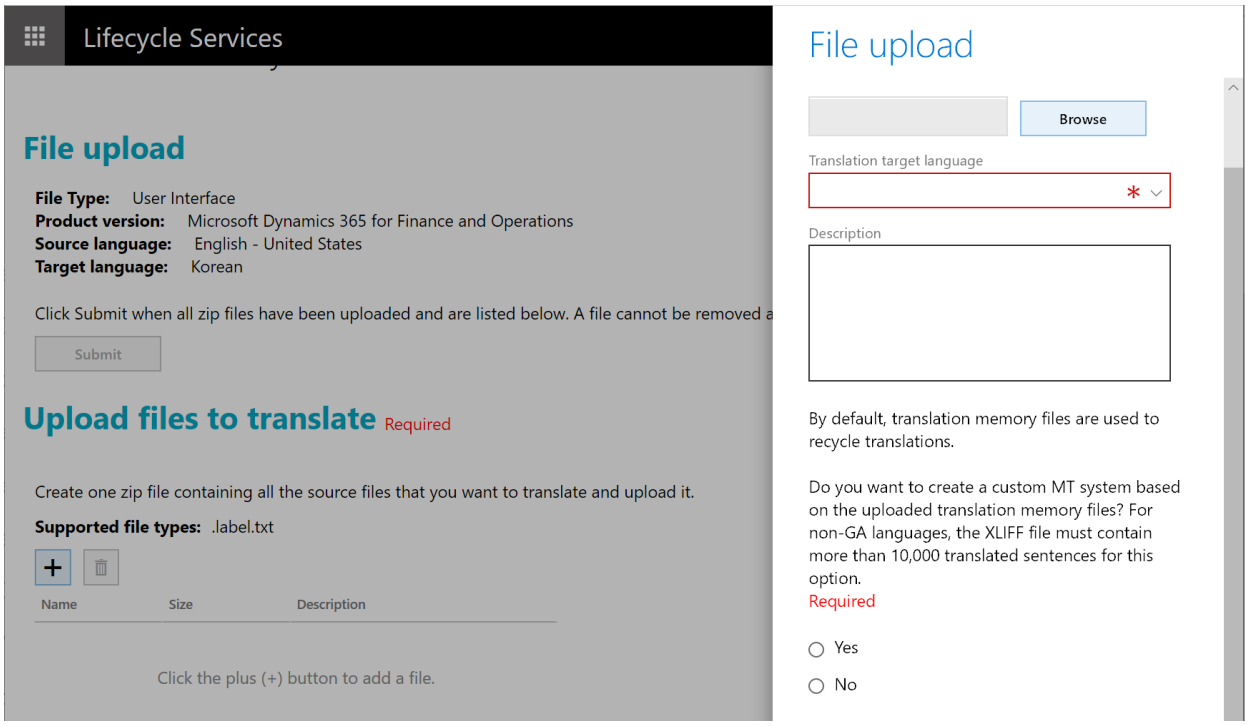
Select the plus sign (+) in each section to open the **File upload** page.

Upload files to translate (Required)

Currently, only files in Microsoft Word (.docx) format are accepted for translation. Create a zip file that includes all the .docx files in the source language that you want to translate from. You can upload only one zip file. Note that DTS doesn't change the source files that you upload. The source files are only used to create files in the corresponding target languages you requested.

Upload XLIFF or TMX translation memory files (Optional)

If you have a TM in Translation Memory eXchange (TMX) format from a previous DTS request, and/or if you have a XLIFF TM from UI file translation, you can attach those TMs so that they can be recycled in the new document that you're submitting. Create a zip file that includes all the TM files. You can upload only one zip file. If you created the translation request for multiple target languages, you must select which target language the TM file is for.



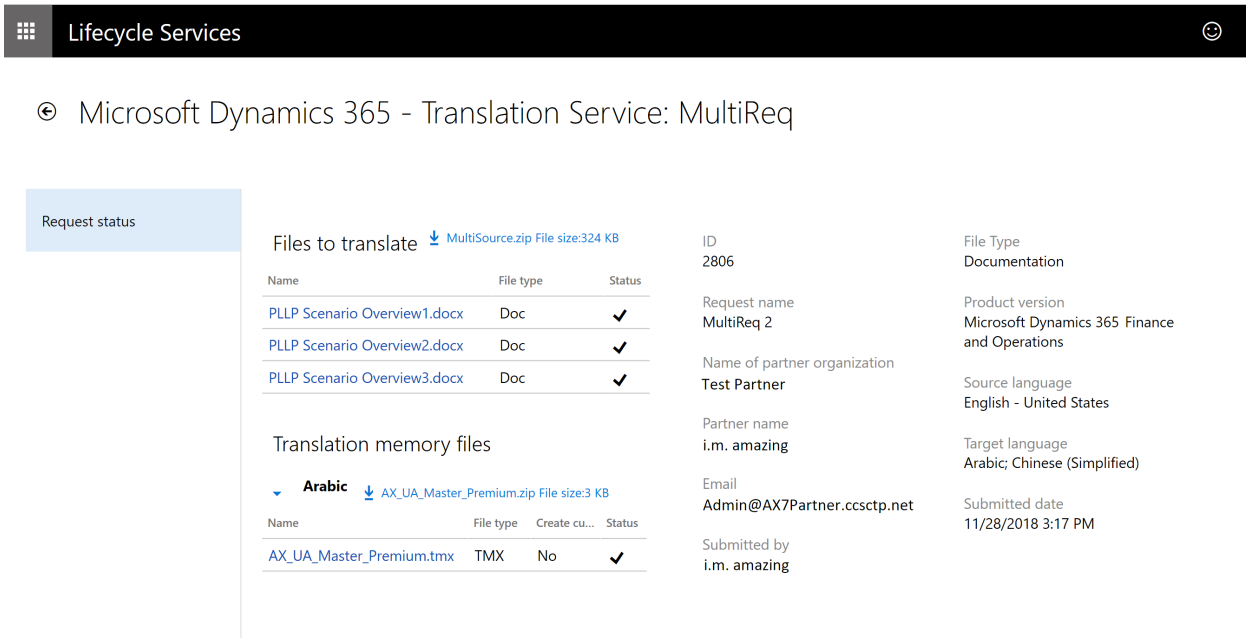
With the translation memory file you are providing, you have an option to decide whether you want to create a

custom MT system trained with it. This option may take longer time to complete the request. You must choose Yes or No to be able to continue with the TM file upload.

After you've finished uploading file, select **Submit** to start the translation process.

After you submit the request, a new request ID is created on the DTS dashboard. If you submitted the request with multiple target languages, you will see each target language status is displayed in a separate line with the same request ID. Selecting a line on the dashboard will extend the dashboard window to the right to show the request summary information.

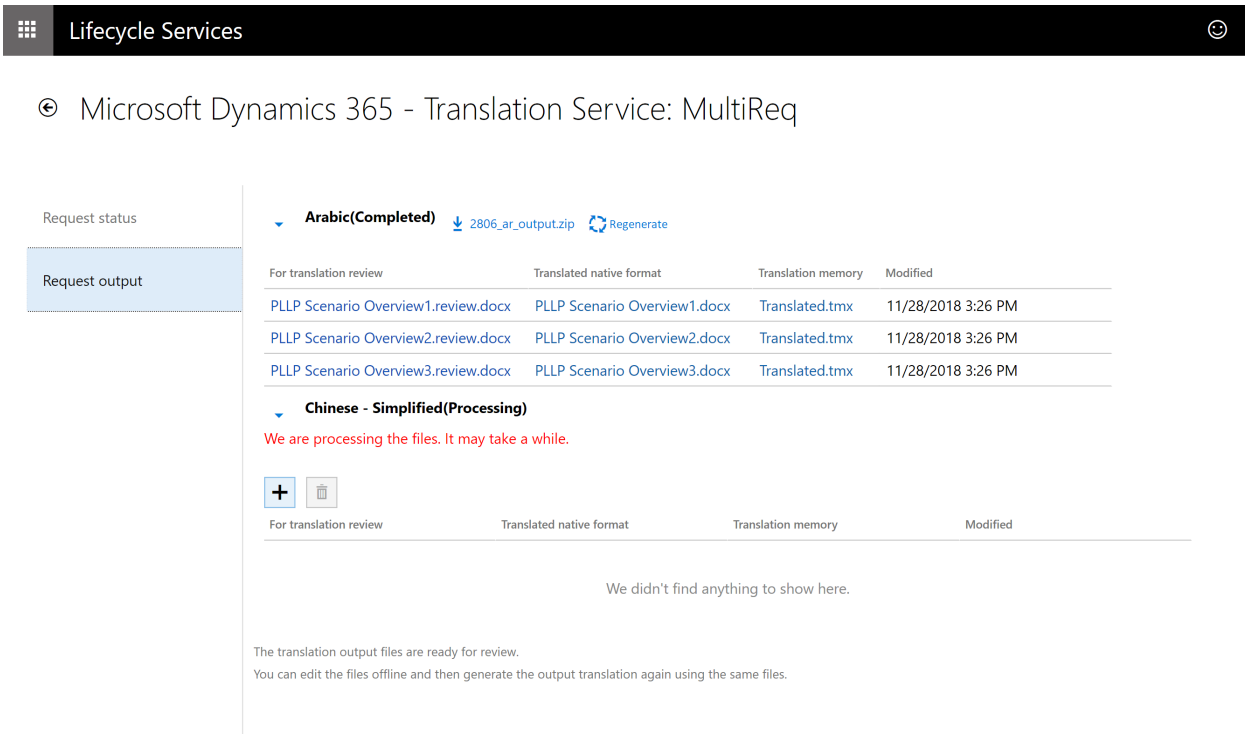
To see the request status, click a request ID link on the dashboard. The **Request status** tab shows the source files list you uploaded with the summary of the request information..



Note that the processing time depends on the number of requests that are in the DTS queue and the word count in the source files that you submit.

After translation is completed

When processing of your translation request is completed, you receive an email notification from DTS. You can then view the result on the **Request output** tab of the request details page. If your request was submitted for multiple target languages, there may be a difference between languages when each language process is done. Expand each language name to see the status.



For documentation translation requests, three types of output file are available after the translation process is completed:

- **For translation review** – Download this file to review and edit the translated document strings in a table view. The file shows the source and target languages segments side by side.
- **Translated native format** – Download this file if you don't intend to review or edit the translations but to pick up the translated file ready to use. This file has the dame formatting style (title, headings, tables, etc.) as the source .docx file that you submitted, and it's ready to be used.
- **Translation memory** – Download this file to recycle these translations the next time that you submit a translation request that uses a newer version of the source document.

Review and edit the translations

DTS provides the translation review file in .docx format. You can download the file from the **Request output** tab of the request details page and open it in Word. The file provides a convenient table view, as shown in the following illustration. Therefore, you can easily compare the text in the source and target languages side by side. After you've finished reviewing the file, you must save it and upload it back to DTS to generate the updated .docx file output in the original formatting style that you submitted.

Segment ID	Segment status	Source segment	Target segment
1	Draft (0%)	*<100/><117><110><103>*Pre Go-live checklist*</103><109></109></110><116>*Microsoft Dynamics 365 for Finance and Operations, Enterprise edition*</116></117>*	*<100/><117><110><103>*Avant mise en service liste de vérification*</103><109></109></110><116>*Microsoft Dynamics 365 pour Finance and Operations, Enterprise edition*</116></117>*
2	Draft (0%)	Customer:	Client :
3	Draft (0%)	Partner:	Partenaire :
4	Draft (0%)	LCS project name:	Nom du projet LCS :
5	Draft (0%)	LCS ID:	ID DE LETTRES DE CRÉDIT :
6	Draft (0%)	Go-live date:	Date de mise en service :
7	Draft (0%)	DD-MM-YYYY	AAAA-MM-JJ
8	Draft (0%)	Dynamics 365 for Finance and Operations, Enterprise edition customers should complete a Pre-Go-live review with the Microsoft FastTrack team before requesting their production environment.	Dynamics 365 pour Finance and Operations, clients Édition entreprise doit remplir une révision live donné avant avec l'équipe Microsoft FastTrack avant de demander son environnement de production.

When you edit the .docx review file, note of the following guidelines:

- Edit only the text in the **Target segment** column.
- Don't add or remove rows.
- Don't change the order of the rows or columns.
- Don't add or remove the red tags. Most red tags represent formatting and styles.
- If you must move the red tags, be careful that you don't switch a start tag (for example, **<116>**) and its end tag (**</116>**).

Regenerate output files

When you've finished reviewing and editing a .docx review file, you must regenerate the output file in the source document style. You can then apply the latest translations (that is, your edited versions of the translations) to the documentation files in the target language.

1. Click the **Regenerate** icon next to the target language section. It brings in the **File upload** slider.
2. Zip the edited .docx files, and then select **Upload**. Don't change the file names that DTS originally provided for the .docx review file.
3. You're prompted to confirm the upload action.
4. Once the regenerate is processed, the **Request output** tab refreshes the content. This process may take some time to complete.

You can repeat the regeneration process as many times as you require.

For more information about the Microsoft Dynamics 365 Translation Service (DTS), see Dynamics 365 Translation Service overview. For information about how to translate a user interface (UI) file, see Translate user interface files.

> Can you tell us about your documentation language preferences? Take a short survey.
>
> The survey will take about seven minutes. No personal data is collected (privacy statement).

Translation memory files

2/18/2021 • 4 minutes to read • Edit Online

Microsoft Dynamics 365 Translation Service (DTS) uses a bilingual XML Localization Interchange File Format (XLIFF) file to store pairs of source languages and target languages. Because XLIFF is based on XML, you can open XLIFF files in any text editor. However, we recommend that you use XLIFF editors that are specifically designed to work with this format. For example, you can use the free Microsoft Multilingual Editor that is available in the Multilingual App Toolkit (MAT).

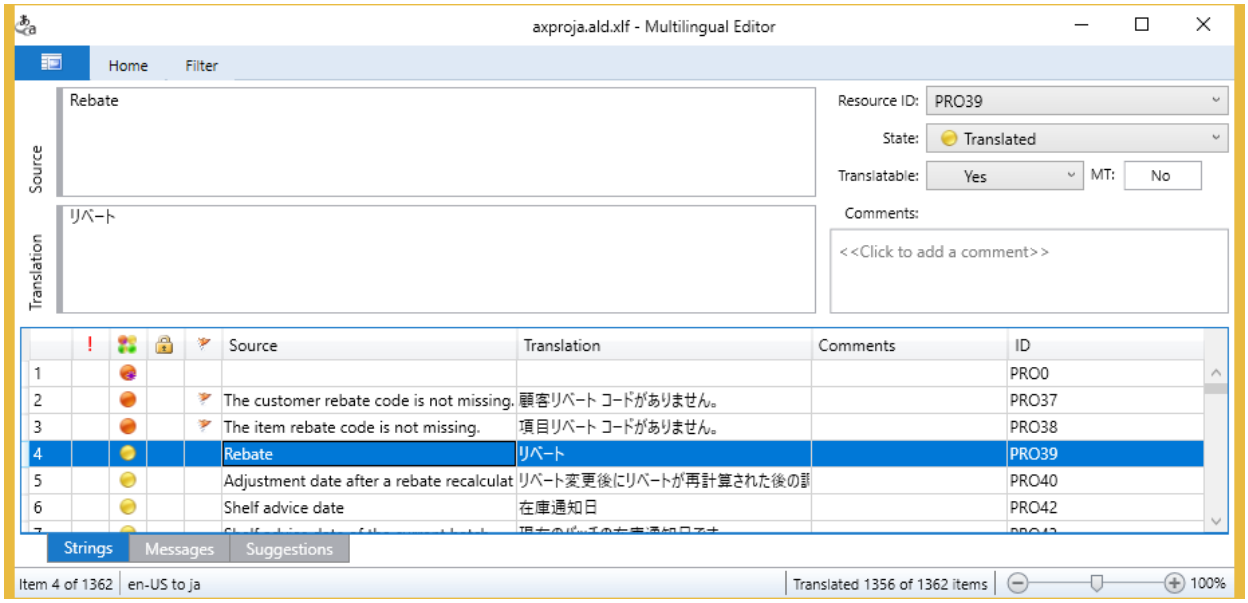
In DTS, you can obtain an XLIFF translation memory (TM) in two ways:

- **Run the Align tool** – When you have files that were previously translated, and you also have corresponding source files, you can use the Align tool to create an XLIFF TM. For more details, see the Creating a translation memory section later in this topic.
- **Complete a translation request** – When a DTS translation request is completed, it provides the XLIFF TMs as part of the request output. You can then use the files the next time that you submit a new translation request that includes the updated source files.

XLIFF files contain a series of translation units (TUs) that are extracted from the source files. The following illustration shows an example of a TU.

```
<trans-unit id="PRO39" translate="yes" xml:space="preserve">
    <source>Rebate</source>
    <target state="translated" state-qualifier="exact-match">リベート</target>
</trans-unit>
```

The following illustration shows the same TU (highlighted in blue) in the Multilingual Editor.



State

Each translation in the XLIFF file is associated with a state value. The state value that DTS assigns to each translation depends on the way that the string is translated. When an XLIFF TM is created by using the Align tool, all translations are marked as **Translated**, because the aligned TUs are produced from known good translations, such as a previous product version.

However, when the XLIFF files are generated through a translation request, two types of state values can be used:

- **Needs Review** – The string has been machine-translated.
- **Translated**, **Final**, or **Signed off** – The string has been recycled. The state value is inherited from the XLIFF TM.

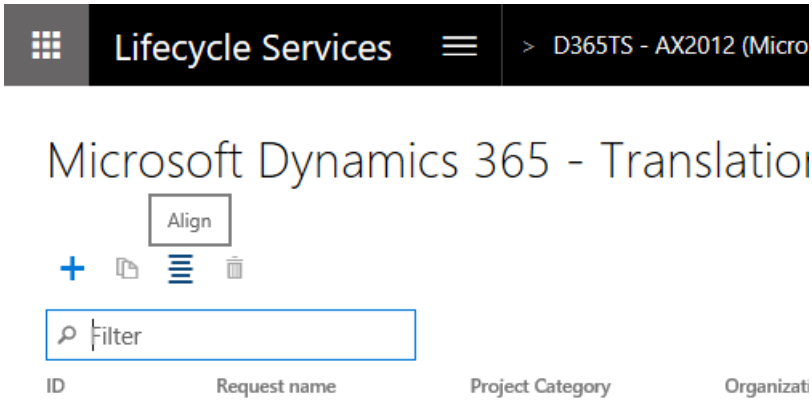
During the post-editing process, you can immediately identify the strings that are marked as **Needs Review**. After you've finished reviewing those strings, you should mark them as **Translated**, **Final**, or **Signed off**, so that they can be used for recycling. Translations that are marked as **Needs Review** aren't included for recycling.

Inherited state values for recycled strings are helpful, because you won't have to review the same string (that is, a string that has the same ID) again.

Creating a translation memory

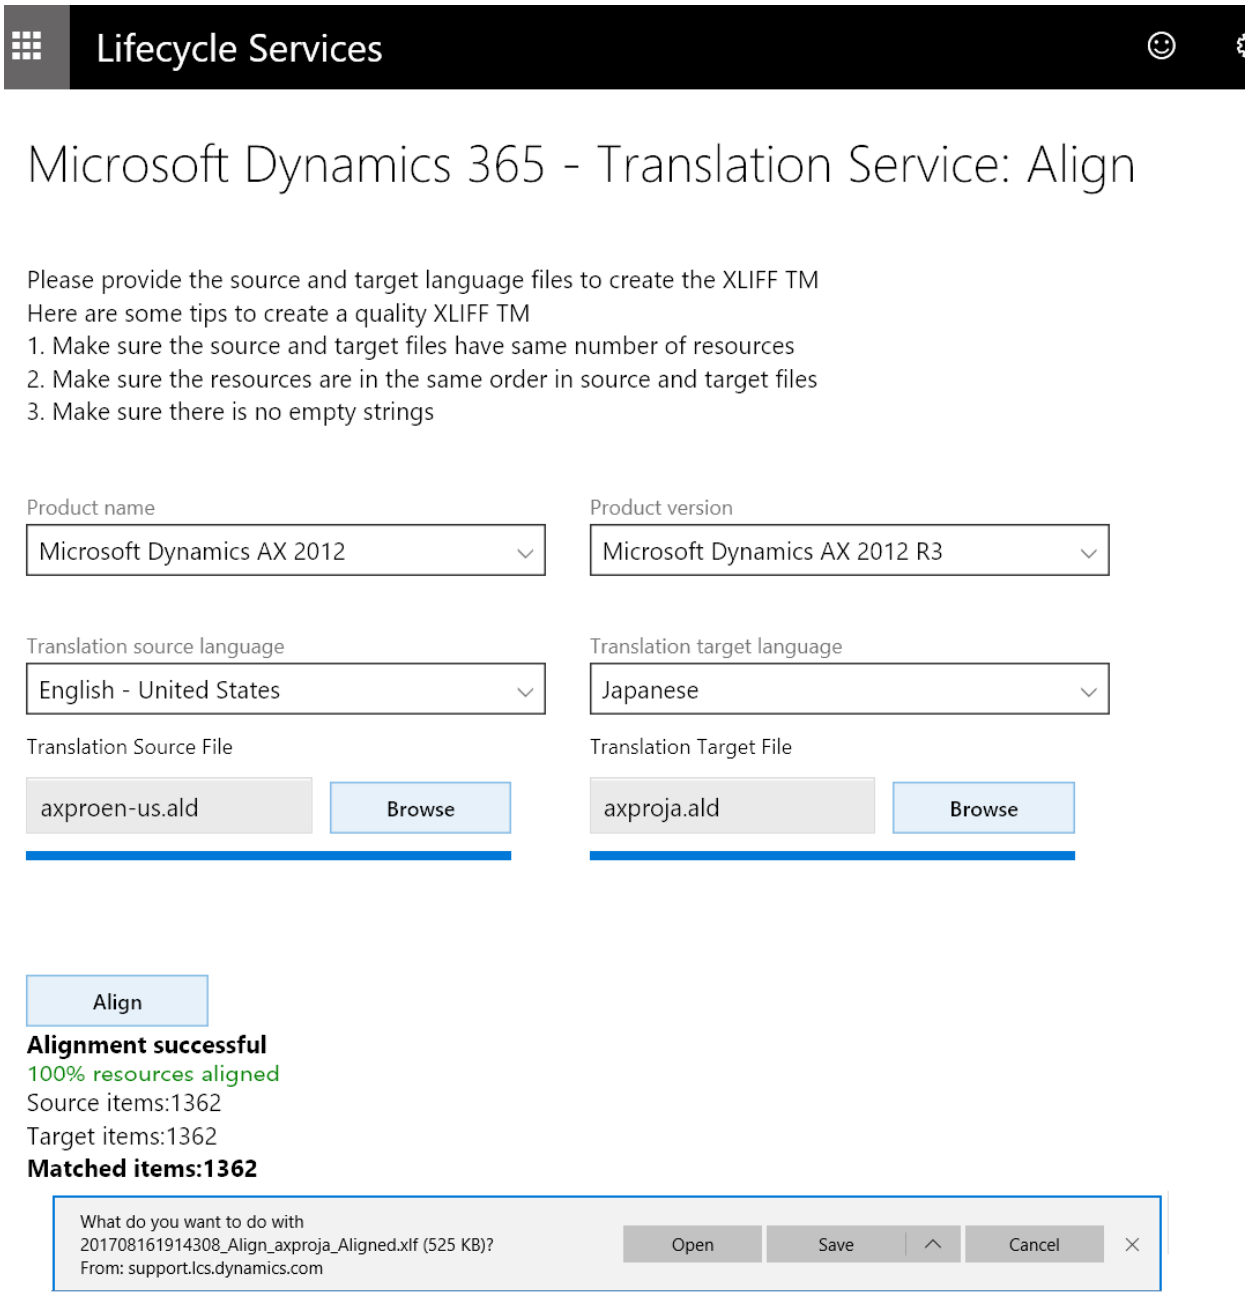
If you have files that were previously translated, you can recycle the translated files for a newer version of the source files by creating a TM that uses XLIFF.

1. On the DTS dashboard, select the **Align** button to start the Align tool.



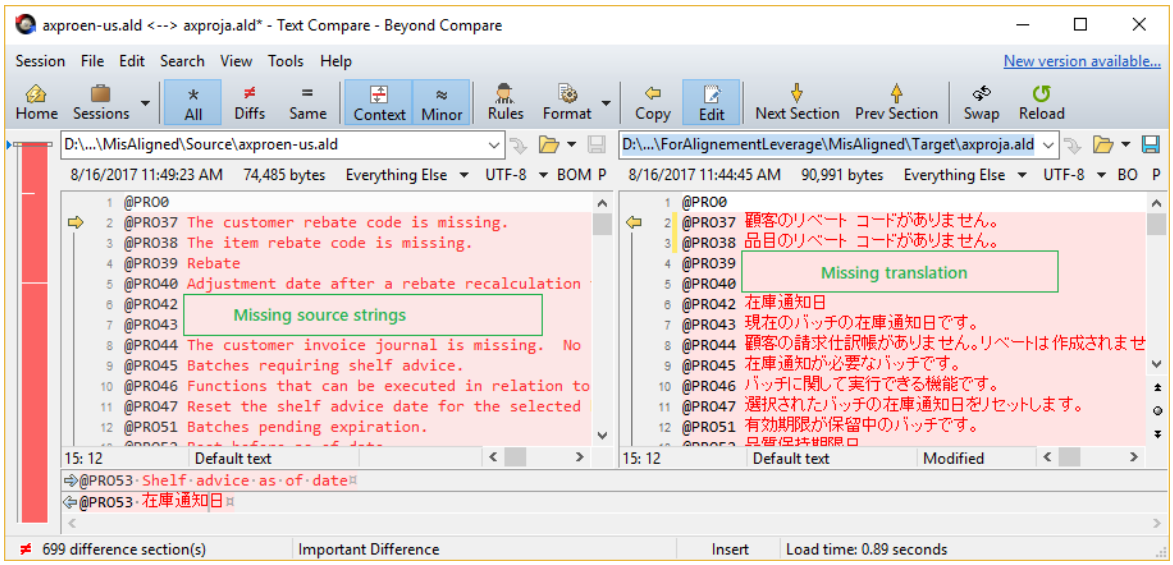
> **NOTE**
> - The Align tool currently supports only user interface (UI) files.
> - To start the Align tool, you might have to explicitly allow pop-up windows in your browser.

2. On the **Align** page, select the source language, the target language, and the files to align.
3. Select **Align** to complete the alignment. When the alignment is completed, a message summarizes the results.

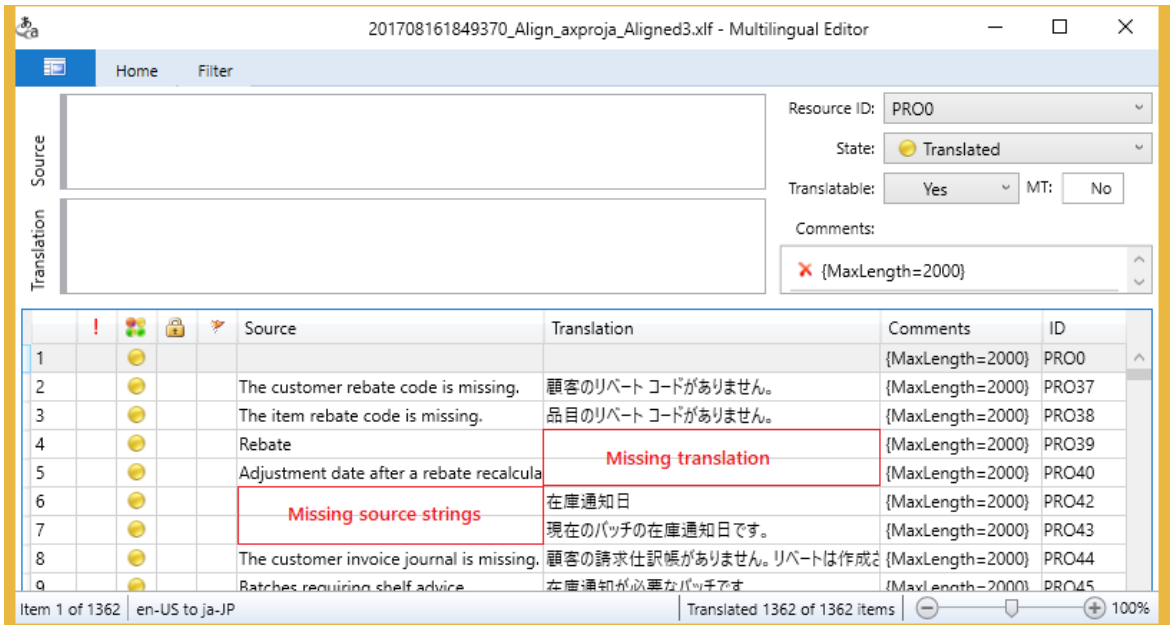


To create the best XLIFF TM, make sure that the following conditions are met:

- Both the source file and the target file have the same number of resources.
- The resources are in the same order in both the source file and the target file.
- There are no empty strings. The following illustration shows examples of empty strings in the source and the target.



Empty strings are inherited by the XLIFF TM. If a **Rebate** string in the source has an empty string in the target, it will likely be translated as an empty string if this XLIFF TM is used.



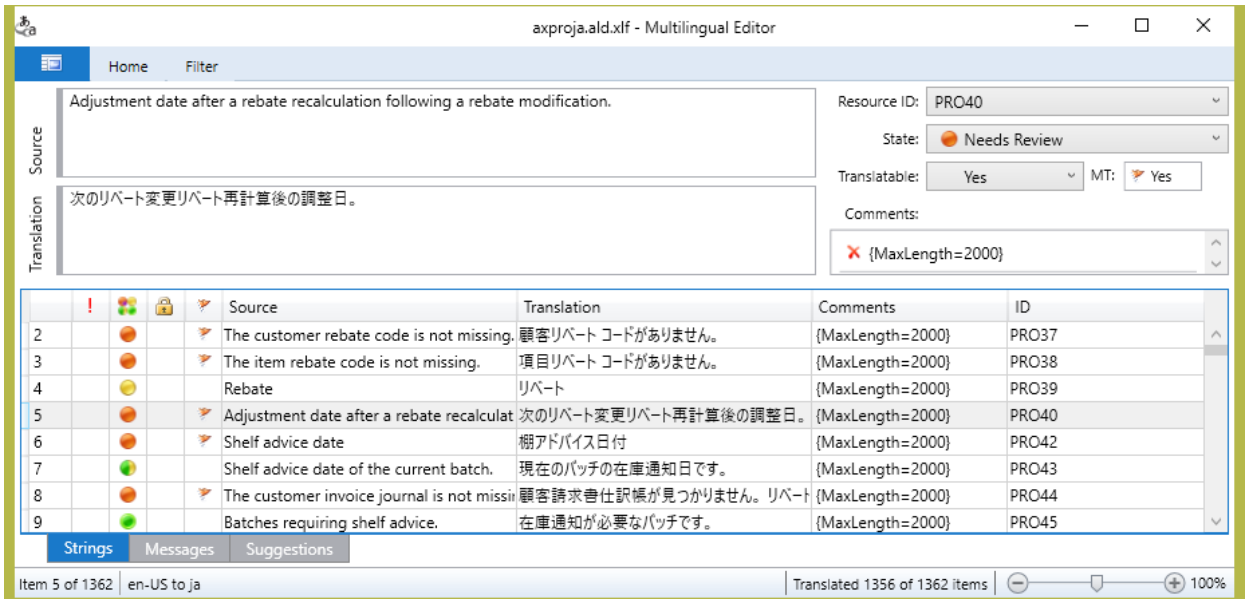
Although the Align tool can resolve some of these issues, it's easier if you prevent them before you see unexpected results in the output.

Review the aligned XLIFF file before you use it as a TM. TUs that have been reviewed should be marked as **Final** or **Signed off**, so that they aren't mistaken for unreviewed TUs.

Editing an XLIFF translation memory

We recommend that you use the free Multilingual Editor, or another XLIFF editor, to review and edit the translations in the XLIFF file that DTS provides. At a minimum, you should review the translations to verify that the translation output meets your product's quality standards.

When you open an XLIFF file in the Multilingual Editor, it resembles the following illustration.



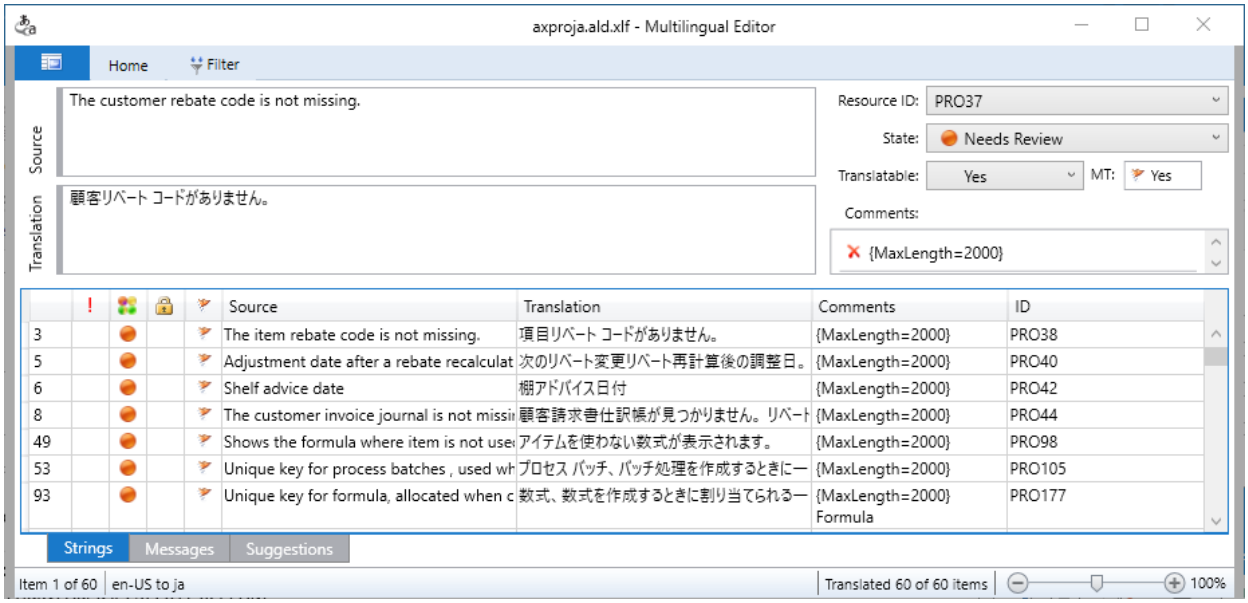
Notice that there is a circle near the beginning of each line. The color of the circle indicates the state of the translation. DTS automatically assigns these states, depending on where the string came from.

- **Red circle** – The string was machine-translated. DTS assigns the **Needs Review** state.

  > **NOTE**
  > The state value that is shown might differ slightly, depending on the XLIFF editor that you're using.

- **Yellow, green/yellow, or green circle** – The string was recycled. DTS inherited the state from the XLIFF TM that was used in the request.

To verify the translations, you can apply a filter to show only strings that are in the **Needs Review** state.



Strings that have been reviewed should be marked as **Translated**, **Final**, or **Signed off**, so that they can be used for recycling. Translations that are marked as **Needs Review** aren't included for recycling.

After you've finished editing the XLIFF TM, remember to have DTS regenerate the refreshed output file in the source format. For more information about how to regenerate the file, see Translate user interface files.

NOTE

Can you tell us about your documentation language preferences? Take a short survey.

The survey will take about seven minutes. No personal data is collected (privacy statement).

Microsoft Power Platform integration with Finance and Operations

2/18/2021 • 5 minutes to read • Edit Online

NOTE

Effective November 2020:

- Common Data Service has been renamed to Microsoft Dataverse. For more information, see Power Automate Blog.
- Some terminology in Microsoft Dataverse has been updated. For example, *entity* is now *table* and *field* is now *column*. For more information, see Terminology updates.

This topic will be updated soon to reflect the latest terminology.

IMPORTANT

This functionality requires version 10.0.12 for Finance and Operations apps, while service update 189 is required for Dataverse. The release information for Dataverse is published on the latest version availability page.

Finance and Operations is a virtual data source in Dataverse, and enables full create, read, update, delete (CRUD) operations from Dataverse and Microsoft Power Platform. By definition, the data for virtual entities doesn't reside in Dataverse. Instead, it continues to reside in the application where it belongs. To enable CRUD operations on Finance and Operations entities from Dataverse, entities must be made available as virtual entities in Dataverse. The allows CRUD operations to be performed, from Dataverse and Microsoft Power Platform, on data that resides in Finance and Operations apps.

Prerequisite reading

To understand the architecture of virtual entities for Finance and Operations apps, you must understand how Dataverse and virtual entities work. Therefore, the following documentation is a prerequisite:

- What is Dataverse?
- Entity overview
- Entity relationships overview
- Create and edit virtual entities that contain data from an external data source
- What is Power Apps portals?
- Overview of creating apps in Power Apps

Virtual entities for Finance and Operations apps

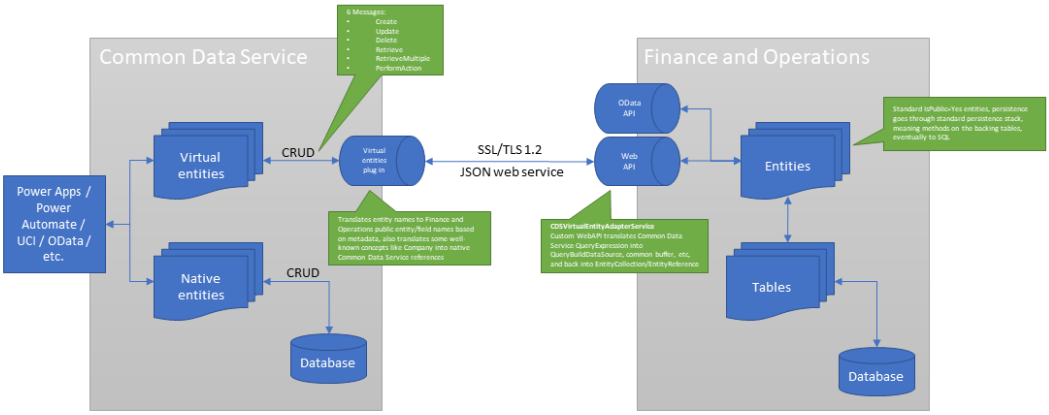
All Open Data Protocol (OData) entities in Finance and Operations are available as virtual entities in Dataverse, and therefore also in Power Platform. Makers can now build experiences in customer engagement apps with data directly from Finance and Operations with full CRUD capability and without copying to Dataverse. Power Apps Portals can be used to build external-facing websites that enable collaboration scenarios for business processes in Finance and Operations.

Virtual entities vs. dual-write

Virtual entities provide a mechanism to use Microsoft Power Platform with Finance and Operations without having to physically copy data to Dataverse. Use this guidance to determine if the requirements will need dual-write or data integrator or virtual entities. Virtual entities and dual-write/data integrator are complementary technologies, meaning that they can be used together if required. Each technology exists for specific scenarios, as explained in Integration strategies.

Architecture

Virtual entities are a Dataverse concept that is useful beyond Finance and Operations. The following illustration shows how the Finance and Operations provider for virtual entities is implemented. Six primary methods are implemented by the provider. The first five methods are the standard CRUD operations: **Create**, **Update**, **Delete**, **Retrieve**, and **RetrieveMultiple**. The last method, **PerformAction**, is used to call OData actions, as described later in this topic. Calls to the Finance and Operations Virtual Entity Data Provider (shown as "VE Plugin" in the illustration) will cause a Secure Sockets Layer (SSL)/Transport Layer Security (TLS) 1.2 secure web call to the CDSVirtualEntityService web API endpoint of Finance and Operations. This web service then converts the queries into calls to the associated physical entities in Finance and Operations, and invokes CRUD or OData operations on those entities. Because a Finance and Operations entity is directly invoked in all operations, any business logic on the entity or its backing tables is also invoked.



During calls, there are two points of translation from Dataverse to Finance and Operations apps. The first point of translation occurs in the VE Plugin, which translates concepts such as entity physical names into Finance and Operations entity names. It also converts some well-known concepts, such as Company references. The web service call still uses the EntityCollection, Entity, and QueryExpression objects to express the operations that are performed, by using the translated entity names and concepts from the VE Plugin. Finally, the CDSVirtualEntityAdapterService web API in Finance and Operations completes the translation from QueryExpression to QueryBuildDataSource and other internal Finance and Operations language constructs.

All calls between Dataverse and Finance and Operations as part of virtual entities are done as service-to-service (S2S) calls by using the Azure Active Directory (Azure AD) application that is specified in the configuration. The user of this application should have access *only* to the CDSVirtualEntityAdapterService web API and the Catalog entity, CDSVirtualEntityListEntity. These privileges are included in the out-of-box security role that is named CDSVirtualEntityApplication. During the S2S calls, Dataverse provides the identity of the user in Dataverse who is invoking the action. The CDSVirtualEntityAdapterService web API looks up the associated user in Finance and Operations and runs the query in the context of that user. Therefore, the S2S call doesn't have to have explicit access to all the Finance and Operations entities. Instead, it can rely on the privileges of the user who is invoking

the action to determine data access.

> **NOTE**
>
> We always recommend that you have both Finance and Operations and Dataverse co-located in the same Azure region to ensure optimal latency in virtual entity calls. When co-located, the virtual entity overhead is expected to be less than 30ms per call.

Power Apps Portal can also access virtual entities. Because Power Apps Portal authorization is based on contact records, a mapping between contact records and Finance and Operations users is maintained in the msdyn_externalportalusermapping table in Dataverse. This table should be editable only by highly privileged users in Dataverse, who have the rights to control the security access of portal users to Finance and Operations virtual entities. Any Finance and Operations user who is set up for Power Apps Portal access must have the CDSVirtualEntityAuthorizedPortalUser security role assigned, and can't have the System administrator or Security administrator role assigned. Regardless of the Power Apps Portal security setting that is applied to virtual entities, the resulting query to Finance and Operations apps is always run as the associated Finance and Operations user, and is subject to that user's entity and row security settings. Anonymous portal access is also supported. For information about this type of access and how it can be done, see Power Apps Portal reference.

Virtual entities for Core HR

Core HR entities can also be virtualized like Finance and Operations entities. For more information, see Core HR virtual entities.

>
> Can you tell us about your documentation language preferences? Take a short survey.
>
> The survey will take about seven minutes. No personal data is collected (privacy statement).

Add-ins overview

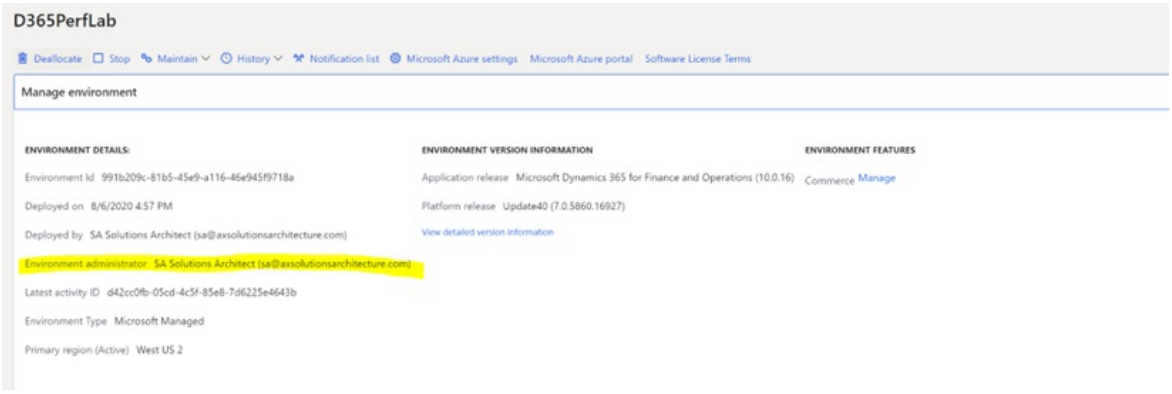
2/18/2021 • 2 minutes to read • Edit Online

Add-ins provide a way to extend the functionality of Finance and Operations apps. The following topics provide some examples of add-ins:

- Planning Optimization overview
- Inventory Visibility Add-in
- Configure export to Azure Data Lake
- IoT Intelligence home page

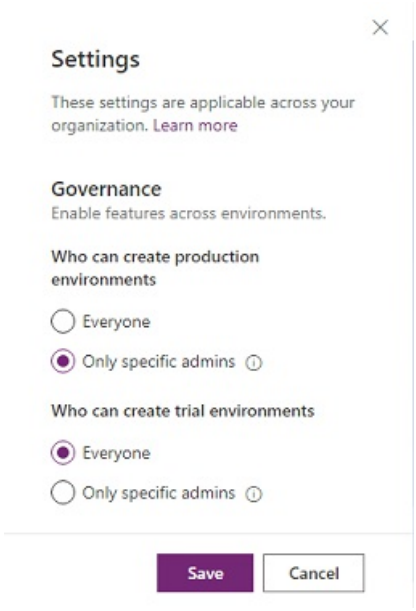
Prerequisites for setting up add-ins

- Make sure that at least 1 gigabyte (GB) of Microsoft Dataverse space is available. Otherwise, setup will fail. You can view your capacity in the Power Platform admin center.
- Identify your Finance and Operations environment administrator. You can find that information in the **Environment details** section.



- Validate your Power Platform environment governance policy. To validate, you must be a **Global administrator** or **Power Platform administrator**.

  1. Sign in to the Power Platform admin center.
  2. Select the gear icon in the upper-right corner of the Power Platform site.



- For organizations that do not allow **Everyone** to create Power Platform production environments, the Finance and Operations environment administrator account must be added as the admin.

  The Finance and Operations environment administrator must be added to one of the following roles. You will need a Global Administrator to perform this action.

  - Global admins
  - Dynamics 365 admins
  - Power Platform admins

  For more information, see Use service admin roles to manage your tenant.

Set up add-ins

> **NOTE**
> If the add-ins that you're planning to install don't require "dual-write linking," you don't have to complete this procedure.

1. After the Finance and Operations environment has been deployed through LCS, open the **Environment details** page in LCS.
2. In the **Power Platform integration** section, select **Setup**.
3. In the **Power platform environment setup** dialog box, select the check box, and then select **Setup** at the bottom of the dialog box.

   > **NOTE**
   > The Dataverse environment is set up so that it includes dual-write functionality. Typically, this setup consumes about 1 GB of Dataverse space.

4. When you receive a message that states that the Microsoft Power Platform environment is being provisioned, select **OK**.

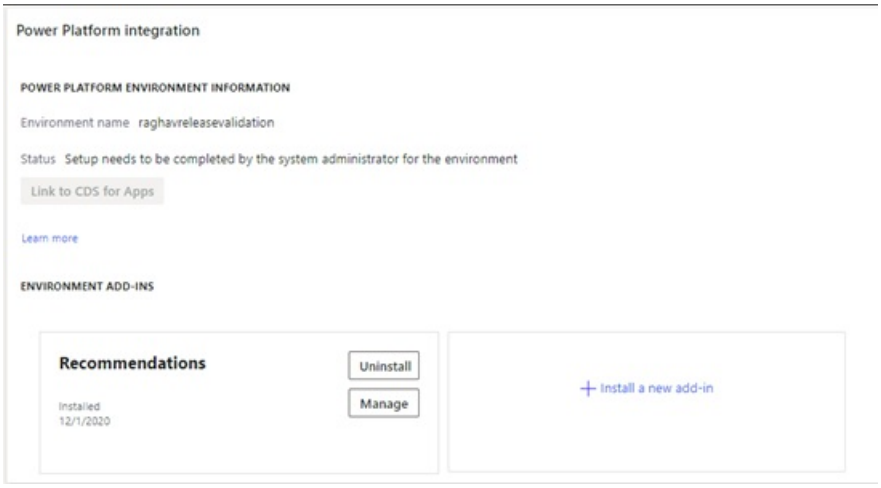
   The **Power Platform integration** section of the **Environment details** page now shows a message that states that the Microsoft Power Platform environment is being provisioned.

5. After a few minutes, refresh the **Environment details** page.

6. In the **Power Platform integration** section, notice that the value of the **Status** field is **Environment setup is in progress**.

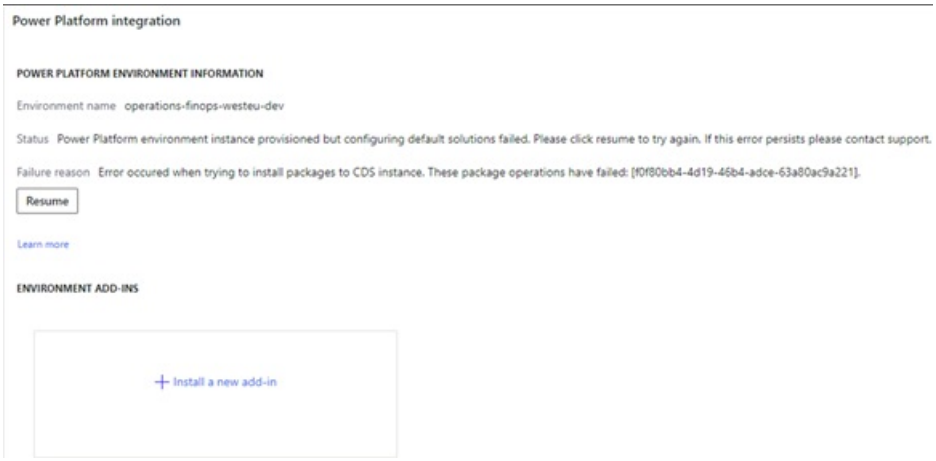
   Typically, the setup takes between 60 and 90 minutes.

   After the Dataverse environment is provisioned, the **Install a new add-in** button becomes available in the **Power Platform integration** section.



Troubleshoot the setup

- Because the setup process tries to set up dual-write functionality, the dual-write setup might sometimes fail after the Dataverse environment is provisioned, as shown in the following illustration. In these cases, the **Install a new add-in** button is still available, so that you can unblock the installation of add-ins. If you want to continue to set up dual-write functionality, select **Resume**.



- Provisioning of the Dataverse environment might sometimes fail because of capacity and licensing issues. In these cases, sign in to the Power Platform admin center, and fix the issues. Then, in the **Power Platform integration** section of the **Environment details** page in LCS, select **Resume**.

Entity modeling

2/18/2021 • 17 minutes to read • Edit Online

NOTE

Effective November 2020:

- Common Data Service has been renamed to Microsoft Dataverse. For more information, see Power Automate Blog.
- Some terminology in Microsoft Dataverse has been updated. For example, *entity* is now *table* and *field* is now *column*. For more information, see Terminology updates.

This topic will be updated soon to reflect the latest terminology.

IMPORTANT

This functionality requires version 10.0.12 for Finance and Operations apps, while service update 189 is required for Dataverse. The release information for Dataverse is published on the latest version availability page.

> The public entity name that is exposed in Dataverse metadata for the Finance and Operations virtual entity uses the physical name of the Finance and Operations entity. This could be different from the public name of the entity as exposed by the OData metadata in Finance and Operations apps.

Building an app requires capabilities to perform relational modeling between entities that are being used in the app. In the context of virtual entities, there will be scenarios where virtual entities and native entities in Dataverse must work together to enable the desired user experience. This topic explains concepts of relational modeling that can be implemented using virtual entities for Finance and Operations.

Generating virtual entities

By default, virtual entities for Finance and Operations apps don't exist in Dataverse. A user must query the catalog entity to view the entities that are available in the linked instance of Finance and Operations. From the catalog, the user can select one or more entities, and then request that Dataverse generate the virtual entities. This procedure is explained in later sections.

Entity fields

When a virtual entity is generated for a Finance and Operations entity, the system tries to create each field in the Finance and Operations entity in the corresponding virtual entity in Dataverse. In an ideal case, the total number of fields will be the same in both entities, unless there is a mismatch in supported data types between Finance and Operations and Dataverse. For data types that are supported, the field properties in Dataverse are set based on the properties in Finance and Operations.

This rest of this section describes supported and unsupported data types. For more information about fields in Dataverse, see Fields overview.

DATA TYPE IN FINANCE AND OPERATIONS	MODELED DATA TYPE IN DATAVERSE

DATA TYPE IN FINANCE AND OPERATIONS	MODELED DATA TYPE IN DATAVERSE
Real	Decimal For information about the possible mismatch, see the next table.
Long	Decimal, where the precision equals 0 (zero)
Int	Integer
String (non-memo), String (memo)	String – single line of text, String – multiple lines of text
UtcDateTime	DateTime (DateTimeFormat.DateAndTime, DateTimeBehavior.TimeZoneIndependent) An empty date (January 1, 1900) in Finance and Operations is surfaced as a null value in Dataverse.
Date	DateTime - (DateTimeFormat.DateOnly, DateTimeBehavior.TimeZoneIndependent) An empty date (January 1, 1900) in Finance and Operations is surfaced as an empty value in Dataverse.
Enum	Picklist Finance and Operations enumerations (enums) are generated as global OptionSets in Dataverse. Matching between the systems is done by using the **External Name** property of values. Enum integer values in Dataverse aren't guaranteed to be stable between the systems. Therefore, you should not rely on them, especially in the case of extensible enums in Finance and Operations, because these enums don't have a stable ID either. OptionSet metadata is updated when an entity that uses the OptionSet is updated.

Fields of the *real* and *long* data types in Finance and Operations are modeled as the *decimal* data type in Dataverse. Because of the mismatch in precision and scale between the two data types, the following behavior must be considered.

USE CASE	RESULTING BEHAVIOR
Dataverse has higher precision.	This use case should never occur unless the metadata is out of sync.
Finance and Operations has higher precision.	During a read operation, the value is rounded to the closest precision value in Dataverse. If the value is edited in Dataverse, it's rounded to the closest precision value in Finance and Operations. During a write operation, the value that is specified in Dataverse is written, because Finance and Operations supports higher precision.
Dataverse has higher scale.	Not applicable

USE CASE	RESULTING BEHAVIOR
Finance and Operations has higher scale.	Dataverse shows the Finance and Operations value, even if it exceeds 100 billion. However, there will be a loss of precision. For example, 987,654,100,000,000,000 is shown in Dataverse as "987,654,099,999,999,900". If the value of this field is edited in Dataverse, Dataverse validation throws an error that the value exceeds the maximum value before that value is sent to Finance and Operations.

The following data types in Finance and Operations aren't supported in Dataverse. Fields of these data types in Finance and Operations entities won't be made available in the corresponding virtual entities in Dataverse. If fields of these data types are used as parameters in Open Data Protocol (OData) actions, those actions won't be available for use in the corresponding virtual entities. For more information about OData actions, see the OData actions section later in this topic.

- AnyType
- BLOB
- Class
- Container
- Guid
- Record
- Time
- UserType
- VarArg
- Void (Void return types on OData actions are supported.)

Data types that are supported in Dataverse but not in Finance and Operations aren't supported in virtual entities for Finance and Operations.

Entity key/primary key

In Finance and Operations, entities can have one or more fields of various data types as the entity key. An entity key uniquely identifies a record in a Finance and Operations entity. Additionally, a record in an entity can be uniquely identified by a record ID primary key of the Int64 type.

In Dataverse, the primary key is always a globally unique identifier (GUID). The GUID-based primary key enables a record in an entity in Dataverse to be uniquely identified.

To bridge the implementation gap between Finance and Operations and Dataverse, the primary key of a virtual entity for Finance and Operations is a GUID (to comply with Dataverse). This GUID consists of the data entity ID in the first 4 bytes, and the record ID of the root data source in the entity as the last 8 bytes. This design satisfies Dataverse's requirement that a GUID be used as the entity key. It also enables the table ID and record ID to be used to uniquely identify the entity record in Finance and Operations.

When using entities in Finance and Operations, you need to ensure that the root data source will always have a unique RecID. If this design is violated, duplicate GUID's will show up in Dataverse for the corresponding virtual entity. Aggregate views are not supported via virtual entities for the same reason because these views may not have unique RecIDs.

Primary field

In Dataverse, each entity must have a primary field. This field must be a single field of the string type. The primary field is used in Dataverse in the following scenarios:

- The default views that are created for an entity include the primary field.
- The quick view form for an entity includes the primary field.
- A lookup to another entity is added to a page and shows the data from the primary field.

Based on this use of the primary field in Dataverse, the primary field for a virtual entity for Finance and Operations is designed to use the entity key of the corresponding entity in Finance and Operations.

Because the primary field in Dataverse is expected to have only one field of the string type, whereas the entity key in Finance and Operations can have multiple fields of various data types, the entity key fields are converted to strings. The strings are concatenated and separated by a pipe (|), to a maximum length of 255 characters. Any value that exceeds 255 is truncated. This virtual entity field that represents the primary field is named **mserp_primaryfield**.

Relations

> **IMPORTANT**
> A write transaction that spans a virtual entity and a native entity is not supported. We do not recommend using this form of transaction, as there is no way to ensure consistency.

Relations in Finance and Operations entities are modeled as one-to-many (1:n) or many-to-one (n:1) relations. These relations are modeled as relationships in the virtual entity in Dataverse. Note that many-to-many (n:n) relations aren't supported in Finance and Operations.

For example, in Finance and Operations, if Entity A has a foreign key to Entity B, this relation will be modeled as an n:1 relationship in virtual entity Entity A in Dataverse. The schema name of this relationship in Dataverse uses the naming convention **mserp_FK_<source entity name>_<relation name>**. This naming convention has a maximum string length of 92 characters. Any relation where the schema name will produce a name that exceeds 92 characters won't be generated in the virtual entity in Dataverse.

The external name of this relationship uses the naming convention **FK_<relation name>**. The external name is used to determine the relation in Finance and Operations when the query that is sent to Finance and Operations is built.

When a relationship is generated for a virtual entity in Dataverse, a new field of the lookup type is also added to the source entity. In the preceding example, when the relationship is created, a new lookup field that uses the naming convention **mserp_fk_<target_entity>_id** is added to source entity Entity A. Because there can be several relations in an entity in Finance and Operations, the same number of lookup fields (one per related entity) will be created in the source virtual entity. When this lookup field is added to a page or a view, it will show the primary field value from the related entity.

A relationship in the virtual entity in Dataverse will be generated only if the related entity in the relation already exists as a virtual entity in Dataverse. In the preceding example, if Entity B doesn't exist as a virtual entity in Dataverse, the relation to Entity B won't be created in Entity A when Entity A is generated as a virtual entity. This relation will be added to Entity A only when Entity B is generated as a virtual entity. Therefore, when a virtual entity is generated for Finance and Operations, validations are done to ensure that only relationships that can be complete and functional are generated in the virtual entity that is being generated.

In summary, a relationship to another Finance and Operations virtual entity might not exist in the virtual entity for either of the following reasons:

- The Finance and Operations entity that is participating in the relationship doesn't exist as a virtual entity.
- The length of the name of the relationship exceeds 92 characters.

Note that if an error is encountered when any part of a Finance and Operations virtual entity is generated in

Dataverse, the virtual entity won't be created at all. If relationships don't exist for either of the preceding reasons, the situation isn't considered an error.

Native entity–to–native entity relationships

Native entity–to–native entity relationships are the standard Dataverse functionality, where relationships are resolved by using the GUID of the related entity. (This GUID is the entity key.) The GUID identifies the unique entity record in the related entity.

Virtual table–to–virtual table relationships

The relationships between two Finance and Operations virtual entities are driven by the relation metadata in the Finance and Operations entities. As was explained earlier, these relations are generated as relationships in Dataverse when the virtual entity is generated. As in the behavior for native entities in Dataverse, these relationships use the GUID to identify the unique record of the entity in Finance and Operations. Semantically, the GUID on the Finance and Operations virtual entity behaves like the GUID on the native Dataverse table. For information about the implementation of the GUID in Finance and Operations virtual entities, see the Entity key/primary key section earlier in this topic.

In the preceding example, the GUID of the related entity is the entity key of Entity B and will be used to build queries to identify a record in Finance and Operation. The relation that Entity A has to Entity B will be used.

Therefore, in effect, the entity name is the only information that is used in a relation that comes from Finance and Operations. The entity name gives access to the primary field in the related entity, so that it can be shown in the lookup. It also gives access to the GUID of the related entity, so that it can be used in other queries, as was explained earlier. The actual field that the relation is built on in the Finance and Operations entity isn't used at all.

Virtual table–to–native table relationship

As was explained earlier, the GUID is the only information that is used to uniquely identify a record in a native Dataverse table (including in native entity–to–native entity relationships) or in a Finance and Operations virtual entity (including in virtual entity–to–virtual entity relationships). However, consider an example where you want to show sales orders from Finance and Operations for Account A in Dataverse. The query that is sent to Finance and Operations for this relationship will have a WHERE clause on the GUID of the entity key of the native accounts entity in Dataverse, because the sales orders must be filtered for a specific account in Dataverse. However, because Finance and Operations doesn't have any information about the GUID of the entity in Dataverse, the query won't return any sales orders. The query will be successful only if the WHERE clause has conditions that are based on the fields that Finance and Operations understands.

Therefore, how can the GUID of the accounts entity in Dataverse be replaced with fields that are in Finance and Operations, in such a way that the query that is sent to Finance and Operations will return the correct list of sales orders?

To solve this issue and enable a rich set of scenarios that allows for virtual entity–to–native entity relationships, relationships can be added to this type of entity. The relation will appear as a relationship when the virtual entity is synced.

In the above example, the relationship between the SalesOrderHeader virtual entity and the Account native entity should be based on the Account Number and Company fields. By default, the native account entity in Dataverse does not have a company field. For this example, we will add a company lookup field named new_testcompany to the native Account entity.

Next, we add a new key named new_accountcompanyidx, which specifies that (accountnumber, new_testcompany) together represent a unique row in the account entity in Dataverse.

The next step is to define this relationship in X++. The following example shows sample X++ code. The names of the fields, index, and mapping information should match the names of the fields and indexes created in Dataverse. In this example, a relationship named “synthaccount” will be created between the virtual SalesorderHeader entity and the native account entity in Dataverse. The mapped fields make up the

new_accountcompanyidx index. The display name for the relationship will be @SYS11307. Note the backslash at the start of the display name. This ensures that the label defines the relationship, so that it is appropriately translated.

The field mapping indicates which field on the virtual entity maps to the field on the native entity. In the field mapping, the key is the virtual entity field, and the value is the native entity field.

```
[CDSVirtualEntitySyntheticRelationshipAttribute('synthaccount', 'account', 'accountcompanyidx',
'\@SYS11307')]
    public static Map syntheticAccountRelationship()
    {
        Map fieldMapping = new Map(Types::String, Types::String);

        // Assumes the Dataverse account entity has a key on [msdyn_accountnumber, msdyn_companyid]
        // Also assumes that the Dataverse cdm_Company entity has a key on [msdyn_companycode]
        fieldMapping.insert(fieldStr(CDSVirtualEntityTestEntity, StringField), 'msdyn_accountnumber');
        fieldMapping.insert(fieldStr(CDSVirtualEntityTestEntity, DataAreaId), 'msdyn_companyid');

        return fieldMapping;
    }
```

The next step is to generate or refresh the virtual entity to get the new relationship. Note that relationships between a virtual entity and a native entity cannot be updated in Dataverse once it is created. The only way to make an update is to physically remove the relationship, refresh the entity, and then physically re-add the relationship in order to resolve the issue.

This relationship looks like a typical GUID-based relationship, but has extra metadata to translate query filters on the relationship into restrictions on the backing fields. The query that is now generated will have a WHERE clause that is based on the fields that Finance and Operations apps recognize. That query will then return the filtered list of sales orders, as expected.

Native entity–to–virtual entity relationships

Native entity–to–virtual entity relationships works much like native entity–to–native entity relationships. Users associate native records with virtual records in Finance and Operations, and the GUID of the virtual entity is saved on the native entity record. As was explained earlier, the entities that participate in a relationship will have the GUID field of the related entity on them. Therefore, when a quotation in Dataverse is associated with a customer in a Finance and Operations virtual entity, the GUID of the customer virtual entity will be saved in the quotation entity. This behavior enables records to be retrieved as expected, by using standard Dataverse functionality.

Enums

Enums in Finance and Operations are modeled as OptionSets in Dataverse. When a virtual entity for Finance and Operations is generated, the required enums are generated as OptionSets. If an OptionSet already exists, it's used instead.

Company

An entity in Finance and Operations can be bound to a company, or it can be global. The virtual entity for a Finance and Operations entity that is bound to a company will have a relationship to the cdm_company entity in Dataverse. The cdm_company entity is a native entity in Dataverse and is part of the Dynamics365Company solution. As always, when a relationship is created, a lookup field is also created in the virtual entity for the related entity (cdm_company in this case). This lookup field is named **Company**, and it must be used to provide an optimal user experience where users can select a value in a list or go to the details of the related record. A field that is named **Company Code** is also added in the virtual entity. The value is a four-character string. This field must be used in programming.

Attachments

Attachments in Finance and Operations entities are supported on a per-entity basis. For example, an invoice header entity will implement an invoice-related attachments entity to enable attachments via entities.

Entities of this type will have relations with the corresponding attachments entity in Finance and Operations. Therefore, they will follow the same pattern as the other relations that were discussed earlier. In other words, Finance and Operations entities that have implemented attachments functionality will also make attachments available by using virtual entities. Finance and Operations entities that don't support attachments also won't support attachments when they are virtualized in Dataverse.

Note that Finance and Operations virtual entities support only the reading of attachments. They don't currently support the creation, update, or deletion of attachments by using virtual entities.

OData actions

OData actions in the Finance and Operations entities are made available as custom actions in Dataverse. For more information about custom actions and what they enable in Dataverse, see Custom actions.

Input and output parameters of the following types are supported. If an input or output parameter is of a different type, the OData action doesn't appear as the SDK message in Dataverse.

- Integer
- String
- Guid
- Boolean
- Date/Datetime

Here are some examples of OData actions that are supported in Finance and Operations entities, but that aren't supported in the corresponding virtual entities in Dataverse:

- RetailStoreTenderTypeTable.queryDistinctTenderTypeIdAndName (a collection of RetailStoreTenderTypeTable entity)
- DocumentRoutingClientApp.syncPrinters (DocumentRoutingClientApp entity)
- DocumentRoutingClientApp.updateJobStatus (DocumentRoutingJobStatus enum)
- DimensionCombination.getCombinationDisplayValue (LedgerJournalACType enum)

Labels and localization

Labels that are defined on metadata, such as entity names and field names in Finance and Operations, are retrieved when virtual entities are generated in Dataverse. The labels are retrieved by passing the list of language locales that are installed in Dataverse. Finance and Operations returns each label as a list of locale/value sets that are then used to construct a label instance in Dataverse. Only the language packs that exist at the time of entity generation or update are included. Additionally, only labels that Finance and Operations has provided a translation for are included. Any missing translations revert to the label ID, such as **@SYS:DataEntity**. After a new language pack is installed in Dataverse, existing entities must be updated to pick up the new label information, if labels in that language exist in Finance and Operations.

Any runtime labels are returned in the language of the current user context. In other words, they are returned in the language that is specified on that user's UserInfo record in Finance and Operations. This behavior also applies to error messages.

Error handling

Finance and Operations create, read, update, and delete (CRUD) business logic on entities and backing tables is

run when it's called through the virtual entity in Dataverse. If any exception is thrown on the Finance and Operations side, the last message in the error log is returned to Dataverse and is thrown as an InvalidPluginExecutionException exception that contains the message from Finance and Operations. Because the Finance and Operations code runs in the context of the user, the language of the error message is based on the language that is specified on the UserInfo record in Finance and Operations. If any messages that are written to the info log in Finance and Operations don't result in an exception, they aren't shown in Dataverse.

Calculated/unmapped fields

Calculated and unmapped fields in Finance and Operations entities are also available in the corresponding virtual entities in Dataverse.

Application lifecycle management for solutions that use virtual entities

2/18/2021 • 5 minutes to read • Edit Online

NOTE

Effective November 2020:

- Common Data Service has been renamed to Microsoft Dataverse. For more information, see Power Automate Blog.
- Some terminology in Microsoft Dataverse has been updated. For example, *entity* is now *table* and *field* is now *column*. For more information, see Terminology updates.

This topic will be updated soon to reflect the latest terminology.

IMPORTANT

This functionality requires version 10.0.12 for Finance and Operations apps, while service update 189 is required for Dataverse. The release information for Dataverse is published on the latest version availability page.

The application lifecycle for an end-to-end solution using Finance and Operations virtual entities will encompass both Finance and Operations as well as Dataverse. This topic explains this in detail.

Solution management

Virtual entities for Finance and Operations don't exist in Dataverse until they are created. Virtual entities must be created inside a solution. The MicrosoftOperationsERPVE solution is used for this purpose. This solution will contain all the virtual entities that are created from an instance of Finance and Operations.

MicrosoftOperationsERPVE is a managed solution. By definition, a managed solution can't be modified after it has been generated. However, MicrosoftOperationsERPVE is a managed solution that grants privileges to update the components (that is, virtual entities) that are inside it. Therefore, new virtual entities can be added to the solution as they are created, and existing virtual entities can be updated as required. Nevertheless, the privileges to modify the managed solution are available only to the platform itself. Users can't make changes directly to the solution.

Because MicrosoftOperationsERPVE is a managed solution, solutions from customers, partners, and independent software vendors (ISVs) can take a dependency on it. This capability allows for consistent application lifecycle management (ALM) for solutions that use and depend on the virtual entities for Finance and Operations.

When a solution that depends on MicrosoftOperationsERPVE is exported, placeholders for the virtual entities that are used in the solution are added in the exported solution. When that solution is imported into another Dataverse environment, the import process also generates the dependent Finance and Operations virtual entities in the MicrosoftOperationsERPVE solution for the Finance and Operations instance that is connected to the Dataverse environment. Therefore, MicrosoftOperationsERPVE must already exist before a solution that depends on it is imported. Otherwise, an error message is shown. Additionally, if a dependent entity isn't available in the Finance and Operations instance, the virtual entity for that entity won't be generated. Virtual entities are generated only for entities that are available.

> **NOTE**
> If a virtual entity already exists in Dataverse and a solution is being imported that now references new fields in the virtual entity which does not exist in Dataverse, a manual refresh must be performed on the virtual entity to get the latest metadata from Finance and Operations.

The following list describes other solutions that Finance and Operations virtual entities require to work, and that must be available in the Dataverse environment:

- **MicrosoftOperationsERPCatalog** – This solution provides a catalog of the available entities in a Finance and Operations instance. It also provides the connection that is used to set up a configuration. For more information, see the later sections of this topic.
- **MicrosoftOperationsVESupport** – This solution provides the virtual entity provider for Finance and Operations apps. The provider can communicate with Finance and Operations apps and Dataverse. For more information, see the next section.
- **Dynamics365Company** – This solution adds the Company entity, which is referenced by all Finance and Operations entities that have a **PrimaryCompanyContext** metadata value.

All these solutions must be present in an environment. Otherwise, virtual entities won't work with Finance and Operations apps. These solutions are packaged together to allow for easier portability across environments.

Managing entities from multiple environments

The MicrosoftOperationsVESupport solution consists of the **msdyn_financeandoperationsvirtualentity** entity. This entity represents the virtual entity data source for Finance and Operations that captures connection setup information. Each record in this entity represents a connection to a Finance and Operations instance.

A catalog is used to list all the entities in a Finance and Operations instance that are available for virtualization in Dataverse (in other words, all the entities in Finance and Operations that are enabled for Open Data Protocol [OData]). The catalog is part of the default MicrosoftOperationsERPCatalog solution and is applicable to a Finance and Operations instance.

Note that each Dataverse environment must point to only one Finance and Operations instance at any time, and each Finance and Operations environment must point to only one Dataverse environment. Therefore, there should be only one record in the **msdyn_financeandoperationsvirtualentity** entity.

The **mserp_financeandoperationsentity** entity that represents the catalog can be queried to list the entities in a Finance and Operations instance. Because this entity is a virtual entity, the catalog is never persisted in Dataverse.

Notice that the name of the catalog entity has the "mserp_" prefix. This prefix identifies the entities in the catalog as Finance and Operations entities. The same prefix is also added to the system names of the virtual entities that are generated for Finance and Operations in the MicrosoftOperationsERPVE solution. Therefore, the maker can distinguish Finance and Operations virtual entities from other entities. The prefix is set in the managed solution and can't be changed.

Managing entities from multiple ISV solutions

One or more ISV solutions will take a dependency on the MicrosoftOperationsERPVE solution to use virtual entities for Finance and Operations. Because custom entities in Finance and Operations use the same catalog as out-of-box entities in Finance and Operations, the virtual entities for custom Finance and Operations entities will also be generated in the MicrosoftOperationsERPVE solution.

The established guidelines and ALM for entity development in Finance and Operations ensure that there are no conflicting entity names across ISV solutions. Therefore, no conflicts of this type can occur when virtual entities are generated in Dataverse for custom Finance and Operations entities from multiple ISV solutions. All virtual

entities for Finance and Operations entities, including custom entities, will have the "mserp_" prefix that was mentioned earlier.

Managing a Finance and Operation instance in a Dataverse environment for virtual entities

One Finance and Operations instance must be linked to a Dataverse environment for virtual entities. The connection setup information that is required is captured in a virtual entity data source for Finance and Operations. This data source is included in the MicrosoftOperationsERPCatalog solution.

Finance and Operations and Dataverse admin reference

2/18/2021 • 5 minutes to read • Edit Online

NOTE

Effective November 2020:

- Common Data Service has been renamed to Microsoft Dataverse. For more information, see Power Automate Blog.
- Some terminology in Microsoft Dataverse has been updated. For example, *entity* is now *table* and *field* is now *column*. For more information, see Terminology updates.

This topic will be updated soon to reflect the latest terminology.

IMPORTANT

This functionality requires Platform updates for version 10.0.12 of Finance and Operations apps and service update 189 for Dataverse. The release information for Dataverse is published on the latest version availability page.

This topic provides step-by-step instructions about how to set up and configure virtual entities for Finance and Operations apps in Dataverse.

Getting the solution

The Dataverse solution for Finance and Operations virtual entities must be installed from Microsoft AppSource virtual entity solution. For more information, see Finance and Operations virtual entity.

Ensure the following solutions are installed in Dataverse.

- **Dynamics365Company** - This adds the **Company** entity, which is referenced by all Finance and Operations entities with a PrimaryCompanyContext metadata value.
- **MicrosoftOperationsVESupport** - This provides the core support for the Finance and Operations virtual entity feature.
- **MicrosoftOperationsERPCatalog** - This provides a list of available Finance and Operations entities through the mserp_financeandoperationsentity virtual entity.
- **MicrosoftOperationsERPVE** - This is the API-managed solution, which will contain the generated virtual entities as they are made visible.

Authentication and authorization

After the solutions are imported in the Dataverse environment, both environments must be set up to connect to each other. Dataverse will call Finance and Operations using Service-to-Service (S2S) authentication, based on an Azure Active Directory (AAD) application. This new AAD application represents the single instance of the Dataverse environment. If you have multiple pairs of Dataverse and Finance and Operations environments, separate AAD applications for each pair must be created to ensure connections are established between the correct pair of Finance and Operations and Dataverse environments. The following procedure shows the creation of the AAD application.

> **IMPORTANT**
> The AAD application must be created on the same tenant as Finance and Operations.

1. Go to https://portal.azure.com > **Azure Active Directory** > **App registrations**.
2. Select **New Registration**. Enter the following information:
   - **Name** - Enter a unique name.
   - **Account type** - Enter **Any Azure AD directory** (single or multi-tenant).
   - **Redirect URI** - Leave blank.
   - Select **Register**.
   - Make note of the **Application (client) ID** value, you will need it later.
3. Create a symmetric key for the application.
   - Select **Certificates & secrets** in the newly created application.
   - Select **New client secret**.
   - Provide a description and an expiration date.
   - Select **Save**. A key will be created and displayed. Copy this value for later use.

The AAD application created above will be used by Dataverse to call Finance and Operations apps. As such, it must be trusted by Finance and Operations and associated with a user account with the appropriate rights in Finance and Operations. A special service user must be created in Finance and Operations with rights *only* to the virtual entity functionality, and no other rights. After completing this step, any application with the secret of the AAD application create above will be able to call this Finance and Operations environment and access the virtual entity functionality.

The next steps walk through this process in Finance and Operations apps.

1. In Finance and Operations, go to **System Administration** > **Users** > **Users**.
2. Select **New** to add a new user. Enter the following information:
   - **User ID** - Enter **dataverseintegration** (or a different value).
   - **User name** - Enter **dataverse integration** (or a different value).
   - **Provider** - Set to **NonAAD**.
   - **Email** - Enter **dataverseintegration** (or a different value, does *not* need to be a valid email account).
   - Assign the security role **CDS virtual entity application** to this user.
   - Remove all other roles including **System user**.
3. Go to **System Administration** > **Setup** > **Azure Active Directory applications** to register Dataverse.
   - Add a new row.
   - **Client ID** - The **Application (client) ID** created above
   - **Name** - Enter **Dataverse Integration** (or a different name).

- **User ID** - The user ID created above.

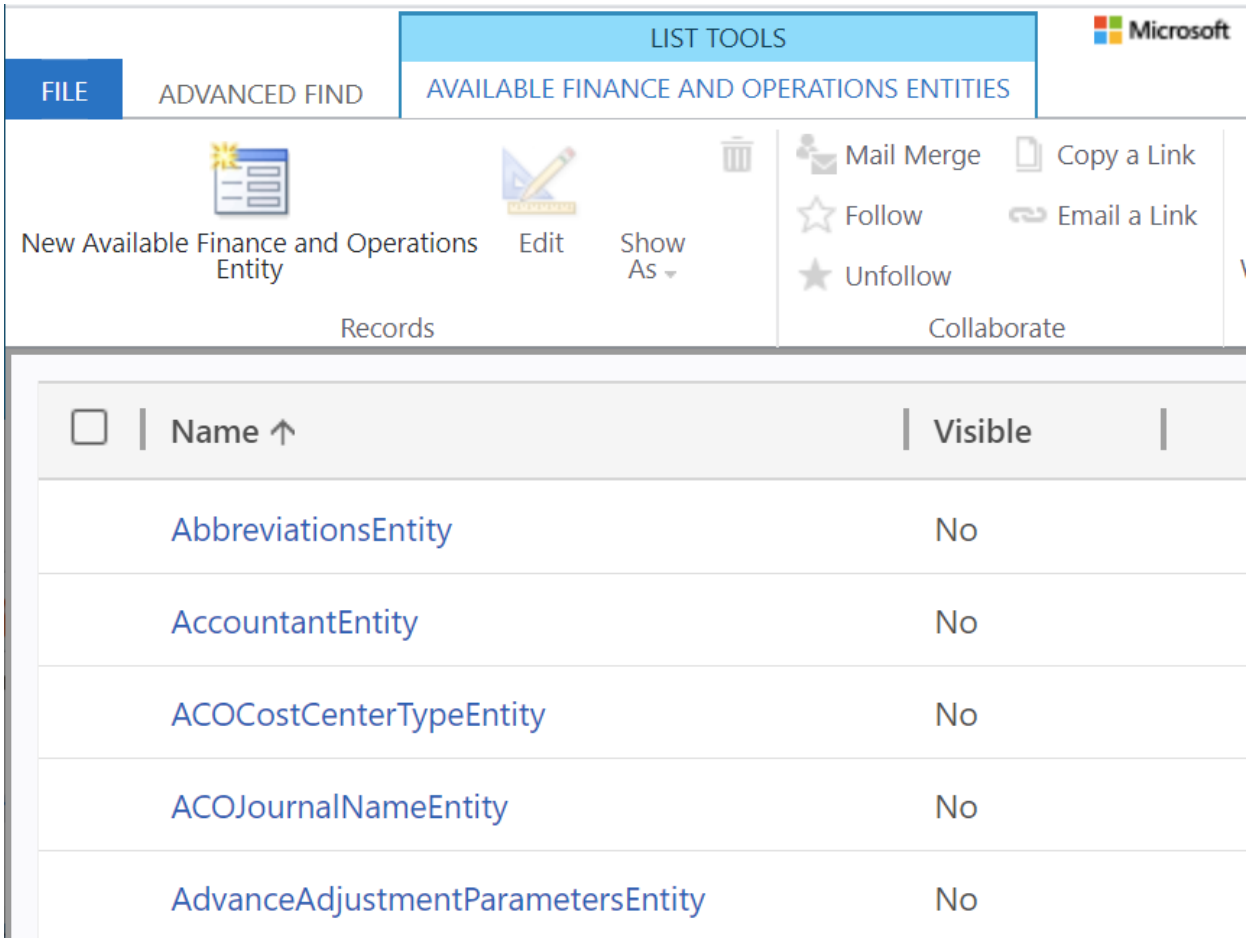
The next step in the process is to provide Dataverse with the Finance and Operations instance to connect to. The following steps walk through this part of the process.

1. In Dataverse, go to **Advanced Settings > Administration > Virtual Entity Data Sources**.
2. Select the data source named "Finance and Operations".
3. Fill in the information from the steps above.
   - **Target URL** - The URL at which you can access Finance and Operations.
   - **OAuth URL** - https://login.windows.net/
   - **Tenant ID** - Your tenant, such as "contoso.com".
   - **AAD Application ID** - The **Application (client) ID** created above.
   - **AAD Application Secret** - The secret generated above.
   - **AAD Resource** - Enter 00000015-0000-0000-c000-000000000000 (this is the AAD application representing Finance and Operations, and should always be this same value).
4. Save the changes.

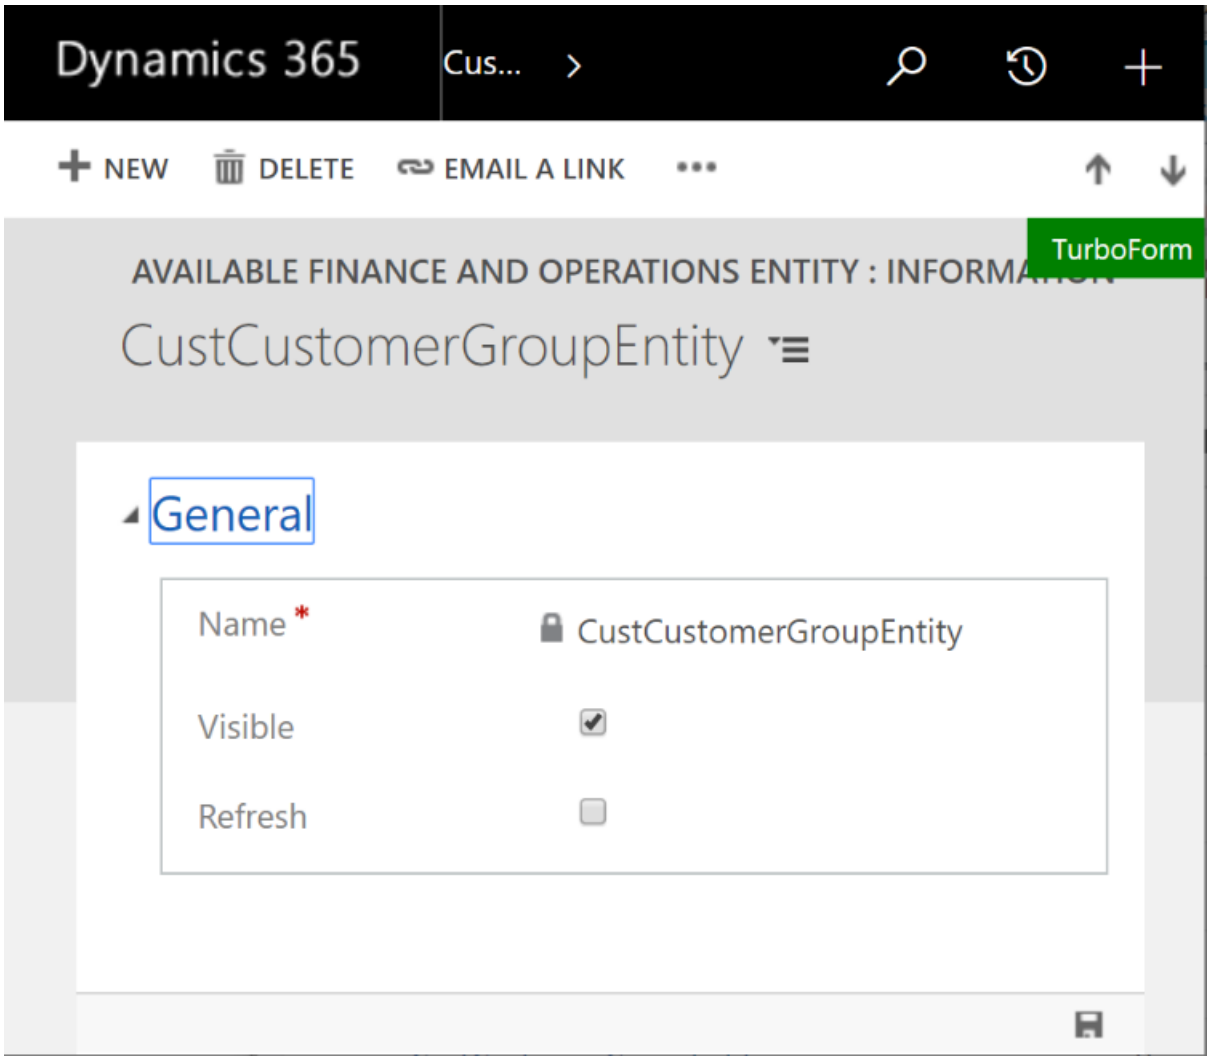
Enabling virtual entities

Due to the large number of OData enabled entities available in Finance and Operations, by default, the entities are not available as virtual entities in Dataverse. The following steps allow for enabling entities to be virtual, as needed.

1. In Dataverse, go to **Advanced find** (filter icon).
2. Look for "Available Finance and Operations Entities" and select **Results**.



3. Locate and open the entity that you want to enable.
4. Set **Visible** to **Yes** and save. This will generate the virtual entity, so that it will appear in all of the appropriate menus, such as the advanced find dialog box.



Refreshing virtual entity metadata

The virtual entity metadata can be force-refreshed when it is expected for the entity metadata in Finance and Operations to have changed. This can be done by setting **Refresh** to **Yes** and saving. This will sync the latest entity definition from Finance and Operations to Dataverse and update the virtual entity.

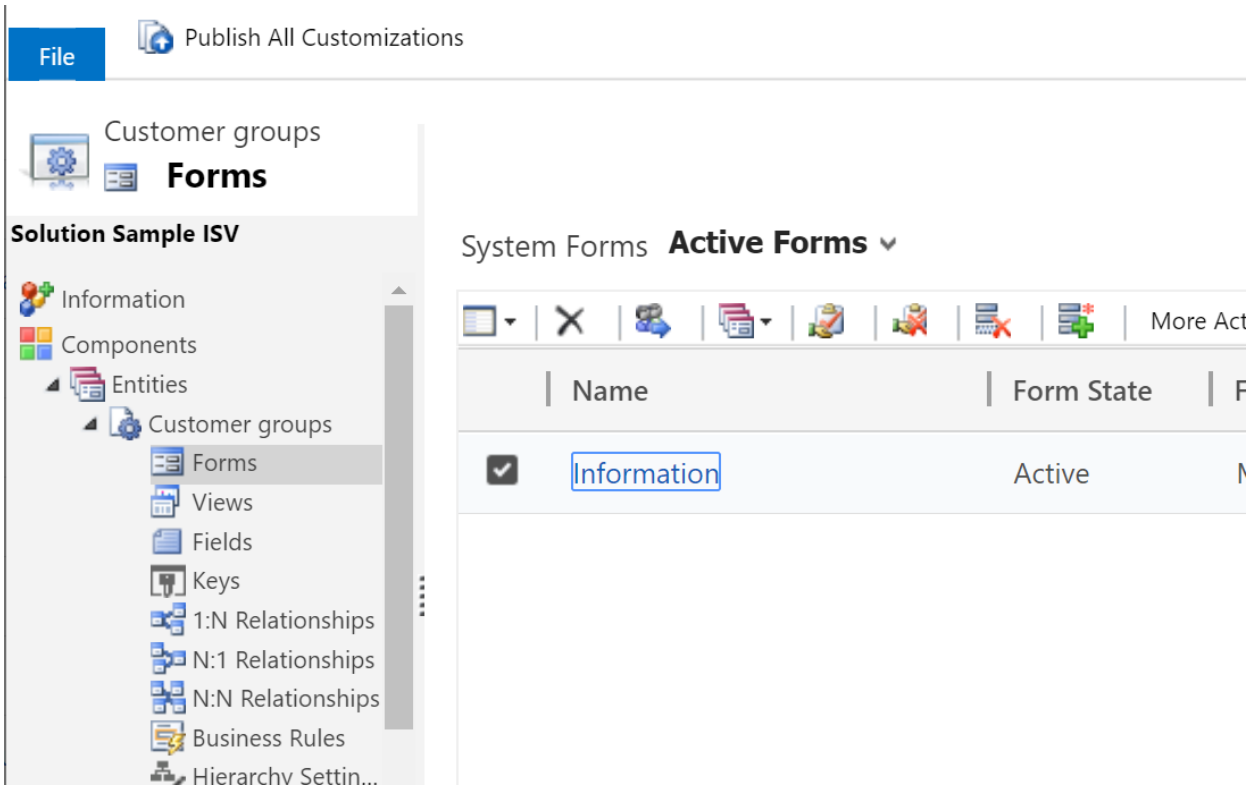
Referencing virtual entities

The virtual entities are all generated in the MicrosoftOperationsERPVE solution, which is API Managed. That means the items in the solution change as you make entities visible/hidden, but it is still a managed solution that you can take dependency on. The standard ALM flow would be to just take a standard reference to a virtual entity from this solution with the **Add existing** option in the ISV solution. It will then show as a missing dependency of the solution and be checked at solution import time. During import if a specified virtual entity does not yet exist, it would automatically be made visible without needing additional work.

To consume virtual entities:

1. Create a separate solution as usual in Dataverse, which will contain the consuming logic.
2. Select **Entities** > **Add Existing**. Select the virtual entity that you want to reference from the list.
3. When prompted to select assets to add, select any forms, views, or other elements that you want to customize, then select **Finish**.

From the development tooling, existing elements such as forms can be modified for the virtual entity. Additionally, new forms, views, and other elements can also be added.



When the solution is exported, it will contain hard dependencies on the virtual entity generated in the MicrosoftOperationsERPVE solution.

NOTE

Can you tell us about your documentation language preferences? Take a short survey.

The survey will take about seven minutes. No personal data is collected (privacy statement).

Power Apps portals with Finance and Operations

2/18/2021 • 3 minutes to read • Edit Online

NOTE

Effective November 2020:

- Common Data Service has been renamed to Microsoft Dataverse. For more information, see Power Automate Blog.
- Some terminology in Microsoft Dataverse has been updated. For example, *entity* is now *table* and *field* is now *column*. For more information, see Terminology updates.

This topic will be updated soon to reflect the latest terminology.

IMPORTANT

This functionality requires version 10.0.12 for Finance and Operations apps, while service update 189 is required for Dataverse. The release information for Dataverse is published on the latest version availability page.

Power Apps portals will enable create, update, and delete (CRUD) operations to Finance and Operations entities that are available as virtual entities in Dataverse. This topic explains the scenarios that are implemented in Power Apps portals for Finance and Operations apps.

Anonymous access from Power Apps portals

Collaboration scenarios in business processes such as bidding or onboarding of prospects in Finance and Operations require that external users participate from the Power Apps portal, even though they aren't users in Finance and Operations apps. The simplicity of anonymous access is appealing in these types of scenarios because the users, who might not be Finance and Operations apps users, don't have to sign in. However, they are expected to perform CRUD operations in Finance and Operations to complete any meaningful tasks in the business processes.

To ensure that only the required entities are enabled for anonymous access, a user in Finance and Operations must be designated as the user who is used for anonymous access. This designation is configured in the **Anonymous portal access user ID** field on the **Virtual entity** tab on the **System parameters** page (**System administration > System parameters**). The designated user can then be assigned to duties and security roles to control access to specific data that must be made available to all users who will interact anonymously from the Power Portal.

Note that because this scenario involves anonymous access, the only user context that matters, from a security perspective, is the user who is designated in the **Anonymous portal access user ID** field.

Authenticated access from Power Apps portals

Fully authenticated user access from Power Apps portals to Finance and Operations lets users in Finance and Operations also interact from Power Apps portals. A user who signs in to the Power Apps portal is also a known user in Finance and Operations who has appropriate security roles based on job requirements. These roles govern the security access to data for the authenticated user in Power Portal. In addition, any Finance and Operations user that is expected to also use Power Apps portal to access Finance and Operations data must also belong to the **CDSVirtualEntityAuthenticatedPortalUser** security role. This provides an additional layer of security and also provides a way to know the total users that are authorized to access from Power Apps portals.

Because Power Apps portals authentication is linked to the Contacts entity in Dataverse, a mapping must be established between the Dataverse contact and the corresponding user in Finance and Operations. This mapping can be done by adding entries to the **msdyn_externalportalusermapping** entity. From a security perspective, the scope of virtual entities that are made available to authenticated users must be configured as **Global** in the Power Apps portal.

When authenticated users from a different tenant need to be added to Finance and Operations as users, you must use the Create new user process in Finance and Operations. This process adds cross-tenant users as Microsoft Azure Active Directory (Azure AD) business-to-business (B2B) guest users.

> **NOTE**
>
> Access from the Power Apps Portal will fail if the user (authenticated or anonynous) has been assigned the System administrator role in any Finance and Operations apps.

Finance and Operations virtual entities FAQ

2/18/2021 • 7 minutes to read • Edit Online

NOTE

Effective November 2020:

- Common Data Service has been renamed to Microsoft Dataverse. For more information, see Power Automate Blog.
- Some terminology in Microsoft Dataverse has been updated. For example, *entity* is now *table* and *field* is now *column*. For more information, see Terminology updates.

This topic will be updated soon to reflect the latest terminology.

IMPORTANT

This functionality requires version 10.0.12 for Finance and Operations apps, while service update 189 is required for Dataverse. The release information for Dataverse is published on the latest version availability page.

This topic is a collection of frequently asked questions about Finance and Operations virtual entities.

Do Tier 1 Finance and Operations environments or demo topologies work?

Yes, Tier 1 and DEVTEST and DEMO topologies should work.

What version of Finance and Operations do I need?

10.0.12 is the minimum version that is required.

Can a solution from an independent software vendor (ISV) take a dependency on virtual entities? What does the application lifecycle management (ALM) look like?

Yes. The virtual entities are all generated in the MicrosoftOperationsERPVE solution, which isAPI-managed In other words, the items in the solution change as you make entities visible or hidden, but the solution is still a managed solution that you can take dependency on. The standard ALM flow just takes a standard reference to a virtual entity from this solution with the **Add existing** option in the ISV solution. Missing dependency of the solution will be checked when the solution is imported and during import, if a specified virtual entity doesn't yet exist, the virtual entity is automatically made visible.

Which entities from Finance and Operations do users see in the catalog in Dataverse?

Generally, users see all entities where **IsPublic** is set to **Yes**. These entities are the same entities that are currently visible in Open Data Protocol (OData).

Do all Microsoft Power Platform users have to be users in Finance and Operations?

Any **interactive user** of Microsoft Power Platform who tries to access Finance and Operations data through a virtual entity must also exist as a user in Finance and Operations. Therefore, technically, not *all* users have to be users in Finance and Operations. Only those users who access Finance and Operations data through virtual entities must be users in Finance and Operations.

A **S2S application user** can also be used to call into virtual entities. For this kind of integration, the application user must be set up in **System administration > Setup > Configure Azure Active Directory Applications**. This allows for applications to integrate with Finance and Operations using virtual entities.

Where do I find the catalog entity?

In the **Advanced find** window, the entity is named **Available Finance and Operations Entities**.

Is there a way to specify a company when I perform data operations on a virtual entity?

Yes. Although the company is implicit in Finance and Operations, it's an explicit field on each company-striped entity in Dataverse. You can use either the **Company Code** field, where the value is a four-character string, or the **Company** field, which is a lookup to cdm_Company. Both approaches provide the same information.

Can I change the prefix for the virtual entities?

No. All Finance and Operations virtual entities should be generated in the MicrosoftOperationsERPVE solution, and they should all have the "mserp_" prefix. This prefix should not be changed. If you have a scenario where you believe the prefix has to be changed, you should share that scenario with Microsoft.

How can I filter data in an app that is created by using Power Apps, based on the current user or any other dynamic criteria, such as today-10?

You can write a pre-operation plug-in on the RetrieveMultiple message of the entity and change the criteria on the query in it. Alternatively, you can write a post-operation plug-in to filter the results before they are returned.

Can I pin a model-driven app into Finance and Operations?

No, it isn't currently possible to pin a model-driven app into Finance and Operations.

How can I show, in the same grid, data from multiple virtual entities that are joined to a physical entity record in Dataverse?

This approach isn't currently possible in Dataverse.

How do I add subcomponents in the new Power Apps experience?

As in the previous Power Apps user interface (UI), you must redo the **Add Existing** operation. After the solution is selected, and Customer Groups has already been added as an entity, follow these steps.

1. Select **Add existing** > **Entity**.
2. Select customer group entity, and then select **Next**.
3. Under **Components**, select **Select components**.
4. Select the fields, relationships, and forms that you want, and then select **Add**.

If I want a default value to be entered in a field during pre-create, will an initValue on the data entity work?

Yes. Here is the order of calls:

1. Dataverse sends a create or update message.
2. All the existing logic on the Finance and Operations entity and backing tables is invoked. This logic includes default value entry that might change values.
3. Dataverse sends another Retrieve (single) message to get the latest copy of the data, including any fields that default values were entered for.

Can I debug Finance and Operations when we do a create, read, update, and delete (CRUD) operation from Dataverse? If so, which process do I have to attach?

Yes, to debug in Finance and Operations, open Visual Studio as an admin. Typically, Finance and Operations apps run under w3wp.exe as a process. However, when you open Visual Studio as an admin, IISExpress.exe is automatically opened, and Finance and Operations is hosted there. You can attach to IISExpress.exe (or to w3wp.exe if not running Visual Studio as an admin). To set breakpoints in the virtual entity code, find the **CDSVirtualEntityAdapter** and **CDSVirtualEntityController** classes. The adapter class is the first class that is called, and it only does serialization/deserialization. It then delegates to the controller class to do the actual queries. Therefore, the controller class is usually the easiest place to put breakpoints.

Does the form business logic in Finance and Operations get called through virtual entities?

Finance and Operations business logic that resides on forms isn't invoked through virtual entities. Instead, you should expect the same behavior that you get through OData access to the same entities. The expectation is that an entity that is exposed to OData (that is, **IsPublic** is set to **Yes**) has appropriate protections to ensure that data

can't be corrupted. If any entity lacks this protection, that situation represents a bug in the entity. If you see differences in entity behavior between OData and virtual entities, that situation represents a bug in the virtual entity feature.

If I develop a new Finance and Operations entity and want to see it in Dataverse, do I have to select Refresh entity list in Finance and Operations? Do I have to do anything in Dataverse?

In theory, no, you don't have to refresh the entity list. At most, you might have to either reset Internet Information Services (IIS) or restart IIS Express, depending on where Application Object Server (AOS) is running. The fact that the list of entities is accurate is cached in SysGlobalObjectCache, which is a per-process cache. Any time that this cache doesn't indicate that the list is accurate, the list is rebuilt. The rebuild process takes about five seconds. Therefore, when you restart your AOS process (w3wp.exe or iisexpress.exe), the list will be accurate the next time that you query it from Dataverse. Additionally, although recompilation *should* flush the SysGlobalObjectCache cache, it might not. In that case, an AOS restart will flush it.

Do you have guidance on when to use a virtual entity and when to use dual-write?

Dual-write is only provided for a few key data entities where the data needs to be natively in Dataverse. Those data entities are not available as virtual entities.

When adding records using virtual entities is there any way to use number sequences?

Yes, if the Finance and Operations entity can auto generate number sequences, then it will work the same way from the virtual entity.

Why does 'search view' not work in Power Apps?

If there are no fields added in the quick find view for the entity, then the search box does nothing. The workaround is to add one or more fields of the entity to the quick find view.

Mobile platform resources

2/18/2021 • 11 minutes to read • Edit Online

By using mobile apps, you can reuse business logic and modeling. Mobile apps enable rich offline and mobile interactions, and provide an easy-to-use designer experience. Developers can create simplified forms in Microsoft Visual Studio and then design mobile apps that expose this functionality. The mobile platform makes it easy to change the forms and mobile app definitions to include customizations that are made to your cloud app.

- Tutorial 4: Adding a lookup to the create new sales order action
- Tutorial 5: Adding a lookup and hiding pages using mobile business logic

Common configurations

These topics describe some common customizations that you can add to your mobile app.

- Localize mobile workspaces
- Help secure mobile workspaces
- Set up clickable fields
- Set up mandatory fields through workspace classes
- Display item counts in a field

Client-side development

Client-side APIs are used in the business logic file, which provides an extensibility layer to the mobile workspace that allows for customization. Some things that you can access and influence through the client-side APIs include:

- Metadata
- Runtime control/page instances
- Business data
- Offline-first business behaviors
- Layout and style

The process for client-side development is described in these topics:

- Client-side design APIs overview

- Business logic events overview
- Client APIs

You can download a sample business logic file (with a .js file name extension) for the Reservation management workspace. Go to Dynamics365-for-Operations-mobile-FleetManagementSamples, open the **business_logic folder**, and locate the FM.js file

Server-side development

Workspace attributes and classes are used to create, configure, and publish workspaces on the server. These server-side X++ APIs can be used instead of using the task recorder-based mechanism to build a workspace. Workspaces created using either mechanism can then be styled and augmented using the client-side APIs.

Server-side development is described in these topics:

- Workspace class overview
- Server APIs (X++)

You can download the sample project (with an .axpp file name extension) for the Fleet Management mobile app. Go to Dynamics365-for-Operations-mobile-FleetManagementSamples and download the **FMMobileApp.axpp** file.

Debugging during development

During development it can be useful to attach a debugger to get more detailed information and insight into what is happening in the background. A web debugger can be used with the client-side JavaScript logic and styling and the Visual Studio debugger can be used with the server-side X++ business logic.

Debugging the client side

Prerequisites

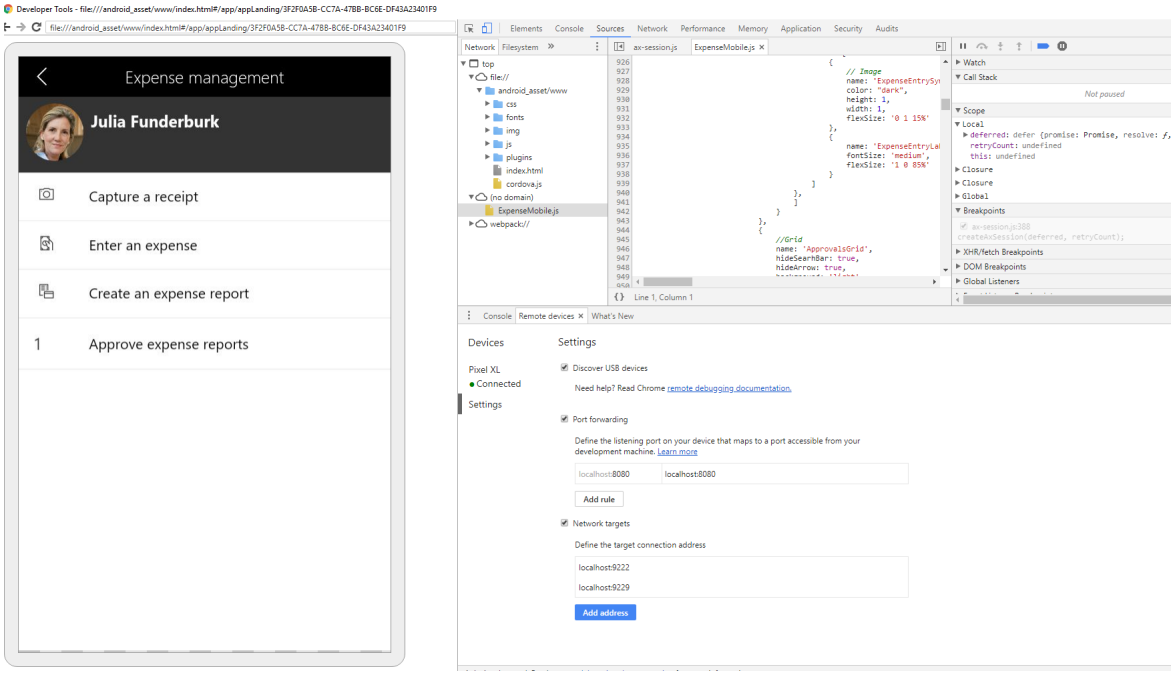
- Android device plus PC
- Azure-hosted development machine (so the mobile device can point to it)

Steps to debug the client side

1. On the web client that is exposed by the Azure-hosted development machine, ensure that there are mobile workspaces published for the Finance and Operations app. For information about publishing a mobile workspace, see Publish mobile workspaces.
2. Install the Android debug apk for the Finance and Operations app on an Android device:
    - One time only, allow the installation of apk files - Go to **Menu** > **Settings** > **Security** and then check **Unknown Sources** to allow the phone to install apps from sources other than the Google Play Store.
    - Uninstall the Finance and Operations app - Ensure that any previous version of the Finance and Operations app has been uninstalled.
    - Download the apk file - From the device's browser, navigate to the latest Finance and Operations Android debug apk on GitHub and click **Download** (or use this direct link to the file).
    - Install the Finance and Operations apk file - Confirm install of the Finance and Operations app via the apk file.
    - Run the debug Finance and Operations app on the device and sign in.
3. Connect to the device from the debugging machine.
    - On the Azure-hosted development machine or a separate PC, follow Android developer instructions to Get Started with Remote Debugging Android Devices. You can also find a wide selection of instructional videos on YouTube by searching for Chrome for Android remote debugging.
4. After you connect the debugger, find the active tab on your device. You may need to click **View more**

tabs on Android. One of the tabs should look similar to `/www.index.html#/app/appList` or `/www.index.html#/app/app_landing`.

Expand the nodes to find the workspace JavaScript, such as **File** > (no domain) > **ExpenseMobile.js**. Click the JavaScript file to view it and add breakpoints.



5. Reflect the mobile device on your desktop so that you can interact with it on the desktop screen.
6. Go to through the desired workspace and forms.
7. If breakpoints are encountered, then the browser developer tools will allow you to control the flow of execution and see the values and parameters being passed.
8. To change styling at runtime, use the elements tab to alter the styling. This will help you determine what elements JavaScript should target and how those elements should be styled.
9. If a needed change is identified, make those changes in JavaScript, and then push those changes into the environment.
10. If more changes or validation is needed, repeat the process.

Debugging the server side

Prerequisites

- Azure-hosted development machine (so the mobile device can point to it)

Steps to debug the server side

1. On the web client exposed by the Azure-hosted development machine, ensure that there are mobile workspaces published for the Finance and Operations app. For information about publishing a mobile workspace, see Publish mobile workspaces.
2. Open the app on your device, point to the Azure-hosted development machine, and sign in.
3. Open Visual Studio on the Azure-hosted development machine and attach the debugger to the w3wp process.
4. After you connect the debugger, find the desired business logic, and insert breakpoints as needed.
5. Either use the app on your device as usual, or reflect the mobile device on your desktop so you can interact with it on the desktop screen.
6. Navigate through the desired workspace and forms.

7. If breakpoints are encountered, then Visual Studio will allow you to control the flow of execution and see the values and parameters being passed.
8. If a needed change is identified, make those changes in X++, and push those changes into the environment.
9. If more changes or validation is needed, repeat the process.

Troubleshooting the app

[Resolved] - No support for iOS14 due to issues with date and time controls

Version 2.2.8 of the Finance and Operations mobile app fixes the known issues with the date and time pickers in iOS14. Ensure that you have the latest version of the app if you are experiencing issues running the application on iOS14.

The Mobile Client app is not working on particular devices

Sometimes the cache associated with the app becomes corrupt or obsolete and needs to be cleared. Unfortunately, the only way to clear the data associated with the app is to uninstall the app. To completely uninstall the app, don't use the "long-press wiggle and x on the app icon" method. Instead, completely uninstall the app by navigating to **Settings** > **General** > **iPhone Storage** > **Finance and Operations (Dynamics 365)**, and then click **Delete App**. After 10-15 seconds, the app can be reinstalled.

On Android devices with non-English regions, the comma can't be used as the decimal separator in an amount field

On Android devices with non-English regions, using a comma as the decimal separator is standard practice. Problems using a comma in an amount field is an Android-specific problem because iPhone works as expected. On Android, use of the comma in an amount field is a problem with the default "gboard" keyboard and some other keyboards. Installing the SwiftKey keyboard (published by Microsoft) allows the entry of commas just like on iPhone: SwiftKey Keyboard.

Change needed for ADFS to support Mobile Client in on-premises environments

If Active Directory Federation Services (ADFS) is in use on the domain and the environment is on-premises, then **ADFS must be configured to provide a regular forms-based authentication screen** instead of using Windows Integrated Authentication (WIA). The Finance and Operations apps for iOS and Android require the regular forms-based authentication screen. ADFS should be configured to only provide WIA for browser clients (use cases). For more information, see Configure intranet forms based authentication for devices that do not support WIA.

Using multi-factor authentication with the Finance and Operations app

The Finance and Operations (Mobile Client) app facilitates user authentication with Azure Active Directory (Azure AD) by presenting the Azure AD sign-in web page within an embedded browser. After a successful sign in, it will retrieve the user token from the cookies and use that when communicating with the user interaction service that it shares with the web client. Some multi-factor authentication mechanisms that involve switching to a different app on the same device will cause the embedded browser to close, so the sign in will fail. The workarounds for this include:

- Different device - Use a different device for the multi-factor authentication response so the app remains active on the original device.
- Multi-factor authentication via phone call - Use a phone call for the multi-factor authentication response so an app switch is not needed.
- Use the "touch and hold" gesture on the authentication notification and then select the **Accept** option. Because the notification acceptance will not require an app switch, the sign in will proceed as usual.

If there are continued problems with MFA authentication, it is helpful to submit the Microsoft Authenticator app

logs and provide support with the resulting Incident ID.

Intune support and conditional access

The Finance and Operations (Mobile Client) app does not have Microsoft Intune policies implemented, so it does not support Intune. Manually adding the app (following Add iOS store apps to Microsoft Intune) is also not supported because the device identifier cannot be passed.

Trouble signing out of the app and signing in with new credentials

If you experience trouble signing out of the app and signing in with new credentials, then you might need to "forget old credentials" on the Azure AD sign-in screen.

- To sign out of the app, follow these steps:
  - Open the app.
  - Sign out of the app.
  - Force close the app.
- To forget old credentials, follow these steps:
  - Open the app.
  - Connect to the server.
  - On the Azure AD sign-in screen, if there are saved credentials, select the ellipsis (...) button on that card, and then select **Forget the credential**.
  - Force close the app.
- To sign in to the app, follow these steps:
  - Open the app.
  - Connect to the server
  - Sign in using the Azure AD sign-in screen.

Troubleshooting app content

I can't figure out how to build or change something in my Mobile Client content

There are many resources that you can leverage to figure out how to build or change content for the Mobile Client.

- Review the documentation provided in the Help system.
- Review the Fleet Management Samples for examples.
- Publish and review the Expense Management workspace, and other standard workspaces, for examples. Demo data for the USSI company is useful when using the Expense Management workspace. The forms and X++ code that make up the Expense Management workspace can be found in the Application Explorer by searching for the "ExpenseMobile" prefix.
- Leverage the Dynamics Community forums by searching for answers and asking questions when needed.

Tips for workspace creation and modification

Here are some tips for workspace creation and modification:

- Create new simplified forms for recording rather than recording large complex forms.
- After recording a form, you have to close the form instead of clicking **Done**, otherwise the form remains open.
- Verify that recordings are correct using the "Job steps".
- Play back recordings using task recorder playback to verify them.
- Don't navigate to a page before starting the recording, because the context from the previous page might need to be captured.
- If you re-record a page with a grid then you need to re-record the link to the Details page because otherwise it won't be there.

- When recording an action, change the value of the fields to add them. When recording is complete, close the form instead of clicking **Save**.
- Lookups in mobile are list pages that have been recorded. **Select field data** and **Select field to display** are used to select the **field to use as the value to save** (data) and the **field to show the user** (display).
- When adding a lookup field, select a value in a lookup instead of just adding the lookup field. This will ensure that the correct value is selected.
- If you re-record a lookup, all the references also need to be re-recorded because the GUID for the lookup will change.
- If you want to add a field to a page, you need to add all the fields again, because the list is cleared at the beginning of each edit. This is a limitation of task recorder. Note that reordering is also not possible.
- In the workspace XML, GUIDs are used as references to forms and controls instead of names. GUIDs are used to ensure uniqueness, but this comes at the cost of maintainability. Those GUIDs are regenerated on each modification, so partial edits are very difficult. The use of GUIDs would be very costly to change, so it is unlikely that changes would be made in the future to use simpler string name references.
- Relationships between form datasources need to be via RecordId instead of string. For example, primary keys of the datasources should not be strings.
- Customers and partners can fork a workspace by creating a copy of it and then make changes as needed.
- There is no check box in mobile. You have to manually bind the field to a Yes/No enum in JavaScript.

Common problems with form recordings

Avoid using forms with these patterns and controls when creating workspace recordings:

- Datasources with DelayedJoin (common on transaction forms).
- FastTabs (common on existing forms).
  - Recorded forms should not have FastTabs because the FastTabs expansion state can interfere with playback.
- Any user interface (UI) that has state, like an expandable or hide/show region.
- There is no check box in mobile. You have to manually bind the field to a Yes/No enum in JavaScript.

Get started with the mobile platform

2/18/2021 • 2 minutes to read • Edit Online

After you acquire a development environment, complete the following procedures to get started with development.

Get the Fleet Management mobile forms

We have created new, purpose-built forms in the **Fleet Management** module. These forms are used specifically for the mobile app and aren't meant to be used through the web client.

1. Download the file that contains the Fleet Management project (.axpp file).
2. Extract the contents of the zip file to a temporary location on the development computer.
3. Import the project (.axpp) file by using Microsoft Visual Studio (click **Finance and Operations** > **Import Project**).
4. After you've imported the project file, build the project or module.

Get the sample workspace

We provide a sample workspace for Reservation management. This workspace is based on the **Fleet Management** module.

1. Download the file that contains the sample workspace (.xml file).
2. Sign in to your non-production client. (You must sign in as an administrator.)
3. In the address bar, add **&mode=mobile** to the end of the URL, and then press Enter.
4. In the client, go to **Settings** > **Mobile app**. The mobile app designer will appear docked next to the client.
5. Click the **Overflow** button (...), and then click **Import**.
6. Click the **Browse** button that appears at the bottom of the page.
7. In the file selection dialog box that appears, select one of the XML files that you previously extracted from the zip file.
8. After the app has been loaded into the mobile app designer, click **Done** at the bottom of the page.
9. Click **Publish workspace**.

Get the mobile app

The mobile app is being made available for the most popular mobile operating systems. You must have a Dynamics 365 Unified Operations instance and valid user credentials in order to log in to the app.

- Android (available now) - Finance and Operations mobile app on the Google Play Store
- iPhone (available now) - Finance and Operations mobile app on the iTunes apps store

You're done! Launch the app from your mobile device to see the sample workspace.

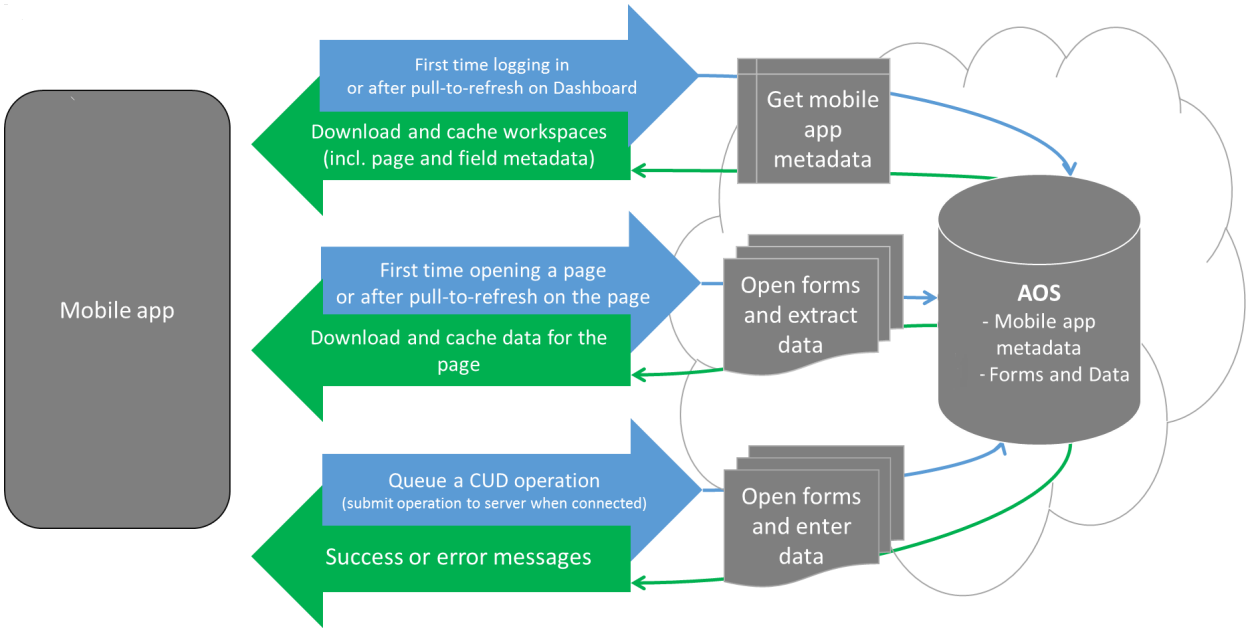
The survey will take about seven minutes. No personal data is collected (privacy statement).

Architecture and design considerations for the mobile platform

2/18/2021 • 3 minutes to read • Edit Online

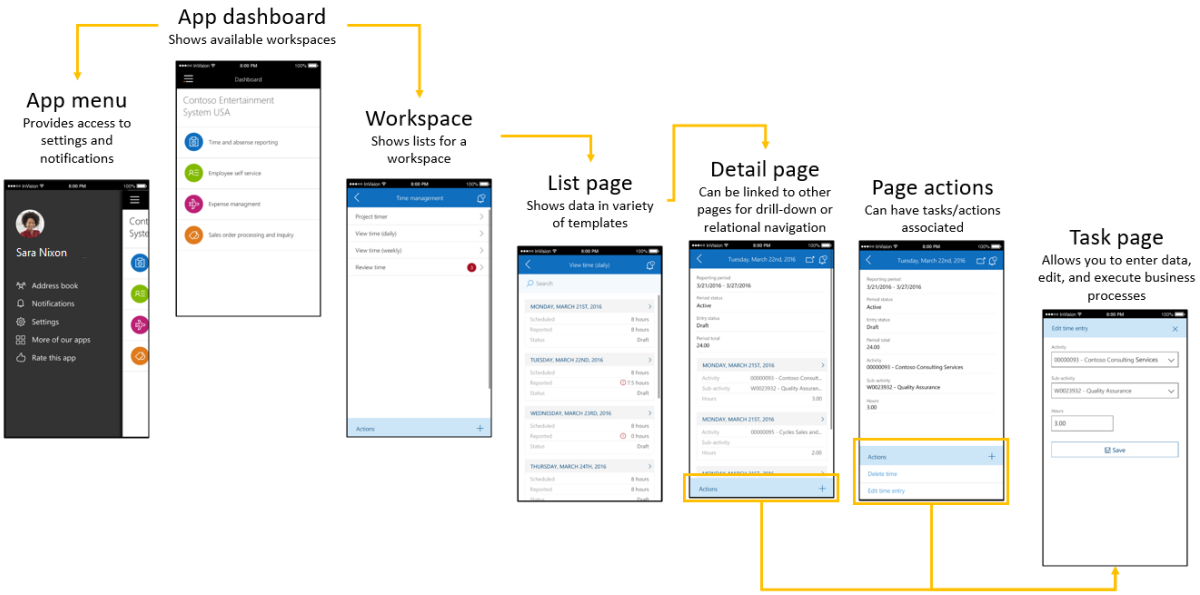
The mobile app communicates with Application Object Server (AOS) to get the metadata for the mobile workspaces (and the pages and the fields that appear on the page), and to get the data for the fields on the pages. Each time that the mobile app requests data for a page, AOS creates a new session that uses the context of the user who is using the mobile app. AOS then uses the user's context to open the corresponding forms (by using the corresponding menu items). AOS can open multiple forms in quick succession and perform actions on those forms (for example, filtering, opening FactBoxes, changing tab pages, and clicking buttons). Any business logic on the forms is also run as usual. Through that process, AOS collects the data values from the requested fields and then sends that data back to the mobile app.



The mobile app platform doesn't assume connectivity to Finance and Operations apps. Activities such as navigation, data view, and data entry don't require server connectivity after data has been cached.

Understanding navigation in the mobile app

Navigation in the mobile app consists of four simple concepts: the dashboard, workspaces, pages, and actions.



- When you start the app, you land on the **dashboard**. On the **dashboard**, you can see a list of **workspaces** that are published in your environment.
- In each **workspace**, you can see a list of **pages** that are available for that workspace.
- On a **page**, you can view data that is collected from one or more forms.
- From a **page**, you can navigate to other **pages** for related data, such as an entity details or lines.
- On a **page**, you can see a list of **actions** that are available for that page.
- **Actions** let you create or edit existing data.

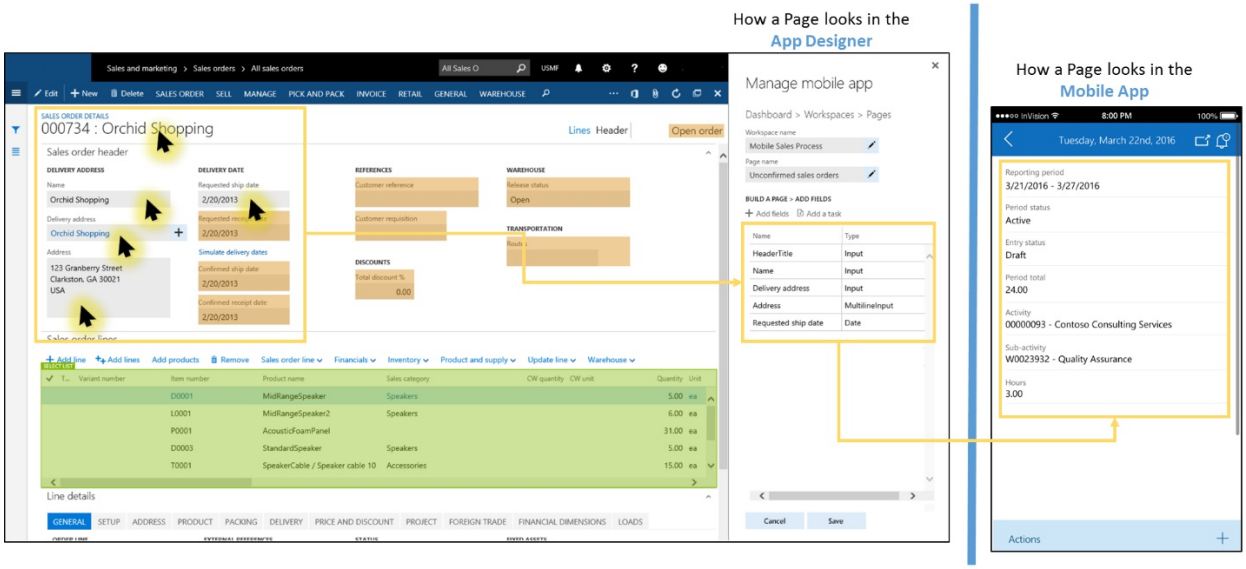
Notes

At any time, you can pull-to-refresh in the mobile app to make the mobile app update its data or metadata. After you edit an existing workspace or publish a workspace, be sure to pull-to-refresh in the mobile app, in either the list of workspaces (if you added a workspace or business logic) or the list of pages (if you modified a page or an action). Workspaces that have been published are visible to all users. In Platform update 3, menu item security automatically hides pages that the user doesn't have access to. If a user doesn't have access to any pages in a workspace, the workspace itself is hidden.

Using the mobile app designer

The mobile app designer lets you select the specific data fields from forms that should appear in the mobile app.

A mobile workspace can be created through designer, using X++ attribute APIs or a combination of both. See Configure workspaces by using the SysAppWorkspace class for more details on using X++ APIs for building a mobile workspace.



1. Open the client.
2. Go to **Settings** > **Mobile app**.
3. Create a new workspace, or select an existing workspace to edit.
4. Specify the name of the workspace, an icon, and a color.
5. Add pages to the workspace, or edit an existing page.
6. Specify the name of the page.
7. Click **Select Fields** to select the data fields to add to the page.
8. Open the forms that have the data fields that you want to add, and then click the yellow plus sign (+) that appears next to the fields. The fields are added in the order that you select them in. You can add fields from multiple forms, in any order.
9. When you've finished selecting fields, click **Done**.
10. If you've added a field list to the page, you will see that the **List** type is specified for one of the items in the field list. You can optionally add a details page for items in that list by following these steps:
    a. Select the list by clicking on it in the designer.
    b. Click **Add details page**.
    c. Repeat steps 6 through 10 as you require.

Refreshing the app after you make changes

TYPE OF CHANGE	DESCRIPTION

TYPE OF CHANGE	DESCRIPTION
New workspaces, deleted workspaces, or changes to the name, color, or icon of a workspace	Pull-to-refresh from the main landing page (dashboard) of the app, where you see the list of workspaces. 
TYPE OF CHANGE	DESCRIPTION
All other changes (new or changed pages or actions, or changes to business logic)	Pull-to-refresh from the workspace that has the edited pages or actions.

Business logic events

2/18/2021 • 2 minutes to read • Edit Online

Mobile workspace business logic events provide places for developers to specify workspace configuration to enhance capability, and implement business-scenario-specific behaviors. All mobile business logic executes in the process of the mobile app, and business logic execution flow is controlled by the Operations mobile app framework.

Code that executes in business logic can make runtime modifications to the metadata of Pages, Actions, and Controls. These runtime modifications overlayer the static metadata that is cached in the app, but the modifications do not directly change the cached static metadata, nor do they affect the static metadata that is stored on the server. These runtime modifications only persist until the app is closed.

Code that executes in the business logic of the app can make runtime modifications to business data that is stored in the app. These modifications (when performed according to correct practices) participate in the normal data processing framework as other business data in the app. That means adhering to the offline-first capabilities and asynchronous save behaviors provided by the framework.

Page design guidelines

2/18/2021 • 7 minutes to read • Edit Online

Before you begin to use the designer to build pages and actions, it's important that you plan the overall design of the mobile workspace that you want to build. We recommend that you orient your design around the entities that you plan to use in the mobile workspace. Don't begin by thinking about the forms that you want to use. From the perspective of the mobile app, the forms are just a mechanism for retrieving data, and the run-time UI behavior of a form isn't applicable to the mobile app. Therefore, you should first identify your entities and the relationships between them. For each entity, the following questions will help you decide how you should design your forms and pages.

How do I create a list view for an entity in the mobile app?

1. Identify or create a form in the web client that contains a grid for the entity.
2. Make sure that the grid is bound to the table that represents the entity.
3. Make sure that the form has a menu item that is root-navigable.
4. Make sure that the form can be opened directly via a URL that includes the menu item parameter.
5. Make sure that the filter pane enables the grid to be filtered based on the desired fields.
6. In the designer, create a page for the entity.
7. In the designer, put only a list on the page.
8. In the designer, put the desired fields in the list on the page.

What if I don't want a list view for this entity?

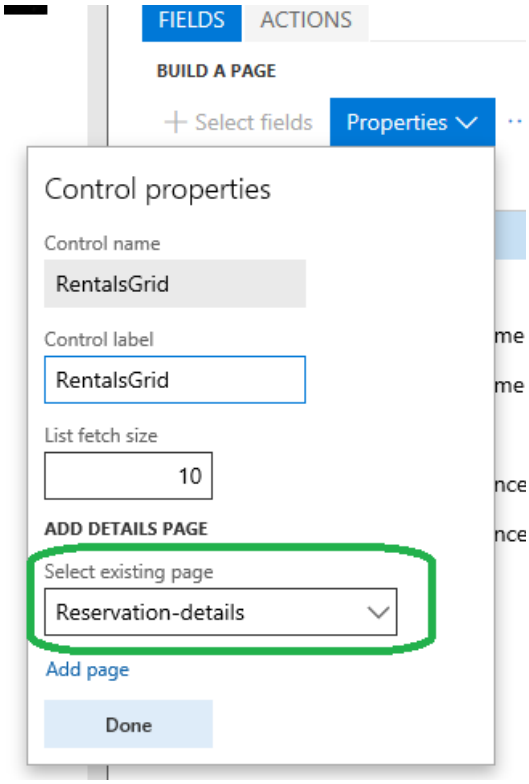
If you want just a details view for an entity, it's likely that the entity is a singleton for a given context (such as a given user or a given company). This pattern applies, for example, to a details view for an employee's own profile in a self-service workspace or a details view for the company context that is used for the current session. See the guidelines for creating a page for a details view.

How do I create a details view for an entity in the mobile app?

1. Identify or create a form in the web client that contains the details view for this entity.
2. Make sure that the Master Root Data Source on the form is bound to the table that represents the entity.
3. Make sure that the form has a menu item that is root-navigable.
4. Make sure that the form can be opened directly via a URL that includes the menu item parameter.
5. In the designer, create a page for the entity.
6. In the designer, put the desired fields on the page.

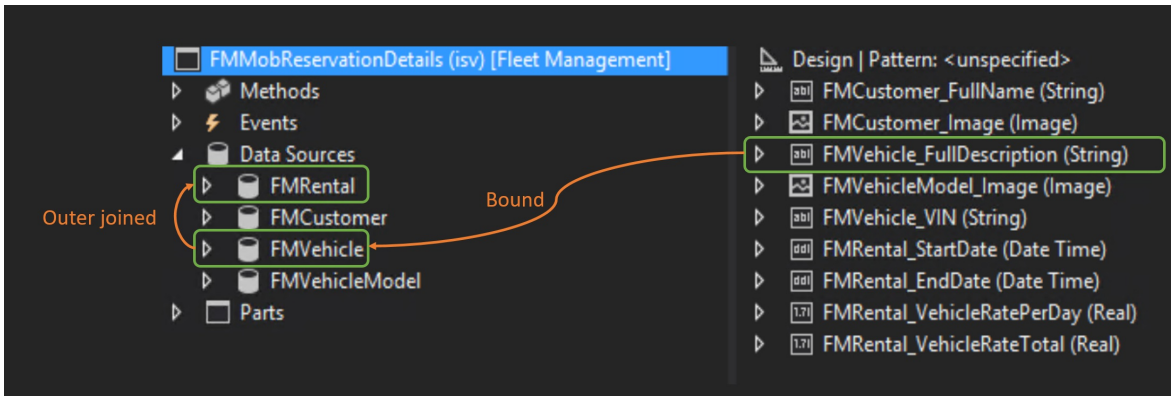
How do I create list-to-details navigation for an entity in the mobile app?

1. Make sure that you've created both a list view page and a details view page for the entity by using the designer.
2. Make sure that the entity for the list view is the same as the entity for the details view. In other words, the table that is bound to the grid on the form that is used for the list view must be the same table that is the Master Root Data Source on the form that is used for the details view.
3. Make sure that the form that is used for the details view can be filtered on a unique key field by using the filter pane.
4. In the designer, make sure that the list view page is linked to the details view page. Click the list, open the properties, and then set the details view page by using the lookup.

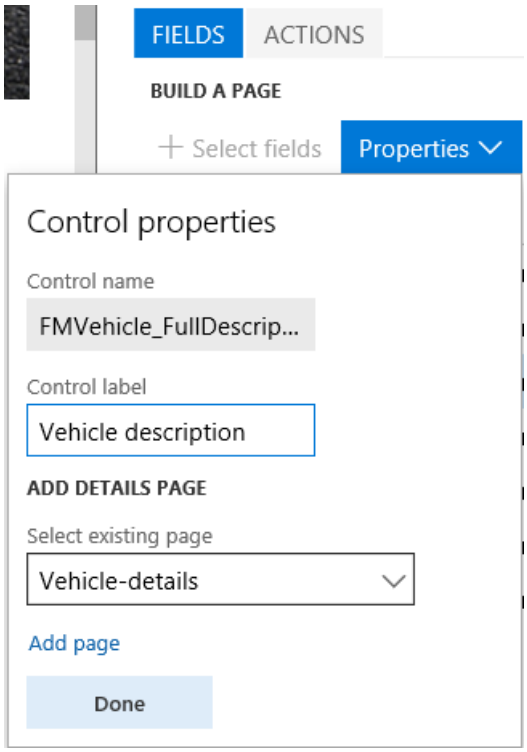


How do I add a reference field that enables navigation to a related entity?

1. Make sure that either a list view page or a details view page exists for the entity that contains the reference.
2. Make sure that the page contains the reference field from the entity that is being referenced.
3. Make sure that the referenced field is bound to the referenced entity's data source, and that the referenced entity is *outer joined* (1-0..1) or *inner joined* (1-1) to the data source for the entity that contains the reference. For example, in the following illustration, FMRental is the entity that contains the reference, and FMVehicle is the referenced entity.



4. Make sure that you've created a separate details view page for the entity that is being referenced.
5. Make sure that the reference field has been added to the page.
6. In the designer, make sure that the reference field has been linked to the details view for the referenced entity. For example, in the following illustration, Vehicle-details is the details view page for the referenced entity.



How do I add a list that contains items from a related entity to a details view page?

How do I make the list show up in-line in the details view?

1. Identify or create a form in the web client that contains the details view for the entity, and make sure that the form adheres to the guidelines in the "How do I create a details view for an entity in the mobile app" section.
2. Make sure that the form contains a grid that is bound to the table that represents the related entity.
3. Make sure that the table for the related entity is *active joined* to the table for the entity that contains the reference.
4. Create a details view page that contains the desired fields for the entity, and that also contains a list that has the desired fields from the related entity.

How do I make the list accessible from a link in the details view (instead of in-line)?

1. Identify or create a form in the web client that contains the details view for the entity, and make sure that the form adheres to the guidelines in the "How do I create a details view for an entity in the mobile app" section.
2. Make sure that the form contains a grid that is bound to the table that represents the related entity.
3. Make sure that the table for the related entity is *active joined* to the table for the entity that contains the reference.
4. Use the form to create a details view page that contains the desired fields for the entity.
5. Use the same form to create a separate list view page that contains only a list that has the desired fields from the related entity.
6. On the details view page, add a PageLinkControl that links to the list view page. Currently, you must use business logic to add the PageLinkControl. The following example show the code that Fleet Management uses.

```
function main(metadataService, dataService, cacheService, $q) {
    return {
        appInit: function (appMetadata) {
            metadataService.addLink(
                'Customer-details', // the Page to add the link to
                'Customer-rentals', // the Page the link goes to
                'cust-rentals-nav-control', // unique name for the control
                'Rentals', // text to display for the link in the UI
                true, // show/hide the count for items on the linked page
                );
        },
    };
}
```

How do I read data from a hidden page?

1. Identify or create a page that contains the controls with the data that you want.
2. Refer to the following code example, which hides the page from the navigation menus, and accesses data on the page using the provided APIs. Note that 'My-Hidden-Page' and 'My-Field-Id' are the names of the page and control, respectively, and can be found when viewing the corresponding page in the designer.

```
function main(metadataService, dataService, cacheService, $q) {
    myField1Value = ''; // This variable will be populated in appInit, and can then be used elsewhere
in the business logic.
    return {
        appInit: function (appMetadata) {
            var myHiddenPage = metadataService.findPage('My-Hidden-Page');
            if(myHiddenPage) {
                var dataPromise = dataService.getPageData(myHiddenPage.Id,'','',0);
                dataPromise.then(function (result) {
                    var myField1Id = metadataService.findControl(myHiddenPage, 'My-Field-1').Id;
                    myField1Value = result.data[myField1Id];
                }
            }
    };
}
```

How do I adjust the number of records returned in a list page using list fetch size?

The number of records returned in a list page is controlled by the **List fetch size** value. The default is 50 records. The **List fetch size** indicates the maximum number of records returned by a page when it first loads, and the maximum number of records returned when search is used to find a specific set of records. Be careful not to make the value too large or it may negatively affect the user experience.

1. In the Mobile App designer,add a page containing a grid and select some fields from the grid.
2. Click the **Grid** node and then click **Properties**.
3. The **Control properties** dialog box will contain a default fetch size of 50 records.
4. Adjust the fetch size as needed.

Action design guidelines

2/18/2021 • 6 minutes to read • Edit Online

Actions let users create, update, or delete data, and also run business processes on that data (such as *submit*, *confirm*, and *post*). A user who completes an action first supplies the data for the action (if the action accepts data input). When the user has finished supplying the data, the action is put into a queue of similar actions (which are sometimes referred to as *data sync operations*). If the device is connected/online, the queue is processed immediately. Otherwise, it's processed the next time that the device is connected. The queue is processed asynchronously and doesn't require the user's attention unless there is an error during data synchronization. Errors of this type can occur because of server-side data validation. Actions are powered by a server-side mechanism that resembles Task recordings. This mechanism extracts the user's input from the action and then automatically runs the business process steps on the server by using the input values that the user supplied. The mechanism automatically opens forms, clicks buttons on the forms, and enters the user's input into controls on the forms. This process of playing back the action against the forms on the server occurs asynchronously, against "headless" forms. The mobile app informs the user when the process is completed, and shows the user any info, warning, or error messages that the forms logged. When you design an action, it's important that you first consider what entity the action is related to. In the current framework, an action must operate on only one entity. An action should not update multiple entities at the same time. For example, an action to create a new sales order should create only the header for the order. It should not also try to create lines, because the lines are separate entities. When you decide to design the action, consider the following questions to determine how to proceed.

How do I design an action that enables an entity to be created?

1. Identify or create a list view page for the entity.
2. Make sure that the form that is used for the list view page includes a **New** button that can be used to add new records to the list.
3. Use the designer to create a new action for the page. While you're designing the action, be careful not to perform any unnecessary actions. Enter data only in those fields that should be available to the user, and click only those buttons that are required (for example the **New** button and the **Save** button).

How do I design an action that enables an entity to be edited?

1. Identify or create a details view page for the entity.
2. Make sure that the form that is used for the details view page includes an **Edit** button that can be used to edit the visible record.
3. Make sure that the form that is used for the details view page lets users open a specific record by applying filters in the filter pane.
4. Use the designer to create a new action for the page. While you're designing the action, be careful not to perform any unnecessary actions. Enter data only in those fields that should be available to the user, and click only those buttons that are required (for example, the **Edit** button and the **Save** button).

How do I design an action that enables an entity to be deleted?

1. Identify or create a details view page for the entity.
2. Make sure that the form that is used for the details view page includes a **Delete** button that can be used to delete the visible record.
3. Make sure that the form that is used for the details view page lets users open a specific record by applying filters in the filter pane.
4. Use the designer to create a new action for the page, and just click **Delete** as a part of the process of designing the action.

How do I design an action that enables a business action to be performed on an entity?

1. Identify or create a details view page for the entity.
2. Make sure that the form that is used for the details view page includes a **Delete** button that can be used to delete the visible record.
3. Make sure that the form that is used for the details view page lets users open a specific record by applying filters in the filter pane.
4. Use the designer to create a new action for the page, and just perform the steps that are required in the business action. You don't necessarily have to enter data in fields as part of the action. For an action such as *submit*, you just have to click the **Submit** button (and acknowledge any confirmations that appear).

How do I design an action that enables a field value to be set via a rich lookup?

Lookups for fields in the mobile app don't have a correlation to the advanced lookup behaviors in the cloud version of the app. Regardless of whether you have a custom lookup in the cloud vesion of the app or an automatic lookup that uses a simple query, the mobile app doesn't run existing lookup code when it must determine which UI to show the user. (Remember that the user might be offline while using the app, and server-side code isn’t run until the action is synchronized.) However, lookup/control overrides such as *modified* are run when the value is set by the mobile back end as it synchronizes the data from the action. When the mobile app detects that a field on an action was selected from a lookup field on a form, it shows a device-native combo box/list picker control, and populates the items by directly querying the backing table of that lookup field. The items in the list show the user data from the TitleField for records in that table. Follow these steps to add the rich lookup experience to your action. This lookup experience includes a full-page multi-column lookup selector that has offline search.

1. Identify or create a list view page for the entity behind the lookup. You can reuse existing list view pages that you've already created.
2. After you've finished designing the action, select the field to add rich lookup functionality to, and then click **Properties**.
3. In the **Control properties** dialog box, select the list view page that you identified or created in step 1, and set the other related properties.

Manage mobile app

Done

4. Save and publish your changes to the action.

If you don't see the property for the existing list view page or can't access the **Control properties** dialog box when you're designing your action, you might be using an older build of the app. In this case, you can still add rich lookup functionality by using a business logic file.

```
function main(metadataService, dataService, cacheService, $q) {
    return {
        appInit: function (appMetadata) {
            metadataService.configureLookup(
                // specify the name of the Action to add the lookup to
                'Add-Reservation',
                // specify the name of the Action's field to add the lookup to
                'FMRental_Customer',
                {
                    // specify the name of the Page for the Entity for the lookup
                        lookupPage: 'All-Customers',
                    // specify the Page's field which contains the value to set on the lookup
                // this value should be the same value you can type into the field on the Form
                        valueField: 'FMCustomer_RecId',
                        // specify the Page's field which contains the value to display to the user
                        // this value is only used for display. The value field is passed to the Form
                        displayField: 'FMCustomer_FullName',
                        // set this to true to enable the rich lookup
                        showLookupPage: true
                }
            );
        },
    };
}
```

How do I prevent an action from appearing in the list of actions for a page?

To prevent an action from appearing in the list of actions for any page, call the following code from the **appInit()** section of your business logic. In this code, **action-name** is the name of your action (as specified in the **Action name** field in the designer).

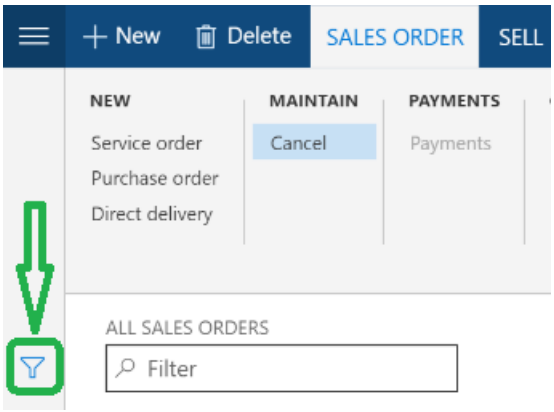
```
function main(metadataService, dataService, cacheService, $q) {
    return {
        appInit: function (appMetadata) {
            metadataService.configureAction('action-name', { visible: false });
        },
    };
}
```

Form design requirements

2/18/2021 • 6 minutes to read • Edit Online

This section provides valuable guidelines for building forms that work well with the mobile app.

- Each form must have an associated Display Menu Item.
  - The Display Menu Item's **Allow Root Navigation** property must be set to **Yes**. This setting enables the mobile framework to open the form that is referenced by the menu item.
- Each form must be directly accessible via its Display Menu Item.
  - To verify accessibility, open the menu item via a URL. Just append **&mi=** to the URL, where the value is the Application Object Tree (AOT) name of your menu item.
  - If the form doesn't open or show data when you access it in this way, the form won't work with the mobile app.
- Each form that shows data must have one Master Root Data Source.
  - This data source must be the first data source on the form (top-most in the designer).
  - This data source must not be joined to any other data sources.
- Each form must work with the data source filters.
  - After you open the form in the web client, open the filter pane by using the **Show filters** button.



Then click **Add a filter field**, and verify that the Master Root Data Source appears as the table for fields in the list of available fields. Other tables can also appear, but the Master Root Data Source **must** appear in this list. Otherwise, the mobile app won't enable searches and navigation that uses context.

  - Searching: The mobile app does online searches against data by using the Filters framework behind the scenes.
  - Navigation that uses context: The mobile app enables list-to-details navigation (and other context-aware navigation) by first opening the target form via the menu item and then using the Filters framework to show only the specified record context.
  - List-to-details navigation: The table that the grid is bound to on form A (the list form) must be the Master Root Data Source on the details form (form B). When a user selects a record in the list on form A, the mobile framework navigates with record context by applying filters on form B that uniquely identify the record.

Design considerations

Using data methods

You can use display methods to show data on pages (both list type pages and detail type pages). However, there

are two key points to remember when you use display methods:

- **Searching** – When a user performs an "online" search (that is, a search that is run against data in the web client instead of locally cached data), the search won't match against display methods, because the Filtering framework in the web client doesn't support searches against data methods. However, when a user does a search against locally cached data, the search will match against display methods, provided that the records have been cached on the device.
- **Offline** – If a user creates or updates data while their device isn't connected to the server, temporary records are created in the local cache. Because these temporary records haven't yet been processed in the web client, if the records have any fields that are automatically populated or defaults by server-side business logic, these fields will remain empty until the records have been synced with the web client. Display methods fall into this category of fields that will be empty for a temporary record.

Designing for offline

Unlike the web client, which is highly connected to the server and maintains an open user session that has open forms on the server, the mobile app creates user sessions (and opens forms) only in short bursts while the app is being synced with the server (via data read for pages, or via data write/update for actions). If there are no actions to sync with the server, and if the local data cache is up to date, the mobile app won't communicate with the server as a user navigates around the app (unless the user triggers an explicit pull-to-refresh). It's important that you keep this data flow pattern in mind while you design pages and actions in the mobile app. You should not expect form logic to run every time that a page is loaded or an action is started. You should also never expect form logic to run while a user is completing an action. Form logic is run only when the action is being synced with the server. The following list describes the only times when you should expect Form logic to run.

Form logic runs right before a page is opened on the mobile app for the first time.

1. When a user first opens a page, the mobile app reaches out to the web client and opens the associated forms. *During this process, logic such as form init and data source init is all run in the usual manner.*
2. The mobile app framework reads the required data directly from the controls on the forms and sends the data back to the mobile app.
3. The mobile app caches the data and shows it in the page on the mobile app.
4. Future attempts to open the page will load the cached data. *These attempts won't run the form logic again, unless the user explicitly refreshes the page or the cache expires. (Currently, the cache set to expire after 30 minutes.)*

Processing an action that has been submitted to the server from the mobile app

1. When a user opens an action and fills in the data in that action, *no form logic is run*. A user can complete an action either offline or online. The system behaves the same way in both cases.
2. After the user clicks **Done/Save** on the action, the mobile app queues a data synchronization operation. This operation will be synced with the server when the mobile app is connected to the Internet.
3. When an Internet connection is detected (which can happen immediately after the action is completed) the mobile app sends the data synchronization operation to the server for processing.
4. While the operation is processed on the server, the framework opens the associated forms and enters the data from the action by passing values into the form controls. *During this process, form logic is run in the usual manner (init, modified, clicked, and so on, are all run).* However, the mobile user might have moved to a different part of the app while this processing is occurring. *Any form logic that shows/hides controls will have no effect on the UI that is seen in the mobile app.* Therefore, to minimize synchronization times, it's best not to include any UI logic on the form.

Building mobile versions of existing forms

If you decide to modify existing forms so that they work with the mobile framework, instead of building new mobile-specific forms, you might have to conditionally change the form's behavior for mobile-specific scenarios. You can use the following static X++ application programming interfaces (APIs) in your X++ code to determine whether the code is being accessed during a session where a web client user is designing pages/actions or

during a session that the mobile framework back end created to load pages/actions for a mobile user. **When a form is being used with the mobile designer**

```
SysTaskRecorderController::isDesigningApp()
```

When a form is being used by the mobile framework back end to load pages and run actions

```
SysTaskRecorderController::isExecutingApp()
```

Form control support

The form controls for the various base data types (strings, dates, and numbers) and grids are supported. However, a few common controls have limited support. **Reference groups** Fields from within Reference groups controls are compatible when you design pages. However, they aren't compatible when you design Actions. Although you might be able to select these fields without experience any issue, Reference groups have a fundamental incompatibility with the mobile framework. We recommend that you not use Reference groups. Instead, add a control directly to the form, and then bind the control directly to the surrogate foreign key (SFK) by using the property sheet.

Configure workspaces by using the SysAppWorkspace class

2/18/2021 • 4 minutes to read • Edit Online

Workspace class, **SysAppWorkspace**, is the starting point to create, configure and publish workspaces on the server. The following categories of APIs are available for use in sysAppWorkspace

- **Workspace attributes** - This is used to create pages, tasks, entities, lookups, relationships in order to build mobile workspaces.
    - Download the sample project for Fleet Management Mobile App. This is an .axpp file found at Dynamics365-for-Operations-mobile-FleetManagementSamples.
    - After downloading the file, open Visual Studio on your Operations development environment, select **Dynamics 365 > Import Project**, and browse for the downloaded project file. On the same dialog box, select **Overwrite** and select **Create a new solution**. After the import is complete, build the solution (or build the Fleet Management model).
    - To review the example, start by reviewing the FMReservationManagementWorkspace class to see all the pages and actions included in the workspace. Use Solution Explorer to find page and task classes, and all the assets included in each. Use the API reference for more details on each API.
    - A mobile workspace can be created through designer pane, using X++ attribute APIs or a combination of both. See the "Use the workspace class to publish workspaces from AOT resources" section below for more details about how to import mobile app metadata from designer to AOT. The sample project Fleet Management Mobile App is a complete mobile app built using X++ attribute APIs.
- **Workspace metadata classes** - This is used to inspect and apply server-side business logic to metadata for mobile workspaces.

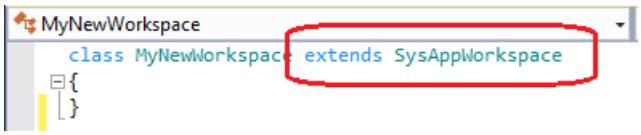
For a complete list of server-side APIs, see Server-side development (workspace X++ APIs).

Create a new workspace class

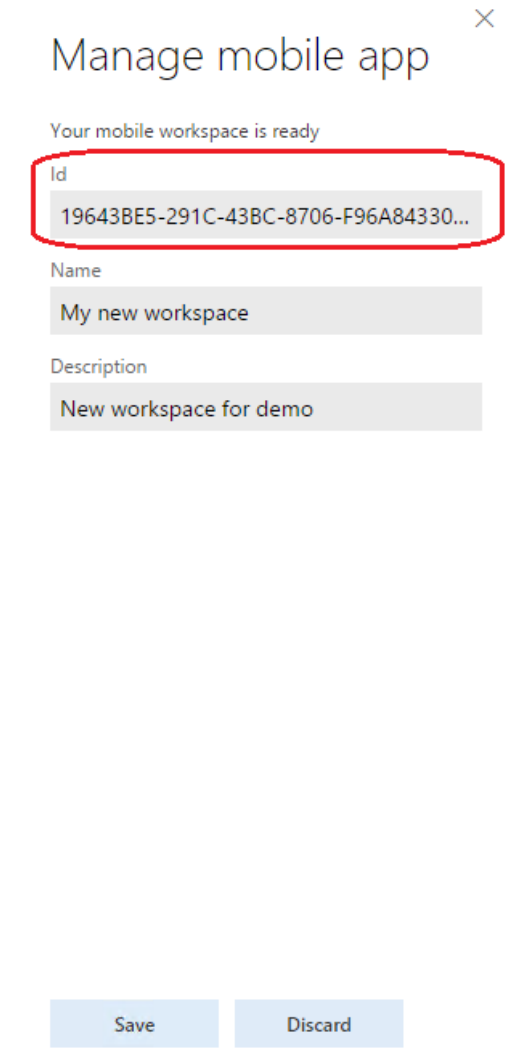
To use the **SysAppWorkspace** class for your workspace, you must create a new class for the workspace by extending the **SysAppWorkspace** class. You can then use the new class to modify workspace metadata. The new class also provides hooks for life cycle management of the mobile app.

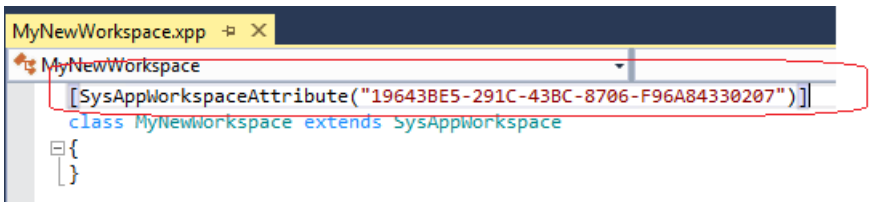
Follow these steps to create a new workspace class for your workspace.

1. Create a new class for your workspace, and extend it from the **SysAppWorkspace** class.

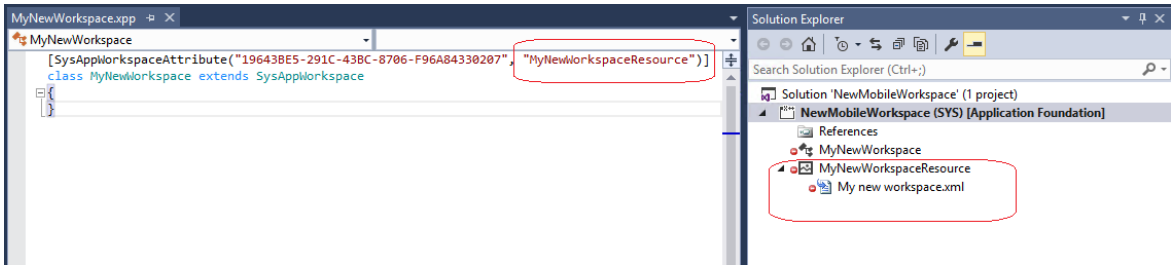


2. Add the **SysAppWorkspaceAttribute** attribute to the new class, and provide the **AppID** value of your workspace. You can find the app ID for your app on the **Summary** page in the mobile app designer.





3. Optional: If your workspace is an Application Object Tree (AOT) resource, provide the AOT resource name as the second parameter for the **SysAppWorkspaceAttribute** constructor.

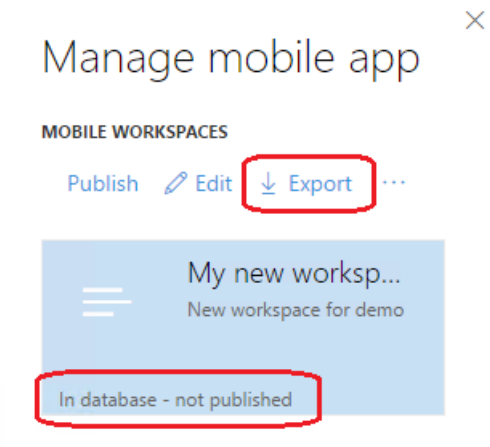


Use the workspace class to publish workspaces from AOT resources

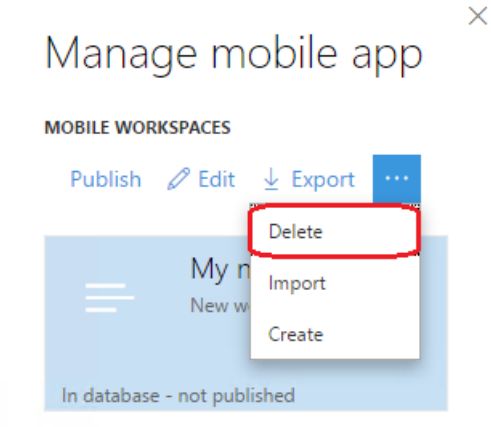
Workspaces can reside in the database. They can also reside in the AOT as resources. To provide visibility into workspaces that are stored in AOT resources, you must create a workspace class and point it to the name of the AOT resource that contains the workspace. Workspaces that are stored as AOT resources can't be edited or deleted by using the mobile app designer. Those workspace can only be exported.

Follow these steps to publish a workspace that resides in an AOT resource.

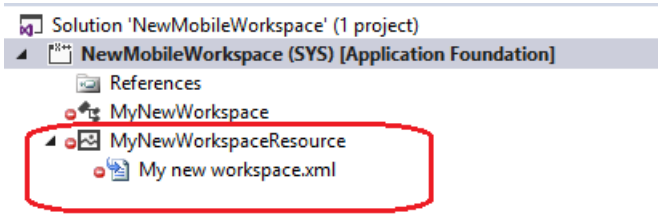
1. When you're developing a workspace that is stored in the database, you must export it from the mobile app designer so that it can be stored as an AOT resource. The workspace is exported as an XML file.



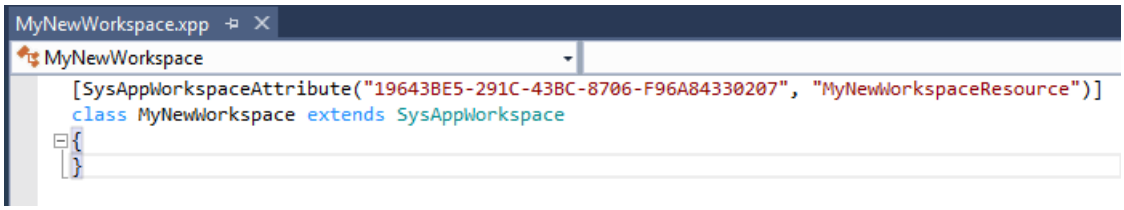
2. Delete the workspace from the mobile app designer. You will load it from an AOT resource later.



3. Create a new AOT resource, and select the exported workspace for the resource.

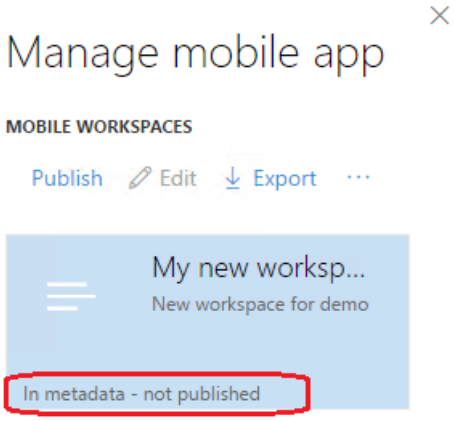


4. Create a new class for your workspace. This class should extend **SysAppWorkspace**. Apply the **SysAppWorkspaceAttribute** attribute to the class, and provide the app ID and the AOT resource name that contains the resource.



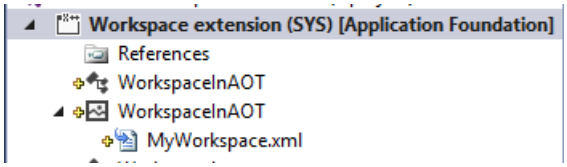
5. Build the class, and reopen the mobile app designer.

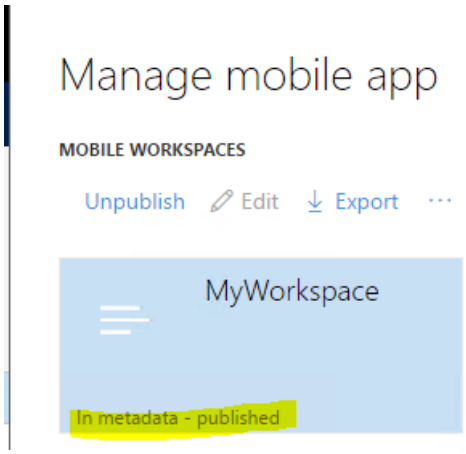
   The workspace is now published. It appears in the designer, but can't be edited or deleted. Note that the workspace is loaded from metadata.



Update a workspace that has already been published

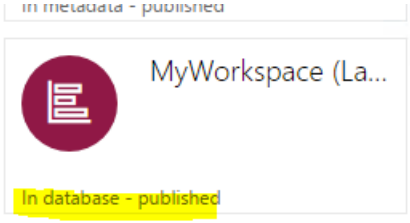
If your workspace is part of an AOT resource, you can't edit it by using the mobile app designer. In the following example, a workspace that is named **MyWorkspace** exists in the AOT, and it has a backing class that is named **WorkspaceInAOT**.

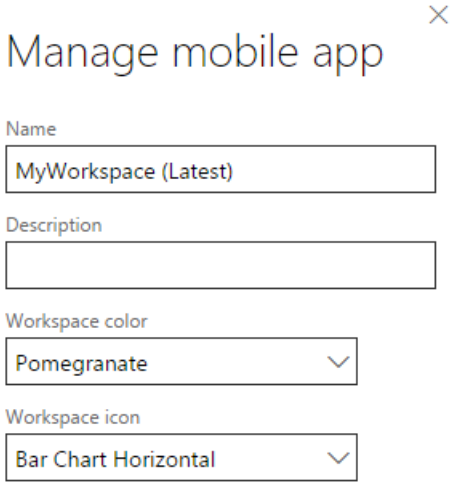




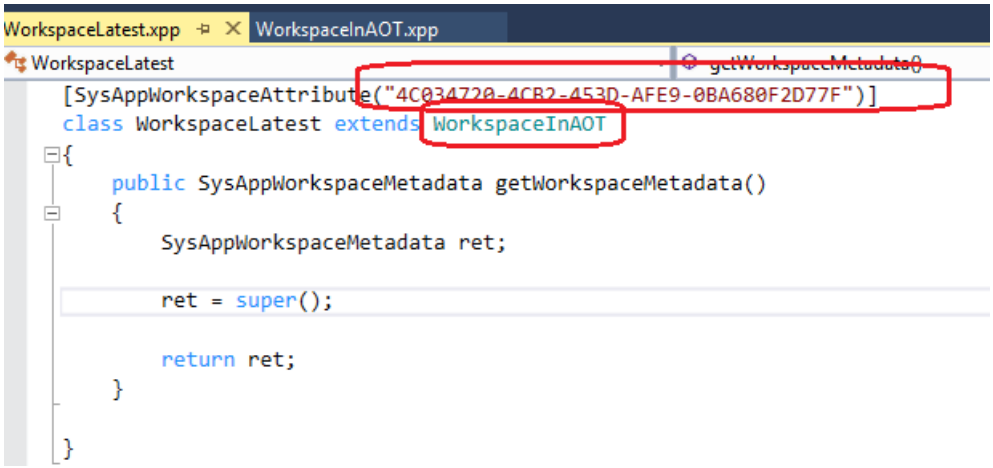
Follow these steps to edit the workspace.

1. Export the workspace by using the mobile app designer. The designer automatically creates new app IDs for workspaces that are stored in the AOT.
2. Import the newly exported workspace by using the mobile app designer.
    a. Optional: Change the name so that the newly added workspace can be distinguished from other workspaces.
    b. Copy the app ID of the newly created workspace.





3. Create a new class that extends your backing class, apply the **SysAppWorkspaceAttribute** attribute, and specify the new app ID.

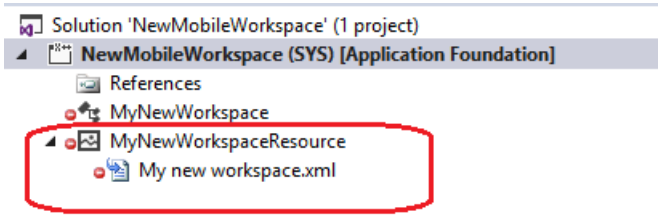


You can now continue to work with your new workspace and the backing class. After you've finished making your changes, you can merge them with the AOT-based workspace.

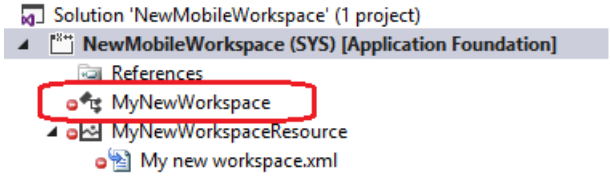
Delete a workspace that is an AOT resource

When a mobile workspace is stored as an AOT resource, you can't delete it by using the mobile app designer. Follow these steps to delete a workspace that exists as an AOT resource.

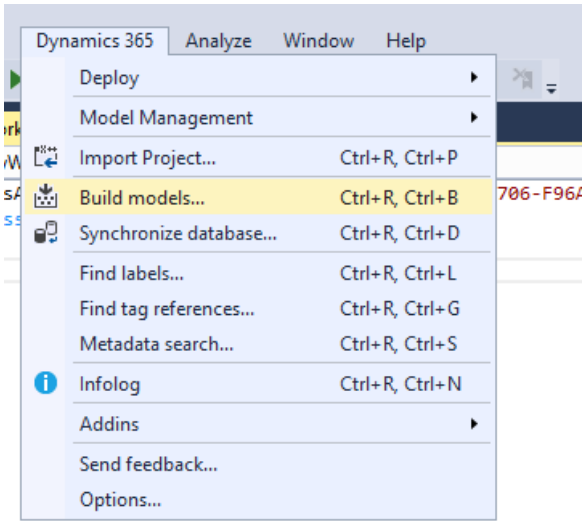
1. Delete the AOT resource that contains the workspace.

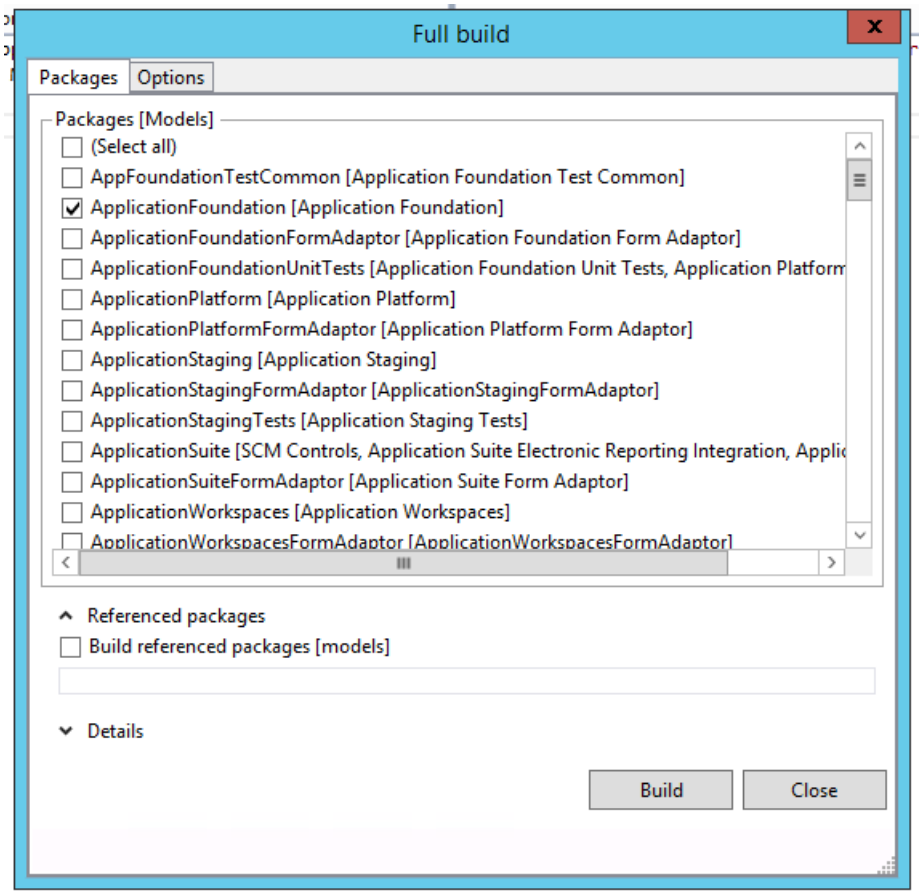


2. Delete the workspace class that was created for the workspace.



3. Do a full model build that contains the AOT resource and the class. The following illustrations shows a full build of the Application Foundation model. The Application Foundation model also contains the AOT resource and workspace class. To speed up the full build, you can clear all the selections on the **Options** tab.





4. When the build is completed, reopen the mobile app designer, and verify that the workspace is no longer there.

Make fields on mobile app pages clickable

2/18/2021 • 2 minutes to read • Edit Online

The fields on a mobile app page can be customized so that they are shown as email addresses, phone numbers, or URLs.

Email field

You can mark a field as an email address field by using business logic. Then, when a user clicks the field, the default mobile email app starts, and the field value appears as the email address in the app.

Phone field

You can mark a field as a phone number field by using business logic. Then, when a user clicks the field, the mobile dialer app starts, and the field value appears as the phone number in the app.

> **NOTE**
> On iOS, if the phone number isn't valid, it might not trigger the mobile dialer app.

URL field

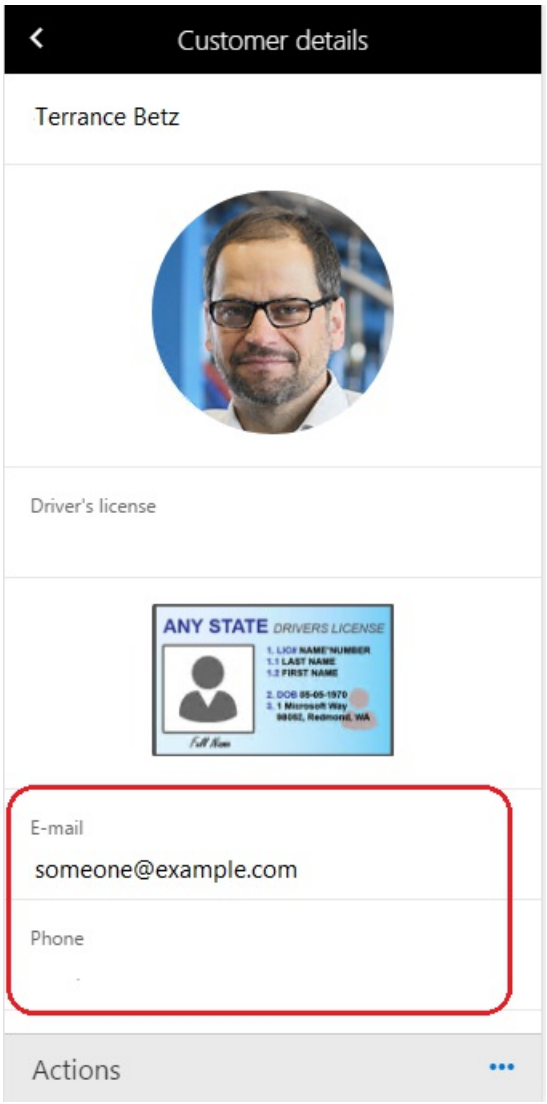
You can mark a field as a URL field by using business logic. Then, when a user clicks the field, the URL opens in the default mobile browser, and the field value appears in the address bar.

> **NOTE**
> On iOS, you must provide a complete URL (that is, a URL that starts with a protocol, such as **https**). Otherwise, the URL isn't opened in the browser. A URL such as `www.microsoft.com` doesn't work. Instead, the URL must be specified as `https://www.microsoft.com`.

Example

This example shows how to configure the customer email address and phone number fields so that they can clicked and opened in the appropriate iOS apps.

Before the fields are customized, they can't be clicked, as shown in the following image.



Follow these steps to specify that a field is a link.

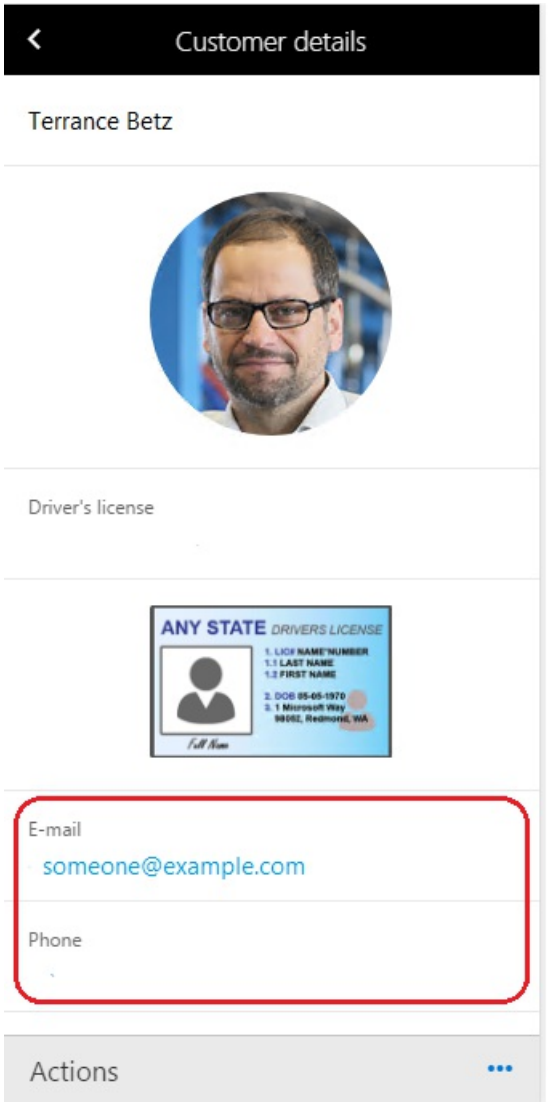
1. Add the following lines to the **appInit** method. You call the **configureControl** method, and pass in the page name and control name. You then supply the **LinkType** value for the control. The following values are supported: **Telephone**, **Email**, and **Url**.

   ```
   metadataService.configureControl('PageName', 'ControlName', { LinkType: 'Telephone' });
   metadataService.configureControl('PageName', ' ControlName ', { LinkType: 'Email' });
   metadataService.configureControl('PageName', ' ControlName ', { LinkType: 'Url' });
   ```

2. Upload the updated business logic file by using the mobile app designer.

3. Update the workspace metadata in the mobile client.

The fields now appear as links.



NOTE

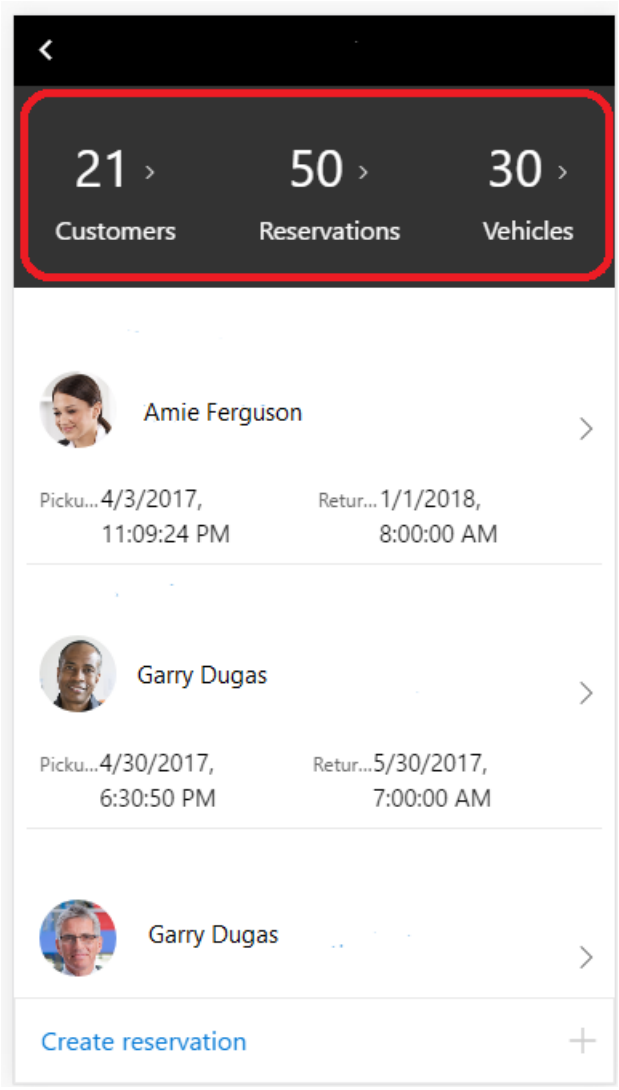
Can you tell us about your documentation language preferences? Take a short survey.

The survey will take about seven minutes. No personal data is collected (privacy statement).

Show counts in fields

2/18/2021 • 2 minutes to read • Edit Online

Although a **pageLink** control can be used to show counts (totals), it can be slow, because it must load the target page before it counts the number of rows. Additionally, the count that is calculated can be incorrect, because there is a limit on the number of rows that are retrieved.

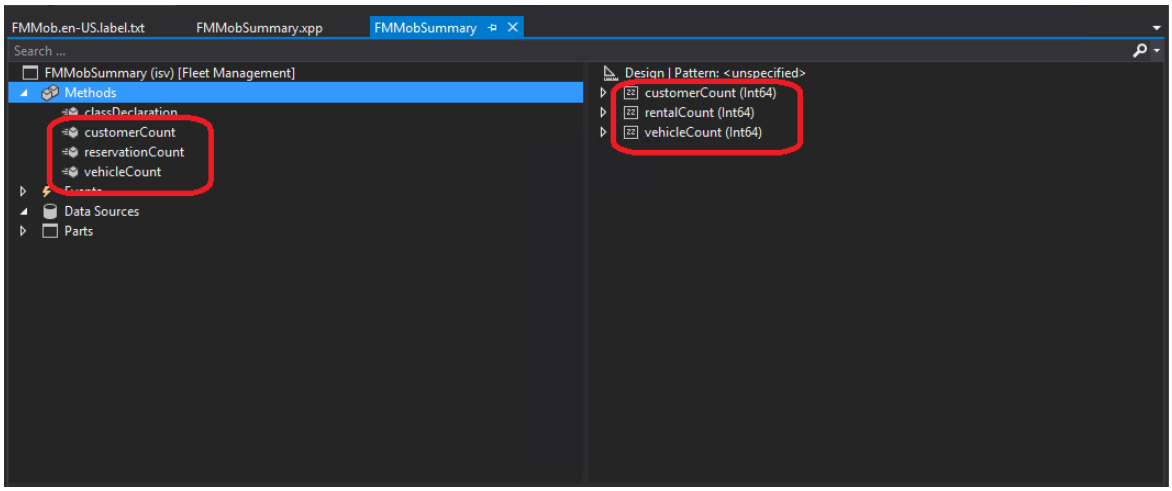


If you want to make mobile workspaces work more quickly, we recommended that you use a regular field to show the count and then model the field as a **pageLink** control in the mobile client.

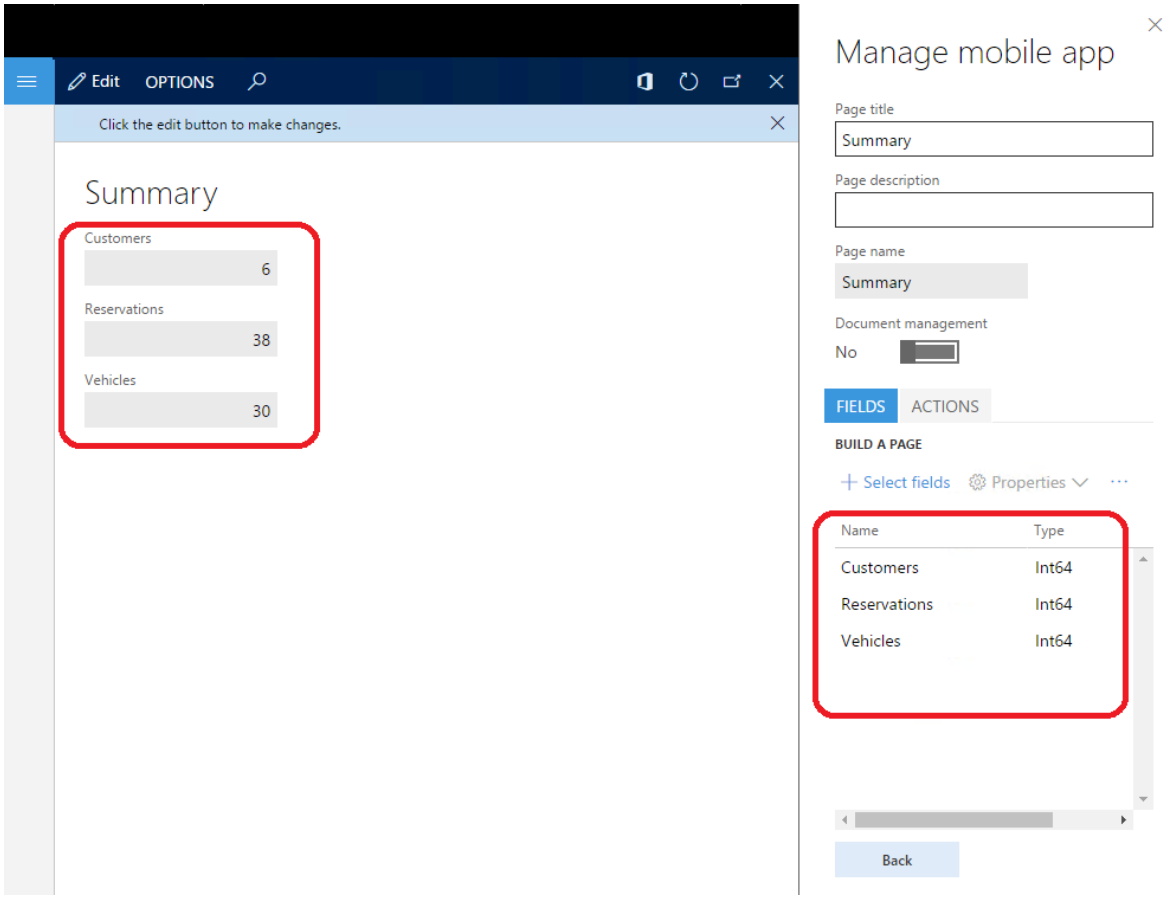
The following example uses the Fleet Management app. In the Fleet Management app, the workspace shows the total number of customers, reservations, and vehicles. Previously, these counts came from a **pageLink** control that had AllCustomers, AllReservations, and AllVehicles as targets. The **pageLink** control loaded the rows and did the count. (This approach isn't the recommended approach.)

Follow these steps to configure the workspace page to use the recommended approach.

1. On the server, create a new form to contain fields that are also on the server. (You can also add the new fields to an existing form). In the following illustration, a new **FMMobSummary** form is created that has three fields.



2. Create a page by using the mobile app designer for the **FMMobSummary** form.



3. Update the business logic to transform the fields into a **pageLink** control. Use the **configureControl** method to add a navigation target to the fields. The fields are then configured as **pageLink** controls. The arguments for the **configureControl** method are the page name, the control name, and an object of properties that must be updated.

4. Update the workspace design. Embed the summary page as a part in the workspace page. Reference the fields that are now configured as **pageLink** controls. Provide a style, and set the **showCount:true** property, so that the count is shown on the **pageLink** control.

```
{
    "type": "Part",
    target: "Summary",
    "flexFlow": "row nowrap",
    "background": "dark",
    "color": "light",
    design:
    {
        "flexFlow": "row nowrap",
        "fontSize": "large",
        "border": "none",
        "justifyItems": "space-around",
        "items":
        [
            {
                name:"customerCount",
                style: "button",
                showCount: true,
            },
            {
                name:"rentalCount",
                style: "button",
                showCount: true,
            },
            {
                name:"vehicleCount",
                style: "button",
                showCount: true,
            },

        ]
    }

},
// lower half - grow or shrink
```

By using this approach, you also get the localized labels for **pageLink** controls. The result is a much faster experience when workspaces are loaded.

> **NOTE**
>
> Can you tell us about your documentation language preferences? Take a short survey.
>
> The survey will take about seven minutes. No personal data is collected (privacy statement).

Help secure mobile workspaces

2/18/2021 • 2 minutes to read • Edit Online

This topic describes how to limit a user's access to a workspace.

Assign a menu item to workspace

Workspaces can be tied to a menu item. Users who don't have access to the menu item can't use the workspace, because the workspace is shown only to users who have rights to the menu item.

If a menu item isn't assigned to a workspace, the workspace is always shown to the user.

Follow these steps to help secure your workspaces by assigning a menu item.

1. Add a **SysAppWorkspaceSecurityAttribute** attribute to the workspace class, and specify the menu item to assign to the workspace.

```
[
    SysAppWorkspaceAttribute("4C034720-4CB2-453D-AFE9-0BA680F2D77F"),
    SysAppWorkspaceSecurityAttribute("BatchGroup")
]
```

2. Build the menu item and workspace. To test your changes, sign in to mobile app by using a user account that does'nt have access to the menu item.

Override the workspaceHidden method

You can also specify whether the workspace is hidden or shown, based on parameters. By overriding the **workspaceHidden** method, you enable your code to control the visibility of the workspace, as shown in the following code example.

```
/// <summary>
/// Used to control if a workspace is hidden or not
/// </summary>
/// <returns>Returns true if the workspace is hidden; otherwise false</returns>
public boolean workspaceHidden()
{
    boolean ret;

    ret = super();

    return ret;
}
```

Add a menu item and override the workspaceHidden method

You can use both the preceding methods in your app. The menu item provides a security check, and the **workspaceHidden** method contains additional logic that is related to the visibility of the workspace.

Localize mobile workspaces

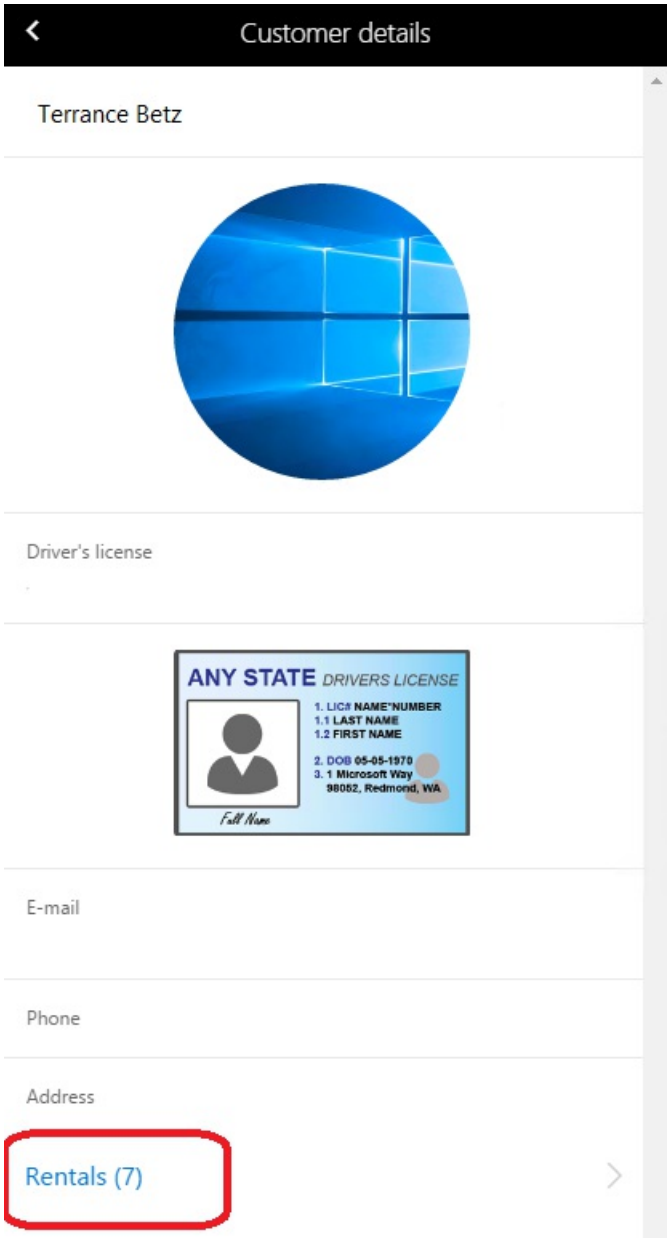
2/18/2021 • 2 minutes to read • Edit Online

You can use workspace classes in several ways to provide localization support to workspaces.

Use config objects to pass localized labels

A config object can be added to the workspace metadata when it's requested by the mobile app. Later, the config object can be used to provide localization support.

For example, the following workspace requires localized labels for the **pageLink** control that you added via the business logic.



The business logic for the app contains a call to the **addLink** method, as shown in the following illustration. This **addLink** method adds a link to the **Rentals** page for the current customer. In this case, the label for the link is **Rentals**. However, because there isn't a localized label for the link, the link always appears as **Rentals**.

```
metadataService.addLink(pageNames.CustomerDetails, pageNames.CustomerRentals, controlNames.CustomerRentals, 'Rentals', true);
```

To use a config object to provide localized labels, follow these steps.

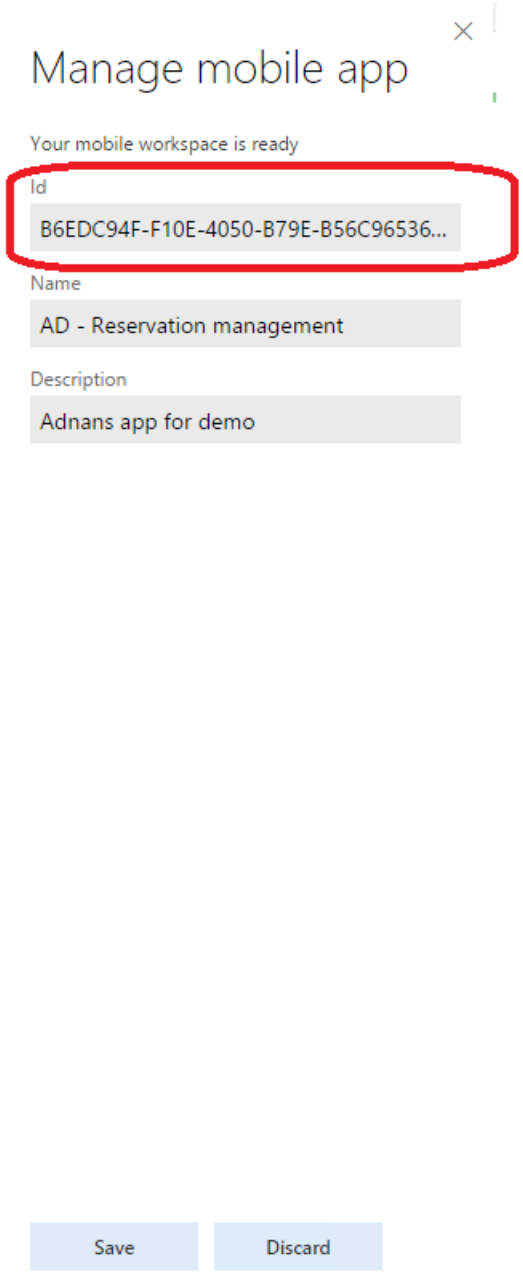
1. Create a config class that contains the fields for the labels. One field, **rentalLinkLabel**, is added to the class that will contain the label for the **pageLink** control. The config class must be a data contract class.

```
[DataContractAttribute('ReservationManagementLabels')]
class ReservationManagementWorkspaceLabels
{
    str rentalLinkLabel;

    [DataMemberAttribute('RentalLinkLabel')]
    public str rentalLinkLabel(str _rentalLinkLabel = rentalLinkLabel)
    {
        rentalLinkLabel = _rentalLinkLabel;
        return rentalLinkLabel;
    }

}
```

2. The config class is used by a workspace class for the workspace. The workspace class requires the **appId** value of the workspace. You can find the app ID in the App designer, as shown in the following illustration.



The following illustration shows what the workspace class looks like when the **appId** value is set on the attribute. The class also contains a method, **addConfig**, that sets a config object that contains the value for the label.

```
[SysAppWorkspaceAttribute("B6EDC94F-F10E-4050-B79E-B56C965368AD")]
class ReservationManagementWorkspace extends SysAppWorkspace
{
    public SysAppWorkspaceMetadata getWorkspaceMetadata()
    {
        SysAppWorkspaceMetadata workspace;

        workspace = super();

        this.addConfig(workspace);

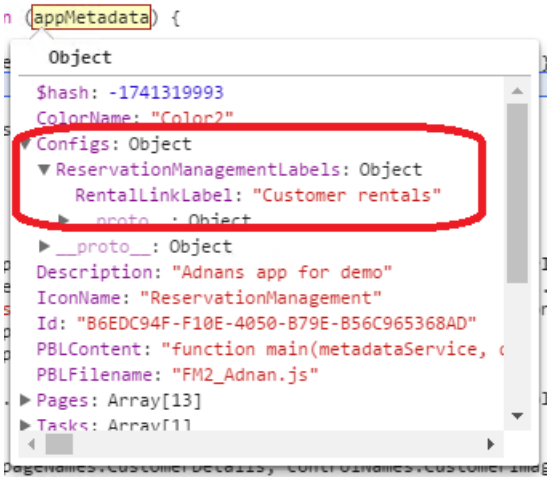
        return workspace;
    }

    private void addConfig(SysAppWorkspaceMetadata _workspace)
    {
        ReservationManagementWorkspaceLabels labelContract = new ReservationManagementWorkspaceLabels();
        labelContract.rentalLinkLabel("@FMMob:FMMob_CustomerRentals");

        _workspace.addConfig("ReservationManagementLabels", labelContract);
    }

}
```

The following illustration shows the config object in the **appInit** call in the mobile app.

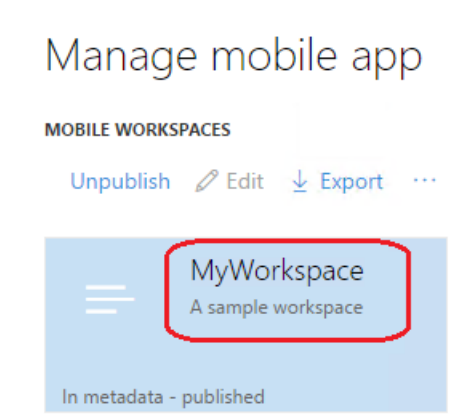


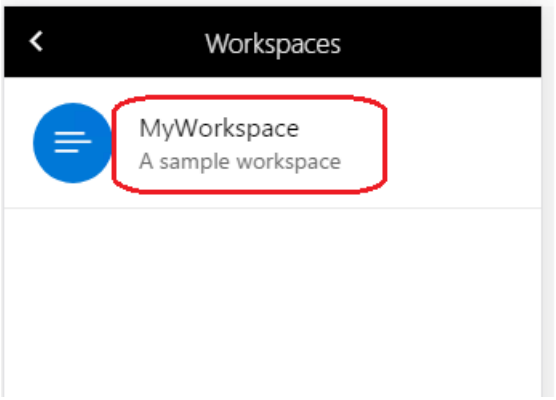
3. The config object can now be used and passed to the **addLink** method instead of the hard-coded label.

```
metadataService.addLink(pageNames.CustomerDetails,
    pageNames.CustomerRentals,
    controlNames.CustomerRentals,
    appMetadata.Configs.ReservationManagementLabels.RentalLinkLabel,
    true);
```

Use a workspace class to update the workspace title and description

A workspace class can be used to provide localized strings for the workspace title and description. If you don't localize the title and description, the fields will be in the language that you implemented them in. In this example, we will localize a workspace where **MyWorkspace** is the title and **A sample workspace** is the description.





1. If you don't have a workspace class for your workspace, create a workspace class.
2. Override the **getWorkspaceMetadata** method to get the workspace metadata. You must have the workspace metadata to provide labels for the workspace title and description fields.
3. Use the **workspaceTitle** and **workspaceDescription** properties to set the workspace title and description from a label. In the following illustration, placeholders are assigned to the **workspaceTitle** and **workspaceDescription** properties.

```
[SysAppWorkspaceAttribute("16DF07A7-B822-4D36-9D61-B388837C8140", "WorkspaceInAOT")]
class WorkspaceInAOT extends SysAppWorkspace
{
    public SysAppWorkspaceMetadata getWorkspaceMetadata()
    {
        SysAppWorkspaceMetadata workspaceMetadata;

        workspaceMetadata = super();

        this.updateWorkspacetitleAndDescription(workspaceMetadata);

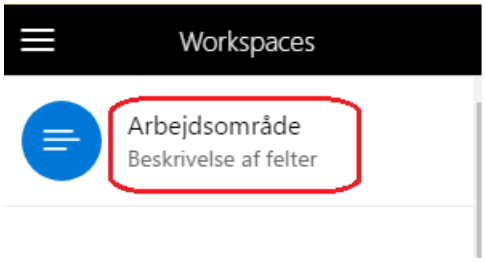
        return workspaceMetadata;
    }

    private void updateWorkspacetitleAndDescription(SysAppWorkspaceMetadata _workspaceMetadata)
    {
        _workspaceMetadata.workspaceTitle("@Client:Workspace");
        _workspaceMetadata.workspaceDescription("@ApplicationFoundation:FieldDescriptionsCaption");
    }

}
```

4. Build the workspace class.
5. Update the app list on the mobile client.

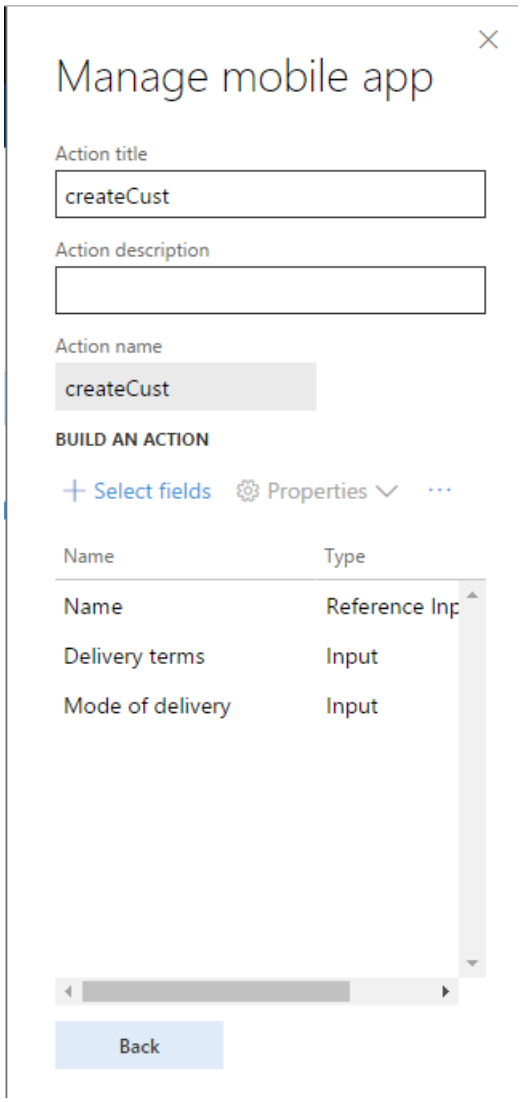
The following illustration shows the title and description on a phone that uses English and Danish.

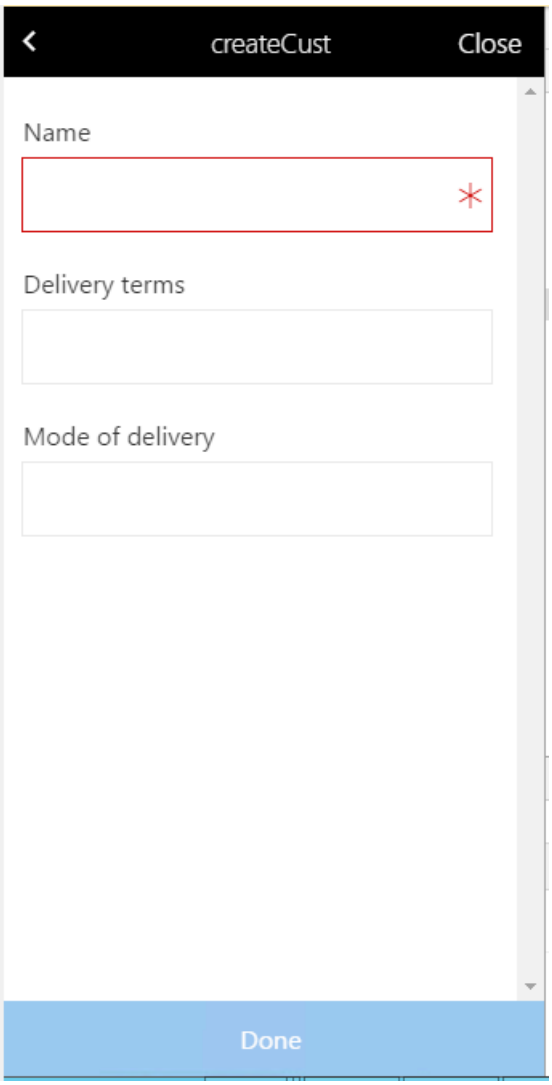


Make fields mandatory by using workspace classes

2/18/2021 • 2 minutes to read • Edit Online

When you use the mobile app designer to select fields for actions, some properties can be inferred. These properties include the field length, the type, and whether the field is mandatory. The workspace classes can be used to update these properties. For example, you might want to specify that the **Name** field is mandatory when a customer record is created, as shown in the following images.





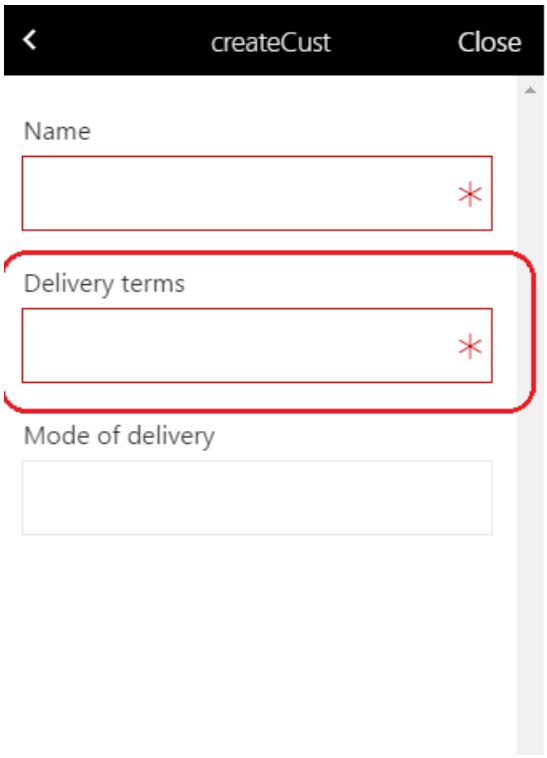
Follow these steps to make the **Delivery terms** field mandatory by using the workspace class.

1. Get the control name by using the app designer. In this example, the control name is **DynamicDetail_DlvTerm**.
2. Add the following code to set the **Mandatory** property for the control. This code uses the reflection-based **setProperty** method to set the **Mandatory** property.

```
public SysAppWorkspaceMetadata getWorkspaceMetadata()
{
    SysAppWorkspaceMetadata appMetadata;
    appMetadata = super();
    var createCustAction = appMetadata.getAction("createCust");
    this.setCustAccountMandatory(createCustAction);
    return appMetadata;
}
private void setCustAccountMandatory(SysAPpActionMetadata _createCustAction)
{
    var custAccount = +createCustAction.getControl("DynamicDetail_DlvTerm");
    custAccount.setProperty("Mandatory", true);
}
```

3. Build the solution, and then update the app metadata on the mobile app.

The **Delivery terms** field is now marked as **Mandatory**, as shown in the following illustration.



NOTE

Can you tell us about your documentation language preferences? Take a short survey.

The survey will take about seven minutes. No personal data is collected (privacy statement).

Server-side development (workspace X++ APIs)

Class SysAppActionAttribute

SysAppActionAttribute used for decorating methods defining actions of workspace

Methods

METHOD NAME	RETURNS	DESCRIPTION
new	void	Creates a new instance of SysAppActionAttribute class
pageMethodName	str	Gets the get method name that forms the page under which this task resides
actionTitle	str	Gets the Action Title
actionDescription	str	Gets the Action Description
crudOperationType	SysAppCRUDOperation	Gets the Crud Operation Type like Create, Update, Delete

Method new

Creates a new instance of SysAppActionAttribute class

```
public void new ([str _actionTitle], [str _actionDescription], [SysAppCRUDOperation _crudOperationType],
[str _pageMethodName])
```

Parameters

PARAMETER NAME	PARAMETER TYPE	OPTIONAL	DESCRIPTION
_actionTitle	str	True	Action title
_actionDescription	str	True	Action description
_crudOperationType	SysAppCRUDOperation	True	CRUD operation like Create, Update, Delete
_pageMethodName	str	True	Name of the method constructing parent page

Method pageMethodName

Gets the get method name that forms the page under which this task resides

```
public str pageMethodName ()
```

Return Value

The page method name that forms the page under which this task resides

Method actionTitle

Gets the Action Title

```
public str actionTitle ()
```

Return Value

The action title

Method actionDescription

Gets the Action Description

```
public str actionDescription ()
```

Return Value

The page description

Method crudOperationType

Gets the Crud Operation Type like Create, Update, Delete

```
public SysAppCRUDOperation crudOperationType ()
```

Return Value

The Crud Operation Type like Create, Update, Delete

Class SysAppActionMetadata

This class can be used to access and update AX mobile workspace action metadata

Methods

METHOD NAME	RETURNS	DESCRIPTION
new	void	
getActionName	str	Returns the action name
actionTitle	str	Gets or sets the action title
actionDescription	str	Gets or sets the action description
actionHidden	boolean	Gets or sets whether action is hidden
actionOrder	int	Gets or sets the action order
getControl	SysAppControlMetadata	Returns the control on the current action having the provided control name
getControlEnumerator	MapEnumerator	Returns a map enumerator that can be used to enumerate action controls. Where Key is control name and value is of type SysAppControlMetadata

Method new

```
public void new (Microsoft.Dynamics.Client.ServerForm.App.TaskMetadata _taskmetadata)
```

Parameters

PARAMETER NAME	PARAMETER TYPE	OPTIONAL	DESCRIPTION
_taskmetadata	Microsoft.Dynamics.Client.ServerForm.App.TaskMetadata	False	

Method getActionName

Returns the action name

```
public str getActionName ()
```

Return Value

The action name

Method actionTitle

Gets or sets the action title

```
public str actionTitle ([str _actionTitle])
```

Parameters

PARAMETER NAME	PARAMETER TYPE	OPTIONAL	DESCRIPTION
_actionTitle	str	True	The action title

Return Value

The action title

Method actionDescription

Gets or sets the action description

```
public str actionDescription ([str _actionDescription])
```

Parameters

PARAMETER NAME	PARAMETER TYPE	OPTIONAL	DESCRIPTION
_actionDescription	str	True	The action description

Return Value

The action description

Method actionHidden

Gets or sets whether action is hidden

```
public boolean actionHidden ([boolean _actionHidden])
```

Parameters

PARAMETER NAME	PARAMETER TYPE	OPTIONAL	DESCRIPTION
_actionHidden	boolean	True	Action hidden value

Return Value

True if the action is hidden; otherwise false

Method actionOrder

Gets or sets the action order

```
public int actionOrder ([int _actionOrder])
```

Parameters

PARAMETER NAME	PARAMETER TYPE	OPTIONAL	DESCRIPTION
_actionOrder	int	True	The action order

Return Value

The action order

Method getControl

Returns the control on the current action having the provided control name

```
public SysAppControlMetadata getControl (str _controlName)
```

Parameters

PARAMETER NAME	PARAMETER TYPE	OPTIONAL	DESCRIPTION
_controlName	str	False	The control name that will be used to search for control

Return Value

An object of SysAppControlMetadata is returned if a control with the provided control name exist on the action; otherwise null

Method getControlEnumerator

Returns a map enumerator that can be used to enumerate action controls. Where Key is control name and value is of type SysAppControlMetadata

```
public MapEnumerator getControlEnumerator ()
```

Return Value

A map enumerator

Class SysAppAttributeHelper

SysAppAttributeHelper class for fetching attributes from all the extended class

Methods

METHOD NAME	RETURNS	DESCRIPTION
getAttributeFromClass	SysAttribute	gets attribute from class

Method getAttributeFromClass

gets attribute from class

```
public SysAttribute getAttributeFromClass (SysDictClass _sysClass, SysAppAttributeType _attributeType)
```

Parameters

PARAMETER NAME	PARAMETER TYPE	OPTIONAL	DESCRIPTION
_sysClass	SysDictClass	False	class for which attributes is required
_attributeType	SysAppAttributeType	False	Type of attribute like SysAppEntityAttribute

Class SysAppCollectionAttribute

SysAppCollectionAttribute used for decorating methods forming list control

Methods

METHOD NAME	RETURNS	DESCRIPTION
new	void	Constructor

Method new

Constructor

```
public void new (str _itemContractName, [str _label], [str _relationshipName])
```

Parameters

PARAMETER NAME	PARAMETER TYPE	OPTIONAL	DESCRIPTION
_itemContractName	str	False	Data contract name of list item
_label	str	True	List control label
_relationshipName	str	True	Relationship name. By default the entity name of the list item is used as relationship name

Class SysAppControlMetadata

Represents an X++ wrapper over the managed ControlMetadata object to facilitate. passing around the object as X++ object

Methods

METHOD NAME	RETURNS	DESCRIPTION
new	void	Creates a new instance of the control metadata
getBaseLanguageId	str	Returns the base language ID for the app
getControlName	str	Returns the control name
controlLabel	str	Gets and sets the control label
controlHidden	boolean	Gets and sets whether the control is hidden
controlOrder	int	Gets or sets the control order
controlMandatory	boolean	Gets or sets the control mandatory
controlAllowNegative	boolean	Gets or sets the control allow negative
controlMaxLength	int	Gets or sets the control max length
getProperty	`anytype`	Gets the control property referenced by the key
setProperty	void	Sets the control property referenced by the key

Method new

Creates a new instance of the control metadata

```
public void new (Microsoft.Dynamics.Client.ServerForm.App.ControlMetadata _controlMetadata, [str
_baseLanguageId])
```

Parameters

PARAMETER NAME	PARAMETER TYPE	OPTIONAL	DESCRIPTION
_controlMetadata	Microsoft.Dynamics.Client.ServerForm.App.ControlMetadata	False	The controlMetadata object
_baseLanguageId	str	True	The base language

Method getBaseLanguageId

Returns the base language ID for the app

```
public str getBaseLanguageId ()
```

Return Value

The base language ID

Method getControlName

Returns the control name

```
public str getControlName ()
```

Return Value

The control name

Method controlLabel

Gets and sets the control label

```
public str controlLabel ([str _controlLabel])
```

Parameters

PARAMETER NAME	PARAMETER TYPE	OPTIONAL	DESCRIPTION
_controlLabel	str	True	The control label

Return Value

The control label

Method controlHidden

Gets and sets whether the control is hidden

```
public boolean controlHidden ([boolean _controlHidden])
```

Parameters

PARAMETER NAME	PARAMETER TYPE	OPTIONAL	DESCRIPTION
_controlHidden	boolean	True	Control hidden value

Return Value

True if the control is hidden; otherwise false

Method controlOrder

Gets or sets the control order

```
public int controlOrder ([int _controlOrder])
```

Parameters

PARAMETER NAME	PARAMETER TYPE	OPTIONAL	DESCRIPTION
_controlOrder	int	True	The control order

Return Value

The control order

Method controlMandatory

Gets or sets the control mandatory

```
public boolean controlMandatory ([boolean _controlMandatory])
```

Parameters

PARAMETER NAME	PARAMETER TYPE	OPTIONAL	DESCRIPTION
_controlMandatory	boolean	True	The control mandatory

Return Value

The control mandatory

Method controlAllowNegative

Gets or sets the control allow negative

```
public boolean controlAllowNegative ([boolean _controlAllowNegative])
```

Parameters

PARAMETER NAME	PARAMETER TYPE	OPTIONAL	DESCRIPTION
_controlAllowNegative	boolean	True	The control allows negative

Return Value

The control allows negative

Method controlMaxLength

Gets or sets the control max length

```
public int controlMaxLength ([int _controlMaxLength])
```

Parameters

PARAMETER NAME	PARAMETER TYPE	OPTIONAL	DESCRIPTION
_controlMaxLength	int	True	The control max length

Return Value

The control max length

Method getProperty

Gets the control property referenced by the key

```
public anytype getProperty (str _key)
```

Parameters

PARAMETER NAME	PARAMETER TYPE	OPTIONAL	DESCRIPTION
_key	str	False	The name of the control property

Return Value

The property value

Method setProperty

Sets the control property referenced by the key

```
public void setProperty (str _key, anytype _value)
```

Parameters

PARAMETER NAME	PARAMETER TYPE	OPTIONAL	DESCRIPTION
_key	str	False	The name of the control property
_value	anytype	False	The value of the control property

Class SysAppEntityAttribute

SysAppEntityAttribute used for decorating data contract entities

Methods

METHOD NAME	RETURNS	DESCRIPTION
new	void	Constructor
name	str	Gets the name of the entity
entityKey	str	Gets the entity key

Method new

Constructor

```
public void new (str _name, str _entityKey)
```

Parameters

PARAMETER NAME	PARAMETER TYPE	OPTIONAL	DESCRIPTION
_name	str	False	Entity name
_entityKey	str	False	Name of the entity's key

Method name

Gets the name of the entity

```
public str name ()
```

Return Value

Name of the entity

Method entityKey

Gets the entity key

```
public str entityKey ()
```

Return Value

Entity key

Class SysAppEntityContext

SysAppEntityContext used for defining entity context

Methods

METHOD NAME	RETURNS	DESCRIPTION
constructFromParams	SysAppEntityContext	Constructs SysAppEntityContext from entityName and entityId
constructFromBuffer	SysAppEntityContext	Constructs SysAppEntityContext from table buffer
entityName	str	Entity name on which filter applies
entityId	str	Field value on which filter applies

Method constructFromParams

Constructs SysAppEntityContext from entityName and entityId

```
public SysAppEntityContext constructFromParams (str _entityName, str _entityId)
```

Parameters

PARAMETER NAME	PARAMETER TYPE	OPTIONAL	DESCRIPTION
_entityName	str	False	Entity name
_entityId	str	False	Entity value

Return Value

Instance of SysAppEntityContext

Method constructFromBuffer

Constructs SysAppEntityContext from table buffer

```
public SysAppEntityContext constructFromBuffer (Common _tableBuffer)
```

Parameters

PARAMETER NAME	PARAMETER TYPE	OPTIONAL	DESCRIPTION
_tableBuffer	Common	False	table buffer forming the entity

Return Value

Instance of SysAppEntityContext

Method entityName

Entity name on which filter applies

```
public str entityName ([str _entityName])
```

Parameters

PARAMETER NAME	PARAMETER TYPE	OPTIONAL	DESCRIPTION
_entityName	str	True	Entity name

Return Value

Entity name

Method entityId

Field value on which filter applies

```
public str entityId ([str _entityId])
```

Parameters

PARAMETER NAME	PARAMETER TYPE	OPTIONAL	DESCRIPTION
_entityId	str	True	Entity value

Return Value

Entity value

Class SysAppFieldAttribute

SysAppFieldAttribute used for decorating methods forming bound fields

Methods

METHOD NAME	RETURNS	DESCRIPTION
new	void	Creates a new instance of SysAppFieldAttribute class

Method new

Creates a new instance of SysAppFieldAttribute class

```
public void new (str _fieldName, str _label)
```

Parameters

PARAMETER NAME	PARAMETER TYPE	OPTIONAL	DESCRIPTION
_fieldName	str	False	Entity field name with which control is bound
_label	str	False	Control label

Class SysAppFieldMultiSelectHelper

A helper class to provide helper methods for multi select scenarios used with D365 mobile app

Methods

METHOD NAME	RETURNS	DESCRIPTION
new	void	Creates a new instance of SysAppFieldMultiSelectHelper class
getSelectedRecIds	container	Returns a container of recIds of the records that were selected
getSelectedValues	container	Returns a container of selected values
getSelectedRecords	Common	Returns a buffer that contains all the selected records.. The buffer is marked as temp.. Later a while-Select can be used to iterate through all the records
setControlValue	void	A setter to set the multiselect control value

Method new

Creates a new instance of SysAppFieldMultiSelectHelper class

```
public void new (TableId _multiSelectTableId, FieldId _valueFieldId, FormStringControl _multiSelectControl)
```

Parameters

PARAMETER NAME	PARAMETER TYPE	OPTIONAL	DESCRIPTION
_multiSelectTableId	TableId	False	The backing tableId for the field
_valueFieldId	FieldId	False	The fieldId for the field that will be shown in the multi select control
_multiSelectControl	FormStringControl	False	The string control that will be the multi select control

Method getSelectedRecIds

Returns a container of recIds of the records that were selected

```
public container getSelectedRecIds ()
```

Return Value

A container of recOds for the records that were selected

Method getSelectedValues

Returns a container of selected values

```
public container getSelectedValues ()
```

Return Value

A container of selected values

Method getSelectedRecords

Returns a buffer that contains all the selected records.. The buffer is marked as temp.. Later a while-Select can be used to iterate through all the records

```
public Common getSelectedRecords ()
```

Return Value

A buffer containing all the selected records

Method setControlValue

A setter to set the multi select control value

```
public void setControlValue (str _value)
```

Parameters

PARAMETER NAME	PARAMETER TYPE	OPTIONAL	DESCRIPTION
_value	str	False	A colon separated value that will be used by SysAppFieldMultiSelectHelper

Class SysAppFilterContext

SysAppFilterContext class that holds context values

Methods

METHOD NAME	RETURNS	DESCRIPTION
entityName	str	Entity name on which filter applies
filterFieldName	str	Field name on which filter applies
filterFieldValueList	List	Gets the list of filter field values based on which filter happens
operator	str	Operator based on which result will be fetched
addFilterFieldValue	void	Adds filter field value

Method entityName

Entity name on which filter applies

```
public str entityName ([str _entityName])
```

Parameters

PARAMETER NAME	PARAMETER TYPE	OPTIONAL	DESCRIPTION

PARAMETER NAME	PARAMETER TYPE	OPTIONAL	DESCRIPTION
_entityName	str	True	Entity name on which filter applies

Return Value

Entity name on which filter applies

Method filterFieldName

Field name on which filter applies

```
public str filterFieldName ([str _filterFieldName])
```

Parameters

PARAMETER NAME	PARAMETER TYPE	OPTIONAL	DESCRIPTION
_filterFieldName	str	True	Field name on which filter applies

Return Value

Field name on which filter applies

Method filterFieldValueList

Gets the list of filter field values based on which filter happens

```
public List filterFieldValueList ()
```

Return Value

List of filter field values based on which filter happens

Method operator

Operator based on which result will be fetched

```
public str operator ([str _operator])
```

Parameters

PARAMETER NAME	PARAMETER TYPE	OPTIONAL	DESCRIPTION
_operator	str	True	Operator based on which result will be fetched

Return Value

Operator based on which result will be fetched

Method addFilterFieldValue

Adds filter field value

```
public void addFilterFieldValue ( _filterFieldValueList)
```

Parameters

PARAMETER NAME	PARAMETER TYPE	OPTIONAL	DESCRIPTION
_filterFieldValueList		False	Filter field values based on which filter happens

Class SysAppLookUpAttribute

SysAppPageAttribute used for decorating pages that are also lookup pages

Methods

METHOD NAME	RETURNS	DESCRIPTION
new	void	Creates a new instance of SysAppLookUpAttribute class
displayFieldName	str	Gets the display field name of lookup control
valueFieldName	str	Gets the value field name of lookup control

Method new

Creates a new instance of SysAppLookUpAttribute class

```
public void new (str _displayFieldName, str _valueFieldName)
```

Parameters

PARAMETER NAME	PARAMETER TYPE	OPTIONAL	DESCRIPTION
_displayFieldName	str	False	Lookup display field. Name of any control of lookup page
_valueFieldName	str	False	Lookup value field. Name of control formed by root data contract constructing lookup page

Method displayFieldName

Gets the display field name of lookup control

```
public str displayFieldName ()
```

Return Value

The display field name of lookup control

Method valueFieldName

Gets the value field name of lookup control

```
public str valueFieldName ()
```

Return Value

The value field name of lookup control

Class SysAppLookupFieldAttribute

SysAppLookupFieldAttribute used for decorating look up fields of action

Methods

METHOD NAME	RETURNS	DESCRIPTION
new	void	Creates a new instance of SysAppLookupFieldAttribute class
entityName	str	Gets the name of the entity with which lookup page is related

Method new

Creates a new instance of SysAppLookupFieldAttribute class

```
public void new ( _name)
```

Parameters

PARAMETER NAME	PARAMETER TYPE	OPTIONAL	DESCRIPTION
_name		False	Name of the entity with which lookup page is related

Method entityName

Gets the name of the entity with which lookup page is related

```
public str entityName ()
```

Return Value

Name of the entity

Class SysAppPageAttribute

SysAppPageAttribute used for decorating methods defining page of workspace

Methods

METHOD NAME	RETURNS	DESCRIPTION
new	void	Creates a new instance of SysAppPageAttribute class
pageTitle	str	Gets the Page Title of the page
pageDescription	str	Gets the Page Description

Method new

Creates a new instance of SysAppPageAttribute class

```
public void new ([str _pageTitle], [str _pageDescription])
```

Parameters

PARAMETER NAME	PARAMETER TYPE	OPTIONAL	DESCRIPTION
_pageTitle	str	True	The page title
_pageDescription	str	True	The page description

Method pageTitle

Gets the Page Title of the page

```
public str pageTitle ()
```

Return Value

The page title

Method pageDescription

Gets the Page Description

```
public str pageDescription ()
```

Return Value

The page description

Class SysAppPageMetadata

This class can be used to access and update AX mobile workspace page metadata

Methods

METHOD NAME	RETURNS	DESCRIPTION
new	void	
getPageName	str	Returns the page name
pageTitle	str	Gets and sets the page title
pageDescription	str	Gets or sets the page description
pageHidden	boolean	Gets and sets whether the page is hidden in the workspace
pageOrder	int	Gets or sets the page order
getControl	SysAppControlMetadata	Returns the control on the current page having the provided control name

METHOD NAME	RETURNS	DESCRIPTION
getControlEnumerator	MapEnumerator	Returns a map enumerator that can be used to enumerate page controls. Where Key is control name and value is of type SysAppControlMetadata

Method new

```
public void new (Microsoft.Dynamics.Client.ServerForm.App.PageMetadata _pageMetadata)
```

Parameters

PARAMETER NAME	PARAMETER TYPE	OPTIONAL	DESCRIPTION
_pageMetadata	Microsoft.Dynamics.Client.ServerForm.App.PageMetadata	False	

Method getPageName

Returns the page name

```
public str getPageName ()
```

Return Value

The page name

Method pageTitle

Gets and sets the page title

```
public str pageTitle ([str _pageTitle])
```

Parameters

PARAMETER NAME	PARAMETER TYPE	OPTIONAL	DESCRIPTION
_pageTitle	str	True	The page title

Return Value

The page title

Method pageDescription

Gets or sets the page description

```
public str pageDescription ([str _pageDescription])
```

Parameters

PARAMETER NAME	PARAMETER TYPE	OPTIONAL	DESCRIPTION
_pageDescription	str	True	The page description

Return Value

The page description>

Method pageHidden

Gets and sets whether the page is hidden in the workspace

```
public boolean pageHidden ([boolean _pageHidden])
```

Parameters

PARAMETER NAME	PARAMETER TYPE	OPTIONAL	DESCRIPTION
_pageHidden	boolean	True	page hidden value

Return Value

True if the current page is hidden in workspace; otherwise false

Method pageOrder

Gets or sets the page order

```
public int pageOrder ([int _pageOrder])
```

Parameters

PARAMETER NAME	PARAMETER TYPE	OPTIONAL	DESCRIPTION
_pageOrder	int	True	The page order

Return Value

The page order

Method getControl

Returns the control on the current page having the provided control name

```
public SysAppControlMetadata getControl (str _controlName)
```

Parameters

PARAMETER NAME	PARAMETER TYPE	OPTIONAL	DESCRIPTION
_controlName	str	False	The control name that will be used to search for control

Return Value

An object of SysAppControlMetadata is returned if a control with the provided control name exist on the page; otherwise null

Method getControlEnumerator

Returns a map enumerator that can be used to enumerate page controls. Where Key is control name and value is of type SysAppControlMetadata

```
public MapEnumerator getControlEnumerator ()
```

Return Value

A map enumerator

Class SysAppProjectionAttribute

SysAppProjectionAttribute used for decorating methods forming unbound fields

Methods

METHOD NAME	RETURNS	DESCRIPTION
new	void	Creates a new instance of SysAppControlMetadataAttributes class

Method new

Creates a new instance of SysAppControlMetadataAttributes class

```
public void new (str _label)
```

Parameters

PARAMETER NAME	PARAMETER TYPE	OPTIONAL	DESCRIPTION
_label	str	False	Control label

Class SysAppRelationalAttribute

SysAppRelationalAttribute used for decorating reference controls

Methods

METHOD NAME	RETURNS	DESCRIPTION
new	void	Constructor

Method new

Constructor

```
public void new ([str _name])
```

Parameters

PARAMETER NAME	PARAMETER TYPE	OPTIONAL	DESCRIPTION
_name	str	True	Property name of the referenced entity

Class SysAppRequestParams

Request class for X++ methods generating details and action pages

Methods

METHOD NAME	RETURNS	DESCRIPTION
entityContext	SysAppEntityContext	Entity context of the request

METHOD NAME	RETURNS	DESCRIPTION
filterContext	List	List of SysAppFilterContext for filter contexts

Method entityContext

Entity context of the request

```
public SysAppEntityContext entityContext ([SysAppEntityContext _entityContext])
```

Parameters

PARAMETER NAME	PARAMETER TYPE	OPTIONAL	DESCRIPTION
_entityContext	SysAppEntityContext	True	Entity context of the request

Return Value

Entity context of the request

Method filterContext

List of SysAppFilterContext for filter contexts

```
public List filterContext ([List _filterContext])
```

Parameters

PARAMETER NAME	PARAMETER TYPE	OPTIONAL	DESCRIPTION
_filterContext	List	True	List of SysAppFilterContext for filter contexts of page

Return Value

List of SysAppFilterContext for filter contexts of page

Class SysAppResponse

SysAppResponse class. This class holds the response object for generated pages and actions

Methods

METHOD NAME	RETURNS	DESCRIPTION
new	void	
jobId	str	Job ID of the request
data	Microsoft.Dynamics.Client.ServerForm.App.CompositeData	Data of the page
failedInAppCall	boolean	Data of the page
commits	List	Commits after task is completed

METHOD NAME	RETURNS	DESCRIPTION
messages	List	Job ID of the request
addMessage	void	Adds message
addCommit	void	Adds commits

Method new

```
public void new ()
```

Method jobId

Job ID of the request

```
public str jobId ()
```

Return Value

jobid of the request

Method data

Data of the page

```
public Microsoft.Dynamics.Client.ServerForm.App.CompositeData data
([Microsoft.Dynamics.Client.ServerForm.App.CompositeData _data])
```

Parameters

PARAMETER NAME	PARAMETER TYPE	OPTIONAL	DESCRIPTION
_data	Microsoft.Dynamics.Client.ServerForm.App.CompositeData	True	Data of the page

Return Value

Data of the page

Method failedInAppCall

Data of the page

```
public boolean failedInAppCall ([boolean _failedInAppCall])
```

Parameters

PARAMETER NAME	PARAMETER TYPE	OPTIONAL	DESCRIPTION
_failedInAppCall	boolean	True	Sets to true if it fails in calling application code

Return Value

True when fails in calling application code

Method commits

Commits after task is completed

```
public List commits ()
```

Return Value

Commits after task is completed

Method messages

Job ID of the request

```
public List messages ()
```

Return Value

Messages after task is completed

Method addMessage

Adds message

```
public void addMessage (SysAppResponseMessage _message)
```

Parameters

PARAMETER NAME	PARAMETER TYPE	OPTIONAL	DESCRIPTION
_message	SysAppResponseMessage	False	message as SysAppResponseMessage object

Method addCommit

Adds commits

```
public void addCommit (SysAppEntityContext _entityContext)
```

Parameters

PARAMETER NAME	PARAMETER TYPE	OPTIONAL	DESCRIPTION
_entityContext	SysAppEntityContext	False	Entity context containing entity name and entity ID of the entity that is committed

Class SysAppResponseMessage

SysAppResponseMessage class for response messages

Methods

METHOD NAME	RETURNS	DESCRIPTION
new	void	Creates a new instance of SysAppResponseMessage class

METHOD NAME	RETURNS	DESCRIPTION
text	str	Gets the message text
type	SysAppMessageType	Gets the message type: info, error, warning

Method new

Creates a new instance of SysAppResponseMessage class

```
public void new (str _text, [SysAppMessageType _type])
```

Parameters

PARAMETER NAME	PARAMETER TYPE	OPTIONAL	DESCRIPTION
_text	str	False	The message text
_type	SysAppMessageType	True	Message Type: info, error, warning

Method text

Gets the message text

```
public str text ()
```

Return Value

The message text

Method type

Gets the message type: info, error, warning

```
public SysAppMessageType type ()
```

Return Value

The message type: info, error, warning

Class SysAppSecurityAttribute

SysAppSecurityAttribute used for decorating methods forming pages and actions. specifies security attribute of page or action

Methods

METHOD NAME	RETURNS	DESCRIPTION
new	void	Creates a new instance of SysAppSecurityAttribute class. This will help in checking if the user logged in has access to the specified menu item and menu item type
menuItemType	MenuItemType	Gets the Menu Item Type of the page

METHOD NAME	RETURNS	DESCRIPTION
menuItemName	MenuItemName	Gets the Menu Item Name of the page

Method new

Creates a new instance of SysAppSecurityAttribute class. This will help in checking if the user logged in has access to the specified menu item and menu item type

```
public void new ([MenuItemName _menuItemName], [MenuItemType _menuItemType])
```

Parameters

PARAMETER NAME	PARAMETER TYPE	OPTIONAL	DESCRIPTION
_menuItemName	MenuItemName	True	Menu Item Name of the page
_menuItemType	MenuItemType	True	Menu Item Type of the page like action, display, or output

Method menuItemType

Gets the Menu Item Type of the page

```
public MenuItemType menuItemType ()
```

Return Value

Menu Item Type of the page

Method menuItemName

Gets the Menu Item Name of the page

```
public MenuItemName menuItemName ()
```

Return Value

Menu Item Name of the page

Class SysAppWorkspace

This is the base class of mobile workspace. Mobile workspace classes need to extend from this class

Methods

METHOD NAME	RETURNS	DESCRIPTION
getEnumValues	List	Called during workspace initialization. Can be used to modify the enum values that are returned to AX mobile
getWorkspaceMetadata	SysAppWorkspaceMetadata	Called during workspace initialization. Can be used to modify the workspace metadata

METHOD NAME	RETURNS	DESCRIPTION
onBeginAppJob	void	Called before the start of execution of AX mobile job
onEndAppJob	void	Called after the end of execution of AX mobile job
workspaceHidden	boolean	Can be used to control whether the workspace is hidden or not. Checks that the current user has access menu item specified by SysAppWorkspaceSecurityAttribute on the workspace class. If the attribute is not specified on the class then it always returns false

Method getEnumValues

Called during workspace initialization. Can be used to modify the enum values that are returned to AX mobile

```
public List getEnumValues (EnumName _enumName)
```

Parameters

PARAMETER NAME	PARAMETER TYPE	OPTIONAL	DESCRIPTION
_enumName	EnumName	False	The enum name

Return Value

A list of enum value

Method getWorkspaceMetadata

Called during workspace initialization. Can be used to modify the workspace metadata

```
public SysAppWorkspaceMetadata getWorkspaceMetadata ()
```

Return Value

An object representing the workspace metadata

Method onBeginAppJob

Called before the start of execution of AX mobile job

```
public void onBeginAppJob (SysAppJobRequest _sysAppJobRequest)
```

Parameters

PARAMETER NAME	PARAMETER TYPE	OPTIONAL	DESCRIPTION
_sysAppJobRequest	SysAppJobRequest	False	A class containing job request parameters

Method onEndAppJob

Called after the end of execution of AX mobile job

```
public void onEndAppJob (SysAppJobResponse _sysAppJobResponse)
```

Parameters

PARAMETER NAME	PARAMETER TYPE	OPTIONAL	DESCRIPTION
_sysAppJobResponse	SysAppJobResponse	False	A class containing job response parameters

Method workspaceHidden

Can be used to control whether the workspace is hidden or not. Checks that the current user has access menu item specified by SysAppWorkspaceSecurityAttribute on the workspace class. If the attribute is not specified on the class then it always returns false

```
public boolean workspaceHidden ()
```

Return Value

Returns true if the workspace is hidden otherwise false

Class SysAppWorkspaceAttribute

Applied on classes that are extended from SysAppWorkspace

Methods

METHOD NAME	RETURNS	DESCRIPTION
new	void	Creates a new instance of SysAppWorkspaceAttribute class
AppId	str	Gets or sets the AppId of the workspace
AppResourceName	str	Gets or sets the AOT Resource name that contains the workspace
WorkspaceHidden	boolean	Gets or sets if the workspace is hidden from designer

Method new

Creates a new instance of SysAppWorkspaceAttribute class

```
public void new (str _appId, [str _appResourceName], [boolean _workspaceHidden])
```

Parameters

PARAMETER NAME	PARAMETER TYPE	OPTIONAL	DESCRIPTION
_appId	str	False	The appId of the workspace
_appResourceName	str	True	The AOT resource name that contains the workspace

PARAMETER NAME	PARAMETER TYPE	OPTIONAL	DESCRIPTION
_workspaceHidden	boolean	True	The workspace is hidden from designer

Method AppId

Gets or sets the AppId of the workspace

```
public str AppId ([str _appId])
```

Parameters

PARAMETER NAME	PARAMETER TYPE	OPTIONAL	DESCRIPTION
_appId	str	True	The AppId of the workspace

Return Value

The AppId of the workspace

Method AppResourceName

Gets or sets the AOT Resource name that contains the workspace

```
public str AppResourceName ([str _appResourceName])
```

Parameters

PARAMETER NAME	PARAMETER TYPE	OPTIONAL	DESCRIPTION
_appResourceName	str	True	The AOT Resource name that contains the workspace

Return Value

The AOT Resource name that contains the workspace

Method WorkspaceHidden

Gets or sets if the workspace is hidden from designer

```
public boolean WorkspaceHidden ([boolean _workspaceHidden])
```

Parameters

PARAMETER NAME	PARAMETER TYPE	OPTIONAL	DESCRIPTION
_workspaceHidden	boolean	True	The workspace hidden

Return Value

Whether the workspace is hidden from designer or not

Class SysAppWorkspaceMetadata

This class can be used to access and update metadata of an AX mobile workspace

Methods

METHOD NAME	RETURNS	DESCRIPTION
new	void	
addConfig	void	Adds a custom config to the mobile workspace metadata
getPage	SysAppPageMetadata	Returns the page with the pageName provided
getPageEnumerator	MapEnumerator	Returns a map enumerator that can be used to enumerate workspace pages. Where key is page name and value is of type SysAppPageMetadata
getAction	SysAppActionMetadata	Returns the action with the actionName provided
getActionEnumerator	MapEnumerator	Returns a map enumerator that can be used to enumerate workspace actions. Where key is action name and value is of type SysAppActionMetadata
getPageNameForRecordingId	str	Returns a pageName if the provided recordingId is used by a workspace page
getActionNameForRecordingId	str	Returns a actionName if the provided recordingId is used by a workspace action
workspaceTitle	str	Gets and sets the workspace title
workspaceDescription	str	Gets and sets the workspace description

Method new

```
public void new (str _appId, [SysAppWorkspaceAttribute _attribute])
```

Parameters

PARAMETER NAME	PARAMETER TYPE	OPTIONAL	DESCRIPTION
_appId	str	False	
_attribute	SysAppWorkspaceAttribute	True	

Method addConfig

Adds a custom config to the mobile workspace metadata

```
public void addConfig (str _configName, object _configValue)
```

Parameters

PARAMETER NAME	PARAMETER TYPE	OPTIONAL	DESCRIPTION
_configName	str	False	A config name
_configValue	object	False	An object of an X++ data contract class

Method getPage

Returns the page with the pageName provided

```
public SysAppPageMetadata getPage (str _pageName)
```

Parameters

PARAMETER NAME	PARAMETER TYPE	OPTIONAL	DESCRIPTION
_pageName	str	False	A page name

Return Value

Returns the pageMetadata if a page with the provided name exists; otherwise null

Method getPageEnumerator

Returns a map enumerator that can be used to enumerate workspace pages. Where key is page name and value is of type SysAppPageMetadata

```
public MapEnumerator getPageEnumerator ()
```

Return Value

A map enumerator

Method getAction

Returns the action with the actionName provided

```
public SysAppActionMetadata getAction (str _actionName)
```

Parameters

PARAMETER NAME	PARAMETER TYPE	OPTIONAL	DESCRIPTION
_actionName	str	False	An action name

Return Value

Returns the ActionMetadata if an action with the provided name exists; otherwise null

Method getActionEnumerator

Returns a map enumerator that can be used to enumerate workspace actions. Where key is action name and value is of type SysAppActionMetadata

```
public MapEnumerator getActionEnumerator ()
```

Return Value

A map enumerator

Method getPageNameForRecordingId

Returns a pageName if the provided recordingId is used by a workspace page

```
public str getPageNameForRecordingId (str _recordingId)
```

Parameters

PARAMETER NAME	PARAMETER TYPE	OPTIONAL	DESCRIPTION
_recordingId	str	False	A recordingId

Return Value

A page name if the supplied recordingId is used by a workspace page; otherwise empty string

Method getActionNameForRecordingId

Returns a actionName if the provided recordingId is used by a workspace action

```
public str getActionNameForRecordingId (str _recordingId)
```

Parameters

PARAMETER NAME	PARAMETER TYPE	OPTIONAL	DESCRIPTION
_recordingId	str	False	A recordingId

Return Value

An action name if the supplied recordingId is used by a workspace action; otherwise empty string

Method workspaceTitle

Gets and sets the workspace title

```
public str workspaceTitle ([str _workspaceTitle])
```

Parameters

PARAMETER NAME	PARAMETER TYPE	OPTIONAL	DESCRIPTION
_workspaceTitle	str	True	The workspace title

Return Value

The workspace title

Method workspaceDescription

Gets and sets the workspace description

```
public str workspaceDescription ([str _workspaceDescription])
```

Parameters

PARAMETER NAME	PARAMETER TYPE	OPTIONAL	DESCRIPTION
_workspaceDescription	str	True	The workspace description

Return Value

The workspace description

Class SysAppWorkspaceSecurityAttribute

Controls the visibility based of workspace based on the menu item tied to this attribute

Methods

METHOD NAME	RETURNS	DESCRIPTION
new	void	Creates a new instance of attribute
WorkspaceMenuItemName	MenuItemName	Gets or sets the workspace menuItem for the workspace security attribute
WorkspaceMenuItemType	MenuItemType	Gets or sets the workspace menu item type for the workspace security attribute

Method new

Creates a new instance of attribute

```
public void new (MenuItemName _workspaceMenuItemName, [MenuItemType _workspaceMenuItemType])
```

Parameters

PARAMETER NAME	PARAMETER TYPE	OPTIONAL	DESCRIPTION
_workspaceMenuItemName	MenuItemName	False	The menu item name to which the workspace needs to be tied
_workspaceMenuItemType	MenuItemType	True	The menu item type

Method WorkspaceMenuItemName

Gets or sets the workspace menuItem for the workspace security attribute

```
public MenuItemName WorkspaceMenuItemName ([MenuItemName _workspaceMenuItemName])
```

Parameters

PARAMETER NAME	PARAMETER TYPE	OPTIONAL	DESCRIPTION
_workspaceMenuItemName	MenuItemName	True	The workspace menu item for the workspace security attribute

Return Value

The workspace menu item for the workspace security attribute

Method WorkspaceMenuItemType

Gets or sets the workspace menu item type for the workspace security attribute

```
public MenuItemType WorkspaceMenuItemType ([MenuItemType _workspaceMenuItemType])
```

Parameters

PARAMETER NAME	PARAMETER TYPE	OPTIONAL	DESCRIPTION
_workspaceMenuItemType	MenuItemType	True	The workspace menu item type for the `workspacesecurity` attribute

Return Value

The workspace menu item type for the workspace security attribute

Client-side design APIs

2/18/2021 • 3 minutes to read • Edit Online

This topic provides an overview of the application programming interfaces (APIs) for client-side design and includes recommendations for using them.

Terminology

The following list includes some frequently used terms that apply to the client-side design APIs.

- **Design** – A property that can optionally be specified on a Page, Action, or other component object to override its default design.
- **Component** – A component can be one of four types:
  - **Block container** (default) – A container that has CSS block behaviors. (In other words, the container is equivalent to an element that has a CSS **display: block** style declaration.)
  - **Flex container** – A container that has CSS flex behaviors. (In other words, the container is equivalent to an element that has a CSS **display: flex** style declaration.)
  - **Control reference** – A component that refers to a control that exists in the static metadata (XML) of the Page or Action.
  - **New control** – A component that instantiates a new control. (In other words, the control doesn't already exist in the static metadata [XML] of the Page or Action.)

    A component is represented in the design by a JavaScript Object Notation (JSON) object, and the properties of this JSON object represent the properties of the component. Almost every JSON object in the design property hierarchy is a component.
- **Item** – A component that is nested in a container.
- **Property** – Several types of properties can be set on a component:
  - Container-specific
  - Item-specific
  - Control-specific
  - List-specific
  - Generic (non-specific)

    Properties are specified as key-value pairs on the component's JSON object. The properties that are applicable depend on the type of component that the property is applied to.

    For properties that have a predefined list of possible values, the first value that is shown in the documentation is the property's default value. In most cases, if you don't specify a property at all (that is, if you omit the property from the JSON object), the property behaves as if you had set its default value.

    Generic properties can be applied to all component types.

    When you specify properties, follow these guidelines:

- You should not enclose property names in quotation marks.
- You must enclose all property values in double quotation marks, unless the documentation specifies otherwise.

- **Inheritance** – If a color, font size, or font weight is applied to a control, all descendant controls inherit the same property, unless they are reassigned. If padding is applied to a control, it's inherited by the item (non-container) descendants of the control. No other properties are inherited.

Using design APIs

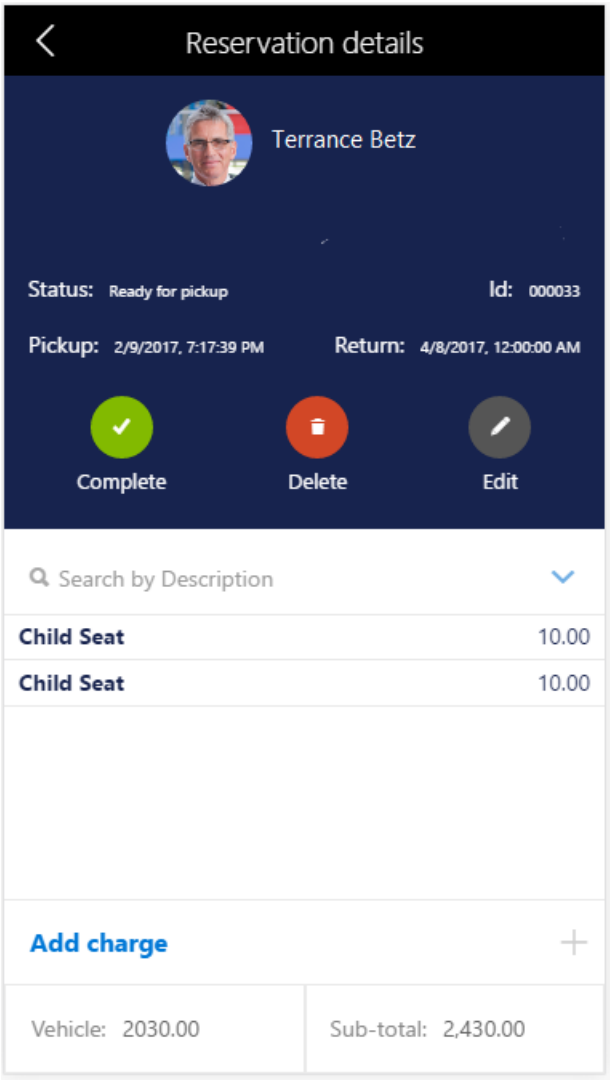
The following code is a modified segment of business logic code from a Reservation Management example. Specifically, this code is from a variable that specifies the design for a reservation details page. Comments are included in the code to highlight a few possibilities.

> **NOTE**
>
> Any color, font size, or font weight that is applied to a control is also applied to all children of that control. Padding is inherited by non-container children. No other properties are inherited. Containers include lists, pages, groups, and parts.

After a control is created that doesn't have any children or items, the control name just has to be written in quotation marks (see **FMCustomer_FullName** in the following code). However, if any customization will be applied to that control, the code must be blocked, and the **name** label must be used (see **FMCustomer_Image** in the following code).

```
// Page root container
"flexFlow":"column nowrap",
"items":[
    // Upper third of page, contains 4 rows
    {
        "flexFlow":"column nowrap",
        "background":"theme", // set background color to the theme color
        "color":"light",      // set the foreground (e.g. font) color to light
        "fontSize":"small",
        "border": "none",
        "padding":"small",
        "items":[
            // Row 1/4 with customer image and name
            {
                "flexFlow":"row nowrap",
                "alignItems":"center",
                "justifyItems":"center",
                "labelStyle":"hidden", // don't show label for field
                "fontSize":"large",
                "fontWeight":"bold",
                "items":[
                    {
                    // Customer image – since we're modifying the imageStyle, etc., this
                    // code must be blocked and the "FMCustomer_Image" must be labeled
                    // with "name".
                        "name":"FMCustomer_Image",
                        "imageStyle":"circular",
                        height:3,
                        width:3
                    },
                    // don't need to create a new object or use the "name" label if
                    // there is no customization
                    "FMCustomer_FullName",
                ]
            },
            // Row 2/4 with vehicle description
            . . .
        }
    }
```

The following illustration shows the customer image, customer name, font, background color, and so on, that preceding code produces.



NOTE

PageState enumeration

2/18/2021 • 2 minutes to read • Edit Online

Represents the various high-level states the a page can be in.

Index

Enumeration members

- error
- loaded
- loading
- offline
- refreshing

Enumeration members

error

error: 10 The page is currently in the error state, but can be refreshed in an attempt to get out of this state.

loaded

loaded: 3 The page is fully loaded and can be refreshed and, if possible, submitted.

loading

loading: 2 The page is currently being loaded.

offline

offline: 1 The page was loaded in the offline mode, thus not refreshable.

refreshing

refreshing: 4 The page is currently refreshing its data.

Application module

2/18/2021 • 2 minutes to read • Edit Online

An application is a unit of runtime execution with sandboxing around concepts and data used inside of it. Each application consists of pages, actions, data queries, and logic that glue them together. An application is primarily described with a declarative metadata system, and can have an accompanying imperative extension model.

The imperative extension of the application is typically defined in a script module with a designated entry point, the main function, which allows the imperative logic to integrate with the application life cycle.

Types

Application

Hierarchy

Application

Properties

NAME	SIGNATURE	DESCRIPTION
minVersion	minVersion: string (optional)	An optional marker to indicate the minimum platform version required by this component. When this value is specified and the component tries to load in an older version of the platform, the corresponding workspace is not loaded and user is directed to install a newer version of the platform.

Methods

NAME	SIGNATURE	DESCRIPTION
appInit	appInit(metadata: ApplicationMetadata): any	This method is invoked at the point the application is about to run, with the instance of the application metadata loaded. The metadata passed in can be still modified to change behaviors before this method returns.

ApplicationMetadata

Hierarchy

ApplicationMetadata

Properties

NAME	SIGNATURE	DESCRIPTION
ColorName	ColorName: string (optional)	The theme color of the application
Configs	Configs: [name: string]: any (optional)	An application can have a set of named config supplied by the author or the resource provider
Description	Description: string (optional)	The description of the application
IconName	IconName: string (optional)	The representative icon of the application
ID	ID: string	The unique identifier of the application
Title	Title: string	The title of the application

Functions

main

main(metadataService: MetadataService, dataService: DataService, cacheService: CacheService, asyncService: AsyncService): Application

The main method of a business logic module. Each business logic module (as JavaScript file) must contain one main method. The method is invoked when the module is loaded and is being initialized. The method must return the component to run from this module.

Parameters

NAME	TYPE	DESCRIPTION
metadataService	MetadataService	
dataService	DataService	
cacheService	CacheService	
asyncService	AsyncService	

Returns Application

Defer module

2/18/2021 • 2 minutes to read • Edit Online

Functions

- all
- defer
- reject
- resolve

Types

Deferred

Hierarchy

Deferred

Properties

NAME	SIGNATURE	DESCRIPTION
promise	promise: Promise <T>	

Methods

NAME	SIGNATURE	DESCRIPTION
reject	reject(error?: any): void	
resolve	resolve(value?: T | PromiseLike <T>): void	

Functions

all

all(...args: any [ ]): Promise <any [ ]>

Parameters

NAME	TYPE	DESCRIPTION
...args	any [ ]	

Returns Promise <any [ ]>

defer

defer <T>(): Deferred <T>

Returns Deferred <T>

reject

reject(error?: any): Promise <any>

Parameters

NAME	TYPE	DESCRIPTION
error?	any	

Returns Promise <any>

resolve

resolve <T>(value?: T | PromiseLike <T>): Promise <T>

Parameters

NAME	TYPE	DESCRIPTION
value?	T	PromiseLike <T>	

Returns Promise <T>

Properties

NAME	SIGNATURE	DESCRIPTION
container	container: boolean (optional)	True if the control is a container.
generic	generic: boolean (optional)	
getDataSource	getDataSource: function(): any	
hidden	hidden: boolean	True if the control is hidden.

Methods

NAME	SIGNATURE	DESCRIPTION
applyDesign	applyDesign(design: Design): void	Applies given design to the design on the control.
dataContext	dataContext(): any	
getDesign	getDesign(): Design	Returns the design object of this control.
isEditable	isEditable(): boolean	Boolean indicating if the control is editable.

NAME	SIGNATURE	DESCRIPTION
metadata	metadata(): ControlMetadata	Returns the metadata object of this control.
parent	parent(): Control | Page	Returns the parent (control or page) of this control.
root	root(): Page	Returns the root form instance (page) of this control.

ControlMetadata

Hierarchy

ControlMetadata

- PageLinkMetadata
- ContainerControlMetadata
- InputControlMetadata
- ImageMetadata

Properties

NAME	SIGNATURE	DESCRIPTION
BoundEntity	BoundEntity: string (optional)	The entity to which the control is bound.
BoundField	BoundField: string (optional)	
Description	Description: string (optional)	Description of the control.
Editable	Editable: boolean (optional)	Boolean indicating if the control is editable.
ExtType	ExtType: ControlType (optional)	The extended control type. For example, a control of type Input might have an extended type of Barcode.
HelpText	HelpText: string (optional)	The keyboard shortcut for a command. For example, "(Shift+F5)"
Hidden	Hidden: boolean (optional)	Boolean indicating if the control is hidden or not.
Id	Id: string (optional)	Identification string for a control.
Label	Label: string (optional)	Label for a control. For example, a control representing a person's first name might have a label "First Name".
Name	Name: string (optional)	Name of a control.
Order	Order: number (optional)	Number indicating the order in which a control will appear on a page.
Type	Type: ControlType (optional)	String indicating the control type.

Type aliases

ControlType

ControlType: "FileUpload" | "Barcode" | "Input" | "MultilineInput" | "Navigation" | "Integer" | "Int64" | "Date" | "DateTime" | "ComboBox" | "Real" | "List" | "Lookup" | "MultiLookup" | "Navigation" | "Image" | "Group" | "Part" | "Calendar" | "HyperLink" | "Timer"

Controls must be assigned any of the types listed in ControlType.

Container module (Client APIs)

2/18/2021 • 4 minutes to read • Edit Online

A container control can contain any number of controls.

Index

Types

- ContainerControl
- ContainerControlDesign
- ContainerControlMetadata

Types

ContainerControl

Hierarchy

Control
└ ContainerControl
└ Group
└ List
└ Part

Properties

NAME	SIGNATURE	DESCRIPTION
container	container: boolean	True if the control is a container. Overrides Control.container
generic	generic: boolean (optional)	Inherited from Control.generic
getDataSource	getDataSource: function(): any	Inherited from Control.getDataSource
hidden	hidden: boolean	True if the control is hidden. Inherited from Control.hidden

Methods

NAME	SIGNATURE	DESCRIPTION
applyDesign	applyDesign(design: Design): void	Applies given design to the design on the control. Inherited from Control.applyDesign
dataContext	dataContext(): any	Inherited from Control.dataContext
getControl	getControl(controlName: string): Control	Given the name of a control, returns the control instance.
getControlById	getControlById(id: string): Control	Given the ID of a control, returns the control instance.

NAME	SIGNATURE	DESCRIPTION
getDesign	getDesign(): Design	Returns the design object of this control. Inherited from Control.getDesign
isEditable	isEditable(): boolean	Boolean indicating if the control is editable. Inherited from Control.isEditable
metadata	metadata(): ContainerControlMetadata	Returns the metadata object of this control. Overrides Control.metadata
parent	parent(): Control | Page	Returns the parent (control or page) of this control. Inherited from Control.parent
root	root(): Page	Returns the root form instance (page) of this control. Inherited from Control.root

ContainerControlDesign

Hierarchy

Design
└ ContainerControlDesign
└ GroupDesign
└ ListDesign
└ PartDesign

Properties

NAME	SIGNATURE	DESCRIPTION
alignItems	alignItems: string (optional)	This property is an alias for the CSS property "align-items". Inherited from Design.alignItems
alignSelf	alignSelf: string (optional)	Inherited from Design.alignSelf
allowScroll	allowScroll: string (optional)	True if the container will allow scrolling when its items do not fit into the container's available space. If a container has an item which may scroll, then set this property to false to prevent nested scrolling areas.
background	background: string (optional)	The background color of the container.
bindings	bindings: any (optional)	Inherited from Design.bindings
border	border: "none" | "solid" | "left" | "right" | "top" | "bottom" (optional)	The border behavior of a control. This property will not be inherited by the children. Inherited from Design.border

NAME	SIGNATURE	DESCRIPTION
color	color: string (optional)	The foreground color of the container. Inherited from Design.color
flexFlow	flexFlow: string (optional)	Specifying this property makes the component a flex container component. Inherited from Design.flexFlow
flexSize	flexSize: string (optional)	One number or two numbers written as a string. For example, "(size to grow) [(size-to-shrink)]" to accommodate available space in the immediate flex container. Inherited from Design.flexSize
fontSize	fontSize: "medium" | "xx-small" | "x-small" | "small" | "large" | "x-large" | "xx-large" (optional)	The proportional text size Inherited from Design.fontSize
fontWeight	fontWeight: "normal" | "bold" (optional)	Normal or bold text. Inherited from Design.fontWeight
itemBorder	itemBorder: "solid" | "none" (optional)	If true, a border will appear around each row in the list.
items	items: string | Design [ ] (optional)	An array containing the components to place inside of the container.
justifyItems	justifyItems: "flex-start" | "flex-end" | "center" | "space-between" (optional)	This property is an alias for the CSS property "justify-content". Inherited from Design.justifyItems
label	label: string (optional)	Inherited from Design.label
labelPosition	labelPosition: "stacked" | "hidden" | "inline" (optional)	Determines how a label is positioned, if at all. By default, labelPosition is set to stacked. Inherited from Design.labelPosition
name	name: string (optional)	Inherited from Design.name
padding	padding: "none" | "small" | "std" (optional)	Allows specifying the component's padding behavior. Inherited from Design.padding
type	type: ControlType (optional)	The type of the control as a string. Inherited from Design.type

ContainerControlMetadata

Hierarchy

ControlMetadata
- ContainerControlMetadata
  - GroupMetadata
  - ListMetadata

└ PartMetadata

Properties

NAME	SIGNATURE	DESCRIPTION
BoundEntity	BoundEntity: string (optional)	The entity to which the control is bound. Inherited from ControlMetadata.BoundEntity
BoundField	BoundField: string (optional)	Inherited from ControlMetadata.BoundField
Description	Description: string (optional)	Description of the control. Inherited from ControlMetadata.Description
Editable	Editable: boolean (optional)	Boolean indicating if the control is editable. Inherited from ControlMetadata.Editable
ExtType	ExtType: ControlType (optional)	The extended control type. For example, a control of type Input might have an extended type of Barcode. Inherited from ControlMetadata.ExtType
HelpText	HelpText: string (optional)	The keyboard shortcut for a command. For example, "(Shift+F5)" Inherited from ControlMetadata.HelpText
Hidden	Hidden: boolean (optional)	Boolean indicating if the control is hidden or not. Inherited from ControlMetadata.Hidden
Id	Id: string (optional)	Identification string for a control. Inherited from ControlMetadata.Id
Label	Label: string (optional)	Label for a control. For example, a control representing a person's first name might have a label "First Name". Inherited from ControlMetadata.Label
Name	Name: string (optional)	Name of a control. Inherited from ControlMetadata.Name
Order	Order: number (optional)	Number indicating the order in which a control will appear on a page. Inherited from ControlMetadata.Order
Type	Type: ControlType (optional)	String indicating the control type. Inherited from ControlMetadata.Type

Properties

NAME	SIGNATURE	DESCRIPTION
container	container: boolean (optional)	True if the control is a container. Inherited from Control.container
generic	generic: boolean (optional)	Inherited from Control.generic
getDataSource	getDataSource: function(): any	Inherited from Control.getDataSource
hidden	hidden: boolean	True if the control is hidden. Inherited from Control.hidden

Methods

NAME	SIGNATURE	DESCRIPTION
applyDesign	applyDesign(IDesign: FieldDesign): void	Applies given design to the design on the control. Overrides Control.applyDesign
dataContext	dataContext(): any	Inherited from Control.dataContext
getDesign	getDesign(): Design	Returns the design object of this control. Inherited from Control.getDesign
getEditableFormattedValue	getEditableFormattedValue(): string | number | Date	Gets a formatted decimal string value of an editable field control.

NAME	SIGNATURE	DESCRIPTION
getEditableValue	getEditableValue(): string | number | Date	Gets the value for an editable field control.
getEntityRef	getEntityRef(): any	Gets value of entityRef binding to control.
getFormattedValue	getFormattedValue(): string	Gets a formatted decimal string value.
getRefLink	getRefLink(): NavigationArgs	Gets the navigation object for a reference link.
getValue	getValue(): any	Gets the value for a field control.
hasRefLink	hasRefLink(): boolean	Returns true if the field has a refLink, otherwise false.
hasUnWrapText	hasUnWrapText(): boolean	Gets wrap text property of control.
isEditable	isEditable(): boolean	Boolean indicating if the control is editable. Inherited from Control.isEditable
metadata	metadata(): FieldMetadata	Returns the metadata object of this control. Overrides InputControl.metadata
parent	parent(): Control | Page	Returns the parent (control or page) of this control. Inherited from Control.parent
root	root(): Page	Returns the root form instance (page) of this control. Inherited from Control.root
setEditableValue	setEditableValue(value: string | number | Date): void	Sets the value for an editable field control.

Events

NAME	SIGNATURE	DESCRIPTION
onDataChanged	onDataChanged: EventHook <null>	An event that is triggered when the input control's data changes. Inherited from InputControl.onDataChanged

alignSelf	alignSelf: string (optional)	Inherited from Design.alignSelf
bindings	bindings: any (optional)	Inherited from Design.bindings
border	border: "none" | "solid" | "left" | "right" | "top" | "bottom" (optional)	The border behavior of a control. This property will not be inherited by the children. Inherited from Design.border
color	color: string (optional)	The foreground color of the container. Inherited from Design.color
flexFlow	flexFlow: string (optional)	Specifying this property makes the component a flex container component. Inherited from Design.flexFlow
flexSize	flexSize: string (optional)	One number or two numbers written as a string. For example, "(size to grow) [(size-to-shrink)]" to accommodate available space in the immediate flex container. Inherited from Design.flexSize
fontSize	fontSize: "medium" | "xx-small" | "x-small" | "small" | "large" | "x-large" | "xx-large" (optional)	The proportional text size Inherited from Design.fontSize
fontWeight	fontWeight: "normal" | "bold" (optional)	Normal or bold text. Inherited from Design.fontWeight
justifyItems	justifyItems: "flex-start" | "flex-end" | "center" | "space-between" (optional)	This property is an alias for the CSS property "justify-content". Inherited from Design.justifyItems
label	label: string (optional)	Inherited from Design.label
labelPosition	labelPosition: "stacked" | "hidden" | "inline" (optional)	Determines how a label is positioned, if at all. By default, labelPosition is set to stacked. Inherited from Design.labelPosition
name	name: string (optional)	Inherited from Design.name
padding	padding: "none" | "small" | "std" (optional)	Allows specifying the component's padding behavior. Inherited from Design.padding
type	type: ControlType (optional)	The type of the control as a string. Inherited from Design.type

FieldMetadata

Hierarchy

InputControlMetadata

└ FieldMetadata

Properties

NAME	SIGNATURE	DESCRIPTION
BoundEntity	BoundEntity: string (optional)	The entity to which the control is bound. Inherited from ControlMetadata.BoundEntity
BoundField	BoundField: string (optional)	Inherited from ControlMetadata.BoundField
DecimalPlaces	DecimalPlaces: number (optional)	The number of decimals that appear on a field of type "Real".
Description	Description: string (optional)	Description of the control. Inherited from ControlMetadata.Description
Editable	Editable: boolean (optional)	Boolean indicating if the control is editable. Inherited from ControlMetadata.Editable
ExtType	ExtType: ControlType (optional)	The extended control type. For example, a control of type Input might have an extended type of Barcode. Inherited from ControlMetadata.ExtType
Formatting	Formatting: any (optional)	Formats a field of type "DateTime" or "Date".
HelpText	HelpText: string (optional)	The keyboard shortcut for a command. For example, "(Shift+F5)" Inherited from ControlMetadata.HelpText
Hidden	Hidden: boolean (optional)	Boolean indicating if the control is hidden or not. Inherited from ControlMetadata.Hidden
Id	Id: string (optional)	Identification string for a control. Inherited from ControlMetadata.Id
Label	Label: string (optional)	Label for a control. For example, a control representing a person's first name might have a label "First Name". Inherited from ControlMetadata.Label

NAME	SIGNATURE	DESCRIPTION
LinkType	LinkType: "Telephone" | "Email" | "Url" (optional)	Assigning the link type of a field allows for the appropriate mobile application to be opened when the link is selected.
Mandatory	Mandatory: boolean (optional)	If set to true then input for the control is required for the task to be completed. Mandatory controls will have a red outline. Inherited from InputControlMetadata.Mandatory
Name	Name: string (optional)	Name of a control. Inherited from ControlMetadata.Name
NumSequence	NumSequence: NumberSequenceConfig (optional)	Used for auto detecting and changing visibility of the number sequence controls in the task or page, based on AX number sequence configuration, through extended business logic. Inherited from InputControlMetadata.NumSequence
Order	Order: number (optional)	Number indicating the order in which a control will appear on a page. Inherited from ControlMetadata.Order
ReferenceAppId	ReferenceAppId: string (optional)	The ID of the app that the field control lives in.
ReferencePageId	ReferencePageId: string (optional)	The ID of the page that the field control lives in.
Style	Style: string (optional)	Styles a field of type "DateTime" or "Date".
Type	Type: ControlType (optional)	String indicating the control type. Inherited from ControlMetadata.Type
UnWrapText	UnWrapText: boolean (optional)	False by default -- text of the page will be wrapped.
WrapText	WrapText: boolean (optional)	If true then the text of the field control will wrap to the next line.

File Uploader module

2/18/2021 • 4 minutes to read • Edit Online

A control for uploading images.

Properties

NAME	SIGNATURE	DESCRIPTION
container	container: boolean (optional)	True if the control is a container. Inherited from Control.container
generic	generic: boolean (optional)	Inherited from Control.generic
getDataSource	getDataSource: function(): any	Inherited from Control.getDataSource
hidden	hidden: boolean	True if the control is hidden. Inherited from Control.hidden
image	image: Image	

Methods

NAME	SIGNATURE	DESCRIPTION
applyDesign	applyDesign(IDesign: FileUploaderDesign): void	Applies given design to the design on the control. Overrides Control.applyDesign
canLoadFromDevice	canLoadFromDevice(): boolean	Returns true if the mobile phone has camera plugin.
dataContext	dataContext(): any	Inherited from Control.dataContext
getDesign	getDesign(): Design	Returns the design object of this control. Inherited from Control.getDesign

NAME	SIGNATURE	DESCRIPTION
getImage	getImage(options: any): Promise <string>	Returns a promise of an object with image data.
getValue	getValue(): any	Gets the value of the entity that is bound to the control. Overrides Value.getValue
isEditable	isEditable(): boolean	Boolean indicating if the control is editable. Inherited from Control.isEditable
loadFromFileSystem	loadFromFileSystem(file: Blob): Promise <any>	
metadata	metadata(): FileUploaderMetadata	Returns the metadata object of this control. Overrides Value.metadata
parent	parent(): Control | Page	Returns the parent (control or page) of this control. Inherited from Control.parent
root	root(): Page	Returns the root form instance (page) of this control. Inherited from Control.root
setCamera	setCamera(camera: any): void	Set the camera object on the control.
setValue	setValue(value: string): void	Sets the value of the control. Inherited from Value.setValue

Events

NAME	SIGNATURE	DESCRIPTION
onDataChanged	onDataChanged: EventHook <null>	An event that is triggered when the input control's data changes. Inherited from InputControl.onDataChanged

NumSequence	NumSequence: NumberSequenceConfig (optional)	Used for auto detecting and changing visibility of the number sequence controls in the task or page, based on AX number sequence configuration, through extended business logic. Inherited from InputControlMetadata.NumSequence
Order	Order: number (optional)	Number indicating the order in which a control will appear on a page. Inherited from ControlMetadata.Order
Type	Type: ControlType (optional)	String indicating the control type. Inherited from ControlMetadata.Type

Group module

2/18/2021 • 4 minutes to read • Edit Online

A group control is a container control that has any number of controls as children.

Index

Types

- Group
- GroupDesign
- GroupMetadata

Types

Group

Hierarchy

ContainerControl
└ Group

Properties

NAME	SIGNATURE	DESCRIPTION
container	container: boolean	True if the control is a container. Inherited from ContainerControl.container Overrides Control.container
generic	generic: boolean (optional)	Inherited from Control.generic
getDataSource	getDataSource: function(): any	Inherited from Control.getDataSource
hidden	hidden: boolean	True if the control is hidden. Inherited from Control.hidden

Methods

NAME	SIGNATURE	DESCRIPTION
applyDesign	applyDesign(IDesign: GroupDesign): void	Applies given design to the design on the control. Overrides Control.applyDesign
dataContext	dataContext(): any	Inherited from Control.dataContext
getChildren	getChildren(): Control [ ]	Returns the list of children associated with this group control.
getControl	getControl(controlName: string): Control	Given the name of a control, returns the control instance. Inherited from ContainerControl.getControl

NAME	SIGNATURE	DESCRIPTION
getControlById	getControlById(id: string): Control	Given the ID of a control, returns the control instance. Inherited from ContainerControl.getControlById
getDesign	getDesign(): Design	Returns the design object of this control. Inherited from Control.getDesign
isEditable	isEditable(): boolean	Boolean indicating if the control is editable. Inherited from Control.isEditable
metadata	metadata(): GroupMetadata	Returns the metadata object of this control. Overrides ContainerControl.metadata
parent	parent(): Control | Page	Returns the parent (control or page) of this control. Inherited from Control.parent
root	root(): Page	Returns the root form instance (page) of this control. Inherited from Control.root

GroupDesign

Hierarchy

ContainerControlDesign
└ GroupDesign

Properties

NAME	SIGNATURE	DESCRIPTION
alignItems	alignItems: string (optional)	This property is an alias for the CSS property "align-items". Inherited from Design.alignItems
alignSelf	alignSelf: string (optional)	Inherited from Design.alignSelf
allowScroll	allowScroll: string (optional)	True if the container will allow scrolling when its items do not fit into the container's available space. If a container has an item which may scroll, then set this property to false to prevent nested scrolling areas. Inherited from ContainerControlDesign.allowScroll
background	background: string (optional)	The background color of the container. Inherited from ContainerControlDesign.background
bindings	bindings: any (optional)	Inherited from Design.bindings

NAME	SIGNATURE	DESCRIPTION
border	border: "none" | "solid" | "left" | "right" | "top" | "bottom" (optional)	The border behavior of a control. This property will not be inherited by the children. Inherited from Design.border
color	color: string (optional)	The foreground color of the container. Inherited from Design.color
flexFlow	flexFlow: string (optional)	Specifying this property makes the component a flex container component. Inherited from Design.flexFlow
flexSize	flexSize: string (optional)	One number or two numbers written as a string. For example, "(size to grow) [(size-to-shrink)]" to accommodate available space in the immediate flex container. Inherited from Design.flexSize
fontSize	fontSize: "medium" | "xx-small" | "x-small" | "small" | "large" | "x-large" | "xx-large" (optional)	The proportional text size Inherited from Design.fontSize
fontWeight	fontWeight: "normal" | "bold" (optional)	Normal or bold text. Inherited from Design.fontWeight
itemBorder	itemBorder: "solid" | "none" (optional)	If true, a border will appear around each row in the list. Inherited from ContainerControlDesign.itemBorder
items	items: string | Design [ ] (optional)	An array containing the components to place inside of the container. Inherited from ContainerControlDesign.items
justifyItems	justifyItems: "flex-start" | "flex-end" | "center" | "space-between" (optional)	This property is an alias for the CSS property "justify-content". Inherited from Design.justifyItems
label	label: string (optional)	Inherited from Design.label
labelPosition	labelPosition: "stacked" | "hidden" | "inline" (optional)	Determines how a label is positioned, if at all. By default, labelPosition is set to stacked. Inherited from Design.labelPosition
name	name: string (optional)	Inherited from Design.name
padding	padding: "none" | "small" | "std" (optional)	Allows specifying the component's padding behavior. Inherited from Design.padding

NAME	SIGNATURE	DESCRIPTION
type	type: ControlType (optional)	The type of the control as a string. Inherited from Design.type

NAME	SIGNATURE	DESCRIPTION
BoundEntity	BoundEntity: string (optional)	The entity to which the control is bound. Inherited from ControlMetadata.BoundEntity
BoundField	BoundField: string (optional)	Inherited from ControlMetadata.BoundField
Description	Description: string (optional)	Description of the control. Inherited from ControlMetadata.Description
Editable	Editable: boolean (optional)	Boolean indicating if the control is editable. Inherited from ControlMetadata.Editable
ExtType	ExtType: ControlType (optional)	The extended control type. For example, a control of type Input might have an extended type of Barcode. Inherited from ControlMetadata.ExtType
HelpText	HelpText: string (optional)	The keyboard shortcut for a command. For example, "(Shift+F5)" Inherited from ControlMetadata.HelpText
Hidden	Hidden: boolean (optional)	Boolean indicating if the control is hidden or not. Inherited from ControlMetadata.Hidden
Id	Id: string (optional)	Identification string for a control. Inherited from ControlMetadata.Id
Label	Label: string (optional)	Label for a control. For example, a control representing a person's first name might have a label "First Name". Inherited from ControlMetadata.Label
Mandatory	Mandatory: boolean (optional)	If set to true then input for the control is required for the task to be completed. Mandatory controls will have a red outline.
Name	Name: string (optional)	Name of a control. Inherited from ControlMetadata.Name
NumSequence	NumSequence: NumberSequenceConfig (optional)	Used for auto detecting and changing visibility of the number sequence controls in the task or page, based on AX number sequence configuration, through extended business logic.

NAME	SIGNATURE	DESCRIPTION
Order	Order: number (optional)	Number indicating the order in which a control will appear on a page. Inherited from ControlMetadata.Order
Type	Type: ControlType (optional)	String indicating the control type. Inherited from ControlMetadata.Type

NumberSequenceConfig

Hierarchy

NumberSequenceConfig

Properties

NAME	SIGNATURE	DESCRIPTION
dataType	dataType: string	The data type is used to lookup whether the number sequence is editable or not on the reference page.
referencePageName	referencePageName: string	Page name of the page that defines if the num sequence is editable.

List module

2/18/2021 • 6 minutes to read • Edit Online

A list is a control that contains any numbers of rows. Each row follows a template for the layout of any number of controls. Lists come in two styles: simple and card.

ContainerControl
└ List

Properties

NAME	SIGNATURE	DESCRIPTION
$accessibility	$accessibility: any	
DefaultSearchColumn	DefaultSearchColumn: string	
container	container: boolean	True if the control is a container. Inherited from ContainerControl.container Overrides Control.container
emptyListMessage	emptyListMessage: string	Settable property to override default empty list message.
enableMultiSelect	enableMultiSelect: boolean	
generic	generic: boolean (optional)	Inherited from Control.generic
getDataSource	getDataSource: function(): any	Inherited from Control.getDataSource
hidden	hidden: boolean	True if the control is hidden. Inherited from Control.hidden
hideEmptyListMessage	hideEmptyListMessage: boolean	If true, no message is shown if the list is empty. To set this property, update the corresponding metadata property via configureControl.

NAME	SIGNATURE	DESCRIPTION
imageFields	imageFields: any [ ]	
performingRemoteSearch	performingRemoteSearch: boolean	
searchQuery	searchQuery: [value: string]: any	

Methods

NAME	SIGNATURE	DESCRIPTION
allowsNavigation	allowsNavigation(): boolean	
applyDesign	applyDesign(IDesign: ListDesign): void	Applies given design to the design on the control. Overrides Control.applyDesign
applySearch	applySearch(): void	
canPerformRemoteSearch	canPerformRemoteSearch(): boolean	
clearSearch	clearSearch(): void	
dataContext	dataContext(): any	Inherited from Control.dataContext
getColumnLabel	getColumnLabel(id: string): string	
getControl	getControl(controlName: string): Control	Given the name of a control, returns the control instance. Inherited from ContainerControl.getControl
getControlById	getControlById(id: string): Control	Given the ID of a control, returns the control instance. Inherited from ContainerControl.getControlById
getControlMetadata	getControlMetadata(controlName: string): Control	
getControlMetadataById	getControlMetadataById(id: string): Control	
getData	getData(): any [ ]	
getDesign	getDesign(): Design	Returns the design object of this control. Inherited from Control.getDesign
getListData	getListData(): any	
getRenderedRows	getRenderedRows(): Row [ ]	

NAME	SIGNATURE	DESCRIPTION
getRowNavigation	getRowNavigation(row: Row): Promise <any> | any	
getRowSelectionCount	getRowSelectionCount(): number	
getRowSelections	getRowSelections(): string [ ]	
getRowTracking	getRowTracking(row: any, index: string): string	
getSearchColumn	getSearchColumn(): string	
getSearchColumnLabel	getSearchColumnLabel(): string	
getSearchableColumns	getSearchableColumns(): any [ ]	
hideSearchBar	hideSearchBar(): boolean	
isEditable	isEditable(): boolean	Boolean indicating if the control is editable. Inherited from Control.isEditable
loadMetaData	loadMetaData(): void	
loadMore	loadMore(): void	
metadata	metadata(): ListMetadata	Returns the metadata object of this control. Overrides ContainerControl.metadata
parent	parent(): Control | Page	Returns the parent (control or page) of this control. Inherited from Control.parent
performRemoteSearch	performRemoteSearch(): void	
root	root(): Page	Returns the root form instance (page) of this control. Inherited from Control.root
selectSearchColumn	selectSearchColumn(column: string): void	
setRowSections	setRowSections(selections: string [ ]): void

Properties

NAME	SIGNATURE	DESCRIPTION
alignItems	alignItems: string (optional)	This property is an alias for the CSS property "align-items". Inherited from Design.alignItems
alignSelf	alignSelf: string (optional)	Inherited from Design.alignSelf
allowScroll	allowScroll: string (optional)	True if the container will allow scrolling when its items do not fit into the container's available space. If a container has an item which may scroll, then set this property to false to prevent nested scrolling areas. Inherited from ContainerControlDesign.allowScroll
background	background: string (optional)	The background color of the container. Inherited from ContainerControlDesign.background
bindings	bindings: any (optional)	Inherited from Design.bindings
border	border: "none" | "solid" | "left" | "right" | "top" | "bottom" (optional)	The border behavior of a control. This property will not be inherited by the children. Inherited from Design.border
color	color: string (optional)	The foreground color of the container. Inherited from Design.color
design	design: GroupDesign (optional)	The design object that will be applied to each row.
flexFlow	flexFlow: string (optional)	Specifying this property makes the component a flex container component. Inherited from Design.flexFlow
flexSize	flexSize: string (optional)	One number or two numbers written as a string. For example, "(size to grow) [(size-to-shrink)]" to accommodate available space in the immediate flex container. Inherited from Design.flexSize
fontSize	fontSize: "medium" | "xx-small" | "x-small" | "small" | "large" | "x-large" | "xx-large" (optional)	The proportional text size Inherited from Design.fontSize

NAME	SIGNATURE	DESCRIPTION
fontWeight	fontWeight: "normal" | "bold" (optional)	Normal or bold text. Inherited from Design.fontWeight
hideArrow	hideArrow: boolean (optional)	Allows an arrow (>) on a default styled navigation control to be hidden.
hideSearchBar	hideSearchBar: boolean (optional)	If true, the search bar will be hidden.
itemBorder	itemBorder: "solid" | "none" (optional)	If true, a border will appear around each row in the list. Inherited from ContainerControlDesign.itemBorder
items	items: string | Design [ ] (optional)	An array containing the components to place inside of the container. Inherited from ContainerControlDesign.items
justifyItems	justifyItems: "flex-start" | "flex-end" | "center" | "space-between" (optional)	This property is an alias for the CSS property "justify-content". Inherited from Design.justifyItems
label	label: string (optional)	Inherited from Design.label
labelPosition	labelPosition: "stacked" | "hidden" | "inline" (optional)	Determines how a label is positioned, if at all. By default, labelPosition is set to stacked. Inherited from Design.labelPosition
name	name: string (optional)	Inherited from Design.name
padding	padding: "none" | "small" | "std" (optional)	Allows specifying the component's padding behavior. Inherited from Design.padding
type	type: ControlType (optional)	The type of the control as a string. Inherited from Design.type

└ ListMetadata

Properties

NAME	SIGNATURE	DESCRIPTION
BoundEntity	BoundEntity: string (optional)	The entity to which the control is bound. Inherited from ControlMetadata.BoundEntity
BoundField	BoundField: string (optional)	Inherited from ControlMetadata.BoundField

NAME	SIGNATURE	DESCRIPTION
Children	Children: ControlMetadata [ ] (optional)	List of metadata for controls that will appear in each row of the list.
Description	Description: string (optional)	Description of the control. Inherited from ControlMetadata.Description
DetailsPageAppId	DetailsPageAppId: string (optional)	App ID of the page that each row in the list will navigate to.
DetailsPageId	DetailsPageId: string (optional)	The ID of the page to which each row will navigate.
Editable	Editable: boolean (optional)	Boolean indicating if the control is editable. Inherited from ControlMetadata.Editable
EmptyListMessage	EmptyListMessage: string (optional)	If set, overrides the default message for empty lists.
ExtType	ExtType: ControlType (optional)	The extended control type. For example, a control of type Input might have an extended type of Barcode. Inherited from ControlMetadata.ExtType
HelpText	HelpText: string (optional)	The keyboard shortcut for a command. For example, "(Shift+F5)" Inherited from ControlMetadata.HelpText
Hidden	Hidden: boolean (optional)	Boolean indicating if the control is hidden or not. Inherited from ControlMetadata.Hidden
HideEmptyListMessage	HideEmptyListMessage: boolean (optional)	If true, the empty list message will be hidden.
HideSearchBar	HideSearchBar: boolean (optional)	If true, the search bar will be hidden.
Id	Id: string (optional)	Identification string for a control. Inherited from ControlMetadata.Id
InfiniteScroll	InfiniteScroll: boolean (optional)	If set to true then the list will allow infinite scroll.
InfiniteScrollPageSize	InfiniteScrollPageSize: number (optional)	Number of rows to load initially and the number of rows to load after the user reaches the end of the currently displayed rows.

NAME	SIGNATURE	DESCRIPTION
Label	Label: string (optional)	Label for a control. For example, a control representing a person's first name might have a label "First Name". Inherited from ControlMetadata.Label
ListStyle	ListStyle: string (optional)	Dictates the list template type.
MultiSelect	MultiSelect: boolean (optional)	If true, then the list will be a multi-select list.
Name	Name: string (optional)	Name of a control. Inherited from ControlMetadata.Name
NonEntityProjection	NonEntityProjection: boolean (optional)	
Order	Order: number (optional)	Number indicating the order in which a control will appear on a page. Inherited from ControlMetadata.Order
Type	Type: ControlType (optional)	String indicating the control type. Inherited from ControlMetadata.Type

Methods

NAME	SIGNATURE	DESCRIPTION
navigationHandler	Optional navigationHandler(row: Row): Promise <any> | NavigationArgs	A function that determines the navigation for a given row.

Events

NAME	SIGNATURE	DESCRIPTION
OnNavigate	OnNavigate: function(navigation: NavigationArgs): any (optional)	An event that is triggered when a pagelink control is selected.
OnRowSelect	OnRowSelect: function(row: Row): void (optional)	An event that is triggered when a row is selected.

Row

Hierarchy

Row

Properties

NAME	SIGNATURE	DESCRIPTION
fieldList	fieldList: Control [ ]	
headerField	headerField: Control	
hidden	hidden: boolean	If true then the row will be hidden.

NAME	SIGNATURE	DESCRIPTION
imageFields	imageFields: Control [ ]	
isSelected	isSelected: boolean	
item	item: any	A container of rendered data.
template	template: Group	Group control that represents the template for a row.

Methods

NAME	SIGNATURE	DESCRIPTION
getControl	getControl(controlName: string): Control	
getControlById	getControlById(id: string): Control	
getControlValueById	getControlValueById(id: string): string	
getRowHeader	getRowHeader(): Control	
getRowId	getRowId(): string	
hasImageField	hasImageField(): boolean	Returns true if the row has an image field.
isEntityCreatedNew	isEntityCreatedNew(): boolean	
isEntityDeleted	isEntityDeleted(): boolean	
isEntityModified	isEntityModified(): boolean	
isEntitySyncPending	isEntitySyncPending(): boolean	
select	select(): any	

Lookup module

2/18/2021 • 4 minutes to read • Edit Online

A lookup is an input control that is used to select an input from a list of options. For example, a lookup could be used to lookup a customer when linking a customer to a new sales order.

Page module

2/18/2021 • 6 minutes to read • Edit Online

The IPage interface encapsulates the various properties, life cycle and event hooks associated with a page in a workspace.

Page data Synchronization

Pages that can submit changes (also referred to as actions) go through various stages before they're completely in sync with the server. As soon as a page is submitted, there are three possible consequences:

- It fails client-side validation: The client logic might prevent the page from being submitted.
- The client is online: The submission is processed as soon as the application-wide sync queue is cleared.
- The client is offline: The submission is added to the application-wide sync queue and stays there as long as the client is offline.

While a submission is waiting to be synchronized, it can be in one of these states:

- Pending: The submission is still pending and can still be edited.
- Processing: The submission is currently being synchronized. In this state, any further edits are not allowed on the page.

After a submission goes through to the server, it can be in one of these states:

- Synchronized: The submission is accepted by the server and is synchronized.
- Error: The server rejects the submission and the page enters an error state.

Multiple pending submissions for a given page and context might be clubbed (and sent) together if the page is deemed to be idempotent. This implies that the server need not process all submissions in any order and depends on the design of the page on the server.

flexFlow	flexFlow: string (optional)	Specifying this property makes the component a flex container component.
flexSize	flexSize: string (optional)	One number or two numbers written as a string. For example, "(size to grow) [(size-to-shrink)]" to accommodate available space in the immediate flex container.
fontSize	fontSize: "medium" | "xx-small" | "x-small" | "small" | "large" | "x-large" | "xx-large" (optional)	The proportional text size
fontWeight	fontWeight: "normal" | "bold" (optional)	Normal or bold text.
justifyItems	justifyItems: "flex-start" | "flex-end" | "center" | "space-between" (optional)	This property is an alias for the CSS property "justify-content".
label	label: string (optional)	
labelPosition	labelPosition: "stacked" | "hidden" | "inline" (optional)	Determines how a label is positioned, if at all. By default, labelPosition is set to stacked.
name	name: string (optional)	
padding	padding: "none" | "small" | "std" (optional)	Allows specifying the component's padding behavior.
type	type: ControlType (optional)	The type of the control as a string.

NavigationArgs

Hierarchy

PageTarget

└ NavigationArgs

Properties

NAME	SIGNATURE	DESCRIPTION
label	label: string (optional)	
options	options: any (optional)	
params	params: PageOptions (optional)	Inherited from PageTarget.params

NAME	SIGNATURE	DESCRIPTION
replace	replace: boolean (optional)	If set to true, removes current view firing navigation from navigation history stack.
to	to: string (optional)	Inherited from PageTarget.to
url	url: string (optional)	If provided, this link is directly opened.

Page

Hierarchy

Page

Properties

NAME	SIGNATURE	DESCRIPTION
children	children: Control [ ]	The list of all direct children controls of the page.
dataLoadedInitially	dataLoadedInitially: Promise <void>	A promise which resolves when the data has loaded for the first time.
initialized	initialized: boolean	True if the page instance has been initialized.
metadata	metadata: PageMetadata	The page metadata.
metadataLoaded	metadataLoaded: Promise <void>	A promise which resolves when the metadata has finished loading.
pageContext	pageContext: string	The current page context.
pageFilter	pageFilter: DataFilter	The current filter applied on the page.
state	state: PageState	The current state of the page.
syncError	syncError: boolean	True if the page's submission is in error state. This normally happens when the server rejects submissions due to validation errors.
syncPending	syncPending: boolean	True if the page's submission is waiting to be synced.
syncProcessing	syncProcessing: boolean	True if the page instance is currently syncing its submission.
syncUnitEditable	syncUnitEditable: boolean	True if it's possible to edit a submission while it's waiting to be synchronized.
title	title: string	The title of the page.

Methods

NAME	SIGNATURE	DESCRIPTION
canSubmit	canSubmit(): boolean	Returns true if action page can be submitted and there are no validation error messages.
close	close(): void	Dispose the page instance and all its lifecycle events.
getAction	getAction(actionName: string): PageLink	Get a page action by name.
getActions	getActions(): PageLink [ ]	Get all page actions.
getControl	getControl(controlName: string): Control	Get a page control by name.
getDesign	getDesign(): Design	Get the design object associated with the page.
getEntityContext	getEntityContext(): EntityRef	Get current entity context.
isEditable	isEditable(): boolean	Returns true if the page is an Action Page
refreshData	refreshData(): Promise <void>	Force refresh page data.
resume	resume(): Promise <void>	Resume a temporarily suspended page.
submit	submit(): Promise <CompleteEventArgs>	Submit an Action.
suspend	suspend(): void	Temporarily suspend a page.

Events

NAME	SIGNATURE	DESCRIPTION
onClose	onClose: EventHook <null>	Event that is raised when a page is closed.
onComplete	onComplete: EventHook <any>	Event that is raised when an action is completed.
onDataLoaded	onDataLoaded: EventHook <any>	Event that fires when the page data has loaded.
onInit	onInit: EventHook <any>	Event that fires when a page instance has been initialized, and the metadata has been loaded.
onPreInit	onPreInit: EventHook <any>	Event that fires when a page instance has been initialized.

NAME	SIGNATURE	DESCRIPTION
onRefresh	onRefresh: EventHook <null>	Event that fires on forced page refresh, before new data has been loaded.
onStateChange	onStateChange: EventHook <null>	Event that fires when the page state changes.
onSubmit	onSubmit: EventHook <PageSubmitArgs>	Event that fires before an action is submitted. It can be intercepted for action validation deferring
onSyncStatusChange	onSyncStatusChange: EventHook <null>	Event that fires when the page sync status changes.

PageMetadata

Hierarchy

PageMetadata

Properties

NAME	SIGNATURE	DESCRIPTION
Controls	Controls: ControlMetadata [ ] (optional)	
Design	Design: Design (optional)	
Id	Id: string (optional)	
QuickSubmit	QuickSubmit: boolean (optional)	
SourcePageId	SourcePageId: string (optional)	
SubmitButtonDesign	SubmitButtonDesign: Design (optional)	
Tasks	Tasks: PageMetadata [ ] (optional)	
Title	Title: string (optional)	

Events

NAME	SIGNATURE	DESCRIPTION
OnDataLoaded	OnDataLoaded: function(sender: Page, dataWrapper: any): void (optional)	
OnInit	OnInit: function(sender: Page): void (optional)	
OnPreInit	OnPreInit: function(sender: Page): void (optional)	
OnSubmit	OnSubmit: function(dataValues: any, args: any): void (optional)	

NAME	SIGNATURE	DESCRIPTION
OnTaskSubmitted	OnTaskSubmitted: function(taskHandle: any, taskOptions: any): any (optional)	
OnTaskSubmitting	OnTaskSubmitting: function(taskOptions: any): any (optional)	

PageOptions

Hierarchy

PageOptions

Properties

NAME	SIGNATURE	DESCRIPTION
appId	appId: string (optional)	
design	design: Design (optional)	
excludeContext	excludeContext: boolean (optional)	
filter	filter: DataFilter (optional)	
filterLocalOnly	filterLocalOnly: boolean (optional)	
pageContext	pageContext: string (optional)	
pageId	pageId: string (optional)	
readOptions	readOptions: IReadOptions (optional)	

PageSubmitArgs

Hierarchy

PageSubmitArgs

Properties

NAME	SIGNATURE	DESCRIPTION
dataValues	dataValues: any	Get the payload of the submit action.
sender	sender: Page	Get the sender page instance of the submit action.

Methods

NAME	SIGNATURE	DESCRIPTION
addMessage	addMessage(message: string, type: any): any	Add a validation error message to be displayed.
cancel	cancel(): any	Prevent the action from submitting.

NAME	SIGNATURE	DESCRIPTION
getMessages	getMessages(): string [ ]	Get all previously added messages
isCancelled	isCancelled(): boolean	Check if the submit action is cancelled.
wait	wait(promise: Promise <any>): any	Wait on a given promise before continuing with the submission.

Control
└ PageLink

Properties

NAME	SIGNATURE	DESCRIPTION
container	container: boolean (optional)	True if the control is a container. Inherited from Control.container
generic	generic: boolean (optional)	Inherited from Control.generic
getDataSource	getDataSource: function(): any	Inherited from Control.getDataSource
hidden	hidden: boolean	True if the control is hidden. Inherited from Control.hidden

Methods

NAME	SIGNATURE	DESCRIPTION
allowsNavigation	allowsNavigation(): boolean	
applyDesign	applyDesign(design: PageLinkDesign): void	Applies given design to the design on the control. Overrides Control.applyDesign
dataContext	dataContext(): any	Inherited from Control.dataContext
getCount	getCount(): number | string	
getDesign	getDesign(): Design	Returns the design object of this control. Inherited from Control.getDesign

NAME	SIGNATURE	DESCRIPTION
getNavigationHandler	getNavigationHandler(): NavigationArgs	
isEditable	isEditable(): boolean	Boolean indicating if the control is editable. Inherited from Control.isEditable
metadata	metadata(): PageLinkMetadata	Returns the metadata object of this control. Overrides Control.metadata
parent	parent(): Control | Page	Returns the parent (control or page) of this control. Inherited from Control.parent
root	root(): Page	Returns the root form instance (page) of this control. Inherited from Control.root
showCount	showCount(): boolean	

PageLinkDesign

Hierarchy

Design

└ PageLinkDesign

Properties

NAME	SIGNATURE	DESCRIPTION
alignItems	alignItems: string (optional)	This property is an alias for the CSS property "align-items". Inherited from Design.alignItems
alignSelf	alignSelf: string (optional)	Inherited from Design.alignSelf
background	background: string (optional)	Sets the background color.
bindings	bindings: any (optional)	Inherited from Design.bindings
border	border: "none" | "solid" | "left" | "right" | "top" | "bottom" (optional)	The border behavior of a control. This property will not be inherited by the children. Inherited from Design.border
color	color: string (optional)	The foreground color of the container. Inherited from Design.color
excludeContext	excludeContext: boolean (optional)	
flexFlow	flexFlow: string (optional)	Specifying this property makes the component a flex container component. Inherited from Design.flexFlow

NAME	SIGNATURE	DESCRIPTION
flexSize	flexSize: string (optional)	One number or two numbers written as a string. For example, "(size to grow) [(size-to-shrink)]" to accommodate available space in the immediate flex container. Inherited from Design.flexSize
fontSize	fontSize: "medium" | "xx-small" | "x-small" | "small" | "large" | "x-large" | "xx-large" (optional)	The proportional text size Inherited from Design.fontSize
fontWeight	fontWeight: "normal" | "bold" (optional)	Normal or bold text. Inherited from Design.fontWeight
hideArrow	hideArrow: boolean (optional)	Allows an arrow (>) on a default styled navigation control to be hidden.
icon	icon: string (optional)	Name of the icon that is displayed in the pagelink control.
justifyItems	justifyItems: "flex-start" | "flex-end" | "center" | "space-between" (optional)	This property is an alias for the CSS property "justify-content". Inherited from Design.justifyItems
label	label: string (optional)	Inherited from Design.label
labelPosition	labelPosition: "stacked" | "hidden" | "inline" (optional)	Determines how a label is positioned, if at all. By default, labelPosition is set to stacked. Inherited from Design.labelPosition
name	name: string (optional)	Inherited from Design.name
navigation	navigation: NavigationArgs (optional)	Navigation object of the pagelink.
padding	padding: "none" | "small" | "std" (optional)	Allows specifying the component's padding behavior. Inherited from Design.padding
showCount	showCount: boolean (optional)	If true, shows a count of the records present in the list on the target page.
style	style: string (optional)	Determines the visual style of the pagelink control. Options: * "inline": takes up the full width its container, with the label in-line with the icon * "button": takes up only as much width as needed by the label, with the label below the icon
type	type: ControlType (optional)	The type of the control as a string. Inherited from Design.type

PageLinkMetadata

Hierarchy

ControlMetadata
└ PageLinkMetadata

Properties

NAME	SIGNATURE	DESCRIPTION
BoundEntity	BoundEntity: string (optional)	The entity to which the control is bound. Inherited from ControlMetadata.BoundEntity
BoundField	BoundField: string (optional)	Inherited from ControlMetadata.BoundField
Description	Description: string (optional)	Description of the control. Inherited from ControlMetadata.Description
Editable	Editable: boolean (optional)	Boolean indicating if the control is editable. Inherited from ControlMetadata.Editable
ExcludeContext	ExcludeContext: boolean (optional)	
ExtType	ExtType: ControlType (optional)	The extended control type. For example, a control of type Input might have an extended type of Barcode. Inherited from ControlMetadata.ExtType
HelpText	HelpText: string (optional)	The keyboard shortcut for a command. For example, "(Shift+F5)" Inherited from ControlMetadata.HelpText
Hidden	Hidden: boolean (optional)	Boolean indicating if the control is hidden or not. Inherited from ControlMetadata.Hidden
Icon	Icon: string (optional)	Name of the icon that is displayed in the pagelink control.
IconSize	IconSize: number (optional)	Determines the size of the icon that is displayed in the pagelink control.
Id	Id: string (optional)	Identification string for a control. Inherited from ControlMetadata.Id
Label	Label: string (optional)	Label for a control. For example, a control representing a person's first name might have a label "First Name". Inherited from ControlMetadata.Label
Name	Name: string (optional)	Name of a control. Inherited from ControlMetadata.Name

NAME	SIGNATURE	DESCRIPTION
Navigation	Navigation: NavigationArgs (optional)	Navigation object of the pagelink.
Order	Order: number (optional)	Number indicating the order in which a control will appear on a page. Inherited from ControlMetadata.Order
ShowCount	ShowCount: boolean (optional)	If true, shows a count of the records present in the list on the target page.
Style	Style: string (optional)	Determines the visual style of the pagelink control.
Target	Target: string (optional)	Name of the target action or page to navigate to when the pagelink is selected.
Type	Type: ControlType (optional)	String indicating the control type. Inherited from ControlMetadata.Type
UseDataContext	UseDataContext: boolean (optional)	

Events

NAME	SIGNATURE	DESCRIPTION
OnNavigate	OnNavigate: function(navigation: NavigationArgs | string): any (optional)	An event that is triggered when the navigation is triggered.

Part module

2/18/2021 • 4 minutes to read • Edit Online

A part is a container control that contains only a page, allowing for a page to be embedded within a page.

getEntityData	getEntityData(entityType: any, entityId: string): any	
getPageData	getPageData(pageId: string, context: any, filter: any, allowedStaleness: number): Promise <PageData>	

MetadataService

Hierarchy

MetadataService

Properties

NAME	SIGNATURE	DESCRIPTION
version	version: string	Gets the version of the platform currently running.

Methods

NAME	SIGNATURE	DESCRIPTION
addControl	addControl(componentName: string, controlName: string, controlType: ControlType, parentContainerName?: string, options?: ControlMetadata): any	
compareVersion	compareVersion(versionToCompare: string): 1 | -1	Compares the current platform version with a reference version.
configureAction	configureAction(actionName: string, options: PageMetadata): any	Configuring an action allows specifying or overriding certain behaviors specific to actions.
configureControl	configureControl(componentName: string, controlName: string, options: ControlMetadata): any	Configuring a control allows specifying or overriding certain behaviors specific to the control. Note that the available behaviors vary by control type.
configureEntity	configureEntity(entityName: string, options: any): any	Configuring an entity allows specifying or overriding certain behaviors specific to the entity.
configureLookup	configureLookup(taskName: string, lookupControlName: string, options: LookupMetadata): any	Configures a field on an action to behave as a lookup. Requires using an existing page which contains a list control.
configurePage	configurePage(pageName: string, options: PageMetadata): any	Configuring a Page allows specifying or overriding certain behaviors specific to the Page.

NAME	SIGNATURE	DESCRIPTION
configureWorkspace	configureWorkspace(options: PageMetadata): any	Configuring a workspace allows specifying or overriding certain behaviors specific to the workspace.
findAction	findAction(actionName: string): PageMetadata	Gets a copy of the current metadata instance of a specified Action, for the purpose of inspecting the metadata (not to be used for changing the metadata).
findControl	findControl(componentMetadata: any, controlName: string): ControlMetadata	Gets a copy of the current metadata instance of a specified control, for the purpose of inspecting the metadata (not to be used for changing the metadata).
findPage	findPage(pageName: string): PageMetadata	Gets a copy of the current metadata instance of a specified page, for the purpose of inspecting the metadata (not to be used for changing the metadata).
getFilterExpression	getFilterExpression(pageName: string, listControlName: string, controlName: string, operator: ExpressionOperator, value: string): DataFilter	Create a DataFilter object for a list control based on the provided options.
getFormReference	getFormReference(componentName: string, filterContext: DataFilter, excludeContext: boolean, filterLocalOnly?: boolean): NavigationArgs	Create an INavigationArgs object for a specific page action to be used with a navigation control.
hideNavigation	hideNavigation(pageNamesToHide: string [ ]): any	Hides the specified page(s) from the default landing page.

PageData

Hierarchy

PageData

Methods

NAME	SIGNATURE	DESCRIPTION
getControlValue	getControlValue(controlName: string): any	Gets the value of a control directly from the data set loaded in the page.
setControlValue	setControlValue(controlName: string, value: any): any	Sets the value of a control directly into the data set loaded in the page.

Type aliases

ExpressionOperator

ExpressionOperator: "Is" | "IsNot" | "Contains" | "BeginsWith" | "EndsWith" | "GreaterThan" | "LessThan" | "GreaterThanOrEqual" | "LessThanOrEqual"

Represents possible values for the expression operator used in defining filters and in other places

Value module

2/18/2021 • 5 minutes to read • Edit Online

Id	Id: string (optional)	Identification string for a control. Inherited from ControlMetadata.Id
Label	Label: string (optional)	Label for a control. For example, a control representing a person's first name might have a label "First Name". Inherited from ControlMetadata.Label
Mandatory	Mandatory: boolean (optional)	If set to true then input for the control is required for the task to be completed. Mandatory controls will have a red outline. Inherited from InputControlMetadata.Mandatory
Name	Name: string (optional)	Name of a control. Inherited from ControlMetadata.Name

NAME	SIGNATURE	DESCRIPTION
NumSequence	NumSequence: NumberSequenceConfig (optional)	Used for auto detecting and changing visibility of the number sequence controls in the task or page, based on AX number sequence configuration, through extended business logic. Inherited from InputControlMetadata.NumSequence
Order	Order: number (optional)	Number indicating the order in which a control will appear on a page. Inherited from ControlMetadata.Order
Type	Type: ControlType (optional)	String indicating the control type. Inherited from ControlMetadata.Type

Application type

2/18/2021 • 2 minutes to read • Edit Online

Represents a runtime instance of an application.

Hierarchy

Application

Index

Properties

- minVersion

Methods

- appInit

Properties

minVersion

minVersion: string (optional)

An optional marker to indicate the minimum platform version required by this component. When this is specified and the component is attempted to be loaded in an older version of the platform, the corresponding workspace is not loaded and user is directed to install a newer version of the platform.

Methods

appInit

appInit(metadata: ApplicationMetadata): any

This method is invoked at the point the application is about to run, with the instance of the application metadata loaded. The metadata passed in can be still modified to change behaviors before this method returns.

Parameters

NAME	TYPE	DESCRIPTION
metadata	ApplicationMetadata	

Returns any

ApplicationMetadata type

2/18/2021 • 2 minutes to read • Edit Online

Represents the declarative metadata of an application

Hierarchy

ApplicationMetadata

Index

Properties

Properties

ColorName

ColorName: string (optional)

The theme color of the application

Configs

Configs: [name: string]: any (optional)

An application can have a set of named config supplied by the author or the resource provider

Description

Description: string (optional)

The description of the application

IconName

IconName: string (optional)

The representative icon of the application

Id

Id: string

The unique identifier of the application

Title

Title: string

The title of the application

NOTE

Can you tell us about your documentation language preferences? Take a short survey.

The survey will take about seven minutes. No personal data is collected (privacy statement).

AsyncService type

2/18/2021 • 2 minutes to read • Edit Online

Provides ability to perform async operations from business logic code.

Hierarchy

AsyncService

Method list

- all
- defer

Methods

all

```
all(...args: any [ ]): Promise <any [ ]>
```

Parameters

NAME	TYPE	DESCRIPTION
...args	any [ ]	

Returns Promise <any [ ]>

defer

```
defer <>(): [Deferred](defer-ideferred.md) <>
```

Creates a deferred object that can be used to return a promise from event handlers (where applicable) and resolve/reject them asynchronously.

Returns Deferred <T>

CacheService type

2/18/2021 • 2 minutes to read • Edit Online

Provides ability to access data from the device cache and update data into the device cache.

Hierarchy

CacheService

ContainerControl type

2/18/2021 • 2 minutes to read • Edit Online

Container control interface with methods and attributes for all container controls. A container control can contain any number of controls.

Hierarchy

Control
  └─ ContainerControl
    └─ Group
    └─ List
    └─ Part

Index

Properties

- container
- generic
- getDataSource
- hidden

Methods

- applyDesign
- dataContext
- getControl
- getControlById
- getDesign
- isEditable
- metadata
- parent
- root

Properties

container

container: boolean

True if the control is a container.

> Overrides Control.container

generic

generic: boolean (optional)

> Inherited from Control.generic

getDataSource

getDataSource: function(): any

> Inherited from Control.getDataSource

hidden

hidden: boolean

True if the control is hidden.

> Inherited from Control.hidden

Methods

applyDesign

applyDesign(design: Design): void

Applies given design to the design on the control. If a design already exists, the prototype chain of the design will be preserved.

> Inherited from Control.applyDesign

Parameters

NAME	TYPE	DESCRIPTION
design	Design	object containing design properties as keys

Returns void

dataContext

dataContext(): any

> Inherited from Control.dataContext

Returns any

getControl

getControl(controlName: string): Control

Given the name of a control, returns the control instance.

Parameters

NAME	TYPE	DESCRIPTION
controlName	string	control name

Returns Control

getControlById

getControlById(id: string): Control

Given the ID of a control, returns the control instance.

Parameters

NAME	TYPE	DESCRIPTION
id	string	control ID

Returns Control

getDesign

getDesign(): Design

Returns the design object of this control.

> Inherited from Control.getDesign

Returns Design

isEditable

isEditable(): boolean

Boolean indicating if the control is editable. Returns false when either the control or its parent is not editable. Returns true when both the control and its parent are editable. Returns true when either the control or its parent is editable and the other is undefined. Returns undefined if both the control's edit-ability and its parent's edit-ability is undefined.

> Inherited from Control.isEditable

Returns boolean

metadata

metadata(): ContainerControlMetadata

Returns the metadata object of this control.

> Overrides Control.metadata

Returns ContainerControlMetadata

parent

parent(): Control | Page

Returns the parent (control or page) of this control.

> Inherited from Control.parent

Returns Control | Page

root

root(): Page

Returns the root form instance (page) of this control.

> Inherited from Control.root

Returns Page

NOTE

The survey will take about seven minutes. No personal data is collected (privacy statement).

ContainerControlDesign type

2/18/2021 • 3 minutes to read • Edit Online

Container control design object has properties specific to all container controls.

Hierarchy

Design
└ ContainerControlDesign
└ GroupDesign
└ ListDesign
└ PartDesign

Index

Properties

- alignItems
- alignSelf
- allowScroll
- background
- bindings
- border
- color
- flexFlow
- flexSize
- fontSize
- fontWeight
- itemBorder
- items
- justifyItems
- label
- labelPosition
- name
- padding
- type

Properties

alignItems

alignItems: string (optional)

This property is an alias for the CSS property "align-items". Please refer to this web page for documentation on the "align-items" property.

> Inherited from Design.alignItems

alignSelf

alignSelf: string (optional)

> Inherited from Design.alignSelf

allowScroll

allowScroll: string (optional)

True if the container will allow scrolling when its items do not fit into the container's available space. If a container has an item which may scroll, then set this property to false to prevent nested scrolling areas.

background

background: string (optional)

The background color of the container. Consider modifying the color attribute in the same container so that fonts overlaying the background color will appear appropriately. Note: if background is set to "theme", the theme color of the app will be used. The following colors are available:

```
blue:           #0078D7;
pomegranate:    #911844;
raspberry:      #8D398F;
darkOrange:     #D24726;
green:          #369F47;
blueberry:      #17234E;
grape:          #432158;
lightBlue:      #5DB2FF;
lightGreen:     #82BA00;
pink:           #DC4FAD;
teal:           #008299;
mediumDarkBlue: #004B8B;
cordovan:       #570000;
darkCordovan:   #380000;
black:          #000000;
lightGray:      #e8e8e8;
light:          #fff   ;
dark:           #333333;
```

bindings

bindings: any (optional)

> Inherited from Design.bindings

border

border: "none" | "solid" | "left" | "right" | "top" | "bottom" (optional)

The border behavior of a control. This property will not be inherited by the children.

> Inherited from Design.border

color

color: string (optional)

The foreground color of the container. This will modify the color of all headers, items, labels, and icons within the container.
Consider setting the background color at the same time as necessary when setting this attribute.
Note: if color is set to "theme", the theme color of the app will be used.
The following colors are available:

```
blue:           #0078D7;
pomegranate:    #911844;
raspberry:      #8D398F;
darkOrange:     #D24726;
green:          #369F47;
blueberry:      #17234E;
grape:          #432158;
lightBlue:      #5DB2FF;
lightGreen:     #82BA00;
pink:           #DC4FAD;
teal:           #008299;
mediumDarkBlue: #004B8B;
cordovan:       #570000;
darkCordovan:   #380000;
black:          #000000;
lightGray:      #e8e8e8;
light:          #fff   ;
dark:           #333333;
```

> Inherited from Design.color

flexFlow

flexFlow: string (optional)

Specifying this property makes the component a flex container component. This property is an alias for the CSS property "flex-flow". Please refer to this web page for documentation on the "flex-flow" property.

> Inherited from Design.flexFlow

flexSize

flexSize: string (optional)

One number or two numbers written as a string. For example, "(size to grow) [(size-to-shrink)]" to accommodate available space in the immediate flex container. This property is an alias for the CSS property "flex". Please refer to this web page for documentation on the "flex" property.

> Inherited from Design.flexSize

fontSize

fontSize: "medium" | "xx-small" | "x-small" | "small" | "large" | "x-large" | "xx-large" (optional)

The proportional text size

> Inherited from Design.fontSize

fontWeight

fontWeight: "normal" | "bold" (optional)

Normal or bold text.

> Inherited from Design.fontWeight

itemBorder

itemBorder: "solid" | "none" (optional)

If true, a border will appear around each row in the list. This property is equivalent to applying the border property individually to all items in the container.

items

items: string | Design [ ] (optional)

An array containing the components to place inside of the container.

justifyItems

justifyItems: "flex-start" | "flex-end" | "center" | "space-between" (optional)

This property is an alias for the CSS property "justify-content". Please refer to this web page for documentation on the "justify-content" property.

> Inherited from Design.justifyItems

label

label: string (optional)

> Inherited from Design.label

labelPosition

labelPosition: "stacked" | "hidden" | "inline" (optional)

Determines how a label is positioned, if at all. By default, labelPosition is set to stacked.

> Inherited from Design.labelPosition

name

name: string (optional)

> Inherited from Design.name

padding

padding: "none" | "small" | "std" (optional)

Allows specifying the component's padding behavior. A component will inherit the padding behavior specified by its parent container components.

> Inherited from Design.padding

type

type: ControlType (optional)

The type of the control as a string.

> Inherited from Design.type

NOTE

Can you tell us about your documentation language preferences? Take a short survey.

The survey will take about seven minutes. No personal data is collected (privacy statement).

ContainerControlMetadata type

- Type

Properties

BoundEntity

BoundEntity: string (optional)

The entity to which the control is bound.

> Inherited from ControlMetadata.BoundEntity

BoundField

BoundField: string (optional)

> Inherited from ControlMetadata.BoundField

Description

Description: string (optional)

Description of the control.

> Inherited from ControlMetadata.Description

Editable

Editable: boolean (optional)

Boolean indicating if the control is editable. False when either the control or its parent is not editable. True when both the control and its parent are editable. True when either the control or its parent is editable and the other is undefined. Undefined if both the control's edit-ability and its parent's edit-ability is undefined.

> Inherited from ControlMetadata.Editable

ExtType

ExtType: ControlType (optional)

The extended control type. For example, a control of type Input might have an extended type of Barcode.

> Inherited from ControlMetadata.ExtType

HelpText

HelpText: string (optional)

The keyboard shortcut for a command. For example, "(Shift+F5)"

> Inherited from ControlMetadata.HelpText

Hidden

Hidden: boolean (optional)

Boolean indicating if the control is hidden or not.

> Inherited from ControlMetadata.Hidden

Id

Id: string (optional)

Identification string for a control.

> Inherited from ControlMetadata.Id

Label

Label: string (optional)

Label for a control. For example, a control representing a person's first name might have a label "First Name".

> Inherited from ControlMetadata.Label

Name

Name: string (optional)

Name of a control.

> Inherited from ControlMetadata.Name

Order

Order: number (optional)

Number indicating the order in which a control will appear on a page.

> Inherited from ControlMetadata.Order

Type

Type: ControlType (optional)

String indicating the control type.

> Inherited from ControlMetadata.Type

ControlMetadata type

2/18/2021 • 2 minutes to read • Edit Online

Interface for the metadata of a control. Overriding control metadata can modify a controls' look and behavior. Properties that can be modified vary by control but every control will have the base properties listed here.

Hierarchy

ControlMetadata
  └ PageLinkMetadata
  └ ContainerControlMetadata

Properties

BoundEntity

BoundEntity: string (optional)

The entity to which the control is bound.

BoundField

BoundField: string (optional)

Description

Description: string (optional)

Description of the control.

Editable

Editable: boolean (optional)

Boolean indicating if the control is editable. False when either the control or its parent is not editable. True when both the control and its parent are editable. True when either the control or its parent is editable and the other is undefined. Undefined if both the control's edit-ability and its parent's edit-ability is undefined.

ExtType

ExtType: ControlType (optional)

The extended control type. For example, a control of type Input might have an extended type of Barcode.

HelpText

HelpText: string (optional)

The keyboard shortcut for a command. For example, "(Shift+F5)"

Hidden

Hidden: boolean (optional)

Boolean indicating if the control is hidden or not.

Id

Id: string (optional)

Identification string for a control.

Label

Label: string (optional)

Label for a control. For example, a control representing a person's first name might have a label "First Name".

Name

Name: string (optional)

Name of a control.

Order

Order: number (optional)

Number indicating the order in which a control will appear on a page.

Type

Type: ControlType (optional)

String indicating the control type.

DataService type

lightGray:      #e8e8e8;
light:          #fff   ;
dark:           #333333;
```

flexFlow

flexFlow: string (optional)

Specifying this property makes the component a flex container component. This property is an alias fo property "flex-flow". Please refer to this web page for documentation on the "flex-flow" property.

flexSize

flexSize: string (optional)

One number or two numbers written as a string. For example, "(size to grow) [(size-to-shrink)]" to acc available space in the immediate flex container. This property is an alias for the CSS property "flex". Ple to this web page for documentation on the "flex" property.

fontSize

fontSize: "medium" | "xx-small" | "x-small" | "small" | "large" | "x-large" | "xx-large" (optional)

The proportional text size

fontWeight

fontWeight: "normal" | "bold" (optional)

Normal or bold text.

justifyItems

justifyItems: "flex-start" | "flex-end" | "center" | "space-between" (optional)

This property is an alias for the CSS property "justify-content". Please refer to this web page for docun on the "justify-content" property.

label

label: string (optional)

labelPosition

labelPosition: "stacked" | "hidden" | "inline" (optional)

Determines how a label is positioned, if at all. By default, labelPosition is set to stacked.

name

name: string (optional)

padding

padding: "none" | "small" | "std" (optional)

Allows specifying the component's padding behavior. A component will inherit the padding behavior s by its parent container components.

type

type: ControlType (optional)

The type of the control as a string.

Methods

applyDesign

applyDesign(IDesign: FieldDesign): void

Applies given design to the design on the control. If a design already exists, the prototype chain of the design will be preserved.

> Overrides Control.applyDesign

Parameters

NAME	TYPE	DESCRIPTION
IDesign	FieldDesign	object containing design properties as keys

Returns void

dataContext

dataContext(): any

> Inherited from Control.dataContext

Returns any

getDesign

getDesign(): Design

Returns the design object of this control.

> Inherited from Control.getDesign

Returns Design

getEditableFormattedValue

getEditableFormattedValue(): string | number | Date

Gets a formatted decimal string value of an editable field control.

Returns string | number | Date

getEditableValue

getEditableValue(): string | number | Date

Gets the value for an editable field control.

Returns string | number | Date

getEntityRef

getEntityRef(): any

Gets value of entityRef binding to control.

Returns any

value of entityRef binding to control

getFormattedValue

getFormattedValue(): string

Gets a formatted decimal string value.

Returns string

getRefLink

getRefLink(): NavigationArgs

Gets the navigation object for a reference link.

Returns NavigationArgs

getValue

getValue(): any

Gets the value for a field control.

Returns any

hasRefLink

hasRefLink(): boolean

Returns true if the field has a refLink, otherwise false.

Returns boolean

hasUnWrapText

hasUnWrapText(): boolean

Gets wrap text property of control.

Returns boolean

isEditable

isEditable(): boolean

Boolean indicating if the control is editable. Returns false when either the control or its parent is not editable. Returns true when both the control and its parent are editable. Returns true when either the control or its parent is editable and the other is undefined. Returns undefined if both the control's edit-ability and its parent's edit-ability is undefined.

> Inherited from Control.isEditable

Returns boolean

metadata

metadata(): FieldMetadata

Returns the metadata object of this control.

> Overrides InputControl.metadata

Returns FieldMetadata

parent

parent(): Control | Page

Returns the parent (control or page) of this control.

> Inherited from Control.parent

Returns Control | Page

root

root(): Page

Returns the root form instance (page) of this control.

> Inherited from Control.root

Returns Page

setEditableValue

setEditableValue(value: string | number | Date): void

Sets the value for an editable field control.

Parameters

NAME	TYPE	DESCRIPTION
value	string | number | Date	value

Returns void

Events

onDataChanged

onDataChanged: EventHook <null>

An event that is triggered when the input control's data changes.

> Inherited from InputControl.onDataChanged

> Inherited from Design.flexSize

fontSize

fontSize: "medium" | "xx-small" | "x-small" | "small" | "large" | "x-large" | "xx-large" (optional)

The proportional text size

> Inherited from Design.fontSize

fontWeight

fontWeight: "normal" | "bold" (optional)

Normal or bold text.

> Inherited from Design.fontWeight

justifyItems

justifyItems: "flex-start" | "flex-end" | "center" | "space-between" (optional)

This property is an alias for the CSS property "justify-content". Please refer to this web page for documentation on the "justify-content" property.

> Inherited from Design.justifyItems

label

label: string (optional)

> Inherited from Design.label

labelPosition

labelPosition: "stacked" | "hidden" | "inline" (optional)

Determines how a label is positioned, if at all. By default, labelPosition is set to stacked.

> Inherited from Design.labelPosition

name

name: string (optional)

> Inherited from Design.name

padding

padding: "none" | "small" | "std" (optional)

Allows specifying the component's padding behavior. A component will inherit the padding behavior specified by its parent container components.

> Inherited from Design.padding

type

type: ControlType (optional)

The type of the control as a string.

> Inherited from Design.type

FieldMetadata type

2/18/2021 • 3 minutes to read • Edit Online

Interface for field metadata.

Hierarchy

InputControlMetadata
└ FieldMetadata

Index

Properties

Properties

BoundEntity

BoundEntity: string (optional)

The entity to which the control is bound.

> Inherited from ControlMetadata.BoundEntity

BoundField

BoundField: string (optional)

> Inherited from ControlMetadata.BoundField

DecimalPlaces

DecimalPlaces: number (optional)

The number of decimals that appear on a field of type "Real". Default = 2; number must be in the range [0:20].

Description

Description: string (optional)

Description of the control.

> Inherited from ControlMetadata.Description

Editable

Editable: boolean (optional)

Boolean indicating if the control is editable. False when either the control or its parent is not editable. True when both the control and its parent are editable. True when either the control or its parent is editable and the other is undefined. Undefined if both the control's edit-ability and its parent's edit-ability is undefined.

> Inherited from ControlMetadata.Editable

ExtType

ExtType: ControlType (optional)

The extended control type. For example, a control of type Input might have an extended type of Barcode.

> Inherited from ControlMetadata.ExtType

Formatting

Formatting: any (optional)

Formats a field of type "DateTime" or "Date". **Note:** if browser does not support `toLocaleString` with options then it will show the entire value.
The options for Formatting depends on the Style that has been chosen: Style: "DateOnly" options, Style: "TimeOnly" options, and options for no style.

Example 1: `{ Style: "TimeOnly", Formatting: { timeZone: "UTC", timeZoneName: "short" } }`

Example 2: `{ Style: "DateOnly", Formatting: { month: "long", day: "numeric" } }` result: March 2

HelpText

HelpText: string (optional)

The keyboard shortcut for a command. For example, "(Shift+F5)"

> Inherited from ControlMetadata.HelpText

Hidden

Hidden: boolean (optional)

Boolean indicating if the control is hidden or not.

Inherited from ControlMetadata.Hidden

Id

Id: string (optional)

Identification string for a control.

Inherited from ControlMetadata.Id

Label

Label: string (optional)

Label for a control. For example, a control representing a person's first name might have a label "First Name".

Inherited from ControlMetadata.Label

LinkType

LinkType: "Telephone" | "Email" | "Url" (optional)

Assigning the link type of a field allows for the appropriate mobile application to be opened when the link is selected.

Mandatory

Mandatory: boolean (optional)

If set to true then input for the control is required for the task to be completed. Mandatory controls will have a red outline.

Inherited from InputControlMetadata.Mandatory

Name

Name: string (optional)

Name of a control.

Inherited from ControlMetadata.Name

NumSequence

NumSequence: NumberSequenceConfig (optional)

Used for auto detecting and changing visibility of the number sequence controls in the task or page, based on AX number sequence configuration, through extended business logic. Example:

```
// hide number sequence reference page from users
metadataService.hideNavigation('numSeqReferencePage');

// parameters to be passed to 'numSequence' flag in configureControl
var configParam = {
     referencePageName: 'numSeqReferencePage',
     dataType: 'HcmPersonnelNumberId'
};

// setup 'PersonnelNumber' control as number sequence in the task 'add-worker'
metadataService.configureControl('add-worker', 'PersonnelNumber', { numSequence: configParam });
```

> Inherited from InputControlMetadata.NumSequence

Order

Order: number (optional)

Number indicating the order in which a control will appear on a page.

> Inherited from ControlMetadata.Order

ReferenceAppId

ReferenceAppId: string (optional)

The ID of the app that the field control lives in.

ReferencePageId

ReferencePageId: string (optional)

The ID of the page that the field control lives in.

Style

Style: string (optional)

Styles a field of type "DateTime" or "Date". Example: `{ Style: TimeOnly }` result: 12:00:00 AM

Type

Type: ControlType (optional)

String indicating the control type.

> Inherited from ControlMetadata.Type

UnWrapText

UnWrapText: boolean (optional)

False by default -- text of the page will be wrapped.

WrapText

WrapText: boolean (optional)

If true then the text of the field control will wrap to the next line.

FileUploader type

2/18/2021 • 2 minutes to read • Edit Online

File uploader control type. A control for uploading files such as images.

Hierarchy

Properties

container

container: boolean (optional)

True if the control is a container.

> Inherited from Control.container

generic

generic: boolean (optional)

> Inherited from Control.generic

getDataSource

getDataSource: function(): any

> Inherited from Control.getDataSource

hidden

hidden: boolean

True if the control is hidden.

> Inherited from Control.hidden

image

image: Image

Methods

applyDesign

applyDesign(IDesign: FileUploaderDesign): void

Applies given design to the design on the control. If a design already exists, the prototype chain of the design will be preserved.

> Overrides Control.applyDesign

Parameters

NAME	TYPE	DESCRIPTION
IDesign	FileUploaderDesign	object containing design properties as keys

Returns void

canLoadFromDevice

canLoadFromDevice(): boolean

Returns true if the mobile phone has camera plugin.

Returns boolean

dataContext

dataContext(): any

> Inherited from Control.dataContext

Returns any

getDesign

getDesign(): Design

Returns the design object of this control.

> Inherited from Control.getDesign

Returns Design

getImage

getImage(options: any): Promise <string>

Returns a promise of an object with image data.

Parameters

NAME	TYPE	DESCRIPTION
options	any	see camera options

Returns Promise <string>

getValue

getValue(): any

Gets the value of the entity that is bound to the control.

> Overrides Value.getValue

Returns any

isEditable

isEditable(): boolean

Boolean indicating if the control is editable. Returns false when either the control or its parent is not editable. Returns true when both the control and its parent are editable. Returns true when either the control or its parent is editable and the other is undefined. Returns undefined if both the control's edit-ability and its parent's edit-ability is undefined.

> Inherited from Control.isEditable

Returns boolean

loadFromFileSystem

loadFromFileSystem(file: Blob): Promise <any>

Parameters

NAME	TYPE	DESCRIPTION
file	Blob	

Returns Promise <any>

metadata

metadata(): FileUploaderMetadata

Returns the metadata object of this control.

> Overrides Value.metadata

Returns FileUploaderMetadata

parent

parent(): Control | Page

Returns the parent (control or page) of this control.

> Inherited from Control.parent

Returns Control | Page

root

root(): Page

Returns the root form instance (page) of this control.

> Inherited from Control.root

Returns Page

setCamera

setCamera(camera: any): void

Set the camera object on the control.

Parameters

NAME	TYPE	DESCRIPTION
camera	any	

Returns void

setValue

setValue(value: string): void

Sets the value of the control.

> Inherited from Value.setValue

Parameters

NAME	TYPE	DESCRIPTION
value	string	

Returns void

Events

onDataChanged

onDataChanged: EventHook <null>

An event that is triggered when the input control's data changes.

> Inherited from InputControl.onDataChanged

FileUploaderDesign type

2/18/2021 • 2 minutes to read • Edit Online

File uploader design object type.

Hierarchy

ValueDesign
└ FileUploaderDesign

Index

Properties

Properties

alignItems

alignItems: string (optional)

This property is an alias for the CSS property "align-items". Please refer to this web page for documentation on the "align-items" property.

> Inherited from Design.alignItems

alignSelf

alignSelf: string (optional)

> Inherited from Design.alignSelf

bindings

bindings: any (optional)

> Inherited from Design.bindings

border

border: "none" | "solid" | "left" | "right" | "top" | "bottom" (optional)

The border behavior of a control. This property will not be inherited by the children.

> Inherited from Design.border

color

color: string (optional)

The foreground color of the container. This will modify the color of all headers, items, labels, and icons within the container.
Consider setting the background color at the same time as necessary when setting this attribute.
Note: if color is set to "theme", the theme color of the app will be used.
The following colors are available:

```
blue:          #0078D7;
pomegranate:   #911844;
raspberry:     #8D398F;
darkOrange:    #D24726;
green:         #369F47;
blueberry:     #17234E;
grape:         #432158;
lightBlue:     #5DB2FF;
lightGreen:    #82BA00;
pink:          #DC4FAD;
teal:          #008299;
mediumDarkBlue: #004B8B;
cordovan:      #570000;
darkCordovan:  #380000;
black:         #000000;
lightGray:     #e8e8e8;
light:         #fff   ;
dark:          #333333;
```

> Inherited from Design.color

flexFlow

flexFlow: string (optional)

Specifying this property makes the component a flex container component. This property is an alias for the CSS property "flex-flow". Please refer to this web page for documentation on the "flex-flow" property.

> Inherited from Design.flexFlow

flexSize

flexSize: string (optional)

One number or two numbers written as a string. For example, "(size to grow) [(size-to-shrink)]" to accommodate available space in the immediate flex container. This property is an alias for the CSS property "flex". Please refer to this web page for documentation on the "flex" property.

> Inherited from Design.flexSize

fontSize

fontSize: "medium" | "xx-small" | "x-small" | "small" | "large" | "x-large" | "xx-large" (optional)

The proportional text size

> Inherited from Design.fontSize

fontWeight

fontWeight: "normal" | "bold" (optional)

Normal or bold text.

> Inherited from Design.fontWeight

justifyItems

justifyItems: "flex-start" | "flex-end" | "center" | "space-between" (optional)

This property is an alias for the CSS property "justify-content". Please refer to this web page for documentation on the "justify-content" property.

> Inherited from Design.justifyItems

label

label: string (optional)

> Inherited from Design.label

labelPosition

labelPosition: "stacked" | "hidden" | "inline" (optional)

Determines how a label is positioned, if at all. By default, labelPosition is set to stacked.

> Inherited from Design.labelPosition

name

name: string (optional)

> Inherited from Design.name

padding

padding: "none" | "small" | "std" (optional)

Allows specifying the component's padding behavior. A component will inherit the padding behavior specified by its parent container components.

> Inherited from Design.padding

type

type: ControlType (optional)

The type of the control as a string.

> Inherited from Design.type

Editable

Editable: boolean (optional)

Boolean indicating if the control is editable. False when either the control or its parent is not editable. True when both the control and its parent are editable. True when either the control or its parent is editable and the other is undefined. Undefined if both the control's edit-ability and its parent's edit-ability is undefined.

> Inherited from ControlMetadata.Editable

ExtType

ExtType: ControlType (optional)

The extended control type. For example, a control of type Input might have an extended type of Barcode.

> Inherited from ControlMetadata.ExtType

HelpText

HelpText: string (optional)

The keyboard shortcut for a command. For example, "(Shift+F5)"

> Inherited from ControlMetadata.HelpText

Hidden

Hidden: boolean (optional)

Boolean indicating if the control is hidden or not.

> Inherited from ControlMetadata.Hidden

Id

Id: string (optional)

Identification string for a control.

> Inherited from ControlMetadata.Id

Label

Label: string (optional)

Label for a control. For example, a control representing a person's first name might have a label "First Name".

> Inherited from ControlMetadata.Label

Mandatory

Mandatory: boolean (optional)

If set to true then input for the control is required for the task to be completed. Mandatory controls will have a red outline.

> Inherited from InputControlMetadata.Mandatory

Name

Name: string (optional)

Name of a control.

> Inherited from ControlMetadata.Name

NumSequence

NumSequence: NumberSequenceConfig (optional)

Used for auto detecting and changing visibility of the number sequence controls in the task or page, based on AX number sequence configuration, through extended business logic. Example:

```
// hide number sequence reference page from users
metadataService.hideNavigation('numSeqReferencePage');

// parameters to be passed to 'numSequence' flag in configureControl
var configParam = {
     referencePageName: 'numSeqReferencePage',
     dataType: 'HcmPersonnelNumberId'
};

// setup 'PersonnelNumber' control as number sequence in the task 'add-worker'
metadataService.configureControl('add-worker', 'PersonnelNumber', { numSequence: configParam });
```

> Inherited from InputControlMetadata.NumSequence

Order

Order: number (optional)

Number indicating the order in which a control will appear on a page.

> Inherited from ControlMetadata.Order

Type

Type: ControlType (optional)

String indicating the control type.

> Inherited from ControlMetadata.Type

container: boolean (optional)

True if the control is a container.

generic

generic: boolean (optional)

getDataSource

getDataSource: function(): any

hidden

hidden: boolean

True if the control is hidden.

Methods

applyDesign

applyDesign(design: Design): void

Applies given design to the design on the control. If a design already exists, the prototype chain of the design will be preserved.

Parameters

NAME	TYPE	DESCRIPTION
design	Design	object containing design properties as keys

Returns void

dataContext

dataContext(): any

Returns any

getDesign

getDesign(): Design

Returns the design object of this control.

Returns Design

isEditable

isEditable(): boolean

Boolean indicating if the control is editable. Returns false when either the control or its parent is not editable. Returns true when both the control and its parent are editable. Returns true when either the control or its parent is editable and the other is undefined. Returns undefined if both the control's edit-ability and its parent's edit-ability is undefined.

Returns boolean

metadata

metadata(): ControlMetadata

Returns the metadata object of this control.

Returns ControlMetadata

parent

parent(): Control | Page

Returns the parent (control or page) of this control.

Returns Control | Page

root

root(): Page

Returns the root form instance (page) of this control.

Returns Page

Group type

2/18/2021 • 2 minutes to read • Edit Online

Group container control type. A group control is a container control that has any number of controls as children.

Hierarchy

ContainerControl
└ Group

getDataSource

getDataSource: function(): any

Inherited from Control.getDataSource

hidden

hidden: boolean

True if the control is hidden.

Inherited from Control.hidden

Methods

applyDesign

applyDesign(IDesign: GroupDesign): void

Applies given design to the design on the control. If a design already exists, the prototype chain of the design will be preserved.

Overrides Control.applyDesign

Parameters

NAME	TYPE	DESCRIPTION
IDesign	GroupDesign	object containing design properties as keys

Returns void

dataContext

dataContext(): any

Inherited from Control.dataContext

Returns any

getChildren

getChildren(): Control [ ]

Returns the list of children associated with this group control.

Returns Control [ ]

getControl

getControl(controlName: string): Control

Given the name of a control, returns the control instance.

Inherited from ContainerControl.getControl

Parameters

NAME	TYPE	DESCRIPTION
controlName	string	control name

Returns Control

getControlById

getControlById(id: string): Control

Given the ID of a control, returns the control instance.

> Inherited from ContainerControl.getControlById

Parameters

NAME	TYPE	DESCRIPTION
id	string	control ID

Returns Control

getDesign

getDesign(): Design

Returns the design object of this control.

> Inherited from Control.getDesign

Returns Design

isEditable

isEditable(): boolean

Boolean indicating if the control is editable. Returns false when either the control or its parent is not editable. Returns true when both the control and its parent are editable. Returns true when either the control or its parent is editable and the other is undefined. Returns undefined if both the control's edit-ability and its parent's edit-ability is undefined.

> Inherited from Control.isEditable

Returns boolean

metadata

metadata(): GroupMetadata

Returns the metadata object of this control.

> Overrides ContainerControl.metadata

Returns GroupMetadata

parent

parent(): Control | Page

Returns the parent (control or page) of this control.

> Inherited from Control.parent

Returns Control | Page

root

root(): Page

Returns the root form instance (page) of this control.

Inherited from Control.root

Returns Page

Properties

alignItems

alignItems: string (optional)

This property is an alias for the CSS property "align-items". Please refer to this web page for documentation on the "align-items" property.

> Inherited from Design.alignItems

alignSelf

alignSelf: string (optional)

> Inherited from Design.alignSelf

allowScroll

allowScroll: string (optional)

True if the container will allow scrolling when its items do not fit into the container's available space. If a container has an item which may scroll, then set this property to false to prevent nested scrolling areas.

> Inherited from ContainerControlDesign.allowScroll

background

background: string (optional)

The background color of the container. Consider modifying the color attribute in the same container so that fonts overlaying the background color will appear appropriately. Note: if background is set to "theme", the theme color of the app will be used. The following colors are available:

```
blue:           #0078D7;
pomegranate:    #911844;
raspberry:      #8D398F;
darkOrange:     #D24726;
green:          #369F47;
blueberry:      #17234E;
grape:          #432158;
lightBlue:      #5DB2FF;
lightGreen:     #82BA00;
pink:           #DC4FAD;
teal:           #008299;
mediumDarkBlue: #004B8B;
cordovan:       #570000;
darkCordovan:   #380000;
black:          #000000;
lightGray:      #e8e8e8;
light:          #fff   ;
dark:           #333333;
```

> Inherited from ContainerControlDesign.background

bindings

bindings: any (optional)

> Inherited from Design.bindings

border

border: "none" | "solid" | "left" | "right" | "top" | "bottom" (optional)

The border behavior of a control. This property will not be inherited by the children.

> Inherited from Design.border

color

color: string (optional)

The foreground color of the container. This will modify the color of all headers, items, labels, and icons within the container.
Consider setting the background color at the same time as necessary when setting this attribute.
Note: if color is set to "theme", the theme color of the app will be used.
The following colors are available:

```
blue:           #0078D7;
pomegranate:    #911844;
raspberry:      #8D398F;
darkOrange:     #D24726;
green:          #369F47;
blueberry:      #17234E;
grape:          #432158;
lightBlue:      #5DB2FF;
lightGreen:     #82BA00;
pink:           #DC4FAD;
teal:           #008299;
mediumDarkBlue: #004B8B;
cordovan:       #570000;
darkCordovan:   #380000;
black:          #000000;
lightGray:      #e8e8e8;
light:          #fff   ;
dark:           #333333;
```

> Inherited from Design.color

flexFlow

flexFlow: string (optional)

Specifying this property makes the component a flex container component. This property is an alias for the CSS property "flex-flow". Please refer to this web page for documentation on the "flex-flow" property.

> Inherited from Design.flexFlow

flexSize

flexSize: string (optional)

One number or two numbers written as a string. For example, "(size to grow) [(size-to-shrink)]" to accommodate available space in the immediate flex container. This property is an alias for the CSS property "flex". Please refer to this web page for documentation on the "flex" property.

> Inherited from Design.flexSize

fontSize

fontSize: "medium" | "xx-small" | "x-small" | "small" | "large" | "x-large" | "xx-large" (optional)

The proportional text size

> Inherited from Design.fontSize

fontWeight

fontWeight: "normal" | "bold" (optional)

Normal or bold text.

> Inherited from Design.fontWeight

itemBorder

itemBorder: "solid" | "none" (optional)

If true, a border will appear around each row in the list. This property is equivalent to applying the border property individually to all items in the container.

> Inherited from ContainerControlDesign.itemBorder

items

items: string | Design [ ] (optional)

An array containing the components to place inside of the container.

> Inherited from ContainerControlDesign.items

justifyItems

justifyItems: "flex-start" | "flex-end" | "center" | "space-between" (optional)

This property is an alias for the CSS property "justify-content". Please refer to this web page for documentation on the "justify-content" property.

> Inherited from Design.justifyItems

label

label: string (optional)

> Inherited from Design.label

labelPosition

labelPosition: "stacked" | "hidden" | "inline" (optional)

Determines how a label is positioned, if at all. By default, labelPosition is set to stacked.

> Inherited from Design.labelPosition

name

name: string (optional)

> Inherited from Design.name

padding

padding: "none" | "small" | "std" (optional)

Allows specifying the component's padding behavior. A component will inherit the padding behavior specified by its parent container components.

> Inherited from Design.padding

type

type: ControlType (optional)

The type of the control as a string.

> Inherited from Design.type

GroupMetadata type

└ GroupMetadata

Index

Properties

Properties

BoundEntity

BoundEntity: string (optional)

The entity to which the control is bound.

> Inherited from ControlMetadata.BoundEntity

BoundField

BoundField: string (optional)

> Inherited from ControlMetadata.BoundField

Children

Children: ControlMetadata [ ] (optional)

List of control metadata for each child control.

Description

Description: string (optional)

Description of the control.

> Inherited from ControlMetadata.Description

Editable

Editable: boolean (optional)

Boolean indicating if the control is editable. False when either the control or its parent is not editable. True when both the control and its parent are editable. True when either the control or its parent is editable and the other is undefined. Undefined if both the control's edit-ability and its parent's edit-ability is undefined.

> Inherited from ControlMetadata.Editable

ExtType

ExtType: ControlType (optional)

The extended control type. For example, a control of type Input might have an extended type of Barcode.

> Inherited from ControlMetadata.ExtType

HelpText

HelpText: string (optional)

The keyboard shortcut for a command. For example, "(Shift+F5)"

> Inherited from ControlMetadata.HelpText

Hidden

Hidden: boolean (optional)

Boolean indicating if the control is hidden or not.

> Inherited from ControlMetadata.Hidden

Id

Id: string (optional)

Identification string for a control.

> Inherited from ControlMetadata.Id

Label

Label: string (optional)

Label for a control. For example, a control representing a person's first name might have a label "First Name".

> Inherited from ControlMetadata.Label

Name

Name: string (optional)

Name of a control.

> Inherited from ControlMetadata.Name

Order

Order: number (optional)

Number indicating the order in which a control will appear on a page.

> Inherited from ControlMetadata.Order

Type

Type: ControlType (optional)

String indicating the control type.

> Inherited from ControlMetadata.Type

HyperLink type

2/18/2021 • 2 minutes to read • Edit Online

Hyperlink control type. Hyperlink control is a control to represent hyperlinks. Pagelinks can also be used in most cases.

Hierarchy

Properties

container

container: boolean (optional)

True if the control is a container.

> Inherited from Control.container

generic

generic: boolean (optional)

> Inherited from Control.generic

getDataSource

getDataSource: function(): any

> Inherited from Control.getDataSource

hidden

hidden: boolean

True if the control is hidden.

> Inherited from Control.hidden

Methods

applyDesign

applyDesign(IDesign: HyperLinkDesign): void

Applies given design to the design on the control. If a design already exists, the prototype chain of the design will be preserved.

> Overrides Control.applyDesign

Parameters

NAME	TYPE	DESCRIPTION
IDesign	HyperLinkDesign	object containing design properties as keys

Returns void

dataContext

dataContext(): any

> Inherited from Control.dataContext

Returns any

getDesign

getDesign(): Design

Returns the design object of this control.

> Inherited from Control.getDesign

Returns Design

getHyperLinkValue

getHyperLinkValue(): string

Returns string

getValue

getValue(): string

Returns the value of the control.

> Inherited from Value.getValue

Returns string

isEditable

isEditable(): boolean

Boolean indicating if the control is editable. Returns false when either the control or its parent is not editable. Returns true when both the control and its parent are editable. Returns true when either the control or its parent is editable and the other is undefined. Returns undefined if both the control's edit-ability and its parent's edit-ability is undefined.

> Inherited from Control.isEditable

Returns boolean

isHyperLinkURLPresent

isHyperLinkURLPresent(): boolean

Returns boolean

metadata

metadata(): HyperLinkMetadata

Returns the metadata object of this control.

> Overrides Value.metadata

Returns HyperLinkMetadata

parent

parent(): Control | Page

Returns the parent (control or page) of this control.

> Inherited from Control.parent

Returns Control | Page

root

root(): Page

Returns the root form instance (page) of this control.

> Inherited from Control.root

Returns Page

setBaseURL

setBaseURL(url: string): any

Parameters

NAME	TYPE	DESCRIPTION
url	string	

Returns any

setValue

setValue(value: string): void

Sets the value of the control.

> Inherited from Value.setValue

Parameters

NAME	TYPE	DESCRIPTION
value	string	

Returns void

Events

onDataChanged

onDataChanged: EventHook <null>

An event that is triggered when the input control's data changes.

> Inherited from InputControl.onDataChanged

Hyperlink design object type.

Hierarchy

ValueDesign
└ HyperLinkDesign

Index

Properties

Properties

alignItems

alignItems: string (optional)

This property is an alias for the CSS property "align-items". Please refer to this web page for documentation on the "align-items" property.

> Inherited from Design.alignItems

alignSelf

alignSelf: string (optional)

> Inherited from Design.alignSelf

bindings

bindings: any (optional)

> Inherited from Design.bindings

border

border: "none" | "solid" | "left" | "right" | "top" | "bottom" (optional)

The border behavior of a control. This property will not be inherited by the children.

> Inherited from Design.border

color

color: string (optional)

The foreground color of the container. This will modify the color of all headers, items, labels, and icons within the container.
Consider setting the background color at the same time as necessary when setting this attribute.
Note: if color is set to "theme", the theme color of the app will be used.
The following colors are available:

```
blue:          #0078D7;
pomegranate:   #911844;
raspberry:     #8D398F;
darkOrange:    #D24726;
green:         #369F47;
blueberry:     #17234E;
grape:         #432158;
lightBlue:     #5DB2FF;
lightGreen:    #82BA00;
pink:          #DC4FAD;
teal:          #008299;
mediumDarkBlue: #004B8B;
cordovan:      #570000;
darkCordovan:  #380000;
black:         #000000;
lightGray:     #e8e8e8;
light:         #fff   ;
dark:          #333333;
```

> Inherited from Design.color

flexFlow

flexFlow: string (optional)

Specifying this property makes the component a flex container component. This property is an alias for the CSS property "flex-flow". Please refer to this web page for documentation on the "flex-flow" property.

> Inherited from Design.flexFlow

flexSize

flexSize: string (optional)

One number or two numbers written as a string. For example, "(size to grow) [(size-to-shrink)]" to accommodate available space in the immediate flex container. This property is an alias for the CSS property "flex". Please refer to this web page for documentation on the "flex" property.

> Inherited from Design.flexSize

fontSize

fontSize: "medium" | "xx-small" | "x-small" | "small" | "large" | "x-large" | "xx-large" (optional)

The proportional text size

> Inherited from Design.fontSize

fontWeight

fontWeight: "normal" | "bold" (optional)

Normal or bold text.

> Inherited from Design.fontWeight

justifyItems

justifyItems: "flex-start" | "flex-end" | "center" | "space-between" (optional)

This property is an alias for the CSS property "justify-content". Please refer to this web page for documentation on the "justify-content" property.

> Inherited from Design.justifyItems

label

label: string (optional)

> Inherited from Design.label

labelPosition

labelPosition: "stacked" | "hidden" | "inline" (optional)

Determines how a label is positioned, if at all. By default, labelPosition is set to stacked.

> Inherited from Design.labelPosition

name

name: string (optional)

> Inherited from Design.name

padding

padding: "none" | "small" | "std" (optional)

Allows specifying the component's padding behavior. A component will inherit the padding behavior specified by its parent container components.

> Inherited from Design.padding

type

type: ControlType (optional)

The type of the control as a string.

> Inherited from Design.type

Properties

Properties

BoundEntity

BoundEntity: string (optional)

The entity to which the control is bound.

> Inherited from ControlMetadata.BoundEntity

BoundField

BoundField: string (optional)

> Inherited from ControlMetadata.BoundField

Description

Description: string (optional)

Description of the control.

> Inherited from ControlMetadata.Description

Editable

Editable: boolean (optional)

Boolean indicating if the control is editable. False when either the control or its parent is not editable. True when both the control and its parent are editable. True when either the control or its parent is editable and the other is undefined. Undefined if both the control's edit-ability and its parent's edit-ability is undefined.

> Inherited from ControlMetadata.Editable

ExtType

ExtType: ControlType (optional)

The extended control type. For example, a control of type Input might have an extended type of Barcode.

> Inherited from ControlMetadata.ExtType

HelpText

HelpText: string (optional)

The keyboard shortcut for a command. For example, "(Shift+F5)"

> Inherited from ControlMetadata.HelpText

Hidden

Hidden: boolean (optional)

Boolean indicating if the control is hidden or not.

> Inherited from ControlMetadata.Hidden

Id

Id: string (optional)

Identification string for a control.

> Inherited from ControlMetadata.Id

Label

Label: string (optional)

Label for a control. For example, a control representing a person's first name might have a label "First Name".

> Inherited from ControlMetadata.Label

Mandatory

Mandatory: boolean (optional)

If set to true then input for the control is required for the task to be completed. Mandatory controls will have a red outline.

> Inherited from InputControlMetadata.Mandatory

Name

Name: string (optional)

Name of a control.

> Inherited from ControlMetadata.Name

NumSequence

NumSequence: NumberSequenceConfig (optional)

Used for auto detecting and changing visibility of the number sequence controls in the task or page, based on AX number sequence configuration, through extended business logic. Example:

```
// hide number sequence reference page from users
metadataService.hideNavigation('numSeqReferencePage');

// parameters to be passed to 'numSequence' flag in configureControl
var configParam = {
     referencePageName: 'numSeqReferencePage',
     dataType: 'HcmPersonnelNumberId'
};

// setup 'PersonnelNumber' control as number sequence in the task 'add-worker'
metadataService.configureControl('add-worker', 'PersonnelNumber', { numSequence: configParam });
```

> Inherited from InputControlMetadata.NumSequence

Order

Order: number (optional)

Number indicating the order in which a control will appear on a page.

> Inherited from ControlMetadata.Order

Type

Type: ControlType (optional)

String indicating the control type.

> Inherited from ControlMetadata.Type

Image type

2/18/2021 • 2 minutes to read • Edit Online

Image control interface for representing images in the mobile app. Images can be of any of the following types: DataUri, Base64, URL, AOTResource, or Symbol.

Hierarchy

Control
└ Image

Index

Properties

- container

container: boolean (optional)

True if the control is a container.

> Inherited from Control.container

generic

generic: boolean (optional)

> Inherited from Control.generic

getDataSource

getDataSource: function(): any

Inherited from Control.getDataSource

hidden

hidden: boolean

True if the control is hidden.

Inherited from Control.hidden

imageSource

imageSource: string

Defines the imageSource.

imageView

imageView: string

Dictates the style of the image.

placeholderClass

placeholderClass: string

symbol

symbol: string

Defines the symbol if the image is of type symbol.

Methods

applyDesign

applyDesign(design: ImageDesign): void

Applies given design to the design on the control. If a design already exists, the prototype chain of the design will be preserved.

Overrides Control.applyDesign

Parameters

NAME	TYPE	DESCRIPTION
design	ImageDesign	object containing design properties as keys

Returns void

dataContext

dataContext(): any

Inherited from Control.dataContext

Returns any

getDesign

getDesign(): Design

Returns the design object of this control.

Inherited from Control.getDesign

Returns Design

isEditable

isEditable(): boolean

Boolean indicating if the control is editable. Returns false when either the control or its parent is not editable. Returns true when both the control and its parent are editable. Returns true when either the control or its parent is editable and the other is undefined. Returns undefined if both the control's edit-ability and its parent's edit-ability is undefined.

Inherited from Control.isEditable

Returns boolean

metadata

metadata(): ImageMetadata

Returns the metadata object of this control.

Overrides Control.metadata

Returns ImageMetadata

parent

parent(): Control | Page

Returns the parent (control or page) of this control.

Inherited from Control.parent

Returns Control | Page

root

root(): Page

Returns the root form instance (page) of this control.

Inherited from Control.root

Returns Page

```

> Inherited from Design.color

flexFlow

flexFlow: string (optional)

Specifying this property makes the component a flex container component. This property is an alias for the CSS property "flex-flow". Please refer to this web page for documentation on the "flex-flow" property.

> Inherited from Design.flexFlow

flexSize

flexSize: string (optional)

One number or two numbers written as a string. For example, "(size to grow) [(size-to-shrink)]" to accommodate available space in the immediate flex container. This property is an alias for the CSS property "flex". Please refer to this web page for documentation on the "flex" property.

> Inherited from Design.flexSize

fontSize

fontSize: "medium" | "xx-small" | "x-small" | "small" | "large" | "x-large" | "xx-large" (optional)

The proportional text size

> Inherited from Design.fontSize

fontWeight

fontWeight: "normal" | "bold" (optional)

Normal or bold text.

> Inherited from Design.fontWeight

height

height: string (optional)

The relative vertical size of the image. Sizes are about equivalent to CSS em sizes.

imageStyle

imageStyle: ImageStyleType (optional)

The style of the image.

justifyItems

justifyItems: "flex-start" | "flex-end" | "center" | "space-between" (optional)

This property is an alias for the CSS property "justify-content". Please refer to this web page for documentation on the "justify-content" property.

> Inherited from Design.justifyItems

label

label: string (optional)

> Inherited from Design.label

labelPosition

labelPosition: "stacked" | "hidden" | "inline" (optional)

Determines how a label is positioned, if at all. By default, labelPosition is set to stacked.

> Inherited from Design.labelPosition

name

name: string (optional)

> Inherited from Design.name

padding

padding: "none" | "small" | "std" (optional)

Allows specifying the component's padding behavior. A component will inherit the padding behavior specified by its parent container components.

> Inherited from Design.padding

type

type: ControlType (optional)

The type of the control as a string.

> Inherited from Design.type

width

width: string (optional)

The relative horizontal size of the image. Sizes are about equivalent to CSS em sizes.

Mandatory

Mandatory: boolean (optional)

If set to true then input for the control is required for the task to be completed. Mandatory controls will have a red outline.

Name

Name: string (optional)

Name of a control.

> Inherited from ControlMetadata.Name

NumSequence

NumSequence: NumberSequenceConfig (optional)

Used for auto detecting and changing visibility of the number sequence controls in the task or page, based on AX number sequence configuration, through extended business logic. Example:

```
// hide number sequence reference page from users
metadataService.hideNavigation('numSeqReferencePage');

// parameters to be passed to 'numSequence' flag in configureControl
var configParam = {
     referencePageName: 'numSeqReferencePage',
     dataType: 'HcmPersonnelNumberId'
};

// setup 'PersonnelNumber' control as number sequence in the task 'add-worker'
metadataService.configureControl('add-worker', 'PersonnelNumber', { numSequence: configParam });
```

Order

Order: number (optional)

Number indicating the order in which a control will appear on a page.

> Inherited from ControlMetadata.Order

Type

Type: ControlType (optional)

String indicating the control type.

> Inherited from ControlMetadata.Type

List type

2/18/2021 • 3 minutes to read • Edit Online

List control type. A list is a control that contains any numbers of rows. Each row follows a template for the layout of any number of controls. Lists come in two styles: simple and card.

Properties

$accessibility

$accessibility: any

DefaultSearchColumn

DefaultSearchColumn: string

container

container: boolean

True if the control is a container.

> Inherited from ContainerControl.container
>
> Overrides Control.container

emptyListMessage

emptyListMessage: string

Settable property to override default empty list message.

enableMultiSelect

enableMultiSelect: boolean

generic

generic: boolean (optional)

> Inherited from Control.generic

getDataSource

getDataSource: function(): any

> Inherited from Control.getDataSource

hidden

hidden: boolean

True if the control is hidden.

> Inherited from Control.hidden

hideEmptyListMessage

hideEmptyListMessage: boolean

If true, no message is shown if the list is empty. To set this property, update the corresponding metadata property via configureControl.

imageFields

imageFields: any [ ]

performingRemoteSearch

performingRemoteSearch: boolean

searchQuery

searchQuery: [value: string]: any

Methods

allowsNavigation

allowsNavigation(): boolean

Returns boolean

applyDesign

applyDesign(IDesign: ListDesign): void

Applies given design to the design on the control. If a design already exists, the prototype chain of the design will be preserved.

> Overrides Control.applyDesign

Parameters

NAME	TYPE	DESCRIPTION
IDesign	ListDesign	object containing design properties as keys

Returns void

applySearch

applySearch(): void

Returns void

canPerformRemoteSearch

canPerformRemoteSearch(): boolean

Returns boolean

clearSearch

clearSearch(): void

Returns void

dataContext

dataContext(): any

> Inherited from Control.dataContext

Returns any

getColumnLabel

getColumnLabel(id: string): string

Parameters

NAME	TYPE	DESCRIPTION
id	string	

Returns string

getControl

getControl(controlName: string): Control

Given the name of a control, returns the control instance.

> Inherited from ContainerControl.getControl

Parameters

NAME	TYPE	DESCRIPTION
controlName	string	control name

Returns Control

getControlById

getControlById(id: string): Control

Given the ID of a control, returns the control instance.

> Inherited from ContainerControl.getControlById

Parameters

NAME	TYPE	DESCRIPTION
id	string	control ID

Returns Control

getControlMetadata

getControlMetadata(controlName: string): Control

Parameters

NAME	TYPE	DESCRIPTION
controlName	string	

Returns Control

getControlMetadataById

getControlMetadataById(id: string): Control

Parameters

NAME	TYPE	DESCRIPTION
id	string	

Returns Control

getData

getData(): any [ ]

Returns any [ ]

getDesign

getDesign(): Design

Returns the design object of this control.

> Inherited from Control.getDesign

Returns Design

getListData

getListData(): any

Returns any

getRenderedRows

getRenderedRows(): Row [ ]

Returns Row [ ]

getRowNavigation

getRowNavigation(row: Row): Promise <any> | any

Parameters

NAME	TYPE	DESCRIPTION
row	Row	

Returns Promise <any> | any

getRowSelectionCount

getRowSelectionCount(): number

Returns number

getRowSelections

getRowSelections(): string [ ]

Returns string [ ]

getRowTracking

getRowTracking(row: any, index: string): string

Parameters

NAME	TYPE	DESCRIPTION
row	any	
index	string	

Returns string

getSearchColumn

getSearchColumn(): string

Returns string

getSearchColumnLabel

getSearchColumnLabel(): string

Returns string

getSearchableColumns

getSearchableColumns(): any [ ]

Returns any [ ]

hideSearchBar

hideSearchBar(): boolean

Returns boolean

isEditable

isEditable(): boolean

Boolean indicating if the control is editable. Returns false when either the control or its parent is not editable. Returns true when both the control and its parent are editable. Returns true when either the control or its parent is editable and the other is undefined. Returns undefined if both the control's edit-ability and its parent's edit-ability is undefined.

> Inherited from Control.isEditable

Returns boolean

loadMetaData

loadMetaData(): void

Returns void

loadMore

loadMore(): void

Returns void

metadata

metadata(): ListMetadata

Returns the metadata object of this control.

> Overrides ContainerControl.metadata

Returns ListMetadata

parent

parent(): Control | Page

Returns the parent (control or page) of this control.

> Inherited from Control.parent

Returns Control | Page

performRemoteSearch

performRemoteSearch(): void

Returns void

root

root(): Page

Returns the root form instance (page) of this control.

> Inherited from Control.root

Returns Page

selectSearchColumn

selectSearchColumn(column: string): void

Parameters

NAME	TYPE	DESCRIPTION
column	string	

Returns void

setRowSections

setRowSections(selections: string [ ]): void

Parameters

NAME	TYPE	DESCRIPTION
selections	string [ ]	

Returns void

Events

onRowCreate

onRowCreate: EventHook <Row>

onRowSelect

onRowSelect: EventHook <Row>

ListDesign type

2/18/2021 • 3 minutes to read • Edit Online

List design object type.

Hierarchy

ContainerControlDesign
└ ListDesign

Index

Properties

Properties

alignItems

alignItems: string (optional)

This property is an alias for the CSS property "align-items". Please refer to this web page for documentation on the "align-items" property.

> Inherited from Design.alignItems

alignSelf

alignSelf: string (optional)

> Inherited from Design.alignSelf

allowScroll

allowScroll: string (optional)

True if the container will allow scrolling when its items do not fit into the container's available space. If a container has an item which may scroll, then set this property to false to prevent nested scrolling areas.

> Inherited from ContainerControlDesign.allowScroll

background

background: string (optional)

The background color of the container. Consider modifying the color attribute in the same container so that fonts overlaying the background color will appear appropriately. Note: if background is set to "theme", the theme color of the app will be used. The following colors are available:

```
blue:          #0078D7;
pomegranate:   #911844;
raspberry:     #8D398F;
darkOrange:    #D24726;
green:         #369F47;
blueberry:     #17234E;
grape:         #432158;
lightBlue:     #5DB2FF;
lightGreen:    #82BA00;
pink:          #DC4FAD;
teal:          #008299;
mediumDarkBlue: #004B8B;
cordovan:      #570000;
darkCordovan:  #380000;
black:         #000000;
lightGray:     #e8e8e8;
light:         #fff   ;
dark:          #333333;
```

> Inherited from ContainerControlDesign.background

bindings

bindings: any (optional)

> Inherited from Design.bindings

border

border: "none" | "solid" | "left" | "right" | "top" | "bottom" (optional)

The border behavior of a control. This property will not be inherited by the children.

> Inherited from Design.border

color

color: string (optional)

The foreground color of the container. This will modify the color of all headers, items, labels, and icons within the container.
Consider setting the background color at the same time as necessary when setting this attribute.
Note: if color is set to "theme", the theme color of the app will be used.
The following colors are available:

```
blue:          #0078D7;
pomegranate:   #911844;
raspberry:     #8D398F;
darkOrange:    #D24726;
green:         #369F47;
blueberry:     #17234E;
grape:         #432158;
lightBlue:     #5DB2FF;
lightGreen:    #82BA00;
pink:          #DC4FAD;
teal:          #008299;
mediumDarkBlue: #004B8B;
cordovan:      #570000;
darkCordovan:  #380000;
black:         #000000;
lightGray:     #e8e8e8;
light:         #fff   ;
dark:          #333333;
```

> Inherited from Design.color

design

design: GroupDesign (optional)

The design object that will be applied to each row.

flexFlow

flexFlow: string (optional)

Specifying this property makes the component a flex container component. This property is an alias for the CSS property "flex-flow". Please refer to this web page for documentation on the "flex-flow" property.

> Inherited from Design.flexFlow

flexSize

flexSize: string (optional)

One number or two numbers written as a string. For example, "(size to grow) [(size-to-shrink)]" to accommodate available space in the immediate flex container. This property is an alias for the CSS property "flex". Please refer to this web page for documentation on the "flex" property.

> Inherited from Design.flexSize

fontSize

fontSize: "medium" | "xx-small" | "x-small" | "small" | "large" | "x-large" | "xx-large" (optional)

The proportional text size

> Inherited from Design.fontSize

fontWeight

fontWeight: "normal" | "bold" (optional)

Normal or bold text.

> Inherited from Design.fontWeight

hideArrow

hideArrow: boolean (optional)

Allows an arrow (>) on a default styled navigation control to be hidden. Note that if the list has DetailsPageId, navigationHandler, or OnNavigate in the metadata then by default the arrows are present in each row of the list to show that the rows are clickable.

This property can only be added through the design object.

hideSearchBar

hideSearchBar: boolean (optional)

If true, the search bar will be hidden.

itemBorder

itemBorder: "solid" | "none" (optional)

If true, a border will appear around each row in the list. This property is equivalent to applying the border property individually to all items in the container.

> Inherited from ContainerControlDesign.itemBorder

items

items: string | Design [ ] (optional)

An array containing the components to place inside of the container.

> Inherited from ContainerControlDesign.items

justifyItems

justifyItems: "flex-start" | "flex-end" | "center" | "space-between" (optional)

This property is an alias for the CSS property "justify-content". Please refer to this web page for documentation

on the "justify-content" property.

> Inherited from Design.justifyItems

label

label: string (optional)

> Inherited from Design.label

labelPosition

labelPosition: "stacked" | "hidden" | "inline" (optional)

Determines how a label is positioned, if at all. By default, labelPosition is set to stacked.

> Inherited from Design.labelPosition

name

name: string (optional)

> Inherited from Design.name

padding

padding: "none" | "small" | "std" (optional)

Allows specifying the component's padding behavior. A component will inherit the padding behavior specified by its parent container components.

> Inherited from Design.padding

type

type: ControlType (optional)

The type of the control as a string.

> Inherited from Design.type

Properties

BoundEntity

BoundEntity: string (optional)

The entity to which the control is bound.

> Inherited from ControlMetadata.BoundEntity

BoundField

BoundField: string (optional)

> Inherited from ControlMetadata.BoundField

Children

Children: ControlMetadata [ ] (optional)

List of metadata for controls that will appear in each row of the list.

Description

Description: string (optional)

Description of the control.

> Inherited from ControlMetadata.Description

DetailsPageAppId

DetailsPageAppId: string (optional)

App ID of the page that each row in the list will navigate to.

DetailsPageId

DetailsPageId: string (optional)

The ID of the page to which each row will navigate.

Editable

Editable: boolean (optional)

Boolean indicating if the control is editable. False when either the control or its parent is not editable. True when both the control and its parent are editable. True when either the control or its parent is editable and the other is undefined. Undefined if both the control's edit-ability and its parent's edit-ability is undefined.

> Inherited from ControlMetadata.Editable

EmptyListMessage

EmptyListMessage: string (optional)

If set, overrides the default message for empty lists.

ExtType

ExtType: ControlType (optional)

The extended control type. For example, a control of type Input might have an extended type of Barcode.

> Inherited from ControlMetadata.ExtType

HelpText

HelpText: string (optional)

The keyboard shortcut for a command. For example, "(Shift+F5)"

> Inherited from ControlMetadata.HelpText

Hidden

Hidden: boolean (optional)

Boolean indicating if the control is hidden or not.

> Inherited from ControlMetadata.Hidden

HideEmptyListMessage

HideEmptyListMessage: boolean (optional)

If true, the empty list message will be hidden.

HideSearchBar

HideSearchBar: boolean (optional)

If true, the search bar will be hidden.

Id

Id: string (optional)

Identification string for a control.

> Inherited from ControlMetadata.Id

InfiniteScroll

InfiniteScroll: boolean (optional)

If set to true then the list will allow infinite scroll.

InfiniteScrollPageSize

InfiniteScrollPageSize: number (optional)

Number of rows to load initially and the number of rows to load after the user reaches the end of the currently displayed rows.

Label

Label: string (optional)

Label for a control. For example, a control representing a person's first name might have a label "First Name".

> Inherited from ControlMetadata.Label

ListStyle

ListStyle: string (optional)

Dictates the list template type. Options:

- "Simple": simple style
- "Card": card style

MultiSelect

MultiSelect: boolean (optional)

If true, then the list will be a multi-select list.

Name

Name: string (optional)

Name of a control.

> Inherited from ControlMetadata.Name

NonEntityProjection

NonEntityProjection: boolean (optional)

Order

Order: number (optional)

Number indicating the order in which a control will appear on a page.

> Inherited from ControlMetadata.Order

Type

Type: ControlType (optional)

String indicating the control type.

> Inherited from ControlMetadata.Type

Methods

navigationHandler

Optional

navigationHandler(row: Row): Promise <any> | NavigationArgs

A function that determines the navigation for a given row.

Parameters

NAME	TYPE	DESCRIPTION
row	Row	row to get navigation handler for.

Returns Promise <any> | NavigationArgs

Events

OnNavigate

OnNavigate: function(navigation: NavigationArgs): any (optional)

An event that is triggered when a pagelink control is selected.

OnRowSelect

OnRowSelect: function(row: Row): void (optional)

An event that is triggered when a row is selected.

NOTE

Can you tell us about your documentation language preferences? Take a short survey.

The survey will take about seven minutes. No personal data is collected (privacy statement).

Lookup type

2/18/2021 • 2 minutes to read • Edit Online

Lookup control type. A lookup is an input control that is used to select an input from a list of options. For example, a lookup could be used to lookup a customer when linking a customer to a new sales order.

Hierarchy

InputControl

True if the control is hidden.

> Inherited from Control.hidden

Methods

applyDesign

applyDesign(IDesign: LookupDesign): void

Applies given design to the design on the control. If a design already exists, the prototype chain of the design will be preserved.

> Overrides Control.applyDesign

Parameters

NAME	TYPE	DESCRIPTION
IDesign	LookupDesign	object containing design properties as keys

Returns void

dataContext

dataContext(): any

> Inherited from Control.dataContext

Returns any

getDesign

getDesign(): Design

Returns the design object of this control.

> Inherited from Control.getDesign

Returns Design

getDisplayValue

getDisplayValue(): string

Returns string

getLookupPage

getLookupPage(): Page

Returns Page

getValue

getValue(): string | number

Returns string | number

isEditable

isEditable(): boolean

Boolean indicating if the control is editable. Returns false when either the control or its parent is not editable. Returns true when both the control and its parent are editable. Returns true when either the control or its parent is editable and the other is undefined. Returns undefined if both the control's edit-ability and its parent's edit-ability is undefined.

> Inherited from Control.isEditable

Returns boolean

metadata

metadata(): LookupMetadata

Returns the metadata object of this control.

> Overrides InputControl.metadata

Returns LookupMetadata

parent

parent(): Control | Page

Returns the parent (control or page) of this control.

> Inherited from Control.parent

Returns Control | Page

root

root(): Page

Returns the root form instance (page) of this control.

> Inherited from Control.root

Returns Page

setEntityRef

setEntityRef(newValue: string | number): Promise <any>

Parameters

NAME	TYPE	DESCRIPTION
newValue	string | number	

Returns Promise <any>

Events

onDataChanged

onDataChanged: EventHook <null>

An event that is triggered when the input control's data changes.

> Inherited from InputControl.onDataChanged

flexFlow

flexFlow: string (optional)

Specifying this property makes the component a flex container component. This property is an alias for the CSS property "flex-flow". Please refer to this web page for documentation on the "flex-flow" property.

> Inherited from Design.flexFlow

flexSize

flexSize: string (optional)

One number or two numbers written as a string. For example, "(size to grow) [(size-to-shrink)]" to accommodate available space in the immediate flex container. This property is an alias for the CSS property "flex". Please refer to this web page for documentation on the "flex" property.

> Inherited from Design.flexSize

fontSize

fontSize: "medium" | "xx-small" | "x-small" | "small" | "large" | "x-large" | "xx-large" (optional)

The proportional text size

> Inherited from Design.fontSize

fontWeight

fontWeight: "normal" | "bold" (optional)

Normal or bold text.

> Inherited from Design.fontWeight

justifyItems

justifyItems: "flex-start" | "flex-end" | "center" | "space-between" (optional)

This property is an alias for the CSS property "justify-content". Please refer to this web page for documentation on the "justify-content" property.

> Inherited from Design.justifyItems

label

label: string (optional)

> Inherited from Design.label

labelPosition

labelPosition: "stacked" | "hidden" | "inline" (optional)

Determines how a label is positioned, if at all. By default, labelPosition is set to stacked.

> Inherited from Design.labelPosition

name

name: string (optional)

> Inherited from Design.name

padding

padding: "none" | "small" | "std" (optional)

Allows specifying the component's padding behavior. A component will inherit the padding behavior specified by its parent container components.

> Inherited from Design.padding

type

type: ControlType (optional)

The type of the control as a string.

> Inherited from Design.type

Properties

BoundEntity

BoundEntity: string (optional)

The entity to which the control is bound.

> Inherited from ControlMetadata.BoundEntity

BoundField

BoundField: string (optional)

> Inherited from ControlMetadata.BoundField

Description

Description: string (optional)

Description of the control.

> Inherited from ControlMetadata.Description

DisplayField

DisplayField: string (optional)

The name of a control on the page, whose value should be displayed to the user. Usually, this value is user-friendly/user-readable text.

DisplayKey

DisplayKey: string (optional)

Editable

Editable: boolean (optional)

Boolean indicating if the control is editable. False when either the control or its parent is not editable. True when both the control and its parent are editable. True when either the control or its parent is editable and the other is undefined. Undefined if both the control's edit-ability and its parent's edit-ability is undefined.

> Inherited from ControlMetadata.Editable

ExtType

ExtType: ControlType (optional)

The extended control type. For example, a control of type Input might have an extended type of Barcode.

> Inherited from ControlMetadata.ExtType

FilterContext

FilterContext: DataFilter (optional)

HelpText

HelpText: string (optional)

The keyboard shortcut for a command. For example, "(Shift+F5)"

> Inherited from ControlMetadata.HelpText

Hidden

Hidden: boolean (optional)

Boolean indicating if the control is hidden or not.

> Inherited from ControlMetadata.Hidden

Id

Id: string (optional)

Identification string for a control.

> Inherited from ControlMetadata.Id

Label

Label: string (optional)

Label for a control. For example, a control representing a person's first name might have a label "First Name".

> Inherited from ControlMetadata.Label

LookupEntity

LookupEntity: any (optional)

The entity that is being looked up in the lookup.

LookupPage

LookupPage: string (optional)

LookupPageId

LookupPageId: string (optional)

Mandatory

Mandatory: boolean (optional)

If set to true then input for the control is required for the task to be completed. Mandatory controls will have a red outline.

> Inherited from InputControlMetadata.Mandatory

MultiSelect

MultiSelect: boolean (optional)

If true, lookup will be configured as a multi-select.

Name

Name: string (optional)

Name of a control.

> Inherited from ControlMetadata.Name

NumSequence

NumSequence: NumberSequenceConfig (optional)

Used for auto detecting and changing visibility of the number sequence controls in the task or page, based on AX number sequence configuration, through extended business logic. Example:

```
// hide number sequence reference page from users
metadataService.hideNavigation('numSeqReferencePage');

// parameters to be passed to 'numSequence' flag in configureControl
var configParam = {
     referencePageName: 'numSeqReferencePage',
     dataType: 'HcmPersonnelNumberId'
};

// setup 'PersonnelNumber' control as number sequence in the task 'add-worker'
metadataService.configureControl('add-worker', 'PersonnelNumber', { numSequence: configParam });
```

> Inherited from InputControlMetadata.NumSequence

Order

Order: number (optional)

Number indicating the order in which a control will appear on a page.

> Inherited from ControlMetadata.Order

ReferenceAppId

ReferenceAppId: string (optional)

ShowLookupPage

ShowLookupPage: boolean (optional)

Type

Type: ControlType (optional)

String indicating the control type.

> Inherited from ControlMetadata.Type

ValueField

ValueField: string (optional)

The name of a control on the page, whose value should be used when committing the data. Usually, this value is a unique key.

ValueKey

ValueKey: string (optional)

Events

OnOptionSelected

OnOptionSelected: function(lookup: any, lookupEntityData: any): void (optional)

An event that is triggered by an option being selected.

OnValueChanged

OnValueChanged: function(value: any): void (optional)

An event that is triggered by a value being changed.

NOTE

Can you tell us about your documentation language preferences? Take a short survey.

The survey will take about seven minutes. No personal data is collected (privacy statement).

MetadataService type

2/18/2021 • 4 minutes to read • Edit Online

Provides ability to access and configure various metadata elements under the application workspace.

Hierarchy

MetadataService

Index

Properties

- version

Methods

- addControl
- compareVersion
- configureAction
- configureControl
- configureEntity
- configureLookup
- configurePage
- configureWorkspace
- findAction
- findControl
- findPage
- getFilterExpression
- getFormReference
- hideNavigation

Properties

version

version: string

(Read-only) Gets the version of the platform currently running.

Methods

addControl

addControl(componentName: string, controlName: string, controlType: ControlType, parentContainerName?: string, options?: ControlMetadata): any

Parameters

NAME	TYPE	DESCRIPTION
componentName	string	

NAME	TYPE	DESCRIPTION
controlName	string	
controlType	ControlType	
parentContainerName?	string	
options?	ControlMetadata	

Returns any

compareVersion

compareVersion(versionToCompare: string): 1 | -1

Compares the current platform version with a reference version.

Parameters

NAME	TYPE	DESCRIPTION
versionToCompare	string	The reference version to compare with

Returns 1 | -1

1 to indicate the platform version is older than the reference version, -1 to indicate that the platform version is newer or same as the reference version

configureAction

configureAction(actionName: string, options: PageMetadata): any

Configuring an action allows specifying or overriding certain behaviors specific to actions. Example:

```
metadataService.configureAction('Edit-Reservation', { properties-to-set });
```

Parameters

NAME	TYPE	DESCRIPTION
actionName	string	The action whose behavior is to be changed
options	PageMetadata	The property bag containing the properties to set on the action

Returns any

configureControl

configureControl(componentName: string, controlName: string, options: ControlMetadata): any

Configuring a control allows specifying or overriding certain behaviors specific to the control. Note that the available behaviors vary by control type. Example:

```
metadataService.configureControl('All-Customers', 'FMCustomer_RecId', { properties-to-set });
```

Parameters

NAME	TYPE	DESCRIPTION
componentName	string	A page or action that contains the control
controlName	string	The control whose behavior is to be changed
options	ControlMetadata	The property bag containing the properties to set on the control

Returns any

configureEntity

configureEntity(entityName: string, options: any): any

Configuring an entity allows specifying or overriding certain behaviors specific to the entity. Example:

```
metadataService.configureEntity("FMCustomer", { properties-to-set });
```

Parameters

NAME	TYPE	DESCRIPTION
entityName	string	An entity name
options	any	The property bag containing the properties to set on the entity

Returns any

configureLookup

configureLookup(taskName: string, lookupControlName: string, options: LookupMetadata): any

Configures a field on an action to behave as a lookup. Requires using an existing page which contains a list control. Example:

```
metadataService.configureLookup('Add-Reservation', 'FMRental_Customer', { lookupPage: 'All-Customers',
valueField: 'FMCustomer_RecId', displayField: 'FMCustomer_FullName'});
```

Parameters

NAME	TYPE	DESCRIPTION
taskName	string	Action name
lookupControlName	string	The control name of the field to be given lookup behavior
options	LookupMetadata	Lookup configuration object

Returns any

configurePage

configurePage(pageName: string, options: PageMetadata): any

Configuring a Page allows specifying or overriding certain behaviors specific to the Page. Example:

```
metadataService.configurePage('Reservation-details', { properties-to-set });
```

Parameters

NAME	TYPE	DESCRIPTION
pageName	string	The page that contains the control
options	PageMetadata	The property bag containing the properties to set on the page

Returns any

configureWorkspace

configureWorkspace(options: PageMetadata): any

Configuring a workspace allows specifying or overriding certain behaviors specific to the workspace. Example:

```
metadataService.configureWorkspace({ properties-to-set });
```

Parameters

NAME	TYPE	DESCRIPTION
options	PageMetadata	The property bag containing the properties to set on the workspace

Returns any

findAction

findAction(actionName: string): PageMetadata

Gets a copy of the current metadata instance of a specified Action, for the purpose of inspecting the metadata (not to be used for changing the metadata). Note: Since metadata can be changed at any time by business logic, you must be mindful of when you use this API to get a copy as it will reflect the state of the metadata at the time the call is made.

Example:

```
var newCustomerTaskMetadata = metadataService.findTask("New-customer");
```

Parameters

NAME	TYPE	DESCRIPTION
actionName	string	An action name

Returns PageMetadata

findControl

findControl(componentMetadata: any, controlName: string): ControlMetadata

Gets a copy of the current metadata instance of a specified control, for the purpose of inspecting the metadata (not to be used for changing the metadata). Note: Since metadata can be changed at any time by business logic, you must be mindful of when you use this API to get a copy as it will reflect the state of the metadata at the time the call is made.

Example:

```
var firstNameControl = metadataService.findControl(newCustomerTaskMetadata, 'FMCustomer_FirstName');
```

Parameters

NAME	TYPE	DESCRIPTION
componentMetadata	any	A metadata instance of the page or action
controlName	string	A control name

Returns ControlMetadata

findPage

findPage(pageName: string): PageMetadata

Gets a copy of the current metadata instance of a specified page, for the purpose of inspecting the metadata (not to be used for changing the metadata). Note: Since metadata can be changed at any time by business logic, you must be mindful of when you use this API to get a copy as it will reflect the state of the metadata at the time the call is made.

Example:

```
var reservationDetailsMetadata = metadataService.findPage("Reservation-details");
```

Parameters

NAME	TYPE	DESCRIPTION
pageName	string	A page name

Returns PageMetadata

getFilterExpression

getFilterExpression(pageName: string, listControlName: string, controlName: string, operator: ExpressionOperator, value: string): DataFilter

Create a DataFilter object for a list control based on the provided options. Example:

```
var filter = metadataService.getFilterExpression(
 pageNames.AllCustomers, controlNames.CustomerList, controlNames.CustomerFullName, "Is", firstCustomerName),
```

Parameters

NAME	TYPE	DESCRIPTION
pageName	string	
listControlName	string	
controlName	string	
operator	ExpressionOperator	

NAME	TYPE	DESCRIPTION
value	string	

Returns DataFilter

getFormReference

getFormReference(componentName: string, filterContext: DataFilter, excludeContext: boolean, filterLocalOnly?: boolean): NavigationArgs

Create an INavigationArgs object for a specific page/action to be used with a navigation control.

Parameters

NAME	TYPE	DESCRIPTION
componentName	string	Name of the action/page
filterContext	DataFilter	
excludeContext	boolean	
filterLocalOnly?	boolean	

Returns NavigationArgs

hideNavigation

hideNavigation(pageNamesToHide: string [ ]): any

Hides the specified page(s) from the default landing page. Example:

```
metadataService.hideNavigation('Select-a-customer', 'Select-a-vehicle');
```

Parameters

NAME	TYPE	DESCRIPTION
pageNamesToHide	string [ ]	Page name(s)

Returns any

MultiLookup type

2/18/2021 • 2 minutes to read • Edit Online

Multi-Lookup control type. Multi-Lookup controls are similar to regular lookups except they allow multiple selections at once.

Hierarchy

InputControl
└ MultiLookup

Index

Properties

- container
- generic
- getDataSource
- getEntityRefs
- hidden
- setEntityRefs

Methods

- applyDesign
- dataContext
- getDesign
- getLookupPage
- isEditable
- metadata
- parent
- root

Events

- onDataChanged

Properties

container

container: boolean (optional)

True if the control is a container.

> Inherited from Control.container

generic

generic: boolean (optional)

> Inherited from Control.generic

getDataSource

getDataSource: function(): any

> Inherited from Control.getDataSource

getEntityRefs

getEntityRefs: function(): string [ ] | number [ ]

hidden

hidden: boolean

True if the control is hidden.

> Inherited from Control.hidden

setEntityRefs

setEntityRefs: function(ids: string [ ] | number [ ]): Promise <any>

Methods

applyDesign

applyDesign(IDesign: MultiLookupDesign): void

Applies given design to the design on the control. If a design already exists, the prototype chain of the design will be preserved.

> Overrides Control.applyDesign

Parameters

NAME	TYPE	DESCRIPTION
IDesign	MultiLookupDesign	object containing design properties as keys

Returns void

dataContext

dataContext(): any

> Inherited from Control.dataContext

Returns any

getDesign

getDesign(): Design

Returns the design object of this control.

> Inherited from Control.getDesign

Returns Design

getLookupPage

getLookupPage(): Page

Returns Page

isEditable

isEditable(): boolean

Boolean indicating if the control is editable. Returns false when either the control or its parent is not editable. Returns true when both the control and its parent are editable. Returns true when either the control or its parent is editable and the other is undefined. Returns undefined if both the control's edit-ability and its parent's edit-ability is undefined.

> Inherited from Control.isEditable

Returns boolean

metadata

metadata(): MultiLookupMetadata

Returns the metadata object of this control.

> Overrides InputControl.metadata

Returns MultiLookupMetadata

parent

parent(): Control | Page

Returns the parent (control or page) of this control.

> Inherited from Control.parent

Returns Control | Page

root

root(): Page

Returns the root form instance (page) of this control.

> Inherited from Control.root

Returns Page

Events

onDataChanged

onDataChanged: EventHook <null>

An event that is triggered when the input control's data changes.

> Inherited from InputControl.onDataChanged

MultiLookupDesign type

2/18/2021 • 2 minutes to read • Edit Online

Multi-Lookup design object type.

Hierarchy

InputControlDesign
└ MultiLookupDesign

Index

Properties

Properties

alignItems

alignItems: string (optional)

This property is an alias for the CSS property "align-items". Please refer to this web page for documentation on the "align-items" property.

> Inherited from Design.alignItems

alignSelf

alignSelf: string (optional)

> Inherited from Design.alignSelf

bindings

bindings: any (optional)

> Inherited from Design.bindings

border

border: "none" | "solid" | "left" | "right" | "top" | "bottom" (optional)

The border behavior of a control. This property will not be inherited by the children.

> Inherited from Design.border

color

color: string (optional)

The foreground color of the container. This will modify the color of all headers, items, labels, and icons within the container.
Consider setting the background color at the same time as necessary when setting this attribute.
Note: if color is set to "theme", the theme color of the app will be used.
The following colors are available:

```
blue:          #0078D7;
pomegranate:   #911844;
raspberry:     #8D398F;
darkOrange:    #D24726;
green:         #369F47;
blueberry:     #17234E;
grape:         #432158;
lightBlue:     #5DB2FF;
lightGreen:    #82BA00;
pink:          #DC4FAD;
teal:          #008299;
mediumDarkBlue: #004B8B;
cordovan:      #570000;
darkCordovan:  #380000;
black:         #000000;
lightGray:     #e8e8e8;
light:         #fff   ;
dark:          #333333;
```

> Inherited from Design.color

flexFlow

flexFlow: string (optional)

Specifying this property makes the component a flex container component. This property is an alias for the CSS property "flex-flow". Please refer to this web page for documentation on the "flex-flow" property.

> Inherited from Design.flexFlow

flexSize

flexSize: string (optional)

One number or two numbers written as a string. For example, "(size to grow) [(size-to-shrink)]" to accommodate available space in the immediate flex container. This property is an alias for the CSS property "flex". Please refer to this web page for documentation on the "flex" property.

> Inherited from Design.flexSize

fontSize

fontSize: "medium" | "xx-small" | "x-small" | "small" | "large" | "x-large" | "xx-large" (optional)

The proportional text size

> Inherited from Design.fontSize

fontWeight

fontWeight: "normal" | "bold" (optional)

Normal or bold text.

> Inherited from Design.fontWeight

justifyItems

justifyItems: "flex-start" | "flex-end" | "center" | "space-between" (optional)

This property is an alias for the CSS property "justify-content". Please refer to this web page for documentation on the "justify-content" property.

> Inherited from Design.justifyItems

label

label: string (optional)

> Inherited from Design.label

labelPosition

labelPosition: "stacked" | "hidden" | "inline" (optional)

Determines how a label is positioned, if at all. By default, labelPosition is set to stacked.

> Inherited from Design.labelPosition

name

name: string (optional)

> Inherited from Design.name

padding

padding: "none" | "small" | "std" (optional)

Allows specifying the component's padding behavior. A component will inherit the padding behavior specified by its parent container components.

> Inherited from Design.padding

type

type: ControlType (optional)

The type of the control as a string.

> Inherited from Design.type

> **NOTE**
>
> Can you tell us about your documentation language preferences? Take a short survey.
>
> The survey will take about seven minutes. No personal data is collected (privacy statement).

MultiLookupMetadata type

2/18/2021 • 2 minutes to read • Edit Online

Multi-Lookup metadata type.

Hierarchy

InputControlMetadata

- Type

Events

- OnLookupPageCreate
- OnLookupPageCreated

Properties

BoundEntity

BoundEntity: string (optional)

The entity to which the control is bound.

> Inherited from ControlMetadata.BoundEntity

BoundField

BoundField: string (optional)

> Inherited from ControlMetadata.BoundField

Description

Description: string (optional)

Description of the control.

> Inherited from ControlMetadata.Description

Design

Design: Design (optional)

Design object for the lookup page that is referenced by the LookupPageId.

Editable

Editable: boolean (optional)

Boolean indicating if the control is editable. False when either the control or its parent is not editable. True when both the control and its parent are editable. True when either the control or its parent is editable and the other is undefined. Undefined if both the control's edit-ability and its parent's edit-ability is undefined.

> Inherited from ControlMetadata.Editable

ExtType

ExtType: ControlType (optional)

The extended control type. For example, a control of type Input might have an extended type of Barcode.

> Inherited from ControlMetadata.ExtType

FilterContext

FilterContext: DataFilter (optional)

FilterLocalOnly

FilterLocalOnly: boolean (optional)

HelpText

HelpText: string (optional)

The keyboard shortcut for a command. For example, "(Shift+F5)"

> Inherited from ControlMetadata.HelpText

Hidden

Hidden: boolean (optional)

Boolean indicating if the control is hidden or not.

> Inherited from ControlMetadata.Hidden

Id

Id: string (optional)

Identification string for a control.

> Inherited from ControlMetadata.Id

Label

Label: string (optional)

Label for a control. For example, a control representing a person's first name might have a label "First Name".

> Inherited from ControlMetadata.Label

LookupPageId

LookupPageId: string (optional)

Page that is hosted within the multi-lookup.

Mandatory

Mandatory: boolean (optional)

If set to true then input for the control is required for the task to be completed. Mandatory controls will have a red outline.

> Inherited from InputControlMetadata.Mandatory

Name

Name: string (optional)

Name of a control.

> Inherited from ControlMetadata.Name

NumSequence

NumSequence: NumberSequenceConfig (optional)

Used for auto detecting and changing visibility of the number sequence controls in the task or page, based on AX number sequence configuration, through extended business logic. Example:

```
// hide number sequence reference page from users
metadataService.hideNavigation('numSeqReferencePage');

// parameters to be passed to 'numSequence' flag in configureControl
var configParam = {
     referencePageName: 'numSeqReferencePage',
     dataType: 'HcmPersonnelNumberId'
};

// setup 'PersonnelNumber' control as number sequence in the task 'add-worker'
metadataService.configureControl('add-worker', 'PersonnelNumber', { numSequence: configParam });
```

> Inherited from InputControlMetadata.NumSequence

Order

Order: number (optional)

Number indicating the order in which a control will appear on a page.

> Inherited from ControlMetadata.Order

ReferenceAppId

ReferenceAppId: string (optional)

ReverseLookupRelation

ReverseLookupRelation: boolean (optional)

ShowPending

ShowPending: boolean (optional)

Type

Type: ControlType (optional)

String indicating the control type.

> Inherited from ControlMetadata.Type

Events

OnLookupPageCreate

OnLookupPageCreate: function(args: any, multiLookup: any): void (optional)

OnLookupPageCreated

OnLookupPageCreated: function(args: any, multiLookup: any): void (optional)

NumberSequenceConfig type

2/18/2021 • 2 minutes to read • Edit Online

Number Sequence Configuration type.

Hierarchy

NumberSequenceConfig

Index

Properties

Properties

dataType

dataType: string

The data type is used to lookup whether the number sequence is editable or not on the reference page.

referencePageName

referencePageName: string

Page name of the page that defines if the num sequence is editable.

Page type

2/18/2021 • 3 minutes to read • Edit Online

Page object type.

Hierarchy

Page

Index

Properties

Methods

Events

Properties

children

children: Control [ ]

(Read-only) The list of all direct children controls of the page.

dataLoadedInitially

dataLoadedInitially: Promise <void>

(Read-only) A promise which resolves when the data has loaded for the first time. The promise continues to stay resolved for the rest of the page life.

initialized

initialized: boolean

(Read-only) True if the page instance has been initialized.

metadata

metadata: PageMetadata

(Read-only) The page metadata.

metadataLoaded

metadataLoaded: Promise <void>

(Read-only) A promise which resolves when the metadata has finished loading.

pageContext

pageContext: string

The current page context.

pageFilter

pageFilter: DataFilter

The current filter applied on the page.

state

state: PageState

(Read-only) The current state of the page.

syncError

syncError: boolean

(Read-only) True if the page's submission is in error state. This normally happens when the server rejects submissions due to validation errors. Refer to this topic for a detailed explanation of page data synchronization.

syncPending

syncPending: boolean

(Read-only) True if the page's submission is waiting to be synced. Refer to this topic for a detailed explanation of page data synchronization.

syncProcessing

syncProcessing: boolean

(Read-only) True if the page instance is currently syncing its submission. Refer to this topic for a detailed explanation of page data synchronization.

syncUnitEditable

syncUnitEditable: boolean

(Read-only) True if it's possible to edit a submission while it's waiting to be synchronized. Refer to this topic for a detailed explanation of page data synchronization.

title

title: string

(Read-only) The title of the page.

Methods

canSubmit

canSubmit(): boolean

Returns true if action page can be submitted and there are no validation/error messages.

Returns boolean

close

close(): void

Dispose the page instance and all its lifecycle events.

Returns void

getAction

getAction(actionName: string): PageLink

Get a page action by name. These include the actions in the action sheet/menu.

Parameters

NAME	TYPE	DESCRIPTION
actionName	string	

Returns PageLink

getActions

getActions(): PageLink [ ]

Get all page actions. These include the actions in the action sheet/menu.

Returns PageLink [ ]

getControl

getControl(controlName: string): Control

Get a page control by name. It recursively searches through all its children pages.

Parameters

NAME	TYPE	DESCRIPTION
controlName	string	

Returns Control

getDesign

getDesign(): Design

Get the design object associated with the page.

Returns Design

getEntityContext

getEntityContext(): EntityRef

Get current entity context.

Returns EntityRef

isEditable

isEditable(): boolean

Returns true if the page is an Action Page

Returns boolean

refreshData

refreshData(): Promise <void>

Force refresh page data.

Returns Promise <void>

resume

resume(): Promise <void>

Resume a temporarily suspended page.

Returns Promise <void>

submit

submit(): Promise <CompleteEventArgs>

Submit an Action.

Returns Promise <CompleteEventArgs>

suspend

suspend(): void

Temporarily suspend a page. For example, when the page is not the active view.

Returns void

Events

onClose

onClose: EventHook <null>

Event that is raised when a page is closed.

onComplete

onComplete: EventHook <any>

Event that is raised when an action is completed.

onDataLoaded

onDataLoaded: EventHook <any>

Event that fires when the page data has loaded. The event may be fired multiple times - every time new data is loaded.

onInit

onInit: EventHook <any>

Event that fires when a page instance has been initialized, and the metadata has been loaded.

onPreInit

onPreInit: EventHook <any>

Event that fires when a page instance has been initialized. This is fired before the metadata has been loaded.

onRefresh

onRefresh: EventHook <null>

Event that fires on forced page refresh, before new data has been loaded.

onStateChange

onStateChange: EventHook <null>

Event that fires when the page state changes.

onSubmit

onSubmit: EventHook <PageSubmitArgs>

Event that fires before an action is submitted. It can be intercepted for action validation/deferring Refer to IPageSubmitArgs to know more about the available options.

onSyncStatusChange

onSyncStatusChange: EventHook <null>

Event that fires when the page sync status changes.

PageData type

2/18/2021 • 2 minutes to read • Edit Online

Represents the data that is loaded into a page.

Hierarchy

PageData

Index

Methods

- getControlValue
- setControlValue

Methods

getControlValue

getControlValue(controlName: string): any

Gets the value of a control directly from the data set loaded in the page. The "value" is loosely defined across all different types of controls and generally indicates the primary single field value displayed or interacted with the control. Some complex controls (e.g a lookup or a list) may not have a simple value and thus cannot be accessed via this API.

Parameters

NAME	TYPE	DESCRIPTION
controlName	string	name of the control whose value is to be retrieved

Returns any

setControlValue

setControlValue(controlName: string, value: any): any

Sets the value of a control directly into the data set loaded in the page. The "value" is loosely defined across all different types of controls and generally indicates the primary single field value displayed or interacted with the control. Some complex controls (e.g a lookup or a list) may not have a simple value and thus cannot be accessed via this API.

Parameters

NAME	TYPE	DESCRIPTION
controlName	string	Name of the control whose value is to be set
value	any	The value to be set

Returns any

NOTE

Can you tell us about your documentation language preferences? Take a short survey.

The survey will take about seven minutes. No personal data is collected (privacy statement).

PageLink type

2/18/2021 • 2 minutes to read • Edit Online

Pagelink control type. A pagelink is a control that navigates to another page.

Hierarchy

Control
└ PageLink

Index

Properties

container

container: boolean (optional)

True if the control is a container.

> Inherited from Control.container

generic

generic: boolean (optional)

> Inherited from Control.generic

getDataSource

getDataSource: function(): any

> Inherited from Control.getDataSource

hidden

hidden: boolean

True if the control is hidden.

> Inherited from Control.hidden

Methods

allowsNavigation

allowsNavigation(): boolean

Returns boolean

applyDesign

applyDesign(design: PageLinkDesign): void

Applies given design to the design on the control. If a design already exists, the prototype chain of the design will be preserved.

> Overrides Control.applyDesign

Parameters

NAME	TYPE	DESCRIPTION
design	PageLinkDesign	object containing design properties as keys

Returns void

dataContext

dataContext(): any

> Inherited from Control.dataContext

Returns any

getCount

getCount(): number | string

Returns number | string

getDesign

getDesign(): Design

Returns the design object of this control.

> Inherited from Control.getDesign

Returns Design

getNavigationHandler

getNavigationHandler(): NavigationArgs

Returns NavigationArgs

isEditable

isEditable(): boolean

Boolean indicating if the control is editable. Returns false when either the control or its parent is not editable. Returns true when both the control and its parent are editable. Returns true when either the control or its parent is editable and the other is undefined. Returns undefined if both the control's edit-ability and its parent's edit-ability is undefined.

> Inherited from Control.isEditable

Returns boolean

metadata

metadata(): PageLinkMetadata

Returns the metadata object of this control.

> Overrides Control.metadata

Returns PageLinkMetadata

parent

parent(): Control | Page

Returns the parent (control or page) of this control.

> Inherited from Control.parent

Returns Control | Page

root

root(): Page

Returns the root form instance (page) of this control.

> Inherited from Control.root

Returns Page

showCount

showCount(): boolean

Returns boolean

2/18/2021 • 3 minutes to read • Edit Online

Pagelink design object type.

Hierarchy

Design
└ PageLinkDesign

Index

Properties

Properties

alignItems

alignItems: string (optional)

This property is an alias for the CSS property "align-items". Please refer to this web page for documentation on the "align-items" property.

> Inherited from Design.alignItems

alignSelf

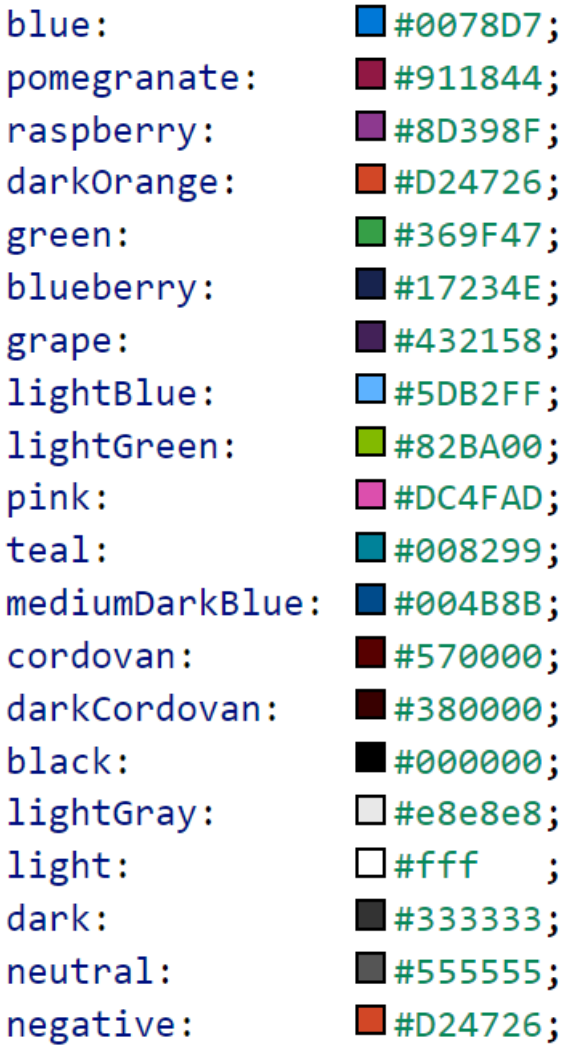
alignSelf: string (optional)

> Inherited from Design.alignSelf

background

background: string (optional)

Sets the background color. If "theme" is used, then the color will match the app's theme color.



bindings

bindings: any (optional)

> Inherited from Design.bindings

border

border: "none" | "solid" | "left" | "right" | "top" | "bottom" (optional)

The border behavior of a control. This property will not be inherited by the children.

> Inherited from Design.border

color

color: string (optional)

The foreground color of the container. This will modify the color of all headers, items, labels, and icons within the container.

Consider setting the background color at the same time as necessary when setting this attribute.
Note: if color is set to "theme", the theme color of the app will be used.
The following colors are available:

> Inherited from Design.color

excludeContext

excludeContext: boolean (optional)

flexFlow

flexFlow: string (optional)

Specifying this property makes the component a flex container component. This property is an alias for the CSS property "flex-flow". Please refer to this web page for documentation on the "flex-flow" property.

> Inherited from Design.flexFlow

flexSize

flexSize: string (optional)

One number or two numbers written as a string. For example, "(size to grow) [(size-to-shrink)]" to accommodate available space in the immediate flex container. This property is an alias for the CSS property "flex". Please refer to this web page for documentation on the "flex" property.

> Inherited from Design.flexSize

fontSize

fontSize: "medium" | "xx-small" | "x-small" | "small" | "large" | "x-large" | "xx-large" (optional)

The proportional text size

> Inherited from Design.fontSize

fontWeight

fontWeight: "normal" | "bold" (optional)

Normal or bold text.

> Inherited from Design.fontWeight

hideArrow

hideArrow: boolean (optional)

Allows an arrow (>) on a default styled navigation control to be hidden. By default, arrows are present in a navigation control.
This property can only be added through the design object.

icon

icon: string (optional)

Name of the icon that is displayed in the pagelink control. Here is a list of available icons.

justifyItems

justifyItems: "flex-start" | "flex-end" | "center" | "space-between" (optional)

This property is an alias for the CSS property "justify-content". Please refer to this web page for documentation on the "justify-content" property.

> Inherited from Design.justifyItems

label

label: string (optional)

> Inherited from Design.label

labelPosition

labelPosition: "stacked" | "hidden" | "inline" (optional)

Determines how a label is positioned, if at all. By default, labelPosition is set to stacked.

> Inherited from Design.labelPosition

name

name: string (optional)

> Inherited from Design.name

navigation

navigation: NavigationArgs (optional)

Navigation object of the pagelink.

padding

padding: "none" | "small" | "std" (optional)

Allows specifying the component's padding behavior. A component will inherit the padding behavior specified by its parent container components.

> Inherited from Design.padding

showCount

showCount: boolean (optional)

If true, shows a count of the records present in the list on the target page. This property is only suitable when the navigation target is a Page which contains on a List control.

style

style: string (optional)

Determines the visual style of the pagelink control. Options:

- "inline": takes up the full width its container, with the label in-line with the icon
- "button": takes up only as much width as needed by the label, with the label below the icon

type

type: ControlType (optional)

The type of the control as a string.

> Inherited from Design.type

PageLinkMetadata type

Properties

BoundEntity

BoundEntity: string (optional)

The entity to which the control is bound.

Inherited from ControlMetadata.BoundEntity

BoundField

BoundField: string (optional)

Inherited from ControlMetadata.BoundField

Description

Description: string (optional)

Description of the control.

Inherited from ControlMetadata.Description

Editable

Editable: boolean (optional)

Boolean indicating if the control is editable. False when either the control or its parent is not editable. True when both the control and its parent are editable. True when either the control or its parent is editable and the other is undefined. Undefined if both the control's edit-ability and its parent's edit-ability is undefined.

Inherited from ControlMetadata.Editable

ExcludeContext

ExcludeContext: boolean (optional)

ExtType

ExtType: ControlType (optional)

The extended control type. For example, a control of type Input might have an extended type of Barcode.

Inherited from ControlMetadata.ExtType

HelpText

HelpText: string (optional)

The keyboard shortcut for a command. For example, "(Shift+F5)"

Inherited from ControlMetadata.HelpText

Hidden

Hidden: boolean (optional)

Boolean indicating if the control is hidden or not.

Inherited from ControlMetadata.Hidden

Icon

Icon: string (optional)

Name of the icon that is displayed in the page link control. Here is a list of available icons.

IconSize

IconSize: number (optional)

Determines the size of the icon that is displayed in the page link control.

Id

Id: string (optional)

Identification string for a control.

Inherited from ControlMetadata.Id

Label

Label: string (optional)

Label for a control. For example, a control representing a person's first name might have a label "First Name".

Inherited from ControlMetadata.Label

Name

Name: string (optional)

Name of a control.

Inherited from ControlMetadata.Name

Navigation

Navigation: NavigationArgs (optional)

Navigation object of the page link.

Order

Order: number (optional)

Number indicating the order in which a control will appear on a page.

Inherited from ControlMetadata.Order

ShowCount

ShowCount: boolean (optional)

If true, shows a count of the records present in the list on the target page. This property is only suitable when the navigation target is a Page which contains on a List control.

Style

Style: string (optional)

Determines the visual style of the page link control. Options:

- "inline": takes up the full width its container, with the label in-line with the icon
- "button": takes up only as much width as needed by the label, with the label below the icon

Target

Target: string (optional)

Name of the target action or page to navigate to when the page link is selected.

Type

Type: ControlType (optional)

String indicating the control type.

Inherited from ControlMetadata.Type

UseDataContext

UseDataContext: boolean (optional)

Events

OnNavigate

OnNavigate: function(navigation: NavigationArgs | string): any (optional)

An event that is triggered when the navigation is triggered.

NOTE

Can you tell us about your documentation language preferences? Take a short survey.

The survey will take about seven minutes. No personal data is collected (privacy statement).

Properties

- dataValues
- sender

Methods

- addMessage
- cancel
- getMessages
- isCancelled
- wait

Properties

dataValues

dataValues: any

Get the payload of the submit action.

sender

sender: Page

Get the sender page instance of the submit action.

Methods

addMessage

addMessage(message: string, type: any): any

Add a validation/error message to be displayed.

Parameters

NAME	TYPE	DESCRIPTION
message	string	
type	any	

Returns any

cancel

cancel(): any

Prevent the action from submitting.

Returns any

getMessages

getMessages(): string [ ]

Get all previously added messages

Returns string [ ]

isCancelled

isCancelled(): boolean

Check if the submit action is cancelled.

Returns boolean

wait

wait(promise: Promise <any>): any

Wait on a given promise before continuing with the submission. All promises attached via wait must resolve before the submit action is performed.

Parameters

NAME	TYPE	DESCRIPTION
promise	Promise <any>	

Returns any

- root

Properties

container

container: boolean

True if the control is a container.

> Inherited from ContainerControl.container
>
> Overrides Control.container

generic

generic: boolean (optional)

> Inherited from Control.generic

getDataSource

getDataSource: function(): any

> Inherited from Control.getDataSource

hidden

hidden: boolean

True if the control is hidden.

> Inherited from Control.hidden

Methods

applyDesign

applyDesign(IDesign: PartDesign): void

Applies given design to the design on the control. If a design already exists, the prototype chain of the design will be preserved.

> Overrides Control.applyDesign

Parameters

NAME	TYPE	DESCRIPTION
IDesign	PartDesign	object containing design properties as keys

Returns void

dataContext

dataContext(): any

> Inherited from Control.dataContext

Returns any

getControl

getControl(controlName: string): Control

Given the name of a control, returns the control instance.

> Inherited from ContainerControl.getControl

Parameters

NAME	TYPE	DESCRIPTION
controlName	string	control name

Returns Control

getControlById

getControlById(id: string): Control

Given the ID of a control, returns the control instance.

> Inherited from ContainerControl.getControlById

Parameters

NAME	TYPE	DESCRIPTION
id	string	control ID

Returns Control

getDesign

getDesign(): Design

Returns the design object of this control.

> Inherited from Control.getDesign

Returns Design

getEntityRef

getEntityRef(): string

Gets value of entityRef binding to control.

Returns string

getPartPage

getPartPage(): Page

Gets the page of the part.

Returns Page

hasTarget

hasTarget(): boolean

Returns true if the part has a target page.

Returns boolean

isEditable

isEditable(): boolean

Boolean indicating if the control is editable. Returns false when either the control or its parent is not editable. Returns true when both the control and its parent are editable. Returns true when either the control or its parent is editable and the other is undefined. Returns undefined if both the control's edit-ability and its parent's edit-ability is undefined.

> Inherited from Control.isEditable

Returns boolean

metadata

metadata(): PartMetadata

Returns the metadata object of this control.

> Overrides ContainerControl.metadata

Returns PartMetadata

parent

parent(): Control | Page

Returns the parent (control or page) of this control.

> Inherited from Control.parent

Returns Control | Page

root

root(): Page

Returns the root form instance (page) of this control.

> Inherited from Control.root

Returns Page

2/18/2021 • 3 minutes to read • Edit Online

Part design object type.

Hierarchy

ContainerControlDesign
└ PartDesign

Index

Properties

Properties

alignItems

alignItems: string (optional)

This property is an alias for the CSS property "align-items". Please refer to this web page for documentation on the "align-items" property.

> Inherited from Design.alignItems

alignSelf

alignSelf: string (optional)

Inherited from Design.alignSelf

allowScroll

allowScroll: string (optional)

True if the container will allow scrolling when its items do not fit into the container's available space. If a container has an item which may scroll, then set this property to false to prevent nested scrolling areas.

Inherited from ContainerControlDesign.allowScroll

background

background: string (optional)

The background color of the container. Consider modifying the color attribute in the same container so that fonts overlaying the background color will appear appropriately. Note: if background is set to "theme", the theme color of the app will be used. The following colors are available:

```
blue:          #0078D7;
pomegranate:   #911844;
raspberry:     #8D398F;
darkOrange:    #D24726;
green:         #369F47;
blueberry:     #17234E;
grape:         #432158;
lightBlue:     #5DB2FF;
lightGreen:    #82BA00;
pink:          #DC4FAD;
teal:          #008299;
mediumDarkBlue: #004B8B;
cordovan:      #570000;
darkCordovan:  #380000;
black:         #000000;
lightGray:     #e8e8e8;
light:         #fff   ;
dark:          #333333;
```

Inherited from ContainerControlDesign.background

bindings

bindings: any (optional)

Inherited from Design.bindings

border

border: "none" | "solid" | "left" | "right" | "top" | "bottom" (optional)

The border behavior of a control. This property will not be inherited by the children.

> Inherited from Design.border

color

color: string (optional)

The foreground color of the container. This will modify the color of all headers, items, labels, and icons within the container.
Consider setting the background color at the same time as necessary when setting this attribute.
Note: if color is set to "theme", the theme color of the app will be used.
The following colors are available:

> Inherited from Design.color

design

design: PartDesign (optional)

Design for the target page.

flexFlow

flexFlow: string (optional)

Specifying this property makes the component a flex container component. This property is an alias for the CSS property "flex-flow". Please refer to this web page for documentation on the "flex-flow" property.

> Inherited from Design.flexFlow

flexSize

flexSize: string (optional)

One number or two numbers written as a string. For example, "(size to grow) [(size-to-shrink)]" to accommodate available space in the immediate flex container. This property is an alias for the CSS property "flex". Please refer to this web page for documentation on the "flex" property.

> Inherited from Design.flexSize

fontSize

fontSize: "medium" | "xx-small" | "x-small" | "small" | "large" | "x-large" | "xx-large" (optional)

The proportional text size

> Inherited from Design.fontSize

fontWeight

fontWeight: "normal" | "bold" (optional)

Normal or bold text.

> Inherited from Design.fontWeight

itemBorder

itemBorder: "solid" | "none" (optional)

If true, a border will appear around each row in the list. This property is equivalent to applying the border property individually to all items in the container.

> Inherited from ContainerControlDesign.itemBorder

items

items: string | Design [ ] (optional)

An array containing the components to place inside of the container.

> Inherited from ContainerControlDesign.items

justifyItems

justifyItems: "flex-start" | "flex-end" | "center" | "space-between" (optional)

This property is an alias for the CSS property "justify-content". Please refer to this web page for documentation on the "justify-content" property.

> Inherited from Design.justifyItems

label

label: string (optional)

> Inherited from Design.label

labelPosition

labelPosition: "stacked" | "hidden" | "inline" (optional)

Determines how a label is positioned, if at all. By default, labelPosition is set to stacked.

> Inherited from Design.labelPosition

name

name: string (optional)

> Inherited from Design.name

padding

padding: "none" | "small" | "std" (optional)

Allows specifying the component's padding behavior. A component will inherit the padding behavior specified by its parent container components.

> Inherited from Design.padding

target

target: PageTarget (optional)

Target page of the part.

type

type: ControlType (optional)

The type of the control as a string.

> Inherited from Design.type

Row type

2/18/2021 • 2 minutes to read • Edit Online

Row controls are what make up a list. A list contains any number of row controls.

Hierarchy

Row

Index

Properties

- fieldList
- headerField
- hidden
- imageFields
- isSelected
- item
- template

Methods

- getControl
- getControlById
- getControlValueById
- getRowHeader
- getRowId
- hasImageField
- isEntityCreatedNew
- isEntityDeleted
- isEntityModified
- isEntitySyncPending
- select

Properties

fieldList

fieldList: Control [ ]

headerField

headerField: Control

hidden

hidden: boolean

If true then the row will be hidden.

imageFields

imageFields: Control [ ]

isSelected

isSelected: boolean

item

item: any

A container of rendered data.

template

template: Group

Group control that represents the template for a row.

Methods

getControl

getControl(controlName: string): Control

Parameters

NAME	TYPE	DESCRIPTION
controlName	string	

Returns Control

getControlById

getControlById(id: string): Control

Parameters

NAME	TYPE	DESCRIPTION
id	string	id can be valueKey or the displayKey of the list control metadata

Returns Control

getControlValueById

getControlValueById(id: string): string

Parameters

NAME	TYPE	DESCRIPTION
id	string	id can be valueKey or the displayKey of the list control metadata

Returns string

getRowHeader

getRowHeader(): Control

Returns Control

getRowId

getRowId(): string

Returns string

hasImageField

hasImageField(): boolean

Returns true if the row has an image field.

Returns boolean

isEntityCreatedNew

isEntityCreatedNew(): boolean

Returns boolean

isEntityDeleted

isEntityDeleted(): boolean

Returns boolean

isEntityModified

isEntityModified(): boolean

Returns boolean

isEntitySyncPending

isEntitySyncPending(): boolean

Returns boolean

select

select(): any

Returns any

Value type

2/18/2021 • 2 minutes to read • Edit Online

Value control type. This is the base class for single value controls.

Properties

container

container: boolean (optional)

True if the control is a container.

> Inherited from Control.container

generic

generic: boolean (optional)

> Inherited from Control.generic

getDataSource

getDataSource: function(): any

> Inherited from Control.getDataSource

hidden

hidden: boolean

True if the control is hidden.

> Inherited from Control.hidden

Methods

applyDesign

applyDesign(design: Design): void

Applies given design to the design on the control. If a design already exists, the prototype chain of the design will be preserved.

> Inherited from Control.applyDesign

Parameters

NAME	TYPE	DESCRIPTION
design	Design	object containing design properties as keys

Returns void

dataContext

dataContext(): any

> Inherited from Control.dataContext

Returns any

getDesign

getDesign(): Design

Returns the design object of this control.

> Inherited from Control.getDesign

Returns Design

getValue

getValue(): string

Returns the value of the control.

Returns string

isEditable

isEditable(): boolean

Boolean indicating if the control is editable. Returns false when either the control or its parent is not editable. Returns true when both the control and its parent are editable. Returns true when either the control or its parent is editable and the other is undefined. Returns undefined if both the control's edit-ability and its parent's edit-ability is undefined.

> Inherited from Control.isEditable

Returns boolean

metadata

metadata(): ValueMetadata

Returns the metadata object of this control.

> Overrides InputControl.metadata

Returns ValueMetadata

parent

parent(): Control | Page

Returns the parent (control or page) of this control.

> Inherited from Control.parent

Returns Control | Page

root

root(): Page

Returns the root form instance (page) of this control.

> Inherited from Control.root

Returns Page

setValue

setValue(value: string): void

Sets the value of the control.

Parameters

NAME	TYPE	DESCRIPTION
value	string	

Returns void

Events

onDataChanged

onDataChanged: EventHook <null>

An event that is triggered when the input control's data changes.

> Inherited from InputControl.onDataChanged

NOTE

Can you tell us about your documentation language preferences? Take a short survey.

The survey will take about seven minutes. No personal data is collected (privacy statement).

lightGray:      #e8e8e8;
light:          #fff   ;
dark:           #333333;
```

> Inherited from Design.color

flexFlow

flexFlow: string (optional)

Specifying this property makes the component a flex container component. This property is an alias for the CSS property "flex-flow". Please refer to this web page for documentation on the "flex-flow" property.

> Inherited from Design.flexFlow

flexSize

flexSize: string (optional)

One number or two numbers written as a string. For example, "(size to grow) [(size-to-shrink)]" to accommodate available space in the immediate flex container. This property is an alias for the CSS property "flex". Please refer to this web page for documentation on the "flex" property.

> Inherited from Design.flexSize

fontSize

fontSize: "medium" | "xx-small" | "x-small" | "small" | "large" | "x-large" | "xx-large" (optional)

The proportional text size

> Inherited from Design.fontSize

fontWeight

fontWeight: "normal" | "bold" (optional)

Normal or bold text.

> Inherited from Design.fontWeight

justifyItems

justifyItems: "flex-start" | "flex-end" | "center" | "space-between" (optional)

This property is an alias for the CSS property "justify-content". Please refer to this web page for documentation on the "justify-content" property.

> Inherited from Design.justifyItems

label

label: string (optional)

> Inherited from Design.label

labelPosition

labelPosition: "stacked" | "hidden" | "inline" (optional)

Determines how a label is positioned, if at all. By default, labelPosition is set to stacked.

> Inherited from Design.labelPosition

name

name: string (optional)

> Inherited from Design.name

padding

padding: "none" | "small" | "std" (optional)

Allows specifying the component's padding behavior. A component will inherit the padding behavior specified by its parent container components.

> Inherited from Design.padding

type

type: ControlType (optional)

The type of the control as a string.

True when either the control or its parent is editable and the other is undefined. Undefined if both the control's edit-ability and its parent's edit-ability is undefined.

> Inherited from ControlMetadata.Editable

ExtType

ExtType: ControlType (optional)

The extended control type. For example, a control of type Input might have an extended type of Barcode.

> Inherited from ControlMetadata.ExtType

HelpText

HelpText: string (optional)

The keyboard shortcut for a command. For example, "(Shift+F5)"

> Inherited from ControlMetadata.HelpText

Hidden

Hidden: boolean (optional)

Boolean indicating if the control is hidden or not.

> Inherited from ControlMetadata.Hidden

Id

Id: string (optional)

Identification string for a control.

> Inherited from ControlMetadata.Id

Label

Label: string (optional)

Label for a control. For example, a control representing a person's first name might have a label "First Name".

> Inherited from ControlMetadata.Label

Mandatory

Mandatory: boolean (optional)

If set to true then input for the control is required for the task to be completed. Mandatory controls will have a red outline.

> Inherited from InputControlMetadata.Mandatory

Name

Name: string (optional)

Name of a control.

> Inherited from ControlMetadata.Name

NumSequence

NumSequence: NumberSequenceConfig (optional)

Used for auto detecting and changing visibility of the number sequence controls in the task or page, based on AX number sequence configuration, through extended business logic. Example:

```
// hide number sequence reference page from users
metadataService.hideNavigation('numSeqReferencePage');

// parameters to be passed to 'numSequence' flag in configureControl
var configParam = {
     referencePageName: 'numSeqReferencePage',
     dataType: 'HcmPersonnelNumberId'
};

// setup 'PersonnelNumber' control as number sequence in the task 'add-worker'
metadataService.configureControl('add-worker', 'PersonnelNumber', { numSequence: configParam });
```

> Inherited from InputControlMetadata.NumSequence

Order

Order: number (optional)

Number indicating the order in which a control will appear on a page.

> Inherited from ControlMetadata.Order

Type

Type: ControlType (optional)

String indicating the control type.

> Inherited from ControlMetadata.Type

Process automation framework development

2/18/2021 • 2 minutes to read • Edit Online

Process automation enables simple scheduling of processes that will be run by the batch server. The process automation framework is a set of APIs that lets you implement process automation.

You should use only the public APIs to implement process automation, and you should follow these guidelines:

- Don't select from, insert into, or directly reference the process automation tables.
- Don't extend the framework or integrate your code with the classes.
- Don't subscribe to table events such as insert, update, and delete. Finance and Operations apps skip most of those events.
- If functionality that you require is missing, submit feature requests.

Microsoft plans to add features in the future. If you integrate too deeply with the process automation framework, your integration might break when those features are added.

Some of the examples for the process automation framework aren't representative of release-quality code. As always, the expectation is that processes that are built by using the framework will follow all best practices and quality standards.

For more information about process automation, see Process automation.

Definitions

TERM	DEFINITION
Poller	The poller is a system-critical batch process that runs every minute and invokes various subsystems of the process automation framework. It consults the schedule to determine which processes are ready to run, and then it invokes the runtime side of the framework to ensure that processes are run.
Scheduled process	A scheduled process is a process that is scheduled in the user interface (UI) by a user. Occurrences for these processes can be seen in a calendar view.
Background process	A background process is also known as a *polled process*. It's a process that runs frequently, without requiring user input, and performs some background processing. Subledger transfer to the general ledger is an example.
Type	In this topic and related topics, the term *type* refers to **ProcessScheduleType**, as discussed in Type registration.
Series	Every process that has a registered type must have a series. Series for scheduled processes are created in the UI by users. Series for background processes are created through series registration. For more information, see Series registration.
Date and time	All framework dates are stored in Coordinated Universal Time (UTC) but shown in the user's preferred time zone.

Tasks

Implementation of a process automation solution consists of a set of tasks, some of which are required and some of which are optional.

Most of the UI customizations aren't supported for background processes. The **Series** list page and logging of results and messages are supported.

TASK	REQUIRED FOR A SCHEDULED PROCESS	REQUIRED FOR A BACKGROUND PROCESS
Type registration	Yes	Yes
Series registration	Not supported	Yes
Process parameters	No	Not supported
User-configurable queries	No	Not supported
Run processes	Yes	Yes
Log results and messages	Yes	Yes
Customize the user interface	No	See Customize the user interface.

NOTE

Can you tell us about your documentation language preferences? Take a short survey.

The survey will take about seven minutes. No personal data is collected (privacy statement).

Type registration

2/18/2021 • 6 minutes to read • Edit Online

To implement a process by using the process automation framework, you must first understand the concept of a *type* in the framework. A type is a unique process that is integrated with the batch framework and that uses the **SysOperations** framework, specifically the **SysOperationServiceController** class. The types are stored in the **ProcessScheduleType** table.

Here are a few examples of different types that are registered with the process automation framework:

- Vendor Payment Proposal (**VendPaymProposalAutomationTypeRegistrationProvider** class)
- Vendor Invoice Posting (**VendInvoicePostProcessScheduleTypeRegistration** class)
- Subledger transfer to general ledger (**SubledgerJournalVoucherTransferServiceRegistration** class)

If an existing process uses **RunBaseBatch**, consider wrapping it with **SysOperationServiceController**. The process automation framework doesn't support **RunBaseBatch**.

To register your type with the process automation framework, you must implement the **ProcessScheduleITypeRegistration** interface. This interface has a single method that returns an instance of **ProcessScheduleTypeRegistrationItem**.

If your process uses a feature flag, you must disable and enable the type as the feature is disabled and enabled, respectively.

- If you disable the feature flag for a type, the type doesn't appear in the user interface (UI). The scheduler won't schedule any occurrences or background processes of that type to run, and the runtime side of the process automation framework won't create any batch jobs for that type.
- If you enable the feature flag for a type, any occurrences or background processes that are scheduled to run in the past will be run immediately. Usually, this behavior is what you want. However, if it isn't what you want, consider disabling any series that is related to the type before you disable the feature flag.

Feature management has events that you can subscribe to. The method that you use to enable and disable types is **ProcessScheduleTypeRegistration.enableOrDisableType**.

Every time that a database synchronization runs, types and series are updated from their definitions in code. The only background settings that aren't updated are those that can be edited by the system admin. The process automation framework does this update by hooking **SysSetup**. The system admin can manually trigger this update through the settings at **System administration > Setup > Initialize background**.

The following example shows a process for a scheduled type. Note the following points:

- A background process doesn't have to set the **Parameter** tab list, because background processes don't support parameters.
- The type name isn't shown in the UI. The name should be a developer-created string such as **VendorInvoiceBatchPosting**. It's used internally as a key to reference your type for various purposes. It **cannot** be a label.
- The type name is used heavily with the **SysPlugIn** pattern. Most of the interfaces that are implemented for the process automation framework follow the **SysPlugIn** pattern and require that the type name be supplied by the **ExportMetadataAttribute**. In most cases in this pattern, the framework invokes the implementation of an interface only for the type that is being operated on, not for other types. Code examples in this topic and related topics follow this pattern.

```
using System.ComponentModel.Composition;

// The VendPaymProposalAutomationTypeRegistrationProvider class handles type registration for Vendor payment
proposal automations.
[Export(identifierStr(Dynamics.AX.Application.ProcessScheduleITypeRegistration))]
public final class VendPaymProposalAutomationTypeRegistrationProvider
implements ProcessScheduleITypeRegistration
{
    private const LabelId Caption = literalStr('@CashManagement:VendPaymProposalAutomationTypeName');
    private const LabelId HelpText =
literalStr('@CashManagement:VendPaymProposalAutomationSeriesWizardHelpText');
    private const MenuItemName SeriesFormMenuItemName =
menuItemDisplayStr(VendPaymProposalAutomationCriteriaSeries);

    [Wrappable(false)]
    public ProcessScheduleTypeRegistrationItem getScheduleTypeRegistrationItem()
    {
        ProcessScheduleTypeRegistrationItem item =
        ProcessScheduleTypeRegistrationItem::construct();
        item.parmName(VendPaymProposalAutomationConstants::RegisteredTypeName);
        item.parmLabelId(Caption);
        item.parmScheduleType(ProcessScheduleProcessType::Scheduled);
        item.parmCompanyScope(ProcessScheduleTypeCompanyScope::SingleCompany);
        item.parmProcessAutomationTaskClassName(classStr(VendPaymProposalAutomationTask));
        item.parmParameterTabItemList(this.constructParameterTabItemList());
        item.parmIsEnabled(VendPaymProposalAutomationFeature::isEnabled());
        return item;
        }

    private List constructParameterTabItemList()
    {
        List criteriaTabItemList = new List(Types::Class);
        ProcessScheduleTypeRegistrationParameterTabItem criteriaTabItem =
        ProcessScheduleTypeRegistrationParameterTabItem::newFromMenuItem(SeriesFormMenuItemName);

        criteriaTabItem.parmCaption(Caption);
        criteriaTabItem.parmHelpText(HelpText);
        criteriaTabItemList.addEnd(criteriaTabItem);
        return criteriaTabItemList;
        }
}
```

The following example shows feature management for a process automation framework type.

```
using System.ComponentModel.Composition;
using Microsoft.Dynamics.ApplicationPlatform.FeatureExposure;
using Microsoft.Dynamics.ApplicationPlatform.FeatureExposure.Implementation;

// The VendPaymProposalAutomationFeature class defines the Vendor Payment Proposal Automation feature.
[Export(identifierStr(Microsoft.Dynamics.ApplicationPlatform.FeatureExposure.IFeatureMetadata))]
internal final class VendPaymProposalAutomationFeature implements IFeatureMetadata,
IFeatureMetadataEnablementNotifiable
{
    private static VendPaymProposalAutomationFeature instance;
    private void new()
    {
    }

    private static void typeNew()
    {
        instance = new VendPaymProposalAutomationFeature();
    }

    [Hookable(false)]
    public static VendPaymProposalAutomationFeature instance()
    {
```

```
        return VendPaymProposalAutomationFeature::instance;
    }

    [Hookable(false)]
    public FeatureLabelId label()
    {
        return literalStr("@CashManagement:VendPaymProposalAutomationFeatureName");
    }

Dynamics.AX.Application.FeatureStateProvider::isFeatureEnabled(VendPaymProposalAutomationFeature::instance()
);
    }
}
```

ProcessScheduleTypeRegistrationItem class

The **ProcessScheduleTypeRegistrationItem** class is used as a part of type registration and contains information that is specific to your type.

METHOD	DESCRIPTION
`public ProcessScheduleTypeName parmName(ProcessScheduleTypeName _name = name)`	The type name that is passed to the **item.parmName** method isn't shown to users. This value is a developer-defined string that is used when various events are invoked. It should be assigned as a constant, not as a label. **Never use a label as a type name.** Use names such as **VendPaymentProposal**.
`public ProcessScheduleProcessType parmScheduleType(ProcessScheduleProcessType _scheduleType = scheduleType)`	This method determines whether the process is scheduled or polled.
`public ProcessScheduleTypeCompanyScope parmCompanyScope(ProcessScheduleTypeCompanyScope _companyScope = companyScope)`	This method determines whether the process is a single-company process or a global process. A single-company process sets the company context in a batch, depending on the company that the user is in when a series is created. If the scope is global, the company context is ignored, and all jobs are in **dat**.
`public LabelId parmLabelId(LabelId _labelId = labelId)`	The label that this method returns is shown to users and represents the display name for your type. An example is **Vendor payment proposal**.
`public className parmProcessAutomationTaskClassName(ClassName _processAutomationTaskClassName = processAutomationTaskClassName)`	The class name that this method returns is the class name of the class that will implement the **ProcessAutomationTask** interface.
`public NoYes parmIsEnabled(NoYes _isEnabled = isEnabled)`	This method determines whether the type that you're registering is enabled by default. If your type is feature-managed, a default value is taken from the state of the feature. Be sure to implement the enabled and disabled feature management events. Enable and disable your type in the process automation framework in the appropriate way, by using **ProcessScheduleTypeRegistration.enableOrDisableType** method. Example code is shown earlier in this topic.
`public List parmParameterTabItemList(List _parameterTabList = parameterTabList)`	A process can have many parameter pages in the UI. These parameter pages contain parameters that are specific to the process. They are surfaced as form parts in the **Create series** wizard and edit occurrence dialog box. For each parameter page, an instance of the **ProcessSchedulelTypeRegistrationParameterTabItem** class must be constructed and returned in the list. If the process doesn't require parameter pages, return **null**. For more information, see Process parameters.
`public static ProcessScheduleTypeRegistrationItem construct()`	This method constructs an instance of the **ProcessScheduleTypeRegistrationItem** class.

ProcessSchedulelTypeRegistrationParameterTabItem class

The **ProcessSchedulelTypeRegistrationParameterTabItem** class represents information that is specific to a

single parameter page.

METHOD	DESCRIPTION
`public MenuItemName parmMenuItemName(MenuItemName _menuItemName = menuItemName)`	The **Create series** wizard supports parameter pages by using embedded form parts. This value is the menu item that goes to the form part that is created by the team that owns the process.
`public LabelId parmCaption(LabelId _caption = caption)`	The caption on the parameter page.
`public LabelId parmHelpText(LabelId _helpText = helpText)`	The Help text for the parameter page.
`public static ProcessScheduleTypeRegistrationParameterTabItem newFromMenuItem(MenuItemName _menuItemName)`	Constructor that initializes the instance with the specified menu item name.

Series registration

2/18/2021 • 6 minutes to read • Edit Online

Every process must have a *series*. The concept of a series in process automation resembles the concept of a meeting series in Microsoft Outlook. However, a series in process automation is a series of scheduled runs of a process. For most scheduled process types, users create the series in the user interface (UI), and series registration never has to be implemented. However, if the process that is being implemented is a schedule series, you can skip this task.

Background processes typically create a series via code, by using series registration, because background processes tend to be "under the hood" processes that don't allow for user interaction. To create a series via code, you implement the **ProcessScheduleISeriesRegistration** interface. This interface contains a single method that returns an instance of **ProcessScheduleSeriesRegistrationItem**.

The process automation framework lets system admins change the default polling interval and unit for background processes.

Here is an example of a test series that is used to test the process automation framework.

```
using System.ComponentModel.Composition;
// Implements the ProcessScheduleISeriesRegistration to register the vendor invoice batch posting task
'Series' with the Process Automation.
[Export(identifierStr(Dynamics.AX.Application.ProcessScheduleISeriesRegistration))]
[ExportMetadata(classStr(ProcessScheduleISeriesRegistration),
classStr(VendInvoicePostProcessScheduleSeriesRegistration))]
internal final class VendInvoicePostProcessScheduleSeriesRegistration implements
ProcessScheduleISeriesRegistration
{

    [Hookable(false)]
    public ProcessScheduleSeriesRegistrationItem
    getProcessScheduleSeriesRegistrationItem()
    {
        ProcessScheduleSeriesRegistrationItem
        processScheduleSeriesRegistrationItem =
        ProcessScheduleSeriesRegistrationItem::construct();

processScheduleSeriesRegistrationItem.parmDescription("@AccountsPayable:VendInvoicePostTaskFeatureSummary");
        processScheduleSeriesRegistrationItem.parmOwnerId(curUserId());

processScheduleSeriesRegistrationItem.parmProcessScheduleSeriesPatternList(this.getSeriesPatternList());

processScheduleSeriesRegistrationItem.parmSeriesName("@AccountsPayable:VendInvoicePostTaskFeatureLabel");

processScheduleSeriesRegistrationItem.parmTypeName(VendInvoicePostTaskConstants::VendorInvoiceBatchPosting);
        return processScheduleSeriesRegistrationItem;
        }

    private List getSeriesPatternList()
    {
        ProcessScheduleSeriesPatternItem processScheduleSeriesPatternItem =
        ProcessScheduleSeriesPatternItem::construct();
        processScheduleSeriesPatternItem.parmUnit(ProcessScheduleUnit::Minute);
        processScheduleSeriesPatternItem.parmPollingInterval(VendParameters::pollingIntervalMinutes());
        List list = new List(Types::Class);
        list.addEnd(processScheduleSeriesPatternItem);
        return list;
    }
}
```

ProcessScheduleSeriesRegistrationItem class

METHOD	DESCRIPTION
`public ProcessScheduleTypeName parmTypeName(ProcessScheduleTypeName _typeName = typeName)`	The name of the type.
`public ProcessScheduleSeriesName parmSeriesName(ProcessScheduleSeriesName _SeriesName = seriesName)`	The name of the series. Be descriptive, so that the purpose of the series is clear from the name.
`public Description parmDescription(Description _description = description)`	The description of the series.
`public UserGroupId parmOwnerId(UserGroupId _ownerId = ownerId)`	The user ID of the owner of the series.

METHOD	DESCRIPTION
`public List parmProcessScheduleSeriesPatternList(List _seriesPatternList = seriesPatternList)`	The list of patterns for the series. Currently, only one pattern per series is supported. However, this limitation might change in the future. Insert an instance of the **ProcessScheduleSeriesPatternItem** class into the list.

ProcessScheduleSeriesPatternItem class

When the pattern is configured, applicable fields are determined based on the unit. Not all methods that are defined in the following table work for all units. The methods that apply to units are defined in the tables later in this section. Other combinations will be ignored. For polled processes, only the unit and the polling interval are used. Other fields are ignored.

METHOD	DESCRIPTION
`public ProcessScheduleUnit parmUnit(ProcessScheduleUnit _unit = unit)`	The unit of time that the series runs in. The unit can be minutes or hours.
`public ProcessScheduleInterval parmPollingInterval(ProcessScheduleInterval _pollingInterval = pollingInterval)`	For polled processes, this value is an integer that, together with the unit, defines how often the process runs.
`public ProcessScheduleDateTime parmStartDate(ProcessScheduleDateTime _startDate = startDate)`	The start date of the series. The time should be set to the empty time.
`public ProcessScheduleDateTime parmEndDate(ProcessScheduleDateTime _endDate = endDate)`	The end date of the series. The time should be set to the empty time.
`public ProcessScheduleDateTime parmTime(ProcessScheduleDateTime _time = time)`	The time when the series should run. The date should be set to the empty date.

Methods that are applicable to the week unit

METHOD	DESCRIPTION
`public NoYes parmOnSunday(NoYes _onSunday = onSunday)`	The days of the week that you want the process to run on by selecting the appropriate methods for the day of the week. For example, **parmOnMonday()** will run the job on a Monday.

Methods that are applicable to the day unit

METHOD	DESCRIPTION
`public NoYes parmDoesRepeatEveryNumberOfDays(NoYes _doesRepeatEveryNumberOfDays = doesRepeatEveryNumberOfDays)`	Indicates whether the process should run every *X* number of days.
`public int parmDailyRepeatInterval(int _dailyRepeatInterval = dailyRepeatInterval)`	Indicates the number of days.
`public NoYes parmDoesRepeatEveryWeekDay(NoYes _doesRepeatEveryWeekDay = doesRepeatEveryWeekDay)`	Indicates whether the process should run every weekday.

Methods that are applicable to the month unit

METHOD	DESCRIPTION
`public NoYes parmDoesRepeatOnDayOfMonth(NoYes _doesRepeatOnDayOfMonth = doesRepeatOnDayOfMonth)`	The process should run on a specific day of every month.
`public Day parmMonthlyRepeatDayOfMonth(Day _monthlyRepeatDayOfMonth = monthlyRepeatDayOfMonth)`	The day of month when the process should run.

Modifying background processes

System admins can modify the polling interval and unit in the process automation framework. However, many background processes that currently exist have their own specific UI that is built to manage these changes. Microsoft provides a way to programmatically modify these values via the following APIs.

METHOD	DESCRIPTION
`public static ProcessScheduleSeriesPollingDetails getPollingDetailsForSeries(ProcessScheduleTypeName _typeName, ProcessScheduleSeriesName _seriesName)`	Gets the polling interval, the unit, and the next scheduled date/time for a polled process.
`public static void setPollingDetailsForSeries(ProcessScheduleTypeName _typeName, ProcessScheduleSeriesName _seriesName, ProcessScheduleSeriesPollingDetails _pollingDetails)`	Enables changes to the polling interval, the unit, and the next scheduled date/time for a polled process.

Validating background process settings

In version 10.0.13, the process automation framework lets system admins modify background process settings via the **Edit background process** section. Some background processes have restrictions on the frequency of their runs. Microsoft has introduced an interface that a background process can implement. When this interface is invoked, it enables the background process to ensure that the unit and polling interval are within their allowed range.

The following example prevents this process from ever being run every minute or every hour. The process can run a maximum of one time per day. However, a process can implement the rules in such a way that more frequent runs are required.

```
using System.ComponentModel.Composition;

// Provider to validate background settings.
[Export(identifierStr(Dynamics.AX.Application.ProcessScheduleISeriesValidateBackgroundDialog))]
[ExportMetadata(extendedTypeStr(ProcessScheduleTypeName), 'ProcessAutomationExploder')]
internal final class ProcessScheduleExplodeAutomationBackgroundDialogValidationProvider implements
ProcessScheduleISeriesValidateBackgroundDialog
{

    public boolean
    validateBackgroundProcessParameters(ProcessScheduleSeriesBackgroundValidationParameters
    _validationParameters)
    {
        ProcessScheduleUnit currentUnit = _validationParameters.parmUnit();
        if (currentUnit == ProcessScheduleUnit::Minute || currentUnit == ProcessScheduleUnit::Hour)
        {
            SysDictEnum enum = new SysDictEnum(enumNum(ProcessScheduleUnit));
            throw Error(
                strFmt("@ProcessAutomationFramework:ProcessScheduleExplodeProcessInvalidUnit",
                enum.value2Label(ProcessScheduleUnit::Minute),
                enum.value2Label(ProcessScheduleUnit::Hour)));
        }
        return true;
    }
}
```

ProcessScheduleISeriesValidateBackgroundDialog interface

The **ProcessScheduleISeriesValidateBackgroundDialog** interface enables background processes to validate user input when users edit background settings via **ProcessScheduleSeriesBackgroundDialog**.

METHOD	DESCRIPTION
`boolean validateBackgroundProcessParameters(ProcessScheduleSeriesBackgroundValidationParameters _validationParameters)`	Implements any validation rules that you have for the process.

ProcessScheduleSeriesBackgroundValidationParameters class

The **ProcessScheduleSeriesBackgroundValidationParameters** class contains the validation parameters that are validated for the background processes that are being edited.

METHOD	DESCRIPTION
`public UserId parmOwnerId(UserId _ownerId = ownerId)`	The owner of the process. It will be used when batch jobs are created, because batch jobs will be created under this user's context.
`public ProcessScheduleUnit parmUnit(ProcessScheduleUnit _unit = unit)`	The unit of time.
`public ProcessScheduleInterval parmPollingInterval(ProcessScheduleInterval _pollingInterval = pollingInterval)`	The polling interval. It defines the number of units of time (as specified by **parmUnit()**) that the process should be run.
`public ProcessScheduleDateTime parmPolledNextScheduledDateTime(ProcessScheduleDateTime _polledNextScheduledDateTime = polledNextScheduledDateTime)`	The next scheduled run of the process in Coordinated Universal Time (UTC).

METHOD	DESCRIPTION
`public ProcessScheduleDateTime parmSleepFromTime(ProcessScheduleDateTime _polledSleepFromTime = polledSleepFromTime)`	Specifies when the sleep should start. The process automation framework lets system admins put a process to sleep for a time range. The process isn't run during this time range, regardless of the setting of **parmPolledNextScheduleDateTime()**. This time range is a maximum of 16 hours and can span the date boundary.
`public ProcessScheduleDateTime parmSleepToTime(ProcessScheduleDateTime _polledSleepToTime = polledSleepToTime)`	Specifies when the sleep should end. The process automation framework lets system admins put a process to sleep for a time range. The process isn't run during this time range, regardless of the setting of **parmPolledNextScheduleDateTime()**. This time range is a maximum of 16 hours and can span the date boundary.

Process parameters

2/18/2021 • 4 minutes to read • Edit Online

In most cases, a process must store custom parameters that are specific to its processes. For example, a process might require a date range or a customer number. You must create your own user interface (UI) and custom tables to show and store these parameters. If a type doesn't have any parameters, you can skip this task.

When a user creates a series in the UI, the **Create series** wizard hosts multiple form parts, each of which contains a related set of parameters. The form parts for the process contain the UI that the user uses to enter the parameters. These form parts are built by the developer of the process and provided through type registration. A form part implements interfaces that let you initialize, validate, and write the custom parameters.

The custom parameter tables typically have two types of records:

- A template record that is bound to the series that serves as a template for all occurrences.
- A record that is specific to an occurrence and contains the parameters that will be used when that occurrence runs. Users can override the parameters for each occurrence as they require.

Parameter tables typically have one foreign key (**RecId**) to the **ProcessScheduleSeries** table and another foreign key (**RecId**) to the **ProcessScheduleOccurrence** table. The template record has a series foreign key, but it doesn't have a foreign key to the occurrence. All other records have both foreign keys.

The following interfaces are used to maintain these parameters.

ProcessScheduleParametersIInitialize interface

The **ProcessScheduleParametersIInitialize** interface lets you initialize parameters when the user interacts with the UI of the process automation framework. The form part that is built for the wizard that shows process-specific parameters implements this interface.

ProcessScheduleParametersIValidate interface

The **ProcessScheduleParametersIValidate** interface lets you validate the parameters that the user enters in the form part.

ProcessScheduleParametersIWrite interface

The **ProcessScheduleParametersIWrite** interface lets you write the parameters to their custom parameter tables.

Example

In the following example, the three interfaces that were just described are used for a sample test process. In this example, the form part contains a single string that is known as a *message*.

```
[Form]
public class ProcessScheduleSampleUptakeFirstFormPart
extends ProcessScheduleParametersFormPart
implements ProcessScheduleParametersIWrite, ProcessScheduleParametersIValidate,
ProcessScheduleParametersIInitialize
{

    private ProcessScheduleSchedulingContract schedulingContract;
```

```
    public void setSchedulingContract(ProcessScheduleSchedulingContract _schedulingContract)
    {
        schedulingContract = _schedulingContract;
    }

    public void initializeForSeriesCreate()
    {
        str text = strFmt("@ProcessAutomationFramework:ProcessScheduleSeriesTestTypeInitSeriesCreate",
curExt());
        ProcessScheduleSampleUptakeParameters_Message.text(text);
    }

    public void initializeForSeriesUpdate()
    {
        ProcessScheduleSampleUptakeParameters parameters =

ProcessScheduleSampleUptakeParameters::findForProcessScheduleSeries(schedulingContract.processScheduleSeries
, true);
        ProcessScheduleSampleUptakeParameters_Message.text(parameters.Message);
    }

    public void initializeForOccurrenceCreate()
    {
        str text = strFmt("@ProcessAutomationFramework:ProcessScheduleSeriesTestTypeInitOccurrenceCreate",
curExt());
        ProcessScheduleSampleUptakeParameters_Message.text(text);
    }

    public void initializeForOccurrenceUpdate()
    {
        ProcessScheduleSampleUptakeParameters parameters =

ProcessScheduleSampleUptakeParameters::findForProcessScheduleOccurrence(schedulingContract.processScheduleOc
currence);
        ProcessScheduleSampleUptakeParameters_Message.text(parameters.Message);
    }

    public void createScheduleSeries(ProcessScheduleSchedulingContract
    _schedulingContract)
    {
        ProcessScheduleSampleUptakeParameters sampleParameters;
        sampleParameters.Message = ProcessScheduleSampleUptakeParameters_Message.valueStr();
        sampleParameters.ProcessScheduleSeries = _schedulingContract.processScheduleSeries.RecId;
        sampleParameters.insert();
    }

    public void updateScheduleSeries(ProcessScheduleSchedulingContract
    _schedulingContract)
    {
        ProcessScheduleSampleUptakeParameters parameters =

ProcessScheduleSampleUptakeParameters::findForProcessScheduleSeries(_schedulingContract.processScheduleSerie
s, true);

        if (parameters)
        {
            ttsbegin;
            parameters.Message = ProcessScheduleSampleUptakeParameters_Message.valueStr();
            parameters.update();
            ttscommit;
        }
    }

    public void createScheduledOccurrence(ProcessScheduleSchedulingContract _schedulingContract)
    {
        ProcessScheduleSampleUptakeParameters occurrenceParameters;
        occurrenceParameters.ProcessScheduleOccurrence =
_schedulingContract.processScheduleOccurrence.RecId;
```

```
        occurrenceParameters.Message = ProcessScheduleSampleUptakeParameters_Message.valueStr();
        occurrenceParameters.insert();
    }

    public void updateScheduledOccurrence(ProcessScheduleSchedulingContract
    _schedulingContract)
    {
        ProcessScheduleSampleUptakeParameters parameters =

ProcessScheduleSampleUptakeParameters::findForProcessScheduleOccurrence(_schedulingContract.processScheduleO
ccurrence,
            true);

        ttsbegin;

        parameters.ProcessScheduleSeries = _schedulingContract.processScheduleSeries.RecId;
        parameters.ProcessScheduleOccurrence = _schedulingContract.processScheduleOccurrence.RecId;
        parameters.Message = ProcessScheduleSampleUptakeParameters_Message.valueStr();

        if (parameters.RecId != 0)
        {
            parameters.update();
        }
        else
        {
            parameters.insert();
        }

        ttscommit;
    }

    public boolean validate()
    {
      boolean isValid = true;
      if (ProcessScheduleSampleUptakeParameters_Message.valueStr() == '')
      {
          isValid = checkFailed("@ProcessAutomationFramework:ProcessScheduleSeriesTestTypeMessageWarning");
      }
      return isValid;
    }
}
```

ProcessScheduleIDeleteOccurrence interface

Implement the **ProcessScheduleIDeleteOccurrence** interface to receive an event that indicates that a user or the system has deleted occurrences. The parameters that are related to that occurrence should be deleted.

This interface is invoked via **SysPlugIn** for a specific type. Use the type name that was created when the type was registered.

Note that a Microsoft Azure SQL Database temp table is passed in so that you can do set-based deletes.

```
using System.ComponentModel.Composition;

// The VendPaymProposalAutomationOccurrenceDeleteProvider class is designed to handle
// deleting the appropriate VendPaymProposalAutomationCriteria records when ProcessScheduleOccurrence
records are deleted.
[ExportMetadata(extendedTypeStr(ProcessScheduleTypeName), 'VendPaymProposalAutomation')]
[Export(identifierStr(Dynamics.AX.Application.ProcessScheduleIDeleteOccurrence))]
internal final class VendPaymProposalAutomationOccurrenceDeleteProvider
implements ProcessScheduleIDeleteOccurrence
{
    private ProcessScheduleSeriesOccurrenceTmp occurrencesExplodedTmp;

    [Wrappable(false)]
    public void deleteOccurrences(ProcessScheduleSeriesOccurrenceTmp _occurrencesExplodedTmp)
    {
        this.initialize(_occurrencesExplodedTmp);
        this.deleteVendPaymProposalAutomationCriteria();
    }

    private void initialize(ProcessScheduleSeriesOccurrenceTmp _occurrencesExplodedTmp)
    {
        occurrencesExplodedTmp.linkPhysicalTableInstance(_occurrencesExplodedTmp);
    }

    private void deleteVendPaymProposalAutomationCriteria()
    {
        VendPaymProposalAutomationCriteria automationCriteria;
        automationCriteria.skipDeleteActions(true);
        automationCriteria.skipDataMethods(true);
        automationCriteria.skipAosValidation(true);
        automationCriteria.skipDatabaseLog(true);
        automationCriteria.skipEvents(true);

        delete_from automationCriteria
            exists join occurrencesExplodedTmp
            where automationCriteria.ProcessScheduleOccurrence ==
occurrencesExplodedTmp.ProcessScheduleOccurrence;
    }
}
```

ProcessScheduleIDeleteSeries interface

The **ProcessScheduleIDeleteSeries** interface resembles **ProcessScheduleIDeleteOccurrence**. The event is invoked whenever a series is deleted. You should delete all parameter records for all occurrences. These records include the series template record.

A SQL Database temp table is passed in so that you can do set-based deletes.

```
using System.ComponentModel.Composition;

// The VendPaymProposalAutomationSeriesDeleteProvider class is designed to handle
// deleting the appropriate VendPaymProposalAutomationCriteria records when ProcessScheduleSeries records
are deleted.
[ExportMetadata(extendedTypeStr(ProcessScheduleTypeName), 'VendPaymProposalAutomation')]
[Export(identifierStr(Dynamics.AX.Application.ProcessScheduleIDeleteSeries))]
internal final class VendPaymProposalAutomationSeriesDeleteProvider
implements ProcessScheduleIDeleteSeries
{

    [Wrappable(false)]
    public void deleteSeries(RefRecId _seriesRecId)
    {
        this.deleteVendPaymProposalAutomationCriteria(_seriesRecId);
    }

    private void deleteVendPaymProposalAutomationCriteria(RefRecId _seriesRecId)
    {
        VendPaymProposalAutomationCriteria automationCriteria;
        automationCriteria.skipDeleteActions(true);
        automationCriteria.skipDataMethods(true);
        automationCriteria.skipAosValidation(true);
        automationCriteria.skipDatabaseLog(true);
        automationCriteria.skipEvents(true);

        delete_from automationCriteria
            where automationCriteria.ProcessScheduleSeries == _seriesRecId;
    }
}
```

ProcessScheduleIExplodeOccurrences interface

When a user creates a new series through the UI, all the future occurrences are generated. Therefore, if the series runs every day, the process automation framework creates an occurrence for every day. This action is known as *generating the series*. The **ProcessScheduleIExplodeOccurrences** event is fired when the series is generated. The series template record should be used as a template to create parameter records for each occurrence in the parameter tables.

A SQL Database temp table is passed in so that you can do set-based creation of parameter records for optimal performance.

In the following example, a parameter table stores a single parameter that is named **Type**. This parameter isn't related to the process automation framework type but is specific to cash flow forecasting.

```
using System.ComponentModel.Composition;

// Provider for cash flow forecast automation generate occurrences.
[Export(identifierStr(Dynamics.AX.Application.ProcessScheduleIExplodeOccurrences))]
[ExportMetadata(extendedTypeStr(ProcessScheduleTypeName), 'LedgerCovTotalProcessAutomation')]
internal final class LedgerCovTotalProcessAutomationExplodeOccurrencesProvider
implements ProcessScheduleIExplodeOccurrences
{
    private void new()
    {
    }

    [Wrappable(false)]
    public void explodeOccurrences(ProcessScheduleSeriesOccurrenceTmp _occurrencesExplodedTmp)
    {
        LedgerCovTotalProcessAutomationSchedulingParameters parameters;
        LedgerCovTotalProcessAutomationSchedulingParameters
        parametersSeriesRecord;

        insert_recordset parameters
        (
            Type,
            ProcessScheduleSeries,
            ProcessScheduleOccurrence
        )

        select Type, ProcessScheduleSeries from parametersSeriesRecord
            where parametersSeriesRecord.ProcessScheduleOccurrence == 0
            join ProcessScheduleOccurrence from _occurrencesExplodedTmp
            where _occurrencesExplodedTmp.ProcessScheduleSeries ==
parametersSeriesRecord.ProcessScheduleSeries
                && _occurrencesExplodedTmp.TypeName ==
LedgerCovTotalProcessAutomationConstants::RegisteredTypeName;
    }
}
```

User-configurable queries

2/18/2021 • 2 minutes to read • Edit Online

This topic describes how to create configurable queries and use them with the process automation framework. If a process won't support user-configurable queries via the **SysQueryForm** form, you can skip this task.

The process automation framework provides limited support for custom queries via the **SysQueryForm** form. A custom query lets a user add custom criteria to limit how a process runs. The framework has logic to extract user-provided custom criteria and tables to store those criteria. The custom query criteria are stored for each occurrence of a given series and can be modified individually. The framework also provides an API to apply the custom criteria to the query that is used to run the process for each occurrence.

> **NOTE**
> When a user applies query criteria, the whole query object isn't saved. Instead the query criteria are saved individually, to allow for better support of query extensions. Therefore, extensions that are made to existing queries for existing query criteria should not cause breaking changes when this approach is used. In this case, a new extension should not require modification or re-creation of the query criteria for a saved series or occurrences. However, modification or re-creation of the query criteria is allowed.

ProcessScheduleIQueryable interface

The **ProcessScheduleIQueryable** interface retrieves the original query (that is, the query as it was before the user modified it) and the user-modified query. These queries are used either to apply criteria when the process runs or to extract criteria when the user makes changes. These criteria are stored by the process automation framework.

This interface is accessed in the criteria form for a given implementation of process automation. For an example of access to this interface, see the **VendPaymProposalAutomationCriteria** form. That form also has a sample implementation of the **SysQueryForm** form.

METHOD	DESCRIPTION
`public Query getOriginalQuery()`	This method gets the original, unmodified query to use as a basis for comparison.
`public Query getQueryForApplicationOrExtractionOfQueryCriteria()`	This method gets the query that has been or will be modified, and that is used to apply or extract query criteria.

> **NOTE**
> The query that is used on the implementation of **ProcessScheduleIQueryable** must have the same structure as the query that is used during the run of the underlying process that is being automated. Any structural deviation that isn't additive in nature will cause runtime errors when the saved query criteria are applied at runtime. To ensure that the query structure remains the same, you should either use a designed query or use shared logic that builds up the query.

ProcessScheduleQueryCriteriaApplicator class

The **ProcessScheduleQueryCriteriaApplicator** class is used to apply the saved query criteria for a given occurrence to the runtime instance of the query that is used when a process is run. This API must be called by an

uptaking process at a point in the run where the query is ready to accept the saved criteria. If a designed query or shared logic that builds up the query is used, this call can typically occur after the query has been correctly initialized. For an example that shows how this API is used, see the **CustVendCreatePaymJournal.constructFromAutomationExecutionContract** method.

METHOD	DESCRIPTION
`public static void applyCriteriaForOccurrenceExecution(Query _queryToApplyCriteria, RefRecId _scheduleOccurrenceRecId)`	

Run processes

2/18/2021 • 4 minutes to read • Edit Online

To run in the process automation framework, a process must implement the **ProcessAutomationTask** interface. The framework uses this interface to provide an instance of **ProcessScheduleWorkItem**. That instance contains information about the series, the occurrence that is being run (if applicable), and the execution ID. You must create the batch task that has to be run, and you must provide the task to the framework. The framework then creates the batch header and the tasks that are provided.

Polled processes don't have occurrences, because they might be run frequently, and those frequent runs will create many more occurrences than you want to track. Instead, you use a unique execution ID to track every run of a polled process. An execution ID is also assigned to scheduled processes.

The **getListOfWorkToBePerformed** method determines whether there is work that must be done. If there is, the method returns a list of batch-enabled classes that inherit from **SysOperationServiceController**. This method must be efficient and fast, because it's run in the context of the polling process. Therefore, you should not do any work in this method except check whether work must be done and create batch tasks for any work that must be done. It's OK if the method returns an empty list, because an empty list indicates that no work must be done. In this case, the process automation framework doesn't create any batch processes.

The process automation framework supports a list for those processes that do parallel processing and that want multiple batch tasks. If the process that is being run is an older process that implements **RunBaseBatch**, it can't be returned through the list. In this case, you have two options:

- Convert the process to **SysOperationServiceController**. For more information, see SysOperations Framework. This option is recommended, if it's feasible.
- Wrap the legacy **RunBaseBatch** class with a new class that inherits from **SysOperationServiceController**. For an example, see **LedgerCovTotalProcessAutomationProcessor** in the Application Object Tree (AOT).

The following example shows an implementation of the **ProcessAutomationTask** interface.

```
using System.ComponentModel.Composition;

// The test class to test the process automation task engine.
[ExportMetadataAttribute(classStr(ProcessAutomationTask),
classStr(ProcessAutomationTaskTestImplementation))]
[ExportAttribute(identifierStr('Microsoft.Dynamics.AX.Application.ProcessAutomationTask'))]
internal final class ProcessAutomationTaskTestImplementation extends ProcessAutomationTask
{

    protected boolean isProcessAutomationEnabledForThisTask()
    {
        return true;
    }

    protected List getListOfWorkToBePerformed()
    {
        ProcessScheduleWorkItem scheduleWorkItemToExecute = this.parmProcessScheduleWorkItem();
        List taskList = new List(Types::Class);
        ProcessAutomationTestProcess testProcess =
ProcessAutomationTestProcess::construct(scheduleWorkItemToExecute);
        taskList.addEnd(testProcess);
        return taskList;
    }

    // Gets and sets the batch job caption that will be used by the batch job scheduled to run this process.
    // Returns the batch caption that will be used for the batch job that will perform the task.
    protected BatchCaption batchJobCaption()
    {
        return "@ProcessAutomationFramework:ProcessScheduleExplodeProcessLabel";
    }
}
```

ProcessScheduleWorkItem class

The **ProcessScheduleWorkItem** class has many pieces of information and is designed to represent a process that must be run.

METHOD	DESCRIPTION
`public ProcessExecutionId parmExecutionId(ProcessExecutionId _executionId = executionId)`	The execution ID is used to log errors. A polled process gets a new, unique execution ID every time that it's run. Because scheduled processes are only ever run one time for each occurrence, each occurrence only ever has one execution ID.
`public RefRecId parmProcessScheduleOccurrenceRecId(RefRecId _scheduleOccurrenceRecId = scheduleOccurrenceRecId)`	The occurrence that is being run. Use this method to reference occurrence-specific parameter information in parameter tables. Polled processes don't have a **RecId** value for an occurrence.
`public RefRecId parmProcessScheduleSeriesPatternRecId(RefRecId _scheduleSeriesPatternRecId = scheduleSeriesPatternRecId)`	The series pattern that the process is associated with. Currently, series can have only one pattern. All parameter records typically have a foreign key to this pattern.
`public ProcessScheduleProcessType parmProcessScheduleType(ProcessScheduleProcessType _scheduleType = scheduleType)`	The schedule type of the process: polled or scheduled.
`public ProcessScheduleTypeName parmProcessScheduleTypeName(ProcessScheduleTypeName _scheduleTypeName = scheduleTypeName)`	The type name that the process and series are associated with, such as **VendPaymentProposal**. This name is an internal developer name and isn't shown to the user.

METHOD	DESCRIPTION
`public List parmLegalEntityList(List _legalEntityList = legalEntityList)`	The list of legal entities that the process will be run against. If the process is a global process, this list will be **null**. If the process is run against a single company, this list will contain a single company. Multiple companies aren't currently supported, but they might be supported in the future.
`public Name getName()`	Returns the occurrence name. If a type is polled, this method returns the series name.
`public ProcessScheduleSeriesName parmSeriesName(ProcessScheduleSeriesName _seriesName = seriesName)`	The name of the series.
`public Name parmOccurrenceName(Name _occurrenceName = occurrenceName)`	The occurrence name. If the process is a polled process, the value will be empty.
`public List parmTaskList(List _taskList = taskList)`	The list of batch tasks that the process automation framework should add to the batch. If this list is **null**, it's assumed that no work must be done, and nothing will be created in a batch.
`public ProcessScheduleDateTime parmScheduledDateTime(ProcessScheduleDateTime _scheduledDateTime = scheduledDateTime)`	The date and time when the process was scheduled to run. This date and time might differ from the actual date and time when the process runs.
`public UserGroupId parmOwnerId(UserGroupId _ownerId = ownerId)`	The owner of the occurrence that is being run.
`public void initializeFromScheduleWorkItem(ProcessScheduleWorkItem _item)`	Initializes an instance of **ProcessScheduleWorkItem** from another instance.

Log results and messages

2/18/2021 • 5 minutes to read • Edit Online

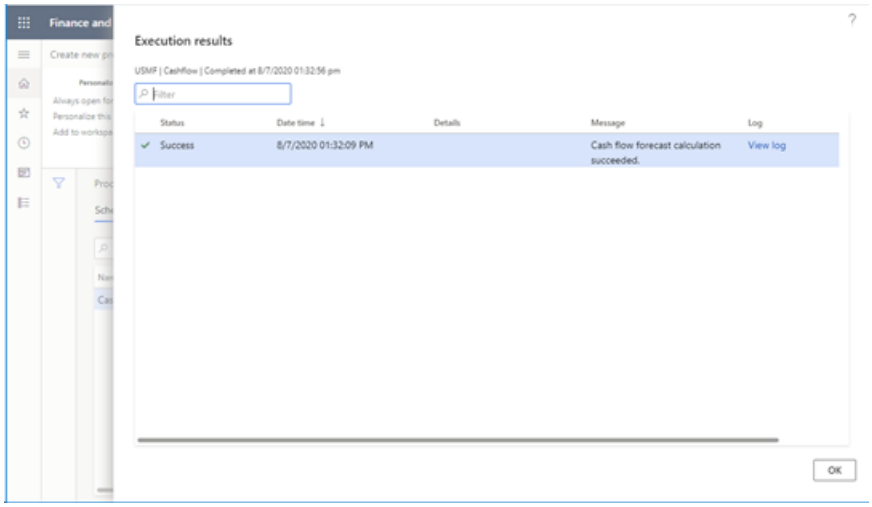
The process automation framework supports logging of results and messages. There are two reasons why a process should log results and messages:

- Results and the message log communicate the state of a process to the system admin or other roles that have access. It's important that process results be monitored and seen by someone. If failures occur, they can be fixed, or an issue can be raised with the process owner.
- Results should communicate what the process did. For example, if the process posts vendor invoices, the results can show all the vendor invoices. In this case, each result will show the status and a link to the vendor invoice.

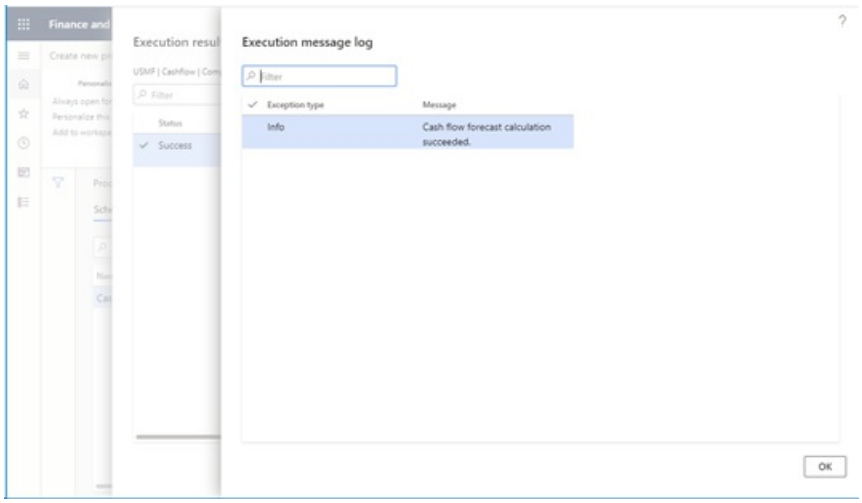
Results and messages are a multilevel logging system. A process has one or more results. Each result has one or more messages that are specific to it. A message is a composition child of the result. A result is typically something that the process is processing. For example, if the process posts vendor invoices, you log each vendor invoice as a result. Then, for each posting of each vendor invoice, you can log multiple messages that are associated with that result. If a vendor invoice is successfully posted, it's OK to leave the message log blank, because the success of the operation should be obvious when users look at the result. If warnings occur, you should write them to the message log, even if posting was successful. These messages provide transparency, so that users can see what each process is doing and what the results are.

Both scheduled processes and polled processes support logging of results and messages. All processes should create a result. At a minimum, the result should communicate the fact that everything was successful. Processes that do work that affects user work and is visible to users should create more detailed results. For the vendor invoice posting example that was used earlier, users might want to see that their invoices have been posted. Results that don't show that information can cause confusion, even if the information is available in other ways.

The following illustration shows the result view.



The following illustration shows the message view. To open this view, select **View log** in the **Log** column in the result view.



ProcessExecutionSourceLink table

The **ProcessExecutionSourceLink** table contains the results that are created while the processing is running. This table contains **RefTableId** and **RefRecId** fields. These fields are links to any source record in Microsoft SQL Server and are typically something that the process is processing. This table also contains **Header** and **Message** fields. The **Header** field will be shown as a column in the result grid. The message can be anything that you want it to be.

For example, if vendor payment proposal is creating a payment journal, the **RefTableId** value is the table ID of the **LedgerJournalTable** table. The **RefRecId** value is the **RecId** value of the **LedgerJournalTable** record that the payment journal created by the running process. In this case, you can set the **Header** field to the journal number. You can even make this value a jump reference, so that users can select the journal number to go directly to the payment journal. You can set the **Message** field to any message that you want to show, such as **Payment journal created successfully**.

If the process is processing many items (for example, if it's posting many invoices), you can create a **ProcessExecutionSourceLink** record for each invoice.

If the number of items that the process is processing is very large (in the millions), and users don't have to see the details of each item, consider summarizing the items into batches. For example, the process for subledger transfer to the general ledger creates a **ProcessExecutionSourceLink** record for each transfer ID that is transferred to the general ledger, not for each voucher that is transferred.

METHOD	DESCRIPTION
`public static void insertSourceLinks(ProcessScheduleTypeName _typeName, ProcessExecutionSourceLinkTmp _tmp)`	This method is new in version 10.0.14. It inserts many results into the **ProcessExecutionSourceLink** table by using set-based insert.
`public static ProcessExecutionSourceLink insertSourceLink(ProcessExecutionSourceLinkItem _sourceLinkItem)`	This method inserts a record into the **ProcessExecutionSourceLink** table.

ProcessExecutionSourceLinkItem class

Instantiate the **ProcessExecutionSourceLinkItem** class, and fill it with values that are required to correctly show your source item.

METHOD	DESCRIPTION
`public static ProcessExecutionSourceLinkItem newFromProcessScheduleWorkItemAndStatus(ProcessScheduleWorkItem _workItem, ProcessExecutionSourceStatus _status)`	Use this constructor to create an instance of **ProcessExecutionSourceLinkItem**. This method correctly initializes many of the required fields from **ProcessScheduleWorkItem**.
`public static ProcessExecutionSourceLinkItem newFromProcessExecutionSourceLink(RefRecId _processExecutionSourceLinkRecId)`	This method constructs an instance of **ProcessExecutionSourceLinkItem** and initializes the instance by using the specified record ID of a **ProcessExecutionSourceLink** record.
`public RefRecId parmSourceRecId(RefRecId _sourceRecId = sourceRecId)`	Set the record ID of the source record. For example, this value might be the record ID of the vendor invoice header table.
`public RefTableId parmSourceTableId(RefTableId _sourceTableId = sourceTableId)`	Set the table ID of the source table. For example, this value might be the table ID of the vendor invoice header table.
`public ProcessExecutionSourceLinkHeader parmHeader(ProcessExecutionSourceLinkHeader _header = header)`	Set the value for the header field. For the vendor invoice posting example that was used earlier, this value might be the invoice number.
`public ProcessExecutionSourceLinkMessage parmMessage(ProcessExecutionSourceLinkMessage _message = message)`	Set the message. For the vendor invoice posting example that was used earlier, this value might be **Posting successful**.
`public ProcessExecutionId parmExecutionId(ProcessExecutionId _executionId = executionId)`	This method sets the execution ID. This value was provided via **ProcessScheduleWorkItem** in the implementation of the **ProcessAutomationTask** interface.

ProcessExecutionMessageLog table

The **ProcessExecutionMessageLog** table contains messages that are related to a single **ProcessExecutionSourceLink** record. You can write any type of message to this table. The message will then be shown to users.

METHOD	DESCRIPTION
`public static void insertMessages(ProcessScheduleTypeName _typeName, ProcessExecutionMessageLogTmp _tmp)`	This method inserts messages into the **ProcessExecutionMessageLog** table by using a set-based insert.
`public static ProcessExecutionMessageLog insertMessage(ProcessExecutionMessageLogItem _errorLogItem)`	This method inserts a message into the message log.

ProcessExecutionMessageLogItem class

The message log stores messages as both strings and label IDs. You don't have to set both values. Label IDs are preferred, because they support translation of messages in the user interface (UI) for the message log. However, the messages are provided for backward compatibility with processes that don't support logging of label IDs.

Use the appropriate constructor for your scenario.

METHOD	DESCRIPTION
`public static ProcessExecutionMessageLogItem newFromProcessExecutionSourceLinkAndMessage(RefRecId _processExecutionSourceLinkRecId, Exception _exception, ProcessExecutionMessage _message)`	
`public static ProcessExecutionMessageLogItem newFromProcessExecutionSourceLinkAndLabel(RefRecId _processExecutionSourceLinkRecId, Exception _exception, LabelId _labelId, container _labelParameters)`	

Customize the user interface

2/18/2021 • 7 minutes to read • Edit Online

The process automation framework supports some customizations of the user interface (UI). Most of this topic is optional, because the framework provides default values for everything. The only exception is the **ProcessScheduleSeries** form. If you intend to show the **ProcessScheduleSeries** form for a specific product area, customizations are required so that the framework can show data that is specific to that product area.

Weekly calendar view

ProcessScheduleIBuildOccurrenceCard interface

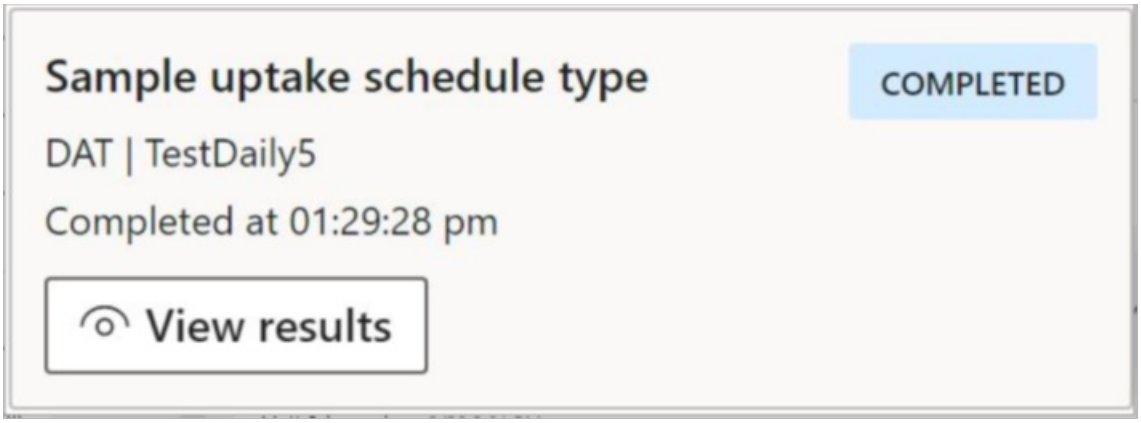
The **ProcessScheduleIBuildOccurrenceCard** interface lets you customize the appearance of occurrence cards in the weekly calendar view. There is a static method on the interface for each status of an occurrence: **Scheduled**, **Waiting**, **Running**, **Successful**, **Failed**, and **Disabled**. You can create a customized occurrence card for each status value. Each of these methods returns an instance of **ProcessScheduleOccurrenceCard**.

The process automation framework provides a default implementation in the **ProcessScheduleOccurrenceCardBuilder** class. You inherit from this class and override the functionality as you require. You then register your derived class via the **SysPlugin** for your specific type. The registration process resembles the process for many of the plug-ins in the framework documentation.

An instance of **ProcessScheduleOccurrenceCardBuilderContract** is passed into each of the methods and can be used to retrieve information about the occurrence. The derived class can invoke the default implementation for each static method that returns the **ProcessScheduleOccurrenceCard** instance, modify whatever is required, and return it.

ProcessScheduleOccurrenceCard class

The **ProcessScheduleOccurrenceCard** class lets you customize the appearance of an occurrence card that is shown in the calendar view. The first two lines are controlled by the process automation framework and can't be modified. In the following illustration, the subheader is the **Completed at** phrase, and the status message is the word **Completed** that has a blue background.



METHOD	DESCRIPTION
`public str parmSubHeader(str _subHeader = cardSubHeader)`	The subheader, which is the third line of the occurrence card that is shown in the previous illustration.

METHOD	DESCRIPTION
`public str parmStatusMessage(str _statusMessage = statusMessage)`	The status message, which represents the status of the process and has a colored background.
`public ProcessExecutionOccurrenceCardStatusColor parmStatusColor(ProcessExecutionOccurrenceCardStatusColor _statusColor = statusColor)`	The color of the background for the status message.

ProcessScheduleIShowOccurrenceCalendarView interface

The **ProcessScheduleIShowOccurrenceCalendarView** interface must be implemented by forms that will show the weekly calendar view. The **ProcessScheduleSeries** form is an example of a form that implements this interface.

METHOD	DESCRIPTION
`ProcessScheduleOccurrenceCalendarViewContract getProcessScheduleOccurrenceCalendarViewContract()`	Return the contract that the weekly view will use to determine which types should be shown.
`void refreshAfterChangeToCalendarView()`	This value is a callback from the weekly view. It indicates that the parent form should be refreshed because of changes in the weekly calendar view.

ProcessScheduleOccurrenceCalendarViewContract class

Use the **ProcessScheduleOccurrenceCalendarViewContract** class to limit the series that the weekly calendar view should show. For an example, see **ProcessScheduleSeries.getProcessScheduleOccurrenceCalendarViewcontract** in the Application Object Tree (AOT).

METHOD	DESCRIPTION
`public static ProcessScheduleOccurrenceCalendarViewContract construct()`	Use this constructor if the intention is to show occurrences for one to many types.
`internal static ProcessScheduleOccurrenceCalendarViewContract newFromScheduleSeries(ProcessScheduleSeries _scheduleSeries)`	Use this constructor if the intention is to show occurrences for a single series.
`public void AddScheduleType(ProcessScheduleTypeName _scheduleTypeName)`	If you aren't showing just one series, use this value to add the types that should be shown.

ProcessScheduleOccurrenceCalendarViewRenderer class

Use the **ProcessScheduleOccurrenceCalendarViewRenderer** class to render the weekly calendar view in an existing form. A form part will be created and correctly initialized. An example of this class is used in the **ProcessScheduleSeries** form.

METHOD	DESCRIPTION
`public static ProcessScheduleICalendarView renderCalendarViewInFormControl(FormGroupControl _containingGroupControl)`	This method renders the weekly calendar view in the specified form group control.

Render interfaces

Several interfaces enable customization of the way that occurrence processes are rendered in the calendar view.

There is one interface for each status that a process can have:

- ProcessScheduleIRenderDisabledOccurrenceCard
- ProcessScheduleIRenderFailedOccurrenceCard
- ProcessScheduleIRenderRunningOccurrenceCard
- ProcessScheduleIRenderScheduledOccurrenceCard
- ProcessScheduleIRenderSuccessfulOccurrenceCard
- ProcessScheduleIRenderWaitingOccurrenceCard

All these interfaces follow the same pattern. An instance of **ProcessScheduleOccurrenceCardRendering** is sent to them. That instance is used to control how the occurrence card is rendered.

For an example, see the **CustVendPaymProposalAutomationOccurrenceCardRenderer** class in the AOT.

ProcessScheduleOccurrenceCardRendering class

METHOD	DESCRIPTION
`public ProcessScheduleOccurrence getOccurrenceBeingRendered()`	This method returns the occurrence that is being rendered on the occurrence card.
`public ProcessExecutionExecutingInformation getOccurrenceExecutionInformation()`	This method returns the running information for the occurrence. This information typically includes the results of the batch job, the start time, and the end time.
`public void makeCardSubHeaderInvisible()`	This method makes the card's subheader invisible. See the illustration earlier in this topic and the content below it to determine which line is the subheader.
`public void makeCardButtonsInvisible()`	This method specifies whether the **Disable** and **Edit** buttons on the occurrence card are invisible.
`public void setColumnsOnOccurrenceCardDetailGroup(int _numberOfColumns)`	This method enables the number of columns on the occurrence card to be customized. By default, there are two columns.
`public FormButtonControl addButtonControl(FormControlName _buttonControlName)`	This method enables a new button to be added to the occurrence card.
`public FormStaticTextControl addStaticTextControl(FormControlName _staticTextControlName)`	This method enables a static text control to be added to the occurrence card.
`public FormStringControl addStringControl(FormControlName _stringControlName, LabelId _stringControlLabel)`	This method adds a string control to the occurrence card.

Series list page

ProcessScheduleISeriesFormController interface

The **Series** list page uses the **ProcessScheduleISeriesFormController** controller to determine which types series will be shown for on the **ProcessScheduleSeries** list page. This class uses the **SysPlugIn** class. The menu item that you use to open the **ProcessScheduleSeries** form is used as the key to invoke the specified plug-in. This key enables each use of this form to customize which types are shown.

```
// Implementation of the ProcessScheduleISeriesFormController for the admin view of the process schedule
Series form.
// This implementation will show series for all process types, both scheduled and polled, on the Series
form.
[Export(identifierStr(Dynamics.AX.Application.ProcessScheduleISeriesFormController))]
[ExportMetadata(classStr(ProcessScheduleISeriesFormController),
menuItemDisplayStr(ProcessScheduleSeriesAdmin))]
internal class ProcessScheduleSeriesFormAdminController implements ProcessScheduleISeriesFormController
{
    [Hookable(false)]
    public ProcessScheduleSeriesFormContract getSeriesFormContract()
    {
        return ProcessScheduleSeriesFormContract::newForAllScheduleTypes();
    }
}
```

ProcessScheduleSeriesFormContract class

The **ProcessScheduleSeriesFormContract** class is a contract that the series list page uses to determine which **ProcessScheduleType** is shown on it. This class can be used in a workspace to show series only for specific types that are related to that workspace.

METHOD	DESCRIPTION
`public void addScheduledScheduleType(ProcessScheduleTypeName _scheduleTypeName)`	Add a specific scheduled type.
`public void addPolledScheduleType(ProcessScheduleTypeName _scheduleTypeName)`	Add a specific polled type.

Results and messages

ProcessExecutionIResultsController interface

The **ProcessExecutionIResultsController** interface lets you customize the results dialog box according to your process. It lets you set the column header label for the **Header** field in the results grid and make the value in the header column a hyperlink. This interface should be implemented by a class that is a plug-in. Here is a sample plug-in.

```
using System.ComponentModel.Composition;

[Export(identifierStr(Dynamics.AX.Application.ProcessExecutionIResultsController))]
[ExportMetadata(classStr(ProcessExecutionIResultsController), 'TestScheduledType')]
public final class ProcessExecutionSampleUptakeExecutionResultsController implements
ProcessExecutionIResultsController
{
    [Hookable(false)]
    public ProcessExecutionResultsDialogContract getResultsDialogContract()
    {
        ProcessExecutionResultsDialogContract contract = ProcessExecutionResultsDialogContract::construct();
        contract.parmSourceLinkHeaderLabel('Sample Header');
        contract.parmShouldSourceLinkHeaderBeLinkToSourceLinkDetails(true);
        return contract;
    }

    [Hookable(false)]
    public void openSourceLinkDetails(RefTableId _refTableId, RefRecId
    _refRecId)
    {
        if (_refTableId == tableNum(SystemParameters))
        {
            Args args = new Args();
            MenuFunction systemParametersMenuFunction = new
MenuFunction(menuItemDisplayStr(SystemParameters), MenuItemType::Display);
            systemParametersMenuFunction.run(args);
        }
    }
}
```

METHOD	DESCRIPTION
`ProcessExecutionResultsDialogContract getResultsDialogContract()`	Return an instance of **ProcessExecutionResultsDialogContract**.
`void openSourceLinkDetails(RefTableId _refTableId, RefRecId _refRecId)`	Implement the logic to open the appropriate menu item that can show the record that is passed in.

ProcessExecutionResultsDialogContract class

The **ProcessExecutionResultsDialogContract** class lets you customize the header column label and specify whether the data in the header column should be rendered as a hyperlink.

METHOD	DESCRIPTION
`public static ProcessExecutionResultsDialogContract newForSourceLinkHeader(LabelId _sourceLinkHeaderLabel, boolean _shouldSourceLinkHeaderBeLinkToSourceLinkDetails)`	Provide the text that should be used as a header column label. Also provide a Boolean value that indicates whether the value in the header column should be rendered as a hyperlink.
`public LabelId parmExecutionResultsDialogCaption(LabelId _executionResultsDialogCaption = executionResultsDialogCaption)`	This method sets the caption for the results dialog box.

ProcessExecutionMessageLogDialog class

The **ProcessExecutionMessageLogDialog** interface enables the message log to be opened in the context of something from the source domain. For example, the message log can be opened from the page for a posted vendor invoice to show the messages that were logged while the vendor invoice was being posted by a process that is enabled for the process automation framework. For this example, the posted vendor invoice page must

implement the **ProcessExecutionMessageLogDialog** interface. By using this interface, you don't have to build your own private results/messaging subsystems.

METHOD	DESCRIPTION
`ProcessExecutionMessageLogContract getContractForMessageLog()`	This method returns an instance of **ProcessExecutionMessageLogContract**.

ProcessExecutionMessageLogContract class

The **ProcessExecutionMessageLogContract** contract lets you limit the message log to a specific item from the source domain. In the **ProcessExecutionSourceLink** table, there must be a record where the **RefRecId** and **RefTableId** values match the values that the contract sends.

METHOD	DESCRIPTION
`public static ProcessExecutionMessageLogContract newForSourceRecord(ProcessScheduleTypeName _typeName, RefTableId _refTableId, RefRecId _refRecId, guid _executionId = emptyGuid())`	This method initializes the contract by using the specified type name, **RefTableId** value, and **RefRecId** value. There should be a matching record in the **ProcessExecutionSourceLink** table. Background processes will have multiple execution IDs. Therefore, the optional parameter for the execution ID should be provided for background processes. For more information, see Type registration.

Regression Suite Automation Tool

2/18/2021 • 5 minutes to read • Edit Online

The Regression suite automation tool (RSAT) significantly reduces the time and cost of user acceptance testing (UAT) of Finance and Operations apps. UAT is typically required before you take a Microsoft application update, or before you apply custom code and configurations to your production environment. RSAT lets functional power users record business tasks by using Task recorder and then convert the recordings into a suite of automated tests, without having to write source code. For more information about Task recorder, see Task recorder resources.

RSAT is fully integrated with Microsoft Azure DevOps for test execution, reporting, and investigation. Test parameters are decoupled from test steps and stored in Microsoft Excel files.

RSAT usage is described in these topics:

- Regression Suite Automation Tool (this topic)
- Regression Suite Automation Tool installation and configuration
- Run Regression Suite Automation Tool test cases
- Validate expected values
- Chain test cases
- Derived test cases
- Regression Suite Automation Tool best practices
- Troubleshoot the Regression Suite Automation Tool

Getting started videos

These videos will help introduce RSAT and get you started.

Use task recorder to create a test case for RSAT

The How to use task recorder to create a test case for the Regression suite automation tool (RSAT) video (shown above) is included in the Finance and Operations playlist available on YouTube.

Create a test plan in Azure DevOps to use with RSAT

The How to create a test plan in Azure DevOps to use with the Regression suite automation tool (RSAT) video (shown above) is included in the Finance and Operations playlist available on YouTube.

How to use RSAT

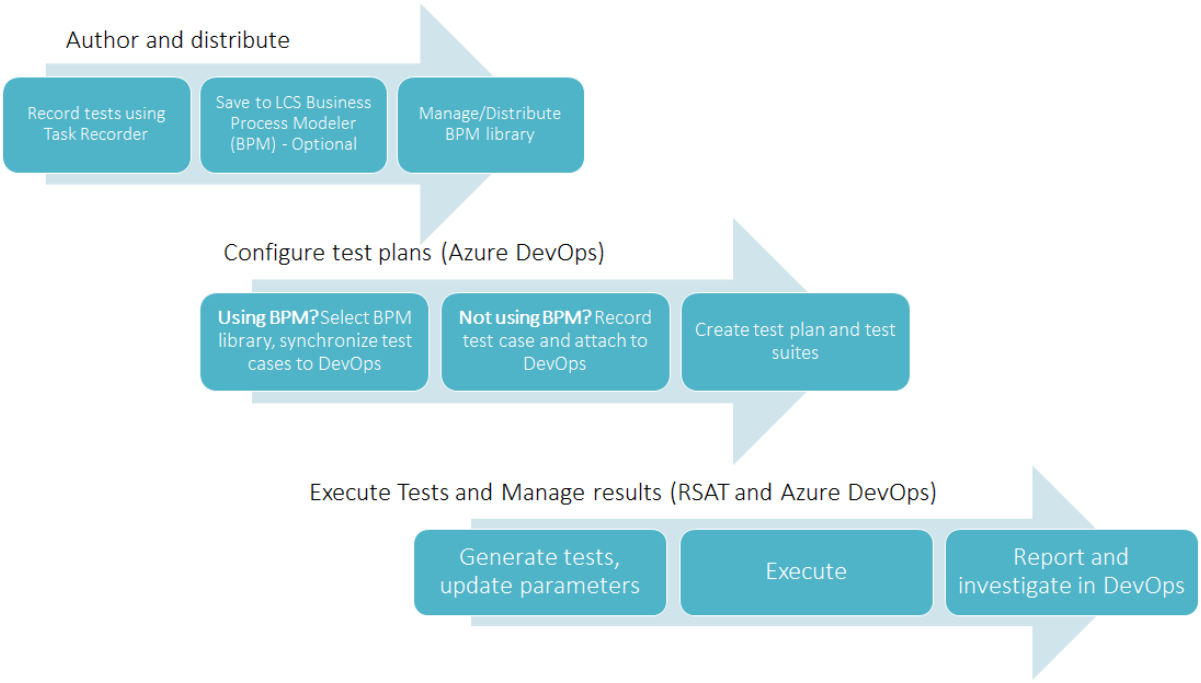
The How to use the Regression suite automation tool (RSAT) video (shown above) is included in the Finance and Operations playlist available on YouTube.

The improved Excel experience in RSAT 2.0

The Improved Excel experience in RSAT 2.0 video (shown above) is included in the Finance and Operations playlist available on YouTube.

End-to-end flow

RSAT is part of the end to end flow described below. RSAT, Microsoft Dynamics Lifecycle Services (LCS), and Azure DevOps provide a set of tools for test case authoring (using Task recorder), distribution, configuration, execution, investigation, and reporting.

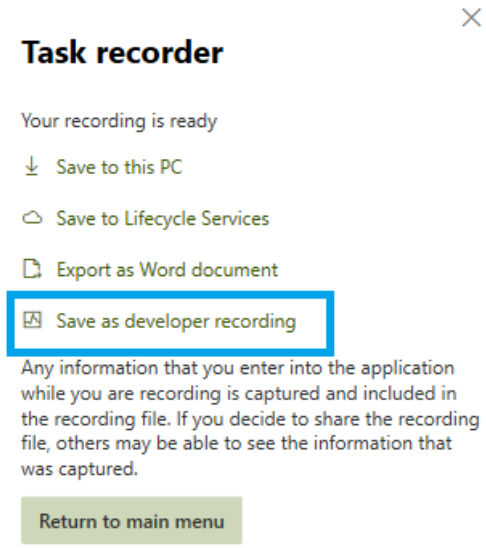


To learn more about this this process, see Create and automate user acceptance tests.

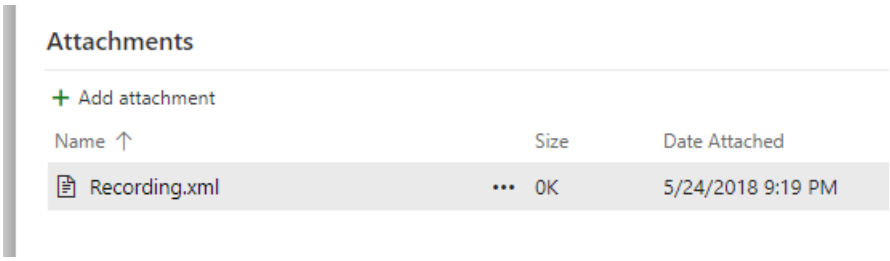
LCS, BPM, and Task Recordings

You aren't required to use the Business process modeler (BPM) tool in LCS. BPM is recommended if you want to enable the management and distribution of test libraries across projects and tenants. These capabilities are especially useful for Microsoft partners and independent software vendors (ISVs). BPM enables the distribution of test libraries as part of LCS solutions.

If you are not using BPM, you can manually create test cases in Azure DevOps and attach developer recording files to your Azure DevOps test cases. You can create developer recording files directly from the Task recorder pane.



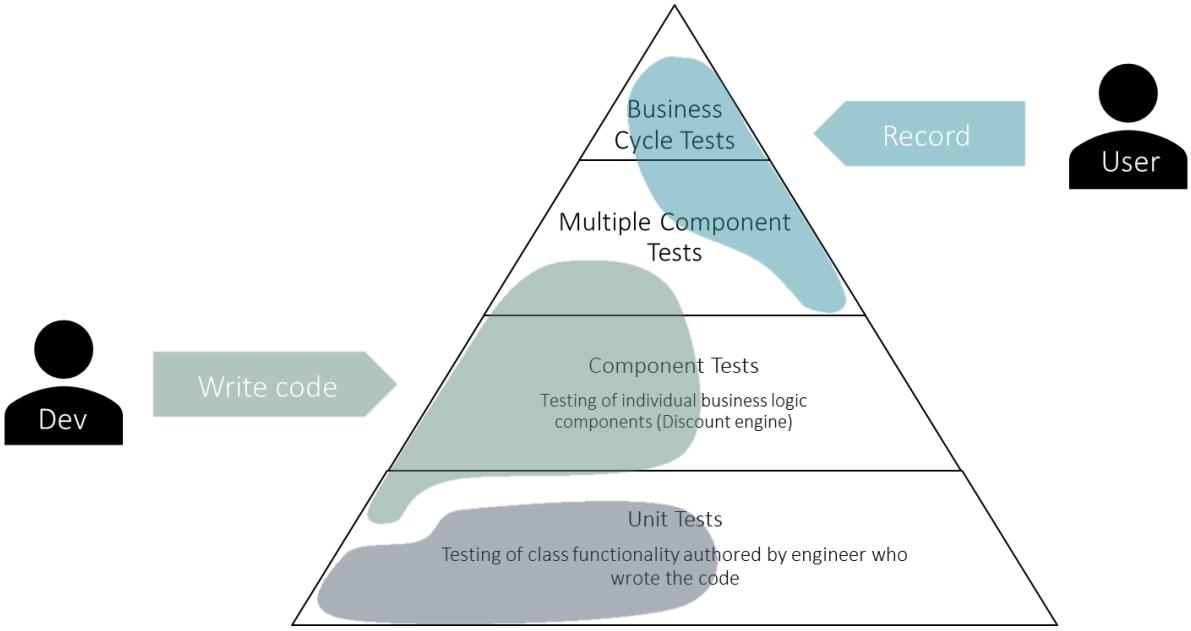
You must name the developer recording file **Recording.xml** before attaching it to the Azure DevOps test case. Alternatively, you can name the recording file **-Test Case Title-.xml**, where **-Test Case Title-** is the DevOps title of the test case.



Intended usage and test classification

Business cycle (business process) testing

The Regression suite automation tool is intended to be used for business cycle tests and scenario tests (multiple component tests) that usually occur at the end of the development lifecycle. This is also referred to as *user acceptance testing*. Business cycle testing consists of a smaller number of test cases than component or unit testing. This is illustrated in the following graphic.



Cloud POS

In addition to testing processes recorded using the Finance and Operations Task recorder, RSAT also supports testing of Cloud POS processes in Dynamics 365 Commerce. For more information about RSAT with Cloud POS, see Test recorder and Regression suite automation tool for Cloud POS.

Warehouse mobile app

You can use RSAT in combination with the Warehouse App Task Validation Framework to automate the testing of warehouse processes. This Tech Talk is a good reference to get started.

Unit and component testing

For unit tests, we do not recommend that you use RSAT. Instead, use the SysTest framework and the build/test automation tools. For component tests, take advantage of the Acceptance test library resources (ATL). ATL is a library of X++ test helpers. When used with the SysTest framework, it offers the following benefits:

- Lets you create consistent test data.
- Increases the readability of test code.
- Provides improved discoverability of the methods that are used to create test data.
- Hides the complexity of setting up prerequisites.
- Supports high performance of test cases.

For more details, see Continuous delivery home page.

Data integration testing

Do not use RSAT for integration tests, instead rely on the data management framework (also known as DIXF). The Data task automation framework enables you to configure and automate the testing of your data integration scenarios.

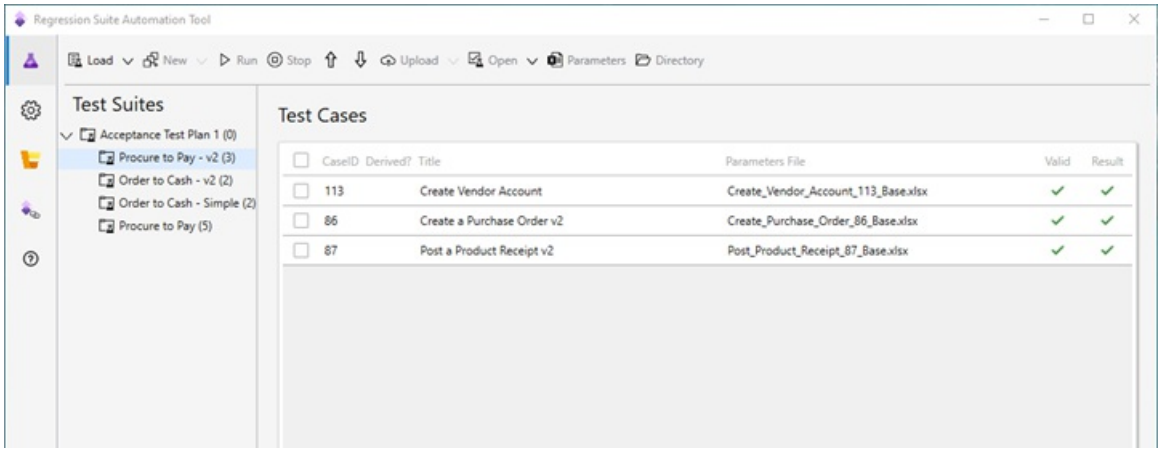
RSAT User interface overview

RSAT 2.1 introduced a modern user interface that simplifies navigation through the main components of the app, including a **Quick links** tab, and quick navigation to DevOps test suites and test runs.

Use the left navigation pane to navigate between the test plan, settings, Cloud POS settings and the quick links page.

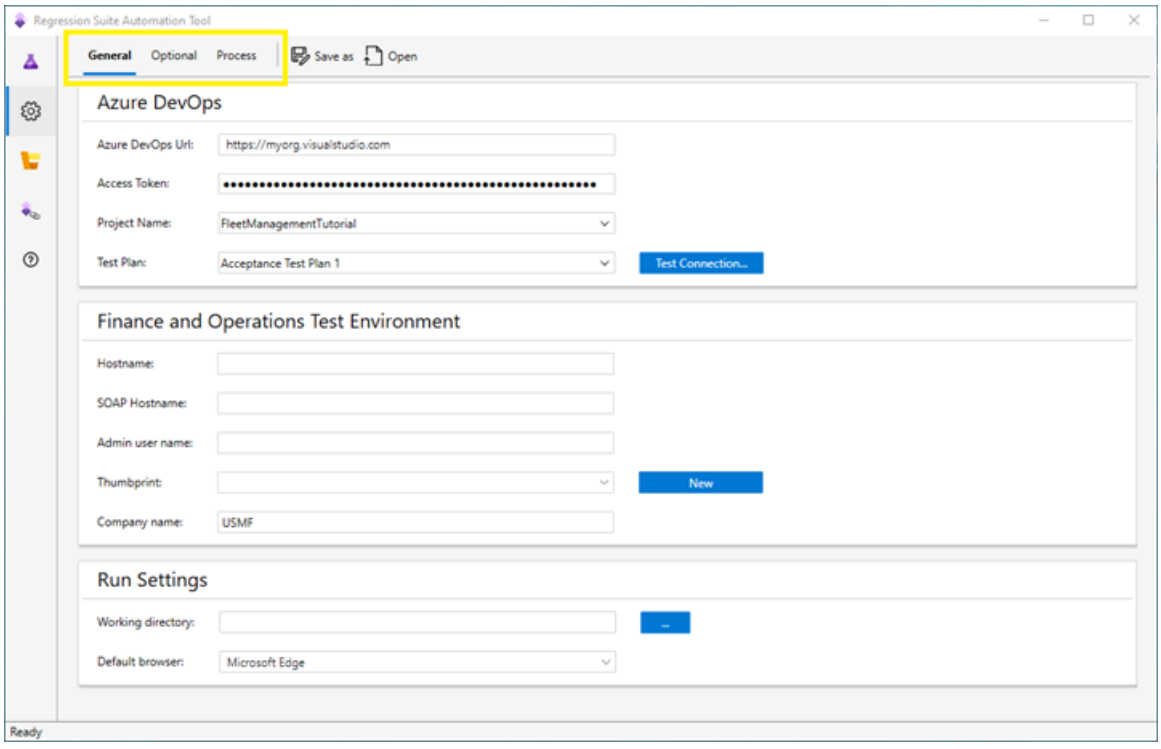
Test Plan

The **Test plan** tab is the main tab that allows you to interact with and execute test cases.



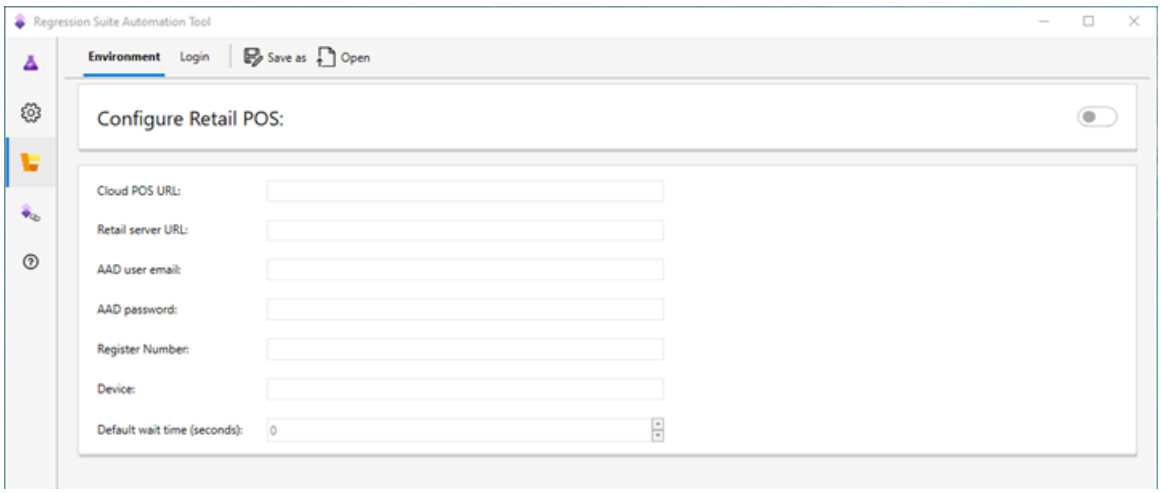
Settings

Select the **Settings** tab to configure RSAT settings. Use the top bar to navigate between general, optional and process settings. You do not need to save your settings, settings are automatically saved as soon as you navigate out of the settings page. You can also save your settings in an RSAT settings file or open an existing settings file.



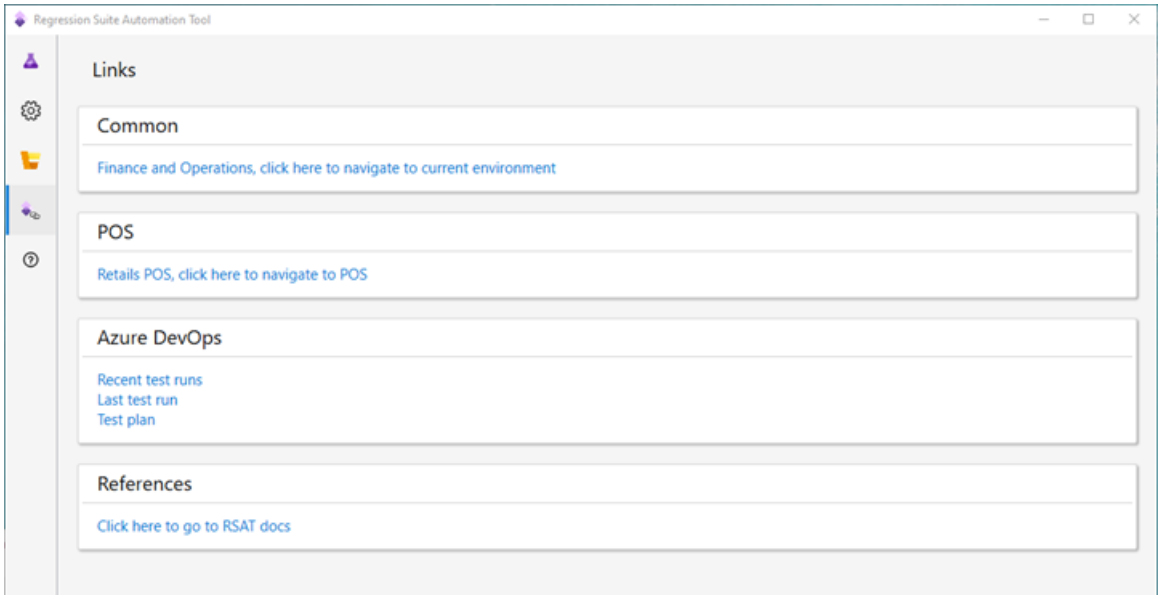
Cloud POS Settings

Select the **Cloud POS Settings** tab to configure RSAT to execute Cloud POS test cases. You do not need to save your settings, settings will automatically be saved as soon as you navigate out of the settings page.



Useful links

The **Links** tab provides new functionality. Select the **Links** tab to quickly navigate to your Finance and Operations environment, Cloud POS, or go to useful Azure DevOps pages showing recent test runs, the last test run, and current test plan. There is also a link to the RSAT docs page.

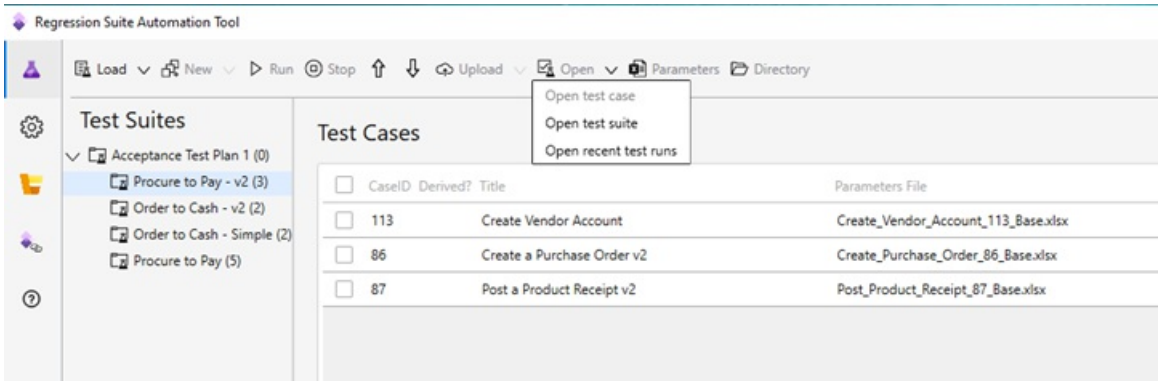


Quick navigation to Azure DevOps

When working with your test plan, the **Open** button now provides 3 options.

- Open the selected test case in Azure DevOps.
- Open the selected test suite.
- Open the recent test runs.

This tab provides quick access to the most relevant pages in Azure DevOps.



NOTE

Can you tell us about your documentation language preferences? Take a short survey.

The survey will take about seven minutes. No personal data is collected (privacy statement).

Regression Suite Automation Tool installation and configuration

2/18/2021 • 10 minutes to read • Edit Online

This topic contains information about how to install and configure the Regression suite automation tool (RSAT).

Prerequisites

Test environment (Prerequisite)

Your test environment must be running Platform update 15 or newer. The Regression suite automation tool must have access to your test environment via a web browser.

Excel

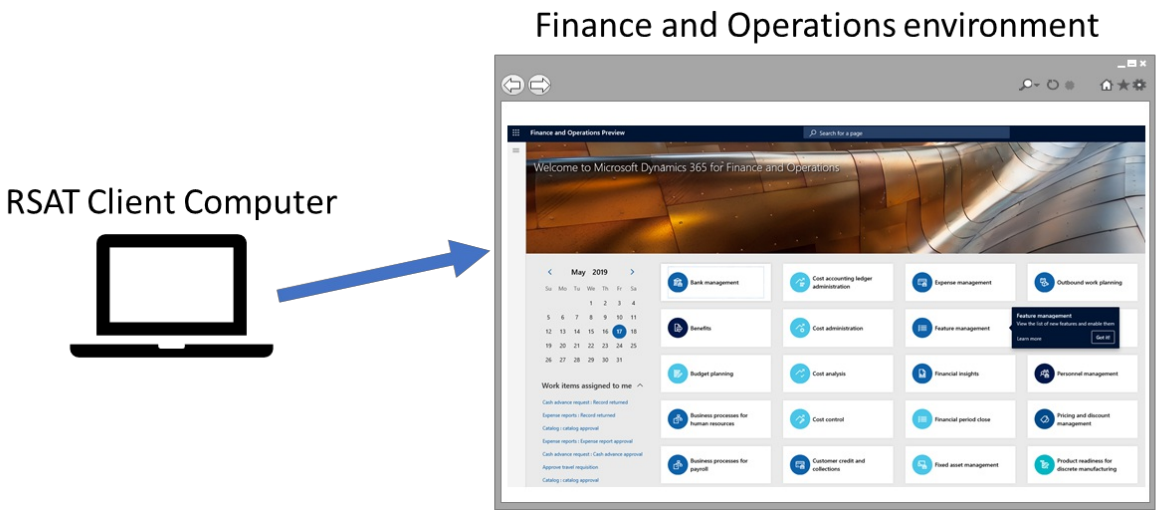
You need Microsoft Excel installed to generate and edit test parameters.

Azure DevOps (Prerequisite)

You must have an Azure DevOps project to store and manage your test cases, test plans, and test case results. You will need an Azure DevOps Test Manager or Test Plans license. For example, if you have a Visual Studio Enterprise subscription, you already have a license to Test Plans. For more information, see Pricing for Azure DevOps Services or Pricing for Azure DevOps Server.

Authentication Certificate

RSAT is designed to be installed on any Windows 10 computer and connect remotely via a web browser to an environment.



To enable secure authentication, RSAT requires a certificate to be installed on the RSAT client computer. The RSAT settings dialog box allows you to automatically create and install the authentication certificate. You will also need to configure the virtual machine (VM) to trust the connection. Follow the instructions in the next sections to install and configure RSAT.

Installation

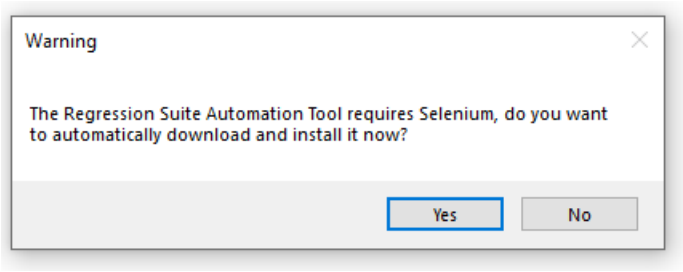
Installer

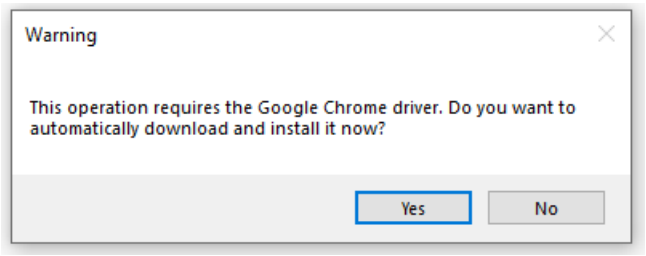
Download the .msi file from the Regression Suite Automation Tool Download to your machine and double-click it to run the installer.

> **NOTE**
>
> If you're using Azure DevOps Server, download and install version 1.210.48249.4 or later.

Selenium and Browser Drivers

RSAT requires Selenium and web browser driver libraries. RSAT will prompt you if needed libraries are missing and will automatically install them for you. Select Yes when you see the following (or similar) messages.



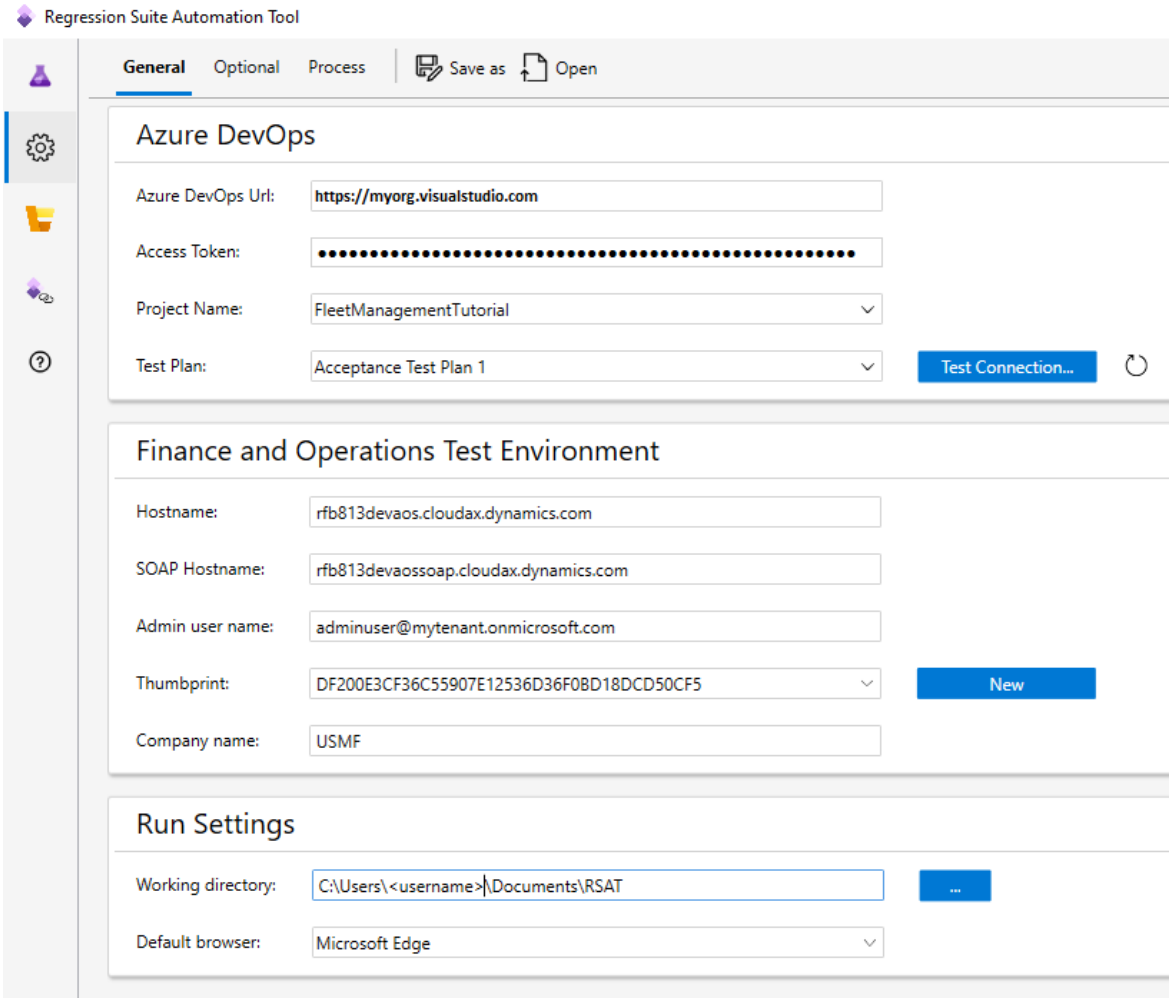


RSAT uses Selenium 3.13.1. The Webdriver library and browser-specific drivers are downloaded to **C:\Program Files (x86)\Regression Suite Automation Tool\Common\External\Selenium**.

Configuration

1. Open RSAT from your desktop.

2. Select the **Settings** tab on the upper left to configure RSAT.



General settings

These settings are required.

Azure DevOps (General settings)

Configure your connection to the Azure DevOps project and test plan.

- **Azure DevOps URL** - This is the URL of your Azure DevOps organization. For example, `https://yourAzureDevOpsUrlHere.visualStudio.com`.

  > **NOTE**
  > If you're using Azure DevOps Server, add **/DefaultCollection** to the end of your Azure DevOps URL.

- **Access Token** - The access token that allows the tool to connect to Azure DevOps. You need to create a personal access token or use an existing one that you have saved. For more information, see Authenticate access with personal access tokens.
- **Project Name** - The name of your Azure DevOps project. RSAT will automatically detect project names and test plans available based the Azure DevOps URL specified. You can then select the Test Project and Test Plan.
- **Test Plan** - The Azure DevOps test plan that contains your test cases. For more information, see Create test plans and test suites.

Select **Test Connection** to test your connection to Azure DevOps.

Test environment (General settings)

Configure your connection to the test environment.

- **Hostname** – The hostname of the test environment, such as myhost.cloudax.dynamics.com. Don't include the https:// or http:// prefix.
- **SOAP Hostname** – The SOAP hostname of the test environment.
  - For demo and development environments (also known as one-box environments), add a **soap** suffix to the hostname. For example, if your hostname is `myhost.cloudax.dynamics.com`, use `myhost.soap.cloudax.dynamics.com` as the SOAP hostname.
  - If you don't know the SOAP hostname of your test environment, you can find it in the web.config file for the AOS server in Infrastructure.SoapServicesUrl.
  - If your test environment is a user acceptance testing (UAT) or higher-tier sandbox environment that has no Remote Desktop access, the SOAP hostname is equal to the hostname.
- **Admin User Name** – The email address of an admin user in the test environment. The admin user name must be the email address of a user who belongs to the System Administrator role on the Finance and Operations test environment that RSAT is connecting to. The user account (email address) must also belong to the same tenant as the test environment. For example, if your test environment's default tenant is contoso.com, the admin user must end with @constoso.com.
- **Thumbprint** – The thumbprint of the authentication certificate that you're using. If you don't have Remote Desktop Protocol (RDP) access to your environment, follow the steps lower in this article to download the certificate from Lifecycle Services and paste the thumbprint here. Otherwise, if you do have RDP access to the environment, follow these steps to generate a self-signed certificate.
  1. Select **New** to create and install a new authentication certificate. When prompted, place the .cer file somewhere so you have it saved for your records.
  2. When the process completes, the new certification is installed in the local machine's trusted root store.

     
  3. The thumbprint of the newly created certificate is automatically inserted on this form. Copy this thumbprint, you will use it in the next section to configure the AOS to trust the connection.
- **Company name** – Specify a company name to use as your default company during creation of Excel parameters files. It can be changed later by editing an Excel file.

Run setting

Configure your local settings.

- **Working directory** - Folder location for storing test automation files, including Excel test data files. For example: **C:\Temp\RegressionTool**.
- **Default browser** - Select the browser to use for test execution. RSAT supports (the new) Microsoft Edge, Microsoft Internet Explorer, and Google Chrome. We recommend Microsoft Edge, which you can download from Introducing the new Microsoft Edge.

Select **Ok** to apply your settings and close the dialog box. Select **Cancel** to cancel your changes and close the dialog. The **Save As** and **Open** buttons allow you to save your settings for reuse later. Select **Save As** to save your current settings into a configuration file on your computer. Select **Open** to restore your settings from a configuration file.

Optional settings

Select the **Optional** tab to configure optional settings.

- **Test Run Prefix** – RSAT reports test run results to Azure DevOps. Test runs are named using the following convention: **<Run ID> <Prefix> <Test Suite>**. Use this setting to set the **<Prefix>**.
- **Test Run Timeout** – The time-out (in minutes) of a test run. All active windows are closed and pending test cases fail when this time-out is reached.
- **Test Action Timeout** – The time-out (in minutes) of individual test steps. When a test step times out, the test case fails.
- **Pause between steps** – The number of seconds to pause between test steps during automated execution of a test case. The default value is **0** (zero). Set this value to force a pause during test execution, for auditing or investigative purposes. You can also specify a pause for an individual test case by changing the **Pause between steps (Seconds)** parameter on the **General** tab of the Excel parameter file for the test case.
- **Fail test on first validation error** – By default, if a test case has multiple validation steps, and there is a validation failure, the test case stops running when the first failure occurs. The test case is then marked as failed. If you want test cases to continue to run until all validations are completed, clear this option. The test case can then evaluate all validations.
- **Fail test on Infolog error** - Check this option to force test cases to fail when an error is encountered in the Finance and Operations Infolog during test case execution.
- **Abort test suite execution on failure** – By default, a test suite run continues even if one of the test cases fails. If you check this setting, the test run is aborted if a test case fails. All the remaining test cases will have a status of **Not Executed**.
- **Enable local file validation rules** - Check this setting to validate whether your test cases are ready for execution. See Validate readiness of test automation files for more details.
- **Enable upload to Azure DevOps** - To prevent accidental upload to Azure DevOps (therefore overriding project-wide recordings and automation files), you can uncheck this setting. This is especially useful when RSAT is deployed on a client machine for execution purposes only, and you want to prevent users from making permanent changes to the test cases.
- **Cloud provider** – Select the provider of the cloud tenant of your test environment. Supported providers are **Global** (Public cloud) and **China** (Sovereign cloud).

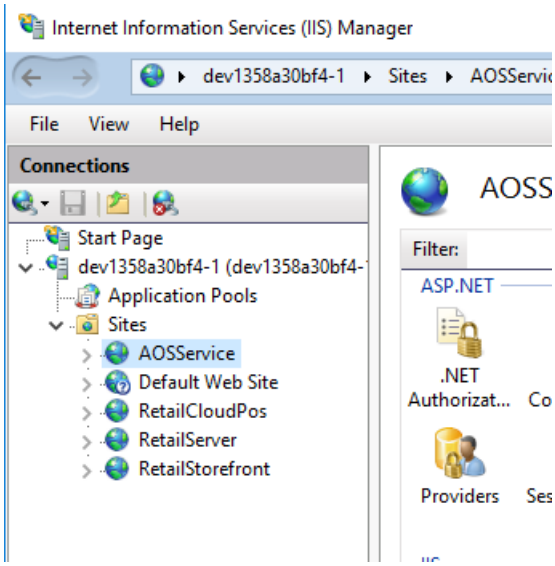
> **IMPORTANT**
> The **Cloud provider** setting is required, and the selected value must be **China** if your Finance and Operations apps were deployed in 21Vianet.

Configure the test environment to trust the connection

If your AOS allows for Remote Desktop connections

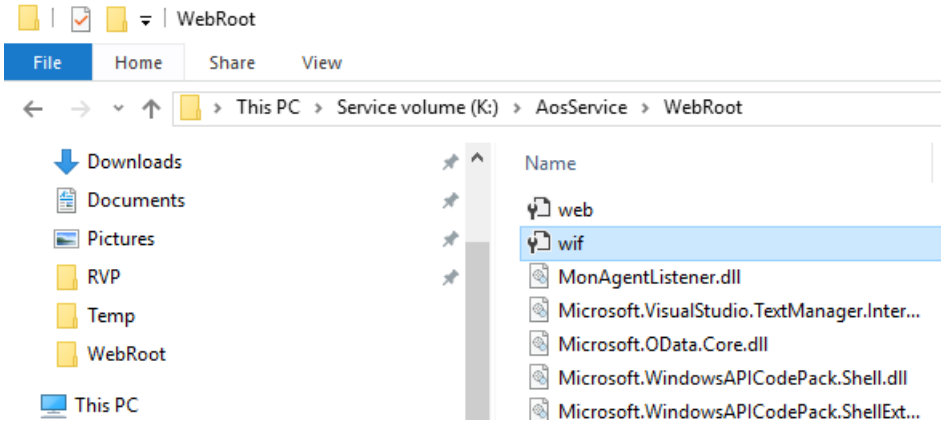
After creating the certificate, configure AOS to trust the test automation connection. On a multi-AOS environment, repeat the following steps for all AOS machines.

1. Open a Remote Desktop connection to the AOS machine.
2. Open IIS and find AOSService in the list of sites.



3. Right-click **AOSService**, then select **Explore**.

4. Open and find the file **wif.config**.



5. Update the **wif.config** file by adding a new authority entry, as shown in the following example. Use **127.0.0.1** for the authority name and paste your certificate thumbprint.

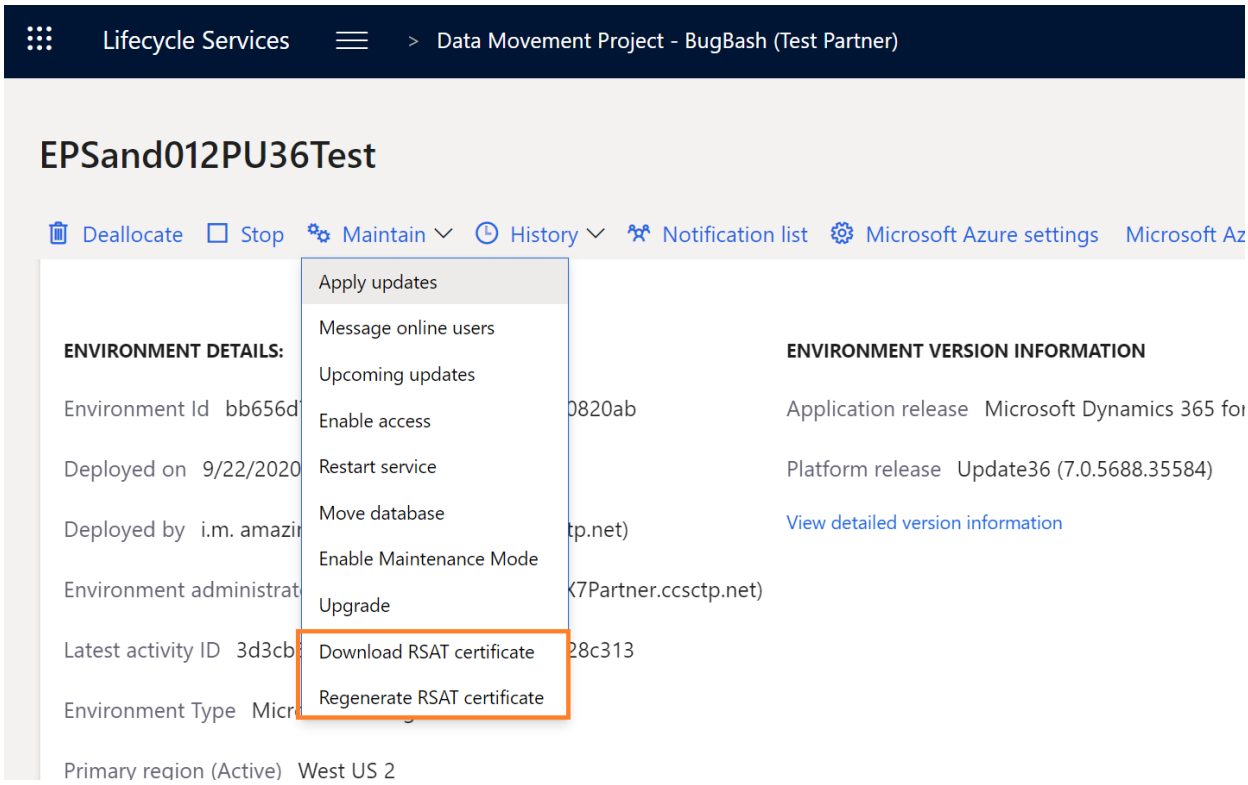
```
<issuerNameRegistry type="Microsoft.Dynamics.AX.Security.SharedUtility.AxIssuerNameRegistry,
Microsoft.Dynamics.AX.Security.SharedUtility">
    <authority name="CN=127.0.0.1">
        <keys>
            <add thumbprint="ccbc124d0a119xxxxxxxxxxxxxxxxxxxx841e797" />
        </keys>
            <validIssuers>
                <add name="CN=127.0.0.1" />
            </validIssuers>
    </authority>
```

If you have no Remote Desktop access to the server

In cases where your Remote Desktop Protocol (RDP) access is removed, such as Microsoft-managed or self-service type sandboxes, Microsoft will generate the certificate for your environment and have it pre-configured. Follow these steps to retrieve the RSAT certificate and use it.

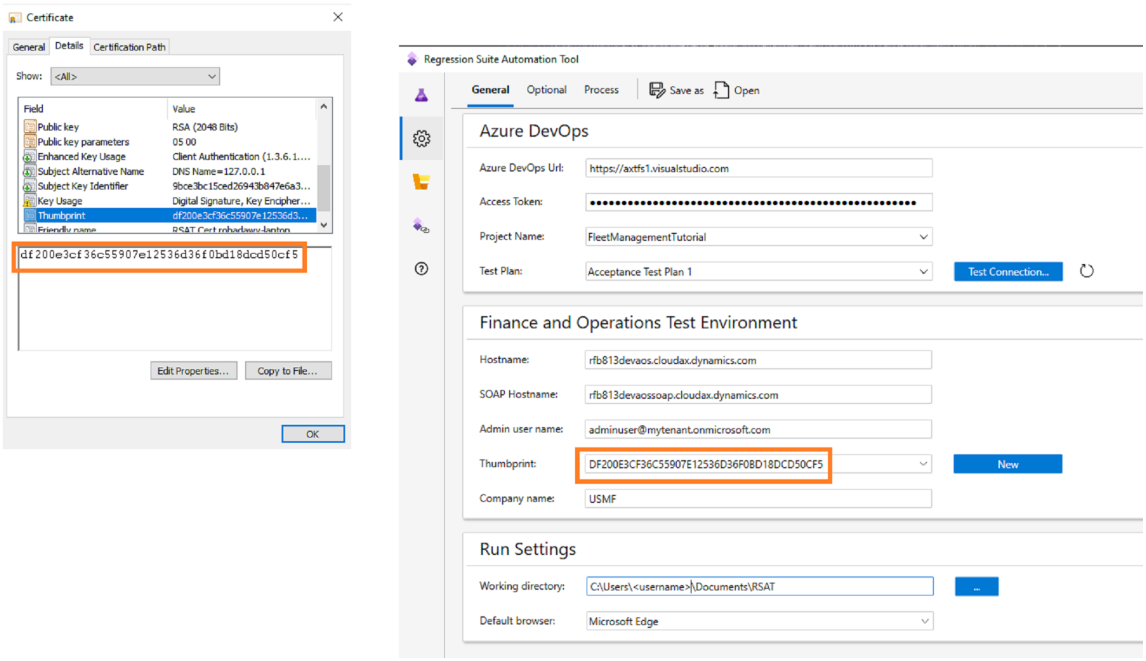
1. Under **Maintain** on your environment details page in Lifecycle Services you'll see two new options.

   - Download RSAT certificate
   - Regenerate RSAT certificate



Use the **Download** button to retrieve the certificate bundle as a .zip file.

2. You'll receive a warning that a clear-text password will be displayed on your screen. You will need the password in subsequent steps. Select **Yes** to continue.
3. Copy the clear-text password for later use. You'll see the .zip file has been downloaded. Inside the .zip file is a certificate (.cer) and a personal information exchange (.pfx) file. Unzip the file.
4. Install the certificate in the local machine's trusted root store:
   - Double-click the certificate (.cer) to open it, and then select **Install Certificate**.
   - Select **local machine**, and then browse to the **Trusted Root Certification Authorities** store to install it in the trusted root store.
5. Install the pfx file in the local machine's personal store:
   - Double-click the personal information exchange (.pfx) file to open it, and select **Local Machine**.
   - Enter the password saved in step 2, and browse to the **Personal** store.
6. Double-click the certificate file to open it. Browse to the **Details** tab, and scroll down until you see the **Thumbprint** section. Select **Thumbprint**, and note the ID in the text box. Select or paste this thumbprint in RSAT settings.



You can now run your tests against the environment using this certificate. The certificate will be autorotated by Microsoft before it expires, at which time you will need to download a new version of this certificate starting from step 1 above. For self-service environments, this will be rotated every 90 days during a downtime window that is closest to the expiry. These downtime windows include customer initiated package deployment, and database movement operations that target the environment.

Manual configuration of authentication certificates

Optionally, you can manually configure the RSAT authentication certificate.

If you are not familiar with this process, get help from your system administrator. Make sure you have Windows Kits installed on your machine. If you do not have Windows Kits installed on your machine, you can download the Windows 10 SDK from Windows 10 SDK. You will need these components for the steps described in this document.

- Windows SDK Signing Tools for Desktop Apps
- Windows SDK for UWP-Managed Apps.

Generate the certificate

You must generate the certificate file on the RSAT client computer. **The certificate must be generated on the same computer that the test tool is running on.** To generate the certificate file, follow these steps:

1. Create the **C:\Temp** folder if it does not already exist on your computer.
2. Open a command-line window as Administrator.
3. Go to the folder where you installed the Windows SDK. Your exact folder may be different, depending on where you have installed the windows SDK). You can also use Windows Kits 8.1.

```
cd c:\Program Files (x86)\Windows Kits\10\bin\10.0.17763.0\x64
```

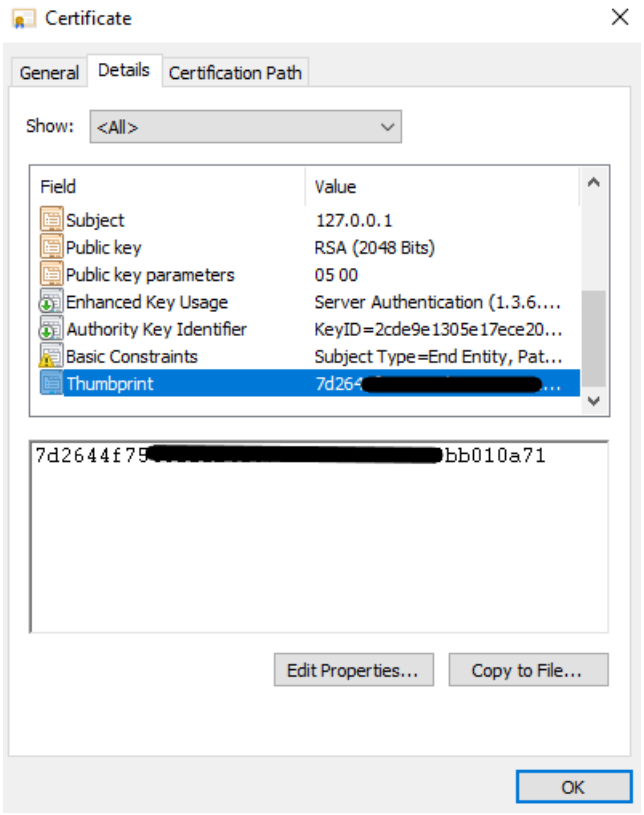
4. Run the following command. When you are prompted to enter a private key password, enter **None**.

```
makecert.exe -n "CN=127.0.0.1" -ss My -sr LocalMachine -a sha256 -len 2048 -cy end -r -eku
1.3.6.1.5.5.7.3.1 c:\temp\authCert.cer
```

Install the certificate to the Trusted Root

To install the certificate, follow these steps:

1. Double-click **authCert.cer** to install the certificate.
2. Select **Install Certificate**.
3. Select **Local Machine** > **Place all certificates in the following Store** > **Browse** > **Trusted Root Certification Authorities** and select **Next** through each screen.
4. Leave the **Password** field blank.
5. In the **Certificate** dialog box, browse to **Details** and look for **Thumbprint**.



6. Copy and save the thumbprint. You will need it to configure the AOS as described earlier in this topic.

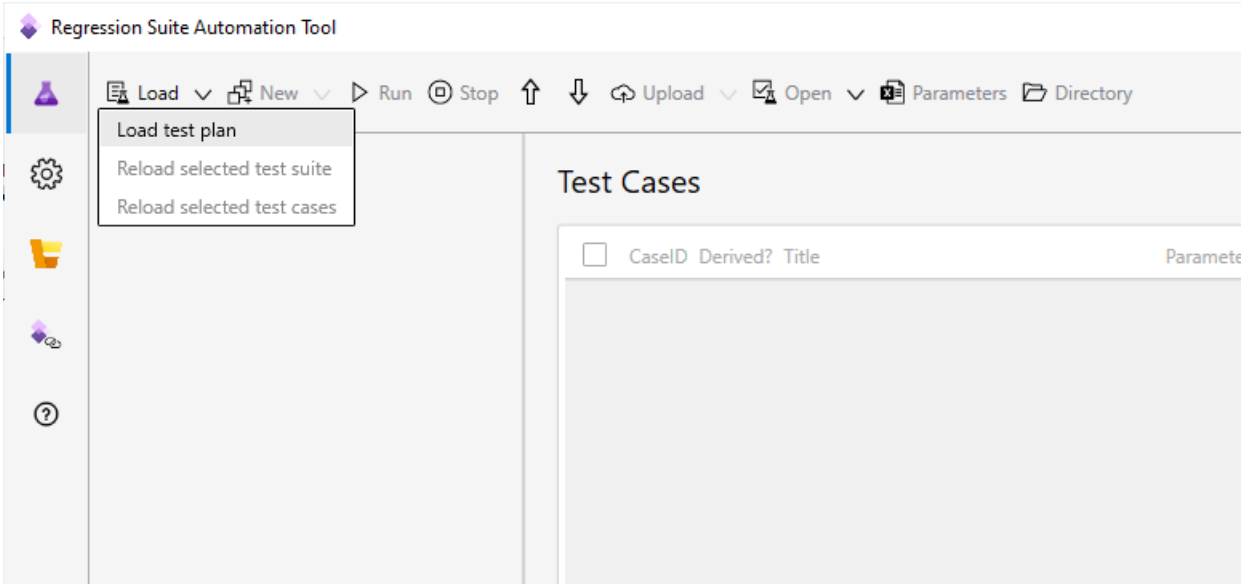
Use the Regression suite automation tool (RSAT)

2/18/2021 • 9 minutes to read • Edit Online

This topic explains how to load test cases from Azure DevOps, generate automation files, modify test parameters, run and investigate results, and save your work back to Azure DevOps.

Load test cases and create automation files

In RSAT, select the **Test Plans** tab and then select **Load** to download test cases and test case automation files. All test cases (and their corresponding attachments) belonging to the test plan specified in the **Settings** tab are downloaded to the local working directory.



Test cases are organized by test suites under a common test plan. These are test suites you created in your Azure DevOps project. Using this tool, you can work with one test suite at a time.

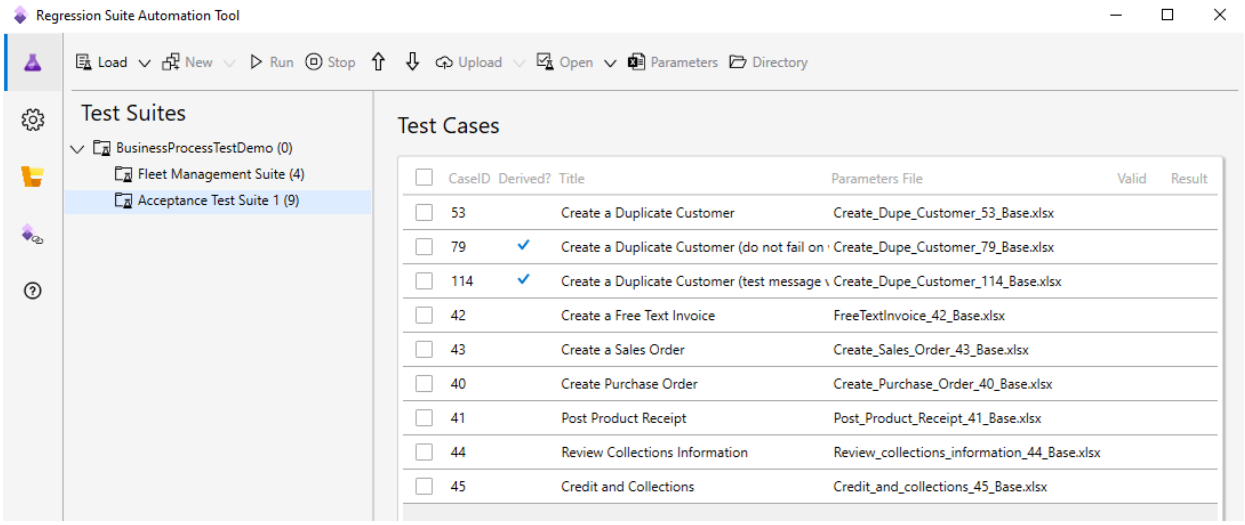
If the tool fails to load any test case, verify that your test plan in Azure DevOps is properly created and contains the desired test suites and test cases.

If this is the first time you are using this test plan, the **Parameters File** column will be blank. You must create test automation files for your test cases.

A test case requires the following attachments for successful execution:

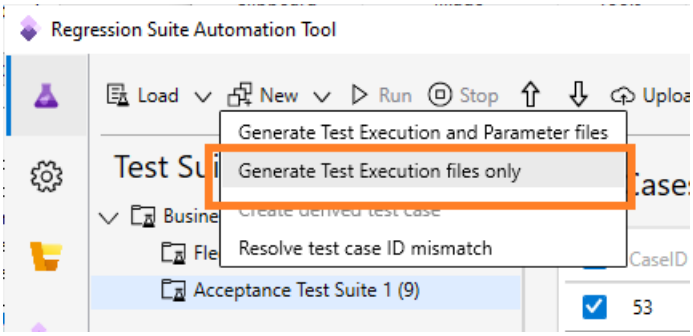
- A **recording file**: This is the recording file created by the Finance and Operations Task recorder. It defines the steps of your test case. It is typically named **recording.xml** or but you can also name it to match the test case title in Azure DevOps. It is attached to the test case in Azure DevOps and downloaded into the **attachment** folder of the local working directory of the test case.
- **Test automation files** consisting of **a test parameter file** (Microsoft Excel file) containing configurable test case parameters and **test execution files**: These files are generated by RSAT to enable automated execution of the test recording. Filenames are suffixed by **_Base.cs**, **_Base.xml**, and **_Base.dll**.

When you select **New**, test automation files are generated in your working directory. The Excel test parameter files will appear on the grid under **Parameters File**.



You can also generate **test execution files** only, without overwriting your parameter files. Select **New** > **Generate Execution Files** to regenerate only execution files and leave Excel files unaffected.

You must generate test execution files when you install a new version of the tool, and when you modify or load a new version of the recording file. In this way, you update your execution files but also preserve the test parameter files.



Modify test parameters

This section describes how to modify Excel files to specify input and validation parameters for your test run. Select one or more test cases to modify, and then select the **Parameters** button (Microsoft Excel symbol) on the toolbar. An Excel window opens for each test case that you selected. Alternatively, you can open the Excel files directly from the working directory.

In addition to the **General** tab, the Excel parameter file contains a **MessageValidation** tab and a **TestCaseSteps** tab.

Select the **TestCaseSteps** tab to configure input and validation parameters of your test case. Input and validation parameters are placed directly next to their corresponding test case step, enabling test authors with context and a simple experience. When you modify parameters, it is clear what steps of the test case you are affecting. You can enter values or formulas in context. Color coding differentiates input parameters from validation steps.

	A	B	C	D
1	***Test Case Steps***			
2	***Step***	***Action***	***Field Name***	***Value***
3	*1*	*Navigate to: SalesTableListPage ("salestablelistpage")*

20	*18*	*Click OK.*		
21				
22				
23				
24				

General | MessageValidation | **TestCaseSteps**

Reusable variables that are copied while recording the test case are also shown in context of the test case step. You can easily locate a variable and copy it to use in subsequent steps and formulas. For more information, see Copy variables to chain test cases.

	A	B	C	D
1	***Test Case Steps***			
2	***Step***	***Action***	***Field Name***	***Value***
3	*1*	*Navigate to: SalesTableListPage ("salestablelistpage")*		
4	*2*	*Click New.*		
5	*3*	*In the Customer account field, type a value.*	**Customer account**	us-010
6	*4*	*Note the value in the Sales order field to reference later {{SalesCreateOrder_SalesTable_SalesId_85_Copy}}*		
7	*5*	*Click OK.*		
8	*6*	*In the list, mark the selected row.*		
9	*7*	*In the Item number field, type a value.*	**Item number**	D0001
10	*8*	*In the Quantity field, enter a number.*	**Quantity**	2
11	*9*	*In the Discount field, enter a number.*	**Discount**	0
12	*10*	*In the Discount percent field, enter a number.*	**Discount percent**	10

Save the Excel files when you are done making edits.

Run a test as a specific user

By default, tests are executed using the admin role. If you want to run the test as a specific security role, specify the email address of a user under the **Test User** parameter in the **General** tab of the Excel parameter file. The **Test User** must be a valid user of the environments you are connecting to. The test will run under the security roles that the specific user belongs to. You need version 1.200 or newer for this feature to be functional.

	A	B
1	General	
2	Field Name	Value
3	Test Case ID	1422
4	Recording Name	Update_user
5	Playback Order	0
6	Company	TEST
7	Test User	alicia@contoso.com
8	Pause between test cases (Seconds)	
9	Action Timeout (Seconds)	
10	Abort test suite execution on failure	FALSE
11	Fail on warning message in the Infolog	FALSE
12	Pause between steps (Seconds)	

Run a test in the context of a specific company

The **General** tab of the Excel parameter file also allows you to specify the name of a legal entity (Company). The test will run in the context of this company. You can specify your default company in the **Settings** dialog box of the tool.

Pause after a specific test step

You can insert a pause between specific test steps. Navigate to the **TestCaseSteps** tab of the Excel parameters file and insert a value (in seconds) in the pause column of a test step. This will pause test cases execution after the test step is completed.

	A	B	C	D	E
1	*Test Case Steps*				
2	*Step*	*Action*	*Field*	*Value*	*Pause*
3	1	*Navigate to: CustTable ("custtablelistpage")*			
4	2	*Click New.*			
5	3	*In the Customer account field, enter or select a value.*	**Customer account**	Test-001	10
6	4	*In the Name field, type a value.*	**Name**	RFB	
7	5	*In the Customer group field, enter or select a value.*	**Customer group**	10	
8	6	*In the Country/region field, type a value.*	**Country/region**	usa	
9	7	*Click Save.*			
10					

If you don't see the **Pause** column, you are using an older version of the Excel parameters file and need to regenerate it. Select the desired test case, then go to **New > Generate Test Execution and Parameter Files**. This may override edits you have made to the parameters file, so you should back up the existing Excel file first.

Other notable test case execution settings

You may find the following settings useful. They are available on the **General** tab of the Excel parameter file.

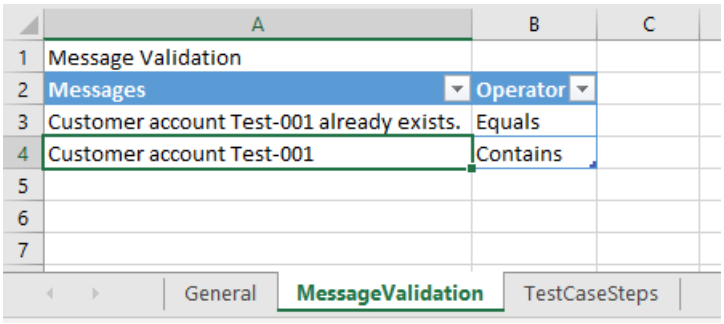
- **Fail on warning message in the Infolog**: By default, test cases fail when an error occurs or a validation step fails. If you also want a test case to fail in response to a warning message, set the **Fail on warning message in the Infolog** option to **True** . This is useful, for example, if a test case adds a duplicate customer record. The default setting is **False**.
- **Abort test suite execution on failure**: If you set the **Abort test suite execution on failure** option to **True**, execution of the test suite is aborted if the test case fails. All the remaining test cases will have a status of **Not Executed**. The default setting is **False**.
- **Pause between steps**: The number of seconds to pause between test steps. This will affect every test step. The default value is **0** (zero).

Infolog and message validation

Excel parameter files that are generated using version 1.200 or newer contain a **MessageValidation** tab.

You can enter messages in this tab under **Message Validation**. After a test case completes execution, it validates that the messages specified here appear in the Infolog. The test case will fail if these messages are not found.

You can specify any expected messages including error messages. Any message specified in this section will cause a test case to fail unless it is found in the Infolog during execution. Two operators are available: **Equals** and **Contains**. If you use **Equals**, then RSAT performs a string comparison with all messages in the Infolog and fails validation if the full message is not found. If you use **Contains**, then RSAT will validate that at least one message in the Infolog contains the string you specify.



You can configure whether string comparison is case sensitive or not in the **Optional** page of the **Settings** tab.

Run

Select **Run** to execute the selected test cases. Only test cases with existing automation files can be run. The tool will open and execute these tests with the data you entered in Excel.

You can modify the order in which test cases are executed using the up and down arrow buttons.

Pause prior to a test case run

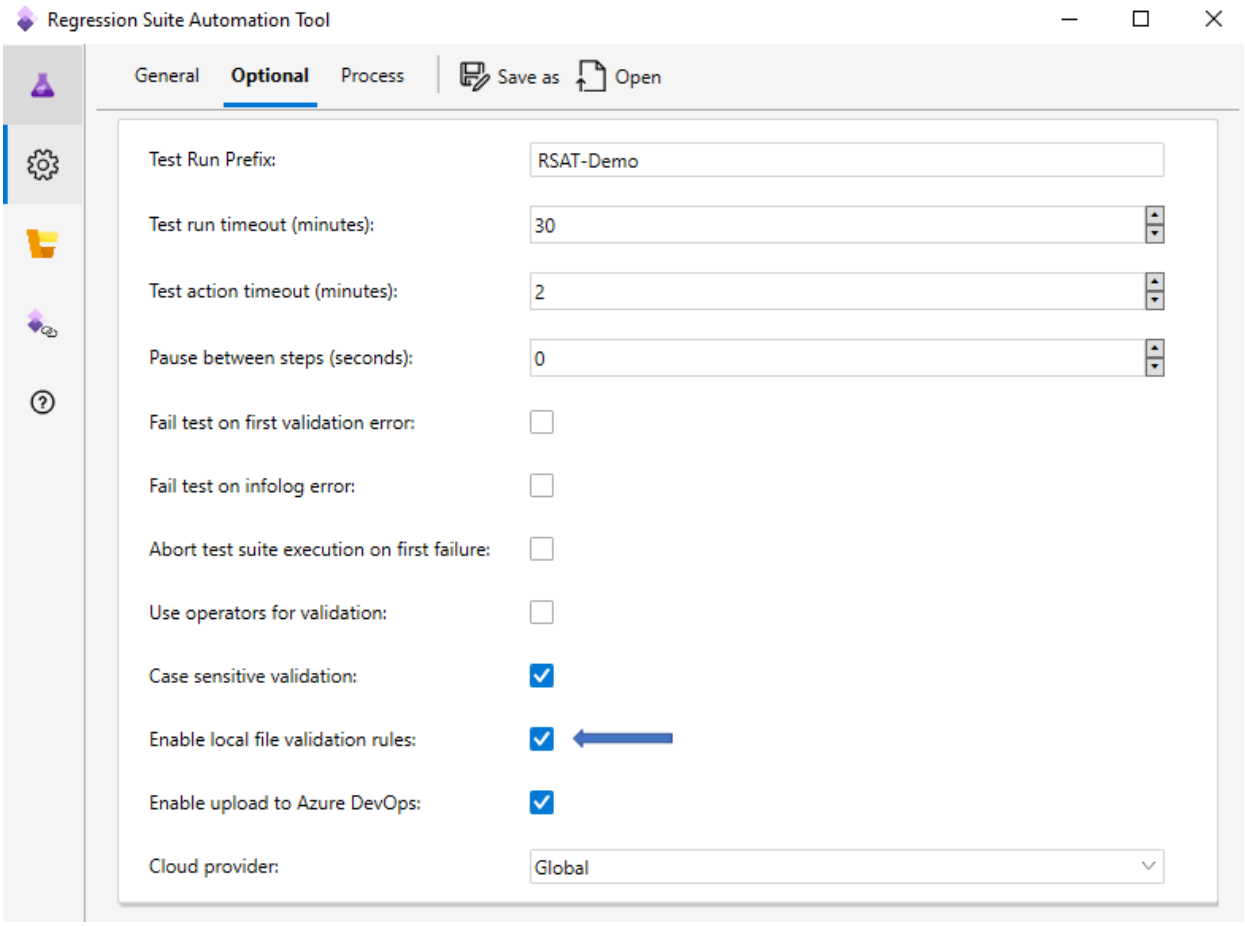
You can add a pause before a test case starts execution. If you want to pause, update the cell **Pause (seconds)** on the **General** tab of the Excel parameters file of the desired test case.

Stop a run

When a test run is in progress, you can select the **Stop** button on the toolbar to cancel the run. Execution stops after the currently running test case completes. The remaining test cases will be marked as **Not Executed** in Azure DevOps.

Validate readiness of test automation files

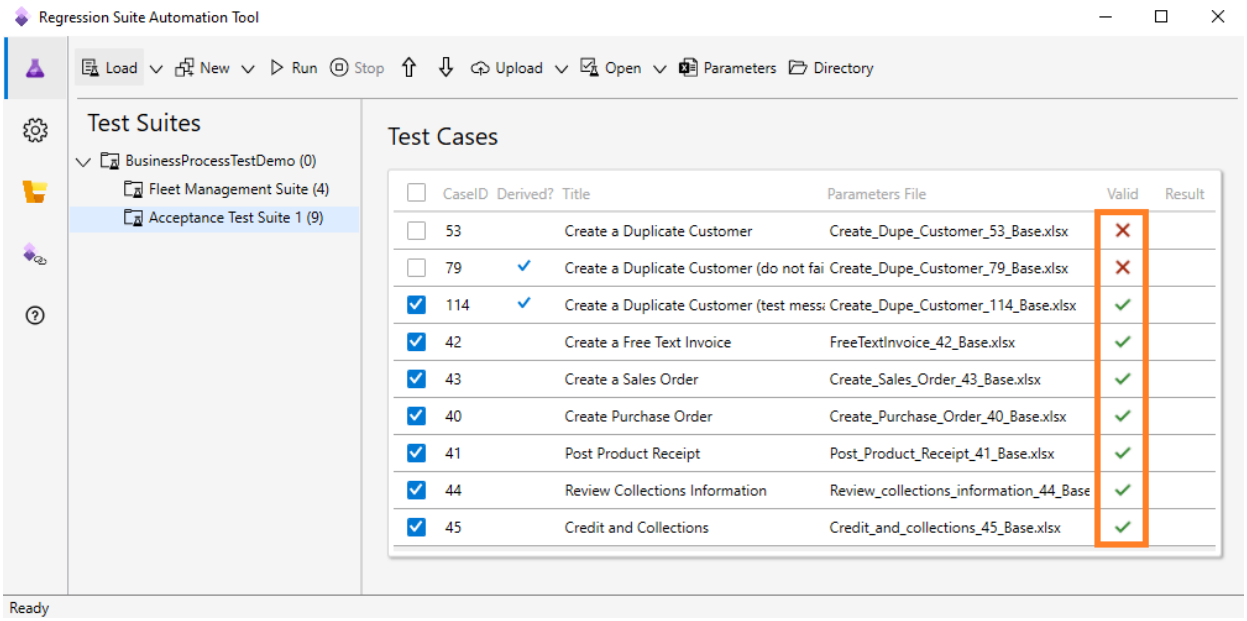
Optionally, you can turn on a setting that validates whether your test cases are ready for execution. This setting prevents unknown errors related to the validity of recordings and test automation files. This option is available as of RSAT version 1.210. You can enable this by selecting the **Settings** tab and then selecting the **Optional** tab.



When enabled, a background process continuously validates the following for each test case.

- The local working directory exists.
- The Excel parameter file exists.
- Test automation files (binary and Xml files) needed for execution exist.
- Test automation files are compatible with current version of RSAT. You must regenerate test automation files when you install a new version of RSAT.
- Test case ID specified in the Excel parameter file matches the test cases ID in Azure DevOps.

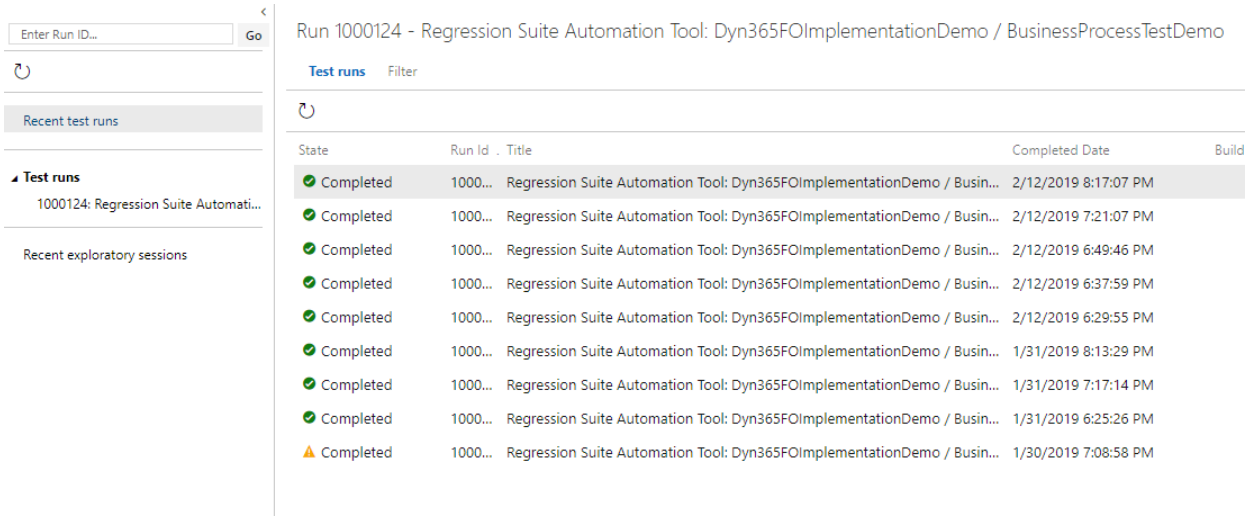
The Valid column in the grid indicates the result of the validation process. If validation fails, click on the **X** in the **Valid** column to view the error and recommended action.



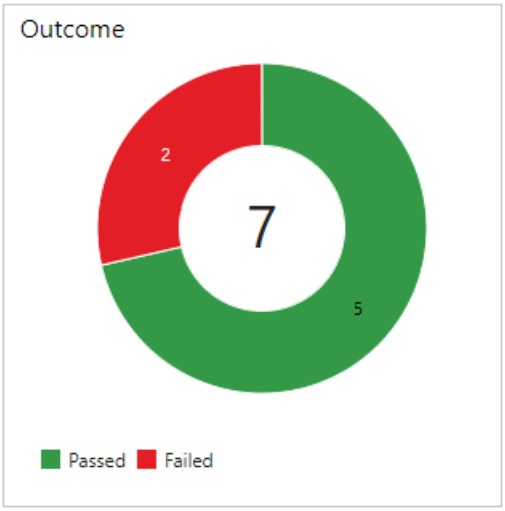
Investigate results

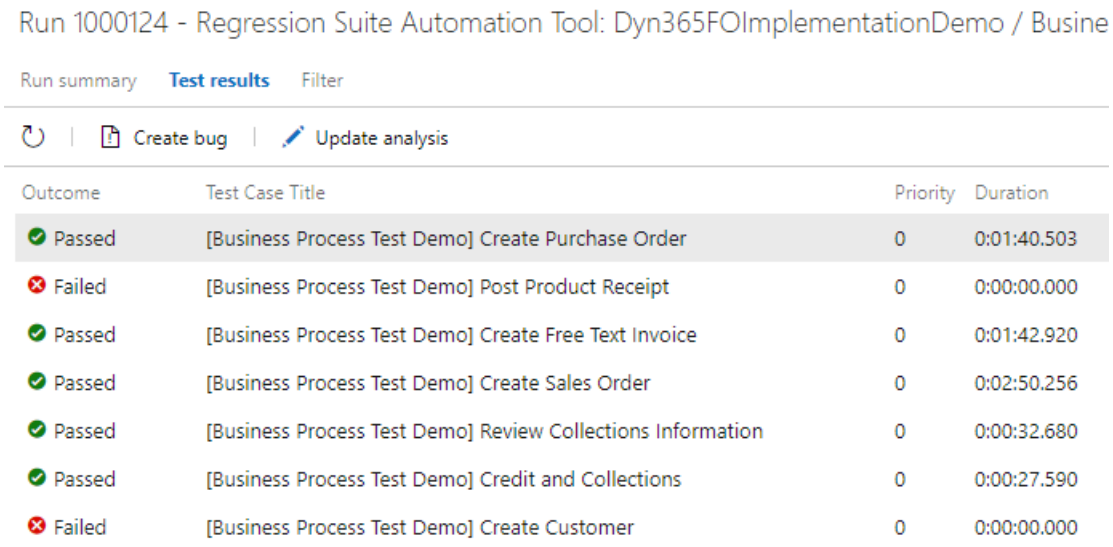
When all test cases complete execution, **Pass** or **Fail** will be populated in the **Result** column. You can click on the result to see error messages.

Additional investigation details are available in Azure DevOps. To view this information, from your Azure DevOps project page, go to **Test > Runs**.

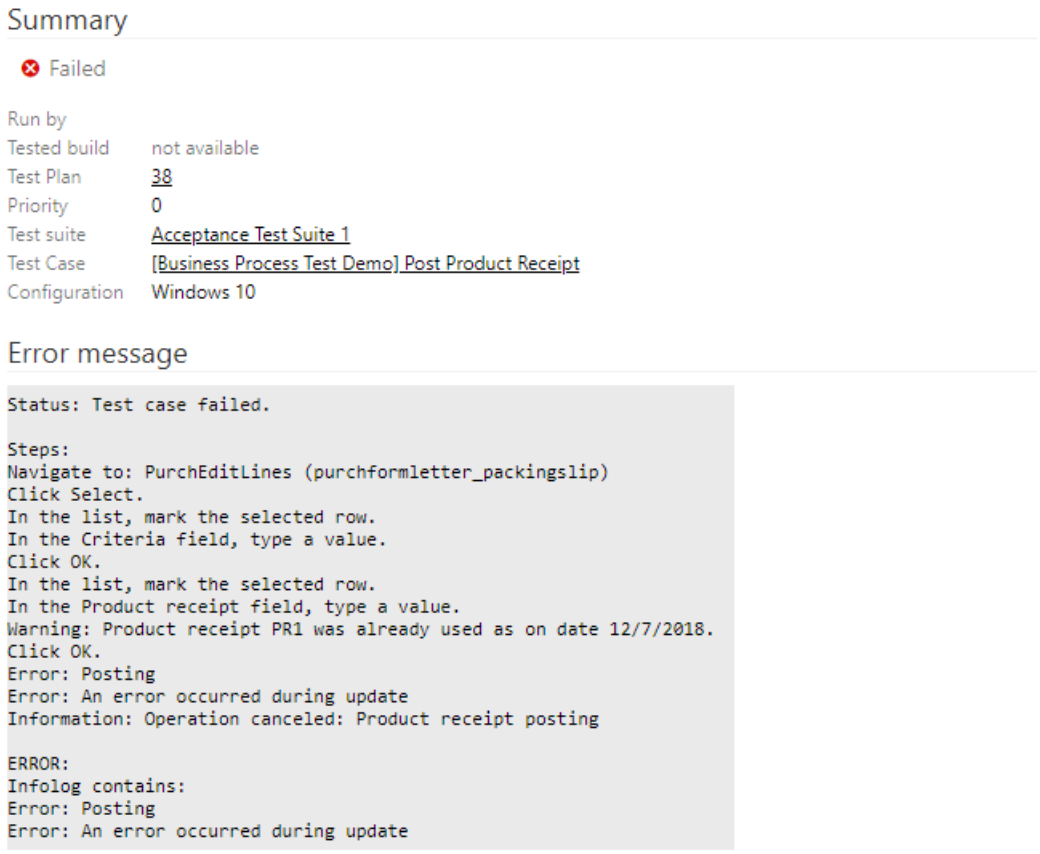


Select the desired test run. It will include the results of all tests that were executed during that run.





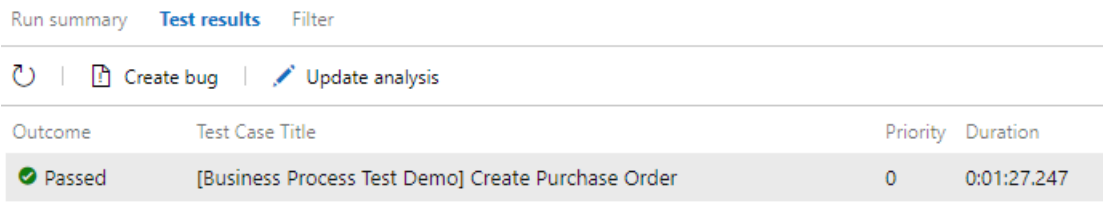
You can open a failed test result and review the **ErrorMessage** section for information about the failure.



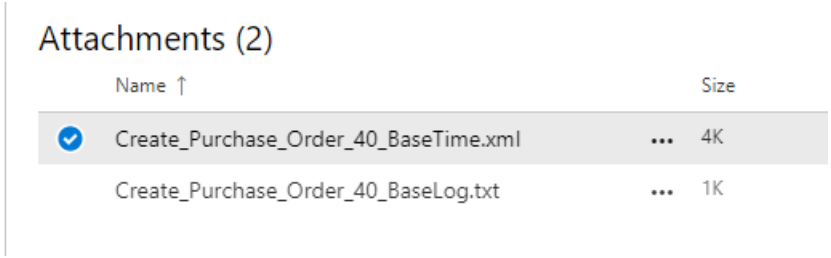
All error messages are also available locally under **C:\Users$YourUserName\AppData\Roaming\regressionTool\errormsg-.txt**.

Test response times

In addition to execution logs, the duration of a test case is also available in the test result.



You can also review the response time of each step of the test case by opening the **BaseTime.xml** file attached to the test result.



You need version 1.200 or newer for response times to be available.

Upload to Azure DevOps to commit your work

To commit your work to Azure DevOps, select **Upload**. This uploads recordings and test automation files, including Excel test parameter files, of all selected test cases to Azure DevOps for future use. After test

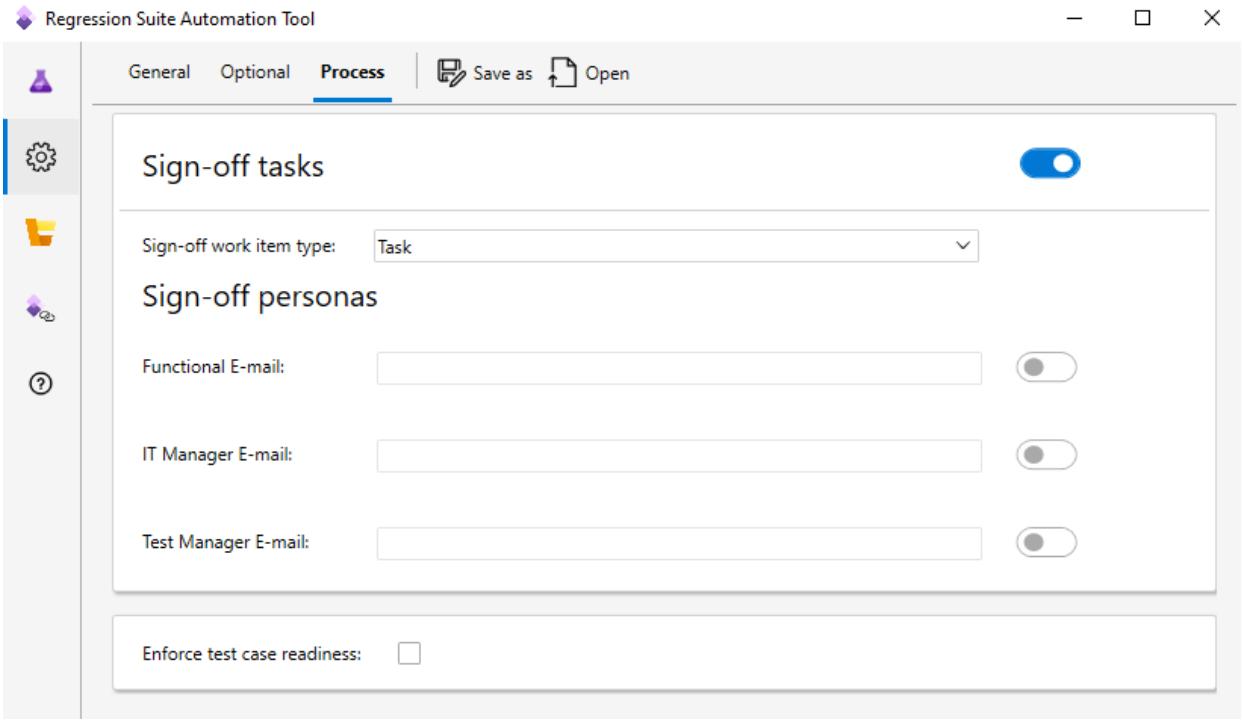
automation files are uploaded to Azure DevOps, the next time you use the Regression suite automation tool, even from a different computer, you can simply use **Load** and then **Run**, without generating test execution files or editing Excel parameter files.

In the upload menu, you also have the option to upload recording files (Task recordings) only.

If you are unsure what test cases to select, and you want to commit all changes (since last load) to Azure DevOps, select **Upload all modified automation files** in the upload menu.

Process compliance

RSAT provides capabilities for managing the readiness of test cases. It also provides a sign-off process for test runs. This is configurable in the **Process** tab under Settings.



Enforce test case readiness

You can set up the test case so that it isn't run unless it has a status of **Ready** in Azure DevOps. Select the **Enforce test case readiness** check box. By default, the check box is cleared.

Signoffs

When your test run is complete, RSAT can create sign-off work items in Azure DevOps. Select the **Sign-off tasks** check box. Then set the type of work item that should be created for each person who signs off. You can select the **Functional**, **IT Manager**, or **Team Manager** role for sign-offs, and then specify appropriate email addresses. Work items will then be created in Azure DevOps and assigned to owners for approval.

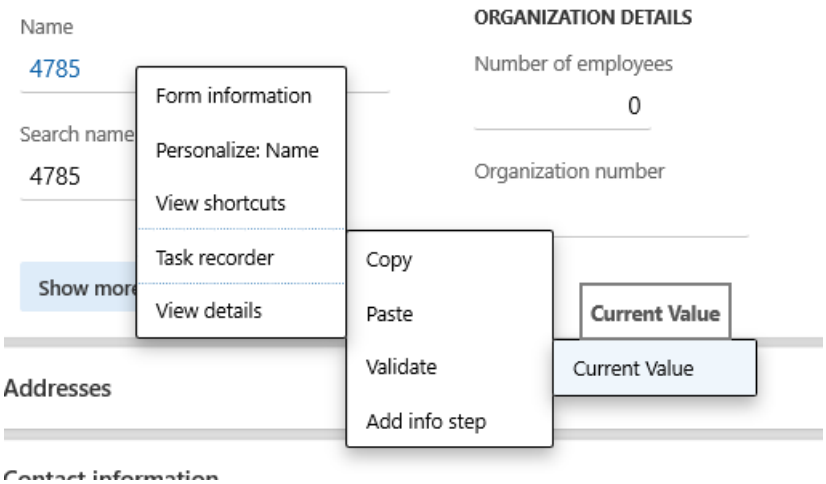
Validate expected values

2/18/2021 • 2 minutes to read • Edit Online

An important component of a test case is validation of expected values. You can define validation parameters during the authoring of your test cases using Task Recorder. While recording, right-click on a control and select **CurrentValue** under the **Task Recorder > Validate** menu. This action becomes a validation step that you can use with the Regression suite automation tool. The control value will become a validation variable in the automatically generated Excel parameters file. The menu item is shown in the following image.



For more information about how to create task recordings, see Task recorder resources.

When RSAT generates the Excel parameter file for a test case, validation steps are added as shown in the image below. You can enter the expected value to use during execution of the test case.

	A	B	C	D
1	***Test Case Steps***			
2	***Step***	***Action***	***Field Name***	***Value***
3	*1*	*Navigate to: SalesTableListPage ("salestablelistpage")*		
4	*2*	*Click New.*		
5	*3*	*In the Customer account field, type a value.*	**Customer account**	us-010
6	*4*	*Note the value in the Sales order field to reference later {{SalesCreateOrder_SalesTable_SalesId_85_Copy}}*		
7	*5*	*Click OK.*		
8	*6*	*In the list, mark the selected row.*		
9	*7*	*In the Item number field, type a value.*	**Item number**	D0001
10	*8*	*In the Quantity field, enter a number.*	**Quantity**	2
11	*9*	*In the Discount field, enter a number.*	**Discount**	0
12	*10*	*In the Discount percent field, enter a number.*	**Discount percent**	10
13	*11*	*Click Totals.*		
14	*12*	*Validate that the value for Sales tax is '54.0000000000000000'.*	**Validate Sales tax**	54
15	*13*	*Validate that the value for Invoice amount is '918.0000000000000000'.*	**Validate Invoice amount**	918
16	*14*	*Click OK.*		
17	*15*	*On the Action Pane, click Sell.*		
18	*16*	*Click Confirm sales order.*		
19	*17*	*Click OK.*		
20	*18*	*Click OK.*		

General | MessageValidation | TestCaseSteps

Validate expected values using operators

You can also use operators in validation steps to validate that a variable is not equal, less than, or greater than a specified value. To use this feature, open the **Settings** tab and select the **Optional** tab. Turn on the setting named **Use operators for validation**. This option is available as of RSAT version 1.210. If you have been using

an older version of the tool, you must regenerate new Excel parameter files to take advantage of this functionality. In the Excel file, a new **Operator** field will appear, as shown in the following image.

	A	B	C	D	E
1	*Test Case Steps*				
2	*Step*	*Action*	*Field*	*Value*	*Operator*
3	1	*Navigate to: SalesTableListPage ("salestablelistpage")*			
4	2	*Click New.*			
5	3	*In the Customer account field, type a value.*	**Customer account**	us-010	
6	4	*Note the value in the Sales order field to reference later {{SalesCreateOrder_SalesTable_SalesId_85_Copy}}*			
7	5	*Click OK.*			
8	6	*In the list, mark the selected row.*			
9	7	*In the Item number field, type a value.*	**Item number**	D0001	
10	8	*In the Quantity field, enter a number.*	**Quantity**	2	
11	9	*In the Discount field, enter a number.*	**Discount**	0	
12	10	*In the Discount percent field, enter a number.*	**Discount percent**	10	
13	11	*Click Totals.*			
14	12	*Validate that the value for Sales tax is '54.0000000000000000'.*	**Validate Sales tax**	54	=
15	13	*Validate that the value for Invoice amount is '918.0000000000000000'.*	**Validate Invoice amount**	918	<>

Validate the state of a control

When recording test cases, Task Recorder supports additional validation action:

- Validate whether a control is enabled or disabled.
- Validate whether a control is editable or read-only.

To take advantage of this validation, you need to be use a Finance and Operations app running on 10.0.13 (or newer) and RSAT 2.0 (or newer). For more information, see Validate.

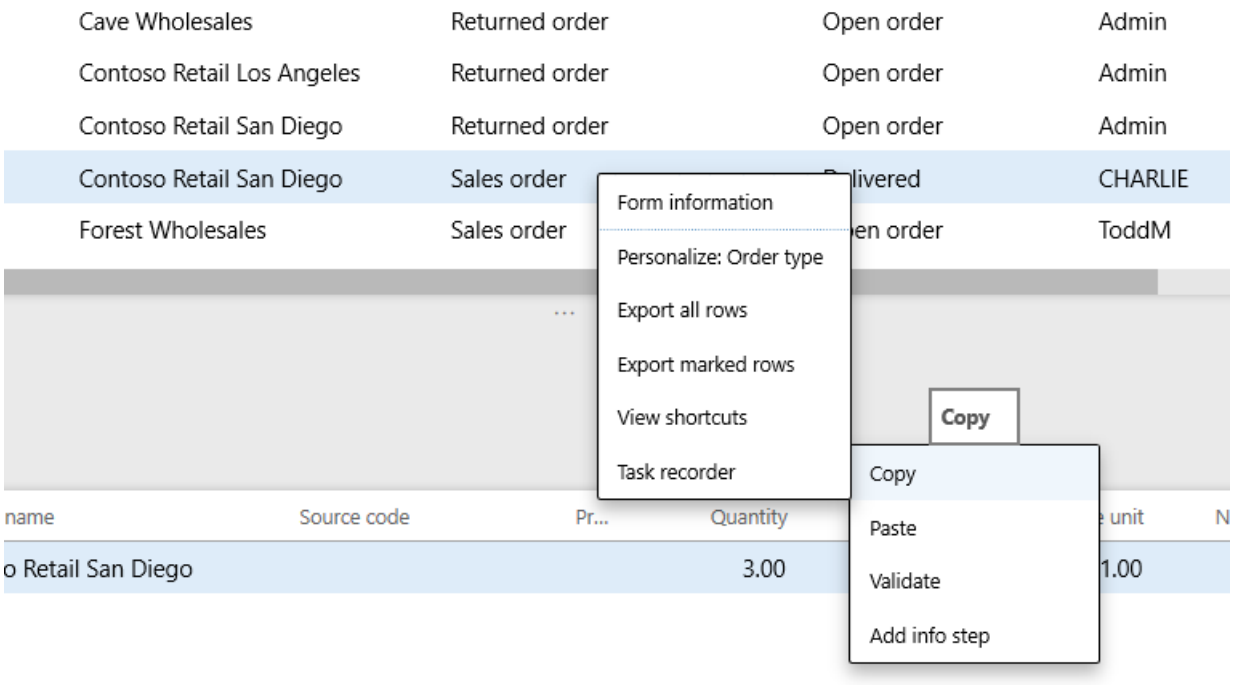
Copy variables to chain test cases

2/18/2021 • 2 minutes to read • Edit Online

One of the key features of the Regression Suite Automation Tool is the chaining of test cases, that is, the ability of a test to pass values to other tests. Test cases are executed according to their defined order in the Azure DevOps test plan, which can also be updated in the test tool itself. It is important to correctly order the tests if you want to pass variables from one test case to the other.

To save the value of a variable while recording the test in Task Recorder, right-click the field and select **Task recorder > Copy**, as shown in the following image. Copying will save the variable in the recording file. This variable can be used in subsequent tests.



When RSAT generates the Excel parameters file, saved variables appear in the **Saved variables** table on the **General** Tab. These variables also appear in the context of the test case steps in the **TestCaseSteps** tab. In the image below, the purchase order ID value was copied during the recording of the test case (step 5). This value is stored in a variable named **{{PurchCreateOrder_PurchTable_PurchId_86_Copy}}**.

	A	B
15	Product version	
16	2.0.65240.0	
17		
18		
19	Saved variables	
20	{{PurchCreateOrder_PurchTable_PurchId_86_Copy}}	
21		

General | MessageValidation | TestCas

	A	B
1	*Test Case Steps*	
2	*Step*	*Action*
3	*1*	*Navigate to: PurchTable ("purchtablelistpage")*
4	*2*	*Click New.*
5	*3*	*In the Vendor account field, type a value.*
6	*4*	*In the Warehouse field, type a value.*
7	*5*	*Note the value in the Purchase order field to reference later {{PurchCreateOrder_PurchTable_PurchId_86_Copy}}*
8	*6*	*Click OK.*
9	*7*	*In the list, mark the selected row.*
10	*8*	*In the Item number field, type a value.*
11	*9*	*In the Quantity field, enter a number.*
12	*10*	*In the Unit price field, enter a number.*
13	*11*	*In the Discount percent field, enter a number.*
14	*12*	*Click the Setup tab.*
15	*13*	*In the Sales tax group field, enter or select a value.*
16	*14*	*Click the Address tab*

General | MessageValidation | TestCaseSteps

To reuse these variables during test playback, copy the variable name and use it in place of a parameter value in the data file of another test (or the same test), as shown below.

	A	B	C	D
1	*Test Case Steps*			
2	*Step*	*Action*	*Field Name*	*Value*
3	*1*	*Navigate to: PurchEditLines ("purchformletter_packingslip")*		
4	*2*	*Click Select.*		
5	*3*	*In the list, mark the selected row.*		
6	*4*	*In the Criteria field, type a value.*	**Criteria**	{{PurchCreateOrder_PurchTable_PurchId_86_Copy}}
7	*5*	*Click OK.*		
8	*6*	*In the list, mark the selected row.*		
9	*7*	*In the Product receipt field, type a value.*	**Product receipt**	=CONCAT("PR",{{PurchCreateOrder_PurchTable_PurchId_86_Copy}})
10	*8*	*Click OK.*		
11				
12				

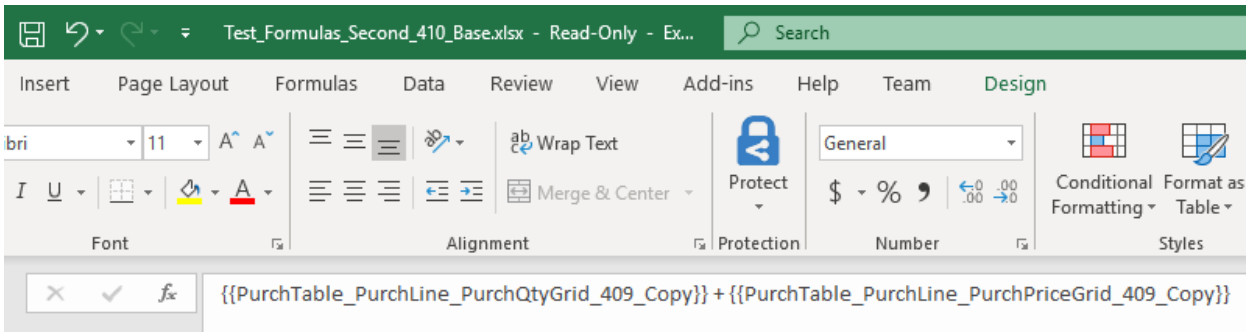
General | MessageValidation | TestCaseSteps

Variables can be used in the same test case where they are defined and can also be passed between tests during the same test run.

Support for formulas of saved variables

You can create formulas that contain saved (copied) variables. If you have been using an older version of the Regression Suite Automation Tool, you will need to regenerate new Excel parameter files to take advantage of this functionality. Supported operators are `+`, `-`, `/` and ''. Only numerical variables can be used in the Regression Suite Automation Tool formulas. Strings or dates are not supported. Always specify variable names within double braces `{{varname}}`. For example, `{{var1}} + {{var2}}`.

In the image below, two different variables are used in a formula.



As of RSAT version 1.220, you can also use Excel functions, such as **ROUND**, **CONCAT**, and **UPPER**, to create formulas with RSAT variables. This feature is implemented using the Excel formula evaluation functionality, so any function supported by Excel is supported by RSAT.

For example,

- To round a value into the nearest whole number, use:

  ```
  =ROUND({{Item_Price_3274_Copy}}, 0)
  ```

- To concatenate strings, use:

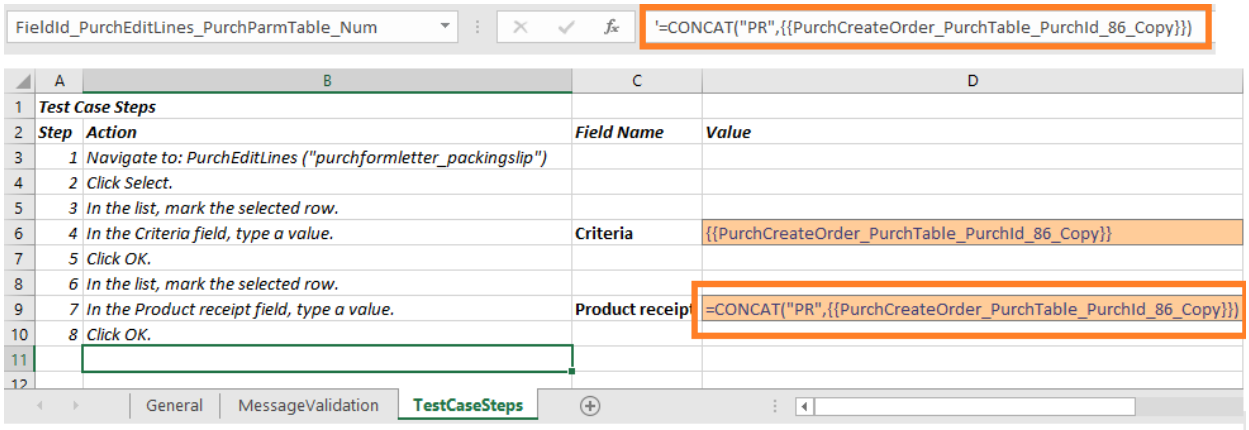
  ```
  =CONCATENATE({{AccountNum_3274_Copy}}, " ", {{ AddressBP_Locator_3274_Copy}})
  ```

- To calculate and format a date and convert it to a string, use:

  ```
  =TEXT(DATEVALUE({{SystemDate_CurrentDate_3276_Copy}}) - 1, "mm/dd/yyyy")
  ```

  Always convert RSAT date values to text for reliable test case execution.

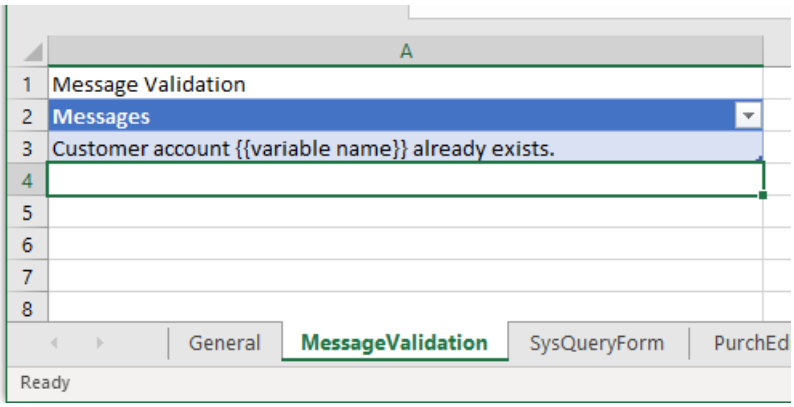
RSAT evaluates these formulas during test execution, so you must precede the formula with a single quote ' to prevent Excel from attempting to prematurely calculate the formula. An example is shown in this image.



Use variables in message validation

You can also use a saved variable as part of a string in the Message Validation tab. Here is an example that validates that the message `Customer account {{variable name}} already exists.`. It appears in the Infolog during test execution. `{{variable name}}` is a variable that is copied during the recording.

Saved (Copied) variables can be used within the same test case or across more than one test case in the same test suite.



NOTE

Can you tell us about your documentation language preferences? Take a short survey.

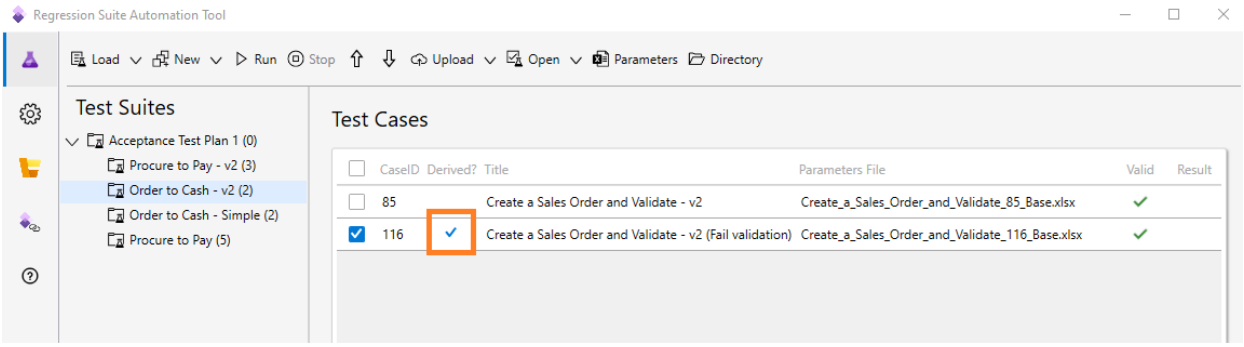
The survey will take about seven minutes. No personal data is collected (privacy statement).

Derived test cases

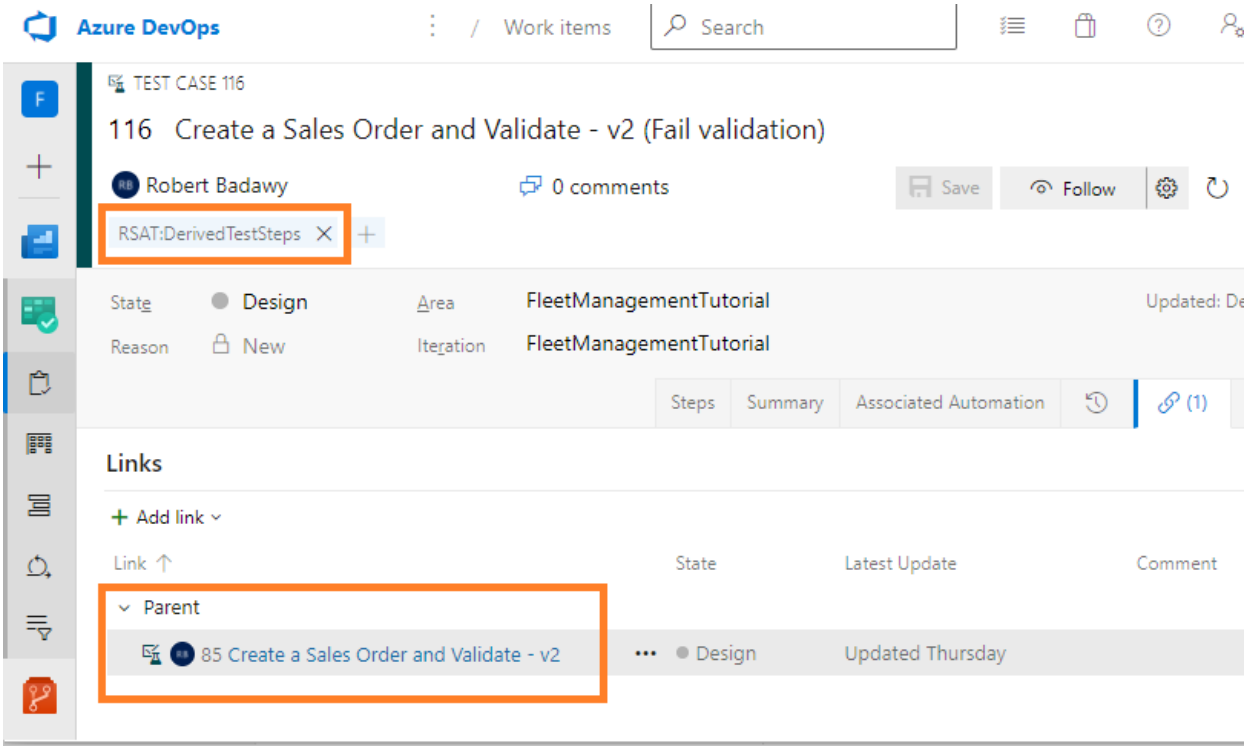
2/18/2021 • 2 minutes to read • Edit Online

The Regression suite automation tool (RSAT) lets you use the same task recording with multiple test cases, so that you can run a task with different data configurations. Select a test case in the Regression suite automation tool and then select **New > Create Derived Test Case**. This creates a child test case in Azure DevOps. The resulting derived test case is linked to its parent test case in Azure DevOps. It has an Excel parameters file attached but no recording file. The derived test case will appear in the Regression suite automation tool grid under the same test suite with the **Derived** column selected. By default, derived test cases are named after their parent test case with a numeric suffix.

In the following image, a derived test case has been created from a test case named **Create a Sales Order and Validate - v2**. The derived test case has been renamed (in Azure DevOps) to **Create a Sales Order and Validate - v2 (Fail validation)**.



In Azure DevOps, a derived test case is a child item of the **Create a Sales Order and Validate - v2** test case and is tagged with the special keyword **RSAT:DerivedTestSteps**.



When you run a derived test case, it will use the recording of its parent test case and its own copy of the Excel parameters file. This will allow you to run the same test with different parameters without the need to maintain more than one recording.

A derived test case does not need to be part of the same test suite as its parent test case, and you can use it in another suite. You can also rename a derived test case. You can edit the Excel parameters file of a derived test case to run it with a different user, a different company, or with different input and validation parameters than its parent test case.

Regression suite automation tool tutorial

2/18/2021 • 13 minutes to read • Edit Online

> **NOTE**
> Use your internet browser tools to download and save this page in pdf format.

This tutorial walks through some of the advanced features of the Regression suite automation tool (RSAT), includes a demo assignment, and describes strategy and key learning points.

Notable Features of RSAT and Task recorder

Validate a field value

RSAT allows you to include validation steps within your test case to validate expected values. For information about this feature, see the article Validate expected values.

The following example shows how you can use this feature to validate whether the on-hand inventory is more than 0 (zero).

1. In the demo data in the **USMF** company, create a task recording that has the following steps:
    a. Go to **Product information management > Products > Released products**.
    b. Use the Quick Filter to find records. For example, filter on a value of **1000** for the **Item number** field.
    c. Select **On-hand inventory**.
    d. Use the Quick Filter to find records. For example, filter on a value of **1** for the **Site** field.
    e. In the list, mark the selected row.
    f. Validate that the value of the **Total available** field is **411.0000000000000000**.
2. Save the task recording as a **developer recording** and attach it to your test case in Azure Devops.
3. Add the test case to the test plan, and load the test case into RSAT.
4. Open the Excel parameter file and go to the **TestCaseSteps** tab.
5. To validate whether the inventory on-hand will always be more than **0**, go to the **Validate Total Available** step and change its value from **411** to **0**. Change the value of the **Operator** field from an equal sign (=) to a greater than sign (>).
6. Save and close the Excel parameter file.
7. Select **Upload** to save the changes that you made to the Excel parameter file to Azure DevOps.

Now, if the value of the **Total Available** field for the specified item in inventory is more than 0 (zero), tests will pass, regardless of the actual on-hand inventory value.

Saved variables and chaining of test cases

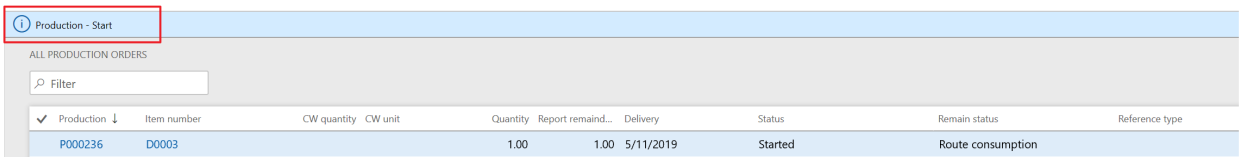
One of the key features of RSAT is the chaining of test cases, that is, the ability of a test to pass variables to other tests. For more information, see the article Copy variables to chain test cases.

Derived test case

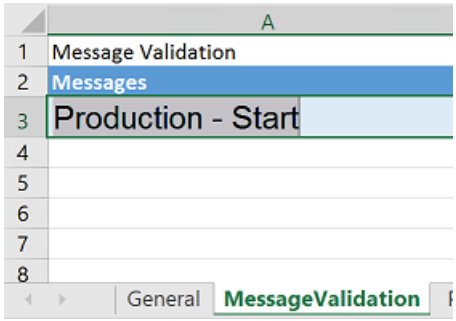
RSAT lets you use the same task recording with multiple test cases, enabling a task to run with different data configurations. See the article Derived test cases for more information.

Validate notifications and messages

This feature can be used to validate whether an action occurred. For example, when a production order is created, estimated, and then started, the app shows a "Production – Start" message to notify you that the production order has been started.



You can validate this message through RSAT by entering the message text on the **MessageValidation** tab of the Excel parameter file for the appropriate recording.



After the test case is run, the message in the Excel parameter file is compared to the message that is shown. If the messages don't match, the test case will fail.

> **NOTE**
>
> You can enter more than one message on the **MessageValidation** tab in the Excel parameter file. The messages also can be error or warning messages instead of informational messages.

Snapshot

This feature takes screenshots of the steps that were performed during task recording. It is useful for auditing or debugging purposes.

- To use this feature, open the **Microsoft.Dynamics.RegressionSuite.WindowsApp.exe.config** file under the RSAT installation folder (for example, **C:\Program Files (x86)\Regression Suite Automation Tool**), and change the value of the following element from **false** to **true**.

  ```
  <add key="VerboseSnapshotsEnabled" value="false" />
  ```

When your run the test case, RSAT will generate snapshots (images) of the steps in the playback folder of the test cases in the working diretory. If you are using an older version of RSAT, the images are saved to **C:\Users\<Username>\AppData\Roaming\regressionTool\playback**, a separate folder is created for each test case that is run.

Assignment

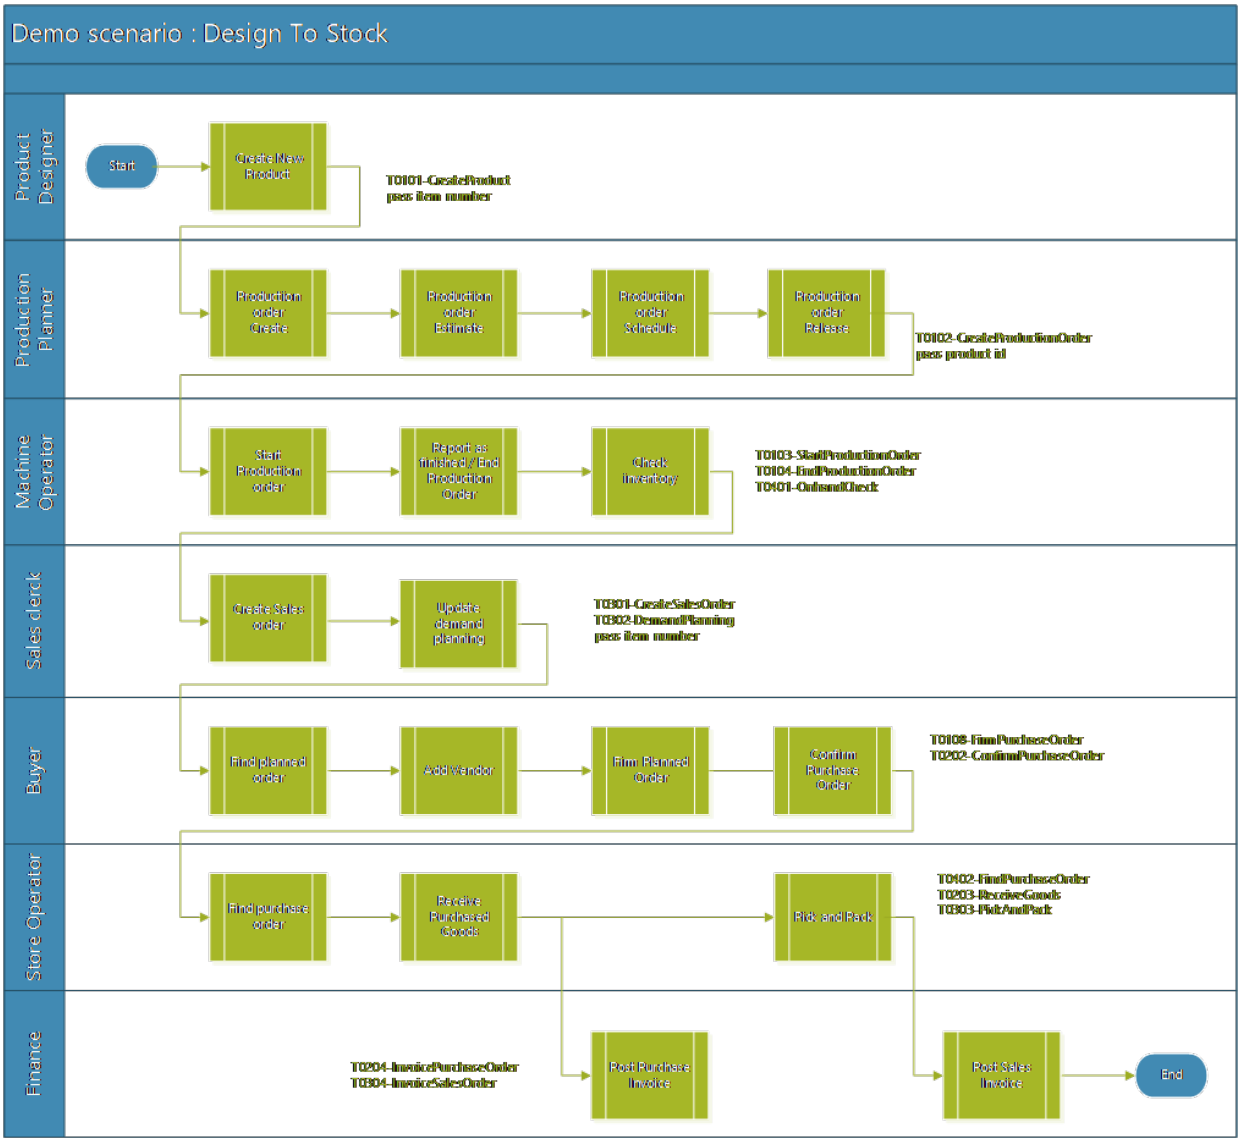
Scenario

1. The product designer creates a new released product.
2. The production manager initiates a production order to bring the stock level to two pieces.
3. Manufacturing starts and ends the production order, and verifies that the on-hand quantity is two pieces.
4. The sales team receives an order for four pieces of the new product. Therefore, the sales team updates the net requirements via the dynamic plan. Because no additional capacity is available, the default order policy is

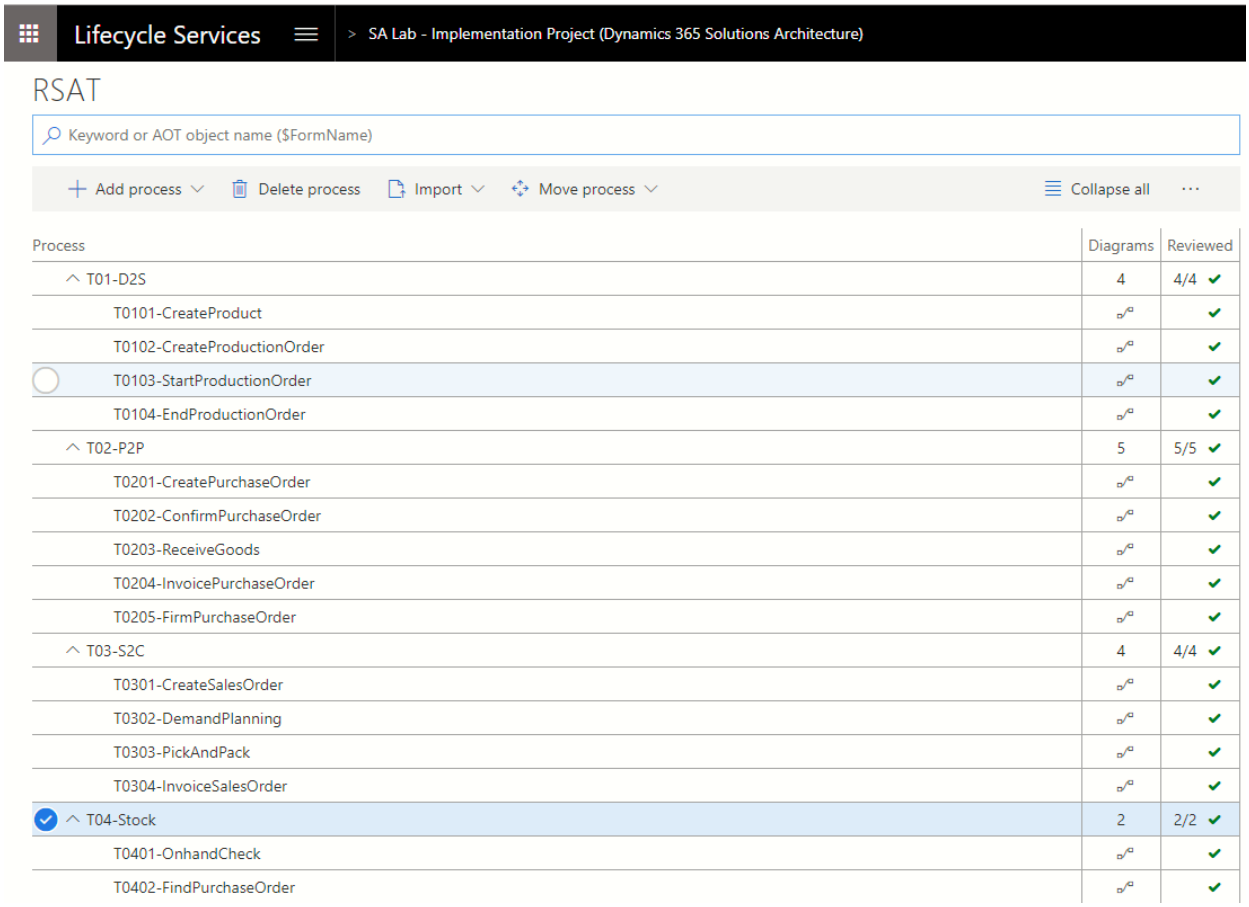
set to "buy instead of make." Therefore, a planned purchase order is created.

5. The buyer adds a vendor, firms the planned purchase order, and then confirms the purchase order.
6. When the goods that were purchased arrive at the store, the store operator searches the related purchase order and receives the goods. Because the order is now completed, goods can be picked and packed against the sales order.
7. Finance posts the purchase invoice and sales invoice.

The following illustration shows the flow for this scenario.



The following illustration shows the business processes hierarchy for this scenario in the LCS Business Process Modeler.



Strategy – Key learning

Data

- Make sure that you have representative data volumes (a copy of production/golden configuration data plus migrated data).
- When you generate new data via Task recorder, create test names that won't conflict with existing names (for example, use a prefix such as **RSATxxx**).
- Use Azure Point-In-Time restore to rerun tests in non-Tier 1 environments.
- Although you can use the **RANDOM** and **NOW** Excel functions to generate a unique combination, the effort is considerably high. Here is an example.

```
product = "AT" &TEXT(NOW(),"yyymmddhhmm")
```

Task recorder

- Define scenarios before you start recording. A well-managed project has predefined test scenarios. To build a test case, consider how predictable the outcome of those test scenarios is.
- Split recordings if they are performed by different roles, or if there is waiting time or an external event before the next step.
- Avoid selecting values in lists. Instead, use text formats, such as **FIFO**, **AudioRM**, and **SiteWH**. When you select in a list, the position of the value in the list is recorded, not the value itself. If items are added to that list, the position of the value can change. Therefore, your recording will use a different parameter, and the rest of the scenario might be affected.
- Think about multi-user behavior. For example, don't assume that your newly created sales order will always be automatically selected. Instead, always use the filter to find the correct order.
- Use the Copy function in Task recorder to save the name of a newly created product so it can be used in

chained test cases.

- Use the Validate function in Task recorder to set checkpoints that verify that steps have been run correctly.

RSAT

- To run the test in another company, you can change the company on the **General** tab of the Excel parameter file. Make sure that settings and data are available in the newly selected company.
- You can change the test user on the **General** tab of the Excel parameter file. Specify the email ID of the user who will run the test case. In this way, the test case can be run by using the security permissions of the specified user.
- To wait before the test is started, you can define a pause on the **General** tab of the Excel parameter file. This pause can be used in a batch job (for example, if a workflow must be run before the next step can be performed.)

Advanced scripting

CLI

RSAT can be called from a **Command Prompt** or **PowerShell** window.

> **NOTE**
>
> Verify that the **TestRoot** environment variable is set to the RSAT installation path. (In Microsoft Windows, open **Control Panel**, select **System and Security > System > Advanced system settings**, and then select **Environment Variables**.)

1. Open a **Command Prompt** or **PowerShell** window as an admin.
2. Navigate to the RSAT installation directory.

   ```
   cd "c:\Program Files (x86)\Regression Suite Automation Tool\"
   ```

3. List all commands.

```
C:\Program Files (x86)\Regression Suite Automation
Tool>Microsoft.Dynamics.RegressionSuite.ConsoleApp.exe help

Usage:
    Microsoft.Dynamics.RegressionSuite.ConsoleApp.exe command
    or
    Microsoft.Dynamics.RegressionSuite.ConsoleApp.exe /settings "C:\Path to\file.settings" command

Available commands:
    ?
    about
    cls
    download
    edit
    generate
    generatederived
    generatetestonly
    generatetestsuite
    help
    list
    listtestplans
    listtestsuite
    listtestsuitenames
    playback
    playbackbyid
    playbackmany
    playbacksuite
    quit
    upload
    uploadrecording
    usage
```

?

Shows help about all available commands and their parameters.

`Microsoft.Dynamics.RegressionSuite.ConsoleApp` `?` `[command]`

?: Optional parameters

`command`: Where `[command]` is one of the commands specified below.

about

Displays the current version.

`Microsoft.Dynamics.RegressionSuite.ConsoleApp` `about`

cls

Clears the screen.

`Microsoft.Dynamics.RegressionSuite.ConsoleApp` `cls`

download

Downloads attachments for the specified test case to the output directory. You can use the `list` command to get all available test cases. Use any value from the first column as a **test_case_id** parameter.

`Microsoft.Dynamics.RegressionSuite.ConsoleApp` `download` `[test_case_id] [output_dir]`

download: required parameters

- `test_case_id`: Represents the test case ID.
- `output_dir`: Represents the output directory. The directory must exist.

download: examples

`download 123 c:\temp\rsat`

`download 765 c:\rsat\last`

edit

Allows you to open parameters file in Excel program and edit it.

```
Microsoft.Dynamics.RegressionSuite.ConsoleApp edit [excel_file]
```

edit: required parameters

- `excel_file`: Must contain a full path to an existing Excel file.

edit: examples

```
edit c:\RSAT\TestCase_123_Base.xlsx
```

```
edit e:\temp\TestCase_456_Base.xlsx
```

generate

Generates test execution and parameter files for the specified test case in the output directory. You can use the `list` command to get all available test cases. Use any value from the first column as a **test_case_id** parameter.

```
Microsoft.Dynamics.RegressionSuite.ConsoleApp generate [test_case_id] [output_dir]
```

generate: required parameters

- `test_case_id`: Represents the test case ID.
- `output_dir`: Represents the output directory. The directory must exist.

generate: examples

```
generate 123 c:\temp\rsat
```

```
generate 765 c:\rsat\last
```

generatederived

Generates a new test case, derived from the provided test case. You can use the `list` command to get all available test cases. Use any value from the first column as a **test_case_id** parameter.

```
Microsoft.Dynamics.RegressionSuite.ConsoleApp generatederived
[parent_test_case_id] [test_plan_id] [test_suite_id]
```

generatederived: required parameters

- `parent_test_case_id`: Represents the parent test case ID.
- `test_plan_id`: Represents the test plan ID.
- `test_suite_id`: Represents the test suite ID.

generatederived: examples

```
generatederived 123 8901 678
```

generatetestonly

Generates only test execution file for the specified test case in the output directory. You can use the `list` command to get all available test cases. Use any value from the first column as a **test_case_id** parameter.

```
Microsoft.Dynamics.RegressionSuite.ConsoleApp generatetestonly [test_case_id] [output_dir]
```

generatetestonly: required parameters

- `test_case_id`: Represents the test case ID.
- `output_dir`: Represents the output directory. The directory must exist.

generatetestonly: examples

```
generatetestonly 123 c:\temp\rsat
```

```
generatetestonly 765 c:\rsat\last
```

generatetestsuite

Generates all test cases for the specified suite in the output directory. You can use `listtestsuitenames` command to get all available test suits. Use any value from the column as a **test_suite_name** parameter.

`Microsoft.Dynamics.RegressionSuite.ConsoleApp` `generatetestsuite` `[test_suite_name] [output_dir]`

generatetestsuite: required parameters

- `test_suite_name`: Represents the test suite name.
- `output_dir`: Represents the output directory. The directory must exist.

generatetestsuite: examples

```
generatetestsuite Tests c:\temp\rsat
```

```
generatetestsuite Purchase c:\rsat\last
```

help

Identical to the ? command.

list

Lists all available test cases.

`Microsoft.Dynamics.RegressionSuite.ConsoleApp` `list`

listtestplans

Lists all available test plans.

`Microsoft.Dynamics.RegressionSuite.ConsoleApp` `listtestplans`

listtestsuite

Lists test cases for the specified test suite. You can use `listtestsuitenames` command to get all available test suites. Use any value from first column as **suite_name** parameter.

`Microsoft.Dynamics.RegressionSuite.ConsoleApp` `listtestsuite` `[suite_name]`

listtestsuite: required parameters

- `suite_name`: Name of the desired suite.

listtestsuite: examples

```
listtestsuite "sample suite name"
```

```
listtestsuite NameOfTheSuite
```

listtestsuitenames

Lists all available test suites.

`Microsoft.Dynamics.RegressionSuite.ConsoleApp` `listtestsuitenames`

playback

Plays back a test case using an Excel file.

`Microsoft.Dynamics.RegressionSuite.ConsoleApp` `playback` `[excel_file]`

playback: required parameters

- `excel_file`: A full path to the Excel file. File must exist.

playback: examples

```
playback c:\RSAT\TestCaseParameters\sample1.xlsx
```

```
playback e:\temp\test.xlsx
```

playbackbyid

Plays back multiple test cases at once. You can use the `list` command to get all available test cases. Use any value from the first column as a **test_case_id** parameter.

`Microsoft.Dynamics.RegressionSuite.ConsoleApp` `playbackbyid`
`[test_case_id1] [test_case_id2] ... [test_case_idN]`

playbackbyid: required parameters

- `test_case_id1` : ID of exisiting test case.
- `test_case_id2` : ID of exisiting test case.
- `test_case_idN` : ID of exisiting test case.

playbackbyid: examples

```
playbackbyid 878
```

```
playbackbyid 2345 667 135
```

playbackmany

Plays back many test cases at once, using Excel files.

```
Microsoft.Dynamics.RegressionSuite.ConsoleApp playbackmany [excel_file1] [excel_file2] ... [excel_fileN]
```

playbackmany: required parameters

- `excel_file1` : Full path to the Excel file. File must exist.
- `excel_file2` : Full path to the Excel file. File must exist.
- `excel_fileN` : Full path to the Excel file. File must exist.

playbackmany: examples

```
playbackmany c:\RSAT\TestCaseParameters\param1.xlsx
```

```
playbackmany e:\temp\test.xlsx f:\rsat\sample1.xlsx c:\RSAT\sample2.xlsx
```

playbacksuite

Plays back all test cases from the specified test suite. You can use `listtestsuitenames` command to get all available test suites. Use any value from first column as **suite_name** parameter.

```
Microsoft.Dynamics.RegressionSuite.ConsoleApp playbacksuite [suite_name]
```

playbacksuite: required parameters

- `suite_name` : Name of the desired suite.

playbacksuite: examples

```
playbacksuite suiteName
```

```
playbacksuite sample_suite
```

quit

Closes the application.

```
Microsoft.Dynamics.RegressionSuite.ConsoleApp quit
```

upload

Uploads all files belonging to the specified test suite or test cases.

```
Microsoft.Dynamics.RegressionSuite.ConsoleApp upload [suite_name] [testcase_id]
```

upload: required parameters

- `suite_name` : All files belonging to the specified test suite will be uploaded.
- `testcase_id` : All files beloning to the specified test case(s) will be uploaded.

upload: examples

```
upload sample_suite
```

```
upload 123
```

```
upload 123 456
```

uploadrecording

Uploads only recording file belonging to the specified test cases.

```
Microsoft.Dynamics.RegressionSuite.ConsoleApp uploadrecording [testcase_id]
```

uploadrecording: required parameters

- `testcase_id`: Recording file belonging to the specified test cases will be uploaded.

uploadrecording: examples

`uploadrecording 123`

`uploadrecording 123 456`

usage

Shows two ways to invoke this application: one using a default setting file, another one providing a setting file.

`Microsoft.Dynamics.RegressionSuite.ConsoleApp` `usage`

Windows PowerShell examples

Run a test case in a loop

You have a test script that creates a new customer. Via scripting, this test case can be run in a loop by randomizing the following data before each iteration is run:

- Customer ID
- Customer name
- Customer address

The customer ID will be in the format *ATCUS<number>*, where <number> is a value between **000000001** and **999999999**.

The following example uses one parameter, **start**, to define the first number that is used. Is uses a second parameter, **nr**, to define the number of customers that must be created. For each iteration, the parameters in the Excel parameter file are changed by using an UpdateCustomer function. Then the RSAT command line is called in a RunTestCase function.

Open Microsoft Windows PowerShell Integrated Scripting Environment (ISE) in admin mode, and paste the following code into the window that is named **Untitled1.ps1**.

```
param ( [int]$start = 1, [int]$nr = 1 )
function UpdateCustomer
{
    param ([string]$paramFilename, [string]$sheetName, [string]$CustId)
    $xl = New-Object -COM "Excel.Application"
    $xl.Visible = $false
    $wb = $xl.Workbooks.Open($paramFilename)
    $ws = $wb.Sheets.Item($sheetName)
    $ws.Cells.Item(3, 2).Value = "ATCUS" + $CustId
    $ws.Cells.Item(4, 2).Value = "Automated Test Customer " + $CustId
    $ws.Cells.Item(8, 2).Value = "Automated Test Street " + $CustId
    $wb.Save()
    $wb.Close()
    $xl.Quit()
    [System.Runtime.Interopservices.Marshal]::ReleaseComObject($xl)
}
function RunTestCase
{
    param ( [string]$filename )
    $cmd = "cd c:\Program Files (x86)\Regression Suite Automation Tool\ &&  "
    $cmd = $cmd + "Microsoft.Dynamics.RegressionSuite.ConsoleApp.exe playback "
    $cmd = $cmd + $filename
    cmd /c $cmd
}
$excelFilename = "full path to Excel parameter file"
l$sheetName = "DirPartyQuickCreateForm"
for ($i = $start; $i -lt $start + $nr; $i++ )
{
    $CustomerId = $i.ToString("000000000")
    Write-Host "customer : " $CustomerId
    UpdateCustomer $excelFilename $sheetName $CustomerId
    RunTestCase $excelFilename
```

Run a script that depends on data in Microsoft Dynamics 365

The following example uses an Open Data Protocol (OData) call to find the order status of a purchase order. If the status isn't **invoiced**, you can, for example, call an RSAT test case that posts the invoice.

```
function Odata_Get
{
    Param ( [string] $environment, [string] $cmd )
    [Net.ServicePointManager]::SecurityProtocol = [Net.SecurityProtocolType]::Tls12
    $tenant = "your tenant"
    $creds = @{
        grant_type = "client_credentials"
        client_id = "your client application Id"
        client_secret = "your client secret"
        resource = $environment
    }
    $headers = $null
    $bearer = Invoke-RestMethod https://login.microsoftonline.com/$tenant/oauth2/token -Method Post -Body
$creds -Headers $headers;
    $headers = @{
        Authorization = "Bearer " + $bearer.access_token
    }
    $Odata_cmd = $environment + '/data/' + $cmd
    return (Invoke-RestMethod -Uri $Odata_cmd -Method Get -Headers $headers -ContentType application/json )
}
function PurchaseOrderStatus
{
    Param ( [string] $environment, [string] $purchaseOrderNumber )
    $cmd = 'PurchaseOrderHeaders?$filter=PurchaseOrderNumber eq '
    $cmd = $cmd + "'" + $purchaseOrderNumber + "'"
    $response = Odata_Get -environment $environment -cmd $cmd
    return $response.value.PurchaseOrderStatus
}
$environment = "https://your environment"
$orderStatus = PurchaseOrderStatus -environment $environment -purchaseOrderNumber '000003'
if ($orderStatus -eq $null) {   write-host 'doesn''t exist'}
elseif ($orderStatus -ne 'invoiced') { RunTestCase "PostInvoice" }
```

Regression suite automation tool best practices

2/18/2021 • 5 minutes to read • Edit Online

This topic describes best practices and common use cases of the Regression suite automation tool (RSAT) and Task recorder.

Author test cases using the Task recorder

When you author task recordings for RSAT, follow these practices:

1. Make sure all your recordings start on the main dashboard.
2. Keep individual recordings short and focus on a business task performed by one user, like creating a sales order. This simplifies maintainability and reusability of test cases.
3. Chart controls are not supported. Any task recording actions related to charts will be ignored by RSAT during test case playback.
4. When creating a recording, make sure to select a tab header even if the tab is already open. For example, you can switch to another tab and then select the needed tab again to activate it before using a control on it. This will make your recording more reliable during test case playback.
5. RSAT cannot play back any test step that is not recognized by the task recorder. For example, you cannot upload a file from the local disk during play back of a test case.
6. RSAT cannot play back a **page refresh** step. Avoid refreshing a page while recording your test.

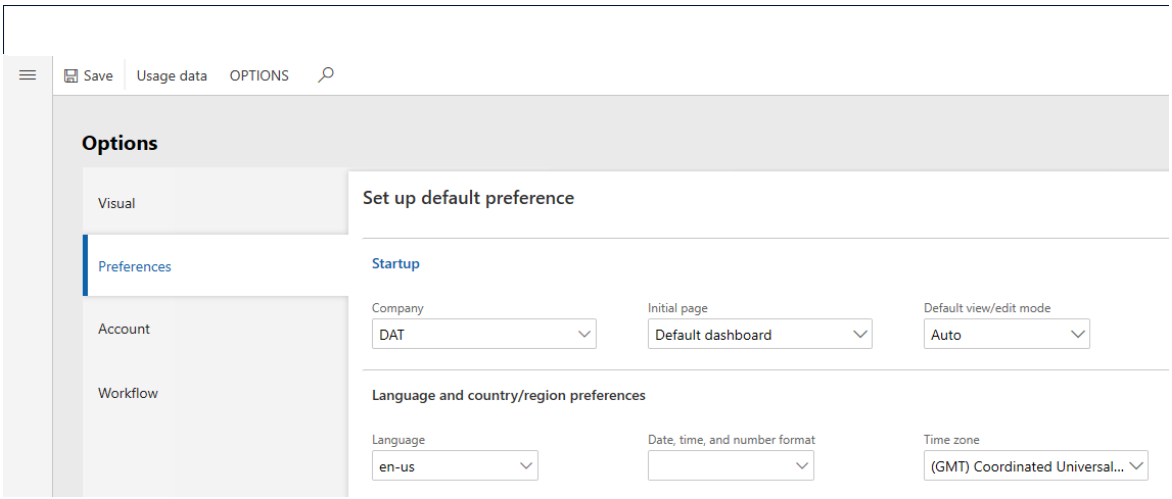
Best practices when using the Regression suite automation tool

1. Upon opening the tool for the first time, select **Settings** and ensure that you have all the needed settings.
2. Before installing a new version of the tool, it is recommended to close and uninstall the previous version.
3. When you install a new version of the tool, regenerate **all** test execution files.

   It is not necessary to regenerate Microsoft Excel parameter files unless you want to take advantage of new features available in a newer format of parameter files.

4. For test parameters that need a unique value, for example, the product receipt number in the **Product Receipt** form or the invoice number in the **Vendor Invoice** form, use the **RandBetween(a,b)** Excel function to generate a unique number every time the test case is executed.
5. The default values in Excel come from the task recording. For **Reference Group** controls such as storage dimensions or tracking dimensions, it stores the key of the lookup instead of the value, for example, 2 instead of **SiteWH**. We recommend that you update these fields with the actual value in Excel so that the test is more robust and resilient to changes.

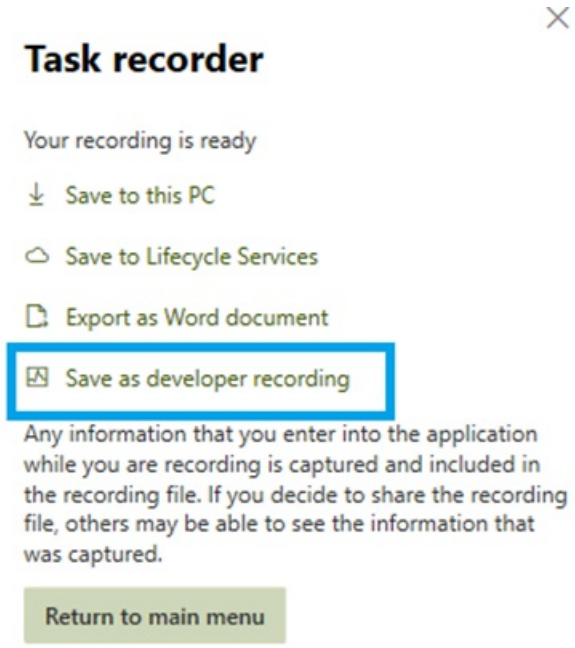
6. It is recommended to set the same locale for **Language** and **Date, time, and number format** settings of your environment prior to running RSAT. If these values are inconsistent, it may result in validation errors.



Manage local recording files

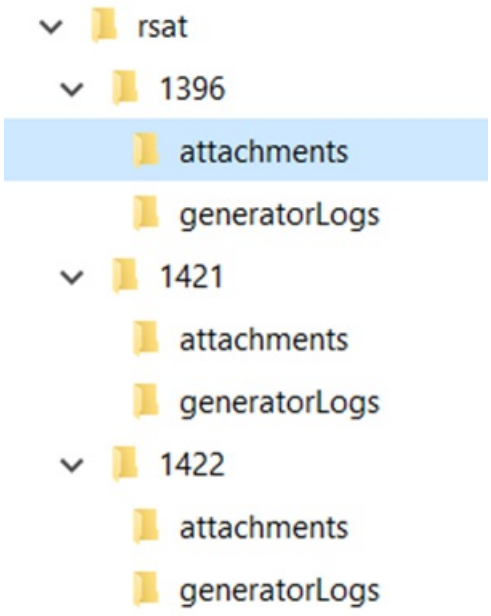
RSAT relies on Azure DevOps to store and manage test recording files (also known as task recordings). When RSAT loads a test plan from Azure DevOps, associated files are downloaded to the current **working directory** on your local computer. (This working directory is defined in RSAT settings.)

In version 1.200.42264.6 and later, it's easier to manage local recording files. You can make changes in Task recorder and then use RSAT to test them, without having to go through the Business process modeler (BPM) or Azure DevOps. When you use Task recorder, after you've finished authoring or modifying a recording, you can save it directly to your local disk as a developer recording.

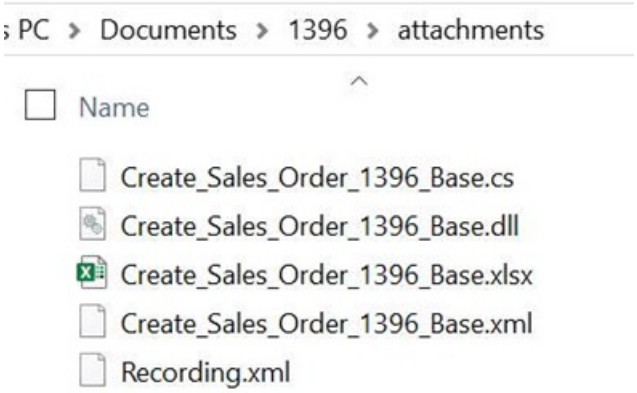


Put the recording file under the working directory that is associated with the test case. For example, if your configured working directory is `C:\Users\<username>\Documents\RSAT`, put the recording file for test case 1234 under `C:\Users\<username>\Documents\RSAT\1234\attachments`. You must name the developer recording file **Recording.xml**. Alternatively, you can name the recording file **-Test Case Title-.xml**, where **-Test Case Title-** is the title of the test case in Azure DevOps.

The following illustration shows an example of a working directory folder structure. You can open the directory directly from RSAT by clicking the folder symbol.



Each test case has its own folder, which is named after the ID of the test case. Test case attachments (recording files, automation files, and Excel parameter files) are downloaded into an attachments folder. Here is an example.



The generatorLogs directory contains log files. It doesn't contain any files that users can modify. You can ignore this directory unless RSAT support explicitly asks you to provide log files from it.

Commit a recording file to Azure DevOps

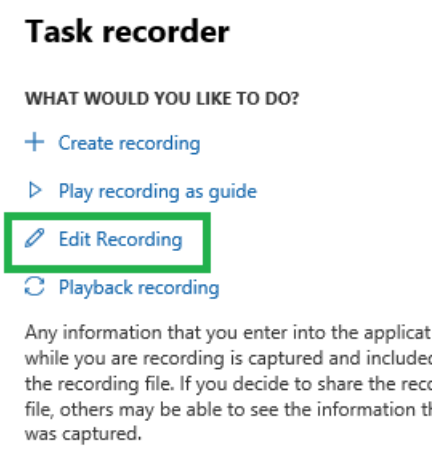
After a recording has been tested and finalized, use RSAT to upload it and commit it to Azure DevOps. The upload button has two options: **Upload automation files** and **Upload recording file**. The second option uploads only your recording file to Azure DevOps.

> **NOTE**
>
> If you're using a version of RSAT that is earlier than 1.200.37255.0, and you upgrade to the latest version, you must reload your test cases from Azure DevOps to download them into the correct directory. Otherwise, RSAT will fail, and you will receive a "File not found" error.
>
> If you're working across several DevOps projects, we recommend that you use a different working directory for each project. Otherwise, attachment files from multiple projects can become commingled in the same directory structure.

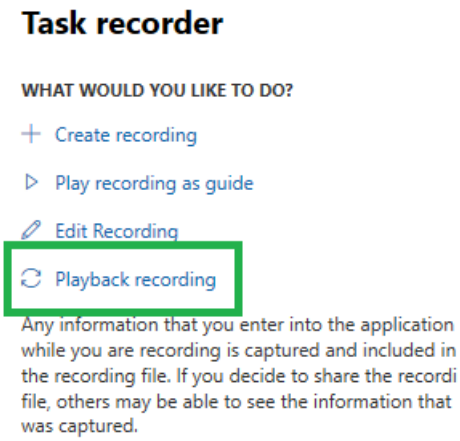
Modify (Edit) a Task recording

If you want to modify an existing task recording, note these best practices.

In the web client, open the Task recorder pane and start editing the recording using the **Edit Recording** option.



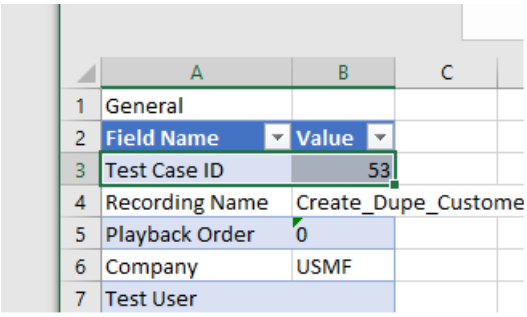
When you've finished editing the recording, play it back in the client, and verify that all the steps work correctly. Playback is required.



After you've finished playing back an edited recording, save it. It's then ready to be used by RSAT.

Copy test cases in Azure DevOps

As you are building your test suites in Azure DevOps, it is handy and common to duplicate test cases along with their attachments. If a copied test case contains an existing Excel parameter file attached, RSAT cannot execute it without manual edits to the Excel file. The **Test Case ID** in the Excel parameter file must match the Azure DevOps test case ID. You will need to edit all copied Excel parameter files. In the following image, the Excel file is associated with Test Case number 53 in Azure DevOps.



As of RSAT version 1.210, this process is easier. To automatically fix all occurrences of a mismatch, select the desired test cases in the grid, and then select **Resolve test case ID mismatch** in the **New** menu.

Can you tell us about your documentation language preferences? Take a short survey.

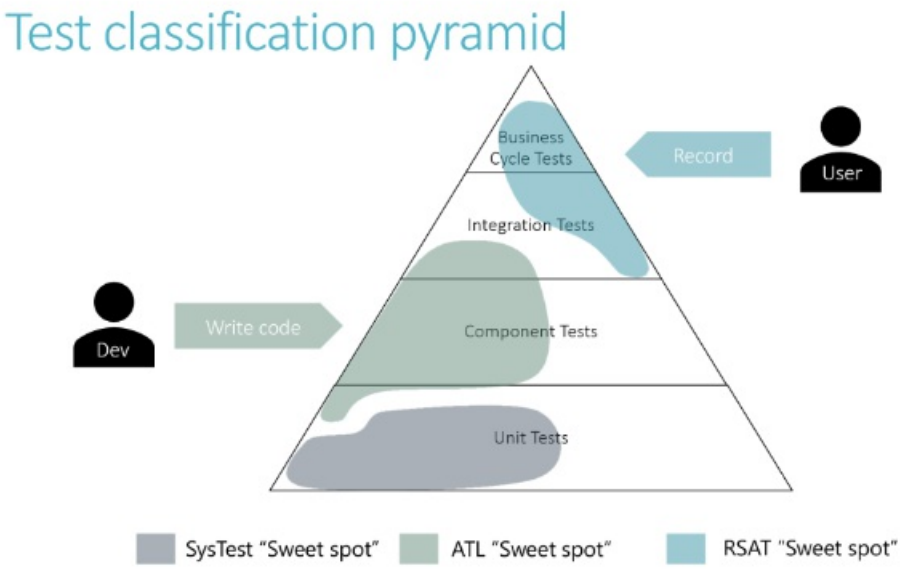
The survey will take about seven minutes. No personal data is collected (privacy statement).

Data agnostic testing using the Regression Suite Automation Tool

2/18/2021 • 2 minutes to read • Edit Online

While the functional validation of an ERP application can't be fully data agnostic, there are multiple phases and approaches for testing. These testing phases include:

- SysTest framework
- ATL frameowrk
- Regression Suite Automation Tool (RSAT)

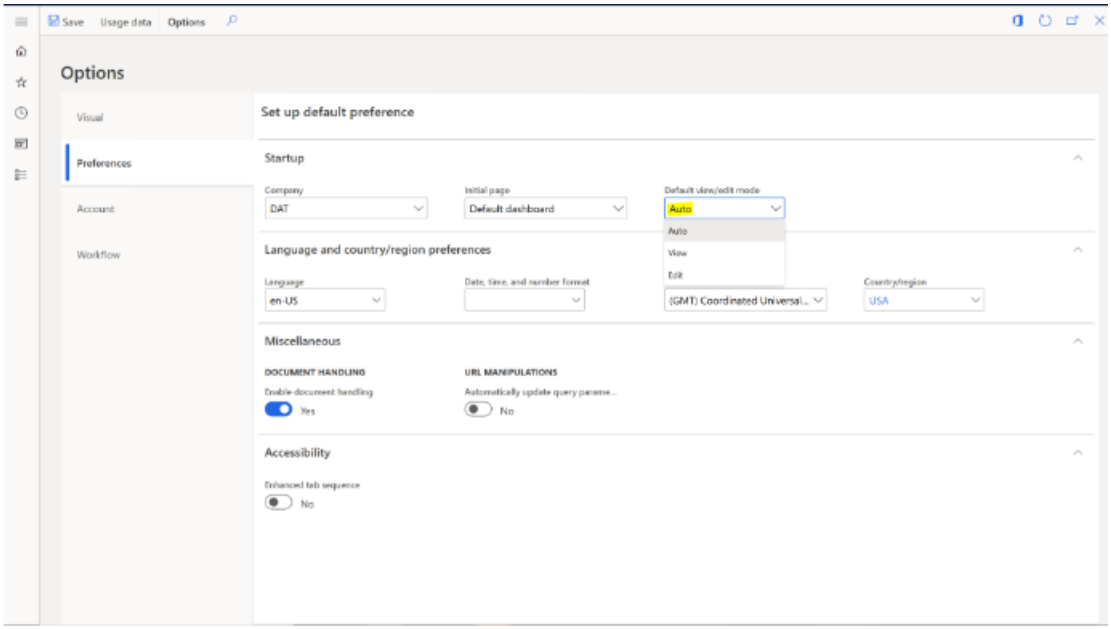


Overview

- **SysTest framework** – The SysTest framework is reliable for writing unit tests. Because unit tests are generally testing a method or function, they should always be data agnostic and dependent only on the input data that is provided as part of the test.
- **ATL framework** – Microsoft has an ATL framework that is an abstraction on the SysTest framework and makes functional test writing much more simple and reliable. This framework should be used for writing component tests or simple integration tests.
- **RSAT** – The RSAT is used for integration tests and business cycle tests. The business cycle tests, also called the regression validation tests, are dependent on existing data. However, these tests can become data agnostic if you consider additional factors.
    - o Where unit tests and component tests are low level and can fully be data agnostic (not dependent on existing dataset), the business cycle or regression validation tests are dependent on some existing data. This data includes setup, configuration settings (parameters), and master data (customer, vendors, items, etc.), but never transaction data. Make sure that during the test, if any of these are being changed, that they are reverted back as part of the final test.
    - Select master data based on certain criteria instead of selecting a particular record. For example, if you

want to select an item based on its dimension values and stock availability, filter the product list with those values, select the first item, and copy the number to be used for future tests. If it's a simple master data line such as customer, vendor, or item, it can be created as part of the automation and used in future tests through chaining.

- o Enter the unique identifiers, such as invoice numbers, through the number sequence or by using Microsoft Excel functions such as =TEXT(NOW(),"yyyymmddhhmm"). This function will provide a unique number every minute, which allows you to track when the action happened. This can be used for variables such as product receipt numbers and vendor invoice numbers. These tests continue to work on the same database again and again, without requiring any restoration.
- Always set the **Edit mode** of the environment to **Read** or **Edit** as the first test case because the default option is **Auto**. The **Auto** options always uses the previous setting and can cause unreliable tests.



- Only validate after you filter on a particular transaction instead of generic validation. For example, for the number of records, filter for the transaction number or the transaction date so that the validation excludes all other transactions.
- If you are checking a customer balance or budget check, save the value first and then add your transaction value to validate the expected result instead of validating a fixed expected value.

NOTE

Can you tell us about your documentation language preferences? Take a short survey.

The survey will take about seven minutes. No personal data is collected (privacy statement).

Troubleshoot the Regression suite automation tool

2/18/2021 • 5 minutes to read • Edit Online

This topic contains information about how to troubleshoot the Regression suite automation tool (RSAT).

Playback logs

To troubleshoot issues that happen during playback of a test case, open the developer error log located at **[RSAT working directory]\[test case ID]\playback\[TestName]Log.txt**. The RSAT working directory is the directory specified in the RSAT settings dialog. Analyze the error message to determine the possible cause of a failure.

> **NOTE**
>
> For RSAT versions prior to 1.210, the log is located at **C:\Users\[YourUserName]\AppData\Roaming\regressionTool\playback\[TestName]Log.txt**.

Generator logs

To troubleshoot errors when generating test execution and parameter files, enable generator logs.

Open the **Microsoft.Dynamics.RegressionSuite.WindowsApp.exe.config** file under the RSAT installation folder (for example, **C:\Program Files (x86)\Regression Suite Automation Tool**), and change the value in the following element from **false** to **true**.

```
<add key="LogGeneration" value="true" />
```

After test execution files are generated, you can find the log file under **[RSAT working directory]\[test case ID]\generatorLogs**

> **NOTE**
>
> For RSAT versions prior to 1.210, the logs are generated under **C:\Users\[Username]\AppData\Roaming\regressionTool\generatorLogs**.

Authentication certificate and installation

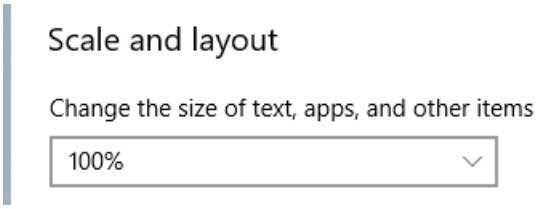
- The authentication certificate must be created and installed by an administrator on the same computer where RSAT is installed. If it is not created by an admin, you will encounter the following error message when you try to run a test case.

```
Cannot access Finance and Operations environment. Verify your settings and make sure the environment is
available.
```

- If you have used a previous version of RSAT on the same computer, close it and uninstall it before installing a new version.

Screen resolution when using Internet Explorer

If you have selected Internet Explorer as your browser, your desktop resolution should be set to 100% to run the tests successfully. To change the settings, use Windows **Display settings > Scale and layout**, as shown in the following image:



Test playback errors

SOAP or HTTP request errors

If you are testing against a Standard Acceptance Test Sandbox environment (Tier2) or any other multi-box environment, and you may receive one of the following errors when you run a test.

```
There was no endpoint listening at
https://<yourURL>soap.sandbox.operations.dynamics.com/Services/AxUserManagement/Service.svc/ws2007FedHttp
that could accept the message. This is often caused by an incorrect address or SOAP action…

An error occurred while making the HTTP request to
<Hostname>/Services/AxUserManagement/Service.svc/ws2007FedHttp. This could be due to the fact that the
server certificate is not configured properly with HTTP.SYS in the HTTPS case. This could also be caused by
a mismatch of the security binding between the client and the server.
```

Assuming that you have specified the correct SOAP hostname in the RSAT settings dialog box, run the following PowerShell scripts on your client computer where the test tool is installed.

```
Set-ItemProperty HKLM:\SOFTWARE\Microsoft\.NETFramework\v4.0.30319 -Name SchUseStrongCrypto -Value 1 -Type
dword -Force -Confirm:$false

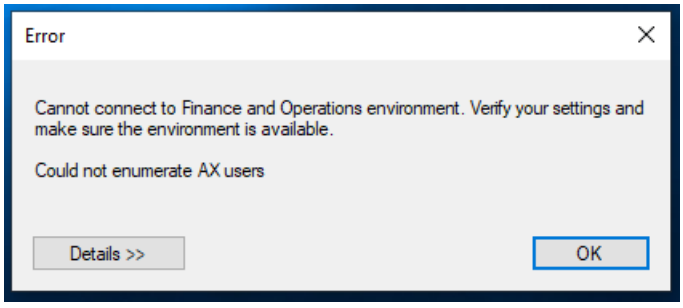
if ((Test-Path HKLM:\SOFTWARE\Wow6432Node\Microsoft\.NETFramework\v4.0.30319))  { Set-ItemProperty
HKLM:\SOFTWARE\Wow6432Node\Microsoft\.NETFramework\v4.0.30319 -Name SchUseStrongCrypto -Value 1 -Type dword
-Force -Confirm:$false}
```

You can also manually set the registry keys.

Cannot enumerate AX users error

You may receive the following error when running a test case, or the error details may contain the following messages.

```
<Message>The type initializer for
'MS.Dynamics.TestTools.CloudCommonTestUtilities.Authentication.UserManagement' threw an exception.</Message>
<Message>Could not enumerate AX users</Message>  (InnerError)`
```



To resolve this error, verify the **Admin user name** specified in the RSAT settings dialog box. The **Admin user**

name must be the email address of a user that belongs to the System Administrator role on the Finance and Operations test environment that RSAT is connecting to. The user account (e-mail address) must also belong to the same tenant as the test environment. For example, if your test environment's tenant is **contoso.com**, the admin user must end with **@constoso.com**.

Unsecured fault exception

If a test case inconsistently fails with the following error, this usually indicates an incomplete configuration of the authentication thumbprints on the AOS virtual machines.

```
<Message>An unsecured or incorrectly secured fault was received from the other party. See the inner
FaultException for the fault code and detail.</Message>
<Message>At least one security token in the message could not be validated.</Message>
```

Typically, this error happens when the test environment has not been configured to trust the certificate that RSAT is using for authentication. (The certificate is identified by the thumbprint specified in your RSAT settings.) For example, the thumbprint could be missing in the wif.config file on the AOS virtual machine of the test environment. If you are running against a standard acceptance test environment (Tier 2 or higher), you might not have configured the authentication thumbprint on all of the AOS virtual machines. Make sure you properly add the thumbprint to the **wif.config** file on all of the AOS machines. For more information, see Configure the test environment to trust the connection.

We have also seen this error when there is a mismatch between the UTC time between the client computer (where RSAT is installed) and the Finance and Operations environment. This is a rare case and only happens if your administrator has incorrectly configured the UTC time. The client computer and Finance and Operations environment can be on different time zones; however, the UTC time on both environments must match because the authentication mechanism relies on this comparison.

Google Chrome Browser

The Google Chrome browser may not work with the Regression suite automation tool due to your Active Directory security settings. In this case, change your RSAT settings to use the new Microsoft Edge or Internet Explorer.

Validating blank dates

If your test case requires validation that a certain control of type Date/Time is blank, you can insert the following value into the Excel cell corresponding to this control: "01/01/1900".

Azure DevOps connectivity

You might you see this error when you select the desired Azure DevOps project in RSAT settings: "The structure path <iteration path> is not valid. Verify your settings and try again". To resolve this error, open the project in Azure DevOps and navigate to the Test Plans. Verify the iteration path defined for each test plan. If the iteration path is similar to what is shown in the error, remove the existing iteration path and add a new one for the test plan and save.

Requirements for publishing apps on AppSource

2/18/2021 • 2 minutes to read • Edit Online

Lifecycle Services (LCS) solution packages for Microsoft AppSource are partner-designed and developed solutions that can be automatically deployed on Microsoft Azure to deliver an end-to-end solution, using industry and vertical-specific content.

This topic points to resources that will help you understand the requirements for creating LCS solutions for Microsoft AppSource. The requirements for creating an LCS solution package fall into the following groups.

- App validation
- Code migration
- Database backup and Data packages
- Business process models
- Methodologies
- Marketing

NOTE

Can you tell us about your documentation language preferences? Take a short survey.

The survey will take about seven minutes. No personal data is collected (privacy statement).

Add methodologies to solutions

2/18/2021 • 2 minutes to read • Edit Online

This topic explains how to create and modify methodologies in Microsoft Dynamics Lifecycle Services (LCS). It also provides information about the requirements for methodologies.

Methodology requirements

The first two phases of your methodology are the Learn and Consume phases from the LCS Solutions Consumption methodology.

During the Learn phase, your product description must be aligned with your business process library, the descriptions or summaries in your marketing material, and the functionality that is supported in the current version of your solution. The Learn phase includes the following tasks:

- **Product description** – Take advantage of your marketing description by adding it to the LCS methodology.
- **Get an overview** – Include content for your solution, such as information about the features and architecture.
- **How to get help** – Include numbers, contacts, or direct links to your company's website, for people who help build and maintain the solution.

The Consume phase is **optional**. It includes tasks that are required in order to complete Conference room pilot 1 (CRP1).

After the Learn and Consume phases, you can add any other steps that are required in order to implement your solution. You can either modify the phases and tasks so that they are aligned with your solution, or use your company's implementation methodology.

Create a new methodology

1. On the LCS home page, select the **Manage methodologies** tile.
2. Select the **New methodology** button (the plus sign [+]).
3. Set values for the fields, and then select **Confirm**.
4. Create phases and tasks.
5. Add any linked tools and resources that are required.

Edit a methodology

1. On the LCS home page, select the **Manage methodologies** tile.
2. Select the methodology to edit.
3. Select the **Edit methodology** button (the pencil symbol), and edit the methodology.

Edit a project's methodology

Follow these steps to edit a methodology in a specific project only.

1. On the project's home page, select the ellipsis (...) button above the project phases, and then select **Edit methodology**.
2. Edit the phases and tasks.
3. Edit the linked tools and resources, if any changes are required.

Change a project's methodology

1. On the project's home page, click the ellipsis (...) button above the project phases, and then click **Change methodology**.
2. In the dialog box that appears, set the **Do you want to keep the existing phases and tasks?** option. If you set this option to **Yes**, the phases and tasks from the methodology that you select in step 3 are added to the end of the current methodology. If you set the option to **No**, the current methodology is replaced with the methodology that you select in step 3.
3. Select a methodology to use with your project.
4. Select **Confirm**.

Additional resources

Requirements for publishing apps on AppSource

Set up Business process modeler libraries

2/18/2021 • 5 minutes to read • Edit Online

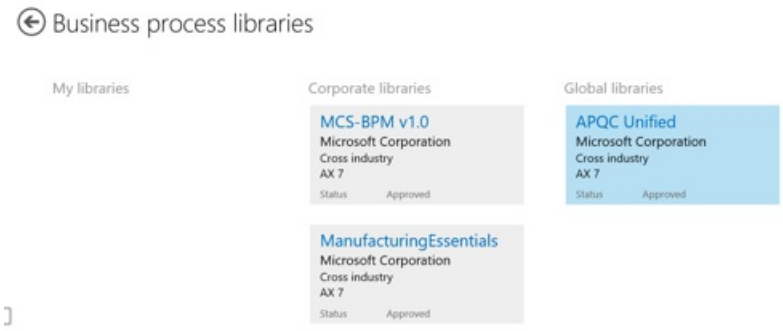
This topic explains how to create and work with Business process modeler (BPM) libraries.

Create a business process library

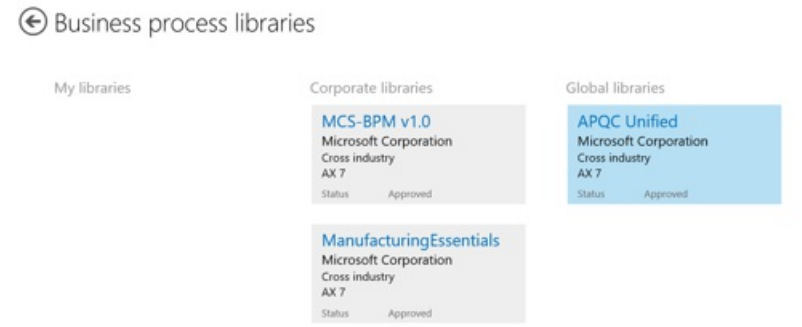
There are two ways to create a BPM library. You can create a new library that has no lines or task recordings, or you can copy an existing library.

1. In Microsoft Dynamics Lifecycle Services (LCS), open a project, scroll to the right until you see the **More tools** section, and then select the **Business process modeler** tile. The **Business process libraries** page that appears has three sections, one for each type of library:

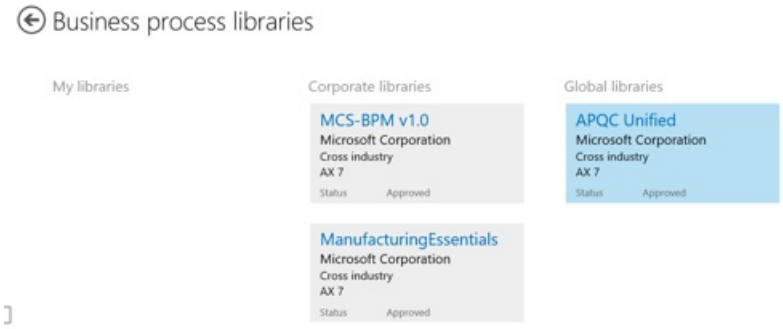
   - **My libraries** – Business processes that users have created or added.
   - **Corporate libraries** – Custom business processes that someone in your organization has uploaded.
   - **Global libraries** – Cross-industry standard business processes.



2. To create a new library, right-click any library, and then, in the lower-left corner of the window, select **Create**. To copy an existing library, right-click that library, and then, in the lower-left corner of the window, select **Copy**.



- **Global libraries** – Cross-industry standard business processes.



3. Enter a name for the library.

The library that you created now appears under **My libraries**.

Update, publish, or delete a business process library

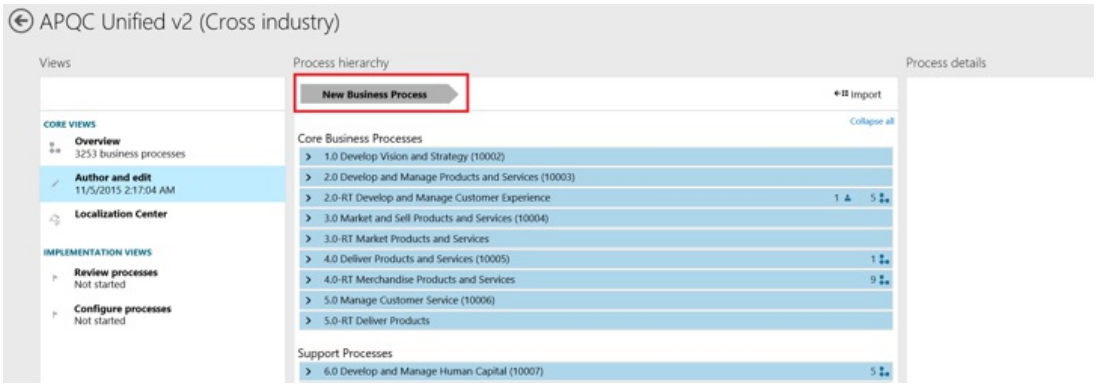
You can change the name or description of a library, publish a library so that other people in your organization can view it, or delete a library.

- On the **Business process libraries** page, right-click the library to update, publish, or delete. Then, in the lower-left corner of the window, select **Edit**, **Publish**, or **Delete**.
  - **Edit** lets you change the name and description of the library.
  - **Publish** creates a copy of the library under **Corporate libraries**. This library will be available to everyone in your organization.
  - **Delete** deletes the library and any information that is stored in it.

Modify a business process library

Follow these steps to change or update the business process lines or hierarchy in your business process library.

1. Select and open the library to update.
2. In the left pane, under **Core views**, select **Author and edit**.
3. Follow one or more of these steps to make the required changes:
   - To rearrange the hierarchy of the business process lines, drag the processes in the hierarchy.
   - To delete a node, select a business process in the center pane, and then select **Delete** in the right pane.
   - To create a new node, drag the **New Business Process** flag at the top of the center pane to the place in the hierarchy where the new node should appear.

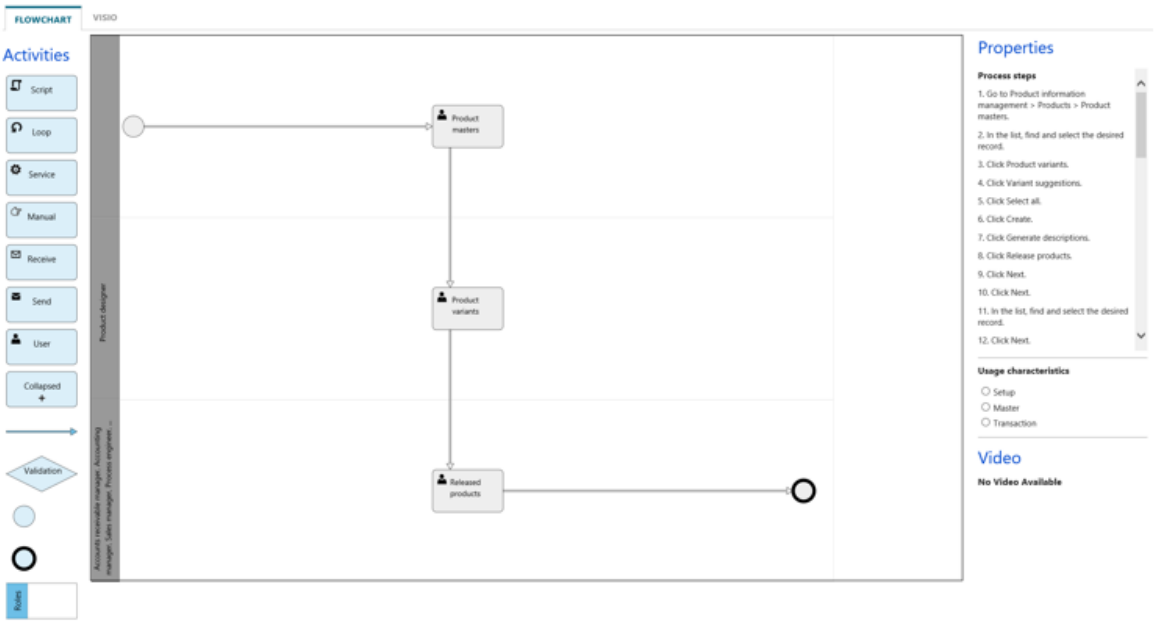


- To import business processes from existing business process libraries, follow these steps:

    a. Select **Import** in the center pane.
    b. On the right side of the page that appears, select the library to import business processes from.
    c. Drag the required business processes into the hierarchy on the left side of the page.

View and modify task recordings in a business process library

1. Open the library that you want to work in.
2. Navigate to the business process line that has a task recording associated with it, and select the link.
3. Drag the tiles under **Activities** to manually modify the flow chart.



4. To upload a Microsoft Visio diagram of the modified flow chart, select the **Visio** tab.

Structure a business process library

There are two sections in business process libraries: **Core Business Processes** and **Support Processes**. The **Core Business Processes** section should include all custom business processes for your solution. All customizations and functionality should be covered in end-to-end scenarios. Task recordings should be created for all processes in this section. Import American Productivity & Quality Center (APQC) processes that are relevant to your solution into the **Support Processes** section. This section should not include any custom business processes. You don't have to create task recordings for processes in this section. Your business process library should be aligned with the descriptions and summaries in your methodology and your marketing material.

Create a task recording and associate it with a business process

Task recordings should be created in an environment that has your custom data and customizations. For reference information about Task recorder, see Task recorder resources.

Create a task recording

1. In your application, select the **Settings** button in the upper-right corner, and then select **Task recorder**.
2. Select **Create recording**.
3. Enter a name and description for the recording.
4. Perform the task that you want to record.

5. When you've completed the task, select **Stop**.
6. If you want to upload your new task recording to LCS, continue to the next section. To save your recording to your local computer or convert the recording to a Microsoft Word document, select the appropriate option.

Associate a task recording with a business process

1. Select **Save to LCS**.
2. Select a business process library.
3. Select the business process line to associate with the recording.
4. Select **OK**.

You can now view the task recording in the business process library in LCS.

Set up and use task guides

Task recordings can be played as task guides. Task guides are used to guide users through the steps for completing business processes. Before you set up and use task guides, create task recordings, and save them to a business process library in LCS.

Set up task guides

1. In your application, select **System administration** > **Setup** > **System parameters**.
2. On the **Help** tab, select the LCS project where the business process library that you want to work with is stored.
3. Select the business process libraries that have the task recordings that you want to play as task guides.
4. Adjust the order of the business process libraries as you require. The order of the business process libraries determines the order that the task guides appear in. Therefore, the task guides for the first business process library appear first when a user uses the task guide functionality.

Use task guides

1. In your application, open the page where you want to run the task guide.
2. In the upper-right corner, select the **Settings** button, and then select **Task recorder**.
3. Select a task guide.
4. Select **Start Task guide**.
5. Follow the steps in the task guide. If you select **Unlock**, you can work without following the task guide.
6. When you've finished, select **Stop Task guide**.

Migrate code for Finance and Operations apps solutions

2/18/2021 • 2 minutes to read • Edit Online

To complete your solution package, the first step is to upgrade your code by using the best practices in **Migrate and Create Finance and Operations Apps Solutions** in Microsoft Dynamics Lifecycle Services (LCS). After that step is completed, you must run the Customization Analysis Report (CAR). This report analyzes your customization and extension models, and runs a predefined set of best practice rules.

To generate the CAR, run the following command on a development environment.

```
xppbp.exe -metadata=<local packages folder> -all -model=<ModelName> -xmlLog=C:\BPCheckLogcd.xml -module=
<PackageName> -car=<reportlocation>
```

Here is an example of this command.

```
xppbp.exe -metadata=C:\Packages -all -model=MyAppSuiteCustomizations -xmlLog=C:\temp\BPCheckLogcd.xml -
module=ApplicationSuite -car=c:\temp\CAReport.xlsx
```

The xppbp.exe file is located in c:\packages\bin or I:\AosService\Packages\LocalDirectory\bin. You must resolve any warnings or errors that appear on the **Issues** tab of the report. You must then submit a copy of the CAR to Microsoft before your validation meeting. For more information, see Customization Analysis Report (CAR). For information about issues and exceptions, see the Customization Analysis Report: Exceptions and known issues post on the Dynamics 365 Community blog.

Extensibility

In Microsoft Dynamics 365 for Finance and Operations version 8.0 (April 2018), all product models are sealed. Therefore, only extension-based customizations are currently supported. For more information about extensibility, see Extensibility.

The first step in completing your solution package is to upgrade your code using the best practices in **Migrate and Create Finance and Operations Apps Solutions** in LCS. After this step is complete, you must run the Customization Analysis report. This report analyzes your customization and extension models, and runs a predefined set of best practice rules.

To generate the Customization Analysis report (CAR), run the following command on a development environment.

```
xppbp.exe -metadata=<local packages folder> -all -model=<ModelName> -xmlLog=C:\BPCheckLogcd.xml -module=
<PackageName> -car=<reportlocation>
```

Here's an example of how this command might look.

```
xppbp.exe -metadata=C:\Packages -all -model=MyAppSuiteCustomizations -xmlLog=C:\temp\BPCheckLogcd.xml -
module=ApplicationSuite -car=c:\temp\CAReport.xlsx
```

The xppbp.exe file is located in *c:\packages\bin* or *I:\AosService\Packages\LocalDirectory\bin)*. Any warnings or

errors that appear on the **Issues** tab of the report must be resolved. A copy of the CAR report must be submitted to Microsoft prior to your validation meeting. For more information, see Customization Analysis Report (CAR) or refer to the Dynamics Community blog for issues and exceptions.

Validate applications for Finance and Operations apps

2/18/2021 • 4 minutes to read • Edit Online

This topic provides information about the requirements that are used to verify that custom code meets Microsoft guidelines, and that a solution package can be successfully bundled and delivered in a Finance and Operations apps environment.

Microsoft requires specific reviews in order to validate the following requirements:

- A partner's custom code meets Microsoft guidelines.
- A Microsoft Dynamics Lifecycle Services (LCS) solution package can be successfully bundled and delivered.
- Core independent software vendor (ISV) business scenarios can be transacted.

Currently, partners must demonstrate that these requirements have been met by doing test deployments and then sharing the results with Microsoft. No code will be deployed on a customer environment that Microsoft hasn't validated. Partners must complete the following curation artifacts and tests:

- Code analysis report (CAR)
- Business process modeler (BPM)/test scripts
- Business database backup
- Project name and description
- Data packages
- Methodology
- Binaries (optional)
- Deployable packages
- Models (code and tests)
- Marketing content

Curation meeting

The following table describes the steps that must be completed before the validation meeting.

PHASE	STEP	ACTIVITY	PROCESS STEPS	SUCCESS CRITERIA
1	1	Validate code.	Run all customer model files by using the CAR tool, and then generate the report.	Successfully create a CAR without any localization, accessibility, performance, or security issues.
1	2	Verify user experience (UX) guidelines.	Follow UX guidelines to implement the workspace correctly.	Reference best practice information in the Migrate and Create methodology section of LCS.

PHASE	STEP	ACTIVITY	PROCESS STEPS	SUCCESS CRITERIA
2	3	Validate the solution package in LCS.	Create a solution package in LCS that includes all the required artifacts.	A solution package that has all the required artifacts has been published in LCS, and a globally unique identifier (GUID) has been created for the solution.
2	4	Deploy an environment.	Deploy a standard environment that has partner code, based on the package contents (code, binaries, and configuration).	Successfully deploy at least one Finance and Operations environment without any errors. The environment configuration (including components and the configuration) is the same as the partner's reference environment. A user can successfully sign in to this environment without any errors.
2	5	Configure and deploy data.	Deploy partner-supplied data in the environment without any errors.	Demonstrate that partner-supplied master and reference data was successfully pushed into the environment without any errors.
2	6	Do a sanity check.	After data has been loaded into the environment, users should be able to complete business transactions (as defined in the scope of the solution).	Users can sign in to the data-loaded environment without any errors. Business transactions can be completed, as defined in the package scope, without any errors.

Detailed curation requirements

The following table provides more information about each curation requirement.

REQUIREMENT	DESCRIPTION
CAR	All major issues that the CAR highlights should be addressed after you upgrade. The CAR must be submitted to Microsoft before the validation meeting.
BPM/test scripts	All task recordings should be completed for the industry vertical that the solution package is designed for and should include end-to-end scenarios.

REQUIREMENT	DESCRIPTION
Business database backup	A business database of your upgraded environment and best practice configurations should be loaded into the Asset library in LCS.
Project name and description	The project name and description should be incorporated into the beginning of the implementation methodology for the solution package.
Data packages	All data packages should be loaded into LCS before the validation meeting. Create data entities for any additional custom fields or tables for your custom functional features. You should be able to modify the data packages and load them into an empty environment, and then consume the data packages in Data Management Framework.
Methodology	The methodology should incorporate an overview of the product. A guided experience to Conference Room Pilot 1 (CRP1) and any other implementation methodology that is specifically tailored to your solution are optional.
Binaries (optional)	Incorporate any required binary files.
Deployable packages	Incorporate the deployable packages that are required in order to bring your custom features and functionality into your environment.
Models (code and tests)	Incorporate any model files that are required for your solution.
Marketing content	Add your marketing content, such as logos, descriptions, and screen shots of your solution package. The solution logo should be app-specific and should not include your company name. The description should be aligned with your custom business processes.

Update and maintenance requirements

If you have a curated solution that is published on AppSource, you must keep the solution up to date. After each major Spring and Fall release, you will have eight weeks to upgrade your code. You must update and test the following artifacts:

- CAR
- Models (code and tests)
- Deployable packages
- BPM/test scripts
- Data packages
- Business database backup

Maintenance process steps

PHASE	NUMBER	ACTIVITY	PROCESS STEPS	SUCCESS CRITERIA

PHASE	NUMBER	ACTIVITY	PROCESS STEPS	SUCCESS CRITERIA
1	1	Validate customer code.	Run all customer model files by using the CAR tool, and generate the report.	Successfully create a CAR without any localization, accessibility, performance, or security issues. All major issues that the CAR highlights should be addressed after you've upgraded to the latest major release. The CAR must be submitted to Microsoft within eight weeks after each major Spring and Fall release.

The survey will take about seven minutes. No personal data is collected (privacy statement).

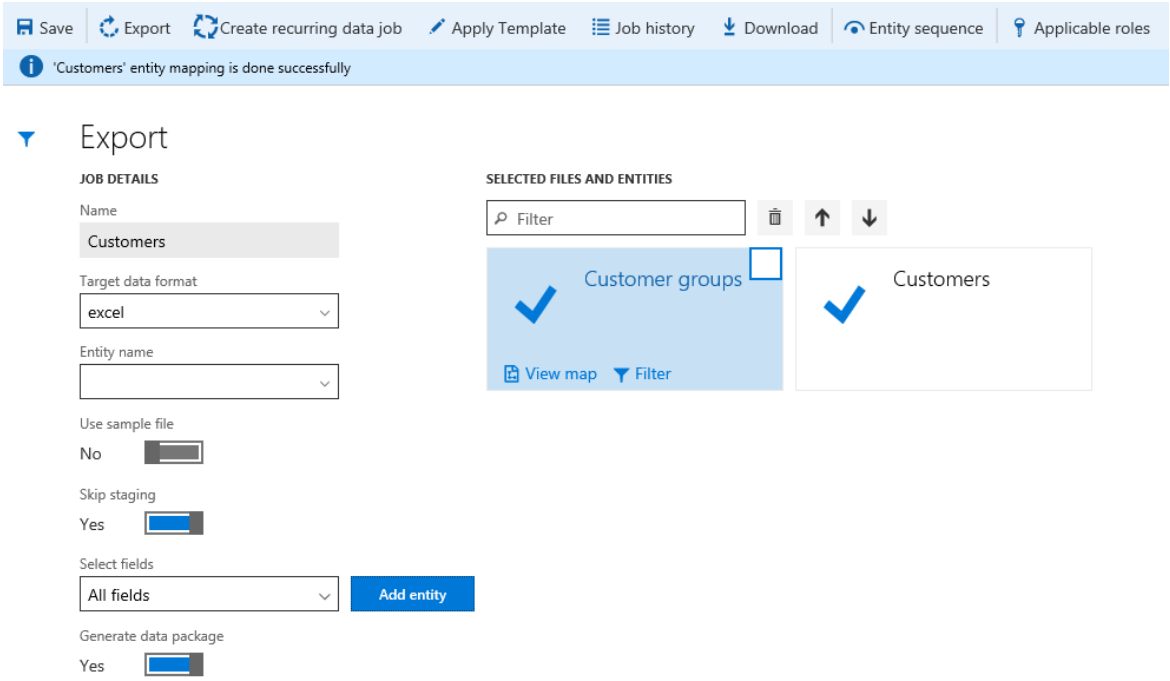
Process and consume data packages in Dynamics 365 Finance and Operations apps solution

2/18/2021 • 10 minutes to read • Edit Online

A data package for a Dynamics 365 Finance and Operations app can consist of one or many data entities. A typical data package consists of a group of entities for a specific task, process, or function. For example, the data entities that are required for general ledger setup might be part of one data package. The format of a data package is a compressed file that contains a package manifest, a package header, and any additional files for the data entities that are included.

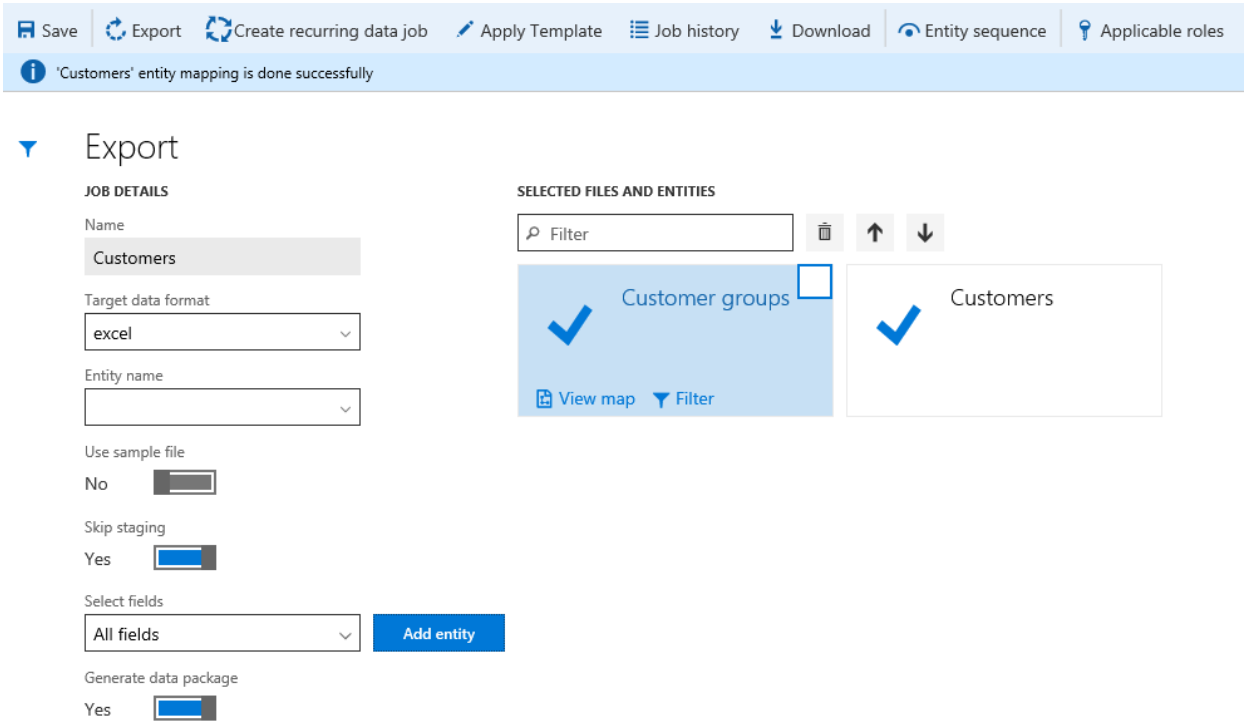
Before you create your data package, plan out what it should include. In this way, you help guarantee that the correct entities, entity sequence, and fields are included. You create a data package by using the **Data management** workspace in your application. Follow these steps to create a data package.

1. In the application, select **System administration** > **Workspaces** > **Data Management IT**.
2. Select the **Export** tile, and then, in the **Name** field, enter **Data project**.
3. In the **Target data format** field, select the format for the export. The data formats that are available include comma-separated value (CSV) format and Microsoft Excel format.
4. In the **Entity name** field, enter or select an entity. You can add multiple entities, but you must add each entity separately.
5. In the **Select fields** field, select a field setting, and then click **Add entity** to add the entity to the project.
6. Repeat steps 4 and 5 to add more entities to the project. **Note:** As you add each entity to the project, a tile appears that contains the entity's name and two buttons: **View map** and **Filter**. To automatically create a data package when you export the data project, set the **Generate data package** option to **Yes**. If you don't set this option, you can create a data package at the time of export.
7. On the Action Pane, click **Export**.
8. Click **Download**. The package is saved to the **Downloads** folder of the computer where the browser session is running. When you work with data packages, you must plan for and consider any prerequisites for the entities that will be included in the packages. For example, the customer groups are required in order to create customers. Therefore, you should either import the customer groups into a package before you import customers, or sequence customer groups within a data package that will be completed before customers are imported. For example, in the following illustration, sequencing is set within the data package. As you can see, the Customer groups entity and Customers entity are part of the Customers data project.

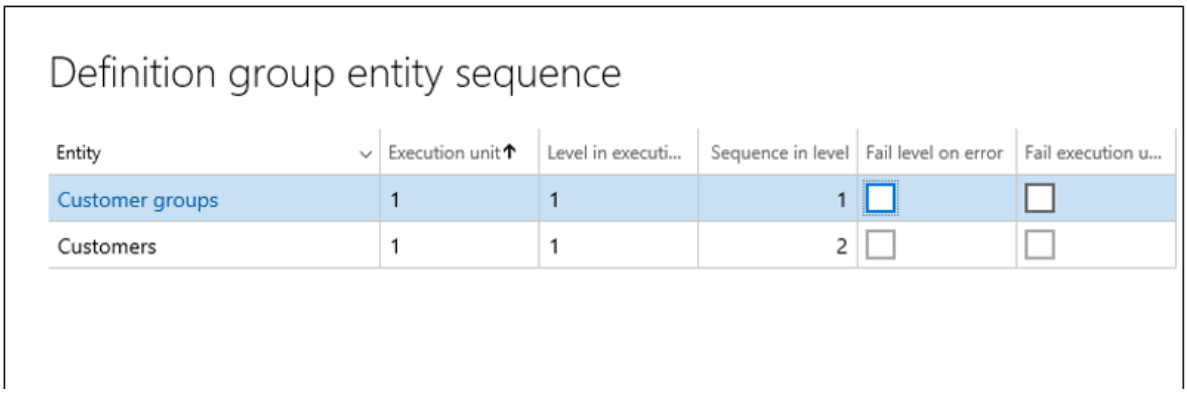


To automatically create a data package when you export the data project, set the **Generate data package** option to **Yes**. If you don't set this option, you can create a data package at the time of export.

9. On the Action Pane, select **Export**.
10. Select **Download**. The package is saved to the **Downloads** folder of the computer where the browser session is running. When you work with data packages, you must plan for and consider any prerequisites for the entities that will be included in the packages. For example, customer groups are required in order to create customers. Therefore, you should either import the customer groups into a package before you import customers, or sequence customer groups within a data package that will be completed before customers are imported. For example, in the following illustration, sequencing is set in the data package. As you can see, the Customer groups entity and Customers entity are part of the Customers data project.



11. On the Action Pane, select **Entity sequence** to open the **Definition group entity sequence** page. Based on the current setup, the Customer groups entity and Customers entity are run at the same level. However, this sequence might not be ideal.



12. To create a better sequence, select the **Customers** entity, and then update the value of the **Execution unit** field from **1** to **2**. This change helps guarantee that customer groups are imported before the Customers entity is run.

Microsoft Dynamics Lifecycle Services (LCS) contains multiple base data packages that you can use to reduce the implementation time. These packages contain the elements that are required in each module/area in order to meet the minimum requirements. For advanced business processes, you might have to add more entities to the list of packages. The data packages that Microsoft publishes on LCS use a numbering sequence that is based on the module, data type, and sequence. Here is an example:

- Module/area number

Module	Module Reference
System administration	01
General ledger	03
Public Sector	04
HRM	05
Accounts payable	10
Accounts receivable	11
Budgeting	12
Cash and bank management	13
Compliance and internal controls	14
Cost accounting	15
Fixed assets	16
Inventory management	19
Master planning	20
Organization administration	21
Payroll	22
Procurement and sourcing	23
Product information management	24
Production control	25
Project management and accounting	26
Retail	27
Sales and marketing	28
Service management	29
Trade allowance management	31
Transportation management	32
Travel and expense	33
Warehouse management	34

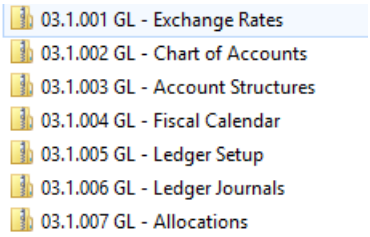
- Data type numbering

Data Type	Data Type Reference
Setup	1
Master	4
Transaction	8

- Numbering format

Numbering Format	
Module # . Data Type Reference . 001 (Sequence Number)	
01.1.001	System / Setup Data / Seq 001
01.1.002	System / Setup Data / Seq 002
01.4.001	System / Master Data / Seq 001
01.4.002	System / Master Data / Seq 002
03.1.001	General Ledger / Setup Data / Seq 001

The names of data packages include the numbering format, which is followed by the module abbreviation and then a description. For example, the following illustration shows the General ledger data packages.



Process data packages

A process data package (PDP) consolidates Data import/export framework (DIXF) data packages into a unified bundle. The PDP is then used to configure a business process or a group of business processes in one business process library. Together, DIXF data packages, dependencies between those packages, and business processes that require the packages for their configuration make up a PDP. This section describes how to create a PDP for your LCS solution package. To create a PDP, you must have the following items and knowledge:

- An implementation business process library for the solution in your working LCS project.
- DIXF data packages that have configurations that follow best practices. These packages should include master and reference data for the whole solution.
- An understanding of the dependencies between the data in the packages.
- An understanding of the data dependencies between the data packages.

Follow these steps to create a PDP.

1. In LCS, select the **Asset library** tile.
2. Select **Data package** as the asset type, and then select the plus sign (+) to add a data package.

Follow these steps to consolidate the data packages that you uploaded to LCS into a single PDP.

1. In LCS, select the **Asset library** tile.
2. Select **Process data package** as the asset type, and then select the plus sign (+) to add a PDP.
3. Enter a name and description for the PDP, and then select **Confirm**.
4. For step 1, "Add business process library," select the implementation business process library that your solution is built for, and then select **Continue**.
5. For step 2, "Add data packages," select **Edit**, and then add the data packages that are required in order to configure the system and enable the business process library transactions to be run. When you've finished adding data packages, select **Select**. The order in which data packages in the PDP are loaded into the system might be important. For example, before a chart of accounts (COA) can be loaded, the legal entity setup and currencies are required. Those data entities are in 01.1.002 System Setup. Therefore, 03.1.1001 COA Setup depends on 01.1.002 System Setup. In the next step, you must make a note of this dependency.
6. For step 3, "Add data package dependencies," select a data package, and then select **Edit**. Select the dependent data packages that must be loaded into your target environment before the data package that you selected, and then select **Select**.
7. For step 4, "Associate business process to data packages," select the business process that should be used to configure the process nodes.

Consume a PDP

> **IMPORTANT**
>
> For the PDP consumption requirement, you have the option to consume data packages directly via the Data Management Framework in your environment. However, note that only the consumption of data packages via the LCS PDP tool is optional. You must still create the PDP and upload it to your Asset library.

The Consume flow lets you review a business process, and apply the configuration and data that are required in order to implement the business process in your environment. To consume PDPs, you must have the following items:

- An implementation business process library for the solution in your working LCS project
- PDPs
- A target environment that includes an existing legal entity

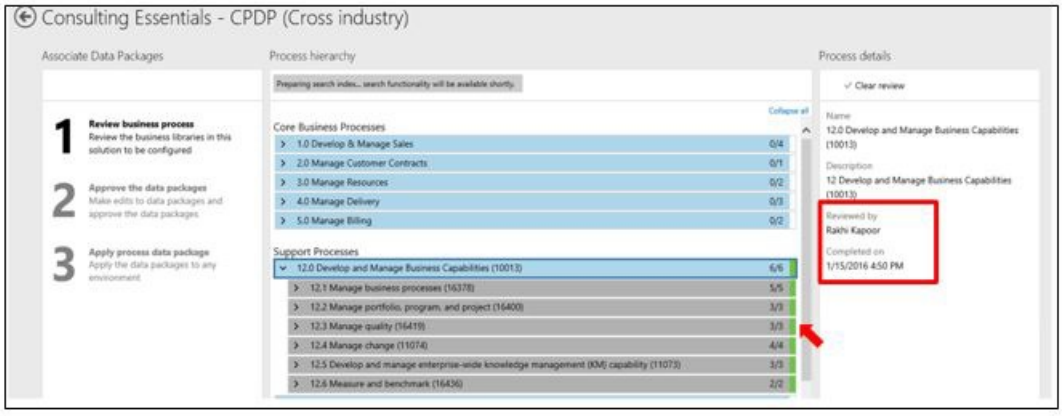
Follow these steps to consume the PDP.

1. In LCS, select the **Asset library** tile.
2. Select **Process data packages** as the asset type, and then select **Consume**.
3. The **Consume process data package** page shows a list of the existing PDP assets. Select the plus sign (**+**) to create a new Consume PDP.
4. Enter a name for the Consume PDP, select the PDP that you created and saved in the Asset library, select a target environment, and then select **Create**.
5. The Consume PDP that you created appears in the list of PDP assets. Select the package.

> **NOTE**
>
> The asset that you created can be consumed only in the target environment that was linked to it.

Review and approve BPMs

- For step 1, "Review business process," review the business process models (BPMs), and then select **Mark as reviewed**. The review status is updated for all dependent processes, and a green bar appears to the right of them. The **Reviewed by** and **Completed on** fields are also updated for each business process.



Review and approve data packages that are associated with a BPM

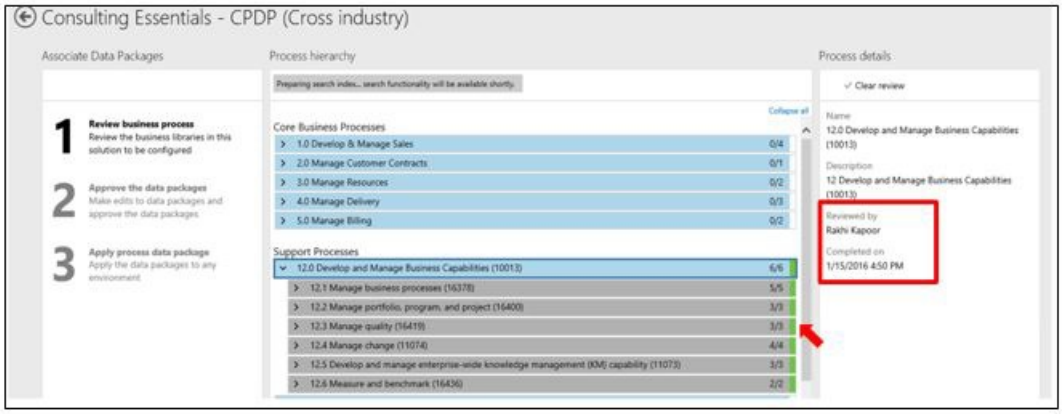
1. In the BPM library that you just reviewed, in the left pane, select **2 Approve the data packages**.
2. Select the business process that is associated with the data packages. The data packages appear in the right pane, under **Process details**. In the right pane, select **Review and Approve**.

3. On the **Consume process data package** page, select a package, and then select **Download** to download the data package. Save the package locally. You can then update the data files in the data package with data that is specific to your target environment. When you've finished updating the data files, select **Upload data package** to upload your changes.
4. After the data package has been updated and completed, select **Approve**. The status is changed to **Approved**. You can approve as many data packages as you require.
5. Select the **Back** button, select **2 Approve the data packages** again, and then select the business process. You should see the **Approved** status in the right pane, under **Process details** > **Dependent packages**.

Apply a process data package

1. In the BPM library, in the left pane, select **3 Apply process data package**.
2. Select the business process, and then, in the right pane, select **Apply Data Packages**.
3. On the **Consume process data package** page, select a package, and then select **Apply**.
4. Select the destination company in the target environment that is linked to the PDP, and then select **Apply**.

- For step 1, "Review business process," review the business process models (BPMs), and then click **Mark as reviewed**. The review status is updated for all dependent processes, and a green bar appears to the right of them. The **Reviewed by** and **Completed on** fields are also updated for each business process.



Review and approve data packages that are associated with a BPM

1. In the BPM library that you just reviewed, click **2 Approve the data packages** in the left pane.
2. Select the business process that is associated with the data packages. The data packages appear in the right pane, under **Process details**. Click **Review and Approve** in the right pane.
3. On the **Consume process data package** page, select a package, and then click **Download** to download the data package. Save the package locally. You can then update the data files in the data package with data that is specific to your target environment. When you've finished updating the data files, click **Upload data package** to upload your changes.
4. After the data package has been updated and completed, click **Approve**. The status is changed to **Approved**. You can approve as many data packages as necessary.
5. Click the **Back** button, click **2 Approve the data packages** again, and then select the business process. You should see the **Approved** status in the right pane, under **Process details** > **Dependent packages**.

Apply a process data package

1. In the BPM library, click **3 Apply process data package** in the left pane.
2. Select the business process, and then, in the right pane, click **Apply Data Packages**.
3. On the **Consume process data package** page, select a package, and then click **Apply**.
4. Select the destination company in the target environment that is linked to the PDP, and then click **Apply**.

View the data package history

- On the **Consume process data package** page, select a package, and then select **History**. You can review the status of the data package. The available information includes the target environment, company, package

name, start and end times, status by data entity, and overall status of the data package. To see the details of any errors that occurred, you can sign in to the target environment.

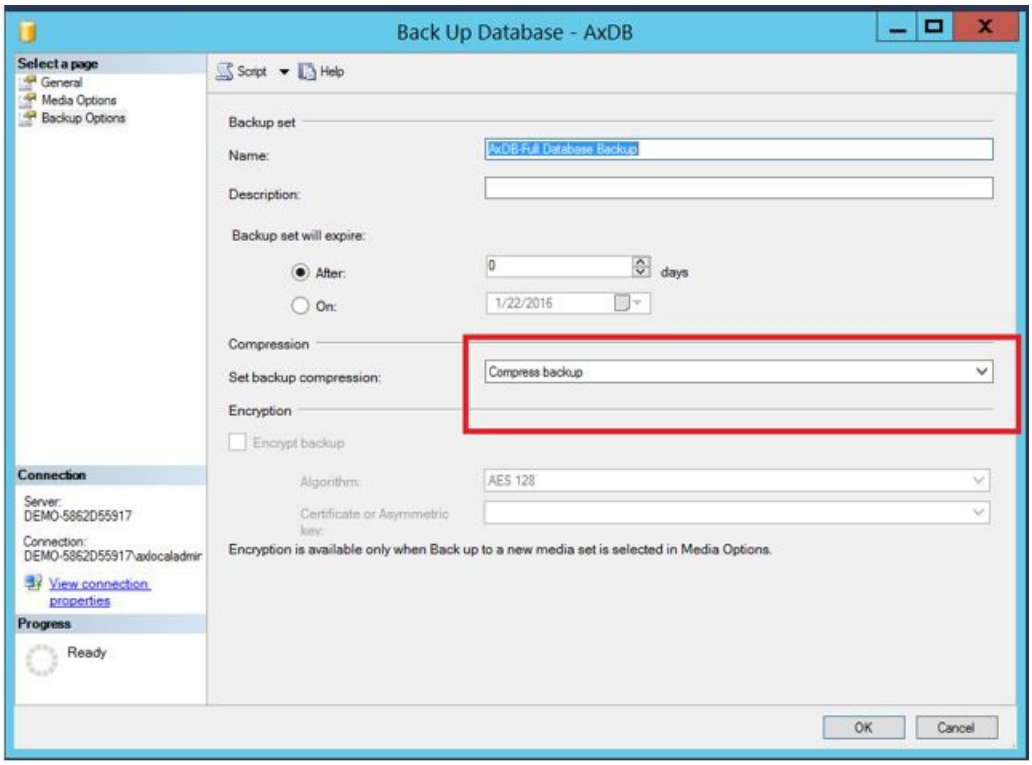
Back up the databases for Finance and Operations apps

2/18/2021 • 2 minutes to read • Edit Online

A backup of theFinance and Operations apps database is required for your Microsoft Dynamics Lifecycle Services (LCS) solution package. When you back up the database, you must include the master, reference, and transactional data that is specific to your solution and industry. This data will be used for your pre-sales demo deployments.

On demo or development environments, the database is typically named AXDBRain. Your database backup should be no larger than 15 gigabytes (GB). Otherwise, a time-out error might occur when you try to upload the database to the Asset library in LCS.

To compress your database backup, in Microsoft SQL Server Management Studio, on the **Back Up Database** page, in the **Set backup compression** field, select **Compress backup**.



On demo or development environments, the database is typically called AXDBRain. Your database backup should be no larger than 15 gigabyte (GB). If your database is larger, a timeout error may occur when you try to upload the database to the Asset library in Lifecycle Services (LCS).

To compress your database backup, in SQL Server Management Studio, on the **Back Up Database** page, in the **Set backup compression** field, select **Compress backup**.

Globalization resources

2/18/2021 • 2 minutes to read • Edit Online

Local and regional deployments

If your government regulations require data to be stored differently or serviced differently than is required for other countries/regions, there might be country/region requirements you must consider during deployment. Consider the following resources that might be relevant to you:

Finance and Operations apps operated by 21Vianet in China

Localization and regulatory features

Finance and Operations apps include functionality for the country/regions documented in the Product localization and translation availability guide. This functionality is enabled based on the primary address of the active legal entity.

This topic includes lists of resources that can help you do the following:

- Learn more about developing country/region-specific solutions.
- Get country/region specific updates.
- Submit and review regulatory alerts.
- Learn how to use country/region specific functionality.

Developing localized solutions

The following resources provides guidance and information that can help developers and ISVs who are creating country/region-specific customizations or are creating a solution for a country that Microsoft does not support.

- Separation of localization models
- Apply country/region context
- Regulatory certification information in feature titles
- Classification of localization features
- Country Codes - ISO 3166

Regulatory updates and communication

The following resources provide information about planned and new localization features.

Regulatory updates

- Regulatory updates
- Localization portal (Updated weekly)
- Issue search in Lifecycle Services (LCS) (Updated daily)

Communication and alerts

- Regulatory watch and communication of regulatory updates
- Submit alerts about country/region-specific regulatory features

Dynamics 365 release plans

The Dynamics 365 release plans provide descriptions of new and enhanced capabilities that are planned for Dynamics 365 business applications and application platforms.

Finance and Operations apps what's new

The What's new or changed in Finance and Operations home page lists the features that are included in specific

releases of the Finance and Operations apps.

Electronic reporting

The Electronic reporting (ER) tool allows you to configure formats for electronic documents in accordance with the legal requirements of various countries/regions. ER lets you manage these formats during their lifecycle. For more information, refer to one of the following topics:

- Electronic reporting (ER) overview
- Manage the Electronic reporting (ER) configuration lifecycle
- Create Electronic reporting (ER) configurations
- Extend the list of Electronic reporting (ER) functions
- Electronic reporting (ER) destinations
- Download Electronic reporting configurations from Lifecycle Services
- Import Electronic reporting (ER) configurations
- Configure Electronic reporting (ER) to pull data into Power BI
- Generate electronic documents and update application data by using ER

Task guides

Task guides are available from the product help pane and they provide a guided walk-through of key business processes. You can open a task guide to read the steps of a business process or you can play a task guide to walk through a business process and enter data.

To find task guides, navigate to a page in in the application and click Help. Task guides that use the page are listed in the help pane. You can also use the help pane to search for task guides by title.

To learn more, see Help system.

Classification of localization features

2/18/2021 • 2 minutes to read • Edit Online

As part of the requirements for LCS solutions for localization and translation, localization features must be classified as either regulatory or competitive in the business process modeler (BPM) library in Microsoft Dynamics Lifecycle Services (LCS). This article explains the difference between these two types of feature and shows how the feature type is used in the title of the feature.

Localization features must be classified as either regulatory or competitive in the Business process modeler (BPM) library in Microsoft Dynamics Lifecycle Services (LCS). The following definitions will help you distinguish the two types of features:

- **Regulatory features** – Organizations that do business in a particular country/region must comply with country/region-specific laws and regulations as they handle their daily business transactions and operations, and meet their legal obligations for activities that are conducted in that country/region. These laws and regulations are enforced, and non-adherence can lead to severe consequences for an organization that does business in that country/region.
- **Competitive features** – This category includes all other features that aren't considered regulatory features according to the preceding definition.

When the BPM library is constructed, the various feature types should be distinguished through the title of the localization solution feature. The label for this title will conform to the following naming convention that indicates the country/region and feature type through prefixes, as shown in the following table.

FEATURE TYPE	FORMAT	EXAMPLE
Regulatory	XX-REG-Feature title	PT-REG-Direct sales Tax report
Competitive	XX-COMP-Feature title	PT-COMP-Country bank payment format

The following table explains the components of the naming convention.

COMPONENT NAME	FORMAT	DESCRIPTION	EXAMPLE
Country/region code	XX	The two-letter ISO country/region code (from the ISO 3166 standard)	PT (= Portugal)
Feature type	REG or COMP	The type of feature	REG
Feature name	Text	A short feature title that describes what the feature is used for	Direct sales tax report

For more information about BPM, see Upload custom business processes to Business process modeler (BPM).

The survey will take about seven minutes. No personal data is collected (privacy statement).

Apply country/region context

2/18/2021 • 3 minutes to read • Edit Online

As part of the requirements for LCS solutions for localization and translation, localization ISV solution providers must implement all country-specific or region-specific functionality so that it can be controlled by country/region context. This article describes how to apply country/region context to meet these requirements. In this article you can find information how you should use country context property and what application objects control user interface elements.

Country/region-specific functionality

You use country/region-specific functionality to help meet the legal, regulatory, and business requirements of individual geographies. A geography is any country or region that is identified by an International Organization for Standardization (ISO) country or region code. The following table highlights the main elements that you use to configure country/region-specific functionality.

ELEMENT	DESCRIPTION
Controlled entity	The controlled entity is a UI element that is hidden or shown, depending on whether its country/region context matches the country/region context of the controlling entity. To enable menus, menu items, and form controls that are based on country/region context to be hidden, a controlled entity includes a **CountryRegionCodes** property on some elements. You use this property to specify the country or region where the element is shown. You find the **CountryRegionCodes** property on the following Application Object Tree (AOT) elements: • Extended data type • Menu and menu items • Enum and enum value • Table and table field • Data entity and data entity field • View and view field • Map and map field • Form control • Tile
Controlling party	The controlling party's role is used to determine whether country/region-specific functionality or UI elements are enabled. The controlling party is defined by the Organization model. Examples include legal entity, customer, vendor, bank, or worker. By default, the legal entity is used as the controlling party. If the country/region context of the controlling party matches the country/region context of the controlled entity, the functionality or UI elements are enabled. You set the country/region context of the controlling party. Any controlled entities that have a matching country/region context are shown.

Using the CountryRegionCodes property

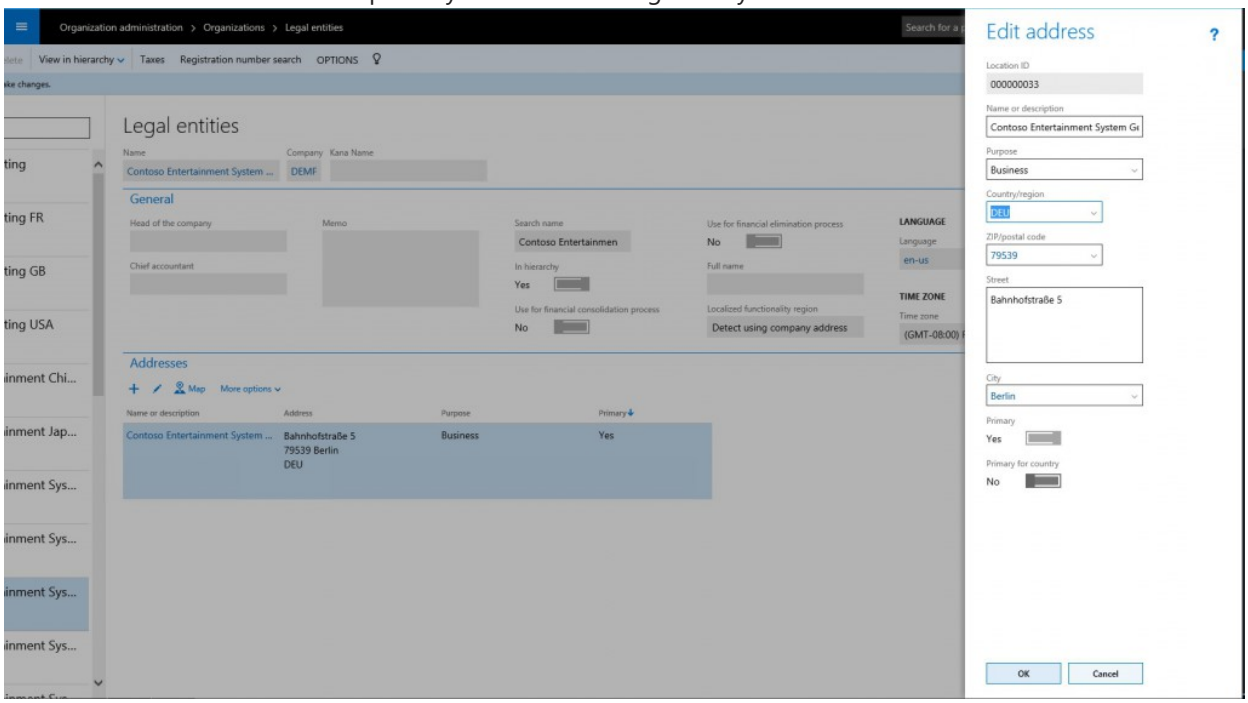
You create country/region context on a controlled entity by setting the ISO code value on the

CountryRegionCodes property. You can find the list of ISO country and region codes on the ISO website. The values of the **CountryRegionCodes** property are compared to the country/region context of the controlling party. If the values match, the element is shown. Otherwise, it's hidden.

> **TIP**
>
> To add more than one ISO country and region code to the **CountryRegionCodes** property, use a comma-separated list.

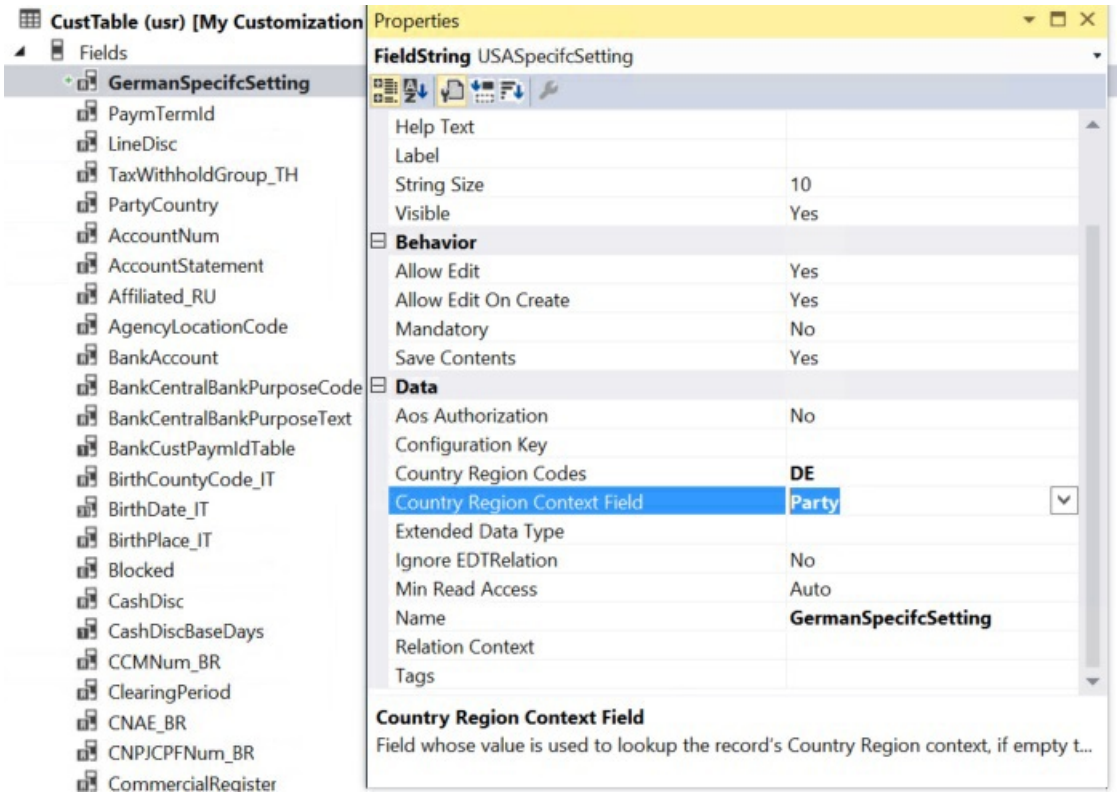
Using the legal entity as the controlling party

The **Country/region** value in the primary address of the legal entity determines the country/region context of the controlling party. The default value of the **Country/region** field is the locale of the system. The following illustration shows how to set the primary address of the legal entity.



Setting another party as the controlling party

You can use another party, such as a customer, bank, or vendor, as a controlling party. For example, you can enable targeted functionality for customers of a specific country/region or require specific validation of vendors from a specific country/region. To set the controlling party, use the **CountryRegionContextField** property of the form, control, or other element. This property lets you select the entity that is the controlling party. The default value is the legal entity. The following illustration shows how to set the **CountryRegionContextField** property for a field.



In this example, the customer becomes the controlling entity. The customer's address is compared with the value of the **CountryRegionCodes** field to determine whether the **GermanSpecifcSetting** field is displayed.

Regulatory certification information in feature titles

2/18/2021 • 2 minutes to read • Edit Online

As part of the requirements for LCS solutions for localization & translation, localization ISV solution providers must include details about any regulatory certifications that the solution requires in order to be legally compliant for sale in the intended market. This article shows how information about certifications is used in the title of the feature.

Regulatory certification can take various forms, from data privacy to certification of compliance with specific regulations. However, one thing that all regulatory certifications have in common is that they are required by the laws and regulations of the country/region of operation. These certifications are enforced, and non-adherence can lead to severe consequences for an organization that does business in that country/region. When the business process library is constructed, regulatory certifications must be identified as regulatory requirements in the Microsoft Dynamics Lifecycle Services (LCS) Business process modeler (BPM) library through the title of the localization solution feature. The label for this title will conform to the following naming convention that indicates the country/region and certification type through prefixes, as shown in the following table.

FEATURE TYPE	FORMAT	EXAMPLE
Regulatory	XX-REG-Certification for xx	PT-REG-Certification for Fiscal printers

The following table explains the components of the naming convention.

COMPONENT NAME	FORMAT	DESCRIPTION	EXAMPLE
Country/region code	XX	The two-letter ISO country/region code (from the ISO 3166 standard)	PT (= Portugal)
Feature type	REG	The type of feature	REG
Certification name	Text	A short title that describes the certification and its application	Certification for Fiscal printers

In the BPM business process library, certifications should be located under **APQC level 8.0 Manage Financial Resources (10009)**.

Example

- APQC level 8.0 Manage Financial Resources (10009)
  - PT-REG-Certification for Fiscal printers

For more information about BPM, see Flowcharts in Business process modeler (BPM).

NOTE

Can you tell us about your documentation language preferences? Take a short survey.

The survey will take about seven minutes. No personal data is collected (privacy statement).

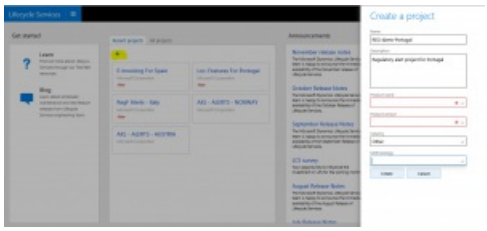
Regulatory watch and communication of regulatory updates

2/18/2021 • 7 minutes to read • Edit Online

As part of the requirements for LCS solutions for localization & translation, localization ISV solution providers must undertake their regulatory watch by taking advantage of localization tools in Microsoft Dynamics Lifecycle Services (LCS).

Set up an alerting project in LCS

Localization independent software vendor (ISV) solution providers must create a new project in Microsoft Dynamics Lifecycle Services (LCS) to record regulatory alerts.



Follow these steps to set up the project.

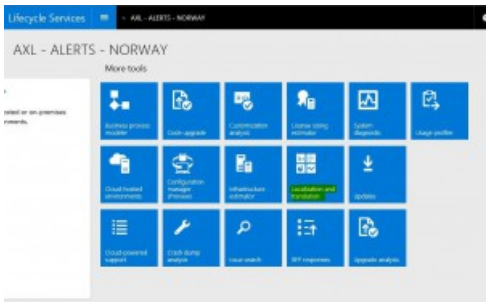
1. Add a new project by clicking the plus sign (+).
2. Enter a name that uses the following project naming convention: **REG-Alerts-Country/region name**
3. Enter a project description.
4. For the product name, specify the latest version of your Dynamics 365 Finance and Operations app.
5. For the product version, specify the latest version.
6. Specify the industry:
   - Select **Other** if the solution is related to all industries.
   - Select an appropriate specific industry.
7. For the methodology, specify **Sure step**.
8. Click **Create**.

Invite participants to the project

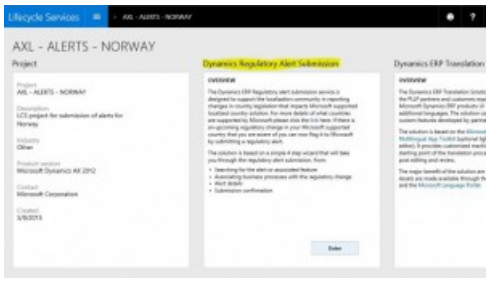
Invite participants that should have access to the project, so that they can submit and review regulatory alerts. For information about how to invite users, see Configure Lifecycle Services (LCS) security.

Access the regulatory alert submission service

1. In your LCS project, scroll to the right side of the page, and then, under **More tools**, click **Localization and translation**.



2. Select **Dynamics Regulatory Alert Submission**, and then click **Enter**. The **Dynamics Regulatory Alert Submission** page opens. Use this page to view any previous alerts that have been submitted by you or your organization.



Submit a regulatory alert

To enter a new regulatory alert, click the plus sign (+) at the top of the form, above the filter. The **Submit regulatory alert** wizard starts. Follow these steps to complete the wizard.

1. On the **Search for existing items** page, follow these steps:

    a. Use Issue search to identify whether a regulatory feature that is related to the alert already exists. Enter search terms to specify criteria such as a keyword, country/region, Microsoft Knowledge Base (KB) number, or Application Object Tree (AOT) object. For example, you can search for the payment term "SEPA" to return related items.

    b. After you've finished entering the search terms, click the **Search** button. Search returns all items that meet search criteria as it searches across both product issues and regulatory features.

    c. You can narrow down the search results by using the filter/criteria that are available.

    d. If you don't find the regulatory feature that you're searching for, you can submit a regulatory alert by clicking **Submit regulatory alert** on the bottom ribbon.

2. On the **Attach business processes** page, follow these steps:

    a. In the **Global business process libraries** field, you can select business process libraries.

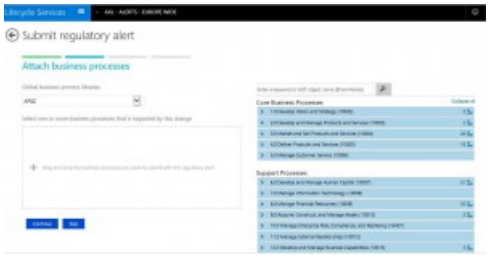
    b. You can enter search criteria to return business processes that are related to a search term. The tool highlights these business processes in yellow.

    c. You can drag business processes into the marked area on the left side of the page. You can select one or many related business processes in the process list. After you've dragged business processes to the marked area on the left, you can edit them further. Deselect business processes by clicking the **x**.

    d. When you've finished, click **Continue** to go to the next page in the wizard. When you receive a

confirmation message, click **Yes**. If no relevant business processes are found, you can skip this page in the wizard.

e. You receive a message that asks whether you want to add the selected business processes to the alert. You can click either **Yes** or **Cancel**.



3. On the **Describe the alert** page, follow these steps:

a. Enter information for the alert in the appropriate fields. Required fields are indicated by a red asterisk (*). The following table provides more information about the submission fields.

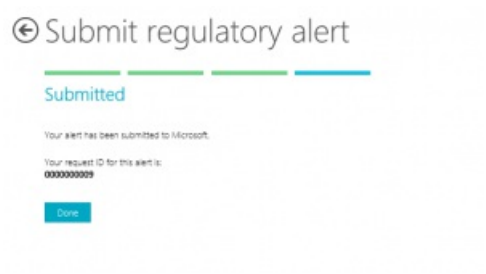
FIELD NAME	FIELD TYPE	DESCRIPTION
Title	Text	A descriptive title to identify the area of impact. For example, you might enter **Changes in invoice document per Jan. 1st 2014**.
Description	Text	A brief, pragmatic overview of the law. The description should focus on issues that are relevant to enterprise resource planning (ERP). It should have three to ten lines of details, so that users gain a high-level understanding of the requirement without having to read the legislation first.
Country	Valid values list	The country/region that the legislation applies to.
Industry	Valid values list	A list of industries, if the requirement applies only to selected industries (for example, Public sector, Retail, or Communication).
Link to legislation	Text (URL format)	Add links to the published law, interpretation guideline, implementation guidance, or any other documentation that will be useful for understanding and implementing the requirement.
Feature reference	Text	The feature reference ID (if it's known).
Law enforcement date	Date	Date from which impacted customers must comply with the law
Government announcement date	Date	The date when the authority announced the change.

FIELD NAME	FIELD TYPE	DESCRIPTION
Latest filing date	Date	The deadline for the first submission of the new/changed report.
Company name	Text	The company name for the person who is submitting the alert.
Contact name	Text	The contact name of the person who is submitting the alert.
Contact email	Email address	The contact email address of the person who is submitting the alert. This value must be in a valid email address format.
Business processes	Default	The business processes are selected through the **Submit regulatory alert** wizard and entered automatically on the submission page.
Comments	Text	Enter any additional information that is related to the alert, and that might be useful for understanding or implementing the requirement. You can add multiple comments. Click **Submit** to save comments separately to the submission page. Comments are saved in order of date.
Attachments	Upload	Add alert attachments by using the attachment tool. Click the **Upload** button to open File explorer. After you select and upload a file, the file is appears as a linked file. You can upload up to three files, each of which can be up 5 MB. To delete a file that you've uploaded by mistake, click **Remove** under the file title. **Important:** Attachments must be publicly available materials. They can't be propriety or customer/partner specific.
Consent check box	Check box	Give appropriate consent to being contacted. The **Submit** button doesn't become available until you select this check box.

b. When you've finished adding all the required fields, you must provide appropriate consent by selecting the consent check box: **By creating this alert I allow Microsoft to contact me in the future for any further information related to this alert. Read the Microsoft Dynamics Lifecycle Services privacy statement for more information.**

c. After you select the check box, the **Submit** button becomes available. Click **Submit** to submit the alert. If you've partially completed an alert, you can save the information that you've already entered for later completion or review. Click **Save** before you submit the alert.

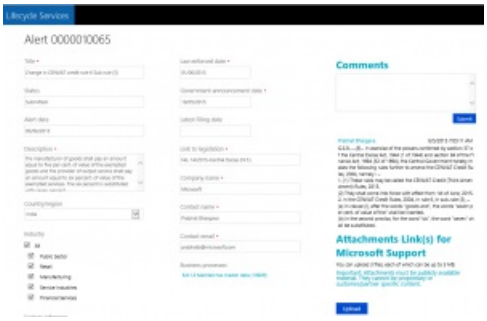
d. When you receive a confirmation message that states that the alert has been successfully submitted, click **Done** to exit the wizard. If you chose to save the alert before you submitted it, an alert ID is generated, and you are notified that the alert has been saved.



Review regulatory alerts that have been entered into the project

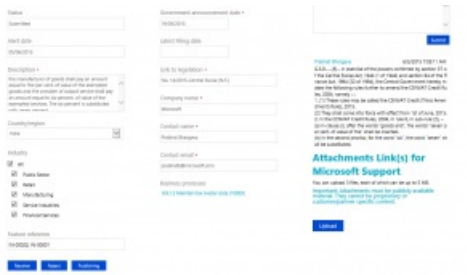
To view the regulatory alerts that have been entered into your alerting project, use the alert grid. This grid provides a high-level list view of the alerts that have been submitted, and shows the alert title, country/region, law enforced date, and so on.

You can search the contents of the grid by using the filter/search field and then selecting from the default search options. You can drill into the detail of an alert by clicking the alert ID, which is a hyperlink. The completed alert submission page opens, where you can review the alert details, and also any comments and attachments.



Process submitted alerts options

After an alert has been submitted to the LCS alert project, you can process it from the grid view by clicking the alert ID hyperlink. Project owners can then change the status of the alert to notify project members whether action will continue to be taken for the alert. Options appear when you drill into details of the alert.



The following table describes the processing options that are available for alerts.

STATUS	STATE	ACTIONS
Submitted	The alert has been submitted to (entered into) LCS by a Loc. Community member.	The alert can be either received or rejected.
Received	The alert has been reviewed by an internal Sol. Partner resource and has been received for further review.	The alert is marked **Received**. A comment and feature reference can be added.
Rejected	The alert has been reviewed by an internal Sol. Partner resource and has been rejected.	The alert is marked **Rejected**. A comment must be added to explain why the alert was rejected.
Reopened	The alert was rejected but has been reopened by a Loc. Community member, and new/additional information has been entered (a comment is mandatory).	The alert can be reviewed again to assess whether it should be received or rejected.

NOTE

Submitted alerts can be rejected for various reasons. Here are some examples:

- The alert is too vague to identify the underlying localization feature.
- The alert is related to an area where no features are localized.
- The alert is related to an area that isn't currently supported by Finance and Operations functionality.

Alerts can be stored in LCS as references.

Further processing, such as potential engineering of a related feature, will be handled in the ISV solution provider's existing systems.

Separation of localization models

2/18/2021 • 2 minutes to read • Edit Online

As part of the requirements for LCS solutions for localization and translation, if a localization solution for previous versions of Dynamics 365 Finance and Operations apps contains both regulatory and competitive features, localization ISV solution providers must split the solution into separate models for each feature type. This article provides information about this requirement.

Multinational customers must comply with regulatory requirements in all countries/regions where they deploy Finance and Operations apps. At the same time, these customers want to minimize the cost of code maintenance. Therefore, if a localization solution for previous versions contains both regulatory and competitive features, the solution must be split into separate models, so that customers can adopt and deploy the features that they require. An effort has been made to split the Application foundation and Application suite stack into multiple models.

The number of models is expected to grow over time. Splitting a monolithic code base provides many benefits, such as better scalability, manageability, and serviceability. The localization requirement to split a localization solution into more granular models builds on this effort. The goal is to provide the same benefits to multinational customers.

After you've classified features as either regulatory or competitive, as described in Classification of localization features, split the code for these features into at least two models, one model for the regulatory features and at least one model for the competitive features. If the competitive features can be split further (for example, into features that are related to Commerce and features that are related to Fixed assets), it's a good idea to split them. However, further splitting isn't mandatory. For more information about how to split the stack into multiple models, see Model split.

Submit alerts about country/region-specific regulatory features

2/18/2021 • 4 minutes to read • Edit Online

This topic describes how to use Microsoft Dynamics Lifecycle Services (LCS) to submit alerts through the Dynamics regulatory alert submission service. This topic also explains how to track planned and released regulatory features through LCS Issue search.

Accessing the regulatory alert submission service

In Dynamics Lifecycle Services (LCS), in your project, scroll to the right side of the page, and then, under **More tools**, click the **Alert service** tile.

The **Dynamics regulatory alert submission** page appears. You can use this page to view any alerts that have previously been submitted by you or your organization.

Submitting a regulatory alert

To enter a new regulatory alert, click the plus sign (+) at the top of the **Dynamics regulatory alert submission** page, above the filter. The **Alert submission** wizard starts. You can complete the following tasks in this wizard:

- Search for existing regulatory items.
- Attach business processes.
- Describe an alert.
- Confirm submissions.

Search for existing regulatory items

Use Issue search to identify whether a regulatory feature, that is related to the alert, already exists.

1. Enter a search term, such as a keyword, country/region, Microsoft Knowledge Base (KB) number, or Application Object Tree (AOT) object. Click the search button. Any items that include the search term, in either product issues or regulatory features, appear in the search results. You can narrow the search by using the filters that are available.
2. If you don't find the regulatory feature that you're looking for, you can submit a regulatory alert by clicking **Submit regulatory alert** at the bottom of the browser window.

Attach business processes

1. In the **Global business process libraries** list, select business process libraries.
2. Enter search criteria to find business processes that are related to the search term. These business processes are highlighted in yellow.
3. In the list on the right side of the page, select one or more related business processes, and drag them into the field on the left . After you've finished, you can edit them further by clearing the selection of business processes.
4. Add the selected business processes to the alert.

Describe the alert

1. Enter information about the alert in the appropriate fields. Required fields are indicated by a red asterisk. The following table provides more information about the fields on the **Describe the alert** page.

Field	Description
Title	Enter a descriptive title to identify the area of impact. For example, enter **Changes in invoice document as of January 1, 2018**.
Description	Enter a brief overview of the law. Your description should focus on issues that are relevant to enterprise resource planning (ERP), so that users can understand the requirements at a high level without having to read the legislation first.
Country	Select the country or region that the legislation applies to.
Industry	Select the industry, if the requirement applies only to specific industries. For example, select **Public sector**, **Commerce**, or **Manufacturing**.
Feature reference	Enter the feature reference, if you know it.
Law enforcement date	Select the date when affected customers must start to comply with the law.
Government announcement date	Select the date when the authority announced the change.
Latest filing date	Select the deadline for the first submission of the new or changed report.
Link to legislation	Enter one or more links to the published law, interpretation guideline, implementation guidance, or any other useful documentation that will help users understand or implement the requirement.
Company name	Enter the company name for the person who is submitting the alert.
Contact name	Enter the name of the person who is submitting the alert.
Contact email	The email address of the person who is submitting the alert.

Business process	The business processes that you selected through the **Alert submission** wizard.
Comments	Enter any additional information that might be help users understand or implement the requirement. Click **Submit** to save your comment. Multiple comments can be added and should be submitted separately. Comments are saved in the order that they are added.
Attachments	Click the **Upload** button, and then browse to select a file to add as an attachment. After you select the file, it's uploaded and appears as a linked file. You can add up to three files that have a size of 5 MB each. To delete files that have been attached, click **Remove** under the title of the file. **Note** Attachments must be publicly available materials. They can't be propriety or customer-specific/partner-specific.

2. After you've finished entering all the information, select the consent check box (**By submitting this regulatory alert, I consent to Microsoft contacting me for additional information about this alert. Microsoft Privacy Statement.**). When you select the check box, the **Submit** button becomes available.

3. Click **Submit** to save and submit the alert.

If you don't have all of the required information, or if you're not yet ready to submit the alert, you can save a partially completed alert.

Confirm your submission

- When the alert is successfully submitted, you receive a confirmation message. Click **Done** to exit the wizard.
- If you save the alert before you submit it, an alert ID is generated, and you receive confirmation that the alert has been saved.

Track the status of regulatory features in Issue search

You can use Issue search in LCS to find planned and released regulatory features, and any associated localization documentation, certifications, and reports. To narrow your search to regulatory features, use the following filters:

- **Category** - Select **Regulatory feature** only.
- **Country/region** - Click **>** to select the country/region that you're interested in.

To narrow the search even more, you can apply the following additional filters

- **Product** - Select the products and product versions that you're interested in.
- **Status** - Select specific statuses.

Get support for Finance and Operations apps or Lifecycle Services (LCS)

2/18/2021 • 2 minutes to read • Edit Online

This topic explains how to get help with Finance and Operations apps or Microsoft Dynamics Lifecycle Services (LCS).

TASK	MORE INFORMATION
Ask the community.	Go to the Dynamics 365 Community page to get help with your questions from the Microsoft Dynamics community.
Get help with questions about licensing.	Contact your partner or a Microsoft sales representative.
Use the **Issue search** tool.	In LCS, use the **Issue search** tool to quickly search for Microsoft Knowledge Base (KB) articles, hotfixes, and workarounds for reported issues. You can see which reported issues are in the process of being fixed for a specific functional area, and which issues have already been fixed. For more information, see Issue search (Lifecycle Services, LCS).
Get in-app support.	Select the **Help** button (**?**) in the upper-right corner of the app, and then select **Support**. Issues are reported on the **Active issues** tab in LCS. There, admins can determine whether they should provide in-house support or submit the issues to Microsoft.
Open a support ticket with the Microsoft Support team.	In LCS, the **Support** tile opens a tool that helps you manage support incidents. To submit issues directly to Microsoft, select the **Support** tile in your LCS project. You can then submit issues in two ways: • On the **Active issue** tab, select your issue, and then select **Submit to Microsoft**. • On the **Submitted to Microsoft** tab, select **Submit an incident**, and then follow the on-screen instructions to submit the incident. After you submit an incident, you will receive an email message from the Microsoft Support engineer who is assigned to your case.
Request new features and functionality.	Visit Dynamics 365 Application Ideas to view, search, or vote for existing ideas, or to add new ideas.

NOTE

Can you tell us about your documentation language preferences? Take a short survey.

The survey will take about seven minutes. No personal data is collected (privacy statement).

Support for Finance and Operations operated by 21Vianet in China

2/18/2021 • 2 minutes to read • Edit Online

Finance and Operations apps provides many self-service support options and support through 21Vianet.

Self-help resources

- Finance and Operations application documentation
- Help resources for Supply Chain Management
- Finance and Operations apps - operated by 21Vianet in China
- Dynamics community
- Microsoft Learn

Assisted support

- Open a support request

Presales support

Pre-sales support phone number: +86 400-886-6134

Pre-sales support provides assistance on subscription features and benefits, plan comparisons, pricing and licensing, and helps to identify the right solution to meet your business needs. In addition, pre-sales support can help you find a Partner, and purchase and sign up for a trial. You can call during local business hours, Monday through Friday.

Billing and subscription management support through 21Vianet

Billing and subscription support telephone number: +86 400-089-0365.

Assistance for billing and subscription management issues is available online or by telephone Monday through Friday during local business hours 9:00 to 18:00 China Standard Time (CST). Billing and subscription management support can be accessed using the same phone number and online service request process as with technical support.

Here are some examples of billing and subscription management issues:

- Signing up for a trial or purchasing a subscription.
- Converting from a trial subscription to a paid subscription.
- Understanding the bill.
- Renewing a subscription.
- Adding or removing licenses.
- Canceling a paid subscription.

Assisted Technical support through 21Vianet

When you experience a technical issue with your deployment, report it to 21Vianet through the LCS portal or by calling the support number at +86 400-089-0365. Technical support hours of operations are Monday through Friday during local business hours 9:00 to 18:00 China Standard Time (CST).

A support request (SR) is handled within hours, depending on the severity of its impact to your business:

- **Critical business impact** - You will receive an initial response within 1 hour or less, and a support representative will work continuously, all day, until the problem is resolved. You will be expected to allocate appropriate resources to work on the request until the problem is resolved and provide accurate contact information to the support personnel handling your case.
- **Non-critical business impact** - You will receive an initial response within 8 hours or less. You will be expected to provide accurate contact information to the support personnel handling your case.

Get Premier support

If you run mission-critical solutions, Premier support offers additional value:

- Proven advisory services designed to maximize your Dynamics 365 investment.
- A designated service delivery manager committed to improving your Dynamics 365 experience.
- Top priority reactive support to help ensure service continuity.

For details about purchasing Premier support, contact your Microsoft Account team. If you have a Premier support plan you can contact support via My Premier Online.

Additional resources

- Dynamics 365 support site for 21Vianet (Chinese)
- Finance and Operations apps - operated by 21Vianet in China
- Model-driven apps in Dynamics 365 - operated by 21Vianet in China
- Dynamics 365 Privacy statement (Dynamics 365 隐私声明)
- Dynamics 365 Service Level agreement (世纪互联在线服务的服务级别协议)
- Dynamics 365 Legal information (Dynamics 365 法律信息)
- Service terms for Dynamics 365 Lifecycle Services

Set up technical support for Finance and Operations apps

2/18/2021 • 9 minutes to read • Edit Online

Prerequisites

Before you can set up technical support, you must acquire a Microsoft Azure Active Directory (Azure AD) account. This account is created when you set up a subscription for one of the Microsoft Dynamics 365 Finance and Operations apps.

Create an Azure DevOps project

The **Support** tile in a Lifecycle Services (LCS) project uses Azure DevOps to store issues that are submitted through the client and issues that are manually created from the **Support** tile in LCS. This functionality requires that a Azure DevOps project be configured in the LCS project that you want to use for support. All users who need to use the **Support** tile to submit an issue must have access to the Azure DevOps project, and must authorize LCS to access Azure DevOps on their own behalf. Most users don't have access to LCS or Azure DevOps. Therefore, in the Azure DevOps project, you should create a special system account that can be used to submit issues.

Create a new Azure DevOps project

1. Go to https://www.visualstudio.com/.
2. Click **Sign in** in the upper-right corner.
3. Sign in by using an AAD account that is in the tenant that your subscription is linked to. If the browser already has your credentials, you won't see the sign-in page and should instead click your name in the upper-right corner.
4. On the right side of the page, under **Accounts**, click **Create a free account now**.
5. Specify an account URL, and then click **Create Account**.
6. Name your project, and specify a process template. Your project should now be created.

Add users to the Azure DevOps project

1. In the upper-left corner, click **Team Services**.
2. On the **Users** tab, click **Add**, and invite users who will use the Support experience to the Azure DevOps account. For each user that you invite, select either **Basic** or **Stakeholder**.
3. In the upper-left corner, click **Team Services**.
4. Click **Browse**, and browse to the project that you created in the previous procedure.
5. In the **Members** section of the project home page, click **Add**, and add the users that you invited in step 2.

Create the Support system user

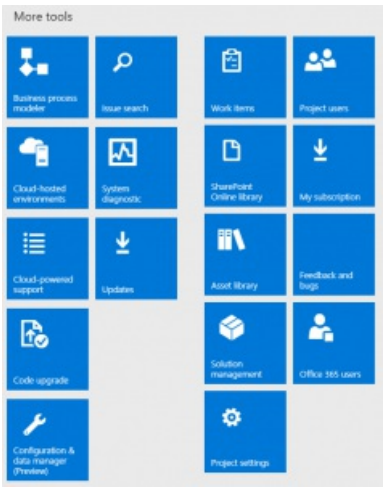
1. Create a new user in your Azure AD tenant, and enter a descriptive name, such as **LcsCpsSystemAccount**.
2. In the upper-left corner, click **Team Services**.
3. On the **Users** tab, click **Add**, and invite the system user that you created in step 1. For this user, select **Stakeholder**.
4. In the upper-left corner, click **Team Services** again.
5. Click **Browse**, and browse to the project that you created earlier.
6. In the **Members** section of the project home page, click **Add**, and add the system user.

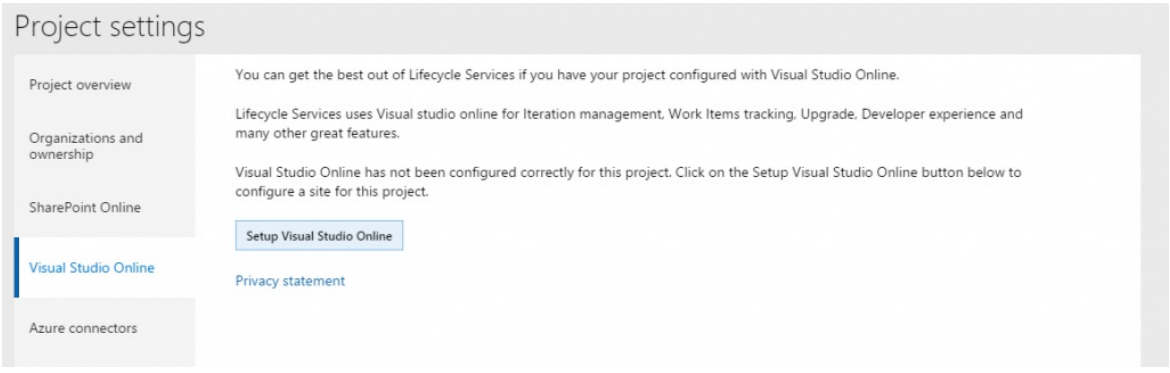
Retrieve the personal access token for the Support system user

1. Sign out of Team Services by clicking the user name in the upper-right corner and then clicking **Sign out**.
2. Sign in to Team Services by using the Support system account that you created in the previous procedure.
3. In the upper-right corner, click the user name, and then click **My profile**.
4. On the **Security** tab, on the **Personal access tokens** tab, click **Add**.
5. Enter a description, such as **LCS Support system account**.
6. Select an expiration date of one year.
7. Click **Selected scopes**, and the select **Work items (read and write)**.
8. Click **Create token**.
9. Copy the token and paste it in a safe location because it won't be accessible after you move away from the page.

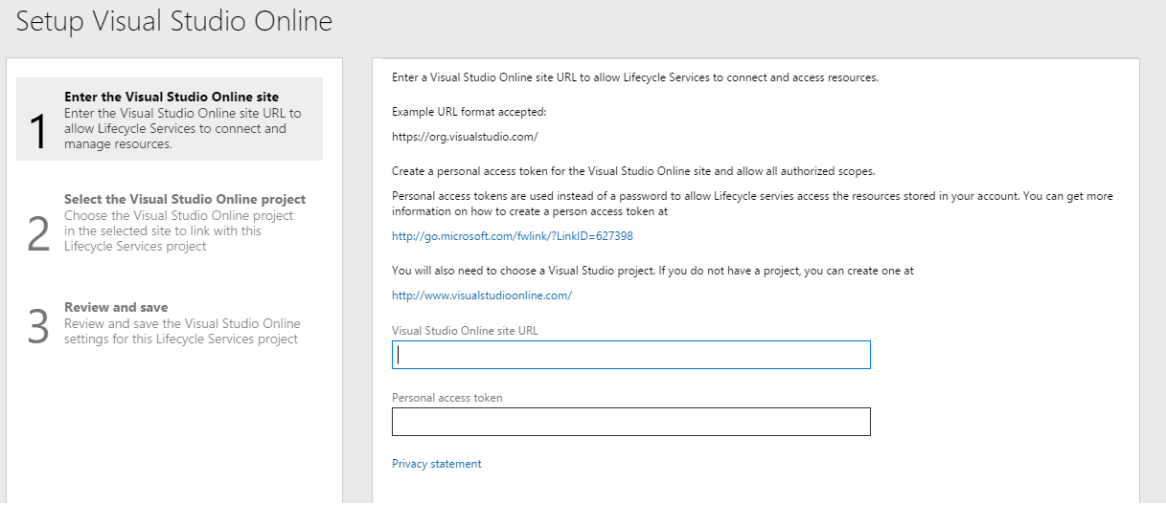
Configure LCS

1. Sign in to LCS by using an account that has the **Owner** role for the LCS project that the application is deployed in.
2. Open the project in LCS.
3. Click **Project settings**, and then click the **Azure DevOps** link.





4. Click **Setup Azure DevOps**.
5. In the **Azure DevOps site URL** field, enter the URL of the Azure DevOps project that you created in the previous section.
6. In the **Personal access token** field, enter the personal access token that you created in the previous section.

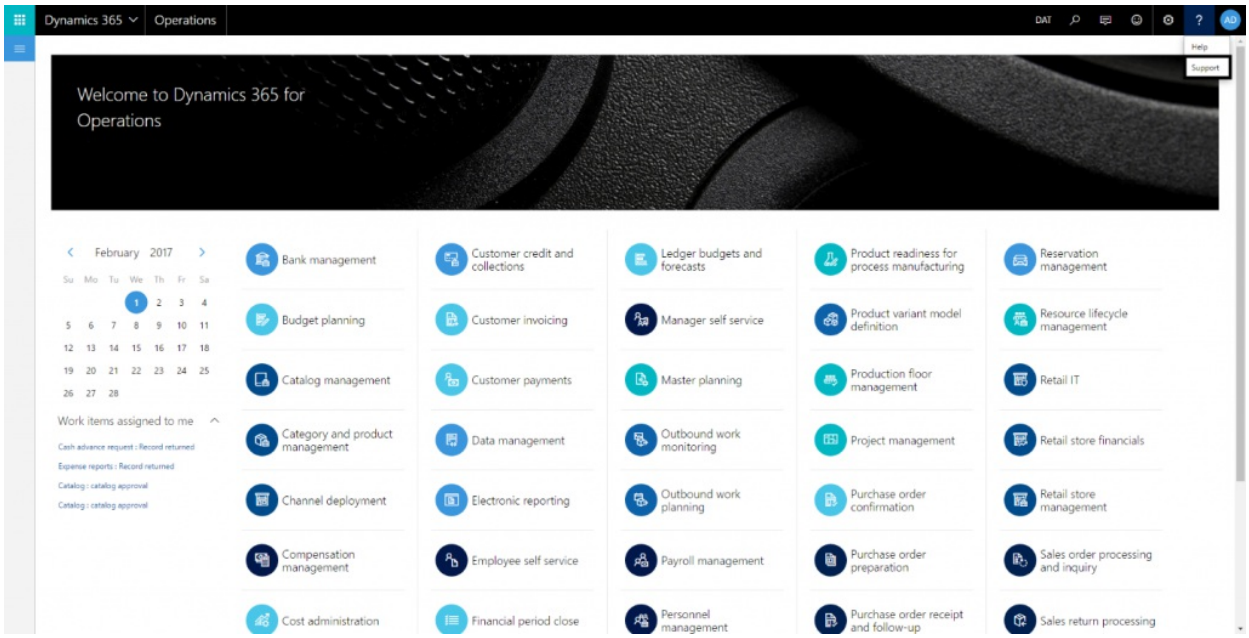


7. Click **Continue**.
8. Select the VSO project to use, and then click **Continue**.
9. Click **Save**.
10. Click **Authorize**.
11. In the confirmation message box, click **OK**.
12. Sign in to Visual Studio Online.
13. Click **Accept**.

Create an issue

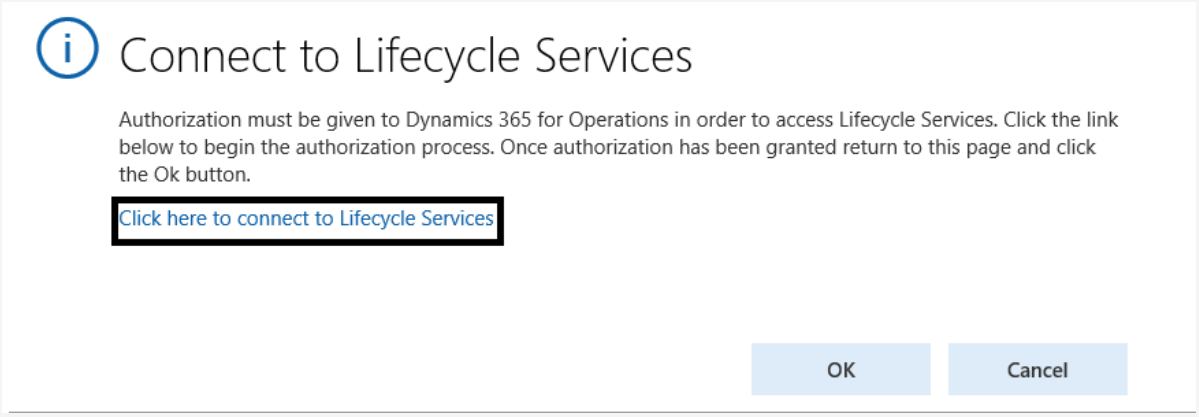
The Support experience has been updated to show updates that are published by Microsoft. In the client, on the top bar, click **?**, and then click **Support**.

> **WARNING**
> If you have an on-premises deployment, the option to search for existing issues and submit a support incident from the on-premises client to your Azure DevOps project is not available.



NOTE

If you haven't already connected to Lifecycle Services (LCS), a dialog box will display where you can connect. Click the link to connect before proceeding.



Search for a fix

After you connect to LCS, you can search for existing Microsoft published updates and fixes. Enter your issue in the **Search** box and press **Enter**.

NOTE

If you don't want the functionality to search for existing fixes enabled for all users, you can remove the **SearchExistingFixes** duty from the System user role and add it to only those roles which you want to have this functionality. Search results are based on the Microsoft Issue Search data that is relevant to your environment. Fixes that you have already installed will not be included in your search results. To view a specific result, click the link to view the details.

Based on the duties assigned to you, you will see either the **Download view** or the **Request view**.

- **Download view** - By default, this view is only available to system administrators. From this view, you can directly download the hotfix.

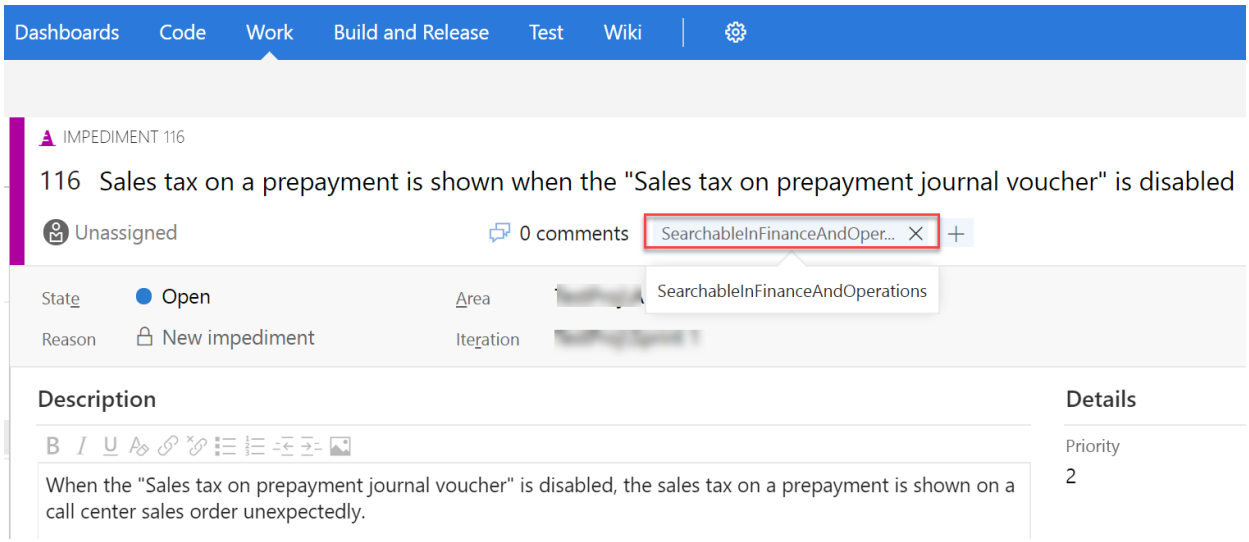
  NOTE

  The duty **DownloadHotfix** controls the ability to directly download fixes from LCS rather than requesting them. Only system administrators will have access to it by default. If you want to assign this duty to users other than system administrators, you can do so by adding the duty to the selected roles.

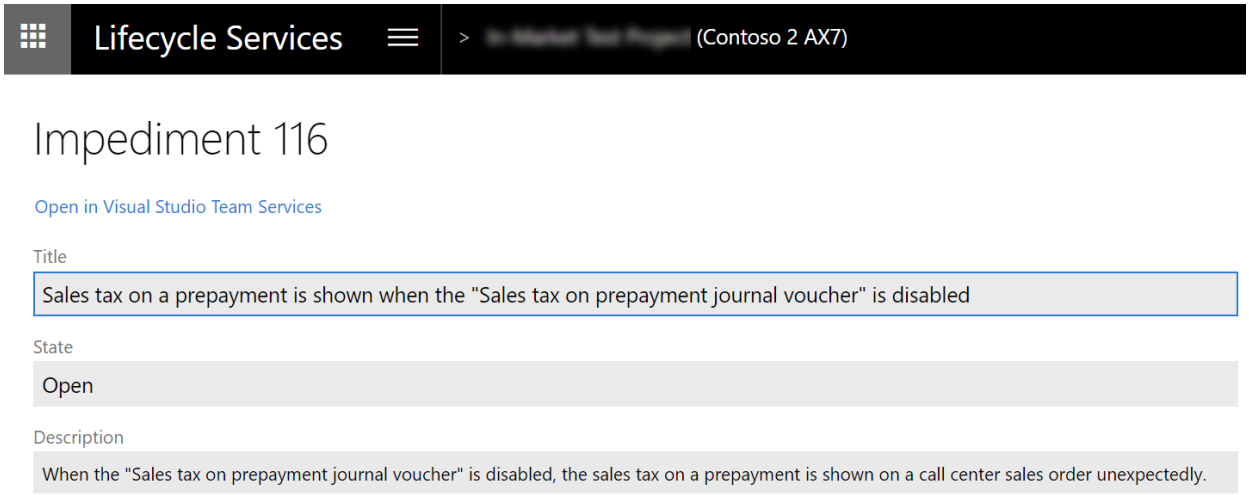
- **Request view** - By default, this view is available to all users who are not system administrators. From this view, you can make a request to download the hotfix. After you submit your request to download the hotfix, a work item will be created in the Azure DevOps project that is associated to your LCS project. The customer IT admin can view all requested hotfixes by clicking the **Support** tile in LCS and then clicking the **Hotfix requests** tab.

Search for project work items in Azure DevOps

The Azure DevOps administrator can publish project work items to your organization users by tagging the work items with **#SearchableInFinanceAndOperations**. The tagged work items will be searchable for users from the client support search box. The search result will include tagged Azure DevOps work items in addition to Microsoft published updates and fixes. The following graphic shows a tagged Azure DevOps work item for publishing.



When you search for published Azure DevOps work items using the support search box, search results show the work item's type, title, state, and description in a new browser tab with **view** mode. Users with proper permissions can edit the work item in Azure DevOps. The following graphic shows the search result of a published Azure DevOps work item.



> **NOTE**
>
> The published Azure DevOps work items are only visible to your organization's users.

Create and submit a new issue

If you don't see a fix in the search results, you can create a new issue by clicking **Create**. This is the same functionality that is available for previous releases and is documented in earlier procedures.

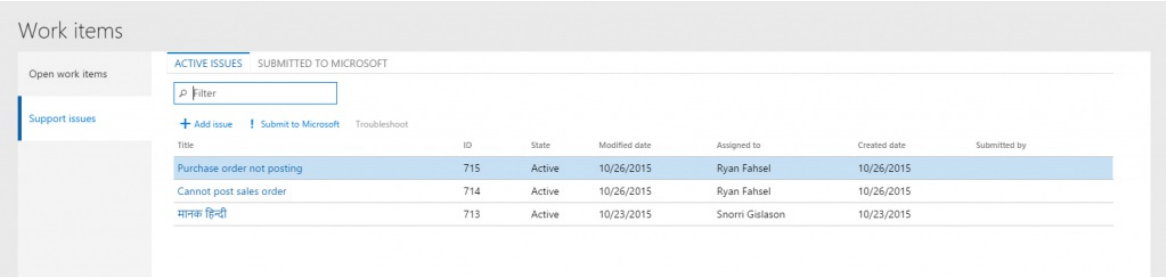
Work with issues in LCS

View issues

In the LCS **Support** tile, issues are stored as work items in the Azure DevOps project that is associated with the LCS project. Specifically, issues are stored as work items of the **Issue** or **Impediment** type, depending on the type of Azure DevOps project, in the **AxAndLcsGeneratedIssues** area. Every work item of one of those types in that area will be included in the list of issues in the **Support** tile. If an issue is modified in Azure DevOps, the changes will be reflected in Support issues. Issues can be assigned to any user in the Azure DevOps project. Users don't need to have access to LCS to work with issues in Azure DevOps.

1. Go to lcs.dynamics.com, and sign in.

2. Open the LCS project that is associated with the environment that you want to view issues for.
3. Click the **Support** tile. A list of the issues that have been created appears.



Edit issues

1. In the **Issues** grid, click the title of an issue.
2. If necessary, sign in to Azure DevOps by using an account that has access to the Azure DevOps project that you set up in the first section of this topic, **Create an Azure DevOps project**.

> **NOTE**
> There is an issue in Azure DevOps, where the link to edit work items doesn't work correctly if sign-in is required. If you see the **Assigned to me** query after you sign in to Azure DevOps, go back to LCS, and click the title of the issue in the issue grid again.

3. The Azure DevOps editor opens. Edit the issue, and then save your changes. The changes will be reflected in the **Support** tile.

Submit an issue to Microsoft

You can submit issues to Microsoft support. When you submit an issue to Microsoft, the information and attachments in the issue can be included in the Microsoft support incident.

LCS users must have a valid Microsoft support plan to submit issues to Microsoft. If you have trouble submitting issues to Microsoft, work with your administrator to make sure that your LCS credentials are added to or associated with your organization's support plan with Microsoft Partner Source Business Center.

1. In the **Issue** grid, select the issue to submit to Microsoft, and then click **Submit to Microsoft**.
2. If your account is associated with multiple support organizations, select the organization to use to create the Microsoft support incident.
3. Use **Issue search** to verify that your issue hasn't already been solved.
4. If **Issue search** doesn't provide a solution to your issue, click **Create incident** at the bottom of the page.
5. Share diagnostic data with the Microsoft support team. By providing version information, your issues can be resolved more quickly.
6. Describe your issue, provide your contact information, and then click **Submit**.

Support settings

> **NOTE**
> The information in this section is not applicable to on-premises deployments.

When you deploy your application from Lifecycle Services, no configuration is required, because the Support tool automatically saves any issues to the same LCS project that Finance and Operations was deployed from. To verify the LCS project that Support uses, go to **System administration** > **Setup** > **System parameters**, and

then click **Help** > **Support Contact**.

Prevent users from creating issues from the client

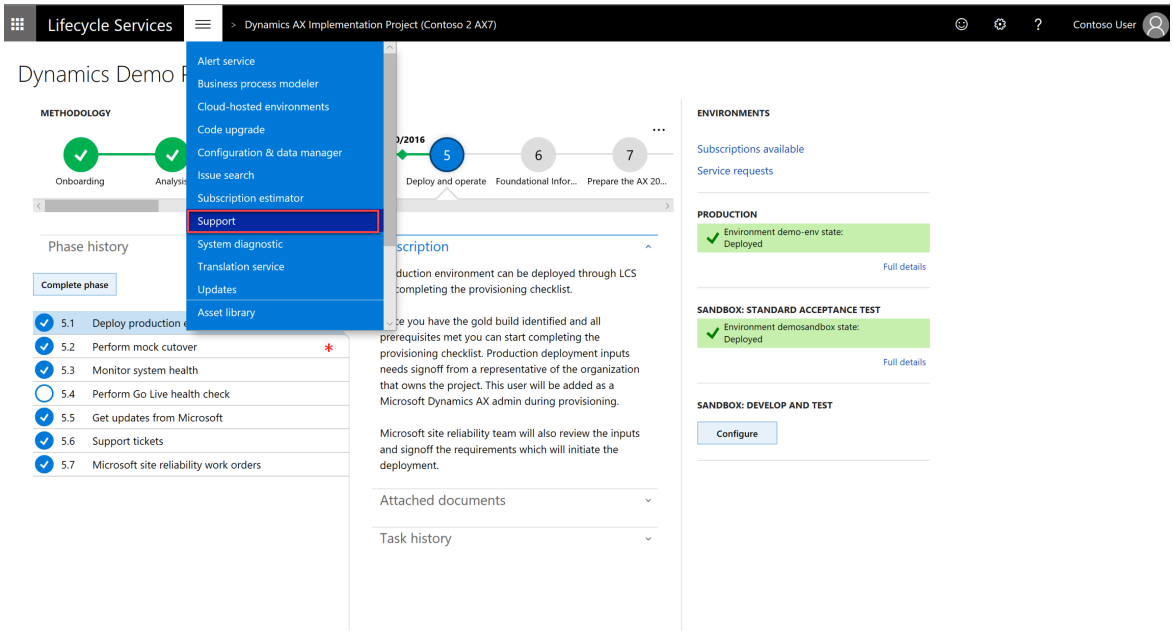
By default, the System user role has the privilege, *SysLCSCPSIssueEntry* assigned. This privilege controls access to the **Contact your support team** menu item on the Help menu. If you want to prevent users from being able to create and submit issues from the client, remove this privilege from the System user role.

Manage support experiences for Finance and Operations apps

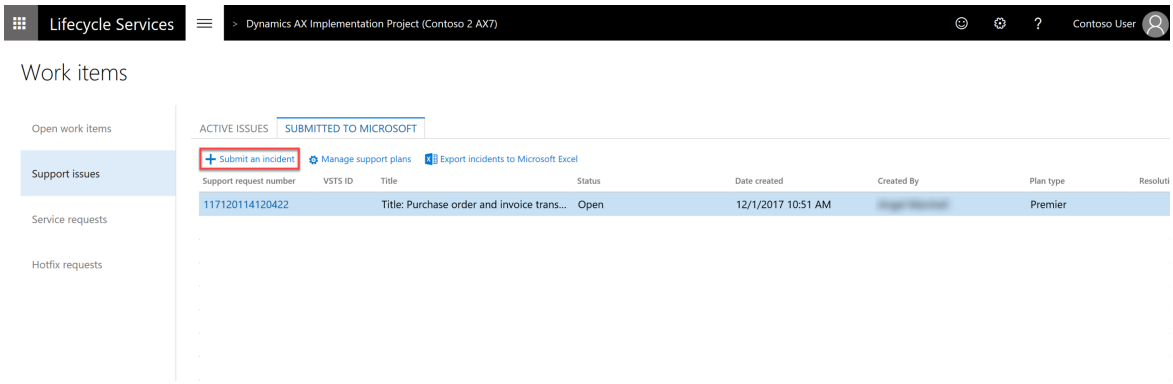
2/18/2021 • 3 minutes to read • Edit Online

Open a new incident

1. In LCS, go to the project for which you want to file a support incident.
2. Click the **Support** tile.



3. On the **Submitted to Microsoft** tab, click the **Submit an incident** button.



4. Select an issue category.
5. Select an issue area.
6. In the **Describe your issue** area, enter the following:
   - Select **Yes** if the issue occurred in an environment. Select the environment name.
   - Enter a short description of your issue in the **Title** field.
   - Provide details about the issue detail and the steps needed to reproduce the error.
   - If applicable, enter an error message.
   - If possible, attach screenshots that illustrate the problem. To do this, click **Attach file from**

computer.

> **NOTE**
>
> When you create an incident, Issue search will populate the top 10 "Possible issue solutions" search results based on the your selection and input, and dynamically refresh these results as more details are provided during support case creation.
>
> Standalone Issue search is still accessible using the drop-down menu if you need to search for more solutions.

7. Enter the primary contact information. These contact details will be used by the customer support team to contact you about the case.
8. Select the support contract and the severity level.
   - Support contracts for on-premises environments have a limited incident count.
   - Support contracts for cloud environments have an unlimited incident count.
   - For on-premises products or cloud environments, from the list of available support contracts, select the support option to use if you have multiple tier support contracts.
9. Click **Submit**.

After you click **Submit**, an incident is created and added to the **Incidents** list. You will receive an email message from the Microsoft Support Engineer assigned to your case.

Support plans in Lifecycle Services

Support plan entitlements are derived based on several different identifiers. Not all will apply to your situation. If you are missing a support plan or entitlement in LCS, determine which identifier is needed to tie it to your project in LCS. If there is more than one organization, note which one is current by clicking on your name in the upper-right corner of LCS. Select the organization that applies to your scenario and contains the benefits that you want to utilize.

Unique contract ID/access ID

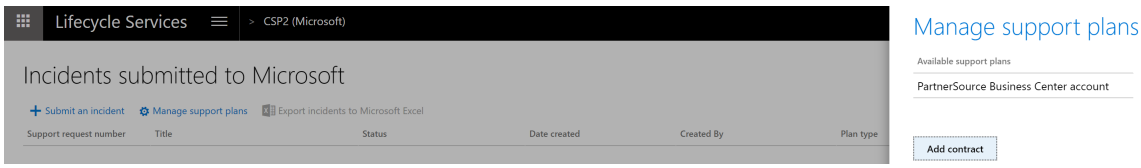
The following online support plans require a unique contract ID/access ID combination linked to your sign-in in LCS:

- Unified
- Premier
- Advanced support for partners

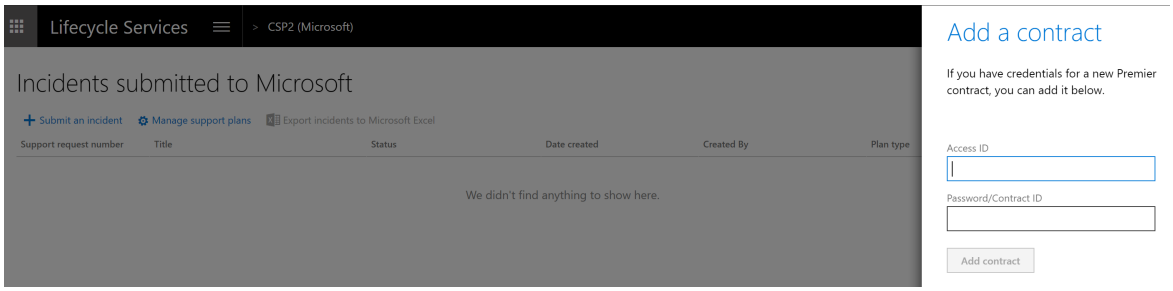
If you do not know your unique contract ID/access ID combination, contact your Microsoft account manager to have an ID created for you.

To link your contract ID/access ID to your account, complete the following steps:

1. From within a project, select **Support** from the main menu, and then select **Manage Support plans**.
2. Select **Add contract**.



3. Enter your access ID and your password or contract ID, and then select **Add contract**.



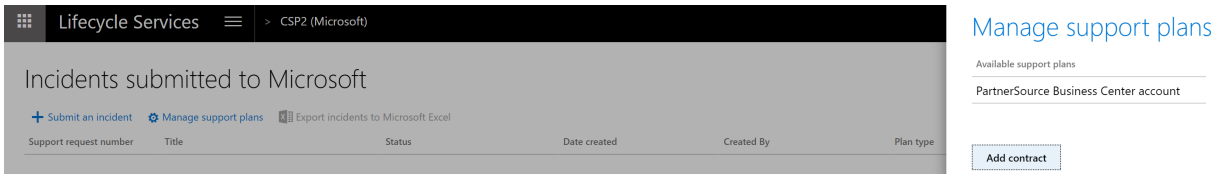
PartnerSource Business Center account

The following support plan incidents can be used as part of your PartnerSource Business Center (PSBC) account if they exist:

> **NOTE**
>
> No online support plans can be utilized through the PSBC account.

- Advanced support for partners on-premises incidents.
- Advantage or Advantage + on-premises incidents.
- Other pay per incident types of plans with an existing incident count in PSBC.

If you do not find the PartnerSource Business Center account, ensure that your sign in is added as a professional in your organization in PSBC. Make sure that you are signing in with the same Microsoft or work account login. This account is only applicable in an on-premises project.



Sign-in specific options

The following incidents and support benefits will appear based on your sign in, if applicable:

- MPN gold and silver incidents.
- Signature cloud support.
- Individual incidents and 5 packs purchased on [support.microsoft.com/supportforbusiness].

> **NOTE**
>
> Incidents must be purchased with a Microsoft account such as @hotmail.com or @outlook.com. Work or Azure Active Directory accounts cannot have incidents tied to them.

Tenant subscription

The following entitlements will appear based on your subscription and ProDirect purchases within your tenant organization:

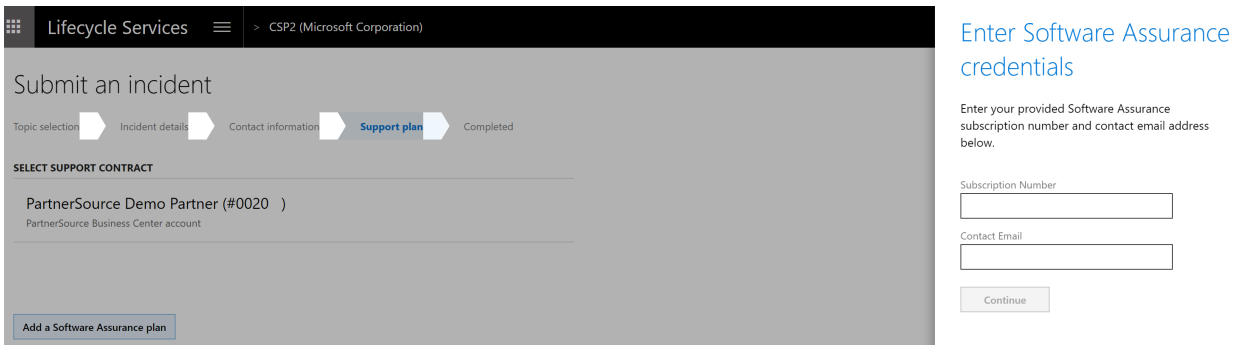
- Subscription
- ProDirect

Software assurance

The following entitlements can be added by linking a subscription number and contact email:

- Software assurance

To add, select **Add a Software Assurance plan** when you create the support incident. Enter the subscription number and the contact email, and then click **Continue**.



Report production outage

For a quick and effective way to escalate issues to Microsoft Support in the event that the services in a production environment are degraded or become unavailable, see Report a production outage.

Phone support

We prefer that you contact Support following the steps in Open a new incident. If you're unable to open a new incident in LCS, phone support is available using Premier phone support.

> **NOTE**
>
> Can you tell us about your documentation language preferences? Take a short survey.
>
> The survey will take about seven minutes. No personal data is collected (privacy statement).

System administration home page

2/18/2021 • 4 minutes to read • Edit Online

This topic points to content for system administrators of Finance and Operations. This content will help you configure the system so that it works smoothly and effectively for your organization.

One Version

In July 2018 we announced a change to the way we deliver Dynamics 365 updates that will help you stay current in a consistent, predictable, and seamless manner. The following topics are intended to provide clarity on the Finance and Operations service updates, processes, and tools you can use to stay current.

- One Version service updates overview
- One Version service updates FAQ
- Service update availability
- Apply updates to cloud environments
- Configure service updates through Lifecycle Services (LCS)
- Pause service updates through Lifecycle Services (LCS)
- Get notified about service updates through Lifecycle Services (LCS)

Implementation management with Lifecycle Services

Microsoft Dynamics Lifecycle Services (LCS) is a collaboration portal that provides an environment and a set of regularly updated services that can help you manage the lifecycle of your Finance and Operations implementations.

The lifecycle of an implementation spans many phases from pre-sales through Analysis, Design and Development, Test, and Deployment to Operation, possibly in multiple iterative roll-outs. It can last a few months to multiple years, based on the scope and complexity of the project and the chosen deployment model, for example, in the managed cloud or on-premises.

The management of the implementation involves many different stakeholders from the customer and partner organizations and, especially in the cloud-hosted deployment model, from Microsoft. The implementation is supported through tools provided on LCS and through processes defined within the Microsoft FastTrack and through the partner's implementation approach.

- Lifecycle Services resources
- Lifecycle Services (LCS) user guide

Deployment

You can deploy in the cloud or on-premises. Cloud deployments offer an enterprise resource planning (ERP) service that is fully managed by Microsoft. On-premises deployments are deployed locally in a customer's data center.

- Software lifecycle policy and cloud releases
- Cloud deployment overview
- System requirements for cloud deployments
- On-premises deployment home page
- System requirements for on-premises deployments

Upgrade

An upgrade can involve moving to a new product version, migrating and upgrading code, moving to an update, or deploying a hotfix.

Although the processes for each type of upgrade are similar, they differ enough that you should review the topics for a specific task before you begin.

- Upgrades, updates, and hotfixes resources

Database management

For information to help you move a database to new environment and restore a database to a specific point in time, see Database movement operations home page.

Security

Finance and Operation apps uses role-based security. Access is granted only to security roles, not to individual users. Users are assigned to roles. A user who is assigned to a security role has access to the set of privileges that is associated with that role. A user who isn't assigned to any role has no privileges.

Role-based security is aligned with the structure of the business. The security roles that a user is assigned to depend on the user's responsibilities in the organization, and their participation in business processes. The administrator grants access to the duties that users in a role perform, not to the program elements that users must use.

Because rules can be set up for automatic role assignment, the administrator doesn't have to be involved every time that a user's responsibilities change. After security roles and rules have been set up, business managers can control day-to-day user access, based on business data.

- Role-based security
- Security architecture
- Encryption in Finance and Operations apps

Batch processing

Many tasks can be run as part of batch jobs. For example, batch jobs can include tasks for printing reports, doing maintenance, or sending electronic documents. By using batch jobs, you can avoid slowing down your computer or the server during typical working hours.

- Batch processing overview
- Batch processing and batch servers

Optimization advisor

- Optimization advisor overview
- Optimization advisor (video)
- Create rules for Optimization advisor

Office integration

The integration with Microsoft Office provides a set of productive, collaborative, and integrated user experiences that take advantage of the Microsoft Office suite. This functionality can help your organization become more efficient and effective.

- Office integration overview

- Office integration tutorial
- Open entity data in Excel and update it by using the Excel add-in
- Create Open in Excel experiences
- Add templates to the Open lines in Excel menu
- Customize the Open in Microsoft Office menu
- Configure and send email
- Troubleshoot the Office integration

Mobile

The Finance and Operations mobile app enables your organization to make its business processes available on mobile devices. After you enable the mobile workspaces for your organization, users can sign in to the app and immediately begin to run business processes from their mobile devices.

- Mobile app home page
- Available mobile workspaces

Process Automation

The process automation framework allows administrators to view and create automated processes that will be scheduled with the batch server. The added layer of visibility of scheduled work is presented in a calendar view that can be extended for use in application areas to allow non-system administrator users to view work that impacts their area.

- Process Automation home page

General administration

- Demo data overview
- Cross-company data sharing
- Add links to your organization's legal terms and privacy statement
- License codes and configuration keys report
- Maintenance mode
- Preconfigured system accounts
- Export business-to-business (B2B) users to Azure Active Directory
- Set the session inactivity timeout
- Build OData metadata cache when AOS starts
- Configure and manage database logging

Add links to your organization's legal terms and privacy statement

2/18/2021 • 2 minutes to read • Edit Online

This topic explains how administrators can add links to their organization's legal terms and privacy statement in the **About** pane of Microsoft Dynamics 365 Finance, Supply Chain Management, and Commerce.

Organizations often need to ensure that the links to their legal terms and privacy statement are readily available and visible to users in order to meet legal and compliance requirements. Administrators of an organization can follow these steps to have the links to their legal terms and privacy statement be available in the **About** pane (**Settings** > **About**).

Add links

1. Go to the **System parameters** page and click **Legal and Privacy.** On this page:
    a. Enter the link to a page that outlines the legal terms for your organization.
    b. Enter the link to a page that outlines the privacy statement for your organization.

    > **NOTE**
    > Make sure that you enter the full URL, starting with either *https* or *http*.

2. Click **Save**.
3. If you are using Commerce, go to the **Distribution schedules** page. On this page:
    a. Select the **1110 – Global configuration** job.
    b. Click **Run now**.

    > **NOTE**
    > To verify that the job completed, go to the **Download sessions** page.

Validate links

Validate the links in Finance, Supply Chain Management, and Commerce

To validate that the links have been added, on the toolbar at the top of the page, click the **Settings** icon, and then click **About**. In the **Links** section of the pane, you should see two new links:

- **Your organization's Legal terms**
- **Your organization's Privacy and Cookies**

Click these links to validate that the appropriate pages open.

NOTE

The links open in a new window, so if you have a pop-up blocker enabled, you will need to add an exception to your pop-up blocker settings to launch a new window.

Validate the links in Modern Point of Sale (MPOS) and Cloud Point of Sale (CPOS)

To validate that the links have been added, go to the **Settings** page. In the **About** section, click the links to validate that the appropriate pages open.

License codes and configuration keys report

2/18/2021 • 2 minutes to read • Edit Online

This topic points you to a report that lists the license codes and configuration keys available in Finance and Operations.

When you purchase Finance and Operations, all functionality is included. By default, some features and functionality that you do not use may be enabled. The administrator should disable the features that are not needed by disabling license codes and configuration keys.

When a license code or configuration key is disabled, the associated module or feature is removed from the user interface. Large sets of functionality, such as modules, are controlled by license codes. Many license codes, in turn, enable configuration keys that allow you to enable and disable functionality at a more detailed level.

To view the report

The **License codes and configuration keys report**, included with the Technical reference reports, lists each configuration key that is available. The report also indicates the license code and menu items associated with each configuration key.

Cross-company data sharing

2/18/2021 • 5 minutes to read • Edit Online

This topic provides information about cross-company data sharing. Cross-company sharing is a mechanism for sharing reference and group data among companies in a Finance and Operations deployment. This feature resembles the virtual companies feature in Microsoft Dynamics AX 2012.

What is this feature and how does it work?

Cross-company data sharing lets you replicate (share) reference and group data among companies. Data integrity is verified before replication occurs.

Here are some examples of cross-company data sharing and the basic logic:

- The same payment terms and payment day definitions are used across 15 legal entities.
- The same terms of delivery are used across seven legal entities in three countries/regions.
- Records created, updated, and deleted in any of the companies within the policy will be replicated immediately, across all the companies.
- Fields that are not selected for sharing are maintained in each company and will not trigger any replication.
- As part of enabling a policy, it is optional to copy any existing records.

Cross-company data sharing has the following limitations:

- It can’t be used to share transactional data between companies.
- Only reference and group data can be shared, or tables that have specifically been enabled. For example, **Data Sharing Type** is set to **Duplicate**.
- It supports replication of fewer than one million total records per job. This total is calculated as the number of shared records × the number of shared companies. The limit is increased to two million records from the Platform Update for version 10.0.10.
- It supports replication for up to 100 companies per policy. The limit is increased to 300 companies from the Platform Update for version 10.0.10.
- Only one level of child relationships is exposed. To protect data consistency, replication doesn't occur if another level is required.
- Fields that reference Financial dimensions, for example **Ledger** or **Default** dimension, can't be shared across companies. o Dimensions hold a loose foreign key reference to the backing dimension data, which can reference both company-specific and non-company specific data. Determining the appropriate action to be taken for each dimension value has inherent complexity and would require a change from the current implementation, which could dramatically impact performance.
- It can’t be used with dual-write.

Policies

Data sharing is managed by defined policies that are saved in data packages. Templates that Microsoft has tested and supports are available as downloadable data packages on Microsoft Dynamics Lifecycle Services (LCS). Policies let you control the following aspects of data sharing:

- The fields that are replicated
- The entities that participate in the replication
- The companies that participates in the sharing

The same company and table can only be in one policy. It is possible to share the same table in more than policy.

This can happen when the limits of records or companies are reached, or to create policies for tables that need to be shared differently for different country/regions.

> **NOTE**
> Only required foreign key fields are selected by default. Optional foreign keys need to be selected manually to be included. The best practice is to add one or more tables when selecting a foreign key field, unless the table has already been added.

Policy templates that Microsoft has tested and supports are available as downloadable data packages on Lifecycle Services (LCS).

> **IMPORTANT**
> Although customers can modify the Microsoft data templates that are available from LCS, this scenario isn't supported.

Conflict resolution

Validation rules are run when a sharing policy is enabled. If inconsistencies are detected, the user who implements the system can choose which records from which company should win.

Considerations for successful data sharing

Several entities in the Microsoft data packages have references that you must consider when you enable the entities. Some data sharing policies can't be enabled if references don't match. Other policies can be enabled, but you should use the Find inconsistency checker tool to verify that your data is consistent. Here are some examples:

- The Production group sharing policy has a reference to a company's chart of accounts. Therefore, all companies that are added to this sharing policy must use the same chart of accounts.
- If you want to enable entities that use number sequences, the number sequence types must be the same across all companies in a sharing policy for those entities.
- Setup options must be the same across the companies that are involved in the sharing policy. Examples of setup options include the setting that specifies whether tax is included by default.

When should I use cross-company data sharing?

Use cross-company data sharing for the following business scenarios:

- Sharing of simple reference and group data in a single deployment
- Sharing among companies that have very similar configurations
- Sharing scenarios that have been explicitly tested by Microsoft

Cross-company data sharing isn't supported for the following scenarios:

- Franchising solutions, where thousands of records are shared across thousands of companies.
- Sharing of transactional records for reporting or management purposes, such as consolidations.
- Sharing across deployments.
- Complex scenarios, such as replication of subtype/supertype tables or tables that have date effectivity rules.
- Tables that do not have a unique index.

Customer and vendor master data sharing

Customer and vendor master data sharing allows you to share customer and vendor data across multiple companies. If you would like to be considered for this feature, complete the Data sharing application and contact

Support.

With the release of Platform update for version 10.0.12, customer and vendor master data sharing can be enabled using the **Customer and vendor master data sharing** feature in the **Feature management** module. There is no need to complete a survey first. It is important to consider limits in the number of records and companies stated above.

> **NOTE**
> Default dimensions set up against a customer or vendor cannot be shared across companies. When configuring the customer or vendor record for cross-company data sharing, the **DefaultDimension** field is disabled, and cannot be included in the data sharing policy.

> Default dimensions hold a loose foreign key reference to the backing dimension data, which can reference both company-specific and non-company specific data. Determining the appropriate action to be taken for each dimension value has inherent complexity and would require a change from the current implementation, which could dramatically impact performance.

Download a cross-company data sharing template from LCS

1. Sign in to LCS.
2. On the home page, click **Shared asset library**.
3. In the **Asset type** list, click **Data package**.
4. Click any of the available data package files to download them.

For details about how to use a template, see Configure financial cross-company data sharing.

Currently supported cross-company data sharing templates

PACKAGE NAME ON LCS	DATA SHARING POLICIES
Financial data sharing templates	• Bank parameters • Ledger journal names • Payment days • Payment schedules • Payment terms • Tax exempt codes

PACKAGE NAME ON LCS	DATA SHARING POLICIES
Supply chain data sharing templates	• Barcode parameters • Barcode setup • Buyer group • Charges group • Commission • Destination code • Non-conformance type • Order entry deadline group • Order origin code • Order pool • Production group • Production pool • Reason for delivery • Supplementary item group • Terms of delivery • Work time calendar

Additional resources

Configure financial cross-company data sharing (Task guide)

Maintenance mode

2/18/2021 • 3 minutes to read • Edit Online

This topic provides information about maintenance mode in Finance and Operations. When maintenance mode is turned on, it provides a safe way for system administrators to make system changes that might affect system functionality. For example, configuration keys can be enabled or disabled. While maintenance mode is on, only system administrators and users who have the **Maintenance mode user** role can sign in to the system. By default, maintenance mode is turned off. When maintenance mode is off, you can't edit the **License configuration** page.

Turn maintenance mode on and off on sandbox and production environments through Lifecycle Services

You can now turn maintenance mode on and off directly through Lifecycle Services (LCS) on your sandbox and production environments. Refer to the following steps to do this:

1. Go to the environment details page and on the **Maintain** menu, click **Enable Maintenance Mode**.
2. In the slider, set **Turn maintenance mode on** for the environment and select **Confirm**.
3. A servicing operation will begin and your system will go into maintenance mode.
4. On completion, the environment state will be **In Maintenance**. At this point, only the system administrator will have access to the environment.
5. After you are done making system-wide changes, you can turn off maintenance mode by clicking **Disable Maintenance Mode** under the **Maintain** menu.
6. This will start a servicing operation that takes your environment out of maintenance mode. You can see the progress of the operation in the environment details page.
7. After this is complete, your environment goes back to the **Deployed** state. Now all users can sign in to the environment.
8. You can check the environment history page to see when the maintenance mode was turned on or turned off. To get to the environment history page, select **History** and **Environment changes** on the environment details page.

Turning maintenance mode on and off for your sandbox and production environment is very similar to a servicing operation. If turning maintenance mode on or off fails, you will see options such as **Resume**, **Rollback**, and **Abort**. You also have the option to **download the logs** to troubleshoot why the operation failed.

Turn maintenance mode on and off in DevTest/Demo environments hosted in a Microsoft subscription

1. Establish an RDP connection to the developer machine.
2. On the developer machine, sign in to SQL Server by using the credentials for the axdbadmin user from LCS. Then switch to the AXDB database, and run the following command.

   ```
   update SQLSYSTEMVARIABLES SET VALUE = 1 where PARM = 'CONFIGURATIONMODE'
   ```

3. Restart the **World Wide Web Publishing Service** to reset IIS.
4. After the service is restarted, the system will be in maintenance mode.

5. When you've completed your maintenance mode activities, repeat steps 2 and 3, but set the value to 0 in step 2.

Turn maintenance mode on and off in DevTest/Demo environments and VHD-based environments hosted in customers' subscription

You can turn on maintenance mode locally by running the following command.

NOTE

On some virtual machines (VMs), the exact location of the Deployment.Setup.exe tool might differ. Check AosServiceWebRootbin.

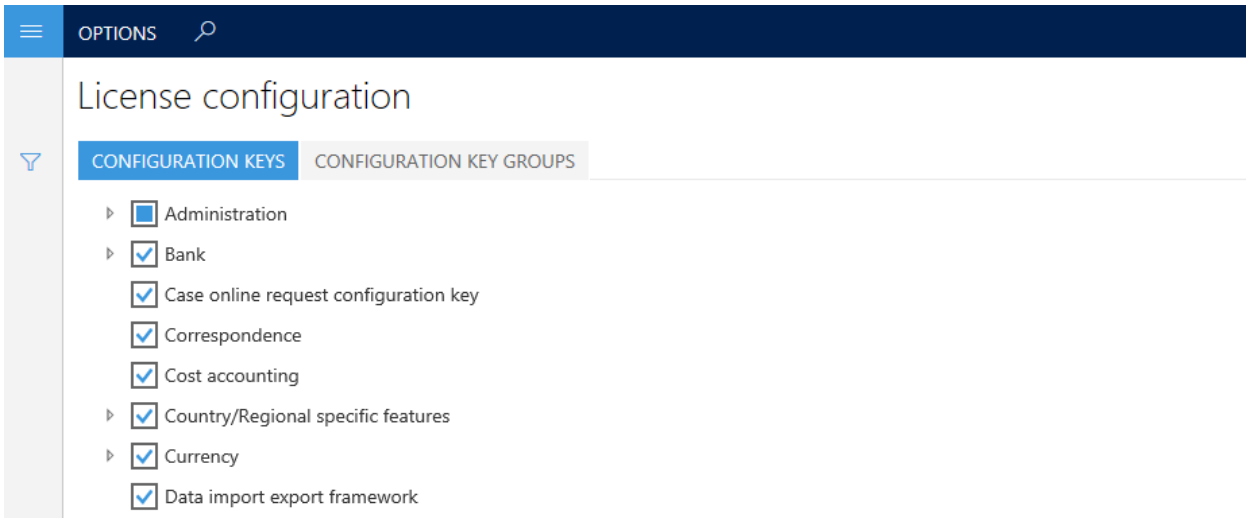
```
J:\AosService\PackagesLocalDirectory\Bin\Microsoft.Dynamics.AX.Deployment.Setup.exe --metadatadir
J:\AosService\PackagesLocalDirectory --bindir
J:\AosService\PackagesLocalDirectory\Bin --sqlserver . --sqldatabase axdb --sqluser axdbadmin --sqlpwd
********* --setupmode maintenancemode --isinmaintenancemode true
```

The following table describes the parameters that are used in this command.

PARAMETER NAME	DESCRIPTION
--setupmode maintenancemode	Use this parameter to inform the setup tool that the system will be put into or taken out of maintenance mode.
--metadatadir	Use this parameter to specify the metadata directory. You should use the default packages directory.
--bindir	Use this parameter to specify the binaries directory. You should use the default packages directory.
--sqlserver	Use this parameter to specify the Microsoft SQL Server. For one-box environments, use a period (.).
--sqluser	Use this parameter to specify the SQL Server user. You should use **AOSUser**.
--sqlpwd	Use this parameter to specify the SQL Server password.
--isinmaintenancemode	Use this parameter to turn configuration mode on or off. Use **true** to turn it on and **false** to turn it off.

Enable (or disable) configuration keys

After the instance of Application Object Server (AOS) is restarted, the system will be in maintenance mode. You can then enable configuration keys, as shown in the following screenshot.



If you try to access the system while in maintenance mode, but you aren't a system administrator or a user who has the **Maintenance mode user** role, you may receive an error message.

You can turn off maintenance mode by running the following command.

```
J:\AosService\PackagesLocalDirectory\Bin\Microsoft.Dynamics.AX.Deployment.Setup.exe --metadatadir
J:\AosService\PackagesLocalDirectory --bindir J:\AosService\PackagesLocalDirectory\Bin --sqlserver . --
sqldatabase axdb --sqluser axdbadmin --sqlpwd ********* --setupmode maintenancemode --isinmaintenancemode
false
```

NOTE

Can you tell us about your documentation language preferences? Take a short survey.

The survey will take about seven minutes. No personal data is collected (privacy statement).

Preconfigured system accounts

2/18/2021 • 2 minutes to read • Edit Online

Pre-configured system accounts are included on deployed environments so that Microsoft can manage and operate the Finance and Operations service and provide specific features to customers. The following table provides information about each account, including the purpose and use case for the account.

IMPORTANT

Do not delete these system accounts. Deleting these accounts will cause a disruption in key functionality provided by Microsoft.

ACCOUNT DETAIL	PURPOSE/USE CASE OF THE ACCOUNT
`Axrunner`	This account is used to monitor the health of the environment and provide alerts when necessary.
`FRServiceUser`	This account is the Financial Reporting service user account, which is used by the Management Reporter application for integrations with Finance and Operations.
`RetailServiceAccount`	This account is used for Retail services to connect to the Finance and Operations environment.
`SysHealthServiceUser` or `Axping` (depending on the deployed product version)	This account is used to monitor the availability and health of the environment and provide alerts when necessary.

NOTE

Can you tell us about your documentation language preferences? Take a short survey.

The survey will take about seven minutes. No personal data is collected (privacy statement).

Export business-to-business (B2B) users to Azure Active Directory

2/18/2021 • 2 minutes to read • Edit Online

You can automatically export business-to-business (B2B) users to Azure Active Directory (Azure AD).

In the past, B2B users were exported manually to a .csv file. Then the Azure AD tenant administrator had to use this file to manually add the users to Azure AD using the Azure portal.

To enable the automatic export feature, a one-time setup and configuration process must be completed. When the process is completed, you can use the **Provision Azure AD B2B user** workflow task to automatically export B2B users to Azure AD.

The one-time set up and configuration means that you'll need to:

1. Set up a B2B invitation service application in Azure AD.
2. Configure the B2B invitation service settings in Finance and Operations.

Set up a B2B invitation service application in Azure AD

The tenant administrator of your Azure AD tenant will need to complete the following steps.

1. Log on to the Azure portal as the tenant administrator.
2. Click **Azure Active Directory** > **Properties**.
3. Copy the **Directory ID** (this is the tenant ID) and save it. You will need this later.
4. Click **App registrations** > **New application registration**.
5. Enter the following information, and then click **Create**.
   a. In the **Name** field, enter the name of the application. For example: **B2B admin application**.
   b. In the **Application type** field, select **Web app /API**.
   c. In the **Sign-on URL** field, enter the URL for Finance and Operations.
6. Click the **App registrations** tab, click the newly created application, copy the **Application ID**, and save it. You will need this later.
7. Click **All settings** > **Required permissions** > **Add**.
8. In the **Add API access** pane, do the following:
   a. Click the **Select an API** tab. Click **Microsoft Graph**, and then click **Select**.
   b. In the **Select permissions** tab, select the following **application permissions** and set them to **Yes**:
      - **Invite guest users to the organization**
      - **Read and write directory data**
      - **Read and write all users' full profiles**
   c. Select the following **delegated permissions** and set them to **Yes**:
      - **Invite guest users to the organization**
      - **Read and write directory data**
      - **Read and write all users' full profiles**

- **Sign in and read user profile**

d. Click **Select** and **Done**.

9. In the **Required permissions** blade, click **Grant Permissions**, and then click **Yes** to assign the permissions.
10. Click **All settings** > **Keys**, and then do the following:
    a. Enter a name of the key in the **Description** field.
    b. Set the expiration duration in the **Expires** field.
11. Click **Save**. Saving the key will display the **Value**.

> **WARNING**
> Be sure to copy the key **Value** after saving the key. This value will not be available when you leave the blade.

Configure the B2B invitation service settings

1. Sign in to Finance and Operations as administrator.
2. Navigate to the **B2B Invitation Configuration** page, and click **Edit**.
3. Select **Enabled**.
4. Verify that the **Tenant ID** is the same as the **Directory ID** (which you noted in step 3 of the previous procedure).
5. In the **Client ID** field, enter the **Application ID** (which you noted in step 6 of the previous procedure).
6. Enter the key **Value**, copied from the above procedure, into the **Application Key** field.
7. **Save** the settings.

Now you can start using the **Provision Azure AD B2B user** workflow task in your workflows to automatically export B2B users to Azure AD.

Role-based security

2/18/2021 • 5 minutes to read • Edit Online

This topic provides an overview of the elements of role-based security in Finance and Operations.

In role-based security, access is not granted to individual users, only to security roles. Users are assigned to roles. A user who is assigned to a security role has access to the set of privileges that is associated with that role. A user who is not assigned to any role has no privileges.

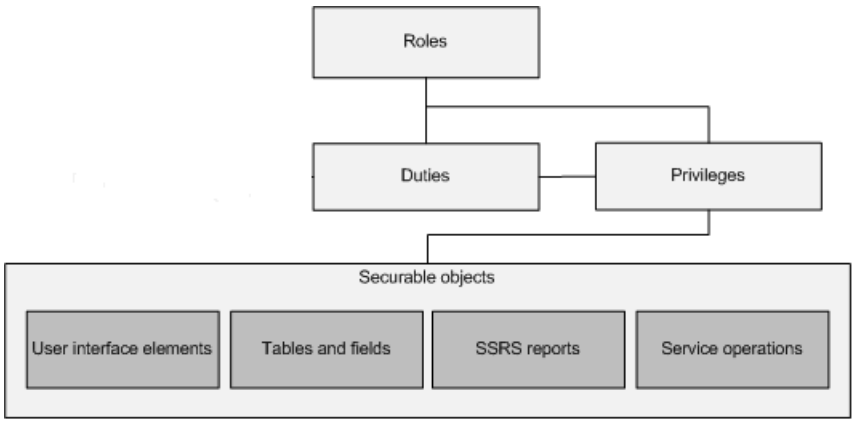
In Finance and Operations apps, role-based security is aligned with the structure of the business. Users are assigned to security roles based on their responsibilities in the organization and their participation in business processes. The administrator grants access to the duties that users in a role perform, not to the program elements that users must use.

Because rules can be set up for automatic role assignment, the administrator does not have to be involved every time that a user's responsibilities change. After security roles and rules have been set up, business managers can control day-to-day user access based on business data.

Overview of role-based security

This section provides an overview of the elements of role-based security. The security model is hierarchical, and each element in the hierarchy represents a different level of detail. Permissions represent access to individual securable objects, such as menu items and tables. Privileges are composed of permissions and represent access to tasks, such as canceling payments and processing deposits. Duties are composed of privileges and represent parts of a business process, such as maintaining bank transactions. Both duties and privileges can be assigned to roles to grant access to Finance and Operations.

The following illustration shows the elements of role-based security and their relationships.



Security roles

All users must be assigned to at least one security role in order to have access to Finance and Operations. The security roles that are assigned to a user determine the duties that the user can perform and the parts of the user interface that the user can view.

Administrators can apply data security policies to limit the data that the users in a role have access to. For example, a user in a role may have access to data only from a single organization. The administrator can also specify the level of access that the users in a role have to current, past, and future records. For example, users in a role can be assigned privileges that allow them to view records for all periods, but that allow them to modify records only for the current period.

By managing access through security roles, administrators save time because they do not have to manage access separately for each user. Security roles are defined one time for all organizations. In addition, users can be automatically assigned to roles based on business data. For example, the administrator can set up a rule that associates a Human resources position with a security role. Any time that users are assigned to that position, those users are automatically added to the appropriate security roles.

Security roles can be organized into a hierarchy. The role hierarchy allows the administrator to define a role based on another role. For example, the sales manager role could be defined as a parent role of the manager role and the salesperson role. A parent role automatically inherits the duties, privileges, and conditions that are assigned to its child roles. Therefore, a user who is assigned to the parent role can perform all of the tasks that users in the child roles can perform. A role can have one or more child roles or one or more parent roles.

By default, sample security roles are provided. All functionality is associated with at least one of the sample security roles. The administrator can assign users to the sample security roles, modify the sample security roles to fit the needs of the business, or create new security roles. By default, the sample roles are not arranged in a hierarchy.

Duties

Duties correspond to parts of a business process. The administrator assigns duties to security roles. A duty can be assigned to more than one role.

In the security model, duties contain privileges. For example, the **Maintain bank transactions** duty contains the **Generate deposit slips** and **Cancel payments** privileges. Although both duties and privileges can be assigned to security roles, we recommend that you use duties to grant access to Finance and Operations.

You can assign related duties to separate roles. These duties are said to be segregated. By segregating duties, you can better comply with regulatory requirements, such as those from Sarbanes-Oxley (SOX), International Financial Reporting Standards (IFRS), and the United States Food and Drug Administration (FDA). In addition, segregation of duties helps reduce the risk of fraud, and helps you detect errors or irregularities.

Default duties are provided. The administrator can modify the privileges that are associated with a duty, or create new duties.

Privileges

In the security model, a privilege specifies the level of access that is required to perform a job, solve a problem, or complete an assignment. Privileges can be assigned directly to roles, however we recommend that you only assign duties to roles. This is so that the privileges are first grouped together into a duty, which makes it easier to maintain.

A privilege contains permissions to individual application objects, such as user interface elements and tables. For example, the **Cancel payments** privilege contains permissions to the menu items, fields, and tables that are required to cancel payments.

By default, privileges are provided for all features in Finance and Operations. The administrator can modify the permissions that are associated with a privilege, or create new privileges.

Permissions

Each function, such as a form or a service, is accessed through an entry point. Menu items, web content items, and service operations are referred to collectively as entry points.

In the security model, permissions group the securable objects and access levels that are required to run a function. This includes any tables, fields, forms, or server side methods that are accessed through the entry point.

NOTE

Can you tell us about your documentation language preferences? Take a short survey.

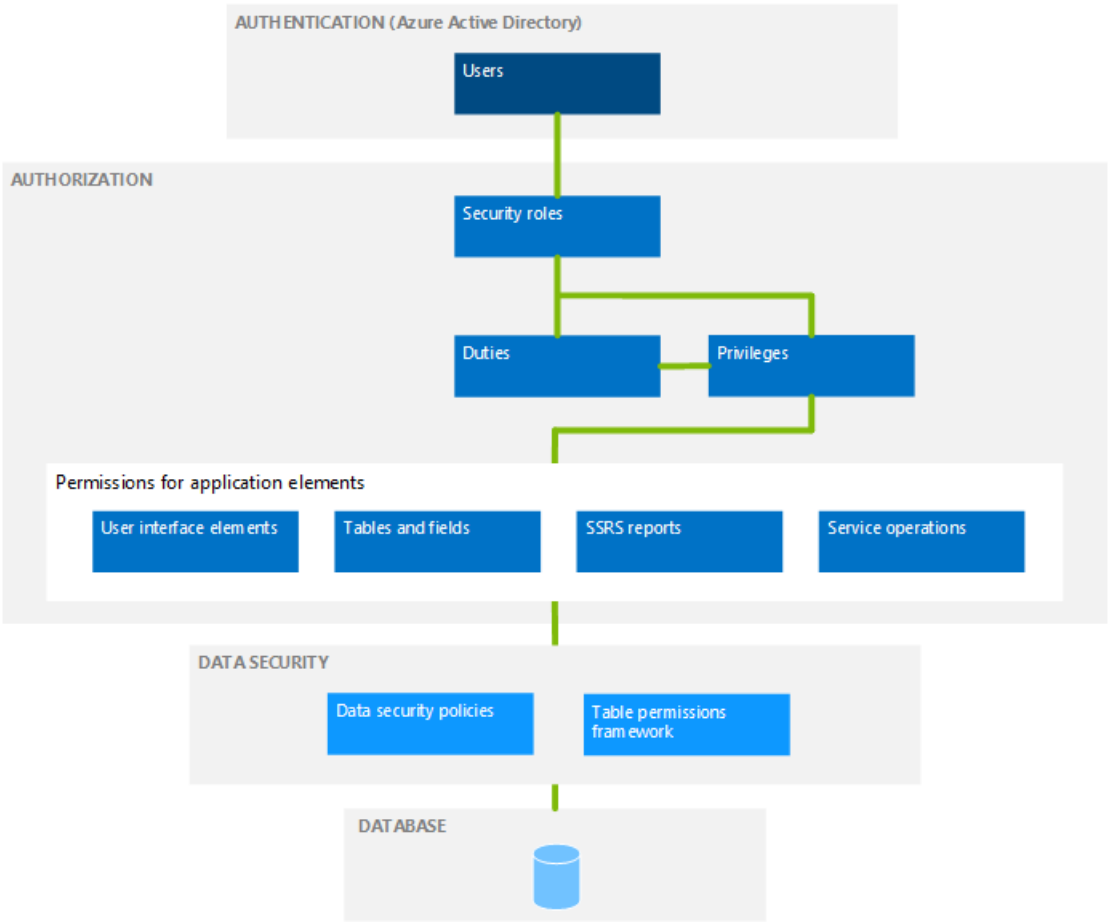
The survey will take about seven minutes. No personal data is collected (privacy statement).

Security architecture

2/18/2021 • 2 minutes to read • Edit Online

This topic provides an overview of the security architecture of Finance and Operations.

When you understand the security architecture, you can more easily customize security to fit the requirements of your business. The following diagram provides a high-level overview of the security architecture.



Authentication

By default, only authenticated users who have user rights can establish a connection.

Microsoft Azure Active Directory (AAD) is a primary identity provider. To access the system, users must be provisioned into a Finance and Operations instance and should have a valid AAD account in an authorized tenant.

Authorization

Authorization is the control of access to Finance and Operations applications. Security permissions are used to control access to individual elements of the program: menus, menu items, action and command buttons, reports, service operations, web URL menu items, web controls, and fields in the Finance and Operations client.

Individual security permissions are combined into privileges, and privileges are combined into duties. The administrator grants security roles access to the program by assigning duties and privileges to those roles.

Context-based security controls access to securable objects. When a privilege is associated with an entry point (such as a menu item or a service operation), a level of access, such as **Read** or **Delete**, is specified. The

authorization subsystem detects the access at run time, when that entry point is accessed, and applies the specified level of access to the securable object that the entry point leads to. This functionality helps to ensure that there is no over-permissioning, and the developer gets the access that was intended.

For more information, see Role-based security.

Data security

Authorization is used to grant access to elements of the program. By contrast, data security is used to deny access to tables, fields, and rows in the database.

Use the extensible data security framework to supplement role-based security by restricting access to table records based on security policies. A security permission, as part of a user role, increases the access a user has to data, while a security policy decreases access to data.

For more information, see Extensible data security policies.

Additionally, the Table Permissions Framework helps protect some data. Data security for specific tables is enforced by Application Object Server (AOS).

Auditing

Auditing of user sign in and sign out is enabled, which means that the system logs when a user signs in or out of the application. A sign out is logged even if the user's session expires or ends.

A system administrator or security administrator can access the audit logs by going to the **User log** page (**System administration** > **Inquiries** > **User log**).

> **NOTE**
>
> Can you tell us about your documentation language preferences? Take a short survey.

> The survey will take about seven minutes. No personal data is collected (privacy statement).

Encryption in Finance and Operations apps

2/18/2021 • 2 minutes to read • Edit Online

Encryption at rest

Microsoft uses encryption technology to protect customer data while at rest in an environment's SQL Server database and Azure Storage.

All instances utilize Microsoft SQL Server Transparent Data Encryption (TDE) and Azure Storage encryption to perform real-time encryption of data when written to the disk at rest.

Finance and Operations apps use server-side encryption using service-managed keys. All key management aspects such as key issuance, rotation, and backup are handled by Microsoft.

In addition to the default encryption at rest provided above, you can use the encryption API available in the **Global** X++ class. The methods **Global::editEncryptedField()** and **Global::editEncryptedStringField()** use the environment-specific data encryption certificate to perform data encryption and decryption. You can use these methods as an additional layer of protection beyond the default encryption at rest technology used for data storage.

Encryption in transit

Connections established between customers and Microsoft datacenters are encrypted, and all public endpoints are secured using industry-standard Transport Layer Security (TLS) 1.2. TLS effectively establishes a security-enhanced browser-to-server connection to help ensure data confidentiality and integrity between desktops and datacenters.

Supported TLS versions

Finance and Operations apps support TLS 1.2 only. Earlier TLS versions, 1.0 and 1.1, are not supported.

Supported cipher suites

Finance and Operations apps only support the following cipher suites:

- TLS_ECDHE_ECDSA_WITH_AES_256_GCM_SHA384
- TLS_ECDHE_ECDSA_WITH_AES_128_GCM_SHA256
- TLS_ECDHE_RSA_WITH_AES_256_GCM_SHA384
- TLS_ECDHE_RSA_WITH_AES_128_GCM_SHA256
- TLS_ECDHE_ECDSA_WITH_AES_256_CBC_SHA384
- TLS_ECDHE_ECDSA_WITH_AES_128_CBC_SHA256
- TLS_ECDHE_RSA_WITH_AES_256_CBC_SHA384
- TLS_ECDHE_RSA_WITH_AES_128_CBC_SHA256

The survey will take about seven minutes. No personal data is collected (privacy statement).

Set the session inactivity timeout

2/18/2021 • 2 minutes to read • Edit Online

> **IMPORTANT**
>
> Some or all of the functionality noted in this topic is available as part of a preview release. The content and the functionality are subject to change. For more information about preview releases, see Service update availability.

The session inactivity timeout setting represents the amount of time a user can be inactive before the user's session times out and closes. It only affects user browser sessions.

You can set the values from 5 minutes to 60 minutes.

This function has a default value of 30 minutes. You can set the value up to 60 minutes, however doing so might cause extra load on the system.

> **NOTE**
>
> This feature is available as of Platform update 29.
>
> If you previously set a session inactivity timeout in the web.config (**WebClientStatefulSessionTimeoutInSeconds** key) through a support request, then that old value will still be honored. The change in default will only affect those who had not explicitly set a new session inactivity timeout in the web config.

To change the value, follow these steps:

1. Select **System administration > Setup > System parameters** to open the **System parameters** page.
2. On the **General** tab, in the **Session management** section, enter a value in the **Session inactivity timeout in minutes** field.
3. Select **Save**.

   If you set the value to greater than 30, you will be prompted to confirm your selection. The confirmation prompt says "Increasing the inactivity session timeout can cause extra load on your system, which can lead to a decrease in performance. Are you sure you want to continue?" The higher the value, the higher the load will be, which can affect negatively system performance. Select **Yes** to save the changes, or **No** to revert to the existing value.

Alerting users before sessions end due to inactivity

To give users awareness of an impending session suspension due to inactivity and to help prevent users from losing any unsaved changes when this occurs, users will be notified before their sessions are set to be terminated due to inactivity and given an opportunity to reconnect. The notice given to the user is dependent on the **Session inactivity timeout** setting.

- If the **Session inactivity timeout** is more than 30 minutes, the user will see a countdown notification starting **5 minutes** before the session is set to close.
- If the **Session inactivity timeout** is between 10 and 30 minutes, the user will see a countdown notification starting **2 minutes** before the session is set to close.
- If the **Session inactivity timeout** is less than 10 minutes, the user will see a countdown notification starting **30 seconds** before the session is set to close.

NOTE

Can you tell us about your documentation language preferences? Take a short survey.

The survey will take about seven minutes. No personal data is collected (privacy statement).

Out-of-box security reports

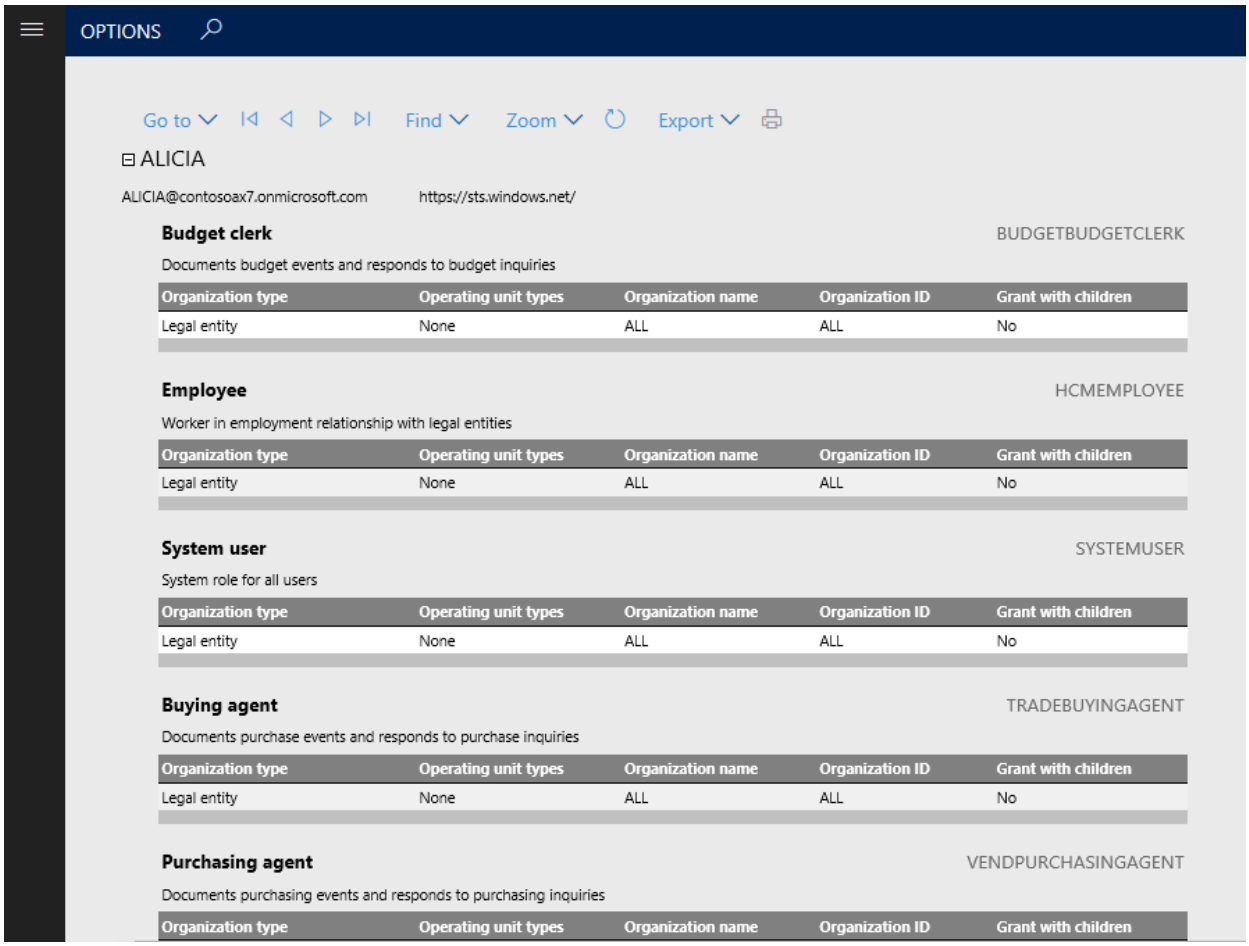
2/18/2021 • 3 minutes to read • Edit Online

Finance and Operations provides a set of rich security reports to help you understand the set of security roles running in your environment and the set of users assigned to each role. In addition to the reports noted in this topic, developers can generate a workbook containing all user security privileges for all roles using **Visual Studio > Dynamics 365 > Addins > View related objects and licenses for all roles**.

Each of the security reports can be found under **System administration > Inquiries > Security.** A description of each report is provided below.

User role assignments

The **User role assignments** report generates a view of the current user role assignments in your system. By default, the report includes all users with roles assigned. You can optionally limit the report to a specific set of users by entering a list of users when generating the report. On the **User role assignments** parameters pane, go to **Records to include** > **Filter.** From here you can add or remove filters to the list of users the report will be generated for.

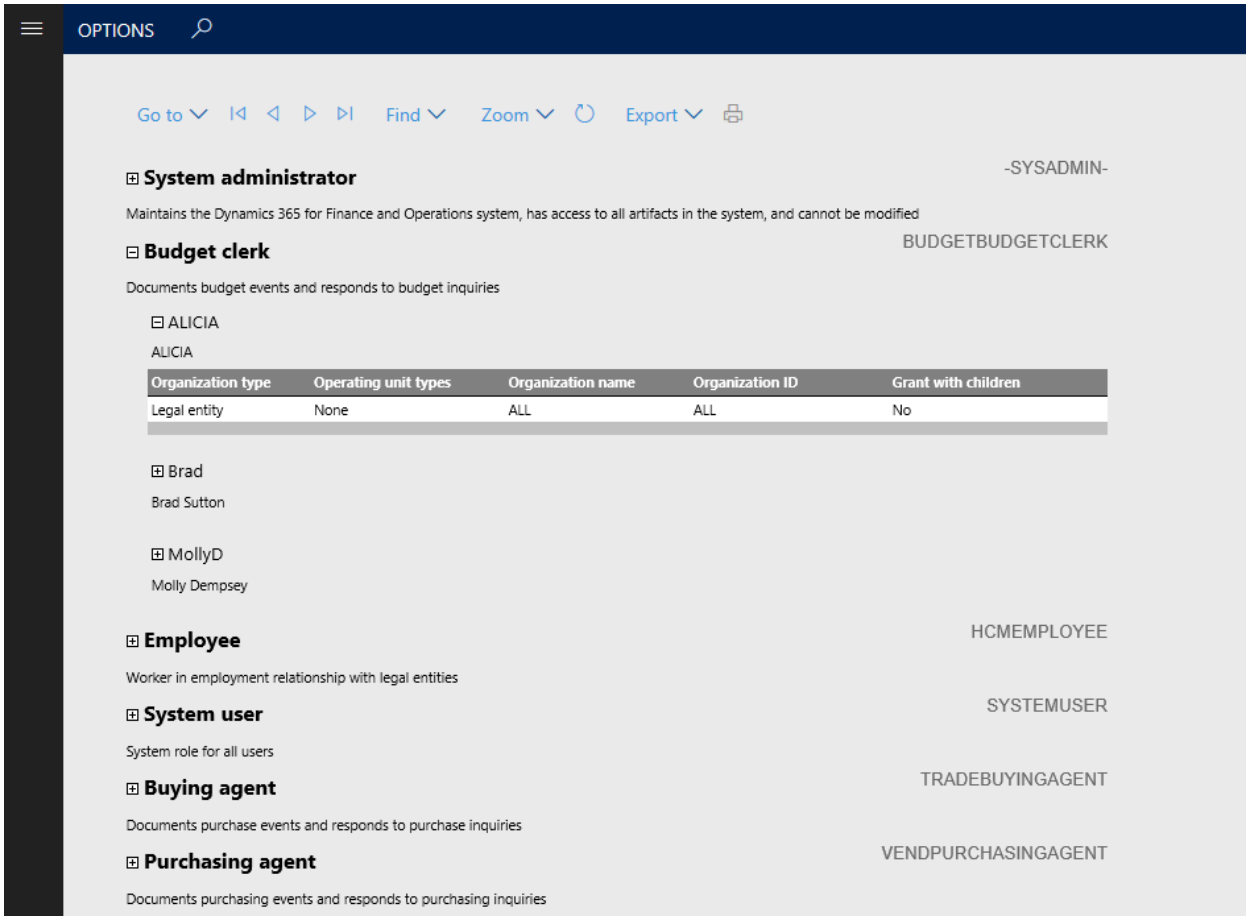


For each user in the report a list of roles is provided, along with any restrictions at the legal entity or organization level.

Role to user assignments

The **Role to user assignment** report provides an aggregation of role assignments. Expanding a role in the

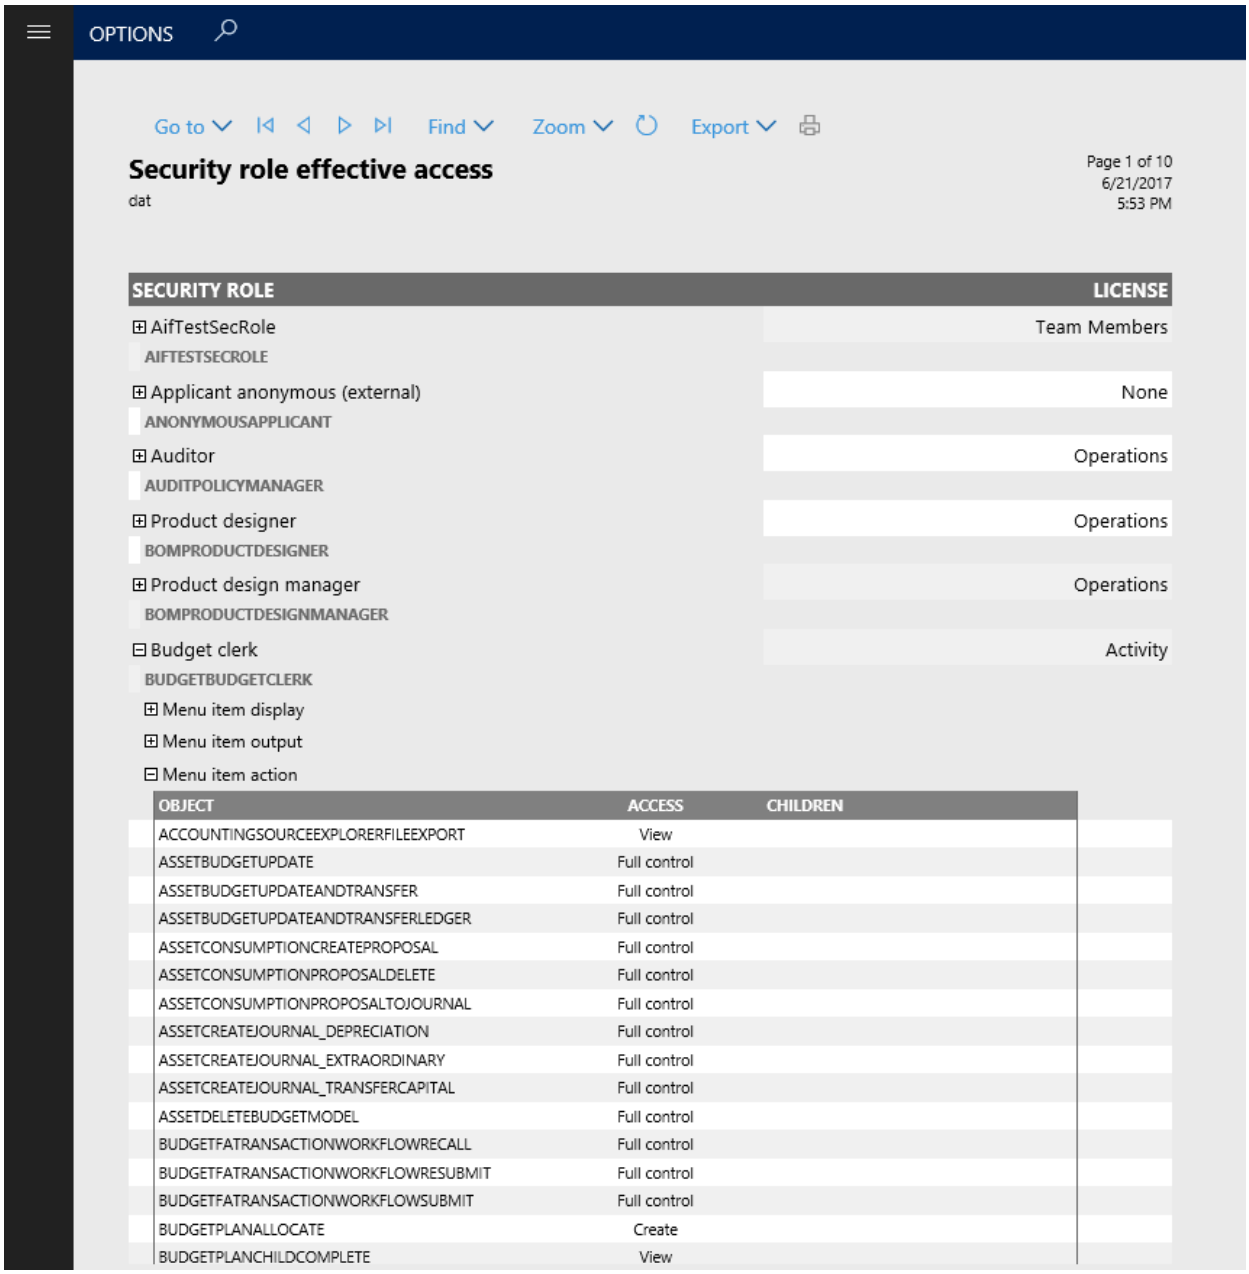
report shows the list of users assigned to the role, and expanding the user name shows any restrictions the role has applied. The same method for filtering the set of users can be applied to this report as described for the **User role assignments** report.



Security role access

The **Security role access** report provides a view of the effective permissions for each security role. This report provides a flattened list of permissions grouped by type across all sub-roles, duties, and privileges contained in the role.

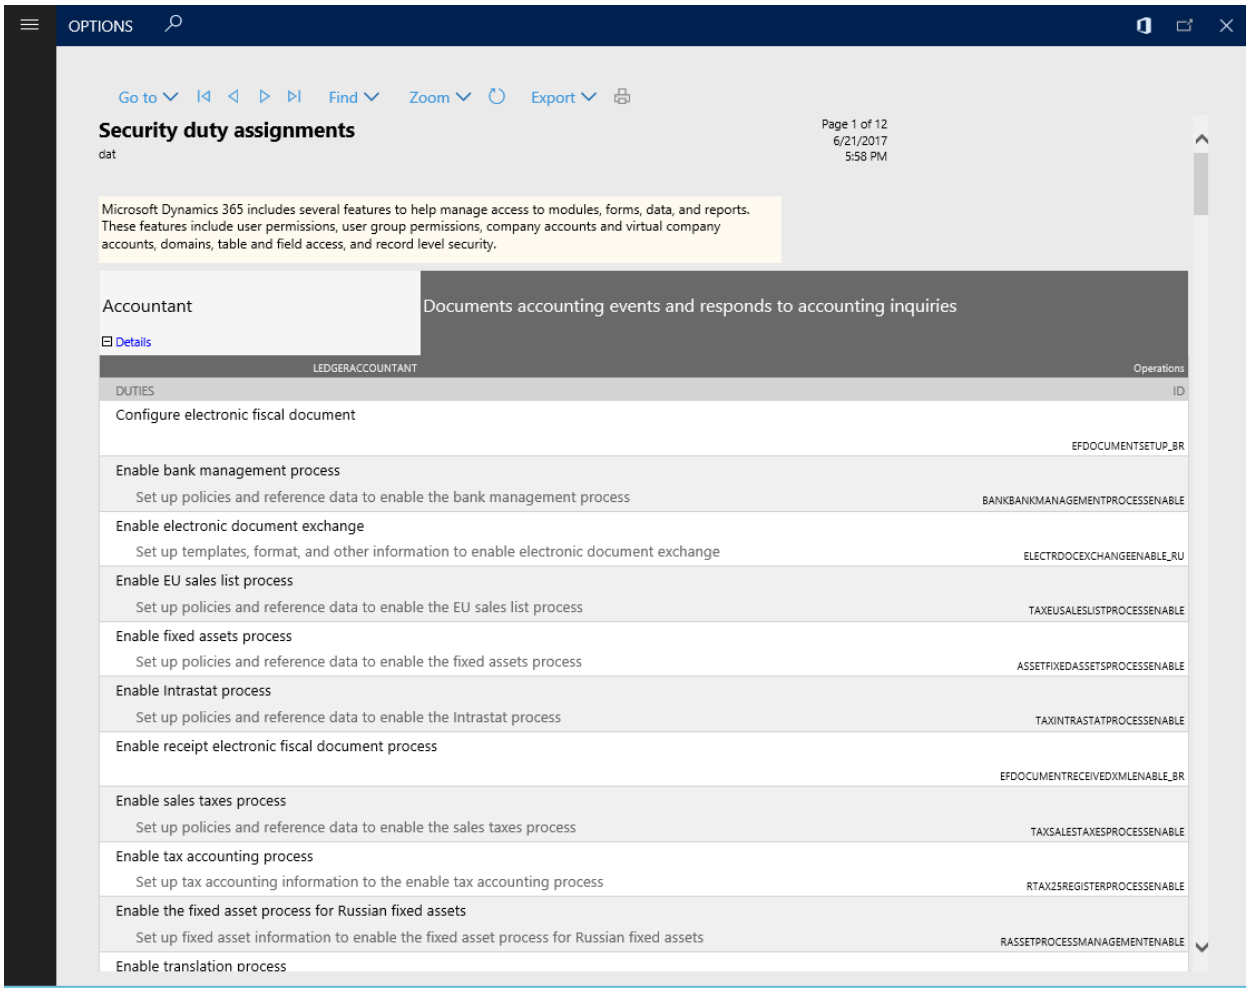
The data set backing the **Security role access** report can be very large, causing the report to take some time to run. If there have been no changes to security roles since the last time the report was run, you can skip building the report by setting the **Rebuild collection** option to **No** on the report parameters pane. This will render the report from the existing data set. If it is the first time the report has run, or there could be changes to the role definitions, the **Rebuild collection** option should be set to **Yes**. You can optionally limit the roles to be included in the report by adding a filter under **Records to include**.



Expanding a role shows the category of objects the role has access to. Expanding one of the object types will show a detailed list of each object of that type included in the role.

Security duty assignments

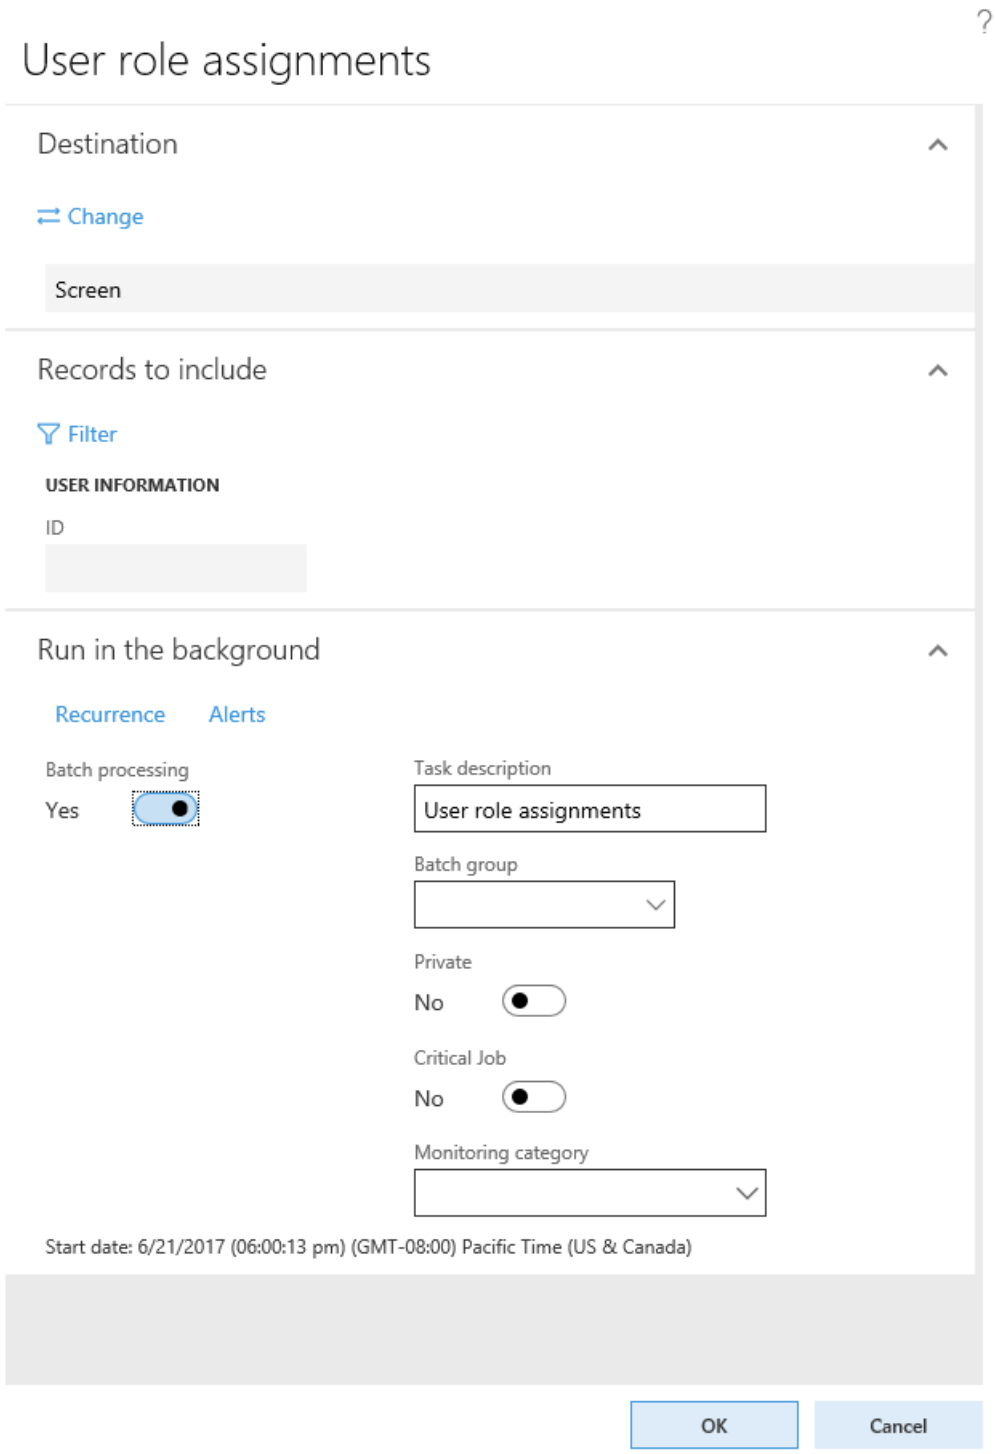
The **Security duty assignments** report provides a view of all the duties contained within a role. This report can be configured to run on any collection of roles to ensure that segregation of duties is maintained between roles. By default, the report will include all roles. To limit the roles included, leverage the filtering provided in the **Records to include** section.



Expanding a role in the **Security duty assignments** report will show each duty assigned to the role, along with details of the duty.

Batch processing of reports

Any of the above reports can be set to run as a batch job by going to the **Run in the background** section of the report's parameter pane. Set **Batch processing** to **Yes**, then provide a batch task job name, batch group, and whether the job should run as Private or Critical. The report will then be created when the batch task runs.



NOTE

Can you tell us about your documentation language preferences? Take a short survey.

The survey will take about seven minutes. No personal data is collected (privacy statement).

Create new users

2/18/2021 • 3 minutes to read • Edit Online

Before you can access Finance and Operations apps, you must first be added to the **Users** page (**System administration** > **Users** > **Users**). Users include internal employees of your organization, or external customers and vendors. Users can be imported or added manually. All users must be correctly licensed for compliant use.

For information about how to buy and license for Finance and Operations apps, see Microsoft Dynamics 365 Licensing Guide.

Assign a license to a user

System admins can assign licenses to users in the Microsoft 365 admin center.

Add an external user in Azure AD and assign a license

External users must be represented in your tenant directory (Azure Active Directory (Azure AD)) so that they can be assigned licenses. Those external users should be added to the tenant in Azure AD as guest users and then assigned the appropriate licenses. A requirement for Finance and Operations apps is that the guest user's company must use Azure AD. For more information, see Add Azure Active Directory B2B collaboration users in the Azure portal.

Import new users from Azure AD

1. Go to **System administration** > **User** > **Users**.
2. On the Action Pane, select **Import users**.
3. Select the users to be imported. The list includes Azure AD users that are currently not users in this environment.
4. Select **Import users**.
5. Select **Close**.

> **NOTE**
>
> The value for the **Company** field will be set based on the current session company for the admin. After import, you must assign roles and organizations as applicable. For more information, see Assign users to security roles. Conditionally, it might also be required to associate the user with a **Person** and to update user options such as language.

Manually add a new user

1. Go to **System administration** > **Users** > **Users**.
2. On the Action Pane, select **New**.
3. In the **User ID** field, enter a unique identifier for the user.
4. In the **User name** field, enter the user's name.
5. In the **Provider** field:

- For internal users, use the defaulted value. For example, your Azure AD tenant prefixed with https://sts.windows.net/.
- For non-Azure AD users, such as Service-2-Service accounts, enter a basic text value. For example, NA. This

value will help avoid incorrect authentication calls that might result in errors if a valid identity provider value is used.

- For external or guest users, add their Azure AD tenant name after https://sts.windows.net/.

6. In the **Email** field, enter the user's full Email/User Principle Name.
7. In the **Company** field, select the default startup company for the user.
8. Select **Save**.

The values for Identity provider and Telemetry ID will be updated based on a Microsoft graph call, when the user record is saved. The Telemetry ID is based on the user's Object ID/Security Identifier (SID) in Azure AD.

> **NOTE**
>
> After you add a user, you must assign roles and organizations as applicable. For more information, see Assign users to security roles. Conditionally, it might also be required to associate the user with a **Person** and to update **User options** such as language.

Change a user ID

To change a user ID, you must rename the key in the database. When you change a user ID by using this procedure, all related user settings are modified to use the new user ID. For example, the usage information in the **SysLastValue** table is updated to reference the new user ID.

> **NOTE**
>
> The user ID is the primary key of the user information table. Renaming the primary key can take some time for existing users because all references to the key are also updated in the database.

1. Go to **System administration > Users > Users**.
2. Select a user in the list and select **Options> Record info**.
3. Select **Rename**.
4. Enter a new and unique value for the User ID, and then select **OK**.
5. Select **Yes** to confirm.

Additional resources

For more options to implement B2B users, see Export B2B users to Azure AD.

For information about preconfigured system accounts, see Preconfigured system accounts

> **NOTE**
>
> Can you tell us about your documentation language preferences? Take a short survey.
>
> The survey will take about seven minutes. No personal data is collected (privacy statement).

User session management

2/18/2021 • 2 minutes to read • Edit Online

The user session setting represents the amount of time a user can be signed in before the user's session expires. After the user's session expires, the user is required to sign in with their credentials.

The **Maximum session length** can be up to 2,160 hours (90 days), with a minimum of 1 hour.

> **NOTE**
> This feature is available in public preview as of version 10.0.16. To enable this feature, go to the Feature management page and enable the **(Preview) Enable session management for users** feature.

To change the maximum session length, follow these steps:

1. Go to**System administration > Users > User session management**.
2. Select **New**.
3. In the new row, select the drop-down menu in the **User ID** field.
4. In the user list, select a user.
5. In **Maximum session length (hours)**, enter a value.
6. Select **Save**.

To update the user's maximum session length:

1. Select the user that you want to update by selecting the row.
2. In **Maximum session length (hours)**, enter a value.
3. Select **Save**.

To delete a user's maximum session length and replace it with another user's session:

1. Select the user that you want to delete by selecting the row.
2. In the **User ID** field, select the drop-down menu and select another user.
3. In the **Maximum session length (hours)** column, enter an hour.
4. Select **Save**.

To delete the user's maximum session length:

1. Select the user that you want to delete by selecting the row.
2. Select **Delete**.

To delete the multiple users' maximum session length:

1. Select the rows that you want to delete.
2. Select **Delete**.

Import users from Azure Active Directory

2/18/2021 • 2 minutes to read • Edit Online

Import select users

This procedure can be used by system administrators to import select users from Azure Active Directory (Azure AD).

1. User will be imported with the current session company as their default company. Change current company if applicable before importing users.
2. Go to **System administration** > **Users** > **Users**.
3. Click **Import users**.
4. Select the users that should be imported and select **Import users**.

After import is completed it will be required to assign roles to users.

Import users in bulk

This procedure can be used by system administrators to import a large number of users from Azure Active Directory. Note that it is not possible to select users when using the Batch import option.

Run the import as a batch job

1. User will be imported with the current session company as their default company. Change current company if applicable before importing users.
2. Go to **System administration** > **Users** > **Users**.
3. Click **Batch import**.
4. Expand the **Run in the background** section.
5. Select **Yes** in the **Batch processing** field.
6. In the **Batch group** field, enter or select a value. This is an optional step.
7. Select **Yes** in the **Private** field. This is an optional step.
8. Select **Yes** in the **Critical job** field. This is an optional step.
9. In the **Monitoring category** field, select an option.
10. Click **OK**.

After import is completed, it will be required to assign roles to users.

Run in a sandbox environment

1. Select **Batch import**.
2. Select **OK**.

Set up segregation of duties

2/18/2021 • 2 minutes to read • Edit Online

You can set up rules to separate tasks that must be performed by different users. This concept is named segregation of duties. For example, you might not want the same person to acknowledge the receipt of goods and to process payment to the vendor. Segregation of duties helps you reduce the risk of fraud, and it also helps you detect errors or irregularities. You can also use segregation of duties to enforce internal control policies. Complete the following procedure to create a rule. You must be a system administrator to complete the procedure.

1. Go to **System administration** > **Security** > **Segregation of duties** > **Segregation of duties rules**.
2. Click **New**.
3. In the **Name** field, type a value for the rule.
4. In the **First duty** field, click the drop-down button to open the lookup.
5. In the list, find and select the desired record. Select the first duty that is controlled by the rule.
6. In the **Second duty** field, click the drop-down button to open the lookup.
7. In the list, find and select the desired record. Select the second duty that is controlled by the rule.
8. In the **Severity** field, select an option. Select the severity of the risk that occurs when the same user or role performs both duties.
9. In the **Security risk** field, type a value. Enter a description of the security risk.
10. In the **Security mitigation** field, type a value. Enter a description of the actions that you take to mitigate the security risk. For example, you can mitigate the risk by conducting more detailed reviews of the process, by conducting a monthly managerial review, or by sharing resources with other departments.
11. Click **Save**.

IMPORTANT

Compliance with the rules for segregation of duties is not verified when you create a rule. You can create a rule that creates a conflict for existing roles. Existing user role assignments can also be in conflict with the new rule. You must validate compliance after you create or modify a rule. For more information, see Identify and resolve conflicts in segregation of duties

NOTE

Can you tell us about your documentation language preferences? Take a short survey.

The survey will take about seven minutes. No personal data is collected (privacy statement).

Identify and resolve conflicts in segregation of duties

2/18/2021 • 2 minutes to read • Edit Online

This topic explains how to identify and resolve conflicts in segregation of duties. You can set up rules to separate duties that must be performed by different users. This concept is named segregation of duties. When the definition of a security role or the role assignments of a user violate the rules, the conflict is logged. All conflicts must be resolved by the administrator. Complete the following procedure to identify and resolve conflicts.

After a rule has been added, verify that all existing roles are compliant.

Verify that existing roles and duties comply with new rules for segregation of duties

1. Go to **System administration** > **Security** > **Segregation of duties** > **Segregation of duties rules**.
2. Select **Validate duties and roles**. If any roles violate the rules, a message is displayed that contains the name of the rule, the role, and the names of the conflicting duties. Conflicting roles must be modified using **Security configuration** and can't include conflicting duties. If no roles violate the selected rule, a message indicates that all roles comply.

> **NOTE**
> The validation is only performed for the selected rule. It is important to validate compliance for each rule.

When you create or modify a role, the rules for segregation of duties are automatically enforced. You cannot assign conflicting duties to a role.

Next, verify that all existing role assignments are compliant.

Verify that user role assignments comply with new rules for segregation of duties

1. Go to **System administration** > **Security** > **Segregation of duties** > **Verify compliance of user-role assignments**.
2. Select **OK**. A notification displays the results of the validation. Conflicts are logged on the **Segregation of duties unresolved conflicts** page.

When you assign users to roles, the rules for segregation of duties are automatically enforced. If you try to assign a user to roles that contain conflicting duties, you receive an error message. You must then resolve the conflict by denying or allowing the additional role assignment. The additional role will be assigned after the assignment is allowed.

> **NOTE**
> Conflicts are currently not verified for users that are assigned roles based on the Active Directory Domain groups.

View and resolve conflicting user role assignments

1. Go to **System administration** > **Security** > **Segregation of duties** > **Segregation of duties unresolved conflicts**.
2. Select a conflict, and then select one of the following actions:

- **Deny assignment**: This will deny the assignment of the user to the additional security role. If you deny an automatic role assignment, the user is marked as excluded from the role. The excluded user isn't granted the access associated with the role and can't be assigned to the role until the administrator removes the exclusion.
- **Allow assignment**: This will override the conflict and allow the user to be assigned to the additional security role. If you override a conflict, you must enter a reason in the **Reason for override** field. All overridden role assignments can be viewed on the **Segregation of duties conflicts** page.

> **NOTE**
>
> If several conflicts are listed for the same user, select the user record and evaluate assigned roles on the **Users** page. To avoid this conflict, validate each rule after it's added or modified.

Assign users to security roles

2/18/2021 • 2 minutes to read • Edit Online

To use anything other than common capabilities in Finance and Operations apps, users must be assigned to security roles. You can assign users to roles automatically, based on rules and business data, exclude users from automatic role assignment, or add users to roles manually.

Automatically assign users to roles

This procedure explains how system administrators can automatically assign users to roles, based on business data.

1. Go to **Navigation pane > Modules > System administration > Security > Assign users to roles**.
2. In the tree, select 'Accounting supervisor'. Select the role that you want to configure the rule for. In this example, select Accounting supervisor.
3. Select **Add rule** to open the dialog menu.
4. In the **Select a query** list, find and select the desired record. Select the query to use for this rule.
5. In the **Membership rule name** list, click the link in the selected row.
6. Select **Edit query**. Edit the query, as needed.
7. Select **OK**.
8. Select **Run automatic role assignment**.
9. Go to **Navigation pane > Modules > System administration > Users > Users** (ideally in a separate browser tab).
10. Review the roles assigned to various users to confirm that the role assignment query was correct. Adjust and re-run if needed.

Exclude users from automatic role assignment

1. Close the page.
2. Go to **Navigation pane > Modules > System administration > Security > Assign users to roles**.
3. In the tree, select 'Accounting supervisor'. Select a role. For this example, select Accounting supervisor.
4. In the **Users assigned to role** menu, select **Manually assign / exclude users**.
5. In the **Assign users to or exclude users from role** list, mark the selected row. Select a user.
6. On the **Action pane**, select **Exclude from role**.
7. Select **Exclude from role** to exclude the selected users from the role. To remove exclusions, select the users that you want to remove exclusions for, and then click **Reset status**. When you remove an exclusion by resetting the user's status, the user's role is assigned automatically. However, the user is not immediately assigned to the role or excluded from the role when you reset the status. Instead, the user is either assigned to the role or removed from the role the next time that the rules for automatic role assignment are run.

Manually assign users to roles

Users who are manually assigned to security roles must also be manually removed by the administrator. These users are not removed from roles by rules for automatic role assignment.

1. Go to **Navigation pane > Modules > System administration > Security > Assign users to roles**.
2. In the tree, select a role, and in the **Users assigned to role** menu, select **Manually assign / exclude users**.

3. In the **Assign users to or exclude users from role**, users that have not been assigned the role are listed with the **Assignment mode** set to **None**. Select one or more users that should be assigned the role.
4. On the **Action pane**, select **Assign to role**. The **Assignment mode** is updated to **Manual** and the users now have a new role assigned.

Import or export a customized security configuration by using Data management

2/18/2021 • 2 minutes to read • Edit Online

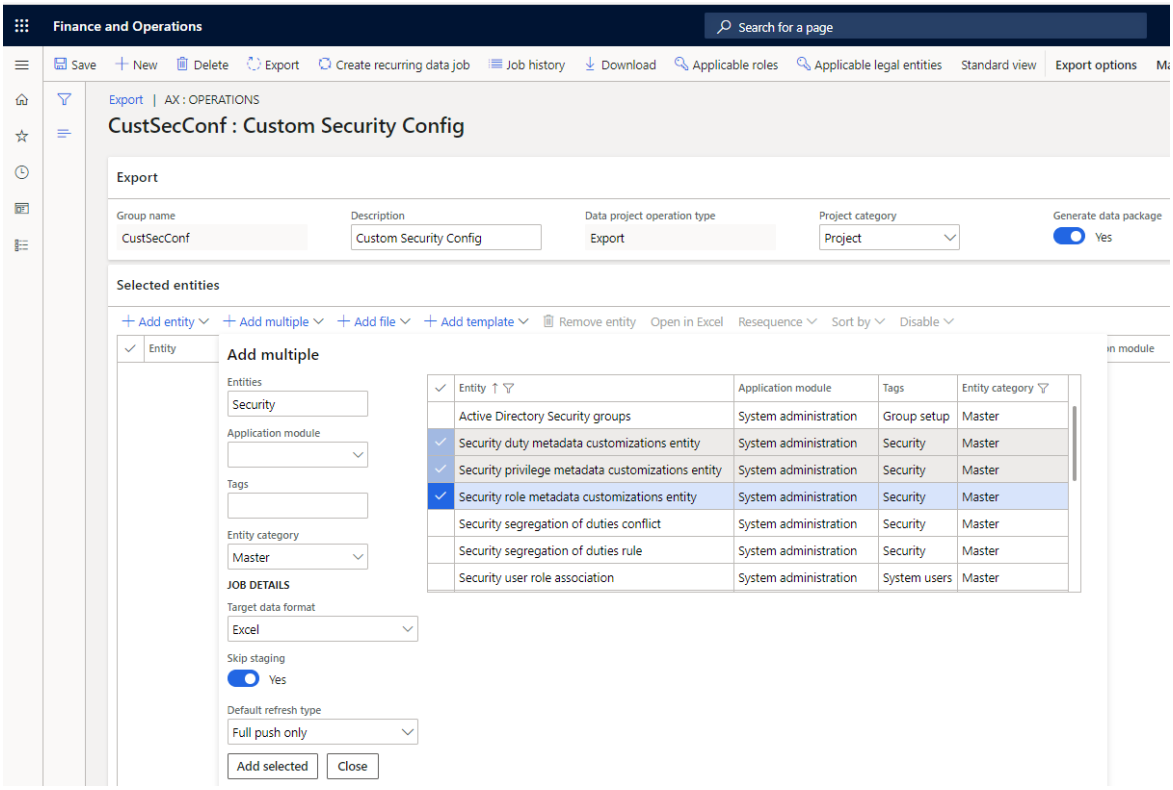
The topic explains how a customized security configuration can be exported and imported across environments by using the Data management framework. This functionality can be used when, for example, a customized security configuration must be moved from a test environment to a production environment.

The following entities hold the customized, role-based security (that is, privileges, duties, and roles) that has been added or modified by using security configuration:

- Security privilege metadata customization entity
- Security duty metadata customization entity
- Security role metadata customization entity

Export customized security configuration

1. Go to **System administration** > **Workspaces** > **Data management**.
2. Select the **Export** tile.
3. In the **Group name** field, enter a name for the group.
4. Set the **Generate data package** option to **Yes**.



5. Select **Add multiple** to open the drop-down dialog box.
6. Filter the entities by setting the following fields:
   - In the **Entities** field, enter **Security**.
   - In the **Entity category** field, select **Master**.

7. In the **Target data format** field, select **Excel**.
8. Select the applicable security customization entities.
9. Select **Add selected**.

   In version 10.0.12 and later, ignore any warning messages about data length. Those messages aren't applicable, because the entities that are included use containers in data package mode.
10. Select **Close**.
11. Make sure that the **Sequence** field is set in the order of the entity dependencies. Privileges should be first, then duties, and finally roles.
12. Select **Export**.
13. Select **Close**.
14. Wait for the job to be completed. Select **Refresh** to view the status.
15. Select **Download package**.
16. Save the package.

Import customized security configuration

1. Go to **System administration** > **Workspaces** > **Data management**.
2. Select the **Import** tile.
3. In the **Group name** field, enter a name for the group.
4. Select **Add file**.
5. Select **Upload and add**.
6. Find the exported package, and then select **Open**.

   In version 10.0.12 and later, ignore any warning messages about data length. Those messages aren't applicable, because the entities that are included use containers in data package mode.
7. Select **Close**.
8. Select **Import**.
9. Select **Close**.
10. Wait for the job to be completed. Select **Refresh** to view the status.

Related security configuration entities

- **SystemSecurityUserRoleOrganizationEntity** – Assignment of organizations to security roles.
- **Security segregation of duties rule** – Segregation of duties rules.
- **Security segregation of duties conflict** – Segregation of duties conflicts. This entity has unresolved conflicts but also reviewed conflicts.

The survey will take about seven minutes. No personal data is collected (privacy statement).

Security diagnostics for task recordings

2/18/2021 • 2 minutes to read • Edit Online

Before you begin

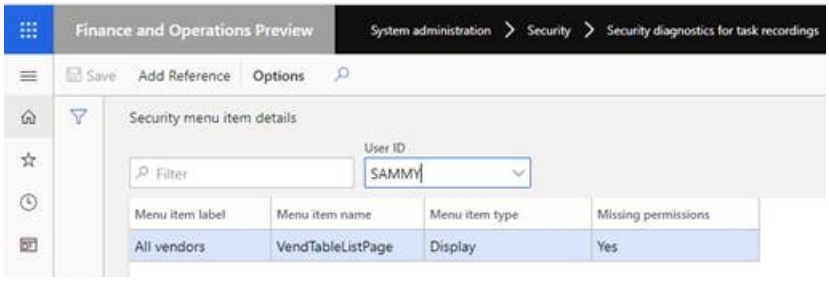
This topic provides information about how to analyze and manage security permission requirements based on a task recording. Before you complete the steps in this topic, you must have a task recording of the business process that you want to analyze. To record a business process, see Task recorder resources.

Manage security for a task recording

1. Go to **System administration** > **Security** > **Security diagnostic for task recording**.
2. Open the task recording from its location. Select **Open from this PC** or **Open from Lifecycle Services**, and then select **Close**.
3. This will open the **Security menu item details** page that lists the security objects required for the process.

> **NOTE**
>
> The **Action** and **Output** menu items are not included in the list.

4. In the **User ID** field, select a user. If the user does not have permissions for some menu items, the **Missing permissions** field will update to **Yes**.



5. Select **Add Reference** to see a list of the security objects, including roles, duties, and privileges that grant the missing permission.
6. Select a security object from the list:

   - If **Role** is selected, select **Add role to user**. This will open the **Assign users to roles** page. For more information, see Assign users to security roles page.
   - If **Duty** is selected, select **Add duty to role**, select the roles that the duty should be added to, and then select **OK**.
   - If **Privilege** is selected, select **Add privilege to duties**, select the roles that the duty should be added to, and then select **OK**.

> **NOTE**
>
> Can you tell us about your documentation language preferences? Take a short survey.
>
> The survey will take about seven minutes. No personal data is collected (privacy statement).

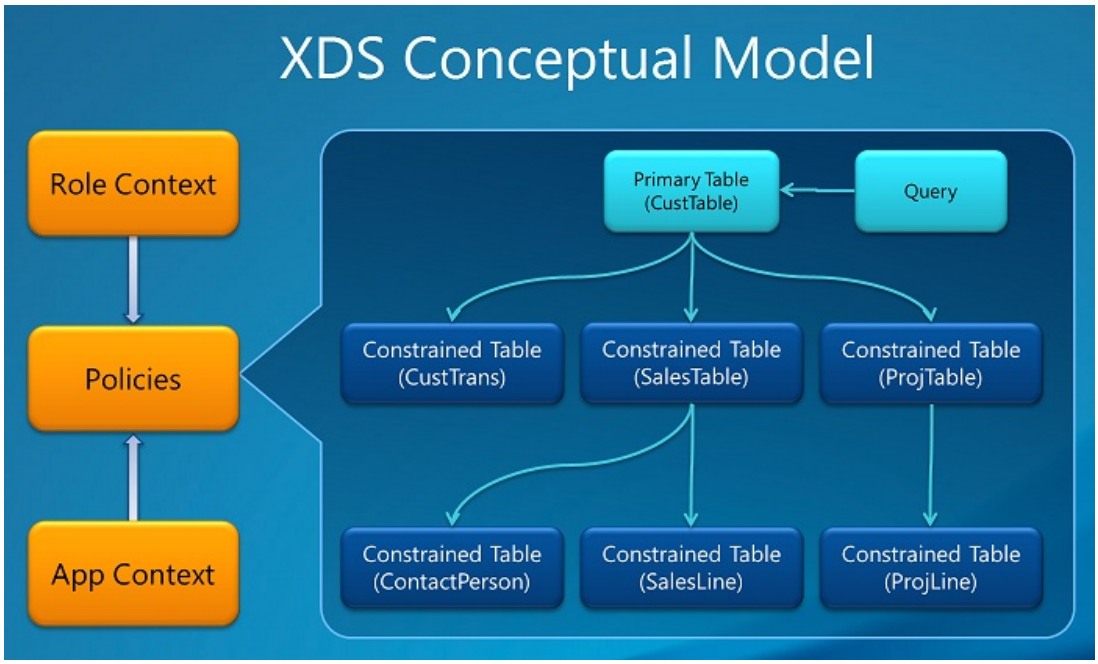
Extensible data security policies

2/18/2021 • 2 minutes to read • Edit Online

This topic provides an overview of Extensible Data Security (XDS) policies in Finance and Operations apps. XDS allows developers to supplement role-based security by restricting access to table records based on security policies. The query in the policy applies a filter and only records that satisfy the conditions of the filter will be accessible from the restricted tables.

Data security policy components

- **Constrained tables**: The table or tables from which data is filtered or secured. For example, in a policy that secures access to customers based on customer group, the **CustTable** would be the constrained table.
- **Primary table**: Used to secure the content of the related constrained table. In the above example, the **CustGroup**table would be the primary table. The primary table must have an explicit relationship to the constrained table.
- **Policy query**: Used to secure the constrained tables content using a range condition on the primary table contents. Only records that are included in the range will be accessible. The range can, for example, be based on a specific value for Customer Group.
- **Context** – Controls the conditions under which a policy is applicable. Two main types of contexts are available:
  - **Role context**: Based on the roles that the user is assigned. There are two sub-options for role context:
    - **RoleName** – Indicates that the security policy is only applied to the application user assigned to the role equal to the value of RoleName.
    - **RoleProperty** – This value is used in combination with the **ContextString** property to specify multiple user roles context. It is applied when the Context String value defined in the **Role Property** field for the policy is the same as the **ContextString** field value for the assigned user roles.
  - **Application context**: Applied if the context string set by the application using the XDS::SetContext API is the same as the value defined in the **Context String** field for the policy.



In the Application Object Tree (AOT), policies and their components are displayed under **Security > Policies**.

Important considerations

The policy query is added to the WHERE clause, or ON clause, on SELECT, UPDATE, DELETE and INSERT operations involving the specified constrained tables. Unless carefully designed and tested, policy queries can have a significant performance impact. Therefore, make sure to follow simple but important guidelines when developing an extensible data security policy. For more information, see the "Developing efficient extensible data security policies" section in Developing Extensible Data Security Policies (White paper) [AX 2012].

When two or more security policies apply, the intersection (not the union) of the records that are included by each policy are the only records that can be accessed. This means that a record must satisfy all the applicable security policies before access to the record is allowed.

Additional resources

For information about how to debug policies, create more advanced policies, including chaining of restricted tables, table relations based on expressions and much more please refer to these resources:

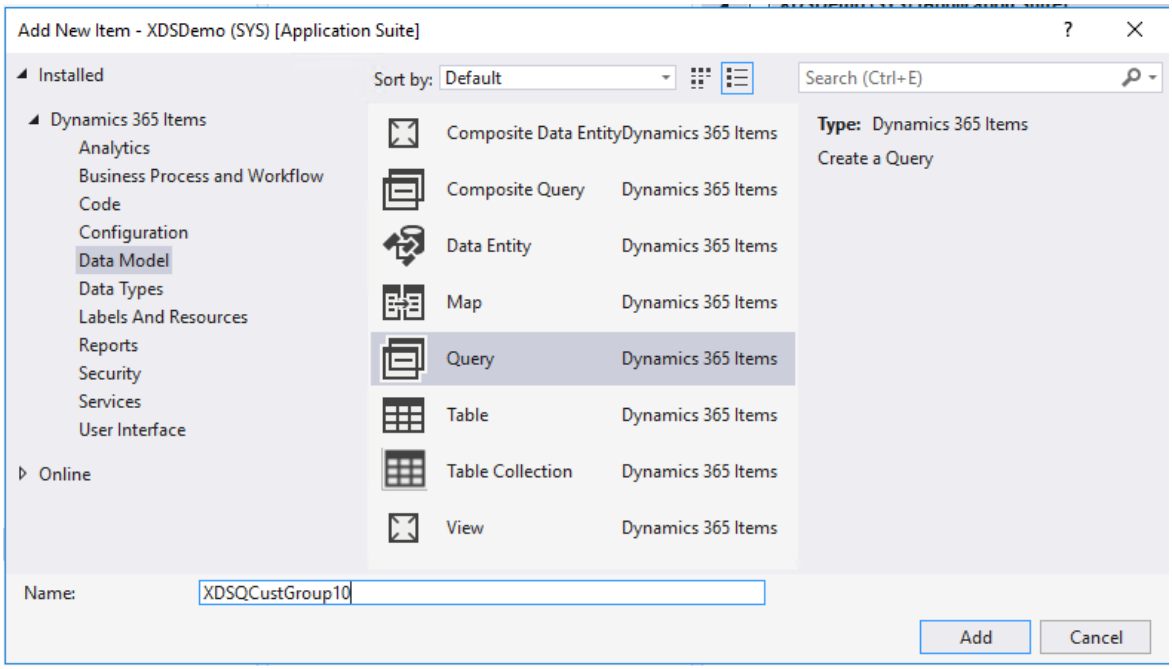
Create a security policy

2/18/2021 • 2 minutes to read • Edit Online

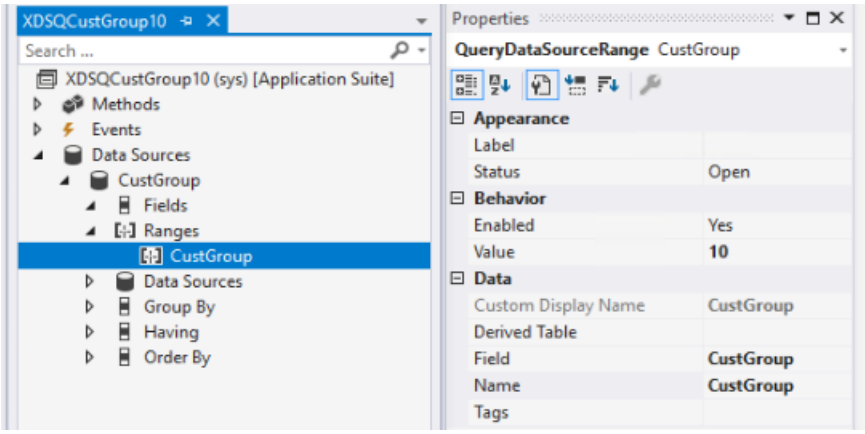
This topic explains how to create a simple security policy that secures access to customers and customer groups, based on a range for a customer group.

Add a new query

1. In Visual Studio, add a new query, such as XDSQCustGroup10, to your project/solution. The query will be used to restrict data access from the **Constraint** table.

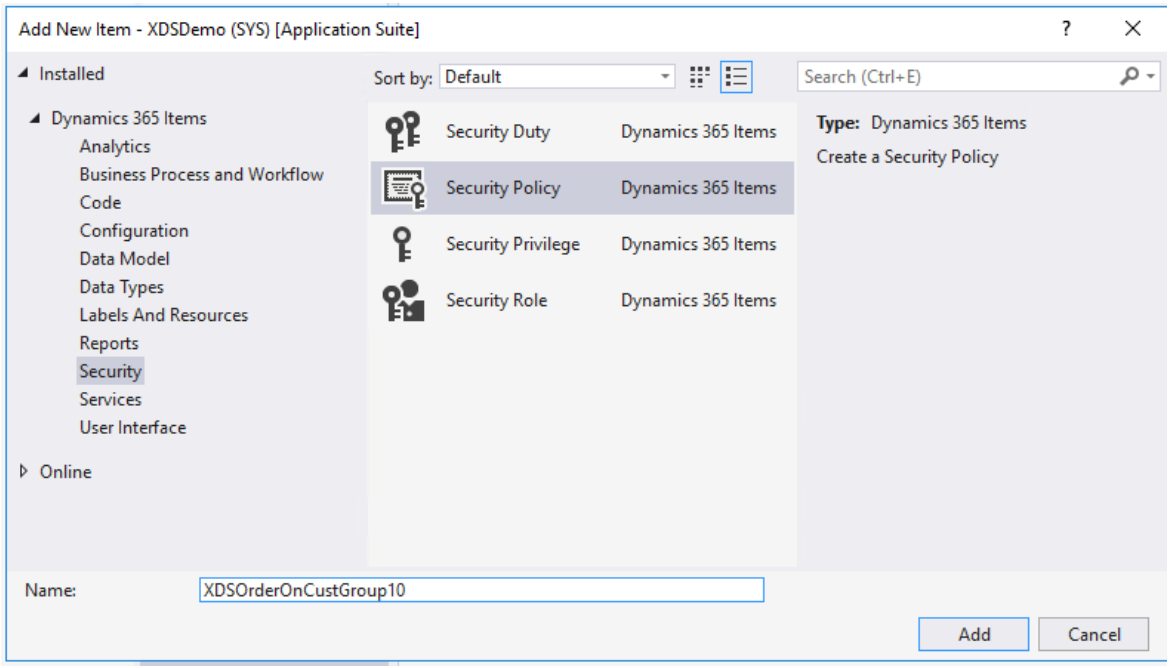


2. Right-click **Data Sources**, and the select **New Data Source**.
3. In the **Table** field, enter the primary table name **CustGroup**.
4. Right-click **Ranges**, and then select **New Range**.
5. Set the **Enabled** field to **Yes**.
6. In the **Data Source** field, enter the primary table name, in this case, 'CustGroup'.
7. In the **Value field**, enter **10** to restrict access to data where CustGroup has value of 10, by defining the Range for the CustGroup field.

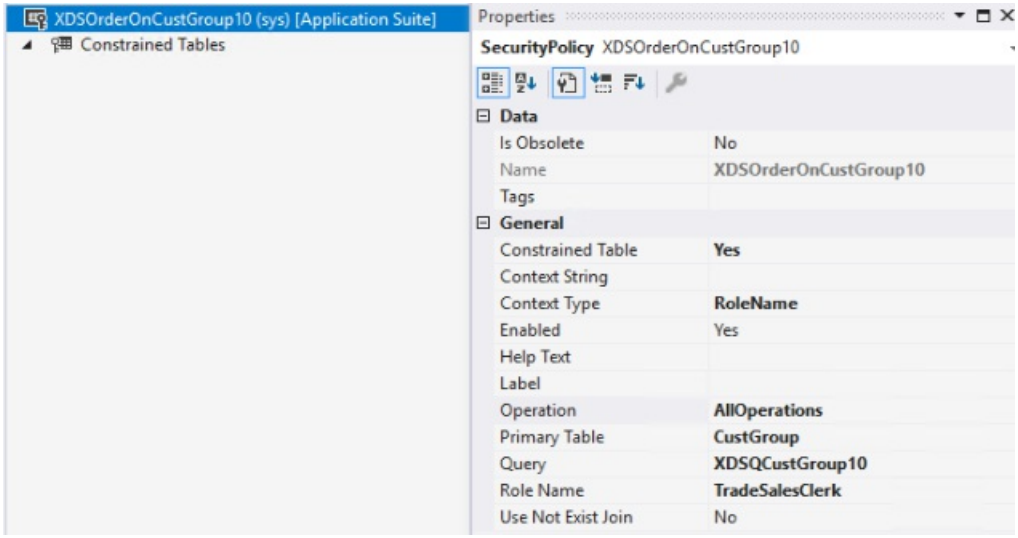


Add a new security policy

1. Add a new security policy, such as XDSCustTableOnCustGroup10.



2. Set **Constrained Table** to **Yes**. This will also secure access to the primary table. In this example this is the **CustGroup** table.
3. Set the **Context Type** field to **RoleName**.
4. Set the **Enabled** field to **Yes**.
5. Set the **Operation** field to **AllOperations**. Other available values for **Operation** include **Select**, **Insert**, **Update**, **Delete**, and **InsertUpdateDelete**.
6. Set **Primary Table** field to **CustGroup**.
7. Set the **Query** field to the name of the query created above, for example 'XDSQCustGroup10'.
8. Set the **Role Name** field to 'TradeSalesClerk'. Because **Context Type** is set to RoleName for this policy, it is required to enter the AOT name for a user role.



9. Next, add constrained tables. In this simple example add one table.

   a. Right-click **Constrained tables**, and then select **New > Constrained Table**.

   b. Set **Constrained** to **Yes**.

   c. In the **Name** field, enter the Constrained table, for example 'CustTable'.

   d. In the **Table Relation** field, enter the relationship to the primary table, in this case 'CustGroup'.

10. As a final step, it is required that you build and synchronize the solution to activate the policy.

Stay compliant with user licensing requirements

2/18/2021 • 5 minutes to read • Edit Online

This topic provides an overview of how customers can stay compliant with the user licensing requirements for Finance and Operations apps, such as Microsoft Dynamics 365 Finance, Dynamics 365 Supply Chain Management, and Dynamics 365 Commerce.

The licensing requirements for users are determined by the security roles that are assigned to those users. Security roles are built based on a hierarchy of:

- Sub-roles
- Duties
- Privileges
- Directly referenced securable objects

For more information, see Role-based security.

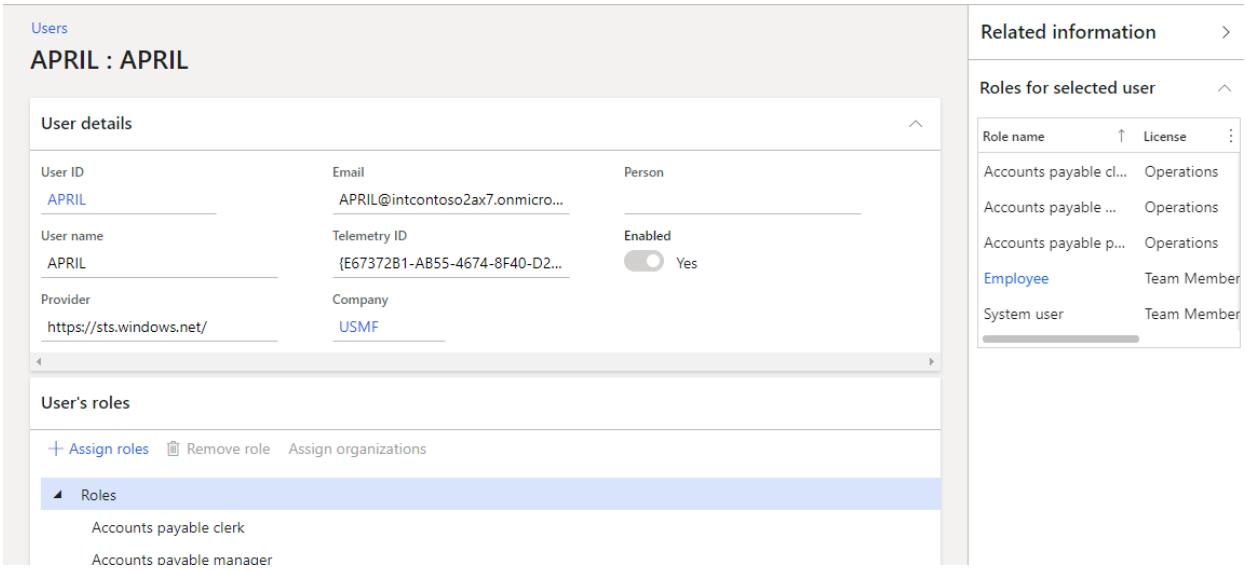
The licensing requirements for users are determined at the organization or tenant level. This topic is focused on the requirements for a single environment. If you have multiple environments, the requirements must be analyzed across all of them.

A licensing requirement is assigned to every securable object. Examples of licensing requirements include **None**, **Team members**, **Activity**, and **Operations**. The **Operations** licensing requirement indicates that a full user license is required. Some privileges are unique to a specific full user license and require a *base* or *attach* license for the full user license be assigned to the user. For more information, see the User license estimator report section later in this topic.

The rest of this topic describes the various tools that you can use to ensure that the actual licensing complies with the expected licensing requirements.

Roles for selected user FactBox on the Users page

You assign roles to users on the **Users** page (**System administration > Users**). You can view license requirements for each role in the **Roles for selected user** FactBox.



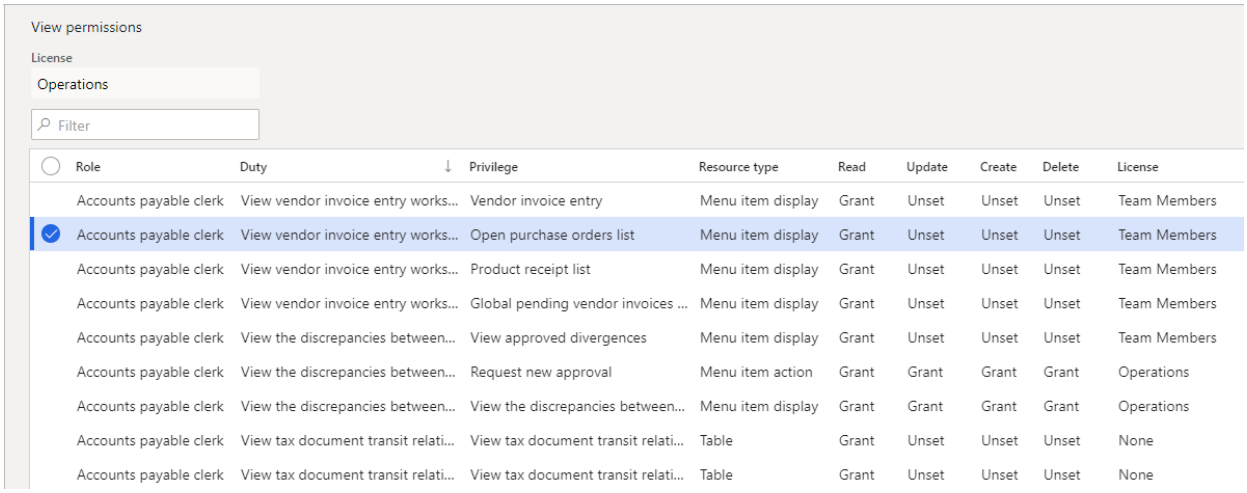
The maximum license requirement determines the actual licensing requirement for a user. If any license

requirement is identified as **Operations**, you must use the User license estimator report to determine the full user licensing requirements.

> **NOTE**
>
> Starting with platform update for version 10.0.15, the required license types are extended to include application specific license types such as Commerce, Finance, and Supply Chain Management. This extension makes it possible to view the actual license requirements when you assign roles to users and when using the Roles for the selected user FactBox. More than one value can be displayed for the required license type.

View permissions page

During security configuration on the **Configure security** page (**System administration > Security > Configure security**), you can select any security object, a role, duty, or permissions, and then select **View permissions** to view all permissions that are currently included and their licensing requirements. The header of the **View permissions** page shows the required license level.

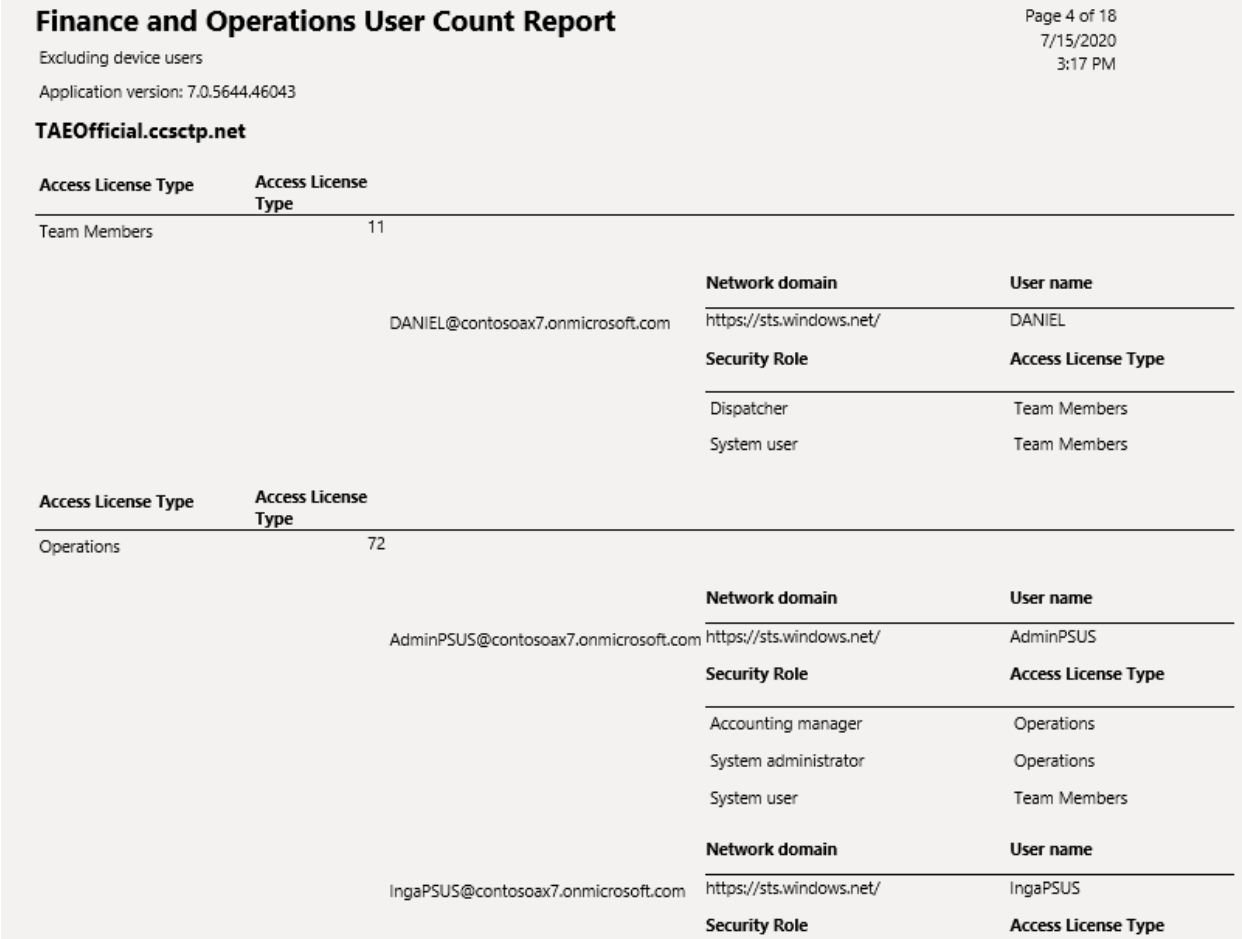


Role	Duty	Privilege	Resource type	Read	Update	Create	Delete	License
Accounts payable clerk	View vendor invoice entry works...	Vendor invoice entry	Menu item display	Grant	Unset	Unset	Unset	Team Members
Accounts payable clerk	View vendor invoice entry works...	Open purchase orders list	Menu item display	Grant	Unset	Unset	Unset	Team Members
Accounts payable clerk	View vendor invoice entry works...	Product receipt list	Menu item display	Grant	Unset	Unset	Unset	Team Members
Accounts payable clerk	View vendor invoice entry works...	Global pending vendor invoices ...	Menu item display	Grant	Unset	Unset	Unset	Team Members
Accounts payable clerk	View the discrepancies between...	View approved divergences	Menu item display	Grant	Unset	Unset	Unset	Team Members
Accounts payable clerk	View the discrepancies between...	Request new approval	Menu item action	Grant	Grant	Grant	Grant	Operations
Accounts payable clerk	View the discrepancies between...	View the discrepancies between...	Menu item display	Grant	Grant	Grant	Grant	Operations
Accounts payable clerk	View tax document transit relati...	View tax document transit relati...	Table	Grant	Unset	Unset	Unset	None
Accounts payable clerk	View tax document transit relati...	View tax document transit relati...	Table	Grant	Unset	Unset	Unset	None

> **NOTE**
>
> Starting with platform update for version 10.0.15, the required license types are extended to include application specific license types such as Commerce, Finance, and Supply Chain Management. This extension makes it possible to identify the specific security objects that determine the actual license requirements while also configuring security. More than one value can be displayed for the required license type.

User license counts report

The **User license counts** report (**System administration > Inquiries > License**) is used to get a count of required licenses per license type (for example, **Team members**, **Activity**, and **Operations**).



Finance and Operations User Count Report

Page 4 of 18
7/15/2020
3:17 PM

Excluding device users

Application version: 7.0.5644.46043

TAEOfficial.ccsctp.net

Access License Type	Access License Type
Team Members	11

DANIEL@contosoax7.onmicrosoft.com

Network domain	User name
https://sts.windows.net/	DANIEL

Security Role	Access License Type
Dispatcher	Team Members
System user	Team Members

Access License Type	Access License Type
Operations	72

AdminPSUS@contosoax7.onmicrosoft.com

Network domain	User name
https://sts.windows.net/	AdminPSUS

Security Role	Access License Type
Accounting manager	Operations
System administrator	Operations
System user	Team Members

IngaPSUS@contosoax7.onmicrosoft.com

Network domain	User name
https://sts.windows.net/	IngaPSUS

Security Role	Access License Type

The report also provides details about each user and the licensing requirements for each assigned role. Users are listed under the highest license type. If the license requirement is identified as **Operations**, you must use the User license estimator report to determine the specific full user licensing requirements.

The **User counts history** report shows total counts per date, but without any details.

> **NOTE**
>
> This report depends on the **Named user license count reports processing** batch job. To determine when the batch was last run, use the **Batch job history** page.

User license estimator report

If the previously mentioned tools have identified that any users require a license of the **Operations** type, you can use the **User license estimator** report (**System administration > Inquiries > License reports**) to get a count of specific licensing requirements for those users. The report includes only those users.

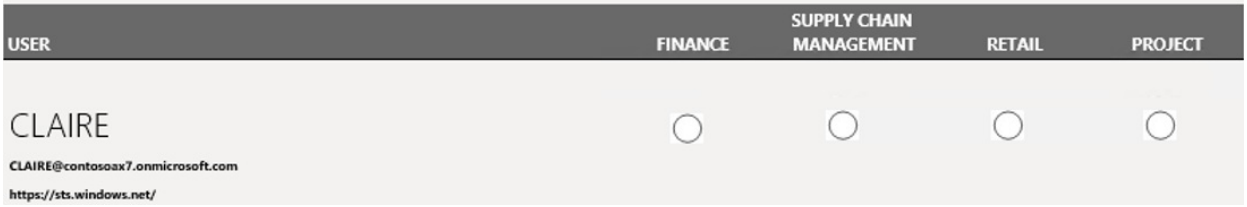
If no privileges that require a specific full user license have been assigned to a user, that user is shown, but no specific full user licenses are marked. That user will be compliant with any full user license that is assigned. In the example in the following illustration, the **Database management administrator** role is assigned to a user, and no other roles that require a license of the **Operations** type are assigned.

Role	Security Role Description	Team Members	Activity	Finance, SCM, Commerce
Administrator				
Data management administrator	Super user for the data management activities in the system. In addition to the capabilities of the DataManagementMigrationUser and DataManagementOperationsUser, this role provides access to the DataManagementITWorkspace - an operational workspace to monitor all data management activities			•

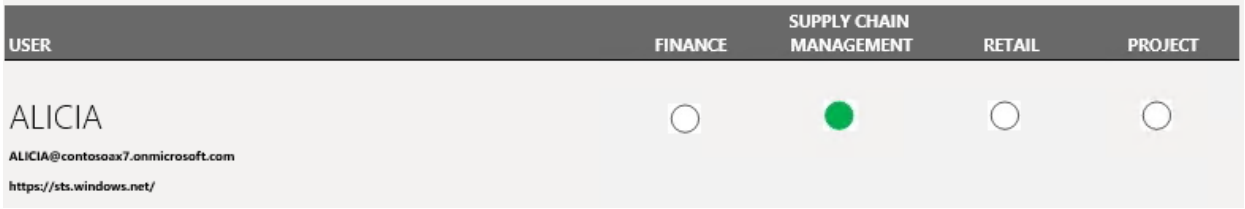
Based on the licensing guide, this user is compliant with any full user license.

Admin rights apply across the Finance, Supply Chain Management, and Commerce apps. For example, if you have a Finance license, you have the admin rights for Finance, Supply Chain Management, and Commerce.

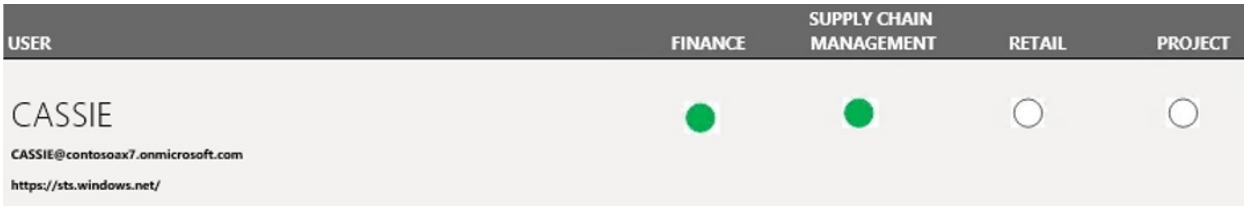
This principle might apply to several roles that are provided by Microsoft and customizations, based on the included privileges. No specific license is indicated for these users on the **User license estimator** report.



Alternatively, if privileges that require a specific full user license have been assigned to a user, that license is indicated when you look at the licenses that are assigned to the user. In the example in the following illustration, the user must have a *base* license for Supply Chain Management.



If privileges that require more than one specific full user license have been assigned to a user, those licenses are indicated when you look at the licenses that are assigned to the user. In this case, the user must have a *base* license for one of the licenses and an *attach* license for all other full user licenses that are required. In the example in the following illustration, the user must have either a *base* license for Finance and an *attach* license for Supply Chain Management, or a *base* license for Supply Chain Management and an *attach* license for Finance.



The totals per specific full user license counts aren't divided into *base* licenses and *attach* licenses.

> **NOTE**
>
> The total count per specific full user license and evaluation of custom privileges are included starting in the release of the platform update for version 10.0.13. The report can't separate the *base* and *attach* license requirements. Therefore, it lists only the total full user licenses requirements.

Additional resources

For information about how to buy and license Finance and Operations apps, see Microsoft Dynamics 365 Licensing Guide.

For information about how to assign licenses to users in the Microsoft 365 admin center, see Assign licenses to users.

Additional user licenses are required when multiple implementation projects exist for the same tenant. For more information, see Multiple LCS projects and production environments on one Azure AD tenant.

View independent software vendor license status

2/18/2021 • 2 minutes to read • Edit Online

This topic explains how you can view the status of independent software vendor (ISV) licenses for Finance and Operations apps, such as Dynamics 365 Finance, Dynamics 365 Supply Chain Management, and Dynamics 365 Commerce.

License codes and configuration keys are part of the ISV licensing model for Finance and Operations apps.

> **NOTE**
> Configuration keys that are provided by Microsoft aren't part of the licensing model for Finance and Operations apps. The keys are only used to enable and disable functionality.

When an ISV license key and code are installed, the corresponding configuration key will be available and enabled on the **License configuration** page.

View ISV license status

Each ISV solution that is tied to a license runs only when a valid license code exists in the customer's environment. Therefore, if an ISV ties their solution to a license, but the customer doesn't have a valid license code, the solution doesn't run. To prevent the loss of functionality, it's important to track the expiration dates, if applicable, for license codes. To view the expiration dates, go to **System administration** > **Setup** > **License configuration**, and select the **License codes** tab.

To avoid downtime, review the expiration dates of the license keys, and if applicable, obtain and import new license keys before moving to a new version. The **License codes** tab shows the expired license codes. The corresponding configuration key won't appear in the **Configuration keys** tab.

Additional resources

For more information about the ISV licensing feature, see Independent software vendor (ISV) licensing.

For more information about how to import ISV licenses into an on-premises deployment, see Independent software vendor (ISV) licensing (on-premises).

For more information about the configuration keys report, see License codes and configuration keys report.

> Can you tell us about your documentation language preferences? Take a short survey.
>
> The survey will take about seven minutes. No personal data is collected (privacy statement).

Process automation

2/18/2021 • 2 minutes to read • Edit Online

Process automation allows simple scheduling of processes that will be run by the batch server. The updated calendar view of the scheduled work allows end users to view and take action on scheduled and completed work.

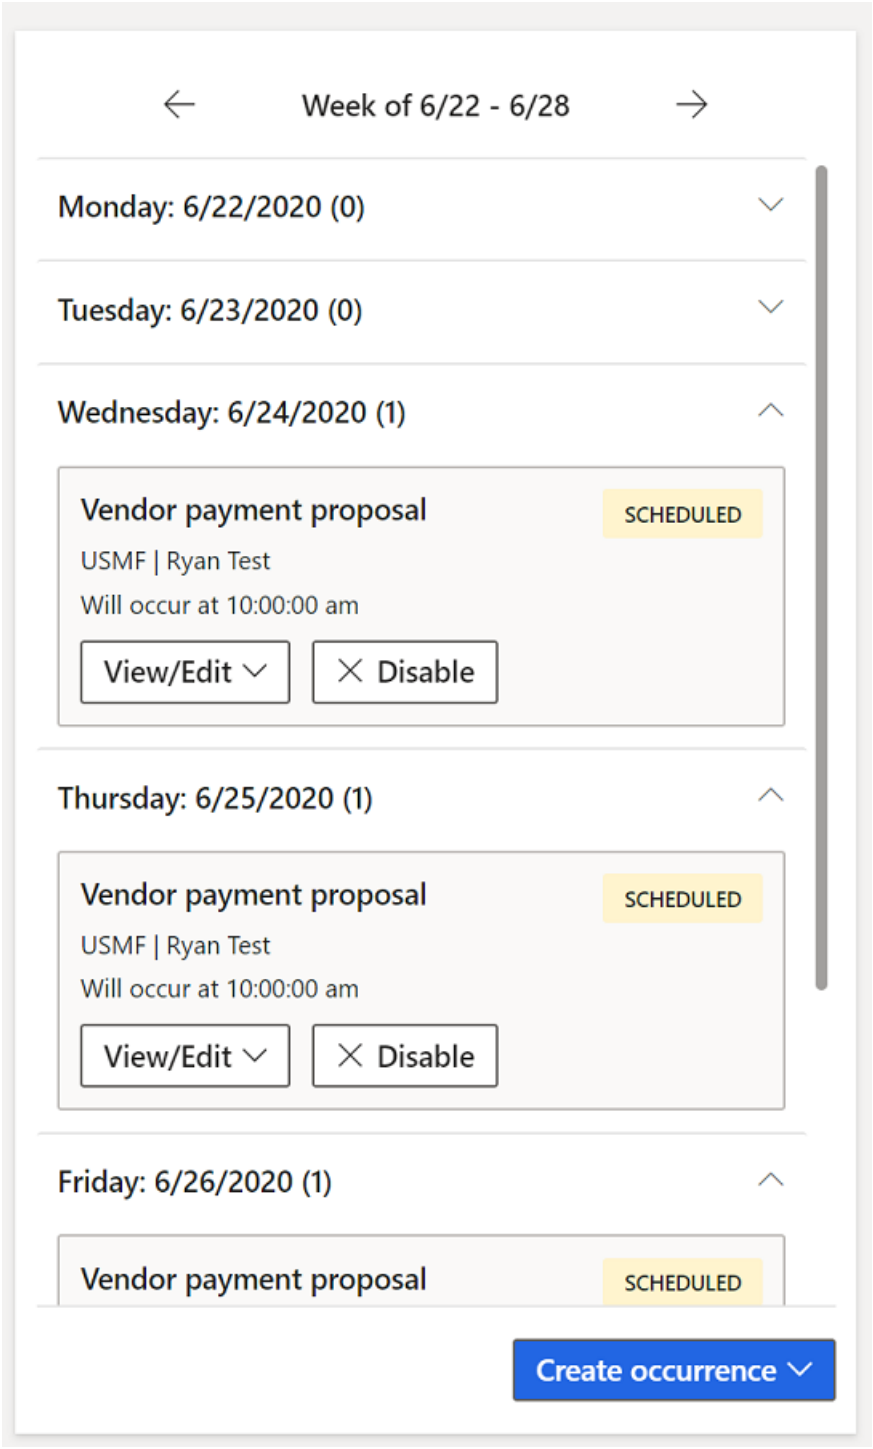
Administration

The central administration page for all process automations is found in the System Administration module under the **Setup** menu. This page will list all automated processes (series) that are set up in the system. It will also allow you to add new process automations directly from this page. After a series is set up, you can manage each series from this list. You can choose to edit the entire series, delete it, view all occurrences in a list view, or disable the series if you would like to pause the scheduled work for a while.

Any processes that are disabled in feature management won't show when the feature is disabled. Additionally, the process automation scheduling engine won't schedule any occurrences or background processes for a disabled feature. Re-enabling the feature will cause any scheduled occurrences or background processes in the past to run immediately.

Calendar view

One of the key benefits of process automation is the ability to see the scheduled work in a simple calendar view. This view allows you to see work for a week at a time. You'll see this view on the right side of the **Process automation** page. It will be populated with the scheduled work for the selected series.



Occurrence changes

Each occurrence can be modified without impacting other occurrences defined by the series that originated them. Occurrences of scheduled work can be edited from the calendar view by selecting the **View/Edit** button and selecting **Occurrence**. This page allows you access to all the settings originally shown in the series setup wizard and provides the ability to make a one-off change for the selected occurrence. An occurrence of scheduled work can also be turned off by selecting the **Disable** button from the calendar view.

Developer documentation

The process automation framework allows developers to extend the process automation framework. The Process automation framework documentation provides information about how you can create custom processes that you require to be run by the batch server scheduled with the process automation wizard and appear in the calendar view automatically.

NOTE

Can you tell us about your documentation language preferences? Take a short survey.

The survey will take about seven minutes. No personal data is collected (privacy statement).

Batch processing overview

2/18/2021 • 2 minutes to read • Edit Online

This topic provides an overview of batch processing.

Many tasks in Finance and Operations can be run as part of batch jobs. For example, batch jobs can include tasks for printing reports, performing maintenance, or sending electronic documents. By using batch jobs, you can avoid slowing down your computer or the server during typical working hours.

The tasks in a batch job can run either sequentially or at the same time. Additionally, you can create dependencies between tasks. In other words, the sequence of tasks can differ, depending on whether an earlier task succeeds or fails.

You can set up recurrence patterns for batch jobs. For example, you can set up a job to process invoices automatically at the end of every month.

To monitor batch jobs, you can set up alerts. Alerts can be sent when the batch job succeeds, fails, or has finished running.

After a batch job has been processed, you can view the history. The history includes any messages that were encountered while the job was running.

Use batch groups to categorize batch tasks and run them on specific servers. The servers in your environment might have different software installed, or they might be available at different times of the day. Batch groups are used to direct batch tasks to the most appropriate server. Tasks in the same batch job can belong to different batch groups.

For example, server A is set up to print reports, and server B is set up to send electronic documents. You can use batch groups to make sure that reporting tasks are run on server A and electronic documents are processed by server B.

For more information, see Batch processing and batch servers.

Batch functions

Administrators and Batch managers can perform common tasks including creating and copying batch jobs, changing a batch job user, and specifying a time period in which a job should not execute. For more information about these tasks, see the following topics:

- Create a batch job
- Batch manager security role
- Active batch periods
- Copy a batch job
- Set up alerts
- Enhanced batch forms
- Clean up the batch job history
- Abort an executing batch job

NOTE

Can you tell us about your documentation language preferences? Take a short survey.

The survey will take about seven minutes. No personal data is collected (privacy statement).

Batch processing and batch servers

2/18/2021 • 5 minutes to read • Edit Online

This topic describes batch processing and batch servers, and how to plan for their use.

The batch framework provides an asynchronous, server-based batch processing environment that can process tasks across multiple instances of Application Object Server (AOS).

You should become familiar with the following aspects of the batch framework:

- A **batch job** is a process that is used to achieve a specific goal. A batch job consists of one or more batch tasks.
- A **batch task** is an activity that is run by a batch job. You can add batch tasks that have multiple types of dependencies to a batch job. You can also configure AOS instances to run multiple threads, each of which runs a task. All batch tasks that are waiting to be run can be run by any available AOS instance that is configured as a batch server. To improve throughput and reduce overall execution time, you can define a batch job as many tasks and then use a batch server to run the tasks against all available AOS instances.
- A **batch group** is an attribute of a batch task. A batch group lets the administrator determine or specify which AOS instance runs the task. When you create a new task, it's put in the default batch group. All batch servers are configured to process the default batch group and the waiting tasks from any job. Additionally, you can create a named batch group, and then set an affinity between that batch group and specific AOS instances. After you create this affinity, only the specified AOS instances will process tasks from the named batch group, and those AOS instances will process tasks from the named batch group only. You can also add the default batch group to the configured servers, if that batch group is required.

Batch server topology planning

The capacity of a batch server is based on the maximum number of threads that can run concurrently on the AOS instance. Each thread runs one batch task. You can add complex dependencies between or among tasks. You can run these tasks in serial steps or parallel steps, depending on the business logic and requirements. All tasks that don't have any dependencies are considered parallel tasks. AOS instances that are configured as batch servers periodically check for tasks that are waiting to be processed. The batch server assigns each parallel task to a thread and starts to process the thread.

You can run multiple threads across multiple AOS instances. Each AOS instance automatically runs multiple threads, depending on that capacity that is defined in the configuration settings. Therefore, parallel tasks from a job can be run on multiple threads across multiple AOS instances.

A batch server checks for available threads one time per minute. Therefore, you might have to wait for a minute before you see that a waiting task is picked up for processing by an available thread.

Batch server management planning

All batch servers can be managed from a single location.

One typical use of batch servers is to load balance jobs across multiple servers. You can set the number of threads that the batch server will process.

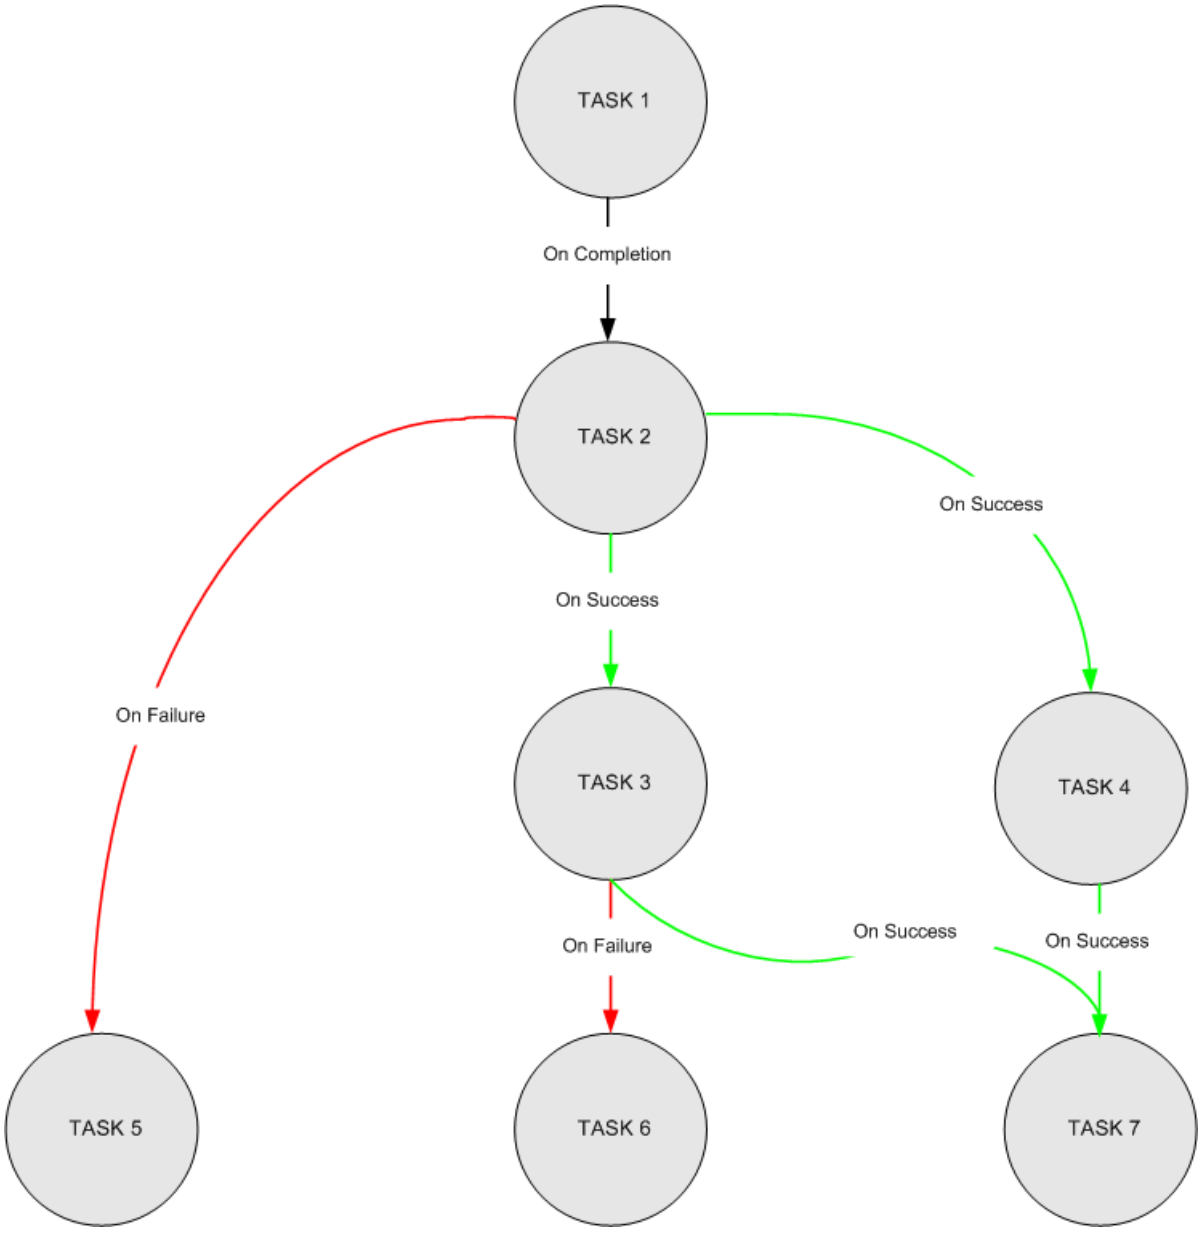
Because batch servers are also active AOS instances that service requests from the client and other associated components, you must carefully determine when an AOS instance should be available to process batches.

Walkthroughs

The following walkthroughs describe how tasks are processed, and how batch groups can be used to associate batch jobs with batch servers.

Batch processing of dependent tasks

For this example, you've created a job that is called JOB 1. As the following diagram shows, the job has seven tasks: TASK 1, TASK 2, TASK 3, TASK 4, TASK 5, TASK 6, and TASK 7.



The tasks have the following dependencies:

- TASK 1 is the first task.
- TASK 2 runs when TASK 1 is completed (regardless of the success or failure of TASK 1).
- TASK 3 runs when TASK 2 is successful.
- TASK 4 runs when TASK 2 is successful.
- TASK 5 runs when TASK 2 fails.
- TASK 6 runs when TASK 3 fails.
- TASK 7 runs when both TASK 3 and TASK 4 are successful.

Two batch servers, Batch1 and Batch2, are configured. Each server has a capacity of one thread.

Imagine that Batch1 checks for waiting tasks, assigns TASK 1 to its thread, and starts to run TASK 1. Although

Batch2 and its single thread are also available, TASK 2 continues to wait until TASK 1 is completed.

As soon as TASK 1 is completed, TASK 2 is ready to be run. This time, imagine that Batch2 checks for waiting tasks, assigns TASK 2 to its thread, and starts to run TASK 2.

If TASK 2 is successful, TASK 3 and TASK 4 are ready to be run. This time, imagine that Batch2 checks for waiting tasks, assigns TASK 3 to its thread, and starts to run TASK 3. Batch1 also checks for waiting tasks, assigns TASK 4 to its thread, and starts to run TASK 4.

If TASK 3 and TASK 4 are successful, one of the batch servers runs TASK 7.

If TASK 2 fails, one of the batch servers runs TASK 5.

If TASK 3 fails, one of the available batch servers runs TASK 6.

Note: For this walkthrough, we are using Batch1 and Batch2 to explain the concept. Any batch server that has available threads will start to run a waiting task. You must create a batch group to determine or specify which batch job runs on which server.

Batch processing that uses batch groups

This example shows how batch jobs can be processed on specific batch servers.

You have three batch servers: AOS1, AOS2, and AOS3. By default, all the batch servers process tasks from all batch jobs, depending on the number of available threads.

You create a named batch group, BG1, and configure it to run on AOS2 and AOS3. Therefore, tasks from jobs in BG1 will run only on AOS2 or AOS3, depending on the number available threads. AOS1 won't process tasks from jobs in BG1. Likewise, AOS2 and AOS3 will process tasks from BG1 only.

You can configure AOS2 and AOS3 to process tasks from other batch groups. These batch groups include the default batch group.

Batch excessive tasks configuration (Batch throttling)

Batch throttling can prevent excessive tasks by limiting the average number of executions of a certain batch class per minute. The default upper-bound is 60 tasks per minute. After that, batch framework will suspend the execution of classes for the offending class for another minute, to prevent that specific class from monopolizing the system resources.

> **NOTE**
>
> The batch framework is able to detect instances when there are no non-throttled tasks to be scheduled and executed at any given time. When this occurs, the batch will try to fetch batch tasks from the throttled classes queue to prevent resources from being idle.

Create a batch job

2/18/2021 • 2 minutes to read • Edit Online

A batch job is a group of tasks that are submitted to an Application Object Server (AOS) instance for automatic processing. Batch jobs are run by using the security credentials of the user who created the job. Use the following procedure to create a batch job. The demo data company used to create this procedure is USMF.

Create the batch job

1. Go to **Navigation pane > Modules > System administration > Inquiries > Batch jobs**.
2. Click **New**.
3. In the **Job description** field, type a value.
4. In the **Scheduled start date/time** field, enter a date and time.
5. Click **Save**.

Create a recurrence

1. On the Action Pane, click **Batch job**.
2. Click **Recurrence**. Use these options to enter a range and pattern for the recurrence.
3. Click **OK**.

Add alerts

1. On the Action Pane, click **Batch job**.
2. Click **Alerts**. Indicate if you want alert messages sent when the batch job ends, has an error, or is canceled. Then specify if you want the alerts to be displayed as pop-up messages.
3. Click **OK**.

Adjust batch job status

1. Go to **System administration > Inquiries > Batch jobs**.
2. Select the appropriate batch job.
3. On the Action Pane, click **Batch job > Functions > Change status**.
4. Select the appropriate status:
   - **Withhold**: Set the batch job as **withhold** so it is withheld from the batch job scheduler. Equivalent to *stop*.
   - **Waiting**: Set the batch job as **waiting** so it is waiting to be picked up by the batch job scheduler. Equivalent to *go*.
5. Click **OK**.

Copy a batch job

2/18/2021 • 2 minutes to read • Edit Online

When you want to create the same jobs for different legal entities, you can use the copy batch job functionality to copy an existing batch job and the batch tasks, including recurrences.

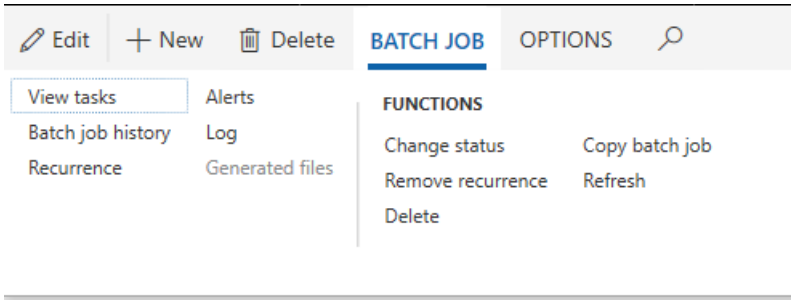
You can set the description, company, schedule start date and time, the recurrence, and the run by account at the same time. When you copy the batch job, any alerts and dependencies from the source job will also be copied.

> **NOTE**
> This feature is available as of Platform update 20.

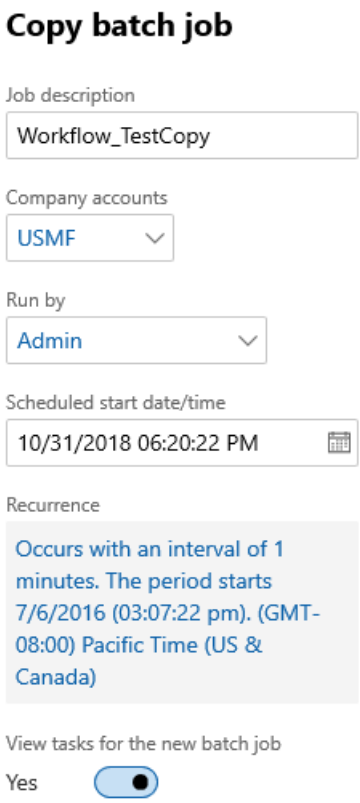
Copy a batch job

Complete the following steps to copy a batch job.

1. Click **System administration** > **Inquiries** > **Batch jobs**.
2. Select the job that you want to copy, and on the Action Pane, click **Batch Job** > **Copy batch job**.



4. Enter or add any changes. If you set **View tasks** to **Yes**, when you click **OK** you will go directly to the **Batch tasks** page for the copied job.



IMPORTANT

The copied batch job will be created with a **Withhold** status, so you will need to enable it. The **Run by** user can also be set to give this user the privilege to run the job without being a Sys Admin.

Enable the batch job

Complete the following steps to enable a batch job.

1. On the **Batch job** page, on the Action Pane, click **Batch job** > **Change status**.
2. Select the **Waiting** status, and then click **OK**.

NOTE

The survey will take about seven minutes. No personal data is collected (privacy statement).

Active batch periods

2/18/2021 • 2 minutes to read • Edit Online

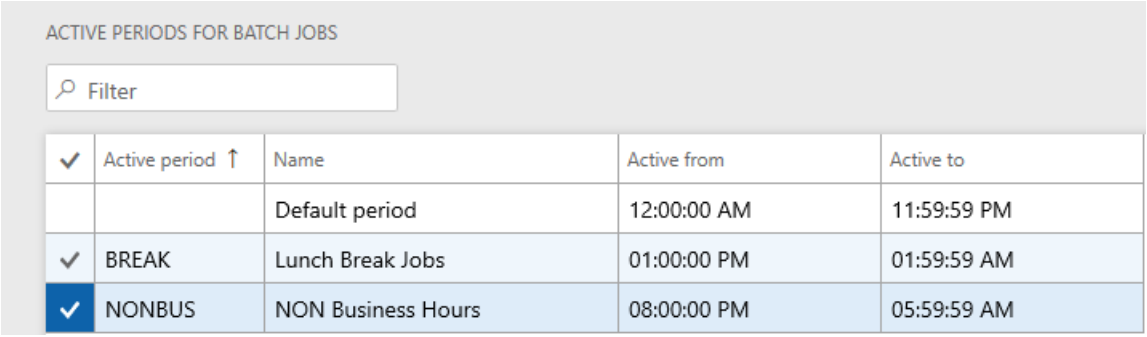
With the release of Platform update 21, an additional level of control over when batch jobs execute is now available. Previously, it was only possible to schedule a batch job to execute every hour for a specified number of hours or until a given date. Administrators can now provide information for an additional active period, such as in the following scenarios:

- Specifying time ranges during which jobs within a batch group can start execution.
- Selecting to run batch jobs outside of office hours only.
- Setting the recurrence for anytime within the active period. For example, you administrator might select to run the batch jobs every hour, but only between the hours of 6:00 PM and 8:00 AM.

> **NOTE**
> This feature is available as of Platform update 21.

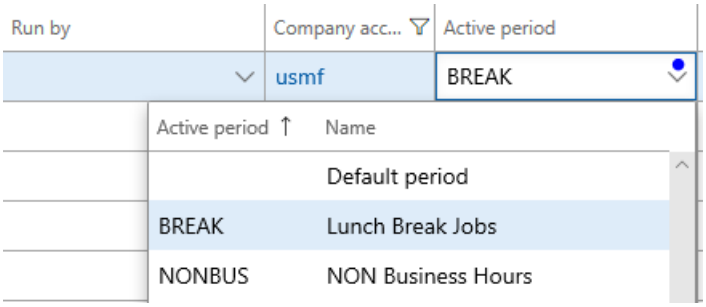
Set up active periods for batch jobs

1. Go to **System administration** > **Setup** > **Active periods for batch jobs**.
2. Enter the name of the batch job, and specify start and end dates that the batch job is active.
3. Click **Save**.



Assign active periods to batch jobs

1. Go to **System administration** > **Inquiries** > **Batch jobs**.
2. Select the batch job that you want to assign a period to, and click **Edit**.
3. In the **Active period** field, select the active period that you want to assign, and then click **Save**.



NOTE

Can you tell us about your documentation language preferences? Take a short survey.

Daylight saving time support for active batch periods

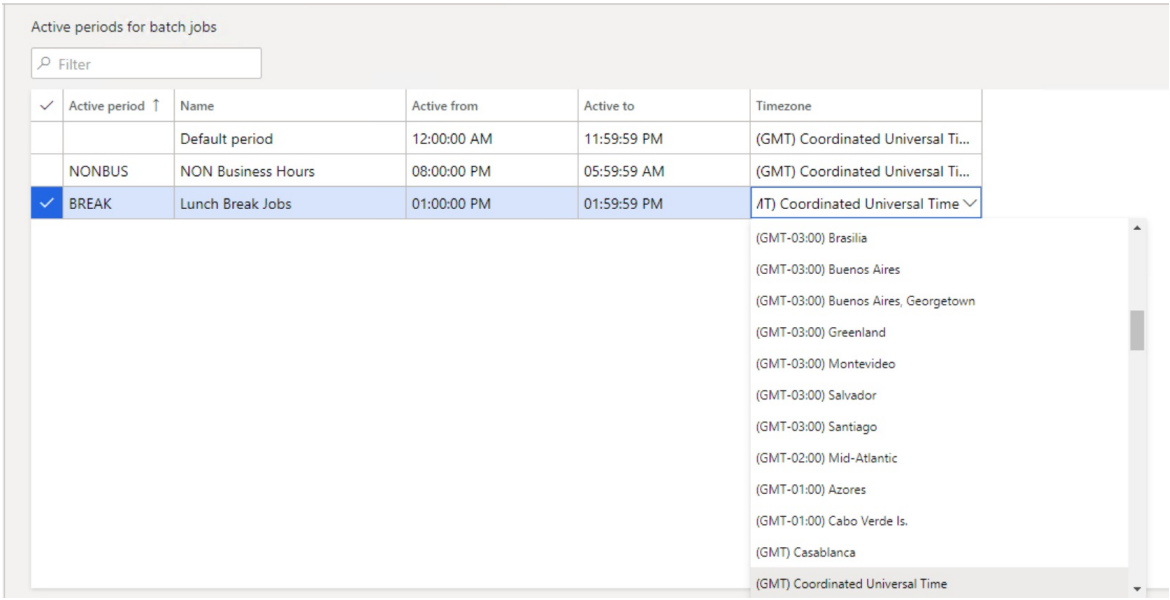
2/18/2021 • 2 minutes to read • Edit Online

Microsoft Dynamics 365 Finance version 10.0.12 includes a **Daylight Saving Time support for batch job active periods** feature that can be turned on in Feature management. This feature introduces daylight saving time (DST) support for the active periods for batch jobs and lets users associate their active periods with different time zones.

> **NOTE**
>
> This feature is a one-way feature. In other words, it can't be turned off after it's turned on.

When this feature is turned on, the following changes occur:

- On the **Active periods for batch jobs** page, a **Timezone** field is added for each active period. This field specifies the time zone that the active period uses. By default, every active period initially uses the Coordinated Universal Time (UTC) time zone.



- The start and end times of existing active periods are adjusted according to the UTC time zone. 'Although the active periods will continue to start and end at the same times that they previously started and ended, the times that are shown might change if the user's preferred time zone isn't UTC.
- Active periods will follow the DST adjustments of the time zones that they are associated with.

> **NOTE**
>

Batch manager security role

2/18/2021 • 2 minutes to read • Edit Online

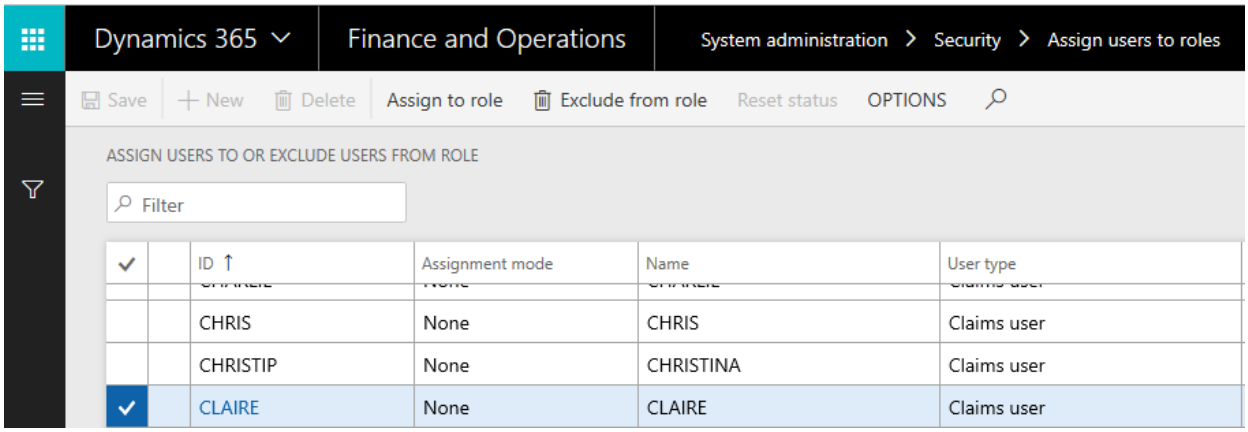
Before Platform update 20, users needed to be assigned to the system admin or IT admin security role to manage batch jobs. With the release of Platform update 20, there is a more targeted role, Batch manager. With this security role, a user now has permissions to copy batch jobs, change who will execute jobs, and specify the time ranges during which jobs can execute. The Batch maintain security privilege is part of the Batch manager security role and it allows a user to create an ad hoc batch job and grant privileges to other users.

> **NOTE**
>
> This feature is available as of Platform update 20.

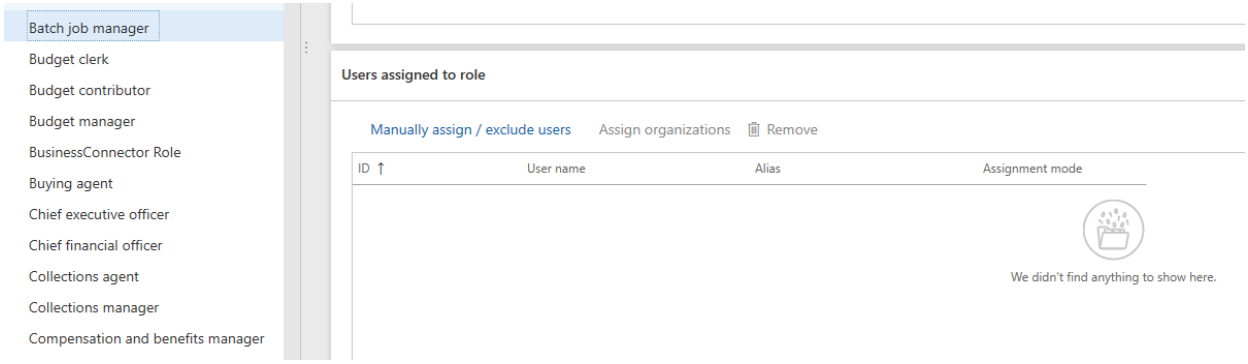
Assign the Batch manager role to a user

Complete the following steps to assign the Batch manager security role to a specific user.

1. Select **System administration** > **Security** > **Assign users to roles**.



2. Select **Batch Job Manager**, and on the left pane, select **Manually assign/exclude user**.

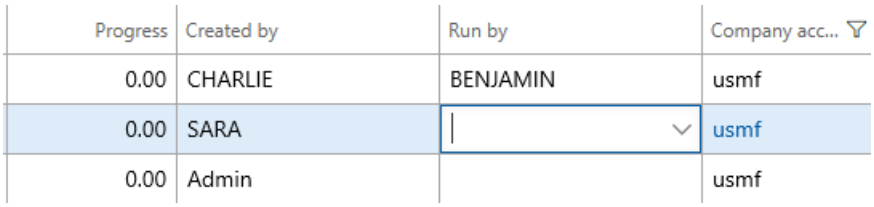


3. Select a user from the list, and then select **Assign to role**.
4. Close the page.

Run by user

The **run by user** functionality allows Batch managers to specify a user to run the batch job. This functionality is useful when you want to change the user who is currently assigned to run the job or if you want to quickly set a

user while copying the batch jobs from one company to another. You can also use this functionality to copy batch jobs.



Progress	Created by	Run by	Company acc...

Set up alerts

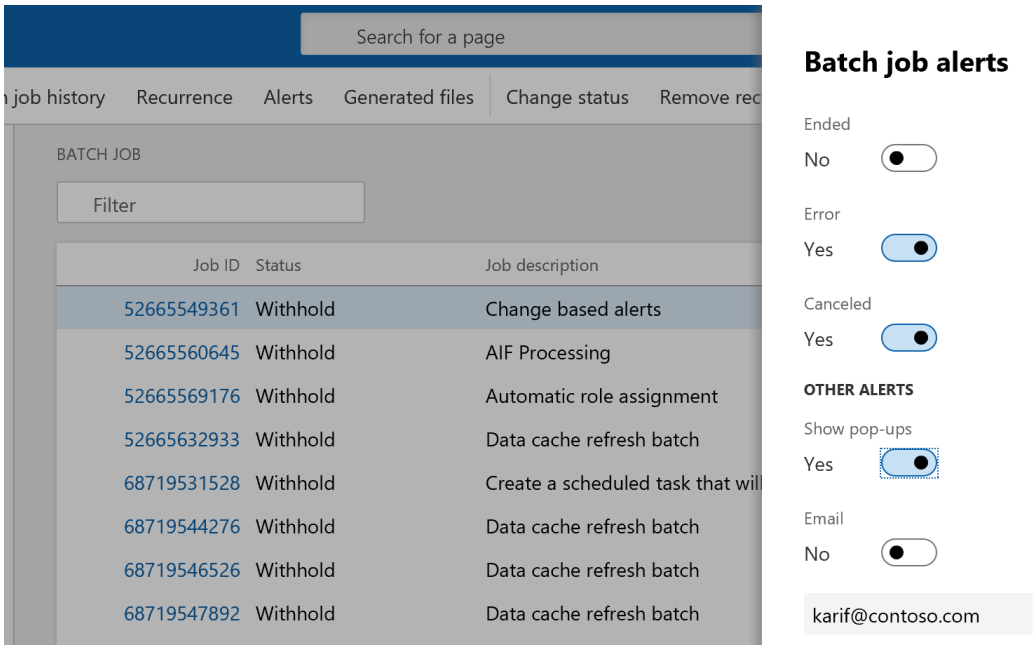
2/18/2021 • 2 minutes to read • Edit Online

Alerts form a notification system for critical events in Finance and Operations. You can use alerts to stay informed about events that you want to track during the workday. You can set up a set of alert rules so that you're alerted when a batch job ends, ends in error, or is canceled. You can select whether the alerts are emailed to you or appear as notifications in the Action center. Alerts can be set up per batch job and per user.

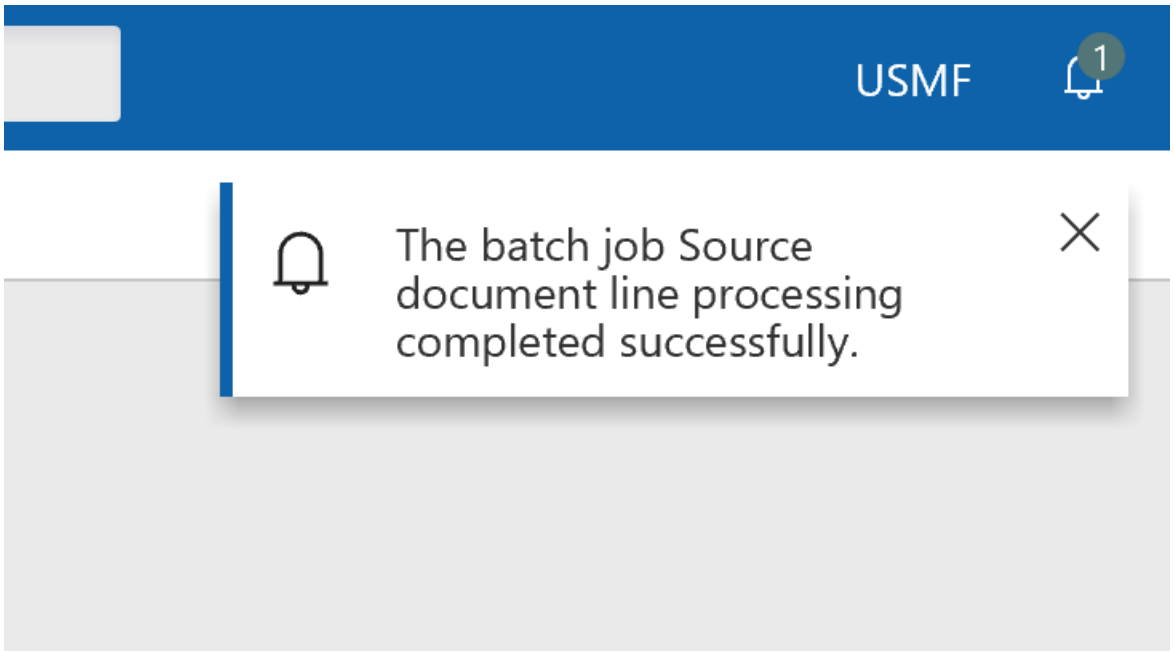
Set up alerts for batch enhanced forms

Follow these steps to set up alerts for batch enhanced forms.

1. Go to **System administration** > **Inquiries** > **Batch jobs**.
2. Select a batch job in the list, and then, on the Action Pane, select **Alerts**.
3. In the **Batch job alerts** dialog box, configure the alerts, and then select **OK**.



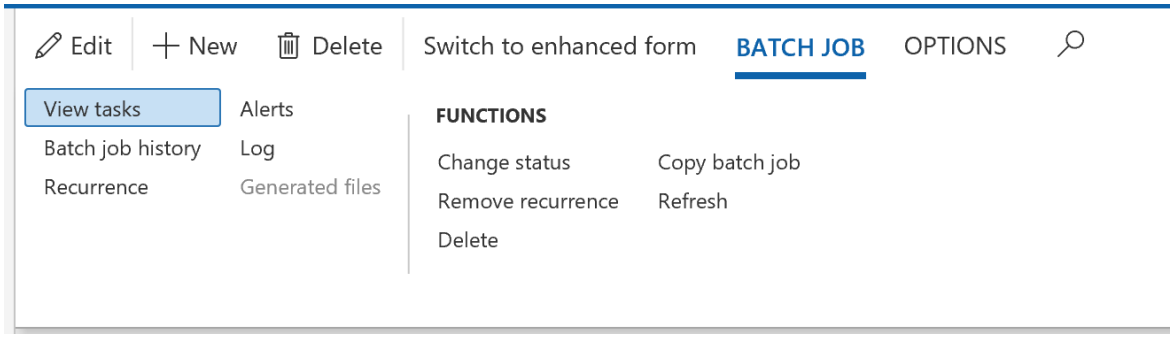
4. Check the Action center for alert notifications.



Set up alerts for batch legacy forms

Follow these steps to set up alerts for batch legacy forms.

1. Go to **System administration** > **Inquiries** > **Batch jobs**.
2. Select a batch job in the list, and then, on the Action Pane, on the **Batch job** tab, select **Alerts**.



3. In the **Batch job alerts** dialog box, configure the alerts, and then select **OK**.

> **NOTE**
>
> To receive email notifications, in the **Batch job alerts** dialog box, set the **Email** option to **Yes**.

> **NOTE**
>

Enhanced batch forms

2/18/2021 • 2 minutes to read • Edit Online

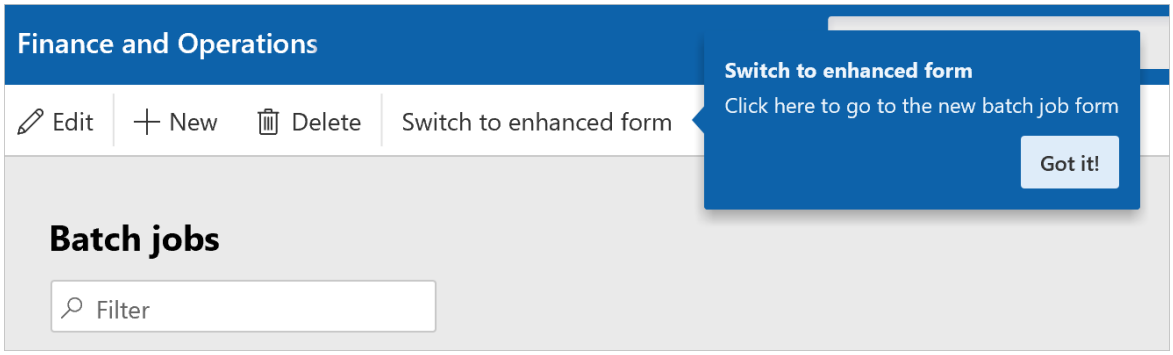
You can open an enhanced detail transaction form by selecting the job ID for a batch job. The enhanced form provides a header and lines that summarize the batch tasks and constraints that are related to the selected batch job.

Switch to the enhanced form

Follow these steps to switch to the enhanced form.

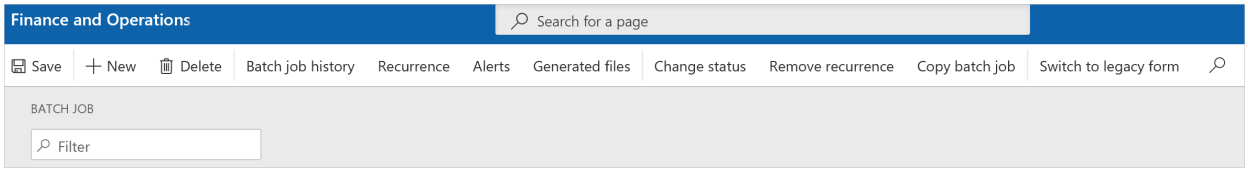
1. Go to **System administration** > **Inquiries** > **Batch jobs**.

   You're notified about the enhanced form. The notification shows the location of the **Switch to enhanced form** button on the Action Pane.



2. Select **Switch to enhanced form**.

To switch back to the unenhanced form, select **Switch to legacy form** on the Action Pane of the enhanced form.



NOTE

Can you tell us about your documentation language preferences? Take a short survey.

The survey will take about seven minutes. No personal data is collected (privacy statement).

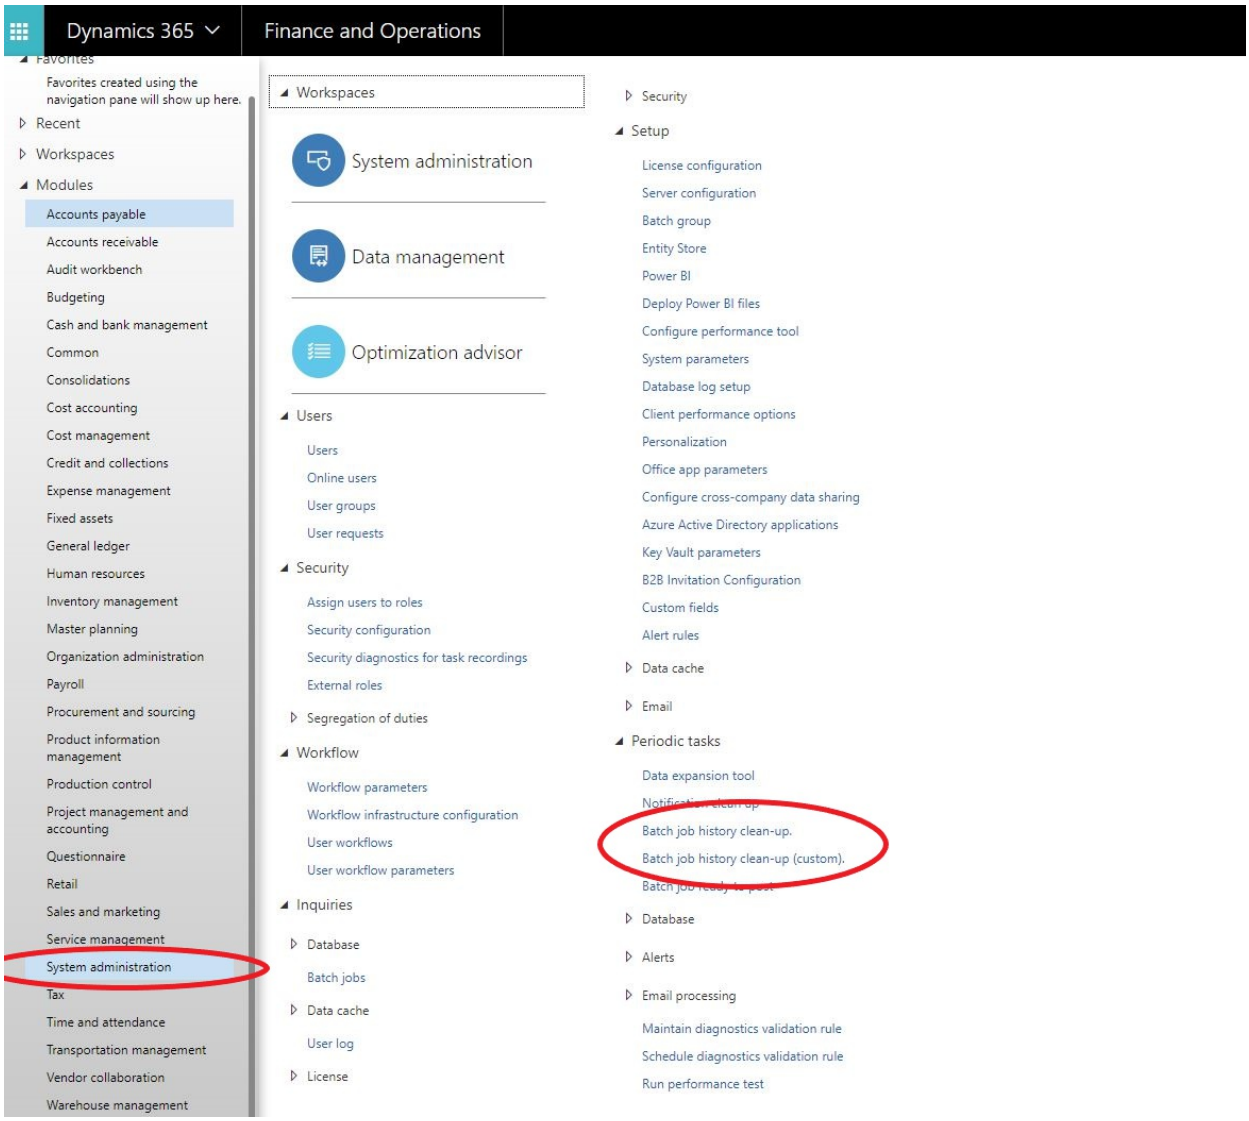
Clean up the batch job history

2/18/2021 • 2 minutes to read • Edit Online

When you run a batch job, a history is recorded. This history can be used to monitor the correct execution of jobs. However, when several batch jobs have been created, especially batch jobs that have a high recurrence, lots of batch job history entries are generated. Too many entries in the history table can negatively affect the performance of future jobs.

Two pages that have been added to the **System administration** module make it easy to clean up the batch job history:

- Batch job history clean-up
- Custom batch job history clean-up



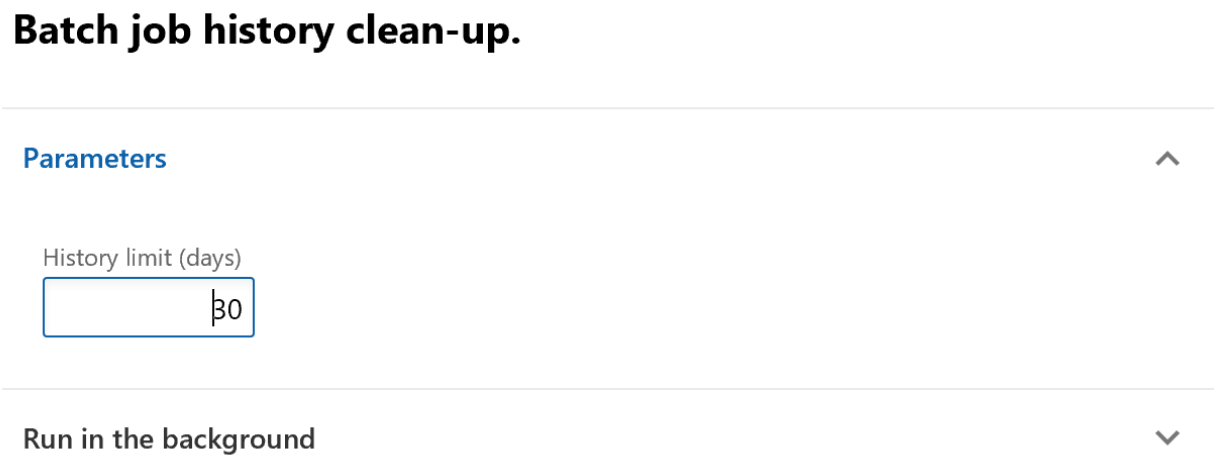
NOTE

We recommend that you regularly clean up the batch job history, and that you do this cleanup outside of business hours.

Batch job history clean-up

Follow these steps to quickly clean up all history entries that are older than a specified number of days.

1. On the **Periodic tasks in System administration** module, select **Batch job history clean-up**.
2. In the **History limit (days)** field, specify the number of days to keep a history of batch jobs.
3. Select **OK**.



Batch job history clean-up (custom)

The custom batch job lets you to apply additional filtering, based on criteria such as status, job description, company, or user. You can also add other filter criteria by selecting the **Filter** button.

1. On the **Periodic tasks in System administration** module, select **Batch job history clean-up (custom)**.
2. In the **History limit (days)** field, specify the number of days to keep a history of batch jobs.
3. On the **Records to include** FastTab, specify any filter criteria that you require, and then select **OK**.
4. Select **OK**.

Cancel an executing batch job

2/18/2021 • 2 minutes to read • Edit Online

NOTE

This feature is available as of Platform update 27.

Sometimes canceling a batch job can take a long time if already executing tasks will take a long time to finish. Canceling the batch job provides a system administrator or batch job manager with the ability to cancel already executing tasks for jobs that are in the process of being canceled. This provides a much faster mechanism to cancel a long running job that is impacting system usage elsewhere.

NOTE

It is important to note that this feature should be used with caution. When you cancel a running process, it is an inherently unsafe action that can lead to data corruption, resulting in either orphaned or incomplete data. This action should only be used to mitigate other issues caused by the running tasks.

Complete the following steps to immediately cancel the running task.

1. Go to **System administration** > **Inquiries** > **Batch jobs**.
2. Select a batch job that has a **Status** of **Canceling**.
3. On the **Batch tasks** tab, select **Cancel** on the task, and then select **OK**.

NOTE

Can you tell us about your documentation language preferences? Take a short survey.

Optimization advisor overview

2/18/2021 • 4 minutes to read • Edit Online

This topic describes how you can use Optimization advisor to help ensure optimal configuration of Finance and Operations.

Overview

Incorrect configuration and setup of a module can adversely affect the availability of application features, system performance, and the smooth operation of business processes. The quality of business data (for example, the correctness, completeness, and cleanliness of the data) also affects system performance, and an organization's decision-making capabilities, productivity, and so on.

The **Optimization advisor** workspace is a tool that lets power users, business analysts, functional consultants, and IT support functions identify issues in module configuration and business data. Optimization advisor suggests best practices for module configuration and identifies business data that is obsolete or incorrect.

Optimization advisor periodically runs a set of best practice rules. A default set of rules is available, however users can also create rules that are specific to their customizations, solutions from independent software vendors (ISVs), and business data. For more information about how to create rules, see Create rules for Optimization advisor.

When a violation of a rule is detected, an optimization opportunity is generated and appears in the **Optimization advisor** workspace. A user can take appropriate corrective action directly from the **Optimization advisor** workspace.

Opportunities can be company-specific or cross-company, depending on the type of setup and data that is being validated. Cross-company opportunities can be viewed from all companies. To view the opportunities for a specific company, you must first select the company.

Standard security policies apply to optimization opportunities. For example, the optimization opportunities that are related to configuration of the **Warehouse management** module are visible only to users who have access to Warehouse management and can change its setup.

When you take action on some optimization opportunities, the system calculates the impact of the opportunity in terms of the reduction in the runtime of business processes. Unfortunately, this feature isn't available for all optimization opportunities.

To learn more about Optimization advisor, watch the short Optimization advisor in Dynamics 365 for Finance and Operations video.

Optimization rules

To view the complete list of Optimization advisor rules and to see how often the rules are evaluated, go to **System administration** > **Periodic tasks** > **Maintain diagnostics validation rule**. Only rules that have a status of **Active** are evaluated. The evaluation frequency can be set to **Daily**, **Weekly**, **Monthly**, or **Unscheduled**.

To trigger the evaluation of unscheduled rules, or to reevaluate periodic rules outside their predefined schedule, go to **System administration** > **Periodic tasks** > **Schedule diagnostics validation rule**. Then, in the **Diagnostic rule validation** dialog box, select an evaluation frequency. All rules that have the specified frequency will be reevaluated.

The current set of optimization rules can be divided into the following categories.

Module configuration and setup

The setup of Warehouse management is a complicated process. To make the process easier, some rules have been introduced to help validate the correctness of the setup. For example, one rule validates the setup of warehouse location directives for fixed product variant locations for sales orders and transfer orders.

Additionally, some rules check whether features that have been enabled are actually used. For example, one rule determines whether you're using the **Master planning** module. If the rule determines that you aren't using the module, an optimization opportunity is generated to suggest that you turn off the planning processes.

System configuration

If specific functionality that is controlled by a configuration key isn't used, an optimization opportunity is generated to suggest that you disable the configuration key. Examples of configuration keys include **Catch weight**, **Budget planning**, **Project**, and **Approved vendor list**.

Business data consistency and cleanup

If master data isn't correct (for example, if you have unit of measure conversions for units that haven't been defined, or if you have unit of measure conversions that have a division by 0 [zero]), an optimization opportunity is generated to suggest that you correct the data.

If you have too many batch job history entries, obsolete items, closed on-hand entries for warehouse enabled items, and so on, or if those entries and items are too old, optimization opportunities are generated to suggest that you clean up the data. By keeping your data clean, you can help improve overall system performance.

Best practices

If you aren't running some business processes according to best practices (for example, if you run inventory pre-closing before the inventory is closed, or if you use the scheduled batch for subledger journal batch transfer), optimization opportunities inform you about the best practice and ask that you follow it.

Optimization opportunities

To view the optimization opportunities that are generated during the evaluation of optimization rules, open the **Optimization advisor** workspace.

In this workspace, you can view more information about an opportunity by selecting **More information**. If you want the system to take action and correct the setup, clean the data, and so on, so that you don't have to open the corresponding pages yourself, select **Take action**.

There is no workflow for optimization opportunities. After you select **Take action** or use a navigation path that is provided in the **More information** dialog box, the optimization opportunity disappears from the list. If the corrective action doesn't completely resolve an issue, the opportunity will be generated again the next time that the rule is evaluated.

If an opportunity doesn't apply to your role, you can select **Hide from my list**. Even if the rule behind this opportunity is triggered again later, you won't see the opportunity in your list.

To deactivate the evaluation of specific rules, select the opportunity that was generated by the rule, and then select **Deactivate analysis**.

Create rules for Optimization advisor

2/18/2021 • 6 minutes to read • Edit Online

This topic explains how to create new rules for **Optimization advisor**. For example, you can create a new rule that identifies which Request for Quotations (RFQ) cases have an empty title. Using titles on cases makes them easily identifiable and searchable. While quite simple, this example shows what can be achieved with optimization rules.

A *rule* is a check on application data. If the condition that the rule evaluates is met, opportunities to optimize processes or improve data are created. The opportunities can be acted upon and, optionally, the impact of the actions can be measured.

To create a new rule for the **Optimization advisor**, add a new class that extends the **SelfHealingRule** abstract class, implements the **IDiagnosticsRule** interface, and is decorated by the **DiagnosticRule** attribute. The class must also have a method decorated with the **DiagnosticsRuleSubscription** attribute. By convention, that is done on the **opportunityTitle** method, which will be discussed later. This new class can be added to a custom model with a dependency on the **SelfHealingRules** model. In the following example, the rule being implemented is called **RFQTitleSelfHealingRule**.

```
[DiagnosticsRule]
public final class RFQTitleSelfHealingRule extends SelfHealingRule implements IDiagnosticsRule
{
…
}
```

The **SelfHealingRule** abstract class has abstract methods that must be implemented in inheriting classes. The core is the **evaluate** method, which returns a list of the opportunities identified by the rule. Opportunities can be per legal entity or can apply to the whole system.

```
protected List evaluate()
{
    List results = new List(Types::Record);

    DataArea dataArea;

    while select id from dataArea
        where !dataArea.isVirtual
    {
        changecompany(dataArea.id)
        {
            container result = this.findRFQCasesWithEmptyTitle();

            if (conLen(result) > 0)
            {
                SelfHealingOpportunity opportunity = this.getOpportunityForCompany(dataArea.Id);
                opportunity.EvaluationState = SelfHealingEvaluationState::Evaluated;
                opportunity.Data = result;
                opportunity.OpportunityDate = DateTimeUtil::utcNow();

                results.addEnd(opportunity);
            }
        }
    }

    return results;
}
```

The method shown above loops over companies and selects RFQ cases with empty titles in the **findRFQCasesWithEmptyTitle** method. If at least one such case is found, then a company-specific opportunity is created with the **getOpportunityForCompany** method. Notice that the field **Data** in the **SelfHealingOpportunity** table is of type **Container**, and can therefore contain any data relevant to the logic specific to this rule. Setting **OpportunityDate** with the current timestamp registers the time of the latest evaluation of the opportunity.

Opportunities can also be cross-company. In this case, the loop over companies is not necessary and the opportunity must be created with the **getOpportunityAcrossCompanies** method.

The following code shows the **findRFQCasesWithEmptyTitle** method, which returns the IDs of the RFQ cases that have empty titles.

```
private container findRFQCasesWithEmptyTitle()
{
    container result;

    PurchRFQCaseTable rfqCase;
    while select RFQCaseId from rfqCase
        where rfqCase.Name == ''
    {
        result += rfqCase.RFQCaseId;
    }

    return result;
}
```

Two more methods that must be implemented are **opportunityTitle** and **opportunityDetails**. The former returns a short title for the opportunity, the latter returns a detailed description of the opportunity, which can also include data.

The title returned by **opportunityTitle** appears under the **Optimization opportunity** column in the **Optimization advisor** workspace. It also appears as the header of the side pane showing more information

about the opportunity. By convention, this method is decorated with the **DiagnosticRuleSubscription** attribute, which takes the following arguments:

- **Diagnostic area** – An enum of type **DiagnosticArea** that describes what area of the application the rule belongs to, such as **DiagnosticArea::SCM**.
- **Rule name** – A string with the rule name. This will appear under the **Rule name** column in the **Dianostics validation rule** form (**DiagnosticsValidationRuleMaintain**).
- **Run frequency** – An enum of type **DiagnosticRunFrequency** that describes how often the rule should be run, such as **DiagnosticRunFrequency::Daily**.
- **Rule description** – A string with a more detailed description of the rule. This will appear under the **Rule description** column in the **Dianostics validation rule** form (**DiagnosticsValidationRuleMaintain**).

> **NOTE**
>
> The **DiagnosticRuleSubscription** attribute is required for the rule to work. Typically, it is used on **opportunityTitle**, but it can decorate any method of the class.

The following is an example implementation. Raw strings are used for simplicity, but a correct implementation requires labels.

```
[DiagnosticsRuleSubscription(DiagnosticsArea::SCM,
                             'Assign titles to Request for Quotation cases',
                             DiagnosticsRunFrequency::Daily,
                             'This rule detects Requests for Quotation with empty titles.')]
public str opportunityTitle()
{
    return 'Assign titles to Request for Quotation cases';
}
```

The description returned by **opportunityDetails** appears on the side pane showing more information about the opportunity. This takes the **SelfHealingOpportunity** argument, which is **Data** field that can be used to provide more details about the opportunity. In the example, the method returns the IDs of the RFQ cases with an empty title.

```
public str opportunityDetails(SelfHealingOpportunity _opportunity)
{
    str details = '';
    container opportunityData = _opportunity.Data;
    int affectedRFQCasesCount = conLen(opportunityData);

    if (affectedRFQCasesCount != 0)
    {
        details = 'The following Request for Quotation cases have an empty title:\n';
        for (int i = 1; i <= affectedRFQCasesCount ; i++)
        {
            PurchRFQCaseId rfqCaseId = conPeek(opportunityData, i);
            details += rfqCaseId + '\n';
        }
    }

    return details;
}
```

The two remaining abstract methods to implement are **provideHealingAction** and **securityMenuItem**.

provideHealingAction returns true if a healing action is provided, otherwise, it returns false. If true is returned,

the method **performAction** must be implemented, or an error will be thrown. The **performAction** method takes a **SelfHealingOpportunity** argument, in which the data can be used for the action. In the example, the action opens the **PurchRFQCaseTableListPage**, for manual correction.

```
public boolean providesHealingAction()
{
    return true;
}

protected void performAction(SelfHealingOpportunity _opportunity)
{
    new MenuFunction(menuItemDisplayStr(PurchRFQCaseTableListPage), MenuItemType::Display).run();
}
```

Depending on the specifics of the rule, it might be possible to take an automatic action using the opportunity data. In this example, the system could generate titles for RFQ cases automatically.

securityMenuItem returns the name of an action menu item such that the rule is only visible to users who can access the action menu item. Security might require that specific rules and opportunities are accessible only to authorized users. In the example, only users with access to **PurchRFQCaseTitleAction** can view the opportunity. Notice that this action menu item was created for this example, and was added as an entry point for the **PurchRFQCaseTableMaintain** security privilege.

> **NOTE**
> The menu item must be an action menu item for security to work correctly. Other menu item types, such as **Display menu items** will not work correctly.

```
public MenuName securityMenuItem()
{
    return menuItemActionStr(PurchRFQCaseTitleAction);
}
```

After the rule has compiled, execute the following job to have it display in the user interface (UI).

```
class ScanNewRulesJob
{
    public static void main(Args _args)
    {
        SysExtensionCache::clearAllScopes();
        var controller = new DiagnosticsRuleController();
        controller.runOperation();
    }
}
```

The rule will display in the **Diagnostics validation rule** form, available from **System administration** > **Periodic tasks** > **Maintain diagnostics validation rule**. To have it evaluated, go to **System administration** > **Periodic tasks** > **Schedule diagnostics validation rule**, select the frequency of the rule, such as **Daily**. Click **OK**. Go to **System administration** > **Optimization advisor** to view the new opportunity.

The following example is a code snippet with the skeleton of a rule including all the required methods and attributes. It helps you get started with writing new rules. The labels and action menu items that are used in the example are only used for demonstration purpose.

```
[DiagnosticsRuleAttribute]
public final class SkeletonSelfHealingRule extends SelfHealingRule implements IDiagnosticsRule
{
    [DiagnosticsRuleSubscription(DiagnosticsArea::SCM,
                                 "@SkeletonRuleLabels:SkeletonRuleTitle", // Label with the title of the
rule
                                 DiagnosticsRunFrequency::Monthly,
                                 "@SkeletonRuleLabels:SkeletonRuleDescription")] // Label with a description
of the rule
    public str opportunityTitle()
    {
        // Return a label with the title of the opportunity
        return "@SkeletonRuleLabels:SkeletonOpportunityTitle";
    }

    public str opportunityDetails(SelfHealingOpportunity _opportunity)
    {
        str details = "";

        // Use _opportunity.data to provide details on the opportunity

        return details;
    }

    protected List evaluate()
    {
        List results = new List(Types::Record);

        // Write here the core logic of the rule

        // When creating an opportunity, use:
        //     * this.getOpportunityForCompany() for company specific opportunities
        //     * this.getOpportunityAcrossCompanies() for cross-company opportunities

        return results;
    }

    public boolean providesHealingAction()
    {
        return true;
    }

    protected void performAction(SelfHealingOpportunity _opportunity)
    {
        // Place here the code that performs the healing action

        // To open a form, use the following:
        // new MenuFunction(menuItemDisplayStr(SkeletonRuleDisplayMenuItem), MenuItemType::Display).run();
    }

    public MenuName securityMenuItem()
    {
        return menuItemActionStr(SkeletonRuleActionMenuItem);
    }

}
```

NOTE

Can you tell us about your documentation language preferences? Take a short survey.

The survey will take about seven minutes. No personal data is collected (privacy statement).

Report a production outage

2/18/2021 • 2 minutes to read • Edit Online

Lifecycle Services (LCS) has a feature called **Report production outage**. This feature is available to all customers who have purchased one or more Dynamics 365 Finance and Operations apps and have implementation projects with a production environment deployed in LCS. This feature provides a quick and effective channel to escalate issues to Microsoft Support in the event that the services in a production environment are degraded or become unavailable.

Following mutually inclusive conditions, a production outage can be defined as one or more system-wide issues on a live production environment that impact multiple users and prevent your business from performing daily operations.

Reporting flow

The following list shows the order in which an issue should be handled:

1. In a live production environment, a customer experiences an outage or other situation with prevents business from continuing.
2. The customer reports a production outage issue by using the LCS Support portal.
3. The customer selects a production outage issue and provides additional information.
4. A Microsoft support engineer acknowledges the production outage ticket within 30 minutes of submission and begins to immediately collaborate with stakeholders to investigate and resolve the issue.
5. A support engineer contacts the customer to provide a status update.

Access and availability

All users who have been added to a customer's implementation project have access to this feature. This includes project owners, organization admins, team members, and environment managers.

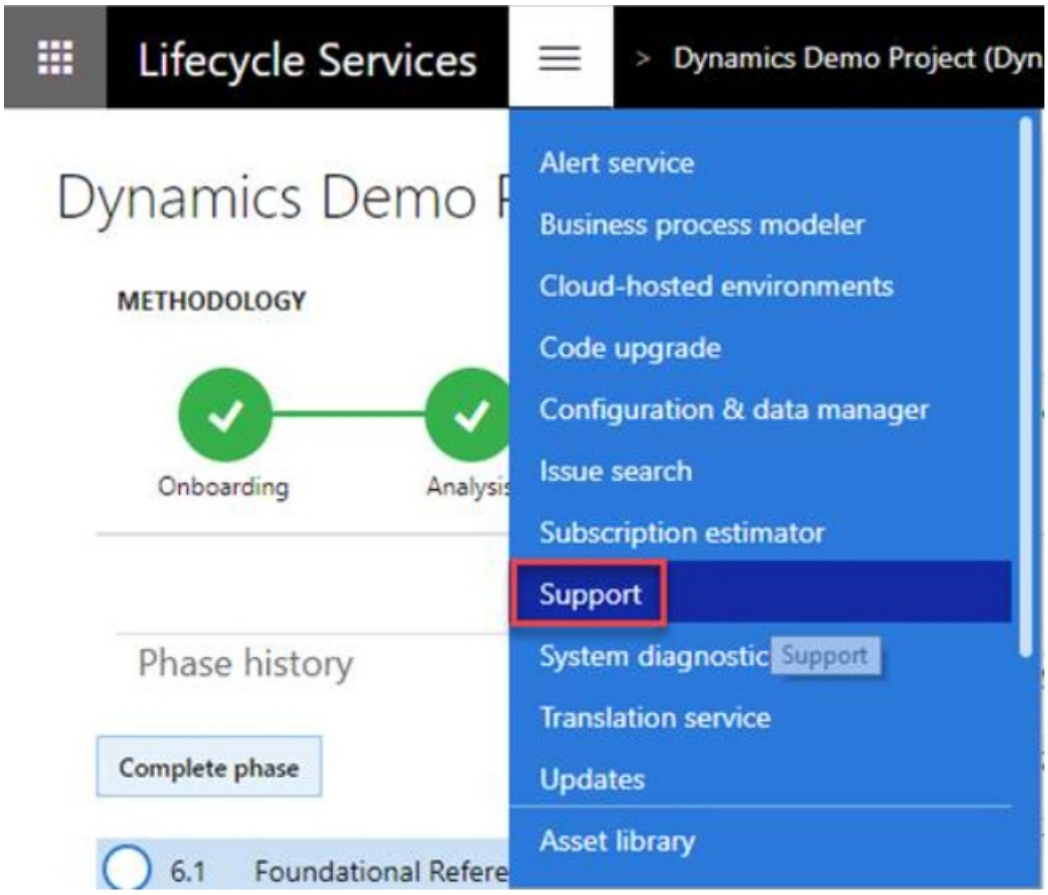
This feature is available for:

- Dynamics 365 Finance
- Dynamics 365 Supply Chain Management
- Environments that are managed by Microsoft
- A production environment in the LCS project
- All support plans

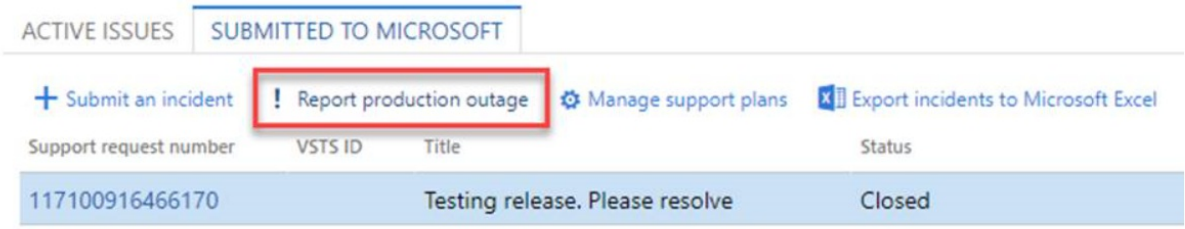
Report a production outage

To report a production outage, follow these steps:

1. Log in to your LCS project.
2. From the hamburger menu, click **Support**.



3. On the **Submitted To Microsoft** tab, click **Report production outage**.



4. Confirm the production outage, select the outage scenario from the drop-down list, and then click **Continue**.
5. Add a title and details about the outage, and then click **Next**.
6. Provide contact information, and then click **Next**.
7. Click **Done**.

If you're unable to report a production outage in LCS, phone support is available.

> **NOTE**
>
> If you don't see your situation listed in the outage scenarios, enter a support incident through LCS. During the initial investigation by a Microsoft support engineer, if it is found that the situation does not meet the current list of production outage scenarios, the support incident will be transferred to the correct support team and service-level agreement (SLA) based on your current support plan.

Configure database logging

2/18/2021 • 3 minutes to read • Edit Online

Database logging provides a way to track specific types of changes to the tables and fields in Finance and Operation apps. Changes that can be tracked include insert, update, delete, and rename key operations. When you configure logging for a table or field, a record of every change to that table or field is stored in the database log table, **sysdatabaselog**, in the environment database.

Database logging can be used for these purposes:

- Create an auditable record of changes to specific tables that contain sensitive information.
- Monitor the use of electronic signatures. By default, all transactions that have been signed by using electronic signatures are logged.

Database logging is intended to track individual transactions. It isn't intended to track automated transactions that are run in batch jobs.

Security for database logging

Database logs can contain sensitive data. By default, any user who has database access can query the database log table (**sysdatabaselog**) by using X++ or alerts, or by querying the database directly. To help protect data, you should restrict permissions on the **sysdatabaselog** table for on-premises deployments.

Database logging and performance

Although database logging can be valuable from a business perspective, it can be expensive with regard to resource use and management. Here are some of the performance implications of database logging:

- The database log table can grow quickly and can increase the size of the database. The amount of growth depends on the amount of logged data that you decide to retain.
- When logging is turned on for a transaction type, each instance of that transaction type causes multiple records to be written to the Microsoft SQL Server transaction log file. Specifically, one record is written for the initial transaction, and one record logs the transaction in the database log table. Therefore, the transaction log file will grow more quickly and might require additional maintenance.
- Database logging can adversely affect long-running automated processes, such as inventory close, calculations for bills of materials (BOMs), master planning, and long-running data imports.
- When logging is turned on for a table, all set-based database operations are downgraded to row-based operations. For example, if you're logging inserts for a table, each insert is done as a row-based insert.

Here are some practices that Microsoft recommends:

- Create a plan for how long you will retain logged data, and how you will archive or delete data.
- Limit log entries, and help improve performance by selecting specific fields to log instead of whole tables.

  > **NOTE**
  > Only updates can be logged for individual fields.

- After you configure database logging, consider increasing the frequency of backups of the SQL Server transaction log.

> **NOTE**
>
> This recommendation applies only to on-premises deployments that have a local instance of SQL Server.

Set up database logging

You can use the **Logging database changes** wizard to set up database logging. This wizard provides a flexible way to set up logging for tables or fields.

1. Go to **System administration** > **Setup** > **Database log** > **Database log setup**.
2. Select **New** to open the **Logging database changes** wizard.
3. Complete the wizard.

Clean up database logs

You can delete database logs as required. You can delete logs for specific tables, delete specific types of database logs, or delete logs based on the date and time when they were created.

> **NOTE**
>
> Records that have been electronically signed can't be deleted from logs.

1. Go to **System administration** > **Inquiries** > **Database** > **Database log**.
2. Select **Clean up log**.
3. Select the method that should be used to select the logs that are deleted. Enter the table ID that the logs refer to, the type of log, or the creation date and time.
4. Use the **Database log cleanup** tab to specify when the log cleanup task should be run.

Consistency check for database log triggers

In Platform update 34, functionality for a consistency check was added. The consistency check is run as part of the **Database log** wizard. It's run after you select **Finish** or after you select **Consistency check** on the **Database log setup** page.

The consistency check will re-create any missing database log triggers. It will also drop any "orphaned" database log triggers that no corresponding configuration is found for. In this way, the consistency check quickly detects and fixes any inconsistencies between the current configuration and the database triggers that are used to implement the logging functionality.

1. Go to **System administration** > **Inquiries** > **Database** > **Database log**.
2. On the **Database log** page, select **Consistency check**.

> **NOTE**
>
> Can you tell us about your documentation language preferences? Take a short survey.
>
> The survey will take about seven minutes. No personal data is collected (privacy statement).

Build OData metadata cache when the AOS starts

2/18/2021 • 2 minutes to read • Edit Online

With the release of Platform update 32, we have introduced the ability to build OData metadata cache when the Application Object Server (AOS) starts, instead of when the first OData request is made. This significantly decreases the response time for the first OData call after an AOS process restart.

This option is useful if your business process can't wait for the OData metadata cache to be built each time that the AOS process restarts. Follow these steps to turn on this feature.

1. Go to **System administration** > **Setup** > **System parameters**.
2. On the **General Tab**, select **Build metadata cache when AOS starts**, and then select **Save**.

> **NOTE**
> When you enable this functionality, the AOS should already be running and should have served one OData request. This means that the cache is already built. This new functionality will take effect during the next AOS restart.

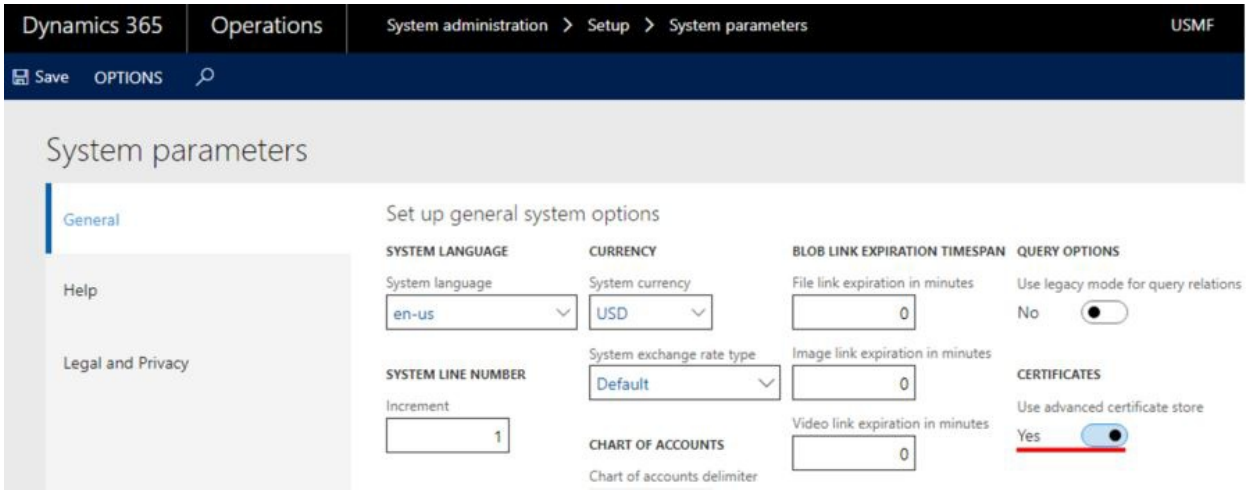
Set up the Azure Key Vault client

2/18/2021 • 3 minutes to read • Edit Online

The functionality for storing advanced certificates lets you define the type of certificate storage that is used in Finance and Operations apps.

The functionality provides two options for storing certificates: local storage and Microsoft Azure Key Vault storage. You can define the option that is used by setting the new **Use advanced certificate store** option on the **General** tab of the **System parameters** page (**System administration** > **Setup** > **System parameters**).

- **Local storage** – This storage option can be used with on-premises deployments and any kind of on-premises development environment. To use it, set the **Use advanced certificate store** option to **No**. This storage option is recommended for development environments that are used for development and validation purposes, where it's necessary to validate the certificate and work with it.
- **Azure Key Vault storage** – This storage option is required for cloud deployments, but it can also be used with on-premises deployed environments and any kind of on-premises development environment. To use it, set the **Use advanced certificate store** option to **Yes**. This storage option is the only option for a production environment in the Azure cloud.



Some setup is required before you can work with certificates that are stored in Key Vault. For information about the required settings, see the following Microsoft Knowledge Base (KB) article: 4040294 - Maintaining Azure Key Vault storage. After you set up the Key Vault storage, you should link to the certificates in Finance and Operations apps.

After the certificate is installed in Key Vault, it must be set up in the application.

1. Go to **System administration** > **Setup** > **Key Vault parameters**.
2. Select **New** to create a new instance.
3. Enter a name and description, and then, on the **General** FastTab, set the fields that are required for the integration with Key Vault storage:

- **Key Vault URL** – Enter the default Key Vault URL if it isn't already defined by the secret reference.
- **Key Vault client** – Enter the interactive client ID of the Azure Active Directory (Azure AD) application that is associated with the Key Vault storage for authentication.
- **Key Vault secret key** – Enter the secret key that is associated with the Azure AD application that is used

for authentication with the Key Vault storage.

> **NOTE**
> If several Key Vault storages are used, you should set up a separate instance for each instance on the **Key Vault parameters** page.

4. On the **Certificates** FastTab, select **Add** to add your certificates. For each certificate, set the following fields:

- **Name**
- **Description**
- **Key Vault certificate secret** – Enter a secret reference to the certificate.

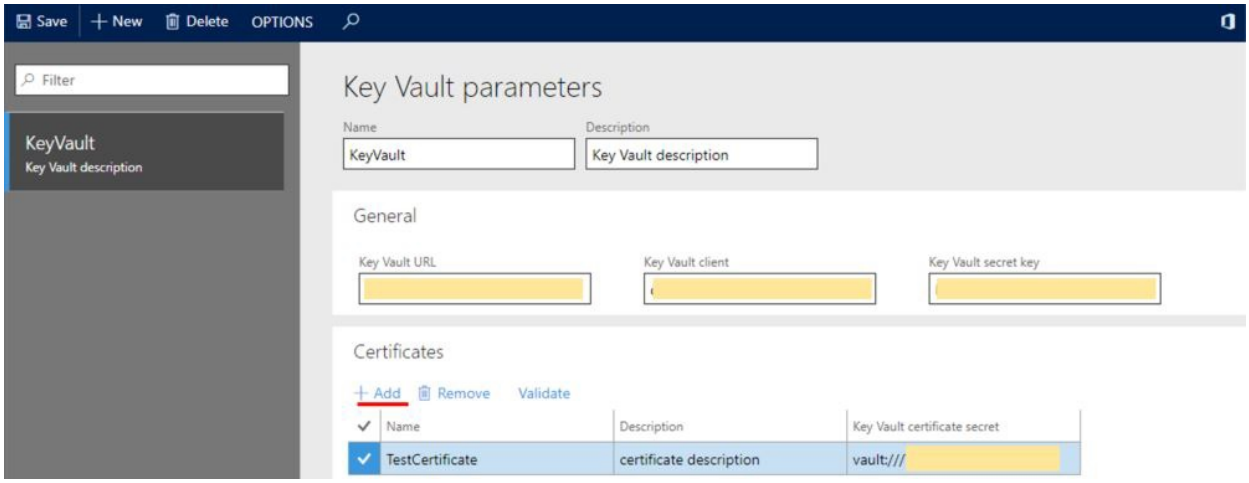
The format of a Key Vault certificate secret must resemble the following example:

vault://<KeyVaultName*>/<SecretName>/<SecretVersion*>

Attributes that are marked with an asterisk (*) are optional. However, the **<SecretName>** attribute is required. In most cases, you can define a Key Vault secret key in the following format:

vault:///<SecretName>

If the secret version isn't defined in the Key Vault secret key, the system retrieves the active certificate that has the latest expiration date.



> **NOTE**
> The Key Vault storage functionality has been extended so that it includes caching of certificates. The following configuration is recommended:

- Specify a secret version in the Key Vault certificate secret.
- After you upload a new version of the existing certificate to the Key Vault storage, update the **<SecretVersion>** attribute in the **Key Vault certificate secret** field.

Use the **Validate** function to verify that you've correctly defined the reference to the certificate, and that the certificate is valid.

> **NOTE**

Cleanup routines in Dynamics 365 Finance and Dynamics 365 Supply Chain Management

2/18/2021 • 10 minutes to read • Edit Online

In Microsoft Dynamics 365 Finance and Dynamics 365 Supply Chain Management, cleanup routines are available in various modules. This topic provides an overview of the routines that are currently available. The information is organized by module.

> **IMPORTANT**
>
> These cleanup routines should be run only after the business has done detailed analysis and confirmed that the data is no longer required.
>
> Always test each cleanup routine in a test environment before you run it in a production environment.

System administration

PATH	DESCRIPTION
System administration > Periodic tasks > Notification clean up	This cleanup routine is used to periodically delete records from the EventInbox and EventInboxData tables. **Recommendation:** If you don't use alert functionality, turn off the alert from the batch job.
System administration > Periodic tasks > Batch job history clean-up	This regular version of the batch job history cleanup routine lets you quickly clean all history entries that are older than a specified number of days. Any entry that was created earlier will be deleted from the BatchJobHistory table, and also from linked tables that have related records (BatchHistory and BatchConstraintsHistory). This version has improved performance optimization, because it doesn't have to run any filtering.
System administration > Periodic tasks > Batch job history clean-up (custom)	This custom batch job history cleanup routine should be used only when specific entries must be deleted. You can clean up selected types of batch job history records, based on criteria such as status, job description, company, or user. You can add other criteria by using the **Filter** button.
System administration > Inquiries > Database > Database Log > Clean up log	This cleanup routine lets you delete database logs as you require. You can delete logs for specific tables, delete specific types of database logs, or delete logs based on the date and time when they were created. **Note:** Records that have been electronically signed can't be deleted from logs.

Data management

PATH	DESCRIPTION
In the **Data management** workspace, select **Job history cleanup**.	This cleanup routine is available in Platform update 29 and later. To use it, you must turn on the **Execution history cleanup** feature in Feature management. In Data management, this routine must be used to schedule a periodic cleanup of the execution history. It replaces the earlier Staging cleanup routine, which is now obsolete (deprecated). The following tables will be cleaned up: • All staging tables • DMFSTAGINGVALIDATIONLOG • DMFSTAGINGEXECUTIONERRORS • DMFSTAGINGLOGDETAIL • DMFSTAGINGLOG • DMFDEFINITIONGROUPEXECUTIONHISTORY • DMFEXECUTION • DMFDEFINITIONGROUPEXECUTION
In the **Data management** workspace, select the **Staging cleanup** tile.	This cleanup routine should no longer be used, because it's obsolete. Instead, use the Job history cleanup routine.

General ledger

PATH	DESCRIPTION
General ledger > Periodic tasks > Clean up ledger journals	This cleanup routine deletes General ledger, Accounts receivable, and Accounts payable journals that have been posted. When you delete a posted ledger journal, all information that is related to the original transaction is removed. **Note:** You should delete this information only if you're sure that you won't have to reverse the ledger journal transactions.

Sales and marketing

PATH	DESCRIPTION
Sales and marketing > Periodic tasks > Clean up > Delete sales orders	This cleanup routine deletes selected sales orders.
Sales and marketing > Periodic tasks > Clean up > Delete quotations	This cleanup routine deletes selected quotations.
Sales and marketing > Periodic tasks > Clean up > Delete return orders	This cleanup routine deletes selected return orders.
Sales and marketing > Periodic tasks > Clean up > Sales update history cleanup	This cleanup routine deletes old update history transactions. All updates of confirmations, picking lists, packing slips, and invoices generate update history transactions. You can view these transactions on the **History on update** page.

PATH	DESCRIPTION
Sales and marketing > Periodic tasks > Clean up > Order events cleanup	This cleanup routine cleans up order events. The next step is to open the **Order event setup** page and clear the check boxes for any order events that aren't required.

Procurement and sourcing

PATH	DESCRIPTION
Procurement and sourcing > Periodic tasks > Clean up > Purchase update history cleanup	This cleanup routine is used to delete all updates of confirmations, picking lists, product receipts, and invoices that generate update history transactions.
Procurement and sourcing > Periodic tasks > Clean up > Delete requests for quotations	This cleanup routine is used to delete requests for quotation (RFQs) and RFQ replies. The corresponding RFQ journals aren't deleted but remain in the system.
Procurement and sourcing > Periodic tasks > Clean up > Draft consignment replenishment order journal cleanup	This cleanup routine is used to clean up draft consignment replenishment order journals.

Warehouse management

PATH	DESCRIPTION
Warehouse management > Periodic tasks > Clean up > Work creation history purge	This cleanup routine is used to delete work creation history records from the WHSWorkCreateHistorytable table. In the dialog box, you specify the number of days to keep the history.
Warehouse management > Periodic tasks > Clean up > Containerization history purge	This cleanup routine is used to delete containerization history from the WHSContainerizationHistory table. In the dialog box, you specify the number of days to keep the history.
Warehouse management > Periodic tasks > Clean up > Wave batch cleanup	This cleanup routine is used to clean up batch job history records that are related to the wave processing batch group.
Warehouse management > Periodic tasks > Clean up > Cycle count plan cleanup	This cleanup routine is used to clean up batch job history records that are related to cycle count plan configurations.
Warehouse management > Periodic tasks > Clean up > Mobile device activity log cleanup	This cleanup routine is used to delete mobile device activity log records from the WHSMobileDeviceActivityLog table. In the dialog box, you specify the number of days to keep the history.
Warehouse management > Periodic tasks > Clean up > Work user session log cleanup	This cleanup routine is used to delete work user session records from the WHSWorkUserSessionLog table. In the dialog box, you specify the number of hours to keep records.

Inventory management

PATH	DESCRIPTION
Inventory management > Periodic tasks > Clean up > Calculation of location load	The WMSLocationLoad table is used to track the weight and volume of items and pallets. The Summation of load adjustments job can be run to reduce the number of records in the WMSLocationLoad table and help improve performance.
Inventory management > Periodic tasks > Clean up > Inventory journals cleanup	This cleanup routine is used to delete posted inventory journals.
Inventory management > Periodic tasks > Clean up > Inventory settlements cleanup	This cleanup routine is used to group closed inventory transactions or delete canceled inventory settlements. By cleaning up closed or deleted inventory settlements, you can help free up system resources. Don't group or delete inventory settlements that are too close to the current date or fiscal year, because part of the transaction information for the settlements will be lost. Closed inventory transactions can't be changed after they have been grouped, because the transaction information for the settlements will be lost. If canceled inventory settlements are deleted, they can't be reconciled with finance transactions.
Inventory management > Periodic tasks > Clean up > Inventory dimensions cleanup	This cleanup routine is used to maintain the InventDim table. To maintain the table, delete unused inventory dimension combination records that aren't referenced by any transaction or master data. The records are deleted, regardless of whether the transaction is open or closed. An inventory dimension combination record that is still referenced can't be deleted, because when an InventDim record is deleted, related transactions can't be reopened.
Inventory management > Periodic tasks > Clean up > Dimension inconsistency cleanup	This cleanup routine is used to resolve dimension inconsistencies on inventory transactions that have been financially updated and closed. Inconsistencies might be introduced if the multisite functionality was activated during or before the upgrade process. Use this routine only to clean up the transactions that were closed before the multisite functionality was activated. **Note:** Don't use this routine periodically.
Inventory management > Periodic tasks > Clean up > On-hand entries cleanup	This cleanup routine is used to delete closed and unused entries for on-hand inventory that is assigned to one or more tracking dimensions. Closed transactions contain a value of **0** (zero) for all quantities and cost values, and they are marked as closed. By deleting these transactions, you can help improve the performance of queries for on-hand inventory. Transactions won't be deleted for on-hand inventory that isn't assigned to tracking dimensions.

PATH	DESCRIPTION
Inventory management > Periodic tasks > Clean up > Warehouse management on-hand entries cleanup	This cleanup routine deletes records in the InventSum and WHSInventReserve tables. These tables are used to store on-hand information for items that are enabled for warehouse management processing (that is, WHS items). By cleaning up these records, you can significantly improve of the on-hand calculations.
Inventory management > Periodic tasks > Clean up > On-hand entries aggregation by financial dimensions	Use This cleanup routine as a tool to aggregate InventSum rows that have 0 (zero) quantities. This routine basically extends the previously mentioned routine by also cleaning up records where the **Closed** field is set to **True**. Basically, this routine is needed to handle scenarios where there are no more quantities in the InventSum table for a combination of inventory dimensions, but there is still a value. Although these values will disappear in some cases, the current design occasionally allows values to remain. For example, if you use batch numbers, each batch number (and the combined site, warehouse, and so on) creates a new record in the InventSum table. When the batch number is sold, you will see that quantity fields are set to **0** (zero). In most cases, the **Financial cost amount** and **Physical cost amount** fields are also set to **0** (zero). However, in standard cost revaluation and other scenarios, the field might still show some amount. This behavior is valid, and it reflects the way that Finance and Supply Chain Management handle the costs at the financial inventory level (for example, the site level). In Finance and Supply Chain Management, inventory value is determined by records in the InventSum table. In some cases, when inventory values in the past are reported, it's determined by inventory transactions (the InventTrans table). Therefore, in the previously described scenario, when you run inventory value reports, Finance and Supply Chain Management initially look at the InventSum table, aggregate all records to the site level, and report the value for the item per site. The data from the individual records at batch number level are never used. Therefore, this routine goes through all InventSum records, finds the records where there is no more quantity (that is, **No open quantities** field is set to **True**). Because there is no reason to keep these records, Finance and Supply Chain Management find the InventSum record for the same item that has the same site, they copy the values from the batch number level to the site level, and they delete the record. Then, when you run inventory value reports, Finance and Supply Chain Management still find the same correct values. Therefore, this routine reduces number of InventSum records, significantly in some cases, and can have a positive impact on the performance of any function that queries that table.
Inventory management > Periodic tasks > Clean up > Cost calculation details	This cleanup routine is used to clean up cost calculation details.

Production control

PATH	DESCRIPTION
Production control > Periodic tasks > Clean up > Production journals cleanup	This cleanup routine is used to delete unused journals.
Production control > Periodic tasks > Clean up > Production orders cleanup	This cleanup routine is used to delete production orders that are ended.
Production control > Periodic tasks > Clean up > Clean up registrations	We recommend that you periodically clean up registrations. This cleanup routine deletes only data that has been processed. **Note:** Make sure that you don't delete registrations that might be required later for documentation purposes.
Production control > Periodic tasks > Clean up > Archive future registrations	This cleanup routine is used to remove future registrations from the raw registrations table.

Master planning

PATH	DESCRIPTION
Master planning > Master planning > Maintain plans > Plan version cleanup	Usually, this cleanup is done automatically. However, automatic cleanup sometimes malfunctions, and orphan data remains in the system. This orphan data slows down queries and causes the database size to grow. We recommend that you do a preventive run one time per month, when master resource planning (MRP) isn't running.

Upgrades, updates, and hotfixes resources

2/18/2021 • 2 minutes to read • Edit Online

Upgrades, updates, and hotfixes can include moving to new product versions, code migration and upgrade, moving to an update, or deploying a hotfix.

The processes for each type of upgrade are similar, but different enough that we think that you should review the topics for a specific task before you begin.

Upgrade from Microsoft Dynamics AX 2012 to Finance and Operations

To get started, review the following topics:

- Upgrade from AX 2012 to Finance and Operations
- Prepare to migrate code to Finance and Operations

Migration from Microsoft Dynamics AX 2009 to Finance and Operations

This Tech Talk video provides an introduction to migration from AX 2009 to Finance and Operations: Dynamics 365 for Operations – Tech Talk: Migration tools.

Upgrade from a previous version of Finance and Operations

The steps for applying updates and upgrading differ between cloud and on-premises implementations.

Cloud

If you are upgrading a cloud version of Finance and Operations, review the following topics:

- Process for moving to the latest update of Finance and Operations
- Apply the latest platform update to environments
- Download updates from Lifecycle Services (LCS)

On-premises

If you are applying updates to an on-premises version of Finance and Operations, review the following topic:

- Apply updates to on-premises deployments
- Redeploy on-premises environments

Hotfixes

- Download updates from Lifecycle Services (LCS)
- Apply updates to cloud environments
- Install metadata hotfixes in development environments
- Patch SQL Server Reporting Services (SSRS) in one-box environments
- Update the Visual Studio development tools

This Tech Talk video provides an introduction servicing (applying code updates, requesting sandbox database

refreshes, and filing support requests): Dynamics 365 for Operations – Tech Talk: Servicing.

For more information, see:

- Refresh database
- Set up technical support for Finance and Operations apps

> **NOTE**

Upgrade from AX 2012 to Finance and Operations

2/18/2021 • 13 minutes to read • Edit Online

IMPORTANT

Upgrade is currently only supported from either Dynamics AX 2012 R2 or Dynamics AX 2012 R3. For each release, please update to the latest available cumulative update before upgrading to latest Finance and Operations application release.

Finance and Operations running Platform update 8 and the July 2017 Application release, and later provides an upgrade path that customers who currently run Microsoft Dynamics AX 2012 can use to move their data and code to Finance and Operations. Currently upgrade from Dynamics AX 2012 R3 and AX 2012 R2 are supported. The upgrade process is built on the following elements:

- Tools to help you bring forward existing custom application code from AX 2012.
- A data upgrade process that you can use to bring your database forward. Therefore, you can upgrade your full transactional history.

IMPORTANT

Dynamics AX 2012 implementations that are running some deprecated features cannot currently be upgraded. For example, upgrade is not possible from systems that are using either virtual companies or data partitions. If you aren't sure whether your system can be upgraded, run the Upgrade analyzer tool.

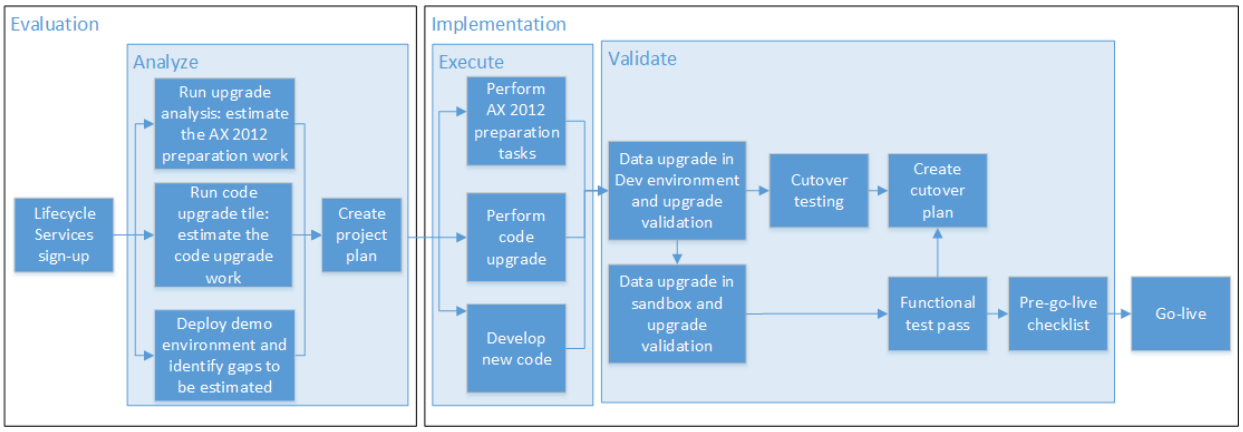
NOTE

Start your cloud migration journey with a no-charge, no-obligation migration assessment though the Dynamics 365 Migration Program.

Overview

The overall upgrade process can be visualized as three overarching phases: Analyze, Execute, and Validate.

The following diagram shows the end-to-end upgrade process, and the activities that we consider part of each phase.



Analyze

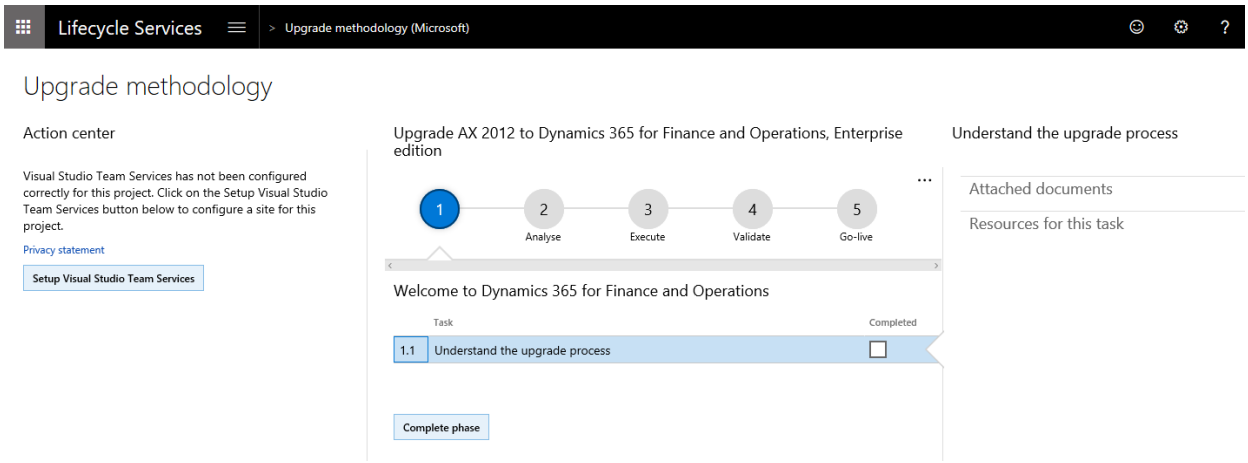
The activities in the Analyze phase help you estimate the effort that is required for the upgrade. They also help you prepare a project plan. These activities can be done before you buy Finance and Operations. They will help you make an informed purchase decision by providing a data point about the effort and resources that you will require.

Sign up for a preview subscription

To sign up for a preview subscription, see Sign up for preview subscriptions.

Select the upgrade methodology

In your new LCS project, set the project methodology to **Upgrade AX 2012 to Dynamics 365 for Finance and Operations**. This methodology is made specially for AX 2012 customers who are upgrading. It describes the three phases in detail and provides links to all the supporting documentation about the process.



Run the upgrade analyzer

The upgrade analyzer tool runs against your AX 2012 environment and identifies tasks that you should do to prepare the AX 2012 environment, to help make the upgrade experience smoother and less expensive:

- **Data cleanup** – This process helps you identify data that you can remove without causing loss of functionality. The tool identifies various types of data that you can reduce by running a cleanup process. For each type of data, an explanation is given about the impact of the cleanup. You then decide whether to run the cleanup process. Part of the cost of your subscription is based on database size. Therefore, by reducing the size, you reduce that component of the subscription cost and also help reduce the time that is required for the upgrade go-live process. A smaller database helps guarantee a faster upgrade.
- **SQL configuration** – This process reviews the SQL configuration and recommends optimizations. By making sure that SQL performs optimally, this process helps reduce the time that is required for the upgrade go-live process.
- **Deprecated features** – This process identifies features that you're currently using, but that aren't available in Finance and Operations. Therefore, the process helps you discover gaps in functionality early. It also provides suggestions for alternatives.

Additionally, as part of this step, you must install a pre-upgrade checklist in your AX 2012 environment. You can use this checklist to enter data that will be required for the upgrade procedure. For example, in one pre-upgrade checklist task, you provide the Microsoft Azure Active Directory (Azure AD) sign-in information for each current AX 2012 user, so that each user will be able to sign in to Finance and Operations.

- If upgrading from AX 2012 R3, install KB 4035163
- if upgrading from AX 2012 R2, install KB 4048614

The output of the upgrade analyzer tool becomes the workstream in the upgrade project plan for your AX 2012 system administrators. For more information, see Upgrade from AX 2012 - Plan by using the Upgrade analyzer tool.

Run the Code upgrade estimation tools

This step takes your code from AX 2012, converts it to the new format, and provides feedback about conflicts that a developer must resolve later. This step forms the basis for the estimate of the cost of your code upgrade.

To complete this step, you must export your code from AX 2012 as a model store export and upload it to the LCS Code upgrade tool. The Code upgrade tool will produce an upgraded version of your code and a report about the remaining conflicts that must be resolved. Your developer can then review both the upgraded code and the report to determine the effort that will be required in order to upgrade your code base.

The output of this step represents the workstream in the upgrade project plan for your Microsoft Dynamics AX developers.

For more information, see Upgrade from AX 2012 - Estimate effort by using the Code upgrade service.

Deploy a demo environment

Demo environments are default environments that contain demonstration data (not your own data) and standard code (no customizations). We recommend that you deploy a demo environment to evaluate new features, and to perform a basic fit gap analysis of standard processes that are used in AX 2012 but that might have changed in Finance and Operations. You can either deploy these demo environments in Azure or downloaded them as a virtual machine (VM) that you run on your own hardware. If you deploy them in Azure, you must provide your Azure subscription, because you're still using a public preview project and haven't yet purchased a subscription.

The output of this step represents the workstream in the upgrade project plan for your functional users or business users.

For more information, see Upgrade from AX 2012 - Deploy a demo environment for analysis

Create a project plan

A template for a project plan is provided in the upgrade methodology. In this step, the output from the previous steps of the Analyze phase is used to fill the project plan for the upgrade project. The project plan will also contain all testing details: data upgrade testing, cutover testing (mock cutover), the functional test pass iterations, and details about the various resource assignments for those tasks.

At this stage, the project plan provides a data point that can help you understand the time and cost of an upgrade.

Execute

During the Execute phase, you work through the tasks that you planned during the Analyze phase. To move to the Execute phase, you must purchase Finance and Operations apps, and you must have available resources that can work on the upgrade.

Switch to the LCS implementation project

The public preview project that you used for the Analyze phase has served its purpose. You can now discard it. For the remaining steps, you require only the project plan that you created in the final step of the Analyze phase.

When you purchase a subscription, you will receive details about how to sign up for a new LCS project. This project is known as an implementation project and will be the new permanent LCS project for your subscription, for as long as you have that subscription. This project differs from the public preview project in that it's managed by Microsoft. Therefore, this project has these characteristics:

- All environments in the project are hosted in Azure.
- The Azure subscription that is associated with the project is managed by Microsoft. Therefore, there is no separate billing for Azure costs. The costs are covered by your subscription.
- The production environment in the project is maintained by Microsoft. Therefore, code deployments,

upgrades, and infrastructure maintenance are run directly by Microsoft, not by your staff.

Identify the project as an AX 2012 upgrade

When you first sign in to your LCS implementation project, you're guided through the **Project Onboarding** wizard. You can always visit the **Project Onboarding** wizard later using the navigation menu next to **Project Settings** in your project.

While on the Project Onboarding wizard, in the **Project Scope** section, you can use the **Legacy System** field to identify the project as an AX 2012 upgrade. It's crucial that you identify the project in this way, so that the sandbox infrastructure that is deployed is compatible with the upgrade process that is outlined here. If this step isn't completed early in the project, you might accidentally deploy your Sandbox on a newer infrastructure that is incompatible with this process. In that case, the upgrade effort might be delayed.

Perform the AX 2012 preparation tasks

Complete the tasks that the upgrade analyzer tool discovered, and that are documented in your upgrade project plan. Your Microsoft Dynamics AX system administrator and database administrator (DBA) must complete these tasks.

Upgrade from AX 2012 - Pre-upgrade checklist for data upgrade

Perform code upgrade

Complete the tasks that were planned during the code upgrade estimation step of the Analyze phase. Your developers must run these tasks.

From this point onward, code changes in AX 2012 should be frozen. Only emergency code changes should be allowed in AX 2012. If a change is made, it must be ported manually to the new code base.

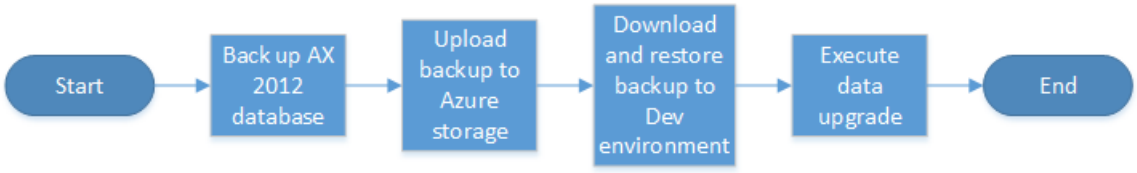
Develop new code

Complete the tasks from the fit gap analysis that was performed during the "Deploy a demo environment" step of the Analyze phase. These tasks will probably be a mixture of functional tasks that define the configuration and development tasks for customizations that are related to new features that are being taken up.

Data upgrade (development environment)

After your code upgrade tasks are completed, you can upgrade your database for the first time. This first upgrade occurs in a development environment, so that you can more easily remediate or debug any issues that are found at this stage. In a development environment, an issue can be debugged immediately, code can be adjusted, and the upgrade can be rerun within minutes. Larger sandbox environments don't offer this agility, and a minimum of several hours will be required in order to debug and remediate issues, update code, deploy the updated code, and rerun the upgrade.

The following illustration shows the process. Just back up the AX 2012 database, upload it to Azure, restore it to the Finance and Operations environment, and then run the data upgrade.



Data upgrade is done through a special type of deployable package. The same mechanism is used to deploy new code from one environment to another environment.

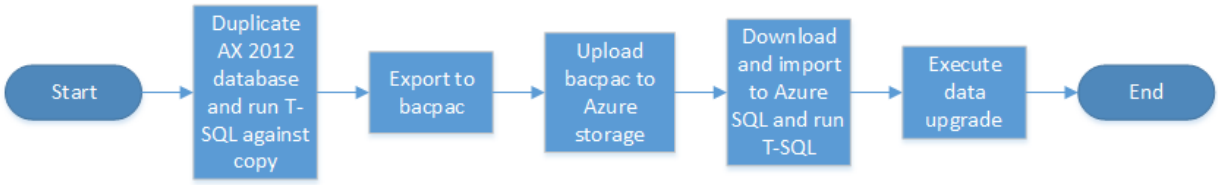
The underlying framework that is used to convert the data in the database during this process is largely the same as the upgrade framework in AX 2012 that is based on X++ batch jobs that run **ReleaseUpdatexxx** classes.

For details, see Upgrade from AX 2012 - Data upgrade in development environments.

Data upgrade (sandbox environments)

When data upgrade in a development environment is completed, the same process can be run in a sandbox environment. The sandbox environment is the environment where business users and functional team members can test business processes by using the upgraded AX 2012 data and code.

The following illustration shows the process for running data upgrade in a sandbox environment. The difference here is that the bacpac tool is used instead of a traditional SQL backup. This tool is required in order to convert between Microsoft SQL Server and Azure SQL Database. It's a standard SQL tool, and isn't specific to Finance and Operations.



For details, see Upgrade from AX 2012 - Data upgrade in sandbox environments.

Validate

When you enter the Validate phase, you will have available environments that include your upgraded custom code and your upgraded data. This phase describes the process of validating and testing that the upgraded environment works as desired. It also describes the process of preparing for go-live.

Perform cutover testing and create a cutover plan

The term *cutover* is used here to describe the final process of putting the new system live. This process consists of the tasks that occur after AX 2012 is turned off and before Finance and Operations is turned on.

The goal of the testing, or *mock cutover* is to practice the cutover process. In this way, you can help guarantee that everyone who is involved in the actual cutover to go-live will have a smooth experience.

There are two main workstreams:

- **Technical workstream** – This workstream is the process of running the data upgrade. Your business will enforce a limit on the amount of downtime that is allowed. During this downtime, neither product database will be available. The technical workstream might have to performance-tune its data upgrade procedure to meet the business's downtime limit.
- **Functional workstream** – After data upgrade, several configuration tasks will be required in the Finance and Operations environment. All these tasks must be documented and quantified, and a resource must be assigned to them, because they must fit together with the technical tasks within the business's downtime limit.

For details, see

- Upgrade from AX 2012 - Post-upgrade tasks
- Upgrade from AX 2012 - Cutover testing (Mock cutover)

Functional test pass

Complete a full functional test pass of all business processes. This test pass will be an extensive retest of all business processes that involve Finance and Operations. These business processes include both old processes that were brought forward from AX 2012 and new processes that involve new features that were taken up for the first time in Finance and Operations.

Depending on code quality, issue remediation and retesting might require several iterations of the functional test pass. When an issue is fixed, be sure to retest all processes that are involved, to help guarantee that the downstream or upstream process isn't affected by the change.

For details, see Upgrade from AX 2012 - Functional test passes.

Pre-go-live checklist

The pre-go-live checklist is a recommended procedure that can help reduce the chance of errors during the final cutover to go-live. One week before go-live is due, stop configuration changes in AX 2012 (that is, under <module>\Setup). This restriction on configuration changes is merely procedural. The Microsoft Dynamics AX system administrators just agree to put changes of this type on hold at this point.

We recommend that you also freeze code changes in the Finance and Operations code base. No further changes should be allowed unless they have been evaluated and have been shown not to block go-live.

After the configuration restriction and code freeze are in place, data upgrade should be run for the last time before cutover. In this way, you can make sure that everything still works as expected.

For details, see Validate: Prepare for go live.

Go live

After you have successfully completed upgrade testing in a Standard or Premier Acceptance Test environment (Sandbox Tier 2 or higher), and you have also completed a successful test cutover, the moment has arrived to upgrade your production environment and go live.

Cutover is the term that we use for the final process of getting a new system live. This cutover process consists of the tasks that occur after Dynamics AX 2012 is turned off but before Finance and Operations is turned on.

For details, see Upgrade from AX 2012 - Cutover process (Go live)

Supported upgrade paths

Upgrade to the cloud version of Finance and Operations is supported from AX 2012 R2 and AX 2012 R3, in private preview.

Upgrade from Dynamics AX 2012 RTM isn't currently supported. Upgrade to the on-premises version isn't currently supported, but support will be added in the future.

Upgrade from AX 2012 - Plan by using the Upgrade analyzer tool

2/18/2021 • 2 minutes to read • Edit Online

IMPORTANT

Upgrade is currently only supported from either Dynamics AX 2012 R2 or Dynamics AX 2012 R3. For each release, please update to the latest available cumulative update before upgrading to latest Finance and Operations application release.

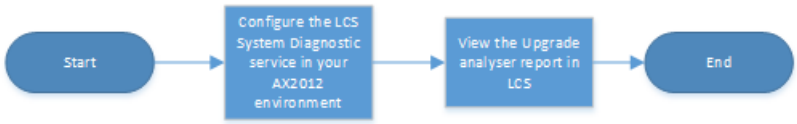
This topic explains how to use the Upgrade analyzer tool to plan your upgrade from Microsoft Dynamics AX 2012. This tool is run against an AX 2012 environment and identifies data that you should clean up in AX 2012 to help reduce the subscription cost for Finance and Operations. The tool also suggests SQL configuration optimizations that can help speed up the upgrade processes. Additionally, the tool warns you if any features that you use in AX 2012 are obsolete in the current version. Therefore, you can plan ways to replace or work around those features.

Upgrade analyzer gathers data from your AX 2012 environment as part of the regular System diagnostic service in Dynamics Lifecycle Services (LCS). For an overview of the System diagnostic service, and for information about how data is collected and pushed back into the cloud so that you can consume it through LCS, see System diagnostics in Lifecycle Services (LCS).

You can view the results of the System diagnostic service in a Microsoft Power BI report in LCS. The report presents a list of tasks that you should complete in the AX 2012 environment.

To access the Upgrade analyzer report, go to https://diag.lcs.dynamics.com/UpgradeAnalysisReport/Report/"ProjectID" (Replace "ProjectID" with your current project ID, which is an integer that can be found in the URL of your current LCS project).

The following illustration shows an overview of the procedure for using Upgrade analyzer.



If you already use the System diagnostic service in your AX 2012 environment, you must configure a new instance of the service on a machine that differs from the existing machine.

For information about how to configure the System diagnostic service in your AX 2012 environment, see Install and run System diagnostics.

Within a few minutes after you configure the System diagnostic service, the AX 2012 environment will appear in your LCS project.

NOTE

Can you tell us about your documentation language preferences? Take a short survey.

The survey will take about seven minutes. No personal data is collected (privacy statement).

Upgrade from AX 2012 - Estimate effort by using the Code upgrade service

2/18/2021 • 2 minutes to read • Edit Online

IMPORTANT

Upgrade is currently only supported from either Dynamics AX 2012 R2 or Dynamics AX 2012 R3. For each release, please update to the latest available cumulative update before upgrading to latest Finance and Operations application release.

This topic explains how to use the Code upgrade service in Microsoft Dynamics Lifecycle Services (LCS) to help estimate the tasks and effort that are required in order to upgrade a code base from Microsoft Dynamics AX 2012 Finance and Operations.

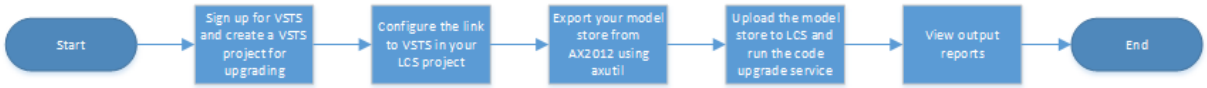
The Code upgrade service converts an export of your AX 2012 model store to the correct format. However, the new version of your code won't be fully functional until a developer resolves any issues that the service identifies but can't resolve itself.

The Code upgrade service performs these actions:

- Directly resolve some types of conflict issues.
- For other issues, log Microsoft Azure DevOps tasks.
- Create a version of your code in the correct format, and check the new version into a new branch of your Azure DevOps project.

In the Analyze phase, we use the report to help estimate the effort that is required in order to complete code conversion activities.

The following illustration shows an overview of the process for configuring the Code upgrade service.



For information about how to configure the Code upgrade service, see Configure the code upgrade service in Lifecycle Services (LCS).

The output of the Code upgrade service is designed to be consumed by a developer. This output will help the developer estimate the effort that is required in order to complete the code upgrade tasks. To form an estimate, the developer must review the tasks that the service generates in Azure DevOps and the new version of the code that the service generates.

NOTE

Can you tell us about your documentation language preferences? Take a short survey.

The survey will take about seven minutes. No personal data is collected (privacy statement).

Upgrade from AX 2012 - Deploy a demo environment for analysis

2/18/2021 • 2 minutes to read • Edit Online

IMPORTANT

Upgrade is currently only supported from either Dynamics AX 2012 R2 or Dynamics AX 2012 R3. For each release, please update to the latest available cumulative update before upgrading to latest Finance and Operations application release.

This topic explains why and how you should deploy a demo environment during the Analyze phase of your project for upgrading from Microsoft Dynamics AX 2012 to Finance and Operations.

By deploying a demo Finance and Operations environment, you gain hands-on experience with the program and can explore new features that you might be interested in. You also have an opportunity to validate differences in the program for your business processes, so that you can identify potential gaps or confirm that no gaps exist. At this stage in your upgrade project, your data and code won't be available in the environment. Therefore, you will have limited ability to validate that everything conforms to your business process. However, this step is the first step in that work stream.

If you haven't yet purchased licenses, and you're using a free trial, you can follow the steps in Deploy a demo environment to deploy a demo environment to a Microsoft Azure subscription that you bring yourself.

If you've already purchased licenses, you received a link to configure a special type of project in Microsoft Dynamics Lifecycle Services (LCS): an implementation project. The implementation project will let you deploy a dev/test environment and a sandbox environment. For more information about this type of environment deployment, see Upgrade from AX 2012 - Data upgrade in sandbox environments.

NOTE

Can you tell us about your documentation language preferences? Take a short survey.

The survey will take about seven minutes. No personal data is collected (privacy statement).

Upgrade from AX 2012 - Data upgrade in development environments

2/18/2021 • 5 minutes to read • Edit Online

IMPORTANT

Upgrade is currently only supported from either Dynamics AX 2012 R2 or Dynamics AX 2012 R3. For each release, please update to the latest available cumulative update before upgrading to latest Finance and Operations application release.

This is an exciting moment in the upgrade project. The output of this task provides the first upgraded dataset from Microsoft Dynamics AX 2012 to the latest Finance and Operations development environment.

Before you run this process in a shared sandbox environment, we recommend that you run it in a development environment. There are two reasons for this approach:

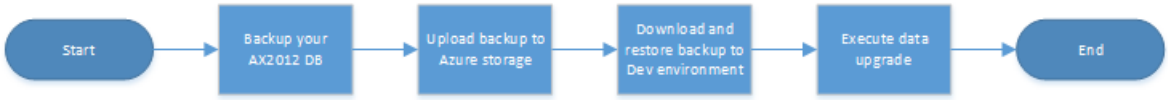
- It provides local data that developers can write and test their custom data upgrade scripts against.
- It helps reduce the overall time that is spent on iterations of the data upgrade process. In a development environment, an issue can be debugged immediately, code can be adjusted, and the upgrade can be rerun within minutes. However, larger sandbox environments don't allow for this level of agility. In those environments, a minimum of several hours will be required to debug and remediate issues, update code, deploy the updated code, and rerun the upgrade.

We strongly recommend that you run the Upgrade analyzer and respond to the issues it identifies before running data upgrade - this will help ensure that your data upgrade is quicker and easier.

NOTE

It's very important that you install the latest version of SQL Server Management Studio before you start this process: Download SQL Server Management Studio.

End-to-end data upgrade process



Back up your AX 2012 database

To back up your AX 2012 database, use the standard Microsoft SQL Server process to produce a BAK file. If you use the compression option when you create the backup, the file size will be smaller, and less time is required in order upload it to and download it from Microsoft Azure Storage.

Upload the backup to Azure Storage

If your developer environment is hosted as a VM locally or in Azure you will need to transfer the 2012 database backup to it. With a local VM you may be able to transfer the file directly across the network (if you have configured the virtual network to allow that) but for an Azure hosted VM we recommend that you upload your backup to Azure Storage (using your own secure file transfer service or SFTP is also a valid option). You would need to provide your own Azure storage account for this. There are free tools to help you to move files between Azure storage, from a command line you can use Azcopy, or for a GUI experience you can use Microsoft Azure storage explorer. Use one of these tools to first upload the backup from your on-premises environment to Azure

storage and then on your download it on your development environment.

Download and restore the backup to the development environment

> **NOTE**
>
> Developer environments that are hosted by Microsoft have limited drive space. We recommend that most AX 2012 customers host their own developer environment by using cloud-hosted environments. By using cloud-hosted environments, you can increase the drive space so that it meets your own specifications.

When you restore the backup to the new development environment, don't overwrite the existing AXDB database. Instead, restore the AX 2012 database next to the original databases. You might also consider using drive D for the data and log files, to help improve performance. However, there is a potential downside to using drive D. If the underlying virtual machine (VM) is deallocated in Azure and then reallocated, drive D will be wiped. In practice, this scenario rarely occurs. Therefore, you might find that the risk is acceptable. To learn more about how to use drive D, see Understanding the temporary drive on Windows Azure Virtual Machines.

To speed up the database restore process, you can change the SQL Server service account to **axlocaladmin**. The restore process can then use instant file initialization. For more information, see Database Instant File Initialization.

After the database is restored, stop the following services:

- World wide web publishing service
- Dynamics 365 for Finance and Operations Batch Management service
- Management Reporter 2012 Process service
- Microsoft Dynamics Lifecycle Services Diagnostic Service
- Data Import / Export service

Next, rename the original AXDB database **AXDB_orig**. This database might be useful as reference later, when you develop code.

```
ALTER DATABASE AXDB SET SINGLE_USER WITH ROLLBACK IMMEDIATE
GO
ALTER DATABASE AXDB MODIFY NAME = AXDB_Orig
GO
ALTER DATABASE AXDB_Orig SET MULTI_USER
GO
```

Finally, rename the newly restored AX 2012 database **AXDB**.

Run the data upgrade deployable package

To get the latest data upgrade deployable package for a target environment that is running the latest update, download the latest binary updates from Microsoft Dynamics Lifecycle Services (LCS) Shared asset library.

1. Sign in to LCS.
2. Select the **Shared asset library** tile.
3. In the **Shared asset** library, under **Select asset type**, select **Software deployable package**.
4. In the list of deployable package files, find the data upgrade package that corresponds to your upgrade. For example, if you're upgrading from AX 2012, the package name starts with AX2012DataUpgrade. Select the package that corresponds to the release you are upgrading to. For example: AX2012DataUpgrade-July2017.

For more information, see Upgrade data in development or demo environments.

Troubleshooting data upgrade script errors

There are options that you let you resume the data upgrade where it last stopped. You can also record any data upgrade script errors with call stacks to a table in the database. For development scenarios, you can skip failed scripts and continue to run the upgrade.

For more details, see the main data upgrade topic.

Recommendation for the first data upgrade run

When you run the data upgrade against your dataset for the first time, and especially when there many customizations or many custom data upgrade scripts, you might find the feature to skip failed scripts useful. By using this feature, you gain visibility into as many errors as possible in one run. Otherwise, only one critical issue is discovered per run. Be aware that, because dependencies exist between scripts, you might receive errors in related child scripts if you skip the parent script. These errors occur only because the parent wasn't run correctly. They will be resolved when the issue in the parent script is resolved.

Upgrade from AX 2012 - Pre-upgrade checklist for data upgrade

2/18/2021 • 4 minutes to read • Edit Online

IMPORTANT

Upgrade is currently only supported from either Dynamics AX 2012 R2 or Dynamics AX 2012 R3. For each release, please update to the latest available cumulative update before upgrading to latest Finance and Operations application release.

This topic describes each task in the Microsoft Dynamics AX 2012 checklist that is associated with data upgrade to Finance and Operations.

Installation

Use the pre-upgrade checklist to enter data that will be required for the upgrade procedure.

- If upgrading from AX 2012 R3, install KB 4035163
- if upgrading from AX 2012 R2, install KB 4048614

Prepare model metadata

During data upgrade, one goal is to maintain element IDs between the existing AX 2012 environment and the upgraded Finance and Operations environment. To accomplish this goal, you must bring a copy of the element IDs from the AX 2012 environment into the Finance and Operations environment. AX 2012 stores element IDs in a table that is named ModelElement. This table is in the model database, which is a separate database from the AX 2012 business data database. During an upgrade to Finance and Operations, you must copy the AX 2012 database to Microsoft Azure. This process can be time consuming.

To avoid copying the whole model database to Azure SQL Database, use the following procedure to replicate the ModelElement table in the business data database. Later, during data upgrade runs, the database synchronization process will retrieve the required information from this replicated table and make sure that element IDs are maintained in the upgraded Finance and Operations environment.

1. In the Finance and Operations data upgrade checklist, click **Prepare model metadata**.
2. When you're prompted, click **Yes**.
3. Wait for the copy process to be completed.

If the process is successful, the task is marked as completed.

Prepare security role metadata

Another goal during data upgrade is to preserve security role assignments. This task resembles the previous "Prepare model metadata" task. Security role information that is stored in the AX 2012 model database must be copied to the AX 2012 business data database, so that the information is preserved in the Finance and Operations environment after upgrade. During data upgrade runs, the same security role will be restored in the upgraded Finance and Operations environment.

1. In the Finance and Operations data upgrade checklist, click **Prepare security role metadata**.
2. When you're prompted, click **Yes**.

3. Wait for the copy process to be completed.

If the process is successful, the task is marked as completed.

Set up user mapping

In AX 2012, users are authenticated against an on-premises Active Directory server. However, in Finance and Operations, users are authenticated against Azure Active Directory (Azure AD). This task provides a form where you can map existing AX 2012 users to equivalent Azure AD users. The AX 2012 users will then be able to access Finance and Operations.

1. In the Finance and Operations data upgrade checklist, click **Set up user mapping**.
2. The **User info email mapping** form appears. Follow one of these steps to fill in the grid:
   - Import users from AX 2012, and then manually fill in the Azure AD email address:
     a. Click **Import from AX**. The grid is filled with existing users.
     b. For each user, enter the corresponding Azure AD email address, as shown in the following illustration.

   - Import users from a file. This option is faster. We recommend that you use this option when many users must be updated.
     a. In a comma-separated values (CSV) file, create the mapping between AX 2012 users and Azure AD email addresses. Your IT department can export a similar mapping from your on-premises Active Directory Domain Services (AD DS). The file should have two columns: **UserId** and **EmailAddress**.

> **NOTE**
> The first row in the file is treated as a header row and will be ignored during the import.

     b. After the file is ready, click **Import from file**, browse to the file, and import it.

        The grid should be filled with the mappings that you specified in the file.

If the imported file contains an entry that isn't valid, an error file is generated.

Validate baseline version

Run this task to validate that the current version can be upgraded.

- In the Finance and Operations data upgrade checklist, click **Validate baseline version**.

If the baseline version is one of the supported baseline versions, the task is marked as completed.

Archive retail salt data

This task is used to migrate the registry key that RetailSaltUtility uses. This tool is used for some deployments where the customer wants to inject a specific random value into the hash that is used to authenticate channel

users.

- In the Finance and Operations data upgrade checklist, click **Archive retail salt data**.

If the process is successful, the task is marked as completed.

> **NOTE**
>
> Can you tell us about your documentation language preferences? Take a short survey.
>
> The survey will take about seven minutes. No personal data is collected (privacy statement).

Upgrade from AX 2012 - Dacpac process to upgrade data in Sandbox Tiers 2-5 environments

2/18/2021 • 10 minutes to read • Edit Online

IMPORTANT

Upgrade is currently only supported from either Dynamics AX 2012 R2 or Dynamics AX 2012 R3. For each release, please update to the latest available cumulative update before upgrading to latest Finance and Operations application release.

This topic is a process guide that will help customers who no longer have Remote Desktop Protocol (RDP) access to their Tier-2 through Tier-5 sandbox environments when they upgrade from Microsoft Dynamics AX 2012 to Finance and Operations apps. By using a new file format this is based on data-tier application packages (DACPACs), and the Database movement toolkit, customers can bring their AX 2012 schema and data into an existing empty database in a sandbox environment.

We **strongly recommend** that you run the data upgrade process in a development environment before you run it in a shared sandbox environment. This approach will help reduce the overall time that is required for a successful data upgrade. For more information, see Upgrade from AX 2012 - Pre-upgrade checklist for data upgrade.

In this process guide, you will learn how to complete the following steps:

- Open firewall access to your sandbox environment database.
- Clear the sandbox database of all objects.
- Publish the schema from your AX 2012 database to the sandbox database.
- Transfer the data from the source database to the target database.
- Apply the data upgrade package from Microsoft Dynamics Lifecycle Services (LCS).
- Copy the database to production for mock go-live validation and actual go-live.

Before you get started

Network latency is a critical component in data transfer. If your source SQL Server is geographically far away or has poor network latency to your sandbox Azure datacenter, then the process can take additional hours or potentially time out. Latency under 75 milliseconds is preferred. You can find your latency using a tool such as Azure Speed Test. If your latency is poor, you should consider backing up your AX 2012 database and restoring it on a cloud-hosted DevTest environment deployed to the same Azure datacenter as your target sandbox. After which you can perform the upgrade steps.

Open firewall access to your sandbox environment database

By default, all sandbox Standard Acceptance Test environments use Azure SQL Database as their database platform. The databases for these environments are protected by firewalls that restrict access to the Application Object Server (AOS) that they were originally deployed with.

However, your public IP address can be used to grant access to your source system. Different methods can be used to grant this access, depending on your environment type and RDP access. Regardless of the method, connection to the database requires that the server and the database be explicitly specified. You can find this information on the environment details page in LCS.

Find the user name record for **axdbadmin**, and make a note of the server and the database in the format **{sqlServer\sqlDatabase}**, such as **spartan-nam-opsprod365433\DBOpsProd365_SandboxUAT_d2145fe**. In this case, the server value for Microsoft SQL Server Management Studio (SSMS) is **spartan-nam-opsprod365433.database.windows.net**, and the database value is **DBOpsProd365_SandboxUAT_d2145fe**. To specify the database, you must select **Options** in the SSMS connection dialog box. Use the **axdbadmin** credentials (user name and password).

Microsoft-managed environments where RDP access is available

If you have RDP access to your sandbox, sign in to the sandbox AOS virtual machine (VM), and open SSMS. In SSMS, enter the server, user name, and password. On the **Options** tab, explicitly enter the database name from the **axdbadmin** record in LCS.

After you're connected, open a query against the database, and enter your IP address in the following Transact-SQL (T-SQL) command.

```
-- Create database-level firewall setting for IP a.b.c.d
EXECUTE sp_set_database_firewall_rule N'AX 2012 Upgrade via RDP', 'a.b.c.d', 'a.b.c.d';
```

Back in your source environment, open SSMS, and try to connect by using the same **axdbadmin** credentials against the User Acceptance Testing (UAT) database. You must verify that you can connect before you move on to the next steps.

Note that firewall rules are deleted whenever you do a database refresh or whenever you do a database import from LCS.

Microsoft-managed environments without RDP access

Follow the process for Enable just-in-time database access to allow-list your IP address to the database.

Before the allow-list entry expires, connect to the sandbox database by entering the server, user name, and password. On the **Options** tab, explicitly enter the database name from the **axdbadmin** record in LCS.

After you're connected, open a query against the database, and enter your IP address in the following Transact-SQL (T-SQL) command.

```
-- Create database-level firewall setting for IP a.b.c.d
EXECUTE sp_set_database_firewall_rule N'AX 2012 Upgrade without RDP', 'a.b.c.d', 'a.b.c.d';
```

A second entry is created in the firewall rules. This entry won't expire. Note that these firewall rules are deleted whenever you do a database refresh or whenever you do a database import from LCS.

Self-service environments

Unfortunately, sandbox environments of the self-service type aren't supported for AX 2012 upgrade scenarios, because they don't currently support data upgrade packages. Microsoft is working to add this support and will update this topic when more information is available.

Clear the sandbox database of all objects

In versions of the Database movement toolkit prior to Version 5, this was an explicit step that customers had to take via SSMS on the target database. However, this is now incorporated into the toolkit in Version 5 and later, and is handled via the PowerShell scripts.

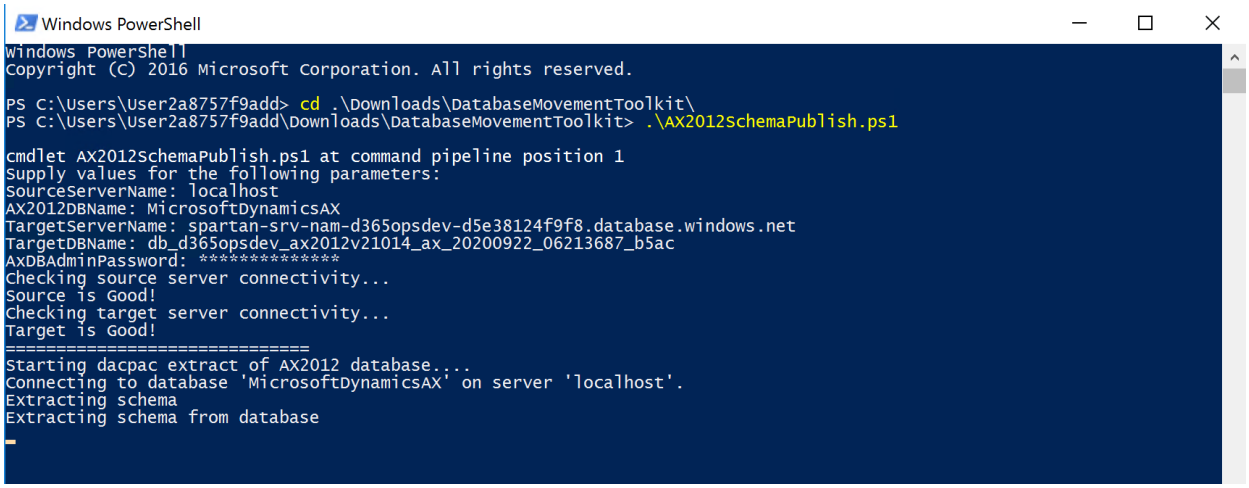
Publish the schema from AX 2012 to the sandbox database

Now that the database is empty, you can publish your non-upgraded 2012 schema. For this step, you should

download the latest version of the Database movement toolkit into your source environment.

Use Windows PowerShell to change the directory to the folder location where you unzipped the Database movement toolkit (for example, C:\dbmovement-toolkit\). Then run the **AX2012SchemaPublish.ps1** script. Use the following parameters:

- **SourceServerName** – The location where your source AX 2012 database is hosted. This location can be **localhost**.
- **AX2012DBName** – The name of your AX 2012 database (for example, **MicrosoftDynamicsAX**).
- **TargetServerName** – The server value of your sandbox database server (for example, **spartan-srv-12345.database.windows.net**). You retrieved this value in a previous step.
- **TargetDBName** – The name of your AXDB database (for example, **d365opsprod-12345**). You retrieved this value in a previous step.
- **AxDBAdminPassword** – The password for the **axdbadmin** database account.



During execution, the script performs a cleanup on the source and target databases. For the source database, it removes any non-essential users and non-essential schemas. If there are errors, it will stop the script and those errors will need to be reviewed. The source for the script is available in the toolkit called **Step1_CleanupSourceDB.sql**. For the target database, it removes all objects in a more thorough manner than was previously documented via SSMS. Any errors will need to be reviewed, and would stop the script. The source for the target cleanup is available in the toolkit called **Step0_CleanupTargetDB.sql**.

After cleanup, the toolkit uses SqlPackage.exe to extract only the database and schema definitions from your AX 2012 database as a 2012DBSource.dacpac file in the working directory. Next, it publishes this file to your sandbox environment by using the Profile.publish.xml publishing profile that is included in the Database movement toolkit. This publishing profile will skip several object types, such as SQL views, SQL users, statistics, and other objects that aren't required for the upgrade. If there are issues with the dacpac publish, you can find a detailed log in the working directory called **PublishDiag.log**.

When the script has finished running, open SSMS, and verify that you can see the tables in the sandbox database. Also confirm that the tables are empty and have no data.

> **NOTE**
>
> If you must start over because of an error, this script is designed to be run again as it will clean up both the source and target databases.

Populate legacy stored procedures

The data upgrade scripts require the legacy stored procedures and functions to be in place prior to running the upgrade. To transfer these scripts use SSMS.

Open SSMS, and connect to your source AX 2012 database. Right-click the database name, and then select **Tasks > Generate scripts**. On the **Introduction** page, select **Next**. On the **Choose Objects** page, select the **Select specific database objects** option, and then select the following check boxes:

- Stored procedures
- User-defined functions

On the **Set Scripting Options** page, select **Advanced**, and ensure the value is set to **Script DROP and CREATE**. Select **OK**, and then select **Save to new query window**. Select **Next** to move through the summary. The query window that appears contains a script that lists all the objects in the correct order so that the objects can be dropped from the database.

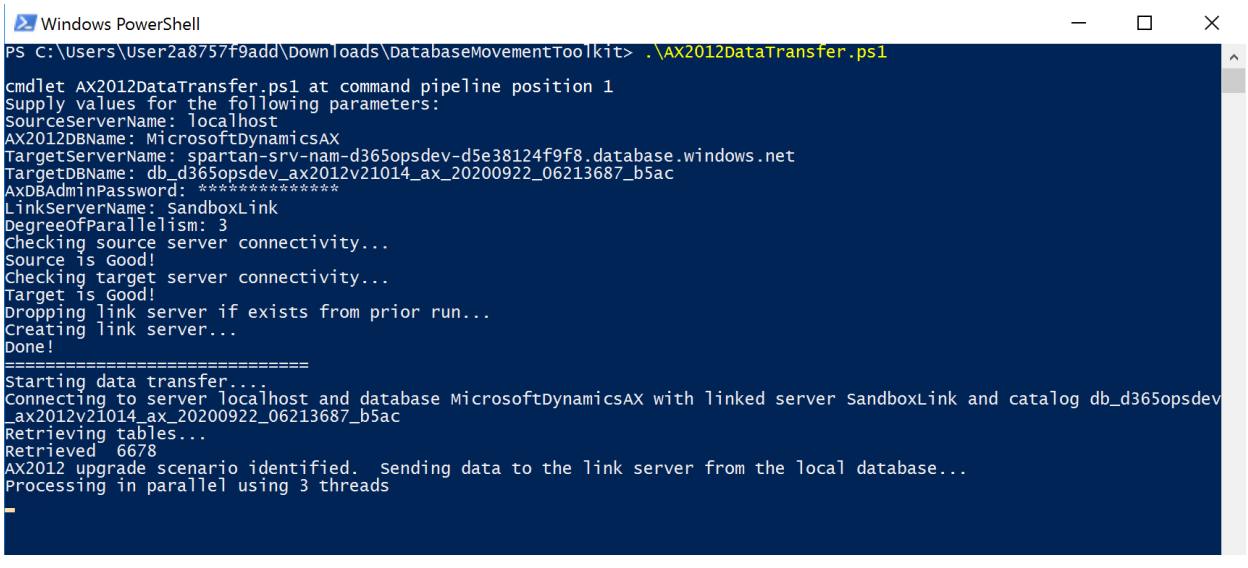
Using the script that was generated, connect to your target database using SSMS, and execute the script. This will create the AX 2012 stored procedures and functions in the target spartan database.

Transfer data from AX 2012 to the sandbox database

Now that the schema is in place, you must transfer the data to the target tables. A SQL-linked server will be used for this transfer. The transfer will also take advantage of parallelism features that are available in the instance of Windows PowerShell version 7.0 or later that is included in the Database Movement toolkit.

Use Windows PowerShell to change the directory to the folder location where you unzipped the Database movement toolkit (for example, C:\dbmovement-toolkit\). Then run the **AX2012DataTransfer.ps1** script. Use the following parameters:

- **SourceServerName** – The location where your source AX 2012 database is hosted. This location can be **localhost**.
- **AX2012DBName** – The name of your AX 2012 database (for example, **MicrosoftDynamicsAX**).
- **TargetServerName** – The server value of your sandbox database server (for example, **spartan-srv-12345.database.windows.net**). You retrieved this value in a previous step.
- **TargetDBName** – The name of your AXDB database (for example, d365opsprod-12345). You retrieved this value in a previous step.
- **AxDBAdminPassword** – The password for the axdbadmin database account.
- **LinkedServerName** – The name of the SQL-linked server to create (for example, **AX2012Link**).
- **DegreeOfParallelism** – The number of tables that should be processed in parallel (for example, **3**). The value should be no more than half of the number of cores that are available in the source environment, because the script is CPU-intensive and RAM-intensive.



During execution, if a linked server between the source server and the sandbox server doesn't already exist, the

script creates one. It then copies data from all the AX 2012 tables to the target database. It uses the **DegreeOfParallelism** parameter to process multiple tables at the same time.

> **NOTE**
> If you must start over because of an error, go back to the Publish the schema from AX 2012 to the sandbox database step.

Apply the data upgrade package from LCS

Now that the schema and the data have been moved to the sandbox environment, you can start the data upgrade process. As a prerequisite, make sure that your LCS project has been configured for AX 2012 upgrade. For more information, see Identify the project as an AX 2012 upgrade.

On the environment details page for your environment, select **Maintain** > **Apply updates**, and wait for the list of packages to be loaded. If you scroll to the bottom of the list, you will see that data upgrade packages are added to it as they are pulled in from the Shared asset library. It might take some time for all the available upgrade packages to be loaded.

Select the upgrade package that matches the version that you want to upgrade to. For example, to upgrade to version 10.0.14, select **AX2012DataUpgrade-10-0-14**.

Troubleshooting data upgrade errors

There are several ways to troubleshoot data upgrade errors. In some cases, you can view the error in the deployable package logs from LCS. For example, you can use this approach when the error is related to starting/stopping services and database synchronization.

If the upgrade fails while an upgrade script is running, you can view the errors in the ReleaseUpdateScriptsErrorLog table in the sandbox database. To access this table, connect to the sandbox database by using the information in previous steps.

If you can fix the data, you can resume the upgrade from LCS. However, note that you can't resume from LCS more than eight times. Any attempt to resume more than eight times will cause another failure, because the servicing systems don't allow more attempts. In this case, you can use the **Abort** button to cancel the upgrade package and try again later.

> **NOTE**
> If you must start over because of an error, go back to the Publish the schema from AX 2012 to the sandbox database step.

Copy the database to production for mock go-live and actual go-live

After the data upgrade is completed, apply the same customization packages from your sandbox environment to your production environment. You can then copy your sandbox environment AXDB database to the production environment.

For information about how to perform the copy operation, see Copy the sandbox database to production.

> **NOTE**
> Can you tell us about your documentation language preferences? Take a short survey.
>
> The survey will take about seven minutes. No personal data is collected (privacy statement).

Upgrade from AX 2012 - Data upgrade in sandbox environments

2/18/2021 • 14 minutes to read • Edit Online

IMPORTANT

Upgrade is currently only supported from either Dynamics AX 2012 R2 or Dynamics AX 2012 R3. For each release, please update to the latest available cumulative update before upgrading to latest Finance and Operations application release.

NOTE

This topic is being phased out in favor of a new process that is based on the dacpac file format. For information about the new process, see Upgrade from AX 2012 - Dacpac process to upgrade data in Sandbox Tiers 2-5 environments.

The output of this task is an upgraded database that you can use in a sandbox environment. In this topic, we use the term *sandbox* to refer to a Standard or Premier Acceptance Testing (Tier 2/3) or higher environment connected to a SQL Azure database. On this environment business users and functional team members can validate application functionality. This functionality includes customizations and the data that was brought forward from Microsoft Dynamics AX 2012.

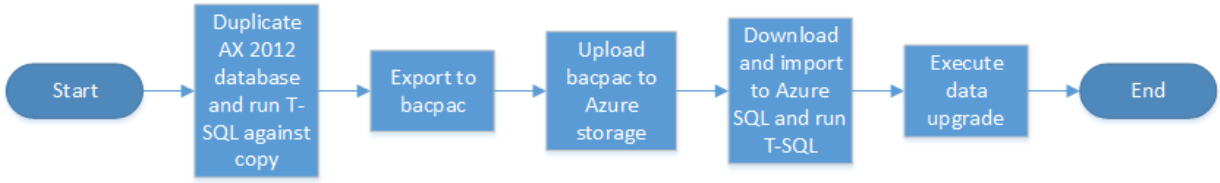
We strongly recommend that you run the data upgrade process in a development environment before you run it in a shared sandbox environment, because this approach will help reduce the overall time that is required for a successful data upgrade. For more information, see Upgrade from AX 2012 - Pre-upgrade checklist for data upgrade.

NOTE

It's very important that you install the latest version of SQLPackage before you start this process. To do this, go to Download and Install SQLPackage. We recommend that you use the .NET Core version. This can be saved and extracted to C:\temp.

Overview of the sandbox data upgrade process

Before you start to upgrade data in a sandbox environment, you will have already upgraded data in a development environment, as explained in Upgrade from AX 2012 - Pre-upgrade checklist for data upgrade. The two processes are very similar. The main difference is that a sandbox environment uses Microsoft Azure SQL Database for data storage, whereas a development environment uses Microsoft SQL Server. This technical difference in the database layer requires that you modify the data upgrade procedure slightly in a sandbox environment, because a backup from the AX 2012 database instance can't just be restored to SQL Database.



Here are the high-level steps in the upgrade process.

1. Turn off the AX 2012 AOS instances.
2. Create a copy of the AX 2012 database. We strongly recommend that you use a copy, because you must delete some objects in the copy that will be exported.
3. Export the copied database to a bacpac file by using a free SQL Server tool that is named SQLPackage.exe. This tool provides a special type of database backup that can be imported into SQL Database.
4. Optional, if you are running import from a cloud-hosted VM, you should upload the bacpac file to Azure storage.
5. Import the bacpac file by using SQLPackage.exe. This can be run from a local server or from a cloud-hosted VM. If you're using a local server, you will need to request JIT access to the Dynamics 365 database and set the required firewall rules. If you're using a cloud-hosted VM, download the bacpac file. You must then run a script against the imported database to reset the SQL database users.
6. Run the appropriate data upgrade package against the imported database.

Turn off the AX 2012 AOS instances

This task involves the AX 2012 system administrator and the server administrators.

Before you turn off AOS instances, you must stop all batch jobs that are running. A long-running batch job that has already started to run will prevent the system from stopping. Plan ahead, so that you can stop your AOS instances when needed. You might have to schedule batches so that they're completed some time before you turn off AX 2012.

You might have other systems that are integrated with the AX 2012 environment. You must also factor these systems into your plan to turn off AX 2012. For example, you might have to turn off the integrated systems some time before you turn off AX 2012 itself, so that any remaining in-flight transactions can be completed. The requirements for integrated systems vary widely from business to business. Therefore, your team of experts must plan for this scenario independently.

Create a copy of the AX 2012 database

You must create a copy of the AX 2012 database that you're upgrading, because you must delete some objects from the database. These objects include any Microsoft Windows authentication users. These changes make the modified database unusable for AX 2012. During this step, you will create a copy of the database and delete these objects.

This step must be done by the database administrator (DBA) or a person who has similar knowledge and experience.

To create a database copy, make a backup of the original database, and restore it under a new name. Make sure that enough space is available for both databases. You can create the copy on a different server. The version of the SQL Server instance that runs the database isn't important.

To perform this action, right-click the source database, and then select **Tasks** > **Backup**. Create a full-copy backup. To avoid overwriting your existing database backups, you might want to save the file under a different name in the backup directory.

Run the T-SQL script to prepare the database

This script prepares the database by removing users, removing procedures related to the AX 2012 RTM model store, cleaning up schemas, dropping views, and dropping references to tempDB.

After the copy is created, run the following Transact-SQL (T-SQL) script against it.

```
--remove NT users as these are not supported in Azure SQL Database
declare
@SQL varchar(255),
@UserName varchar(255)

set quoted_identifier off

declare     userCursor CURSOR for
select name from sys.sysusers where (isntuser = 1 or isntgroup =1) and name <> 'dbo'

OPEN userCursor
    FETCH userCursor into @UserName
    WHILE @@Fetch_Status = 0
       BEGIN
           set @SQL = 'DROP USER [' + @UserName + ']'
           exec(@SQL)
           FETCH userCursor into @UserName
       END
CLOSE userCursor
DEALLOCATE userCursor

go

--remove any AX 2012 RTM model store procedures that still exist
declare
@SQL varchar(255),
@procname varchar(255)

set quoted_identifier off

declare     procCursor CURSOR for
select name from sys.procedures where name like 'XI_%' or name like 'XU_%'

OPEN procCursor
    FETCH procCursor into @procname
    WHILE @@Fetch_Status = 0
       BEGIN
           set @SQL = 'DROP PROCEDURE [' + @procname + ']'
           exec(@SQL)
           FETCH procCursor into @procname
       END
CLOSE procCursor
DEALLOCATE procCursor

go

--If you receive a message that you cannot delete users because they own a schema, then check which schema
the user owns.
--Either change the ownership to another user (for example to dbo) or drop the schema if it does not contain
any objects.
--The examples below are for an AX 2012 demo environment. You will need to edit this for your specific
environment.

    if exists (select 1 from sys.schemas where name = 'contoso\admin')
begin
    drop schema [contoso\admin]
end
if exists (select 1 from sys.schemas where name = 'contoso\Domain Users')
begin
    drop schema [CONTOSO\Domain Users]
end
go

--drop all views in the current database because some refresh the tempDB, which is not a supported action in
Azure SQL Databases
declare
```

```
@SQL2 varchar(255),
@ViewName varchar(255)

set quoted_identifier off

declare     viewCursor CURSOR for

select viewname = v.name
from sys.views v
order by v.name

OPEN viewCursor

FETCH viewCursor into @ViewName
    WHILE @@Fetch_Status = 0
       BEGIN
           set @SQL2 = 'DROP VIEW ' + @ViewName
           exec(@SQL2)
           FETCH viewCursor into @ViewName
       END
CLOSE viewCursor
DEALLOCATE viewCursor
go

-- Drop the following procedure because it contains a tempDB reference that is not supported in Azure SQL
Database
If exists (select 1 from sys.procedures where name = 'MaintainShipCarrierRole')
begin
    drop procedure MaintainShipCarrierRole
end
```

Export the copied database to a bacpac file

> **NOTE**
>
> This topic is being phased out in favor of a new process that is based on the dacpac file format. For information about the new process, see Upgrade from AX 2012 - Dacpac process to upgrade data in Sandbox Tiers 2-5 environments.

Export the copied database to a bacpac file by using the SQLPackage.exe tool. This step should be done by the DBA or a team member who has equivalent knowledge.

> **IMPORTANT**
>
> It's very important that you install the latest version of SQL Server Management Studio before you start this step. Although SQLPackage is present in earlier versions of Management Studio, it won't work correctly for this step unless you first install the latest version.

This step is important, because the export will have to be done again during the downtime before go-live. Here are some tips:

- The bacpac process is very I/O and CPU intensive. Therefore, run the export on a high-powered machine.
- SQLPackage should be run locally on the machine that hosts the database. Don't run SQLPackage on a local laptop that you connect to the database machine, because this process is also network intensive.

Next, open a **Command Prompt** window as an administrator, and run the following commands.

```
cd C:\Program Files (x86)\Microsoft SQL Server\130\DAC\bin\

SqlPackage.exe /a:export /ssn:localhost /sdn:<database to export> /tf:D:\Exportedbacpac\my.bacpac
/p:CommandTimeout=1200 /p:VerifyFullTextDocumentTypesSupported=false
```

Here is an explanation of the parameters:

- **ssn** (source server name) – The name of the SQL Server to export from. For this process, the parameter should always be set to **localhost**.
- **sdn** (source database name) – The name of the database to export.
- **tf** (target file) – The path and name of the file to export to. The folder should already exist, but the file will be created by the process.
- **/p:CommandTimeout** – The per-query timeout value. This parameter enables larger tables to be exported without a timeout.

Upload the bacpac file to Azure storage or the LCS Asset Library

The bacpac file you have created will need to be copied to the AOS machine in your Azure hosted sandbox environment. There are several reasons for this:

1. The Azure SQL Database instance used by your Tier 2 (or higher) sandbox environment has firewall rules preventing access from outside of the environment itself.
2. Performance of bacpac import is multiple times faster when importing from a machine within the same Azure datacenter as the Azure SQL database instance.

You can choose how you would like to move the bacpac file to the AOS machine - you may have your own SFTP or other secure file transfer service. We recommend to use our Azure storage, which would require that you acquire your own Azure storage account on your own Azure subscription (this is not provided within the Dynamics subscription itself). There are free tools to help you to move files between Azure storage, from a command line you can use Azcopy, or for a GUI experience you can use Microsoft Azure storage explorer. Use one of these tools to first upload the backup from your on-premises environment to Azure storage and then on your download it on your development environment.

Another option is to use the Asset library in Microsoft Dynamics Lifecycle Services (LCS). However, the upload and download will take longer than Azure storage. To use this option:

1. Sign in to your project in LCS and go to your Asset library.
2. Select the Database backup tab.
3. Upload the bacpac file. Since the removal of RDP access to Sandbox AOS servers, we recommend that you use a cloud-hosted environment running in the same region as the sandbox environment to import the file. You can download the bacpac onto the cloud-hosted VM by signing in to LCS on that machine and downloading it from the LCS Asset library.

Import the bacpac file into SQL Database

> **NOTE**
>
> This topic is being phased out in favor of a new process that is based on the dacpac file format. For information about the new process, see Upgrade from AX 2012 - Dacpac process to upgrade data in Sandbox Tiers 2-5 environments.

During this step, you will import the exported bacpac file into the SQL Server database instance that your sandbox environment uses. As stated above, since the removal of RDP access to Sandbox AOS servers, we recommend that you use a cloud-hosted environment running in the same region as the sandbox environment

to import the file. You can request JIT access to the database and run from a local server. To do that, follow the process for Enable just-in-time database access to allow-list your IP address to the database.

You must first install the latest version of Management Studio on your cloud-hosted VM or local server. You will then import the file by using the SQLPackage.exe tool.

If you are using a cloud-hosted environment, for performance reasons, we recommend that you put the bacpac file on drive D on the AOS machine. On Azure virtual machines (VMs), drive D is a physical disk that typically has higher performance than other available disks.

Open a **Command Prompt** window as an administrator, and run the following commands.

```
cd C:\Program Files (x86)\Microsoft SQL Server\130\DAC\bin\

SqlPackage.exe /a:import /sf:D:\Exportedbacpac\my.bacpac /tsn:<azure sql database server
name>.database.windows.net /tdn:<New database name> /tu:sqladmin /tp:<password from LCS> /mp:64
/p:CommandTimeout=1200 /p:DatabaseEdition=<Edition> /p:DatabaseServiceObjective=<Service objective>
/p:DatabaseMaximumSize=<Maximum size>
```

Here is an explanation of the parameters:

- **sf** (source file) – The path and name of the file to import from.
- **tsn** (target server name) – The name of the SQL Azure server to import to. The name can be found in LCS. Suffix it with **.database.windows.net**.
- **tdn** (target database name) – The name of the database to import to. The database should not already exist. The import process will create it.
- **tu** (target user) – The SQL user name for the target SQL Database instance. We recommend that you use **sqladmin**. You can retrieve the password for this user from your LCS project.
- **tp** (target password) – The SQL password for the target SQL database instance.
- **mp** (max parallelism) - Specifies the degree of parallelism for concurrent operations running against a database. The default value is 8. A value of 64 provides the best performance in most scenarios.
- **/p:CommandTimeout** – The per-query timeout value. This parameter enables larger tables to be exported without a timeout.
- **/p:DatabaseEdition** – Specifies the edition of the database such as Basic, Standard, Premium, GeneralPurpose, BusinessCritical, or Hyperscale. To meet performance requirements and comply with your service agreement, use the same service objective level as the current Finance and Operations database (AXDB) on this environment. You can check the value for the existing database by using Management Studio. Right-click the database, and then select **Properties**.
- **/p:DatabaseServiceObjective** – Specifies the performance level of the database such as S1, P2, P4, or GP_Gen5_8. To meet performance requirements and comply with your service agreement, use the same service objective level as the current Finance and Operations database (AXDB) on this environment. You can check the value for the existing database by using Management Studio. Right-click the database, and then select **Properties**.
- **/p:DatabaseMaximumSize** – Defines the maximum size in GB of an Azure SQL database. You may need to use this parameter to allow a large database to be imported.

After you run the commands, you may receive the following warning. You can safely ignore it.

If you receive an error message about a non-valid value, double-check your parameters. If they are okay, you may need to use a newer version of SqlPackage. You can use the Windows .NET Core version without the need to install. It is a .zip file that can be extracted to C:\Temp\Sqlpackage-dotnetcore, for example. Now when you import the database, instead of using the Sqlpackage.exe under C:\Program Files (x86) you can use the

Sqlpackage.exe in C:\Temp\Sqlpackage-dotnetcore.

Run a T-SQL script to update the database

Run the following script against the imported database. The script performs the following actions:

- Recreates database users
- Sets the correct performance parameters
- Enables the SQL Query Store feature

```
CREATE USER axdeployuser FROM LOGIN axdeployuser
EXEC sp_addrolemember 'db_owner', 'axdeployuser'

CREATE USER axdbadmin WITH PASSWORD = 'password from lcs'
EXEC sp_addrolemember 'db_owner', 'axdbadmin'

CREATE USER axruntimeuser WITH PASSWORD = 'password from lcs'
EXEC sp_addrolemember 'db_datareader', 'axruntimeuser'
EXEC sp_addrolemember 'db_datawriter', 'axruntimeuser'

CREATE USER axmrruntimeuser WITH PASSWORD = 'password from lcs'
EXEC sp_addrolemember 'ReportingIntegrationUser', 'axmrruntimeuser'
EXEC sp_addrolemember 'db_datareader', 'axmrruntimeuser'
EXEC sp_addrolemember 'db_datawriter', 'axmrruntimeuser'

CREATE USER axretailruntimeuser WITH PASSWORD = 'password from lcs'
EXEC sp_addrolemember 'UsersRole', 'axretailruntimeuser'
EXEC sp_addrolemember 'ReportUsersRole', 'axretailruntimeuser'

CREATE USER axretaildatasyncuser WITH PASSWORD = 'password from lcs'
EXEC sp_addrolemember 'DataSyncUsersRole', 'axretaildatasyncuser'

ALTER DATABASE SCOPED CONFIGURATION  SET MAXDOP=2
ALTER DATABASE SCOPED CONFIGURATION  SET LEGACY_CARDINALITY_ESTIMATION=ON
ALTER DATABASE SCOPED CONFIGURATION  SET PARAMETER_SNIFFING= ON
ALTER DATABASE SCOPED CONFIGURATION  SET QUERY_OPTIMIZER_HOTFIXES=OFF
ALTER DATABASE imported-database-name SET COMPATIBILITY_LEVEL = 130;
ALTER DATABASE imported-database-name SET QUERY_STORE = ON;
```

Run the data upgrade deployable package

For Tier-2 sandbox environments, you can now run the data upgrade package directly from LCS, just as you can do for Tier-1 DevTest environments. To apply the package, go to your environment in LCS, and select **Maintain** > **Apply updates**. Scroll to the bottom of the list, and wait for the data upgrade packages to be loaded from the Shared asset library. It might take some time for the packages to be loaded. If no data upgrade packages appear in the list, go to your project settings in LCS, and make sure that your legacy system is set to **AX2012 Upgrade**. You can then apply the packages.

The name of the package that you select should match your version. For example, to upgrade to version 10.0.14, select **AX2012DataUpgrade-10-0-14**.

For more information, see Upgrade data in development or demo environments.

Upgrade a copy of the database in a development environment

It is highly recommended to have upgraded the same database in a development environment. If you have a copy of the database available for development environments, it will be much easier to investigate bugs that are found in the upgraded sandbox environment.

NOTE

Can you tell us about your documentation language preferences? Take a short survey.

The survey will take about seven minutes. No personal data is collected (privacy statement).

Data upgrade process for AX 2012 to Dynamics 365 Finance + Operations (on-premises)

2/18/2021 • 13 minutes to read • Edit Online

This topic describes the process for upgrading Microsoft Dynamics AX 2012 databases to Dynamics 365 Finance + Operations (on-premises) version 10.0.x. Currently, upgrade is supported only from either Dynamics AX 2012 R2 or Dynamics AX 2012 R3.

> **IMPORTANT**
>
> This topic explains the process for doing a data upgrade only. For information about how to do a code upgrade, see the upgrade guides that are available for cloud versions. The code upgrade tooling is available only through Microsoft Dynamics Lifecycle Services (LCS).

AX 2012 upgrade to Dynamics 365 Finance + Operations (on-premises)

Two upgrade methods are currently supported:

- **Upgrade from inside the VHD** – This method involves copying your database into the virtual hard disk (VHD) and running the upgrade from inside the VHD. Overall, this method is easier.
- **Upgrade where the VHD points to your database** – This method involves pointing the VHD upgrade process to your database. The upgrade process is still run from inside the VHD.

> **NOTE**
>
> The VHD doesn't require external network access to run the upgrade process.

Prerequisites

1. Sign up for a preview subscription.
2. For each AX 2012 release, update to the most recent cumulative update that is available before you upgrade to the most recent Finance + Operations application release.
3. Install the pre-upgrade checklist. For more information, see Installation.
4. Go through the data upgrade preparation steps. You can skip the "Set up user mapping" step. This step is relevant only for cloud-hosted upgrades.
5. Make a backup of your database (MicrosoftDynamicsAX). For more information, see Create a Full Database Backup.
6. In LCS, go to the Shared asset library by selecting the tile on the right side of the page. Then, under **Select asset type**, select **Downloadable VHD**, and download all parts of the VHD package that most closely matches the version that you will upgrade to in your on-premises environment. The image requires a large amount of disk space. Therefore, be sure to download and extract the package on a drive that has enough free space.
7. The files that you downloaded are a self-extracting zip file. Extract the VHD to a location that has a good amount of free space.

8. Use Hyper-V to start a virtual machine (VM) and attach the VHD. (Note that the VM must be Generation 1.)
9. Connect to the VM. For information about the credentials, see Running the Virtual Machine (VM) locally.
10. Depending on your planned on-premises target version of 10.0.x and the VHD image that you downloaded, you might have to download and apply the required application update and platform update from the Shared asset library. Under **Select asset type**, select **Software deployable package**. For more information, see Install deployable packages from the command line.

    > **IMPORTANT**
    > In any case, make sure that you've applied the most recent quality update to your VHD, to ensure that it contains the most recent fixes for doing data upgrades.

11. If you have any extensions or customizations, install them on the VHD now. Otherwise, the upgrade process will remove any data that is related to customizations. If you must prepare your environment before the upgrade, check with your independent software vendor (ISV) or value-added reseller (VAR).

Upgrade from inside the VHD

1. Restore the backup that you created to the OneBox VM. For more information, see Restore a Database Backup Using SSMS.
2. Optional: If the name of your restored database isn't **AXDB**, open Windows PowerShell as an administrator, and run the following script.

   ```
   .\Configure-On-Premises-Upgrade.ps1 -DatabaseName '<DB-name>'
   ```

   > **NOTE**
   > Replace **<DB-name>** with the name of your database (for example, **AXDB**). If you want to edit more values, see the appendix later in this topic.

   The script will run a database connection test to verify that the information that you provided is valid.
3. In LCS, go to the Shared asset library. Under **Select asset type**, select **Software deployable package**, and then select **AX2012DataUpgrade-10-0-8** to download the **MajorVersionDataUpgrade.zip** file.
4. Copy the file, paste it in the desired location (for example: **c:\D365FFOUpgrade**), and unzip it.
5. Open a Command Prompt window as an administrator, change the directory to the folder that you just unzipped, and run the following commands.
   a. `AxUpdateInstaller.exe generate -runbookid=upgrade -runbookfile=upgrade.xml -topologyfile=defaulttopologydata.xml -servicemodelfile=defaultservicemodeldata.xml`
   b. `AxUpdateInstaller.exe import -runbookfile=upgrade.xml`
   c. `AxUpdateInstaller.exe execute -runbookid=upgrade`
6. After the upgrade process is successfully completed, back up the newly upgraded database. If you have customizations from ISVs or VARs, check whether you must run some post–data upgrade scripts.
7. Restore the database into your on-premises environment's SQL Server, but give it a name that differs from the name of the AX 2012 database (for example, name it **AXDBupgraded**). The restored database must be configured. Follow the steps in Configure the Finance + Operations database.
8. Deploy a new Dynamics 365 Finance + Operations (on-premises) environment.

- If you have customizations, follow these steps:

    a. In LCS, go to the Shared asset library.

    b. Under **Select asset type**, select **Model**, and then download **Dynamics 365 Finance + Operations on-premises, Version 10.0.x Demo Data**. Select the version that is closest to the 10.0.x environment that you will deploy as the on-premises baseline.

    c. Use the restore backup option for SQL Server to create a new database from this file. (Typically, this database is named **AXDB**.) For more information, see Restore a Database Backup Using SSMS.

    d. The demo database must be configured. Follow the steps in Configure the Finance + Operations database.

    e. In LCS, set up a new environment, and deploy it with version 10.0.x. For more information, see Set up and deploy on-premises environments (Platform update 12 and later). When you deploy the environment, the name of the database that you specify should be the name of the database that you created earlier (typically **AXDB**).

    f. Apply your own customizations, and ISV and VAR modules, to the newly created 10.0.x environment. Otherwise, when the environment is initially synced with the database, it will delete any customization-related or extension-related data.

    g. Shut down on-premises Application Object Server (AOS), Business Intelligence (BI), and Management Reporter (MR) servers, or stop the services from the Azure Service Fabric portal by selecting **Deactivate (Restart)**.

    h. Rename or delete the demo database (typically **AXDB**) that you used for deployment, and then rename your new database (typically **AXDBupgraded**) to the name that the demo database had (typically **AXDB**).

    i. The renamed database must be configured. Follow the steps in Configure the Finance + Operations database.

    j. Start on-premises AOS, BI, and MR servers, or start the services from the Service Fabric portal by selecting **Activate**.

    > **NOTE**
    > The Database synchronization process will be triggered when the AOS nodes start up, and your environment will be unavailable until the process is completed.

- If you don't have customizations, follow these steps:

    a. Optional: Rename your old database (typically **AXDBold**), and then rename your new database (typically **AXDB**). In the next step, make sure that you enter the name of the upgraded database.

    b. In LCS, set up a new environment, and deploy it with version 10.0.x (Redeploy). For more information, see Set up and deploy on-premises environments (Platform update 12 and later).

Upgrade where the VHD points to your database

1. Back up the database from your on-premises environment (typically **AXDB**). For more information, see Create a Full Database Backup (SQL Server).

2. Restore the backup that you just created into the database server, and give it a different name (for example, **AXDBtoupgrade**). For more information, see Restore a Database Backup Using SSMS.

3. Open Windows PowerShell as an administrator, and run the following script.

```
.\Configure-On-Premises-Upgrade.ps1 -DatabaseName '<DB-name>' -DatabaseServer '<SqlServerName>' -
DatabaseUser '<User>' -DatabasePassword '<Password>'
```

NOTE

- Replace **<DB-name>**, **<SqlServerName>**, **<User>**, and **<Password>** with the values that you require.
- Only SQL Server authentication is officially supported for this upgrade. For more information, see Create a Database User.
- You must add the certificate authority certificate that signed your SQL Server certificate to the trusted certificate authorities store in your Onebox VHD. For more information, see Installing the trusted root certificate.
- Make sure that the database user that you use has the **sysadmin** server role, or at least **All Privileges**, assigned on the database that you want to upgrade. Also make sure that the user has permissions to access tempDB. Step 6 of the upgrade process will fail if these conditions aren't met.
- When you install the certificate authority certificate in the OneBox VHD, make sure that you use the fully qualified domain name (FQDN) or IP address to connect to the database that appears there. If you can't access the database by using the domain name, because it doesn't point to that server, edit your hosts file, and add the FQDN and the IP address that the FQDN should be resolved to.

4. In LCS, go to the Shared asset library. Under **Select asset type**, select **Software deployable package**, and then select **AX2012DataUpgrade-10-0-8** to download the **MajorVersionDataUpgrade.zip** file.
5. Copy the file, paste it in the desired location (for example: **c:\D365FFOUpgrade**), and unzip it.
6. Open a Command Prompt window as an administrator, change the directory to the folder that you just unzipped, and run the following commands.
   a. `AxUpdateInstaller.exe generate -runbookid=upgrade -runbookfile=upgrade.xml -topologyfile=defaulttopologydata.xml -servicemodelfile=defaultservicemodeldata.xml`
   b. `AxUpdateInstaller.exe import -runbookfile=upgrade.xml`
   c. `AxUpdateInstaller.exe execute -runbookid=upgrade`
7. If you have customizations from ISVs or VARs, check whether you must run some post–data upgrade scripts.
8. Run the **Configure-OnpremUpgrade.ps1** script by using the values that are stated in the Resetting the VHD database (Optional) section later in this topic.
9. Configure your upgraded database for Finance + Operations by following the steps in Configure the Finance + Operations database.
10. Deploy a new Dynamics 365 Finance + Operations (on-premises) environment.
    - If you have customizations, follow these steps:
      a. In LCS, go to the Shared asset library.
      b. Under **Select asset type**, select **Model**, and then download **Dynamics 365 Finance + Operations on-premises, Version 10.0.x Demo Data**. Select the version that is closest to the 10.0.x environment that you will deploy as the on-premises baseline.
      c. Use the restore backup option for SQL Server to create a new database (typically **AXDB**) from this file. For more information, see Restore a Database Backup Using SSMS.
      d. The demo database must be configured. Follow the steps in Configure the Finance + Operations database.
      e. In LCS, set up a new environment, and deploy it with version 10.0.x (Redeploy). For more

information, see Set up and deploy on-premises environments (Platform update 12 and later). When you deploy the environment, the database that you should specify should be the database that you configured earlier (typically **AXDB**).

f. Apply your own customizations, and ISV and VAR modules, to the newly created 10.0.x environment. Otherwise, when the environment is initially synced with the database, it will delete any customization-related or extension-related data.

g. Shut down on-premises AOS, BI, and MR servers, or stop the services from the Service Fabric portal.

h. Rename or delete the demo database (typically **AXDB**) that you used for deployment, and then rename your new database (typically **AXDBupgraded**) to the name that the demo database had (typically **AXDB**).

i. Start on-premises AOS, BI, and MR servers, or start the services from the Service Fabric portal.

> **NOTE**
> The Database synchronization process will be triggered when the AOS nodes start up, and your environment will be unavailable until the process is completed.

- If you don't have customizations, follow these steps:

  a. Optional: Rename your old database (typically **AXDBold**), and then rename your new database (typically **AXDB**). In the next step, make sure that you enter the name of the upgraded database.
  b. Set up a new environment, and deploy it with version 10.0.x. For more information, see Set up and deploy on-premises environments (Platform update 12 and later).

Configuring existing users

If you followed either of the previous procedures, you can sign in by using the Administrator user that you specified in LCS. However, none of your other users can sign in until they have been configured for the new system. Run a **Select** statement against your USERINFO table, and make a note of the value in the **NETWORKDOMAIN** field for the Administrator user (for example, `https://adfs.contoso.com/adfs` or `http://adfs.contoso.com/adfs/services/trust`). Then, for all interactive users who should be able to sign in, set the **NETWORKDOMAIN** field to the same value that the Administrator user has. The **NETWORKALIAS** field must also be modified. In Finance + Operations, this field is set to the user's email address (for example, `testuser@contoso.com`).

Resetting the VHD database (Optional)

If you used the **Configure-On-Premises-Upgrade.ps1** script, run the following command to reset your database to the default configuration.

```
.\Configure-OnPremUpgrade.ps1 -DatabaseName 'AxDB' -DatabaseServer 'localhost' -DatabaseUser 'axdbadmin' -
DatabasePassword 'AOSWebSite@123'
```

Appendix

Using the Configure-On-Premises-Upgrade.ps1 script

IMPORTANT

This script is intended to be run only from a OneBox VHD environment.

The script requires that you pass at least the **DatabaseName** parameter. If you don't pass this parameter, the script automatically requests it.

You can pass an additional parameter, such as **DatabaseServer** or **DatabaseUser**, if you want. However, in this case, the script will request all additional parameters. This behavior occurs because the script will assume that you want to point the database connection to a machine outside the VM. Therefore, those parameters are required to correctly establish the connection.

The following parameters can be passed to the script:

- **-DatabaseName** – The name of the database to upgrade.
- **-DatabaseServer** – The database server that contains the Finance + Operations database.
- **-DatabaseUser** – The user name for SQL Server Authentication.
- **-DatabasePassword** – The password for SQL Server Authentication.

After the configuration has been passed, the script uses the new parameters to run a database connection test. If the script can't connect to the database, we recommend that you debug the connection from SQL Server Management Studio or another tool.

Configure-On-Premises-Upgrade.ps1

```
<#
.Synopsis
    Configures a OneBox deployment to upgrade an OnPrem 7.x database to OnPrem 10.0.x

.DESCRIPTION
    This must be executed before the upgrade process is carried out.

.EXAMPLE
    .\Configure-OnPremUpgrade.ps1 -DatabaseName 'AxDB'

    .\Configure-OnPremUpgrade.ps1 -DatabaseName 'AxDB' -DatabaseServer '127.0.0.1' -DatabaseUser 'axdbadmin'
-DatabasePassword 'secretPass'
#>
[CmdletBinding()]
param
(
    # Database server containing Microsoft Dynamics 365 for Operations, on-premises database.
    [AllowNull()]
    [string] $DatabaseServer,

    # Database name that you want to upgrade.
    [Parameter(Mandatory = $true)]
    [string] $DatabaseName,

    # Username for SQL Authentication.
    [AllowNull()]
    [string] $DatabaseUser,

    # Password for SQL Authentication.
    [AllowNull()]
    [string] $DatabasePassword
)

    Write-Host "`nThe connection to the Database Server was successful!" -ForegroundColor Green

}
```

Troubleshooting

- Exception calling "Open" with "0" argument(s): "Cannot open database "AxDB1" requested by the login. The login failed. Login failed for user 'axdbadmin'." You supplied the Wrong database name or the user doesn't have access to that database.
- Exception calling "Open" with "0" argument(s): "A network-related or instance-specific error occurred while establishing a connection to SQL Server. The server was not found or was not accessible. Verify that the instance name is correct and that SQL Server is configured to allow remote connections. (provider: Named Pipes Provider, error: 40 - Could not open a connection to SQL Server)". The script could not establish a connection with the SQL Server specified. Check the ip/fqdn and port that you used.
- Exception calling "Open" with "0" argument(s): "Login failed for user 'axdbadmin'." The supplied login credentials are not correct.

Upgrade from AX 2012 - Cutover testing (Mock cutover)

2/18/2021 • 5 minutes to read • Edit Online

IMPORTANT

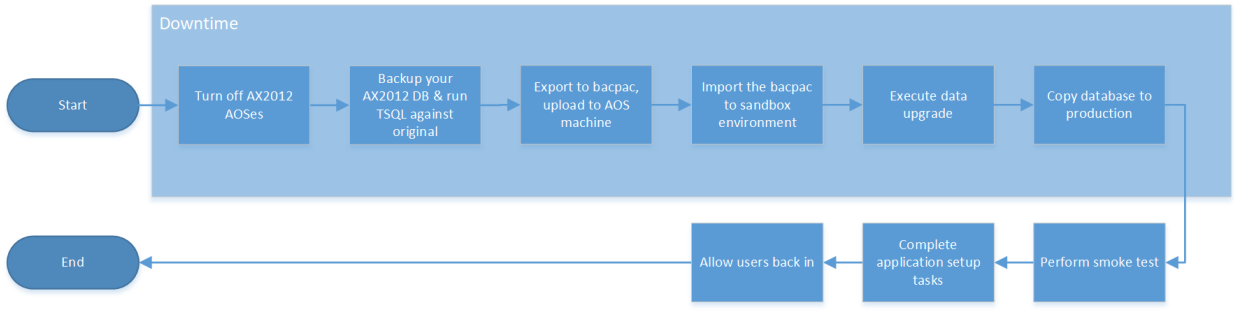
Upgrade is currently only supported from either Dynamics AX 2012 R2 or Dynamics AX 2012 R3. For each release, please update to the latest available cumulative update before upgrading to latest Finance and Operations application release.

Cutover is the term that we use for the final process of getting a new system live. The cutover process consists of the tasks that occur after Microsoft Dynamics AX 2012 is turned off, but before Finance and Operations is turned on. The purpose of upgrade cutover testing (mock cutover) is to practice the cutover process, to help guarantee a smooth experience for everyone who is involved during the actual cutover to go-live.

There are three main workstreams during a cutover:

- **Technical workstream** – This workstream includes the data upgrade execution process. Your business will enforce a limit on the amount of downtime that is allowed. During this downtime, neither AX 2012 nor Finance and Operations will be available. This workstream might have to tune the data upgrade procedure to meet the business's downtime limit.
- **Functional workstream** – This workstream includes the configuration tasks that are performed after the data upgrade is completed. All these tasks must be documented and quantified, and a resource must be assigned, because both the functional workstream and the technical workstream must fit within the business's downtime limit.
- **AX 2012 rollback** - This workstream includes rolling back to an AX 2012 environment. Although it's unlikely that you will have to roll back, it's very important that you have a tested process in case you require it.

The following illustration shows the overall process for cutover to go-live as it will occur in the production environment.



The mock cutover process is very similar to a basic data upgrade validation in a sandbox environment. We assume that you are familiar with that process, and have already performed it. Mock cutover differs in the following ways:

- After you perform a data upgrade in the sandbox environment, a LCS other type service requests is needed to copy your upgraded database from the data upgrade sandbox environment into your production environment. The email template below is provided for your use

> [!Copy] This is a request for 2012 data upgrade database copy from the sandbox environment to production. I acknowledge that this will overwrite the database currently in production.

- We added the following tasks:
  - Perform a smoke test.
  - Complete application setup tasks. This step can be large, depending on the functionality that is used. During this step, the functional team configures new application functionality so that it's ready to be used in the upgraded system.
  - Allow users back in. Notify your user base that the upgrade is completed and that they can use the system again.

> **NOTE**
> In this article, we use the term *sandbox* to refer to a Standard or Premier Acceptance Testing (Tier 2 or 3) or higher environment connected to a SQL Azure database.

Technical workstream

The technical workstream involves various technical team members: the database administrator (DBA), the AX 2012 system administrator, server administrators, and developers who are familiar with AX 2012 and Finance and Operations.

During cutover testing, the technical team is focused on performance and reliability testing of the data upgrade process, to make sure that it meets the business's downtime limit. Many elements of hardware and software are involved in this process. Some of these elements are on-premises, whereas others are in the Microsoft cloud. In addition, many elements of custom application code and standard code are involved. The result of this testing should be confidence in the cutover process for your environment.

Technical workstream process

> **NOTE**
> For the technical workstream, the cutover testing process is the same as the high-level steps of the actual/go-live cutover process.

For the technical workstream, the cutover testing process is the same described in Upgrade from AX 2012 - Data upgrade in sandbox environments.

Functional workstream

After data upgrade, several configuration tasks will be required in the new environment. The goal of this workstream is to document and quantify all configuration tasks, and to assign a resource to each task, to help guarantee that these tasks can be done together with the technical workstream during the downtime window.

Typically, functional tasks involve changing the values of specific system parameters or other configuration data. These tasks are identified through the full functional test pass, which is a separate activity from the cutover testing. When a task of this type is identified, it should be reviewed together with the functional resource and your developer.

Larger changes might require that a new custom data upgrade script be written to update the data during the data upgrade process. However, the functional resource can manually run smaller changes through the new system after data upgrade.

Larger changes that have new data upgrade scripts must be tested. Therefore, one or more additional iterations of the MajorVersionDataUpgrade.zip package will have to be run. It's important that you weigh the cost of running the package again against the cost of manual data entry.

For each manual change, a task must be added to the cutover plan document. This task must show the following details:

- What is the task, and what must be done?
- Who must do it?
- How long does it take?

Add users, and perform functionl tests

When you have fully configured your environment, add users, and perform appropriate testing.

Roll back to AX 2012

The goal of this task is to restore the database by using the backup that was made when AX 2012 was turned off, and then turn AX 2012 back on. The state of integrated systems might also have to be restored. However, because integrated systems vary from business to business, you must plan for this scenario independently, based on your specific circumstances. Although it's unlikely that you will have to roll back, it's very important that you have a tested process in case you require it.

Upgrade from AX 2012 - Post-upgrade tasks

2/18/2021 • 3 minutes to read • Edit Online

IMPORTANT

Upgrade is currently only supported from either Dynamics AX 2012 R2 or Dynamics AX 2012 R3. For each release, please update to the latest available cumulative update before upgrading to latest Finance and Operations application release.

This topic describes the tasks that you might have to perform in Finance and Operations apps, like Dynamics 365 Finance and Dynamics 365 Supply Chain Management, after you complete a code and data upgrade from Microsoft Dynamics AX 2012. A process data package (PDP) that is available in Microsoft Dynamics Lifecycle Services (LCS) includes links to the following menu items. This PDP will fill in the **Data validation checklist** workspace. The **Data validation checklist** workspace lets users track a project and monitor the tasks that are required in order to complete it.

Document management

If you use document management, existing documents or attachments that are stored in the database should be migrated to Microsoft Azure Blob storage. To complete this migration, use the **Migrate files** button on the **Migrate files** tab on the **Document management parameters** page. This operation is not critical as document management can still access file stored in the database, but the files can take considerable database storage and the retrieval is less efficient. The file migration process will migrate all possible database files to Microsoft Azure Blob storage, reporting on any failures and continuing. If any errors are reported, attempt running the file migration process again.

If the file migration process isn't able to complete without failure, this may be that the files stored in the database are corrupt, which Microsoft is unable to repair. If this is the case, you can request a non-business critical support case be opened to enable conversion of the attachments into note records, which will retain any previous notes as well as the names of the files that were stored in the database. Note that the files themselves cannot be recovered.

Print management

If you use Print management, the references to network printers from AX 2012 won't be valid. You must set up and reference network printers on the **Document routing** page. For more information, see Install the Document Routing Agent to enable network printing.

Commerce

After you complete the upgrade from AX 2012, you must configure registers and devices.

To configure a register, click **Retail and Commerce** > **Channels** > **Stores**. Select the row for the channel, and then expand the **Registers** FactBox. Click **More**, click **New**, and complete the setup of the register.

To configure a device, click **Retail and Commerce** > **Channel setup** > **POS Setup**, and then click **New**.

Additionally, you must run all jobs (9999) for the channel database. Click **Retail and Commerce** > **Headquarters setup** > **Commerce scheduler** > **Channel database**. Select the row for the appropriate channel database, and then click **Full data sync**. Select the **9999** (**All jobs**) distribution schedule, and then click **OK**. Click **OK** again to run the job.

Service industries

After you complete the upgrade from AX 2012, you must set up resource capacity roll-up and project ledger intercompany posting.

To run the Resource capacity roll-up batch job, click **Project management and accounting** > **Inquiries and reports** > **Capacity synchronization**. You must run this batch job to set up the resource and resource calendar reservation data. This data will be required if you use project resource scheduling. For more information, see Project resourcing.

To enable project ledger intercompany posting, click **Project management and accounting** > **Setup** > **Posting** > **Ledger posting setup**. On the **Cost accounts** tab, in the **Ledger account types** field, select **Intercompany cost**, and then enter the details of the lending legal entity. On the **Revenue accounts** tab, in the **Ledger account types** field, select **Intercompany revenue**, and then enter details of the borrowing legal entity.

Budget planning

After you complete the upgrade from AX 2012, you must set up Budget planning columns and layouts. To complete this setup, click **Budgeting** > **Setup** > **Budget planning** > **Budget planning configuration**.

Additionally, you must update Budget planning processes so that they use the appropriate layout for each budget stage. To update Budget planning processes, click **Budgeting** > **Setup** > **Budget planning** > **Budget planning process**.

For more information about Budget planning upgrade, see Upgrade budget planning.

Upgrade from AX 2012 - Functional test passes

2/18/2021 • 2 minutes to read • Edit Online

IMPORTANT

Upgrade is currently only supported from either Dynamics AX 2012 R2 or Dynamics AX 2012 R3. For each release, please update to the latest available cumulative update before upgrading to latest Finance and Operations application release.

After data upgrade is completed, we recommend that you complete a full functional test pass of all business processes. In a full functional test pass, you do an extensive retest of all business processes that are performed by using Finance and Operations. Tests should include both processes that have been brought forward from Microsoft Dynamics AX 2012 and new processes that use features from Finance and Operations.

Depending on your code quality, bug remediation and retesting might require several iterations of the functional test pass. After a bug is fixed, take care to retest all processes that are involved, to make sure that no downstream or upstream processes are affected by the change.

Old data vs. new data

As you create a list of tests to perform, consider the impact of old data versus new data. This type of testing will help you uncover data-related bugs. The code that created the old and new data might be very different, and this difference can be a common root cause of bugs.

For example, if the business process that you're testing is cancellation of a purchase order, can you cancel a purchase order that was started before it was upgraded to the new system? Can you also cancel a purchase order that was started after the upgrade to the new system?

We used a very simple example here, but the testing requirement can be more complex, because many business processes in the system are interconnected, and the effect of old data versus new data effect is cumulative.

For example, here are the stages of a production test flow:

1. The item master is designed and released to a legal entity.
2. Item requirements are created.
3. Production orders are generated.
4. Purchase orders are generated.
5. Production order processing occurs (shop floor).
6. Vendor payment (payment of purchase orders) occurs, and so on.

In this production test flow, each stage can be performed by using either new records or old records as input. The result is a matrix of tests that covers every combination of old and new data. For some processes, test matrices might seem excessive, and they might actually be excessive in practice. Therefore, you can decide to focus on certain combinations that you predict will be used the most. However, it's still helpful for you to know what you aren't covering. Make a conscious decision, where you know what you have, what you're going to focus most of the testing on, and what you're not going to focus on.

NOTE

Can you tell us about your documentation language preferences? Take a short survey.

The survey will take about seven minutes. No personal data is collected (privacy statement).

Upgrade from AX 2012 - Prepare for go-live

2/18/2021 • 2 minutes to read • Edit Online

> **IMPORTANT**
> Upgrade is currently only supported from either Dynamics AX 2012 R2 or Dynamics AX 2012 R3. For each release, please update to the latest available cumulative update before upgrading to latest Finance and Operations application release.

As the go-live date approaches, it's important that you implement this series of steps to help ensure that the source Microsoft Dynamics AX 2012 system and the upgrade process both remain stable and consistent for go-live.

As part of this process, you must lock down any further code changes or application setup changes before you run the final cutover test.

Code freeze

All code changes in the AX 2012 environment should be frozen. Implement an escalation process to handle any critical issues that appear in AX 2012. By default, any new code changes that are required should be implemented only in the new system, not in the AX 2012 environment. Implementation of proposed code changes in the AX 2012 environment should be discussed at the management level. If a code change is made in AX 2012, the same change must be made in the new system. In that case, another iteration of cutover testing and functional testing might be required.

Application configuration freeze

All application configuration changes should be frozen in the AX 2012 environment, because these changes could affect how the new system behaves or how the data upgrade scripts behave. Configuration changes are changes in the AX 2012 application that are related to the configuration of system functionality. By freezing these changes, you help guarantee the stability of the data upgrade process.

Because configuration changes are typically controlled by the AX 2012 system administrator or a small group of trusted super users, we don't recommend that you enforce the freeze by changing security access. Instead, implement the freeze through a business process that is communicated to those users. Changes to security access might require a code change (changes to the role definitions themselves) or a configuration change (reassignment of users), and these changes could affect the upgrade process.

Running the final cutover test

After no further code or setup changes will occur, run a final cutover test to make sure that all data and code upgrade tasks still run as expected.

> **NOTE**
> You must complete this step even if you freeze code and setup changes at the beginning of the upgrade project, because the data itself changes every day. This final cutover test also validates that the current data is upgraded successfully.

Make sure that functional testing is performed against this last upgraded copy.

At this point in the upgrade project, we recommend that you categorize any bugs that are found:

- **Blocking** – The upgrade project can't proceed until every bug of this type is fixed. The upgrade must be postponed, and can proceed only after the bug is remediated and the cutover test is run again. For a bug to be classified as blocking, it must meet these conditions:
  - It prevents a critical business process from being completed.
  - No workaround or mitigation is available for it.
- **Non-blocking** – The upgrade project can proceed. Bugs of this type can be fixed in the upgraded system.

Upgrade from AX 2012 - Go live (Cutover)

2/18/2021 • 3 minutes to read • Edit Online

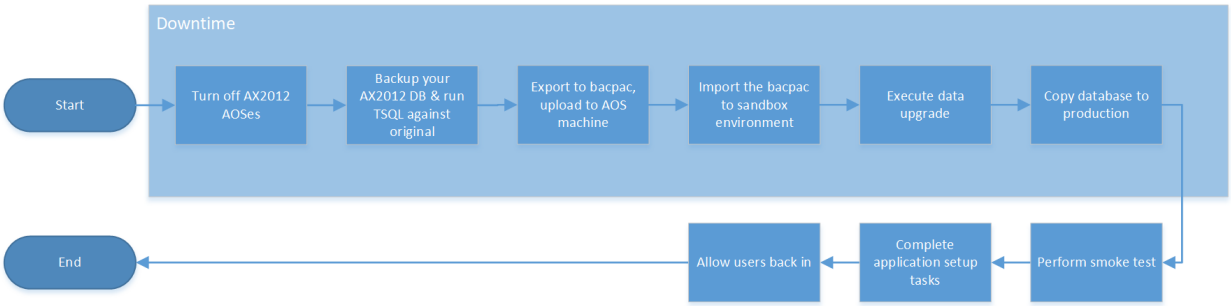
IMPORTANT

Upgrade is currently only supported from either Dynamics AX 2012 R2 or Dynamics AX 2012 R3. For each release, please update to the latest available cumulative update before upgrading to latest Finance and Operations application release.

After you have successfully completed upgrade testing in a Standard or Premier Acceptance Test environment (Sandbox Tier 2 or higher), and you have also completed a successful test cutover, the time has arrived to upgrade your production environment and go live.

Cutover is the term that we use for the final process of getting a new system live. This cutover process consists of the tasks that occur after Microsoft Dynamics AX 2012 is turned off but before Finance and Operations is turned on. Before you plan your final cutover, you need to successfully complete one successful mock cutover as described in Cutover testing

The following illustration shows the overall process for cutover to go-live as it will occur in the production environment.



NOTE

In this topic, we use the term *sandbox* to refer to a Standard or Premier Acceptance Testing (Tier 2 or 3) or higher environment connected to a SQL Azure database.

Overall process

The high-level steps of the production environment upgrade process are the same as the Mock cutover process, refer to Upgrade from AX 2012 - Cutover testing (Mock cutover) for detailed instructions.

1. Turn off the AX 2012 AOS instances
2. Create a copy of the AX 2012 database. We strongly recommend that you use a copy, because you must delete some objects in the copy that will be exported.
3. Export the copied database to a bacpac file by using a free SQL Server tool that is named SQLPackage.exe. This tool provides a special type of database backup that can be imported into SQL Database.
4. Upload the bacpac file to Azure storage.
5. Download the bacpac file to the Application Object Server (AOS) machine in the sandbox environment, and then import it by using SQLPackage.exe. You must then run a script against the imported database to reset the SQL database users.
6. Run the appropriate data upgrade package against the imported database.

Prerequisites

Before you can perform an upgrade in the production environment the following prerequisites must be met:

- Complete the code upgrade and data upgrade in a sandbox environment and successfully completed a functional test pass
- Deploy the production environment. Before the option to request the deployment of the production environment lights up you must have completed:
  - The Subscription estimator in LCS. We use this to help us size your production environment because it provides details of the throughput you'll require.
  - The Test phase of the methodology in LCS. This is to help ensure that you're at the stage in your project where you're ready to start testing in the production environment.
  - After a request is submitted to Microsoft to deploy the production environment, it will take roughly 24 hours to deploy, so ensure that you leave enough time for this to happen.
- Apply all necessary updates and customizations (AOT deployable packages) to the production environment. There should not be any code change after signing off on a Mock cutover.
- To schedule an upgrade, request a timeslot with the DSE team by submitting "Other" type service requests from LCS as described in the Upgrade from AX 2012 - Cutover testing (Mock cutover). This is to ensure that the preferred timeslots will be available for you. Be aware that there is significantly higher demand for slots during the weekend, so requesting these as far in advance as possible will help attain your preferred schedule.

Make the chart of accounts delimiter unique

2/18/2021 • 2 minutes to read • Edit Online

In Microsoft Dynamics AX 2012, you could use the same delimiter for your chart of accounts and dimension values. In current versions of Finance and Operations, you cannot have the same delimiter for the chart of accounts and dimension values. If there is a duplicate delimiter, you can change it after upgrade.

This feature is available in the following versions:

- Finance and Operations version 8.0
- Finance and Operations version 7.1, KB 4094701 Cannot enter the financial dimensions when the dimension values contain the chart of accounts delimiter
- Finance and Operations version 7.2, KB 4092967 Cannot choose sub-project as dimension when sub-project format contains the dimension delimiter

Update delimiter

If there is a conflict with the chart of accounts, the chart of accounts delimiter and the project/subproject ID format can be changed. No other dimension delimiters can be changed.

- You can change the chart of accounts delimiter after upgrade in **General ledger parameters** > **Chart of accounts and dimensions** > **Change delimiter**.
- If the only conflict is with the project/subproject ID format, you can change that value in **Project management and accounting parameters** > **General** > **Modify subproject format**.

How to determine if your environment requires updated delimiters

If delimiters in your upgraded environment are conflicting, you may experience instability when entering values in a segmented entry control or dimension entry control. This means that you will need to always use lookups or a flyout menu when entering account and dimension combinations.

Upgrade single-voucher journals and currency revaluations

2/18/2021 • 2 minutes to read • Edit Online

Some organizations enter journals that contain a single voucher that has more than one customer or vendor, and they also run the Accounts receivable or Accounts payable foreign currency revaluation process. This topic describes the steps that these organizations should follow when they upgrade to Microsoft Dynamics 365 for Operations version 1611.

Follow these steps when you upgrade to Microsoft Dynamics 365 for Operations version 1611.

1. Before you upgrade to Finance and Operations, run the foreign currency revaluation processes for Accounts receivable and Accounts payable. Set the **Method** field to **Invoice date**. A revaluation transaction is created that reverses the last foreign currency revaluation. Therefore, the open transactions are valued at their original accounting currency.
2. Upgrade to version 1611.
3. Run the Accounts receivable and Accounts payable foreign currency revaluation processes again. This time, set the **Method** field to **Standard**. A new revaluation transaction is created that is based on the current exchange rates. This transaction records the unrealized gain/loss and the correct summary ledger account.

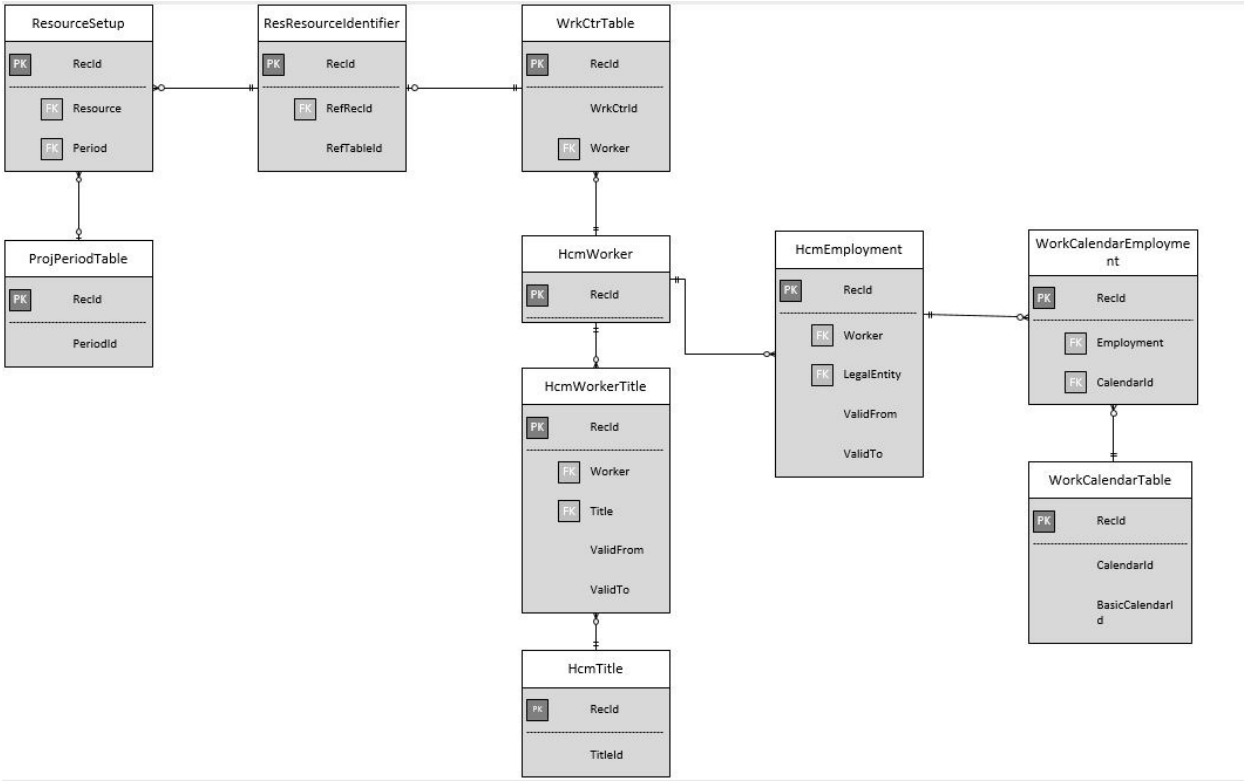
Project resource scheduling data model

2/18/2021 • 7 minutes to read • Edit Online

This topic provides information about the Project resource scheduling data model.

Physical data model for Project resource scheduling

The following diagram represents the data design structure of the Project resource scheduling physical data model.



Tables

The following table provides a list of additional tables that support the Resource management data model.

TABLE	DESCRIPTION
ResResourceIdentifier	Stores all resources and a subset of records from the **WrkCtrTable** table that are identified as resources. When a resource is added, a record will be added to the **WrkCtrTable **table. A record will also be added to this table with a Foreign Key reference to the new record in the **WrkCtrTable** table.
ResourceSetup	Specifies a resource's property. This table replaced the **ProjWorkerSetup** table in Dynamics AX 2012.
ResBooking	Stores all resource booking type reservations. This table replaced some of the information stored in the **PSASchedEmplReservation** table in Dynamics AX 2012.

TABLE	DESCRIPTION
ResAssignment	Stores all resource assignment type reservations. This table replaced some of the information stored in the **PSASchedEmplReservation** table in Dynamics AX 2012.
ResourceResourceCategorySetup	Stores the resource default project role association that is validated by a time range. This is a time effective table which has a Foreign Key to **ResResourceIdentifier.RecId** and a Foreign Key to **PSASchedRole.RecId** with **ValidFrom** and **ValidTo** fields. The **PSASchedRole** table is used to store the project role.
ResCalendarCapacity	This is a data denormalized table based on **WorkCalendarTable**, **WorkCalendarDate**, and **WorkCalendarDateLine** to calculate resource capacity. The calculation is based on the resource associated calendar date line definition, which is specified in the **WorkCalendarDataLine** table. The data in this table can be generated by running the **Synchronize resource capacity roll-ups** batch job.
ResRollUpCalendar	This is a data denormalized table based on **ResCalendarCapacity**. The data in this table is used by the **ResRollUpWriter** class to speed up the process of adding resource records to the **ResRollup** table. The data in this table can be generated by running the **Synchronize resource capacity roll-ups** batch job.
ResRollUp	This is a data denormalized table based on **ResBooking**, **ResAssignment**, and **ResRollUpCalendar** for performance improvement. This table contains all of the capacity and reservation data for time scales, including Day, Week, Month, Quarter, and Half year, for all resources. This data is accessed by the **AvailabilityView** control, which is included with any resource scheduling X++ form that includes this control, like the **Resource availability** form. The data in this table can be generated by running the **Synchronize resource capacity roll-ups** batch job. Data is updated for every resource reservation action such as adding a new resource, booking, assignment, and reservation cancellation.

Views

The following table provides a list of the most informative views that you can use to access the Resource management data model.

VIEW	DESCRIPTION
ResResourceWorkCenterView	This view is based on **ResResourceIdentifier** joining to **WrkCtrTable**, which captures only the fields that are required for resource management.
ResourceView	This view is based on **ResResourceIdentifier**, which is only based on **ResResourceWorkCenterView**. In a future release it can be extended to more than **ResResourceWorkCenterView** if a resource record will be saved on more than just **ResResourceWorkCenterView**.

VIEW	DESCRIPTION
ResourceWorkerView	This view replaces the **HcmWorker** table, which is based on **ResResourceIdentifier**. **WrkCtrTable** has a worker field which is a Foreign Key to **HcmWorkerTable**. This view includes all **WrkCtrTable** resource which worker field is not 0.
ResourceLegalEntityView	This view replaces the **HcmEmployment** table. This is the resource legal entity (LE) view, which is a union of **ResourceWorkerLegalEntityView** and **ResourceOtherLegalEntityView**. The purpose of this view is to look up the resource legal entity as well as the associated valid from and valid to date. For example, an **HcmWorker** resource can be hired by multiple LEs with different ValidFrom and ValidTo dates. If the worker is hired by multiple LEs, then this worker resource will have multiple records in this view. If the resource is not a **HcmWorker**, then this resource will have only one record and **validFrom** = **minDate** and **ValidTo** = **maxDate**.
ResourceCalendarView	This view replaces **WorkCalendarTable**. This view contains the calendar **RecId** of the resource. This is a union view of **ResourceWorkerCalendarView**, R**esourceOtherCalendarView**, and **ResourceGroupResourceCalendarView**. To look up the resource calendar, users should first look up the **ResourceLegalEntityview**. This is because a resource should have a different calendar depending on the resource's legal entity. First, locate the record from **ResourceLegalEntityView** and get the **RefRecId** and **RefTableId** fields. Then, look up **ResourceCalendarView** by setting **ResourceLegalEntityRefRecId** = **ResourceLegalView.RefRecId** and R**esourceLegalEntityRefTableId** = **ResourceLegalView.RefTableId**.
ResourceCategoryView	This view shows the resource category (the resource role for a worker resource), which is based on the **PSASchedRole** table.
ResSkillHcmView	This view is based on **HcmSkill** to capture all the skills that are defined in the **HcmSkills** table.
ResCertificateHcmView	This view is based on **HcmCertificateType** to capture all the certificates that are defined on the **HcmCertificateType** table.
ResEducationHcmView	This view is based on **HcmEducationDiscipline** to capture all the education disciplines that are defined in the **HcmEducationDiscipline** table.
ResProjectHcmView	This view is based on **ProjTable** to capture all projects that exist in the **ProjTable**.
ResRoleView	This view is based on **ResourceCategoryView** to capture all resource categories.

VIEW	DESCRIPTION
ResCharacteristicView	This view is the union view of **ResSkillHcmView**, **ResCertificateHcmView**, **ResEducationHcmView**, **ResProjectHcmView**, and **ResRoleView**. This view is used to gather all the characteristics that are defined as selectable criteria for the resource search feature.
ResResourceCharacteristicView	This view is the union view of **ResResourceCharacteristicHcmView**, **ResResourceResourceCategoryView**, **ResResourceNameView**, and **ResResourceRoleCharacteristicView**. This view is used to identify the characteristics that are associated with a resource for the resource search feature.
ResCalendarCapacityView	This view is based on **ResCalendarCapacity**, which contains calendars that are specified in **WorkCalendarTable** with capacity details.
ResCapacityView	This view shows the resource's capacity per hour.
ResResourceCapacityWorkDaysView	This view is based on **ResCapacityView**, which shows the resource capacity per day.
ResAssignmentView	This view is based on the table **ResAssignment**, which stores the activity resource assignments to either project or quotation work breakdown structure (WBS) task.
ResBookingView	This view is based on the table **ResBooking**, which stores the activity resource bookings to a project or quotation.

Changes that will affect tables and fields

These sections contain information regarding code changes to tables and fields that are part of the feature implementation related to Project resource scheduling.

Resource scheduling

The table **PSASchedEmplReservation** is no longer used to store a resource's reservations. Instead, reservations are stored in the **ResAssignment** and **ResBooking **tables. Both tables use the **Activity resource** field Foreign Key for **PSAProjSchedRole.RecId** to store a resource's reservation. The **PSAProjSchedRole** table is the project team table that has the **Resource** field Foreign Key to **ResourceView.RecId** and the **ResourceLegalEntity** field Foreign Key to **CompanyInfo.RecId** to identify which resources are the project's or quotation's team members. If the **PSAProjSchedRole.Resource** field = 0, then this activity resource is a planned resource. A planned resource is a shadow resource that is not backed by an actual resource. **PSAProjSchedRole.ResourceCategory** is a Foreign Key to **PSASchedRole** that stores the role of this team member. The **ResourceResourceCategorySetup** table stores the default time effective resource/role association. However, the resource can be reserved to any role defined by **PSAProjSchedRole.ResourceCategory,** ignoring the default role definition on the **ResourceResourceCategorySetup** table. Regarding WBS versioning, the tables **ProjPlanVersions** and **ProjPlanVersionDetails** store the WBS tasks versions. Initially, all WBS task data will be stored on these tables while the user is editing the WBS tasks content. After the user clicks the **Publish** button, the task data will be pushed to the original hierarchy tables (**smmActivities** and **PSAActivitySetup**). The resource management feature requires data in the original hierarchy tables and requires a published WBS.

Price by resource and resource category

The pricing tables, **ProjCostPriceExpense**, **ProjCostSalesPrice**, and **ProjRevenueSalesPrice** have a Foreign Key from **ResourceView.RecId**. The tables **ProjHourCostPrice**, **ProjHourSalesPrice**, and **ProjTransferPrice** have a Foreign Key from **ResourceView.RecId**. The field **ResourceCategory** is part of the Foreign Key for **ResourceCategoryView.RecId**. This is done so that pricing is based on a resource instead of a worker and enables pricing setup by resource category.

Common methods to get resource field and lookup resources

There are several resource methods in the **ResourceFacade** class. The following table includes some of the most common methods.

CLASS.METHOD	DESCRIPTION
ResourceFacade.findByWorker()	Look up the resource record ID by **HcmWorker** record ID.
ResourceFacade.findOrCreateByWorker()	Look up the resource record ID by **HcmWorker** record ID. If the resource record ID is not found, then a resource record ID will be added to the **ResResourceIdentifier** table and the resource record ID will be returned.
ResourceFacade.findByResourceID()	Look up the resource record ID by resource ID.
ResourceFacade.get...	There are many get methods supported for the resource in the **ResourceFacade** class. Resource related values like **Resource ID**, **Resource calendar**, **Resource legal entity**, and **Resource period** can be queried from the **ResourceView**, **ResourceLegalEntityView**, **ResourceCalendarView**, and **ResourceSetup** tables.

Facade classes

The following table lists the facade classes that you can use as a starting point to interact with the Resource management data model.

CLASS	DESCRIPTION
ActivityFacade	Contains the methods to retrieve an activity's properties, including **ID**, **Quotation ID**, **Project ID**, **Booked/assigned capacity**, **Remaining capacity**, **Calendar**, **Activity number**, and **Root project activity**.
ActivityResourceFacade	Contains the methods to retrieve an activity's resource properties including **Calendar**, **Name**, **Resource category**, **Resource legal entity**, **Is generic resource**, and **Is team member**.
PeriodFacade	Contains the methods to retrieve period properties including **Start and End date**, **Period ID**, and **Period name**.
ResourceCalendarFacade	Contains the methods to retrieve the resource's calendar properties including **Calendar data area ID**, **Calendar ID**, **Calendar RecID**, **Capacity**, and **Dates**.
ResourceCategoryFacade	Contains the methods to retrieve the resource's default resource **Category**, **ID**, **Name**, and **Type**.

CLASS	DESCRIPTION
ResourcePeriodFacade	Contains the methods to retrieve the resource's period date range and update the period method.
ResourceWorkerFacade	Contains the methods to retrieve the **Employment** type.

Workflow subsystem updates in Finance and Operations

2/18/2021 • 2 minutes to read • Edit Online

This topic reviews the workflow system in Finance and Operations. It describes the changes that have been implemented since Microsoft Dynamics AX 2012 and also includes links to more information about the workflow system.

The workflow system in Finance and Operations will be familiar to you if you've used Dynamics AX 2012. For more information about the workflow subsystem in Dynamics AX 2012, see the following topics.

TO LEARN ABOUT THIS SUBJECT	SEE THIS TOPIC
The workflow system	https://technet.microsoft.com/library/dd309672.aspx
Workflow types by module	https://technet.microsoft.com/library/dd362043.aspx
Workflow elements	https://technet.microsoft.com/library/dd309626.aspx
Workflow actions	https://technet.microsoft.com/library/dd362144.aspx
Workflow participants	https://technet.microsoft.com/library/dd309598.aspx
Workflow examples	https://technet.microsoft.com/library/dd309636.aspx
Developing a workflow	https://msdn.microsoft.com/library/cc967389.aspx
Implementing a workflow	https://msdn.microsoft.com/library/cc585061.aspx

Primary changes to the workflow system

Here are the primary changes that have been implemented in Finance and Operations:

- Integration with the new Application State Machine feature enables workflow events to be bound to state transitions on the underlying entity's state machine. This binding enables business logic to be centralized within the state machine and also enables the workflow system to be a declarative consumer of that state machine. The workflow metadata can reference a state transition that is performed when a specific workflow event occurs. Therefore, you can do state transitions within a workflow without writing any additional code.
- The workflow editor is now a program that you click one time to download. The editor communicates with Finance and Operations by using services, which means that you can carry forward the rich, graphical workflow design experience from Dynamics AX 2012.
- Workflow development wizards have been ported into Microsoft Visual Studio.

Transition from Analysis Services cubes to aggregate models

2/18/2021 • 2 minutes to read • Edit Online

This topic explains how in-memory, real-time aggregate models are used for analytics, and why we transitioned from using Server Analysis Services (SSAS) cubes.

The world is moving to real-time, proactive analytics. Reporting and trending on historical data is being replaced by up-to-the-second visualizations and proactive guidance. In-memory, real-time aggregate models now replace the perspectives that were previously used for analytics.

A historical look at perspectives and cubes

We envision embedded insights playing a key role in the Finance and Operations user experience. This vision has driven us to invest in building analytic capabilities within the product. In Dynamics AX 4.0, we introduced the concept of *perspectives*. The objective was to present a simpler view of the ERP schema, specifically modeled for reporting. This simpler view was referred to as perspectives. In Dynamics AX 4.0, the system generated reporting models (SMDL models) that enabled you to create ad-hoc reports with SQL Server Report Builder. In Dynamics AX 2009, we added the capability to generate SQL Server Analysis Services (SSAS) projects using metadata definitions in perspectives. These projects become cubes when deployed to an SSAS server. In Dynamics AX 2012, we improved modeling in perspectives and improved tooling support for managing the lifecycle of SSAS projects. You could use Excel, as well as Power View, to explore data and create reports with cubes in Dynamics AX 2012. The SMDL technology was also deprecated. In Dynamics AX 2012, we stopped generating SMDL models.

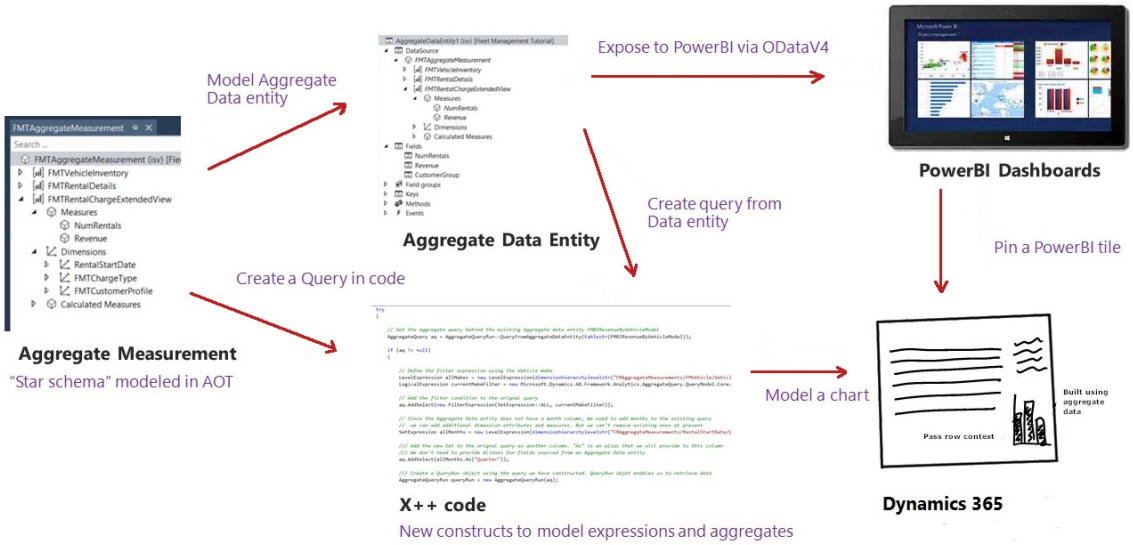
How perspectives are used now

As a developer, your "contract" with the system was a perspective. The system generated "stuff" to help you achieve your end goal. In Dynamics AX 2012, the "stuff" that was generated was SSAS projects. So the contract between you (the developer) and the system (the BI framework), was as follows:

- You modeled perspectives.
- The system generated the "stuff" needed to enable you to build visuals and reports.

Perspectives are now modeled using add-ins for Visual Studio. (Visual Studio is now the development environment.) Perspectives are comprised of *aggregate measurements* and *aggregate dimensions*. As a developer, you have the ability to model simpler schemas for answering business questions using aggregate measurements and aggregate dimensions. Aggregate measurements can be used to define data entities (called *aggregate data entities*) which can be directly bound to Finance and Operations forms as a data source. Aggregate data entities can also be used to

- Expose data to PowerBI.
- Access data programmatically using the AXQuery object.



NOTE

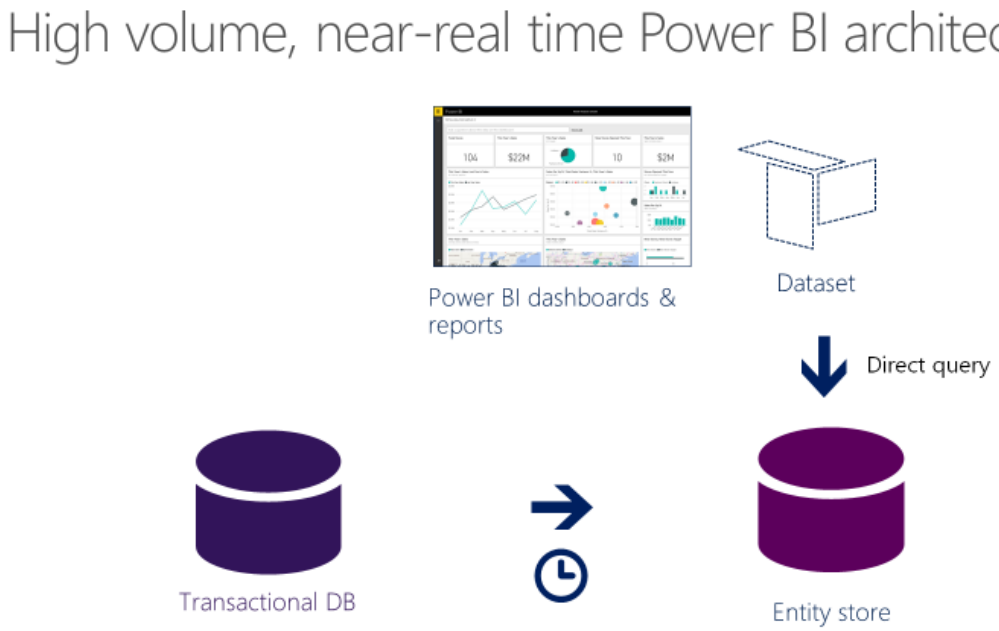
Migrate upgraded AX 2012 R3 sales cubes to the entity store

2/18/2021 • 13 minutes to read • Edit Online

In this tutorial, you'll migrate an upgraded Microsoft Dynamics AX 2012 R3 cube schema to the entity store in a Finance and Operations application. You'll use the sales cube that was included in Dynamics AX 2012 R3 as an example.

The entity store will support near real-time Microsoft Power BI integration scenarios, as shown in the following diagram. For an overview of Power BI integration with entity store, see Power BI integration with entity store.



New Power BI features included in the May 2016 and November 2016 updates

This tutorial requires the Dynamics 365 for Operations May 2016 update or later. You will use the following new capabilities in this tutorial:

- Stage an aggregate measurement in the entity store and refresh the data from Dynamics AX. You might prefer this option over in-memory real time aggregate measurements when:
  - You upgrade a Dynamics AX 2012 cube.
  - Your aggregate measurements are very large.
  - Data freshness (latency) from a few minutes up to a few hours is acceptable for reporting.
- Use the batch framework to schedule a recurring refresh. For this release, only a full refresh is enabled.
- Create reports using Power BI desktop in a developer/test environment.
- Leverage the direct query option when creating Power BI content. For example, you can create larger models without relying on OData as the data refresh mechanism.
- Migrate reports from your development environment to a production environment using Lifecycle Services (LCS).
- As a partner or an ISV you can distribute Power BI content as part of an LCS solution to your customers.
- **If you're using the November update (platform release 1611)** or later, some steps in this document

are part of the process to refresh the entity store - you do not need to perform them manually.

Change upgraded aggregate measurement properties

As part of the code upgrade process, analysis services projects from the Application Object Tree (AOT) in Dynamics AX 2012 can be migrated to the new aggregate measurements metadata format.

1. Launch Visual Studio and create a new project in Application Suite.

   > **NOTE**
   > You can create a model and include the customized aggregate measurement within that model. For more information, see Customize through extension and overlayering.

2. Open Application Explorer. Go to **Analytics** > **Perspectives** > **Aggregate measurements**. You will notice a set of aggregate measurements that were upgraded from Dynamics AX 2012 R3, as well as the measurements that ship in the current version.

3. Select **SalesCube**. Right-click and select **Duplicate in project**.

4. An aggregate measurement with the name **SalesCubeCopy** will be added to the project.

5. Rename this measurement. Select **SalesCubeCopy** in Solution Explorer. Right-click and select **Rename**. Enter **SalesCubeV2** as the new name.

6. Double-click **SalesCubeV2** to launch the Aggregate measurement designer. Notice the structure of the aggregate measurement that was migrated from Dynamics AX 2012.

7. The Sales cube in Dynamics AX 2012 encompassed a broad subject area related to Sales. In this case, let's create a smaller, more focused Power BI model using the metadata that was upgraded. Expand the **Sales Order Lines** measure group and review the list of measures and dimension references.

   > **NOTE**
   > Leveraging the modeling capabilities you can quickly make a few enhancements to this model. Suggestions for improvements:
   >
   > - Replace views/tables that have been used to model the measure group (and/or dimensions) with an entity. You can model an entity using the underlying view and replace the view with the corresponding entity. This will enable you to leverage upcoming features such as incremental refresh and security.
   > - Remove unwanted dimension references by adding the corresponding field to the attributes node. For example, the Sizes dimension reference can be removed because the **Size** field in the measure group is sufficiently descriptive. This will improve the runtime performance of queries as well as refresh times.

8. Select the **SalesCubeV2** root node in the Aggregate measurement designer. Right-click and select **Properties**.

9. During upgrade, aggregate measurements are set to the legacy property flag, **SSASCube**. You need to change this property to one of two supported usage types. Previously, **InMemoryRealTime** was supported as usage for aggregate measurements. **StagedEntityStore** is supported as a new usage type.

   > **NOTE**
   > Modify the usage property to InMemoryRealTime if you plan to use the Aggregate measurement for embedded BI scenarios as well as Power BI integration. If you are using the Aggregate measurement only for Power BI or Cortana Intelligence Suite integration, select **StagedEntityStore**.

10. Save the project. Right-click the project in Solution Explorer and select **Rebuild**.
11. After the rebuild operation is finished, save the project, and then close Visual Studio. This completes the development work. You will author reports as a report developer or a power user.

Refresh the entity store

As an administrator you can configure the refresh of the aggregate measurement using the client.

1. Launch the Dynamics AX client and navigate to **System Administration** > **Setup** > **Entity Store**. The **Entity Store** form shows a list of aggregate measurements that are available for deployment to the entity store.
2. Notice that **Sales Cube** (which was upgraded from Dynamics AX 2012) is not available for deployment to the entity store. **SalesCubeV2**, which you created in the previous step, can be deployed to the entity store.
3. Select **SalesCubeV2** from the list, and click the **Refresh** button. The **Refresh** dialog box will display. Expand the **Run in the background** tab.
4. Provide a descriptive name in the **Task description** field. Optionally, you can select the **Recurrence** tab and create a recurring schedule instead of a one-time refresh. Click **OK**.
5. The system will create a batch job for refresh of the aggregate measurement in the entity store.

Authoring a report on Sales by State with Power BI desktop

This step requires that you the install Power BI desktop tool that can be downloaded from Microsoft Power BI Desktop.

1. Launch Power BI desktop. You may need to apply updates. A welcome page will display. Click **Get data**.
2. Alternatively, when Power BI desktop launches, on the **Home** tab select **Get Data** > **SQL Server**.
3. In the **SQL Server Database** dialog box, enter the server name and the name of the entity store database. If you deployed a developer environment, you can enter "." as the server name and **AxDW** as the database name. If you are working in a test environment, you need to get these parameters from your system administrator
4. Select the **DirectQuery** option. In this exercise, you will create Power BI reports that are executed directly on the entity store. If you had used the **Import** option, Power BI would cache data from the entity store and you would need to periodically refresh the Power BI model. **Import mode is currently not supported with reports written using entity store**. Click **OK**.
5. Next you will see the **Navigator** dialog box. Navigator enables you to select tables and views from the entity store that you want to report on. Enter **Sales** in the search box. The system will filter entities that are related to the **SalesCubeV2** aggregate measurement that was previously created.

   > **NOTE**
   > The entity store stages the aggregate measurements that have been created. While entities within each aggregate measurement are prefixed and stored as individual tables, Power BI desktop enables you to combine data from multiple aggregate measurements.

6. You will create a report that shows sales by state. Select **SalesCubeV2_Customer** and **SalesCubeV2_CustomerInvoices** from Navigator and click **Load**.
7. You will notice Power BI designer with **Fields** present in the entities that you have chosen (on the far right), as well as available visualization.

Create a surrogate key that links customers and invoices (applies to Platform versions before November 2016

update)

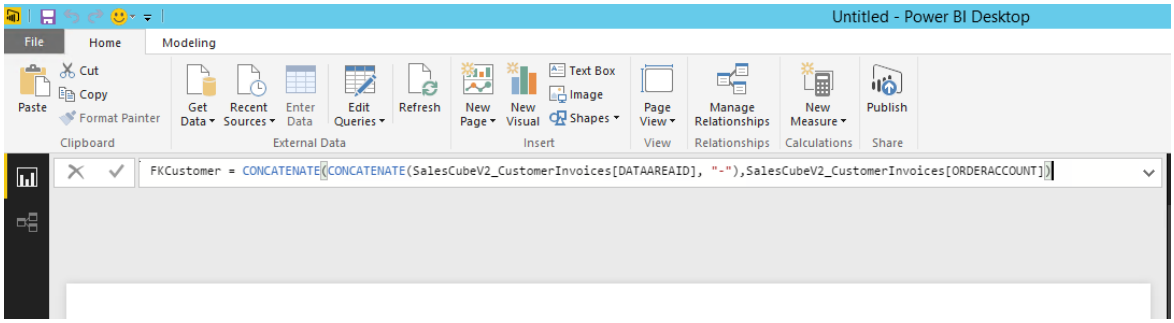
> **NOTE**
>
> Surrogate keys are generated in aggregate measurements staged into entity store. Power BI desktop does not enable you to relate table joins using multiple fields (also known as, composite keys). The **SalesCubeV2_Customer** entity does not have a surrogate key (such as AX RecID) defined in it. Next, you will create a surrogate key that enables relating a customer entity to invoices.

1. Select the ellipsis (...) icon next to the **SalesCubeV2_CustomerInvoices** entity. Right-click and select **New Column**.
2. Enter the following expression in the **Formula editor** window.

```
FKCustomer = CONCATENATE(CONCATENATE(SalesCubeV2_CustomerInvoices[DATAAREAID], "-"),
SalesCubeV2_CustomerInvoices[ORDERACCOUNT])
```

> **NOTE**
>
> When you enter the first few letters of the field name or function, the editor will display a list of candidate fields. This is called a type-ahead feature. You can either copy and paste this expression or use the type-ahead feature.

3. When completed, your formula should look similar to the following.



4. Notice that a new field, **FKCustomer**, is shown in the list of fields for the **SalesCubeV2_CustomerInvoices** table. Because this field is used to relate two tables, you can hide it from end users by right-clicking the field and selecting the **Hide** option.
5. Next, create a similar field in the **SalesCubeV2_Customer** table. Select the ellipsis (...) icon next to **SalesCubeV2_Customer** entity. Right-click and select **New Column**.
6. Enter the following expression in the **Formula editor** window.

```
FKCustomer = CONCATENATE(CONCATENATE(SalesCubeV2_Customer[DATAAREAID], "-"),
SalesCubeV2_Customer[CUSTOMER])
```

7. Notice that the field **FKCustomer** is shown in the list of fields for the **SalesCubeV2_Customer** table. Because this field is used for relating two tables, you can hide it from end users by right-clicking the field and selecting the **Hide** option.

Relate invoices and customers

NOTE

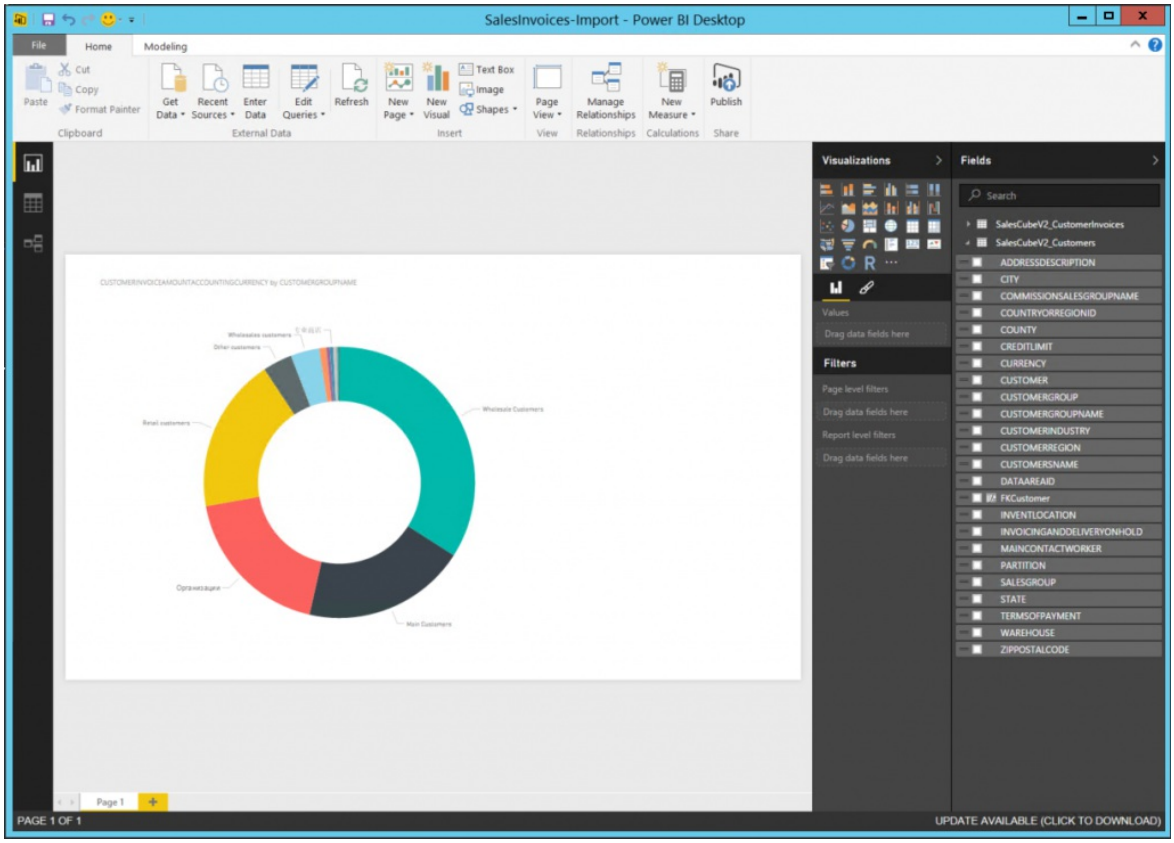
You can relate the surrogate keys already created within entity store. If not, you must relate the surrogate keys that you created manually. Next you will create a relationship between **SalesCubeV2_CustomerInvoices** and **SalesCubeV2_Customers** entities.

1. Click the **Manage Relationships** button on the Power BI ribbon. You will see the **Manage Relationships** dialog box. Click the **New** button.
2. In the **Create Relationship** dialog box, select **SalesCubeV2CustomerInvoices** as the first table in the drop-down list. Scroll to the right and select the **FKCustomer** field as the column to relate to.
3. In the second drop-down list select **SalesCubeV2Customer** as the table. Scroll to the right and select **FKCustomer** as the column to relate to.
4. Select the **Make this relationship active** option if it is not already selected. Click **OK** to continue.
5. You will notice the newly created relationship in the **Manage Relationships** dialog box. Click the **Close** button.

Create a Sales by state report

1. To create a report that shows sales by customer group, drag the **CustomerInvoiceAmountAccountingCurrency** field from the **SalesCubeV2_CustomerIncoices** table and drop it on the Power BI desktop canvas. Next, drag the **CustomerGroupName** field in the **SalesCubeV2_Customer** table to the same grid.

2. Change the chart type to a doughnut chart. You should see a report similar to the following.



3. You can create additional visuals using the Power BI desktop. When you save, you will notice that the file has a **PBIX** extension.

4. Save the report to your desktop.

5. At this point the report is fully functional (with data from your environment) and you can continue to use the Power BI desktop or upload this report to PowerBI.com and continue with data exploration.

6. Next, you will migrate this report to a production environment using LCS so that you can see this report with production data and share it with other users.

Publish the report and the model

Publishing a report and model requires uploading the report to Lifecycle Services, migrating the aggregate measurement to your production environment, configuring the client to point to the correct LCS library, and publishing your reports in your production environment.

Upload the report to Lifecycle Services

Microsoft Dynamics Lifecycle Services (LCS) is the tool used to migrate development artifacts from developer to production environments. In the May 2016 update, LCS supports migrating PBIX files (authored using the entity store) between environments.

1. Open LCS from the developer environment. If you haven't created a project in the LCS environment, create a project.
2. Scroll to the right and you will notice the **Asset Library** icon. Click the icon and launch **Asset Library**.

Notice that the asset library enables adding **PowerBI report models** (PBIX files) as implementation artifacts to a project.

1. Select the plus (+) icon to add a new asset.
2. Provide a name and a description. Click **Upload** and then locate the file that you saved in an earlier step.
3. After you successfully upload the file, click **Confirm**. Notice that the file is uploaded into LCS as an implementation asset. LCS supports managing versions and releases for Power BI reports. You can maintain several versions and publish reports to other environments, just as you would for other implementation artifacts. Because you added the PBIX files as an asset within an LCS project, environments that you deployed using that project will have access to this report.
4. Optionally, you can publish this report so that all of your projects can access the shared assets. If you are a partner or an ISV, and want to share this report with your customers, you would share this asset to your global library and enable your customers to import the asset into their respective LCS projects. To do this, select the **Save to my library** option.

Migrate the aggregate measurement to a production environment

1. You need to migrate the aggregate measurement that you modified in the developer environment to the production environment. You can follow the instructions in Generate a deployable package. create-apply-deployable-package.md.
2. After you successfully publish the model, perform the steps outlined in the **Refresh the entity store** section of this tutorial, so that the entity store is updated with data.

Configure an LCS project

If you haven't already done so, associate your environment with an LCS project so that Finance and Operations apps can consume assets within the project.

1. Launch the client from the instance that you want to use to deploy the Power BI reports. Typically this is the test or a production instance where you want to see a report with a different set of data than what you worked with as a report developer.

2. Open **System Administration** > **Setup** > **System parameters**. Select the **Help** tab. Using the **Lifecycle services help configuration** list box, select the LCS project that you uploaded the PBIX file to. Click **Save**.

> **NOTE**
>
> This form will only show the LCS projects that the current user has access to. If this step is being performed by an administrator, either the administrator needs to have access to the project, or the PBIX artifacts need to be imported into a project that the administrator has access to.

Publish Power BI reports to a production environment

1. Open **System Administration** > **Setup** > **Deploy PowerBI** from the client. You will see the file that you uploaded to LCS.
2. Select the **Sales Report** file and select the **Deploy Power BI files** option on the menu bar.

> **NOTE**
>
> You may be asked to consent publishing to the PowerBI.com service. Click the link to provide consent. When consent is complete, you need to go back to the original browser window and click the **Close** button.

3. After you successfully publish the file, the Power BI report will appear in your PowerBI.com subscription. You will notice that the report now points to the entity store in the production environment.

Continuing with PowerBI.com

As an administrator or a power user, you have successfully authored and published a Power BI report to the production environment using the entity store. You can perform several additional steps using Power BI functionality.

- Optionally, you can apply record-level security to the dataset to restrict users from seeing data they are not allowed to view in Power BI.
- You can create an organizational content pack and share it among users in a group.
  - You can export datasets, reports, and dashboards from your PowerBI.com instance as a new content pack to a selected group of users.
  - Note that organizational content packs adhere to any record-level security rules that you defined at the dataset level.
- Users can personalize their workspaces by adding Power BI tiles or reports.

Model aggregate data

Upgrade budget planning

2/18/2021 • 11 minutes to read • Edit Online

There are significant differences in budget planning between Microsoft Dynamics AX 2012 and Dynamics 365 Finance. Some features were not upgraded and therefore require reconfiguration. This topic explains what must be reconfigured and also describes new features that should be considered after the upgrade is completed.

Budget planning in Finance has many enhancements that weren't available in Dynamics AX 2012. This topic explains the changes that customers who upgrade must make. It also points out the new features that should be considered in the upgrade process. Because of the extent of the changes, any existing budget plans will not be able to be opened until the changes that are outlined in this topic are made. However, reports should continue to work and not require additional changes.

Overview of changes

Many significant changes have been made in Budgeting for Finance and Operations. These changes are intended to make Budget planning easier to configure and more reusable, to reduce year-over-year maintenance and setup. The following areas in AX 2012 no longer exist in Finance:

- Budget plan templates (Budget planning configuration)
- Budget plan folders (Budget planning configuration)
- Scenario constraints (Budget planning configuration)
- Templates for Budget planning stage rules and templates (Budget planning process)
- Matrix fields for worksheet templates
- Budget plan Microsoft Excel template wizard

Some new concepts can't be directly upgraded from the previous functionality. Therefore, you must complete some reconfiguration to address these new concepts. The following sections describe the concepts that have replaced the items in the preceding list.

Columns

Columns are a new concept that replace parts of the Excel template and also matrix fields. Columns can represent a period, month, quarter, year, or all time. The time reference is dynamic. It points to a relative period or year in reference to the budget process. For example, a **Prior Year January** column references fiscal period 1 for year -1. A column is specific to a budget plan scenario, such as actuals or budget request.

Layouts

Layouts are a new concept that replace the Excel template. Layouts contain the columns that define which budget or actuals data and periods should be shown. Layouts are also shared between the client and the Excel add-in. Therefore, the user experience when you enter or view data in the Finance and Operations client is better than the user experience in AX 2012. To enter data in the Finance client, you're no longer limited to viewing and entering a single scenario in a transaction view. Instead, a comparison view lets you easily view and enter amounts for multiple periods and accounts at the same time. Layouts can also be defined so that you can enter and view currency, comments, and other optional data. Layouts also let you define which ledger dimensions and dimension descriptions should be shown. Layouts also incorporate scenario constraints to define which columns in a template can be edited and which columns should be available in Excel. After you define a layout, a template is generated for it. This template, in turn, creates the corresponding Excel template. You can then edit the Excel template to incorporate more formulas and formatting, and then upload it again. Layouts are then assigned to each stage rule on the **Budget planning process** page. Therefore, the layouts replace templates, which were assigned and used in a similar manner.

Budget planning processes

Budget planning processes are mostly the same as in AX 2012. The most significant change is the replacement of templates with layouts. If any processes were previously completed in AX 2012, the processes are updated to a status of in-progress so that changes can be made. You must assign layouts will need for each stage rule to determine which scenarios and time periods appear when the plan is opened in the client. The layouts also determine which Excel template is opened outside Dynamic 365 Finance so that you can view the budget. **Default account structure** is a new required field for the Budget planning process. For each Budget planning process, assign the primary account structure that should be used for budgeting.

Attachments

In AX 2012, justification documents were saved to an attachment folder. No previous justification documents are upgraded. Justification documents are now stored in the database. If this information should be saved in the upgraded version, you can upload final justification documents for each plan as an attachment by using the **Justification** button on the Action Pane. In AX 2012, Excel worksheets for each budget plan were created based on the template. In Finance, all plans open a copy of the layout. However, no changes to the Excel file are saved. Any formulas or supporting information that were used on a per-plan basis must be added via comments, a justification document, or some other supplemental process.

Configuring an upgraded environment from AX 2012

To help you determine how to configure the upgraded system, the following example uses an upgraded budget process from AX 2012 demo data. Default configuration data for columns were created to help with the upgrade process. You can update or delete this default data if doesn't meet your configuration requirements. **Note:** There are new required fields that won't be set in the system. If you get stuck on a page, such as the **Budget planning configuration** page, and can't navigate away, you can close your browser and then reopen it to a different page to enter details in the correct order. There are required fields that aren't yet set. Therefore, issues might occur until everything is configured and all required fields have been set. This topic explains how to set these fields, as required. Here are some of these required fields:

- **Budget planning process** page: **Default account structure** field
- **Budget planning process** page: **Layout** field on the **Budget planning stage rules and layouts** FastTab

Define columns and layouts

1. On the **Budget planning configuration** page, click the **Columns** tab. As part of the upgrade, new columns are automatically created based on your budget plan lines. Columns now use dynamic dates, where the time and year are offset from the fiscal year that is defined in the Budget planning process. **Note:** For performance reasons during upgrade, it's assumed that all budget cycles represent calendar years, not fiscal years. If you use fiscal years, you must make edits to correctly map the columns to their fiscal year. For example, the following elements existed in AX 2012:

   - Budget plan scenarios: Actuals, Baseline, Budget Request, Budget Approved
   - Budget plan lines for all scenarios in 2017, and Actuals for both 2017 and 2016

   The following columns will be created in Finance and Operations:

COLUMN NAME	BUDGET PLAN SCENARIO	COLUMN TIME PERIOD	YEAR OFFSET
Jan Scenario 1	Actuals	1	0
Jan Scenario 2	Baseline	1	0
Jan Scenario 3	Budget Request	1	0
Jan Scenario 4	Budget Approved	1	0

COLUMN NAME	BUDGET PLAN SCENARIO	COLUMN TIME PERIOD	YEAR OFFSET
Jan Scenario 5	Actuals	1	-1
Feb Scenario 1	Actuals	1	0
...	...	...	...

In this example, a column that is named **Jan Scenario 1** is created for the most recent budget plan transaction data that is found where transactions exist in January. A similar column is created for each scenario that has data. After columns exist for all periods in that year, columns are created for previous years.

2. Change the column names and descriptions, and any other details, either manually in the client or by doing bulk updates through the Excel add-in that points to the budget plan columns data entity. Any filters that were previously set for matrix fields are now set within the columns.
3. Create a new budget plan layout. A layout points to several columns to define the view that appears in Excel and the client. The layout first requires that you specify a ledger dimension set to determine which financial dimensions can be entered. After you specify the dimension set, click **Descriptions** to select dimension descriptions to include in the layout.
4. On the **Layout elements** FastTab, click **Add** to add metadata for each row, such as a currency, a comment, or a budget class that determines revenue versus expense rows. Next, add columns for the time period, and scenarios that apply to this budget cycle and stage. You can make these changes manually in the client or through the Excel add-in that points to the budget plan layout elements data entity.
5. For each layout element, select whether the column should be editable, and whether the column should also appear in the Excel workbook for this layout. **Note:** For our historical plans, you might want to consider a layout that shows 12 monthly columns for any budget plan scenarios for that process.

Update budget planning processes to use the appropriate layout for each budget stage

1. On the **Budget planning process** page, select the process to configure.
2. On the Action Pane, click **Edit**.
3. Specify the default account structure for this budget process. **Default account structure** is a new required field that must be set.
4. On the **Budget planning stage rules and layouts** FastTab, in the **Layout** field, select a layout that was previously configured, and that is appropriate for this stage.
5. Continue to select the same or different layouts for the various budget planning stages, and then save your changes.

Additional features to consider in your budgeting process

Budget planning workspace

This workspace is designed for both the budget owner and individual budget contributors. It has links to any budget documents that require your attention. It also has reports and key performance indicators (KPIs) for the budget process. The budget administrator can define the current Budget planning process for all users on the **Budgeting parameters** page. On the **Workspace settings** tab, the **Budget planning** FastTab includes a field where you can select the budget planning process.

Alternate layouts

Alternate layouts are a new feature that lets you view plans in different layouts. One or more layouts can be

provided as options. You can then view a budget plan in a monthly layout or a quarterly layout. You define alternate layouts on the **Budget the planning stage rules and layouts** FastTab on the **Budget planning process** page.

Budget milestones

As part of the budget process, it's vital that you understand key dates and deadlines. You can now configure dates so that they have descriptions. Budgeting users will see these descriptions when they open budgets to edit or view anything that is assigned to them.

Copy from Budget Plan allocation

A new allocation method lets you distribute from a parent plan to a child plan without having to go through an intermediate level in the hierarchy. This method is especially useful for customers who previously created financial dimension just for budget distribution and approvals.

Generating budget plans from new budget sources

The following options were added as periodic processes. These options let you generate a budget plan by using existing data from another module as the starting point:

- Generate Budget Plan from Demand Forecast
- Generate Budget Plan from Supply Forecast
- Generate Budget Plan from Project
- Generate Budget Plan from Budget Register

More complete tracking of amounts

In AX 2012, budget planning had a single plan amount that was stored for each value. In Finance, the data model has been expanded. There are now accounting currency, transaction currency, and reporting currency amounts for each value. During the upgrade, these new columns are automatically filled in for existing data.

Do not convert currency in aggregation

Typically, when a child plan is aggregated to a parent level, the amounts are automatically converted from the transaction currency to the accounting currency for the organization. When you set the **Do not convert currency in aggregation** option to **No** the aggregated amounts remain in the original currency. Therefore, this option allows for more accurate adjustments that are affected by exchange rate fluctuations.

Looking back from a budget plan to other modules that contributed to the budget

Budget plans can be generated from demand or supply forecasts, project, and other areas. The Budget plans by dimension set inquiry includes several options that let you run queries to identify the data that was the source for the budget plan.

Overwrite or append to plan for allocation schedules

If there are multiple sources for amounts that must be distributed, you can specify that the amounts should be additive. In this case, the amounts don't overwrite any existing amounts. Instead, they are appended to the existing amounts.

Default financial dimension set for budget planning configuration

The **Budget planning configuration** page now includes a field where you can specify the default financial dimension set. Although this field is an optional field, it might be required for certain inquiries. It might also be required if you want to group or filter reports grouping by dimension set.

Data entities

Several data entities have been added to enable rapid implementation of Budget planning. The entities also let you make many changes through Excel. Therefore, you don't have to create items one at a time through the client. Here is a list of the new data entities:

- Entity name

- Budget parameters
- Budget plan parameter
- Budget plan scenarios
- Budget plan stages
- Budget plan workflow stage
- Budget plan allocation schedules
- Budget plan stage allocations
- Budget plan priorities
- Budget plan columns
- Budget plan layout elements

AX 2009 upgrade - Use the Data migration tool to migrate from Dynamics AX 2009 to Finance and Operations

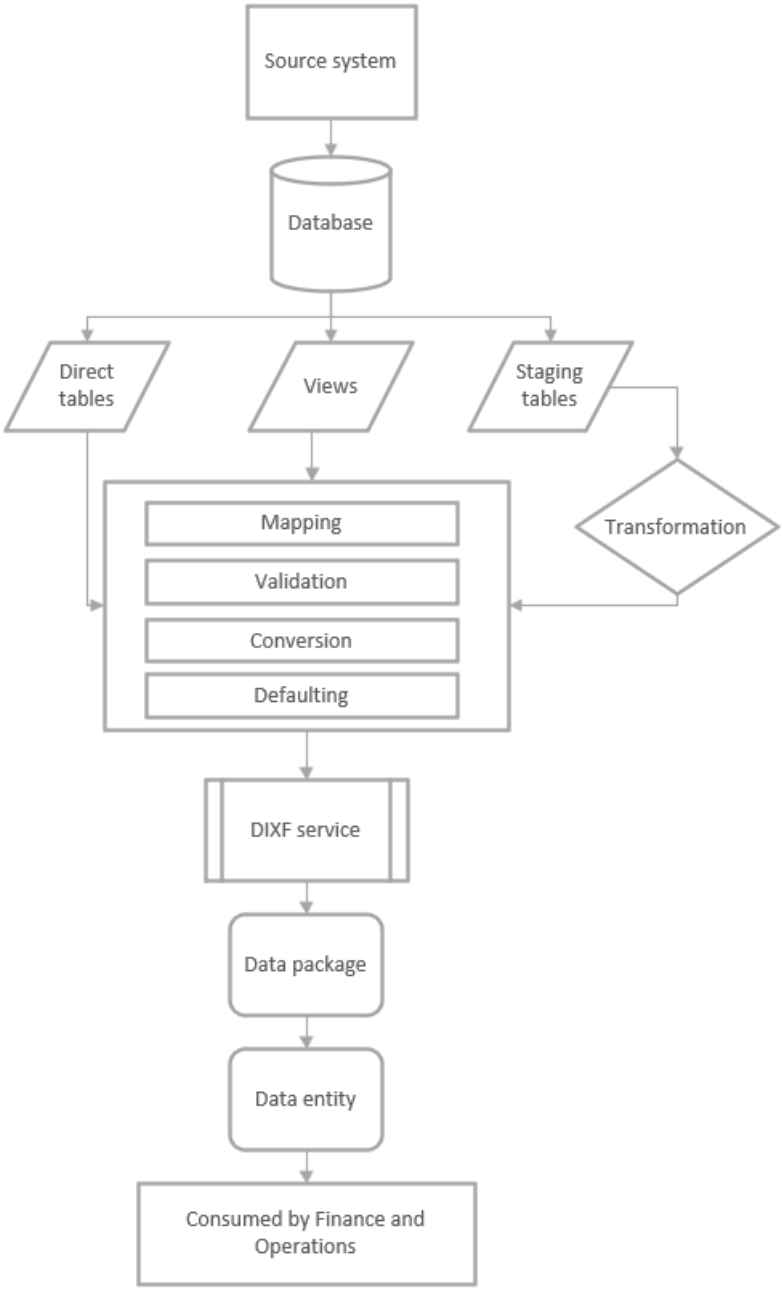
2/18/2021 • 2 minutes to read • Edit Online

You can use the Microsoft Dynamics AX 2009 Data migration tool (DMT) to migrate your data from AX 2009 to Finance and Operations. Using the DMT is the only supported upgrade path from AX 2009. The DMT helps you find and fill gaps between the table schemas for each version, as well as helping you move your data.

> **NOTE**
>
> Start your cloud migration journey with a no-charge, no-obligation migration assessment though the Dynamics 365 Migration Program.

Architecture

The following illustration describes the architecture of the DMT, and how data from the source system (AX 2009) is processed and moved to the target system (Finance and Operations).



Data migration process

The following illustration shows the overall process of collecting and preparing the data in your AX 2009 instance and then importing that data into your new environment.

Before you can use the DMT to export data from the source environment (AX 2009), you must complete the following pre-processing tasks:

- Mapping the table fields between the source and target environments
- Applying conversions to the source data
- Setting up default values for the source data
- Applying query filters

Because there can be multiple legal entities in the source system, you must select the legal entities that contain

the data to migrate. For the selected legal entities, you can review the source tables and their row counts. You can also view any virtual companies. Finally, you can analyze virtual companies that legal entities are attached to and the related tables.

Successful migration of exported data requires that a source table be mapped to an equivalent target data entity. You set up the mapping by using a Microsoft Excel mapping file that allows for automatic mapping of the source and target fields of each table. The mapping file also includes the data from the schema of the new data entities and the default data that is required in some tables.

Before you can migrate data from AX 2009, you must complete the following tasks to meet the migration requirements:

- Select target dimensions that correspond to the source dimensions that are populated based on the selected legal entities.
- Review the inventory dimensions that are included with the selected legal entities.
- Select the chart of accounts for each legal entity, or consolidate multiple legal entities into a single chart of accounts.
- Complete the basic ledger setup.
- Apply data conversions to the source data, based on the extended data type (EDT) of the field.

AX 2009 migration – Install the Data migration tool

2/18/2021 • 5 minutes to read • Edit Online

This topic explains how to set up the Data migration tool (DMT) so that you can migrate data from Microsoft Dynamics AX 2009 to Finance and Operations.

> **IMPORTANT**
> At this time, the DMT is in private preview. If you are interested you can sign up for the Preview Program. The public release date for the DMT has not been set.

Prerequisites

- Microsoft SQL Server 2008/2012/2014/2016.
- The Microsoft .NET Framework version 4.5 or later.
- Microsoft SQL Server machine that has Microsoft SQL 2012 Native Client installed.
- The Microsoft SQL Server Integration Services (SSIS) service is installed and running on the machine where the DMT service will be installed.
- SQL Server authentication must support both SQL authentication and Microsoft Windows authentication.
- Microsoft Access database engines that follows the version guidance in the following table.

	SQL SERVER 2008	SQL SERVER 2012 AND LATER
No Microsoft Office on the VM	Access engine 32-bit	Access engine 64-bit
Microsoft Office 32-bit	Access engine 32-bit	Access engine 64-bit
Microsoft Office 64-bit	Access engine 32-bit and 64-bit	Access engine 64-bit

- Microsoft Dynamics AX 2009 SP1 5.0.1000.52 or later.
- The prerequisite patch (axpatch.exe) installed. To find the patch, from the location where you downloaded and extracted the zip file, go to <pre-requisiteforpatch><application>.

Install DIXF service

1. Go to the location where you extracted the zip file, and then, in the **DIXF msi** folder, right-click **DIXF_Service_x64.msi**, and select **Run**.
2. When the wizard starts, select **Next**.
3. Accept the license terms, and then select **Next**.
4. Select an account for the service, and then select **Next**. The account should have admin rights. If you select the **Network Service** check box, verify that the network service account has admin rights. Otherwise, clear the check box, and enter an admin account user name and password. Then select **Next**.
5. Select the SQL Server version, and then select **Next**.
6. Select **Install**, and then, when the wizard is completed, select **Finish**.

Copy binaries

Go to the location where you extracted the zip file, and copy the following files to the **Program Files (x86)\Microsoft Dynamics AX\50\Client\Bin** folder:

- Microsoft.Dynamics.AX.Framework.Tools.DMT.dll
- Interop.Shell32.dll

Install DMT components for AX 2009

There are two ways to install the DMT. You can use the combined XPO file or an application hotfix. If you're using a Microsoft Dynamics Lifecycle Services (LCS) Implementation project, use the application hotfix. Installation takes approximately seven hours.

Combined XPO file

1. Extract the combined XPO file from **DMT_V1.0\CombinedXPO**.
2. Import the combined XPO file into AX 2009.
3. Copy the label file from **DMT_V1.0\Label file** to the **Program Files\Microsoft Dynamics AX\50\Application\Appl\<NameOfYourDeployment>** folder.
4. Restart the Application Object Server (AOS) instance.
5. In AX 2009, select **Data migration** > **Setup** > **Compile and synchronize DMT application**.

Note that the combined XPO file is imported into the layer that the user is signed in to.

Application hotfix

1. Go to **DMT_V1.0\ApplicationHotfix\DynamicsAX2009-KB4010403-SP1**, right-click **setup.exe**, and then select **Run**.
2. In AX 2009, in the Application Object Tree (AOT), notice that the **LegalEntityId** field has been added to the **DMTCustomerAddressView** and **DMTVendorAddressView** views.
3. Select **Data migration** > **Setup** > **Compile and synchronize DMT application**.

Parameter setup

Go to the location to where you extracted the zip file, and find **defaultvalue.xlsx**.

> **NOTE**
> The file is saved in .xlsx format. Don't change the extension. When you provide this file as input for the **Default configuration** parameter, select **All Files** so that you can select the .xlsx format. If you don't select this format, errors will occur when you start to generate mappings.

1. In AX 2009, select **Data migration** > **Setup** > **Configure default maps**, and enter the appropriate information in the following fields:
   - **Default configuration** – Enter the path of the Microsoft Excel file.
   - **Export file path** – Enter the server path that can be accessed by the service.
   - **SQL Server user and password** – Enter the SQL authentication credentials for the AX 2009 database.
2. Close the form.
3. Under **Setup**, select **Configure connections**, and enter the appropriate information on the following fields:
   - **DIXF service host** – Enter the host name of the DIXF service installation.

- **Tenant URL** – Enter the URL for the application tenant. If you aren't sure of the tenant, see the web.config file for the Finance and Operations application.

> [!NOTE} In the Azure Portal, when you create a new app in the Azure Active Directory (AAD), you can select from two options. **Web API** and **Native**. In this instance, select **Native** and grant permissions to native AAD app.

Multi-box setup

For a multi-box setup, you must have the following machines:

- Machine A, where the AX 2009 database and DIXF service are installed
- Machine B, where the AX 2009 AOS instance is installed
- Machine C, where the AX 2009 client is installed

In this three-machine setup, machine C is configured to connect to the AOS instance on machine B. Machine B is connected to the database that is configured on machine A.

DIXF service machine prerequisites (machine A)

The DIXF service on machine A has the following prerequisites:

- SQL Server 2008/2012/2014
- The .NET Framework version 4.5
- Access database engines
  - **For SQL Server 2008:** Access engine 32-bit and 64-bit (if Microsoft Excel is 64-bit)
  - **For SQL Server 2012 or later:** Access engine 64-bit
- AX 2009 database (configured on SQL Server)

AOS machine prerequisites (machine B)

The AOS installation on machine B has the following prerequisites:

- AX 2009 AOS Server
- Application files

Client machine prerequisites (machine C)

The client installation on machine C has the following prerequisites:

- AX 2009 client

Shared folder permissions

The path of the default configuration file and the export package file should be shared, and client users and the DIXF service should have read/write access to these files. To grant this access, select **Data migration** > **Setup** > **Configure and generate maps**, and then select **Validate path** to verify that the required access is available.

Set up parameters

1. Select **Data migration** > **Setup** > **Configure connections**.
2. In the **DIXF service host** field, enter the name of the remote machine where the DIXF service is installed. By default, the name is **localhost**.
3. Select **Validate** to validate that the client can access the DIXF service.

Workarounds

If you receive an error message that states, "DIXF service is unavailable," complete the following workaround to enable a service connection for port 7000.

1. Open port 7000, and then, for inbound rules on the DMT service machine, select **Firewall settings**, and then select **Run** > **wf.msc**.
2. Select **Inbound Rules** > **New rule**, and then, on the **Rule Type** tab, select **Port**, and then select **Next**.
3. In the **Specific local ports** field, enter **7000**, and then select **Next**.
4. Select **Allow the connection**, and then select **Next**.
5. Select all three check boxes to apply all the rules, and then select **Next**.
6. Enter the name of the rule, and then select **Finish**.
7. Repeat these steps for outbound rules.

AX 2009 migration – Generate maps

2/18/2021 • 2 minutes to read • Edit Online

Before you can migrate your data from Microsoft Dynamics AX 2009 to Finance and Operations, you must align your source data with your target environment. This topic explains how to generate source-to-target mappings.

Before you can generate maps, you must provide the target URL, tenant URL, and service app ID to validate the connection.

> **NOTE**
> When you create a new app under Microsoft Azure Active Directory (Azure AD) in the Azure portal, you have two options, **Web API** and **Native**. Select **Native**, and grant permissions to the native Azure AD app.

Prerequisites

Before you generate the data maps between the source and target environments, you must install the Data migration tool (DMT). For more information, see AX 2009 migration - Install the Data migration tool.

Generate maps

Follow these steps to generate maps for data migration.

1. In AX 2009, in the navigation pane, go to **Data migration** > **Setup** > **Configure connections**.
2. Review the field information to verify that it's correct, and then click **Validate**.
3. After the validation is completed, close the form.
4. Under **Setup**, click **Configure and generate maps**.
5. Verify that the information in the form is correct, and then click **Validate path**.
6. After validation is completed, click **Generate maps**.

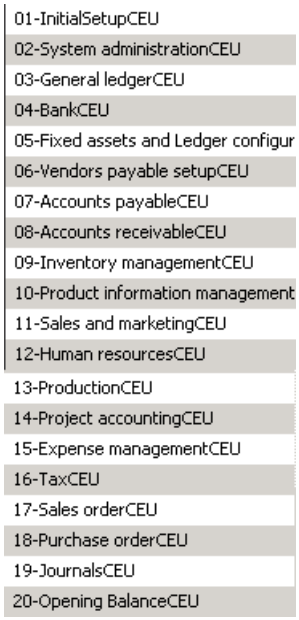
> **NOTE**
> Can you tell us about your documentation language preferences? Take a short survey.
>
> The survey will take about seven minutes. No personal data is collected (privacy statement).

AX 2009 migration – Create package templates

2/18/2021 • 2 minutes to read • Edit Online

Packages are created by following a predefined sequence. This sequence is based on the dependencies that the data entities have on each another. Because of these dependencies, when you import data entities, you must import the data entities in the defined order. Otherwise, you might encounter issues during import and configuration.

The Data migration tool (DMT) provides twenty predefined templates, as shown in the following illustration.



You can customize an existing template, or you can create your own templates as you require.

Follow these steps to view and select the entity lists that will be used in the templates for migration.

1. In Microsoft Dynamics AX 2009, click **Data migration** > **Common forms** > **Entity list**, and then click **Apply sequence**. Close the message box.
2. Verify that the correct legal entity is selected, and then, in the **Show** field, select to view either all entities or only those entities that should be considered for migration.
3. In the **Template name** field, select a template.
4. In the **Module selected** pane, select the module that contains the data entities to migrate.
5. On the **Entity details** tab, select the **Select for migration** check box for every entity line that you want to migrate.
6. Click **Apply sequence**.
7. To create a customized template, in the Application Object Tree, go to **Resources**, and create a new template in XML format.

AX 2009 migration – Create migration groups

2/18/2021 • 2 minutes to read • Edit Online

When you create a definition for migration, you determine which entities should be packaged and exported together, and then put all the entities together in a migration group. A migration group is a set of entities that must be processed in a sequence, or that can logically be grouped together. The entities in a migration group are exported together, either from the source to staging or directly to a file package. In a migration group, you also associate legal entities. Migration groups must be set up before you begin the export process.

Follow these steps to create a migration group.

1. In Microsoft Dynamics AX 2009, in the navigation pane, click **Data Migration** > **Common forms** > **Create migration group**.
2. In the **Migration group** form, press CTRL+N or click **New** to create a new migration group.
3. Enter a name for the migration group. Then press Tab to move to the **Company** field, and click **Select company**.
4. In the **Select company accounts** form, select one or more companies to add to the migration group, and then click **OK**.
5. In the **Migration group** form, click **Entity**, and select the lines to include in the migration.
6. Fill in any gaps in the field mapping, as required.
7. Click **Apply sequence**, and then close the form.

AX 2009 migration – Export packages

2/18/2021 • 2 minutes to read • Edit Online

You can use the Data Import/Export Framework (DIXF) service in Microsoft Dynamics AX 2009 to retrieve data that must be migrated to Finance and Operations. The export process is completed through a job ID. When you export, you can specify how the export job is defined. You can select the source data to export, the conversion value, and the field mapping. You can also apply a query to each source to limit what is exported.

The export package that the Data migration tool (DMT) generates can consist of one or many data entities. A typical data package consists of a group of entities for a specific task, such as import. For example, the data entities that are required for system setup might be part of one data package. The format of a data package is a compressed file that contains a package manifest, a package header, and any additional files for the data entities that are included.

Before you create a data package, plan out what should be included. In this way, you help guarantee that the correct entities, entity sequence, and fields are included.

Follow these steps to export the data package.

1. In AX 2009, in the navigation pane, click **Data migration** > **Common** > **Create migration group**.
2. In the **Migration group** form, select the migration group to export, and then click **Export now**.
3. In the **Export data** form, update the export file path as required, and then click **OK**.

AX 2009 migration – Import packages

2/18/2021 • 2 minutes to read • Edit Online

Data can be imported for a group of logically related entities that are sequenced in the correct order. You have three options for importing Microsoft Dynamics AX 2009 data that you want to migrate:

- AX 2009
- Finance and Operations

AX 2009

You can import data for migration directly from the source system. Follow these steps.

1. In AX 2009, in the navigation pane, click **Data migration**.
2. Go to **Common** > **Create migration group**.
3. In the **Migration group** form, select the migration group to export, and then click **Export now**.
4. In the **Export data** form, select the **Import package in target** check box, and then click **OK**.

Finance and Operations

You can import data for migration by using your Finance and Operations environment. Follow these steps.

1. Sign in to your environment by using an Administrator role.
2. On the dashboard, select the **Data Management** workspace.
3. Select **Import**.
4. Enter the name of the package, and then, in the **Source data format** field, select **Package**.
5. Select **Upload**, and then select the appropriate package file from the location for the data that is being imported. All the files from the package are imported.

Code migration and upgrade home page

2/18/2021 • 2 minutes to read • Edit Online

Migrate your code

To migrate your code from Dynamics AX 2012 to Dynamics 365 Finance, Supply Chain Management, or Commerce, use the "Migrate and Create Solutions" methodology in Lifecycle Services.

Key concepts

The following links (also included in the methodology) describe key concepts and steps in the migration process. The links are listed here in the order that we recommend you read them.

- Prepare to migrate code to Finance and Operations
- Model split
- Removed or deprecated features for Finance and Operations
- Deprecated APIs

Additional concepts

- Solve dependencies among models by using delegates during code migration
- How to import a SQL Server Analysis Services Project into the AOT
- Upgrades, updates, and hotfixes resources
- Workflow subsystem updates in Finance and Operations
- Migrate upgraded AX 2012 R3 sales cubes to the entity store

Prepare to migrate code to Finance and Operations

2/18/2021 • 10 minutes to read • Edit Online

This topic describes how the Lifecycle Services code upgrade service and Visual Studio tools help you migrate your code and metadata from Dynamics AX 2012 R3 to Finance and Operations. Most of these steps also apply to code migration between two major versions of Finance and Operations.

Prerequisites

You will need access to a Finance and Operations development environment using Remote Desktop, and be provisioned as an administrator on the instance. We recommend you become familiar with some of the Finance and Operations development, customization, and user interface concepts before you upgrade your code. Here are some references.

- Development tools
- Models and packages
- X++ programming language
- Extensions and Overlayering
- User interface development

Overview of the code migration process

Model split

The Finance and Operations application is split into several packages, or assemblies:

Platform Packages

- Application Platform
- Application Foundation
- Test Essentials

Application Packages

- Application Suite
- Other application packages.

ISV and customer code that is migrated from Dynamics AX 2012 R3 will be re-baselined into the correct package.

Auto-migration using the LCS Code Upgrade service

The LCS code upgrade service takes a Dynamics AX 2012 R3 model store as input and completes the following tasks:

- Converts metadata into the latest format.
- Re-baselines metadata, by moving and merging, into the right model.
- Provides an estimation to understand the effort required to upgrade the solution.
- Runs migration rules that auto-migrate parts of a solution.
- Runs migration rules that inform developers what to manually fix by using TODOs.
- Automatically checks-in the upgraded solution into your Azure DevOps project.

To configure and run the code upgrade service, see Configure the code upgrade service in Lifecycle Services

(LCS).

Manual migration steps

After you upgrade your code using the LCS code upgrade service configure your developer VM and Azure DevOps to connect to the upgraded code branch.

- Configure one-box development environments
- Configure the Azure DevOps mapping during code migration

The code upgrade service will provide with Visual Studio solutions that you can open to compile your code. A **code merge** solution for all elements that contain conflicts and an **upgraded** solutions for all your upgraded elements. Typically, you can compile the application by fixing compilation errors in the order shown below. The order is determined based on the package dependencies graph, start with the lowest package in the graph. To determine package dependencies, see Models and packages. A typical order is Application Platform, Application Foundation, Directory, ...etc., Application Suite. For each of your upgraded models:

- Fix merge conflicts.
- Fix compilation errors related to a model split (references across packages).
  - Typical error messages are:
    - <Element Type> X refers to <Element Type> Y which does not exist.
    - The name <Name> does not denote a class, a table or an extended data type.
  - For example, your overlayering customizations may be referencing elements or code that are higher in the package dependency graph:
    - A method in the Directory model is referencing a table in the Application Suite package.
    - A form in the Directory package is referencing a data source in the Application Suite package.
  - You will have to refactor your code to address these dependencies by moving model elements or business logic to higher level packages.
  - Solve dependencies among models by using delegates during code migration describes how to use delegates to solve some of these issues.
- Fix compilation errors.

After you have resolved all of the compilation errors, all packages will compile. Next, you must complete the following tasks:

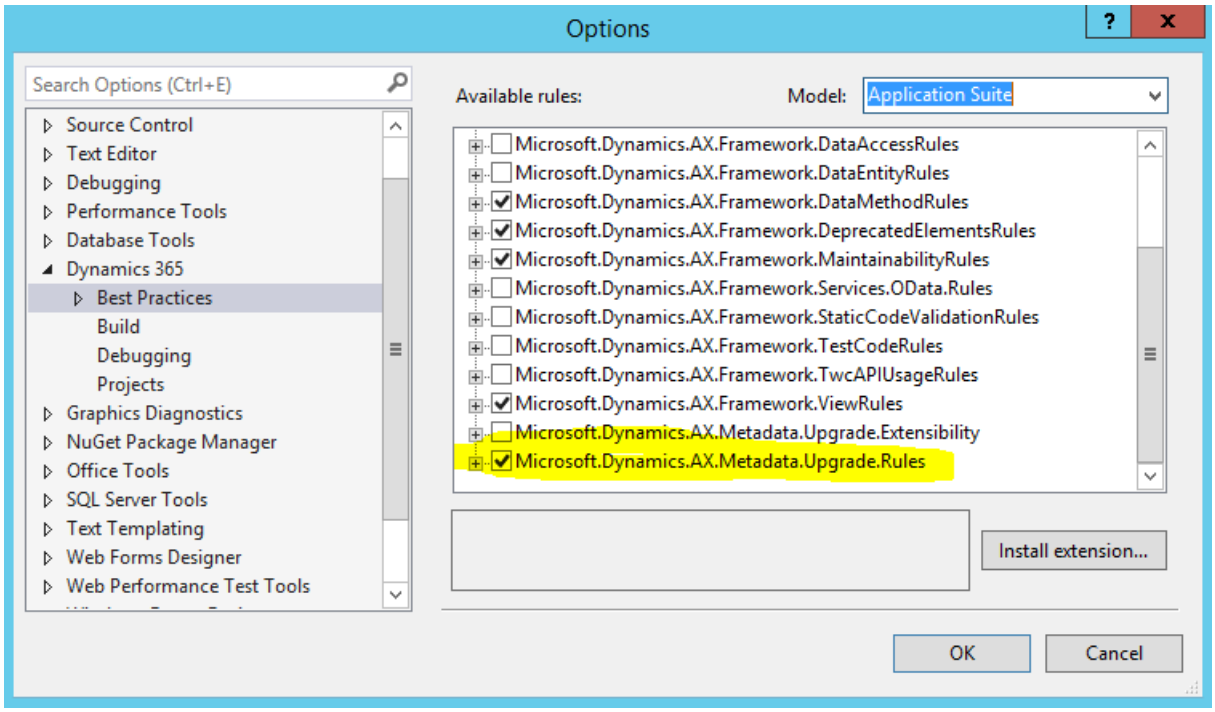
1. Address guided code upgrade TODOs and code upgrade-specific best practice warnings. Some examples and details are in the sections below.
2. Replace deprecated controls, for example, ActiveX or find an alternative.
3. Apply form patterns and sub patterns to all forms.
4. Validate that all scenarios work in multiple browsers with different sizes for custom patterns.
5. Write and run tests.

Best practice setup

In the Best Practice framework, there is a subset of Best Practice warnings that need to be resolved to complete migration. This applies if you are migrating from Dynamics AX 2012 R3 or earlier.

1. In Visual Studio, click **Dynamics 365 > Options > Best Practices**.
2. In the **Model** drop-down menu, select **Application Suite** (Repeat with all models you are working on)

These rules should be set to "ON" while migrating your solution. The setting is driven by an XML file in the AxRuleSet folder. For example, see the Application Suite xml file, BPRules.xml, located under C:\Packages\ApplicationSuite\Foundation\AxRuleSet.



To complete the migration, you need to fix all migration-specific Best Practice rules. The errors will show up in the error list as warnings. In the error list, you will see compiler warnings and best practice errors. Best Practice errors are prefixed with the text **BP**. For example, **BPErrorFormControlPatternUnspecified**.

Debugging

By default, Finance and Operations optimizes the debugging experience for the files that you are working on. As a result, when you step into a file (F11) that is not in your project, the PDBs are not loaded and you can't debug the code. To work around this, change the project debugging setting by clicking **Dynamics 365 **> **Options** > **Debugging**. Verify that the **Load symbols only for items in the solution** check box is not selected. This option is selected by default because it improves the debugger speed significantly. Another debugging setting that you may want to turn off is Intellitrace. Intellitrace collects the complete execution history of an application. It creates a lot of noise in the IDE when debugging. To turn off Intellitrace, click **Options** > **IntelliTrace** > **Enable IntelliTrace**, clear the check box, and then click **OK**. Note that Intellitrace is only available in the Enterprise version of Visual Studio.

Address code migration tasks

When metadata is migrated to Finance and Operations, multiple auto-upgrade scripts are run. In the case where developers need to complete manual migration tasks, TO DOs and Best Practices (BP) have been added.

- TO DOs are prefixed with `/* TODO: (Code Upgrade)`, and need to be fixed as a part of code migration.
- BP migration specific rules also need to be fixed as part of code migration.

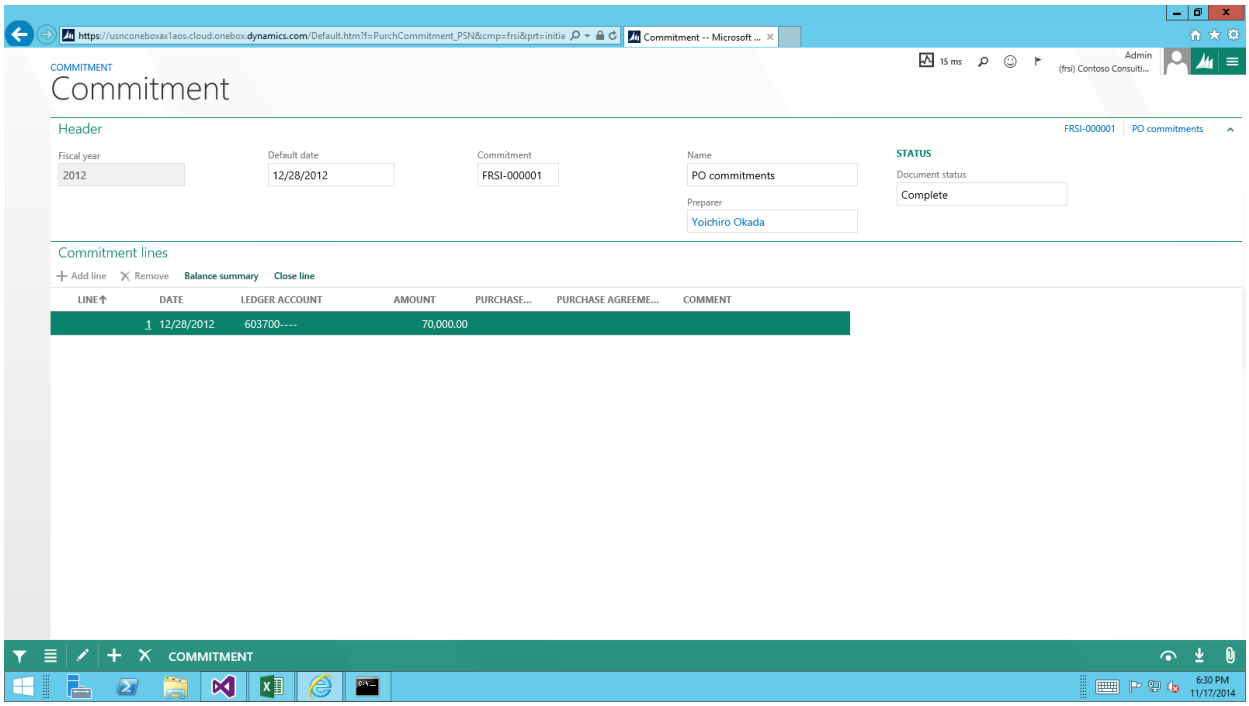
This example below uses the **PurchCommitment_PSN** form to walk you through the migration task of fixing navigation. Specifically, you will see examples of duplicate buttons and Action Pane TODOs.

Setup

1. In Visual Studio, open **Application Explorer**, and search for the form, PurchCommitment_PSN.
2. Click **OK**.
3. Right-click the project and select **Properties**.
4. In the Model property, select **Application Suite**.
5. In the Company property, select FRSI.
6. Note: The form is located in the French demo data company FRSI.

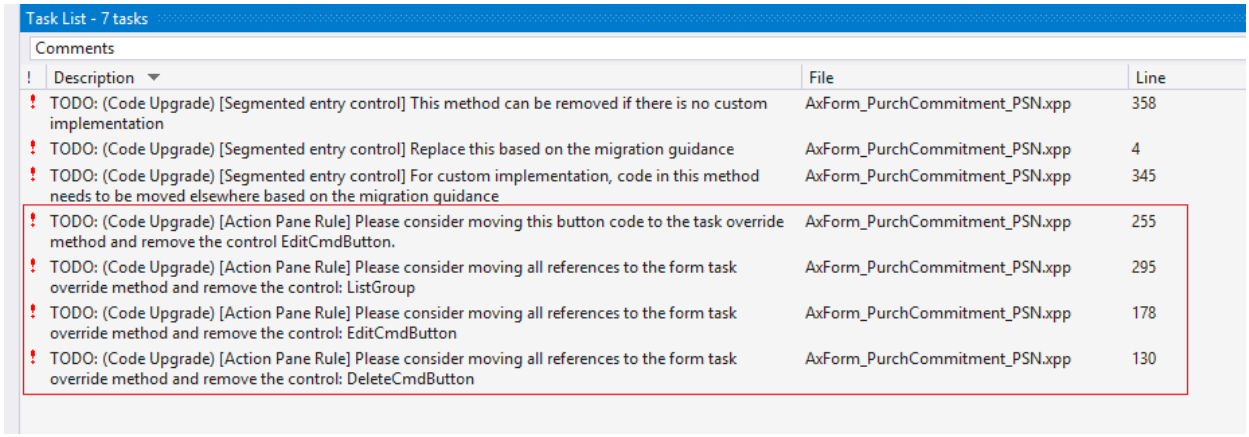
7. Press **Ctrl+F5** to see the form.

While the form looks complete, there are still code migration tasks necessary to be migration-complete.



Navigation migration tasks

1. In Visual Studio, build the project, and then on the toolbar, click **View** > **Task List**.
2. Click the **Comments** drop-down list to view the TO DO: (Code Upgrade) tasks.
3. In the list, find the ActionPane TODOs.



Code upgrade rule - Action Pane

In Finance and Operations, the following core actions are provided as system-defined buttons:

- New
- Delete
- Edit
- Export

As part of the auto-migration, the Action Pane rule is run to identify redundant buttons. To complete this part of migration, you need to manually:

- Remove or move the code.
- Delete redundant controls in the application code.

NOTE

In the section below, we will provide examples of how to migrate and modify the code on modeled buttons that replicate system-defined buttons. However, in practice, before making changes similar to those made in this article, the code must first be evaluated with respect to the scenario to determine if it is still needed. First, fix the TODO for the DeleteCmdButton, which duplicates the system-defined Delete button.

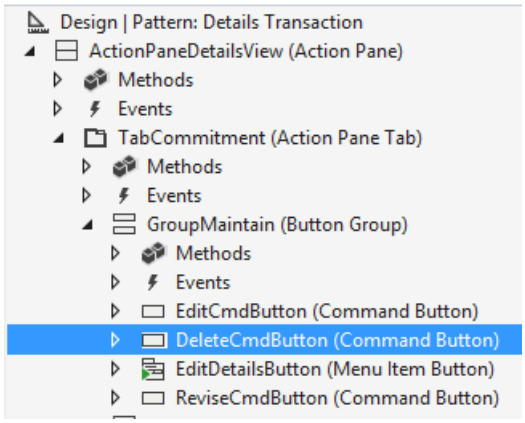
1. In Visual Studio, find the TODO shown below, and then double-click the TODO.

2. Replace the TODO and the line of code as shown below.

   - The state of the system-defined **Delete** button is controlled by the AllowDelete property on the firstmaster datasource. By setting AllowDelete to false, the delete task is kept from executing when the keyboard shortcut is used.

```
// Delete button
/* TODO: (Code Upgrade) [Action Pane Rule] Please consider moving all references to the form
task override method and remove the control: DeleteCmdButton */
deleteCmdButton.enabled(purchCommitmentHeader && purchCommitmentHeader.canDelete());
PurchCommitmentHeader_DS.allowDelete(purchCommitmentHeader &&
purchCommitmentHeader.canDelete());
```

3. In the editor, find and remove DeleteCmdButton from the form design.



4. Press **Ctrl+S** to save the form.

   - Next, we will focus on the EditCmdButton that duplicates the system Edit button, handing the two TODOs associated with this button as well as removing this button.

5. In Visual Studio, find the TODO shown below, and then double-click the TODO.

6. Because the visibility of the **Edit** button is controlled by the View/Edit mode of the form, you will need to modify this code so it sets that property. Replace the TODO and the line of code as shown in the following graphic.

```
/* TODO: (Code Upgrade) [Action Pane Rule] Please consider moving all references to the form task
override method and remove the control: EditCmdButton */
editCmdButton.enabled(purchCommitmentHeader && isInDraftOrUnderRevisionStatus &&
!isInWorkFlowReviewState && !isLineReferenced);

if(purchCommitmentHeader && isInDraftOrUnderRevisionStatus && !isInWorkFlowReviewState &&
!isLineReferenced)
{
    element.design().ViewEditMode(ViewEditMode::Auto);
}
else
{
    element.design().ViewEditMode(ViewEditMode::View);

}
```

7. Double-click the other TODO for this button.

8. Inspect the code on the modeled **Edit** button. This logic will need to be moved to the form's task() method.

```
[Control("CommandButton")]
class EditCmdButton
{
    /* TODO: (Code Upgrade) [Action Pane Rule] Please consider moving this button code to the task
override method and remove the control EditCmdButton. */
    void clicked()
    {
        if (purchCommitmentHeader.WorkflowApprovalState ==
            PurchCommitmentWorkflowApprovalState_PSN::Approved)
        {
            if (Box::yesNo(strFmt("@SPS2140", purchCommitmentHeader.CommitmentNumber),
                DialogButton::No) == DialogButton::Yes)
            {
                super();

                PurchCommitmentHeader_PSN::setWorkflowState(purchCommitmentHeader.RecId,
                    PurchCommitmentWorkflowApprovalState_PSN::NotSubmitted);
            }
        }
        else
        {
            super();
        }
    }
}
```

9. On the left side of the Visual Studio designer, right-click **Methods** > **Override**, and select **Task**, to add an override for the form's Task method.

10. Update the task method as shown below so that the code from above is triggered when the system-defined **Edit** button is clicked.

```
///
    ///
    ///
    ///
    ///
    public int task(int _taskId)
    {
        #Task
        int ret;

        switch (_taskId)
        {
            case #taskEditRecord:

                if (purchCommitmentHeader.WorkflowApprovalState ==
PurchCommitmentWorkflowApprovalState_PSN::Approved)
                {
                    if (Box::yesNo(strFmt("@SPS2140", purchCommitmentHeader.CommitmentNumber),
DialogButton::No) == DialogButton::Yes)
                    {
                        ret = super(_taskId);

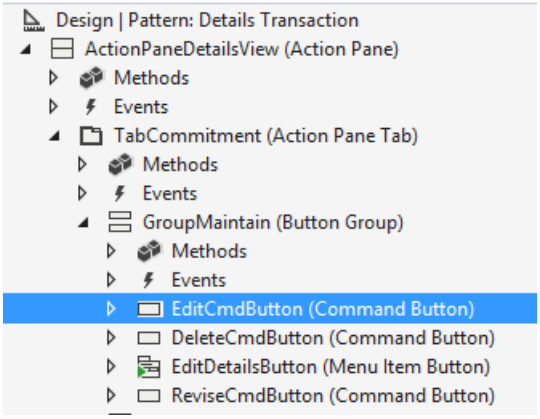
                        PurchCommitmentHeader_PSN::setWorkflowState(purchCommitmentHeader.RecId,
PurchCommitmentWorkflowApprovalState_PSN::NotSubmitted);
                    }
                }
                else
                {
                    ret = super(_taskId);
                }

                break;

            default:
                ret = super(_taskId);
                break;
        }

        return ret;
    }
```

11. In the Editor, find and remove the **EditCmdButton** from the form design.



12. Press **Ctrl+S** to save the form.

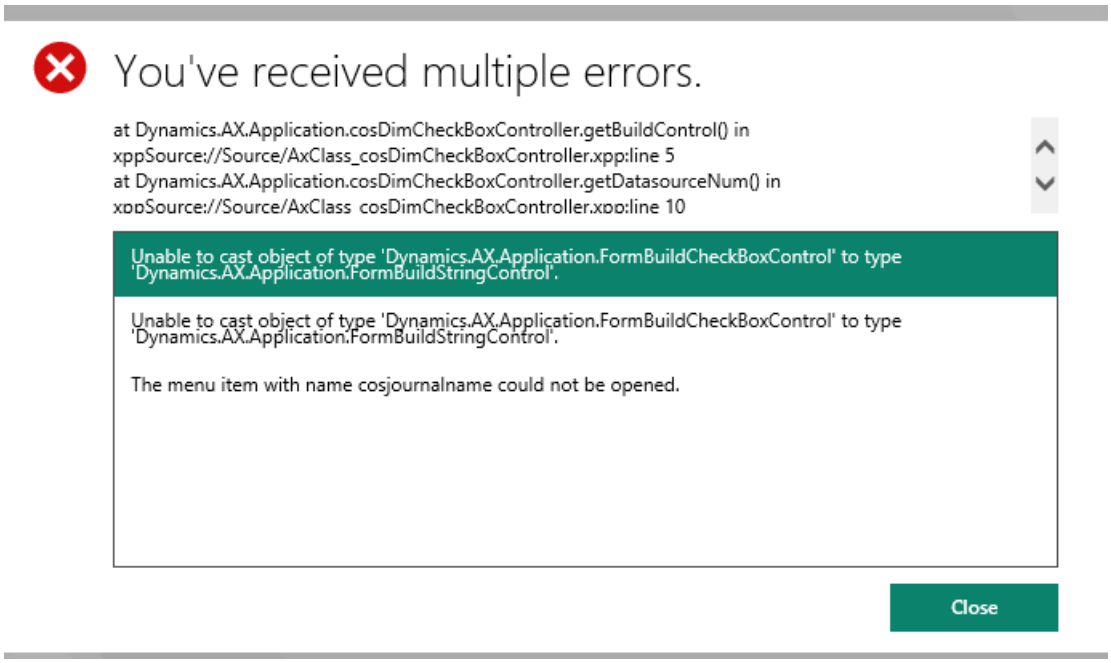
13. Press **Ctrl+F5** to view the form. Notice the **Delete** and **Edit** buttons in the **Commitment** tab have been removed.

Resolve casting exceptions

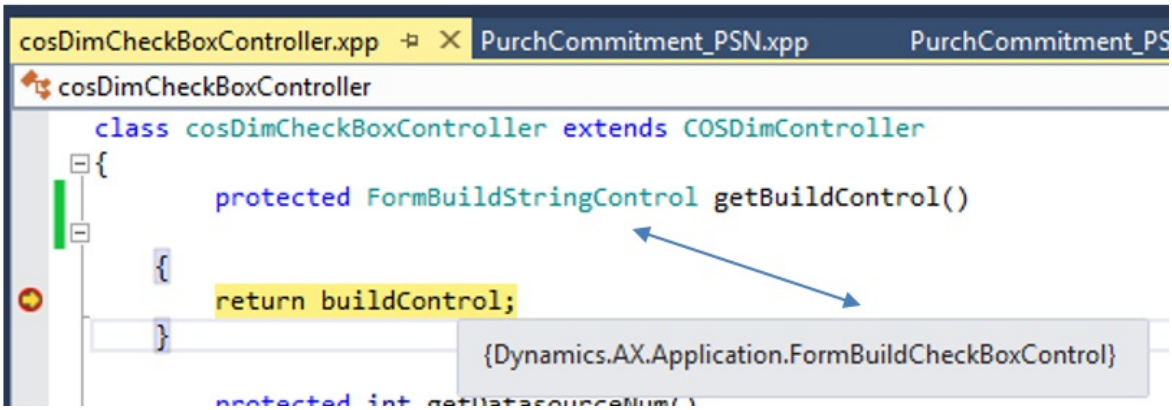
In Finance and Operations, X++ is completely intermediate-language (IL) based and therefore has a stricter runtime type behavior than the interpreted Dynamics AX2 012. This stricter runtime type behavior can generate exceptions in migrated Dynamics AX 2012 R3 metadata. It is likely you will encounter these exceptions during your migration. The casting exceptions can be raised in different runtime scenarios, such as down-casting, casting runtime to design time objects, and side-casting. In the section below, we will walk through an example where a form, CosJournalName, is generating controls at runtime, and has a type mismatch which causes a .NET exception because it is strongly typed.

Example: Side-casting exception

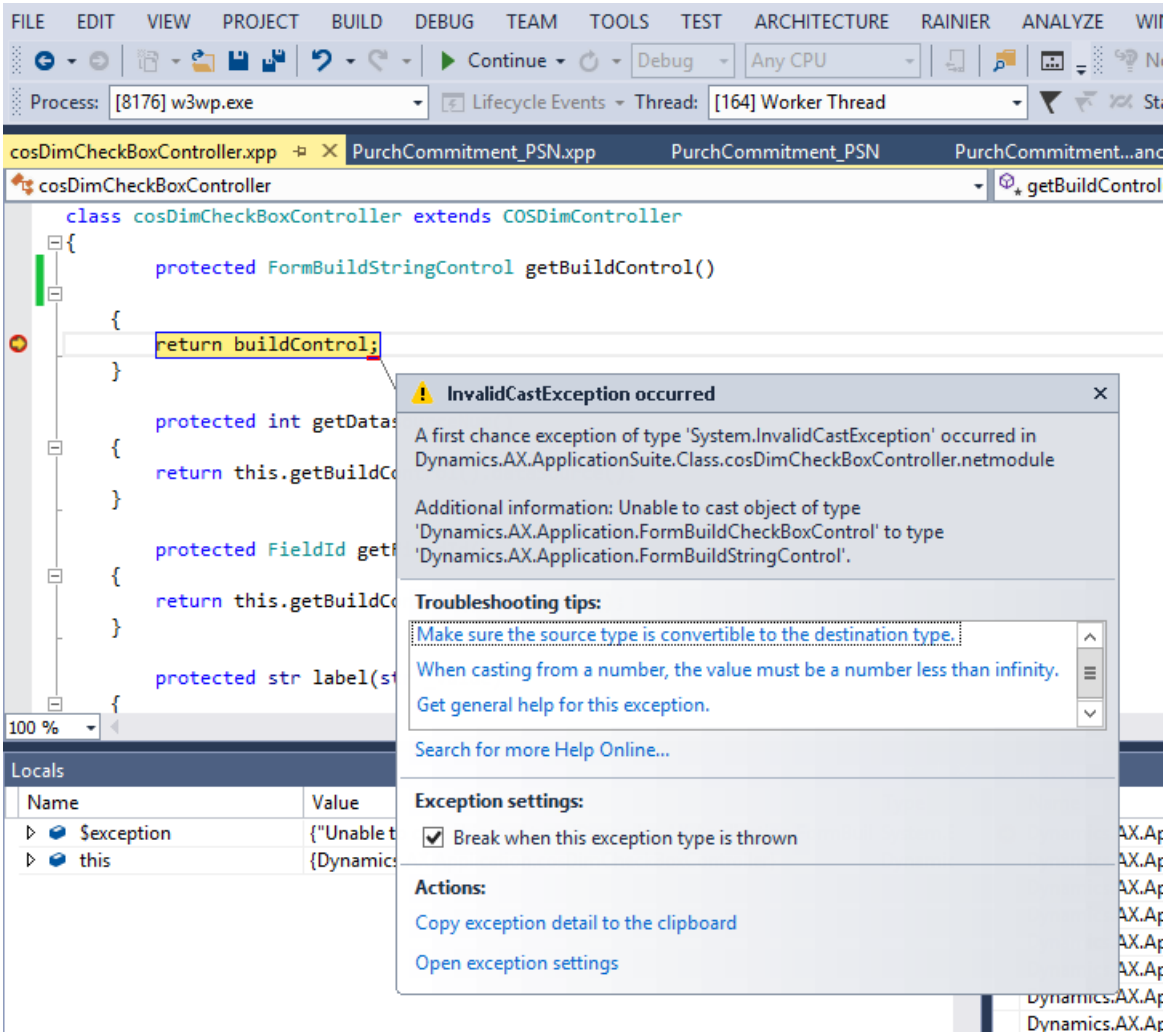
1. In Visual Studio, select and right-click **Project Properties**, and verify that USMF is the default company.
2. Add the display menu item CosJournalName to your project, and set the menu item as your Startup object.
3. Add the CosJournalName form to your project.
4. Add the cosDimCheckBoxController class to your project.
5. Rebuild your project.
6. Press **Ctrl+F5** to run the form.
7. Note that you will get an exception, similar to the following, when running the form.



8. Right-click the class, cosDimCheckBoxController, and then select **View Code**.
9. Set a breakpoint on the cosDimCheckBoxController::getBuildControl().
10. Press **F5**.
    - The breakpoint will be hit. This is where the casting error occurs. The reason for the casting error is because we are trying to return a control of type: FormBuildCheckboxControl and the object is expecting FormBuildStringControl.
11. Hover over the buildcontrol to see the type and notice the differences.



12. Press **F10** to hit the exception.

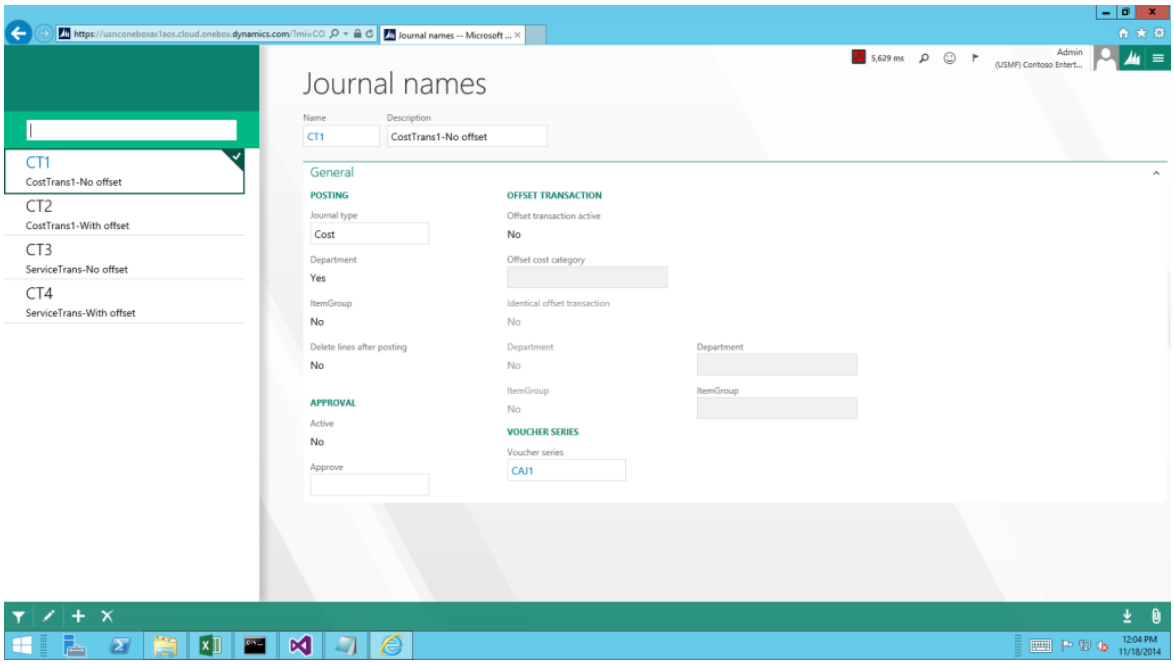


13. Stop debugging.

14. To fix the exception, change the method declaration from FormBuildStringControl to FormBuildCheckBoxControl.

```
protected FormBuildStringControl getBuildControl()
protected FormBuildCheckBoxControl getBuildControl()
```

15. Rebuild the project, and press **Ctrl+F5**. The form should open successfully because the casting error is resolved.



Migrating context menus and mouse double-click code

Refer to these topics to migrate code Dynamics AX 2012 that deals with context menus and mouse double-click actions.

- Code migration - Context menu code
- Code migration - Mouse double-click logic

Configure the Azure DevOps mapping during code migration

2/18/2021 • 2 minutes to read • Edit Online

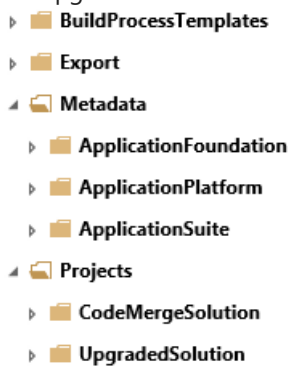
This tutorial shows how to map your development box to the Azure DevOps project after the Lifecycle Services (LCS) code upgrade service has completed.

The LCS code upgrade service automatically checks your upgraded code into Azure DevOps. You will then need to map your development box to the upgrade folder/branch in your Azure DevOps project (The name of the upgrade folder/branch depends on the version you migrated to). Within your upgraded folder, you will find three folders:

- Export
- Metadata
- Projects

Key concepts

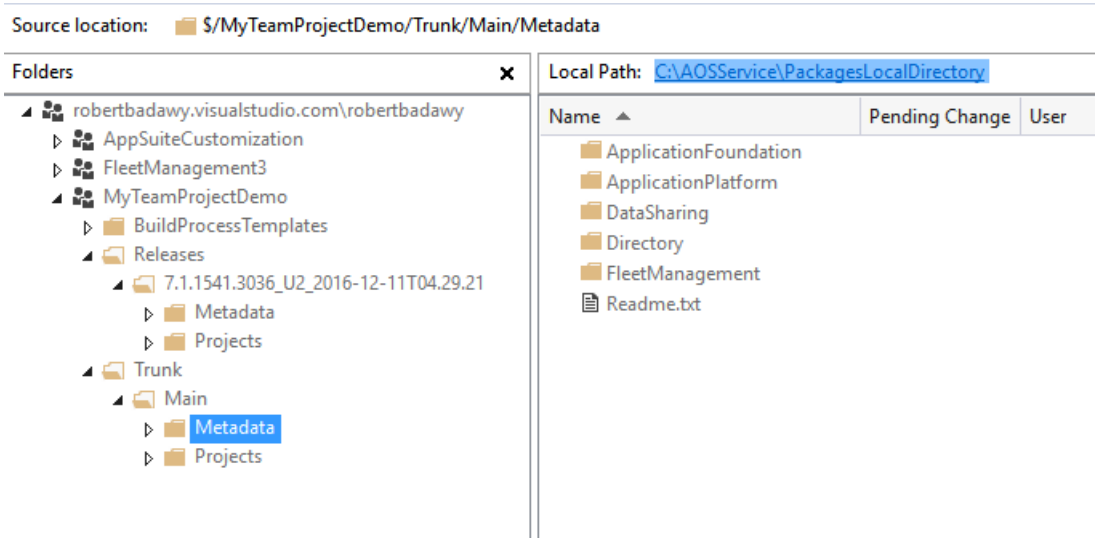
- **Export** is the project that contains the XML files after exporting from Microsoft Dynamics AX 2012. This project is your metadata in XML format before it is upgraded. This project is only relevant if you are upgrading from Dynamics AX 2012.
- **Metadata** is your upgraded code (metadata XML file).
- **Projects** are two solutions that you can use during upgrade. One solution, CodeMergeSolution, is the solution that contains projects with the elements that have conflicts and need to be resolved. The other solution, UpgradedSolution, contains a collection of projects, one for each upgraded model. For example, in Azure DevOps, you should see something like the following structure.



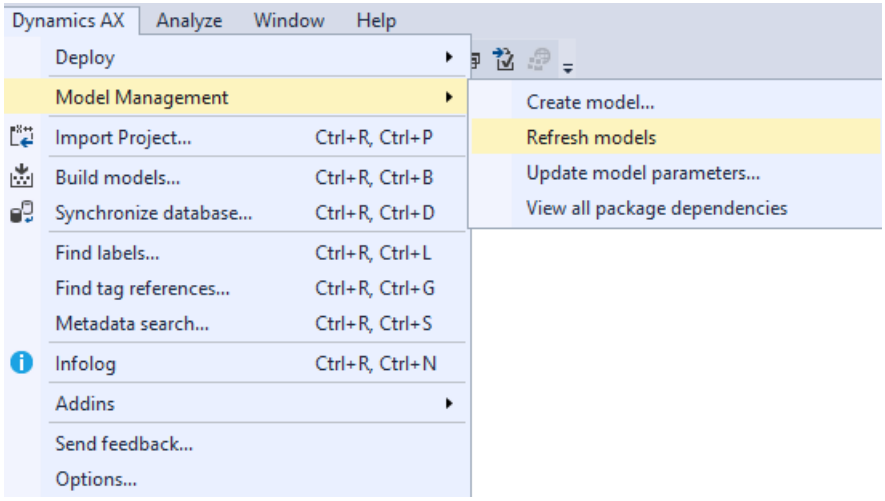
Map Azure DevOps to your development box

1. In Visual Studio, connect to your account by going to **Team explorer** > **Select Team Projects** > **Servers** > **Add.**
2. Enter the URL to your team project. Select **Close**.
3. Make sure the Azure DevOps account shows up. On the right, choose the project that you want to work on. Select **Connect**.
4. Now you need to map your workspace to the Azure DevOps folders. Go to the **Source Code Explorer** and do this mapping:
   a. Projects >
      - For **Visual Studio 2015** : C:\Users\<username>\Documents\Visual Studio 2015\Projects
      - For **Visual Studio 2017** or newer : C:\Users\<username>\source\repos

b. Metadata > C:\AOSService\PackagesLocalDirectory
   - On cloud VMs, this folder is located on the I:\, J:\ or K:\ drive
   - On earlier versions, this folder is C:\packages
   - **Important**:
     - If you are migrating from Dynamics AX 2012 R3 or earlier, you will be mapping to the metadata folder under the **Main** branch.
     - If you are migrating between two product versions, you will be mapping to the metadata folder under one of the **Releases** branch.



After you have mapped these folders, you can synchronize the code to your local box. Right-click **Metadata** and select **Get latest**. Similarly synchronize the Projects folder. After synchronizing the metadata folder, refresh your models in Visual Studio from **Finance and Operations** > **Model Management** > **Refresh Models**.



You are now ready to open your projects, resolve conflicts, build, test, and complete your code migration.

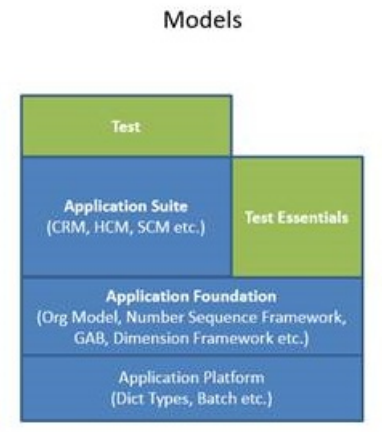
Model split

2/18/2021 • 3 minutes to read • Edit Online

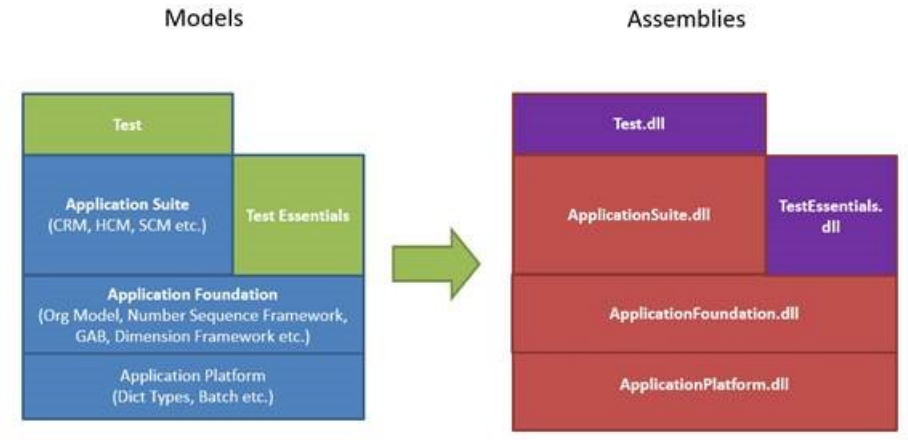
This topic explains the split of the stack into three main models - the Application Platform, the Application Foundation, and the Application Suite.

Overview

Developing modular code is the driving force behind the model split. Splitting the stack into multiple models provides many benefits, including faster compile time and a greater distinction between partner's IP in production. There are three main models: the **Application Platform**, the **Application Foundation**, and the **Application Suite**.



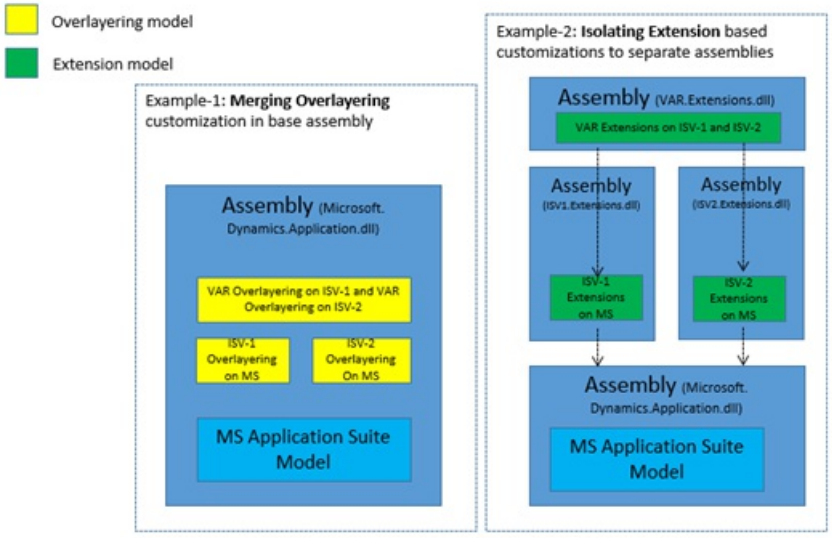
The **Application Platform** is the lowest model and contains the lowest level elements that interface with the kernel. The **Application Object Server** (**AOS**) can be started with only the **Application Platform**. The **Application Foundation** sits atop the **Application Platform** and contains framework functionalities that are shared by all applications. Finally, the **Application Suite** sits atop the **Application Foundation** and contains application specific elements. The Model Breakdown table in the appendix provides examples of components in each of these models. Each model is compiled into its own assembly with dependencies on lower layer model assemblies. The **Application Platform** does not depend on any other models. This implies a direct mapping of the model to an assembly.



Developing in the modular stack allows changes to be made in the **Application Suite** and compiled without touching the rest of the stack. Only models with new changes need to be compiled, greatly reducing compile time. More information can be found in the "Model Breakdown" section at the end of this article.

Customizing models

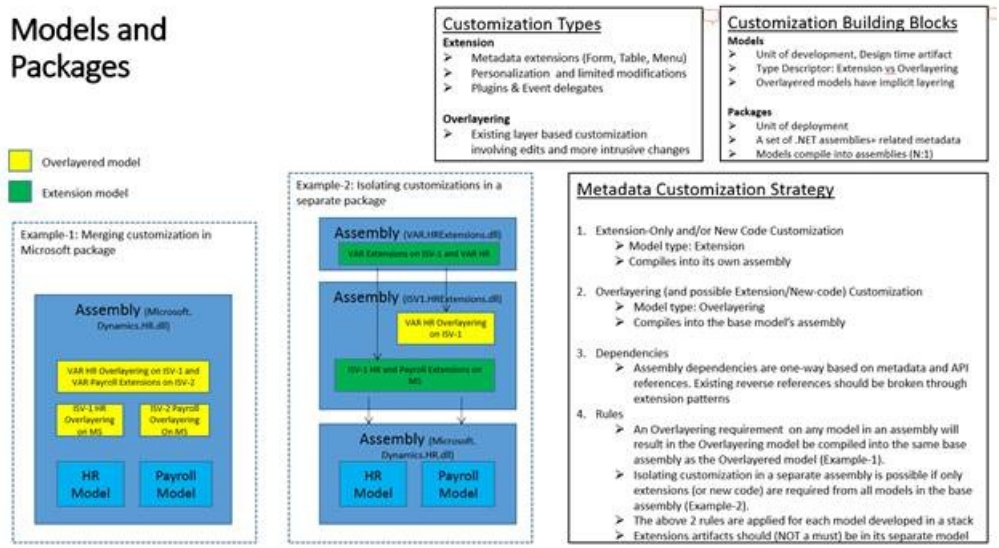
There are two methods for customizing: overlayering and extensions. Overlayering allows for changes to be made at multiple layers that alter, or overlay, elements in models at lower levels. Extensions allow for new elements to be added or code to be attached to element events or plug-in points. The type of customization used impacts how a model will be compiled and ultimately packaged. One or more models are compiled into an assembly. An assembly, its non-code metadata, and its compiled artifacts, form a package. A package is an independent deployable unit. A model that contains only extension customizations can be compiled into its own assembly and be deployed in its own package. A model that contains any overlayering must be compiled into the assembly based on the overlayed model.



Using extensions has several advantages, including:

- For application lifecycle management purposes, you need to manage only your extension artifacts.
- Building a customization does not require you to recompile the entire application.
- In the cloud, Microsoft can install, patch, upgrade, and change internal APIs without affecting your customizations.
- You can service your solutions independently without concerns about other customizations.

There are currently support code extensions, table extensions, form extensions, menu extensions, and enum extensions. The Extensions section in Customize through extension and overlayering and Customize model elements through extension provide a more detailed explanation on how to use extensions. Extensions should be used on supported elements wherever possible and are best applied when no change to existing Microsoft code is needed. A change to mask a method's functionality requires overlayering to change the code itself. Overlayering should be in areas not covered by extensions and when the customization alters the base functionality. The illustration below summarizes differences between the two customization strategies.



Model breakdown

Model	Concept
Application Platform	The Application Platform interfaces to kernel functionalities that are application logic agnostic. The AOS can be started with just this model. • AIF base objects • Batch • Form base objects • RunbaseSysOperations* base objects • DictXX objects • Appl, Info, Global, ClassFactory • Data access objects • Helper Classes • ENUM/EDT/Macros/ConfigKey/LicenseCode

Application Foundation	• Application foundation features:
	  ◦ Dimension framework
	  ◦ Global Address Book
	  ◦ Number Sequence
	  ◦ OrgModel
	• Feature areas:
	  ◦ Business Intelligence
	  ◦ Reports
	  ◦ Upgrade framework
	  ◦ Security
	  ◦ E-Signature
	  ◦ Data Import/Export
	  ◦ Workflow
	• SYS objects:
	  ◦ Best Practices
	  ◦ CheckList
	  ◦ Policy
	  ◦ RecordTemplate
	• Miscellaneous:
	  ◦ Currency
	  ◦ Unit of Measure

Application Suite	• Supply Chain Management • Human Capital Management • Professional Services, etc.

NOTE

Can you tell us about your documentation language preferences? Take a short survey.

The survey will take about seven minutes. No personal data is collected (privacy statement).

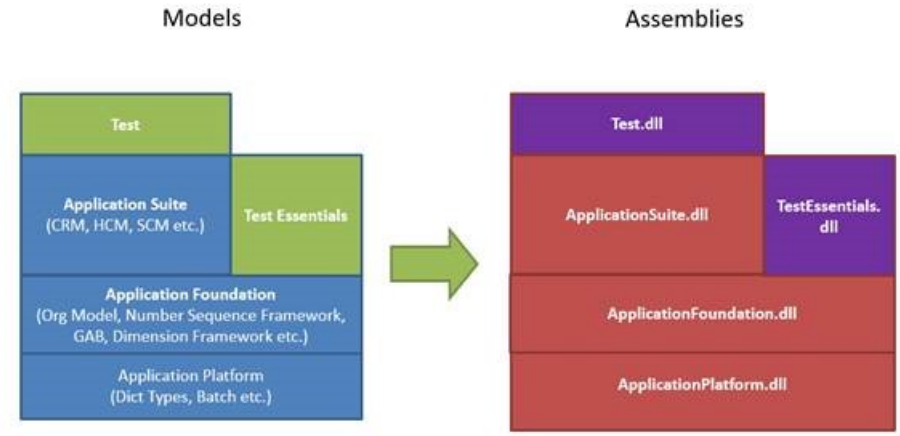
Solve dependencies among models by using delegates during code migration

2/18/2021 • 6 minutes to read • Edit Online

This topic explains how delegate methods serve as a means for defining a contract between the delegate instance and the delegate handler.

Overview

Finance and Operations is split into several models, with each model in separate package. The principal 3 models are Application Platform, Application Foundation, and Application Suite. With the model split, a hierarchy has been created where a higher model can take dependencies and access elements in the models below, but not in models above. For example, in this setup, Application Suite has full access to its elements, Application Foundation's elements, and Application Platform's elements. Application Foundation can access its own elements and those of Application Platform. Finally, Application Platform can only access its own elements. To learn about models and packages, see Models and packages.



While the model split provides many benefits, it creates a problem when trying to access elements defined in higher models. Delegates are the recommended method for accessing elements in higher models from a lower model. Delegates are very similar to events in that when a delegate instance is invoked, a handler with compatible signature code is executed. This permits higher layer code, the handler, to be called by lower layer code, the delegate instance.

Create delegates and handlers

A delegate declaration must have three things:

- The delegate keyword
- Type void
- Empty method

Delegate methods serve as a means for defining a contract between the delegate instance and the delegate handler. A delegate takes no action itself. This is enforced by having a void type and having no code in the method.

```
delegate void applyDiscountDelegate(real _receiptTotal, EventHandlerResult _result)
{
}
```

Adding the **SubscribesTo** keyword to a method creates a static delegate handler. **SubscribesTo** requires the class name of the delegate, and the string name of the delegate method.

In order for a delegate to be properly handled, the delegate method declaration, the delegate instance, and the delegate handler must have the *same* method signature. For example, the delegate instance below takes two inputs, a real number and an EventHandlerResult, matching the delegate declaration and handler signatures above.

```
[SubscribesTo(classStr(SimpleTax), delegateStr(SimpleTax, applyDiscountDelegate))]
public static void applyDiscountDelegateHandler(real _receiptTotal, EventHandlerResult _result)
{
    real discountedTotal = _receiptTotal * (1-DiscountRate);
    _result.result(discountedTotal);

}
```

Due to the fact that delegates do not have a return value, an EventHandlerResult is passed as a parameter to provide access to the needed result value after the delegate has returned. This topic focuses on static delegate handlers using the SubscribesTo. The delegate functionality from Dynamics AX 2012 remains. How to use X++ Delegates in Dynamics AX 2012 is a great blog post on MSDN by Microsoft developer Marcos Calderon on delegate concepts in Dynamics AX 2012. These concepts still apply.

Example scenarios

Overlaying an existing delegate

In many cases where delegates are needed, the code that was formerly overlayed has already been moved to a delegate handler by Microsoft. In these instances, Microsoft created delegates that can be leveraged and the code can be overlayed in a similar manner in the delegate handler. In this scenario, an Independent Software Vendor (ISV) is migrating code from Dynamics AX 2012 R3 where they have overlayed the showSalesTax() method in the LogisticsEntityPostalAddressFormHandler class. After migration, the CodeUpgrade project will contain the LogisticsEntityPostalAddressFormHandler with the *Your Solution*, *Microsoft AX 2012,* and *Microsoft AX* sections to resolve for the showSalesTax() method. The commented Your Solution section shows that the showSalesTax() method was overlayed by adding an additional table to approve showing sales tax from. This overlay is shown between the <isv> tags circled in red below.

```
////Your Solution
///
/*
public boolean showSalesTax()
{
    boolean showTaxField;

    switch (this.getCallerRecord().TableId)
    {
        case tableNum(CustTable) ,
        tableNum(VendTable) ,
        tableNum(smmBusRelTable) ,
        tableNum(CompanyInfo) ,
        tableNum(InventSite) ,
        tableNum(InventLocation),
        //<isv>
        tableNum(MYISVTable),
        //</isv>
        tableNum(HcmWorker):
            showTaxField = true;
            break;

        default:
            showTaxField = false;
    }
    return showTaxField;

}
*/
```

When comparing this overlay with the code from Dynamics AX 2012, this is a simple change. The overlay has added an additional table to the switch statement.

```
////Microsoft AX 2012
/*
public boolean showSalesTax()
{
    boolean showTaxField;

    switch (this.getCallerRecord().TableId)
    {
        case tableNum(CustTable) ,
            tableNum(VendTable) ,
        tableNum(smmBusRelTable) ,
        tableNum(CompanyInfo) ,
        tableNum(InventSite) ,
        tableNum(InventLocation),
        tableNum(HcmWorker):
            showTaxField = true;
            break;

        default:
            showTaxField = false;
    }
    return showTaxField;

}
*/
```

However, the section for Finance and Operations does not appear to resemble either of the Dynamics AX 2012 code snippets.

```
////Microsoft AX 7
/*
public boolean showSalesTax()
{
    boolean showTaxField = false;

    EventHandlerResult result = new EventHandlerResult();

    this.showSalesTax_delegate(this.getCallerRecord().TableId, result);

    if (result.result() != null)
    {
        showTaxField = result.result();
    }

    return showTaxField;
}
*/
```

Upon deeper inspection, the code is calling a delegate method, showSalesTax_delegate().

```
this.showSalesTax_delegate(this.getCallerRecord().TableId, result);
```

The use of a delegate implies that code has been moved to another location. The showSalesTax_delegate() has been declared in the Application Foundation and handled in the Application Suite. To view the code that has been moved, find the delegate handler. The **Finding Delegates and Handlers** section contains methods to locate delegates and handlers. After finding the delegate handler method in the Application Suite, we see the code that has been moved from the showSalesTax() method. The same overlayered changes applied in Dynamics AX 2012 can be applied in the delegate handler.

```
[SubscribesTo(classStr(LogisticsEntityPostalAddressFormHandler),
delegatestr(LogisticsEntityPostalAddressFormHandler, showSalesTax_delegate))]
public static void onShowSalesTax_delegate(TableId _callerTableId, EventHandlerResult _res)
{
    switch (_callerTableId)
    {
        case tableNum(CustTable):
        case tableNum(VendTable):
        case tableNum(smmBusRelTable):
        case tableNum(CompanyInfo):
        case tableNum(InventSite):
        case tableNum(InventLocation):
        case tableNum(HcmWorker):
            _res.result(true);
            break;

        default :
            _res.result(false);
    }
}
```

After adding the new table to the switch statement in the delegate handler, the code will function as it did in Dynamics AX 2012.

```
[SubscribesTo(classStr(LogisticsEntityPostalAddressFormHandler),
delegatestr(LogisticsEntityPostalAddressFormHandler, showSalesTax_delegate))]
public static void onShowSalesTax_delegate(TableId _callerTableId, EventHandlerResult _res)
{
    switch (_callerTableId)
    {
        case tableNum(CustTable):
        case tableNum(VendTable):
        case tableNum(smmBusRelTable):
        case tableNum(CompanyInfo):
        case tableNum(InventSite):
        case tableNum(InventLocation):
        //<isv>
        case tableNum(MYISVTable):
        //</isv>
        case tableNum(HcmWorker):
            _res.result(true);
            break;

        default :
            _res.result(false);
    }
}
```

Adding a new delegate

In this scenario, we will modify an existing tax calculation method that resides in the Application Foundation to account for discounts created in the Application Suite. The following class in the Foundation layer calculates the tax based on the gross total.

```
public class SimpleTax
{

    public real ReceiptTotal;

    public real TaxRate;

    public real calculateTotalTax()
    {
        //   calculates tax on gross total.
        real totalTax;

        totalTax = this.ReceiptTotal * this.TaxRate;

        return totalTax;

    }
```

In the Application Suite, we have introduced the notion of discounts by adding a ProductDiscount class that contains the current discount.

```
public class ProductDiscount
{

    public static real DiscountRate;

}
```

The TaxCalculator class, in the lower Foundation layer, does not have access to the DiscountRate in the Suite layer and must use a delegate to update receipt total to use in the tax calculation. In the SimpleTax class, we create a delegate method, applyDiscountDelegate, with the state information that is needed by the handler in the signature. A delegate method is always empty because its only purpose is to define the contract between the delegate instance and the handler.

```
delegate void applyDiscountDelegate(real _receiptTotal, EventHandlerResult _result)
{
}
```

> **NOTE**
>
> The signature for the delegate declaration, the delegate instance, and the delegate handler must match. We now have to create an instance of the delegate at the point in the code where we would like the delegate handler to be run. The changes in between the <isv> tags represent the added code.

```
public real calculateTotalTax()
{
    //   calculates tax on gross total.
    real totalTax;

    //<isv>
    EventHandlerResult result;
    this.applyDiscountDelegate(this.ReceiptTotal, result);
    this.ReceiptTotal = result.result();
    //</isv>

    totalTax = this.ReceiptTotal * this.TaxRate;

    return totalTax;

}
```

With the delegate in place, we now add a handler method in the Application Suite layer that has access to the discount information.

```
[SubscribesTo(classStr(SimpleTax), delegateStr(SimpleTax, applyDiscountDelegate))]
public static void applyDiscountDelegateHandler(real _receiptTotal, EventHandlerResult _result)
{
    real discountedTotal = _receiptTotal * (1-DiscountRate);
    _result.result(discountedTotal);

}
```

Using the SubscribesTo keyword, we tie the applyDiscountDelegateHandler method as a handler to the applyDiscountDelegate delegate.

> **NOTE**
>
> There can be more than one handler per delegate. There is **not** a defined order in the processing of handler methods. If order is important, delegate handler pairs should be chained together. With the final classes below, when the calculateTotalTax() method is run, the applyDiscountDelegate is fired and handled, updating the receiptTotal to provide an accurate tax calculation.

Full Code

SimpleTax class in the Application Foundation Layer

```
public class SimpleTax
{

    public real ReceiptTotal;

    public real TaxRate;

    public real calculateTotalTax()
    {
        //   calculates tax on gross total.
        real totalTax;

        //<isv>
        EventHandlerResult result;
        this.applyDiscountDelegate(this.ReceiptTotal, result);
        this.ReceiptTotal = result.result();
        //</isv>

        totalTax = this.ReceiptTotal * this.TaxRate;

        return totalTax;

    }

    //<isv>
    delegate void applyDiscountDelegate(real _receiptTotal, EventHandlerResult _result)
    {
    }
    //</isv>
}
```

ProductDiscount class in the Application Suite layer

```
//<isv>
public class ProductDiscount
{

    public static real DiscountRate;

    [SubscribesTo(classStr(SimpleTax), delegateStr(SimpleTax, applyDiscountDelegate))]
    public static void applyDiscountDelegateHandler(real _receiptTotal, EventHandlerResult _result)
    {
        real discountedTotal = _receiptTotal * (1-DiscountRate);
        _result.result(discountedTotal);

    }

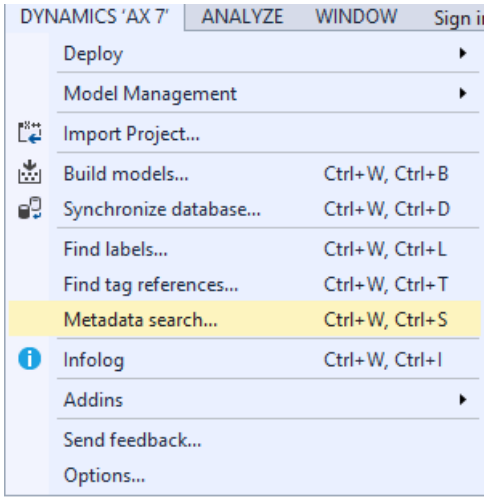
}
//</isv>
```

Find delegates and handlers

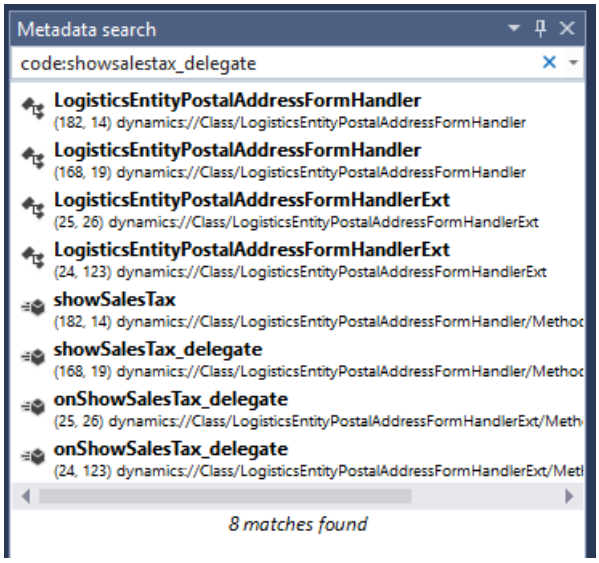
There are three key ways to find delegates and handlers

- Metadata search
- Class references
- SubscribesTo references

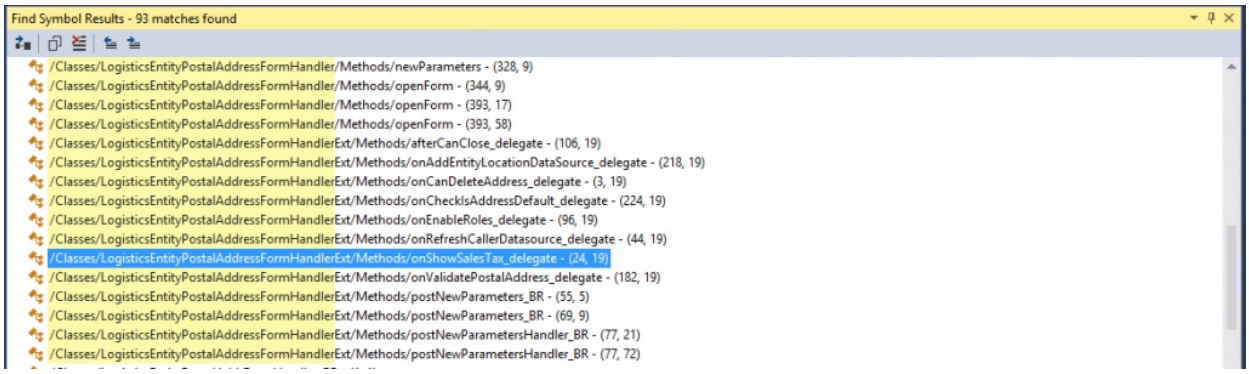
The Metadata search tool, described on the Metadata search in Visual Studio page, is the best way to find either delegates or their handlers. In Visual Studio, go to **Dynamics 365 > Metadata Search** to open the metadata search tool.



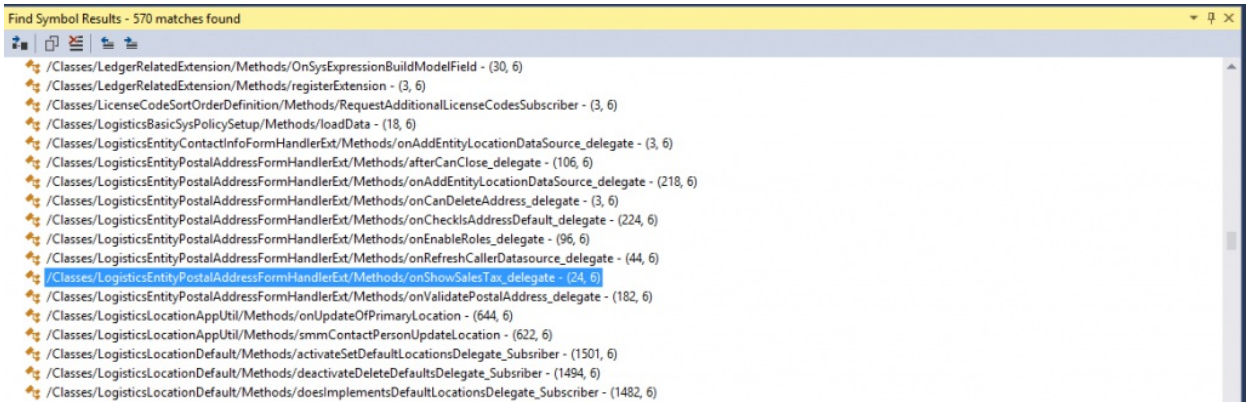
In the search field, type "code:<delegate name>" which will restrict the search to code and find any use of the delegate name, returning both the delegate and handler. Metadata search will search the entire code base and may take some time to complete, but will return any use of the search term in code.



Methods two and three can be used in parallel to the metadata search. The class where a delegate is defined can also serve as a means to narrow down the search for a delegate or handler. The SubscribesTo keyword requires the class name where the delegate was defined. Visual Studio's find references (right-click the class name > find references) will return a list of files that reference the class. This list will include both the class definition where the delegate is declared and the handler referencing the class. Finding class references is not a perfect method and will require some manual searching through class references. However, it produces a smaller subset of files and can be faster than a metadata search.



Similar to finding class references, finding all references can be done on the SubscribesTo keyword. The resulting list will include all static delegate handlers. Manually going through this list provides another means for finding static delegate handlers. This will not return dynamically declared delegate handlers that do not use the SubscribesTo keyword.



Process for moving to the latest update of Finance and Operations

2/18/2021 • 2 minutes to read • Edit Online

This topic explains the process of updating or upgrading to the latest release of Finance and Operations. It describes the overall process and supported scenarios, but it doesn't provide detailed instructions for every step of the process.

For information about the contents of each release of Finance and Operations, see What's new or changed in Finance and Operations home page.

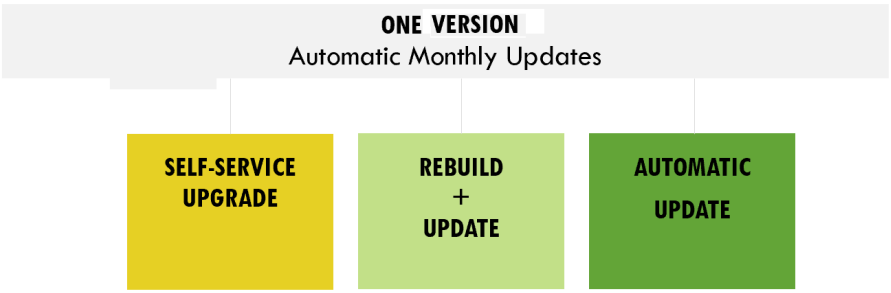
For information about One Version service updates, see the One Version service updates overview.

> **NOTE**
>
> For those looking to upgrade to Finance and Operations from Microsoft Dynamics AX 2012, please see Upgrade from AX 2012 to Finance and Operations.

Definitions

- **Upgrade** – The process of moving from one official release of Finance and Operations to the next release, for source environments prior to version 8.0. Some examples are the move from 7.1 to 7.3, or from 7.3 to 10.0.1. The process involves setup of a free sandbox environment, code upgrade, and data upgrade.
- **Update** – The process of applying a binary package to an environment to move it from one official release of Finance and Operations to the next release, for source environments starting with version 8.0. This process has lower downtime requirements and doesn't involve data upgrade.

Paths to One Version



There are three primary paths to get to the latest version of Finance and Operations. Each path is referenced below with a link to detailed steps.

Self-service upgrade

Applicable starting version: Microsoft Dynamics 365 for Finance and Operations 7.0 (RTW), 7.1 (1611), 7.2 (July 2017), 7.3.
Scope: Complex
This path involves code refactoring to Extensions, and Data Upgrade in a DevTest, Sandbox, and eventually a Production environment.

Self-service upgrade to the latest version.

Rebuild and update

Applicable starting version: Microsoft Dynamics 365 for Finance and Operations 8.0
Scope: Moderate
This path involves removing Microsoft X++ hotfixes, and creating a merged update package.

Update environments from version 8.0 to 10.0.X.

Automatic update

Applicable starting version: Finance and Operations 8.1.0+
Scope: Simple
This path involves configuring your project for continuous updates.

Configure service updates through Lifecycle Services (LCS).

Self-service upgrade to the latest version

2/18/2021 • 13 minutes to read • Edit Online

IMPORTANT

This topic applies to the following starting versions:

- Microsoft Dynamics 365 for Operations version 1611 (November 2016) (also known as version 7.1)
- Microsoft Dynamics 365 for Finance and Operations, Enterprise edition (July 2017) (also known as version 7.2)
- Microsoft Dynamics 365 for Finance and Operations, Enterprise edition 7.3

In this tutorial, you will learn how to perform these tasks:

- Understand which version to select.
- Refactor your customizations as extensions.
- Run the data upgrade in a development environment.
- Do a self-service upgrade in a sandbox user acceptance testing (UAT) environment.
- Do a self-service upgrade in a production environment.

Understand which version to select for upgrade

To align the self-service upgrade process to support continuous updates, each new release will cause the oldest release version to be discontinued.

For example, you have application version 7.3 with Platform update (PU) 23. Currently, the supported upgrade versions are 8.1.3 with PU 23, 10.0.0 with PU 24, and 10.0.1 with PU 25. When the next release, 10.0.2 with PU 26, is made generally available, it will be added to the available upgrade options, and 8.1.3 with PU 23 will be removed.

Because of this continuous process of adding a new version and removing the oldest version, we recommend that customers upgrade to the latest version that is available. In that way, you have two months in which you can upgrade your sandbox environment and then later upgrade your production environment to the same version.

If you choose to upgrade your sandbox environment to version 8.1.3 with PU 23 and Microsoft then releases version 10.0.2 with PU 26, so that version 8.1.3 with PU 23 is removed as an upgrade option, **you will be blocked** from upgrading your production environment. In this case, you must start over in the sandbox environment and upgrade to a newer supported version.

Targeted release schedule

NOTE

The dates in this table are subject to change. Upgrades are available a minimum of two weeks and a maximum of six weeks after the date of general availability (GA) for new customers. In addition, **support for upgrades that have a target version of application 7.3 ends in March 2020**.

SELECTABLE VERSIONS	GA OF THE LATEST VERSION FOR NEW CUSTOMERS	GA OF THE LATEST VERSION FOR UPGRADE
7.3 with PU 23 – PU 25 8.1.3 with PU 23 – 10.0.1 with PU 25	Week of April 8, 2019	Week of April 29, 2019
7.3 with PU 24 – PU 26 10.0.0 with PU 24 – 10.0.2 with PU 26	Week of May 13, 2019	Week of May 27, 2019
7.3 with PU 25 – PU 27 10.0.1 with PU 25 – 10.0.3 with PU 27	Week of June 10, 2019	Week of June 24, 2019
7.3 with PU 26 – PU 28 10.0.2 with PU 26 – 10.0.4 with PU 28	Week of July 8, 2019	Week of July 29, 2019
7.3 with PU 27 – PU 29 10.0.3 with PU 27 – 10.0.5 with PU 29	Week of September 17, 2019	Week of September 30, 2019
7.3 with PU 28 – PU 30 10.0.4 with PU 28 – 10.0.6 with PU 30	Week of October 11, 2019	Week of October 28, 2019
7.3 with PU 29 – PU 31 10.0.5 with PU 29 – 10.0.7 with PU 31	Week of November 29, 2019	Week of December 30, 2019
7.3 with PU 30 – PU 32 10.0.6 with PU 30 – 10.0.8 with PU 32	Week of January 17, 2020	Week of February 17, 2020
7.3 with PU 31 – PU 33 10.0.7 with PU 31 – 10.0.9 with PU 33	Week of March 3, 2020	Week of March 30, 2020
10.0.8 with PU 32 – 10.0.10 with PU 34	Week of April 8, 2020	Week of April 27, 2020

Refactor your customizations as extensions

To prepare for upgrade, you must refactor any customizations that were overlays as extensions. We recommend that you deploy a new development environment on the latest version, create a new branch in version control, and follow the guidance in Migrate from overlayering to extensions.

If you have no overlays and are already using extension for 100 percent of your customizations, we still recommend that you create a new branch for the upgrade effort in version control. If any Microsoft X++ hotfixes are installed, you must delete them from version control, because they aren't applicable to the latest version.

Run the data upgrade in a development environment

Run the data upgrade process on a copy of your source database. If your environment is already live in production, the source database is a copy of the production database. Otherwise, it's your most current database that is running the old version.

Run this process in the development environment that is running the release that you're upgrading to. This step is a validation process that is done by a developer. It helps the developer verify that the data upgrade can be successfully completed by using the specific set of customizations in the environment, without requiring any manual intervention.

To make a copy of your production database, follow the steps in Export a copy of the standard user acceptance

testing (UAT) database.

To run the data upgrade process, follow the steps in Upgrade data in development or demo environments.

> **IMPORTANT**
>
> - Data upgrade in a development environment is a required step. It helps reduce the risk of extended downtime and upgrade errors later, when you upgrade sandbox UAT and production environments.
> - Several application hotfixes might be required before you can upgrade data. Before you redeploy your existing development environment, verify whether these hotfixes are required. Install the required hotfixes, and check them in to Microsoft Azure DevOps. This step can be completed only in the old version of your development environment. For a list of the hotfixes that are required in various situations, see Upgrade data in development or demo environments.

Upgrade your Tier 2+ Standard Acceptance Test sandbox environment

When you've completed the code upgrade and have been able to do an end-to-end data upgrade in your development environment without having to manipulate data in Microsoft SQL Server, you can begin the process in your sandbox environment.

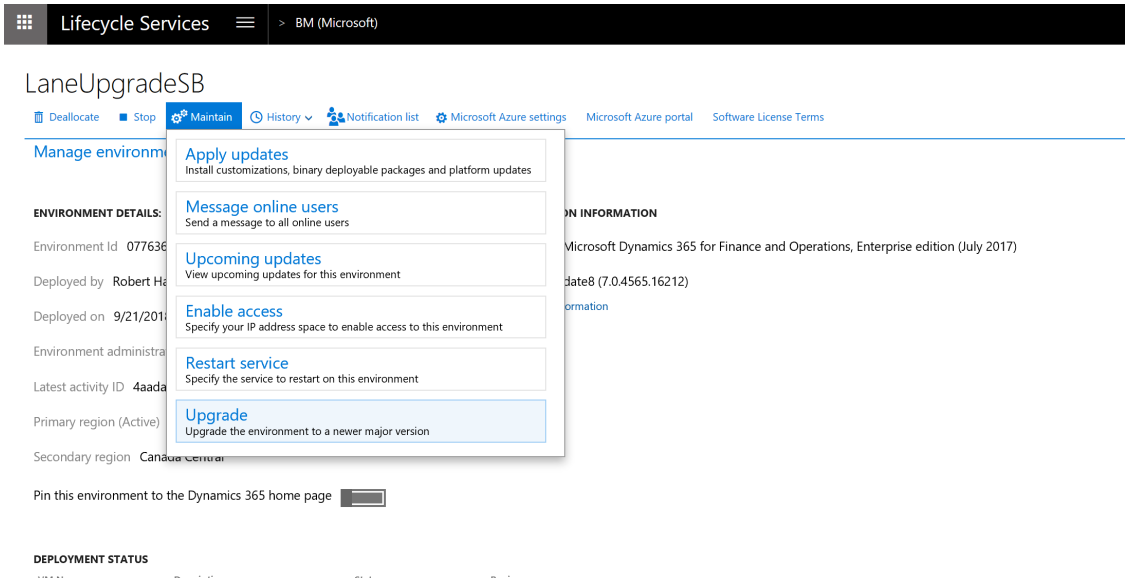
Prerequisite

Before you begin your upgrade, we highly recommend that you make sure that your sandbox environment has the latest production data. If the data set is up to date, you can have more confidence that the upgrade will work in the production environment. To complete this step, use the Refresh for training purposes tutorial.

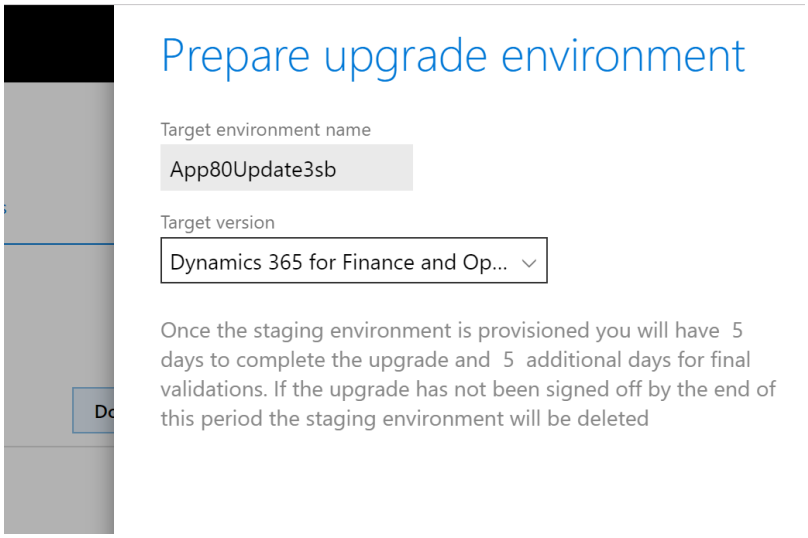
> **IMPORTANT**
>
> Changing Integrated Software Vendor (ISV) solutions, including changing the ISV license code/metadata, during upgrade is strictly not supported. If you are installing a new ISV solution or removing an existing ISV solution, you should do this before or after your upgrade. It cannot be performed during self-service upgrade.

Begin the upgrade

In your sandbox environment, on the **Maintain** menu, select **Upgrade**.



A dialog box appears, where you can select the latest combination of an application version and a platform update.

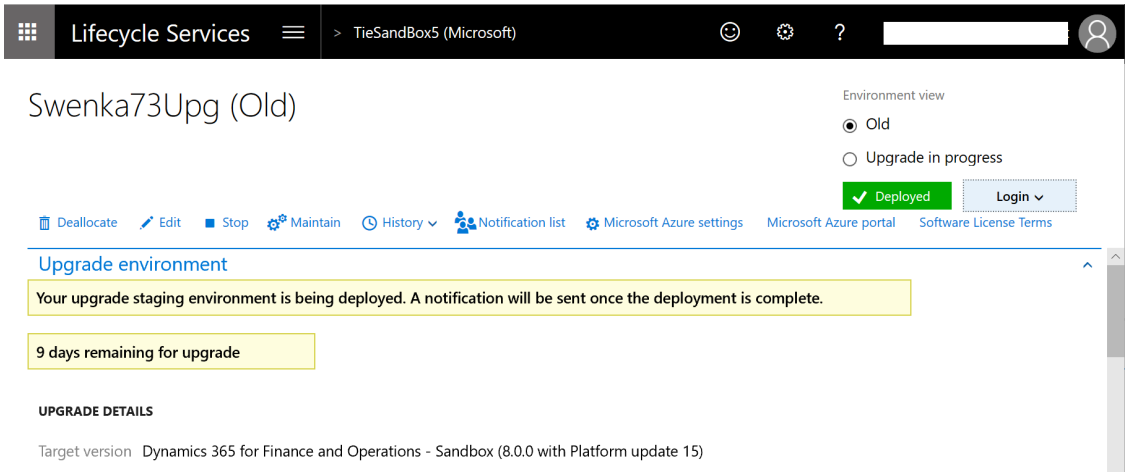


IMPORTANT

If you receive an error that states that preparation failed, see the Known issues section later in this topic.

Preparation

The environment details page is refreshed, and options for two sandbox environments now appear in the upper-right corner. By selecting the options, you can switch between your old sandbox environment and your new upgrade-in-progress sandbox environment.



The preparation stage can take eight hours or longer, because it resembles a full environment deployment. The upgrade-in-progress environment is connected to an empty Azure SQL database to speed up deployment, and it runs on the newer version that you selected to deploy.

During this time, your original sandbox environment is left untouched. There is no downtime impact at this stage.

IMPORTANT

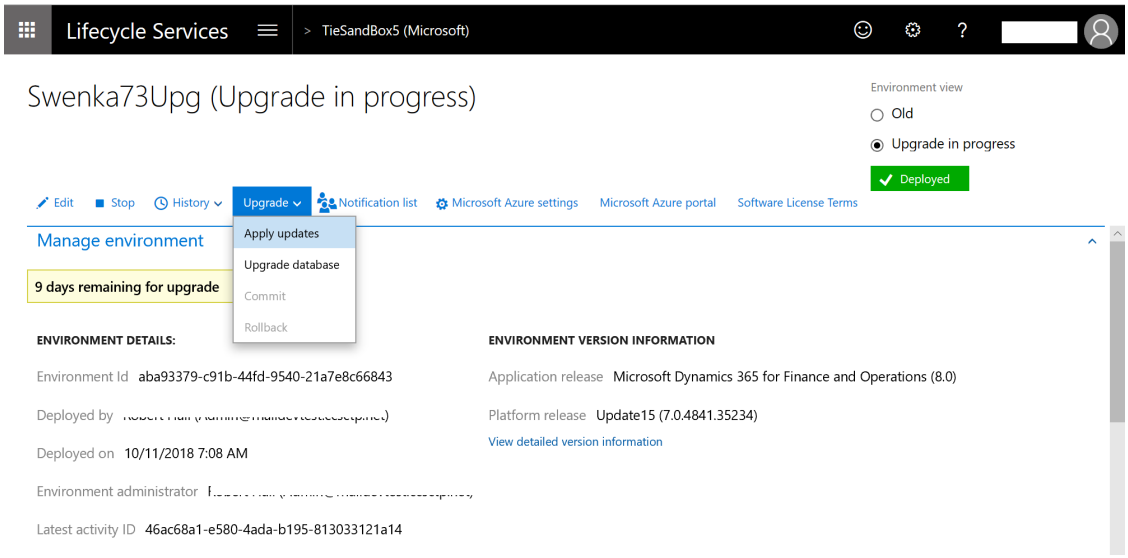
If you receive an error that states that staging deployment failed, the Microsoft Dynamics Service Engineering (DSE) team will be notified and will proactively resolve the issue for you. This issue can occur if Azure doesn't have the required resources available in your region. Microsoft DSE will work with the Azure engineers to allocate more resources. When staging deployment is successfully completed, you will receive an email.

Package application

After staging deployment is completed, go back to the environment details page, and switch to the **Upgrade in progress** view. In this view, you will now see an **Upgrade** menu.

The **Upgrade** menu includes an **Apply updates** option. You can select this option to apply your software deployable packages to the new environment. These packages include any binary packages, whether they are from an independent software vendor (ISV) solution, your own customization packages, or platform binary update packages.

We highly recommend that you apply the latest platform update as your first step. If you're upgrading to version 8.1, we recommend that you get the latest binary update package, such as 8.1.3. This package will also include the latest platform update. In this way, you help guarantee that you have the latest hotfixes that are available and help reduce errors later in the process.

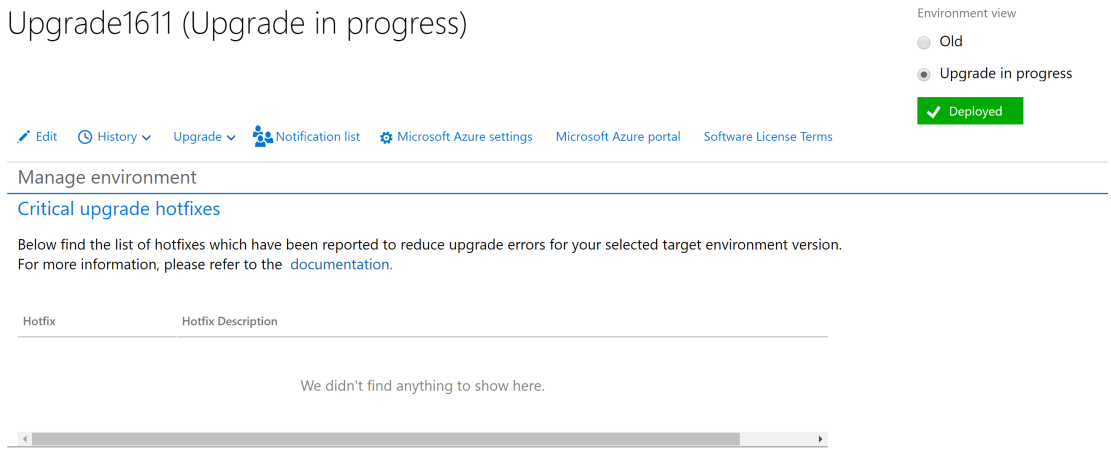


When you apply a new package to the environment, the process is the same as the process for regular environment servicing. When package application is completed, you must use the **Sign Off** button for that package before you can move on or apply another package.

If package deployment fails, you can use the **Rollback** button to reverse it. Note that this button is **not** the same as the **Rollback** option on the **Upgrade** menu.

Critical hotfixes

As use of the self-service upgrade process has increased, Microsoft has found that several hotfixes are critical to success for various target versions. For example, if you're upgrading to version 7.3, a list of Microsoft Knowledge Base (KB) articles that have consistently resolved issues with data upgrade, Retail components, or performance will appear.



The goal is that this list should be empty before you begin the **Data Upgrade** step of the process. The hotfixes in these KB articles must be installed in your upgrade-in-progress environment.

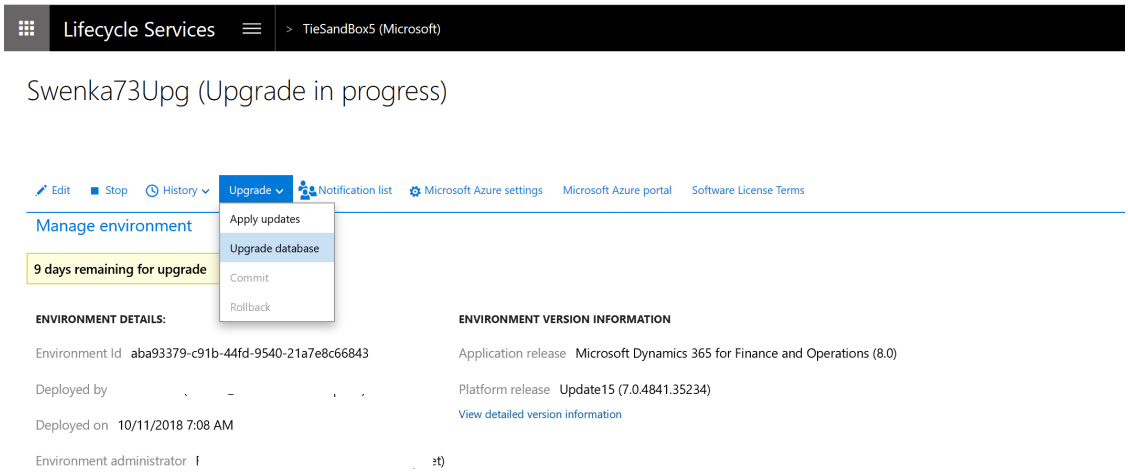
Data upgrade and environment swap

After all packages are applied to your upgrade-in-progress sandbox environment, and you've signed off on

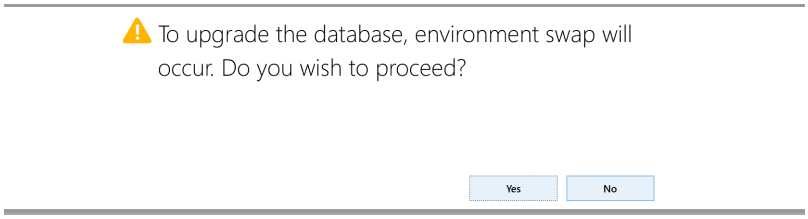
them, you can begin the data upgrade.

> **IMPORTANT**
> This stage begins the downtime for your original sandbox environment.

On the **Upgrade** menu, select **Data upgrade**.



Your original sandbox environment is turned off, and the database connection is swapped so that your new environment is connected to the original database. This process can take up to one hour.



Next, the data upgrade package for your target version is automatically applied. The time that is required to apply the data upgrade package varies, depending on the size of your database.

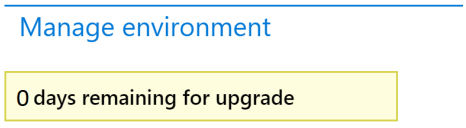
If the data upgrade fails, you must select **Rollback** on the **Upgrade** menu to restore your database to the point that it was at before the data upgrade began. Before you do a rollback, we highly recommend that you download the logs to determine the root cause of the failure. In this way, you can help guarantee that your next data upgrade execution will go more smoothly.

Upgrade days remaining

Because the self-service upgrade process provides a parallel environment at no additional cost to you, there is a time limit on how long this environment can be used. Currently, this time limit is set to 10 calendar days and begins when you select **Upgrade** on the **Maintain** menu to start the process.

What happens when the time limit expires?

There are three possible outcomes when the timer reaches 0 (zero):



- If you haven't yet started the **Data Upgrade** step, the new environment is queued for deletion. In this scenario, the upgrade-in-progress environment was provisioned, and customizations and packages were optionally applied. However, no data was upgraded, and the original environment never incurred downtime.
- If you ran the **Data Upgrade** step but then later performed a rollback, the new environment is queued for deletion. In this scenario, the old environment is the primary environment, because the data upgrade was

rolled back.

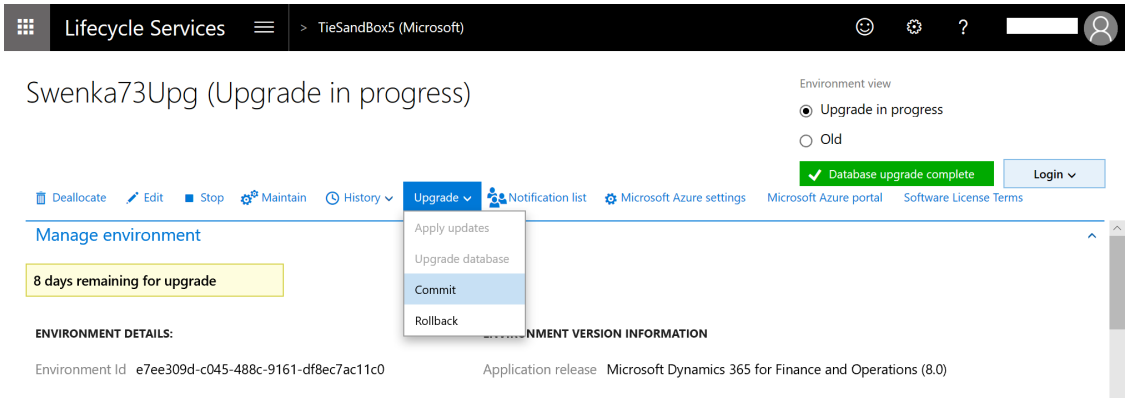
- If you've run the **Data Upgrade** step but haven't yet committed the upgrade, no actions are performed, and no environments are deleted. You can remain in this state until you commit or do a rollback. If you decide to do a rollback, and the timer is at 0 (zero), the new environment will be deleted.

> **IMPORTANT**
>
> **Rollback is only available, at maximum, for 30 calendar days. This is due to the nature of point-in-time restore.** If you try to perform a rollback after 30 days have passed, you will be forced to commit the upgrade, delete the environment, and redeploy on the previous version.

The original environment is queued for deletion only after you commit the upgrade as a success.

Commit or roll back

After the data upgrade package is applied, you can review the environment, and your users can perform business validation activities. If this validation is successful, you can mark the whole upgrade as a success by selecting **Commit** on the **Upgrade** menu. You must commit the upgrade before you can move on to your production environment. After you commit the upgrade, the original environment is queued for deletion.



If the business validation fails, you can select **Rollback** on the **Upgrade** menu. This option will do a point-in-time restore of the database, swap the database connection back to your original sandbox environment, and bring your original sandbox environment back online. The sandbox environment will then be back in its previous state. Be aware, as stated above, that rollback is only possible for up to 30 calendar days.

Post-upgrade actions

After you've signed off on your upgrade, you must update aggregate measurements. Aggregate measurements must be updated after every major upgrade. To update them, go to **System Administration** > **Setup** > **Entity Store**, and then select **Refresh**.

> **NOTE**
>
> You can schedule this update to run by using batch processing.

Upgrade production

After you've committed the upgrade in the sandbox UAT environment, you've finished the upgrade process in the sandbox environment. You can now begin the same process in your production environment. The steps that you follow are the same.

If you encounter an issue that causes excessive downtime during your production upgrade, use the Report production outage process to alert Microsoft and get help.

Upgrade additional environments

You can upgrade additional sandbox environments in the same way. You also can deallocate and delete your

other sandbox environments, and then redeploy on the newer version. By using the Refresh database self-service action, you can copy in the upgraded database from another sandbox or production environment.

Known issues

Prepare operation could not start. Microsoft support has been notified. If the issue persists, please contact support with this ID.

This known issue involves environment certificates on the Microsoft Dynamics Lifecycle Services (LCS) back end. If it affects you, submit a support ticket, and include the activity ID from the error message. Microsoft will work to resolve the issue. Microsoft is compiling a list of affected environments and intends to proactively fix this issue in the future.

I want to cancel the upgrade and try again later.

To cancel an upgrade, you can select **Cancel Upgrade** on the **Maintain** menu. The **Maintain** menu is available in the **Old** view (for the original sandbox environment), not in the **Upgrade in progress** view (for the new sandbox environment).

Upgrade failed at step X: DVT script for service model: MRProcessService.

This DVT error is intermittent and can be resolved by using the **Resume** button for your data upgrade package. When you select **Resume**, the process resumes at the same step. Microsoft is trying to reliably reproduce this issue and intends to produce a fix in the future.

Application configuration sync failed. Call to TTSCOMMIT without first calling TTSBEGIN.

This TTSCOMMIT error is intermittent and can be resolved by using the **Resume** button for your data upgrade package. When you select **Resume**, the process resumes at the same step. (This issue is fixed in PU 21.)

> **NOTE**
>
> Can you tell us about your documentation language preferences? Take a short survey.
>
> The survey will take about seven minutes. No personal data is collected (privacy statement).

Update environments from version 8.0 to 10.0.X

2/18/2021 • 7 minutes to read • Edit Online

This topic explains the steps required to update existing Finance and Operations 8.0 environments to 10.0.X application releases.

Background

Traditionally, moving to a newer application version has involved a rigorous upgrade that includes deployment of additional virtual machines, code upgrade, data upgrade, and scheduling several days in advance with the Microsoft Dynamics Service Engineering (DSE) team. You will notice that we are making the uptake of the latest version simpler, and this will continue to improve over time.

> **NOTE**
>
> We are supporting an update experience as compared to a full upgrade. This is possible because there are **no Data Upgrade or Code Upgrade** steps between the 8.0 and 10.0.X application schema. The target environments will be updated just like you would apply a Platform update.

The high-level process to update from version 8.0 to 10.0.X includes the following:

1. Deploy 10.0.X developer and build environments.
2. Branch in version control and remove any application hotfixes.
3. Recompile custom extensions and/or ISV solutions.
4. Produce a single software deployable package.
5. Merge a deployable package with the 10.0.X binary update package.
6. Deploy to target environments for validation.
7. Deploy to Production.

Deploy 10.0.X developer and build environments

Using Lifecycle Services, deploy at least one developer environment and a single, new build environment on application 10.0.X release.

On average this takes 3-4 hours and can be done simultaneously. For the build environment, **Create a new agent pool** and assign it to this environment on the **Advanced options** screen.

In Azure DevOps, visit your existing Build Definition and ensure that it is not using your new agent pool for 10.0.X. This will keep your new build agent from trying to compile older application code.

Apply the latest binary update to your build and development servers

In Lifecycle Services, go to the **build server** that you deployed in step 1. Using the **Update** tiles at the bottom of the **Environment details** page, grab the latest updates available and store it in your project's **Asset Library** using the **Save package** button. For example, this could be saving the 10.0 Platform update 24 package to the **Asset Library**.

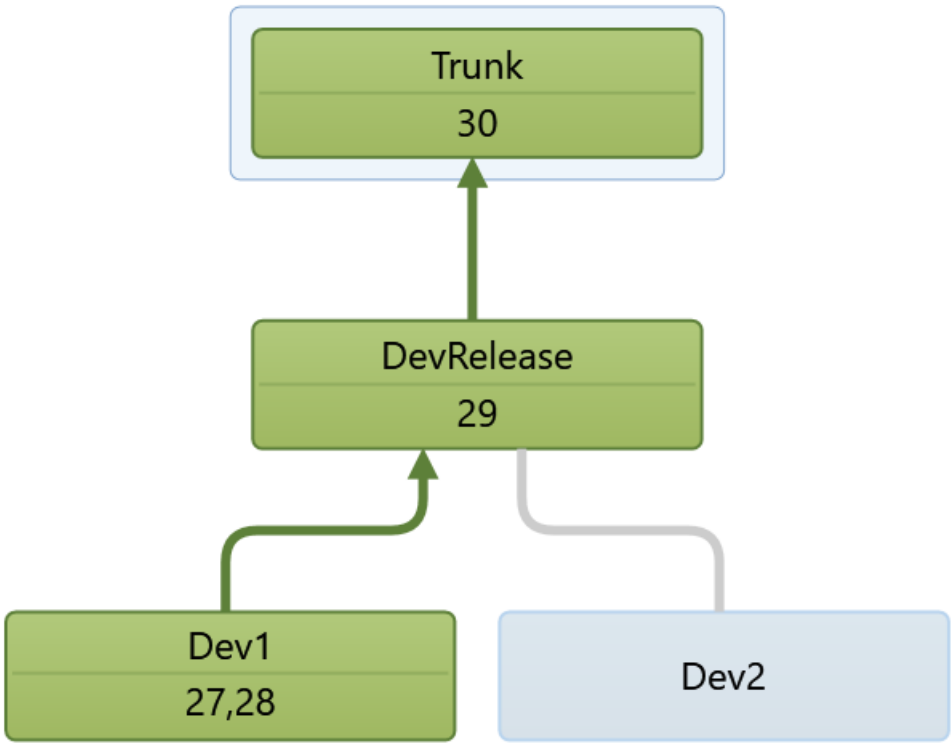
Apply this same package back to the build server where you saved the package, as well as any of the new 10.0.X developer environments you have deployed.

NOTE

We recommend taking the latest updates such as 10.0 Platform update 24 which will be available from the **Update** tiles when you deploy your 10.0 Platform update 24 build server. If your tiles show a count of "0" on the build server, then you can pull the related package from the shared asset library for your version. If your tiles show a count greater than 0, this is the better package to pull and use.

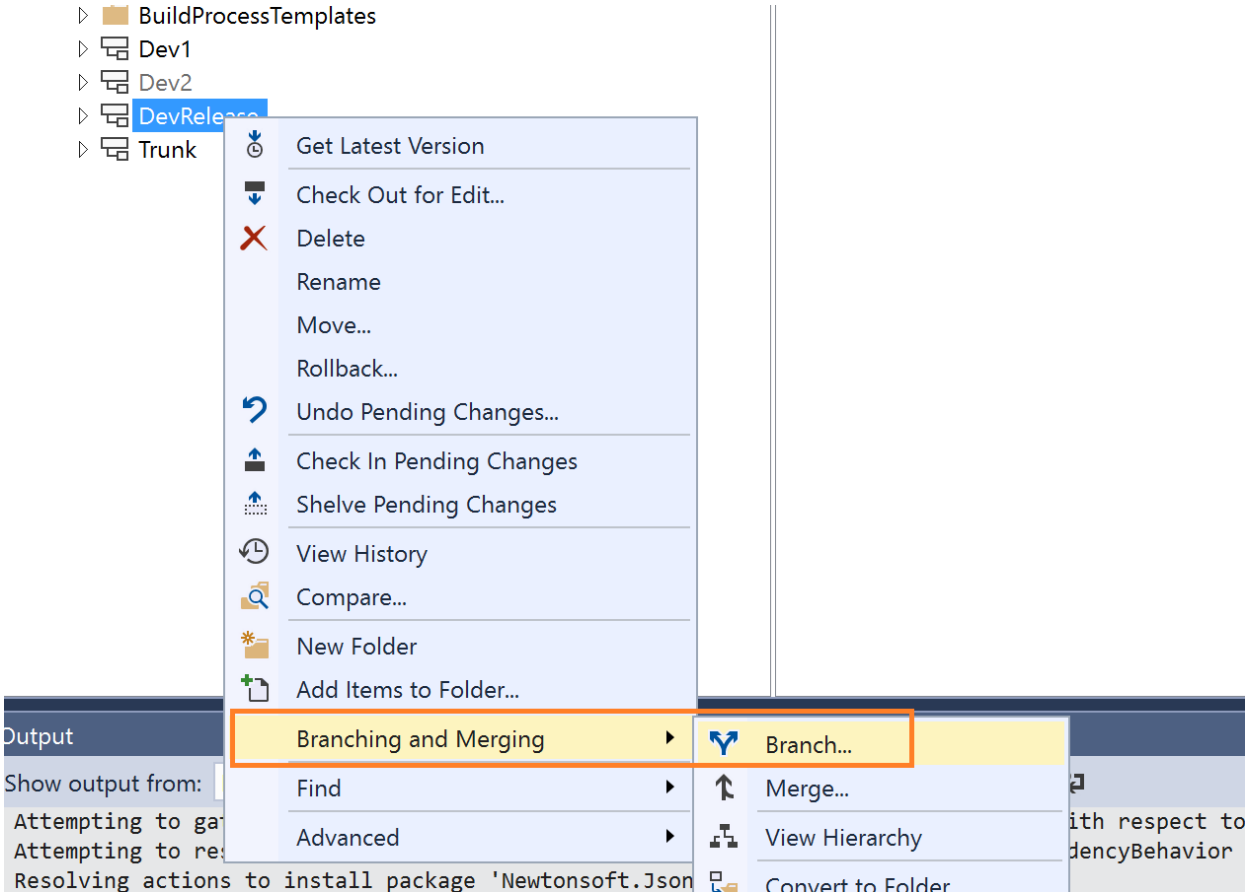
Begin branch work for version control and remove any application hotfixes

While the new environments are deploying, begin the branching work for your update. Use the following branch structure in version control as an example. Branching design varies for each customer, so be careful to adjust your steps accordingly based on how your branches are set up.



Prepare using Visual Studio

On any other development machine (other than the new ones being deployed), open Visual Studio and visit the Source Control Explorer. You will create a new branch that will be isolated for the 10.0.X update.



Next, delete any Microsoft package folders in this branch. You can have packages, such as ApplicationSuite, checked in from applying hotfixes on 8.0 which need to be removed. When only your custom packages or ISVs remain, check these changes in to the branch.

> **IMPORTANT**
> It is critical that this is done before you map version control workspaces on your new development environments. This is to avoid the deletion of the Microsoft hotfixes to cascade to your working environment and delete untouched 10.0.X application code.

Recompile custom extensions and/or ISV solutions

Now you are ready to map this branch to a new development environment and compile your extensions and ISV solutions if they have provided you with source code. If your ISVs have only provided binary packages, you can check them in to source control, and the build environment will merge the binaries with your extension package to produce a single software deployable package. Additional information on this process can be found at Deployable packages from third parties. This will help later when you merge your package with the 10.0.X binary update.

> **NOTE**
> This **step is necessary** as the 10.0.X application code is not backward compatible with 8.0 from a binary level. In future application releases this step will be optional.

Produce a single software deployable package

After you have compiled in a developer environment and there are no errors to resolve, start a build in Azure DevOps using your new 10.0.X build environment agent that was setup earlier. When this is complete, a deployable package artifact will be attached to your build results. Download this package and upload it to the

Lifecycle Services Asset Library. This single package should have all of your extensions and ISV solutions.

Merge the deployable package with the 10.0.X binary update package

In your project's **Asset Library**, locate both your new 10.0.X software deployable package (your customization package that includes your ISVs) and the 10.0.X PU2X binary update package that was saved in Step 1 at the beginning of the topic. Highlight both packages and select **Merge**. This will combine the files into a merged update package. You can now apply this package to your various test environments.

> **NOTE**
> You can't move this merged package between different Lifecycle Services projects. The merge references other packages in your Asset library, and those packages won't be found in a different project.

Deploy to target environments for validation

Using the merged update package, deploy this to your various test environments. For more on how to do this, see Apply updates to cloud environments. This merged update package can be deployed to your Tier1/OneBox environments as well as Tier-2 sandboxes. At a minimum, you must deploy this to the sandbox Tier-2 environment that comes with your subscription. After you have finished with validation, mark the merged update package as a Release Candidate.

Deploy to Production

After you have marked the Release Candidate in your Asset Library, you can schedule the deployment to your Production environment. This will follow the same process for applying other software deployable packages.

Known issues

GlobalUpdate script for service model: AOSService with error 'The specified module 'C:\Program Files\Microsoft Security Client\MpProvider'

This error is transient and can be ignored. To bypass, hit the **Resume** button from Lifecycle Services.

Deploying the 10.0.X binary update to Developer environments causes ApplicationSuite compilation errors

The package can be applied to your 8.0 environments and it will update your source code. Compiling of your extension packages should not be impacted. If you had overlayering and have removed objects from the ApplicationSuite package, and try to recompile it, you may run in to errors. Until this is resolved, please redeploy your developer environments on 10.0.X and sync in your source code from version control.

Cannot find 10.0.X binary update package on the All Binary Updates tile on the My environment details page

It was originally communicated that the package would be found on the **All Binary Updates** tile. To prevent customers who want to simply get the latest binaries for release 8.0 from accidentally updating to release 10.0.X, we have moved the binary package to the Shared Asset Library. This topic has been updated to reflect this change.

Deployment of my environment fails with error on duplicate objects

By default, in Visual Studio when an object is extended, it is created with a name of Object.*Extension1*. This name could clash if Microsoft introduces new extensions of the same object. If this occurs, your deployment will fail with an error similar to the following:

```
Exception calling "CreateRuntimeProvider" with "1" argument(s): "Runtime metadata is invalid because the
same metadata artifact has been defined in multiple assemblies. \nFirst 10 conflicting names:
SystemAdministration.Extension1. \nSee metadata events for complete list."
```

To prevent this from occurring, ensure that you compile your extensions on an 10.0.X developer machine. To resolve this issue, rename any of your extension objects with a vanity extension naming convention, such as SystemAdministration.*Customer*.

Deployment on my environment fails with error on DVTs or ETWs

There is a known issue where IIS/Application Pools are not fully restarted when the DVT or ETW step runs. The failure occurs because the DVTs are trying to connect to your environment's URL. To resolve this issue, click **Resume** on your deployment in LCS to retry the step. We are working to add a timer and automatic retry to resolve this issue.

Software lifecycle policy and cloud releases

2/18/2021 • 9 minutes to read • Edit Online

This topic outlines the lifecycle and support policies for the Finance and Operations online service.

Modern Lifecycle Policy

The Finance and Operations online service is covered by the Modern Lifecycle Policy. The Modern Lifecycle Policy covers products and services that are serviced and supported continuously. For more information about this policy, see Modern Lifecycle Policy. Licensed customers must stay current with updates to the Finance and Operations online service in accordance with the following servicing and system requirements:

- Customers purchasing subscriptions of Finance and Operations and operating on the following application versions will experience continuous updates of the Platform and Financial Reporting. Microsoft will continually update these components with the option to postpone up to 3 consecutive service updates.
    - Dynamics 365 for Operations version 1611 (November 2016)
    - Dynamics 365 for Finance and Operations, Enterprise edition (July 2017)
    - Dynamics 365 for Finance and Operations, Enterprise edition 7.3
    - Dynamics 365 for Finance and Operations, version 8.0 (April 2018)
- Platform versions maintain backward compatibility with the application versions that are supported at the time of the platform release within the application support lifecycle. For more information about platform versions, see Cloud platform monthly updates FAQ.
- Critical fixes and non-critical updates are handled in the following way:
    - **Critical fixes** – Critical fixes include security fixes and any fixes that are required to adhere to the availability service level agreement (SLA) that the service supports. Critical fixes will be made available in the latest platform update version and in the latest service update for customers operating on version 8.1. In addition, to help protect the customer and the online service, Microsoft might apply critical fixes directly to a customer's environment. If a critical fix must be applied, Microsoft will notify the customer about the required downtime window (if there will be any downtime) and apply the fix to the applicable environment. The critical fix will update the system to the latest update version.
    - **Non-critical updates** – Customers operating on the following application releases must update to the most current Finance and Operations platform and financial reporter version to deploy non-critical updates.
        - Dynamics 365 for Operations version 1611 (November 2016)
        - Dynamics 365 for Finance and Operations, Enterprise edition (July 2017)
        - Dynamics 365 for Finance and Operations, Enterprise edition 7.3
        - Dynamics 365 for Finance and Operations, version 8.0 (April 2018)

      Customers operating on release 8.1 must update to the most current service update to deploy non-critical updates.

NOTE

Application and platform releases expire at the end of the month of their software lifecycle.

Microsoft will not provide any fixes to issues on versions that have reached end of service. Microsoft will also not investigate or troubleshoot any issue that you may encounter on an older version. If you encounter an issue on a version that has reached end of service, you will be required to update to the latest update and report the issue if it persists.

All environments will continue to be operated by Microsoft. All automatic processes around your environments, such as monitoring or self-healing, will also continue as is for supported versions.

Dates and versions for application and platform releases

Table 1: Continuous update releases

For information about the new features included in each release, click the links in the **Version** column.

RELEASE	MAJOR RELEASE OR SERVICE UPDATE	VERSION	BUILD NUMBER	AVAILABILITY	END OF SERVICE
Dynamics 365 for Finance and Operations	Major release	10.0	10.0.8	April 2019	Not applicable (continuously updated)*
Dynamics 365 for Finance and Operations	Major release	8.1	8.1.136	October 2018	Not applicable (continuously updated)*

* Indicates a major release is required to be updated through service updates. Service updates are cumulative in nature and may include updates for some or all of the following components: Platform, Application, Financial Reporting, Retail, and operating system updates. You will be required to have an update that's no older than 3 service updates. The 8.1.x version series will be replaced by version 10.0, which is targeted for release in April 2019. For more information, see One Version service updates FAQ.

Table 2: Application releases

For information about the new features included in each release, select the links in the **Version** column.

RELEASE	MAJOR OR MINOR RELEASE	VERSION	BUILD NUMBER	AVAILABILITY	END OF SERVICE
Dynamics 365 for Finance and Operations	Major release	8.0	8.0.30	April 2018	April 30 2019
Dynamics 365 for Finance and Operations, Enterprise edition	Major release	7.3	7.3.11971.56116	December 2017	April 30 2019*
Dynamics 365 for Finance and Operations, Enterprise edition	Major release	July 2017	7.2.11792.56024	June 2017	April 30 2019

RELEASE	MAJOR OR MINOR RELEASE	VERSION	BUILD NUMBER	AVAILABILITY	END OF SERVICE
Dynamics 365 for Operations	Major release	1611	7.1.1541.3036	November 2016	April 30 2019
Dynamics AX	Minor release	7.0.1	7.0.1265.23014	May 2016	June 2017
Dynamics AX	Major release	7.0	7.0.1265.3015	February 2016	June 2017

* All customers must be on the latest version of Finance and Operations by April 2019. However, we are making an exception for customers who have unfulfilled extension requests that have been submitted to Microsoft. Those customers who submitted extensibility requests by January 1, 2019, will be supported on version 7.3 until their extensibility requests are fulfilled. Customers are expected to upgrade to the latest version within 90 days of the extensibility request being fulfilled. For more information, see One Version service updates FAQ.

Table 3: Platform releases

For information about the new features included in each release, select the links in the **Release** column.

RELEASE	BUILD NUMBER	AVAILABILITY	EXPIRATION DATE
Platform update 31	7.0.5457	January 2020	N/A (Continuously updated)
Platform update 30	7.0.5407	November 2019	N/A (Continuously updated)
Platform update 29	7.0.5372	October 2019	N/A (Continuously updated)
Platform update 28	7.0.5314	July 2019	N/A (Continuously updated)
Platform update 27	7.0.5286	June 2019	N/A (Continuously updated)
Platform update 26	7.0.5257	May 2019	N/A (Continuously updated)
Platform update 25	7.0.5222	April 2019	N/A (Continuously updated)
Platform update 24	7.0.5179	March 2019	N/A (Continuously updated)
Platform update 23	7.0.5126	January 2019	N/A (Continuously updated)
Platform update 22	7.0.5095	December 2018	N/A (Continuously updated / Retired)
Platform update 21	7.0.5073	October 2018	N/A (Continuously updated / Retired)
Platform update 20**	7.0.5030	October 2018	N/A (Continuously updated / Retired)
Platform update 15*	7.0.4841	March 2018	N/A (Continuously updated / Retired)
Platform update 12	7.0.4709	November 2017	November 2018
Platform update 11	7.0.4679.35176	October 2017	October 2018

RELEASE	BUILD NUMBER	AVAILABILITY	EXPIRATION DATE
Platform update 10	7.0.4641.16233	August 2017	August 2018
Platform update 9	7.0.4612.35162	July 2017	July 2018
Platform update 8	7.0.4565.16212	June 2017	June 2018
Platform update 7	7.0.4542.16189	May 2017	May 2018
Platform update 6	7.0.4509.16180	April 2017	April 2018
Platform update 5	7.0.4475.16165	March 2017	March 2018
Platform update 4	7.0.4425.16161	February 2017	February 2018
Platform update 3	7.0.4307.16141	November 2016	November 2017
Platform update 2	7.0.4230.16130	August 2016	August 2017
Platform update 1	7.0.4127.16103	May 2016	May 2017
Platform 7.0	7.0.4030.16079	February 2016	January 2017

** Platform updates 16, 17, 18, and 19 have not been made generally available.

* Platform updates 13 and 14 have not been made generally available.

Table 4: Application updates

The application updates listed below consist of a small subset of application enhancements released on top of Finance and Operations versions 8.0, 7.3, and 7.2 (July 2017). These updates do not affect the support lifecycle of the release--support is in-line with the policies for each release.

Note that application updates are not cumulative. The individual packages only contain the enhancements that were included in that specific release. However, if there is a dependency between two packages, then both packages will be included.

For information about the new features included in each update, click the links in the **Version** column.

RELEASE	VERSION	BUILD NUMBER	AVAILABILITY
Dynamics 365 for Finance and Operations	8.1.3: KB 4470000 Microsoft Dynamics 365 for Finance and Operations version 8.1.3 with Platform update 23*	8.1.227	January 2019

The survey will take about seven minutes. No personal data is collected (privacy statement).

Apply the latest platform update to environments

2/18/2021 • 7 minutes to read • Edit Online

This topic explains how to apply the latest platform release to your Finance and Operations environment.

Overview

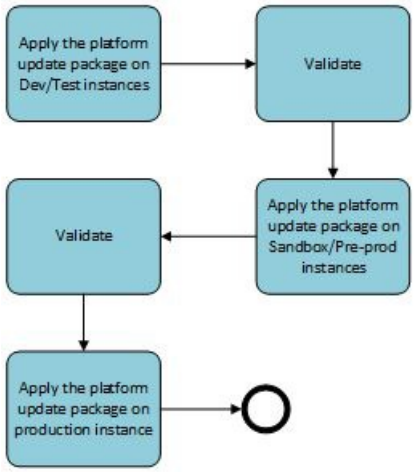
In Finance and Operations, the platform consists of the following components:

- Binaries such as Application Object Server (AOS), the data management framework, the reporting and business intelligence (BI) framework, development tools, and analytics services.
- The following Application Object Tree (AOT) packages:
  - Application Platform
  - Application Foundation
  - Test Essentials

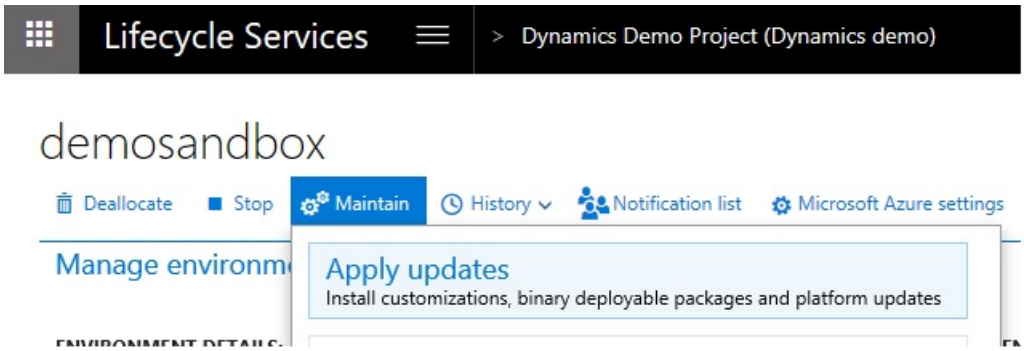
> **IMPORTANT**
>
> To move to the latest platform, your Finance and Operations implementation **cannot** have any customizations (overlayering) of any of the AOT packages that belong to the platform. This restriction was introduced in Platform update 3, so that seamless continuous updates can be made to the platform.

Overall flow

The following illustration shows the overall process for upgrading the platform to the latest update.



If you are already running on Platform update 4 or later, updating to the latest release is a simple servicing operation. After the platform update package is in your LCS asset library, follow the flow to apply an update from the LCS environment page. Select **Apply updates** under **Maintain**, then select the platform update package.



Learn how to **get the latest platform package and apply it to an environment deployed through LCS** in the next section.

Apply the latest platform update package

There are two ways to get the latest platform update package in LCS from your environment page.

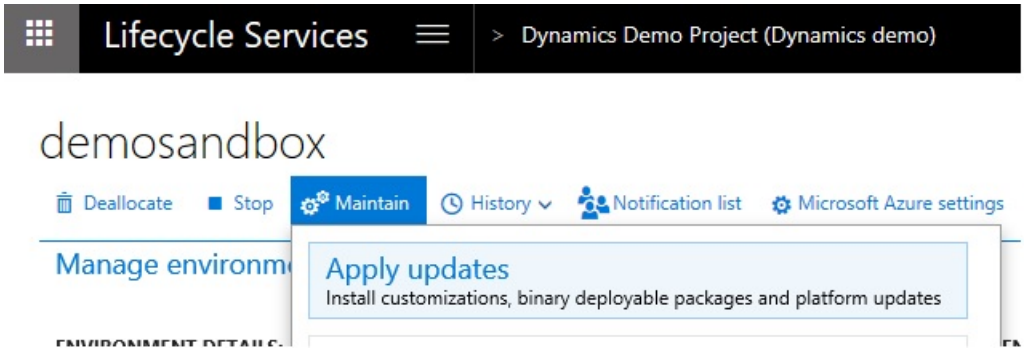
- Click the **Platform binary updates** tile
- Click the **All Binary Updates** tile to see a list of combined package of application and platform binary updates. (As of Platform update 4, binary updates from LCS include an upgrade to the latest platform).

> **NOTE**
> Tiles on an environment's page in LCS show only the updates that are applicable to your environment based on the current version and state of the environment.

Get the latest platform update package by clicking on one of the two tiles as mentioned above. After reviewing the fixes included in the platform, click **Save Package** to save the package to the project asset library.

From a process perspective, deploying a platform upgrade package resembles a binary hotfix deployable package.

- To apply a platform update package to your cloud development, build, demo, tier-2 sandbox, or production environment, update directly from LCS.



For more details, follow the instructions for applying a binary hotfix in Apply updates to cloud environments.

NOTE

Migrate files for Document management: After upgrading to Platform update 6 or later, an administrator needs to click the **Migrate Files** button on the **Document management parameters** page to finish the upgrade process. This will migrate any attachments stored in the database to blob storage. The migration will run as a batch process and could take a long time, depending on the number and size of the files being moved from the database into Azure blob storage. The attachments will continue to be available to users while the migration process is running, so there should be no noticeable effects from the migration. To check if the batch process is still running, look for the **Migrate files stored in the database to blob storage** process on the **Batch jobs** page.

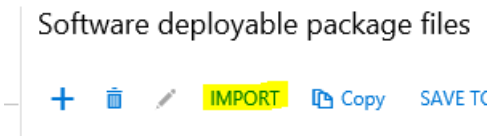
Apply a platform update to environments that are not connected to LCS

This section describes how to apply a platform update package to a *local development environment* (one that that is not connected to LCS).

How to get the platform update package

Platform update packages are released by Microsoft and can be imported from the Shared asset library in Microsoft Dynamics Lifecycle Services (LCS). The package name is prefixed with **Dynamics 365 Unified Operations Platform Update**. Use these steps to import the platform update package:

1. Go to your LCS project's Asset library.
2. On the **Software deployable package** tab, click **Import** to create a reference to the platform update package.



3. Select the desired platform update package.

NOTE

The package in the Shared Asset library may not correspond to the latest build (with hotfixes) of the desired platform release. To guarrantee the latest build, use the LCS environment page as described earlier in this article.

Apply the platform update package to your development environment

NOTE

These instructions apply only to environments that cannot be updated directly from LCS.

Install the deployable package

1. Download the platform update package (AXPlatformUpdate.zip) to your virtual machine (VM).
2. Unzip the contents to a local directory.
3. Depending on the type of environment that you're upgrading, open the PlatformUpdatePackages.Config file under \AOSService\Scripts, and change the **MetaPackage** value.
   - If you're upgrading a development or demo environment that contains source code, change the **MetaPackage** value to **dynamicsax-meta-platform-development**.
   - If you're upgrading a runtime environment, such as a tier-2 sandbox environment or another

environment that doesn't contain source code, the default value, **dynamicsax-meta-platform-runtime**, is correct.

> **NOTE**
> Step 3 is not applicable when upgrading to Platform update 4 or later.

4. Follow the instructions for installing a deployable package. See Install deployable packages from the command line.

5. If you're working in a development environment, rebuild your application's code.

Example

```
AXUpdateInstaller.exe generate -runbookid="OneBoxDev" -topologyfile="DefaultTopologyData.xml" -
servicemodelfile="DefaultServiceModelData.xml" -runbookfile="OneBoxDev-runbook.xml"

    AXUpdateInstaller.exe import -runbookfile=OneBoxDev-runbook.xml

    AXUpdateInstaller.exe execute -runbookid=OneBoxDev
```

Install the Visual Studio development tools (Platform update 3 or earlier)

> **NOTE**
> Skip this section if you are updating to Platform update 4 or later, development tools are automatically installed as part of installing the deployable package.

Update the Visual Studio development tools as described in Update the Visual Studio development tools.

Regenerate form adaptor models

Form adaptor models are required for test automation. Regenerate the platform form adaptor models, based on the newly updated platform models. Use the xppfagen.exe tool to generate the form adaptor models. This tool is located in the package's bin folder (typically, j:\AosService\PackagesLocalDirectory\bin). Here is a list of the platform form adaptor models:

- ApplicationPlatformFormAdaptor
- ApplicationFoundationFormAdaptor
- DirectoryFormAdaptor

The following examples show how to generate the form adaptor models.

```
xppfagen.exe -metadata=j:\AosService\PackagesLocalDirectory -model="ApplicationPlatformFormAdaptor" -
xmllog="c:\temp\log1.xml"

xppfagen.exe -metadata=j:\AosService\PackagesLocalDirectory -model="ApplicationFoundationFormAdaptor" -
xmllog="c:\temp\log2.xml"

xppfagen.exe -metadata=j:\AosService\PackagesLocalDirectory -model="DirectoryFormAdaptor" -
xmllog="c:\temp\log3.xml"
```

Install the Data Management service (Platform update 3 or earlier)

> **NOTE**
>
> Skip this section if you are updating to Platform update 4 or newer, the data management service is automatically installed as part of installing the deployable package.

After the deployable package is installed, follow these instructions to install the new Data Management service. Open a **Command Prompt** window as an administrator, and run the following commands from the .\DIXFService\Scripts folder.

```
msiExec.exe /uninstall {5C74B12A-8583-4B4F-B5F5-8E526507A3E0} /passive /qn /quiet
```

If you're connected to Microsoft SQL Server Integration Services 2016 (13.0), run the following command.

```
msiexec /i "DIXF_Service_x64.msi" ISSQLSERVERVERSION="Bin\2012" SERVICEACCOUNT="NT AUTHORITY\NetworkService"
/qb /lv DIXF_log.txt
```

If you're connected to an earlier release of Microsoft SQL Server Integration Services, run the following command.

```
msiexec /i "DIXF_Service_x64.msi" ISSQLSERVERVERSION="Bin" SERVICEACCOUNT="NT AUTHORITY\NetworkService" /qb
/lv DIXF_log.txt
```

Apply the platform update package on a build environment (Platform update 6 or earlier)

> **NOTE**
>
> Skip this section if you are updating to Platform update 7 or newer. This was a prerequesite step for build environments.

If the build machine has been used for one or more builds, you should restore the metadata packages folder from the metadata backup folder before you upgrade the VM to a newer platform update. You should then delete the metadata backup. These steps help ensure that the platform update will be applied on a clean environment. The next build process will then detect that no metadata backup exists and will automatically create a new one. This new metadata backup will include the updated platform. To determine whether a complete metadata backup exists, look for a BackupComplete.txt file in I:\DynamicsBackup\Packages (or C:\DynamicsBackup\Packages on a downloadable virtual hard disk [VHD]). If this file is present, a metadata backup exists, and the file will contain a timestamp that indicates when it was created. To restore the deployment's metadata packages folder from the metadata backup, open an elevated Windows PowerShell **Command Prompt** window, and run the following command. This command will run the same script that is used in the first step of the build process.

```
if (Test-Path -Path "I:\DynamicsBackup\Packages\BackupComplete.txt") { C:\DynamicsSDK\PrepareForBuild.ps1 }
```

If a complete metadata backup doesn't exist, the command will create a new backup. This command will also stop the Finance and Operations deployment services and Internet Information Services (IIS) before it restores the files from the metadata backup to the deployment's metadata packages folder. You should see output that resembles the following example.

```
6:17:52 PM: Preparing build environment...* <em>6:17:53 PM: Updating Dynamics SDK registry key with
specified values...</em> <em>6:17:53 PM: Updating Dynamics SDK registry key with values from AOS web
config...</em> <em>6:17:53 PM: Stopping Finance and Operations deployment...</em> <em>6:18:06 PM: **A backup
already exists at: I:\\DynamicsBackup\\Packages. No new backup will be created</em><em>.</em> <em>6:18:06
PM: **Restoring metadata packages from backup...</em>** <em>6:22:56 PM: **Metadata packages successfully
restored from backup</em><em>.</em> <em>6:22:57 PM: Preparing build environment complete.</em> <em>6:22:57
PM: Script completed with exit code: 0</em>
```

After the metadata backup has been restored, delete (or rename) the metadata backup folder (DynamicsBackup\Packages), so that it will no longer be found by the build process.

Apply the platform update package

After you've prepared your build environment for this update, apply the platform update package by using the same method that you use on other environments.

Additional resources

Process for moving to the latest update of Finance and Operations

Upgrade data in development or demo environments

2/18/2021 • 17 minutes to read • Edit Online

This topic explains how to upgrade an older database to the latest Finance and Operations application release.

The topic provides instructions for upgrading your Finance and Operations database in a Tier 1 environment to the latest update. A Tier 1 environment is also known as a development, one-box, or demo environment.

In Tier 2 or higher environments, including Production, you will run through the self-service upgrade steps as outlined in Self-service upgrade to the latest version.

IMPORTANT

- You do **not** have to upgrade your database if you're updating to the latest **platform** of Finance and Operations. Platform updates are backward-compatible. This topic applies only to the process of upgrading between releases of Finance and Operations applications, such as an upgrade from Microsoft Dynamics 365 for Operations version 1611 (November 2016) to Finance and Operations 8.0.
- This process doesn't apply to the upgrade of document attachments that are stored in Microsoft Azure blob storage.
- All upgraded custom code has to be applied on the environment before running the data upgrade process.
- If you are on version 8.0 or later, there is no longer a data upgrade between application versions.

Before you begin

1. Back up your current database.
2. You must have a functional environment that is already successfully running the update.
3. In the **source** environment, you must install one of the following hotfixes, depending on the version that you're upgrading from. These hotfixes correct an issue in the SysSetupLog logic, so that the upgrade process can detect the version that you're upgrading from:

   - **If you're upgrading from the November 2016 release (also known as 1611 or 7.1, build 7.1.1541.3036):** KB 4023686, "'Could not find source system version information' error when you upgrade to the latest Application Release."
   - **If you're upgrading from the July 2017 release (also known as 7.2, build 7.2.11792.56024):** No hotfix is required for this version.
   - After you install application hotfixes required in this step, run a full database synchronization. This step is especially important for golden database environments. A full database synchronization fills the SysSetupLog table, which is used when the database is upgraded. Don't run the database synchronization from Microsoft Visual Studio for this step, because the SysSetup interface won't be triggered. To trigger the SysSetup interface, run the following command from an Administrator **Command Prompt** window.

```
cd J:\AosService\WebRoot\bin>

Microsoft.Dynamics.AX.Deployment.Setup.exe -bindir "J:\AosService\PackagesLocalDirectory" -
metadatadir        J:\AosService\PackagesLocalDirectory -sqluser axdeployuser -sqlserver
localhost -sqldatabase axdb -setupmode sync -syncmode fullall -isazuresql false -sqlpwd \
<password for axdeployuser\>
```

4. If you're upgrading from Microsoft Dynamics AX 2012, install the following application X++ hotfixes in the destination environment before you run the data upgrade:
   - KB 4033183 - Dynamics AX 2012 R2 or Dynamics AX 2012 R3 Pre-CU8 non-retail upgrade fails with Object not found for dbo.RETAILTILLLAYOUTZONE.
   - KB 4040692 - Dynamics AX 2012 R3 to Microsoft Dynamics 365 for Operations 7.2 upgrade fails on RetailSalesLine duplicate index on SalesLineIdx.
   - KB 4035490 - Performance issue with GeneralJournalAccountEntry MainAccount field upgrade script.
5. If you're upgrading to Dynamics 365 Finance version 10.0.9 or 10.0.10, install the quality updates in the destination environment before you run the data upgrade.
6. If you're upgrading a database that began as a standard demo data database, you must also run the following script. This step is required because the demo data contains bad records for some kernel X++ classes.

   ```
   delete from classidtable where id >= 0xf000 and id <= 0xffff
   ```

7. Make sure that all Commerce Data Exchange (CDX) jobs have been successfully run, and that there is no unsynchronized transactional data in the cloud version of the channel database.

Select the correct data upgrade deployable package

To obtain the latest data upgrade deployable package for a target environment that is running the latest update, download it from the Microsoft Dynamics Lifecycle Services (LCS) Shared asset library.

1. Sign in to LCS.
2. Select the **Shared asset** library tile.
3. In the Shared asset library, under **Select asset type**, select **Software deployable package**.
4. In the list of deployable package files, find the data upgrade package that corresponds to your upgrade.
   - If you're upgrading from AX 2012, the package name starts with **AX2012DataUpgrade**. Select the package that corresponds to the release you are upgrading to. For example, **AX2012DataUpgrade-10-0**.
   - If you're upgrading from a previous release to the latest 10.0.X release, the package name is **DataUpgrade-10-0**.
   - If you're upgrading from a previous release to a preview release, the package name contains PREVIEW. For example, **DataUpgrade-10-0-2-PREVIEW**.
5. Select the package that corresponds to the release that you are upgrading to.

Upgrade the database

1. Extract the data upgrade deployable package to **C:\Temp** or a location of your choice.

> **NOTE**
>
> Skip this step if this is a development environment that is connected to LCS and you are planning to execute the data upgrade process directly from LCS.

2. Import or restore a backup of the source database (the database that you will be upgrading) to the demo or development environment that is already running the latest update that you want to upgrade to. Leave the existing database in place, and name your new database **imported_new**.

> **NOTE**
>
> If you are validating the data upgrade of your production database running on the earlier release: To copy a database from a production environment back to a demo or development environment, follow the steps in Export a copy of the standard user acceptance testing (UAT) database.
>
> For better upload/download speed between Azure virtual machines (VMs), we recommend that you use AzCopy. For information about how to download AzCopy, and how to use it to copy to or from an Azure blob store, see Transfer data with the AzCopy Command-Line Utility.

3. Rename the original database by adding the suffix **_orig**. Rename the newly restored database so that it has the same name as the original database. In this way, the two databases switch places.

```
ALTER DATABASE <original Dynamics 365 database> MODIFY NAME = <original Dynamics 365 database>_ORIG
ALTER DATABASE imported_new MODIFY NAME = <original Dynamics 365 database>
```

4. Create a backup of the source database, in case you have to revert to it. This step is important because the following steps will modify the source database.

5. Execute the data upgrade package from the **C:\Temp\DataUpgrade** folder (the location that you extracted the deployable package to earlier). Executing a data upgrade package is similar to installing any software deployable package. For detailed instructions, see Install deployable packages from the command line. Start at the section titled **Generate a runbook from the topology** then execute the steps in the section **Install a deployable package**.

> **NOTE**
>
> If you are upgrading a database on a development environment, you can instead execute the data upgrade package directly from the LCS environment page, using the **Maintain > Apply Updates** servicing functionality. This does not require the user to be a local Administrator on the development VM. This is available as of the February release of LCS.
>
> This will upgrade your Finance and Operations database, channel database, and reset the Financial reporting database.

Re-enable SQL change tracking

Run the following SQL against the upgraded database to make sure that change tracking is enabled at the database level. You must specify the name of your database in the **alter database** command.

```
ALTER DATABASE [<your AX database name>] SET CHANGE_TRACKING = ON (CHANGE_RETENTION = 6 DAYS, AUTO_CLEANUP =
ON)
```

Refresh the data entities list

If you have upgraded to Platform update 14 or later, then you will need refresh the data entity list in the Data management workspace (**Data management** > **Framework parameters** > **Entity settings** > **Refresh entity list**) to ensure that the entity list is rebuilt on the latest platform and that the required metadata is available for data management operations.

Troubleshoot upgrade script errors

This section provides information that can help you troubleshoot various issues.

Rerun the runbook after a data upgrade script failure

A data upgrade deployable package enables the runbook to be rerun in a more granular manner than a typical deployable package. The data upgrade scripts begin to be run at Step 5 of the runbook. If you experience a failure during Step 5, view the output in the command window to learn which substep you reached. For example, if you reached substep 5.3, use the following command to rerun from that substep.

```
AXUpdateInstaller.exe execute -runbookid=upgrade -rerunstep=5.3
```

When you're debugging, you don't have to rerun the whole data upgrade piece and database synchronization. You can keep rerunning just the script that fails.

View more details about a script error

Upgrade scripts run in X++ by using a batch process that the runbook installer starts. In Application Explorer in Visual Studio, some classes that you can view are prefixed with **ReleaseUpdate**. If an upgrade script fails during the runbook process, you can learn more about the reason for the error by opening Microsoft SQL Server Management Studio and running the following code to query ReleaseUpdateScriptsErrorLog.

```
select \* from RELEASEUPDATESCRIPTSERRORLOG
```

You can add this code to a new runnable class in Visual Studio, and directly observe, debug, and rework its behavior.

Skip failed scripts

> **IMPORTANT**
> This process is intended to be used only in a development scenario.

You can skip all scripts that have failed a specific number of times, and move to the next viable scripts. This functionality helps with the troubleshooting process. By design, the process is very manual, so that you're less likely to unintentionally skip scripts.

In the ReleaseUpdateConfiguration table, there is a new field that is named **ScriptRetryCount**. The value in this field controls how many times the runbook process will rerun scripts before it ignores them. When the runbook is run, the system updates the **ReleaseUpdateScriptsErrorLog.ErrorCount** field every time that a specific script fails. A new row is created for each script.

In the DataUpgrade package folder, under ..\AosServices\Scripts\, there is a script that is named IgnoreBlockingScripts.ps1. Run this script from an Administrator Windows PowerShell window to skip all scripts where **ScriptRetryCount**=**ErrorCount**. Then rerun the runbook step that failed, so that scripts will be ignored. The **ReleaseUpdateScriptsErrorLog.Ignored** field will also be set for each script that is skipped. Therefore, you can easily identify skipped scripts later.

Monitor the duration of scripts that are run

Every script that is successfully run records the number of minutes that it took in the

ReleaseUpdateScriptsLog.DurationMins column. Therefore, you can easily identify the longest-running scripts when you're trying to tune the performance of the data upgrade process. Note that the duration is the amount of time that each script takes to run. However, because multiple scripts run in parallel, the sum of values in the **DurationMins** column will exceed the overall duration of the upgrade process.

Known issues

A duplicate key was found for the object that is named dbo.RESOURCESETUP

When you upgrade a database, you might receive the following error message during the database synchronization phase of the runbook process:

> Database execution failed: The CREATE UNIQUE INDEX statement terminated because a duplicate key was found for the object name 'dbo.RESOURCESETUP' and the index name 'I_6716AK'

This issue is a known issue that will be resolved in a future hotfix. The workaround is to delete the duplicate rows from the table by running the following SQL script against the database from Management Studio.

```
delete RS from ResourceSetup as RS
join ResResourceIdentifier as RRI on RRI.RecId = RS.Resource_
join WrkCtrTable as WCT on WCT.RecId = RRI.RefRecId
join DirPartyTable as DPT on DPT.DataArea = WCT.DataAreaId
where DPT.DataArea != '' and RS.LegalEntity != DPT.RecId
```

A record can't be selected in Dimension hierarchy nodes (CAMDataDimensionHierarchyNode)

When you upgrade a database, you might receive the following error message during the database synchronization phase of the runbook process:

> Cannot select a record in Dimension hierarchy nodes (CAMDataDimensionHierarchyNode). Dimension hierarchy: 0. The SQL database has issued an error. Object Server DynamicsAXBatchManagement: [Microsoft][ODBC Driver 13 for SQL Server][SQL Server]Invalid column name 'RELATIONTYPE'.

This issue is a known issue that will be resolved in a future release. The workaround is to create a missing field in several tables by running the following SQL script against the database from Management Studio.

```
SET ANSI_NULLS ON
GO
SET QUOTED_IDENTIFIER ON
GO
DROP PROCEDURE IF EXISTS [DBO].PATCHRELATIONTYPE
GO

CREATE PROCEDURE [DBO].PATCHRELATIONTYPE
        @TABLENAME SYSNAME
    AS
    BEGIN
        DECLARE @TABLEID  INT ;
        DECLARE @FIELDID  INT ;
        DECLARE @FIELDNAME  SYSNAME;
        DECLARE @SQLTATEMENT NVARCHAR(1024);
        DECLARE @TOTALRECORDS INT;
        DECLARE @ParmDefinition   NVARCHAR(150);

        SET NOCOUNT ON;

        SELECT @FIELDNAME = 'RELATIONTYPE';
        SELECT @FIELDID = 61453; --Hardcoded in code DBFIELD_DISCRIMINATOR
        IF OBJECT_ID(@TABLENAME, 'U') IS NULL
        BEGIN
```

```
            PRINT @TABLENAME + ' table does not exists. Please provide a base table';
            RETURN;
        END

        IF EXISTS(SELECT 1 FROM SYS.COLUMNS
            WHERE NAME = @FIELDNAME
            AND OBJECT_ID = OBJECT_ID(@TABLENAME))
        BEGIN
            PRINT @TABLENAME + ' table contains RelationType. No patching needed.';
            RETURN;
        END
        PRINT @TABLENAME + ' table does not contain RelationType.';
        SELECT @TABLEID = ID FROM TABLEIDTABLE WHERE NAME = @TABLENAME;
        IF @@ROWCOUNT <> 1
        BEGIN
            PRINT @TABLENAME + ' was not present in TABLEIDTABLE. Cannot proceed!!';
            RETURN;
        END

        -- Ensure that instancerelationtype is added. We don't want to randomly add relationtype to any
table.
        IF NOT EXISTS (SELECT \* FROM SQLDICTIONARY WHERE TABLEID = @TABLEID AND NAME =
'InstanceRelationType')
        BEGIN
            PRINT @TABLENAME + ' table does not exist. Please provide a base table';
            RETURN;
        END

        -- Ensure SQLDictionary is populated
        IF NOT EXISTS (SELECT \* FROM SQLDICTIONARY WHERE TABLEID = @TABLEID AND FIELDID = @FIELDID)
        BEGIN
            INSERT INTO SQLDICTIONARY (TABLEID, FIELDID, ARRAY, NAME, SQLNAME, FIELDTYPE, STRSIZE, SHADOW,
RIGHTJUSTIFY, NULLABLE, FLAGS, RECVERSION)
            VALUES (@TABLEID,@FIELDID,1, @FIELDNAME, @FIELDNAME, 49, 0, 0, 0, 0, 0, 1);
            PRINT 'Inserted into SqlDictionary';
        END

        -- Actual alter statement
        SELECT @SQLTATEMENT = 'ALTER TABLE ' + @TABLENAME +  ' ADD ' + @FIELDNAME + ' BIGINT NOT NULL
DEFAULT 0';
        PRINT 'Issuing ' + @SQLTATEMENT;
        EXEC (@SQLTATEMENT);

        SELECT @SQLTATEMENT = 'UPDATE ' + @TABLENAME +  ' SET RELATIONTYPE = 0';
        PRINT 'Issuing ' + @SQLTATEMENT;
        EXEC (@SQLTATEMENT);
    END;
GO
exec PatchRelationType  'CAMDATADIMENSIONHIERARCHYNODE'
exec PatchRelationType  'CAMDataJournal'
exec PatchRelationType  'CAMDataCostAccountingLedgerSourceEntryProvider'
exec PatchRelationType  'CAMDataImportedDimensionMember'
```

An index can't be created on InventDistinctProduct

When you upgrade a database, you might receive the following error message during the database synchronization phase of the runbook process:

> Cannot create index on InventDistinctProduct a duplicate key exists on column Product.

This issue is a known issue that will be resolved in a future release. The workaround is to delete all records in the InventDistinctProduct table and then resume the runbook from the current step. The records in the InventDistinctProduct table are disposable. They will be regenerated the first time that Finance and Operations is started, when an item is created, or when MRP is run. To delete all records in InventDistinctProduct, run the following query against the current database from Management Studio.

```
truncate table InventDistinctProduct
```

To resume the runbook from the current step, run the following command.

```
axupdateinstaller execute -runbookid=<your runbook name> -rerunstep=<the last step number>
```

For example, you can use this command.

```
axupdateinstaller execute -runbookid=dataupgrade -rerunstep=5.4
```

An exchange rate can't be found when demo data is upgraded

When you upgrade a demo database, you might receive the following error message when you deploy the data upgrade package:

> An exchange rate cannot be found for exchange rate type Default between currencies INR and BRL on exchange date 12/1/2014.

Because you're upgrading demo data, look in the TrvUnreconciledExpenseTransaction table, which is where the expense line is. Change the currency to **USD**. (Because the data is demo data, you don't have to be careful to preserve this expense line.)

```
update TrvUnreconciledExpenseTransaction
set transactioncurrencycode = 'USD'
where transactioncurrencycode = 'INR'
```

Alternatively, go to the original environment that the data came from (such as the old version), and add the missing exchange rate at **General Ledger** > **Currencies** > **Currency exchange rates**. You must add records for Indian rupee (INR) and Brazilian real (BRL) that cover 2014. Then bring that database into your new environment, and start the upgrade against that database.

The interpreter evaluation stack has grown during a call to the kernel

If you've enabled database logging on a kernel table such as UserInfom, you might receive the following error message:

> Executing step: 5.1
> prereq for data upgrade
> prereq for data upgrade
> Unhandled exception More Information: The interpreter evaluation stack has grown during a call to the kernel method xRecord::Delete (), height before call: 0, height after call: 3. Unhandled exception More Information: KernelInstance: Kernel is accessing deleted memory
> The step failed

To resolve this issue, review the database log setup at **System administration** > **Setup** > **Database log setup**. Remove records for kernel tables as you require.

The batch process fails to start

The batch process can fail if the environment was left in maintenance mode after the configuration keys were changed. To resolve this issue, turn maintenance mode off, and then resume the runbook process.

The system fails to locate or generate a user GUID

You might receive the following error message:

> ...Unhandled exception More Information: System failed to locate or generate a user GUID...

To resolve this issue, rerun the runbook step that failed. You will then be able to continue.

Pre-sync or post-sync errors on ReleaseUpdateDB71_LedgerPeriodClose

You might receive one of the following error messages on the **preSyncLedgerPeriodCloseTemplateTask**, **updateMenuItemTypeForCurrencyReval**, or **updateLedgerPeriodCloseTemplateTask** method in the **ReleaseUpdateDB71_LedgerPeriodClose** class:

> Cannot execute the required database operation. The SQL database has issued an error. Object Server DynamicsAXBatchManagement: [Microsoft][SQL Server Native Client 11.0][SQL Server]Invalid column name 'TEMPLATE'. INSERT INTO LedgerPeriodCloseTemplateTaskTmp (TEMPLATE, AREA, NAME, MENUITEM, MENUITEMTYPE, TARGETDAYSFROMPROJECTCOMPLETE, DUETIME, LEGALENTITYSELECTION, RECVERSION, PARTITION, RECID, CLOSINGROLE, LINENUM) SELECT T1.TEMPLATE, T1.AREA, T1.NAME, T1.MENUITEM, T1.MENUITEMTYPE, T1.TARGETDAYSFROMPROJECTCOMPLETE, T1.DUETIME, T1.LEGALENTITYSELECTION, T1.RECVERSION, T1.PARTITION, T1.RECID, T1.CLOSINGROLE, 0 FROM LedgerPeriodCloseTemplateTask T1 session 1013 (Admin) Microsoft.Dynamics.Ax.Xpp.ErrorException: Cannot execute the required database operation. The SQL database has issued an error.
>
> Cannot execute the required database operation. The SQL database has issued an error. Object Server DynamicsAXBatchManagement: [Microsoft][SQL Server Native Client 11.0][SQL Server]Invalid column name 'MENUITEMTYPE'. UPDATE LedgerPeriodCloseTemplateTaskTmp SET MENUITEMTYPE = 0 WHERE MENUITEMTYPE = 2 AND MENUITEM = 'LedgerExchAdj' AND PARTITION = 5637144576 session 1013 (Admin) Microsoft.Dynamics.Ax.Xpp.ErrorException: Cannot execute the required database operation. The SQL database has issued an error.
>
> Cannot execute the required database operation. The SQL database has issued an error. Object Server DynamicsAXBatchManagement: [Microsoft][SQL Server Native Client 11.0][SQL Server]Invalid column name 'TEMPLATE'. INSERT INTO LedgerPeriodCloseTemplateTask (TEMPLATE, AREA, NAME, MENUITEM, MENUITEMTYPE, TARGETDAYSFROMPROJECTCOMPLETE, DUETIME, LEGALENTITYSELECTION, RECVERSION, PARTITION, RECID, CLOSINGROLE, LINENUM) SELECT T1.TEMPLATE, T1.AREA, T1.NAME, T1.MENUITEM, T1.MENUITEMTYPE, T1.TARGETDAYSFROMPROJECTCOMPLETE, T1.DUETIME, T1.LEGALENTITYSELECTION, T1.RECVERSION, T1.PARTITION, T1.RECID, T1.CLOSINGROLE, T1.LINENUM FROM LedgerPeriodCloseTemplateTaskTmp T1 session 1013 (Admin)

To resolve this issue, use Management Studio to manually drop the LedgerPeriodCloseTemplateTaskTmp table from the database. Then rerun the runbook step. This issue will be fixed in a future hotfix.

Table Sync Failed for Table: WarrantyGroupConfigurationItem

If you're upgrading to Dynamics 365 Finance version 10.0.9 or 10.0.10, you might receive the following error message during data upgrade:

> Table Sync Failed for Table: WarrantyGroupConfigurationItem

To resolve the issue, roll back the database upgrade, install the quality updates in the destination environment, and then rerun the data upgrade.

KB number 3170386

If KB number 3170386 isn't installed, you will receive the following error message:

> GlobalUpdate script for service model: AOSService on machine .... Etc .... UpgradeServiceHelper::WaitForDataUpgradeToComplete(Object[]... The step failed

This error is caused by a failure in the pre-sync or the post-sync substep of the data upgrade. Follow these steps to determine which substep failed and the details of the failure.

> **NOTE**
> You can't rerun the failed runbook step until the pre-sync or post-sync substep has been manually completed, and the AutoDataUpgrade.config file has been updated to skip the substeps that have already been run.

1. In File Explorer, in the **DataUpgradeAosServiceScripts** folder, sort by descending order of the date when files were last modified, and then look at the file at the top of the list to determine which substep failed.
   - If the top file is named **dbUpgrade*PreSync*Monitor.error.log**, the pre-sync substep failed.
   - If the top file is named **dbUpgrade*PostSync*Monitor.error.log**, the post-sync substep failed.
2. In Management Studio, run the following **SELECT** statement.

   ```
   SELECT * FROM RELEASEUPDATELOG
   ```

   The second-to-last record in the result set will have the errors and call stacks for all the failures.

DMF errors

If you receive either of the following Data Migration Framework (DMF) errors, download hotfix KB number 3170386, and then restart the upgrade process.

DMF pre-sync error

> Batch error: initial.DAT.ReleaseUpdateDB70_DMF.updateIntegrationActivityExecutionMessageIdPreSync (Batch:AOS-F01B9F0CCC8, 9, Info, Error,):[[1][3,Cannot execute the required database operation. The SQL database has issued an error.][3,Object Server DynamicsAXBatchManagement:][3,[Microsoft][SQL Server Native Client 11.0][SQL Server]Incorrect syntax near 'GO'.][3,

DMF post-sync error

> Batch error: initial.DAT.ReleaseUpdateDB70_DMF.updateIntegrationActivityExecutionMessageIdPostSync (Batch:AOS-F01B9F0CCC8, 9, Info, Error,):[[1][3,Cannot execute the required database operation. The SQL database has issued an error.][3,Object Server DynamicsAXBatchManagement:][3,[Microsoft][SQL Server Native Client 11.0][SQL Server]Incorrect syntax near 'GO'.][3,

Encrypted fields in demo data

After upgrade, values in encrypted fields in the database will be unreadable. However, new values that are entered in these fields after upgrade will be readable. This behavior occurs because of a technical limitation that is related to the certificate that is used for data encryption. The following table shows the fields that are affected.

TABLE.FIELD	DATA EXISTS IN DEMO DATA
CreditCardAccountSetup.SecureMerchantProperties	Yes
ExchangeRateProviderConfigurationDetails.Value	Yes
RetailChannelPaymentConnectorLine.SecureMerchantProperties	Yes

TABLE.FIELD	DATA EXISTS IN DEMO DATA
RetailConnDatabaseProfile.ConnectionString	Yes
RetailHardwareProfile.SecureMerchantProperties	Yes
RetailHardwareProfileMerchantInfoEntity.SecureMerchantProperties	Yes
FiscalEstablishment_BR.ConsumerEFDocCsc	No
FiscalEstablishmentEntity.CSC	No
FiscalEstablishmentStaging.CSC	No
HcmPersonIdentificationNumber.PersonIdentificationNumber	No
HcmWorkerActionHire.PersonIdentificationNumber	No
SysEmailSMPTPassword.Password	No
SysOAuthUserTokens.EncryptedAccessToken	No
SysOAuthUserTokens.EncryptedRefreshToken	No

Process for moving to the latest update of Finance and Operations

NOTE

Can you tell us about your documentation language preferences? Take a short survey.

The survey will take about seven minutes. No personal data is collected (privacy statement).

Update the Visual Studio development tools

2/18/2021 • 2 minutes to read • Edit Online

This topic explains how to update the development tools.

Use this tutorial to update your Visual Studio development tools with a new version. It explains how to uninstall your existing Visual Studio development tools and install the new extension. The new extension is in the form of an installable VSIX file. This file is a part of the binary hotfix available on the Dynamics Lifecycle Services (LCS) site. The VSIX file is located in the **DevToolsService\Scripts** folder of the binary hotfix package.

> **NOTE**
> You do not need to follow the instructions in this article if you are upgrading your Finance and Operations platform to Platform update 4 or newer. It is an automatic step that is part of the platform upgrade process.

Uninstall the existing Visual Studio extension

In order to install a new version of the development tools, you'll need to uninstall the existing version first. Verify the version of the development tools that you have installed. If you don't have it installed, you can skip this section.

Verify your current version of the Visual Studio extension

1. Open the Visual Studio **Help > About Microsoft Visual Studio** dialog and find **Finance and Operations Developer Tools**.
2. Select it and click **OK**.

Uninstall the extension

1. Open the Visual Studio **Tools > Extensions and Updates** dialog.
2. Select **Finance and Operations Visual Studio Tools** and click **Uninstall**.
3. When the extension is uninstalled, exit Visual Studio.

Install a new version of the extension

1. Make sure Visual Studio is not running.
2. Double-click (or right-click and **Open**) the VSIX file of the new version.
3. Follow the installation instructions.
4. When installation is complete, you can start Visual Studio and start developing your application.

> **NOTE**
> Can you tell us about your documentation language preferences? Take a short survey.

Plan and prepare for compiling code against the latest update

2/18/2021 • 2 minutes to read • Edit Online

With the rollout of the One Version servicing plan, Microsoft is committed to backward compatibility from a binary and functional perspective. For detailed information about One Version, see One Version service updates FAQ. Even with backward compatibility as a priority, there are situations where development activities may result in required code changes. Some of those situations are described below.

- When Microsoft makes an enumeration extensible, it is considered a binary compatible change. The compiler checks for unsafe extensible enumeration operations that depend on the integer value of a non-extensible enumeration. Any partner code that contains unsafe extensible enumeration operations will have compiler errors when re-compiled and will need to be modified. For more information, see Add values to enums through extension.
- To avoid possible unresolved references when compiling, a partner model should reference the top-level modules and sub-modules. If this is not done, a Microsoft change that adds new resources in an unreferenced sub-module may cause an unresolved reference. To resolve the compilation error, add the sub-module as a reference.
- Some methods will be attributed as obsolete to signal that they will be fully deprecated in the future. Any compiler warning that is generated due to the calling or wrapping of an obsolete method should be investigated to ensure that the expected code path still exists. In some cases, Microsoft code will directly call the new method in place of the obsolete method. When this happens, the code built around the obsolete method will not execute when expected.

Apply updates to on-premises deployments

2/18/2021 • 8 minutes to read • Edit Online

This topic explains how to apply supported updates to Dynamics 365 Finance + Operations (on-premises). All updates to on-premises environments are done through Microsoft Dynamics Lifecycle Services (LCS).

Search for and download updates

For more information about how to find the updates that you can apply to your on-premises environment, see Issue search in Lifecycle Services (LCS). For information about how to download updates from the tiles in the **Updates** section of the **Environment details** page in LCS, see Download updates from Lifecycle Services (LCS).

> **NOTE**
>
> When you are updating an on-premises environment, always select updates from the update tiles on the **Environment** details page. If you select updates from another location, the updates might not work.

Update an on-premises deployment

You can apply updates to an on-premises environment either during deployment or after the deployment is completed.

While an on-premises environment is being deployed, you can select to deploy a custom package in the **Advanced** settings. For more information about how to apply customizations or application X++ updates, see Develop and deploy custom models to on-premises environments.

To apply updates to an on-premises environment after it has been deployed, in LCS, on the **Environment details** page for the environment, under **Maintain**, select **Apply updates**.

> **NOTE**
>
> You can apply updates after deployment only on environments that have Platform update 12 for Finance and Operations or later. The environment must also have the latest version of the local agent available in LCS. For more information, see Update the local agent. If you're on a platform version that is older than Platform update 12, you can reconfigure an environment that is already deployed to update the customizations or update to the latest platform release. For more information about how to redeploy an environment, seeRedeploy on-premises environments.

Apply application or binary updates through LCS

The following steps can be used to apply X++, All Binary, or Platform binary updates.

> **IMPORTANT**
>
> The application of updates requires downtime for your environment. Therefore, no business transactions can be performed in the environment during the update. When you complete the following steps, verify that the system isn't being used, and that an official downtime notice has been communicated to all system users.

> **IMPORTANT**
> To move to the latest platform, always select the platform update from the **Platform Binary Updates** tile on the **Environment** details page. If you select updates from another location, the updates might not work.

Prerequisites

- Before you begin, complete a full backup of the Management Reporter (MR), Microsoft Dynamics AX, and Microsoft SQL Server Reporting Services (SSRS databases). Although the code is restored through LCS, the database must be manually restored to help guarantee that there is no data loss.
- Update your environment to the latest build of Platform update 12.
- Update the local agent to the latest version. For more information, see Update the local agent.
- Depending on the type of update, complete the following steps to generate a deployable package:
  - **Platform binary updates** – Download or save the update directly to the Asset library in LCS by following the steps in Download updates from Lifecycle Services (LCS).
  - **Application binary updates** – Download or save the update directly to the Asset library in LCS by following the steps in Download updates from Lifecycle Services (LCS).
  - **Application X++ updates** – Download the required hotfix to your development environment, and then follow the steps in Create deployable packages of models.
  - **Customizations** – Follow the steps in Develop and deploy custom models to on-premises environments.

Update a sandbox environment

1. In the LCS Asset library, upload the deployable package that was generated in the "Prerequisites" section of this topic to the**Software deployable packages**tab.
2. In LCS, open the on-premises implementation project, and then open the **Environment details** page of the environment to update.
3. Under **Maintain**, select **Apply updates**. A slider shows the updates that were uploaded to the Asset library. Note that only packages that are marked as **Valid** in the Asset library appear.

If you are on local agent version 2.1.0 and higher, complete the following steps.

1. Select the update, and then click **Prepare**. Clicking on **Prepare** will prepare your on-premises environment for servicing.

   > **NOTE**
   > During preparation, the environment state will be **Deployed** but the Deployment status field will show the progress of Preparation. Steps such formatting the package and downloading the package are executed during preparation. The environment is not directly touched during preparation and hence there is no downtime during the preparation phase. Users can continue to use the system during preparation.

2. After the preparation is complete, you will see **Abort** and **Update Environment** buttons. To start applying the update, click **Update Environment**. If preparation fails, see the "Resolve a failed update application" section later in this topic.
3. In the confirmation message, select **Yes**. The servicing operation has started on this environment. This is the start of the downtime on your environment.
4. The environment state is changed from **Deployed** to **Deploying**.
5. After the update is completed, the environment state is changed back to **Deployed**. If application of the

update fails, the environment state is changed to **Failed**. For information about what to do if package application fails, see the "Resolve a failed update application" section later in this topic.

6. Open the **History** and **Environment details** pages to view the operations that were performed on the environment. You can also view a record of major actions that were performed on the environment, such as deployments, servicing, and rollbacks.

If you are on local agent version lower than 2.1.0, complete the following steps.

1. Select the update, and then click **Apply**.
2. In the confirmation message, select **Yes**. The servicing operation has started on this environment. This is the start of the downtime on your environment.
3. Environment state changes from **Deployed** to **Preparing**.

> **NOTE**
> During preparation, steps such formatting the package and downloading the package are executed during preparation. The environment is not directly touched during preparation and hence there is no downtime during the preparation phase. Users can continue to use the system during preparation. However, we recommend that the downtime starts when the environment enters the Preparing state.

4. After preparation is complete, the environment state is changed from **Preparing** to **Deploying**.
5. After the update is completed, the environment state is changed back to **Deployed**. If application of the update fails, the environment state is changed to **Failed**. For information about what to do if package application fails, see the "Resolve a failed update application" section later in this topic.
6. Open the **History** and **Environment details** pages to view the operations that were performed on the environment. You can also view a record of major actions that were performed on the environment, such as deployments, servicing, and rollbacks.

Update a production environment

Before you update a production environment, you must successfully complete the package application update on a sandbox environment.

1. In the project for the sandbox environment that you applied the package to, open the Asset library, and then, on the **Software deployable packages** tab, select the package, and mark it as a **Release candidate**.
2. On the **Environment details** page, under **Maintain**, select **Apply updates**. In the dialog box, only packages that are marked as a **Release candidate** are shown.
3. Select the Release candidate package to be applied to the Production environment.
4. The rest of the Update flow is the same as that of a sandbox environment. Your update experience will differ based on the version of the local agent running on your environment. We recommend that you always run with the latest version.

Resolve a failed update application

When preparation fails, the environment state is **Deployed**. When the application of an update fails, the environment state is **Failed**. The first step is to determine why there is a failure. The location of the logs varies, depending on the stage where the failure occurred:

- **Preparation stage:** If the operation fails during the **Preparation** stage, the logs are uploaded to LCS. In the log files, select **Download logs** to download the log files. If the package has any merge issues, the error is included in the log file.
- **Deploying stage:** If the operation fails during the **Deploying** stage, the logs are located in the on-premises

environment. You must sign in to the environment, and then access the logs and event viewer.

For more information about how to use the troubleshooting logs, see Troubleshoot on-premises deployments.

After you review the logs and determine the cause of the failure, complete one of the following operations to restore the environment to a healthy state. No actions can be performed on an environment that is in a **Failed** state. The environment must first be restored to a healthy state.

- **Retry failed operation** – If update application fails, select **Retry** to recover from the failed operation.
- **Abort failed operation** – Because there is no change made to the on-premises environment, if the preparation fails, you have the option to cancel the operation. Select **Abort** to cancel the preparation.
- **Roll back the update** – To roll back the update that failed, select **Rollback**. Before you start the rollback, you must restore the database to the last known good state. When you select **Rollback**, the environment is restored to the last known good state. The environment state is then changed to **Preparation**, then to **Deploying**, and then to either **Deployed** or **Failed**.

  > **NOTE**
  > The **Rollback** button doesn't roll back the database. You're responsible for restoring the database to the last known backup that was made before update application. This step is critical to help guarantee that there is no data loss.

- **Refresh the state** – If update application fails during the **Preparation** stage, the failure is on the LCS side, and update application hasn't yet started. Therefore, the on-premises environment is in a good state. To restore the LCS environment state to **Deployed**, on the project dashboard page, select **Refresh**.
- **Delete and redeploy an environment** – If the retry and rollback options don't work, you must delete and redeploy the environment. To delete the environment, on the project dashboard page, select **Delete**. You then see the option to configure the environment.

  > **IMPORTANT**
  > This option should **not** be used on a production environment. However, it can be used on a sandbox deployment to restore the environment to a healthy state.

  > Because this option requires that you do a fresh deployment of the environment, you lose any updates that were previously applied. Any customizations and binary updates must be reapplied to the environment.

> **NOTE**
> Can you tell us about your documentation language preferences? Take a short survey.
>
> The survey will take about seven minutes. No personal data is collected (privacy statement).

Redeploy on-premises environments

2/18/2021 • 3 minutes to read • Edit Online

At some point, you might have to redeploy your on-premises environment. This could be to apply a new platform update or because of changes or issues in your implementation. Before you delete the environment you are currently working with, you should save your configuration setting information to use when you redeploy. This topic describes how to save configuration settings and how to redeploy your environment.

Save your configuration

Before you delete the environment you plan to update, use the following steps to save your configuration.

1. In LCS, navigate to **Project Settings** > **On-prem Connectors**.
2. Select the connector to your environment, and then click **Edit**.
3. On the **Edit connector** tab, navigate to **Configure Agent** > **Enter Configuration**.
4. Copy the value of the Download Fileshare location in the **Configuration Settings** section. You will need this later.
5. Log in to the on-premises environment file share machine and copy the **\agent\wp\StandaloneSetup\config.json**. You can use the configuration settings in this json file to redeploy your environment.

Configuration settings

The following tables provide information about configuration settings. Use the **Configuration setting** value from the .json file that you saved in the previous procedure.

Active Directory Federation Services settings

FIELD	CONFIGURATION SETTING
The email address of the user who will be the initial administrator (such as, `adminuser@yourdomain.com`)	components.(AOS).parameters.provisioning.adminPrincipleName.value
ADFS OpenID metadata endpoint for the Dynamics 365 Application group. (such as, https://[federation-service-name]/adfs/.well-known/openid-configuration)	components.(AOS).parameters.activeDirectory.adfsMetadata.value
ADFS OpenID Connect client ID for the AOS application group	components.(AOS).parameters.activeDirectory.adfsClientId.value
ADFS OpenID Connect client ID for the Financial Reporting application group	components.(FinancialReporting).parameters.aad.nativeClientAuthentication.clientId.value

SQL database configuration

FIELD	CONFIGURATION SETTING
SQL SERVER	components.(AOS).parameters.database.dbServer.value
AX DATABASE	components.(AOS).parameters.database.dbName.value

FIELD	CONFIGURATION SETTING
FINANCIAL REPORTING DATABASE	components.(FinancialReporting).parameters.mrdb.dbName.value

File share settings

FIELD	CONFIGURATION SETTING
The file share path for the Microsoft Dynamics 365 instance. This share is used as the document store for files uploaded by users.	components.(AOS).parameters.storage.fileSharePath.value
The File share certificate thumbprint for the Microsoft Dynamics 365 instance.	components.(AOS).parameters.storage.sharedAccessThumbprint.value

> **NOTE**
>
> When you copy the file path configuration value from .json file to LCS UI, make sure to remove the extra backslashes. For example, configuration value **\\DC1\D365FFOStorage** from the .json file should be **\DC1\D365FFOStorage** in the LCS UI.

SSRS configuration settings

FIELD	CONFIGURATION SETTING
The IP Address of the SSRS instance.	components.(AOS).parameters.biReporting.persistentVirtualMachineIPAddressSSRS.value
The thumbprint used by the SSRS application to communicate with AX Service.	components.(ReportingServices).parameters.reportingClientCertificateThumbprint.value

Configure service settings

FIELD	CONFIGURATION SETTING
DYNAMICS 365 DNS INFORMATION - The DNS host name of the Microsoft Dynamics 365 instance, such as ax.d365ffo.onprem.contoso.com.	components.(AOS).parameters.infrastructure.hostName
AOS SERVICE PRINCIPAL USER SETTINGS - The domain user account to run the AX service, such as yourdomain\axserviceuser.	components.(AOS).parameters.infrastructure.principalUserAccountName *
MR SERVICE PRINCIPAL USER SETTINGS - The group managed service account (gMSA) to run the MR application service, such as yourdomain\Svc-FRAS$.	components.(FinancialReporting).parameters.ApplicationServicePrincipalUser.accountName.value *
The group managed service account (gMSA) to run the MR process service, such as yourdomain\Svc-FRPS$.	components.(FinancialReporting).parameters.ProcessServicePrincipalUser.accountName.value *

FIELD	CONFIGURATION SETTING
The group managed service account (gMSA) to run the MR click-once service, such as yourdomain\Svc-FRCO$.	components.(FinancialReporting).parameters.ClickOnceServicePrincipalUser.accountName.value *

> **NOTE**
> Remove the extra backslash from the Principal username cofiguration value in the .json file before entering in the LCS UI. For example, contoso\\AXServiceUser should be entered as contoso\AXServiceUser in LCS.

Application certificate settings

FIELD	CONFIGURATION SETTING
The thumbprint of the Data Encryption certificate.	components.(AOS).parameters.database.dataEncryptionCertificateThumbprint.value
The thumbprint of the Data Signing certificate.	components.(AOS).parameters.database.dataSigningCertificateThumbprint.value
The thumbprint of the Session Authentication certificate.	components.(FinancialReporting).parameters.sessionAuthenticationCertificateThumbprint.value
The thumbprint of the SSL certificate used for WCF/SOAP support.	components.(AOS).parameters.infrastructure.sslCertificateThumbprint.value
The thumbprint used by the Management Reporter to communicate with AX service.	components.(FinancialReporting).parameters.tokenSpec.certThumbprint.value

Redeploy your environment

The following instructions provide information about how to update or redeploy your environment with a new platform or topology.

1. In LCS, navigate to the **Environments** blade in your on-premises project.
2. Click **Delete** to delete your environment.

   > **NOTE**
   > Deleting the environment will not delete the database, infrastructure or Local agent. Only the Service Fabric applications are deleted.

3. Wait for a few minutes and verify that the deployment is deleted. To confirm the deployment is deleted, log in to the on-premises environment and navigate to the Service Fabric Explorer.

   The following applications should be deleted:

   - AXBootstapperAppType

- AXSFType
- FinancialReportingType
- RTGatewayAppType
- ReportingService

  The following on-premises service fabric agent applications should not be deleted:

- LocalAgentType
- MonitoringAgentAppType

4. After all of the applications in step 3 are deleted, go back to LCS and click **Configure**.
5. Select the new topology for your platform.
6. Enter the environment name. You can use the same name or enter a new one.
7. Click **Advanced Settings**. You can now use the relevant configurations from the .json file that you saved to configure your environment.

In-place upgrade process for on-premises environments

2/18/2021 • 12 minutes to read • Edit Online

This topic provides the detailed process for upgrading on-premises environments of Finance and Operations from version 7.x to 10.0.x.

> **NOTE**
> Please perform the upgrade with your sandbox environment before upgrading your production environment.

On-premises upgrade from version 7.x to 10.0.x

> **NOTE**
> Be aware that this upgrade process takes time to complete and Finance and Operations will be inaccessible for the entire duration of the data upgrade.

To upgrade from version 7.x to 10.0.x, there are two possible paths that are currently supported.

An overview of each path is given below:

- **Upgrading from within VHD** - This path involves copying your database into the virtual hard disk (VHD) and executing the upgrade inside it. Overall, this is the simpler method.
- **Upgrading with VHD pointing to your database** - This path involves pointing the VHD upgrade process to your database. The upgrade process is still executed from within the VHD.

> **NOTE**
> The VHD does not need external network access in order to carry out the upgrade process.

Prerequisites

1. In Lifecycle Services (LCS), go to the Shared Assets Library (right side of the screen).
2. Under **Select asset type**, choose **Downloadable VHD**, and download all parts of the VHD package that closely matches the version you will be upgrading to in your on-premises environment. The image requires a high amount of disk space, so be sure to download and extract on a drive with adequate free space.
3. The files that you downloaded are a self-extracting zip file. Extract the VHD to a location with a good amount of free space.
4. Using Hyper-V, launch a virtual machine (VM) and attach the VHD. (Note that the machine must be Generation 1.)
5. Connect to the VM. You can find the credentials in Running the Virtual Machine (VM) locally.
6. Depending on your planned on-premises target version of 10.0.x and the VHD image you downloaded, you may need to download and apply the required Application and Platform Update from the Shared

Asset Library under **Select asset type** and **Software deployable package**. For more information, see Install deployable packages from the command line.

7. If you have any extensions or customizations install them into the VHD now, otherwise the upgrade process will remove any data related to customizations. Check with your independent software vendor (ISV) or value-added reseller (VAR) if you need to prepare your environment before the upgrade.

Upgrading from within VHD

1. Shut-down on-premises AOS, BI, and MR servers or stop the Service Fabric Host Service in each of the nodes and set to disabled.
2. Back up your database from your on-premises environment (typically AXDB). For more information, see Create a Full Database Backup.
3. In the VHD, go to C:\AOSService\PackagesLocalDirectory\Bin\CustomDeployablePackage and copy the MinorVersionDataUpgrade zip file.
4. Paste the file wherever you want and unzip it. For example: c:\D365FFOUpgrade\
5. Open a Command Prompt as Administrator and change the directory to the unzipped folder in step 4.
6. Restore the backup that you created into the OneBox VM. For more information, see Restore a Database Backup Using SSMS.
7. Optional: If the name of your restored database is not AXDB, using PowerShell with administrator privileges, execute:

```
.\Configure-On-Premises-Upgrade.ps1 -DatabaseName '<DB-name>'
```

> **NOTE**
> Substitute with the appropriate value in your case (for example, AXDB). If you would like to edit more values, refer to the appendix of this topic.

   The script will run a database connection test to check that the information you provide is valid.

8. Using the Command Prompt from step 5, execute the following commands:

   a.
   ```
   AxUpdateInstaller.exe generate -runbookid=upgrade -runbookfile=upgrade.xml -
   topologyfile=defaulttopologydata.xml -servicemodelfile=defaultservicemodeldata.xml
   ```

   b. `AxUpdateInstaller.exe import -runbookfile=upgrade.xml`

   c. `AxUpdateInstaller.exe execute -runbookid=upgrade`

   During the execution of cleanup for data upgrade you may encounter an error:

   ```
   Stack trace: Call to TTSCOMMIT without first calling TTSBEGIN.\' on category \'Error\'.
   ```

   To resolve this, re-run the step with this command:

   ```
   AxUpdateInstaller.exe execute -runbookid=upgrade -rerunstep=\<failed-step\>
   ```

9. When the upgrade process has finished successfully, back up the newly upgraded database. If you have customizations from ISVs or VARs, check if you have to run some post data upgrade scripts.
10. Restore the database into your environment with a different name from the production one (for example, AXDBupgraded).

11. Start on-premises AOS, BI, and MR servers, or start the services from the Service Fabric portal.

12. In LCS, open the project, and then, in the **Environments** section, delete the deployment. The applications should start to disappear from Service Fabric Explorer in the environment. This process may take longer depending on the number of nodes that you have. Check the service fabric explorer to verify that all applications have been deleted before deploying a new environment. Note that LCS might indicate that the environment is deleted before the actual process is finished.

13. If you had customizations:

    a. In LCS, go to the Shared Assets Library.

    b. Under **Select asset type**, choose **Model** and download: Dynamics 365 for Finance and Operations on-premises, Version 10.0.x Demo Data. Select the version closest to the 10.0.x environment that you will deploy as the on-premises baseline.

    c. Use this file to create a new database (typically AXDB) using the restore backup option from SQL server. For more information, see Restore a Database Backup Using SSMS.

    d. The database will need to be configured. Follow the steps in Configure the Finance and Operations database.

    e. In LCS, set up a new environment and deploy it with version 10.0.x (Redeploy). For more information, see Set up and deploy on-premises environments (Platform update 12 and later). When you deploy, the database that you specify should be the one created in step 13c (typically AXDB).

    f. Apply your own customizations as well as ISV/VAR modules, to your newly created 10.0.x environment. Otherwise, when the environment initially syncs with the database it will delete any customization or extensions related data.

    g. Shut-down on-premises AOS, BI, and MR servers, or stop the services from the Service Fabric portal.

    h. Rename or delete the demo database (typically AXDB) used in the deploy and then rename your new database (typically AXDBupgraded) to the name that the demo database had (typically AXDB).

    i. Start on-premises AOS, BI, and MR servers, or start the services from the Service Fabric portal.

14. If you didn't have customizations:

    a. (Optional) Rename your old database (typically AXDBold) and then rename your new database (typically AXDB). Make sure that in the next step you input the name of the upgraded DB.

    b. In LCS, set up a new environment and deploy it with version 10.0.x (Redeploy). For more information, see Set up and deploy on-premises environments (Platform update 12 and later).

15. (Optional) If deployment fails because the financial reporting module failed, on the database that you are using for the new environment (typically AXDB), run the following command:

```
ALTER TABLE RETAILTERMINALTABLE ADD CONSTRAINT PK_RecId PRIMARY KEY
CLUSTERED (RECID)
```

Upgrading with VHD pointing to your database

1. Shut-down on-premises AOS, BI, and MR servers, or stop the services from the Service Fabric portal.

2. Back up your database from your on-premises environment (typically AXDB). For more information, see Create a Full Database Backup (SQL Server).

3. Restore the backup that you just created into the database server and give it a different name (AXDBtoupgrade). For more information, see Restore a Database Backup Using SSMS.

4. Once connected, go to C:\AOSService\PackagesLocalDirectory\Bin\CustomDeployablePackage and copy the MinorVersionDataUpgrade zip file.
5. Paste the file wherever you want and unzip it. For example: C:\D365FFOUpgrade\
6. Open a Command Prompt as Administrator and change the directory to the unzipped folder from step 5.
7. Open a new PowerShell as Administrator and execute:

```
.\Configure-On-Premises-Upgrade.ps1 -DatabaseName '<DB-name>' -DatabaseServer '<SqlServerName>' -
DatabaseUser '<User>' -DatabasePassword '<Password>'
```

> **NOTE**
>
> Substitute <*> with the values you require.

> **NOTE**
>
> - Only SQL Server authentication is officially supported for this upgrade. For more information, see Create a Database User.
> - You will need to add the Certificate Authority certificate that signed your SQL Server certificate to the OneBox trusted certificate authorities. For more information, see Installing the trusted root certificate.
> - Make sure the database user you use has the sysadmin server role assigned or at least All Privileges on the database you want to upgrade and has permissions to access tempDB. Step 6 of the upgrade process will fail if this is not true.
> - When you install the Certificate Authority in the OneBox, make sure you use the FQDN or IP for connecting to the database that appears there. If you can't access it by using the domain name because it doesn't point to that server, edit your hosts file and add the DN and the IP it should resolve to.

8. Using the Command Prompt from step 6, execute the following commands:

   a.
   ```
   AxUpdateInstaller.exe generate -runbookid=upgrade -runbookfile=upgrade.xml -
   topologyfile=defaulttopologydata.xml -servicemodelfile=defaultservicemodeldata.xml
   ```

   b. `AxUpdateInstaller.exe import -runbookfile=upgrade.xml`

   c. `AxUpdateInstaller.exe execute -runbookid=upgrade`

   During the execution of Cleanup for data upgrade you may encounter an error:

   ```
   Stack trace: Call to TTSCOMMIT without first calling TTSBEGIN.\' on category \'Error\'.
   ```

   To resolve this, re-run the step with this command:

   ```
   AxUpdateInstaller.exe execute -runbookid=upgrade -rerunstep=\<failed-step\>
   ```

9. If you have customizations from ISVs or VARs, verify if you have to run some post data upgrade scripts.
10. Start on-premises AOS, BI, and MR servers, or start the services from the Service Fabric portal.
11. In LCS, open the project, and then, in the **Environments** section, delete the deployment. The applications should start to disappear from Service Fabric Explorer in the environment. This process may take longer depending on the number of nodes you have.
12. If you had customizations:

    a. In LCS, go to the Shared Assets Library.

b. Under **Select asset type**, choose **Model** and download: Dynamics 365 for Finance and Operations on-premises, Version 10.0.x Demo Data. Select the version closest to the 10.0.x environment that you will deploy as the on-premises baseline.

c. Use this file to create a new database (typically AXDB) using the restore backup option from SQL server. For more information, see Restore a Database Backup Using SSMS.

d. The database will need to be configured. Follow the steps under Configure the Finance + Operations database.

e. In LCS, set up a new environment and deploy it with version 10.0.x (Redeploy). For more information, see Set up and deploy on-premises environments (Platform update 12 and later). When you deploy, the database that you should specify should be the one created in step 12c (typically AXDB).

f. Apply your own customizations as well as ISV/VAR modules, to your newly created 10.0.x environment. Otherwise when the environment initially syncs with the database it will delete any customization or extensions related data.

g. Shut-down on-premises AOS, BI, and MR servers, or stop the services from the Service Fabric portal.

h. Rename or delete the demo database (typically AXDB) used in the deploy and then rename your new database (typically AXDBupgraded) to the name the demo database had (typically AXDB).

i. Start on-premises AOS, BI, and MR servers, or start the services from the Service Fabric portal.

13. If you didn't have customizations:

    a. (Optional) Rename your old database (typically AXDBold) and then rename your new database (typically AXDB). Make sure that in the next step you input the name of the upgraded database.

    b. Set up a new environment and deploy it with version 10.0.x. For more information, see Set up and deploy on-premises environments (Platform update 12 and later).

14. (Optional) If deployment fails because the financial reporting module failed, on the database that you are using for the new environment (typically AXDB), run the following command:

```
ALTER TABLE RETAILTERMINALTABLE ADD CONSTRAINT PK_RecId PRIMARY KEY
CLUSTERED (RECID)
```

Appendix

Configure-On-Premises-Upgrade.ps1 usage

> **IMPORTANT**
>
> This script is only meant to be run from a OneBox VHD environment.
>
> The script requires that you pass at least the DatabaseName parameter. If you don't pass it, the script will automatically request it.

If you want to pass an additional parameter like DatabaseServer, or DatabaseUser you can do so but this will cause the script to ask you for all additional parameters. This happens because the script will assume that you want to point the database connection to a machine outside the VM and those parameters will be required to correctly establish the connection.

The parameters that can be passed to the script are:

- **-DatabaseName** - Database name that you want to upgrade.

- **-DatabaseServer** - Database server containing Finance and Operations (on-premises) database.
- **-DatabaseUser** - Username for SQL Authentication.
- **-DatabasePassword** - Password for SQL Authentication.

After configuration has been passed, the script will execute a database connection test with the new parameters. If the script is unable to connect we recommend that you use Microsoft SQL Server Management Studio or some other tool to debug the connection from there.

Configure-On-Premises-Upgrade.ps1

```
<#
.Synopsis
   Configures a Onebox deployment to upgrade an OnPrem 7.x database to OnPrem 10.0.x

.DESCRIPTION
   This must be executed before the upgrade process is carried out.

.EXAMPLE
   .\Configure-OnPremUpgrade.ps1 -DatabaseName 'AxDB'

   .\Configure-OnPremUpgrade.ps1 -DatabaseName 'AxDB' -DatabaseServer '127.0.0.1' -DatabaseUser 'axdbadmin'
-DatabasePassword 'secretPass'
#>
[CmdletBinding()]
param
(
    # Database server containing Microsoft Dynamics 365 for Operations, on-premises database.
    [AllowNull()]
    [string] $DatabaseServer,

    # Database name that you want to upgrade.
    [Parameter(Mandatory = $true)]
    [string] $DatabaseName,

    # Username for SQL Authentication.
    [AllowNull()]
    [string] $DatabaseUser,

    # Password for SQL Authentication.
    [AllowNull()]
    [string] $DatabasePassword
)

$webroot = "C:\AOSService\webroot"

$TestDbPass = $web.SelectSingleNode("configuration/appSettings/add[@key='DataAccess.SqlPwd']").value

#Setting up connection test.

$dbConn = New-Object System.Data.SqlClient.SqlConnection

$dbConn.ConnectionString = "Data Source=$TestDbServer;User
ID=$TestDbUser;Password=`"$TestDbPass`";Database=$TestDbName"

try{

    $dbConn.Open()

    $result = $true

}

catch{

    $result = $_.Exception.Message
```

```
    $result = $_.Exception.Message

}
Finally{

    $dbConn.Close()

}

$commandParameter = " -encrypt `"$webroot\web.config`""

Start-Process $command $commandParameter -PassThru -Wait

if($result -ne $true){

    Write-Host "`nThe connection to the Database Server failed:" -ForegroundColor Red
    Write-Host $result -ForegroundColor Red

}
else{

    Write-Host "`nThe connection to the Database Server was successful!" -ForegroundColor Green

}
```

Troubleshooting

- Wrong database name or user doesn't have access to that database: Exception calling "Open" with "0" argument(s): "Cannot open database "AxDB1" requested by the login. The login failed. Login failed for user 'axdbadmin'."
- Could not establish a connection. Check ip/fqdn and ports: Exception calling "Open" with "0" argument(s): "A network-related or instance-specific error occurred while establishing a connection to SQL Server. The server was not found or was not accessible. Verify that the instance name is correct and that SQL Server is configured to allow remote connections. (provider: Named Pipes Provider, error: 40 - Could not open a connection to SQL Server)"
- Login credentials are not correct. Exception calling "Open" with "0" argument(s): "Login failed for user 'axdbadmin'."

Download updates from Lifecycle Services (LCS)

2/18/2021 • 6 minutes to read • Edit Online

This topic covers what updates you should expect to see and how you can get the latest updates using Lifecycle Services (LCS).

Get updates

To view available updates:

1. Sign in to LCS using your credentials.
2. In the LCS project, select an environment.
3. On the **Environment** page, scroll down to see the **Available updates**.

Types of updates

- **Binary updates** are pre-compiled and cumulative. Every subsequent binary update includes all previous updates. These updates don't have to be compiled in a development environment, and they can be applied directly to a non-development environment from LCS.

  If you're running an environment that has Commerce functionality and a customized instance of Cloud point of sale (POS), you must complete the additional steps that are listed under the SDK packaging. For Microsoft Dynamics 365 Commerce, all updates, even updates for application models, are released as binary updates.

  For all versions of Commerce and Finance and Operations apps that are version 8.1 and later, all updates, including updates for application models, are released as binary updates.

- **X++ updates** include updates to specific application functionality in application models. These updates can be independently downloaded and applied. You can select specific X++ updates to apply to your environment. Dependent X++ updates are automatically selected and downloaded. X++ updates are source code updates. Before they can be applied to a non-development environment, X++ updates must be compiled in a developer environment and merged with any customizations. X++ updates apply only to version 8.0 and earlier.

Update option by product and version

Based on your product and version, you will have different update options from Lifecycle Services.

Finance and Operations apps

- **Application version 8.1 and later (One Version)** - All updates for version 8.1 and later will have the One Version service update experience. It will be a cumulative, combined binary update of all of the application and platform updates. There will be no granular X++ updates starting with this release.

  Based on your environment version and the service update availability, you will have the option to choose the updates available to your environment. Each update option is associated with a version number and a build number.

  You may see one or more of the following update options.

UPDATE	DESCRIPTION	AVAILABILITY
Quality update	A quality update is a cumulative, roll-up build that contains fixes for known issues that are specific to the service update.	A quality update is available when your environment is running the same version of the current service update (n), or when your environment is running on one version older than the current service update (n-1). For example, if the current service update is version 10.0.2, you will have the option to choose a quality update if you're running version 10.0.2, or if you're running one version older, which is 10.0.1. There will be no quality update available for any version that's older than 2 versions of the current service update. You will have to apply the latest service update to stay current.
Service update	A service update is the version currently automatically applied to customer environments based on the LCS project update settings. A service update is a cumulative, roll-up build that contains new features, functionality, and the related quality update that is generally available.	A service update is available if your environment has not been updated to the current service update version available for auto-update. Only the designated sandbox or production environment will be auto-updated if you have configured the update settings for the LCS project. However, you can manually apply the current service update version to other sandbox environments or your cloud-hosted environments.
Upcoming service update	An upcoming service update is the latest version that is generally available for self-update. An upcoming service update is a cumulative, roll-up build that contains new features, functionality, and the related quality update that is generally available.	An upcoming service update will be made generally available for self-deployment approximately 2 weeks prior to when Microsoft starts automatically applying this version based on your update settings for the LCS project.

- **Application version 7.3 with Platform update 4 and later** - This release will still have the granular X++ updates. Starting with Platform update 4, no overlayering is allowed on the platform modules, which means that the **Platform binary updates** tile is available to provide the platform updates as a cumulative update.

  For customers that are on this combination, you will see the following tiles:

  - **All X++ updates** - This tile shows all the granular X++ updates released by Microsoft.
  - **Critical X++ updates** - This tile shows recommended KBs that are based on the telemetry data in your production environment. This tile will only show Production environments and a subset of the updates shown under the **All X++ updates** tile that are recommended for your environments.

- **All binary updates** - This tile shows a combined, cumulative binary update for both the Application and Platform.
- **Platform binary updates** - This tile shows only the Platform binary updates. If you want to update only the platform, you can get the update from this tile.

- **Application version 7.1, 7.2, 8.0, or earlier (except version 7.3) with Platform update 32 and earlier** - The product versions noted here are out of service. No new X++ updates are available. You can apply the X++ updates that have been released previously but no new X++ update will be published to LCS.

  Also, a platform update will not be available starting with **Platform update 33**. This means that you will not be able to apply the platform only update package if your application version is 7.1, 7.2, or 8.0 and earlier (except version 7.3). If you're running any of these versions, you need to upgrade to the latest version to stay with the latest feature and functionality. For more information, see One Version service updates FAQ.

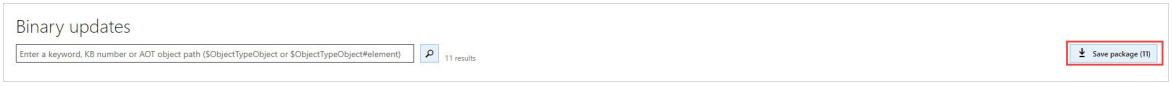
> **NOTE**
>
> If you are on a release that is noted above, you need to upgrade as soon as possible.
>
> For the X++ updates that have been released for these versions, they are available from Issue Search in Lifecycle Services.

Download binary updates

To download binary updates, follow these steps in LCS.

1. Select any of the binary update options, including Quality update, Service update, All binary updates, and Platform binary updates to view the combined list of application and platform binary updates.
2. On the **Binary updates** page, select **Save package**.

   > **NOTE**
   >
   > You will not be able to select Knowledge Base (KB) articles to be saved because binary updates will automatically save all KBs in an update package.

3. On the **Review and save updates** page, select **Save package**.
4. In the **Save package to asset library**, enter the **Name** and **Description**, and select **Save package**.
5. Select **Done** to return to the environment page.
6. You'll see the saved binary package in the asset library.

Download X++ updates

To download X++ updates, follow these steps in LCS.

1. Select the **All X++ updates** tile to view the list of available application updates for an environment, or select the **Critical X++ updates** tile for the application updates that are recommended for your production environment.
2. On the **Add updates** page, select the applicable Knowledge Base (KB) numbers, and then select **Add** to

add selected KBs to the download package.

> **NOTE**
>
> For X++ updates, you can download all available updates at this point. Click **Select all**, and then select **Add** to add all KBs to the download package.

3. Select **Download package**.
4. On the **Review and download hotfixes** page, you can review the hotfixes that you selected, discard the package, return to the hotfix selections, or download the final hotfix package.
5. Download the package, and select **Done**.

Additional resources

- Apply updates to cloud environments
- Install metadata hotfixes in development environments

>
> The survey will take about seven minutes. No personal data is collected (privacy statement).

Apply updates to cloud environments

2/18/2021 • 9 minutes to read • Edit Online

This topic describes how you can use Microsoft Dynamics Lifecycle Services (LCS) to automatically apply updates to cloud environments.

> **IMPORTANT**
> Updates are applied using deployable packages. Applying updates causes system downtime. All relevant services will be stopped, and you won't be able to use your environments while the package is being applied. You should plan accordingly.

Supported environments

All environments deployed through Lifecycle Services are supported.

> **NOTE**
> If you have a build environment, you can only use LCS to apply Binary updates and Data upgrade packages. You can't use LCS to apply an Application Deployable package.

For other environments (listed below), you must use Remote Desktop Protocol (RDP) to connect to the environment and install from the command line. For information about manual package deployment, see Install deployable packages from the command line.

- Local development environments (Downloadable virtual hard disk [VHD])
- Multi-box dev/test environments in Microsoft Azure (Partner and trial projects)

Key concepts

Before you begin, you should understand *deployable packages*, *runbooks*, and the *AXInstaller*. A deployable package is a unit of deployment that can be applied in any environment. A deployable package can be a binary update to the platform or other runtime components, an updated application (AOT) package, or a new application (AOT) package. The AXInstaller creates a runbook that enables installing a package. For more details, see Packages, runbooks, and the AXUpdateInstaller in depth at the end of this topic.

Supported package types

- **AOT deployable package** – A deployable package that is generated from application metadata and source code. This deployable package is created in a development or build environment.
- **Application and Platform Binary update package** – A deployable package that contains dynamic-link libraries (DLLs) and other binaries and metadata that the platform and application depend on. This is a package released by Microsoft. This is available from the **All binary updates** tile from LCS.
- **Platform update package** – A deployable package that contains dynamic-link libraries (DLLs) and other binaries and metadata that the platform depend on. This is a package released by Microsoft. This is available from the **Platform binary updates** tile from LCS.
- **Commerce deployable package** – A combination of various packages that are generated after the Commerce code is combined.
- **Merged package** – A package that is created by combining one package of each type. For example, you can

merge one binary update package and one AOT package, or one AOT package and one Commerce deployable package. The packages are merged in the Asset library for the project in LCS.

> **NOTE**
>
> A binary package and a Commerce deployable package can't be included in the same merged package.
>
> For information about how to download an update from LCS and what you see in the tiles based on your environment version, see Download updates from Lifecycle Services (LCS).
>
> If your environment is on an application version 8.1 and later, then the **Platform Update package** does not apply to your environment. Starting with 8.1 and later releases, **Application and Platform Binary update package** is the one that applies since application and platform will be combined into a single cumulative package and will be released by Microsoft. Also note that you will no longer be applying granular X++ hotfixes and will get all application and platform updates together. This means that on the environment details page, clicking on **View detailed version information** will not have details on the granular hotfixes or KBs applied as there is no way to apply them.

Prerequisite steps

- **Make sure that the package that should be applied is valid.** When a package is uploaded to the Asset library, it isn't analyzed. If you select the package, the package status appears in the right pane as **Not Validated**. A package must pass validation before it can be applied in an environment by using the following procedures. The status of the package will be updated in the Asset library to indicate whether the package is valid. We require validation to help ensure that production environments aren't affected by packages that don't meet the guidelines.

  There are three types of validations:

  - Basic package format validations
  - Platform version checks
  - Types of packages
- **Make sure that the package is applied in a sandbox environment before it's applied in the production environment.** To help ensure that the production environment is always in a good state, we want to make sure that the package is tested in a sandbox environment before it's applied in the production environment. Therefore, before you request that the package be applied in your production environment, make sure that it has been applied in your sandbox environment by using the automated flows.
- **If you want to apply multiple packages, create a merged package that can be applied first in a sandbox environment and then in the production environment.** Application of a single package in an average environment requires about 5 hours of downtime. To avoid additional hours of downtime when you must apply multiple packages, you can create a single combined package that contains one package of each type. If you select a binary package and an application deployable package in the Asset library, a **Merge** button becomes available on the toolbar. By clicking this button, you can merge the two packages into a single package and therefore reduce the total downtime by half.
- **Make sure that the Application binary update package is applied to your dev/build environment before it is applied to your sandbox and production environment** - If the application binary package is applied directly to your Tier 2+ sandbox environment but is not applied on your dev/build environment, the next time you move an AOT package from dev/build box (which does not have the same application binaries as your sandbox environment) to sandbox, some of the application binaries will be overwritten with what is in your dev/build environment. This could result in a regression of the version of your sandbox environment.

Apply a package to a non-production environment by using LCS

Before you begin, verify that the deployable package has been uploaded to the Asset library in LCS.

1. For a binary update, upload the package directly to the Asset library. For information about how to download an update from LCS, see Download updates from Lifecycle Services (LCS). For an application (AOT) deployable package that results from an X++ hotfix, or from application customizations and extensions, create the deployable package in your development or build environment, and then upload it to the Asset library.
2. Open the **Environment details** view for the environment where you want to apply the update.
3. Click **Maintain** > **Apply updates** to apply an update.
4. Select the package to apply. Use the filter at the top to find your package.
5. Click **Apply**. Notice that the status in the upper-right corner of the **Environment details** view changes from **Queued** to **In Progress**, and an **Environment updates** section now shows the progress of the package. You can refresh the page to check the status.
6. Continue to refresh the page to see the status updates for the package application request. When the package has been applied, the environment status changes to **Deployed**, and the servicing status changes to **Completed**.

Apply a package to a production environment by using LCS

In a production environment, customers can schedule a downtime for when they want the update to be applied.

> **IMPORTANT**
> An important prerequisite for applying a package to a production environment is that the package must be successfully applied to at least one sandbox environment in the same project.

1. After the update is successfully applied in a sandbox environment, go to the project's asset library. On the **Asset library** page, select the **Software deployable package** tab, select the package that you want to move to production, and click **Release candidate**. This indicates that this package is ready for production deployment.
2. Open the **Environment details** view for the production environment where you want to apply the package.
3. Select **Maintain** > **Apply updates** to apply the package.
4. Select the package to apply in your production environment, and then click **Schedule** to submit a request to apply it.

   > **NOTE**
   > The list of packages includes only the packages that have been successfully signed off in the sandbox environment, and that have been marked as release candidates.

5. Specify the date and time to schedule the package application. Click **Submit**, and then click **OK** to confirm. Note that your environments will be unavailable to perform business while the package is being applied.
6. At the scheduled downtime, package deployment will start.
7. After the environment is serviced, you can monitor the status. The **Servicing status** field indicates the status of package application. Additionally, a progress indicator shows the number of steps that have

been run, out of the total number of steps that are available.

8. After the deployment is successfully completed, the **Servicing status** field is set to **Completed**.
9. If package application isn't successfully completed, Microsoft will investigate the issue. The **Servicing status** field will indicate that package application has failed. The environment will be rolled back to a good state.

Troubleshoot package deployment failures

If package deployment fails, see the Troubleshoot package application issues topic.

Applying updates and extensions

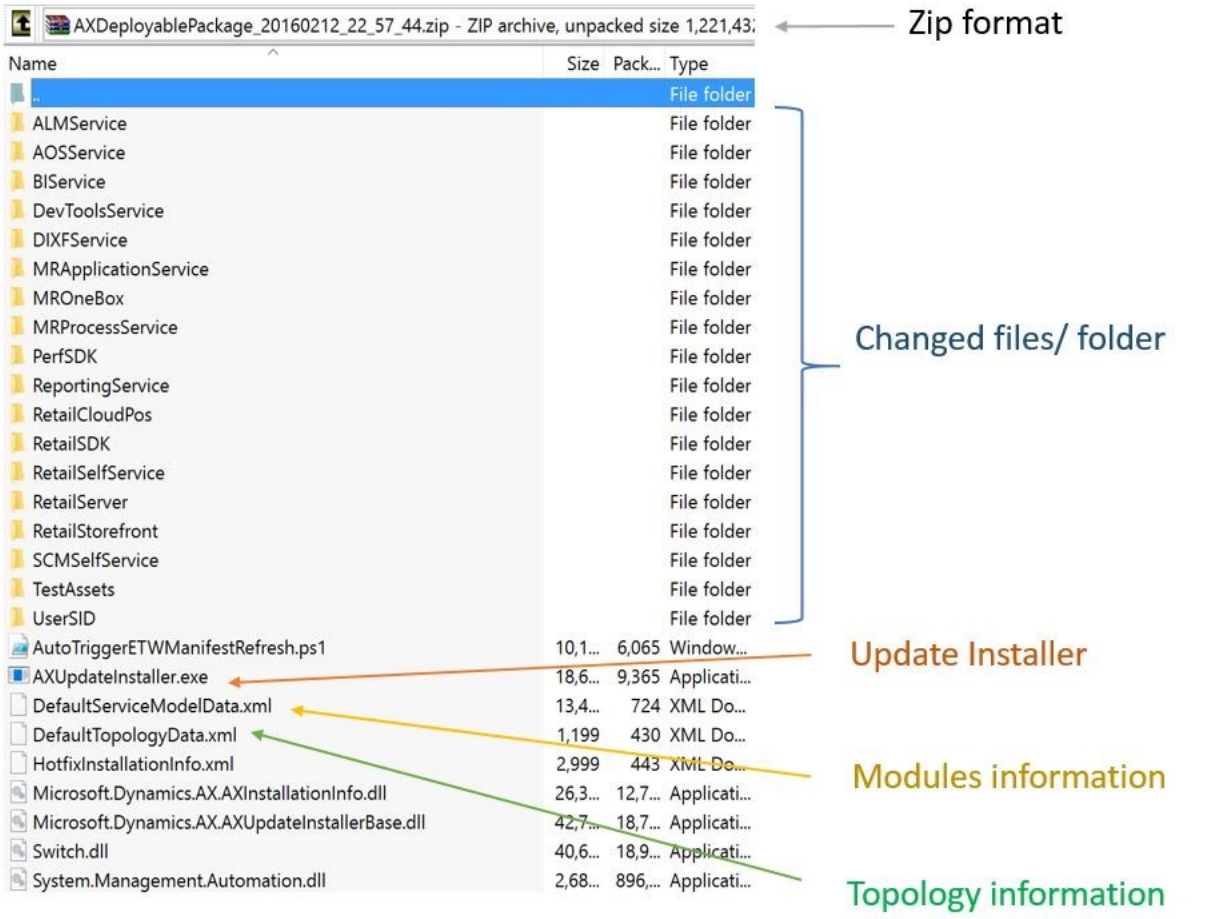
If you are updating a Tier-2 Sandbox or Production environment on application version 8.1.2.x or newer and have initialized Cloud Scale Unit, you will also need to update Commerce channel components. For more information, see Update Retail Cloud Scale Unit.

If you're using components (such as Modern POS), after you've applied updates and extensions in your environment, you must also update your in-store components. For more information, see Configure, install, and activate Modern POS (MPOS).

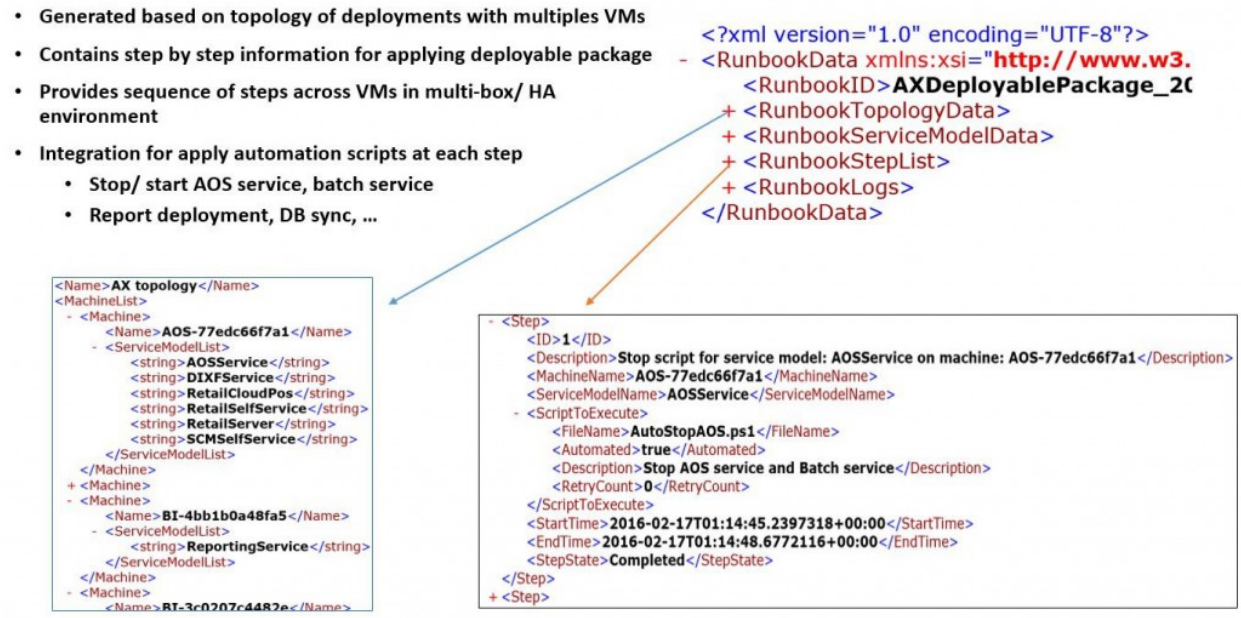
Packages, runbooks, and the AXUpdateInstaller in depth

Deployable packages, runbooks, and the AXUpdateInstaller are the tools you use to apply updates.

Deployable package – A deployable package is a unit of deployment that can be applied in an environment. A deployable package can be a binary update to the platform or other runtime components, an updated application (AOT) package, or a new application (AOT) package. Deployable packages downloaded from LCS or created in a development environment cannot be applied across product types. For example, a Finance deployable package cannot be applied in a Commerce app environment, and vice versa. If you have an existing customization for a Finance and Operations app that is compatible with the Commerce app, and you would like to apply it to a Commerce environment, you will need to re-package your source code in a Commerce development environment, and conversely if moving in the other direction.



Runbook – The deployment runbook is a series of steps that are generated in order to apply the deployable package to the target environment. Some steps are automated, and some steps are manual. AXUpdateInstaller lets you run these steps one at a time and in the correct order.



AXUpdateInstaller – When you create a customization package from Microsoft Visual Studio or a Microsoft binary update, the installer executable is bundled together with the deployable package. The installer generates the runbook for the specified topology. The installer can also run steps in order, according to the runbook for a specific topology.

Additional resources

Install deployable packages from the command line

NOTE

Can you tell us about your documentation language preferences? Take a short survey.

The survey will take about seven minutes. No personal data is collected (privacy statement).

Install metadata hotfixes in development environments

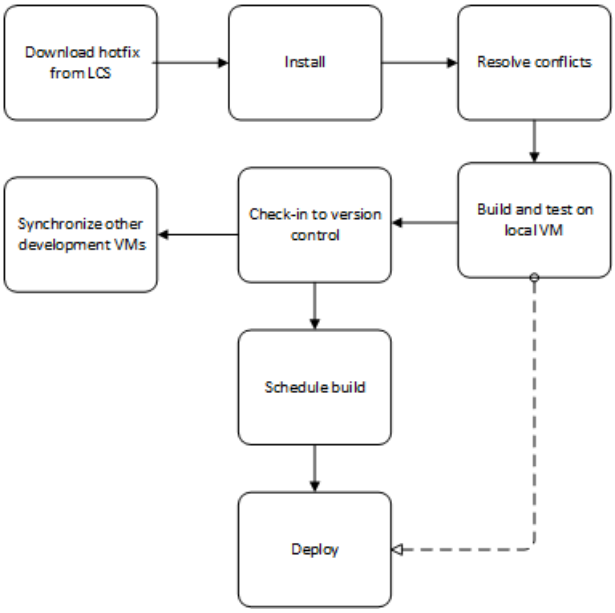
2/18/2021 • 6 minutes to read • Edit Online

This topic will guide you through installing an Application Metadata hotfix on your development environment.

A metadata hotfix package contains changes (metadata or X++ source code) to model elements (XML files) in your development environment. A hotfix can also contain new model elements. A metadata hotfix package is in the form of an SCDP file. This article describes the process for installing a metadata hotfix package and explains how to share the package with other developers who are working on the same project.

Overall flow

The following diagram shows the overall flow.



Download the hotfix from LCS

For instructions about how to download a hotfix, see Download updates from Lifecycle Services (LCS). After you download the zip file, extract the SCDP metadata hotfix package from it, and put it in a local folder.

Install the hotfix

Before you begin

- This topic assumes that your packages folder is located at c:\AOSService\PackagesLocalDirectory\Bin. On some virtual machines (VMs), it might be located at c:\Packages, i:\AOSService\PackagesLocalDirectory\Bin, or k:\AOSService\PackagesLocalDirectory\Bin.
- If you're not using Microsoft Azure DevOps or another source control system, create a backup of your packages folder (which is also known as the metadata store). We don't recommend that you do development unless you use Azure DevOps.
- If you have Azure DevOps or Microsoft Team Foundation Server (TFS) version control, make sure that there are no files in the **Pending Changes** list of your current workspace. If you have pending changes, we recommend that you submit them or shelve them before you install the metadata hotfix.

Install the metadata hotfix package

To invoke the installation of the metadata hotfix, you can call the SCDPBundleInstall.exe utility from a command prompt. SCDPBundleInstall.exe is located in your packages bin folder.

Without version control (not recommended)

If you're not using Azure DevOps or TFS for source control, use the following command.

```
SCDPBundleInstall.exe -install -packagepath=<scdp file containing the hotfix> -metadatastorepath=<metadata
packages root folder>
```

With version control (recommended)

If you're using Azure DevOps or TFS for source control, follow the steps below: **Prepare** the installation of the hotfix package using the command below. This step is not available if you are using a platform that is older than Platform update 2 (August 2016))

```
SCDPBundleInstall.exe -prepare -packagepath=<scdp file containing the hotfixes> -metadatastorepath=<metadata
packages root folder> -tfsworkspacepath=<path of local workspace folder> -tfsprojecturi=<URI of the Azure
DevOps or TFS project collection>
```

This will create a changeset of all the existing files on your environment that will be modified by the hotfix package, the prepare command will not install the hotfixes. Here is an example.

```
SCDPBundleInstall.exe -prepare -packagepath=c:\temp\hotfixbundle1234.axscdppkg -metadatastorepath=
c:\AOSService\PackagesLocalDirectory -tfsworkspacepath= c:\AOSService\PackagesLocalDirectory -
tfsprojecturi=https://myaccount.visualstudio.com/defaultcollection
```

Check-in your pending changes to create a backup of these files in your version control system. This will enable rolling back the hotfixes if needed. **Install** the hotfix package using the command below.

```
SCDPBundleInstall.exe -install -packagepath=<scdp file containing the hotfixes> -metadatastorepath=<metadata
packages root folder> -tfsworkspacepath=<path of local workspace folder> -tfsprojecturi=<URI of the Azure
DevOps or TFS project collection>
```

If you are using a platform that is older than Platform update 2 (August 2016), you do not need to specify the **-install** option. Here is an example.

```
SCDPBundleInstall.exe -install -packagepath=c:\temp\hotfixbundle1234.axscdppkg -metadatastorepath=
c:\AOSService\PackagesLocalDirectory -tfsworkspacepath= c:\AOSService\PackagesLocalDirectory -
tfsprojecturi=https://myaccount.visualstudio.com/defaultcollection
```

Azure DevOps/TFS parameters let you add the files that are modified by the package to your list of pending changes in Team Explorer.

Required parameters

```
/packagepath=[Path of the local scdp file containing the hotfixes downloaded from Lifecycle Service (LCS)]

/metadatastorepath=[Path of the local metadata store folder, such as c:\AOSService\PackagesLocalDirectory]
```

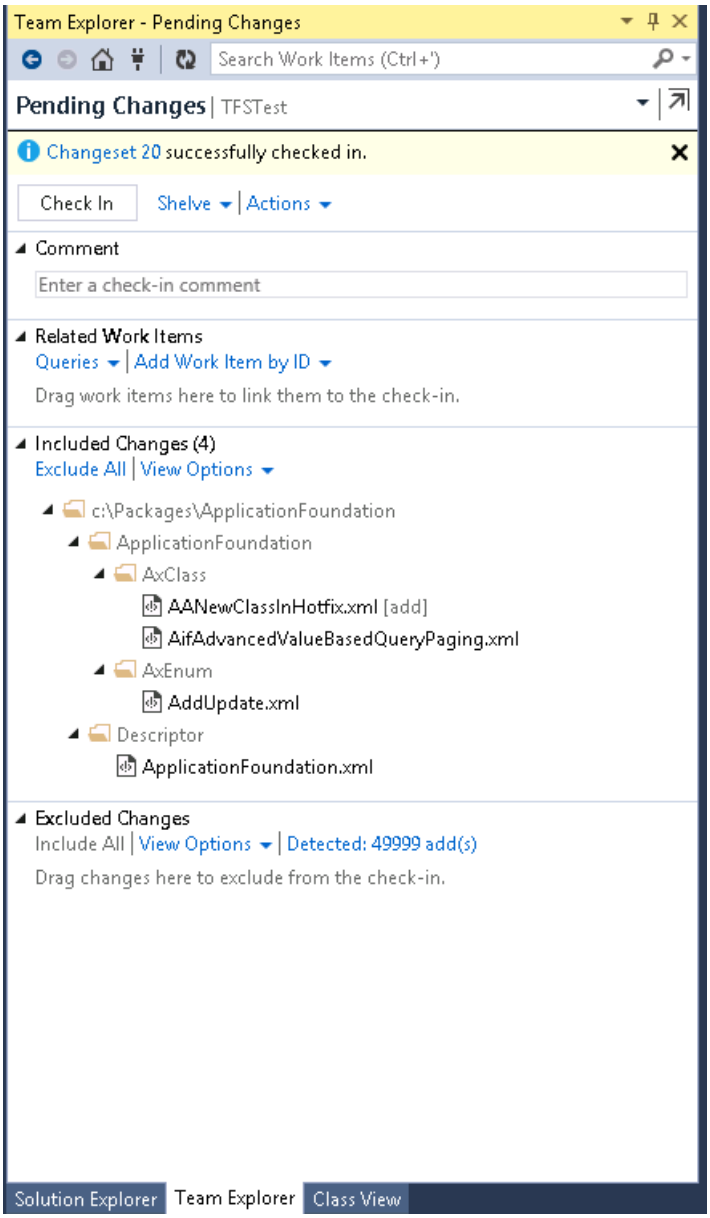
TFS parameters

If you're using Azure DevOps or TFS for source control, you should specify the following two parameters.

```
/tfsprojecturi=[URI of the TFS Project to connect to]

/tfsworkspacepath=[Path of the local workspace, usually equal to the metadatastorepath]
```

After the install command is invoked, the package installation process begins. As part of the installation process, some XML files in your metadata store folder will be updated to reflect the changes that were made in the fix itself. If you're using Azure DevOps or TFS, these files will be added to the list of included changes in the **Pending Changes** window in Team Explorer.



Resolve conflicts that are generated by the installation of the hotfix

Sometimes, a metadata hotfix package contains changes to objects that have been customized in higher-layer models. In this case, the installation process automatically generates conflicts that must be resolved after the hotfix has been installed. The development tools let you create a project that groups all items that have conflicts. For example, if you have a VAR layer model in the Application Suite package that customizes the VendTable form, and you install a hotfix that modifies the VendTable form in the Sys layer model, conflicts might occur in your VAR layer model.

1. Click **Dynamics 365** > **Addins** > **Create project from conflicts**.
2. In the dialog box, select a model to check for conflicts.
3. Click **Create project**. A project is generated that contains only those elements in the selected model that

were found to have conflicts after the hotfix was applied.

4. Open the designer for the conflicting element to view conflicts, and resolve them by using the tools that are provided.

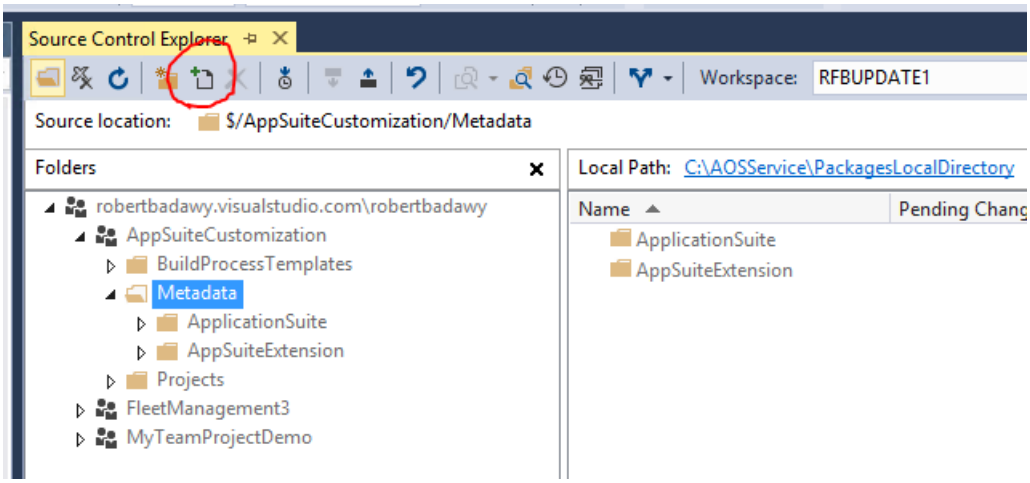
Build and test on a local VM

Build all models that are affected by the hotfix, and test your application.

Check pending changes in to version control

When you're satisfied with all changes that are related to this update, check in your pending changes to Azure DevOps by using Team Explorer in Microsoft Visual Studio. Enter a comment in the **Comment** field, and then click **Check In**. A history of the changes is preserved in your source code repository.

> **NOTE**
>
> If you use a build environment for build and test automation, the build automation process can build metadata hotfix files are in your Azure DevOps project. A hotfix can be built only if the descriptor file of the model that it belongs to is checked in to version control. For example, if the hotfix installation process modified a file that belongs to the Directory model (this file will appear in your list of pending changes), make sure that the descriptor file of the Directory model (c:\AOSService\PackagesLocalDirectory\Directory\Descriptor\Directory.xml) is already checked in to your Azure DevOps project. If it isn't checked in, manually add it to your list of pending changes before you check in by using Source Control Explorer.



Synchronize other development VMs

After a hotfix has been installed on a development VM as described in this article, you don't have to reinstall, resolve conflicts, and validate on other development VMs that are connected to the same Azure DevOps project. Developers and testers who are connected to the same Azure DevOps project can just synchronize the changes into their local VM and then build.

Deploy

After you've applied a metadata hotfix to your development environment, resolved conflicts, and validated your changes, you must create a deployable package and apply your changes to your test or sandbox environment. If you use a build instance for build and test automation, the build process will automatically create the deployable package for you. For more information, see Create deployable packages of models.

NOTE

Can you tell us about your documentation language preferences? Take a short survey.

The survey will take about seven minutes. No personal data is collected (privacy statement).

Patch SQL Server Reporting Services (SSRS) in one-box environments

2/18/2021 • 3 minutes to read • Edit Online

The following procedure is for one-box development environments only.

Patch the Reporting Service

The following procedure is for one-box development environments only.

- Download the patch .zip file from Lifecycle Services (LCS).
- If there are any font files in the Reporting Service patch's data folder, install these to the machine where SQL Server Reporting Services (SSRS) is running. For more information about installing fonts on Windows, see How to install or remove a font in Windows. Any fonts that have already been installed do not need to be installed again.
- Copy the files in the Reporting Services patch scripts folder to the Report plug-in folder located under C:\Packages\Plugins\AxReportVmRoleStartupTask.
- Change the directory to the Report plug-in folder where you stored the script files.
- Using one of the methods listed below, replace the old instance of reporting extensions.
  - Remove/reinstall the reporting extension. The remove/reinstall option requires that redeploy all reports after you have finished the reinstallation..
  - Manually copy binaries to the sql server binary folder. If you choose to manually copy the files, then you do not need to redeploy reports.

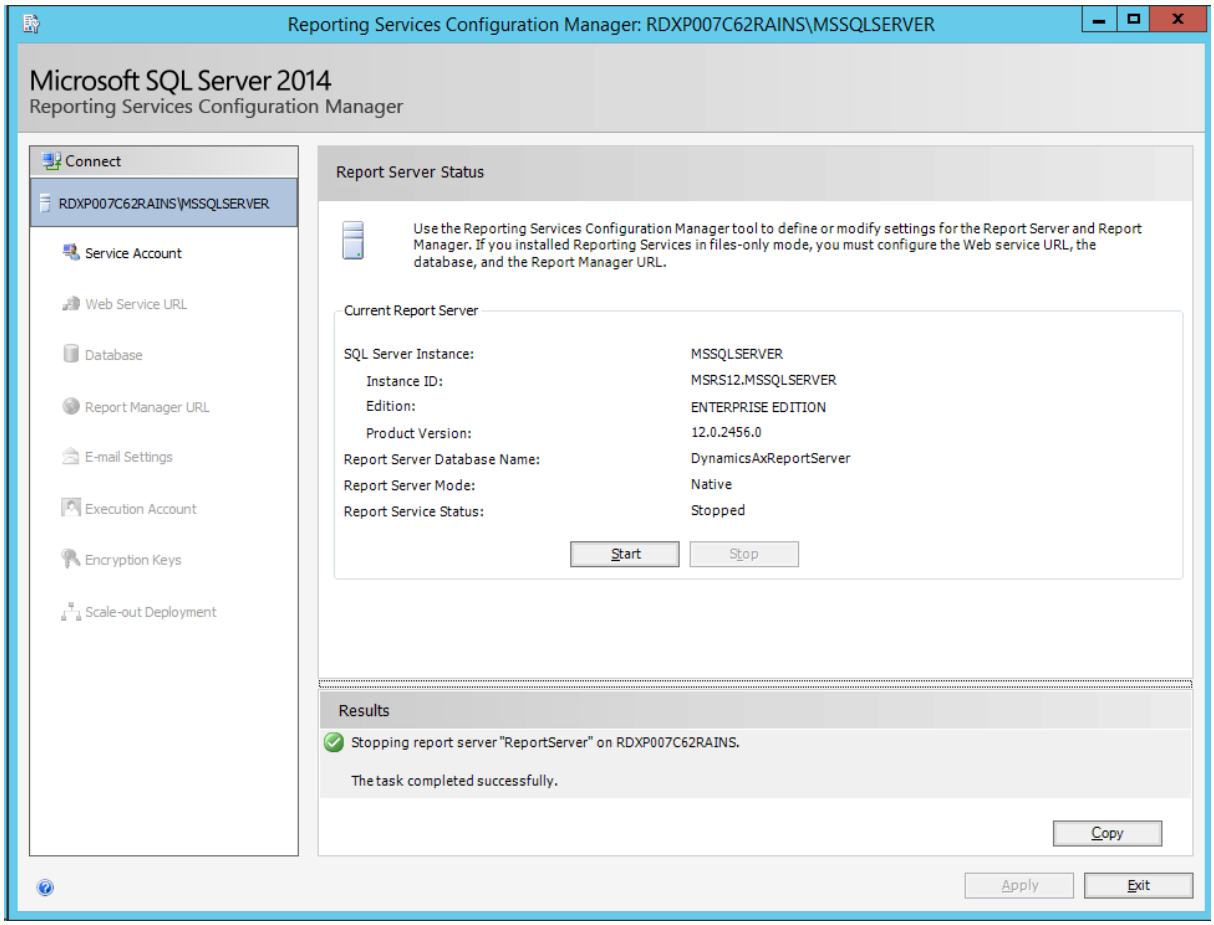
Remove/reinstall the reporting extension

Complete the following procedure as a user in the administrator group for the machine where SSRS is running.

- Using Windows PowerShell, remove the Dynamics SSRS extension by running the following script:
  - PowerShell .\DeploySsrsExtension.ps1 –UninstallOnly
- In PowerShell, reinstall the Dynamics SSRS extension by running the following script:
  - PowerShell .\DeploySsrsExtension.ps1
- Removing the reporting extension removes all the reports. If you have removed and then reinstalled the reporting extension, it is necessary to re-deploy the reports by running the following script:
  - Powershell .\DeployAllReportsToSsrs.ps1
- This task will take 20 to 30 minutes to complete.

Manually copy binaries to the SQL Server binary folder

1. Stop SQL Server Reporting Services. This can be done either from the **Services management** console or from the **Reporting Services Configuration Manager**.



2. Find the SQL Server Reporting Services binary folder. This folder is usually located at C:\Program Files\Microsoft SQL Server\MSRS11.MSSQLSERVER\Reporting Services\ReportServer\bin.
3. If any of the following files are in the patch, copy them to the SQL Server Reporting Services bin folder.* *

> **NOTE**
>
> Patches can either be full patches, which would contain all of the files used by the service, or incremental patches, which contain only the files that have changed. If you have an incremental patch, then some files may not be included. Files not included in the patch do not need to be replaced.

- Microsoft.Dynamics.AX.Framework.Services.Platform.Client.dll
- Microsoft.Dynamics.Framework.ReportsExtensions.dll
- Microsoft.Dynamics.Framework.Reports.dll
- Microsoft.Dynamics.ApplicationPlatform.SSRSReportRuntime.Instrumentation.dll
- Microsoft.Dynamics.ApplicationPlatform.SSRSReportRuntime.man
- Microsoft.Dynamics.Platform.Integration.ClientSdk.Abstraction.dll
- Microsoft.Dynamics.AX.Framework.Reports.Shared.dll
- Microsoft.Dynamics.AX.Framework.EncryptionEngine.dll
- Microsoft.Dynamics.AX.Framework.Utilities.dll
- Microsoft.Dynamics.ApplicationSuite.Reporting.BusinessLogic.dll
- Microsoft.Dynamics.ApplicationPlatform.Environment.dll
- Microsoft.Dynamics.AX.ReportConfiguration.axc
- Microsoft.WindowsAzure.ServiceRuntime.dll
- Microsoft.IdentityModel.dll
- msshrtmi.dll

Restart SQL Server Reporting Services.

Reporting service installation

The following changes are made with the reporting service installation: The following files will be copied into Reporting service bin folder (C:\Program Files\Microsoft SQL Server\MSRS11.MSSQLSERVER\Reporting Services\ReportServer\bin), and the corresponding SSRS config files will be updated so that SSRS is aware of the extension.

- Dynamics.AX.Framework.Services.Platform.Client.dll
- Dynamics.Framework.ReportsExtensions.dll
- Dynamics.Framework.Reports.dll
- Dynamics.ApplicationPlatform.SSRSReportRuntime.Instrumentation.dll
- Dynamics.ApplicationPlatform.SSRSReportRuntime.man
- Dynamics.Platform.Integration.ClientSdk.Abstraction.dll
- Dynamics.AX.Framework.Reports.Shared.dll
- Dynamics.AX.Framework.EncryptionEngine.dll
- Dynamics.AX.Framework.Utilities.dll
- Dynamics.ApplicationSuite.Reporting.BusinessLogic.dll
- Dynamics.ApplicationPlatform.Environment.dll
- Dynamics.AX.ReportConfiguration.axc
- WindowsAzure.ServiceRuntime.dll
- IdentityModel.dll
- msshrtmi.dll

An SSRS service account will be updated to use the local system. A new SSRS catalog database DynamicsAxReportServer and temp database DynamicsAxReportServerTempDB database will be created, and SSRS will be configured to use these two databases. The default catalog database ReportServer and ReportServerTempDBstill exist, but are set to not be used by reporting services. The SSRS service will be updated to use Windows Authentication. An xml configuration file ReportPVMConfiguration.xml will be created in the SSRS bin folder for the report runtime. A report root folder named **Dynamics** and a new security role named **DynamicsBrowser** will be created. Both AOS Web application AppPool identity and batch service account will be added to this custom role. Note that during deployment, the report folder will be deleted and then recreated. Therefore all the previously deployed reports will be deleted from the SSRS server. After you reinstall the reporting extension, you must redeploy the reports.

Update the Visual Studio development tools

2/18/2021 • 2 minutes to read • Edit Online

This topic explains how to update the development tools.

Use this tutorial to update your Visual Studio development tools with a new version. It explains how to uninstall your existing Visual Studio development tools and install the new extension. The new extension is in the form of an installable VSIX file. This file is a part of the binary hotfix available on the Dynamics Lifecycle Services (LCS) site. The VSIX file is located in the **DevToolsService\Scripts** folder of the binary hotfix package.

> **NOTE**
> You do not need to follow the instructions in this article if you are upgrading your Finance and Operations platform to Platform update 4 or newer. It is an automatic step that is part of the platform upgrade process.

Uninstall the existing Visual Studio extension

In order to install a new version of the development tools, you'll need to uninstall the existing version first. Verify the version of the development tools that you have installed. If you don't have it installed, you can skip this section.

Verify your current version of the Visual Studio extension

1. Open the Visual Studio **Help > About Microsoft Visual Studio** dialog and find **Finance and Operations Developer Tools**.
2. Select it and click **OK**.

Uninstall the extension

1. Open the Visual Studio **Tools > Extensions and Updates** dialog.
2. Select **Finance and Operations Visual Studio Tools** and click **Uninstall**.
3. When the extension is uninstalled, exit Visual Studio.

Install a new version of the extension

1. Make sure Visual Studio is not running.
2. Double-click (or right-click and **Open**) the VSIX file of the new version.
3. Follow the installation instructions.
4. When installation is complete, you can start Visual Studio and start developing your application.

> **NOTE**
> Can you tell us about your documentation language preferences? Take a short survey.
>
> The survey will take about seven minutes. No personal data is collected (privacy statement).

Removed or deprecated features in previous releases

2/18/2021 • 51 minutes to read • Edit Online

NOTE

Effective November 2020:

- Common Data Service has been renamed to Microsoft Dataverse. For more information, see Power Automate Blog.
- Some terminology in Microsoft Dataverse has been updated. For example, *entity* is now *table* and *field* is now *column*. For more information, see Terminology updates.

This topic will be updated soon to reflect the latest terminology.

IMPORTANT

This topic is no longer updated. To see a current list of features that have been removed or deprecated from Finance and Operations apps, search for **"Removed or deprecated features"** content that relates to the app you're using.

This topic describes features that have been removed or deprecated from Dynamics 365 for Finance and Operations and previous releases of that product.

- A *removed* feature is no longer available in the product.
- A *deprecated* feature is not in active development and may be removed in a future update.

This list is intended to help you consider these removals and deprecations for your own planning.

Detailed information about objects in Finance and Operations apps can be found in the Technical reference reports. You can compare the different versions of these reports to learn about objects that have changed or been removed in each version of Finance and Operations apps.

Finance 10.0.7 with Platform update 31

Chinese voucher types without Account groups selection

Reason for deprecation/removal	Changed to the feature with account groups selection.
Replaced by another feature?	Yes
Product areas affected	Application
Deployment option	All
Status	Deprecated: By December 1, 2020, we plan to no longer support Chinese voucher types setup without Account groups selection. Find more details about new feature design in What's new in 10.0.7

Finance and Operations 10.0.6 with Platform update 30

DimensionHash.getHash(str _message)

Reason for deprecation/removal	Windows is deprecating the use of SHA1, as documented in Windows Enforcement of SHA1 Certificates.
Replaced by another feature?	Yes
Product areas affected	Application
Deployment option	All
Status	Deprecated: By April 1, 2020, developers must use the platform APIs found in the class **HasFunction**.

Hash.ComputeSHA1Hash(string message)

Reason for deprecation/removal	Windows is deprecating the use of SHA1, as documented in Windows Enforcement of SHA1 Certificates.
Replaced by another feature?	Yes
Product areas affected	Platform
Deployment option	All
Status	Deprecated: By April 1, 2020, developers must use the platform APIs found in the class **HasFunction**.

FormDateTimeControl.setUtcString()

Reason for deprecation/removal	We are retiring the **setUtcString()** method, because a better replacement method is available.
Replaced by another feature?	Yes
Product areas affected	Platform
Deployment option	All
Status	Deprecated: By October 1, 2020, we plan to no longer support the **setUtcString()** method. Developers should be using the **setUtcDateTime()** method instead.

Blacklist report (IT) – Feature reference IT-00001

Reason for deprecation/removal	Not legally required.
Replaced by another feature?	No
Product areas affected	Italian localization
Deployment option	All
Status	Deprecated: By October 1, 2020, we plan to no longer support the **Blacklist report (IT) – Feature reference IT-00001**.

Domestic tax report – Feature reference IT-00003

Reason for deprecation/removal	Not legally required.
Replaced by another feature?	No
Product areas affected	Italian localization
Deployment option	All
Status	Deprecated: By October 1, 2020, we plan to no longer support the **Domestic tax report – Feature reference IT-00003**.

Finance and Operations 10.0.5 with Platform update 29

US Payroll tax updates

Reason for deprecation/removal	We are retiring tax updates for the US Payroll functionality due to low usage and enhanced functionality that is now offered via strategic integrations.
Replaced by another feature?	Yes
Product areas affected	Payroll
Deployment option	All
Status	Deprecated: By July 31, 2024, we plan to no longer provide tax updates to US Payroll customers. The functionality will remain in the product, but enhancements will no longer keep the functionality up to date, and any product defects will be evaluated on a case-by-case basis.

> **NOTE**
>
> This represents a change from the original discontinuation date of October 1, 2021. For more information, see Tax updates being retired for US Payroll feature in Microsoft Dynamics 365 for Finance and Operations.

Data management staging clean up

Reason for deprecation/removal	Does not meet the core requirements that are needed for scheduling periodic cleanup.
Replaced by another feature?	Yes, the Job history cleanup feature is being added to meet the scenarios holistically.
Product areas affected	Data management
Deployment option	All
Status	Deprecated: Target timeframe for the functionality to be removed is December 2020.

Finance and Operations 10.0.4 with Platform update 28

France: FEC Accounting data export in XML

Reason for deprecation/removal	Replaced by TXT format, **French FEC audit file** is available through **General ledger** > **Periodic tasks** > **Data export**.
Replaced by another feature?	Yes
Product areas affected	General ledger
Deployment option	All
Status	Deprecated. Target timeframe for the functionality to be removed is July 2020.

Legacy navigation bar

Reason for deprecation/removal	Header alignment with other Dynamics and Office products. For more details, see Updated navigation bar that aligns with the Office header.
Replaced by another feature?	Starting in Platform update 24, a restyled navigation bar that features search was introduced.
Product areas affected	Web client

Deployment option	All
Status	Deprecated: Starting in April 2020, the legacy navigation bar will no longer be available. Until that point, customers can revert to the legacy navigation bar through the **Client performance options** page.

Finance and Operations 10.0.2 with Platform update 26

Legacy default action behavior

Reason for deprecation/removal	The legacy behavior for default actions in grids results in an unexpected column having the default action link after grid columns have been reordered via personalization. The new sticky default action feature corrects this. For more details, see Sticky default actions in grids.
Replaced by another feature?	Starting in Platform update 21, a feature for "sticky default actions" was introduced. This feature can be enabled on the **Client performance options** page.
Product areas affected	Grids in the web client
Deployment option	All
Status	Deprecated: Starting in April 2020, sticky default actions will be the default behavior, without a mechanism to revert to the legacy behavior.

Legacy "is one of" filtering experience

Reason for deprecation/removal	The "is one of" filtering experience went through a redesign in Platform update 22,with the plan for this to eventually be the only "is one of" filtering experience.
Replaced by another feature?	Starting in Platform update 22, an improved "is one of" filtering experience became available on the **Client performance options** page. For more information, see Optimized is one of filtering experience.
Product areas affected	Web client
Deployment option	All
Status	Deprecated: Starting in April 2020, the improved "is one of" experience will be the default behavior, without a mechanism to revert to the legacy behavior.

Parameter to enable sales orders with multiple project contract funding sources

Support for creating project-based sales orders where the project contract has multiple funding sources is

enabled with the **Project management parameters** setting **Allow sales orders for project with multiple funding sources**. By default, this parameter is not enabled.

Reason for deprecation/removal	The functionality will always be enabled after the parameter is removed.
Replaced by another feature?	No. The functionality to support project-based sales orders with multiple funding sources will always be enabled.
Product areas affected	The **Allow sales orders for projects with multiple funding sources** parameter will be removed. The following methods will be modified when the parameter is removed: **ctrlSalesOrderTable** method in **ProjStatusType** class, **validate** method for **ProjId** field, and **run** method in **SalescreateOrder** form. The following methods will be deprecated when the parameter is removed: **IsSalesOrderAllowedForMultipleFundingSources** in **ProjTable** table file, **IsAllowSalesOrdersForMultipleFundingSourcesParamEnabled** method in **ProjTable** table file, **AllowSalesOrdersForMultipleFundingSources** data field in **ProjParameters** form and **ProjParameterEntity** files, **IsAssociatedToMultipleFundingSourcesContract** private method in **ProjTable** table file.
Deployment option	All
Status	Deprecation is planned for the April 2020 release wave.

Legacy workflow reports for tracking and instance status

Reason for deprecation/removal	The legacy workflow reports for tracking and instance status are being deprecated because they are no longer referenced from the navigation. The report names are WorkflowWorkflowInstanceByStatusReport and WorkflowWorkflowTrackingReport.
Replaced by another feature?	The workflow history form can be used instead.
Product areas affected	Web client
Deployment option	All
Status	Deprecated: Target timeframe for the functionality to be removed is April 2020.

Finance and Operations 10.0.1 with Platform update 25

Deprecated APIs and potential breaking changes

Deriving from internal classes is deprecated

Reason for deprecation/removal	Before Platform update 25, it was possible to create a class or table that derives from an internal class/table that is defined in another package/module. This is not a safe coding practice. As of Platform update 25, the compiler will display a warning.
Replaced by another feature?	The compiler warning will be replaced by an error in Platform update 26. This change is backward compatible at runtime, which means that Platform update 25 or newer can be deployed on any sandbox or production environment without the need to modify custom code. This change only affects development and compile time.
Product areas affected	Visual Studio development tools
Deployment option	All
Status	Deprecated: The warning will become a compilation error in Platform update 26.

Overriding internal methods is deprecated

Reason for deprecation/removal	Before Platform update 25, it was possible to override an internal method in a derived class that is defined in another package/module. This is not a safe coding practice. As of Platform update 25, the compiler will display a warning.
Replaced by another feature?	This warning will be replaced by a compile error in Platform update 26. This change is backward compatible at runtime, which means that Platform update 25 or newer can be deployed on any sandbox or production environment without the need to modify custom code. This change only affects development and compile time.
Product areas affected	Visual Studio development tools
Deployment option	All
Status	Deprecated: The warning will become a compilation error in Platform update 26.

Finance and Operations 10.0.0 with Platform update 24

Renaming released products

Reason for deprecation/removal	When you use the **Rename primary key** function to change the ItemId of a released product, only direct foreign key references are updated. Any other references to the released product, such as from production orders, will retain the old ItemId. As a result, there could be inconsistent data that will eventually block business processes.

Replaced by another feature?	No.
Product areas affected	Product information management
Deployment option	All
Status	Removed as of Finance and Operations 10.0.0 with Platform update 24.

Finance and Operations 8.1.3 with Platform update 23

SQL Server Reporting Services ReportViewer Control

Customers can use the **Export** action provided by the embedded SQL Server Reporting Services (SSRS) ReportViewer control to download documents produced by Finance and Operations applications. This HTML-based presentation of the report offers users a non-paginated preview of the document.

Reason for deprecation/removal	The non-paginated nature of the HTML-based preview experience does **not** deliver fidelity with the physical documents ultimately produced by Finance and Operations. By fully embracing PDF as the standard format for business documents, users are able to take advantage of a modern viewing experience with improved performance when producing application reports.
Replaced by another feature?	Going forward, PDF documents will be the default format for reports rendered by Finance and Operations.
Product areas affected	This change does **not** impact customer scenarios where reports are distributed electronically or sent directly to printers.
Deployment option	All
Status	Deprecated: A removal date has not been set for this feature. The functionality to automatically preview application reports using an embedded PDF viewer is planned for the May 2019 Platform update.

Client KPI controls

Embedded key performance indicators (KPIs) could be modeled in Visual Studio by a developer and further customized by the end user.

Reason for deprecation/removal	The native client controls used to define KPIs have low customer uptake and rely on a developer to add trackable metrics.

Replaced by another feature?	PowerBI.com service delivers world-class tooling for defining and managing KPIs based on data from external sources. In an upcoming release, we plan to enable you to embed solutions hosted on PowerBI.com in application workspaces.
Product areas affected	This update will prevent developers from introducing new KPI controls in Visual Studio designer.
Deployment option	All
Status	Deprecated: A removal date has not been set for this feature.

Deprecated APIs and future breaking changes

Field groups containing invalid field references

Reason for deprecation/removal	It is possible for table metadata definitions to have field groups containing invalid field references. If deployed, this can cause runtime failures in Financial Reporting and SQL Server Reporting Services (SSRS). This issue is currently categorized as a *compiler warning* rather than an *error*, meaning that the deployable package creation and deployment can proceed without fixing the issue. To fix this issue: 1. Remove the invalid field reference from the table field group definition. 2. Recompile. 3. Ensure any warnings or errors are addressed.
Replaced by another feature?	This warning will be replaced by a compile error in the future.
Product areas affected	Visual Studio development tools
Deployment option	All
Status	Deprecated: The warning is a compile-time error with platform updates for version 10.0.11 of Finance and Operations apps.

Complete list

To access the full list of APIs that are being deprecated, see Deprecation of methods and metadata elements.

Finance and Operations 8.1 with Platform update 20

Batch transfer rules for subledger journal account entries

The Synchronous transfer mode is being deprecated in the General ledger parameters. This mode is replaced by Asynchronous and scheduled batch only, which already exist as options for transfer. For additional information, see the General Ledger Parameters – Batch transfer rules blog.

Reason for deprecation/removal	We are removing the synchronous option due to performance impact to the system.
Replaced by another feature?	Asynchronous and scheduled batch are options to use in place of Synchronous.
Product areas affected	General Ledger, Accounts payable, Accounts Receivable, Procurement, Expense
Deployment option	All
Status	Deprecated: Target timeframe for the functionality to be removed is the 10.0 version.

Electronic reporting for Russia

Feature for configuring .txt and .xml file formats of declarations.

Reason for deprecation/removal	Replaced with Electronic reporting.
Replaced by another feature?	Yes.
Product areas affected	General Ledger
Deployment option	All
Status	Removed as of Finance and Operations 8.1 with Platform update 20.

Financial reports generator for Russia

A tool for setting up data collection for accounting and tax reports, and to export data to XLS and DOC report templates. Functional parts: Export data to XLS and DOC report templates, queries, fixed requisites are removed.

Reason for deprecation/removal	Removed parts are replaced with Electronic reporting.
Replaced by another feature?	Yes. Financial reports setup user interface should be used for setting up data collection rules by GL accounts or tax registers. Export data to various file types, fixed requisites and query-like data collection rules should be configured in Electronic reporting.
Product areas affected	General ledger.
Deployment option	All
Status	Removed as of Finance and Operations 8.1 with Platform update 20.

Integration with external providers for sending electronic reporting through communication channels for

Russia

Feature exporting generated electronic files of declarations to folder for further sending to official providers of electronic reporting as well as importing state back.

Reason for deprecation/removal	Replaced with electronic messages configurable feature.
Replaced by another feature?	Yes.
Product areas affected	General Ledger, Tax
Deployment option	All
Status	Removed as of Finance and Operations 8.1 with Platform update 20.

Profit tax register wizard

Feature for creating templates for new profit tax registers. This feature creates X++ objects for new registers, which are then created as templates with the appropriate calculation logic added in.

Reason for deprecation/removal	Feature is not compatible with the Finance and Operations extensibility model.
Replaced by another feature?	No
Product areas affected	Tax
Deployment option	All
Status	Removed as of Finance and Operations 8.1 with Platform update 20.

Finance and Operations 8.0 with Platform update 15

No features have been removed or deprecated with this release. Platform update 15 is cumulative and contains new or changed features from Platform update 13, Platform update 14, and Platform update 15.

Finance and Operations, Enterprise edition 7.3 with Platform update 12

Personalized product recommendations

Starting February 15, 2018, retailers will no longer be able to display personalized product recommendations on a point of sale (POS) device. For more information, see Product recommendations overview.

Reason for deprecation/removal	We are removing the current version of the product recommendation service as we redesign this feature with a better algorithm and newer retail-oriented capabilities.

Replaced by another feature?	No. However, after Spring 2018, we plan to bring back this feature to leverage a new recommendation service.
Product areas affected	Personalized product recommendations in POS.
Deployment option	All
Status	Removed as of February 15, 2018. This affects customers running Dynamics 365 for Operations 1611 and later.

Extension of the list of Electronic reporting (ER) functions

The possibility to introduce custom functions to be used in the ER expression builder (for more information, see Extend the list of Electronic reporting (ER) functions) is not supported any more. Due to changes of the ER APIs, the API to call built-in functions from the ER expression builder became internal and can't be extended any longer.

Reason for deprecation/removal	Code sealing initiative
Replaced by another feature?	None. Whenever a new built-in function is needed, a new extension request must be addressed to the ER framework team. As a temporary work around while the requested function is under development by the ER team, the required logic can be programmed as a method of a custom application class. This method can be accessed in an ER expression as a property of the added ER data source of the **Application\Class** type that refers to that custom application class.
Product areas affected	Electronic reporting framework
Deployment option	All
Status	Removed as of Finance and Operations, Enterprise edition 7.3.

Inventory by item group and Inventory by inventory dimension aging reports

These two reports are no longer supported in Finance and Operations. Instead, the **Inventory aging** report can be used to improve the user experience.

Reason for deprecation	Duplicate functionality
Replaced by another feature?	Yes. The two reports have been replaced by the **Inventory aging** report.
Product areas affected	Inventory management, Cost management

Deployment option	All
Status	Deprecated: The menu items for the two reports have been removed in version 7.3. However, the code for the reports remains in the product. The plan is to remove the code in a future release.

Power BI content packs available on AppSource

The **Cost management**, **Financial performance**, and **Retail channel performance** content packs, available on the Microsoft AppSource site, are deprecated as a consequence of product updates in Microsoft Power BI. System administration forms used to deploy these content packs to PowerBI.com are also being deprecated in Finance and Operations.

Reason for deprecation/removal	Product updates in Microsoft Power BI.
Replaced by another feature?	The **Cost management**, **Financial performance**, and **Retail channel performance** content packs, available on the AppSource site, are being replaced by analytical applications which allow for solution integrations at the database level. For more information about analytical applications, see Embedded Power BI in workspaces.
Product areas affected	Cost management, Finance, and Retail
Deployment option	Cloud only (Integration with PowerBI.com is not supported in on-premises deployments.)
Status	Deprecated: Target timeframe for the functionality removal is Q2 2018.

Standard UI in data management workspace

The standard UI in data management is the legacy UI, which is the default UI presented to the users when they visit the data management workspace.

Reason for deprecation/removal	We are investing in providing new user experiences in the new UI.
Replaced by another feature?	The new UI called *Enhanced views* is replacing the old UI.
Product areas affected	Data management workspace
Deployment option	All
Status	Deprecated: Target timeframe for the functionality to be removed is Q2 2018.

Excise, Sales Tax, Service Tax for India

These taxes have been subsumed into Indian GST.

Reason for removal or deprecation	These taxes have been subsumed into Indian GST.
Replaced by another feature?	Indian GST
Product areas affected	Tax
Deployment option	All modules
Status	Deprecated: A removal date has not been set for this feature.

File Validation Utility (FVU) for India

Reason for removal or deprecation	Lack of customer usage
Replaced by another feature?	No
Product areas affected	Indian withholding tax
Deployment option	All modules
Status	Deprecated: A removal date has not been set for this feature.

TDS/TCS certificate for India

Users can download this from the government portal.

Reason for removal or deprecation	Lack of customer usage
Replaced by another feature?	No
Product areas affected	Indian withholding tax
Deployment option	All modules
Status	Deprecated: A removal date has not been set for this feature.

Export/import (EXIM) incentive scheme for India

Reason for removal or deprecation	Lack of customer usage
Replaced by another feature?	No
Product areas affected	Import and export

Deployment option	All modules
Status	Deprecated: A removal date has not been set for this feature.

Dynamics 365 for Retail 7.2

Personalized product recommendations

Starting February 15, 2018, retailers will no longer be able to display personalized product recommendations on a point of sale (POS) device. For more information, see Product recommendations overview.

Reason for deprecation/removal	We are removing the current version of the product recommendation service as we redesign this feature with a better algorithm and newer retail-oriented capabilities.
Replaced by another feature?	No. However, after Spring 2018, we plan to bring back this feature to leverage a new recommendation service.
Product areas affected	Personalized product recommendations in POS.
Deployment option	All
Status	Removed as of February 15, 2018. This affects customers running Dynamics 365 for Retail 7.2 and later.

Finance and Operations, Enterprise edition July 2017 with Platform update 8

Currency conversion for accounting and reporting currencies

Currency conversion for accounting and reporting currencies was introduced when the euro was introduced.

Reason for deprecation/removal	Limited usage and addition of the Copy legal entity functionality as a replacement.
Replaced by another feature?	No, but the Copy legal entity and Configurations features were added to make it easier to move to a company that has changing core requirements.
Product areas affected	Financial management
Status	Deprecated: A removal date has not been set for this feature.

Warehouse mobile devices portal

Warehouse mobile devices portal (WMDP) was a standalone component that was intended for on-premises self-deployment. This component is no longer supported in Finance and Operations. A native app that improves the user experience has replaced the functionality of WMDP.

Reason for deprecation/removal	Duplicate functionality.
Replaced by another feature?	Yes. This feature has been replaced by Finance and Operations - Warehousing. For more information about setup and prerequisites, see Install and configure the Warehousing app overview.
Product areas affected	Warehouse management, Transportation management
Deployment option	Warehouse mobile devices portal (WMDP) was a standalone component that was intended for on-premises self-deployment.
Status	Deprecated: Target timeframe for the functionality to be removed is Q4 2019.

Advanced bank reconciliation matching rule for manual matching

A matching rule was used to select and mark a bank document when documents were manually matched in the reconciliation worksheet.

Reason for deprecation/removal	Limited usage.
Replaced by another feature?	No. Column filtering capabilities should be used to find documents for reconciliation.
Product areas affected	Cash and bank management
Deployment option	All
Status	Removed as of July 2017.

Dynamics 365 for Operations 1611 with Platform update 3

AEB payment formats for Spain

The Consejo Superior Bancario payment formats were used to send remittance files to the bank for customer payments and vendor payments. The content of these formats was determined by the Asociación Española de Banca. It covers Cuaderno 19, 32, 58, 34.

Reason for deprecation/removal	The payment formats are no longer used.
Replaced by another feature?	Yes, ISO20022 Credit transfer and Direct debit payment formats for Spain
Product areas affected	Accounts payable, Accounts receivable

Status	Deprecated: A removal date has not been set for this feature.

Bank payments transfer for Lithuania

Bank payment transfers were generated and printed by using the Payment transfer (LT) export format for Lithuania. The Lithuanian market began to use LITAS, the unified electronic banking system, in 2005.

Reason for deprecation/removal	The payment formats are no longer used.
Replaced by another feature?	Yes, ISO20022 Credit transfer payment format for Lithuania
Product areas affected	Accounts payable
Status	Deprecated: A removal date has not been set for this feature.

BBS Direkte Remittering payment formats for Norway

BBS Direkte Remittering payment formats include customer payment collection export (direct debit) and return message import.

Reason for deprecation/removal	The payment formats are no longer used.
Replaced by another feature?	The AvtaleGiro customer payment format for Norway can be used to generate direct debit messages. Return message import will be implemented in future releases.
Product areas affected	Accounts payable, Accounts receivable
Status	Deprecated: A removal date has not been set for this feature.

Chart of Accounts tool for Spain

This tool is used when a chart of accounts in Spain requires major changes. Users can import a new chart of accounts in Microsoft Excel or text format, and can also import financial statements.

Reason for deprecation/removal	Limited usage
Replaced by another feature?	No
Product areas affected	General ledger
Status	Deprecated: A removal date has not been set for this feature.

Dom80 payment format for Belgium

Legacy Belgian payment format for payment collection (direct debit).

Reason for deprecation/removal	The payment format is no longer used.
Replaced by another feature?	Yes, ISO 20022 Direct debit payment format for Belgium
Product areas affected	Accounts receivable
Status	Deprecated: A removal date has not been set for this feature.

DTA/EZAG payment formats for Switzerland

DTA/EZAG formats are integrated into the ESR system, because they can carry on the reference number. Because the reference number isn't mandatory, these formats can be used to process any vendor payments. These formats are used by companies that have a bank account in a location other than "Postfinance."

Reason for deprecation/removal	The payment formats are no longer used.
Replaced by another feature?	Yes, ISO20022 Credit transfer payment format for Switzerland
Product areas affected	Accounts payable
Status	Deprecated: A removal date has not been set for this feature.

EDIFACT-DIRDEB payment format for Austria

EDIFACT-DIRDEB payment format for payment collection (direct debit).

Reason for deprecation/removal	The payment format is no longer used.
Replaced by another feature?	Yes, ISO 20022 Direct debit payment format for Austria
Product areas affected	Accounts receivable
Status	Deprecated: A removal date has not been set for this feature.

EDIVAT for Belgium

EDIVAT is an obsolete Belgian standard for electronic declaration via secure mail. Dynamics AX 2012 retains the read-only solution to enable access to the historical data.

Reason for deprecation/removal	The functionality is no longer used.
Replaced by another feature?	No

Product areas affected	General ledger
Status	Deprecated: A removal date has not been set for this feature.

eGiro EDIFACT CREMUL payment import format for Norway

eGiro is based on the international UN EDIFACT CREMUL (Multiple Credit Advice Message) standard that is used for automatic posting of customer payments. In Dynamics AX, eGiro is implemented as a customer payment import format.

Reason for deprecation/removal	The payment format is no longer used.
Replaced by another feature?	Yes, the ISO20022 Camt.054 notification import.
Product areas affected	Accounts receivable
Status	Deprecated: A removal date has not been set for this feature.

External inventory for Poland

Evidence of goods that are taken from a vendor for sales without purchase. Goods that are handled in external inventory don't affect standard inventory, and can be sold and then purchased automatically. This process creates real inventory movements.

Reason for deprecation/removal	Replaced by another feature
Replaced by another feature?	Yes, the core Inbound consignment functionality
Product areas affected	Accounts payable, Inventory management
Status	Deprecated: A removal date has not been set for this feature.

Financial reports generator for Eastern Europe

A tool is used to set up data collection for accounting and tax reports, and to export data to XLS and DOC report templates.

Reason for deprecation/removal	Limited usage
Replaced by another feature?	No. The tool will be replaced by Electronic reporting configurations in future releases.
Product areas affected	General Ledger

Status	Deprecated: A removal date has not been set for this feature.

Import of customer payment transactions for Finland

You can select an import format for Finnish payments to import customer payment transactions from an external file that the bank provides.

Reason for deprecation/removal	The payment format is no longer used.
Replaced by another feature?	Yes, the ISO20022 Camt.054 notification import.
Product areas affected	Accounts receivable
Status	Deprecated: A removal date has not been set for this feature.

Import of payment transactions into a general ledger journal for Finland

A format that is specific to Finland is used to import accounting transactions into the general ledger.

Reason for deprecation/removal	The payment format is no longer used.
Replaced by another feature?	Yes, the ISO20022 Camt.053 bank statement import using Advanced Bank Reconciliation.
Product areas affected	Accounts receivable
Status	Deprecated: A removal date has not been set for this feature.

Integration with Isabel synchronized (CIS) for Belgium

Isabel is the framework for electronic banking in Europe and is a de-facto standard in Belgium.

Reason for deprecation/removal	Integration with Isabel client has been discontinued.
Replaced by another feature?	No. The payment formats that are no longer used are replaced by ISO20022 Credit transfer payment format for Belgium.
Product areas affected	Accounts payable
Status	Deprecated: A removal date has not been set for this feature.

Modifications in the chart of accounts and accounting rules for Spain

This feature is used for changes in the chart of accounts and accounting rules in Spain. It maps accounts to help

transform the old chart of accounts into the new chart of accounts, and compares the previous fiscal year with the new fiscal year, even if they were posted to different account numbers.

Reason for deprecation/removal	Limited usage
Replaced by another feature?	No
Product areas affected	General ledger
Status	Deprecated: A removal date has not been set for this feature.

Pagamento Fornittori vendor payment format

Legacy Italian payment format for credit transfers.

Reason for deprecation/removal	The payment format is no longer used.
Replaced by another feature?	Yes, ISO20022 Credit transfer payment format for Italy
Product areas affected	Accounts payable
Status	Deprecated: A removal date has not been set for this feature.

Payment export formats for Estonia

The Telehansa and Teleservice formats are used for bank payment export.

Reason for deprecation/removal	The payment formats are no longer used.
Replaced by another feature?	Yes, ISO20022 Credit transfer payment format for Estonia
Product areas affected	Accounts payable
Status	Deprecated: A removal date has not been set for this feature.

Payment file archive for Norway

When payment files are generated, the file archive automatically archives all files that are created, even files that were previously written or read.

Reason for deprecation/removal	Replaced by another feature
Replaced by another feature?	Yes, Electronic reporting archived jobs

Product areas affected	Accounts payable, Accounts receivable, Organization administration
Status	Deprecated: A removal date has not been set for this feature.

Payment import formats for Estonia

The Telehansa and TeleTeenus formats are used for bank payment import.

Reason for deprecation/removal	The payment formats are no longer used.
Replaced by another feature?	Yes, the ISO20022 Camt.054 bank notification import.
Product areas affected	Accounts receivable
Status	Deprecated: A removal date has not been set for this feature.

Payroll information in Human Resources

Human Resources Payroll information

Reason for deprecation/removal	This functionality has been replaced by core Payroll and Human Resources pages.
Replaced by another feature?	**Benefits**, **Earnings**, and other related pages that were previously in US Payroll have been reconfigured, and are now part of the core Human Resources configuration to help support external payroll processing. This functionality is accessed by using the **Human Resources 1** > **Payroll** configuration key.
Product areas affected	Human Resources, Payroll
Status	Removed as of Dynamics 365 for Operations version 1611.

Performance management goal workflow

Performance management includes goal management and integration with performance reviews.

Reason for deprecation/removal	Performance management was redesigned, and the number of goal pages was reduced to simplify the process.
Replaced by another feature?	No. Goals are visible to managers through the Manager Self Service portal, and can be changed and viewed by the manager.
Product areas affected	Human capital management

Status	Removed as of Dynamics 365 for Operations version 1611.

Postgirot and Postgirot Utland payment formats for Sweden

Postgirot and Postgirot Utland payment formats for Sweden.

Reason for deprecation/removal	The payment formats are no longer used.
Replaced by another feature?	Yes, ISO20022 Credit transfer payment format for Sweden
Product areas affected	Accounts payable
Status	Deprecated: A removal date has not been set for this feature.

Radio frequency identifier

Radio Frequency Identification (RFID) is a data-collection technology that uses electronic tags to store identification data and a no-line-of-sight requirement reader to capture the identification data.

Reason for deprecation/removal	Low customer usage and a limited feature set.
Replaced by another feature?	No
Product areas affected	Inventory management
Status	Removed as of Dynamics 365 for Operations 1611.

Report about state invoices numbering for Latvia

Latvian legislation provides specific rules about the numbering of sales invoices. The functionality lets you assign specific numbers to sales invoices, based on the user or user group. You can then generate a report or an XML file. You can also print a report about invoice numbers that are used.

Reason for deprecation/removal	The state invoice numbering no longer has to be maintained. The report about used invoice numbers is no longer required.
Replaced by another feature?	No
Product areas affected	Accounts receivable
Status	Deprecated: A removal date has not been set for this feature.

Set up the names of the manager and general accountant of a company for Lithuania

The names of the manager and the general accountant of a company can be specified in the company

information and used in different local report printouts.

Reason for deprecation/removal	Replaced by another feature
Replaced by another feature?	Yes, the setup of officials can be used for the same purpose.
Product areas affected	Accounts payable, Accounts receivable, Cash and bank management
Status	Deprecated: A removal date has not been set for this feature.

Shipping carrier interface

Reason for deprecation/removal	Duplicate functionality
Replaced by another feature?	Partially replaced by Transportation management
Product areas affected	Sales and marketing, Inventory management
Status	Removed as of Dynamics 365 for Operations version 1611.

Telepay payment formats for Norway

Telepay payment formats include vendor payment export (credit transfer) and customer payment collection (direct debit).

Reason for deprecation/removal	The payment formats are no longer used.
Replaced by another feature?	Yes, ISO20022 Credit transfer payment format and AvtaleGiro customer payment format for Norway, as well as pain.002 and camt.054 bank notification return files import.
Product areas affected	Accounts payable, Accounts receivable
Status	Deprecated: A removal date has not been set for this feature.

Vendor payment export formats for Finland

Two formats for exporting payments are available for Finland. LM02 (FI) is used for domestic payments, and LUM2 (FI) is used for foreign payments.

Reason for deprecation/removal	The payment formats are no longer used.
Replaced by another feature?	Yes, ISO20022 Credit transfer payment format for Finland

Product areas affected	Accounts payable
Status	Deprecated: A removal date has not been set for this feature.

Warehouse management II

Reason for deprecation/removal	The Warehouse management II solution (WMS II) that was available in the **Inventory management** module duplicates functionality that is in the **Warehouse management** module that was released in Dynamics AX 2012 R3.
Replaced by another feature?	The **Warehouse management** module that was released in AX 2012 R3, Dynamics AX 2012 R3 CU8, and Dynamics AX 2012 R3 CU9 replaces the Warehouse management II features. The new module has more advanced features and more flexible warehouse management processes than Warehouse management II.
Product areas affected	Inventory management, Sales and marketing, Procurement and sourcing
Status	Removed as of Dynamics 365 for Operations version 1611.

Worker reminders in Human Resources

Human Resources Payroll information

Reason for deprecation/removal	Low usage
Replaced by another feature?	No
Product areas affected	Human resources
Status	Removed as of Dynamics 365 for Operations version 1611

Workflow for creating goals

A workflow for managing the creation of employee goals is one of several workflows that were available to help coordinate the performance management process.

Reason for deprecation/removal	Performance management has been completely redesigned in Finance and Operations.

Replaced by another feature?	The redesigned Performance management feature gives more control over the content of the goals, the measurements that are used to track progress, and the attachment of supporting documentation. Goals can be stored as templates and then reused. This feature can help you set up additional goals for your employees more quickly.
Product areas affected	Human capital management
Status	Removed as of Dynamics 365 for Operations version 1611.

Dynamics AX 7.0

Ability to cancel changes to a vendor invoice

Reason for deprecation/removal	Performance enhancement
Replaced by another feature?	No
Product areas affected	Accounts payable
Status	Removed as of Dynamics AX 7.0.

AIF, AxD, and AxBC integrations

In Application Integration Framework (AIF), data can be exchanged with external systems through business logic that is exposed as services. Dynamics AX includes services that are based on documents and .NET Business Connector (AxBC). A document is created by using XML. The XML includes header information that is added to create a *message* that can be transferred into or out of Dynamics AX. Examples of documents include sales orders and purchase orders. However, almost any entity, such as a customer, can be represented by a document. Services that are based on documents use the **Axd <Document>** classes.

Reason for deprecation/removal	The architecture of AIF and AxDs could not be scaled to a cloud service. There were performance issues around bulk import.
Replaced by another feature?	This feature is replaced by the Data Import/Export framework, which supports recurring bulk import/export. For AxBC, we recommend that you use the actual tables.
Product areas affected	AxDs, AxBCs, and AIF
Status	Removed as of Dynamics AX 7.0.

Billing code rate scripts

Billing scripts were used to calculate billing rates for billing codes. This scripts required custom development in the C Sharp or Visual Basic programming language. In the current version of Dynamics AX, the **billing code rate scripts** are not supported.

Reason for deprecation/removal	The support for the custom C Sharp or Visual Basic scripts was not added in Dynamics AX 7.0.
Replaced by another feature?	No
Product areas affected	Public sector, Accounts receivable
Status	Removed as of Dynamics AX 7.0.

BOMs without BOM versions

When the **BOM versions** configuration key was disabled, bill of materials (BOM) versions were hidden in all forms, and the system forced a 1:1 relationship between released products and BOMs. In the current version of Dynamics AX, the **BOM versions** configuration key can't be disabled.

Reason for deprecation/removal	Using a configuration key to control BOM versions doesn't scale in a cloud environment.
Replaced by another feature?	No
Product areas affected	Product information management, Inventory management
Status	Removed as of Dynamics AX 7.0.

Brazilian Bordero

Specific method of payment for Brazilian companies

Reason for deprecation/removal	Support for the Brazilian Bordero method of payment has been discontinued from Brazilian localization
Replaced by another feature?	No
Product areas affected	Accounts payable
Status	Deprecated: A removal date has not been set for this feature.

Brazilian Sintegra statement

Federal tax statement for ICMS tax

Reason for deprecation/removal	This statement is no longer applicable in some Brazilian states.
Replaced by another feature?	No. Users can use Generic Electronic reporting tool to configure the statement if required under specific situations.

Product areas affected	Fiscal books
Status	Deprecated: A removal date has not been set for this feature.

Brazilian SCAN contingency mode for NF-e

(SCAN) contingency environment is used to generate, export, and import the status of a Nota Fiscal eletrônica (NF-e) when the environment of Secretaria da Fazenda (SEFAZ) is not available.

Reason for deprecation/removal	This method of contingency is no longer applicable in all Brazilian states
Replaced by another feature?	No
Product areas affected	Accounts receivable
Status	Deprecated: A removal date has not been set for this feature.

Business Analyzer

This mobile application let users review key business metrics.

Reason for deprecation/removal	This functionality has been replaced by another feature.
Replaced by another feature?	The Monitor financial performance content pack for Microsoft Power BI will include key financial metrics that were previously available in Business Analyzer.
Product areas affected	General ledger
Status	Deprecated: The use of Business Analyzer has been deprecated.

Business statistics

The setup of business statistics inquiries that can help you analyze the performance of the organization

Reason for deprecation/removal	Legacy approach to business intelligence (BI), low customer usage, and a limited feature set
Replaced by another feature?	New BI solutions for the current version of Dynamics AX
Product areas affected	Procurement and sourcing, Accounts payable, Sales and marketing, Accounts receivable
Status	Removed as of Dynamics AX 7.0.

Change document date function in Invoice approval journal

Reason for deprecation/removal	Low usage
Replaced by another feature?	Yes. The document date on the posted vendor transaction can be changed.
Product areas affected	Accounts payable
Status	Removed as of Dynamics AX 7.0.

ClieOp03 payment format for the Netherlands

Reason for deprecation/removal	The format is no longer applicable in the Netherlands, because it has been replaced by SEPA functionality.
Replaced by another feature?	SEPA payments export
Product areas affected	All modules
Status	Deprecated: A removal date has not been set for this feature.

Compliance Center

The Compliance Center was an Enterprise Portal site for managing the documentation requirements for compliance initiatives that are related to the Sarbanes-Oxley law.

Reason for deprecation/removal	Lack of customer usage. Microsoft SharePoint includes the same capability that was available in the Compliance Center.
Replaced by another feature?	No
Product areas affected	Compliance and internal controls
Status	Removed as of Dynamics AX 7.0.

Connector for Microsoft Dynamics

This tool was used to integrate key data from Microsoft Dynamics CRM to Dynamics ERP applications.

Reason for deprecation/removal	This functionality has been replaced by another feature.
Replaced by another feature?	Dataverse
Product areas affected	Connector for Dynamics

Status	Removed as of Dynamics AX 7.0.

Container unit and multi dimension on-hand

Reason for deprecation/removal	Duplicate functionality
Replaced by another feature?	Yes. Since AX 2012, this functionality has been replaced by the consolidated batch orders feature set. This feature set includes the consolidated on-hand view.
Product areas affected	Product information management, Production control, Inventory management, Sales and marketing
Status	Removed as of Dynamics AX 7.0.

Cue group metadata

Reason for deprecation/removal	Cue groups were used to display one or more Cues in the FactBox area. There was limited uptake, and there were also performance concerns, because a record change in a parent form caused one query per Cue in the Cue group.
Replaced by another feature?	No
Product areas affected	All modules
Status	Removed as of Dynamics AX 7.0.

Cue metadata

Reason for deprecation/removal	Cue metadata was limited to count or sum information.
Replaced by another feature?	Tile metadata was introduced to provide more flexibility for modeling. For example, you can model current counts, navigation, and key performance indicators (KPIs). Count tile metadata is the direct replacement of the Cue metadata.
Product areas affected	All modules
Status	Removed as of Dynamics AX 7.0

Danish check format

Reason for deprecation/removal	Support for the Danish check format layout has been discontinued, and the report has been removed from DK localization.
Replaced by another feature?	No
Product areas affected	All modules
Status	Deprecated: A removal date has not been set for this feature.

Data partitions

Data partitions provide a logical separation of data in the Dynamics AX database.

Reason for deprecation/removal	Data partitions were introduced in Dynamics AX 2012 R2 to enable data isolation. In a common scenario, a company has subsidiaries, and the data from one subsidiary should not be visible to another subsidiary, even though both subsidiaries are managed by the same IT department. However, extra scripts and management overhead throughout the program were required in order to create new partitions and populate them with data, and to back up partition data. In the cloud, where we have access to platform as a service (PaaS) database services (Microsoft Azure SQL Database), it's much more efficient to use a database as the isolation container than to do isolation in the program. Regardless of whether data partitioning is required for subsidiaries, for multiple tenants, or just for scale, we believe that the scenarios can be handled better through multiple instances of Finance and Operations.
Replaced by another feature?	Customers using data partitions must use multiple instances of Finance and Operations if database level separation is a critical issue.
Product areas affected	All modules
Status	Removed as of Dynamics AX 7.0.

Database and file share storage for attachments

Dynamics AX 2012 allowed storage of attachments in the database and in file shares. Both of those options are no longer supported.

Reason for deprecation/removal	Files share storage is no longer supported because cloud-hosted environments cannot communicate with local file shares. Database storage has been deprecated in favor of Azure Blob storage. Azure Blob storage is equivalent to storage in the database, as documents can only be accessed through Finance and Operations client forms. This provides the added benefit of providing storage that doesn't negatively affect the performance of the database. Blob storage is the default storage mechanism for Document Management and works immediately.
Replaced by another feature?	Database storage has been deprecated in favor of Azure Blob storage.
Product areas affected	All modules
Status	Removed as of Dynamics AX 7.0.

Delimitation

Reason for deprecation/removal	No use of the functionality was found.
Replaced by another feature?	No
Product areas affected	Time and attendance
Status	Removed as of Dynamics AX 7.0.

Desktop client

Reason for deprecation/removal	The Dynamics AX client experience has been redesigned to improve usability across multiple platforms and devices.
Replaced by another feature?	The new web client is based on the desktop Form metadata and programming model that have been modified to provide a rich web platform.
Product areas affected	All modules
Status	Removed as of Dynamics AX 7.0.

Direct database connection

In Dynamics AX 2012 R3, Retail Modern POS could connect directly to the Channel DB in similar fashion to Enterprise POS. This was in addition to the standard communication method of Retail Modern POS communicating through Retail Server.

Reason for deprecation/removal	Direct database connectivity required lower security protocols and was primarily used to achieve the highest levels of performance. Due to the performance and security enhancements that have occurred in Finance and Operations, this functionality now causes more issues than it solves.
Replaced by another feature?	No. Only standard Retail Server communication is now supported.
Product areas affected	Channel DB/Retail Modern POS
Status	Removed as of Dynamics AX 7.0.

Dutch SWIFT MT940

Reason for deprecation/removal	Generic functionality is now used instead of localized functionality.
Replaced by another feature?	Yes, this functionality has been replaced by Advanced bank reconciliation functionality.
Product areas affected	All modules
Status	Deprecated: A removal date has not been set for this feature.

eBilanz (XBRL for Germany)

This functionality provided eXtensible Business Reporting Language (XBRL) output that is intended specifically for the German eBilanz taxonomy.

Reason for deprecation/removal	Lack of customer usage
Replaced by another feature?	This feature hasn't been replaced by another feature, but multiple specialized XBRL packages that provide rich XBRL functionality are available for the German market.
Product areas affected	Management Reporter
Status	Deprecated: A removal date has not been set for this feature.

Enterprise Portal client

Reason for deprecation/removal	A single client platform has been provided.

Replaced by another feature?	The new web client is based on the desktop form metadata and programming model that have been modified to provide a rich web platform.
Product areas affected	All modules
Status	Removed as of Dynamics AX 7.0.

Environmental sustainability

Reason for deprecation/removal	Low customer usage and a limited feature set
Replaced by another feature?	No
Product areas affected	Compliance and internal controls, Accounts payable
Status	Removed as of Dynamics AX 7.0.

Form ActiveX and Managed Host controls

Reason for deprecation/removal	The ActiveX and Managed Host controls are based on the deprecated desktop client.
Replaced by another feature?	The extensible control framework supports building new controls that are based on HTML, CSS, and JavaScript, and is a first-class control in the Microsoft Visual Studio Tooling environment.
Product areas affected	All modules
Status	Removed as of Dynamics AX 7.0.

Generate prenotes by using a batch

Prenote generation can't be done by using a batch, but it can still be done by a user.

Reason for deprecation/removal	No form exists to persist and display the resulting prenote file when it's generated by using a batch.
Replaced by another feature?	Prenotes can still be generated, and the user has control over the location where the file is saved.
Product areas affected	Accounts payable, Accounts receivable, Cash and bank management
Status	Removed as of AX 7.0.

German DTAUS payment export and account statement import (totals and transactions)

Reason for deprecation/removal	The format is no longer applicable in Germany, because it has been replaced by Single Euro Payments Area (SEPA) functionality.
Replaced by another feature?	Yes, this functionality has been replaced by SEPA payment export and advanced bank reconciliation functionality for importing account statements.
Product areas affected	All modules
Status	Deprecated: A removal date has not been set for this feature.

German DTAZV payment format in domestic Currency

Reason for deprecation/removal	The format is no longer applicable in Germany, because it has been replaced by SEPA functionality.
Replaced by another feature?	SEPA payments export
Product areas affected	Accounts payable
Status	Deprecated: A removal date has not been set for this feature.

German MT940 import

Reason for deprecation/removal	Generic functionality is now used instead of localized functionality.
Replaced by another feature?	Yes, this functionality has been replaced by Advanced bank reconciliation functionality.
Product areas affected	All modules
Status	Deprecated: A removal date has not been set for this feature.

German XML EU Sales list

Reason for deprecation/removal	The XML format for German EU Sales List reporting is no longer supported. Only the ELMA5 text file format can be used to submit the EU Sales List report to the German Tax Office.
Replaced by another feature?	No

Product areas affected	Tax
Status	Deprecated: A removal date has not been set for this feature.

GL SSRS reports

Reports that include the following menu items have been removed: **Summary trial balance**, **Detailed trial balance**, **Chart of accounts**, **Audit trail**, **Balances**, and **Balance list**.

Reason for deprecation/removal	Financial Microsoft SQL Server Reporting Services (SSRS) reports have been replaced by Management Reporter capabilities and default reports.
Replaced by another feature?	Management Reporter (labeled **Financial reporting** in the current version of Dynamics AX)
Product areas affected	General ledger
Status	Removed as of Dynamics AX 7.0.

InfoPart and FormPart metadata

Reason for deprecation/removal	InfoPart and FormPart metadata enabled the creation of FactBoxes for two different clients.
Replaced by another feature?	InfoPart metadata, which was a simplified form definition, is converted into a Form by upgrade tooling. FormPart metadata, which referenced a Form, is replaced by a more direct reference that is created by upgrade tooling.
Product areas affected	All modules
Status	Removed as of Dynamics AX 7.0.

Main account list page

A list of accounts for the legal entity and related balance information

Reason for deprecation/removal	Balance information is available on the **Trial balance** list page by account and dimension.
Replaced by another feature?	**Main accounts** contains the same list of accounts that the **Main account** list page contained. The grid view in **Main accounts** also shows an even smaller, grid-like view.
Product areas affected	General ledger

Status	Removed as of Dynamics AX 7.0.

Malaysia and Singapore bank cash flow report

This feature let the user print a cash flow report that shows transactions and details of the cash inflows and outflows for a specific date range for selected bank accounts.

Reason for deprecation/removal	The same information can be obtained from the Inquiry bank transaction.
Replaced by another feature?	The Inquiry bank transaction
Product areas affected	Cash and bank management
Status	Deprecated: A removal date has not been set for this feature.

Mexican CFD electronic invoice

This feature enabled the generation of Mexican electronic invoices by using the Comprobante Fiscal Digital (CFD) method, where the company signs the invoice by requesting the related authorization from the government. This feature also provides a monthly report that includes all electronics invoices that were issued in the period.

Reason for deprecation/removal	The method is no longer applicable. The generation of electronic invoices by using the CFD method was deprecated by the tax authorities and replaced by the Comprobante Fiscal Digital a través de Internet (CFDI) method, where the signing is delegated to the third-party provider (PAC). The monthly report has been removed, and an inquiry option lets users inquire about historical transactions.
Replaced by another feature?	No
Product areas affected	Account receivables, Project
Status	Deprecated: A removal date has not been set for this feature.

Mexico realized and unrealized VAT

Dynamics AX 2012 managed unrealized value-added tax (VAT) by using Mexico-specific functionality for unrealized tax.

Reason for deprecation/removal	Duplicate functionality
Replaced by another feature?	Yes, this functionality has been replaced by standard conditional sales tax functionality that is provided by Core.

Product areas affected	Tax
Status	Deprecated: A removal date has not been set for this feature.

Microsoft Outlook integration

Reason for deprecation/removal	This functionality has been replaced by Microsoft Exchange Server integration.
Replaced by another feature?	Yes
Product areas affected	Sales and marketing
Status	Removed as of Dynamics AX 7.0.

Private blocking of inventory and warehouse management journals

The inventory and warehouse journals no longer support the ability to mark a journal as private for a selected user. Only the process of blocking journals as private for user groups and blocking during editing is supported.

Reason for deprecation/removal	No use of the functionality was found.
Replaced by another feature?	No
Product areas affected	Inventory management
Status	Removed as of Dynamics AX 7.0.

Product builder

Product builder was used to dynamically configure items from a sales order, purchase order, production order, sales quotation, project quotation, or item requirement. Based on a product model that had modeling variables, the user could select values to meet the customer requirements and get a unique product variant that had a BOM and route.

Reason for deprecation/removal	Product builder exposed X++ code to end users and isn't supported in the current version of Dynamics AX. It has been removed to avoid duplicate maintenance efforts on overlapping, sizeable codebases.
Replaced by another feature?	Yes. The constraint-based configuration was introduced in Dynamics AX 2012 where the depreciation of Product builder in future versions was already announced. The constraint-based configuration technology is selected on the product masters to enable the configuration. To learn more, see Product configuration overview.

Product areas affected	Product information management, Sales and marketing
Status	Removed as of Dynamics AX 7.0.

Production Floor app

This is the app for tablet devices running Windows 8.1 RT and Windows 8.1 Pro.

Reason for deprecation/removal	With the change to a web-based client, it is possible to deliver similar functionality through the native Dynamics AX 7.0 client. The Job Card Device provides a production floor user interface that is optimized for touch and tablet form factors.
Replaced by another feature?	Yes. The Job Card Device, which is a native part of Dynamics AX 7.0.
Product areas affected	Production control
Status	Deprecated: A removal date from the Microsoft store has not yet been set for this feature.

Rename product dimension

This feature let you change the name of one of the three standard product dimensions (size, color, or style) to a name that better suited your business requirements. Renaming included all the labels where the product dimension name was used.

Reason for deprecation/removal	The current version of Dynamics AX doesn't support label changes at run time.
Replaced by another feature?	No
Product areas affected	Product information management
Status	Removed as of Dynamics AX 7.0.

Retail Server connectivity using HTTP

In Dynamics AX 2012 R3, the Retail Server could function using HTTP communication (non-secured). This was in addition to the standard communication using HTTPS.

Reason for deprecation/removal	Due to new security requirements, only secured communication using TLS 1.2 (or above, as available) is now supported. The self-service installer will automatically configure the computer for this communication.
Replaced by another feature?	No. Only standard HTTPS communication is now supported.

Product areas affected	Retail Server
Status	Removed as of Dynamics AX 7.0.

Role Center pages

Reason for deprecation/removal	Role Center pages were built on the deprecated Enterprise Portal platform, which has been replaced by the new web client platform in the current version of Dynamics AX.
Replaced by another feature?	The new Workspace form pattern provides users with a process-centered design that provides easy access to commonly used tasks within that process.
Product areas affected	All modules
Status	Removed as of Dynamics AX 7.0

Sales tax jurisdictions

Reason for deprecation/removal	Low customer usage and a limited feature set
Replaced by another feature?	No
Product areas affected	US sales tax
Status	Removed as of Dynamics AX 7.0.

Sites Services

Sites Services let you build websites that extend your business processes to the Internet without IT support.

Reason for deprecation/removal	The Microsoft Azure infrastructure that is used by Dynamics AX has new capabilities that can be used instead (for example, Azure sites).
Replaced by another feature?	No
Product areas affected	HR recruiting, Case management, Request for quotes, Vendor registration, Collaborative workspaces for opportunities and campaigns
Status	Removed as of Dynamics AX 7.0.

SSAS demand forecasting strategy

Reason for deprecation/removal	The design of the feature cannot be supported in the new cloud architecture.
Replaced by another feature?	Azure Machine Learning demand forecasting strategy
Product areas affected	Master planning
Status	Removed as of Dynamics AX 7.0.

Vendor invoice pool excluding posting details

Reason for deprecation/removal	Low usage. This functionality has been replaced by the Invoice journal that has workflow functionality.
Replaced by another feature?	Workflow capabilities of the Invoice journal.
Product areas affected	Accounts payable
Status	Removed as of Dynamics AX 7.0.

Virtual company accounts

The virtual companies feature is no longer supported in Dynamics AX. The virtual companies feature let users set up tables that could be shared by a set of companies. For a description of the feature, see Company accounts and Virtual company accounts. The feature works by grouping tables into collections that are assigned to virtual companies, which are groups of existing "real" companies. Queries are created so that all the companies in the virtual company can access the data in the tables of the associated table collections.

Reason for deprecation/removal	- Virtual companies must be set up before data is stored in the tables. Retrofitting virtual companies onto an existing implementation is very difficult. - Because there has been so much data normalization in the current version of Dynamics AX, it has become difficult to know what to add to the table collections. For example, it's difficult to know which tables to share. All the tables referenced from tables that are in a virtual company must also added. Because of table normalization, even simple master data that is spread across multiple tables must be part of the virtual company. Any mistake that is made here will cause functional issues. - When a table is part of a virtual company, it loses information about the origin of the data, and only the virtual company is recorded.
Replaced by another feature?	Global tables can be used to make tables accessible from all companies. Currently, there is no replacement.
Product areas affected	All modules

Status	Removed as of Dynamics AX 7.0.

Windows 8 tablet app

The Windows 8 tablet app provided functionality for expense entry and approval.

Reason for deprecation/removal	Finance and Operations is compatible with tablets. The tablet app is no longer required.
Replaced by another feature?	No.
Product areas affected	Expense management
Status	Removed: This functionality is only available for Dynamics AX 2012 R3.

Workplanner

Reason for deprecation/removal	Low usage
Replaced by another feature?	No, but the **Profile relation** page, which is opened from the **Profile groups** page, supports the same business scenario as the deprecated **Workplanner** page.
Product areas affected	Time and attendance
Status	The code has not been removed. However, the form, JmgWorkPlanner, was not migrated.

X++ financial statements

Reason for deprecation/removal	This functionality has been replaced by another feature.
Replaced by another feature?	Management Reporter (labeled **Financial reporting** in the current version of Dynamics AX)
Product areas affected	General ledger
Status	Removed as of Dynamics AX 2012

Deprecation of methods and metadata elements

2/18/2021 • 2 minutes to read • Edit Online

As the Microsoft code base continues to evolve, some methods and metadata elements will no longer be required. Microsoft will mark these obsolete methods and metadata elements for deprecation.

- Methods are marked with the **SysObsolete** attribute. Typically, this attribute recommends an alternative to the method.
- For metadata elements, the **IsObsolete** property is set to **Yes**.

The deprecation is compatible with both binaries and design time. The referencing code will continue to work as expected, and no immediate action is required. During compilation, any references to deprecated artifacts are reported as compile **warnings**.

Cleanup of deprecated elements

After a period of at least 12 months, Microsoft might delete obsolete methods and metadata elements.

However, if telemetry shows that any obsolete methods or metadata elements are still used, Microsoft will **not** delete them, to reduce the risk that consumers will be broken.

Minimize your risk of being affected

Here are some tips that you, as a consumer of the Microsoft code base, can use to avoid being affected when methods and metadata elements are deprecated:

- Compile your code base at least every 12 months on top of the latest code base. If you receive any warnings because deprecated artifacts are used, address those warnings as soon as possible.
- Avoid **new** dependencies on deprecated artifacts. Microsoft might have just deleted the artifact, because there is a time window between when releases and telemetry are available.

List of deprecated methods and metadata elements

For reference, download the Microsoft Excel file, available on the Deprecation of methods and metadata elements page of CustomerSource, which shows the artifacts that have been marked for deprecation in each major release.

Deprecated APIs

2/18/2021 • 14 minutes to read • Edit Online

This document provides the list of deprecated APIs and migration guidance for some of the deprecated APIs.

Overview

A number of APIs from Dynamics AX 2012 have been identified. The reason for the deprecation for each API varies. Most commonly, the reasons are one of the following:

- Not suited/applicable to the new client.
- Degrade performance.
- Chatty (cause lot of traffic back and forth between server and client).
- Redundant (framework automatically handles these now).

Throughout this table, under the
Reason for Deprecation heading, "the client" refers to the web client.

List of deprecated APIs

OBJECT	TYPE	NAME	NOTES
ActionPane	Method	tabChanged	Updates to ActionPanes (or controls inside of ActionPanes) should be done based on the active row, not when the tab becomes active.
ActionPaneTab	Method	selectionChanged	Updates to ActionPaneTabs (or controls inside of ActionPaneTabs) should be done based on the active row, not when the tab becomes active.
Box	Method	yesNoTextMenu-LinkText	
ComboBox	Method	getEditText	**Overview** N/A **Reason for deprecation** Redundant. **Migration notes** Use getText instead.

OBJECT	TYPE	NAME	NOTES
DataSet DataSetNode DataSetRun	Class		**Overview** Used in Dynamics AX 2012 with Enterprise Portal. **Reason for deprecation** Not applicable in the client. **Migration notes** **Remove calls to these APIs from your code.**
DataSourceMethodInfo DataSourceMethodInfoList	Class		
DDEClient DDEServer DLL DLLFunction HDC HWnd Thread WinAPINative WinGDI	Class		**Overview** N/A **Reason for deprecation** Specific to Dynamics AX 2012 Windows client and not compatible with the client. **Migration notes** Remove usage of these APIs from your code.
DocumentManagement-Helper	Class		
Form	Method	addhistory currentHistoryName currentHistoryState updateHistory	**Overview** Used in Dynamics AX 2012 with address bar. **Reason for deprecation** Navigation model in the client has changed. **Migration notes** Remove calls to these APIs from your code.
Form	Method	arrange	
Form	Method	controlCallingMethod	
Form	Method	controlMethod-Overload controlMethod-OverloadObject	**Overview** Used in Dynamics AX 2012 to register override methods. **Reason for deprecation** This is not a clean and recommended way to register override methods. **Migration notes** Use registerOverrideMethod instead.
Form	Method	copy cut paste	

OBJECT	TYPE	NAME	NOTES
Form	Method	delAutoCompleteString getAutoCompleteString setAutoCompleteString	**Overview** Used in Dynamics AX 2012 to set, get, and delete automatic suggestions. **Reason for deprecation** Specific to Dynamics AX 2012 Windows client. **Migration notes** Remove calls to these APIs from your code.
Form	Method	firstField	
Form	Method	formOnTop	**Overview** Used in Dynamics AX 2012 to manage windows and navigation. **Reason for deprecation** The client has a new navigation model. **Migration notes** Remove calls to these APIs from your code.
Form	Method	hWnd installMessageProc removeMessageProc	**Overview** N/A **Reason for deprecation** Specific to Dynamics AX 2012 Windows client and not compatible with the client. **Migration notes** Remove usage of these APIs from your code.
Form	Method	isPreloadedInstance	**Overview** Used in Dynamics AX 2012 with preloading. **Reason for deprecation** Preloading is not applicable in the client. **Migration notes** Remove calls to these APIs from your code.
Form	Method	lastField nextField nextGroup prevField prevGroup	

OBJECT	TYPE	NAME	NOTES
Form	Method	Lock lockWindowUpdate unLock	**Overview** These methods were used to prevent the redrawing of windows when performing a set of UI updates. Without these the window would be redrawn in response to each individual change leading to bad end-user experience and degraded performance. **Reason for deprecation** These methods are specific to the Windows client and are no longer needed for the client. **Migration notes** A code upgrade rule has been provided to remove occurrences of these APIs. You can safely remove any calls to these APIs from your code.
Form	Method	print printPreview send	**Overview** Used in Dynamics AX 2012 to override the Auto Report generation for the form **Reason for deprecation** Microsoft 365 integration offers a better user experience in the client. The 'Export' function is available for the user in the Dynamics AX client forms. **Migration notes** Remove calls to these APIs from your code.
Form	Method	redraw resetStatusBar-BackgroundColor setStatusBar-BackgroundColor sysColorChanged	**Overview** Used to control styles or colors. **Reason for deprecation** Remove ability for developers to specify the colors via API for consistent visuals. **Migration notes** A code upgrade rule has been provided to remove occurrences of the redraw API. Remove usage of these APIs from your code.
Form	Method	reload	

OBJECT	TYPE	NAME	NOTES
Form	Method	resetSize	**Overview** This method was used when controls were added/removed from a form causing its size to change. Without it the window might not be correctly sized to account for the added/removed controls. **Reason for deprecation** These methods are specific to the Windows client and are no longer needed for the client. **Migration notes** You can safely remove any calls to these APIs from your code.
Form	Method	resize	
FormActiveXControl FormAnimateControl FormBuildActiveXControl FormBuildAnimateControl FormBuildManaged-HostControl FormBuildSegmented-EntryControl FormManagedHostControl FormSegmented-EntryControl	Class		**Overview** These were used to host or create various custom controls for Dynamics AX 2012. **Reason for deprecation** These technologies will not work with the client. **Migration notes** Application developers need to build replacement controls where needed using the control extensibility features.
FormControl	Method	beginDrag dragDrop dragLeave dragOver dragOverEx dragText drop dropEx dropFile endDrag	**Overview** Used to enable drag-and-drop scenarios in Dynamics AX 2012. **Reason for deprecation** Drag-and-drop scenarios are not supported in the client. **Migration notes** Remove usage of these APIs from your code and refactor to enable the scenarios without dependency on drag-and-drop functionality.
FormControl	Method	calcControlSize	

OBJECT	TYPE	NAME	NOTES
FormControl	Method	command processBase processForm processLink processPicture processTitle	**Overview** Was marked for deprecation in Dynamics AX 2012. **Reason for deprecation** N/A **Migration notes** Remove calls to these APIs from your code.
FormControl	Method	context showContextMenu	**Overview** This method was used when controls were added/removed from a form causing its size to change. Without it the window might not be correctly sized to account for the added/removed controls. **Reason for deprecation** These methods relied on APIs that are specific to the Windows client. **Migration notes** Use getContextMenuOptions and selectedMenuOptions instead.
FormControl	Method	copy cut paste	
FormControl	Method	dateTextChange	
FormControl	Method	editControl	
FormControl	Method	hasControl-PositionOverride	
FormControl	Method	helpField	
FormControl	Method	hWnd	**Overview** N/A **Reason for deprecation** Specific to Dynamics AX 2012 Windows client and not compatible with the client. **Migration notes** Remove usage of these APIs from your code.
FormControl	Method	inputSearch	
FormControl	Method	itemChanging	
FormControl	Method	keyDown	

OBJECT	TYPE	NAME	NOTES
FormControl	Method	labelMouseDblClick mouseDblClick	**Overview** The FormControl.labelMouseDblClick (int x, int y, int button, Boolean Ctrl, Boolean Shift) method is called when the label for a control is double-clicked. It provides the x, y co-ordinates of the mouse pointer, a Boolean to indicate which mouse button was clicked and Booleans to indicate whether the Ctrl and Shift key were pressed. The FormControl.mouseDblClick (int x, int y, int button, Boolean Ctrl, Boolean Shift) method is similar in function to the labelMouseDblClick method. The difference is that this method is called whenever there is a double-click (not just on the labels). **Reason for deprecation** The double-click action does not translate well to web-based application and touch-based scenarios. Additionally they might end up being chatty in many instances. **Migration notes** The recommended replacement for these methods is to use a button and the **clicked** event.
FormControl	Method	labelMousedown labelMouseup mouseDown mouseEnter mouseLeave mouseMove mouseUp	**Overview** Used to detect and respond to mouse events. **Reason for deprecation** These are not touchscreen friendly and not supported in the client. **Migration notes** Remove usage of these APIs from your code and refactor to enable the scenarios without dependency on mouse events.
FormControl	Method	onHScroll onVScroll	
FormControl	Method	paint	

OBJECT	TYPE	NAME	NOTES
FormControl	Method	prefColumnSize	**Overview** Used in Dynamics AX 2012 to control width and height **Reason for deprecation** Not applicable in the client. **Migration notes** Set the width and height explicitly instead.
FormControl	Method	selectionChanging	
FormControl	Method	setScrollInfo	
FormControl	Method	size	
FormControl	Method	updateWindow	
FormControl / FormDesign	Property	AcquireFocus	
FormControl / FormDesign	Property	ActiveBackCol ActiveBackColor ActiveBackColorRGB ActiveForeColor ActiveForeColorRGB AlternateRowShading BackgroundColor BackgroundColorRGB BackStyle BackStyleRGB CharacterSet ColorScheme DrawFocusRect ForegroundColor ForegroundColorRGB GridLines GridLinesStyle PromptRect	**Overview** Used to control styles or colors. **Reason for deprecation** Remove ability for developers to specify the colors via API for consistent visuals. **Migration notes** Remove usage of these APIs from your code.
FormControl / FormDesign	Property	AlignChild AlignChildren AlignControl Border BottomMargin BottomMarginMode ColumnSpace ColumnSpaceMode ColumnSpaceValue Left LeftMargin LeftMarginMode LeftMode RightMargin RightMarginMode SizeHeight SizeWidth TabAppearance TabAutoChange TabLayout TabMode TabPlacement Top TopMargin TopMarginMode TopMode VerticalSpacing VerticalSpacingMode VerticalSpacingValue	**Overview** Used to control layout. **Reason for deprecation** Remove ability for developers to control layout using this property to achieve a consistent layout. **Migration notes** **Remove usage of these APIs from your code. Use styles or CSS instead.**

OBJECT	TYPE	NAME	NOTES
FormControl / FormDesign	Property	AllowDocking AlwaysOnTop ArrangeGuide ArrangeWhen ContainerScroll-HorizontalOffset ContainerScroll-VerticalOffset IMEMode MaximizeBox MinimizeBox Mode NeededAccessLevel ProgressType Securable SecurityKey StatusBarStyle WindowResize	**Overview** N/A **Reason for deprecation** Specific to Dynamics AX 2012 Windows client, no longer needed. **Migration notes** Remove usage of these APIs from your code.
FormControl / FormDesign	Property	Bold	
FormControl / FormDesign	Property	CanScroll	
FormControl / FormDesign	Property	DisabledImage DisabledImageLocation DisabledResource	
FormControl / FormDesign	Property	DisplayTarget HyperLinkDataSource HyperLinkMenuItem SaveFilter SaveSize	**Overview** Used in Dynamics AX 2012 with Enterprise Portal **Reason for deprecation** Not applicable in the client. **Migration notes** Remove calls to these APIs from your code.
FormControl / FormDesign	Property	Font	
FormControl / FormDesign	Property	FontSize	
FormControl / FormDesign	Property	Frame FramePosition	**Overview** N/A **Reason for deprecation** Remove ability for developers to control frames via metadata. **Migration notes** Remove usage of these APIs from your code.
FormControl / FormDesign	Property	HideToolbar HorizontalScrollBarVisible Scrollbars VerticalScrollBarVisible	**Overview** N/A. **Reason for deprecation** Remove ability for developers to control scrollbars via metadata. **Migration notes** Remove usage of these APIs from your code.
FormControl / FormDesign	Property	ImageMode	
FormControl / FormDesign	Property	ImageName	

OBJECT	TYPE	NAME	NOTES

FormControl / FormDesign	Property	Underline	
FormDataRow	Class		

OBJECT	TYPE	NAME	NOTES
FormDataSource	Property	autoNotify	**Overview** Was marked for deprecation in Dynamics AX 2012. **Reason for deprecation** N/A **Migration notes** Remove usage from your code.
FormDataSource	Method	cacheOnlyMode	
FormDataSource	Method	cacheRemoveRecord	
FormDataSource	Method	defaultMark	

OBJECT	TYPE	NAME	NOTES
FormDataSource	Method	findRecord findValue	**Usage** The FormDataSource.findRecord (Common record) method finds a specific record in the data source and makes it the current record. The FormDataSource.findValue(FieldId field, str value) method find a specific value in a specific field in the data source and makes the corresponding record the current record. It uses the FormDataSource.findRecord method for this. **Reason for deprecation** These methods use linear searching and load a large number of records in memory and negatively impact performance. **Migration notes** Replace with new APIs. Replace findRecord with positionToRecord and findValue with positionToRecordByValue. New APIs do not work in some cases, most notably with Temp tables and Views. The framework will throw an exception in those cases. If replacing with new APIs is not possible, recommended replacement is to call **element.args(). lookupRecord(recordToFind)** Followed by **FormDataSource.research(false);** FormDataSource is the data source that contains the record you want to find. Passing in a “false” argument to research causes it to not retain the current position since we want to change the position to the record we found using args.lookupRecord avoids resetting sort order, ranges, etc.
FormDataSource	Method	getDataRow	
FormDataSource	Method	markAllLoadedRecords	

OBJECT	TYPE	NAME	NOTES
FormDataSource	Method	maxPagingRowCountValue pagingEnabled startRowIndex setPagingParameters totalNumberOfRows	**Overview** Used in Dynamics AX 2012 with Enterprise Portal **Reason for deprecation** Not applicable in the client. **Migration notes** Remove calls to these APIs from your code.
FormDataSource	Method	print	
FormDesign	Method	cssClass localWebMenu showWebHelp supportReload	**Overview** Used in Dynamics AX 2012 with Enterprise Portal **Reason for deprecation** Not applicable in the client. **Migration notes** Remove calls to these APIs from your code.
FormObjectSetNotify	Method	onPaging- ParametersChanged	
FormObjectSetPaging- ParamsChangedEvtArgs	Class		
Global xInfo	Method	endLengthyOperation startLengthyOperation	**Overview** These methods were used to show/stop showing a progress indicator during long running operations. **Reason for deprecation** In the client, the system automatically takes care of showing/hiding the progress indicator and calls to these APIs are not needed. **Migration notes** You can safely remove any calls to these APIs from your code.
Image	Method	captureScreen captureWindow clipboardCopy clipboardPaste crop displayImage displayOrign exportBitmap flip getImageDimensionUnits getPixel height imageInfo imageSpotlight promoteColor reduceColorOctree resize rotate saveImage saveType transparent width	

OBJECT	TYPE	NAME	NOTES
ListPage Page	Method	activeActionPane-TabNames	**Overview** This method was used to find the active action pane tab. **Reason for deprecation** In the client, Action Pane tabs are handled client-side only, the server is not aware of the state. **Migration notes** **Remove usage of this API from your code.**
MessageWin	Class		
Object	Method	notify notifyAll wait	**Overview** Used to block and wait for an interaction/operation and notify to unblock. **Reason for deprecation** These calls are deprecated for all objects except formRun and it's derivatives. **Migration notes** Calls to these APIs from formRun or it's derivatives are allowed. Calls to these APIs from any other object should be removed.
Object	Method	objectOnServer	**Overview** Used to determine whether an object is on the server. **Reason for deprecation** This is redundant and no longer required because all objects are on the server. **Migration notes** You can safely remove calls to these APIs from you code. It will always evaluate to true.

OBJECT	TYPE	NAME	NOTES
Object	Method	setTimeOut	**Overview** This method existed on Object, but was non-functional. The implementation on FormRun was used as a timer to delay the execution of a piece of logic. **Reason for deprecation** The browser based client no longer supported this implementation. **Migration notes** Use the new setTimeOutEx method on the FormRun instead. Note that the setTimeOutEx method expects the callback to accept a parameter of type AsyncTaskResult, example: myCallBack(AsyncTaskResult result).
PopupMenu	Class		**Overview** Used in Dynamics AX 2012 to get splitters that let users change the size of the two parts that are split. **Reason for deprecation** Relied on APIs that are specific to the Dynamics AX 2012 Windows Client and cannot be used with the client. **Migration notes** Use ContextMenu instead.
SysExcel	Class		**Overview** The SysExcel classes used COM to create and edit Excel workbooks. **Reason for deprecation** SysExcel relied on calls to Excel COM objects from the client. Those COM objects are not on the server and COM calls are highly discouraged going forward. **Migration notes** Use the OpenXML .NET framework APIs instead. We are investigating the creation of an assembly that wraps OpenXML to make it easier to call from X++.

OBJECT	TYPE	NAME	NOTES
SysINetMai SysMailer SmmOutlook	Class		**Overview** These email related classes used predominantly client-side technologies that are no longer available and/or are highly discouraged. **Reason for deprecation** The SysINetMail class is being deprecated because it used client-side MAPI. The SysMailer class is being deprecated because it used CDO (a variant of OLE messaging). The classes beginning with SmmOutlook are being deprecated since they use Outlook COM objects. **Migration notes** Sending email via SMTP using the SysMailerNet class will be supported going forward. We are also actively working on client-side interactive email capabilities.
SysFormSplitter	Class		**Overview** Used in Dynamics AX 2012 to get splitters that let users change the size of the two parts that are split. **Reason for deprecation** No longer needed in the client. **Migration notes** Controls automatically provide the functionality. You can safely remove any calls to these APIs from your code. A code upgrade rule may be created in the future to automatically remove the usage.
SysListPageHelper	Class		
SysSetupFormRun	Class		**Overview** Used to by classes to indirectly extend FormRun. **Reason for deprecation** Has been merged with FormRun class. **Migration notes** Use the FormRun class instead.
TextBuffer	Method	fromFile	Use the .NET StreamReader class instead.

OBJECT	TYPE	NAME	NOTES
TextBuffer	Method	toFile	Use the .NET StreamWriter class instead.
Thread	Class		**Overview** N/A **Reason for deprecation** Specific to Dynamics AX 2012 Windows client and not compatible with the client. **Migration notes** Consider replacing with the new runAsync method or remove usage of these APIs from your code.
WinAPI	Class		**Overview** N/A **Reason for deprecation** Specific to Dynamics AX 2012 Windows client and not compatible with the client. **Migration notes** Remove usage of these APIs from your code. Replace file access APIs, such as WinAPI::getTempPath, WinAPI::fileExists, with the new file APIs.
WinAPIServer	Method	cryptProtectData cryptUnprotectData	**Overview** The WinAPIServer::cryptProtectData(CryptoBlob _unEncryptedDataBlob) and WinAPIServer::cryptUnProtectData(CryptoBlob _encryptedDataBlob) methods were used to encrypt and decrypt sensitive data. **Reason for deprecation** These methods are best suited to desktop usage and not recommended for web-based application usage. They also have a negative impact on performance. **Migration notes** Use the .NET framework APIs and well-known hashing/security algorithms instead.

OBJECT	TYPE	NAME	NOTES
xApplication	Method	runAsync	**Overview** In Dynamics AX 2012 the xApplication::runAsync method was used to make asynchronous calls to methods. **Reason for deprecation** Replaced with methods better suited to the client. **Migration notes** Use runAsync methods on the Global or FormRun classes instead. These new versions of runAsync enable the caller to make an async call to a static X++ class method. They leverage the .NET System.Threading.Tasks library to execute an async method in X++. The use of the System.Threading.Tasks.Task type allows the developer to take advantage of the rich set of features available in .NET.
xGlobal	Method	clientKind	**Overview** Most commonly used to detect presence of client, such as an interactive session. **Reason for deprecation** Replaced with a method better suited to the client. **Migration notes** Use global::hasGUI method instead.
xGlobal	Method	computerName	
xGlobal	Method	forceFormPreload	**Overview** Used in Dynamics AX 2012 with preloading. **Reason for deprecation** Preloading is not applicable in the client. **Migration notes** Remove calls to these APIs from your code.
xGlobal	Method	terminalServer	
xInfo	Method	directory	
xInfo	Method	navPane	

OBJECT	TYPE	NAME	NOTES
XmlDocument	Method	LoadSave	
XmlWriter	Method	CreateNewFile	
XppCompiler	Class

The survey will take about seven minutes. No personal data is collected (privacy statement).

User interface development home page

2/18/2021 • 3 minutes to read • Edit Online

This topic contains links to topics about developing user interface elements.

The user interface for Finance and Operation applications differs significantly from the interface for Microsoft Dynamics AX 2012. The client in Dynamics AX 2012 is a Microsoft Win32 application that has extensions that use ActiveX, WinForm, or WPF controls. The X++ application logic runs on the client for the form and table methods, and some logic occurs on the server. For controls, both the X++ logic application programming interface (API) and the physical Win32 control are tightly connected on the client. The client is an HTML web client that runs in all major browsers. These browsers include Microsoft Edge, Internet Explorer 11, Chrome, and Safari (see System requirements). The move to a web client has produced the following changes to client forms and controls:

- The physical presentation of forms and controls is now HTML, JavaScript, and CSS within the browser.
- Form controls are split into logical and physical parts. The X++ logical API and related state run on the server.
- The logical and physical parts are kept in sync through service calls that communicate changes from each side. For example, a user action on the client creates a service call to the server that is either sent immediately or queued so that it can be sent later.
- The server tier keeps the form state in memory while the form is open.

The form metamodel continues to be used to define controls and application logic. This approach supports almost all the existing Form, Form DataSource, and Form Control metamodel and X++ override methods. However, some control types, properties, and override methods have been removed, either because of incompatibility with the new platform or for performance reasons. For example, ActiveX and ManagedHost controls can no longer be used to add custom controls, because they are incompatible with the HTML platform. Instead, a new extensible control framework has been added that lets you add additional controls.

Tutorials

Build the Rental Charge Type form

2/18/2021 • 5 minutes to read • Edit Online

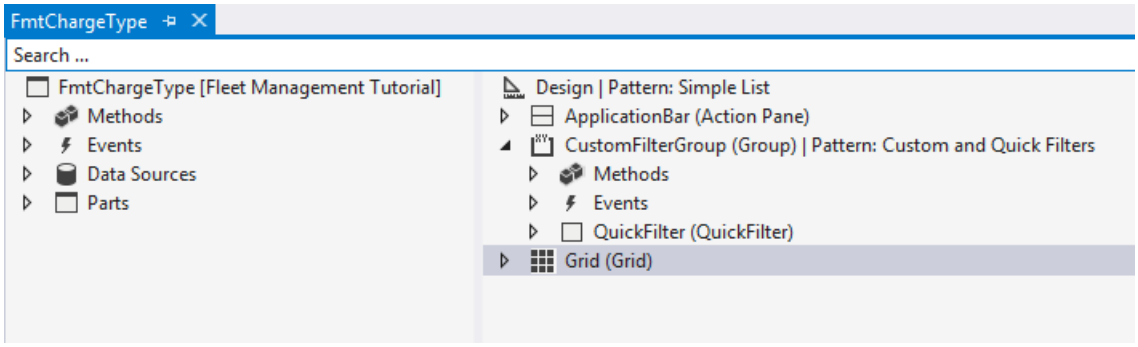
In this lab you'll create a Simple List form. A Simple List form can show reference or secondary data that has six or fewer fields. For example, the form that you create will list and describe the types of rental charges.

Prerequisites

For this tutorial, you'll need to access the environment using Remote Desktop, and be provisioned as an administrator on the instance. For more information, see Access Instances.

Overview

To create the form, you'll start from the existing form, **FmtChargeType**. This form uses the Simple List pattern. The following illustration shows the **FmtChargeType** form with the required controls from the Simple List pattern.



Adhering to the form pattern ensures that this Simple List form has the same structure and layout as other Simple List forms.

Key concepts

- Create a Simple List form using a pattern.
- Bind a table to the form.
- Add controls to the form.
- View the form using Visual Studio and a browser.

Setup

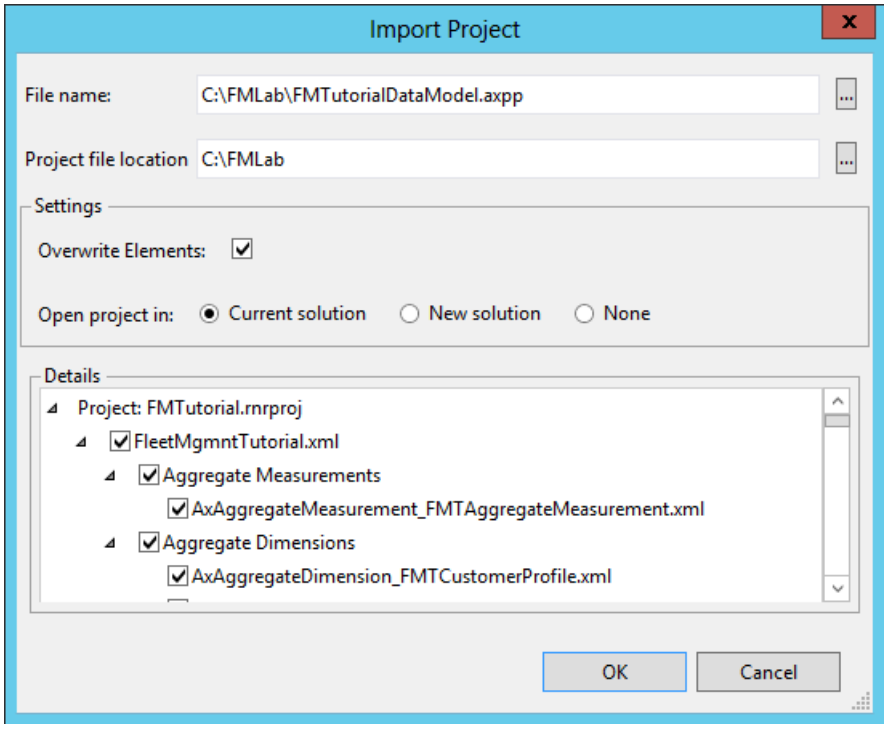
Import the tutorial project and transactional data

Use Visual Studio to import the tutorial project. The tutorial project includes the artifacts that you'll use to complete this tutorial. Use Visual Studio to open the FMTutorial project and load the data for the tutorial. You'll use the FMTDataHelper class to load data for the Fleet Management tutorial. If this is the first tutorial you're working on, review Access Microsoft Instances and make sure you provision your administrator user if you're working on a local VM.

1. Download the Fleet Management sample from https://github.com/Microsoft/FMLab, save it to **C:**, and unzip it.

2. On the desktop, double-click the Visual Studio shortcut to open the development environment.

3. On the **Finance and Operations** menu, click **Import Project**.
4. In the **Import Project** window, next to the **Filename** text box, click the ellipsis button.
5. In the **Select the file to import** window, browse to C:\FMLab, click FMTutorialDataModel.axpp, and then click **Open**.
6. In the **Project file location** text box, enter C:\FMLab.
7. Select the **Overwrite Elements** option, and the **Current solution** radio button. The following illustration shows the completed **Import Project** dialog box.



8. Click **OK**.
9. In **Solution Explorer**, expand **Classes, and** under the **FMTutorial** project, right-click **FMTDataHelper**, and then click **Set as Startup Object**.
10. On the **Build** menu, click **Rebuild Solution**. Use the rebuild to make sure that all of the files in the project are built regardless of timestamps. You can view the build progress in the **Output** window.
11. After the build completes, press **Ctrl+F5** to run the project. The browser will open and run the class that imports the data.

Open the FMTutorial project

Use Visual Studio to open the FMTutorial project. If you have Visual Studio open and have already loaded the FMTutorial project, you can continue to the next section.

1. If the development environment isn't already open, on the desktop, double-click the Visual Studio shortcut to open the development environment.
2. On the **File** menu, click **Open** > **Project/Solution**.
3. In the **Open Project** dialog box, browse to C:\FmLab\FMTutorial, select the **FMTutorial** solution, and then click **Open**
4. The FMTutorial project appears in **Solution Explorer**.

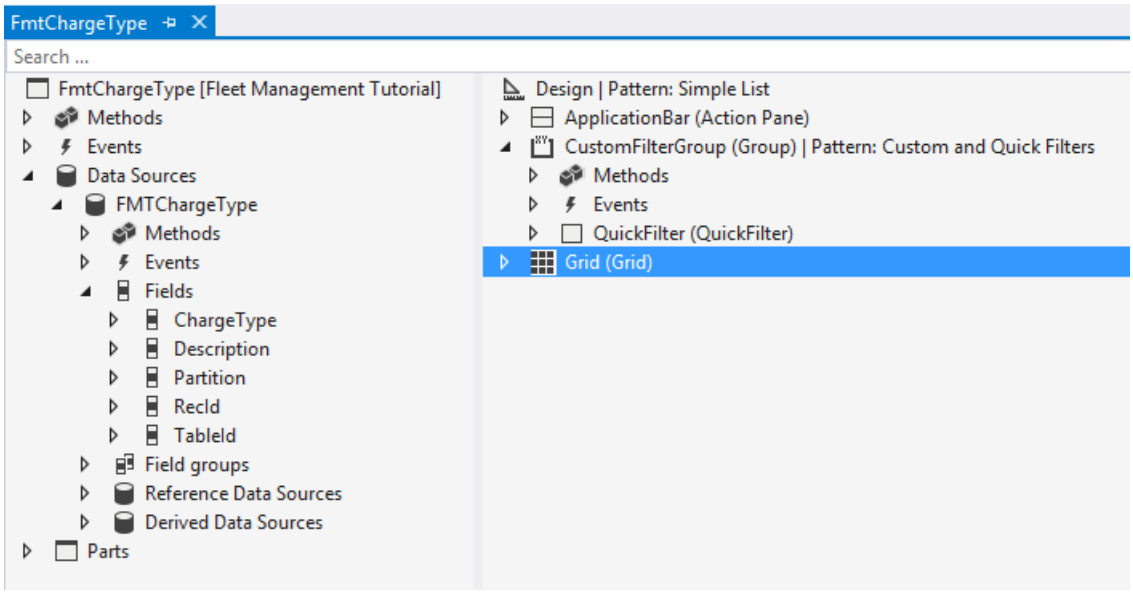
Use a template to create the form

Use Visual Studio to create the **FmtChargeType** form. You'll use a template for building the Simple List form. You'll also add a data source to the form and add fields to the data grid.

1. In **Solution Explorer**, right-click the **FMTutorial** project, point to **Add**, and then click **Existing Item**.
2. In the **Add Existing Item** window, browse to C:\FmLab, click **AxForm_FmtChargeType**, and then click **Add**. The **FmtChargeType** form appears at the bottom of the **FMTutorial** project in **Solution Explorer**.
3. In **Solution Explorer**, double-click **FmtChargeType**. The form opens in the Form designer.
4. Add the **FmtChargeType** table as the data source for the form. Right-click **Data Sources,** and then click **New Data Source**. A data source node is added.
5. Click the data source node from the previous step. In the **Properties** window, populate the following properties with the specified values.

PROPERTY	VALUE
Table	FMTChargeType
Name	FMTChargeType *Be sure to specify the value for the Table property first. This property will automatically update to use that same value.*

The following illustration shows **Data Sources** after you add the **FMTChargeType** table.



6. In the Form designer, click **Design**. In the **Properties** window, populate the following properties with the specified values.

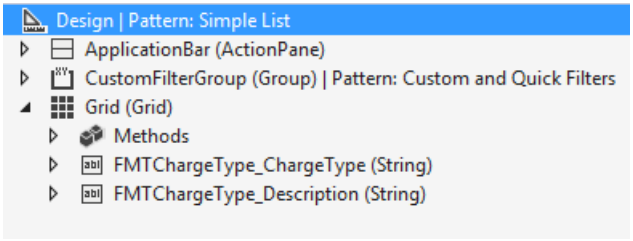
PROPERTY	VALUE
Caption	Rental charge types *This is the label that appears at the top of the form.*
Data Source	FMTChargeType *Use this property to specify the data source for the form.*

7. In the Form designer, click **Design** > **Grid**.
8. Bind the FMTChargeType data source to the grid that appears in the simple list form. In the **Properties** window, in **Data Source**, enter **FMTChargeType**.

9. You have to specify the data source before you add fields to the grid. You can then use the fields from the data source to add columns to the grid. Add two fields from the data source to the grid. The fields you add will appear as columns on the Simple List form. Expand the FMTChargeType data source **Fields** node in the left pane. Press **Ctrl** and then click the following fields:

    - ChargeType
    - Description

10. Drag the selected fields to **Design** > **Grid** in the right pane. The following illustration shows the grid after the grid node is expanded and the two fields are added.



11. In the Form designer, click **Design** > **CustomFilterGroup** > **QuickFilter**.

12. In the **Properties** window, click **TargetControl**, and then select **Grid** to bind the **QuickFilter** control to the grid on the form.

13. Click **File** > **Save FmtChargeType**.

View the form

Use Visual Studio to build and run the **FmtChargeType** form.

1. In **Solution Explorer**, right-click the **FmtChargeType** form, and then click **Set as Startup Object**.

2. Press Ctrl+F5 to build and run the form.

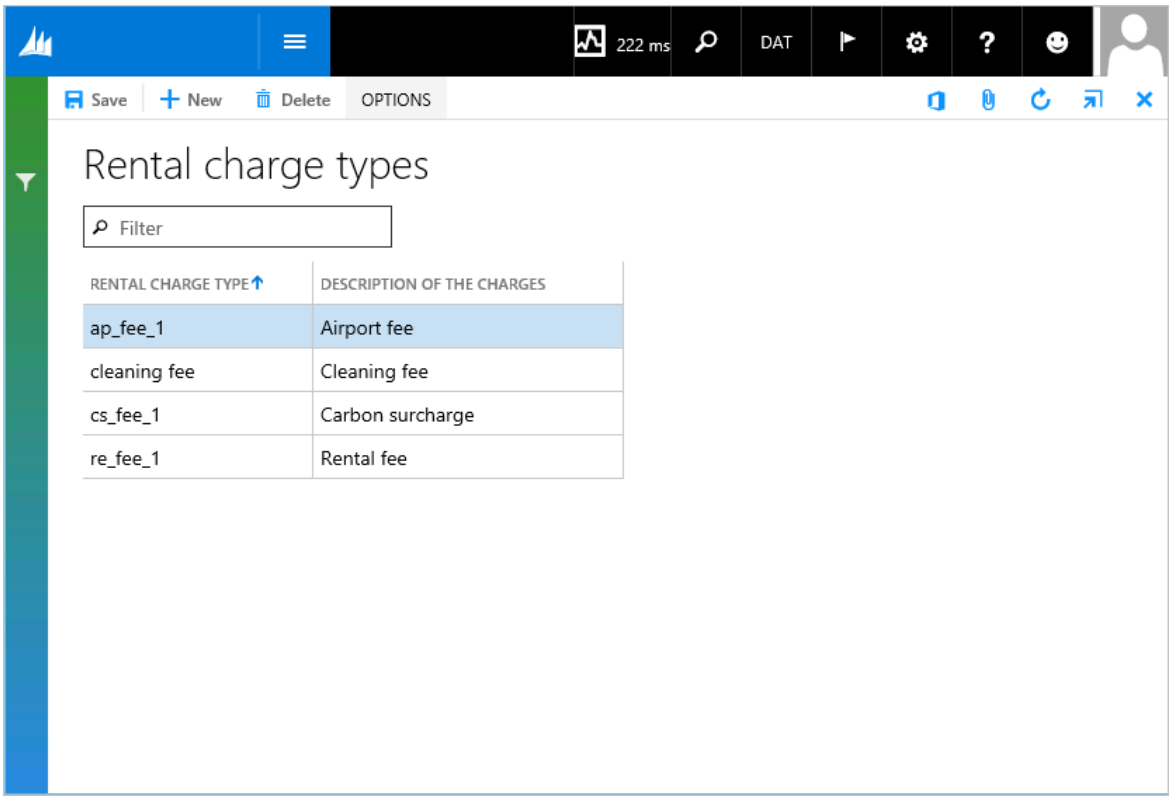
3. The form opens in Internet Explorer.

4. To add a rental charge type, click **New** in the Action Pane at the top of the form. Add the following information.

RENTAL CHARGE TYPE	DESCRIPTION
cleaning	Cleaning fee

5. In the Action Pane, click **Save**.

6. Refresh the browser to see the new record in the list. The following illustration shows how the form should look.



7. The form opens in view mode. Click **Edit** in the Action Pane to switch the form into edit mode. To return to view mode, click **Options** and then **Read mode**.

NOTE

Can you tell us about your documentation language preferences? Take a short survey.

The survey will take about seven minutes. No personal data is collected (privacy statement).

Build the Customer form

2/18/2021 • 10 minutes to read • Edit Online

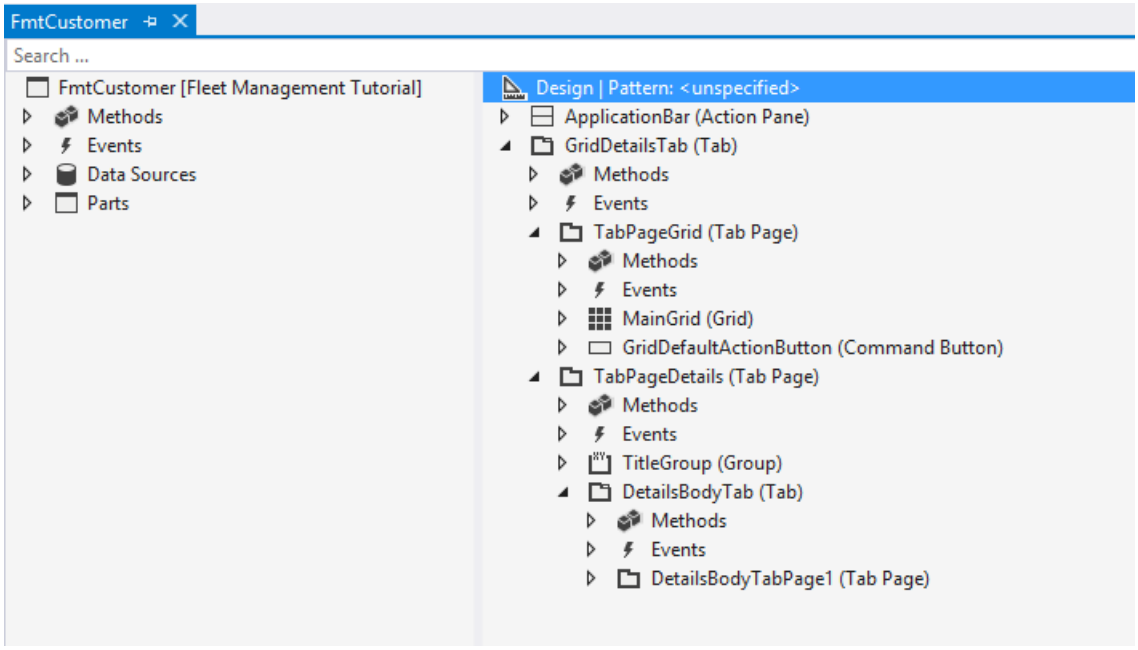
In this lab you'll create a Master Details form and apply the appropriate form pattern and subpatterns. A Master Details form shows primary data that has many fields. For example, the form that you create will show customer information.

Prerequisites

For this tutorial, you will need to access the environment using Remote Desktop, and be provisioned as an administrator on the instance. For more information, see Access Instances.

Overview

To create the form, you'll start from the existing form, **FmtCustomer**. The form represents the old Master Details template. As a part of the tutorial, you'll apply the Master Details pattern, which will enforce a consistent structure for this form type. The following illustration shows the **FmtCustomer** starting artifact.



Key concepts

- Create a Master Details form.
- Apply a form pattern to a form.
- Use the Visual Studio pattern add-ins to get information about form/model pattern coverage.
- Apply subpatterns to form controls.
- View the form using Visual Studio and a browser.
- Determine the amount of remaining patterns work in a model.

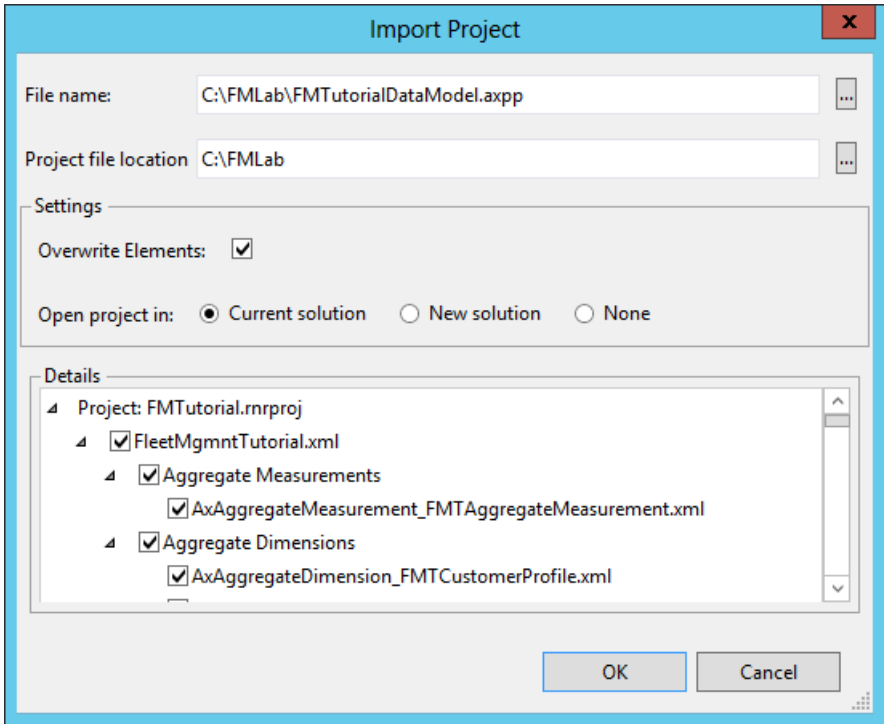
Setup

Import the tutorial project and transactional data

Use Visual Studio to import the tutorial project. The tutorial project includes the artifacts you will use to

complete this tutorial. Use Visual Studio to open the FMTutorial project and load the data for the tutorial. You will use the FMTDataHelper class to load data for the Fleet Management tutorial. If this is the first tutorial you are working on, review Access Instances and make sure you provision your administrator user if you're working on a local VM.

1. Download the Fleet Management sample from https://github.com/Microsoft/FMLab, save it to **C:**, and unzip it.
2. On the desktop, double-click the Visual Studio shortcut to open the development environment.
3. On the **Finance and Operations** menu, click **Import Project**.
4. In the **Import Project** window, next to the **Filename** text box, click the ellipsis button.
5. In the **Select the file to import** window, browse to **C:\FMLab**, click FMTutorialDataModel.axpp, and then click **Open**.
6. In the **Project file location** text box, enter **C:\FMLab**.
7. Select the **Overwrite Elements** option and the **Current solution** radio button. The following illustration shows the completed **Import Project** dialog box.



8. Click **OK**.
9. In **Solution Explorer**, expand **Classes**, and under the **FMTutorial** project, right-click **FMTDataHelper**, and then click **Set as Startup Object**.
10. On the **Build** menu, click **Rebuild Solution**. You use the rebuild to make sure all files in the project are built regardless of timestamps. You can view the build progress in the Output window.
11. After the build completes, press **Ctrl+F5** to run the project. The browser will open and run the class that imports the data.

Open the FMTutorial project

Use Visual Studio to open the FMTutorial project. If you have Visual Studio open and have already loaded the FMTutorial project, you can continue to the next section.

1. If the development environment is not already open, on the Desktop, double-click the Visual Studio shortcut

to open the development environment.

2. On the **File** menu, click **Open** > **Project/Solution**.
3. In the **Open Project** dialog box, browse to C:\FmLab\FMTutorial, select the **FMTutorial** solution, and then click **Open**.
4. The FMTutorial project appears in **Solution Explorer**.

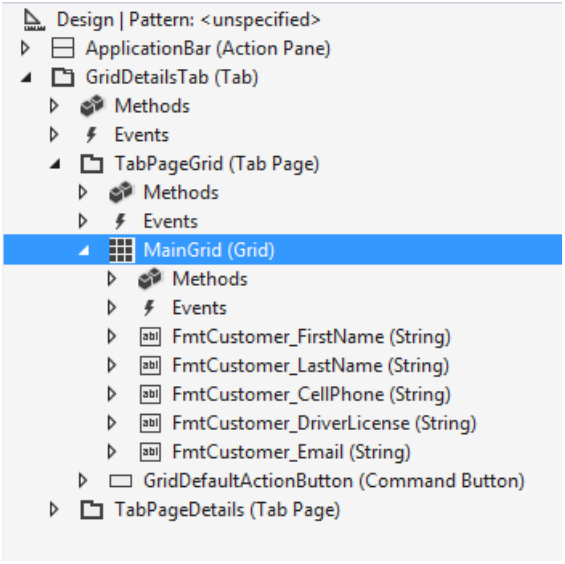
Use a template to create the form

Use Visual Studio to create the **FmtCustomer** form. You'll use a template to create a new master details form. The data source for this tutorial is provided by the starter form. However, you'll add fields to the grid and details view and apply the Master Details form pattern.

1. In **Solution Explorer**, right-click the **FMTutorial** project, point to **Add**, and then click **Existing Item**.
2. In the **Add Existing Item** window, browse to C:\FmLab, select **AxForm_FmtCustomer**, and then click **Add**. The **FmtCustomer** form appears at the bottom of the **FMTutorial** project in Solution Explorer.
3. In Solution Explorer, double-click **FmtCustomer**. The form opens in the form designer.
4. In the Form designer, click **Design**. In the **Properties** window, specify the following values.

PROPERTY	VALUE
Data Source	FmtCustomer
Caption	Customers

5. In the Form designer, click **Design** > **GridDetailsTab** > **TabPageGrid** > **MainGrid**, and then click **MainGrid**.
6. In the **Properties** window, click **Data Source**, and then select **FmtCustomer** to bind the **FmtCustomer** table to the grid. You can now use the fields from the data source to add columns to the grid.
7. Click **Data sources** > **FmtCustomer** > **Fields** to add fields to the grid.
   a. Click **FirstName**, press and hold the **Ctrl** key, and then select the following additional fields in the order shown:
      - LastName
      - CellPhone
      - DriverLicense
      - Email
   b. Drag the highlighted fields to **Design** > **GridDetailsTab**> **TabPageGrid** > **MainGrid**. The following illustration shows the grid after expanding the grid node and adding the fields.



8. Click **Save**.
9. Click **Design** > **GridDetailsTab** > **TabPageDetails** > **TitleGroup** to add the record header to the details view.
10. Click **HeaderTitle**. In the **Properties** window, specify the following values.

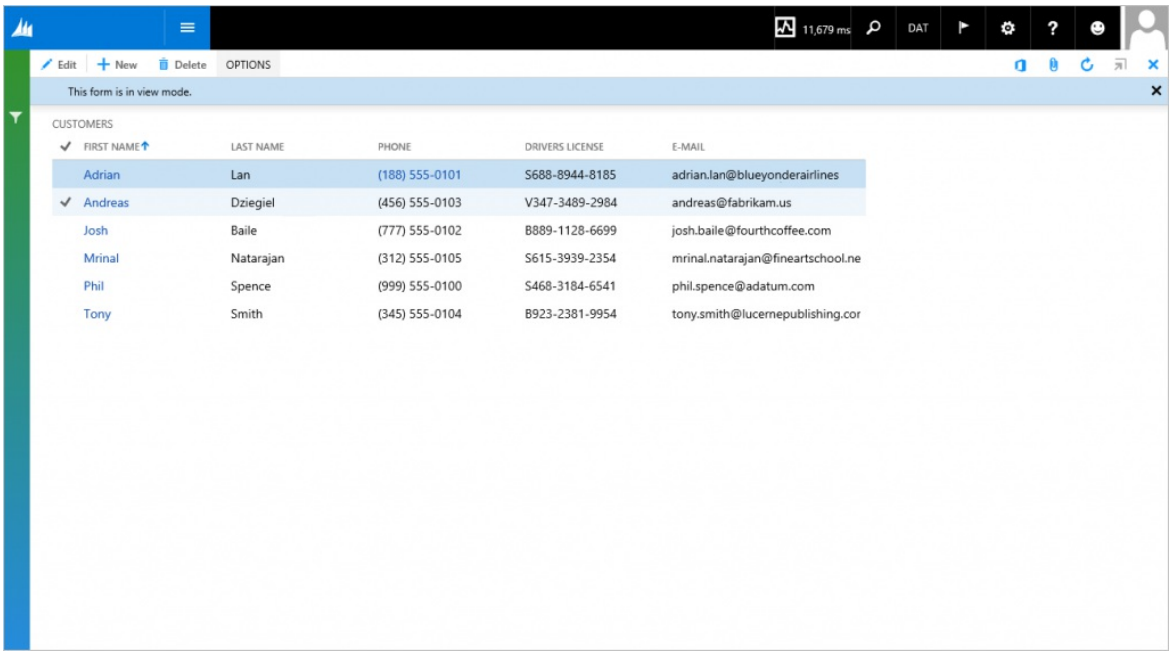
PROPERTY	VALUE
Data Source	FmtCustomer
Data Method	titleFields

11. Click **Design** > **GridDetailsTab** > **TabPageDetails** > **DetailsBodyTab** > **General** to add content to the details view.
    a. Click **FmtCustomer** > **Data sources** > **FmtCustomer** > **Fields**, press and hold the Ctrl key, and then select the following fields:
        - FirstName
        - LastName
        - CellPhone
        - DriverLicense
        - Email
    b. Drag the highlighted fields onto **General**, and then click **Save**.

View the form

Run the form to verify that it loads correctly.

1. In **Solution Explorer**, right-click **FmtCustomer**, and then click **Set as Startup Object**.
2. Press **Ctrl+F5**. The grid view should render like the following illustration.

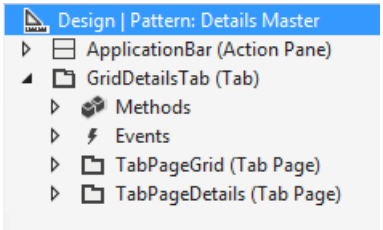


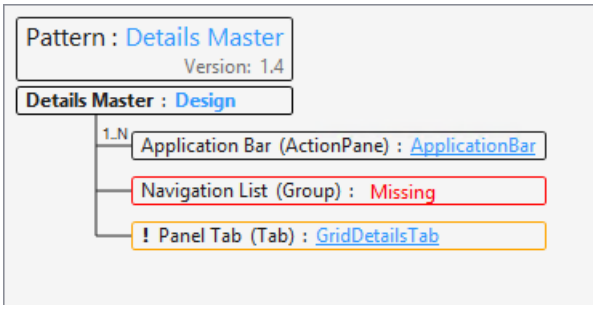
3. On the application bar, click **Open in Microsoft Office** > **Export to Excel** > **Customers** to send the information in the grid view to a Microsoft Excel spreadsheet. (If a dialog appears asking if you're sure you want to leave the page, click "Leave this page".) When asked, click **Open** to view the data in Excel.
4. Close Excel.
5. Click **Tony** to navigate to the details view for that record.
6. Click **Close** (or the browser Back button) to go back to the grid view.

Apply a pattern to the form

Use Visual Studio to apply the Master Details form pattern to the **Customer** form. Applying a form pattern ensures your form has the expected structure. It also simplifies the design experience by automatically setting the values of properties in the nodes that are part of the pattern.

1. Right-click **Design**, point to **Apply pattern,** and then click **Details Master**.

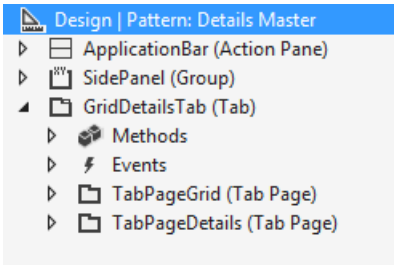


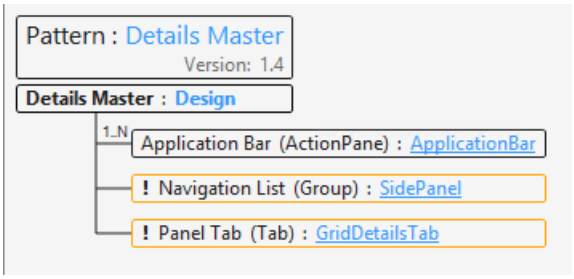


2. Add the missing Navigation List group. The red highlighting in the Patterns Information Panel indicates that this control is missing.
   a. Right-click **Design**, point to **New**, and then click **Group**.
   b. In the **Properties** window, in the **Name** property, enter **SidePanel**.

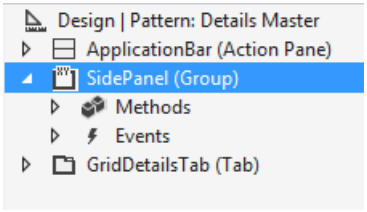
c. Click **SidePanel**, and press **Alt+Up** to move this group above the **GridDetailsTab (Tab)**.

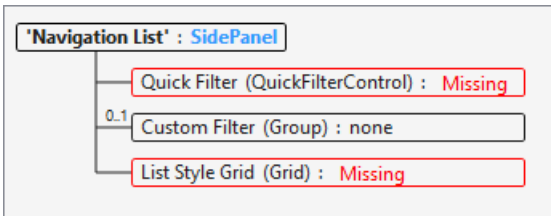
3. Click **Design** again. The yellow highlighting around the **Navigation List** and the **Panel Tab** indicate that there are problems that need to be resolved under each of these nodes before the pattern can be successfully applied.





4. In the Patterns Information Panel, click **SidePanel**.





5. Add the missing controls.

a. Right-click **SidePanel**, point to **New**, and then click **QuickFilter**.

b. In the **Properties** window, specify the following values.

PROPERTY	VALUE
Name	SidePanelQuickFilter
Target Control	MainGrid *This QuickFilter should have the same columns available for filtering as the main grid on the form*

c. Right-click **SidePanel**, point to **New**, and then click **Grid.**

PROPERTY	VALUE
Name	NavigationList

PROPERTY	VALUE
Datasource	FmtCustomer

6. Add identifying fields to the Navigation list. Right-click **NavigationList**, point to **New**, and then click **String**.

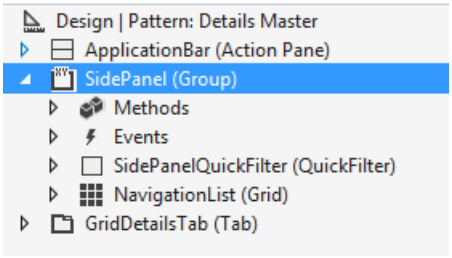
   a. In the **Properties** window, specify the following values.

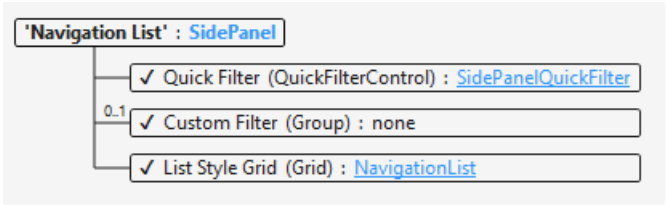
PROPERTY	VALUE
DataSource	FmtCustomer
DataMethod	fullName
Name	FmtCustomer_FullName

   b. Expand **Data Sources** > **FmtCustomer** > **Fields** to add phone numbers to the Simple list.

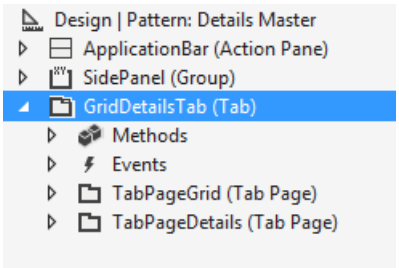
   c. Drag the **CellPhone** field onto the grid under **Design** > **SidePanel** > **NavigationList**.

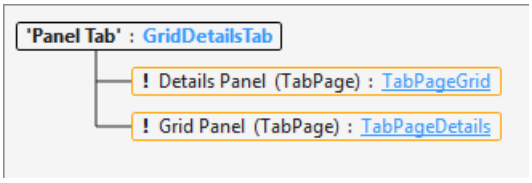
7. Click **SidePanel**. Notice the **Patterns Information Panel** is now indicating that the controls in this subtree are in full compliance with the pattern.





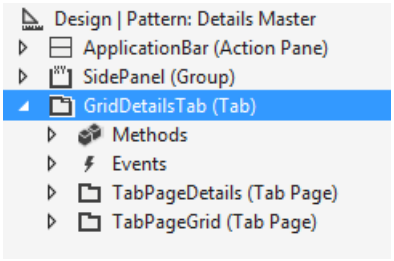
8. Click **Design** > **GridDetailsTab**. The yellow highlighting around the subnodes indicates that there are problems that need to be resolved under both nodes before the form pattern can be successfully applied.

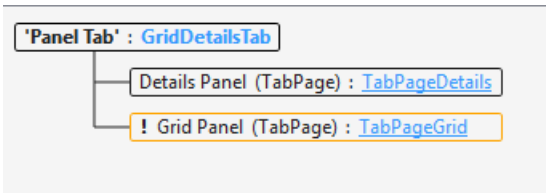




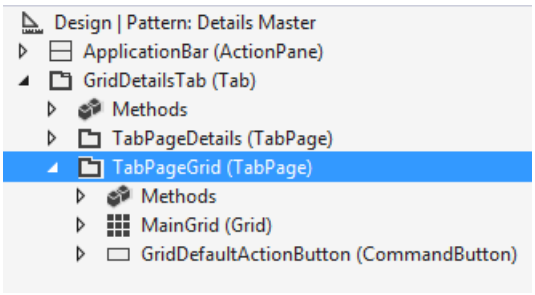
9. Notice that the pattern expects the **Grid Panel** to be after the **Details Panel**. Click **TabPageGrid** and press **Alt+Down** to move that tab below the **Details Panel**.

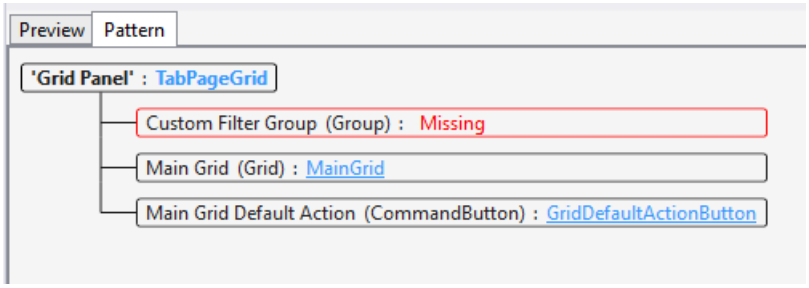
10. Click **GridDetailsTab**. The **TabPageDetails** tab page now adheres to the pattern. However, the **TabPageGrid** tab page needs additional attention.





11. Click **TabPageGrid**. Focus in the designer is now on **TabPageGrid**, and the **Patterns Information Panel** has been updated.



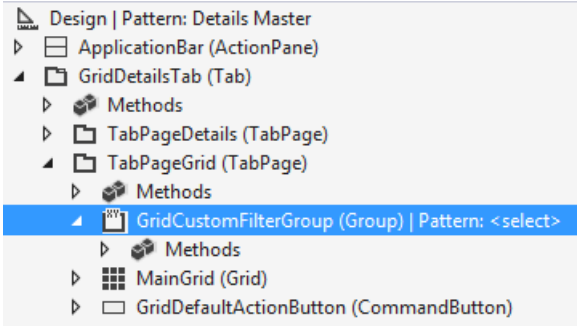


12. The **Patterns Information Panel** now indicates a missing Group control at the top of the **TabPageGrid** container.

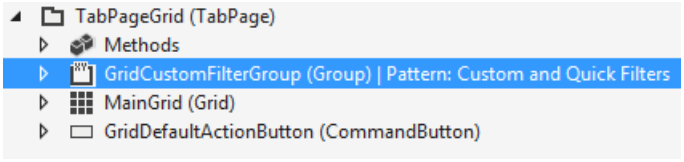
    a. Right-click **TabPageGrid**, point to **New**, and then click **Group**.

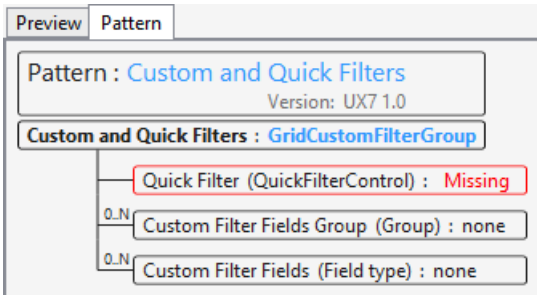
    b. Press **Alt+Up** two times to position the group as the first control in the group.

    c. In the **Properties** window, in the **Name** property, enter **GridCustomFilterGroup**.



13. The pattern is looking for a subpattern to be applied to **GridCustomFilterGroup**. Right-click **GridCustomFilterGroup**, point to **Apply pattern**, and then click **Custom and Quick Filters**.





14. The **Custom and Quick Filters** subpattern requires a QuickFilter control.

    a. Right-click **GridCustomFilterGroup**, point to **New**, and then click **QuickFilter**.

    b. In the **Properties** window, specify the following values.

PROPERTY	VALUE
Name	MainGridQuickFilter
Target Control	MainGrid

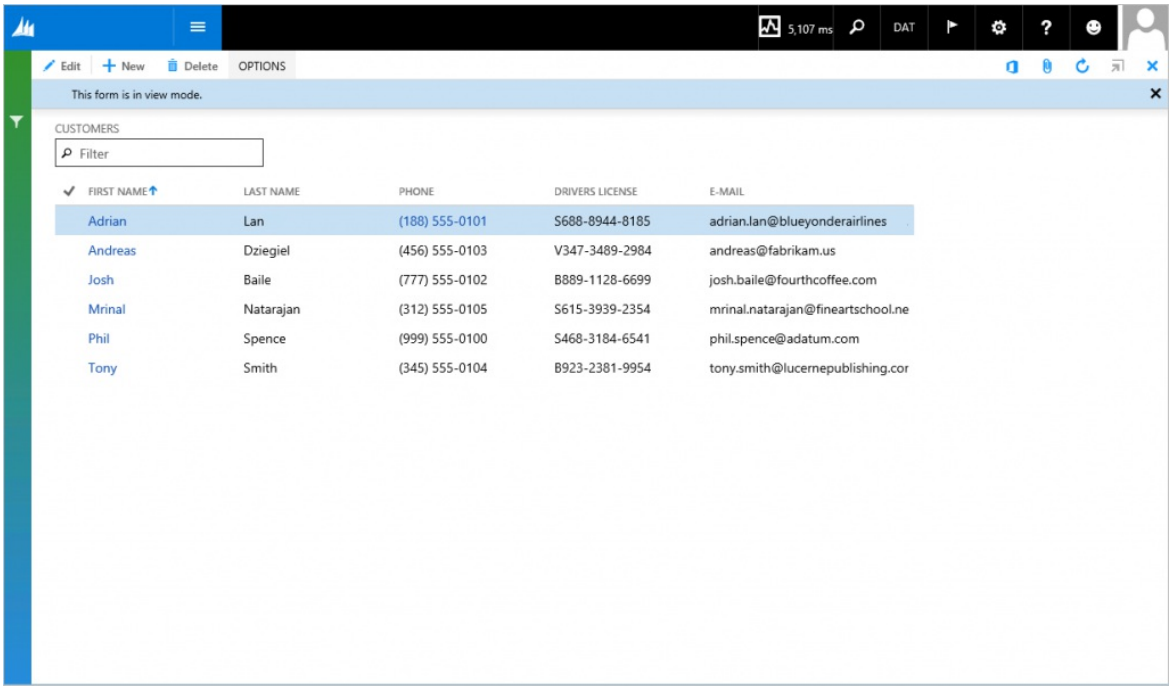
15. Browse up the control tree to design and notice how the **Patterns Information Panel** now shows no issues under each of the controls.

16. Press **Ctrl+S** to save the form.

View the details form

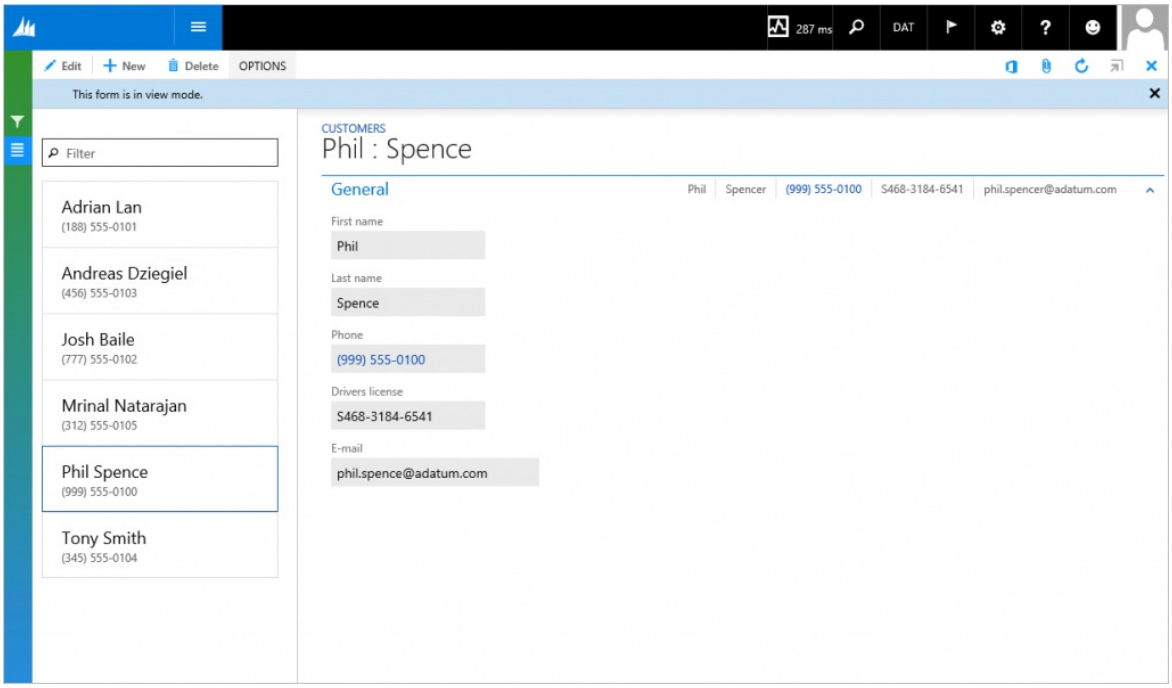
Run the form to see the Details view and the Grid view.

1. Press **Ctrl+F5** to run the project. The following illustration shows how the grid view appears.



2. Click **Phil** to go to the details view for that record.

3. Click the **Show list** button on the left side of the form to open the navigation list.

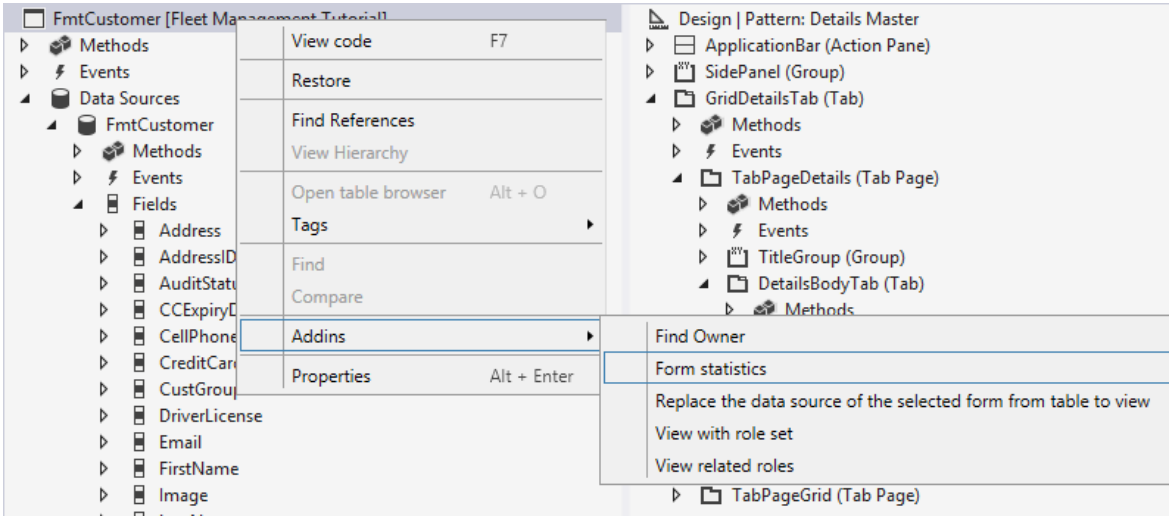


4. To go back to the grid view, click **Close** (or the browser Back button).

5. Return to Visual Studio.

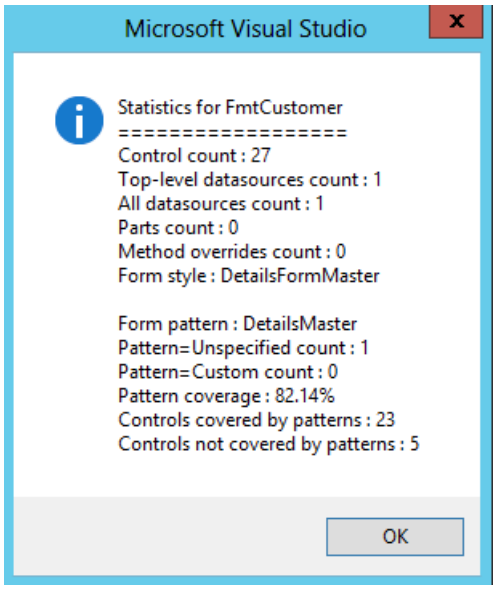
Add subpatterns

1. In Visual Studio, in the Form designer, right-click **FmtCustomer**, point to **Addins**, and then select **Form statistics**.

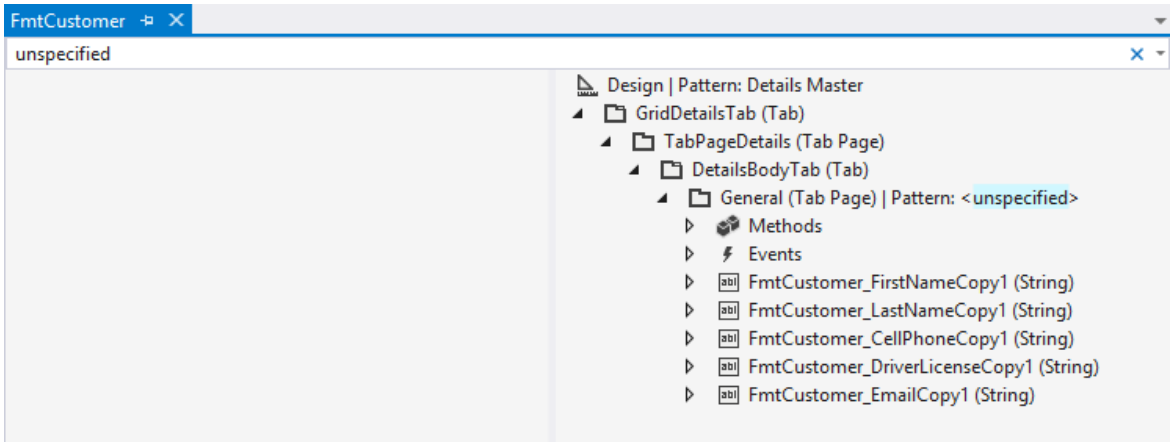


The **Form Statistics** add-in provides several useful data points about the state of the form. This includes:

- **Pattern=Unspecified count** – The number of nodes for which no form pattern or subpattern has been applied.
- **Pattern=Custom count** – The number of nodes for which a custom pattern was applied, meaning the structure did not fit with any existing pattern.
- **Pattern coverage** – The percentage of controls on the form that are covered by the form pattern or a subpattern. A value of 100% indicates a fully covered form.

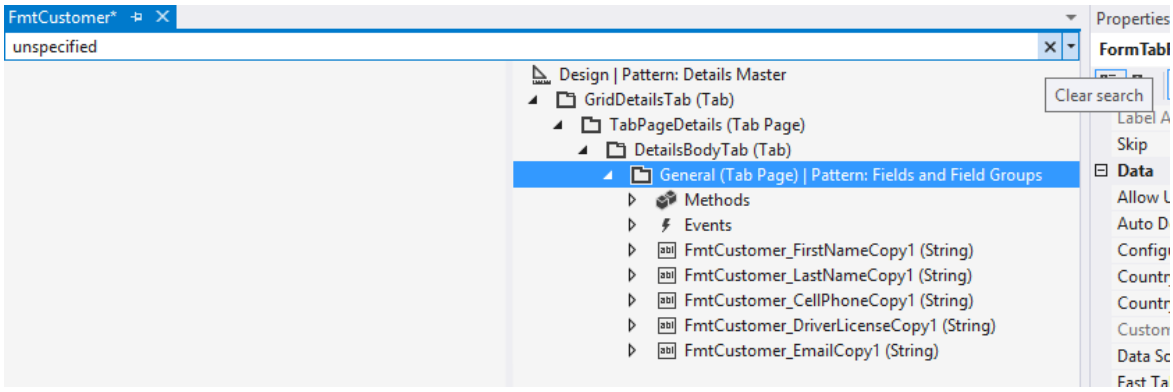


2. To complete pattern coverage for this form, the Pattern=Unspecified count should be zero. Use the Visual Studio form search to find all instances of “unspecified “in the form.



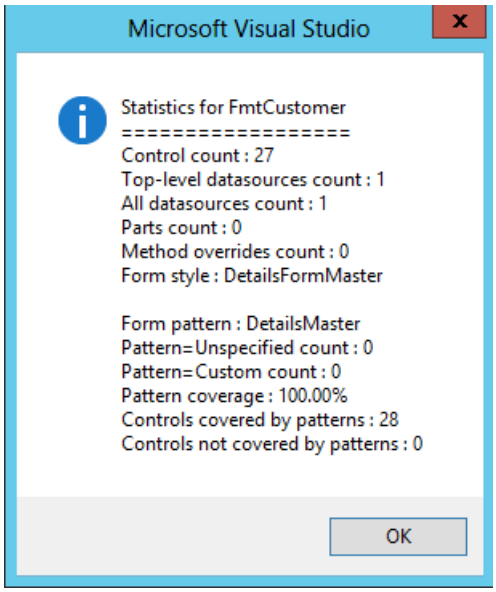
3. Because the **General** tab page contains only input controls and no custom layout is required for this FastTab, the Fields and Field Groups pattern should be applied to guarantee a responsive layout. Right-click **General**, point to **Apply pattern**, and then select **Fields and Field Groups**.

4. On the far right of the screen, click **Clear search**.



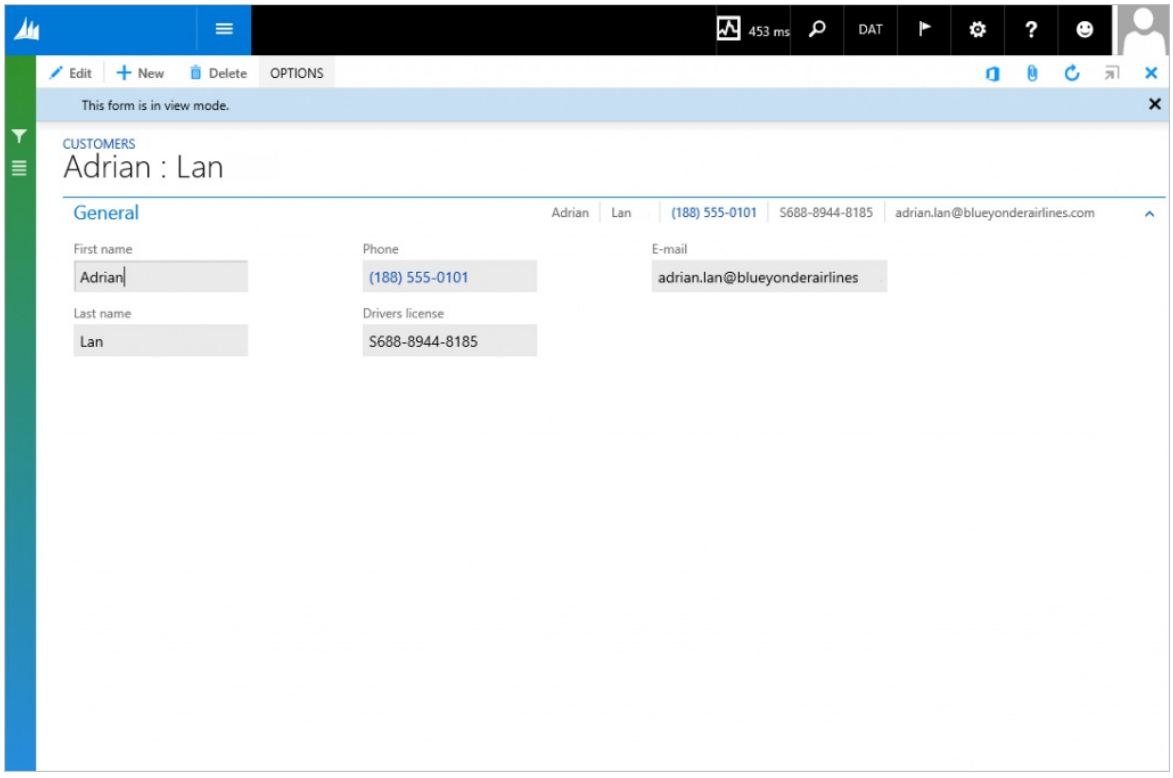
5. Press **Ctrl+S** to save the form.

6. Repeat step 1 to run the **Form Statistics** add-in a second time to verify the form is fully covered by patterns.



7. Press **Ctrl+F5** to run the project and see the updated form.

8. Click **Adrian** to go to the details view. The following illustration shows how the details view now appears after applying the Fields and Field Groups subpattern so that the fields lay out responsively. By changing the browser width, you'll see how the field layout adjusts to better fill the width of the browser.

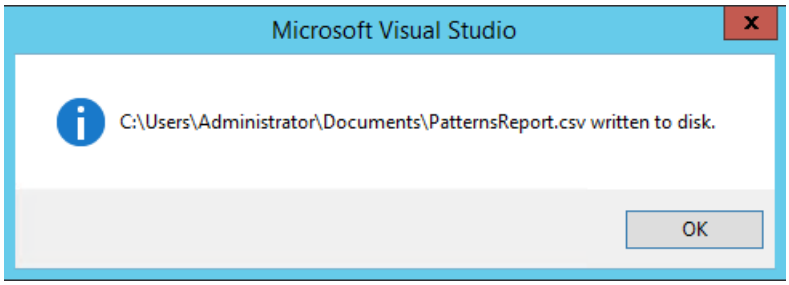


9. Return to Visual Studio

Determine the amount of remaining patterns work in a model

1. Click **Finance and Operations**, point to **Addins**, and then select **Run form patterns report**.

   A notification dialog will be shown when the form patterns report has been generated.



2. Open the PatternsReport file in Excel.

3. Filter the report to the Fleet Management Tutorial model.

   a. Click **Data** > **Filter**.

   b. Filter the **Model** column to FleetMgmntTutorial.

	A	B	C	D	E	F	G	H
1	Model	Form	Style	Pattern	Controls	Covered controls	Percent covered controls	Patte
83	FleetMgmntTutorial	FMTBiChartsPart	FormPart		8	0	0	
84	FleetMgmntTutorial	FmtChargeType	SimpleList	SimpleList	7	7	100	
85	FleetMgmntTutorial	FMTClerkWorkspace	Workspace	Workspace	17	14	82.35	
86	FleetMgmntTutorial	FmtCustomer	DetailsFormMaster	DetailsMaster	28	28	100	
87	FleetMgmntTutorial	FMTPickingUpTodayPart	FormPart		7	0	0	
88	FleetMgmntTutorial	FMTRentalRatesPart	FormPart		6	0	0	
89	FleetMgmntTutorial	FMTReturningTodayPart	FormPart		7	0	0	
6981								
6982								

The report shows pattern-related information regarding the forms in this model including the top-level form pattern currently applied, and the percentage of controls on the form covered by patterns. This can be used to track the remaining patterns work in one or more models.

Build navigation

2/18/2021 • 6 minutes to read • Edit Online

In this tutorial, you will add navigational elements to a workspace and the navigation pane.

Prerequisites

For this tutorial, you need to access the environment using Remote Desktop, and be provisioned as an administrator on the instance. For more information, see Access Instances.

Key concepts

- A *workspace* is an overview page that is specific to a particular subject area. Workspaces are common to all users. In this tutorial, you will add content into an existing workspace.
- The *dashboard* is the default home page for each user.
- *Tiles* are securable objects that can be shown on a workspace or the dashboard. They can be secured by using menu items.

Setup

If this is the first tutorial that you are working on, review Access Instances and make sure that you provision your administrator user if you are working on a local VM.

Import the tutorial project

If you have already imported the Fleet management tutorial project, skip to the next section.

1. Download the Fleet Management sample from https://github.com/Microsoft/FMLab, save it to **C:**, and unzip it.
2. In Visual Studio, on the **Finance and Operations** menu, click **Import Project**.
3. In the **Import Project** window, next to the **Filename** text box, click the ellipsis button.
4. In the **Select the file to import** window, browse to **C:\FMLab**, click **FMTutorialDataModel.axpp,** and then click **Open**.
5. In the Project file location text box, enter **C:\FMLab.**
6. Select the **Overwrite Elements** option, and then click **OK**.

Import transactional data

1. In Visual Studio, open the **FMTutorial** project. On the **File** menu, point to **Open**, and then click **Project/Solution**.
2. In the **Open Project** dialog box, browse to C:\FMLab\FMTutorial, and then click FMTutorial. Click **Open**. The **FMTutorial** project appears in **Solution Explorer**.
3. Use the FMTDataHelper class to load data for the Fleet Management tutorial. In **Solution Explorer**, in the FMTutorial project, expand **Classes**, right-click **FMTDataHelper**, and then click **Set as Startup Object**.
4. From the **BUILD** menu, click **Rebuild Solution**. You use the rebuild to update the timestamps of the imported artifacts. You can view the build progress in the **Output** window.
5. Press **Ctrl+F5** to run the project and load the data.

Add a tile to the tutorial workspace

First, we will add a new tile to the form FMTClerkWorkspace.

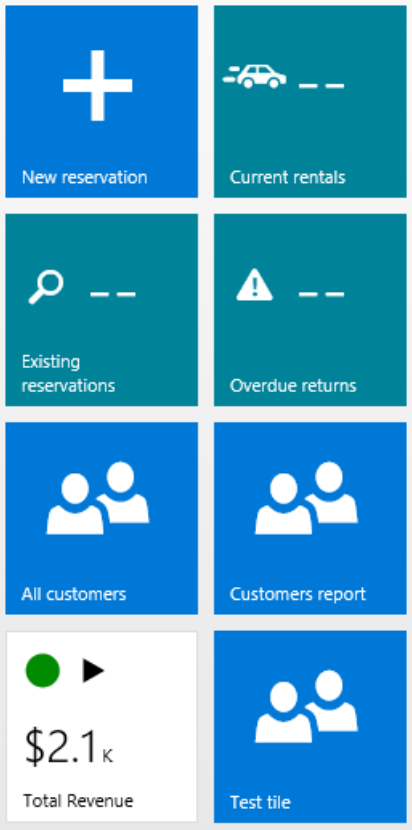
1. In **Solution Explorer**, expand **Forms** and then double-click **FMTClerkWorkspace**.
2. In the designer, expand **PanoramaBody**.
3. Right-click **TileContainer**, and then click **New** > **Tile Button.**
4. Specify the following properties for the new tile button.

PROPERTY	VALUE
Text	Test tile
Tile	FMTAllCustomersTile

   This will create a duplicate of the existing **All customers** tile.

5. In **Solution Explorer**, click **Forms** > **FMTClerkWorkspace**, right-click, and then select **Set as Start-up Object**. Setting a start-up object is necessary to allow Visual Studio to launch when you press Ctrl+F5 in step 7. Setting this form as the start-up object will cause the work-in-progress Fleet management clerk workspace to appear after you press Ctrl+F5. We will preview this form again later in detail.
6. Right-click **FMTutorial**, and then click **Rebuild**.
7. Press **Ctrl+F5** to run the project.

After you build and run the project, the Fleet management clerk workspace will launch. The new tile named, **Test tile**, that you created will be included in the first section of the workspace, at the end of the set of tiles.



NOTE

The tile will not navigate anywhere when clicked. To enable this, you can define a Menu Item Name on FMTAllCustomersTile, under **Tiles** in **Solution Explorer**.

Add a new workspace to the navigation pane

Next, we will add the FMTClerkWorkspace form to the navigation pane. We will do this in two locations:

- The **All workspaces** list.
- A new item in the area list containing a menu structure that shows the workspace.

Create a menu item that points to the FMTClerkWorkspace workspace

1. Right-click **FMTutorial**, point to **Add**, and then click **New Item**.
2. Click **AX Artifacts** > **User Interface** > **Display Menu Item**. In the **Name** property, enter **FMTClerkWorkspace**.
3. Click **Add**.
4. Specify the following properties for the new menu item.

PROPERTY	VALUE
Label	Reservation management tutorial
Object	FMTClerkWorkspace

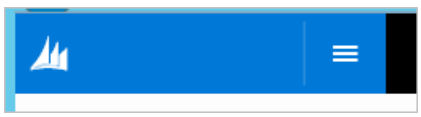
Create a tile that points to the FMTClerkWorkspace workspace menu item

1. Right-click **FMTutorial**, point to **Add**, and then click **New Item**.
2. Click **AX Artifacts** > **User Interface** > **Tile**. In the **Name** property, enter **FMTClerkWorkspace**.
3. Click **Add**.
4. Specify the following properties for the new tile.

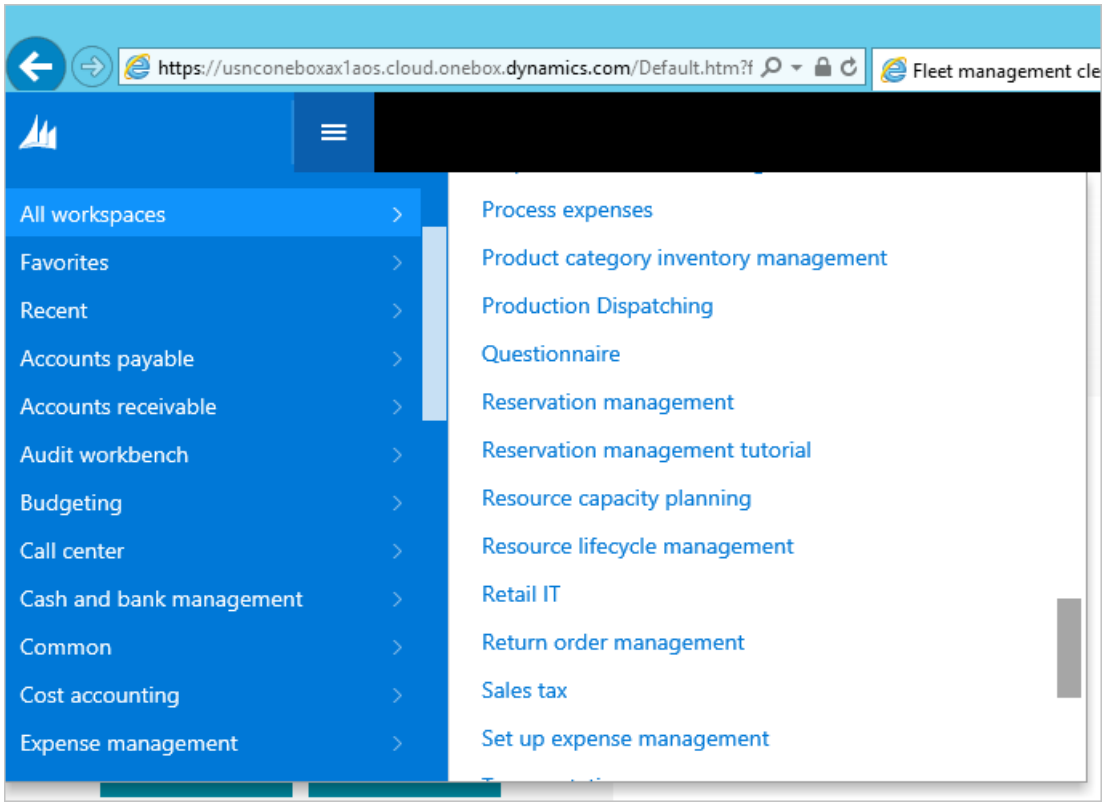
PROPERTY	VALUE
MenuItemName	FMTClerkWorkspace

Add a menu extension for the navigation pane

1. In **Application Explorer**, click **User Interface** > **Menus**, right-click **NavPaneMenu**, and then click **Create extension**.
2. In **Solution Explorer**, double-click **NavPaneMenu.Extension**.
3. In the designer, right-click **NavPaneMenu.Extension**, point to **New**, and then click **Submenu**.
4. Select the new submenu. In the **Name** property, enter **NavPaneMenuFleetTutorial**.
5. In **Solution Explorer** or **Application Explorer**, locate the **FMTClerkWorkspace** tile, and drag it onto the newly created submenu. Click **Save**.
6. Right-click **FMTutorial**, and then click **Rebuild**.
7. Press **Ctrl+F5** to run the project. After you build and run the project, the navigation pane will contain a link to the new workspace. Open the navigation pane by clicking the navigation pane button (three lines) at the top right of the application window.



8. When you open the navigation pane, select **All workspaces**, and scroll down in the list after it opens. You should see the following new Reservation management tutorial workspace in the list.



Add the form to the main menu structure

Now you'll add a new main menu section that contains a tile that points to the tutorial workspace. You will then add a link to the same form in this section. This will demonstrate the appearance of a non-workspace form link.

1. In Visual Studio, in **Solution Explorer**, right-click **FMTutorial**, point to **Add**, and then click **New Item**.
2. Click **AX Artifacts** > **User Interface** > **Menu**. In the **Name** property, enter **FleetManagementTutorial**.
3. Click **Add**.
4. In **Solution Explorer**, double-click the new menu **FleetManagementTutorial** if it isn't already open.
5. In the properties list, set the **Label** property to **Fleet management tutorial**.
6. In the designer, right-click **FleetManagementTutorial**, and click **New** > **Submenu**.
7. Specify the following properties for the new submenu.

PROPERTY	VALUE
Name	Workspaces
Label	Workspaces

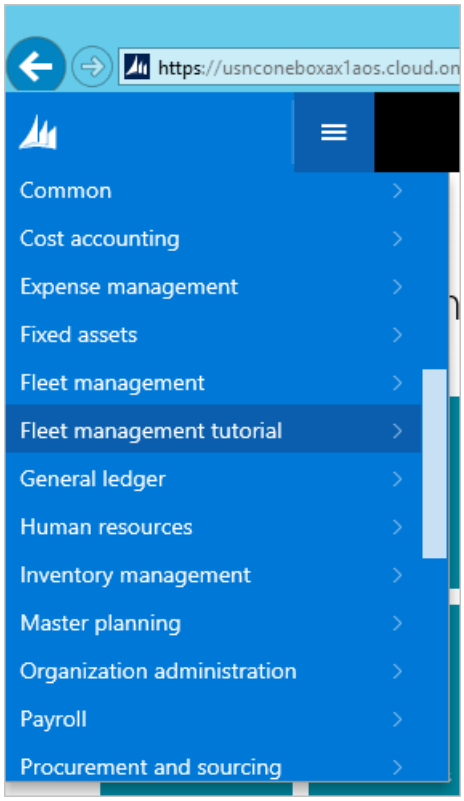
8. In **Solution Explorer** or **Application Explorer**, locate the **FMTClerkWorkspace** display menu item and drag it onto the new **Workspaces** submenu.
9. In the designer, right-click **FleetManagementTutorial**, and then click **New** > **Submenu**.
10. Specify the following properties for the new submenu.

PROPERTY	VALUE
Name	Common
Label	Common

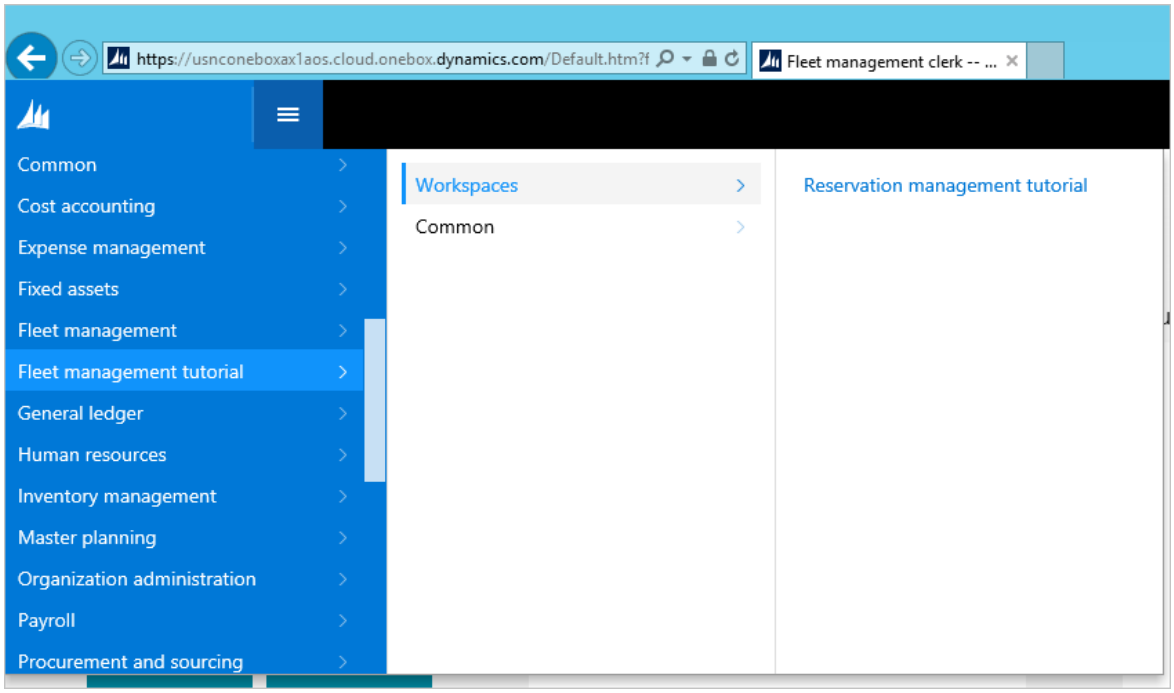
11. In **Solution Explorer** or **Application Explorer**, locate the **FMTClerkWorkspace** display menu item and drag it onto the new **Common** submenu.
12. In **Application Explorer**, click **User Interface** > **Menus** > **MainMenu**. Right-click **MainMenu**, and then click **Create extension**.
13. In **Solution Explorer**, locate and open the new extension. Select and double-click **MainMenu.Extension** to open it.
14. In the designer, right click **MainMenu.Extension**, point to **New**, and then click **Menu reference**.
15. Specify the following properties for the new menu reference.

PROPERTY	VALUE
Name	FleetManagementTutorial
Menu Name	FleetManagementTutorial

16. Click **Save**.
17. Right-click **FMTutorial**, and then click **Build**.
18. Press **Ctrl+F5** to run the project.
19. Go to the main menu section you just modified. Open the navigation pane and scroll down until you see the new top-level **Fleet management tutorial** menu. You may need to clear your browser cache by pressing **Ctrl+F5**.



20. Click **Fleet management tutorial** > **Workspaces** to expand that submenu. Your navigation pane should look like the following.



If you click on the **Common** submenu, you will see the menu item that you modeled there. You can click either of these links to check that you have set up the references correctly. If you have set up the references correctly, the tutorial workspace you're working on should open when clicked on.

Modify a workspace with a tile, list, and data cache

2/18/2021 • 22 minutes to read • Edit Online

In this tutorial, you will create a new tile and include it in the summary section of a workspace, build a new list for a workspace, and create a data cache for the list in the workspace.

Prerequisites

For this tutorial, you must access the environment by using Remote Desktop, and you must be provisioned as an administrator on the instance. For more information, see Deploy and access development environments.

Key concepts

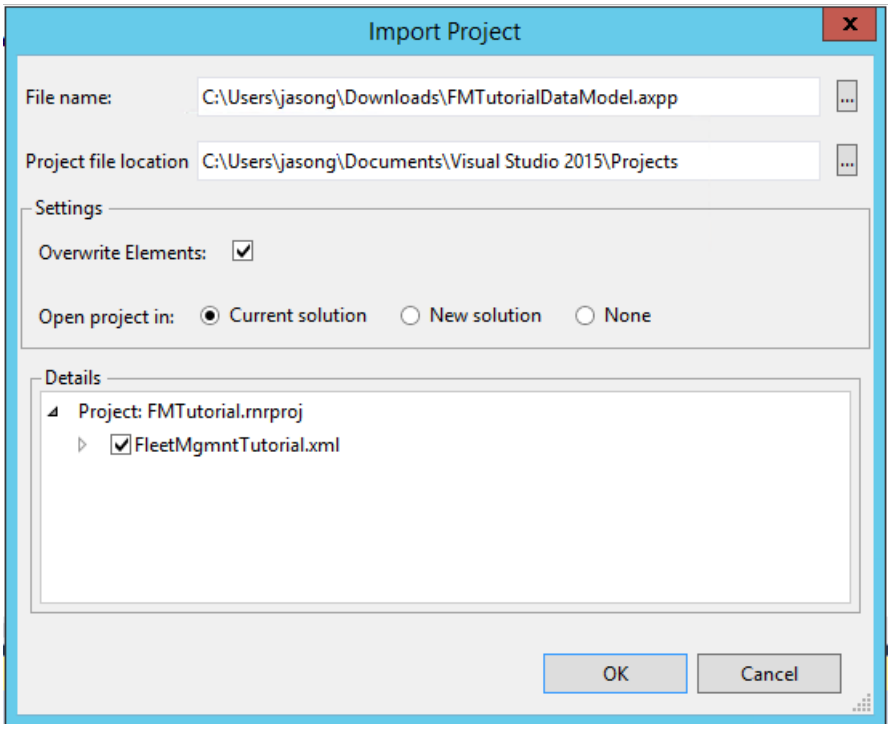
- Learn about and use form patterns that are related to workspaces.
- Create a new tile, and include it in the **Summary** section of a workspace.
- Build a new list for a workspace.
- Create a data cache for the list in the workspace.

Setup

Import the tutorial project and transactional data

Use Microsoft Visual Studio to import the tutorial project. The tutorial project includes the artifacts that you will use to complete this tutorial. Use Visual Studio to open the FMTutorial project and load the data for the tutorial. You will use the **FMTDataHelper** class to load data for the Fleet Management tutorial. If this is the first tutorial that you're working on, review Deploy and access development environments, and make sure that you provision your administrator user if you're working on a local virtual machine (VM).

1. Download the **FMTutorialDataModel.axpp** file from the Microsoft Dynamics Lifecycle Services (LCS) methodology, and copy it to the **Downloads** folder of the VM.
2. On the desktop, double-click the Visual Studio shortcut to open the development environment.
3. On the **Dynamics 365** menu, click **Import Project**.
4. In the **Import Project** dialog box, next to the **File name** field, click the ellipsis (...) button.
5. In the **Select the file to import** dialog box, browse to the **Downloads** folder, click **FMTutorialDataModel.axpp**, and then click **Open**.
6. Select the **Overwrite Elements** check box and the **Current solution** option. The following illustration shows the completed **Import Project** dialog box.



7. Click **OK**.
8. In Solution Explorer, expand **Classes**, and then, under the **FMTutorial** project, right-click **FMTDataHelper**, and then click **Set as Startup Object**.
9. On the **Build** menu, click **Rebuild Solution**. Use the rebuild to make sure that all the files in the project are built, regardless of timestamps. You can view the build progress in the **Output** window.
10. After the build is completed, press **Ctrl+F5** to run the project. The browser opens and runs the class that imports the data.

Open the FMTutorial project

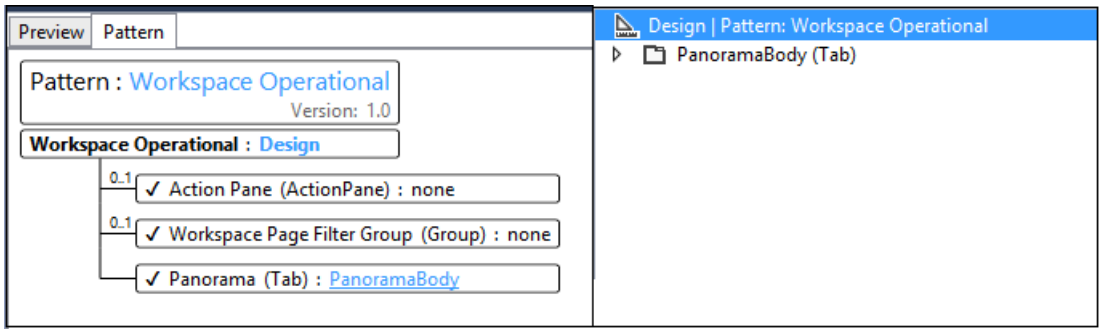
Use Visual Studio to open the FMTutorial project. If you have Visual Studio open and have already loaded the FMTutorial project, you can continue to the next section.

1. If the development environment isn't already open, on the desktop, double-click the Visual Studio shortcut to open it.
2. On the **File** menu, click **Open** > **Project/Solution**.
3. In the **Open Project** dialog box, browse to **Documents** > **Visual Studio 15.0** > **Projects**, select the **FMTutorial** solution, and then click **Open**.
4. The FMTutorial project appears in Solution Explorer.

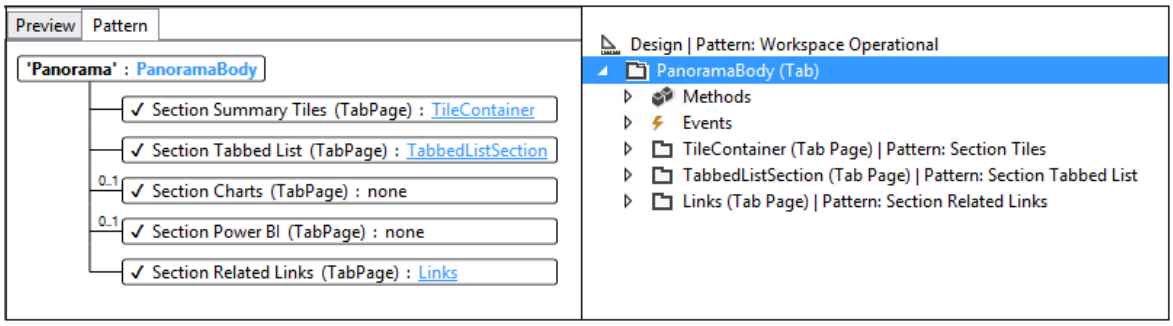
Exercise 1: Understand the operational workspace pattern

Before you start to make adjustments to **FmtClerkWorkspace** form, you will look at the current state of the form to better understand what content is already there and how that contents fits the Operational Workspace pattern.

1. In Solution Explorer, double-click the **FmtClerkWorkspace** form to open it in the designer.
2. Click the **Design** node.
3. Click the **Pattern** tab. Operational workspaces have an optional Action Pane and optional filter group (as indicated by the 0..1 notation to the left of those nodes). However, the panorama-style tab is required by this pattern. The **Patterns** tab shows that the PanoramaBody control matches the required Tab in the pattern, but there are no corresponding controls for the optional items at this level of the pattern.



4. Click **PanoramaBody**.



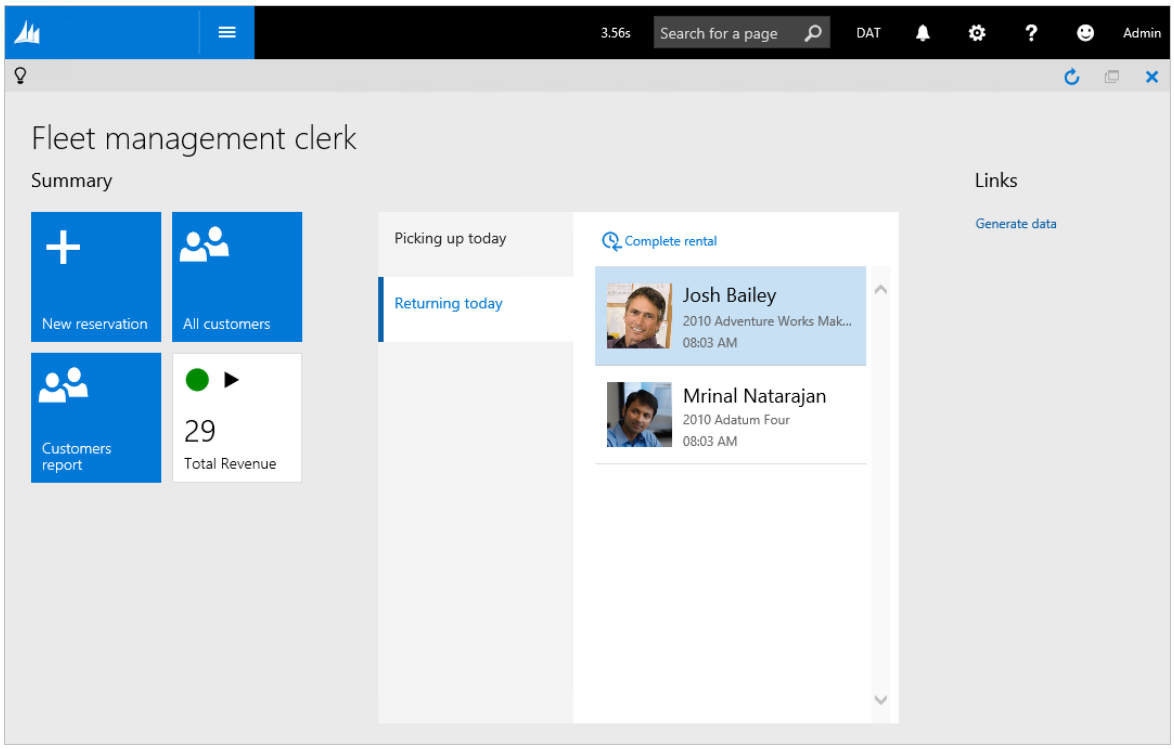
All workspaces have three required sections:

- **Summary section** – This section is intended to contain tiles or form parts, which correspond to a card or chart.
- **Tabbed list** – This section consists of one or more lists of data that is relevant to the user's work. Only one list is shown at a time, and each list can optionally include local filters and actions. Individual lists are modeled inside form part controls.
- **Related links** – This section consists of important or commonly used links for this activity or persona.

Operational workspaces can optionally include a panorama section that contains up to two charts (the Section Charts tab page) and a Power BI section.

View the workspace

1. In Solution Explorer, right-click the **FmtClerkWorkspace** form, and then click **Set as Startup Object**.
2. Press **Ctrl+F5** to build and run the form. The form opens in Internet Explorer.



Exercise 2: Create a new tile for the workspace

Now that you understand the content structure of a workspace, you will see how to add content to a workspace. For example, one important piece of information for this workspace might be the number of rentals that are currently in progress. In this section, you will add the required metadata to add a new tile to the **Summary** section of the **FmtClerkWorkspace** form to show this information. To make this tile work correctly, you will have to add four metadata artifacts: a query, a menu item, a tile, and a tile button.

Add a query that retrieves current rentals

All tiles require a backing query to retrieve the correct information.

1. In Solution Explorer, in the **FMTutorial** project, right-click the **Queries** folder, point to **Add**, and then click **New item**.
2. Click **Dynamics 365 Items** > **Data Model** > **Query**. For the **Name** property, enter **FMTRental_Current**.
3. Click **Add**.
4. If the new **FMTRental_Current** query isn't already open in the designer, double-click it in Solution Explorer.
5. In the designer, right-click **Data Sources**, and then click **New Data Source**.
6. In the **Properties** window, set the following properties.

PROPERTY	VALUE
Table	FMTRental
Dynamics Fields	Yes

7. Right-click **Ranges**, and then click **New Range**.
8. In the **Properties** window, set the following properties.

PROPERTY	VALUE
Field	State
Value	InProgress

9. Right-click **Order By**, and then click **New Field**.
10. In the **Properties** window, set the following properties.

PROPERTY	VALUE
Direction	Descending
Data Source	FMTRental
Field	StartDate

11. Press **Ctrl+S** to save.

Add the corresponding menu item

1. In Solution Explorer, in the **FMTutorial** project, right-click the **Menu items** folder, point to **Add**, and then click **New item**.
2. Click **Dynamics 365 Items** > **User Interface** > **Display menu item**. Set the **Name** property to **FMTRental_Current**.
3. Click **Add**.
4. If the new **FMTRental_Current** menu item isn't already open in the designer, double-click it in Solution Explorer.
5. In the **Properties** window, set the following properties.

PROPERTY	VALUE
Label	@FMT197 This value corresponds to "Current rentals".
Object	FMTRental
Query	FMTRental_Current

6. Press **Ctrl+S** to save.

Add a tile

1. In Solution Explorer, in the **FMTutorial** project, right-click the **Tiles** folder, point to **Add**, and then click **New item**.
2. Click **Dynamics 365 Items** > **User Interface** > **Tile**. Set the **Name** property to **FMTCurrentRentalsTile**.
3. Click **Add**.
4. If the new **FMTRental_Current** tile isn't already open in the designer, double-click it in Solution Explorer.
5. In the **Properties** window, set the following properties.

PROPERTY	VALUE
Size	ShortWide
Menu Item Name	FMTRental_Current
Type	Count

6. Press **Ctrl+S** to save.

Tiles also have a refresh frequency property that controls how often the counts on the tiles are automatically updated. The value that is set for this property should be based on the demand for updated counts, together with query execution speed against volume data. For guidance about how to set this property, see Tile and List Caching for Workspaces. For this lab, the default value of 10 minutes will be enough.

Add a tile button to the workspace form

1. In Solution Explorer, double-click the **FmtClerkWorkspace** form to open it in the designer.
2. Right-click **Design** > **PanoramaBody** > **TileContainer**, point to **New**, and then click **Tile Button**.
3. Press **Alt+Up arrow** four times to move the tile button to the top of TileContainer.
4. In the **Properties** window, set the following properties.

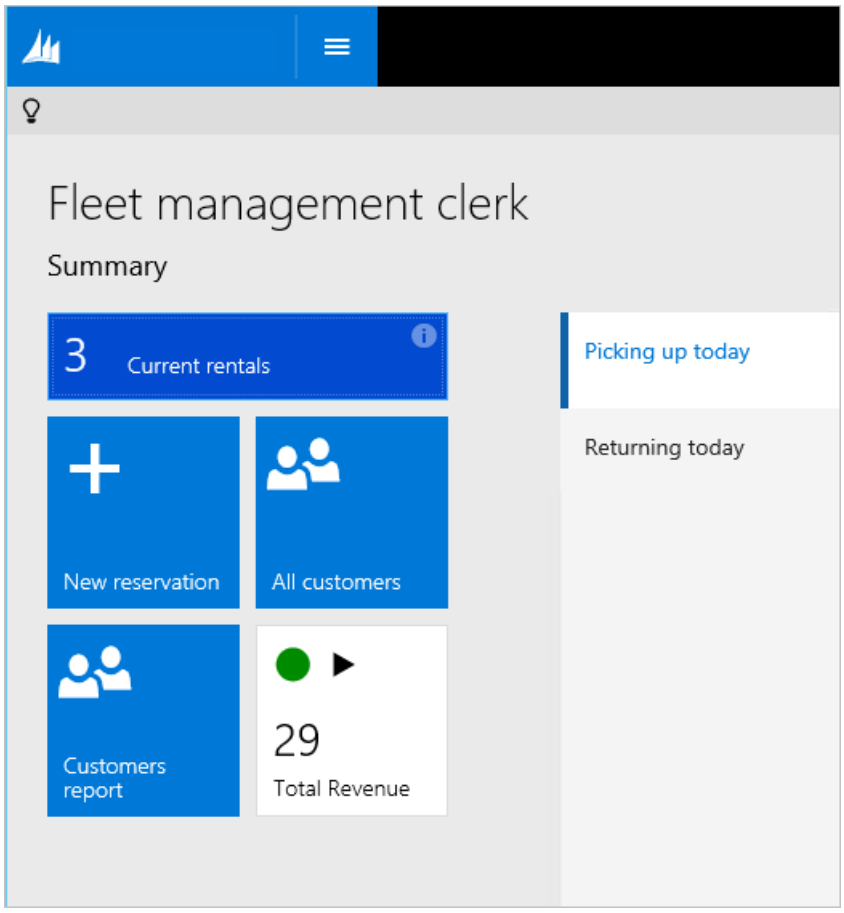
PROPERTY	VALUE
Name	FMTCurrentRentalsTile
Tile	FMTCurrentRentalsTile

5. Press **Ctrl+S** to save.

View the new tile on the workspace

Use Visual Studio to build and run the updated **FmtClerkWorkspace** form.

1. In Solution Explorer, right-click the **FmtClerkWorkspace** form, and then click **Set as Startup Object**.
2. Press **Ctrl+F5** to build and run the form. The form opens in Internet Explorer.

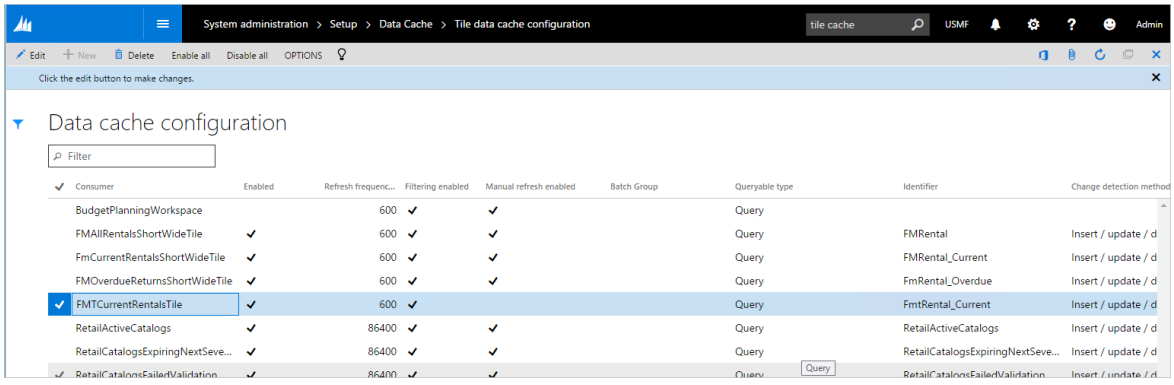


3. Click the **Current rentals** tile. You go to the **Rentals** page, which should be filtered to the three current rentals.
4. Click the **Back** button or the **Close** button to return to the workspace.
5. Click on the small **i** button in the upper-right corner of the **Current rentals** tile. You see information about how current the data in the tile is. Additionally, a link is provided that you can use to manually refresh the tile to view updated data.

View tile data cache values at run time

A system administrator can modify tile cache parameters at run time by using the **Tile data cache configuration** page.

1. Click in the navigation search field on the navigation bar.
2. Type **Tile data**, and then click **Tile data cache configuration** in the search results.
3. Find the **FMTCurrentRentalsTile** record.



From this page, the system administrator can perform several run-time modifications to a tile cache. For example, the system administrator can enable/disable the data cache, modify the refresh frequency, and

enable/disable the ability to manually refresh the count tile. Note that tile caches are registered when a form that has a tile is first opened. Therefore, the list of tiles that is shown in your environment might differ from the list in the preceding illustration.

Exercise 3: Create a new tabbed list in the workspace

Next, you will next see how to include an additional list in the workspace. This section will give you some experience with building forms and will also expose you to form patterns. You will add a list of available vehicles, so that you will be able to initiate a new rental by selecting an available vehicle. In this section, you will just add the new list to the new workspace but won't add the action to initiate the rental. To add this list, you will have to complete the following tasks:

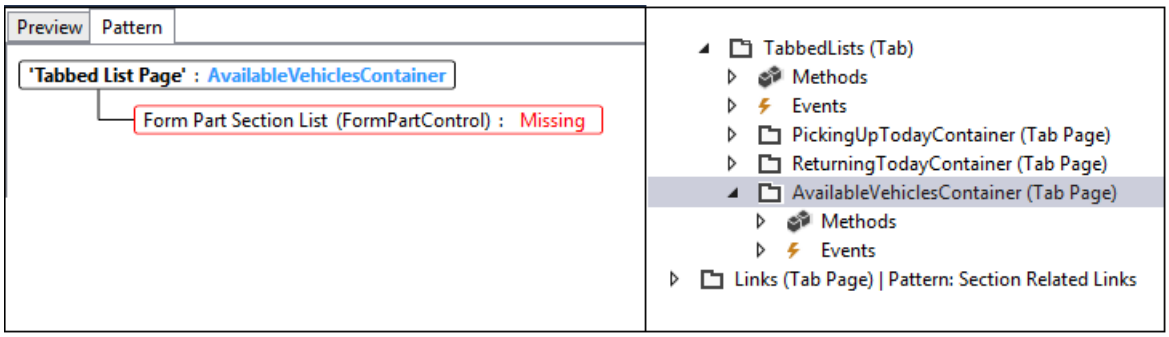
1. Add a new tab page to the workspace.
2. Add a new form that has the list content.
3. Add a new menu item that points to the new form.
4. Add a new query to limit the vehicles to available vehicles.

Add space in the workspace for a new list

1. In Solution Explorer, double-click the **FmtClerkWorkspace** form to open it in the designer.
2. Right-click **Design** > **PanoramaBody** > **TabbedListSection** > **TabbedLists**, and then click **New Tab Page**.
3. In the **Properties** window, set the following properties.

PROPERTY	VALUE
Name	AvailableVehiclesContainer
Caption	@FMT199 This value corresponds to “Available vehicles”.

4. Right-click **AvailableVehiclesContainer**, point to **New**, and then click **Form Part**. **Form Part** is the only control type that the Operational Workspace pattern allows here. This control will be used to link to the form that you will build to hold the content for this section.



5. In the **Properties** window, set the **Name** property to **AvailableVehiclesPart**.
6. Press **Ctrl+S** to save.

Add a new form that has the new workspace content

1. In Solution Explorer, in the **FMTutorial** project, right-click the **Forms** folder, point to **Add**, and then click **New item**.
2. Click **Dynamics 365 Items** > **User Interface** > **Form**. Set the **Name** property to **FMTAvailableVehicles**.
3. Click **Add**.

4. If the new **FMTAvailableVehicles** form isn't already open in the designer, double-click it in Solution Explorer.

5. Add the **FmtVehicle** table as a data source for the form.

   a. Right-click **Data Sources**, and then click **New Data Source**.

   b. Click the new data source node. In the **Properties** window, set the following properties.

PROPERTY	VALUE
Table	FMTVehicle
Name	FMTVehicle **Note:** Be sure to specify the value for the **Table** property first. This property is automatically updated so that it uses the same value.

6. Add the **FmtVehicleModel** table as a second data source for the form.

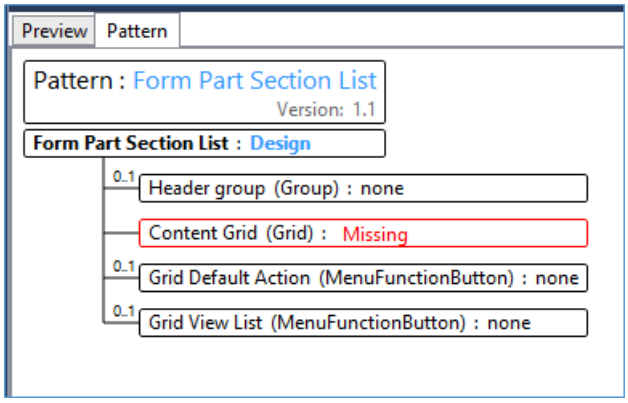
   a. Right-click **Data Sources**, and then click **New Data Source**.

   b. Click the new data source node. In the **Properties** window, set the following properties.

PROPERTY	VALUE
Table	FMTVehicleModel
Name	FMTVehicleModel **Note:** Be sure to specify the value for the **Table** property first. This property is automatically updated so that it uses the same value.
Join Source	FMTVehicle
Link Type	Inner Join

7. Notice the **Pattern: <select>** notation next to **Form Design**. This indicates the required pattern for this node. Right-click **Design**, point to **Apply pattern**, and then click **Form Part Section List**. This form pattern is typically used by workspace lists.

8. Click the **Pattern** tab to see the expected content for this pattern. This information will help guide you as you create content for the form. **Note:** In the future, we plan to provide a mechanism for automatically creating a form structure, based on a selected form pattern.



In particular, this pattern looks for the following elements:

- An optional header group that contains any filters and actions that are required for this workspace list.

- A required grid. As the red border in the preceding illustration indicates, the patterns engine can't currently find this element.
- An optional default action, which can provide navigation to a backing form for an individual record in the grid.
- An optional button that takes the user to a backing form that shows the full list of items in this section.

9. Right-click **Design**, point to **New**, and then click **Grid**.
10. In the **Properties** window, set the following properties. **Note:** The grid that we are building will contain cards and will be two cards wide.

PROPERTY	VALUE
ExtendedStyle	cardList
Multi Select	No
Style	List
Data Source	FMTVehicle
Name	VehicleList
Visible Columns Mode	Fixed
Visible Columns	2

11. Right-click the **VehicleList** grid, point to **New**, and then click **Group**.
12. In the **Properties** window, set the **Name** property to **VehicleCard**.
13. Right-click the **VehicleCard** group, point to **Apply pattern**, and then click **Business Card – Three Fields**.
14. Right-click the **VehicleCard** group, point to **New**, and then click **Image**.
15. In the **Properties** window, set the following properties.

PROPERTY	VALUE
Data Source	FMTVehicleModel
Data Method	vehicleImage

16. Expand **Data Sources** > **FMTVehicle** > **Fields**.
17. Drag the **VehicleId** and **DisplayRelationType** fields into the **VehicleCard** group.
18. Right-click **Design**, point to **New**, and then click **Group**. Update the new group's **Name** property to **HeaderGroup**.
19. The new HeaderGroup element requires a subpattern, because there are two variants for the arrangement of filters and actions in these sections. Right-click **HeaderGroup**, point to **Apply pattern**, and then click **Filters and Toolbar – Inline**.
20. Right-click **HeaderGroup**, point to **New**, and then click **Group**. Update the new group's **Name** property to **FilterGroup**.

21. Right-click **FilterGroup**, point to **New**, and then click **QuickFilter**.
22. In the **Properties** window, set the following properties.

PROPERTY	VALUE
Name	VehicleQuickFilter
Target Control	VehicleList

23. Press **Ctrl+S** to save.

Add a new query that limits the data to available vehicles

1. In Solution Explorer, in the **FMTutorial** project, right-click the **Queries** folder, point to **Add**, and then click **New item**.
2. Click **Dynamics 365 Items** > **Data Model** > **Query**. Set the **Name** property to **FMTAvailableVehicles**.
3. Click **Add**.
4. If the new **FMTAvailableVehicles** query isn't already open in the designer, double-click it in Solution Explorer.
5. In the designer, right-click **Data Sources**, and then click **New Data Source**.
6. In the **Properties** window, set the following properties.

PROPERTY	VALUE
Table	FMTVehicle
Dynamics Fields	Yes

7. Right-click **Ranges**, and then click **New Range**.
8. In the **Properties** window, set the following properties.

PROPERTY	VALUE
Field	Status
Value	Available

9. Press **Ctrl+S** to save.

Add a new menu item that references the new form

1. In Solution Explorer, in the **FMTutorial** project, right-click the **Menu items** folder, point to **Add**, and then click **New item**.
2. Click **Dynamics 365 Items** > **User Interface** > **Display menu item**. Set the **Name** property to **FMTAvailableVehicles**.
3. Click **Add**.
4. If the new **FMTAvailableVehicles** menu item isn't already open in the designer, double-click it in Solution Explorer.

5. In the **Properties** window, set the following properties.

PROPERTY	VALUE
Object	FMTAvailableVehicles
Query	FMTAvailableVehicles

6. Press **Ctrl+S** to save.

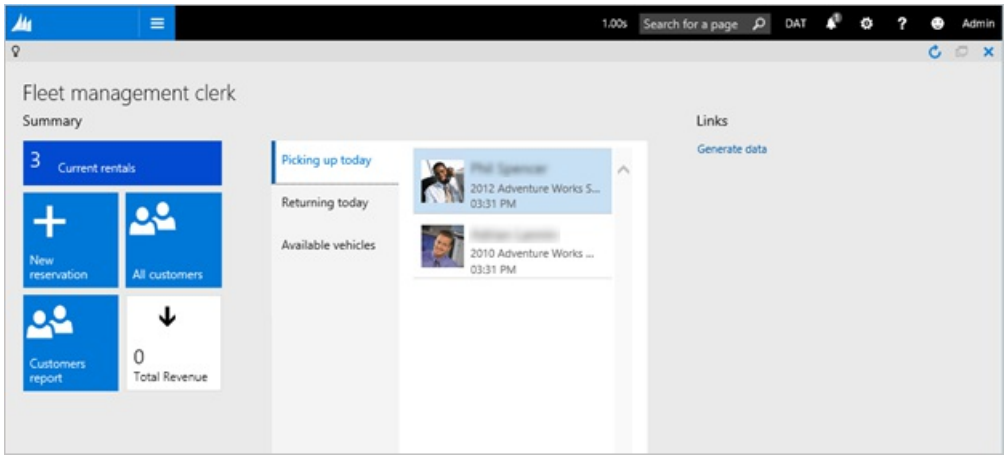
Link the new list to the workspace

1. In Solution Explorer, double-click the **FmtClerkWorkspace** form to open it in the designer.
2. Click **Design** > **PanoramaBody** > **TabbedListSection** > **TabbedLists** > **AvailableVehiclesContainer** > **AvailableVehiclesPart**.
3. In the **Properties** window, set the **Menu item name** property to **FmtAvailableVehicles**.

View the new menu item

Use Visual Studio to build and run the updated **FmtClerkWorkspace** form.

1. In Solution Explorer, right-click the **FmtClerkWorkspace** form, and then click **Set as Startup Object**.
2. Press **Ctrl+F5** to build and run the form. The form opens in Internet Explorer.



3. Click the **Available vehicles** tab to see the new list.
4. Click in the QuickFilter, type **Lit**, and then press **Enter** to filter down to Litware model vehicles that are available.

Exercise 4: Create a backing data cache for a list

For lists that have expensive queries, or lists where multiple users might use and work from the same workspace, consider caching the list to improve performance. In this section, you will add the necessary artifacts to create a data cache for a list. These artifacts include a query that maps fields to the cache, a table that holds the cache, and a class that provides the mapping between the query and the table. You will then uptake this cache on one of the tabbed lists in the workspace.

Add a query that maps fields to the data cache

The first step is to build a query that will be used to populate the cache table. This query should include all the tables that you want to get your cache data from, and it should limit the results to those records/columns that you want cached.

1. In Solution Explorer, in the **FMTutorial** project, right-click the **Queries** folder, point to **Add**, and then click **New item**.

2. Click **Dynamics 365 Items** > **Data Model** > **Query**. Set the **Name** property to **FMTPickupAndReturnQuery**.
3. Click **Add**.
4. If the new **FMTPickupAndReturnQuery** query isn't already open in the designer, double-click it in Solution Explorer.
5. In the designer, right-click **Data Sources**, and then click **New Data Source**.
6. In the **Properties** window, set the following properties.

PROPERTY	VALUE
Table	FMTRental
Dynamics Fields	No

7. Add the following five fields to the FMTRental data source. For each field, right-click **Fields**, point to **New**, and then click **Field**. In the **Properties** window, set the **Field** property as appropriate.
   - StartDate
   - EndDate
   - Vehicle
   - State
   - RentalId
8. Right-click **Ranges**, and then click **New Range**.
9. In the **Properties** window, set the following properties.

PROPERTY	VALUE
Field	State
Value	1..2 **Note:** This value will cache rentals that are Ready for Pickup or In Progress.

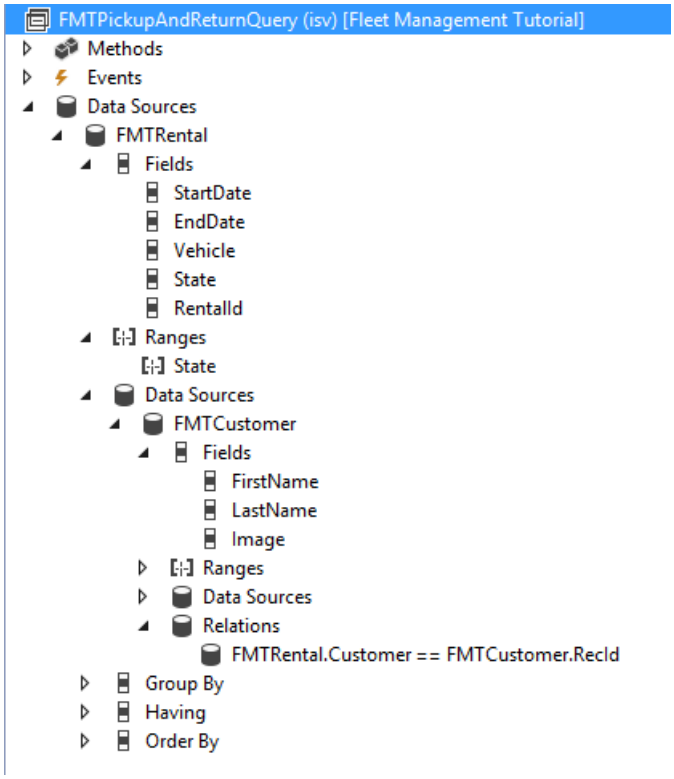
10. Under **FMTRental**, right-click **Data Sources**, and then click **New Data Source**.
11. In the **Properties** window, set the following properties.

PROPERTY	VALUE
Table	FMTCustomer
Dynamics Fields	No

12. Add the following three fields to the FMTCustomer data source. For each field, right-click **Fields**, point to **New**, and then click **Field**. In the **Properties** window, set the **Field** property as appropriate.
    - FirstName
    - LastName
    - Image
13. Right-click **Relations**, and then click **New Relation**.
14. In the **Properties** window, set the following properties.

PROPERTY	VALUE
Join Data Source	FMTRental
Field	Customer
Related Field	RecID

The query that you've constructed should match the following illustration.



15. Press **Ctrl+S** to save.

Add a cache table

The second step is to define a table that has the fields that are returned from the cache query. You must also add a **SysDataCacheContextId** field that will be used to map the cache row to the base framework cache tables. Additionally, you should also define any required relations between this table and other tables, and also any data methods that you require that involve the cached fields.

1. In Solution Explorer, in the **FMTutorial** project, right-click the **Tables** folder, point to **Add**, and then click **New item**.
2. Click **Dynamics 365 Items** > **Data Model** > **Table**. Set the **Name** property to **FMTPickupAndReturnTableCache**.
3. Click **Add**.
4. If the new **FMTPickupAndReturnTableCache** table isn't already open in the designer, double-click it in Solution Explorer.
5. In the designer, right-click **Fields**, and then add the following fields. For each field, the following table shows the data type and the extended data type (EDT) or enum type.

FIELD TYPE	FIELD NAME	EDT/ENUM TYPE
String	FirstName	FirstName (EDT)
String	LastName	LastName (EDT)
Container	Image	Bitmap (EDT)
Int64	Vehicle	FMTVehicleRecId (EDT)
Utc Date Time	StartDate	StartDateTime (EDT)
Utc Date Time	EndDate	EndDateTime (EDT)
Int64	SysDataCacheContextId	SysDataCacheContextId (EDT)
Enum	State	FMTReservationState (Enum)
String	RentalId	FMTRentalId (EDT)

6. In the designer, right-click **Relations**, point to **New**, and then click **Relation**.
7. In the **Properties** window, set the following properties.

PROPERTY	VALUE
Name	FMTRental
Related Table	FMTRental

8. Right-click the **FMTRental** relation, point to **New**, and then click **Normal**.
9. In the **Properties** window, set the following properties.

PROPERTY	VALUE
Field	RentalId
Related Field	RentalId

10. In the designer, right-click **Mappings**, and then click **New**.
11. In the **Properties** window, set the **Map** property to **SysDataSetCacheTableMap**.
12. Click **Id**. In the **Properties** window, set the **Map Field To** property to **RecId**.
13. Click **SysDataCacheContextId**. In the **Properties** window, set the **Map Field To** property to **SysDataCacheContextId**. **Note:** If the field doesn't appear in the list, you might have to save the table first, by pressing **Ctrl+S**.
14. Press **F7** to view the table's code. Alternatively, right-click **FMTReturnAndPickupTableCache**, and then click **View Code**.
15. Add the following display methods to the table. The form will use these methods later.

```
public display FMTName fullName()
{
    return this.FirstName + ' ' + this.LastName;
}
public display container customerImage()
{
    ImageReference imgRef;
    container imgContainer = this.Image;
    if(imgContainer == connull())
        {
            imgRef = ImageReference::constructForSymbol("Person");
            imgContainer = imgRef.pack();
        }
        return imgContainer;
}
public display str rentalVehicle()
{
    FMTVehicle vehicle;
    str value;
    if(this.Vehicle == 0)
    {
        value = "No vehicle assigned";
    }
    else
    {
        select vehicle where vehicle.RecId == this.Vehicle;
        value = vehicle.Description;
    }
    return value;
}
```

16. Press **Ctrl+S** to save.

Adding a cache class that links the query and table

The third step is to create a class that defines the relationship between the cache query and the catch table.

1. In Solution Explorer, in the **FMTutorial** project, right-click the **Classes** folder, point to **Add**, and then click **New item**.
2. Click **Dynamics 365 Items** > **Code** > **Class**. Set the **Name** property to **FMTPickupAndReturnClass**.
3. Click **Add**.
4. If the new **FMTPickupAndReturnClass** class isn't already open in the designer, double-click it in Solution Explorer.
5. Add the following code to the class.

```
[SysDataSetExtension(classStr(FMTPickupAndReturnClass)), // The name of this class
SysDataSetCacheTableExtension(tableStr(FMTPickupAndReturnTableCache))] // The name of the cache table
class FMTPickupAndReturnClass extends SysDataSetQuery implements SysIDataSet
{
    public SysDataCacheRefreshFrequency parmRefreshFrequency()
    {
        return 600; // Cache refresh frequency, in seconds.
    }
    public SysQueryableIdentifier parmQueryableIdentifier()
    {
        return queryStr(FMTPickupAndReturnQuery); // The name of the query.
    }
    public SysDataCacheTypeId parmCacheTypeId()
    {
        return tableNum(FMTPickupAndReturnTableCache); // The name of the table.
    }
    public static FMTPickupAndReturnClass construct()
    {
        return new FMTPickupAndReturnClass();
    }
}
```

6. Press **Ctrl+S** to save.

Uptake the data cache on a list in the workspace and table

After you've set up the data cache, you can start to use the cache in your forms. In this section, you will update one of the workspace lists so that it uses the data cache.

1. In Solution Explorer, double-click the **FMTReturningTodayPart** form to open it in the designer.
2. Expand the **Data Sources** node.
3. Delete the **FMTCustomer** data source.
4. Click the **FMTRental** data source. In the **Properties** window, set the **Table** property to **FMTPickupAndReturnTableCache**.
5. Click **Design** > **ReturningTodayGrid**. In the **Properties** window, set the **Data Source** property to **FMTPickupAndReturnTableCache**.
6. Inside **ReturningTodayGrid**, click **CustomerImage**. Update the **Data Source** property to **FMTPickupAndReturnTableCache** and the **Data Method** property to **customerImage**.
7. Inside **ReturningTodayGrid**, click **FirstNameCopy1**. Update the **Data Source** property to **FMTPickupAndReturnTableCache** and the **Data Method** property to **fullName**.
8. Press **F7** to view code for the form.
9. Instrument the form so that it can react to data caching, as shown in the following code.

```
[Form]
public class FMTReturningTodayPart extends FormRun implements SysIDataSetConsumerForm
{
    public void registerDatasourceOnQueryingEvent()
    {
        FMTPickupAndReturnTableCache_DS.OnQueryExecuting +=
            eventhandler(this.parmDataSetFormQueryEventHandler().prepareDataSet);
    }
}
```

10. Press **Ctrl+S** to save.

Update the action above the list so that it works with the cache table

Actions that are performed from the workspace might expect records from the base tables. Therefore, these actions might have to be updated so that they work with the cache table. In this example, the **FmtCompleteRecord** form currently expects a **FMTRental** record as context. Therefore, this form must be updated so that it works correctly with either a base rental record or a cache table record as context.

1. In Solution Explorer, double-click the **FmtCompleteRental** form to open it in the designer.
2. Press **F7** to view the form's code.

```
public void init()
{
    //If this form was opened with a Rental as context
    if(element.args() != null && element.args().record() != null && element.args().record().TableId
== tablenum(FMTRental))
    {
        //Get the Rental context
        rentalDS = FormDataUtil::getFormDataSource(element.args().record());
        rental = element.args().record();
        if(rental != null)
        {
            select firstonly forupdate vehicle where vehicle.RecId == rental.Vehicle;
        }
    }
    super();
}
```

3. Update the **init()** method so that it matches the following code.

```
public void init()
{
    //If this form was opened with a record context
    if(element.args() != null && element.args().record() != null))
    {
        //Get that context
        rentalDS = FormDataUtil::getFormDataSource(element.args().record());
        if(element.args().record().TableId == tableNum(FMTPickupAndReturnTableCache))
        {
            FMTPickupAndReturnTableCache cacheRecord = element.args().record();
            select firstonly forupdate rental where rental.RentalId == cacheRecord.RentalId;
        }
        else if(element.args().record().TableId == tableNum(FMTRental))
        {
            rental = element.args().record();
        }
        if(rental != null)
        {
            select firstonly forupdate vehicle where vehicle.RecId == rental.Vehicle;
        }
    }
    super();
}
```

4. Press **Ctrl+S** to save.

Update the Returning today query so that it works with the cache table

1. In Solution Explorer, double-click the **FmtRental_ReturningToday** query to open it in the designer.
2. Expand the **Data Sources** node, and then click **FMTRental**.
3. In the **Properties** window, update the **Table** property to **FMTPickupAndReturnTableCache**. **Note:** The **Name** property should be updated automatically to the same value.
4. Press **Ctrl+S** to save.

View the updated query

Use Visual Studio to build and run the updated **FmtClerkWorkspace** form.

1. In Solution Explorer, right-click the **FmtClerkWorkspace** form, and then click **Set as Startup Object**.
2. Press **Ctrl+F5** to build and run the form. The form opens in Internet Explorer.
3. Click the **Returning today** vertical tab.
4. Click **Complete rental** for the second record in the list.
5. Set **End Mileage** to **200**, and then click **OK**. Notice that the rental that you just returned still appears in the list.

Make sure that your workspace is responsive

You must make sure that your lists remain up to date after a user performs an action that should remove a record from the list (for example, the user completes a rental). In this section, we will instrument that action to help guarantee that the workspace reacts appropriately.

1. In Solution Explorer, double-click the **FmtCompleteRental** form to open it in the designer.
2. Press **F7** to view the code for the form.
3. Locate the **clicked()** code for **OKButton**. Near the end of this method is a research call on the calling form's data source. Just before that line of code, add the following **if** statement to delete the processed rental from the cache table.

```
. . .
if(rentalDS.table() == tableNum(FMTPickupAndReturnTableCache))
{
    //Delete updated record from backing cache
    FMTPickupAndReturnTableCache cacheRecord = element.args().record();
    cacheRecord.delete();
}
rentalDS.research(true);
}
```

4. Press **Ctrl+S** to save.

View the updated form

Use Visual Studio to build and run the updated **FmtClerkWorkspace** form.

1. In Solution Explorer, right-click the **FmtClerkWorkspace** form, and then click **Set as Startup Object**.
2. Press **Ctrl+F5** to build and run the form. The form opens in Internet Explorer.
3. Click the **Returning today** vertical tab.
4. Click **Complete rental** for the second record in the list.
5. Set **End Mileage** to **100**, and then click **OK**. Notice that the rental that you just returned no longer appears in the list.

Navigation concepts

2/18/2021 • 7 minutes to read • Edit Online

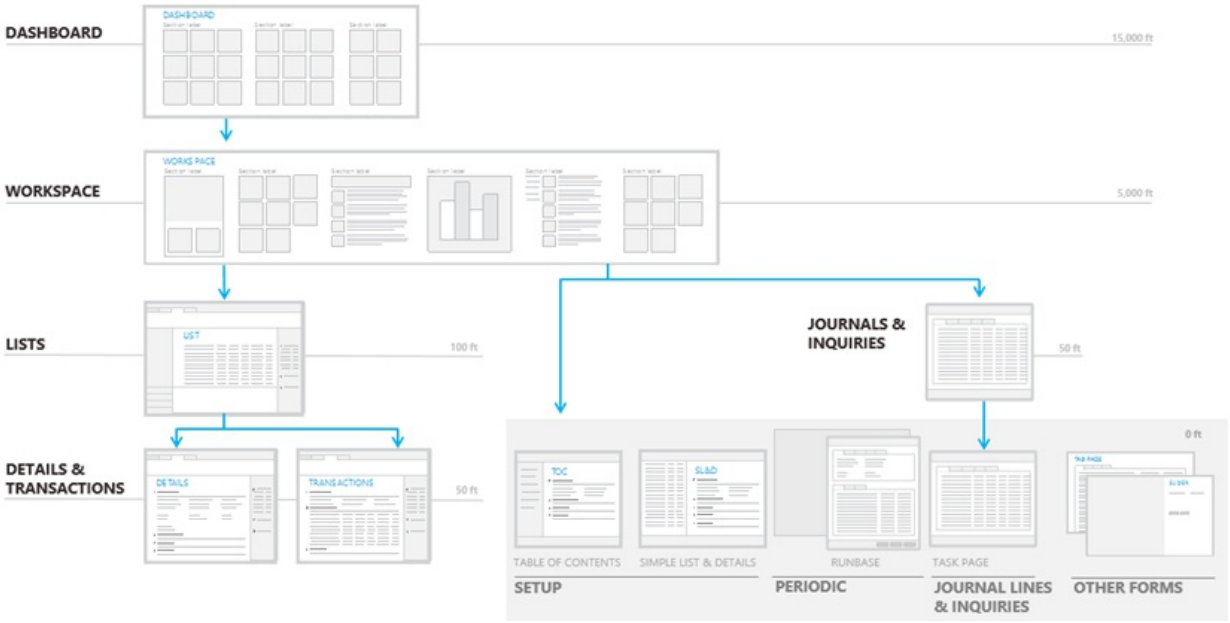
This articles describes the primary navigation concepts including the dashboard, the new navigation search feature, the navigation pane, workspaces, and tiles.

Navigation concepts

The primary navigation concepts are:

- Dashboard
- Navigation pane
- Workspaces
- Tiles
- Navigation search

The dashboard is a new concept, whereas the navigation pane and workspaces are updates to existing concepts. To implement the navigation concepts, the user interface model uses several standard page types. When you create an application, you should follow the conventions for these pages to present a consistent experience for the user. The following diagram shows an overview of the standard page types and how they fit together.



The following sections provide more detail about the pages that underlie these concepts. They include information about the modeling of these and other types of pages.

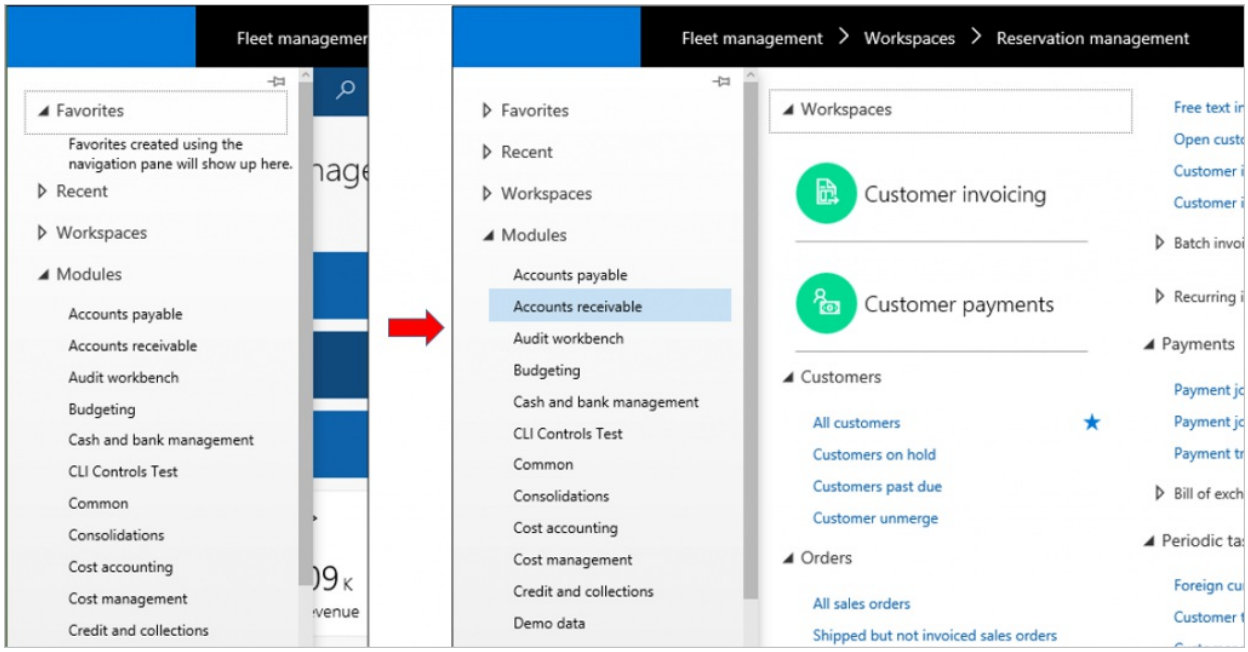
Dashboard

The dashboard is the first page that users see when they access the client. The dashboard contains tiles that show important details from the system. Content that was previously displayed in Cues on Role Center pages in Microsoft Dynamics AX 2012 is now available on the dashboard. You can return to the dashboard at any time by clicking **Dynamics 365** on the navigation bar at the top of the application frame.

The dashboard primarily consists of a large section of workspace tiles. There might also be a Getting Started tool, which isn't shown in the preceding screenshot. The dashboard's workspace tile section is built from a menu structure that has its root in the **NavPaneMenu** menu. The menu is modified by a set of menu extensions, and those extensions contain one or more tile references that correspond to the tiles that users see in that section.

Navigation pane

The navigation pane provides access to workspaces, main menu elements, recently opened forms, and user-defined favorites. The user can open the navigation pane by clicking the **Show navigation pane** button under the navigation bar. The navigation pane consists of four collapsible sections. The **Favorites** section provides quick access to the list of forms the user has explicitly marked as a favorite. Marking a form as a favorite is accomplished by clicking the star icon next to the form in the navigation pane. The **Recent** section lists the forms the user has most recently visited. The set of workspaces a user has access to is conveniently shown in the **Workspaces** section. Finally, the **Modules** section provides the full list of modules. Clicking on a module will open the right side of the navigation pane, where the user can navigate to the desired page in that module.
Note: In this screenshot, **All customers** has been marked as a favorite, and therefore it will appear in the **Favorites** list.



Like the workspace tiles on the dashboard, the elements that are listed in the navigation pane are generated at runtime, based on a menu structure. The same root menu (**NavPaneMenu**) that defines the set of workspaces on the dashboard also defines the navigation pane. Here's an example of the logical structure for the navigation pane:

- NavPaneMenu (menu)
  - NavPaneMenuFleet (menu extension)
    - "Reservation management" (tile reference)

Workspaces

Workspaces are activity-oriented pages that are designed to increase a user's productivity by providing information that answers the targeted user's most pressing activity-related questions and allows the user to initiate their more frequent tasks. Access to the various workspaces depends on the roles that users have in the organization. Much of the list and business intelligence (BI) content from the old Role Center pages is exposed on workspaces. To navigate to a workspace, you can click a tile on the dashboard, click a link in the navigation pane, or find the workspace using the navigation search feature (see the next section).

Workspaces are simply a different type of modeled forms. The system differentiates workspaces by **Form.Design.Style**=**Workspace** (this value is defined as part of the Workspace form pattern). A workspace consists of a caption (which is defined on **Form.Design.Caption**) and a panorama (that is, a tab control). A panorama contains sections of content that are relevant to the task for which the workspace is intended. These sections are modeled as tab pages. The first section will generally be a set of tiles that users can click to begin

new tasks or access lists of items. The second section contains a set of relevant lists for the activity. The last section contains a number of links to pages that are important but not frequently used for this activity. In between the list and links section are a few optional sections that might contain charts and graphs. One important distinction of workspaces is that they do not have a data source. If the content (such as a list or chart) requires a data source, you must model that content on an independent form of type **Form part**, and then reference that form part on the workspace. Form parts can be hosted on other forms, and each can have its own data source.

Tiles

Windows 8 introduced the concept of tiles, and you will see them used in the client. A tile is a rectangular button that behaves like a menu item button. It is used to navigate to or open pages. In addition, tiles can display relevant data, such as counts or key performance indicators (KPIs). A tile can include images that provide the user with additional visual context. You can create the following types of tiles.

TYPE	EXAMPLE	DESCRIPTION
Standard		This type of tile does not show any business data.
Count		This type of tile shows a count of the items in the referenced form's query. Note that the tile in this example uses the **ShortWide** size.
KPI		This type of tile shows a summary of data from a KPI.
Link		This type of tile points to a URL. The tile has the same appearance as a tile of the **Standard** type.

For modeling, you first create a tile element, which is an abstract element. The tile element is then referenced on a form by a tile button element. Multiple tile button elements can refer to a single tile. Tiles are defined first by the **Type** property (which has valid values of **Standard**, **Count**, **KPI**, and **Link**). After you specify the type, you specify the following minimum properties for each type:

- **Standard** and **Count**:
  - Label
  - Menu Item Name

    - Menu Item Type
- **KPI**:
    - Label
    - KPI
- **Link**:
    - Label
    - URL

After these properties are defined, your tile is complete. To make the user experience richer, you can optionally extend tiles of the **Standard** and **Link** types so that they include images. Use the following properties to add images.

PROPERTY	DESCRIPTION
Image Location	See the information about basic button behavior in Actions.
Normal Image	See the information about basic button behavior in Actions.
Tile Display	Define how the image appears on the tile.

The following are the valid options and corresponding behaviors for the **Tile Display** property.

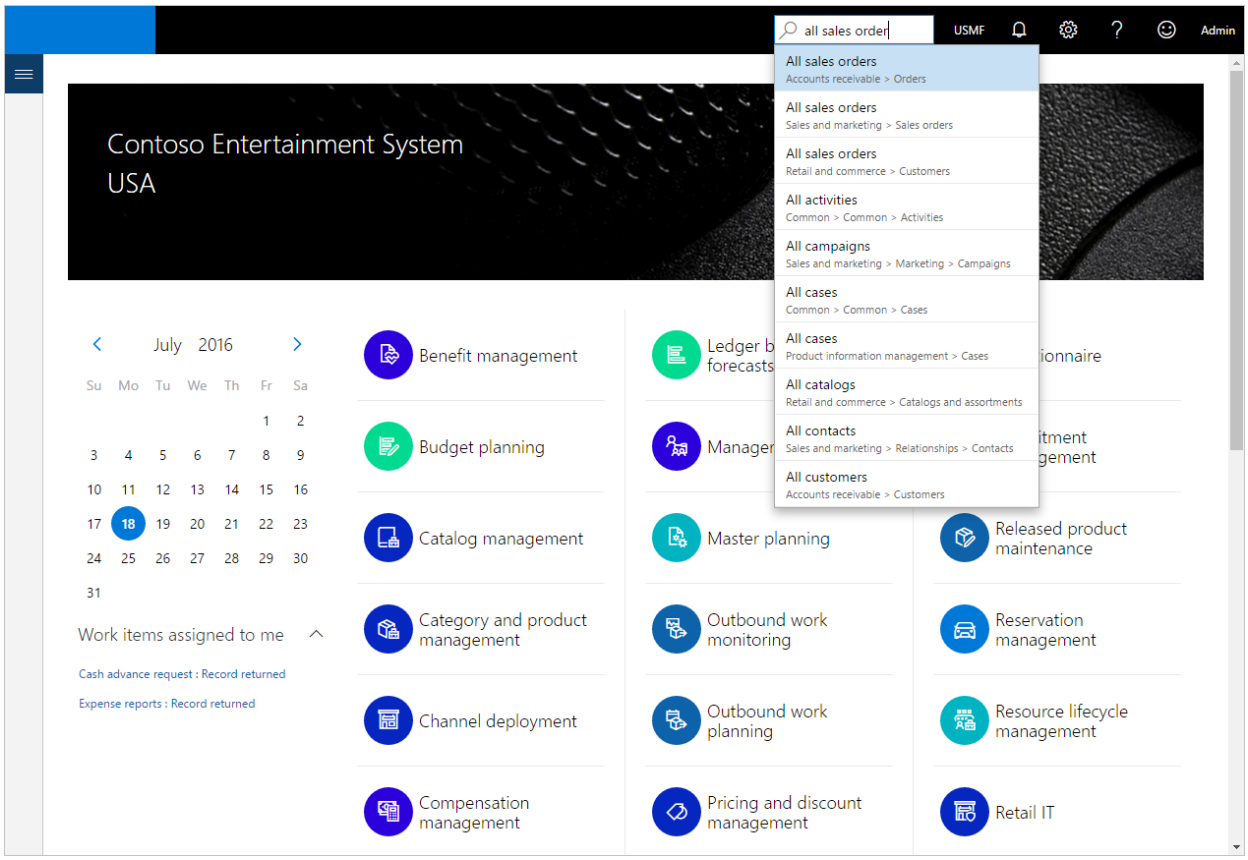
VALUE	DESCRIPTION
Auto	The behavior is the same as the behavior for **TextAndImage**.
TextAndImage	The tile shows the specified label and the image in a small container above it. For example, the **App links** tile uses this value.
TextOnly	The other two image-related properties are ignored, and only the label is shown.
ImageOnly	The label is ignored, and only the image is shown.
BackgroundImage	The specified image is expanded to fill the tile from edge to edge, and the label is overlaid on the image in the same location. Shading is applied behind the text to ensure that it remains legible.

Note: The following limitations apply when the **BackgroundImage** value is used:

- If a symbol is used, it isn't displayed.
- The image that you specify isn't resized. Therefore, you must create an image of the appropriate size to guarantee that it fills the tile correctly. Currently, a standard-sized tile is a square that is 130 pixels on each side.

Navigation search

There is a convenient search mechanism for finding and navigating to forms and workspaces that appear in the navigation pane and on the dashboard. For example, a search on the keywords "all sales order" returns a list of navigation elements that match those keywords.



The search keywords are matched not only to the caption of the navigation elements but also to the corresponding path. For example, a search on the keywords "ven bal report" returns results that match "vendor balance" in the caption and "report" in the path.

The survey will take about seven minutes. No personal data is collected (privacy statement).

Page layout in the web client

2/18/2021 • 7 minutes to read • Edit Online

This topic discusses layout in the web client. Layout is a design process that specifies how controls appear on a page.

Introduction

Layout is a design process that specifies how the controls on a page appear in the web client. Layout occurs within container controls. The following table lists the container controls.

CONTAINER	DESCRIPTION
Form.Design	The root of the page. It functions as a special kind of container.
Group	The general-purpose container control. Group controls can be nested as required.
Tab	A control that contains TabPage controls and has many possible **Tab.Style** values, such as **Tab**, **FastTab**, **Vertical Tab**, and **Panorama**.
TabPage	The appearance of each TabPage control depends on its **Tab.Style** value.
ButtonGroup	A special type of Group control that contains buttons.

A grid is a special type of control that has some container behaviors, such as flexible sizing (**SizeToAvailable**). However, a grid has special visualizations and isn't a general-purpose container control.

Layout: Dynamics AX 2012 vs. Finance and Operations apps

Layout in Dynamics AX 2012

In Microsoft Dynamics AX 2012, the arrangement of controls in containers is almost always vertical, and columns are manually set to provide some horizontal spread.

Examples

Columns=1 1 2 3 **Columns=2** 1 4 2 5 3 In Dynamics AX 2012, sizing is achieved via the **Height** and **Width** properties. If **Height** and **Width** are set to **Auto**, the size is as large as the child controls require. If **Height** and **Width** are set to **Column**, the container is as large as it can be within the parent container. By default, **Height** and **Width** are set to **Auto** for every container.

Layout in Finance and Operations

In Finance and Operations, layout is controlled by the same basic properties that control layout in Dynamics AX 2012. However, additional options have been added to support a more responsive layout. In particular, the layout of a page is based on the following factors:

- The arrangement method that is specified by the **ArrangeMethod** property.
- The columns that are specified by the **Columns** property.
- The sizing that is specified by the **HeightMode**, **WidthMode**, **Height**, and **Width** properties.

ArrangeMethod property

The **ArrangeMethod** property specifies a base arrangement method for a container. For this property, Finance and Operations apps have all the options from AX 2012. However, they also have a **HorizontalWrap** option that is intended for tile layouts in panoramas. The following table describes the various options for the **ArrangeMethod** property.

OPTION	DESCRIPTION
Vertical	Controls are arranged vertically. If columns are also used, controls are arranged vertically inside the generated columns. This option is the default value for Groups and for TabPages where **Tab.Style** is set to a value other than **Panorama**.
HorizontalLeft	Controls are arranged horizontally, and they are left-aligned and bottom-aligned inside the parent container.
HorizontalRight	Controls are arranged horizontally, and they are right-aligned and bottom-aligned inside the parent container.
HorizontalWrap	Controls are arranged inside columns of fixed width that wrap horizontally. This option is typically used for tile layouts in panorama sections. It's the default value for TabPages where **Tab.Style** is set to **Panorama**.

ColumnsMode property

For the **ColumnsMode** property, Finance and Operations apps have a **Fill** option to support responsive layouts. When the property is set to this value, columns automatically flow as required. The following table describes the various options for the **ColumnsMode** property.

OPTION	DESCRIPTION
Fill	Columns are generated to fill the available horizontal space or vertical space, depending on the container type. If the container is a Panorama-style tab, this option generates columns to fill it along the vertical axis. For all other containers (Groups, Tab-style Tabs, and all other styles of Tabs), this option generates columns to fill the container along the horizontal axis.
Fixed	Specify the number of columns that the **Columns** property should generate. Controls are evenly distributed among the columns, and their order is maintained. If the controls can't be distributed evenly among the columns, the leftmost columns receive extra controls first. This option is the default value for all controls.

HeightMode/WidthMode properties

In Finance and Operations apps, sizing is done via two pairs of size properties: **WidthMode** and **Width**, and **HeightMode** and **Height**. The following table describes the various options for these properties.

OPTION	DESCRIPTION
SizeToAvailable	Fill the available space along the vertical (or horizontal) axis inside the parent container. If the parent container has **SizeToContent** height (or width), the child's height (or width) is also **SizeToContent**, unless there is a sibling in the container that can provide a height (or width). This option is the default value for Grids and Tabs (of all styles).
SizeToContent	The height (or width) of the container should be the height (or width) of its contents. This option is the default value for Groups and all other controls except Tabs. FastTabs that aren't always expanded also have **SizeToContent** height.
Manual	The height (or width) is manually sized. Set **HeightMode** (or **WidthMode**) to **Manual**, and then set **Height** (or **Width**) to a fixed number of pixels. **Note:** Microsoft doesn't recommend that you use manual heights and widths, because they don't adapt to changes in form density.

Note that if a value of **Auto** is used for these properties, the behavior is automatically determined at runtime. Typically, a value of **Auto** for these properties causes the same behavior as a value of **SizeToContent**, as in AX 2012.

Interactions between the ArrangeMethod and Columns properties

If **ArrangeMethod**=**HorizontalLeft** or **HorizontalRight**, the **Columns** property has no effect, because items are laid out in strict horizontal arrangement and no wrapping is used. If **ArrangeMethod**=**Vertical**, columns are arranged vertically, and the controls are either distributed evenly among the columns (**Fixed**), or distributed to fill the available horizontal or vertical space (**Fill**). If **ArrangeMethod**=**HorizontalWrap**, columns are arranged, and horizontal wrapping is used at a fixed column width of 280 px. Typically, this option is used to wrap tile layouts.

Examples

ArrangeMethod=HorizontalWrap

ArrangeMethod=**HorizontalWrap** and **Columns**=**1**

1 2
3 4
5 6
7 8
9

ArrangeMethod=**HorizontalWrap** and **Columns**=**2**

1 2	6 7
3 4	8 9

5	

ArrangeMethod=HorizontalWrap and **Columns=Fill**

For this example, we assume that only three lines of items can fit in the container height.

1 2	7 8	13 14
3 4	9 10	15
5 6	11 12	

ArrangeMethod=Vertical

ArrangeMethod=Vertical and **Columns=1**

1
2
3
...

ArrangeMethod=Vertical and **Columns=2**

1	5
2	6
3	7
4	8

ArrangeMethod=Vertical and **Columns=Fill**

For this example, we assume that only three lines of items can fit in the container height.

1	4	7
2	5	8
3	6	

ArrangeMethod=Vertical and **Columns=Fill** on a FastTab

For this example, we assume that the width of the FastTab can fit four columns.

1	3	5	7
2	4	6	8

Breakable groups

When you set **ColumnsMode** to **Fill** to dynamically create columns, based on the amount of available space, groups of fields can be split into multiple columns. The **Breakable** property on Group controls lets developers ensure that controls in a group aren't distributed across columns. The default value for this property is **Yes**, which indicates that the contents of the group can be split between groups. To keep a group together all the time, set **Breakable** to **No**. Note that **Breakable** applies only to the first level in nested groups.

Guidelines for using layout properties

ColumnsMode=Fill

- Don't nest containers that have **ColumnsMode** set to **Fill**. Set **ColumnsMode** to **Fill** only on the direct parent container of the controls/fields that you want to responsively fill the available space.
- Don't set **HeightMode** to **SizeToAvailable** on any child controls of a container that has **ColumnsMode** set to **Fill**. **ColumnsMode=Fill** tries to calculate an average height of all controls across columns to balance them as much as possible. However, our layout CSS and calculations can't handle **SizeToAvailable** children, and this setting doesn't necessarily make sense.
- Don't set **WidthMode** to **SizeToAvailable** on any child controls of a container that has **ColumnsMode** set to **Fill**. Otherwise, the child controls will take up all the available width, and all controls will appear in one column.
- Container that have **ColumnsMode=Fill** should have **WidthMode** set to **SizeToAvailable** (if you're using fill-width containers such as Tabs and Groups) or **HeightMode** set to **SizeToAvailable** (if you're using fill-height containers such as Panorama sections).

HeightMode/WidthMode=SizeToAvailable

- If you use **WidthMode=SizeToAvailable**, make sure that parent containers in the form have **WidthMode** set to **SizeToAvailable**, not **SizeToContent**. **SizeToAvailable** containers inside **SizeToContent** containers are overridden and become **SizeToContent** containers.

Dynamics Symbol font

2/18/2021 • 2 minutes to read • Edit Online

The Dynamics Symbol font defines the set of out-of-box symbols that are available in the product. These symbols are primarily used for buttons, tiles, and image controls. In every release, there might be updates to this font. For example, symbols might be added or removed.

To access the list of available symbols (the name and an image) for every release that updated the Symbol font, visit the Dynamics Symbol Font page. A description of the various locations where symbols are used in the product and usage guidelines for each location is also included.

NOTE

Can you tell us about your documentation language preferences? Take a short survey.

The survey will take about seven minutes. No personal data is collected (privacy statement).

Saved views

IMPORTANT

Some or all of the functionality noted in this topic is available as part of a preview release. The content and the functionality are subject to change. For more information about preview releases, see Service update availability.

Introduction

Personalization plays an important role in allowing users and organizations to optimize the user experience to meet their needs. For more details on personalization, see Personalize the user experience.

Traditional personalization let users have only one set of personalizations per page. The **Saved views** feature expands on personalization in several important ways:

- Views permit users to have multiple named sets of personalizations per form, which they can quickly switch between as needed. This allows a user to create multiple optimized views of a page, where each view has been tailored to fit the needs of performing a particular business task.
- Views created for particular page types can also include user-added filters or sorts, which allows users to quickly return to commonly filtered datasets. See the What pages support views section for more details.
- Views can be published to users in specific security roles and specific legal entities. Therefore, any user who has a specified role and access to a specified legal entity can access and use that view, even if that user doesn't not have permission to personalize. This publish capability lets organizations define corporate, standard views that are optimized for their business. For more information, see the Managing personalizations at an organizational level with views section.
- Unlike traditional personalization, views aren't automatically saved when a user performs personalizations or filters a list. Explicit saves are required to give users the flexibility to create a view before or after the changes that are associated with that view have been made. This requirement also ensures that view definitions aren't unintentionally changed by filters or personalizations that aren't intended for long-term use. Items that the system automatically stores as part of typical page usage (for example, column widths, or the expanded or collapsed state of sections) will be saved per view.
- Views can be added to workspaces as tiles, lists, or links. Therefore, a filtered data set can be surfaced in a workspace, and users can associate a set of personalizations that is relevant to that data set with a tile or link.

Switching between views

After views have been made available for an environment, the top of any page that supports views will include a collapsed view selector control that shows the name of the current view.

There are two size variations to the view selector:

- **Large view selectors** – Pages that prominently feature a list will have a larger view selector for a few reasons. Most importantly, the larger view selector indicates the pages where the view can include user-defined filters. Because filters are included in the views, the larger selector size is also warranted as the view names will often be the best description of the data shown on the screen and the expectation is that users will switch between views more often on these page types.
- **Small view selectors** – All other full-screen pages (except workspaces and the dashboard) have a smaller view selector that appears next to the page caption. Views on these pages include only personalizations, not

user-defined filters. On these pages, the caption or record title is often the most important information at the top of the page. The smaller size of the view selector also reflects the lower frequency of view switching that is expected on these pages.

If you select the view name, the view selector is opened and shows the list of available views for the page.

- **Standard view** – The **Standard** view is the out-of-box view of the page, where no personalizations are applied.
- **Personal views** – The views without padlocks represent your personal views. These are views that either you have created or that an administrator has given to you.
- **Locked views** – Some views (such as the **Standard** view and any views that are published to your role) have a padlock symbol next to them in the view selector. This symbol indicates that you can't edit those views. However, changes that reflect page usage are automatically saved. These changes include changes to the width of a grid column, and changes to the expanded or collapsed state of a FastTab. Nevertheless, if you have personalization privileges, you can use the **Save as** action to make a personal view that is based on a locked view.
- **New views** – Published views that haven't yet been opened have a spark symbol to the left of the view name.

To switch to a different view, first open the view selector and then select the view that you want to load.

Creating and modifying views

Unlike traditional personalization, views aren't automatically saved when a user personalizes the page, or when a user applies a filter to a list or sorts it. An explicit action is required to save these changes to a view. This requirement gives users the flexibility to create a view before or after the changes that are associated with that view have been made. It also ensures that view definitions aren't unintentionally changed by one-time filters or personalizations. Note that typical page usage items (for example, column widths, or the expanded or collapsed state of sections) are automatically saved to the current view, even for locked views.

To ensure that the current state of the view is known, when you start to change a view by personalizing or filtering it, an asterisk (*) appears next to the current view name. This symbol indicates that you're looking at an unsaved, modified version of that view.

If you want to save those changes, follow these steps.

1. Select the view name to open the view selector.
2. To modify the existing view, select **Save**. Note that this action isn't available for locked views.
3. To create a new view:
    a. Select **Save as**.
    b. Enter a view name and (optionally) a description.
    c. Select **Save**.

Changing the default view

The default view is the view that the system tries to open when you first open the page. You should set the default view to the view that you expect to use most often.

> **NOTE**
> There is a single, global default view across companies. If you change the default view, that view will be opened by default, regardless of the legal entity that you're currently in.

To change the default view for a page, follow these steps:

1. Switch to the view that you use as the default.
2. Select the view name to open the view selector.
3. Select **More** and then **Pin as default**.

Alternatively, when you create a new view (by using the **Save as** action), you can make that new view the default view by setting the **Pin as default** option before you save the view.

Note that, in some cases, the query that is associated with the default view isn't run when you first open a page. For example, if you open the page through a tile, the tile's query will be run, regardless of the query that is associated with the default view. Additionally, if you open a page that has a **Standard** view that already has a defined query, the original query will be run instead of the default view's query. In this case, you will receive an informational message when the view is loaded. If you switch views after the page has been loaded, the view query should be able to be run as expected. In version 10.0.10 and later, the informational message that you receive will have an embedded action that lets you load the default view's query directly.

Managing personal views

The **Manage my views** dialog box gives you basic maintenance capabilities over your personal views and the order of views in the view selector. To open this page, select the view name to open the view selector drop-down menu, select **More**, and then select **Manage my views**.

For a list of available views for that page, the following set of actions are available.

- **Change the default view** – Use the **Pin as default** action to make the currently selected view the default view for this page.
- **Reorder your views** – Use the **Move up** and **Move down** actions to rearrange your views in a specific order.
- **Rename a view** – Use the **Rename** action to change the name of the currently selected personal view. This action is turned off for locked views.
- **Delete a view** – Use the **Delete** action to permanently delete the currently selected view from the page. There is no way to recover a view after you remove it.

Any changes made in this dialog box will take effect after you select the **Save** button.

Managing personalizations at an organizational level with views

To help you understand how saved views help improve management of personalizations at an organizational level, this section describes some differences in personalization management with and without the **Saved views** feature.

Without views, administrators would apply a set of personalizations for a page to a user or a group of users via the Personalization page. If those users had personalization rights, the personalizations would be applied to that page. However, there was no ability to prevent users from further personalizing the page, which meant the organization could not ensure that its users had a consistent user interface. If any of those users didn't have personalization rights, the personalizations given to them by an administrator were not loaded. Further, if new users were hired into an organization, administrators needed to manually load a set of personalizations for the user. There was no automatic mechanism for specifying that a certain set of personalizations should be available for users in that role.

The **Saved views** feature makes organizational management of personalizations much easier, primarily because views can be published to groups of users. After a view has been published, any user who has one of the defined security roles and access to one the specified legal entities can see and use the view, even if that user doesn't have access to personalization. Although every user has a copy of the published view, where page usage

items are automatically applied, no user can save personalizations or query updates to a published view. In other words, published views are locked. Additionally, if new users are assigned to roles in legal entities that views were published to, they will automatically see the views that are associated with their roles and legal entities. No additional action is required by the admin. Likewise, if users change roles in an organization or are given access to different legal entities, they might no longer be able to access the views that were previously published to them. Again, no additional action is required by the admin.

Updates to a published view can easily be distributed to users by republishing the view to the appropriate security roles and legal entities.

The publish capability allows organizations to define corporate standard views that are optimized for their business, targeted at users in specific security roles.

Publishing views

During the publishing process, views can be assigned to one or more security roles for one or more legal entities. Therefore, any user who has access to a legal entity and is assigned to one of those roles can access and use the views. However, the user can't edit the views. By default, system admins have access to the **Publish** action in the view selector drop-down menu. However, other trusted users in your organization can also be given access to view publishing via the new **Saved views administrator** role.

To publish a view, follow these steps:

1. Create and save a personal copy of the view that you want to publish.
2. With that view currently loaded, select the view name to open the view selector drop-down menu.
3. Select the **More** button and then select **Publish**. The Publish dialog box will open.
4. Enter a name for the view. The name that you enter is the name that users who receive this view will see in their view selectors. The names of published views for a page must be unique. No duplicate names are allowed, even if the list of roles or legal entities that the views are applied to differ.
5. **Update 10.0.17 or later:** If the **(Preview) Translation support for organization views** feature is turned on, you can add translations for your view name in as many languages as your organization requires by selecting the **Translations** button next to the **Name** field. The view name will then be shown to users in their current language. You can also set the default language to specify the translation that will be shown to users who are running languages that no translation is defined for.
6. Optional: Enter a description for the view, so that users who receive this view can better understand its purpose.
7. Determine whether the view should be published as the default view for the selected users. When a view is made the default view, users will see it the next time that they open the target page. The single, global default view of every targeted user will be changed. However, users can still change their default view after publishing has occurred.
8. Add the security roles that correspond to the users who are being targeted by this view.
9. Determine whether you want to publish the view to the child roles of each security role that is selected. If you do, select the **Include child roles** check box in the row for the appropriate security roles. Note that this check box isn't available for roles that don't have child roles.
10. Add the legal entities that this view should be available for.
11. Select **Publish**.

Note that in some environments, it may take some time (up to an hour) before users see the published view.

NOTE

Be aware of the following expectations when you publish a view to a legal entity, or when you publish a view as the default view.

- If you publish a view as the default view to all or some legal entities, you change the single, global default view of every targeted user. If a user has roles where multiple views are published as the default view, the last view that was published will be used as the user's default view.
- If you publish a view to a legal entity, but you don't publish it as the default view, users will initially see the view in the view selector only for the specified legal entities. However, after the view is loaded for the first time, it will always be in the user's view selector for that page, regardless of the legal entity.

Modifying a published view

After you publish a view, you might find that you want to change it. Although you can't make live changes to a published view, because these views are locked for editing for all users (including publishers), you can republish a view to update it.

If the changes that you want to make to a published view only involve the publish parameters (the name and description of the view, or the security roles the view is published to), do the following:

1. Switch to the published view for the parameters that you want to update.
2. On the view selector drop-down menu, select **Republish**. If you're using version 10.0.12 or earlier, you must select **Publish** and then **Yes** to update the existing view.
3. Update the name, description, security roles, and legal entities for the view.
4. Select **Publish**. If you originally selected this published view as the default view, it will be the default view for users again after you republish it.

If the changes to the published view involve modifications of the personalizations or filters that are associated with the view, follow these steps.

1. Load the published view that you want to change.
2. Make the required changes to the local draft.
3. On the view selector drop-down menu, select **Republish**.
4. Select **Yes** to indicate that you want to publish the view together with its unsaved changes.
5. Adjust any publishing parameters that require adjustment, and then select **Publish**.

Managing published views

Like managing personal views, the **Manage my views** dialog box gives users with publish privileges basic maintenance capabilities over that page's published views (in addition to their own personal views). To open this page, select the view name to open the view selector drop-down menu, select **More**, and then select **Manage my views**.

Although all users have a **My views** tab that show their personal views, users who have publish privileges also have an **Organization views** tab that shows all the published and unpublished views for that page. Because several users might be publishing views, it's important that you be able to manage the full list of published views, even if you aren't the user who published a given view.

For the list of all published views for the page, the following set of actions are available.

- **Republish** – Use the **Republish** action to republish a view after publishing parameters (name, description, security roles, or legal entities) are changed.
- **Publish** – Use the **Publish** action to publish a view that is currently unpublished.

- **Unpublish** – Use the **Unpublish** action to make a view inactive. The view will still be available in the system, but users won't see it in the view selector until the view is published again.
- **Save as personal** – Use the **Save as personal** action to create a personal draft copy of the published view. This capability can help you understand the contents of a view that wasn't published to you or that hasn't yet been published. You can also use it to edit and then republish a view.
- **Delete** – Use the **Delete** action to permanently delete a published or unpublished view. This action also removes the view for all users in the system. The removal of published views takes effect after the **Save** button is selected. After a view is deleted, it can't be recovered.

Managing views globally

Although some management capabilities are surfaced on every page, as indicated in this topic, **system administrators** and **saved view administrators** can manage views more holistically for the system via the **Personalization** page. In particular, this page has the following sections and capabilities:

- **Published views** – This section lists all views that have been published for your organization. From here, you can republish a view after you adjust the security roles or legal entities that the view targets. You can also export, delete, or unpublish views. You can use the **Save as personal** action to create a personal copy of a view, so that you can update the view or gain a better understanding of its contents.
- **Unpublished views** – This section lists all the organization views in your system that aren't currently published. These views most often come into the system through the import capability. You can publish, export, or delete these views. The **Quick publish** action that was added in version 10.0.12 enables multiple views from this section to be published in one action, by using the existing security role and legal entity configurations. You can use the **Save as personal** action to create personal copies of these views, so that you can gain a better understand their contents.
- **Personal views** – This section lists all views that have been created by users in the system. From here, you can publish a personal view to the organization, or copy one or more of these views to other users. You can also export or delete these views as required.
- **User settings** – Select a user to view, or adjust the user's ability to use personalization either for the whole system or for specific pages that the user has visited. You can view and interact with the user's personalizations in the system. You can also delete all personalizations for that user or reset feature callouts for the user. If feature callouts are reset, any pop-up windows that introduced new features and that the user previously dismissed will appear again the next time that the user encounters those features.
- **System settings** – You can temporarily turn off personalization for all users in the system. In this case, no personalizations are applied for any user, and all pages are reset to their default state. If you turn personalization back on later, all personalizations are reapplied. You can also permanently delete all personalizations for all users in the system. Personalizations that have been deleted can't be recovered. Therefore, before you perform this task, be sure to export any personalizations that you might want later.

Users who have access to the **Personalization** page can also import personal or organization views by using the **Import views** button on the Action Pane. For organization views, you can select **Publish immediately** to make the views available to users without an additional explicit publish.

Known issues

For a list of known issues with saved views, please see Build forms that fully utilize saved views.

Frequently asked questions

How do I enable saved views in my environment?

NOTE

The **Saved views** feature requires the Personalization system in Finance and Operations to be enabled. If personalization is turned off for the entire environment, views will be disabled even if you follow steps below.

You can turn the **Saved views** feature on and off through Feature management in any environment. After it's turned on, saved views will be enabled in all subsequent user sessions.

What happens to existing personalizations when views are enabled?

When views are enabled, any existing personalizations for a user and form are saved into a new view called **My view** that is automatically set as the default view. This is meant to ensure that there is a consistent user experience before and after views are enabled, except for the view selector control appearing on forms.

What pages support views?

Views are available on most, but not all pages. Specifically, views are currently available on all full-screen pages except for dashboards and workspaces. Non-full-screen pages, which include dialog boxes, drop-down dialogs, lookups, enhanced previews, currently do not support views. View support for additional page types, such as workspaces and dialog boxes, may be considered for a future update.

Who is allowed to publish views?

Only system admins and users who have been assigned to the **Saved views administrator** role have the rights to publish views.

Why am I not able to save filters with this view?

There are a few reasons why a filter may not appear to save with a view:

- The page may not support saving filters as part of the view definition. Note that only pages with large view selectors allow personalizations and query modifications to be saved as a view. See the **Switching views** section for more information.
- The page in question may not properly support views, as it may ignore the view query completely or may operate on a temporary table whose data is not persistent.

What data will I see when I visit a page?

For pages that have small view selectors (only personalizations can be saved to the view), you will see the same data as you always have when you visit the page.

For pages that have large view selectors (both personalizations and queries can be saved to the view), you will typically see the data that is linked to the query that is associated with your default view. There are two main exceptions:

- If you navigate to a page from a tile, the tile query will execute regardless of the query associated with the default view. If you created that tile after views have been enabled, selecting a tile will open the page with the view associated with that tile.
- If you navigate to a page and that entry point includes a query, the original query will execute originally in place of the default view's query. You should be alerted when this occurs via an informational message when the view is loading. You can also confirm by switching to this view after the page loads, as that should allow the view query to execute regardless.

Build forms that fully utilize saved views

2/18/2021 • 9 minutes to read • Edit Online

Saved views are an important expansion of personalization capabilities Finance and Operations applications. While the Saved views topic provides general details about this feature, this topic focuses on the more technical elements of saved views as well as aspects of form development that may be impacted by views.

"User-perceived" pages

Traditionally, a set of personalizations has a 1:1 link to a modeled form. For many pages, this makes sense to the user, as the user's perception of the page matches the way in which the form is modeled. However, in some cases the 1:1 link of a modeled form to a set of personalizations is not intuitive or obvious because users do not see or care about the boundaries between modeled forms.

Saved views try to eliminate this confusion by letting users create views on "user-perceived" pages. Therefore, users don't have to understand how forms are modeled to understand how and when personalizations are applied. Consider the following two scenarios:

- **More than one "user-perceived" page in a single modeled form:** The standard modeling of Master Details and Transaction Details forms (for example, the **CustTable** and **PurchTable** forms, respectively) consists of more than one "user-perceived" page: a grid page and a details page.

  Because users are not aware when this transition from list to details crosses a form boundary (nor do they need to know this), view support in Details forms is handled differently to allow views to be defined separately for the grid and details portions. This means that the view selector for the "grid" and "details" can show different sets of available views. The special casing of view support on these forms also allows the "grid" views to allow filters in their view definitions, whereas the "details" view only need personalizations.

- **More than one modeled form in a single "user-perceived" page:** The ability to embed subforms into modeled forms (via FactBoxes or form parts) leads to situations where more than one modeled form corresponds to a single "user-perceived" page. For example, consider the details portion of the **All customers** page, which has a number of FactBoxes and two FastTabs whose contents come from form parts. With traditional personalization, contrary to a user's expectations, exporting the personalizations for the **CustTable** form would not include personalizations on any FactBox or any personalizations done inside the **Addresses** or **Contact information** FastTabs. Equally unexpected for users, any personalizations done on these subforms would also be reflected in other parts of the application where these form parts are used. For example, changes to the **Addresses** FastTab in the **All customers** page would also result in the same changes appearing in the **Addresses** FastTab in the **All vendors** page.

  With views, the personalization scope of form parts has been modified to match user expectations. In particular, subform personalizations are now tied to the base form where they are made. This means that exporting a view on the **All customers** details page will include personalizations from the base **CustTable** form as well as any personalizations in FactBoxes or form parts modeled in that portion of the form. Similarly, any personalizations done on the **Addresses** FastTab (form part) on the **All customers** page will not be reflected in other forms where that form part is used.

These are highly technical modifications to the personalization subsystem that are only available when view is enabled. These modifications are important for ensuring that users have a predictable and understandable experience with views.

View support

The style of a form determines the level of support for views.

- Views include queries for forms, such as:
  - List pages
  - Simple lists
  - Grid portions of Master Details and Transaction Details forms
- Views do not include queries, such as:
  - Any other full-page form
  - Details portions of Master Details and Transaction Details forms
- Views that are not currently supported include:
  - Dashboards
  - Workspaces
  - Dialogs
  - Secondary forms like drop-down dialogs, lookups, and enhanced previews

Modifying forms to fully utilize views

While most forms will work well with saved views, there are some areas that may require changes to form logic so that views work as expected on these forms without causing confusion. Here are some key items to keep in mind during development of new forms.

- X++ code late in the form startup cycle can interfere with views working as users expect. In particular, be aware of the following items:
  - Modifications of the query after **super()** of **executeQuery()** or after **super()** of **run()** can cause the query aspect of a view to be ignored.
  - Form changes after **super()** of **run()** can cause some user personalizations to be incorrectly applied to the default view.
- Extra work may be required to ensure the values of custom filters always align to the current view or query.
  - To make sure that custom filters work correctly with saved views, the platform still has additional work to better support these controls. Once that support is available, uptake will be required by any form that has custom filters. More information will be provided when the recommended approach has been finalized.
- Looking forward, in the long-term, views are meant to replace modeled secondary list pages.
  - Typically, secondary list pages, such as **Customers on hold**, are menu items that point to the same form but have a different query. Because menu items that pass in queries override any query that is defined on the default view, these entry points can cause confusion for users. The current long-term plan is to make secondary list pages obsolete (deprecated) and move them to views. However, that effort hasn't yet been started.
  - To avoid user confusion between form caption (such as "All customers") and view name (such as "My customers"), consider renaming form captions to be the name of the corresponding entity. For example, instead of a form caption of "All customers" or "All sales orders", the form caption would be modified to "Customers" and "Sales orders".

Known issues

This section provides a list of known issues for saved views while the feature is in a preview state.

Open issues

- A view does not get marked as having unsaved changes after using custom filters, which are the filters above a grid excluding the QuickFilter. If custom filter conditions have been saved to a view, the custom filter controls may not correctly reflect the current query.
- View support for workspaces, dashboards, and dialog boxes.
- [KB 4553227] After adding (reference group) fields via personalization, the fields remain blank.
- If the Filter pane is open when switching to a different view, the Filter pane will not update to reflect the filters on the target view.
- Cannot move a view with a QuickFilter condition saved to it to another environment. The fix in release 10.0.13 more gracefully handles the situation, but does not allow these conditions to move between environments.

Fixed in release 10.0.16

- [KB 4590240] Grid resize does not work properly when switching views with the old grid
- [KB 4600209] Personalizations of form parts are not reflected when switching views
- [KB 4590224] Focus can start on the wrong control when saved views is enabled
- [KB 4562254] Table permission error after accessing a shared custom workspace
- [KB 4600210] Unexpected client error when switching to the Hide tool
- [KB 4599871] Workspaces do not open if personalization is turned off for user / Unbound controls cannot be set as mandatory via personalization
- [KB 4594453] Duplicate key exception for forms opening as full-page forms and dialogs

Fixed in release 10.0.15

- (Quality update) [KB 4599871] Workspaces do not open if personalization is turned off for user / Unbound controls cannot be set as mandatory via personalization
- (Quality update) [KB 4600209] Personalizations of form parts are not reflected when switching views
- [KB 4594452] Duplicate record error when interacting with some subforms (form parts)
- [KB 4586310] Attachments page loses context after switching views
- [Bug 494204] Error when deleting/clearing personalizations from User options > Personalization

Fixed in release 10.0.14

- (Quality update) [KB 4594452] Duplicate record error when interacting with some subforms (form parts)
- (Quality update) [KB 4600209] Personalizations of form parts are not reflected when switching views
- (Quality update) [KB 4584077] Error when exporting multiple views
- (Quality update) [KB 4584775] Record position lost when switching between list and details
- [Bug 481290] Error when trying to re-import personalizations to a set of users
- [KB 4582745] Error triggered when importing user views from one environment to another

Fixed in release 10.0.13

- (Quality update) [KB 4594452] Duplicate record error when interacting with some subforms (form parts)
- (Quality update) [KB 4600209] Personalizations of form parts are not reflected when switching views
- (Quality update) [KB 4584077] Error when exporting multiple views
- (Quality update) [KB 4582719 and KB 4578126] When multiple personalization records exist for a form, the wrong one can be selected and loaded
- [Bug 481283] Error opening a form after moving a view with a QuickFilter condition between environments
- [Bug 481608] Database sync fails because of a unique index violation on the FormRunConfigurationPublishedView table
- [Bug 474817] User options > Personalization doesn't list all personalizations for the user

- [KB 4574781] Duplicate record exception on saving a view
- [KB 4575278] Tiles, lists, and links lose their link to the published view if the view is republished

> **NOTE**
> Because additional information is needed to restore the link, re-linking will not occur for any pinned elements from published views prior to 10.0.13. To mitigate, you will need to re-publish your views after updating to 10.0.13 and re-pin the elements to your workspace.

- [KB 4575285] Publishing to an existing view name overwrites configuration changes already made
- [KB 4574778] Pin and publish as default do not respect companies that the view was published to
- [KB 4568154] View import flow doesn't surface if views apply to the grid or details aspect of Details pages
- [KB 4568152] Users are able to export the Standard view
- [KB 4568151] Published views recipients are not updated after republishing from a different legal entity
- [KB 4562137] Views published to a parent security role are not applied to child roles
- [KB 4564528] QuickFilter default field personalization isn't working as expected with views

Fixed in release 10.0.12

- (Quality update) [KB 4582719] When multiple personalization records exist for a form, the wrong one can be selected and loaded
- [Bug 486275] Strange tooltip behavior for saved views
- [KB 4568122] Unexpected queries applied after enabling views
- [KB 4562152] Migration of personalizations after enabling saved views throws exception in some cases
- [KB 4568121] Default view personalizations not applied for users without personalization rights
- [KB 4568119] Error may occur when importing a workspace or adding a tile or list to a workspace with views enabled
- [KB 4568118] Error when trying to open the view selector when user has a large number of views
- [KB 4568148] Old custom user workspaces aren't shown in the Personalization form after enabling views

Fixed in release 10.0.11

- (Quality update) [KB 4562147] Importing personalizations to a large number of users is timing out
- [KB 4549735] Personalization form missing from security role
- [KB 4568116] Views are not marked as having unsaved changes after using Advanced filter or sort
- [KB 4568117] Crash when attempting to import old personalization formats
- [KB 4568115] Views can be published with no name
- [KB 4564908] Unsaved filters and personalizations reflected in some views

Fixed in release 10.0.10/Platform update 34

- (Quality update) [KB 4560406] Importing personalizations to a large number of users is timing out
- (Quality update) [KB 4564906] Personalization form doesn't load/Loading a published view for the first time takes a long time
- [KB 4568114] Views can be published to a blank legal entity
- [kB 4568113] "View query cannot be applied" message shown when loading a view that modifies existing filters

Test forms that use custom patterns

2/18/2021 • 3 minutes to read • Edit Online

This topic how to test forms using custom patterns.

Introduction

By adhering to form patterns, you gain various benefits. For example, form patterns correctly set layout properties so that forms are laid out responsively. However, when form pattern coverage is lacking (for example, there currently isn't support for many extensible controls), or when a form or container has unique requirements/uses that don't fit any pattern, developers can set the pattern to Custom. The developer then becomes responsible for ensuring a correct and responsive form layout.

Forms that use custom patterns

You can find the forms that use custom patterns by using the **Form Patterns** report. For information on running the report, see Form pattern add-ins. After running the report, filter the **Percent covered controls** column to show forms that have less than 100-percent coverage. For forms that have a top-level Custom pattern, **Custom** will appear in the **Patterns** column.

Testing configurations

Key resolution

- 1366 × 768 is a typical resolution on screen sizes that are between 12 and 23 inches. Therefore, this resolution provides a good baseline for testing.
- It's also a good idea to test on a higher resolution, such as 1920 × 1080.

Parameters

- Browser
  - Internet Explorer 11
  - Google Chrome
  - Microsoft Edge
  - Apple Safari (on iPad) – You'll have to point Safari to a cloud URL.
    - Landscape and portrait modes
- Density
  - Low density
  - High density
- Viewport size
  - Maximized window
  - Snap view (half the screen) to simulate portrait mode on a tablet
- Zoom
  - 50 to 200 percent

Steps

Follow these steps. At each step, examine your form for layout issues. As part of your examination, look at all tab pages, and any groups that can expand/collapse content.

1. Open a browser window at full-screen size, and navigate to your form/control (in low density). It's a good

idea to starting your testing at a resolution of 1366 × 768.

2. Press the Windows logo key+Left Arrow to switch the browser window to Snap view (half the screen).
3. Slowly resize the browser horizontally back to full width. Stop at intervals, and evaluate the form layout.
4. Slowly resize the browser vertically from full height to half-screen height. Stop at intervals, and evaluate the form layout.
5. Maximize the browser window to full-screen size. Adjust the zoom levels (50 percent, 75 percent, 125 percent, 150 percent, and 200 percent), and evaluate the form layout.
6. Do a sanity check in high density.
7. Do a sanity check in other browsers.

Visual issues that you might encounter

Questions to answer while you're testing

- Is the form usable?
- Can I reach everything on the form? (You might have to move multiple scrollbars in smaller viewports.)

Issues that might suggest problems with the layout metadata

- Form content isn't being adjusted based on the available space.
- Grids and other "fill" controls aren't taking up the full height/width.
- Containers aren't showing up at all (there are no scrollbars that you can use to get to parts of the form).
  - This issue can occur with **SizeToAvailable** containers when there is no available height/width.
- There are extra (unnecessary) scrollbars.
  - You should expect more scrollbars in smaller viewports, especially because some containers (for example, grids and tab pages) have a minimum height.
  - This issue can occur with **SizeToContent** containers that should be **SizeToAvailable**.

Other known/expected issues

- Horizontal scrollbars appear on Toolbars.
  - Where there isn't enough width to show all the buttons on a Toolbar, a horizontal scrollbar will appear. This issue will be resolved soon by a framework deliverable that will implement overflow behavior on Toolbars.
- Random input control borders are missing at various zoom levels.
  - This is a known issue and is tracked by 1721990.
- Grids receive extra scrollbars, because the space that is available for the grid is less than the grid's minimum height (200 px).
  - We have a future work item to investigate reducing/removing this minimum height.
- When StaticText controls that have **SizeToAvailable** width are inside a group that also has **SizeToAvailable** width, horizontal scrollbars appear at some widths (Internet Explorer only).
  - The browser has a calculation error that sometimes causes scrollbars to appear in this scenario.

Appendix

Information/guidelines about layout

For information about the layout properties, and for guidelines about scenarios that you should avoid, see Page layout.

NOTE

Can you tell us about your documentation language preferences? Take a short survey.

The survey will take about seven minutes. No personal data is collected (privacy statement).

Create shareable, secured URLs (deep links)

2/18/2021 • 3 minutes to read • Edit Online

Learn how to create shareable, secured URLs to forms and records.

Overview

The URL Generator enables developers to create shareable and secured URLs (also known as deep links) to specific forms that are root navigable. An optional data context can be passed to the form to display filtered or specific data when the form is opened. The URL Generator enables scenarios such as embedding links in reports, email, and external applications, enabling users to quickly and easily locate the specified forms or data by simply navigating using the generated link.

Purpose

- Empower developers to generate URLs that can be used to navigate to root navigable forms in a specified instance.
- Empower developers to optionally specify a data context that should be displayed when navigating to the specified form.
- Empower users to share, save, and access the generated URLs from any browser with Internet access.
- Secure the URLs to prevent unauthorized access to the system, forms, or data.
- Secure the URLs to prevent exposure of sensitive data or tampering.

Security

Site access

Access to the domain/client is controlled through the existing login and SSL mechanism.

Form access

Access to forms is controlled through Menu items, as Menu items are the entry points where security is enforced. If a user navigates using a URL that contains a Menu item that the user does not have access to, then the Menu item security will prevent the form from opening. The user will receive a message indicating that they do not have the necessary permissions to open the form. Note that deep links will only work for Menu items that allow root navigation.

Data access

Access to data is controlled through the existing form-level queries. When a form is opened with a generated URL, the form will run its existing form-level queries, which restrict the user's access to data. The data context that is specified in the generated URL is consumed after these form-level queries are applied, and results only in further filtering of the data displayed to the user. In short, a generated URL can, at most, open a form and display all of the data that a form would display to the user based on the form-level queries. A generated URL cannot grant a user access to data that is otherwise inaccessible on the form when not using the generated URL.

Usage

The URL Generator is a .NET library that is accessible from X++, under the following namespace.

```
Microsoft.Dynamics.AX.Framework.Utilities.UrlHelper.UrlGenerator
```

Requirements

The URL Generator must be used from code running on the AOS, in an active user session or batch process. This requirement ensures that the URL can be secured through encryption specific to the instance that generates the URL. At a minimum, the following information must be specified and passed to the URL Generator in order to generate a working URL.

- **Host URL**
  - The URL of the web root for the instance. For example: `https://ax.dynamics.contoso.com/`
- AOT name of the **Menu Item Display**
  - The menu item display to be used to open the form.
- **Partition**
  - The partition to use for the request.
- **Company**
  - The company to use for the request.

Example

```
// gets the generator instance
var generator     = new Microsoft.Dynamics.AX.Framework.Utilities.UrlHelper.UrlGenerator();
var currentHost   = new System.Uri(UrlUtility::getUrl());
generator.HostUrl = currentHost.GetLeftPart(System.UriPartial::Authority);
generator.Company = curext();
generator.MenuItemName = <menu item name>;
generator.Partition = getCurrentPartition();

// repeat this segment for each datasource to filter
var requestQueryParameterCollection = generator.RequestQueryParameterCollection;
requestQueryParameterCollection.AddRequestQueryParameter(
    <datasource name>,
    <field1>, <value1>,
    <field2>, <value2>,
    <field3>, <value3>,
    <field4>, <value4>,
    <field5>, <value5>
);

System.Uri fullURI = generator.GenerateFullUrl();

// to get the encoded URI, use the following code
fullURI.AbsoluteUri
```

Accessibility in forms, products, and controls

2/18/2021 • 8 minutes to read • Edit Online

This topic describes best practices for enabling accessibility in your form, product, or control. An accessibility checklist is also included.

Accessibility is about inclusion, that is, a person with a disability can perform the same task as a person without that disability. Making an accessible control or form should be as fundamental as making it secure, high-performing, or easy-to-understand.

Keyboard

The bedrock of accessibility is keyboard-only access. When you can use the keyboard to perform all the actions of a form, then it can be utilized by a non-sighted person or a person with restricted or limited use of their hands. This means that all controls can be reached via the tab sequence, direct action (such as **Ctrl+S** for Save), or through some other shortcut key that enables the user to move to a control, such as Navigation Pane, App Bar, Message Center, or Message Bar. A simple test is to simply disconnect your mouse and complete all core and secondary scenarios using only the keyboard.

Color

The use of color is encouraged and is a common way to express state or status of a record or other piece of information. However, color cannot be the only way that state or status is communicated. An accompanying symbol, help text, or additional column should include a textual description of the state or status. A simple test is to identify all use of color in your system and ensure that color isn't being used to express a state or status. A common example is to use the color red to indicate "needs attention," or the color green to mean an "OK" status.

Images

When showing an image there should be a label that describes the image. If the image expresses state or status of a record, then accompanying help text or an additional column should include a textual description of the state or status. If the image is symbolic, like a logo, then it doesn't require a textual description. If you have an image on a form or grid to convey a status, such as "in progress", ensure that the image has a tooltip that can then be read to someone who is utilizing a screen reader.

```
public display container statusImageDataMethod()
{
    ImageReference statusImage;
    if (this.Status == NoYes::Yes)
    {
        statusImage = ImageReference::constructForSymbol(ImageReferenceSymbol::Accept, "Accept");
        // a product ready example would use a label in place of an embedded string
    }
    else
    {
        statusImage = ImageReference::constructForSymbol(ImageReferenceSymbol::Cancel, "Cancel");
        // a product ready example would use a label in place of an embedded string
    }
    return statusImage.pack();
}
```

Extensible controls

Extensible controls are simply an extension of the controls that are provided by the framework, but require the same usability and accessibility. In addition, widgets or other visually rich controls, such as segmented entry controls or charts, should provide an Accessible Rich Internet Applications (ARIA) tag that is hidden from the sighted user, but provides an introduction to the blind user through a screen reader that describes the use of the control. Every action in an extensible control must be possible with a keyboard.

Layout and dynamic management of forms

A visually impaired or blind user cannot be surprised by significant or unexpected re-laying out of a form based on an action such as selecting a value or entering input.

Accessibility checklist

MEASURE	DESCRIPTION	SUCCESS CRITERIA	VALIDATED (X)
Keyboard-only access to all functions	Drill downs, lookups, hyperlinks, data input actions, and shortcut keys.	All action may be completed without the use of a mouse.	
Visible focus indicator		It's always apparent which control has focus.	
Focus order	Cannot "jump to" a non-logical location.	Tabbing doesn't jump to a non-logical portion or unexpected portion of the form.	
Focus trapping	Cannot be "trapped" in a control, focus must be able to move out of control using the keyboard.	Tabbing into a control should allow tabbing out or a keyboard equivalent that lets them escape.	
Images of text	Cannot use an image to display text.	For example, you cannot have a button label that is an image of text. Logos are exempt.	
Using color	Color alone cannot be used to convey status or state.	All status indicators on a form or grid must have unique shape or texture for each color. See the "Color" section in this document for more information.	
Text contrast	Minimum 4.5:1 ratio.	Extensible controls should use framework color theming to ensure compliance.	
User input instructions	Widgets or other multi-step controls must have a usability overview label or help text (can be embedded in ARIA tag).	When using a screen reader, the control must be introduced and its label or purpose described.	

MEASURE	DESCRIPTION	SUCCESS CRITERIA	VALIDATED (X)
Change of context	Changing the setting of, or entering data into any UI component must not automatically cause an unexpected change of context that might disorient the user without first notifying the user that the change of context will occur.	For example, selecting a value in a drop-down box or clicking a check box shouldn't change the layout of the form unexpectedly or in a non-standard way.	
Consistent UI	Widgets or other elements must work consistently across the product. There cannot be two similar looking or modeled elements that behave differently.	For example, selecting a check box shouldn't open a window.	
Fine motor control	Cannot require use of the mouse. Must support "sticky keys."	User cannot be forced to click a moving target (pull right) or any other action that requires a mouse. The same action must also be possible with the keyboard.	
Use of video	Video (with audio) must have accompanied text.	When showing pre-recorded content, the deaf person must have supporting text to consume the content.	
Use of images		All images must be accompanied by text that describes the specific content. For example, a "tooltip" or secondary column in a grid that describes and matches the state or status.	
Communication	Use of VoIP or other telecommunication device or software, such as Skype, must be accessible and usable from the keyboard.	Any use of VoIP or telecommunication is a legal obligation.	
Navigation		Navigation controls must communicate that navigation will occur if executed.	

Extensible controls – insights for accessibility

An extensible control is simply an extension of the framework. The interaction of the extensible control should be considered no different than any other framework control. When the control is a visually-rich widget that offers mouse actions, the author needs to ensure that equivalent, keyboard access functionality is available. A widget may not run in an "accessible mode" that is different than the standard presentation. Instead the widget

must offer similar functionality without the need to activate or toggle state of the control. All uses of color should be based on themed colors so that when the mode is "High Contrast" your color scheme matches the theme change. The World Wide Web Consortium (WC3) website provides guidance for Supported States and Properties. This site is a helpful resource for ARIA tags and provides the definitions that you see below.

Controls should do this

Introduce itself

Importantly, your control should not only identify itself by name, but (using a label or ARIA tag) give a brief introduction on how it works. Make sure your descriptive text is supplied via a framework label for localization.

- *aria-describedby* - Identifies the element (or elements) that describes the object.

Introduce itself - example

```
<http://www.w3.org/TR/WCAG20-TECHS/ARIA1.html>
<button aria-label="Close" aria-describedby="descriptionClose" onclick="myDialog.close()"></button>
<div id="descriptionClose">Closing this window will discard any information entered and return you to the
main page</div>
```

Indicate when it is busy

It may not always be clear to the visually-impaired user why the control isn't responsive. Providing a "busy" message helps in these cases.

- *aria-busy (state)* - Indicates whether an element, and its subtree, are currently being updated.

Indicate when it is busy - example

```
<p aria-live=”polite” aria-busy=”true”></p>
```

Indicate that the contents have been validated and are invalid

The async nature will result in a dynamic field state change. The message bar will introduce itself to the visually-impaired user, and the control itself should express an invalid state.

- *aria-invalid (state)* - Indicates the entered value does not conform to the format expected by the application.

Indicate when a field is readonly

- *aria-readonly* - Indicates that the element is not editable, but is otherwise operable. See related *aria-disabled*.

Indicate that the field requires input (mandatory)

The sighted user understands that a field is mandatory through a visual symbol. The non-sighted user will need an identifying tag.

- *aria-required* - Indicates that user input is required on the element before a form may be submitted.

Describe the state of a toggled value

A toggle control has a toggled state. This tag will express that state.

- *aria-pressed (state)* - Indicates the current "pressed" state of toggle buttons. See related *aria-checked* and *aria-selected*.
- *aria-valuenow* - Defines the current value for a range widget. See related *aria-valuetext*.
- *aria-valuetext* - Defines the human readable text alternative of *aria-valuenow* for a range widget.

Controls could do this

Indicate an expanded state

Complex interactions can be learned, but current state isn't always easy to determine without experimentation. When using an *aria-expanded* tag, the control describes its current state. An example is tabbing to a tab or FastTab section of a control.

- *aria-expanded (state)* - Indicates whether the element, or another grouping element it controls, is currently expanded or collapsed.

Describe applicable context menu

Finance and Operations apps provide a context menu. When the application author has provided functionality to the current control or context, you can announce that functionality.

- *aria-haspopup* - Indicates that the element has a pop-up context menu or sub-level menu.

Other miscellaneous controls

- *aria-live* - Indicates that an element will be updated, and describes the types of updates the user agents, assistive technologies, and user can expect from the live region.
- *aria-multiline* - Indicates whether a text box accepts multiple lines of input or only a single line.
- *aria-multiselectable* - Indicates that the user may select more than one item from the current selectable descendants.
- *aria-orientation* - Indicates whether the element and orientation is horizontal or vertical.
- *aria-setsize* - Defines the number of items in the current set of listitems or treeitems. Not required if all elements in the set are present in the DOM. See related *aria-posinset*.
- *aria-sort* - Indicates if items in a table or grid are sorted in ascending or descending order.
- *aria-valuemax* - Defines the maximum allowed value for a range widget.
- *aria-valuemin* - Defines the minimum allowed value for a range widget.

Customize field descriptions

2/18/2021 • 2 minutes to read • Edit Online

This article describes how you can customize existing field descriptions and add your own descriptions.

There are descriptions for some of the more complex fields. These descriptions appear when you hover over a field. You can customize these descriptions if, for example, you want to add company-specific information. You can also add descriptions for additional fields. You create field descriptions by using the **HelpText** property for field controls. The **HelpText** property is no longer specified for table fields and data types, as it was in previous versions. Additionally, the inheritance of the **HelpText** property from data types and table fields to form controls is obsolete. Field descriptions are intended to be specific to an individual field, in the context of the other controls and information that are available on the page. To add and customize field descriptions, you must have access to the development environment. Like other metadata changes, new descriptions should be added in a new model to prevent them from being overwritten when a new version of Operations is released. For more information, see Customize through extension and overlayering.

Customize a field description or add a new description

The same procedure is used to customize existing field descriptions and to add new field descriptions. However, when you customize an existing description, you replace the existing label reference.

1. In Application Explorer, find the relevant page (form), and add it to your project.
2. In the node for the page, find the relevant field control. Make a note of the name, so that you can use it as part of the label ID.
3. Add a new label for your description. You can follow the conventions that Microsoft uses to name the label files for field descriptions and to create the label file IDs. For more information, see the next section.
4. In the **HelpText** property of the field control, add a reference to the label.

Label file names and label IDs

The field descriptions that are provided by Microsoft are stored in separate label files. There is one label file per module per model. The pattern for the label file names is FieldDescriptions_*ModuleName*_*ModelName*.*CountryCode*.label.txt. Here are some examples:

- FieldDescriptions_AccountsPayable_ApplicationFoundation.en-US.label.txt
- FieldDescriptions_SystemAdministration_ApplicationFoundation_en-US.txt

The pattern for label IDs is @FieldDescriptions_*ModuleName:PageName*_*ControlName*. Here are some examples:

- @FieldDescriptions_AccountsPayable:CustSettlement_CustSettlement_OffsetCompany is the ID for the label for the **Company accounts** field (CustSettlement_OffsetCompany) on the **Customer settlement** page (CustSettlement).
- @FieldDescriptions_ProcurementAndSourcing:PurchLineBackOrder_LinkViewCheckBox is the ID for the label for the **Link on change view** option (LinkViewCheckBox) on the **Backorder purchase lines** page (PurchLineBackOrder).

Action controls

2/18/2021 • 11 minutes to read • Edit Online

Actions are an essential component of any enterprise resource planning (ERP) system, and are triggered by mouse click, keyboard, or touch.

Introduction

Actions are an essential component of any enterprise resource planning (ERP) system. Actions can be accessed through various mechanisms:

- Buttons on standard Action Panes
- Buttons on Toolbars
- Buttons directly on the form canvas
- Right-click context menus
- Keyboard shortcuts
- The new action search feature

Note that, in general, actions that are triggered by right-click context menus or keyboard shortcuts are meant to have a corresponding button available elsewhere in the user interface. Action controls can be triggered by using touch or a mouse click. Many system-provided actions can also be triggered by using the keyboard. In the future, we plan to provide functionality so that developers and end users can also define their own keyboard shortcuts.

Buttons

Buttons are the foundation of action controls. They can be modeled inside of standard Action Panes or in Toolbars, which are discussed later in the article. They can also be added as stand-alone buttons on the page (for example, the **OK** and **Cancel** buttons at the bottom of a dialog box, or buttons for actions that are specific to an individual field). The following button types continue to be available:

- A **button** is a basic button, for which the entire functionality must be implemented in code.
- A **command button** specifies a command or task to run.
- A **menu item button** specifies a menu item to navigate to or run.
- A **drop dialog button** opens a flyout dialog box, the contents of which are retrieved via a menu item.
- A **menu button** is a button container that opens a flyout that contains a list of other buttons.

In general, buttons continue to take advantage of the same properties as the buttons in previous versions. The following sections discuss a few properties that are related to button visualization, with particular focus on changes from previous versions.

Button Display

The **Button Display** property controls what information (including the button label and/or image) appears on the button. The allowed values for this property depend on where the button is located (for example, inside an Action Pane). Here are some of the location restrictions on the **Button Display** property:

- Buttons inside Menu Buttons must be set to **Text Only** or **Auto** (which is interpreted as **Text Only** in this case).
- Buttons inside Action Pane tabs on Standard Action Panes must be set to **Text Only** or **Auto** (which is interpreted as **Text Only** in this case).

- **Image Only** buttons should be used only for on-canvas buttons that are inline with a field.

For more details about how to use the **Button Display** property in various form locations, see the "Button image guidelines" section of the General form guidelines article. The following table shows the values for the **Button Display** property.

BUTTON DISPLAY VALUE	DESCRIPTION
Auto	The button has the content (text and/or image) that is defined (but only content that is allowed for the button's location).
Text Only	Only text appears on the button.
Image Only	Only an image appears on the button.
Text with Image Above	Both an image and text appear on the button. The text appears above the image.

Note that the other values of **Button Display** from Microsoft Dynamics AX 2012, such as **Background Image** and other relative positioning of text and image, are no longer supported.

Button Images

In previous versions, images or icons were often shown on buttons to help users recognize those buttons. In the current version, the number of images that are used for this purpose has been drastically reduced. Fewer images produce a cleaner, more modern user interface. Additionally, there was a desire to indicate processes and tasks by using more common symbols instead of multiple subtly different images. For more details about how images are used on buttons, see the "Button image guidelines" section of the General form guidelines article.

Two metadata properties are used to define an image for a button: **Image Location** and **Normal Image**. The allowed values for the **Normal Image** property depend on the value of the **Image Location** property. In previous versions, Embedded Resources (kernel resources) were heavily used to specify button images or icons. However, with the shift to the web, this image format option is no longer available. Instead, a new image format (Symbol font) has been added, and the expectation is that all buttons that require images will use this format (**Image Location** = **Symbol**). The primary reason for this change is that a symbol font is the best performing and most scalable image format. For a list of the full set of symbols that are supported, see Dynamics Symbol font article. The following table shows the recommended and preferred method for assigning images to buttons.

PROPERTY	VALUE
Image Location	Symbol
Normal Image	The name of the symbol font glyph

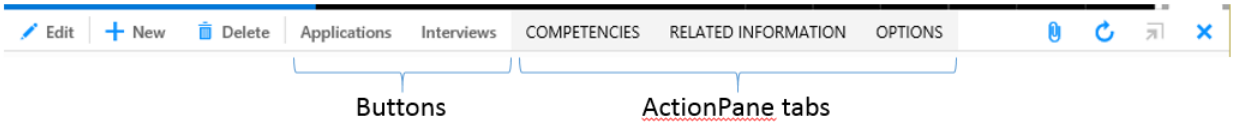
Button Style

In general, the **Button Style** property defines how a button is shown in the user interface. The exceptions are buttons that are modeled inside an Action Pane or Toolbar, because the **Button Style** property is disregarded in those cases. Instead, those buttons are rendered by using the style specially designated for buttons in those types of containers. For buttons that are modeled directly on the form canvas (outside Action Panes), the following button styles are available.

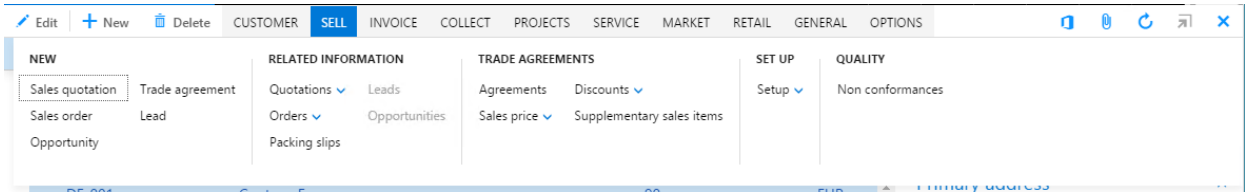
STYLE	EXAMPLE	DESCRIPTION
Standard (Auto)	Show more fields	The traditional button appearance
Command link	Vendors Customers	A combination of a small square block or image on the left, and a label on the right
Link	Current rentals	A button that has the appearance of a hyperlink

Standard Action Panes

The standard Action Pane is the primary location for page-level actions. It consists of both system-defined actions (actions that aren't explicitly modeled but are automatically added by the framework) and developer-defined actions (actions that are explicitly modeled in either Action Pane tabs or Button Groups). Developers can promote the most frequently used actions directly to the standard Action Pane by modeling Button Groups directly under the Action Pane. However, Action Pane tabs can still be used to group actions and provide access via a flyout. The following illustration shows a standard Action Pane that includes system-defined buttons, two promoted developer-defined actions, and a set of Action Pane tabs.



The following illustration shows the flyout that appears to show additional commands when an Action Pane tab is clicked.



System-defined buttons

Several system-defined buttons are added automatically to pages. The following table shows the list of system-defined buttons that are added to the Action Pane. For more information about how these buttons behave and how to manage them, see the System-defined buttons article.

BUTTON	NAME	COMMENTS
New	New	Create a new record for the first master data source.
Delete	Delete	Delete the currently selected record for the first master data source.
Edit	Edit	Switch to **Edit** mode.
	Show filters	Open the **Filter** pane.

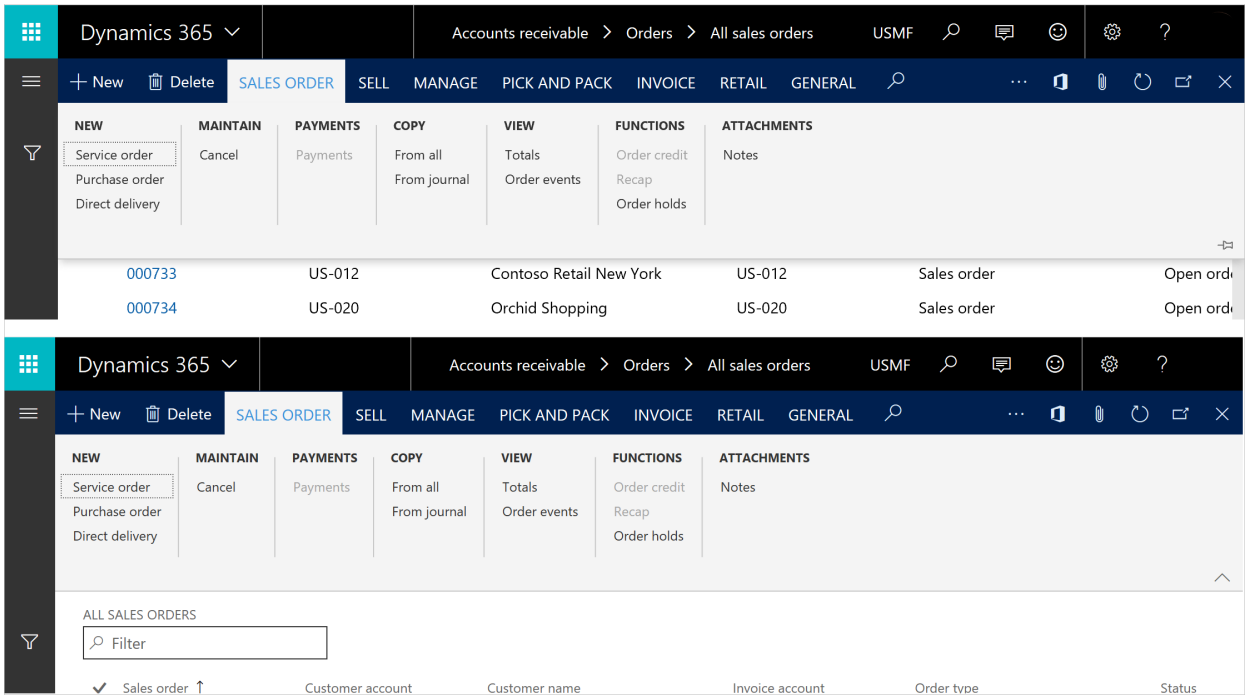
BUTTON	NAME	COMMENTS
	Show list	Toggle visibility of the navigation list on the details pages.
	Attach	Attach a document.
	Refresh	Update all the data on the page.
	Close	Close the page (equivalent to clicking the browser's **Back** button).
	Open in Microsoft Office	Open or export to Microsoft Excel. More Office integration is planned.
	Popout	Pop out the current form into a new dynalinked window.

Pinning the Action Pane

The standard Action Pane supports the ability for the user to "pin" or "unpin" the Action Pane as desired.

When the Action Pane is pinned open, an Action Pane tab is expanded and pushes the form content below it (e.g. it does not overlap anything on the form). In this mode, there is a chevron button in the lower right corner of the expanded Action Pane tab to "unpin" the Action Pane.

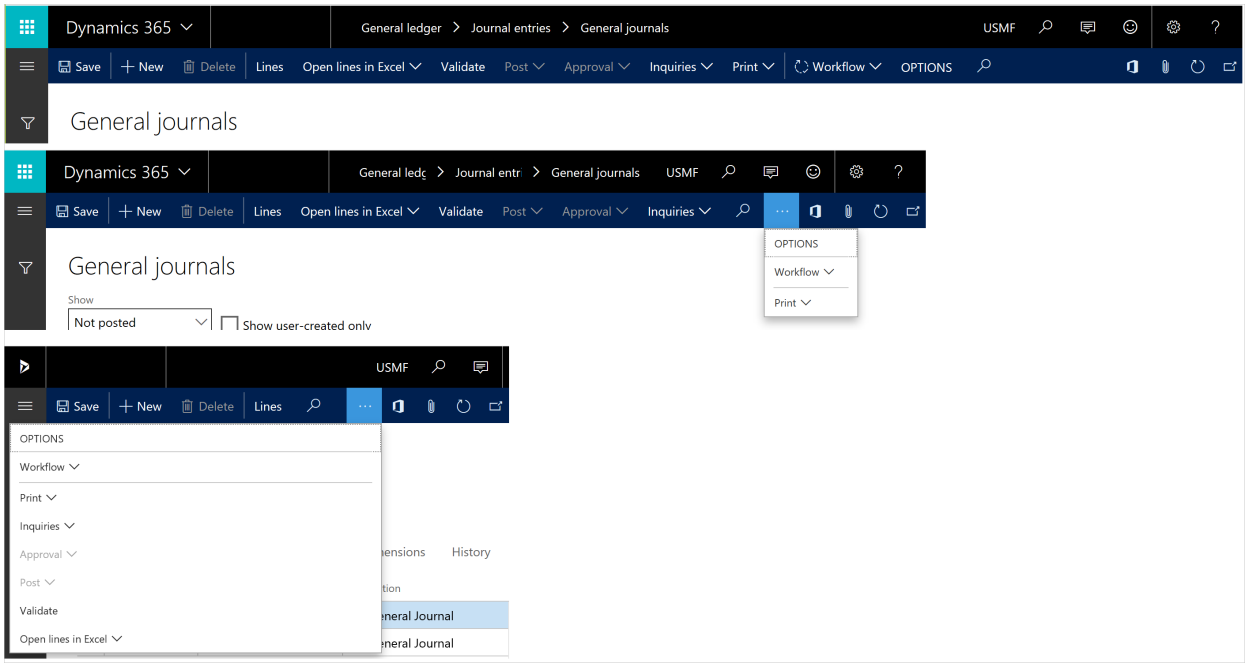
When the Action Pane is not pinned open, clicking on an Action Pane tab opens it as a flyout on top of the form content. The lower right corner of the Action Pane tab flyout has a pushpin button that can be clicked to pin the Action Pane open.



Overflow behavior in the Action Pane

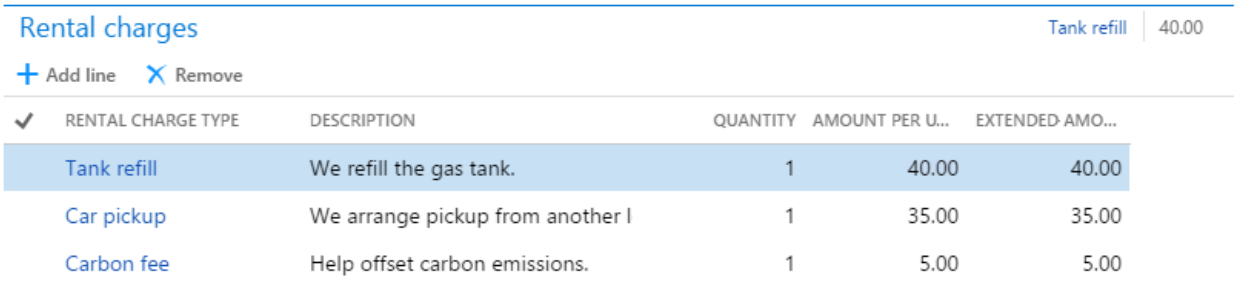
Standard Action Panes include an overflow feature that adds a responsive element to forms and eliminates the need for a horizontal scrollbar in the Action Pane. When the browser width is insufficient to show the entire Action Pane contents, an overflow menu automatically appears in the Action Pane and includes any buttons and

Action Pane tabs that did not fit given the browser width. Items are added one-by-one starting with the rightmost actions from the Action Pane. Note the system actions on the right side of the Action Pane do not participate in the overflow behavior.



Toolbars

Toolbars (previously called Action Pane strips) are Actions Panes that have the **Style** property set to **Strip**. They are used for actions that have a specific context and aren't page-level actions. They are primarily used for actions that are specific to a FastTab, tab, or grid. The actions in a Strip-styled Action Pane are shown horizontally in a Toolbar. The following illustration shows a Toolbar that has two buttons for adding and removing lines from this **TransactionDetails** form.



Overflow behavior in Toolbars

Toolbars have the same overflow feature as standard Action Panes. See the section above for more details.

Toolbars allow developers to provide a cleaner action story by designating certain buttons to always render in overflow. This makes it easier to differentiate actions that users will commonly use versus those that are infrequently or rarely used. This behavior is controlled by a new metadata property called **AlwaysInOverflow** that exists on Button groups inside Toolbars.

Right-click context menus

Some actions can also be accessed via shortcut menus (right-click context menus). Depending on the context of the right-click, you see either the browser's default context menu or the application context menu, which shows both system-defined actions and developer-defined actions.

- If you right-click on an image, in an editable field, or if text is selected, then the browser's context menu will appear. This is to provide access to browser functionality like **Cut**, **Copy**, and **Paste**. Actions cannot be embedded into context menus because browsers do not allow programmatic access to the system

clipboard for security reasons.

- Other right-click targets (for example, on a field label or on the value of a read-only control) should trigger the context menu.

> **NOTE**
> Context menus are intended to provide an alternate route to a command, and should not be only way to execute a command. Therefore, any action that is added to a control's context menu should also have a corresponding action that is available outside the context menu.

The programming model for modifying context menus differs from the model used in previous releases. In Dynamics AX 2012, the **PopupMenu** class was used. This class relies on Microsoft Windows application programming interfaces (APIs). However, because these APIs aren't available on the web, replacement APIs have been created to provide similar functionality. For more information, see Code migration - Context menu code.

Keyboard shortcuts

Keyboard shortcuts are another mechanism for triggering some actions. Many actions that had shortcuts in Dynamics AX 2012 continue to have shortcuts in Operations. However, because of browser restrictions, the key combination that is used to trigger a particular action might differ.

The following table shows some important keyboard shortcuts that are available. For the full list of current keyboard shortcuts, see the Keyboard shortcuts article. In the future, we plan to provide mechanisms so that developers and end users can define shortcuts for other actions.

KEY COMBINATION	ACTION	COMMENTS
Alt+N	Create a new record	The keyboard shortcut for creating a new record (unlike the system-defined **New** button on the Action Pane) is contextual. It creates a new record that is based on the data source of the control that currently has the focus.
Alt+Del (or Alt+F9)	Delete record	The keyboard shortcut for deleting a record (unlike the system-defined **Delete** button on the Action Pane) is contextual. It deletes based on the data source of the control that currently has the focus.
Alt+S (or Ctrl+S)	Save a record	
F2	Toggle edit mode	Switch the form between **View** mode and **Edit **mode.

Action search

Dynamics AX 2012 included a Key Tips feature that let users run any command in an action pane by pressing Alt and then a series of letters. The action search feature has been implemented as the replacement for the old Key Tips functionality. Action search can be accessed through a search field that is located in the standard action pane at the top of the form. Currently, it's represented by a magnifying glass icon in the action pane (note this is different from the navigation search feature in the navigation bar). In the action search field, you can type the beginning of the name of the action that you want to perform in the field (typically, only two to four characters

are required). This search mechanism then finds all buttons in visible action panes on the form that match the search string. You can then use click the button in the result list to run the command. For productivity, focus then returns to your last position in the form after the button has been triggered. You can also initiate action search by pressing Ctrl+' or Alt+Q. Pressing the keyboard shortcut again will return focus to your last position in the form.

Input controls and grid column sizes

2/18/2021 • 2 minutes to read • Edit Online

This topic describes how to create a consistent look and feel for forms by controlling the size of controls and grids.

Overview

Many frameworks offer complete freedom over the width of input controls. However, that level of freedom can lead to inconsistent presentation of data and a non-uniform layout for similar forms. For example, the customer name in one form might show 10 characters of information, whereas the customer name in another form might show 20 characters of information. To provide streamlined, easy-to-read interfaces, discrete sizing helps guarantee consistent presentation of data. The introduction of discrete sizing is a significant change to the basic input controls. The control framework attempts to provide a fresh, clean user experience that provides simplicity and consistency. As part of an attempt to provide consistent and uniform layout of forms, each input control is sized to one of four sizes: extra-small (XS), small (S), medium (M), or large (L). These sizes are determined by inspecting the explicitly specified width in the **DisplayLength** property of the control or the corresponding extended data type (EDT).

Sizing grid columns

Column sizing in a grid control differs slightly from the legacy algorithm, which tried to provide an initial appealing presentation for each grid, based partly on the contents of the first page of data. The new approach disregards the contents of the first page of data. Instead, the end user decides which columns are most important to view and the ideal viewing width for each of those columns. By using personalization, each user can change the width of grid columns, and the client keeps track of that user's preference. In the new, simplified approach, the default column sizing is based on 75 percent of the base input control sizing. In most cases, we recommended that developers not override the default sizing. However, if you must resize the column width programmatically or in the model, see the next two sections of this article for guidance.

Discrete sizing

SIZE	CHARACTER RANGE	SIZE IN PIXELS (PX)
XS	0–5	60
S	6–15	120
M	16–30	180
L	>30	240

Note: The explicit number of pixels will likely vary over time as the user interface evolves. Developers should not rely on explicit pixel sizing.

Forcing a desired discrete size

As the previous table shows, if you change the width of a grid-hosted control from 6 characters to 15 characters, you don't affect the width of the column. The layout engine gives the same width to all control widths that are in

the 6-to-15-character range, because controls in this range are considered small (S). If you want to extend the control to medium (M) size, the width value must be set to a value that is more than 16 characters and less than 31 characters. For guidance about how to size input controls, see the following table. In some cases, the use of a form pattern will override or hide developer-defined sizing.

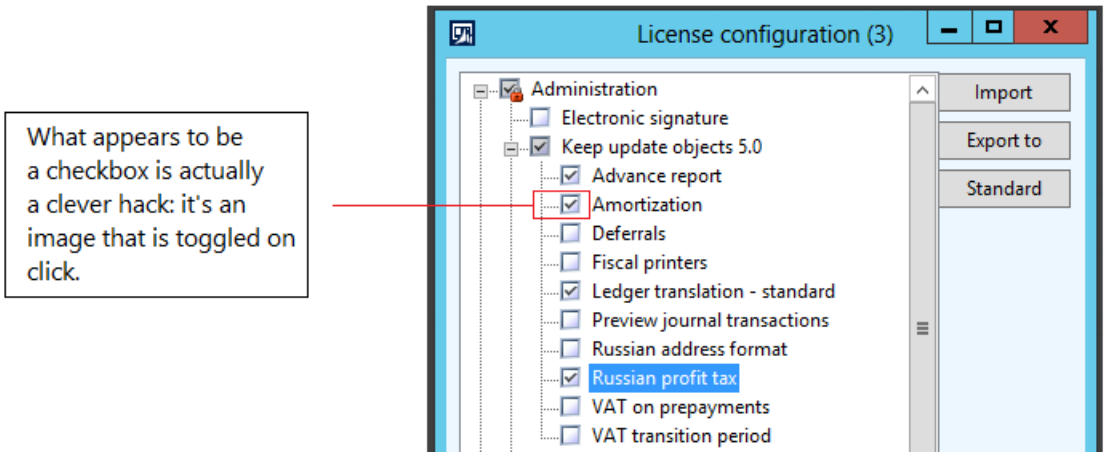
PROPERTY	VALUE	DESCRIPTION
DisplayLengthMode	Auto	Use the kernel's default value.
DisplayLengthMode	Fixed	Use the developer-defined **DisplayLength** value.
WidthMode	Auto	Use the kernel's default sizing behavior.
WidthMode	Fixed	Use the developer-defined **Width** value.
WidthMode	Column Width	Use size-to-parent behavior.
DisplayLength	N	The developer-defined control width, which is specified in characters. (Values are mapped to the sizing groups that are listed in the previous table.)
Width	N	The developer-defined control width, which is specified in pixels.

Check box support in tree controls

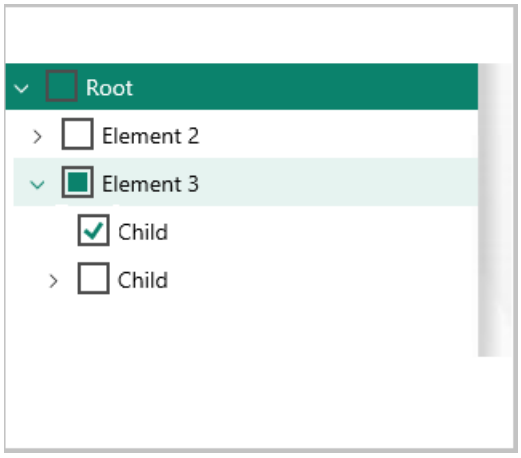
2/18/2021 • 4 minutes to read • Edit Online

This article is intended as a primer for using check box controls in the tree control. It's not a general "how to" for using tree controls.

Microsoft Dynamics AX 2012 includes several examples of tree controls that were enhanced so that they both show data in a tree hierarchy and let the user select one or more nodes by using check boxes. In Dynamics AX 2012, the tree control had no built-in support for check box controls. Instead, an image of a check box was added for each node in the tree control. The image state for each node was then toggled as the user clicked the check box.



The current version has greatly simplified the experience for the developer. Check box support is now built into the tree control.

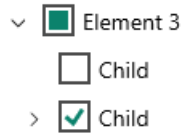


You no longer have to use images to include a check box, and you also don't have to explicitly set the state of the check box state when it's selected. The control doesn't use images, and the check box state is managed in the way that you would expect for a tri-state check box. Examples of tri-state check boxes can be found in most installation scenarios. When tri-state check boxes are used, if the user selects a parent node, all children of that parent also become selected. The check box interaction is independent of the node's expand/collapse functionality. When the parent node is collapsed (no children are visible), a check mark on the parent node indicates that all children are also selected. However, if one child of a parent that has multiple children isn't selected, the appearance of the parent node changes. The check box no longer contains a check mark but is filled in. This state is considered a partial check. Therefore, a parent node has three states:

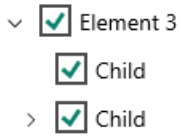
- Checked
- Unchecked
- Partial

If the user clicks the check box on a parent node that is in a partial state, the state of the parent and all its children changes to checked. (The parent node and all its child nodes are now selected.)

Parent node in a partial state

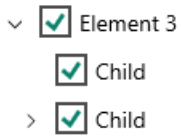


Parent node and all child nodes in a checked state after the parent node is selected

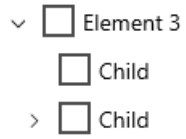


If the user clicks the check box on a parent node that is in a checked state, the state of the parent and all its children changes to unchecked. (The parent node and all its child nodes are now cleared.)

Parent node in a checked state

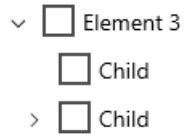


Parent node and all child nodes in an unchecked state after the parent node is cleared

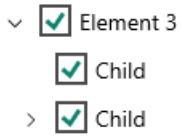


If the user clicks the check box on a parent node that is in an unchecked state, the state of the parent and all its children changes to checked. (The parent node and all its child nodes are now selected.)

Parent node in an unchecked state



Parent node and all child nodes in a checked state after the parent node is selected



A child node that has no children (in other words, a child node that isn't a parent itself) has only two states: checked and unchecked. A child node that is the only child in a checked state affects the state of its parent. If a child node is selected, the state of its parent changes to partial. **Note:** A single node in a tree also has a

“selected” state to indicate that it's the current node. This state differs from the checked state.

Tree controls that contain check boxes in Dynamics AX 2012

The following example is from SysConfiguration.

1. The program checks for the **mouseDown** event.
2. When the **mouseDown** event is detected, the program determines whether the user clicked the node or the image.
3. If the user clicked the image, the program toggles the image state.

None of this code is required for the current version.

```
int mouseDown(int x, int y, int button, boolean ctrl, boolean shift)
{
    int idx,f;
    FormTreeItem        parentNode, node;
    int                 parentMode;
    boolean             enabled;
    #FormTreeControl;
    [idx,f] = this.hitTest(x,y);
    parentNode  = this.getItem(this.getParent(idx));
    node        = this.getItem(idx);
    if (node)
    {
        if(parentNode)
        {
            if (element.enabled(parentNode.data()))
            parentMode = true;
        }
        else
            parentMode  = true;
        if ((f & #FTCHT_ONITEMICON) && parentMode)
        {
            if (!node.overlayImage())
            {
                enabled = (element.enabled(this.getItem(idx).data()) ? false : true);
                element.enabled(this.getItem(idx).data(), enabled);
                element.drawTree();
            }
            return 1;
        }
    }
    return super(x, y, button, ctrl, shift);
}
```

In the current version, you still set the selected state for scenarios where the user is presented with preselected nodes. Additionally, the developer can still set the state explicitly when the FormTreeItem is created. However, instead of specifying the current image, the developer now sets the **stateChecked** property on the FormTreeItem. If developers must know when the state of a check box changes, they can override the **checkedStateChanged()** method.

Basic check box use for tree controls in the current version

Make sure that the **Check Box** property on the modeled tree control is set to **Yes**. To explicitly set the state on a node, use the following code.

```
formTreeItem.stateChecked(FormTreeCheckedState::Checked);
formTreeControl.setItem(formTreeItem);
```

To interrogate a node for its current state, use the following code.

```
FormTreeItem formTreeItem = formTreeControl.getItem(formTreeControl.getSelection());
FormTreeCheckedState currentState;
if (formTreeItem != null)
{
    currentState = formTreeItem.stateChecked();
    switch (currentState)
    {
        case FormTreeCheckedState::Unchecked:
            /* unchecked */
            break;
        case FormTreeCheckedState::Checked:
            /*checked */
            break;
        case FormTreeCheckedState::Partial:
            /* parent has children checked */
            break;
        default:
            /* shouldn't get here */
            break;
    }
}
```

To react to or track the checked state of a node (**idx** is the node index), use the following code.

```
public void checkedStateChanged(int _Idx, FormTreeCheckedState _newState)
{
    super(_Idx, _newState);
}
```

The survey will take about seven minutes. No personal data is collected (privacy statement).

Filtering options

2/18/2021 • 8 minutes to read • Edit Online

This topic explains the filtering options that are available.

Introduction

Microsoft Dynamics AX 2012 offers the following filtering options.

FILTER OPTION	DESCRIPTION
Filter by grid	The user defines filter conditions in input fields below the grid column headers.
Filter by selection (filter by field)	The user selects a field value and uses that value as a filter condition.
Advanced filter	The user opens a dialog box that contains advanced filtering options (filter on columns, not on the form; join additional data sources; sort by multiple columns; and so on).

Finance and Operations offers the following filtering options.

FILTER OPTION	DESCRIPTION
Filter Pane	An inline pane that slides in from the left, and that contains multiple filter criteria that can be applied to the targeted content.
QuickFilter	A framework-provided filtering mechanism that can appear above any list or grid, and that provides fast single-column filtering.
Grid column filtering	The user can define filter conditions and perform single-column sorting by using a drop dialog that is opened from the grid column header.
Advanced filter/sort	For most advanced filtering scenarios, the migrated **Advanced filter** form from Dynamics AX 2012 is still available.

Filter expressions

One important difference between filtering in Finance and Operations apps and filtering in Dynamics AX 2012 is related to the way that query symbols are used when filter values are defined (for example, "*" to match 0 or more characters, or ".." to specify a range of values to match). In Dynamics AX 2012, these symbols are highly visible during the filtering experience. For example, for the filter by grid option, if a user selects the **contains** operator on a field, the system translates that operator by adding wildcard characters (*) to each end of the current expression. In the current version, the query symbols are implied by the selected operator and aren't injected into the user interface. This makes filtering more intuitive and simpler for users. For users who want to specify additional filter conditions by using specific query symbols, or users who must enter more complex

conditions, the **matches** operator is provided for each data type. For all other operators, the query symbols are interpreted as literals. For example, the filter condition "First name MATCHES A" finds all records where the first name starts with the letter A. However, the filter condition "First Name IS A*" finds records where the first name is literally equal to "A*." The following table shows how the client translates between Finance and Operations apps filter operators and Dynamics AX 2012 query syntax.

FILTER OPERATOR	FINANCE AND OPERATIONS APPS QUERY SYNTAX
Is “circle” / Is equal to “circle”	“circle”
Is not “circle” / Is not equal to “circle”	“!circle”
Is one of “circle”, “square”, “circlesquare”	“circle,square,circlesquare”
Contains “circle”	“*circle*”
Does not contain “circle”	“!*circle*”
Begins with “circle”	“circle*”
After “circle” / Greater than “circle”	“>circle”
Greater than or equal “circle”	“circle..”
Before “circle” / Less than “circle”	“<circle”
Less than or equal “circle”	“..circle”
Between “square” and “circle”	“square..circle”

Any query syntax that doesn't match the preceding templates is interpreted as the **matches** operator.

Note that the syntax for looking for blank values in a column remains the same as AX2012. With either the **matches** operator or the **is equal to** operator, you can type **""** to retrive rows with blank values for the current column. For example, **First Name IS ""** will finds all records where the first name is blank.

Filter Pane

The Filter Pane provides an easy-to-use interface for filtering full page lists. The Filter Pane is an inline pane that slides in from the left side of the screen and pushes the page content to the right, so that users can see the data that they want to filter. Users open this filter mechanism by clicking the system-defined **Show filters** button on the left side of the page. After it has been opened, the Filter Pane remains visible until the user goes to a new page, or until the user closes the Filter Pane by using the **Hide filters** button.

When is the Filter Pane available?

Currently, the Filter Pane is available for all forms except the following forms:

- Drop dialogs
- Dialogs
- Enhanced previews
- Lookups
- Form parts
- Parts

- Table of contents form type
- Forms that have no data sources

Note: The availability of the Filter Pane on particular forms and form types is evolving, so this list might change.

What data does the Filter Pane work on?

Because the Filter Pane is targeted at full page lists, it works only on the tables and fields that are directly joined (by inner/outer joins) to the first master data source on the form. This filtering mechanism isn't intended for filtering on secondary collections, or for filtering on other root data sources and their directly joined data sources. Other filtering mechanisms (QuickFilter, grid column filtering, and so on) are available to meet these other requirements.

What fields are initially shown in the Filter Pane?

Here is how the fields that are initially shown in the Filter Pane are selected:

1. All ranges/filters that currently exist on the query (only non-hidden filters/ranges are shown) are used.
2. If no ranges filters currently exist on the query, the fields from the primary index from the first master data source are used.
3. If there are no fields from the primary index from the first master data source, the TitleFields that are defined directly on the first master data source are used. If no TitleFields are defined, no default fields are shown. (Currently, if the first master data source extends another table (for example, table B), we don't show the TitleFields from table B. However, we plan to add that check in the future.)

Can I control the default fields that appear in the Filter Pane?

Developers can make sure that a particular field appears in the Filter Pane by adding an empty filter for that field to the query. For an example, see the **FmCustomer** form, which adds the filters post super() in form init(). Note that after an empty field has been added to guarantee that it appears in the Filter Pane, the fields in the Filter Pane will always be those that are explicitly on the query, and will never be the TitleFields or fields from the primary index on the first master data source.

I don't want users to be able to filter on a specific field or modify an existing filter. How do I accomplish this?

Developers can affect whether users can modify/add filters on certain fields by changing the status of the filters. The allowed values are in the **RangeStatus** enum:

1. **Open (default)** – The user can see and modify this filter.
2. **Locked** – The user can see the filter value but can't modify it. The user also can't add another filter on this column.
3. **Hidden** – The user can't see that there is a filter on this column. The user also can't add another filter on this column.

Can I control the fields that appear in the Add a filter field list in the Filter Pane?

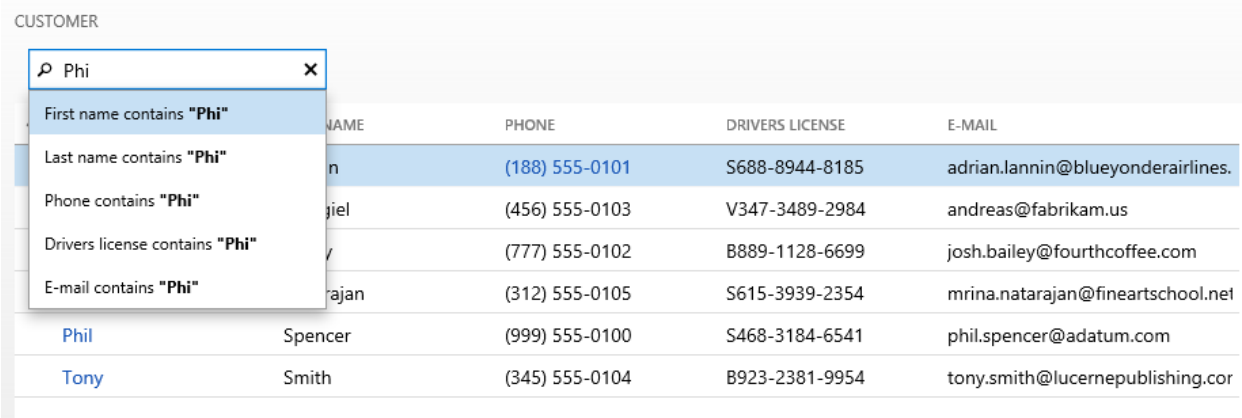
The fields that appear in the **Add a filter field** list are all the filterable fields from the query that involves the first master data source on the form. Therefore, developers can't control the fields that appear in this list. Usually, if you see unexpected fields or can't find the fields that you want to filter on, the fields that you're expecting are either on a different master data source (not the first) or on a child collection.

How is the Filter Pane used?

The Filter Pane is simple and straightforward to use. First, select a filtering operator in the list that is associated with each filter field. Note that the set of operators that appears depends on the data type of the field. Then enter an appropriate value for the filter condition, and click **Apply**. The form is updated based on the filter criteria that you specified.

QuickFilter

In Dynamics AX 2012, the QuickFilter was a framework control that was automatically added only to list pages. In Finance and Operations apps, the QuickFilter is now a modeled control that can be associated with any grid in the system. As the user starts to type, a column selector drop-down appears to guide the user toward the column that the filter will be applied to. The developer can also specify the default column for the QuickFilter. If no column is specified by the developer, the default column is the first field that can be filtered in the grid.



Why don't I have a column selector in my QuickFilter?

Column selectors are shown only for QuickFilters that are attached to grids. If you don't see a column selector, the most likely reason is that the **TargetControl** property on the QuickFilter is blank. This property must point to the grid that it should operate on. If the **TargetControl** property is set correctly, but you don't see a column selector, you might not have any filterable columns in your grid. In addition to non-text controls (such as images), controls that are bound to data methods aren't filterable.

Can I use the QuickFilter to filter other collection controls (such as trees)?

Yes, you can use the QuickFilter to filter other collection controls, but you must manually wire up the filtering. Here are the general steps:

- Leave the **TargetControl** property blank.
- Override the **applyFilter()** method on the QuickFilter.
- Write code in that method to perform the desired filtering.

Grid column header filtering/sorting

In Finance and Operations apps, the grid filtering experience is more closely aligned with the experience in Microsoft Excel. When the user clicks a column header (for columns that can be filtered), a drop dialog appears, and the user can use it to filter the column. The filtering experience here mimics the filtering experience in the Filter Pane. Additionally, there are options to sort the grid based on the column that is currently selected.

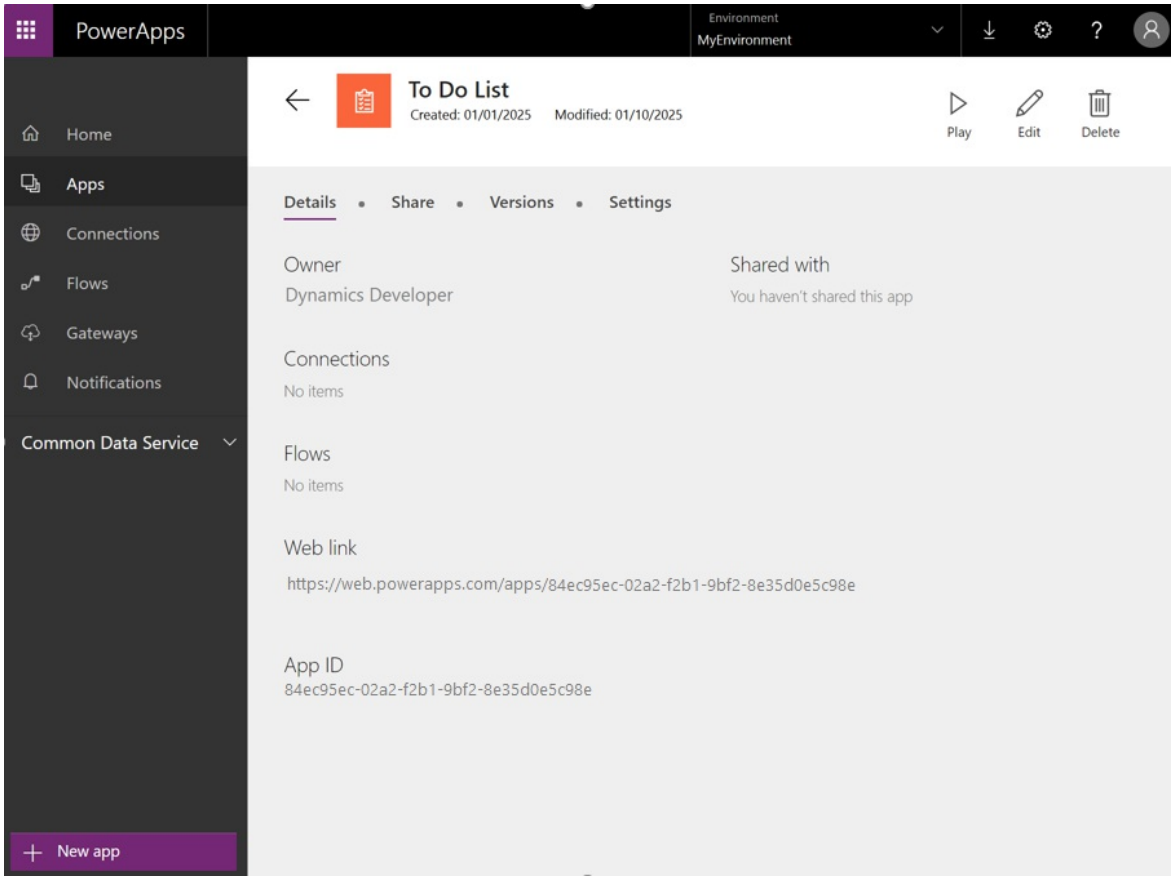
Power Apps Host control

2/18/2021 • 2 minutes to read • Edit Online

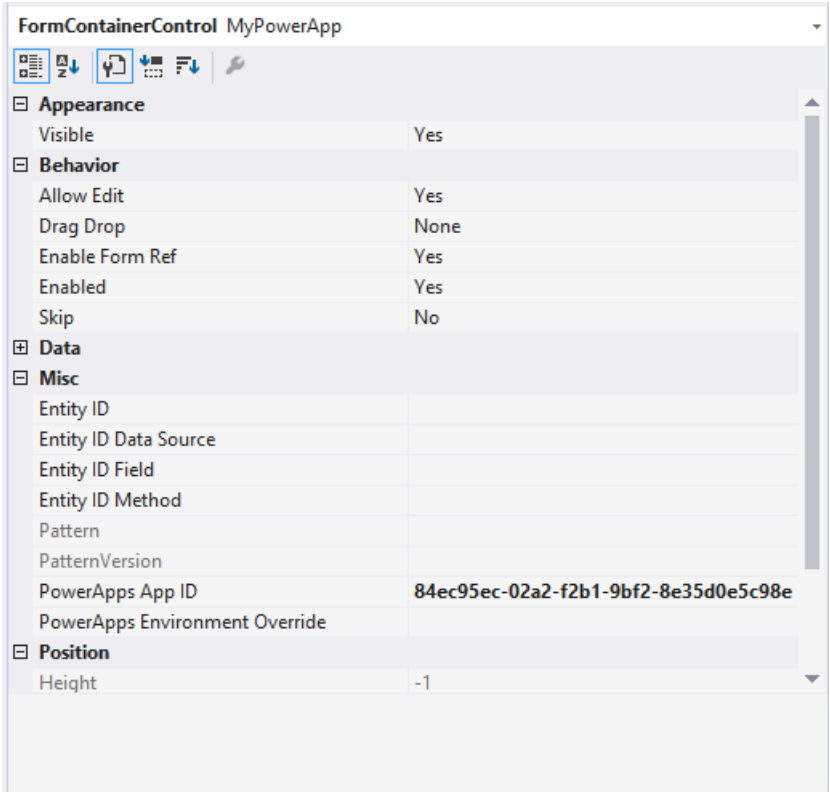
In Microsoft Power Apps, you can manage organizational data through apps that you created, or apps that someone else created and shared with you. Apps run on mobile devices such as phones or in a browser. Apps can also be embedded in Finance and Operations apps by developers using the Microsoft Visual Studio developer experience. To learn more about Power Apps, see https://powerapps.microsoft.com.

Host an app from Power Apps on a page

1. In Power Apps, find the web-based app that you want to host, and record or copy the **App ID** value.



2. In Visual Studio, open your project, and then, in the form designer, add an instance of a Power Apps Host control to your page.
3. In the **Properties** pane, enter the **App ID** value.
4. If your app shares or is linked to the current data source on your page, you can pass the ID of the primary or linked key field for the data that you want your app to show. In this case, provide the ID as the value of the **Entity ID**, **Entity ID Data Source/Field**, or **DataMethod** property. This value will then be passed to your app as a parmeter value, and your app must use that value to obtain the linked data.



5. In some cases, your app might be hosted in a development or sandbox Power Apps environment that is provided by Microsoft. In this case, you must supply that override URL as the value of the **Power Apps Environment Override** property.

Sizing is determined by the container that you put your control in. If you put your control in a form pattern that has limited available space, and your app has been designed to be larger than the available space, your embedded app will have scroll bars.

Code migration - Context menu code

2/18/2021 • 3 minutes to read • Edit Online

A programming model is required for context menus (shortcut menus). This topic outlines the process for migrating context menu code from Microsoft Dynamics AX 2012 to Finance and Operations. It also includes user experience (UX) guidelines for context menus.

In Dynamics AX 2012 and earlier versions, developers modified right-click context menus (shortcut menus) by using the **PopupMenu** class. This class relied on Microsoft Windows application programming interfaces (APIs) that aren't available on the web. In Finance and Operations, the **ContextMenu** APIs have been created as replacements to provide similar functionality. Previously, the **context()** and **showContextMenu()** method overrides were the entry points for modifying context menus for specific controls. These overrides typically contained code to add options to the context menu, and also to process the user's selection. The code for processing the user's selection used a wait model. Because these overrides are being removed and the wait model is being eliminated, developers must now create two overrides: **getContextMenuOptions()** to add options to the context menu and **selectedMenuOption()** to process the user's selection.

Migrate context menu code

Migration from the **PopupMenu** APIs to the **ContextMenu** APIs can be broken down into three main steps.

Step 1. Add a constant for each menu option that must be added

The old **insertItem()** method in the **PopupMenu** class returned an identifier for the menu option that was being added. This identifier was saved into a variable for future reference. Because developers will define the menu identifier, it's a good idea to define constants for each option to help with code readability.

- At the form level, add a constant for each menu option that is being added to the context menu. The value must be unique within each context menu. Note that you must modify the old variable name if it conflicts with another variable on the form or control.

Before

```
public void context()
{
    ...
    int listCreateRoot = listMenu.insertItem("@SYS5480");
    ...
```

After

```
[Form]
public class MainAccount extends FormRun
{
    ...
    public const int listCreateRoot = 1;
    ...
```

Step 2. Build the context menu

Construct the list of submenus and menu options, and add it to the control's context menu.

1. Add the **getContextMenuOptions()** method override on the control.
2. Create a new context menu and a list to hold the options that you will add to the menu:

- ContextMenu menu = new ContextMenu();
- List menuOptions = new List(Types::Class);

3. Add menu options to the list:
   - ContextMenuOption option = ContextMenuOption::Create(label,identifier);
   - menuOptions.addEnd(option);
4. Add the list of options to the menu.
   - menu.ContextMenuOptions(menuOptions);
5. Modify the **return** statement.
   - return menu.Serialize();

Step 3. Process the user selection from the context menu

1. Add the **selectedMenuOption()** method override on the control.
2. Move the **switch()** statement for processing options into this override.

Code example

This section illustrates the migration of a context menu from Dynamics AX 2012 to Finance and Operations. The **MainAccount** form is used as an example.

Original code

```
public void context()
{
    PopupMenu  listMenu        = new PopupMenu(element.hWnd());
    int        listCreateRoot  = listMenu.insertItem("@SYS5480");
    int        selectedMenu;
    selectedMenu = listMenu.draw();
    switch (selectedMenu)
    {
        case -1:
            break;
        case listCreateRoot:
            mainAccount_ds.create();
            break;
        default:
            break;
    }
}
```

Migrated code

```
// Define new form-level constant for each context menu option
public const int listCreateRoot = 1;
// Define new override on the control for building the context menu
public str getContextMenuOptions()
{
    str ret;
    ContextMenu menu = new ContextMenu();
    ContextMenuOption option = ContextMenuOption::Create("@SYS5480", listCreateRoot);
    List menuOptions = new List(Types::Class);
    // Add label and ID of menu option
    menuOptions.addEnd(option);
    menu.ContextMenuOptions(menuOptions);
    return menu.Serialize();
}
// Define new override on the control for processing the user selection
public void selectedMenuOption(int selectedOption)
{
    switch (selectedOption)
    {
        case -1:
            break;
        case listCreateRoot:
            mainAccount_ds.create();
            break;
        default:
            break;
    }
}
```

UX guidelines for context menus

As you migrate context menus, consider the following guidelines:

- The most important commands should be at the top of the menu.
- Remove commands that don't apply to the current state of the element that is the target of the right-click.
- Right-click is a shortcut. Therefore, the commands on the context menu should **always** be available in other places on the page.
- Don't create submenus of context menus. Submenus are hard to use and aren't touch-friendly.
- Limit the number of menu items to five.

Code migration - Mouse double-click logic

2/18/2021 • 3 minutes to read • Edit Online

In Finance and Operations, the **mouseDblClick()** override has been deprecated, and you will need to move this logic to new controls.

In Microsoft Dynamics AX 2012, the mouse double-click event was used for various reasons. For example, it helped provide a better user experience and provided an alternative way to run certain scenarios. Here are some examples of common usage patterns:

- Moving elements between two lists or tree controls
- Opening a new form to get more details about the selected field
- Running complex business logic
- Selecting a field in a lookup

Strategy overview

Before you begin to use the form, it's a good idea to fix all best practice warning messages that state, "The mouseDblClick control method has been deprecated and should not be used." Otherwise, the form might be useless, or it might work only in limited ways.

Migrate code from mouseDblClick() methods

As we mentioned earlier, there were various reasons for using the **mouseDblClick()** method in Dynamics AX 2012. This section explains how to migrate some of the most common scenarios.

Moving items between two lists controls

In Dynamics AX 2012, a mouse double-click was often used in List Panel scenarios, where two list controls appeared side by side. Often, when a user double-clicked an item in one list control, that item was moved to the second list control. Migration of this **mouseDblClick()** scenario involves alignment to the List Panel pattern. You have two options for migrating this usage pattern:

- Use the **SysListPanel** class itself, which provides the logic and the buttons for moving items between the two list controls.
- If you can't use the **SysListPanel** class (because the lists aren't ListViews, or the class isn't appropriate for the given situation), you can manually model the controls by following the List Panel sub-pattern. This pattern includes buttons for moving items between lists, but the developer will have to add the correct logic to make these buttons work.

Opening a new form

In another common usage pattern in Dynamics AX 2012, the user double-clicked a field to open a new form that showed more detailed information about that field. You have several options for migrating this usage pattern:

- Use a single-click to open a backing form that shows more details about a field. This functionality is automatically implemented for many fields that are based on table relations, and you can implement it manually by overriding the **jumpRef()** method on a control. The preferred migration route is to move the code from **mouseDblClick()** into a **jumpRef()** override, so that the navigation will be aligned with other fields in the system.
- Model a new button on the form, and move the logic from the **mouseDblClick()** method into the button's **clicked()** method. You should use this approach only for non-input field controls (for example, a Tree

control) in which a **jumpRef()** override doesn't exist.

- Add a right-click context menu (shortcut menu) option. However, note that UX guidelines specify that the commands on context menus should **always** be available in other locations on the page. A **View details** command is automatically added to the right-click context menu for controls that have an overridden **jumpRef()** method. Therefore, this approach should be used only as an optional addition to the previous migration route (modeling a new button). For more information about how to add context menu options, see Code migration - Context menu code.

Moving logic to a button control

In another common usage pattern in Dynamics AX 2012, the double-click caused complex business logic to run. For this scenario, the preferred migration route is to model a new button on the form, and then move the logic from **mouseDblClick()** into the new button's **clicked()** method.

Selecting a field in a lookup

In some custom lookups in Dynamics AX 2012, code was added so that the user could double-click a row in a grid (or an element in a tree) to select the value and close the lookup. For this scenario, the recommended migration route is to add a **Select** button at the bottom of the lookup form to enable record selection.

UX guidelines

As you migrate mouse double-click methods, you should consider the following guidelines:

- To move items between controls, use the **SysListPanel** class or the ListPanel pattern whenever possible.
- When you add buttons to replace mouse double-click logic, put the button as close as possible (contextually) to the control.
- In some cases, you might have to redesign the form to accommodate the logic that was present in the **mouseDblClick()** method.

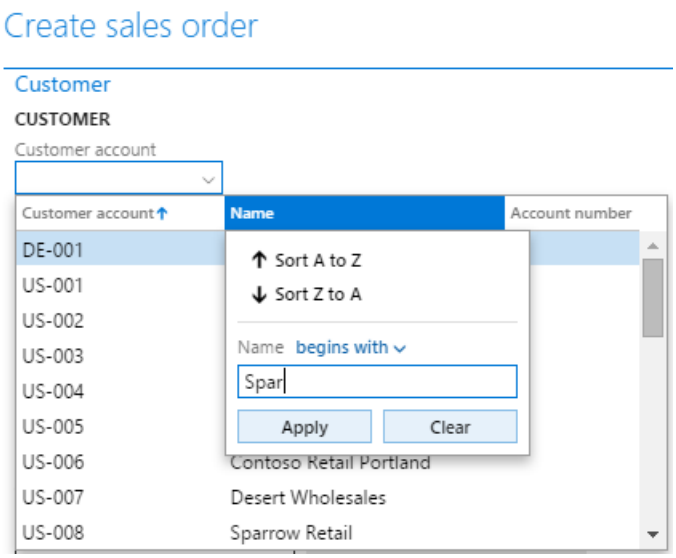
Contextual data entry for lookups

2/18/2021 • 14 minutes to read • Edit Online

In data entry scenarios, it is common for a user to attempt to identify an entity in terms of some more descriptive or natural language attribute if that entity is formally identified by a synthetic key, such as a number sequence. The contextual data entry feature allows users to type in either the synthetic key or a more descriptive attribute directly into a lookup field. This page explains how contextual data entry works and also provides implementation details and tips for developers who want their lookups to have this behavior.

Introduction

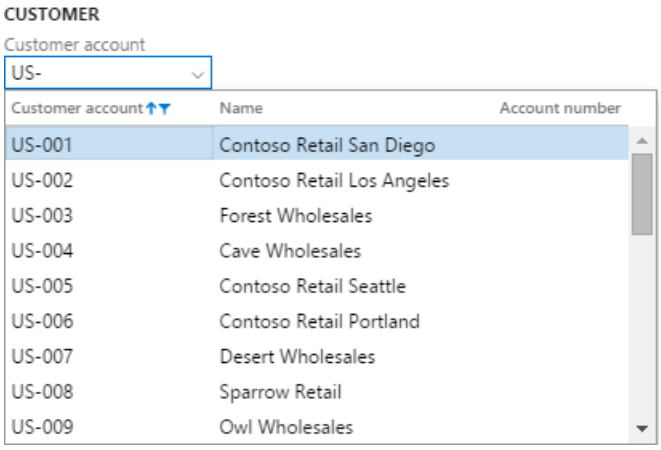
In data entry scenarios, it is common for a user to attempt to identify an entity in terms of some more descriptive or natural language attribute if that entity is formally identified by a synthetic key, such as a number sequence. A user will typically attempt to enter an **Account Name** instead of an **Account ID** for the **Customer Account** when creating a Sales Order. This is because most interaction with a customer is done using their actual name instead of some synthetic identifier. Unfortunately, any user's attempt to enter an **Account Name** will fail because the **Customer account** control's underlying foreign key relates to a field that is a synthetic key —a number sequence—and Dynamics AX 2012 (and older) will always attempt to validate the entered value directly. Therefore, if the **Account ID** was unknown to the user, the user would be forced to perform some type of searching step, such as opening the **Customer account** control's lookup and filtering on the **Account Name** column to identify the correct **Account ID** (see the image below).



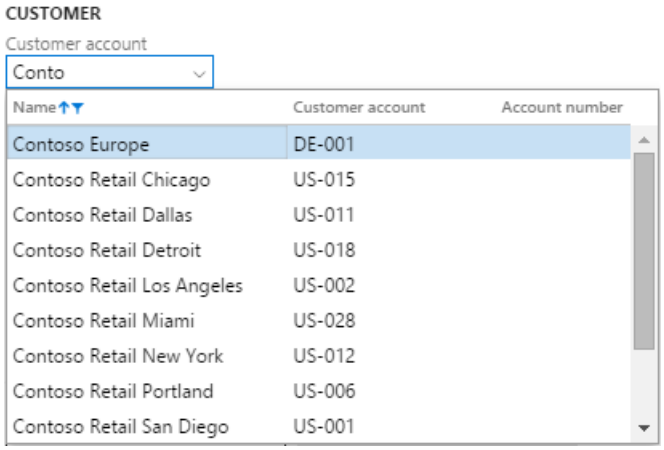
This user experience is not optimal and is being addressed by data entry efficiency and productivity. The platform adds initial support for contextual data entry, where the system automatically attempts to understand whether the user's entered data is in the context of the key field or some other more descriptive or well-understood field, and handle it appropriately. **For the remainder of this document, we'll generically refer to these types of fields as ID (synthetic) and NAME (descriptive) fields, respectively.**

Contextual lookup forms

Just like keyboard data entry, all system-generated lookup forms are also now contextual, meaning that filtering and sorting occur in the context of the data the user has entered. Using the create a Sales Order scenario as an example, the user will see the lookup shown below if an ID is entered.



If a NAME is entered, then the user will see the following lookup. Notice how the NAME column is moved first in the Grid, and how the lookup is sorted and filtered upon when the user's data is in the context of NAME.



Contextual data entry implementation details

Behavior

In the context of the Sales order create scenario mentioned above, the contextual data entry feature will allow the user to be able to freely type in either the ID or NAME without performing any laborious search process. In detail, the following behaviors will occur:

1. If the user enters a complete ID reference, the value will be taken directly.
2. If the user enters a complete and unique NAME reference, the value will be automatically translated into an ID and then processed.
3. If the user enters a non-complete ID or NAME reference (such as *Micro* instead of *Microsoft*), but it still uniquely matches either ID or NAME via a BEGINS WITH predicate, then the value will be translated into its complete ID and then processed.
4. If the user enters a non-complete ID or a non-unique NAME and there are multiple matches, then a *disambiguation* lookup will be presented to the user to select which value was actually intended.

See Appendix A for more detailed sample scenarios of contextual data entry.

Prerequisites

To maintain functional correctness and reasonable performance, the following constraints were added to the application of the behaviors described in the previous section:

1. **Title Field 2** is the NAME field**.
2. The NAME field must either be covered by an index ***OR*** belong to a Table whose *Cache Lookup* property is set to *EntireTable*. All contextual lookup behavior will be disabled if this requirement is not met for performance reasons. **NOTE: An index should only be added for NON TRANSACTIONAL tables**

because of index maintenance costs. Also note that you will **likely want to mark this index as non-unique** (Allow Duplicates = Yes).

3. If a control is using a custom lookup form (such as SysTableLookup; FormHelp on an EDT) then the disambiguation behavior described previously will not be turned on by default. This is because these custom lookup forms (and even surrounding modified and lookup method overrides) can and will do advanced things such as presenting a dialog, which are not desirable in the context of contextual lookups.

Handling custom lookup forms requires additional knowledge and will be covered in its own section.

Programming model additions

The behaviors and rules expressed in *Listings 1* and *2* are contained primarily by a new X++ class called *FormControlAmbiguousReferenceResolver*. *FormControlAmbiguousReferenceResolver* uptake in application code will be necessary in more advanced scenarios. Its use will be described later in the document. In addition to the *FormControlAmbiguousReferenceResolver* class, a new control override called *resolveAmbiguousReference* has been added. R*esolveAmbiguousReference* acts as a hook point in the system for translating what the user typed into a value that the system is expecting. The basic flow is as follows:

1. The user enters a value into a control and removes focus.
2. An interaction is sent from the client to the server, indicating that a new value has been entered. The appropriate command is executed on the server.
3. Before the command attempts to process the value entered by the user, it makes a call to *resolveAmbiguousReference* to give the system a chance to translate the value into the expected domain.
4. The super implementation of resolveAmbiguousReference creates an instance of *FormControlAmbiguousReferenceResolver* which executes the rules described above.

The value returned from *resolveAmbiguousReference* is used for the remainder of the command's execution. Validate() and modified() operate against the returned value.

Standard lookup uptake

Add an index that covers TitleField2

TitleField2 defines the default definition of NAME. In order to enable ID and NAME contextual data entry, *TitleField2* must be either indexed OR belong to a table with *CacheLookup* set to *EntireTable*. If the table containing *TitleField2* does not yet define an index covering *TitleField2* **and, importantly, the table does not have a high volume of CUD (Creates/Updates/Deletes*)**, then add a **non-unique** index (Allow Duplicates = Yes) covering *TitleField2*. This will cause the system to start executing the contextual data entry behavior, except for the custom lookup limitation described in the Prerequisites section. *Adding an index on high-volume transactional tables may incur a noticeable performance penalty due to index maintenance costs.

Enable disambiguation behavior for custom lookup scenarios

Custom lookup implementations can provide advanced or non-typical behaviors, such as presenting dialogs. Therefore, the system disables the default disambiguation behavior when a custom lookup scenario is detected. To opt into the default disambiguation behavior, override the *resolveAmbiguousReference* method (as shown below) **on the control hosting the lookup**. Note that the second parameter to the *resolveAmbiguousReferenceForControl* call is what overrides the default behavior of not performing disambiguation for custom lookup scenarios.

```
public str resolveAmbiguousReference()
{
    FormControlAmbiguousReferenceResolver::resolveAmbiguousReferenceForControl (this, true);
}
```

Make custom lookup forms contextual

As mentioned earlier, all system-generated lookup forms automatically consider the context of the data entered into their host control. This includes most lookup forms generated via *SysTableLookup*. Modeled custom lookup forms, by their nature, cannot be fully-handled by the system and must be modified to match the behavior and visuals of contextual lookups forms.

1. If the data contained by the host control is in the context of ID, then:
    a. Make the ID column first in the Grid.
    b. Sort and filter by ID.
2. If the data contained by the host control is in the context of NAME, then:
    a. Make the NAME column first in the Grid,
    b. Sort and filter by NAME,

The following scenarios illustrate some custom lookups, along with the recommendation for how to enable contextual data entry in these cases.

Scenario 1: Custom lookup defined via the FormHelp property on an EDT

Custom lookups defined via FormHelp (even though modeled) still go through normal kernel-based lookup generation routines. Therefore, the kernel still has hooks to make some changes to the lookup form. Specifically, the lookup system has enough information to apply the correct filters and sorts; however, it is NOT known which controls should be moved in the lookup's grid. (While an educated guess could be made based on bindings, that guess may be incorrect in more advanced lookup form designs.) If your custom lookup form is leveraging the `SysTableLookup::filterLookupPreRun` and `SysTableLookup::filterLookupPostRun` methods, then uptake the (new) optional parameters on `filterLookupPostRun` to have the NAME control moved automatically, as shown.

```
public class MyCustomLookupForm extends FormRun
{
    public void run()
    {
        FormStringControl lookupHostControl = SysTableLookup::getCallerStringControl(this.args());
        boolean isFiltered = SysTableLookup::filterLookupPreRun(lookupHostControl, ID_Control,
FormDataSourceToFilter);

        super();

        SysTableLookup::filterLookupPostRun(isFiltered, lookupHostControl.text(), ID_Control,
FormDataSourceToFilter,
            new FormControlAmbiguousReferenceResolver(callingControl), NAME_Control);
    }
}
```

If your lookup form isn't using the *SysTableLookup::filterLookup** methods, and you don't want to uptake those methods, then you can simply add a control move as shown below.

```
public class MyCustomLookupForm extends FormRun
{
    public void init()
    {
        super();
        this.applyControlOrdering();
    }

    private void applyControlOrdering()
    {
        FormControl callerControl = SysTableLookup::getCallerControl(this.args());
        if (FormControlAmbiguousReferenceResolver::isControlValueMappedToAlternativeField(callerControl))
        {
            Grid.moveControl(ID_Control.id(), NAME_control.id());
        }
        else
        {
            Grid.moveControl(NAME_Control.id(), ID_Control.id());
        }
    }
}
```

Scenario 2: Override of lookup method manually launching a form

Unlike Scenario 1, lookup forms launched by completely manual mechanisms, such as the class factory, have no kernel hooks. Therefore, it is the responsibility of the lookup form to adhere to the contextual data entry behaviors. The easiest way to do this is to leverage the SysTableLookup::filterLookup* methods (similar to Scenario 1) except include one additional parameter to indicate that sorting should also be maintained. An example is shown below.

```
public class MyCustomLookupForm extends FormRun
{
    public void run()
    {
        FormStringControl lookupHostControl = SysTableLookup::getCallerStringControl(this.args());
        boolean isFiltered = SysTableLookup::filterLookupPreRun(lookupHostControl, ID_Control,
FormDataSourceToFilter);

        super();

        SysTableLookup::filterLookupPostRun(isFiltered, lookupHostControl.text(), ID_Control,
FormDataSourceToFilter,
            new FormControlAmbiguousReferenceResolver(callingControl), NAME_Control, true);
    }
}
```

Advanced lookup uptake

Scenario 1: Overriding ID and NAME bindings

If you want to use a set of fields other than what is chosen by default, you must manually construct an instance of *FormControlAmbiguousReferenceResolver* and provide the optional parameters representing the custom bindings. This specialized instance must be used in an override of *resolveAmbiguousReference* and in a custom lookup form (including *SysTableLookup*, which also accepts an instance of *FormControlAmbiguousReferenceResolver*). A custom binding cannot currently be specified in kernel-generated lookups. Methods currently accepting custom ID and NAME bindings:

1. FormControlAmbiguousReferenceResolver
    - Constructor
    - resolveAmbiguousReferenceForControl

- surrogateFKHelperForAlternativeFieldMapping
- isControlValueMappedToAlternativeField

Here's an end-to-end example of how to provide custom bindings.

```
[Control Hosting Lookup]
public str resolveAmbiguousReference()
{
    return FormControlAmbiguousReferenceResolver::resolveAmbiguousReferenceForControl(
        this, true, AbsoluteFieldBinding::construct(IDField, Table),
        AbsoluteFieldBinding::construct(SomeOtherNAMEField, Table));
}

[Custom Lookup Form]
public class MyCustomLookupForm extends FormRun
{
    public void run()
    {
        FormStringControl lookupHostControl = SysTableLookup::getCallerStringControl(this.args());
        boolean isFiltered = SysTableLookup::filterLookupPreRun(lookupHostControl, ID_Control,
FormDataSourceToFilter);

        super();

        SysTableLookup::filterLookupPostRun(isFiltered, lookupHostControl.text(), ID_Control,
FormDataSourceToFilter,
            new FormControlAmbiguousReferenceResolver(callingControl,
AbsoluteFieldBinding::construct(IDField, Table),
            AbsoluteFieldBinding::construct(SomeOtherNAMEField, Table)), NAME_Control, true);
    }
}
```

Scenario 2: Custom resolution logic

It’s possible to use custom resolution logic by overriding resolveAmbiguousReference and leveraging something other than FormControlAmbiguousReferenceResolver. Note that this logic needs to be common to the hosted lookup form so that keyboard and lookup-based entry stay in sync.

```
public str resolveAmbiguousReference()
{
    // In this sample, allow “looser” data entry by simply picking the first record that matches, if any.
    CLI_Job _job;
    str mappedValue = this.text();
    if (strLen(mappedValue) > 0)
    {
        select firstonly _job order by _job.Title where _job.Title like mappedValue + “*”;
    }

    if (_job.RecId)
    {
        mappedValue = _job.Title;
    }

    return mappedValue;
}
```

Appendix Detailed usage scenarios for contextual data entry

For the scenarios, assume there is a table called "TableA" with PK field "ID" and index field "Name", with the FK we're trying to enter that is related to the ID (the user ultimately needs to pick an ID). Note that any algorithms that depend on like/begins with are assuming string fields. We won't be able to provide high fidelity resolution behavior on, for example, integral types.

Scenario 1: User enters a valid ID of "1234" The super() implementation of resolveReference first queries against TableA.ID with the appropriate predicate. The query finds a single record, and returns the user's entered value to be further processed by validate and modified. Validation passes and the user sees "1234" in the UI.

Scenario 2: User enters an invalid ID of "4321" The super() implementation of resolveReference first queries against TableA.ID. The query does not find any records, so a second query is performed against the Name field (SELECT TOP 2 FROM TableA WHERE TableA.Name LIKE "4321%"). Still, no record is found, so "4321" is passed through to validation, which fails. The user sees "4321" in the browser as well as a validation error.

Scenario 3: User enters a valid Name of "ACME" The super() implementation of resolveReference first queries against TableA.ID. The query does not find any records, so a second query is performed against the Name field (SELECT TOP 2 FROM TableA WHERE TableA.Name LIKE "ACME%"). This query does find a single record (unique reference), so the lookup automatically returns the corresponding TableA.ID. Validate and modified continue executing in the context of that value. Validation passes, and ultimately the user sees the ID value for ACME in the browser (for example, ACME would switch to 1234 in the browser).

Scenario 4: User enters an invalid Name of "ACNE" The super() implementation of resolveReference first queries against TableA.ID. The query does not find any records, so a second query is performed against the Name field (SELECT TOP 2 FROM TableA WHERE TableA.Name LIKE "ACNE%"). This query does not find any records, so the lookup passes ACNE through to validation, which fails. The user sees "ACNE" in the browser as well as a validation error.

Scenario 5: User enters an ambiguous Name of "ACME" In this case, assume there are two records in the database: one with Name "ACME W" and another with "ACME E". The super() implementation of resolveReference first queries against TableA.ID. The query does not find any records, so a second query is performed against the Name field (SELECT TOP 2 FROM TableA WHERE TableA.Name LIKE "ACME%"). This query finds two records, so it cannot make any further assumptions. A disambiguation lookup is presented to the user showing "ACME W" and "ACME E" as choices. The user picks "ACME E". resolveReference then takes the records selected by the user and redirects it to the ID of "ACME E". Validate and modified continue execution in the context of the ID of "ACME E". The browser ultimately displays the ID of "ACME E" (for example, 1234).

Scenario 6: User enters an ambiguous Name of "ACME" and doesn't make a choice in the disambiguation lookup In this case, assume there are two records in the database: one with Name "ACME W" and another with "ACME E". The super() implementation of resolveReference first queries against TableA.ID. The query does not find any records, so a second query is performed against the Name field (SELECT TOP 2 FROM TableA WHERE TableA.Name LIKE "ACME%"). This query finds two records, so it cannot make any further assumptions. A disambiguation lookup is presented to the user showing "ACME W" and "ACME E" as choices. The user doesn't make a selection from the lookup. Therefore "ACME" is passed through to validate and modified. Validation fails and the user is presented with a validation failure message. The browser still displays a value of "ACME".

Scenario 7: User enters a "valid" ID of "12" and presents the lookup form Prior to presenting the lookup, the system queries against TableA.ID (SELECT TOP 1 FROM TableA WHERE TableA.ID LIKE '12%'). The query finds a record and therefore assumes the user must be operating in the context of ID. It presents the lookup, filtering and sorting by ID.

Scenario 8: User enters an invalid ID of "4321" and presents the lookup form Prior to presenting the lookup, the system queries against TableA.ID (SELECT TOP 1 FROM TableA WHERE TableA.ID LIKE '4321%'). The query does not find a matching record and therefore assumes the user is entering a Name. The lookup is presented as filtered and sorted by Name (no records shown in this case).

Scenario 9: User enters a "valid" Name of "AC" and presents the lookup form Prior to presenting the lookup, the system queries against TableA.ID (SELECT TOP 1 FROM TableA WHERE TableA.ID LIKE 'AC%'). The query does not find a matching record and therefore assumes the user is entering a Name. The lookup is presented as filtered (those records matching "begins with AC") and sorted by Name in alphabetical order.

Scenario 10: User enters an invalid Name of "EM" and presents the lookup form Prior to presenting the lookup, the system queries against TableA.ID (SELECT TOP 1 FROM TableA WHERE TableA.ID LIKE 'EM%'). The query does not find a matching record and therefore assumes the user is entering a Name. The lookup is presented as filtered and sorted by Name. No records are found and therefore the user is presented with an empty lookup.

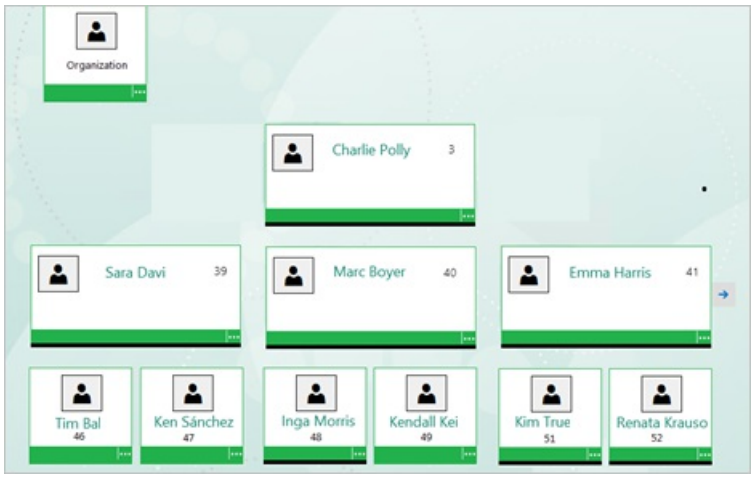
HierarchyViewer control

2/18/2021 • 3 minutes to read • Edit Online

This article provides information about the HierarchyViewer control, which lets you represent hierarchical relationships for people, products, or organizations.

Overview

The HierarchyViewer control lets you represent hierarchical relationships for people, products, or organizations. It's used primarily as a graphical means to help you understand hierarchical relationships in a traditional top-down manner, and as way to navigate to the entity that is represented by the focused node. The HierarchyViewer control lets you walk through deeply nested, multilevel content in a compact space. The control expands and collapses nodes to control the parts of the tree structure that are shown. Because it's an unbound control, the HierarchyViewer data is managed by an abstraction class and is used primarily as a way to visualize data in a simple tree relationship. For hierarchy data in a traditional tree, there is a standard tree control.



The HierarchyViewer control shows, at most, three levels on a single branch at any time. A breadcrumb trail shows the path of parents down the current tree branch. The top level shows the current top node and will always have one member. This member isn't necessarily the root. The second level, the child node, can have an indefinite number of member nodes. By default, three of these member nodes are shown on each page. The number of member nodes that is shown can be set by using the **Number of children** property. The control will page right and left through the members of the child level. The last level, the grandchild node, can have an indefinite number of member nodes. The number of visible member nodes is controlled by the **Number of Grandchildren** property. The HierarchyViewer control will page up and down through members of the grandchild level. The interactive display of nodes requires no business logic.

Business logic interaction

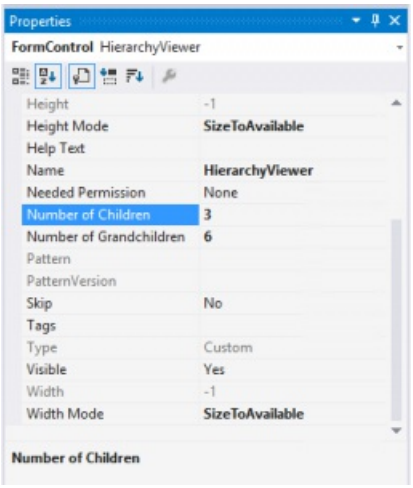
The HierarchyViewer control offers data visualization and navigation. The HierarchyViewer control is a read-only control. It can be used to select an entity (employee, product, or organization), and corresponding data can then be managed though other display and input fields on the form, outside the HierarchyViewer control. This is accomplished by a selection event that is raised on each user focus on each node.

```
public void init(){
    …
    // HierarchyViewer is the auto-declared name for the control.
    // handleNodeSelected is your event handler.
    HierarchyViewer.notfiyNodeSelected += eventhandler(element.handleNodeSelected);
}
public void handeNodeSelected(int _nodeId)
{
    // do something
}
```

Authoring a HierarchyViewer instance

To create a HierarchyViewer instance:

1. In the form designer, add an instance of HierarchyViewer to your form.
2. In the **Properties** pane, accept the default number of visible children and grandchildren, or set new values.



The HierarchyViewer control is primarily a visually interactive way of navigating or interrogating nodes in a static manner. The HierarchyViewer control isn't bound to a data source. Instead, the control is managed by a corresponding controller class that extends the base **HierarcyDesignerBase**. You initialize that class with data, and bind to the control instance and the visible fields of the HierarchyViewer node.

A typical use of the control is to initialize a server-side “in-memory” map of the hierarchy and then dynamically update the control as the user interactively explores the hierarchy by using load-on-demand semantics.

```
public void init()
{
    HcmPositionNode node;
    nodeMap = new Map(Types::Int64, Types::Class);
    hierarchyMap = new Map(Types::Int64, Types::Int64);
    firstNodeId = 0;
    // Initialize the organization node
    node = HcmPositionNode::newParameters(this.getNextNodeId(), HcmPositionNodeType::Enterprise, -1, 0,
"@SYS317690", "");
    rootNode = node;
    if (selectedNode == null)
    {
        selectedNode = rootNode;
    }
    this.insertNewNodeAndUpdateParent(node);
}
```

Override the **applyBuild** method of the control. This is where you will pass the instance of your controller class.

```
    public void applyBuild()
{
    super();
    YourControllerClass controller = new YourControllerClass();
    this.initControl(controller);
}
```

You don’t have to populate the whole node structure. Instead, you can populate nodes on demand.

```
public void initHcmPositionFromCurrentNode(HcmPosition _hcmPosition)
protected void insertNewNodeAndLoadDescendants(HcmPositionNode _node, int _depth, HcmPositionNode
_parentNode = null, Common _common = null)
protected void loadNodeDescendants(HcmPositionNode _node, int _depth, Common _common = null)
```

Changing node visuals

You can't change node visuals. The intended design is for the control to offer a set of unbound controls that have a default layout that you can manipulate by using an **ExtendedStyle** property to offer a predefined set of alternatives that the author can select.

Lookup controls

2/18/2021 • 3 minutes to read • Edit Online

This article discusses how to enable lookup behavior on controls. It also discusses how to create multi-select lookups and outlines lookup scenarios that are no longer supported.

Enabling lookup behavior in controls

Controls bound to an Extended Data Type

Controls with their Extended Data Type property set (no FormDataSource in play) will have a lookup under the following conditions:

1. If the EDT has its Table Relations or Table References node populated.
2. If the FormHelp property is set (custom lookup); doesn't require rule #1 to be true.
3. If the control has lookup or lookupReference overridden. Note, this rule also applies to fully unbound controls (no EDT, field, or data method). This includes overrides via registerOverrideMethod and others.

Controls bound to a form data source

Controls that are bound to a data source will have a lookup under the following conditions: **Field bound**

1. "lookup" or "lookupReference" (Reference Controls) methods are overridden.
    a. If the FormDataSource field has lookup or lookupReference overridden.
    b. If the control has lookup or lookupReference overridden.
        - This includes overrides via registerOverrideMethod and others.
2. If the field has an EDT, then rule #2 from the "Controls bound to an Extended Data Type" section applies.
3. If the bound field maps to a relation per DBFGetRef rules.
    a. High level rules:
        a. If there is an EDT relation backing the field, with the Table Relations node populated and Ignore EDT Relations is false on the field, the relation is used (has a lookup).
        b. If there is a relation mapping to the field and any fixed field link conditions are satisfied, the relation is used (has a lookup).
            a. Validate must be "Yes".
        c. Note the special case of migrated EDT relations which occur when:
            a. Field is backed by an EDT with the Relations node populated.
            b. Field is backed by a TABLE relation with the "EDTRelation" set to Yes.
            c. The table relation link has the SourceEDT set to the appropriate EDT.
        d. You can also have cases where IgnoreEDTRelation is set to true on a field, in which case a lookup will occur only if rule #3.1.2 of this section is true.

Data method bound

1. If the return type of the data method is an EDT, then rules #1 and #2 from the "Controls bound to an Extended Data Type" section apply.
2. If the control has lookup or lookupReference overridden.
    - This includes overrides by using registerOverrideMethod.

Multiselect lookups

Available system forms for building multi-select lookups

There are currently two system forms for creating multi-select lookups:

- SysLookup – Multiselect based on an Enum.
- SysLookupMultiselectGrid – Multiselect based on a collection of data.

What happened to the SysLookupMultiselect form?

SysLookupMultiselect was marked for deprecation in Microsoft Dynamics AX 2012 and has been removed. Any use of this form for multiselect lookup scenarios should be migrated to use SysLookupMultiselectGrid. For an example, see the form tutorial_LookupMultiSelectGrid.

Unsupported lookup scenarios

Creating multiple lookup forms when the lookup button is used

An error may occur if you create multiple lookup forms when the lookup button is used. For example, overriding the 'lookup' method and creating a new lookup form, but also calling 'super' (which will create another lookup form).

Using SelectedControl() to determine which control is hosting a lookup

Using SelectedControl() to determine which control is hosting a lookup is unsupported. While it may work in some cases, it will fail in others. For example, in disambiguation lookups, no control is selected on the parent form since the act of leaving the control is what triggers a disambiguation lookup. As an alternative to using SelectedControl(), there are a few other ways to retrieve the control that is hosting the lookup:

- Check the 'selectTarget' of the lookup form.

```
FormStringControl selectTarget = formRun.selectTarget();
```

- Check the 'callerFormControl' on the lookup form args. Note that SysTableLookup::getCallerControl(Args args) encapsulates that call.

```
FormStringControl argsCallerFormControl = args.callerFormControl();
```

Note that the selectTarget and callerFormControl will be set automatically if the lookup form instance is spun up automatically by the kernel. If the form instance is created in app code, these can be set manually as shown below.

```
public void lookup()
{
    Args args = new Args(formStr(<formName>));
    args.caller(element);
    args.callerFormControl(this);
    FormRun formRun = classfactory.formRunClass(args);
    formRun.init();
    this.performFormLookup(formRun);
}
```

Creating a slider dialog (instead of a lookup form) when the lookup button is used

Lookup controls should open lookup forms when the lookup button is used (not slider dialogs or other kinds of forms). The first reason for this is product consistency. The second and more important reason is that opening a slider dialog from a lookup is incompatible with the new type-ahead feature in lookups.

The survey will take about seven minutes. No personal data is collected (privacy statement).

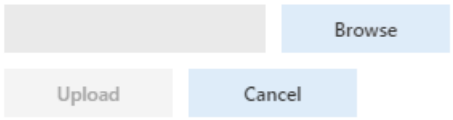
File upload control

2/18/2021 • 4 minutes to read • Edit Online

This topic provides information about the file upload control. This control lets users upload files.

Overview

The file upload control lets users upload a file. It also lets developers control the upload process and manage the file that is uploaded, based on their requirements.



The file upload control can have three styles. You control the style by using the **Style** property.

- The **Standard** style shows the file name field together with **Browse**, **Upload**, and **Cancel** buttons.
- The **Minimal** style shows only the **Browse** button.
- The **MinimalWithFileName** style shows the file name field and the **Browse** button.

The **FileTypesAccepted** property of the file upload control lets you limit the types of files that users can upload. The file types that users can upload are primarily controlled by the associated upload strategy. The **FileTypesAccepted** property on the file upload control should be used only if further restrictions are required. If the upload control tries to specify file types that are restricted by the upload strategy, the **Browse** button becomes unavailable.

ALLOWED FILE TYPES	ALLOWED FILE TYPES FROM THE UPLOAD STRATEGY	FINAL RESULT
".jpg,.png"	".jpg,.png,.gif,.txt"	".jpg,.png"
"image/png"	"image/*"	"image/png"
"image/*"	"image/png"	The **Browse** button is unavailable.
".jpg,.png,.gif,.txt"	".jpg,.png"	The **Browse** button is unavailable.

You can use the **OnBrowseButtonClicked**, **OnUploadAttemptStarted**, and **OnUploadCompleted** overrides to hook into the various stages of the file upload process. You can also create custom file upload strategies and associate them with a file upload control by using the **FileUpload Strategy Class** property.

Design classes

There are two base classes that developers can work with for the file upload control:

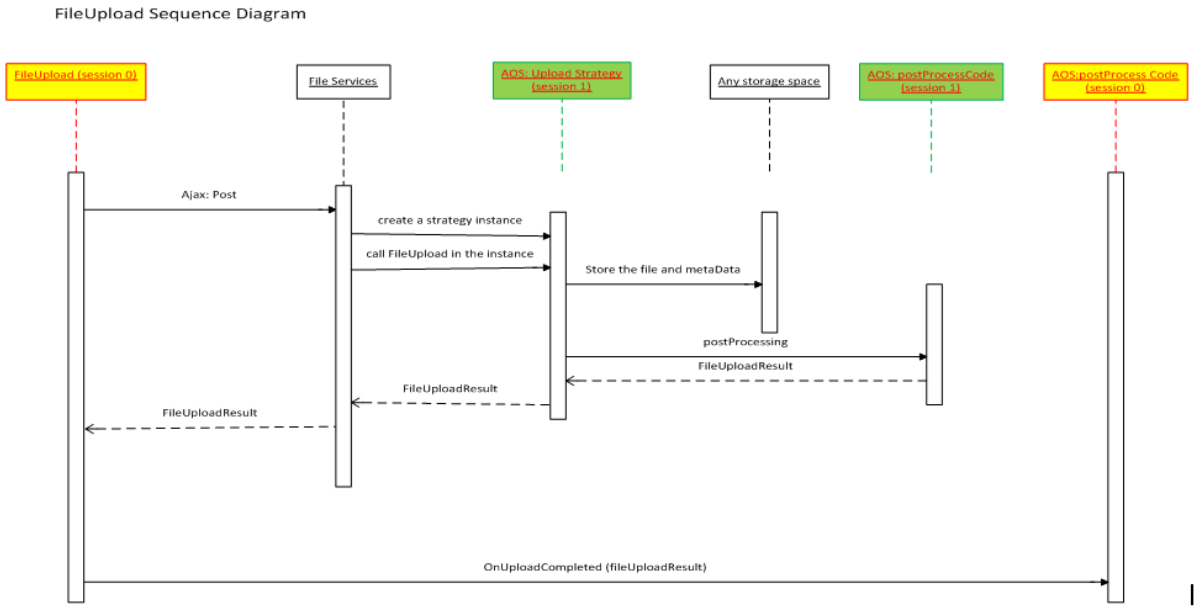
- **Upload strategy class** – This base class lets developers control various parameters that should be enforced for uploaded files, such as the types of files that a user can upload and the maximum size of a file. It also lets developers determine where and how the uploaded file should be stored. All derived classes used for upload strategies must inherit from the abstract **FileUploadStrategyBase** class.
- **Upload result class** – This base class lets developers access the details of a file that was uploaded by a user,

such as its name, content type, and upload status. It also lets developers open and delete the corresponding file. All derived classes used for specializing upload results must inherit from the abstract **FileUploadResultBase** class.

The framework provides a default upload strategy class that is named **FileUploadTemporaryStorageStrategy** and a default upload result class that is named **FileUploadTemporaryStorageResult**. This upload result class stores uploaded files to the temporary blob storage and provides a download URL. Developers can also implement their own custom upload strategy and upload result classes as required. For the upload strategy, two abstract methods from the **FileUploadStrategyBase** class must be implemented: **uploadFile** and **getResultClassName**. The **uploadFile** method handles where and how the file is stored. The **getResultClassName** method retrieves the upload result class that is used in this strategy. The **FileUploadResultBase** class has fields for the file name, the upload status, the content type of the file, and the log message. This class can be extended as required. All new properties should be able to be serialized and deserialized. The **openResult** method opens the file as a stream, and the **deleteResult** method deletes the file from the corresponding data storage.

Sequence diagram

The file upload control accepts the file and upload strategy in the client, and sends them to the file services. The file services start a new session, create an instance of a strategy class, and call the **uploadFile** method. When the **uploadFile** method has finished storing the file in the data source, a file upload result class returns to the file services. This class is sent back to the client, which might trigger the **OnUploadCompleted** event to deal with the post-process.



Scanning uploaded files for viruses and malicious code

Before you upload a file into the system, you might want to scan it for viruses or malicious code. Therefore, in version 10.0.12 and later, an extension point is available so that customers can integrate the file scanning software of their choice into the file upload process. Similar extension points are also available for scanning attachments. For more information about those extension points, see Configure document management.

IMPORTANT

Out of the box, Finance and Operations apps don't scan files for viruses and malicious code, and we don't recommend specific software for file scanning. Instead, customers are responsible for choosing their own file scanning software, and for adding the appropriate code to the delegate handlers so that they can use the software or service of their choice to scan files.

In particular, the **FileUploadResultBase** class exposes the **delegateScanStream()** delegate. This delegate applies to any file upload scenario where the **Upload strategy class** has been specialized. The upload process will fail if the scanning service determines that the file is malicious.

Implementation details

The following example of the **ScanDocuments** class shows boilerplate code for the handler. For general information about how to implement handlers for delegates, see EventHandlerResult classes in request or response scenarios.

```
    public final class ScanDocuments
    {

        [SubscribesTo(classStr(FileUploadResultBase), staticDelegateStr(FileUploadResultBase,
delegateScanStream))]
        public static void FileUploadResultBase_delegateScanStream(System.IO.Stream _stream,
EventHandlerRejectResult _validationResult)
        {
            if (!ScanDocuments::scanStream(_stream))
            {
                _validationResult.reject();
            }
        }

        private static boolean scanStream(System.IO.Stream _stream)
        {
            /*
            Custom implementation required for connecting to a scanning service
            If document scanning process found an issue, return false; otherwise, return true;
            */
            return true;
        }
    }
```

The survey will take about seven minutes. No personal data is collected (privacy statement).

System-defined buttons

2/18/2021 • 10 minutes to read • Edit Online

This topic describes the system-defined buttons.

Overview

Several system-defined buttons are automatically present on the Action Pane. In general, these system-defined buttons should be applicable and should kept available to the end user. However, in rare cases (for example, if a more specialized control is required, or if a system-defined button isn't useful or applicable for a particular form), developers might have to explicitly suppress or override a system-defined button. For example, in some situations, a MenuButton that lets the user select from multiple "New" options might be preferable to the system-defined **New** button.

List of system-defined buttons

The following tables give the full list of system-defined buttons. The tables also provide information that will be useful if these buttons must be conditionally or completely suppressed or overridden.

Common buttons

BUTTON	BUTTON NAME MACRO*	COMMENTS
Export		Don't suppress this button.
Attach	#SystemDefinedAttachButton	Don't suppress this button, because we will suppress it on forms that aren't set up for attachments.
Show filters	#SystemDefinedShowFiltersButton	By default, **Visible**=**No** on TOC forms.

* System-defined button name macros are found in the SysSystemDefinedButtons macro file.

Buttons that are specific to Details forms

These buttons are an integral part of the Details form experience. Therefore, it's very unlikely that you'll have to suppress these buttons.

BUTTON	BUTTON NAME MACRO*	COMMENTS
Change view	#SystemDefinedShowMenuButton	This button exists under the **Options** Action Pane tab.
Grid view	#SystemDefinedGridViewButton	
Details view	#SystemDefinedDetailsViewButton	
Line details view	#SystemDefinedLineDetailsViewButton	
Header details view	#SystemDefinedHeaderDetailsViewButton	

BUTTON	BUTTON NAME MACRO*	COMMENTS
Show list	#SystemDefinedShowListButton	

* System-defined button name macros are found in the SysSystemDefinedButtons macro file.

Form styles that have no system-defined buttons

For several form styles, it doesn't make sense to add system-defined buttons, primarily because these forms don't have standard Action Panes. The following form styles never receive system-defined buttons:

- Dashboard
- Dialog
- DropDialog
- FormPart
- Lookup
- Sitemap
- Wizard

Suppressing most or all of the system-defined buttons

If you find that you're suppressing most or all of the system-defined buttons on a form, you should reexamine your form style (**Form.Design.Style**) or pattern, and reconsider the purpose of the form. Should the form be a dialog instead? (By default, dialogs don't receive any system-defined buttons.) Often, forms that are in this situation have **Style**=**Auto** and would be more appropriate as dialogs. If your form should not technically be a dialog, there is no currently no metadata or code that can automatically suppress all the system-defined buttons at the same time. Unless you switch the form to a form style that doesn't receive any system-defined buttons, you must to suppress/override each button individually (see the other sections in this article). This scenario should be extremely rare.

New and Delete system buttons

The **New** and **Delete** buttons are currently added by the kernel, and are controlled via special metadata properties. These buttons always work on the first master data source on the form.

When are these buttons available by default?

Forms usually have system-defined **New** and **Delete** buttons. These buttons appear on a form under the following conditions:

- The form has a style that allows for system-defined buttons.
- There is at least one data source on the form.

How do I affect the visibility of the New and Delete buttons on a form, but still allow the standard New and Delete tasks to fire via keyboard shortcuts?

Use the **ShowNewButton** and **ShowDeleteButton** properties on **Form.Design** to control the visibility of the **New** and **Delete** buttons on a form. Note that if the data sources still let the user create and delete records, the keyboard shortcuts will continue to work even if the system buttons aren't visible.

PROPERTY	VALUE	DESCRIPTION
Form.Design.ShowNewButton	No	Suppress the system-defined **New** button on the form.

PROPERTY	VALUE	DESCRIPTION
Form.Design.ShowDeleteButton	No	Suppress the system-defined **Delete** button on the form.

How do I affect the state (enabled/disabled) of the New and Delete buttons, and the associated task behavior on a form?

To affect both the state of the **New** and **Delete** buttons and the associated task behavior on a form, use the **AllowCreate** and **AllowDelete** properties on the first master data source. Additionally, the associated keyboard shortcuts will have no effect if you use this approach to disable the **New** and **Delete** buttons.

PROPERTY	VALUE	DESCRIPTION
Form.Datasources.<FirstMasterDatasource>.AllowCreate	No	The form doesn't allow record creation. The form has a disabled system-defined **New** button.
Form.Datasources.<FirstMasterDatasource>.AllowCreate	Yes	The form allows record creation. The form has an enabled system-defined **New** button (if it's visible).
Form.Datasources.<FirstMasterDatasource>.AllowDelete	No	The form doesn't allow record deletion. The form has a disabled system-defined **Delete** button.
Form.Datasources.<FirstMasterDatasource>.AllowDelete	Yes	The form allows record deletion. The form has an enabled system-defined **Delete** button (if it's visible).

> **NOTE**
> If the form has a New record action, that button control overrides the enabled state of the system-defined **New** button.

How do I change the behavior of the New task (either by clicking the button or by using the keyboard shortcut)?

There are three mechanisms for changing the behavior of the New task:

- Use the **New Record Action** property. This property is currently available only on **Form.Design**, and the referenced action will be triggered for **all** CommandButtons that call the **New** command on the form, even CommandButtons that are bound to secondary collections. In the future, the **New Record Action** property will be placed on all container controls to provide better control over the property's scope. Note that, currently, the **New Record Action** property also can't be defined as a Menu Button or Drop Dialog Button.

PROPERTY	VALUE	DESCRIPTION
Form.Design.NewRecordAction	The control name from the form	This property overrides the New task to perform the specified action.

- (Recommended) Use eventing. In particular, there are pre-events and post-events for record creation and deletion, where you can put code that is meant to run before and after these actions. See the following code example.

```
[Form]
public class Form1 extends FormRun
{
    public void init()
    {
        super();
        element.dataHelper().RecordCreating += eventhandler(this.PreRecordCreate);
        element.dataHelper().RecordCreated  += eventhandler(this.PostRecordCreate);
        // similar methods exist for deletion:
        // element.dataHelper().RecordDeleting, element.dataHelper().RecordDeleted
        //
        // explicit actions can be triggered via:
        // element.dataHelper().RecordCreate(), element.dataHelper().RecordDelete()
    }
    public void PreRecordCreate(FormRunServiceArgs _cancellableArgs)
    {
        //  I can add my logic here that gets invoked before the global creation task
        // if I need to, I can cancel the "super" of the task by doing:
        // _cancellableArgs.cancel()
    }
    public void PostRecordCreate()
    {
        //  I can add my logic here that gets invoked after the global creation task
    }
}
```

- Create an override on the **create()** or **delete()** method on the corresponding data source.

How do I change the behavior of the New button (but not the task)?

Imagine that you want to replace the system-defined **New** button with a menu button that lets the user select among several "New" options. Therefore, you complete the following tasks:

1. Hide the system-defined **New** button.
2. Model your own button for the New action.

However, at this point, the system-behavior for New still fires when the keyboard shortcut is invoked. If you want to make this modeled **New** button fire when the keyboard shortcut is pressed, you must set this button as the NewRecordAction on **Form.Design**. As we noted in the previous section, the action will currently be fired for all CommandButtons that call the New task on the form. Therefore, you should not use this approach on forms that have multiple data sources.

Edit, Done, Save, and Restore system buttons

The **Edit**, **Done**, **Save**, and **Restore** buttons let users switch the edit mode of the form as they require. Because this capability is critical, these buttons can't currently be suppressed. However, if a form should always be in **Edit** mode or should always be in **View** mode, you can use the **ViewEditMode** property to achieve that effect, and the buttons won't appear on the form. Note that most forms should be left as **ViewEditMode=Auto**. Don't set **ViewEditMode=View** or **ViewEditMode=Edit** for purely cosmetic reasons, but only if the form will always be read-only or will always be editable.

FORM.DESIGN.VIEWEDITMODE	FORM BEHAVIOR	SYSTEM-DEFINED BUTTON BEHAVIOR
View	The form is always in **View** mode.	None of these buttons (**Edit**, **Done**, **Save**, and **Restore**) are shown, because the framework assumes that they aren't needed.

FORM.DESIGN.VIEWEDITMODE	FORM BEHAVIOR	SYSTEM-DEFINED BUTTON BEHAVIOR
Edit	The form is always in **Edit** mode.	Only the **Save** and **Revert** buttons are shown, because the user can't exit **Edit** mode. The **Revert** button is on the framework-provided **Options** tab.
Auto	The form can be switched between **View** mode and **Edit** mode.	In **View** mode, the **Edit** button is shown on the Action Pane. In **Edit** mode, the **Save** button is shown on the Action Pane, and the **Read mode** and **Revert** buttons are shown on the framework-provided **Options** tab.

Can I conditionally suppress or show the Edit button?

If a form is editable at some points and read-only at other points, the logic that is used to determine whether the user can edit the form can be used to set the **ViewEditMode** property at run time. When the form should be read-only, set **ViewEditMode=View**. When the form can be either edited or viewed, set **ViewEditMode=Auto**.

How do I run additional code when the Edit button is clicked?

To have additional code run when the user clicks the **Edit** button, use eventing (see the example in the "How do I change the behavior of the New task (either by clicking the button or by using the keyboard shortcut)?" section earlier in this article). Specifically, use the following events:

- To subscribe to view/edit mode switching, use these events:
  - element.viewEditModeHelper().EditModeSwitching
  - element.viewEditModeHelper().EditModeSwitche
- To query the current view/edit mode, use these events:
  - element.viewEditModeHelper().isInEditMode()
  - element.viewEditModeHelper().IsInViewMode()
- To trigger view/edit mode switching, use these events:
  - element.viewEditModeHelper().setViewEditMode(ViewEditMode::Edit)

Refresh, Popout, and Close system buttons

The **Refresh**, **Popout**, and **Close** buttons are system buttons that are located on the right side of the Action Pane. The **Refresh** button is used to refresh all data on the form. The **Popout** button is used to move the current form into a separate window. The **Close** button closes the form (essentially, this button clicks the browser's **Back** button). These system buttons are integral components and can't currently be suppressed.

Other system-defined buttons

The remaining system-defined buttons are added during **Form.Init**. They are added only if a control of the same name doesn't already exist.

How do I run additional code together with a system-defined button or change the behavior of the button?

- For view switching buttons (for example, buttons that switch to the grid view, details view, header view, or lines view), you should override the **pageActivated()** method on the individual TabPage.
- For system-defined buttons that have pre-eventing/post-eventing (for example, **New**, **Delete**, and **Edit**), you can subscribe to the appropriate events. See the corresponding sections for **New**/**Delete** and **Edit** buttons for information about specific events for those buttons.

- For system-defined buttons that don't call a task directly (for example, **SystemDefinedShowMenuButton** and **SystemDefinedShowListButton**), you can register an override on the button through a **registerOverrideMethod()** call to have additional code run when the system-defined button is clicked.

```
public void overrideFunction(FormCommandButtonControl _command)
    {
        // Put any pre-super code here
        // This serves as the call to super()
        _command.clicked();
        // Put any post-super code here
    }
```

How do I suppress any of these system-defined buttons on a form, but without suppressing any corresponding task?

In general, we don't recommend that you suppress any of the system buttons. Their presence provides consistency to actions on forms. However, the buttons currently appear in some situations where they aren't as useful. We have future work items to address many of these situations. For example, have work items for the following tasks:

- Suppress the **Attach** button on forms that aren't configured to allow attachments.
- Suppress the **Export** button on forms that have no grids.
- Suppress the **Show filters** button on forms that don't have a main grid.

However, if you must suppress one of these buttons (strongly discouraged), you can find the control via code and set its visibility to **false**, as shown in the following code example. Use SysSystemDefinedButtons macros, where they are available, to reference the button names.

```
FormCommandButtonControl attachButton;

    public void init()
    {
        #SysSystemDefinedButtons

        super();

        attachButton= this.control(this.controlId(#SystemDefinedAttachButton)) as FormCommandButtonControl;
        attachButton.visible(false);
    }
```

Images on a page or in a grid

2/18/2021 • 13 minutes to read • Edit Online

This topic describes the steps for displaying images on a page or in a grid. The topic also provides background about some of the ways that images can be used, and the APIs that are used.

> **NOTE**
> For accessibility, when you use an image to indicate status or show data, the image must be accompanied by a tooltip, enhanced preview, label, or other textual representation that describes the value or status that the image represents.

Finance and Operation apps do not use embedded resources for images. Instead, it uses lightweight symbols. The coding pattern has changed slightly to support the new image control.

For ImageList uses, the runtime accepts the old **ImageID** value and maps it to a symbol, so that existing code continues to work.

> **NOTE**
> In some cases, there is no image even after runtime mapping, and this behavior is intentional.

AX 2012 displays images in a grid column to indicate status. These images were sometimes retrieved from embedded resources that are no longer available.

AX 2012 offers the following storage options for images:

- An embedded resource where images are offered as part of the kernel itself
- An Application Object Server (AOS) resource where developers or independent software vendors (ISVs) can add their own image resources
- A file location where developers or ISVs can load images at run time
- A database field that is stored as a bitmap

The following storage options are available for images:

- An AOS resource where developers or ISVs can add their own image resources
- A URL location where developers or ISVs can load images at run time
- A database field that is stored as a container.
- A symbol font, where images are rendered by name from the font

Images that are stored as AOS resources allow for the use of an image that isn't categorized as user data, and can be used with your application.

> **NOTE**
> If there are legacy embedded resource images that UX has approved for use, those embedded images can be manually transferred to an AOS resource and used.

A typical web application maintains a collection of images on an Internet Information Services (IIS) server and just provides a URL to the image. Although this approach is supported, we don't expect that it will be used very much. Instead, we expect that the symbol font will be used as an image source.

Of course, application logic will store an image in a database to allow for strong employee photos, product images, and so on, and this approach is a first-class experience.

A symbol font is the most performant and scalable image format. We expect that characters from the symbol font will be used for most application use cases (grid row by row status, button images, and so on).

For the list of symbols that are available in the symbol font, see Symbol font.

Image type: Symbol

PROS	CONS
• Usually, the symbol font is the smallest payload to send to the client. • You can easily customize the images by using Cascading Style Sheets (CSS). • The symbol font should already be cached on the user's computer. Therefore, no extra bandwidth is used, and there are no additional network requests that might slow down page loads. • Colors can be controlled by themes. • The images are automatically scaled on high-DPI displays.	A limited number of framework-defined symbols is available.

Design time

Image location: Symbol **Typical image:** "Person"

Run time

Sometimes, you don't have an image for a particular record in a grid, but you don't want an empty space where the image should be. The following example shows how you can use a display method to check for an image value, and then substitute a placeholder image instead.

```
public display container customerImage()
{
    ImageReference imgRef;
    container imgContainer = this.Image;
    if(imgContainer == connull())
    {
        // there is no image… the container is null
        // show a generic person outline image
        imgRef = ImageReference::constructForSymbol("Person");
        imgContainer = imgRef.pack();
    }
    return imgContainer;
}
```

Image type: AOT Resource

PROS	CONS
In addition to the pros of using URL images (see the next section), AOT resources are modeled and managed by the development tools.	A limited number of framework-defined images is available.

Design time

| You just create a new resource and then save the image into the Application Object Tree (AOT) resource. When

you model your image control on a page, you specify the resource name, not the image name. This approach is typically used for legacy images (icons) that don't have equivalents in the symbol font. **Image location:** AOTResource **Typical image:** "ResourceMicrosoft Dynamics AX" (a .jpg is added to resources) |

Run time

```
public display container imageDataMethod()
{
    ImageReference imgClass =
            ImageReference::constructForAotResource(
              "ResourceMicrosoft Dynamics AX");
    return imgClass.pack();
}
```

Image type: URL Image

PROS	CONS
• This approach provides an easy way to reference any image anywhere on web. • This approach supports full-color images. • The web browser can cache the image, based on the settings of the server that hosts the image.	• The transfer size isn't as small as it is for symbols, but it's reasonable. The URL is sent as a string for each control that uses the image. The browser then downloads the image from the URL, and from that point, standard browser caching rules apply. • You can't easily theme the images by using CSS. • Unless the URL points to a Scalable Vector Graphics (SVG) file, the image isn't automatically scaled on high-DPI displays.

Run time

The following example shows an image that uses a URL that is contained in a string.

```
public display container imageDataMethod()
{
ImageReference imgClass = ImageReference::constructForUrl(this.ImageURL);
return imgClass.pack();
}
```

This code sends a small JavaScript Object Notation (JSON) message to the control on the client. This message instructs the control to treat the image as a URL and let the browser do the work of downloading the image. No download occurs on the server. **Storing an image URL in a database table** You can also have a container field for the image column on your table. You can then use code that resembles the following example to store the **ImageReference** pack.

```
ImageReference imgClass;
CLIControls_ImageTable imgTable;
ttsbegin;
imgClass = ImageReference::constructForUrl(
    "http://dynamics/PublishingImages/ERPLogos/DynamicsLogo.jpg");
imgTable.ImageField = imgClass.pack();
imgTable.insert();
ttscommit;
```

This code causes the user's browser to download the image from the specified URL. The use of ImageReference involves some overhead, but this approach lets you use a single application programming interface (API) to handle images that are created from binary data, URLs, AOT resources, or symbols. You can even mix and match image types between rows of data.

Image type: Binary Image

PROS	CONS
Usually, this approach offers the easiest migration if the **Image** class in X++ was already used, or if binary images were previously stored in the database.	• This approach involves the largest transfer size, because the binary image is encoded as a string and sent to the client as part of the interaction. • The browser can't cache the images. • For a grid, the binary-encoded image is sent for every row, even if multiple rows use the same image. Therefore, this approach can lead to very large transfer sizes in the interactions. • You can't easily theme the images by using CSS. • The images aren't automatically scaled on high-DPI displays.

DESIGN TIME	RUN TIME
Using a database field This approach is typically used to display data, such as employee pictures and product images. You can bind directly to a field, or you can use a display method. Data Source Data Field Data Method	Typically, the images are loaded from database, and no additional code is required. For cases where the image is managed in a data method, see the data method examples.

Display methods and images (three return types)

When you use a display method for an image type to show an image in a grid, three return types are understood by the image control that works with the framework. All three return types can be used to display an image.

- Int (imagelist array index)
- Container (image instance)
- ResID (which is mapped to a symbol)

> **NOTE**
>
> ResID and Int are the same return types. If the **imageList** property of the image control instance has been assigned an instance value, the display method return value is considered an array index into the imagelist. If the **imageList** property is **null**, the return value is used to map a legacy ResID to a symbol.

Images in a grid and the legacy ImageList collection

In AX 2012 and earlier versions, a common use pattern for displaying images is to store an image as a resource or use a kernel-supplied image resource, and then at run time, extract that image and place it in a reusable collection that is known as an ImageList. The guidance is to use lighter-weight symbol images. You should rewrite all legacy code so that it uses symbols directly. You should also replace all code that uses the ImageList collection. If you don't make these changes, the legacy ImageList collection won't display images, because use of this collection relies on embedded (kernel) resources that no longer exist. Therefore, to support legacy code until it can be updated, the ImageList collection maps the ResID for an embedded resource to a new font-based symbol to help guarantee that any code that uses the ImageList collection will continue to run and provide an image.

Using the imageList property for backward compatibility

An image control has a property that is named **imageList**. You pass in an instance of the ImageList collection to this property. In this way, the image is an array of images that you select via the array number.

```
public void init()
{
    int imgCnt;

    // create an imagelist instance
    Imagelist imageList = new ImageList(ImageList::smallIconWidth(), Imagelist::smallIconHeight());

    super();

    // add images to the instance (return value is not needed)
    // Note that a legacy ResID is used in the new Image contstructor.
    // This is a compatibility mapping of resource to symbol.
    imgCnt = imagelist.add(new Image(#ImageInfo));
    imgCnt = imagelist.add(new Image(#ImageWarning));
    imgCnt = imagelist.add(new Image(#ImageError));

    // pass the image list instance to the control
    ImageListDM.imageList(imageList);
}

// at runtime, select the image you want to show: when the control has an imagelist instance,
// this int value is used to index into that array
public display int imageListDataMethod()
{
    int imgCnt = imageCnt mod 3;
    imageCnt++;
    return imgCnt;
}

/*
    Note: The legacy image resource ID's #ImageInfo, #ImageWarning, #ImageError are
    mapped from the legacy resource id to a symbol name in the X++
    class ImageLoader
*/
```

Display method that returns an ImageRes (legacy image resource ID)

```
// this is an example of backward compatibility the use of ImageRes will become obsolete
display ImageRes checkIfError(HRMCompEventEmpl _hrmCompEventEmpl)
{
    if (!_hrmCompEventEmpl.RecId)
    {
        return 0;
    }
    if (_hrmCompEventEmpl.Status == HRMCompEventEmplStatus::Ignore   ||
        _hrmCompEventEmpl.Status == HRMCompEventEmplStatus::Approved ||
        _hrmCompEventEmpl.Status == HRMCompEventEmplStatus::Loaded)
    {
        return 0;
    }
    else
    {
        if (_hrmCompEventEmpl.ErrorStatus == HRMCompEventErrorStatus::Error)
        {
            return #ImageError;
        }
        if (_hrmCompEventEmpl.ErrorStatus == HRMCompEventErrorStatus::Warning)
        {
            return #ImageWarning;
        }
        if (_hrmCompEventEmpl.ErrorStatus == HRMCompEventErrorStatus::Info)
        {
            return #ImageInfo;
        }
    }
    return 0;
}
```

Display method that returns a container

```
public display container checkIfError(HRMCompEventEmpl _hrmCompEventEmpl)
{
    ImageReference  imageReference;
    container       imageContainer;
    if (_hrmCompEventEmpl.RecId && _hrmCompEventEmpl.Status == HRMCompEventEmplStatus::Created)
    {
        switch (_hrmCompEventEmpl.ErrorStatus)
        {
            case HRMCompEventErrorStatus::Error:
                imageReference = ImageReference::constructForSymbol('Error');
                break;
            case HRMCompEventErrorStatus::Warning:
                imageReference = ImageReference::constructForSymbol('Warning');
                break;
            case HRMCompEventErrorStatus::Info:
                imageReference = ImageReference::constructForSymbol('Info');
                break;
        }
    }
    if (imageReference)
    {
        imageContainer = imageReference.pack();
    }
    return imageContainer;
}
```

Obtaining and displaying an image from the user by using file upload

Model a page that has an image control and a **FileUpload** button.

```
// model a new FileUpload control (style=minimal)
// class declaration
FileUpload uploadControl;

// form init() create a callback event handler to be notified when upload is complete
public void init()
{
    //when uploading an image, this method is called upon completion.
    uploadControl = FileUpload1;
    uploadControl.notifyUploadCompleted +=  eventhandler(this.UploadCompleted);
}

// form close() release the callback event handler
public void close()
{
    // when the form closes, release the eventhandler for file upload callback
    //  FileUpload uploadControl;
    super();
    //  uploadControl = FileUpload1;
    uploadControl.notifyUploadCompleted -=  eventhandler(this.UploadCompleted);
}

// when the upload completes, grab the image and store it in the database
/// <summary>
/// This method is called by the file upload mechanism, when the upload completes
/// </summary>
public void UploadCompleted()
{
    Binary binaryImage;
    System.Net.WebClient webClient;
    System.IO.MemoryStream stream;
    String255 myUrl;
    if(uploadControl.uploadSuccess())
    {
        InteropPermission perm = new InteropPermission(InteropKind::ClrInterop);
        perm.assert();

        // BP Deviation Documented
        webClient = new System.Net.WebClient();

        // BP Deviation Documented
        // if success, downloadURL contains the path to the Azure blob location for the file
        stream = new System.IO.MemoryStream(webClient.DownloadData(uploadControl.downloadUrl()));

        // grab the data and assign to the image field
        binaryImage = Binary::constructFromMemoryStream(stream);

        // assign to the database field (type=container)
        FMVehicleModel.Image = binaryImage.getContainer();

        CodeAccessPermission::revertAssert();
    }
}
```

Example of in-memory bitmap manipulation

In this example, an image is created from scratch. However, developers can also load a bitmap from an alternative source and then manipulate the image as desired (for example, by cropping, stretching, or resizing, or by changing the opacity). After any manipulation is completed, the developers can display the image by using the image control, or they can assign it to a data source field.

```
public void clicked()
{
    Binary binaryImage;
    Image  image;
    int x,y;

    super();

    InteropPermission perm = new InteropPermission(InteropKind::ClrInterop);
    perm.assert();

    /*
    In this example, we'll create a bitmap programmatically, we'll use a memory
    Stream o'bytes to then convert to the container format the image control expects.
    */
    System.Drawing.Bitmap bitmap = new System.Drawing.Bitmap(100,100);
    System.IO.MemoryStream myStream = new System.IO.MemoryStream();

    // draw some stuff (or load a bitmap from an alternative source)
    for( x=0; x < bitmap.Height; ++x)
    {
        for( y=0; y< bitmap.Width; ++y)
        {
            bitmap.SetPixel(x,y,System.Drawing.Color::White);
        }
    }

    for(x=0; x < bitmap.Height; ++x)
    {
        bitmap.SetPixel(x,x, System.Drawing.Color::Red);
    }

    // move our bitmap to an in memory stream
    bitmap.Save(myStream, System.Drawing.Imaging.ImageFormat::Bmp);

    // stream goes to raw binary
    binaryImage = Binary::constructFromMemoryStream(myStream);

    // create a blank image and copy our binary data to the image format
    image = new Image();
    image.setData(binaryImage.getContainer());

    // copy the image data to the image control
    MyImage.image(image);

    // alternatively, skip the image conversion step and assign directly to the data field
    binaryImage = Binary::constructFromMemoryStream(myStream);

    // assign to the database field (type=container)
    datafield.Image = binaryImage.getContainer();

    CodeAccessPermission::revertAssert();
}
```

Additional examples (URL, binary, and symbol)

The following table explains two concepts: Image Class and FormImageControl.

Image Class	This class is a run-time representation of an image.	Four constructors: • Image::ConstructBinary(INT64Encode); • Image::ConstructSymbol(SymbolName); • Image::ConstructURL(URL); • Image::Construct(ResourceName);
FormImageControl	This control is used to add an image at run time.	.image(new image());

Using a display method to show an image from a URL string

In this example, a display method is used to translate a string that contains a URL to the format that the image control expects.

```
public display container imageDataMethod()
{
    ImageReference imgClass = ImageReference::constructForUrl(this.ImageURL);
    return imgClass.pack();
}
```

This code sends a small JSON message to the control on the client. This message instructs the control to treat the image as a URL and let the browser do the work of downloading the image. No download occurs on the server.

Using a display method to show a blank image

There might be times when you have no image for a particular record in a grid, but you don't want an empty space where the image should be. This example shows how you can use a display method to check for an image value and then substitute a placeholder image instead.

```
public display container customerImage()
{
    ImageReference imgRef;
    container imgContainer = this.Image;
    if(imgContainer == connull())  // there is no image… the container is null
    {
        imgRef = ImageReference::constructForSymbol("Person");  // show a generic person outline image
        imgContainer = imgRef.pack();
    }
    return imgContainer;
}
public display container statusImageDataMethod()
{
    ImageReference statusImage;
    if (this.Status == NoYes::Yes)
    {
        statusImage = ImageReference::constructForSymbol("Accept");
    }
    else
    {
        statusImage = ImageReference::constructForSymbol("Cancel");
    }
    return statusImage.pack();
}
```

Taking an image URL and storing the image in table

You can have a container field for the image column on your table. You can then use code that resembles the following example to store the **ImageReference** pack.

```
ImageReference imgClass;
CLIControls_ImageTable imgTable;
ttsbegin;
imgClass = ImageReference::constructForUrl(
    "http://dynamics/PublishingImages/ERPLogos/DynamicsLogo.jpg");
imgTable.ImageField = imgClass.pack();
imgTable.insert();
ttscommit;
```

Like the display method that is described in the "Using a display method to show an image from a URL string" section, this code causes the user's browser to download the image from the specified URL. Although this approach involves some overhead, you can use a single API to handle images that are created from binary data, URLs, AOT resources, or symbols. You can even mix and match image types between rows of data.

Font and background colors for input, table, and grid controls

2/18/2021 • 3 minutes to read • Edit Online

This topic provides information about the new color picker control that lets users select a color.

Traditionally, color has been considered an ideal way to communicate with a user. For example, the color red is often used to draw the user's attention to information that is important. However, some users can't distinguish certain colors or shades, and some users are blind. Therefore, we don't recommend that you use color alone to communicate information to the user. Instead, you should use color together with a symbol or additional text to convey information to all users.

Color selection in Dynamics AX 2012

In Microsoft Dynamics AX 2012, color selection had these characteristics:

- It used the Win32 color picker.
- It required Win32 application programming interfaces (APIs) for RGB/decimal conversion. (The input control accepted a decimal value for RGB.)

```
Public void lookup()
{
    #DEFINE.COLORVALUE(64)
    Int r,g,b
    container choosencolor;
    Binary customcolors = new Binary(#COLORVALUE);
    CCColor colorvalue;

    Super();

    [r,g,b] = WinAPI::RGBint2Con(this.backgroundColor());

    chosenColor = WinAPI::chooseColor(element.hWnd(),r,g,b, customColors, true);

    If(chosencolor)
    {
        [r, g, b] = chosencolor;
        Colorvalue = WinAPI::RGB2int(r,g,b);
        This.backgroundColor(colorValue);
        employeeWorkPlannerForm.parmAbsensceColor(colorvalue);
        Employeetable.columns(employeeworkplannerform.numberofcolumns());
        Absenscecolorparm = colorvalue;
    }
}
```

Color selection for input controls

In the current version, the color picker control is a standard control type. The color picker control can be put directly in a form, or it can be used as part of a custom lookup for an integer or string control. The following example shows how to interact with the color picker control in a custom lookup. However, the code is similar if you put the color picker in a form and provide the user with a button to select a color.

- A color picker control can be hosted in a form or a custom lookup to let the user visually pick a color or specify an RGB value.

- The return value is a decimal value that can be assigned directly to an input control property. (No run-time RGB conversion is required.)

```
[Control("String")]
class stringControl
{
    /// <summary>
    ///
    /// </summary>

    public void lookup()
    {
        int color = hex2Int(this.valueStr());
        color = ColorSelection::selectColorStringControl(this, color);
        this.text(int2hex(color));
        this.backgroundColor(color);
    }
}

[Control("Integer")]
class integerControl
{
    /// <summary>
    ///
    /// </summary>
    public void lookup()
    {
        int color = this.value();
        color = ColorSelection::selectColor(this, color);
        this.value(color);
        this.backgroundColor(color);
    }
}
```

Using color in a table control

There is no design-time experience for coloring input controls. In other words, you can't model an input control so that it's "blue" by default. However, there are run-time capabilities that let you change color values. The following example shows how you can change the way that the cells of a table control are colored.

```
public FormControl editControl(int column, int row)
{
    stringEdit.colorScheme(FormColorScheme::RGB);
    stringEdit.backgroundColor(WinAPI::RGB2int(225,225,125));
    stringEdit.foregroundColor(WinAPI::RGB2int(8,10,200));
}
```

	Column1	Column2	Column3	Column4	Column5	Column6
ROW1	Text 1	Text 2	Text 3	Text 4	Text 5	
ROW2	Text 2	4	Text 6	8	Text 10	✓
ROW3	Text 3	6	Text 9	12	Text 15	
ROW4	Text 4	8	Text 12	16	Text 20	✓
ROW5	Text 5	10	Text 15	20	Text 25	

Using color in a grid control

```
public void displayOption(Common _record, FormRowDisplayOption _options)
{
    CLIParentTable table;
    table = _record;

    if(!cleared)
    {
        _options.affectedElementsByControl(CliParentTable_AInt.id());
        _options.affectedElementsByControl(CliParentTable_AEnum.id());
        _options.affectedElementsByControl(CliParentTable_AString.id());
        _options.affectedElementsByControl(CliParentTable_EditMethodString.id());

        if(table.AInt<=20)
        {
            _options.backColor(WinAPI::RGB2int(255,165,0));
        }
        else if( table.AInt>20 &&  table.AInt <60)
        {
            _options.backColor(WinAPI::RGB2int(255,255,0));
            _options.fontItalic(true);
            _options.textColor(WinAPI::RGB2int(255,0,127 ));
            _options.fontStrikethrough(true);
        }
        else
        {
            _options.backColor(WinAPI::RGB2int(128,0,128));
                _options.fontUnderline(true);
        }
    }

    super(_record, _options);
}
```

Static RGB instead of run-time conversion from integer to RGB values

Previously, run-time conversion that used **WinAPI::RGB2Int** was required, because the Win32 color picker returned an RGB value, whereas the background color APIs accepted an integer. This run-time conversion isn't required, because the new color picker returns an integer to match the control's consumption of an integer. Additionally, it's understood that .NET code often uses RGB values for colors. Therefore, in those cases, run-time conversion of colors isn't required for each use. Instead, you can define static color variables. Here are three examples.

```
Static int GrayColor = 220 + 220 <<#offset8 + 220<<offset16;

Static int GrayColor = 0xdcdcdc

Static int GrayColor = 14474460; // DCDCDC or 220,220,220
```

Right-to-left language support and bidirectional text

2/18/2021 • 12 minutes to read • Edit Online

In the area of right-to-left (RTL) language support, one consideration is the combination of RTL text and left-to-right (LTR) text in the same string. This topic discusses the issue of bidirectional text and how it's handled.

A great example of right-to-left language support: Microsoft Word

In the area of right-to-left (RTL) language support, one consideration is the combination of RTL text and left-to-right (LTR) text in the same string. One example of a program that implements this functionality correctly is Microsoft Word. If you're trying to understand the correct behavior of mixed language presentation, you can use Word for validation. The problem is that most software just implements the Unicode standard to display bidirectional data, without evaluating how that data is actually used. Additionally, there's no attempt to provide the interactive experience that the user actually requires.

To understand how Word "gets it right" and provides a great experience, you can inspect the XML of a Word document. There, you will see that Word tracks (and stores together with the run of characters) the keyboard that is used to enter each character, and that it treats each character as a member of the language that is associated with the keyboard. Therefore, the character is given the behavioral aspects of that language.

Keeping track of character orientation in a financial program that might record billions of transactions and multi-billions of characters would produce significant transnational and spatial overhead if we stored contextual information for each character. Therefore, this behavior would be considered only for special conditions.

Bidirectional text

To support Arabic and Hebrew, both of which are RTL languages, there is an RTL orientation for the controls in each form, so that an RTL reader can interact with the form in a natural reading manner. For the most part, RTL orientation of the controls works as expected and provides RTL users with the experience that they expect. Finance and Operations apps and modern browsers support RTL orientation, and Finance and Operations app conform to that functionality. However, in some cases, extensible controls (custom controls) require special code to orient their elements correctly.

A point of reference in this article is the Win32 CEdit control, which is used primarily for standard text entry (account name, description, user name, and so on, in Microsoft Dynamics AX 2012). The behavior of the HTML Input control mimics the functionality of the CEdit control. Therefore, the same behavior applies to Finance and Operations.

The CEdit control is a Win32 control that is governed by the rules for bidirectional text management that are defined by the Unicode standard. Bidirectional text occurs when the control hosts both RTL text (such as Arabic or Hebrew) and LTR text within the same string of characters.

When you evaluate the examples in this article, remember that, regardless of the orientation of the form (RTL or LTR), the actual text that is presented is never reversed or "mirrored." English text is always read LTR and Arabic/Hebrew text is always read RTL. When LTR and RTL text are combined, the reader must jump to the beginning of the run of characters in a given orientation. For example, when a mixed string is read from right to left, the individual words might be read like this:

——————> <—————— ——————> <——————

English and Arabic/Hebrew text together: Bidirectional issues

The visual presentation (glyphs) of English, Arabic, and Hebrew characters on the corresponding keyboards clearly differ. However, those three keyboards also share some symbols. These symbols include numerals, and formatting characters such as parentheses, brackets, and underscores. According to the Unicode bidirectional algorithm, when these characters are used in a bidirectional string, their RTL/LTR orientation depends on **the context of the characters that surround them**. From the Unicode standard:

> **NOTE**
>
> You can find the Unicode display algorithm at https://www.unicode.org/reports/tr9/. (Section 3.3.4 of the algorithm describes how to position neutrals.)

- Characters that have a weak bidirectional type determine their directionality according to their proximity to other characters that have strong directionality.
- Characters that have a neutral bidirectional type determine their directionality from either the surrounding strong text or the embedding level.

The following table describes the bidirectional character types.

CATEGORY	TYPE	DESCRIPTION	GENERAL SCOPE
Strong	L	Left-to-Right	LRM, most alphabetic, syllabic, Han ideographs, non-European or non-Arabic digits, …
Strong	LRE	Left-to-Right Embedding	LRE
Strong	LRO	Left-to-Right Override	LRO
Strong	R	Right-to-Left	RLM, Hebrew alphabet, and related punctuation
Strong	AL	Right-to-Left Arabic	Arabic, Thaana, and Syriac alphabets, most punctuation specific to those scripts, …
Strong	RLE	Right-to-Left Embedding	RLE
Strong	RLO	Right-to-Left Override	RLO
Weak	PDF	Pop Directional Format	PDF
Weak	EN	European Number	European digits, Eastern Arabic-Indic digits, …
Weak	ES	European Number Separator	Plus sign, minus sign

CATEGORY	TYPE	DESCRIPTION	GENERAL SCOPE
Weak	ET	European Number Terminator	Degree sign, currency symbols, …
Weak	AN	Arabic Number	Arabic-Indic digits, Arabic decimal and thousands separators, …
Weak	CS	Common Number Separator	Colon, comma, full stop (period), Non-breaking space, …
Weak	NSM	Nonspacing Mark	Characters marked Mn (Nonspacing_Mark) and Me (Enclosing_Mark) in the Unicode Character Database
Weak	BN	Boundary Neutral	Default ignorables, non-characters, and control characters, other than those that are explicitly given other types
Neutral	B	Paragraph Separator	Paragraph separator, appropriate Newline Functions, higher-level protocol paragraph determination
Neutral	S	Segment Separator	Tab
Neutral	WS	Whitespace	Space, figure space, line separator, form feed, General Punctuation spaces, …
Neutral	ON	Other Neutrals	All other characters, including OBJECT REPLACEMENT CHARACTER

The fundamental problem with the Unicode standard for bidirectional text is that it fails to capture the user's intent. Therefore, the algorithm will move characters around within the same string, and put them in a location that the user didn't specify or doesn't want. This issue is troublesome for accounting and financial systems, because the data that users enter into the system might not match the corresponding source documents.

As we mentioned, Arabic, English, and Hebrew keyboards share some of the same characters. However, in some cases, those characters are positioned differently, depending on the keyboard that was used to type them, and/or the context of the surrounding characters and the orientation of the input control. These language-neutral characters include commas, periods, parentheses, hyphens, and underscore characters.

In some cases, the rules for displaying the same characters varies between languages. Additionally, those rules can change, depending on the kind of data that is displayed. For more information about this issue, see the "Issue: The hyphen used together with numbers: Language-specific behavior" section, later in this article.

Some people expect that characters that are entered in RTL mode will appear the same when the form is viewed

in LTR mode. In other words, the expectation is that a customer can have some users who use Hebrew and others who use English on the same installation or in the same company.

Issue: The underscore character used together with numbers

Description: 123_456 appears as 456_123, although the user wants it to appear as 123_456.

Example: The user wants to enter an item number (such as 123_456) or a journal name (such as BA_Chk_Rev) that includes underscore characters for grouping purposes.

There is a difference between the Unicode standard and what our users want to see in a financial program. Even Word presents 123_456 as 456_123 for both Arabic and Hebrew. This behavior occurs because the underscore character is a grouping mechanism. It splits the number into groups of numbers that can be read from right to left.

Numbers are read from left to right in Arabic and Hebrew. "Item" numbers, regardless of the combination (RTL_LTR_RTL, LTR_RTL_LTR, Neutral_RTL, and so), should appear exactly the same in a paragraph of any direction or alignment. This issue isn't easy to resolve for plain text programs. All the customer knows is that the physical item number is (from left to right) 123_456, and that the string should appear as 123_456 in every language, so that the number that users see always matches what they know the physical number is.

Control behavior: None of the off-the-shelf controls provide the desired behavior. Word fails too.

WPF RICHTXT	WIN32 CEDIT	WIN32 RICHTXT	WORD
No	No	No	No

Workarounds:

- When you're using an English keyboard, use a different delimiter. For example, enter **123.456** or **123/456**.
- When you're using a Hebrew keyboard, use a different delimiter. For example, enter **123.456**. The slash character (/) on a Hebrew keyboard produces a period (.).

Recommendation: None of the off-the-shelf controls provide the requested behavior. One alternative is to identify fields that must allow for this directional formatting and flag those fields as LTR for data input (right-aligned for display purposes). The program can't automatically determine that a field must have this behavior. Therefore, if we expose an RTL/LTR flag, a customizer can modify targeted fields for the desired behavior. Although this approach enables this specific scenario, it's important to understand that, if you extend the scenario by using characters in a combination of RTL and LTR languages, you will introduce other issues. Another alternative is to educate users about the fundamental behavior when underscore characters and numbers are used together. When underscore characters and numbers are required, users can then use a workaround to obtain the desired display behavior.

> **NOTE**
> The underscore character doesn't present an issue when you combine English and RTL languages (pattern: RTL_LTR_RTL). Therefore, if you force a control to LTR when the input includes numbers/text/underscore characters, the behavior won't be as expected. Users will have to manually reposition the cursor after each use of an underscore when they type RTL text. However, the behavior will be as expected for the use of numbers/text/underscore characters.

Hebrew: קשגכ_english_יקנקרק

Arabic: شقلاهؤ_english_شقشلاهؤ

Issue: The hyphen used together with numbers: Language-specific

behavior

Description: LTR is expected for Hebrew, whereas RTL is expected for Arabic.

Example: Item names that include numbers Arabic and Hebrew treat the hyphen differently when it's used together with numbers. An Arabic keyboard treats the hyphen as an RTL character, whereas a Hebrew keyboard treats it as an LTR character. Therefore, similar typed strings should be presented differently, depending upon the keyboard that was used. Some readers will be familiar with this example from a meeting of interested parties: 1-2-3-a-b-c

Arabic: The desired behavior is correct in Dynamics AX 2012. 1-2-3-ؤ-لال-ش

Hebrew: The desired behavior is incorrect in Dynamics AX 2012. 1-2-3-ב-נ-ש

The Unicode standard doesn't provide for language-specific or keyboard-specific behavior. Instead, it supplies fundamental bidirectional behavior and treats the hyphen as an RTL character. Therefore, it presents the Arabic string correctly but the Hebrew string incorrectly.

Control behavior: The WPF RichTxt control produces the correct/desired behavior for each language.

WPF RICHTXT	WIN32 CEDIT	WIN32 RICHTXT	WORD
Yes	No	No	Yes

Workarounds for the Hebrew user:

- Don't type hyphens between the numbers. For example, if you type 1 2 3-A-B-C on a Hebrew keyboard, it appears in RTL as C-B-A-3 2 1. You should assume that the ABC order is correct for Hebrew, which is an RTL language. The English ABC text is reversed here for demonstrative purposes.
- Use a different delimiter between the numbers. For example, the slash character (/) on a Hebrew keyboard produces a period (.).

Recommendation: This pattern is an issue for Hebrew users who want to use numbers or hyphens in item names. Therefore, a global solution might not be appropriate, because there are exceptions. Phone numbers, Social Security numbers, and other source document identification numbers are always read LTR.

The WPF RichTxt control provides the desired behavior according to the strict guidance. However, it isn't clear that this behavior is always the desired behavior. That is, phone numbers, US Social Security numbers, and so on, should always be read and appear in LTR order, regardless of the language orientation. The alternative is to identify fields that must enable this behavior. The program can't automatically determine that a field must have this behavior. Therefore, you might have to use a descriptive property on the control, so that users can specify "Structured Formatting." If none of these approaches can be achieved, you must educate Hebrew users about the fundamental behavior when hyphens are used together with numbers. Users can then use one of the preceding workarounds to get the desired display behavior, by omitting the hyphens between numbers.

Hebrew example: (Desired and correct Operations for both Arabic and the Hebrew example in Hebrew)

Pattern: First (עברית) hyphen second (English) hyphen third (שלום) hyphen forth (Hello)

Correct: עברית-English-שלום-Hello

Pattern:

1. First (English letter) hyphen second (Hebrew letter) hyphen
2. First (Hebrew letter) hyphen second (English letter) hyphen

A RTL form appears as desired:

1. ש--a

2. -aש-

Exception for phone numbers: Often, Arabic users don't have to use hyphens in phone numbers, because international phone numbers rarely use hyphens to separate digits. Any fundamental changes in the behavior of hyphens (for example, if you introduce use of the WPF RichTxt control) will cause phone numbers to appear incorrectly for Arabic users.

Phone numbers are always read LTR and often include hyphens. Phone numbers sometimes appear correctly, when they are shown in a grid through a display method that presents the string as LTR.

Currently, the input of phone numbers by using numbers and hyphens produces the correct display, such as 701-225-2188.

There is an issue with phone numbers if you try to use a US pattern that includes parentheses.

Arabic/Hebrew/English (desired): (701)225-2188

Arabic (actual):)701(225-2188

Hebrew (actual):)701(225-2188

Recommendation: Expose an RTL flag for controls or an extended data type for phone numbers. A customizer can force the control into LTR mode. This approach will let users enter values in the order that they want.

Issue: LTR text combined with neutral characters in RTL input

Description: English text is combined with parentheses or other neutral characters.

Example: A company name together with the company abbreviation, such as "Dynamics (DAT)"

In a typical example, the company name is followed by the company abbreviation, which is enclosed in parentheses. In this case, "Dynamics (DAT)" is shown as "(Dynamics(DAT". This behavior occurs because the closing parenthesis isn't surrounded by two English characters. Therefore, the parenthesis is treated as an RTL character. It's changed to the RTL closing parenthesis and moved to the end of the string (in RTL orientation).

Control behavior: None of the controls provide the desired behavior.

WPF RICHTXT	WIN32 CEDIT	WIN32 RICHTXT	WORD
No	No	No	Yes

The WPF RichTxt control has a flag that tries to format text according the first character in the string. Although the algorithm **should** fix this issue, it doesn't.

Workarounds: Don't use weak or neutral characters for grouping when you use English. For example, use "Dynamics DAT".

Recommendation: None of the controls provide the desired behavior. You must educate users about the fundamental behavior when weak or neutral characters are used together with English text. Don't use weak or neutral characters unless English characters appear on each side.

Create icons for workspace tiles

2/18/2021 • 2 minutes to read • Edit Online

This topic provides guidelines and recommendations for creating and assigning icons to custom workspace tiles.

The dashboard contains a set of workspace tiles to which the user has access. Each of these tiles contains an icon specific to that workspace. For out-of-the-box workspaces provided by Microsoft, the icons used on the workspace tiles generally correspond to a symbol from the Dynamics Symbol font. This topic discusses the guidelines and recommendations for creating and assigning icons to tiles for workspaces created by Microsoft Certified Partners or individual customers.

Implementation details

For workspace icons, we recommend using an AOT resource for the icon. While the out-of-the-box symbols will work, we recommend creating your own so that multiple workspaces don't use the same icons. For each workspace that needs an icon, create a new image file that adheres to the guidelines below. Note that the recommended guidance for newer versions of the product has changed.

Modeling details

When you create a workspace tile, you need to follow these guidelines:

- Add an AOTResource for each new icon.
- On the tile corresponding to the workspace, set the following properties:
  - ImageLocation=AOTResource
  - NormalImage=<name of AOTResource>

Icon creation

Guidelines for creating images for custom workspace tiles are below. The recommended dimensions for the image and icon are based on the out-of-the-box workspace icons. While images of other sizes are allowed, the size and positioning of the icon relative to the full image should be maintained regardless of the image size.

Following these recommendations ensures that your workspace icon matches the styling and size of other workspace icons and that the content of your workspace icon does not get cropped by the CSS applied to the image.

- The image file should be a PNG file with a 1:1 aspect ratio.
- The recommended minimum image size is 50 × 50 pixels (px), where the icon is contained in a square that is centered in the image. For the minimum 50 × 50 px image size, the icon should be contained in a **30 × 30 px** square in the center of the image.

  > **NOTE**
  >
  > The crispness of out-of-box workspace icons and custom workspace icons might differ at different zoom levels. The reason for this difference is that images in PNG format have a fixed resolution, whereas out-of-box workspace icons are font glyphs that scale smoothly. For better resolution at different zoom levels, consider creating larger images with the same relative dimensions. For example, create 200 × 200 px or 400 × 400 px images.

- The icon should have a **white background with transparent content**.

- The framework will set a default background color for the transparent portions of your image so that it will match the current user theme.

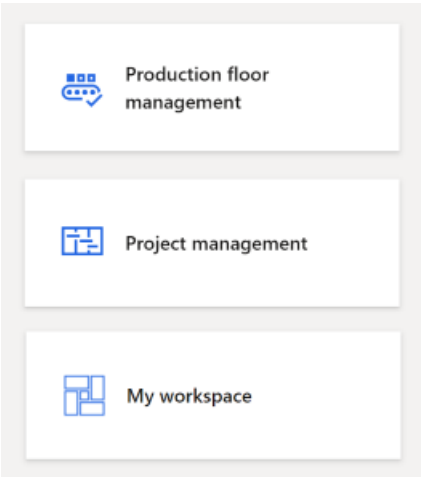
Example

Consider the following image/icon that is to be used for a new workspace.

This icon would be converted to an image with a **white background and transparent content** with the icon centered in a larger image canvas as shown.

To understand how this relates to the sizing recommendations, here is the workspace icon image overload with the new sizing recommendations.

Using this image on a workspace tile yields the following result on the dashboard.



NOTE

Can you tell us about your documentation language preferences? Take a short survey.

The survey will take about seven minutes. No personal data is collected (privacy statement).

Public JavaScript APIs for extensible controls

2/18/2021 • 2 minutes to read • Edit Online

This topic shows where to find documentation about the public JavaScript APIs that can be used by extensible controls.

To minimize future breaks in extensible controls, an effort has been made to differentiate between the public and non-public JavaScript application programming interfaces (APIs) available to extensible controls. Control authors should ensure they only use public APIs, as **any non-public API may be removed or modified in a future release**. One of the planned modifications is to prefix the names of the non-public APIs with underscores to clearly denote access level. Documentation for the full set of public APIs can be found in Extensible Controls - Public JavaScript APIs.

Control checklist

2/18/2021 • 14 minutes to read • Edit Online

This article categorizes and describes all the release criteria for controls.

Introduction

Typically, when you author a new control, the primary focus is on scenario functionality and technical implementation. However, before a control can be considered ready for shipment, it should conform to a set of best practice, quality, and development release criteria, as outlined in this article.

Control criteria checklist

This checklist assumes that you're familiar with the basics of control development. The following items highlight important implementation requirements that should be met by all controls.

Basic usage ready

A control must meet these requirements to be considered a functionally compatible and complete control.

Classes

These naming conventions are best practices but aren't functional requirements of a control:

- The Runtime class is named **[Name of control]Control**.
- The Design-time class is named **Build[Name of control]Control**.
- Any control-specific Component classes are named **[Name of control][Name of component]Component**.
- Any generic Component classes are named **Build[Name of component]Component**.

Resources

These naming conventions are best practices but aren't functional requirements of a control:

- The HTML Resource is named **[Name of control]HTM**, and the physical file is named **[Name of control].htm**.
- The JavaScript Resource is named **[Name of control]JS**, and the physical file is named **[Name of control].js**.

X++ Runtime

These items apply to the "Runtime" X++ class.

- FormControlAttribute is supplied with the build class name.
- The FormControlAttribute is supplied with the template ID.
- FormControlAttribute is supplied with the resource bundle path.
- The **FormTemplateControl** class is extended (directly or through inheritance).
- A FormProperty exists for each change-tracked property (that is, each property that must be read in the client JavaScript).
- The **New** method initializes each FormProperty instance.
- The **setTemplateId** and **setResourceBundleName** inherited methods are called with the same values that are supplied in the FormControlAttribute.
- The **ApplyBuild** method is used to interpret any design-time properties, and to apply design-time properties to the run-time properties as appropriate for the control.

- A Property getter/setter method exists for each FormProperty.
- A FormPropertyAttribute is supplied on each FormProperty's getter/setter method.
- **Anytype** is used as the argument type for FormProperties that have **FormPropertyKind::BindableValue**.
- All FormProperties are specified as **ReadOnly** to the JS class, via the third argument to the FormPropertyAttribute.
  - This argument affects only the read/write behavior that is seen by JavaScript, not by X++.
  - We don't recommend that you allow JavaScript to write directly to properties, because every property state change should be validated. We recommend that you use FormCommands for this purpose, instead of writeable properties.
- FormCommands that allow the state of FormProperties to be changed must validate that the control is in a valid state to allow for the property change.
  - Controls that are disabled, read-only, invisible, and so on, should prevent inappropriate state changes.

X++ Design time

These items apply to the "Design/Build" X++ class:

- The FormDesignControlAttribute is supplied with the control common name, **[Name of control]**, without "Control" appended at the end.
  - The name that is supplied here will appear in Microsoft Visual Studio when the control is added to a form.
- A backing field exists for each design-time property.
- A Property getter/setter exists for each design-time property.
- A FormDesignPropertyAttribute is supplied to each design-time property.
- No code outside of the Design property getters/setters should exist in this class. (In other words, there should be no **new()** methods, and so on.)

HTML

These items apply to the .htm file, which is also referred to as the resource bundle:

- External resources, such as scripts, style sheets, and other HTM files, are loaded by using HTML standard <script> and <link> tags.
- All external resource loading tags are placed above the outermost HTML element in the file, so that they are loaded and processed first.
- The template ID is supplied via the **id** attribute on the outermost HTML element.
- The visibility of the outermost HTML element is bound to the **Visible** property.
- The sizing of the outermost HTML element is bound to the sizing binding handler.
- Binding handlers are used to programmatically modify HTML. (APIs such as getElementById in the JavaScript constructor aren't used.)

JavaScript

- The whole JavaScript code is wrapped in an anonymous function.
- Localizable strings are stored in the Globalize culture info object.
- Localizable strings are also stored in a label file, according to the instructions in Create localizable labels.
- Default values are provided for all properties that aren't initialized inside the constructor.
- The JavaScript constructor is added to the control JavaScript namespace.
- A reference to **this** is stored in an object that is named **self**, and **self** is used instead of **this** throughout the constructor.
- The base JavaScript control behaviors are inherited.
- Default values are applied by using a framework utility function.
- Client-side properties are defined in the scope of the constructor and are added to **self**.
- Observable and computed properties are used only for UI-bound behaviors.

- A prototype exists and contains all static methods that are specific to the control.
- Binding handlers that are specific to the control are stored in the control's namespace (not in the global control namespace).
- The control doesn't use or load external plug-ins (Microsoft ActiveX, Flash, Java, and so on).

Interactivity

CSS/LESS

- Prefix all class names with the template ID to prevent conflicts with other controls.
- Don't use class names that are defined on other controls, because those classes can change.

Layout and resizing

- The control uses the Sizing API for its outermost element. This requirement helps guarantee that the framework can correctly size and arrange the outermost element of the control.
- For advanced layout scenarios for elements that are contained in the control, use CSS Flexible Boxes, which are supported by the HTML standard.

Browser support

- The control correctly renders and supports all intended user interaction patterns on all supported browsers:
  - Microsoft Edge/Internet Explorer 11
  - The latest version Chrome
  - The latest version of iPad/MacOS Safari

Tab sequence

- Make sure that the control meets the W3C standards for tab sequence.

Globalization

Right-to-left languages

- Full RTL support will arrive after RTW.

Localizable labels

- The control uses a label file for UI text that is used only on the client side (not used in X++). For instructions about how to create and use these labels, see Create localizable labels.

Task Recorder compatibility

- Basic recording support
  - For any control that accepts user input, or that a user can interact with, input/actions must be recordable by Task Recorder. For Task Recorder to record the input, the control must use the SysTaskRecorder X++ API to specify the properties that should be recorded.
- Basic task guide support
  - For any control that can be recorded by using Task Recorder, the control should have task guide support. This support includes verifying that the task guide pop-up prompt points to the correct UI elements of the control, based on the input/action that was recorded.
  - In addition, validate that, when the task guide is locked ("on-rails"), the user can interact with the expected parts of the control. For example, for a combo box control, the user should be able to open the drop-down box to select a value, in addition to typing the value directly.
- Advanced recording support
  - Support for Cut, Copy, Paste, and Validate can be evaluated on a per-control basis. There are JavaScript and X++ methods that controls can implement to enable these features.

Threat modeling the control

- Vulnerabilities in the logical control (X++/C++) that are related to serialization/deserialization of data types, and command/property execution, should be reviewed and fixed.
  - Serialization threats are related to the way that the control parses or interprets data types.

    - Any serializer for data types (except the built-in X++ Data Contracts and primitive type serialization) must be reviewed.
    - Any parser must be reviewed to verify that it doesn't allow for arbitrary code execution or other exploitation.
    - Any data access queries that are executed by the control (or by any helper classes that the control uses) must be evaluated and reviewed.
  - Command/property execution threats are related to the way that the logical control handles an action that the control determines to be invalid.
    - Example of a command threat: A click command is executed when the control is in a disabled state. You must make sure that the click command is handled appropriately, based on the control state.
    - Example of a property thread: A property change is executed when the control is ready-only. You must make sure that the property change is handled appropriately, based on the control state.
  - You must review the use of any .NET libraries to make sure that the .NET library is also secure.
- Vulnerabilities that are related to the client-side parts of the control (HTML, JavaScript, CSS, third-party libraries) should follow general secure web development principles. Specific examples include XSS vulnerabilities.
  - Any control that renders user data as HTML/JavaScript/CSS exposes an XSS vulnerability that must have mitigations identified.
  - Any control that renders external content in an iFrame exposes an XSS vulnerability that must have mitigations identified.
  - Any control that makes calls to third-party services must have mitigations identified and requires direct review by the client team.
  - Any control that handles authentication must have mitigations identified.

Control criteria details

This section explores the control criteria in more detail.

Basic usage ready

X++ Runtime

- **FormControlAttribute** Each control must supply the FormControlAttribute to the class declaration. The attribute must specify the build/design-time class that accompanies the control. The attribute must also specify the HTML template ID and the physical HTML file name (the resource bundle name).
- **FormTemplateControl** Each control must extend FormTemplateControl to participate in the control lifecycle.
- **FormProperty** Each control must declare FormProperties for every statically defined property that must participate in the change tracking system. For properties that are used only on the server side, no FormProperty is required.
- **New** Each control must implement the **New** method in order for its properties to participate in the change tracking system that propagates value changes between the client and server parts of the control. Inside the **New** method, each FormProperty
- **ApplyBuild** Each control must implement the **ApplyBuild** method in order for the control to be initialized based on the values that are set on it at design time. This method is primarily used to copy or transform design-time values into their Runtime equivalents. However, not all design-time properties must have Runtime equivalents, and not all Runtime properties must source their initial values from design-time properties.
- **Property getter/setter** Each control must implement property getters/setters for every FormProperty that is used by the control. These methods should be parm methods. Therefore, the names should begin with “parm” for methods that are getters/setters, “get” for methods that are only getters, and “set” for methods

that are only setters. At a minimum, a FormPropertyAttribute must be supplied to each method, together with a FormPropertyKind and the name of the property as it should be made accessible to the HTML and JavaScript in the client.

HTML

- **Template ID** Each control must provide an HTML **id** attribute on the outermost HTML element of the control's markup. In order for the control to be loaded at run time, this ID must match the ID that is supplied to the FormControlAttribute.
- **Scripts and style sheets** Each control must use HTML standard <script> and <link> tags to consume other JavaScript or CSS files. These tags should be placed at the beginning of the HTML file for the control, before the HTML definition element for the control. If the files that must be loaded have dependencies, make sure that the order of the <script> or <link> loading tags is appropriate. Tags that appear first are loaded first. To load JavaScript or CSS from AOT Resources, use a site root–relative path (/Resource/Scripts or /Resources/Styles).
- **Data binding** Each control can participate in the HTML binding framework through use of the **data-dyn-bind** attribute on HTML elements that are contained in the control. The binding attribute enables HTML element properties to be bound to observable or computed properties that are located in the current data context.

JavaScript

- **Script encapsulation** Each control must wrap all its JavaScript in an anonymous function. This requirement helps prevent the framework's global JavaScript namespace from being populated with control-specific logic.
- **Localizable strings** Each control must use the Globalization API to store any string messages that are used by the control's JavaScript. Therefore, the control's JavaScript should not hard-code any strings that are displayed in the UI. Instead, the JavaScript should reference the string messages that are stored via the Globalization API. To load strings in the globalization object in HTML and JavaScript, you can use the $dyn.label API and pass in the identifier of the label. For more information, see Create localizable labels.
- **Default values** Each control must provide default values for any properties that aren't initialized in the JavaScript. Therefore, any properties for which values are passed in to the JavaScript constructor on initialization (that is, the FormProperties in the X++ Runtime class) must provide a default-value dictionary for these properties.
- **JavaScript constructor** Each control must implement a constructor in the controls namespace. This constructor is the first line of code that will be executed when the control is loaded in the client. After the constructor is completed, the constructor's associated object, *this*, is passed in to the HTML as the default data context.
- **Inheriting base control** Each control's constructor must "inherit" from the base JavaScript control class. The base JavaScript control class contains behaviors that are required by each control.
- **Applying default values** Each control must use the provided framework function to apply the default values to the control's properties.
- **Adding client-side properties/functions** Each control can add client-side-only properties and functions to the JavaScript class, in addition to the server-side FormProperties and Commands that are passed in to the control constructor. The pattern for adding client-side-only properties/functions is to maintain a local copy of the *this* object and add the functions/properties to the local copy. After the control constructor is completed, all properties, functions, FormProperties, and Commands that have been added will be available in the HTML as the default data context.
- **Adding observable and computed properties** Each control can add client-side-only properties that participate in the observability patterns of the client. An observable property is initialized by using the $dyn.observable([initial value]) function. A computed property is initialized by using the $dyn.computed([function(){}]) function. Controls should use observable/computed properties sparingly, because these property can significantly harm performance if they are used incorrectly.
- **Control JavaScript prototype** Each control must implement a JavaScript prototype that extends the base control prototype. The prototype should contain any "static" JavaScript methods (methods that require no

references to local variables) that are used by the control.

Interactivity

Layout and resizing

- To enable the form developer to determine the control layout and size, set the width and height that are specified by the form developer on the control by using the $dyn.layout.sizing API, as shown in the following code. This is standard code that should be applied to all HTML control templates.

```
<div id="MyControl" data-dyn-bind="
sizing: $dyn.layout.sizing($data)>
</div>
```

Task Recorder recording support

Controls must use the SysTaskRecorder X++ API to indicate which actions on the control are "recordable."

- For controls that enable values to be set via properties, **SysTaskRecorder::addPropertyUserAction** should be called when the value is being set in X++. This method call tells Task Recorder to record the setting of the property.
- A similar method exists for commands (**SysTaskRecorder::addCommandUserAction**).

For more information, see Control the text that Task Recorder generates for a control.

Task Recorder playback support

- Task Recorder uses the control's properties and commands to play back the control. The control must make sure that the commands and properties that it instructs Task Recorder to record can also be executed by Task Recorder when the control is played back. Task Recorder will rely on the interactable names for the properties and commands. The interactable name for a method is the name that is specified in the FormPropertyAttribute or the FormCommandAttribute.

Task guide support

The task guide will ask the JavaScript part of the control for the DOM element that the task guide should point to. All controls inherit basic task guide support, where the default DOM element is the outermost element of the control.

- A control can provide finer-grained details about where the task guide should point by implementing the getTaskGuideParams function in the JavaScript prototype for the control. This function accepts an argument (which is frequently named **options**), and this argument has a property that is named **target**. This **target** property accepts the jQuery element that the task guide should point to.
- In addition, the argument will contain information about the action that was originally recorded for the control, such as the property/command name and any arguments. The control can react to the various properties/commands that it supports by supplying the target with the DOM element that corresponds to the property/command that the user recorded.
- For some advanced scenarios, the target can also be supplied with an observable. The control can then update this observable with various DOM elements, based on events that the control exposes. This can be done by initializing the target with the observable (which contains a DOM element), and then observing an event and updating the DOM element via code in the event handler.

Task Recorder copy/paste/validate support

For controls that need to support either Copy, Paste, or Validate (mainly for advanced X++ testing purposes), the SysTaskRecorder API exposes static methods that enable the control to inform Task Recorder when a value has been copied, pasted, or validated.

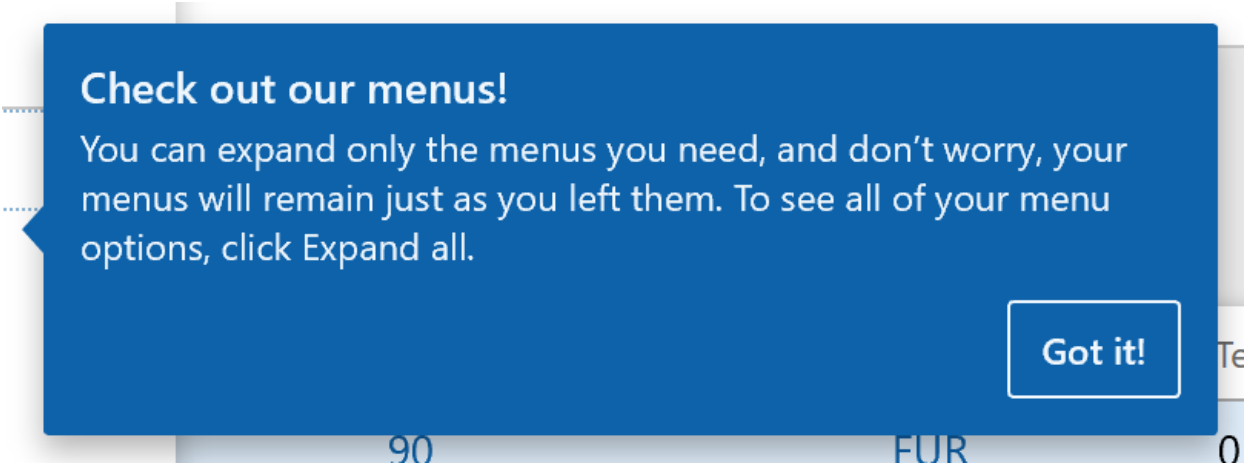
Feature callouts

2/18/2021 • 2 minutes to read • Edit Online

Introduction

While documentation is helpful for explaining new features, it's also important to raise awareness of these new capabilities as users encounter the feature while using the product. As a result, feature callouts are available in Platform update 26. You can use feature callouts to point out a new capability to a user and optionally provide a hyperlink for the user to learn more about the feature.

In this topic, the APIs that are used to construct feature callouts are discussed in detail.



The "Got it" button

When a feature callout is triggered, the user can simply click the **Got it** button to dismiss the popup. This saves the state of this feature callout in the personalization subsystem, which prevents that specific feature callout from being triggered again.

Resetting feature callouts

Even though the feature callout state is stored in personalization, clearing personalizations will not delete the state of all previously dismissed feature callouts. Instead, separate actions have been added to reset all feature callouts so that they fire again. These actions are located on the **Personalization** tab on the **Usage data** page as well as on the **Manage per user** tab on the **Personalization** page.

Disabling feature callouts

If needed, administrators can turn off feature callouts for an environment using the **Feature callouts enabled** option on the **Client performance options** page.

Implementation details

The SystemNotificationsWhatsNewManager class contains two variant APIs for triggering a feature callout.

AddWhatsNewWithActionLink()

Add a feature callout to a control with a "Learn more" link that is configured to open the documentation associated with the new product capability.

Parameters

PARAMETER	DESCRIPTION
ruleID	Generate a unique GUID.
title	Provide a (localized) title.
bodyText	Provide a (localized) description.
targetControl	Provide the name of the control you want to attach the feature callout to.
urlLink	Provide the URL to open in a new tab when the "Learn more" link is clicked. If a URL is not specified, then a "Learn more" link will not be displayed.

AddWhatsNew()

Add a feature callout to a control without a "Learn more" link.

Parameters

PARAMETER	DESCRIPTION
ruleID	Generate a unique GUID.
title	Provide a (localized) title.
bodyText	Provide a (localized) description.
targetControl	Provide the name of the control you want to attach the feature callout to.

Example

The following code snippet will trigger a feature callout attached to the control named *TestStringControl*.

```
public void init()
{
     super();

     SystemNotificationsWhatsNewManager::AddWhatsNewWithActionLink(
          MyTestKey,
          "My title" ,
          "My description",
          TestStringControl.name(),
          "https://www.microsoft.com"
     );
}
```

Notes

- Multiple feature callouts can be shown on a page at one time.
- Only one feature callout is allowed per control. If multiple callouts exist, the last one to get triggered will be displayed.

NOTE

Can you tell us about your documentation language preferences? Take a short survey.

The survey will take about seven minutes. No personal data is collected (privacy statement).

Slider and MessageBox dialogs

2/18/2021 • 2 minutes to read • Edit Online

Dialogs

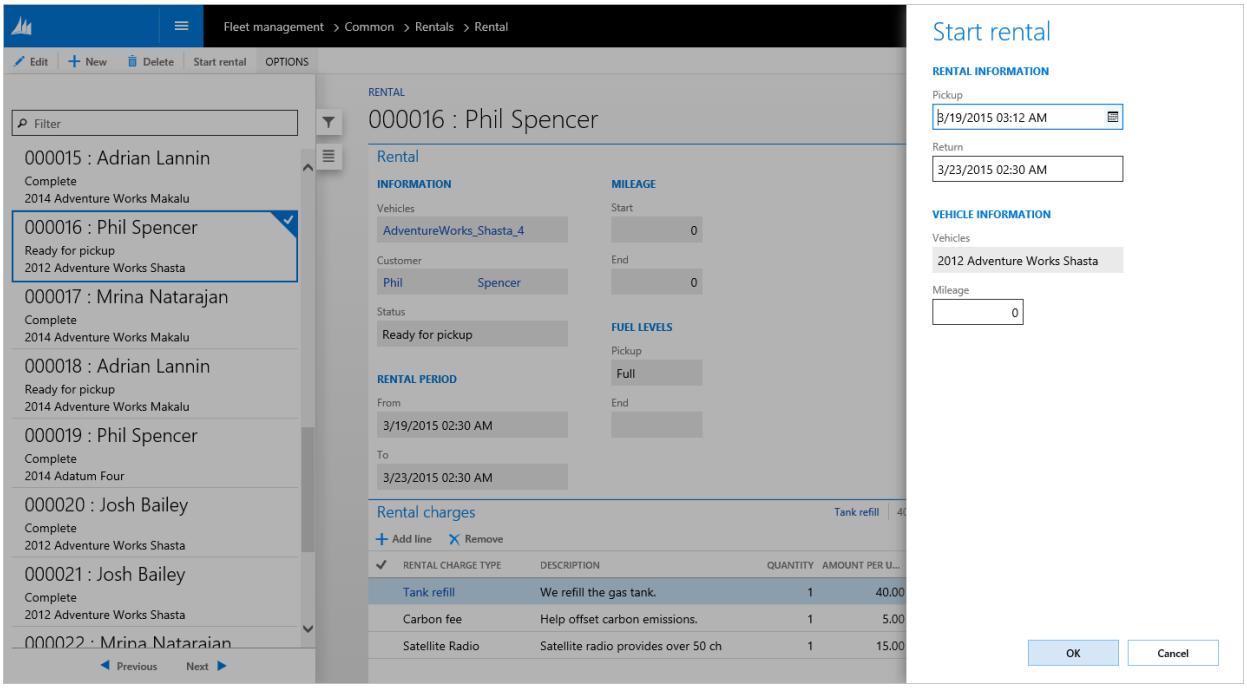
There are two dialogs that replace the existing dialog box, the Slider and the MessageBox from Dynamics AX 2012:

- Slider
- MessageBox

The following sections discuss the specific goals for each concept.

Slider

The slider, or slider dialog, is a dialog box that "slides" in on top of the active page's content from the right edge of the screen. In the following screen shot, the slider is the white region that has the caption **Start rental** on the right side of the window. Notice that the area to the left of the slider is shaded to help the user understand that the page beneath the slider isn't currently available for interaction.



After a slider opens, the user can dismiss it in two ways:

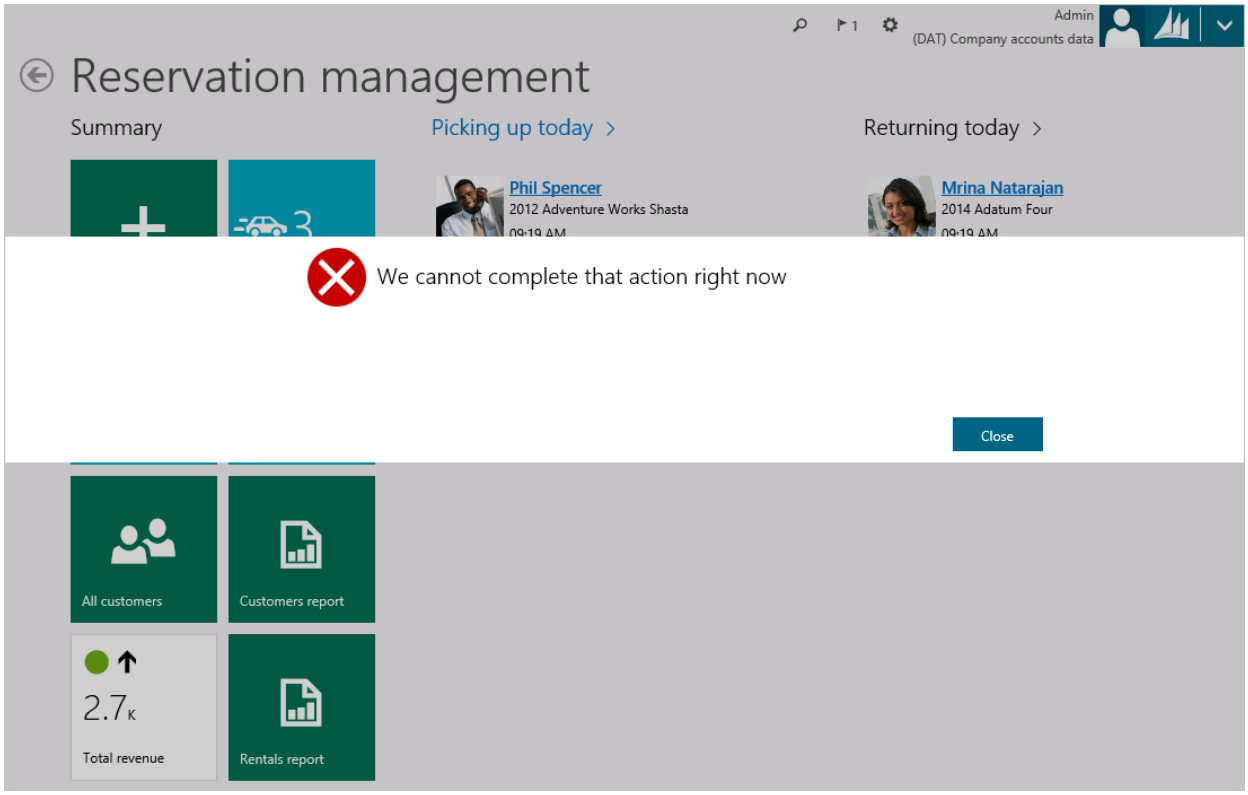
- Perform an action within the slider that causes the underlying form to dismiss itself. For example, click **Cancel**, or enter required information and then click **OK**.
- Click outside the slider in the shaded area to the left. This cancels the slider, and no further actions are performed.

A slider contains a modeled form and is used to gather information from the user. Therefore, a slider should be used in most situations where a dialog box has been used in the past. For example, a slider is typically used when the user creates a new record, as in the preceding screen shot. However, a slider should not be used for simple notifications or messages to the user. For these situations, a MessageBox should be used, as described in the next section. To model a slider, you create a form, and then set the **Style** property to **Dialog** on the **Form.Design** node. You then model the form elements that you require (for example, fields and buttons). The

caption is defined by **Form.Design.Caption**. To simplify the process for creating sliders, we have provided the **SysBPStyle_Dialog** form as a template for modeling slider dialogs. To use this template, copy it into a new form, and then extend it as you require.

MessageBox

A MessageBox is a type of dialog that is rendered as a "lightbox" on top of an existing page. A MessageBox appears as a full-width modal pop-up. The following screen shot shows an example of a MessageBox.



A MessageBox is the correct mechanism to use when you must interrupt the user to notify the user about a critical situation. For example, a MessageBox is used to display a Message center error message to the user. Because a MessageBox is modal, the user can't interact with the page beneath the MessageBox until that MessageBox has been dealt with or dismissed. In the preceding screen shot, notice that the page is obscured by the MessageBox. Additionally, the areas above and below the MessageBox are shaded to help the user understand that the page isn't currently available for interaction. Be aware that, unlike a slider, the user can't dismiss a MessageBox by clicking outside it, in the shaded areas. A MessageBox can be triggered by using either the Box application programming interface (API) or any of the methods that are described earlier for triggering the display of an error. For more information, see the Message API: Message center, message bar, message details.

Messaging APIs - Action center, message bar, and message details

2/18/2021 • 5 minutes to read • Edit Online

This topic describes the messaging system in Finance and Operations apps, specifically in terms of the application programming interfaces (APIs) that are used to create and route messages to end users.

Introduction

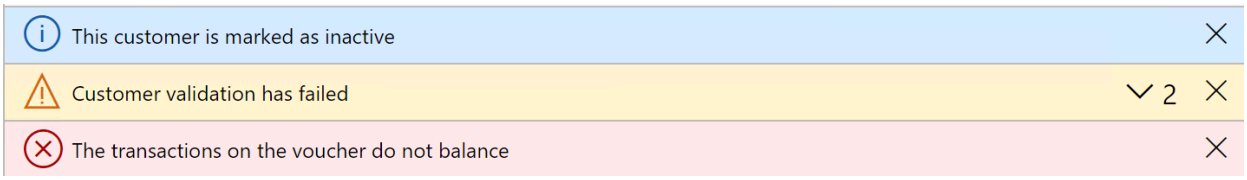
A new messaging system was created for Finance and Operations apps to improve this experience. Compared to earlier versions, the messaging system for Finance and Operations apps includes the following features:

- Improved association of a message with its context (form versus global).
- Improved level of interruption (none, subtle, and interrupting).
- Improved clarity between types of messages and their use.
- The control that is used to display messages is deterministic and based on form context.

Backwards compatibility of info(), warning()/checkfailed(), and error()

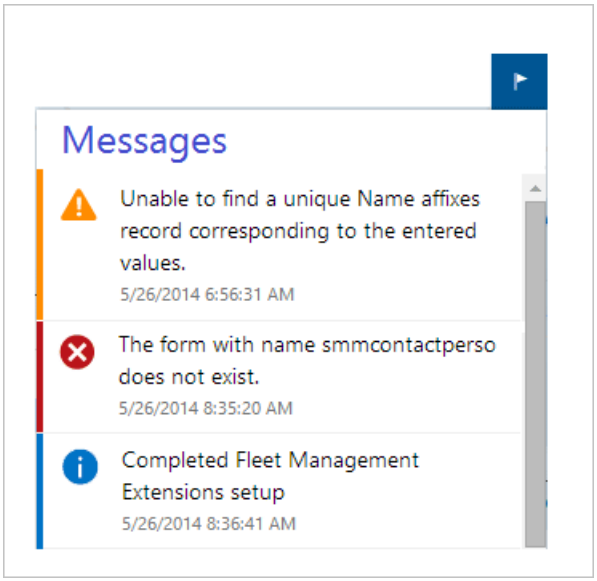
The **info()**, **warning()**, and **error()** application programming interfaces (APIs) from earlier versions of Finance and Operations apps are still supported; however, these APIs now sit upon the framework's new messaging system. Messages are routed deterministically to the message or Action center (in a non-interrupting manner) by using the context of the API call to determine the best way to present the message to the user. In general, if the use of the API originated from a form, the message appears in a message bar on that same form. (Drop dialogs and slider dialogs are both considered forms.)

The following illustration shows **info**, **warning/checkfailed**, and **error** message bars that correspond to page actions, or synchronous-authored messages that come from **info()**, **warning()**, and **error()**.



> **NOTE**
>
> If these APIs are called from a slider dialog, but that slider dialog is closed before the message appears, the message is shown in a message bar on the slider dialog's parent page. If that slider dialog is closed before the message appears, and there is no parent page, the message is routed to the Action center. The messaging API never fails to show a message. If an appropriate host page isn't found, the message is sent to the Action center.

If **info()**, **warning()/checkfailed()**, or **error()** is called from an asynchronous process (for example, a batch), there is no form context to consider, and the messages are sent to the Action center. (To open the Action center, click the **Show messages** button on the navigation bar.) The following illustration shows examples of each type of message in the Action center.



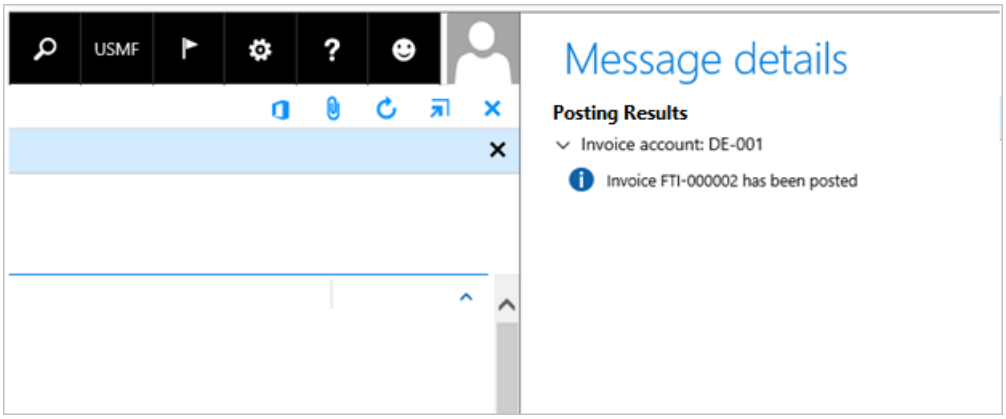
NOTE

Use the **Box()** API to express an interrupting error to the user.

Backwards compatibility of SetPrefix()

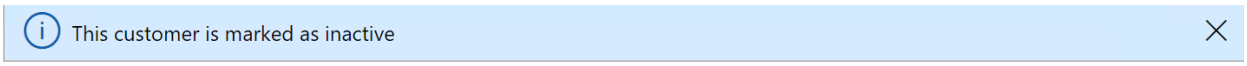
Finance and Operations apps also support the **SetPrefix()** API for backwards compatibility. However, in the messaging system, the results of **SetPrefix()** don't actively interrupt the user; instead, the results are collected and stored (as in previous versions), and a message bar or Action center notification is presented to the user. This notification indicates that the related task has been completed, and that it might have messages that the user should review. The "Notification of results" message actually uses the task's first call to **SetPrefix()** to frame the message. This behavior is similar to the behavior in previous versions, where the first call was the "title" of the results. In this example, "Posting Results" comes from the application's first call to **SetPrefix()**.

The user can then click **Message details** to open the new **Message details** pane.



Message()

The **Message** API provides some useful messaging capabilities. The **Message()** API gives you more control over the lifecycle of a message by allowing you to explicitly add and remove messages. This API can be useful when validation messages need to be removed at times other than when a save boundary has been crossed, or for displaying informational messages about aspects of the user's experience that aren't necessarily related to data validation. In this example, the message is shown when the current record is displayed.



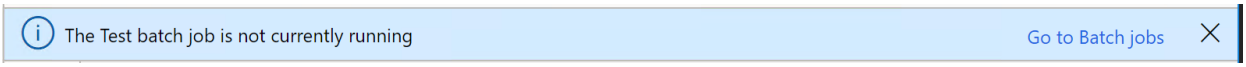
```
messageId = Message::Add(MessageSeverity::Informational, "The customer is marked as inactive");
```

The message can then be cleared when a new record is shown on the page.

```
Message::Remove(messageId);
```

Starting in version 10.0.10 / Platform update 34, you can use the **Message::AddAction()** method to embed an action within a message. This method supports adding a single action that is associated with a display or action menu item, which is then visualized as a link button. The actions are only supported in messages that are routed to the message bar until version 10.0.16 / Platform update 40, at which time these actions can be seen in messages that are routed to the Action center or the Message details pane.

In this example, a message is triggered for a system administrator indicating a particular required batch job is not running and exposes an action to go directly to the **Batch jobs** page.



```
MenuItemMessageAction actionData = new MenuItemMessageAction();
actionData.MenuItemName("BatchJob");
str jsonData = FormJsonSerializer::serializeClass(actionData);

int64 messageId = Message::AddAction(MessageSeverity::Informational, "The Test batch job is not currently
running", "Go to Batch jobs", MessageActionType::DisplayMenuItem, jsonData);
```

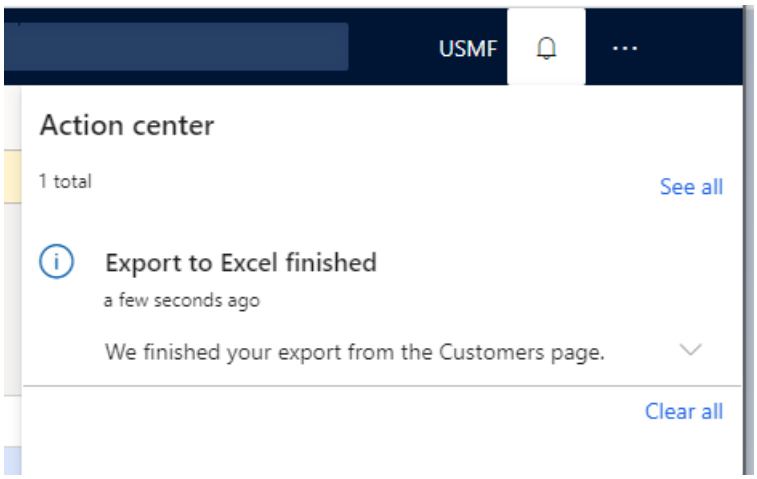
The following messaging types are supported: **MessageSeverity::Info**, **MessageSeverity::Warning**, and **MessageSeverity::Error**. Messages that use the **Message()** API are also deterministic. They can be routed to a message bar or the Action center.

SystemNotificationsManager()

The **SystemNotificationsManager()** API targets notifications designed to be sent to the Action center. This API provides the following features:

- Associating one or more actions to the notification
- Routing a notification to a set of users, or to all the users in one or more security roles
- Defining an expiration date for the notification
- Tracking the state of the notification (e.g. you can mark a notification as "Completed")

In this example, a notification is raised after an export to Excel is completed by a user. The message will be available in the Action center for the next 48 hours, after which the link to the exported file is no longer available.



```
// Set up the notification
SystemNotificationDataContract notification = new SystemNotificationDataContract();
notification.Users().value(1, curUserId());
notification.Title("Export to Excel finished");
notification.RuleId('ExcelStaticExport');
notification.Message("We finished your export from the Customers page");
notification.ExpirationDateTime(DateTimeUtil::addHours(DateTimeUtil::utcNow(), 48));

// Set up the action associated with the notification
SystemNotificationActionDataContract action = new SystemNotificationActionDataContract();
action.Message("Click to download");
action.Type(SystemNotificationActionType::AxActionMenuFunction);

SystemNotificationMenuFunctionDataContract actionData = new SystemNotificationMenuFunctionDataContract();
actionData.MenuItemName(menuItemActionStr(ExportToExcelStaticOpenFileAction));
actionData.Data(fileName);
action.Data(FormJsonSerializer::serializeClass(actionData));
notification.Actions().value(1, action);

SystemNotificationsManager::AddNotification(notification);
```

Messaging system for Finance and Operations apps

2/18/2021 • 10 minutes to read • Edit Online

This topic describes the rich, powerful messaging system in Finance and Operations apps.

A new messaging system was created for Finance and Operations apps to improve this experience. Compared to earlier versions, the messaging system for Finance and Operations apps includes the following features:

- Improved association of a message with its context (form versus global).
- Improved level of interruption (none, subtle, and interrupting).
- Improved clarity between types of messages and their use.
- The control that is used to display messages is deterministic and based on form context.

Where can messages be surfaced to users?

Messages in Finance and Operations apps are generally shown in one of these places: message bars, the Action center, or message boxes.

Message bars – Messages for synchronous tasks on the current page

Message bars are available on primary pages, and in drop dialogs and slider dialogs. Message bars are used primarily for data validation. They can also be used to communicate messages about the state of a page or data, such as messages that are used for date effectivity. Message bars can express **info**, **warning**, and **error** statuses. Message bars should not be used for messages that require the user's immediate attention. A message bar appears when a message is first received and must be used to communicate messages only about the current page. Messages that are sent to message bars are associated with the current page. Therefore, when the user navigates away from a page that includes message bars, those messages won't appear on the new page. However, if the user navigates back to the original page, the page's messages will once again appear. Include the following information in messages:

- The condition that generated the message.
- The result if the user continues without resolving the condition that generated the message.

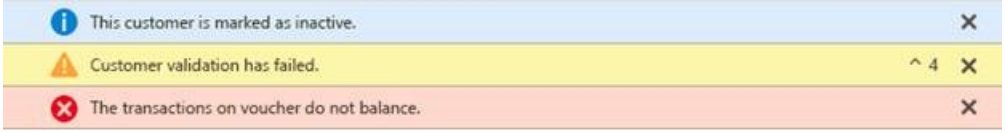
Examples

```
This customer is marked as inactive.
```

```
Customer validation has failed.
```

```
The transaction on voucher do not balance.
```

Presentation



Action center – Messages from asynchronous tasks

The Action center is located in the navigation bar. It contains messages that don't require any immediate action by the user and aren't required for the current task to continue. Typical examples include feedback from

background processes such as a batch job or report completion. The Action center can express **info**, **warning**, and **error** statuses. Before it's opened, the Action center indicates the number of messages that have been received since last time that it was opened.

The Action center can hold up to 500 messages. Messages are then cycled on a first in, first out basis.

Message boxes – Errors and immediate notifications (completed synchronous operations)

Use message boxes to alert users about issues that require immediate attention. Because message boxes interrupt users and prevent them from continuing until the message is read and dismissed, they should be used only for messages that users can't handle later. Include the following information in error messages that appear in message boxes:

- The error that occurred.
- The cause of the error.
- Information about how to resolve the error.

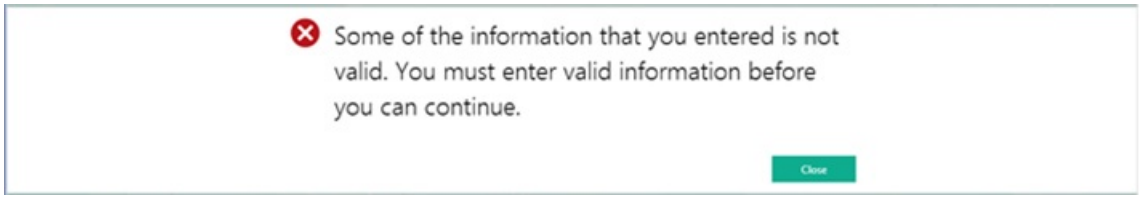
An error message should include the following two components:

- **The main instruction** – This text appears in bold.
- **The message details** – This text appears below the main instruction.

Examples

- You can't delete the reference number because the reference number is used in version %1.
- You have insufficient rights to perform this export.
- The root folder for catalog import processing is not configured. Configure the root folder using the Vendor catalog import parameters form.

Presentation



Messages of the **error** type block the user's interaction by overlaying the current page with a modal "light box" that contains the message.

Should I show the user a notification, a warning, or an error?

In earlier versions of Finance and Operations apps, the **info**, **warning** (**checkFailed**), and **error** statuses weren't always used consistently across scenarios. A message might be reported as a warning in one scenario but as an error in another scenario. When you're deciding which status to express, use these definitions:

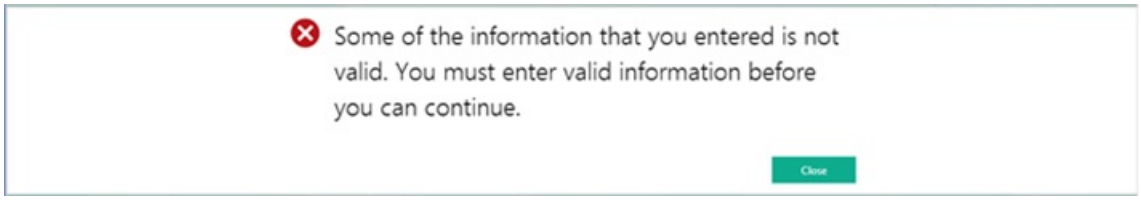
- **Notification** – A notification informs the user about events that might or might not be related to the current user activity. A notification can be caused by a user action or a system event, or it can provide information from the program that might be useful. Typically, a notification doesn't require immediate user action. You notify the user by using the **info()** application programming interface (API).
- **Warning** – A warning alerts the user about a condition that might cause an issue in the future. Specifically, a warning is used for data that is in an incorrect state. Although any attempt to use this invalid data might produce an error, the fact that the current state of the data is incorrect isn't an error condition, and *the user should only be warned about the incorrect state of the data*. You express data validation issues by using the **warning()** or **checkFailed()** API.

> **NOTE**
>
> Because of the way that the system handles the cleanup of validation messages, when the **warning()** or **checkFailed()** API is used, the return value of **validate()** should *always* be set to **false**. Otherwise, warning messages might not be shown to the user.

- **Error** – An error alerts the user about a problem that has already occurred. A user action that has failed is an error condition. Errors can be *non-interrupting* (*passive*) or *interrupting*. In a non-interrupting error, users can perform other activities before they try to correct the issue. In an interrupting error, users can't proceed or complete the task until they correct the error condition. You express a passive (non-interrupting) error by using the **error()** API. You express an interrupting error by using the **box::** API.

Should this message interrupt the user?

If a task (batch job or other operation) fails, it's often appropriate to notify the user passively. Because the user can correct the issue and retry the operation at any time, the user doesn't have to be notified immediately. In these cases, the **error()** API is appropriate, and the user doesn't receive an interrupting dialog. However, in other cases, the user can't proceed until the issue is corrected. For example, if the user tries to save a page that still has invalid data, the client interrupts the user by presenting an error dialog. In these cases where it's more appropriate to interrupt the user by presenting a dialog, the **box::** API should be used.



Will my message end up in a message bar or in the Action center?

The messaging system is *deterministic*. In other words, the messaging system uses the context of the call to determine the best way to show the message to the user. Messages are shown either in a message bar that appears at the top of pages or in the Action center, which appears in the navigation bar. The location of the message depends on where in code the message is sent from.

In general:

- If the message is caused by a page action that is synchronous (that is, the user must wait for the result), the result is shown in a message bar on the current page. (The exception is a slider dialog that was closed immediately after the action was started. Messages for slider dialogs "bubble up" to the parent page.)
- If the message is caused by an action (for example, a batch job) that is asynchronous (disconnected) and the user can continue to perform other tasks or even navigate to another page while that action is being processed, the message is routed to the Action center.

Messaging from asynchronous or long-running background tasks

A (potentially) long-running task should not present a message bar to the user, because message bars at the top of a page are used to present information about the current page, not some background task that might have started hours earlier. In some cases, a user who has many background tasks running continues to navigate between pages while the tasks are being completed. Therefore, messages that are presented on the current page to notify the user about background tasks are easily overlooked or ignored. Therefore, by design, background tasks send their messages to the Action center. When a new message appears in the Action center, a notification informs the user, who might be waiting for the results of an asynchronous task.

Messaging from dialogs and slider dialogs

The deterministic messaging system tries to send messages to the current page. However, not every call from a

dialog or slider dialog is routed to that dialog or slider. In some cases, the messaging system sends the message to the parent page instead. This behavior can occur when the messaging system is called while the dialog or slider is being closed. In some cases, the messaging system can be called when the close process for the dialog or slider is started, but the client interrupts the close process for valid reasons. Therefore, there is a "point of no return," after which the messaging system no longer tries to send a message to the dialog or slider, and instead sends the message to the parent page. When the user clicks the **OK** button on the form is entering its closing sequence, shown in the code example that follows.

```
closeOK()
{
    // current form
    super(); // calls close()
    // parent or message center
}
Close()
{
    // current form
    super();// point of no return
    // parent or message center
}
```

If the client calls **closeOK()** or **close()** directly, then the final result might be the page or the parent page.

When are validation messages cleaned up?

With the messaging system in use for Finance and Operations apps, the validation message (called using the same APIs) appears in a message bar on the page itself in a passive manner. The invalid value remains but is flagged as invalid. The user can continue to enter data and can correct the validation issue at any point before the data is saved.

When a validation issue has been corrected so that the corresponding message in the message bar is no longer valid, the messaging system removes the message. The timing of message removal depends on the level where the validation logic is defined.

- If the validation logic is defined at the control or field level, the message is removed when a valid value is entered in the control or field.
- If the validation logic is defined at the table level, the message is removed the next time that the user crosses a save boundary.

If the developer needs more control over when a message needs to be removed from the UI, the **Message()** API can be utilized. See the Messaging APIs article for more details.

I'm migrating from an older version. How do I change my existing code to use the new messaging system?

In many cases, no changes are required. The messaging framework was designed to innovate and maintain backward compatibility for many common scenarios. In some cases, the program might improve the wording of messages. Alternatively, the program might use **error()** instead of **warning()**, or **warning()** instead of **error()**, to better align with the usage guidance (warnings are for data that isn't valid, whereas errors are for failed actions). In other cases, you might decide that messages that appear on a slider dialog are more appropriate for the parent page.

How to create a collection of related messages?

You use **SetPrefix()** to create collections of related messages [See the Messaging APIs for more details on **SetPrefix()**. This API is largely backward compatible but is presented in a non-interrupting manner. A results

window isn't opened directly; instead, the user is passively notified by either an Action center message or a message bar on the page that started the task that used the **SetPrefix()** API to group the result messages into a collection. The message severity shown to the user reflects the severity of the most critical message in the collection. For example, if the collection contains no errors or warnings, the message bar is of the **info** type.

If the collection contains one or more calls to **warning()**, the message bar is of the **warning** type.

If the collection contains one or more calls to **error()**, the message bar is of the **error** type.

The use of **SetPrefix()** is also deterministic. In other words, if you use **SetPrefix()**, and there is no page context (for example, an asynchronous batch operation), the notification of results is sent to the Action center, which isn't associated with any page.

Form patterns for migrated forms

2/18/2021 • 12 minutes to read • Edit Online

This topic provides information that will help you select the best form pattern for the forms that you migrate.

Introduction

The selection of a form pattern is an important step in the process of migrating a form. A pattern that is a good fit for the target form reduces the amount of migration work that is required. By contrast, a pattern that isn't a good fit can cause wasted time and effort. Therefore, it's important that you do some investigation, so that you can select the best form pattern for the form that you're migrating. Here is some guidance and tips for determining the appropriate pattern for a form:

- Investigate the form's metadata in the form designer. Pay close attention to the following details:
  - Form name
  - Form.Design.Style
  - Control names
  - The way that the controls are organized
  - The number and names of the data sources
- Investigate the form's visuals by running the form and looking at the way information is displayed.

Selecting a form pattern via metadata

Use Form.Design.Style for guidance

The **Form.Design.Style** property often contains the name of the pattern that was previously targeted for the form. If the **Style** property correctly matches the metadata, you can use the following table to find a pattern that is likely to be a good fit for the form.

FORM.DESIGN.STYLE VALUE	CORRESPONDING PATTERN
DetailsFormMaster	Details Master
DetailsFormTransaction	Details Transaction
Dialog	Dialog
DropDialog	Drop Dialog
FormPart, where there are just fields	Form Part FactBox Card
FormPart, where there is a grid	Form Part FactBox Grid
ListPage	List Page
Lookup	Lookup
SimpleList	Simple List

FORM.DESIGN.STYLE VALUE	CORRESPONDING PATTERN
SimpleListDetails, where there are 2–3 fields in the navigation list (recommended)	Simple List Details – List Grid
SimpleListDetails, where there are and 4–5 fields in the navigation list	Simple List Details – Tabular Grid
SimpleListDetails, where there is a tree (rare)	Simple List Details – Tree
TableOfContents	Table of Contents
Auto, where there is an **Overview** tab, a **General** tab, and a single data source	Task Single
Auto, where there are two sets of **Overview** tabs, **General** tabs, and/or headers plus lines	Task Double
Auto, where there is focus on a single record	Simple Details
Auto, where the form name ends in "Lookup"	Lookup
Auto, where there is a single tab control and **Next**/**Previous** buttons	Wizard
Auto, where the form name ends in "Wizard"	Wizard
Auto, where there is just a grid and some buttons	Simple List

When a form doesn't match the Style property

Sometimes, a form has an incorrect **Form.Design.Style** property value.

FORM.DESIGN.STYLE VALUE	WHAT THE FORM MIGHT ACTUALLY BE
DetailsFormMaster	DetailsFormTransaction, if there is lines detail, or if controls have names that contain "lines"
SimpleList	SimpleListDetails, if there is more than just a grid and some custom filter fields
SimpleListDetails	SimpleList, if there is just a grid and some custom filter fields
SimpleList	ListPage, if there are numerous FactBoxes in the **Parts** node, or if the form has a corresponding Details Form

Selecting a form pattern via visuals

Although this approach is less useful than looking at the form metadata, you can get a lot of information about a form by running and examining it. Use the form visuals as an additional data point to help you select a form pattern. Look through the screen shots of migrated forms to find a form that looks like the target form. Additionally, make sure that the description or intent of the pattern matches the description/intent of the form.

Selecting a form pattern via the designer

Right-click the **Design** node of the target form, select **Apply pattern**, and then click the pattern to apply.

Form pattern reference guide

List of classes of top-level form patterns

FORM PATTERN	WHAT IT'S USED FOR
Details Master (two variants)	A form that displays the details of a complex entity
Details Transaction	A form that displays the details of a complex transaction entity and its lines (for example, and order and its lines)
Dialog (six variants)	A form that is used as a dialog to gather a set of information
Drop Dialog (two variants)	A form that is used as a drop dialog to gather a small set of information to provide context for an action
FactBox (two variants)	A Microsoft Dynamics AX 2012 FactBox that displays information about a related record or set of records
List Page	A Dynamics AX 2012 List Page
Lookup (three variants)	A form that is used as a lookup
Simple Details (four variants)	A form that is focused on a single record
Simple List	A form that displays details for a simple entity as a grid that has fewer than 10 fields per record
Simple List & Details (three variants)	A form that displays information about an entity of medium complexity
Table of Contents	A form that displays setup information or loosely related information sets
Task (two variants)	A legacy form pattern that is used to display master or transaction entities
Wizard	A form that displays a set of tab pages to the user to gather information in a predetermined order
Operational Workspace	A form that is used to display an overview of an activity and is meant to be a primary means of navigation
Workspace Panorama Sections (three variants)	A form that is used to show content for a panorama section (via a Form Part Control) in the Operational Workspace

Finding forms that currently use a particular form pattern

For a full list of forms that are currently using a particular form pattern, generate the **Form Patterns** report from within Microsoft Visual Studio. For information on running the report, see Form pattern add-ins. You can filter the report in Excel to find forms that use a particular pattern.

Form pattern visuals and descriptions

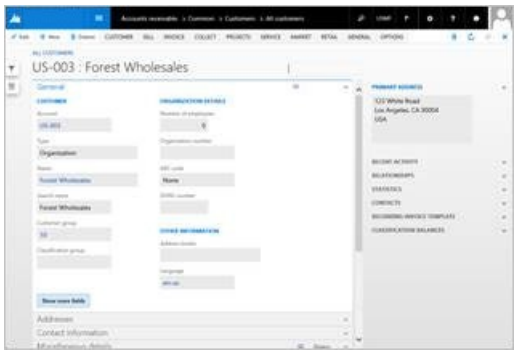
For each form pattern class, information is provided about each variant. This information includes a short

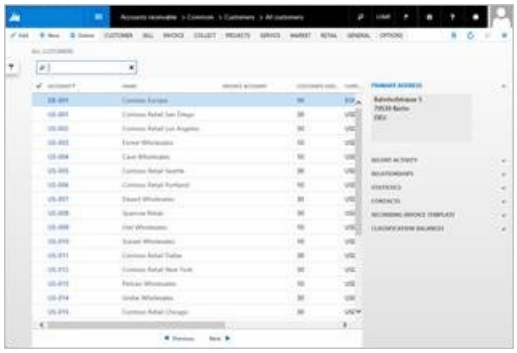
description and an illustration of an example form.

Details Master

Details Master[Default] This form pattern is used to display the details of a complex entity on FastTabs. It includes a grid view and a details view.

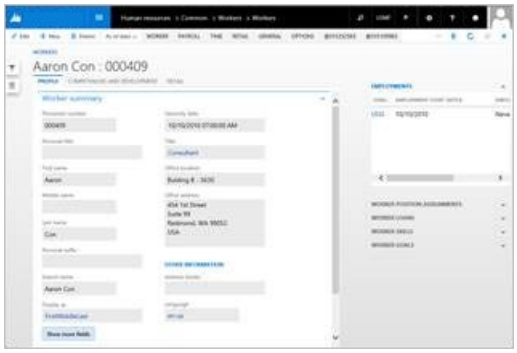
Form: CustTable

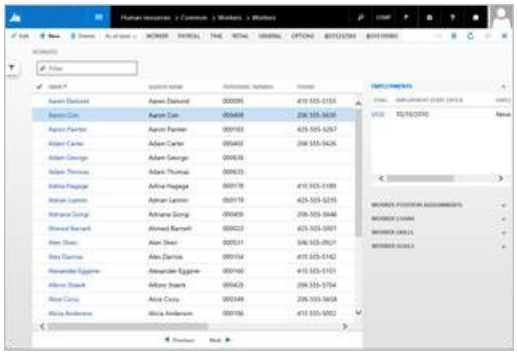




Details Master w/ Standard Tabs Use this Details Master variant when your form has a large number of FastTabs (>15) that can be grouped into categories.

Form: HcmWorker

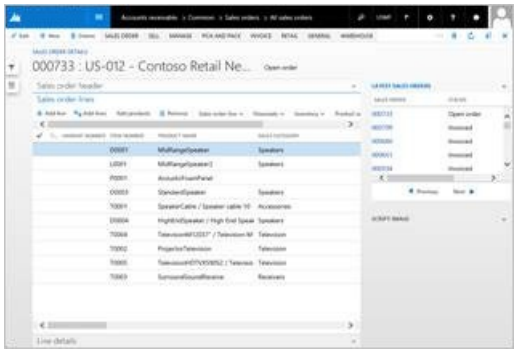


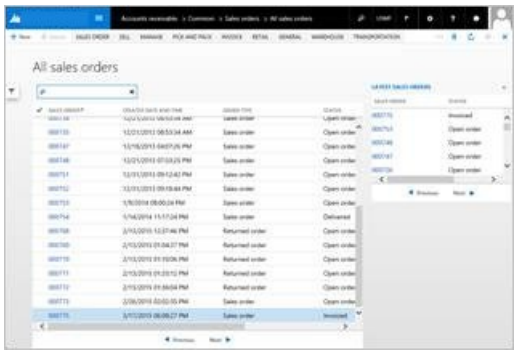


Details Transaction

Details Transaction Use this form patter to show the details of a complex transaction entity and its lines (for example, an order and its lines).

Form: SalesTable





Dialog

Dialog – Basic[Default] This form pattern is used to gather or show a set of information.

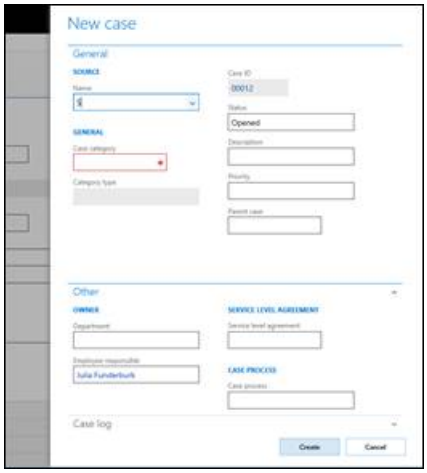
Form: ProjTableCreate

Dialog – Read Only Use this Dialog variant when your Dialog just displays information that can't be edited. It has only a **Close** button.

Form: SalesTablePostings

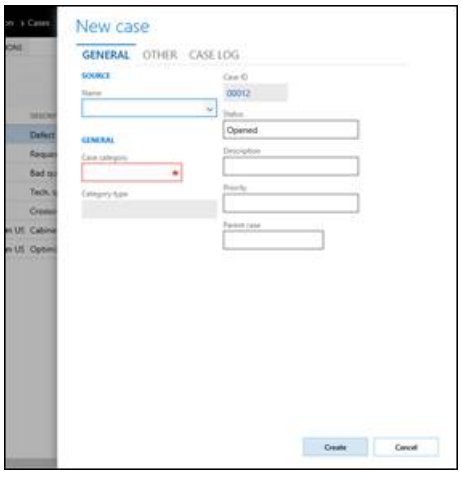
Dialog – FastTabs Use this Dialog variant when your Dialog content is grouped into FastTabs.

None currently in product.



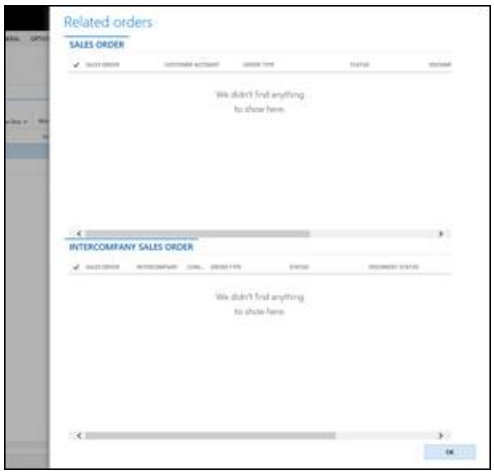
Dialog – Tabs Use this Dialog variant when your Dialog content must be grouped into tabs.

Form: CaseDetailCreate



Dialog – Double Tabs Use this Dialog variant when your Dialog content has two tabs that are stacked on top of each other.

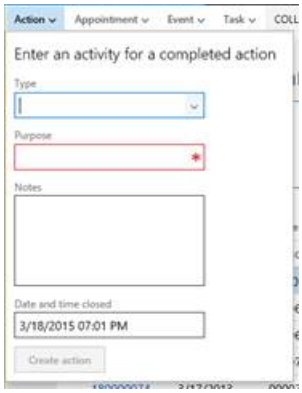
Form: PurchTableReferences



Drop Dialog

Drop Dialog[Default] This form pattern is used to initiate actions when the number of fields is small (less than five).

Form: CustCollectionsNewActivityAction



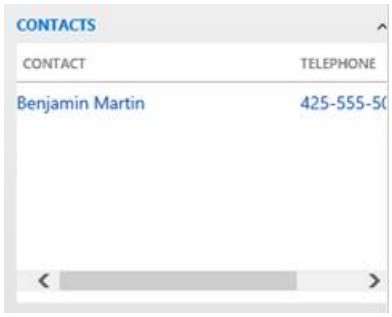
Drop Dialog – Read Only Use this Drop Dialog variant when the fields in the Drop Dialog aren't editable. No **OK/Close** button is modeled.

No example currently exists in the product.

FactBox

FactBox Grid Use this FactBox variant to show a child collection of related information.

Form: ContactsInfoPart



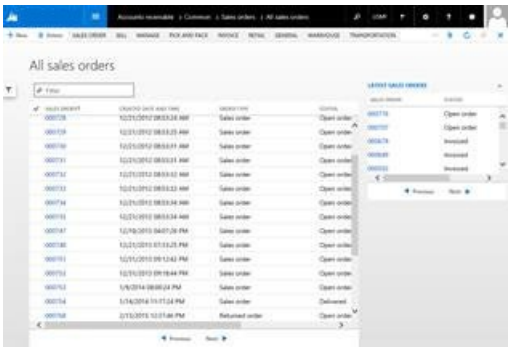
FactBox Card Use this FactBox variant to show a set of related fields.

Form: CustStatisticsStatistics

List Page

List Page The Dynamics AX 2012 list page that is just a grid that is optimized for browsing records and acting on those records.

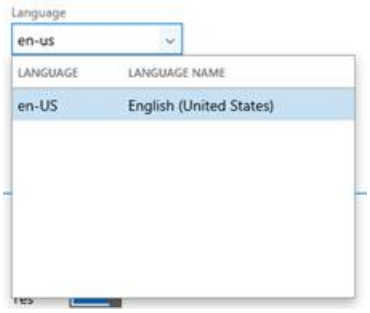
Form: SalesTableListPage



Lookup

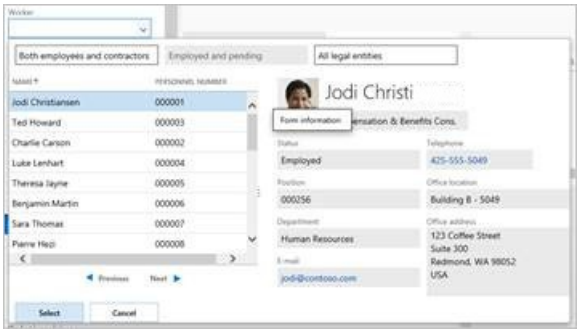
Lookup Basic[Default] This form pattern is used if the lookup form is a grid or tree that has optional filters or buttons at the bottom.

Form: SysLanguageLookup



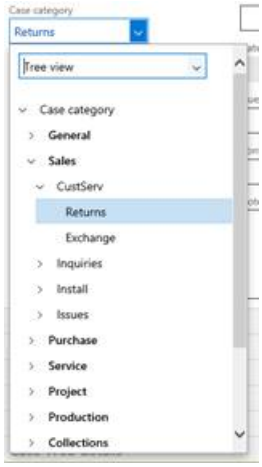
Lookup w/Preview Use this Lookup variant when, in addition to the basic pattern, a preview of the current record is also shown.

Form: HcmWorkerLookup



Lookup w/Tabs Use this Lookup variant when there are multiple views of a lookup (for example, a grid view/tree view or multiple filtered lists).

Form: CaseCategoryLookup



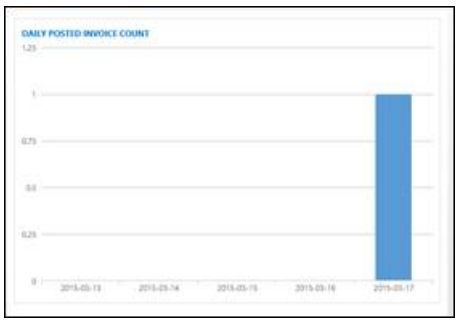
Panorama Section

Form Part Section List Use this form pattern to show a list in a workspace section. This should be modeled as a separate form and rendered in the workspace via a Form Part Control.

Form Part Section List - Double Use this variant when you must also show a secondary list. This secondary list isn't initially visible.

Hub Part Chart Use this variant to show a chart in a workspace section. This should be modeled as a separate form and rendered in the workspace via a Form Part Control.

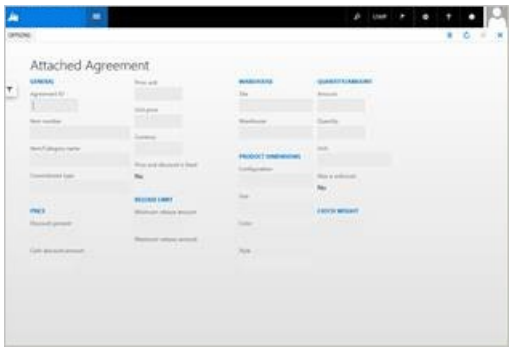
Form: VendInvoiceJourCountChart



Simple Details

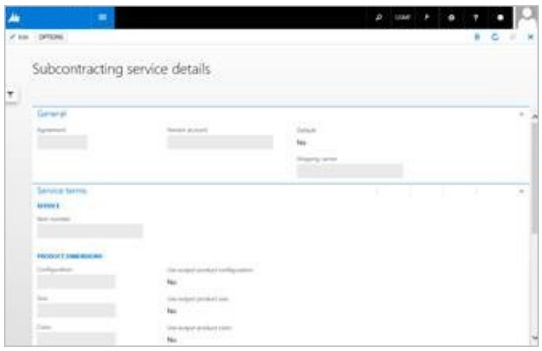
Simple Details w/Toolbar and Fields Use this form pattern to show fields for a single base record.

Form: AgreementLine



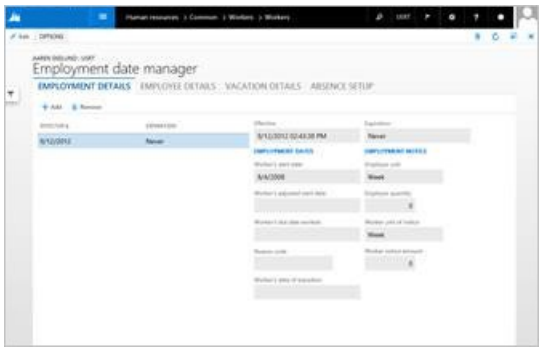
Simple Details w/FastTabs Use this Simple Details variant when the record's information is organized into FastTabs.

Form: PlanActivityServiceDetails



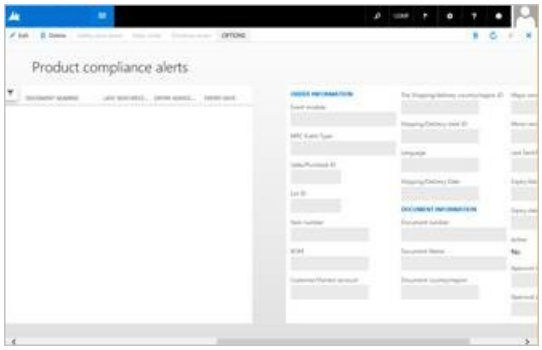
Simple Details w/Standard Tabs Use this Simple Details variant when the record's information is organized into regular tabs.

Form: HcmEmploymentDateManager



Simple Details w/Panorama Use this Simple Details variant to display a record's information in a horizontally scrolling panorama.

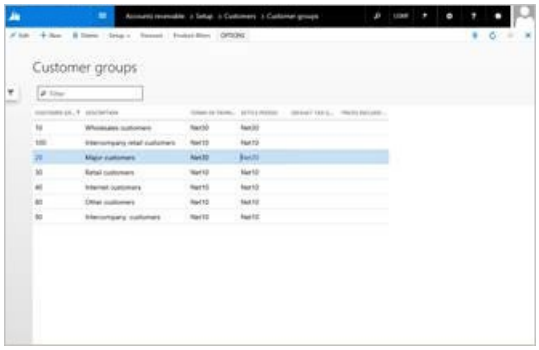
Form: PdsMRCEventTracker



Simple List

Simple List This form pattern is used to maintain data for simple entities.

Form: CustGroup

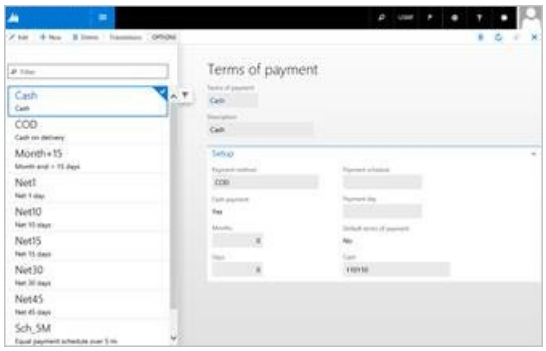


Simple List and Details

Simple List & Details – List Grid[Default] This form pattern is used to maintain data for entities of medium complexity. A list grid that has 2–3 fields in the navigation list is the preferred pattern for this form style in the

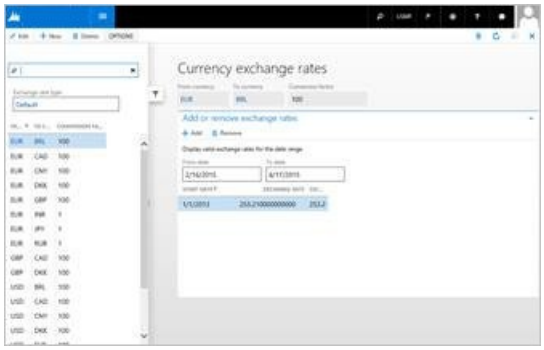
current version.

Form: PaymTerm



Simple List & Details – Tabular Grid Use this Simple List & Details variant if you require more than three fields in the list part of the form.

Form: ExchangeRate



Simple List & Details – Tree Use this Simple List & Details variant if the list part of the form is a tree.

Form: FiscalCalendars

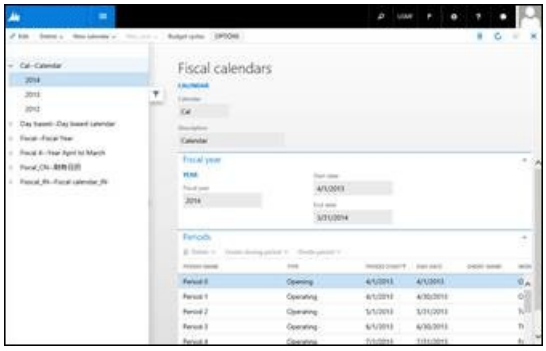


Table of Contents

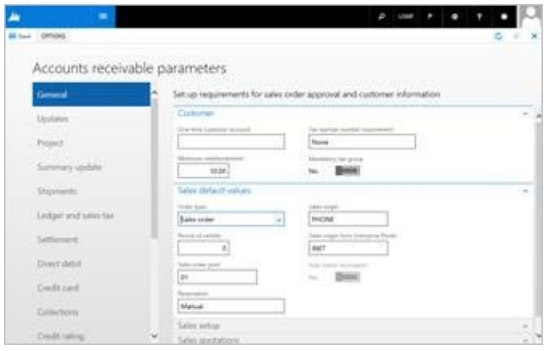
Table of Contents Use this form pattern to show setup information or loosely related information sets.

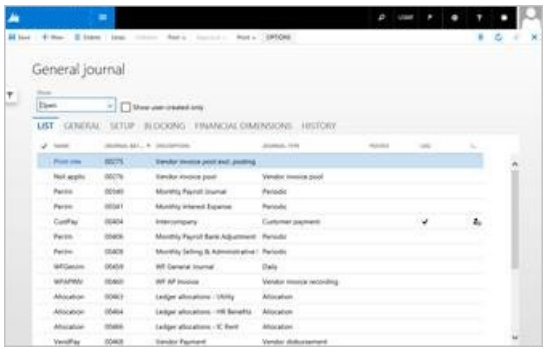
Form: CustParameters



Task

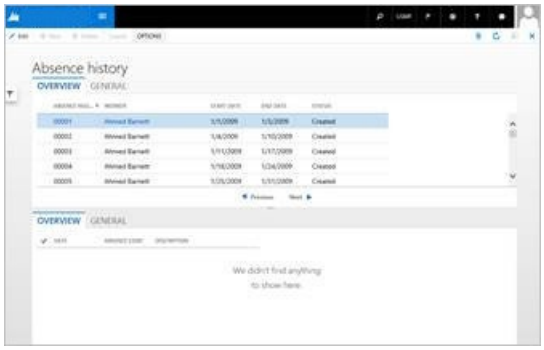
Task Single This legacy form pattern is used to display entities. It should be used only for migration, not for new forms.

Form: LedgerJournalTable



Task Double This legacy form pattern is used to display transaction entities. It should be used only for migration, not for new forms.

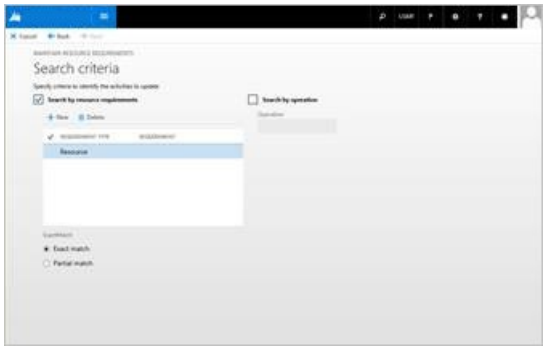
Form: HRMAbsenceTableHistory



Wizard

Wizard This form pattern is used to display a set of page views to the user to gather information in a predetermined order.

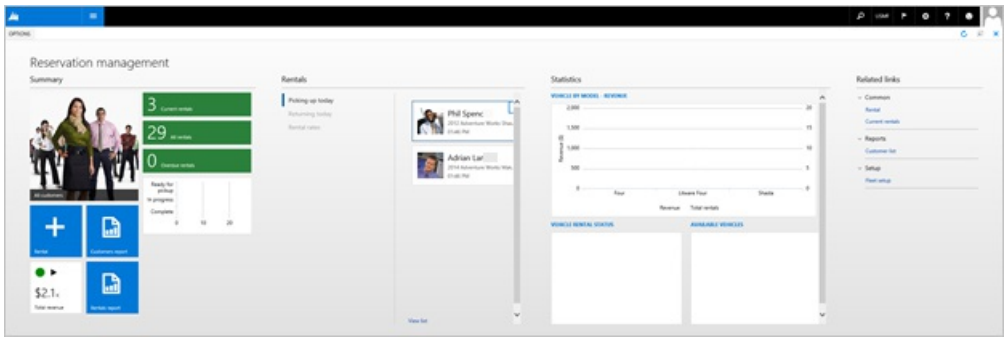
Form: WrkCtrBulkResReqEditWizard



Workspace

Operational Workspace[Default] This is the preferred, performance-enhanced variant of the Workspace pattern.

Form: FmClerkWorkspace



Workspace: This is the old Workspace pattern. It will be removed soon, so don't use it. It is included here only for completeness.

Do not use.

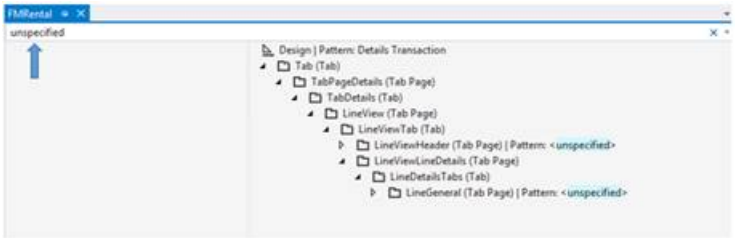
Subpattern reference guide

List of subpattern classes

FORM PATTERN	WHAT IT'S USED FOR
Custom Filters (two variants)	Containers that display QuickFilters and any other modeled custom filters
Fields (five variants)	Containers that primarily display individual fields
Dimension Expression Builder	Containers that include a Dimension Expression Builder control
Dimension Entry Control	Containers that include a Dimension Entry Control
List Panel	Containers that display two lists that users move items between
Nested Simple List and Details	Containers that are used to embed a simpler Simple List and Details form inside a section in a form
Toolbar and Fields	Containers that display actions above a set of fields
Toolbar and List (two variants)	Containers that display actions above 1–2 grids
Workspace-related (eight variants)	Containers that correspond to various sections inside an Operational Workspace

Finding containers that require that a subpattern be applied on a form

When a form is open in the Visual Studio designer, you can easily search for containers that must still have subpatterns applied by searching for "unspecified" in the control search box at the top of the designer (as shown in the following screen shot).



Subpattern visuals and descriptions

For each subpattern class, information is provided about each variant. This information includes a short description and an illustration of an example form.

Custom Filters

Custom Filters Use this form pattern when custom filters are modeled. QuickFilter isn't required.

Form: LedgerJournalTable (TopFields)

Custom and Quick Filters Use this variant when a QuickFilter is required.

Form: CustTable (CustomFilterGroup)

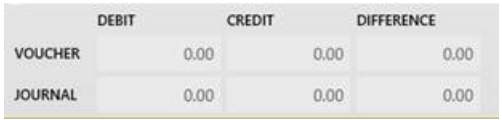
Fields

Fields and Field Groups Use this form pattern to get a responsive layout for containers that contain only fields.

Form: InventLocation (LocationNames)

Tabular Fields Use this form pattern to get a structured layout of fields. It is intended primarily for totals.

Form: LedgerJournalTransVendPaym (Balances)



Fill Text Use this form pattern when a single input control requires full width.

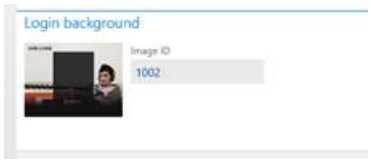
Form: FmRental (Notes)

Horizontal Fields and Button Group Use this form pattern when a field has an inline action.

Form: SalesTable (GroupHeaderAddressHeaderOverview)

Image Preview Use this form pattern for containers that have image controls (and optional related fields).

Form: RetailVisualProfile (Login)



Toolbar and List

Toolbar and List Use this form pattern on containers that have only actions and a grid.

Form: VendTable (TabCommunication)

Toolbar and List – Double Use this Toolbar and List variant when the containers have two grids.

Form: SalesQuickQuote (TabPageExistingItems)

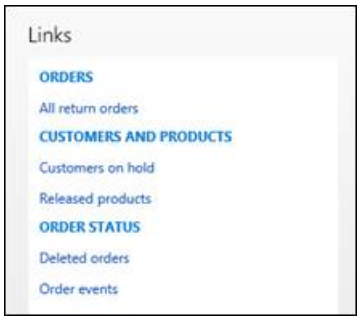
Workspace Related

Section Tiles Use this variant to show a set of tiles/charts in a workspace section. This should be modeled in a tab page on the workspace form. Charts are defined by using Form Part Controls

Form: SalesOrderProcessingWorkspace

Section Related Links Use this variant to show a set of hyperlinks in a workspace section. This should be modeled in a tab page on the workspace form.

Form: SalesOrderProcessingWorkspace



Section Tabbed List Use this variant when multiple list variants must be included. Only one is shown at a time.

Section Stacked Chart Use this variant when you must include up to two charts in an Operational Workspace.

Section PowerBI Use this variant when a Power BI section must be included.

Workspace Page Filter Group Use this form pattern to add a single filter to your workspace.

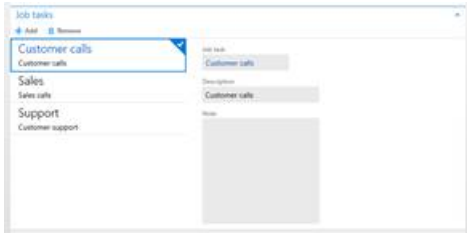
Filters and Toolbar – Stacked Use this subpattern in the Form Part Section List pattern, so that actions appear below filters.

Filters and Toolbar – Inline Use this subpattern in the Form Part Section List pattern, so that filters and actions appear on the same line.

Other

Nested Simple List & Details Use this form pattern to embed a simpler Simple List & Details form inside a tab or group.

Form: HcmJob (TaskTabPage)



List Panel Use this form pattern when users must move items back and forth between two lists.

Form: CLIControls_ListPanel (FormTabPageControl1)

Toolbar and Fields Use this form pattern on containers that have only actions and fields

Form: HcmPosition (WorkerAssignmentTabPage)

Dimension Entry Control Use this form pattern on tab pages that have only a Dimension Entry Control.

Form: CustTable (TabFinancialDimensions)

Dimension Expression Builder Use this form pattern on containers that include a Dimension Expression Builder control.

Form styles and patterns

2/18/2021 • 13 minutes to read • Edit Online

This topic describes the concept of form patterns and discusses the process for applying and removing patterns. A list of frequent questions are also answered in this topic.

Dynamics AX 2012: Form styles and templates

In Microsoft Dynamics AX 2012, several form styles were introduced and formalized. Primary data types are represented by the List Page and Details Form styles. Secondary data types are represented by the Simple List and Details Form and Simple List Form styles. In addition to these core form types, other form styles exist for supporting forms, such as Table of Contents for settings and Drop Dialog for dialog forms, and Lookup for lookup forms. Other less formal form patterns, such as Wizard, also exist. Developers who wanted to build a new form of a specific style in Dynamics AX 2012 often used the corresponding template form as a starting point. After they included form content and made any modifications that were required, developers could then run the Form Style Checker add-in to validate their form in terms of structure and property values against that form style's template form.

Finance and Operations: Form patterns

Form patterns (a new concept that is the evolution of the Dynamics AX 2012 form templates, style, and Form Style Checker) are now an integrated part of the form development experience. These patterns provide form structure, based on a particular style (including required and optional controls), and also provide many default control properties. In addition to top-level form patterns, subpatterns can be applied to container controls, and that provide guidance and consistency for subcontent on a form (for example, on a FastTab). Patterns have made form development easier by providing a guided experience for applying patterns to forms to guarantee that they are correct and consistent. Patterns help validate form and control structures, and also the use of controls in some places. Patterns also help guarantee that each new form that a user encounters is immediately recognizable in appearance and function. Form patterns can provide many default control properties, and these also contribute to a more guided development experience. Because patterns provide many default layout properties, they help guarantee that forms have a responsive layout. Finally, patterns also help guarantee better compatibility with upgrades. Many of the existing form styles and templates from Dynamics AX 2012 continue to be supported. However, legacy form styles and templates that aren't supported have a migration path. Because the foundational elements are built based on those legacy form styles and patterns, the transition is as easy as possible.

Applying patterns

Applying a pattern is a straightforward process that can modify properties on multiple containers and controls on a form. Here is the standard flow for applying patterns:

1. Acquire the target.
2. Determine the pattern.
3. Apply the pattern.
4. Handle errors.

Acquire the target

First, you must identify a target form and add it to your project. The **Form Patterns** report that is generated by using a Microsoft Visual Studio add-in can help you find forms that don't have patterns. For information on

running the report, see Form pattern add-ins. Open the report file in Microsoft Excel, and filter to a form that has no pattern. Then, in Visual Studio, open Application Explorer, and find the form. Right-click the form, and then select **Add to project**. When you open the form in the designer, it should have the **Pattern: <unselected>** designation on the design node.

Determine the pattern

Decide which pattern to apply. The available patterns include those that are based on Dynamics AX 2012 form templates, and also patterns that are designed for Finance and Operations scenarios. If you require help selecting a pattern, see the Selecting a Pattern topic. For more detailed information about specific patterns, see the individual pattern guideline documents. For more information about applying a pattern, see Select a form pattern.

Apply the pattern

You can apply a pattern in three ways:

- Using metadata
- Using visuals
- Using the designer For more information about applying a pattern, see Select a form pattern.

Handle errors

Information about the pattern appears on the **Pattern** tab. To learn about the pattern structure, click the control names on the **Pattern** tab to navigate the pattern structure. When you save or build the form, the pattern errors appear in the error list in Visual Studio.

- Double-click an error to go to the control that the error was reported for, if the control exists.
- If a control is missing, follow one of these steps:
  - If the control already exists on the form but is in a different place, move the control to the correct place, as indicated by the pattern.
  - If the control doesn't exist, create the control.

Subpatterns

After you apply a pattern to a form, you might have to apply subpatterns to the form's container controls. The process is similar to applying a pattern to a form: acquire the target, determine the subpattern, apply the subpattern, and handle any errors. To find container controls on the form that require subpatterns, search for "unspecified" in the search box at the top of the form designer in Visual Studio. These controls should have the **Pattern: <select>** designation in the form designer. For each container, you should examine the contents and select the most appropriate subpattern. Like form patterns, the available subpatterns cover common container layouts from Dynamics AX 2012 but also include several new subpatterns. If you require help selecting a subpattern, see Selecting a Pattern. For more detailed information about specific subpatterns, see the individual subpattern guideline documents. After you've selected a subpattern, right-click the control in the form designer, select **Apply pattern**, and then click the subpattern to apply.

Frequently asked questions

What does applying a pattern do?

By applying a pattern, you can change multiple properties on multiple nodes in one quick action. Therefore, it's important that you understand what is happening.

Where do I find information about a pattern?

The **Patterns Information** panel (the **Patterns** tab under the form designer), the error list (**View** > **Error List**), and the form statistics add-in (right-click the form name in the form designer, and then select **Add-ins** > **Form Statistics**) all provide valuable information when you're trying to apply patterns. When you apply patterns, it's

important that you have patience, read, and proceed at a steady pace. Pattern guideline documents are also available for each pattern and subpattern. These documents contain a lot of additional information, such as information about when to use a particular pattern, what is included in the pattern, and UX guidelines to beware of when you use a pattern.

What do I do if I make a mistake when I am applying a pattern?

If you make a mistake, there are several actions that you can take:

- **Undo** – The Undo command (Ctrl+Z) is usually available for all actions, even for applying and removing a pattern.
- **Remove the pattern** – If you applied the wrong pattern, remove the pattern by right-clicking and then selecting **Remove pattern**. Note that properties are applied to nodes after a pattern is successfully applied without errors. Therefore, even after a pattern is removed, any properties that were changed by the pattern will still be set to the new values.
- **Revert** – When all else fails, take advantage of the source control system, and revert the changes that were made to a form.

Why are some properties hidden when the pattern has been applied?

Patterns enforce properties after the pattern structure has been successfully met. A property that is controlled by the pattern is hidden from developers because developers don't have to worry about that detail. This makes the development experience cleaner by reducing the "noise" in the Property Pane from properties whose values have been set by the patter and thus cannot be modified by a developer while the pattern is applied. Developers who are interested in the properties that a pattern is setting can remove the pattern. All the property values will then be visible on all the controls that are covered by the pattern.

How do I identify the set of forms that I should be doing more pattern work on?

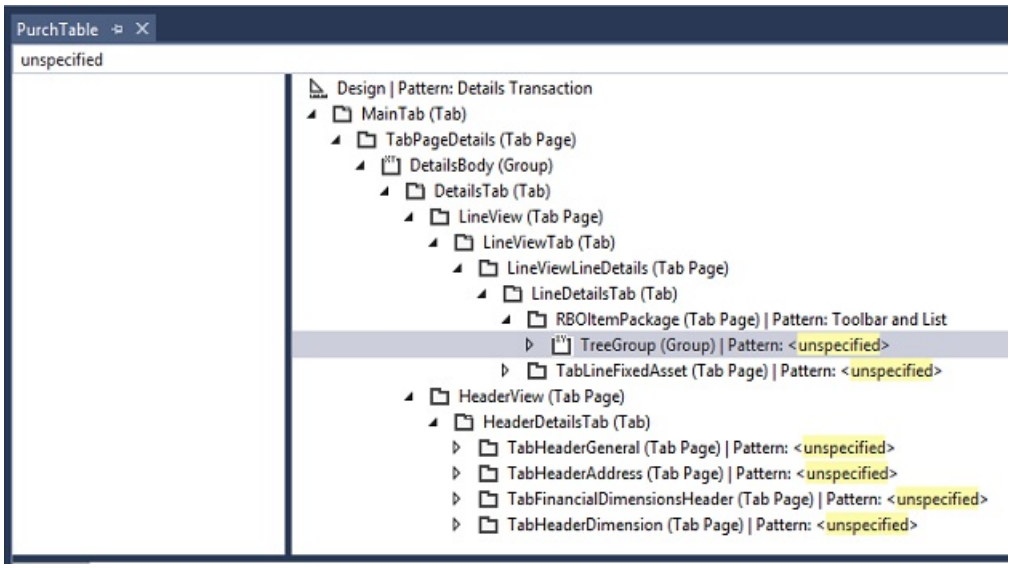
To identify the set of forms that still have remaining patterns work, you should generate and consult the **Form Patterns** report. For information on running the report, see Form pattern add-ins.

- **Filter the "Pattern" column to only show "(Blanks)"** - This will show all the forms with no form pattern applied (no pattern specified on Form.Design).
- **Filter the "Unspecific count" column to only those values "greater than 0"** - This will show all forms where a pattern is expected on either Form.Design or a container control somewhere on the form. You can combine this filter with the previously mentioned filter on the "Pattern" column to show only forms with subpattern work remaining.

Note that there are no remaining patterns work left in your models if there are no rows after the filters described previously are applied. If you want to make sure that all your forms are fully covered by patterns (meaning no unspecified nodes and no Custom nodes), filter the report down to those rows that have "Percent covered controls" less than 100 percent.

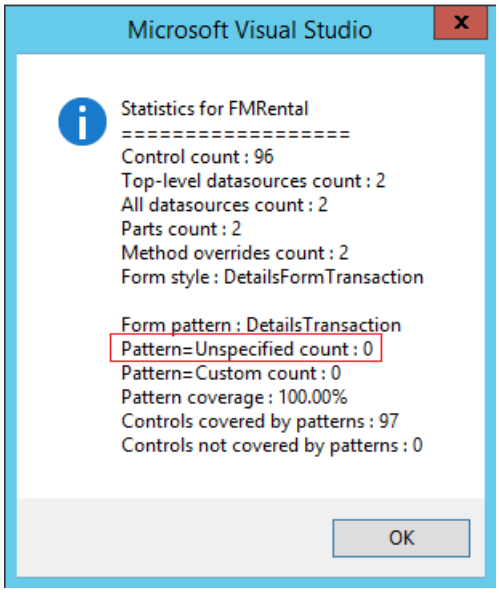
How do I find places in a form where a pattern can be applied?

To find container controls in the form that must still have a pattern applied, search for “unspecified” in the form designer. This search will highlight all the nodes in the form that have the **Pattern: <unspecified>** designation. You can then examine each container individually to apply the most appropriate subpattern.



How do I check whether more pattern work must still be done on a form?

To determine whether more pattern work must be done on an open form, right-click the form in the designer, and then select **Addins** > **Form statistics**. If the **Pattern=Unspecified** count is more than 0 (zero), the form still has containers that must have a pattern applied. Ideally, every form should also have a **Pattern=Custom** count of 0 (zero) and a **Pattern coverage** value of 100 percent. These values indicate that the form is fully covered by patterns.



Why isn't static text allowed inside the Fields and Field Groups subpattern? Isn't static text allowed in forms any longer? What do I do with the static text that the Fields and Field Groups subpattern doesn't accept? How can I show user Help instead of static text?

Static text in a form is often used as a highly visible mechanism for providing form help. Many patterns, such as the Toolbar and List subpattern and the Fields and Field Groups subpattern, don't allow static text to be placed directly on a form. Although user assistance is a good idea, it can often be provided in other ways. At a high level, the goal is to provide better labels and a more understandable user interface, so that explicit Help content isn't required. However, when explicit Help content is required, it should be provided as field HelpText or form-level Help content. If the static text explains the meaning of an image in a grid, consider using a tooltip to provide assistance when the user hovers over (for a mouse) or touches and holds (for touch) that image. Follow these steps to deal with static text on the form:

1. Determine a replacement for the static text on the form:

    - Consider whether the user information that is provided via static text is still required.
    - Consider whether field labels can be made more descriptive.

- Consider whether field HelpText would be appropriate.
- Consider whether form-level Help content would be appropriate.

2. After a replacement has been determined and implemented, remove the static text, and then apply the pattern.

3. If a replacement can't be implemented yet, leave the static text, and continue to use **Pattern:Custom**.

Why can't I change WidthMode on fields in the Fields and Field Groups subpattern? Why can't I specify a manual width on fields in the Fields and Field Groups subpattern?

Both the HeightMode and WidthMode properties are not available on controls inside the Fields and Field Groups subpattern because that subpattern intentionally sets the HeightMode and WidthMode properties to be SizeToContent on input controls. An input control with a SizeToContent width is sized based on a mapping of DisplayLength to one of four pre-defined discrete sizes (extra small, small, medium, or large). This discretization of input control widths was done in an attempt to provide a fresh, clean user experience that is simple and consistent (minimizing the jagged edges caused by arbitrarily wide fields). The discrete sizes were also chosen in a way that allows these fields to be combined together to form organized and visually appealing sets of fields (since the larger field sizes are multiples of the smallest field size in terms of width).

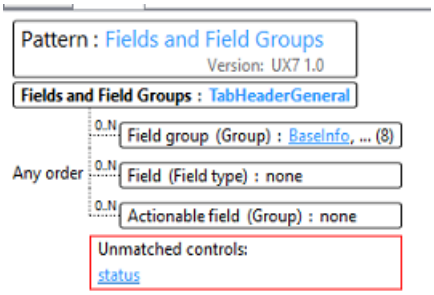
In general, there are two other width options available for fields that are not currently allowed in the Fields and Field Groups subpattern:

- **SizeToAvailable** - We cannot allow SizeToAvailable width controls inside of this subpattern because this sizing option does not work with the ColumnsMode=Fill layout algorithm (nor does it make sense when trying to decide how to best lay out controls into columns)
- **Manual** - Controls with manual widths should be rare; the vast majority of controls should be SizeToAvailable or SizeToContent. Manual-width controls introduce inconsistency into the discrete set of field widths and column widths, especially given the fact that these controls do not adapt their size based on the user-selected density. Manual-width controls may also present difficulties in ensuring a responsive design, as they may be set to sizes that are larger than can be accommodated by a particular viewport. In an effort to preserve the desired responsive field layout and clean interface and since manually-sized controls should be extremely rare, we have opted to not allow them in the Fields and Field Groups subpattern.

Your current options for scenarios where a manually sized control is needed include using a Custom pattern (which is reasonable given the field requires a "custom" size) as well as potentially using the Fill Text subpattern for a wider field (which allows a single full-width field per container, though we plan to extend the Fill Text subpattern to allow an arbitrary number of full-width fields).

Why do I have "unmatched" groups when I try to apply the Fields and Field Groups subpattern?

Groups and controls appear as "unmatched" in the **Pattern Information** panel if they, or any controls inside them, aren't allowed by the pattern.



There are two typical reasons why groups appear as "unmatched" in the Fields and Field Groups subpattern:

- There is more than one level of group depth. **Solution:** Refactor the groups so that they have only one level of depth inside the container that you're trying to apply the Fields and Field Groups subpattern on.
- There is an image or static text inside the group. **Solution:** Remove or relocate that control, if you can.

What do I do if my form is close to a form pattern but deviates in some way that makes it Custom?

Some forms are structurally close to a defined form pattern, but because some aspects don't fit the pattern, a Custom pattern is applied to the form. In this case, you might still be able to get some benefits of the form pattern (for example, the layout properties can be set automatically) by following these steps.

1. Modify your form so that it fully fits the pattern (for example, move or temporarily remove any controls that deviate from the pattern).
2. Apply the desired pattern.
3. Save the form, so that the property values are set by the pattern.
4. Remove the pattern.
5. Move the controls that deviate from the pattern back to their original location.

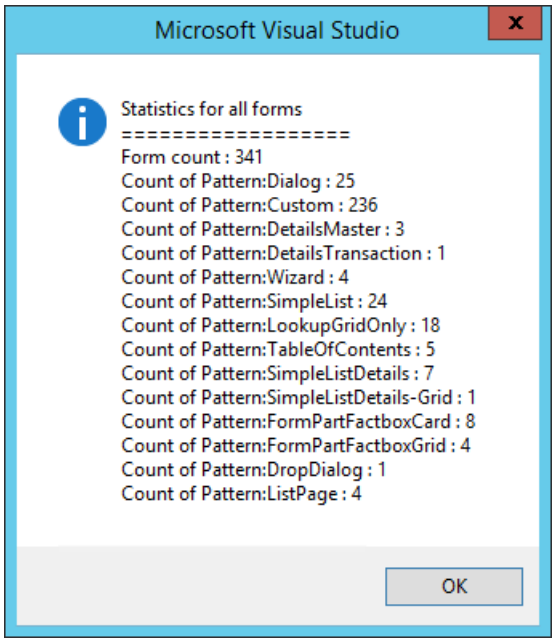
Visual Studio add-ins that support form patterns

2/18/2021 • 2 minutes to read • Edit Online

The tools for Visual Studio include a number of add-ins that support pattern usage.

Form statistics add-in

The **Form statistics** add-in provides a summary of the pattern usage for forms. When you access the **Form statistics** add-in from the **Dynamics 365** menu, it displays statistics for all forms. When you access the add-in from the shortcut menu for a form that is open in the form designer, it displays statistics for that form only.



Forms Pattern report

The **Form Patterns** report provides pattern information about every form, including whether the form uses a top-level form pattern, is a custom form, or is not specifying a form pattern. To generate the **Form Patterns** report, start Microsoft Visual Studio, click the **DYNAMICS 365** menu, expand **Add-ins**, and then click **Run the form patterns report**. The process will take several seconds. After the report has been generated, a dialog box will provide the location of the report. Browse to the specified location, and open the file in Microsoft Excel. You can then filter the report down to the models that interest you.

For more information about Visual Studio add-ins, see Tools add-ins for Visual Studio.

General form guidelines

2/18/2021 • 13 minutes to read • Edit Online

This topic contains the guidelines that apply to all forms, regardless of form pattern. This checklist must be used in addition to any pattern-specific guidelines.

Verification checklist

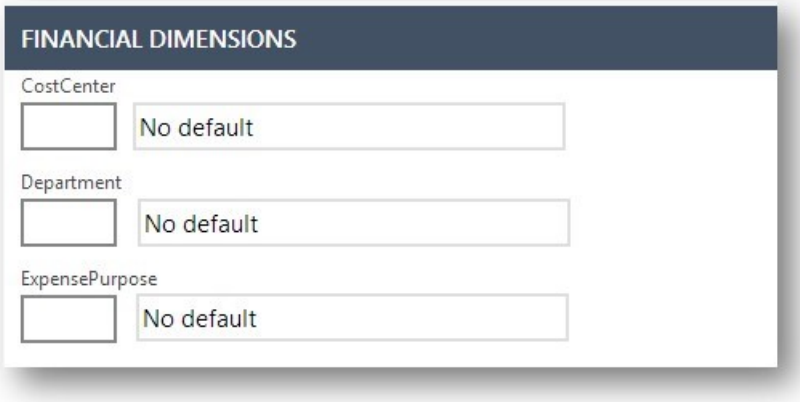
The verification checklist shows the steps for manually verifying that the form complies with the UX guidelines. This checklist doesn't include any guidelines that will be enforced automatically through the development environment. Open the form in the browser, and walk through these steps.

Standard form guidelines

Specific form patterns and subpatterns might have exceptions to these guidelines.

- The form layout is responsive when the browser is resized or the app is run on different device sizes. In other words, all the fields should be accessible to the user either by reflowing the layout or by scrolling to the fields.
- Make sure that the form's default View/Edit state is correct. By default, forms are in View mode. If a form should always be in Edit mode, you must explicitly set **Form.Design.ViewEditMode=Edit**.
  - The View/Edit state should be appropriate to the state of the entity. For example, if the state of the entity is **Posted**, and the form can't be edited, the default state should be View mode (and Edit mode should be disabled).
- **Form captions**:
  - Avoid setting the form caption programmatically. Instead, consider setting the **TitleDataSource** property on the form design node to enable the framework to provide the caption dynamically.
  - If you can't avoid setting the form caption programmatically, make sure that it's short (no more than 30 characters). This guideline exists because a large font size is used for the form in some form types.
    - **Exceptions:** Custom Lookups, FactBoxes
  - Form captions should provide the user with the context of the "type" of entity. The font size and the position of the form caption will vary, depending on the type of form.
  - Don't use the form caption to convey contextual information such as the parent record or other status information.
- All labels in the form are in sentence case. The framework guarantees consistency by putting some elements, such as Group labels, FactBox captions, Action Pane tab labels, and Button Group labels, in ALL CAPS. These strings should still be added in sentence case, but the framework will display them in all caps.
- All labels in the form are spelled correctly and use proper grammar.
- Avoid overriding the formatting alignment for extended data types (EDTs).
- When custom filters are used, no more than five should be specified. Instead, consider pre-populating the filter pane with fields.
- Occasionally, a decision must be made to determine whether a control should be temporarily disabled or hidden. The following information can help you make this determination:

    - A control should be temporarily disabled if the specific conditions must be met before the control can be enabled, and the user must first perform some action to meet those conditions.
    - A control should be hidden from the user if there is nothing that the user can do to enable or edit the control.
        - **Exception:** The control is used to convey status to the user.
- No UX guidelines are violated when security is applied for the various roles that have access to this form.
    - **Example:** For role A, field A **is not** required, but for role B, field A **is** required.
- No UX guidelines are violated when country/region codes are applied.
- Two fields can share a single label. Group the fields into a group, and set the **FrameType** property of the group to **GroupedFieldsLabel**.



Other form guidelines

- Use a StaticText control instead of StringEdit for multi-line read-only text. StringEdit controls are semantically incorrect for informational text, because they can never be edited. Additionally, StringEdit controls typically have a border and different layout characteristics than StaticText controls, and these differences negatively affect the user experience.
- Controls that are always read-only but data-bound should be marked as **ViewEdit**=**View**.
- (Dialogs and Drop Dialogs only) The button that is chosen as the default button should be the safest, most secure response to the task that the user is performing. For example, the default button should correspond to the main instruction of a Dialog or Drop Dialog.
    - If safety and security aren't factors, the button that is most likely to be clicked or that is most convenient for the user should be chosen as the default button.
    - **Exception:** Don't select a destructive response as the default button, unless there is an easy, obvious way to undo the command.

Field state guidelines

It's important that the state of a field be set correctly. The state of the field communicates key information about what the user can do and how to do it. The following table outlines key guidelines about when to use the various field states. **Note:** In the past, field states weren't used correctly. People interchangeably used **Enabled**=**No** and **Readonly**=**Yes**. Note the semantic differences between the two states:

- **Enabled**=**No** – The data **is not** valid.
- **Readonly**=**Yes** – The data **is** valid.

STATE	DESCRIPTION
Enabled=No	Disabled fields tell the user that the field isn't valid in the current state of the entity. Use the **Enabled** property to disable a field and prevent data input. A disabled field (**Enabled**=**No**) has these characteristics: • The field is visually presented so that it looks unavailable. The text will be gray to indicate a "not valid" appearance. • The field's value is unimportant and won't be sent to the server for processing. • The field is skipped in the tab sequence. A disabled field might become enabled by actions that the user takes in the form. If the user can never enable a field, consider hiding the field instead.
Readonly=Yes	For read-only fields, the data is valid in the current context but can't be edited. The field isn't skipped in the tab sequence. If the value can never be edited, consider using **ViewEditMode**=**View** for the field.
ViewEditMode=View	Use this state when the value in a field can never be edited by the user and is for informational purposes only.
Secured	Fields are typically hidden if they are secured. In grids, each row can define different levels of security for each column. Therefore, for cells where the user has no access, a padlock appears in the field. This isn't an application-controlled ability and occurs automatically.
Not available	Similar to secured fields, data can appear in a grid where each row has a different set of columns. In this case, cells that aren't applicable to a row display a "not" symbol. This isn't an application-controlled ability and occurs automatically.

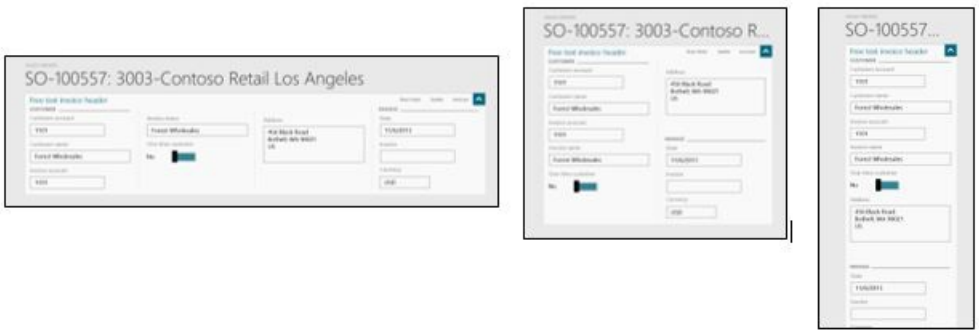
Mandatory field guidelines

Mandatory fields are fields that the user must supply values for to guarantee database referential integrity and business logic integrity. By marking fields as mandatory, you provide an important indicator about what the user must do.

- All mandatory fields are marked.
- Mandatory fields should be set on metadata concepts in this order:
  1. Table
  2. Data source
  3. Form field
- Mandatory fields should be set programmatically, based on the state of the record. For example, a field that is required in order to post an entity should be marked as mandatory.
  - If the user receives a validation message about an empty field, but that field isn't marked as mandatory, the user experience is negatively affected.

FastTabs guidelines

- The fields in groups should flow across the FastTab.



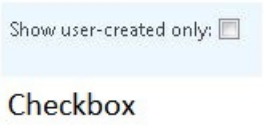
- The content of the first FastTab should be fully visible without scrolling. FastTabs should never horizontally scroll when the fields are displayed.
- The first FastTab should contain the most important fields for this entity (the fields that will be edited most often).
- FastTabs should display summary information.
  - **Exceptions:**
    - FastTabs that contain only a grid aren't expected to display summary fields.
    - Dimensions FastTab pages can't display summary fields, because this functionality isn't currently supported.
- If the FastTab contains a grid, it should follow the Toolbar and List subpattern guidelines.

Radio button guidelines

- Follow all standard Microsoft guidelines for radio buttons. Specifically, observe these guidelines:
  - The radio button control is used to select one option from a set of mutually exclusive choices.
  - There are between two and seven choices. If there are more than seven choices, use a combo box instead.
  - If none of the options is a valid choice, there is another option to reflect this situation, such as **None** or **Does not apply**.
  - Selection of a radio button doesn't perform commands, display other windows, such as a dialog box, or dynamically show/hide other controls that are related to the selection.
  - One radio button option is always selected by default. (However, see the exceptions at the MSDN guidelines link.)
  - The default option is the safest (that is, the option prevents loss of data or system access) and most secure and private option that is available. Alternatively, the default option is the most likely and convenient option.
  - Every radio button has a label.
- If subordinate controls are required for the selection of a radio button, follow these guidelines:
  - The subordinate controls are visible and appear to the right of or below the radio button.
  - Using the subordinate control selects the radio button.
  - The subordinate controls aren't nested radio buttons that have other radio buttons or check boxes.
- Options are listed in a logical order:
  - From the most likely to be selected to the least likely to be selected
  - From the simplest operation to the most complex operation
  - From the least risk to the most risk

Check box and toggle guidelines

Toggle buttons are typically used instead of traditional check boxes.



Checkbox

Toggle

- Follow all standard Microsoft guidelines for check boxes. Specifically, observe these guidelines:
  - By default, use toggle buttons instead of check boxes in forms. The label must follow the Microsoft guidelines for check box labels.
    - **Exceptions:**
      - Use a check box when a large number of related options must be set in a group.
      - Use a check box inside Custom Filter Group subpatterns.
      - Groups where a check box is used on the frame to collect related fields. *This exception is currently under review to add clarity.*
  - Don't use check boxes/toggle buttons as a progress indicator.
  - Don't use check boxes to initiate a command. However, a message box can be shown to the user to refine or clarify the choice.
  - Write the label so that it describes the selected state of the check box. The meaning of the cleared state must be the unambiguous opposite of the selected state.
  - For a group of check boxes, use similar phrasing, and try to keep the length of all labels about the same.
  - Use positive phrasing. Don't phrase a label so that selection of the check box means that an action is **not** performed.

Selection panel guidelines

- Occasionally, you'll require a discrete list of options that the user can select from, where each option presents the same interface. Don't use radio buttons to present the list of options. Instead, use a combo box control inside a Custom Filter Group .
- If the selection list is common to a set of items, the combo box should appear above all the items that are affected.

General grid guidelines

- Grids should be sorted on the first column and in ascending order, unless the scenario requires a different sort order:
  - The identifier (ID) field for documents (Sales Order ID, Purchase Order ID, and so on)
  - The name/description field for entities (Vendor name, Customer name, and so on)
  - Depending on the scenario, sorting can be on another column that makes business sense, such as the sequence number or date.
- **Editable grids**:
  - You must show and set the mandatory fields in the grid. It's not acceptable to alert the user to a missing mandatory field only when the record is saved.
  - All editable grids must have a **New/Delete** or **Add/Remove** button in a toolbar above the grid, or in the global Action Pane.
- Order the columns so that the most important columns are on the left. Amount columns are most usable for a user when they are placed in the rightmost position in the grid.
- Image columns can be used to convey state information for an entity or process, such as the workflow status.
- In general, the image column should be placed on the left side of the grid, and there should not be a column label. The meaning of the image should be indicated by the tooltip.
- Numeric columns should be right-aligned. All other columns should be left-aligned.
- If the form can be opened in View mode and can be used to create records in Edit Mode, the property of the

root data source that is connected to the grid should be **Insert If Empty**=**No**. This setting will prevent situations where a user sees and selects a blank record when a read-only form is opened.

Entity status field guidelines

- The entity status must appear in the upper-right of the form, to the right of the title fields. The Details form patterns provide an optional Group where status fields can be defined.

Standard Action Pane guidelines

- The Standard Action Pane is at the top of the form and follows the standard Action Pane guidelines.
  - **Exceptions:** Dialog, Drop Dialog, Lookups
- For application-added actions, labels for similar actions should be used consistently across all Action Panes.
- If the name of the button doesn't adequately explain the action, a supplemental description should be shown in the tooltip.
- Actions on an Action Pane should apply to the whole entity. Never put actions that apply only to portions of the entity on the Action Pane. Instead, use local toolbars that are near the objects that will be acted on.
- There should be no more than 10 tabs on a Standard Action Pane.
  - There should be between one and eight actions per group.
  - The first tab is the home tab. It should have the same name as the entity and should be singular.
- **Activity tabs**:
  - Actions that are related to a specific activity should be grouped into an appropriately named Activity tab.
  - These tabs should be given the names of activities that the user will understand. The names should consist of action verbs.
  - Remove system-defined actions from Activity tabs.
  - **New** and **Maintain** groups group actions, such as **New**, **Delete**, **Edit**, and **Save**, that are related to these primary actions. The exception is **New** actions that are related to secondary types within the entity.
  - Remove duplicate **Refresh**, **Attachments**, **Export to Excel**, **Restore**, **OK**, and **Done** buttons.
- **General tab**:
  - If there are common, infrequent actions that aren't related to a specific activity, they should appear on the last tab, which should be named **General**.
  - Commands that appear on the **General** tab should not be repeated on other tabs.

Buttons on canvas guidelines

- Buttons in the content area of a form that are related to the form, not to a specific field, should be placed on the standard Action Pane or in a Toolbar.

Button image guidelines

- Buttons that require images should use symbols for their images.
- If both an image and text are shown on a button, the image must be to the left of the text. No other configurations are supported.
- **Standard Action Pane**:
  - Buttons that replace the system **New/Delete** buttons should use the New/Delete symbols.
  - Common actions should have **ButtonDisplay**=**Auto**, unless they have symbols that are used by other system buttons. In that case, they should be **TextOnly**. Consult UX if there are other common actions that you believe should have symbols assigned.

    - Other uncommon actions should be **TextOnly**.
    - Images aren't supported on Action Pane tabs.
- **Toolbars**:
    - **Add/Remove** (if applicable) should be the first buttons, should use the Add/Remove symbols, and should have both images and text (**ButtonDisplay**=**Auto**).
    - Common actions should be moved just to the right of the **Add/Remove** buttons. These actions can also have both images and text (**ButtonDisplay**=**Auto**). If no appropriate image exists, these can be **TextOnly**.
    - Subsequent uncommon actions should be **TextOnly**.
- **Inside MenuButtons**:
    - Images aren't supported on buttons in MenuButtons.

Appendix

Frequently asked questions

This section will have answers to frequently asked questions that are related to this guideline/pattern.

- **What types of fields aren't supported as summary fields on Fast Tabs?**
    - For performance reasons, we don't currently support reference groups and display methods. Additionally, unbound fields can't be used as summary fields.

Details Master form pattern

2/18/2021 • 4 minutes to read • Edit Online

This topic provides information about the Details Master form pattern. A details form is the primary method for entering data.

Usage

A details form is the primary method for entering data. These forms let the user view, edit, and act upon data. All content on these form types is structured into FastTabs that can be expanded and collapsed, so that multiple FastTabs can be open at the same time. The FastTabs can contain fields or a grid, and each FastTab can have a local toolbar. Two patterns are described in this document:

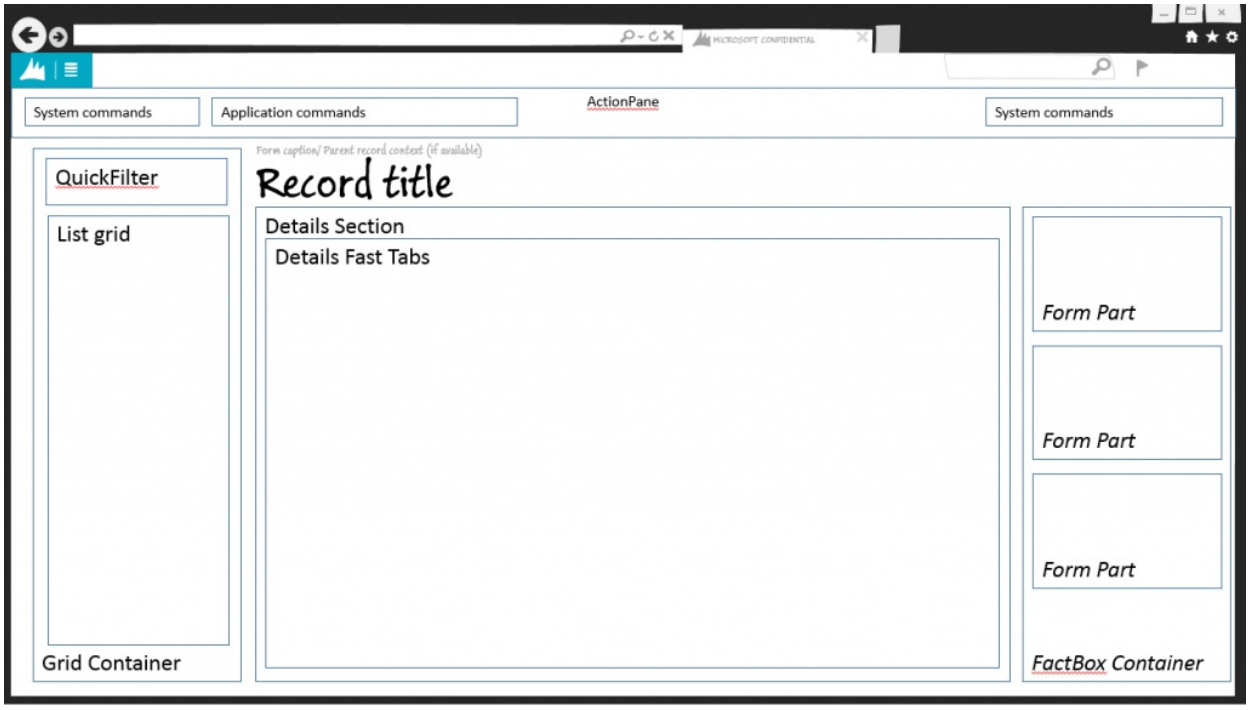
- **Detail Master** – This is the basic Detail Master pattern. This is the pattern that you should use by default.
- **Detail Master w/ Tabs** – You should use this pattern when an entity requires many FastTabs (more than 15) that can be grouped into categories.

In both cases, the grid view is structured the same.

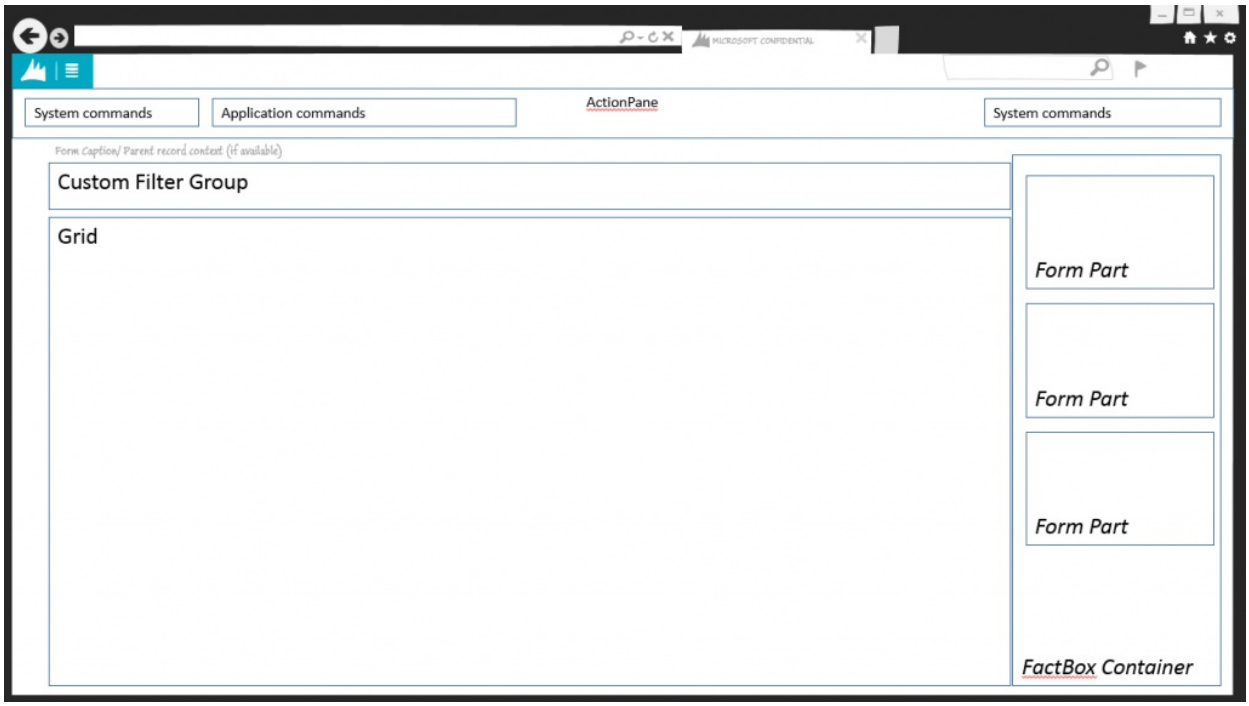
Wireframe

Details Master

Details view

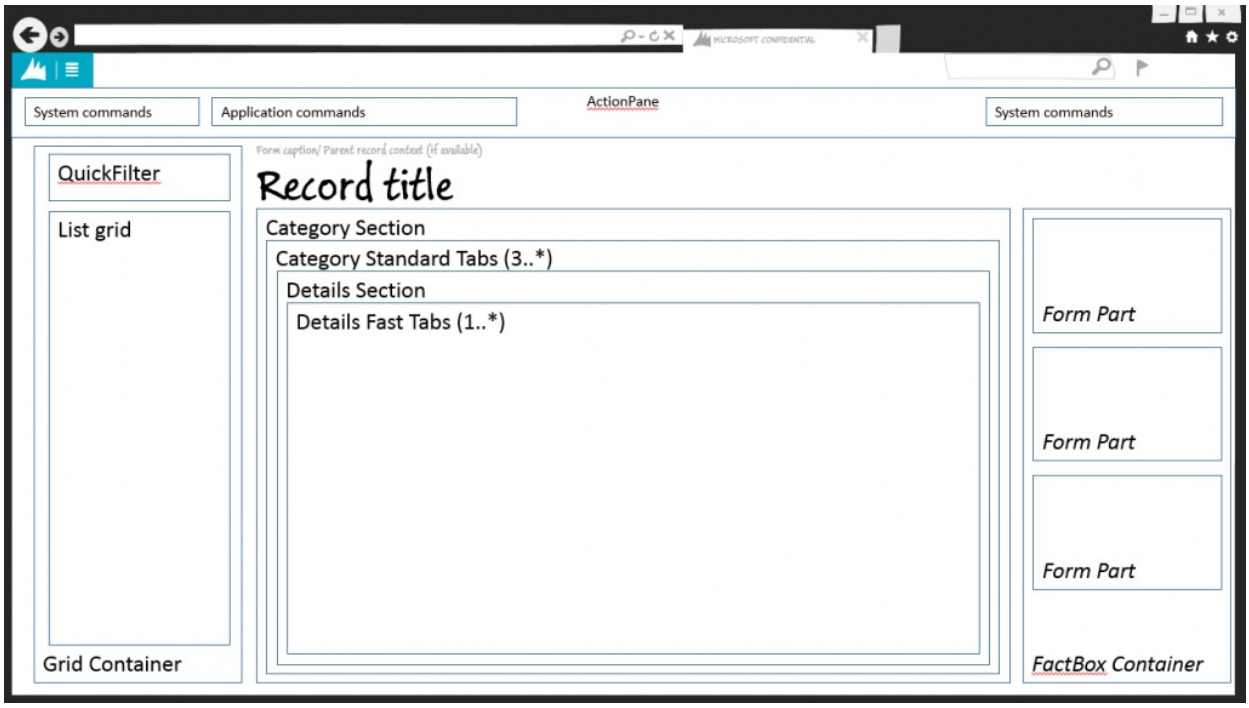


Grid view

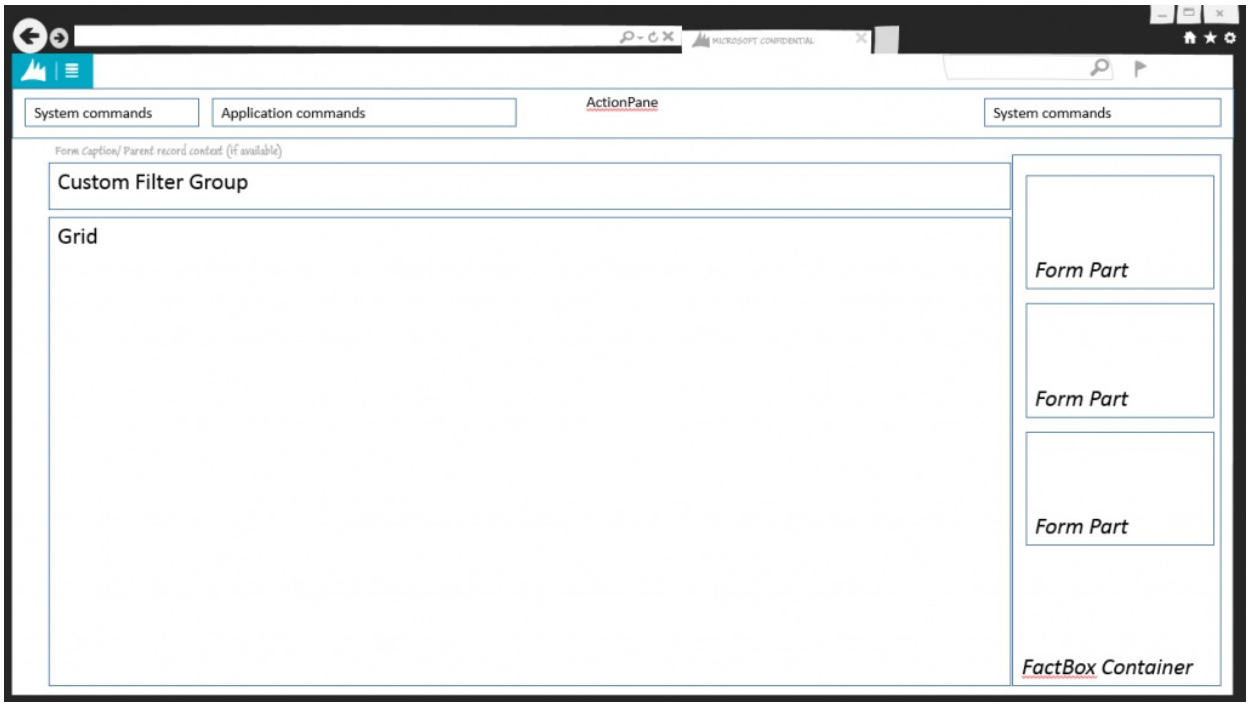


Details Master with Standard Tabs

Details view



Grid view



Pattern changes

Here are the main changes to this pattern since Microsoft Dynamics AX 2012:

- Added a List style grid to the left of the Details view content.
- Merged List Page and Details Master into a single form.
  - Improves performance when moving between a list and details.
  - Enables bulk editing in the initial list.
  - Allows for elimination of the list page preview pane.
- View/Edit, New, Delete, Save, Refresh, Attachments, and Export to Excel actions are all provided by the foundation and should not have explicit app buttons unless the foundation-provided button is removed.
- Master Details forms that previously used the TOC extension should now use the Master Details w/Standard Tabs pattern.

Model

Details Master (basic) – High-level structure

- Design
  - ActionPane (ActionPane)
  - SidePanel (Group)
    - QuickFilter
    - *CustomFilters (Group) [Optional]*
    - NavigationList (Grid, Style=List)
  - MainTab (Tab ShowTabs=No)
    - DetailsTabPage (TabPage)
      - TitleGroup (Group)
        - HeaderTitle (String)
        - *EntityStatus (Group) [Optional]*

StatusFields (1..N)

- DetailsTab (Tab Style=FastTabs)
  - DetailsTabPage (TabPages *repeats 1..N*)
- GridTabPage (TabPage)
  - CustomFilterGroup (Group)
    - QuickFilter
    - *OtherFilters ($Field) [0..N]*
  - MainGrid (Grid)
  - MainGridDefaultAction (CommandButton)

Details Master with Standard Tabs – High-level structure

- Design
  - ActionPane (ActionPane)
  - SidePanel (Group)
    - QuickFilter
    - *CustomFilters (Group) [Optional]*
    - NavigationList (Grid, Style=List)
  - MainTab (Tab ShowTabs=No)
    - DetailsTabPage (TabPage)
      - TitleGroup (Group)
        - HeaderTitle (String)
        - *EntityStatus (Group) [Optional]*
          - StatusFields (1…N)
      - CategoryTab (Tab Style=Tabs)
        - CategoryTabPage (TabPages *repeats 3..N*)
          - TabHeader (Group)
          - DetailsTab (Tab Style=FastTabs)
            - DetailsTabPage (TabPages *repeats 1..N*)
    - GridTabPage (TabPage)
      - CustomFilterGroup (Group)
        - QuickFilter
        - *OtherFilters ($Field) [0..N]*
      - MainGrid (Grid)
      - MainGridDefaultAction (CommandButton)

Core components

1. Apply the DetailsMaster pattern on **Form.Design**.
2. Address BP Warnings:
   a. **Design.Caption** isn't empty.

b. Form must be referenced by at least one menu item.
c. **TabPage.Caption** isn't empty.

- Custom Filter Group

UX guidelines

The verification checklist shows the steps for manually verifying that the form complies with UX guidelines. This checklist doesn't include any guidelines that will be enforced automatically through the development environment. Open the form in a browser, and walk through these steps. **Standard form guidelines:**

- Standard form guidelines have been consolidated into the Microsoft Dynamics AX General Form Guidelines document.

Detail Master guidelines:

- There should not be any duplicate **New** and **Delete** buttons.
- Should use FastTabs to group the fields instead of traditional tabs. The Details Master w/Standard Tabs pattern groups these related FastTabs into traditional tabs.
  - In its **default** state, the content of the first FastTab should be fully visible without scrolling.
  - **FastTabs** guidelines have been consolidated into the General Form Guidelines document.
- **ActionPane** guidelines have been consolidated into the General Form Guidelines document, in the ActionPane guidelines section.
- **Page title area:**
  - The following format should be used: "<ID> : <Description>"
  - A link to the Details page should be provided in the Main Menu when the List page has been merged into the Details page.
  - The page title should be in a plural form.
- **FactBox** guidelines have been consolidated into the FactBox Form Patterns document.
- **Navigation list grid:**
  - The list style grid should not have fields within a grid row that cause the row to span more than three lines.
    - Typically, just the ID and Description are sufficient.
    - There should be at least two fields.
- **Grid view:**
  - The grid has 2 to 15 fields. Typically, all mandatory fields are included, so that records can be created in the grid.
  - A linked field lets the user open the details for the selected record.
  - The Quick filter should default to the most likely field for a filter scenario.
  - **Grid:**
    - The **ID** field should be the first column (if it's needed in the grid). Otherwise, the **Name** field should be the first column.

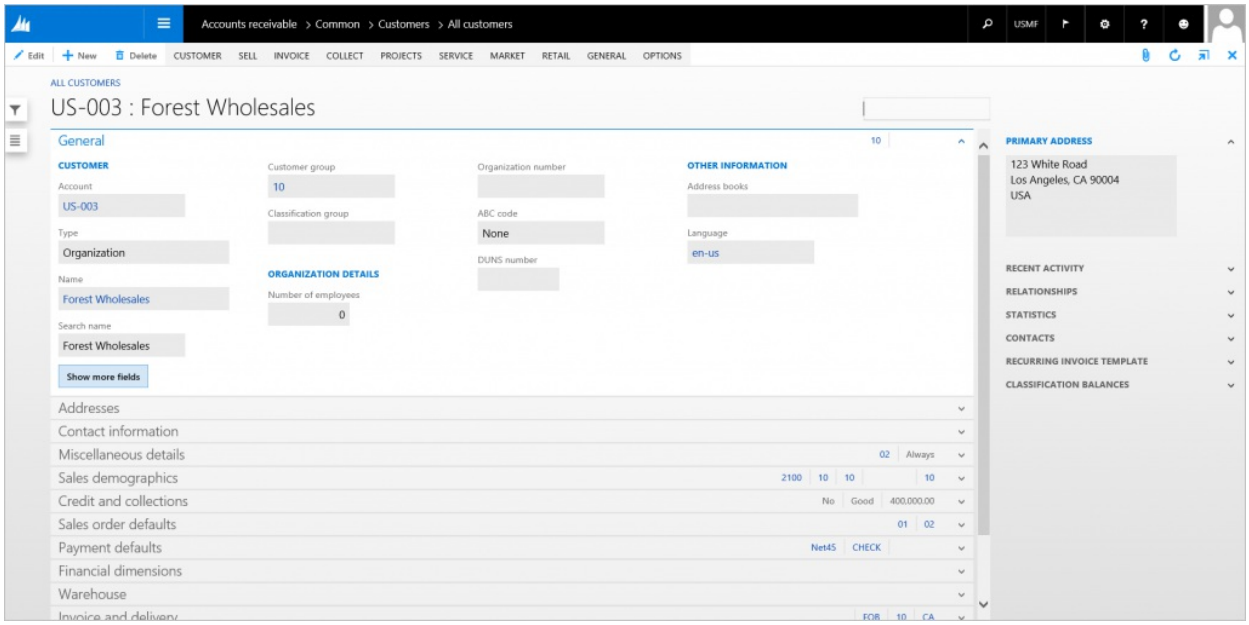
- Additional grid guidelines have been consolidated into the General Form Guidelines document, in the Grid guidelines section.

Examples

Details Master (basic)

Form: CustTable

Details view (navigation list off)



Details view (navigation list on)

Details Transaction form pattern

2/18/2021 • 4 minutes to read • Edit Online

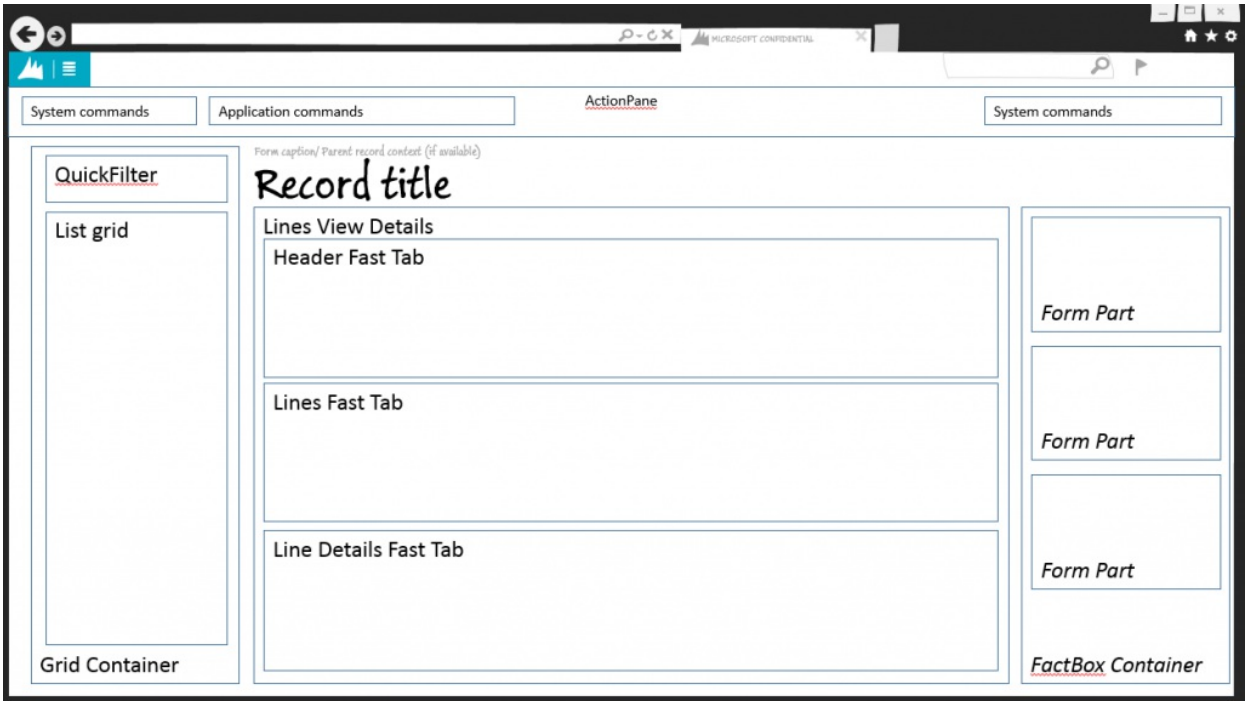
This topic provides information about the Details Transaction form pattern. Forms that use this pattern can have two details views that the user can switch between - a Header view and a Line view.

Usage

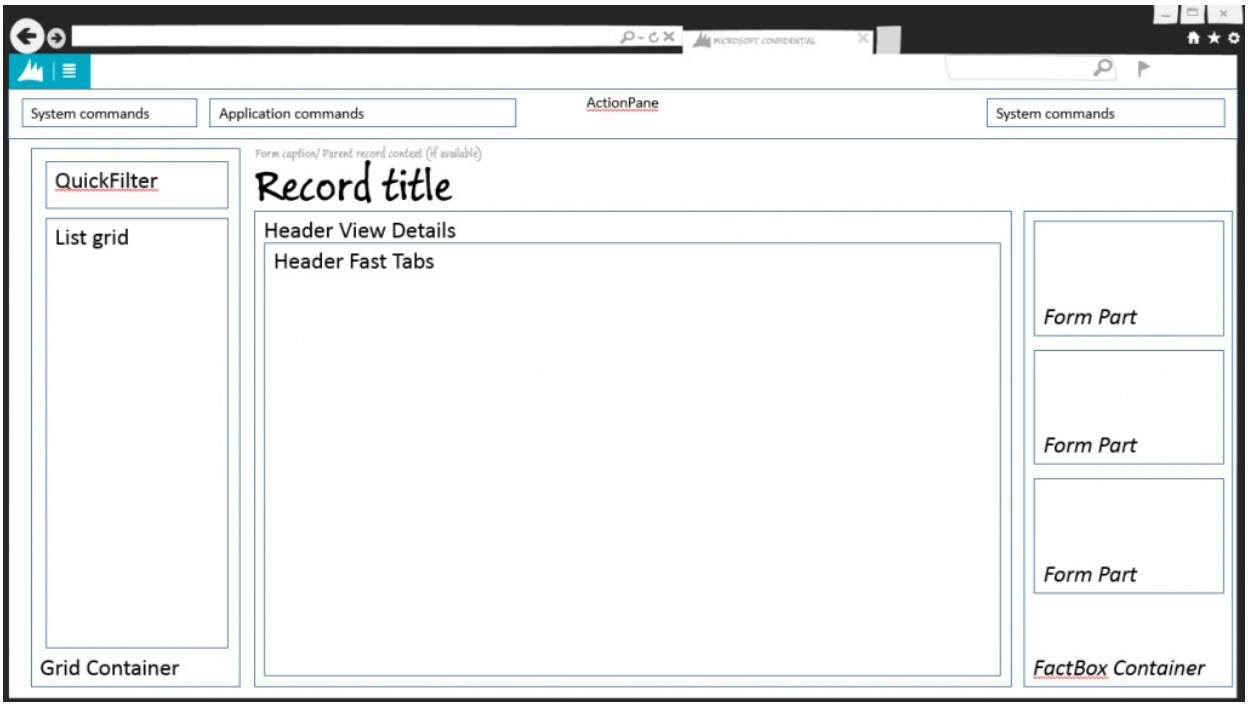
A details form with lines (Details Transaction form) consists of one form that can have two details views that the user can switch between. The Header view contains all fields that are related to or part of the header. The Line view contains the lines grid, line details, and a section that contains a collection of the most important header fields.

Wireframe

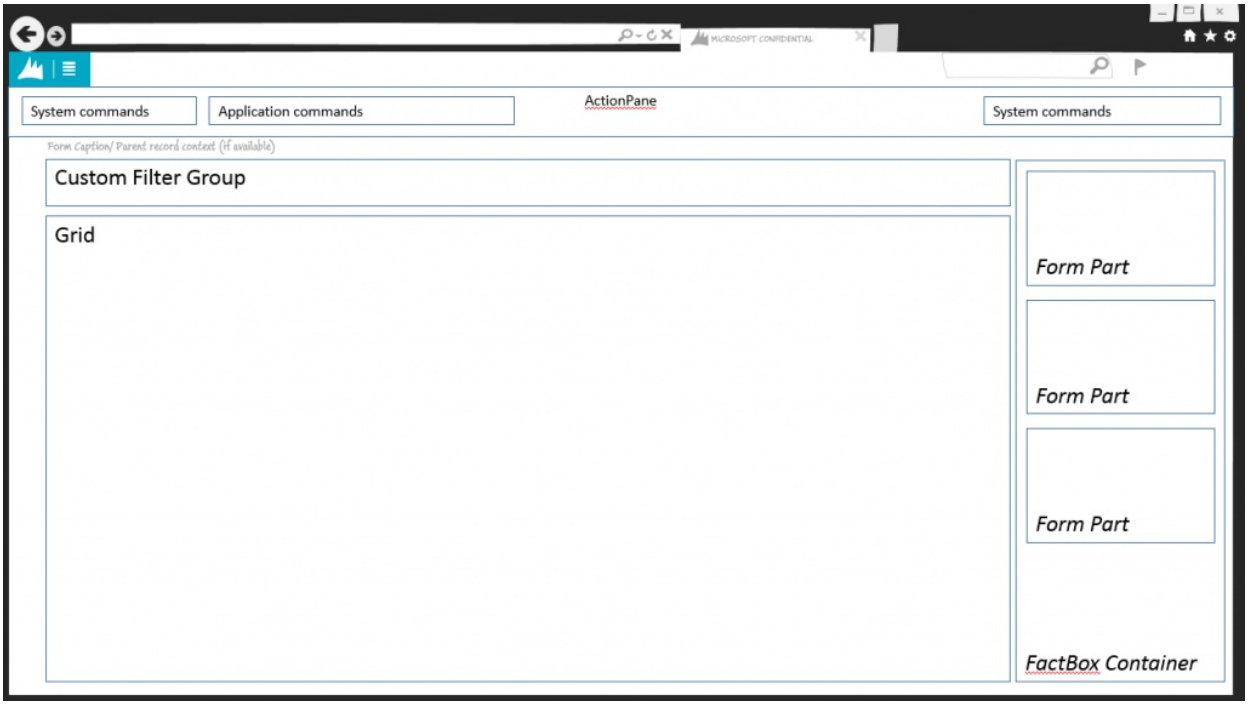
Line view



Header view



Grid view



Pattern changes

Here are the main changes to this pattern since Microsoft Dynamics AX 2012:

- A List style grid has been added to the left of the Details view content, which is shown in either Header view or Line view.
- List Page and Details Master have been merged into a single form. This change has the following benefits:
  - It improves performance when users move between the list and details.
  - It enables bulk editing in the initial list.
  - It allows for elimination of the list page preview pane.
- View/Edit, New, Delete, Save, Refresh, Attachments, and Export to Excel actions are all provided by the foundation and should not have explicit app buttons unless the foundation-provided button is removed.

Model

High-level structure

- Design

UX guidelines

The verification checklist shows the steps for manually verifying that the form complies with UX guidelines. This checklist doesn't include any guidelines that will be enforced automatically through the development environment. Open the form in the browser, and walk through these steps. **Standard form guidelines:**

- Standard form guidelines have been consolidated into the Microsoft Dynamics AX General Form Guidelines document.

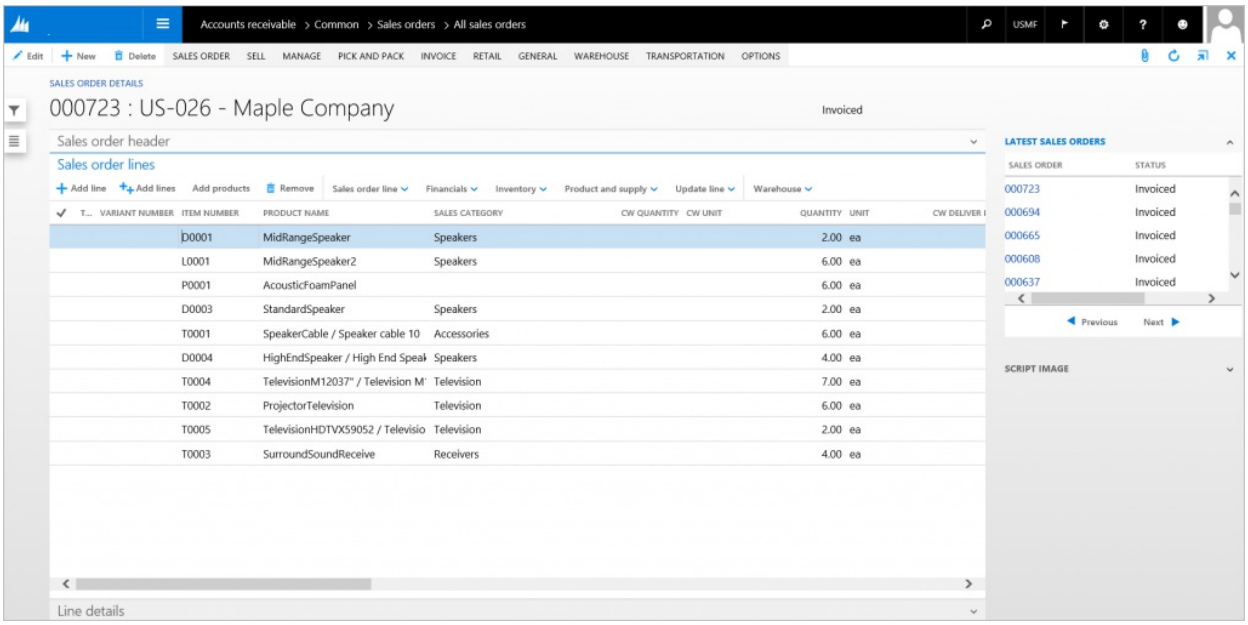
Detail Transaction guidelines:

- There should not be any duplicate **New** and **Delete** buttons.
- **ActionPane** guidelines have been consolidated into the General Form Guidelines document, in the ActionPane guidelines section.
- In its **default** state, the content of the first FastTab should be fully visible without scrolling.
- **FastTabs** guidelines have been consolidated into the General Form Guidelines document.
- **Page title area**:
  - The following format should be used: **<ID> : <Description>**
  - A link to the Details page should be provided on the Main Menu after the List page has been merged into the Details page.
  - The page title should be in a plural form.
- **Navigation list grid**:
  - The list style grid should not have fields within a grid row that spans more than three lines.
    - Typically, just the ID and Description are sufficient.
    - There should be at least two fields.
  - The last field should be the total of the transaction.
- **Grid view**:
  - The grid has 2 to 15 fields. Typically, all mandatory fields are included, so that records can be created in the grid.
  - A linked field lets the user open the details for the selected record.
  - By default, the Quick Filter should use the most likely field for a filter scenario.
  - Focus should be in the Quick Filter when the list page is opened.
  - **Grid**:
    - The **ID** field should be the first column, followed by the master entity **ID** and **Name** fields.
    - Additional grid guidelines have been consolidated into the General Form Guidelines document, in the Grid guidelines section.
  - **FactBox** guidelines have been consolidated into the FactBox Form Patterns document.

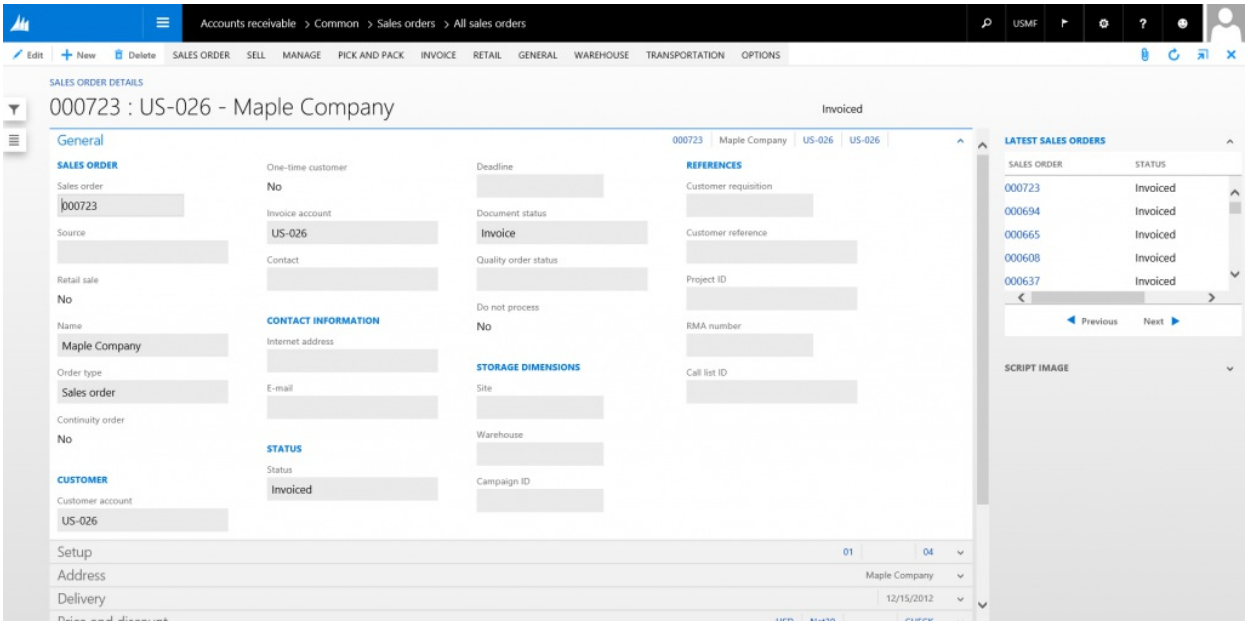
Example

Form: **SalesTable**

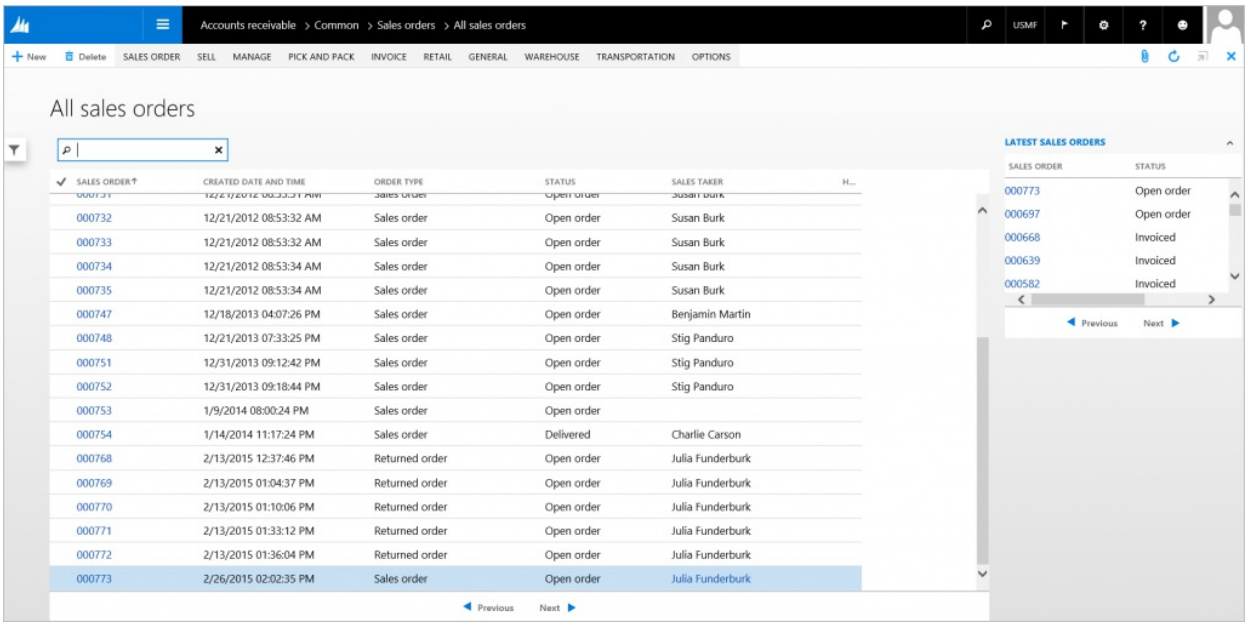
Line view



Header view



Grid view



Appendix

Frequently asked questions

This section will have answers to frequently asked questions that are related to this guideline/pattern.

- **Why is the Header view compulsory?**
  - The Header view is compulsory for the Details Transaction pattern. Initially, the Header view might not have more than the Line view header summary information. However, over time, it will be extended by application teams, internationalization teams, partners, and customers. It's important that the Header view be available for future modifications. In addition, a consistent and dependable form structure has benefits for usability and upgrade reasons.

Form Part Section List form patterns

2/18/2021 • 3 minutes to read • Edit Online

This topic provides information about the Form Part Section List form patterns. These workspace-specific patterns have been developed to show filtered lists inside workspaces.

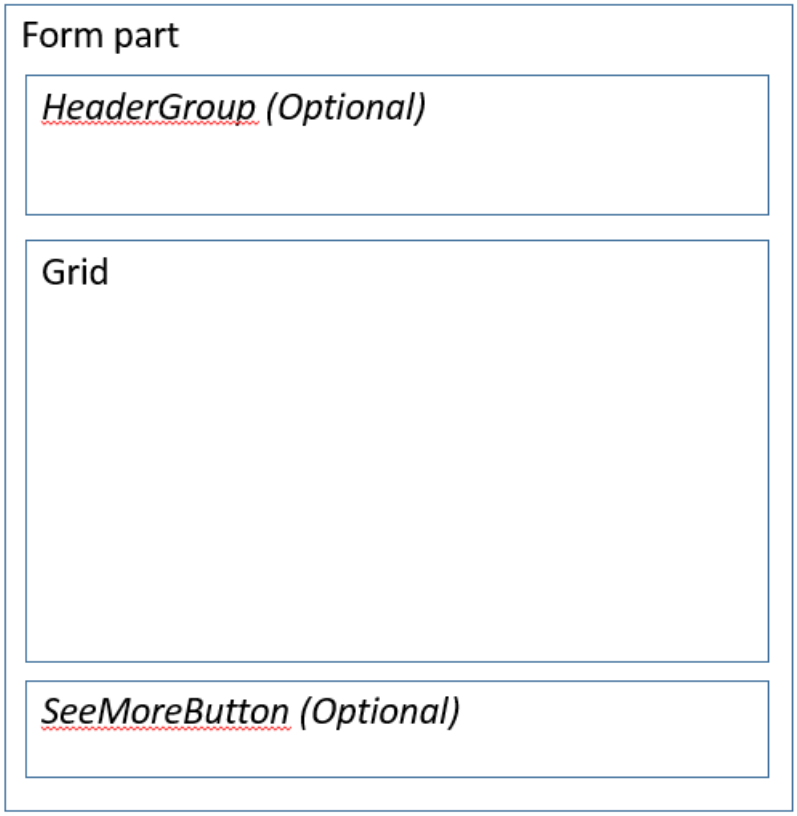
Usage

The Form Part Section List form patterns are workspace-specific patterns that are used to show filtered lists. The tabbed section of the workspace contains a set of vertical tabs. Each tab contains a Form Part Control that points to a form that contains one of the Form Part Section List patterns. Two patterns are described in this article:

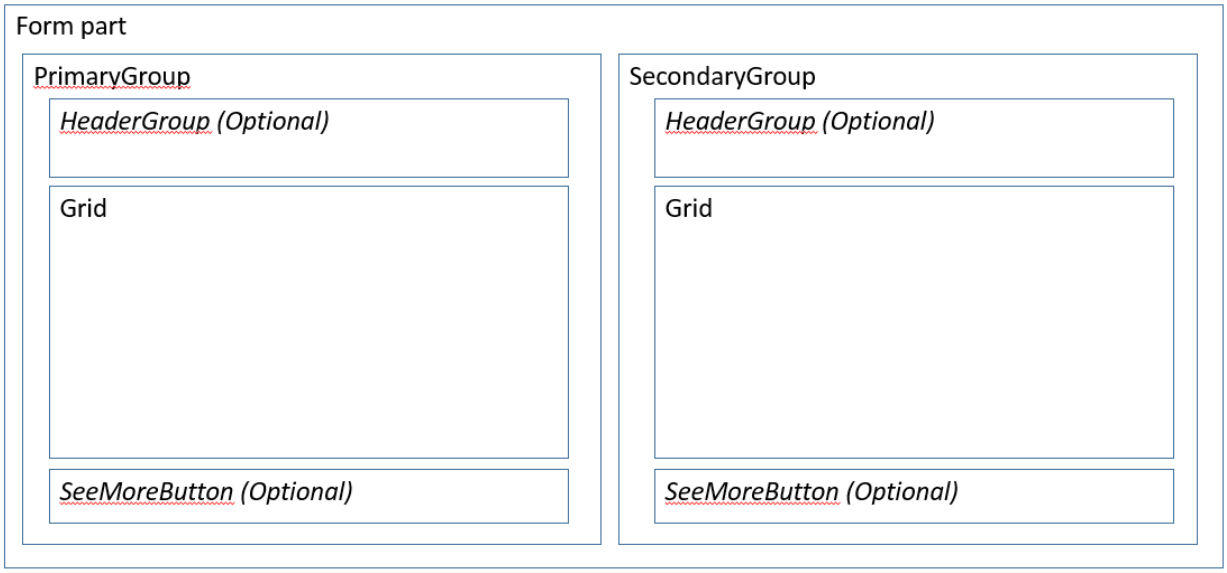
- **Form Part Section List** – This is the default Section pattern. It allows for a single list of data, together with an optional header group that contains filters and/or actions. Most content areas in the tabbed section of a workspace will use this pattern.
- **Form Part Section List - Double** – This variant enables a second list of data to appear to the right of the primary list. By default, the secondary list is hidden. To show it, the user clicks a button on the Toolbar above the primary list.

Wireframe

Form Part Section List



Form Part Section List - Double



Pattern changes for Finance and Operations

These patterns did not exist for Microsoft Dynamics AX 2012.

Model

Form Part Section List: High-level structure

- Design | Container
  - *Header (Group) [Optional]* – This must use one of the Filters and Toolbar subpatterns.
  - Grid
  - *GridDefaultAction (Button) [Optional]*
  - *SeeMoreButton (Button) [Optional]*

Form Part Section List - Double: High-level structure

- Design | Container
  - PrimaryGroup (Group)
    - *Header (Group) [Optional]* – This must use one of the Filters and Toolbar subpatterns.
    - Grid
    - *GridDefaultAction (Button) [Optional]*
    - *SeeMoreButton (Button) [Optional]*
  - SecondaryGroup (Group)
    - *Header (Group) [Optional]* – This must use one of the Filters and Toolbar subpatterns.
    - Grid
    - *GridDefaultAction (Button) [Optional]*
    - *SeeMoreButton (Button) [Optional]*

Core components

1. Apply the appropriate Form Part Section List pattern on **Form.Design**.
2. In the backing Operational workspace form, set the Form Part control on the corresponding vertical tab to point to a menu item that points to this form.

Related container patterns

- Section Tabbed List

- Filters and Toolbar

UX guidelines

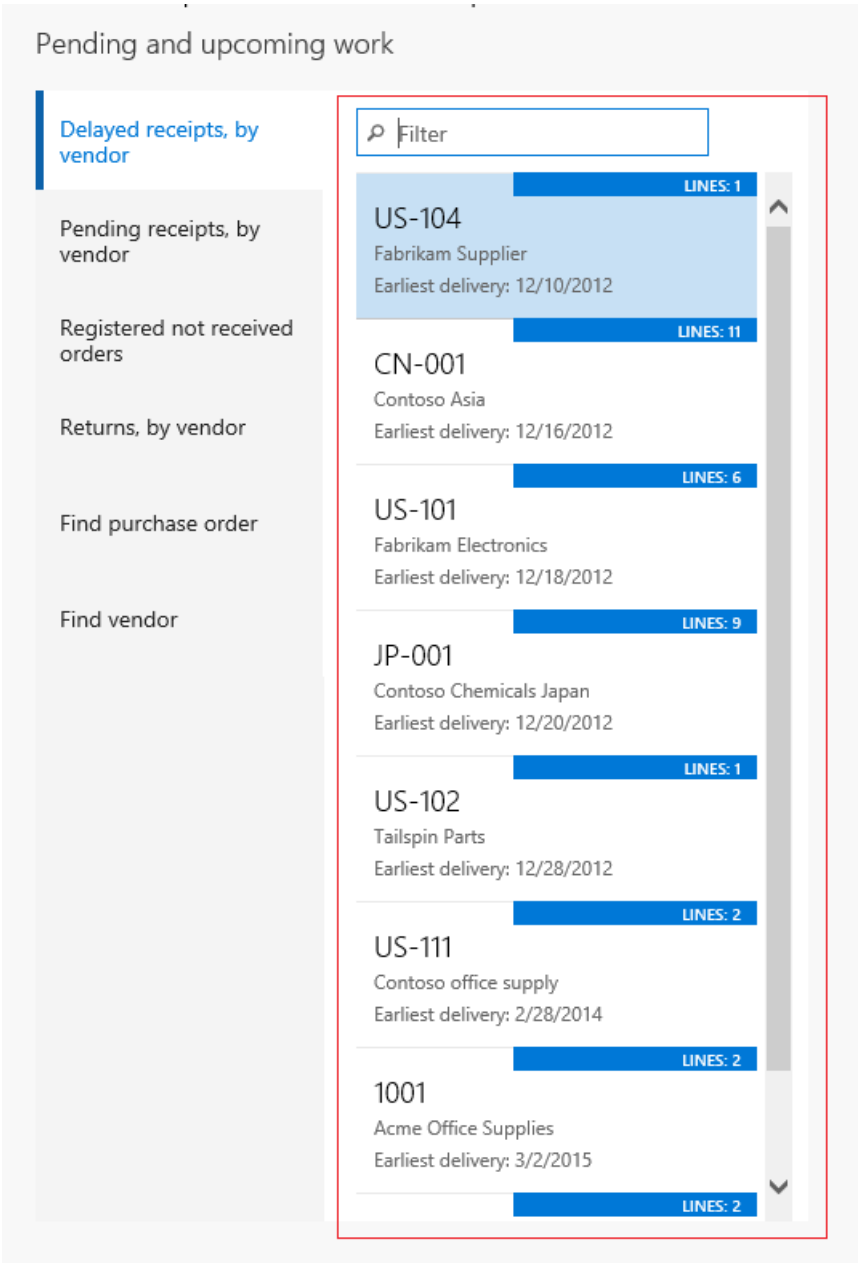
The verification checklist shows the steps for manually verifying that the form complies with UX guidelines. This checklist doesn't include any guidelines that will be enforced automatically through the development environment. Open the form in the browser, and walk through these steps.

- **General form guidelines**
  - Standard form guidelines have been consolidated into the General Form Guidelines document.
- **Pattern-specific guidelines**
  - If a backing form exists, and especially if not all the records are shown in the list, a **See more** button should appear at the bottom of the list, so that the user can see the full list.
  - Up to two important filters exist above the list.
  - Up to three frequently used actions exist above the list.
- **Grid**
  - Lists are filtered down to an interesting, relatively small set of data.
  - List grids have no more than three lines of data per row.
  - Card grids show no more than four fields (not including an image).
  - Tabular grids show no more than eight fields.
- **Form Part Section List - Double guidelines**
  - If both lists have actions and/or filters, both list must use the same Filters and Toolbar subpattern (either the Stacked variant or the Inline variant).

Examples

Form Part Section List

Form: **PurchOrderProcessReceiptsWorkspace** > **PurchOrdersWithDelayedReceiptsPart** (**All workspaces** > **Purchase order receipt and follow-up**)



Form Part Section List - Double

Form: **BudgetTrackingWorkspace** > **BudgetTransactionPart** (**All workspaces** > **Ledger budgets and forecasts**)

List Page form pattern

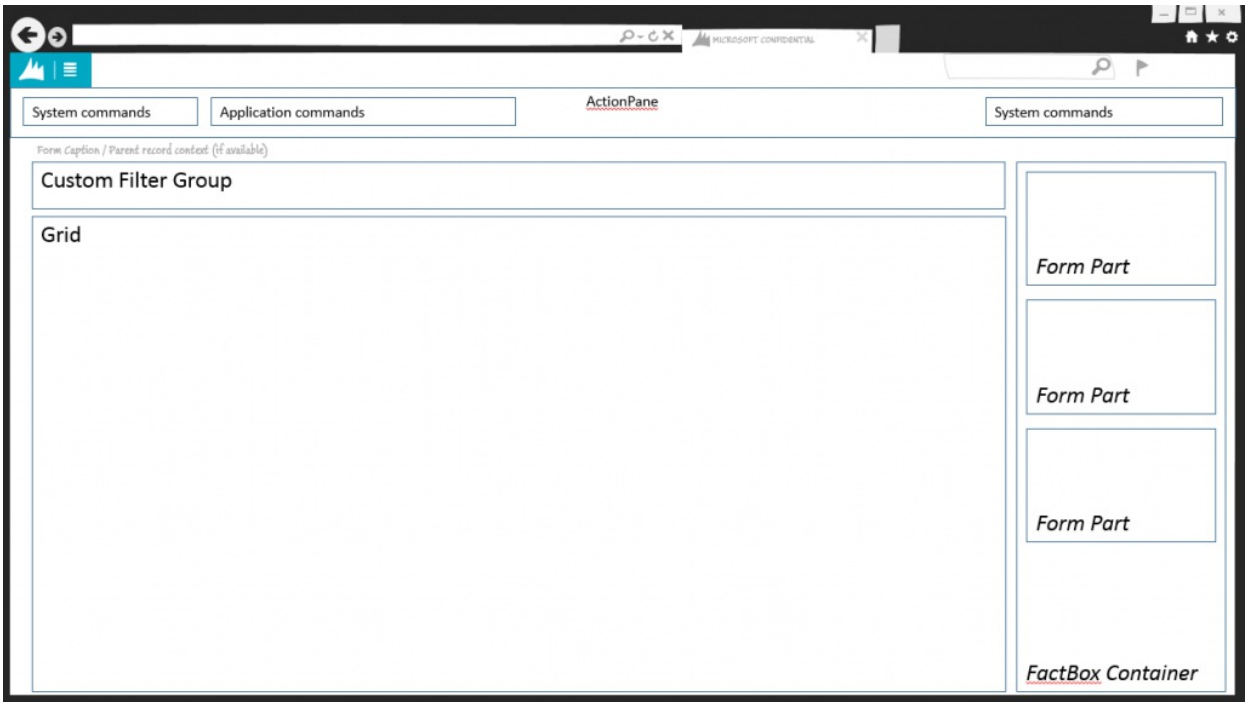
2/18/2021 • 4 minutes to read • Edit Online

This article provides information about the List Page form pattern. A list page presents a set of data on a UI that is optimized for browsing records, so that you can find and work with a specific record.

Usage

A list page presents a set of data on a user interface that is optimized so that you can browse records, find the right record, and then take an action upon that record. The list page lets the user search, filter, and sort the data. FactBoxes on the right side of the grid show related data for the active record. Actions that are relevant to the record are located on the ActionPane at the top of the page. The use of this pattern is now discouraged when there is a 1:1 correspondence between the List Page and Details page. Current guidance is to use this pattern only in other situations, such as when list pages have no backing details pages or have multiple backing details page (for example, when project quotations and sales quotations are shown together in the same List Page).

Wireframe



Pattern changes

Here are the main changes to this pattern since Microsoft Dynamics AX 2012:

- FormTemplate/InteractionClass is now optional when you build new pages.
- List Page and Details Master/Details Transaction are merged into a single form when there is a 1:1 correspondence between the List Page and Details Page.
  - Improves performance when the user moves between the list and details.
  - Allows for bulk editing in the initial list.
- The **Preview** pane has been eliminated.

Model

High-level structure

- Design
  - ActionPane (ActionPane)
  - Custom Filter (Group)
    - Quick Filter (Quick Filter)
    - *OtherFilters ($Field) [0..N]*
  - Grid (Grid)

Core components

1. Apply the ListPage pattern on **Form.Design**.
2. Address BP Warnings:
   a. **Design.Caption** isn't empty.
   b. The form must be referenced by at least one menu item.
   c. **TabPage.Caption** isn't empty.
   d. **TabPage.DataSource** isn't empty.
   e. The primary data source has **AllowEdit**=**No**, **AllowCreate**=**No**, and **AllowDelete**=**Yes**.
   f. **Grid.DefaultAction** references the button that opens the child form.
   g. **Grid.DefaultLabelAction** references a label to show in the grid context menu.

UX guidelines

The verification checklist shows the steps for manually verifying that the form complies with UX guidelines. This checklist doesn't include any guidelines that will be enforced automatically through the development environment. Open the form in the browser, and walk through these steps. **Standard form guidelines:**

- Standard form guidelines have been consolidated into the General Form Guidelines document.

List Page guidelines:

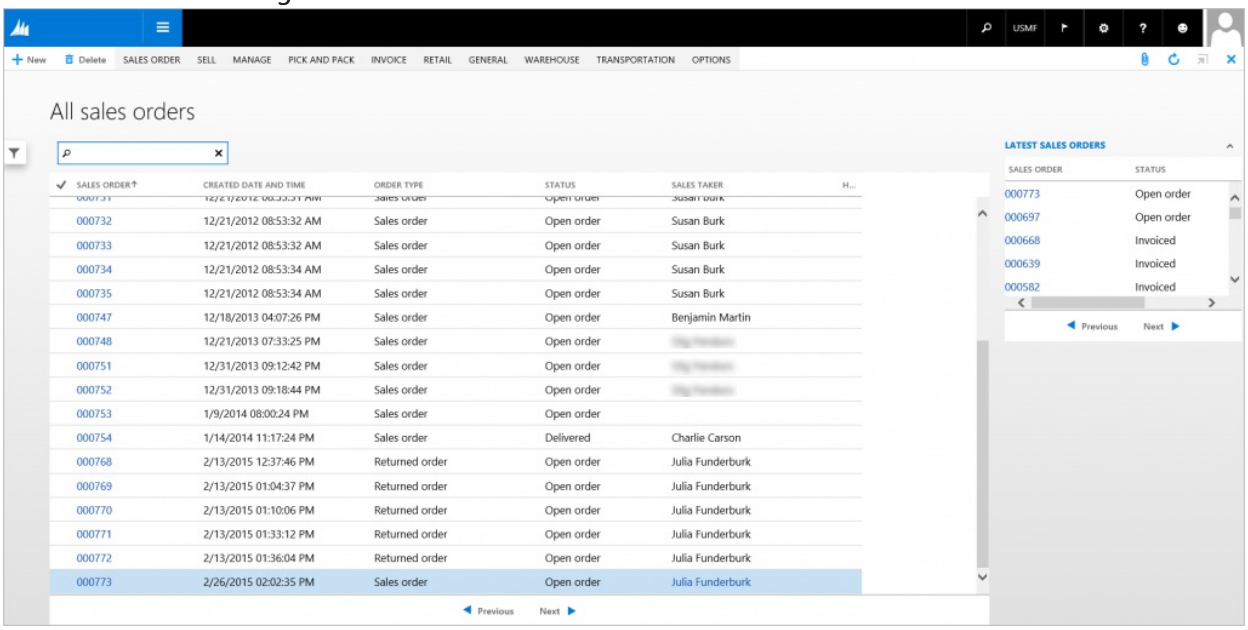
- Have fewer than 15 fields in the grid.
- The first textual/data column should be displayed as a link that goes to the appropriate details form. To do this, make sure that the grid has a default action to enable the hyperlink for the first column.
- A Quick Filter should appear above the list. By default, the QuickFilter should use the most likely field for a filter scenario.
- There should not be any duplicate **New** and **Delete** buttons.
- A link to the List page should be provided in the Main Menu.
- Focus should be in the Quick Filter when the list page is opened.
- **Page title area**:
  - The page title should be in a plural form.
  - For primary list pages, the title should be the name of the entity.
  - For secondary list pages, the title should reflect an activity or status.
- **Grid**:

- For transactional entities, the **ID** field should be the first column, followed by the master entity **ID** and **Name** fields.
- For master entities, the **Name** field should be the first column, followed by the **ID** field.

- **ActionPane** guidelines have been consolidated into the Dynamics AX General Form Guidelines document in the ActionPane guidelines section.
- **FactBox** guidelines have been consolidated into the FactBox Form Patterns document.

Examples

Form: **SalesTableListPage**



Appendix

Frequently asked questions

This section will have answers to frequently asked questions that are related to this guideline/pattern.

- **What do I do with the Preview pane when I migrate the form?**

  You can do one of the following:

  - Remove the **Preview** pane altogether if it no longer makes sense.
  - Remove the large header, and leave the **Preview** pane as is.
  - Split the **Preview** pane into multiple logical FactBoxes if the current one is too tall.
    - For a transaction preview, the lines would go into their own FactBox and should be limited to five lines.
    - For a transaction preview, rework the lines into a FactBox card pattern, where the lines are summarized into a count and a lines grid is shown in an enhanced preview when the user hovers over the count value.

Open issues

- **How to handle secondary list pages**
  - Stay in navigation (no app changes needed).
  - Create role-tailored views (after future framework support is added).

The survey will take about seven minutes. No personal data is collected (privacy statement).

Simple Details form pattern

2/18/2021 • 2 minutes to read • Edit Online

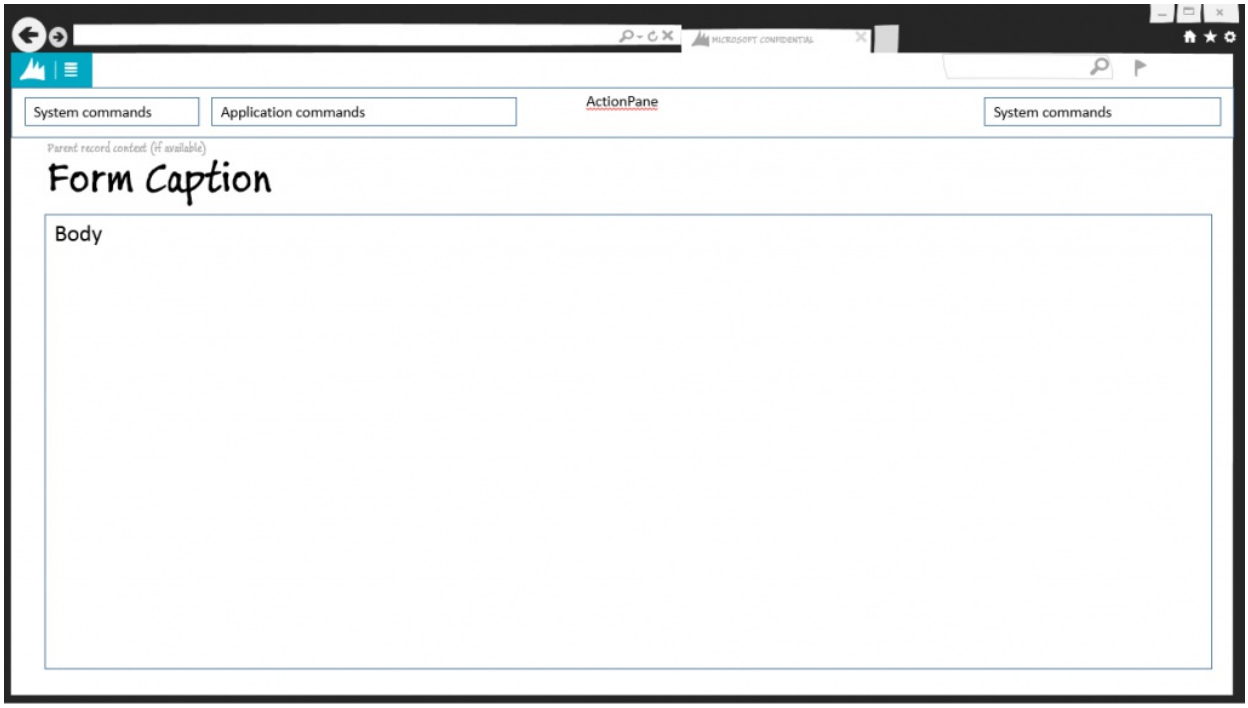
This article describes the Simple Details form pattern. This pattern is used when only a simple set of fields must be presented to the user.

Usage

The Simple Details pattern is used when only a simple set of fields must be presented to the user. Examples include the display of totals and customer balances. Typically, view mode is used for the Simple Details pattern. However, in cases where the form provides editable information, the edit mode should be synced to the parent form. Four patterns are described in this document:

- **Simple Details w/Toolbar and Fields** – This is the basic Simple Details pattern, in which several fields are displayed in the form. The fields can optionally appear inside Groups.
- **Simple Details w/Fast Tabs** – This is the Simple Details pattern that should be used when fields are organized into FastTabs.
- **Simple Details w/Standard Tabs** – This is the Simple Details pattern that should be used when fields are organized into traditional tabs.
- **Simple Details w/Panorama** – This is the Simple Details pattern that should be used when information is intended to be displayed in a panorama format.

Wireframe



Pattern changes

There are no planned changes for the use of this pattern in the current version of Microsoft Dynamics AX.

Model

Simple Details w/Toolbar and Fields – High-level structure

- Design
  - ActionPane (ActionPane)
  - Body (Group) – **Note:** A field subpattern is used.

Simple Details w/FastTabs – High-level structure

- Design
  - ActionPane (ActionPane)
  - *HeaderGroup (Group) [Optional]*
  - Body (Tab, Style=FastTabs)
    - BodyTabPages (TabPage repeats 1..N)
  - *FooterGroup (Group) [Optional]*

Simple Details w/Standard Tabs – High-level structure

- Design
  - ActionPane (ActionPane)
  - *HeaderGroup (Group) [Optional]*
  - Body (Tab, Style=Tabs)
    - BodyTabPages (TabPage repeats 1..N)
  - *FooterGroup (Group) [Optional]*

Simple Details w/Panorama – High-level structure

- Design
  - ActionPane (ActionPane)
  - Body (Tab, Style=Panorama)
    - BodyTabPages (TabPage repeats 1..N)
  - *FooterGroup (Group) [Optional]*

Core components

1. Apply the SimpleDetails pattern on **Form.Design**.
2. Address BP Warnings:
   a. **Design.Caption** isn't empty.
   b. The form must be referenced by at least one menu item.
   c. **TabPage.Caption** isn't empty.
   d. MainMenu must not contain menu items that reference a SimpleDetails form.

Commonly used subpatterns

- Fields and Field Groups
- Toolbar and Fields
- Tabular Fields
- Toolbar and List

UX guidelines

The verification checklist shows the steps for manually verifying that the form complies with UX guidelines. This

checklist doesn't include any guidelines that will be enforced automatically through the development environment. Open the form in the browser, and walk through these steps. **Standard form guidelines:**

- Standard form guidelines have been consolidated into the Dynamics AX General Form Guidelines document.

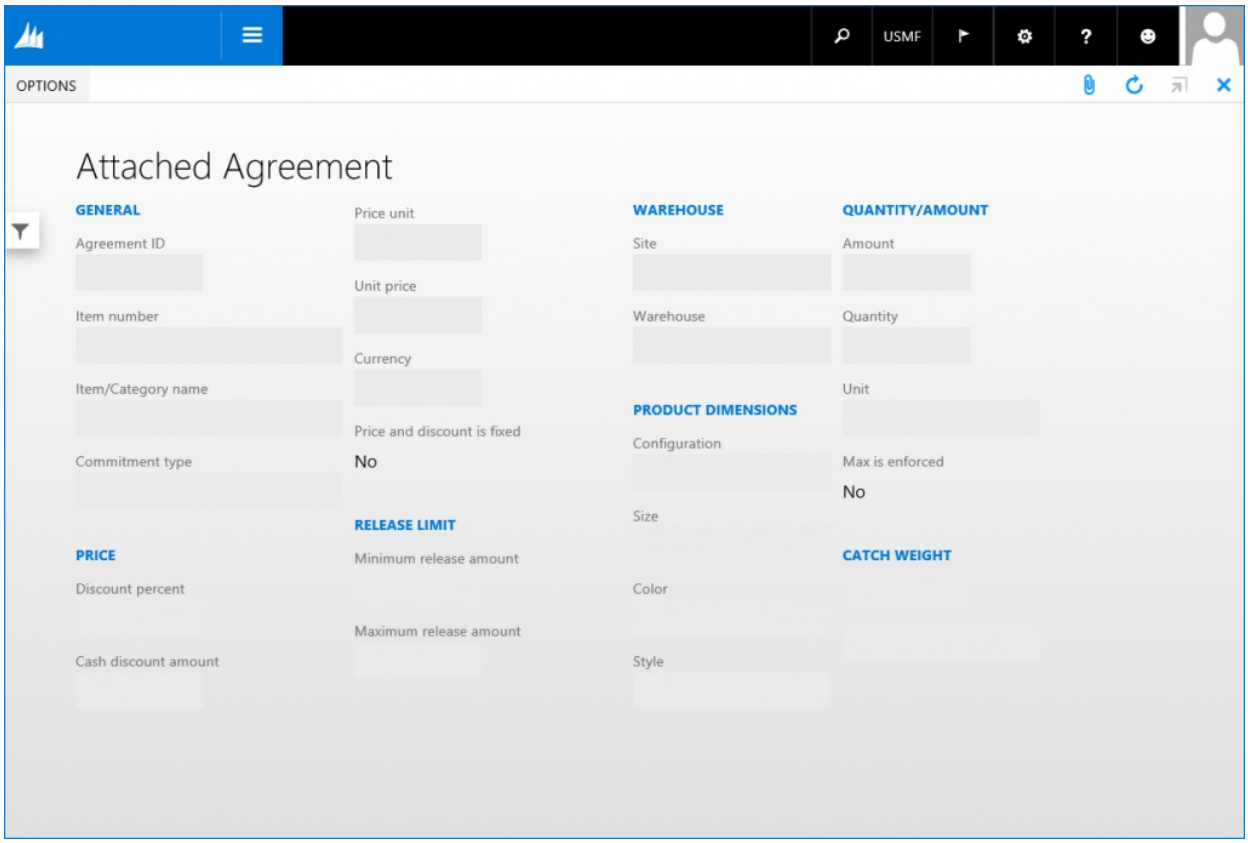
Simple Details guidelines:

- The form page should display a Form Caption that accurately describes the entity.
  - The Form Caption should be in a singular form.

Examples

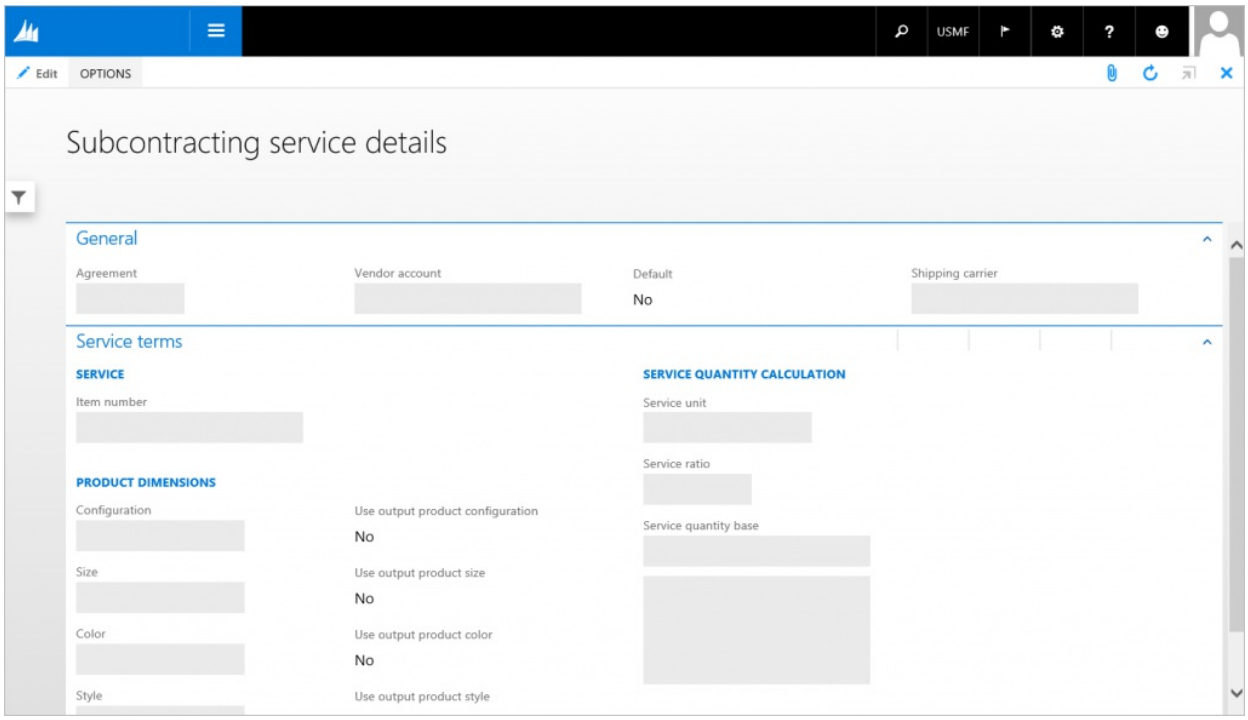
Simple Details w/Toolbar and Fields

Form: **AgreementLine**



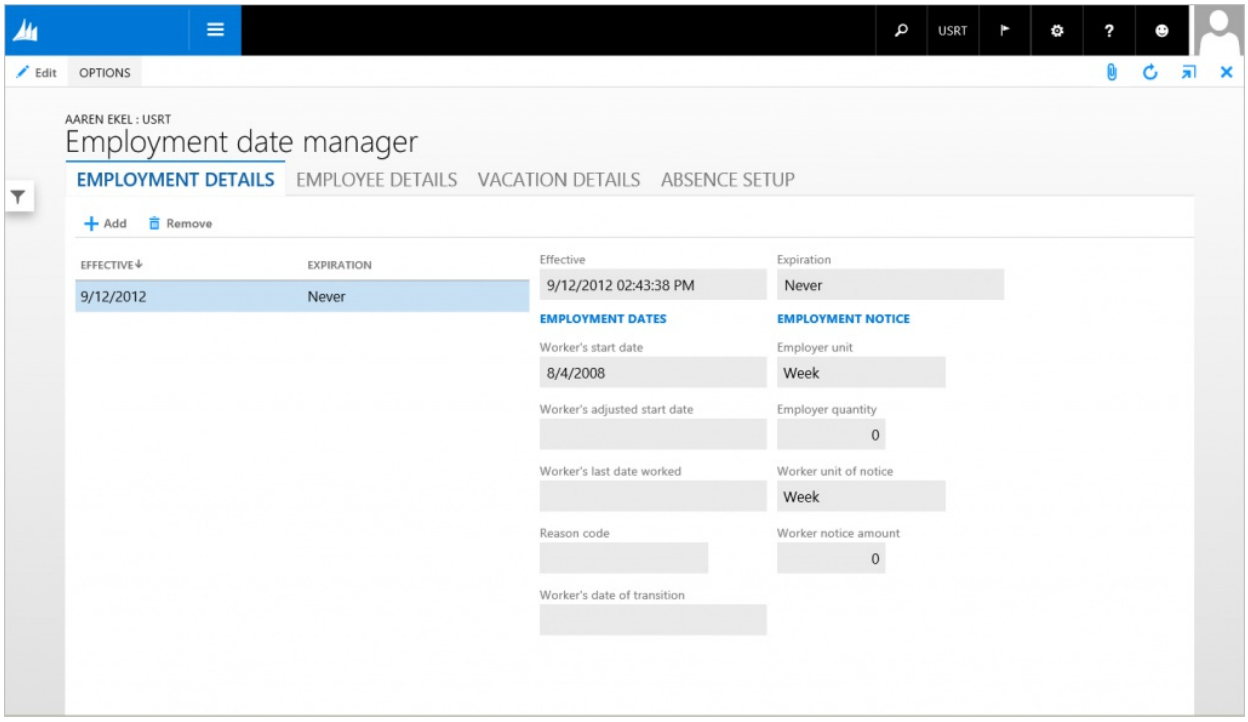
Simple Details w/FastTabs

Form: **PlanActivityServiceDetails**



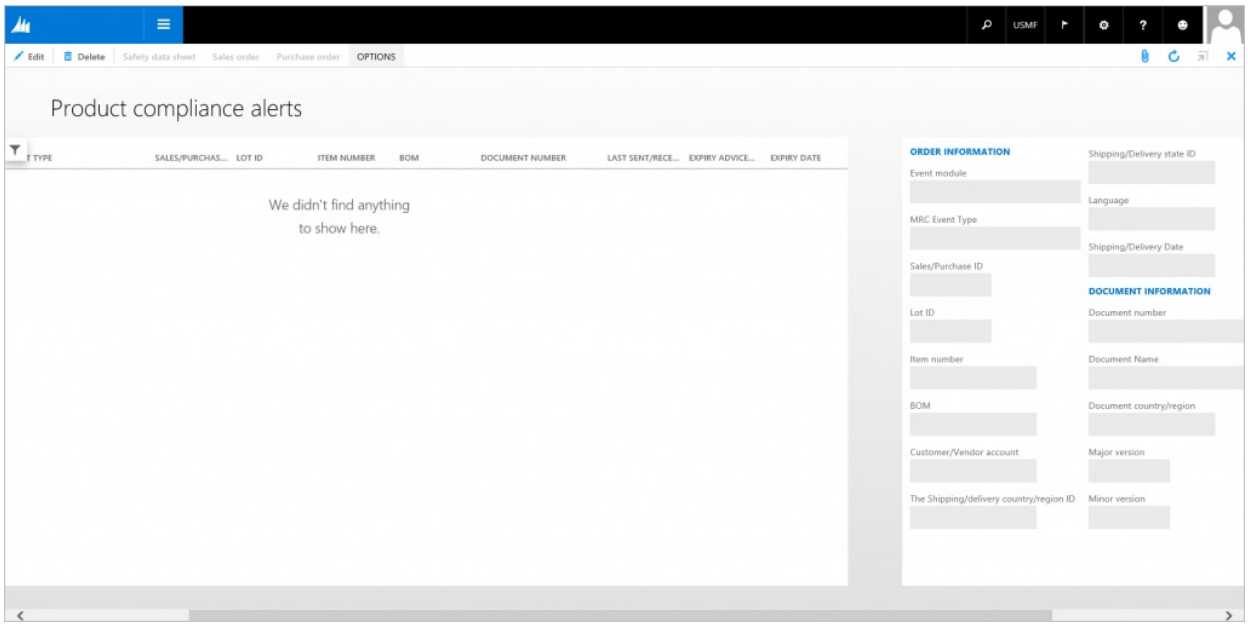
Simple Details w/Standard Tabs

Form: **HcmEmploymentDateManager** (Click **Human Resources** > **Common** > **Workers** > **Workers**, click **General** > **Versions** > **Employment History**, and then click **Date Manager**.)



Simple Details w/Panorama

Form: **PdsMRCEventTracker**



Appendix

Frequently asked questions

This section will have answers to frequently asked questions that are related to this guideline/pattern.

Open issues

- Investigate whether Simple Details forms that show a small amount of related content should have a different presentation than a full-page form.

> **NOTE**
>
> Can you tell us about your documentation language preferences? Take a short survey.
>
> The survey will take about seven minutes. No personal data is collected (privacy statement).

Simple List and Details form pattern

2/18/2021 • 5 minutes to read • Edit Online

This topic provides information about the Simple List and Details form pattern. This pattern is used to maintain data for entities of medium complexity.

Usage

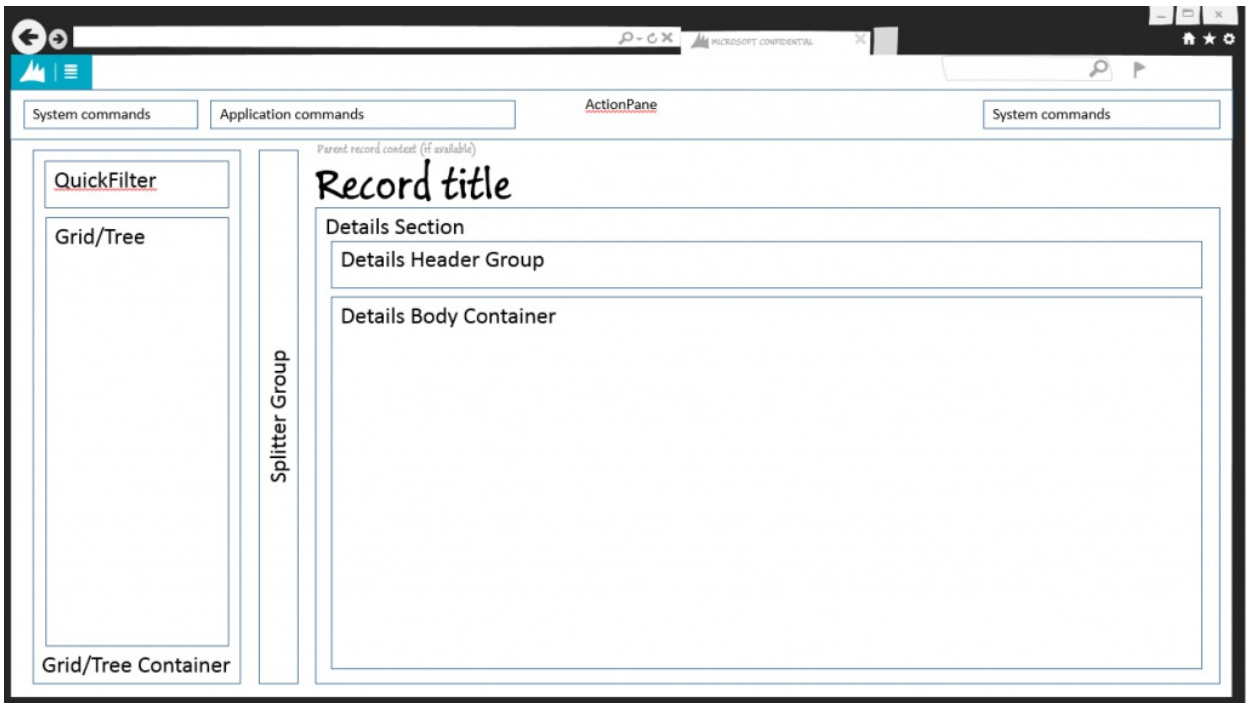
The Simple List and Details (SL+D) pattern is used to maintain data for entities of medium complexity. Entities of medium complexity are those entities that have six or more fields. The Simple List pattern should be used for simple entities that have fewer than six fields. There are some exceptions where entities that have up to 15 fields are still considered simple entities. The Simple List and Details pattern is prescribed when these conditions are met:

- The underlying data has more than six fields.
- There are between zero and five child data collections.

Three patterns are described in this document:

- **Simple List and Details – List Grid** – This is the basic SL+D pattern. This is the pattern that should be used by default.
- **Simple List and Details – Tabular Grid** – This is the SL+D pattern that should be used if the number of fields in the "simple list" part of the form is larger than expected (see the "Pattern changes" section later in this article).
- **Simple List and Details – Tree** – This is the SL+D pattern that should be used if the "simple list" part of the form is actually a tree.

Wireframe



Pattern changes

Here are the main changes to this pattern since Microsoft Dynamics AX 2012:

- The top ActionPane strip control has been converted to a standard ActionPane.
- **New**, **Delete**, and **Edit** buttons are provided by the framework.
- View mode is used by default.
- A Quick Filter control has been added above the "list" part of the form.
- Whenever possible, use the list-style grid for the "list" part of the form. A tabular grid is an acceptable alternative in some situations, such as when these conditions are met:
  - Multiple fields of the same type (for example, three date fields) would not be distinguishable in the list-style grid.
  - The user's task is to compare a sequence of dates/numbers across rows in the list (for example, date effective dates or route step numbers).
  - The number of fields in the grid is larger than expected (if each row takes up more than three lines in the list-style grid).
- Fields in the header group are arranged horizontally instead of vertically.
- FactBoxes are allowed.
- The form structure has been simplified (the BodyGroup container has been removed).

Model

High-level structure

- Design
  - ActionPane
  - NavigationList (Group)
    - Quick Filter
    - *CustomFilterGroup (Group) [Optional]*
    - ListStyleGrid (Grid) | Tree | TabularGrid (Grid)
  - VerticalSplitter (Group) *[only allowed for Tree or TabularGrid variants]*
  - DetailsHeader (Group)
  - DetailsTab (Tab)

Core components

1. Apply one of the SimpleListDetails patterns on **Form.Design**.
2. Resolve required BP checks:
   a. Set **Design.Caption** the same as the label that is used on the **Name** property of the table.
   b. Set **Design.Datasource** the same as **Grid.Datasource**.
   c. Set the primary data source to **InsertIfEmpty**=**No**.
   d. Set the primary **ActionPane.DataSource** the same as **Grid.Datasource**.
   e. Set **Grid.Datasource** to the primary data source.

Commonly used subpatterns

- Fields and Field Groups
- Toolbar and List
- Toolbar and Fields
- Nested Simple List and Details

UX guidelines

The verification checklist shows the steps for manually verifying that the form complies with UX guidelines. This checklist doesn't include any guidelines that will be enforced automatically through the development environment. Open the form in the browser, and walk through these steps.

Standard form guidelines:

- Standard form guidelines have been consolidated into the Microsoft Dynamics AX General Form Guidelines document.

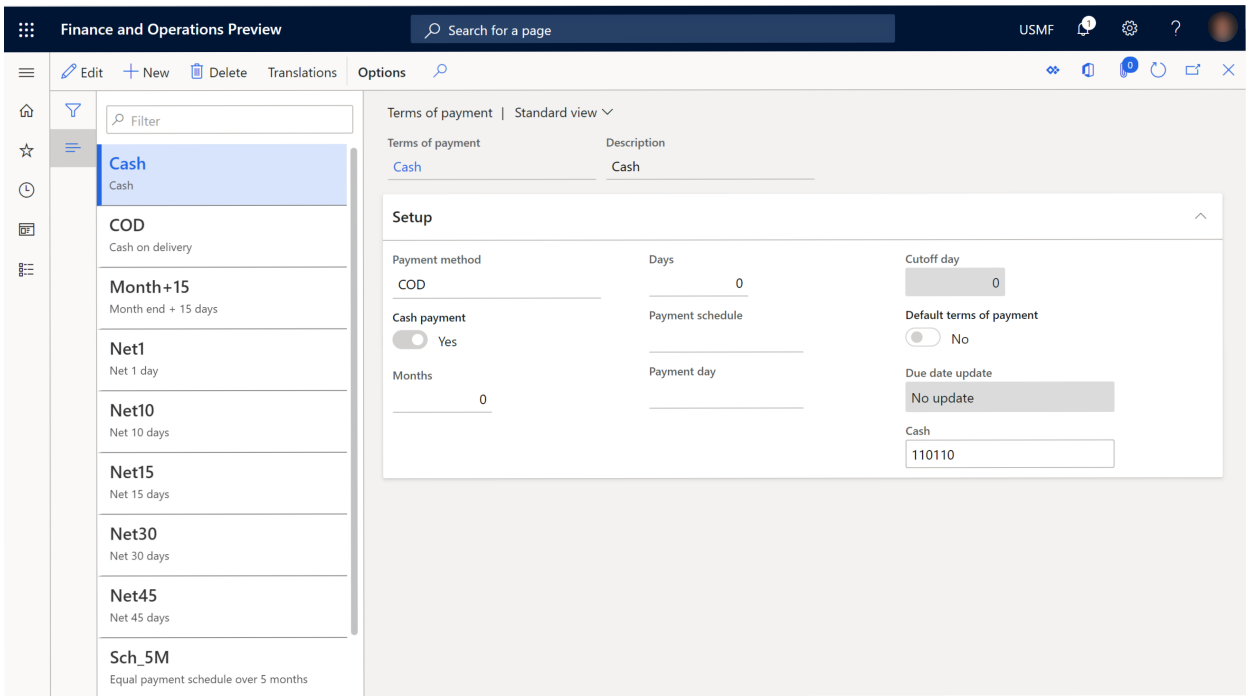
Simple list & detail guidelines:

- The page should display a Form Caption that accurately describes the entity.
  - The Form Caption should be in plural form.
- There should not be duplicate **New** or **Delete** buttons.
- By default, the Quick Filter should use the name or description column.
- Guidelines for custom filters have been consolidated into the Custom Filter Group subpattern document.
  - There should be no more than two custom filter fields in a SL&D form.
- There should be a tabular grid, a list-style grid, or a tree control on the left edge of the form.
  - List-style grids should display no more than three rows (lines) for each record in the List-style grid. Typically, just the ID and Description are sufficient.
  - Between two and five fields should be used for the list on the left.
  - A tabular grid can be used in some unique situations but isn't generally recommended.
    - If a tabular grid is used, it should **not** be editable.
  - When there is no data, the grid or tree control should not automatically add a new record.
- A **Details** section should be displayed on the right of the form:
  - The list fields (whether they are from a list, tabular grid, or tree) should be the first fields in Header Group. They should appear in the same order that they appear in the grid or tree, so that the user can edit and see the labels of the fields.
- Simple List and Detail forms must **not** have these elements:
  - Standard tabs to group fields

Examples

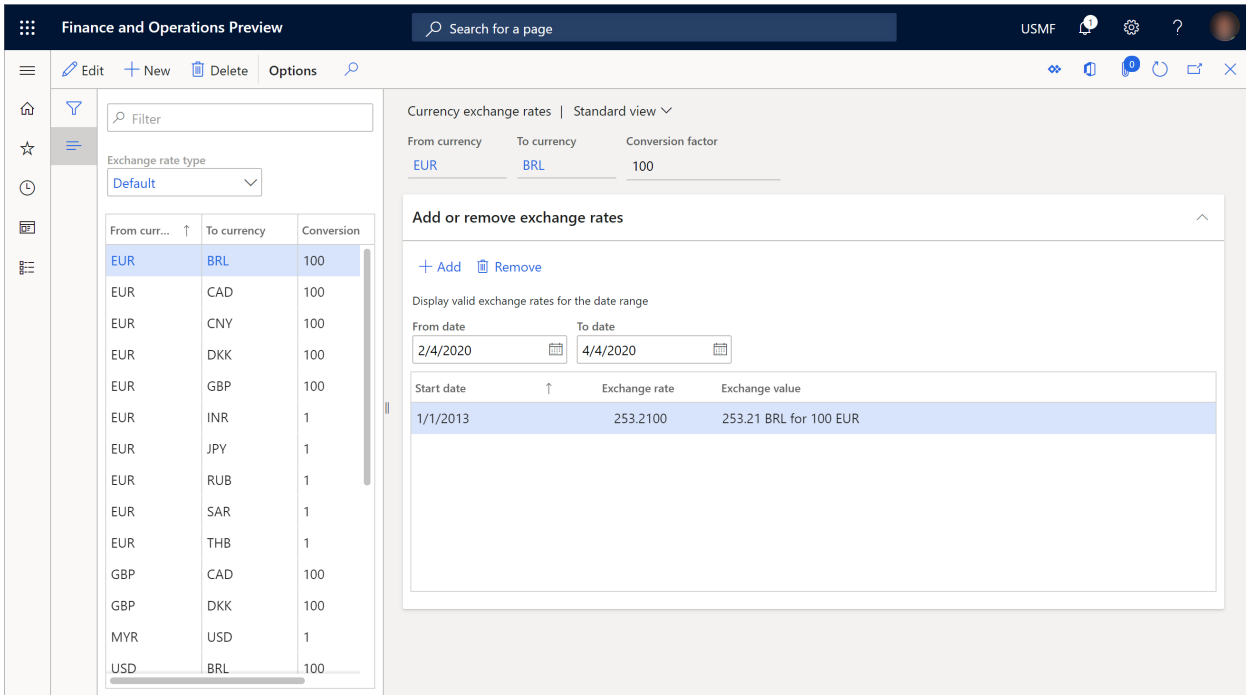
Simple List and Details – List Grid

Form: **PaymTerm**



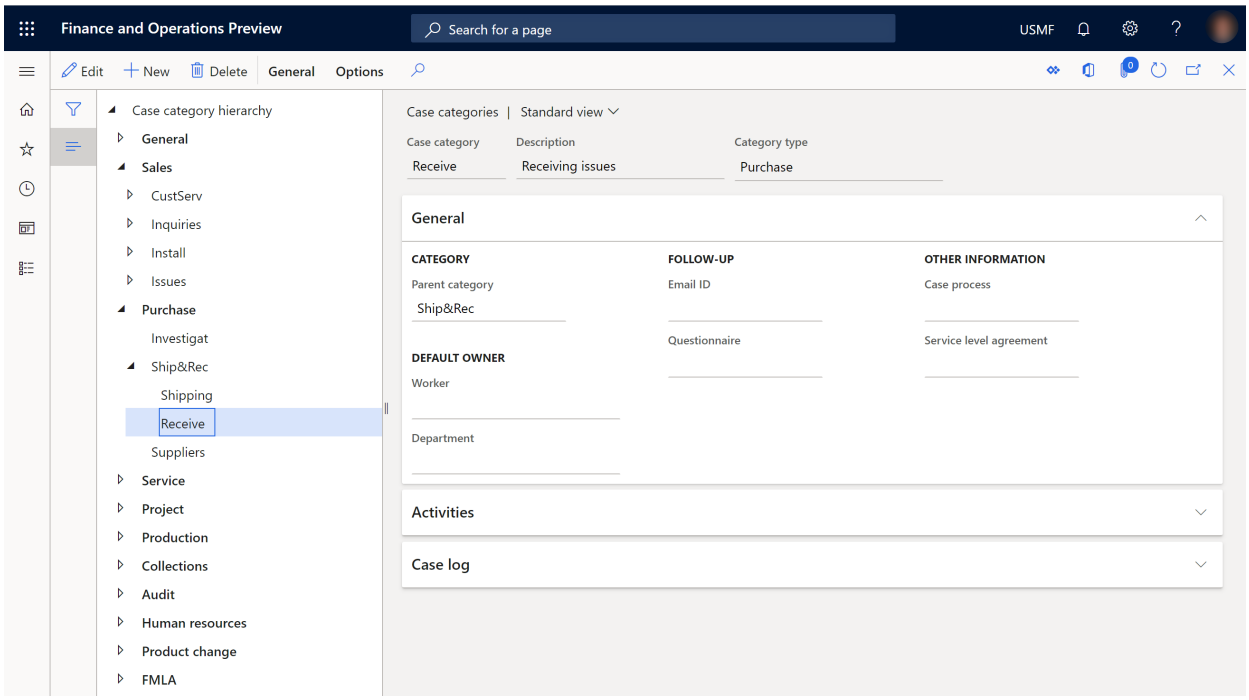
Simple List and Details – Tabular Grid

Form: **ExchangeRate**



Simple List and Details – Tree

Form: **CaseCategorySetup**



Appendix

Frequently asked questions

This section will have answers to frequently asked questions that are related to this guideline/pattern.

- **When do I use icons on actions in the toolbars?**
  - See the Button Image Guidelines in the General Form Guidelines document.

Open issues

- **How can a developer move between the ListStyleGrid and the TabularGrid patterns?**
  - Currently, developers must manually move between the patterns.
- **Are we going to allow modeling without FastTabs in the details body?**
  - Although we require FastTabs in the details body, we plan to eventually hide the FastTab header if only one FastTab is visible.
- **How do we allow for exceptions to the FastTab rule for legacy situations such as the Interest form?**
  - Whenever possible, refactor the form to fit the SL&D pattern (as the **Interest** form has done). Otherwise, use custom containers.
- **How do we prevent hyperlinks on fields in the UI?**
  - For some fields, you can **set IgnoreEDTRelation=Yes** to prevent hyperlinks in the UI. Regardless (as of Platform update 17), you can set **EnableFormRef=No** on an input control to disable a hyperlink.

Simple List form pattern

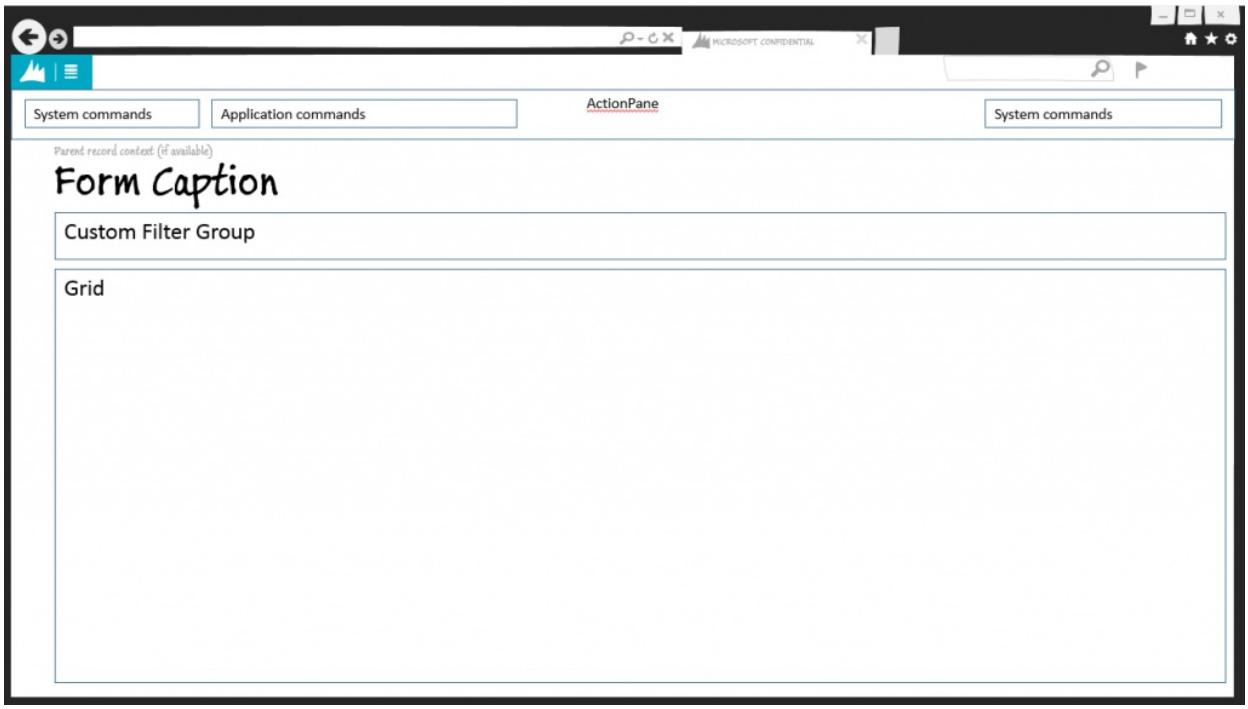
2/18/2021 • 2 minutes to read • Edit Online

This article provides information about the Simple List form pattern. This pattern is used to maintain data for simple entities.

Usage

The Simple List pattern is used to maintain data for simple entities. Simple entities are entities that have six or fewer fields and no parent/child relationships. There are some exceptions where entities that have up to 15 fields are still considered simple entities.

Wireframe



Pattern changes

Here are the main changes to this pattern since Microsoft Dynamics AX 2012:

- The top ActionPane strip control has been converted to a standard ActionPane.
- **New**, **Delete**, and **Edit** buttons are provided by the framework.
- View mode is used by default.
- A Quick Filter has been added above the grid.
- When the form is used as a dependent form, the parent form record context is automatically shown above the form caption.
  - The page title group for dependent form usage was removed, because it will be provided by the framework.
- The pattern allows for multiple selections in the grid.

Model

High-level structure

- Design
  - ActionPane (ActionPane)
  - Custom Filter (Group)
    - Quick Filter (Quick Filter)
    - *OtherFilters ($Field) [0..N]*
  - TabularGrid (Grid)
  - *Footer (Group) [Optional]*

Core components

1. Apply the SimpleList pattern on **Form.Design**.
2. Address BP Warnings:
   a. **Design.Caption** isn't empty.
   b. **Design.DataSource** isn't empty.
   c. **Grid.Datasource** must be set.
   d. The form must be referenced by at least one menu item.
   e. **Design.Datasource** is set the same as **Grid.Datasource**.
   f. The primary key field of the primary data source's table has **IgnoreEDTRelation**=**Yes**.
   g. The grid must not contain more than 15 fields.

Commonly used subpatterns

- Custom Filter Group

UX guidelines

The verification checklist shows the steps for manually verifying that the form complies with UX guidelines. This checklist doesn't include any guidelines that will be enforced automatically through the development environment. Open the form in the browser, and walk through these steps.

Standard form guidelines:

- Standard form guidelines have been consolidated into the Microsoft Dynamics AX General Form Guidelines document.

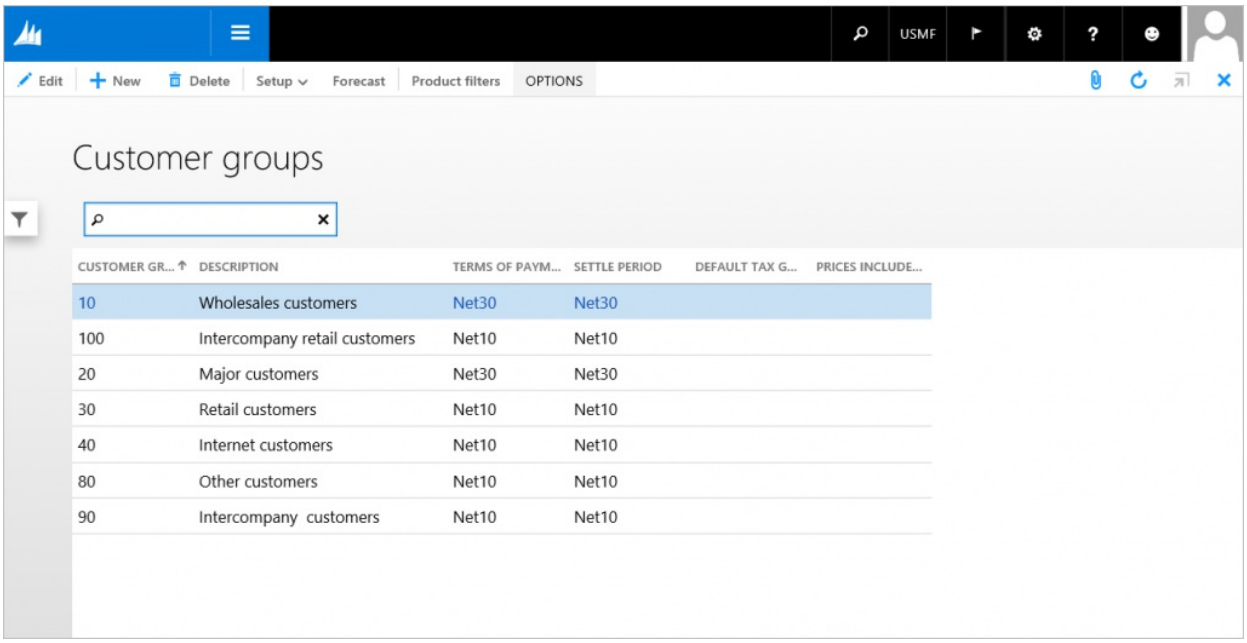
Simple list guidelines:

- By default, the Quick Filter should use the name or description column.
- The list can display up to 15 columns.

  Note: This guideline has been relaxed from AX 2012.
- There should not be any duplicate **New** or **Delete** buttons.
- The page title should be in a plural form.
- When there is no data, the grid should not automatically add a new record.

Examples

Form: **CustGroup**



Note: We plan to extend the grid lines to the right and bottom edges in a future client deliverable.

AX 2012 content

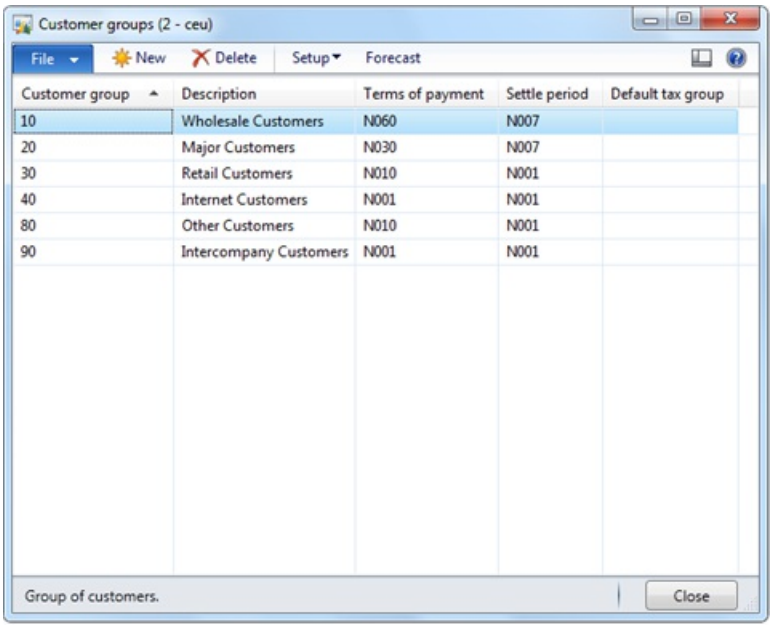

Table of Contents form pattern

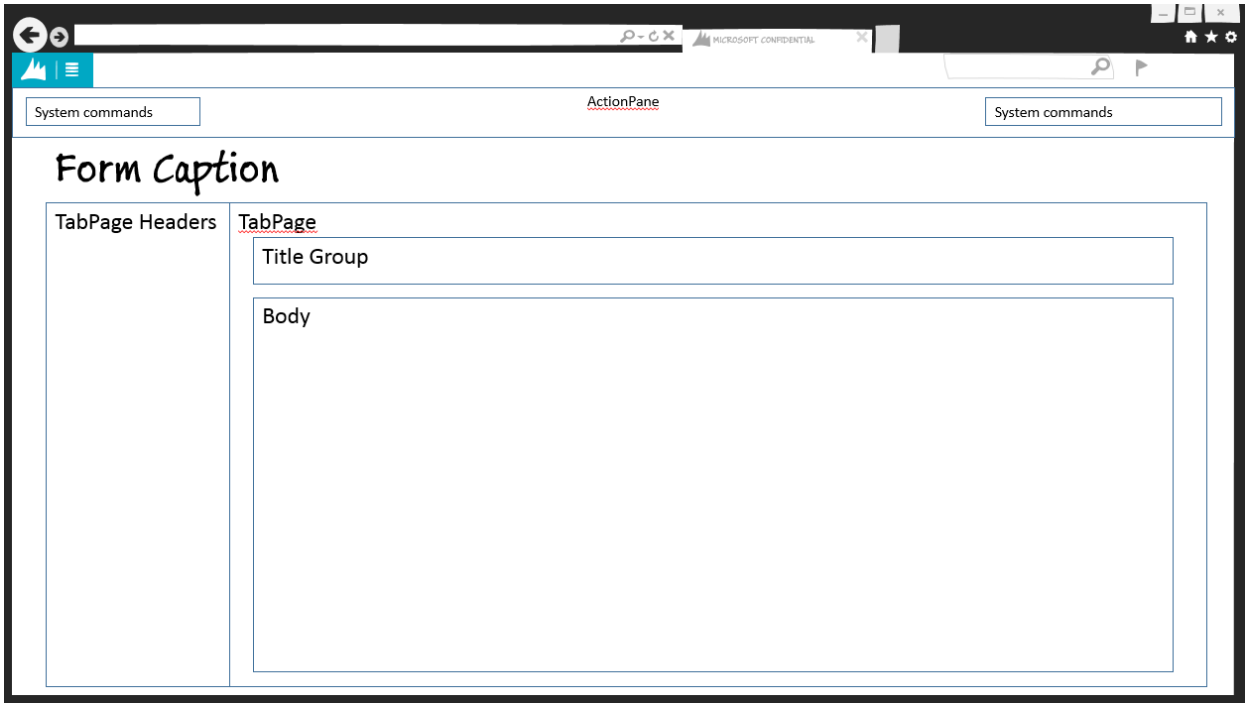
2/18/2021 • 3 minutes to read • Edit Online

This article provides information about the Table of Contents form pattern. This pattern should be used when two or more logically related forms are required for setup configuration.

Usage

The Table of Contents pattern should be used when two or more logically related forms are required for setup configuration. The vertical arrangement of tabs implies the order of completion. This form pattern is also used for collections of unrelated items, such as tab pages that have a different root entity per tab. This form pattern contains a collection of smaller content regions, each of which follows a container subpattern such as Toolbar and List, Nested Simple List and Details, or Fields and Field Groups.

Wireframe



Pattern changes

Here are the main changes to this pattern since Microsoft Dynamics AX 2012:

- The Content Body child container uses dynamic columns for a responsive layout.
- An optional secondary instruction has been added under the Title Group.

Model

High-level structure

- Design
  - Tab (Style=VerticalTabs)
    - TabPage *[repeats 1..N times]*

    - Title (Group)
        - MainInstruction (StaticText)
        - *SecondaryInstruction (StaticText) [Optional]*
    - Body (Group) | FastTabContent (Tab)

Core components

- Apply the TableOfContents pattern on **Form.Design**.
- Address BP Warnings:
    - **Design.Caption** isn't empty.
    - The form must be referenced by at least one menu item.
    - **TabPage.Caption** isn't empty.
    - **TabPage.DataSource** isn't empty.
    - **StaticText.Text** isn't empty.

Commonly used subpatterns

Each BodyGroup will use one of the following container patterns for the content in the Table of Contents section:

- Fields and Field Groups
- Toolbar and List
- Toolbar and Fields
- Nested Simple List and Details
- Tabular Fields
- List Panel

UX guidelines

The verification checklist shows the steps for manually verifying that the form complies with UX guidelines. This checklist doesn't include any guidelines that will be enforced automatically through the development environment. Open the form in the browser, and walk through these steps.

Standard form guidelines:

- Standard form guidelines have been consolidated into the Microsoft Dynamics AX General Form Guidelines document.

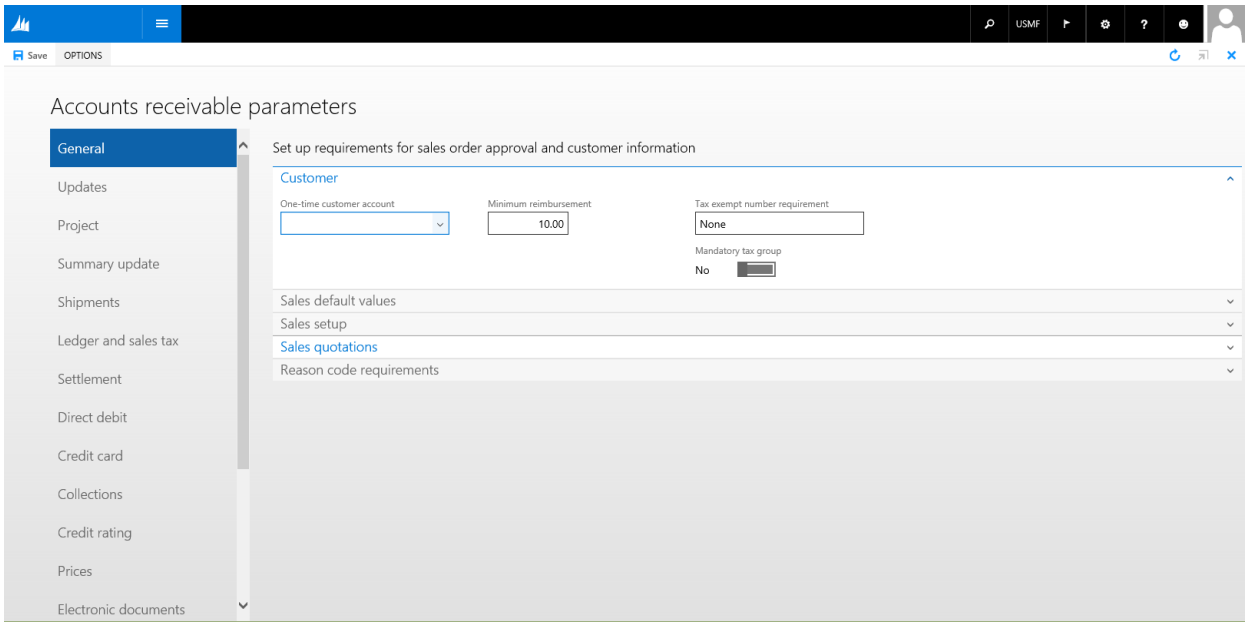
Table of contents guidelines:

- The supplemental instruction, if it's shown, is composed of a complete, concise sentence in sentence case and has end punctuation.
- TOC tabs should appear in the same sequence that is typically used to enter information.
- The first tab in the list should be highlighted when the form is opened, unless the form is opened in the context of a specific task from another form.
- The **content area** for the TOC content should primarily be one of three patterns: Simple List, Simple List and Details, or Simple Details.
    - Simple List content should follow the subpattern guidelines.
    - Simple List and Details content should follow the Nested Simple List and Details subpattern guidelines.
    - Simple Details content should follow the Toolbar and Fields subpattern guidelines.
    - FastTabs should follow the FastTab guidelines in the Dynamics AX General Form Guidelines document.
    - Actions appearing on a Toolbar on a tab page.
- A TOC form should **not** have the following:

- Application actions on a standard ActionPane. (It should have only framework actions.)
- FactBoxes.
- Standard tabs on a TOC tab page.

Examples

Form: **CustParameters**



Appendix

Frequently asked questions

This section will have answers to frequently asked questions that are related to this guideline/pattern.

- **What do I do with 'Global' buttons?**
  - There have been several cases where a button is required in order to initialize data or sync information between services. Because we allow only system buttons on the standard Action Pane in this pattern, we recommend that these buttons go in one of two places:
    - On the tab page that the action is most closely related to.
    - If a place doesn't exist, on a toolbar on the first tab page of the pattern.

Task Double form pattern

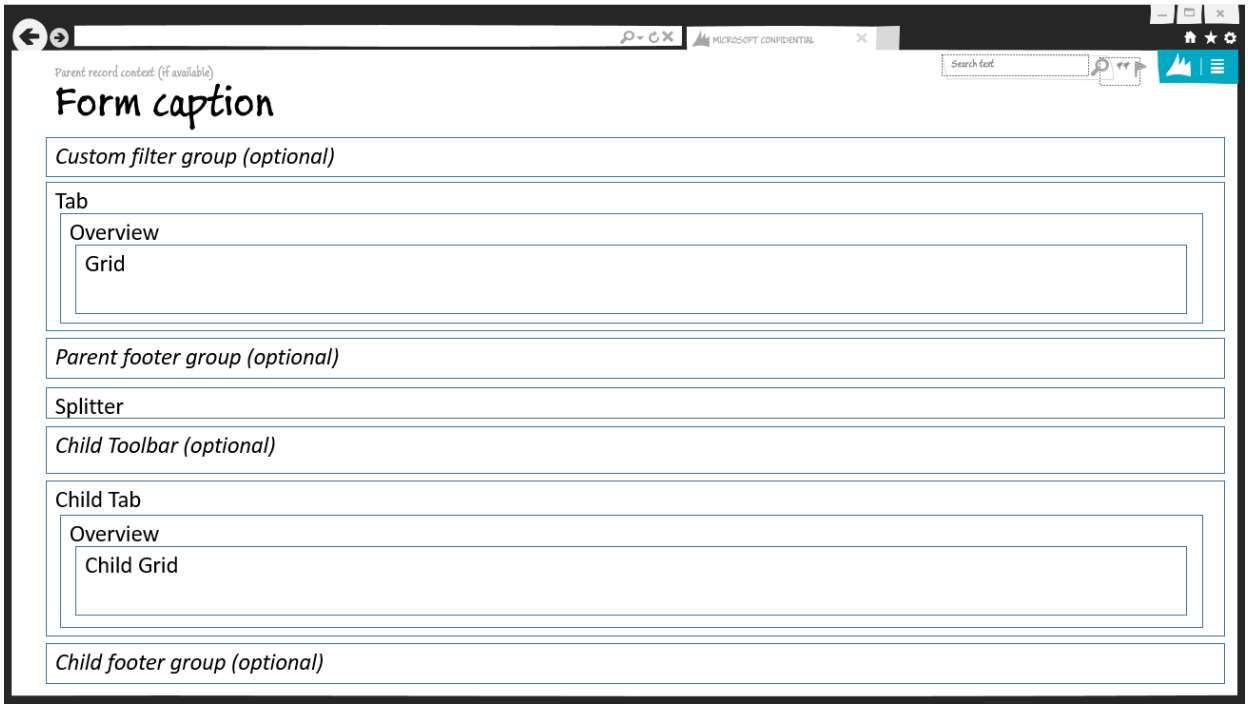
2/18/2021 • 2 minutes to read • Edit Online

This article provides information about the Task Double form pattern. This pattern was previously used to present a parent and child entity in the same form.

Usage

This type of form has previously been used when you wanted to present parent/child entities in the same form. This isn't a recommended pattern for new forms. No new forms should be created that use this pattern. This pattern will provide structure and stability for legacy forms, and will also provide a migration path to more modern form patterns.

Wireframe



]

Pattern changes

Here are the main changes to this pattern since Microsoft Dynamics AX 2012:

- The form opens in view mode.
- The top ActionPane strip control has been converted to a standard ActionPane.
- The **Overview** label on the parent tab has been changed to **List**.
- The contents of the tab container use dynamic columns for a responsive layout.
- The label for the child tab's list should be **<x> list**, where **<x>** is replaced by an appropriate string, based on the entity. For example, if the child entity is usually called Charges, the label for the tab should be **Charges list**.
  - Exception: If the child entity is "lines" of some sort, the word "list" should not be added to the end.

Model

High-level structure

- Design
  - ActionPane (Action Pane)
  - *CustomFilter (Group) [Optional]*
  - ParentTab (Tab)
    - ParentList (TabPage) – **Note:** The Toolbar and List subpattern is used.
    - General (TabPage repeats 0..N)
  - *ParentFooterGroup (Group) [Optional]*
  - HSplitter (Group)
  - *ChildToolbar (ActionPane) [Optional]*
  - ChildTab (Tab)
    - ChildList (TabPage) – **Note:** The Toolbar and List subpattern is used.
    - General (TabPage, repeats 0..N)
  - *ChildFooterGroup (Group) [Optional]*

Core components

1. Apply the Task Double pattern on **Form.Design**.
2. Address BP Warnings:
   a. **Design.Caption** isn't empty.
   b. The form must be referenced by at least one menu item.
   c. **TabPage.Caption** isn't empty.
   d. **TabPage.DataSource** isn't empty.
   e. **StaticText.Text** isn't empty.

Task Single form pattern

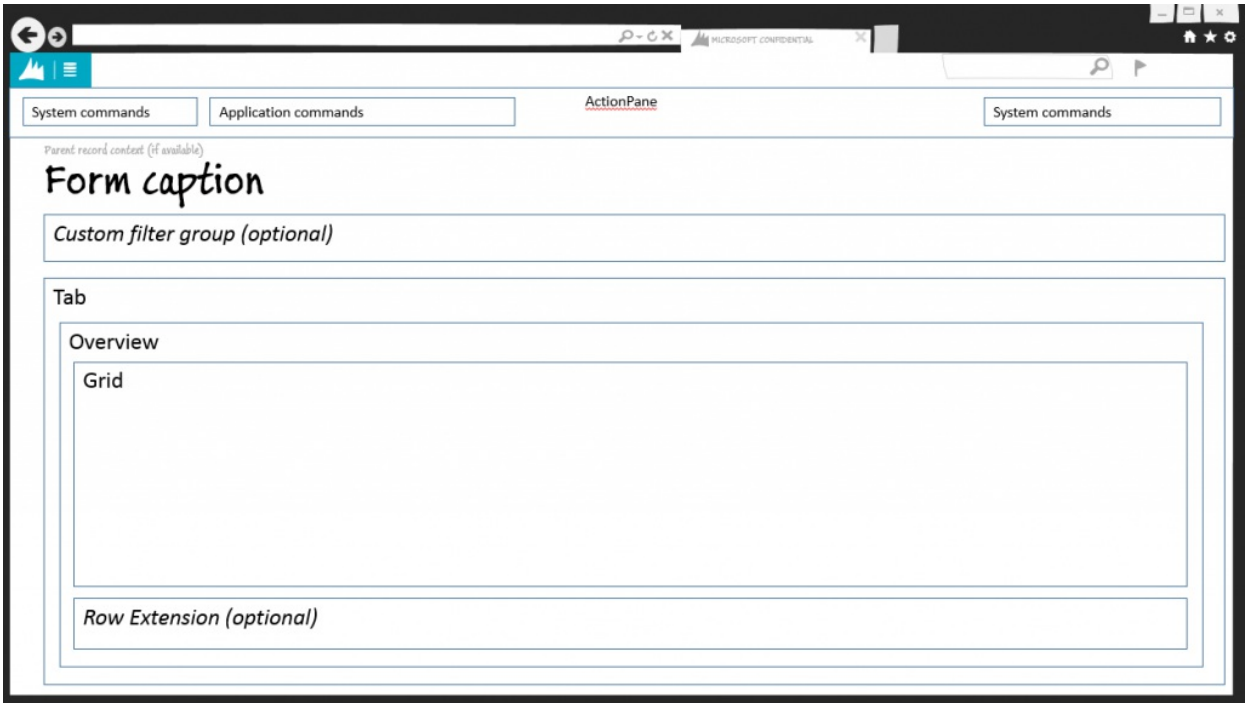
2/18/2021 • 2 minutes to read • Edit Online

This article provides information about the Task Single form pattern. This pattern was previously used to present data that users would perceive as originating from a single data source that had multiple records.

Usage

This type of form was used when you wanted to present data that users will perceive as originating from a single data source with multiple records. This isn't a recommended pattern for new forms. No new forms should be created that use this pattern. This pattern will provide structure and stability for legacy forms, and will also provide a migration path to more modern form patterns.

Wireframe



Pattern changes

Here are the main changes to this pattern since Microsoft Dynamics AX 2012:

- The form opens in view mode.
- Commands have been moved to the standard ActionPane from a Toolbar (ActionPane strips).
- The **Overview** label on the first tab has been changed to **List**.
- The content of the tab container uses dynamic columns for a responsive layout.

Model

High-level structure

- Design
    - ActionPane (Action Pane)

- *CustomFilter (Group) [Optional]*
- Tab (Tab)
  - Overview (TabPage)
    - Grid (Grid)
    - *RowExtension (Group) [Optional]*
  - General (TabPage, repeats 0..N)
- *FooterGroup (Group) [Optional]*

Core components

1. Apply the TaskSingle pattern on **Form.Design**.
2. Address BP Warnings:
   a. **Design.Caption** isn't empty.
   b. The form must be referenced by at least one menu item.
   c. **TabPage.Caption** isn't empty.
   d. **TabPage.DataSource** isn't empty.
   e. **StaticText.Text** isn't empty.

Wizard form pattern

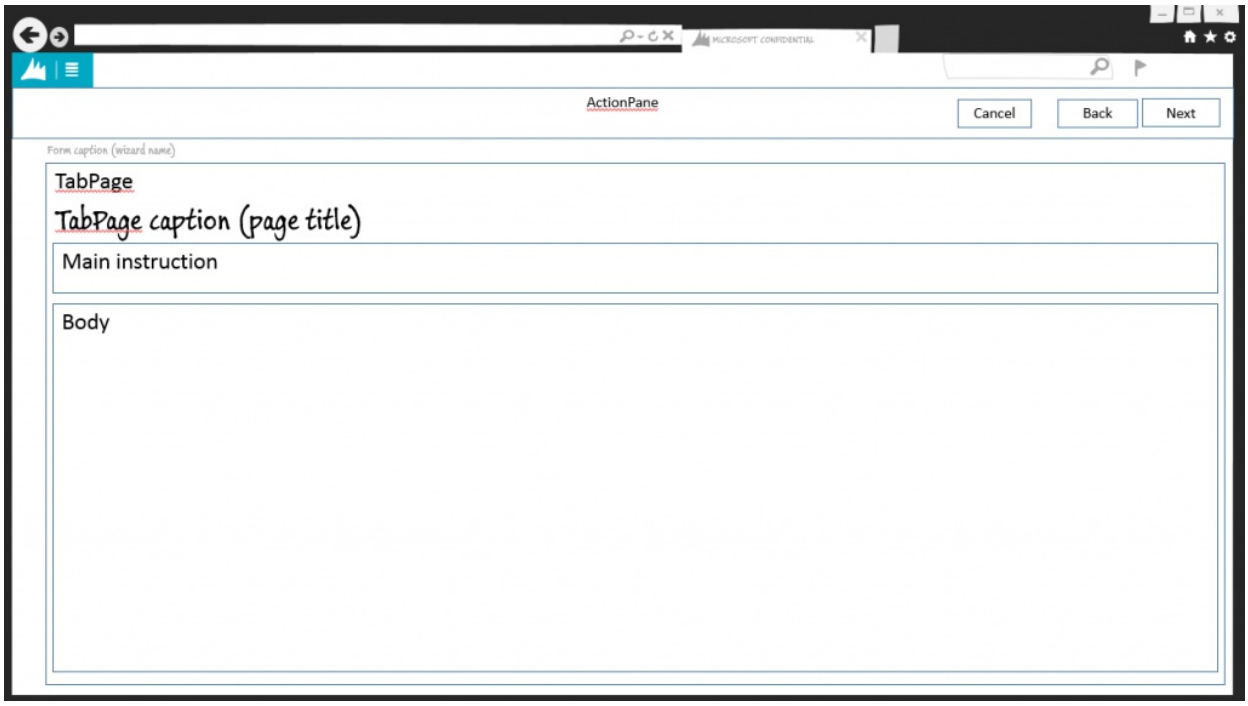
2/18/2021 • 2 minutes to read • Edit Online

This article provides information about the Wizard form pattern. A wizard is a special form of user assistance that takes the user through a task by using an ordered series of tab pages.

Usage

A wizard is a special form of user assistance that takes the user through a task by using an ordered series of tab pages. Wizards are especially useful for complex or infrequent tasks that the user might have difficulty learning or doing, or for tedious, frequently performed tasks.

Wireframe



Pattern changes

Here are the main changes to this pattern since Microsoft Dynamics AX 2012:

- The secondary instruction for a wizard step was previously defined in the Help Text property of that step's Tab Page. This instruction will now be modeled on the Tab Page as a Static Text control.

Model

High-level structure

- Design (Style=Wizard; Caption=<wizard title>)
  - WizardContent (Tab)
    - WizardContentPage (TabPage) *[repeats 1..N times, can be named anything; Caption set to page title]*
      - MainInstruction (StaticText)

    - Body (Group)

Core components

1. Apply the Wizard pattern on **Form.Design**.
2. Address BP Warnings:
    a. **Design.Caption** isn't empty.
    b. The form must be referenced by at least one menu item.
    c. **TabPage.Caption** isn't empty (for all wizard content pages).
    d. **MainInstruction.Text** isn't empty (for all wizard content pages).

Commonly used subpatterns

- Fields and Field Groups
- Toolbar and List
- Toolbar and Fields
- List Panel

UX guidelines

The verification checklist shows the steps for manually verifying that the form complies with UX guidelines. This checklist doesn't include any guidelines that will be enforced automatically through the development environment. Open the form in the browser, and walk through these steps.

Standard form guidelines:

- Standard form guidelines have been consolidated into the Microsoft Dynamics AX General Form Guidelines document.

Wizard guidelines:

- Each tab page should have a title.
- Each tab page should have a main instruction.
- Content should be subdivided into logical groups per page.
- A wizard should have **<Next>** and **<Previous>** buttons on the appropriate pages.
- The user should also be able to cancel the wizard, and cancellation should return to the state that existed before the wizard was started.
- Only one question should be asked per wizard page (tab page).
- When a set of choices is presented to the user, radio buttons should be used to make the alternatives clear, even if a check box or combo box is otherwise acceptable.
- Wizard forms must **not** have these elements:
    - FactBoxes
    - FastTabs

Examples

Form: **WrkCtrBulkResReqEditWizard**

Workspace form pattern

2/18/2021 • 4 minutes to read • Edit Online

This topic discusses workspace form patterns. Workspaces are the primary way that users navigate to tasks and specific pages. A workspace should be created for every significant business activity that is supported.

Usage

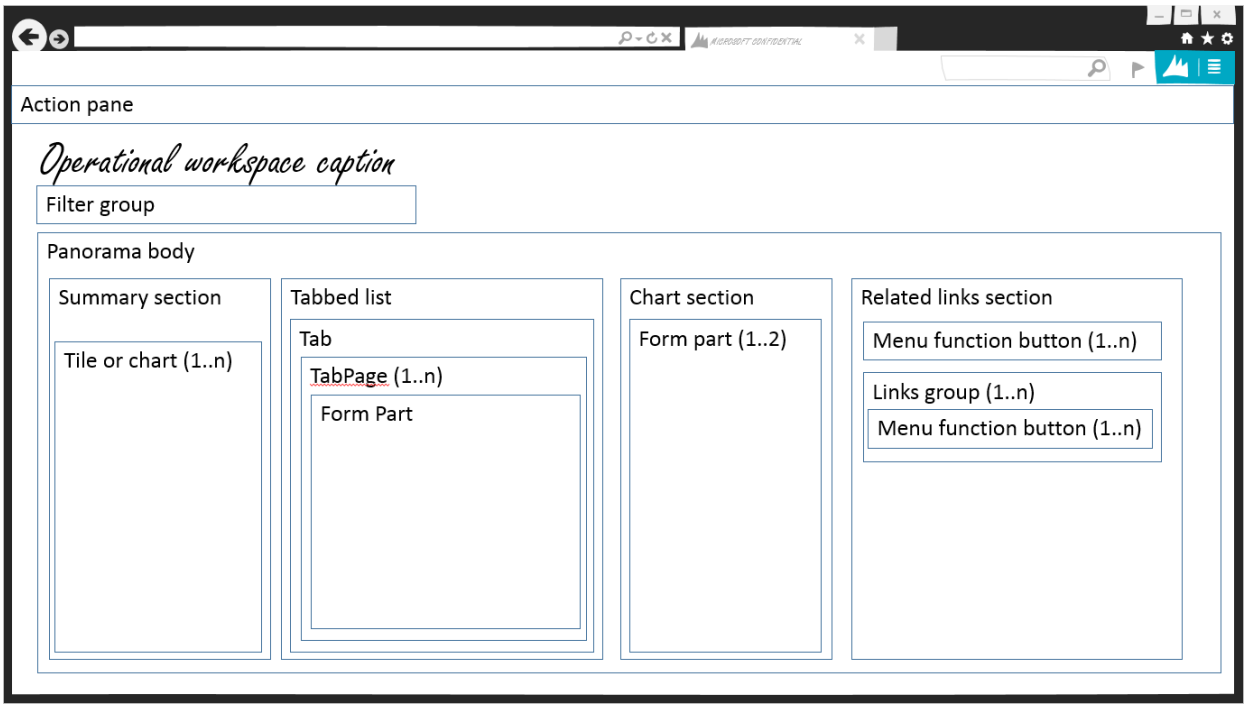
Workspaces are a new concept, and are meant to be the primary way that users navigate to tasks and specific pages. A workspace should be created for every significant business "activity" that you want to support. An "activity" is less granular than a task and more granular than a legacy "area page." A workspace is intended to provide a one-page overview of the activity, and to help users understand the current status, the upcoming workload, and the performance of the process or user. Users should be able to start the most typical tasks for the activity directly from the workspace. If possible, users should also be able to complete tasks directly in the workspace, based on the overview that they just received. Currently, there are two workspace patterns:

- **Tabbed workspace**: Instead of forcing a horizontally-scrolling panorama for content, this pattern uses standard tabs to allow the development of vertically-scrolling workspaces. This is particularly being used to embed Power BI reports into workspaces. Additional subpatterns to help define content inside these tabs will likely be provided in the future.
- **Operational workspace**: This is the standard pattern currently used for workspace development. Because of the set of components that are permitted in it, this pattern has superior performance over the deprecated "workspace" pattern. For this reason and to ensure visual and behavioral consistency with the other workspaces in the system, we recommend that you use this pattern.
- (Deprecated) **Workspace**: This pattern is only mentioned for the sake of completeness. Do **not** use this pattern. It will soon be removed from the product.

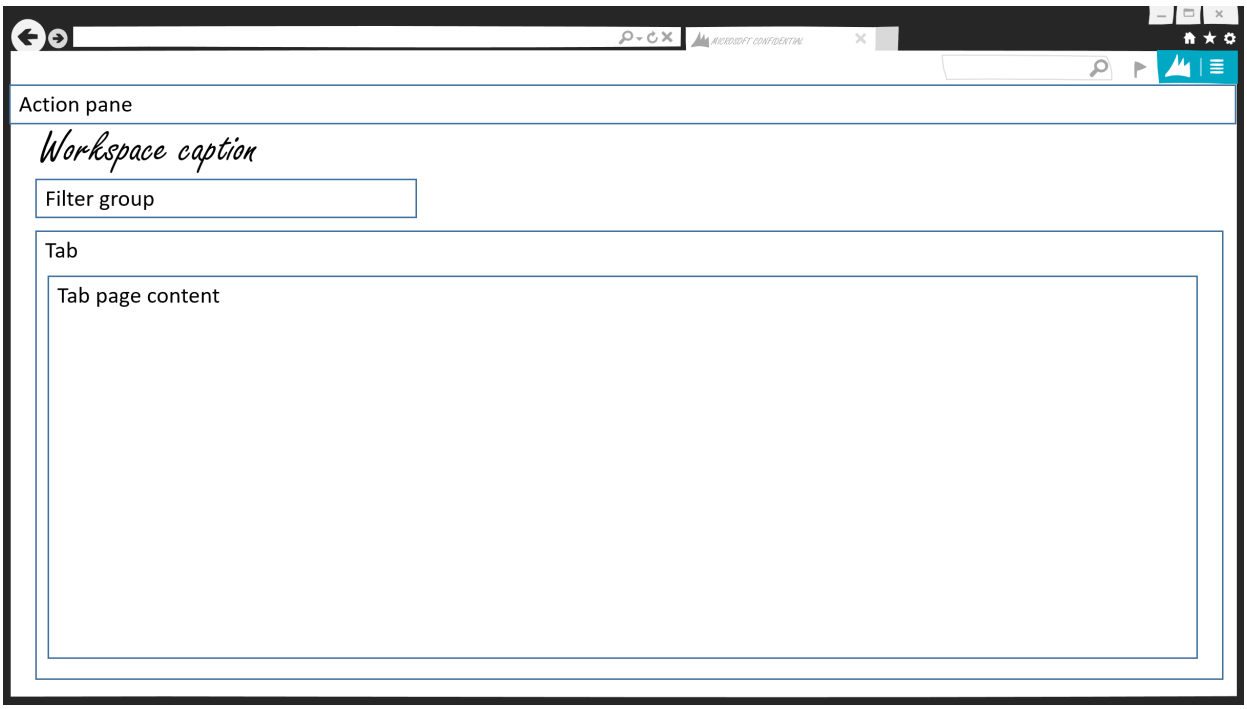
The rest of this topic will focus on the Operational workspace pattern and the Tabbed Workspace pattern, as the original Workspace pattern is deprecated and should not be used.

Wireframe

Operational workspace



Tabbed workspace



Pattern changes for Finance and Operations

The Microsoft Dynamics AX 2012 Role Center has been replaced by multiple activity-focused workspaces.

Model

Operational workspace – High-level structure

- Design
  - *Action pane (ActionPane) [Optional]*
  - *Workspace page filter group (Group) [Optional]* – This must use the Workspace Page Filter Group subpattern.
  - Panorama (Tab)

    - Section summary tiles (TabPage) – This must use the Section Tiles subpattern.
    - Section tabbed list (TabPage) – This must use the Section Tabbed List subpattern.
    - *Section charts (TabPage) [Optional]* – This must use the Section Stacked Chart subpattern.
    - *Section PowerBI (TabPage) [Optional]* – This must use the Section PowerBI subpattern.
    - Section related links (TabPage) – This must use the Section Related Links subpattern.

Tabbed workspace – High-level structure

- Design
    - *Action pane (ActionPane) [Optional]*
    - *Workspace page filter group (Group) [Optional]* – This must use the Workspace Page Filter Group subpattern.
    - StandardTab (Tab)
        - ContentTabPage (1..N)

Core components

- Apply the appropriate Workspace pattern on **Form.Design**.
- Address BP Warnings:
    - **Form** must be referenced by at least one menu item.
    - **TabPage.Caption** isn't empty (for all panorama sections).

Commonly used subpatterns

- Workspace Page Filter Group
- Section Tiles
- Section Tabbed List
- Section Stacked Chart
- Section PowerBI
- Section Related Links

Related patterns

- Form Part Section List
- Section Chart

UX guidelines

The verification checklist shows the steps for manually verifying that the form complies with UX guidelines. This checklist doesn't include any guidelines that will be enforced automatically through the development environment. Open the form in the browser, and walk through these steps.

- Standard form guidelines
    - Standard form guidelines have been consolidated into the General Form Guidelines document.
- Workspace form guidelines
    - Use a noun phase for the page title, and avoid general words. The page title should not duplicate the title of an area page.
    - The page title should begin with the noun that users would have in mind.
    - All sections must have a title.
    - A section typically spans the width of two to four standard tiles.

    - Any section that uses a FormPartControl to display content should have **HeightMode** set to **SizeToAvailable** on the FormPartControl.
- Actions
    - Include only frequently used commands.
    - Actions on the Action Pane should be related to the whole workspace (not a specific section of it).
        - **Exception:** A single "New" action can be put as a tile in the **Summary** section if it's very frequently used.
    - Group variations of the same command on drop-down menus.
        - **Examples:** New sales quote, New sales order, New return order
- Filters
    - Zero to five filter fields are allowed on a workspace.
        - Only a single field can be put under the page title
        - The remaining filters must be in a workspace configuration dialog.

Example

Operational workspace

Form: **FMClerkWorkspace**

Advanced selection form pattern

2/18/2021 • 2 minutes to read • Edit Online

This article provides information about the Advanced Selection form pattern. This Dialog form pattern lets users filter and select items from a large, wide list. Like the List Panel pattern, this pattern should be used when the primary user task is to select a set of items.

Usage

The Advanced Selection form pattern should be used when the primary user task is to select a set of items. This task is usually accomplished through a multi-select list. However, in many scenarios, users must select items that aren't contiguous and, at the same time, must see the set of items that they are selecting. This pattern resembles the List panel pattern, in that the user selects items in one list and adds them to another. However, this pattern allows for custom filters and a "wide" list on top, and uses most of the screen "real estate" of the page (typically, it's a Large dialog). Use this pattern when a user must be able to filter and select in a large, wide list.

Related patterns

- List Panel subpattern
- Dialog form pattern

UX guidelines

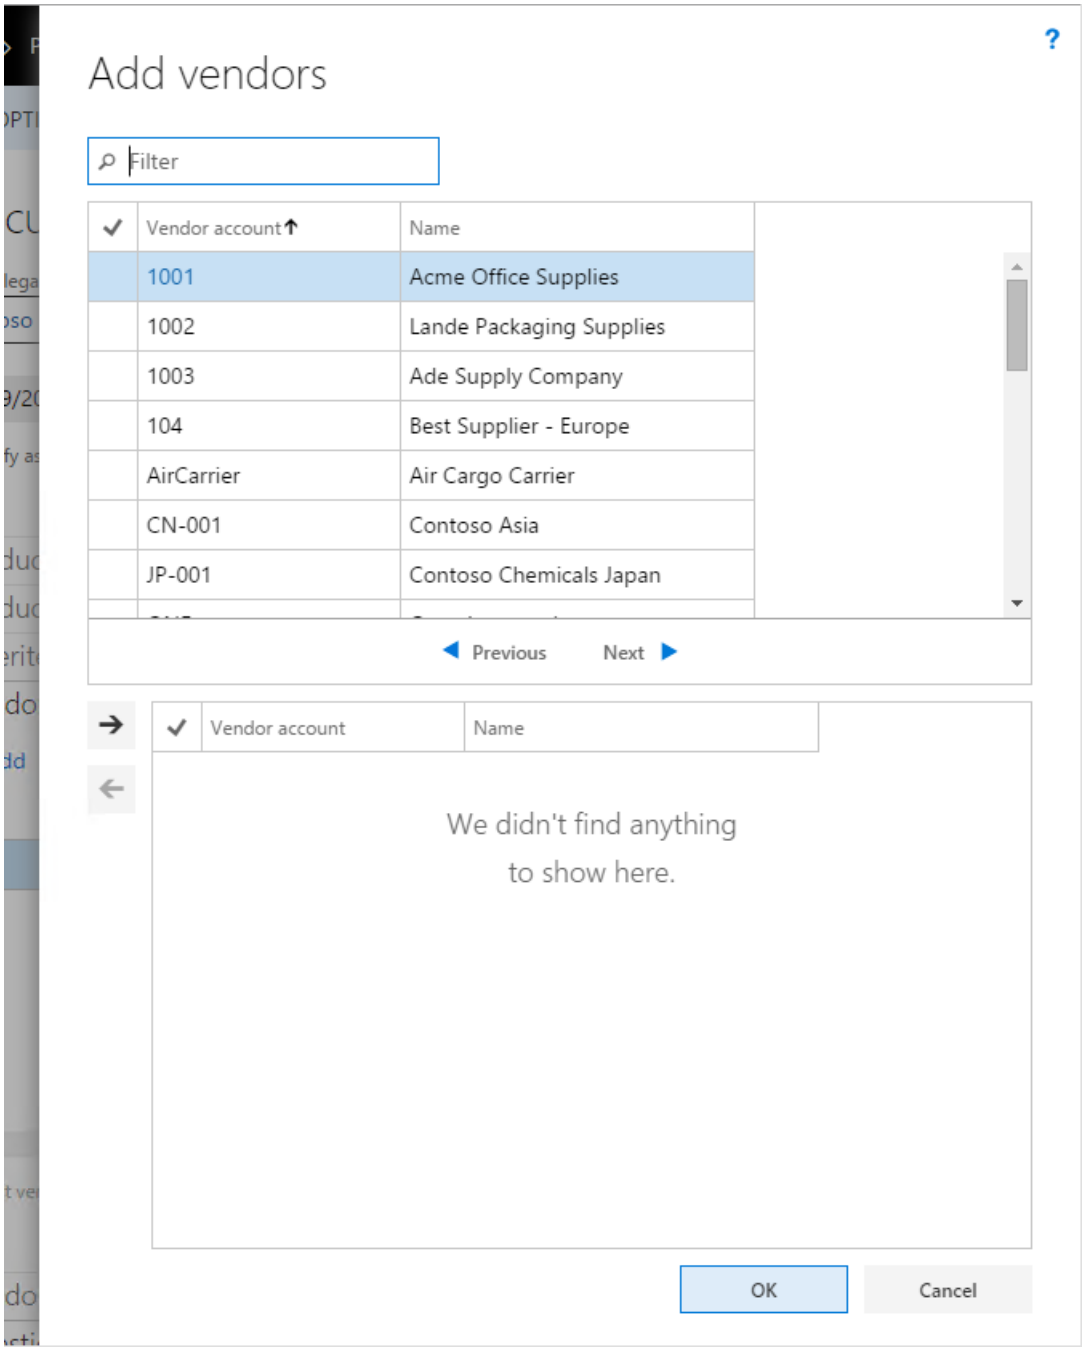
The verification checklist shows the steps for manually verifying that the form complies with UX guidelines. This checklist doesn't include any guidelines that will be enforced automatically through the development environment. Open the form in the browser, and walk through these steps.

- **Standard form guidelines:**
  - Standard form guidelines have been consolidated into the General form guidelines document.
- **Advanced selection guidelines:**
  - By default, the Quick filter should use the name or description column.
  - The list can display up to 15 columns. **Note:** This guidelines has been relaxed since Microsoft Dynamics AX 2012.
  - The main instruction should instruct users what they need to do.
  - When there is no data, the grid should not automatically add a new record.

Example

Form: **ProcCategoryAddVendor** (Click **Procurement and sourcing** > **Procurement categories**. On the **Vendors** FastTab, click **Add**.)

> [NOTE] This form no longer utilizes this pattern; however, the image shows an example of what a typical Advanced selection form pattern looks like.



NOTE

Can you tell us about your documentation language preferences? Take a short survey.

The survey will take about seven minutes. No personal data is collected (privacy statement).

Dialog form pattern

2/18/2021 • 8 minutes to read • Edit Online

This topic provides information about the Dialog form pattern. A dialog box represents an action or activity that users can explicitly commit or cancel. It's used when a user initiates a specific task or process, and the system requires user input about how or whether to proceed.

Usage

A dialog box represents an action or activity that users can explicitly commit or cancel. It's used when a user initiates a specific task or process, and the system requires user input about how or whether to proceed. Dialogs are modal and require that users interact with the controls in the dialog before they can return to the parent page. Dialogs also can have multiple sizes. Selection of a dialog size is subjective, and will vary, depending on the form elements that you've modeled on the dialog. The sizes are as follows:

- **Small** – This size is a one-column-wide dialog. If your dialog contains a relatively small amount of content (all simple fields, and no wide tables or other wide elements), you can probably use this size.
- **Medium** – This size is a two-column-wide dialog. If your dialog contains more content than can comfortably fit within a small dialog, but a full-width dialog isn't required, you should use this size.
- **Large** – This size is a three-column-wide dialog. If your dialog contains more content than can comfortably fit within a medium dialog, but a full-width dialog isn't required, you should use this size.
- **Full** – A large dialog is nearly the full width of the browser viewport. Its size varies, depending on the viewport width, and it will always be the largest dialog size option. Use this size if your dialog has a lot of wide elements, or if it requires an unusually large amount of horizontal space.

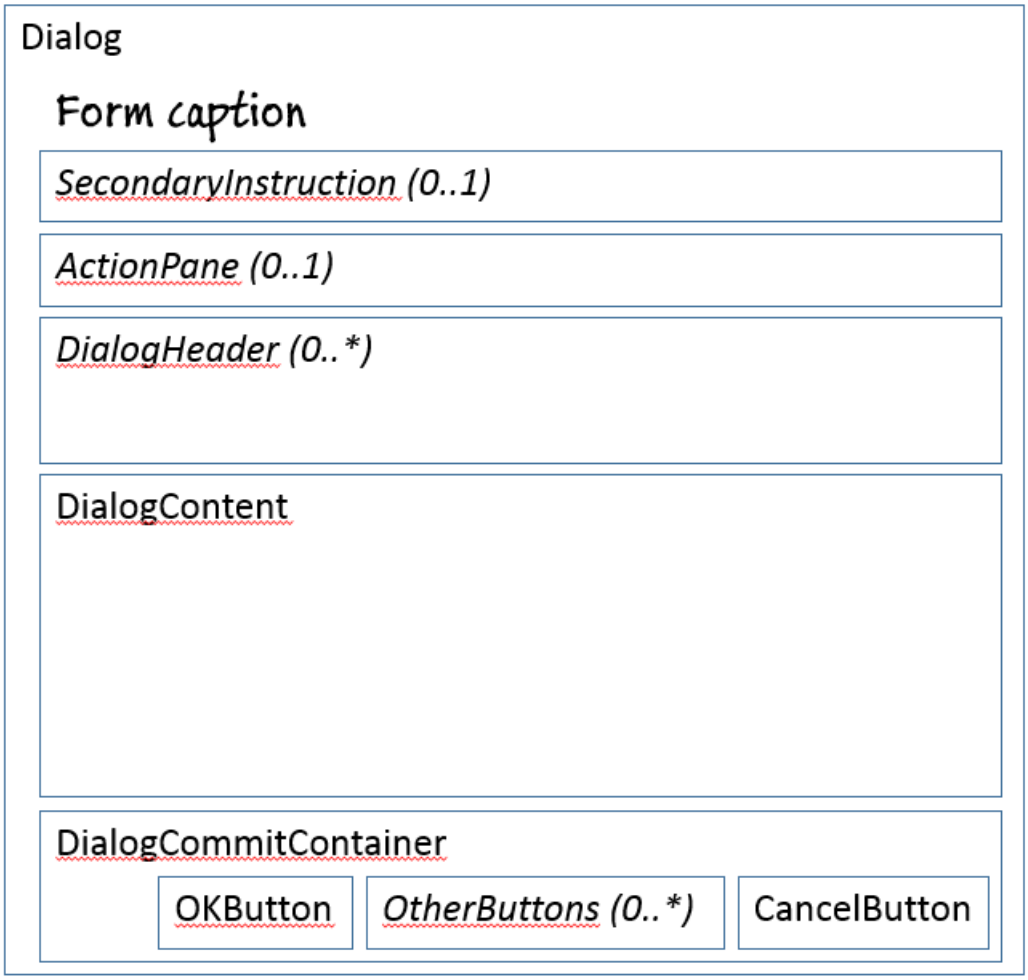
For more detail about the various dialog sizes, see the table in the appendix of this topic, under "Selecting the correct dialog size." We strongly recommend that you review that table. Five patterns are described in this document:

- **Dialog** – This is the basic dialog pattern. Use this dialog if you don't have a reason to use one of the other Dialog patterns.
- **Dialog w/tabs** – This is a more specific version of the Dialog pattern. It incorporates a Tab control in the dialog. You can also optionally provide a header for the Tab, and also a footer.
- **Dialog w/FastTabs** – This closely resembles the Dialog w/tabs pattern but uses FastTabs instead of regular tabs to organize the information.
- **Dialog w/double tabs** – This closely resembles the Dialog w/tabs pattern but has a second Tab control immediately after the first one.
- **Dialog (read only)** – This pattern is for informational forms that aren't editable. The user can still switch between tabs or a view selector, but direct manipulation of input fields isn't allowed. This dialog variation also includes a **Close** button instead of **OK** and **Cancel** buttons.

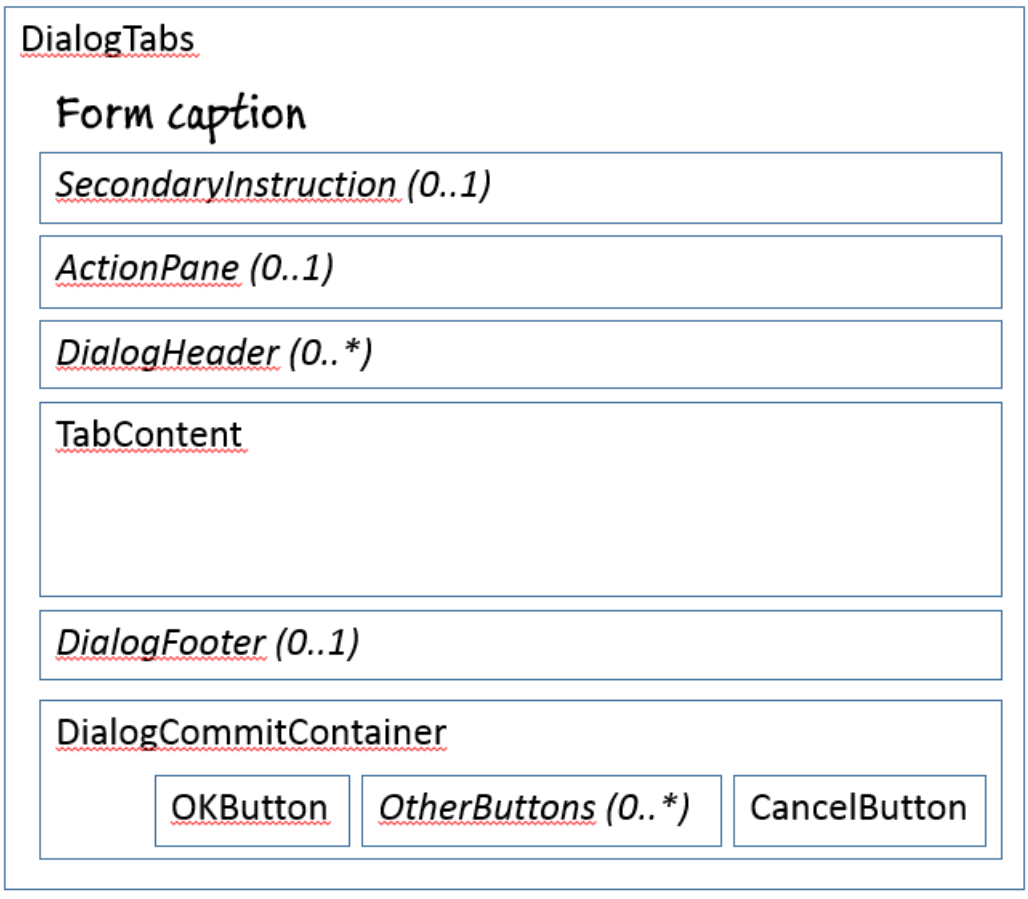
Wireframe

The following sections show the wireframes for the four dialog types that are included in this article.

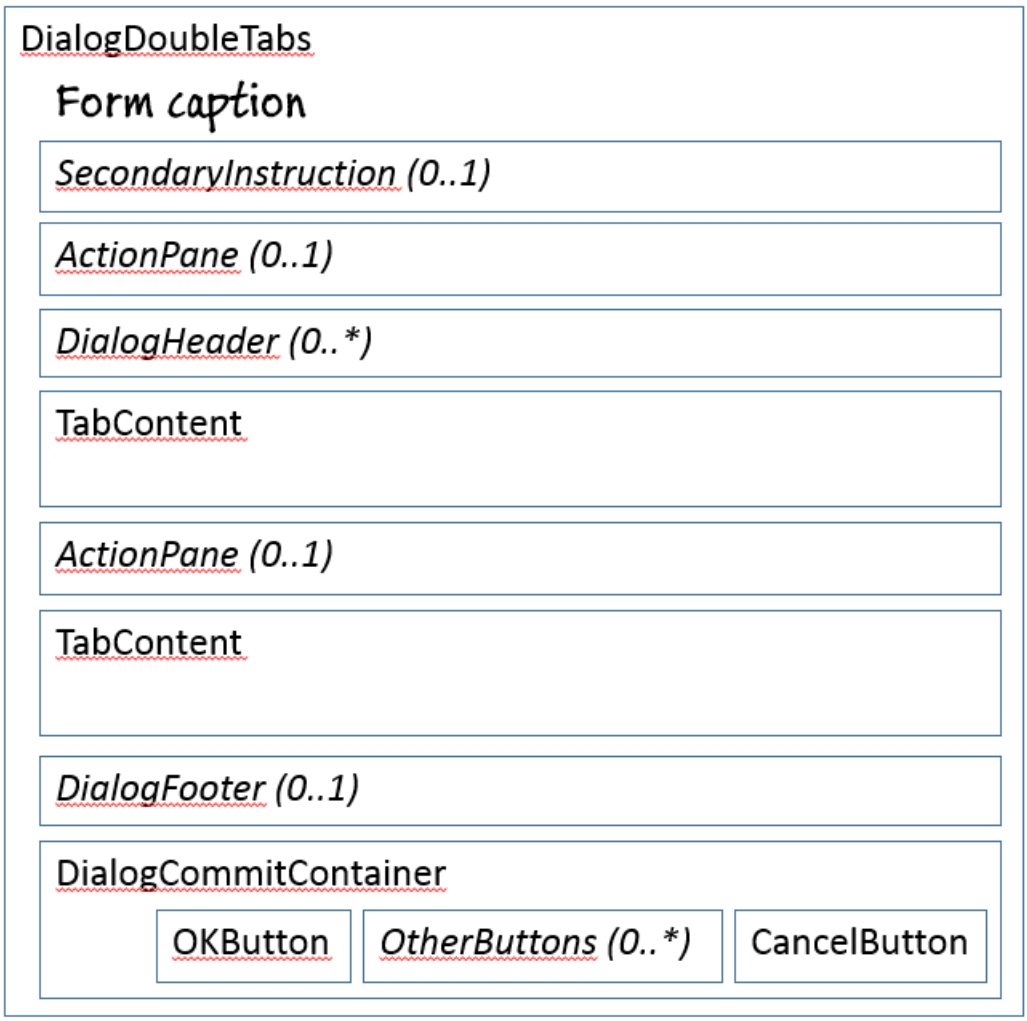
Dialog



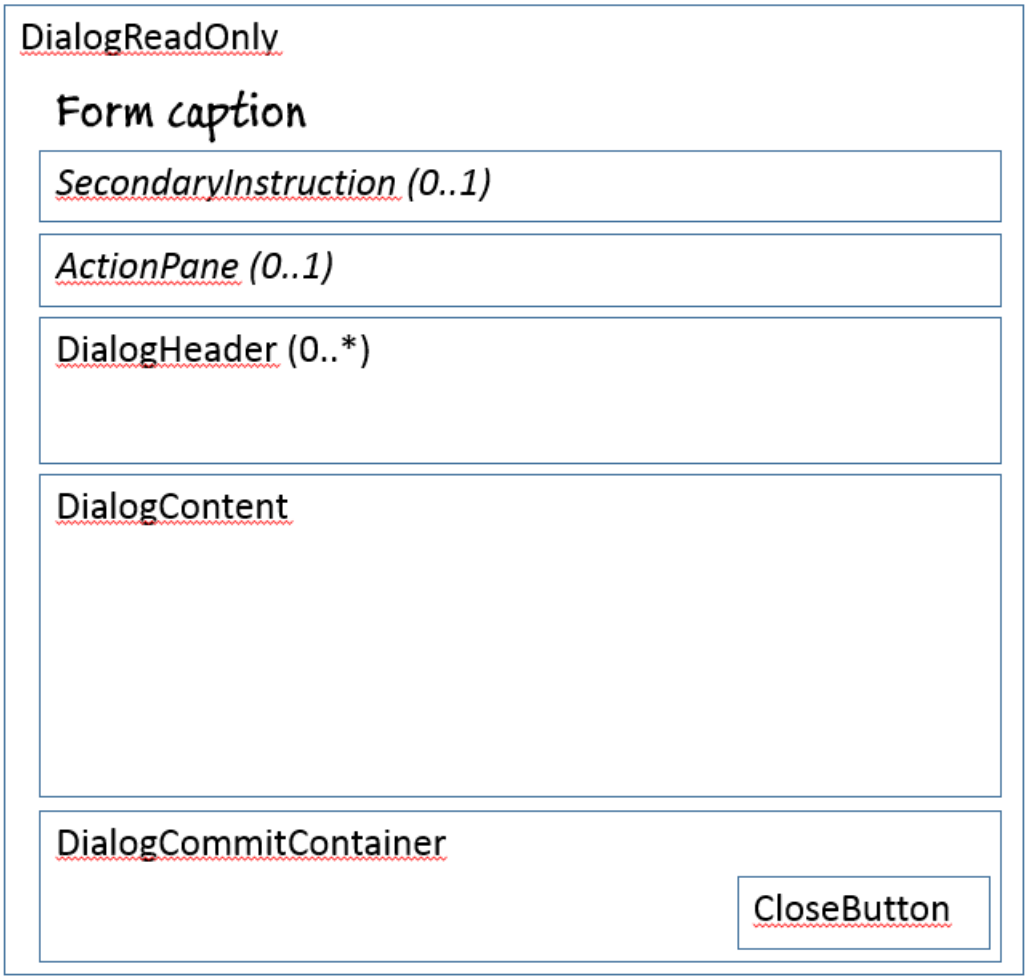
Dialog w/tabs and Dialog w/FastTabs



Dialog w/double tabs



Dialog (read only)



Pattern changes

Here are the main changes to this pattern since Microsoft Dynamics AX 2012:

- The form caption serves as the MainInstruction. Therefore, a modeled MainInstruction control is no longer required.
- Manual handling of error messages is no longer required.
- In some cases, buttons will scroll off the bottom of the slider if the form content exceeds the available height.
- Slider dialogs have their own message bar (because the main message bar is obscured when a slider is open).

Model

Dialog (basic) – High-level structure

- Design
    - *SecondaryInstruction (StaticText) [Optional]*
        - *ActionPane (ActionPane) [Optional]*
        - *DialogHeader (Group, can repeat) [Optional]*
        - DialogContent (Group, repeats 1..N)
        - DialogCommitContainer (ButtonGroup)
            - OKButton ($Button)
            - *OtherButton ($Button, can repeat) [Optional]*
            - CancelButton ($Button)

Dialog w/Tabs and Dialog w/FastTabs – High-level structure

- Design
  - *SecondaryInstruction (StaticText) [Optional]*
  - *ActionPane (ActionPane) [Optional]*
  - *DialogHeader (Group, can repeat) [Optional]*
  - TabContent (Tab)
    - TabPage (TabPage, repeats 1..N)
  - *DialogFooter (Group) [Optional]*
  - DialogCommitContainer (ButtonGroup)
    - OKButton ($Button)
    - *OtherButton ($Button, can repeat) [Optional]*
    - CancelButton ($Button)

Dialog w/double tabs – High-level structure

- Design
  - *SecondaryInstruction (StaticText) [Optional]*
  - *ActionPane (ActionPane) [Optional]*
  - *DialogHeader (Group, can repeat) [Optional]*
  - TabContent (Tab)
    - TabPage (TabPage) [1..*]
  - TabContent (Tab)
    - TabPage (TabPage) [1..*]
  - *DialogFooter (Group) [Optional]*
  - DialogCommitContainer (ButtonGroup)
    - OKButton ($Button)
    - *OtherButton ($Button, can repeat) [Optional]*
    - CancelButton ($Button)

Dialog (read only) – High-level structure

- Design
  - *SecondaryInstruction (StaticText) [Optional]*
  - *ActionPane (ActionPane) [Optional]*
  - *DialogHeader (Group, can repeat) [Optional]*
  - DialogContent (Group, repeats 1..N)
  - DialogCommitContainer (ButtonGroup)

    CloseButton ($Button)

Core components

- Apply the Dialog pattern on **Form.Design**.
- Address BP Warnings:

- **Design.Caption** isn't empty.
- The form must be referenced by at least one menu item.
- **StaticText.Text** isn't empty.

Related patterns

- Drop Dialog

Commonly used subpatterns

- Fields and Field Groups
- Toolbar and List
- Toolbar and Fields
- Fill Text

UX guidelines

The verification checklist shows the steps for manually verifying that the form complies with UX guidelines. This checklist doesn't include any guidelines that will be enforced automatically through the development environment. Open the form in the browser, and walk through these steps. **Standard form guidelines:**

- Standard form guidelines have been consolidated into the General Form Guidelines document.

Dialog guidelines:

- Focus should be in the first editable field in the dialog box when the dialog box is first opened.
  - **Exception:** If the dialog is read-only, focus should be on the **Close** button.
- A dialog must have a **main instruction** at the top.
  - A final period should not be included if the instruction is a statement. If the instruction is a question, a question mark should be included.
- A secondary instruction to the user can optionally be included, and it should present additional information that will help the user understand or use the dialog box. The secondary instruction should consist of a complete sentence in sentence case and should have end punctuation.
- A dialog must have a **content** area.
- For editable dialogs:
  - The content area should contain only the controls that are required in order to complete the task.
  - Constrained input controls, such as selection lists, check boxes, radio buttons, and command links, should be used to avoid validation errors.
  - Reasonable default values for each input should be provided whenever possible.
  - Controls should not cause another dialog to appear during validation.
    - Warning messages for validation issues should be displayed in a message bar as soon as possible.
- For read-only dialogs:
  - The content area should only contain controls that are non-editable or only allow the user to switch the data is displayed, such as a view selector.
  - Programmatically changing the value of a field should not cause validation errors.
  - If your dialog has multiple tabs, the tab that has the most content must define the selection of the dialog width.
- A dialog must have a **commit** button area:
  - For an editable dialog only, there is a commit button that starts the action that is implied by the main instruction.
  - The labels should make sense on their own and should be a response to the main instruction.
  - For both editable and read-only dialogs, the right-most button is a **Cancel** button that cancels the

operation without side-effects.

- There is a button that is marked as the default button for the dialog.
- The button that is selected as the default button should be the safest, most secure response to the task that the user is performing, such as the main instruction of a Dialog or Drop Dialog.
  - If safety and security aren't factors, the button that is most likely to be clicked or that is most convenient for the user should be selected as the default button.
  - **Exception:** Don't select a destructive response as the default unless there is an easy, obvious way to undo the command.

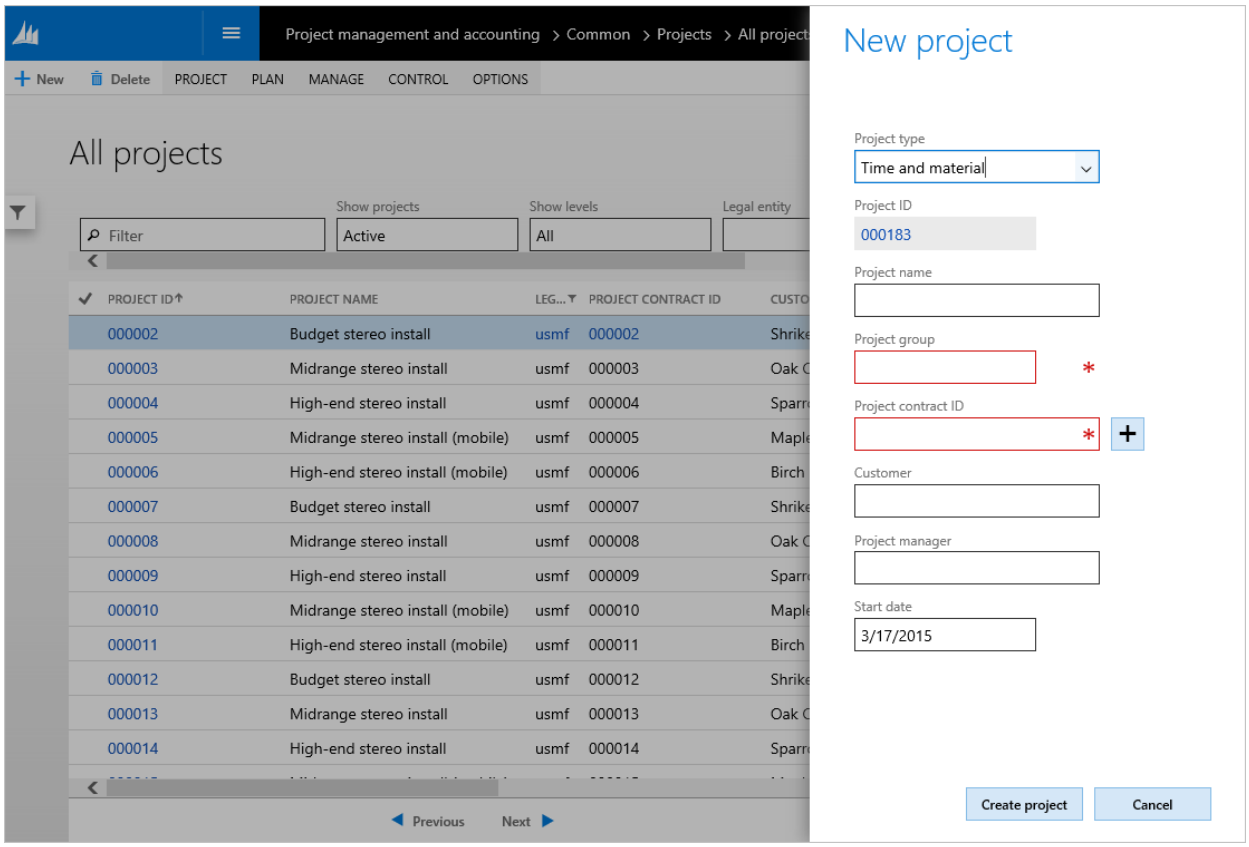
A dialog should **not** have these elements:

- FactBoxes

Examples

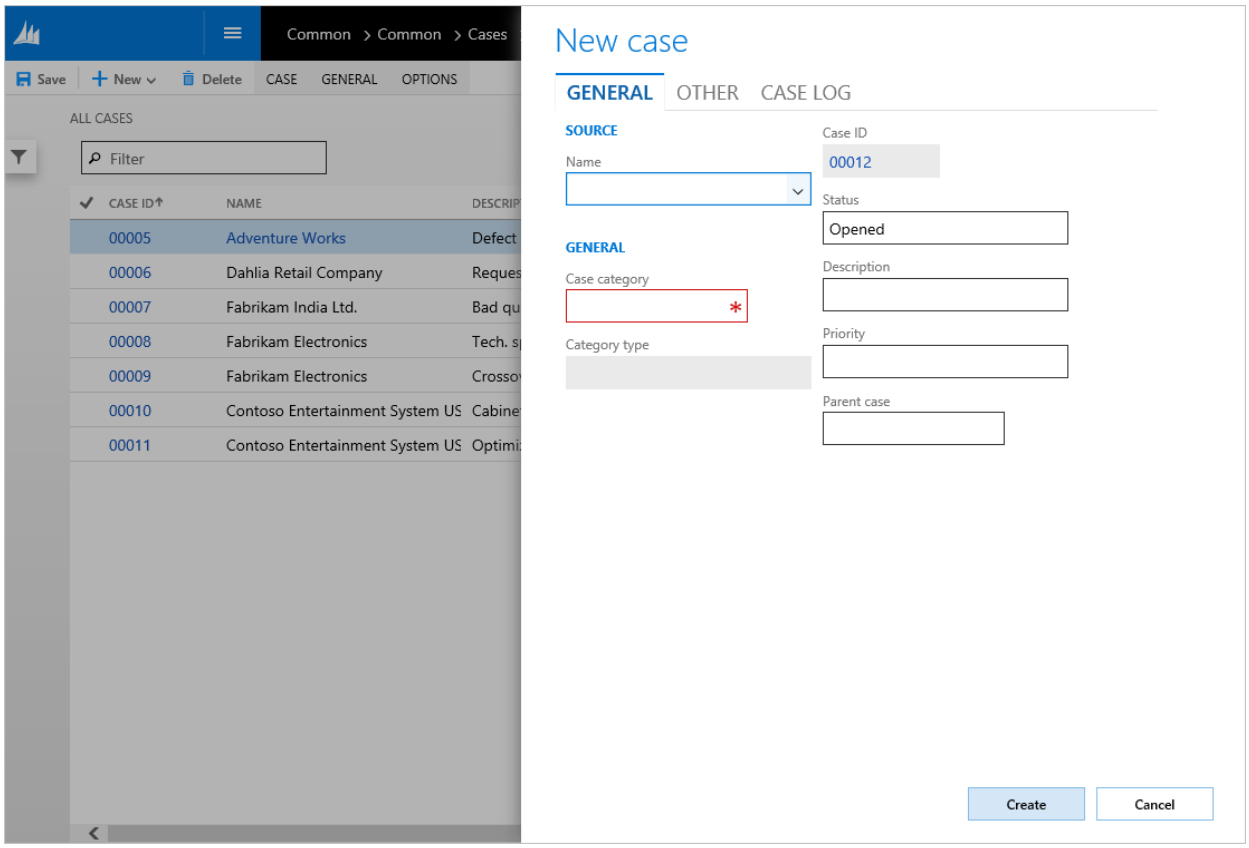
Dialog (basic)

Form: **ProjTableCreate** (Click **Project management and accounting** > **Common** > **Projects** > **All projects**, and then click **New**.)



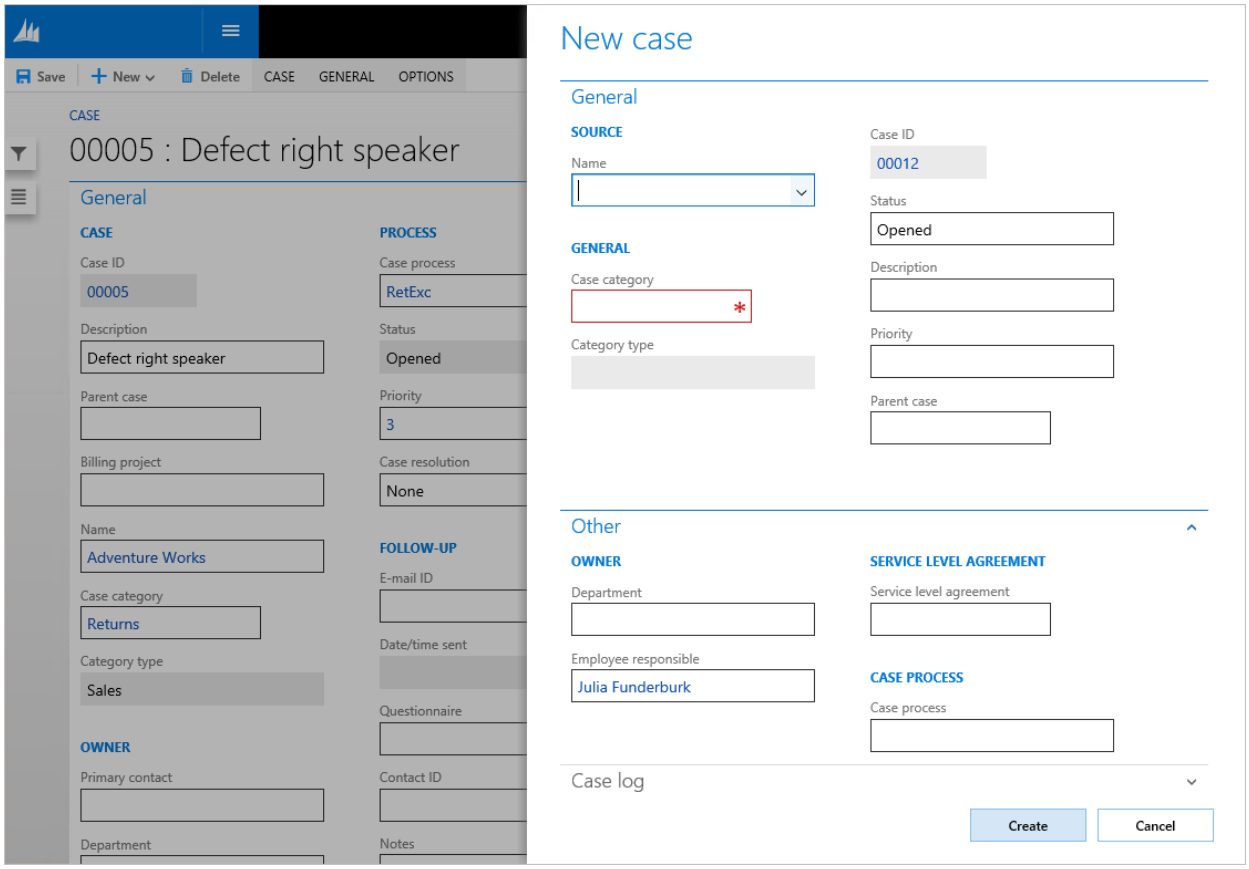
Dialog w/tabs

Form: **CaseDetailCreate** (Click **Common** > **Common** > **Cases** > **All cases**, and then click **New**.)



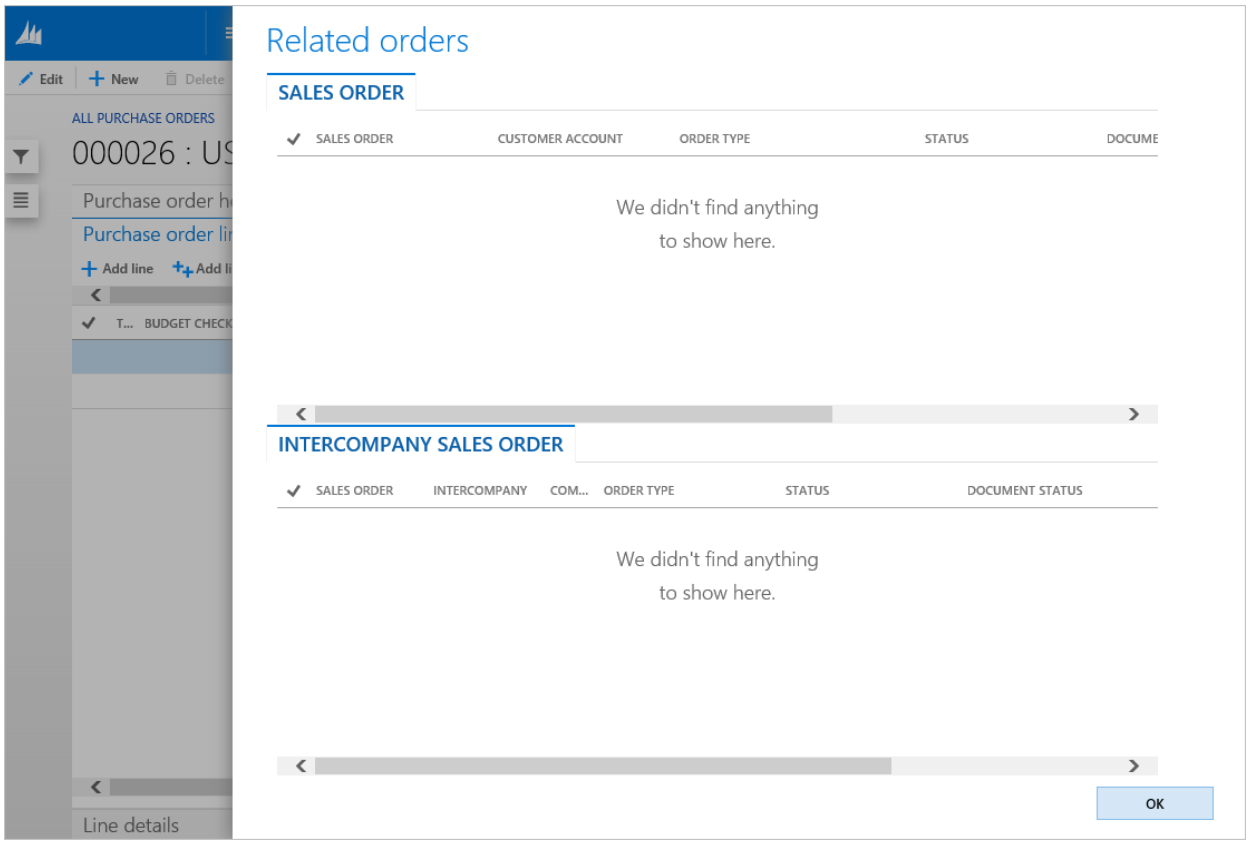
Dialog w/FastTabs

This example shows a modified version of the **CaseDetailCreate** form, because the product currently includes no examples of forms that use this pattern.



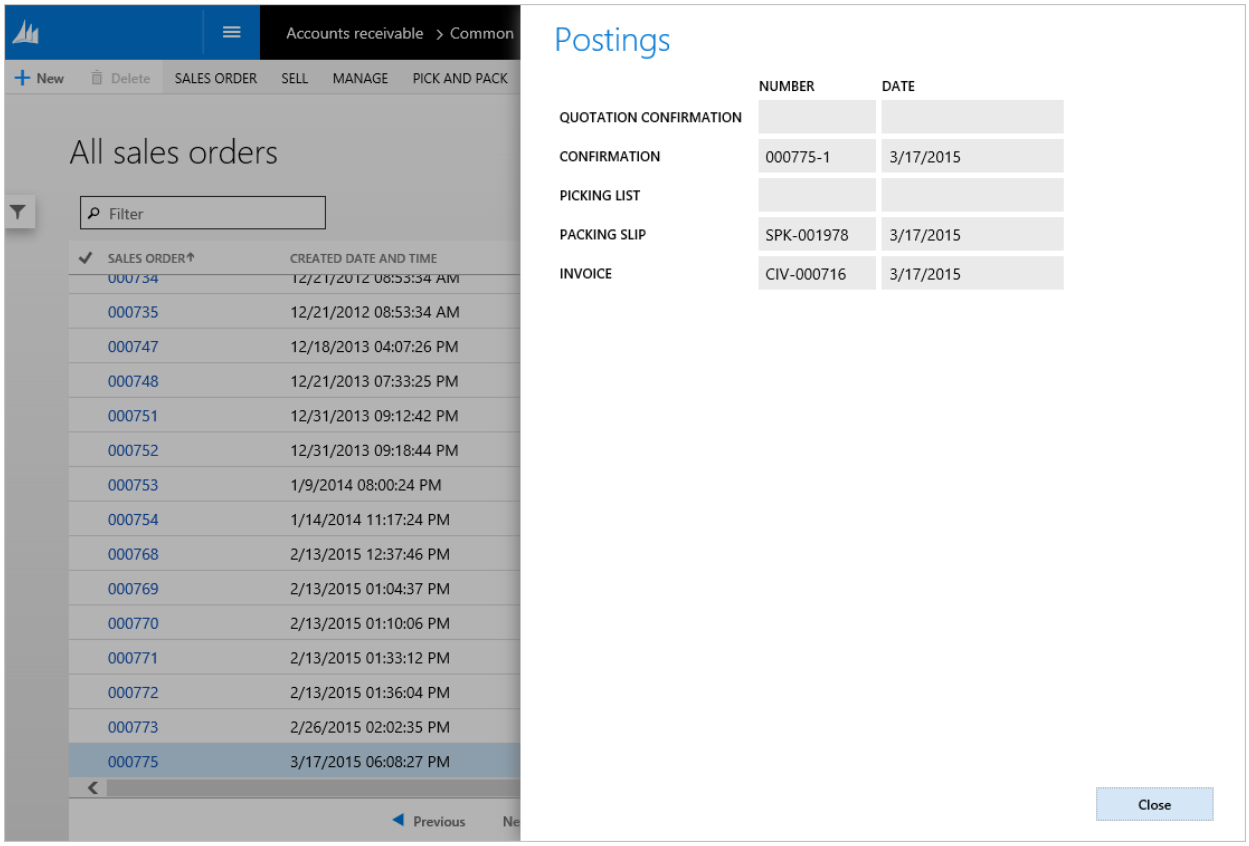
Dialog w/double tabs

Form: **PurchTableReferences** (Click **Accounts payable** > **Common** > **Purchase orders** > **All purchase orders**, and then click **General** > **Related information** > **Related orders**.)



Dialog (read only)

Form: **SalesTablePostings** (Click **Accounts receivable** > **Common** > **Sales orders** > **All sales orders**, and then click **General** > **Related information** > **Postings**.)



Appendix

Frequently asked questions

This section will have answers to frequently asked questions that are related to this guideline/pattern.

Open issues

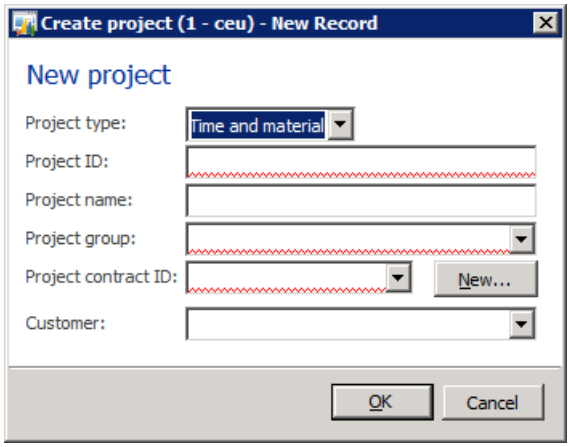
- **How does this pattern handle the More info link in dialogs?**
  - **More info** usage is assumed to be a custom pattern unless we have enough cases to justify the addition of a new pattern.
- **Should the pattern be modified to force OK/Cancel buttons to use CommandButtons instead of any button type?**
  - We will be looking at making this change in the future.

Selecting the correct dialog width

TYPE OF CONTENT	SMALL DIALOG	MEDIUM DIALOG	LARGE DIALOG	FULL DIALOG	NOTES
Columns of content	The slider fits one column of content.	The slider fits two columns of contents	The slider fits three columns of content.	The slider fits the viewport width minus peek.	The maximum number of columns depends on the width of the fields in the column. Therefore, the width is defined as *x* × 100% field size.
Horizontal scroll	No horizontal scrolling	Avoid horizontal scrolling.	Avoid horizontal scrolling.	OK, provided that the control buttons and commit buttons are visible	
Vertical scroll	No vertical scroll for typical scenarios (FastTabs can be expanded for special cases). Otherwise, use a Medium dialog.	Yes	Yes	Yes	Avoid putting so much content in the dialog that you cause vertical scrolling of the contents. If your dialog is vertically scrolling at a typical screen resolution, you should make the dialog larger.
FastTabs	Strongly discouraged	OK but discouraged	Yes	Yes	
Tabs	Yes	Yes	Yes	Yes	Switching tabs or expanding FastTabs should never cause jumps in the dialog size. The largest tab content must define the choice of the dialog size.

TYPE OF CONTENT	SMALL DIALOG	MEDIUM DIALOG	LARGE DIALOG	FULL DIALOG	NOTES
List/hierarchy	Yes	Yes	Yes	Yes	
Field groups	Yes	Yes	Yes	Yes	
Nested field groups	No nested field groups that have a mixed layout direction (matrix or tabular layout)	Multiple-column layout	Multiple-column layout	Yes	
Custom controls	Yes	Yes	Yes	Yes	
Grid	Yes, but no horizontal scrolling	Yes, but no horizontal scrolling	Yes, but no horizontal scrolling	Yes	The maximum number of columns depends on the width of the fields in the column. Therefore, the width is defined by *x* × 100% field size.

AX 2012 content



Drop Dialog form pattern

2/18/2021 • 4 minutes to read • Edit Online

This topic provides information about the Drop Dialog form pattern. This pattern is used to initiate actions when the number of fields is seven or fewer.

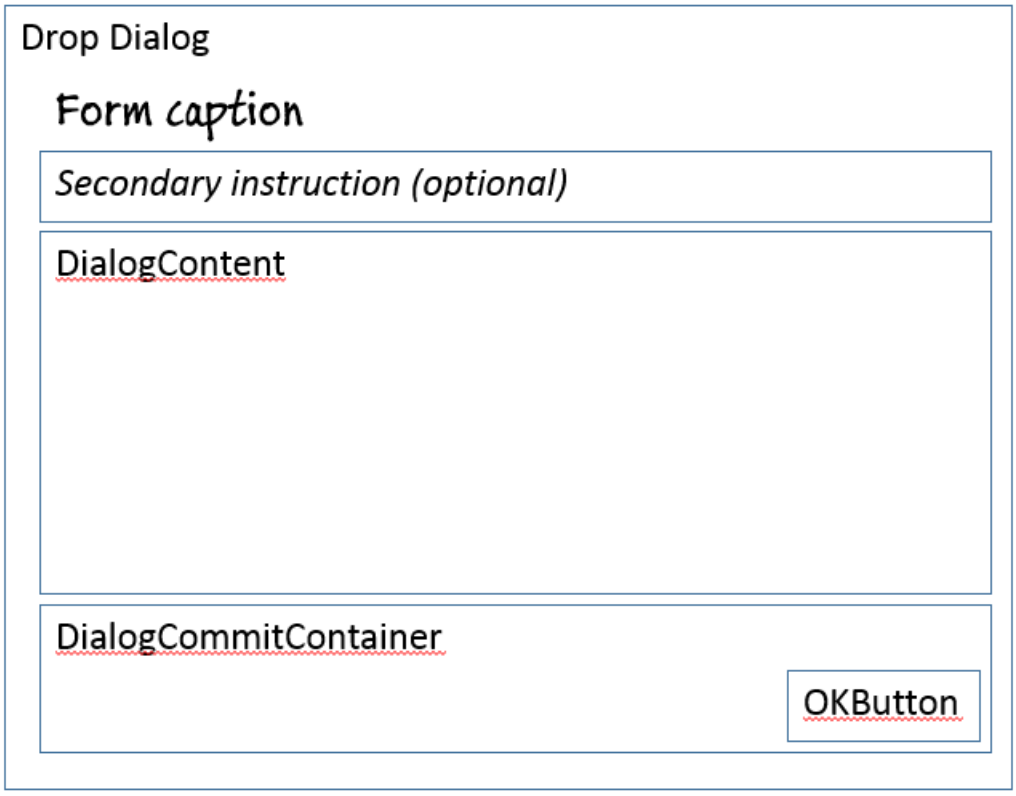
Usage

The Drop Dialog pattern is used to initiate actions when the number of fields is seven or fewer. Drop dialogs are quick and easy for users to use, and are more lightweight than a full dialog that is presented as a slider. Drop dialogs should feel as lightweight to use as a menu. Two patterns are described in this document:

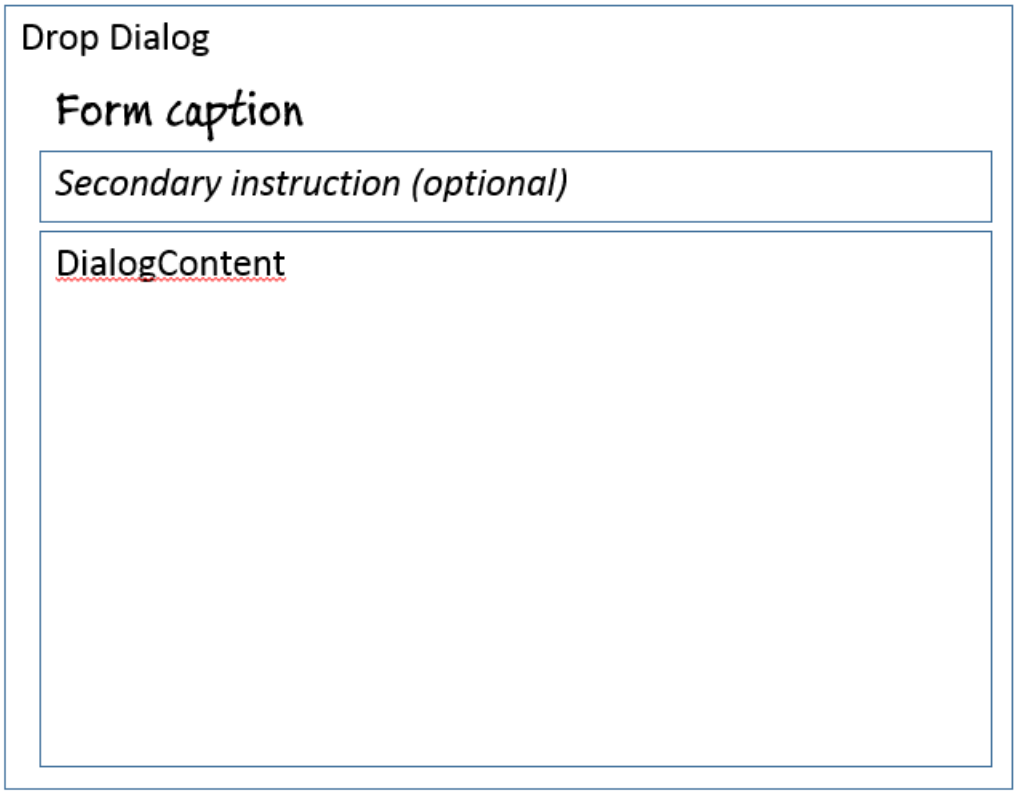
- **Drop dialog** – This is the basic Drop dialog pattern. If your Drop dialog is editable, this is the correct pattern to use.
- **Drop dialog (read only)** – This Drop dialog pattern is for informational forms that aren't editable. This variation doesn't have an **OK** button.

Wireframe

Drop dialog (basic)



Drop dialog (read only)



Pattern changes

Here are the main changes to this pattern since Microsoft Dynamics AX 2012:

- Manual handling of error messages is no longer required.

Model

Drop dialog (basic) – High-level structure

- Design
  - *SecondaryInstruction (StaticText) [optional]*
  - DialogContent (Group)
  - DialogCommitContainer (ButtonGroup)
    - OKButton ($Button)

Drop dialog (read only) – High-level structure

- Design
  - *SecondaryInstruction (StaticText) [optional]*
  - DialogContent (Group)

Core components

- Apply the Drop Dialog pattern on **Form.Design**.
- Address BP Warnings:
  - **Design.Caption** isn't empty.
  - The form must be referenced by at least one menu item.
  - **StaticText.Text** isn't empty.

Related patterns

- Dialog

Commonly used subpatterns

- Fields and Field Groups
- Toolbar and List

UX guidelines

The verification checklist shows you the steps for manually verifying that the form complies with UX guidelines. This checklist doesn't include any guidelines that will be enforced automatically through the development environment. Open the form in the browser, and walk through these steps. **Standard form guidelines:**

- Standard form guidelines have been consolidated into the General Form Guidelines document.

Drop dialog guidelines:

- A Drop dialog should be used if the following conditions exist:
  - There are seven or fewer fields.
  - The user can enter the information quickly.
  - Minimal field validation is required.
  - There are no buttons that open additional child forms.
    - **Exceptions:** Lookups, Enhanced preview, and View details navigation
  - There is no editable grid (select-only grids are allowed).
- Focus should be in the first editable field on the Drop dialog when it is first opened.
- A Drop dialog should have a **main instruction** (form caption) at the top.
  - The main instruction should be used to explain concisely what the user should do in the Drop dialog. The instruction should be a specific statement, an imperative direction, or a question. Good instructions communicate the user's objective with the Drop dialog rather than focusing purely on the mechanics of manipulating it.
  - A final period should not be included if the main instruction is a statement. If the instruction is a question, a question mark should be included.
  - Besides the main instruction, a secondary instruction to the user should be displayed, and it should present additional information that will help the user understand or use the Drop dialog. The secondary instruction should consist of a complete sentence in sentence case and should have end punctuation.
    - **Exception:** If the additional instruction merely repeats the main instruction with slightly different wording, don't include it.
- A Drop dialog should have a **content** area.
  - Constrained input controls should be used to avoid validation errors. Examples include selection lists, check boxes, radio buttons, and command links.
  - Reasonable defaults for each input should be provided whenever possible.
- A Drop dialog should have a **commit** button area that:
  - Does **not** have a **Cancel** button.
  - Has a button that is marked as the default button of the Drop dialog (if a button exists).
  - The label of the default button should be a verb that implements the action that is described in the main instruction. For example, if the main instruction is "Create new product," the button label should be **Create**. If there is no appropriate verb for the button, use **OK**.
  - The commit button area should have specific commit button labels that make sense on their own and are a response to the main instruction.

A Drop dialog should **not** have the following:

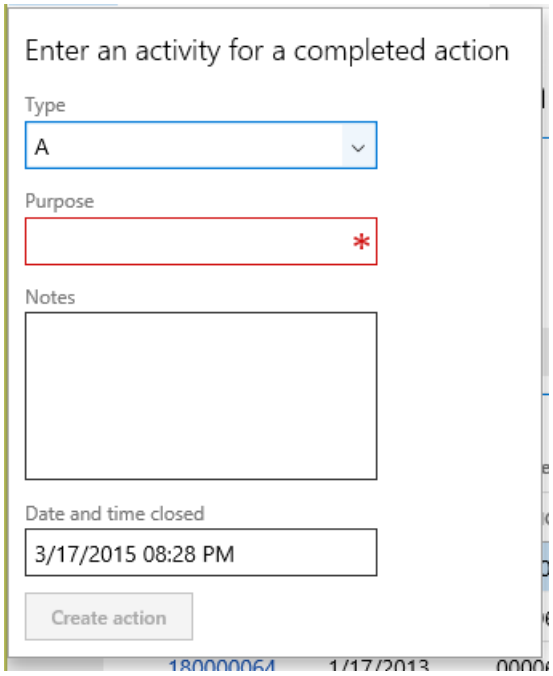
- A toolbar or ActionPane anywhere in the Drop dialog.

- Buttons that navigate to another page or open other dialogs. (Enhanced previews are allowed.)
- Field groups. There are exceptions, such as a radio button or check box group.
- A tab control.
- FactBoxes.
- FastTabs.

Examples

Drop dialog (basic)

Form: **CustCollectionsNewActivityAction** (Click **Accounts receivable** > **Common** > **Collections** > **Collections**, select a row to move to details, and then click **Action**.)



Drop dialog (read only)

This pattern isn't currently used in the product.

Appendix

Frequently asked questions

This section will have answers to frequently asked questions that are related to this guideline/pattern.

Open issues

- **Should a vertical Fields and Field Groups subpattern be added for Drop dialogs?**
  - No, you should use the normal Fields and Field Groups pattern.
- **Should buttons be left-aligned or right-aligned?**
  - Right-aligned. The pattern is currently enforcing this.

NOTE

Can you tell us about your documentation language preferences? Take a short survey.

The survey will take about seven minutes. No personal data is collected (privacy statement).

Lookup form pattern

2/18/2021 • 3 minutes to read • Edit Online

This topic provides information about the Lookup form pattern. Custom lookup forms should be used when a standard framework-provided lookup would not provide the correct data, or when advanced visualization of the data is required.

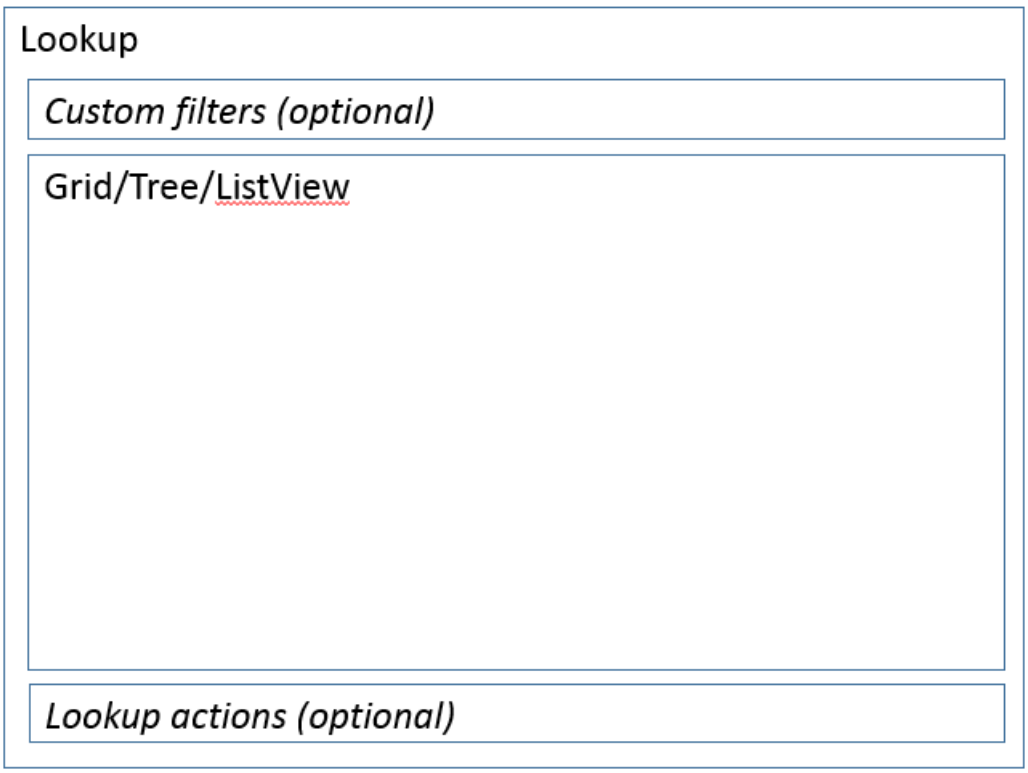
Usage

Custom lookup forms should be used when a standard framework-provided lookup (which is typically generated by using the AutoLookup field group that is defined on the table definition), would not provide the correct data, or when advanced visualization of the data is required. Three patterns are described in this document:

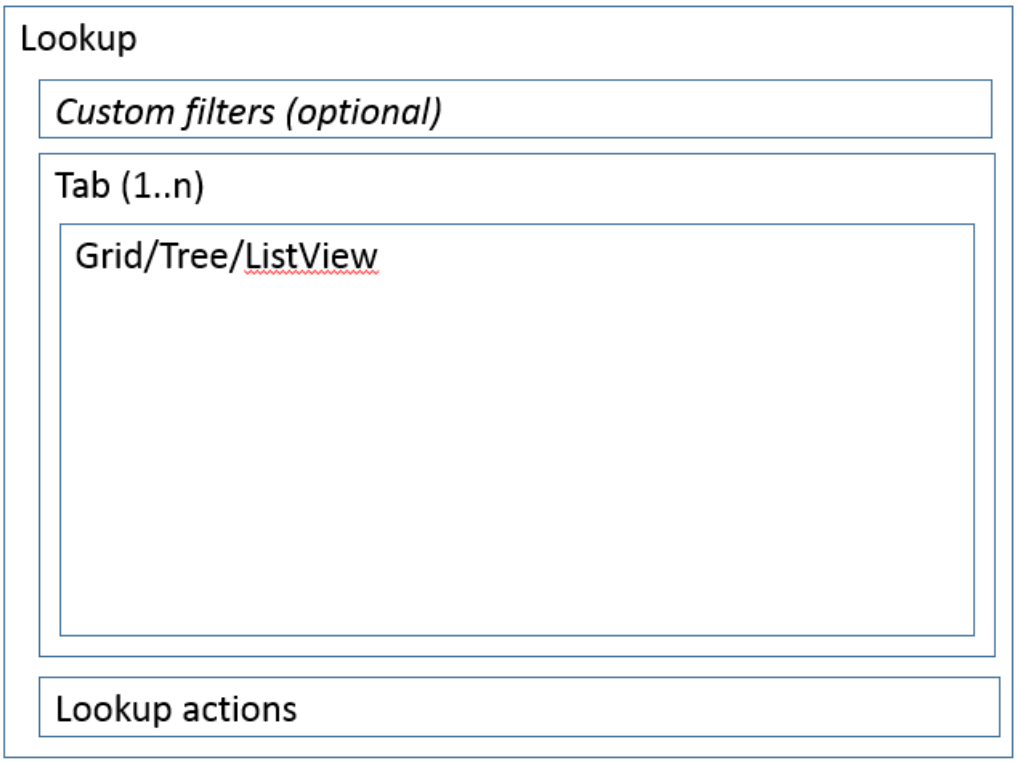
- **Lookup basic** – This is the basic Lookup pattern that has just one list or tree, and also optional custom filters and actions.
- **Lookup w/tabs** – This Lookup pattern is used when more than one view of the lookup can be made available to the user. Tab captions aren't shown. Instead, the tab is selected through a combo box.
- **Lookup w/preview** – This more advanced Lookup pattern enables a preview of the current record in the lookup grid.

Wireframe

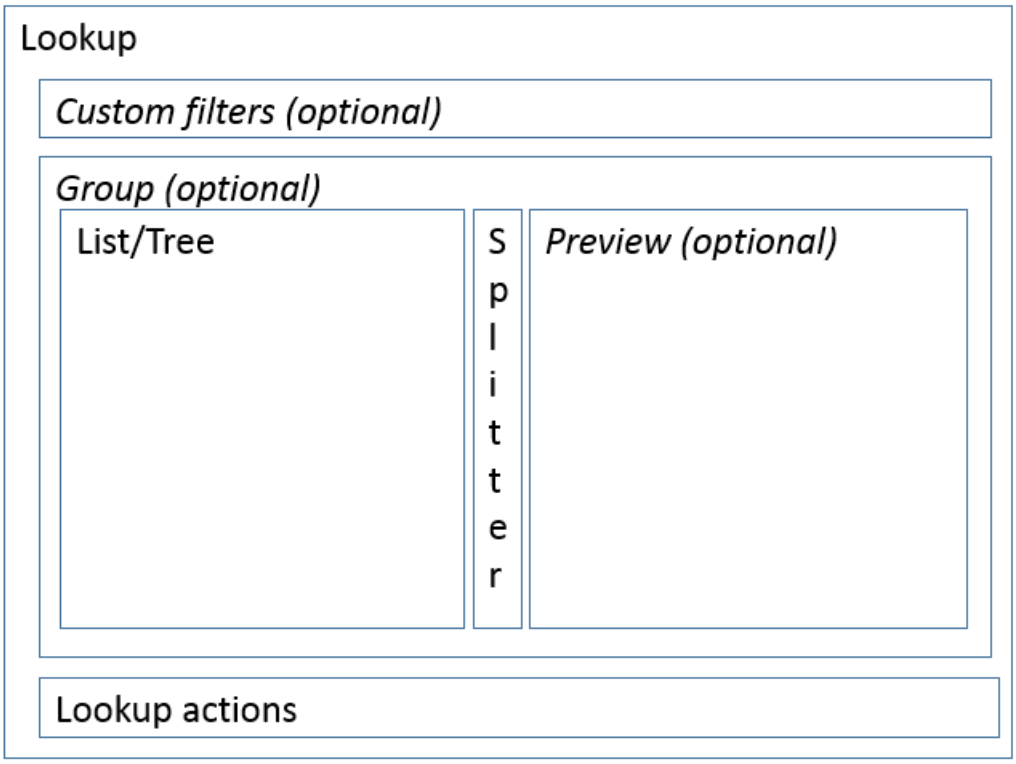
Lookup basic



Lookup with tabs



Lookup with preview



Pattern changes

Here are the changes to this pattern since Microsoft Dynamics AX 2012:

- Tabs should be hidden and controlled by a combo box.
- Optionally add a splitter/preview.

Model

Lookup basic – High-level structure

- Design
  - *CustomFilter (Group) [Optional]*
  - Grid | Tree | ListView
  - *LookupActions (Group) [Optional]*

Lookup w/tabs – High-level structure

- Design
  - *CustomFilter (Group) [Optional]*
  - LookupTab (Tab)
    - LookupTabPage (TabPage, repeats 1..N)
      - Grid | Tree | ListView
  - *LookupActions (Group) [Optional]*

Lookup w/preview – High-level structure

- Design
  - *CustomFilter (Group) [Optional]*
  - LookupContent (Group)
    - Grid | Tree | ListView
  - VerticalSplitter (Group)
    - Preview (Group)
  - LookupActions (ActionPane)

Core components

- Apply the Lookup pattern on Form.Design.
- Address BP Warnings:
  - EDT.FormHelp must reference a form where Style=Lookup.

Commonly used subpatterns

- Custom Filter Group

UX guidelines

The verification checklist shows the steps for manually verifying that the form complies with UX guidelines. This checklist doesn't include any guidelines that will be enforced automatically through the development environment. Open the form in a browser, and walk through these steps. **Standard form guidelines**

- Standard form guidelines have been consolidated into the General Form Guidelines document.

Lookup guidelines

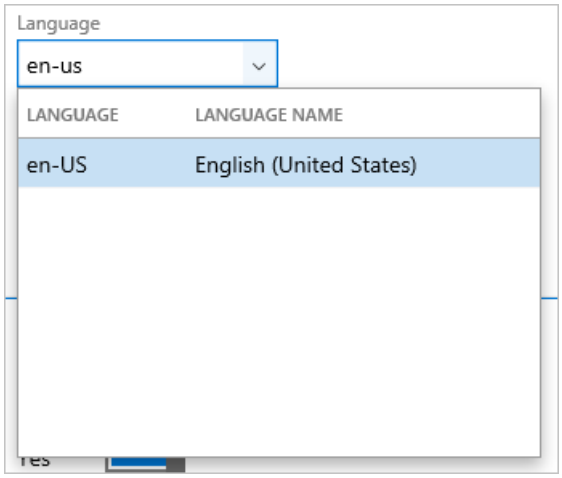
- **Grid** guidelines have been consolidated into the General Form Guidelines document, in the Grid guidelines section.
- If you must show different "views" (tabs) within the lookup, use a combo box to let the user to switch between tabs.
- You can optionally use a tree view in the lookup. Also consider providing a standard grid because of the complexity that is involved in showing additional fields of data in a tree.
- Don't have more than five columns in the grid. The lookup resizes to show all columns, so five columns is very wide.

- The **optional preview area**:
  - The area should help the user choose between two or more records that are similar. For example, if you have two employees who are named John Smith, the preview should provide enough information to help the user differentiate these two people.
  - Don't show editable fields in the preview.
- **Custom filter** guidelines have been consolidated into the Custom Filter Group subpattern document.

Examples

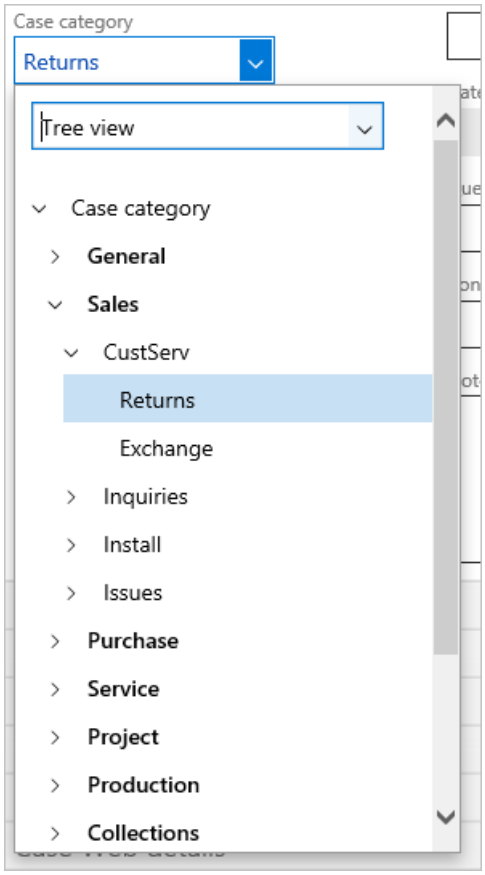
Lookup basic

Form: **SysLanguageLookup** (Click **Settings** > **User settings** on the navigation bar.)



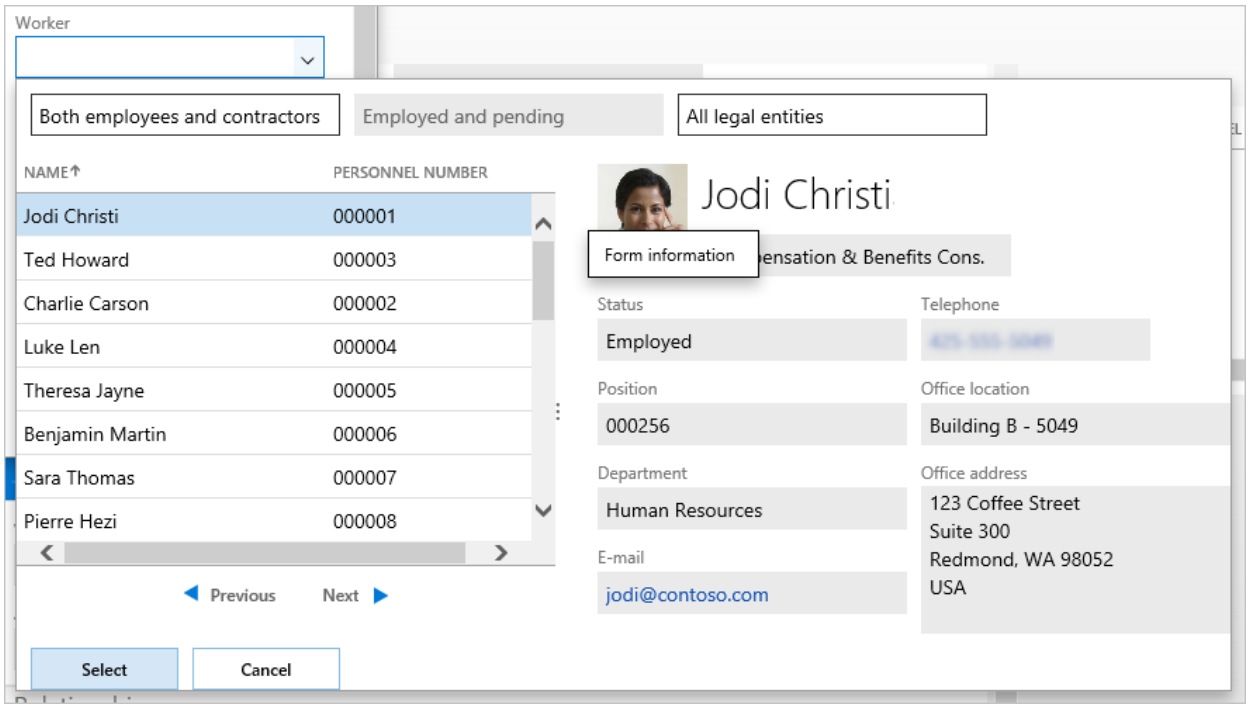
Lookup with tabs

Form: **CaseCategoryLookup** (Click **Common** > **Common** > **Cases** > **All cases**, and then select a case to go to the details.)



Lookup with preview

Form: **HcmWorkerLookup** (Click **Human resources** > **Common** > **Organization** > **Positions** > **Positions**, and then click a record to go to the details. Expand the **Worker assignment** FastTab, click **New**, and then click the drop-down arrow in the **Worker** field.)



Appendix

Frequently asked questions

This section will have answers to frequently asked questions that are related to this guideline/pattern.

- **How do I switch between tabs in the Lookup w/tabs pattern?**
  - The Lookup w/tabs pattern intentionally sets **ShowTabs** to **No** on the Tab control. These forms are meant to model an unbound combo box in the custom filter group. This combo box is used instead of tab headers to switch tabs.
  - To do this, follow these steps:
    1. Call the **SysLookup::tab2ComboBox** method post **super** in form **run()** to populate the combo box with captions from visible tabs in the lookup.

       ```
       // Generate view combobox based on tabs
       tab2ComboBoxItemMap = SysLookup::tab2ComboBox(Tab, switchView);
       ```

    2. Override **modified()** on the combo box to update the visible tab, based on the selected value in the combo box.

       ```
       Tab.tabChanged(Tab.tabValue(), tab2ComboBoxItemMap.lookup(this.selection()));
       ```

Open issues

- **Can we incorporate the most recently used values into lookups?**
  - App modeling can make this work right now (for example, the Currency lookup). We are considering general framework support for this feature in the future.

AX 2012 content

SysLanguageLookup (Lookup basic)

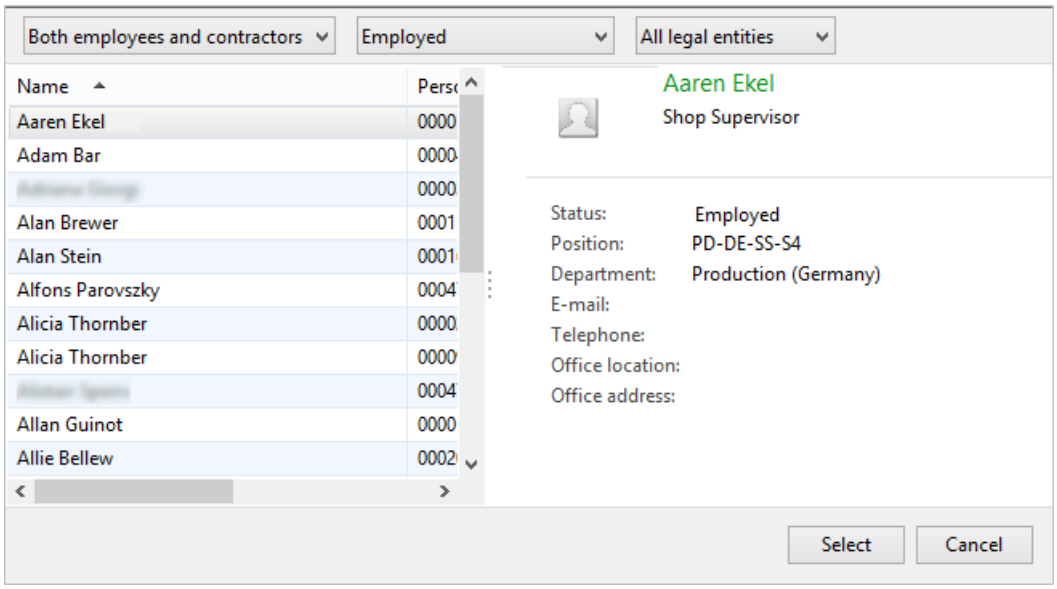
HcmWorkerLookup (Lookup with preview)



NOTE

Can you tell us about your documentation language preferences? Take a short survey.

The survey will take about seven minutes. No personal data is collected (privacy statement).

FactBox form patterns

2/18/2021 • 3 minutes to read • Edit Online

This topic provides information about the FactBox form patterns. FactBoxes are used to provide related information for a record.

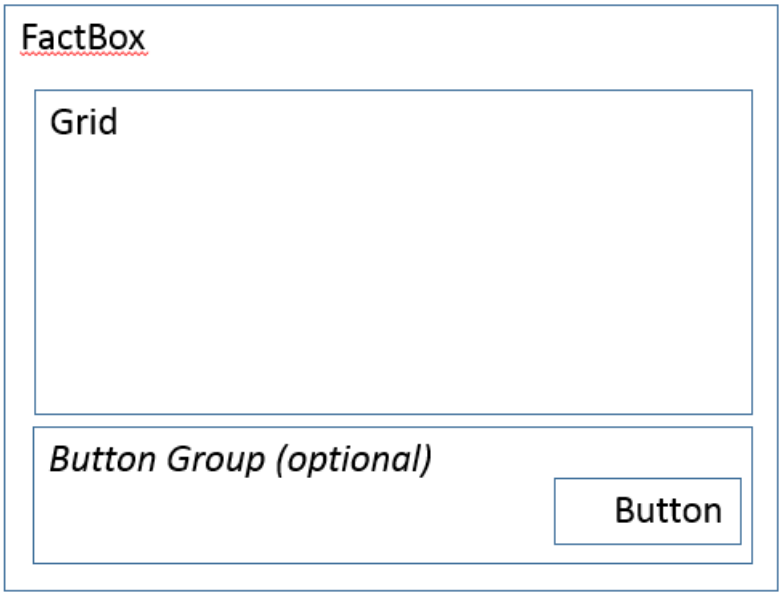
Usage

In general, FactBoxes are used to provide "related information" for a record. They help guarantee that the user doesn't have to open additional forms to get important information, such as totals, balances, overdue orders, and email addresses. The Factbox Grid pattern should be used when there is a child collection (potential for multiple rows) of related information. Two patterns are described in this document:

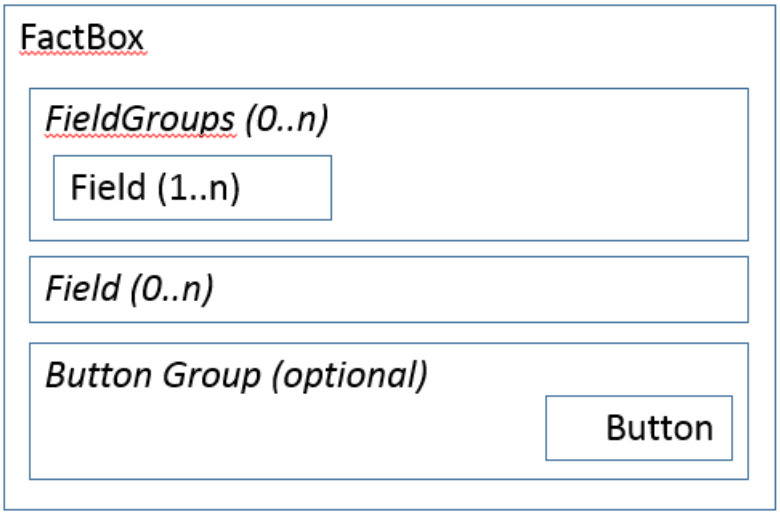
- **Form Part FactBox Grid** – This FactBox pattern is used when there is a child collection (potential for multiple rows) of related information.
- **Form Part FactBox Card** – This FactBox pattern is used when there is just a set of related fields that must be shown.

Wireframe

Form Part FactBox Grid



Form Part FactBox Card



Pattern changes

Here are the main changes to this pattern since Microsoft Dynamics AX 2012:

- A group has been added around the optional button to make it easier to position the button.

Model

Form Part FactBox Grid – High-level structure

- Design
  - Grid
  - *GridDefaultAction (Button) [Optional]*
  - *ButtonGroup (ButtonGroup) [Optional]*
    - Button

Form Part FactBox Card – High-level structure

- Design
  - *FieldGroups (Group) [0..N]*
    - Fields ($Fields, 1..N)
  - *Fields ($Field) [0..N]*
  - *ButtonGroup (ButtonGroup) [Optional]*
    - Button

Core components

- Apply the FactBox pattern on **Form.Design**.
- Address BP Warnings:
  - **Design.Caption** isn't empty.
  - **Grid.DataSource** isn't empty.

UX guidelines

The verification checklist shows the steps for manually verifying that the form complies with UX guidelines. This checklist doesn't include any guidelines that will be enforced automatically through the development environment. Open the form in the browser, and walk through these steps. **Standard form guidelines:**

- Standard form guidelines have been consolidated into the General Form Guidelines document.

FactBox general guidelines:

- If a backing form exists, the FactBox should have a **(More...)** link defined that goes to the appropriate backing form. The names of the FactBox and backing form should be similar.
- The title should not be a verb or a verb phrase.
- The title should not contain a label to a specific record.
- FactBoxes should not display fields that let a user enter data by typing with the keyboard.
- The title should accurately describe the content and should not be truncated when the FactBox area is at its default size.

FactBox grid guidelines:

- One to four columns should be displayed.

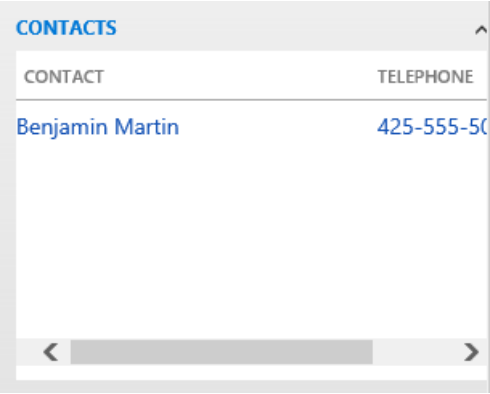
FactBox card guidelines:

- Each field should have a label.
- The ID and name of the header or the line that content is displayed for in the FactBox should not be displayed.
- Two to ten fields should be displayed.
- Currency indicator fields should be displayed as the last field in the FactBox.

Examples

Form Part FactBox Grid

Form: **CustTable** > **ContactsInfoPart**



Form Part FactBox Card

Form: **CustTable** > **CustStatisticsStatistics**

Appendix

Frequently asked questions

This section will have answers to frequently asked questions that are related to this guideline/pattern.

- **How do I make the More button work?**
  - The **More** button at the bottom of the FactBox takes the user to a backing form that contains the full list of related records. This button should be implemented by using a regular Button control that overrides the **clicked** method as shown in the following example. Be sure to fill in the **TableRef** and **ListPageRef** properties on the table that provides data for the grid.

```
[Control("Button")]
class More
{
public void clicked()
    {
        super();
        FormPartUtil::openShowMoreForm(element, <TableName>);
    }
}
```

Open issues

- **Should field labels be on the left side in FactBoxes to support a more compact visual?**
  - We plan to allow **LabelPosition**=**Left** inside FactBoxes.

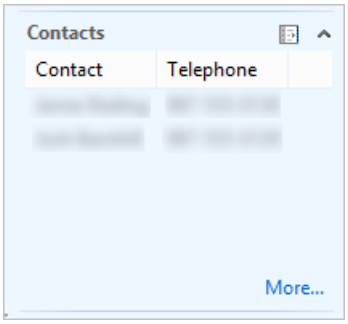
CustTable > ContactsInfoPart



Custom Filter Group subpattern

2/18/2021 • 3 minutes to read • Edit Online

Usage

This subpattern is used to show a small collection of input controls (no more than five) that apply a custom filter to a grid or form section. Fields in the Custom Filter Group should be limited to the following field types, which have constrained inputs and can be applied to the query:

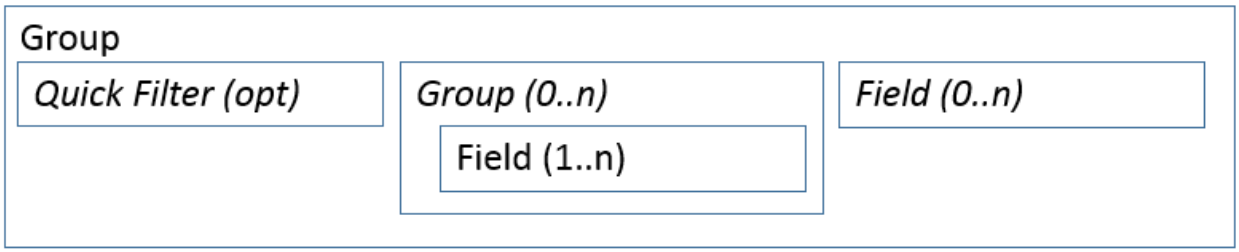
- StringEdits with Lookups
- Date fields
- ReferenceGroup
- Comboboxes
- Checkboxes
- Quick Filter

Two patterns are described in this document. The only difference between these patterns is whether the Quick Filter control is mandatory or optional:

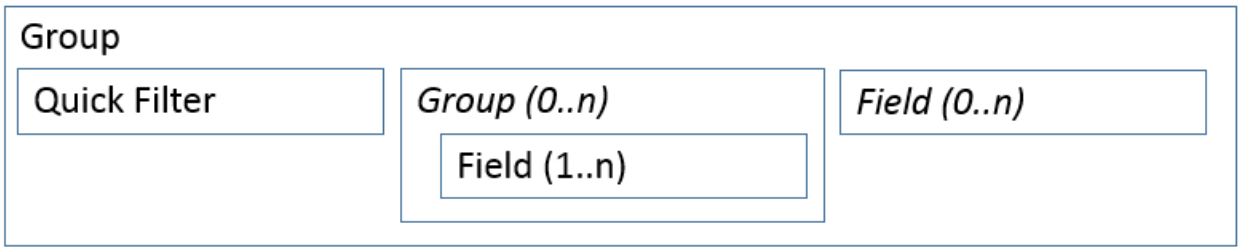
- **Custom Filters** – In this subpattern, the QuickFilter control is optional.
- **Custom and Quick Filters** – In this subpattern, the QuickFilter control is mandatory.

Wireframes

Custom Filters



Custom and Quick Filters



Model

Custom Filters – High-level structure

- CustomFilter (Group)
  - *QuickFilter (QuickFilter) [Optional]*
  - *FieldGroups (Group) [0..N]*

    - Fields ($Field) [1..N]
  - *Fields ($Fields) [0..N]*

Custom and Quick Filters – High-level structure

- CustomFilter (Group)
  - QuickFilter (QuickFilter)
  - *FieldGroups (Group) [0..N]*
    - Fields ($Field) [1..N]
  - *Fields ($Fields) [0..N]*

Core components

- Apply a custom filter-container pattern to a Group control.
- Address BP Warnings:
  - Input controls within the CustomFilterGroup should not have a DataSource or DataField assigned.

Related container patterns

None

Related modeling

Use QueryFilter, not QueryBuildRange, for all custom filters. QueryBuildRange doesn't work correctly with outer-joined fields.

UX guidelines

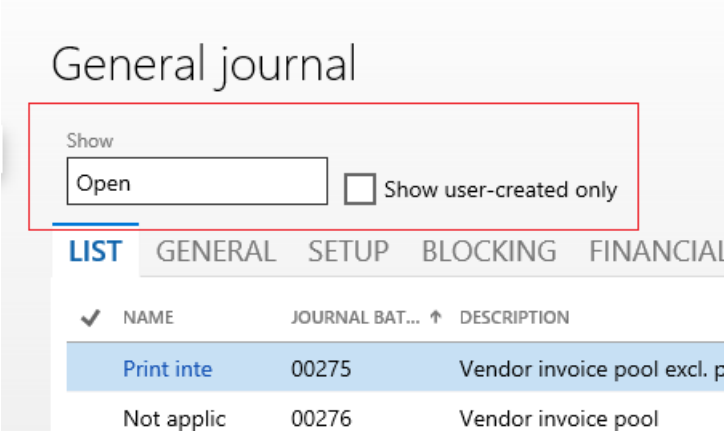
The verification checklist shows the steps for manually verifying that the form complies with UX guidelines. This checklist doesn't include any guidelines that will be enforced automatically through the development environment. Open the form in a browser, and walk through these steps.

- **Standard form guidelines:**
  - General form guidelines
- **Custom Filter Group guidelines:**
  - All controls (except QuickFilter) are constrained input controls. Open-ended controls, such as strings, integers, and reals, should not be used.
  - Field labels are turned off to save space. For example, no label is needed for a combobox that has the values **Open**, **Closed**, **Posted**, and All.
    - Show labels when the filter values do not provide sufficient context for the user to understand what the filter does. For example, a date field provides no context, and the user requires a label to understand what type of date is specified (for example, **Created date**).
    - Either all labels are turned off, or all labels are turned on. Don't mix unlabeled filters and labeled filters.
    - **Exception:** When you use a check box–style Boolean, the label can be left on, even though other fields don't show a label.
  - There should not be more than five controls in the custom filter group.

Examples

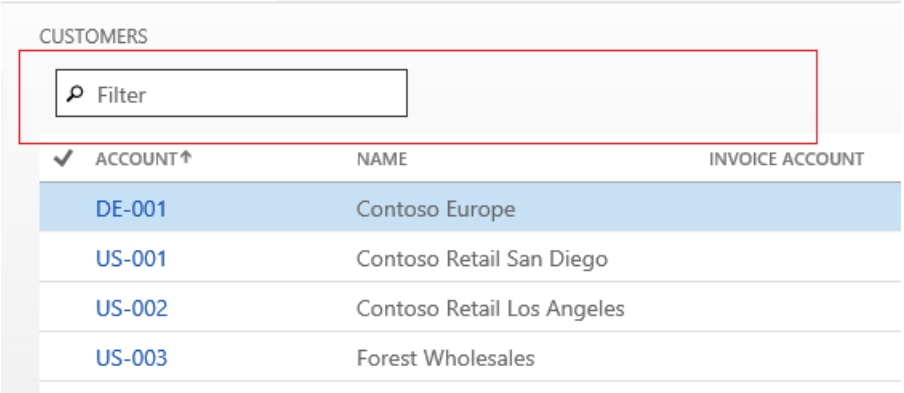
Custom Filters

Form: **LedgerJournalTable (TopFields)**



Custom and Quick Filters

Form: **CustTable (CustomFilterGroup)**



Resources

Typically used by form patterns

- List Page

Appendix

Frequently asked questions

This section will have answers to frequently asked questions that are related to this guideline/pattern.

- **What do I do with the legal entity?**
  - "Legal entity" is a typical custom filter that belongs in the Custom Filter Group.
- **Should the custom filter be above the toolbar of a list?**
  - We think that the custom filter belongs as close to the grid as possible, because it more directly affects the list, just as the commands in the toolbar do. Additionally, this position makes the logical order of the elements consistent across different page patterns.

Open issues

- **Do we allow Show More/Less in the Custom Filter Group? An example is BudgetAnalysisInquiry_PSN.**
  - No, that will currently be a custom container. If we have enough examples, we might add a new container subpattern.
- **Does the pattern limit the possible input types to those that allow constrained input values?**

- The pattern currently allows any input, but it's against guidelines to have inputs that have unconstrained values.

- **Do we allow groups to be used as custom filter groups?**
  - We do allow them now, to make migration easier and to identify Custom Filter group locations. However, we encourage you to use only a small set of fields in these situations (and we might eventually enforce this).

Fields and Field Groups subpattern

2/18/2021 • 2 minutes to read • Edit Online

This topic provides information about the Field and Field Groups form subpattern. This is the most common data entry subpattern. It uses a dynamic number of columns to present multiple fields or groups of fields.

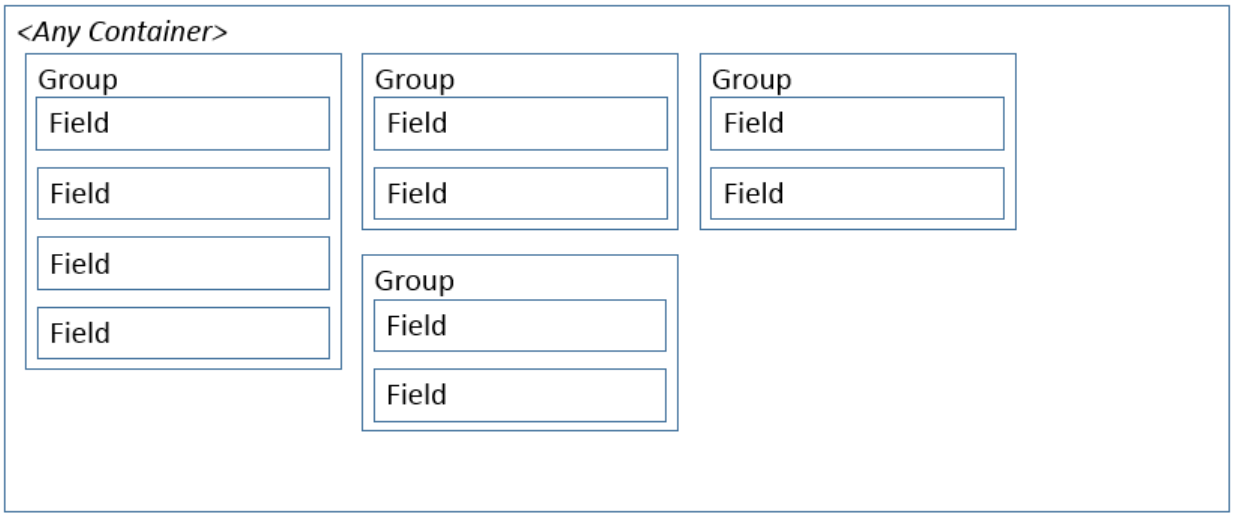
Usage

Field and Field Groups is the most common data entry subpattern and uses a dynamic number of columns to present multiple fields or groups of fields. This subpattern is not used with controls that have dynamic height or width (for example Grid, Tree, RadioButton, ListBox, or ListView), or controls that have larger height or width (for example, Chart). The group controls within this pattern can be used either to group fields under a label or to bind to a table field group.

Typical contents

- Groups or Fields as immediate children of the FastTab
- Groups containing Fields
- Can contain other subpatterns:
  - Horizontal fields and button group

Wireframe



Pattern changes

Here are the main changes to this pattern since Microsoft Dynamics AX 2012:

- Removed explicit columns and the use of groups to force fields into two or three (or more) columns.
- Changed from fixed columns to dynamic columns.

Model

High-level structure

- [Container] (Columns=Fill)
  - *FieldGroups (Group) [0..N]*

    - Fields ($Field) [1..N]
    - *ActionableFields (Group) [0..N]* mimics the Horizontal Fields and Button Group subpattern
  - *Fields ($Field) [0..N]*
  - *ActionableFields (Group) [0..N]*

Core components

- Apply the FieldsAndFieldGroups subpattern to the container control.
- Address BP Warnings:
  - No additional BP checks are required beyond the AX6.3 BP that were checks carried forward.

Related patterns

- Horizontal Fields and Buttons Group

UX guidelines

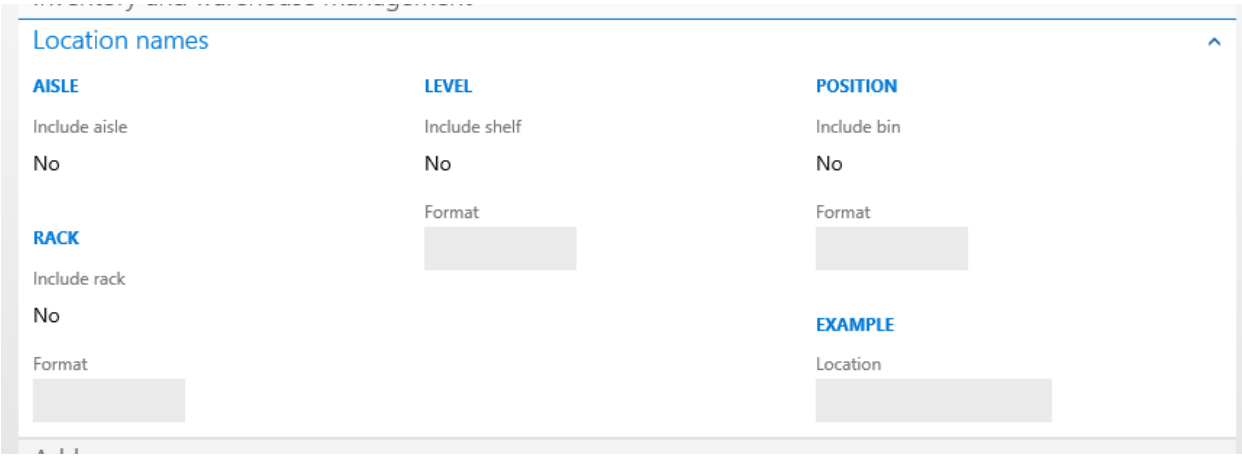
The verification checklist shows the steps for manually verifying that the form complies with UX guidelines. This checklist doesn't include any guidelines that will be enforced automatically through the development environment. Open the form in a browser, and walk through these steps.

- **Standard form guidelines:**
  - Standard form guidelines have been consolidated into the General Form Guidelines document.
- **Fields and Field Groups guidelines:**
  - The fields in groups should flow across the entire page.

  - When possible, remove unnecessary field group labels.
  - Verify that you have an understandable grouping for your fields.
  - Either all fields should be in Groups that have labels, or no Group labels should be shown.

Examples

Form: **InventLocation (LocationNames)**



Resources

Typically used by patterns

- Simple List and Details
- Table of Contents
- Details Master
- Details Transaction

Appendix

Frequently asked questions

This section will have answers to frequently asked questions that are related to this guideline/pattern.

Open issues

- Tooling must allow explicit use of the HorizontalFieldsButtonsGroup subpattern instead of mimicking content in the pattern definition.

InventLocation

Filters and Toolbar subpatterns

2/18/2021 • 3 minutes to read • Edit Online

This topic provides information about the Filters and Toolbar subpatterns. These workspace-specific subpatterns have been developed to show filters and/or actions inside panorama sections that host lists and charts.

Usage

The Filters and Toolbar subpatterns are workspace-specific subpatterns that have been developed to show filters and/or actions inside panorama sections that host lists and charts. Fields in the filtering parts of these subpatterns should be limited to the following field types. All these field types have constrained inputs and can be applied to the query.

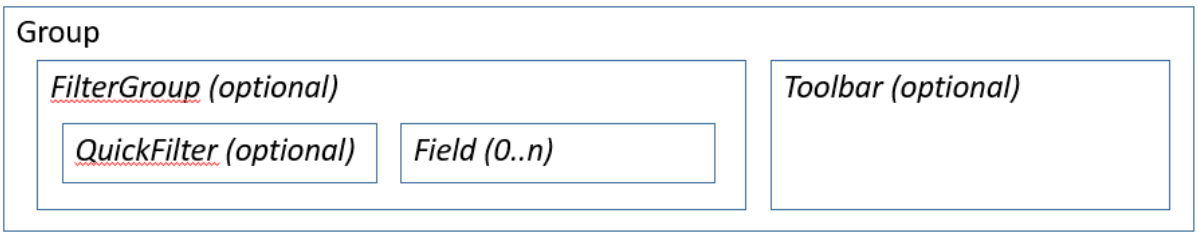
- StringEdits with Lookups
- Date fields
- ReferenceGroup
- Comboboxes
- Checkboxes
- Quick Filter

Two subpatterns are described in this article:

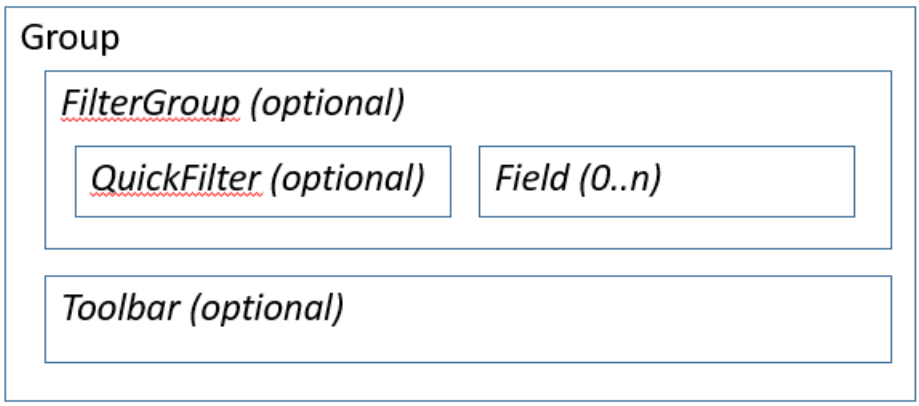
- **Filters and Toolbar - Inline** – In this subpattern, any defined actions appear on the same line as the filter fields.
- **Filters and Toolbar - Stacked** – In this subpattern, any defined actions appear on a separate line below the filter fields.

Wireframe

Filters and Toolbar - Inline



Filters and Toolbar - Stacked



Model

Filters and Toolbar - Inline: High-level structure

- Group (ArrangeMethod=HorizontalLeft)
  - *FilterGroup (Group) [Optional]*
    - *QuickFilter (QuickFilter) [Optional]*
    - *FilterFields ($Field) [0..N]*
  - *Toolbar (ActionPane) [Optional]*

Filters and Toolbar - Stacked: High-level structure

- Group (ArrangeMethod=Vertical)
  - *FilterGroup (Group) [Optional]*
    - *QuickFilter (QuickFilter) [Optional]*
    - *FilterField1 ($Field) [Optional]*
    - *FilterField2 ($Field) [Optional]*
  - *Toolbar (ActionPane) [Optional]*

Core components

Apply the correct Filters and Toolbar subpattern to the container control.

Related container patterns

- Form Part Section List
- Section Chart

UX guidelines

The verification checklist shows the steps for manually verifying that the form complies with UX guidelines. This checklist doesn't include any guidelines that will be enforced automatically through the development environment. Open the form in the browser, and walk through these steps.

- Filters and Toolbar guidelines
  - The **Stacked** variant should be used over narrow lists and charts.
  - The **Inline** variant should be used over wider lists and charts.
- Filters
  - No more than two filter fields should be used in a Filter group. If you require more than two filter fields, an action on the Toolbar can be used to open a Drop Dialog that has more filter fields.
  - The filter fields should not have labels. The context should be obvious from the field value.

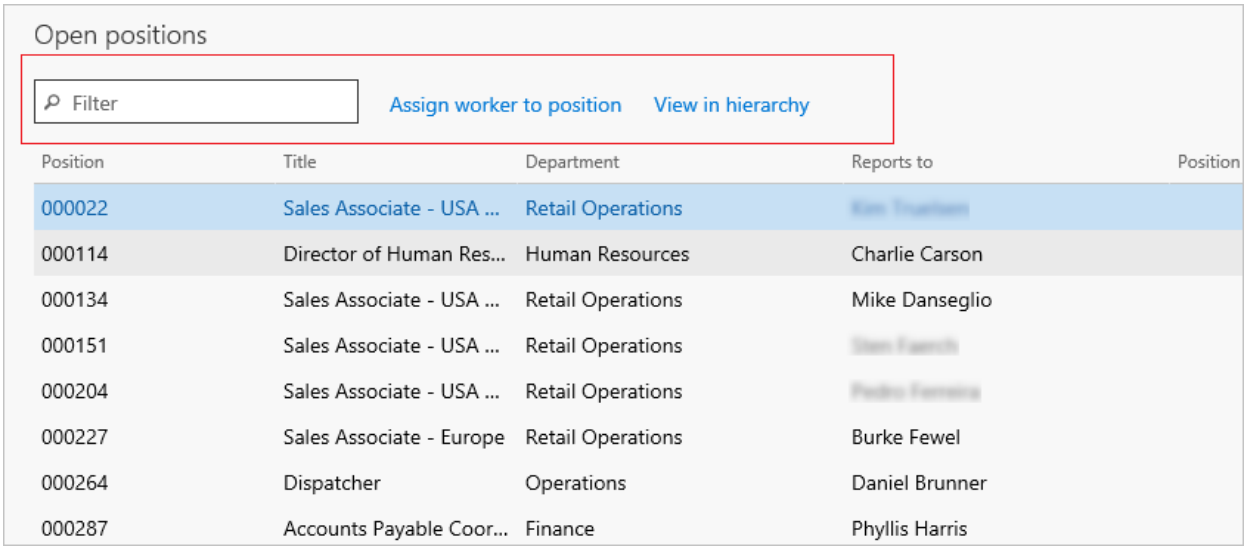
- The combined width of filter fields should not cause the section to become larger than the grid or chart in the section, and should not cause an extra scrollbar on the filters.

- Actions
  - Include only frequently used commands that help users complete tasks in the workspace.
  - No more than three actions should appear on the Toolbar. One action on the Toolbar can be used as a drop-down list of up to three additional actions.

Examples

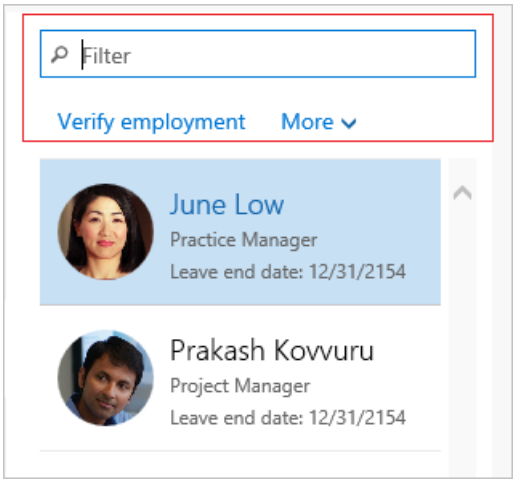
Filters and Toolbar - Inline

Form: **HcmWorkforceManagement** > **HcmOpenPositionsPart** (**All workspaces** > **Workforce management**)



Filters and Toolbar - Stacked

Form: **HcmWorkforceManagement** > **HcmWorkerOnLeaveListPart** (**All workspaces** > **Workforce management**)



Appendix

Frequently asked questions

This section will have answers to frequently asked questions that are related to this guideline/pattern.

Open issues

Why does the Inline variant allow for an arbitrary number of filter fields, but the Stacked variant allows a maximum of three (a QuickFilter and two custom filters)?

Two factors contribute to this discrepancy:

- A UX guideline specifies a maximum of two filters in these sections (and one of those filters could be a QuickFilter). Therefore, the Stacked variant more closely complies with the guideline.
- The number of fields in the Stacked variant is limited for aesthetic reasons. The filter fields in this variant are intended to take up the full width of the list/chart that appears below them, and their width is therefore **SizeToAvailable**. When this variant is used above narrow lists, as it's intended to be used, that setting can cause very narrow filter fields when more than two filter fields are used. The Inline variant is intended to be used above wider charts/lists. Therefore, the original pattern definition allowed for an arbitrary number of fields. Nevertheless, we do plan to address this discrepancy in the number of allowed filter fields between the two variations in the future.

Fill Text subpattern

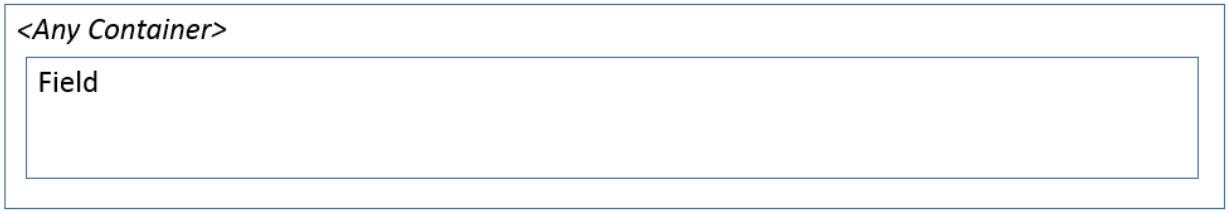
2/18/2021 • 2 minutes to read • Edit Online

This article provides information about the Fill Text subpattern. This subpattern is used when a single String or StaticText control must stretch to the full width of the container, so that users have more space to enter information.

Usage

Fill Text is used when you need a single String or StaticText control to stretch to the full width of the container. This subpattern is typically used for multi-line string controls that require more space for users to enter information.

Wireframe



Model

High-level structure

[Container]

String | StaticText

Core components

- Apply the Fill Text subpattern to the container control.

Related container patterns

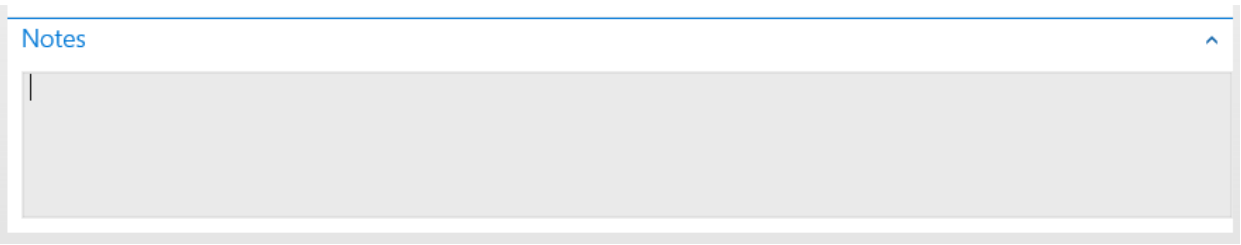
- Fields and Field Groups

UX guidelines

None

Examples

Form: **FmRental (Notes)**



Resources

Typically used by patterns

- Details Master
- Details Transaction
- Simple Details
- Simple List and Details
- Table Of Contents
- Wizard

Appendix

Frequently asked questions

This section will have answers to frequently asked questions that are related to this guideline/pattern.

Open issues

- The pattern currently sets the **HeightMode** property of the control to **SizeToAvailable**. This can produce very tall string controls if the pattern is used in a **SizeToAvailable** container. We're investigating whether this control should use **SizeToContent** height, or whether it should not set the property at all and should instead let the developer decide the appropriate control height.

Horizontal Fields and Buttons Group subpattern

2/18/2021 • 2 minutes to read • Edit Online

This article provides information about the Horizontal Fields and Buttons Group form subpattern. This subpattern is used when actions must be defined for an individual field on a form.

Usage

This subpattern is used when actions must be defined for an individual field on a form. The buttons are laid out just to the right of the field to visually associate the actions with the field. The buttons should display only an icon (no text). Actions that are associated with a section or an entire form should be placed in a Toolbar or ActionPane above that section or form.

Typical contents

- 1–2 fields
- 1–3 buttons

Wireframe

Pattern changes

Here are the main changes to this pattern since Microsoft Dynamics AX 2012:

- The layout of fields and buttons will use a single column, where **ArrangeMethod=HorizontalLeft**.

Model

High-level structure

- Group (ArrangeMethod=HorizontalLeft)
  - Field
  - *Field (optional)*
  - Buttons (1–3 buttons)

Core components

- Apply the HorizontalFieldsButtonsGroup subpattern to the container control.
- Address BP Warnings:
  - There should be no more than three buttons.
  - No additional BP checks are required beyond the AX6.3 BP checks that were carried forward.

Related patterns

- Toolbar and Fields
- Horizontal Fields

UX guidelines

The verification checklist shows the steps for manually verifying that the form complies with UX guidelines. This checklist doesn't include any guidelines that will be enforced automatically through the development environment. Open the form in a browser, and walk through these steps.

- **Standard form guidelines:**
  - Standard form guidelines have been consolidated into the General Form Guidelines document.
- **Horizontal Fields and Buttons Group guidelines:**
  - The width of the fields + buttons should not exceed the standard size of a column.
  - Buttons should have a symbol image assigned.
  - Buttons should have tooltips.
  - There should be a maximum of three buttons. The last button can be a menu button.

Examples

Form: **SalesTable (GroupHeaderAddressHeaderOverview)**

The survey will take about seven minutes. No personal data is collected (privacy statement).

Image Preview subpattern

2/18/2021 • 2 minutes to read • Edit Online

This article provides information about the Image Preview form subpattern. This subpattern can be used for most images that appear within a form container, especially within a FastTab or Group.

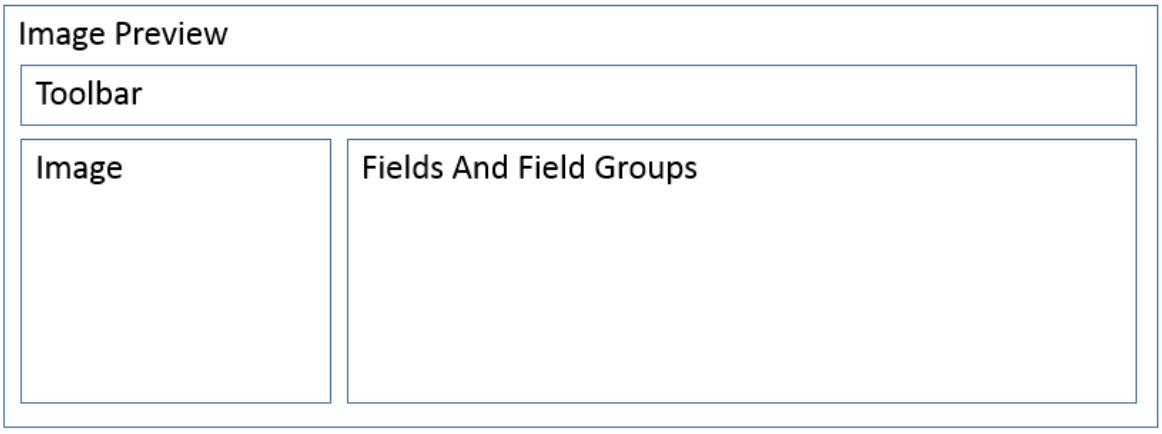
Usage

Image Preview can be used for most images that appear within a form container, especially within a FastTab or Group. This subpattern can be used in conjunction with the FieldsAndFieldGroup and FillText subpatterns to combine images and any associated fields. This subpattern isn't used for tiles or buttons, or for field status images.

Typical contents

- Toolbar (ActionPane where **Style**=**Strip**)
- Image
- Can contain subpatterns:
  - Fields and Field Groups
  - Fill text

Wireframe



Pattern changes

Here are the main changes to this pattern since Microsoft Dynamics AX 2012:

- Fields are to the right of the image, if there are any fields.
- An ActionPane above the image can be used for associated actions (for example, Upload and Select).

Model

Image only – High-level structure

- [Container] (Columns = Fixed – 1)
  - *Toolbar (ActionPane) [Optional]*
  - Image

Image and fields – High-level structure

- [Container] (Columns = Fixed – 1)
  - *Toolbar (ActionPane) [Optional]*
  - Image
  - Group
    - Image
    - Group - Note: uses a fields subpattern

Core components

- Apply the Image Preview subpattern to the container control.
- Address BP Warnings:
  - No additional BP checks are required beyond the AX6.3 BP checks that were carried forward.

Related container patterns

- Fields and Field Groups
- Fill Text

UX guidelines

The verification checklist shows the steps for manually verifying that the form complies with the UX guidelines. This checklist doesn't include any guidelines that will be enforced automatically through the development environment. Open the form in a browser, and walk through these steps.

- **Image Preview guidelines:**
  - Any fields should be placed to the right of the image.

List Panel subpattern

2/18/2021 • 2 minutes to read • Edit Online

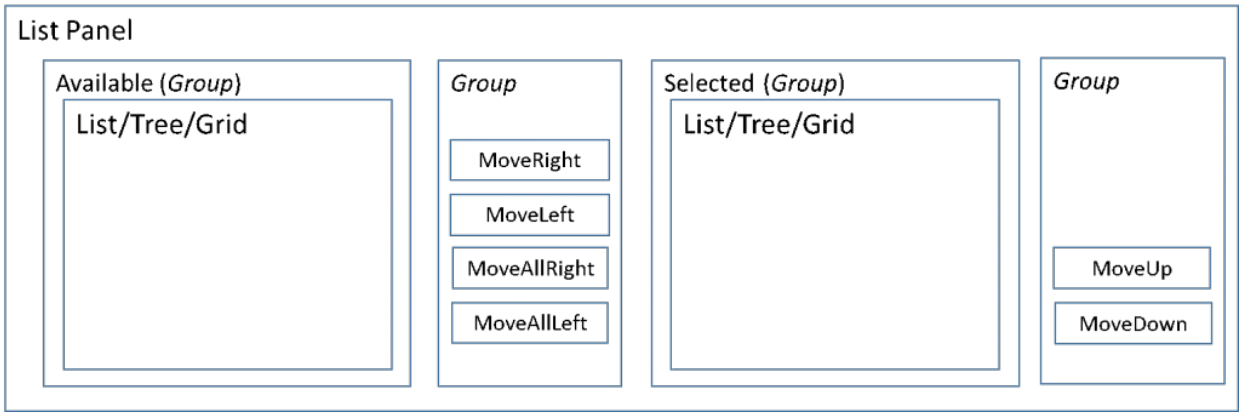
This article provides information about the List Panel form subpattern. Application teams use this subpattern to manage two lists that move data between each other.

Usage

List Panel is the subpattern that application teams use to manage two lists that move data between each other. This pattern is meant to represent a modeled version of the **SysListPanel** class (programmatic) approach of managing two lists that move data between each other. The List Panel subpattern can be applied on the following controls:

- TabPage control
- Group control

Wireframe



Pattern changes

Here are the main changes to this pattern since Microsoft Dynamics AX 2012:

- List (Grid/ListView) and Tree controls are supported.
- The right panel is the selected section.
- The left panel is the available section.
- Six buttons are available as actions:
  - Add
  - Remove
  - Add All (Optional)
  - Remove All (Optional)
  - Move Up (Optional)
  - Move Down (Optional)

Model

High-level structure

- [Container]

- *CustomFilterGroup (Group) [Optional]*
- ListPanelGroup (Group)
  - AvailablePanel (Group)
    - Grid | Tree | ListView | ListBox
  - ActionPanel (Group)
    - AddButton (Button)
    - RemoveButton (Button)
    - *AllAllButton (Button) [Optional]*
    - *RemoveAllButton (Button) [Optional]*
  - SelectedPanel (Group)
    - Grid | Tree | ListView | ListBox*
  - *MoveUpDownPanel [Optional]*
    - MoveUpButton (Button)
    - MoveDownButton (Button)

Core components

- Apply the ListPanel subpattern to the container (TabPage or Group) control.
- Address BP Warnings:
  - No additional BP checks are required beyond the AX6.3 BP checks that were carried forward.

UX guidelines

The verification checklist shows the steps for manually verifying that the form complies with UX guidelines. This checklist doesn't include any guidelines that will be enforced automatically through the development environment. Open the form in a browser, and walk through these steps.

- **Standard form guidelines:**
  - Standard form guidelines have been consolidated into the General Form Guidelines document.

Nested Simple List and Details subpattern

2/18/2021 • 3 minutes to read • Edit Online

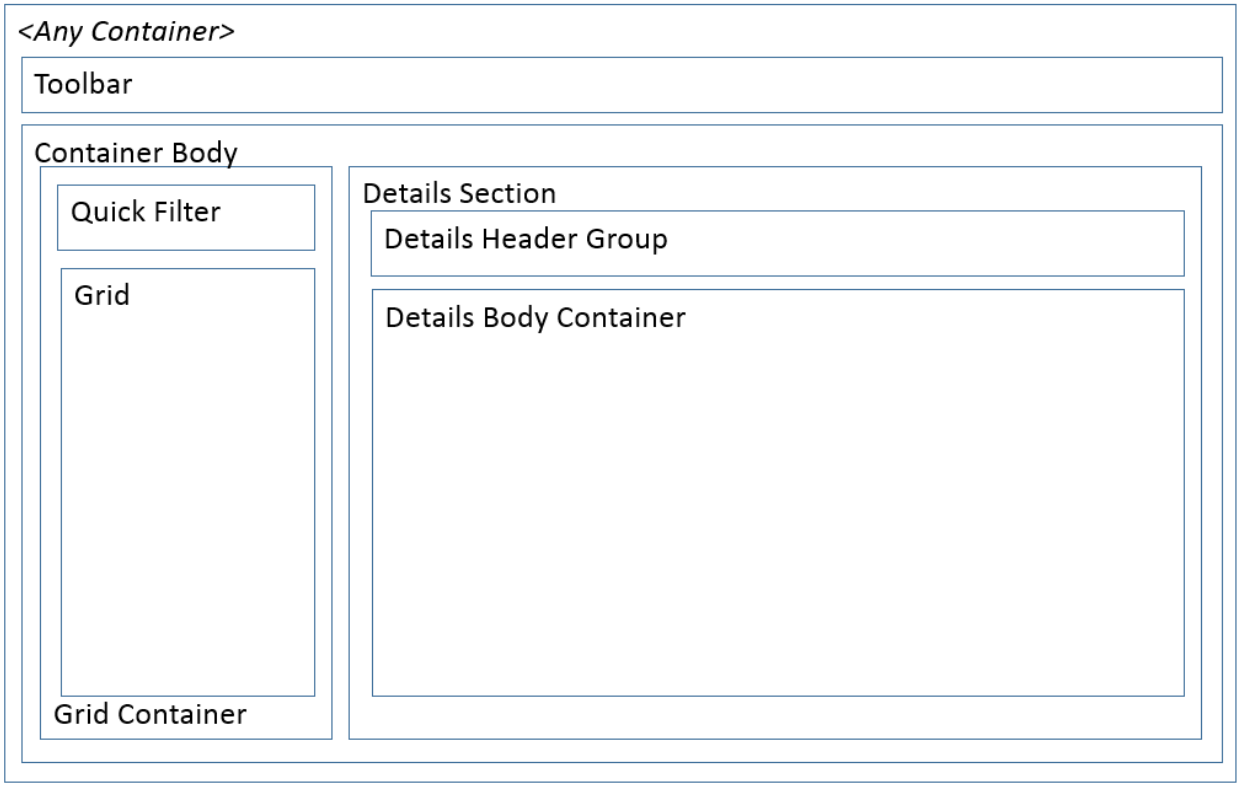
This topic provides information about the Nested Simple List and Details (NSL+D) subpattern. This subpattern is used to display information about a secondary or child entity when that child entity is presented within another form type.

Usage

This article describes a variant of the Simple List and Details (SL+D) pattern that is named the Nested Simple List and Details (NSL+D) subpattern. Whereas the SL&D form pattern is used to display information about the primary entity on the form, the NSL+D subpattern is used to display information about a secondary or child entity when that child entity is presented within another form type. The amount of information that is related to the child entity should be too much for a grid (10 or more fields) but not enough for the child entity to deserve its own form. The NSL+D subpattern has a few differences from the SL+D form pattern:

- You may not nest an NSL+D subpattern within another NSL+D subpattern.
- The NSL+D subpattern uses a Toolbar for contextual actions.
- The details portion of the NSL+D subpattern is simpler than the SL+D pattern. The NSL+D subpattern uses only groups, whereas the SL+D pattern organizes content into FastTabs.

Wireframe



Pattern changes

Here are the main changes to this pattern since Microsoft Dynamics AX 2012:

- This pattern is new. Any pattern changes to the SL+D pattern can be found in the Simple List and Details pattern document.

Model

High-level structure

- <Container>
  - ActionPane (ActionPane Style=Strip)
  - ContainerBody (Group Columns=2)
    - ListContainer (Group)
      - Grid | Tree | ListView
    - DetailsContainer (Group)
      - DetailsHeader (Group)
      - *DetailsGroup (Group) [Optional]*

Core components

1. Apply the NestedSimpleListDetails subpattern to the container control.
2. Resolve the required BP checks:
   a. Set **Grid.Datasource=<secondary data source>**.
   b. Set grid data source **InsertIfEmpty=No**.
   c. Set **ActionPane.DataSource=<same data source as grid>**.
   d. Set Toolbar Command Add properties.
   e. Set Toolbar Command Remove properties.
   f. If the grid data source is read-only, make sure that there are no **Add/Remove** buttons on the Toolbar.

UX guidelines

The verification checklist shows the steps for manually verifying that the form complies with the UX guidelines. This checklist doesn't include any guidelines that will be enforced automatically through the development environment. Open the form in a browser, and walk through these steps.

Standard form guidelines

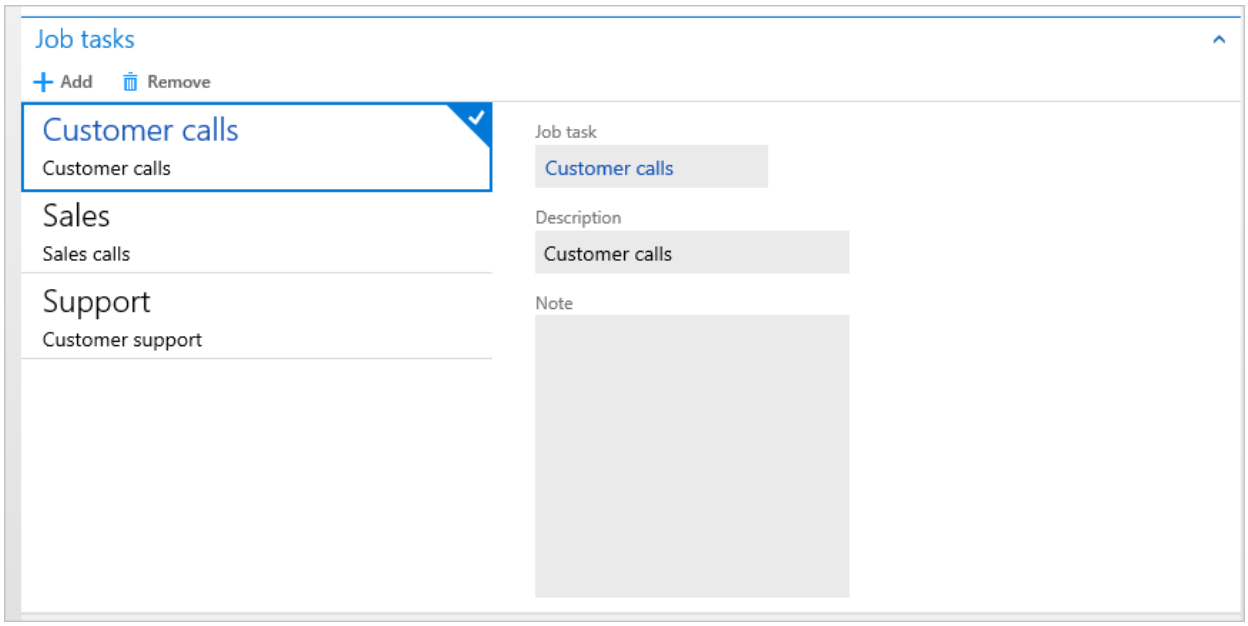
- Standard form guidelines have been consolidated into the General Form Guidelines document.

Nested simple list & detail guidelines

- There should not be duplicate **New** or **Delete** buttons.
- If a **grid** is used for the list portion of the pattern:
  - The grid should be a **list-style** grid.
  - List-style grids should display no more than three rows (lines) for each record in the List style grid. Typically, just the ID and Description are sufficient.
  - When there is no data, the grid control should not automatically add a new record.
- A **details** section that is displayed on the right of the Container Body:
  - Display the grid columns as the first fields in the Details Header Group, in the same order that they are displayed in the grid.
  - When a record is added, focus should go to the first field in the details section.

Examples

Form: **HcmJob** (**TaskTabPage**)



Resources

Typically used by patterns

- Simple List and Details
- Table of Contents
- Details Master
- Details Transaction

Appendix

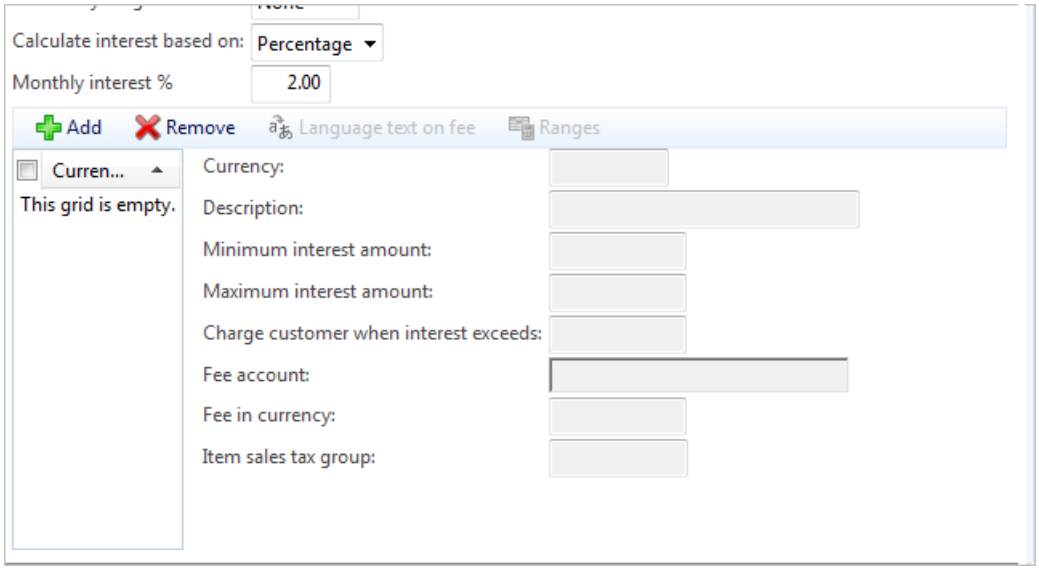
Frequently asked questions

This section will have answers to frequently asked questions that are related to this guideline/pattern.

Open issues

- **The details area of the nested pattern should not have FastTabs. The framework should verify/enforce this.**
  - Currently we aren't allowing tabs of any kind inside this pattern.

AX 2012 content



NOTE

Can you tell us about your documentation language preferences? Take a short survey.

The survey will take about seven minutes. No personal data is collected (privacy statement).

Section Chart form pattern

2/18/2021 • 2 minutes to read • Edit Online

This topic provides information about the Section Chart form pattern. This pattern is primarily used in conjunction with the Operational Workspace pattern, and specifically on forms that contain a chart control.

Usage

The Section Chart form pattern is intended to be used primarily in conjunction with the Operational Workspace pattern. Specifically, the chart section or summary section contains Form Part Controls that point to forms that contain charts. These referenced forms are intended to use the Section Chart pattern.

Tabular Fields subpattern

2/18/2021 • 2 minutes to read • Edit Online

This article provides information about the Tabular Fields subpattern. This subpattern is used to show information efficiently in a tabular format.

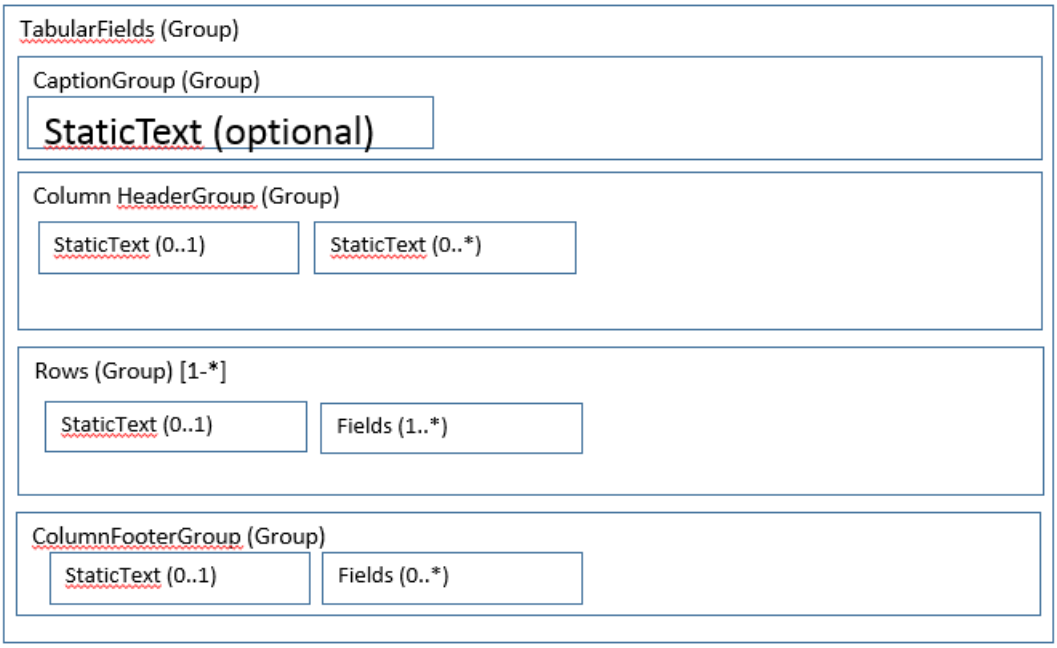
Usage

This subpattern is used to show information efficiently in a tabular format. The fields are arranged in a table that contains rows and columns, and that optionally contains column headers, row labels, a caption, and a footer. The Tabular Fields subpattern can be applied on the following controls:

- TabPage control
- Group control

Wireframes

Structural wireframe



Pattern changes

In previous releases of Microsoft Dynamics AX, there was no formally accepted way to model this pattern. Therefore, this pattern was modeled in many inconsistent ways that must be modified to match the current pattern. The most common way to model this pattern was to use groups for columns. However, groups are now used for the rows. The primary reason for this change was to better match the HTML/CSS constructs, and it also helps keep the tab sequence and semantics of a table.

Model

High-level structure

- TabularFields (Group*)
  - CaptionGroup (Group)
    - *TableCaption (StaticText) [Optional]*
  - TableHeaderRow (Group)
    - *Column0Label (StaticText) [Optional]* – **Note:** This static text fills col0, row0 with a blank.
    - ColumnLabels (StaticText) [1..N] – **Note:** These are the normal column headers.
  - TableRows (Group) [1..N]
    - *RowLabel (StaticText) [Optional]*
    - RowValues ($Field) [1..N] OR SecondaryColumnLabel (StaticText) [1..N]
  - TableFooterGroup (Group)
    - *Column0Label (StaticText) [Optional]* – **Note:** This static text fills col0, footer with a blank.
    - *RowValues ($Field) [0..N]* – **Note:** All the footer fields are in view mode.

Note that the four groups in the top-level tabular fields are mandatory structural elements. However, the contents of all those groups exception the Rows (Group) are optional. Additionally, note that Tabular Fields can also be used on a TabPage control. The structure is the same as the structure that is shown here.

Core components

Apply the Tabular Fields pattern on the top-level group or tab page. Address the pattern errors and problems.

UX guidelines

No manual verification is required.

Examples

Form: **LedgerJournalTransVendPaym (Balances)** (**Accounts payable** > **Journals** > **Payment journal** > **Lines**)

	DEBIT	CREDIT	DIFFERENCE
VOUCHER	0.00	0.00	0.00
JOURNAL	0.00	0.00	0.00

Toolbar and List subpattern

2/18/2021 • 2 minutes to read • Edit Online

This article provides information about the Toolbar and List form subpattern. This subpattern is used to show child collections for the parent entity as either a tabular grid or a tree.

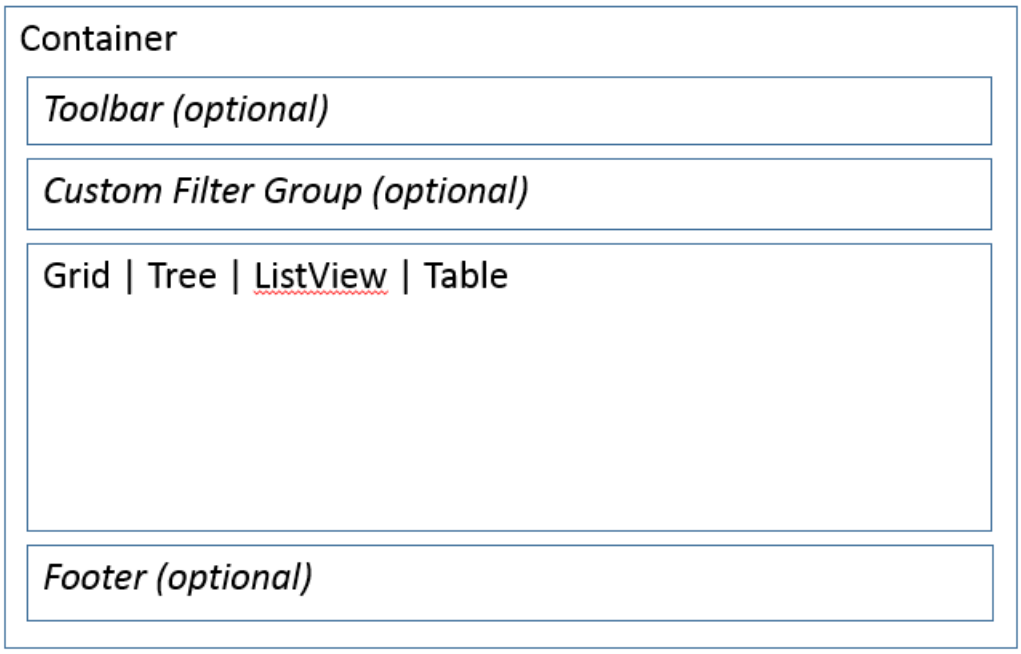
Usage

This subpattern is used to show child collections for the parent entity as either a tabular grid or a tree. The toolbar contains fewer than 10 actions. If a grid is used, it contains fewer than 10 fields. This article describes two patterns:

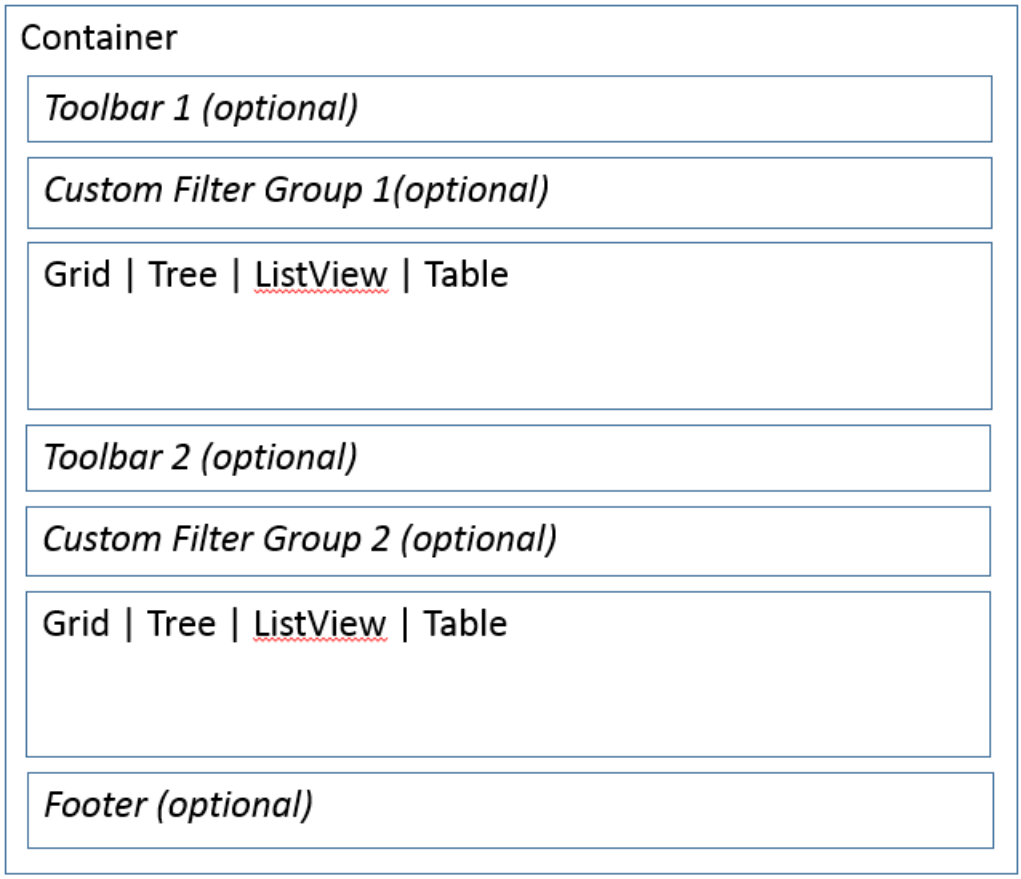
- **Toolbar and list** – This is the basic version of the pattern and should be used by default.
- **Toolbar and list (double)** – This variant includes two lists and an optional toolbar above each list.

Wireframes

Toolbar and list



Toolbar and list (double)



Model

Toolbar and list – High-level structure

- [Container]
  - *Toolbar (ActionPane, Style=Strip) [Optional]*
  - *CustomFilterGroup (Group) [Optional]*
  - Grid | Tree | ListView | Table
  - *Footer (Group) [Optional]*

Toolbar and list (double) – High-level structure

- [Container]
  - *Toolbar1 (ActionPane, Style=Strip) [Optional]*
  - *CustomFilterGroup1 (Group) [Optional]*
  - Grid | Tree | ListView | Table
  - *Toolbar2 (ActionPane, Style=Strip) [Optional]*
  - *CustomFilterGroup2 (Group) [Optional]*
  - Grid | Tree | ListView | Table
  - *Footer (Group) [Optional]*

Core components

- Apply the ToolbarList subpattern to a container control.
- Address BP Warnings:
  - **Grid.DataSource** must not be empty.
  - No additional BP checks are required beyond the AX6.3 BP checks that were carried forward.

Related patterns

- Toolbar and Fields

UX guidelines

The verification checklist shows the steps for manually verifying that the form complies with UX guidelines. This checklist doesn't include any guidelines that will be enforced automatically through the development environment. Open the form in the browser, and walk through these steps.

Workspace Page Filter Group subpattern

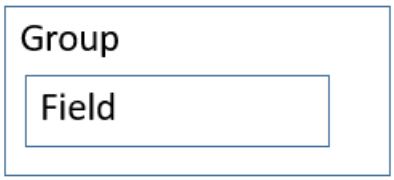
2/18/2021 • 2 minutes to read • Edit Online

This article provides information about the Workspace Page Filter Group subpattern. This subpattern is used as part of the Operational Workspace pattern when a workspace must expose a single workspace-wide filter on the form.

Usage

The Workspace Page Filter Group subpattern is used as part of the Operational Workspace pattern, specifically when a workspace must expose a single workspace-wide filter on the form.

Wireframe



Pattern changes for Microsoft Dynamics AX

This pattern didn't exist in Microsoft Dynamics AX 2012.

Model

High-level structure

- Group
  - Field ($Field)

Core components

Apply Workspace Page Filter Group to the appropriate group in an (operational) workspace.

Related container patterns

- Custom Filter Group
- Operational workspace

UX guidelines

The verification checklist shows the steps for manually verifying that the form complies with UX guidelines. This checklist doesn't include any guidelines that will be enforced automatically through the development environment. Open the form in the browser, and walk through these steps.

- The filter field should have a drop-down that contains the list of available values.
- The expectation is that the filter field will be modified multiple times per day by the target user. If the filter field is modified less often or is primarily static, it should be put in a configuration dialog.
- If more filter fields are needed, they should be put in a configuration dialog (up to five filter fields).

Examples

Form: **ReqCreatePlanWorkspace** (**All workspaces** > **Master Planning**)

Build extensible controls

2/18/2021 • 22 minutes to read • Edit Online

This topic describes how to create new application controls that have a property sheet in Visual Studio and have server-side business logic.

Prerequisites

For this tutorial, you must access the environment by using Remote Desktop, and you must be provisioned as an administrator on the instance. For more information, see Deploy and access development environments.

Overview

The Control Extensibility Framework lets you create new application controls. You can use the same tools that Microsoft uses to build controls that are already present in the program, such as the chart control. Three important artifacts are involved in the process of developing an extensible control:

- **The X++ build class** – The build class lets a developer define the properties that appear in the Microsoft Visual Studio property sheet for the control. The developer can also define the modeling behavior for the control when it's used in the form designer. The build class is consumed by the run-time class to initialize the state of the control based on the value of properties in the property sheet.
- **The X++ run-time class** – The run-time class lets a developer define server-side business logic and data access patterns for an extensible control. Two concepts that are specific to building extensible controls are the *properties* and *commands* that the X++ class defines. Each property and command that is defined is serialized into a JavaScript view model at run time, and can be consumed by the client parts of the extensible control (the HTML and JavaScript). These properties and commands are the main channels for moving information between the server-side and client-side parts of the control.
- **The control HTML and JavaScript** – Each control uses HTML, JavaScript, and CSS files to define control visualization and client-side interaction patterns. By using the Microsoft Dynamics HTML binding syntax together with jQuery, a developer can consume the properties and commands that are defined in X++ to design powerful data-driven UI.

All three artifacts of extensible control development are explained in more detail in the following sections.

Key concepts

- Defining an extensible control's design-time behavior
- Defining an extensible control's run-time behavior
- Defining an extensible control's view by using HTML and CSS
- Defining an extensible control's view model by using JavaScript

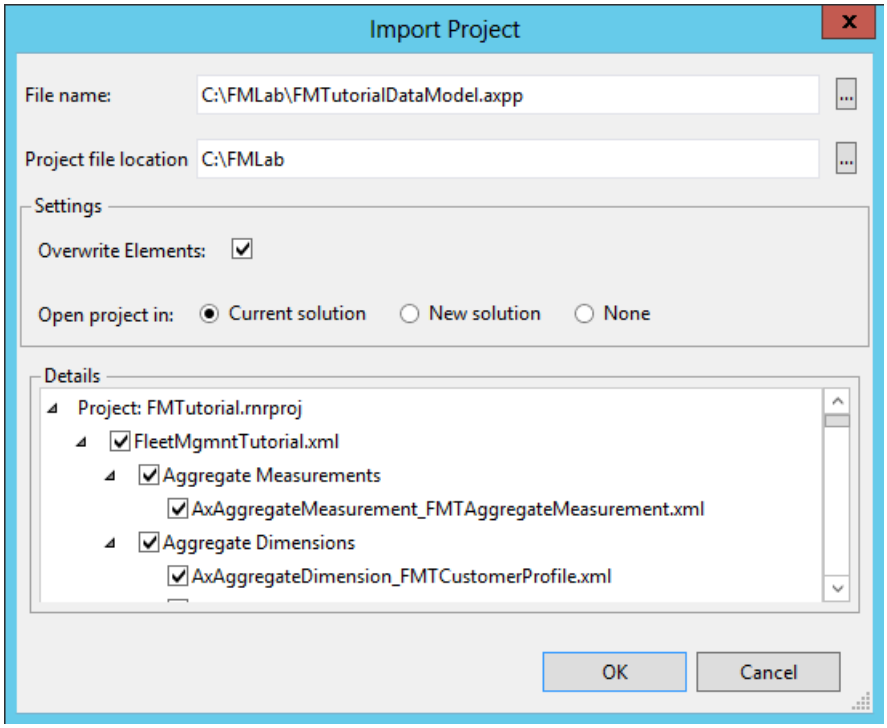
Setup

Import the tutorial project and transactional data

Use Visual Studio to import the tutorial project. The tutorial project includes the artifacts that you will use to complete this tutorial. Use Visual Studio to open the FMTutorial project and load the data for the tutorial. You will use the **FMTDataHelper** class to load data for the Fleet Management tutorial.

1. Download the Fleet Management sample from https://github.com/Microsoft/FMLab, save it to **C:**, and unzip it.

2. On the desktop, double-click the Visual Studio shortcut to open the development environment.
3. On the **Dynamics 365 **menu, click **Import Project**.
4. In the **Import Project** dialog box, next to the **File name** text box, click the ellipsis button (...).
5. In the **Select the file to import** dialog box, browse to **C:\FMLab**, click **FMTutorialDataModel.axpp**, and then click **Open**.
6. In the **Project file location** field, enter **C:\FMLab**.
7. Select the **Overwrite Elements** check box and the **Current solution** option. The following screen shot shows the completed **Import Project** dialog box.



8. Click **OK**.
9. In Solution Explorer, under the **FMTutorial** project, expand **Classes**.
10. Right-click **FMTDataHelper**, and then click **Set as Startup Object**.
11. On the **BUILD** menu, click **Rebuild Solution**. You use the rebuild to make sure that all the files in the project are built, regardless of timestamps. You can view the build progress in the **Output** window.
12. After the build is completed, press Ctrl+F5 to run the project. The **Login** form closes when authentication succeeds, and then the data is loaded.

Set up aggregate data

Use FMTAggregateMeasurements to populate the Microsoft SQL Server Analysis Services database with aggregate data.

> **NOTE**
> These steps must be completed immediately after you use the **FMTDataHelper** class to import data. You may **NOT** need to do these steps if the aggregate measure is "InMemoryRealTime", depending on what tutorial files you have.

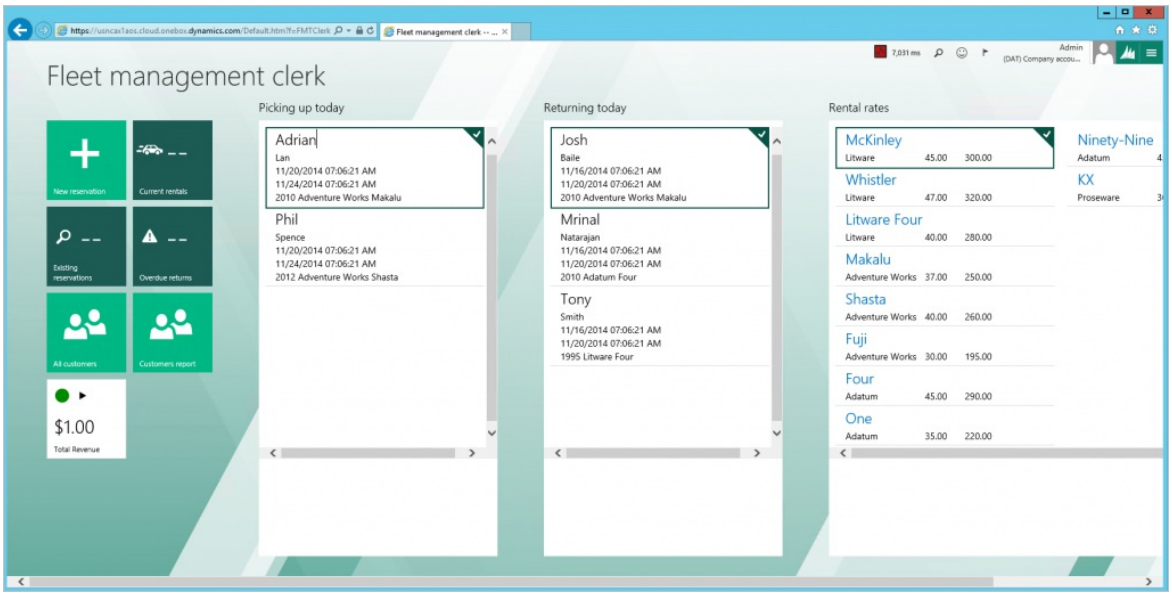
1. In Solution Explorer, under **Analytics**, double-click **FMTAggregateMeasurement**.
2. In the designer, right-click **FMTAggregateMeasurement**, and then click **Deploy and Process**.

Preview the clerk workspace

Before you begin to build the contact control, look at the appearance of the current implementation. In the following sections, you will use the Control Extensibility Framework to enrich the visualization of the controls and the form.

1. In Solution Explorer, expand **Forms**, right-click **FMTClerkWorkspace**, and then click **Set as Startup Object**.

2. Press Ctrl+F5 to open the **Fleet management clerk** page in Internet Explorer. As the following screen shot shows, the data on this page appears as a simple grid in a list style that contains several string and date controls.



3. Exit Internet Explorer.

Modify the build class for the contact control

To save time, you will work on a partially completed extensible control that is named the contact control. You will extend the contact control to complete its design, run-time, and visualization behaviors. The partially completed contact control already supports multiple title fields, subfields, and action buttons. However, it doesn't currently support an image. To add image support, you must extend the design experience for the contact control. You will add a data field that can specify image data.

Technical overview

To see an example of a build class, in Solution Explorer, expand **Classes**, right-click **FMTBuildContactControl**, and then click **View Code**. The class code appears in the code editor. **FMTBuildContactControl** is the build class for the contact control. For each extensible control, the build class defines the properties that the control shows in the property sheet. The build class also defines the modeling experience for the control in the Visual Studio form designer. There are three primary design-time behaviors that you can define for an extensible control. Each behavior is declaratively defined by using a **FormDesign** attribute. Here are the design-time behaviors that you can define:

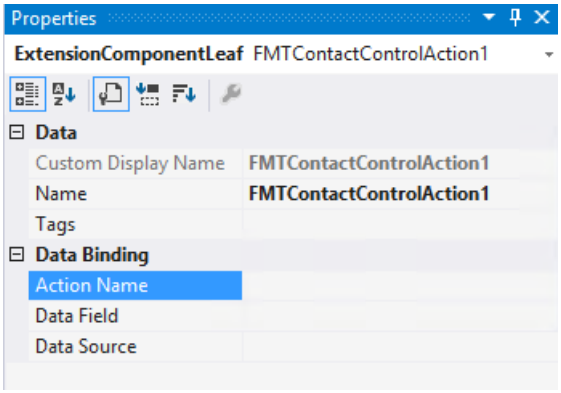
- **Name** – You can specify the control name that appears in the form designer when you add the control to a form. To specify the name, add a **FormDesignControlAttribute** attribute to the build class declaration of the extensible control. For example, the following declaration of the **FMTBuildContactControl** class shows the attribute.

```
[FormDesignControlAttribute("FMT Contact Control")]
Class FMTBuildContactControl extends FormBuildControl
```

- **Designer properties** – These are the properties that you see in the property sheet when you add the control to a form. There are several attributes that let you add various types of designer properties. For example, the **FormDesignPropertyAttribute** attribute adds a property to the property sheet, and the property name and the section are supplied as arguments to the attribute. For example, the following code adds the **Action Name** property to the **FMTContactControlAction** class.

```
[FormDesignPropertyAttribute("Action Name", "Data Binding")]
public str parmActionName (str _actionName = actionName){...}
```

The following screen shot shows how this property appears in the **Properties** pane in Visual Studio.

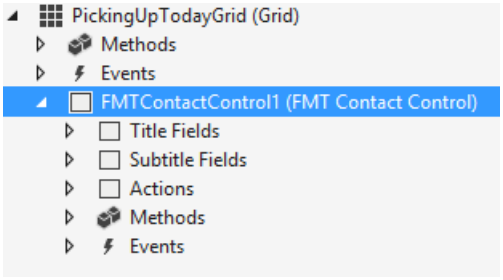


- **Child design components** – These are child nodes that you see after you add the control to a form. There are two types of child design components: leaf and leaf collection.
  - A leaf is defined by using a **FormDesignComponentAttribute** attribute on an X++ method that accepts or returns another build class. The build class determines the properties that the leaf has in the property sheet.
  - A leaf collection is defined by using a **FormDesignComponentCollectionAttribute** attribute. The allowable leaf types for the collection are defined by using **FormDesignComponentValidChildAttribute** attributes.

For example, the following code adds a leaf collection that is named **Actions** for the **FMTBuildContactControl** class.

```
[FormDesignComponentCollectionAttribute("Actions"),
FormDesignComponentValidChildAttribute(classstr(FMTContactControlAction), "Action")]
public List parmActions(List _actions = actions){...}
```

The following screen shot shows how the specified child design component appears when you add the control to a form.



Tutorial steps

1. Check that the code for the **FMTBuildContactControl** class appears in the code editor. If it doesn't, in Solution Explorer, expand **Classes**, right-click **FMTBuildContactControl**, and then click **View Code**.

2. Add a child design component to the FMTBuildContactControl class. A child design component lets a developer who places the control in a form to specify the image that appears on the control. In this step, you will add the **FormDesignComponentAttribute** attribute to create a new entry in the property sheet. You will then add the **FormDesignPropertyDataFieldAttribute** attribute, which indicates that the new designer property enables the selection of a data field.

   a. Add the highlighted code that follows to the declarations for the class. This code adds the **FormBindingDataField** field to the X++ that the **FMTBuildContactControl** class is using.

```
[FormDesignControlAttribute("FMT Contact Control")]
class FMTBuildContactControl extends FormBuildControl
{
    str dataSource;
    FormBindingDataField imageField;
    List titleFields;
    List subFields;
    List actions;
```

   b. Add the following code to the **FMTBuildContactControl** class. Add this method after the designer property for the data source.

```
[FormDesignComponentAttribute ("Image")]
public FormBindingDataField parmImageField(FormBindingDataField _imageField =
imageField)
{
    if(!prmisdefault(_imageField))
    {
        imageField = _imageField;
    }
    return imageField;
}
```

> **NOTE**
>
> The child design component will show the properties that are available on the **FormBindingDataField** build class. This is appropriate, because you want to enable image data binding to a data field and data source. This is all that is required to add a designer property to the build class of the contact control.

3. Press Ctrl+S to save your changes, and then close the code editor.

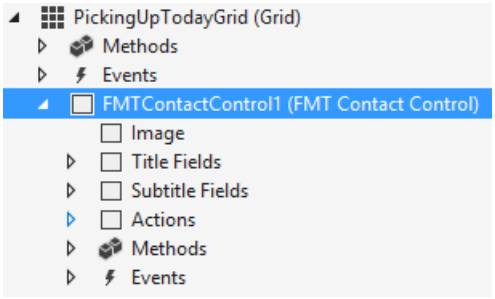
4. In Solution Explorer, right-click **FMTutorial**, and then click **Build**.

5. If the **FMTPickingUpTodayPart** form isn't already open, expand **Forms**, and then double-click

FMTPickingUpTodayPart. The form opens in the form designer.

6. In the form designer, expand **Design** > **PickingUpTodayGrid**, and then select and delete the controls that currently appear in the grid.

7. Right-click **PickingUpTodayGrid**, point to **New**, and then click **FMTContactControl**. Expand the **FMTContactControl** node, and notice that **Image** appears as a new child design component. The following illustration shows the contact control in the form designer.



You must also update the run-time class for the contact control to consume the design-time changes. You will revisit adding the control to the form and specifying data bindings and property values later.

8. Press Ctrl+S to save your changes, and then close the form designer.

Modify the runtime class for the contact control

Next, you must modify the run-time class to read the data source and data field for the image from the build class. You must also create a run-time property, so that the image data is available to the control's client HTML and JavaScript.

Technical overview

To see an example of the run-time class, in Solution Explorer, expand **Classes**, right-click **FMTContactControl**, and then click **View Code**. The class opens in the code editor. **FMTContactControl** is the run-time class for the contact control. The class defines the run-time behavior of the contact control. The run-time class typically contains X++ for data access or business logic. In addition, there are two primary run-time behaviors that are related to extensible controls that you define in the run-time class. Each behavior is declaratively defined by using an attribute.

- **Run-time properties of the control** – These properties can be of two types:
  - *Static properties*, which are set via code or initialized with values from designer properties.
  - *Bindable properties*, for which the run-time value is determined by a binding to a data source and data field combination.

  Run-time properties are declared by using **FormPropertyAttribute** attributes. The following example shows a property declaration in **FMTContactControl**.

```
[FormPropertyAttribute(FormPropertyKind::Value, "TitleFields")]
public List parmTitleFields(List _value = titleFieldsProperty.parmValue()){...}
```

  The **FormPropertyAttribute** attribute accepts two arguments:

  - The first argument indicates to the framework the kind of JavaScript view model property to create.
    - If you supply **BindableValue**, a **ReferenceProperty** is generated in the JavaScript view model. A **ReferenceProperty** updates itself when data changes in the data source.
    - If you supply **Value**, a **ValueProperty** is generated in the JavaScript view model. A developer

must write code to update the value of a **ValueProperty**.

- The second argument of the attribute sets the name for the property as it will be defined in the JavaScript view model.

> **NOTE**
>
> Don't be concerned if **TitleFields** don't seem to be bound to data because the example uses a **Value** property. The **TitleFields** property returns a List that contains **FormBindingDataFields**, each of which is data-bound. The X++ method that has the **FormPropertyAttribute** attribute is a simple getter/setter that uses a **FormProperty** as the backing field. The **FormProperty** contains the logic for updating the property, based on value or data source changes. It also serves as the backing field for the property.

- **Run-time commands for the control** – Commands enable the client parts of the control to trigger X++ logic, based on client-side user interactions. Commands are declared by using a **FormCommandAttribute** attribute. The single argument specifies the name of the command as it will appear in the JavaScript view model. The following example shows a command declaration in **FMTContactControl**.

```
[FormCommandAttribute("ExecuteAction")]
public void executeAction(str _actionName){...}
```

Tutorial steps

1. Verify that the **FMTContactControl** class is open in the code editor. If it isn't, in Solution Explorer, expand **Classes**, right-click **FMTContactControl**, and then click **View Code**.

2. Add a run-time property for the image data to **FMTContactControl**. In the **FMTContactControl** class, declare a **FormProperty** that is named **imageFieldProperty**, as shown by the highlighted line in the following example.

```
[FormControlAttribute(...)]
class FMTContactControl extends FormTemplateControl
{
    FormProperty dataSourceProperty;
    FormProperty imageFieldProperty;
    FormProperty titleFieldsProperty;
    FormProperty subtitleFieldsProperty;
    FormProperty actionsProperty;
```

3. Add the following X++ method after the **parmDataSource** X++ method. The new method will serve as the getter/setter for **imageFieldProperty**.

> **NOTE**
>
> You don't return the value of the image data here, because the framework will let you bind to the data in the client, as you will see later.

```
        [FormPropertyAttribute(FormPropertyKind::BindableValue, "ImageField")]
        public str parmImageField(anytype _value = imageFieldProperty.parmValue())
        {
            if(!prmisdefault(_value))
            {
                imageFieldProperty.setValueOrBinding(_value);
            }
            return "";
        }
```

4. Initialize **imageFieldProperty** by adding the highlighted line in the following example to the new method of **FMTContactControl**.

```
        public void new(FormBuildControl _build, FormRun _formRun)
        {
            super(_build, _formRun);

            this.setTemplateId("FMTContactControl");
            this.setResourceBundleName("/Resources/Html/FMTContactControl");

            dataSourceProperty = this.addProperty(methodstr(FMTContactControl,
parmDataSource), Types::String);
            imageFieldProperty = this.addProperty(methodstr(FMTContactControl,
parmImageField), Types::String);
            titleFieldsProperty = this.addProperty(methodstr(FMTContactControl,
parmTitleFields), Types::Class);
            subtitleFieldsProperty = this.addProperty(methodstr(FMTContactControl,
parmSubtitleFields),
               Types::Class);
            actionsProperty = this.addProperty(methodstr(FMTContactControl, parmActions),
Types::Class);
        }
```

5. Now supply the binding to **imageFieldProperty** by adding the highlighted line in the following example to the **applyBuild** method of **FMTContactControl**.

```
        ...
        if(build)
        {
            this.parmDataSource(build.parmDataSource());
            this.parmImageField(FormBindingUtil::initBinding(build.parmImageField().parmDataSou
            rce(), build.parmImageField().parmDataField(), this.formRun()));

        ...
```

6. Press Ctrl+S to save the changes. You've now finished modifying the run-time class. Next, you will update the HTML view to display the image.

Modify the HTML for the contact control

The HTML of the contact control is where you add UI elements, such as text boxes, images, and buttons, that interact with the properties and commands that are defined in the run-time class. Extensible controls use a declarative HTML-based binding syntax to bind HTML element behaviors to properties, commands, JavaScript expressions, and JavaScript functions. These bindings are parsed at run time, and the resulting HTML is injected

into the DOM. The following section explains a few of the bindings that are used in FMTContactControl.htm to add an image to the control.

Technical overview

The **bind** attribute, together with the **text** binding handler enables binding to the **text** property of an HTML element. For example, the following HTML uses the **bind** attribute and the **text** binding handler.

```
<span data-dyn-bind="text:'Hello World!'"></span>
```

The preceding HTML is equivalent to the following HTML.

```
<span>Hello World!</span>
```

You will see the benefits of the binding when you bind to properties or commands. For example, if you have a view model property that is named **FirstName**, you can bind to it as shown in the following example. Here, **$data** is the object that contains the view model properties and commands.

```
<span data-dyn-bind="text: $data.FirstName"></span>
```

The HTML output changes, based on the current value of **FirstName**. The following example shows the output if **FirstName** has a value of **John**.

```
<span>John</span>
```

If the value of the **FirstName** property changes for some reason (for example, X++ or JavaScript was run to update the property), the binding is automatically reevaluated, and the HTML output immediately reflects the change. All binding handlers follow this pattern of automatic reevaluation when the binding value changes. The **if** and **foreach** binding handlers are unique in that they perform DOM manipulation based on the binding values.

- To conditionally add an element to the DOM, use the **if** binding handler and supply the condition under which the element should be added. If the condition is false, the element isn't added to or removed from the DOM, and no bindings that are associated with the element are evaluated. Of course, if the binding value that is supplied to **if** changes, an element that was removed will be added to the DOM again, and the bindings will be evaluated.
- To iterate over an array of elements, use the **foreach** binding. This is useful when nearly identical HTML elements must be displayed.

The following table shows some of the other binding handlers.

BINDING HANDLER	DESCRIPTION
css	Specify a CSS class, based on a condition.

BINDING HANDLER	DESCRIPTION
style	Apply CSS styles, and bind the values to properties.
attr	Bind an HTML attribute.

In addition to using HTML elements inside the HTML for your control, you can also add framework controls such as CheckBox, Group, Tile, SectionContainer, Label, and List to your control. Instead of binding handlers, each framework control enables binding values to be passed to its view model properties. For example, a **CommandButton** is added by using the **role** attribute.

```
    <div data-dyn-role="CommandButton" ></div>
```

In this case, **ActionCommand** can be supplied with a JavaScript function.

```
    <div data-dyn-role="CommandButton"
         data-dyn-bind="ActionCommand: function(){alert('Hello World!')}"></div>
```

One additional feature of the HTML binding syntax is the context-aware nature of bindings. By default, the context of all HTML elements is set to the JavaScript view model for the control. However, the context changes in certain circumstances. For example, for a **foreach** binding, every child element that is nested inside the hosting element (the element that has the **foreach** binding) obtains the current item in the loop as the context. To access the context of the parent element when you're inside of a **foreach** binding, use the **$parent** object. The following example from FTMContactControl.htm will help make this point clearer.

```
<div data-dyn-bind="foreach: Actions">
    <div data-dyn-role="CommandButton"
        data-dyn-bind="ImageType: 'Symbol', ImageName: $data.ActionName,
        ActionCommand: function(){$parent().ButtonClicked($data)}">
    </div>
</div>
```

Actions is a List property that is available on the control's JavaScript view model. This property was defined in the **FMTContactControl** run-time class. Each action in the **Actions** list has **Data Source**, **Data Field**, and **Action Name** properties. Within the **foreach** loop, **$data** refers to the current action, and **$data.ActionName** cam retrieve the **ActionName** property from the current action in the loop. Within the loop, view model properties on the control aren't accessible via **$data**. Instead, **$parent** can be used to retrieve the view model properties.

Tutorial steps

Add the HTML for the **ImageField** property that you created in the run-time class.

1. In Solution Explorer, expand the **Resources** folder under the **FMTutorial** project, and double-click **FMTContactControlHTM**. The FMTContactControl.htm file opens in the HTML editor.
2. Add the following HTML to the FMTContactControl.htm HTML. The gray text is shown just for placement context.

```
    <div class="contact">

        <span data-dyn-bind="if: $data.ImageField">
            <span data-dyn-role="Image" data-dyn-bind="Height: '70', Width: '70', Value:
$data.ImageField"></span>
        </span>

...
```

3. Press Ctrl+S to save the changes to FMTContactControl.htm.

In the preceding example, you use the framework image control to render the image. **Value** is a property that is defined on the Image control. This property lets you specify the value for the image data. The image control supports several kinds of image types, but for this example, you're concerned with only two possible types: URLs and Base64 strings. Because the image type depends on data that is known only at run time, you will use a property that derives this information, **ImageValue**. You might notice that no such property is defined in the run-time class for **FMTContactControl**. Therefore, this property isn't part of the automatically generated JavaScript view model for that control, and it also isn't defined on **$data**. To make the **ImageValue** property accessible via **$data**, you must extend the automatically generated JavaScript view model to add the property.

Review the JavaScript for the contact control

As was mentioned earlier, for every X++ method that has either a **FormPropertyAttribute** or **FormCommandAttribute** attribute, a JavaScript property or command is generated and made accessible to an extensible control's HTML via the view model. You can extend this view model with additional properties and commands that are defined only on the client. In other words, the properties and commands have no associated X++ methods. After you extend the view model, the additional client-only properties and commands can be used in bindings via the **$data** object.

Technical overview

The Control Extensibility Framework offers many functions that help with data bindings and data access. Some of the functions that are used in FMTContactControl.htm, such as **$field** or **$model**, make it easy to access the data source and its fields from the HTML bindings. These functions are functional aliases that are used in the HTML bindings for JavaScript functions that are defined by the framework. Within the extended JavaScript view model, the equivalent, non-aliased functions are **$dyn.getField** and **$dyn.getModel**. You can also use jQuery within the extended JavaScript view model by using the **$** symbol. The following example shows the standard pattern that is used to define a constructor for the extended JavaScript view model. In this example, you save a reference to **this**, apply the base **Control** class behaviors, and then combine the automatically generated properties and commands with the properties and command from the extended view model.

```
        $dyn.controls.ContactControl = function (props) {
        var self = this;

        $dyn.ui.Control.apply(this, arguments);

        $dyn.ui.applyDefaults(this, props, $dyn.ui.defaults.ContactControl);
...
```

The **self** variable now contains all properties and commands that are generated from the X++ run-time class. The following example shows how to add a client-only property to extend the view model.

```
self.ActionTypes = {
            Email: function (action) {
                var url = 'mailto:' + $dyn.value(action.Value);
                self.Open(url);
            },
            Phone: function (action) {
                var number = $dyn.value(action.Value);
                number = number.replace(/\D/g, '');
                if (number.length == 10) {
                    // assume US country code
                    number = "1" + number;
                }
                var tel = "callto://+" + number;
                self.Open(tel);
            }
        };
```

The **self** variable will then contain all the properties and commands that are generated from the X++ run-time class, and also the **ActionTypes** property that was added as a client-only property. There are many more topics that are related to building view models for controls, but they are outside the scope of this tutorial. For this tutorial, we don't need to make any changes to the view model for **FMTContactControl**. Therefore, you can close the FMTContactControl.js file and proceed to the next section.

Add the extensible control to the Fleet Management workspace

You will now update the **Fleet Management Clerk** workspace so that it uses the contact control that you just completed.

1. In Solution Explorer, expand **Forms**, and then double-click **FMTPickingUpTodayPart**. The form opens in the form designer.
2. In the form designer, expand **Design** > **PickingUpTodayGrid**.
3. If there is an existing contact control, delete it. You must remove and then re-add the control, so that the form designer picks up the X++ changes that you made. Right-click the existing control, and then click **Delete**.
4. Right-click **PickingUpTodayGrid**, point to **New**, and then click **FMT Contact Control**.
5. Click the **FMTContactControl1** node that you just added, and set the **Data Source** property to **FMTCustomer**.
6. Expand the **FMTContactControl1** node, click **Image**, and then, in the **Properties** pane, set the following properties.

PROPERTY	VALUE
Data Source	FMTCustomer
Data Field	Image

7. Create new title fields:
    a. Right-click **Title Fields**, and then click **New Title Field**.
    b. Click the **Title Field** node that you just created, and then, in the **Properties** pane, set the following properties.

PROPERTY	VALUE
Name	FirstName
Data Source	FMTCustomer
Data Field	FirstName

c. Right-click **Title Fields** again, and then click **New Title Field**.

d. Click the **Title Field** node that you just created, and then, in the **Properties** pane, set the following properties.

PROPERTY	VALUE
Name	LastName
Data Source	FMTCustomer
Data Field	LastName

8. Create new subtitle fields:

a. Right-click **Subtitle Fields**, and then click **New Subtitle Field**.

b. Click the **Subtitle Field** node that you just created, and then, in the **Properties** pane, set the following properties.

PROPERTY	VALUE
Name	StartDate
Data Source	FMTRental
Data Field	StartDate
Formatting Expression	Pickup {0}

c. Right-click ***Subtitle Fields*** again, and then click ***New Subtitle Field***.

d. Click the **Subtitle Field** node that you just created, and then, in the **Properties** pane, set the following properties.

PROPERTY	VALUE
Name	EndDate
Data Source	FMTRental
Data Field	EndDate
Formatting Expression	Return {0}

e. Right-click **Subtitle Fields** again, and then click **New Subtitle Field**.

f. Click the **Subtitle Field** node that you just created, and then, in the **Properties** pane, set the following properties.

PROPERTY	VALUE
Name	VehicleDescription
Data Source	FMTVehicle
Data Field	Description

g. Press Ctrl+S to save your changes.

9. Copy **PickingUpTodayGrid** by right-clicking in the grid and clicking **Copy**.
10. In Solution Explorer, click **Forms** > **FMTReturningTodayPart**, and then double-click **FMTReturningTodayPart**. The form opens in the form designer.
11. Expand **Design**, right-click **ReturningTodayGrid**, and then click **Delete**.
12. Right-click **Design**, and then click **Paste**.
13. Select the **PickingUpTodayGrid** grid that you just added to the **FMTReturningTodayPart** form. Set the **Name** property to **ReturningTodayGrid**, and then press Ctrl+S to save the changes to the **EMTReturningTodayPart** form.
14. In Solution Explorer, find the **FMTRentalRatesPart** form. Double-click the form to open it in the form designer, and then click **Design** > **RentalRatesGrid**.
15. Delete each field from **RentalRatesGrid**. To remove the fields, click the first field, hold down the Shift key while you click the last field, and then press Delete.
16. Right-click in the grid, point to **New**, and then click **FMT Contact Control**.
17. Expand **FMTContactControl1**, click **Image**, and then, in the **Properties** pane, set the following properties.

PROPERTY	VALUE
Data Source	FMTVehicleModel
Data Field	Image

18. Right-click **Title Fields**, and then click **New Title Field**.
19. Click the title field node that you just created, and then, in the **Properties** pane, set the following properties.

PROPERTY	VALUE
Name	VehicleModel
Data Source	FMTVehicleModel
Data Field	Model

20. Right-click **Subtitle Fields**, and then click **New Subtitle Field**.

21. Click the **Subtitle Field** node that you just created, and then, in the **Properties** pane, set the following properties.

PROPERTY	VALUE
Name	VehicleMake
Data Source	FMTVehicleMake
Data Field	Make

22. Right-click **Subtitle Fields**, and then click **New Subtitle Field**.
23. Click the **Subtitle Field** node that you just created, and then, in the **Properties** pane, set the following properties.

PROPERTY	VALUE
Name	RatePerDay
Data Source	FMTModelRate
Data Field	RaterPerDay **Note:** The **Data Field** value must match the table field name. If you correct the spelling error, the values won't match, and you will receive a run-time error.
Formatting Expression	${0} per day

24. Right-click **Subtitle Fields**, and then click **New Subtitle Field**.
25. Click the **Subtitle Field** node that you just created, and then, in the **Properties** pane, set the following properties.

PROPERTY	VALUE
Name	RatePerWeek
Data Source	FMTModelRate
Data Field	RatePerWeek
Formatting Expression	${0} per week

26. Press Ctrl+S to save your changes to **FMTRentalRatesPart**.
27. In Solution Explorer, right-click the **FMTClerkWorkspace** form, and then click **Set as Startup Object**.
28. Press Ctrl+F5 to open the updated contact control in Internet Explorer.

> **NOTE**
>
> If you receive a JavaScript error, you might have to clear the Internet Explorer cache, so that the browser loads the new JavaScript file:

a. When you're prompted to open the debugger, click **No**.
b. While Internet Explorer is open, press F12 (or click **Settings** > **F12 Developer Tools**), and then press Ctrl+R.
c. In the **Clear Browser Cache** dialog box, click **Yes**.
d. Reload the page by pressing Ctrl+F5.

In this tutorial, you've seen how you can use X++ when you define the design-time and server-side behaviors for a control, and how you can consume a powerful HTML-based and JavaScript-based framework when you design the UI and user interaction patterns. The Control Extensibility Framework helps provide a separation between the modeled behavior of a control and its physical manifestation. As a best practice, you should try to maintain this loose coupling between data, metadata, and UI when you build extensible controls.

Bidirectional or right-to-left support

To validate right-to-left (RTL) support for your extensible control, you simply need to set the **dir** (direction) attribute on the HTML document. When this attribute is changed, the browser will automatically change the layout direction of your control. You should make sure that your control doesn't implement any styling which interferes with this layout. Instead of setting this attribute manually, you can also validate by placing your control on a form, and then selecting a RTL language. Selecting a RTL language will cause the client to also update the **dir** attribute appropriately. For more information, see dir attribute in the HTML standards.

> **NOTE**
>
> Can you tell us about your documentation language preferences? Take a short survey.
>
> The survey will take about seven minutes. No personal data is collected (privacy statement).

Keyboard shortcuts for extensible controls

2/18/2021 • 5 minutes to read • Edit Online

Keyboard shortcuts are an important consideration when you create any extensible control. This topic provides information that will help you choose keyboard shortcuts for your extensible controls. It also outlines the recommended method for implementing keyboard shortcuts for extensible controls.

Overview

For accessibility, it's essential that keyboard-only users be able to use controls. Therefore, keyboard shortcuts are an important consideration when you create any extensible control. This topic provides information that will help you choose key combinations to use as keyboard shortcuts. It highlights the shortcuts that are currently used by Finance and Operations apps and supported browsers, shortcuts that are planned for implementation, and shortcuts that one or more browsers don't allow to be overridden. This topic also outlines the recommended way to implement keyboard shortcuts for extensible controls.

Choosing a key combination

When you're trying to choose a key combination to use as a keyboard shortcut, it's important that you be aware of other existing shortcuts. In this way, you help guarantee that your shortcut won't overlap an existing shortcut. If you try to collide with an existing shortcut, one of the following outcomes might occur:

- The new keyboard shortcut might not work, because a browser doesn't allow that key combination to be overridden, or a framework-provided shortcut takes precedence over the new shortcut.
- The new keyboard shortcut might remove expected keyboard functionality, because users expect specific key combinations to perform specific functions in a browser. Alternatively, you might override framework-provided shortcuts or other control shortcuts, so that keyboard-only users can't use them.

Because of these potential issues, we recommend that you adhere to this guidance when you choose a key combination:

- **Don't** choose any key combination that is currently used by Finance and Operations apps, or that is planned for future implementation.
- **Do** pick key combinations that will work in all supported browsers.
- **Do** be careful when you override shortcuts that are used by a supported browser. You should not suppress shortcuts for important or frequently used browser functionality.
- **Do** use longer key combinations (three keys) for control-specific behavior. Shorter combinations should be reserved for user-defined keyboard shortcuts.
- **Don't** choose any key combination that involves Ctrl+Alt, because this combination maps to Alt+Gr for some Eastern European languages and will conflict with other shortcuts.

Keyboard shortcut links

Here are links to the keyboard shortcuts that are documented for Finance and Operations apps and supported browsers:

- Keyboard shortcuts
- Microsoft Edge
- Google Chrome
- Internet Explorer 11
- Apple Safari

Planned keyboard shortcuts

In addition to the keyboard shortcuts that are currently used, there are several shortcuts that are planned for future implementation. To avoid conflicts with framework-provided shortcuts, you should not choose the following key combinations for extensible controls.

SHORTCUT	FUNCTIONALITY
F3	Move to the nearest QuickFilter.
Alt+F3	Add a filter that is based on the value of the current control (Filter by value).
Alt+Shift+F3	Clear all user-defined filters.
F6	Move to the nearest toolbar.
Shift+F7	Move to the toast message.

Browser/operating system keyboard shortcuts to avoid

Keyboard shortcuts that correspond to important functionality

The following table provides a short, non-exhaustive list of keyboard shortcuts that correspond to important functionality in a browser or operating system. You should not choose the key combinations in this table.

SHORTCUT	FUNCTIONALITY
Ctrl+A	Select all the text in the current field, or select all content on the page.
Ctrl+C	Copy.
Ctrl+V	Paste.
Ctrl+X	Cut.
F5	Refresh the page.
Ctrl+F5	Refresh the page, and ignore cached content.
Shift+F10	Simulate a right-click.
Tab / Shift+Tab	Move to the next/previous control.
Ctrl+Tab / Ctrl+Shift+Tab	Move to the next/previous browser tab.
Alt+Tab / Alt+Shift+Tab	Move to the next/previous application.
Alt+Right arrow / Alt + Left arrow	Go to the next/previous page in the browser history.

Keyboard shortcuts that can't be overridden by some browsers

Some browsers don't allow the following keyboard shortcuts to be overridden. Therefore, you should not choose the following key combinations, because the shortcut won't work in all browsers.

Alt+A	Alt+T	Ctrl+F4	Alt+Tab

Alt+C	Alt+V	Alt+F5	Alt+Shift+Tab
Alt+D	Ctrl+W	Alt+F6	Spacebar
Alt+Shift+D	Ctrl+Shift+W	Alt+Shift+F6	Alt+Shift+Backspace
Alt+E	Alt+X	F12	Ctrl+Pause/Break
Alt+F	Ctrl+Shift+0	Ctrl+Esc	Ctrl+Shift+Pause/Break
Alt+H	Ctrl+Shift+7	Ctrl+Shift+Esc	Ctrl+Page up
Ctrl+N	F1	Alt+Esc	Ctrl+Page down
Ctrl+Shift+N	Ctrl+F1	Alt+Shift+Esc	Ctrl+Plus sign (+)
Ctrl+Shift+Q	Ctrl+Shift+F1	Ctrl+Tab	Shift+Plus sign (+)
Ctrl+T	Shift+F1	Ctrl+Shift+Tab	Ctrl+Minus sign (–)

Implementing keyboard shortcuts

We recommend that you use the registration mechanism that is described in this section to implement keyboard shortcuts. There are several benefits to registering a control's shortcuts in this manner:

- You specify only the modifier keys that you want. If any other modifiers are pressed, the shortcut won't run. Therefore, a keyboard shortcut that is defined for Ctrl+Down arrow won't be triggered if Ctrl+Shift+Down arrow is pressed.
- You can reuse code.
- If you return **false** from the handler function, propagation won't stop on the event. If you return **true** (or if you don't specify a return value), propagation will stop.
- Ctrl and Meta modifiers are treated the same. Therefore, you can specify keyboard shortcuts that will work for both iOS and Microsoft Windows. For example, the shortcut Ctrl+G on Windows will be translated to Meta+G on iOS.
- Built-in telemetry for the keyboard shortcuts is used.

Define a keyboard shortcut

1. Define a Shortcuts object on the control's prototype. Then define the keyboard shortcuts inside the Shortcuts object. These shortcuts should have the following structure. Make sure that the key code that you're trying to use is defined in the $dyn.ui.KeyCodes object.

```
Shortcuts: {
    Name: {
        Keys: { modifier1: true, modifier2:true,
            keyCode: $dyn.ui.KeyCodes.* },
        // Only specify the modifiers you need
        // (between alt, ctrl/meta, shift)
        Handler: function (evt) {
            // Code to handle shortcut.
        },
        // Additional code.
}
```

   If more than one key code should apply to your keyboard shortcut, pass in an array of codes, as shown

here.

```
Keys: {modifier1:true,
    keyCode:[$dyn.ui.KeyCodes.*, $dyn.ui.KeyCodes.*, ... ] }
// Note: If any of these keyCodes match then the handler is called. I.E.
// The keyCodes in the array are OR'd not AND'd
```

2. Add the keydown handler by using the following code.

```
keydown: function (event) {
    $dyn.util.handleShortcuts(this, event);
},
```

3. Bind the keyDown handler. The keyDown handler is automatically bound for form objects. Other controls must be manually bound to the keyDown handler, as for any regular binding.

> **IMPORTANT**
> "keyDown" is case sensitive.

```
<div data-dyn-bind="keyDown: $data.keydown"></div>;
```

Examples

Here is a Form example.

```
Shortcuts: {
    Save: {
        Keys: { ctrl: true, keyCode: $dyn.ui.KeyCodes.letterS },
        Handler: function (evt) {
            var control = evt ? $dyn.context(evt.target) : undefined;
            this.executeShortcuts(true, "SaveRecord", control);
        },
    },
    New: {
        Keys: { alt: true, keyCode: $dyn.ui.KeyCodes.letterN },
        Handler: function (evt) {
            var control = evt ? $dyn.context(evt.target) : undefined;
            this.executeShortcuts(true, "NewRecord", control);
        },
    },
    Delete: {
        Keys: { alt: true, keyCode: $dyn.ui.KeyCodes.deleteKey },
        Handler: function (evt) {
            this.executeShortcuts(false, "DeleteRecord");
        },
    },
    // Additional code
}
```

Here is a Dialogs example that extends the Form control.

```
Shortcuts: $dyn.extendPrototype($dyn.controls.Form.prototype.Shortcuts, {
    InvokeDefaultButton: {
        Keys: { keyCode: $dyn.ui.KeyCodes.enter },
        Handler: function (evt) {
            this.executeShortcuts(false, "InvokeDefaultButton");
        }
    },
})
```

Extensible control programming reference

2/18/2021 • 34 minutes to read • Edit Online

This topic provides reference content for extensible control programming.

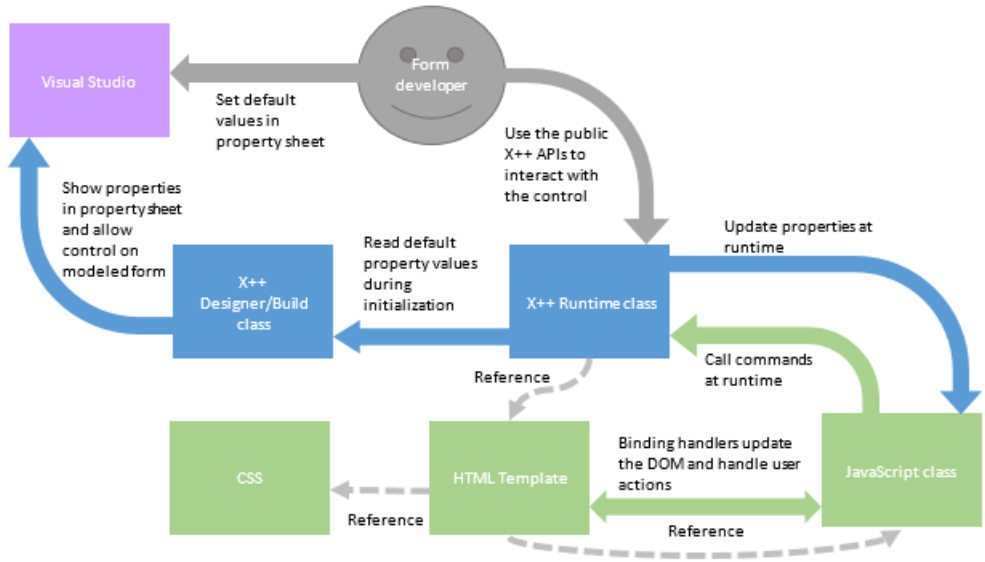
This document describes the API, HTML, and JavaScript support for creating extensible controls.

Examples

This document contains small code snippets that show how to use each API that is documented. More complete examples of finished controls that leverage many of these APIs can be found on Github. Extensible Control Examples on Github

Control block diagram

This high-level diagram illustrates the key components of an extensible control and how they interact with each other. Your extensible control solution will contain two X++ classes that implement your control. The runtime class implements the runtime data, presentation, and behavior of your control. The build class defines how your control is displayed in Form Designer, Property Window, and Application Explorer.



X++

The X++ API of your control is the Form-developer-facing API. Be sure to consider the APIs and behaviors you want to provide to the Form developer when designing the X++ APIs for your control.

Runtime: The X++ runtime class

The runtime class defines the public, developer-facing API for your control. It also contains the runtime logic for your control. The job of the runtime class is to maintain the state of the control via the control's properties.

Runtime: Class declaration

Declare an X++ class that extends **FormTemplateControl** or a type derived from **FormTemplateControl**. ***FormTemplateControl* contains basic properties that are necessary for every control, such as the Template ID and the Resource Bundle. The following example extends the base control class, **FormTemplateControl**.

```
class MyControl extends FormTemplateControl
```

Runtime: FormControlAttribute

You must apply the **FormControlAttribute** attribute to the X++ class declaration.

```
[FormControlAttribute(<Template ID>, <Resource Bundle Path>, <Build class name>))]
```

You must supply the following arguments:

- **Template ID**: A string that specifies the ID of the template. The Template ID is the JavaScript class name & the HTML element ID of the control. By convention, the TemplateID matches the class name of the control's runtime class.
- **Resource Bundle Path**: A string that specifies the path to the resource bundle. The Resource Bundle Path is the web path where the main HTM files are located. At runtime, the Client framework will load the HTM file specified by the Resource Bundle Path. At runtime, the Client framework will search the Resource Bundle for the HTML element with an ID matching the specified Template ID. At runtime, the Client framework will instantiate the JavaScript class specified by the Template ID. This path is relative to the root of the web directory.
- **Build class name**: A string that specifies the name of the build class. The build class name is the X++ class that determines the design-time behavior. At design time, the Visual Studio framework reflects over this attribute and loads the specified X++ class as the designer class. At runtime, the X++ framework will instantiate the specified X++ class as the build class in the super of applyBuild().

The following example shows a typical class and attribute declaration for a control named "MyControl".

```
[FormControlAttribute('MyControl', '/resources/html/MyControl', classStr(MyControlBuild))]
class MyControl extends FormTemplateControl
```

Runtime: FormCommandAttribute

The **FormCommandAttribute** is applied to a method in your control class, which allows the method to be called from a control's JavaScript class. A method with this attribute applied is called a **command.** Use the **FormCommandAttribute** on only the X++ methods that need to be accessed directly from the control's JavaScript class. An X++ method serving as a command can only accept string arguments. The method must perform the necessary operations to serialize or deserialize the string arguments into other types. The **FormCommandAttribute** has no effect on the behavior of the X++ method when the method is used from within X++. The **FormCommandAttribute** exposes the X++ method as an external endpoint that is accessible from JavaScript. As such, every command should be threat modeled and tested for exploits, and should perform validation on all of its arguments. The underlying X++ method should be declared private so that it is not accessible from X++. If X++ code needs to access this method's behavior, then a separate X++ method should be declared as public without the **FormCommandAttribute.** This public method should contain any shared code that is needed by both X++ and JavaScript. The private X++ method with the **FormCommandAttribute** can then call this public method to access the shared code. This practice allows the command to perform logic that is specific to calls coming from JavaScript (such as argument type deserialization, argument validation, security validation, etc.) before executing the core shared X++ logic. You supply the following arguments to the **FormCommandAttribute** constructor:

- **Name**: A required string that specifies the name of the command. A few best practices for naming Properties:
  - Capitalize the first letter, and use PascalCase.

    - Use a verb in the name.
    - Include the Property name if the Command is used to read/write a FormProperty (ex: Set_<PropertyName>)
    - Do not use any of the names of inherited JavaScript properties.
- **Execute immediate**: An optional boolean that specifies whether calls to this command are deferred or require immediate execution. By default, commands have **Execute immediate** set to **true,** so calls are not deferred. Most commands likely require immediate execution because their X++ logic must run before allowing the user to complete their next action. However, commands that have no side-effects on the user's ability to take their next action can likely be safely deferred to gain a performance benefit. For commands that can be deferred, set Execute immediate to **false** to reduce network chattiness.

The following example declares a command with the name of "SetText".

```
[FormCommandAttribute("SetText")]
private void setText(str value)
{
    // Add implementation code here.
}
```

Runtime: FormPropertyAttribute

The **FormPropertyAttribute** is applied to a method in your control class, which allows an X++ method to be called as a **FormProperty** getter/setter from the control's JavaScript class. A method with this attribute applied is called a **property.** Only use the **FormPropertyAttribute** on those X++ methods which need to be accessed directly from the control's JavaScript class. The **FormPropertyAttribute** has no effect on the behavior of the X++ method when the method is used from within X++. Every property exposes an endpoint to the browser. As such, every property should be threat modeled and tested for exploits. The underlying X++ method should be declared private so that it is not accessible from other X++ code. If other X++ code needs to access the property, then declare a separate public X++ method without the **FormPropertyAttibute,** and move the shared property logic to this method. Then call this method from the private X++ method with the **FormPropertyAttribute. This practice allows the property to perform logic that is specific to calls coming from JavaScript (such as argument type deserialization, argument validation, security validation, etc.) before executing the core shared X++ logic.** The underlying X++ method must accept and return the desired type of the property. If the desired type if an EDT, the property must accept and return the base type of the EDT. The supported property types are:

- X++ primitive types
- X++ data contracts (whose members are also supported types)
- X++ List (whose items are also supported types)

You supply the following arguments to the **FormPropertyAttribute** constructor:

- **FormPropertyKind:** A required **FormProperyKind** value that specifies the type of the property. Use **FormPropertyKind::Value** for Properties not bound to a data source field, and use **FormPropertyKind::BindableValue** for properties that may be bound to a data source field.
- **Name:** A required string that specifies the name of the property. A few best practices for naming properties:
    - Capitalize the first letter, and use PascalCase.
    - Do not use any of the names of inherited JavaScript properties
- **Read only**: An optional boolean that specifies whether this property is writable from the control's JavaScript class. By default, properties have **Read only** set to **false,** so they are writeable. This argument does not affect the ability to write to this property from X++. To make the X++ method read only, remove all method arguments from the method declaration. A majority of properties should not be writable from the control's JavaScript class. Because most property values require validation, a command should be used as a setter for

the property so that validation logic is can be run before the backing property is set.

- **Execute immediate**: An optional Boolean that specifies whether writes to this property are deferred or require immediate execution. By default, properties have **Execute immediate** set to **false,** so writes are deferred. Because the majority of properties should not be writeable form the control's JavaScript class, the **Execute immediate** flag defaults to **false** and provides performance benefits. Even in the case of properties that are writable from the control's JavaScript class, the performance side effects of immediate execution should be carefully considered before enabling the behavior.

The following example shows a typical property declaration. Most properties share the same boilerplate code for getting/setting, as shown below. The textProperty variable is the backing FormProperty field for this property.

```
[FormPropertyAttribute(FormPropertyKind::Value, "Text", true)
private str parmText(str _value = textProperty.parmValue())
{
    if(!prmIsDefault(_value))
    {
        textProperty.setValueOrBinding(_value);
    }
    return textProperty.parmValue();
}
```

Runtime: FormProperty

Behavior

FormProperty is an X++ derived type used by the control framework for the synchronization of property values between X++ and JavaScript. **FormProperty** objects are considered the backing fields used internally by properties. Each **FormProperty** is typically used in 4 places throughout a control's X++ runtime class:

1. The **FormProperty** is declared, usually right below the class declaration
2. The **FormProperty** is instantiated in the **new** method of the class
3. The **FormProperty** is initialized in the **applyBuild** method of the class
4. The **FormProperty** is read and written in the X++ method for the property

The following example shows a **FormProperty** being used in a typical controls' X++ runtime class.

```
[FormControlAttribute("MyControl", "/resources/html/MyControl", classStr(BuildMyControl))]
class MyControl extends FormTemplateControl
{
    FormProperty textProperty;

    public void new(FormBuildControl _build, FormRun _formRun)
    {
        super(_build, _formRun);

        this.setTemplateId("MyControl");
        this.setResourceBundleName("/resources/html/MyControl");
        textProperty = this.addProperty(
        methodStr(MyControl, parmText), Types::String);
    }

    public void applyBuild()
    {
        BuildMyControl build;

        super();

        build = this.build();
        if(build)
        {
            this.parmText(build.Text());
        }
    }

    [FormPropertyAttribute(FormPropertyKind::Value, "Text", true)
    private str parmText(str _value = textProperty.parmValue())
    {
        if(!prmIsDefault(_value))
        {
            textProperty.setValueOrBinding(_value);
        }
        return textProperty.parmValue();
    }
}
```

Runtime: new method

The **new** method on a control's X++ runtime class is called as a part of instantiating the control on a form. For the details on when the **new** method is called in the form lifecycle, please see the Control Lifecycle Diagrams. This method is used for instantiation of a control's FormProperties and setting the control's Template ID and Resource Bundle Path. See typical use of the **new** method in the example for FormProperty.

Runtime: applyBuild method

The **applyBuild** method on a control's X++ runtime class is called as a part of instantiating the control on a form. For the details on when the **applyBuild** method is called in the form lifecycle, please see the Control Lifecycle Diagrams. This method is used for initialization of a control's FormProperties to their default values, or to the values specified by the form developer who placed the control on the form. See typical use of the **applyBuild **method in the example for FormProperty.

Runtime: FormBindingUtil::initbinding method

The **FormBindingUtil** is an API provided by the control framework. It is used to bind FormProperties to data fields and data methods on a data source. The following example binds the data field with name "Value" on the data source with name "DataSource1" to the textProperty FormProperty of the runtime class.

```
[FormControlAttribute("MyControl", "/resources/html/MyControl", classStr(BuildMyControl))]
class MyControl extends FormTemplateControl
{
    FormProperty textProperty;

    public void new(FormBuildControl _build, FormRun _formRun)
    {
        super(_build, _formRun);
        this.setTemplateId("MyControl");
        this.setResourceBundleName("/resources/html/MyControl");
        textProperty = this.addProperty(
        methodStr(MyControl, parmText), Types::String);
    }

    public void applyBuild()
    {
        BuildMyControl build;

        super();

        build = this.build();
        if(build)
        {
            this.parmText(FormBindingUtil::initBinding(
            "DataSource1", "Value", this.formRun()));
        }
    }

    [FormPropertyAttribute(FormPropertyKind::Value, "Text", true)
    private str parmText(str _value = textProperty.parmValue())
    {
        if(!prmIsDefault(_value))
        {
            textProperty.setValueOrBinding(_value);
        }
        return textProperty.parmValue();
    }
}
```

Design time: The X++ build class

The build class defines the design time behavior of your control. This class determines which properties appear in the property sheet, and how the control behaves when it is modeled in the Form designer. The job of the design time class is to capture design time information for the runtime class to access later on.

Design time: Class declaration & FormDesignControlAttribute

The FormDesignControlAttribute is necessary for the control to appear in the Visual Studio Form designer when right-clicking on the design node of the form. If the FromDesignControlAttribute is missing, then the control can only be added to a form via imperative X++ code (i.e. via the addControlEx method on the form).

```
[FormDesignControlAttribute("MyControl")]
class MyControlBuild extends FormBuildControl
{

}
```

Design time: FormDesignPropertyAttribute

Placing this attribute on a method in the design time class will result in a new property with the name specified

by the first argument (and in the section specified by the second argument) appearing the property sheet for this control, with the corresponding X++ method operating as the getter/setter for the property.

```
[FormDesignControlAttribute("MyControl")]
class MyControlBuild extends FormBuildControl
{
    str text;

    [FormDesignPropertyAttribute("Text", "Data")]
    public str Text(str _value = text)
    {
        if(!prmIsDefault(_value))
        {
            text = _value;
        }
        return text;
    }
}
```

Design time: FormDesignProperty** **Attribute

There are a number of FormDesignProperty attributes which may be applied alongside the standard FormDesignPropertyAttribute for specialized behavior in the property sheet. The specialized behavior includes enabling the property as a combobox which allows selecting from a list of a values. The different types of lists that used are enumerated below. Whenever the user selects an item from the combobox, the string name of that item is passed into the X++ method getter/setter with the attribute.

- [FormDesignPropertyDataSourceAttribute] - Shows a list of the data sources on the form.
- [FormDesignPropertyDataFieldAttribute(<data source name>)] - Shows a list of the data fields on the specified data source.
- [FormDesignPropertyDataMethodAttribute(<data source name>)] - Shows a list of the data methods on the specified data source.
- [FormDesignPropertyFieldGroupAttribute(<data source name>)] - Shows a list of the field groups on the specified data source.
- [FormDesignPropertyExtendsClassAttribute(<class name>)] - Shows a list of the classes which extend the specified class.
- [FormDesignPropertyImplementsAttribute(<interface name>)] - Shows a list of the classes which implement the specified interface.
- [FormDesignPropertyReferenceAttribute(<FormDesignPropertyReferenceType::<type>)] - Shows a list of the specified AOT artifacts with the given type. The supported types are:
  - Table
  - View
  - Map
  - EDT
  - BaseEnum
  - Query
  - Class
  - Form
  - MenuItemDisplay
  - MenuItemOuput
  - MenuItemAction
  - Tile
  - KPI

The following example shows standard properties used to allow a Form developer to specify the Data Source and Data Field for the design time class.

```
[FormDesignControlAttribute("MyControl")]
class MyControlBuild extends FormBuildControl
{
    str dataSource;
    str dataField;
    str dataMethod;

    [FormDesignPropertyAttribute("Data source", "Data"),
     FormDesignPropertyDataSourceAttribute]
    public str DataSource(str _value = dataSource)
    {
        if(!prmIsDefault(_value))
        {
            dataSource = _value;
        }
        return dataSource;
    }

    [FormDesignPropertyAttribute("Data Field", "Data"),
     FormDesignPropertyDataFieldAttribute(methodStr(MyControlBuild, DataSource))]
    public str DataField(str _value = dataField)
    {
        if(!prmIsDefault(dataField))
        {
            dataField = _value;
        }
        return dataField;
    }

    [FormDesignPropertyAttribute("Data Method", "Data"),
     FormDesignPropertyDataMethodAttribute(methodStr(MyControlBuild, DataSource))]
    public str DataMethod(str _value = dataMethod)
    {
        if(!prmIsDefault(dataMethod))
        {
            dataMethod = _value;
        }
        return dataMethod;
    }
}
```

A control with a design time class like the one above can then bind to the specified data source and data field inside of the applyBuild method, as show below.

```
public void applyBuild()
{
    BuildMyControl build;

    super();

    build = this.build();
    if(build)
    {
        this.parmText(FormBindingUtil::initBinding(
        build.DataSource(), build.DataField(), this.formRun(), build.DataMethod()));
    }
}
```

If you supply both a data field and data method to FormBindingUtil::initBinding, the data field binding will override the data method binding.

HTML

HTML: Framework attributes

The following section documents the HTML attributes that are used in the control framework for control development.

data-dyn-bind

data-dyn-bind, the data binding attribute, standardizes many common DOM manipulations - such as modifying an element's attributes, properties and CSS, or handling DOM events - through a declarative HTML-based API. The data binding attribute allows for these behaviors without requiring complex JavaScript. Using the data binding attribute rather than writing complex JavaScript can save the control developer valuable time by making things such as designing, debugging and maintaining the control much easier. However, complex JavaScript is still available when scenarios require its use. The data binding attribute binds HTML element behaviors to values supplied by the control developer. The values supplied can be simple JavaScript variables, JavaScript comparison or arithmetic expressions, JavaScript functions and JSON objects. The values supplied can also be observable variables, created using the APIs described in this document. The way in which the supplied value is bound to the HTML element is determined by the binding handler that is used with the data binding attribute. A list of all supported binding handlers is provided in this document. The data binding attribute requires the following syntax when used with any binding handler. The syntax for **data-dyn-bind** is:

```
data-dyn-bind="[first binding handler]: [value to bind to]"
```

The data binding attribute accepts a comma-separated list of binding handler-value pairs, so you can supply more than one binding handler to the binding attribute at a time. The following example binds the **visible** property of the div element to true, and binds the **textContent** property of the div element to "Hi".

```
data-dyn-bind="text: 'Hi', visible: true"
```

The data binding attribute is a custom HTML attribute understood by the control framework. The data binding attribute can be applied to any HTML element. Some HTML elements may not have the behavior which the binding handler modifies. For example, using the text binding handler on an **<svg>** element will not show the text since the **<svg>** element does not have a textContent property. The control framework reads and executes the data bindings specified in the control's template at runtime. The lifecycle for the control in the browser can be summarized as follows:

1. The control's HTM file is loaded by the browser.
2. Any script or resource files referenced in the HTM file are also loaded by the browser. Steps 1 and 2 are executed only once during a user's session, even if there are multiple instances of the control.
3. The JavaScript class's constructor for the control is call and passed with the X++ properties for the control instance.
4. The control's template is copied from the HTM file and into the browser's memory.
5. HTML elements in the control's template are processed for data binding in hierarchical order (depth first), and data bindings on each element are executed in order from left-to-right
6. The final HTML, including the original data binding attributes as well as any other markup added by the binding handlers or by the framework, is added to the browser's DOM and rendered for the user to see.
7. Later, when the value of an observable changes, any binding handlers subscribed to the observable are re-executed and the live DOM is updated in real-time.

HTML: Binding handlers

attr

The **attr** binding handler applies the supplied HTML attribute and value to the element. For a list of HTML attributes see W3 Schools – HTML Attributes. The arguments are passed in as an object array. Each argument is dual-valued. The first value is the name of the attribute, and the second value is the value of the attribute.

- **Name**: a string that specifies the desired name of the attribute to create.
- **Value or Expression:** a string that specifies the value to set on the attribute. If an expression is supplied, the value returned by evaluating the expression will be used.

The following example creates the title and name attributes and sets their value.

```
<!-- the markup in the HTML template -->
<div data-dyn-bind="attr: {title: 'Hello', name: 'Greeting'}"></div>

<!-- the markup in the browser after the binding handler is applied -->
<div title="Hello" data-dyn-bind="attr: {title: 'Hello', name: 'Greeting'}" name="Greeting"></div>
```

The following example uses expressions and functions. However, using JavaScript functions as in-line HTML like the example below is not recommended.

```
<!-- the markup in the HTML template -->
<div data-dyn-bind="attr: {title: false? 'Hello':'World', name: function(){return 'Greetings';}()}"></div>

<!-- the markup in the browser after the binding handler is applied -->
<div title="World" data-dyn-bind="attr: {title: false? 'Hello':'World', name: function(){return
'Greetings';}()}" name="Greetings"></div>
```

click

Behavior

Subscribes the supplied function to the click event on the element. For more information on subscribing to the click event see jQuery – click().

Arguments

EventHandler (function)

The function to call when the event is raised.

Example 1

The following example shows an alert message “Hello” when the element is clicked.

```
// In your control’s code-behind JS file
<script>
... // boilerplate code
self.ElementClicked = function (event) {
    /* handle the click event */
    alert('Hello');
};
...
</script>

<!-- In your control’s template HTM file -->
<div data-dyn-bind="click: $control.ElementClicked"></div>
```

The following example prevents the click event on child elements from bubbling up to parent elements. The example below will show only one alert with message “Hello” when the child element is clicked.

```
// In your control’s code-behind JS file
<script>
... // boilerplate code
self.ParentElementClicked = function (event) {
    /* handle the click event */
    alert('Hi');
};

self.ElementClicked = function (event) {
    /* prevents the event form bubbling up to parent elements*/
    event.stopPropagation();

    /* handle the click event */
    alert('Hello');
};

...
</script>

<!-- In your control’s template HTM file -->
<div data-dyn-bind="click: $control.ParentElementClicked">
<div data-dyn-bind="click: $control.ElementClicked"></div>
</div>
```

The following example prevents the browser default behavior from executing. For anchor tags, the default hyperlink behavior is prevented, so the browser will not navigate to the link when the element is clicked.

```
// In your control’s code-behind JS file
<script>
... // boilerplate code
self.LinkClicked = function (event) {
        /* handle the click event */
        alert($dyn.format('Navigation to ' + {0} + ' was prevented', $(event.target).attr("href")));

        /* prevents the default event behavior */
        event.preventDefault();
};
</script>

<!-- In your control’s template HTM file -->
<a href="https://www.microsoft.com" data-dyn-bind="click: $control.LinkClicked">Click here</a>
```

css

Behavior

Adds or removes the specified CSS class name(s) to the element, based on the specified condition(s). Note that expressions supplied to the binding handler are only executed once.

Arguments

The arguments are passed in as an object array. Each argument is dual-valued. The first value is the Class name, and the second value is the Condition.

Class name (string)

The CSS class name to add to the element.

Condition (expression)

The condition on which to add the CSS class name. If the condition evaluates to true, the CSS class name is added. If the condition evaluates to false, the CSS class name is removed. If a supplied condition takes a dependency on an observable (via $dyn.value), then the condition will be re-evaluated whenever the observable value changes, and the associated CSS class name will be added/removed based on the new condition. The following example adds the CSS class names "red", "green", and "yellow".

```
// In your control's code-behind JS file
<script>
... // boilerplate code
self.red = function () { return true; };
self.yellow = $dyn.observable(true);
...
</script>

<!-- the markup in the HTML template -->
<div data-dyn-bind="css: {green: true, red: $control.red, yellow: $dyn.value($control.yellow)}"></div>

<!-- the markup in the browser after the binding handler is applied -->
<div class="green red yellow" data-dyn-bind="css: {green: true, red: $data.red, yellow:
$dyn.value($control.yellow) }"></div>
```

event

Behavior

Subscribes the supplied event handler to the specified DOM event. For a list of supported DOM events, see jQuery - Event.

Arguments

For details on the arguments to the event binding handler, see jQuery - .bind(). The following example subscribes to the mouseover event and shows an alert when the element is hovered.

```
// In your control's code-behind JS file
<script>
... // boilerplate code
self.elementHovered = function (event) { alert($dyn.format('{0}',$(event.target).text()))};
...
</script>

<!-- the markup in the HTML template -->
<div data-dyn-bind="event: {mouseover: $data.elementHovered}">Greetings!</div>
```

foreach

Behavior

Repeats the content of the child element, updating the binding context of each child based on the supplied data. Supply ***only one*** child element inside of the element with the **foreach** binding. This one element is the element that will be cloned and repeated. Any other additional elements or content will be removed when the binding is applied. Binding handlers are executed in the order in which they appear on the element. Since the **foreach** binding changes the binding context, it is a best practice to always place the **foreach** binding after all other bindings on the element. This will ensure that preceding bindings are not affected by the binding context created by the **foreach** binding. To avoid performance issues, be careful to not create unintentional dependencies on observables inside of your **foreach.** Do not access an observable in the array using **$dyn.value** from within the child elements of the **foreach,** as the **foreach** binding has already subscribed to the observables in the array. Instead, use **$dyn.peek** to access an observable's value once without creating a subscription.

Arguments

Data (array list or JSON object)

The list of items to bind the child element to. If an array list is supplied, the binding context is an item in the array. If a JSON object array is supplied, the binding context is one of the object's properties.

Scope variables

When inside the scope of the **foreach,** the following scope variables are useful and can be used on the repeatable child element: $data, index, control, your own scope variables. The following example uses **foreach** to render a span element for each color in the array.

```
// In your control’s code-behind JS file
<script>
... // boilerplate code
self.colors = ['Red','Blue','Green'];
...
</script>

<!-- the markup in the HTML template -->
<div data-dyn-bind="foreach: $control.Colors">
<span data-dyn-bind="text: $data"></span>
</div>

<!-- the markup in the browser after the binding handler is applied -->
<div data-dyn-bind="foreach: $control.colors">
<span data-dyn-bind="text: $data">Red</span>
<span data-dyn-bind="text: $data">Blue</span>
<span data-dyn-bind="text: $data">Green</span>
</div>
```

The following examples shows a nested **foreach** binding. This example showcases how to use the index framework scope variable and custom scope variables to access the binding context from the parent element.

```
    // In your control’s code-behind JS file
<script>
... // boilerplate code
self.colors = [
    {
        Name: 'Red',
        Variants: ['Maroon','Burgundy','Sunrise']
    },
    {
        Name: 'Green',
        Variants: ['Sage','Forest','Lime']
    },
    {
        Name: 'Blue',
        Variants: ['Navy','Sky','Ice']
    }
];
...
</script>
<!-- the markup in the HTML template -->
<div data-dyn-bind="foreach: $control.colors">
<div data-dyn-bind="vars: {$BaseIndex: $index, $BaseColor: $data.Name}">
<div data-dyn-bind="foreach: $data.Variants">
<div data-dyn-bind="text: $BaseIndex+'.'+$index+' '+$data+' '+$BaseColor"></div>
</div>
</div>
</div>
<!-- the markup in the browser after the binding handler is applied -->
<div data-dyn-bind="foreach...">

</div>
</div>
</div>
```

if

Behavior

Conditionally renders and binds the child elements of the element with this binding. This binding handler only operates on the child elements. It will not show/hide the element with the binding, nor will this binding show/hide the text content of the element with the binding. Bindings on the child elements will only be executed if the condition evaluates to true. Once the bindings on child elements have been evaluated once they will remain data bound even if the condition changes to false. This means that any calculations caused by bindings on child elements will continue to operate even after the child elements are hidden. Consider this when evaluating the performance of your control.

Arguments

Condition (expression)

Determines whether to render the children elements. The following example conditionally binds the **show** and **text** elements.

```
    // In your control’s code-behind JS file
<script>
... // boilerplate code
self.show = $dyn.observable(false);
self.text = "Hello";
...
</script>
<!-- the markup in the HTML template -->
<div data-dyn-bind="if: $control.show">
<div data-dyn-bind="text: $control.text"></div>
</div>
<!-- the markup in the browser after the binding handler is applied -->
<div data-dyn-bind="if: $control.show">
</div>
// Later on, the value of the “show” observable changes to true
<script>
...
self.show(true);
...
</script>
<!-- the markup in the browser after the binding handler is re-applied due to the observable value changing
-->
<div data-dyn-bind="if: $control.show">
<div data-dyn-bind="text: $control.text">Hello</div>
</div>
```

sizing

Behavior

Specifies the height and width of the control. The sizing binding handler should always be applied to the root element of the template (the element that has the id attribute), and supplied the height and width values from the X++ instance of the control by using the $dyn.layout.sizing helper function. See Example 1.

Arguments

The arguments are passed an object containing height and width properties.

Height (int)

Determines the height in pixels of the element on which the binding handler is applied.

Width (int)

Determines the width in pixels of the element on which the binding handler is applied. The following example specifies the size of **MyControl**.

```
<!-- the markup in the HTML template -->
<!-- this boilerplate binding ensures that the control’s container is sized based on the height and width
properties -->
<div id="MyControl" data-dyn-bind="sizing: $dyn.layout.sizing($control)"></div>
<!-- the markup in browser after the binding handler is applied will vary based on the height and width
properties defined in $control -->
```

The following example makes the control large or small depending on the value of the **bigbox** variable.

```
// Later on, the value of the “show” observable changes to true
<script>
...
self.bigBox = true;
...
</script>
<!-- the markup in the HTML template -->
<div data-dyn-bind="sizing: {height: $control.bigBox?50:10, width: $control.bigBox?50:10}"></div>
<!-- the markup in the browser after the binding handler is applied -->
<div style="width: 50px; height: 50px;" data-dyn-bind="sizing: {height: $control.bigBox?50:10, width:
$control.bigBox?50:10}"></div>
```

text

Behavior

Binds to the textContent property of the element. The text binding handler is meant to be used with UI text. It is not meant to bind non-string values (such as numbers, dates or Booleans) to the element. Convert all values into strings before supplying them to the binding handler, by using the dyn.format function. The text binding handler will replace all of the content inside of the element with the binding, whether or not the existing content is HTML or simple text.

Arguments

Text (string)

The text to bind to. The following example binds the textContext property of the div element to the text property on the control.

```
// In your control’s code-behind JS file
<script>
... // boilerplate code
self.text = "Hello";
...
</script>
<!-- the markup in the HTML template -->
<div data-dyn-bind="text: $dyn.format('{0}',$control.text)"></div>
<!-- the markup in browser after the binding handler is applied -->
<div data-dyn-bind="text: $dyn.format('{0}',$control.text)">Hello</div>
```

vars

Behavior

Creates an HTML scope variable with the supplied name and value. The created scope variable is accessible only from bindings in the template. In addition, the scope variable is inherited by child elements. Binding handlers are executed in the order in which they appear on the element. Since the vars binding adds variables to the binding context, it is a best practice to always place the vars binding before all other bindings on the element. This will ensure that the subsequent bindings can access scope variables added by the vars binding. Do not create scope variables with any of the following names, as these names are reserved for framework scope variables: $control, $data, $index, and $value.

Arguments

Scope variables (object array)

The object array whose keys are the scope variable names and whose values are the initial values for the scope variables. The following example creates scope variables named "Hello" and "World" and displays their values.

```
<!-- the markup in the HTML template -->
<div data-dyn-bind="vars: {$myVar: 'Hello', $myObs: $dyn.observable('World')}">
<span data-dyn-bind="text: $dyn.format('{0} {1}!', $myVar, $myObs)">
</span>
</div>
<!-- the markup in browser after the binding handler is applied -->
<div data-dyn-bind="vars: {$myVar: 'Hello', $myObs: $dyn.observable('World')}">
<span data-dyn-bind="text: $dyn.format('{0} {1}!', $myVar, $myObs)">
Hello World!
</span>
</div>
```

Example 2

For an example, see the foreach binding handler examples.

visible

Behavior

Sets the visibility of the element. Always supply the visible binding handler on the root element of the template, and bind to the *Visible* property from the X++ control. This will ensure that the control respects the *Visible* property when it is set by a form developer or when it is set by the framework. If a control is initialized with its *Visible* X++ property set to false, then the control will not appear on the form, and it the control’s template will not be loaded in the browser. If the control’s *Visible* X++ property is set to true at a later time, then the control’s

template will be loaded and instantiated in the browser at that time. A control's *Visible* X++ property can be inherited from its parent controls on the form. An element's visibility may be controlled by its parent elements, controls and containers, regardless of whether the visible binding handler is applied. The cascading nature of visibility is a standard HTML behavior and is not specific to the control framework.

Arguments

Visible (boolean)

Determines whether the element is visible or not. The following example sets the visibility of the control's outermost div element.

```
// In your control's code-behind JS file
<script>
... // boilerplate code
self.Visible(false); // set the X++ observable property to false
...
</script>
<!-- the markup on the root element of the HTML template -->
<div id="MyControl" data-dyn-bind="visible: $control.Visible">Hello World!</div>
<!-- the markup in browser after the binding handler is applied -->
<div id="MyControl" style="display: none;" data-dyn-bind="visible: $control.Visible">Hello World!</div>
```

HTML: Scope variables

Scope variables can be used when binding values to binding handlers. Scope variables are only accessible from within the control's HTML template, and can only be used with the data binding attribute. Scope variables are neither accessible from other HTML attributes nor from the control's JavaScript class, but scope variables can be used in inline JavaScript expressions, functions and JSON objects that are passed to binding handlers.

$control

The *$control* scope variable provides the bindings in the HTML template with access to the properties and functions on the control's JavaScript instance. The following example binds visibility of the div element to the of Visible property of the control.

```
<div id="MyControl" data-dyn-bind="visible: $control.Visible"></div>
```

$data

The *$data* scope variable provides elements with access to their current binding context. Only variables defined in $data (the binding context) or scope variables, can be used inside of HTML bindings. Variables that do not exist in the current binding context and do not exist as current scope variable cannot be accessed from an HTML binding. In most cases the binding context will be the control's JavaScript instance, so *$data* and *$control* will be equivalent. However, in some cases the binding context can change. For example, for elements inside of a **foreach** binding, *$data* provides the elements with access to the current array item. In cases involving multiple nested **foreach** bindings, elements in a nested binding may need access to the array item in a parent **foreach** binding. To access items in the parent **foreach** binding, you may create a scope variable which will be accessible to elements in the nested **foreach** biding. For an example, see the foreach binding handler examples.

$index

The $index scope variable provides a 0-based index of the array item when in a **foreach** binding. For an example, see the foreach binding handler examples.

JavaScript: Inherited properties

Visible

The **Visible** property is inherited from the base JavaScript class (via **$dyn.ui.Controls.apply**). There is also a **Visible** property in X++ that the runtime class in inherits from the base **FormControl** X++ class. Simply bind this property to the visible binding handler and place it on the root element of the HTML template for your

control. The framework takes care of the rest. The following example shows how to use the Visible property.

```
<!-- the markup in the HTML template -->
<div id="MyControl" data-dyn-bind="visible: $control.Visible"></div>
```

Observable framework

$dyn.observe

Usage

Subscribes a function to changes of an observable. We recommend that you use dispose.

```
$dyn.observe(observable, observer, [context], [disposableObserver])
```

Arguments

Observable (observable)

Instance of an observable. Or a function, which will become a $dyn.computed.

Observer (function)

Function is invoked upon registration and also later when the observable is updated. Function is invoked with one argument, the value of the observable. If Observer returns false, then we un-subscribed automatically.

Context (options, optional)

Context to pass to the Observer. The Context becomes the ***this*** variable inside of the observer.

DisposableObserver (options, optional)

Unsubscribes the supplied DisposableObserver

Returns

Subscription (object)

Observable, ID, Dispose function (public) used to unsubscribe The following example subscribes to the myObs observable, and executes the supplied function whenever the myObs observable value changes.

```
$dyn.observe(myObs, function (value) { console.log(value);});
```

The following example shows how a function can automatically subscribe to observables simply by accessing the observable using $dyn.value. The first function is treated like an observable whose value is dependent upon the value of two other observables (FirstName and LastName). Every time one of the observables (FirstName or LastName) changes its value, then the first function has also changed its value. When this happens, the second function (the callback function) will log the concatenation of the observable values to the console.

```
self.FirstName = $dyn.observable("Joanne");
self.LastName = $dyn.observable("Gordon");
$dyn.observe(
    function () {
        // Joann + " " + Gordon
        return $dyn.value(self.FirstName) + " " + $dyn.value(self.LastName);
    },
    function (value) {
        // "Joanne Gordon"
        console.log(value);
    }
);
```

The following example performs similarly to the previous example. However, this example uses a computed observable, named myComp, to handle the concatenation.

```
self.FirstName = $dyn.observable("Joanne");
self.LastName = $dyn.observable("Gordon");
self.myComp = $dyn.computed(function () {
    // Joanne + " " + Gordon
    return $dyn.value(self.FirstName) + " " + $dyn.value(self.LastName);
});
$dyn.observe(
    self.myComp,
    function (value) {
        // "Joanne Gordon"
        console.log(value)
    );
},
{FirstNameLabel: label1, LastNameLabel: label2}
);
```

$dyn.observable

Usage

Creates an observable variable.

```
$dyn.observable([initial value])
```

Arguments

Initial value (optional)

The value to initialize the observable to.

Returns

Observable (function)

The newly created observable The following example creates and observable variable named "Hello".

```
var greeting = $dyn.observable("Hello");
```

$dyn.value

Usage

Accesses the value of an observable variable. When **$dyn.value** is called from inside of an observer function (such as an observer passed to **$dyn.observe** or **$dyn.computed**, as well as the binding expression passed to a binding handler) a dependency on the observable is created. This will cause the binding handler or callback to re-execute whenever the value of the observable changes. Because this dependency is created automatically when using **$dyn.value**, it is important to only use **$dyn.value** when you intentionally wish to create such a dependency. If you wish to access the value of an observable without creating a dependency, you should use $dyn.peek.

```
$dyn.value(observable)
```

Arguments

Observable

The observable property whose value to access.

Returns

Value

The current value in the observable property The following example returns the value of variable named observable and prints it to the console.

```
console.log($dyn.value(observable));
```

$dyn.peek

Usage

Accesses the value of an observable variable, without creating a dependency. For more information about dependency, see the $dyn.value function.

```
$dyn.peek(observable)
```

Arguments

Observable

The observable whose value to access.

Returns

Value

The current value in the observable The following example returns the value of variable named observable and prints it to the console.

```
console.log($dyn.peek(observable));
```

$dyn.computed

Usage

Wraps a function with an observability scope. If observables are accessed from inside of the function by using the **$dyn.value** function, then the function will re-execute whenever the values of those observables change. Observables that are accessed by using **$dyn.peek** will not cause the function to re-execute when their values change.

```
$dyn.computed(observer, [context], [disposableObserver])
```

Arguments

Observer (function)

Function is invoked upon registration and can also be invoked later due to an observable value change. The Observer automatically observes any observables that are accessed using $dyn.value from within the scope of the function.

Context (options, optional)

Context to pass to the Observer. The Context becomes the *this* variable inside of the observer.

DisposableObserver (options, optional)

Unsubscribes the supplied DisposableObserver

Returns

Anything (optional)

If the Observer returns a value, then that value will also be returned by the call to **$dyn.computed** on the first time **$dyn.computed** is called (upon registration) as well every time the observer is invoked.

Framework functions

$dyn.callFunction

Usage

Calls the apply method on specified function. Is cannot be used during an interaction.

Arguments

Function (function or observable)

The function to call. If an observable is supplied, the current value of the observable will be retrieved and used as the function.

This (object, optional)

The object to assign to *this* within the scope of the function.

Arguments (array, optional)

The arguments to pass to the supplied function.

Callback (function, optional)

The callback function to call when the supplied Function has returned. The callback will be passed any values that are returned by the function that is called. The following example calls the **apply** function on the **printName** function.

```
self.Name = "Joanne M Gordon";
var printName = function () {
    console.log(this.Name);
};
$dyn.callFunction(printName, self);
```

The following example calls the **getWholeName** function.

```
var getWholeName = function (first, middle, last) {
    var wholeName = first + " " + middle + " " + last;
    return wholeName;
};
var printName = function (wholeName) {
    console.log("Your name is: " + wholeName);
};
var firstName = "Joanne";
var middleName = "M";
var lastName = "Gordon";
$dyn.callFunction(getWholeName, null, [firstName , middleName, lastName], printName);
```

$dyn.format

Usage

Builds a string using the supplied values according to the supplied format.

Arguments

Format (string)

The format in which to build the string. Use bracket notation for placeholders.

Values (optional)

The comma separated values to use in the format

Returns

FormattedString (string)

The string after formatting has been applied The following example builds a string with the first, middle initial, and the last name.

Example 1

```
var first = "Joanne";
var middle = "M";
var last = "Gordon";
var $dyn.format("Your name is : {0} {1} {2}", first, middle, last);
```

$dyn.label

Usage

Provides access to any labels stored via the Globalization API.

Arguments

Identifier (string)

The label ID, as specified to the Globalization API.

Returns

Value (string)

The label string in the current culture, if the Identifier is found. Otherwise, returns the supplied Identifier as a string. The following example returns and prints the label named "greeting".

```
Globalize.addCultureInfo("en", {
    messages: {
        "greeting": "Hello!"
    },
});
console.log($dyn.label("greeting"));
```

CSS

Add namespaces to all CSS class names by prepending the class name with the control's template ID. This will prevent your control and its styles from conflicting with other controls in the client.

Flexbox

For advanced layout scenarios we encourage using Flexbox. Flexbox is compatible with the Extensible Control framework. Using CSS flexible boxes (Mozilla Developer Network) Please see the public Flexbox documentation for explanations and examples of the following topics:

- Responsive layouts
- Building columns and rows
- Arranging elements horizontally or vertically
- Arranging nesting elements
- Auto-sizing elements to stretch and shrink
- Locking/Freezing elements
- Building scrollable elements

Control extensibility

2/18/2021 • 2 minutes to read • Edit Online

This article describes the architecture that lets developers extend the user interface and also define new user interface patterns.

You can extend the existing application user interface (UI) and can also define entirely new UI patterns to create compelling new user experiences. By using modern tools such as HTML5, CSS3, and jQuery, developers can define customized visualizations of business data and drastically enhance the program's interaction patterns.

Server-side architecture

The Control Extensibility Framework takes advantage of the existing and familiar X++ language for developing server-side data access and business logic. There are no artificial restrictions on the code that developers write to build extensible controls. Instead, developers can declaratively define the modeling experience and the run-time behavior through a set of X++ class and method attributes. A developer defines one class for the design-time behavior (the X++ Build Class) and one class for the run-time behavior (the X++ RunTime class).

- In the X++ Build Class, attributes enable the definition of design-time behaviors such as custom properties in the property sheet, the addition of child controls, and extra modeling components.
- In the X++ Runtime Class, attributes are used to define the run-time properties and commands that the extensible control will access from the client. The X++ Runtime Class consumes the X++ Build Class to initialize the run-time properties, based on the values and data bindings that are specified in the property sheet.

Client-side architecture

The client-side behavior for the control is defined by using HTML and JavaScript. In the context of a Model-View-ViewModel architecture, the HTML for the control is the View, and the JavaScript is the viewmodel. The Control Extensibility Framework provides an HTML-based binding syntax that enables elements in the HTML View to be bound to data fields and properties in the JavaScript viewmodel. In addition, the framework enables visualization behavior to be defined based on conditional expressions or logical evaluations that can react to changes in viewmodel properties or business data. The JavaScript viewmodel is automatically generated at run time, based on the properties and commands that are defined in the X++ runtime for the control. This automatically generated viewmodel lets a developer define an HTML View that consumes the properties and commands that are defined in X++. If a developer wants additional client-side properties and commands, or wants to implement visualization behavior that can't be declaratively defined in the HTML View, the developer can extend the automatically generated viewmodel. The developer can take advantage of the JavaScript framework in conjunction with the powerful jQuery library.

Control extensibility architecture overview

The following diagram shows the artifacts that are involved and their relation to each other.

Create localizable labels

2/18/2021 • 5 minutes to read • Edit Online

This article explains how to create localizable labels for client components and HTML/JavaScript controls.

This article details the process for creating **localizable** labels for client components and HTML/JavaScript controls. This process uses the existing localization tools and process for labels to bring localization support to client components and HTML/JavaScript controls. The following process relies on the label resource controller that can serialize label files into their JavaScript equivalents so that the labels can be used by the client components and HTML/JavaScript controls. The label resource controller is deployed automatically. It is an MVC service that is located at the /Resources/Labels endpoint.

1. Create a label file

Use the developer tools to create a new label file for your control's area, or use an existing label file for your control's area. A control's area is determined by the owning team.

- For extensible controls, your goal should be to create one label file for each HTM resource file. If multiple HTM resources share the same set of labels, only one label file should be required for the set of HTM resource files.
- For client controls and components, in general, controls that share a lot of the same functionality (for example, the Input controls: StringEdit, ComboBox, CheckBox, and so on) should also share the same label file.

Don't use a label file that also contains labels that are only used in X++. The whole label file is serialized when it's loaded by the client, so be sure to keep the labels that aren't required by the client components/controls in a separate label file.

2. Add label strings to the label file

Use the developer tools to add label strings to the label file. **Example for extensible controls:**

- **Label file name:** ClockControl
- **Label ID:** Seconds
- **Label string:** seconds

3. Request the label file as a JavaScript file by using Resource manager

Use the script loading tag to load the JavaScript file. The loading tag should reference the label file from /Resources/Labels, because the label resource controller is located there. **Note:** For extensible controls, the controller automatically appends the label file name to the beginning of the label identifier in JavaScript.

```
<script src="/Resources/Labels/ClockControl.js"></script>
```

The JavaScript file that is returned will contain code that resembles the following example.

```
Globalize.addCultureInfo("en-us", {
    messages: {
        ClockControl_Seconds: "seconds"
    }
});
```

The culture information is injected automatically, based on the current user's culture. No action is required on the part of the control to set, modify, or read the user's culture. The preceding code adds each of your label strings to the jQuery Globalize label storage. You can then reference your labels throughout your HTML and JavaScript. The JavaScript code in the script file is run the moment that the file is loaded by the browser. Therefore, your labels are immediately ready for use. Be sure to add the label script loading tag **after** any other script loading tags in your HTML. The script loading tags are processed in order, from top to bottom. By loading the label script last, you help guarantee that no other scripts cause conflicts or override the labels that are set in the script label file.

4. Use localizable labels in HTML and JavaScript

The following framework application programming interface (API) can be used in HTML (inside **data-dyn-bind**) or in JavaScript to access the labels. **HTML**

```
<!-- Example of using a localizable label with a Label Control. Supply the label to the "Text" property on
the control -->
<div data-dyn-role="Label" data-dyn-bind="Text: $dyn.label('ClockControl_Seconds')"></div>
<!-- Example of using a localizable label with a basic HTML element. Supply the label to the "text" binding
handler for the element -->
<div data-dyn-bind="text: $dyn.label('ClockControl_Seconds')"></div>
```

JavaScript

```
/* Example of using a localizable label in JavaScript. */
var string mylabel = $dyn.label('ClockControl_Seconds');
```

You can also pass the label ID via a variable in HTML or JavaScript. **HTML**

```
<div data-dyn-bind="text: $dyn.label($data.SecondsLabel)"></div>
```

JavaScript

```
var string mylabel = $dyn.label(self.SecondsLabel);
```

The **$dyn.label** API will find the appropriately named label and return the string that can be used to display text to the user. This API will automatically select the label, based on the current user's culture.

Troubleshooting

If you have correctly created a label file, and the label has been deployed, you should be able to load the JavaScript version of the label file directly from the browser. You can access the JavaScript label file by navigating to the home page in the client and appending the following path to the URL: **/Resources/Labels/MyLabelFile.js**, where **MyLabelFile** is the name of the label file without the language suffix. For a deployed label file that is named MyLabelFile.en-us, follow these steps:

1. Navigate to the home page, and sign in. (On one-box deployments, the URL of the home page is `https://usncax1aos.cloud.onebox.dynamics.com/en/`.)

2. Make sure that the desired language has been set by going to **Options** > **Language and Region**. (You don't have to change the language if it's already set to the language that you want.) Now that the user's language has been set in the current session, the label resource controller will know what language to use when the label file is loaded.
3. To load the JavaScript version of the label file, navigate to the label file by adding **Resources/Labels/MyLabelFile.js** to the URL. (On one-box deployments, the whole URL is `https://usncax1aos.cloud.onebox.dynamics.com/en/Resources/Labels/MyLabelFile.js`.)
4. The corresponding label file will be JSON-serialized, and the browser will either show the text on the current tab or prompt you to download the .js file. If you download the file, you can then open it locally to inspect it.

If the browser doesn't find the file, you might have mistyped the name of the label, or you might not have deployed the label correctly. There is never a physical .js file for the label in the web folder /Resources/Labels. The .js file is dynamically generated by the label resource controller.

Microsoft Visual Studio form previewer

The form previewer isn't currently configured to load labels via the label resource controller. The form previewer will load only labels that are defined directly in the .js file for the code behind (located at /Resources/Scripts). Until the form previewer is updated so that it can load .js files from the label resource controller, make sure that you also define the labels in the .js file for the code behind of the control. The dependency on these labels will be removed in a future update.

Extensible control layout guidelines

2/18/2021 • 2 minutes to read • Edit Online

This article provides guidelines that you should follow when you specify the layout and sizing of extensible controls.

Dos and don'ts for achieving the desired layout

- Don't use the layout classes on your control directly. (For example, **layout-container** and **layout-horizontal** are classes that you might see on controls in the DOM.) Instead, use the layout binding handlers to apply these classes. Internet Explorer uses a different layout framework, and to add some inline styles to elements, this framework requires the extra binding information that the handlers provide. Therefore, make sure that the classes are **not** hard-coded into the controls.
- Don't use absolute positioning (**position: absolute** and **top/bottom/left/right** positions) for elements that are children of a container that uses the layout binding handler. Absolute positioning of these elements prevents the CSS classes that are applied from laying things out correctly.
- Be careful about using **width: 100%** and **height: 100%**. These settings might not always work when they are combined with our layout CSS classes. If you want filling behavior, it's a good idea to use the **$dyn.layout.Size.available** option of the sizing binding handler instead.

Layout binding handlers

Layout

Used to apply **ArrangeMethod** and **Columns** attributes to containers Options: **arrangeMethod**, **Columns**, **Children**

ArrangeMethod

- $dyn.layout.ArrangeMethod.vertical
- $dyn.layout.ArrangeMethod.horizontalLeft
- $dyn.layout.ArrangeMethod.horizontalWrap
- $dyn.layout.ArrangeMethod.horizontalRight
- $dyn.layout.ArrangeMethod.none (No layout CSS classes should be applied to the element.)

Columns

- **$dyn.layout.Columns.fill** – Use this constant. Depending on the control, either "fill" and "balanced" columns are used.
- **$dyn.layout.Columns.fixed** – Use a fixed value, such as **1**, **2**, or **3**.

Children

- Use **$data.Children** if the content handlers (append, replace) will be used to append children through this container. It should be used only if this control is a container.

Example usage:

```
<div data-dyn-bind="layout: { arrangeMethod: $dyn.layout.ArrangeMethod.vertical, columns: '1' }"> </div>
```

Sizing

Height/width

- **$dyn.layout.Size.available (SizeToAvailable)** – Fill the available space in that direction.

- **$dyn.layout.Size.content (SizeToContent)** – Size to the contents in that direction.
- **$dyn.layout.Size.fixed (Manual)** – A fixed pixel value.

Example usage:

```
<div data-dyn-bind="sizing: { height: $dyn.layout.Size.available, width: $dyn.layout.Size.content }"> </div>
```

Things to note about the sizing binding handler:

- When you use the sizing binding handler in combination with the **SizeToAvailable** option (**$dyn.layout.Size.available**), the layout binding handler must be used on the parent ** **/DOM element. This is how we know which axis to fill along (horizontal or vertical).

Should you use layout/sizing handlers or set the properties directly?

- If your extensible control inherits from a client control (such as Group or PivotItem), you won't use the binding handlers directly on the ** ** that is associated with that control, because the binding is already there. However, you might have to set the properties as you want them directly in the **data-dyn-bind** attribute.

Example:

```
<div data-dyn-role="Group" data-dyn-bind="ArrangeMethod: $dyn.layout.ArrangeMethod.vertical, Columns:
$dyn.layout.Columns.fill, Height: $dyn.layout.Size.available"></div>
```

FAQ

Is my control being laid out as expected?

A good way to tell is to inspect the element and look for the desired classes.

- Layout classes to look for, depending on the options applied:
  - layout-container
  - layout-vertical
  - layout-horizontal
- Sizing classes to look for:
  - For **$dyn.layout.Size.available**, you should see either **fill-width** or **fill-height**.
  - For manual size, you should see either **fixed-height** or **fixed-width**.
  - For **$dyn.layout.Size.content**, there should be no extra classes, and the manual height/width should be specified inline on the element.

If these classes don't appear as you expected, examine the usage of your binding handlers, and make sure that you've read through the list of dos and don'ts on this page.

Control the text that Task Recorder generates for a control

2/18/2021 • 4 minutes to read • Edit Online

This article describes how Task recorder determines what instruction label to generate for controls. It then explains how you can make sure that these labels are meaningful for the user.

Every control must have useful and meaningful instruction labels, so that the task guide, Microsoft Word document, and Help content meet Content Publishing standards for readability. We must first define two terms:

- **Control label** – The value that comes from the label property on the control.
- **Instruction label** – The label that a control instructs Task recorder to use when it's describing how to use that control (for example, "Click OK" or "In the First name field, enter 'John'").

When a control logs an event to Task recorder, three methods can be used to determine the instruction label that is shown to the user:

- As part of logging the Task recorder event, the control might specify an exact instruction label ID to use. As a best practice, here is how label IDs should be named: [client control type name]_[property or command name] For manual specification of an instruction label ID, see the code example later in this article (**OptionalInstructionLabelIDOverride**).
- If the control doesn't explicitly specify an instruction label ID, Task recorder looks in the SysTaskRecorderLabel file to try to find an existing instruction label ID that fits the following naming syntax: [client control type name]_[property or command name] If an instruction label ID of this type is found, Task recorder uses it.
- If a label can't be determined by using the preceding methods, Task recorder falls back to a more general-purpose instruction label. The general purpose instruction labels are in the SysTaskRecorder label file. There is one general-purpose instruction label for commands and another for properties.
  - Here is the general purpose instruction label for commands:
    - **Label ID:** CommandUserAction
    - **Label string:** %2 the %1
  - Here is the general purpose instruction label for properties:
    - **Label ID:** PropertySetValue
    - **Label string:** In the %1 field, enter %2

When Task recorder has determined which instruction label to use (via one of the preceding three methods), it strFormats the label by using the following arguments:

- **%1** – This argument is the control label. Task recorder gets the control label by inspecting the label on the intractable. However, a control can override this label and provide its own label. See the code example later in this article (**OptionalControlLabelOverride**).
- **%2** – This argument is either the value (for properties) or the command name (for commands). This value will be the value that the control sent to Task recorder as part of logging the event. However, the raw data value can be ugly or meaningless to an end user. Therefore, a control can also provide a more user-friendly version of the value that Task recorder can display instead of the raw data value. See the code example later in this article (**OptionalValueLabelOverride**).
- **%3–%5** – These are command arguments and are used rarely. However, grids use them to record the row number, for example.

Case study

Let's use the Checkbox control as a case study for improvement. Currently, an instruction label isn't specified for the Checkbox via either method 1 or method 2 (see the previous section of this article). Therefore, the general-purpose property instruction label is used instead. If someone records selecting the Checkbox for a field that is named **Show infolog on failure**, the Task recorder output currently looks like this:

> In the Show infolog on failure field, enter True.

However, typical end users might not know what it means to set a Checkbox to **True**. Therefore, a suggested improvement is for the Checkbox to produce a label that looks like this:

> Check Show infolog on failure.

To make this improvement, someone must add a new label ID. That user must then use the label ID when the event is logged to Task recorder by using method 1:

- **Label ID:** Checkbox_Value
- **Label string:** "%2 %1."

This change produces output that looks like this:

> True Show infolog on failure.

This isn't quite what we want to see. Therefore, in addition, when the Checkbox logs the property change event to Task recorder, it should pass in a specific *value label* that says either "Check" or "Uncheck." If the control explicitly specifies a value label, Task recorder will use that value label instead of the raw data value that was recorded (**True** or **False**, in this case). See the code example later in this article (**OptionalValueLabelOverride**). After the user creates the new label and specifies the value label when the event is logged to Task recorder, the control will have suitable text output:

> Check Show infolog on failure.

Finally, the Checkbox should have a second instruction label for "example value" usage of the Checkbox. "Example value" represents a special way that Task recorder displays an instruction label to the user. The author of the task recording can specify whether the task guide should instruct users to enter the same values that were entered when the guide was recorded, or whether the task guide should instruct users to enter their own values that are specific to their business requirements. Example value instruction labels have the following label ID syntax: [client control type name]_[property name]_Example For the Checkbox example, the value label would look like this:

- **Label ID:** Checkbox_Value_Example
- **Label string:** "Check or uncheck the %1 field."

The following code example shows how property change events are logged to Task recorder by an X++ control. Similar application programming interfaces (APIs) exist for C++ kernel controls. Command events have a similar API.

```
[FormPropertyAttribute(FormPropertyKind::Value, #MyPropertyName)]
    public str value(str_value = valueProperty.parmValue())
    {
        if(!prmIsDefault(_value))
        {
            using (var scope = SysTaskRecorder::addPropertyUserAction(#MyPropertyName, this, _value,
[OptionalInstructionLabelIDOverride], [OptionalValueLabelOverride], [OptionalControlLabelOverride]))
            {
                // Property set logic goes here
                valueProperty.setValueOrBinding(_value);
            }
        }
    }
```

Build operational workspaces

2/18/2021 • 6 minutes to read • Edit Online

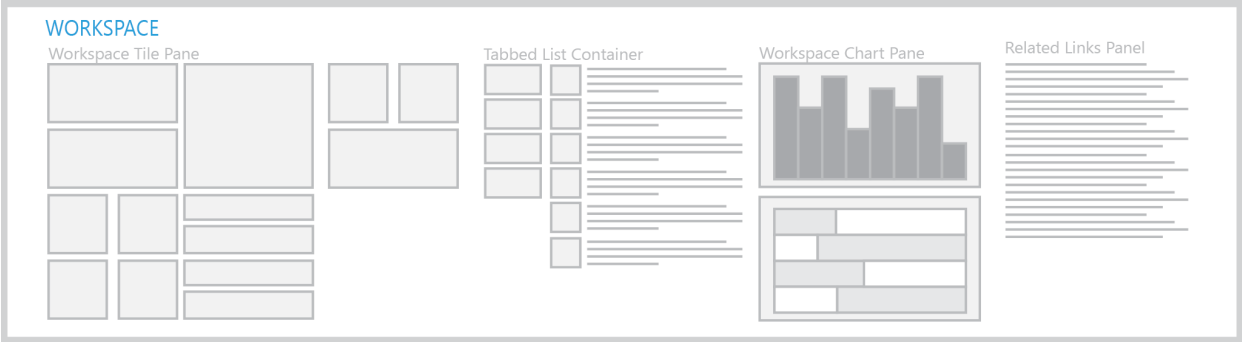
This topic provides detailed information about workspaces and the patterns and subpatterns that are used to build operational workspaces.

A workspace is defined as...

- Part of the primary navigation mechanism.
- A form that supports a business activity (a logical group of tasks that make up the work of a target persona).
- A way to provide an initial overview and to increase productivity in the activity by allowing simple tasks to be completed directly in the workspace.

Workspaces have the following goals...

- Enable the user to understand the current state of the activity to support informed decisions.
- Let users navigate to deeper pages by selecting data, which avoids round-trips to pages with no information.
- Let users perform light tasks in the workspaces to avoid round-trips to deeper pages.
- Complete an activity without leaving the workspace.
- Reduce the need for navigation.
- Provide visual impact.
- Be constructed using prescriptive patterns and best practices that lead to minimal COGS and fast response times.



To accomplish these goals, the operation workspace pattern was developed.

Examples

An example of a workspace is the **Reservation management** workspace in **Fleet management**. You can get to it by accessing the menu item **FMClerkWorkspace**. The workspace, shown above, has the following items:

- **Summary** - Contains tiles and a chart.
- **Rentals** - Contains a vertical tab control having three pages - the first is selected, and you can see the corresponding content on the rightmost side.
- **Statistics** - Contains stacked charts.
- **Related links** - Contains a series of grouped menu item links to forms of relevance to this user and activity.

The overall form, as well as each of the sections within, are defined using UX patterns and subpatterns. The corresponding patterns are described in detail in the following sections.

Patterns and subpatterns

When building an operational workspace, you must use the patterns and subpatterns defined for that purpose. These patterns and subpatterns are described below. In general, when a control is cited within a pattern's structure, it will be described as: Common name (ControlType) [cardinality] If cardinality isn't specified, then the item is required exactly once. Simple patterns and subpatterns have the structural tree omitted.

Patterns

There are the top-level patterns for use with operational workspaces.

Workspace Operational

This pattern is the primary operational workspace pattern and should be applied to the **Design** node of the operational workspace form. It will prescribe the following structure:

- Design
  - ActionPane (ActionPane) [0..*]
  - Workspace Page Filter Group (Group) [0..1]
    - Subpattern: Workspace Page Filter Group
  - Panorama (Tab)
    - Section Summary Tiles (TabPage)
      - Subpattern: Section tiles
    - Section Tabbed List (TabPage)
      - Subpattern: Section Tabbed List
    - Section Charts (TabPage) [0..1]
      - Subpattern: Section Stacked Chart
    - Section-Related Links (TabPage)
      - Subpattern: Section-Related Links

Form Part Section List

This pattern is used for **Form Part** forms containing a list. These lists are referenced within the Section Tabbed List TabPage in the Workspace Operational pattern.

- Design
  - Header Group (Group) [0..1]
    - Subpattern: Filters and toolbar - Inline OR Subpattern: Filters and Toolbar - Stacked
  - Content Grid (Grid)
  - Default Action Button ($Button - any type of button) [0..1]
  - See All Menu Item (MenuFunctionButton) [0..1]

Hub Part Chart

This pattern is used for **Form Part** forms containing a chart control. These chart forms are referenced within two subpatterns: Section Tiles and Section Stacked Chart. It requires exactly one Chart control.

Subpatterns

Workspace Page Filter Group

This subpattern is referenced in the pattern Workspace Operational, in Workspace Page Filter Group. It allows for a single input control, which can be used to filter the workspace as a whole.

Section Tiles

This subpattern is referenced in the pattern Workspace Operational, in Section Summary tiles. It allows for both tiles and charts. Any number of tiles and charts can be defined, in any order. Tiles are defined with TileButton controls, and charts are defined with Form Part controls. A chart Form Part must have dimensions that match those of a normal tile, to ensure the chart flows correctly with the tiles displayed.

Section Tabbed List

This subpattern is referenced in the pattern Workspace Operational, in Section Tabbed List. It allows for multiple list containers to be modeled, each of which ultimately references a Form Part that points to a form containing the desired list. It requires the following structure:

- Tabbed List (Tab)
  - Tabbed List Page (TabPage) [0..*]
    - Form Part Section List (FormPartControl). **Note**: The referenced form must use the form pattern, Form Part Section List.

Section Stacked Chart

This subpattern is referenced in the pattern Workspace Operational, in Section Stacked Chart. It allows for up to two charts, which will be rendered in a vertically stacked orientation. It requires the following structure:

- Tab page (TabPage)
  - First Chart FormPart (FormPartControl) [0..1]
  - Second Chart FormPart (FormPartControl) [0..1]

Section-Related Links

This subpattern is referenced in the pattern Workspace Operational, in Section-Related Links. It allows for a series of links, with one level of nesting permitted. It requires the following structure:

- Tab page (TabPage)
  - Menu Function Button (MenuFunctionButton) [0..*]
  - Links Group (Group) [0..*]
    - Menu Function Button (MenuFunctionButton) [1..*]

Filters and Toolbar – Inline

This subpattern is referenced in the pattern Form Part Section List, in Header Group. It allows for some filters and a toolbar, all on the same line. It requires the following structure:

- Group (Group)
  - Filter Group (Group) [0..1]
    - Quick Filter (QuickFilterControl) [0..1]
    - Custom Filter Fields ($Field – any type of field) [0..*]
  - Toolbar (ActionPane) [0..1]

Filters and Toolbar - Stacked

This subpattern is referenced in the pattern Form Part Section List, in the Header Group. It allows for some filter fields on one line, and a toolbar on a line below those filters. It requires the following structure:

- Group (Group)
  - Filter Group (Group) [0..1]
    - Quick Filter (QuickFilterControl) [0..1]
    - Filter Field 1 ($Field - any type of field) [0..1]
    - Filter Field 2 ($Field - any type of field) [0..1]
  - Toolbar (ActionPane) [0..1]

Future best practices check

There are a few best practice (BP) checks that will eventually be built for workspaces. These checks are intended to provide guidance to the user about items that are recommended for performance or design reasons.

Filters are covered by indexes

This check is intended to ensure that any field that is modeled for use as a field on a workspace-wide filter is covered by an index. This check will help ensure that performance remains superior when users are taking

advantage of these filters.

Chart parts only contain OLAP charts

When a workspace contains a chart, that chart is modeled as a separate form, and that form is referenced on the workspace via a Form Part control. The intent of this check is to ensure that any such charts ultimately referenced from a workspace are only using OLAP data.

Count tiles have queries defined

A tile caching system has been implemented to improve performance of workspaces, as these forms generally contain several count tiles. For these count tiles to work correctly with the caching system, each tile must have a query defined. That query may be defined on the tile or on the menu item referenced by the tile. The intent of this BP check is to ensure a query is defined in one of these two locations for all count tiles.

Tile and list caching for workspaces

2/18/2021 • 10 minutes to read • Edit Online

It's important that workspaces perform well, and that they be responsive (that is, the data that appears in a workspace is refreshed as expected and kept up to date). This topic discusses framework support for caching data that is used for tiles and lists.

Introduction

Workspaces are intended to be the hub of activity for most users. They display a wealth of information that is collected from various sources. Therefore, you must make sure that workspaces perform well and are responsive (that is, the data shown in the workspace is refreshed as expected and/or kept up to date). Caching can help guarantee great workspace performance when data comes from poorly performing queries, and is especially useful when multiple users require access to the same set of data at the same time. For example, if a grid on a form uses a complex (that is, low-performing) query, you can cache the results so that they are available for subsequent loads of the form. This article discusses framework support for caching data that is used for tiles and lists. In terms of a responsive workspace, when users navigate to a workspace (or return to it), they expect that the data in the workspace will be relatively up to date. For example, if a user takes an action that changes the data for a list or tile in a workspace, the workspace should reflect that change immediately after the action is performed (if the action was taken directly from the workspace) or when the user returns to the workspace form (if the action was taken on a different form). This article describes techniques for making sure that this type of data refresh occurs (both metadata and code) for both tiles and lists.

Count tiles

Automatic data caching

The framework automatically sets up data caching behind any defined count tile. Therefore, no extra code is required in this case. A **Refresh Frequency** metadata property on Tiles determines how often the count on the tile is automatically updated. The following table describes the options and guidance for this property.

VALUE	WHEN TO USE
As Fast As Permissible (5 seconds)	Query execution time is 25 ms or less, and there is demand to see the updated value all the time.
10 Minutes	Query execution time is less than 250 ms, and updated data must be seen periodically
24 Hours	Query execution time is less than 2000 ms, and/or the count isn't expected to change often or up-to-date counts are vital.

Refresh management

Count tiles that show values that represent pending work should be fairly responsive. Ideally, the fastest possible refresh frequency should be defined for these tiles, so that the count that appears on a workspace tile is always within five seconds of being up to date. Because this quick refresh rate should be set only on performant queries (queries that have an execution time of less than 25 ms), the first recommendation is that you work on query performance for count tiles, to try to get query execution under the 25-ms threshold. In general, achieving this execution speed requires two things:

- A selective WHERE condition on the query Preferably, the conditions on the query should reduce the result

set to fewer than ~500 records, and ideally to fewer than ~100 rows.
- An index structure that can act on the selective WHERE condition

See the "Common mistakes and tips for query optimization" section for details about how to evaluate and improve query performance to achieve these execution speeds. For tiles that have backing queries and can't meet the 25-ms execution speed threshold, the refresh frequency on the tile should be set to one of the lower values (for example, 10 minutes or 24 hours). If the values must be updated more frequently for tiles that have less-efficient queries (which should be rare), you can add the following code to manually refresh the cache when an action is taken that will affect the cached set.

```
TileDataService::forceRefresh(tilestr(<tileName>), formRun)
```

An example of a data set that might not change often is products that have no configuration. A tile that shows this count might have a refresh frequency of 10 minutes. However, the tile count might still appear responsive if the products form is instrumented to force-refresh the data cache when a configuration is defined for a product that previously had no configuration.

Workspace lists

Although the framework automatically sets up data caches for count tiles, manual setup is required for lists that must use data caching. Here are the high-level steps for introducing cached data for a list:

1. Create a query that references all the columns that you want in the cached data set.
2. Create a table that contains all the fields that you want to cache.
3. Create a class that defines a mapping between the cache query and cache table.
4. Add/reference the cached table as a data source on your form.

Each of these steps is described in detail in the following sections and is paired with an example from the Fleet workspace (Reservation Management).

Cache query

First, you must create a query that will be used to populate the cache table. This query should have the following characteristics:

- It should be against the tables that you want to get your cache data from.
- It should limit the results to the results that you're actually interested in.
- It should select only the fields that you want to cache. **Note:** Each data source should have **DynamicFields**=**No** to avoid extraneous fields.

Cache table

Next, you must define a table that contains a set of fields that match the fields from the cache query. In addition to those fields, you must also add a field that is named **SysDataCacheContextId** (Int64). This field is used to map the cache row to the base cache tables. You'll define a mapping on the table, between the SysDataSetCacheTableMap table's **Id** and **SysDataCacheContextId** fields and the cache table's **RecId** and **SysDataCacheContextId** fields, respectively. You can also define relations between this table and others, in addition to data methods that use the cached fields.

Cache class

The third step is to create a class that defines the relationship between the cache query and the cache table. This class requires that a few attributes be defined, and it must also extend and implement the appropriate framework data caching classes. The following code shows the corresponding class from the Reservation Management workspace.

```
[SysDataSetExtension(classStr(FMPickupAndReturn)), // The name of this class
SysDataSetCacheTableExtension(tableStr(FMPickupAndReturnCache))] // The name of the cache table
class FMPickupAndReturn extends SysDataSetQuery implements SysIDataSet
{
    public SysDataCacheRefreshFrequency parmRefreshFrequency()
    {
        return 600; // Cache refresh frequency, in seconds.
    }
    public SysQueryableIdentifier parmQueryableIdentifier()
    {
        return queryStr(FMPickupAndReturnQuery); // The name of the query.
    }
    public SysDataCacheTypeId parmCacheTypeId()
    {
        return tableNum(FMPickupAndReturnCache); // The name of the table.
    }
    public static FMPickupAndReturn construct()
    {
        return new FMPickupAndReturn();
    }
}
```

In some circumstances, you might also have to implement the **parmQueryableToCacheMapping()** method. This method is required when at least one column name in your cache table doesn't match the name of the corresponding column in the backing table (for example, if you must add two fields that have the same name but are from different tables). In this case, you can implement this method to define the column mapping between the cache table and the backing tables. The syntax is the same as the syntax for the **Query::Insert_RecordSet()** method (https://msdn.microsoft.com/library/query.insert_recordset.aspx).

```
public Map parmQueryableToCacheMapping()
{
    Map sourceToTargetMap = super();
    return sourceToTargetMap;
}
```

Form implementation

After you've built your cache query, table, and class, you're ready to use the cache on your form. Add the cache table to your form as a data source, and reference it just as you would reference any other data source. In order for the form to correctly take advantage of caching, some code is required.

1. In a **registerDatasourceOnQueryingEvent()** method, add an event handler to the data source's **OnQueryExecuting** event that calls **prepareDataSet**,. This requires that the form class implement **SysIDataSetConsumerForm**.
2. If you want the form to use filtering, as provided by a workspace-wide filter, in a **registerDatasourceOnQueryingEvent()** method, register **applyFilter** on the **OnQueryExecuting** event. This requires that the form class implement **SysIFilterConsumerForm**.
3. If the form must react when a parent form's filters change (for example, a workspace-wide filter), implement **SysIFilterEventHandler** on the form class, and include an **onFilterChanged()** method that calls **executeQuery()** on the cache data source.

The following code is an example from the **FMPickingUpTodayPart** form, which is one of the tabbed lists on the Reservation Management workspace.

```
[Form]public class FMPickingUpTodayPart extends FormRun
implements SysIFilterConsumerForm, SysIDataSetConsumerForm, SysIFilterEventHandler
{
    public void registerDatasourceOnQueryingEvent()
    {
        FMPickupAndReturnCache_DS.OnQueryExecuting +=
eventhandler(this.parmDataSetFormQueryEventHandler().prepareDataSet);
        FMPickupAndReturnCache_DS.OnQueryExecuting
+=eventhandler(this.parmFilterFormQueryEventHandler().applyFilter);
    }
    public void onFilterChanged()
    {
        FMPickupAndReturnCache_DS.executeQuery();
    }
}
```

Additional examples

In addition to the previous examples, you can refer to **SysFoundationTestOpenHeaderDataset**, which is used on **SysFoundationTestOpenHeadersFormPart** (which is itself referenced in **SysFoundationTestWorkspace**). This form uses the same method that is described earlier, but also includes some caching of a query aggregate count.

Refresh management

Lists of data in workspaces should also be responsive to user actions, especially if those actions cause records to no longer meet the criteria for appearing in the list. For example, you have a list of car rentals that are scheduled to start today. Every time that an employee initiates a rental record from that list with a customer, that record should no longer appear in the workspace list. Two mechanisms are available for keeping this list up to date:

- If the user takes an action that removes the record from the list, code can be added to guarantee that the list is immediately updated by refreshing the data source. If the data source is a cache data source, and the refresh frequency is slow, you might want to delete the corresponding records from the cache data source before you call **refresh**, to avoid having to force-refresh the cache.
- If the first option doesn't meet your requirements, you can asynchronously refresh form parts at a time interval. This option can be set up by using the **AutoRefreshInterval** property on the FormPart control.
    - For workspaces that have user interaction, the cache refresh frequency should be set based on query performance. In this case, the current recommendation is to not set the **AutoRefreshInterval**. Instead, rely on the user to manually refresh the workspace to bring in more data. Alternatively, you consider using an infrequent auto-refresh. However, in this case, the user's current selection will not be retained if the list is updated while the user is interacting with it.
    - A small percentage of workspaces are intended for viewing purposes only (no user interaction). These workspaces should use set the **AutoRefreshInterval** property programmatically to match the current refresh frequency of the backing cache. (Use **SysIDataCacheConfiguration.parmRefreshFrequency()** to retrieve the current refresh frequency of a cache, because it can be modified by the system administrator at run time.)
    - FormParts that have Charts should set the **AutoRefreshInterval** property to periodically show updated chart data.

Common mistakes and tips for query optimization

Here a few general guidelines to consider when you optimize queries. This isn't an extensive guide to query optimization but provides just a few simple guiding principles.

- **Trace the statement by using SQL Profiler.** Attach the Microsoft SQL Server Profiler to the database, and capture the SQL statement that you want to optimize. You can use the tuning template that is provided in a default installation. Don't forget to disable tracing after you've obtained the statement that you're interested

in. For more information, see https://msdn.microsoft.com/library/ms175047.aspx.

- **Always look at the query plan.** In Microsoft SQL Server Management Studio, make sure that you've enabled **Include actual Execution Plan**. Look at the query plan, and watch out for any warnings. The thickness of the arrows indicate how many rows have been fetched and brought to the next step.
- **Compare CPU milliseconds and logical I/O.** One good way to determine whether a change to a given SQL statement improved the statement is to look at the logical I/O and CPU milliseconds. To obtain these numbers, use the following statements in the query editor:
  - set statistics time on
  - set statistics io on
- **Always clear caches when you measure a statement.** To make sure that Microsoft SQL Server isn't using a cached execution plan, it's advisable that you flush the cache when you rerun a statement. To flush the cache, run the following two commands:
  - dbcc dropCleanBuffers
  - dbcc freeProcCache
- **Here are some common patterns to watch out for:**
  - **Missing index:** Analyze your WHERE conditions, and make sure that a selective index exists.
  - **Processing the same table/row many times:** Especially when you do joins, try not to repeat yourself. Minimize the number of times that the same table/row must be processed. If you have tables that must be part of the result set but aren't used to narrow down the result set, move them as far out as possible (especially in union queries).
- **Test on volume data.** To identify issues in your query, always run it on volume data.

Task recorder resources

2/18/2021 • 33 minutes to read • Edit Online

This topic describes how to use Task recorder to record business processes.

Overview

Task recorder

Task recorder for Finance and Operations apps is a utility that lets users record business processes for several different use cases. Here are some examples:

- Step-by-step guided tours of a specific business process in the application itself
- Documentation of a business process as a Microsoft Word document that can optionally include screenshots
- Regression tests for a business process
- Automatic playback of a business process in the application

Task recorder for Finance and Operations apps boasts high responsiveness, a flexible extensibility application programming interface (API), and seamless integration with consumers of business process recordings. Task recorder is also integrated with the Business process modeler (BPM) tool in Microsoft Dynamics Lifecycle Services (LCS), so that users can continue to organize their recordings. However, users can no longer produce business process diagrams from recordings.

Task recorder can automatically generate application regression tests from business process recordings and play back previously recorded processes. These features also include test-specific gestures that let users take full advantage of Task recorder.

Architecture

Task recorder can record user actions in the client with exact fidelity, because every control is instrumented to notify Task recorder about the execution of user actions. The control notifies Task recorder that an event has occurred and passes all the relevant information about the corresponding user action in real time. From this information, Task recorder can capture the type of user action (for example, a button click, value entry, or navigation) and any data that is related to the user action (for example, the input data value and type, form context, or record context). Task recorder persists the information with enough detail to ensure that a playback of the recording can run the recorded actions exactly as they were performed by the user.

Basic configuration

Task recorder is included with every Finance and Operations app, and lets users begin to record business processes immediately after they open the client for the first time.

> **IMPORTANT**
>
> The **Task guides** tab is currently not available in Commerce or Human Resources. We are currently working to enable this functionality in a future release. Task guides in the Getting Started experience in Human Resources remain available to cover basic functionality. Procedural help is also available on the docs.microsoft.com site (https://docs.microsoft.com/dynamics365/) for both Commerce and Human Resources.

Start a new recording

The following steps show how to use Task recorder to start a new recording.

1. Open the product, and sign in. It's a good practice to refresh the browser before each new recording. A refresh creates a new user session and restarts Task recorder. Therefore, it provides the most stable recording experience.

2. Select the company that you want to use while recording. If this is your first time using Task recorder, you can follow along as this tutorial creates a sample recording based on a Fleet Management business process. You will need to load the Fleet demo data to follow along:

   a. Go to **Dashboard > Fleet Management > Fleet setup**.
   b. Click **Load demo data**.
   c. When the data is finished loading, click **Close**.
   d. Go back to the **Dashboard** by clicking the product name in the navigation bar.

3. Go to **Settings > Task recorder**.

4. The **Task recorder** pane is opened. You can click the **Close** button (**X**) in the upper-right corner to close the **Task recorder** pane before you begin a new recording. You can reopen the pane by following the previous steps.

5. Click **Create recording**.

6. Enter a name for the recording and click **Start**. Recording begins the moment **Start** is clicked. For the Fleet example in this tutorial, we'll use the name "Create a new rental reservation."

   While you're recording, you can click the **Close** button (**X**) in the upper-right corner to hide the **Task recorder** pane without stopping the recording. You can reopen the pane by clicking the **Task recorder** button that appears at the top of the page. This button appears only while recording is in progress.

   > **NOTE**
   > If the Saved views feature is turned on, recordings should be created by using either published views or the standard view, to ensure that recordings work reliably for users.

7. Task recorder enters **recording mode**. The pane shows information and controls that are related to the process of recording.

Now you're ready to record a business process using Task recorder. If you're following this guide as a first-time user, you may complete the following Fleet Management scenario as an example. Otherwise, you can record your own application scenario.

Record a Fleet Management scenario

1. In the **Task recorder** pane, click **Start sub-task**.
2. Set **Name** to "Create a new rental customer". Leave the **Comment** field blank.
3. Click **OK**. The task is added to the step list.
4. Go to **Dashboard > Fleet Management > Reservation Management**.
5. Go to **All customers** under the **Summary** tab.
6. In the Action Pane, click **New**.
7. Enter a first and last name for the customer.
8. Click **Save**.
9. In the **Task recorder** pane, click **End sub-task**.
10. Return to the **Reservation Management** workspace by clicking the browser back button twice.
11. In the **Task recorder** pane, click **Start sub-task**. Name the task "Rent a vehicle to the new customer". Click **OK**.
12. Click (**+**) **Rental** under **Summary**.

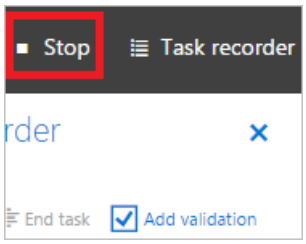
13. Under **Information**, select a "1975 Litware McKinley" as the vehicle.
14. Under **Information**, set the customer to the one just created.
15. Expand the **Discounts** section.
16. Click **Add** under **Discounts** and add the Frequent Customer discount. Click **OK**.
17. In the Action Pane, click **Start Rental**.
18. Set the return date to some date in the future.
19. Click **OK**.
20. In the **Task recorder** pane, click **End sub-task**.
21. Click **Stop** at the very top of the page.

Recording a business process

After you've started your recording, you can perform your business process just as you would typically perform it by using the web client. As you interact with the product, new steps are added to the step list in the **Task recorder** pane. In this section, you will learn about other actions that you can perform while you're recording a business process, to take full advantage of Task recorder's capabilities.

Stop

Stop is used to end the recording session. Before you click **Stop**, you should make sure that the recording is completed, because this action isn't reversible. When you click **Stop**, you're taken to the download options screen.



Start/End sub-task

Start/End sub-task lets a user specify the beginning and end of a set of grouped steps in a recording. Click the **Start sub-task** button to add a "Sub-task" step to the end of the current list of recorded steps. The sub-task will include all steps that you perform from this point until you click the **End sub-task** button. When you click the **End sub-task** button, an "End sub-task" step is also added to the list of recorded steps.

> **NOTE**
> You must start a sub-task before you perform/record the steps that you want to include in the task. Then, after you've performed/recorded all the steps that you want to include in the task, you must end the sub-task.

Sub-tasks are purely an organization tool, and consumers of business process recordings can interpret the task groupings in useful ways. Because tasks can be nested inside other tasks, they provide the flexibility to organize very long and complex business processes.

Delete/Restore step

Delete/Restore step enables a user to remove steps from the recording, or undo the removal of a step from the recording. You must first select the step in the Steps list that you want to delete/restore, and then click the **Delete/Restore step** button.

> **NOTE**
>
> The behavior of the **Delete** button changes when you play back a recording. In playback mode, a deleted step can't be restored after playback has passed the point where it would have run the deleted step. For example, you load a recording that contains three steps, and then you delete step 2 before you start playback. You can restore step 2 only as long as playback hasn't run step 3. After you start playback, and playback has "skipped" step 2 (because you deleted it) and run step 3, you won't be able to restore step 2. Because step 2 wasn't run and therefore wasn't recorded, it can't be retroactively added back into the recording at its previous position.

Add developer placeholder

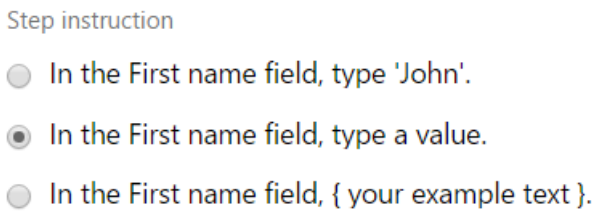
Add developer placeholder lets the user add a placeholder step to the list of recorded steps. This placeholder step doesn't appear when the task guide is viewed, and it isn't run during maintenance of a recording. It's used only by the Regression suite automation tool (RSAT) or the X++ code generator that enables an X++ test to be created from a task recording. When the code generator creates an X++ test, it automatically adds a method stub to the generated code. The developer can then add X++ code into this method stub. The automated code will call the validation when the generated test is run at the point in the recording where this placeholder was added.

Enriching steps in a recording

There are various options for enriching a step in a recording. For example, you can adjust the text that is associated with a step and add information about a specific step. This section describes the step enrichment capabilities that are available. To access these options, click the **Edit step** button on a specific step of a recording.

Step instruction

The **Step instruction** is the primary text that is displayed for this step in the task guide. There are usually 2-3 alternative options for step instructions, and they appear in the following order when editing the annotation.



This image shows the annotation options for changing a step.

- **Preferred value instruction** This type of instruction will direct the user to enter the same data that was used when the step was recorded. *Example*: In the First name field, enter 'John'.
- **Example value label** This type of instruction will direct the user to enter their own data, indicating that the data that was used when the step was recorded was only *Example* data. *Example*: In the First name field, enter a value.

  If users click the **See more** button on this step when they play the recording as a task guide, they will be able to see the data that was used when the step was recorded. This recorded data value will be labeled as an *Example* data value.

  > **NOTE**
  >
  > Steps that are not related to fields, such as clicking buttons, opening forms, or selecting records from a lookup, do not set *Example value label* as an option when annotating.

- **User-supplied value label** This step instruction contains placeholder text, which the author can fill in with their own text. For steps which have an **Example value label** option, the placeholder allows substituting the text which normally specifies the data to enter. This is useful for scenarios where neither the **Preferred value label** nor the **Example value label** sufficiently express the data that should be used for this step.

  - *Example label*: In the First name field, enter *{your example text}*.
  - *Example label after supplying the placeholder text*: In the First name field, enter the customer's name.

  For steps which do not have an **Example value label** option, the placeholder allows substituting all of the label text. Steps associated with buttons, for example, do not have **Example value labels**, so you may replace the entire label text with your own text.

  - *Example label before replacement*: Click Post.
  - *Example label after replacement*: To post the order, click Post.

Titles and notes

Titles and notes provide places for user-specified text to be associated with a step in a task guide.

- **Title** – The title lets you specify the text that appears above the step instruction for this step in the task guide. The title a good place to put text that you want users to read before they complete the action that is indicated by the step instruction.
- **Note** – You can use a note to specify text that appears in the expandable section of the pop-up for this step in the task guide. A note is a good place to put optional reading material or other information that might be useful to users, but that they aren't required to read to complete the action that is indicated by the step instruction.

Change recorded values

Starting in version 10.0.12, you can adjust the values that are recorded in basic input controls (for example, simple text, numeric, date, and picklist fields), without having to re-record those steps. Note that lookup controls and reference groups aren't currently supported.

Hide from task guide

The **Hide this step** option lets the author prevent specific steps from appearing in the task guide. This option is useful for hiding steps that are required for the task recording to run in playback mode, but that should not be seen by users. Examples of these steps include copy steps, system-generated steps, and data clean-up steps. If you hide a sub-task, all the steps that are recorded inside that sub-task will also be hidden.

Using control gestures

The basic recording capability lets a user record an end-to-end business process by using Task recorder, but without adding overhead to the process. In some circumstances, more advanced recording features can be used to create even richer business process recordings. Each of the following gestures is found under the **Task recorder** option on the shortcut menu (also known as a right-click menu or context menu) for a control and causes a step to be added to the recording. If the gesture isn't supported for a control, it won't appear on the shortcut menu for that control.

Copy

The **Copy** gesture lets you copy the value for the current control to the Task recorder "clipboard." That value can then be used later as part of a **Paste** or **Validate** gesture. Because values from multiple controls might have to be pasted, the Task recorder clipboard maintains a list of all control values that have been copied in the recording.

Paste

The **Paste** gesture lets you paste a value from a previous **Copy** gesture in the same recording. The Task recorder

paste function works like the standard paste function that users might be familiar with, but it has an additional benefit when it's used during recordings. Because Task recorder will replay the recorded **Copy** and **Paste** commands during playback, if the copied control has a different value than it had during recording, Task recorder will paste the current value instead of the value that the copied control had during recording. This feature is useful in scenarios where the copied control has a value that can change between environments (for example, recID values or number sequences).

There is an additional benefit from using the **Copy** and **Paste** gestures when test code is generated. For any control where the value is set via the **Paste** command, Task recorder doesn't have to create a parameterized input variable for that control's value, because it's set based on another control's value. This feature can be very useful in scenarios where an entity such as a customer is created, and an identifier for that entity is frequently entered during the recording. Instead of manually re-entering the customer name or ID throughout the scenario, and causing Task recorder to generate a parameterized input variable for each entry, the user can copy the customer name or ID one time, and then repeatedly paste it. In this case, Task recorder will generate a single parameterized input variable to represent the customer name or ID. This feature can make it much easier to change the input data for a generated test.

Validate

The **Validate** gesture lets you insert a step that validates the value of the targeted control. This gesture always uses equality to validate the control value. *Validations aren't currently run during recording playback.* Instead, they are run only when the generated test code is run. Two kinds of validation are available:

- **Current value validation** will capture the targeted control's value at the time of recording and use it to generate an assertion in the test code. In the list of validation options on the shortcut menu, **Current value** is always first.
- **Reference value validation** will use the value of a previously copied control when generating an assertion in the test code. This allows creating assertions that are resilient to changes in the data, since the value is not hardcoded into the test code. In the list of validation options on the shortcut menu, **Reference value validation** follows the format [AOT name of copied control: current copied value].

Additional options are available in version 10.0.13 and later. Here are some examples:

- **Enabled/Disabled** validates that the targeted control's state is enabled (or disabled), and then uses that validation step to generate an assertion in the test code.
- **Read-only/Editable** validates that the targeted control's state is read-only (or editable), and then uses that validation step to generate an assertion in the test code.

Add info step

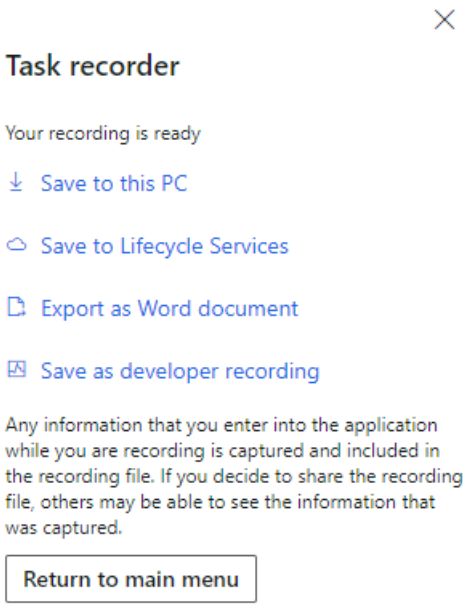
The **Add info step** gesture lets you insert a step and supply your own text for it. This feature is useful primarily for creating task guides. An **informational step** (or **info step** for short) is a task guide step where the instruction text for the step is user-specified. Info steps are useful for describing actions that are a part of the scenario but must occur outside the client. For example, a scenario might require the user to search for item inventory or check an email for information.

You can specify where an info step should appear in the task guide. The info step can point to a control on the page, if the step is associated with the control. Alternatively, the info step can appear in the upper right of the page, if the step is external to the client, or if it's an explanation that applies to the whole page.

> **NOTE**
>
> Because info steps are manually specified steps and are not automatically recorded by Task recorder when the user takes an action on a control, the info step does not have the capability to automatically progress when a user completes the step in the task guide. Because the info step is not associated with taking an action in the client, there is no action for a task guide to detect that the user has completed in order to automatically progress to the next step.

Options after a recording is completed

After you click **Stop** to end your recording session, several options are shown so that you can save the files that are related to the completed recording. Select **Save to this PC**, and save the task recording package to your desktop. You will use this file later.



Save to this PC

One option after you finish your recording is to download the task recording package (an .axtr file) to your computer. This file can be loaded later via the **Task recorder** pane, so that the recording can be played as a task guide or edited.

Save to Lifecycle Services (LCS)

When you save your recording to an LCS library, it's published on the specified business process in a BPM library. If the selected LCS library is set as a Help library, you will be able to find the task guide for the recording by searching the **Help** menu.

> **NOTE**
> To be able to save a recording to an LCS library, the user must be in the Azure Active Directory (Azure AD) tenant that the environment was deployed from.

Export as Word document

The Microsoft Word document for your recording contains the recorded steps as well as any screenshots that were captured.

Save as developer recording

The raw recording file (developer recording) is useful for developer scenarios, such as test code generation and scenarios where RSAT is used.

Playing back a recording

The **playback** functionality of Task recorder can automatically run the steps of an existing recording by using the pages and values that were originally recorded. Playback mode can be used to update an existing recording if changes were made to the underlying application, and those changes altered the business process steps that are required for the scenario. It's important to remember that, in this mode, Task recorder simultaneously re-

records the steps and plays them back. When the playback is completed, a new recording is produced that reflects both the steps that were run from the existing recording and any new steps that the user manually performed. Any steps that aren't run either by the user or automatically by Task recorder aren't included in this new recording.

To play back an existing recording, follow these steps.

1. Refresh the browser tab.

   > **NOTE**
   > It's a good practice to refresh the browser before each new recording.

2. Open the **Task recorder** pane.
3. Click **Playback recording**.
4. Click **Open from this PC** to load a recording from a previously downloaded Task recorder package (.axtr file).
   - If you're reading this guide for the first time and following along, choose the "Create a new rental reservation" file that you downloaded previously.
5. Click **Start**.

When you play back a recording, additional actions are available in the **Task recorder** pane.

Play next pending step

Play next pending step runs the next step in the recording. This action is useful because it gives you more control over the playback speed when you want to analyze the effects of a single step. This action has a side-effect that it's important to be aware of. When you click **Play next pending step**, any open lookups, drop-down dialog boxes, or Action Pane tabs might be dismissed, because this action removes focus from those elements. For these situations, we recommend that you use **Play all pending steps** instead.

Play all pending steps

Play all pending steps begins sequential execution of the remaining steps in the recording, and continues until either playback is paused or all steps have been run. During playback, the **Play all pending steps** button is replaced by a **Pause** button that can be used to pause playback. If playback can't successfully run a step for any reason (for example, because it can't find a button that has been renamed), Task recorder will skip that step, and playback will automatically be paused. In this way, the user has an opportunity to replace the obsolete step by completing the new steps in the client. Task recorder will record the new steps and ignore the step that was skipped. The user can then click **Play all pending steps** to continue playback for the remaining steps. After the recording is completed, the user can download the updated recording. This recording will contain all the steps of the original recording, but will exclude any skipped steps and include any new steps.

Play to selected step

Play to selected step behaves like **Play all pending steps**, but it lets you play only a subset of the steps instead of all the steps. In the list, select the step that you want playback to stop at, and then click **Play to selected step**. Task recorder will begin to run the steps in the list and will stop when it has run the step that you selected.

Editing a recording

Although you can edit a recording through the playback functionality, there is also a mode that lets you make simple edits to a recording without having to replay the whole recording. To access this feature, click **Edit recording** after you open the **Task recorder** pane. You can use this feature to make the following edits:

- Insert steps into a recording without re-recording the whole file.
- Move steps under a sub-task without re-recording the whole file.
- Adjust the name and description of the recording.

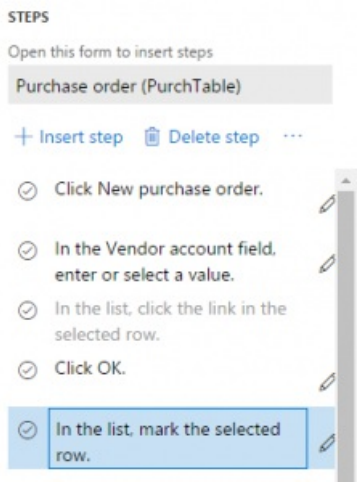
Insert steps without re-recording the entire file

You can add a step anywhere in a task recording without playing back or re-recording the whole file.

1. Select the step after which you want the new step to be inserted. Make sure the step is highlighted.

   In order for task recorder to insert a step, you must have the correct page open. The correct page is the page on which the new step occurs. Task recorder has a mechanism that determines what the active page is, and will disable the functionality if the correct page isn't open.

   
   When you are on the correct page, **Insert step** becomes available.

2. Click **Insert step**.

   When you click **Insert step**, Task recorder switches to recording mode. Any action that is performed in the user interface (UI) will now be recorded and inserted into the recording as steps.

3. Click **Stop**.

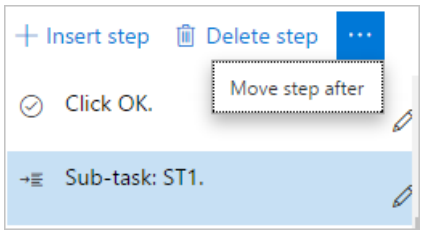
   Recording mode is stopped, and you can now continue to edit the recording. For example, you can repeat this process to insert steps in other places in the recording, or you can move sub-tasks as described in the next section.

4. When you've finished editing the task recording, click **Done editing**, and then select one of the options to save or publish the recording.

Move steps under a sub-task without re-recording the entire file

You can move steps under a sub-task without playing back or re-recording the entire file. You can also move the sub-task step or the end sub-task step if you want to group an existing block of steps.

1. Select the step or sub-task step that you want to move. Make sure that the step is highlighted.
2. Click **Move step after**. To access this command, you might have to select the ellipsis (...) button.



3. Select the step or sub-task step that you want to move the step or sub-task step after. Task recorder will move the step.

4. To move the end sub-task step, select it, click **Move step after**, and then select the step that you want the end sub-task step to be after.

   If you want the first step in the task guide to be within a sub-task, create a sub-task step as the second step, and then move the first step into it. You can add or move as many steps or sub-tasks as needed.

5. When you've finished editing the task recording, click **Done editing**, and then select one of the options to save or publish the recording.

Adjust the recording name and description

You can adjust values of the **Recording name** and **Recording description** fields. If you want to see more steps in the Task recorder editing pane, you can also collapse the section that shows the recording name and description.

Playing a task guide

A **task guide** is a user-focused experience that lets the user follow a guided step-by-step set of instructions to complete a business scenario by using a task recording. The user is instructed to complete each step through an animated pop-up prompt that will move across the page and point to the UI element that the user should interact with. The prompt will also tell the user how to interact with the element. For example, it might state, "Click here" or "In this field, enter data." Each step that the user is instructed to complete is based on a step that was originally recorded in the task recording. Because the task recording file contains the data that describes the step that was originally recorded, the task guide can automatically determine when the user has completed the step as expected. It then automatically moves on to the next step.

> **NOTE**
>
> One way that the task guide determines that a user has completed a step is by detecting when the value in a field has changed. Although the task guide doesn't require that a specific value be set, it does require that the field value be changed in order to determine that the step was completed. The user must change the field value, and then press the **Tab** key or click in an area outside the UI element. Only at that point does the client detect that the field value has changed, and it can then proceed to run any required application validation or business logic. Therefore, before the task guide can determine that the step was completed by the user, it relies on the client to detect that the field value has changed.

What can a task guide allow a user to do?

When a user is completing a task guide, the client behaves in the same manner, with the same data, security, and validation rules as it does when the user is not completing a task guide. There is no difference of behavior in the client that would allow a user to take an action that they cannot otherwise take when they are not completing a task guide. When a user is completing a task guide:

- Any data the user enters is subject to the same data validation rules as when not playing the task guide.
- Any data the user enters may be saved, and the user may modify data according to the same restrictions and rules as when not playing the task guide.
- Any security mechanisms the user encounters behave the same as when the user is not playing the task guide.
- Any forms or controls the user accesses are subject to the same security and access mechanisms as when the user is not playing the task guide.

The "On-rails" feature of task guides

By default, when a user begins a task guide, they are placed "on-rails". These "rails" prevent the user from *clicking* on elements other than the element the task guide is pointing to. When the user tries to click on something outside of the UI element that the task guide is pointing to, the task guide pop-up will animate to let the user know that they cannot progress until they complete the current step of the task guide.

While a user is prohibited from *clicking* on other elements, the user is not prevented from tabbing through the other controls on the form, and the user is not prevented from using keyboard shortcuts. This is by design, as the "on-rails" feature is designed for and targeted at first-time users, who are expected to primarily use the mouse as they become familiar with the application.

More advanced or experienced users can turn off the "on-rails" feature when they complete a task guide. At any point during the task guide, these users can turn off the rails by clicking the **Unlock** button that appears on the Task recorder toolbar at the top of the page. This button can also be used to restore the rails at any point during the task guide. In some situations, the task guide might automatically turn off the "on-rails" feature. When the rails are turned off, the user can click UI elements just as they do when the task guide isn't running. The "on-rails" feature might be automatically turned off in the following situations:

- The user is being directed to go to a page by using the navigation pane or navigation search.
  - Because the user can use either entry point, the task guide doesn't point to a specific entry point, and it doesn't prevent the user from using either entry point.
- The task guide enters an error state (see the next section for a list of error states).
- The task guide is showing an info step.

Error detection

An *error state* occurs when the task guide is not able to point to the UI element that is associated with the current step because the UI element is not visible on the screen. When the task guide detects that the current step requires the user to interact with a UI element that is not visible, then the task guide pop-up will move to the upper-right side of the screen. These causes of an error state can be simplified into two categories.

The control is not visible on the form

This error state usually occurs when the user has opened or closed the incorrect tab, FastTab, collapsible section, FactBox, or pop-out menu.

Because the UI element that is needed for the current step is somewhere on the current form, but it is not visible on the screen, the task guide pop-up will simply move to the upper-right side of the screen while displaying the same instruction that informs the user of the action they need to take.

Because the task guide can't find the UI element on the screen, the user must manually determine what is causing the UI element to be hidden and then make the element visible on the screen. The task guide pop-up will automatically detect that the UI element is visible and will reposition itself so that it's pointing at the now-

visible element.

The control is not on the form

This error state usually occurs when the user has gone to the wrong form, either by navigating to the wrong form or by leaving the correct form.

Because the UI element is not visible on the screen, the task guide pop-up will move to the upper-right side of the screen. In addition, when the task guide detects the user is on the wrong form, the task guide pop-up text will change to inform the user of the form they should navigate to.

In some cases, the task guide pop-up will not mention the form by name. This is because the user may need to navigate to a dynamic form. A dynamic form is a form that is not modeled, frequently known as a runtime-generated form. These sorts of forms do not have a proper name. Some examples of runtime-generated forms include simple and custom lookups. The way for a user to navigate to a lookup form is to re-open the lookup.

Next step and Previous step

The **Next step** and **Previous step** buttons appear in the task guide pop-up and let a user manually control the flow of the task guide. When these buttons are clicked, the task guide will go to the next or previous step. The task guide doesn't verify that the user has completed a step before it goes to the next or previous step.

The task guide **never** automatically completes any step for the user, even when the **Next step** and **Previous step** buttons are used. Use of these buttons can cause an error state if the previous or next step refers to a UI element that isn't on the current page. When the user is completing an info step, the only way to proceed is to use the **Next step** button. This action is required because an info step doesn't represent an action that was recorded on any UI element. Because no action was recorded in the task recording, the task guide doesn't have the necessary information to determine what action it should expect the user to complete.

The See more button

When the **See more** button is clicked, the task guide pop-up expands to show additional information that is related to the step. The additional information is often optional reading material that isn't required for the user to successfully complete the step. The following information might be included:

- An **Example** value
  - The Example value is the value that was originally used when the task recording was created.
  - Example values appear only for steps that use non-lookup fields. These fields include text fields, number fields, date fields, combo boxes, and check boxes.
- A **Note**
  - A Note may contain scenario-specific information that will help provide context to the user about the current step of the task guide.

Taking screenshots in Task recorder

By using a **pre-release** Chromium browser extension that works for both the new (Chromium-based) Microsoft Edge browser and Google Chrome, Task recorder can take screenshots of the browser as a user records a business process. After the user completes the recording, Task recorder can use these screenshots to generate Microsoft Word documents. To turn on this functionality, follow these steps to install the pre-release Chromium extension that enables Task recorder to take screenshots during recording.

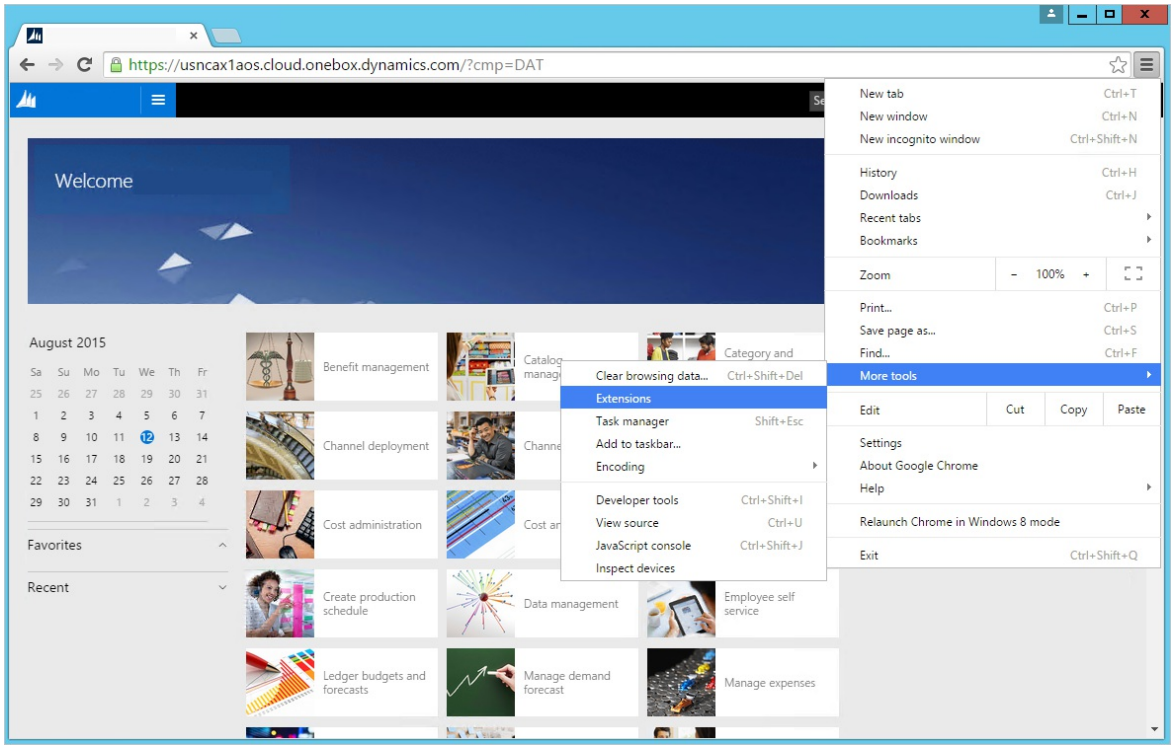
1. Download the **FMLabTaskRecorderScreenshot** folder that contains the extension from GitHub, at https://github.com/Microsoft/FMLab.
2. **On-premises deployments only:** Adjust the manifest for the extension so that it matches the following code. Replace <hostname> with the base URL for your environment.

```
...
"content_scripts": [
    {
        "matches": ["https://*.dynamics.com/*", "<hostname>"],
        "js": ["screenshot.js"]
    }
    ...
```

3. **21Vianet deployments only:** Adjust the manifest for the extension so that it matches the following code. Replace **.com** with **.cn**

```
...
"content_scripts": [
    {
        "matches": ["https://*.dynamics.cn/*"],
        "js": ["screenshot.js"]
    }
    ...
```

4. Open the latest Microsoft Edge browser or Google Chrome.
5. Select **Settings and more > Extensions** in Microsoft Edge (or **Customize and control Google Chrome > More tools > Extensions** in Google Chrome).



6. Select **Developer mode**.
7. Click **Load unpacked extension**.
8. Browse to the folder that contains the Task recorder extension by using the path **FMLab-master > FMLab > TaskRecorderScreenshot**, and then select **Select Folder**.
9. Make sure that **Enabled** is selected so that extension is turned on.
10. Restart the browser.

Task recorder will now take screenshots of the tab where the client is running. These screenshots are available for one week after the recording has been played. (If you're running a platform version that is earlier than

Platform update 16, the screenshots are available for only 15 minutes.) If the screenshots have expired, you can regenerate them by playing the task recording again.

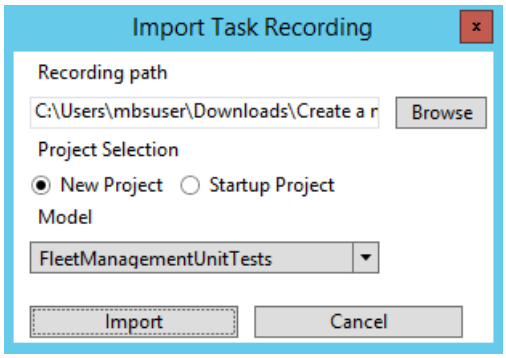
Note that Task recorder **does not** capture screenshots from other tabs or of the user's desktop.

Generating tests from a recording

After a business process recording has been completed by using Task recorder, a developer can import the raw developer recording file (.xml file) into Visual Studio to create an X++ test. The import tool generates a human-readable X++ test from the recording, and translates any control gestures, validations, or tasks into the appropriate test code.

Import a recorded test

1. Open Visual Studio by using the Finance and Operations development tools.
2. Go to **Dynamics 365 > Addins > Import task recording**.
3. In the **Import task recording** menu, use the **Browse** button to locate a previously downloaded recording file.
4. Optionally, choose to have the generated test code be added to the startup project. This requires that a solution containing a project is set as the startup project. This will place the generated X++ test into the same model as the project.
5. If you're creating a new project, select the model for the project. The generated X++ test will be put in this model. For the generated test to be successfully built, the model must have references to the **TestEssentials** model.
6. Click **Import**.



7. In the **New Project** dialog box, provide a name for the project.
8. After the project is created, the user can open and inspect the generated code.
9. To run the test, build the project.
10. Go to **Test > Windows >Test Explorer**.

Appendix

Controls that are known to have incomplete support for Task recorder

- Table
- Filter pane, which is the filter that pops out from the left side
  - When adding filters to the filter pane, the steps are delayed. The steps do not get recorded until the user clicks "Apply" on the Filter pane.
- Enhanced previews
  - No planned support for recording gestures inside of enhanced previews. While recording, enhanced

previews will be disabled.

- No extensible controls are supported out of the box, except Segmented Entry.
  - Extensible control owners need to individually build support for Task recorder.

Controls that can be recorded, but have limited support for the Copy/Paste/Validate gestures

- Date/Time
  - Doesn't support copy/pasting "Never" as a value.
- Image
  - No ability to copy/paste/validate an image value.
- Filter pane
  - Copy/Paste works, but the UI will not show the pasted data. You can proceed as if it pasted correctly.
- Message box
  - You cannot validate the text in the message box.

Controls that are known to have incomplete support for being used in a task guide

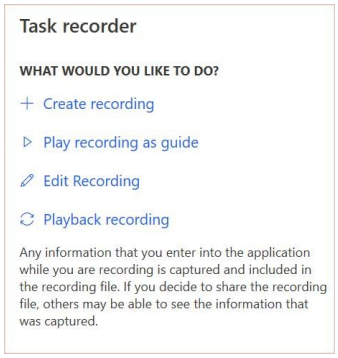
- Quick Filter, which is the filter control that appears above lists
  - Does not support displaying a "generic value" during the task guide. Currently displays the value that was used during recording.
- Filter pane, which is the filter that pops out from the left side
  - The task guide does not point to the individual elements within the Filter pane that need to be clicked on.

Task Recorder quick reference

2/18/2021 • 5 minutes to read • Edit Online

This article provides a quick reference sheet that explains what each button in the Task recorder menus does.

Main menu



Create recording

Choose this option to begin creating a new recording.

Play recording as guide

Choose this option to see what your recording looks like when viewed as a Help topic or played as a Task guide.

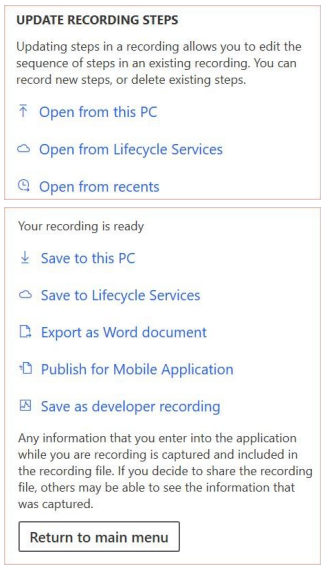
Edit recording

Choose this option if you need to change the recording's name, description, or the text that is displayed in the steps.

Playback recording

Choose this option if you need to add or remove steps. You can also use this mode to automatically play a recording.

Open and save options



Open/Save from/to this PC

These options allow you to open a recording that is saved on your computer, or save a recording to your computer.

Open/Save from/to Lifecycle Services

This option allows you to open a recording that has been saved to a Lifecycle Services library, or save a recording to a Lifecycle Services library.

Open from recents

This option allows you to pick from a list of Task recordings that you have recently created.

Export as Word document

This option allows you to download a Word document that contains the list of steps in the recording.

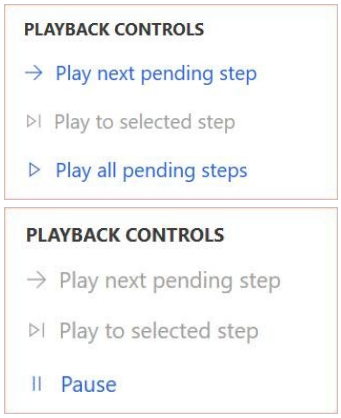
Publish for Mobile Application

This option allows you to publish the task recording for a mobile application.

Save as developer recording

This option allows you to save the task recording as a developer recording.

Playback controls



Play next pending step

This option will cause Task recorder to execute and record the next pending step, which is indicated by the arrow in the Steps list.

Play to selected step

This option will cause Task recorder to begin playing and recording pending steps, beginning at the next pending step and pausing after playing the step that was selected in the list when this option was clicked.

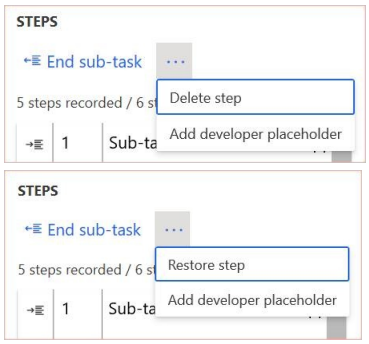
Play all pending steps

This option will cause Task recorder to play and record all remaining pending steps, until there are no remaining pending steps.

Pause

This option only appears while playback is in progress. This option allows you to pause playback manually.

Step actions



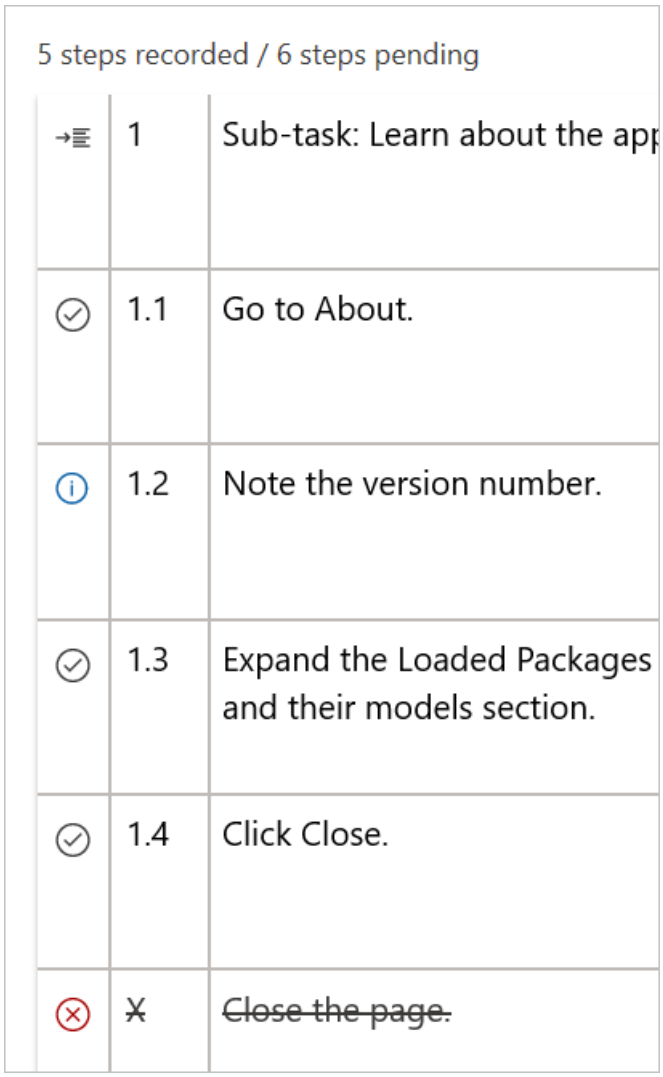
Start sub-task/End sub-task

These options allow you to add special steps to the recording. These special steps are task steps, and you can use them to indicate when a sub-task begins and when it ends. These options are disabled while playback is in progress.

Delete step/Restore step

These options allow you to remove steps from the recording. If you delete a pending step, it will be skipped during playback, and it will not be recorded. If you delete a recorded step, then it will be flagged for removal and it will not be included in the recording when you save the recording. You can only restore steps that have been successfully recorded. You cannot delete a task while it is in progress.

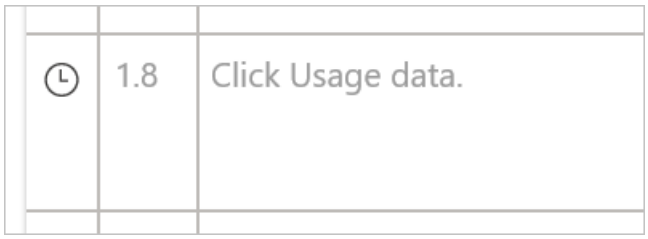
Steps list



Step counter

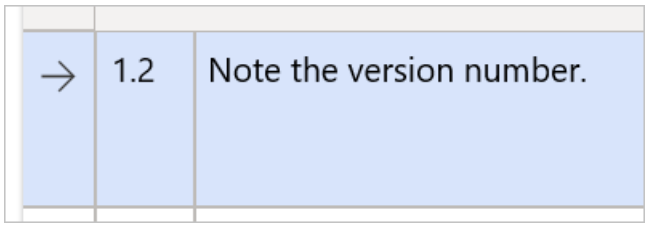
This keeps track of how many steps have been recorded. This includes steps played by using the Playback controls, as well as steps recorded by actions that you take in the client.

Pending step



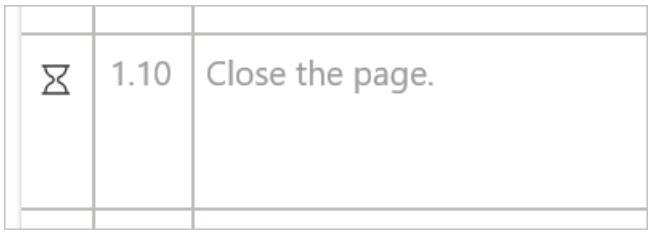
This symbol represents a step that is pending and has not been recorded yet. Pending steps can be played using the Playback controls. When a pending step is played successfully, it is recorded and the symbol will update appropriately. *Pending steps are not included in the recording when you save the recording.* You must first play the pending steps so that they are recorded. If the steps are played and recorded successfully, then they will be included when you save the recording.

Next pending step



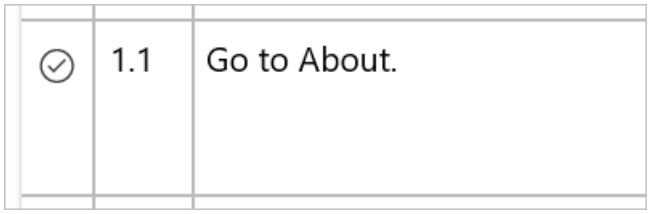
This symbol represents the next pending step. If you start playback, this is the first step that will be played.

Queued pending step



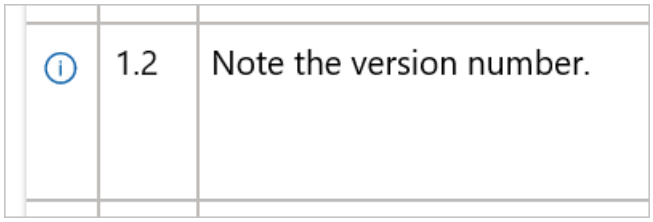
This symbol represents pending steps that are queued for playback. This symbol is updated either when playback pauses, or when the queued pending step is played.

Recorded action step



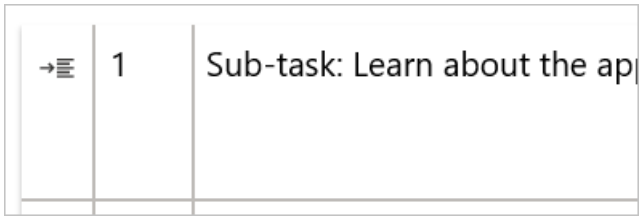
This symbol represents steps that were recorded successfully, either from being played back, or manually recorded by you.

Recorded info step



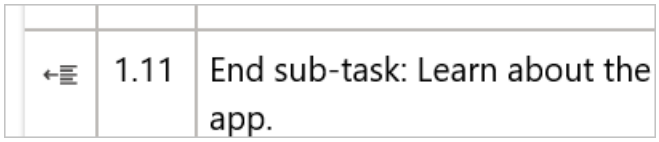
This symbol represents an info step that was played and recorded. Info steps do not result in any action being executed on the application.

Recorded begin sub-task step



This symbol indicates the beginning of a sub-task. Sub-task steps do not result in any action being executed on the application.

Recorded end sub-task step

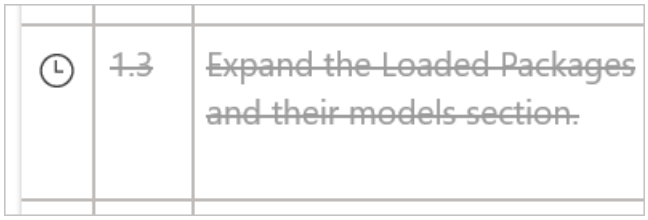


This symbol indicates the end of a sub-task. Sub-task steps do not result in any action being executed on the application.

Deleted recorded step

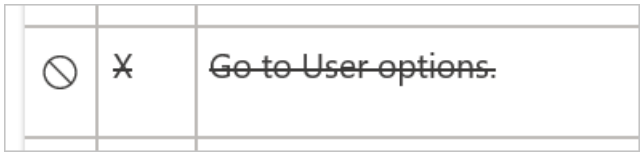
This symbol represents a successfully recorded step that you have marked for deletion. Recorded steps that are marked for deletion will not be included when you save the recording. If a step has been successfully recorded when you decide to delete it, then you have the option to restore the deleted step before you save the recording.

Deleted pending step



If you delete a pending step, it will retain its pending symbol until it is played. When it is played, it will be skipped. You can restore a pending step as long as it has not been played and skipped.

Skipped step



This symbol represents a step that was deleted while it was pending, and was skipped during playback. Skipped steps are not played and are not recorded. Because skipped steps are not recorded, they are not included when you save the recording. You cannot restore a skipped step.

Error step

This symbol represents a step that was attempted by the playback system, but was not successful in being played. Error steps are not recorded, and are not included when you save the recording. You cannot restore an error step. Playback will automatically pause when an Error step is encountered. This gives you the opportunity to record replacement steps before continuing playback. An error step may occur for the following reasons:

- The step could not play because the form or lookup needed by the step was not open.
- The step could not play because the button or field needed by the step was disabled, not visible, or not present on the form.
- The step could not play because the name of the form or name of the control has changed.
- The step could not play because of a framework change to the control.

Create documentation or training with Task Recorder

2/18/2021 • 8 minutes to read • Edit Online

This topic explains what Task recorder and task guides are, how to create task recordings, and how to customize Microsoft task guides and include them in your Help.

> **IMPORTANT**
> You can record your own task guides for Dynamics 365 Human Resources, but you won't be able to save them to a Business Process Modeler (BPM) library or open them from the Help pane at this time. You can save them locally or to a network location, and then open and replay them using Task recorder.

Learn about Task recorder

Task recorder is a tool that you can use to record actions that you take in the product user interface (UI). When you use Task recorder, all of the events that you perform in the UI that are executed against the server—including adding values, changing settings, removing data—are captured. The steps that you record are collectively called a *task recording*. Task recordings can be used in many ways:

- **Task recordings can be played as task guides.** Task guides are an integral piece of the Help experience. A task guide is a controlled, guided, interactive experience through the steps of a business process. The user is instructed to complete each step by way of a pop-up prompt (or "bubble"), which will animate across the UI and point to the UI element that the user should interact with. The "bubble" also provides information about how to interact with the element, such as "Click here" or "In this field, enter a value." A task guide runs against the user's current data set and the data that is entered is saved in the user's environment.
- **Task recordings can be saved as Word documents.** This allows you to easily produce printable training guides.

You can create your own task recordings, play task recordings provided by Microsoft, or modify Microsoft-provided task recordings to reflect your configuration. For more information about Task recorder, see Task recorder.

Plan your task recording

Whether you're creating a new task recording or basing your recording on a Microsoft task recording, keep the following information in mind.

- Plan your recording like you would a video. Make all your decisions ahead of time.
- Walk through the business process once or twice without recording it to understand the steps.
- When you walk through the process before you record, notice where you use shortcut keys or the **Enter** key, so that you can avoid using them during the actual recording.
- Identify the following:
  - Do you want to group steps together into sub-tasks? Sub-tasks visually set apart sections of a process. For example, if you are creating a recording for "Creating and releasing a product," you may want to group together the steps that are required to create a product, and then group together the steps that are required to release the product. Sub-tasks also make longer processes easier to read.

- Do you want to add annotations, and if so, where? See "Understand the different types of annotations" below for more information.
- What values will you add in the various fields as you complete the steps of the business process? It is a good idea to know what you'll select or enter as you proceed so that you don't backtrack or fix mistakes as you're recording.

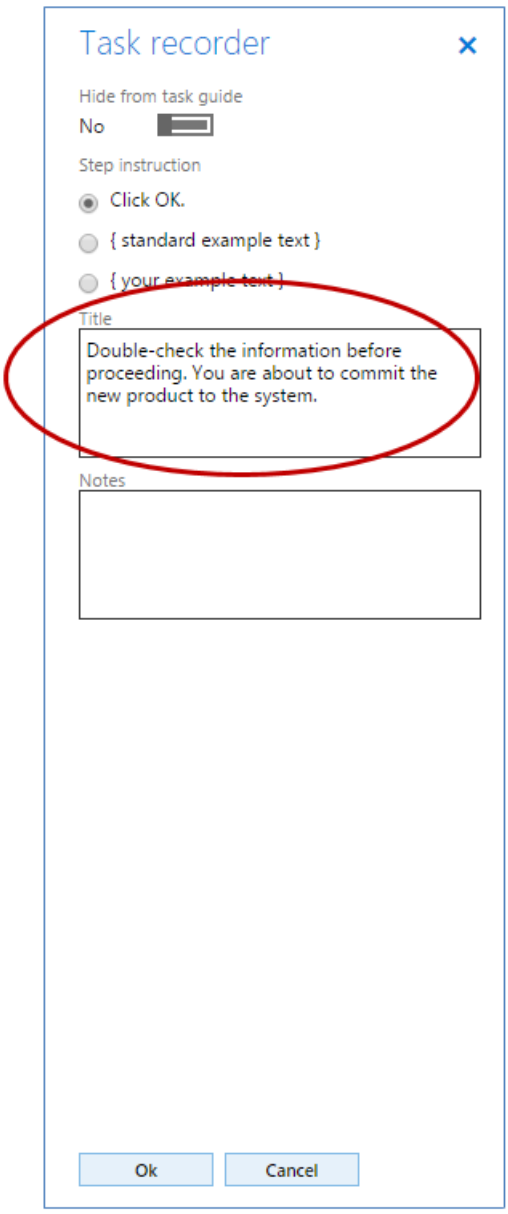
Write your description and annotations ahead of time

- At the beginning of each task recording, there's a description field that allows you to enter an introduction to the recording. It is a good idea to write and save the description ahead of time in a separate document so you can copy and paste it into the task recording when you are recording. That way, you can spend time refining the text when you aren't in the process of recording. Cutting and pasting the text makes the recording process go more quickly and smoothly.
- For each step in a task recording, you can create annotations. During playback of a task guide, annotations appear in the "bubble" as notes above or below the text for the step. When viewed as text in the Help pane, annotations appear as text inline in the step. As with the description, it is a good idea to write and save your annotations in a separate document. When you're recording the task recording, cut and paste the annotations in from that document.

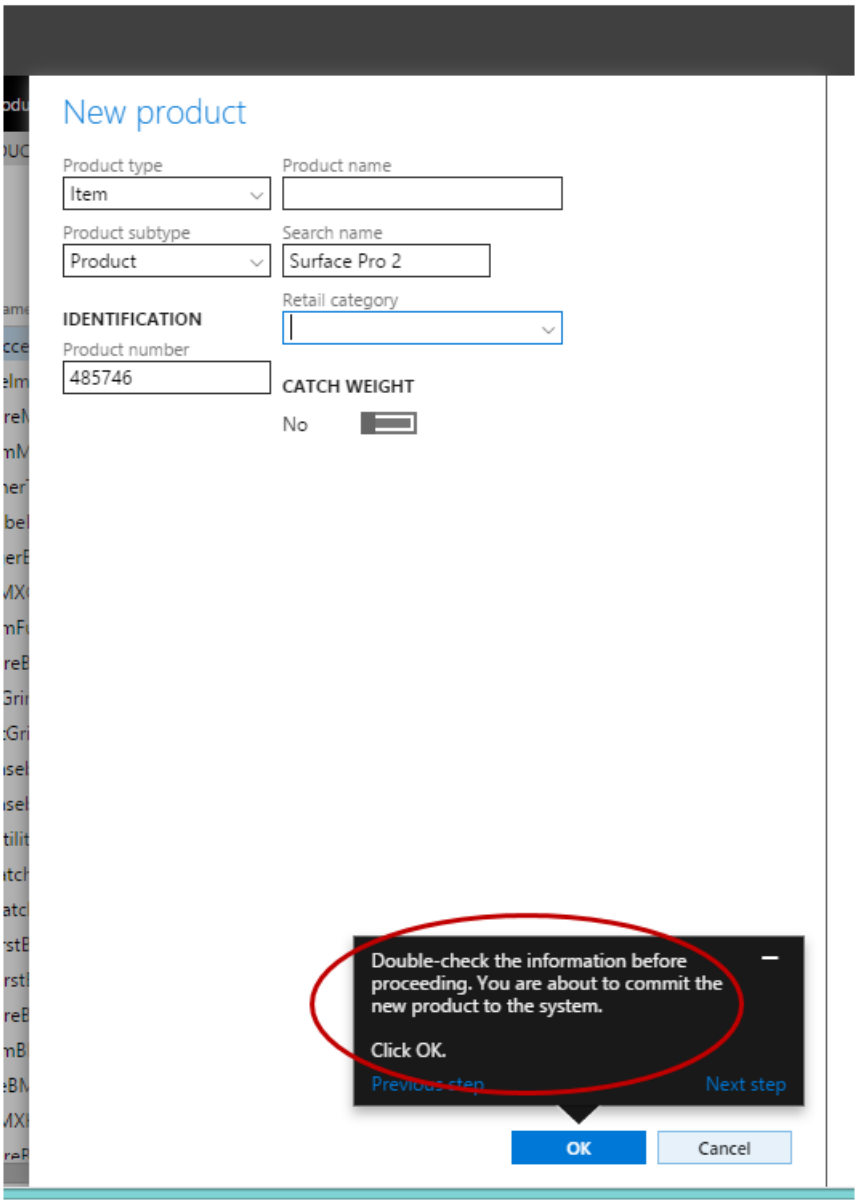
Understand the different types of annotations All annotations are optional. Only add them when they'll provide helpful information to the user.

- **Title**: A title annotation will appear before the step text that task recorder automatically generates. In the task guide, the title annotation appears above the automatically generated text. Use this type of annotation to explain why the user is doing the step or to give additional context.

This is the editing pane that you see when you add an annotation as you create your recording. Enter a title annotation in the **Title** box.

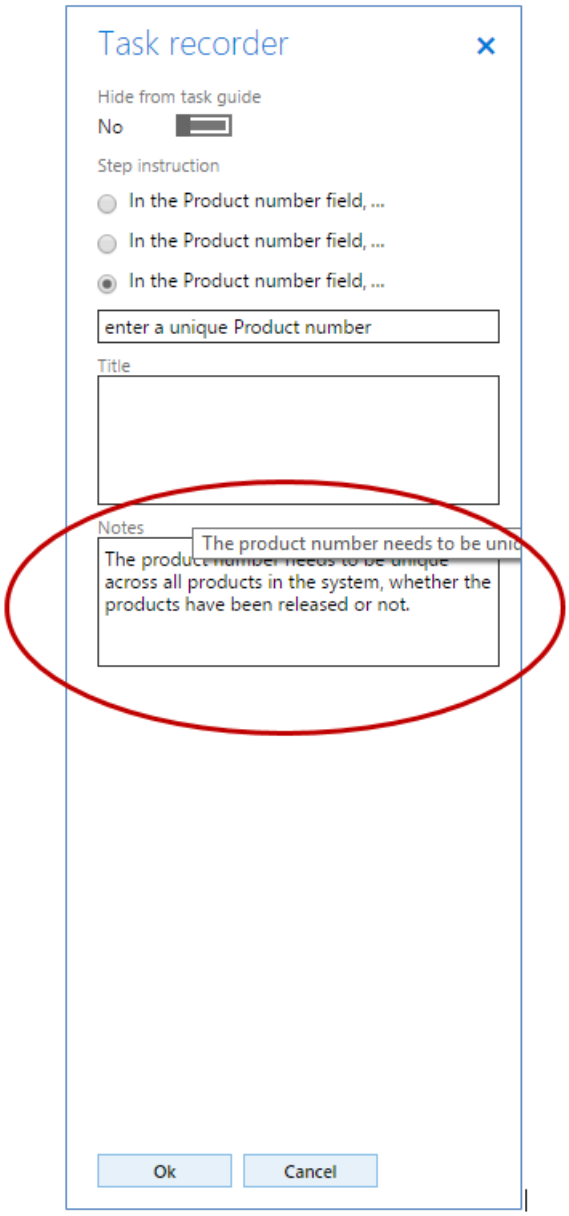


This is what the title annotation looks like in the "bubble" in the task guide.

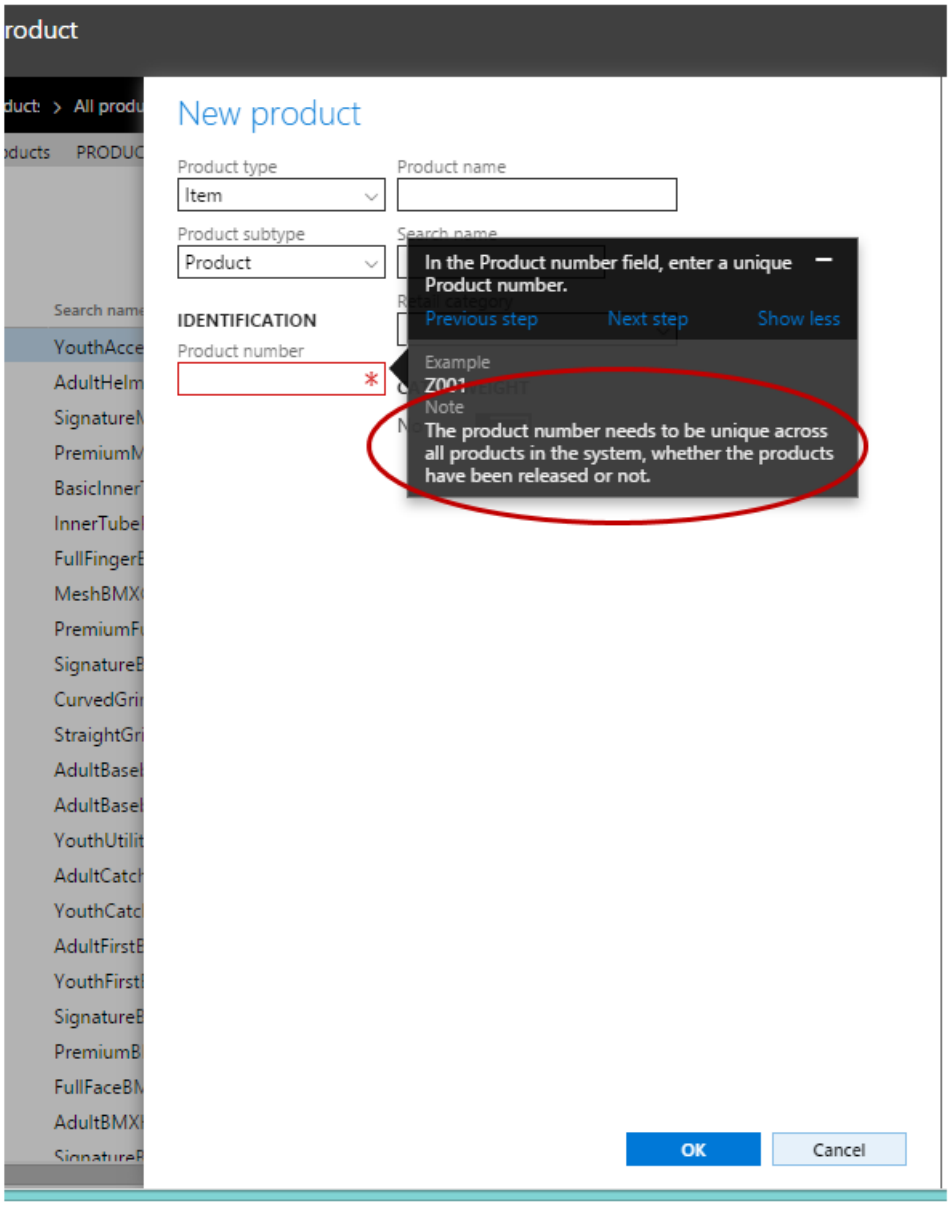


- **Notes:** A notes annotation will appear after the step text that task recorder automatically generates. In the task guide it will only be visible if the user clicks the **Show more** link in the task guide bubble. Use this type of annotation to describe anything that a user needs to know to complete the step.

This is the editing pane that you see when you add an annotation as you create your recording. Enter a notes annotation in the **Notes** box.



This is what the notes annotation looks like in the "bubble" in the task guide.



- **Info step**: These annotations are created by right clicking on a control or anywhere on a form < **Task recorder** < **Add info step.** Info steps appear as a numbered step at whatever point you insert it, even though no action was recorded in the UI. You can add a form-level info step or an info step associated with a control. When an info step is associated with a form, the task guide "bubble" will appear someplace on the form, with no pointer, when the task guide is played. When an info step is associated with a control, the task guide "bubble" will point to the control when the task guide is played. In the Help pane, an info step annotation will appear as a numbered step with whatever text you entered. Use info steps to prepare the user for the next steps, to describe steps that need to be done outside of the application, or to refer to other recordings (although you cannot create hyperlinks in annotations).

Determine how long to make your recording

- The user will generally either read or play the recording from start to finish, so don't combine steps or tasks that are better done separately.
- Try not to record a long scenario that spans multiple sub-processes. For example, "Operate in-store customer service desk" is too broad; break it up into shorter tasks such as "Accept returns" and "Add to gift card."
- If a task can be carried out as part of several different business processes, create a separate recording for it, and you can refer to it in the other recordings.
- If the process involves multiple tasks that the person likely does all at once, you can keep the tasks in one

recording, for example, “Set up and assign functionality profiles.”

- If it is something someone does once (such as configuration) and then another task that they can do immediately afterward but may do repeatedly, and on its own, break them up into two task recordings.

Decide where, in the UI, to start a recording The page that you are on when you start recording a task recording affects which page the task guide is displayed for. For example, if you want your task recording to be listed in the Help pane when a user clicks Help on the General ledger parameters page, you must start your recording on the General ledger parameters page. **Save recordings as .axtr files** When you are done creating or editing a task recording, you are presented with several options for how you want to download, or save the recording. You can download the file as a task recording package (.axtr), download it as a raw recording file (.xml), download it as a Word document, or save the file to an LCS library. It is a good idea to always save your task recording as a task recording package file (.axtr). This will help make maintenance of the file easier if procedures or annotations need to change later. If you want to download the file as a Word document, also save it as a task recording package file.

Create your task recording

For detailed walk-through steps, see Task recorder resources.

Copy and customize Microsoft's task recordings

You can download and edit Microsoft's task recordings to use them for your own Help documentation or training materials. To download a Microsoft task recording, follow these steps:

1. Open Task recorder. Task recorder is located in the **Settings** menu.
2. In the Task recorder pane, click **Maintain a recording.**
3. Under **Where is the recording**, click **It is in an LCS library**.
4. Click **Select the LCS library**.
5. Select the Microsoft global library.
6. In the tree, select the business process library node that the task recording is associated with.
7. Click **OK**.
8. Click **Start**.
9. At this point, step through the recording, changing any steps as you go to re-record it. **Note**: If you only need to change the text of a recording, you can open the recording in **Edit a recording's annotations** mode, and then save it.
10. After the recording has played to the end, click **Stop** in the task recorder bar at the top of the screen.
11. Choose how you want to save the task recording.

This topic provides a list of the help topics and other resources in Dynamics 365 Supply Chain Management.

What's new and in development

Go to the Dynamics 365 Roadmap to see what new features are released and what new features are in development.

Core concepts and tasks

Select a feature area to learn more about it.

- Asset management
- Cost accounting
- Cost management
- Inventory management
- IoT Intelligence
- Master planning
- Procurement and sourcing
- Product information management
- Production control
- Sales and marketing
- Service management
- Transportation management
- Warehouse management

Dynamics 365 Finance

For information on Dynamics 365 Finance, go to the Finance home page.

Videos

This short video summarize the new supply chain management features added to Microsoft Dynamics 365 for Finance and Operations version 8.0 (April 2018).

- Synchronize a work order between Field Service and Finance and Operations

These short videos summarize the new supply chain management features added to Microsoft Dynamics 365 for Finance and Operations, Enterprise edition 7.3 (December 2017).

- Prospect to cash integration
- Optimization advisor
- Use warehouse template to copy configuration

These short videos summarize the new supply chain management features added to Microsoft Dynamics 365 for Finance and Operations, Enterprise edition (July 2017).

- Get started with Cost accounting

- Cost control mobile workspace
- Use Excel for cost analysis
- Approve purchase orders on a mobile device
- Visual scheduling with Gantt chart for production and batch orders

The following tech conference recordings discuss supply chain management functionality from previous versions of Finance and Operations. This functionality is now part of Dynamics 365 Supply Chain Management; the same concepts still apply, and the procedures are similar in the current version.

- **Cost management:**
  - Overview of Cost management
- **Master planning:**
  - Extend the demand forecasting functionality
  - Master planning - tips and tricks for troubleshooting performance
  - Help! MRP is slow!
- **Product information management:**
  - Product configurator in Microsoft Dynamics AX
- **Warehouse management:**
  - Get the best out of your warehouse management system
  - Dynamics AX 2012 R3: Advanced warehouse management - A day in the life of process manufacturing
- **Production control videos:**
  - Subcontracting operations and activities in manufacturing
- **Transportation management videos:**
  - Transportation management (TMS) in the new Microsoft Dynamics AX

Blogs

There are many topics about manufacturing and supply chain management on the Dynamics AX Manufacturing R&D Team Blog and Supply Chain Management in Dynamics AX R&D Team Blog. Most of these were written for the previous version, but the same concepts still apply, and the procedures are similar in the current version.

White papers

- Lean manufacturing: Capable to promise and kanban job scheduling
- BOM calculation by using a costing sheet

eLearning courses

Task guides

Additional help is available as task guides inside Finance and Operations. To access task guides, click the Help button on any page.

Videos

Check out the how-to videos that are now available on the Microsoft Dynamics 365 YouTube Channel.

Country/region functionality

Country/region regulations affect tax setup and other areas of financial management. Refer to the Localization and regulatory features section of our help content to learn about country/region-specific functionality.

Additional content

Supply chain management functionality covers parts of the procure-to-pay process that includes requisitioning, ordering, receiving, invoicing and paying for the goods and services your organization purchases. Refer to the Supply Chain Management home page for information about the capabilities for managing purchases, inventory, and manufacturing.

Commerce home page

2/18/2021 • 2 minutes to read • Edit Online

Dynamics 365 Commerce—built on the proven Dynamics 365 Retail capabilities—delivers a comprehensive omnichannel solution that unifies back-office, in-store, call center, and digital experiences. Dynamics 365 Commerce enables you to build brand loyalty through personalized customer engagements, increase revenue with improved employee productivity, optimize operations to reduce costs and drive supply chain efficiencies, ultimately delivering better business outcomes.

This release enables the creation of digital experiences using built-in web authoring and development tools to produce engaging and intelligent digital storefronts. A connected marketing and headless commerce platform further enable the seamless management of content, assets, promotions, inventory, and pricing across all channels.

- **Everything to build and run digital commerce:** Streamline your business and end-to-end commerce solution that scales to your needs across traditional and emerging channels. Built-in web authoring and development tools enable you to create engaging intelligent digital storefronts, while a connected marketing and headless commerce platform enables seamless management of content, assets, promotions, inventory, and pricing across channels.
- **Build loyalty and exceed customer expectations:** Use clienteling tools to gain a comprehensive view of your customer and respond to their needs at every level of engagement, based on customer profile, history, and preferences that flow across physical and digital channels. Empower your employees to foster lasting relationships through AI-driven recommendations, customer insights, and loyalty programs that elevate brand appeal.
- **Flexible and intelligent omnichannel experience:** Unify physical and digital commerce by providing consistent experiences to customers across cloud search and discovery, product reviews, wish lists, inventory, gift cards, and loyalty. Allow customers to purchase when, how, and where they want, on any device—while providing choice around modern payment methods and product collection or delivery.
- **Streamline operations using AI in the cloud:** Drive omnichannel commerce experiences and integrated, optimized back-office operations through ingrained, pervasive, and context-aware cloud intelligence. Use advanced merchandising, inventory management, distributed order management, and pricing and promotion to innovate and stay ahead of competition.Derive insights by visualizing and analyzing comprehensive and consistent data across all aspects of your business. Use AI-driven technologies to provide accessible websites, protect your business against payment fraud, and efficiently moderate user-generated content like ratings and reviews.

Core concepts and tasks

Select a feature area to learn more about it.

- Configure a Commerce preview environment
- Commerce architecture
- Set up your channels
- Merchandising your products and services
- Manage your orders
- Manage your customers
- Manage your financials

- Manage your e-Commerce site
- Fraud protection
- Commerce development and extensibility
